European Hematology Association (EHA)

The European Hematology Association (EHA) aims to promote excellence in clinical practice, research and education in European hematology.
EHA was founded in June 1992 and today – with over 3200 members from 100 countries – is a consolidated representative of European hematologists.

Our aim

- To become the official European representative of hematology and hematologists – especially where research, education and regulatory issues are concerned – and to become a conduit for European harmonization;
- To promote the creation of a highly attractive market for practitioners and researchers in Europe thus fostering the mobility of hematologists in and to Europe;
- To reach out and offer a platform to countries that wish to further develop excellence in hematology;
- To promote education, training and scientific research in hematology in Europe;
- To exchange and disseminate knowledge and scientific information in the field of hematology.

Our activities

- Organizing an annual scientific and educational congress in a major European city;
- Dissemination of medical research, both basic and clinic, through the Haematologica/The Hematology Journal;
- Collaborating with other leading organizations in the field of hematology and oncology;
- Providing postgraduate education through the annual congress, tutorials and workshops;
- Supporting junior basic and clinical researchers in the development of their careers through the EHA Fellowship Program.
- Strengthening the quality and professional status of hematology throughout Europe by accrediting scientific meetings and providing CME accounts.

EHA Membership

If you recognize the need for a strong European Hematology Association and would like to take advantage of the various activities of the Association, you may wish to become a member of the EHA and contribute to its objectives.

Benefits of EHA membership:
- Subscription to Haematologica/ The Hematology Journal, including on-line access
- Reduced registration fee for the EHA Annual Congresses
- Eligible to the EHA Fellowship Program
- Eligible to apply for the EHA-ASH Translational Research Training in Hematology (TRTH) Award
- EHA Newsletter
- EHA E-bulletin
- Access to jobposting section
- Access to EHA membership database
- Access to webcast sessions of the EHA Annual Congress

15TH CONGRESS
JUNE 10 - 13, 2010
BARCELONA

Word of welcome

On behalf of the EHA Board and the Scientific Program Committee we would like to welcome you to Barcelona for the 15th Congress of the European Hematology Association.

This year, over 2100 abstracts have been submitted - a new record- showing the growing significance of the EHA-Congress to hematologists in Europe and abroad. The Scientific Program Committee is pleased with the steadily increasing quality of the data presented. From these abstracts, an exciting program has been composed including the Presidential Symposium (6 best abstracts), Simultaneous Oral Sessions and Poster Sessions with organized poster walks.

On behalf of the EHA Board, the committees and all people involved in this years' EHA congress, we thank you for coming to Barcelona and hope that this Abstract Book will provide you with an important reference of the recent advances in hematology research.

Background. Inter-individual variations in genes encoding drug metabolizing enzymes and transporters have been demonstrated to influence the response to therapy. However so far, how these genetic variations interact to produce specific drug related phenotypes in Philadelphia-positive (Ph^+) acute lymphoblastic leukemia (ALL) has not yet been investigated. *Aim.* In order to investigate potential genetic structure and related pharmacogenetic profiles, around 2000 variants in more than 200 genes involved in drug absorption, distribution, metabolism and elimination were genotyped and studied with a population genetics approach in 45 Ph^+ ALL patients. *Methods.* The Drug Metabolizing Enzymes and Transporters (DMET™, Affymetrix) platform, covering more than 90% of the most biologically relevant drug absorption, distribution, metabolism and excretion (ADME) markers was used for successfully genotyping 1931 variants in Ph^+ ALL patients treated with the tyrosine kinase inhibitor Dasatinib. A model-based clustering method for inferring population structure using genotype data was applied by means of the Structure software assuming a model in which there are K populations - each one of them being characterized by a set of allele frequencies at each locus - to which individuals are probabilistically assigned according to their genotypes. Distribution of the genetic variance observed among the identified leukemia sub-groups was investigated with a locus by locus Analysis of the Molecular Variance (AMOVA) by means of the Arlequin 3.01 package, exploiting information on genotypes allelic content and frequencies. *Results.* Three different sub-groups (G1, G2, G3), made up of 2, 12 and 31 patients respectively, were identified in the examined ALL sample, according to their different patterns of allele frequency. A statistical support for this finding was provided by AMOVA results which pointed out a substantial level of genetic differentiation among G1 and the other two sub-groups (Fst=0.099, P<0.001) and a milder but still remarkably significant differentiation between G2 and G3 (Fst=0.020, P<0.001). Fst values for each genotyped variant were also computed in order to single out those changes which were actually responsible for such statistical significances. As regards the comparison of allele frequencies among G1 and G2-G3, 56 variants, affecting the NAT1, NAT2, CYP1A2, CES2, CYP1A2, CDA, SLC22A1, CYP3A5, CYP2B6, CYP3A43, FMO2, UGT1A1, CYP3A7 and VKORC1 genes, showed very high (>0.3) and significant Fst values; whereas a total of 50 loci, located on the NAT2, VKORC1, CYP4F2, CYP2B6, UGT2B7 and CYP2D6 genes, showed moderate to high (>0.08) significant Fst values in the G2/G3 comparison. *Conclusions.* Differences of allele frequencies observed among the identified ALL sub-groups prove that an evident genetic structure is detectable in our sample by genotyping loci involved in drug metabolism.

INTACT APOPTOSIS SIGNALING IN PEDIATRIC ALL IS ASSOCIATED WITH PROLONGED NOD/SCID ENGRAFTMENT, LOW EXPRESSION OF ANTI-APOPTOTIC MOLECULES AND FAVORABLE PATIENT OUTCOME

M Queudeville, F Seyfried, S Eckhoff, KM Debatin, L Meyer

University of Ulm, Ulm, Germany

Background. Defects in cell death signaling have been attributed to be responsible for treatment failure and relapse in acute leukemia. We recently reported the importance of intact apoptosis signaling for good outcome in pediatric ALL and AML in two retrospective studies. Using a NOD/SCID mouse xenotransplant model for pediatric ALL we have also shown that rapid engraftment of primary ALL cells (short time to leukemia/TTLshort) is characteristic for early relapse of the corresponding patient. *Aims.* In this prospective study the impact of the functional integrity of apoptosis signaling in xenograft ALL samples on NOD/SCID engraftment and patient outcome was investigated. Furthermore, expression of apoptosis regulating molecules was analyzed and correlated to NOD/SCID engraftment, treatment response and apoptosis signaling. *Methods.* Primary BCP-ALL samples (N=20) obtained at diagnosis were transplanted onto NOD/SCID mice and time to leukemia (TTL) was estimated as weeks from transplant to onset of disease for each sample transplanted. Apoptosis signaling in xenograft leukemia samples was assessed by flowcytometry analyzing two key apoptogenic events, cytochrome c release and caspase-3 activation. Expression of the anti-apoptotic molecules Mcl-1, XIAP, Bcl-2 and Livin was analyzed by qRT-PCR. *Results.* Of the 20 ALL samples transplanted 6 led to rapid leukemia manifestation in the recipient animals (TTLshort) with an inferior relapse free survival of the corresponding patients in contrast to 14 patients with TTLlong phenotype (log rank P.002). Apoptosis signaling was investigated in xenograft leukemia samples by analysis of caspase-3 activation and cytochrome c release. Both events were closely correlated to each other indicating intact signaling in patients stratified into non-high risk groups, patients showing good response to treatment (remission on day 15, negative MRD on day 33), and patients without relapse. In contrast, no correlation was found in patients with poor outcome. Most importantly, intact apoptosis signaling was also found in TTLlong but not in TTLshort patients strongly indicating that mitochondrial cytochrome c release and consecutive apoptosome formation resulting in activation of downstream effector caspases such as caspase 3 is characteristic for a long engraftment phenotype and prognostic favorable ALL. The functional integrity of this apoptogenic checkpoint is subsumed by the parameter cytochrome c related activation of caspases (CRAC). Patients with positive CRAC values reflecting intact apoptosis signaling showed a significantly superior relapse free survival in contrast to patients with disturbed cytochrome c related caspase activation/negative CRAC (log rank, P<.001). Transcript expression of apoptosis regulating molecules was analyzed. A correlation of cytochrome c release and caspase-3 activation indicating proficient apoptosis signaling was exclusively observed in leukemia samples with low expression of the anti-apoptotic molecules Mcl-1, XIAP, Bcl-2 and Livin. Furthermore, patients samples with low Mcl-1 expression showed a significantly longer time to leukemia (TTL) and lower blast cells on day 8 than samples with high Mcl-1 expression. *Conclusions.* Thus, the propensity leukemia cells to undergo apoptosis (CRAC positive) leads to prolonged engraftment upon transplant in the NOD/SCID/huALL model (TTLlong), is associated with low expression of anti-apoptotic molecules, and results in favorable treatment response and superior survival of pediatric ALL patients.

0003

PHOSPHOPROTEOMIC PROFILING OF PEDIATRIC T-LINEAGE ACUTE LYMPHOBLASTIC

G Milani, B Accordi, M Giordan, S Bresolin, M Sciro, L Galla, G TeKronnie, G Basso

University of Padova, Padova, Italy

Background. T-lineage Acute Lymphoblastic Leukemia (T-ALL) accounts for about 15% of paediatric ALL. Although the outcome of T-ALL has improved with current therapies, T-ALL paediatric patients remain at risk for early relapse. It is therefore very important to develop more specific and less toxic therapies through the identification of molecules, such as aberrantly activated phosphoproteins that offer the possibility to use specific kinase inhibitors. *Aim.* The aim of this research was to study the phosphorylation profile of paediatric T-ALL patients at diagnosis, through Reverse Phase Protein Arrays (RPPA), to find aberrantly activated phosphoproteins. *Methods.* We analyzed 98 paediatric patients with T-ALL using RPPA technique. This innovative approach allows to investigate post-translation modifications, such as phosphorylation, and thus to characterize the activation state of cellular protein networks. For all patients included in this study informed consent was obtained following the tenets of the Declaration of Helsinki. Twenty-seven samples were from the Padova hospital and were directly processed whereas 71 patients were from other Italian hospitals. The whole proteome of each patient was immobilized on nitrocellulose coated glass slides and each slide was stained with a different antibody, for a total of 53 antibodies. Protein expression/activation was compared between patients subgroups defined by clinical/molecular features. *Results.* We first found that the phosphorylation state of samples from Padova is comparable with that of samples from other Italian hospitals. Shipment of samples to Padova at room temperature does not influence in a systematic way protein phosphorylation, thus allowing the study by RPPA also for samples collected in other centers. Comparison between T-ALL patients with and without del(1p32) revealed that mTOR(S2448) is differentially activated between these two groups (t test with Benjamini-Hochberg multiplicity corrections P=0.003). This protein kinase that regulates cell growth and survival is less activated in 1p32 deleted patients. We then compared relapsed vs non relapsed patients. Statistical analysis revealed that PKCα(S657) is hyperactivated in the non relapsed group (t test with Benjamini-Hochberg multiplicity corrections P=0.02). Moreover, we performed a Relapse Free Survival analysis through Kaplan-Meier estimates. We searched a threshold value for PKCα(S657) that resulted in the largest difference in survival between the two groups defined by that threshold: PKCα(S657) threshold 50750.33, log rank test with Holm corrections P=0.02. Patients who show PKCα(S657) lower than 50750.33 have a higher probability to relapse: 15 of 32 (47%) patients with PKCα(S657) lower than 50750.33 relapsed, while among the 58 patients with PKCα(S657) higher than 50750.33 only (17%) relapsed. Of note, mRNA expression analysis for mTOR and PKCα did not reveal any significant difference in gene expression levels among the above studied T-ALL patients. *Conclusions.* This research identified the different activation state of proteins in subgroups of T-ALL patients with clinical relevance that may be explored for new therapies.

0004

COMBINED BCL-2 AND MTOR INHIBITION IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

S Iacovelli,[1] MR Ricciardi,[1] S Decandia,[1] P Bergamo,[2] A Miele,[1] A Vitale,[1] AM Testi,[1] MT Petrucci,[1] M Milella,[2] R Foà,[1] A Tafuri[1]

[1]Haematology Sapienza University of Rome, Rome, Italy; [2]Medical Oncology A Regina Elena National Cancer Institute, Rome, Italy

Background. Acute lymphoblastic leukemia (ALL) is a malignant disorder of lymphoid progenitor cells. Leukemic cells resistant to induction chemotherapy lead to persistence of disease or relapse and ultimately to patients' death. We have previously observed that ABT-737 (kindly provided by Abbott Laboratories), a Bcl-2/Bcl-xL (BH3 mimetic) inhibitor, exerts potent cell growth inhibition and apoptosis induction in ALL cell lines and primary samples. It has also been reported that deregulation of mTOR signalling is frequently found in ALL and mTOR inhibition by CCI-779 is associated with anti-leukemic effects in pre-clinical models. *Aim.* Aim of the study was to investigate in ALL cell lines and primary leukemic blasts the effect on cell proliferation and apoptosis of ABT-737 and CCI-779 alone or in combination *Results.* In MOLT-4 cells, ABT-737 induced a dose and time-dependent growth inhibition (IC-50= 198 nM) followed, at higher concentrations (250-500 nM), by apoptosis induction. In contrast, CEM-S (IC-50=12.1 μM), JURKAT (IC-50=66 μM), DAUDI (IC-50=67.8 μM) and RAJI (IC-50=1.6×10^{20} μM) proved resistant. Western Blot (WB) analysis revealed that all of them share Mcl-1 overexpression, already reported as a resistant factor to ABT-737. When we explored the effects of CCI-779 on the aforementioned cell lines, only minor cytotoxic effects were found at higher concentrations (IC-50 ranging between 0.5 μM to 28.2 μM), as demonstrated in the MOLT-4 cells which showed a biphasic dose response with a flat curve (35-55% growth inhibition) at concentrations ranging between 1 nM and 5000 nM (IC50=9,87 μM). Apoptosis induction, as measured by Annexin-V positivity, was not observed until 72h at 10000 nM. Instead, cell cycle effects were noticed, as shown by a S-phase decrease, from 38.03%±3.7 (vehicle) to 27.7±7.8% at 5000nM (P=0.03). Aiming at investigating the activity of ABT-737 plus CCI-779 on the resistant phenotypes, we exposed JURKAT cells to the above combination (each of them at 1000nM). A significant (P=0.04) induction of apoptosis was found, as measured by an increase of the sub-G1 peak, to 47.7±5.9% (CCI-779+ABT-737) compared to the effects of the single agents (17.4±1.5% and 4.2±1.5% in the presence of ABT-737 and CCI-779, respectively). WB analysis revealed in the presence of CCI-779 and, particularly, its combination with ABT-737, a decrease of Mcl-1 level. Results obtained on primary cells from 8 ALL patients treated *in vitro* with of ABT-737 (ranging from 50 to 100 nM) and CCI-779 (ranging from 5000-10000 nM) alone or in combination, showed an increase of the sub-G1 peak in 5/8 and in 3/8 samples exposed to ABT-737 and to CCI-779, respectively, while synergistic effects on apoptosis induction were found in 2/8 primary samples. *Summary/Conclusions.* We observed that CCI-779 can potentiate growth inhibition and apoptosis induction of ABT-737 on ALL cells. Interestingly, the combined use of both inhibitors exerts synergistic cytotoxic effects on the JURKAT cells, mediated by the down-regulation of Mcl-1. Pre-clinical studies on an initial series of primary ALL samples, support the investigation of the active oral ABT-737 compound, ABT-263, as a novel therapeutic approach in ALL, aimed at overcoming selected resistance mechanisms.

0005

GENOME WIDE ANALYSIS REVEALS WNT11, A NONCANONICAL WNT GENE AS A TARGET OF THE ETS TRANSCRIPTION FACTOR ERG

L Mochmann,[1] J Bock,[1] J Ortiz-Tanchez,[1] C Schlee,[1] K Neumann,[2] WK Hofmann,[3] E Thiel,[1] C Baldus[1]

[1]Charite, Campus Benjamin Franklin, Berlin, Germany; [2]Charite, Campus Mitte, Berlin, Germany; [3]University Hospital Mannheim, Mannheim, Germany

Background. ERG is an ETS transcription factor that is involved in leukemogenesis and mRNA overexpression is associated with poor prognosis in patients with T-cell acute lymphoblastic (T-ALL) and acute myeloid leukemia (AML). Normal *ERG* expression peaks during T-cell lineage commitment and furthermore is required for hematopoietic stem cell maintenance. Thus far, ERG transcriptional networks in leukemia are unknown. *Methods.* Herein, a genome-wide analysis of ERG target genes was conducted in a T-ALL cell line by chromatin immunoprecipitation-chip (ChIP-chip). Enriched ERG-bound DNA and total chromatin were differentially hybridized to high resolution tiled promoter chip array. *Results.* Of the significantly fluorescent annotated regions derived from duplicate ChIP-chip experiments, a total of 340 annotated genes were categorized using DAVID Gene Ontology Tools. Significant biological processes of the candidate genes with gene count out of total are listed as follows: cellular processes (232), biological regulation (118) and developmental processes (98). These data suggest a broader functional role or anomalous role for ERG in leukemia. In addition, 17 candidate promoter regions resulted in >2-fold enrichment over total chromatin by quantitative PCR. Notably, candidate genes *WNT2, WNT9A, WNT11, CCND1* and *FZD7*, of the WNT signaling pathway, were among the 17 candidate genes. Expression of *WNT11*, the most significantly enriched gene promoter by ChIP-chip, was directly reduced by 40-50% with siRNA knockdown of *ERG* (70-90% transcript level knockdown). Conversely, through a Tet-on ERG-inducible cell based system in K562 cells, *ERG* induction (>50-fold

relative to uninduced status) substantially upregulated *WNT11* mRNA expression ranging from 10 to 100-fold relative to the uninduced status from 3 independent clones. Moreover, modulation of glycogen synthase 3β (GSK-3β), a central regulator in WNT signaling, was inhibited with 6-bromoindirubin-3'-oxime (BIO) addition in the Tet-on *ERG* inducible system. *ERG*-induced cells treated with BIO (1-2 μM) elicited a growth advantage at 72 hours over uninduced BIO treated cells in a WST proliferation assay. Thus, application of GSK-3β inhibitor (BIO) confers resistance upon *ERG* induction. Lastly, ChIP of primary bone marrow samples of six newly diagnosed acute leukemia patients (one T-ALL and five AML) and one healthy bone marrow donor showed that *WNT11* promoter enrichment correlated with ERG mRNA expression. *Conclusions.* ERG transcriptional networks in leukemia are revealed in this study. Specifically, we demonstrated that ERG functionally is a positive regulator of *WNT11*. From our observation of a proliferation advantage of *ERG* induction in combination with GSK3-β inhibition, we propose a functional role for ERG as an upstream regulator in the WNT pathway.

0006

HUMAN BONE-MARROW MESENCHYMAL STEM CELLS PROTECT B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA CELLS FROM APOPTOSIS IN VITRO BY UPREGULATING NOTCH-3 AND -4 ON BOTH CELL TYPES

AH Nwabo Kamdje, F Mosna, F Bifari, V Lisi, E Mimiola, O Perbellini, G Pizzolo, M Krampera

University of Verona, Verona, Italy

Background. Notch signaling pathway plays a crucial role in promoting self-renewal in either normal hematopoietic and leukemic stem cells. In fact, deregulation of Notch signaling is involved in the pathogenesis of several forms of acute lymphoblastic leukemia (ALL), most importantly in the T-ALL with the translocation t(7;9)(q34;q34.39). However, little is known about the role of Notch signaling in B-lineage ALL. Bone marrow-derived mesenchymal stem cells (BM-MSCs) are non-hematopoietic precursors that may support hematopoietic progenitors using Jagged-1/Notch-1 signaling. *Aims.* to evaluate the role of the Notch signaling pathway in the maintenance of B-ALL cells in coculture with BM-MSCs. *Methods.* MSCs were obtained from normal BM samples collected after informed consent, and expanded up to passage 3-4, displaying a homogeneous mesenchymal immunophenotype and multipotent differentiation capability. B-ALL cells were obtained by density gradient centrifugation from BM samples of 5 newly-diagnosed patients with high blast count (mean purity: 91.2%, range: 82-97), and were cocultured with BM-MSCs at 10/1 ratio for 3, 7 and 28 days. Apoptosis of B-ALL cells was evaluated by Annexin-V/7-AAD staining, while proliferation was assessed with the Carboxyfluorescein-diacetate Succinimyl-ester (CFSE) method and flow cytometry. Expression of Jagged-1 and Notch-1, -2, -3 and -4 was assessed on both cell types with flow cytometry. *Results.* At each time point the number of surviving B-ALL cells was increased by the coculture with BM-MSCs (day 3: 56.5±1.6% vs 73.5±0.2%, P<0.001; day 7: 15.8±2.7% vs 58.0±1.4%, P<0.001; day 28: 4.6±1.5% vs 30.6±2.1%, P<0.001). This finding was due to a dramatic reduction in apoptosis rather than to the proliferation of B-ALL cells, which was negligible. At the same time, the expression of Notch-1, Notch-3, Notch-4 and Jagged-1 by B-ALL was markedly upregulated by the coculture with BM-MSCs (Notch-1: 1.7±0.6% vs 21.0±1.3%, P<0.001; Notch-3: 5.3±0.7% vs 16.3±0.7%, P<0.001; Notch-4: 1.8±0.5% vs 3.8±0.8%, P<0.001; Jagged-1: 8.4±0.7% vs 37.4±1.5%, P<0.001; all at day +3). On the other hand, Notch-3 and -4 were upregulated on BM-MSCs (Notch-3: 8.8±1.1% vs 54.8±1.1%, P<0.001 at day +3; 7.9±0.7% vs 88.5±1.7%, P<0.001 at day +7; Notch-4: 1.0±0.2% vs 5.8±0.5%, P<0.001 at day +3; 2.2±0.3% vs 48.5±1.4%, P<0.001 at day +7). Notch-2, expressed at low levels at basal conditions on both B-ALL and MSCs, became undetectable from day +3 onwards. We then blocked all the Notch signaling with the γ-secretase inhibitor XII: consequently, B-ALL cells were all dead at day +3 when cultured alone, but still 42.5±0.5% of the total population was alive by coculturing B-ALL with BM-MSCs. We next blocked single Notch receptors through specific neutralizing antibodies: 61.2±0.4%, 51.4±0.5% and 30.8±0.8% of B-ALL cells were still alive using anti-Notch-1, -3 and -4 antibodies, respectively (Figure 1). *Conclusions.* considered together, these data show how BM-MSCs contribute to the survival of B-ALL blasts by activating Notch signaling. Notch-3 and -4 appear mainly responsible for these phenomena and might become future additional targets in the treatment of B-ALL.

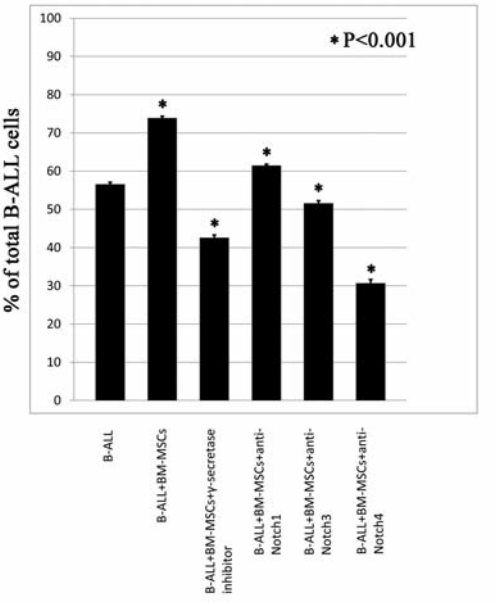

Figure 1. Viable B-ALL cells at day +3 of culture.

RNAI MEDITED SILENCING REVEALS TEL/AML1 IS DISPENSABLE FOR LEUKEMIC CLONE SURVIVAL

M Zaliova,[1] J Madzo,[2] G Cario,[3] J Trka[1]

[1]2nd Faculty of Medicine, Charles University Prague, Prague, Czech Republic; [2]University of Chicago, Chicago, USA; [3]University Hospital Schleswig-Holstein, Kiel, Germany

Backround. Translocation (12;21), the most frequent chromosomal aberration in childhood ALL results in TEL/AML1 fusion gene. TEL/AML1 hybrid protein most likely acts as an aberrant transcription factor that deregulates AML1-dependent transcription but its target genes, and thus also the exact role in leukemic cells remain unknown. *in vivo* studies showed that TEL/AML1 itself is not sufficient to cause leukemia but may induce a preleukemic state characterized by the increased numbers of multipotent or B-cell progenitors with an incomplete block of differentiation. Role of TEL/AML1 for leukemic clone establishment is being studied intensively, however, relevance of TEL/AML1 fusion gene for definitive leukemia persistance has not been approached yet. *Aims.* To address this question and to explore the potential of TEL/AML1-targeted therapy, we aimed to study the effect of RNAi-mediated TEL/AML1 silencing on leukemic cells. *Methods.* Transfection of siRNAs was used to silence TEL/AML1 and AML1 genes. HeLa cells were transfected by lipofection, REH and UOC-B6 cells (only available TEL/AML1-positive cell lines) by rectangular pulse-electroporation. TEL/AML1 level was monitored at mRNA and protein levels using qRT-PCR and western blot, respectively. Cell viability was measured using trypan blue staining followed by microscopy, apoptosis rate was monitored by staining with annexin V and propidium iodide using flow cytometry. Analysis of DNA content using staining with propidium iodide was performed to assess cell-cycle distribution. Incorporation of nucleoside analogue was measured by flow cytometry to analyse *de novo* DNA synthesis as an indicator of proliferation rate. GEP was performed in TEL/AML1-positive cells after TEL/AML1 silencing. *Results.* We designed eleven different siRNAs specifically targeting the fusion sequence to silence TEL/AML1 but prevent silencing of TEL and AML1 wild type alleles. In the first step siRNAs efficiency was measured in HeLa cells transgenic for TEL/AML1-ires2-EGFP reporter as a decrease of EGFP fluorescence by flow cytometry. In the second step five most efficient siRNAs were tested at mRNA level in TEL/AML-positive leukemic cell line. Two most efficient siRNAs were pooled and used for TEL/AML1 knock-down in REH and UOC-B6 TEL/AML1-positive cell lines. Applying two rounds of transfection within 48 hours interval we achieved 74% and 86% TEL/AML1 protein knockdown in REH and UOC-B6 cells, respectively. Seemingly counter-intuitively (based on the results from studies on other fusion oncogenes including BCR/ABL,

AML1/ETO, E2A/PBX1), TEL/AML1 silencing neither decreased cell viability, nor induced apoptosis. On the contrary, TEL/AML1 depletion was accompanied by modest but significant increase in the fraction of S-phase cells and corresponding rise in the proliferation rate. Opposite effects on cell cycle and proliferation were induced by AML1 silencing, supporting our hypothesis that TEL/AML1 may block previously demonstrated AML1 role in G1/S progression through the cell cycle. In line with the lack of effect on cell viability and discreet effect on cell-cycle distribution and proliferation we found no significant changes in global gene expression pattern upon TEL/AML1 depletion. *Conclusions.* Our data indicate, that TEL/AML1 is dispensable for leukemia persistence, at least in studied cell lines, and, as such, would not be a suitable target for gene specific therapy.

CHARACTERIZATION OF THE NOVEL ABL1 FUSION TO THE PUTATIVE TUMOR SUPPRESSOR GENE SHIP1 IN ALL

P Kakadia,[1] B Tizazu,[2] G Mellert,[1] K Spiekermann,[1] S Bohlander[2]

[1]Labor für Leukämiediagnostik, Munich, Germany; [2]Klinische Kooperationsgruppe Leukämie am Hämatologikum des Helmholz Zentrums M, Munich, Germany

Background. BCR/ABL is the most common fusion gene in leukemia. The BCR/ABL fusion is the hallmark of CML and is frequently associated with B-lineage ALL. Up to now only 5 other mostly rare fusion partners of ABL1 have been described: ETV6, RCSD1, EML1, NUP214 and ZMIZ1. Here, we describe a novel fusion of ABL1 to SHIP1 (Inositol Polyphosphate-5 Phosphatase, INPP5D) in an 18-year-old woman with c-ALL. *Aim.* We aimed to characterize the SHIP1-ABL1 fusion at the genomic, molecular and functional level. *Methods.* Fluorescence *in situ* hybridization (FISH) analysis was performed using the BCR/ABL1 and SHIP1/ABL1 dual color dual fusion (DCDF) probes. Coimmunoprecipitations were performed by co-expressing differentially tagged versions of the SHIP1/ABL1 protein. The dimerization domain of SHIP1 was mapped using the Yeast-two hybrid (Y2H) system. Ba/F3 cells were stably transduced with a retroviral vector expressing SHIP1/ABL1 or various deletion mutants of SHIP1/ABL1. *Results.* Sequence analysis of an unexpected PCR product obtained from the diagnostic screening for a BCR-ABL1 fusion from a patient with c-ALL, revealed an in-frame fusion of the first 343 amino acids of SHIP1 to the second exon of the ABL1. The SHIP1/ABL1 fusion protein contains an SH2 domain in the SHIP1 portion (amino acids 2 to 102) and the ABL1 protein starting from exon 2. As the SHIP1 gene is located on 2q37 and is transcribed centromere to telomere like the ABL1 gene on 9q34, we predicted the SHIP1/ABL1 fusion to be on chromosome 2. Interestingly, FISH analyses using a BCR/ABL1 DCDF probe on metaphase chromosomes did not show an ABL1 signal on chromosome 2 but detected four ABL1 signals in interphase nuclei. Additional analyses with various combinations of SHIP1 and ABL1 probes revealed the presence of two SHIP1/ABL1 and one ABL1/SHIP1 fusion in the interphase nuclei from the patients. By using an anti-FLAG antibody an HA-SHIP1/ABL1 protein coimmunoprecipitated with a FLAG-SHIP1/ABL1 protein. This suggested that the SHIP1/ABL1 fusion is using a similar dimerization-dependent kinase activation mechanism like the other ABL1 fusion proteins. SHIP1/ABL1 transduced Ba/F3 cells exhibited IL3 independent growth, which was sensitive to Imatinib. Moreover, we could show that the expression of the SHIP1/ABL1 fusion protein in Ba/F3 cells leads to strong tyrosine phosphorylation of a number of proteins including STAT5a, MAPK, CRKL, and SHIP1/ABL1 itself. Using the Y2H system we were able to show that amino acids 100 to 343 of SHIP1 are necessary and sufficient for dimerization and for the induction of factor independent growth of Ba/F3 cells. *Conclusions.* Since SHIP1 functions as a negative regulator of myeloid proliferation and SHIP1 knockout mice develop a myeloproliferative syndrome-like disease, it is tempting to speculate that in addition to the activation of the ABL1 tyrosine kinase, the formation of the SHIP1/ABL1 fusion might contribute to cellular transformation by compromising the putative tumor suppressor function of SHIP1 through: 1) haploinsufficiency and 2) a dominant negative effect mediated by the interaction between SHIP1/ABL1 and SHIP1. This is the first report describing genetic lesions of SHIP1 in ALL.

IL-27 ERADICATES PEDIATRIC B-ALL CELLS IN VIVO BY TARGETING TUMOR INITIATING CELLS

I Airoldi,[1] C Cocco,[1] S Canale,[1] C Frasson,[2] E Ognio,[3] E Seganfreddo,[2] D Ribatti,[4] E Di Carlo,[5] G Basso,[2] C Dufour[1]

[1]G.Gaslini Institute, Genova, Italy; [2]University of Padova, Padova, Italy; [3]National Institute of cancer research, Genova, Italy; [4]University of Bari, Bari, Italy; [5]G. d'Annunzio University Foundation, Chieti, Italy

Background. B-acute lymphoblastic leucemia (B-ALL) is the most common pediatric hematologic cancer which derives from aberrant expansion of early B lymphocytes in the bone marrow (BM). B-ALL is organized as a cellular hierarchy sustained by tumor initiating cells (TIC) at the apex which are the only cells with self-renewal ability, which generate both rapidly proliferating clonogenic progenitors and leukemic blasts, and maintain the bulk population of cancer cells. TIC are quiescent, slowly dividing cells and are refractory to chemotherapeutic agents that kills highly proliferating cells within the tumor. Therefore, complete eradication of this tumor may depend on the efficacy of therapies that target also TIC cells. IL-27 is a pro-inflammatory cytokine and shows anti-tumor activity in different murine solid tumors through indirect mechanisms such as immune stimulation and/or inhibition of angiogenesis. *Aims.* Objective of this study was to investigate the role of IL-27 as potential anti-tumor agent against primary B-ALL cells *in vivo* by targeting blasts and/or TIC populations. No information is available on the role of IL-27 in these cells. *Methods.* Blasts and TIC from BM of B-ALL patients after informed consent were tested for the expression of both chains of IL-27 receptor (R) (i.e. gp130 and WSX-1), by flow cytometry. The *in vivo* experiments were performed using primary B-ALL cell samples injected into SCID/NODIl2rg-/- (NOG) mice that were treated with PBS (controls) or human recomibinant (hr) IL-27. The IL-27 anti-tumor activity was evaluated in terms of tumor mass formation and spreading. Leukemic cells were searched at the primary site of tumor cell inoculation (subcutaneously and in the peripheral blood) as well as in the lymphoid organs (spleen, BM, lymph nodes) by flow cytometry and immuohistochemical analysis. In order to demonstrate unambiguously that IL-27 functions directly on B-ALL cells we cultured primary B-ALL cells in the presence or absence of hrIL-27 and tested them for apoptosis and proliferation (flow cytometry) and angiogenesis by chorioallantoic membrane (CAM) assay. *Results.* Both blast and TIC popultions expressed complete IL-27R. In the *in vivo* experiments, B-ALL cells were found in the PB, BM and spleens from controls, whereas the same cells were present in the BM only from IL-27 treated animals. The TIC population was also reduced in the BM from treated mice as compared to BM of controls. The *in vitro* experiments showed that IL-27 inhibited proliferation and angiogenesis, and induced apoptosis of B-ALL cells, demonstrating that IL-27 targets directly neoplastic B-ALL cells. *Conclusions.* Taken together, our results show for the first time that IL-27 inhibits B-ALL spreading *in vivo* and may act against both leukemic blasts and TIC. This study may open new perspectives for playing therapeutic protocols based on such double anti-tumor effect by IL-27, and aimed to obtained a complete eradication of B-ALL in pediatric patients at diagnosis and/or relapse.

NOTCH3: A MORE PROMINENT PLAYER THAN NOTCH1 IN THE PATHOGENESIS OF T-ALL?

E Radwan,[1] E Ferretti,[2] S Checquolo,[2] P Grazioli,[2] C Talora,[2] H Moussa,[3] A Campese,[2] M El-Ansary,[1] S Hussein,[1] D Yassin,[3] A Kamel,[3] I Screpanti[2]

[1]Faculty of Medicine, Cairo University, Cairo, Egypt; [2]Sapienza University of Rome, Rome, Italy; [3]NCI, Cairo University, Cairo, Egypt

Background. T-acute lymphoblastic leukemia (T-ALL) includes several subtypes that correlate with genetic aberrations at different stages of thymocyte differentiation. NOTCH family controls various steps of T-cell development; hence dysregulated NOTCH signaling could be involved in the development of T-ALL. NOTCH3 gene was previously shown to be expressed in all T-ALL patients, whereas its expression was reduced in remission; it is associated with the expression of HES1 and the invariant chain of pre-TCR (p-Talpha). Thus, a T-ALL signature characterizes the active or relapsing disease. NOTCH1 was discovered as a partner gene in the rare t(7;9), representing <1% of T-ALLs, yet about 50% of human T-ALLs were noted to harbor activating point mutations in NOTCH1 that lead to aberrant activation of NOTCH signaling, placing it at the center of T-ALL pathogenesis. Other studies

reported that NOTCH1 expression was not pathognomonic for T-ALL, as it was detected not only in normal peripheral blood T lymphocytes but also in non-T cell leukemias. More recently NOTCH1 activating mutations were reported as secondary events in T-ALL. *Aims.* The aim was to study the expression of the main genes involved in the NOTCH pathway, to verify the possible specific role of NOTCH1 versus NOTCH3 in the pathogenesis of T-ALL and to correlate the level of the expression of such genes to other prognostic parameters. *Methods.* Under informed consent the study was performed on 46 T-ALL patients (38 children/8 adults, 33 males/13 females); 12 cases of precursor B-ALL and 13 healthy subjects served as control groups. Gene expression was evaluated using Real Time PCR. *Results.* NOTCH1, NOTCH3, pTalpha and HES1 expression was increased in T-ALL compared to precursor B-ALL (P=0.015-0.044) and healthy subjects (P=0.0001-0.022). Genes expression was higher in children compared to adults; the difference was significant for NOTCH3 (P=0.02) and pTalpha (P=0.005). The genes level in early, intermediate and late T-ALL was examined. Due to the comparable level of gene expression in both intermediate and late T-ALL they were considered as one group in comparison with early T-ALL. Gene expression was higher in intermediate and late T-ALL group compared to early T-ALL for all the studied genes (P=0.006-0.016) except for HES1 (P=0.11). A correlation was found between NOTCH1 and NOTCH3 (r=0.508/P=0.0001) and between each of them and pTalpha (r=0.481, P=0.0001 and r=0.871,P=0.0001 respectively). HES1 moderately correlated with NOTCH1 (r=0.48, P=0.021). No association was encountered between genes expression and any of the prognostic parameters: age, TLC, mediastinal involvement, CNS involvement, hepatosplenomegaly, or lymphadenopathy except for a high expression of NOTCH1 in association with hemoglobin level <10 g/dL (P=0.049) and a negative correlation between them (r=-0.476/P=0.003). NOTCH3/NOTCH1 ratio was calculated for the different groups. Both T-ALL and precursor B-ALL showed comparable ratios to each other (P=0.312) while both showed a higher ratio in comparison to healthy subjects (P=0.0001 and 0.013 respectively) *Conclusions.* Our study confirms a pivotal role of NOTCH pathway in the pathogenesis of T-ALL together with pTalpha and HES1. The higher NOTCH3/NOTCH1 ratio suggests that NOTCH3 dysregulation may play a more central role than NOTCH1 in ALL pathogenesis.

0011

THE PROSURVIVAL CYTOKINE ANGIOPOIETIN-1 IS OVEREXPRESSED IN T(4;11)-POSITIVE ALL AND REGULATED IN A MLL/AF4-DEPENDENT MANNER

P Garrido Castro,[1] S Bomken,[1] J Vormoor,[1] J Greil,[2] O Heidenreich[1]

[1]Newcastle University, Newcastle upon Tyne, UK; [2]Dept. of Paediatric Haematology and Oncology, University Children's Hospital, Heidelberg, Germany

Background. The chromosomal translocation t(4;11)(q21;q23) marks an acute lymphoblastic leukaemia (ALL) subtype prevalent in infants and associated with poor outcome. ALL cells carrying this translocation express the fusion gene MLL/AF4; in concordance with the adverse prognosis of t(4;11)-positive paediatric ALL, cell lines expressing MLL/AF4 are associated with resistance to chemotherapy-related stress and cell death. In order to address the functional role of MLL/AF4 in leukaemogenesis and leukaemic maintenance, we employ siRNA oligonucleotides targeting the fusion site of the MLL/AF4 transcript inherent of our cell line model, the t(4;11)-positive ALL cell line SEM. As previously reported by us, sustained MLL/AF4 depletion induces cell death. Gene expression profiling of the SEM cell line transfected with siMLL/AF4 revealed a subset of differentially expressed angiogenic genes, most prominently ANGIOPOIETIN-1 (ANGPT1), a proangiogenic cytokine previously reported to play a role in proliferation and survival of acute myeloid leukaemia (AML) cells, but to date not implicated in ALL. Recently, ANGPT1 signalling has been linked to haematopoietic stem cell (HSC) quiescence and bone marrow (BM) niche maintenance; pathways activated downstream of ANGPT1 include several prosurvival cascades associated with leukaemia, such as PI3K/AKT, MAPK and STAT3/5 signalling. *Methods.* ANGIOPOIETIN mRNA transcript levels were analysed by real-time RT-PCR (Q-RT-PCR), and ANGPT1 protein secretion determined using enzyme-linked immunosorbent assay (ELISA). Expression of ANGIOPOIETIN receptors and integrins was detected using RT-PCR. The MLL/AF4 status of cells was modulated using fusion transcript-specific siRNA oligonucleotides; successful knock-down was monitored by Q-RT-PCR. *Results.* Screening of a B-cell precursor ALL cell line cohort showed ANGPT1 mRNA expression to be restricted to the t(4;11) ALL subtype, where it is upregulated up to 100-fold compared to peripheral blood B cells from healthy donors. High levels of ANGPT1 were also detected in 11q23 rearranged infant ALL patient samples. Conversely, 11q23 rearranged AML cell lines show substantially lower ANGPT1 levels. Notably, in addition to its expression being restricted to t(4;11)-positive ALL, ANGPT1 levels are dependent on MLL/AF4; reduction of ANGPT1 mRNA and protein levels correlated with siRNA-mediated MLL/AF4 depletion in a time-dependent manner. Conversely, ANGIOPOIETIN-2 (ANGPT2), the biological antagonist of ANGPT1 and an independent prognostic marker in AML, showed increased RNA levels in response to MLL/AF4 knockdown in SEM cells. Expression analyses of receptors reported to mediate ANGPT1 and ANGPT2 signalling revealed presence of the integrins ITGB1 and ITGB5 in t(4;11)-positive ALL cell lines, enabling an autocrine function of secreted ANGPT1. *Conclusions.* Here we report for the first time a possible implication of ANGIOPOIETIN-1 in t(4;11) ALL, as defined by its overexpression and the regulation of mRNA and protein levels by the MLL/AF4 status of cells. ANGPT1 signalling represents an attractive potential target, both in an autocrine manner and in the context of crosstalk with the BM niche, which may promote ALL cell survival. We are currently assessing the functional role of ANGPT1 in t(4;11) ALL cells.

COMBINED INTERPHASE FLUORESCENCE IN SITU HYBRIDIZATION (CI-FISH) DELINEATES THE GENOMIC PROFILE OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN

R La Starza,[1] V Pierini,[1] B Crescenzi,[1] C Matteucci,[1] V Nofrini,[1] A Leszl,[2] G Cazzaniga,[3] P Gorello,[1] S Romoli,[1] A Lettieri,[3] F Aversa,[1] G Basso,[2] C Mecucci[1]

[1]University of Perugia, Perugia, Italy; [2]Università degli studi di Padova, Padova, Italy; [3]Ospedale S Gerardo, Monza, Italy

Background. In T-cell acute lymphoblastic leukemias (T-ALL) diverse molecular lesions deregulate genes involved in cell cycle control, proliferation, differentiation, survival and apoptosis. Our combined interphase fluorescence *in situ* hybridization (CI-FISH) assay reliably detected cryptic aberrations and elucidated preferential and forbidden associations of multiple genetic events concurring in adult T-ALL pathogenesis.[1] It also provided great advantages of major savings in time, costs and biological material as it combined over eight molecular assays in one slide. *Aims.* To extend our CI-FISH assay to include 30 loci/genes for a pilot study in children with T-ALL. *Methods.* We analysed 33 cytogenetic pellets of children with T-ALL who were enrolled and uniformly treated under the AIEOP LLA 2000 protocol. Immunophenotyping indicated early pre-T in 16 cases, thymic in 10, and mature in 7. Karyotyping was informative in 10 (30%), showing abnormalities in 4 (12%), but failed in the others. RT-PCR detected *MLL-ENL* and *CALM-AF10* fusion in 1 case each. *Results.* CI-FISH was abnormal in 30/33 patients, detecting ≥2 genetic changes in 20. Mono- or bi- allelic del(9)(p21)/CDKN2AB deletion was the most frequent abnormality (17 patients; 51%). In 5/17 cases del(9)(p21)/*CDKN2AB* included JAK2/9p24 and PAX5/9p13 and in 4/17 cases it included PAX5. Monoallelic del(6)(q16)/GRIK2 was found in 5 cases (15%). *TCRB*-rearrangements were detected in 5 patients (15%): inv(7)(p15q34)/*TCRB-HOXA* (2 cases), t(7;11)(q34;p15)/*TCRB-LMO1* (2 cases), t(7;9)(q34;q32)/*TCRB-TAL2* (1 case). *TCRA/D* underwent rearrangement in 3 cases: t(11;14)(p13;q11)/*TCRAD-LMO2* (2) and t(10;14)(q24;q11)/*TCRAD-HOX11* (1). Other expected changes were: del(1)(p32)/*SIL-TAL1* (8 cases), *TLX3*-translocation (5), *CALM-AF10* (3), MYB duplication (2), *MLL*-translocation, dup(9)(q34)/*ABL1-NOTCH1-NUP214*, and *PTEN*/10q24, *WT1*/11p13, and *ETV6*/12p13 deletion (in 1 case each). We detected loss of LEF1/4q25, in 2 cases, and of IKAROS/7p11, 1 case. Genomic imbalances which have still not been characterised molecularly were observed in individual cases: 1p32/SIL-TAL1 and 5q35/*TLX3* losses, 1p32/*SIL-TAL1* and 17q11/*NF1* gains. *Summary/conclusions.* Although conventional cytogenetics and RT-PCR were uninformative in the majority of T-ALL cases our new CI-FISH assay identified molecular lesions in 91% of cases and multiple changes in 60%. It provided a picture of a myriad of genomic lesions in T-ALL, the roles of which as driver or passenger hit still needs investigation. Remarkably, 73% of our cases could be classified according to well-established gene expression profiling signatures, i.e. *SIL-TAL1*; *CALM-AF10*, *MLL*, and *HOXA*; *TLX3*; *LMO1* and *LMO2*. Two broad groups of predominant associations emerged: the del(9)(p21)/*CDKN2AB* was preferentially associated with *HOX11L2*, *LMO1*, or *CALM-AF10* while the del(6)(q16)/

GRIK2 appeared preferentially associated with *TAL2* or LMO2. Approximately 18% of children had del(9)(p21)/CDKN2AB alone or associated with loss of *GRIK2*/6q16 or gain of *NF1*/17q11. In conclusion, as present findings indicate our CI-FISH assay is a valid tool in the genetic characterization of pediatric T-ALL, we propose its use in the diagnostic work-up. Its application in large prospective studies will serve to evaluate the clinical impact of a genome-based classification in this specific ALL subtype. *Aknowledgments.* PRIN 20078C9NRT_003.

PROMOTER REGION HYPERMETHYLATION CONTRIBUTES TO C-MET DOWNREGULATION IN PEDIATRIC MLL-REARRANGED BCP-ALL

B Accordi, G Milani, L Marchioretto, L Galla, M Sciro, G Te Kronnie, G Basso

University of Padova, Padova, Italy

Background and Aims. c-Met is the tyrosine-kinase receptor for HGF. We previously observed that c-Met is expressed in normal B cells and in TEL/AML1-rearranged patients,[1] while its expression is strongly reduced in MLL-rearranged BCP-ALL patients. c-Met forms a protein complex with Fas in TEL/AML1-rearranged leukemias, and the activation of the c-Met pathway was demonstrated to result in increased Fas-mediated apoptosis. This implies that c-Met has an important role in cellular homeostasis and enhanced pharmacological response of TEL/AML1 BCP-ALL cells, and c-Met downregulation in MLL-rearranged leukemias could contribute to chemotherapy resistance observed in these patients. We decided to investigate by which mechanisms c-Met transcription is regulated in BCP-ALL with particular attention to MLL-rearranged cells, first of all focusing on the methylation status of the c-Met promoter. *Methods.* For all patients included in this study the informed consent was obtained following the tenets of the Declaration of Helsinki. We analyzed c-Met expression by SybrGreen RQ-PCR in 22 TEL/AML1-, 14 MLL-rearranged patients and the two human cell lines REH (BCP-ALL with TEL/AML1) and RS4;11 (BCP-ALL MLL-rearranged). REH and RS4;11 cells were treated with 5-aza-dc to test c-Met expression induction by demethylation treatment. To determine the methylation status of the c-Met promoter region in patients (15 TEL/AML1, 13 MLL) and cell lines we then performed bisulfite modification, Methylation Specific PCR (MS-PCR) and sequencing. Quantification of methylation status was performed by measuring relative peak heights in MS-PCR sequencing.[2] *Results.* TEL/AML1-rearranged patients express c-Met more than MLL-rearranged ones (Wilcoxon test, P=0.0001). Demethylating treatment of 72h induced c-Met expression by 150 times in RS4;11 cells, while only 15 times in REH cells. MS-PCR demonstrated that RS4;11 cells are completely methylated, while REH cells are only partly methylated. All MLL-rearranged patients show both methylated and unmethylated bands, while 2/15 TEL/AML1-rearranged patients are completely unmethylated. To better define the difference in the methylation status between MLL- and TEL/AML1-rearranged patients, the degree of methylation of the 6 CpG islands included in the MS-PCR methylated amplicones were quantified by MS-PCR sequencing. We measured the relative peak heights of C (corresponding to methylated C) and T (corresponding to unmethylated C) at the CpG sites. The methylation degree of TEL/AML1-rearranged patients was relatively even (17-50%) at the 6 CpG sites, whereas the methylation level of MLL-rearranged specimens ranged from 45-89%. *Conclusions.* As expected from our preliminary results, c-Met expression was found to be downregulated in MLL-rearranged human BCP-ALL. Responsible of this downregulation appears to be, at least in part, a higher methylation degree of its promoter region. As to our knowledge this is the first study reporting c-Met methylation levels in human cancers. This research will give new insights on the molecular mechanisms at the base of chemotherapy resistance observed in MLL-rearranged patients.

THE GERMLINE STEM CELL SELF-RENEWAL GENE PIWIL2 IS EXPRESSED IN BOTH MALIGNANT AND NON-MALIGNANT LYMPHOID CELLS

N Bomken,[1] S Mysina,[1] C Bomken,[2] O Heidenreich,[1] H Vormoor[1]

[1]Newcastle University, Newcastle Upon Tyne, UK; [2]Newcastle Hospitals NHS Foundation Trust, Newcastle Upon Tyne, UK

Background. The *PIWI-Like* genes (*PIWIL1-4*) are human homologues of the highly conserved family of PIWI-PAZ Domain genes. The protein products of this family perform a central role in endogenous RNA interference pathways. However, PIWI-Like proteins and their non-coding RNA partners, known as PIWI interacting RNA's, function via novel and poorly understood mechanisms, distinct from classical RNA interference. In health, *PIWIL2* is believed to be expressed only in germline stem cells where it is essential for self renewal. More recently, *PIWIL2* expression has been identified in a number of human malignancies raising the possibility that it is involved in the self-renewal programme of cancer stem cells. This gene has been designated as cancer-testis antigen 80. *Aims*. This project aimed to investigate the role of *PIWIL2* in the self-renewal programme of cancer stem cells in childhood acute lymphoblastic leukaemia. Unexpected expression of *PIWIL2* in normal peripheral leukocytes extended the scope of the project to include a wider range of normal leukocyte populations. *Methods*. Following sequencing of the *PIWIL2* amplicon to ensure specificity, quantitative RT-PCR was used to assess expression of the *PIWI-Like* genes. Expression in the t(4;11)(q21;23) positive cell line SEM was modified by transfection of cells with siRNAs specific for the *PIWIL2* transcript. Healthy donor leukocyte populations were purified by immunomagnetic cell separation to provide $CD3^+$ T lymphocytes, $CD19^+$ B lymphocytes, $CD14^+$ monocytes, $CD15^+$ granulocytes. Purity was assessed by flow cytometry, complemented by morphological analysis. *Results*. Expression of *PIWIL2* was demonstrated in a range of acute leukaemic cells lines and primary leukaemic blasts. Expression in the SEM cell line was knocked-down following transfection with *PIWIL2* specific siRNA. Initial studies suggest a substantial proportion of *PIWIL2* transcript may be retained within the nucleus, limiting overall knock-down. Peripheral lymphoid cells from five healthy donors (three male) showed consistent expression of *PIWIL2* and *PIWIL4* (known universal expression), whilst *PIWIL1* and *PIWIL3* were not expressed. Monocytes maintain expression of *PIWIL2*, although to a lesser degree than lymphocytes. Terminally differentiated granulocytes showed no expression of *PIWIL2*. *Conclusions.* Expression of the germline stem cell self-renewal gene *PIWIL2* in cell line and primary acute lymphoblastic leukaemia specimens suggests that this gene may have a role in the self-renewal of leukaemic stem cells. Originally, we hypothesised that the specificity of this gene for germline stem cells and malignant diseases would make it an attractive target for novel therapy development. However, the unexpected finding in the present study - that mature lymphoid cells, a population known to possess substantial potential for clonal expansion and self-renewal also expresses *PIWIL2* - raises doubt over the suitability of *PIWIL2* as a therapy target. Furthermore, the potential role of *PIWIL2* in other mature tissue stem cells should be considered. This work will now be extended to assess the expression of PIWI-Like genes in $CD34^+$ haematopoietic stem cells where we hypothesise *PIWIL2* will play a role in self-renewal.

SQSTM1: A NEW PARTNER FOR NUP214 IN ADULT T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

D Di Giacomo,[1] P Gorello,[1] R La Starza,[1] M Messina,[2] L Elia,[2] S Chiaretti,[2] MC Puzzolo,[2] V Pierini,[1] B Crescenzi,[1] A Santoro,[3] L Brandimarte,[1] M Martelli,[1] R Foà,[2] C Mecucci[1]

[1]University of Perugia, Perugia, Italy; [2]University La Sapienza, Rome, Italy; [3]Ospedale V. Cervello, Palermo, Italy

Background. NUP214, a FXFG nucleoporin located on the cytoplasmic side of the nuclear pore complex (NPC), plays a critical role in cell cycle progression and import/export trafficking. In T-cell acute lymphoblastic leukemia (T-ALL) *NUP214* fusions appear to predict a poor prognosis. So far two *NUP214* fusions were identified in T-ALL: when cryptic del(9q) is present SET fuses with *NUP214*, while episomal amplification leads *NUP214* to rearrange with ABL1. Supervised gene expression profiling (GEP) analysis in adult T-ALL identified *SET-NUP214* positive cases with high expression of HOXA cluster genes, MEIS1 and NUP214, and low expression of *SET, FNBP1*. *C9orf78* and *USP20* genes.[1] Among 69 cases of T-ALL, an additional case emerged at GEP analysis with over-expression of *HOXA, MEIS1, NUP214*, and also of *SET*. This 20-year old man with a chemo-resistant pre-T ALL showed 46,XY, del(6p) karyotype at diagnosis. *Aims.* To investigate last case as an hypothetical new rearrangement involving NUP214 in T-ALL. *Methods.* We set up FISH assays with RP1-112N13 for the 9q sub-telomere, RP11-143H20, flanking the *3'NUP214*, RP11-544A12, spanning the gene, and two overlapping fosmids, G248P89801E11 (exons 25-31) and G248P8659A12 (exons 31-36). Additional FISH experiments were done with 5q35-qter probes: RP11-117L6, RP11-286C20, RP11-549A4, RP11-319K2, RP11-718N2, RP1-240G13. NESTED RT-PCR was performed using primers SQSTM1_ex3_528F (5'-TGCCCAGACTACGACTTGTG-3') / NUP214_ex36_6543R (5'-AGTAATCATGCGCCTTGTGAGTT-3'), for the first amplification round, and SQSTM1_ex4/5_763F (5'-AATCAGCTTCTGGTCCATCG-3')/NUP214_ex33/34_6337R (5'-CAAAGCTGAACCCTCCTGTG -3') for the second. PCR products were cloned into pGEM-T easy vector system and sequenced. *Results.* FISH probe RP11-143H20 gave two signals on normal chromosomes 9 while RP11-544A12 and RP1-112N13 gave 3 signals on chromosomes 9 and on der(5). The *NUP214* breakpoint fell between G248P89801E11, which was retained on chromosome 9, and G248P8659A12, translocated to der(5). The 5q35 breakpoint was telomeric to RP11-718N2, a ~1.7Mb region containing 15 candidate genes, with an appropriate centromere-telomere orientation. GEP indicated down-regulation of genes telomeric to *SQSTM1*, which was thus selected as first candidate gene. RT-PCR detected an amplification product of 852bp. Molecular cloning and sequencing identified the in-frame fusion between nucleotide 849 (exon 5) of *SQSTM1* and nucleotide 6014 (exon 33) of *NUP214*. Nested-PCR and molecular screening of 60 T-ALL adults did not identify any additional case. *Conclusions. SQSTM1* point mutation and over-expression were described in congenital Paget's Bone Disease and solid tumours, respectively. No translocations involving *SQSTM1* have been reported, yet. In this adult with T-ALL *NUP214/9q34* rearranged with *SQSTM1* as a result of a cryptic unbalanced translocation with an apparently normal chromosome 5, i.e, ish der(5)t(5;9)(q35;q34). As in other NUP214 leukemic fusions, the FG repeats were maintained, suggesting similarities with leukemic recombinations of other nucleoporins such as NUP98. However, together with the NUP214 FG repeats, the SQSTM1 N-terminal structural and regulatory motifs, such as the Zinc-finger domain may contribute to the leukemogenic process. To elucidate the incidence and the clinical impact of *NUP214* rearrangements in T-ALL we strongly recommend *NUP214* FISH screening in large prospective studies. DDG and PG shared co-authorship. *Aknowledgements*. PRIN 20078C9NRT_003

INSULIN RECEPTOR SUBSTRATE 1 (IRS1) AND 2 (IRS2) SIGNALING IN HUMAN ACUTE LEUKEMIAS; A POSSIBLE ROLE OF IRS SIGNALING IN THE LEUKEMIA PHENOTYPE

J Machado-Neto, P Favaro, M Lazarini, A Antolini, L Fröhlich-Archangelo, A Duarte, F Costa, S Saad, F Traina

Faculty of Medical Sciences, University of Campinas, Campinas, Brazil

Background. Insulin-like growth factor 1/Insulin Receptor Substrates (IGF-I/IRS) signaling pathway plays an important role in the development of various cancers such as breast, colon and prostate. In ALL Philadelphia-positive, IRS1 expression was noted to be overexpressed and correlated negatively with survival. IRS proteins, including IRS1 and IRS2 play an important role in mTOR/P70S6K and MAPK pathways, through their interaction with effectors such as PI3K, SHP2 and Grb2. PI3K and Grb2 activation leads to higher ERK1/2 and mTOR phosphorylation, respectively, culminating in a proliferation increase. Despite both IRS-1 and IRS-2 being two important adaptor molecules essential for intracellular signaling of insulin and IGF-I, the distinct biological pattern of IRS-2 versus IRS-1 and their roles in acute leukemia remains an interesting issue to be clarified. *Aims.* To investigate IRS1 and IRS2 expression in leukemia cell lines and AML and ALL patient bone marrow samples. We also evaluated the effects of IRS1 knockdown, by lentiviral vector, in MAPK and mTOR signaling pathways in K562 cell line. *Methods.* Myeloid (HL60, P39, KG1, K562, NB4) and lymphoid cell lines (Jurkat, MOLT-4, Raji and Daudi) were used. Primary leukemia cells were obtained from bone marrow of 22 AML and 10 ALL patients. Normal hematopoietic cells were obtained from bone marrow of 07 healthy donors. The National Ethical Committee Board approved the study. Real-time RT-PCR analysis from total bone marrow cells and western blot from mononuclear cells were performed to determine differential expression of IRS1 and IRS2. Specific shRNA-expressing lentiviral vector to IRS1 gene was used in K562 cell line. Western blot and immunoblotting with specific antibodies was used to evaluate ERK and P70S6K expression and phosphorylation. *Results.* IRS1 gene and protein expression were observed in all leukemia cell lines studied, whereas IRS2 gene and protein were preferentially expressed in myeloid cell lines. Decreased IRS1 and IRS2 gene and protein expression was observed in primary AML cells compared to normal hematopoietic cells. The relative gene expression of IRS1 was 0.40 [1.41-0.10] for AML versus 0.009 [7.14-0.008] for normal cells (P=0.03); of IRS2 was 4.53 [9.37-1.00] for AML versus 0.98 [4.34-0.10] for normal cells (P=0.007). IRS1 and IRS2 phosphorylation was not detectable in AML samples. In ALL samples, IRS1 expression was not significantly different from normal hematopoietic cells (0.60 [11.64-0.008] versus 0.40 [1.41-0.10], P>0.05). IRS2 expression was decreased in primary ALL compared to normal cells (0.11 [0.53-0.01] versus 4.53 [9.37-1.00], P<0.0001). Interestingly, IRS1 phosphorylation was slightly increased in ALL samples compared to normal cells. IRS1 silencing (65% of inhibition) in K562 cells resulted in decreased ERK and P70S6K phosphorylation. *Conclusions.* IRS1 and IRS2 are differentially expressed in AML and ALL cells. The up-regulation and phosphorylation of IRS1 in ALL cells suggests an important role of IRS1 in the leukemia phenotype. In K562 cells (Philadelphia-positive cells) lacking IRS1, the decreased phosphorylation of ERK and P70S6K indicates a down-regulation of MAPK and mTOR pathways. Further studies would be necessary to better elucidate the role of IRS1 and IRS2 in leukemogenesis. This work was supported by FAPESP and CNPq.

EVI1 OVEREXPRESSION ROLE IN ACUTE LYMPHOBLASTIC LEUKEMIA

S Fumero,[1] MT Gómez Casares,[1] CE López Jorge,[1] H Luzardo,[1] JD González San Miguel,[2] G Santana,[1] MA García Bello,[3] J López Brito,[1] K Quiroz,[1] S De La Iglesia,[1] A Lemes,[1] T Molero[4]

[1]Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas De Gran Canaria, Spain; [2]Hospital Universitario Insular, Las Palmas De Gran Canaria, Spain; [3]Unidad de Investigacion Hospital, Universitario de Gran Canaria Doctor Negrin, Las Palmas De Gran Canaria, Spain; [4]Hospital Universitario de Gran CANARIA Doctor Negrin, Las Palmas De Gran Canaria, Spain

Background. The ecotropic viral integration site 1 (EVI1), located in chromosome 3q26, has been recognized in the last years as one of the most aggresive oncogenes associated with neoplastic diseases of myeloid cells. The inappropiate expression of EVI1 without rearrangements of chromosome 3q26 has been implicated in the development or progression of Acute Myeloblastic Leukemia (AML). Correlation between overexpression of EVI1 and high risk AML is a frecuent discussion issue in the literature. In our knowledge, EVI1 overexpression has not been associated with lymphoid pathology and its prognostic value in Acute Lymphoblastic Leukemia (ALL) has not been evaluated yet. *Aims.* To analyze the incidence of EVI1 expression in ALL and its value as a prognostic factor. *Methods.* The study was performed restrospectively on a total of 48 patients with ALL. Expression of EVI1 gen ($EVI1^+$) was examined in bone marrow samples and/or peripheral blood at diagnosis by QRT-PCR, adapting the technique developed by M. Russell et al (Blood 1994) to the LightCycler 480 system, using as a fluorescent tracer SybrGreen I. Survival curves were plotted following the Kaplan Meier method and differences between the curves were analyzed with the Log Rank test. *Results.* Out of 48 patients, 12 overexpressed EVI1 (26,1%). We also analyzed other cytogenetic lesions that are frequently seen in association with $EVI1^+$. Results showed that within 12 cases $EVI1^+$, 3 patients were Ph^+ (25%), deletion of chromosome 7 was found in only 1 case (8.3%), translocations involving 11q23 in 2 cases (16.6%) and a normal caryotype in 3 cases (25%). 3q26 chromosmal abnormalities weren't found. In contingent-valuation study (Fisher test) associations between EVI1 overexpression and Philadelphia cromosome were not observed. In the $EVI1^+$ group the complete remission was achieved up to a 67% of the patients compared to the 86% achieved in the EVI1- group (p (Mantel-Haenszel)= 0.098). Survival curves didn't show any significant differences in overall survival (OS) and disease free survival (DFS) when compared the $EVI1^+$ and EVI1- population, though we observed an initial higher mortality in the EVI^+ group. Neither significant differences in OS and DFS were observed when compared EVI^+/Ph^+ and EVI^+/Ph^- population. *Conclusions.* 1) Our study shows for the first time EVI1 overexpression in a high percentage of ALL. 2) No relationship was found between the expression of EVI1 with normal caryotype or other cytogenetc alterations previously related to EVI1. 3) There is a trend toward a lower achievement of CR in the EVI1+ group compared with the EVI1- group, without statistical relevance. This may be due to the low number of samples in this study. It seems that EVI1 overexpression doesn't have an important role in the OS, DFS or relapse in ALL patients.

IN PEDIATRIC LYMPHOBLASTIC LEUKEMIA OF B CELL ORIGIN A SMALL POPULATION OF PRIMITIVE BLAST CELLS IS NON-CYCLING, CONSISTENT WITH LEUKEMIA STEM CELLS

A Hirt, AM Schmid, R Ammann, K Leibundgut

Pediatric Hematology-Oncology, Bern, Switzerland

Background and *Aims.* In pediatric precursor-B cell acute lymphoblastic leukemia (PBC ALL), the majority of blast cells express the B cell antigen CD19. However, a minor fraction of blast cells lack CD19 expression corresponding to a more primitive cell population. Investigations on cell proliferation in pediatric ALL are usually based on the entire leukemic cell population reflecting the proliferative behavior of the predominant $CD19^+$ blast cells. In light of the ongoing debate on the immunophenotype of leukemia stem cells in pediatric PBC ALL, we analyzed the proliferative characteristics of ALL cells at different stages of immunophenotypic maturation. *Methods.* Isolated mononuclear bone marrow cells of 16 children with untreated PBC ALL were stained with monoclonal antibodies against CD19 and CD3 and then separated by fluorescence-activated cell sorting (FACScan Becton-Dickinson). The sorted cells were incubated *in vitro* with bromo-deoxy-uridine (BrdU) and, after preparation of cytocentrifuge smears, stained with an anti-BrdU antibody to enable detection of cells in the S phase of the cell cycle (BrdU-LI). In addition, individual smears of sorted CD19-CD3- cells were stained with monoclonal antibodies against myeloperoxidase (MPO), glycophorin A (GLA), CD34 or CD10. Because the data were non-normally distributed median and interquartile ranges (IQR) were calculated. *Results.* Bone marrow cells were sorted into $CD19^-CD3^+$, $CD19^+CD3^-$ and $CD19^-CD3^-$ populations. Whereas the $CD19^+CD3^-$ cell compartment represented a pure blast cell population, the $CD19^-CD3^-$ compartment was composed of both leukemic blast cells and residual normal hematopoietic cells. Therefore, smears were stained for MPO and GLA to exclude normal hematopoietic cells. By staining of sorted $CD19^-CD3^-$ cells for CD34 or CD10 the compartment of these blast cells was further subdivided. The relative frequencies and the BrdU-LI of these subpopulations are shown in the Table. *Conclusions.* In untreated pediatric PBC ALL the continuous expansion of the leukemic cell population is exclusively based on the proliferative activity of $CD19^+$ blast cells. The very low proliferative activity of primitive $CD19^-$ blast cells is consistent with self-renewal but not with expansion. Due to their immature immunophenotype and their low proliferative activity, $CD19^-$ blast cells may represent leukemia-initiating cells. Whereas actively proliferating $CD19^+$ cells may be killed by current treatment approaches, the primitive non-cycling population may survive and subsequently contribute to disease relapse.

Table.

Immunophenotype	Frequency in % median (IQR)	BrdU-LI in % median (IQR)
All leukemic cells	100	7.1 (5.3-8.1)
$CD19^+$ leukemic cells	97.5 (96.2-98.3)	7.2 (5.7-8.8)
$CD19^-$ leukemic cells	2.4 (1.8-3.5)	0.2 (0.1-0.5)
$CD19^-CD34^+$ leukemic cells	1.4 (0.6-2.8)	0.2 (0.1-0.4)
$CD19^-CD34^-$ leukemic cells	0.8 (0.5-1.6)	<0.1 (0-0.1)
$CD19^-$ leukemic cells	2.4 (1.8-3.5)	0.2 (0.1-0.7)
$CD19^-CD10^+$ leukemic cells	1.2 (0.6-2.1)	0.3 (0-0.7)
$CD19^-CD10^-$ leukemic cells	1.3 (0.4-2.0)	<0.1 (0-0.2)

$CD34^+CD38^-$ LEUKEMIC STEM CELL PROFILE CORRELATED WELL WITH THE CYTOGENETIC AND MOLECULAIRE FEATURES IN ACUTE MYELOIDE AND LYMPHOIDE LEUKEMIA AT DIAGNOSIS

A Plesa,[1] X Thomas,[1] L Campos,[2] I Tigaud,[3] S Hayette,[3] MP Pages,[3] F Solly,[2] P Flandrin-Gresta,[2] Y Chelgoum,[4] FE Nicolini,[4] L Vila,[5] D Treille Ritouet,[5] S Morisset,[6] Y Bertrand,[7] D Guyotat,[2] M Michallet,[4] C Dumontet[5]

[1]Edouard Herriot Hospital, Laboratory of Hematology, Lyon, France; [2]Laboratory of Haematology and Department of Haematology, Nord Hospital, Saint Et, Saint Etienne, France; [3]Laboratory of Cytogenetics and Molecular Biology, CHLS, Lyon, France, Lyon, France; [4]Department of Haematology and BMT Unit, Edouard Herriot Hospital, Lyon, France, Lyon, France; [5]Laboratory of Hematology, Edouard Herriot Hospital, Lyon, France, Lyon, France; [6]Statistical and Clinical Research of Haematology department, Edouard Herriot Hos, Lyon, France; [7]Department of Pediatric Hematology, IHOP, Lyon, France, Lyon, France

Background. Acute leukemia is thought to arise from a rare putative 'leukemic stem cell'(LSC) that is capable of self-renewal and formation of leukemic blasts. CD38 is expressed in acute lymphoblastic leukemia (ALL) and in acute myeloide leukemia (AML) and its prognostic significance is still unknown. *Aims.* We investigated CD34 and CD38 expression in 93 AML and 73 ALL adults and paediatric patients, and we asked if the frequency of LSC at diagnosis is correlated with specific cytogenetics or molecular events and with the CR and survival. *Methods.* Diagnosis of leukaemia was based on FAB and WHO classifications. Blasts

were identified by CD45dim/SSC characteristics. The "LSC profile" was defined as % of $CD34^+CD38^-$ in $CD34^+$ gated cells and based on rMFI of CD38 from all $CD34^+$ and $CD45^{dim}$/SCC gated cells. *Results.* CD38 was lower in AML-M3 compared to other FAB subtypes. Interestingely, we observed that higher frequency of $CD34^+CD38^-$ was more associated with secondary AML or AML-MRC (myelodysplasia-related changes), but was similar among the primary AML. We show that reduced relative mean fluorescence of CD38 on $CD34^+$ cells correlate well with the cytogenetics unfavourable and intermediate risk groups in the adults AML (P 0.082 or P 0.014 for variance test). The Ph^+ ALL patients showed significant lower CD38 expression than in nonPh^+ patients (P 0.0032). Overall survival favored AML and ALL patients with higher CD38 levels. *Conclusions.* Our results showed that frequency of LSC profile at diagnosis could be predictive for cytogenetics and moleculaire features in acute leukaemia. Screening of $CD34^+CD38$p-value cells is a simple flow cytometry method that might be considered to design a multicolor panel setting in parallel with MRD evaluation. The goal in leukaemia therapy is to eradicate LSC and targeting them after reaching CR should be required. The possibility to detect and characterize LSC should help to reach this goal.

0021

DIVERSE ASPARAGINE SYNTHETASE EXPRESSION IN LYMPHOID BLASTS IS NOT RELEVANT TO THE SENSITIVITY TO L-ASPARAGINASE

I Hermanova, J Trka, JS Starkova

Charles University, 2nd Faculty of Medicine, Prague, Czech Republic

Background. Acute lymphoblastic leukaemia (ALL), the most common haematological malignancy in childhood, is treated by combined chemotherapy, which includes the enzyme L-Asparaginase (L-Asp). The cytotoxic effect of L-Asp consists in its ability to deplete extracellular asparagine and glutamine. The sensitivity of primary ALL cells to this depletion is traditionally explained by decreased activity of glutamine-dependent enzyme asparagine synthetase (ASNS). Despite the fact that increased ASNS level was indeed shown to be connected with L-Asp resistance, the exact relationship between ASNS expression and L-Asp sensitivity has not been elucidated so far. Glutamate dehydrogenase (GDH) is an enzyme necessary for glutamine synthesis. Microarray analysis showed significantly lower expression of GDH gene in primary TEL/AML1$^+$ blasts in comparison with TEL/AML1[-], which might lead to deficiency of glutamine in these cells and consequently higher sensitivity to L-Asp. *Aims.* The aim of this study was to pursue the association of ASNS gene expression, protein level and sensitivity to L-Asp in ALL cell lines and primary paediatric ALL samples. We also focused on the role of GDH in the L-Asp mechanism of action. *Methods.* ALL patient samples and 4 leukemic cell lines were used in this study: Nalm6 (TEL/PDGFRB$^+$); RS4;11 (MLL/AF4$^+$); REH (TEL/AML1$^+$) and UOCB6 (TEL/AML1$^+$). The gene expression was determined by qRT-PCR, ASNS protein content was detected by Western Blot. The L-Asp sensitivity was evaluated by MTS assay. Gene knock-down was performed by electroporation of specific siRNA. *Results.* We showed that ASNS protein levels reflected ASNS mRNA levels and these. correlated negatively with L-Asp sensitivity. UOCB6 as the most resistant cell line (IC_{50}=0.04U/mL) had the highest expression of ASNS (normalized ASNS, nASNS=4.946), followed by NALM6 (IC50=0.01U/mL; nASNS=1.8), REH (IC50=0.6×10^{-4}; nASNS=1.176) and RS4;11 (IC50=0.3×10^{-4}; nASNS=0.024). Detection of protein content in primary ALL blasts was not possible due to significantly lower (2log) ASNS gene expression compared to cell lines. We were interested in how the sensitivity to L-Asp is affected by ASNS gene silencing. Gradient knock-down was realized in 2 ALL cell lines: REH with intermediate basal expression and RS4;11 with very low basal expression. A gradual silencing of ASNS gene in REH cell line led to gradual increase of L-Asp sensitivity till the level of 50%. Further knock-down did not influence the L-Asp sensitivity. The reduction of ASNS did not potentiate L-Asp cytotoxicity in RS4;11 cell line with primary lowest ASNS expression. We found lower GDH gene expression in primary TEL/AML1$^+$ compared to TEL/AML1$^-$ leukaemias (P=0.019). Silencing of GDH gene in TEL/AML1$^+$ REH cell line increased L-Asp sensitivity. *Conclusions.* Our data demonstrate that in cells with very low ASNS expression, as shown in primary ALL blasts of various subtypes, the difference in ASNS levels is not relevant to the sensitivity to L-Asp. We identified GDH as a new player in the response to cytotoxic effect of L-Asp. Furthermore, we suggest a relationship between ASNS and GDH based on our observations of increased GDH expression in cells with silenced ASNS gene.

Background. T-cell acute lymphoblastic leukemia (T-ALL) is a heterogeneous subtype of acute lymphoblastic leukemia with cure rate of approximately 70%. Significant effort is currently being aimed at better understanding of T-ALL biology. This could contribute to better subclassification of patients into risk groups and, in result, it could lead to improved therapy adjustment. DNA methylation seems to be a possible disease delineating marker. Different authors note that the DNA methylation status changes in various tumours, compared to healthy tissues. Methylation patterns are known to be specific for tumour types and hence, potentially, could be used as a tumour marker. *Aim.* We investigated promoter methylation status of 16 genes known to be involved in T-ALL pathology (NFkB, CDKN1C, SYK, CDH1, sFRP1, NES1, CDKN1B, p73, FBXW7, ASPP1, ADAMTS5, DIABLO, WIF1, RB1, CDKN2A, LATS1). *Patients and Methods.* The study group consisted of 54 consecutive children with T-ALL treated at 11 centers of Polish Pediatric Leukemia and Lymphoma Study Group (PPLLSG). We also analyzed peripheral blood T cells from 11 healthy children at similar age as controls. Additionally, we tested thymocytes at different developmental stages pooled from 5 healthy donors: DN1, DN2, DN3, ISP, $DP3^-$, $DP3^+$, SP $CD4^+$, SP $CD8^+$, TCRαβ and TCRγδ. Patient, control and thymic DNA was first modified by sodium bisulfite and then, promoter regions of each gene of interest were analyzed by methylation specific PCR (MS-PCR). *Results.* The CpG methylation pattern in the study group of T-ALL patients was altered when compared to the control group of healthy children, showing hypermethylated promoter regions in 7 out of 16 analyzed genes (43%) (sFRP1, CDH1, NES1, WIF1, CDKN1C, DIABLO and SYK). However, when T-ALL group was compared to thymic subsets, the CpG methylation pattern was altered in promoter regions of only 3 of 12 (25%) genes analyzed until now. When T-ALL group was compared to thymic subsets, hypermethylation was observed for ADAMTS5 gene (in 57% of patients), CDH1 (50% patients), CDKN1C (26% patients). No change in methylation pattern was observed for sFRP1, DIABLO, CDKN1B, ASPP1, p73, FBXW7, LATS1 and RB1. CDKN2A seems to be hypomethylated in T-ALL compared to healthy T cell subsets. Additionally, methylation status seems to be changing depending on the developmental stage of thymocyte. *Conclusions.* The results of our study indicate that DNA hypermethylation occurs in T-ALL, which largely seems to reflect the differentiation stage arrest, at which maturation of T cell entering tumor transformation was stopped. However, we postulate that altered methylation patterns of several genes (ADAMTS5, CDH1, CDKN1C) might be related to T-ALL pathogenesis and might possibly be useful for T-ALL subclassification and, in the future, for better therapy adjustment.

0023

QUANTITATIVE ASSESSMENT OF WT1 EXPRESSION FOR MONITORING MINIMAL RESIDUAL DISEASE IN ACUTE LEUKEMIA PATIENTS

I Shmunk,[1] E Koneva,[1] M Lyubchenko,[2] M Rusakov,[2] M Kiseleva,[2] Y Markova,[2] M Zakharova,[2] O Korobitsina,[2] A Korobkin,[2] A Burmistrova[3]

[1]Chelyabinsk Regional Haemotransfusion Station, Chelyabinsk, Russian Federation; [2]Department of Hematology, Chelyabinsk Regional Clinical Hospital, Chelyabinsk, Russian Federation; [3]Chelyabinsk State University, Chelyabinsk, Russian Federation

Wilms' tumor 1 (WT1) gene encodes a transcriptional factor involved in normal cellular development and is abnormally expressed in many types of haematological malignancies. It is over-expressed in most cases of acute myeloid leukemia (AML). *Aims.* Our study aims to estimate the usefulness of WT1 expression quantitative assessment for monitoring MRD and for relapse prediction in acute myeloid leukemia and in acute lymphoblastic leukemia (ALL). *Methods.* Real time quantitative RT-PCR was made according to the Europe Against Cancer Protocol. WT1 transcript level was determined in BM samples of adult patients with AML (except acute promyelocytic leukemia) and ALL. We examined the samples of 65 patients with AML and 33 patients with ALL at diagnosis. We also analyzed 106 specimens of AML patients and 100 specimens of ALL patients during follow-up. The obtained WT1 values were normalized with respect to the βGUS transcripts. *Results.* The median value of WT1 levels at diagnosis was 649 (range 1,6-8462) in AML patients and 1188 (range 1,5-14879) in ALL patients (no statistical difference in Student's t-test). The median value of WT1 levels of patients in complete remission was 4,3 (range 1,1-9,7) for AML and 7,5 (range 1,0-36,5) for ALL (P=0,05) . At diagnosis 91% of AML patients and 61% of ALL patients showed the expression of WT1 one log higher than the median values in complete remission. There were 2 patients (10%) with BCR-ABL (one p190 and one p210) within the ALL subgroup with high WT1 expression at diagnosis whereas within the ALL patients with low WT1 expression at diagnosis were 7 ones (54%) with BCR-ABL (6 patients with p190 and 1 with p210) (10% versus 54%, P=0,02 in chi-sguare test with Yate's correction). We had 6 patients with T-ALL, all of them showed the over-expression of WT1 at diagnosis. In the patients bearing a fusion gene transcript we performed a simultaneous analysis of WT1 and fusion-gene transcript expression: in 15 patients with AML (7 AML1-ETO, 1 CBFβ-MYH11, 2 BCR-ABL, 1 DEK-CAN, 4 MLL duplications) and in 15 patients with ALL (9 BCR-ABL, 3 MLL-AF4, 1 MLL-ENL, 2 E2A-PBX1). It was found the parallelism between the dynamics of WT1 level and fusion-gene transcript level during follow-up. The haematological relapse was correlated with the increase of WT1 expression: 8 AML patients had a median of 1545 (range 140-2578) and for 7 ALL patients a median value was 263 (range 8,0-2665) in relapse (no statistical difference in Mann-Whitney U test). We observed that the increase of WT1 level was occurred earlier than the relapse was stated for AML patients and also for ALL patients with high WT1 expression at diagnosis. Except one AML patient with BCR-ABL (p190): the increase of fusion gene expression was occurred in haematological remission without the increase of WT1 level. Conclusion. Quantitative assessment of WT1 expression may be useful for detection of MRD and can predict imminent relapse during follow-up in patients without additional molecular markers in AML and in ALL with high WT1 expression at diagnosis.

IDENTIFICATION OF CRITICAL TUMOR SUPPRESSOR GENES (TSGS) AND NEW PROGNOSTIC FACTORS IN HUMAN MYELOID DISORDERS USING RETROVIRAL INSERTION MUTAGENESIS

R Beekman, M Valkhof, S Erkeland, E Taskesen, J Peeters, P Valk, V Rockova, W van Putten, B Löwenberg, I Touw

Erasmus MC, Rotterdam, Netherlands

Background. Although a major improvement in diagnostic tools for AML and MDS has been established in the past few years, the exact (epi)genetic defects underlying these diseases are still unknown in many patients. Genome-wide methods (e.g. gene expression profiling, arrayCGH and methylation profiling) are currently being used to better understand the etiology of these diseases. Although these techniques generate invaluable information, it remains difficult to discriminate "drivers"contributing to the pathogenesis of these disorders from "passengers, which do not. Other approaches, as retroviral integration mutagenesis in mice have been proven powerful to identify "driver"genes which play an essential role in human myeloid malignancies. *Aims.* We aimed to identify new candidate TSGs in human myeloid malignancies. This was achieved by developing a new approach to retroviral integration mutagenesis to enrich for TSGs in combination with extensive comparative analysis in human AML. *Methods*. Genomic DNA of 6 murine tumors, induced by Graffi 1.4 murine leukemia virus, was isolated and digested. Methylated viral integration sites (mVIS) were determined using a combination of methylated DNA immunoprecipitation (MeDIP), inverse PCR and promoter array hybridisation. Genes flanking mVIS were identified using CEAS and their human orthologues were determined in HomoloGene. Gene expression and arrayCGH data of a *de novo* AML cohort were used for further comparative studies and DAVID was used for functional annotation analysis. *Results.* We identified 615 known (e.g. CDKN2A and CDKN2B) and new candidate TSGs. Interestingly, 149 candidates were down regulated in 454 *de novo* AML patients compared to 11 normal CD34 positive counterparts. These were enriched for genes involved in cell cycle regulation, specifically with functions in mitotic spindle formation (MAD2L2, PRC1) and genomic stability (H2AFX, SMC1A, DDX11 and DDX12). Secondly, we identified 271 genes down regulated within one or multiple AML subgroups (defined by the WHO). Strikingly, these were enriched for genes involved in DNA damage and repair, indicating that down regulation of different critical genes all may lead to a suboptimal function of DNA damage and repair pathways within different AML subgroups. Additionally, we identified 56 candidate TSGs located at small regions affected by deletion causing LOH in one or multiple AML cases, 30 of which (53,6%) were located on chromosome 7. Loss of chromosome 7 is usually seen in MDS progression towards AML and in AML with a poor prognostic outcome. Although minimal affected regions are identified, it remains unclear which are the critical genes on chromosome 7 that contribute to leukemogenesis. The 30 identified genes are potential candidates playing a role in this process. Interestingly, the relevance of the study was even further illustrated by the identification of 4 TSGs candidates with prognostic value in AML. *Conclusion.* By using a new approach to retroviral integration mutagenesis in mice and extensive comparative studies in human AML, we identified many new potential TSGs. Not only the enrichment of these genes for essential molecular pathways, as DNA damage and repair, but also the identification of new potential prognostic factors demonstrate the high potential of this screen.

0025

CHARACTERISATION OF AML1-ETO9A LEUKAEMIOGENESIS USING AN INDUCIBLE MURINE MODEL

O Tsoulaki,[1] G Lacaud,[2] V Kouskoff[3]

[1]Paterson Institute for Cancer Research, Manchester, UK; [2]Cancer Research UK Stem Cell Biology, Manchester, UK; [3]Cancer Research UK Stem Cell Haematopoiesis Group, Manchester, UK

Background. Acute Myeloid Leukaemia (AML) is dependent on a small subfraction of cells, termed Leukaemia Initiating Cells (LICs) (or "Leukaemia Stem Cells", LSCs). These cells display the ability to self-renew and initiate, maintain or regenerate the disease. Recent studies have demonstrated that within the bone marrow (BM) not only a cell

subset with an immature HSC-like phenotype, but also committed myeloid progenitors can acquire LIC function to sustain AML. One of the common genetic abnormalities associated with around 12% of *de novo* AML involves the t(8;21)(q22;q22) chromosomal translocation, which generates the AML1-ETO (AE) DNA-binding fusion protein. Studies in mouse models have demonstrated that additional secondary mutagenic events are required for AE leukaemogenesis. However, the truncated AML1-ETOtr (AEtr) and AML1-ETO9a (AE9a) C-terminal AE isoforms have been shown to promote AML in mouse retroviral transduction-transplantation models. Thus, AE9a seems to play a key role in the multistep model of AML pathogenesis. *Aims.* To better define the role of AE9a as an initiating mutation we aim to develop an AE9a inducible murine model of AML. This system will allow us to investigate at different disease stages the effect of AE9a on LICs and on disease progression. *Methods.* We have generated a tet-on mouse line using Embryonic Stem (ES) cells with a hemagglutinin (HA)-tagged-AE9a-IRES-GFP inducible cassette. AE9a mice were also backcrossed with p53-null mice. To restrict the expression of AE9a to the haematopoietic system bone marrow (BM) cells from the generated mouse lines were used in transplantation assays to reconstitute sublethally irradiated recipients following doxycycline treatment. Alterations of the haematopoietic system were investigated by flow cytometry, haematological and histological analysis and molecular assays. *Results.* Our data suggest that AE9a-expressing murine cells display enhanced replating ability in methocult cultures *ex vivo*. The replated cells confer an immature immunophenotype but are not able to dramatically expand. *in vivo* AE9a induction demonstrates the presence of a GFPlowLin+/-cKit-/low cell population, as well as the emergence of a GFPhiLin-Sca1-cKit$^+$ immature, premalignant subpopulation, which progressively increases over time. This GFPhi cell subset emerges initially in the BM following infiltration of the peripheral blood (PB) and spleen and disappears after dox withdrawal. Preliminary experiments suggest that this cell population cannot be transplanted in secondary recipients. Interestingly, AE9a enforced expression in a p53-null background can lead to a more rapid accumulation of the GFPhi subpopulation following disease development with a latency of 21-48 days. *Summary/Conclusions.* Altogether, our data demonstrate that although AE9a impairs normal haematopoiesis, it can not induce AML without additional mutations. Thus, the proposed AE9a inducible model could be a useful tool for the dissection of the multistep pathogenesis of leukaemia and for the better understanding of the LIC origin.

LOSS OF RKIP IN ACUTE MYELOID LEUKEMIA WITH A MONOCYTIC PHENOTYPE

A Zebisch,[1] A Woelfler,[1] K Hiden,[1] C Bodner,[1] F Quehenberger,[2] A Drasche,[3] D Pirkebner,[3] O Rath,[4] K Blyth,[4] R Delwel,[5] E Taskesen,[5] W Kolch,[6] J Troppmair,[3] H Sill[1]

[1]Division of Hematology, Medical University of Graz, Graz, Austria; [2]Medical Informatics, Statistics and Documentation, Medical University of Graz, Graz, Austria; [3]Daniel Swarovski Research Laboratory, Innsbruck Medical University, Innsbruck, Austria; [4]The Beatson Institute for Cancer Research, Glasgow, UK; [5]Department of Hematology, Erasmus University Medical Center, Rotterdam, Netherlands; [6]Systems Biology Ireland, University College Dublin, Dublin, Ireland

Background. RAF kinase inhibitor protein (RKIP) has been described as a negative regulator of the RAS-mitogen activated protein kinase (MAPK) signaling cascade. Several solid neoplasms show decreased or absent expression of RKIP and its role as a metastasis suppressor has been firmly established in animal models and studies of human tumors. *Aims.* As constitutive activation of the RAS-MAPK pathway occurs frequently in acute myeloid leukemia (AML), we investigated the involvement of RKIP in the pathogenesis of this disorder. *Methods.* RKIP protein expression was analyzed by Western blot and subsequently correlated to AML subgroups as represented by the French-American-British (FAB) classification. Results were confirmed using a microarray data set of 285 AML patients (GEO accession GSE1159). Stable transfection of RKIP was performed in THP-1 and 32D cells and soft agar colony formation assays were performed. Proliferation was measured by BrdU-incorporation and apoptosis by Caspase-3 and PARP cleavage, respectively. Differentiation assays were performed in HL-60 AML cells by incubation with 1,25 dihydroxyvitamin D3 (1,25 D3) following RKIP overexpression or knockdown. *Results.* Twenty-one of 96 (22%) AML patients' samples and five of 19 (26%) AML cell lines, but none of ten purified CD34$^+$ hematopoietic stem and progenitor cell specimens exhibited complete or partial loss of RKIP. To test the biological consequences of RKIP loss in AML, we examined the effect of introducing an RKIP transgene in the monocytic AML cell line THP-1, which is characterized by decreased RKIP expression. Re-expression of RKIP induced a decrease in cell numbers, a finding that was confirmed in murine 32D hematopoietic cells. Reduced cell numbers were due to a decrease in proliferation, rather than increased apoptosis. Importantly, the oncogenic potential of THP-1 cells - as assessed by colony formation in soft agar - was significantly diminished following RKIP reconstitution. When we correlated RKIP expression with morphological criteria of leukemic cells in 96 AML patients, RKIP loss was significantly correlated to subgroups with a monocytic phenotype (FAB types M4 and M5; $P = 2.13\times10^{-7}$). This finding could be corroborated in a previously described transcriptomic data set of 285 AML patients ($P = 1.6\times10^{-8}$). To test for a causative role of RKIP silencing in the development of a monocytic phenotype, we performed cell differentiation assays using the immature AML cell line HL-60. Its monocytic differentiation, induced by treatment with 1,25 D3, was paralleled by significant RKIP downregulation. Concomitant knockdown of RKIP with siRNA further increased differentiation, whereas RKIP overexpression resulted in inhibition of maturation indicating that RKIP is cooperating in the development of a monocytic AML phenotype. *Summary/Conclusions.* Loss of RKIP is a frequent molecular event in AML and highly associated with a monocytic phenotype. In contrast to solid tumors, RKIP acts as a tumor suppressor in hematopoietic cells and is causally contributing to the development of a monocytic phenotype of AML blasts.

DIFFERENTIAL RESPONSES TO CXCR4 ANTAGONISM IDENTIFY TWO BIOLOGICAL DISTINCT SUBTYPES OF ACUTE MYELOID LEUKEMIA IN TRANSPLANTED NOD/SCID MICE

Y Zhang,[1] D Jouni,[1] S Patel,[2] A Betems,[3] M Wittner,[1] H Dombret,[4] P Coppo,[5] P Opolon,[6] N Fujii,[7] M Ito,[8] W Vainchenker,[1] S De Botton,[9] F Louache[1]

[1]INSERM U1009, Institut Gustave Roussy, Villejuif, France; [2]Department of Cell Biology, Saint-Louis Hospital, Paris, France; [3]Institut Gustave Roussy, Inserm U[1009], Villejuif, France; [4]Saint-Louis Hospital, Paris, France; [5]Saint-Antoine Hospital, Paris, France; [6]CNRS UMR8121, Villejuif, France; [7]Kyoto University, Graduate School of Pharamceutical Sciences, Kyoto, Japan; [8]Medical Research Department, Central Institute for Experimental Animals, Kawasaki, Japan; [9]Division of Hematology, Institut Gustave Roussy, Villejuif, France

Background. Stromal cell-derived 1 (SDF-1)/CXCR4 interactions participate in the development of leukemic blasts in acute myeloid leukaemia (AML) influencing their trafficking, survival and differentiation. *Aims. and Methods.* We used the xenotransplantation model of nonobese diabetes/severe combined immunodeficiency rcnull (NOG) mice reconstituted with human primary cells from AML patients and 2 small molecule competitive antagonists of CXCR4, AMD3100 and TN140 to better define the role of CXCR4/SDF-1 on the leukemic blast burden within the bone marrow and in extramedullary sites. *Results.* We first investigated the correlation between CXCR4 expression or function on leukemic blasts and their ability to engraft the bone marrow of NOG mice in 34 patients. Using flow cytometric analyses, we observed that CXCR4 membrane expression was highly variable between patients. In most cases, the cells expressed relatively low levels of CXCR4. This expression did not correlate with engraftment. In addition, SDF-1 responsiveness evaluated by transwell migration only marginally correlated with engraftment. However, in these initial analyses, we observed that the differences between engrafters and nonengrafters were significant if the cut-point migration is set to 20%. Patients with higher chemotactic response to SDF-1 had a significantly increased NOG repopulating ability. In order to evaluate the importance of CXCR4/SDF-1 axis in AML development, NOG mice reconstituted with cells from 6 different patients were treated with optimal concentration of either AMD3100 or TN140 for 1 week. We observed that CXCR4 inhibition by TN140 (used as a single therapy) had profound inhibitory effects on the proliferation and the development of extramedullary dissemination of the disease in this xenotransplantation for 3 patients. These patients had initially high CXCR4 level on blasts. *Conclusions.* These findings demonstrate that CXCR4/SDF-1 axis contribute to organ infiltration in AML with extramedullary leukemia. In addition, CXCR4 blocking agents effectively antagonize SDF-1 promoting leukemic development in selected patients characterized by high CXCR4 expression.

0028

HIGH BRE EXPRESSION IS ASSOCIATED WITH T(9;11)(P21;Q23) AND A FAVORABLE OUTCOME IN PEDIATRIC ACUTE MYELOID LEUKEMIA

B Balgobind,[1] C Zwaan,[2] D Reinhardt,[3] T Arentsen-Peters,[2] I Hollink,[2] V de Haas,[4] G Kaspers,[5] E Bont,[6] A Baruchel,[7] J Stary,[8] C Meyer,[9] R Marschalek,[10] U Creutzig,[11] R Pieters,[2] M van den Heuvel-Eibrink[2]

[1]Sopgia Children's Hospital - Erasmus MC, Rotterdam, Netherlands; [2]Sophia Children's Hospital - Erasmus MC, Rotterdam, Netherlands; [3]Medical School Hannover, Hannover, Germany; [4]Dutch Childhood Oncology Group (DCOG), The Hague, Netherlands; [5]VU University Medical Center, Amsterdam, Netherlands; [6]Beatrix Children's Hospital, University Medical Center Groningen, Groningen, Netherlands; [7]St. Louis Hospital, Paris, France; [82]nd Medical School, Charles University, Prague, Czech Republic; [9]Zafes, Diagnostic Center of Acute Leukemias (DCAL), Goethe-University of Frankfu, Frankfurt, Germany; [10]ZAFES, Diagnostic Center of Acute Leukemias (DCAL), Goethe-University of Frankfu, Frankfurt, Germany; [11]University Hospital Muenster, Muenster, Germany

Background. One important cytogenetic subgroup of pediatric acute myeloid leukemia (AML) is characterized by translocations of chromosome 11q23, which accounts for 15-20% of all cases with an evaluable chromosome analysis. In most of these cases, the mixed lineage leukemia (MLL) gene is involved. More than 50 fusion translocation partners of the MLL gene have been identified and outcome differs by translocation partner, suggesting differences in the biological *Background. Aim.* In the present study, we used supervised analysis of gene expression profiles to identify and analyze differentially expressed genes between the different MLL-rearranged AML cases by translocation partners that may underline the observed differences related to outcome. *Methods.* We used microarrays to generate gene expression profiles of 245 pediatric AML cases, including 53 MLL-rearranged cases. To find gene expression signatures characteristic for the different groups, an empirical Bayes linear regression model was used. *Results.* Using these profiles, we were able to identify a specific gene expression signature for t(9;11)(p22;q23), the most common 11q23 rearrangement in AML, and identified BRE (brain and reproductive organ-expressed) as one of the genes to be discriminative for t(9;11)(p22;q23) (P<0.001). The mean average VSN normalized expression for BRE in the t(9;11)(p22;q23) subgroup was 3.7-fold higher compared with that in other MLL-rearranged cases (P<0.001). Validation by RQ-PCR confirmed this higher expression in t(9;11)(p22;q23) cases (P<0.001). In addition, we confirmed that overexpression of BRE was predominantly found in t(9;11)(p22;q23) in an independent gene expression profile cohort (Ross et al, Blood 2002). Remarkably, patients with high BRE expression showed a significant better outcome for 3 year disease free survival (pDFS) (80±13 vs. 30±10%, P=0.02) within the MLL-rearranged AML. Moreover, multivariate analysis, including, age, WBC and favorable karyotype, showed that next to favorable karyotype, BRE overexpression is an independent favorable prognostic factor within pediatric AML for DFS (HR=0.2, P=0.03). However, *in vitro* studies did not identify differences in cell proliferation, apoptosis or drug sensitivity for overexpression of BRE. *Summary/Conclusions.* Recently, overexpression of BRE has been described in hepatocellular and oesophageal carcinomas. However, to the best of our knowledge, BRE had never been associated with hematological malignancies before. Our study shows that overexpression of BRE is predominantly found in MLL-rearranged AML with a t(9;11)(p22;q23). Moreover, high BRE expression is an independent favorable prognostic factor due to a reduced relapse rate in remission. So far, we could not elucidate the exact underlying mechanism, but *in vitro* experiments did not provide evidence for differences in cell proliferation, drug sensitivity or apoptosis. Further research is warranted to explore this and to identify the link between MLL-AF9 and the transcription of BRE. Our data show that within pediatric MLL-rearranged AML specific factors, i.e. translocation partner and overexpression of specific genes, can refine risk stratifications and the development of novel therapeutic targets.

0029

DIFFERENTIAL ROLE OF MYELOID TRANSCRIPTION FACTORS, C/EBPα AND PU.1 IN LEUKEMOGENESIS BY MLL-FUSION ONCOGENES

Y Fukuchi,[1] K Kuroda,[1] K Sadahira,[1] T Kitamura,[2] Y Ikeda,[1] S Okamoto,[1] H Nakajima[1]

[1]Keio University School of Medicine, Tokyo, Japan; [2]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Background. MLL translocations found in acute leukemia possess unique clinical characteristics. They have over 50 different fusion partners and show poor prognosis. These MLL fusion proteins lost H3K4 methyltransferase activity of wild-type MLL, but gained the ability to induce aberrant expression of HoxA cluster genes. Moreover, these proteins are able to transform hematopoietic stem/progenitor cells into leukemic stem cells (LSCs). Previous studies have shown that C/EBPα and PU.1, well-known myeloid specific transcription factors, were common molecular targets of myeloid malignancies. We and others have recently shown that C/EBPα and PU.1 are negative regulators of hematopoietic stem cells, suggesting that these transcription factors may play a role in the generation of LSCs. Because we have little knowledge on the role of C/EBPα and PU.1 in MLL-leukemia, we asked whether these key myeloid transcription factors are involved in the leukemogenesis by MLL-fusion proteins. *Aims.* We aimed to clarify the role of C/EBPα and PU.1 in the leukemogenesis induced by MLL-fusion oncogenes. Notably, we focused on the role of these transcription factors during the stages of leukemia initiation and progression. *Methods.* 5-FU (150 mg/kg) treated bone marrow (BM) cells from C57BL/6J mice were harvested, pre-stimulated with recombinant mouse (rm) SCF, rmIL-6, rhFL, rhTPO (50 ng/mL each), then transduced with pMYs-IG-MLL-ENL or pMXs-IG-MLL-Septin6. These cells were serially replated in methylcellulose, then transferred to rmIL-3 (10 ng/mL) containing liquid culture (immortalized cells), or were transplanted into lethally irradiated recipients (primary leukemic cells). MLL-ENL (or MLL-Septin6) immortalized cells or MLL-ENL primary leukemic cells were transduced with pMXs-IRed-C/EBPα-ER or pMXs-IRed-PU.1-ER. After sorting of GFP+DsRed+ cells, these cells were serially replated in methylcellulose with or without 4-hydroxytamoxifen (4-HT) (1 μM), or were treated with or without 4-HT (1 μM) for 5 days, then transplanted into sublethally irradiated secondary recipients. BM cells from PU.1 +/- mice, or E14.5 fetal liver (FL) cells from PU.1 knockout or +/- mice were harvested, pre-stimulated with rmSCF, rmIL-6, rhFL, rhTPO, then transduced with pMYs-IG-MLL-ENL. These cells were also transplanted into lethally irradiated recipients. *Results.* Overexpression of PU.1, but not C/EBPα, suppressed the serial replating capacity of the cells immortalized by MLL-ENL and MLL-Septin6. Moreover, activation of PU.1 suppressed the propagation of MLL-ENL leukemic cells in the secondary transplanted animals. In contrast, activation of C/EBPα did not eradicate leukemic cells in the same settings. PU.1 deficiency perturbed leukemia development by MLL-ENL. Haploinsufficiency of PU.1 delayed leukemia development by MLL-ENL and prolonged survival of the recipients. *Summary/Conclusions.* These results indicate that the dosage of PU.1 activity has profound impact on the self-renewal of LSCs and *in vivo* leukemia formation induced by MLL-fusion oncoproteins. Therefore, PU.1 may serve as a potential therapeutic target for MLL-leukemia.

0030

TET2 MUTATIONS OCCUR IN OVER 20% OF ADULTS WITH DE NOVO CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA, AND THEIR PREVALENCE INCREASES WITH AGE: A CANCER AND LEUKEMIA GROUP B STUDY

K Metzeler,[1] K Maharry,[1] D Margeson,[1] J Curfman,[1] H Becker,[1] M Radmacher,[1] K Mrózek,[1] K Holland,[1] S Whitman,[1] Y Wu,[1] S Schwind,[1] W Blum,[1] B Powell,[2] T Carter,[3] M Baer,[4] A Carroll,[5] J Kolitz,[6] M Caligiuri,[1] R Larson,[7] G Marcucci,[1] C Bloomfield[1]

[1]The Ohio State University Comprehensive Cancer Center, Columbus/ OH, USA; [2]Wake Forest University Comprehensive Cancer Center, Winston-Salem/NC, USA; [3]University of Iowa, Iowa City/IA, USA; [4]University of Maryland, Baltimore, MD, USA; [5]University of Alabama at Birmingham, Birmingham, AL, USA; [6]North Shore University Hospital, Manhasset/NY, USA; [7]University of Chicago, Chicago/IL, USA

Background. Mutations in the *tet oncogene family member 2* (TET2) gene occur in various myeloid malignancies, including myelodysplastic syndromes, myeloproliferative neoplasms, and secondary and *de novo* acute myeloid leukemia (AML). The frequency and age distribution of *TET2* mutations and their association with clinical characteristics and other molecular markers have not been defined in *de novo* cytogenetically normal (CN-) AML. *Aims.* To determine the incidence and spectrum of *TET2* mutations and their association with patient characteristics and outcomes in a relatively large cohort of *de novo* CN-AML patients. *Methods.* Pretreatment marrow or blood samples from 339 *de novo* CN-AML patients (age range, 18-81 years [y]) enrolled on cytarabine/daunorubicin-based CALGB protocols [CALGB 8525, 8923, 9420, 9621, 9720, 19808, 10201] were studied for mutations in TET2 and a panel of oth-

er genetic alterations (*NPM1, WT1, CEBPA,* and *IDH1/IDH2* mutations, *FLT3* internal tandem duplications and tyrosine kinase domain mutations, MLL partial tandem duplications). All coding exons of *TET2* (GeneBank accession NM_001127208) were PCR-amplified from genomic DNA; mutations were identified by direct sequencing. Known single nucleotide polymorphisms, synonymous sequence changes, and intronic variations were not considered as mutations. *Results.* Overall, 101 *TET2* mutations were found in 75/339 patients (22%): 46 patients had single heterozygous mutations, 24 patients had two, and one patient had three mutations. In the four remaining patients, mutations appeared to be homozygous or hemizygous, suggesting loss of heterozygosity at the *TET2* locus. Of the 101 mutations, 38 were frameshift mutations, 29 missense mutations, 26 nonsense mutations, two in-frame insertions/deletions, and 6 affected splice sites. We did not identify "hot spots"for nonsense and frameshift mutations, which occurred throughout all coding exons. However, the majority of missense mutations and in-frame changes (22/31 mutations) clustered in the two evolutionarily conserved regions of the gene. *TET2* mutations were significantly more common in CN-AML patients aged ≥60y (41/150; 27%) than in patients <60y (34/189; 18%) (P=.048). The proportion of TET2 mutated patients gradually increased with age, from 10% in adults <30y to 31% in patients aged ≥70y. Moreover, the proportion of patients with double *TET2* mutations was also higher among patients ≥60y (18/41; 44%) than among younger patients (7/34; 21%) (P=.049). We observed no correlation between the presence/absence of any *TET2* mutation and other pretreatment characteristics (leukocyte and platelet counts, hemoglobin level, blast percentage, FAB category, or extramedullary involvement). Both *IDH1* and *IDH2* mutations were less common in *TET2* mutant than in *TET2* wild-type patients, although the difference only reached statistical significance in patients ≥60y, where *IDH1/IDH2* and *TET2* mutations were mutually exclusive (IDH1, P=.006; IDH2, P<.001). No significant association with other molecular markers and no impact of *TET2* mutations on clinical outcome (complete remission rate, disease-free, or overall survival) were observed in either age group. *Summary*. *TET2* mutations are relatively frequent in *de novo* CN-AML patients, and their prevalence increases with age. The presence of *TET2* mutations is inversely associated with *IDH1/IDH2* mutations but not with other molecular markers or clinical characteristics, and seemingly does not affect outcome.

0031

BONE MARROW FAILURE IN ACUTE MYELOID LEUKEMIA IS INDUCED BY A BLOCK IN DIFFERENTIATION OF NORMAL HEMATOPOIETIC STEM CELLS

D Taussig,[1] F Miraki-Moud,[1] A Lister,[1] D Bonnet,[2] J Gribben[1]

[1]St Bartholomew's Hospital, London, UK; [2]Cancer Research UK London Research Institute, London, UK

Background. Bone marrow failure (reduced production of neutrophils, platelets and erythrocytes) is an important cause of morbidity and mortality in leukemia. The mechanism of bone marrow failure in AML (Acute myeloid leukemia) is believed to be different to that seen in lymphoid malignancies such as chronic lymphocytic leukemia (CLL). In AML bone marrow failure occurs early in the disease course. By contrast, in CLL the blood count may be relatively preserved even where the majority of cells in the marrow are leukemic. *Aim.* Understand the mechanism of bone marrow failure in AML. *Methods.* Two approaches were used to study bone marrow failure: 1) Six primary AML samples were transplanted into immunodeficient mice to see the effect of the AML on normal residual hematopoietic cells. Immunophenotyping was used to assess numbers of normal mouse differentiated cells (mouse $CD45^+$ Lineage marker$^+$), normal progenitors (mouse $CD45^+$ Lineage$^-$ $CD117^+$) and normal hematopoietic stem cells (HSCs) (mouse $CD45^+$ Lineage$^-$ $CD117^+$ $CD150^+$ $CD48^-$) within the mouse bone marrow. Mice were sacrificed at different time points to allow us to follow the evolution of marrow failure. Colony forming assays and transplant assays were used to complement the immunophenotyping. 2) We have recently shown that the $CD34^+$ fraction of certain types of AML is normal and contains normal colony forming units (thought to equate to normal progenitors) and normal SCID-repopulating cells (thought to equate to normal HSCs)(Taussig et al Blood 2010). We used these types of AML to study the numbers of normal HSCs ($CD34^+$ $CD38^-$) and progenitor cells ($CD34^+$ $CD38^+$) in the bone marrow at diagnosis. *Results.* Within the immunodeficient mice two phases were observed as the AML developed. In the first phase, the numbers of normal differentiated cells and normal progenitors were significantly reduced while the number of HSCs was not significantly different to controls (Figure 1). Functional assessments using colony forming assays and secondary transplants confirmed the phenotyping data. Annexin-V (a marker of apopotosis) staining on normal hematopoietic cells from mice transplanted with AML was not significantly different to controls. In the second phase the numbers of HSCs, progenitors and differentiated cells were all reduced. Within humans the number of normal progenitors was reduced by approximately 10 fold in the bone marrow of AML patients (P<0.05) while the number of normal HSCs was not significantly different to control (Controls n=28, AML patients n=12). These effects were similar to that seen in the first phase in the mice. The data are consistent with a block in differentiation of normal HSCs. *Conclusions.* AML induces bone marrow failure by blocking differentiation of normal residual HSCs in a mouse model of AML and in humans. By further understanding this mechanism it may be possible to reverse this process and ameliorate the effects of bone marrow failure.

INFLUENCE ON OUTCOME OF THE NPM1/FLT3-ITD MOLECULAR STATUS FOR AML PATIENTS IN FIRST COMPLETE REMISSION TREATED BY AUTO- OR ALLO-HSCT: RESULTS OF THE PROSPECTIVE GOELAMS LAM-2001 TRIAL

R Guièze,[1] P Cornillet-Lefebvre,[1] B Lioure,[1] O Blanchet,[1] A Pigneux,[1] C Recher,[1] B Witz,[1] N Fegueux,[1] C Bulabois,[2] D Bouscary,[3] N Vey,[4] M Delain,[1] P Turlure,[1] C Himberlin,[1] J Harousseau,[5] F Dreyfus,[6] N Ifrah,[1] M Béné,[1] P Chevallier[1]

[1]Goelams, CHU, Clermont-Ferrand, France; [2]GOELAMS, CHU, Grenoble, France; [3]GOELAMS, Hôpital Cochin, Paris, France; [4]Goelams, Institut Paoli Calmettes, Marseille, France; [5]Goelams, CLCC Nantes Atlantique René Gauducheau, Nantes, France; [6]Goelams, Hôpital Cochin, Paris, France

Background. The prognostic value of NPM1 and FLT3-ITD mutations has now been well established in AML patients with normal karyotype (NK). An international expert panel, on behalf of the European Leukemia Net (ELN), has recently proposed to include NPM1mut/FLT3-ITDwt NK-AML patients in a favorable prognostic subset (Döhner *et al.*, Blood 2010). Autologous hematopoietic stem cell transplantation (auto-HSCT) represented a good alternative therapeutic option for patients without sibling HSC donor. However, the impact of auto-HSCT vs allo-HSCT according to molecular status has been poorly studied. The prognostic impact of the NPM1/FLT3-ITD status was evaluated here in a cohort of 135 NK AML patients prospectively treated by allo-HSCT or auto-HSCT within the randomized GOELAMS LAM-2001 trial (Lioure, ASH 2006, abstracts 319 & 608). *Patients and Methods.* A total of 135 NK-AML patients, aged between 18 and 60 years old (median 47), who had reached a first complete remission (CR) were characterized for NPM1/FLT3-ITD status using previously reported methods (Schnittger *et al.*, Blood 2002 & 2005). According to the ELN classification, the NPM1mut/FLT3-ITDwt status was compared to all other combinations. Randomization allotted these patients to receive an allo-HSCT in case of an available HLA sibling donor while patients lacking such a donor were randomized between one (Arm A) or two (Arm B) auto-HSCT(s). The conditioning regimen was Busulfan + HDM 140 mg/m^2 in Arm A. In Arm B patients received first an auto-HSCT conditioned by HDM 200 mg/m^2 followed by a second auto-HSCT conditioned as for arm A. *Results.* Forty-one patients were programmed to receive an allo-HSCT including 16 with a favorable molecular status, while 94 patients were programmed to receive 1 (n=48) or 2 (n=46) autografts, including 30

with a favorable molecular status. Comparisons of 4-year LFS and OS according to different sub-groups are given in Table 1. No significant difference was observed according to the NPM1/FLT3-ITD molecular status in the group of allo-HSCT patients. Conversely, in the auto-HSCT group, 4-year LFS and OS appeared to be significantly higher in the NPM1mut/FLT3-ITDwt sub-group as compared to other patients (P=0.01 for both). As for the overall auto-HSCT group, no significant benefit of double auto-HSCT vs. single auto-HSCT could be observed regarding each subset of molecular profile. Among the NPM1mut/FLT3-ITDwt subgroup, there was no benefit for allo-HSCT as compared to auto-HSCT. Since there was no significant difference in outcome between allo-HSCT and auto-HSCT patients, the whole cohort was tested for the significance of the molecular status. The statistically significant favorable impact of NPM1mut/FLT3-ITDwt was retrieved in this whole group. *Conclusions.* Molecular analysis of available samples of the GOELAMS LAM-2001 trial of younger AML patients with NK in first CR confirms the favorable prognostic impact of the NPM1mut/FLT3-ITDwt status in patients treated with a single or double auto-HSCT. This procedure represents a valid therapeutic option, providing similar outcomes as allo-HSCT which is not recommended anymore. For patients with other molecular profiles of NPM1/FLT3-ITD, allo-HSCT has to be considered, since this strategy conferred the same outcome as in patients with the favorable mutational status.

Table 1. Outcomes according to different sub-groups.

Normal Karyotype AML	4-year LFS		4-year OS	
Allo-HSCT N=41				
NPM1mut/FLT3-ITDwt N=16	62%		69%	
Other NPM1/FLT3-ITD status N=25	60%	P=NS	55%	P=NS
Auto-HSCT N=94				
1 auto-HSCT N=48	46%		57%	
2 auto-HSCT N=46	41%	P=NS	50%	P=NS
NPM1mut/FLT3-ITDwt N=30	58%		73%	
Other NPM1/FLT3-ITD status N=64	36%	**P=0.01**	44%	**P=0.01**
NPM1mut/FLT3-ITDwt				
1 auto-HSCT N=16	68%		72%	
2 auto-HSCT N=14	49%	P=NS	57%	P=NS
Other NPM1/FLT3-ITD status				
1 auto-HSCT N=32	35%		42%	
2 auto-HSCT N=32	37%	P=NS	47%	P=NS

INDUCTION OF A CD8+ T CELL RESPONSE TO THE MAGE CANCER TESTIS ANTIGEN BY COMBINED TREATMENT WITH AZACITIDINE AND SODIUM VALPROATE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASIA

O Goodyear,[1] I Novitzky-Basso,[2] S Siddique,[2] G Ryan,[1] P Vyas,[3] J Cavenagh,[4] P Moss,[1] C Craddock[2]

[1]University of Birmingham, Birmingham, UK; [2]Centre for Clinical Haematology, Queen Elizabeth Hospital, Birmingham, UK; [3]Weatherall Institute of Molecular Medicine, John Radcliffe Hospital NHS Trust, Oxford, UK; [4]Department of Haematology, St Bartholomew's Hospital, London, UK

Background. Epigenetic therapies, including DNA methyltransferase (DNMT) and histone deacetylase (HDAC) inhibitors, represent important new treatment modalities in haematological malignancies but their mechanism of action remains unknown. Cancer testis antigens (CTAgs) represent a family of immunodominant proteins normally expressed only in germ line tissue. As a consequence immunological tolerance to CTAgs is not ordinarily established. We and others have demonstrated that the CTAg MAGE is expressed in AML. Since epigenetic therapies result in tumor specific up-regulation of MAGE expression this represent a promising and manipulable tumor antigen in AML. We reasoned that up-regulation of MAGE antigens by DNMT and HDAC inhibitors may induce an immunologically mediated anti-tumor response and contribute to their clinical activity in patients with high risk AML. *Aims.* We therefore characterised the immune response to MAGE antigens in patients with AML undergoing treatment with the epigenetic therapies 5'-azacitidine (AZA) and sodium valproate (VPA). *Methods.* CD8+ T cell responses to MAGE antigens were measured in 21 patients with *de novo* or relapsed AML undergoing treatment on a Phase II clinical trial incorporating AZA (75 mg/m^2 × 7 days per 28 day cycle) and VPA (1-2.5 g daily administered continuously as tolerated). All patients gave informed consent and the clinical trial was approved by the Local Research Ethics Committee. Clinical responses to combined treatment with AZA/VPA were assessed using criteria defined by Cheson. MAGE-specific CD8+ T cells were measured in peripheral blood using a CD137 expression and enrichment assay. In some patients responses were also quantitated by the interferon gamma cytokine secretion assay (Miltenyi Biotec). *Results.* CD8+ CTL responses to MAGE antigens were documented in only 1/21 patients prior to commencement of therapy. 12 patients received at least three cycles of VAL/AZA therapy and were assessable for induction of an immunological response. Of these, treatment with VAL/AZA induced a CD8+ T cell response to MAGE antigens in 10 patients of whom 7 achieved a major clinical response (CR or PR). Responses were maintained over-time (70-799 days) and the CTL response increased in frequency with repeated cycles in the majority of cases. A polyclonal T cell line was generated from one patient and tetramer staining of this line confirmed peptide specificity. The MAGE-specific CTL response detected in two patients was further validated using the IFN-γ cytokine secretion assay. Characterization of the memory phenotype of the CD8+ MAGE-specific response indicated that they were effector memory demonstrating recent T cell activation. Comparison with a control group of 66 patients with high risk AML treated with VAL/AZA demonstrated that generation of a MAGE specific T cell response was associated with a significantly increased chance of achieving a major clinical response (P= 0.038). *Conclusions.* This is the first demonstration of a MAGE specific CTL response in AML. Furthermore, it appears that epigenetic therapies have the capacity to induce a CTL response to MAGE antigens *in vivo* which may contribute to their clinical activity in AML. These data identify a novel mechanism by which epigenetic therapies may induce an anti-tumor response in AML and other malignancies.

DISTINCT CLINICAL AND BIOLOGICAL CHARACTERISTICS OF ADULT PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA WITH ADDITIONAL SEX COMB-LIKE 1 (ASXL1) MUTATION

HH Huang, WC Chou, HA Hou, CY Chen, HF Tien

National Taiwan University Hospital, Taipei, Taiwan

Background. Additional sex comb-like 1 (ASXL1) is a member of Enhancer of Trithorax and Polycomb genes and is involved in chromatin modification and retinoic acid pathway regulation. Recent studies showed mutation in this gene in various myeloid malignancies such as myelodysplastic syndrome (MDS), myeloproliferative neoplasm (MPN), and MDS/MPN. However, the ASXL1 mutation in *de novo* acute myeloid leukemia (AML) has not been comprehensively investigated. In this study, we studied this mutation in a large cohort of Chinese primary AML patients. *Aims.* To analyze ASXL1 mutation in adult *de novo* AML patients. *Method*s. We retrospectively analyzed mutation in ASXL1 exon 12 by polymerase chain reaction (PCR) and direct sequencing in 501 adult Chinese AML patients, who were diagnosed at the national Taiwan university hospital from 1995 to 2007. The result was then correlated with the clinical presentations, laboratory data and a panel of 13 important genetic mutations in AML. *Results*. ASXL1 mutations in exon 12, including frame shifting and non-sense mutations, were found in 54 patients (10.8%). The most frequent type is insertion of G between nucleotide 1934 and 1935. The mutation occurred more frequently in elder (P<0.001) and male patients (P=0.016), and was significantly associated with FAB M0 subtype (P=0.003), isolated trisomy 8 (P=0.003), RUNX1 mutation (P<0.001), and expression of HLA-DR (P<0.001) and CD 34 (P=0.020). In contrary, this mutation was inversely associated with NPM1 mutation (P=0.001), FLT3/ITD (P=0.004), and t(15;17) (0/38 vs. 54/425, P=0.029). Among the patients who received standard induction chemotherapy (n=360), those with ASXL1 mutation had lower complete remission rate (85.9% vs 65.2%, P=0.015) and worse overall survival than those without ASXL1 mutation (median overall survival 14 months vs 58 months; P=0.009). This survival difference remained significant when the patients with acute promyelocytic leukemia were excluded (median, 14.0 months vs. 31 months, P=0.023), and became even more pronounced in the subgroup with intermediate cytogenetics (P=0.007). Multivariate analysis including covariates NPM1 mutation, FLT3/ITD, age, and cytogenetics showed a borderline poor prognostic impact of ASXL1 mutation on overall sur-

vival (P=0.049). *Conclusion.* Our study revealed distinct clinical and biological features of *de novo* adult AML patients bearing ASXL1 mutation.

0035

SUPPRESSOR OF CYTOKINE SIGNALING (SOCS1) COOPERATES WITH FLT3-ITD IN THE DEVELOPMENT OF MYELOPROLIFERATIVE DISEASE BY PROMOTING THE ESCAPE FROM EXTERNAL CYTOKINE CONTROL

C Brandts, N Pavankumar Reddy, H Serve

University of Frankfurt, Frankfurt, Germany

Background. Internal tandem duplications of the receptor tyrosine kinase FLT3 (FLT3-ITD) are frequently found in acute myeloid leukaemia and lead to constitutive activation of the receptor. Gene expression analysis comparing cells expressing FLT3-ITD with FL-stimulated cells expressing wild-type FLT3 demonstrated differences in STAT5 target genes. Among the most differentially regulated genes were members of the SOCS (suppressor of cytokine signaling) family, which are known to terminate cytokine signalling by inhibition of JAK kinases. This finding was surprising, as expression of SOCS proteins is associated with anti-proliferative effects. *Aims.* We hypothesised that SOCS proteins function as conditional oncogenes in the context of FLT3-ITD by protecting transformed cells from external cytokine control. The aim of this study was to examine the role of SOCS proteins in FLT3-ITD mediated disease. *Methods.* First, we performed *in vitro* experiments in cell lines and primary AML samples to confirm the microarray data. We performed functional experiments in murine bone marrow cells expressing either SOCS1, FLT3-ITD or both. Finally, *in vivo* bone marrow transplantation experiments were performed to determine the influence on latency and phenotype in this cell system. *Results*. Here we show that FLT3-ITD leads to induction of the suppressors of cytokine signaling (SOCS) family proteins in cell lines, murine bone marrow and patient samples. As SOCS proteins are known to inhibit - rather than promote - growth of hematopoietic cells, we investigated their role in FLT3-ITD mediated transformation. While SOCS1 expression severely impaired cytokine-induced colony growth of murine bone marrow, it failed to inhibit FLT3-ITD supported colony growth, indicating resistance of FLT3-ITD to SOCS1. Also, SOCS1 co-expression did not affect FLT3-ITD mediated signaling or proliferation. Importantly, SOCS1 co-expression inhibited interferon-γ signaling and protected FLT3-ITD cells from interferon-γ mediated growth inhibitory effects. In a murine bone marrow transplantation model, the co-expression of SOCS1 and FLT3-ITD significantly shortened the latency of a myeloproliferative disease when compared to FLT3-ITD (P=0.01). *Summary/Conclusions.* These data demonstrate that in the context of the oncogene FLT3-ITD, SOCS1 acts as a conditional oncogene: expression of SOCS proteins shields FLT3-ITD-expressing cells from external cytokine control, thereby cooperating in the development of a myeloproliferative disease.

THE NON-HOMEODOMAIN SPLICE VARIANT HOXA9T CAUSES LEUKEMIA ON ITS OWN AND COLLABO-RATES WITH HOXA9 TO INDUCE SHORT - LATENCY AML IN MICE

C Stadler,[1] V Rawat,[2] K Petropoulos,[1] W Hiddemann,[1]
M Feuring-Buske,[2] C Buske[2]

[1]*Clinical Cooperative Group Leukemia, Helmholtz Zentrum Muenchen, Munich, Germany;* [2]*Institute of Experimental Cancer Research, CCCU and University Hospital, Ulm, Germany*

Background. Alternative splicing is known to affect more than half of all human genes, and has been proposed as a primary driver of the evolution of phenotypic complexity in mammals. Various Hox genes are known to produce alternative transcripts encoding different isoforms whose physiological relevance during development is not yet understood. Hoxa9 is a homeo-box transcription factor with a central role in both hematopoiesis and leukemia. High level of HOXA9 expression is a characteristic feature of acute myeloid leukemia (AML) and is associated with dismal prognosis. Previously a highly conserved alternative splice variant - trun-cated Hoxa9 (Hoxa9T) - has been identified that lacks the homeodomain. So far the biological relevance of Hoxa9T in normal and malignant hematopoiesis is not known. *Aim.* The aim of this project is to identify, characterize and understand the role of the Hoxa9T isoform and Hoxa9 in normal and malignant hematopoiesis. *Methods.* Expression of Hoxa9 and Hoxa9T was analysed in human and murine normal and malignant hematopoiesis by qPCR. To understand the function of the naturally occurring splice variant of HOXA9 we generated two mutants: first, we silenced the pseudo-intron rec-ognition sites of Hoxa9 wild-type to eliminate splicing of Hoxa9 (Hoxa9 FL) and secondly we generated Hoxa9T. *in vivo* function of Hoxa9T was tested in the syngenic murine bone mar-row transplantation model and colony forming unit spleen assay (CFU-S). *Results.* Expression levels of Hoxa9 and Hoxa9T were significantly higher in KSL cells com-pared to normal total BM (>90-fold and >20-fold, respectively). Interestingly, Hoxa9T was higher expressed in murine BM progenitors compared to Hoxa9. HOXA9 and HOXA9T were co-expressed in human leukemic cell lines as well as in 115 AML patient samples with normal karyotype. Interestingly, 90% of the analyzed AML patient samples showed an aberrant ratio between HOXA9 and HOXA9T expression compared to highly purified $CD34^+$ bone marrow cells of healthy donors (ratio=3.2). The vast majority of the AML patients (69%) showed an increased ratio of expression due to an elevated HOXA9- versus HOXA9T-expression, whereas 21% showed a decrease in this ratio. To test the hematopoietic activity of different Hoxa9 iso-forms, we performed CFU-S assay. All the different Hoxa9 forms (Hoxa9WT, Hoxa9T and Hoxa9FL induced an increase in the frequency of short - term repopulating stem cells com-pared to the empty retroviral control in CFU-S assay (n at least12). Importantly, activity of Hox9WT and Hoxa9FL could be further enhanced by co-expression of Hoxa9T. In contrast to the splicable Hoxa9WT (n=21, 135 d), overexpression of Hoxa9T in the BM transplantation model induced AML only after long median latency of 214 days (n=21). Also the non-spliced isoform Hoxa9FL did show a delay in median latency compared to Hoxa9WT (median latency 208 vs. 135 days). To confirm the hypothesis that this delay is due to a loss of Hoxa9T, we co-expressed Hoxa9T and Hoxa9FL (n=10) which again led to a median latency of 144 days comparable to Hoxa9WT. *Conclusions.* These results indicate that that the leukemogenic po-tential of Hoxa9 depends on the collaboration with its own spliced isoform

0037

HIGH-RESOLUTION MOLECULAR ALLELOKARYOTYPING IDENTIFIES NOVEL UNIPARENTAL DISOMY AND FOCAL COPY NUMBER ALTERATIONS IN ACUTE PROMYELOCYTIC LEUKEMIA (APL)

I Iacobucci,[1] E Ottaviani,[1] V Guadaguolo,[1] A Lonetti,[1] N Testoni,[1]

F Lo Coco[6]

[1]*Institute of Hematology Seràgnoli, Bologna, Italy;* [2]*Dept. of Clinical and Biological Sciences, University at Orbassano, Turin, Italy;* [3]*Chair and Division of Hematology and Bone Marrow Transplantation, AOU Udine, Udine, Italy;* [4]*Department of Hematology and Transplants, University of Siena, Siena, Italy;* [5]*Ceinge-Advanced Biotechnology, University of Naples Federico II, Naples, Italy;* [6]*Department of Biopathology, University Tor Vergata, Rome, Italy*

Introduction. Experimental evidence obtained in transgenic mice revealed that PML-RARA is necessary but not sufficient for the development of APL, suggesting that additional genetic mutations are also required for its development. *Aim.* To define whether additional submicroscopic genomic alterations may characterize APL and may be used to better classify the disease by dissection of genomic subsets. *Patients and Methods.* 105 adult patients with acute myeloid leukemia were analyzed. These cases included all French-American-British subtypes, miscellaneous cytogenetic abnormalities and normal karyotype subgroups. Among these, the M3 subtype included 28 patients, representing the 33% of the whole study population. Genomic DNA was isolated from blast cells and applied to Genome-Wide Human SNP 6.0 array (Affymetrix, Santa Clara, CA) following the manufacturer's instructions. Fluorescence *in situ* hybridization, quantitative PCR and nucleotide sequencing were used to confirm genomic alterations. *Results.* A wide spectrum of different copy number alterations (CNAs) were identified in all cases and no significant difference in the average number of alterations was detected among different leukemia cytogenetic subgroups except for the complex subgroup, which had an average of 55 CNA/patient. In APL cases an average of 8 CNAs per case (range, 1-24) was found. The macroscopic alterations were rare, confirmed conventional cytogenetics and involved trisomy of chromosome 8 in 3 cases, loss of chromosome 6, loss of chromosome 20 and deletions on chromosome 9 and 7. Microscopic CNAs (<1.5 Mbps) involved every chromosome at least once and predominantly chromosomes 1, 2, 9, 15 and 17. For each alteration we interrogated a collated library of copy-number variants (CNVs, Database of Genomics Variants and USCS Genome Browser) to assure that these regions were not known as CNVs and therefore to decrease the noise of raw copy number data.

Genetic gains were more common than losses and their median size was 300 kb (range 0.2- 1.4 Mb). The majority of lesions were not recurrent, being identified in only a single patient. Focal genetic alterations were detected at the breakpoints of t(15;17)(q22;q21) in PML and RARA genes, in genes involved in activation of transcription (loss of LMX1 on 1q23.3, loss of MLXIPL and BCL7 on 7q11.23), regulation of cell cycle (gain of PVT1 and MYC on 8q24) and cell adhesion (gain of NCAM1 on 11q23). In order to identify potential pathogenetic alterations, all microscopic CNAs were compared with the list of genes from the Cancer genome project (http://www.sanger.ac.uk/genetics/CPG/Census) finding out that six alterations involved a known cancer-related gene. Most of these genes encode tyrosine kinase proteins (ERBB4) or transcription factors (ETV1, ETV6, ERG). Copy neutral loss of heterozygosity events affected 1p34.2-1p32.3, 10p11.2 (MLLT10), 11p11.2 (WT1, CDKN1C, HRAS). Finally, patients with more than 10 CNAs were found to be associated with a worse prognosis. *Conclusions.* These data demonstrate that different cooperating events may be involved in the generation of APL. Furthermore, these novel findings may be used to stratify patients according to genomic changes. CLINICAL IMPLICATIONS OF A SPECIFIC METHYLATION PROFILE IN ACUTE MYELOID LEUKEMIA

A Ana, J Cervera, E Such, M Ibañez, I Gómez, E Barragán, O Fuster, I Luna, B Costan, F Moscardó, M Sanz

Hospital La Fe, Valencia, Spain

Background. Several reports have identified a growing number of genes that may be inactivated due to aberrant hypermethylation in acute myeloid leukemia (AML). However, in most cases the methylation status has been investigated in small number of AML patients and, therefore, its clinical impact has not been yet clarified. *Objectives*. To analyze the clinical relevance of aberrant methylation in a panel of key cancer genes: p15INK4B, RARB, p73, APAF1, SHP1, CDH1 and BLU in a large series with *de novo* AML. These genes were selected based on previous reports where aberrant methylated genes in AML were identified. *Methods.* Bone marrow samples from 184 AML patients at diagnosis were analyzed (110 male/74 female; median age: 60 yr, range: 16-92). Genomic DNA was extracted using standard protocols. After bisulphite treatment DNA was amplified with Methylation Specific Polymerase Chain Reaction using primers specific to the methylated and unmethylated alleles of the genes. *Results.* The methylation frequencies were as follows: 59% p15INK4B, 43% BLU, 42% CDH1, 41% p73, 33% SHP1, 30% RARB and 22% APAF1. A total of 163 patients (88%) had at least one gene methylated. Only three patients were found to have concurrent methylation of the seven genes studied. Aberrant methylation of any individual gene was compared with patient characteristics, including: age, sex, WBC count, FAB subtype, cytogenetic risk groups and FLT3-ITD mutations. Methylation of p15INK4B and RARB were associated with a leukocyte count ≤10×10^9/L (P=0.04), while methylation of p73 was associated with age ≤60 years (P=0.04) and leukocyte count ≤ 10×10^9/L (P= 0.02). In univariate analysis, methylation of p15INK4B and BLU were found to have a negative impact in both overall survival (OS) and relapse-free survival (RFS). Therefore, we classified AML patients into two methylation groups according to the presence of concurrent methylation of both p15INK4B and BLU, irrespective of the other genes methylated, (Group A) and the rest of patients (Group B). In univariate analysis, patients belonging to the Group A had a significantly reduced OS than Group B at 4 years (10% versus 28%, respectively, P=0.005), disease-free survival (DFS) (25% versus 6%, respectively, P=0.009) and RFS (28% versus 47%, respectively, P=0.04). In multivariate analysis, the concurrent methylation in both p15INK4 and BLU genes retained an independent adverse significance for OS, DFS and RFS. Similar results were obtained when the analysis was restricted to patients younger than 60 years with intermediate risk cytogenetics. Patients belonging to Group A had a significantly reduced DFS than Group B at 4 years (23% versus 48%, respectively, P=0.03) and RFS (27% versus 66%, respectively, P=0.003). *Conclusions.* Our results indicate that simultaneous aberrant methylation affecting key cancer genes is a common phenomenon in AML. Moreover, the concurrent methylation of p15INK4 and BLU seems to be an important factor in predicting the clinical outcome of AML patients.

IL-12 DEBULKS PEDIATRIC ACUTE MYELOID LEUKEMIA CELLS BY ACTING ON TUMOR INITIATING CELLS IN VIVO

E Ferretti,[1] D Montagna,[2] E Di Carlo,[3] C Cocco,[1] D Ribatti,[4] E Ognio,[5] F Locatelli,[2] V Pistoia,[1] I Airoldi[1]

[1]G.Gaslini Institute, Genoa, Italy; [2]IRCCS Policlinico San Matteo, Pavia, Italy; [3]G. d'Annunzio University and Ce.S.I. Aging Research Center, G. d'Annunzio, Chieti, Italy; [4]Department of Human Anatomy and Histology, University of Bari, Bari, Italy; [5]Animal Model Facility, Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy

Background. Acute myeloid leukemia (AML) is a hematologic tumor which represents 15-20% of all childhood acute leukemias and is responsible for more than half of leukemic death in these patients who frequently relapse. The bulk tumor is continuously regenerated and sustained by rare tumor initiating cells (TIC), that proliferate slowly thus resulting refractory to chemotherapeutic agents that target highly proliferating cells within the tumor. Therefore, complete eradication of the bulk tumor may depend on efficacy of therapies that target TIC. IL-12 is an immunomodulatory cytokine which functions as anti-tumor agent in solid and hematologic malignancies through direct effects on tumor cells, stimulation of the immune system and anti-angiogenic mechanisms. The ability of IL-12 to target the bulk AML cells has never been investigated. *Aims.* Therefore, we asked whether this cytokine may affect *in vivo* blast AML cells and TIC compartment. *Methods.* First, the expression of both chains of the IL-12 receptor was investigated, by flow cytometry, in TIC and in blast AML cells, obtained from pediatric patients at diagnosis (n=16). Next, the *in vivo* IL-12 anti-tumor activity was evaluated by sub-cutaneous (s.c) and intra-venous (i.v.) inoculation of primary AML cells into SCID/NOD Il2rg-/- (NOG) mice that were treated with human recombinant (hr)IL-12 or PBS (controls). AML cells were analyzed at the primary site of tumor cell inoculation, in the peripheral blood and lymphoid organs (e.g. bone marrow and spleen) using human cell surface markers and flow cytometry analysis and/or immunohistochemistry. The IL-12 anti-tumor activity *in vivo* was tested in terms of inhibition of tumor mass formation, cell spreading and angiogenesis. *Results.* We found that i) primary blast AML cells and TIC express both chains of the IL-12R at surface level, ii) AML cells injected into NOG mice displayed enriched TIC population as compared to the original AML cell sample, iii) AML cells injected s.c. into NOG mice gave rise to a tumor mass including TIC at the primary site of cell inoculation. TIC and bulk tumor were eliminated by hrIL-12 treatment, iv) hrIL-12 treatment hindered AML cell homing to the spleen and bone marrow once injected i.v., v) TIC were virtually absent in spleens and bone marrow from NOG mice inoculated with AML cells and subsequently treated with hrIL-12, and viii) IL-12 reduced primary AML angiogenesis *in vitro*. *Conclusion.* The novelty of these results is manifold and may be deals with the demonstration that IL-12 may target blast AML cells and TIC *in vivo*.

THE VENT-LIKE HOMEOBOX GENE VENTX IS A NOVEL HUMAN HEMATOPOIETIC FACTOR, WHICH PROMOTES MYELOID DEVELOPMENT AND IS HIGHLY EXPRESSED IN ACUTE MYELOID LEUKEMIA

V Rawat,[1] N Arseni,[2] M Mulaw,[2] F Ahmed,[2] S Thoene,[1] H Bernhard,[2] T Sadlon,[3] R Andrea,[3] W Hiddemann,[2] S Bohlander,[2] C Buske,[1] M Feuring-Buske[1]

[1]The Institute of Experimental Cancer Research, Ulm, Germany; [2]Clinical Cooperative Group Leukemia, Helmholtz Zentrum Muenchen,, Munich, Germany; [3]Leukaemia Laboratory, Child Health Research Institute, North Adelaide, Australia

Background. Recent studies suggest that a variety of regulatory molecules active in embryonic development such as clustered and non-clustered homeobox genes play an important role in normal and malignant hematopoiesis. Since it was shown that the Xvent-2 homeobox gene is part of the BMP-4 signalling pathway in Xenopus, it is of particular interest to analyse the function of its only recently discovered human homologue VENTX in normal hematopoietic and leukemic development. *Aim.* The aim of this project is to identify, characterize and understand the role of the Vent-like homeobox gene VENTX in normal and malignant haematopoiesis. *Methods.* Expression of the VENTX gene was analysed in human normal and malignant haematopoiesis by microarray and qPCR. To test the impact of VENTX2 overexpression on human clonogenic progenitor cells, $CD34^+$ cord blood (CB) cells

were retrovirally transduced with VENTX or empty vector and we performed *in vitro* and *in vivo* assays. *Results.* So far we and others have not been able to identify a murine Xenopus xvent gene homologue. However, we were able to document the expression of this gene by qPCR in human lineage positive hematopoietic subpopulations. Amongst committed progenitors VENTX was significantly 13-fold higher expressed in $CD33^+$ BM myeloid cells (4/4 positive) compared to $CD19^+$ BM lymphoid cells (5/7 positive, P=0.01). Of note, expression of VENTX was negligible in normal $CD34^+/CD38^-$ but detectable in $CD34^+$ BM human progenitor cells. In contrast to this, leukemic $CD34^+/CD38^-$ from AML patients (n=3) with translocation t(8,21) showed significantly elevated expression levels compared to normal $CD34^+$ BM cells (n=5) (50-fold higher; P≤0.0001). Furthermore, patients with normal karyotype NPM1c+/FLT3-LM- (n=9), NPM1c-/FLT3-LM^+ (n=8) or patients with t(8;21) (n=9) had an >100 fold higher expression of VENTX compared to normal $CD34^+$ BM cells and a 5- to 7.8-fold higher expression compared to BM MNCs. Gene expression and pathway analysis demonstrated that in normal $CD34^+$ cells enforced expression of VENTX initiates genes associated with myeloid development and downregulates genes involved in early lymphoid development. Functional analyses confirmed that aberrant expression of VENTX in normal $CD34^+$ human progenitor cells induced a significant increase in the number of myeloid colonies compared to the GFP control with 48±6.5 compared to 28.9±4.8 CFU-G per 1000 initially plated $CD34^+$ cells (n=11; P=0.03) and complete block in erythroid colony formation with an 81% reduction of the number of BFU-E compared to the control (n=11; P<0.003). In a feeder dependent co-culture system, VENTX impaired the development of B-lymphoid cells. In the NOD/SCID xenograft model, VENTX expression in $CD34^+$ CB cells promoted generation of myeloid cells with an over 5-fold and 2.5-fold increase in the proportion of human $CD15^+$ and $CD33^+$ primitive myeloid cells compared to the GFP control (n=5, P=0.01). Summary: Overexpression of VENTX perturbs normal hematopoietic development, promotes generation of myeloid cells and impairs generation of lymphoid cells *in vitro* and *in vivo*. Taken together, these data extend our insights into the function of human embryonic mesodermal factors in human hematopoiesis and indicate a role of VENTX in normal and malignant myelopoiesis.

0041

BIOLOGICAL CHARACTERIZATION OF AML AT THE SINGLE CELL LEVEL BASED ON RESPONSE TO DNA DAMAGING AGENTS

W Fantl,[1] D Rosen,[1] M Minden,[2] S Putta,[1] T Covey,[1] YW Huang,[1] A Cesano,[1] G Nolan[3]

[1]Nodality Inc, South San Francisco, CA, USA; [2]Princess Margaret Hospital, Toronto, ON, Canada; [3]Stanford University, Stanford, CA, USA

Background. Standard approaches to treating AML are predominantly based on DNA damaging agents. Yet the long-term outcomes of these patients continue to be sub-optimal, most likely due to the cytogenetic and molecular heterogeneity of the disease. We hypothesized that this heterogeneity is reducible to a limited number of intracellular signaling phenotypes that can classify the disease into biologic, mechanistic and clinical subgroups relevant to disease management. A very relevant technology for evaluating these responses is single cell network profiling (SCNP) utilizing flow cytometry which differs from most proteomic technologies by measuring multiple modulated signaling responses at the single cell level and in a manner associated with cell type and other co-expressed proteins. *Aims.* In this study SCNP was utilized to define myeloid growth factor and cytokine-mediated intracellular signaling responses in AML samples and how they relate to *in vitro* responsiveness to DNA damaging agents currently used in therapeutic regimens. Identification of pathways associated with responsiveness or refractoriness to DNA damaging agents may inform the choice of specific therapeutic regimens. *Methods.* Modulated Jak/Stat and PI3K pathway activity was measured after exposure of 34 diagnostic non-M3 AML blasts to myeloid growth factors (e.g Flt3L, SCF), cytokines (e.g G-CSF, GM-CSF) and interleukins (e.g IL-6, IL-27). DNA damage response (DDR) and apoptosis pathway activity of AML blasts exposed to etoposide was determined by measuring levels of p-Chk2 and cleaved PARP respectively. Samples were processed for cytometry by paraformaldehyde/methanol fixation and permeabilzation followed by incubation with panels of fluorochrome-conjugated antibodies that recognize cell surface proteins to delineate cell subsets and intracellular pathway molecules. *Results.* Analysis of modulated Jak/Stat and PI3K pathway responses in individual patient samples identified blast subgroups with distinct pathway profiles: A) high Jak/Stat activity B) high PI3K activity C) high activity in both pathways D) low activity in both pathways. *in vitro* exposure of samples to etoposide revealed three distinct "DDR/apoptosis"profiles: 1) AML blasts with a defective DDR and failure to undergo apoptosis 2) AML blasts with proficient DDR and failure to undergo apoptosis 3) AML blasts with proficiency in both DDR and apoptosis. AML samples from clinical responders fell within the third "DDR/apoptosis"profile and had low PI3K and Jak/Stat signaling responses. However, AML blasts from clinically non-responsive cases fell within all the Jak/Stat and PI3K pathway profiles A-D and within all the "DDR/apoptosis"profiles 1-3. Notably, analysis of Jak/Stat, PI3K and apoptosis pathway responses characterized biologically distinct patient-specific profiles of chemo-resistance, even within cytogenetically and phenotypically uniform patient subgroups. *Conclusions.* SCNP revealed cell subsets with distinct signaling, DDR and apoptosis responses between AML samples. The data from this study generated the hypothesis that the requirements for chemo-sensitivity are very restricted: low PI3K and Jak/Stat signaling and proficient DDR and apoptosis. By contrast many pathway aberrations could result in refractoriness to chemotherapy. Further dissection of these and additional pathways in independent AML sample cohorts could provide guidance for the most appropriate choice of therapy in individual patients.

0042

A HIGH AMOUNT OF $CD34^+$ CD38LOW/NEG $CD123^+$ CELLS HAS AN ADVERSE IMPACT ON DISEASE FREE AND OVERALL SURVIVAL IN AML PATIENTS TREATED BY INTENSIVE CHEMOTHERAPY

V Bardet,[1] A Green,[2] F Vergez,[3] J Tamburini,[2] N Gallay,[3] B Gaillard,[4] M Pannetier,[2] A Neyret,[2] N Chapuis,[2] N Ifrah,[5] F Dreyfus,[5] C Demur,[3] C Lacombe,[2] P Mayeux,[2] D Bouscary,[2] C Recher[3]

[1]GH Cochin-Saint Vincent de Paul-la Roche Guyon, PARIS, France; [2]Institut Cochin, Département d' Immuno-Hématologie, Paris, France; [3]CHU Purpan, Toulouse, France; [4]CHU Reims, Reims, France; [5]Goelams, Angers, France

Background. The characterization of new prognosis tools is of major importance in acute myeloid leukemia (AML). The high expression of CD123 (the IL3 alpha chain receptor/IL3-R) on myeloid blast cells was previously reported as a marker of adverse outcome in AML and anti-IL3-R therapies are currently in development and may be useful to prevent AML relapses. The $CD34^+$ $CD38^{low/neg}$ $CD123^+$ phenotype identifies a subset of AML cells enriched in leukemic stem cells. *Aims.* The aim of the study was to evaluate the prognostic impact of the amount of $CD34^+$ $CD38^{low/neg}$ $CD123^+$ cells detected at diagnosis among the AML bulk. *Patients and Methods.* Quantification of blast cells with the CD34+ CD38low/neg $CD123^+$ phenotype was achieved by flow cytometry in 144 patients with *de novo* AML (median age 56 y). Distribution among cytogenetic groups was: unfavourable 15%, intermediate 65% and favourable 19%. The survival studies were performed for 116 CD34 positive patients homogeneously treated according to intensive chemotherapy trials from the French GOELAMS group. Informed consent was obtained in accordance to the declaration of Helsinki. *Results.* The percentage of $CD34^+$ $CD38^{low/neg}$ $CD123^+$ cells (LSC%) is highly variable between samples (0-67%, median: 2.7%) and appeared independent from the FAB classification, the age or the cytogenetic group. The LSC% has no impact on the achievement of complete remission (CR=85%) among the 116 patients treated with intensive chemotherapy but is higher in patients who died (3.7 vs 0.6%, P=0.003) or relapsed (4.3 vs 0.7%, P=0.02). With a 1% cut-off, LSC% is tightly correlated with overall survival (OS), with a median survival of 32 months versus 16 months (P=0.005). Similarly, the disease free survival (DFS) is 37 vs 11 months in the 91 patients who achieved complete remission (CR) (P=0.001). Considering the intermediate cytogenetic group (n=75), the LSC% is also predictive for a better OS (32 vs 16 months, P=0.017) and DFS (37 vs 14 months, P=0.01), even in the Flt3 wild type subgroup (OS: 78 vs 26 months, P=0.01). Interestingly, in CBF leukemias (n=25), the LSC% is still predictive for a better DFS (36 vs 13 months, P=0.02). *Conclusion.* This study emphasizes the prognosis impact of the $CD34^+$ $CD38^{low/neg}$ $CD123^+$ cell burden in AML patients, which is predictive of shorter OS and DFS when representing over 1% of the leukemic cells, regardless of the usual prognosis categories. We provide here a new prognosis marker that may be easily translated to the clinical practice in AML although it remains to be validated on a large prospective cohort of patients. Moreover, new therapies targeting this subpopulation could help to improve outcome in AML patients.

Acute myeloid leukemia - Biology 2

THE MOLECULAR PATHWAYS AFFECTED BY THE AML ASSOCIATED ONCOFUSION PROTEINS AML1-ETO AND PML-RAR

J Martens,[1] M Laakso,[2] A Brinkman,[1] K Francoijs,[1] F Simmer,[1] L Altucci,[3] E Vellenga,[4] H Stunnenberg[1]

[1]NCMLS, Nijmegen, Netherlands; [2]University of Helsinki, Helsinki, Finland; [3]Seconda Universita degli Studi di Napoli, Napoli, Italy; [4]University Medical Center Groningen, Groningen, Netherlands

Background. Recurring chromosomal abnormalities have been identified in a variety of cancers, but are most frequently associated with hematological malignancies such as acute myeloid leukemia (AML) and acute lymphocytic leukemia (ALL). At present, more than 1000 recurring cytogenetic abnormalities have been reported for AML alone. Three main cytogenetic changes have been detected in leukemic cells: chromosomal deletions, inversions and translocations, with translocations being by far the most frequent. In addition to transcriptional activation of proto-oncogenes these cytogenetic changes often cause gene fusions. In these cases the translocation splits the genes on both partner chromosomes leading to the juxtaposition of part of each gene. The resulting fusion gene often encodes a chimeric protein. Although many of the breakpoints involved in specific chromosomal translocations have been cloned, in most cases the role of the chimeric oncofusion proteins in tumorigenesis is not elucidated. *Aim.* A rational approach towards the definition of specific treatment for AML requires identification of the molecular mechanisms that are utilized to transform hematopoietic progenitors. For this, we wished to characterize the genome-wide binding profiles of the fusion products of 2 translocations that are frequently associated with AML: t(8;21) and t(15;17) and characterize their common gene programs and associated pathways. *Methods.* Both cell lines and patient blasts expressing either PML-RAR or AML1-ETO were subjected to chromatin immunoprecipitation experiments using sets of antibodies that could recognize different epitopes within the oncofusion proteins. Precipitated DNA was subsequently analyzed with large-scale sequencing techniques allowing the identification of the global binding patterns of the chimeric proteins. *Results.* Comparison of AML1-ETO and PML-RAR target regions revealed many common target genes, amongst which the hematopoietic master regulator SPI1/PU.1. In addition, bioinformatic analysis of the common binding sites revealed that both proteins target various signaling pathways. Finally, genome-wide epigenetic studies revealed decreased histone acetylation upon binding of both proteins, suggesting the involvement of the oncofusion proteins in the recruitment of enzymes that modulate histone acetylation levels. *Conclusions.* Together, these results suggest that the molecular mechanisms AML1-ETO and PML-RAR use to transform hematopoietic progenitors significantly overlap. The results suggest that both proteins utilize the recruitment of histone deactylases to modulate expression of genes important for hematopoietic differentiation and for various signaling pathways.

TARGETED INHIBITION OF MTOR BY AZD8055 BLOCKS PROTEIN TRANSLATION AND HAS ANTI-LEUKEMIC ACTIVITY IN ACUTE MYELOID LEUKEMIA

L Willems,[1] N Chapuis,[1] A Green,[1] V Bardet,[1] N Jacque,[1] S Park,[1] N Ifrah,[2] F Dreyfus,[3] S Guichard,[4] P Mayeux,[1] C Lacombe,[1] D Bouscary,[1] J Tamburini[1]

[1]Institut Cochin Inserm U1016, Paris, France; [2]CHU Angers, Angers, France; [3]Hôpital Cochin, service d'Hématologie, Paris, France; [4]Astrazeneca, Macclesfield, UK

Background. The treatment of acute myeloid leukemia (AML) still represents a challenge. Major efforts are therefore made to develop targeted molecules against deregulated signaling pathways that sustain AML cells growth and survival. The mTOR serine/threonine kinase belongs to two separate complexes, mTORC1 and mTORC2. The mTORC1 complex, which is inhibited by rapamycin in most models, controls mRNA translation through the phosphorylation of the translation repressor 4E-BP1. The frequent activation of mTORC1 in primary AML cells underscored this complex as a major target for AML therapy. However, the allosteric inhibition of mTORC1 by rapamycin has only modest effects in AML. The rather low anti-leukemic activity of rapamycin has already been linked to different resistance mechanisms. We recently showed that the translation process is deregulated and resistant to rapamycin in AML. Moreover, the mTORC2 complex, which is responsible for the full activation of the oncogenic kinase Akt through its PDK2 activity, is generally reported as resistant to rapamycin. Finally, mTORC1 inhibition by rapamycin induces a positive feedback on the PI3K/Akt signaling involving mTORC2 activity. The AZD8055 compound (AstraZeneca, UK) is an ATP-competitive inhibitor specific of the mTOR kinase. We thus hypothesized that direct inhibition of the catalytic activity of mTOR by AZD8055 could overcome the rapamycin resistance phenotype in AML. *Materials and Methods.* AZD8055 was used from 1 nM to 1000 nM. The anti-leukemic activity of AZD8055 was tested in both human AML cell lines (MV4-11, MOLM-14, OCI-AML3) and in 20 primary AML samples all included in trials initiated by the French GOELAMS group. Protein translation was tested by 7Methyl Guanosine cap affinity assay, polysomes analysis and [3H]Leucine incorporation assay. Blast cell proliferation and apoptosis were quantified by [3H]Thymidine incorporation and annexin-V staining, respectively. *Results.* We first observed that in contrast to rapamycin, AZD8055 dose-dependently inhibits mTOR catalytic activity, attested by the inhibition of mTOR S2481 phosphorylation. Accordingly, AZD8055 blocks mTORC1 activity, attested by the decrease of P70S6K T389 phosphorylation and also mTORC2 activity, as shown by the inhibition of Akt S473 and of NDRG1 T346 phosphorylations. Furthermore, AZD8055 inhibits the rapamycin-resistant phosphorylation of the translation repressor 4E-BP1 on T37/46, T70 and S65 residues. This results in a marked inhibition of mRNA translation in AML cells, attested by (i) an inhibition of the assembly of the translation initiating complex eIF4F, (ii) a shift from large to small polysomes in AZD8055-treated AML cells and (iii) a decreased expression of the oncogenic cap-dependant proteins Bcl-xL, c-Myc and cyclinD1. Accordingly, AZD8055 has a marked anti-leukemic activity in AML. Indeed, it strongly reduces the proliferation of AML cells and blocks the cell-cycle progression. AZD8055 also represses the clonogenic growth of AML progenitors and induces in the killing of AML blast cells, but not of normal $CD34^+$ hematopoietic cells. *Conclusion.* AZD8055 compound demonstrates a remarkable anti-leukemic activity through specific inhibition of both mTORC1 and mTORC2 activities in AML cells. The absence of toxicity against normal hematopoietic cells ex vivo highly suggests a favourable therapeutic index, which emphasize the development of AZD8055 as a clinical candidate for therapy in AML.

0045

TARGETING HEMATOPOIETIC STEM CELLS EXPANSION IN C/EBPALPHA MUTANT AML

O Bereshchenko,[1] C Nerlov,[2] C Riccardi[1]

[1]University of Perugia, Perugia, Italy; [2]EMBL, Monterotondo, Italy

Background. Acquisition of oncogenic mutations in stem cells is an attractive model for multistep tumorigenesis in highly self-renewing tissues. We therefore demonstrated that acute myeloid leukemia (AML) is a multistep disease with premalignant hematopoietic stem cells (HSC) expansion preceding the formation of leukemia initiating cells (LIC) with committed myeloid phenotype. Patient-derived C-terminal C/EBPalpha mutations increase the proliferation of long-term hematopoietic stem cells (LT-HSCs) in a cell-intrinsic manner and override normal HSC homeostasis, leading to expansion of premalignant HSCs. Such mutations impair myeloid programming of HSCs and block myeloid lineage commitment when homozygous. N-terminal C/EBPalpha mutations instead are silent with regards to HSC expansion, but allow the formation of committed myeloid progenitors, the templates for LICs. The combination of N- and C-terminal C/EBPalpha mutations incorporates both features, leading to accelerated AML development in mice, thus explaining the most prevalent C/EBPalpha mutation pattern in AML patients. *Aims*. Since HSC expansion in biallelic C/EBPalpha mutant AML is associated with accelerated disease, these expanding HSCs represent a novel target for cancer therapy, distinct from successively generated LICs. We would like to find genetic and pharmacologic ways to impede abberrant mutant HSC expansion. Cell cycle analysis have demonstrated that all mutant HSC compartments including LT-HSCs have increased cycling, suggesting that they can be targeted by antiproliferative drugs used in conventional chemotherapy. We use cytosine arabinoside (Ara-C) to check whether 1) it leads to selective mutant HSCs apoptosis and consequent drop in cell number; 2) whether it affects long-term survival of leukemic mice. *Methods.* We

use recently described mouse model of biallelic C/EBPalpha mutant AML. We perform Ara-C treatments in radiation chimeras competitively transplanted with a mix of wild type and C/EBPalpha mutant fetal liver cells. This way the effect of chemotherapy is evaluated on both wild-type and mutant HSCs in the same mouse. Apoptosis in wild type (CD45.1+) and mutant (CD45.2+) LT-HSCs is measured by fluocytometry (LT-HSCs are defined as Lin-c-kit+Sca-1+CD150+) using AnexinV/SytoxBlue staining. Frequency and total number of HSCs is calculated in mice after 24 and 72 hours post-treatment. *Results*. We found that Ara-C efficiently and selectively induced apoptosis in mutant HSCs and downregulated their frequency and total number. However it did not lead to their complete elimination. Future studies will focus on characterization of the Ara-C resistant cells to find possible combination treatment strategies to block HSC expansion and slow down or prevent leukemia progression. *Summary*. This study provides proof of principle that hyper-proliferating mutant LT-HSCs can be selectively targeted by antiproliferative agents. Future work will focus on characterization of therapeutic relevance of the described results and finding complementary pathways that would allow elimination or proliferation block of the residual leukemogenic HSCs.

0046

TARGETING IRON HOMEOSTASIS INDUCES CELLULAR DIFFERENTIATION AND SYNERGIZES WITH DIFFERENTIATING AGENTS IN ACUTE MYELOID LEUKEMIA

C Callens,[1] S Coulon,[1] J Naudin,[1] I Radford-Weiss,[1] N Boissel,[2] E Raffoux,[2] H Dombret,[2] E Macintyre,[1] I Moura,[3] O Hermine[1]

[1]Hôpital Necker, Paris, France; [2]Hopital Saint Louis, Paris, France; [3]Inserm U699-Faculté Bichat, Paris, France

Background. Differentiating agents have been proposed to overcome the impaired cellular differentiation in acute myeloid leukemia (AML). However, only the combinations of all-trans retinoic acid or arsenic trioxide with chemotherapy have been successful, and only in treating acute promyelocytic leukemia. Iron is required as a cofactor for a number of critical cellular enzymes involved in energy metabolism and cell proliferation and therefore is essential for all living cells. Iron chelators represent an alternative anti-cancer therapy and effectively induce cell growth arrest and apoptosis in prostate and melanoma cancer cells *in vitro* and *in vivo*. *Aims.* We aimed to characterize the molecular mechanisms underlying the anti-tumor effect of iron-chelating therapeutic approaches and to validate their potential value in AML therapy. *Methods*. We worked with HL60, OCI-AML3, THP1, U937 and NB4 leukemia cell lines and peripheral blood cells issued from AML patients and healthy donors after obtaining their written informed consent. Cell differentiation was assessed by CD14 and CD11b expression and esterases activity. Fluorescence analysis was used to determine the relative levels of reactive oxygen species (ROS). Mitogen-activated protein kinases (MAPKinases) and Vitamin D (VD) pathways were studied by RQ-PCR and western blots. *in vitro* observations were confirmed in a nude mice model subcutaneous xenografted with HL60 and OCI-AML3 cell lines. *Results.* Here we showed that iron homeostasis is an effective target in the treatment of AML. Iron chelating therapy induces the differentiation of leukemia blasts and normal bone marrow precursors into monocytes/macrophages in a manner involving modulation of ROS expression and the activation of MAPKinases. By comparing the pattern of genes induced by VD and iron-chelating agents in a non-supervised transcriptome analysis, we found that thirty percent of the genes most strongly induced by iron deprivation are also targeted by VD, a well-known differentiating agent. Iron chelating agents induce expression and phosphorylation of the VD receptor, and iron deprivation and VD act synergistically. VD magnifies activation of MAPK JNK and the induction of VD receptor target genes. The efficacy of differentiation therapy was further evaluated *in vivo* in a mouse tumor xenograft model. The combination of VD with DFO significantly reduced tumor growth. When used to treat one AML patient refractory to chemotherapy, the combination of iron chelating agents and VD resulted in reversal of pancytopenia and blast differentiation. *Conclusions.* We propose that iron availability modulates myeloid cell commitment, and that targeting this cellular differentiation pathway together with conventional differentiating agents provides new therapeutic modalities for AML. This combined therapy would be particularly useful in elderly patients who are not eligible for high dose chemotherapy and bone marrow transplantation. This association could be also relevant in other diseases involving a deregulation of BM differentiation, such as myelodysplastic syndromes. Additional clinical studies are needed to validate its efficacy.

0047

MONITORING OF ABERRANTLY METHYLATED GENES IN AML PATIENTS

H Hájková, R Petrbokova, L Novakova, J Cermak, C Haskovec

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Changes in methylation pattern are well known to be involved in pathogenesis of patients with acute myeloid leukemia (AML). Aberrant methylation pattern has been described as a potential biomarker for cancer cells detection. The aim of the current study was to introduce quantitative methylation specific real-time PCR based method called MethyLight for routine monitoring of disease progression by quantifying the level of methylation. We also searched for novel genes influenced by DNA methylation. To evaluate DNA methylation levels of patients with AML, 52 AML samples at diagnosis and 196 at remission were examined. Median follow-up after diagnosis was 16 months (range 2-30) Genes previously described as often affected by hypermethylation either in hematological or other malignancies were chosen. These genes included: CDKN2B, ESR1, ECAD, DAPK1, CALCA, ICAM1, MYOD1, SOCS1, TIMP-3 and TERT. 100% methylated DNA was utilized as a reference to which methylation levels were expressed as a percentage of methylated reference (PMR). We also searched for novel genes affected by DNA hypermethylation. ML-2 cell line were treated for 3 days with 1 μM decitabine alone, 0.1 μM TSA alone or decitabine plus TSA, followed by Human Signal Transduction Pathway Finder PCR expression array. We confirmed high methylation frequency of studied genes (75%) in 52 AML patients at diagnosis. The most frequently hypermethylated genes were the following: CDKN2B (71%), ECAD (63%), CALCA (50%) and MYOD1 (33%). All remission samples showed negativity for methylation, which means they were under the level of methylation found in normal peripheral blood cells. Reoccurrence of DNA hypermethylation in AML patients with at least one hypermethylated genes at diagnosis were observed in disease relapse (5/5). After cultivation of ML2 cell line about 15 genes were significantly upregulated by twofold or greater when comparing to the control without hypometylating agents. Comparison of gene expression patterns in the treated versus control cells has revealed cohorts of genes that play role in differentiation (EGR1, CEBPB, BMP2), activation of immune system (CCL2, CCL20, IL8, IL4R, ICAM1), apoptosis (BAX, IL1A, LTA, GADD45A) and cell cycle regulation (CDKN1A, CDKN2B). The EGR1 gene was of particular interest, because it has been desribed as a potential tumour suppressor gene in hematological malignancies. We verified changes in EGR1 expression by performing TaqMan RQ-RT PCR not only in cultivated cells but also in AML patients at diagnosis versus healthy donors. A substantial proportion of AML patients were noted to have decreased level of EGR1 expression. To clarify the correlation between EGR1 expression and methylation, bisulfite sequencing was performed. It showed no correlation between changes in EGR1 expresion and aberrant DNA promoter methylation. Our data demonstrate the utilization of methylation biomarkers for monitoring minimal residual disease in AML patients and the clear connection between reoccurrence of DNA hypermethylation and disease reoccurrence. Further studies on the rest of upregulated genes after decitabine and TSA exposure are ongoing.

Supported by NS10632-3/2009 and OC10042.

Introduction. Acute myeloid leukemia (AML) is a heterogeneous group of pathology with variable response to treatment. In addition to the age and leukocytosis at diagnosis, cytogenetic abnormalities are key factors to assess prognosis. Although the identification of alteration affecting *CEBPa*, *NPM1* and *FTL3* improved the characterization of

AML, the variability can not be completely explained and several genomic alterations are likely to be discovered. In this study, we performed genomic profiling on a cohort of 130 AML patients in order to identify new genomic alterations and determine candidate gene potentially involved in oncogenesis or tumoral progression. *Methods.* This study was conducted on a cohort of 130 AML patients who have reached complete remission (CR). Cases were classified according to MRC cytogenetic classification (28 favourable; 85 intermediates, 7 adverse, 10 without any informative karyotype). Patients were aged from 3 to 65. Cases were distributed across all French-American-British (FAB) classes except M3 (8 M0, 25 M1, 39 M2, 26 M4 and 11 M4Eo, 12 M5, 2 M6, 1 M7), In all patients, DNA was extracted from bone marrow sample obtained at diagnosis and after CR achievement. Paired diagnosis and CR DNAs were analyzed using Affymetrix SNP Array 6.0 in order to distinguish acquired from constitutional anomalies. Acquired Copy number variations (CNA) were validated on a custom Agilent microarray 105k. *Results.* In this cohort, we found 209 genomic abnormalities in 73 patients (56%): 197 CNA and 13 copy neutral losses of heterozygoty (partial uniparental disomy or UPD). Each patient had 0 to 16 anomalies (median=1). Among CNA, deletions were more frequent than gains (130 vs 66). CNA spanned from 8 kb to 191 MB (median of gains 24 MB, median of losses 2 MB). 116 of them had not been detected by conventional cytogenetics. UPD spanned from 23 MB to 150 MB (median, 33 MB). In our cohort, anomalies were located over all chromosomes except chromosome 14 and were particularly frequent on chromosomes 2, 7, 11, 16, 17, and 21 (54% of all anomalies). We defined 72 minimal common regions which were altered in at least 2 patients. Among the 43 common regions shorter than 5 Mb, 16 contain at least one gene reported in AML or cancer: Among the 73 patients with CNA or UPD, 17 had a normal karyotype (30% of patients with normal cytogenetics). Frequency of CEBPa and FLT3 mutations (*FLT3*-TKD) was not significantly different in comparison to patients without any CNA or UPD. However, *FLT3* duplication (*FLT3*-ITD) and NPM1 mutations were significantly associated with the absence of CNA or UPD (respectively P=0.01 and P<0.001). This lower frequency of *NPM1* mutations was still significant within the intermediate cytogenetic subclass (P<0.001). *Conclusions.* In our cohort, CNA or UPD was detected in 56% of patients, frequently altering gene previously reported in oncogenesis. These alterations were associated with a specific genotype. In association with conventional cytogenetic, microarray Genomic profiling could better define prognosis subgroup

ACCUMULATION OF 2-HYDROXYGLUTARATE (2-HG) IN NORMAL KARYOTYPE AML PATIENTS WITH IDH1 MUTATION

E Ghazaly,[1] P Smith,[1] H Quentmeier,[2] H Drexler,[2] S Iqbal,[1] D Taussig,[1] B Young,[1] A Lister,[1] S Joel,[1] J Fitzgibbon[1]

[1]QMUL School of Medicine, London, UK; [2]DSMZ-German Collection of Microorganisms and Cell Cultures, Braunschweig, Germany

Background. Heterozygous mutations in isocitrate dehydrogenase 1 (*IDH1*) were recently identified in AML using massively parallel DNA sequencing. These mutations occur in ~8% of AMLs and appear to have a higher frequency in normal karyotype patients. The *IDH1* gene is a major mutational target in brain cancer, where the mutation leads to a gain-of-function. This results in the production and accumulation of 2-HG from the normal IDH1 metabolic product α-ketoglutarate, produced by the unaffected copy of the protein. *Aim.* In this study we set out to determine whether elevated 2-HG resulting from *IDH1* mutations is also present in acute leukaemia. *Methods.* R132 mutation screening was performed by PCR-sequencing in 66 AML cell-lines and 48 normal karyotype AMLs. Intracellular 2-HG concentration in primary AML cells was determined using a LC/MS-MS technique. *Results.* The R132 mutation was not detected in any of the 66 AML cell lines tested, but was present in 4/48 (8.5%) normal karyotype primary cases of AML. Three samples showed a R132H mutation with one sample containing an R132C alteration. Sufficient stored material was available from *IDH1* mutated (n=3) and wild-type (n= 25) primary AMLs to determine intracellular 2-HG. Markedly elevated 2-HG was found in all three of the mutated cases (531, 919 and 1765 ng/10^6 cells). In contrast, in 25 of 25 primary AMLs without the mutation intracellular 2-HG was <17.5 ng/10^6 cells. In $IDH1^{WT}$ AML cell lines, exposure to exogenous 2-HG at concentrations of 1-10 µg/mL resulted in intracellular concentrations of 380-670 ng/10^6 cells. Although the uptake of 2-HG was not linear, the resulting intracellular concentration was similar to that seen in $IDH1^{MUT}$ cells. *Conclusions.* Markedly elevated 2-HG levels are found in AML cells heterozygous for mutations in *IDH1* and likely lead to elevated 2-HG in cells of the neighbouring microenvironment. We are currently investigating the mechanisms by which elevated 2-HG may be linked to leukaemogenesis or outcome.

THE FOUR AND A HALF LIM DOMAIN PROTEIN 2 (FHL2) INTERACTS WITH CALM AND IS HIGHLY EXPRESSED IN ACUTE ERYTHROLEUKEMIA

Z Pasalic,[1] P Greif,[1] V Jurinovic,[2] M Mulaw,[1] P Kakadia,[1] S Bohlander[1]

[1]Helmholtz Center-CCG Leukemia, Munich, Germany; [2]Institute for Medical Informatics, Biometry and Epidemiology, Munich, Germany

Background. The CALM/AF10 fusion resulting from the translocation t(10;11)(p13;q14) is found in acute myeloid leukemia (AML), T-cell acute lymphoblastic leukemia (T-ALL) and malignant lymphoma. The CALM/AF10 fusion gene has been shown to cause biphenotypic leukemia in a murine bone marrow transplant model. The CALM (Clathrin Assembly Lymphoid Myeloid leukemia gene) protein is a clathrin assembly protein which plays a role in clathrin-mediated endocytosis and trans Golgi network trafficking. AF10 is a putative transcription factor likely involved in processes related to chromatin organization. *Aim/Method*. To learn more about the function of CALM/AF10 fusion protein, we searched for protein interaction partners of CALM using a yeast-two-hybrid screen. *Results.* The four and a half LIM domain protein FHL2 was identified as one of the putative CALM interacting partners. The CALM-FHL2 interaction was confirmed by GST pull-down and co-immunoprecipitation experiments. Additionally, in co-localization studies CALM and FHL2 could be shown to co-localize in the cytoplasm. Gene expression profiling (Affymetrix based) of chronic myeloid leukemia (CML) and AML samples showed high expression of FHL2 in CML and in AML samples with complex aberrant karyotypes compared to AML with normal karyotypes or balanced chromosomal translocations. The higher expression of FHL2 in CML and in AML with complex aberrant karyotypes did not reach statistical significance at the 0.05 level but suggested a trend, which was then examined in a larger patient cohort (n=308). This analysis showed a significantly higher FHL2 expression in patients with AML M6 (acute erythroid leukemia) and also in AML patients with complex aberrant karyotypes compared to AML patients with normal karyotypes. Erythroleukemia and AML with complex aberrant karyotypes have a poor prognosis. Interestingly, high FHL2 expression in breast- gastric-, colon-, lung- as well as in prostate cancer has also been shown to be associated with an adverse prognosis. *Conclusions.* The interaction of FHL2 and CALM/AF10 makes it tempting to speculate that this interaction is in part responsible for the poor prognosis of CALM/AF10 positive leukemias. FHL2 is highly expressed in poor prognosis leukemias like erythroleukemia and AML with complex aberrant karyotypes.

GENOME WIDE STUDY OF DNA METHYLATION IN AML

M Saied

Institute of Cancer, London, UK

DNA methylation is the most stable epigenetic modification and has a major role in cancer initiation and progression. The two main aims for this research were, firstly, to use the genome wide analysis of DNA methylation as a method for better understanding the development of acute myeloid leukemia (AML). The second aim was to detect differentially methylated genes between the subtypes of AML and normal bone marrow. We used the methylated DNA immunoprecipitation technique followed by high-throughput sequencing by Illumina Genome Analyser II (MeDIP-seq) for 9 AML patients for whom ethical approval has been obtained. The samples include 3 processing t(8;21), 3 t(15;17) translocations and 3 normal karyotype (NK) plus 3 Normal Bone Marrow (NBMs) from healthy donors. The number of reads generated from Illumina ranged between 18- 20 million paired-end reads/lane with a good base quality from both ends (base quality >30 represent 75%-85% of reads). The reads have been aligned using 2 algorithms (Maq and Bowtie) and the methylation analysis was performed by Batman software (Bayesian Tool for Methylation Analysis). The preliminary results of 4 cases of leukemia [2 of t(8;21), one case of t(15;17), one case of NK] and a NBM sample showed that the average promoter methylation in the 5 samples ranged between 0.3-0.5 (Batman score >0.6 equals methylation). The median of chromosomes' methylation in the NK leukemia was significantly less than the other 4 cases (P<0.05). An inverse correlation was observed between CpG

observed/expected ratio and promoter methylation in both leukemic patients and in NBM (Spearman r= -0.6201, P<0.0001). The investigation of the 35,072 promoter regions identified 740 genes, which showed a significantly higher methylation level in leukemic cases in comparison to NBM (P<0.0001). Among these genes previously identified as having distinctive methylation patterns in cancer e.g. DLK1, PITX2, MYOD1, AMN, MAEL, TERT and CYP1B1. The full results of genome wide analysis of the 12 samples will be presented.

NUCLEOPHOSMIN (NPM) IS UNIVERSALLY DEREGULATED IN ACUTE PROMYELOCYTIC LEUKEMIA

M Sukhai, M Thomas, Y Xuan, S Mahindra, T Zhang, P Reis, S Kamel-Reid

University Health Network, Toronto, Canada

Background. NPM is a multifunctional nucleolar phosphoprotein with roles in ribosome biogenesis, centrosome duplication, p53 response and DNA repair, and is commonly mutated in Acute myelogenous leukemia (AML). NPM is juxtaposed with retinoic acid receptor α (RARα)) in Acute Promyelocytic Leukemia (APL), raising the possibility that NPM functions are disrupted in this leukemia. *Aims.* We therefore sought to determine the extent of NPM deregulation in the U937-NPM-RARα+ cell line model, and to extend this analysis more generally to APL. Methods and *Results.* Immunofluorescent microscopy (IF) demonstrated abnormal distribution of NPM in patient-derived APL cells carrying NPM-RARα or PML-RARα, as well as cell lines expressing X-RARα: NPM was distributed into abnormally large aggregates within the nucleus and/or throughout the cytoplasm. NPM distribution reverted to normal after 48 hr of treatment with 1.0 μM all-trans retinoic acid (ATRA). NPM protein levels were also significantly increased in X-RARα+ cell lines. This is likely due to an alteration at the protein level, as NPM mRNA expression was unaffected by X-RARα, and no mutations were detected in the NPM locus. Indeed, we found that NPM protein half-life was increased in U937 cells expressing X-RARα. Taken together, these data suggested a potential disruption in nucleolar architecture in APL cells. Alterations in size and number of nucleolar organizing regions (NORs) in NB4 and U937-X-RARα cells were evident by light microscopy, when compared to U937 controls. Defects in nucleolar organization may lead to altered ribosome biogenesis, protein synthesis, as well as cell size and proliferation. Ribosomal RNA precursor expression was found to be increased significantly in U937-NPM-RARα cells, compared to controls. Relative cell volume, assessed by a flow cytometric assay, was moderately increased, by approximately 10% (mean of 5 independent replicates) in NPM-RARα$^+$ cells, while cell proliferation rates were significantly increased, and doubling time decreased, compared to U937 controls. Analysis of protein synthesis rates in U937-NPM-RARα$^+$ cells indicated that the incorporation of a fluorescent Methionine analogue was twice that in control U937 cells. Finally, in order to determine the applicability of our *in vitro* functional assays to APL patients, we analyzed pre-rRNA and 18S rRNA expression in bone marrow RNA extracted at diagnosis from 16 APL patients (10 BCR1/2 and 6 BCR3), in order to determine whether evidence of elevated nucleolar function were found in APL. When taken as a group, 10/16 APLs had elevated 18S rRNA levels (>1.5-fold compared to normal BM); 8/16 had similarly elevated pre-rRNA levels. Overall, pre-rRNA levels were elevated an average of 2-fold compared to normal controls, while 18S rRNA levels were elevated an average 1.8-fold (P<0.05 for both comparisons). *Summary/Conclusions.* We therefore present the first evidence that NPM may be universally deregulated in APL, leading to defective NPM function within the leukemic cell.

IDENTIFYING MECHANISMS OF MLL-FUSION ONCOGENICITY IN ACUTE MYELOID LEUKAEMIA

V Walf-Vorderwuelbecke,[1] J de Boer,[1] S Horton,[2] H Osaki,[1] K Pearce,[3] M Hubank,[1] O Williams[1]

[1]*UCL Institute of Child Health, London, UK;* [2]*Department of Hematology, UMCG, Groningen, Netherlands;* [3]*UCL Genomics, London, UK*

The MLL gene, located on 11q23, is involved in a large number of chromosomal translocations, including t(9;11)(p22;q23) and t(11;19)(p22;q23). These translocations encode the MLL-AF9 and MLL-ENL fusion transcription factors and are prevalent in infant acute leukaemia and treatment-related leukaemia. Leukaemias associated with these translocations have a particularly poor outcome. In order to identify novel mediators of MLL-fusion oncogenic activity, and gain a more complete understanding of the molecular pathways involved, we developed a system for conditional expression of the MLL-ENL fusion. Using a dual retroviral 'Tet-Off' system, we have previously immortalised primary mouse haematopoietic progenitor cells (HPC) and demonstrated that loss of MLL-ENL expression resulted in decreased HoxA gene expression, terminal myeloid differentiation *in vitro* and reversal of established leukaemia *in vivo*. These experiments have now been extended to generate conditionally immortalised MLL-AF9 myeloid cell lines. We aimed to define critical target genes involved in the immortalisation pathways of MLL-fusion oncogenes, by analysing both MLL-AF9 and MLL-ENL immortalised cells. Global gene expression analysis after treatment of immortalised cells with Doxycycline, confirmed the dependency of known transcriptional target genes, such as genes of the HoxA cluster, Meis1 and cMyb, on the presence of MLL-fusions. In addition our analysis revealed the differential expression of a number of genes known to be involved in cancer, for example Msi2. We have used shRNA knock-down of these target genes to analyse survival, proliferation and differentiation of the immortalised cells. This study will establish whether interfering with identified target genes may offer novel approaches to disrupt MLL-fusion activity and offer new targets for therapeutic strategies.

REGULATION OF THE LEUKEMIA ASSOCIATED ETO NUCLEAR REPRESSOR GENE IS DRIVED BY GATA-1 IN ERYTHROID/ MEGAKARYOTIC CELLS

A Ajore, S Dhanda, G Gullberg, O Olsson

Lund University, Lund, Sweden

Background. The Eight-Twenty-One (ETO), a nuclear co-repressor gene, is part of the AML1-ETO fusion protein produced by the chromosomal translocation t(8:21) in acute myeloid leukemia. ETO gene consists of 13 exons distributed over 87 kb of genomic DNA and belongs to the ETO homologue family. Expression of this gene has been reported in a variety of tissues as well as in erythroid cells. The normal function of ETO is essentially unknown and the gene regulatiom is also unknown. *Aims.* We tried to identify structural and functional promoter elements upstream of the coding sequence of the ETO gene in order to explore lineage-specific hematopoietic ETO expression to give clues to function. *Methods.* Transcription start site (TSS) was identified by RNA Ligase Mediated Rapid Amplification of c-DNA Ends (RLM-RACE). Reporter constructs of ETO proximal promoter upstream to the luciferase reporter gene in pGL3 Basic vector was made and activity was tested in hematopoietic cells. Chromatin immunoprecipitation (ChIP) and Electrophoretic mobility shift assays (EMSA) were performed to identify the promoter driving transcription factors. *Results.* A putative proximal ETO promoter was identified upstream of the transcription start site. Hematopoietic expression of an ETO promoter was specifically observed upon transfection in erythroid/megakaryocytic cells, which have appropriate endogeneous ETO gene activity. Results from electrophoretic mobility shift and antibody supershift assays showed GATA-1 of the nuclear extracts of erythroid/megakaryocytic cells to bind *in vitro* to probe including the GATA site within the conserved region of the ETO promoter. Furthermore, results from chromatin immunoprecipitation showed GATA-1 binding *in vivo* to elements within the conserved region of the ETO promoter. The results suggest that GATA-1 may have a role in activation of the ETO gene in cells

with erythroid/megakaryocytic potential. Leukemia associated AML1-ETO fusion gene strongly suppressed the ETO promoter in erythroid/megakaryocytic cells. *Conclusions.* We demonstrate that the GATA-1 transcription factor binds and transactivates the ETO proximal promoter in an erythroid/megakaryocytic-specific manner. Thus, trans-acting factors that are essential in erythroid/megakaryocytic differentiation govern ETO expression. We speculate that ETO is involved in repressing genes associated with self-renewal and proliferation. Suppression of the ETO gene by AML1-ETO could facilitate the AML1-ETO induced block of erythroid lineage commitment.

0055

THE IMPACT OF LENGTH AND INTEGRATION SITE OF THE INTERNAL TANDEM DUPLICATION OF FLT3 GENE ON THE CLINICAL OUTCOME OF PATIENTS WITH AML

J Markova, K Burcková, J Maaloufová, P Cetkovsky, J Schwarz

Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic

Background. FLT3/ITD is known to confer poor prognosis in AML patients owing to higher incidence of relapses, shorter disease free survival and overall survival (OS). However, there may be differences in outcome even within the *FLT3*/ITD$^+$ group of patients. *Aims.* We have analysed the impact of the length and integration site of ITDs on patients' clinical outcome. *Methods and patients*. The presence of *FLT3*/ITD was examined by RT-PCR. Positive patients were recognized according to abnormally longer PCR products in gel electrophoresis and confirmed by direct sequencing. We have studied 93 AML patients positively screened for *FLT3*/ITD. The median age at diagnosis was 51.5 (18.3-81.0) years; the initial median WBC count was 56.6×10^9/L ($0.7\text{-}488.0\times10^9$/L). 17/93 (18.3%) patients had APL. *Results.* The majority of *FLT3*/ITD$^+$ cases had a single duplication. Two ITDs were present in 11 (11.4%) cases and one patient carried three different ITDs. 5 patients lacked the wild-type allele. The size of ITDs varied between 12-120 bp. Borderline length of 39 bp was set up, and in patients with more than one ITD, the longest was used for further analyses. WBC counts at diagnosis were not influenced by the length of ITD. Among non-APL AML (AML) cases, patients with ITD ≤39 bp had lower complete remission (CR) rate (13/29; 44.8%) compared to those with longer ones (25/39; 64.1%; P=0.0567). In contrast, among APL patients, lower CR rate was observed in patients with longer ITDs (5/8; 62.5% vs. 7/8; 87.5%; P=0.1241). In AML, relapses insignificantly more frequently occurred in cases with longer ITD (13/26; 50.0%) than in those with shorter ones (5/13; 38.5%; P=0.2478). An opposite result was again found in APL patients, 3/7 cases with ITD ≤39 bp relapsed whereas no relapse among 5 patients with longer ITD was observed (P=0.0455). The length of ITD influenced OS neither in APL nor in AML subgroups. Among 81 patients with a single *FLT3*/ITD, 61 (75.3%) had their ITDs integrated in juxtamembrane (JM) domain (between codons 572-609) and 20 cases within the tyrosine kinase (TK) domain 1. These patients had significantly higher WBC counts at diagnosis (medians 107.7 vs. 54.3×10^9/L; P=0.0334). Patients carrying ITD in JM domain more easily reached CR (34/60; 56.7% vs. 8/20; 40.0%; P=0.0981). Relapses were observed in 6/9 (66.7%) patients with TK1 and in 12/34 (35.3%) cases with JM domain insertions (P=0.0449). The OS was longer in cases with ITDs integrated within JM domain (10.7 vs. 1.8 months; P=0.0774). *Conclusions.* We have confirmed inferior outcome of AML patients with ITDs integrated within the TK1 domain (codons 610-615). They more often relapsed and accordingly, had shorter OS than patients with ITDs in JM domain. The longer ITDs tended to correlate with higher CR rates and with more relapses, therefore the resulting OS was nearly identical in patients with longer and shorter ITDs. The opposite holds true for APL: less CRs and less relapses were seen in cases with longer ITDs. The position rather than the length of *FLT3*/ITD can prognostically stratify *FLT3*/ITD$^+$ AML.

0056

ABERRANT EXPRESSION OF THE CAUDAL-LIKE HOMEOBOX GENE CDX4 INDUCES ERYTHROID LEUKEMIA IN THE MURINE BONE MARROW TRANSPLANTATION MODEL

S Thoene,[1] V Rawat,[2] N Vegi,[2] L Quintanilla-Fend,[3] M Feuring-Buske,[2] C Buske[2]

[1]Insitute for Experimental Tumor Research, Ulm, Germany; [2]Institute for Experimental Tumor Research, Ulm, Germany; [3]Institute for Pathology, Tuebingen, Germany

Background. In normal hematopoiesis, balanced expression of developmental factors such as homeobox genes is important for fate decision. Aberrant expression of these factors has been shown to contribute to development of leukemia. The caudal-like Cdx members are important upstream regulators of Hox genes during embryogenesis and as such have the potential to act as potential oncogenes. *Aim.* In this study the effect of aberrant *Cdx4* expression on murine hematopoiesis was to be analyzed *in vitro* and *in vivo* using the murine BM transplantation model. *Methods.* To test the impact of aberrant Cdx4 expression on the level of murine progenitors, 5-FU enriched BM cells were retrovirally transduced with Cdx4 as well as empty vector control and analyzed by *in vitro* and *in vivo* assays. Expression of Cdx4 in different hematopoietic subpopulations was analyzed by qPCR and microarray experiments were performed to identify possible target genes. *Results.* Expression analyses showed high expression of Cdx4 in early murine hematopoietic progenitors followed by a highly significant downregulation towards the more differentiated hematopoietic stages (P=0.005). Among different lineage positive hematopoietic subpopulations, Cdx4 was lowest expressed in Ter119$^+$ erythroid precursors. *In vitro*, overexpression of *Cdx4* conferred proliferative potential to BM progenitors in liquid expansion assay. Expression of Cdx4 conferred serial replating capacity to murine BM progenitors compared to empty vector control (CFU total after 2nd replating: $2.6\times10^7\pm3.2\times10^6$ SEM/ 500 input cells in 1st CFC, n=8). Interestingly, immunophenotyping of the colonies revealed a significant 4.1-fold increase of erythroid Ter119$^+$ cells in 1° and 72.9-fold increase in 2° CFC (n=4, P=0.02 and 0.05, respectively). Even after 4th CFC colonies were positive for expression of Ter119. Lethally irradiated mice received 16±6% SEM Cdx4-GFP$^+$ BM cells together with GFP$^-$ helper cells. PB analysis after four week post transplantation revealed a GFP-positivity of 41.8±6% SEM (n=11) indicating a growth advantage of Cdx4-overexpressing BM cells. Furthermore, immunophenotypic analysis of GFP$^+$ cells showed multilineage engraftment indicating a role of Cdx4 in the expansion of short-term progenitors without perturbation of their hematopoietic differentiation program. In contrast to the data previously published by Bansal *et al*. in BALB/c mice where Cdx4 was shown to induce AML with myelomonocytic features, all our Cdx4-transplanted mice died with a median latency of 309 days which by Ter119 staining was histopathologically diagnosed as erythroid leukemia (n=10). Furthermore immunophenotyping revealed the majority of the leukemic cells to be positive for CD71 expression. Secondary mice died after a median of 74 days. At time of death, Cdx4-transplanted mice displayed splenomegaly with massive erythroid infiltration, a severely decreased lymphoid:myeloid ratio <1:5 and presence of erythroid blasts in PB, BM and spleen. Gene expression profiling of BM progenitor cells transduced with Cdx4 showed deregulation of genes involved in signal transduction processes as well as leukemogenic *Hox* genes compared to empty vector control. *Conclusions.* Overexpression of Cdx4 confers serial replating capacity to transduced murine BM progenitor cells and *in vivo* induces erythroid leukemia. This suggests Cdx4 to be a novel factor in the development of erythroid leukemia.

0057

THE CALM/AF10 INTERACTOR CATS IS A SUBSTRATE OF KIS, A POSITIVE REGULATOR OF CELL CYCLE PROGRESSION IN LEUKEMIA CELLS

L Fröhlich Archangelo,[1] P Pernambuco Filho,[1] F Traina,[1] V Manceau,[2] A Maucuer,[2] S Bohlander,[3] S Saad[1]

[1]Hematology and Hemotherapy Center, Campinas-SP, Brazil; [2]Institut du Fer à Moulin-INSERM, Paris, France; [3]CCG-Leukemia & HelmholtzZentrum, Munich, Germany

Background. CATS is a phosphoprotein initially identified in a Y2H screen as the CALM (PICALM) interacting protein expressed in thymus and spleen. The CATS interaction region of CALM is contained in the leukemogenic fusion protein CALM/AF10, which is found in acute myeloid leukemia (AML), acute lymphoblastic leukemia (ALL) and in malignant lymphoma. CATS sequesters CALM/AF10 in the nucleolus and interferes with the transactivation capacity of CALM/AF10 in a dose-dependent manner. However, the involvement of CATS in malignant transformation seems to go beyond its interaction with CALM/AF10. CATS is highly expressed in leukemia, lymphoma and tumor cell lines but not in non-proliferating T-cells or PBLs. The protein levels of CATS are cell cycle-dependent, induced by mitogens (e.g. PHA) and correlate with the proliferative state of the cell. Thus CATS can be viewed as a marker for proliferation. Aim. To further study CATS function, we searched for CATS interacting proteins. In addition, we analyzed KIS protein expression in primary cells from MDS and leukemia patients. *Methods and Patients.* CATS was used as a bait

in a yeast two-hybrid screen. Protein interaction identified was confirmed by coimmunoprecipitation of overexpressed proteins. *in vitro* kinase assay was performed to investigate whether CATS is a substrate of KIS and to map the residue within CATS, which is phosphorylated. KIS expression was analyzed on bone marrow mononuclear cells (MNCs) of MDS, AML and ALL patients by Western blotting. We studied 05 healthy donors, 11 MDS patients (07 low-risk [RA/RARS] and 04 high-risk [RAEB/RAEBt] according to FAB classification), 07 AML and 1 ALL. *Results.* We identified the kinase interacting with stathmin (KIS or UHMK1) as a CATS interacting partner. KIS is a nuclear serine/threonine kinase that possesses an RNA recognition motif and phosphorylates and regulates the activity of RNA associated factors. Moreover KIS positively regulates cell cycle progression through phosphorylation of p27KIP in leukemic cell lines. We confirmed the CATS-KIS interaction in the yeast system and by co-IP for both CATS isoforms. Using kinase assay we could show that CATS is a substrate for KIS being strongly phosphorylated on its serine 131, which lies within the SGSP consensus sequence for KIS phosphorylation. Finally, Western blotting analysis revealed elevated levels of KIS in MDS, AML and ALL compared to the control samples. *Summary/Conclusions.* Our results show that CATS not only interacts with but is also a substrate for KIS, suggesting that CATS function might be modulated through phosphorylation events. The identification of the CATS-KIS interaction further supports the hypothesis that CATS plays an important role in the control of cell proliferation. Moreover the elevated levels of KIS in hematological malignances suggest that KIS could regulate CATS activity and/or function in highly proliferating leukemic cells. Thus our results indicate that CATS function might be important to understand the malignant transformation mediated by CALM/AF10.

I-B KINASE OVERCOMES PI3K/AKT AND ERK/MAPK TO CONTROL FOXO3A ACTIVITY IN ACUTE MYELOID LEUKEMIA

N Chapuis,[1] S Park,[1] L Leotoing,[1] J Tamburini,[1] F Verdier,[1] V Bardet,[1] A Green,[1] L Willems,[1] F Agou,[2] N Ifrah,[3] F Dreyfus,[4] G Bismuth,[1] V Baud,[1] P Mayeux,[1] C Lacombe,[1] D Bouscary[1]

[1]Institut Cochin, Paris, France; [2]Institut Pasteur, Paris, France; [3]CHU Angers, Angers, France; [4]Hopital Cochin APHP, Paris, France

Background. The human FOXO transcription factors, which include FOXO1, FOXO3a, FOXO4 and FOXO6, function as tumour suppressors by upregulating genes involved in cell cycle control (p27Kip1 and p21Cip1) or apoptosis (Fas-L and Bim). Loss of FOXO function due to genetic defects or posttranslational modifications are commonly observed in cancers. In acute myeloid leukemia (AML), chromosomal breakpoints involving FOXO3a and FOXO4 result in the suppression of FOXO transcriptional activity. Furthermore, deregulation of oncogenic kinases such Akt, ERK1/2 and IKK is frequently observed in AML. Interestingly, these kinases have been proposed to negatively regulate FOXO3a activity in most models by promoting its translocation from the nucleus to the cytoplasm and its proteasomal degradation via phosphorylation on different residues. *Aims.* We speculated that loss of FOXO3a tumour suppressor function may be a common feature of AML. We therefore analysed FOXO3a regulation by the PI3K/Akt, ERK/MAPK and IKK signaling pathways in both primary AML samples and a MV4-11/FOXO3a-GFP cell line. *Methods.* Bone marrow samples were obtained from 38 newly diagnosed AML patients included in trials initiated by the French GOELAMS group. PI3K/Akt ERK/MAPK and IKK signaling pathways were inhibited respectively using IC87114, UO126 and a specific IKKγ/NEMO-antagonistic peptide (referred as anti-Nemo). FOXO3a localization was tested using immunofluorescence. Primary AML cells and MV4-11 cells were infected with a lentivirus expressing either a FOXO3A-GFP or a FOXO3aS644A-GFP fusion protein. Expression of p21Cip1 and Fas-L mRNA was assessed on purified GFP^+ blast cells using qRT-PCR. Blast cell proliferation and apoptosis were quantified by [3H]-thymidine incorporation and annexin-V staining respectively. *Results.* We focused our study on FOXO3a as we found, using qRT-PCR and Western Blot analysis, that it was the only FOXO protein constantly expressed in primary AML cells. We observed in all AML samples tested that FOXO3a is inactivated due to its cytoplasmic localization. This inactivation of FOXO3a is not due to deregulation of the PI3K/Akt or ERK/MAPK signaling pathways as neither PI3K/Akt nor ERK1/2 specific inhibition results in FOXO3a nuclear translocation. In contrast, specific inhibition of IKK with the anti-Nemo peptide induces FOXO3a nuclear localization thereby suggesting that the deregulated activity of IKK in leukemic cells could be responsible for the inactivation of FOXO3a via its phosphorylation on S644. To confirm this result, leukemic cells from one patient and MV4-11 cells were infected with a lentivirus expressing a FOXO3aS644A-GFP mutant protein in which the IKK phosphorylation is abrogated. We found that the FOXO3aS644A-GFP protein is localized primarily within the nucleus in both AML cells and MV4-11 cells infected whereas FOXO3a-GFP protein is retained in the cytoplasm. This nuclear localization of FOXO3aS644A-GFP protein in MV4-11 cells correlates with an increased mRNA level of the FOXO3a target genes p21Cip1 (2.3-fold) and Fas-L (2.4-fold). Accordingly, FOXO3aS644A-GFP protein expression markedly decreased cell proliferation (reduction of 67%) and induced a slight but significant apoptotic response (2.5-fold increase; P=0.011). *Conclusion.*. Our results show that IKK controls FOXO3a activity and emphasize the control of FOXO3a activity as a new mechanism implicated in the pro-leukemic effects of IKK deregulation in AML.

OVEREXPRESSION OF EVI-1 AND MN1 MAY PREDICT WORSE OUTCOME IN *DE NOVO* AML WITH MLL TRANSLOCATIONS

DC Liang,[1] LY Shih,[2] TL Lin,[2] CF Huang,[2] CH Chang,[2] MC Kuo,[2] CL Lai,[2] TH Lin[2]

[1]Mackay Memorial Hospital, Taipei, Taiwan; [2]Chang Gung Memorial Hospital and Chang Gung University, Taipei, Taiwan

Background and purpose Our previous study showed that overexpression of BAALC and MN1 predicted worse outcome in *de novo* AML with partial tandem duplication of MLL (Blood 114: 415a, 2009). The prognostic relevance of overexpression of FLT3, BAALC, EVI-1, MN1, FHIT and ERG genes in AML patients with MLL translocation (MLL-T) was not clear. We aimed (1) to measure the mRNA expression levels of these genes in AML patients with MLL-T, (2) to compare the expression levels of these genes with normal controls, and (3) to determine their prognostic significance. *Patients and Methods.* Bone marrow samples from 60 *de novo* AML patients with MLL-T at diagnosis were analyzed. The MLL fusion partners included AF4 (n=2), AF6 (n=10), AF9 (n=19), AF10 (n=8), ELL (n=10), ENL (n=3), and other rare subtypes (n=8). Real-time quantitative PCR assay with TaqMan probe was performed to measure the expression of genes in patients and controls. The expression levels of target genes were calculated as the copy number of each gene normalized to the copy number of ABL control gene and were dichotomized at the median value to low and high expression groups. The event-free survival (EFS) and overall survival (OS) were compared between the two groups. *Results.* MLL-T patients had significantly higher expression levels of FLT3 (P<0.0001), EVI-1 (P<0.0001) and a borderline higher level of MN1 as compared to controls (P=0.053) (Table 1). The EFS of the 48 patients who received standard induction chemotherapy was 33.0±8.7 mos (95% CI: 15.9 - 50.1 mos) and OS was 36.2±7.9 mos (95% CI: 20.7 - 51.7 mos). The CR rates were significantly different between low and high expression groups for EVI-1 (P=0.019), a borderline significance for FHIT (P=0.072) and MN1 (P=0.059), but no significant differences for FLT3, BAALC, or ERG. There were a borderline difference in EFS between high and low expression of EVI-1 (P=0.087) and MN1 (P=0.068). Patients with low expression of EVI-1 had a borderline longer OS than those with high expression levels (p = 0.066). No significant difference in OS was observed for MN1 expression. The EFS and OS were not significantly different between low and high expression groups for FLT3, BAALC, FHIT, and ERG. *Conclusions.* Our results showed that in MLL-T, there were overexpression of FLT3, and EVI-1, and a borderline overexpression of MN1. The patients with lower expression levels of EVI-1 and MN1 had a higher CR rate and favorable survival.

FISH TO INVESTIGATE TET2 INVOLVEMENT IN THERAPY-RELATED MYELODYSPLASTIC SYNDROMES (T-MDS) AND ACUTE MYELOID LEUKEMIA (T-AML)

P Bernasconi,[1] I Dambruoso,[2] M. Boni,[2] C Astori,[2] P Zappasodi,[2] PM Cavigliano,[2] I Giardini,[2] B Rocca,[2] R Zappatore,[2] C Calvello,[2] M Caresana,[2] E Brusamolino,[2] C Castagnola,[2] M Lazzarino[2]

[1]Fondazione IRRCS Policlinico San Matteo, Pavia, Italy; [2]Divisione di Ematologia Fondazione IRCCS Policlinico San Matteo, Italy

Recently, deletions/mutations of the TET2 gene, a tumour suppressor gene mapped at band 4q24, have been revealed as an early event in the pathogenesis of many disparate myeloid disorders. TET2 mutations are discovered in 24% of t-MDS/t-AML patients whereas deletions in only 5% of patients. Based on these findings, the present study was aimed at establishing the incidence of band 4q24 deletions/structural defects in a series of 93 t-MDS/t-AML examined between January 1993 and January 2009 and to test whether TET2 deletions were correlated with any peculiar gene mutation and clinical findings. Our patients were forty-seven females and forty-six males, whose median age was 59 years (range 25-78). Nine patients had received radiotherapy (RT) only, fifty-one chemotherapy only and thirty-three both treatment modalities. Overall, alkylating agents (AA) were given to sixty-three patients, topoisomerase inhibitors (TI) to twenty-five and antracyclines (A) to five patients. Patients treated with AA developed t-MDS after a median time of 66 months (range 55-78) and t-MDS had a median duration of 11 months (range 4-17). In contrast, patients treated with TI and A developed t-AML without a preceding t-MDS after a median time of 18 months (range 12-26). At our observation, eighty-five patients presented with t-AML and eight patients with t-MDS. On clinical diagnosis, 81 patients (84.9%) presented clonal cytogenetic abnormalities involving chromosome 5 only (22.3%), chromosome 7 only (30.1%), both chromosomes (25.8%) and recurring balanced rearrangements (16.1%). A structural defect of chromosome 4 was revealed by conventional cytogenetics (CC) in three patients. A der(4)t(1;4)(p22;q23) and a t(3;4)(q21;q24) were revealed in one patient each, a 4q deletion in two. Up to now FISH with the 144B4 (mapped at 14q22.3), 810D13, 571L19, 414I7 (all mapped at 4q23), 356L5 and 16G16 (both covering the TET2 gene at band 4q24), 642P17, 788K3, 752J12 (all mapped at 4q24) and 66J16 (mapped at 4q25) probes was carried out in 24 patients. All these probes were obtained from BACPAC Resources Center at C.H.O.R.I. (Oakland, USA), labelled and applied as previously reported. The cut-off values for interphase FISH (i-FISH) were obtained from the analysis of 300 nuclei from ten normal samples and were fixed at 10%. The patient with the unbalanced t(1;4) translocation showed that 88% of interphase and mitotic cells had lost the 356L5, 16G16, 788K3 and 642P17 probes and had maintained the 752J12 and 66J6 probes. So, this patient presented a loss of the TET2 gene and of the 788K3 and 642P17 probes even if the breakpoint of the chromosomal translocation was localized at band 4q25. The other three patients presented a cryptic deletion of the 356L5, 16G16 and 788K3 probes. In conclusion, i) FISH is a good method for identifying cryptic TET2 deletions, as the chromosomal area containing this gene is often deleted independently of the chromosomal breakpoints; ii) TET2 deletions are rare events occurring at an incidence of 5.1%. The 16% frequency of our study is probably due to bias in sample collection; iii) TET2 deletion is not always associated with chromosome 4 rearrangements on conventional cytogenetics.

Acute myeloid leukemia - Clinical 1

PROGNOSTIC VALUE OF THE ALLELIC BURDEN OF FLT3 INTERNAL TANDEM DUPLICATION IN PATIENTS WITH INTERMEDIATE-RISK CYTOGENETICS ACUTE MYELOID LEUKEMIA DEPENDS ON UNDERLYING MUTATIONAL STATUS OF NPM

M Pratcorona,[1] S Brunet,[2] J Nomdedéu,[2] M Torrebadell,[3] JM Ribera,[4] M Tormo,[5] R Duarte,[6] L Escoda,[7] R Guàrdia,[8] MP Queipo de Llano,[9] O Salamero,[10] C Pedro,[11] JM Martí,[12] M Díaz-Beyá,[1] J Sierra,[2] J Esteve[3]

[1]IDIBAPS, Hospital Clinic, Barcelona, Spain; [2]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [3]Hospital Clínic, Barcelona, Spain; [4]Hospital Germans Trias i Pujol, Badalona, Spain; [5]Hospital Clínico, Valencia, Spain; [6]Hospital Duran i Reynals, Hospitalet de Llobregat, Spain; [7]Hospital Joan XXIII, Tarragona, Spain; [8]Hospital Josep Trueta, Girona, Spain; [9]Hospital Virgen de la Victoria, Malaga, Spain; [10]Hospital Vall d'Hebron, Barcelona, Spain; [11]Hospital del Mar, Barcelona, Spain; [12]Hospital Mútua Terrassa, Terrassa, Spain

FLT3 internal tandem duplication (FLT3-ITD) confers an adverse prognosis to patients with intermediate-risk AML (IR-AML), with a high risk of relapse. Nonetheless, FLT3-ITD allelic burden has been reported to modulate the unfavourable prognosis of this mutation, and this effect might be influenced by NPM mutational status. In this context, we aimed to analyze the prognostic impact of the ratio FLT3-ITD/FLT3 wild type (FLT3wt) in IR-AML patients according to NPM status. We analyzed 409 patients (age: 51, 17-73) diagnosed with *de novo* IR-AML included in three consecutive CETLAM trials (LAM-94, LAM-99, and LAM-03), with available molecular information. NPM mutation (NPMmut), FLT3-ITD, CEBPA mutations (CEBPAmut), and MLL partial tandem duplication (MLL-PTD) were determined as previously described. The FLT3-ITD/FLT3wt ratio (FLT3 ratio) was defined as the ratio of the area under the curve of the mutated and wild-type peaks obtained by Genescan. NPMmut was detected in 205 patients (50%), 93 of them with concomitant FLT3-ITD (23%), 45 patients (11%) harbored a wild-type NPM (NPMwt) with FLT3-ITD, 25 patients had CEBPAmut, and MLL-PTD was identified in 11. In the overall series, complete response rate (CR), survival (OS), and relapse incidence (RI) were 82.6% (95% CI: 0.79-0.86), 40±4% (5-yr), and 48±5% (5-yr), respectively. Independent prognostic variables were age (P=0.006), WBC at diagnosis (<0.001), and NPM status (P=0.002) for CR achievement, and WBC at diagnosis (P<0.001, relative risk, RR=1.004, 1.002-1.007) and molecular category (NPMmut/FLT3wt vs. other; P<0.001, RR=2.79, 1.9-4.05) for relapse.

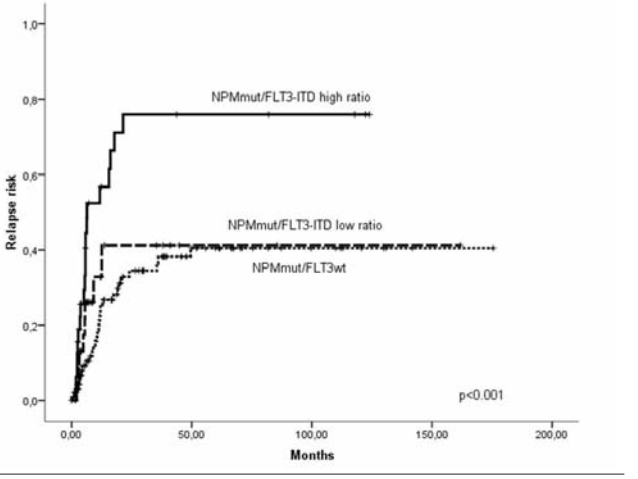

Figure.

Moreover, among patients with FLT3-ITD, FLT3 ratio showed independent prognostic value (P=0.037). The effect of FLT3 ratio on RI was further analyzed according to NPM status. For this purpose, FLT3 ratio was categorized in two groups (below or above the median value, 0.613). In patients with NPMmut, RI did not differ between patients with a low FLT3 ratio and those patients lacking FLT3-ITD (Figure). In accordance, two molecular categories were defined: a group of patients

with low-risk features (LOWRISK: NPMmut without FLT3-ITD or low FLT3 ratio, or CEBPAmut), and another group of high-risk molecular lesions (HIGHRISK: NPMwt regardless FLT3-ITD, high FLT3 ratio, or MLL-PTD). Thus, LOWRISK patients showed a better outcome compared to HIGHRISK patients, with an inferior RI (5-yr RI: 40±5% vs. 72±4%, P<0.001) and longer OS (5-yr: 58±4% vs. 31±4%, P<0.001). Finally, the effect of post-remission strategy in CR1 was analyzed according to this categorization. Thus, in LOWRISK patients, a similar outcome was observed after autologous stem-cell transplantation (HSCT) and allogeneic HSCT. On the contrary, in the HIGHRISK subgroup, alloHSCT in CR1 was followed by a significantly decreased RI (31±8% vs. 64±6%, P=0.001) and a trend to a longer survival (5-yr OS: 57±8% vs. 34±6%, P=0.07). In conclusion, FLT3-ITD allelic burden influences the outcome of patients with IR-AML, and this effect seems to interact with NPM mutational status. Thus, RI of patients with NPMmut IR-AML and low FLT3 ratio was similar to that of NPMmut IR-AML patients lacking FLT3-ITD. Therefore, estimation of FLT3 ratio might refine the prognosis determined by molecular markers, although its prognostic impact should be confirmed in a prospective fashion.

DYNAMIC SINGLE CELL NETWORK PROFILES (SCNP) IN AML ARE ASSOCIATED WITH PATIENT RESPONSE TO STANDARD INDUCTION THERAPY

A Cesano,[1] M Minden,[2] D Rosen,[1] S Putta,[1] A Cohen,[1] W Fantl,[1] U Gayko,[1] S Kornblau[3]

[1]Nodality, South San Francisco, USA; [2]Princess Margaret Hospital, Toronto, Canada; [3]MD Anderson Cancer Center, Houston, USA

Background. Complete response (CR) to induction chemotherapy is observed in approximately 60% of patients with FAB non-M3 Acute Myeloid Leukemia (AML) at diagnosis. However, no methods exist to predict with high sensitivity/specificity the disease response to standard AML induction chemotherapy at the level of individual patients. *Aims.* We performed a comprehensive functional assessment of intracellular signaling pathways to predict the likelihood of response to standard induction therapy in two sequential training cohorts of AML samples (N=34 and 88) *Methods.* Single Cell Network Profiling (SCNP) is an approach for analyzing and interpreting post-translational protein modifications (e.g. phosphorylation, acetylation etc.) at the single cell level. This technology allows simultaneous characterization of the range of critical cellular processes within AML, such as growth (cell cycle), viability (apoptosis), DNA damage, presence and function of drug transporters, and in-vitro effects of therapies on signaling networks. Using viable cells, measurements are made on endogenous proteins before and after exposure to extracellular modulators such as growth factors, cytokines or drugs. The modulators are meant to mimic the stimuli that the cell encounters in the body and are chosen to evoke a response from the cell that echoes how the signaling system is normally, or abnormally, patterned. The proteomic readout in the presence or absence of a specific modulator is termed "signaling node". Signaling nodes are evaluated within cells from samples that have associated relevant clinical information regarding response to the therapy of interest. Multivariate analysis can then be performed to create predictive models that can be validated in subsequent independent studies. *Results.* In the first study, univariate analysis identified multiple "signaling nodes"that correlated with response to induction chemotherapy (i.e. AUCROC ≥0.66; P≤0.05) at a level greater than age, a known factor associated with response to induction therapy. After accounting for age, similar findings were observed in the second study. For patients < 60 years old, CR was associated with the presence of intact apoptotic pathways. In patients ≥60 years old, non-response (NR) was associated with FLT3 ligand mediated increase in phospho (p)-Akt and p-Erk. Results were independent of cytogenetics, secondary AML, or FLT3 mutational status. Finally, we observed the value of multivariate models using independent nodes since they can provide improved sensitivity/specificity over single nodes performance. *Summary/Conclusions.* The data emphasize the value of quantitatively measuring single cell networks (SCN) under modulated conditions as a basis for the development of highly predictive tests for response to induction chemotherapy. These SCN profiles are predictive of disease outcome and distinct from other known prognostic factors such as age, secondary AML, and cytogenetics and importantly should be validated in future, independent studies.

0062

PHASE 1 STUDY OF SORAFENIB IN PATIENTS WITH REFRACTORY ACUTE LEUKEMIAS AND MYELODYSPLASTIC SYNDROMES

A Al-Kali, G Borthakur, H Kantarjian, F Ravandi, W Zhang, M Konopleva, J Wright, S Faderl, S Verstovsek, S Mathews, M Andreef, J Cortes

UT MD Anderson Cancer Center, Houston, USA

Background. Activation of Ras/Raf/MEK/Erk (MAPK) signaling cascade is ubiquitous in cancer and represents attractive targets for cancer therapy. Inhibition of MAPK pathway has been shown to impair cell growth and survival of acute myeloid leukemia (AML) cell lines and primary samples with constitutive MAPK activation. Sorafenib is a Raf kinase inhibitor with additional inhibitory activity against fms-like tyrosine kinase 3 (FLT3) with internal tandem duplication (ITD) mutation. *Aim.* Define the maximal tolerated dose (MTD) for sorafenib in patients (pts) with relapsed/ or refractory acute leukemias and advanced myelodysplastic syndrome (MDS). *Methods.* Pts received one of two different schedules: Schedule "A": Once or twice daily, 5 days per week, every week; and Schedule "B": Once or twice daily, for 14 days every 21 days. Evaluation of response was done according to the modified International Working Group (IWG) criteria. Dose escalations were carried out in standard "3+3"design with a starting dose of 200 mg twice daily. Correlative studies using whole-blood samples were collected day 1, day 4 and day 14 during administration of the first course of sorafenib. Pts signed an informed consent. *Results.* From 2006 to 2009, 50 pts were enrolled (including 48 pts with AML) at UTMDACC in a phase I study: 31 to schedule A and 19 to schedule B. Median age was 61 years (range, 21 to 88 years) with a median 3 prior therapies. Forty pts had positive FLT3 ITD/ and or TKD mutation. Dose limiting toxicities were grade 3/4 hypertension, hyperbilirubinemia, and amylase elevation. The recommended phase 2 dose in hematologic malignancies is 400 mg twice daily for both schedules. Complete remissions (CR) or CR with incomplete recovery of platelets (CRp) were achieved in 5 pts. Significant reduction in bone marrow and/or peripheral blood blasts was seen in an additional 17 pts. Eleven of these responses (including 3 CR/CRp) lasted for 2 cycles or beyond. Two thirds of patients with AML and FLT3 ITD responded. Apoptosis induction and changes in mitochondrial membrane potential were significantly increased in peripheral blood mononuclear cells in patients with FLT3 ITD mutation on days +1 and +4 compared to baseline. *Conclusions.* Sorafenib is an active and well tolerated agent in AML with FLT3 ITD mutation. Sorafenib-based combinations are warranted in pts with AML, particularly in those with FLT3 ITD.

0063

IN ACUTE MYELOID LEUKEMIA, THE USE IN INDUCTION OF STANDARD DOSE CYTARABINE IS ASSOCIATED WITH A BETTER QUALITY OF RESPONSE AS COMPARED TO AN INDUCTION REGIMEN CONTAINING HIGH DOSE CYTARABINE

L Maurillo, F Buccisano, A Spagnoli, MI Del Principe, B Neri, MG Cefalo, G De Angelis, A Picardi, C Ditto, E Ammatuna, G Del Poeta, W Arcese, F Lo Coco, S Amadori, A Venditti

Fondazione Policlinico Tor Vergata, Rome, Italy

Background. The clinical advantage of high-dose cytarabine (HDAC) in induction chemotherapy for acute myeloid leukemia (AML) is still controversial. *Aims.* The purpose of our study was to explore the impact on the "quality of response"of an induction regimen containing standard dose cytarabine (SDAC) versus HDAC by measuring minimal residual disease (MRD) once CR was achieved. *Methods.* MRD was determined by multiparametric flow cytometry on bone marrow samples collected at the end of induction and consolidation therapy. The threshold for MRD negativity was set below a number of 3.5×10^{-4} residual leukemic cells. We evaluated 123 patients with *de novo* AML, enrolled sequentially in DCE arm of AML10 (n=40) and in AML12 (n=83) EORTC/GIMEMA randomized trials between 1995 and 2007. In DCE arm of AML10, induction treatment combined AC (100 mg/m^2, day 1-10), etoposide (50 mg/m^2, day 1-5), and on days 1,3,5, daunorubicin (50 mg/m^2). In AML12 trial, patients received the same treatment of DCE arm except for AC dose that was 100 mg/m^2, day 1-10 or 3000 mg/m^2/q12 hrs on days 1, 3, 5, and 7 according to randomization. As consolidation, all patients received AC (500 mg/m^2/q12 hrs day 1-6) and daunorubicin (50 mg/m^2, day 4-6). Median age was 45 yrs (range 18-60), 73 males and 50 females. Seventy-five patients were treated with SDAC regimen and 48 with HDAC regimen. The two groups

were well balanced in terms of FAB distribution, WBC count, cytogenetics, FLT3 and NPM1 mutation and post-remissional transplantation therapy (autologous or allogeneic). *Results.* After induction, we observed a significantly (P=0.01) higher frequency of MRD negativity in SDAC arm vs HDAC arm (78.4% vs 21.6%, respectively). After consolidation, this figure was confirmed (78.6% vs 21.4%, P=0.005). At this stage, 4 further patients treated in the SDAC arm, became MRD negative, whereas only one of the HDAC arm did so. Overall, median level of MRD was significantly lower in SDAC group both after induction (1.1×10^{-2} vs 4.1×10^{-2}, P=0.02) and consolidation (5.3x10-3 vs 3x10-2, P=0.007). Based on the combination of MRD status after consolidation and AC schedule delivered, we identified 4 different groups of patients. Five years OS for SDAC-MRDneg, HDAC-MRDneg, HDAC-MRDpos and SDAC-MRDpos was 66%, 45%, 29% and 24%, respectively (P=0.008). Similarly, 5 years RFS for SDAC-MRDneg, HDAC-MRDneg, HDAC-MRDpos and SDAC-MRDpos was 66%, 45%, 34% and 18%, respectively (P=0.0002). Since 16 patients, 7 in the SDAC and 9 in the HDAC group, died because of toxic complications, cumulative incidence of relapse (CIR) was also evaluated. Five years CIR for SDAC-MRDneg, HDAC-MRDneg, HDAC-MRDpos and SDAC-MRDpos was 21% (95% CI, 19-21), 15% (95% CI, 12-24), 51% (95% CI, 55-60), and 75% (95% CI, 74-76), respectively (P<0.0001). *Conclusions.* Delivery of an induction regimen containing daunorubicin, etoposide and SDAC given for 10 days, results in a more efficient clearance of leukemic burden compared to a similar regimen HDAC based. Such superior efficiency translates into a better "quality"of response, as demonstrated by the more frequent achievement of a MRD negative status, and then into a more favorable outcome.

0064

PRIMING WITH ARSENIC TRIOXIDE IMPROVES THE OUTCOME OF NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA PATIENTS <60 YEARS OLD TREATED WITH HIGH-DOSE CYTARABINE AND IDARUBICIN

M Wetzler,[1] C Andrews,[1] LA Ford,[1] S Tighe,[1] M Barcos,[1] S Sait,[1] AM Block,[1] M Baer,[2] J Thompson,[1] E Wang,[1] H Baumann[1]

[1]Roswell Park Cancer Institute, Buffalo, USA; [2]University of Maryland Greenebaum Cancer Center, Baltimore, USA

Background. Constitutive signal transducer and activator of transcription (STAT) 3 activity was shown to be present in leukemia cells from approximately 50% of acute myeloid leukemia (AML) patients (pts) and to correlate with adverse treatment outcome. We have shown that arsenic trioxide (ATO) down-regulates STAT3 activity in AML cells within six hours with a reduction of cell survival manifested after 48 hours *in vitro*. We therefore hypothesized that *in vivo* exposure of AML cells to ATO prior to induction chemotherapy might sensitize the blasts to the chemotherapy agents. *Aim.* To conduct a phase I clinical trial to evaluate the biologically effective and/or the maximally tolerated dose of ATO administered prior to induction chemotherapy with high-dose cytarabine (Hidac) and idarubicin (Ida) for previously untreated AML in pts <60 years old. *Methods.* We compared retrospectively the outcome of the 61 <60 year old AML pts enrolled on our phase I clinical trial with ATO followed by Hidac/Ida to that of 118<60 year-old previously untreated AML pts undergoing induction therapy at Roswell Park Cancer Institute with Hidac/Ida without ATO. All pts signed informed consent. *Results.* There was no significant difference in the median age (47.0 vs. 45.5; Wilcoxon P=0.7) or presenting white blood cell count (9.0 vs. 17.8; Wilcoxon P=0.8) between pts treated with Hidac/Ida and those treated with ATO/Hidac/Ida. Similarly, the two cohorts had similar representation of pts with *de novo* AML (79% vs. 87%; Fisher P=0.2). Finally, the two cohorts had similar karyotype subgroup representation [favorable/intermediate/unfavorable 14%/48%/39% vs. 14%/51%/ 35%; Fisher P=0.9]. The complete remission (CR) rate was similar between the two cohorts (72% vs. 66%; Fisher P=0.40). A total of 41% of the Hidac/Ida pts proceeded to an allogeneic transplantation in first CR compared to 49% of the ATO/Hidac/Ida pts (Fisher P=0.3). The median follow-up for pts treated with Hidac/Ida was 17.4 months compared to 19.4 months for the pts treated with ATO/Hidac/ida (Wilcoxon P=0.7). Interestingly, the overall survival of pts treated with ATO/Hidac/Ida was significantly better compared to those treated with Hidac/Ida (median survival 39.9 vs. 17.6 months.; logrank P=0.039). *Summary.* Priming with ATO improved the outcome of <60 year old AML pts treated with Hidac/Ida compared to historical controls. These data, if reproduced in a randomized phase III clinical trial, suggest that priming the leukemia-initiating cells with ATO may be a means to enhance the effect of chemotherapy.

0065

TWO-STEP RESPONSE-ORIENTED INDUCTION PREDICTS LONG-TERM OUTCOME OF ADULT PATIENTS WITH STANDARD- AND HIGH-RISK ACUTE MYELOID LEUKAEMIA (AML): A NORTHERN ITALY LEUKAEMIA GROUP (NILG) STUDY

Raffaele, Milano, Italy; [10]Hematology Hosp.Circolo Fondazione Macchi, Varese, Italy; [11]Hematology Istituto Nazionale Tumori, Milano, Italy; [12]Hematology Hospital S. Gerardo, Monza, Italy; [13]Cytogenetic Unit OO.RR, Bergamo, Italy

Background. In AML it is unclear whether long-term survival of different risk groups is affected by complete remission (CR) being achieved after the first or second chemotherapy course, the approach to patients who fail a first conventional cycle is not standardized, and relatively few of these cases enter CR repeating the same induction programme. *Aims.* A two-step response-oriented induction was designed to optimize CR results, adopting a sequential high-dose schedule for patients refractory to standard chemotherapy cycle 1. This report describes the relationship between achievement of CR after cycle 1 or 2 and the probability of survival at 5 years in different risk groups. *Methods*. CR induction therapy consisted of (1) standard ICE therapy followed, in refractory cases, by (2) sequential HAI (ICE: idarubicin 12 mg/m^2/d dd 1-3, etoposide 100 mg/m^2/d dd 1-5, cytarabine 100 mg/m^2/bd dd 1-7, G-CSF from d 8; s-HAI: idarubicin 17.5 mg/m^2/d dd 1 and 8, cytarabine 3 g/m^2/bd dd 2, 3, 9, and 10, G-CSF from d 11). Patients were stratified as standard- or high-risk (SR, HR) according to cytogenetics (i.e. favourable, unfavourable) and additional risk factors in case of intermediate/normal/unknown cytogenetics (HR with any: WBC count >50×10^9/L, FAB class M0/6/7, hepato/splenomegaly, MDS-related/secondary AML, FLT3/ITD mutation; SR with none).

Survival probabilities at 5 years according to risk class (SR, HR) and CR achieved after cycle 1 or 2 (C1, C2) NR denotes refractory AML; all patients (A); patients with de novo AML aged <60 years (B)

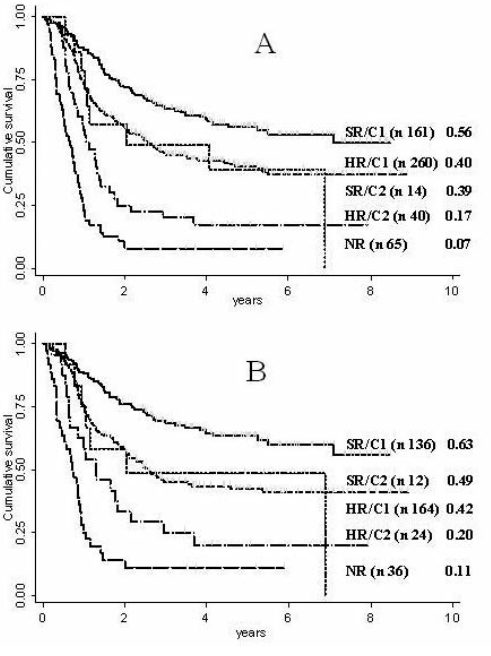

Figure 1.

Results. The prospective NILG-AML 01/00 study enrolled 581

patients, with median age 52 years (range 19-68). Cytogenetic risk groups were favourable 8.5% (n=50), intermediate/normal 59% (n=342; [SR=123; HR=219]), unfavourable 20.5% (n=120), unknown 12% (n=69 [SR=24; HR=45]). SR (n=197) and HR (n=384) groups differed significantly (P<0.05) with regard to WBC count (median 9.2 vs. 15.3), adverse FAB classification (0% vs. 15.5%), MDS/secondary AML (1% vs. 22%), hepato/ splenomegaly (5.5% vs. 28%), and FLT3/ITD$^+$ status (2% vs. 33%). After ICE cycle 1, CR was 82% in SR and 68% in HR (P=0.002) and 129 patients had resistant AML (22%); 95 ICE-refractory patients (73.6%; SR=22, HR=73) had s-HAI cycle 2, with a response rate of 64% in SR vs. 55% in HR (P=0.46). Thus final CR rate was 89% in SR and 78% in HR. Planned postremission therapy was allogeneic stem cell transplantation in HR and/or late responders, high-dose cytarabine cycles in SR early responders. Looking at long-term outcome, 5-year survival varied significantly according to both risk class and achievement of CR after cycle 1 or 2: 56% vs. 39% in SR (P=0.004), and 40% vs. 17% in HR (P=0.0000). The best outcome was observed in SR early responders aged <60 years with *de novo* AML (Figure 1). *Conclusion*s. Because the number of cycles to CR impacts on long-term survival of both SR and HR patients, the achievement of CR at cycle 1 should be a primary therapeutic endpoint of clinical studies. Patients who fail standard induction should not repeat the same regimen; for these cases, schedules like s-HAI yielding a >50% success rate are preferable.

A PHASE II STUDY OF GTI-2040, AN ANTISENSE TO RIBONUCLEOTIDE REDUCTASE IN COMBINATION WITH HIGH-DOSE CYTARABINE IN RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

B Klisovic,[1] W Blum,[1] P Chen,[1] Z Xie,[1] S Liu,[1] A Walker,[1] S Devine,[1] R Garzon,[1] J Byrd,[1] M Wetzler,[2] H Sayar,[3] L Damon,[4] C Grosskreutz,[5] S Solomon,[6] P Murray,[7] K Chan,[1] G Marcucci[1]

[1]The Ohio State University, Columbus, USA; [2]Roswell Park Cancer Institute, Buffalo NY, USA; [3]Indiana University Simon Cancer Center, Indianapolis IN, USA; [4]UCSF Medical Center, San Francisco CA, USA; [5]Mount Sinai Hospital, New York NY, USA; [6]Northside Hospital, Atlanta, GA, USA; [7]Lorus Therapeutics, Toronto, Ontario, Canada

Background. GTI-2040 is a 20-mer antisense to the R2 component of ribonucleotide reductase (RNR) mRNA. RNR is required for the conversion of ribonucleotides to deoxyribonucleotides, a crucial step during DNA synthesis and repair. Cytarabine (AraC) is a cytotoxic agent converted into AraC triphosphate (AraCTP) and is the backbone of several regimens in acute myeloid leukemia (AML). AraCTP competes with deoxycytidine for DNA incorporation, and AraC cytotoxicity correlates with AraCTP incorporation into DNA. Therefore, we hypothesized that RNR downregulation by GTI-2040 results in decreased levels of endogenous deoxycytidine, leading to a preferential DNA incorporation of AraCTP and increased cytotoxic activity. *Aims.* To test this hypothesis, we undertook a multi-center, Simon two stage Phase II (P2) study of GTI-2040 plus high dose cytarabine (HiDAC) in patients with relapsed or refractory AML (ages 18-59 years). The primary objective was to determine the overall response rate (complete remission (CR) and CR with incomplete blood count recovery (CRi)) of GTI-2040 with HiDAC. Secondary objectives included pharmacokinetic (PK) studies including intracellular GTI-2040 and exploration of the combination's pharmacodynamic (PD) activity, including changes in dNTPs, NTPs, and AraCTP. *Methods*. Patients received HiDAC at 3 gm/m^2 every 12 hours for a total of 8 doses and GTI-2040 5 mg/kg/day continuous infusion (CI) for 6 days beginning 24 hours before HiDAC (P2 group). To further explore the PD activity of the combination, an additional PD group received the same HiDAC dose and schedule with GTI-2040 5 mg/kg/day CI for 4 days beginning 24 hours after HiDAC initiation. In the Stage 1 P2 arm, if 3 or more patients achieved CR/CRi, the regimen would be deemed worthy of further study. All patients provided informed consent. *Results.* Twenty-five patients were enrolled; 15 in the P2 group and 10 in the PD arm. Median age was 43 years (range 18-59 years); men comprised 72% of patients. Fourteen patients (56%) had primary refractory AML, 9 (36%) had relapsed less than 1 year after achieving first complete remission (CR1), and 2 (8%) had relapsed >1 year after achieving CR1. Overall, 15 (60%) pts had received prior HiDAC. Fourteen patients (56%) had intermediate risk cytogenetics, and 11 (44%) had adverse risk karyotypes by CALGB classification. Toxicities were comparable to those observed with HiDAC therapy alone. Grade 3/4 treatment emergent non-hematologic toxicities at least possibly related and seen in 2 or more patients included febrile neutropenia, catheter related infections, and reversible elevations in ALT/AST. Only 1 patient had a grade 3 reversible cerebellar toxicity. Overall, 7 (28%) patients (P2 arm n=4; PD group n=3) achieved CR/CRi (CR n=6; CRi n=1) and 1 patient achieved partial remission. Pharmacokinetic parameters and intracellular GTI-2040 concentration evaluated using an ELISA-based assay developed by our group, and dNTP/NTP, and AraCTP levels using a LC-MS/MS assay will be presented. *Summary/Conclusions.* The combination of GTI-2040/HiDAC was tolerable and met efficacy criteria for Stage 2 enrollment. Safety and efficacy demonstrated in this Phase II and prior Phase I in similar high risk AML patients supports further development in a larger randomized trial. [NCI R21 CA133879-01]

MYELOID LEUKEMIA OF DOWN SYNDROME - MONITORING OF MINIMAL RESIDUAL DISEASE

D Reinhardt,[1] K Reinhardt,[1] K Boehmer,[1] A Sander,[1] C Neuhoff,[1] U Creutzig[2]

[1]Hannover Medical School, Hannover, Germany; [2]University children´s Hospital Muenster, Muenster, Germany

Background. Children with Down syndrome (DS) have a 5 to 10% risk of transient leukemia (TL) and a ~2% risk of myeloid leukemia (ML-DS). Children with ML-DS had a favorable outcome with less intensive chemotherapy compared to non-DS AMKL. Somatic mutations of the GATA1 gene were detected in almost all DS TL and ML-DS children's. *Aims.* To demonstrate the feasibility to monitor the GATA1 positive leukemic clone (minimal residual disease, MRD). We compared the MRD monitoring by qPCR, immunophenotyping and morphology. *Patients.* In Germany 56 children with ML-DS (f=26; m=34; age 1.56 years (0.7-4.0) were enrolled to the ML-DS 2006 registry. Treatment consisted of 4 courses of chemotherapy with significantly lower cumulative dosages of cytarabine (27.4 g/m^2) and anthracyclines (190 mg/m^2) compared to conventional protocols (AML-BFM 2004: cytarabin 47.3 g/m^2; anthracyclines 450 mg/m^2). The median WBC was 4.7g/l (range 1-160 g/L), Hb 9.5g/dL (3.1-13.4), platelets 45 g/L (1.5-257 g/L). Four children of the cohort had trisomy 21 mosaicism. *Methods.* Morphology, immunophenotyping and molecular genetics were centrally performed. For screening of GATA1 mutation a direct sequencing of exon 1, 2, and 3 was performed. If no mutation could e detected blasts sorting or subcloning was added. For monitoring of GATA1 mutant clone we used a qPCR with patient specific TaqMan probes and primers. The standard curve was a serial dilution series of initial patient DNA. We achieved a sensitivity of 10 -5 and quantitative range of 10 -4. As negative control we used the cell line 293T (Human embryonic kidney cell line) and healthy donor DNA. *Results.* GATA 1 mutations were confirmed in 54 patients (96%). GATA1 detection was not possible in 2 patients with initial blasts count less than 2% and lack of sufficient material. The 3-years-eventfree and overall survival were 94±3% and 96±2%, respectively. Two children died early due to infections. All others were in complete remission (follow-up 2 years; 0,2-4 yrs). Sixteen children had a history of TL (28%). In 4 out of them, the GATA1 clone have been successfully monitored by qPCR. All patients showed spontaneous reduction of blasts after TL, however never became negative (all time points >10^{-4}) by qPCR monitoring and developed ML-DS within 0.7 to 3.2 years. To date 15/56 children with ML-DS the GATA1 mutant clone has been monitored prospectively. By morphology and immunophenotyping the blasts decreased from 30.5% (5-76% at diagnosis to 2.4% (0.4-4.5%). After the 3rd element only one child remain MRD- positive. The qPCR confirmed the results, although the sensitivity was about 1-log higher). All 54 patients are still in continuous complete remission with a median follow-up of 2.3 years (0.5 to 4.3 years). *Conclusions*. This preliminary data demonstrates the feasibility to monitor MRD in children with ML-DS. The GATA1 clone specific qPCR showed a high sensitive and might help to define new risk groups in ML-DS aiming further reduction of treatment intensity.

0068

PHASE I CLINICAL TRIAL OF THE ANTI-CD33 IMMUNOTOXIN HUM195/RGEL IN PATIENTS (PTS) WITH ADVANCED MYELOID MALIGNANCIES

A Al-Kali,[1] A Dean,[2] M Talpaz,[3] H Kantarjian,[1] S Faderl,[1] E Jabbour,[1] F Ravandi,[1] S O'Brien,[1] M Rosenblum,[1] J Cortes[1]

UT MD Anderson Cancer Center, Houston, USA; [2]UTMDACC, Houston, USA; [3]University of Michigan, Ann Arbor, USA

Background. HuM195 is a humanized version of the mouse M195 anti CD-33 monoclonal antibody. CD33 is heavily expressed on the surface of myeloid leukemia cells. The anti-CD33 immunotoxin HuM195/rGel combines HuM195 with recombinant gelonin, a RNA glycosidase that

inhibits protein synthesis. *Aim.* The primary objective of this study was to determine the safety and toxicity of HuM195/rGel in pts with refractory or relapsed leukemia. *Methods.* Pts age ≥18 years with relapsed or refractory AML, RAEB-t, RAEB, CMML or CML-AP/BP and CD 33 expression ≥80% by flow cytometry, were eligible. Pts received doses of 2.5 to 10 mg/m^2 using a standard 3 + 3 design. Therapy was administered over 2 one-hour infusions per week for 2 weeks followed by a 2 week period of observation. Pts taken off study before 28 days for reasons other than toxicity were replaced for MTD calculations. *Results.* 28 patients were enrolled: 23 AML, 4 MDS, and 1 CMML. Median age was 68 years, median number of prior therapies was 2, median peripheral blood blasts 24%, median bone marrow blasts 39%, and median percentage of CD 33 was 95%. The highest achieved blood levels of HuM195/rGel were 200-300 ng/mL which cleared with a half-life of ~20 hrs. Two (<10%) out of 23 patients developed antibodies to the rGel portion of the drug as assessed by ELISA. Twenty two pts were evaluable for dose limiting toxicity (DLT). Two patients developed DLT (allergic reaction) at a dose of 10 mg/m^2, thus 7mg/m^2 was declared the maximum tolerated dose. Drug related adverse events at ≤7mg/m^2 include: grade ≤ 2 fever and chills at all dose levels. Six (27%) out of the evaluable patients had a ≥50% decrease in PB blasts or BM blasts. In addition, 4 pts had an increase in platelet count to >100×10^9/L and 4 pts demonstrated increased neutrophils to >1×10^9/L. There were no complete or partial responses. *Conclusions.* HuM195/rGel can be administered safely at doses up to 7 mg/m^2 with an improvement in the tumor load in some patients.

0069

FAVORABLE OUTCOME IN PATIENTS WITH ACUTE MYELOID LEUKEMIA WITH NPM1 MUTATION AUTOGRAFTED AFTER CONDITIONING WITH HIGH DOSE CONTINUOUS INFUSION IDARUBICIN AND BUSULPHAN

F Ferrara,[1] T Izzo,[1] A Viola,[2] R D'Elia,[1] C Criscuolo,[1] C Riccardi,[1] G Muccioli,[3] F Pane,[3] S Palmieri[1]

[1]Hematology and stem cell tranpslantation unit, Naples, Italy; [2]Hematology and Stem Cell Tranpslantation Unit, Naples, Italy; [3]Ceinge, Federico II University, Naples, Italy

Background. Mutations of the nucleophosmin gene (NPM1), in the absence of concurrent FLT3-internal tandem duplication (FLT3-ITD) have impressive prognostic value in patients with acute myeloid leukemia (AML), carrying normal karyotype (NK). However, while there is a general consent that allogeneic stem cell transplantation (SCT) has no role in patients with NPM1$^+$FLT3$^-$ AML in first complete remission (CR), no studies have specifically focused on the therapeutic results of autologous SCT (ASCT) in NK AML patients presenting with NPM1$^+$/FLT3$^-$ genotype. *Aims.* To describe treatment results from a series of 19 patients with NPM$^+$/FLT3$^-$ autografted in first CR after conditioning with a regimen, named BuI, based on high dose continuous infusion idarubicin and Busulphan and perform a comparison with a control group of 80 NK AML patients with no or different molecular abnormalities. *Methods.* Ninety-nine consecutive patients with NK AML, treated at our Institutions between April 2003 and June 2009, in which ASCT was actually given in first CR were analyzed. There were 62 male patients (64%) and 37 female patients (36%) with a median age of 54 years (range 15-77). Overall 83 patients (84%) were diagnosed as having *de novo* AML, while in 16 patients (16%) AML arose after a previously diagnosed myelodysplastic syndrome (MDS). *Results.* Overall, 19 out of 99 patients autografted after conditioning with BuI regimen (19%) had NPM1 mutation in absence of FLT3 mutations. The control group, accounting for 80 patients, included sixteen cases (15%) with both mutations, 10 (12%) with FLT3/ITD mutation and no NPM1 mutation, and 54 (68%) in whom neither NPM1 nor FLT3 mutations were detectable. Median time from CR achievement to ASCT was similar between the two groups (3 months, range 2-5 for NPM1$^+$ patients) as opposed to 3 for the control group (range 2-6), p: 0.87. The median survival (OS) for the whole patient population was 34 months, the median disease free survival (DFS) was 22 months. Median OS and DFS were significantly longer for patients with isolated NPM1 mutation as opposed to controls (OS: not reached vs. 25 months, P:0.02; DFS: not reached vs. 16 months, P:0.007, respectively). Of interest, patients with isolated NPM1 mutation had a better outcome in terms of either survival or DFS as compared to the group of 16 NMP1$^+$/FLT3$^+$ patients. Relapse post-ASCT occurred in 3 out of 19 patients with NPM1 isolated mutation (16%), 2 with *de novo* AML and 1 with AML post-MDS, as opposed to 49 of 80 in the control group (61%), P:0.001. Overall, second CR was achieved in 12 out of 52 relapsed patients (23%) and was almost exclusively limited to those whose first CR lasted more than 6 months. *Summary and Conclusions.* Our study suggest that BuI regimen results in favorable clinical outcome in patients with isolated NPM1 mutation and could be investigated in a randomized study versus other conditioning regimes or repeated courses of chemotherapy with high dose cytosine-arabinoside.

0070

VORELOXIN SINGLE-AGENT TREATMENT OF OLDER PATIENTS (AT LEAST 60 YEARS) WITH PREVIOUSLY UNTREATED ACUTE MYELOID LEUKEMIA: FINAL RESULTS FROM A PHASE 2 STUDY WITH 3 SCHEDULES

R Stuart,[1] F Ravandi,[2] L Cripe,[3] M Maris,[4] M Cooper,[5] S Dakhil,[6] R Stone,[7] F Turturro,[8] J Fox,[9] G Michelson[9]

[1]Medical University of South Carolina, Charleston, SC, USA; [2]University of Texas MD Anderson Cancer Center, Houston, TX, USA; [3]Indiana University Cancer Center, Indianapolis, IN, USA; [4]Rocky Mountain Blood and Marrow Transplant Program, Denver, CO, USA; [5]St. Francis Hospital, Indianapolis, IN, USA; [6]Cancer Center of Kansas, Wichita, KS, USA; [7]Dana-Farber Cancer Institute, Boston, MA, USA; [8]LSUHSC Feist Weiller Cancer Center, Shreveport, LA, USA; [9]Sunesis Pharmaceuticals, Inc., South San Francisco, CA, USA

Background. Voreloxin, an anticancer quinolone derivative that inhibits topoisomerase II, has demonstrated clinical activity in ovarian cancer and acute myeloid leukemia (AML). Final results are reported from this phase 2 study (N=113). *Aims.* Assess clinical activity and safety/tolerability of voreloxin treatment in 3 dosing schedules. *Methods.* Eligible patients provided informed consent and had AML (WHO subtype, except APL) considered unlikely to benefit from standard induction therapy, with ≥1 adverse risk factor: age ≥70, secondary AML, intermediate (I) or unfavorable (U) cytogenetics, or PS=2. Voreloxin was administered by short (≤10 min) IV infusion in 3 dosing schedules: A, weekly (qwk) ×3 (days [d] 1, 8, 15) at 72 mg/m^2 (N=29); B, qwk×2 (d 1, 8) at 72 mg/m^2 (N=35); and C, twice weekly (biw) ×1 (d 1, 4) at 72 (N=29; C72) or 90 mg/m^2 (N=20; C90) for up to 4 cycles. *Results.* Median age was 74 years, most patients were male with an ECOG PS 0 or 1, and cytogenetics were I (46%) or U (42%) per 2010 NCCN guidelines. The overall remission rate (ORR=CR+CRp [complete remission + CR with incomplete platelet recovery]) across all doses and schedules was 34% (range, 25-41%) and 74% of CR were in first cycle. Reinduction resulted in CR or CRp for 35% of those reinduced. By schedule, ORR was 41% for A, 29% for B, 38% for C72, and 25% for C90. No dose response was observed between C72 and C90. All-cause mortality rates were lowest in C72 (7% at 30 days, 17% at 60 days) compared with A, B, and C90. Median duration of remission (DR) was 10.7 months (mo) for A (median too early to evaluate [TETE] for B, C72, or C90). Median overall survival (OS) was 8.7 mo (A), 5.8 mo (B), 7.3 mo (C72, preliminary); C90 is TETE. One-year OS was 38% for A and TETE for other schedules. Across all schedules, the most common nonhematologic adverse events grade ≥3 were febrile neutropenia (49%) and infections: pneumonia (28%) and sepsis/bacteremia (28%). Overall safety profile was more acceptable for C72 than for A and appeared further improved over B. ORR was 30% for patients ≥75 years. *Summary/Conclusions.* Voreloxin induced durable remissions in 3 dosing schedules. Schedules B and C maintained activity and improved tolerability over A. Schedule C72 is appropriate for further development based on ORR, all-cause mortality, and safety profile.

0071

PERSISTENCE OF CYTOGENETIC ABNORMALITIES AT THE TIME OF COMPLETE REMISSION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA: PROGNOSTIC SIGNIFICANCE AND THE ROLE OF ALLOGENEIC STEM CELL TRANSPLANTATION

Y Chen, E Cortes, Z Estrov, S Faderl, W Qiao, S Pierce, T Kadia, M De Lima, H Kantarjian, F Ravandi

The University of Texas M. D. Anderson Cancer Center, Houston, USA

Background. Cytogenetic abnormalities are identified in about 55% of adult patients with acute myeloid leukemia (AML) and are the most important pretreatment factors for predicting the clinical outcome. Prognostic significance of persistent cytogenetic abnormalities at the time of CR and the potential role of allogeneic stem cell transplantation (SCT) in this setting is not well established. *Aims.* To determine the prognostic significance of persistent cytogenetic abnormalities at CR and the role of SCT in this setting. *Methods.* We identified 357 patients with newly diag-

nosed AML (excluding acute promyelocytic leukemia) with cytogenetic abnormalities at initial diagnosis who achieved CR after receiving induction on various frontline protocols between January 2000 and February 2009 at UTMDACC. Among these, 254 patients had a successful bone marrow cytogenetic analysis performed at CR and are the subject of this analysis. We compared the outcome of 183 (72%) patients with normal cytogenetics at CR with 71 (28%) patients who had abnormal karyotype at CR. Overall, 66 patients received SCT at CR. Among them, 51 (77%) patients had normal, and 15 (23%) had abnormal cytogenetics. Kaplan-Meier and Cox proportional hazards regression model were used for statistical analysis. *Results.* The median age of the 254 patients was 52.5 years (range, 16 to 86 years) and the median follow-up was 21 months (range, 3 to 115 months). Patients with cytogenetic abnormalities at CR had significantly shorter CR duration (CRD) (median 6.6 months; P<0.0001) and overall survival (OS) (11.3; P<0.001) compared to patients with normal cytogenetics at CR (39.6 and 45.5 respectively). In multivariable model, after adjusting for other covariates, persistent cytogenetic abnormalities at CR was an independent predictor for shorter CRD (P<0.0001) and shorter OS (P<0.0001); patients with abnormal cytogenetic at CR were more likely to relapse or die than those with normal cytogenetic (2.97 and 2.51 times, respectively). Among patients with cytogenetic abnormalities at CR, those who underwent SCT had significantly better CRD (P=0.01) and OS (P=0.01). *Conclusions.* The presence of cytogenetically abnormal cells at the time of CR is a predictor of relapse, shorter CR duration and shorter overall survival.

0072

REMISSION INDUCTION CHEMOTHERAPY INCLUDING GEMTUZUMAB OZOGAMICIN OFFERS DURABLE REMISSION IN ELDERLY PATIENTS WITH AML AFTER ALLOGENEIC OR AUTOLOGOUS STEM CELL TRANSPLANTATION

KS Eom, HJ Kim, WS Min, BS Cho, SE Lee, DG Lee, SM Choi, S Lee, YJ Kim, CK Min, SG Cho, DW Kim, JW Lee, CW Park

Catholic Blood and Marrow Transplantation Center, Seoul, South-Korea

Background. The incidence of acute myeloid leukemia (AML) increases with age but, the prognosis for these elderly patients is dismal. Recent studies have examined the feasibility and efficacy of autologous stem cell transplantation (ASCT) and of reduced intensity conditioning (RIC) stem cell transplantation (SCT) in this population. One key factor that limits the application of SCT for AML of the elderly is the low CR rate achieved by conventional chemotherapy. To improve CR rates, several novel approaches including the use of gemtuzumab ozogamicin (GO) with or without conventional chemotherapy have been attempted. We previously reported on the effectiveness and safety of GO in combination with attenuated conventional chemotherapy in order to improve CR rates in the elderly patients with AML Over 70% of these patients were found to respond to the regimen with acceptable toxicity, which enabled a considerable portion to become potential candidates for SCT. *Aims.* Few reports have been issued regarding the impact of GO as a remission induction regimen on the outcome of SCT in a homogenous population, such as, in elderly patients with AML in first CR (CR1). Here, we analyzed the results of SCT in elderly patients with AML who achieved CR1 with a GO-containing regimen. *Methods.* We included elderly patients (≥55 years) with AML who were medically fit for chemotherapy and achieved CR1 on our institutional protocol including GO. Patients in RIC-SCT group were given a RIC regimen consisting of fludarabine (30 mg/m^2/d, for 5 days) and busulfan (3.2 mg/kg/d, for 2 days). GVHD prophylaxis was undertaken by administering calcineurin inhibitor plus methotrexate. Patients assigned to ASCT were prepared using our modified TAM regimen, which consisted of fractionated total body irradiation, followed by intermediate-dose AraC, and melphalan. *Results.* A total of 54 patients with AML were treated using our institutional remission induction protocol. Of these, 41 patients (75.9%) achieved CR and 17 patients (41.5%) of the patients received RIC-SCT or ASCT; 9 patients received RIC-SCT, and 8 patients received ASCT. We also arbitrarily divided the patients into CD33-high (≥60%) and low (<60%) groups according to CD33 positivity in BM samples at the time of diagnosis. Fourteen patients were allocated to the CD33-high group. With a median follow up of 40.4 months, probabilities of OS, DFS, RI, and NRM at 3 years for all 17 patients were 58.2%, 47.1%, 42.2%, and 18.1%, respectively. OS and DFS were not statistically different in the two transplant groups (Figure 1). Patients without chronic GVHD demonstrated superior disease free survival. On the other hand, those that developed acute GVHD demonstrated inferior OS and DFS. Patients with low BM CD33 expression showed significantly lower OS and DFS than those with high expression. RI was significantly higher in CD33 low group than in CD33 high group. No difference was observed in NRM according to CD33 expression. *Conclusions.* This study has several implications for SCT in elderly patients with AML. First, it shows that GO can improve survival in elderly patients with AML who receive SCT by improving the CR rate; furthermore, this improvement was more marked in the setting of ASCT. This allows a larger proportion of patients to undergo SCT, which is believed to be a potentially curative treatment modality in this population. Second, we reconfirm the impact of acute and chronic GVHD on NRM and relapse, and therefore, on survival. Third, our findings raise the possibility that BM CD33 expression is an important prognostic factor when GO is used for remission induction.

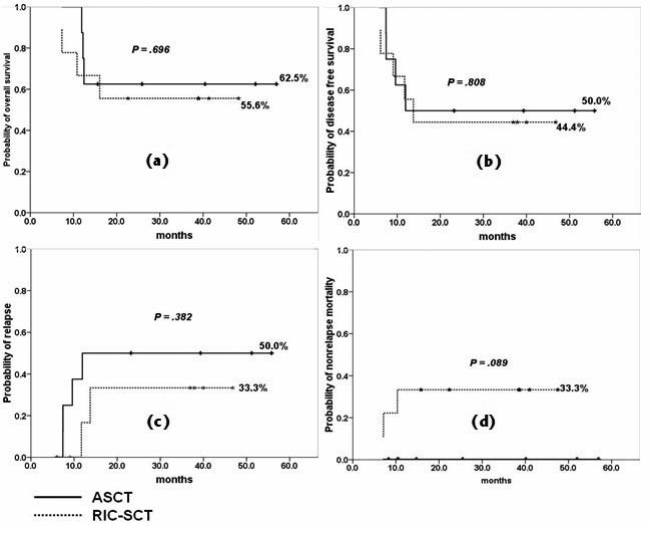

Figure 1. Outcomes according to transplant modalities

0073

PHASE 2 TRIAL OF VORINOSTAT (SAHA) IN COMBINATION WITH GEMTUZUMAB OZOGAMICIN AS INDUCTION AND POST-REMISSION THERAPY IN OLDER PATIENTS WITH PREVIOUSLY UNTREATED ACUTE MYELOID LEUKEMIA (AML)

B Walter,[1] B Medeiros,[2] M Nielsen-Stoeck,[1] E Harrington,[1] B Powell,[3] C Schiffer,[4] F Appelbaum,[1] E Estey[1]

[1]Fred Hutchinson Cancer Research Center, Seattle, USA; [2]Stanford University, Stanford, USA; [3]Comprehensive Cancer Center of Wake Forest University, Winston-Salem, USA; [4]Barbara Ann Karmanos Cancer Center, Wayne State University, Detroit, USA

Background. Gemtuzumab ozogamicin (GO), an immunoconjugate between a humanized anti-CD33 antibody and a toxic calicheamicin-γ1 derivative, causes DNA damage and apoptosis in AML cells. Preclinical studies have demonstrated that histone deacetylase (HDAC) inhibitors such as vorinostat increase CD33 expression and lower the apoptotic threshold to calicheamicin-γ1. These studies prompted a phase 2 study of vorinostat as chemosensitizer with GO in patients with untreated non-APL AML. *Methods.* After informed consent is obtained, patients receive vorinostat 400 mg orally once daily on days 1-9 and GO 3 mg/m^2 on day 8; hydroxyurea is given to reduce the WBC <10,000/μL before beginning vorinostat. Therapy is repeated for residual disease on day 14, the protocol was amended after 8 enrolled patients to allow a third induction course before response assessment. Patients who achieve either complete remission (CR) or CR with incomplete blood count recovery (CRi) are eligible for 1 cycle of consolidation treatment with vorinostat and GO in the same doses. In patients aged ≥70 years and ECOG performance status (PS) 2-3 (Group 1), the primary outcome of interest is 30-day survival while the primary objective in other patients (Group 2) is determination of the CR/CRi rate after induction therapy. The statistical design monitors CR/CRi rate separately in Group 2 patients with normal or favorable cytogenetics (Group 2A) and other cytogenetics (Group 2B) while allowing results from Group 2A to affect stopping Group 2B and vice versa. In Group 2A, stopping would occur if the probability was >97% that the true CR/CRi rate was <45% while in Group 2B, the criterion probability was 98% and the reference CR/CRi rate was <30%. The 97% and 98% cut-offs were chosen so that there would be no more than 10% probability of early

stopping if the true CR/CRi rates were at least 45% or 30% in Group 2A or 2B, respectively. *Results.* 25 patients, median age 73 (range, 61-80) years, median PS 1.5 (range, 0-3), 60% with secondary AML, have been enrolled: 9 in Group 1 (including 1 with favorable cytogenetics), 8 in Group 2A, and 8 in Group 2B. Among 25 evaluable patients, CR/CRi rates are 1/9 in Group 1, 3/8 in group 2A (2 patients negative for minimal residual disease by flow cytometry), and 0/8 in Group 2B. 1 patient died before day 30 from sepsis in Group 1 and Group 2B. Among the 4 patients with CR/CRi (all CR as best response), 2 received further consolidation therapy with high-dose cytarabine, and 1 patients is undergoing allogeneic stem cell transplantation. Remissions are ongoing at 1, 3, 7 and 8 months. Treatment has been well tolerated with grade 3 hypertension (2 cases) the only notable toxicity besides cytopenias, infections, and infusion-related reactions. Given the above CR/CRi rates and pre-specified stopping rules, the study has closed to accrual in Group 2B while continuing to accrue in Group 1 and Group 2A (registered at ClinicalTrials.gov as NCT00673153). *Conclusions.* Vorinostat in combination with GO has anti-AML activity that may mostly be confined to patients with normal karyotype AML.

0074

A SCORING SYSTEM INCLUDING MOLECULAR GENOTYPE TO PREDICT THE ACHIEVEMENT OF COMPLETE REMISSION IN PATIENTS WITH PRIMARY ACUTE MYELOID LEUKEMIA

S Brunet,[1] M Tormo,[2] J Esteve,[2] JM Ribera,[2] M Hoyos,[2] J Nomdedéu,[2] R Duarte,[2] A Llorente,[2] R Guardia,[2] MP Queipo de Llano,[2] J Besalduch,[2] I Heras,[2] J Bargay,[2] C Pedro,[2] JM Marti,[2] J Bueno,[2] P Torres,[2] D Hernández,[2] J González,[2] A García,[2] L Font,[2] M Arnan,[2] A Oriol,[2] D Gallardo,[2] R Goterris,[2] E Montserrat,[2] J Sierra[2]

[1]Hospital Sant Pau, Barcelona, Spain; [2]On behalf of CETLAM Cooperative Group, Valencia, Spain

Aim. To analyze the prognostic impact of molecular genotype on the achievement of complete remission (CR), in patients with primary (*de novo*) AML (M3 excluded) *Patients and Methods.* Between december-2003 and November-2009, 606 patients up to 70 years-old were included in the CETLAM AML-03 protocol. Induction therapy consisted in one or two courses of idarubicin, intermediate dose ara-C and etoposide, in addition to G-CSF priming from day 0. Cytogenetics classification was as in the MRC studies: Favorable prognosis (FP), intermediate (IP) and adverse (AP). In the IP group, molecular analysis of NPM1 (NPM1+) mutations, CEBPA mutations and internal tandem duplication of FLT3 gene (ITD/FLT3) was performed. In the AP group, the absence (MK-) or presence of monosomal karyotype (MK+) was studied; MK+ was defined as 2 or more autosomal monosomies, or one monosomy and >1 structural alteration. *Results.* Median age of the series was 53 years (range, 18-73). In 543 (89%) patients cytogenetic data were available; of them, 68 (13%) had FP, 391 (72%) IP (included 248 with normal cytogenetics) and 84 (15%) AP. In the FP group or CBF leukemia, 35 (51%) had the AML1/ETO fusion and 33 (49%) the CBF/MYH11. In the IP group, 72 patients (18%) were $NPM1^+$/FLT3w, 102 (26%) were DIT/$FLT3^+$, 18 (5%) were $CEBPA^+$. The remaining 100 (25%) patients had incomplete molecular information. In patients with AP, 42 were MK- and 31 MK^+. Overall, 457 (77%) of 600 patients evaluable achieved a CR. The rate of CR according to cytogenetics was: FP 91%, IP 77% and AP 70%, P=0.01. In AML with favourable genotype that includes CBF leukaemia, $NPM1^+$/$FLT3^-$ and $CEBPA^+$/$FLT3^-$, RC rates ranged from 91-94% and of note no refractoriness was observed. In patients with AP, CR rate was 76% if MK^- and 63% if MK+ (P=0.48). Multivariate analysis showed that favourable genotype and WBC $<50\times10^9$/L had a positive impact for CR. According to these factors we developed a predictive score, low-risk: favourable genotype and WBC $<50\times10^9$/L, intermediate-risk (1 factor), and high-risk, non favourable genotype and $>50\times10^9$/L with a significant CR rate, 94%, 79%, and 60% respectively, P<0.0001). Moreover, in the favourable genotype those with <50 years-old and WBC $<50\times10^9$/L had a CR rate of 97% vs 69% for those >50 years-old and WBC $>50\times10^9$/L vs 93% with the remaining combinations, P=0.01. *Summary.* Genetic characterization is nowadays mandatory in AML. CR rate is high and refractoriness exceptional in the presence of CBF leukaemia, or NPM1 or CEBPA mutations without DIT/FLT3. WBC is an additional prognostic factor. Using the above score, CR rate can be predicted accurately. Furthermore, in favourable genotype the combination of age and WBC could separate 3 groups of patients with different CR rates. *Supported in part by grants: GR1-01075, ECO07/90065, PI080672 and RD06/0020/0101.*

INVASIVE ASPERGILLOSIS: A NEW IMPORTANT RISK FACTOR ON SHORT AND LONG-TERM SURVIVAL OF AML PATIENTS

M Michallet,[1] T Benet,[2] S Kraghel,[1] M Sobh,[1] M El Hamri,[1] G Cannas,[1] F Nicolini,[3] H Labussiere,[1] S Duscastelle-Lepretre,[1] F Barraco,[1] Y Chelghoum,[1] X Thomas,[1] M Nicoll,[2] A Bienvenu,[4] F Persat,[4] P Vanhems[2]

[1]Edouard Herriot Hospital, Lyon, France; [2]Laboratoire d'Hygiène, Edouard Herriot Hospital, Lyon, France; [3]Hopital Edouard Herriot, Lyon, France; [4]Laboratoire de Parasitologie et de Mycologie Médicale, Edouard Herriot Hospital, Lyon, France

Background. Invasive aspergillosis (IA) remains an important cause of death for acute myeloid leukemia (AML) patients. Recently a lot of efficient innovative agents have been proposed as curative, empiric and more recently prophylaxis therapy in the IFI setting. It has been demonstrated that some agents used either as early treatment or prophylaxis of IFI had a significant impact on early survival (Day 100) of AML patients. *Objectives*. To study the impact of IA incidence during induction therapy for AML patients on short and long term overall survival. *Methods.* A retrospective cohort study was performed in the Hematology department of the Edouard Herriot Hospital, Lyon (France). Patients with newly diagnosed AML between 01/01/2004 and 31/12/2007 were retrospectively included and the follow-up was censored at 30/06/2009. Data were extracted from medical charts and from the prospective surveillance of IA (EORTC diagnosis criteria). The patients with IA after post induction evaluation were excluded (N=5). A Cox proportional hazard model with diagnosis of IA and post induction evaluation (complete remission [CR] of AML or failure of chemotherapy) as the main exposure besides age, year of inclusion, WHO status, cytogenetic group, kind of induction chemotherapy, and hematopoietic stem cell transplantation, was fitted. *Results.* Overall, 262 patients counting for 149 370 patient-days were analysed, the median age at diagnosis was 56.6 years (47.9-64.2 years), and 196 (75%) had CR. There were 58 (22%) IA cases with a median interval between induction and IA of 30 days (range, 16-27 days); 29 (50%) IA were possible, 24 (41%) probable, and 5 (9%) proven. At the last follow-up, 165 (63%) patients died with a median overall survival of 18 months (95% confidence interval [95% CI] 14-23 months). The 4 year-survival of patients having had IA was 14%, and without IA 32% (P=0.01). The 2 year-survival of patients achieving of CR was 54% vs. 5% for patients with failure of chemotherapy was 5% (P<0.001). Cox multivariate analysis showed that patients in CR with IA presented a higher risk of death compared to patients in CR without IA (Hazard ratio=1.66, 95% CI 1.05-2.65, P=0.031). In addition, IA was associated with a higher risk of death in patients with failure of chemotherapy compared to patients in CR without IA (Hazard ratio=6.43, 95% CI 3.72-11.10, P<0.001). The WHO status, cytogenetic group and kind of induction chemotherapy were associated with lower survival.

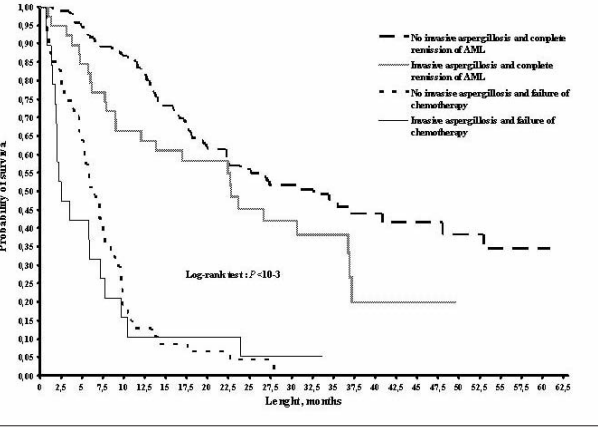

Figure.

Conclusions. IA was associated with a high risk of death in AML patients whether they were in CR or failure after induction chemotherapy. Cytogenetic group or WHO status are not modifiable risk factors for death in this population while prevention of IA with environmental procedures or using individual prophylaxis will improve survival outcome.

0076

A PROGNOSTIC AND PREDICTIVE CLASSIFICATION FOR SURVIVAL AFTER COMPLETE REMISSION IN INDUCTION THERAPY OF ACUTE MYELOID LEUKEMIA

M Pfirrmann,[1] S Soucek,[2] C Thiede,[2] M Bornhaeuser,[2] T Thomas,[2] G Ehninger,[2] M Schaich[2]

[1]Ludwig Maximilian University, Munich, Germany; [2]University Hospital, Dresden, Germany

Background. In the AML 96 study of the Study Alliance Leukemia (SAL), 586 patients with *de novo* or secondary acute myeloid leukemia (AML) and no karyotype t(8;21) achieved complete remission (CR) after two cycles of induction therapy. *Aims.* For these 586 patients, we sought to identify parameters evaluated at diagnosis which provide prognostic information with respect to overall survival. In addition, the predictive value of these parameters was investigated within each of the specific post-remission therapies comprising allogeneic hematopoietic stem cell transplantation, chemotherapy with high-dose cytarabine, or autologous stem cell transplantation (autologous SCT). *Methods.* Candidate variables were diagnosis (*de novo*, post-myelodysplastic syndrome, or treatment-induced secondary AML), age at diagnosis, sex, cytogenetic risk, leukocyte count, platelet count, FLT3-ITD mutant-to-wild-type ratio, NPM1 and CEBPA mutation status, and the percentages of CD34 expression, POX-positive blasts, and blasts in bone marrow at day 15 after start of induction therapy. In contrast to a first approach, continuous variables were not categorized. Instead, fractional polynomials in the multiple (stratified) Cox regression modeling were allowed. Stratification was necessary for the general prognostic model to account for differences in survival probabilities between the possible post-remission therapies. The resulting linear predictor of a model was categorized into risk groups to aid medical decision making. *Results.* At first, the introduction of a new (binary) risk group variable proved to be appropriate: Unfavorable risk was defined by either poor cytogenetic risk or treatment-induced AML. All other patients were considered to have standard risk. The final multiple model comprised the variables age, new risk group, FLT3-ITD mutant-to-wild-type ratio, and the percentages of CD34 expression (all P<0.005). Of 463 patients with data on these variables, 235 (51%) had died. The linear predictor of the final model was categorized into three risk groups with significantly different survival probabilities (P<0.0001). The low-risk group was composed of 201 patients (71 died) with a four-year survival probability of 0.65. The same number of patients (112 died) was allocated to the intermediate-risk group. The four-year survival probability was 0.44. The 61 patients of the high-risk group (52 died) had a four-year survival probability of 0.12. Also within each of the post-remission therapies, the three risk groups were able to predict patient groups with significantly different survival probabilities (all P<0.0005). In addition, in each risk group it was possible to identify a treatment which appears to be the most promising and which was not the same for all risk groups. *Conclusions.* Four variables were identified as independent prognostic factors for survival after CR in induction therapy. The corresponding prognostic score resulted in three risk groups also with predictive survival differentiation within each of the post-remission therapies. The treatment with the best survival probabilities differed between risk groups. Hence, the prognostic and predictive classification supports risk-adapted treatment and provided new hypotheses for treatment optimization.

FINAL RESULTS OF A PHASE 2 PHARMACOKINETIC/PHARMACODYNAMIC (PK/PD) STUDY OF COMBINATION VORELOXIN AND CYTARABINE IN PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

J Roboz,[1] J Lancet,[2] L Cripe,[3] F Ravandi,[4] A List,[2] J Fox,[5] G Michelson,[5] J Karp[6]

[1]Cornell University/New York Presbyterian Hospital, New York, NY, USA; [2]Moffitt Cancer Center, Tampa, FL, USA; [3]Indiana University Cancer Center, Indianapolis, IN, USA; [4]University of Texas MD Anderson Cancer Center, Houston, TX, USA; [5]Sunesis Pharmaceuticals, Inc., South San Francisco, CA, USA; [6]Sidney Kimmel Cancer Center, Baltimore, MD, USA

Background. Voreloxin (VOR), an anticancer quinolone derivative that inhibits topoisomerase II, is active in ovarian cancer and acute myeloid leukemia (AML). Nonclinical studies showed synergistic activity of VOR and cytarabine (ara-C) (Scatena Cancer Chemother Pharmacol 2010). *Aims.* Assess clinical activity and safety/tolerability of combination VOR/ara C treatment; characterize PK/PD profile. *Methods.* Phase (ph) 1b results were presented previously (Proc ASCO 2009). Ph 2 expansions in first relapse (frel) and primary refractory (pref) AML were at 80 mg/m^2 VOR/400 mg/m^2 ara-C by 24-hr CIV in schedule A (A) and 90 mg/m^2 VOR/1 g/m^2 ara-C by 2-hr IV infusion in schedule B (B). VOR dosing days 1, 4; ara-C daily ×5. Up to 4 cycles allowed. Response determined by IWG criteria. Blood, urine, and bone marrow aspirate (BMA) collected for PK or PD analysis. Ph 2 populations pooled and subset analysis of pref/early frel (efrel) outcome performed as safety/efficacy results were comparable in A and B. All patients provided informed consent. *Results.* CR+CRp+CRi (ORR) was 32% (12/37) frel and 25% (8/32) pref; most were CR (17 of 20). Fourteen ph 2 patients went to transplant (12 responders, 1 partial responder, 1 treatment failure). As of a data cutoff of 8 Jan 2010, preliminary median overall survival (OS) was 7.8 months (mo) (95% CI 4.7-10.2). All-cause mortality was 3% (2/69) at 30 days and 8% (5/63) at 60 days. Activity was similar in patients with efrel (CR1 ≤12 mo) and pref (ORR 28%, OS 7.3 mo [95% CI 6.0-9.9]), a patient group with poor outcomes. Nonhematologic grade ≥3 adverse events >10% at VOR 70-90 mg/m^2: aggregated (ag) upper GI mucositis 17%; ag lower GI mucositis 9%; febrile neutropenia 37%; ag sepsis/bacteremia 23%, ag infections 15%, and ag pneumonia 10%; hypokalemia 19%. PK/PD: VOR PK was dose proportional and unaffected by ara-C. DNA damage PD response seen with increased pDNA PKcs/pCHK2 in BMA of 15/23 patients at ≥34 mg/m^2 VOR/ara-C. *Summary/Conclusions.* Activity of combination VOR with intermediate dose ara-C is promising, and supports the planned randomized pivotal phase 3 study in relapsed or refractory AML. Safety and activity profile in the subset of pref and efrel (CR1 ≤12 mo) patients: ORR (28%), 30- and 60-day all cause mortality (<10%), and OS (7.3 mo) compares favorably with recent data for other AML therapies (Litzow BJH 2009; Giles Blood 2009).

WT1 EXPRESSION IN PERIPHERAL BLOOD HAS NO PROGNOSTIC VALUE BUT CAN PROVIDE MORE USEFUL INFORMATION ON MRD COMPARED TO BM IN CHILDREN WITH AML

K Kramarzova,[1] BL Boublikova,[2] K Muzikova,[2] J Stary,[2] J Trka[2]

[1]Charles University, [2]nd Faculty of Medicine, Prague, Czech Republic; [2]CLIP, Department of Paediatric Haematology and Oncology, Charles University, Prague, Czech Republic

Background. The Wilms' tumor gene 1 (WT1) is highly expressed in a large proportion of human acute leukaemias and other haematological malignancies. In the majority of studies on childhood AML, the WT1 detection is realized by analysis of bone marrow samples (BM), although there are some suggestions that peripheral blood (PB) is more suitable for this purpose, especially in adult AML. *Aims.* To investigate the correlation between WT1 levels in BM and PB, we analyzed 90 patients with *de novo* childhood AML. Normal PB samples and normal or regenerating MRD-negative BM samples were used as controls to define the range of physiological WT1 levels. *Methods.* RQ-PCR for absolute quantification of total WT1 was designed according to Europe Against Cancer Program. *Results.* We detected the WT1 expression in 92% of BM and 91% of PB samples. Physiological expression of WT1 in unsorted BM and PB of healthy donors samples was 29 and 1.4 WT1/ABL×10^4 NCN (range 22-115 and 0.2-13.2), respectively. WT1 overexpression (defined as >1.5-fold higher than maximum of physiological level) was found in 75% of BM and 80% of PB samples. The median of WT1 level in BM was 0.2 log higher in comparison with PB (P=0.01) and we found an excellent correlation between the values detected in BM and PB (correlation coefficient 0.89, P<0.0001). There was no relation between WT1 levels in PB or BM and the percentage of blasts. The difference in WT1 expression between patients' samples and healthy controls was 2.0 log for BM and 3.1 log for PB. Overall, we found significantly higher WT1 expression in childhood AML than in ALL (P<0.001 for BM, P<0.0001 for PB). According to FAB classification, M3 was associated with the highest WT1 (P<0.0001 for both BM and PB) and patients with M5 AML had the lowest WT1 expression (P<0.0001 for both BM and PB). Standard risk patients expressed higher WT1 than high risk patients (P<0.0001 for both BM and PB). We did not find any correlation between WT1 level and age, sex, d15 treatment response and relapse-free or overall survival. *Conclusions.* In contrast to studies in mostly adult AML, we demonstrate no prognostic significance of WT1 expression at diagnosis of paediatric AML. Based on this representative group of patients we can conclude that PB samples are suitable for detection of WT1 expression. Moreover, the more significant difference between WT1 level detected in patients' samples and the level found in normal PB suggests that the peripheral blood can

provide more useful information on MRD in childhood AML.

THE PRESENCE OF P-GLYCOPROTEIN (MDR1) AFFECTS THE ABILITY OF AML PATIENTS TO ACHIEVE COMPLETE REMISSION; RESULTS OF A METAANALYSIS OF THE LITERATURE

A Lundberg,[1] A Ajami,[1] JP Marie[2]

[1]*Antisoma Inc, Cambridge, USA;* [2]*Hopital DIEU departement d'hematologie et d'oncologie Clinique, Paris, France*

Background and Aims. The expression of P-gp is highly prevalent in acute myeloid leukemia (AML). Current treatment options, including anthracyclines and anthracenediones, are substrates for P-gp. A meta-analysis was carried out to evaluate the influence of P-gp on treatment outcome in AML. *Methods.* Studies investigating P-gp (function and/or protein and/or mRNA) in AML and reporting the relevant outcomes (in particular, complete remission [CR]) were considered for this meta analysis. Only patients diagnosed with AML, and who either proceeded to treatment with anthracycline drugs or mitoxantrone, or who had previously been treated with anthracyclines or mitoxantrone, were eligible to be included in the meta-analysis. The primary analysis population for the meta-analysis was the Evaluable Population (EP), that is, all patients from included studies whose P-gp status was known. Studies for inclusion in the meta-analysis were identified in a thorough literature search, including the PubMed database, using a pre-specified search algorithm. The incidence of P-gp was tabulated by publication and overall. The odds ratio (OD) for CR (positive versus negative P-gp status) was tabulated by publication with 95% confidence interval (CI). *Results.* 74 studies were included in the analysis. Odds ratios could be calculated from 55 studies which provided 4549 patients evaluable for both CR and P-gp status. The median CR rate across all studies was 65%; CR rates were 78% in Pgp- and 47% in Pgp+ patients. Of all 55 publications, 49 gave OD<1, including 31 with statistical significance. Of the 6 publications which gave OD>1, none reached statistical significance. The overall odds-ratio for CR (positive versus negative P-gp status) was 0.257 (95% CI, 0.200-0.329). *Conclusions.* CR is much less likely to occur in patients with P-gp expression. These patients should be considered for treatment options that are unaffected by P-gp.

IN ADDITION TO GRANULOPOIESIS, HUMAN BONE MARROW ADIPOCYTES INHIBIT ALSO ERYTHROPOIESIS THROUGH CELL-CELL CONTACT BUT INDEPENDENTLY OF NEUROPILIN-1

Z Belaid,[1] Y Lepelletier,[2] A Beaulieu,[3] G Courtois,[2] A Thiry,[3] A Colige,[1] MP Defresne,[4] O Hermine[5]

Background. Fat cells are heterogeneously present in the bone marrow (BM) and replace hematopoietic cells in BM failure disorders such as aplastic anemia. There is growing evidences showing that bone marrow adipocytes play an active role in the regulation of hematopoiesis. Adipocytes are the main stromal cells in femoral bone marrow. With age, their number increases in the bone marrow cavity, and simultaneously, erythropoiesis and granulopoiesis decrease. In our previous study we demonstrated that human bone marrow adipocytes block granulopoiesis through inhibition of G-CSF production by a mechanism involving direct cell-cell contact and neuropilin-1. *Aim.* The aim of this study was to investigate whether or not adipocytes inhibit erythropoiesis and if so by which mechanism. Material and *Methods.* Adipocytes and $CD34^+$ were isolated from femoral bone marrow and iliac crest aspirate obtained from patients undergoing hip surgery. The ethical committee and donor's consents are obtained. Adipocytes and $CD34^+$ were co-cultured either in direct cell-cell contact or in absence of cell contact using 0.4 µm transwell chamber leading only to culture medium exchanges. The effect of adipocytes on $CD34^+$ differentiation is assessed in the absence of exogenous cytokine except for erythropoietin (Epo) (2UI/mL) for erythropoiesis. Neuropilin-1 was neutralized by an increased amount of a polyclonal antibody (0-20 µg/mL). Co-cultures were stopped after one to five weeks. Medium were collected for cytokine production by ELISA analysis, and erythropoiesis was evaluated by May-Grünwald Giemsa staining of cytospin and glycophorin-A (GPA) detection by flow cytometry analysis. Experiments were also performed *in vivo* by engrafting $CD34^+$ and adipocytes into the kidney capsule of NOD/SCID mice. *Results.* Analysis of *in vitro* co-cultures and *in vivo* transplantation of Adipocyte and $CD34^+$ cells in NOD/SCID mice led to macrophages (Mo) and dendritic cells (DC) differentiation. Likewise, Adipocytes produced SCF, M-CSF and GM-CSF. Adipocytes established cell-cell contacts with Mo, which were not critical for their differentiation since in transwell assays M-CSF was produced and Mo were also obtained. In contrast, adipocytes impaired erythopoiesis even in the presence of high dose of Epo whereas granulopoiesis inhibition was restored by the addition of G-CSF. In transwell assays erythropoiesis and granulopoieis concomitantly to G-CSF production were restored. We postulated that NP-1 could be involved in this inhibition since: 1) NP-1 is differentially expressed between hematopoietic iliac crest BM (rich in hematopoietic cell and weakly NP-1 positive) and femoral BM (poor in hematopoietic cells and highly NP-1 positive); 2) the expression of NP-1 increased in adipocytes and $CD34^+$ co-cultures; 3) the role of NP-1 in the modulation of cytokine production including Tpo and Flt-3 ligand by stromal cells previously reported and 4) NP-1 plays a role in various cell-cell contact systems. In adipocytes and $CD34^+$ co-cultures, NP-1 neutralization led to G-CSF production and granulopoiesis restoration but has no impact on erythropoiesis inhibition even in presence of high dose of Epo. *Conclusions.* Bone marrow adipocytes block both erythropoisis and granulopoiesis by two different mechanisms. Full understanding of these mechanisms may provide new targeted therapies in bone marrow failure including aplastic anemia.

PROFILING OF MICRORNA EXPRESSION IN PURIFIED HEMATOPOIETIC POPULATIONS AND IN SINGLE CELLS

F Kuchenbauer,[1] O Petriv,[2] A Delaney,[3] V Lecault,[4] A White,[2] D Kent,[5] L Marmolejo,[5] M Heuser,[6] T Berg,[5] M Copley,[5] J Ruschmann,[5] S Sekulovic,[5] F Antignano,[5] E Kuroda,[5] V Ho,[5] C Benz,[5] T Halim,[5] V Giambra,[5] G Krystal,[5] C Eaves,[5] F Takei,[5] A Weng,[5] J Piret,[7] M Marra,[3] R Humphries,[5] C Hansen[4]

[1]University Ulm, Ulm, Germany; [2]Center for High-Throughput-Biology, Vancouver, Canada; [3]Genome Science Centre, Vancouver, Germany; [4]Department of Physics and Astronomy, Vancouver, Canada; [5]Terry Fox Laboratory, Vancouver, Canada; [6]Hannover Medical School, Hannover, Germany; [7]Michael Smith Laboratories, Vancouver, Canada

Background. The hematopoietic system is comprised of a large number of highly specialized cell types that occupy distinct niches and which perform a diversity of functions ranging from innate immune response to oxygen transport. All these cell types are thought to be derived from a common stem cell and represent a hierarchal tree of differentiation. microRNAs (miRNAs) are critical players in orchestrating this differentiation. Due primarily to technical limitations in the analysis of limited cell populations the program of miRNA expression across the hematopoietic tree is largely unknown. *Aims/Methods*. Here we report the development of a microfluidic RT-qPCR approach for global miRNA profiling in limited populations and apply this to expression analysis of 27 distinct cell populations from the murine hematopoietic system. Expression of 288 miRNAs in each population was measured in multiple replicates for a total of over 80,000 RT-qPCR assays using microfluidic qPCR arrays (Fluidigm Biomark™ Dynamic Array). Using synthetic miRNA standards the sensitivity and efficiency of each assay was calibrated to allow for accurate comparison of expression across species and populations. In addition we show this technique is capable of measuring up to 12 miRNA species at single-cell resolution. *Results.* We demonstrate that global miRNA profiling of the murine hematopoietic tree allows for direct and independent reconstruction of the known hierarchal relationships. We further find that the number of miRNA species expressed in a cell population is not correlated with differentiation state and that miRNA expression patterns in stem cell and progenitor populations are closely related with major reprogramming upon commitment to a single lineage. Single cell measurements further show that miRNA expression levels are tightly regulated within highly purified populations, suggesting that miRNA may be suitable biomarkers for assessing heterogeneity in a given population. *Summary/Conclusions.* Taken together, we show that miRNA expression patterns determine the differentiation state of a hematopoietic cell as well as its cellular identity. We could not identify a stem cell specific miRNA, but multiple differentially expressed miRNAs. Our findings as well as our novel approach to minimize method-induced biases provide the basis to unravel the role of miRNAs in stem cells in particular and hematopoiesis in general.

DOWN-REGULATION OF THE RUNX1-TARGET GENE NR4A3 CONTRIBUTES TO THE PRELEUKEMIC STATE IN FAMILIAL PLATELET DISORDER/ACUTE MYELOGENOUS LEUKEMIA

D Bluteau,[1] L Gilles,[2] R Favier,[2] W Vainchenker,[2] H Raslova[2]

[1]INSERM, Villejuif, France; [2]INSERM U1009, Villejuif, France

RUNX1 (AML1) encodes a DNA binding α-subunit of the core binding factor (CBF), a heterodimeric transcription factor. RUNX1 is a master regulatory gene in hematopoiesis and its disruption, most frequently by chromosomal translocations, is one of the most common aberrations in acute leukemias. Inactivating or dominant-negative mutations in the RUNX1 gene have been also identified, e.g. in pedigrees of familial platelet disorders with a variable propensity to develop acute myeloid leukemia (FPD/AML) 1. We performed a comparative analysis of hematopoietic stem cells in two FPD/AML pedigrees with distinct RUNX1 germ line mutations, i.e. the R139stop in a pedigree without AML and the R174Q mutation in a pedigree with AML. R174Q mutation induced a marked increase in the clonogenic potential of immature $CD34^+CD38^-$ progenitors, which demonstrated some self-renewal capacities, a property that lack R139stop progenitors. This increased proliferation correlated with a profound reduction in the expression of NR4A3, a gene previously involved in leukemia development. Furthermore we demonstrated that NR4A3 was a direct target of RUNX1 and that restoration of NR4A3 expression partially reduced the clonogenic potential of patient progenitors. We propose that the down-regulation of NR4A3 contributes to establishing the preleukemic state in RUNX1 mutated hematopoietic progenitors.

[1]Hopital Saint-Louis, Paris, France; [2]Hopital Saint-Louis, Inserm UMR 940, Paris, France; [3]IGBMC, INSERM U596; CNRS UMR 7104; Université de Strasbourg, Illkirch, France; [4]Hopital Robert Debre, Paris, France; [5]Universite de Franche Comte, Besançon, France; [6]Hopital Avicenne, Service d'Hematologie, Bobigny, France

Background. Granulopoiesis is under the control of cytokines and their receptors but also of intracellular transcription factors aimed at regulating specific gene expression along the differentiation. Retinoic Acid regulates the expression of target genes through the binding of its specific receptors (RARs) and the recruitment of Histone Acetyl transferases (HAT) such as CPB/P300 on the promoter of these genes leading to chromatin remodelling. The presence of the PML-RARα fusion protein in Acute Promyelocytic Leukemia (APL) cells leads to differentiation blockade which can be overcome by therapeutic concentrations of ATRA. However, ATRA resistance may occur in case of mutations in the ligand binding domain of PML-RARα as in the UF-1 cell line. *Aims.* We took advantage of the UF-1 cell line RA resistant model to analyse the potential role of cytokine activated signalling pathways such as MAP Kinases to identify key steps that could enhance RA induced granulocytic differentiation. *Methods.* RA resistant UF-1 and RA responsive NB4 cells were used. Differentiation was studied by CD11b and CD11c expression and by oxydo reduction analysis using the NBT test. RA target genes expression was analysed by qRT-PCR. Presence of RA receptors, HAT proteins and acetylated histones on the promoter regions of RA target genes was analysed by ChIP experiments. *Results.* UF-1 cells treated with G-CSF and RA but not G-CSF alone were able to differentiate similarly to the NB4 cells treated by RA alone. G-CSF allowed to restore RA transcriptional activity as the expression of RA target gene such as RARα2 and RARβ2 was reinduced. Also, the recruitment of RARα, CBP/P300 and acetylated histones H3 and H4 in RA activated promoter regions were restored in UF-1 cells 1 hour after double treatment to a level similar to NB4 cells treated by RA alone. After RA treatment we observed in NB4 cells, but also in UF-1 cells, an early activation of the p38MAPK pathway concomitant of PML-RARα and RARα phosphorylation. It is likely that p38MAPK response is not altered in RA resistant cells. Furthermore, G-CSF did not modify the p38MAPK response to RA in UF-1 cells. Then we focused on the MEK-ERK1/2 pathway because G-CSF induced a strong phosphorylation of p42/p44 ERK1/2 and the specific MEK inhibitor UO126 completely abrogated the differentiation of UF-1 cells treated by G-CSF and RA. This was confirmed using siRNA directed to p42 and p44. The MEK-ERK pathway was involved in the regulation of RA transcriptional activity as a pretreatment by UO126 totally abolished the reinduction of RA target genes by the double treatment. Furthermore, the RA + G-CSF induced recruitments of the transcription factor RARα CBP/P300 and acetylated histones H3 and H4 at RA target genes promoter were strongly antagonised. *Conclusions.* These results demonstrate that specific cytokine activated pathways can participate in the regulation of nuclear receptor activity and chromatin remodelling. We identified the MEK-ERK pathway as specifically involved in the enhancement of RA induced granulocytic differentiation. This represents a new potential target to extend differentiating therapy to RA resistant AML.

GATA-1 MEDIATES PIGM TRANSCRIPTION IN IGD AND NORMAL ERYTHROID TISSUES

J Costa,[1] M Nolasco,[1] G Silva,[1] M Layton,[2] A Almeida,[1] A Karadimitris[2]

[1]Instituto Português de Oncologia Francisco Gentil de Lisboa, Lisboa, Portugal; [2]Imperial College London, Hammersmith Hospital, London, UK

Background. Inherited glycosylphosphatidylinositol (GPI) deficiency (IGD) is characterised by thrombosis and epilepsy but minimal hemol-

ysis; by contrast, intravascular hemolysis is a major feature of acquired GPI deficiency, i.e., paroxysmal nocturnal hemoglobinuria. IGD is caused by a -270C>G mutation that disrupts binding of the transcription factor (TF) Sp1 to the core promoter of the mannosyltransferase-encoding gene PIGM. In IGD patients, GPI expression in blood cells is variable: for example, while GPI synthesis in granulocytes is severely deficient, it is nearly normal in erythrocytes, explaining thus the absence of significant intravascular hemolysis in IGD and suggesting an erythroid-specific transcriptional regulation of PIGM. *Aims.* We tested the hypothesis that the erythroid/megakaryocytic-specific TF GATA-1 is a critical regulator of PIGM transcription and can rescue GPI biosynthesis even in the presence of the C>G mutation. *Methods and Results.* Bioinformatic analysis predicted the existence of three GATA-1 binding motifs - S1, S2 and S3- in the promoter of PIGM. Consistent with a role of GATA-1 in the transcriptional regulation of PIGM, promoter activity as assessed by reporter assays in which luciferase activity is driven by a 2Kb wild type (WT) PIGM promoter construct was higher in the erythroid K562 than in the myeloid HL60 cells. Reporter activity was proportionally increased for both a 2Kb (WT) or c>g mutated (Mut) construct when co-transfected with GATA-1. This effect was abrogated when shorter constructs not containing the predicted GATA-1 motifs were used, suggesting GATA-1 acts through these distally located motifs. In support of this, reporter assays using promoters with the predicted motifs inactivated individually or in combination suggested that all 3 GATA-1 motifs are active; more so the proximal S1 motif which supported transcription even in the presence of the c>g mutation. By contrast, the distal S2 &S3 motifs appeared to require an intact Sp1 site to activate transcription. Taken together these data suggest that GATA-1 acts on the PIGM promoter through Sp1-dependent and -independent mechanisms. The functional significance of S1-3 motifs as GATA-1 binding sites was also confirmed *in vivo* by chromatin immunoprecipitation (ChIP) assays in K562 cells. Further underpinning its functional significance as an important transcriptional regulator of PIGM in erythroid cells, reduction of GATA-1 protein levels by 70% in K562 cells using siRNA was associated with a 30% reduction in PIGM mRNA as compared to scramble control while enforced expression of GATA-1 in the GATA-1-negative patient B cells led to a partial correction of the GPI deficient phenotype as assessed by flow cytometry. *Conclusions.* These results indicate that GATA-1 is critical for the tissue-specific transcriptional control of PIGM in erythroid cells and it can support sufficient transcriptional activity even of the mutated PIGM promoter explaining thus the absence of significant haemolysis in IGD.

THE EVI1 TRANSCRIPTION FACTOR REPRESSES ITS OWN TRANSCRIPTION IN HUMAN CELLS

M Maicas, I Vázquez, MA García-Sánchez, N Marcotegui, C Ciraqui, E Guruceaga, M Alonso, A Conchillo, MD Odero

CIMA, University of Navarra, Pamplona, Spain

The EVI1 gene (3q26) codes for a transcription factor with important roles in development and leukemogenesis. At present, 3q26 rearrangements are the only known mechanism that leads to EVI1 overexpression; however, transcriptional activation of this gene has been reported in about 9-20% AML patients with no 3q26 abnormalities, and is also associated with an unfavorable outcome. Our aim was to analyze the promoter region of EVI1 to look for transcription factors that could regulate its transcription. *Material and Methods.* Bioinformatic analysis to identify hypothetical transcription factors binding sites in the genome, and validation by chromatin immunoprecipitation (ChIP) and luciferase assays. *Results.* Bioinformatic analysis within the 3,000bp upstream region of the TSS of the EVI1 gene using MATCH and TFSEARCH softwares identified several transcription factors involved in hematopoiesis, including Evi1. This result would suggest the possibility of Evi1 being a regulator of its own expression. ChIP assays confirmed that Evi1 binds to 3 of the 8 DNA predicted sites. To identify if Evi1 is directly responsible for its promoter activity, we generated seven constructs comprising different promoter regions. Cotransfection with EVI1 showed reduced luciferase activity in a dose-dependent way, suggesting that Evi1 acts as a repressor transcription factor of its own expression. To find out whether Evi1 itself regulates its transcription or other factors were required, we produced promoter constructs carrying mutations in a single or in several EVI1 binding sites. None of these constructs affected the luciferase activity. In spite of the results, the dose-dependent effect observed prompted us to investigate the putative cooperation between different regions among the promoter. We generated serial deletions in the reporter construct carrying different EVI1-binding sites. This approach allowed us to identify a functional region of 318pb in the proximal promoter region of EVI1, where there are several binding sites for transcription factors with important roles in hematopoiesis. Taken together, these results would suggest that Evi1 represses its own expression, probably through the interaction with other proteins. Further studies are in progress to identify these putative transcription factors.

THE EFFECT OF NILOTINIB AND DASATINIB ON TELOMERASE ACTIVITY AND REGULATION IN K562 CELLS

S Shapira,[1] G Granot,[2] R Mor-Tzuntz,[2] P Raanani,[3] O Uziel,[2] M Lahav,[4] O, Shpilberg[3]

[1]Felsenstein Medical Research Center, Petah Tikva, Israel; [2]Felsenstein Medical Research Center, Beilinson Hospital, Tel Aviv University, Petah Tikva, Israel; [3]Felsenstein Medical Research Center and The Institute of Hematology, Petah Tikva, Israel; [4]Felsenstein Medical Research Center, Medicine A, Beilinson Hospital, Petah Tikva, Israel

Background. The cytogenetic hallmark of chronic myeloid leukemia (CML) is the t[9;22] [q34;q11] translocation creating the BCR-ABL oncogene encoding for the BCR-ABL tyrosine kinase oncoprotein. BCR-ABL activity leads to uncontrolled cell proliferation and reduced apoptosis, resulting in malignant expansion of bone marrow stem cells. Since CML is caused by this distinct genetic lesion, it was possible to design an effective targeted molecular therapy. Imatinib is a tyrosine kinase inhibitor selective for BCR-ABL indicated for treatment of CML. Despite significant hematologic and cytogenetic responses, resistance to imatinib may occur. In order to override resistance, 2nd-generation tyrosine kinase inhibitors (TKIs), such as nilotinib and dasatinib, were developed. The clinical activity of imatinib, nilotinib and dasatinib is attributed mainly to their kinase inhibitory effect. However, we have recently shown that imatinib significantly inhibits telomerase activity in K562 cells sensitive and resistant to imatinib and in CML patients. We further showed that telomerase inhibition in these cells is most likely due to downregulation of the AKT-signal transduction cascade (Exp Hematol 38:27-37, 2010). *Aims.* We hypothesize that similar to imatinib, the new TKIs target telomerase and the signaling pathways upstream of it. Our goals are to study the effects of nilotinib and dasatinib on telomerase activity and regulation at the transcriptional and post-translational levels in $BCR^{-}ABL^{+}$ (K562) and BCR-ABL- (HL60) myeloid cell lines and in CML patients. *Methods.* The effect of nilotinib and dasatinib on cell survival is assessed by WST-1 proliferation and FACS assays. Telomerase activity following exposure of the cells to the new TKIs is evaluated by the TRAP assay. The effect of these agents on telomerase regulation is measured by real-time PCR, Western blot, nuclear and cytoplasmic fractionation and chromatin immunoprecipitation assays. *Results.* We show that similar to imatinib, the new TKIs target telomerase and reduce its activity by ~90% in $BCR\text{-}ABL^{+}$ (K562) cells. Nilotinib and dasatinib also caused a reduction in telomerase activity in the $BCR\text{-}ABL^{-}$ cell line, HL60. We show that these agents exert their effect on telomerase in an indirect manner. Telomerase regulation involves transcriptional and post-translational steps. At the transcriptional level: The promoter of the catalytic subunit of telomerase, hTERT, contains Sp1 binding sites. Phosphorylated-Sp1 activates the hTERT promoter. At the post-translational level: Telomerase is active when phosphorylated by AKT, and inactive when dephosphorylated by protein phosphatase 2A (PP2A). We demonstrate that the reduction observed in telomerase activity is a result of transcriptional (90% reduction in hTERT mRNA expression) and post-translational (hTERT phosphorylation) modifications generated by these TKIs. *Summary/Conclusions.* Since telomerase is activated in ~90% of human tumors, it has become an extremely attractive target for new anticancer interventions. Our results demonstrate the ability of imatinib, nilotinib and dasatinib to inhibit telomerase activity in $BCR\text{-}ABL^{+}$ as well as in BCR-ABL- cell lines, implying that these agents inhibit telomerase activity in a BCR-ABL independent manner. Thus, this study shows that cells, known to be resistant to these agents with regards to their effect on BCR-ABL, could still be sensitive to their effect on other cellular components such as telomerase.

NOVEL MUTATIONS AT THE TNFRSF6 GENE IN SPANISH PATIENTS WITH AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME (ALPS)

O De La Calle-Martín,[1] L Martinez-Martinez,[1] C Gonzalez-Santesteban,[1] M Rubiales,[1] Y Barrios,[2] J Estella,[3] P Soler,[4] I Badell[1]

[1]Hospital de Sant Pau, Barcelona, Spain; [2]Hospital Universitario de Canarias, Tenerife, Spain; [3]Hospital Sant Joan de Deu, Barcelona, Spain; [4]Hospitals Vall d'Hebron, Barcelona, Spain

Background. The autoimmune lymphoproliferative syndrome (ALPS) is a genetic disorder of lymphocyte apoptosis. ALPS is characterized by childhood onset of lymphadenopathy, hepatosplenomegaly, autoimmune cytopenias, elevated (>1.5%) double negative T (DNT; CD3$^+$, TCRalpha-beta+, CD4-, CD8-) lymphocytes in peripheral blood and an increased risk of lymphoma. Most cases (>65%), known as ALPS Type Ia, are associated with dominant heterozygous germline mutations in the gene TNFRSF6 encoding the protein for CD95 (Fas). *Methods.* We studied 32 individuals from different Spanish Hospitals. Selected ALPS patients meet Clinical (lymphadenopathy, splenomegaly and/or cytopenias) and Laboratory (hypergammaglobulinemia and elevated DN T cells) criteria. TNFRSF6 gene was analized by DNA sequencing in all the patients. If there was found a splicing mutation, cDNA was also analised. In selected cases, where no TNFRSF6 mutation was found, TNFSF6 (Fas ligand) and CASP-10 (caspase-10) genes were evaluated by sequencing. *Results.* 26 patients (81%) were found to be heterozygous for a single TNFRSF6 mutation (ALPS Ia). Seven different alterations were identified affecting exons 2, 8 and 9. Four of these mutations were not previously described. The mutations include insertions, splicing defects, missense and nonsense mutations. The other 6 patients do not have any mutation in TNFRSF6, TNFSF6 or CASP-10 gene. Hence, they were classified as ALPS III. As compared to controls and healthy relatives bearing the same genetic alterations, ALPS Ia patients demonstrated significantly higher IL-10 and IgE serum levels. Those markers were also elevated in ALPS III patients but on a much less remarkable fashion, with one exception. That later case is a female child with ALPS and a severe clinical presentation, with very high IL-10, IgG, IgA and IgE levels. In this ALPS patient, mutations in TNFRSF6, TNFSF6, CASP-8, CASP-10, N-Ras and FADD genes have been excluded. *Conclusions.* The combination of elevated DNT counts (>1.5%) with increased IL10 and IgE serum levels in blood is strongly linked to the presence of a FAS mutation. This enables the targeting of patients with clinical features of ALPS to have a more directed evaluation particularly in regard to DNA sequencing for FAS mutations, and other apoptosis-related genes. Several novel FAS mutations were found in the Spanish patients.

BCR-ABL INDUCED TRANSFORMATION UNCOVERS A CRITICAL ROLE OF C-JUN IN VEGF REGULATION

C Schneckenleithner,[1] E Zebedin,[2] V Sexl,[2] K Kollmann,[2] R Ott,[2] R Scheicher,[2] L Kenner,[3] M Mayerhofer[1]

[1]Medical University Vienna, Vienna, Austria; [2]Medical Universtity Vienna, Department of Pharmacology, Vienna, Austria; [3]Ludwig Bolzmann Institute for Cancer Research, Vienna, Austria

Background. Dysregulation of AP-1 transcription factors is a frequent event in human cancer. The loss of the AP-1 family member JunB has been observed in human myeloid and B lymphoid leukaemia and is associated with a poor prognosis. In contrast, c-Jun is frequently overexpressed in human cancer and is considered a proto-oncogene. In particular, c-Jun has been shown to be involved in p53 mediated apoptosis. *Aim.* In this study, we have investigated the role of c-Jun for p185BCR-ABL induced leukemia. *Methods.* We therefore worked with p185BCR-ABL transformed c-junΔ/Δ CD19-CRE cell lines. To analyze tumor formation, we injected leukemic cells subcutaneously and intravenously into immuno-compromised mice. We used a pMSCV-c-Jun-puro based retrovirus and a murine VEGF-A construct to determine the interplay of these two proteins in leukemia/lymphoma. *Results.* Whereas previous studies have shown that the loss of JunB in leukemic cells accelerates disease progression, we could show that the lack of c-Jun is associated with increased disease latency. Both, leukemia and lymphoma formation is delayed. Interestingly, c-Jun deficient p185BCR-ABL transformed cells were not capable to form lymphomas over a certain size. Histological analysis of the tumor tissue revealed a drastically reduced vessel density in c-Jun deficient lymphomas accompanied by a central necrosis of the tumors. Accordingly, real time PCR experiments showed decreased VEGF levels in c-junΔ/Δ tumor cells when compared to control cells. Re-expression of VEGF in c-Jun deficient p185BCR-ABL transformed cells partially reverted the phenotype and resulted in an increased tumor size. *Conclusions.* Thereby our study identified c-Jun as a key regulator of VEGF synthesis in p185BCR-ABL transformed cells.

NITRIC OXIDE PRODUCTION BY BONE MARROW STROMAL CELLS REGULATES HEMATOPOIETIC PROGENITOR CELL SURVIVAL THROUGH ADHESIVE INTERACTIONS

D Jouni, Y Zhang, A Betems, C Hurtaud, M Wittner, V Joulin, F Louache

Institut Gustave Roussy, Inserm U1009, Villejuif, France

Nitric oxide (NO) is a small gaseous molecule with diverse roles including the regulation of cell proliferation, differentiation, apoptosis, adhesion and migration. NO is derived from L-arginine by the nitric oxide synthase (NOS) family of enzymes. At least three distinct NOS isoforms have been identified in mammalian cells including the endothelial (eNOS), neuronal (nNOS) and inducible (iNOS). Recently, we have shown that NO donors induce CXCR4 expression in human CD34 positive cells suggesting that NO production may regulate the migration and adhesion of hematopoietic progenitors. To determine the relevance of these findings and define the role of NO in the biology of hematopoietic progenitor cells, we first investigated NOS expression in hematopoietic and non-hematopoietic cells. Using quantitative reverse transcription-PCR analysis, we demonstrate that nNOS, and eNOS isoforms are highly expressed in Human Umbilical Vein Endothelial Cells (HUVEC) and osteoblastic cell lines, but there was no or low expression of these NOS in hematopoietic cells. In agreement with these analyses, we found large amounts of nitrite (a stable derivative of NO) in the culture medium of stromal MS5 (a cell line used in laboratories to support hematopoiesis) and osteoblasic (MG-63) cell lines. To determine the biologic effects of NO on hematopoietic progenitor cell survival, cord blood CD34$^+$ cells were cultured on MS5 cells in the presence/absence of NOS inhibitor (L-NAME) for three days, then hematopoietic progenitor numbers were determined by culture in a semi-solid medium and colonies were quantified. Treatment with L-NAME reduced colony number by 33, 42 and 54% with 10, 100 and 500 µM L-NAME concentrations, respectively. This effect is NO specific since the diminution of progenitor number was reverted by adding NO donor in the culture medium. To understand how NO can regulate hematopoiesis, we investigated its effect on CXCR4 and AML1(Runx1) expression. We found that inhibition of NO production by stromal cells results in diminution of CXCR4 and AML1 RNA messenger levels. To determine if the observed NO effects on hematopoiesis are related to adhesion, cultures were performed in transwell plates separating CD34$^+$ cells from MS5 cells. When CD34$^+$ cells were separated from stromal cells, L-NAME treatment did neither affect progenitor number nor AML1 expression. These results indicate that NO is produced by bone marrow stromal cells and regulates the survival of hematopoietic progenitor cells through a contact dependent pathway.

CDK6 AS TUMOR SUPPRESSOR OR PROMOTER - P16INK4A MAKES ALL THE DIFFERENCE

K Kollmann,[1] R Ott,[2] G Heller,[3] C Schneckenleithner,[2] W Warsch,[2] A Schmatz,[2] S Zoechbauer-Mueller,[3] L Kenner,[4] G Hoefler,[5] M Freissmuth,[2] M Malumbres,[6] V Sexl[2]

[1]Institute of Pharmacology, Vienna, Austria; [2]Medical University of Vienna, Institute of Pharmacology, Vienna, Austria; [3]Medical University of Vienna, Department of Medicine I, Vienna, Austria; [4]Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria; [5]Medical University of Graz, Department of Pathology, Graz, Austria; [6]Centro Nacional de Investigaciones Oncologicas, Cell Division and Cancer Group, Madrid, Spain

Background. Small molecular compounds directed against cell cycle kinases are currently developed and tested for their optimal clinical use to treat cancer in people. The kinase Cdk6 is expressed at high levels in lymphoid malignancies. *Aim.* We therefore studied the impact of Cdk6 for p185BCR-ABL and NPM-ALK driven tumorigenesis. *Methods.* We analyzed p185BCR-ABL and NPM-ALK driven lymphoma/leukemia in $Cdk6^{+/+}$ and $Cdk6^{-/-}$ mice. We used a pMSCV-Cdk6-puro based retrovirus to analyze the effect of Cdk6 over-expression in p185BCR-ABL transformed wild type cells *in vivo* and *in vitro*. Chromatin-immunoprecipitation showed the relation between Cdk6 and p16INK4a. The use of a pMSCV-Cdk6R31CΔC-puro and a pMSCV-Cdk6K43M-puro based retrovirus cleared the role of the C-terminus and the kinase activity of Cdk6 for p16INK4a regulation. We analyzed the protein levels of Cdk6 and p16INK4a in human B- and T-cell lymphoma tissue arrays by immunohistochemistry. *Results.* As anticipated, tumor formation was strongly delayed in a $Cdk6^{-/-}$ background due to a reduced proliferation of the transformed lymphoid cells. Surprisingly, a similar outcome was observed upon enforced Cdk6 expression in lymphoid tumor cells. p185BCR-ABL driven lymphoma/leukemia induced with decreased incidence and increased latency. This unexpected tumor suppressing property of Cdk6 was accounted to the finding that Cdk6 bound to the promoter of the tumor suppressor, p16INK4a and caused its expression in a kinase independent fashion. Studies of human B- and T-cell lymphomas confirmed an inverse relationship between Cdk6 and p16INK4a. *Summary/Conclusions.* Hence, a tumor promoting effect of elevated Cdk6 levels - as observed in lymphoid malignancies - required a disrupted p16INK4a expression. This insight is of major importance to anticipate and predict which patients will benefit from a treatment interfering with Cdk6.

ERYTHROPOIETIC EFFECTS OF IL-17: INVOLVEMENT OF MAPKS AND GATA TRANSCRIPTION FACTORS

A Krstic, J Kocic, S Mojsilovic, I Okic, V Ilic, V Cokic, JF Santibanez, G Jovcic, D Bugarski

Institute for Medical Research, Belgrade, Serbia

Background. Interleukin (IL)-17 is the founding member of the unique family of inflammatory cytokines, produced exclusively by newly defined Th17 cell subset. Particularly important for the role of IL-17 in host defense is its ability to link T-cell function and hematopoiesis through stimulation of granulopoiesis and neutrophil trafficking. However, as demonstrated in our previous studies, IL-17 also affects the cells of erythroid lineage stimulating development of early erythroid progenitors, BFU-E, but suppressing the growth of late stage erythroid progenitors, CFU-E, from normal murine bone marrow. *Aims.* Although we also revealed that at least part of *in vitro* IL-17 effect related to the inhibition of CFU-E is mediated by p38 MAPK phosphorylation, the mechanisms and signaling cascades underlying erythopoietic effects of IL-17 remained largely unknown. The aim of the present study was to investigate the involvement of other two members of MAPK family, JNK and ERK, as well as GATA hematopoietic transcriptional regulators, in IL-17-mediated effects on murine bone marrow erythropoietic progenitors. *Methods.* The contribution of JNK and ERK1/2 MAPKs to the effects of IL-17 on proliferation and differentiation of erythropoietic progenitors was examined by culturing murine bone marrow cells in methylcellulose with IL-17, in the presence or absence of specific pharmacological inhibitors of JNK and MEK1/2-ERK1/2 MAPK pathways. In addition, the influence of IL-17 on the expression of GATA-1, which is essential for terminal erythroid differentiation, and GATA-2, transcription factor involved in expanding primitive hematopoietic progenitors, was determined in murine bone marrow cells by immunoblotting. *Results.* The obtained results demonstrating that pharmacological inhibitor of the MEK1/2-ERK1/2, PD98059, abrogated the growth inhibitory effect of IL-17 on CFU-E, indicated the role of MEK/ERK MAPK pathway in IL-17-induced inhibition of CFU-E growth. Besides, for the IL-17-induced stimulation of BFU-E progenitor cells, the involvement of JNK and/or MEK/ERK MAPK pathways was suggested, since pharmacological inhibitors of both JNK and MEK1/2-ERK1/2 MAPKs, SP600125 and PD98059 respectively, decreased the growth stimulatory effect of IL-17 on BFU-E. Furthermore, enhanced expression level of GATA-1 and no effect on GATA-2 was observed in murine bone marrow cells after IL-17 stimulation. Also, no evidence for JNK and ERK MAPK signaling in IL-17-mediated effects on GATA-1 was demonstrated, since in both unstimulated and IL-17-stimulated bone marrow cells, JNK and MEK1/2-ERK1/2 inhibitors enhanced GATA-1 expression, implicating the role for these MAPKs in GATA-1 downregulation. *Conclusions.* These observations pointed to the involvement of JNK and ERK MAPKs in IL-17-induced effects on both early and late stage erythroid progenitors, BFU-E and CFU-E, from murine bone marrow. Moreover, the results concerning transcription factors evidenced a role for GATA-1 in erythropoietic activity of IL-17, which, in light of previous data demonstrating that overexpression of GATA-1 inhibits differentiation of erythroid cells, could be related to IL-17-mediated inhibition of CFU-E growth.

CPG OLIGONUCLEOTIDE AND INTERLEUKIN-2 STIMULATION REVEAL UNEXPECTED PROGNOSTICALLY RELEVANT CHROMOSOMAL LESIONS IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL)

P Bernasconi,[1] M Boni,[2] R Zappatore,[2] I Dambruoso,[2] I Giardini,[2] PM Cavigliano,[2] B Rocca,[2] C Calvello,[2] M Caresana,[2] E Orlandi,[3] M Lazzarino[2]

[1]Fondazione IRRCS Policlinico San Matteo, Pavia, Italy; [2]Divisione di Ematologia Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [3]Divisione di Ematologia, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Current evidence suggests that the CpG oligonucleotide (ODN) in combination with interleukin-2 (IL-2) (ODN+IL-2) can increase CC detection rate of chromosomal abnormalities and complement FISH results. Based on these findings, the present study analysed the results obtained by the ODN+IL2 combination, pokeweed mitogen (PKWM) and iFISH in seventy-two B-CLL diagnosed at our Institution between January 2007 and December 2009. Moreover, it evaluated the existence of any possible correlations between chromosomal findings and clinical outcome. There were forty-five males and twenty-seven females with a median age of 62 years (range 42-83). According to Binet, forty-one patients (56.1%) were considered as stage A, twenty-four (32.8%) as stage B and eight (10.9%) as stage C. PKWM revealed clonal abnormalities in nine patients (12.3%) and did not yield any mitotic figure in eight patients (10.9%), whereas the ODN+IL-2 combination revealed clonal defects in 59% of patients and did not provide any mitotic figures in only three patients (4.1%). In five patients both cultures demonstrated the same clonal defect in a similar percentage of metaphases. In addition, the ODN+IL-2 combination revealed a complex karyotype (≥ three defects) in eight patients (10.9%), two chromosomal defects in eight patients (10.9%) (including four with the rearrangement of band 17p13 and two with the rearrangement of band 11q13), a +12 in ten patients (13.6%) and various translocations in eleven patients (15.0%). iFISH was carried out with the B-CLL FISH probe panel (Vysis, Downers Grove, IL, USA) and revealed clonal abnormalities in 67.1% of patients. The most common defects were: 13q- (46.5% of patients), +12 (10.9% of patients), 11q- (6.8% of patients) and 17p- (5.4% of patients). Two patients with a normal FISH pattern presented a +12 in ODN+IL-2 cell cultures and all the four with the loss of one p53 signal on iFISH showed structural defects of band 17p13 with the ODN+IL2 combination. In addition, when the thirty-four patients with a 13q- on iFISH were investigated with the ODN+IL2 combination, fourteen (41.1%) presented a normal chromosomal pattern, eight (23.5%) another defect, six (17.6%) a complex karyotype, three (8.8%) a 13q deletion and three no *Results.* From a clinical point of view, all the eight patients who showed a complex karyotype were classified as stage C; among the eleven patients who harboured chromosomal translocations, seven were classified as stage B and four as stage A; all the other patients were classified as stage A. In conclusion, i) the results provided by the ODN+IL2 combination and iFISH are complementary since the former examines the entire karyotype and the second specific chromosomal regions; ii) due to their sub-microscopic nature, 13q- and 11q- were rarely revealed by the ODN+IL-2 combination which may probably stimulate a minor +12 clonal cell population as confirmed by the lack of trisomic nuclei on iFISH; iii) the loss of one p53 signal on iFISH is frequently due to an unbalanced rearrangement; iv) complex karyotypes and chromosomal translocations are associated with an advanced Binet stage and 13q deletions if included in a complex karyotype lose their favourable prognostic impact.

0094

INCIDENCE OF CYTOGENETIC ABNORMALITIES IN NEWLY DIAGNOSED BINET STAGE A B-CLL AND RELATIONSHIP WITH PROGNOSTIC BIOMARKERS: UPDATED RESULTS ON 319 PATIENTS INCLUDED IN THE PROSPECTIVE O-CLL1 GISL STUDY

Background. Biologic risk factors such as immunoglobulin variable heavy chain (IgVH) gene mutation status and CD38 and ZAP-70 expression levels, along with genomic aberrations, have been identified in B-CLL and their prognostic impact has been intensively evaluated in the disease. *Aims.* We investigated the incidence of the known major cytogenetic alterations (+12 and 13q14, 17p13, 11q23 deletions) in Binet A B-CLL patients included in the prospective multicenter O-CLL1 GISL trial. The study was performed by FISH in 319 out of 377 patients enrolled to date. *Methods.* Molecular markers characterization and FISH analyses were previously reported (Cutrona et al. Haematologica, 2008; Fabris et al. GCC, 2008). *Results.* At least one abnormality was found in 209/319 (65.5%) cases. The most frequent abnormality was del(13)(q14), which was detected in 160 cases (50%) followed by +12 (42/319, 13 2%) (one case harboring 17p13 deletion), del(17)(p13) (8/319, 2.5%) and del(11)(q23) (18/319, 5.6%). 13q14 deletion was found as a sole abnormality in 142 (44.5%) patients; in the remaining cases, it was combined with +12 (3 pts) and 17p13 (4 pts) or 11q23 deletions (11 pts). The 13q deletion was found as a monoallelic deletion in 127/160 (79.3%); in the remaining 33 cases the presence of a biallelic deletion was found in >20% of interphase nuclei. No acquisition of new cytogenetic aberrations was evidenced among the 13 patients developing progressive disease (range, 6 to32 months; median, 20 months). In only one case, the proportion of nuclei with 17p13 and 13q14 deletions increased from the time of diagnosis (from 33% to 92%). Biomarkers data were available in all of the patients. CD38 percentages (mean value±sem) were 9.3±1.5, 16.2±2.0, 53.4±5.4, 23.3±1.1,47.3±13.6, 35.1±10.3 for del(13)(q14), normal karyotype, +12, del(11)(q23), del(17)(p13) and multiple alterations, respectively (P<0.0001). The percentages of IgVH mutations significantly correlated with cytogenetic alterations; namely, 5.5±0.3 for cases with del(13)(q14), 4.6±0.4 for normal karyotype, 2.6±0.5 for +12, 0.3±0.2 for del(11)(q23), 1.9±1.1 for del(17)(p13) and 1.2±0.6 for multiple alterations

(P<0.0001). Similarly, a significant correlation was found for ZAP-70 expression: namely 33.5±1.8 for cases with del(13)(q14), 38.6±2.2 for normal karyotype, 47.5±3.5 for +12, 71.4±8.2 for del(11)(q22), 38.3±12.5 for del(17)(p13) and 46.0±6.1 multiple alterations (P<0.0001). Finally, cytogenetic abnormalities were clustered in 3 risk groups [i.e. low del(13)(q14) and normal; intermediate (+12); and high risk del(11)(q23) and del(17)(p13)] and correlated with a scoring system in which patients were stratified in 4 different groups according to the absence (group 0) or presence of 1 (group 1), 2 (group 2) or 3 (group 3) biomarkers (Morabito et al., BJH, 2009,). Notably, 154/162 cases scoring 0, gathered in the low FISH group, whereas 16/20 high FISH risk cases clustered in scoring 2-3 (P<0.0001). *Conclusions.* Our data indicate that cytogenetic abnormalities predicting unfavorable prognosis show a relatively low incidence in newly diagnosed Binet stage A B-CLL patients and are significantly associated with negative prognostic biomarkers predictive of disease progression. Furthermore, preliminary results in a limited number of cases indicate that the acquisition of new abnormalities seem to be an infrequent event during disease progression.

Background. TP53 is a transcription factor that plays pivotal role in the process of DNA repair and apoptosis. In 10-20% of patients with chronic lymphocytic leukemia (CLL) the TP53 pathway is affected by genomic TP53 mutation, aberrant mRNA splicing or by dysfunction of cooperating protein partners. It has been reported that in CLL, chemotherapy induces evolution of TP53 mutated subclones that might lead to the progression of the disease. In our study (from January 2005 to December 2009), we have analyzed TP53 mutation status in 2,435 consecutive CLL samples, including 1,287 diagnostic samples and 1,148 samples during the follow-up. The follow-up comprised 181 CLL patients, for whom clone-specific assays to monitor minimal residual disease have been prepared. *Aims.* The aim of the study was to address mutational status of TP53 gene, modes of inactivation/modulation of the TP53 gene and the possibility of clonal evolution of TP53 mutated subclones in a large cohort of 2,435 CLL patients. *Methods.* At the time of diagnosis, mutational status of TP53 gene was determined using direct sequencing and functional assay FASAY, as described elsewhere.[1] Assays to monitor minimal residual disease (MRD) have been prepared based on the sequence of clonal IgVH rearrangement(s) identified at the time of diagnosis, as described in.[2] Nine temperature-sensitive mutants TP53 and a novel splicing variant delta ex6 were molecularly cloned and characterized.[3] *Results.* In a cohort of 1,287 diagnostic CLL samples, we have identified 237 TP53 variants (18.4%), including point mutations, insertions, deletions, temperature-sensitive mutations and aberrant splicing variants (Table 1).

Table 1 shows the list of TP53 mutants, identified in our cohort of 1,287 diagnostic CLL samples, which in vitro biological properties have been tested using functional assay FASAY. Temperature-sensitive mutants are highlighted in blue.

227 TP53 variants have fully penetrant transactivation-defective mutant phenotype *in vitro*. Additional 10 mutants display temperature-sensitive properties with mutant phenotype at permissive conditions and wild type phenotype at non-permissive conditions. In 1,148 follow-up samples analyzed for the MRD level in 181 CLL patients undergoing chemo/immunotherapy or bone marrow transplant we have never observed clonal evolution, contrary to the data described in.[4] *Summary/Conclusions.* TP53 mutations/variants are diverse and affect most of the coding sequence of TP53. Though there are few known hot-spot mutations with proven biological functions, there is still a large number of TP53 mutations, which biological functions have not been assessed previously. The majority of TP53 mutations/variants are activating, but some of them have unusual characteristics (e.g. temperature sensitivity), or might represent aberrant splicing isoforms expressed at variable levels over the time. Moreover, results based on 1,148 follow-up CLL samples indicate that evolution of mutated TP53 subclones triggered by chemotherapy does not seem to play a major role in CLL progression.

TP53 GENE SEQUENCING IDENTIFIES A PECULIAR MUTATION PROFILE AND CORRELATION WITH P53 PROTEIN DYSFUNCTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS AT DIFFERENT PHASES OF THE DISEASE

M Marinelli, N Peragine, S Santangelo, EM Ghia, V Di Maio, I Del Giudice, F Mauro, S Tavolaro, A Guarini, R Foà

Sapienza University of Rome, Roma, Italy

Background. Several biological and genetic properties in chronic lymphocytic leukemia (CLL) patients have an important prognostic value for the stratification into risk categories. TP53 mutations, as well as 17p deletions, make the disease particularly aggressive and chemoresistant. *Aims.* To evaluate the incidence and profile of TP53 mutations in CLL patients at different phases of the disease and assess their correlations with specific p53 functional alterations. *Methods.* We investigated 446 CLL patients: 158 at diagnosis, 234 at progression and 54 with chemoresistant disease. Screening for TP53 mutations (exons 4-9) was performed by sequencing. p53 function was examined by immunoblotting on CLL cells, after exposure to ionizing radiation (IR). IR-induced apoptosis was verified using annexin/propidium iodide staining and flow cytometry analysis. *Results.* We found an overall incidence of TP53 mutations of 8% (36/446 patients) with the subsequent distribution: 4/158 (2.5%) patients at diagnosis, 23/234 (9.8%) patients with progressive disease and 9/54 (16.7%) chemoresistant patients. In all groups, TP53 mutations were mainly missense mutations in exons 5-8, with the highest incidence in exon 8, but we also observed 4 nonsense mutations and 4 microdeletions exclusively affecting progressive and chemoresistant patients. Among 37 mutations, 25 (67.6%) showed a heterozygous and 12 (32.4%) a homozygous status. In particular, 25/33 (75.7%) missense mutations were transitions and 8 of 33 (24.3%) were transversions. Eighty-two CLL patients were examined for p53 functionality. Sixty patients had a normal p53 response to IR. Apoptosis was significantly (P=0.07) higher after IR (53.2%±15.2 vs 74.6%±14.1). All these patients showed a wild type TP53 gene sequence. Twenty-two patients, 1/12 at diagnosis, 12/51 with progressive and 9/19 with chemoresistant CLL, showed an impaired p53 response to IR. In 12/22 (54.5%) p53 was present and increased after IR (type I dysfunction); in 9/22 (41%) p53 was present but did not increase after IR (type II dysfunction) and in 1/22 (4.5%) p53 was undetectable also after IR (type III dysfunction). TP53 mutations were detected in all dysfunctional samples except for 5 chemoresistant CLL. In these latter cases, other potential causes of p53 dysfunction are under investigation. In 7/9 type I dysfunction was associated with heterozygous missense TP53 mutations in the DNA binding domain (exons 5-8). Six of 7 patients with type II dysfunction showed missense mutations but mainly in homozygous status. Furthermore, type II dysfunction was associated with TP53 mutations affecting not only exons 6 and 8 but also exons 4 and 9; no mutations within exon 7 were observed. Finally, type III response was associated with a nonsense homozygous mutation that introduced a

stop codon at position 213 of exon 6. Interestingly, type I dysfunctions were partially resistant to radiation-induced killing (40.4±13.9% pre- vs 50.5±16.9% post-IR), while type II and III dysfunctions were completely radioresistant (63.4±28.2% pre- vs 62.9±28.3% post-IR). *Conclusions.* We showed the highest incidence, as well as the more complex TP53 mutations and dysfunctions, among progressive and chemoresistant CLL patients. The association between p53 dysfunctions and TP53 mutations, observed in this study, may help to improve the characterization of TP53 mutated patients.

0097

TP53 MUTATIONS ARE INFREQUENT IN NEWLY-DIAGNOSED CHRONIC LYMPHOCYTIC LEUKEMIA

F Murray,[1] N Zainuddin,[1] M Kanduri,[1] R Gunnarsson,[2] K Ekström Smedby,[3] G Enblad,[1] J Jurlander,[4] G Juliusson,[2] R Rosenquist[1]

[1]Uppsala University, Uppsala, Sweden; [2]Lund University, Lund, Sweden; [3]Karolinska Institutet, Stockholm, Sweden; [4]Rigshospitalet, Copenhagen, Denmark

Background. Chronic lymphocytic leukemia (CLL) patients frequently carry TP53 mutations in conjunction with deletion of the remaining 17p allele. However, recent studies have reported that a small proportion (3-5%) of CLL patients bearing TP53 mutations can display an intact 17p allele. These patients tend to have rapid disease progression, display a complex karyotype and are associated with chemorefractoriness. *Aim.* While *TP53* mutation frequencies have mostly been reported on referral cohorts, which may therefore have a biased collection of more aggressive cases, the aim of the present study was to determine the *TP53* mutation frequency in a newly-diagnosed cohort of CLL patients from a population-based material. *Methods.* A total of 268 Scandinavian CLL patients were analyzed for recurrent genomic aberrations and mutation of the *TP53* gene by sequencing of exons 4-8. *Results.* Representing the indolent nature of this cohort, 67% of patients harbored mutated IGHV genes, 77% were in Binet Stage A and 76% had either no recurrent aberration or displayed 13q-deletions. 17p-deletion was detected in only 10 cases (3.7%). Overall, *TP53* mutations were detected in 10 of 268 (3.7%) CLL patients; where 7 cases showed a concomitant 17p deletion and only 3 (1.1%) carried *TP53* mutations without 17p-deletion. Furthermore, we confirmed a significant decrease in overall survival (P<0.0001) and time to treatment (P=0.01) for patients with both *TP53* mutations and 17p-deletions, compared to patients without any mutation or deletion. Of three patients with only *TP53* mutations, all displayed mutated IGHV genes. One patient displayed a trisomy 12 and died 66 months after diagnosis while the remaining two patients displayed 13q-deletions and were alive >9 years after diagnosis. This is in line with the recent notion that 17p-deleted patients with mutated IGHV genes can display a more stable disease. *Summary.* We confirm the high prevalence of *TP53* mutation in 17p-deleted patients, and the associated poor survival of this patient group. The prevalence of *TP53* mutations in the absence of 17p-deletion appears lower in newly diagnosed CLL patients than the frequency reported by earlier studies. Thus, this finding further supports the notion that *TP53* mutations are rare at disease onset and instead arise during CLL progression. FM, NZ and MK contributed equally as first authors.

CLL-SPECIFIC RESEQUENCING MICROARRAY AS A TOOL FOR CLL RESEARCH AND DIAGNOSTICS

J Lochmanova,[1] B Tichy,[2] K Plevova,[2] P Dobes,[2] V Navrkalova,[2] J Malcikova,[2] L Rocnova,[2] M Mraz,[2] J Zeleny,[2] B Dvorakova,[2] J Mayer,[2] M Trbusek,[2] S Pospisilova[2]

[1]University Hospital Brno, Brno, Czech Republic; [2]University Hospital Brno, Masaryk University, Brno, Czech Republic

Background. Chronic lymphocytic leukemia (CLL) is characterized by a progressive accumulation of functionally incompetent B lymphocytes. Its highly variable clinical course is mostly determined by the combination of two biological factors: mutational status of the immunoglobulin heavy-chain variable region (IgVH) and four prominent genomic aberrations, i.e. deletions 11q22-23, 13q14, 17p13 and trizomy of chromosome 12. An impact of gene mutations on CLL progression is much less clear. Recently, several studies have shown a clear association between mutations in the TP53 (locus 17p13) or ATM (locus 11q22-23) tumor-suppressor genes and disease progression and chemo refractoriness. *Aims.* The aim of this project was to introduce a fast and reliable tool for resequencing of the selected genes, whose alterations may have a negative impact on CLL pathogenesis and/or therapeutic response. *Methods.* We have designed a custom resequencing microarray (Affymetrix, 50K) for exons and exon/intron splicing sites for the genes TP53, ATM, BCL6, RB1, CDKN2A, C-MYC, FAS, SH2D1A (SH2 domain-containing protein 1A), SOCS1 (suppressor of cytokine signaling 1) and for 110 pre-micro RNAs including approx. 20 nucleotides from pri-miRNAs. The selected genes were amplified from genomic DNA using long range PCRs ranging from 1 (e.g. C-MYC) to 19 (ATM) reactions per gene. Amplicons were pooled, fragmented and cohybridized on the array according to the manufacturer's protocol. *Results.* In this ongoing project we focus primarily on the high-risk CLL patients. Until now, 25 samples including 4 wt/healthy controls and 21 CLL patients have been sequenced. 11 harbored TP53 mutation previously identified by using different methodology (functional yeast analysis coupled with direct sequencing) and 10 manifested ATM deletion in >90% of cells. Known mutations in the TP53 gene served for assessing of the microarray ability to identify various types of mutations. We have observed that all missense mutations and common polymorphisms are readily identifiable. Short (1-2 nt) and long deletions (tens of nt) are detectable only if the second allele is missing (detected by FISH). Until now, we have detected four mutations and six common SNPs in the ATM gene; in all cases the mutations accompanied 11q22-23 deletion on the second allele. Two of them were missense substitutions, which had been detected previously in lymphoid tumors; remaining two affected splicing sites of the exons 28 and 46. So far, eight SNPs have been detected by the resequencing analysis in the miRNAs; one in the mature miRNA (miR-412), four in the pre-miRNAs (pre-miR-453, pre-miR-146a, two in pre-miR-27a) and three in the pri-miRNAs (pri-miR-154, pri-miR-100, pri-miR-126). *Summary/Conclusions.* The resequencing microarray may serve as an appropriate tool to dissect some important questions concerning the high-risk CLL. It can bring insight into e.g. mutual relationship between inactivation of the TP53 and ATM genes, identification of mutations in the miRNAs related to CLL pathogenesis or detection of potential mutations in the RB1 gene in cases with 13q14 deletion encompassing the corresponding locus. In comparison with classical sequencing approaches, the resequencing methodology is more robust, cheaper and much less time consuming.

EVALUATION OF TP53 MUTATIONS WITH THE AMPLICHIP P53 ARRAY IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): HIGHER SENSITIVITY AND CORRELATION WITH CLINICAL OUTCOME

S Chiaretti,[1] S Tavolaro,[2] M Marinelli,[2] M Messina,[2] I Del Giudice,[2] F Mauro,[2] S Santangelo,[2] V Di Maio,[2] A Piciocchi,[3] M Magliozzi,[4] N Peragine,[2] S Truong,[5] N Patten,[5] J Lawrence,[5] EM Ghia,[2] M Nanni,[2] A Guarini,[2] R Foà[2]

[1]Sapienza University of Rome, Rome, Italy; [2]Dept. of Cellular Biotechnologies and Hematology, Sapienza University, Rome, Italy; [3]GIMEMA Data Center, Rome, Italy; [4]IRCCS, Ospedale Casa Sollievo della Sofferenza, San G. Rotondo and CSS-Mendel, Rome, Italy; [5]Roche Molecular Systems, Inc., Pleasanton, USA

Background. Given the growing evidence that TP53 alterations are predictors of progression and survival in chronic lymphocytic leukemia (CLL), its screening is essential in an optimal patients' management. *Aims.* We evaluated 98 untreated CLL cases for TP53 mutations combining direct sequencing and the AmpliChip p53 Research Test, a microarray-based resequencing assay (Roche Molecular Systems, Inc., Pleasanton, CA). The results obtained were compared and correlated with different clinico-biological parameters. Finally, we studied the gene expression profile associated with TP53 alterations. *Methods.* For sequencing analysis, TP53 exons 5, 6, 7 and 8 were amplified from genomic DNA by PCR and the expected products were excised from the gel and purified. Sequences data were compared with wild-type (WT) sequences. The AmpliChip p53 Research Test allows sequencing of exons 2-11: genomic DNA was amplified in two separate PCR reactions. Subsequently, PCR products were fragmented, hybridized, stained and scanned. Each array queries 1268 nucleotide positions, investigated by individual probesets that contain five probes: 1 for WT sequence, 3 for possible single base substitutions and 1 for single base deletions. Each probe contains multiple copies of an oligonucleotide sequence. The mutation detection algorithm detects single base pair substitutions and deletions. Samples from CLL patients also underwent microarray analysis using the HGU133 Plus 2.0 Affymetrix arrays. T-test analysis was

performed comparing TP53-mutated vs WT samples and del(17p) cases vs the remaining CLL, respectively. *Results.* The AmpliChip p53 Research Test detected 17 mutations (17.3%) in 14 patients, with an incidence of 17.2% vs 7.1% in progressive vs stable cases, respectively; a significant association between TP53 mutations and del(17p) was recorded. Comparison with TP53 sequencing indicated a higher sensitivity of the AmpliChip p53 Research Test: 8 mutations were detected by both techniques, 9 only by the array, although 3 were in exons not routinely screened by sequencing, while the latter failed to identify 2 microdeletions.TP53 mutations, detected by the AmpliChip p53 Research Test, were associated with a worse Overall Survival (P=0.0002). Furthermore, we identified a common pattern of gene expression in CLL cases with TP53 alterations, with a more distinct signature associated with del(17p) rather than TP53 mutations. Finally, a high percentage of codon 72 polymorphism was recorded in CLL patients. *Conclusions.* The AmpliChip p53 Research Test is a simple and non-time consuming method, that appears to be more sensitive than sequencing, and useful as a prognostic tool. This study confirms a high percentage of TP53 mutations in CLL with unfavorable outcome and a significant association between TP53 aberrations and del(17p). TP53 alterations were coupled with a specific gene profile, with a more distinctive signature associated with del(17p) than TP53 mutations, most likely due to a concomitant gene dosage effect. Further investigations on the role of codon 72 polymorphism, highly represented in CLL, are ongoing.

Background. Deletion of TP 53 gene located on 17p13.1 are detected by interphase fluorescence *in situ* hybridization (FISH) in about 8-10% of chronic lymphocytic leukemia (CLL) patients. This deletion is associated with an aggressive disease and poor therapy response. Recent studies using conventional metaphase cytogenetics in some cases revealed that mechanism other than interstitial deletion could lead to loss of critical chromosomal regions in CLL cells. *Aims.* The aim of our study was to characterize cytogenetic mechanism of 17p deletion in CLL patients using advanced methods of metaphase cytogenetics. *Methods.* We performed metaphase cytogenetics, metaphase FISH and multicolour FISH (M-FISH) analysis on cohort of 27 CLL patients with TP 35 deletion previously detected using interphase FISH. Metaphase analysis was performed on peripheral blood samples using 72 hour cultivation with CpG oligonucleotides and IL-2 stimulation. Metaphase FISH with various DNA probes (Abbott-Vysis, Downers Grove, IL, USA) and multicolour FISH with 24-color painting probe mix (MetaSystems, Altusshein, Germany) were also performed. *Results.* Metaphase cytogenetics, FISH and M-FISH analysis of 27 patients with TP 53 deletion revealed: 8 patients with a simple deletion of short arm of chromosome 17, one patient with 17p deletion caused by isochromosome 17q formation and 18 patients (67%) with 17p affected by unbalanced translocation. Unbalanced translocation associated with formation of dicentric chromosome on derivative chromosome 17 was detected in 11 patients and pseudodicentric chromosome was present in 2 patients. Four patients had a dic(17;18)(p11.2;p11.2); in other 7 cases with dicentric formation, the chromosome partners were as follows: 4p, 8q, 9p(2x), 20p, and 21p(2x). In 5 patients with 17p translocation without dicentric chromosome, 1p/13q, 3q, 4p, 12q and 15q were translocated on 17p. In two cases, 2 resp. 4 independent clones with 17p unbalanced translocation with different partner chromosomes were detected. Unbalanced translocation cases were associated with del 13q (5x), del 11q (1x) and trisomy 12 (1x), detected by interphase FISH; cases with 17p deletion had only del 13q (5x). In cases with 17p translocation, cytogenetic analysis shown that substantial part or complete short arm is probably missing due to translocation, but this fact should be proven by sequential metaphase FISH analysis using different 17p probes. In total, 13 out of 18 patients with translocation and 5 out of 8 patients with deletion had complex chromosomal aberrations. There was no difference in number of patients with comlex karyotype and mean number of aberrations per case between 17p deletion and 17p translocation groups. All 14 patients with 17p translocation and 5 of 6 patients with 17p deletion with available data had unmutated IgVH. Correlation with selected clinical and biological data of patients will be presented. Summary. We confirmed that unbalanced translocation is a frequent mechanism for 17p deletion in CLL patients. 17p deletion due to unbalanced translocation is afrequently accompanied by dicentric chromosome formation. Dic(17;18)(p11.2;p11.2) seems to be a recurrent chromosomal aberration in CLL.

GENE EXPRESSION SIGNATURE OF P53 MUTATED AND/OR DELETED CHRONIC LYMPHOCYTIC LEUKAEMIA CELLS IDENTIFIES ARHGDIA AS A GENE UNIVERSALLY OVEREXPRESSED IN CLL

M Dal Bo,[1] P Secchiero,[2] M Degan,[1] D Marconi,[1] R Bomben,[1] MG Di Iasio,[2] D Benedetti,[1] A Zucchetto,[1] F Luciano,[3] C Simotti,[3] G Pozzato,[4] G Gaidano,[5] G Del Poeta,[3] F Forconi,[6] G Zauli,[2] V Gattei[1]

[1]Centro di Riferimento Oncologico, Aviano, Italy; [2]University of Ferrara, Ferrara, Italy; [3]S. Eugenio Hospital and University of Tor Vergata, Rome, Italy; [4]Maggiore General Hospital, University of Trieste, Trieste, Italy; [5]Amedeo Avogadro University of Eastern Piedmont, Novara, Italy; [6]University of Siena, Siena, Italy

Background. p53 deletion at 17p13.1 and p53 mutations have been identified as having adverse prognostic relevance in B-cell chronic lymphocytic leukemia (CLL). In fact, disruption of p53 by point mutations and/or deletion at 17p13 occurs in a fraction of cases at diagnosis and predicts poor survival and chemorefractoriness. *Aims.* to analyze the gene expression profile (GEP) related to p53 "disruption" in CLL. *Methods.* purified cells from twenty PB CLL samples, characterized for p53 mutations and including 13 p53 wild type ($p53^{wt}$) cases, 7 p53 deleted or mutated ($p53^{del/mut}$) cases of which 5 with del17p13 and p53 mutations, 1 with del17p13 alone, and 1 with p53 mutations alone, were utilized for performing gene expression profile (GEP) experiments; bioinformatic analyses of GEP data were performed with gene set enrichment analyses (GSEA); validations and quantitative gene expression studies on CLL and normal B cells were performed by quantitative real-time PCR (qRT-PCR). *Results.* comparing the constitutive GEP of 13 $p53^{wt}$ versus 7 $p53^{del/mut}$ cases, we obtained 72 (26 up-regulated, 46 down-regulated of which 31 belonging to the 17p segment) differentially expressed genes in $p53^{del/mut}$ cases. The transcripts representing the constitutive gene expression signature of $p53^{del/mut}$ CLL cases were tested with GSEA, focusing on the positional gene sets corresponding to human chromosome and cytogenetic bands. According to this analysis, the gene set containing genes related with the short arm of chromosome 17 presented the lowest nominal P (P=0.002, FDR-q=0.001). Consistently, $p53^{del/mut}$ CLL cases were characterized by a significant enrichment in down-regulated genes located in the 17p segment, including several genes known to display proapoptotic activities (e.g. *PSMB6*, *RPL26* and *ZBTB4*) whose lower expression in $p53^{del/mut}$ compared to $p53^{wt}$ cases was confirmed by qRT-PCR validations (PSMB6, P=0.003; RPL26, P=0.03; ZBTB4, P=0.02). Notably, 26 out of 72 differentially expressed genes turned out to be upregulated in $p53^{del/mut}$ CLL. Among these genes we focused on *ARHGDIA*, a Rho GDP dissociation inhibitor with a well-known antiapoptotic activity mediating cellular resistance to chemotherapy agents. The up-regulation of this gene in $p53^{del/mut}$ versus $p53^{wt}$ CLL cases was confirmed in qRT-PCR experiments (P=0.0257). Moreover, using the same qRT-PCR approach, overall higher expression levels of *ARHGDIA* were detected in a different series of 43 CLL samples when compared to normal B cells of PB samples from 15 healthy donors (P<0.0001). Furthermore, no differences in *ARHGDIA* expression levels were detected between various CLL categories, obtained according to IGHV gene status, FISH groups, and CD38, CD49d or ZAP-70 expression, although CLL cases carrying a 17p13 deletion (6 cases) were among those expressing high levels of *ARHGDIA* transcripts. *Conclusions.* the gene expression signature of $p53^{del/mut}$ CLL cases is in keeping with the higher aggressiveness and chemorefractoriness of $p53^{del/mut}$ CLL. Moreover, in agreement with *ARHGDIA* overexpression detected in other human tumors (e.g. ovarian, breast and colorectal cancers), the higher expression levels of *ARHGDIA* in CLL compared to expression levels of normal B cells from healthy donors points out a possible role for *ARHGDIA* as new therapeutic target or early detection biomarker.

Background. Although no common genetic defect has been described in chronic lymphocytic leukemia (CLL), recurrent genomic aberrations (i.e. deletions of chromosome 11q, 13q, 17p and trisomy 12) are important for prognostication. Recent development of high-resolution microarray techniques provides effective detection of the known recurrent aberrations and simultaneous exploration of overall genetic complexity such as small copy-number alterations (CNAs) and copy-number neutral loss of heterozygosity (CNN-LOH), which may contribute to pathogenesis and prognosis in CLL. In addition, comparison of array based genomic profiles from CLL samples taken at diagnosis and at follow-up allows a detailed evaluation of clonal evolution (CE). *Aims.* To investigate genomic aberrations in newly diagnosed CLL patients by applying high resolution SNP-arrays, and to evaluate CE in follow-up samples from patients grouped according to treatment status and IGHV mutation status. *Methods.* 250K SNP-arrays were applied for identification of CNAs and CNN-LOH in 370 CLL samples taken at diagnosis from a population-based Scandinavian cohort and in 43 follow-up samples obtained 5-8 years from diagnosis. *Results.* Genomic aberrations were identified in 90% of diagnostic samples, where the majority of samples (71%) carried between 1 and 3 CNAs, 16% showed 4-9 aberrations, while only 2% were highly complex (≥10 CNAs). The known recurrent alterations were found in 70% of patients; del(13q) 55%, trisomy 12 10.5%, del(11q) 10%, and del(17p) 4%. The deletions of 13q covered the miR-15/miR-16 in 96% of cases and the ATM and TP53 genes where included in all cases with 11q and 17p deletions, respectively. Additional recurrent CNAs included gains of chromosome 2p (2.2%), 8q (1.9%) and deletions of 4p (1.4%), 8p (1.9%) and 14q (1.6%). Genomic complexity was correlated to an unfavorable outcome, however, the patients with a higher number of CNAs most often carried the poor prognostic del(11q) and del(17p). Recurrent copy-number neutral loss-of-heterozygosity (CNN-LOH) was detected on chromosome 13q in 13 samples (3.5%) and 11 of these patients also carried a homozygous del(13q). Interestingly, in the follow-up study, CE was observed in 8/18 (44%) patients with unmutated IGHV genes, and in 4/15 (27%) IGHV mutated and treated patients. In contrast, untreated IGHV mutated patients (n=10) did not acquire additional aberrations. Acquisition of del(13q) was the most common secondary event, detected in both IGHV unmutated and mutated patients, whereas aberrations on chromosome 6q, 8p, 9p and 10q were only acquired in IGHV unmutated patients. *Summary*. Whole-genome screening with SNP-arrays revealed that a high frequency of the newly diagnosed CLL patients carry genomic aberrations, where an increasing genomic complexity was associated with an unfavorable prognosis, but also with the presence of poor-prognostic recurrent aberrations. Evaluation of CNN-LOH identified recurrent regions on chromosome 13q. The presence of a homozygous del(13q) in most of these cases implies a novel mechanism for homozygous loss of miR-15/16 in CLL. Finally, in the follow-up study, CE was associated with aggressive disease, since novel aberrations arose in IGHV unmutated and IGHV mutated/treated patients, but not in IGHV mutated/untreated patients.

HIGH-DENSITY SCREENING REVEALS A DIFFERENT SPECTRUM OF GENOMIC ABERRATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH 'STEREOTYPED' IGHV3-21 AND IGHV4-34 B CELL RECEPTORS

N Cahill,[1] M Marincevic,[1] R Gunnarsson,[2] A Isaksson,[3] M Mansouri,[1] H Göransson,[3] M Rasmussen,[3] M Jansson,[1] F Ryan,[4] K Karlsson,[2] HO Adami,[5] F Davi,[6] J Jurlander,[7] G Juliusson,[2] K Stamatopoulos,[8] R Rosenquist[1]

Papanicolaou Hospital, Thessaloniki, Greece

Background. Multiple chronic lymphocytic leukaemia (CLL) subsets with virtually identical, 'stereotyped' B-cell receptors (BCRs) have been identified in up to 30% of patients. These subsets show similar immunoglobulin heavy (IGH) and light-chain gene usage, and share an aminoacid identity ≥60% in the heavy complementarity determining region 3 (CDR3), the main determinant of antigen specificity. These striking findings of stereotypy have implied antigen involvement in leukemogenesis. Interestingly, stereotypy has also been indicated to influence the clinical course, e.g. stereotyped IGHV4-34 (subset #4) shows a more indolent disease and a low median age at diagnosis than non-stereotyped IGHV4-34 patients. Conversely, IGHV3-21 patients with stereotyped (subset #2) and non-stereotyped (non-subset #2) BCRs share an equally poor overall survival, independent of IGHV mutational status, although stereotypy has been associated with shorter time to progression and poor-prognostic markers. Today limited knowledge exists about the spectrum of aberrations in these different subsets. *Aim.* Screening for whole-genome events in biologically/clinically divergent CLL with stereotyped/non-stereotyped IGHV3-21 and IGHV4-34 BCRs and comparison to our recent array based study on a population-based CLL material. *Methods.* We applied 250K SNP-arrays to study copy-number aberrations (CNAs) and copy-number neutral loss-of-heterozygosity (CNN-LOH) in stereotyped IGHV3-21 (subset #2, n=29), stereotyped IGHV4-34 (subset #4, n=17; subset #16, n=8), non-subset #2 IGHV3-21 (n=13) and non-subset #4/16 IGHV4-34 (n=34) patients. *Results.* Over 90% of subset #2 and non-subset #2 carried CNAs, whereas 75-76% of subset #4 and subset #16 showed CNAs. Subset #2 and non-subset #2 displayed a higher average number of aberrations compared to subset #4. However, compared to our array-based CLL study, subset #2/non-subset #2 cases were no more complex when accounting for all CNAs. del(13q), the only recurrent aberration detected in subset #4 (35%), was substantially more frequent in subset #2 (79%) compared to other CLL studies. Furthermore, del(11q) encompassing the ATM gene was more frequent in subset #2 and non-subset #2 (31% and 23%) relative to subset #4, non-subset #4/16 patients and other CLL studies. These aberrations may be important in IGHV3-21 pathogenesis, particularly as concurrent 11q and 13q deletions were frequent in subset #2 cases. We detected some novel aberrations, however few were overlapping. A concurrent gain on chromosome 2q and a loss at 3p were identified in two subset #2 cases. In IGHV4-34, three recurrent aberrations were observed on chromosome 2q, 7q and 14q but not in any particular subset. Small non-recurring CNN-LOH regions were frequent in all subset- and non-subset groups. Larger (>3 Mbp) overlapping CNN-LOH regions were detected on chromosome 6 in two non-subset #4/16 patients and on chromosome 20 in one subset #2 and non-subset #2 case. Recurrent CNN-LOH was detected on chromosome 13q (5 cases), independent of BCR stereotypy. *Conclusions.* Genomic aberrations were more common in subset #2 and non-subset #2 compared to subset #4. High del(11q) frequency in subset #2 patients may be linked to their adverse outcome. Conversely, the lower prevalence of CNAs and the absence of poor-prognostic aberrations in subset #4 may reflect an inherent low-proliferative disease preventing accumulation of genomic alterations.

0104

CHRONIC LYMPHOCYTIC LEUKEMIA WITH DELETION OF 13Q14 OR 11Q22-23 - EVIDENCE FOR A COMMON PATHOGENETIC PATHWAY FROM GENE EXPRESSION DATA

T Herold,[1] V Jurinovic,[2] C Buske,[3] S Bohlander[1]

[1]University Hospital Grosshadern, Ludwig-Maximilians-University (LMU), Munich, Germany; [2]Institute of Bioinformatics and Epidemiology, LMU Munich, Munich, Germany; [3]Institute of Experimental Tumor Research, University of Ulm, Ulm, Germany

Background. Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with survival rates ranging from months to decades. About 40% of CLL cases have deletions of chromosomal band 13q14 and approximately 10% of cases show deletions in chromosome bands 11q22-23. Cases with 13q14 deletion as sole abnormality have a good prognosis, whereas cases with 11q22-23 deletion have one of the worst prognosis. Interestingly, the 13q14 and 11q22-23 regions show ancestral synteny in the zebrafish genome. It is therefore tempting to speculate that there might be a common molecular mechanism linking 11q- and 13q-deleted cases of CLL. *Aims.* We aimed to examine the gene expression profile of conserved genes located in 13q14 and 11q22-23 in CLL cases with deletions in these regions. *Methods.* Microarray-based gene expression profiling and FISH analysis were performed on 151 CLL patients. In addition, we performed quantitative real time PCR for selected genes (*ARHGAP20* and *TP53*) on 116 well defined CLL samples in which more than 66% of the cells were positive for the FISH marker. *Results.* We examined the 13q14 and 11q22-23 regions for differentially regulated genes in subgroups defined by FISH in our microarray dataset. Surprisingly, the expression levels of the Rho GTPase activating protein 20 (*ARHGAP20*) which is located in the commonly deleted region in 11q22-23 showed - counterintuitively - a significantly higher expression in CLL cases with 11q22-23 deletions compared to cases with no detectable genetic lesion or trisomy 12. Additional analysis using quantitative real time PCR confirmed these observations with *ARHGAP20* being significantly higher expressed in cases with 11q deletions and interestingly also in cases with 13q deletions. *TP53* was used as control gene and showed the expected reduction of expression levels in 17p deleted cases due to haploinsufficiency. *Summary/Conclusions.* Despite its location in the deleted region on 11q22-23, *ARHGAP20* is up regulated in 11q-deleted cases suggesting a complicated mechanism of regulation. Very interestingly, *ARHGAP20* was found to be the target of chromosomal translocations in rare cases of CLL. The *ARHGAP20* gene encodes an evolutionary highly conserved protein and is located in a common ancestral region in the zebrafish genome, harboring genes from human chromosomal regions 13q14 and 11q22-23. The fact that *ARHGAP20* is unexpectedly highly expressed in cases with 11q22-23 deletions and in cases with 13q deletions suggests a molecular connection between 11q- and 13q-deleted cases of CLL. Our findings also suggest a prominent role of *ARHGAP20* in the pathogenesis of CLL.

0105

DETAILED ANALYSIS OF DEL(13Q14) BY HIGH-RESOLUTION SNP ARRAY AND PROGNOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA

J Edelmann,[1] K Holzmann,[2] R Busch,[3] M Hallek,[4] H Döhner,[1] S Stilgenbauer[1]

[1]University Clinic Ulm, Ulm, Germany; [2]Microarray Core Facility, Ulm, Germany; [3]Technical University, Munich, Germany; [4]German CLL Strudy Group, Cologne, Germany

Background. Genomic aberrations are important prognostic factors in chronic lymphocytic leukemia (CLL) [Döhner et al., NEJM, Dec. 2000]. Among those del(13q14) is the most frequent one and has been associated with a good prognosis. Its underlying pathogenetic mechanism, however, is still not fully understood. With the development of single-nucleotide polymorphism (SNP) arrays a method has become available for high-resolution genome profiling. We sought to precisely map 13q deletion sizes and correlate the molecular data with clinical outcome. *Material and Methods.* We studied samples of CLL patients enrolled in the CLL8 trial of the German CLL Study Group (GCLLSG). DNA of CD19 separated mononuclear cells was hybridized to the Affymetrix® 6.0 SNP array. Unpaired analysis for DNA copy number changes was performed against 20 own reference samples using the aroma affymetrix software package. The range of each del(13q) was revised by displaying the normalized data in dCHIP SNP. FISH analysis (13q, 11q, 12q and 17p) was performed on all samples. Cases were grouped by their deletion size into quartils and by their copy number status for RB1. Clinical correlation for overall response (OR), overall survival (OS) and progression free survival (PFS) was performed for each group and tested for statistical significance by a Chi-square test. *Results.* Del(13q14) was found in 57% of all samples; in 35,5%, del(13q14) was the sole abnormality as assessed by our routine FISH panel. The minimal deleted region was 277.250 kb in size. On the centromeric site it was defined by the probesets CN_654150 and CN_654151 that have an intermarker distance of 8.692 kb and cover a segment harboring the two microRNAs mir15a and mir16. Deletions on 13q showed a high heterogeneity in size, ranging from 294 kb to 68 Mb; one case had a monosomy 13. Quartile two started with a deletion size of 1.231 Mb, quartile three with a size of 2.687 Mb, and quartile four with a size of 9.057 Mb. Patients with a del(13q) >9 Mb in size (quartile four) had a lower OR rate (P=0.028), a shorter OS (P=0.01) and in trend a shorter PFS (P=0.089). Patients whose deletion encompassed RB1 had in trend a shorter OS (P=0.141), whereas there was no effect on OR or PFS. Among patients who had del(13q14) as sole abnormality, deletion size >9 Mb (P=0.044) and concurrent loss of RB1 (P=0.021) predicted inferior OS, whereas there was no effect on OR or PFS. *Conclusions.* In our patient cohort, the minimal deleted region in 13q14 spanned 277.250 kb and contained the two previously described microRNAs mir15a and mir16. Deletion sizes greater than 9 Mb predicted inferior outcome both in the cohort of all 13q14 deleted patients as well as those harboring 13q14 deletion as sole abnormality, suggesting that additional genes outside the minimal deleted region may add to the pathogenesis of the disease.

0106

INTRACLONAL DIVERSIFICATION OF IMMUNOGLOBULIN GENES IDENTIFIES TWO DISTINCT MOLECULAR SUBTYPES OF RICHTER TRANSFORMATION

D Rossi,[1] V Spina,[1] C Deambrogi,[1] S Rasi,[1] M Cerri,[1] A Bruscaggin,[1] F Forconi,[2] R Marasca,[3] A Carbone,[4] V Gattei,[5] D Capello,[1] G Gaidano[1]

[1]Division of Hematology, Amedeo Avogadro University, Novara, Italy; [2]Division of Hematology and Bone Marrow Transplantation, University of Siena, Siena, Italy; [3]Division of Hematology, University of Modena, Modena, Italy; [4]Division of Pathology, CRO, Aviano, Italy; [5]Division of Experimental Hematology, CRO, Aviano, Italy

Background. The pathogenetic mechanisms underlying CLL transformation to Richter syndrome (RS) are poorly understood and might involve antigen stimulation. In B-cell neoplasia, analysis of intraclonal diversification (ID) of immunoglobulin (IGHV) genes provides information on tumor immunogenetics. Aim. We investigated ID in RS (all DLBCL), in order to i) define RS clonal evolution; and ii) assess the role of antigen stimulation in clonally related vs unrelated RS. *Methods.* The study was based on 43 samples: i) 10 clonally related CLL/RS pairs; ii) 3 clonally unrelated RS; and, for comparison, iii) 20 *de novo* DLBCL. Fifty IGHV subclones were analysed per sample. Mutations observed in only one subclone were defined unconfirmed (UCM). Partially shared mutations were defined confirmed (CM). The normalized mutation frequency (NMF) was calculated according to the formula: (CM+UCM)/number of subcloned sequences x sequence length. Phylogenetic analyses was performed with MEGA4. In order to define the load of oncogenic molecular lesions, RS were analysed for: i) mutations of TP53, CARD11, TNFAIP3/A20, BLIMP1, BCL6, PIM1, PAX5, TTF, c-MYC, CD79A/B, EZH2; ii) chromosomal abnormalities of BCL2, BCL3, BCL6, c-MYC, MYCN, ATM, TP53, 6q21. Informed consent was obtained. *Results.* Clonally related RS were classified as unmutated (100% homology; 5/10), minimally mutated (99.0-99.9% homology; 2/10) or borderline mutated (98.0-98.9% homology; 3/10). Stereotyped HCDR3 occurred in 5/10 cases (subset 8: 2/5; subset 2: 2/5; subset 6: 1/5; subset 7:1/5). The NMF of IGHV ongoing mutations significantly decreased from CLL (mean: 0.95×10^{-3}) to RS (mean: 0.17×10^{-3}) (P=0.002). All CLL phases displayed ID (CID: 6/10; UID: 4/10), that, at RS transformation, was switched off in 5/10 cases. ID-positive RS carried a significantly higher number of genetic lesions (mean: 3) than ID-negative RS (mean: 1) (P=0.045). Genealogic trees showed that RS and CLL clones originated from a common progenitor cell in 9/10 cases, whereas in 1 single case RS evolved from a later CLL subclone (Figure 1). Clonally unrelated RS were classified as unmutated (2/3) or minimally mutated (1/3), and carried stereotyped HCDR3 in 1/3 cases (subset 1). All 3 clonally unrelated RS carried CID. Accordingly, the NMF was significantly higher in clonally unrelated RS (mean: 1.0×10^{-3}) compared to clonally related RS (P=0.001). Finally, ID in RS was similar to ID of *de novo* DLBCL sharing

the same non-GCB profile (P>0.050). *Conclusions.* The conclusions of our study are multifold. First, differences in ID reinforce the notion that clonally related and clonally unrelated RS are distinct biological entities. Second, clonally related RS originate from the same common progenitor of the CLL clone, rather than evolving from a later CLL subclone. Third, among clonally related RS, the association between ID and high load of oncogenic molecular lesions might reflect the predisposition to genetic instability of RS cases targeted by somatic hypermutation. In this setting, accumulation of genetic lesions might favor transformation. Fourth, in clonally related ID-negative RS, the tumor clone carries few genetic lesions and is selected to maintain the BCR, suggesting a role of high affinity antigen stimulation in disease development.

Background. IGHV1-69 gene identifies the most common IGHV gene in chronic lymphocytic leukemia (CLL) and is dominant in unmutated CLL (U-CLL). It is often rearranged to form stereotyped HCDR3 patterns that may suggest antigen selection of the leukemic clones. One of stereotypes is the IGHV1-69/D3-16/J3 subset 6 that may produce antibodies binding non-muscle myosin on apoptotic cells, with potential consequences on clinical behavior (Chu CC, Blood 2010, prepublished). *Aims.* to investigate the prognostic significance of mutational status and of stereotypic B-cell receptors in IGHV1-69$^+$ CLL. *Methods.* Nucleotide sequences of the tumor IGHV1-69/D/J rearrangement, clinical and molecular prognostic parameters at diagnosis and clinical status at follow-up of 271 IGHV1-69$^+$ CLL patients were obtained from 14 different hematological institutes in Italy. CLL B-cell derived IGHV1-69 rearrangements were scanned for HCDR3 stereotypic patterns and assigned to subsets according to the criteria by Murray *et al.* (Blood, 2008;111:1524533). Time to progression requiring first treatment according to NCI criteria (TTFT) was used as the primary endpoint to measure behavior of all or of Rai stage 0 CLL, with mutated (M) or unmutated (U), stereotyped or not stereotyped IGHV1-69 rearrangements. *Results.* Of 271 IGHV1-69$^+$ CLL, 245 (90,4%) were unmutated, 154/257 (59,9%) revealed stereotypic patterns and 15/257 (5.8%) belonged to subset 6. Subset 6 IGHV1-69 rearrangements were unmutated in 14/15 (93.3%) CLL. TTFT was significantly shorter in IGHV1-69+ U-CLL than in IGHV1-69+ M-CLL (29 vs 101 months, P=.001 in all IGHV1-69+ CLL; 52 vs 142 months in Rai 0 IGHV1-69+ CLL, P=.001), while was no different between the CLL assigned or not assigned to subsets (31 vs 37 months in all IGHV1-69+ CLL, 52 vs 78 months in IGHV1-69+ Rai 0 CLL, P=NS). However, specific analysis of the CLL-specific subset 6 revealed TTFT longer than the remaining IGHV1-69$^+$ U-CLL either in all stages (52 months vs 27 months, P=.05) or in stage 0 (no events vs 49 months, P=.016). We expanded the analysis to all IGHV1-69+ and non IGHV1-69+ subsets 1, 3, 8, 9 and 28 (n=50) that also react with autologous non-muscle myosin (Chu CC, Blood, 2010, prepublished). Most remarkably, we found that TTFT of subset 6 was longer than the other anti-myosin subsets (26 months in all stages, P=.021; 44 months in Rai stage 0, P=.02). *Conclusions.* our analysis documents and confirms that unmutated status of IGHV, and not stereotypy, is a relevant prognosticator in CLL. However, the good prognosis of Rai 0 U-CLL assigned to subset 6 suggests a differential clinical behavior irrelevant of unmutated status of this specific subset, particularly if identified in early stage (Rai 0) CLL.

Martino, Genova, Italy; [6]Divisione di Ematologia, Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy; [7]Azienda Ospedaliero-Universitaria Ospedali Riuniti di Trieste, Internal Medicine, Trieste, Italy; [8]Divisione di Diagnostica delle Malattie Linfoproliferative, IST, Genova, Italy; [9]Dipartimento di Oncologia/Ematologia, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy; [10]Centro di Ricerca per lo Studio delle Leucemie, Fondazione IRCS, Milano, Italy

Background. Most CLL clones express both sIgM and IgD and the two isotypes share the same antigen-specific combining site. Evidence collected so far supports the notion that both sIgM and sIgD actively participates in the process of clonal expansion since the neoplastic cells could be continuously stimulated *in vivo* possibly by self antigens. *Aims.* Since cell stimulation implies the existence of a viable BcR, we have investigated the effect of stimulating CLL cells *in vitro* by cross-linking their sIgM. The data were correlated with clinical features to investigate a potential involvement of cell stimulation in clonal expansion and disease progression. *Methods.* CLL B-cells, purified from 106 patients, were exposed to aμAb *in vitro* and then apoptosis was measured after 48hrs by tested by annexin V apoptosis assay. Patients were subdivided into three groups, depending upon the type of response observed (inhibition, I; death, D; and null response, N). *Results.* The risk of treatment start was significantly higher ingroup D cases (68 cases, H.R. 2.3, 95% C.I. 1.1-4.9, P=0.038) than in the remaining cases (N+I) (H.R.=1). We previously reported the predictive role of the *in vitro* response to aδ-Ab in the same cohort of patients (Morabito F, Br J Haematol 2009). Out of the 68 cases belonging to group D by aμ-Ab cross-link, 44 showed a null response to aμ-Ab cross-link (N cases), 16 were rescued from apoptosis (I cases), while only 6 cases were also induced to die by aδ-Ab cross-link. Response to aμAb (H.R. 2.8, 95% C.I. 1.2-6.3, P=0.012) remained an independent prognostic indicator also when aδAb was considered (H.R. 2.7, 95% C.I. 1.4-5.5, P=0.012). When patients were stratified according to the response to the two stimuli, 24 cases responding to both stimuli (D and I cases for IgD cross-linking and D cases for IgM cross-linking)) experienced a significantly shorter TFS (HR 6.4, 95% C.I. 1.8-22.6), than cases responding only to aμAb (44 cases) or to aδAb (17 cases). The latter tow patient groups behaved like cases patients with an N response to aδAb or an N or I response to aμ-Ab. After adjustment for CD38 and ZAP-70 expression, and IgVH mutational status, only the response to BCR receptor engagement retained a statistically significant association with the risk of starting treatment. Finally, to investigate whether the groups outlined above showed differences in their gene expression pattern, 70 samples were profiled on Affymetrix HG-

U133A arrays and a multi-class supervised analysis using SAM was carried out on the four groups. We identified 143 differentially expressed genes (150 probes) which specifically distinguished the group responding to IgD from the remaining groups. The 113 genes resulting as preferentially upregulated in the IgD responders with respect to the other 3 classes were mainly involved in intracellular signaling cascade functions (21/113), whereas protein transport (7/30) and transcription (4/30) were found among the negatively modulated functions. *Summary/Conclusions.* Response to sIgD and sIgM cross-linking may represent an additional predictor of disease progression and mayprovide useful information on the mechanisms potentially leading to disease progression.

BRUTON'S TYROSINE KINASE INHIBITORS TARGET B CELL RECEPTOR- AND NURSELIKE CELL-DEPENDENT ACTIVATION OF CHRONIC LYMPHOCYTIC LEUKEMIA B CELL

E Ponader,[1] E Evans,[2] W Wierda,[1] M Keating,[1] J Burger[1]

[1]M.D.Anderson Cancer Center, Houston, USA; [2]Avila Therapeutics Inc., Waltham, USA

Background. Bruton's tyrosine kinase (Btk) is emerging as a therapeutic target in chronic lymphocytic leukemia (CLL). Btk plays an important role in the B cell receptor (BCR) signaling pathway and the development and homeostasis of normal B-lymphocytes. *Aims.* We investigated the effect of three different Btk inhibitors on CLL cell activation after BCR triggering with anti-IgM. Also, these compounds were assessed in CLL co-cultures with nurselike cells (NLC). The compounds disrupt the BCR signaling pathway by selectively targeting Btk (AVL-292 and Compound A) or by targeting Btk and Lyn (Compound B). *Methods.* Viability of CLL cells was determined after 24, 48 and 72 hours of anti-IgM stimulation or NLC co-culture in the presence or absence of the compounds by staining with DiOC6 and propidium iodide (PI). Concentrations of the chemokines CCL3 and CCL4 in CLL cell supernatants after BCR triggering or after co-culture with NLC was analyzed by ELISA. CCL3 and CCL4 are secreted by CLL cells in response to BCR triggering and in NLC-cocultures and function as surrogate markers for BCR responsiveness (Blood 114:1029-37, 2009). The inhibition of Btk phosphorylation was demonstrated by immunoblotting for P-Y223 Btk. To analyze the specific interaction of Btk with the different compounds, a Btk occupancy assay was performed.

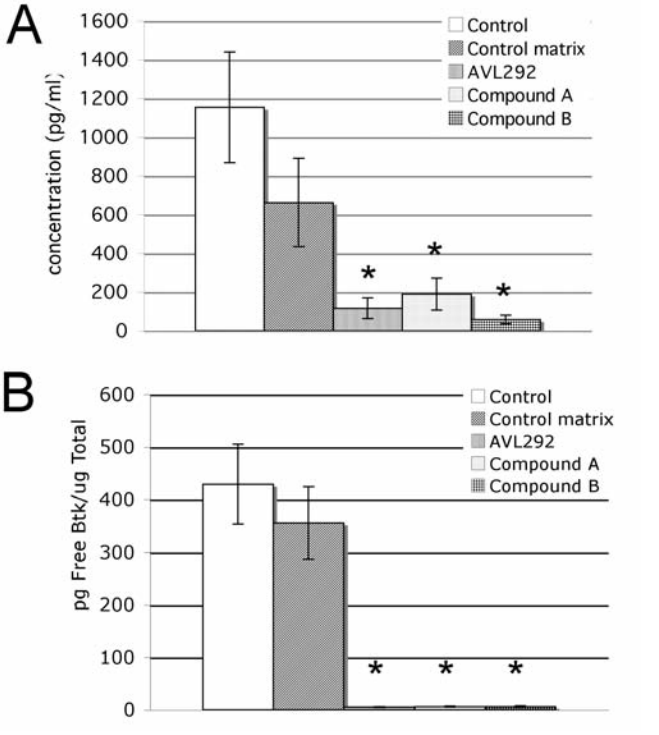

Figure 1. (A) CCL4 expression (B) compound-free Btk protein.

Results. 24 hours after BCR stimulation with anti-IgM, CLL cell viability was significantly reduced by the Btk/Lyn inhibitor Compound B (53.6±6.0% compared to 81.1±3.5% in controls, n=8). Compound B also reduced CLL cell viability in NLC co-cultures (41.6±8.3% compared to 69.5±7.7% in control at 24h, n=8). Both Btk-specific inhibitors were less effective in causing CLL cell death under these conditions, and decreases in viability with these agents were not significant. As expected, high levels of CCL3 and CCL4 were detected in CLL supernatants after 24h of incubation with anti-IgM. Induction of these chemokines was significantly inhibited by Compound B (CCL3: 8.5±0.7 pg/mL versus 1913±76 pg/mL in the control; CCL4:45.1±3.5 pg/mL compared to 4122±159 pg/mL in the control). The other inhibitors had no significant effects on the secretion of CCL3/CCL4 after anti-IgM stimulation. In co-culture with NLCs, the secretion of CCL3 and CCL4 was significantly inhibited by all compounds as shown in Figure 1 A (CCL3: 42.8±27.9 pg/mL with AVL-292, 65.2±19.5 pg/mL with Compound A, 42.8± 27.9 pg/mL with Compound B, compared to 471.5± 160.6 pg/mL in the controls; CCL4: 116.1±52.7 pg/mL with AVL-292, 187.9±82.7 pg/mL with Compound A, 58.4±22.3 pg/mL with Compound B, compared to 1154.2± 286.8 pg/mL in the control, n=6). Phosphorylation of Btk on Y223 was inhibited by both Btk-targeting compounds (AVL-292, Compound B). The occupancy assay revealed complete occupation of Btk by all compounds compared to the control (Figure 1 B). *Conclusions*. Our data demonstrate that the tested compounds are effective in inhibiting BCR- and NLC-derived activation signals in CLL cells. Differences in efficacy of the specific Btk inhibitors versus the Btk/Lyn inhibitor indicate that there is a differential responsiveness to Btk inhibition, depending on the mode of BCR activation. Supra-physiologic BCR triggering by anti-IgM is less responsive to selective Btk inhibitors. In contrast, these Btk-selective agents were extremely effective in blocking NLC-induced CCL3/4 secretion. Because NLC may represent a more relevant mode of CLL cell stimulation than anti-IgM, and because of the exciting therapeutic activity of another Btk inhibitor (PCI-32765) in CLL, these findings indicate that the tested inhibitors represent promising therapeutic agents for CLL patients, alone or in combination with other active agents.

BCR-SIGNALING PROFILES ASSOCIATED WITH PROGNOSIS AND PROGRESSION IN B-CLL

MT Scupoli,[1] O Perbellini,[2] F Cioffi,[2] R Chignola,[3] E Evensen,[4] R Zanotti,[2] I Nichele,[2] O Lovato,[5] G Pizzolo[2]

[1]University of Verona, Verona, Italy; [2]University of Verona, Department of Clinical and Experimental Medicine, Verona, Italy; [3]University of Verona, Department of Biotechnology, Verona, Italy; [4]Nodality, Inc, San Francisco, USA; [5]University of Verona, Interdepartmental Center LURM, Verona, Italy

Background. B-cell chronic lymphocytic leukemia (B-CLL) patients exhibit a variable clinical course. Several biological parameters have been shown to be associated with clinical outcome in CLL. Among them, the most reliable markers are represented by the absence of somatic mutations within the immunoglobulin variable heavy chain genes (IGHV), the expression of CD38 antigen, or the presence of the ZAP-70 tyrosine kinase. These parameters of poor clinical outcome are structurally and/or functionally linked to B-cell Receptor (BCR) expressed by CLL cells, thereby strengthening the hypothesis that antigenic stimulation mediated by the BCR represents a driving event in the onset and progression of the malignant B cells. *Aims.* We investigated whether different BCR signaling networks may distinguish clinical-biological groups of CLL patients. *Methods.* We applied a "network level"analysis of BCR signaling by measuring single-cell profiles of phosphoprotein networks by flow cytometry. We evaluated the response to BCR engagement in primary cells isolated from 27 CLL patients by analyzing the phosphorylation states of 5 phosphoproteins on the route of BCR signaling, including p-Syk, p-NF-kappaB, p-Erk1/2, p-p38 and p-JNK. BCR was cross-linked by incubating cells with anti-IgM antibodies. *Results.* Unsupervised clustering analysis distinguished BCR response profiles of phosphoproteins that differentiated cases of CLL with mutated IGHV from those with unmutated IGHV (P=0.0003), cases with low levels of CD38 expression from those with high levels (P=0.0004) and cases with ZAP-70-negative leukemic cells from cases that were ZAP-70-positive (P=0.001). Furthermore, the same BCR response profiles were also associated with time to progression (P=0.0014) and with overall survival (P=0.049), as assessed by Kaplan-Meier curves and the log-rank test. Independent survival analysis of time to progression via fitting Cox proportional hazards models comprising clinical covariates and/or BCR network response to modulation demonstrated that measuring modulated BCR network signaling can

yield improved prognostic information compared to CD38 status alone (likelihood ratio test 5.8 for CD38 versus 10.6 for signaling) and enhance prognostic assessment using IGHV status (likelihood ratio test for IGHV = 14.8 versus for IGHV + signaling = 17.9). *Conclusions.* This study shows that single-cell profiles of BCR phosphoprotein networks are associated with prognostic parameters, disease progression and overall survival in CLL.

THE INFLUENCES OF B-CELL RECEPTOR STIMULATION AND ZAP70 EXPRESSION ON MRNA AND MIRNA EXPRESSION PROFILES IN CHRONIC LYMPHOCYTIC LEUKEMIA

V Pede, E Naessens, P Mestdagh, J Vandesompele, J Philippé, B Verhasselt

University Ghent, Ghent, Belgium

Prognosis of B-Chronic Lymphocytic Leukemia (CLL) is variable, but can be predicted by prognostic markers. The most commonly used prognostic markers include the presence or absence of certain genetic aberration, the mutation status of the immunoglobulin variable heavy chain genes and the expression level of ZAP70. MicroRNA's (miRNAs) are small non-coding RNA molecules that regulate protein expression by targeting the mRNA of protein-coding genes resulting in repression of translation. miRNAs have been shown to be involved in cancer, apoptosis and cell metabolism. In CLL, miRNA expression profiling studies revealed different miRNA profiles associated with known prognostic factors. Since this association is not mechanistically explored and little is known about the regulation of miRNA expression, we investigated the influence of B-cell receptor (BCR) stimulation and ZAP70 protein expression on the miRNA expression profile and interrelate this with a mRNA expression profile. Recently, we demonstrated that clinically significant genes such as ZAP70 could be efficiently overexpressed in CLL cells by electroporation of mRNA (Van Bockstaele F. *et al.* Leukemia 2007). After electroporation we stimulated the cells with anti-IgM-polyacrylamid beads to activate the BCR-signaling pathway and to activate the introduced ZAP70 protein. As a negative transfection control we electroporated uncapped mRNA that remains untranslated in the cell, anti-IgA-polyacrylamid beads (anti-IgA) were used as negative control for stimulation. We determined the miRNA expression profile using a megaplex TaqMan miRNA assay (Mestdagh P. et al. Nucleic Acids Res 2008) together with a Human Illumina Gene Expression beadChip to investigate the differences in mRNA profile. After stimulation, expression of many miRNAs is affected. The most significant differences are the upregulations in hsa-mir-132, hsa-mir-146a and hsa-miR-222. A known target of hsa-miR-146a is IRAK-1 (IL-1 receptor-associated kinase 1). In our micro-array we do see a downregulation after 24 hours of this mRNA and with the use of a real-time qPCR we could confirme these *Results.* Besides IRAK-1, the influenced genes are involved in chemotaxis, cell signalling and cell survival. ZAP70 has no influence on miRNA expression, except for those expressed at very low level. The effect of ZAP70 expression on mRNA profiles will be determined. After stimulation we see that a lot of miRNAs and mRNA genes are regulated. Stimulation of the B-cell receptor activate the NF-kB pathway and this pathway is responsible for at least two different expressed miRNAs. In the future we will further explore the role of these miRNAs and we will try to correlate some differences in miRNA expression with the mRNA expression profile. Further, our data suggest that aberrant ZAP70 expression have no influences on miRNA expression profiles in CLL.

0112

CONSTITUTIVE LEVELS OF PHOSPHORYLATED ERK 1&2 PREDICT OVERALL SURVIVAL AND TIME TO FIRST TREATMENT IN CHRONIC LYMPHOCYTIC LEUKAEMIA

R Bailey,[1] L Eagle,[2] J Pointon,[2] R Brathwaite,[2] J Abbott,[3] P Evans,[4] J Greenman,[2] L Cawkwell,[2] D Allsup[3]

[1]Hull York Medical School, Hull, UK; [2]University of Hull, Hull, UK; [3]Hull & East Yorkshire NHS Trust, Hull, UK; [4]Leeds Teaching Hospitals NHS Trust, Leeds, UK

Background. Chronic lymphocytic leukaemia (CLL) is a clinically heterogeneous disease characterised by an accumulation of malignant B lymphocytes. Central to the survival of CLL-cells is the B-cell Receptor (BCR), a structurally complex molecule which contains an immunoglobulin molecule with antigenic specificity. The Extracellular Regulated Kinase isoforms are active when phosphorylated forming an important part of the intracellular signal transduction mechanism linking the BCR to effector mechanisms such as nuclear transcription factors. Increased levels of phosphorylated Extracellular Regulated Kinase (pERK) are found in CLL cells induced to proliferate and inhibition of the ERK pathway promotes chemotherapy induced apoptosis in B-cell lines. *Aims.* We investigated the relationships between pERK isoforms 1&2 (pERK1&2) concentrations and overall survival (OS) as well as time to first treatment (TTFT) in a cohort of patients with CLL. *Methods.* Lymphocytes were isolated from patients with CLL attending Haematology Clinic at the Hull and East Yorkshire NHS Trust. Collections were made after taking informed consent according to the Declaration of Helsinki with Local Ethics Committee approval (05/Q1104/33). pERK1&2 concentrations were measured quantitatively using ELISA according to the manufacturers protocol (#SUV1018, RnD Systems) in 99 such cases. The mutational status of the variable region of the immunoglobulin gene (IgVH status) was determined in all cases. The pERK1&2 concentration measured was correlated with clinical stage, IgVH, ZAP70 and CD38 status. The pERK1&2 concentration measurements were then ranked and those in the upper quartile were regarded as being elevated. Statistical analysis was performed to assess the relationships between an elevated pERK1&2 concentration and OS / TTFT. *Results.* pERK1&2 concentrations showed a statistically significant relationship with Binet and modified Rai stage (P=0.014 and P=0.049 respectively). There were no correlations between pERK1&2 concentration and CD38 or ZAP70 status (P=0.582 and P=0.609 respectively). A correlation with IgVH status (P=0.038) was detected. An elevated pERK1&2 concentration in the upper quartile of measured results was found to predict a reduced OS (P=0.043). When sub-analysis was performed with stratification by IgVH status the predictive power of an elevated pERK1&2 concentration for OS remained in the IgVH mutated cohort (P=0.011) but not in the IgVH unmutated cohort (P=0.887). An elevated pERK1&2 concentration was also found to predict TTFT (P=0.050). Cases with an elevated pERK1&2 concentration had a median TTFT of 8 months compared to 31 months for those with a low concentration. Sub-analysis by CD38, ZAP70 and IgVH status showed no confounding effects (P=0.566, P=0.898 and P=0.346 respectively). *Conclusions.* Our results demonstrate that increased intracellular pERK1&2 concentration can be used to predict reduced OS and TTFT. An unmutated IgVH status was associated with higher absolute pERK1&2 concentrations suggesting that increased intracellular signalling activity may be one mechanism which links IgVH status and prognosis. The findings suggest that inhibition of the pERK pathway may offer a novel therapeutic approach to the management of bad risk CLL.

0113

DEMONSTRATION OF PHARMACODYNAMIC TARGET INHIBITION AND CHEMOKINE MODULATION IN PATIENTS WITH CLL FOLLOWING TREATMENT WITH CAL-101, A SELECTIVE INHIBITOR OF THE P110 DELTA ISOFORM OF PI3K

J Lannutti, A Meadows, A Kashishian, B Steiner, K Webb, S Peterman, A Yu, A Giese

Calistoga Pharmaceuticals, Seattle, USA

Background. It is well established that deregulation of the PI3K signaling pathway plays an important role in the etiology of human hematologic malignancies. PI3K pathway signaling is mediated by the Class I isoforms (α, β, δ, and γ). We have previously demonstrated that in primary samples from patients with chronic lymphocytic leukemia (CLL), that both constitutive PI3K pathway activation as well as induced activation in response to microenvironmental factors are PI3Kδ-dependent and promote tumor cell survival. CAL-101 is a highly selective and potent p110δ inhibitor (EC50 of 65 nM in a whole blood assay) with >200-fold selectivity over the other class I PI3K isoforms and no activity against Class II and III PI3K family members or other PI3K-related proteins including mTOR and DNA-PK. *Aim.* In an ongoing Phase 1 study enrolling patients with CLL, we sought to determine the effects of CAL-101 treatment on PI3K signaling and to identify evidence of both pathway activation and effects on the tumor microenvironment. *Methods.* Phospho-AKT expression in CLL cells was measured by flow cytometry using antibodies specific for pAKTS473 and pAKTT308. Plasma concentrations of CCL3, CCL4 and CXCL13 were measured by ELISA. *Results.* Serial blood samples from CLL patients with circulating leukemic cells were collected during the clinical trial. Prior to CAL-101 dosing, a high level of constitutive pAKTT308 was observed in all

patients CLL cells (n=11) whereas pAKTS473 was only seen infrequently. At the dose levels evaluated (100 and 150 mg BID) inhibition of constitutive pAKTT308 was nearly complete at 4 hours post dosing on Day 1 and prior to dosing on Day 8. Activation of CLL cells *in vitro* by BCR crosslinking results in the production of CCL3 and CCL4 that was inhibited by CAL-101 treatment. Average plasma concentrations of CCL3 (160 pg/mL) and CCL4 (274 pg/mL) are increased approximately 5-fold in patients with CLL (n=17) compared to normal subjects. In CLL patients treated (n=17) with CAL-101, the concentrations of CCL3 and CCL4 were decreased by 2 to 5-fold in the first week of dosing across all dose levels evaluated (range 50 to 350 mg BID). The B-cell chemokine CXCL13 has been implicated as a pro-survival factor in the interaction between CLL cells and the tumor microenvironment. The average plasma concentration of CXCL13 (240 pg/mL) was 10-fold higher in CLL patients compared to normal subjects. CAL-101 treatment decreased CXCL13 plasma concentration 2 to 5-fold in the first week of dosing across all dose levels evaluated. *Conclusions.* We demonstrate that treatment of CLL patients with CAL-101 results in PI3Kδ target inhibition and reduction of disease-related chemokines produced by both the CLL cells and the tumor microenvironment. These effects are consistent with evidence of clinical activity as measured by a decrease in lymphadenopathy and provide potential biomarkers for drug effect and anti-tumor activity.

0114

MECHANISMS OF ACTION OF TYPE-I AND TYPE-II CD20 MONOCLONAL ANTIBODIES ARE IMPACTED BY TUMOR CELL LOAD

J Beurskens,[1] M Jansen,[2] P Boross,[2] S De Haij,[1] L Bevaart,[2] J Golay,[3] P Parren,[1] J van de Winkel,[1] J Leusen[2]

[1]Genmab, Utrecht, Netherlands; [2]University Medical Center Utrecht, Utrecht, Netherlands; [3]Ospedali Riuniti di Bergamo, Bergamo, Italy

Background. CD20 represents a well-established target for immunotherapy of B-cell malignancies and autoimmune diseases, particularly through the chimeric antibody rituximab (RTX) which is most widely used. Recently, we described ofatumumab (OFA), a novel human CD20 monoclonal antibody (mAb), which binds a unique membrane-proximal epitope encompassing both the large and small loop on the CD20 molecule. In October 2009, the US FDA approved OFA, under the trademark Arzerra, for the treatment of fludarabine- and alemtuzumab-refractory chronic lymphocytic leukemia. Development of OFA is continuing in multiple additional indications. RTX and OFA are type I CD20 mAbs for which antibody-dependent cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC) have been identified as important *in vivo* mechanisms of action. Type II CD20 mAbs, such as B1 and 11B8, in contrast, have been suggested to primarily induce tumor cell kill via ADCC and induction of apoptosis. Complement-dependent cell-mediated cytotoxicity (CDCC) is an effector mechanism which has not yet received much attention. Tumor cell killing by CDCC is mediated via binding of the complement receptor CR3 to complement deposits on target cells. *Aim*. We now investigated the impact of tumor cell load on the mechanisms of action of type-I and type-II CD20 mAbs. *Methods.* The effector mechanisms of RTX, OFA (type I) and 11B8 (type II) CD20 mAbs were studied in novel well-controlled, intraperitoneal, syngeneic EL4-CD20 tumor models set up in wild type and various knock-out mice. We studied tumor cell killing following a short (24 hours) challenge with relatively low (5×10^5 cells) or high (5×10^6 cells) tumor burden. *Results.* All three mAbs (OFA, RTX and 11B8) were effective against a low burden of EL4-CD20 tumor cells in wild type mice, FcγR knock-out mice, FcγR-signalling deficient mice and CR3 knock-out mice. Depletion of complement by cobra venom factor, however, completely inhibited killing. We did not find any evidence for a role of apoptosis induction. Interestingly, OFA and RTX also effectively killed tumor cells in the high tumor burden models, whereas 11B8 did not. Tumor cell kill by OFA and RTX was abrogated in FcγRIII knock-out (but not FcγRI knock-out) mice, CR3 knock-out mice and after depletion of complement. This indicates that under these conditions complement activation as well as CDCC and ADCC are important for tumor kill. *Summary/Conclusions* CD20 mAbs may employ different mechanisms for tumor killing which vary in importance dependent on tumor load. Complement activation plays a critical role in both low and high tumor burden models. This study supports the hypothesis that cooperation of ADCC and CDCC with CDC may be critical for optimal CD20 mAb efficacy.

0115

OFATUMUMAB TARGETS A CONFORMATIONAL MEMBRANE-PROXIMAL EPITOPE WHICH CONTAINS AMINO ACIDS LOCATED IN THE SMALL AND LARGE LOOPS OF CD20

J Engelberts, F Beurskens, W Mackus, J Bakker, T Vink, A Tiebout, R de Jong, J van de Winkel, P Parren

Genmab, Utrecht, Netherlands

Background. CD20 represents a well-established target for immunotherapy of B-cell malignancies. Arzerra® (ofatumumab, OFA) is a novel human CD20 monoclonal antibody currently approved for fludarabine-and alemtuzumab-refractory chronic lymphatic leukemia (CLL). Proposed mechanisms of action for OFA include the induction of cell killing via the Fc-mediated effector functions; antibody-dependent cellular cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC). *Aim*. Based on previous studies we postulate that OFA's exceptional efficacy in activating these effector functions is related to its recognition of a unique membrane-proximal epitope, comprising amino acids in both the small (7 amino acid) and large (44 amino acid) loop of the CD20 molecule. *Methods*. To map OFA's cognate epitope in detail, we generated mutants via site-directed mutagenesis and performed a structure function analysis. To ensure normal surface expression, we employed a strategy in which we generated hybrid CD20 molecules using small loop sequences derived from the MS4A superfamily of which CD20 is a member, and which includes proteins sharing similar structure and limited sequence homology. *Results.* Thus, a complete substitution of the CD20 small loop almost completely abrogated OFA binding. Binding of rituximab (RTX) was not affected. A similar loss of OFA binding was observed when amino acids were replaced at three positions in the small loop (A74T, I76A, and Y77S), in which Y77, in particular, seemed to be crucial. Binding of OFA was also abrogated by mutations in the large loop (T159K, N163D and N166D). Notably, the cognate CD20 epitope for RTX was completely distinct and RTX binding was not affected by any mutations in the small loop, or other mutations affecting OFA binding for that matter. *Summary/Conclusion*. In conclusion, our data show that binding of OFA, but not RTX, is disrupted by amino acid substitutions in the CD20 small loop. Small loop amino acids A74-I76-Y77 are most important and complement the previously identified large loop amino acids T159-N163-N166 in the OFA epitope. The specific involvement of the CD20 small loop, which comprises only 7 extracellular amino acids, presumably positions OFA very close to the membrane, which allows it to harness effector mechanism-mediated killing most efficiently.

0116

GA101 DISPLAYS HIGHER ANTI-LEUKEMIC ACTIVITY MAINLY TROUGH ENHANCED ADCC IN CHRONIC LYMPHOCYTIC LEUKEMIA

L Ysebaert,[1] E Laprevotte,[1] E Gross,[1] C Klein,[2] JJ Fournié,[1] G Laurent,[1] A Quillet-Mary[1]

[1]INSERM U563, Toulouse, France; [2]Roche, Zurich, Switzerland

Background. The efficacy of anti-CD20 monoclonal antibodies (mAb) is a function of direct cell death (DCD), complement dependent cytotoxicity (CDC) and antibody dependent cellular cytotoxicity (ADCC). It is difficult to separate the relative contribution of each mechanism *in vivo*. However, *in vitro* tests may help to delineate the relative contribution of each pathway and would allow researchers to better define the mechanism of each pathway. This would allow clinicians to better define mAb and possibly tailor immunomodulation strategies. *Aims.* To investigate the principle mechanism by which GA101, a new type II glycoengineered CD20 mAb, currently in Phase III clinical trials, exerts its activity against fresh B-cell lymphocytic leukemia (CLL) cells. *Methods.* B cell depletion by either Rituximab (RTX) or GA101 was assessed by a flow cytometric B-cell depletion assay using Ficoll-separated peripheral blood mononuclear cell (PBMC) fraction issued from untreated B-CLL patients (n=5) and healthy donors (n=5) in complement heat-inactivated medium. B-cell depletion from PBMC encompasses DCD/ADCC mechanisms. Same experiments were performed with sorted $CD19^+$ leukemic B-CLL cells (n=3) to assess DCD in the absence of effector cells (no ADCC). In these experiments, 10 million cells/mL were incubated in the presence of RTX (10 µg/mL) or GA101 (10 µg/mL) for 7 days. In addition, conventional Cr51 release assays (to assess pure ADCC) were also performed using B-CLL cell as targets and autologous PBMC as effectors (n = 6, using a low E:T ratio of 0.4/1) from CLL patients who received Fludarabine Cyclophosphamide Rituximab (FCR), to assess autologous ADCC after immunochemothera-

py, an unexplored pre-clinical requisite for any maintenance strategy. *Results.* RTX and GA101 induced low rate of depletion in samples containing purified leukemic B-CLL cells (18% and 15%, respectively), suggesting that these two antibodies displayed low intrinsic DCD against purified B-CLL cells. When used in PBMC fraction from normal donors, RTX and GA101 were more potent, but induced similar depletion of normal B-cells (57% and 56% for RTX and GA101, respectively). However, when used in PBMC fraction from B-CLL patients, GA101 appeared to be much more efficient than RTX, with median leukemic cell clearance as high as 97%, compared to only marginal depletion with RTX (P<0.01). Given CLL cells have significantly lowered CD20 density (mean 19000 Antibodies Bound per Cell vs 81000 ABC in healthy B cells, P<0.001), this data indicates that GA101 efficiency is higher on B-CLL than on normal B cells. Finally, GA101 was also more effective than RTX in autologous ADCC assay (patients' effectors against own CLL cells), with mean CLL lysis of 13.85%, versus 7.34% for RTX and <1% with IgG1 control (P<0.05). *Summary*. This study supports the notion that GA101 harness higher ADCC capacity for CLL patients effector cells (as compared to RTX). In particular, we observed that ADCC is measurable before and even after FCR pre-treatment. Taken together these data argue for the use of this antibody in B-CLL therapy.

0117

LUMILIXIMAB MODULATES PI3-K/AKT PATHWAY AND INDUCES APOPTOSIS IN CLL CELLS

M Shehata,[1] S Schnabl,[1] E Ponath,[1] D Demirtas,[1] M Hilgarth,[1] S Badrnya,[1] S Tauber,[1] M Bilban,[1] K Eigenberger,[1] J Schwarzmeier,[1] A Gaiger,[1] R Hubmann,[1] C Zielinski,[1] S Hughes,[2] A Maclaren,[2] U Jaeger[1]

[1]Medical University of Vienna, Vienna, Austria; [2]Biogen Idec Inc., Maidenhead, Berkshire, UK

Background. Chronic lymphocytic leukemia (CLL) is characterized by a defect in apoptosis mechanisms and the high expression of CD23. Lumiliximab is a monoclonal antibody against CD23 which has been shown to exert a promising therapeutic effect in CLL *in vivo* and to induce apoptosis in $CD23^+$ lymphoma cells *in vitro*. *Aims.* The aim of this study was to investigate the molecular mechanism of action of lumiliximab in CLL cells and its role in the regulation of the anti-apoptotic PI3-K/Akt cascade signaling in primary CLL cells. *Methods.* PBMC from CLL patients were exposed to lumiliximab (1-50 µg/mL) for 1-15 days in co-culture with autologous primary human stromal cells which prevent spontaneous apoptosis of CLL cells. Cell viability was assessed by flow cytometric analysis using annexin V/PI staining and by MTT assays. *Results.* The results showed that single exposure to lumiliximab had a moderate effect on cell viability (<1 fold increase in apoptosis rate compared to untreated controls). However, repeated exposure to lumiliximab had a significant pro-apoptotic effect selectively in the $CD19^+/CD5^+/CD23^+$ cells. Western blotting demonstrated that lumiliximab decreased the levels of Bcl-2, Mcl-1 and Hsp70 protein expression. In addition, it resulted in a significant decrease in the phosphorylation of Akt (Ser473) and dephosphorylation of the tumor suppressor PTEN (Ser380) suggesting the involvement of the PI3-K/Akt/PTEN cascade in priming CLL cells to undergo apoptosis by lumiliximab. Pre-incubation of CLL cells with lumiliximab enhanced the pro-apoptotic effect of PI3-K inhibitor LY292004 and the casein kinase-2 (CK2) inhibitor apigenin. Microarray analysis and pathway exploration revealed that lumiliximab regulates several sets of genes which are involved in chemokine signaling, cytokine/cytokine receptor interaction, oxidative stress, PI3-K and integrin signaling, complement cascade and Toll-like receptor signaling. *Conclusions.* The data demonstrate that exposure to Lumiliximab is effective in priming CLL cells to undergo apoptosis through inactivation of the PI3-K/Akt pathway. The data also provide further evidence of a promising therapeutic role for lumiliximab in CLL and a rationale for lumiliximab-based drug combinations to improve treatment of this disease and other disorders associated with increased expression of CD23.

0118

ABNORMAL IMMUNOGLOBULIN SERUM FREE LIGHT CHAINS RATIO IS ASSOCIATED WITH UNFAVORABLE PROGNOSTIC MARKERS AND IS A PREDICTOR OF TREATMENT FREE SURVIVAL IN CHRONIC LYMPHOCYTIC LEUKEMIA

F Morabito,[1] R De Filippi,[2] M Gentile,[1] G Iaccarino,[2] I Attolico,[3] G Cutrona[4] A Neri,[5] M Ferrarini,[4] B Amoroso,[6] S Molica,[7] G Del Poeta,[8] A Pinto[2]

Pascale, Napoli, Italy; [3]UO di Ematologia, Ospedale San Carlo, Potenza, Italy; [4]Divisione di Oncologia Medica C, Istituto Nazionale per la Ricerca sul Cancro, Genova, Ital; [5]Centro di Ricerca per lo Studio delle Leucemie, Fondazione IRCS, Milano, Ital; [6]Cliniical Research Direction, The Binding Site,, Birmingham, UK; [7]Dipartimento di Oncologia/Ematologia, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy; [8]Division of Haematology, Ospedale S. Eugenio, University Tor Vergata, Roma, Italy

Background. Assessment of sFLC concentrations and ratio is a powerful tool to qualify response stringency and duration in patients with multiple myeloma. The presence of an abnormal sFLC ratio also represents a risk factor for progression in different types of plasma cell dyscrasias. Being a sensitive, simple and highly reproducible indicator of B-cell clonality, the sFLC test is particularly attractive as a putative prognostic marker in CLL as compared with current assays including CD38 or ZAP-70, FISH analysis, or evaluation of IgVH gene mutational status. *Patients and Methods*. To assess the prognostic value of sFLC testing in CLL, 248 untreated CLL (Binet stage A=162, B=26, C=44) patients (138 males; median age 64 yrs) were enrolled in a collaborative retrospective study. TFS was calculated from diagnosis to first treatment. Median follow-up was 2.7 years (range 1-20) and 83 of 232 patients analyzed for clinical outcome received treatment by the end of the study. Cryopreserved (-80°C) serum samples were collected and sFLC levels were determined in the reference study laboratory using a particle-enhanced, high-specificity, homogeneous FLC immunoassay [Freelite; The Binding Site, Birmingham, UK, performed on a Delta Nephelometer (Radim)]. *Results.* ZAP-70, CD38 and IgVH mutational analyses were performed in 217 (80 $ZAP\text{-}70^+$), 226 (47 $CD38^+$) and 178 (62 unmut-IgVH) cases, respectively. FISH in 129 cases: normal (52 cases), 13q14.3 deletion (31), trisomy 12 (15), 11q22.3 (11) and 17p13.1 (17). An abnormal sFLC ratio was found in 85 cases (73κ, 12λ). No significant correlation emerged between sFLC abnormality and Binet stage, while a significant association was demonstrated with CD38 (P<0.0001) and ZAP-70 (P=0.005) expression and IgVH mutation status (P=0.033); FISH results showed no correlation with abnormal sFLC testing. Univariate Cox analysis showed a statistically significant higher risk of treatment initiation in Binet B+C pts (HR=1.6, 95% C.I. 1.1-2.5, P=0.034), $CD38^+$ (HR=2.2, 95% C.I. 1.4-3.5, P=0.002), $ZAP\text{-}70^+$ (HR=5.6, 95% C.I. 3.5-9.3, P<0.0001), unmut-IgVH (HR=3.8, 95% C.I. 2.2-6.4, P <0.0001), and in cases deleted for 17p13.1 and 11q (HR=4.1, 95% C.I. 1.5-5.0, P=0.001). To assess the prognostic relevance of sFLCs, patients were subdivided into normal or abnormal ratio groups. The analysis revealed a significantly higher risk of progressing to treatment for patients with abnormal sFLCs (HR=2.5, 95% C.I. 1.6-4.0, P<0.0001). Notably, sFLCs retained an independent association with TFS even when adjusted for either Binet stage, CD38 or ZAP-70 expression, IgVH mutational status and FISH abnormalities. *Summary/Conclusion.* While the correlation of ZAP-70 and CD38 expression, and IgVH mutational status indicates that an abnormal sFLC ratio could identify patients with a more aggressive subtype of CLL, the lack of association with Binet staging suggest the sFLC ratio is not simply reflecting disease bulk but rather mirrors specific biological features of tumor cells. A prospective confirmation of the predictive prognostic power of the sFLC ratio will be of utmost relevance given that sFLC assay is a simple and highly reproducible test as compared to the more complex determination of IgVH mutation status involving DNA sequencing or ZAP-70 status where significant inter-laboratory variation exists.

Chronic myeloid leukemia - Biology 1

GENOMIC SEGMENTAL DUPLICATIONS ARE INVOLVED IN THE OCCURRENCE OF T(9;22) REARRANGEMENT IN CHRONIC MYELOID LEUKEMIA

F Albano,[1] L Anelli,[1] A Zagaria,[1] N Coccaro,[1] P D'Addabbo,[2] V Liso,[1] M Rocchi,[2] G Specchia[1]

[1]*Hematology-University of Bari, Bari, Italy;* [2]*Genetics-University of Bari, Bari, Italy*

Background. A crucial role of segmental duplications (SDs) of the human genome has been demonstrated in chromosomal rearrangements associated with several genomic disorders. Limited knowledge is yet available on the molecular processes resulting in chromosomal rearrangements in tumors. The t(9;22)(q34;q11) causing the 5'BCR/3'ABL gene formation has been detected in more than 90% of chronic myeloid leukemia (CML) cases. *Aims.* In 10-18% of CML patients genomic deletions were detected on der(9) chromosome next to translocation breakpoints. The molecular mechanism triggering the t(9;22) and deletions on der(9) is still unknown. Our study presents an experimental evidence of the involvement of SDs in the genesis of the t(9;22) translocation in CML and in the occurrence. *Methods.* We studied 71 cases with der(9) deletions by FISH. Fine-mapping of deletions was performed using appropriate bacterial and Phage P1-derived artificial chromosome clones. The mapping of all breakpoints revealed an evident breakpoints clustering, on both chromosomes 9 and 22, in two regions of about 2 Mb in size. Indeed, these regions contained the breakpoints detected in 54 out of 60 (90%) patients bearing chromosome 9 deletions and in all patients with chromosome 22 sequences loss. Bioinformatic analysis of chromosome 9 and chromosome 22 genomic regions involved in the deletions was performed to search for features that could correlate with the breakpoints clustering. To this aim, the breakpoint regions were subdivided into 250 Kb intervals. *Results.* The most striking result was the fact that both clusters contain a previously described 76-kb duplicon, shared by chromosome 9 and 22 (SD_9/22). The SD_9/22 is the only duplication located inside the breakpoints clustering region on chromosome 9, whereas the chromosome 22 clustering region harbors several duplications. A remarkable feature of the chromosome 9 clustering region was the high frequency of Alu repeats. The mean Alu frequency overall on chromosome 9 is 10.8%, whereas the average Alu content on this cluster is 31.3%. Accordingly, as expected, the content in LINE sequences of the region was relatively low. Gene distribution analysis of chromosome 9 and 22 showed that both SD_9/22 map inside gene-poor regions. A statistically significant negative association was observed between the number of breaks and the distance from SD_9/22, on both chromosomes 9 (P=0.01) and 22 (P=0.006), respectively. The relationship between the breaks and the interspersed repeats revealed, on chromosome 9, a positive linear regression with Alu repeats (P=0.04), and a negative one with LINEs (P=0.04). Very similar conclusions were obtained by comparing the distance from the SD_9 and the Alu (P= 0.03, positive) and LINE distribution (P=0.02, negative). No statistically significant relationship was observed on chromosome 22. *Conclusions.* In our study the involvement of SDs was proposed to explain the recurrent t(9;22) translocation in CML and the genomic deletions that could accompany the rearrangement. At the light of these findings, the analysis of secondary non-recurrent events could represent a new methodological approach able to identify architectural elements involved in the occurrence of recurrent primary rearrangements in human neoplasia.

FOXO TRANSCRIPTION FACTOR ACTIVITY IS PARTIALLY RETAINED IN QUIESCENT CML STEM CELLS AND INDUCED BY TYROSINE KINASE INHIBITORS IN CML PROGENITOR CELLS

F Pellicano,[1] G Helgason,[1] E Allan,[1] B Huntly,[2] T Holyoake[1]

[1]*University of Glasgow, Glasgow, UK;* [2]*Department of Haematology, Cambridge, UK*

Background. Chronic Myeloid Leukaemia (CML) is a clonal disease initiated and maintained by the tyrosine kinase BCR-ABL. BCR-ABL signaling activates the PI3K/AKT pathway (amongst others), leading to inhibition of the transcriptional activity of the FOXO family proteins. ABL-specific tyrosine kinase inhibitors (TKIs), whilst effective against mature CML cells, induce little apoptosis in stem/progenitor cells. In addition, TKIs exert potent anti-proliferative effects in stem/progenitor cells through a poorly understood mechanism. FOXO transcription factors are known to transcriptionally modulate proteins that induce cell cycle arrest. Therefore, BCR-ABL-mediated inhibition of FOXO may contribute to CML cell proliferation and malignant transformation. *Aims.* To investigate the mechanism of TKI-induced G1 arrest in primary CML stem/progenitor cells in relation to FOXO proteins. *Methods.* We performed *in vitro* experiments by flow cytometry analysing phosphorylation of FOXO1, 3a and 4 in CML $CD34^+$ and $CD34^+38^-90^-$CML cells treated with 150 nM dasatinib for 24 h. Western blotting and immuno-fluorescence were used to show relocation of total FOXO1, 3a and 4 from the cytoplasm (inactive) to the nucleus (active) after dasatinib treatment. *Results.* We showed that in $CD34^+$ CML cells FOXO1, 3a and 4 (FOXOs) were phosphorylated, predominantly cytoplasmic and inactive, consequent to BCR-ABL expression. TKIs, such as dasatinib, decreased phosphorylation of FOXOs, leading to their re-localisation from cytoplasm to nucleus, thus inducing cell cycle arrest. Interestingly, despite BCR-ABL activity, primitive quiescent CML stem cells ($CD34^+38^-90^-$) showed low levels of FOXO phosphorylation, resembling the pattern in normal stem cells. *Conclusions.* These results demonstrate that TKI-induced G1 arrest in CML progenitor cells is mediated by re-activation of FOXOs, whilst quiescence of CML stem cells is, at least in part, regulated by sustained FOXO activity. These data contribute to our understanding of CML stem cell quiescence and TKI activity, suggesting new strategies to target CML stem/progenitor cells by preventing or reversing this effect.

0121

ABT-737 COOPERATES WITH TYROSINE KINASE INHIBITORS TO INDUCE APOPTOSIS OF CHRONIC MYELOID LEUKEMIA CELLS THROUGH BCL-XL INHIBITION AND IAP PROTEINS DOWN-REGULATION

K Airiau

U876 INSERM, Pessac, France

BCR-ABL confers an apoptosis-resistant phenotype due to its kinase activity. Several pro- and anti-apoptotic proteins of the Bcl-2 family modulate the apoptotic signal. Amongst them, anti-apoptotic Bcl-xL and Mcl-1 are induced by BCR-ABL. Conversely, Bim expression strongly affects tyrosine kinase inhibitor-induced apoptosis and Bim-depleted cells were unable to undergo apoptosis when treated by either imatinib (IMA) or nilotinib (NIL). It has been shown that Bim actually is an indirect activator of apoptosis through its anti-Bcl-xL, -Mcl-1 and -Bcl-2 effects. Recently, ABT-737, a small molecule which binds Bcl-2 and Bcl-xL but not Mcl-1, was shown to induce apoptosis in several tumour cell types. In this study, we verify if ABT-737 could cooperate efficiently with the Bim stabilizing TKI. The ABT-737 ability to displace the Bcl-2 family proteins interaction was investigated by co-immunoprecipitation on K562 cells. ABT-737 decreased the BIM/Bcl-XL interaction in cell free system as in intact cells and increased the BIM/MCL-1 interaction supporting the complementary effects of TKI (stabilizing Bim) and ABT-737. K562 cells were incubated with increasing concentrations of either imatinib or nilotinib, alone or in combination with ABT-737, in a constant ratio. Both TKI and ABT-737 induced a dose dependant apoptosis and the combination of both TKI with ABT-737 resulted in a synergistic cooperation to induce apoptosis as assessed using the Calcusyn software. Similar experiments were performed on CD34 expressing cells from 12 CML patients, and the strong synergism of ABT-737 with both TKI was confirmed. To elucidate the mechanisms underlying this cooperation, we analyzed the Bcl-2 family proteins expression and confirmed the increase of Bim and the decrease of Bcl-xL due to TKI treatment while ABT-737 remained without effect. The expression of several anti-apoptotic proteins was also analyzed. Surprisingly, the TKI/ABT-737 association induced a strong decrease in two IAP family members: XIAP and cIAP1. This decrease was accompanied by an increase in caspase 3 activation. Cell sorting experiments showed that the IAP decrease preceded the drop in mitochondrial membrane potential and caspase 3 activation. This led us to investigate the role of the IAP family proteins in the TKI treatment response by using the LBW-242, a Smac mimetic inhibitor of IAPs. K562 cells were incubated with imatinib alone or in combination with LBW-242, in a constant ratio. Both IMA and LBW-242 induced a dose dependant apoptosis and the combination of IMA with LBW-242 resulted in a synergistic cooperation to induce apoptosis. Similar experiments with similar results were performed on CD34 expressing cells from 10 CML patients, confirming the adverse effect of IAPs on TKI-induced apoptosis. The ABT-737/TKI cooperation to induce apoptosis of CML cells can be explained by the increase in Bim content induced by TKI associated to the inactivation of Bcl-2, -xL

by ABT-737. However, a side effect at the level of the caspase inhibitors XIAP and cIAP1 also seems to participate, resulting in a strong synergism. Thus, the association of BH3- and/or Smac-mimetics with TKI treatment could be a facilitating strategy to induce apoptosis in some BCR-ABL expressing cells resistant to TKI alone.

HIGH-RESOLUTION MOLECULAR KARYOTYPING OF CHRONIC MYELOID LEUKEMIA PATIENTS IN BLAST CRISIS BY 6.0 SNP-ARRAYS IDENTIFIES FOCAL COPY NUMBER ALTERATIONS AFFECTING ONCOGENES AND TUMOR SUPPRESSOR GENES

S Soverini,[1] S Colarossi,[1] A Gnani,[1] A Poerio,[1] F Castagnetti,[1] A Astolfi,[2] S Formica,[2] F Palandri,[1] I Iacobucci,[1] M Amabile,[1] G Marzocchi,[1] S Luatti,[1] N Testoni,[1] G Gugliotta,[1] G Rosti,[1] M Baccarani,[1] G Martinelli[1]

[1]University of Bologna, Bologna, Italy; [2]Paediatric Oncology and Haematology Unit, University of Bologna, Bologna, Italy

Background. Despite the striking efficacy of targeted therapy for chronic myeloid leukemia (CML), a proportion of patients (pts) still experience progression from the initial chronic phase to an acute phase (blast crisis; BC) characterized by high disease aggressiveness and poor prognosis. BC is known to be associated with accumulation of additional genetic alterations, but these alterations have so far been only partially characterized. *Aims.* We have used Human 6.0 SNP Arrays (Affymetrix) to perform high-resolution molecular karyotyping of 30 DNA samples from BC (myeloid, n=23; lymphoid, n=7) CML pts. *Methods.* The 6.0 SNP Array technology relies on 1.8 million markers evenly spaced across the genome, with a median inter-marker distance <700 bp. So, we decided to exploit the unprecedented resolution of Human 6.0 SNP Arrays and the ability of Genotyping Console 3.0.2 (Affymetrix) software to pinpoint the borders of these CNAs. We thus aimed our analysis to the identification of very small CNAs that may have been missed by previous studies - all using less sensitive assays. Gains/losses mapping to known regions of copy number variation (CNV) were excluded. *Results.* Our approach revealed a number of focal gains or losses ranging from 4 to 47Kb, affecting a single gene or, more frequently, only part of a gene. Amplifications were as frequent as monoallelic deletions and involved the promoter region and or one or more exons. In some cases, a complex pattern of amplification of some exons and monoallelic deletion of others was recognized within the same gene. These alterations were found in 2 to 12 pts each, and involved the following genes: AKT3; CDC73; RB1; JAK2; JAK1; ERG; ETS1; SMAD; PIK3CA; EPHA3; RUNX1T1; ETV1; AKT2; MDM4; KALRN; FHIT; K-RAS; PTEN; FAF1; SKAP2; PTCH1; GAS2; FGFR2; SOS1; NRG1; MET; PBX4; ETV5; N-RAS, HGF, TEC; PAK2; H-RAS. The precise anatomy of alterations will be presented. Deeper characterization at the DNA and RNA level by polymerase chain reaction and sequencing is ongoing. All the genes identified in our screening were transcription factors, adaptor proteins, receptor and non-receptor kinases involved in cell proliferation and apoptosis - with a known role as oncogenes or tumor suppressors or oncogene/tumor suppressor interactors. *Conclusions.* Our results confirm a high degree of heterogeneity in the alterations detectable in BC CML pts. In conclusion, the power of 6.0 SNP Array technology allowed us to detect previously unidentified alterations targeting whole or part of key oncogenes or tumor suppressors whose deregulation may play a role in determining the aggressive phenotype of BC CML and which may represent potential therapeutic targets. Supported by European LeukemiaNet, AIL, AIRC, PRIN, Fondazione del Monte di Bologna e Ravenna.

NON RANDOM DISTRIBUTION OF GENOMIC FEATURES IN BREAKPOINT REGIONS INVOLVED IN CHRONIC MYELOID LEUKEMIA CASES WITH VARIANT T(9;22) OR ADDITIONAL CHROMOSOMAL REARRANGEMENTS

F Albano,[1] L Anelli,[1] A Zagaria,[1] N Coccaro,[1] P Casieri,[1] L Vicari,[2] A Russo Rossi,[1] V Liso,[1] M Rocchi,[3] G Specchia[1]

[1]Hematology-University of Bari, Bari, Italy; [2]Service of Medical Genetics, Cardarelli Hospital, Napoli, Italy; [3]Genetics-University of Bari, Bari, Italy

Background. The t(9;22)(q34;q11), generating the Philadelphia (Ph) chromosome, is found in more than 90% of patients with chronic myeloid leukemia (CML). At diagnosis, in 5-10% of CML patients the Ph chromosome is derived from variant translocations other than the standard t(9;22). *Aims.* The aim of this study was to perform an accurate breakpoints identification and bioinformatic analysis of other chromosomes involved in variant t(9;22) or in concomitant chromosomal rearrangements apart from the t(9;22). *Methods.* Four hundred and fifty two consecutive CML patients in chronic phase were analyzed by conventional cytogenetic analysis and by FISH experiments with probes specific for ABL and BCR genes. All breakpoints on other chromosomes involved in variant t(9;22) and in additional rearrangements have been characterized by FISH experiments and bioinformatic analyses. Breakpoint regions on other chromosomes involved in variant t(9;22) and additional rearrangements were included in 250 Kb size intervals. Each interval was checked for the presence of interspersed repeats classes (Alu and LINE repeats), segmental duplications (SDs), GC content, gene density, and miRNA. *Results.* The molecular cytogenetic analysis revealed 50 CML cases identifying three main subgroups: i) cases with variant chromosomal rearrangements other than the classic t(9;22)(q34;q11) (9.5%); ii) cases with cryptic insertions of ABL1 into BCR, or vice versa (1.3%); iii) cases bearing additional chromosomal rearrangements concomitant to the t(9;22) (1.1%). Bioinformatic analysis showed that the majority of breakpoints on chromosomes involved in variant or additional chromosomal rearrangements showed a high frequency of Alu repeats. In fact, 41 out of 58 (71%) breakpoints showed an Alu content of more than one whereas the remaining 17 out of 58 (29%) had a content of less than one. Instead, the LINE content was lower than one in 44 out of 58 (76%) breakpoints. Most of the analyzed breakpoints map within gene-rich regions in 45 out of 58 (78%) breakpoints. Moreover, 49 out of 58 (84%) breakpoints revealed a low SDs density. A GC content >1 was detected in 43 out of 58 (74%) breakpoints. The search for miRNAs revealed a different density from the expected value in 33 out of 58 (57%) breakpoint regions. In detail, in 29 (88%) and 4 out of 33 (12%) breakpoints a higher or lower number of miRNA than the expected value was identified, respectively. In the remaining 25 out of 58 (43%) breakpoints no miRNA was revealed in the 4 Mb analyzed intervals. *Conclusions.* This study revealed a high content of Alu repeats, genes density, GC frequency, and miRNAs in the great majority of the analyzed breakpoints, suggesting their potential involvement in the CML pathogenesis. In conclusion, our findings demonstrate that the involvement of chromosomes other than 9 and 22 is not a random event but could depend on specific genomic features.

0124

NAMPT, A MEDIATOR OF NORMAL GRANULOCYTIC DIFFERENTIATION, IS DOWN-REGULATED IN CHRONIC MYELOID LEUKAEMIA VIA CHROMATIN MODIFICATION

J Khorashad, M Hu, D Hopmeier, M Daghistani, P May, G Gerrard, D Marin, D Milojkovic, J Apperley, L Foroni, J Goldman, A Karadimitris, A Reid

Imperial College London, London, UK

Background. Chronic myeloid leukaemia (CML), a haematological malignancy initiated by the BCR-ABL1 fusion, is characterised by an overproduction of immature granulocytes. The BCR-ABL1 gene fusion is acquired at the stem cell level, but the precise events that govern the proliferation and differentiation of the CML clone are poorly understood. In normal haemopoiesis, the NAMPT gene (also known as PBEF1) was recently shown to mediate G-CSF-induced myeloid differentiation via the NAD pathway, raising the possibility that this gene may be involved in the pathogenesis of CML. *Aims.* To confirm the role of NAMPT in granulocytic differentiation and to investigate the expression of NAMPT in CML. *Methods.* A MIGR1 retroviral construct containing NAMPT was used to transduce murine haemopoietic stem cells (HSCs). Cells were stained with granulocytic marker Gr-1 conjugated with PE and monocytic/macrophage marker Cd11b conjugated with APC and subjected to flow-cytometric analysis. NAMPT expression in granulocytes and CD34 cells from CML patients and normal individuals was assessed by TaqMan-based real-time RT-PCR. Allelic ratio testing was performed by pyrosequencing (for SNPs) or capillary electrophoresis using Genescan fragment analysis software (for the insertion/deletion polymorphism). For assessment of nuclease sensitivity, normal and CML granulocytes were fixed, permeablised and treated with micrococcal nuclease prior to real-time PCR using primers within the NAMPT promoter. The methylation status of the NAMPT promoter was assessed by cloning and bisulphite sequencing. *Results.* In keeping with published data we observed increased granulocytic differentiation in murine haemopoietic stem cells transduced with NAMPT. Interestingly, however, we found that NAMPT levels in granulocytes from chronic phase CML patients at presentation (n=20) were 410-fold low-

er than normal controls (n=30; P<0.0001; CML range 0.7-19.7, normal range 128-4470). NAMPT expression in CD34 cells from CML patients was also low, but not significantly different to expression in normal CD34 cells. We then performed several investigations into the mechanism of NAMPT silencing. Allelic ratio testing using an insertion deletion polymorphism and 3 SNPs within the NAMPT locus revealed no evidence of loss of heterozygosity. Application of a real-time PCR-based quantitative nuclease sensitivity assay revealed decreased nuclease sensitivity in the promoter region of NAMPT in CML granulocytes, but not in normal granulocytes, in keeping with chromatin condensation in this region. There was no evidence of methylation in CpG islands of the promoter by cloning and bisulphite sequencing, suggesting an alternative mechanism of chromatin modification. *Conclusions.* Taken together our findings indicate disease-specific epigenetic silencing of NAMPT in CML. This would be in keeping with the recent suggestion that NAMPT functions as a tumour suppressor gene. Alternatively, downstream BCR-ABL1 signalling pathways may initiate granulocytic differentiation independently of NAMPT, bypassing the stage at which the gene is usually activated.

BCR-ABL BUT NOT JAK2 V617F INHIBITS ERYTHROPOIESIS THROUGH THE RAS SIGNAL BY INDUCING P21CIP1/WAF1

M Tokunaga, S Ezoe, H Tanaka, Y Satoh, I Matsumura, Y Kanakura

Osaka University Graduate School of Medicine, Suita, Osaka, Japan

Background and *Aims.* BCR-ABL is a causative tyrosine kinase (TK) of chronic myelogenous leukemia (CML). In CML patients, anemia is commonly observed in contrast to marked leukocytosis. This phenotype is quite different from that of polycythemia vera caused by JAK2 V617F, although both TKs activate common downstream molecules at the hematopoietic stem cell level. To clarify this mechanism, we investigated the effects of BCR-ABL and JAK2 V617F on erythropoiesis. *Methods.* We introduced BCR-ABL, JAK2 V617F, and active forms of their downstream molecules: N-RasE12 (N-Ras), 1*6 STAT5A (STAT5) and $p110^{CAAX}$ (phosphatidylinositol 3-kinase), into murine bone marrow LSK (Lineage-$Sca\text{-}1^{hi}CD117^{hi}$) cells by retrovirus system. After 5 days of culture with murine stromal MS-5 cells, the fraction of $CD45^{low}TER\text{-}119^{+}$ erythroid cells was evaluated by flow cytometry. *Results.* BCR-ABL reduced the erythroid fraction while JAK2 V617F did not (proportions: Mock, 11.4%; BCR-ABL, 5.4%; JAK2 V617F, 12.0%). Also, BCR-ABL but not JAK2 V617F reduced the number of BFU-E. Among their downstream molecules, 1*6 STAT5A and $p110^{CAAX}$ increased the numbers of both erythroid (2.8- and 1.9-fold, respectively) and myeloid cells (4.9- and 3.0-fold, respectively). On the other hand, N-RasE12 reduced the number of erythroid cells (0.28-fold) in contrast to the significant increase in myeloid cells (3.6-fold). In immunoblotting, ERK was more intensely phosphorylated in BCR-ABL-transfected Ba/F3 cells than in JAK2 V617F-transfected cells, suggesting that different growth status of erythroid cells between these TKs results from the preferential activation of Ras signal by BCR-ABL. As for the mechanism through which Ras promotes myelopoiesis but suppresses erythropoiesis, we examined the effect of GATA-1, a transcription factor expressed in erythroid but not in myeloid lineage, on Ras signaling. In Ba/F3 cells transduced with N-RasE12 and GATA-1/ERT, activation of GATA-1 by 4-Hydroxytamoxifen completely suppressed Ras-dependent growth and survival. Luciferase assays and immunoblotting revealed that GATA-1 blocked the activity of Ras/Raf/MEK/ERK signaling at the level of MEK. In GST pull-down assays, GATA-1 interacted with MEK directly. Together, these data indicate that GATA-1 blocks Ras/Raf/MEK/ERK mitogenic signal through the direct interaction with MEK. Oncogenic Ras, while promoting cell growth, also causes growth arrest to act against malignant transformation. Because this response is mediated by several pathways involving cell cycle regulators such as p53, $p16^{INK4a}$, $p19^{ARF}$ and $p21^{CIP1/WAF1}$, we investigated their roles in Ras-induced suppression of erythropoiesis. Expression of N-RasE12 in LSK cells from p53, p16INK4a/$p19^{ARF}$ or $p21^{CIP1/WAF1}$-wild-type/knock-out mice revealed that the proportion of erythroid cells reduced by N-RasE12 was restored only by $p21^{CIP1/WAF1}$ deficiency (wild-type, 3.0%; knock-out, 5.2%). Also, expression of N-RasE12 in $p21^{CIP1/WAF1}$-knock-out cells increased the erythroid cell number compared with Mock-transduced wild-type and knock-out cells. Although $p21^{CIP1/WAF1}$ is a transcriptional target of p53, our results indicate that Ras suppresses erythropoiesis through $p21^{CIP1/WAF1}$ in a p53-independent manner. *Conclusions.* In Ras-induced suppression of erythropoiesis, GATA-1 blocks growth-promoting signals by direct interaction with MEK, leading to the relative dominance of growth-suppressing signals. We also identified $p21^{CIP1/WAF1}$ as a central mediator in Ras-induced suppression of erythropoiesis. These mechanisms would be helpful for explaining how respective TKs reveal different disease phenotypes.

MIR-451 MAY POSITIVELY REGULATE MDR1 IN CHRONIC MYELOID LEUKEMIA

T Lopotova, M Zackova, V Polivkova, H Klamova, J Moravcova, K Machova Polakova

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

MicroRNAs (miRNAs) are small single-stranded RNAs that regulate gene expression by inhibiting translation or by decreasing stability of target mRNAs. Aberrant expression of miRNAs has been associated with some hematological malignancies. Previously, we observed expression changes of miR-451 at different stages of chronic myeloid leukemia (CML) and different responses to imatinib in comparison to healthy control using microRNA arrays. We validated aberrant expression of miR-451 by real-time PCR on the cohort of 116 patient samples of total leukocytes representing: diagnosis (Dg; 100% Ph^{+}) n=15, major molecular response (MMR; <0.1% BCR-ABL) n=26, suboptimal response/therapy failure (SR/TF; 30-100% Ph^{+}) n=29, hematological relapse (Hr; 100% Ph^{+}) n= 24 and accelerated phase together with blast crisis (AP/BC; 10-79% blasts) n=22. Down-regulation of miR-451 was found in 73% (11/15) of Dg, 71% (17/24) of Hr and 55% (12/22) of AP/BC patient samples in comparison to healthy controls (n=11). On the other hand expression of miR-451 was up-regulated in some MMR (12/26) and SR/TF (10/29) patient samples. To explore possible consequences of miR-451 differential expression in response to imatinib, we investigated in this study the expression of multidrug resistant gene (MDR1) that was described to be activating by miR-451 in human cancer cells (Zhu et al., Biochemical Pharmacology 2008,26:582). Using real-time PCR we found down-regulated MDR1 expression on the same cohort of patient samples among healthy control in Dg, Hr and AP/BC, and up-regulated MDR1 levels in MMR and SR/TF, which suggested correlation between miR-451 and MDR1 expressions and supported results of Zhu *et al.* (2008). To confirm our data found *in vivo*, we treated leukocytes of newly diagnosed patients (n=6) with imatinib *in vitro*. Inhibition effect of imatinib was proved by decreased p-Crkl levels (Western blot) and decreased WT1 transcript levels (real-time PCR) (Svensson *et al.,* Leukemia,21:2485). Apoptosis was checked by RNA degradation levels and by annexing V staining to avoid its interference to expression analyses. Also we checked that imatinib free cultivation after 2h, 24h, 48h and 78h did not affect expression of WT1, miR-451, MDR1 and p-CRKL levels. JURL and CML cell lines were used as positive controls and leukocytes of healthy donors (n=3) were used as negative controls. Imatinib naïve patient leukocytes and BCR-ABL positive cell lines expressed down-regulated miR-451 and MDR1 and high BCR-ABL activity. We showed that miR-451 levels and MDR1 mRNA levels increased together with inhibition of BCR-ABL activity in imatinib treated leukocytes. In conclusion, from our expression data *in vivo* and *in vitro* it seems that miR-451 may positively regulate MDR1 expression in CML. Moreover, our data showing increased levels of MDR1 in leukocytes of CML patients in MMR as well as increased levels of MDR1 and inhibited BCR-ABL activity in leukocytes of CML patients treated with imatinib *in vitro* suggested that MDR1 is unlikely to mediate imatinib resistance in CML patients, which is in agreement with Hatziieremia *et al.* (Experimental Hematology 2009;37:692).

Supported by GACR GP301/08/P154, MZOUHKT2005, and Novartis Oncology for imatinib mesylate substance provision.

PTCH1: NEW TARGET FOR MONITORING CHRONIC MYELOID LEUKAEMIA AND THERAPY

G Cirmena,[1] M Cea,[1] A Garuti,[1] I Rocco,[1] C Palermo,[1] AM Carella,[2] F Patrone,[1] A Ballestrero[1]

[1]University of Genoa, Genoa, Italy; [2]Division of Hematology, Azienda Ospedaliera Universitaria San Martino, Genoa, Italy

Background. Chronic myeloid leukemia (CML) is characterized by the expansion of a leukemic stem cell clone carrying a Philadelphia translocation, which outgrows the non-malignant haematopoietic stem cells. The existence of a leukemia stem cell population may account for drug-resistance and relapse during treatment. The tyrosine kinase inhibitors (TKIs) imatinib, nilotinib and dasatinib, all show impressive rates of complete cytogenetic response in chronic phase (CP) CML.

However, the majority of responding CP CML patients have detectable BCR-ABL transcripts which might arise from a population of quiescent CML stem cells not effectively targeted by TKIs. Recent studies have indicated that the Hedgehog (Hh) pathway, a developmental pathway with roles in primitive and adult hematopoiesis, is activated in a wide variety of human cancers, included CML, via upregulation of Smoothened (SMO), a seven-transmembrane domain receptor protein. Notably several highly conserved members of this pathway are inappropriately activated such as Ptch1 (surface receptor regulator of SMO). *Aims.* Better understanding of the role of Hh signaling in CML, to identify predictive and pharmacodynamic markers of tumour responses. In this study, we identified PTCH1 as a molecular marker in Bcr-Abl-positive leukemic stem cells. *Methods and results.* in order to examine the functional role of Hh signaling in CML, we treated cells line K562 with the naturally occurring inhibitor of SMO, cyclopamine (2-10 µM), alone and with TKIs imatinib (1000-125 nM). After 48h we measure specific cell death staining with propidium iodure and flow-citometry. The inhibition of Hh signaling failed to affect survival of cell lines. Remarkably, imatinib and cyclopamine showed a potent synergistic interaction consistently exhibiting combination indices below 1 upon exposure to a wide range of drugs concentrations (Figure 1). Subsequently, we analyzed the Ptch1 mRNA levels in 20 CP-CML patients (8 high, 4 intermediate and 8 low Sokal risk respectively) on bone marrow samples collected at diagnosis. Using RQ-PCR we founded that PTCH1 is significantly upregulated (3-fold) at the mRNA level in bone marrow $CD34^+$ of CML patients (40%). Surprisingly 6/8 (75%) of high Sokal risk tested showed up-regulation of upstream effector Ptch1 (indicative of active Hh signalling). We also studied normal $CD34^+$ bone marrow cells of healthy donors (n=3) and found that they did not express PTCH1 mRNA level by RQ-PCR otherwise K562 cell lines. Additionally we used as positive control a patient with Gorlin syndrome. Afterwards we measured Ptch1 together with BCR-ABL levels during the follow-up emphasizing that the most patients with high level of Ptch1 at diagnosis developed an Abl KD mutation (8/10). *Conclusions.* We showed for the first time a reciprocal correlation between BCR-ABL levels and activation of Hedgehog signalling in CML. We suggest that the aberrant Hh pathway activation is a feature of patients with CML Sokal high risk and a striking link with the development of Abl KD mutation is showed. Finally we suggest that Pcth1 could represent a surrogate marker for the molecular monitoring and a novel target to support classical TKIs treatment.

TWIST-1, A NEW PROGNOSTIC FACTOR IN CHRONIC MYELOID LEUKEMIA

A Hamdan,[1] M Cosset,[1] M Jeanpierre,[1] M Hayette,[2] V Voeltzel,[1] X Mahon,[3] E Nicolini,[2] M Maguer-Satta[1]

[1]INSERM U590, Lyon, France; [2]Hospices Civils de Lyon, Centre Hospitalier Lyon Sud,, Pierre Bénite, France; [3]INSERM U876, Université Victor Segalen-2, Bordeaux, France

Chronic Myeloid Leukemia (CML) is one of the better characterized models for studying the properties of cancer stem cells and resistance to tyrosine kinase inhibitors. A significant proportion of CML patients develop resistance to these agents, and in 30% of cases, the mechanism of resistance is unknown. Analysis by Affymetrix chip of the sensitive and resistant forms of the CML cell line, KCL22, showed that the oncogene TWIST-1 is deregulated in Imatinib resistant cell line. Therefore, we studied the expression of Twist-1 and its involvement in the resistance of leukemic cells in samples from CML patients. For this study, we used primary blood cells from samples of healthy donors and CML patients at diagnosis, during follow-up of the disease and in the phase of relapse. Informed consent for the use of these cells for research was obtained in accordance with the Declaration of Helsinki and with approval from the Hospice Civils de Lyon ethic committee. Furthermore, we used cell lines, KCL22 and LAMA84 established from CML, for which we have sensitive and resistant clones to be cultured with 1 µM of Imatinib. We analyzed the expression of Twist-1 by qPCR in the two cell populations $CD34^+$ and $CD34^-$ obtained by CD34 immunomagnetic separation from patients with CML. Our results showed an overexpression of TWIST-1 during the progression of CML and in resistance to Imatinib. The analysis of 26 patient samples at diagnosis showed an overexpression of Twist-1 in 9 resistant patients to 9 including 4 patients that developed cytogenetic resistance without mutation or overexpression of BCR-ABL in the 12 months following their treatment. Furthermore, we observed by qPCR and Western blot analysis that TWIST-1 is overexpressed in Imatinib resistant clones of KCL22 and LAMA84 cell lines as compared to their sensitive counterpart. Finally, the use of siRNA specific for Twist-1 in resistant LAMA84 cells partially restored their sensitivity to Imatinib as shown by a decrease in the number of cells and viability in the presence of Imatinib. These results suggest a direct involvement of Twist-1 resistance in Chronic Myeloid Leukemia in the presence of Imatinib. Our results demonstrate for the first time that Twist-1 is a molecular marker to identify, at diagnosis, potentially resistant CML and monitor their response to treatment, even when the resistance mechanism is unknown.

THE AURORA-KINASE INHIBITOR AS703569 EXERTS GROWTH-INHIBITORY AND APOPTOSIS-INDUCING EFFECTS IN PRIMARY CML CELLS AND CELL LINES EXPRESSING VARIOUS IMATINIB-RESISTANT BCR/ABL MUTANTS

K Gleixner,[1] H Herrmann,[2] B Peter,[3] K Blatt,[1] K Schuch,[1] W Pickl,[1] S Samantha,[4] C Sillaber,[1] P Valent[1]

[1]Medical University of Vienna, Vienna, Austria; [2]Ludwig Boltzmann Cluster Oncology, Vienna, Austria; [3]University of Veterinary Medicine, Vienna, Austria; [4]TA Oncology, R&D Merck, Rockland, USA

Imatinib resistance is a major clinical problem and challenge in chronic myeloid leukemia (CML). In most patients, drug-resistant mutants of BCR/ABL are detectable. Although several of these mutants still are responsive to second generation BCR/ABL kinase inhibitors such as nilotinib or dasatinib, drug responses are often short-lived. In addition, the BCR/ABL mutant T315I confers resistance against all conventional second-generation BCR/ABL inhibitors, including nilotinib, dasatinib, and bosutinib. More recent data suggest that several Aurora kinase inhibitors (AuK) block BCR/ABL T315I. We examined the growth-inhibitory effects of the AuK AS703569 (Merck-Serono, Darmstadt, Germany) on primary CML cells (chronic phase, n=4), the CML cell line K562, and Ba/F3 cells transfected with various drug-resistant mutants of BCR/ABL. As assessed by 3H-thymidine-uptake, AS703569 was found to inhibit the proliferation in imatinib-sensitive and imatinib-resistant K562 cells, in primary CML cells in all donors tested (n=4) as well as in Ba/F3 cells harbouring various imatinib-resistant mutants of BCR/ABL (E255K, Y253F, H396P, T315I). The effects of AS703569 on BCR/ABL-transformed cells were dose-dependent with IC50 values ranging between 10-100 nM in K562 cells, 10-1000 nM in primary CML cells, and 1-100 nM in Ba/F3 cells exhibiting BCR/ABL mutants.

Growth-inhibitory effects of AS703569 on CML cells were accompanied by signs of DNA endoreduplication and signs of apoptosis suggesting the involvement of multiple mechanisms and drug actions. To confirm drug effects on BCR/ABL, Western blot experiments using anti-pCrkL were performed and revealed that AS703569 blocks BCR/ABL activity at 1 μM in both K562 cells and Ba/F3 cells harbouring BCR/ABL T315I. In addition, AS703569 was found to block Aurora kinase A phosphorylation in K562 cells. In summary, our data show that the novel AuK AS703569 produces growth inhibition and apoptosis in BCR/ABL-transformed cells including those harbouring imatinib-resistant BCR/ABL mutants. Whether AS703569 also produces anti-CML effects in patients with advanced CML remains at present unknown.

HEME OXYGENASE 1 (HO-1) MAY HAVE A ROLE IN RESISTANCE OF CML CELLS TO FIRST AND SECOND GENERATION TKIS

D Tibullo,[1] I Barbagallo,[2] A Branca,[3] I Giallongo,[3] P La Cava,[3] N Parrinello,[3] V Del Fabro,[3] E Spina,[3] P Spina,[3] O Di Bartolo,[3] ME Schinocca,[3] V Di Martina,[3] R Palazzolo,[3] F Di Raimondo[3]

[1]University of Catania, Catania, Italy; [2]Department of Biological Chemistry, Medical Chemistry and Molecular Biology, Catania, Italy; [3]Department of Biomedical Sciences, Division of Hematology, Ospedale Ferrarotto, Catania, Italy

Background. The advent of imatinib, an inhibitor targeted specifically for BCR-ABL, represented a significant medical advance in Chronic myeloid leukemia (CML) therapy. However, some patients become resistant or intolerant to treatment and second generation tyrosin kinase inhibitors (TKIs) may overcome these problems. Heme oxygenase (HO) is a rate-limiting enzyme in heme degradation (from hemoproteins and hemoglobin), leading to the generation of free iron, biliverdin and carbon monoxide. HO-1 expression has been reported as an important protective endogenous mechanism against physical, chemical and biological stress. It has been recently showed that the BCR/ABL oncoprotein promotes expression of HO-1 in CML cells and an over expression of HO-1 is able to inhibit imatinib induced apoptosis. We therefore investigated if an increased HO-1 activity is able to make cells resistant to second generation TKIs such as nilotinib and dasatinib. *Methods.* K562 cells were incubated for 24 hrs with imatinib 1 uM, or dasatinib 2 nM, or nilotinib 100 nM alone, or with an inductor of HO-1 (Hemin 50 uM, HE, or Cobalt protoporphyrin, CoPP, 10 uM) or the combination of both. After drug treatment, the viability of cells was evaluated by the ATP-lite1step assay (PerkinElmer). Gene expression of HO-1, HO-2 (the non-inducible form of heme oxygenase), and Nrf2 (Nuclear factor erythroid-derived 2) (a protein that regulates many factors involved in the oxidative stress, including HO-1) was assessed by Real time PCR (Applied Biosystems, 7900 Fast Real Time PCR). In addition, we evaluated stress oxidative production by measuring the ROS formation. The results are expressed as mean±S.E.M. and the statistical analysis was performed using student's t test. A value of $P<0.05$ was considered as significant. *Results.* We found that HO-1 gene expression was increased about 300 fold after HE or CoPP treatment either alone or in the presence of IM, while the expression of Nrf2 and HO-2 was not changed. The addition of HE or CoPP was able to overcome the inhibitory effect of IM (1 uM) on K562 cells ($P<0.002$) while the cytotoxic effect of IM was restored by adding an inhibitor of HO-1 (Tin-mesoporphyrin, SnMP, 10 uM) to the combination ($P<0.002$). Almost identical results were obtained with dasatinib and nilotinib ($P<0.002$). Moreover, IM 1uM was able to increase ROS formation, and this effect was inhibit by HE or CoPP and restored in presence of SnMP. *Conclusions.* In conclusion, we confirm that HO-1 may represent a mechanism of resistance to IM and we showed that the same mechanism may apply to the other TKI (dasatinib and nilotinib). It remains to better define the role of ROS in this mechanism of resistance.

0131

THE TUMOUR SUPPRESSOR PTEN: DIFFERENTIAL EXPRESSION PATTERNS IN CHRONIC MYELOID LEUKAEMIA AND THE ROLE OF PROMOTER METHYLATION

G Gerrard, S Hill, J Khorashad, A Bazeos, J Apperley, L Foroni

Imperial College London, London, UK

Background. Chronic Myeloid Leukaemia (CML) is a broadly tri-phasic myeloproliferative neoplasm initiated by the BCR-ABL1 fusion oncogene and resultant fusion protein. Disease progression from an indolent chronic phase (CP) via an intermediate accelerated phase (AP) to an aggressive blast crisis (BC) is often characterised by the accrual of multiple genetic abnormalities, although the mechanism driving this process is poorly understood. PTEN (Phosphatase and Tensin Homolog) is a tumour suppressor gene, whose protein product acts as a phosphatase antagonist of PI3K/AKT and its down-regulation or loss has been described in several types of malignancies and is linked to disease progression. *Aims.* The aims of this project were to investigate PTEN expression in CML and to ascertain whether promoter CpG hypermethylation was a factor in its down-regulation. *Methods.* Gene expression of and PTEN was determined using real-time quantitative PCR (RT-qPCR) in a total of 75 patient samples in varying stages of CML and 23 normal blood samples. Differences in expression between normal, diagnostic, BC and remission samples were evaluated using the Kruskal-Wallis with Dunn's Post Test. Protein levels were determined in 10 CML patients (6 Diagnostic, 1 AP, 3 Remission) through flow cytometry. PTEN promoter hypermethylation was investigated by performing methylation-specific PCR (MSP) and methylation-sensitive restriction assays (MSR) targeting previously characterised CpG islands in the intronic region 5' to exon 1. The PCR products were run on 2% agarose gels. *Results.* RT-qPCR data showed that PTEN was significantly ($P<0.001$) down-regulated at presentation and AP/BC compared with normal and remission levels. Mean protein expression levels, as measured by flow cytometry and expressed as a ratio against the background fluorescence maxima, were 3.08, 4.72, and 12.70 for the diagnostic, AC and remission, respectively. Neither the MSP nor the MSR assay showed any significant CpG methylation upon gel visualisation. *Conclusions.* PTEN expression is significantly down-regulated in both diagnostic and BC CML samples when compared to normal and remission samples, and this was also seen at the protein level. Results from the MSP and MSR assays for promoter hypermethylation suggest that CpG methylation is not significantly involved in the down-regulation of PTEN in CML.

Chronic myeloid leukemia - Clinical 1

0132

LONG TERM OUTCOME (PROGRESSION-FREE SURVIVAL) IN PATIENTS RECEIVING NILOTINIB FOR IMATINIB FAILURE WHO MEET SUBOPTIMAL RESPONSE CRITERIA ACCORDING TO EUROPEANLEUKEMIA NET 2009 CML RECOMMENDATIONS

M Baccarani,[1] F Giles,[2] O Ottmann,[3] J Reynolds,[4] R Woodman,[5] P le Coutre,[6] H Kantarjian[7]

[1]University of Bologna, Bologna, Italy; [2]CTRC at The UT Health Science Center, San Antonio, USA; [3]Johann Wolfgang Goethe University, Frankfurt, Germany; [4]Novartis Pharma AG, Basel, Switzerland; [5]Novartis Pharmaceuticals Corporation, East Hanover, USA; [6]Universitätsmedizin Berlin, Berlin, Germany; [7]The University of Texas M. D. Anderson Cancer Center, Houston, USA

Background. The EuropeanLeukemia Net (ELN) 2009 recommendations for the treatment of patients with newly diagnosed Philadelphia chromosome positive (Ph+) chronic myeloid leukemia in chronic phase (CML-CP) with imatinib is an important tool for physicians and now includes provisional recommendations for treatment milestones with nilotinib and dasatinib for patients with CML-CP who fail imatinib (Baccarani et al, J Clin Oncol. Dec 2009). *Aims.* In this landmark analysis, the response of patients with imatinib-resistant or -intolerant Ph+ CML-CP (N = 321) treated with nilotinib in the 2101 nilotinib phase 2 study was evaluated based on 2009 ELN suboptimal response criteria for second-line TKIs. *Methods.* Patients were grouped into 3 cohorts based on ELN 2009 recommendations: better than suboptimal response, suboptimal response, or treatment failure (and warnings). A landmark analysis of these 3 cohorts was conducted at 3-, 6-, and 12-month milestones from the initiation of nilotinib to determine the progression-free survival (PFS) of patients at 12 and 24 months. Patients who progressed or died prior to the landmark assessment date were excluded from the analysis at each given time point. *Results.* At 3 months, the majority of patients on nilotinib (57%) had a response better than ELN suboptimal response and achieved a PFS of 93% at 12 months and 79% at 24 months. Only a few patients (6%) were considered ELN suboptimal responders at 3 months and these patients had a PFS rate of 76% and 59% at 12 and 24 months, respectively. Those with early treatment failure had a PFS rate of 70% at 12 months and 41% at 24 months. At 6 months, similar trends were noted for all 3 patient cohorts (Table). The largest cohort of suboptimal responders occurred using the 12-month criteria (n=70). At the 12-month landmark, patients with better than suboptimal response and suboptimal response were comparable in terms of 24-month PFS rates (P=.1227) while patients with treatment failure had the poorest PFS and this was significantly lower (P<.0001) (Table). *Conclusions.* This analysis demonstrates the 24-month PFS for patients with suboptimal response to second-line nilotinib at 12 months was similar to patients who had better than suboptimal response. These results suggest that the 2009 ELN provisional criteria for suboptimal response to second generation TKIs needs refinement as the designation of suboptimal response does not appear to predict for worse prognosis at all treatment milestones.

Table.

	n	PFS at 12 months	PFS at 24 months
3-month milestone			
Better than suboptimal	125	93%	79%
Suboptimal	13	76%	59%
Treatment failure	81	71%	41%
6-month milestone			
Better than suboptimal	86	100%	86%
Suboptimal	29	89%	71%
Treatment failure	91	82%	51%
12-month milestone			
Better than suboptimal	47	NA	94%
Suboptimal	70	NA	87%
Treatment failure	63	NA	46%

Background. Imatinib 400 mg/day represents the current standard treatment for patients with chronic phase (CP) CML. Recently presented randomized phase III trials revealed conflicting results concerning the more potent efficacy of high dose imatinib. *Design and Methods.* We present the first results from the final analysis of the multicenter, randomised, 2-arm phase III CELSG CML 11 "ISTAHIT"trial evaluating imatinib high dose (HD) induction (800 mg/day for 6 months) followed by 400 mg/day as maintenance (experimental arm B) compared to continuous imatinib standard dose (arm A) in pre-treated CP CML patients. All patients have finished a 12 months period of detailed documentation followed by a 12 months period of treatment continuation and/or follow up. ClinicalTrials.gov Identifier: NCT0032726). *Results.* 113 patients were randomized into arm A and 114 patients into the experimental arm B. No significant differences between treatment groups were observed regarding sex (44.5% male, 55.5% female), age (median: 46 years for both groups), and different pre-treatments, which included hydroxyurea (96%), interferon (72%), busulfan (17%) and "others"(26%; mainly AraC±other drugs). In contrast to complete hematological responses, major cytogenetic responses (MCyR) were significantly higher at 3 and 6 months in the HD arm B (month 3: 25.8% arm A, 48.3% arm B, P=0.002; month 6: 41.9% arm A, 58.8% arm B, P=0.029). Higher MCyR rates were also detected in the HD arm B during the imatinib maintenance phase from month 7 to 24 (month 12, i.e. the primary endpoint: 56.8% arm A, 64.4% arm B; month 24: 71.3% arm A, 73.9% arm B), but did not reach statistical significance. Of note, the effect of HD imatinib was even more pronounced on complete cytogenetic response (CCyR) rates with significantly improved CCyR rates during imatinib HD therapy (month 3: 7.5% arm A, 29.9% arm B, P<0.001; month 6: 20.4% arm A, 47.4% arm B, P<0.001) and thereafter (month 12: 31.8% arm A, 52.9% arm B, P=0.006). In line with these findings, major molecular response (MMRIS) rates were also significantly better at 3, 6 and even at 24 months in the HD arm B (month 3: 4.5% arm A, 15.7% arm B, P=0.007; month 6: 10.3% arm A, 34.3% arm B, P<0.001; month 24: 27.4% arm A, 43.2% arm B, P=0.036). In contrast to comparable non-haematological toxicities during the first 6 months of therapy, grade 3/4 haematological toxicities were significantly more common in the imatinib HD arm B (anaemia 1% arm A, 14% arm B, P<0.001; leukopenia/neutropenia 21% arm A, 35% arm B, P=0.033; thrombocytopenia 12% arm A, 30% arm B, P=0.001). *Conclusions.* Although the primary endpoint of the study (i.e. the achievement of a MCyR at 12 months) was not reached, this first randomized phase III trial in pre-treated CP-CML patients supports the concept of more rapid and higher rates of cytogenetic and molecular remissions with higher doses of imatinib. Moreover, this trial confirms the safety as well as the remarkable therapeutic efficacy of imatinib in heavily pretreated CP CML with MCyR rates of >70% and CCyR rates of ≥50%.

Background. Imatinib (IM) is the golden standard for the front-line treatment of chronic myeloid leukaemia (CML). Our knowledge on the long term outcome of CML patients treated with IM in early chronic phase (ECP) is mostly based on the IRIS trial, a company-sponsored study. Only few other independent reports, based on relatively smaller monocentric experiences and/or with a short follow-up, have been published. *Aims.* To provide an independent evaluation of the treatment responses and the long-term outcome of ECP Ph+ CML patients treated with imatinib mesylate in a large national multicentric experience. *Methods.* Between January 2004 and April 2007, 559 patients were enrolled in an observational study and in 2 independent interventional studies of the GIMEMA CML WP (Clin Trials Gov. NCT00514488 and NCT00510926). Response monitoring was based on conventional cytogenetic examination of bone marrow cell metaphases every 6 months and RT Q-PCR evaluations of blood cells after 3, 6, 12 months, and every 6 months thereafter. Definitions: major molecular response (MMR): BCR-ABL/ABL ratio <0.1% IS; failures (according to European LeukemiaNet criteria): no complete hematologic response (CHR) at 6 months, no cytogenetic response (CgR) at 6 months, no partial CgR at 1 year, no complete CgR (CCgR) at 18 months, loss CHR or CCgR, progression or death; events: failure or treatment discontinuation for any reason. All the calculations have been made according to the intention-to-treat principle. *Results.* 559 patients were treated with 400 mg (76%) or 800 mg (24%) IM daily. The median follow-up is currently 54 months. Either responses and outcome, overall and by Sokal score, are detailed in Table 1. Considering all the patients, the CCgR rate was 79% at 12 months, and 88% overall; the MMR rate was 54% at 12 months, and 83% overall. The 5-year event-free survival, failure-free survival and overall survival were 71%, 81% and 91%. The responses of low and intermediate risk patients were not significantly different (data not shown). All responses of high risk patient were significantly inferior. *Conclusions.* Our data confirms the results of IM treatment in a large, nationwide, multicentric experience, and point out that better therapeutic strategies should be developed for high risk patients.

Table 1.

	Total	Low Risk	Int. Risk	High Risk	p value
Patients, n (%)	559	219 (39)	216 (39)	124 (22)	/

EARLY MOLECULAR RESPONSE TO NILOTINIB IN PATIENTS WHO FAILED IMATINIB IS ASSOCIATED WITH A HIGHER PROBABILITY OF CYTOGENETIC RESPONSE IN CHRONIC MYELOID LEUKEMIA (CML)

T Hughes,[1] D Kim,[2] G Martinelli,[3] S Branford,[4] M Müller,[5] L Beppu,[6] H Goh,[2] S Soverini,[3] Y Shou,[7] J Reynolds,[8] R Woodman,[9] H Kantarjian,[10] G Saglio,[11] J Radich,[6] A Hochhaus[12]

D. Anderson Cancer Center, Houston, USA; [11]University of Turin, Orbassano, Italy; [12]Universitätsklinikum Jena, Jena, Germany

Background. Nilotinib is a potent and selective inhibitor of the BCR-ABL kinase, approved for the treatment of chronic phase (CML-CP) or accelerated phase (CML-AP) Philadelphia chromosome positive (Ph+) CML in adult patients resistant to or intolerant of prior therapy, including imatinib. Patients treated with nilotinib for imatinib failure may experience different response dynamics than those treated with imatinib in the frontline setting. Many patients treated with nilotinib in the second line achieved early cytogenetic responses with a median time to MCyR and CCyR of 2.8 months and 3.3 months, respectively. *Aims.* A previous landmark analysis demonstrated the predictive value of molecular response at 3 months on nilotinib for the achievement of subsequent cytogenetic response (Branford S, *et al.* Blood 2009;114:1275-6). Here, we investigated whether early molecular response before 3 months was associated with subsequent cytogenetic response. *Methods.* Imatinib resistant or intolerant patients with CML-CP (N=321) enrolled on the phase 2 registration trial of nilotinib were grouped by 1-month BCR-ABL transcript levels. Landmark analyses were performed to evaluate the probability of cytogenetic response with a minimum of 24 months follow-up. *Results.* Overall, 19% of patients achieved molecular response of BCR-ABL (IS) ≤ 10% within 1 month of starting nilotinib. Patients with BCR-ABL (IS) >1% - ≤10% (n=37) had a higher probability of achieving MCyR by 12 months (84%) compared with patients with BCR-ABL (IS) >10% (55%) (n= 202; P<.0001). The probability of achieving CCyR by 12 months was also higher in patients with BCR-ABL (IS) >1% -≤10% compared with patients with BCR-ABL (IS) >10% (72% vs. 38%; P<.0001). Similar trends in the probability of achieving MCyR and CCyR on nilotinib by 12 months were observed for patients when analyzed by the presence or absence of baseline mutations (Table). Similar results were also seen when analyzing the probability of cytogenetic response by 24 months. *Conclusions.* Molecular response to nilotinib at 1 month was associated with cytogenetic responses by 12 months, even in the presence of baseline mutations. While treatment decisions based on 1 month BCR-ABL transcript levels are not recommended, these data indicate that reductions in BCR-ABL transcripts may occur before 3 months on nilotinib and were associated with subsequent cytogenetic responses in these patients.

Table. Estimated MCyR and CCyR by 12 months by BCR-ABL levels at 1 month on nilotinib therapy.

	BCR-ABL (IS) at 1 Mo (%)		
	> 1 – ≤ 10	> 10	P-value (log-rank test)
MCyR by 12 Months			
All pts, n = 239	84%	55%	< .0001
Pts with baseline mutations, n = 95	76%	42%	< .0001
Pts without baseline mutations, n = 121	89%	64%	< .0001
CCyR by 12 Months			
All pts, n = 241	72%	38%	< .0001
Pts with baseline mutations, n = 96	58%	25%	.0022
Pts without baseline mutations, n = 122	89%	45%	< .0001

0136

ONLY A HIGH RELATIVE RISK (SOKAL OR EURO) PREDICTS FOR RESPONSE TO IMATINIB. AN EUROPEAN LEUKEMIANET EUTOS STUDY

J Hasford,[1] G Rosti,[2] V Hoffmann,[1] R Hehlmann,[3] J Guilhot,[4] F Nicolini,[5] B Simonsson,[6] G Ossenkoppele,[7] L Montrucchio,[8] C Piccolo,[8] M Pfirrmann,[1] M Baccarani[2]

[1]Ludwig-Maximilians-University Munich, Munich, Germany; [2]St Orsola University Hospital, Department of Hematology and Oncology, Bologna, Italy; [3]Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, German; [4]Clinical Investigation Center, CIC 802 INSERM, Poitiers, France; [5]Hopital Edouard Herriot, Department of Hematology, Lyon, France; [6]Department of Hematology, University Hospital, Uppsala, Sweden; [7]VU University Medical Center, Department of Haematology, Amsterdam, Netherlands; [8]Novartis Farma S.p.A., Origgio / VA, Italy

The EUTOS (European Treatment and Outcome Study) CML Registry dataset contains the data of 1955 patients who were enrolled in prospective studies of treatment with Imatinib (IM) or IM-containing regimes in France (n = 526), Germany and Switzerland (n = 657), Italy (n = 513), the Nordic Countries (Denmark, Finland, Norway, Sweden, n = 140), and the Netherlands (n = 119). Eligibility criteria were diagnosis of chronic phase Ph^+ or $BCR\text{-}ABL^+$ CML between 2002 and 2006, age ≥18 years, and start with any kind of IM-based treatment in a prospective study within 6 months from diagnosis. The data of these patients were analyzed to identify the baseline and the response-related factors which are associated with outcome. The baseline characteristics that have been associated with response and outcome in all CML studies are represented by two risk scores (Sokal *et al.*, Blood 1984;63:789-799; Hasford *et al.*, JNCI 1998;90:850-858) including age, spleen size, platelet count and the percent of blood myeloblasts, eosinophils and basophils, prior to any treatment. These risk scores were based on data of patients treated with conventional chemotherapy and with Interferon-α based regimes, respectively. In the pre-IM era, both risk classifications identified three risk groups, low, intermediate and high. The Sokal Score's cutpoints correspond to a relative risk (RR) and lie at <0.8, 0.8-1.2 and >1.2. The Euro Score's cutpoints lie at <781, 781-1480, and >1480. After the introduction of IM, both risk classifications were already reported to be of some utility (reviewed in Baccarani et al, Blood 2006; 108: 1809-20 and JCO 2009;27:6041-6051) but so far they were not specifically analysed and validated for prognostic value. Since the best early surrogate marker of late outcome is the complete cytogenetic response (CCgR) and since the lack of a CCgR at 18 months is identified as a "failure"in IM-treated patients (Baccarani *et al.*, JCO 2009;27:6041-6051), we analysed the relationship between risk class and CgR at 18 months. The analysis was based on 728 (Sokal score) and 727 (Euro score) patients in whom the information on the CgR response at 18±2 months was available. We have calculated also the cumulative incidence of CCgR at 3 years, based on all patients where the risk could be determined (1710 for Sokal, 1707 for Euro). The data are reported in Table 1, showing that although the overall difference was significant for both scores, the most important difference was between high risk patients and low, or low + intermediate risk patients.

Table 1. Result: sokal and euro score versus CCgR.

		LOW		INTERMEDIATE		HIGH
Sokal.	No. (%)	667 (39%)		628 (37%)		415 (24%)
Sokal.	Cumulative incidence of CCgR at 3 years, %	95%	°	93%	°	82%
Sokal.	No. (%) with a Cg test at 18 months	303		279		146
Sokal.	No. (%) in CCgR at 18 months	281 (93%)	*	251 (90%)	*	115 (78%)
Hasford.	No. (%)	655 (38%)		860 (50%)		192 (11%)
Hasford.	Cumulative incidence of CCgR at 3 years, %	93%	°	91%	°	79%
Hasford.	No. (%) with a Cg test at 18 months	295		373		59
Hasford.	No. (%) in CCgR at 18 months	274 (93%)	+	323 (87%)	+	49 (83%)

° p-values: < 0.001 for Low + Intermediate vs. High (over the whole observation time, Gray test)

* p-values: Low vs. Intermediate 0.23; Intermediate vs. High 0.002; Low vs. High < 0.001 (Chi^2-Test)

+ p-values: Low vs. Intermediate 0.01; Intermediate vs. High 0.46; Low vs. High 0.02 (Chi^2-Test)

In conclusion, in IM-treated patients both scores were validated, with particular emphasis on the high risk. These data support the European LeukemiaNet recommendations identifying a high risk score as a baseline warning factor (Baccarani *et al.*, JCO 2009;27:6041-6051), and emphasize the importance of collecting and reporting sound clinical data before any treatment, so as to make it possible to calculate the risk. However both scores are under revision, in order to improve their prognostic value and to investigate which other prognostic factors can be of help in the tyrosine kinase inhibitors era.

0137

ACTIVE DOSE RE-ESCALATION OF NILOTINIB FOLLOWING DOSE REDUCTION IS ASSOCIATED WITH IMPROVED EFFICACY IN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA (CML-CP) WHO FAIL IMATINIB

F Nicolini,[1] DW Kim,[2] A Turkina,[3] G Alimena,[4] HK Al-Ali,[5] Z Shen,[6] S Jootar,[7] G Smith,[8] C De Souza,[9] P Dorlhiac-Llacer,[10] D Rizzieri,[11] S Lyon-Caen,[12] M Berton,[13] T Szczudlo,[14] P le Coutre[15]

[1]Hôpital Edouard Herriot, Lyon, France; [2]The Catholic University of Korea, Seoul, South-Korea; [3]Hematology Research Center, Moscow, Russian Federation; [4]University La Sapienza, Rome, Italy; [5]Universitätsklinikum Leipzig AöR, Leipzig, Germany; [6]Rui Jin Hospital, Shanghai, China; [7]Mahidol University, Salaya, Thailand; [8]St. James's University Hospital, Leeds, UK; [9]University of Campinas-SP, Campinas, Brazil; [10]Universidade de São Paulo, Campinas, Brazil; [11]Duke University Medical Center, Durham, USA; [12]Analysis Group, Inc, Washington DC, USA; [13]Novartis Pharma AG, Basel, Switzerland; [14]Novartis Pharmaceuticals Corporation, East Hanover, USA; [15]Universitätsmedizin Berlin, Berlin, Germany

Background. Nilotinib is approved for the treatment of CML-CP in adult patients resistant to or intolerant of prior therapy, including imatinib. Overall, nilotinib is generally well tolerated with minimal cross-intolerance to imatinib and limited off-target effects. In the Expanding Nilotinib Access in Clinical Trials (ENACT) study, the duration of grade 3/4 study-drug related AEs was typically short (1-3 weeks) with the onset of new such AEs decreasing over time. Despite this, more than 50% of eligible patients did not undergo re-escalation to the optimal dose of 400 mg BID. *Aims.* The purpose of this analysis was to study the impact of nilotinib dose re-escalation on responses in the ENACT study. *Methods.* We analyzed patients with CML-CP from ENACT who failed prior imatinib, initiated nilotinib at 400 mg BID, and had ≥ 1 nilotinib dose reduction (N=999). Dose re-escalation was recommended but not mandated, as per protocol. Analysis of the correlation of dose re-escalation with cytogenetic response was performed on all available CML-CP patients from participating ENACT sites. The French subset of patients from ENACT was also analyzed separately to assess patients who are being monitored for molecular response according to ELN recommendations. The starting dose was 400 mg BID with 400 mg QD used for dose reduction due to AEs. Re-escalation was permitted when AEs ≤ to Grade 1. *Results.* Of 1,376 patients with CML-CP who failed prior imatinib and initiated nilotinib 400 mg BID (59% resistant, 40% intolerant, 1% both), 999 (77%) had ≥1 nilotinib dose reduction; 444/999 (44%) attempted re-escalation to 400 mg BID and 385/444 (87%) successfully re-escalated (for ≥28 days without dose interruption of >5 days). In patients who successfully re-escalated, subsequent median dose intensity was high at 796 mg/day (near planned dose) and was maintained for a median of 220 days. Patients who successfully re-escalated to nilotinib 400 mg BID experienced higher cytogenetic responses than patients who did not attempt re-escalation (n=555) or in whom successful re-escalation was not possible (n=59). Overall, major cytogenetic response (MCyR) was achieved in 52% of patients who had successful re-escalation and in 43% who did not. Within the French subset (n = 165), 125 (76%) had ≥1 dose reduction; 41/125 (33%) attempted a re-escalation to 400 mg BID and 36/41 (88%) were successfully re-escalated. Overall, MCyR was achieved in 75% of patients who had a successful re-escalation to 400 mg BID and in 53% who did not. Major molecular response (MMR) was achieved in 47% of patients who re-escalated and in 44% who did not. *Conclusions.* Active re-escalation of nilotinib following dose reduction results in an increased probability of cytogenetic and molecular response in patients with CML-CP, especially when combined with regular monitoring. The use of the approved nilotinib doses (400 mg BID starting dose and 400 mg QD reduced dose) is associated with improved patient response rates when re-escalation is used appropriately.

0138

HIGH BCR-ABL EXPRESSION LEVELS AT DIAGNOSIS MAY PREDICT UNFAVOURABLE CML RESPONSES TO IMATINIB THERAPY

F Stagno,[1] P Vigneri,[2] S Stella,[2] V Del Fabro,[1] M Massimino,[2] P Spina,[1] O Di Bartolo,[1] F Di Raimondo[1]

[1]*Hematology Section, Ferrarotto Hospital, Catania, Italy;* [2]*General Pathology Section, Dept.of Biomedical Sciences, Catania, Italy*

Background and Aims. The advent of BCR-ABL tyrosine kinase inhibitors (TKIs) such as imatinib mesylate (IM) dasatinib and nilotinib (NIL) has dramatically changed the natural history of Chronic Myeloid Leukemia (CML). However, it is still unclear if: i) BCR-ABL transcript variants (i.e. e13a2, e14a2) predict response to IM; ii) high levels of BCR-ABL transcripts at diagnosis are indicative of an aggressive leukemic clone displaying increased genomic instability. *Patients and Methods.* To address these issues we assessed BCR-ABL transcripts in 135 patients with chronic phase (CP) CML accrued at our Institution between January 2003 and June 2009. All patients received IM therapy at 400 mg daily with the exception of ten who were enrolled in an investigational trial and received NIL-therapy at 800 mg daily. Median follow-up was 27 months (range 3-54). Hematological, cytogenetic and molecular responses were rated according to the European Leukemia Net (ELN 2006) guidelines. Peripheral blood samples were used for BCR-ABL determination by quantitative real-time polymerase chain reaction, following the suggested recommendations and according to the International standardized Scale (IS). *Results.* CP-CML patients included in this series were initially stratified according to BCR-ABL transcript variants and analyzed for their main clinical, cytogenetic and molecular characteristics. Age, sex, hemoglobin, white blood cells (WBC), platelets counts and Sokal score did not differ between the two populations. We also found no statistical difference between the two CML groups when considering rates of complete cytogenetic remission after 12 months of treatment (P=1.0). The only significant difference between the two subgroups was the amount of BCR-ABL expression at diagnosis, with e13a2 individuals displaying much higher levels of BCR-ABL as compared to those with the e14a2 variant (P<0.0001). We next clustered all subjects in optimal responders (ORs) and suboptimal/resistant (S/R) patients according to the 2006 ELN criteria and correlated response to therapy with different clinical and molecular characteristics. We found that only the amount of BCR-ABL transcripts at diagnosis predicted response to IM, with an increased number of S/R patients in the group expressing higher levels of BCR-ABL. Indeed, the median amount of BCR-ABLIS transcript at diagnosis displayed by patients that failed TKI therapy or achieved a suboptimal response was significantly higher (106.68IS) than that of patients obtaining an optimal response (67.2IS; P=0.01). As WBC counts were not significantly different between ORs and S/R patients (P=0.5), increased amounts of BCR-ABL transcripts are probably representative of the aggressiveness of the leukemic clone that, in turn, might identify CML patients at higher risk of progression. *Conclusions.* In summary, our findings support the notion that high levels of BCR-ABL expression at the time of diagnosis may identify CML patients less likely to benefit from IM therapy.

0139

RAPID INITIAL DECLINE IN BCR-ABL LEVELS IS ASSOCIATED WITH SUPERIOR RESPONSES IN IMATINIB-RESISTANT OR -INTOLERANT CHRONIC MYELOID LEUKEMIA PATIENTS IN CHRONIC PHASE (CML-CP) TREATED WITH NILOTINIB

A Stein,[1] Y Shou,[1] D Bottino,[2] YL Chia,[1] R Woodman,[2] G Martinelli,[3] T Hughes,[4] M Müller,[5] L Beppu,[6] E Gottardi,[7] S Branford,[8] S Soverini,[3] H Goh,[9] A Hochhaus,[10] D Kim,[9] G Saglio,[7] J Radich[6]

[1]*Novartis Institutes for BioMedical Research, Cambridge, USA;* [2]*Novartis Pharmaceuticals Corporation, East Hanover, USA;* [3]*University of Bologna, Bologna, Italy;* [4]*Royal Adelaide Hospital, Adelaide, Australia;* [5]*Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany;* [6]*Fred Hutchinson Cancer Research Center, Seattle, USA;* [7]*University of Turin, Orbassano, Italy;* [8]*SA Pathology, Adelaide, Australia;* [9]*The Catholic University of Korea, Seoul, South-Korea;* [10]*Universitätsklinikum Jena, Jena, Germany*

Background. A mathematical model established using molecular data from patients with newly diagnosed CML-CP who were randomized to the imatinib arm of the International Randomized Study of Interferon and STI571 (IRIS) trial demonstrated that the majority of patients experienced a biphasic decline in BCR-ABL transcripts, with a rapid initial decline (α) followed by a steady long-term decline (β). *Aims.* Here we have applied this model to the molecular response data from patients with CML-CP with prior resistance or intolerance to imatinib treated with nilotinib 400mg bid. *Methods.* Patients from the nilotinib phase 2 registration study who had at least 24 months of follow-up and a sufficient number of PCR data points to support parameter estimation were included in the model (N=259). The time course of BCR-ABL transcript reduction (IS) was modeled as a biexponential function ($R(t) = Ae^{\alpha t} + Be^{\beta t}$). Patient parameters were estimated using nonlinear mixed effects modeling. The α parameter describes the initial decline in log10 (R) upon treatment start while β describes the shallower slope of the subsequent log10 (R) dynamics in patients. *Results.* As with patients treated with imatinib on IRIS, the patient population was well-described by this model. However, unlike in IRIS, the majority of patients displayed monophasic dynamics where only the α slope was observable. Also in contrast to IRIS, the α parameter showed a bimodal distribution (Fig 1b), with patients displaying 1 of 2 typical responses, a shallow α slope corresponding to a lesser initial decline in BCR-ABL transcripts (> -5/yr; n=165) or a steep α slope (< -5/yr; n = 94) (Figure 1a, 1c). A steep α slope (36% of pts) was associated with superior responses and event-free survival (EFS), with 24 month rates of complete cytogenetic response, major molecular response, and EFS of 94%, 77% and 83% for patients with α < -5/yr versus 25%, 6%, and 40% for patients with α > -5/yr (P<.0001 for all comparisons). Three PCR data points collected within months 3-6 of therapy could reliably estimate the α slope. The β parameter, generally observable only in patients with a steep α, was similar to that seen in IRIS, with a median yearly steady state reduction in log10 transcript levels of -0.66/yr (range, -3.5/yr-5.9/yr). Only 9 (3.6%) patients had $\beta > 0$ with 95% confidence, suggestive of molecular relapse. *Conclusions.* Mathematical modeling demonstrated that treatment with nilotinib can be described by 2 main parameters: an initial decline in BCR-ABL transcript levels (α) and a longer, more sustained decline (β). Two patterns emerged in the slope of the initial decline, steep (α < -5/yr) or shallow (α > -5/yr). A steep α was shown to be associated with superior response and EFS outcomes. This bimodal distribution of α, which could be estimated using PCR data collected during the first 3-6 months of therapy, may be an early predictive tool for longer-term outcomes of patients on second-line nilotinib who have failed prior imatinib therapy.

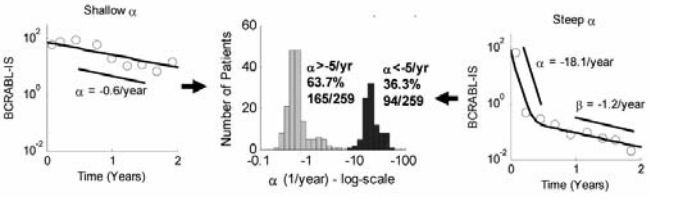

Figure 1. a) Typical shallow α patient; b) distribution of a slopes; c) typical step α patient.

Background. Despite the outstanding results of imatinib (IM) for the treatment of chronic myeloid leukemia (CML), some patients show poor molecular response to IM therapy. A number of factors may underlie this variability, including BCR-ABL mutations, Sokal risk score at baseline, and pharmacokinetics-related interindividual variation affecting IM metabolism and/or drug transporters. Recently, it has been suggested by several large studies that variation in trough IM plasma levels can affect IM response among CML patients. However, contradictory data showing no correlation between trough IM plasma concentration and molecular response has also recently been reported. In

Japan, several groups independently evaluated IM pharmacokinetics in CML patients and the majority have not reported a significant correlation between trough IM plasma concentration and response. *Aims and Methods.* To further examine and clarify the potential correlation between steady state trough IM plasma concentration and clinical response in Japanese chronic-phase CML patients, we integrated data from six independent studies. To determine trough IM plasma concentrations, a central laboratory was utilized that employed high-performance liquid chromatography-tandem mass spectrometry. The study protocol was approved by the Ethics Committee and all patients gave written informed consent. *Results.* Three hundred fourteen Japanese patients with chronic-phase CML and a median age of 60 years (range; 16-91 years) were integrated in this analysis (male vs. female, 189 vs. 125). One hundred ninety (60.5%), 59 (18.8%), 48 (15.3%), and 17 (5.4%) patients were treated with 400 mg, 300 mg, <300 mg, and >400 mg of IM daily, respectively, and the median duration of IM therapy was 1435 days. The mean and median trough IM plasma concentrations were 1010.5 ng/mL and 900 ng/mL, respectively, and the distribution of trough IM plasma concentration at all doses is illustrated in Figure 1. Among the 190 patients treated with 400 mg daily, weak correlations between trough IM plasma concentration and age (r^2=0.033), body weight (r^2=0.027), and body surface area (r^2=0.04) were observed; however, the large interpatient variability in trough concentrations suggests that these associations are likely not clinically significant. When patients were divided into quartiles based on trough IM plasma concentration distribution, no correlations with baseline characteristics were detected. Notably, significant differences among the quartiles in the percentage of patients with a complete cytogenetic response (CCyR; P=0.008) and a major molecular response (MMR; P=0.007) were identified. In addition, trough IM plasma concentration at all doses was significantly higher among patients with a MMR than those without a MMR (P=0.0003). Among the patients treated with 400 mg, a significant difference in trough IM plasma concentration between those with a MMR than those without a MMR (P=0.023) was again detected. *Conclusions.* Higher trough IM plasma concentration was associated with the likelihood of achieving a CCyR or a MMR in our large Japanese CML patient cohort. Thus, in addition to BCR-ABL mutation analysis, our data indicate that clinical IM blood-level testing may improve the efficacy of IM therapy among CML patients.

OCT-1 EXPRESSION LEVELS PREDICT MOLECULAR RESPONSES IN CHRONIC PHASE CML PATIENTS ON FIRST LINE IMATINIB TREATMENT

P Erben,[1] H Daikeler,[2] B Hanfstein,[2] M Agrawal,[2] J Popa,[2] S Saussele,[2] WK Hofmann,[2] A Hochhaus,[3] M Müller[2]

[1]Universitätsmedizin Mannheim, Universität Heidelberg,, Mannheim, Germany; [2]Universitätsmedizin Mannheim, Universität Heidelberg, Mannheim, Germany; [3]Universitätsklinikum Jena, Jena, Germany

Background. Most newly diagnosed chronic phase CML patients exhibit cytogenetic and molecular responses under imatinib therapy. However, resistance and suboptimal response occur in a cohort of patients. BCR-ABL kinase domain mutations and several BCR-ABL independent mechanisms, such as cytogenetic aberrations and clonal evolution are considered as leading causes of resistance and progression. White *et al*. have shown that imatinib efficacy depends on intracellular drug levels which are influenced by the activity of the influx human organic cationic transporter protein (OCT-1) and efflux transporter protein multidrug resistance 1 (MDR1) (White *et al.*, Blood 2006; Mahon *et al.*, Cancer Res 2008). *Aims.* We therefore analyzed the predictive role of MDR1 and OCT-1 expression levels of chronic phase CML patients on molecular responses during first line therapy with imatinib. *Patients and Methods.* A cohort of 133 newly diagnosed chronic phase CML patients (47 f, 86 m; median age 53 years, range 16-75) treated with imatinib 400 mg/day in the German CML Study IV were investigated. Median follow-up for achievement of MMR (BCR-ABL expression according to the international scale ≤0.1%) was 16 months (range 5-75). MDR1, OCT-1 and BCR-ABL mRNA expression levels were determined by quantitative reverse transcription PCR (qRT-PCR) using LightCycler™ technology, normalized against beta-glucuronidase (GUS) expression and standardized according to the international scale (IS). Log-rank tests were performed to compare the time to MMR. *Results.* Within 12, 18 or 24 months of imatinib therapy, 24%, 44% and 54% of patients achieved MMR. After 12, 18 or 24 months, patients with OCT-1/GUS ratios ≥0.69 (46%) achieved MMR in an estimated rate of 30%, 52% and 63%, whereas those with initial OCT-1/GUS ratios <0.69 (54%) showed MMR in 17%, 36% and 44%, respectively (12 months, P=0.068; 18 months, P=0.045; 24 months, P=0.015). No correlation between MDR1/GUS ratios and the achievement of MMR was found after 12, 18 or 24 months. *Conclusions.* Pre-treatment expression levels of OCT-1 appear to predict the achievement of MMR under imatinib therapy in chronic phase CML patients over a period of 2 years of therapy.

0142

BOSUTINIB FOR THIRD-LINE TREATMENT OF CHRONIC PHASE (CP) CHRONIC MYELOID LEUKEMIA (CML) FOLLOWING RESISTANCE OR INTOLERANCE TO IMATINIB (IM) AND DASATINIB (D)

C Gambacorti-Passerini,[1] J Cortes,[2] A Zaritskey,[3] E Bullorsky,[4] J Navarro,[5] H Khoury,[6] N Besson,[7] T McMullan,[8] S Arkin,[8] T Brümmendorf[9]

[1]University of Milano Bicocca, Monzo, Italy; [2]MD Anderson Cancer Center, Houston, TX, USA; [3]Saint-Petersburg Pavlov State Medical University, Saint-Petersburg, Russian Federation; [4]Hospital Británico, Buenos Aires, Argentina; [5]Hospital Rebagliati, Lima, Peru; [6]Winship Cancer Institute of Emory University, Atlanta, GA, USA; [7]Wyeth, a subsidiary of Pfizer, Paris, France; [8]Pfizer, Collegeville, PA, USA; [9]Universitätsklinikum Aachen, Aachen, Germany

Background. Bosutinib (SKI-606) is an orally available, dual Src/Abl kinase inhibitor. *Aims.* A phase I-II study was conducted to evaluate safety and efficacy of bosutinib in patients (pts) with CP CML after failure of imatinib and dasatinib subsequently. *Methods.* After collection of informed consent, pts received bosutinib 500 mg orally, daily. *Results.* Of 90 CP pts with prior exposure to IM and D, 43% were male, median age was 57 (21-79) years, and time from CML diagnosis to start of bosutinib was 6.5 (0.6-18.3) years, with a median follow-up of 17 months (0.3-35). The most frequent treatment emergent adverse events (TEAEs) were gastrointestinal (diarrhea (81%), nausea (46%), vomiting (38%)). These effects were low-grade, early onset and usually subsided spontaneously within the first 4 weeks of treatment (median duration of 27 days). Grade 3/4 TEAEs occurring in ≥5% of pts were diarrhea (8%) and rash (7%). Grade 3/4 hematologic lab abnormalities included thrombocytopenia (20%), neutropenia (10%) and anemia (9%). Few non-hematologic Grade 3/4 lab abnormalities were observed, notably 1 pt (1%) with elevated amylase, 4 pts (4%) with elevated lipase, and no occurrence of hyperglycemia or QTc prolongation. One incidence of grade 3 pleural effusion was observed with a pt in the setting of concomitant pneumonia and a history of recurrent pleural effusions on D. Median daily dose was 492mg for I-treated/DAS-resistant, 383mg for I-treated/DAS-intolerant pts; 32 pts (36%) required dose-reductions and 20 pts (22%) discontinued permanently bosutinib for toxicity. Among 40 pts with baseline testing, 18 (45%) had a Bcr-Abl mutation. In evaluable pts with mutations, 56% complete hematologic response (CHR) and 27% major cytogenetic response (MCyR) were observed, for evaluable pts with no mutation, 89% CHR and 38% MCyR. In pts with F317L, CHR occurred in 2/3 evaluable pts and MCyR in 2/4 evaluable pts. Hematologic responses were also observed in patients with M244V, G250E, Y253F, including 2/3 evaluable pts with P-loop mutations achieving CHR. No clinical activity was detected in pts with T315I. *Summary/Conclusions.* Bosutinib has an acceptable toxicity profile in CP CML patients with resistance or intolerance to both IM and D, with primarily low-grade and transient gastrointestinal AEs. Bosutinib demon-

strated clinical activity in the third-line setting, with 39% of pts achieving MCyR, including 30% with CCyR.

Background. Elderly CML patients treated with Imatinib (IM) in early chronic phase (CP) have similar cytogenetic response and survival compared with younger patients, but they show a lower compliance to standard IM therapy (400 mg/day). *Aims.* The aim of the study is to investigate if a stable CCgR that has been achieved with standard (daily administration) IM therapy can be maintained with the same dose of IM given intermittently (INTERIM). *Methods.* This interim analysis was conducted in 88 elderly patients (≥65 years) with Ph+ chronic myeloid leukemia (Ph+ CML) and with stable complete cytogenetic response (CCgR), who were enrolled in the INTERIM study and who, at present, are evaluable after a median of 13 months from the start of the study (28th April 2008) (range: 2-20 months). Briefly, INTERIM consisted on the intermittent administration of IM at the same dose given at the time of enrollment, by the following schedule: 1 week on / 1 week off for the 1st month; 2 weeks on / 2 weeks off for the 2nd and 3rd month; 1 month on / 1 month off from the 4th month thereafter. The CgR status has been assessed by FISH on peripheral blood every 3 months and if FISH (% of Ph+ cells) increased more than 1% in two consecutive examinations, evaluation of marrow cells metaphases was performed to confirm the loss of CCgR and to check for additional cytogenetic abnormalities. Quantitative molecular assessment of BCR-ABL transcript by RQ-PCR on peripheral blood was also due every 3 months during the study and mutational analysis of ABL was performed in case of loss of CCgR. In cases of loss of CCgR INTERIM was stopped and standard therapy (daily administration) was resumed. After 12 months, the patients who are in continuous CCgR are advised to continue the intermittent study schedule and to be followed indefinitely. *Results.* Of the 88 patients, 71, 68, 53 and 30 completed the 3rd, 6th, 9th and 12th month, respectively. The preliminary results of the first 12 months are reported here. The distribution of patients according to FISH results are shown in the Figure 1. As reported, only few patients (from 1 to 16%) showed an increased number of Ph+ cells by FISH >1%, but all maintained a CCgR when checked by conventional cytogenetic. Concerning the molecular response, as showed in Figure 2, 93 to 84% of patients maintained a major molecular response MMR (<0.1) according to International Scale (IS). *Conclusions.* The preliminary results at 12 months do not show negative trends both for cytogenetic and molecular response. These data suggest that INTERIM may be a useful strategy to test the minimum effective dose of IM and it could be proposed as a new treatment schedule in elderly patients to maintain a stable CCgR previously achieved with standard IM therapy

Acknowledgments: This work was supported in part by CML-Leukemia Net.

THE PREDICTIVE IMPACT OF MDR1 EXPRESSION AND PRE-TUMOR BURDEN ON MOLECULAR, CYTOGENETIC AND CLINICAL OUTCOME OF CML PATIENTS ON NILOTINIB THERAPY AFTER IMATINIB FAILURE

M Agrawal,[1] P Erben,[1] B Hanfstein,[1] J Popa,[1] WK Hofmann,[1] J Reynolds,[2] L Robin,[2] A Leitner,[1] R Woodman,[2] A Hochhaus,[3] M Müller[1]

[1]Medizinische Fakultät Mannheim, Universität Heidelberg, Mannheim, Germany; [2]Novartis Pharmaceuticals Corporation, East Hanover, USA; [3]Universitätsklinikum Jena, Jena, Germany

Background. Nilotinib has shown to be effective in case of resistance or intolerance to imatinib. Mutations in the BCR-ABL kinase domain and various BCR-ABL independent mechanisms, e.g. clonal evolution and pathways bypassing BCR-ABL are considered as leading causes of resistance. Besides, efficacy of imatinib and nilotinib depends on intracellular drug levels, which are influenced by the activity of the efflux transporter protein multidrug resistance 1 (MDR1). Cell proliferation data suggest overexpression of MDR1 as a cause of resistance to nilotinib (Mahon et al., Cancer Res 2008). *Aims.* We assessed the predictive impact of MDR1 expression levels and pre-treatment tumor burden of imatinib resistant CML patients on molecular and cytogenetic responses and progression-free survival (PFS) during second line therapy with nilotinib. *Methods.* Imatinib resistant patients in chronic phase CML treated with nilotinib (n=84) were investigated in a phase II study (AMN2101). Baseline BCR-ABL mutations were detected by D-HPLC and direct sequenc-

ing. MDR1 and BCR-ABL mRNA expression levels were determined by quantitative reverse transcription PCR (qRT-PCR) using LightCycler™ technology, normalized against beta-glucuronidase (GUS) expression and standardized according to the international scale (IS). Log-rank tests were performed to compare the time to major molecular response (MMR, BCR-ABL IS ≤0.1%), complete cytogenetic response (CCyR), and PFS. *Results.* Within 12 or 24 months of nilotinib therapy, 24% and 29% of patients achieved MMR. After 12 or 24 months, patients with MDR1/GUS ratios ≥2.0 (62%) achieved MMR in an estimated rate of 34%, whereas those with initial MDR1/GUS ratios <2.0 (38%) showed MMR in 13%, respectively (P=0.030). Further, BCR-ABL load prior to nilotinib revealed a significant impact on consecutive molecular response. BCR-ABL IS <28% separated best concerning prediction of MMR after 12 and 24 months (58% vs 20% and 58% vs 36%, P=0.0013). CCyR was attained in 52% and 57% of the patients with MDR1/GUS ratios ≥2.0 after 12 and 24 months, whereas those with MDR1/GUS ratios <2.0 showed CCyR in 25% and 35% (P=0.036). Moreover, a MDR1/GUS ratio at 2.0 also significantly dichotomized two groups for achievement of PFS: patients presenting MDR1/GUS ratios ≥2.0 reached PFS rates of 88% and 73%, whereas those with MDR1/GUS ratios <2.0 attained PFS in 71% and 50% after 12 and 24 months (P=0.036). *Conclusions.* Pre-treatment expression levels of MDR1 predict MMR, CCyR and PFS of imatinib resistant chronic phase CML patients within the first two years of treatment with nilotinib. These findings might allow risk stratification in order to tailor the individualized second line therapy in CML and should be validated prospectively.

0145

PRETREATMENT BCR-ABL TUMOR BURDEN AND MUTATION STATUS ARE INDEPENDENTLY PREDICTIVE FOR MOLECULAR RESPONSE IN CHRONIC PHASE CML PATIENTS TREATED WITH DASATINIB AFTER IMATINIB FAILURE

B Hanfstein,[1] P Erben,[1] T Ernst,[2] T Schenk,[2] M Agrawal,[1] WK Hofmann,[1] A Hochhaus,[2] M Müller[1]

[1]*Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany;* [2]*Universitätsklinikum Jena, Jena, Germany*

Background. Major molecular response (MMR) is achieved in a substantial proportion of chronic phase chronic myeloid leukemia (CML-CP) patients treated with dasatinib after failure of imatinib therapy. However, recently published data suggest that the proportion is strongly dependent on the time of changing the TKI regimen. Since an early change has been shown to predict a better outcome, cutoff levels in the molecular scope are needed to determine the optimal time of dasatinib treatment initiation and to further specify prognostic groups. *Aims.* We sought to evaluate the prognostic significance of pretreatment BCR-ABL levels and BCR-ABL kinase domain mutation status for long term molecular outcome in CML-CP patients after failure of imatinib therapy. *Methods.* 135 CML-CP patients (72 male, 63 female, median age 61 years, range 22-77) with resistance to imatinib were included into the CA 180-013 phase II study (Bristol-Myers Squibb, Wallingford, CT) and received 70 mg dasatinib twice daily. 1,197 peripheral blood samples were analyzed by quantitative RT-PCR of BCR-ABL and beta-glucuronidase (GUS) and direct sequencing of the rearranged ABL kinase domain. The BCR-ABL/GUS ratio was determined according to the international scale (IS). *Results.* Median pretreatment BCR-ABL expression (IS) was 42.0% (range 3-215%), median BCR-ABL (IS) at the end of follow-up was 15.3% (range 0-214%) with a median follow-up of 21.9 months (range 0-35). BCR-ABL expression (IS) of less than 20% predicts a high cumulative incidence of achieving BCR-ABL (IS) levels of less than 1%, termed good molecular response (GMR). In the good risk group 15 of 25 pts (60.0%) achieved a GMR after a median of 8.3 months, in the poor risk group a GMR was achieved by 38 of 110 pts (34.5%) after a median of 32.6 months (P=0.0089). To evaluate the prognostic significance of baseline mutations four groups were defined: (i) mutation-negative pts (n=57), (ii) pts harboring mutations reported to be sensitive to dasatinib in cell proliferation assays including those with no reported IC50 value (n=51), (iii) pts harboring mutations reported to confer a relevant loss of sensitivity to dasatinib (n=24; L248V, n=2; G250E, n=10; Q252H, n=2; E255K, n=3; E255V, n=2; F317L, n=4; F486S, n=1), and (iv) pts harboring T315I (n=3). Proportions of pts achieving GMR were 36.8%, 52.9%, 20.8% and 0.0% for groups i to iv, respectively. Median time to GMR resulted in one single significant difference, i.e. between group ii (10.3 months) and group iii (not defined, P=0.0247). Median pretreatment BCR-ABL levels of 41.1%, 40.1%, 40.3% and 42.7% for groups i to iv showed no significant difference indicating an independence of baseline mutation status and tumor load. *Conclusions.* The BCR-ABL tumor load in the situation of imatinib failure is highly predictive for the subsequent dasatinib response in CML-CP patients indicating the need for an early change in TKI regimen. Differences in BCR-ABL tumor load are not mediated by BCR-ABL mutations achieved under imatinib treatment.

[1]*Universitätsmedizin Berlin, Berlin, Germany;* [2]*Osaka City University Hospital, Osaka, Japan;* [3]*Azienda Ospedaliera Bianchi Melacrino Morelli, Reggio Calabria, Italy;* [4]*Universitätsklinikum Jena, Jena, Germany;* [5]*Royal Adelaide Hospital, Adelaide, Australia;* [6]*The University of Texas M. D. Anderson Cancer Center, Houston, USA;* [7]*University of Chicago, Chicago, USA;* [8]*University of Turin, Orbassano, Italy;* [9]*Novartis Pharmaceuticals Corporation, East Hanover, USA;* [10]*Novartis Institutes for BioMedical Research, Cambridge, USA;* [11]*Novartis Pharma AG, Basel, Switzerland;* [12]*Saitama Medical University, Saitama, Japan;* [13]*Royal Liverpool University Hospital, Liverpool, UK*

Background. Results from ENESTnd at 12 months demonstrated superior efficacy of nilotinib at doses of 300 mg BID and 400 mg BID over imatinib 400 mg QD. *Aims.* To perform a PK and exposure-response analysis of nilotinib in patients with newly diagnosed CML-CP. *Methods.* Full PK profiles of nilotinib were obtained at steady-state from a subgroup of 34 patients, and sparse (pre-dose/Cmin and 3-hr post-dose/Cmax) concentration data were obtained over 12 months from 542/563 (96%) treated patients. *Results.* Nilotinib concentrations were stable over 12 months in both arms (Cmin: 1158±568 ng/mL [median 1097 ng/mL] for 300 mg BID; 1340±621 ng/mL [median 1217 ng/mL] for 400 mg BID). The average nilotinib Cmin and Cmax were 15.7% and 14.8% higher in the 400 mg BID arm than the 300 mg BID arm. The estimated relative bioavailability ratio was 0.84 for nilotinib 400 mg BID to nilotinib 300 mg BID. Male patients had 10% lower bioavailability and systemic exposure than female patients. Although this difference was statistically significant, it was not considered clinically meaningful based on the observed interpatient variability in nilotinib PK. Age, body weight, ethnicity, and racial group did not significantly affect nilotinib PK. Adverse events on the study were typically transient and infrequently led to discontinuation of study drug. Total bilirubin elevation was higher in patients with higher nilotinib concentrations. For example, patients with nilotinib Cmin in quartiles Q1 (<829 ng/mL, n=113), Q2/3 (≥829 and ≤1569 ng/mL, n=229) and Q4 (>1569 ng/mL, n=113), had grade 3/4 bilirubin elevation of 0.9%, 4.8% and 7.1%, respectively. Logistic regression analysis confirmed a significant correlation between nilotinib daily AUC and total bilirubin elevation of all grades. There was no clinically relevant correlation between nilotinib exposure and elevation in AST or lipase. On average, an increase of 1000 ng/mL in nilotinib serum concentrations was associated with minimal increase in QTcF (4.2 to 6.9 msec). Although there was no apparent relationship between major molecular response at 12 months and average nilotinib Cmin, there was a weak positive correlation of uncertain significance (P = .097, Cochran-Mantel-Haenszel test for ordinal variables) between BCR-ABL transcript level reductions at 12 months and nilotinib Cmin (Table 1).

Table 1.

	Nilotinib C_{min}		
	< 829 ng/mL	≥ 829 and ≤ 1569 ng/mL	> 1569 ng/mL
	n = 113	n = 229	n = 113
	n (%)	n (%)	n (%)
Cumulative BCR-ABL (IS) ratio at 12 months			
≤ 0.0032%	1 (0.9)	10 (4.4)	8 (7.1)
≤ 0.01%	9 (8.0)	23 (10.0)	15 (13.3)
≤ 0.1%	45 (39.8)	101 (44.1)	52 (46.0)
≤ 1%	78 (69.0)	186 (81.2)	94 (83.2)
≤ 10%	93 (82.3)	206 (90.0)	100 (88.5)

Conclusions. There was a less than proportional dose-exposure relationship between nilotinib 300 mg BID and nilotinib 400 mg BID in the ENESTnd study. Exposure was stable over the 12 month treatment course at both doses. Demographics were not a clinically important

factor affecting nilotinib PK. The study is ongoing and additional PK data will be available.

0147

PHARMACOGENETICS OF IMATINIB IN NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA PATIENTS SHOWS EVIDENCE OF ASSOCIATION BETWEEN IMATINIB TRANSPORTERS AND METABOLIZING ENZYMES GENOTYPE AND MOLECULAR RESPONSE

S Soverini,[1] S Angelini,[2] M Barnett,[3] E Turrini,[2] M Thornquist,[3] G Ravegnini,[2] G Rosti,[1] A Gnani,[1] S Colarossi,[1] P Hrelia,[2] T Kalebic,[4] M Baccarani,[1] G Martinelli[1]

[1]University of Bologna, Bologna, Italy; [2]Department of Pharmacology, University of Bologna, Bologna, Italy; [3]Fred Hutchinson Cancer Research Center, Seattle, USA; [4]Novartis Oncology, Florham Park, USA

Background. Imatinib mesylate (IM) is the first-choice treatment in chronic myeloid leukemia (CML), with excellent response rates. Major and possibly complete molecular responses are the current goals of therapy, but not all patients (pts) achieve these milestones - hence the need to find biological predictors of response in order to guide therapy optimization. *Aims.* We investigated if single nucleotide polymorphisms (SNPs) influencing IM delivery may account for differences in response. *Methods.* We have genotyped a panel of 20 SNPs affecting the activity of the cytochrome p450 isoforms (CYP3A4, CYP3A5) and of the transporters (ABCB1, ABCG2, hOCT1, OATP1A2, OCTN1) implicated in IM metabolism/transport in a subset of pts enrolled in the TOPS trial - a randomized phase III study of IM 400 mg/d vs IM 800 mg/d in newly diagnosed CML. A total of 189 pts were genotyped (156 Caucasian, 22 Asian and 11 non-Caucasian and non-Asian pts). Median follow-up time is 29 months. Additive models, with SNPs represented as the number of minor alleles, were used to assess association between individual SNPs and response outcomes. Summary measures based on SNPs from the same gene and those related functionally (uptake and efflux) were defined as the number of alleles, across the genes of interest, hypothesized to be associated with favorable response. The association of polymorphisms and SNP summary measures with complete cytogenetic response (CCgR) and major molecular response (MMR) at 12 months was assessed with exact Ps based on Cochran-Armitage trend tests. Survival analysis methods were used to examine the relationship between SNPs and cumulative incidence of major cytogenetic response (MCgR), CCgR, MMR, complete molecular response (CMR). Cumulative incidence curves were compared with log-rank tests of trend, assuming an additive genetic model. *Results.* Five SNPs (hOCT1: rs4646277, rs4646278, MDR1: rs1128501, Cyp3A4: rs28371759 and Cyp3A5: rs28365083) were homozygous for the major allele for all patients and were excluded from the analyses. Comparison of genotype frequencies according to the patient's demographic characteristics revealed differences between Asian and Caucasian subgroups. Among Caucasian, the following SNPs and/or haplotypes correlated with cumulative incidence of MMR: a) OCTN1 rs1050152 number (no.) of major alleles (A) (P=0.03); b) CYP3A4 rs2740574 no. of minor alleles (G) (P=0.04); c) hOCT1 gene total no. of major alleles (rs72552763, rs12208357, rs683369, rs2282143) (P=0.03); d) uptake (total no. of major alleles in hOCT1 rs72552763, rs12208357, rs683369, rs2282143, OCTN1 rs1050152, OATP1A2 rs11568563) (P=0.003). In addition, the following SNPs and/or haplotypes correlated with cumulative incidence of complete molecular response (CMR): a) MDR1 rs60023214 no. of major alleles (C) (P=0.005); b) uptake (total no. of major alleles in hOCT1 rs72552763, rs12208357, rs683369, rs2282143, OCTN1 rs1050152, OATP1A2 rs11568563) (P=0.009). *Conclusions.* Our results suggest that although ethnicity needs to be taken into account, pharmacogenetics of IM may be helpful in identifying pts who need treatment optimization. Confirmation in larger series is warranted to further test the predictive value of the SNPs identified in this study.

Background. Since imatinib registration, most of the information on safety and efficacy of this therapy was collected through clinical trials. Thus, the context of imatinib failure is currently insufficiently documented. Therefore, members of the ELN established the IFP CML subregistry in order to collect failure pts. *Aims.* Failure is defined as 1) resistance, i.e. no haematological response (HR) or no cytogenetic response (CgR), unsatisfactory responses, loss of responses according to the ELN management recommendations (Baccarani, J Clin Oncol, 2009) and 2) toxicity leading to imatinib discontinuation. Objectives are to describe the categories of failure, demographic patterns, clinical and biological profiles of pts, treatments before failure, therapeutic decisions and outcome thereafter. *Methods.* To be included in the IFP sub-Registry, failure pts should be at least 18 years old with Ph^+ CML in chronic phase at the start of imatinib therapy. Eligibility was irrespective of treatments prior to imatinib and enrolment in clinical trials. Based on notification, data have been centralized since 2005 and 1000 cases are expected. *Results.* As of February 2010, 918 pts were registered by 23 IFP study groups from 16 countries (Austria, Czech Republic, Denmark, Finland, France, Germany, Israel, Italy, The Netherlands, Poland, Spain, Russia, Slovak Republic, Sweden, Switzerland and UK). Median age at diagnosis was 52 years (range: 12-88), 54% of pts being male. At the time of failure, 60% of pts have never been included in an imatinib clinical trial. Reasons for registration were: no or unsatisfactory response in 38% of the cases, including no complete HR (7%), no CgR at all (16%), and no major CgR (15%). Loss of responses occurred in a further 38% of the cases collected, including 14% of progression to accelerated phase or blast crisis. The remaining (24%) cases were recorded because of toxicity leading to imatinib discontinuation (20%) or toxicity combined with unsatisfactory responses (4%). With a median follow-up of 5 years since diagnosis (range: 1 month - 31 years), 769 cases were documented. The median duration of imatinib therapy was 25 months (range: 2 weeks - 103 months). Among these cases, 38% were previously treated with an interferon-based regimen. At the time of failure, 63% were treated with imatinib 400 mg alone or in combination with other drugs and 27% with various imatinib dosages. After failure, 47% of the pts have been switched to other tyrosine kinase inhibitors, 14% were transplanted, and 39% received several lines of treatment, high-dose chemotherapy and/or other compounds such as omacetaxine. At 8 years from imatinib start, the estimated rates of survival were 67% (95% CI: 60-71%) overall, 83% when toxicity leading

to imatinib discontinuation and 65% otherwise (P=0.015). *Conclusions.* This sub-registry is the first attempt to collect and provide detailed information about clinical features of patients who failed imatinib therapy, within and outside of clinical trials. The study is being conducted in accordance with the principles and guidelines of the European Community and is linked to the ELN. Completion of the data is ongoing. More detailed analyses will be presented.

CML PATIENTS ACHIEVED CYTOGENETIC RESPONSE WITH LOW IMATINIB PLASMA LEVEL ARE CHARACTERIZED BY HIGH IMATINIB BONE MARROW FLUID LEVEL

S Kutsev,[1] O Oxenjuk,[1] Y Shatokhin,[1] O Serdjuk,[2] E Ovsyannikova,[3] A Turkina[4]

[1]Rostov State Medical University, Rostov-on-Don, Russian Federation; [2]Krasnodar Regional Oncology Hospital, Krasnodar, Russian Federation; [3,12]Astrakhan State Medical Academy, Astrakhan, Russian Federation; [4]Research Hematology Center RAMS, Moscow, Russian Federation

Background. Imatinib has shown the high effectiveness in chronic myeloid leukemia (CML) therapy. Recent papers have demonstrated that the achievement of complete cytogenetic response (CCyR) and major molecular response (MMR) to imatinib therapy may be relates with more than 1000 ng/mL Imatinib plasma level (IPL). However large inter-individual variability of IPL is peculiar for Imatinib-treated CML patients. Some patients achieve CCyR and MMR with significantly lower than 1000 ng/mL IPL. The Aim of this study is to compare the Imatinib bone marrow fluid level (IBMFL) with IPL in CML patients achieved CCyR and patients with failure or suboptimal response. *Methods.* IBMFL and IPL were detected in 170 CML patients with Imatinib treatment duration more than 12 months. The age of patients was 20-80. Male/female ratio was 73/97. 126 patients were in CP CML and 44 patients in AP CML. Imatinib doses were 400 mg QD (n=94), 600 mg QD (n=66) or 800 mg BD (n=10). Bone marrow and blood samples were collected simultaneously 1-72h after the last IM dose intake. Bone marrow samples were collected for cytogenetic analysis according to therapy protocol. 300 µL of each bone marrow sample were used for IBMFL test. All patients gave informed consent before sampling. Imatinib concentration were determined by a validated LC/MS/MS method. Exclusion criteria: imatinib dose 800 mg BD (10 pts), blood sampling less than 21 h (45 pts) and more than 27 h (13 pts), nonadherens (4 pts), the dilution of BM samples by blood (bone marrow cell count $<20\times10^9$/L , M/E ratio <2)(28 pts). Totally 68 patients were included in analysis. *Results.* Cytogenetic analysis have revealed that 42 patients have achieved CCyR and 26 have achieved suboptimal response or failured to achieve cytogenetic response. The median of IPL in patients with CCyR was 1135 [536-2519] ng/mL, IBMFL - 1818 [708-5827] ng/mL , IBMFL/IPL ratio was 1,8 [0,7-3,4]. The median of IPL in patients with failure or suboptimal response was 1069 [197-1963] ng/mL, IBMFL - 1647 [250-3959] ng/mL, IBMFL/IPL ratio was 1,3 [0,8-3,6]. Among 42 patients achieved CCyR IPL more than 1000 ng/mL were revealed in 26 (61,9%) patients with the median of IPL - 1547 [1021-2519] ng/mL, IBMFL - 2701 [1175-5827] ng/mL, IBMFL/IPL ratio - 1,7[0,9-3,4] . Less than 1000 ng/mL were founded in 16 (38,1%) patients achieved CCyR with the median of IPL - 731 [536-998] ng/mL, IBMFL - 1342 [708-2735] ng/mL, IBMFL/IPL ratio - 1,8 [0,7-2,8]. Among 16 patients achieved CCyR with low IPL (<1000 ng/mL) IBMFL is more than 1000 ng/mL and significantly exceed IPL in 14 (87,5%) patients with IBMFL/IPL ratio 1,9 [1,4-2,8]. *Conclusions.* Imatinib level in bone marrow fluid is higher than in blood plasma in most cases. The achievement of CCyR in cases with low level of imatinib concentration in plasma is associated with higher level of imatinib in bone marrow.

HOCT1 M420 DELETED TRANSCRIPT LEVELS PREDICT POOR CLINICAL OUTCOME FOR IMATINIB TREATED CML PATIENTS

L Wang,[1] A Giannoudis,[2] G Austin,[2] T Liloglou,[2] G Xinarianos,[2] J Clark,[2] A Kishore,[2] M Pirmohamed,[2] R Clark[2]

[1]Royal Liverpool University Hospital, Liverpool, UK; [2]University of Liverpool, Liverpool, UK

Background. Human organic cation transporter 1 (hOCT1) transports imatinib into haematological cells. However, whilst we and others have shown that hOCT1 transcript levels are predictive of outcome in imatinib treated CML, this is not universally agreed. These variable results may be because differing PCR primer locations have variable detection of functionally relevant single nucleotide polymorphisms (SNPs) in hOCT1. Here we focus on a 3-nucleotide deletion at M420, the commonest hOCT1 SNP in the general population (allele frequency 14-19%) and which is known to modify hOCT1 mediated metformin transport. *Methods.* In our original primer set (Wang et al, Clin. Pharm. Therap. 2008), the forward primer covers the M420del SNP site. New primers were designed with similar PCR efficiency shifted away from M420del SNP. Both pairs of primers were then used for hOCT1 transcript quantification on 13 "test"and 53 "validation"CML samples, using optimised real time PCR conditions on a LightCycler. *Results.* In 5 cases without M420del, equal amounts of hOCT1 transcripts were detected by the two sets of primers. In 6 cases heterozygous for M420del, the apparent hOCT1 transcript levels measured by the original primers were 50% of those measured by the new primers. In 2 cases homozygous for M420del, hOCT1 transcripts were undetectable by the original primers, though were detectable by the new primers at levels comparable to M420 wild type cases. The original primers therefore detect purely M420 wild type transcripts, while the new primers detect both M420 wild type and M420del transcripts, which was confirmed by sequencing the PCR product. To assess whether M420del SNP predicts clinical outcome, hOCT1 transcript levels were measured using both sets of primers in 53 "validation"newly diagnosed chronic phase patients who then received first line imatinib. M420del SNP were determined by PCR pyrosequencing and cloning sequencing. In cases heterozygous for M420del, apparent transcript levels were significantly lower with the original than with the new primer sets (P=0.03), whereas little difference was seen in cases without M420del. Using the original primer set, patients achieving complete cytogenetic response (CCR) after 12 months of imatinib treatment had higher apparent transcript levels than patients with no cytogenetic response (NCR) (P=0.01). In contrast, using the new primer set, no significant difference in transcript levels was seen between CCR vs. NCR patients. Survival analysis showed that patients with high transcript levels as defined by the original primers had superior event free survival (EFS) and progression free survival (PFS) than cases with low apparent expression (P=0.03 and 0.01, respectively. Log-rank analysis); however, with the new primers, EFS and PFS were not significantly different between patients with high vs. low transcript levels. *Conclusions.* These data illustrate that a) M420 wild type transcript levels (as measured by our original primers) correlate with the outcome of treatment while actual hOCT1 transcript levels (as assessed here by our new primers) may not, and b) M420del may be a clinically important SNP that predicts outcome of imatinib treatment. Further investigation of the role of hOCT1 M420del SNP is required.

D. Anderson Cancer Center, Houston, USA; [9]Novartis Pharmaceuticals Corporation, East Hanover, USA; [10]Novartis Institutes for BioMedical Research, Cambridge, USA; [11]SA Pathology, Royal Adelaide Hospital, Adelaide, Australia

Background. Nilotinib is a potent and the most selective BCR-ABL kinase inhibitor, approved for the treatment of chronic phase (CML-CP) and accelerated phase (CML-AP) Philadelphia chromosome positive (Ph^+) CML in adult patients resistant to or intolerant of prior therapy, including imatinib. BCR-ABL transcript levels and the detection of new mutations have been reported to be a predictor of response outcomes in patients with CML, including those with imatinib resistance (Branford et al, Blood. 2008;112(11):128). *Aims.* Here we examined the association between newly detectable BCR-ABL mutations, presence or absence of baseline mutations, resistance to or intolerance of imatinib, and initial molecular response to nilotinib in patients with Ph^+ CML-CP treated in the phase 2 nilotinib registration study 2101. *Methods.* Patients with Ph^+ CML-CP (N = 321) with imatinib resistance (78%) or intolerance (22%) were included in this post-hoc analysis. All patients had at least 24 months of follow-up. Landmark analyses were performed based on BCR-ABL transcript levels at 3 months (≤1%, > 1-≤10%, and > 10% BCR-ABL (International Scale, IS). *Results.* Newly detectable mutations were observed in 56 of 290 (19%) patients with available baseline mutation data, including 51 of 200 (26%) imatinib-resistant and 5 of 90 (6%) imatinib-intolerant patients. Patients with baseline mutations and resistance to prior imatinib had a higher probability of newly detectable mutations compared with patients without baseline mutations (P < .0001) and imatinib-intolerant patients (P=.0002). In patients with baseline mutations or those resistant to imatinib therapy, BCR-ABL levels at 3 months did not predict for newly detectable mutations, including mutations less sensitive to nilotinib (Y253H, E255K/V, F359C/V, T315I) (Table). Molecular response to nilotinib treatment at 3 months also did not predict for newly detectable mutations in patients without baseline mutations and those intolerant of imatinib. *Conclusions.* In this analysis, detection of new mutations was more likely in patients with baseline mutations and imatinib resistance. Molecular response to nilotinib at 3 months did not correlate with detection of new mutations within 24 months of initiating nilotinib therapy. Other factors predictive of newly detectable mutations should be explored.

Table 1. Occurrence of newly detectable mutations by 24 months according to BCR-ABL trascription levels at 3 months on nilotinib.

	BCR-ABL levels at 3 Months (IS, %)			
	≤ 1	> 1-≤ 10	> 10	P-value
Occurrence of newly detectable mutations by 24 mo (%)				
Pts with baseline mutations, n = 79	21	17	45	.258[a], .983[b]
Resistant pts, n = 158	21	14	28	.146[a], .532[b]
Occurrence of less sensitive mutations by 24 mo (%)				
Pts with baseline mutations, n = 79	21	17	21	.983[a], .919[b]
Resistant pts, n = 158	11	10	16	.556[a], .858[b]

[a]Comparison of > 1-≤10 vs > 10

RECURRENT VENOUS THROMBOEMBOLISM AND POST-THROMBOTIC SYNDROME AFTER CATHETER-DIRECTED THROMBOLYSIS IN DEEP VENOUS THROMBOSIS

I Kleven,[1] A Rosalis,[2] L Pederstad,[1] T Enden,[3] PM Sandset,[3] W Ghanima[1]

[1]Østfold Hospital Trust Fredrikstad, Fredrikstad, Norway; [2]Oslo University Hospital-Aker Hospital, Oslo, Norway; Oslo University Hospital-Ullevål Hospital, Oslo, Norway

Background. In the present study we investigated the risk of recurrence in patients who were given additional catheter directed thrombolytic therapy (CDT) to conventional treatment with heparin for severe proximal deep vein thrombosis (DVT). We have shown that such treatment significantly increases recanalization and patency. Based on recent studies suggesting higher risk of recurrence in patients with residual vein thrombosis, we hypothesized that CDT would be associated with lower risk of recurrence. *Aims.* To determine the rate of VT recurrence and frequency of post-thrombotic syndrome (PTS) following treatment with CDT. *Methods*. We identified patients treated with CDT in 4 hospitals in the Norwegian South-Eastern Health Region during 1999-2006. Sixty-eight consented to participate in this study. Patients met for investigation during May 2009 -Jan 2010. PTS was assessed by the Villalta score. *Results.* Median age (inter-quartile range =IQR) of 68 patients was 41 (33-56) years; 51 females (75%). Median duration of follow-up was 6.3 years (IQR 4.8-8.1 years). Recurrent VT was encountered in 5 of 21 (24%: 95% CI 9-47.5%) on AC, and in 10 of 47 (21%: 95% CI 11-36%) after discontinuing AC. The recurrences were DVT in 13 (86%), Pulmonary embolism in 1 (7%) and retinal vein thrombosis in 1 (7%). The 10-years probability of VT recurrence in all patients after discontinuation of AC is estimated to 32%. DVT was classified as provoked in 34 (71%) and unprovoked in 14 (29%). Significantly higher recurrence rate was seen in patients with unprovoked compared to provoked DVT (log rank test P=0.008) (Figure). Elastic compression stockings (ECS) were used in 60 patients (88%). According to Villalta score 43 patients (64%: 95% CI 51-75%) had no PTS; 15 (22%: 13-34) had mild, 6 (9%: 4-19) had moderate and 3 (4%: 1-13) had severe PTS. *Summary/Conclusions.* This study provides the longest follow-up data reported on rates of recurrence and PTS after CDT. The 10-years probability of VT recurrence after discontinuation of AC is estimated to 32%, which is in line with that found after conventional anticoagulation (Prandoni et al: Haematologica 2007;92). The incidence of PTS in this study was comparable to that reported following conventional treatment (Schulman. J Thromb Haemost 2006;4). In conclusion, there is no indication that CDT provides any benefit over conventional treatment in term of reduction in VT recurrence or PTS

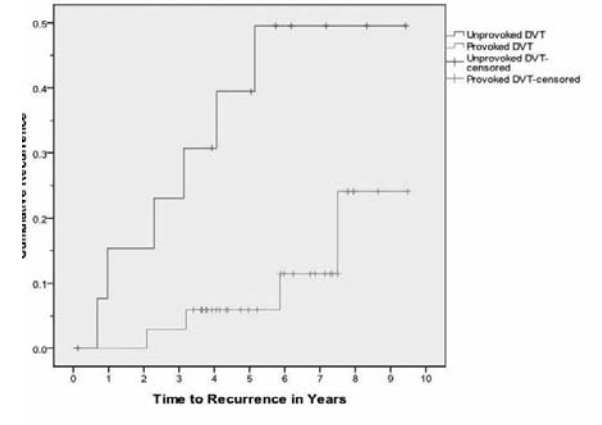

Figure. Recurrence in provoked and unprovoked DVT.

0153

BODY HEIGHT AND SEX-RELATED DIFFERENCES IN INCIDENCE OF VENOUS THROMBOEMBOLISM: A DANISH FOLLOW-UP STUDY

M Severinsen,[1] S Johnsen,[2] K Overvad,[3] C Dethlefsen,[4] S Kristensen[5]

[1]Aalborg Hospital, Aarhus University Hospital, Aalborg, Denmark; [2]Department of Clinical Epidemiology, DK-8000 Aarhus, Denmark; [3]Department of Epidemiology, School of Public Health, Aarhus University, DK-8000 Aarhus, Denmark; [4]Center for Cardiovascular Research, Aalborg Hospital, Aarhus University, DK-9100 Aalborg, Denmark; [5]Department of Clinical Biochemistry, Aalborg Hospital, DK-9100 Aalborg, Denmark

Background. Pulmonary embolism (PE) and deep venous thrombosis (DVT) share many risk factors, and most studies regard these diseases as one entity namely venous thromboembolism (VTE). However, it is well known that people who have had a PE event recur as PE more frequently than patients who have had a primary DVT event indicating that some people are more predisposed for PE than others, i.e. some people are for some reasons more likely to embolise from a DVT into PE. It is unknown whether sex influences the presentation of VTE as DVT or PE and the impact of body height on the presentation of VTE has not been evaluated. *Aim.* to compare the incidence rate of VTE, DVT and PE between men and women and to clarify to which extent any sex-related differences are mediated by body height and other known risk factors for VTE. *Methods.* We computed sex-specific incidence rate of VTE, DVT and PE and estimated the crude and adjusted incidence rate ratios of VTE, DVT and PE using Cox regression for men versus women participating in the prospective study Diet, Cancer and Health. We controlled for body mass index, body height, leisure-time physical activity and smoking dose. *Results.* In total, 56,014 people were followed for a median of 10.2 years during which 641 incident VTE events were verified. Table 1 shows the incidence rates of VTE, DVT and PE, including idiopathic and provoked events, in men and women, and the crude and adjusted incidence rate ratios for men versus women. The crude IRR was 2.00 [95% CI: 1.61-2.49] for DVT and 1.14 [95% CI: 0.90-1.44] for PE for men versus women, showing that the crude incidence rate of DVT was double as high in men than women, but no difference in the crude incidence rate of PE were found between the two sexes. In contrast, the adjusted incidence rate ratios were 1.06 [95% CI: 0.75-1.50] for DVT and 0.60 [95% CI: 0.41-0.87] for PE for men versus women. The main confounder in the analyses was body height whereas adjustment for BMI, smoking status, and physical activity only resulted in minor changes of the estimates. This shows that men and women at the same body height, BMI, smoking status, and level of physical activity had the same risk of DVT, whereas the risk of PE were significant higher in women. The same tendency was found for idiopathic and provoked VTE. *Summary/Conclusions.* In conclusion, in this middle-aged population, men experienced a higher incidence of VTE due to a higher incidence of DVT. The higher incidence among men appeared to be mediated mainly by body height. Controlled for body height, the incidence of PE was notably lower among men compared with women.

Table 1.
Incidence rates (IR) and incidence rate ratios (IRR, i.e. IR_{men} / IR_{women}) of venous thromboembolism (VTE), deep venous thrombosis (DVT), and pulmonary embolism (PE) per 1000 person years at risk. Adjusted for BMI, body height, physical activity, smoking status. [95 % confidence intervals].

	IR, total [95% CI]	IR, men [95% CI]	IR, women [95% CI]	IRR, crude [95% CI]	IRR, adjusted [95% CI]

0154

IN KINDREDS WITH INHERITED THROMBOPHILIA THE VENOUS THROMBOTIC RISK OF THE CARRIERS IS DEPENDENT ON THE CLINICAL PHENOTYPE OF THE PROBAND

E Rossi, A Ciminello, T Za, S Betti, G Leone, V De Stefano

Institute of Hematology, Catholic University, Rome, Italy

Background. Laboratory screening for inherited thrombophilia is recommended for patients with previous venous thromboembolism (VTE) or obstetric complications (OC). Universal screening (US) before oral contraceptive intake or pregnancy is discouraged, being not cost-effective. Nevertheless, a growing number of individuals are labeled as carriers of inherited thrombophilia because of inappropriate laboratory testing. Whether the identification of all the asymptomatic affected relatives should be pursued in order to prevent VTE is debated. *Aims.* To assess in kindreds with inherited thrombophilia the thrombotic risk of the carriers according to the type of the alteration and to the clinical phenotype of the proband. *Patients and Methods.* We carried out a retrospective family cohort study on 1,722 relatives (M/F 769/953) of 563 probands diagnosed as carrying thrombophilia because of a history of VTE (1,090 relatives from 340 kindreds), OC (257 relatives from 86 kindreds), premature arterial thrombosis (AT) (113 relatives from 31 kindreds), or US (262 relatives from 106 kindreds). In 517 kindreds the proband carried factor V Leiden (FVL) and/or prothrombin G20210A (PTGA), whereas in the remaining 46 the proband had a deficiency of antithrombin (AT), protein C (PC) or S (PS), alone or combined with FVL or PTGA; all the probands had been referred for counselling and familial screening. The relative risk for deep venous thrombosis (DVT) was estimated as a hazard ratio (HR) comparing the thrombosis-free survival curves of the carriers in respect to the non-carriers. *Results.* Inherited thrombophilia was detected in 968 relatives (56.2%); the total observation-years were 37,727 for carriers and 29,548 for non-carriers. DVT occurred in 46 carriers (incidence 1.2 per 1,000 individual-years) and in 11 non-carriers (incidence 0.37 per 1,000 individual-years). Overall, the risk for DVT was significantly increased in the carriers only in the kindreds of the probands diagnosed because of previous VTE (HR 2.40, 95%CI 1.14-4.05). No increase in risk was detectable among the carriers who were relatives of the probands diagnosed because of OC, AT, or US, whatever the type of alteration present in the kindred. In the kindreds of the probands with FVL and/or PTGA and previous VTE, the risk for DVT in the carriers was marginally increased (HR 1.97, 95%CI 0.89-3.92). In the kindreds of the probands with deficiency of natural anticoagulants (AT, PC, or PS) and previous VTE, the HR for DVT in respect to the non-carriers was 4.66 (95%CI 0.80-10.21) in the overall carriers, and 15.36 (95%CI 3.06-60.91) in the relatives with AT deficiency. *Conclusions.* Familial screening for inherited thrombophilia is only justified for probands with history of VTE. In this setting, the risk for DVT is about doubled in the carriers of FVL and/or PTGA, and is exceedingly high in the carriers of AT deficiency.

HEMOSTATIC FACTORS AND MORTALITY BY ACUTE LUNG INJURY IN SEVERE SEPSIS SYNDROME

O Gutierrez,[1] A Muriel,[2] A Dueñas,[3] E Fernández,[3] B Gonzalez-Mena,[3] E Fernández-Fontecha,[3] A Cantalapiedra,[3] J Tortosa,[3] J Blanco,[2] J García-Frade[3]

[1]Hospital Universitario Rio Hortega, Valladolid, Spain; [2]Critical Care Dep. Hospital Universitario Rio Hortega, Valladolid, Spain; [3]Hematology Dep. Hospital Universitario Rio Hortega, Valladolid, Spain

Background. Sepsis often presents disseminated intravascular coagulation and acute lung injury (ALI) and acute respiratory distress syndrome (ARDS), related to severity of the disease. The aim of this study is to assess the dynamics and magnitude of the coagulation and fibrinolysis plasma markers in the severe sepsis syndrome and the relation with mortality associated to ALI / ARDS. *Methods.* 2619 patients in intensive care units of 13 hospitals were screened at admission and daily for severe sepsis, and presence of ALI / ARDS. 311 septic patients were included during a 6 months period, according to definition of ACCP Consensus Conference 1992 and Resp Critical Care Consensus Conference 1994. The state of the coagulation system was assessed by measurements of values of thrombin-antithrombin complex (TAT), and Protein C (PC). The fibrinolytic system was assessed by the measurement of plasmin-antiplasmin complex (PAP) and plasminogen-activator inhibitor type 1 (PAI-1). Enzyme linked immuno-assay methods in plasma were used. The samples were collected at diagnosis, and at days 3

and 7 from the first episode of severe sepsis in a random sample of 145 patients. Non-parametric U Mann-Whitney test stablished differences between patients with ALI / ARDS and the other septic patients, and between survivors with non survivors ALI / ARDS patients. *Results.* There were 92 (63,5%) patients with diagnostic of ALI / ARDS during the first seven days after admission, and 63 (68,5%) died. Plasma concentrations of fibrinolytic inhibitor PAI-1 were higher at day 1 in patients with the presence of lung injury (91.6 vs 50.7, P=0.04). Non-survivors ALI / ARDS patients had higher levels of PAI-1 at day 1 (91.6 vs 50.2, P=0.02) and day 3 (63.2 vs 45, P=0.01). Patients with ALI / ARDS during all the first week had higher levels of PAI-1 at day 1. When lung injury appeared at day 3 or 7, previous higher levels of PAI-1 at day 1 (154 vs 46.5, P=0.03) or day 3 (126 vs 30, P=0.01) were associated to mortality. No other hemostatic markers analized had significative relation with the presence of ALI / ARDS. *Conclusions.* High plasma concentration of fibrinolytic inhibitor PAI-1 is correlated with the presence of lung injury / acute respiratory distress syndrome in septic patients. PAI-1 could be considered an mortality predictor in patients with severe sepsis and ALI / ARDS.

SPLENECTOMY AND THROMBOSIS: THE CASE OF THALASSEMIA INTERMEDIA

K Musallam,[1] M Cappellini,[2] A El-Beshlawy,[3] M Karimi,[4] S Daar,[5] K Belhoul,[6] M Saned,[6] C Cesaretti,[2] A Taher[1]

[1]American University of Beirut Medical Center, Beirut, Lebanon; [2]University of Milan, Milano, Italy; [3]Cairo University, Cairo, Egypt; [4]Shiraz University of Medical Sciences, Shiraz, Iran; [5]Sultan Qaboos University, Muscat, Oman; [6]Al Wasl Hospital, Dubai, United Arab Emirates

Background. The pathophysiological mechanisms that lead to the hypercoagulable state in splenectomized patients with thalassemia intermedia (TI) have been identified. However, clinical characteristics of patients who eventually develop overt thromboembolic events (TEE) are poorly studied. *Aims.* To identify factors that characterize splenectomized TI patients who develop TEE as compared to splenectomized and non-splenectomized patients who do not develop TEE. *Methods.* Data was retrieved from the Thalassemia Intermedia Registry, a database of 584 TI patients currently registered at six comprehensive care centers in Lebanon, Italy, Iran, Egypt, United Arab Emirates, and Oman. Institutional review boards at each center approved the study protocol. Three Groups of patients were identified: Group I, splenectomized patients with a documented TEE (n=73); Group II, age- and sex-matched splenectomized patients without TEE (n = 73); and Group III, age- and sex-matched non-splenectomized patients without TEE (n=73). Collected data included demographics, laboratory parameters, disease-complications, and received treatments that may influence TEE development and reflected the period prior to TEE occurrence in Group I. *Results.* The mean age was 33.1±11.7 years (range, 15-60 years) for Group I (at TEE), 33.3±11.9 (range, 9-75 years) for Group II, and 33.4±13.1 (range, 6-76 years) for Group III; (P=0.991). The male to female ratio was 33:40, 35:38, and 34:39 for Groups I, II, and III; respectively (P=0.946). There was no statistically significant differences in mean hemoglobin (Group I: 9.0±1.3 g/dL, Group II: 8.8±1.2 g/dL, Group III: 8.7±1.3 g/dL; P=0.174) or fetal hemoglobin (Group I: 45.9±28.0%, Group II: 54.4±32.8 g/dL, Group III: 44.2±27.2 g/dL P = 0.429) levels between Groups. However, nucleated red blood cell (RBC) counts were highest among Group I (mean, 410.8±299.2×10^6/L), followed by Group II (mean, 301.0±130.7×10^6/L), then Group III (mean, 241.0±130.5 ×10^6/L); P = 0.015. Similarly platelet counts were highest among Group I (mean, 712.6±192.5×10^9/L), followed by Group II (mean, 506.3 ±142.1×10^9/L), then Group III (mean, 319.8±125.5×10^9/L); P<0.001. There was no statistically significant difference in the proportion of patients with diabetes mellitus, heart failure, abnormal liver function, or prothrombotic mutations. However, a higher proportion of patients had pulmonary hypertension in Groups I (31.5%) and II (28.8%) as compared to Group III (2.7%); P<0.001. The highest proportion of patients receiving transfusion therapy was in Group III (74%), followed by Group II (65.8%), then Group I (43.8%). There was no statistically significant difference in the proportion of patients receiving aspirin, anticoagulants or hydroxyurea between the three Groups. Multivariate logistic regression analysis revealed that patients in Group I are more likely to be non-transfused, have pulmonary hypertension, have nucleated RBC counts > 250×10^6/L, and platelet counts > 500×10^9/L. *Summary/Conclusions.* Transfusion naivety, pulmonary hypertension, and high platelet and nucleated RBC counts characterize splenectomized TI patients who develop TEE.

VENOUS THROMBOEMBOLISM DURING AUTOLOGOUS STEM CELL TRANSPLANTATION FOR HAEMATOLOGICAL MALIGNANCIES

J Crispin,[1] M Vazquez[2]

[1]Canberra Hospital, Woden, Australia; [2]Australian National University, Canberra, Australia

Background. There is an established risk of venous thromboembolism (VTE) with solid tissue malignancies. Recent evidence indicates an increased risk also with haematological malignancies, including during myelosuppressive therapy for acute leukaemia. Current guidelines suggest pharmacological prophylaxis in hospitalised cancer patients, but the incidence of VTE during autologous stem cell transplantation is unknown, and there are potential risks of pharmacological VTE prophylaxis during myeloablative chemotherapy. *Aim.* To establish the risk of VTE during autologous stem cell transplant. *Method.* A retrospective review of all patients undergoing autologous stem cell transplant for haematological malignancies at our institution was undertaken to determine the incidence of radiologically confirmed symptomatic VTE and the presence of concurrent risk factors. *Results.* One hundred eighty four patients had follow up for at least one month following discharge and were included in the analysis. There were two deaths within the follow-up period (1 graft failure, 1 progressive disease). Non-Hodgkin lymphoma (NHL) and myeloma were the most common indications for transplant, with BEAM and melphalan, respectively the most common conditioning regimens. Twelve patients had a history of prior VTE, of whom three had pharmacological prophylaxis, which was withheld during severe thrombocytopenia in two cases.A total of four (2.2%) patients had confirmed VTE. None had had a prior event. Three events were related to central venous catheters. Only one patient (0.5%) had a VTE not associated with a venous catheter, developing an above knee deep vein thrombosis after discharge. Two of 9 patients with peripherally inserted central catheters (PICC) developed catheter associated thrombosis, which was the only significant risk factor. No patients in this cohort had veno-occlusive disease of the liver. *Conclusions.* Autologous stem cell transplant with BEAM or melphalan has a low risk of venous thromboembolism and pharmacological prophylaxis is not recommended. The use of PICC lines carried a higher risk of thrombosis.

0158

CLINICAL CHARACTERISTICS AND OUTCOME OF PATIENTS WITH FACTOR V LEIDEN OR PROTHROMBIN G20210A AND A FIRST EPISODE OF VENOUS THROMBOEMBOLISM. FINDINGS FROM THE RIETE REGISTRY

T Gadelha,[1] V Roldán,[2] R Lecumberri,[3] J Trujillo-Santos,[4] R Del Campo,[5] R Poggio,[6] M Monreal[7]

[1]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [2]Department of Haematology. Universidad de, Murcia, Spain; [3]Department of Haematology. Clínica Universitaria de Navarra., Pamplona, Spain; [4]Department of Internal Medicine. Hospital Universitario Santa María de Rosell, Murcia, Spain; [5]Department of Haematology. Hospital Son Llatzer, Palma de Mallorca, Spain; [6]Department of Internal Medicine Thrombosis Center. Ospedale Galliera, Genoa, Italy; [7]Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol, Barcelona, Spain

Background. Asymptomatic individuals with factor V Leiden or prothrombin G20210A are at a higher risk to develop venous thromboembolism (VTE), but little is known about the clinical characteristics of the VTE in these patients. *Patients and Methods.* RIETE is an ongoing registry of consecutive patients with acute VTE. Our aim was to compare the clinical characteristics and outcome of those with a first episode of VTE and factor V Leiden, prothrombin G20210A, or no thrombophilia. *Results.* As of May 2009, 22428 patients had been enrolled with a first episode of VTE. Of these, 345 had factor V Leiden, 261 prothrombin G20210A, 2399 tested negative. Sixty-two percent of VTE episodes in women were associated with an acquired risk factor, 40% in men. Among women with factor V Leiden or prothrombin G20210A, contraceptive use and pregnancy accounted for 63% and 67% of such risk factors. Patients with factor V Leiden presented with pulmonary embolism less often (31% vs. 51% or 45%, respectively), and only had Sat O2 levels <90% less frequently (4.5% vs. 17% and 20%, respectively). There were no differences between subgroups in the incidence of recurrent VTE, either during or after discontinuation of anticoagulant therapy. *Conclusions.* Most episodes of VTE in women (not men) with factor V Leiden or prothrombin G20210A were associated with an acquired risk factor (mostly preg-

nancy or contraceptive use). Only a minority of patients with factor V Leiden presenting with acute PE had hypoxaemia.

0159

ROLE OF PROCOAGULANT MICROPARTICLES IN ARTERIAL ATHEROTROMBOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M Tassies, P Patricio, G Espinosa, M Plasin, J Monteagudo, R Cervera, J Reverter

Hospital Clinic, Barcelona, Spain

Background. Microparticles (MPs) are a key component in the haemostatic response. *Aim.* To analyze the procoagulant activity of MPs and its correlation with arterial thrombosis and preclinical atherosclerosis in patients with systemic lupus erythematosus (SLE). *Methods.* We included 100 patients with SLE (27 with associated APS, 36 with antiphospholipid antibodies -aPL- but without APS and 37 without aPL). Early atherosclerosis was evaluated by ultrasonographic study of carotids measuring intima-media wall thickness and presence of arteriosclerotic plaque. Procoagulant MPs were assessed by a functional assay in which MPs were captured through annexin V and then thrombin was formed by the addition of activated factor X, activated factor V and prothrombin (Hyphen BioMed, Neuville, France). *Results.* A total of 16 episodes of arterial thrombosis in 8 patients with APS, 7 without aPL and 1 patient with aPL have been registered. SLE patients with associated APS had greater prevalence of plaque than patients without aPL or with aPL but without APS (51.9% vs 24.3% vs 22.2%). No differences were seen in procoagulant MPs according the gender or the age of the patients. Overall, there was a significant relationship between procoagulant MPs and the presence of carotid plaque (16.7±8.6 nM vs 12.7 ±7.3 nM; P=0.02) and the number of carotid plaques (14.5±4.0 nM in patients with one plaque and 17.3±10.3 nM in patients with 2 or more plaques; P=0.02). In addition, a relationship between arterial thrombotic events and the procoagulant activity (18.7±9.5 nM with events vs 13.0±7.2 nM without events, P=0.007). *Conclusions.* Procoagulant MPs may be implicated in arterial thrombosis and atherosclerosis in SLE patients.

Partially founded by Spanish grant FIS 05/0204

THROMBOSIS IN RELATION TO VON WILLEBRAND FACTOR, VWF PROPEPTIDE AND ADAMTS13 PROTEASE LEVELS IN PHILADELPHIA CHROMOSOME NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

D Adamidou,[1] E Rouka,[1] M Palasopoulou,[2] N Giannakoulas,[2] D Bartzoudis,[1] E Bouronikou,[2] G Vassilopoulos,[2] P Matsouka,[2] D Kyriakou[1]

[1]Blood Donation Center-University Hospital of Larisa, Larisa, Greece; [2]Haematology Clinic-University Hospital of Larisa, Larisa, Greece

Background. Thrombohemorrhagic events are the main cause of mortality and morbidity in Philadelphia chromosome negative myeloproliferative disorders (MPNs). Hyper viscosity and activated endothelium due to interaction of the elevated cellular components together with the comorbitities arising from patients older age compose a thrombophilic environment. The JAK2V617F mutation further contributes to this hypercoagulable state as it is related to high white cell count and platelets adhesion and activation. Von Willebrand factor (vWF) which is cleaved by ADAMTS13 protease plays central role in hemostasis while ppvWF is a good indicator of vWF synthesis. *Aim.* We measured vWF and ppvWF levels and ratio (ppvWF/vWF) as well as ADAMTS13 activity in MPNs steady state patients (no event for at least 6 months prior to evaluation).We evaluated their fluctuation in terms of thrombosis manifestation and identified risk factors for thrombotic events. *Methods.* A total of 37 patients, 18 males/19 females, with median age 53(20-81) and median follow up period 76 m (3-140) were evaluated. Eleven were diagnosed with polycythemia vera, 22 with essential thrombocytosis and 4 with primary myelofibrosis. Control group consisted of 92 healthy blood donors after written agreement. All clinical and laboratory data were concurrently recorded. ADAMTS13 activity was measured by fluorescent technique (FRETS), vWF and ppvWF antigen levels by ELISA (U/dl).We used Real Time PCR to assess JAK2V617F mutation status. All patients were screened for VLeiden and Pr20210 mutations by PCR- based techniques. *Results.*We found lower ADAMTS activity in patients plasma compared to control group (99.4% and 125% respectively, P<0.001). Inverse correlation was noticed between ADAMTS and vWFAg (P<0.05) in patients while the latest was strongly correlated with ppvWF levels (P<0.001).).Thrombotic events occurred in 11/37 patients (7 CNS/2 DVT/1 BuddChiari). JAK2V617F was carried by 22/37 and only 1 was heterozygous for VLeiden. Acquired Von Willebrand Syndrome was not noticed. Higher levels of vWF were measured in patients with thrombotic history compared both to healthy group (P<0.003) and patients without thrombosis (mean vWFAg 133.82 and 77 U/dl respectively).In multivariate analysis, JAK2V617F mutation (P<0.036), vWFAg steady state levels (P<0.030) and ratio (ppvWF/vWF) (0.044) were independent factors related to thrombosis. *Summary*. In our study group vWFAg steady state levels strongly correlated with thrombosis. The (ppvWF/vWF) ratio differentiated in terms of thrombotic history, suggesting that in MPN patients with thrombosis both synthesis and clearance of mature vWF were equally affected while in patients not suffering of thrombosis increased vWF clearance may balance hypercoagulable diathesis. We found lower ADAMTS13 activity, yet not abnormal in MPNs patients. In agreement with current literature JAK2V617F was found independent risk factor related to thombosis. There is need for prospective follow up of the measurements done in order to establish their prognostic value in steady-state Philadelphia Chromosome Negative Myeloproliferative Neoplasms.

0161

LEVELS OF CIRCULATING MICROPARTICLES IN PATIENTS WITH GYNAECOLOGICAL MALIGNANCY - A CASE-CONTROL STUDY

S Zahra, J Anderson, D Stirling, C Ludlam

Royal Infirmary of Edinburgh, Edinburgh, UK

Background. Microparticles (MPs) are important biological effectors, considered to be responsible for several patho-physiological processes. They carry surface antigens and proteins that allow inter-cellular signalling, and they are thought to have an important role in prothrombotic conditions, being able to support and also initiate thrombosis through their surface expression of negatively charged phospholipids +/- tissue factor respectively. It is well known that cancer patients are at an increased risk of venous thromboembolism (VTE), approximately 4 to 5 times more than the general population, and patients with cancer who suffer a VTE have a worse prognosis from a malignancy point of view. Being able to accurately predict the risk of VTE would allow patients at a high risk of VTE to be treated with primary thromboprophylaxis, potentially improving their malignancy-related prognosis. The level of circulating MPs, especially platelet derived MPs, has been reported to be elevated in several prothrombotic disorders, including malignancy. *Aims.* To compare the level of circulating MPs in patients with gynaecological malignancy with the level of MPs in a control group of patients with benign gynaecological conditions. We also wanted to establish if the level of MPs was predictive of the incidence of VTE. *Methods.* We recruited 64 patients with gynaecological malignancy and 45 control patients with benign gynaecological conditions. Written informed consent was obtained from all patients prior to taking blood samples. The MPs were isolated using flow cytometry. The MPs and their cell of origin were positively identified by gating on size (<1µm) and positivity for cell specific antigens (CD41 - platelet MPs (PMPs), CD144 - endothelial MPs (EMPs), CD45 - leucocyte MPs (LMPs). We also measured the total number of tissue factor (TF) (CD142) positive MPs. All the MP analysis was done on fresh plasma samples, within 2 hours of collection. *Results.* The median level of circulating PMPs, EMPs, LMPs and TF+ve MPs was similar in the patient and control group with no statistically significant difference: PMPs 1407(161-24014)/µL vs 1164 (58-16,111)/µL [P=0.22], EMPs 636(104-5177)/µL vs 506(109-8362)/µL [P=0.51], LMPs 1513(137-12,335)/µL vs 1308(210-11,702)/µL [P=0.81], TF+ve MPs 814(88-5506)/µL vs 909(121-3518)/µL [P=0.68]. Only 5 (7.8%) of the patients with gynaecological malignancy were diagnosed with a VTE event (none of the control group suffered a VTE event); again there was no statistically significant difference between the malignant patients with VTE and the malignant patients without VTE (P=0.13 for PMPs) however the number of patients diagnosed with a VTE is too small to draw firm conclusions. *Summary*. In conclusion the circulating MP level was similar in patients with gynaecological malignancy and in women with benign gynaecological conditions. Larger numbers of patients with both gynaecological malignancy and VTE are needed to establish any correlation between the level of MPs and the risk of VTE.

0162

ORAL ANTICOAGULANT THERAPY (OAT) IN PATIENTS WITH FONTAN SURGERY

M Infante,[1] F Carretero Lopez,[2] J Sanchez Ramirez,[1] AM Rodriguez Huerta,[1] G Perez Rus,[1] J Diez Martin,[2] C Pascual Izquierdo[1]

[1]Hospital universitario Gregorio Marañon, Madrid, Spain; [2]Gregorio Marañon, Madrid, Spain

Thrombotic events have been reported as a major cause of morbidity after the Fontan procedure. There is no consensus about the type and duration of postoperative anticoagulation prophylaxis, due to the high risk of bleeding complications, the difficulties in monitoring and the questionable therapeutic compliance in children. In spite of the lack of long term prospective studies in this situation, the ACCP has recommended in their guidelines OAT following Fontan or Glenn operation for at least 6 months. This has also been our practice in our institution during the period of study. *Aim of the study.* To analyze the efficacy and complications of OAT in our pediatric patients after undergoing the Fontan operation. *Methods.* Retrospective chart review of all the children treated with OAT in our institution between 1995 and 2009. All patients were treated initially with acenocumarol 0,2 mg/kg, except the Fontan patients, who received 0,1 mg/kg. Target INR was 2-3 for all patients, except for prosthetic valve recipients, in which target INR was 2,5-3,5.The Mann-Whitney test was used to compare the rate of complications, and the percentage of visits out of target INR between the Fontan patients and the rest of the cohort. *Results.* There were 68 children (29 female/ 39 males) aged between 1 month and 17 years, who received OAT with a range of follow up between 4 months and 14 years: 27 after Fontan operation (Group A), an 39 for other reasons (Group B: n=6 prosthetic heart valves, n=12 non prothetic valve cardiopathy, n=21 treatment of thromboembolic disease.The average follow-up was similar in both groups (median of 6.5 months in group A vs.7.5 months in group B). There were few complications: 1 mild epistaxis and 1 thrombotic event in group B, and none in group A. There were no differences in the proportion of controls outside the target range between both groups; there was a moderate proportion of controls outside the target range of INR, with equal distribution above and below the range. The median dose used to achieve the target INR was 0.3 mg/kg/d in Group A and 0.4 mg/kg/d in Group B. *Conclusions.*Oral Anticoagulant therapy is safe and effective in pediatric patients, with very low rates of thrombotic or hemorragic complications including those undergoing the Fontan surgery.

0163

LOW DOSE ASPIRIN AND ENOXAPARIN IN ANTIPHOSPHOLIPID SYNDROME (APS) ASSOCIATED WITH RECURRENT PREGNANCY LOSS (RPL)

L Noble,[1] J Herrada,[1] W Kutteh[2]

[1]Texas Tech University, El Paso Texas, USA; [2]University of Tennessee, Memphis, Tennessee, USA

Background. Pregnant women with APS associated with RPL treated with unfractionated heparin (UFH) and low dose aspirin (ASA) resulted in an 80% viable infant delivery (Am J Obstet Gynecol 1996:174:1584-9). *Aims.* To evaluate the efficacy and side effects of treatment with low molecular-weight heparin (enoxaparin) combined with low dose ASA in patients with positive antiphospholipid antibodies and RPL. *Methods.* Prospective, single-institution observational study. 31 patients (pts) were enrolled. Mean chronological age was 33.4 years. All pts had 2 or more first trimester losses and had a complete evaluation for RPL including anatomical, hormonal, infectious, chromosomal, and immunological. A standard ELISA was employed to detect the presence of IgG, IgM, and IgA serum antibodies against the phospholipids cardiolipin, inositol, serine, and ethanolamine. All pts received ASA 81 mg orally and enoxaparin 40 mg subcutaneously daily as soon as the serum pregnancy test became positive. Pts were monitored at close intervals. *Results.* Obstetrical outcome: Preterm 1 (3%); Term 26 (84%); Abortion 4 (13%). Bleeding episodes: Major 0; Minor (epistaxis) 3 (10%). Mode of delivery (n=27): Cesarean section (C/S) 12 (45%); Vaginal 15 (55%).Average blood loss at delivery: C/S 975 cc; Vaginal 550 cc. Epidural Hematomas: 0. Deep Venous Thrombosis: 0. Maternal Thrombocytopenia: 0. *Conclusions.* The use of low dose ASA combined with enoxaparin during pregnancy for the prevention of RPL in women with APS appears to be safe. When compared with historical controls it seems to be at least as effective as UFH and low dose ASA.

0164

THE IMPACT OF ANEMIA, C-REACTIVE PROTEIN AND MEAN PLATELET VOLUME ON THIRTY-DAY MORTALITY IN PATIENTS WITH ACUTE ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION TREATED WITH PRIMARY ANGIOPLASTY

M Vrsalovic,[1] M Marusic Vrsalovic,[2] B Getaldic,[3] N Vrkic[3]

[1]Sestre Milosrdnice University Hospital, Zagreb, Croatia; [2]Clinical Institute of Laboratory Diagnostics, Dubrava University Hospital, Zagreb, Croatia; [3]Clinical Institute of Chemistry, Sestre Milosrdnice University Hospital, Zagreb, Croatia

Background. Anemia, C-reactive protein and mean platelet volume (an indicator of platelet activation) are independent predictors of adverse outcome in patients with acute myocardial infarction. *Aims.* Due to their interrelated pathophysiology, the purpose of the study was to examine them together in the clinical setting. *Methods.* The study included 543 patients (pts) with first ST-segment elevation myocardial infarction (STEMI), admitted to the University hospital from January 2001 to December 2007. In all the pts angioplasty of the culprit lesion was performed (only pts with <12 h after the onset of symptoms were included and pts with malignant or inflammatory disease were excluded from the study). Whole group characteristics: 62% man, mean age 65 years, diabetes in 27%, hypertension in 64%, current smoking in 35%, hyperlipidemia in 34%, infarct related artery: left anterior descending artery in 43%, left circumflex artery in 14%, right coronary artery in 43%, Killip class >1 in 14%, multivessel disease in 54%, TIMI flow: >1 pre PCI in 22%, >1 post PCI in 96%. Hematocrit (Hct), C-reactive protein (CRP) and mean platelet volume (MPV) were obtained at the time of admission and samples were processed within 1 h of venepuncture. The primary end point was all-cause mortality within 30 days after admission. *Results.* 41 pts (7.5%) died during the 30-day follow-up. Nonsurvivors (NS) were older, more frequently females and were more likely to have diabetes (P<0.01). Less smokers and pts with dyslipidemia were in NS group (P<0.01). Congestive heart failure, anterior location of the myocardial infarction and multivessel disease were more prevalent in NS group, as well as worse baseline and final TIMI flow (P<0.01), while time to treatment was comparable in both groups. CRP (24.7 mg/L vs 12.6 mg/L, P<0.001) and MPV (8.92 fL vs 8.54 fL, P=0.001) were higher, while Hct (38.8% vs 41%, P<0.001) was lower in NS. Platelet count did not differ between the groups (P=0.55). In the univariable analyses anemia (Hct <39% for men and <36% for women), elevated CRP (>6.7 mg/L) and MPV (>8.5 fL) (cutoff points of CRP and MPV were calculated with ROC analysis) were significantly associated with the primary outcome (P<0.01). After multivariable adjustment for gender, age, cardiovascular risk factors, Killip class>1, TIMI flow, multivessel disease, anterior infarction and the remaining two of the examined laboratory parameters, the odds ratios in prediction of 30-day mortality were: 3.67 (P=0.005), 2.94 (P=0.03) and 1.35 (P=0.40), for anemia, elevated CRP and MPV respectively. *Conclusions.* Anemia and CRP, but not MPV, are independently related to short term mortality in pts with STEMI treated with primary percutaneous coronary intervention.

THE MAGELLAN STUDY METHODOLOGY: RIVAROXABAN COMPARED WITH ENOXAPARIN FOR THE PREVENTION OF VENOUS THROMBOEMBOLISM IN HOSPITALIZED MEDICALLY ILL PATIENTS

T Cohen,[1] T Spiro,[2] H Büller,[3] W Byra,[4] D Hu,[5] R Hull,[6] A Mebazza,[7] G Merli,[8] S Schellong,[9] A Spyropoulos,[10] V Tapson[11]

[1]King's College Hospital, London, UK; [2]Bayer Healthcare Pharmaceuticals Inc., Montville, New Jersey, USA, [3]Academic Medical Centre, Amsterdam, Netherlands; [4]Johnson and Johnson Pharmaceutical Research and Development LLC, Raritan, USA; [5]People's Hospital of Peking University, Beijing, China; [6]Foothills Hospital, Calgary, Canada; [7]Lariboisière University Hospital, Paris, France; [8]Thomas Jefferson Medical Center, Philadelphia, USA; [9]Dresden-Friedrichstadt Hospital, Dresden, Germany; [10]Henderson Research Center, Hamilton, Canada; [11]Duke University Medical Center, Durham, USA On behalf of: The MAGELLAN Investigators

Background. Results of recently completed trials comparing low molecular weight heparins (LMWH) or pentasacharride with placebo controls in medically ill patients have provided convincing evidence for venous thromboembolism (VTE) prevention. The efficacy and safety of VTE prevention with oral rivaroxaban 10 mg od for 35 days has been demonstrated in elective hip replacement patients. *Aims.* To compare treatment with oral rivaroxaban once daily for up to 39 days to short-

er term treatment with subcutaneous enoxaparin 40 mg once daily for up to 14 days and to compare short term rivaroxaban with short term enoxaparin both administered for up to 14 days for VTE prevention and safety in hospitalized medically ill patients. *Methods.* Study design: A multinational, multicenter, randomized, double-blind, double-dummy, active comparator controlled study in patients with current and likely ongoing reduced mobility. All enrolled patients receive study medication, undergo mandatory bilateral lower limb venous ultrasonography on Day 10±4 and on Day 35±4, and are followed for an additional 60 days. Symptomatic VTE is investigated at anytime. Inclusion criteria: Age ≥40 hospitalized with: heart failure, active cancer; or acute ischemic stroke with leg paresis. Or acute infection, acute inflammatory or rheumatic disorders or acute respiratory insufficiency, immobilized, and with at least one risk factor e.g: age >75 years, previous venous thromboembolism, previous cancer or heart failure, severe venous disease, thrombophilia, recent major surgery or serious trauma, hormone replacement therapy, morbid obesity (body mass index ≥35 kg/m^2). Exclusion criteria: Include an increased risk of bleeding; prohibited drugs or procedures: e.g anticoagulant therapy; concomitant conditions or diseases such as: allergies, severe renal or liver disease. Outcomes: The primary efficacy outcome is the composite of asymptomatic proximal DVT detected by mandatory compression ultrasonography, symptomatic proximal and distal DVT, symptomatic PE and fatal VTE reported during the treatment phase of the study: The primary safety outcome is the composite of major bleeding events and non-major clinically relevant bleeding events. All subjects have rivaroxaban levels measured at various time points. In selected centers, a full PK/PD profile is performed. Pharmacogenetics and health economic outcomes are also being assessed. Statistical *Methods.* Primary efficacy analysis: There are two efficacy analysis populations, pertaining to the two primary efficacy endpoints. The study is powered at the 90% level to show non-inferiority at Day 10±4 days and superiority at Day 35±4 days. ~8000 patients will be randomized from ~530 sites in 52 countries. The first patient was enrolled in December 2007. *Results.* Current status: 01 March 2010, ~7300 subjects have been enrolled into the study from ~530 actively recruiting centers in 52 countries. Mean age is ~70 years, ~46% are female, ~34% have heart failure, ~9% have active cancer. ~15% have acute ischemic stroke, ~37% have acute infectious and inflammatory diseases including acute rheumatic diseases and ~22% have acute respiratory insufficiency. *Summary/Conclusions.* The MAGELLAN study will determine the efficacy and safety of an extended duration of treatment with rivaroxaban compared to current standard of care.

0166

TREATMENT OF DEEP VEIN THROMBOSIS WITH CONTINUOUS IV INFUSION OF LMWH IN CHILDREN IN THE YEARS 2003 - JUNE 2009

V Fiamoli, J Blatny

Children´s University Hospital Brno, Brno, Czech Republic

Backround. Incidence of the thrombosis is age dependent with the lowest risk in the childhood. Children mostly suffer from vein thrombosis. Occurrence of thrombosis in children is 0,07/10 000, but it is higher among hospitalized children (3,5/10 000). Low molecular weight heparin (LMWH) is preferred treatment of deep vein thrombosis (DVT) in children. The most frequent way of application of LMWH is via subcutaneous injection. The treatment with continuous iv infusion might be advantageous (no pain, probably lower risk of bleeding related to shorter half-life) especially in patient with permanent i.v. access. This approach was adopted from the treatment with unfractionated heparin. *Aims.* To prove efficacy and safety of the treatment of deep vein thrombosis with LMWH by continuous intravenous infusion in children in the pilot project. *Methods*. In this pilot retrospective study we present group of 32 children with DVT, who were treated with continuous infusion of LMWH for their first thrombosis from 2003 till June 2009. Our current data are an update of those presented on ASH 2006. There were 18 (56%) boys and 14 (44%) girls. Duration of the treatment with LMWH was modified in accordance with the course of thrombosis (monitored by Doppler ultrasound with compression). The median duration of the treatment was 13,5 days (ranging from 5 to 44 days). The dose of LMWH was adjusted according to antiXa levels. Required therapeutic range was 0,5-1 IU/mL. The median dose of LMWH was 240IU/kg/24h, with minimal dose 200 IU/kg/24h and maximal dose 330 IU/kg/24h. *Results.* The treatment with continuous infusion led to total recanalisation of the vein in 11 cases (34.4%), partial recanalisation was achieved in 16 (50%) patients. Only five (15.4%) patients were without any recanalisation. We have not noticed any bleeding as adverse event of the treatment in any of our patients. *Conclusion.* We would like to point out that the treatment of DVT with continuous infusion of LMWH in children might be efficient and safe alternative to SC application under certain circumstances especially in children with indwelling central venous lines or who are endangered by the risk of bleeding complications for example in children with thrombocytopenia. By means if this treatment we can avoid repeated painful subcutaneous injections and thus increased child's quality of life.

0167

COAGULATION AND FIBRINOLYSIS STATUS IN PATIENTS WITH MULTIPLE SCLEROSIS

C Kanonidou, S Arampatzi, E Kanonidou, S Prodromidou, K Thisiadou, K Chalvatzi, S Spiroglou, D Lazaridou, A Nikolaidou, E Diza

Ahepa University Hospital, Thessaloniki, Greece

Backround. Multiple sclerosis (MS) is an inflammatory demyelinating disease of the central nervous system (CNS) of unknown etiology and is the most common neurologic entity in young adults. In general, the inhibition of the plasminogen activator system and the subsequent accumulation of fibrin have been associated with axonal damage in multiple sclerosis lesions.In an animal model of multiple sclerosis (experimental autoimmune encephalomyelitis), abnormalities in fibrinolytic state and fibrin deposition have been reported around CNS blood vessels. *Aims.* The objective of this study was to evaluate the levels of blood coagulation and fibrinolysis components of the hemostasis system in patients with multiple sclerosis. *Methods.* A total of 47 (36 females and 11 males, mean age 36.7±8.3 years) patients suffered from various clinical forms and at various stages of MS were enrolled to the study. Patients with co-existing liver, renal, hematological or other autoimmune diseases and those under anticoagulant treatment were excluded. Twenty (14 females and 6 males, mean age 42.4±6.7 years) healthy adults consisted the control group. Coagulation and fibrinolysis parameters were measured in plasma samples using an automated analyser (ACL Top, ALAPIS). Results were statistically analysed using Student's t test. *Results.* The laboratory parameters examined are shown in Table 1. D-dimer levels were significantly higher (P=0.04) in MS patients when compared to the control group. In female patients D-dimer levels were observed to be higher (249.78±121.29), but not significantly (P=0.34) in comparison to those of the male MS group (224.83±129.32). FVIII values were also significantly higher (P=0.007) in MS patients. FXII was also increased but not significantly important compared to the control group. Plasma PT, aPTT, fibrinogen, protein C, antithrombin-III and protein S activity, activated protein C resistance, lupus anticoagulant, coagulation factors V, VII, XI, plasminogen and α2-antiplasmin levels were not different between the two groups. *Summary/Conclusions.* The study shows a significant increase in FVIII levels and D-Dimer in patients with MS. The coagulation and fibrinolytic alterations should be further investigated and correlated with MS clinical forms, progression and treatment of the disease in order to achieve a better understanding of the role of the hemostasis system in the pathogenesis of MS.

Table 1. Coagulation and fibrinolysis parameters in patients with MS

Coagulation parameters	MS patients	Control patients	*p*-value
PT (sec)	11,13±0,82	11,19±0,60	0,76
INR	0,92±0,06	0,92±0,04	0,95
aPTT (sec)	27,94±4,06	29,45±2,67	0,14
Fibrinogen (mg/dl)	341,75±62,73	344,47±44,73	0,86
Protein C (%)	125,69±25,62	113,12±16,24	0,07
ATII (%)	110,9±16,35	103,26±15,82	0,09
Protein S (%)	94,24±14,70	100,47±18,20	0,19
APC-r Ratio	2,56±0,40	2,70±0,38	0,23
LA Ratio	1,06±0,11	1,06±0,06	0,84
FVIII (%)	162±67,13	112,88±29,40	0,007*
FXI (%)	156,95±49,18	138,71±38,13	0,38
FV (%)	115,53±30,33	115,67±25,48	0,99
FXII (%)	111,40±21,24	113,00±26,55	0,84
FVII (%)	100,05±23,46	103,13±19,30	0,74
Fibrinolysis parameters	**MS patients**	**Control patients**	***p*-value**
D-Dimer (ng/dl)	240,94±115,09	174,81±89,10	0,04*
Plasminogen (%)	103,00±17,00	99,50±8,83	0,62
α2-antiplasmin (%)	103,55±20,75	104,81±11,90	0,82

INCIDENCE OF VENOUS THROMBOEMBOLISM IN PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA: A RETROSPECTIVE ANALYSIS OF 42 PATIENTS

D Lekovic, P Miljic, M Mitrovic, M Gotic, B Mihaljevic

Institute of Hematology, Clinical Center Serbia, Belgrade, Serbia

Background. Primary mediastinal large B-cell lymphoma (PMBCL) is a rare subtype of diffuse large B-cell lymphoma, arising in a mediastinum. Compression of large mediastinal vessels is common in patients with PMBCL, predisposing these patients to venous thrombosis. The incidence of this complication is still unknown. *Aim.* The aim of our retrospective study was to analyze the incidence and risk factors for venous thromboembolic disease (VTE) and its correlation with clinical and laboratory variables, as well as with survival in patients with PMBCL. *Patients and Methods.* We analysed 42 PMBCL pts who were treated at The Clinical Center of Serbia between June 1999 and November 2009. Evidence of VTE, the time to thrombotic event and risk factors to these trombotic events were sought. We compared age, gender, risk factors, laboratory variables (Hb, Le, Tr), hemostasis parameters (fibrinogen, PV, PTT, D-dimer), diameter of mediastinal tumor mass, incidence of syndrome venae cava superior (SVCS) and survival between two groups of PMBCL patients: patients with VTE (VTE group) and those without VTE (NVTE group). All patients with VTE received low molecular weight heparin (LMWH). The median follow up was 59 months. *Results.* In the VTE group there were 15/42 pts (36%) while 14 pts had deep venous thrombosis and 1 had pulmonary emboli. Mean age in VTE group was 38±15 (M/F=5/10) while in NVTE was 32±10 (M/F=8/19). Ten patients (24%) had a thrombosis at the moment of diagnosis PMBCL, while in five (12%) thrombosis occurred during the course of the disease. The majority of patients had the thrombosis of v. subclaviae and v. jugularis internae (10 pts), while 1 pts had thrombosis of v. cavae superior, 1 v. femoralis and 1 v. axillaris. The majority of patients in the VTE group had a risk factor which were distributed as follows: 9 pts (60%) were smokers (F/M=46%/54%); 2 (5%) had a history of surgery within the last 3 months; 3 (7%) had a pregnancy; 1 (2%) was taking the oral contraceptive pill; 1 (2%) had the previous history of VTE; 1 (2%) had the AFS and 1 (2%) was heterozygote for mutation FII 20210A. Leukocytes and platelets at diagnosis were not statistically different between patients in the VTE and the NVTE group. According to hemostasis variables, patients in the VTE group had significantly higher fibrinogen (P=0.02) and D-dimer (P=0.001). Also, patients in the VTE group had significantly larger diameter of mediastinal tumor mass (P=0.01) and the incidence of SVCS (P=0.009). The 4-yrs overall survival for the VTE group and NVTE group were 51% and 68,5% respectively (log rank P=0.058). *Conclusions.* Venous thromboembolism is a common complication in PMBCL patients, especially in those with large (bulky) mediastinal tumor mass. VTE could be the initial manifestation of PMBCL and according to our results negatively influences survival in PMBCL patients.

Clinical bleeding

HYPERFIBRINOLYSIS DURING LIVER TRANSPLANTATION: CAN POINT-OF-CARE THROMBOELASTOGRAPHY REPLACE PROPHYLAXIS? COMPARING ANTIFIBRINOLYSIS AND VOLUME OF BLOOD PRODUCTS TRANSFUSED - ONE CENTER'S EXPERIENCE

I Pereira, G Marques, C Bento, J Ferrão

Coimbra University Hospitals, Coimbra, Portugal

Background. Bleeding during liver transplantation (LT) can be due to the primary disease, peri-operatory complications, and hyperfibrinolysis (HF), and can be controlled with blood products (BP) - packed red blood cells (PRBC), platelet concentrate (PC) and fresh frozen plasma (FFP). Prophylaxis with aprotinin minimized bleeding due to HF until its approval was discontinued. Point-of-care rotational-thromboelastography (ROTEG) evaluates platelet function, coagulation and fibrinolysis, identifying bleeding due to HF, which can be specifically treated with antifibrinolytics. *Aim.* To compare the use of antifibrinolytics and BP during LT when prophylaxis was used, and after point-of-care ROTEG was introduced, to evaluate whether ROTEG-directed treatment offers equal results to prophylaxis. *Methods.* We reviewed 293 LT performed in our Hospital from January 2004 to December 2009. We excluded 64 pediatric transplants, 8 cases with incomplete charts, and 86 transplants for familial amyloid polyneuropathy (never subjected to prophylaxis in our center). *Results.* Patients who underwent Prophylaxis used 10.04±10.75 units of PBRC, compared to 25.20±16.87 for those without prophylaxis who were Treated for HF (P<0.001) and 11.07±16.88 for those without prophylaxis who were Untreated (P=NS). Use of FFP was 10.97±14.83 units in the Prophylaxis patients, 41.94±22.34 in the Treated (P<0.001) and 18.55±20.76 in the Untreated (P=NS). Use of PC was 7.88±7.93 units in the Prophylaxis patients, 15.35±9.37 in the Treated (P=0.006) and 5.60±8.11 (P=NS) in the Untreated. Of the patients who underwent point-of-care ROTEG, those who had HF and were treated (HF-Treated) used 27.57±17.57 units of PRBC, while those who were not (HF-Untreated) consumed 15.17±21.11 (P=NS); the use of FFP was 45.57±23.04 units in the HF-Treated patients and 24.83±26.96 in the HF-Untreated (P=0.049); the use of PC was 16.92±9.32 units in the HF-Treated patients and 6.75±8.01 in the HF-Untreated (P=0.006). In the HF-Treated group, the volume of PRBC administered before treatment was started was 21.64±16.87 units, of FFP was 34.64±21.69, and of PC was 8.71±5.40. Compared to patients undergoing prophylaxis, consumptions in those with ROTEG-confirmed spontaneous absence of HF were 8.78±13.06 units of PRBC (P=NS), 16.93±17.55 of FFP (P=NS) and 4.04±6.73 of PC (P=0.021). *Discussion and Conclusions.* We found that patients who underwent prophylaxis consumed BP on par with those who spontaneously never developed HF, while the use of BP was significantly higher in patients without prophylaxis, treated with antifibrinolytics. Considering patients without prophylaxis with ROTEG-confirmed HF, we identified two subsets - one with lower consumption of BP, not specifically treated for HF, and one with a high consumption of BP, treated for HF (after extensive transfusion). These results, coupled with the fact that antifibrinolysis in HF should not worsen bleeding, suggest that the patients who were treated were the ones who were showing uncontrolled hemorrhage. Treatment with antifibrinolytics after extensive bleeding has started is unsatisfactory, and offers worse results in terms of BP use than were obtained with prophylaxis with aprotinin. Point-of-care ROTEG could improve on the present results if antifibrinolysis is instituted as soon as ROTEG-evidence of HF is found, and not only after bleeding has started.

0170

TREATMENT OF ACENOCUMAROL-ASSOCIATED COAGULOPATHY WITH ORAL VITAMIN K

M Briz, MJ Muruzabal

Hospital Sierrallana, Torrelavega, Spain

Background. Optimal treatment for acenocumarol anticoagulated patients with a high INR is not well established as most studies have included warfarin treated patients. The few studies including acenocumarol over-anticoagulated patients come to the conclusion that vitamin K is not necessary and can be dangerous as most patients become under-anticoagulated. However the use of oral vitamin K in

these patients has become routine clinical practice in many acenocumarol clinics and hospitals. *Aims.* To determine the percentage of patients over-anticoagulated with acenocumarol achieving their therapeutic INR range the following day after administration of oral vitamin K individualised according to initial INR. To determine the impact of patient age, gender, weight, height, body surface area, acenocumarol daily dose, target INR and CYP2C9 and VKORC1 polymorphism on the rate of INR reversal. *Methods.* Patients on acenocumarol treatment with INR >5 asymptomatic o with mild bleeding were included. The day's dose of acenocumarol was omitted and oral vitamin K1 (phytomenadione) was administered according to the following diagram: none for INR <6, 1 mg for INR 6-9.9, 2 mg for INR 10-14.9, 3 mg for INR 15-19.9 and 4 mg for INR ≥20. INR was again determined the following day (day +1). Written informed consent was obtained. *Results.* Three hundred events (135M/165F) were included in the study. Total number of patients was 248, with 45 of them having more than one episode requiring vitamin K. Median age was 79 years (range 19-98). Initial INR ranged from 5.1 to 22.1 (median 6.1). In 157 events only omission of acenocumarol was required, while 143 events required vitamin K in addition (1 mg in 115 events, 2 mg in 20 events, 3 mg in 6 events and 4 mg in 2 events). Median INR at 24 hours was 2.49 (range 1.1-10.7). Out of the 300 analysed events, INR at day +1 was in range in 140 (46.7%) and in 226 (75.3%) it was within a safe range of INR 1.8 to 4.0. Within the group needing vitamin K, 28% of patients had INR <1,8 at day +1. *Conclusions.* Acenocumarol withdrawal and vitamin K administration according to initial INR lowers INR to a safe range in most patients. However treatment of patients whose INR is <1.8 at day +1 needs improvement by lowering vitamin K dose and/or by identifying other responsible factors. The influence of clinical factors and CYP2C9 and VKORC1 polymorphisms on the extent of INR reversal will be retrospectively determined. Authors are grateful to the medical staff at the Haematology Section of Sierrallana Hospital and the Health Centres in the Primary Health Care areas in Torrelavega-Reinosa for their help.

Table.

INR AT DAY +1	TARGET RANGE	INR<1.8	INR 1.8-4.0	INR>4.0
ALL EVENTS (n=300)	140 (46.7%)	43 (14.3%)	226 (75.3%)	31 (10.3%)
No vitamin K (n=157)	82 (52.2%)	3 (1.9%)	135 (86%)	19 (12.1%)
With vitamin K (n=143)	58 (40.6%)	40 (28%)	91 (63.6%)	12 (8.4%)

CANCER-RELATED DISSEMINATED INTRAVASCULAR COAGULATION: FIRST LINE THERAPY WITH PLASMA-DERIVED PROTEIN C

S Siragusa, A Malato, L Lo Coco, G Saccullo, A Russo, V Abbadessa

University of Palermo, Palermo, Italy

Background. Cancer-related disseminated intravascular coagulation (DIC) is a rare but life-treating condition. Acute management is mainly based on administration of fresh-frozen plasma (FFP) and Antithrombin (AT) with the aim of restoring coagulation factors deficiency. The Protein C (PC) pathway is a modulator of the coagulation as well as the inflammatory system; PC deficiency leads to increased activation of the coagulation system, resulting in thrombin generation. Some clinical trials have demonstrated the efficacy of administering activated recombinant (a-r) PC in adult patients with sepsis-related coagulopathy, but increasing the risk of major bleeding. Plasma-derived PC has a self-limiting process in determining anticoagulation thus it seems more suitable than a-rPC in patients at high risk for bleeding, such as cancer patients. *Aims.* To describe the efficacy and safety of PC concentrate to restore physiological values in adult cancer patients with overt DIC. Study Design. Not controlled clinical trial (NCCT). Materials and *Methods.* Adult cancer patients affected by DIC, having PC plasma concentration less than 50%, were treated with PC concentrate (Ceprotin®, Baxter) as an adjusted bolus of 30 to 50 UI/Kg/die to restore normal PC values (70-120%). Clinical outcomes (bleeding, thrombosis and mortality) were recorded up to a follow-up of 28 days from the initial diagnosis of DIC. PC activity, WBC, platelets, D-dimer, fibrinogen, PT, aPTT, AT and DIC score were measured after 12, 24, 48, 7 and 10 days. *Results.* Twenty-two patients were included over a period of 3 years; among them 16 had solid cancer and 6 had haematological cancer. All patients had advanced/metastatic neoplasm. PC concentrate normalized PC activity in all patients within 48h and remained upper the lower normal value for the following days. Baseline PC levels were lower in non-survivors than in survivors although this difference was non-significant. During the study period, there was a significant increase of platelets, fibrinogen, PT, AT, and a significant decrease of D-dimer, aPTT and DIC score (Table 1). No bleeding or thrombosis were observed; mortality at 28 days was 35%. *Conclusions.* Our investigation shows that PC concentrate is safe and normalizes laboratory variables in cancer patients with overt DIC.

Table. Changes in laboratory findings obtained from all patients during the study period (mean±SD)

	Baseline	24 h	48 h	72 h	7th day	14th day
PC (%)	27.3 ± 7.1	71 ± 15.6*	85.9 ± 12.5*	91.2 ± 11.6*	92.2 ± 13.4*	99.1 ± 13.5*

ORTHOPEDIC SURGERIES IN SEVERE HEMOPHILIA PATIENTS ON A SHOE STRING BUDGET

F Jijina

Seth GS Medical college and KEM hospital, Mumbai, India

Background. Management of severe hemophilia patients, in resource poor developing countries remains a major challenge to the care givers. The problems are further compounded in patients requiring surgeries. Thus, even orthopedic surgeries in hemophilia patients require much more planning and effort than in non hemophilics. Several studies have shown that osteoporosis is a universal phenomenon in hemophiliacs' all over the world. The magnitude of this osteoporosis is much more in developing countries and hence the prevalence of complications and fractures of the long bones is also much higher. *Methods.* Over the last 10 years, our Comprehensive Hemophilia Care Center has carried out various orthopedic surgeries in 20 hemophilia patients with fractures and pseudotumors, age range from 8 - 45 years. Of these 6 had hemophilia B (5 severe, 1 moderate), 14 had hemophilia A (1 moderate, 13 severe) and 3 hemophilia A patients had inhibitors. The factor concentrates used for the surgeries were optimized, from our previous experience, along with generous use of anti fibrinolytic drugs, oral, parenteral and local. *Results.* The factor concentrates used in the 20 surgeries ranged from 5000-32,000 units, (mean 12039.47±21.09 units SEM). 2 of the patients with inhibitors received modest doses of FEIBA (3000 - 7000 units) and 1 received FEIBA and factor VIIa. All 3 patients also received parenteral anti fibrinolytic drugs. 2 patients developed inhibitors postoperatively and had significant bleeding, requiring blood transfusions. 1 patient without inhibitors had moderately severe bleed and wound infection, needing prolonged blood product and antibiotic support. Factor support was given only for 7 - 10 days in all patients; most of the patients received anti fibrinolytic drugs. All the patients were discharged with good functional activity, without any mortality or residual morbidity due to the surgery. *Summary/Conclusions.* The present study clearly shows that major orthopedic surgery in patients with severe hemophilia can be accomplished with 30-35% of the total amount of factor concentrates which is utilized in the developed countries, without compromising on the outcome. This has been possible by reducing the amount of factor, accepting a lower trough level, intra and post operative use of anti fibrinolytic drugs. The use of FEIBA works out too expensive in our inhibitor patients; thus by adding

adjuvant anti fibrinolytic drugs, we have been able to cut down the requirement of FEIBA from 75-100 units/kg/dose, to as little as 25 units/kg/dose without increasing the inherent thrombotic risk of this combination and still achieving good hemostasis. This has major implications for hemophilia care not only in developing countries but also in the developed countries where the health systems are strained due to the very high cost of lifelong hemophilia care.

0173

A FAVORABLE OUTCOME OF DISSEMINATED INTRAVASCULAR COAGULATION IN CHILDREN USING RECOMBINANT THROMBOMODULIN

H Yagasaki, M Kato, E Nishikawa, H Shichino, C Chin, H Mugishima

Nihon University, Tokyo, Japan

Background. Disseminated intravascular coagulation (DIC) is a serious complication that can occur during treatment of hematological malignancies and severe infection. Conventional treatment of DIC consists of heparin administration as well as platelet transfusion or fresh frozen plasma (FFP) supplementation. Recombinant thrombomodulin (rTM) has been developed as a new-type treatment that inhibits Factors Va and VIIIa by activating protein C. A phase III randomized study demonstrated the superiority of rTM to heparin; however, pediatric patients were not included in this study and no data for children with DIC is currently available. From July 2009, we therefore began treatment of 10 children with DIC using rTM.Aim To elucidate the efficacy and safety of rTM against DIC by retrospectively analyzing the outcome in 10 children with DIC (5 boys and 5 girls, age ranging from 1 day to 13 years old). *Methods*. Diagnosis of DIC was made according to the diagnostic criteria of the Japanese Ministry of Health and Welfare. rTM (130 U/kg/day for 2 newborns and 380 U/kg for the remaining 8 patients) was administered daily. No other anti-DIC agent except flesh frozen plasma and platelet transfusion was used concomitantly. *Results*. The causes of DIC were hematological disorders (n=6) and severe infection (n=4). A coagulation test at diagnosis showed the following abnormalities: median platelet count of 31×10^3/L, median prothrombin time (PT) ratio of 1.5 (normal: 0.9-1.1), median fibrin degradation products (FDP) level of 16.4 mg/L (normal: <4.0 mg/L), median D-dimer level of 11.4 mg/L (normal: <1 mg/L), median ATIII level of 84% (normal: 70-130), and median fibrinogen level of 3.54 g/L (normal: 1.5-4.0). rTM was used for a median of 5 days, ranging from 3 to 13 days. After 6 days of administration, laboratory data improved as follows (median): PT ratio, FDP, D-dimer, ATIII and fibrinogen levels were 1.28, 7.0 mg/L, 2.7 mg/L, 111% and 3.6 g/L, respectively. DIC was resolved at 3-5 days after administration of rTM in 7 patients. In contrast, the 2 newborns (diagnosed with Down's syndrome-associated transient myeloproliferative disorder and acute lymphoblastic leukemia with mixed lineage leukemia gene rearrangement, respectively) failed to recover from DIC. In both patients, pulmonary bleeding and intracranial bleeding occurred during or after rTM treatment, and they died of liver dysfunction and multiple organ failure at 19 and 21 days old, respectively. The remaining 8 patients were well at 2-7 months after the diagnosis of DIC. *Conclusion.* rTM was highly effective in 7 out of the 10 children with DIC examined, resolving the DIC within 5 days. However, the outcome in the 2 newborns examined was unfavorable. Both patients presented a persistently low level of fibrinogen due to severe liver failure despite daily supplementation of FFP. Our treatment with rTM, FFP and platelet transfusion was suboptimal for these 2 patients. A more effective treatment strategy to prevent life-threatening bleeding must therefore be explored in patients with hepatic dysfunction. Overall, however, the current results are encouraging for children with severe DIC. Nevertheless, since rTM has so far been licensed only in Japan, more clinical investigations and a prospective study are necessary to clarify the distinct effectiveness of this novel drug.

0174

PLATELET FUNCTION AND COAGULATION ABNORMALITIES IN TYPE 1 GAUCHER PATIENTS: EFFECTS OF ENZYME REPLACEMENT THERAPY

M Mitrovic,[1] N Suvajdzic Vukovic,[1] I Elezovic,[1] P Miljic,[1] Z Sumarac,[2] D Janic,[3] M Djordjevic,[4] M Petakov,[5] T Nikolic,[6] P Rodic,[3] I Djunic[1]

[1]Institute of Hematology, CCS, Beograd, Serbia; [2]Institute of Medical Biochemistry, CCS, Beograd, Serbia; [3]University Children Hospital, Beograd, Serbia; [4]Medical and Child Health Care InstituteDr Vukan Cupic, Beograd, Serbia; [5]Institute of Endocrinology, Diabetes and Metabolic Diseases, CCS, Beograd, Serbia; [6]Institute of Radiology, CCS, Beograd, Serbia

Background. Coagulation abnormalities and platelet disfunction were reported in Gaucher patients (GP) and might attribute to bleeding tendency. Data concerning the effects of enzyme replacement therapy (ERT) on coagulation abnormalities and platelet function are few and controversial. *Aim.* To investigate the impact of ERT (Cerezyme®) on bleeding tendency and haemostatic parameters of GP. *Methods.* 31 Serbian treatment-naive type 1 GP (M/F 17/14; median age 49 years, splenectomized 9/31) were studied. Complete blood count, protrombin time (PT), activated partial tromboplastin time (aPTT) and coagulation factors activities were measured according to standard *Methods.* Platelet aggregation (PA) was assessed by a whole-blood aggregometer with collagen 10 μmol/L (Col10) and 5 μmol/L (Col5), adenosine5-diphosphate 10 μmol/L (ADP10) and 5 μmol/L (ADP5), ristocetin (Ris) 1.25 mg/mL, epinephrine (EPI) 10 μmol/L and arachnoid acid (AA) 2 mmol/L (normal PA≥60% for all inducers). Spleen volumes (SV) were assessed by CT and declared in MN ratio (MN = measured volume/normal volume). 21/31 patients were treated with Cerezime®. Bleeding tendency and haemostatic parameters were assessed after 6, 12 and 24 months of ERT (ERT6,12,24). *Results.* Pretreatment: Bleeding episodes (2 severe) were registered in 10/31GP. Mean platelet count (PC) was 150×10^3/L (range: 46-428); 22/31 GP had PC<150×10^3/L. PT (median 61%, range 43-72) and aPTT (median 41.45s, range 35.20-56.70) values were abnormal in 16/31 and 13/31 GP, respectively. The most frequent clotting factor deficiency was of FV (9/31). PA abnormalities were registered in 19/31 GP; 6/19 GP had reduced response to ≥2 inducers. PA was reduced in response to EPI (7/19 GP, mean 0.57) and AA (7/19 GP, mean 0.58). Mean PA values were normal in response to ADP5, ADP10, Col5, Col10 and Ris but the abnormal PA was registered in 19/19, 4/19, 13/19, 6/19 and 3/19 GP, respectively. SV inversely correlated with PC and reduced response to Col5, AA and ADP5 (P<0.05) Bleeding GP had significantly lower PC, higher chitotriosidase level and greater SV comparing to the non bleeding (P<0.01). After ERT: N° of bleeding GP significantly decreased after ERT6 (1/10 GP; P<0.01) and desapeared at ERT24. PC significantly increased at ERT6 and remained in normal range till ERT24 (Plt6 240×10^3/L, Plt12 240×10^3/L, Plt24 295×10^3/L; P<0.01). At ERT24 5/21 GP were still trombocytopenic. PT increased significantly from ERT0 to ERT24 (PT0 75%, PT6 73%, PT12 77%, PT24 85%; P<0.01). vWF increased significantly at ERT6 and ERT24 (vWF0 65%, vWF6 68%, vWF12 65%, vWF24 87%; P<0.01). N° of GP with abnormal PA decreased significantly at ERT6 (5/19; P<0.05). PA on AA and EPI normalized at ERT6: 0.76 and 072 respectively. At ERT24 the abnormal PT, APTT, vWF and PA values were still registered in 8, 1, 1 and 3 GP, respectively. Chitotriosidase level and SV significantly decreased acheaving: Chito24 1872 nmol/L P<0.05, spleen MN24 9, P<0.05. *Conclusions.* Bleeding together with decreased levels of coagulation factors and abnormal PA were registered in a considerable number of our GP. Cerezyme significantly decreased bleeding tendency and increased PC, PA and PT. Our data suggest that spleen and total body burden of glucocerebroside may contribute to the platelet disfunction and bleeding.

0175

INCREASED BONE METABOLIC TURNOVER IN PATIENTS WITH HEMOPHILIA

N Rajic,[1] T Icin,[2] I Urosevic,[3] I Savic,[3] A Savic[3]

[1]Clinical Centre of Vojvodina, Novi Sad, Serbia; [2]Clinic of Endocrinology, Clinical centre of Vojvodina, Novi Sad, Serbia; [3]Clinic of Hematology, Clinical Center of Vojvodina, Novi Sad, Serbia

Osteoporosis, as a clinical issue in patients with haemophilia, is rather recently recognized. Both disorders may be accompanied with chronic pain, progressive invalidity, loss of independence and increased mortality. We performed osteodensitometry using dual X-ray absorptiometry (DXA) in 12 adult patients with haemophilia A or B (median age 42 years), aiming to assess the incidence and severity of osteoporosis. Also, parameters of metabolic activity of the bone were measured (serum levels of osteocalcin, beta-cross laps, vitamin D (25 OH-D), calcium and parathyroid hormone /PTH/). We compared those results with result of a control group. Age and sex matched control group were patients from other clinics having risk factors for osteoporosis, who underwent DXA. Parameters of bone metabolic activity were compared to dataset from central laboratory, originating from age and sex matched group of patients from other clinics of our Clinical centre. Statistical tests performed were: t-test and other tests of descriptive statistic. Using WHO criteria based on values of bone mineral density (BMD) and Z score, 1 patient with haemophila had osteopenia (8.3%) and 2 had osteoporosis (16.6%). There were no statistical significance comparing lumbal and femoral BMD and Z scores from patients with

haemophilia and control group. But, some values of bone metabolic activity parameters were significantly higher in patients with haemophilia then in control group-osteocalcin was elevated in 4 patients (33.3%) (Median 40,5 vs. 26,8 ng/mL, P<0.05) and beta-cross laps in 8 patients (66.6%) (Median 771.3 vs. 305.3 pg/mL P<0.05). Other parameters (vitamin D, PTH and calcium) did not differ significantly. Osteoporosis seems to be frequent in patients with haemophilia, since a quarter of our patients had decreased bone mineral density. Lack of significant differences in DXA parameters between patients with haemophilia and those with known high risk for osteoporosis (control group), suggest that haemophilia itself is a risk factor for osteoporosis. Although, blood samples for measuring bone metabolic activity in patients with haemophilia were taken few hours or days after bleeding in joints or soft tissues, we suggest that our patients had highly increased metabolic turnover of the bone. We are aware that many factors could influence on the results of bone metabolic activity (comorbidity, age, life habits etc.), but we consider that our results raise a question about supplementation with vitamin D and calcium recently after bleeding episodes in patients with haemophilia.

0176

INHERITED BLEEDING DISORDERS IN THE PEDIATRIC AGE GROUP: SINGLE CENTER EXPERIENCE

G Mokhtar, A Tantawy, A Adly, M Shams

Faculty of Medicine, Ain Shams University, Cairo, Egypt

Objectives: The present study aimed to assess the prevalence and clinical presentation of inherited bleeding disorders in the Pediatric Hematology Unit, Children's Hospital, Ain Shams University, Cairo,Egypt. *Methods.* The hospital based registry was used to analyze the data of patients presenting with bleeding disorders along a period of 14 years starting from January 1st 1994 to December 31st 2007. The tests performed for diagnosis included mainly CBC, bleeding time (BT), platelet count, prothrombin time (PT), activated partial thromboplatin time (aPTT) and platelet Aggregation with ADP and ristocetin. , and bone marrow (BM) aspiration whenever necessary. *Results.* 687 patients with bleeding disorders were identified among 2949 hematology patients diagnosed in the Pediatric Hematology Unit in 14 years .Inherited defects of coagulation were observed in 187 (27.2%) of patients with bleeding disorders; hemophilia A was diagnosed in 132 patients (70.6%), hemophilia B in 26 patients (13.9%), factor I deficiency in 4 patients (2.1%), factor V deficiency in 3 patients (1.6%), factor X deficiency in 8 patients (4.2%), factor VII deficiency in 5 patiens(2.6%) , factor XIII deficiency in 2 patients(1.1%) , combined factor deficiency in 4 patients (2.1%) , and unclassified coagulation disorders in 3 cases (1.6%).Among 500 patients with platelet disorders immune thrombocytopenia was most common (74.8%), Glanzman's thrombasthenia was diagnosed in 56 patients (11.2%), Von Willebrands disease in 33 patients (6.6%), Bernard Soulier Syndrome in 5 patients (1%) and Chediak Higashi Syndrome in 2 patients (0.4%). In 30 patients (6%), the platelet function defect could not be classified into any specific subtypes.Most cases of coagulation disorders were diagnosed in the age group < 1 year (26.7%) and the median age was 33 months, while most cases of platelet disorders were diagnosed in the age group 6-<10 years and the median age was 72 months.In the present study 413 cases were males and 274 cases were females. All cases of Hemophilia A and B were male cases, while (30.8%) of other coagulation factors deficiencies and all unclassified were females. In inherited platelet disorders 52.6% were females . The presenting symptoms of coagulation disorders were in descending order: (25.1%) post circumcision bleeding, (22.5%) ecchymosis, (20.9%) hemoarthrosis and (15%) epistaxis.Among the presenting symptoms of rare coagulation disorders (other than hemophilia A and B), the most common symptoms were postcircumcision bleeding (20%)and bleeding umbilical stump (20%), followed by epistaxis (12%), hemoarthrosis (8%) and hematomas (4%). In our study , the presenting symptoms in rare inherited platelet disorders were as follows: purpura in(45.6%) , ecchymosis in (43.4%), epistaxis (20.4%) and bleeding gums (11.8%).Conclusion :The clinical expression of the inherited bleeding disorders is variable and may present challenges in both diagnosis and management. The awareness of the increased risk of these disorders will lead to higher index of suspicion and thus earlier diagnosis of severely affected infants who are at risk of serious bleeding.Centralisation and processing of data in reference centres is mandatory to increase knowledge on these uncommonand complex disorders, with the purpose of improving the management of these particular patients.

IMPACT OF VON WILLEBRAND DISEASE ON HEALTH RELATED QUALITY OF LIFE IN A PEDIATRIC POPULATION

E de Wee,[1] K Fijnvandraat,[2] A de Goede-Bolder,[3] E Mauser-Bunschoten,[4] H Eikenboom,[5] P Brons,[6] F Smiers,[7] R Tamminga,[8] J van der Bom,[9] F Leebeek[10]

[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]Pediatric Hematology, Emma Children's Hospital AMC, Amsterdam, Netherlands; [3]Pediatrics, Erasmus MC, Sophia Children's Hospital, Rotterdam, Netherlands; [4]Creveldklinick and Hematology, University Medical Center Utrecht, Utrecht, Netherlands; [5]Thrombosis and Hemostasis, Leiden University Medical Center, Leiden, Netherlands; [6]Paediatric Haematology and Oncology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [7]Oncology, Leiden University Medical Center, Leiden, Netherlands; [8]Paediatric Haematology-Oncology, University Medical Center Groningen, Groningen, Netherlands; [9]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [10]Hematology, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands

Von Willebrand Disease (VWD) is the most frequent inherited bleeding disorder, whether VWD affects quality of life in children is unknown. This study determined health-related quality of life (HR-QoL) in children with VWD. All Dutch children known with moderate or severe VWD (defined as VWF:Ag or VWF:RCo ≤ 30%) were asked to participate. In total 133 children, 78 boys and 55 girls, aged 0-15 years participated. HR-QoL was assessed using the Infant and Toddler Quality of Life Questionnaire (ITQOL) in the age group 0-5 years, and the Child Health Questionnaire (CHQ) parent form for children aged 6-15 years. Bleeding severity was measured using the Tosetto Bleeding Score (TBS). In young children two domains showed lowered scores compared to normative data: general health (P<0.001), and parental impact time (P<0.001). Older children had lower scores than the normative data for four domains: physical functioning (P<0.001), role functioning emotional-behavioural (P=0.027), general health (P<0.001), physical summary (P<0.001). Type of VWD did not influence HR-QoL in young children. In older children different scores were observed between type 1 and 3 for six domains, and type 2 and 3 for three domains with a lower score for type 3 patients. The quartile of children aged 6-15 years with the highest TBS had lower HR-QoL in 9 domains in comparison to the quartile of children with the lowest TBS. Children with VWD have lower HR-QoL scores than children of the general population. In older children HR-QoL is associated with both type of VWD and TBS.

0178

CIRCUMSTANCES OF DIAGNOSIS AND CLINICAL FEATURES IN MILD/MODERATE FORMS OF INHERITED RARE BLEEDING DISORDERS AND OF VON WILLEBRAND DISEASE OBSERVED IN HAEMOPHILIA CENTRE OF PAVIA. ITALY

G Gamba,[1] N Montani,[2] F Lodo,[1] A Trinchero,[2] N Ghidelli[2]

[1]University of Pavia, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [2]University of Pavia, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background. The haemorrhagic manifestations in mild/moderate forms of Rare Bleeding Disorders (RBD) and of von Willebrand disease (vWd) usually do not present clinical impact; furthermore screening clotting times may be normal or only slightly prolonged so that a variability of occasions induces to make a diagnosis. *Aim of the study*. To evaluate the circumstances of diagnosis and the bleeding patterns in mild/moderate RBD and vWd observed in the Centre of Haemophilia and other Congenital Coagulopathies of Pavia. *Patients*. 77 subjects (43 women) aged between 6 and 78 yrs; 33 with RBD including deficiencies of F XI (13), F VII (11), F X (2), F V (3), ipodysfibrinogenemia (2), F X+FXII (1), F VIII+FVII (1); 44 with vWd. *Results.* Circumstances of diagnosis: RBD Familiarity 40%, Abnormal clotting test 25%, cutaneous-mucosal haemorrhages* 20%, post-surgical bleeding 15%; vWd cutaneous-mucosal haemorrhages* 34%; familiarity 29%, post-surgical bleeding 23%, abnormal clotting test 14% (*including menorrhagia). Pattern of bleeding: In both RBD and vWd menorrhagia was present in 80% of women and post-partum haemorrhages in 7% of women with RBD and in 12% of women with vWd. In all patients: cutaneous-mucosal haemorrhages (%) RBD 40, vWd 66; post-surgical bleeding (%) RBD 20, vWd 30; deep haematomas (%) RBD 5, vWd 10.Haemarthroses were observed in one subject with F XI deficiency and in one subject with vWd. The bleeding manifestations were gen-

erally mild to moderate requiring RBC infusions in only seven patients, whereas in menorrhagia iron supplementation was frequently indicated. *Summary/Conclusions.* The main clinical manifestations of moderate/mild forms of RBD and vWd are cutaneous-mucosal haemorrhages and, in women, menorrhagia with occurrence in some subjects of postpartum haemorrhages. In RBD the diagnosis is frequently made because of familiarity or of abnormal clotting tests. In mild/moderate forms excessive post-surgical bleeding represents an occasion of diagnosis in about 1:5 patient with vWd and about 1:7 patient with RBD.

0179

DENGUE HEMORRHAGIC FEVER IN HEMOPHILIC PATIENTS: AGGRAVATION OF BLEEDING RISK

A. Chuansumrit, K Tangnararachakit, N Sirachainan, A Khositseth, T Kuptanon, S Wanitkun, W Withurawanit, D Songdej

Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

Background. Dengue virus infection is commonly found in tropical countries. Pediatric patients including hemophiliacs are risk to be infected. The clinical manifestations of dengue virus infection vary from asymptomatic to mild degree of flu-like symptom of dengue fever and severe degree of dengue hemorrhagic fever (DHF). *Material and Methods.* Six moderate to severe hemophilia patients (4 hemophilia A, 2 hemophilia B) with the age ranging from 5 to 16 years of age were included in the study. The inversion of intron 22 was found in four hemophilia A patients. All of them presented with high fever, lethargy, loss of appetite, and bleeding manifestations at skin, epistaxis, gastrointestinal tract and hemothorax with the presumptive clinical diagnosis of DHF according to the criteria of World Health Organization. *Results.* The severity of DHF was graded according to the World Health Organization as follow: grade 1 with only positive tourniquet test (n=1), grade 2 with bleeding manifestation (n=1), grade 3 with threatening shock and massive bleeding (n=2) and grade 4 with profound shock and massive bleeding (n=2). All patients had their serological confirmation of dengue virus infection .They received appropriated fluid therapy to maintain the effective circulation during the febrile stage of leakage from increased vascular permeability and adequate blood component therapy of platelet concentrate, fresh frozen plasma, cryoprecipitate and factor concentrate. In addition, appropriate airway management, effective cardiovascular circulation, and infection control including hospital-acquired bacterial and fungal infection should be comprehensively provided. Dengue virus-associated hemophagocytic syndrome should be looked for and treated accordingly. *Conclusions.* Dengue virus infection is one of the serious complication among hemophilic patients in tropical countries. Aparted from vascular leakage, severe bleeding manifestation is one of the serious adverse event to unfavorable outcome.

EPIDEMIOLOGY OF HEMOPHILIA IN MARTINIQUE (FRENCH WEST INDIES)

S Mayeur,[1] E Jeliazkova,[1] C Lebris,[1] S N'Diaye,[1] S Pierre Louis,[1] C Negrier,[2] Y Plumelle,[1] A Brebion[1]

[1]CHU Fort de France, Fort de France, Martinique; [2]Centre de traitement, Lyon, France

Background. Hemophilia is a common form of hereditary bleeding disorder wide-spread in the world. It has an X-linked genetic transmission. Hemophilia A is due to deficiency of factor VIII and hemophilia B is due to deficiency of factor IX. Martinique is an island in the Caribbean, with a population consisting of 400 000 habitants. The half-breed population is mainly of Afro-Caribbean descendents. *Aims.* Census of hemophiliacs in Martinique. We have analyzed the type of hemophilia, the severity of the disease, the genetic mutations and the serology of hepatitis A, B, C, HIV, HTLV1; the presentation of factor VIII antibodies and the reasons of death. *Methods.* Census of hemophiliacs for the period 2000-2007. Data was taken from the medical charts at the Regional center for the treatment of hemophilia in Martinique and the interviews with the families. *Results.* A total of 76 patients with hemophilia was included, 67(88.2%) patients with hemophilia A and 9 (11.8%) patients with hemophilia B, of these 9(11.8%) with severe hemophilia, 5(6.8%) with moderate hemophilia and 62(81.6%) patients with hemophilia minor. Average age at the diagnosis: 2 years old for the cases of severe hemophilia, 16.5 years old for the mild hemophilia. Circumstances of discovery of the disease: haemorrhages 26 patients, blood tests 29 patients, family history 21 patients. Serological status: HAV 12 (15.7%), HBV 9 (11.8%) all born before 1980, HCV 17 (22.3%) born before 1987, HIV 7 (9.2%) all of them co infected with HCV and born before 1985, HTLV none. Factor VIII antibodies inhibitors: 2 patients (2.6%). Number of deaths: 3 (3.9%). Reasons of death: cerebromeningeal haemorrhage 1, HIV cardiomyopathy 1, HCV hepatocellular carcinoma 1. The principal genetic abnormalities for severe hemophilia A: inversion of the intron 22, deletion of the exons 1-6, deletion C6703 in the exon 25, for moderate hemophilia A: Cys 554 Phe, for minor hemophilia A: Leu 2053 Phe and Met 2255 Val, and for severe hemophilia B: point mutation, for minor hemophilia B: Phe 299 Val. *Conclusions.* The haemophiliac population of Martinique had the same epidemiological features when compared with the data from a Caucasian population. Contrary to the data in the literature concerning severe haemophiliacs, of African origin, the rate of inhibitors in our population wasn't superior. The genetic mutations were common for the majority of mutations. 5 mutations were not described.

0181

INHIBITORS AND LUPUS ANTICOAGULANT IN CONGENITAL HAEMOPHILIA

D Antic, I Elezovic, P Miljic, L Davidovic, P Djoric

Clinical Center Serbia, Belgrade, Serbia

Background. Patients with haemophilia can develop alloantibodies (inhibitors), as serious complication of replacement therapy, or autoantibodies which change coagulation, or both of them. *Aim.* This work describes two haemophilic patients with specific inhibitors and lupus anticoagulant (LA). *Results.* A 19 years old male patient with severe Haemophilia A and previously detected inhibitor and HCV infection developed intracranial hemorrhages. He was treated with rFVIIa 90 μg/kg/2h. Because very bad venous access he was prepared for central venous catheter (CVC) with 120 mg/kg/2h of rFVIIa. Four hours after implementation of CVC, severe neck oedema and breathless were developed and FEIBA was added at dosage of 80 U/kg. CT scan of the neck is shown diffuse large hematoma in muscle and soft tissue without mediastinal hemorrhage. Angiography confirmed that catheter was well implemented. Surgical exploration was shown that CVC has been placed through the muscle. Hemorrhage in the muscle produced severe compartment syndrome of the neck. Catheter was removed without bleeding. During second postoperative day severe compartment syndrome on the neck was dramatically evolved. Sutures have been removed immediately and respiratory function was improved. Control APTT was near normal (42.7s), and treatment was continued with concentrate of hFVIII in dosage of 4.000 U every 8h, during next 7 days, without bleeding. During the treatment with concentrate of FVIII levels of FVIII were in normal range. On day 14, APTT prolonged with increment of FVIII inhibitors. The treatment with hFVIII concentrate was stopped and rFVIIa continued. Second patient is 50 years old male with mild Haemophilia B and HCV infection who had time-depending inhibitors, and FIX inhibitors of 32 BU was detected. Plasma dilution test shown that higher dilution correlated with increase of FIX at it was corresponded with LA. LA 1.5 was detected by DRRVT. Before tooth extraction patient received 1800 U of FIX concentrate and one hour later APTT was prolonged but FIX was increased from 9% to 28%. Patient did not bleed after tooth extraction. It is well known that haemopilia, inhibitor, and LA prolonged APTT but it is not possible to be measured contribution each of them. Measurement of APTT in PRP before and after frozen and thaw in water bath on 37°C, shown decrease APTT from 90.7s to 72.9 s (Ratio=1.25) but inhibitors of FVIII were similar 5.6 BU and 5.4 BU respectively. Repeated test, when patient had FVIII inhibitors 13 BU were shown that APTT of PRP, after frozen and thaw on 37°C, shortened from 115s to 85.9s (Ratio=1.34). After frozen and thaw, platelets released phospholipids which neutralised LA and shortened APTT on the level which coresponded to haemophilia with inhibitors. *Conclusions.* It is well known that haemopilia, inhibitor and LA prolonged APTT but it is not possible to be measured contribution each of them. Usage of more than one test increase the chance of detecting LA and it may be helpful to differentiate LA from specific inhibitors. Differentiation of LA from FVIII inhibitors is crucial for different therapeutic management.

0182

CENTRAL NERVOUS SYSTEM BLEEDING IN RARE BLEEDING DISORDERS: SINGLE CENTER EXPERIENCE

O Salcioglu,[1] A Akçay,[1] H Sen,[1] G Aydogan,[1] F Akici,[1] D Tugcu,[1] Z Baslar[2]

[1]Minister of Health Istanbul Bakirkoy Woman and Children Disease Education, Istanbul, Turkey; [2]Istanbul University, Cerrahpasa Medical School, Internal Medicine, Department of, Istanbul, Turkey

Rare bleeding disorders (RBDs) are autosomal recessively inherited disorders. Their frequency are approximately 1:500 000 to 1:2 000 000 in general population. Central nervous system is the most important site of severe bleeding in these patients. We assessed 109 patients retrospectively, who were diagnosed with RBDs (fibrinogen, FII, FV, FVII, FX, FXI, FXIII deficiencies) between 1990 and 2010. 69 patients were male and 40 were female. Their ages were ranging from one week to 19 years. Familial consanguinity was present in 38.2% of the patients 37.6% of these patients were asymptomatic. They were diagnosed by family histories or preoperative laboratory studies. Of these 109 patients 10 of them were diagnosed with fibrinogen deficiency, 5 with Factor V deficiency, 73 with VII deficiency, 11 with Factor X deficiency, 7 with Factor XI deficiency, 2 with Factor XIII deficiency. Easy bruising and skin bleeding 66.8%, hemarthroses 22.7%, oral cavity bleeding 21.2%, central nervous system bleeding 17.4%, epistaxis 17.4% and gastrointestinal bleeding 9.6% were the most common bleeding sites in our group. These 14 central nervous system bleeding cases were diagnosed as FVII deficiency (n:8, 57.1%), FX deficiency (n:4, 28.6%), FV deficiency (n:1) and fibrinogen deficiency (n:1). The presenting age of patients with central nervous system hemorrhages were in the first 3 months (71.5%). Since in our country consanguinity marriage is still a problem, hemorrhagic disorders in early month of life may be due to rare factor deficiency. In this study we aimed to emphasize early diagnose and prophylaxis of these disorders.

Clinical platelets

CHRONIC IDIOPATIC THROMBOCYTOPENIC PURPURA (ITP) IN ADULTS - RETROSPECTIVE STUDY - SINGLE CENTER EXPERIENCE

CO Ionita,[1] I Ionita,[1] DE Nicola,[2] G Borzak,[2] R Pacurar,[2] M Ionita,[1] RG Cioaca,[1] H Ionita[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. The investigation and management of patients with chronic adult ITP varies widely and there is a lack of data on current treatment strategies in Europe. *Aims.* To contribute to a better understanding of the treatment and healthcare resource utilization of chronic ITP patients in Romania. *Methods.* This is part of a comprehensive project investigating the burden of chronic ITP and which involves both expert opinion as well as real patient data. A retrospective study for 350 ITP patients was performed. Patients' demographics, medical history, current treatments and side effects, as well as medical resource utilization were abstracted from the patient's medical charts for the 12 months prior to their most recent visit. *Results.* The mean age of the total patient sample was 49,1 years with 59% women and 41% men. Median time from the first diagnosis of ITP to the start of the observational period was 27 months. Prior to the observational period, 35% of patients had been splenectomized and the most frequently reported treatment was corticosteroids. During the observational period, 72% of all patients were treated and received 1-9 different medical treatments (mean 2.5). The most frequent reasons given for treatment were platelet count (72%), followed by bleeding symptoms (35%). Corticosteroids represented 71% of treatments given, followed by IVIg (13%), azathioprine (5%) and rituximab. Splenectomies (6% of patients) and platelet transfusions (2% of patients) were rarely performed during the observational period. 2% patients refused to undergo splenectomy during the period. In addition to regular monitoring of platelet levels, 81% of patients visited their hematologist 1 to 6 times during the year of observation. Main reasons for a visit were a low platelet count (48% of visits) and bleeding (19% of visits). Overall, 35% of patients required hospitalization; 8% of these were in an intensive care unit. 89% of hospitalizations were due to ITP (low platelet count, 69%, bleeding 31%) and 7% of hospitalizations were due to ITP treatment related side effects. Mean duration of hospitalization was 10,3 days. *Conclusions.* The retrospective chart review of 350 patients is the largest study to date of its kind in ITP and provides the first results of actual treatment practices, outcomes and medical resource utilization in our country. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP even through two thirds of them were actively treated. Corticosteroids were the most widely used treatment, followed by IVIg.

SAFETY ANALYSIS OF LONG-TERM ROMIPLOSTIM USE IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (ITP)

F Rodeghiero,[1] D Provan,[2] D Cines,[3] R Stasi,[4] M Tarantino,[5] K Nie,[6] S Jun[6]

[1]Department of Cell Therapy and Hematology, Vicenza, Italy; [2]Centre for Haematology, The Royal London Hospital, London, UK; [3]Department of Pathology and Laboratory Medicine and Medicine, Philadelphia, USA; [4]Department of Haematology, St. George's Hospital, London, UK; [5]University of Illinois College of Medicine, Peoria, USA; [6]Amgen Inc., Thousand Oaks, USA

Background. ITP is characterized by low platelet counts and increased risk of bleeding. Romiplostim is an Fc-peptide fusion protein (peptibody) that increases platelet production by binding to and activating the thrombopoietin (TPO) receptor, and is approved for the treatment of adult chronic ITP. We conducted a safety analysis of data pooled from all ITP romiplostim clinical studies. *Aim.* To evaluate the safety of long-term romiplostim treatment using the largest available set of clinical data. *Methods.* Data from 13 romiplostim clinical studies (patients treated from October 2003 to June 2009) in patients with ITP were analyzed. Patients received romiplostim, placebo, or standard of care (SOC); data from placebo/SOC patients were pooled. Given that the study time for patients while receiving romiplostim or placebo/SOC was not equal, adverse events were adjusted for study duration and reported as rates per 100 patient-years. *Results.* Data from 718 patients (59% female) were pooled, corresponding to over 1000 patient-years on

study. In studies where information on prior ITP treatment was collected, 100% of patients (482/483) had received ≥1 prior ITP treatment, and 38% had a splenectomy. The mean baseline platelet count from the first ITP studies that the patient enrolled in was 20×10⁹/L (SD: 16×10⁹/L). In total, 580 patients received romiplostim; 65 received placebo/SOC; and 73 received placebo/SOC in the parent study and romiplostim in the subsequent study. The median duration of exposure to romiplostim was 52 weeks (range 1-250 weeks). The average weekly romiplostim dose was 3.5 mcg/kg. Fifteen percent of romiplostim-treated patients and 22% of placebo/SOC-treated patients discontinued their parent ITP study. Adverse events were reported in 92% of romiplostim patients and 94% of placebo/SOC patients. The most frequently reported adverse events (rates per 100-patient years, romiplostim vs placebo) were: headache, (79 vs 58), contusion (60 vs 50), and epistaxis (46 vs 53). There appeared to be reductions in the rate of bleeding events in the romiplostim group compared to the placebo/SOC group, but the confidence intervals overlapped (Table 1). Adverse events of interest in the treatment of ITP with TPO mimetics include thrombosis events, bone marrow reticulin events, neoplasms, and hematopoietic malignancies. These events were analyzed in both the romiplostim and placebo/SOC groups (Table). The rate of thrombotic events was comparable between the romiplostim and placebo/SOC groups. Reticulin was detected in the bone marrow of 12 patients who received romiplostim; in 4 patients for whom post-treatment follow-up biopsies were available, reticulin grade either decreased or remained the same after romiplostim withdrawal. The rate of all neoplasms and of hematopoietic malignancies was lower in the romiplostim group than the placebo group. Two patients developed neutralizing antibodies to romiplostim but did not develop neutralizing antibodies to TPO. *Conclusions.* This integrated analysis provides long-term safety information from all available ITP romiplostim clinical studies, with some patients treated for close to 5 years. No new safety signals were identified with the long-term use of romiplostim and the adverse event profile was consistent with that previously reported.

CIRCULATING COLLAGEN III N-PROPEPTIDE IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) TREATED WITH THROMBOPOIETIN AGONISTS

W Ghanima,[1] HC Hasselbalch,[2] P Junker,[3] S Gudbrandsdottir,[4] J Bussel[5]

[1]Østold Hospital Trust Fredrikstad, Fredrikstad, Norway; [2]Department of Oncology-Hematology, Roskilde Hospital, University of Copenhagen, Copenhagen, Denmark; [3]Department of Rheumatology, Odense University Hospital, Odense, Denmark: [4]Department of rheumatology, Copenhagen University hospital, Copenhagen, Denmark; [5]Weill Medical College of Cornell University, New York, USA

Background. Thrombopoietin receptor agonists (TpoRA) have shown high efficacy in ITP. They act by stimulating thrombopoietin receptors leading to increased platelet production. However, concerns have been raised over the increased bone marrow fibrosis (BMF) that has been reported in a number of treated patients. BMF is related to accelerated megakaryocytic proliferation thought to be due to release of cytokines, which stimulate fibroblasts leading to collagen deposition. Collagen is synthesized as procollagen precursors to be transformed into collagen after the cleavage of the N and C terminal propeptides with the procollagen peptide (PIIINP) released into the circulation. Serum PIIINP has been suggested as a marker for fibroproliferative activity in the BM in various myeloproliferative disorders. *Aims.* To assess circulating PIIINP levels in ITP patients treated with TpoRA and to explore whether PIIINP levels correlate with the grade of fibrosis in the BM. *Methods.* BM biopsies were available in 27 ITP patients treated with TpoRA. In 3 patients only pretreatment BM were available. Frozen sera were collected at different time points during treatment; samples were available in 25 patients. BM fibrosis was graded into grades 0-to-4. Serum samples were analysed for PIIINP by RIA (Orion Diagnostics, Finland). According to previous publications median PIIINP in healthy subjects was 3.4 µg/L (range 2.9-3.5). *Results.* Median age of 27 patients was 51years. Median platelet counts (Inter-quartile range IQR) at initiation of TpoRA and time of last PIIINP measurement were 16×10⁹/l (13-38) and, 59×10⁹/L (30-100), respectively. Post-treatment serum samples were available in 22 patients. Median (IQR) PIIINP was 5.6 µg/L (4.1-7.3). Median (IQR) PIIINP was 4.7 (3.7-6.0) in grad 0/1 (n=13), 5.8 (4.6-7.2) in grade 2 (n=9) and 9.1 in grade 4 (n=2). Although PIIINP seemed to increase with increasing grades of BMF, the differences were not statistically significant. PIIINP was negatively associated with the duration of treatment (Spearman's rho =0.51, P=0.016) (Figure 1). Multiple samples were available in 3 patients and illustrated the levels of PIIINP decreasing with time. Mean duration of treatment for patients with reticulin grades 0/1 and 2 were 873 days (SE138) and 452 days (SE106) respectively (P=0.02). *Summary/Conclusions.* TpoRA treated ITP patients have elevated levels of circulating PIIINP, but these did not increase significantly with increasing degrees of BMF. PIIINP levels in the TPO-RA treated ITP patients were higher than in patients with transitional myelofibrosis disorders/polycythemia vera 4.3 µg/L (1.1-8.3), but lower than idiopathic myelofibrosis 8.8 µg/L (7.4-10.7). Interestingly, we found a negative association between PIIINP and duration of treatment, In line with that, we found an inverse relation between the duration of treatment and the grade of fibrosis. These findings may indicate an initial elevation or a pre-treatment increase in fibroproliferative activity that seems to fade away with time on treatment with TPO-RA. This novel finding needs to be verified in prospective studies and its mechanism better understood in the setting of no evidence of decreased efficacy over the same time period.

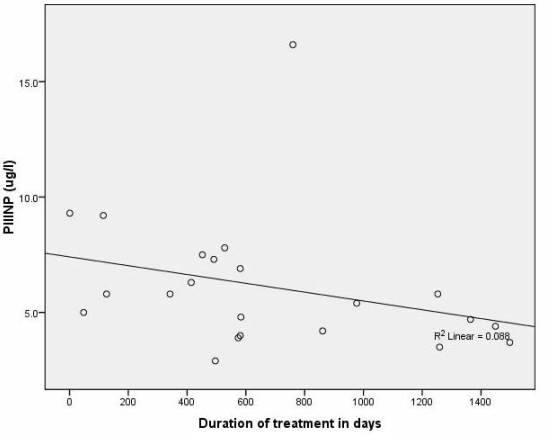

Figure 1. Association between PIIINP and treatment duration.

EFFECT OF ELTROMBOPAG ON PLATELET RESPONSE, BLEEDING AND REDUCTION IN CONCOMITANT ITP MEDICATIONS IN ADULTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (ITP) AND BASELINE PLATELETS =15,000/µL

I Pabinger,[1] C Marcher,[2] A Khelif,[3] S Vasey,[4] A Brainsky[4]

[1]Medizinische Universitaet Wien, Vienna, Austria; [2]Odense University Hospital, Odense, Denmark; [3]Farhat Hached Hospital, Sousse, Tunisia; GlaxoSmithKline, Collegeville, USA

Background. Chronic idiopathic (immune) thrombocytopenic purpura (ITP) is characterized by autoantibody-induced platelet destruction and reduced platelet production, leading to low platelet counts (<150,000/µL). Bleeding and bruising signs are largely dependent on platelet counts. Eltrombopag treatment in ITP is aimed at minimizing the risk of bleeding and bruising, and reducing or discontinuing con-

comitant ITP medications by elevating and maintaining platelets to safe levels. *Aim.* To assess effects of eltrombopag on platelet response, bleeding symptoms, and reduction in concomitant ITP medications in ITP patients with baseline platelet counts ≤15,000/μL in the 6-month placebo-controlled, phase 3 study, RAISE (Cheng et al Blood. 2008;112:400). *Methods.* Patients with chronic ITP and platelet counts <30,000/μL who failed ≥1 previous treatment received the standard of care and were randomized to placebo or 50 mg eltrombopag daily. The dose of eltrombopag was increased to 75 mg on or after day 22 for patients who did not achieve a platelet response of ≥50,000/μL. Patients achieving platelet counts >200,000/μL had their dose reduced to ≤25 mg. Bleeding was prospectively evaluated using the WHO bleeding scale. The odds of responding to eltrombopag relative to placebo were calculated using a logistic regression model for the subset of patients with a baseline platelet count of ≤15,000/μL from the RAISE study. *Results.* In RAISE, 97 patients had baseline platelet counts ≤15,000/μL (67 receiving eltrombopag and 30 placebo). Analysis of this subset showed significant clinical benefit from eltrombopag treatment, with the odds of responding significantly higher compared to placebo (P<0.0001). Response to eltrombopag 75 mg in this subset was observed in 56% of patients who required dose escalation compared to 10% of patients in the placebo group. Even though patients with a baseline platelet count >15,000/μL reported more instances of no bleeding (grade 0) compared to patients with baseline platelet counts ≤15,000/μL, the odds of bleeding were significantly reduced in the eltrombopag group with platelet counts ≤15,000/μL compared to placebo (P<0.001). Of 29 patients in the eltrombopag group with baseline platelet counts ≤15,000/μL and concomitant ITP medications at baseline, 19/29 (66%) discontinued or reduced at least 1 concomitant ITP medication compared to 4/15 (27%) in the placebo group. Of this population, 14/19 (74%) eltrombopag-treated patients did not require any rescue medication after a sustained reduction or permanent discontinuation of a baseline ITP medication, compared to 1/4 (25%) placebo-treated patient (Table). The incidence of adverse events (AE) in the overall population was similar in the eltrombopag and placebo groups with approximately 90% of patients experiencing at least 1 AE. Serious AEs in the described subset occurred in 9% of eltrombopag-treated patients compared to 30% of patients in the placebo group. *Conclusions.* The RAISE study reported increased platelet counts, decreased bleeding, and reduction in concomitant baseline ITP medications in patients with ITP treated with eltrombopag relative to placebo. This subset analysis shows that eltrombopag-treated patients with baseline platelet counts ≤15,000/μL have a less robust response but still obtain significant benefit in terms of platelet response, bleeding symptoms, and reduction in concomitant ITP medications relative to placebo.

Table. Reduction on concomitant ITP medications in patients with baseline platelet counts ≤15,000/mL.

	Placebo N=30[a] n (%)	Eltrombopag N=67 n (%)
Baseline ITP medication	15 (50)	29 (43)
Reduced/discontinued ≥1 baseline ITP medication	4/15 (27)	19/29 (66)
Permanently discontinued or sustained reduction[b]	1/4[c] (25)[d]	14/19 (74)[d]

a. One patient with missing baseline platelet count.
b. Excludes patients who subsequently required rescue medication (increase in dose of baseline concomitant medication, new ITP medication, platelet transfusion, or splenectomy).
c. One patient discontinued danazol due to serious adverse events of renal function test abnormality, alanine aminotransferase increase, hyperkalemia.
d. These values are based on the subpopulation that reduced or discontinued ≥1 baseline ITP medication.

ITP, immune thrombocytopenia.

ANTIGENIC DIFFERENCES IN PATIENTS WITH TYPE 1 GAUCHER DISEASE RECEIVING VELAGLUCERASE ALFA OR IMIGLUCERASE ENZYME REPLACEMENT THERAPY IN CONTROLLED CLINICAL TRIALS

C Ruiz, S Barzegar, A Clarke, J Durant, J Lyczak, J Milhaven, M Nadeau, T Nguyen, S Oommen, L Pan, D Rabinovich, B Rickenbach, P Shi, M Concino, P Martini, S Alderucci, B Strack-Logue, M Séllos-Moura

Shire Human Genetic Therapies, Cambridge, USA

Background. Gaucher disease results from a deficiency in the lysosomal enzyme, acid beta-glucosidase. In type 1 Gaucher disease, enzyme replacement therapy with human acid beta-glucosidase can reverse most disease symptoms. However, development of antibodies to therapeutic proteins may impact patient safety, efficacy and drug pharmacokinetics. *Aims.* To compare antibody responses in patients receiving either velaglucerase alfa or imiglucerase. *Methods.* Patients who participated in the velaglucerase alfa Phase III studies (TKT032, TKT034 and HGTGCB-039) were monitored for development of anti-drug antibodies (ADA). Of 99 patients treated, 82 received velaglucerase alfa and 17 received imiglucerase. All patients gave informed consent. Calibrated, sequential, direct bridging electrochemiluminescence (ECL) methods were developed and validated for velaglucerase alfa and imiglucerase. Samples positive in the bridging assay were confirmed and isotyped using quantitative radioimmunoprecipitation (RIP) assays (for IgG ADA) or indirect binding ECL immunoassays (for IgE, IgA and IgM). Isotype-specific goat-human hybrid controls were developed for the latter. All ADA-positive samples were tested for neutralizing antibodies (NAb) using methods based on *in vitro* inhibition of enzyme activity. All patient specimens were evaluated for ADA in parallel in a masked fashion. *Results.* ADA-positive cut-points for both therapeutics were established as 5 and 4 ng/mL in the ECL bridge and RIP assays, respectively. In study TKT032, 25 naïve patients were treated with velaglucerase alfa for 12 months and only 1 patient developed IgG ADA and NAb in response to velaglucerase alfa. In study TKT034, 40 patients who had been previously treated with imiglucerase, were treated with velaglucerase alfa for 12 months. No patient became anti-velaglucerase ADA-positive, despite the presence of 3 patients who had pre-existing anti-imiglucerase ADA at baseline. In study HGT-GCB-039, 17 naïve patients were treated with velaglucerase alfa and 17 naïve patients with imiglucerase for 9 months, with identical doses. No velaglucerase alfa-treated patient developed any ADA. Four imiglucerase-treated patients developed IgG ADA (of whom 1 developed NAb) in response to imiglucerase. *Conclusions.* Highly sensitive and equivalent methods were developed, standardized and validated to directly assess and compare patient antibody response to velaglucerase alfa and imiglucerase treatments. The results show seroconversion in 1% of patients treated with velaglucerase alfa and in 23% of patients who were treated with imiglucerase, suggesting significant antigenic differences between velaglucerase alfa and imiglucerase.

0188

ENZYME REPLACEMENT THERAPY WITH VELAGLUCERASE ALFA SIGNIFICANTLY IMPROVES KEY CLINICAL PARAMETERS IN TYPE 1 GAUCHER DISEASE: POSITIVE RESULTS FROM A RANDOMIZED, DOUBLE-BLIND, GLOBAL, PHASE III STUDY

A Zimran,[1] A Lukina,[2] MF Ben Dridi,[3] I Kisinovsky,[4] E Crombez,[5] K Bhirangi,[5] D Elstein,[1] E Gonzalez[6]

[1]Shaare Zedek Medical Center, Jerusalem, Israel; [2]National Research Center for Haematology, Moscow, Russian Federation; [3]La Rabta Hospital, Tunis, Tunisia; [4]Your Health S.A., Buenos Aires, Argentina; [5]Shire Human Genetic Therapies, Cambridge, USA; [6]Sanatorio Español, Asunción, Paraguay

Background. Type 1 Gaucher disease, resulting from deficiency of glucocerebrosidase, leads to anemia, thrombocytopenia, hepatomegaly, splenomegaly and skeletal abnormalities. The current gold standard treatment is enzyme replacement therapy (ERT) using recombinant glucocerebrosidase manufactured in Chinese hamster ovary cells. Velaglucerase alfa is a new ERT being investigated for use in type 1 Gaucher disease. Unlike recombinant enzymes, it is produced by gene activation in a human cell line. *Aims.* To evaluate the efficacy and safety of velaglucerase alfa in type 1 Gaucher disease. *Methods.* Twenty-five treatment-naïve, anemic, type 1 Gaucher disease patients (age range 4-62 years) were randomized to intravenous velaglucerase alfa 60 U/kg (n=12) or 45 U/kg (n=13) every other week for 12 months. All patients gave informed consent. *Results.* At 12 months, mean hemoglobin concentration increased in both groups (60 U/kg: 23.3% increase, +2.43±0.32 g/dL, P=0.0001; 45 U/kg: 23.8% increase, +2.44±0.47 g/dL, P=0.0001), as did mean platelet count (60 U/kg: 65.9% increase, +50.9±12.×10^9/L, P=0.0016; 45 U/kg: 66.4% increase, +40.9±13.6×10^9/L; P=0.0111). Mean spleen volume decreased in both groups (60 U/kg: 50% decrease, -1.92±0.51% body weight, P=0.0032, from 14.0 multiples of normal [MN] at baseline to 5.75 MN; 45 U/kg: 40% decrease, -1.87±0.60% body weight, P=0.0085; from 14.5 to 9.5 MN) as did liver volume (60 U/kg: 17% decrease, 0.84±3.3% body weight, P=0.0282, from 1.46 to 1.22 MN; 45 U/kg: 6% decrease, -0.30±0.29% body weight, P=0.3149, from 1.40 to 1.24 MN). Velaglucerase alfa was generally well tolerated with no drug-related serious AEs, and no patient withdrew due to an AE. The most common AEs were headache, nasopharyngitis, injury, arthralgia, cough, and pyrexia. A single patient developed antibodies. *Conclusions.* In this global, multicenter study, velaglucerase alfa 60 U/kg and 45 U/kg was generally well tolerated and effective as a first-line treatment for adults and children with type

1 Gaucher disease. All clinical parameters measured demonstrated clinically meaningful improvements after 12 months, with a greater response seen with velaglucerase alfa 60 U/kg.

0189

EVALUATION OF EFFICACY AND SAFETY OF LONG-TERM ROMIPLOSTIM TREATMENT FOR PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP) ENROLLED IN AN OPEN-LABEL EXTENSION STUDY: A PATIENT COHORT-ANALYSIS

J Kuter,[1] A Newland,[2] J Bussel,[3] J Wasser,[4] K Nie,[5] S Jun[5]

[1]Massachusetts General Hospital, Boston, USA; [2]Department of Haematology, The Royal London Hospital, London, UK; [3]New York Presbyterian Hospital, Departments of Pediatrics and Medicine, New York, USA; [4]Manchester Memorial Hospital, Manchester, USA; [5]Amgen Inc., Thousand Oaks, USA

Background. ITP is an autoimmune disease characterized by low platelet counts due to both increased platelet destruction and suboptimal platelet production. Romiplostim, a novel peptibody that increases platelet production similarly to thrombopoietin, is approved for the treatment of adult chronic ITP and patients have been treated in an open-label extension study for more than 5 years. *Aims.* To evaluate the safety and efficacy of long-term romiplostim treatment among cohorts of patients with different disease characteristics and different lengths of exposure to romiplostim. *Methods.* Eligible patients had completed a prior romiplostim study without significant changes in their medical history. Informed consent was obtained from all patients. Romiplostim was administered once weekly by subcutaneous injection, with dose adjustments to maintain platelet counts in the target range (50 to 200×10^9/L). Patients were divided into 4 cohorts based on their date of study enrollment (corresponding to key protocol changes over time). Protocol changes over time included lowering the maximum allowed romiplostim dose and removing the baseline platelet count requirement. Exposure-adjusted adverse event rates were expressed as rates per 100 patient-weeks to account for different exposures on-study. *Results.* Overall, 291 patients received romiplostim. Certain baseline patient characteristics differed among the 4 cohorts (Table) and were most prominent in cohort 4, which contained largely nonsplenectomized patients, who enrolled immediately after completing their prior study and had higher baseline platelet counts and shorter history of ITP. Duration of romiplostim treatment in this study varied from ≤244 weeks in cohort 1 to ≤72 weeks in cohort 4. As median treatment duration increased, there was no trend for increased rates of adverse events (Table).

Table.

	Cohort 1 N = 34 6166 pt-wks	Cohort 2 N = 90 11754 pt-wks	Cohort 3 N = 31 2857 pt-wks	Cohort 4 N = 136 5113 pt-wks	Overall N = 291 25890 pt-wks
Enrollment period	April 2004 to February 2005	February 2005 to May 2006	May 2006 to October 2007	October 2007 to May 2009	-
Maximum allowed romiplostim dose at enrollment, mcg/kg	30	15	10	10	-
Study entry platelet count criteria, x10^9/L	≤ 50	≤ 50	≤ 50	none	-
Median (Q1, Q3) baseline platelet count, x10^9/L	18 (10, 24)	19 (11, 33)	13 (6, 32)	113 (55, 190)	35 (15, 96)
Splenectomy, % (n)	77% (26)	53% (48)	61% (19)	2% (2)	33% (95)
Median (Q1, Q3) duration ITP, years	9 (4, 16)	6 (3, 13)	11 (4, 15)	3 (2, 7)	5 (2, 11)
Median (min, max) duration of treatment in extension study, weeks	222 (1, 244)	151 (2, 240)	96 (3, 144)	36 (4, 72)	48 (1, 244)
Adverse event, rate (n)	27.4 (1687)	19.9 (2341)	30.5 (871)	15.1 (771)	21.9 (5670)
Serious adverse event, rate (n)	0.9 (56)	0.9 (111)	1.8 (52)	1.0 (4)	1.0 (270)
Treatment-related adverse event, rate (n)	2.3 (144)	1.4 (167)	0.9 (25)	1.3 (67)	1.6 (403)
Treatment-related serious adverse event, rate (n)	0.2 (11)	0.1 (8)	0.4 (12)	0.1 (7)	0.1 (38)
Deaths, rate (n)	0 (0)	0.1 (6)	0.1 (3)	0.1 (4)	0.1 (13)
Bleeding events, rate (n)	3.2 (200)	3.0 (353)	4.0 (113)	1.7 (89)	2.9 (755)
Platelet count ≥ 50x10^9/L, n (%)	28 (82%)	85 (94%)	27 (87%)	133 (98%)	273 (94%)

n =number of adverse events, pt-wks = total patient-weeks, rate = exposure adjusted AE incidence rate per 100 patient-weeks ((n/pt-wk)x100)

The median average weekly dose across the overall study population was 4 mcg/kg (interquartile range: 2 to 7 mcg/kg). The mean weekly dose remained stable within cohorts and was consistently highest in cohort 1, in which patients had been allowed to receive romiplostim at higher doses and had more severe disease, and was lowest in cohort 4. Almost all patients (94%) experienced a platelet count ≥50×10^9/L during the study. After the first week, overall median platelet counts remained within the target range for the duration of the study. Median weekly platelet counts among cohorts were similar to median weekly platelet counts overall and were consistently highest in cohort 4. *Conclusions.* In this study, the safety profile of romiplostim in ITP patients did not worsen with longer duration of treatment, and was similar among cohorts of ITP patients with different baseline characteristics. The ability to sustain platelet count increases with a stable romiplostim dose over months to years was not affected by changes to the protocol and patient population over time although the median dose and platelet count were slightly different.

LOW DOSE RITUXIMAB AS SALVAGE THERAPY IN ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)

F Zaja,[1] ML Battista,[2] M Defina,[3] N Vianelli,[4] S Palmieri,[5] M Bocchia,[3] M Medeot,[2] S Volpetti,[6] S De Luca,[6] F Ferrara,[5] M Isola,[7] M Baccarani,[4] R Fanin[6]

[1]Azienda Ospedaliera S. Maria Misericordia, Udine, Italy; [2]Clinica Ematologica, DIRM, Azienda Ospedaliera Universitaria S. M Misericordia, Udine, Italy; [3]Department of Hematology, Ospedale Sclavo, Siena, Italy; [4]Institute of Hematology L. A. Seragnoli, Bologna, Italy; [5]Department of Hematology, Ospedale Cardarelli, Napoli, Italy; [6]Clinica Ematologica, DIRM, Azienda Ospedaliero Universitaria, Udine, Italy; [7]Chair of Statistic DIRM, University of Udine, Udine, Italy

Backgrounds. Rituximab (RTX) 375 mg/sqm weekly for 4 weeks has significant activity in adults with primary ITP. In this setting, several evidences support the possible use of lower doses of RTX. *Aims.* To investigate the short and long term activity and safety of low dose RTX as salvage therapy in previously treated symptomatic ITP. *Methods.* Forty-eight adult patients, median age 41 years, male/female sex ratio 18/30, median weight 74 kg (range 42-112), median platelets count 30×10^9/L, were treated prospectively with RTX at the fixed dose of 100 mg iv weekly for 4 weeks. All patients gave informed consent. Results were evaluated considering: overall and complete responses (ORR and CR: platelet level equal to/more than 50 and 100×10^9/L), the time to ORR and to CR (TTR and TCR: time necessary to reach a platelet number equal to/more than 50 and 100×10^9/L), the relapse rate, the relapse free survival (RFS: interval between initial response and the loss of the best response previously achieved) and the treatment free survival (TFS; interval between initial response and the necessity of beginning rescue therapy). *Results.* All patients completed the therapeutic program receiving the 4 infusions of RTX. ORR and CR were achieved in 29 (60%) and 19 (40%) patients, respectively. Univariate logistic regression showed that CR was associated with weight OR=0.95, CI95%[0.91;0.99] and age OR=0.96, CI95%[0.93;0.99], showing that CR probability decreases with age and weight increases. No association was found out with ORR. In the stepwise logistic regression only weight was associated with CR, OR=0.95, CI95%[0.91;0.99]. In responding patients, the median TTR and TCR were 35 days (range: 7-112) and 51 days (range: 7-150), considerably longer than those observed with standard dose in patients with similar characteristics (Haematologica 2003;88:538). The median time of observation, in responding patients, was 18 months (range 3-41 months). Sixteen out of 29 responding patients (55%), 10 out of 19 CR (53%) and 6 out of 10 PR (60%), relapsed and 14 needed further treatments. The cumulative RFS and TFS probabilities were 61% and 70% at 12 months and 45% and 51% at 24 months, respectively. Overall, therapy was well tolerated and only 2 patients experienced mild chills during the first infusion of rituximab. One patient, 1 month after the end of Rituximab, developed a transient interstitial pneumonia. No other infectious, haematological or extra-hematological complications were documented during follow up. *Conclusions.* If compared with previous results observed with standard dose RTX, in ITP, salvage therapy with low dose RTX: i) seems to lead to similar initial response rate; ii) has longer TTR and TCR; iii) yields to worse long term effect with higher incidence of relapses.

0191

SAFETY AND EFFICACY OF VELAGLUCERASE ALFA IN PATIENTS WITH GAUCHER DISEASE TYPE 1 PREVIOUSLY TREATED WITH IMIGLUCERASE: 1-YEAR, MULTICENTER, PHASE III CLINICAL TRIAL

A Grabowski,[1] G Pastores,[2] R Mardach,[3] C Eng,[4] L Smith,[5] P Fernhoff,[6] J Charrow,[7] M Heisel-Kurth,[8] N Longo,[9] W Rhead,[10] P Harmatz,[11] A Mehta,[12] P Giraldo,[13] A Tylki-Szymanska,[14] E Crombez,[15] A Zimran[16]

[1]Cincinnati Children's Hospital Medical Center, Cincinnati, USA; [2]NYU School of Medicine, New York, USA; [3]Kaiser Permanente, Los Angeles, USA; [4]Baylor College of Medicine, Houston, USA; [5]Children's Mercy Hospital, Kansas City, USA; [6]Emory University, Decatur, USA; [7]Children's Memorial Hospital, Chicago, USA; [8]Children's Hospitals of Minnesota, Minneapolis, USA; [9]University of Utah, Salt Lake City, USA; [10]Children's Hospital of Wisconsin, Milwaukee, USA; [11]Children's Hospital Oakland, Oakland, USA; [12]Royal Free Hospital, London, UK; [13]Hospital Universitario Miguel Servet, Zaragoza, Spain; [14]Children's Memorial Health Institute, Warszawa, Poland; [15]Shire Human Genetic Therapies, Cambridge, USA; [16]Shaare Zedek Medical Center, Jerusalem, Israel

Background. Gaucher disease is caused by a deficiency in the enzyme glucocerebrosidase, leading to progressive accumulation of glucocerebroside within macrophages and subsequent tissue and organ damage, typically of the liver, spleen and bone marrow. Enzyme replacement therapy (ERT) reduces organomegaly and improves hematological parameters, and thus remains the preferred treatment for Gaucher disease. Imiglucerase, a recombinant enzyme produced in Chinese hamster ovary cells, has been used for treatment of Gaucher disease for some years, while velaglucerase alfa is a recently developed replacement enzyme, and is produced by gene activation in a human fibroblast cell line, with an identical amino acid sequence to the naturally occurring protein. *Aims.* To examine the safety of every other week dosing of velaglucerase alfa in patients with Gaucher disease type 1 previously receiving ERT with imiglucerase, and to evaluate changes from baseline to Month 12 in hemoglobin concentration, platelet count, and liver and spleen volume. *Methods.* In this open-label, 12-month study, patients at least 2 years of age were eligible to receive velaglucerase alfa at a dose equal to their prior imiglucerase regimen, with the infusion administered over 1 hour. Patients were eligible to receive home therapy. All patients gave informed consent. *Results.* Patients were enrolled in the US (11 sites), Europe (3 sites) and Israel (1 site). Of 41 patients enrolled, 40 received study drug (18 male, 22 female; age range, 9-71 years, 25% <18 years). Four patients had been previously splenectomized. Median prior imiglucerase use was 67 months (range 22-192 months); three patients tested positive for anti-imiglucerase antibodies prior to receiving velaglucerase alfa. Velaglucerase alfa doses were: ≤22.5 U/kg (n=14), 22.5-37.5 U/kg (n=12), 37.5-52.5 U/kg (n=7), and >52.5 U/kg (n=7). Velaglucerase alfa was generally well tolerated with most adverse events of mild or moderate severity. No patient experienced a life-threatening adverse event, 7 severe adverse events were reported in 5 patients, and 5 treatment-emergent serious adverse events were reported in 4 patients. One patient (in the 15 U/kg group) experienced an anaphylactoid reaction that led to discontinuation; no other patients discontinued due to adverse events. No patients developed IgG antibodies to velaglucerase alfa, including the 3 patients who tested positive for anti-imiglucerase antibodies at screening. Clinical parameters (hemoglobin concentration, platelet counts, and liver and spleen volume) were sustained at therapeutic levels through 1 year of velaglucerase alfa treatment (Table).

Table. Clinical parameters.

	n	Baseline median	Mean change or % change from baseline to month 12	90% CI	Clinically significant cutoffs
Hemoglobin (g/dL)	40	10.8	–0.1	–0.3, 0.1	–1, 1
Platelet count (x10^9/L)	40	162	7.0%	0.5%, 13.5%	–20%, 20%
Normalized liver volume (% of body weight)	40	1.9	0.0%	–2.6%, 2.6%	–15%, 15%
Normalized spleen volume (% of body weight)	36	0.5	–5.6%	–10.8%, –0.4%	–15%, 15%

Conclusions. Adult and pediatric patients with Gaucher disease type 1, who were previously treated with imiglucerase for a minimum of 6 months, were successfully transitioned to velaglucerase alfa, with stability in clinical measures of disease over 12 months' treatment with velaglucerase alfa.

0192

EFFECT OF INDIVIDUALIZED ELTROMBOPAG DOSING ON PLATELET RESPONSE IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA

R Stasi,[1] O Meyer,[2] S Vasey,[3] A Brainsky[3]

[1]St George's Hospital and Medical School, London, UK; [2]Institute of Transfusion Medicine, Charité, Berlin, Germany; [3]GlaxoSmithKline, Collegeville, USA

Background. In the chronic idiopathic (immune) thrombocytopenic purpura (ITP) phase 2 dose-finding study, TRA100773A, eltrombopag effectively raised platelet counts in a dose-dependent manner with 70% and 81% of patients responding (platelet counts ≥50,000/μL) at 50 mg and 75 mg, respectively. The relationship between eltrombopag dose and platelet response allowed subsequent studies to individualize dose based on platelet response. *Aims.* To assess the effect of individualized eltrombopag dose modifications on platelet response in two phase 3 studies (a 6-week study [TRA100773B] and a 6-month study [RAISE]) in adult patients with chronic ITP. *Methods.* Patients with chronic ITP and platelet counts <30,000/μL who failed ≥1 previous treatment received the standard of care and were randomized to either placebo or eltrombopag at a starting dose of 50 mg daily. For patients who did not respond to eltrombopag 50 mg, the dose was increased to 75 mg on or after day 22. In the RAISE study, patients who achieved platelet counts >200,000/μL on eltrombopag 50 mg daily had their dose reduced to ≤25 mg. *Results.* In 46% (35/76) of patients in TRA100773B, the dose of eltrombopag was increased from 50 mg to 75 mg for insufficient platelet response (<50,000/μL); 31% (11/35) subsequently responded to 75 mg. In RAISE, patients who did not achieve platelet counts ≥50,000/μL on eltrombopag 50 mg had the dose increased to 75 mg. From day 29 to the end of treatment, the percentage of patients receiving the 75 mg dose ranged from 29% to 53%. In RAISE, patients who achieved platelet counts >200,000/μL on 50 mg were downtitrated to ≤25 mg. Throughout the study, approximately 20% of the patients at each visit were on a ≤25 mg dose. The percentage of patients responding relative to the doses received at each visit is shown in the Figure: (1) the proportion of patients responding on the 25 mg dose was >70% for the majority of visits because only patients who had achieved a platelet count response of >200,000/μL received the dose decrease, and (2) the proportion of patients responding on the 50 mg dose was 50% at day 22 and >70% for the majority of the remaining visits. As in TRA100773B, only patients who failed to respond to the 50 mg dose were considered for a dose increase to 75 mg; therefore, a subpopulation of harder-to-treat patients was exposed to the 75 mg dose. Despite this, response to eltrombopag 75 mg was observed after 1 week in >15% of patients and in 30% to 46% of patients throughout the remainder of the 6-month study. *Conclusions.* Individualized dosing allowed patients sensitive to eltrombopag to receive a lower dose while enabling patients who did not achieve target platelet counts to receive a higher dose. Dose increase can result in a higher number of patients achieving an increased platelet count level over a 6-month period.

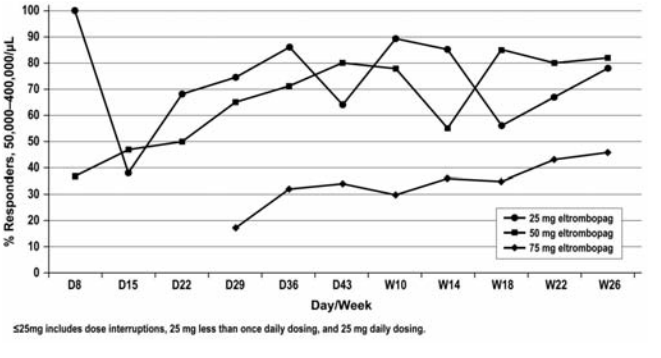

Figure. Proportion of responders by dose at each nominal isit.

0193

LOW DOSES OR HIGH DOSES OF PREDNISONE FOR CHILDREN AND ADOLESCENTS WITH UNTREATED SEVERE IDIOPATHIC THROMBOCYTOPENIC PURPURA: RESULTS OF A RANDOMIZED STUDY

F Giona,[1] A Barone,[2] G Palumbo,[1] ML Moleti,[1] AM Testi,[1] A Piciocchi,[3] C Santoro,[1] A Amendola,[4] MG Mazzucconi,[1] M Vignetti,[1] R Foà,[1] F Mandelli[3]

[1]*Sapienza University, Rome, Italy;* [2]*Hospital of Parma, Parma, Italy;* [3]*GIMEMA Foundation, Rome, Italy;* [4]*S. Carlo Hospital, Potenza, Italy*

Background. Management of children with newly diagnosed idiopathic thrombocytopenic purpura (ITP) is still debatable, as well as the dosage of corticosteroids in symptomatic patients. *Aims.* This single center prospective randomized study was designed to evaluate the short, medium and long-term efficacy of treatment with two different doses of Prednisone (PDN) in children with untreated severe ITP. *Methods.* Previously untreated ITP patients aged >12 months to <20 years, with platelets (PLTs) <20,000/mmc with or without bleeding or PLTs >20,000/mmc with bleeding were stratified by age (<10 and >10 years) and randomized to receive PDN 0.25 mg/kg/day (Arm A) or PDN 2 mg/kg/day (Arm B) for 3 weeks, stopped during the fourth week. Informed consent was obtained in all cases. Treatment evaluation was performed: at the 3rd, 4th and 8th week (short time), 6th and 12th month (medium time), 5th year and in October 2009 with a follow-up questionnaire (long-term). Treatment response was defined as: complete (CR) with PLTs >150,000/mmc, partial (PR) with PLTs ≥50,000 and <150,000/mmc; no response (NR) with PLTs <50,000/mmc; relapse was defined when PLTs decreased <50,000/mmc in patients in CR or PR. *Results.* From March 1987 to February 1999, 91 patients (40 males, 51 females) with a median age of 9.6 years (range: 16 months-19.11 years) were randomized into 2 groups at our Center in Rome: 47 in Arm A and 44 in Arm B. Overall, 73 patients (80%) had PLT counts <20,000/mmc, 85 (93%) presented bleedings, 38 (42%) had a history of viral infections or vaccinations, 42 (46%) had taken drugs; 8 patients (9%) were hospitalized. As shown in Table 1, the short-term evaluation showed response in 37/44 patients (84%) belonging to Arm B compared to 12/43 patients (28%) in Arm A (P<0.01) at the 3rd week. At the 8th week the response increased to 56% in Arm A, compared to 79% in Arm B (P 0.06). Follow-up response showed no differences between Arms A and B at the 6th and the 12th month. Time to response ranged from 5 days to 18 months in Arm A and from 5 days to 5 months in Arm B (P<0.01). Five patients (Arm A) were lost to follow-up; 25/81 (31%) (Arm A: 14; Arm B: 11) relapsed after a median of 11 months (range: 2-88); 13 underwent splenectomy after 9 months to 10 years (Arm A:9; Arm B:4); 14/86 (16%) (Arm A: 8; Arm B: 6) developed an autoimmune disorder. At the 5th year, overall responders were 39/46 (85%) in Arm A and 42/43 (98%) in Arm B (P=0.01). In October 2009, 43/44 contacted patients agreed to be interviewed (median time from diagnosis: 17.6 yrs): 38/43 patients (88%) were in CR, equally distributed in Arms A and B. No long-term side effects were observed. *Conclusions.* In our study high dose corticosteroids induce a rapid PLT count increase and long-term response in ITP children. Otherwise, the different PDN dosages does not seem not to affect the medium response time, relapse rate, subsequent splenectomy and development of autoimmune disorders.

Table 1.

Evaluation Time	N° of Responders (CR + PR)/ Evaluable patients (%)		N° of NR (%)		p value
	Arm A	Arm B	Arm A	Arm B	
3rd week	12 (7+5)/ 43 (28%)	37 (25+12)/ 44 (84%)	31/43 (72%)	7/44 (16%)	<0.01
4th week	16 (7+9)/ 43 (37%)	35 (21+14)/ 43 (81%)	27/43 (63%)	8/43 (19%)	< 0.01
8th week	24 (12+12)/ 43 (56%)	33 (21+12)/ 42 (79%)	19/43 (44%)	9/42 (18%)	0.06
6th month	26 (19+)/ 42 (62%)	30 (22+8)/ 42 (71%)	16/42 (38%)	12/42 (29%)	N.S.
12th month	33 (22+11)/ 40 (83%)	34 (25+9)/ 41 (83%)	7/40 (17%)	7/41 (17%)	N.S.
5th year	39/46 (85%)	42/43 (98%)	7/46 (15%)	1/43 (2%)	0.01

THE ROLE OF RETICULATED PLATELETS IN THE ASSESSMENT OF THROMBOCYTOPENIA AETIOLOGY

AT Simões,[1] L Casalinho,[2] R Barreira,[1] A Alves Pereira,[1] J Ferreira,[1] AC Oliveira,[1] AP Gonsalves,[1] MA Marques,[1] M Duarte,[1] R Salvado,[1] ML Ribeiro[1]

[1]*Centro Hospitalar de Coimbra, EPE, Coimbra, Portugal;* [2]*Escola Superior de Tecnologia da Saúde, Coimbra, Portugal*

Background. Reticulated platelets (RP) are platelets recently released from the bone marrow, containing more cytoplasmic RNA components than mature platelets. RP reflect the bone marrow thrombopoietic activity and is a useful new hematology parameter to distinguish thrombocytopenias caused by enhanced destruction of platelets from the hypoplasic thrombocytopenias. *Aims.* We present the RP evaluation in peripheral blood samples from patients with destructive thrombocytopenias. *Methods.* Thirty patients with thrombocytopenia: 6 Disseminated Intravascular Coagulation (DIC) (4 doing treatment); 18 Idiopathic Thrombocytopenic Purpura (ITP) (12 doing treatment); 6 thrombocytopenia of unknown cause (2 doing treatment). Control group: 15 healthy subjects. Platelet counts were performed on CELL-DYN ® Sapphire haematology analyzer using optical and immunologic (CD61) methodology. Reticulated platelet counts were done after staining with CD4K 530. SPSS 15.0 was used for statistical analysis. *Results.* Thrombocytopenic patients had a mean platelet volume (MPV) higher than control group (11 fL ±3.2 and 8.7 fL±1,2, respectively). A negative correlation (r = - 0.632) was observed between Optical Platelet (PLTo) and MPV. RP number was higher in the patient group than in the control group (8.3×10^9/L ±4.2 and 6.6×10^9/L ±1,9 respectively) as well as the RP percentage: 22.9% (minimum 1.7; maximum 98.6) vs the control group: 2.8% (minimum 1.3; maximum 4.7). Student's dependent samples t-test for the RP of the untreated patients group vs control group counts was: means difference=33.761; t=3.161 e P=0.0091. A negative correlation (r=-0.643) was found between PLTo and RPs counts. The untreated patients (n=12), irrespective of the pathology, had much higher RPs than patients already being treated (n=18) with appropriate therapeutics for each disease (mean 48.8%; minimum 6.5; maximum 98.6; and mean 6.9%; minimum 1.7; maximum 26.1, respectively). The correlation between CD61 and PLTo counts was very good (r=0.996). *Conclusions.* Patients with destructive thrombocytopenia, when compared with normal controls, have differences in the platelet size and in RP counts, and the ranges depend on the thrombocytopenia severity. Thrombocytopenic patients had increased MPV, as well as RPs, which can be explained by the fact that bone marrow, trying to compensate a low platelet number, releases more immature platelets with a higher MPV. PLTo and CD61 counts have a very strong correlation, showing that monoclonal CD61 marker is not necessary in these cases, bringing an economic benefit. A significant statistical difference was observed between non treated patients group RPs and control group. The parameter RP can be a valuable diagnostic tool in distinguishing thrombocytopenias resulting of enhanced destruction from hypoplasic thrombocytopenias, due to its simplicity, ready availability, leading to less invasive procedures with economical benefits. However, further complimentary studies should be performed.

0195

MANAGEMENT OF RELAPSED ADULT IMMUNE THROMBOCYTOPENIC PURPURA: LONG-TERM RESULTS

C Lalayanni, S Tsimperis, A Papalexandri, P Baliakas, C Apostolou, D Mallouri, R Saloum, A Anagnostopoulos, A Fassas

Hematology Department - BMT Unit, G. Papanikolaou Hospital, Thessaloniki, Greece

Background. Adult immune thrombocytopenic purpura (ITP) is mostly a chronic disease and a considerable portion of patients experience recurrent relapses. Second-line treatment for these patients will require various treatment modalities including splenectomy. *Aims-Methods.* A total of 258 cases of patients with ITP who have been treated in our department over the past decade were reviewed retrospectively for response to second-line treatment modalities. *Results.* Of 258 cases referred, 186 newly diagnosed patients, with a median age of 51 years, required first-line therapy. Corticosteroids were used in 161 of them (87%) resulting in a complete (CR) and partial response (PR) rate of 65% and 19%, respectively. Mean and median duration of response were 43 and 16 months, respectively. Of the 186 initially treated

patients, 114 received second-line treatment. Forty eight patients were re-treated with corticosteroids and response rates were CR: 54% and PR: 23%, with a mean duration of second remission of 18 months and a median of 12 months. Corticosteroids as third (or higher) line of treatment were used in 40 patients with CR: 45% and PR: 20%; mean and median duration of response were 21 and 12 months, respectively. Response rates to corticosteroids did not exhibit significant differences between lines of treatment. A decreasing tendency in response duration was observed, but without statistical importance (Pearson correlation -0.034, P=0.8). Thirty-nine patients underwent splenectomy with a high response rate, 92% (36/39). Thirteen of these (36%) relapsed at a median of 4 (1-160) months. The 5-year response probability was 64% with a median duration of response 120 months (95% CI: 60-180). Five patients who relapsed after splenectomy responded to low-dose steroids. Rituximab was administered in 32 patients as a second or higher line of treatment in a dose schedule of 375 mg/m^2 weekly for 4 weeks. A 60% CR rate (19/32) was noted, with a mean and median response duration of 31 and 39 months, respectively (95% CI: 24-55). Ten patients (31%) maintained long term (2 to 5 years) responses to Rituximab. Re-administration of the drug in 3 cases resulted in new responses, of similar duration. No long-term side effects were observed. Vinca alkaloids (vicristine/vinblastine) were used in 46 patients. Half of them, showed some degree of short response (median 5 months). Ten patients received danazol, with a response rate of 58% which was sustained on treatment only. A small number of relapsed patients received other forms of treatment: anti-Rhesus globulin (3pts.), cyclosporine (3pts.), cyclophosphamide (5pts.) and thrombopoetin analogues (2pts). *Summary/Conclusions.* Among the usual second-line treatments for ITP, splenectomy still shows the highest response rates and longest response duration. Steroids are effective in relapsed ITP but the response is short. Rituximab can induce long-term responses in a subset of patients, without significant toxicity. Thrombopoetin analogues still require longer observation periods.

0196

HROMBOCYTOPENIA AND PLATELET INDICES IN SEPTIC NEONATES

K Kefala-Agoropoulou, I Evdoridou, K Sarafidis, E Diamanti, V Soubassi, V Drossou

[1]*st Neonatology Department, Aristotle University, Hippokration Hospital Thessaloniki, Greece*

Background. Severe thrombocytopenia (PLT 0-30k/μl) is a common finding in septic neonates with the severity depending on the type of sepsis. Platelet indices (platelet distribution width-PDW, mean platelet volume-MPV, plateletcrit-PCT) may contribute to diagnosis and follow-up of sepsis. *Aims.* To evaluate the incidence of thrombocytopenia and the changes of the platelet indices in septic neonates in relation to the causative microorganism [gram-positive (gram+) and gram-negative (gram-)] and the gestational age. *Methods.* 154 neonates with sepsis (94 gram+, 60 gram-) were studied. Platelet count and indices were recorded on the day of positive (time 1) and the day of negative blood culture (time 2) as well as at the minimum platelet count (nadir of thrombocytopenia)(time NAD), and they were correlated with the GA and the type of sepsis (gram+ and gram-). *Results.* 99/154 neonates (46/94 gram+, 53/60 gram-) developed thrombocytopenia, that was severe in 39/99 (31/39 with Gram- sepsis). On time 1, 13 neonates had already severe thrombocytopenia (10/13 with gram- sepsis). Severe thrombocytopenia was associated with unfavorable outcome in both gram+ and gram - sepsis (P=0.02). The NAD was 2,85 days (SD 2,27) in gram+ sepsis and 3,076 days (SD 2,86) in gram- sepsis. In all GA groups, PDW levels were significantly lower in gram- sepsis (mean 17,77%; SD 1,47) than in gram+ sepsis (mean 18,74%; SD 1,91) (P=0.05). Also, MPV was lower in gram- sepsis (mean 9,45fl; SD 1,39) than in gram+ sepsis (mean 11,03fl; SD 2,72). Significantly lower values were observed in neonates with GA 32-36 weeks (P=0.02). PCT was significantly lower in gram-sepsis. *Conclusions.* Severe thrombocytopenia is more common in gram-sepsis, especially in neonates with birth weight <1000 g. It may persist despite the return of blood cultures to negative and it is associated with unfavorable outcome. In gram- sepsis, platelets remain small with normal to low levels of PDW and MPV, whereas in gram+ sepsis they tend to be large as PDW and MPV levels increase. Thus, neonates suffering gram+ sepsis possibly are able to manage thrombocytopenia better than neonates with gram- sepsis who are at high risk of developing severe hemorrhagic manifestations.

0197

INCIDENCE AND EPIDEMIOLOGYC CHARACTERISTICS OF ITP (IMMUNE THROMBOCYTOPENIA) IN ASTURIAS (SPAIN)

M Fernández Rodríguez,[1] A Bernardo-Gutierrez,[2] I Soto-Ortega,[2] J Corte-Buelga,[2] M Fernandez-Urgelles,[2] M Rodriguez-Pinto[2]

[1]*Huca, Oviedo, Spain;* [2]*HUCA, Oviedo, Spain*

ITP is considered the most frequent cause of isolated thombopenia. Very few studies are found in the bibliography about the incidence of this illness and none are found in our country. Those which are at hand not always use the same criteria and nomenclature. Recently the EHA thrombopenia group has published an agreement for the standardization of the terminology in this patients. Given all that and in accordance with the nomenclature suggested by the EHA thrombopenia group, we have planned the research of the patients with isolated thrombopenia who come to our department. *Objectives.* to determine the incidence of isolated thrombopenia and ITP in the asturian population in the IV sanitary area. To analyse which diagnosis have derived from the research on this patients. To describe the socio-demographic and clinical characteristics of patients with isolated thrombopenia and ITP. *Methods.* descriptive and retrospective study of the patients who came for the first time to be treated as an out-patient for isolated thrombopenia for a period of three years excluding those under 18 years old. The data were collected in an Excel data base and were analysed with an statistical package SPSS. *Results.* Incidence of isolated thrombopenia: 138.6/million people/year. Incidence of ITP: 66.8/million people/year. Number of cases of isolated trombopenia: 138. Mean age: 56.8 years old. 73 males/ 65 females. Derived diagnosis: primary ITP: 48, ITP linked to autoinmune disease: 15, ITP induced by drugs: 3, hepathopaty: 19, infection: 8, hemathological illness: 7, transitory thrombopenia non subsidiary: 5, macrothrombocitopenia: 2, bone marrow toxicity: 2, splenic abduction: 1, multifactorial: 1, in process of diagnostic: 6. Total cases of ITP: 66. Mean age: 54.1 years old. Distribution by sex according to age: >60 years 17 males/10 females; <60 years 14 males/ 25 females (P=0.02). Casual diagnosis in 28.78% of the cases. The presence of haemorrhage at the moment of the diagnosis was meaningfully bigger in patients with 20×10^9 platelets/L than in those of bigger numbers (purple 94.7%, others 21.1%). Treatment: corticoids 34.8%, gammaglobulins: 7.9%, splenectomy: 3%, transfusions 4.5% and others 12.1%. In the last visit 39.9% were found in complete response, 57.57% in response and 3.03% corticoid-dependents. Comparing ITP with other thrombopenias: they present more haemorrhage (purple), fewer number of platelets at the time of the diagnosis and bigger percentage of antiplatelet antibodies. Primary ITP with respect to the autoinmune associated one, presents more purple and fewer numbers of of platelets at diagnosis. *Conclusions.* The incidence of isolated thrombopenia in our study is 138.6/million people/year and of ITP is 66.8/million people/year, ligthly superior to the published. In our series ITP is the main cause of isolated thrombopenia; it is more frequent among women in young population and among men in population older than 60 years old. 28.8% are accidental diagnosis. With respect to other thrombopenias ITP has fewer platelet counts at the time of the diagnosis, more frequency of purple and bigger percentage of antiplatelet antibodies.

0198

NATURAL COURSE OF CHILDHOOD CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA

YJ Shim,[1] KS Lee,[1] HS Ahn,[2] TJ Hwang,[3] JY Kim[4]

[1]*Kyungpook National University Hospital, Daegu, South-Korea;* [2]*Seoul National University Hospital, Seoul, South-Korea;* [3]*Chonnam National University Hospital, Gwangju, South-Korea;* [4]*Chungbuk National University Hospital, Cheongju, South-Korea*

Background. Acute idiopathic thrombocytopenic purpura (ITP) is common disorder in childhood with favorable prognosis. But about 20% of ITP children have persistent thrombocytopenia under 150,000/μL over 6 months (chronic ITP). There is no drug for cure of chronic ITP so far despite of various remedies including steroid, immunoglobulin (Ig), anti-D Ig, and rituximab. *Aims.* We analyzed the natural course of childhood chronic ITP after long term follow up in order to predict the prognosis of them. *Methods*. We reviewed the medical records of chronic ITP children from 1988 to 2009 in Kyungpook National University Hospital. We excluded the patients who had secondary causes of thrombocytopenia like lupus, hepatitis, aplastic anemia, hematologic malignancy, or von Willebrand disease. *Results.* There were total 244 ITP children and 59 among them (24.2%) were chronic (male: female = 30:29) in spite of

being treated with steroid, Ig, or anti-D Ig. Two underwent splenectomy, so 57 children were involved in this study. The initial platelet count was mean 23,000/μL (3,000/μL~91,000/μL) and their age at diagnosis was 5.4 (0.4~14.7) years. The mean follow up period was 5.2 (0.7~16.8) years. We classified them into 3 groups (NP, normal platelet count group; LP, low number of platelet but over 50,000/μL group; VLP, very low platelet level under 50,000/μL group) according to their last blood tests after long term monitoring. Finally, 21 of 57 chronic ITP children (36.8%) were affiliated to NP, and their last platelet count was 207,000/μL (150,000/μL~317,000/μL). In process of time, NP was increased (10.3% after 2 years, 27.6% after 4 years, and 36.2% after 8 years of observation). The mean timescale for recovering was 3.5 (0.7 ~ 8.3) years and the mean age at cure was 8.6 (1.2~18.6) years. And they were tracked for mean 5.2 (0.9~12.2) years. Other 20 children (35.1%) were belonged to LP and their last number of platelet was 81,000/μL (50,000/μL~128,000/μL). The other sixteen children (28.1%) were VLP. Their mean platelet level at diagnosis (15,000/μL, ranging from 4,000/μL to 46,000/μL) was lower in comparison with those of NP (25,000/μL) and LP (27,000/μL). And their mean tracing period (3.9 years, ranging from 0.8 to 15.8 years) was shorter than NP (5.2 years) and LP (6.4 years). So it is necessary to observe VLP closely for some years ahead. Their last platelet count was 24,000/μL (9,000~45,000/μL). *Conclusions*. Among chronic ITP children, 36.8% were recovered after long term follow up and total 71.9% showed the platelet count over 50,000/μL without any problems in everyday life. Therefore it is important to examine them regularly over several years, and perform splenectomy selectively.

HIGH DOSE DEXAMETHASONE AS FRONT LINE THERAPY FOR ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA

F Zaja,[1] ML Battista,[2] S De Luca,[3] S Volpetti,[3] M Medeot,[2] S Buttignol,[2] A Sperotto,[2] F Patriarca,[2] L Marin,[2] R Fanin[3]

[1]Azienda Ospedaliera S. Maria Misericordia, Udine, Italy; [2]Clinica Ematologica, DIRM, Azienda Ospedaliera Universitaria S. M Misericordia, Udine, Italy; [3]Clinica Ematologica, DIRM, Azienda Ospedaliero Universitaria, Udine, Italy

Background. Prednisone (PDN) 0.5 to 2 mg/kg/d is generally considered the first standard line therapy for adult patients with previously untreated symptomatic Primary Immune Thrombocytopenia (ITP). The therapeutic outcome with PDN is dismal since, despite initial high response rate, most of patients lose their response after PDN withdrawn and suspension, necessitating rescue therapy. In this setting, previous phase II studies highlighted the possible higher therapeutic activity of one or more courses of high dose dexamethasone (HD-DXM; 40 mg/d for 4 days) to achieve and maintain hematological sustained remission. In particular, a recent report (Blood 2007;109:1401-7) indicated that three or four bi-weekly HD-DXM courses may provide 85% initial response rate and 60% relapse-free survival at 15 months in adult patients (≥18 years). *Aims.* To evaluate the activity and safety of HD-DXM in newly diagnosed adult patients with ITP. *Methods.* Twenty patients, median age 44 years (range 19-74), with previously untreated symptomatic ITP were treated prospectively with oral HD-DXM 40 mg/d for 4 consecutive days to be repeated every 15 days for three total courses. Patients median baseline platelet count was 10×10^9/L. Response assessment was evaluated considering the rate of initial overall and complete response (OR, CR; platelet level ≥ 50×10^9/L and ≥100×10^9/L after the end of the third HD-DXM course) and the relapse rate. *Results.* Fifteen patients completed the therapeutic program as initially scheduled while 5 had an early interruption because of insufficient response and need of other therapy. Ten, 4 and 2 patients necessitated further steroids or IVIG administration during the interval between the three HD-DXM courses. The rate of initial OR and CR was 40% each (8/20). The median period of observation in responding patients was 8.5 months (range 1-25). Two out of 8 responder patients relapsed; therefore 6 out of the initial 20 patients (30%) achieved and maintained response. One patient developed pneumonia during HD-DXM while no other relevant side effects were documented. *Conclusions.* In this single institution experience, treatment with HD-DXM did not seem to significantly improve ITP outcome if compared to the results expected with standard steroid therapy .

0200

PREDICTION OF COURSE OF ITP IN CHILDREN

T Uglova, O Krasko

BRCPOH, Minsk Region, Belarus, Republic of Belarus

Immune thrombocytopenic purpura (ITP) is the most common acquired bleeding disorder of childhood. The prognosis of patient's ITP course at time of diagnosis will allow to individualize the therapy. *Material and Methods.* We examined 264 children at age 1-18 years with *de novo* ITP treated at BRCPOH. All patients received written information about the study and gave informed consent. Level of circulating $CD3^+$, $CD3^+HLA^-DR^+$, $CD4^+CD8^-$, $CD4^-CD8^+$, $CD19^+$, $CD16^+CD56^+$, $CD3^+CD16^+CD56^+$ lymphocytes were measured at diagnosis in all patients by flow cytometric analysis. Serum concentration of IgG, IgM, IgA was determined by nephelometric method. Serum concentration of total IgE was determined by chemiluminescence's technique with the use of test-system of anti-IgE-monoclonal antibodies. To build prediction rules within subgroups decision tree technique was applied. *Results.* There were 126 boys and 138 girls in the survey. There were 147 children (55,6%) with the acute form of disease (group I) and 117 children (44,4%) succeedingly developed chronic form of disease (group II). Median of age of children of group I is 3,5 years, group II - 7,5 years. Relative risk of developing chronic ITP in subgroups with age ≥6 years is 2,05 (1,23÷3,44) (F-test (two-tailed), P<0.01). Absolute and relative number of B-lymphocytes is higher at children of group I in comparison to the children of group II (P<0.01). We did not find significant differences in the presence of IgG, IgM, IgA at children of the analyzed groups. Another important fact is the significant increase of concentration of IgE at children of group II in comparison to group I (P=0.000006). *Conclusion.* We developed the decision-making model of prediction of the course of *de novo* ITP at children: Acute ITP: 1) at boys older than 6 years old with initial total serum IgE less than 70 ME/l; 2) at girls older than 6 years with initial total serum IgE than 70ME/L and IgG less than 12 g\L; 3) at children of 1-6 years old with initial total serum IgE less than 35ME/l and $CD19^+$cells more than 12%; 4) at girls of 1-6 years old with initial total serum IgE less than 35ME/L and $CD19^+$cells less than 12%; 5) at children with initial total serum IgE less than 60ME/l and $CD19^+$cells more than 12% and platelet count on Day 28 less than 150×10^9/L; 6) at children with initial total serum IgE less than 60 ME/l and platelet count on day 28 more than 150×10^9/L. Chronic ITP: 1) at children older than 6 years old with initial total serum IgE more than 70 ME/l; 2) at children of 1-6 years old with initial total serum IgE more than 35 ME/L ; 3) at girls older than 6 years old with initial total serum IgE less than 70 ME/L and IgG more than 12 g/L; 4) at boys of 1-6 years old with initial total serum IgE less than 35ME/l and CD19+ cells less than 12%; 5) at children with initial total serum IgE less than 60 ME/l, $CD19^+$cells less than12% and platelet count on day 28 less than 150×10^9/L.

0201

EFFICACY AND SAFETY OF SPLENECTOMY IN IMMUNE THROMBOCYTOPENIC PURPURA: RESULTS OF 38 CASES

M Medhaffar,[1] M Abid,[2] B Belhaj,[1] H Bellaaj,[1] N Affes,[2] S Hdiji,[1] N Ajmi,[1] O Kassar,[1] M Beyrouti,[2] M Elloumi[1]

[1]Hematologie Clinique, Sfax, Tunisia; [2]Chirurgie générale, Sfax, Tunisia

Background. Glucocorticoïds are the first-choice treatment of immune thrombocytopenic purpura (ITP), resulting in a good response in 70-80% cases. However, relapses occur in the third of cases. For these and for selected patients with acute refractory ITP, splenectomy may produce a good response. We report the outcome of ITP splenectomized patients. *Patients and Methods.* We retrospectively analysed the data of 38 patients (children and adults) who underwent splenectomy for ITP between 1995 and 2008. For these patients we studied the indication of splenectomy, the time between diagnosis and splenectomy, response to splenectomy and the possible complications related to splenectomy (thrombosis, infection[3DOTS]). *Results.* Between 1995 and 2008 thirty eight patients (11 children and 27 adults) were splenectomized for ITP. The mean time between diagnosis and splenectomy was 24 month. 35 patients had a chronic cortico-resistant or cortico-dependent ITP. Three patients with cortico-resistant ITP were splenectomized two months after the diagnosis: pregnancy (one case) and serious hemorrhagic events (two cases). The overall response rate was 86% (24 adults and 9 children). Two women (8%) and two children (22%) relapsed. They were retreated with Glucocorticoïds and achieved a good persistent response. One patient developed a thrombosis after splenectomy.

We have noted any serious infection during follow-up. *Conclusions.* This study shows that splenectomy is a safe and an effective procedure for chronic ITP with a high rate of good response as described on the litteraure (60-80%). However a long follow-up was needed to detect tardive relapse. Splenectomy is and still the 2nd line choice treatement in our country and further studies were required to establish whether other treatment of chronic ITP, such as anti-D, anti-CD20 and analogue of thrombpoïetine will delay splenectomy.

0202

RITUXIMAB IN IMMUNE THROMBOCYTOPENIC PURPURA: TRANSIENT RESPONSES, LOW RATE OF SUSTAINED REMISSIONS AND POOR OUTCOME OF REFRACTORY PATIENTS

A Aleem,[1] A Alaskar,[2] F Algahtani,[1] M Rather,[2] M Almahayni,[1] A Al-Momen[1]

[1]King Khalid University Hospital, King Saud University, Riyadh, Saudi Arabia; [2]Department of Oncology, King Abdulaziz Medical City, Riyadh, Saudi Arabia

Management of patients with immune thrombocytopenia (ITP) refractory to standard treatment is difficult. Recent studies show that rituximab, a chimeric anti-CD20 monoclonal antibody, is useful in the treatment of ITP. *Methods.* We retrospectively studied 24 patients (16 females) who received 29 rituximab treatments (off label) for relapsed or refractory ITP. *Results.* Nineteen patients had primary (idiopathic) disease and five patients had secondary ITP (3 CLL, 1 NHL, 1 SLE). Patients had received a median of 3 treatment regimens before (range 1-8) and 11 patients had prior splenectomy. Responses were achieved in 19 of 29 (66%) treatments. The median time to response was 3 weeks (range 1-20) from the start of therapy and median duration of response was 13 weeks (range 1 week -55 months). Responses were mostly short lived and after a median follow-up of 22 months (range 2-70), 10 (34%) responses were sustained after 6 months, 7 (24%) responses sustained after one year and only 5 patients continued to have a response at the last visit after 8, 10, 24, 30 and 54 months of follow-up. Previous splenectomy correlated with a poor response (p 0.034). Patients who failed rituximab and had prior multiple treatments including splenectomy, had a poor outcome of further therapies. *Summary.* We conclude that rituximab is well tolerated and is useful in some patients with relapsed or refractory ITP; however, only about one fifth of patients achieved sustained remissions. Patients refractory to rituximab have a poor response to further treatment.

0203

LOW-DOSE RITUXIMAB IN ADULT PATIENTS WITH PERSISTENT/CHRONIC PRIMARY IMMUNE THROMBOCYTOPENIA: A SINGLE CENTER EXPERIENCE

F Biondo, C Santoro, E Baldacci, A Cafolla, MS De Propris, A Guarini, A Leporace, F Torelli, R Foà, MG Mazzucconi

Ematologia, Rome, Italy

Background. It is known that treatment with standard weekly dose of Rituximab (375 mg/m^2) for 4 weeks is effective in primary immune thrombocytopenia (pITP); recent literature data support the use of lower doses of Rituximab in these patients. *Aim.* To investigate the efficacy of low-dose Rituximab in patients with persistent/chronic pITP. *Patients and Methods.* Ten adult pITP patients (5 males, 5 females; median age 40.5 years [19.8-63.8]) were treated with Rituximab (weekly dose 100 mg i.v., for four consecutive weeks). Median time between diagnosis and start of Rituximab was 1.6 years (0.5-12.4). All patients had already received at least one line of therapy (median 2, 1-3): standard-dose prednisone, pulsed high-dose dexamethasone, immunoglobulins, splenectomy. At the start of Rituximab, the median platelet count was 17×10^9/L (5-30×10^9/L). Response definition was as follows: complete response (CR), platelet count ≥100×10^9/L; partial response (PR) >50 <100×10^9/L; minimal response (MR) >30 ≤50×10^9/L; no response (NR) ≤30×10^9/L. After completing therapy, patients were evaluated for platelet count after 1 and 3 months, and thereafter every 3 months. Peripheral blood B lymphocytes were evaluated by flow-cytometry as CD20$^+$ cells before treatment, 1 and 3 months after stopping therapy, and then every 3 months up to recovery. *Results.* One month after the end of Rituximab, all patients were evaluable for response: seven responses (4 CR, 2 PR, 1 MR, 70%) and 3 NR (30%) were observed. At the 3rd month's evaluation, responses were 6 (4 CR, 2 PR 60%), NR were 2 (20%) and relapses were 2 (20%). Median follow-up of all treated patients was 5.5 months (3.3-19.7); median follow-up of all responder patients was 5.5 months (3.3-16.3). At the last control, 6 patients were in persistent responses (4 CR, 2 PR 60%), while 4 were NR. Before starting therapy, all cases were valuable for flow-cytometry studies. The median baseline value of peripheral blood CD20$^+$ B cells was 289.5/μL (85-856). One month after completing treatment, all cases showed absence of circulating CD20$^+$ cells. At the last available control, all patients had still not recovered the baseline CD20$^+$ cells count. Only one side effect a case of influenza-like illness was observed. *Conclusions.* At the last follow-up, 6 out of 10 patients with persistent/chronic pITP (60%) showed a persistent response to low-dose Rituximab (4 CR, 2 PR). The response seems to be independent from the post-therapy CD20$^+$ cells counts. No serious infections were observed during the clinical follow-up. No patient had to stop therapy because of severe side effects.

0204

ADULT IMMUNE THROMBOCYTOPENIC PURPURA: MANAGEMENT AND LONG TERM OUTCOME OF 168 CASES

M Medhaffar,[1] S Hdiji,[1] B Belhaj,[1] H Bellaaj,[1] I Jedidi,[2] N Ajmi,[1] O Kassar,[1] C Kallel,[2] M Elloumi[1]

[1]Hematologie Clinique, Sfax, Tunisia; [2]Hematologic Laboratory, Sfax, Tunisia

Background. Immune thrombocytopenic purpura (ITP) is an acquired disease characterized by an immunological peripheral platelet destruction. ITP occur at any age and had a more chronic evolution in adult. We report the therapeutic results and outcome of adult ITP. *Patients and Methods.* Between January 1995 and December 2008, we retrospectively analyzed the data of 168 adults with ITP diagnosis. The first treatment was Glucocorticoïds: Prednisone® 1 mg/kg/day during 4 weeks followed by a degression, dose and duration were adapted to the elderly and the diabetics. The evaluation at days 28 are complete response (CR) if platelet count is higher than 100 G/L, partial response (PR) if platelet count is higher than 50 G/L and failure if platelet count is lower than 50 G/L. For patient with chronic evolution (up on six month) we evaluated various therapeutic lines such as high dose of glucocorticoïds (bolus of methylpredisolone), Vincristine®, Danatrol® and splenectomy. *Results.* One hundred sixty eight adults (114 women and 55 men) with a median age of 43 years (16 to 100 years) were followed over fourteen year period. One hundred forty two (84%) patients achieved good response (CR+PR) to prednisone®. Fifty one (36%) patients relapsed in a median of 11 months of response. Sixteen patients received bolus of solumedrol in 2nd and 3rd line with 43% PR rate. Five patients received Vincristine® with only one CR. Ten patients received Danatrol® with two persistent CR. Twenty five patients underwent Splenectomy in 2nd, 3rd and 4th line, the response rate was 87%. A chronic evolution was noted in 42% cases particularly in women. Finally, we have noted any death related to thrombopenia or treatement. *Conclusions.* Glucocorticoïds is the first-choice treatement for ITP resulting in a response in 84% as like as reported studies. However relapse occurs in the third of cases. Splenectomy remains the treatement of choice in 2nd line in our country comparing to the cost and results of rituximab. We have noted more frequent chronic evolution particularly in women.

0205

TREATMENT WITH RITUXIMAB IN REFRACTORY ITP PATIENTS. EXPERIENCE AND FOLLOW-UP IN 9 PATIENTS BETWEEN 2005-2009

M Perera, N Navarro, A Suarez, H Luzardo, J Lopez, T Molero

Hospital Universitario de Gran Canaria Dr. Negrin, Las Palmas, Spain

Background. Refractory immune thrombocytopenic purpura (ITP) is defined as persistent severe thrombocytopenia (<20.000 platelets) for more than 3 months and no response to conventional first-line therapies. Despite the fact that splenectomy is still considered the 'gold standard' treatment in many countries for the management of chronic ITP the risk of severe morbidity resulting from surgery or overwhelming post splenectomy infections and late relapse that persists during long-term follow-up represents a major concern. Rituximab could be an effective and safe splenectomy-avoiding strategy in adults with chronic ITP. Responses rates about 40% have been demonstrated with minimal side effects, suggesting it would be an effective first-line therapy in refractory ITP associated with autoantibody-mediated disorders (AD). *Aim.* To retrospectively collect data on refractory IPT patients treated with Rituximab in our Hospital to evaluate the efficacy and safety of this therapy regimen. *Patients and Methods.* 9 adult patients were treated with Rituximab (R) between 2005-2009 (7 female; 2 male). Five patients received Rituximab post splenectomy and four prior to splenectomy.

Three patients were previously diagnosed with AD (1 Sjögren syndrome, 1 systemic lupus erythematosus, and 1 polyserositis). All patients received steroids or intravenous gamma globulin (IVIG) in addition to R in order to maintain adequate platelet levels. Rituximab (375 mg/m^2; Roche France, Paris, France) was infused intravenously weekly for 4 weeks. No complications during the infusion or the follow up time were observed. *Results.* Platelet count greater than 150,000 was considered a complete response (CR), and platelet count greater than 50,000 was a partial response (PR). CR was achieved in 100% (5) of the patients who received Rituximab after splenectomy (Table 1) in 1.6 months. Relapse occurred in 40% (2) of these patients, who then received a second dose of Rituximab. It was well tolerated and they responded again. Only 50% (2) of the patients who received Rituximab before splenectomy (Table 2) achieved CR (they were treated earlier) whereas the other 50% (2) achieved PR and subsequently, 75% of these patients relapsed. One received a second dose of Rituximab and achieved PR, another was splenectomized and is in a real CR and the last one remained refractory. *Conclusions.* in our experience, Rituximab is a good treatment for refractory ITP. According to new guidelines, we also observed that it is achieved more qualitative and long-term responses when it is used after splenectomy. However, it is also an effective treatment for patients who could not be splenectomized. Due to the wide variety of responses in these patients randomized clinical trials in splenectomized and non- splenectomized patients with refractory ITP is needed in order to establish new guidelines.

IMPACT OF CYTOKINE LEVELS ON HRQOL IN PATIENTS WITH ITP

M Pinheiro,[1] J Solomon,[1] P Hazavi,[2] H Liebman,[3] J Bussel[1]

[1]Weill Cornell Medical College, New York, USA; [2]University of Southern California, Los Angeles, USA; [3]University of Southern California-Keck School of Medicine, Los Angeles, USA

Background. Immune ThrombocytoPenia (ITP) is a heterogeneous acquired autoimmune disorder in which antibodies and T cell mediated effects under cytokine influence combine to create variable levels of platelet destruction. In addition to the autoimmune features and presumably explained by them, fatigue-related symptoms are commonly seen in ITP, seem to fluctuate with treatment and often disappear when platelet counts increase. *Aims.* This study investigated potential clinical effects of IL-6, IL-8 and TNF-α levels on ITP patients and correlated these findings with Health Related Quality of Life (HRQoL). *Methods.* Patients with chronic ITP older than 15 years old were enrolled in 2009 at the Platelet Disorders Center at the Weill-Cornell Medical Center, NY. They completed the Short-Form 36 questionnaire (SF-36), a well-standardized instrument and Multidimensional Fatigue Inventory (MFI), a specific fatigue-related questionnaire. Laboratory testing included CBC, immature platelet fraction (IPF), TSH, ferritin, iron + TIBC, ESR, CRP, blood IL-6, IL-8 and TNF-α levels. Non-parametric measures of correlation were performed using the Spearman' rank correlation coefficient and differences between subgroups were analyzed by Mann-Whitney-Wilcoxon test. *Results.* 61 patients with a mean age of 52 years (61% women) were enrolled. The mean platelet counts were 86,000/uL (range of 4,000-352,000/uL). 52.4% had had previous splenectomy and 65.6% were classified as refractory ITP either by failure of response to splenectomy (81%) or relapse (19%). Sixty-six% of the patients were on treatment: 65% Tpo-R agents and 35% 'Other' (5% steroids, 12.5% Rigel, 10% IVIG+solumedrol, 2.5% rituximab and 5% Danazol/Azathioprine). IL-6 serum levels above the upper limit of normal (>1.7 pg/mL) were found in 42.6% of the patients (n=26), and within this subgroup the lowest levels belonged to splenectomized patients. All patients in remission (n=4) had normal levels of IL-6. Statistically significant negative correlations were found between the age and physical function domain of SF36 (P<0.0001). For IL-6 levels, significant negative correlations were found on 5 domains of SF-36 adjusted by BMI, age and gender; and positively for one scale of MFI (see table). ESR was negatively correlated with SF-36 in the same domains as IL-6 (the highest was with physical function; P=0.0097). CRP was only negatively correlated with role emotional domain (P=0.0114). MFI had a positive correlation with ESR on physical fatigue scale (P=0.0011) and reduced activity (P=0.0079) but was not correlated with CRP. Splenectomy status, gender, platelet counts, MPV, IPF absolute, IPF%, ferritin, TSH, IL-8 and INF-alpha were not correlated with other scores. *Summary/Conclusions.* The present study demonstrated that a substantial subset of ITP patients has high levels of IL-6 and these levels were correlated with worse performance on HRQoL measurements. ESR was also correlated with certain scales suggesting that besides thrombocytopenia, ITP may be characterized as a sub-clinical inflammatory state which explain its constitutional symptoms. We conclude that high levels of cytokines such as IL6, derived from the reticuloendothelial system which is chronically activated in ITP, may result in a cytokine-induced behavior including fatigue observed on ITP patients.

Background. Recently, the cytogenetic category "monosomal karyotype"(MK) has been proposed in acute myeloid leukemia (AML) defined by the presence of one single monosomy (excluding isolated loss of X or Y) in association with at least one additional monosomy or structural chromosome abnormality (excluding core binding factor [CBF] AML) (Breems et al. 2008). MK was associated with a dismal outcome. *Aims.* To determine the prognostic impact of MK, in relation to the current World Health Organization (WHO) AML classification. *Methods.* The study included 3,174 adult AML patients (median age, 54.5 years; range, 16-85 years) entered on 5 AMLSG protocols between 1993 and 2008. In 2,832 of the 3,174 (89%) patients cytogenetic analysis could successfully be performed. Data on the mutation status of NPM1 and FLT3 (internal tandem duplication [ITD] and tyrosine kinase domain mutation [TKD]) was available in 2,832 (89%) and 2,604 of 3,174 (82%) patients, respectively. 1,478 of the 2,832 (52%) patients had an abnormal karyotype; after exclusion of isolated losses of sex chromosomes (n=23), CBF AML (n=311) as well as t(15;17) (n=109), 1,035 cytogenetically abnormal cases were considered for further analysis. Median follow-up for survival was 3.7 years. *Results.* 294 (28%) cases exhibited a MK and 348 a complex karyotype defined by ≥3 abnormalities (CK; 34%), with 229 cases categorized as having MK and CK. 138 (47%) MK cases had one autosomal monosomy (AM), 156 (53%) had two or more AM. MK cases harbored the following recurrent genetic abnormalities: inv(3)/t(3;3), n=34 (12%); t(6;9), n=2 (1%); t(v;11q23), n=7 (2%); mutated NPM1, n=4 (1%). In 13 (4%) MK cases, an unbalanced translocation with formation of a derivative chromosome led to a formal monosomy in the ISCN karyotype designation, but in fact without loosing the whole chromosome. In MK patients, complete remission rate was 34%, and 3-year overall survival was 9% (95%-CI, 6-14%). Among patients with CK, the additional presence of a MK was associated with an inferior prognosis (P<0.0001), whereas among patients with MK, the presence of a CK only had a marginal impact on outcome (P=0.03). With respect to the number of AM within the MK category, patients with two or more AM had an inferior outcome compared with one AM (P=0.01). We were interested whether MK retained its prognostic significance when cases with recurrent genetic abnormalities (WHO 2008) and those with derivative chromosomes containing part of lost chromosomes were excluded (MK-R). Again, MK-R conferred a dismal prognosis in patients with CK (P=0.001). In multivariable Cox regression analyses in patients with at least one cytogenetic abnormality (n=1,035), MK-R retained its impact as an independent adverse prognostic factor (HR, 2.0; 95%-CI 1.54-2.60). *Conclusions.* In this large cohort of adult AML patients, MK was an independent adverse prognostic factor, even when cases with recurrent genetic abnormalities or derivative chromosomes were excluded.

0208

PROGNOSTIC IMPACT OF MINIMAL RESIDUAL DISEASE (MRD) MONITORING DURING THERAPY AND FOLLOW UP IN NPM1 MUTATED ACUTE MYELOID LEUKEMIA: RESULTS OF THE AML STUDY GROUP (AMLSG)

J Krönke,[1] R Schlenk,[1] KO Jensen,[1] K Eiwen,[1] M Habdank,[1] D Späth,[1] J Krauter,[2] A Ganser,[2] G Göhring,[3] B Schlegelberger,[3] M Lübbert,[4] M Wattad,[5] T Kindler,[6] H Salih,[7] HG Mergenthaler,[8] K Götze,[9] K Döhner,[1] H Döhner[1]

[1]Internal Medicine III, University of Ulm, Ulm, Germany; [2]Hematology, Hemostasis, Oncology, and Stem Cell Transplantation, Hannover Medica, Hannover, Germany; [3]Institute of Cell and Molecular Pathology, Hannover Medical School, Hannover, Germany; [4]Internal Medicine I, University of Freiburg, Freiburg, Germany; [5]Evangelic Hospital Essen-Werden Hematology, Essen, Germany; [6]Internal Medicine III, Johannes Gutenberg-University, Mainz, Germany; [7]Department of Hematology/Oncology, Eberhard-Karls University, Tübingen, Germany; [8]Department of Oncology, Klinikum Stuttgart, Stuttgart, Germany; [9]Department of Internal Medicine III, Technical University of Munich, München, Germany

Background. Mutations in the *nucleophosmin 1* (*NPM1*) gene represent the most frequent gene mutations in acute myeloid leukemia (AML), with highest incidence (50-60%) in cytogenetically normal (CN)-AML. So far, there are no studies evaluating the prognostic value of *NPM1* mutation (*NPM1mut*) based assessment of minimal residual disease (MRD) in a larger cohort of younger AML patients (pts) enrolled on prospective clinical trials. *Aims.* To evaluate the prognostic value of *NPM1mut* MRD levels in younger (16 to 60 years) AML pts harbouring NPM1 mutations type A, B or D. *Methods. NPM1mut* specific, RNA based real-time PCR was applied to assess MRD in a total of 1100 samples [bone marrow (BM), n=1083; peripheral blood, n=17] from 214 AML pts who were enrolled in the AMLSG 07-04 and AML HD98A treatment trials of the AML Study Group. Dilution series showed a maximum sensitivity of 10-6 and high specificity as no wildtype NPM1 could be detected. *Results.* Pretreatment transcript levels were not associated with clinical characteristics (e.g., age, white cell counts, BM blasts) and did not impact relapse-free (RFS) and overall survival (OS). For evaluation of the prognostic impact of MRD levels during therapy we performed multivariate analysis at several time points during and after treatment. *NPM1mut* levels as continuous variable were significantly associated with RFS and OS after induction I (P=.0024; P=.008), induction II (P<.001; P<.001), consolidation I (P<.001; P<.001) and at the end of treatment (P<.001; P<.001). For the two clinically important MRD checkpoints, namely after double induction and at the end of therapy, achievement of PCR negativity highly discriminated two prognostic groups (P<0.001). In our study molecular relapse during follow up was defined by a threshold value of 500 *NPM1mut*/10^4 abl since some patients in continuous complete remission showed intermittent low *NPM1mut* expression in BM. All 26 pts exceeding this threshold relapsed after a median interval of 61 days (range, 11 to 709 days). However, in 5 pts (10% of all evaluated pts) relapse prediction failed due to inadequate increase of *NPM1mut* expression levels (n=2) or complete loss of the NPM1 mutation at the time of relapse (n=3). *Conclusions. NPM1mut* expression levels during therapy, in particular at early time points (after induction I and II) are of prognostic importance in *NPM1mut* AML. During follow up, a threshold value was defined that allows the early prediction of clinical relapse and may guide preemptive treatment in future clinical trials.

0209

GATA-2 OVEREXPRESSION IS A NOVEL POOR PROGNOSIS MARKER IN ACUTE MYELOID LEUKEMIA PATIENTS

C Vicente,[1] A Conchillo,[1] I Vázquez,[1] MA García-Sánchez,[1] X Cortés,[1] N Marcotegui,[1] MJ Larráyoz,[2] MJ Calasanz,[2] MD Odero[1]

[1]CIMA, University of Navarra, Pamplona, Spain; [2]University of Navarra, Pamplona, Spain

Acute myeloid leukemia (AML) is a heterogeneous group of hematological neoplasias associated with accumulation of acquired genetic alterations and epigenetic changes in hematopoietic progenitor cells. The GATA-2 (3q21) gene codes for a transcription factor with an important role in the hematopoiesis. GATA-2 is widely expressed in progenitor cells and its level gradually declines during cell differentiation. Moreover, GATA-2 is essential for the production and expansion of hematopoietic stem cells, and for their proliferation and survival in adult

bone marrow. There is evidence that GATA-2 deregulation has a role in leukemia, although so far there are few data. Our aim was to investigate the prevalence and prognostic impact of GATA-2 overexpression in AML. We analyze the expression of GATA-2 by real-time quantitative PCR in a series of 259 patients with AML at diagnosis, and evaluated its association with well-known clinical, cytogenetic and molecular prognostic factors. GATA-2 was overexpressed in 97 out of 259 patients (37.5%), confirming that it is a recurrent event in AML; moreover, it was associated with normal karyotype (NK) (45/105, 43%) and 3q aberrations (11/20, 55%). These results prompted us to further study the molecular characteristics of patients with NK. GATA-2 overexpression was significantly associated with FLT3-ITD (58.8% vs. 32.8%; P=0.017) and NPM1 mutations (54% vs. 23.5%; P=0.005). Significant differences were also found when patients were divided into 4 groups according to the mutated phenotype of these genes: both wild type (17.4%), FLT3-ITD+ (36.4%), NPM1+ (36%), and FLT3-ITD/NPM1+ (92%) (P=0.0003). GATA-2 overexpression was also associated with WT1 (49.4% vs. 15%; P=0.005) and EVI1 overexpression (70% vs. 32.7%; P=0.004). In this series, 113 patients received induction therapy and were included in the survival analysis: 55 were male and 57 female, with a median age of 61 years. As expected, significant differences in overall survival (OS) according to age, cytogenetic group, and complete remission rate were found (P<0.01). Patients with GATA-2 overexpression had significant worse OS (P=0.036) and event free survival (P=0.039). In the stratified analysis by age, the prognostic impact of GATA-2 overexpression was particularly high in patients older than 60 years (P=0.040). We also found that OS was significantly shorter in patients with GATA-2 overexpression and no FLT3-ITD, according to the stratified analysis by FLT3-ITD mutations (P=0.022). In the same way, the prognostic impact of GATA-2 overexpression was particularly high in patients with WT1 overexpression (P=0.05). When performing the multivariate analysis, GATA-2 overexpression was an independent prognostic parameter for OS (P=0.043). In conclusion, GATA-2 overexpression is a recurrent molecular event with an unfavorable prognostic impact in AML, especially in patients older than 60 years. Advanced age is the most important prognostic factor for determining outcome in AML, therefore, it is important to identify genetic markers that could categorize cases within this subgroup. Moreover, our results show that GATA-2 deregulated expression is significantly associated with other markers of poor prognosis in AML, and could discriminate a subgroup of patients with worse prognosis in cases with NK AML and no FLT3 mutations.

COMPLEX ABERRANT KARYOTYPE NEWLY DEFINED - THE STRONGEST PROGNOSTIC FACTOR IN ADVANCED CHILDHOOD MYELODYSPLASTIC SYNDROME

G Göhring,[1] K Michalova,[2] H Beverloo,[3] D Betts,[4] J Harbott,[5] O Haas,[6] G Kerndrup,[7] L Sainati,[8] E Bergstraesser,[4] H Hasle,[9] J Starý,[10] M Trebo,[6] M van den Heuvel-Eibrink,[11] M Zecca,[12] E van Wering,[13] A Fischer,[7] P Noellke,[7] F Locatelli,[14] C Niemeyer,[7] B Schlegelberger[1]

[1]Hannover Medical School, Hannover, Germany; [2]Charles University, Prague, Czech Republic; [3]Erasmus University Medical Center, Rotterdam, Netherlands; [4]University Children's Hospital, Zürich, Switzerland; [5]Justus Liebig University, Giessen, Germany; [6]St. Anna Children's Hospital, Vienna, Austria; [7]University Hospital, Odense, Denmark; [8]University of Padova, Padova, Italy; [9]Aarhus University Hospital Skejby, Aarhus, Denmark; [10]University Hospital Motol, Prague, Czech Republic; [11]Sophia Children's Hospital, Rotterdam, Netherlands; [12]IRCCS Policlinico San Matteo, Pavia, Italy; [13]Dutch Childhood Oncology Group, The Hague, Netherlands; [14]Ospedale Bambino Gesù, Rome, Italy

Background. Karyotypic complexity has been reported to be associated with a poor or very poor prognosis. We therefore compared the outcome of children with advanced MDS identified by the traditional definition of complex karyotype, i.e. ≥3 or ≥5 chromosomal aberrations, with that of patients with a monosomal karyotype, a recently described highly unfavorable risk category in adult acute myeloid leukemia (AML). Moreover, we evaluated the prognostic significance of structural complex aberrations, a new definition of complex karyotype by the EWOG-MDS study group. *Aims.* To identify cytogenetic risk factors predicting outcome in children with advanced myelodysplastic syndrome (MDS) treated with or without hematopoietic stem cell transplantation. *Patients and Methods.* Cytogenetic analyses of 192 children prospectively enrolled in studies EWOG-MDS 98 and EWOG-MDS 2006 were centrally reviewed. Subgroups of patients with monosomy 7 or complex karyotypes (≥3 or ≥5 aberrations, monosomal karyotype, structural complex karyotype) were analyzed with respect to overall survival (OS). Structural complex constitutes a new definition of complex karyotype characterized by ≥3 chromosomal aberrations including at least one structural aberration, excluding clonal evolution of monosomy 7. *Results.* Five-year OS in patients with ≥ 3 clonal aberrations which were not structural complex did not differ from that observed in patients with monosomy 7 or a normal karyotype. Of the patients with at least two autosomal monosomies, all but one also had a structural complex karyotype. A monosomal karyotype with at least one autosomal monosomy and one or more structural aberrations that did not fulfill the criteria of structural complex did not predict an unfavorable prognosis. Cox regression analysis revealed the presence of a monosomal and structural complex karyotype to be strongly associated with poor prognosis (Hazard Ratio, HR 4.6, P <0.01). Notably, a structural complex karyotype without a monosomy was associated with a very short 2-year OS probability of 14% (HR 14.5; P <0.01). *Conclusions.* The presence of a structural complex karyotype was the strongest independent prognostic marker predicting poor outcome in children with advanced MDS.

Background. Estimation of BCR-ABL mRNA levels is an important indicator of therapeutic response for patients with chronic myeloid leukemia and Philadelphia-chromosome positive acute lymphoblastic leukemia, but there is substantial variation in the real time quantitative PCR (RQ-PCR) methodology employed, what control gene is used for normalisation and how results are reported. An international scale (IS) has recently been established that is anchored to two key points defined in the IRIS trial: a common baseline (100% BCR-ABLIS) and major molecular response (0.1% BCR-ABLIS). To help propagate and improve the accessibility of the IS we sought to develop internationally accredited BCR-ABL reference reagents. *Aims.* Following an evaluation of candidate cell lines, the aim of the international collaborative study was to manufacture and evaluate a reference material panel comprising four different dilution levels of freeze dried preparations of K562 cells diluted in HL60 cells and assign fixed% BCR-ABL / control gene IS values to each material. *Methods.* Development of the materials was co-ordi-

nated by the UK National Genetics Reference Laboratory (Wessex) in conjunction with the National Institute for Biological Standards and Control (NIBSC). Four dilutions of K562 in HL60 corresponding approximately to 10%IS (BCR/ABL 4 08/198), 1%IS (BCR/ABL 3 08/196), 0.1%IS (BCR/ABL 2 08/194) and 0.01%IS (BCR/ABL 1 08/192) BCR-ABL / ABL were prepared. 3 mL glass ampoules were filled with 1.5 x 106 cells (0.5ml) for freeze drying and approximately 3500 vials of each material were produced. Field trial evaluation of the reagents was performed by 10 laboratories with stable and validated conversion factors (6 European Union, 1 Canada, 3 Asia/Australasia). *Results.* The mean amount of total RNA extracted from the reference material panel was 15.1 µg. The coefficient of variation (CV) of%BCR-ABL / control gene for each reference material indicated that the variability between ampoules was no greater than the variability of the assay on patient samples. Accelerated degradation studies showed that after 10 months of storage there has been a reduction in the BCR-ABL/control gene transcript ratio (the critical unit of minimal residual disease measurement) for ampoules maintained +56°C and +45°C but that at +37°C or below the material was stable. The mean values assigned to the reference materials following conversion to the IS are%BCR-ABL/ABL; 0.0118, 0.1112, 1.1672 and 10.7469,%BCR-ABL/BCR; 0.0195, 0.1753, 1.6627 and 16.3129 and%BCR-ABL/GUSB; 0.0071, 0.0749, 0.8295 and 10.1235. *Summary.* This study indicated that the freeze dried materials were suitable for use as reference materials for the quantitation of BCR-ABL mRNA (b3a2 transcript) using RQ-PCR. The materials were approved as the 1st International Genetic Reference Panel quantitation of BCR-ABL translocation by RQ-PCR by the Expert Committee on Biological Standardization of the World Health Organization in November 2009 and are available from NIBSC (www.nibsc.ac.uk) for the calibration of secondary reference reagents.

0212

HETEROGENEITY OF FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

E Sieni,[1] V Cetica,[2] D Pende,[3] G Griffiths,[4] A Santoro,[5] B Ciambotti,[2] C De Fusco,[6] C Micalizzi,[7] L Moretta,[7] M Aricò[2]

[1]Department Pediatric Hematology-Oncology, AOU Meyer, Florence, Italy, Florence, Italy; [2]Department Pediatric Hematology-Oncology, AOU Meyer, Florence, Italy; [3]Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy; [4]Cambridge Institute for Medical Research, Addenbrooke's Hospital, Cambridge, UK; [5]U.O. Ematologia I, A.O. V. Cervello, Palermo, Italy; [6]Oncoematologia Pediatrica, Ospedale Pausillipon, Napoli, Italy; [7]Istituto Giannina Gaslini, Genoa, Italy

Background. Familial Hemophagocytic Lymphohistiocytosis (FHL) is a rare immune deficiency with uncontrolled inflammation, characterized by fever, hepatosplenomegaly, cytopenia and hemophagocytosis. A similar clinical picture may result from mutations in different genes involved in the cellular cytotoxicity machinery, which function is abolished or severely reduced in the majority of patients. Several disease-related genes have been identified over the last 10 years: PRF1 (FHL2, OMIM 603553), UNC13D (FHL3, OMIM 608898), STX11 (FHL4, OMIM 603552). A fourth gene, STXBP2, was identified very recently as responsible for a defect of Munc18-2 (FHL5, OMIM 613101). A very similar picture has been reported also in patients with other genetic defects, including X-linked lymphoproliferative disease (XLP1, OMIM 308240), and XIAP (XLP2, OMIM 300635), Griscelli Syndrome (GS, OMIM 607624) due to RAB27A mutation, Chédiak-Higashi Syndrome (CHS, OMIM 214500) due to LYST mutation, CATCH22 Syndrome (OMIM 188400) and lysinuric protein intolerance (LPI, OMIM 222700) due to SLC7A7 mutation. *Aims.* We report the experience of the FHL Registry over 20 years (Aricò M. Leukemia 1996). *Methods.* A total of 532 patients have been reported to the Registry with suspected FHL according to the diagnostic criteria established by the Histiocyte Society. A genetic study was performed on 352 cases by direct sequencing of currently known FHL related genes. *Results.* In 143 patients a genetic marker was identified. They were reported from the following countries: Italy, n=113; England, n=14; Uruguay, n=4; USA, n=4; Spain, n=3; Germany, n=2; France, n=1; Belgium, n=1; Colombia, n=1. The genetic diagnoses were as follows: FHL3 n=62 (43%), FHL2 n=58 (41%), XLP n=8 (6%), FHL5 n=7 (5%), GS n=3, CHS n=2, LPI n=2, CATCH22 n=1. Although the clinical picture is similar in FHL2 and FHL3, the median age at diagnosis was younger in FHL2 (median 2.3 months) than in FHL3 (5.3 months). It is remarkable that one quarter of the patients was diagnosed when older than 4.5 years, the older patient being 27-year old. *Conclusions.* Current diagnostic approach is based on clinical criteria and flow-cytometry for perforin expression and granule release assay, and may be supported by cytotoxicity assay. Mutation analysis is mandatory for identification of the familial marker. Prevalence of FHL3 appears to be comparable to that of FHL2, with FHL5 accounting for a minority of cases while FHL4 was never diagnosed in this series. Based on the current knowledge, a genetic defect may be assigned to about 80% of the familial cases, thus supporting indication to hematopoietic stem cell transplantation, and allowing selection of familial donors, counselling, and family planning.

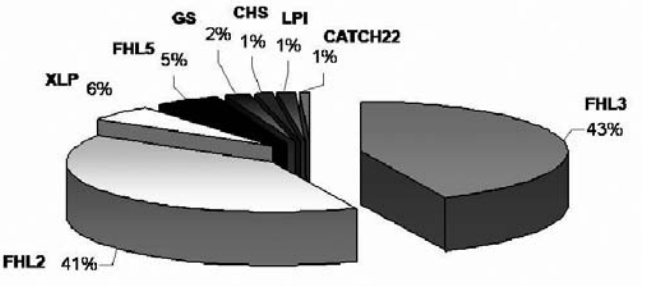

Figure. Distribution of different types of FHL.

CYTOGENETIC FOLLOW-UP IN PATIENTS WITH IN MYELODYSPLASTIC SYNDROME TREATED WITH LENALIDOMIDE: IMPACT OF KARYOTYPING AND FLUORESCENCE IN SITU HYBRIDIZATION

G Göhring,[1] A Giagounidis,[2] W Hofmann,[1] G Buesche,[1] H Kreipe,[1] M Cazzola,[3] P Fenaux,[4] E Hellström-Lindberg,[5] B Schlegelberger[1]

[1]Hannover Medical School, Hannover, Germany; [2]St. Johannes Hospital, Duisburg, Germany; [3]University of Pavia, Pavia, Italy; [4]Hôpital Avicenne, Bobigny, France; [5]Karolinska Institutet, Stockholm, Sweden

Background. Lenalidomide has been shown to be particularly active in MDS patients with del(5q) leading to transfusion independence in over two-thirds of patients with low and intermediate risk MDS and 5q deletion. Patients without a cytogenetic response had a significantly increased risk of progression. Therefore, careful monitoring of the cytogenetic response is extremely important in all MDS patients treated with lenalidomide. *Aims.* In order to optimize therapy control of MDS patients treated with lenalidomide, we have reviewed the cytogenetic data of patients treated with lenalidomide within the MDS-003 and MDS-004 study and compared the results obtained by different methods like karyotyping and FISH. *Methods.* Our cohort included 302 patients with transfusion-dependent anemia due to low- or intermediate-1-risk myelodysplastic syndrome associated with a 5q deletion with or without additional cytogenetic abnormalities. Patients were enrolled in the studies MDS-003 (n=42) or MDS-004 (n=260). Cytogenetic and molecular cytogenetic investigations were performed according to standard procedures. Whenever possible, 25 metaphases obtained from 24-hour and in some cases also from 48-hour cultures were analysed. Fluorescence *in situ* hybridization (FISH) for deletion 5q was included in each investigation. *Results.* We have reviewed 1075 cytogenetic and FISH analyses of 302 MDS patients with del(5q) treated with lenalidomide. A complete cytogenetic investigation based on at least 25 metaphases and FISH based on the analyses of at least 200 interphase nuclei was made in 835 (78%) of the investigations. The median detection rate of a deletion in 5q in metaphases and interphases was 54% and 33%, respectively (P<0.05). Overall, classical banding analysis was significantly more sensitive in detecting a deletion 5q. In 19 patients and in 39 investigations, del(5q) was detected by karyotyping only. Thus, a cytogenetic non-response or relapse of the disease would have been missed if only FISH analyses would have been performed. In 8 patients undergoing a karyotypic evolution, and in 17 investigations neither the del(5q) nor additional chromosome aberrations were detected by FISH - in contrast to karyotyping. *Conclusions.* Classical banding analysis was significantly more sensitive in detecting a deletion 5q than FISH. This result can be explained by a proliferative advantage of cells with a deletion 5q. In conclusion, to optimize the treatment strategy and therapy control of patients treated with lenalidomide and identify cytogenetic non-response or progressions as early as possible, both classical banding analysis and FISH should be performed in follow-up investigations.

0214

IDENTIFICATION OF A CONSTITUTIONAL T(16;21) INVOLVING 16P13 ATF7IP2 AND 21Q22 RUNX1 LOCI AS A NOVEL GENETIC MECHANISM IN FPD/AML

A Buijs,[1] S van der Crabben,[1] B van der Zwaag,[1] E van Binsbergen,[1] M Poot,[1] O de Weerdt,[2] M van Gijn,[1] K Nieuwenhuis[1]

[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]St. Antonius Hospital, Nieuwegein, Netherlands

Familial platelet disorder with propensity to myeloid malignancy (FPD/AML) is an autosomal dominant disorder characterized by platelet abnormalities and a predisposition to AML. FPD/AML is caused by inherited mutations of 21q22 *RUNX1*. Given the clinical heterogeneity of FPD/AML, the syndrome could be overlooked, and has resulted in SCT of patients from affected siblings. Recently, we and others reported on constitutional *RUNX1* copy number changes that would go unnoticed by sequencing, as a second pathogenomic mechanism in FPD/AML. We therefore have implemented array CGH and FISH for *RUNX1* in diagnosing three FPD/AML families. We present the identification of two novel *RUNX1* mutations by sequencing (G143R and Q235X). In a third family no *RUNX1* abnormality was detected in the proband by sequencing or array CGH on AML bone marrow. However, by FISH we identified a *RUNX1* gene rearrangement resulting from a cryptic t(16;21)(p13;q22). The constitutionality of the t(16;21) *RUNX1* rearrangement as the third pathogenomic mechanism in FPD/AML was demonstrated by FISH on cells from the urinary tract epithelium and buccal mucosa. The 16p13 breakpoint was confined by FISH to *ATF7IP2* (*MCAF1*). ATF7IP2 is a transcription factor involved in proliferation in human cancer by epigenetic transcriptional control of Sp1-dependent maintenance of telomerase activity. This is the first report on a constitutional chromosome translocation with an oncogene rearrangement as a pathogenomic mechanism in a hematological malignancy. Our data indicate that FISH for *RUNX1* has to be performed for structural anomalies along with sequencing and copy number analysis in diagnosing FPD/AML.

0215

A MUTATED NOTCH1 GENE IS PROGNOSTIC FAVORABLE IN PEDIATRIC LEUKEMIA OF T-CELL ORIGIN

I Sjogren,[1] J Abrahamsson,[2] A Staffas,[1] T Martinsson,[1] L Palmqvist[1]

[1]Institute of Biomedicin, Gothenburg, Sweden: [2]Institute of Clinical Sciences, Gothenburg, Sweden

Background. Acute lymphoblastic leukemia (ALL) is the most common pediatric leukemia. ALL with T-cell origin (T- ALL) accounts for 15% of these and have a worse prognosis than ALL of B-cell origin. With intensive treatment protocols event free survival approaches 80% for T-ALL but the outcome for the remaining 20% is dismal. A major goal is therefore to find markers that can identify patients at high risk for relapse or treatment resistant disease already at diagnosis in order to offer these patients intensified or alternative treatment approaches. *Aim.* The aim of the study was to investigate genetic alterations in pediatric T-ALL and to determine their prognostic significance. *Material and Methods.* Thirty-three pediatric T-ALL samples were analyzed for the presence of mutations in the NOTCH1 and FBWX7 genes. In addition, genetic alterations were investigated with molecular allelokaryotyping (250K Nsp SNP-array), conventional and spectral karyotyping (SKY), flourescence *in situ* hybridization (FISH) and multiplex ligation-dependent probe amplification (MLPA) analysis. All T-ALL patients included in the study were diagnosed and treated at one single centre 1991-2008 according to common NOPHO ALL protocols. *Results.* Mutational analysis included analysis of two regions in the NOTCH1 gene, the heterodimerization domain (HD) and the proline/glutamic acid/serine/threonine (PEST) domain, and the FBWX7 gene. NOTCH1 mutations were found in 25 patients (76%). A double-mutation (both HD and PEST) was found in 6 patients (18%). A single HD mutation was found in 10 patients (30%), and two of these also had an FBWX7 mutation. A single PEST mutation was found in 9 patients (27%), one of these also had a FBWX7 mutation. Correlation analysis showed a significantly better disease-free survival for patients with NOTCH1 gene mutated leukemia at 5 years (57% vs. 22%, P=0.011) with a clear trend towards better overall survival (57% vs. 33%, P=0.073). All analyzed patient samples presented one or more genomic lesions in addition to NOTCH1 or FBWX7 gene mutations. Diploid or near-diploid karyotypes predominated in the material. Eight patients had an apparently normal karyotype and six cases had a complex karyotype. Three patients had balanced translocations including two t(11;14)(p13;q11) and one t(9;13)(p12;q?) translocation. Isochromosome, i(9)(q10), was seen in one case and i(17)(q10) in two cases. Molecular allelokaryotyping identified mainly genetic losses in T-ALL and 205 copy number changes (CNC) were detected, including 158 deletions, 25 gains and 22 uniparental disomies (UPD). All chromosomes but chromosome 22 and the X chromosome were affected. The most frequently affected chromosomes were 5, 7, 9, 11 and 14. Loss of 9p21.3 (p16/CDKN2A) was the most frequent aberration and detected in 80% of the cases. No significant correlation was found for any of the genetic aberrations with the presence of a NOTCH1 gene mutation or clinical outcome. The presence of a NOTCH1 gene mutation did not correlated with the level of white blood cells at diagnosis. *Conclusions.* A NOTCH1 gene mutation was found in more than 3/4 of investigated pediatric cases of T-ALL and was associated with a significantly better disease free survival.

ORIGIN OF THE INV(16)(P13Q22) IN *DE NOVO* AND THERAPY-RELATED ACUTE MYELOID LEUKEMIA

B van der Reijden,[1] A Simons,[1] D Monteferrario,[1] R Giles,[2] M Hoffer,[3] G de Greef,[4] B Löwenberg,[4] T de Witte,[1] C Haferlach,[5] S Schnittger,[5] M Breuning,[3] J Jansen[1]

[1]RUNMC, Nijmegen, Netherlands; [2]UMCU, Utrecht, Netherlands; [3]LUMC, Leiden, Netherlands; [4]EUMC, Rotterdam, Netherlands; [5]MLL, Munich, Germany

Background. Therapy-related acute myeloid leukemia (t-AML) may arise after cytostatic and genotoxic therapies for various malignancies. The incidence of t-AML is about 5% of all cases with AML and this subtype of leukemia is associated with low survival rates. Some drugs that are used to treat primary tumours are responsible for the generation of chromosomal translocations in t-AML. For instance, topoisomerase II inhibitors may trigger the formation of chromosomal translocations that play a causal role in the development of t-AML. This assumption is based on the fact that genomic translocation breakpoints observed in patients with t-AML cluster near topoisomerase cleavage sites while breakpoints in *de novo* AML are randomly distributed over large areas. *Aims/Methods.* The chromosomal rearrangement inv(16)(p13q22) is found in both *de novo* and t-AML. This aberration results in a CBFB-MYH11 fusion gene that plays an essential role in leukemogenesis. To gain insight into the mechanisms causing the inv(16) we characterized genomic CBFB and MYH11 breakpoints from 29 cases with *de novo* AML and compared these to 6 cases with t-AML. Primary tumours observed in patients with t-AML included mammary (n=2), cervix (n=2) and ovarian carcinomas (n=1) and acute lymphoblastic leukemia (n=1). The latency between the initial diagnosis and the development of t-AML varied from 2 to 6 years. Treatment regimens for primary tumours included cyclophosphamide, fluorouracil, methotrexate, carboplatin, etoposide, tamoxifen, epirubicin, cisplating and radiation. Genomic breakpoints were characterized by direct sequencing of obtained PCR products. *Results.* We observed that genomic CBFB and MYH11 breakpoints in *de novo* AML were random-

ly distributed. Importantly, the genomic breakpoints in patients with t-AML did not cluster. In fact, the distribution was very reminiscent of that observed in *de novo* AML. Because some patients with t-AML were originally treated with topoisomerase inhibitors we studied whether topoisomerase inhibition resulted in double strand DNA breaks in CBFB and MYH11. While the topoisomerase inhibitor etoposide readily induced genomic breakpoints in the MLL locus, we did not observe these in the relevant CBFB and MYH11 regions in leukemia cell lines. *Discussion*. These data may suggest that the inv(16) in t-AML and *de novo* AML are induced by a common mechanism but that cytostatic and genotoxic drugs as used in cancer therapy are not implicated in this process. It is well known that the CBFB-MYH11 fusion is essential for leukemogenesis but other mutations are required for the development of full blown leukemia. Thus, cytostatic and genotoxic drugs may induce mutations that together with the inv(16) result in therapy-related AML.

HIGHER PREVALENCE OF ADVERSE PROGNOSTIC GENETIC ABERRATIONS AND IGH-MUTATION STATUS IN PATIENTS WITH SMALL LYMPHOCYTIC LYMPHOMA AS COMPARED TO CHRONIC LYMPHOCYTIC LEUKEMIA

M Stevens-Kroef, R Raymakers, P Rombout, M Prenter, A Simons, L Kossen, C Jansen, T Feuth, J van Krieken, P Groenen

Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background. Chronic lymphocytic leukemia (CLL) and small lymphocytic lymphoma (SLL) are considered the same entity. It has been convincingly shown that the clinical course and the overall survival of patients with chronic lymphocytic leukemia (CLL) largely depend on molecular parameters, such as specific genetic abnormalities, mutational status of the variable region of the immunoglobulin heavy chain genes (IGHV) and the usage of specific VH genes. However, knowledge on mutation status and genomic aberrations on diagnostic specimens from SLL patients have hardly been reported in the literature. *Aim.* The prevalence of molecular prognostic parameters in classical SLL was compared to those in CLL with lymph node involvement and to CLL without lymph node involvement. *Methods.* Genomic DNAs extracted from lymph nodes or peripheral blood cells of patients with SLL (n=22), patients with lymphocytosis and affected lymph nodes (n=16) and patients with B-CLL (n=82) were analyzed for IGH-mutation status and VH-family usage. Chromosome aberrations such as 11q-, +12, 13q- and 17p- were determined by multiplex ligation dependent probe amplification (MLPA). *Results.* The majority of lymph node samples from SLL patients (64%) showed unmutated IGH-variable gene segments, which was significantly higher than in the samples of CLL patients (30%). In contrast, high-risk chromosome abnormalities (11q-, 17p-, +12) were more prevalent in patients with lymph node involvement (SLL + CLL; 48%) as compared to CLL patients without (21%). After combining the VH-mutation and chromosome aberration data, 73% of the SLL patients exhibited adverse prognostic factors, which is also significantly higher (43%) as compared to CLL patients without lymph node involvement. CLL patients with lymph node involvement exhibited almost equal frequencies of poor risk chromosome aberrations (50%), but lower frequencies of unmutated IGH genes (38%), as compared to patients with SLL. Interestingly, usage of the VH3-21 gene was not found in patients with SLL or CLL with lymph node involvement. Usage of the VH1-69 gene (all unmutated) was frequently found in patients with SLL (27%), of which half of the cases exhibited adverse chromosome aberrations as well. *Conclusions.* SLL patients show a higher occurrence of adverse prognostic molecular genetic parameters as compared to CLL patients. For optimal patient care, we recommend integrated assessment of VH-gene mutational status and chromosome aberrations on the same diagnostic specimen.

0218

CHROMOSOMAL ABNORMALITIES IN TRANSFORMED PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS (MPN) ARE ASSOCIATED TO THE TRANSFORMATION SUBTYPE AND INDEPENDENT OF THE JAK2 AND THE TET2 MUTATIONS.

F Nguyen-Khac,[1] C Lesty,[2] V Eclache,[3] L Couronne,[4] O Kosmider,[5] J Andrieux,[6] M Collonge-Rame,[7] D Penther,[8] M Lafage,[9] C Bilhou-Nabera,[10] E Chapiro,[11] MJ Mozziconacci,[12] F Mugneret,[13] N Gachard,[14] E Lippert,[15] S Struski,[16] N Dastugue,[16] C Cabrol,[17] O Bernard[4]

Evolution to myelofibrosis (MF), acute myeloid leukemia or myelodysplastic syndrome (AML/MDS) may occur over time in MPN patients most likely due to the acquisition of additional mutations. The Groupe Francophone de Cytogenetique Hematologique has collected and reviewed 82 patients with transformation of MPN (66 AML/MDS and 16 MF). All patients gave informed consent in agreement with the Helsinki declaration. JAK2V617F and TET2 mutations were searched for in 40 and 32 patients, respectively. Significantly more -7/del(7q) (P=0.004) and -5/del(5q) (P=0.03) were found in AML/MDS with a higher incidence of dup1q (P=0.01) and trisomy 9 (P=0.04) in MF. Some specific chromosomal abnormalities occurred together, for example -5/del(5q) and -17/del(17p) (P=0.0007). In multivariate analysis, two factors were independently associated with an inferior overall survival (OS); AML/MDS transformation (P<0.0001) and -5/del(5q) abnormality (P=0.02). Although both giving rise to loss of 7q, der(1;7) differed from other 7q deletions in terms of distribution (lower frequency of AML/MDS, P=0.02), association with chromosomal abnormalities (absence of -5/del(5q), P=0.003; increased del(20q), P=0.05), and longer OS (P=0.0007). We detected 24/40 (60%) JAK2V617F and 8/25 (32%) TET2 mutations in samples following transformation, ranging from wild-type to mutated forms of both genes. The mutated and wild-type forms of the genes were not found to be associated with a specific chromosomal abnormality. There was no evidence that JAK2 or TET2 mutations were associated with the type of MPN transformation, whereas the type of cytogenetic abnormalities were strongly linked, perhaps indicating that they play a specific role in the transformation process. The observation that certain chromosomal changes were found together suggested an oncogenic cooperation between them.

DYSREGULATION OF MIR-92A, AS A POSSIBLE APOPTOSIS INHIBITOR, INDICATES POOR PROGNOSIS IN ACUTE LYMPHOBLASTIC LEUKEMIA

J Ohyashiki, T Umezu, M Kurada, K Ohyashiki

Tokyo Medical University, Tokyo, Japan

Background. The miR-17-92 cluster is a polycistronic miRNA gene, encoding six miRNAs (miR-17, miR-18a, miR-19a, miR-19b, miR-20a, and miR-92), and several studies have suggested the importance of the miR-17-92 cluster in immune cell development, as well as in lymphomagenesis. Recently, we have shown that the down-regulation of miR-92a in plasma is a novel biomarker in human leukemia (Tanaka et al, 2009, PLoS One 4(5): e5532), however, the precise mechanisms of miR-92a dysregulation in leukemia cells have not been fully elucidated. *Aims.* The aim of this study was to determine plasma and cellular miR-92a expression levels in acute leukemia patients, in order to clarify whether or nor it could be an independent prognostic factor, and to establish a novel therapeutic strategy using miR-92a in acute leukemia. *Methods.* Total RNA was isolated from both mononuclear cells and plasma obtained from 91 acute leukemia patients. This study was approved by the institutional review board of Tokyo Medical University (no. 930: approved on June 24, 2008). Written informed consent was obtained from all patients according to the Declaration of Helsinki prior to collection of the specimens. Expression of miR-92a was quantified using TaqMan® MicroRNA assays using 2-ΔΔCt *Methods.* The miR-92a expression was normalized to U6B or miR-638 expression, yielding a -

ΔCt value. *Results.* In healthy volunteers, the miR-92a expression level in cells ranged from 0.92 to 1.62 (mean±SD, 1.26±0.23) and those in plasma varied from 0.22 to 3.58 (mean±SD, 1.2±0.92). The miR-92a expression level in plasma was significantly lower, approximately one hundredth, in both acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) compared to normal controls (P<0.0001). Unlike miR-92a expression in plasma, there was a considerable variation of miR-92a expression in acute leukemia cells: the miR-92a expression level varied from 0.12 to 4.72 (mean±SD; 1.01±1.05) in AML, and it ranged from 0.22 to 10.00 (mean±SD; 2.23±2.34) in ALL. The miR-92a expression level was significantly higher in ALL cells compared to normal controls (P=0.0272), while there was no significant difference between AML cells and normal controls (P=0.3848) . Notabley, ALL patients with over-expressed miR-92a had poor outcomes (P=0.0186). The knock-down of miR-92a by antisense oligonucleotide revealed an increase of apoptotic cells in Raji and OM9;22 cells, indicating that miR-92a may contribute as a possible apoptosis inhibitor in a subset of ALL. *Conclusions.* Although questions still remain about the dynamics of miR-92a in leukemia cells, our results highlight the dysregulation of miR-92a in acute leukemia cells. Our findings suggest that the quantification of miR-92a in leukemia cells can be used as a prognostic marker in ALL, and it can be used for monitoring leukemia patients together with measurement of plasma miR-92a in both ALL and AML patients.

0220

ABNORMAL EXPRESSION OF MIR-9 INDICATES POOR PROGNOSIS IN AML PATIENTS

K Maki, T Yamagata, K Sasaki, K Mitani

Dokkyo Medical University, School of Medicine, Tochigi, Japan

*Background.*miRNAs are small non-coding RNAs that suppress protein translation by interacting with 3' untranslated regions (UTR) of target mRNAs. Recent studies suggest that abnormal expression of miRNAs contributes to the development of various cancers, including hematological malignancies. RUNX1 is a Runt family transcription factor critical for normal hematopoiesis. Inactivation of RUNX1 function through chromosomal translocations or gene mutations results in the development of acute myelogenous leukemia (AML) and myelodysplastic syndrome. We speculate that aberrant expression of miRNAs negatively regulating RUNX1 mRNA could be another underlying molecular basis in suppressing RUNX1 function. [Aims] To test the above hypothesis with the samples of AML patients, we first evaluated expression levels of miRNA whose seed sequences reside within the 3' UTR of human RUNX1 mRNA (referred as RUNX1-related miRNA). Secondly, we analyzed the relationship between its abnormal expression and clinical features. *Methods.* Bone marrow samples were collected from 87 AML patients at diagnosis (FAB-M0, 7; M1, 11; M2, 29; M3, 13; M4, 10; M5, 10; M6, 6; and M7, 1) and 23 healthy controls at Dokkyo Medical University Hospital between 2000 and 2009. This study was approved by ethical committee of our institute, and written informed consents were provided by all of the patients. Total RNAs were isolated with the mirVana miRNA Isolation kit (Applied Biosystems), and Taqman MicroRNA Assays (Applied Biosystems), was used to quantify the RUNX1-related miRNAs including miR-9, miR-18a, miR-27a, miR-27b, miR-30a-5p, miR-30b, miR-30c, miR-30d, miR-30e-5p and miR-199a. Differences in overall survival (OS) and relapse-free survival (RFS) were analyzed with the Kaplan-Meier method, and both univariate and multivariate statistical analysis were performed using SPSS software. *Results*. Among the RUNX1-related miRNA, about 15% of AML patients expressed miR-9 that was barely detected in other AML patients and the controls. We divided the AML patients into two groups, miR-9$^+$ group (n=16) and miR-9(-) group (n=71), based on the expression level of miR-9. Between these two groups, there were no significant differences in known AML prognostic factors such as age, white blood cell count at diagnosis, and FLT3-ITD or FLT3-TKD mutations. In Kaplan-Meier analysis, miR-9$^+$ group exhibited significantly inferior OS and RFS compared to miR-9$^-$ group. Because complete remission rate was comparable between these two groups, these results suggest that miR-9$^+$ group were more likely to relapse than miR-9(-) group. Univariate and multivariate analysis showed that expression of miR-9 was an independent prognostic predictor for both OS and RFS. *Summary/conclusions*. We analyzed expression levels of RUNX1-related miRNA which could potentially suppress protein expression of RUNX1 in a AML patient cohort, and found that miR-9 was specifically expressed in a part of these patients. Because aberrant expression of miR-9 emerged as a strong negative prognostic factor, there could be a causative relationship between the aberrant expression and leukemogenesis. To fully understand the molecular pathogenesis in miR-9-overexpressing leukemia, we need to identify other targets of miR-9 than RUNX1 mRNA.

MOLECULAR CHARACTERIZATION OF A NOVEL CHROMOSOMAL TRANSLOCATION T(12;14)(Q23;Q11.2) IN T-LYMPHOBLASTIC LYMPHOMA BETWEEN THE T CELL RECEPTOR DELTA DELETING ELEMENTS AND THE HYPOTHETICAL GENE C12ORF42

G Przybylski,[1] K Dittmann,[2] P Grabarczyk,[2] G Dölken,[2] S Gesk,[3] L Harder,[3] E Landmann,[4] R Siebert,[3] C Schmidt[2]

[1]Institute of Human Genetics, Poznan, Poland; [2]Universität Greifswald, Greifswald, Germany; [3]Institute of Human Genetics, Christian-Albrechts-University, Kiel, Germany; [4]Pädiatrische Hämatologie und Onkologie, Zentrum für Kinderheilkunde und Jugendm, Giessen, Germany

Chromosomal aberrations have diagnostic, prognostic and therapeutic consequences in haematological malignancies. By combining fine-tiling comparative genomic hybridization (FT-CGH) and ligation-mediated PCR (LM-PCR) we established a fast and robust approach to precisely characterize chromosomal breakpoints. Using this approach we characterized at the molecular level novel chromosomal translocation t(12;14)(q23;q11.2) in T-lymphoblastic lymphoma occurring during the deletional rearrangement of the T cell receptor delta gene (TRD), which normally is a pivotal step in T cell differentiation towards the alpha/beta versus the gamma/delta lineage and generates the T cell receptor excision circles (TREC) used to determine the proliferative history of T cells. We found that this rearrangement disrupted the hypothetical gene C12orf42, and brought into proximity to the TRA enhancer the Achaete-scute complex homolog 1 (ASCL1) gene, which encodes a member of the basic helix-loop-helix (BHLH) family of transcription factors and is overexpressed in medullary thyroid cancer and small cell lung cancer. This broad applicable method for detailed molecular analysis of chromosomal abnormalities shall facilitate the identification of new target genes for molecular therapy of malignant diseases.

0222

EVALUATION OF CYTOGENETICS WHOLE-GENOME 2.7M ARRAY AS A NEW CLINICAL TOOL FOR DETECTING CYTOGENETIC ABNORMALITIES FOR CHRONIC LYMPHOCYTIC LEUKEMIA PROGNOSIS. A COMPARISON WITH INTERPHASE FISH

A Puiggros,[1] F Solé,[1] A Ferrer,[1] M Salido,[1] E Abella,[1] E Gimeno,[1] E Puigdecanet,[1] L Nonell,[2] AB Galván,[1] M Rodríguez,[1] C Melero,[1] R Navarro,[1] S Serrano,[1] L Florensa,[1] B Espinet[1]

[1]Hospital del Mar-IMIM, Barcelona, Spain; [2]IMIM-Hospital del Mar, Barcelona, Spain

Background. Chronic lymphocytic leukemia (CLL) is a hematologic malignancy with a variable clinical course. Many CLL prognostic factors have been defined. Among them, cytogenetic abnormalities such as del(17p) and del(11q) have been tightly related to progression and shorter overall survival. In CLL, the most recurrent cytogenetic abnormalities are del(13q), del(11q), trisomy 12, del(17p) and del(6q), detected in up to 60-70% of patients by interphase fluorescence *in situ* hybridization (iFISH). Recently, array-based karyotyping has gained acceptance as a new tool for detecting genomic imbalances with higher resolution and better cost/benefit ratio than other techniques used nowadays. *Aims.* To analyze cytogenetic alterations in CLL using a newly developed Cytogenetics Whole-Genome 2.7M (Affymetrix). To identify recurrent or non- previously defined prognostically important aberrations in CLL. To compare array results with G-banding cytogenetics and iFISH and correlate them with clinical and molecular data to test array-CGH as a clinical tool in CLL. *Methods.* Eighteen patients with CLL were included in the study (11M/7F, median age 74) previous to any treatment. DNA was extracted from whole peripheral blood and submitted to Cytogenetics Whole-Genome 2.7M array. All patients were also studied by G-banding cytogenetics and iFISH with the classical CLL panel (11q22.3, CEP 12, 13q14 and 17p13 probes). *Results.* FISH analysis detected recurrent aberrations in 11/18 (61.1%). The most common alteration was del(13q) (eight patients, 44%), followed by trisomy 12 (four patients, 22%). Del(17p) and del(11q) were found in one patient each as unique deletion (5.6%). Whole Genome 2.7M array could detect aberrations tested by iFISH probes in a total of eight patients. Losses in 13q were the most frequently detected (5 cases, 27%), trisomy 12 was detected in four (22%) and del(11q) in a single

patient. Losses found in 13q14 cytoband ranged from 111 to 2940 Kb and the minimal common deleted region size was 11Kb (49522757-49634282). Only one deletion contained the region where miR15 and miR16 were located. Array-CGH results were concordant with iFISH in 15 patients but failed to detect del(13q) in three cases and del(17p) in one patient. Samples with deletions missed by array-CGH had been detected in less than 25% of cells analyzed by iFISH. Contrarily, array-CGH did not detect any abnormality missed by iFISH probes. Additional gains and losses were identified in 14 patients. A deletion of 5q32-q34 in one case, and trisomies for chromosomes 18 and 19 had already been detected by G-banding cytogenetics. However, gains of full length 2p and 22q arms and other smaller abnormalities had not been identified by conventional techniques. *Conclusions.* Recurrent aberrations with prognostic impact have been identified in more patients using iFISH techniques. Cut-off values for Whole Genome 2.7M sensitivity have found to be 25% due to low tumoral infiltration. Array-CGH allowed to detect other alterations with unknown clinical significance, some of them previously detected by G-banding cytogenetics. These results are preliminar. Additional patients should be analysed to demonstrate the Whole Genome 2.7M applicability in clinical practise for CLL. *Acknowledgements*. Red Temática de Investigación Cooperativa en Cáncer No. RD07/0020/2004.

Hamburg Eppendorf, Hamburg, Germany; [4]U.O. Ematologia I, A.O. V. Cervello, Palermo, Italy; [5]Unit of Hematology-Oncology, AO S.M. Misericordia Hospital, Perugia, Italy; [6]Childhood Cancer Research Unit, Karolinska institutet, Stockholm, Sweden; [7]Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy; [8]Cambridge Institute for Medical Research, Addenbrooke's Hospital, Cambridge, UK

Background. Familial Hemophagocytic Lymphohistiocytosis (FHL) is a genetically heterogeneous disorder characterized by fever, hepatosplenomegaly, cytopenia and frequent central nervous system involvement. In most cases the natural course is rapidly fatal unless appropriate treatment is applied. Since 2003, mutations of UNC13D, the gene encoding Munc 13-4, a protein essential for cytolytic granule fusion to the cell surface membrane, have been recognized as the cause for FHL3 (OMIM 608898). Previously published reports on FHL are based on limited cohorts of patients from single centres, with the only exception of a recent genotype-phenotype study of FHL2. *Aims.* The aim of the present study is to analyze genotype-phenotype correlations in a large cohort of patients with FHL3. *Methods.* The consortium established between Italy, Germany and Sweden planned to pool in a common database data on presenting features, mutations, and cytotoxic function from individual patients with FHL3 diagnosed on the basis of documented biallelic UNC13D mutations. Statistical analysis was performed by SPSS 11.5 software; P<0.05 was considered as significant. *Results.* a total of 83 patients (46 male, 37 female; median age: 4,4 months) with FHL3 were reported from the following centres: Florence, Italy (n=54), Hamburg, Germany (n=16), Stockholm, Sweden (n=13). They had been diagnosed between 1981 and 2009. The ethnic origin was as follows: Caucasian, n=57, Turkish, n=8, Asian, n=7, Hispanic, n=4 (not reported, n=4). Regarding diagnostic criteria, thrombocytopenia was present in 96%, splenomegaly in 95%, fever in 89%, anaemia in 86%. Central nervous system involvement was present in 50/80 (62%) patients, a proportion which is significantly higher than in FHL2 (n=31/86; 36%; P=0.001). Granule release capacity detected by CD107a expression, NK activity and Munc 13-4 protein expression were absent or reduced in all patients analyzed with the exception of a single patient with an atypical phenotype and compound heterozygocity for a missense and a frameshift mutations. 53 different mutations were observed, including 15 novel ones: 17 missense, 14 frameshift, 12 nonsense and 10 splice errors. No private mutations for specific ethnic groups were found. To explore the correlation between specific mutations and age at diagnosis, we grouped the patients according to the functional impact of the mutations; the groups were defined as two disruptive (nonsense, frameshift and selected splice errors) mutations, two missense mutations, and a third group including compound heterozygous with one missense and one disruptive mutation. Patients with disruptive mutations had a significantly younger age at onset (P=0.001). *Conclusions.* UNC13D mutations are scattered over the entire gene, without hot spots. Despite different ethnic and geographic origin of the patients, there are apparently no ethnic-specific mutations. The clinical picture of FHL3 is comparable to that of FHL2, although CNS involvement appears to be more frequent. The granule release assay appears to be a very sensitive tool for screening of FHL3.

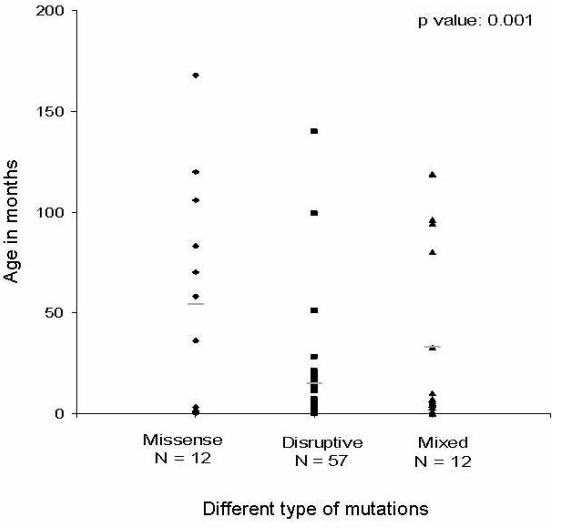

Figure. Different types of mutations and age of onset

GENOMIC PROFILING USING SNP-BASED MICROARRAYS IN A DIAGNOSTIC SETTING FOR THE IDENTIFICATION CHROMOSOMAL ABNORMALITIES IN ACUTE LYMPHOBLASTIC LEUKEMIA

A Simons,[1] M Stevens-Kroef,[1] N El Idrissi-Zaynoun,[1] S van Gessel,[1] R Kuiper,[2] A Geurts van Kessel[1]

[1]Radboud University Medical Center, Nijmegen, Nijmegen, Netherlands; [2]Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background. Gross cytogenetic anomalies are being used as diagnostic, prognostic and therapeutic markers in the clinical management of acute lymphoblastic leukemia (ALL). Recently, it has become clear that ALL cells frequently harbor relevant disease-related submicroscopic chromosomal abnormalities. Although karyotyping is generally considered as the gold standard in the genetic diagnosis of ALL, this method is limited by its capacity to detect only those copy number changes that are microscopically visible (>5-10 Mb in size). In contrast, SNP-based microarray analyses allow a genome-wide detection of copy number changes less than 100 kb in size. Such analyses also overcome some of the other major limitations of karyotyping such as low success rates due to inadequate metaphase yield and/or poor banding quality. *Aim.* To investigate whether microarray-based genomic profiling is applicable in a routine diagnostic setting. *Methods.* For our analyses we used a 250k SNP microarray platform. In order to rule out irrelevant (benign) copy number variations (i) thresholds for copy number aberrations were set at >5 Mb and (ii) smaller gains or losses were interpreted as aberrant only in case they coincided with known (recurrent) aberrations as reported in the literature or in the "Atlas of Genetics and Cytogenetics in Oncology and Haematology"(http://atlasgeneticsoncology.org/). *Results.* Cytogenetic, FISH and SNP-based microarray data of 60 diagnostic ALL samples were compared. Through microarray analysis, almost all numerical abnormalities as found by karyotyping were detected. More importantly, in the majority of samples additional small recurrent abnormalities with a known prognostic relevance were detected. As expected, balanced chromosomal abnormalities were not identified. Therefore, it remains recommended to apply FISH and/or PCR-based methods for the detection of translocations with a known diagnostic/prognostic impact (e.g. BCR-ABL1) in addition to microarray analysis. *Conclusions.* We demonstrate that SNP-based microarray analysis serves as a comprehensive and reliable diagnostic tool for the identification of clinically relevant chromosome aberrations in ALL.

UNINTENTIONAL 'STEM CELL TRANSPLANT' FOLLOWING A LIVER TRANSPLANT IN A PATIENT WITH MONOSOMY 7 AML

J Jeffries,[1] P Page,[1] M Rindl,[1] R Doak,[1] M Velangi,[2] D Kelly,[2] M Griffiths[1]

[1]Birmingham Women's Hospital, Birmingham, UK; [2]Birmingham Children's Hospital, Birmingham, UK

A 16 year old female developed 100% hematopoietic donor chimerism from a female liver transplant donor. She initially received a conventional sibling stem cell transplant (SCT) for monosomy 7 AML in January 2008. By April 2008 she had relapsed and following chemotherapy, received a second, matched unrelated male donor SCT in August 2008. Full donor chimerism was achieved. In November 2008 she developed graft versus host disease (GVHD) resulting in liver failure, and had a liver transplant. Within 3 weeks of the liver transplant, the male second donor chimerism level fell to 3% after a period of profound neutropenia, with no evidence of AML relapse. Chimerism analysis revealed the appearance of DNA of multiple unknown origins, with one unknown origin subsequently becoming dominant. Further investigation identified the origin as the female liver donor. Over an 8 week period full engraftment of liver donor hematopoiesis occurred and persists 9 months after the transplant with no GVHD, despite complete HLA mismatch. Engraftment of passenger hematopoiesis following solid organ transplant has been described previously, but is exceptionally rare, including a case of complete hematopoietic chimerism and tolerance of a liver allograft from a male donor in a 9 year old girl.

0226

DETECTION OF RARE COPIES OF BCR-ABL1 TRANSCRIPT IN PATIENTS WITH PHILADELPHIA POSITIVE (PH+) ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) WITH A HIGH SENSITIVE NANOFLUIDIC ARRAY

A Lonetti,[1] I Iacobucci,[1] A Ferrari,[1] C Papayannidis,[1] S Paolini,[1] D Cilloni,[2] MC Abbenante,[1] V Guadagnuolo,[1] F Pane,[3] M Baccarani,[1] G Martinelli[1]

[1]Institute of Hematology Seràgnoli, Bologna, Italy; [2]Dept. of Clinical and Biological Sciences, University at Orbassano, Turin, Italy; [3]Haematology Unit and Dep. of Biochemistry and Medical Biotechnology, CEINGE, University of Naples, Italy

Background. Ph+ ALL is observed in about 20-30% of adult ALL and is associated with a very poor prognosis and early relapse. Tyrosine kinase inhibitors have improved overall treatment results, with a rapid response and a complete remission (CR) rate ranging 90%. Nevertheless most patients experienced hematological relapse in a short time, also after hematopoietic stem cell transplantation. Molecular analysis based on quantitative assays (i.e. quantitative polymerase chain reaction, qPCR) provides detection of residual leukemic cells measuring BCR-ABL1 transcript level and becomes necessary in the monitoring of minimal residual disease to confirm molecular CR and to detect early relapse. *Aim.* To investigate the efficacy of a high sensitive method based on nanofluidic platform (Fluidigm Corporation, South San Francisco, CA) to detect and quantify residual and rare BCR-ABL1 copies in Ph+ ALL patients who obtained molecular remission as assessed by conventional qPCR. *Methods and Patients.* The 12.765 Digital array (Fluidigm) is a nanofluidic biochip that consists in twelve panels, each containing 765 individual reaction chambers of 6 nL volume. Samples are portioned prior to qPCR into the single chambers of the panel; as fluorescent signal is produced only in chambers containing copies of the target sequence, digital array provides an absolute quantification by counting the number of positive reactions. Following amplification, digital raw data are processed by the BioMark Digital PCR Analysis software (Fluidigm), that estimates the true number of molecules per chamber using the Poisson probabilistic distribution. At the time of writing, we analyzed 22 Ph+ ALL samples (11 positive for the P190 BCR-ABL1 isoform and 11 for the P210) who were in complete (87%) or major (13%) molecular response (BCR-ABL1/ABL ratio ≤0.001 or <0.1, respectively) as assessed by conventional qPCR; RNA integrity was evaluated using the control gene ABL. *Results.* First, we assessed the sensitivity and reproducibility of the assay using six serial dilutions of plasmids (Ipsogen) expressing known copy number of BCR-ABL1 P190 transcript (10000; 1000; 100; 50; 10; 1 copies). A 2 µL volume of input cDNA was loaded and two panel for each dilution were used. Analysis parameter chosen for digital raw data processing were automated set threshold of 0.65 and target Ct range 20-40. Results showed a detection rate until a copy of target sequence and a pairing significantly effective between replicates (P=0.0014, Paired t TEST analysis). We then analyzed duplicates of Ph+ ALL samples with a positive control for each chip: digital array resulted positive in 58% of complete molecular response samples, with 5.5 as median number of copies detected (range 0.5-11). *Conclusions.* The Fluidigm nanofluidic platform provides a high sensitive assay, able to detect until a single copy of BCR-ABL1 transcript with greater accuracy than conventional qPCR, as demonstrated for samples in molecular remission, and could provide an accurate monitoring method for Ph+ ALL CR patients. Further studies to confirm these results are actually ongoing. DIAGNOSING CML - DETECTION OF BCR-ABL1 PROTEIN BY FLOW CYTOMETRY

C Lucas, J Fagan, A Carter, B Swale, R Clark, RJ Harris

Royal Liverpool University Hospital, Liverpool, UK

Background. In investigating patients with neutrophilia and/or thrombocytosis, it is important to exclude chronic myeloid leukaemia (CML). Definitive diagnosis of CML requires detection of either the t(9;22) Philadelphia chromosome translocation (by metaphase spreads or FISH), or the fusion gene BCR-ABL1 by PCR. These techniques however are usually confined to specialist regional laboratories, are costly and may take valuable time to complete. Since most patients with neutrophilia and/or thrombocytosis do not have CML, a rapid and simple screening test for CML would be quite valuable. This could be achieved by the demonstration of the expression of the BCR-ABL1 protein, but this has hitherto been technically difficult because of the lack of a specific antibody that could reliably distinguish BCR-ABL1 protein. *Aims.* We investigated if the newly developed BCR-ABL protein kit (BD Biosciences) could accurately identify BCR-ABL1 fusion protein and be used as a rapid screening test for the identification of CML patients. *Methods*. Peripheral blood samples from known CML patients, and patients with neutrophilia and/or thrombocytosis suspected of having CML (n =75) were collected, as well as normal healthy controls (n=22). Each sample was analysed for BCR-ABL1 translocation both by PCR and with the BCR-ABL protein kit. For the BCR-ABL protein kit, cells were lysed; lysates were first incubated with BCR-antibody-coated capture beads (recognising an epitope upstream of BCR at the 5' end of the m-bcr region) and subsequently with PE-labelled detector ABL antibodies (recognising an ABL epitope downstream of exon 3). Samples were analysed by standard flow cytometry.

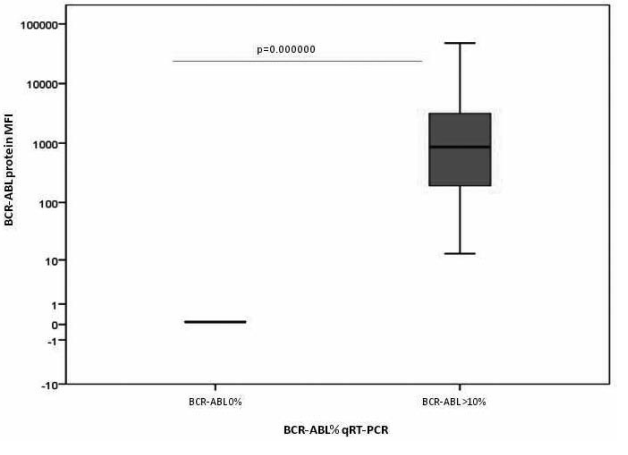

Figure 1.

Results. The BCR-ABL protein kit has the capability to produce a result in 4 hours. All CML patients were positive using the BCR-ABL protein kit. Conversely, all samples that were BCR-ABL1 negative by PCR showed no BCR-ABL1 protein. Samples from 22 healthy controls were negative by both methods. Where positive, BCR-ABL1 protein was readily detected in both total leukocytes and mononuclear cell (MNC) samples. Results were higher in MNC (P=0.014) likely due to absence of granulocytic enzymes. For CML patients with a BCR-ABL1 ratio >10%, the detection of BCR-ABL protein was highly significant

(P<0.001). For partially treated CML patients with a BCR-ABL1 ratio between 1-10%, the protein level was still significant, but treated CML patients with a BCR-ABL1 ratio <1% often had undetectable BCR-ABL1 protein. Using BCR-ABL1 positive K562 cells serially diluted with a BCR-ABL1 negative cell line (U937), the limit of sensitivity of the BCR-ABL1 protein assay was 0.4%. K562 cells cultured with 5 μM imatinib or 150 nM dasatinib for up to 96 hours showed a time dependent decrease in BCR-ABL1 protein level. *Summary/Conclusions.* No difference in results was observed when using PCR or the BCR-ABL1 protein kit. The BCR-ABL protein kit showed 100% accuracy with no false negative or positive findings, confirming that it can be used as an effective screening test for CML patient identification. Moreover, the BCR-ABL protein kit has the advantage that it can be rapidly (4 hours) performed in any laboratory with flow cytometry capabilities, eliminating the need for more elaborate time-consuming and costly techniques.

N-RAS GENE MUTATIONS ARE INDICATIVE OF AN UNFAVORABLE OVERALL SURVIVAL PROGNOSIS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES, BUT NOT IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

R Stemberkova, P Lassuthova, H Cechova, M Stankova, P Hrabakova, J Jencik, H Zizkova, J Cermak

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background. N-ras gene encodes small protein with GTPase activity, which is involved in the cell signal transduction. Point mutations alter the conformation of the protein resulting in its stable activation. Activating mutational changes of the N-ras gene are thought to play an important role in the development of numerous human cancers, including hematological malignancies. *Aims.* Point mutations of the N-ras gene were studied in patients with myelodysplastic syndromes (MDS) and *de novo* acute myeloid leukemia (AML) with the aim to evaluate its association with clinical outcome and disease progression. *Methods.* Using polymerase chain reaction and bidirectional direct sequencing, we analyzed 107 MDS patients (17xRA/RARS, 34xRCMD, 4x5q-, 23xRAEB1/2, 19xsAML, 10xMDS/MPS) and 73 *de novo* AML patients (5xM0, 14xM1, 21xM2, 6xM3, 21xM4, 5xM5, 1xM6) for point mutations in codons 12 and 13 of the N-ras proto-oncogene. *Results.* Mutations were present in 8% (9/107) of MDS patients and in 18% (13/73) of *de novo* AML patients. In MDS group, mutations were found mainly in codon 12 (7 of 9 mutations), two patients had mutations in both codons. Mutations were found with significantly higher frequency in patients with advanced MDS forms (8 of 9 mutations, P=0.014) in comparison to early forms. Significantly increased frequency of mutations in comparison to MDS was detected in AML (P=0.02). In AML patients, mutations were detected in codons 12 and 13 with an approximately same rate (7/13 and 6/13). Between AML subtypes, significantly increased frequency of the N-ras mutations was found in AML M2 subtype (6/13, P=0.018). All detected N-ras mutations lead to an exchange of amino acids. The most common observed base substitution was GGT to GAT in codon 12. In MDS patients we observed higher mutational variability, than in AML. MDS patients with N-ras mutations had significantly shorter survival period (median 9 months) than those without mutations (median 59 months, P=0.001). No difference in survival was obtained in AML patients with and without mutations (median 16 months, P=0.82). The presence of N-ras gene mutations was not associated with blasts count in analyzes tissue not in MDS, nor in AML patients. *Summary*. We showed that N-ras mutations are significantly associated with shorter overall survival period in patients with MDS, but not in patients with AML, although in this group were mutations detected with higher frequency. We proved the tendency of increasing number of detected mutations with disease progression towards advanced MDS forms. Thus, our findings point out the significance of the N-ras gene mutations in assessment of an individual MDS patients risk and usefulness as possible prognostic marker of MDS.

BONE MARROW HAEMATOPOIESIS IN THE SECOND TRIMESTER OF FETAL LIFE IS STRONGLY BIASED TOWARDS B-LYMPHOPOIESIS AND IS SEVERELY IMPAIRED AT THE EBP-CBP TRANSITION IN DOWN SYNDROME

A Roy,[1] G Cowan,[1] G Bohn,[1] M Hu,[1] O Tunstall-Pedoe,[1] N Ehsanullah,[1] J Chan,[2] C Mattar,[2] P Bennett,[1] P Vyas,[3] A Karadimitris,[1] I Roberts[1]

[1]*Imperial College London, London, UK;* [2]*National University Hospital, Singapore, Singapore;* [3]*MRC Molecular Haematology Unit; University of Oxford, Oxford, UK*

Background. Children with Down syndrome (DS;trisomy 21;T21) have increased susceptibility to autoimmune disease and lymphopenia-associated infection as well as a 12-fold increased risk of B-acute lymphoblastic leukaemia (ALL), while T-ALL is rare, suggesting that T21 may specifically perturb B-lineage development. While acute myeloid leukaemia in DS children is characterised by an identifiable 'pre-leukaemic' phase with prenatal acquisition of GATA1 mutations which is preceded by expansion of fetal liver megakaryocyte-erythroid progenitors, DS-ALL does not present neonatally and a similar 'pre-leukaemic' phase has not been identified. Our lab recently showed that T21 itself causes increased self-renewal of CMP and strongly biases their differentiation towards the megakaryocyte-erythroid lineage. *Aims.* To test the hypothesis that T21 perturbs B-lymphopoiesis. *Methods.* We analysed B-lymphoid progenitors in fetal liver, bone marrow (BM) and cord blood (CB) in DS compared to disomic controls. *Results.* B-cell progenitors (BCP) at all differentiation stages were detectable in normal second trimester fetal liver where they formed 16.6±1% of the total $CD34^+$ population. The majority of normal fetal liver BCP were committed BCP ($CD34^{int}$-lo$CD19^+$;10.6±1.6% of $CD34^+$ cells) with a lower frequency of early B progenitors (EBP;$CD34^{hi}CD127^+CD19^{neg}CD10^{neg}$;5.1±1.1% of $CD34^+$). By contrast, in DS fetal liver, BCP frequency and numbers were severely reduced (4.0±1.3% of $CD34^+$) with particular reduction in committed BCP ($CD34^{int\text{-}lo}CD19^+$;0.7±0.25%) and relative preservation of EBP (2.4±1.1%) which was recapitulated by *in vitro* differentiation on OP9-stroma. By comparison with normal fetal liver, BCP were present in large numbers in normal second trimester fetal BM where they formed 51.1±3.4% of $CD34^+$ cells. Although all stages of BCP were present in second trimester BM, EBP formed 4.9±1% of $CD34^+$ and most BCP (45.1±4%) were committed CD19+BCP. Similar to DS fetal liver, BCP in second trimester DS BM were markedly reduced in numbers and frequency (21.2±3.2% of $CD34^+$ cells) predominantly due to low numbers of committed $CD19^+$BCP (14.5±3.4%) with a smaller reduction in EBP (3.1±0.4 vs 4.9±1% of $CD34^+$). JAK2 R683 mutations were not detected in any samples. BCP were also reduced in CB from term DS pregnancies compared with normal disomic term CB (5.5±0.8 vs 8.4±0.4%) due to a profound reduction in committed CD19+BCP (0.9±0.3 vs 3.9±1.2% of $CD34^+$) and, in contrast to DS fetal liver and BM, EBP in DS CB were increased compared to normal term CB (2.1±0.3 vs 0.9±0.2% of $CD34^+$). Numbers of mature B cells in DS CB were normal (12.8±0.2 vs 13.8±0.5%) suggesting compensatory expansion from the reduced BCP pool. *Conclusions.* These data show for the first time that: 1.all stages of BCP development occur in second trimester human fetal liver as well as BM; 2.B-lymphopoiesis is extremely active, constituting >50% of all haematopoiesis at the progenitor level, in second trimester BM; and 3.abnormal B-cell development in DS begins in fetal life with progressive block in EBP maturation to $CD19^+$ committed BCP. These abnormalities in DS are apparent in BM and CB, as well as fetal liver, suggesting they persist in post-natal life and may underlie the abnormal immune responses and increased susceptibility to B-ALL in children with DS.

DEVELOPMENTAL STAGE-SPECIFIC INTERPLAY BETWEEN GATA1 AND IGF SIGNALING IN FETAL HEMATOPOIESIS AND LEUKEMOGENESIS

JH Klusmann,[1] K Heitmann,[1] F Godinho,[2] A Maroz,[1] D Reinhardt,[1] S Orkin,[2] Z Li[3]

[1]*Hannover Medical School, Hannover, Germany;* [2]*Children's Hospital, Boston, USA;* [3]*Brigham & Women's Hospital, Boston, USA*

Oncogene-mediated transformation of hematopoietic cells has been

extensively studied, but little is known about the molecular basis for restriction of oncogenes to certain target cells and differential cellular context-specific requirements for oncogenic transformation between infant and adult leukemias. Understanding cell type-specific interplay between signaling pathways and oncogenes is essential for developing targeted cancer therapies. Here, we addressed the vexing issue of how developmental restriction is achieved in Down syndrome acute megakaryoblastic leukemia (DS-AMKL), characterized by a triad of fetal origin, mutated GATA1 (GATA1s), and trisomy 21. We demonstrate overactivity of insulin-like growth factor (IGF) signaling in authentic human DS-AMKL and in a DS-AMKL mouse model generated through retroviral insertional mutagenesis. ShRNA mediated IGF1R knockdown in DS-AMKL cell lines (CMK, CMY) led to a dramatic reduction of transduced cells, whereas no substantial effect was observed in 'control' cell lines, including K562, CHRF288-11, and M-07. Pharmacological activation and repression of IGF1R signaling followed by *in vitro* culture, CFU assays and intracellular phosphoprotein staining showed that in both murine and primary human AMKL cells expressing GATA1s, the IGF/IGF1R/mTOR pathway is highly activated and is the major mitogenic pathway for growth. We observed a significant delay of leukemia onset upon IGF1R knockdown after transplantation of G1s-mAMKL cells into RAG2$^{-/-}$ recipients. Furthermore, we could show that fetal, but not adult, hematopoietic progenitors are dependent on IGF pathway. Gene set enrichment analysis revealed that the mitogenic activity of IGF1R is exerted at the transcriptional level by activation of E2F target genes. GATA1 restricts IGF-mediated activation of the E2F transcription network to coordinate proliferation and differentiation. Failure to directly interact and repress E2F transcription factors in mutated GATA1s converges with overactive IGF signaling to promote cellular transformation of DS fetal progenitors, whereas the hyperproliferative phenotype of Gata1s fetal MPs can be rescued by shRNA mediated repression of global E2F transcription activity. Thus, our study reveals a complex, fetal stage-specific regulatory network, underscores context-dependent requirements during oncogenesis and explains resistance to transformation of ostensibly similar adult progenitors.

0231

CPG-ODN 2006 AND HUMAN PARVOVIRUS B19 GENOME CONSENSUS SEQUENCES SELECTIVELY INHIBIT GROWTH AND DEVELOPMENT OF ERYTHROID PROGENITOR CELLS

YM Guo,[1] K Ishii,[2] M Hirokawa,[1] H Tagawa,[1] H Ohyagi,[1] Y Michishita,[1] K Ubukawa,[1] J Yamashita,[1] T Ohteki,[3] N Onai,[3] K Kawakami,[2] W Xiao,[4] K Sawada[1]

[1]Akita University Graduate School of Medicine, Akita, Japan; [2]Tohoku University Graduate School of Medicine, Sendai, Japan; [3]Tokyo Medical and Dental University, Tokyo, Japan; [4]The First Affiliated Hospital of China Medical University, Shenyang, China

Background. Recent studies have shown that anemia is commonly observed following exposure to pathogens or pathogen-derived products, which are recognized via toll-like receptor (TLR) 9. TLR9 has evolved to recognize unmethylated CpG dinucleotides that are relatively common in bacterial and viral genomic DNA, but not in vertebral genomes. CpG DNA is generally most active as synthetic single-stranded (ss) oligodeoxynucleotide (ODN) sequences 20-30 nucleotides long, containing two to three CpG motifs with a modified nuclease-resistant backbone, typically a phosphorothioate (PS) backbone in which one of the non-bridging oxygen atoms at each of the natural (wild) phosphodiester (PO) linkages is replaced with a sulfur. Previous studies in mice have linked anemia and suppressed erythropoiesis induced by the CpG-ODN with PS backbone to indirect effects of proinflammatory cytokines produced by accessory cells. Of note is that CpG ODN with different backbones and different sequence motifs can induce dramatically different profiles and kinetics of immune activation. *Aims.* We aimed to precisely characterize the role of the best-characterized ligand for TLR9, CpG-ODN 2006, during hematopoiesis focusing on different backbones. *Methods.* Highly purified human CD34$^+$ cells were induced for proliferation and differentiation to erythroid lineage in the presence of interleukin-3, stem cell factor and erythropoietin (EPO) and the direct effects of CpG-ODN 2006 on hematopoietic progenitors were investigated focusing on different backbones. *Results.* CpG oligodeoxynucleotide (ODN)-2006 with PO (2006-PO) but not with the PS backbone, selectively inhibited the erythroid growth derived from human CD34$^+$ cells. The inhibitory effects of 2006-PO on erythroid growth depended on the ODN sequence and backbone, but not on the CpG-motif. 2006-PO was internalized by the erythroid progenitors within 30 min; however, expression of TLR9 mRNA was not detected in these cells. 2006-PO directly inhibited BFU-E growth, resulted in the accumulation of cells in S and G2/M phases, and increased cell-size and frequency of apoptotic cells. These features were similar to those observed in erythroid progenitors infected with human parvovirus B19 (B19) that causes pure red cell aplasia. The consensus sequence of 2006-PO was defined as 5'-GTTTTGT-3' which was located in the P6-promoter region of B19, and inhibited erythroid growth in a sequence specific manner and down-regulated expression of EPOR. 2006-PO down-regulated expression of erythropoietin receptor (EPOR) mRNA and EPOR, while did not affect the expression of GATA-2, GATA-1, friend of GATA-1 (FOG-1), EKLF and RPS19 mRNA. 125I-EPO binding assay showed a decrease of the specific binding of 125I-EPO to the cells treated with 2006-PO. B19 genome extracted from serum also inhibited erythroid growth and down-regulated expression of EPOR on glycophorin A+ cells. *Summary/Conclusions.* The data presented in the current study describe for the first time the presence of a ssDNA consensus sequence in both synthetic ODN-2006 and the B19 genome, and that this site selectively inhibits erythroid growth. The inhibition of erythroid growth by the consensus sequence was also accompanied by the inhibition of EPOR expression. These results provide a possible insight into our understanding of the mechanisms of human parvovirus B19-mediated inhibition of erythropoiesis.

0232

ESSENTIAL ROLE OF AN ANTI-APOPTOTIC MOLECULE ANAMORSIN FOR BOTH INTRINSIC AND EXTRINSIC REGULATION OF MURINE FETAL LIVER HEMATOPOIESIS

A Tanimura

Osaka University Graduate School of Medicine, Osaka, Japan

Background and *Aims.* Anamorsin (AM, also called CIAPIN-1) is an anti-apoptic factor, which we originally isolated as a molecule that confers factor-independent survival on hematopoietic cells (J.Exp.Med. 199(4), 2004). AM has no structural homology to any known anti-apoptosis molecules such as Bcl-2 and IAP family members. AM-deficient (AM-/-) mice are embryonic lethal at late gestation due to the defect of definitive hematopoiesis. In this study, we performed a series of experiments to characterize the hematopoietic defects in AM-/- fetal liver (FL). *Methods.* The expression levels of AM in murine hematopoietic cells were evaluated by quantitative PCR (qPCR) method. FL hematopoietic stem cells (Lin-Sca1+c-Kit+, LSKs) were sorted from embryonic day (E) 14.5 wild-type (WT) and AM-/- FL and subjected to clonogenic assay, competitive repopulation (CRU) assay, and limiting dilution assay. LSKs isolated from E14.5 FL were cocultured with subconfluent FL stromal cells. After 7-days of incubation, hematopoietic cells floating from the stromal layer were collected and analyzed for colony forming activities. *Results.* AM was ubiquitously expressed in hematopoietic cells derived from E9.5-10.5 aorta-gonad-mesonephros (AGM) region, E14.5 FL, and adult bone marrow. qPCR analysis using E14.5 FL cells demonstrated that AM was more abundantly expressed in immature stem/progenitor cells than in mature cells expressing lineage-specific marker such as Mac1 or Ter119. Total number of hematopoietic cells was significantly decreased in all lineages in AM-/- FL compared to WT FL, which was more apparent in hematopoietic stem (% of LSK: 1.8 vs. 0.6 (n=5, P<0.05)) and progenitor (% of Lin-c-Kit+: 15.7 vs. 8.4 (n=5, P<0.05)) fractions. Also, *in vitro* colony assay, FL cells from E14.5 AM-/- embryos gave rise to less (approximately one third compared to WT) colonies in all colony types. In primary transplantation, there was a 5- to 8-fold reduction of donor-derived cells in each lineage in mice transplanted with AM-/- FL LSKs 4 weeks after transplantation. The limiting dilution assay showed that CRU frequency was severely decreased in AM-/- FL LSKs (1/755 in AM-/- vs. 1/177 in WT (n=18, P<0.05)). In addition, AM-/- FL LSKs had less long-term reconstituting ability in the secondary transplantation. Next, we analyzed whether AM deficiency might affect the function of FL stoma cells to support hematopoiesis. Interestingly, although stromal cells from WT FL supported colony-forming activities of AM-/- FL LSKs, those from AM-/- FL hardly supported growth of WT FL LSKs, indicating that, in addition to the defect in hematopoietic cells, the stromal function to support hematopoiesis was also impaired in AM-/- embryos. *Conclusions.* In AM-/- fetal liver, total number of hematopoietic cells was decreased, which was more prominent in immature hematopoietic stem/progenitor cells than in matured cells. Also, AM-/- hematopoietic stem/progenitor cells had less reconstituting activities in terms of the frequency of CRU and long-term maintenance. Further-

more, AM was required for the function of fetal liver cells to support hematopoiesis. These results indicate that AM deficiency causes both cell autonomous and extrinsic defects in fetal liver hematopoiesis. Further precise molecular mechanisms responsible for these defects will be presented in the meeting.

0233

TGF-BETA TRANSDUCED MESENCHYMAL STEM CELLS AMELIORATE AUTOIMMUNE COLLAGEN-INDUCED ARTHRITIS BY REGULATING TREG-TH17 CELLS AND OSTEOCLAST DIFFERENTIATION

SG Cho,[1] MJ Park,[1] HS Park,[2] ML Cho,[2] HJ Oh,[2] BH Chung,[1] YG Cho,[2] JW Lee,[1] HY Kim,[2] JW Park[1]

[1]Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, South-Korea; [2]A Rheumatism Research Center, Catholic Research Institutes of Medical Science, Seoul, South-Korea

Bone marrow derived mesenchymal stem cells (MSCs) are multipotent cells that regulate immune responses. MSCs have recently been shown to prevent autoimmunity such as autoimmune encephalomyelitis (EAE) and diabetes. However, their therapeutic effect in rheumatoid arthritis (RA) remains controversial. In this study, we examined the therapeutic potential of TGF-β transduced MSCs in experimental autoimmune rheumatoid arthritis (RA), an accepted animal model of collagen-induced arthritis (CIA). We show that the systemic infusion of syngeneic TGF-β transduced MSCs prevented arthritis development and reduced bone erosion/cartilage destruction. Treatment with genetically modified MSCs expressing TGF-β potently suppressed type II collagen (CII) specific T cell proliferation and downregulated pro-inflammatory cytokine production. These therapeutic effects were associated with an increase in type-II collagen-specific $CD4^+Foxp3^+$ regulatory T cells and an inhibition of Th17 cell formation in the peritoneal cavity and spleen. Furthermore, TGF-β-MSCs migrated to inflamed joints, and such migrations inhibited osteoclast differentiation. Our results demonstrated that gene transfer of TGF-β to MSCs limits the development of arthritis in a model of CIA and joint inflammation. These data suggest that modulating T cell-mediated immunity by gene-modified MSCs provides a novel therapeutic approach for RA

0234

IDENTIFICATION OF LONG-TERM REPOPULATING HEMATOPOIETIC STEM CELLS WITHOUT NEGATIVE SELECTION

Y Kubota,[1] I Lieberam,[2] J Jessell,[2] SI Nishikawa[1]

[1]Riken Center for Developmental Biology, Kobe, Japan; [2]Columbia University, New York, USA

Background. In the last two decades, identification of hematopoietic stem cells (HSCs) has been improved by using both multi-color FACS and *in vivo* competitive reconstitution assay. However, conventional staining protocols need many antibodies that include both positive and negative markers. Furthermore, information for location of HSCs in hematopoietic tissues is also important to understand HSC behavior and HSC-microenvironment (niche) interaction *in vivo*. Current methods for purification of HSCs largely depend on negative-selection such as lineage markers, CD34, Flk2 and CD48. Though negatively stained cells can easily be discriminated by FACS, identification of negative cells is very difficult by nonquantitative immunofluorescence on fixed and embedded tissue sections. Thus, simple method using only positive markers is preferable for fulfilling the above requirements. *Design and Methods.* In this study, we performed a stringent comparative gene profiling analysis to identify genes preferentially expressed in the HSC population. Among the selected HSC-specific genes, we focused on genes encoding cell surface protein, and identified plexin domain containing 2 (Plxdc2) as a novel positive marker for long-term HSCs. Plxdc2 is a single-pass type I membrane protein which is expressed in tumor vessels but not in most normal tissues. Because anti-Plxdc2 antibody is not available for FACS, we used Plxdc2::GFP knock-in mouse for subsequent analyses. *Results.* In whole bone marrow (WBM) of Plxdc2::GFP knock-in mouse, GFP^+ cells are less than 0.2%. Competitive reconstitution assay clearly showed that all HSCs are included in Plxdc2::GFP^+ fraction. Limiting dilution competitive repopulation assays revealed that one out of every 3.5±0.6 (29%) intravenously injected $Plxdc2^+$ $c\text{-}Kit^+$ $Sca\text{-}1^+$ Lineage cells long-term multilineage reconstituted irradiated mice. However, in WBM GFP^+ population, more than 50% of the cells are c-Kit-/low, $Sca\text{-}1^+$, Lineage- uncharacterized fraction. In order to further purify long-term HSCs in Plxdc2::GFP^+ cells, we investigated the additional marker. Throughout the screening of various known HSC-related markers, we selected CD150 (Slamf1). The frequency of $Plxdc2^+$ $CD150^+$ cells in WBM is only 0.01%, suggesting that long-term HSCs are highly enriched by only two positive markers. *Conclusions.* We propose new and simple method for identification of long-term HSCs without using negative markers. Single cell reconstitution assay of $Plxdc2^+$ $CD150^+$ cells, immunofluorescence analysis on bone sections to detect HSCs, production of anti-Plxdc2 monoclonal antibody and analysis of Plxdc2-deficient mice (Plxdc2GFP/GFP mice) are our ongoing tasks.

THE ASB2α UBIQUITIN LIGASE COMPLEX AS A REGULATOR OF THE CROSSTALK BETWEEN HEMATOPOIETIC STEM CELLS AND THEIR MICROENVIRONMENT

I Lamsoul, C Burande, M Erard, C Moog-Lutz, P Lutz

Institute of Pharmacology and Structural Biology, IPBS, CNRS/UPS UMR[5089], Toulouse, France

Background. Understanding the molecular mechanisms controlling early steps of hematopoietic differentiation that are deregulated in leukemia cells and characterizations of properties of hematopoietic stem cells (HSCs) and leukemic stem cells are major challenges not only for the development of therapeutic approaches to targets leukemic stem cells *in vivo* but also for engraftment of normal HSCs following transplantation. Our previous work identified the *ASB2* gene as a retinoic acid response gene and as a target gene of the oncogenic PML-RARα fusion protein in acute promyelocytic leukemia cells. However it is specifically expressed in normal immature hematopoietic cells and so is likely to be relevant during early hematopoiesis. The *ASB2* gene encodes ASB2α protein that is the specificity subunit of an E3 ubiquitin ligase complex and that triggers polyubiquitination of Filamins leading to their degradation by the proteasome. We recently demonstrated that ASB2α, through Filamin degradation, can regulate integrin-dependent functions. Because integrins play a major role in HSC adhesion to the hematopoietic niche, ASB2α may modulate the balance between adhesion and migration of HSCs and therefore their cell fate within the hematopoietic niche. *Aims.* Functional assays and molecular approaches were performed to get structural and functional insights into the ASB2α E3 ubiquitin ligase complex. *Methods and Results.* To assess the role of ASB2α in hematopoietic cell adhesion, hematopoietic cells stably transfected with inducible vectors encoding ASB2α or an E3 ubiquitin ligase defective mutant were labeled and allowed to adhere on wells coated with fibronectin, the main ligand of β1 integrins. We show that ASB2α enhances adhesion of hematopoietic cells to fibronectin. Furthermore, this effect was recapitulated in Filamin knockdown cells. To further investigate ASB2α function, structural and cell biology studies were carried out. By structural homologies and site-directed mutagenesis, we have defined regions of ASB2α and Filamin proteins that are necessary for co-localization and subsequent ASB2α-induced Filamin degradation. Importantly, the defined region of ASB2α involved in this process is similar to the binding domains of other Filamin ligands involved in cell motility. Thus, ASB2α may displace Filamin from these proteins before triggering Filamin polyubiquitylation and degradation by the proteasome. *Summary/Conclusions.* Our results demonstrated that ASB2α is a regulator of integrin-dependent adhesion and initiation of migration of hematopoietic cells. This control of hematopoietic cell motility derives from a specific determinant of ASB2α that is involved in the recruitment of its substrate (Filamin) leading to its subsequent degradation. The hallmark of HSCs is their repopulation and motility (adhesion and migration) potentials. Indeed, HSC mobilization, homing, and repopulation are sequential events with physiological roles. Because interactions between HSCs and their microenvironment are broken during cell mobilization and re-established to enable efficient bone marrow homing and retention, ASB2α may represent a novel pathway controlling the status of HSCs within the hematopoietic niche and thus, a potential drug target for therapeutic strategies involving HSC engraftment.

0236

TNF-ALPHA UPREGULATES THE EXPRESSION OF HES1, HEY1 AND GATA3 IN HEMATOPOIETIC STEM CELLS, IN A NOTCH-DEPENDENT WAY, DURING T-LYMPHOPOIESIS

R Panepucci,[1] L Oliveira,[2] J Schiavinato,[2] A Araujo,[1] M Orellana,[1] P Palma,[2] D Covas,[2] M Zago[1]

[1]INCTC-Fundherp, FMRP-USP, Ribeirao Preto, Brazil; [2]INCTC-Fundherp, FMRP-USP., Ribeirao Preto, Brazil

Background. We have previously shown that umbilical cord blood (UCB) hematopoietic stem cells (HSC), as compared to bone marrow (BM) HSC, express higher levels of NOTCH and NF-κB pathway components and transcriptional targets. Those differences would relate to the higher potential to generate T-lymphocytes observed for UCB HSC, *in vitro* and *in vivo*. In line, treatment of HSC with TNF-α, an agonist of the NF-κB pathway (also expressed at higher levels in UCB HSC), increases the generation of T-cells. Nevertheless, the molecular mechanisms by which TNF-α promotes T-lymphopoiesis are not known. *Aims.* To evaluate the influence of TNF-α in Notch signaling. Material and *Methods.* Human CD34$^+$ HSC were immunomagnetically purified from UCB (obtained after informed consent) and co-cultured (12h) with cells expressing the Notch ligand Delta like 1 (OP9-DL1), or not (OP9), and in the presence or absence of TNF-α (0.25 ng/mL) and the Notch inhibitor DAPT (10 nM). The same culture conditions were carried with HSC pre-treated with the protein synthesis inhibitor cycloheximidine (CHX). Real-time PCR was used to quantify NOTCH transcriptional targets (GATA3, HES1 and HEY1). GAPDH levels were used for normalization and relative expression levels were obtained using HSC co-cultured with OP9 cells as reference samples. *Results.* Transcript levels of HEY1 and HES1 were upregulated upon co-culture with OP9-DL1 cells. Interestingly, their levels were further up-regulated by TNF-α, but, only in the absence of DAPT, indicating a Notch-dependent positive effect. As expected for direct Notch targets, the upregulation induced by OP9-DL1 cells occurred even in HSC treated by CHX, nevertheless, while CHX treatment further increased the expression of HES1, the induction of HEY1 was reduced. These latter results indicate that proteins synthesized during the co-culture period may act negatively in the transcription of HES1 and positively on HEY1. In line, the effect of TNF-α on HES1 expression was higher on CHX treated HSC, as compared to non treated cells, while, the effect of TNF-α on HEY1 expression was lower on CHX treated HSC. Despite these changes, the positive effect of TNF-α was still present in CHX treated HSC, indicating the existence of a molecular signaling mechanism independent of *de novo* protein synthesis. For GATA3, no upregulation was evident in HSC co-cultured solely with OP9-DL1 cells, nevertheless, CHX and TNF-α upregulated GATA3 expression additively. Finally, in the presence of both, CHX and TNF-α, DAPT reduced the expression of GATA3, indicating a dependence on Notch signaling. Summary. Our results indicate that the positive effect of TNF-α on T-lymphopoiesis may partially derive from a Notch-dependent molecular signaling mechanism (independent of *de novo* protein synthesis) that contributes for the transcriptional upregulation of Notch targets. Furthermore, our results indicate the existence of positive and negative feedback mechanisms, acting trough *de novo* synthesized proteins, controlling the expression of HEY1 and HES1, respectively.

ADIPOSE TISSUE AS A DEDICATED RESERVOIR OF FUNCTIONAL MAST CELLS

S Poglio,[1] F De Toni-Costes,[2] C Durand,[3] E Espinosa,[4] E Arnaud,[2] P Laharrague,[2] L Casteilla,[2] B Cousin[2]

[1]CNRS-UMR 5241, Toulouse, France; [2]CNRS UMR 5241, Toulouse, France; [3]CNRS UMR5241, Toulouse, France; [4]INSERM U563, Toulouse, France

Background. Adipose tissue (AT) has long been studied for its metabolic role. Since ten years, numerous studies have focused on the hematopoietic mature cells harboured in this tissue, i.e. lymphocytes and macrophages. These mature resident cells have been largely studied for their involvement in the onset of obesity. Beside mature macrophages and lymphocytes, the presence of hematopoietic stem cells (HSC) has been proposed although their differentiation potentials are still questioned. *Aims.* The aim of this study was to identify potential HSC in murine AT and to characterize their function both *in vitro* and *in vivo*. *Methods.* Putative murine adipose derived HSC were identified by flow cytometry by using cell surface antigens described in BM (KTLS phenotype). These cells were then sorted and used for both *in vitro* and *in vivo* studies. *in vitro*, KTLS cells were plated in long term cultures (LTC) and colony forming cell (CFC) assays. Colonies generated in both types of culture were phenotypically and functionally characterized. In parallel, competitive repopulation assays were performed with adipose derived KTLS cells, in order to quantify and analyze their progeny *in vivo*. *Results.* AT harbours numerous c-kit$^+$/CD90$^{lo/Lin-}$/Sca1$^+$ (KTLS) cells, with a frequency 100 times higher than in BM. *in vitro*, these KTLS cells generate both macrophages and mast cells in LTC, and differentiate only into functional mast cells in CFC assays. After *in vivo* transplantation, adipose-derived KTLS preferentially migrate towards organs such as AT, intestine, lung and skin where they generate mast cells and macrophages but failed to commit to lymphoid lineage. *Summary/Conclusions.* Our results demonstrate that AT is a source of KTLS cells dedicated to generate mast cells and macrophages. Due to its abundance in adult organism, AT would thus constitute a major source of myeloid progenitors able to home to different organs. The identification of such cells in human AT would be of interest in cell therapy.

PARTICIPATION OF THE PROGENY OF MARKED BY LENTIVIRAL VECTOR MESENCHYMAL STEM CELLS IN THE DEVELOPMENT OF HEMATOPOIETIC MICROENVIRONMENT

J Drize, V Sats, A Zhironkina, A Svinareva, N Shipounova

National Research Hematological Center, Moscow, Russian Federation

Background. Colony forming units fibroblast (CFU-F) are the polypotent progeny of mesenchymal stem cells (MSCs). Role of CFU-F in the formation of all elements of hematopoietic stromal microenvironment is still obscure. Proliferative potential of CFU-F is limited and unlike MSCs they are not capable of transfering hematopoietic microenvironment in mice. After implantation of femur bone marrow plug or adherent cell layer (ACL) from long-term bone marrow culture (LTBMC), but not CFU-F derived colonies, under renal capsule of syngeneic recipients the ectopic hematopoietic foci form. Stromal cells in such foci are derived from donor MSCs while hematopoietic cells have recipient's origin. The size of the foci formed is proportional to the femur equivalent transplanted and can be used for semi-quantitative determination of MSC number. *Aims.* The aim of the study was to investigate the involvement of marked progeny of murine MSCs in formation of stromal hematopoietic microenvironment. *Methods.* ACLs of 2-week-old LTBMCs were infected with 100 mkl of concentrated (108 viral particles/mL) self-inactivating (SIN) HIV LeGO vector encoding EGFP (all plasmids and Phoenix cells were placed by Prof. Boris Fehse) in 3 ml of alfaMEM with 10% FCS and 8 mkg/mL polybrene for 6 hours. In 2, 8, 14 and 16 weeks after the infection ACL cells were trypsinized and plated 25, 50, 100 and 200 cells/well of 96-well plate for CFU-F analysis in alfaMEM supplemented with 20% FCS and 5 ng/mL FGF2. In separate experiments 2-3 weeks after infection ACLs were implanted under the renal capsule of syngeneic mice. In 6 weeks the number of marked CFU-Fs was measured among nucleated cells from the foci formed. *Results.* In 2, 8, 14 and 16 weeks after infection the proportions of marked cells in infected ACLs were 9.7, 31, 5 and 8.8% correspondingly. The efficiency of marked CFU-Fs cloning was 1 cell per 118±39 on week 8 and per 690±280 on week 14. Obviously the number of marked stromal cells in the ACLs is proportional to the number of marked CFU-F.ACLs implanted under the renal capsule of syngeneic mice contained 19.5±8.0% EGFP positive cells. The size of the foci formed was (3.3±0.5)×10^6 cells. Most of the tiny bones developed in the foci were EGFP positive as revealed PCR analysis. The concentration of CFU-Fs in ectopic foci formed was 33.5±21.7 per 106 cells that is similar to the concentration of CFU-Fs in the bone marrow. The proportion of marked CFU-Fs among total CFU-Fs was 8.97±1.18%. *Conclusions.* Revealed interconnection between the frequency of marked CFU-Fs and the proportion of marked differentiated stromal cells in the ACLs suggests that exactly CFU-Fs are the progenitors of developed hematopoietic microenvironment. Marked with lentiviral vectors MSCs are able to transfer hematopoietic microenvironment at least twice and keep the ability to produce the considerable number of marked progeny. The data indicate the advantages of MSCs as targets for gene therapy due to their longevity, ability to self-renew and to produce the differentiated progeny with the integrated gene of interest.

VITAMIN D RECEPTOR (VDR) INDUCTION IS CRITICAL FOR LANGERHANS-TYPE DC LINEAGE COMMITMENT OF COMMON HUMAN MONOCYTE/DC PROGENITORS

J Jurkin, F Göbel, S Richter, S Konradi, N Yasmin, A Elbe-Bürger, C Vaculik, H Strobl

Medical University Vienna, Vienna, Austria

Langerhans cells (LCs) represent highly abundant dendritic cells (DCs) that form tight networks of hematopoietic cells in stratified epithelial tissues, however lineage commitment processes leading to their differentiation from hematopoietic stem cells remain poorly defined. The cytokine TGF-β1 is both sufficient and necessary for the induction of LC generation from human myeloid progenitor cells *in vitro*, and is similarly required for murine LC differentiation *in vivo*. We here searched for transcription factors induced or repressed by TGF-β1 concomitant with LC lineage commitment of myeloid progenitor cells. $CD34^+CD45RA^+CD19^-$ umbilical cord blood cells were stimulated for 48 h *in vitro* using a cytokine combination that induces common monocyte/LC progenitor cells. TGF-β1 addition to these cells induces LC commitment, while in its absence, cells alternatively differentiated into monocytes. Gene array profiling identified the VDR to be rapidly induced (within 6 h) during TGF-β1-dependent LC commitment. Ectopic retroviral VDR expression strongly augmented LC induction, whereas VDR inhibition abrogated LC differentiation. In line with this, epidermal LCs show a nuclear VDR expression pattern. Therefore, VDR induction downstream of TGF-β1 promotes LC commitment of shared monocyte/LC progenitors.

HDAC AND SIRT INHIBITION DIFFERENTIALLY MODULATE CELL FATE DECISIONS DURING NEUTROPHIL AND MEGAKARYOCYTE DIFFERENTIATION

M Bartels,[1] R Polak,[1] C Geest,[2] M Bierings,[1] M Buitenhuis,[3] P Coffer[1]

[1]UMC Utrecht, Utrecht, Netherlands; AMC, Amsterdam, Netherlands; [3]Erasmus MC, Rotterdam, Netherlands

Background. The clinical use of chromatin modulating drugs, such as histone deacetylase (HDAC) inhibitors, for the treatment of bone marrow failure and hematopoietic malignancies has increased dramatically over the last few years. In addition, the use of a distinct group of HDAC inhibitors, SIRT-inhibitors, is being investigated in pre-clinical studies. Nonetheless, little is currently known concerning the effects of both class I/II HDAC- and SIRT-inhibitors on normal myelopoiesis. *Aims.* To compare and contrast the effects of HDAC inhibitors on normal myeloid development and identify specific targets of HDAC inhibition in hematopoietic progenitors *Methods*. We utilized an ex-vivo differentiation system in which umbilical cord blood derived $CD34^+$ cells were treated with trichostatin A (TSA), sodium butyrate (SB) and valproic acid (VPA) to evaluate the effect of HDAC inhibitor treatment on myeloid lineage development, proliferation, and terminal neutrophil differentiation. In addition we investigated the effects of VPA and the SIRT-inhibitor nicotinamide (NAM) on megakaryocyte/erythroid progenitor (MEP) differentiation and terminal megakaryocyte differentiation. *Results.* TSA treatment modestly reduced progenitor proliferation, while SB and VPA resulted in concentration dependent effects on proliferation and apoptosis. Addition of VPA uniquely stimulated $CD34^+$ proliferation, while SB treatment both quantitatively and qualitatively inhibited terminal neutrophil differentiation. Addition of 100 μM VPA resulted in increased numbers of mature neutrophils with a block in differentiation at increasing concentrations. VPA treatment increased the percentage and absolute number of MEPs, yet resulted in a dramatic decrease in terminal megakaryocyte differentiation. In contrast with the effects of VPA on megakaryocyte development, addition of the SIRT inhibitor NAM resulted in a significant increase in the percentage of mature megakaryocytes and increase in polyploidy. However, this effect was accompanied by a significant decrease in megakrayocyte progenitor proliferation. Preliminary results have demonstrated that treatment of $CD34^+$ progenitors with 100 μM VPA in combination with 1mM NAM inreased both the precentage and absolute number of mature megakaryocytes. Treatment of myeloid progenitors with all HDAC inhibitors resulted in increased histone acetylation and TSA, SB and VPA were found to also have differential effects on the acetylation of non-histone proteins. *Summary/Conclusions.* Individual HDAC inihibitor treatment has specific effects on cell fate decisions during myeloid development. These data provide novel insights in the effects of HDAC inhibitors on regulation of normal hematopoiesis and are of importance when considering utilizing these compounds for the treatment of myeloid malignancies and bone marrow failure syndromes. Moreover, these data confirm the distinct roles of class I and II HDACs (inhibited by TSA, SB and VPA) compared to class III HDACs, better known as Sirtuins (inhibited by NAM) in normal hematopoiesis. Together, these data underline the important role of acetylation in regulation of normal hematopoiesis and thereby contribute to a better understanding of the pathogenesis of myeloid malignancies

0241

PHENOTYPIC AND FUNCTIONAL CHARACTERISTICS OF TISSUE NON SPECIFIC ALKALINE PHOSPHATASE (TNSALP) POSITIVE BONE MARROW FIBROBLASTIC RETICULAR CELLS IN MURINE RADIO-INDUCED APLASIA

G Poncin,[1] C Humblet,[1] Z Belaid,[1] A Thiry,[1] K Oda,[2] P Crine,[3] J Millàn,[4] M Defresne[1]

[1]Université de Liège, Liège, Belgium; [2]Niigata University, Niigata, Japan; [3]Enobia, Montréal, Canada; [4]Burnham's institute, La Jolla, USA

Background. Bone marrow aplasias are characterized by a peripheral blood cells deficit resulting from a deficiency in the production of one or several blood cells lineages in bone marrow. Some of these aplasias are able to regenerate, others don't respond to treatment. In most of the cases, spontaneously regenerating bone marrows are characterized by the presence in the whole marrow cavity, of fibroblastic cells presenting a strong alkaline phosphatase activity (ALP), this activity has completely disappeared in irreversible bone marrow aplasias. *Aims.* The aim of our work is to analyze phenotypic and functional characteristics of these ALP positive reticular cells and to test a possible role of ALP in haematopoietic regeneration. *Methods.* Mice were submitted to a total body irradiation with a 4Gy rate of gamma rays. Femoral bone marrows were removed at several time points after irradiation and put in culture in adequate conditions to form CFU-Fs colonies. CFU-Fs from non irradiated mice were used as control. Phenotype of CFU-Fs was analysed, and their haematopoietic supportive capacities were tested. *Results.* In a first step, we have studied ALP positive cells and haematopoietic cells evolution in a murine model of reversible radio-induced aplasia. We have demonstrated that the density of the ALP network and the number of ALP positive cells increase strongly in the first three days following irradiation. This increase precede haematopoietic regeneration and isn't a result of ALP positive cells proliferation. *in vitro* studies have also demonstrated that this increase in ALP activity is due to the expression of both TNSALP (tissue non specific alkaline phosphatase) and PMCA whose mRNA expression progressively increase after irradiation. Observations suggest that ALP cells differentiated from mesenchymal stem cells: the number of CFU-Fs is proportional to the number of *in situ* bone marrow ALP cells and the proportion of ALP positive cells increase in CFU-Fs from irradiated bone marrows, ALP cells keep self renewal and differentiation capacities and express common marker of mesenchymal stem cells ($CD106^+$, $Sca\text{-}1^+$, $CD11b^-$, $CD45^-$ and $flk1^-$). They also expressed pre-osteoblastic markers (runx2 and osteocalcin). To test their function in haematopoiesis, we have realized co-cultures of CFU-Fs and haematopoïetic precursors ($ckit^+$, $sca\text{-}1^+$, lin^-). We observed that, CFU-Fs from irradiated bone marrow, characterized by a high proportion of TNSALP positive cells and a strong expression of sdf-1 (stroma derived factor-1), strongly stimulate the proliferation of haematopoietic precursors and induce their differentiation into the myelo-monocytic and granulopoietic lineages. Studies at a late embryonic stage, on TNSALP deficient mice demonstrated a deficit in granulopoiesis as well as in the growth of the myelo-monocytic lineages. *Summary/conclusions.* All these data suggest that TNSALP reticular cells, directly derived from mesenchymal stem cells play a role in normal haematopoiesis and in regeneration of bone marrow aplasia by inducing proliferation and differentiation of myelo-monocytic and granulocytic precursors by a mechanism still to be elucidated.

0242

IFNα ACTIVATES DORMANT HSCS *IN VIVO*

M Essers,[1] S Wurzer,[2] A Kern,[2] R Lutz,[2] A Trumpp[3]

[1]HI-Stem, Heidelberg, Germany; [2]DKFZ, Heidelberg, Germany; [3]Hi-Stem, Heidelberg, Germany

Haematopoietic stem cells (HSCs) in mouse bone marrow are located in specialized niches as single cells. During homeostasis, signals from this environment keep some HSCs dormant, which preserves long-term

self-renewal potential, while other HSCs actively self renew to maintain haematopoiesis. In response to haematopoietic stress, dormant HSCs become activated and rapidly replenish the haematopoietic system. The signalling molecules promoting the exit of HSCs out of the dormant stage remain largely unknown. We have recently uncovered that in response to treatment of mice with interferon-alpha (IFNα), HSCs efficiently exit G0 and enter an active cell cycle. HSCs respond to IFNα treatment by increased phosphorylation of STAT1 and PKB/Akt, expression of IFNα target genes and up-regulation of stem cell antigen-1 (Sca-1). HSCs lacking either the interferon-α/β receptor (IFNAR), STAT1 or Sca-1 are insensitive to IFNα stimulation, demonstrating that STAT1 and Sca-1 mediate IFNα induced HSC proliferation. Since the induced activation of HSCs upon IFNα treatment is only observed *in vivo* and not *in vitro*, we are examining the change in HSC-niche interactions upon IFNα stimulation. Although dormant HSCs are resistant to the anti-proliferative chemotherapeutic agent 5-FU, HSCs pre-treated (primed) with IFNα and thus induced to proliferate are efficiently eliminated by 5-FU exposure *in vivo*. Conversely, HSCs chronically activated by IFNα are functionally compromised and are rapidly out competed by non-activatable IFNAR$^{-/-}$ cells in competitive repopulation assays. Data on a possible role for STAT1 and Sca-1 in this chronic IFNα treatment will be presented. In summary, while chronic activation of the IFNα pathway in HSCs impairs their function, acute IFNα treatment promotes the proliferation of dormant HSCs *in vivo*. These data may help to clarify the so far unexplained clinical effects of IFNα on leukemic cells, and raise the possibility for novel applications of type I interferons to target cancer stem cells.

BONE MARROW STROMA FROM MULTIPLE MYELOMA PATIENTS EXHIBITS MODIFIED RESPONSES TO TOLL-LIKE RECEPTOR ACTIVATION

M Pevsner-Fischer[1], S Levin[1], T Hammer[1], Y Cohen[1], F Mor[2], M Mayorov[3], G Wagemaker[4], A Nagler[3], I Cohen[1], D Zipori[1]

[1]Weizmann Institute of Science, Rehovot, Israel; [2]Rabin Medical Center, Beilinson Campus, Petah Tikva, Israel; [3]Chaim Sheba Medical Center, Tel Hashomer, Israel; [4]Erasmus MC, Erasmus University Medical Center, Rotterdam, Netherlands

In human multiple myeloma (MM) the tumor cells exhibit strict dependence on bone marrow (BM) stromal elements. It has been suggested that in turn, MM cells modify multipotent stromal cells (MSCs) of the BM, and thereby the functions of MSCs may be compromised. We did not find phenotypic differences between MSCs from the bone marrow of MM patients and control donors. However, the analysis of responses of MSCs to toll-like receptor (TLR) ligands, revealed intrinsic differences between the MM and control populations. The activation of TLR-2 and TLR-4 by corresponding ligands augmented MSC proliferation in both MM and control MSCs. Different TLR ligands induced divergent effects on MSCs stimulated into adipogenesis and osteogenesis, ranging from augmentation to inhibition of differentiation. MM and control MSCs responded by IL-6, IL-8 and activin A secretion to TLR activation. However, in MSC derived from MM patients IL-8 secretion and ERK1/2 phosphorylation diverged from that of controls in response to TLR-2 activation. The persistence of these changes in long-term passage MSCs from MM patients suggests that these cells are intrinsically modified and consequently respond differently to TLR activation.

AMPK INHIBITION INDUCES APOPTOSIS IN PEDIATRIC B-ALL CELLS WITH MLL GENE REARRANGEMENTS

B Accordi,[1] V Espina,[2] M Giordan,[1] A VanMeter,[2] L Galla,[1] G Milani,[1] M Sciro,[1] R De Maria,[3] G Te Kronnie,[1] E Petricoin,[2] L Liotta,[2] G Basso[1]

[1]University of Padova, Padova, Italy; [2]George Mason University, Manassas, VA, USA; [3]Istituto Superiore di Sanità, Rome, Italy

Background and Aims. Remarkable progress has been made in the past decade in pediatric Acute Lymphoblastic Leukemia (ALL) treatment, reaching cure rates of about 80%, but therapy is not yet effective in all cases. Infants with MLL gene rearrangements form the most striking example of patients who have not benefited from the improved treatment regimens. Consequently, current interest focuses on identifying new specific molecular targets to find new patient-tailored therapies. Thus, to identify aberrantly activated signal transduction pathways in MLL-rearranged patients, we used Reverse Phase Protein Microarrays (RPMA). This innovative technique can be used to quantify a highly multiplexed "portrait"of hundreds of signalling proteins at once from small clinical samples in a very reproducible, precise, sensitive and high-throughput manner. We further investigate RPMA results with *in vitro* studies testing the effects of a specific kinase inhibitor on apoptosis induction in leukemia cell lines. *Methods.* We compared with RPMA the signal transduction pathways working state of 8 MLL-rearranged patients vs 41 without known genomic translocations ones. The informed consent was obtained from all patients following the tenets of the Declaration of Helsinki. Phosphorylation status of 92 signalling proteins was analyzed. Based on RPMA results, we tested through proliferation and apoptosis assays the effect of Compound C, an AMPK inhibitor, on selected B-ALL human cell lines: 2 MLL-rearranged (SEM and RS4;11) and 2 non-translocated (MHH-CALL-2 and MHH-CALL-4). We then performed additional experiments to describe Compound C-induced apoptosis. *Results.* MLL-rearranged patients show an hyper-activated pathway that, through AMPK phosphorylation, leads to BCL-2 activation. Selected cell lines respond very differently to AMPK inhibition. GI50 (Growth Inhibition) at 48h is 0.2 μM for SEM, 3 μM for RS4;11, and 26 μM for non-translocated cell lines. LC50 (Lethal Concentration) at 48h is 7.5 μM for SEM, 8.5 μM for RS4;11 and 38 μM for non-translocated cell lines. Compound C treatment induces activation of Caspase-3, mitochondrial depolarization, ROS production, PARP cleavage, and DNA fragmentation. *Conclusions.* Our results thus demonstrate that the AMPK pathway is hyperactivated in MLL-rearranged patients, and it appears to directly contribute to the survival of MLL-rearranged cells. This study emphasizes the importance of protein pathway analysis as a route for discovery of functional derangement that may be functional, causative agents of cancer. Our data suggest AMPK as a new molecular target and encourage further studies of AMPK inhibitors as potential new drugs for treatment of MLL-rearranged leukemia patients.

0245

INTEGRATION OF GLOBAL SNP-BASED MAPPING AND EXPRESSION ARRAYS WITH MICRORNA PATTERNS REVEALS DEREGULATED MIRNAS AND THEIR GENE CANDIDATE TARGETS IN ACUTE MYELOID LEUKEMIA

L Garcia-Orti, I Cristobal, M Marcotegui, E Guruceaga, V Segura, A Orta, C Vicente, E Bandrés, MD Odero

CIMA, University of Navarra, Pamplona, Navarra, Spain

Acute myeloid leukemia (AML) is a heterogeneous clonal disease that results from multiple genetic alterations in hematopoietic stem cells. Genetic aberrations have decisive importance in the biology and clinical outcome of patients with AML; however, most patients relapse within 1-2 years. Therefore, improved predictive biomarkers are needed to identify other genetic alterations that collaborate in AML development. Deregulated miRNA expression plays a crucial role in tumorigenesis. Recent studies have shown some of the mechanisms through miRNA deregulation contribute to cancer: mutations, chromosomal translocations, epigenetic alterations, or a defective miRNA biogenesis. However, the role of DNA copy number variations (CNV) in deregulation of miRNAs in AML remains unclear. Our aim was to identify if CNV affects the deregulation of miRNAs in AML, and if that could affect the expression levels of their target genes. We analyzed 16 AML cell lines using 500K-SNP arrays (aSNP) (Affymetrix), analysis of 250 miRNAs by q-RT-PCR, and mRNA expression arrays (HG-U133A). After analyzing CNV in the cell lines, we evaluated if a significant gene dosage effect could be identified in the expression levels of specific miRNAs located within CNV segments generated by the genome-wide analysis. We identified 17 miRNAs with a significative correlation ($P<0.05$) between their expression and the CNV of the region: 14 up-regulated and located in a genomic region of amplification, and 3 down-regulated miRNAs, localized in regions with genomic deletions. The 14 miRNAs up-regulated comprise 5 clusters in 2 different amplified regions. MiR-100 and miR-125b, clustered in 11q24.1, have been described to be highly expressed in pediatric AML. There were 4 miRNA clusters on 14q32.31. In cluster A are located miR-379 and miR-494 ($P<0.001$), that have been described to control neuronal development. Cluster B is integrated by miR-127, miR-432, and miR-433, expressed in a compact space by using overlapping coding regions, which are implicated in fetal development. Interestingly, miRNAs belonging to clusters C and D of this region have been described to be up-regulated in adults with AML, (miR-154, miR-409-5p, and miR-370, miR-376A, miR-382, miR-134, and miR-485-5p) ($P<0.001$). Only 3 down-regulat-

ed miRNAs were located in regions with deletions: miR-15a (P=0.001) and miR-16 (P=0.033), clustered in 13q14.3; and miR-7 (P=0.05), located on 9q21.32. The implication of these miRNAs in tumorigenesis is well known. These results prompted us to perform a correlation between these miRNAs and the mRNA arrays in the cell lines to assess if their predicted target genes are also affected. We obtained a set of genes candidates whose altered expression is likely consequence of an aberrant miRNA regulation. In conclusion, the deregulation of some miRNAs could be explained by their location in genomic regions affected by genomic aberrations. Moreover, our integrative approach by aSNP, mRNA arrays, together with miRNA expression patterns in AML cell lines allowed us to identify 17 miRNAs, which could have an important role in AML, and their putative targets. Further functional studies are in progress.

0246

HYPOXIA MAINTAINS STEMNESS OF ENDOTHELIAL PROGENITOR CELLS

N Hofmann, A Reinisch, K Schallmoser, E Rohde, M Absenger, R Birner-Gruenberger, D Strunk

Medical University of Graz, Graz, Austria

Vascular homeostasis, remodeling and regeneration are maintained by tightly regulated vessel wall-derived somatic endothelial colony-forming progenitor cells (ECFCs). Despite promising experimental data, both cellular therapeutic vasculogenesis as well as anti-angiogenic therapy targeting ECFCs are of rather limited efficiency in clinical trails. A better understanding of vascular biology is thus urgently needed to develop alternative concepts for vascular regeneration and anti-angiogenic cancer therapy. Currently we believe that hypoxia in ischemic and tumor tissue is a key factor driving the revascularization machinery. *in vivo*, most cells exist under a defined oxygen pressure considerably below air oxygen. *in vitro*, isolated cells are usually treated under air oxygen conditions and encounter sudden reduced oxygen when re-injected for therapy. We hypothesized that differences between ex vivo and *in vivo* oxygen levels influence ECFC function and thus represent a key factor in vascular regenerative therapy. NORMOXIA has been used variably in the literature describing a wide spectrum of oxygen levels. We therefore designated the oxygen level present *in vivo* in the venous environment to be termed EUOXIA (41.5±3.4 mmHg) throughout this study. Oxygen levels above EUOXIA are defined as HYPEROXIA (139.8±2.9 mmHg) and below EUOXIA as HYPOXIA (27.4±7.3 mmHg). Adult human ECFCs were isolated and propagated directly from whole venous blood using a novel recovery strategy. During cell culture, pooled human platelet lysate (pHPL) entirely replaced fetal bovine serum (FBS). Progenitor cell phenotype, hierarchy, long-term proliferation, wound repair as well as migratory and vasculogenic functions were monitored under Euoxia as compared to hypoxic conditions or air oxygen levels commonly used in standard laboratory practice. Molecular regulation of cellular responses to different oxygen levels was assessed by flow cytometry and proteomic profiling. ECFC colony size was decreased under hypoxic compared to euoxic oxygenation, paralleled by a loss of high proliferative potential (HPP) ECFCs under Hypoxia. The absolute colony number (3.2±0.2 colonies per ten ECFCs seeded per cm^2) remained unchanged independent of oxygen levels. Hyperoxic conditioning resulted in an increase in proliferation in primary and long-term cultures and significantly augmented HPP colonies (60±18% of total colonies) as compared to hypoxic (0%) and euoxic (9±6%) oxygen levels. Vascular wound repair in scratch assays and *in vitro* Matrigel® vascular-like network formation was improved with escalating oxygen supply. Reoxygenation of hypoxic and euoxic ECFCs even lead to enhanced proliferation and function. Proteomic analysis of ECFCs identified several heat shock and antioxidant proteins involved in the oxygen-dependent regulation of migratory and proliferative responses. Reversible inhibition of ECFC function by hypoxic and euoxic oxygen levels indicates the presence of a silencing mechanism. These data suggest that hypoxic and euoxic oxygen levels maintain the ECFC stem/progenitor cell characteristic. Culture conditions for the clinical scale expansion of ECFCs may play a decisive role for their efficiency in therapeutic vasculogenesis. Revascularization of hypoxic tissues after ischemic injury by ECFCs must be indirectly mediated and are therefore further investigated.

GENOMIC STABILITY IN LONG-TERM CULTURED MESENCHYMAL STROMAL/STEM CELLS

K Schallmoser, E Rohde, A Reinisch, A Obenauf, C Bartmann, G Lanzer, W Linkesch, D Strunk

Medical University of Graz, Graz, Austria

Human multipotent mesenchymal stromal cells (MSCs) are currently being tested in clinical trials for immunomodulatory and regenerative therapies. We and others have recently established MSC propagation with pooled human platelet lysate (pHPL) as a substitute for fetal bovine serum (FBS). As serious doubts regarding the use of MSCs cultured with FBS and their possible genomic instability have arisen, we investigated safety aspects of short- and long-term cultures with FBS in comparison to pHPL. Unmanipulated bone marrow aspirates were seeded in alpha-MEM with pHPL. Clinical-scale expanded MSCs were harvested directly after primary culture (short-term). Representative cultures were continued for long-term expansions where each directly compared pHPL and FBS stimulation for a maximum of 46 to 51 population doublings until MSC proliferation ceased. Comparative genome hybridization (array-CGH) was carried out with short- as well as long-term expanded MSCs using a whole genome microarray platform and CGH analysis software. pHPL is highly efficient in stimulating MSC expansion resulting in 780±150 million MSCs after one passage. Flow cytometry revealed more than 95% viability, more than 95% CD73/90/105 reactivity and less than 2% hematopoietic contamination. We were able to show adipo-/osteo-/chondrogenic differentiation potential, endotoxin levels below 0.025 EU/mL and negative bacterial/fungal/mycoplasma testing. In all short-term MSC products, array-CGH revealed balanced genomic profiles. We detected several small copy number variations previously found in healthy individuals not associated with phenotype changes. In contrast, after long-term culture with FBS as well as pHPL, MSCs showed *de novo* copy number amplifications not reported in the database of genomic variants. Despite a high proliferation rate in the short-term pHPL-driven cultures, MSCs showed genomic stability according to array-CGH *Results.* These data support our earlier findings that MSCs expanded under humanized conditions did not form tumors *in vivo* in animal experiments. It is not clear whether *in vitro* genomic variations in long-term propagated MSCs under humanized as well as xenogeneic culture conditions may be associated with the risk of malignant transformation rather than representing replicative senescence. Therefore safety concerns have to be vigilantly addressed parallel to the clinical use of MSCs.

PHOSPHOPROTEOMIC PROFILING OF LEUKEMIA CELLS

H Yoshihara,[1] H Shimada,[2] H Shima,[2] M Tomita,[3] Y Ishihama[3]

[1]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan; [2]Department of Pediatrics, Keio University School of Medicine, Shinjuku, Tokyo, Japan; [3]Keio University, Tsuruoka, Japan

Protein phosphorylation on serine, threonine, and tyrosine is well established as a crucial regulatory posttranslational modification in eukaryotes. While conventional biochemical methods failed to obtain a snapshot of the phosphoproteomes, advances in mass spectrometry (MS) methods have paved the way for indepth mapping of phosphorylation sites. Recently, we developed a phosphopeptide enrichment method using hydroxy acid-modified metal oxide chromatography (HAMMOC) with titania and zirconia (Rappsilber J et al., Nat. Protoc 2007). In HAMMOC, thousands of phosphorylated sites can be identified from limited protein amounts (<100 microgram per sample), enabling the application to the clinical tissue samples. HAMMOC can work effectively for clarification of pathways activated by aberrant tyrosine kinase activation. Fusion protein BCR-ABL is caused by the t(9;22)(q34;q11) translocation, which encodes the constitutively activated tyrosine kinase. Development of the tyrosine kinase inhibitor imatinib had provided a remarkable improvement in the outcome of BCR-ABL-positive chronic myeloid leukemia (CML) or acute lymphoblastic leukemia (ALL). Although, there still remains a challenge how the leukemia acquires imatinib resistance and progress to blast crisis in CML or relapse in ALL. Identification of new pathways and molecules activated by BCR-ABL offers new insights into the pathophysiology of CML and BCR-ABL-positive ALL, and may also provide further development of molecular targeted therapy. Here, we present the phosphoproteome of leukemic cells measured by HAMMOC-based shotgun proteomics approaches. BCR-ABL-positive leukemic cell lines

were digested with Lys-C and trypsin, followed by HAMMOC to enrich phosphopeptides. NanoLC-MS/MS was performed to obtain peptide-fragmentation spectra, and the data were analyzed to identify peptides and proteins by means of automated database search using Mascot (Matrix Science). We have identified more than 1,800 phosphorylated sites through analysis of BCR-ABL-positive cells. BCR-ABL-positive leukemic cell lines formed a phosphopeptide-cluster in parallel analysis of multiple cell lines suggesting a unique signaling phosphorylation pathway in BCR-ABL-positive cells. We are currently analyzing the changes in phosphorylation status when BCR-ABL signaling was modified. One mechanism proposed for resistance to tyrosine kinase inhibitor in CML is the innate insensitivity of primitive quiescent CML stem/progenitor cells, which account for residual disease and evolve to blast crisis. We are verifying phosphorylation of normal hematopoietic stem cells (HSCs), which data will be informative for phosphorylation status of cancer stem cells. In conclusion, our comprehensive method for identifying phosphopeptides is suitable for experiments to study cell signaling networks, which require the enrichment of many phosphopeptides from real complex mixtures with a wide dynamic range. It can be adapted for a wide range of cancer cells which aberrant phophorylated signaling is involved.

SENESCENCE-ASSOCIATED GENE EXPRESSION CHANGES IN MESENCHYMAL STROMAL/STEM CELLS

K Schallmoser,[1] C Bartmann,[1] E Rohde,[1] S Bork,[2] C Guelly,[1] A Obenauf,[1] A Reinisch,[1] P Horn,[2] A Ho,[2] W Linkesch,[1] G Lanzer,[1] W Wagner,[2] D Strunk[1]

[1]Medical University of Graz, Graz, Austria; [2]University of Heidelberg, Heidelberg, Germany

Based on promising experimental studies with mesenchymal stromal cells (MSCs), a variety of clinical applications have been initiated. Extensive propagation to yield enough MSCs for therapy may result in replicative senescence and thus hamper long term functionality *in vivo*. Highly variable proliferation rates of MSCs in the course of long-term expansions under varying culture conditions may already indicate different propensity for cellular senescence. We hypothesized that senescence-associated regulated genes differ in MSCs propagated under different culture conditions. Human bone marrow-derived MSCs were cultured either by a highly efficient two-step protocol or by serial passaging in three different growth conditions. Culture media was either supplemented with fetal bovine serum in varying concentrations or pooled human platelet lysate. All MSC preparations revealed significant gene expression changes upon long-term culture. Especially genes involved in cell differentiation, apoptosis and cell death were up-regulated, whereas genes involved in mitosis and proliferation were down-regulated. Furthermore, overlapping senescence-associated gene expression changes were found in all MSC preparations. Long-term cell growth induced similar gene expression changes in MSCs independent of isolation and expansion conditions. A panel of genes will be presented that might offer a practicable approach to assessing MSC quality with regard to the state of replicative senescence in advance of therapeutic application.

EPIGENETIC INACTIVATION OF THE MIR-34A IN HEMATOLOGICAL MALIGNANCIES

C Chim, KY Wong, J Qi

Queen Mary Hospital, Hong Kong, China

Background. miR-34a is a transcriptional target of p53, and implicated in carcinogenesis. *Aim.* We studied the role of miR-34a methylation in a panel of hematological malignancies including acute leukemia (AML, ALL), chronic leukemia (CLL and CML), multiple myeloma (MM) and non-Hodgkin's lymphoma (NHL). *Methods.* The methylation status of miR-34a promoter was studied in 12 cell lines and 188 diagnostic samples by methylation-specific PCR. *Results.* miR-34a promoter was unmethylated in normal controls but methylated in 75% lymphoma and 37% myeloma cell lines. Hypomethylating treatment led to re-expression of pri-miR-34a transcript in lymphoma cells with homozygous miR-34a methylation. In primary samples at diagnosis, miR-34a methylation was detected in 4% CLL, 5.5% MM samples, and 18.8% of NHL at diagnosis but none of ALL, AML and CML (P=0.011). In MM patients with paired samples, miR-34a methylation status remained unchanged at progression. Amongst lymphoid malignancies, miR-34a was preferentially methylated in NHL (P=0.018), in particular natural killer/T cell (NK/T cell) lymphoma. *Summary.* Amongst hematological malignancies, miR-34a methylation is preferentially hypermethylated in NHL, in particular NK/T cell lymphoma, in a tumor-specific manner, therefore the role of miR-34a in lymphomagenesis warrants further study.

GLOBAL GENE EXPRESSION REVEALS A SET OF GENES THAT MAY BE INVOLVED IN THE PHENOTYPE OF BETA THALASSEMIA MAJOR AND INTERMEDIA

A Cunha

Federal State University of Sao Carlos, Sao Carlos, Brazil

Background. Beta thalassemia is one of the most common monogenic diseases that reduce the production of hemoglobin. The homozygote state is generally classified into two types, according to the severity of symptoms: thalassemia major (also known as Cooley's anemia) and thalassemia intermedia. Of the two types, thalassemia major is more severe. Patients with thalassemia intermedia maintain the hemoglobin level between 7-11 g/dL and do not require regular transfusions. The cause for this milder clinical condition may be an association with the hereditary persistence of fetal hemoglobin (HPFH), co-inheritance of alpha-thalassemia and other genetic factors. However, in some cases the same genetic mutation leads to different phenotypes of thalassemia (major and intermedia), suggesting the involvement of unknown genes in metabolic pathways related to disease prognosis. *Aims.* In this study we used Serial Analysis of Gene Expression (SAGE), Subtractive Suppressive Hybridization Library (SSH) and Real Time PCR (RT-PCR) to analyze global gene expression in a $CD34^+$ culture and reticulocyte of two patients homozygous for the same genetic mutation (CD39), but with different phenotypes of beta thalassemia (major and intermedia). In these patients, all the polymorphisms and mutations in the gamma and beta globin gene as well as all other known associated factors were evaluated and no difference was found. *Methods.* Global gene expression was evaluated in the reticulocyte and $CD34^+$ cultures using SSH and SAGE respectively. In this culture, cells were collected on the 10^{th} day, when cell proliferation and hemoglobin production are intense. To identify the genes that were differentially expressed between the SAGE libraries, a $P<0.01$ and fold ≥ 5 were considered as statistically significant. For the SSH libraries the genes that appeared only in one of the libraries were considered as differential. *Results.* The global aspects of the transcriptome were very similar between the patients and a small set of genes was identified as differentially expressed between the two patients. We found 38 genes overexpressed in thalassemia major (TM) and 42 in thalassemia intermedia (TI). Between these, we found several genes related with important metabolic pathways like protein binding (KLHL12, OAZ1), transcription factors (MAFF, EYA3), apoptosis (SEPT14, BCL2L11, CARD8, SMAD4), cell adhesion (OCIAD1), DNA repair (APEX1, MORF4L1, RAD23), heme biosynthesis (FECH, HMBS), alpha globin stabilization (PCBP2) and drug resistance (ABCB10). Some of these genes, such as PCBP2, EYA3, ABCB10 and APEX1 are described for the first time in association with beta thalassemia, and their expression was evaluated by Real time PCR, confirming the results found in the libraries. *Conclusions*. The results indicated that the global aspects of the transcriptome were similar, and that the up and down regulation of a small set of genes could be responsible for the differences in the severity of symptoms observed in these patients. The results of this study may contribute to a better comprehension of beta thalassemia, as well as to the identification of new therapeutic target genes. Supported by FAPESP

LOW NUMBERS OF PERIPHERAL BLOOD CD19+/CD27+ MEMORY B LYMPHOCYTES AND ALTERED LEVELS OF SERUM IMMUNOGLOBULINS IN PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

K Pyrovolaki, I Mavroudi, MC Flessa, H Koutala, M Kaparou, A Kozana, M Spanoudakis, C Gemetzi, H Papadaki

University of Crete School of Medicine, Heraklion, Greece

Background. Chronic idiopathic neutropenia (CIN) is a disorder of granulopoiesis characterized by increased apoptosis of bone marrow granulocytic progenitor cells due to the presence of pro-inflammatory cytokines mainly produced by activated T-lymphocytes. Infections are uncommon in CIN patients but their frequency and severity, when present, do not always correlate with the severity of neutropenia. *Aims.* To investigate parameters of humoral immunity in patients with CIN with special focus on the quantitative and qualitative characteristics of peripheral blood B lymphocyte subsets and serum immunoglobulin levels. *Methods.* We studied 46 patients fulfilling the previously defined diagnostic criteria for CIN and 24 age- and sex-matched healthy controls after informed consent. We initially evaluated the proportions of $CD19^+$, $CD20^+$, $CD21^+$ and $CD22^+$ peripheral blood B cells by flow-cytometry. Further analysis of B cell subpopulations was performed on the basis of expression of CD19, IgD, CD38 and CD27 surface markers for the evaluation of the proportion of $CD19^+/IgD^+/CD27^-$ total naïve cells, $CD19^+/IgD^+/CD38^+$ activated naïve cells, $CD19^+/C27^+/IgD^+$ memory cells and $CD19^+/CD27^+/IgD^-$ classical memory cells. We also evaluated baseline surface expression of CD40 on B cells and CD40Ligand expression on immunomagnetically sorted $CD3^+$ T-cells upon stimulation with PMA plus ionomycin. Finally, we evaluated serum levels of IgG1, IgG2, IgG3, IgG4, IgA and IgM by routine nephelometry. *Results.* The proportion of $CD19^+$, $CD20^+$, $CD21^+$ and $CD22^+$ B cells did not differ significantly between in CIN patients and healthy controls. Similarly, the proportion of total naïve $CD19^+/IgD^+/CD27^-$ and activated naïve $CD19^+/IgD^-/CD38^+$ B cells did not differ significantly between CIN patients and healthy controls. Interestingly, however, the proportion of both memory B cell subpopulations namely the $CD19^+/C27^+/IgD^+$ and $CD19^+/CD27^+/IgD^-$ were significantly lower in CIN patients (0.69±0.08% and 1.29±0.74%, respectively) compared to controls (1.11±0.14% and 1.89±0.94%, respectively; P=0.0046 and P=0.013, respectively). The proportion of CD40 expressing $CD19^+$ cells and the intensity of CD40 expression (expressed as mean fluorescence intensity) did not differ significantly between CIN patients and controls whereas the expression of CD40Ligand on mitogen-induced purified $CD3^+$ T-cells did not differ significantly between patients and controls. These data suggest that the lower proportion of memory B cells in CIN patients is not due to impaired activation of surface CD40 by its cognate ligand. The levels of IgM were higher and the levels of IgA and IgG3 lower in CIN patients compared to controls (P<0.0001, P<0.0001 and P<0.0001, respectively). Interestingly, an inverse correlation was found between the levels of IgM and the proportion of classical memory $CD19^+/CD27^+/IgD^-$ cells in the patients (r= -0,4696, P=0.0034). *Summary/Conclusions.* CIN patients display disturbances of B lymphocytes as shown by the low proportions of memory B cell subsets and the altered immunoglobulin levels. Given that normal B cell differentiation and immunoglobulin production depend not only on intercellular interactions but also on environmental cytokine milieus, we assume that the altered levels of cytokine with a B-cell stimulating effect such as TGF-β and IL-10 previously described in CIN may have a role in the above abnormalities.

0253

ECTOPIC EXPRESSION OF MIR-125B BLOCKS GRANULOCYTIC DIFFERENTIATION BY TARGETING MULTIPLE SIGNALLING PATHWAYS

E Surdziel, M Cabanski, I Dallmann, A Ganser, M Scherr, M Eder

MHH Hannover, Hannover, Germany

Background. Granulopoiesis is a tightly regulated process controlled by interaction of cytokines and lineage-specific transcription factors. miRNAs may provide an additional level of control but the functional role of individual miRNAs for granulocytic differentiation is not clearly defined. *Aim.* The aim of this study was to analyze the functional role of individual miRNAs in granulocytic differentiation. *Methods.* We used 32D cells, a murine IL-3-dependent myeloid progenitor cell line, as a model system to study G-CSF-induced granulocytic differentiation. miRNA-based microarray and miR-qRT-PCR were both used to screen for differentially expressed miRNAs at sequential stages of granulocytic differentiation. For selected miRNAs, gain- and loss-of-function phenotypes were generated using lentiviral gene transfer of pre-miRNAs and antagomiRs, respectively. Proliferation/differentiation kinetics (trypan blue dye exclusion, PI staining), cell morphology (May-Grunwald staining), mRNA expression (Real-time PCR) and immunophenotype (flow cytometry) were evaluated. In addition, miRNA-dependent impact on granulocytic differentiation was analyzed in bone marrow-derived murine lineage negative progenitor cells (Lin^-). Lin- cells were lentivirally transduced, sorted and subjected to clonogenic assays. Colony number as well as cell morphology and expression of myeloid surface markers were assessed. Furthermore, several bioinformatic algorithms (PicTar, miRDB, Target Scan, RNA22) were used to predict putative miRNA targets, and modulation of target expression was evaluated using western blotting. Finally, the impact of validated candidate genes on granulocytic differentiation was assessed by lentivirally expressed shRNAs. *Results.* We identified and functionally analysed several miRNAs (including miR-34a-c, -125b, -155, 181b, 223, 291a, 370) potentially involved in regulation of granulocytic differentiation. Ultimately, we focused on miR-125b since neither overexpression nor antagonization of other evaluated miRNAs affected this process. Stable ectopic expression of miR-125b completely blocked G-CSF-induced granulocytic differentiation of both 32D progenitors and Lin- cells. Flow cytometric analysis of myeloid-related surface markers revealed absence of Gr1 and abrogated CD11b expression in 32D/miR-125b compared to 32D/miR-control cells. Furthermore, overexpression of miR-125b dramatically changed the expression pattern of myeloid-related transcription factors, such as STAT3, C/EBPα, C/EBPε, and PU.1. Consequently, transcriptional profiling of genes encoding primary and secondary granule components (MPO, G-CSFR, LZM, LCN2) revealed significant alternation in their expression. Clonogenic assays of Lin- cells demonstrated that miR-125b cultures generated more and larger colonies as compared to miR-control cells, indicating elevated number of cells per colony. Morphological analysis of cells isolated from methylcellulose revealed a block of granulocytic differentiation of Lin-/miR-125b cultures without blast transformation. In addition, we predicted and evaluated several signalling pathways potentially regulated by miR-125b, such as the BCL-2 family, JAK-STAT and MAPKs. Particularly, BAK1 protein level was significantly reduced by miR-125b overexpression. However, RNAi targeting BAK1 resulted only in a delay but not a block of granulocytic differentiation. *Conclusions.* Although several miRNAs were predicted to play a role in granulocytic differentiation, only stable ectopic expression of miR-125b completely blocks this process in both 32D and primary Lin- cells. BAK1 is a validated target of miR-125b, but reduction of BAK1 protein level alone is not sufficient to mediate the described phenotype. Therefore, additional molecular mechanisms must be involved in miR-125b-mediated block of G-CSF-induced granulocytic differentiation.

INVASIVE FUNGAL DISEASES IN FRENCH PATIENTS WITH HEMATOLOGIC MALIGNANCY OR RECIPIENTS OF HEMATOPOIETIC STEM CELL TRANSPLANTATIONS

R Herbrecht,[1] C Cordonnier,[2] JP Gangneux,[3] D Caillot,[4] A Auvrignon,[5] A Thiébault,[6] NC Gorin,[7] A Baruchel,[8] M Michallet,[9] A Fisher,[10] Y Bertrand,[11] P Preziosi,[12] F Ruiz[12]

[1]Hôpital Hautepierre, Strasbourg, France; [2]Hôpital Henri Mondor, Créteil, France; [3]Hôpital Pontchailloux, Rennes, France; [4]Hôpital Le Bocage, Dijon, France; [5]Hôpital Armand Trousseau, Paris, France; [6]Hôpital Michallon, Grenoble, France; [7]Hôpital St Antoine, Paris, France; [8]Hôpital Robert Debré, Paris, France; [9]Hôpital Edouard Herriot, Lyon, France; [10]Hôpital Necker, Paris, France; [11]Institut d'Hématologie et d'Oncologie Pédiatrique, Lyon, France; [12]Clinsearch, Bagneux, France

Background. Invasive fungal diseases (IFD) are a major problem and a frequent cause of death in immunosuppressed patients such as neutropenic patients or recipients of hematopoietic stem cell transplantation. *Aims.* The purpose of this work was to describe incident invasive fungal disease, in patients with hematologic malignancy or recipients of hematopoietic stem cells transplantation. *Methods.* Incident and prevalent IFD were collected and documented during an observational prospective study conducted in 37 hematologic facilities scattered across

the French territory. All patients with a suspected IFD were to be included. Information about patients' background disease and treatment, clinical features, medical imaging and mycological results were collected and after the start of any non-prophylactic antifungal treatment (referred to as "day 0"henceforth). IFD diagnosis at day 0 and day 7 were classified according to the 2008 revised definitions from the European Organization for Research and Treatment of Cancer/Mycosis Study Group (EORTC/MSG). Informed consent was obtained from all participants. *Results.* Eighty-one French hematologic facilities were offered to participate, 41 accepted and 37 did include 420 patients, 299 adults and 121 children, between December 2007 and December 2008. Three of these patients experienced two fungal infections during the course of the study, thus 423 episodes are described below. Characteristics of these patients and episodes are summarized on the attached table. At day 0, 75 (18%) episodes were possible mould infections, 59 (14%) where probable or proven mould infections, 30 (7%) were proven yeast infections and 250 (59%) did not meet EORTC/MSG criteria. At day 7, 76 (18%) episodes were possible mould infections, 80 (19%) were probable or proven mould infections (mostly due to Aspergillus spp) and 38 (9%) were proven yeast infections, (mostly due to Candida spp). The remaining 224 (53%) were insufficiently documented to be classified according to EORTC/MSG definitions. Thus mould infections represented 79% of documented fungal infections. *Conclusions.* Overall, 47% of suspected IFD in French hematologic patients are documented by mycology and/or typical clinical or radiological aspects the seventh day of antifungal treatment. Four in five documented fungal infections are mold infections, mostly due to Aspergillus species. The remaining are mostly due to Candida species.

Patients' characteristics and IFD diagnosis at day seven after starting antifungal treatment (n = 420 patients, 423 suspicions of IFD)

	n	(%)
Gender (male)	236	(56%)
Age (≥ 18 years)	299	(71%)
Underlying disease		
Acute myeloblastic or lymphoblastic leukemia	258	(61%)
Hodgkin's or non Hodgkin's lymphoma	53	(13%)
Multiple myeloma	18	(4%)
Myelodysplastic syndrome	16	(4%)
Chronic leukemia	13	(2%)
Aplastic anemia	10	(2%)
Other	52	(12%)
Hematopoietic stem cell transplantation	115	(27%)
Autologous	40	(35%)
Allogeneic	75	(65%)
Diagnosis at day 7 of the episode (EORTC/MSG definitions)		
Proven yeast disease (mostly *Candida spp*)*	37	(9%)
Proven mold disease (mostly *Aspergillus spp*)	12	(3%)
Probable mold disease*	73	(17%)
Possible mold disease	72	(17%)
Possible fungal disease	2	(1%)
Insufficiently documented episode	226	(54%)

IFD, Invasive fungal disease.
* One patient had both a proven *Candida* infection and a probable *Aspergillus* infection

OPTIMIZED RADIOLOGICAL DIAGNOSIS OF HEPATIC CANDIDIASIS DURING THE TREATMENT OF ACUTE LEUKEMIAS

G Stüssi, U Petrausch, T Frauenfelder, K Arn, U Schanz

University Hospital, Zürich, Switzerland

Background. Intensive treatment of acute leukemias is associated with long-lasting neutropenias carrying a high risk for bacterial and fungal infections. Hepatic candidiasis is a frequent complication in patients receiving intensive chemotherapy for acute leukemia. *Aim.* Hepatic lesions may be detected by computerized tomographic (CT) scans of the thorax or abdomen, but there is no standardized CT protocol for the diagnosis and follow-up of hepatic candidiasis. *Methods.* All patients underwent sequential thoraco-abdominal CT scans using multi-detector-row CT scanners. We retrospectively analysed the size and the volume of hepatic fungal lesions in 24 thoraco-abdominal CT of 20 consecutive patients treated for acute leukemia during arterio-venous (chest CT) and porto-venous phase (abdomen CT). The size of the lesions was correlated with the density values of liver parenchyma and liver veins in the two CT phases. *Results.* The diagnosis of hepatic candidiasis was made after induction chemotherapy (50%), after consolidation therapy (5%), before allogeneic stem cell transplantation (30%), during re-induction chemotherapy (5%), during follow-up after allogenic transplantation (5%), or during best supportive care (5%). The median absolute neutrophil count at the time of radiological diagnosis was 2.47×10^9/L (range 0.06-18.76$\times10^9$/L). At the time of CT scan, four patients (20%) were in neutropenia (ANC 0.06, 0.24, 0.46, 0.56$\times10^9$/L). C reactive protein levels (median 86 ng/L, 1-273) and the alkaline phosphatase levels (median: 162 U/L, 56-785) were clearly elevated, whereas liver enzymes were within the normal range (AST: 28.5 U/L, 8-234, ALT: 26 U/L, 16-96). The mean number of hepatic lesions per patient was 31 (range: 3-105) in the chest and 26 (3-81) in the abdomen CT (P=0.026). The mean total volume of all lesions was 6.45 mL in the chest and 4.07 mL in the abdomen CT representing a 1.6 fold difference between the two CT scans (P=0.008). The total volume of the lesions negatively correlated to the absolute contrast difference between liver parenchyma and liver vein (Pearson correlation, r=-0.62; P=0.002). *Conclusions.* The chest CT provides a superior distinction of hepatic lesions due to a delayed perfusion of the outer rim of the fungal lesions resulting in an extended visibility. The chest CT is superior to the abdominal CT for initial diagnosis and follow-up of hepatic candidiasis.

0256

INFECTIONS DUE TO KLEBSIELLA IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: RISK FACTORS FOR SEVERE SEPSIS/SEPTIC SHOCK AND MORTALITY

R Jeddi, H Ghédira, R Ben Amor, Y Ben Abdennebi, L Aissaoui, W Bouteraâ, K Kacem, R Ben Lakhal, H Ben Abid, Z Belhadjali, A Turki, B Meddeb

Aziza Othmana University Hospital, Tunis, Tunisia

Background. Klebsiella species are major nosocomial pathogens causing serious infection in neutropenic setting. The aim of this study was to evaluate risk factors for severe sepsis/septic shock and mortality by infection due to klebsiella. *Methods.* This study was conducted in a teaching hospital to evaluate the clinical profile of infection due to Klebsiella species and to determine risk factors for severe sepsis/ septic shock defined according to the criteria of the American College of Chest Physicians/Society of Critical Care Medicine Consensus Conference, and risk factors for mortality. *Results.* Between 2005 and 2009 a total of 160 Klebsiella isolates (118 *K.pneumonia*, 28 *K. oxytoca*, 7 *K terrigena*, 7 others species) were collected in 130 patients: 59 (45.4%) acute myeloid leukemia, 56(43.1%) acute lymphoid leukemia,8(6.2%) lymphoma, and 7 (5.3%) aplastic anemia.The median age was 26 years (range, 2-60 years).There was a trend towards higher incidence of isolates during the year 2006 (37.5%, P=0.05).The common sites of the isolates were blood culture (47.5%), stools (30.5%) and perineal lesion (9.5%). Median duration of neutropenia before isolates was 8 days (0-71days).The major clinical symptoms were from the digestive tracts (34%) and the respiratory tract (17.5%). Susceptibility profile to antibiotics revealed that about 53.7% of isolates were Extended-spectrum β-lactamase producing (ESBL)-Klebsiella.Severe sepsis and septic shock occurred respectively in 27.5 and 12.5% of the episodes. Attributed mortality was 17.7% (23/130). By univariate analysis factors associated with severe sepsis/septic shock were (P<0.0001): disease status (CR vs non CR), neutropenia >8 days, respiratory signs, fever > 3 days on antibiotic therapy, concomitant infection, bilirubin > 50 μmol/L, low prothrombin time, serum bicarbonate <18 mmol/L, serum lactate> 2.4 mmol/l, hemoglobin<70 g/L,and proteinemia <55 g/L. For mortality predictive factors were (P<0.0001): respiratory signs, fever > 3 days on antibiotic therapy, concomitant infection, bilirubin > 50 μmol/L, hemoglobin<70 g/L, proteinemia<55g/L, and elevated a PTT. By multivariate analysis factors found to be associated with severe sepsis/septic shock were: disease status (P=0.038), serum lactate >2.4 (P=0.005), fever > 3 days on antibiotic therapy (P<0.0001), isolate from blood culture (P=0.018) and bilirubin >50 μmol/L (P=0.046). Predictors of mortality were: involvement of respiratory tract (P=0.006), ESBL -Klebsiella (P=0.018), concomitant infection (P<0.0001), fever >3 days on antibiotic therapy (P=0.018). *Conclusions.* This study revealed that resistant fever to antibiotic therapy (>3 days), inappropriate initial antibiotic therapy, isolated ESBL Klebsiella, pulmonary infection ,and concomitant infection are the most predictors of mortality in patient with hematological malignancies and Klebsiella infection.

0257

THE USE OF CARDIAC BIOMARKERS IN DETECTION OF CARDIOTOXICITY ASSOCIATED WITH CONVENTIONAL AND HIGH-DOSE CHEMOTHERAPY FOR ACUTE LEUKEMIA

J Horacek,[1] L Jebavy,[2] M Tichy,[1] M Vasatova,[1] P Zak,[3] J Maly[3]

[1]University Hospital Hradec Kralove, Hradec Kralove, Czech Republic; [2]Faculty of Military Health Sciences, Hradec Kralove, Czech Republic; [3]Faculty of Medicine Hradec Kralove, Hradec Kralove, Czech Republic

Background. Cardiotoxicity is a potentially serious complication of hematooncology treatment that can significantly impair patient's quality of life. The greatest risk for development of cardiotoxicity represent anthracyclines (ANT) and high-dose chemotherapy (HD-CT). Various methods including cardiac biomarkers have been recommended for monitoring of cardiotoxicity in oncology. In this context, experience with new potential biomarkers of cardiac injury is very limited. *Aims.* Monitoring of cardiotoxicity of conventional and HD-CT with multiple biomarkers of cardiac injury - glycogen phosphorylase BB (GPBB), heart-type fatty acid binding protein (H-FABP), cardiac troponins (cTnT, cTnI), creatine kinase MB (CK-MB mass), myoglobin. *Methods.* A total of 47 adult acute leukemia patients were studied - 24 patients treated with conventional CT containing anthracyclines (ANT, mean total cumulative dose 463.2±114.3 mg/m^2) and 23 patients treated with HD-CT (myeloablative preparative regimen Bu/Cy2 or Cy/TBI) followed by hematopoietic cell transplantation (HCT). All patients had normal liver and renal functions during the study. Cardiac biomarkers were assessed prior to treatment (before CT/HD-CT), after first CT with ANT, after last CT with ANT in the first group, after HD-CT and after HCT in the second group. Values above the reference range based on a number of cardiology studies and recommended by the manufacturers (Roche, Randox) were considered elevated. The cut-off values for cardiac injury were as follows: 7.30 µg/L for GPBB, 4.50 µg/L for H-FABP, 0.40 µg/L for cTnI, 4.80 µg/L for CK-MB mass and 76.0 µg/L for myoglobin. *Results.* Before CT/HD-CT, all biomarkers of cardiac injury were below the cut-off values in all patients. GPBB increased above the cut-off (7.30 µg/L) in 4 (16.7%) patients after first CT and in 5 (20.8%) patients after last CT with ANT. GPBB increased above the cut-off in 5 (21.7%) patients after HD-CT and remained elevated in 5 (21.7%) patients after HCT. CTnI became elevated (above 0.40 µg/L) in 2 (8.3%) patients after first and last CT with ANT. Both patients with cTnI positivity had elevated GPBB. Other tested biomarkers (H-FABP, CK-MB mass, myoglobin) remained below the cut-offs during the study. *Conclusions.* Our results suggest that GPBB could become a sensitive biomarker for detection of acute cardiotoxicity associated with conventional CT containing ANT and HD-CT followed by HCT. The predictive value for development of cardiomyopathy in the future is not clear and will be evaluated during a prospective follow-up. Based on our data, a larger prospective and multicenter study would be most desirable to define the potential role of new cardiac biomarkers in the assessment of cardiotoxicity in hematooncology.

IMPLEMENTATION OF A CLINICAL PRACTICE GUIDELINE FOR CHILDREN WITH CANCER PRESENTING WITH FEVER AT EMERGENCY ROOM

S Pakakasama, K Surayuthpreecha, U Pandee, U Anurathpan, V Maleevan, U Udomsubprayakul, P Butthep, P Santanirand, N Sirachainan, S Hongeng

Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

Background. Febrile neutropenia (FN) is a common complication after chemotherapy administration. Patients with FN may develop severe infection, septic shock, and death. To improve the outcome of oncologic children presented with FN, we developed a clinical practice guideline for these patients to receive a rapid evaluation and the shortened time of first dose antibiotic at emergency room (ER). *Aims.* To evaluate compliance of the clinical practice guideline for children with cancer presenting with fever at our ER and the adverse outcomes after using this guideline. *Methods.* We performed a retrospective cohort study of oncologic children presenting with fever at our ER after the clinical guideline was implemented from January 2007 to December 2008 (cases). The control group was the children with cancer who presented with fever during January 2005 to December 2006. We evaluated the compliance of the clinical guideline by recording the time of initial clinical and laboratory assessment and door-to-antibiotic time. The adverse outcomes of the patients including septic shock and death were determined. *Results.* There were 170 febrile episodes after using the guideline. About half (49.4%) of the patients received clinical assessment and laboratory result within 60 min, whereas the antibiotics were administered within 120 min in 80%. The median of the door-to-antibiotic time was significantly decreased after the implementation of the guideline (75 min vs 180 min, P<0.001). Prevalence of septic shock and intensive care unit admission of cases were significantly reduced compared to controls (P=0.011 and 0.016, respectively). No infection associated mortality was found in the intervention group. After using the guideline, length of stay of cases was significantly shorter than controls (P=0.001). *Conclusions*. Using the clinical practice guideline for oncologic children with fever was found to reduce the adverse outcomes and improve survival of these patients.

0259

EARLY DIAGNOSIS, GUIDANCE OF THERAPY AND IDENTIFYING HIGH MORTALITY SUBGROUPS OF NEUTROPENIC PATIENTS WITH SEPSIS: ROLE OF PROCALCITONIN

F Al Sabty,[1] E Demeckova,[1] S Kubalova,[1] L Sopko,[2] M Mistrik[2]

[1]University Hospital, Bratislava, Slovakia; [2]Comenius University, Bratislava, Slovakia

Background. early diagnosis and appropriate therapy of sepsis is a daily challenge in neutropenic patients. Sepsis during neutropenia suffer from a lack of specific clinical symptoms and signs, microbiological cultures require time and may not be positive in sepsis patients. Among the newest biomarkers for sepsis, procalcitonin (PCT) has the highest diagnostic accuracy. Plasma PCT level is a marker of the inflammatory response of the human body to a non-viral infection. Elevated values are highly suggestive of bacterial infection with systemic consequences. *Aims.* to assess the potential role of PCT in the early diagnosis and in the prognosis of neutropenic patients with sepsis. *Methods.* we included 148 neutropenic patients: 40 (27%) with systemic inflammatory response syndrome - SIRS (febrile neutropenia without source of infection), 63 (43%) with sepsis (febrile neutropenia with documented infection) and 45 (30%) with septic shock. All patients were treated in the intensive care unite of hematology department with daily monitoring of inflammatory markers (C- reactive protein (CRP) and PCT). Positive blood cultures were recorded. Patients were treated according to the local guidelines for febrile neutropenia with modification according to the microbiological *Results.* SIRS and sepsis definition was done according the ACCP/SCCM - criteria. *Results.* 43/45 (96%), 44/63 (70%) and 14/40 (35%) patients in septic shock, sepsis and SIRS group respectively had positive PCT level (≥0.5 ng/mL) (P<0.0001) (Table 1).

Table 1.

	SIRS (%)	Sepsis (%)	Septic shock (%)	*P*
No. of pts	40 (27)	63 (43)	45 (30)	
PCT ng/ml				< 0.0001
< 0.5	26 (65)	19 (30)	2 (4)	
≥ 0.5 < 2	10 (25)	20 (32)	2 (4)	
≥ 2 < 10	4 (10)	14 (22)	10 (22)	
≥ 10	0	10 (16)	31 (69)	
Blood culture				
+	0	46 (73)	28 (62)	0.23
-	40 (100)	17 (27)	17 (38)	
CRP mg/l				
Mean ± Std.	156 ± 90	179 ± 80	262 ±135	0.15
Range	1- 455	25 – 370	10 – 542	

PCT level was statistically significant when compared between SIRS and sepsis (P=0.02), SIRS and septic shock (P<0.0001), sepsis and septic shock (P=0.001). The mean serum level of CRP was 156 mg/L (±90 standard deviation - SD) in SIRS and 179 mg/L (±80 SD) in sepsis group (Mann Whitney test, P=0.15), while in septic shock group was 262 mg/L (±135 SD) (Mann Whitney test, P<0.0001). Blood culture was positive in 46 (73%) and 28 (62%) patients with sepsis and septic shock respectively (P=0.23). There was a direct correlation between serum level of PCT and positive blood culture (P<0.0001). 2 (3%) patients died in sep-

sis group with PCT > 10 ng/mL, while 18 (40%) patients died in septic shock group (14 with PCT>10 ng/mL and 4 with PCT >2<10 ng/mL) (P=0.012). There was strong correlation between plasma level of PCT and mortality (P=0.001). The sensitivity of PCT was 96% and 70% in septic shock and sepsis respectively. Specificity was 65%. The positive predictive value was 75% and the negative predictive value was 93% in septic shock and 56% in sepsis. Likelihood Ratio (LR) was 1.09 and 1.5 in sepsis and septic shock. The test efficiency was 68% in sepsis and 81% in septic shock. *Conclusions.* daily measurement of PCT for an early and effective diagnosis is recommended in all neutropenic patients in whom sepsis and a systemic inflammatory response is suspected. PCT is also useful in monitoring the course and severity of systemic inflammatory response. Persistently elevated levels of PCT are associated with poor outcome and are viewed as failure of therapy.

0260

HEPATITIS B INFECTION IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES, CLINICO-BIOLOGICAL EXPRESSION AND OUTCOME

L Balint-Gib,[1] A Oprisoni,[2] S Arghirescu,[3] A Isac,[1] C Jinca,[4] E Boeriu,[4] V Ordodi,[4] O Ciocarlie,[4] C Banciu,[4] M Serban[4]

[1]Emergency Children Hospital Louis Turcanu, Timisoara, Romania; [2]University of Medicine and Pharmacy Victor Babes Timisoares, Timisoara, Romania; [3]University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania; [4]University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania

Background. Hepatitis B virus (HBV) infection, with a frequency between 8% and 12% in various European countries, represents a major challenge in patients with hematological malignancies. The immunosupresion induced by the underlying disease or by the treatment, has important impact on the outcome of HBV infection. *Aims.* We aim to analyze the frequency of HBV infection in patients with hematological malignancies, the HBV type, the clinical and biological expression and infection impact on patients evolution, taking into consideration malignancy and HBV infection treatment options. *Methods.* The study was performed on 12 patients with HBV infection admitted for conventional chemotherapy and/or hematopoietic stem cell transplantation (HSCT) of a hematological malignancy: Hodgkin lymphoma (HL), non-Hodgkin lymphoma (NHL), acute lymphoblastic leukemia (ALL) and acute myeloid leukemia (AML) between 2000 and 2009. The tested HBV infection markers were: surface antigen/antibody (HbsAg/HbsAb), "e"antigen/antibody (HbeAg/HBeAb), anticore antibody (HBcAb) total/IgM subtype, HBV-DNA copies level. *Results.* Out of 311 children, 5 (1.6%) were HBV infected. The underlying disease was ALL in 3 cases, B cell-NHL in two cases and HL in one case. From 75 adults admitted for an autologous/allogeneic HSCT 7 (9.33%) had a HBV infection. The hematological malignancy that required a HCST was HL in 3 cases, B-cell NHL in two cases, ALL and AML, each in one case. In all cases the route of infection was unknown. 10/12 patients were active carriers ($HBsAg^+$, HBeAg+/-, HBsAb-, $HBcAb^+$, increased transaminases levels, HBV-DNA≥20000 copies/mL for wild HBV type or ≥2000 copies/mL for pre-core mutant HBV type) and 2/12 patients were inactive carriers. In 6/10 cases the HBV was a wild type and in 4/10 cases a pre-core mutant type. Considering malignancy as a vital priority chemotherapy was started immediately. In 5/7 cases the HBV infection enforced the HSCT delay with 6 to 24 months. The treatment was started with interferon-α (IFNα) in 5 cases, with lamivudine in 5 cases and with entecavir in one case, concomitant with conventional chemotherapy in 10/11 cases. One patient did not receive any antiviral treatment. In 3/5 cases the resistance to IFNα developed after 6-12-18 months of treatment and the lamivudine was started. The lamivudine resistance determined the switch to entecavir in 1/5 cases. In 3/11 treated cases the HBV-DNA became undetectable after 6 months (entecavir), 12 months (IFNα) and 16 months (lamivudine). One patient presented a HBV infection relapse at the lamivudine interruption, one remained HBsAg carrier and one remained HBV negative. None of the patients developed hepatic failure or died from HBV infection complications. *Conclusions.* The HBV infection represents an important comorbidity in patients with hematological malignancy, much frequent in adulthood. In children the use of anti-HBV vaccine starting 1990 seems to have a great influence in reducing the infection rate. One major challenge in the management of these patients is represented by the development of antiviral therapy resistance. In contrast to literature cited evolution, in our study none of the patients developed severe hepatic manifestation.

IMMUNOGLOBULIN LEVELS AND INFECTIONS IN PATIENTS RECEIVING RITUXIMAB EITHER AS INDUCTION OR AS MAINTENANCE THERAPY

M Stamouli, M Dadakaridou, M Kotsopoulou, C Megalakaki, P Repousis, N Tragomalos, I Triantafyllopoulou, D Maltezas, A Rekliti, V Hatziantoniou, A Alexopoulos, C Mitsouli

Metaxa Hospital, Piraeus, Greece

Background. Rituximab is a monoclonal anti-CD20 antibody that has been widely used for more than a decade to treat patients with haematologic malignancies and autoimmune diseases. In the pivotal single agent rituximab trial, hypogammaglobulinemia occurred in only 14% of cases and was not associated with significant infectious complications. However, several infections related to rituximab have been reported in the literature, especially when it is used in combination with chemotherapy or as maintenance therapy although immunoglobulin levels have not been systematically recorded. *Aims.* The objective of this study was to observe the fluctuation of immunoglobulin levels as well as the incidence of infections in patients receiving rituximab. *Methods.* The study included 96 patients (43 men and 53 women; age range: 23-86 years, mean: 64 years) who were treated in the Day Clinic of our hospital for the past two years (January 2008-February 2010). Among these patients 17 were treated with rituximab as a single agent, while 79 patients received rituximab combined with chemotherapy. In the latter group 26 patients were subsequently given rituximab as maintenance therapy for a maximum of two years. Serum quantitative immunoglobulin levels (IgG, IgA, IgM) were measured each time the patients were treated in the Day Clinic and their medical files were reviewed retrospectively in order to record the infectious complications that developed during their treatment. Patients in whom any of the three gammaglobulin components studied was below the lower limit of normal before the commencement of therapy were excluded from the study. *Results.* a. rituximab as a single agent: hypogammaglobulinemia was observed in 7 (41%) cases, but it was rather subtle and involved almost exclusively the IgM component (median value: 0,31g/L with a lower limit of normal at 0,40g/L). No infections were reported. b. rituximab combined with chemotherapy: hypogammaglobulinemia was observed in 66 patients (83%). The most frequently affected immunoglobulins were IgG (n=49) and IgM (n=47), while IgA was low in 24 patients. In patients with hypogammaglobulinemia, the most profoundly affected component was IgM (median value: 37.5% below the lower limit of normal), followed by IgA and IgG (median values: 27% and 17% below the lower limit of normal respectively). Hypogammaglobulinemia persisted throughout the period of maintenance therapy although in two cases it was partially restored. A total of 42 of infections were reported in 31 patients. Among them 22 were attributed to neutropenia. In the remaining 20 non-neutropenic infections, hypogammaglobulinemia was observed in 15 cases (75%). Four non-neutropenic infections developed during maintenance therapy. *Summary/Conclusions.* Rituximab has been used extensively for more than a decade and its efficacy and safety are now well established. However close monitoring of patients and observation of immunoglobulin levels may be necessary in cases where rituximab is combined with chemotherapy. It should be emphasized that increased vigilance is also necessary throughout the period of maintenance therapy (even after the end of it) because hypogammaglobulinemia is present for a long time and may put patients at a high risk of infections.

0262

CYTOMEGALOVIRUS REACTIVATION AFTER AUTOLOGOUS STEM CELL TRANSPLANT FOR B-CELL MALIGNANCIES: SOMETHING TO DEAL WITH. A PROSPECTIVE STUDY ON 92 CONSECUTIVE PATIENTS

G Visani,[1] L Malerba,[1] B Guiducci,[1] S Barulli,[1] M Lucesole,[1] F Loscocco,[1] I Tommasini,[2] G Polenta,[2] P Tontini,[2] M Rocchi,[3] A Isidori[1]

[1]Hematology and Stem Cell Transplant Center, Pesaro, Italy; [2]Pharmacy, Antiblastic Service, San Salvatore Hospital, Pesaro, Italy; [3]Insitute of Biomathematics, Urbino University, Urbino, Italy

Background. Cytomegalovirus (CMV) reactivation is a frequent complications of allogeneic stem cell transplantation. However, information regarding the incidence and the clinical impact of CMV reactivation after autologous stem cell transplant (ASCT) are lacking. *Aims.* The aim of the study was to assess the incidence of CMV reactivation after autologous stem cell transplantation in lymphoproliferative diseases.

Moreover, we searched for possible pre-transplant variables influencing CMV reactivation after transplant. *Methods.* 92 patients consecutively submitted to ASCT for B-cell malignancies were monitored for CMV reactivation. Twenty-nine patients had multiple myeloma, 63 a lymphoproliferative disease (HD, NHL, CLL). Twenty-seven patients received ASCT for a resistant disease, whereas 65 for a newly diagnosed disease. Thirty-six patients received anti-CD-20 antibody as a part of the frontline therapy before ASCT. The conditioning regimen was BEAM for 47/92 patients, high-dose Melphalan for 28/92 patients and BAVC or Busulphan/Endoxan for the remaining 17 patients. Sixty-six patients received peripheral blood stem cells rescue after high dose therapy, whereas 26 got bone marrow stem cells. CMV reactivations were monitored twice weekly with the polymerase chain reaction (PCR) assay in all patients, starting after the engraftment. *Results.* Twenty-five out of 92 patients (27%) presented a CMV reactivation. The vast majority of patients (17/25, 68%) reactivated CMV after 30 or more days from transplant. Moreover, 15/25 patients (60%) presenting a CMV reactivation had received prior Rituximab. Ten out of 25 patients (40%) presented symptoms such as fever, vomiting, arthralgia or profound asthenia at reactivation. Moreover, CMV reactivation was associated with moderate to severe neutropenia in 8/25 patients. All patients reactivating CMV were treated with intravenous (iv) ganciclovir given 7.5 mg/kg once daily for a median of 20 days (range: 6-40). Discontinuation of antiviral therapy required at least two consecutively negative PCRs performed at least 3 days apart each other. All patients experienced a negativization of CMV-specific PCR after a median of 12 days of therapy (range: 9-34). None of the patient developed CMV disease. Moreover, no late infections or other side effects were observed during the long-term follow-up period. *Conclusions.* Our experience clearly demonstrates that a significant proportion of patients submitted to ASCT develop a CMV reactivation after transplant, frequently symptomatic, requiring antiviral therapy. We underline the necessity of a stringent monitoring of CMV reactivation after ASCT, specially for patients receiving therapy with anti-B lymphocytes monoclonal antibodies before transplant.

0263

VORICONAZOLE OR ITRACONAZOLE FOR PREVENTION OF INVASIVE FUNGAL INFECTIONS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLOHCT) - FOCUS ON PATIENT PREFERENCE AND LONG-TERM TOLERABILITY

I Marks,[1] C Kibbler,[2] G Cook,[3] A Glasmacher,[4] C Heussel,[5] A Pagliuca,[6] P Ribaud,[7] C Solano,[8] M Tarallo,[9] R Chambers,[9] H Schlamm,[9] M Kantecki[10]

[1]University Hospitals Bristol Foundation Trust, Bristol, UK; [2]Royal Free Hospital, London, UK; [3]Leeds Teaching Hospitals, Leeds, UK; [4]Rheinische Friedrich Wilhelms Universität, Bonn, Germany; [5]Radiology, Thoraxklinik at University Hospital, Heidelberg, Germany; [6]King's College Hospital, London, UK; [7]Hôpital Saint-Louis, Paris, France; [8]Hospital Clínico Universitario de Valencia, Valencia, Spain; [9]Pfizer Inc, New York, USA; [10]Pfizer IO, Paris, France

Background. The IMPROVIT study compared voriconazole to itraconazole as primary antifungal prophylaxis in alloHCT recipients. Although there was no difference in breakthrough fungal infection rates or survival at 180 days, voriconazole was better tolerated for longer durations in this study. *Aims.* To identify the major reasons for the difference in tolerability between these 2 antifungal agents when used as primary prophylaxis in alloHCT recipients. *Methods.* Data for this analysis were collected in a prospective, randomized, open-label, multicenter comparative study of voriconazole compared with itraconazole for primary prophylaxis in alloHCT recipients (note: neither agent has an approved indication for antifungal prophylaxis). Informed consent was obtained from all patients. Trial design and results have been described previously (Marks D. *et al.* Presented at ICAAC 2009. Abstract M-1249a). However, patient data from 1 study center (10 voriconazole patients and 14 itraconazole patients) were subsequently excluded from all efficacy analyses because of clinical trial conduct issues. Success of antifungal prophylaxis was defined as ability to continue study drug for at least 86 days, with survival free from breakthrough fungal infection for 180 days after alloHCT. Patients completed a Treatment Satisfaction Questionnaire for Medication (TSQM) at day 14, self-evaluating each agent in terms of effectiveness, side effects, convenience, and global satisfaction; a scale score was generated from the responses for each domain, with higher scores indicating greater satisfaction. Treatment group comparisons of continuous variables were performed using the 2-sample t-test. A stepwise Cox regression was used to explore the dependent relationship between TSQM scores and treatment completion status. *Results.* In the revised analysis of this study, 224 patients received voriconazole and 241 received itraconazole as primary antifungal prophylaxis. Treatment groups remained well matched for baseline characteristics. Success of prophylaxis at day 180 was significantly higher with voriconazole than with itraconazole (48% vs 33%; adjusted 95% CI for difference: 8%, 25%; P<0.01). Survival rates at day 180 were similar (84% with voriconazole vs 85% with itraconazole; P=NS), as were the incidences of breakthrough fungal infection (1% vs 2%, respectively). Patients were able to tolerate voriconazole for longer periods compared with itraconazole: 96 vs 68 days, respectively (P<0.01). The most common reason for inability to complete 86 days of study drug prophylaxis was intolerance, which was the case for 22% of itraconazole and 7% of voriconazole patients (P<0.01). More than 60% of patients completed TSQM questionnaires at day 14: TSQM scores were significantly higher (P<0.01) for voriconazole in the domains of effectiveness, convenience, and global satisfaction; no significant difference was observed between voriconazole and itraconazole in terms of patient-assessed side effects (Table). Of note, the global satisfaction score was found to be a significant predictor of a patient's ability to complete at least 86 days of prophylaxis (P=0.02 on Cox regression). *Conclusions.* Reanalyzed data from the IMPROVIT study were consistent with previous findings. The superiority of voriconazole in the primary end point of this study was driven by its better long-term tolerability, which was reflected in higher patient-reported TSQM scores for effectiveness, convenience, and global satisfaction.

Table. Mean TSQM scores at day 14.

TSQM Domain	Voriconazole (N = 224)	Itraconazole (N = 241)	*P* Value
Effectiveness	75 ± 18	68 ± 19	0.0026
(% responders)	(62%)	(62%)	
Side effects	92 ± 19	88 ± 23	0.1728
(% responders)	(63%)	(63%)	
Convenience	75 ± 17	65 ± 21	<0.0001
(% responders)	(66%)	(65%)	
Global satisfaction	71 ± 16	63 ± 19	0.0003
(% responders)	(65%)	(64%)	

0264

CYTOMEGALOVIRUS MAY HAVE A ROLE IN THE PATHOPHYSIOLOGY OF CHRONIC IDIOPATHIC NEUTROPENIA

E Dalpa, E Kourepini, K Pyrovolaki, M Spanoudakis, D Spandidos, G Eliopoulos, H Papadaki, G Sourvinos

University of Crete School of Medicine, Heraklion, Greece

Background. Chronic idiopathic neutropenia (CIN) is an acquired granulocytic disorder characterised by a prolonged, unexplained reduction in the number of circulating neutrophils. Increased apoptosis of bone marrow (BM) myeloid progenitor cells due to an inflammatory BM milieu and presence of activated T-lymphocytes have been implicated in the pathophysiology of the disease. The cause of these abnormalities and the trigger of T-cell activation, remain unknown. *Aims.* To evaluate the possible involvement of cytomegalovirus (CMV) and other herpesviruses in the pathophysiology of CIN. *Methods.* BM cells were obtained from posterior iliac crest aspirates from 22 patients fulfilling the previously defined diagnostic criteria for CIN and 11 haematologically normal subjects, after informed consent. Total BM cells as well as immunomagnetically sorted $CD3^+$, $CD14^+$ and $CD34^+$ BM cells and serum from patients and controls were assessed for CMV detection by means of PCR and Fluorescent *in situ* hybridization (FISH). Long-term BM cultures (LTBMCs) were also set up in patients and healthy controls for CMV detection in the adherent cell layer that mirrors the BM microenvironment cells. LTBMCs were also used for functional experiments. Patient and control LTBMC stromal cells were also tested for presence of other herpesviruses, namely Herpes Simplex Virus (HSV)-1/-2, Varicella zoster virus (VZV), Human Herpes Virus (HHV)-7, HHV-8 and Epstein Barr Virus (EBV) by PCR. *Results.* CMV was detected by PCR in BM cells of 50% of CIN patients whereas it was not identified in any subject of the control group. Viremia in the serum was limited

to 1 CIN case. Further investigation for the identification of CMV genome in $CD3^+$, $CD14^+$ and $CD34^+$ BM cells, representing T-lymphocytes, monocytes/macrophages and progenitor cells respectively, and also in stromal cells from LTBMCs, revealed the presence of viral DNA in the latter cell type, exclusively. FISH applied in the adherent (stromal) cells of LTBMCs from CIN patients confirmed the presence of CMV genome in 0.1% of the cell population. Infection of normal LTBMCs with a CMV strain expressing Enhanced Green Fluorescence Protein (EGFP) resulted in viral latency at the stromal cells, whereas CMV could establish a lytic infection at the stromal cells in LTBMCs only when the non-adherent BM cells had been removed. The clonogenic potential of the non-adherent cell fraction in CMV-infected LTBMCs was lower compared to the mock-infected cultures ($P<0.05$). Interestingly, HSV-1/-2, VZV, HHV-7, HHV-8 and EBV genome was not detected in LTBMC adherent layers of patients or controls, indicating the pathophysiologic significance of the CMV identification in patient samples. *Summary/Conclusions.* CMV is frequently detected in BM stromal cells of patients with CIN. We postulate that the CMV latent infection of BM microenvironment cells may affect the growth of haemopoietic progenitor cells and may, therefore, have a role in the pathopysiology of neutropenia in the affected subjects.

0265

LATE ONSET NEUTROPENIA IN VLBW NEONATES

K Kefala-Agoropoulou, I Evdoridou, P Papakyriakidou, E Tsepketzh, E Agakidou, V Drossou

Hippokration Hospital, Thessaloniki, Greece

Background. Late-onset neutropenia is one of the hematological abnormalities of prematurity. It usually emerges after the third week of age and it is triggered by short-term bone marrow failure to respond to increased needs. *Aim.* To evaluate the severity and outcome of late-onset neutropenia in very low birth weight (VLBW) premature neonates. *Methods.* Premature infants with BW<1500 g who developed late-onset neutropenia without any apparent cause were studied retrospectively. All infants were healthy on the onset of neutropenia. *Results.* Late-onset neutropenia was recorded in 35 preterm infants (19 boys) with gestation age 28.7±1.8 weeks and birth weight 1101.1±213.8 g. Fifteen (43%) had gestation age <28 weeks. At the onset of neutropenia, the age was 46.25±16.76 days (range17-121 days), the mean white blood cell count was 5375±1885K/uL and the mean neutrophil count was 872.8±251.8 K/uL with values <1000 K/uL in 14 (40%). On follow up, the absolute neutrophil count decreased to <1000 in 27 (77%, P=0.004) preterm infants. There were no significant differences in absolute neutrophil count between preterm infants with gestation age <28 weeks and those with gestation age 29-32 weeks. Mean duration of neutropenia was 19±2 days (range 2-159 days). A two-phase alleviation of neutrophils occurred in 8 infants, with an interval of 9-41 days. 6 infants developed prolonged neutropenia (up to 159 days). The duration and severity of neutropenia was inversely correlated with gestation age. 9 patients were treated with granulocyte-colony stimulating factor (G-CSF) (1-3 days). In 4 patients neutropenia relapsed following G-CSF discontinuation but spontaneously resolved. No infant developed infection during the late-onset neutropenia. *Conclusions.* Late-onset neutropenia is a benign condition that is not associated with increased morbidity of VLBW premature infants despite the extremely low count of neutrophils which may occur.

0266

IMMUNE DYSFUNCTION IN PATIENTS WITH GAUCHER DISEASE: IMPACT OF DISEASE SEVERITY AND ENZYME REPLACEMENT THERAPY

A Khalifa, A Tantawy, E Sherif, A Sadek, N Tiseer

Faculty of Medicine, Ain Shams University, Cairo, Egypt

*Background.*Gaucher disease (GD), the most common lysosomal storage disorder, is a heterogenous multisystem condition. Recurrent infections have been described as a cause of morbidity. A number of immunologic abnormalities have been demonstrated in GD patients. Objectives: This work aimed to assess humoral and cell mediated immunity and phagocytic function in GD patients in relation to parameters of disease severity and enzyme replacement therapy (ERT) .Methods :The study comprised 16 GD patients, 12 males and 4 females , 4 Type I and 12 type III GD. Their age at study entry ranged between 6 months and 16 years (mean 7.82±4.25 years).Ten patients were receiving ERT (recombinant imiglucerase) and 6 newly diagnosed patients before ERT. Baseline assessment included: complete blood count, coagulation profile , liver and renal function tests. Radiological investigations were performed for bony changes and abdominal ultrasound for organ volumes. Bone marrow examination was done for all patients as well as liver and /or splenic puncture in selected patients. β-glucosidase in leucocytes and plasma chitotriosidase were determined. Serum immunoglobulins (Igs): IgG, IgM ,IgA were estimated by immunoturbidimetry and serum IgE by ELISA .Peripheral blood lymphocyte subsets (CD3,CD19, CD4,CD8 and CD56) were analyzed by flow cytometry. Phagocytic function of polymorphonuclear cells (PMNs) was evaluated by candida killing activity measured by cytomorphological method. *Results.* Polyclonal gammopathy was detected in 8/16 patients (50%). Serum IgM level was elevated in 87.5% (14 out of 16 patients),and 13 patients (81.2%) had elevated IgG level. Monoclonal IgA gammopathy was detected in 9 patients (56.2%) and monoclonal IgE gammopathy in 5 patients (31.2%). Serum levels of all immunoglobulin classes were higher in treated patients compared with untreated patients, the difference was significant for serum IgG ($P=0.04$) and IgA ($P=0.03$). Decreased expression of B-cell marker (CD19) was present in 12 patients (75%). T lymphocyte dysfunction in the form of reduced expression of CD3 was found in 10 patients (62.5%)and inverted CD4/CD8 ratio in 10 patients (62.5%). Natural killer cell marker (CD56) expression was reduced in 9/16 patients (56.2%). Phagocytosis and lytic activity of PMNs were also markedly decreased in 31.2% and 50% of patients respectively. Among treated patients a significant positive correlation was detected between phagocytic and lytic indices and duration of ERT ($r=0.058$, $P=0.03$) . An inverse significant correlation was found between serum IgG and IgA and duration of ERT ($r= -0.61$, $P=0.019$) and ($r= -0.74$, $P=0.014$) respectively. Age, gender and other parameters of disease severity (hemoglobin level, platelets count) were not related to the immune profile as well as the absence or presence of neurological disease (type I versus type III). *Conclusions.* Serum immunoglobulin abnormalities and lymphocyte function defects appear to be common in GD. Markedly compromised phagocytic function was demonstrated that could be improved with regular ERT. Such abnormalities in the immune system could impair host defense, and may be of particular importance in the pathogenesis of recurrent infections in Gaucher patients

0267

COMPARABILITY OF A NEW BIOSIMILAR GRANULOCYTE-COLONY STIMULATING FACTOR WITH ITS REFERENCE PRODUCT

A Makhson,[1] F Sörgel,[2] A Schwebig,[3] S Balser[3]

[1]Moscow City Oncology Clinical Hospital [62], Moscow, Russian Federation; [2]Institute for Biomedical and Pharmaceutical Research, Nürnberg-Heroldsberg, Germany; [3]Sandoz Pharmaceuticals, Holzkirchen, Germany

Background. Approval of biosimilars in Europe is provided on the basis of comparable quality, safety and efficacy with an existing reference product. EP2006 (filgrastim) is a recently approved biosimilar recombinant human granulocyte-colony stimulating factor (G-CSF) which used Neupogen® as its reference product. *Aims.* To compare EP2006 with its reference product by way of physicochemical and biological protein characterisation, pharmacokinetic (PK) and pharmacodynamic (PD) data and evaluation of clinical efficacy and safety. *Methods.* A wide array of standard and advanced analytical tests were performed to characterise protein identity, purity and stability of EP2006 and its reference product, including peptide mapping with UV detection and mass determination, circular dichroism (CD) and NMR spectroscopy, matrix-assisted laser desorption/ionisation-time of flight (MALDI-TOF) mass spectrometry and liquid chromatography electrospray ionisation (LC-ESI) mass spectrometry, gel isoelectric focussing (IEF), cation-exchange chromatography and reverse-phase high performance liquid chromatography (RP-HPLC). Biological characterisation included comparison of G-CSF receptor binding affinity by surface plasmon resonance spectroscopy, an *in vitro* cell proliferation assay, and Western blot immunological binding. A total of 146 healthy volunteers received EP2006 and Neupogen® as subcutaneous (SC) injections of 1 μg/kg (n=24), 2.5 μg/kg (n=28), 5 μg/kg (n=28) or 10 μg/kg (n=40) or as a single intravenous 5 μg/kg dose (n=26) in four double-blind, randomised crossover phase I studies. Absolute neutrophil count (ANC), $CD34^+$ cell count and PK parameters were assessed. Supportive efficacy and safety data were obtained from a single-arm open-label phase III study in which 170 patients with breast cancer undergoing doxorubicin and docetaxel chemotherapy received SC EP2006 (300 or 480 μg daily depending on whether body weight < or ≥60 kg) from day 2 of each chemotherapy cycle. *Results.* The primary structures of EP2006

and Neupogen® were shown to be identical by peptide mapping and other tests. CD and NMR spectroscopy demonstrated that both products have comparable secondary and tertiary structures. RP-HPLC, IEF and other methods showed that both products had a similar impurity profile. Stability profiles and degradation pathways were similar for both products with no aggregates being detected. Comparable affinity with the G-CSF receptor GCSFR/CD114 was obtained using surface plasmon resonance spectroscopy, and comparable *in vitro* bioactivity was shown in a cell proliferation assay. Similar affinity to anti-G-CSF antibodies were shown on a Western blot. In phase I studies, EP2006 and Neupogen® had comparable effects on ANC and $CD34^+$ count with confidence intervals within predefined equivalence boundaries. PK parameters also showed bioequivalence. EP2006 was effective and well tolerated in patients with breast cancer. *Conclusions.* These results show the comparability of EP2006 and its reference product.

CLINICAL AND BIOLOGICAL SPECTRUM OF LARGE GRANULAR L YMPHOCYTE PROLIFERATIONS

F Suarez, FS De Fontbrune, V Asnafi, D Ghez, B Deau-Fischer, L Lhermite, R Delarue, C Brouzes, E Macintyre, B Varet, O Hermine, F Suarez

Hopital Necker-Enfants Malades, Paris, France

Background. Large granular lymphocytes (LGL) are considered to be activated cytotoxic cells of T or NK lineage and may be observed in various settings ranging from autoimmune, viral or neoplastic disorders. LGL associated with neutropenia and/or arthralgia are considered a distinct entity where a pathogenic role of LGL is suspected. *Aims.* The precise spectrum of clinical and biological manifestations associated with LGL is unclear. We retrospectively reviewed the files of patients followed at our institution for whom an LGL expansion was detected by smear or immunophenotypic analysis. *Methods.* T and NK LGL expansions were systematically explored in patients with unexplained neutropenia, absolute lymphocytosis or LGL detected on blood smear examination. Clonality and immunophenotype were assessed by TCRg PCR and flow cytometry respectively. LGL were considered primitive when no other cause was identified before or during the six months following LGL identification or were otherwise considered secondary. *Results.* We identified 113 consecutive patients followed between 1992 and 2009 (44 males and 69 females). Mean age at diagnosis was 57 years (17.5-88.5). 62 (55%) were primitive and 51 (45%) were secondary. A T-cell phenotype was noted in 92 cases (81%) and NK LGL were noted in 14 patients (12%). A T-cell clone was detected in 59/102 (58%) of cases. Neutropenia was present in 59/113 (52%) and was more common in primary compared to secondary LGL (63 vs 25% respectively, P<10-3). Infections were more common in the secondary group (25% vs. 11%, P<0.05). In patients with neutropenia, mean absolute neutrophils were 0.8 (0-1.6G/L) and was similar in both groups. The average lymphocyte count was higher in the secondary group (5.0 vs 3.3 G/L, P<10-3). Arthralgias were present in only 20 patients (11 primitive and 9 secondary). Clinical and biological manifestations of autoimmunity were present in 12 and 23 patients with primary LGL and 12 and 12 patients with secondary LGL respectively. Absolute count of LGL was neither correlated to neutropenia nor to arthralgias. Among the secondary cases, 40 (78%) had haematological malignancies (14 Myeloma/MGUS, 11 low grade B-cell lymphomas, 2 diffuse large B-cell lymphomas, 7 acute leukemias, 3 myelodysplastic syndromes). Eight patients had received allogeneic stem cell transplantation (7 for acute leukaemia, 1 for myelodysplastic syndrome). In the latter group, the diagnosis of LGL was made after the transplantation procedure. Twelve patients had undergone splenectomy. After a median follow up of 36.5 months (0-195), 7 patients had died, 6 of causes unrelated to LGL and 1 of secondary acute leukaemia following treatment with cyclophosphamide. *Conclusions.* Both primary and secondary LGL are more commonly of T-cell phenotype. Although neutropenia is more frequent in primary LGL it is rarely symptomatic. Neither the presence of a T-cell clone nor the absolute number of LGL correlate with neutropenia or symptoms. A high proportion of LGL are associated with indolent B-cell malignancies neoplasias or splenectomy. Survival does not appear to differ from the general population in primary LGL. This study underscore the indolent course of primary LGL.

0269

NEUTROPHIL APOPTOSIS IN NEUTROPENIC PATIENTS WITH HEPATITIS C INFECTION: ROLE OF CASPASES 3, 10, AND GM-CSF

S Aref, A Doaa, F Manal, EM Nadia, A Emaad, M Aymen

Mansoura Faculty of Medicine, Mansoura, Egypt

Patients with chronic HCV infection are prone to increased susceptibility bacterial infection due to neutropenia complicating the course of this disease.The molecular mechanism of neutrophil apoptosis has not been clearly defined. Neutrophils harvested from neutropenic patients with Hepatitis C infection (n=26), and nine age and sex-matched healthy control subjects were examined for the degree of apoptosis. Neutrophil apoptosis was quantified by flow cytometry through determination of Annexin V expression at 0 time (fresh neutrophil), and 24 hs culture. Neutrophils from healthy subjects were also incubated with either 10% heterologous normal or neutropenic sera with and without 10 ul GM-CSF. Caspase 3, 10 were assessed colormetrically in neutrophils at 0 time and after 24hs culture. At 0 time culture the neutrophil apoptosis of the HCV patients was insignificantly higher as compared to that of normal control (P=0.059). At 24 hours culture, patients neutrophils cultured with their own sera showed neutrophil apoptosis significantly increased as compared to that at 0 time culture and this effect was significantly attenuated in similar culture with addition of GM-CSF (P<0.001). On the other hand patients neutrophil cultured with normal sera showed insignificantly increased neutrophil apoptosis at 24 hs culture as compared to that at 0 time culture. Caspases 3, and10 activities were significantly higher in patients neutrophils after 24hs cultured with patients own sera as compared to 0 time culture (P<0.001 for both). Addition of GM-CSF to the culture down regulates the caspase 3, 10 activities. The correlation study between annexin -V expression and caspases activities revealed a borderline positive correlation between annexin -V and caspase 3 (r=0.376, P=0.058), and significant positive correlation with caspase 10 activity (r=0.494, P=0.01). These findings suggest that enhanced neutrophil apoptosis demonstrated in neutropenic patients with HCV infection is through activation of Caspase 10 and is attenuated by GM CSF.

Maria Nuova, Reggio Emilia, Reggio Emilia, Italy; [4]Dipartimento di Ematologia, Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggi, Reggio Calabria, Italy; [5]UO Ematologia PO San Vincenzo, Taormina, Taormina, Italy; [6]UO Ematologia, AO SS Annunziata, Taranto, Taranto, Italy; [7]Dipartimento di Oncologia e Ematologia, Università degli Studi di Modena e Reggi, Modena, Italy; [8]Divisione di Ematologia, Azienda Ospedaliera Papardo, Messina, Messina, Italy;[9]Dipartimento di Ematologia ed Oncologia, Presidio Ospedaliero, Pescara, Pescara, Italy

Background. Indolent non-follicular lymphomas (NFo-NHL) include small lymphocytic lymphoma (SLL), lymphoplasmacytic lymphoma (LPC), marginal zone lymphoma (MZL). This heterogeneous group show different presenting features, behaviour pattern and treatment outcome. This subset of lymphomas have been relatively poorly investigated, and only retrospective studies or prospective trials involving limited series have so far been published. *Aims.* In 2002 the Gruppo Italiano Studio Linfomi (GISL) initiated LL02 prospective multicenter phase II trial, with the aim to evaluate the efficacy and safety of FC combination as front-line therapy of NFo-NHL patients. *Methods.* Between July 2002 and September 2006, 63 adult patients affected by NFo-NHL in active disease phase, were consecutively enrolled in 12 GISL hematological centres. After histologic revision, 61 patients could be enrolled in the study (36 males and 25 females, median age 64 yrs, range 40-75). The series included 22 cases of SLL, 11 LPC, 25 MZL, 3 CD5 negative NHL cases. Patients were treated with a dose of 25 mg/sqm Fludarabine plus 250 mg/sqm Cyclophosphamide administered intravenously daily for 3 days; each cycle was repeated every 28 days for 6 courses; an intermediate evaluation was performed after the third cycle. During the treatment patients received oral thrimethoprim-sulphametoxazole and fluconazole prophylaxis. *Results.* Two patients were excluded because no further information after registration have been obtained. Six patients were withdrawn before the intermediate evaluation for early toxicity: 2 lethal infective episodes (WHO grade 4), 3 haematological toxicities (WHO grade 3-4) and 1 renal toxicity (WHO grade 4). After the intermediate evaluation, 51/59 patients (86.4%) had an objective response (ORR) with a 22% of complete remission (CR) and 64.4% of partial remission (PR). Among the 53 remaining patients, 43 completed the planned treatment of six cycles, 3 five cycles, 3 four cycles, 2 three cycles and 1 progressed after first cycle. At the final evaluation the ORR percentage was 83% with a 40.6% of CR (24 pts) and 42.3% of PR (25 pts); three patients were in progressive disease (5.0%) and one in stable disease (1.6%). On the basis of intention to treat analysis, after a follow-up of 60 months, the median overall survival (OS) was 64%, the progression free survival (PFS) was 54% and the failure free survival was 39%. The median remission duration was 26 months. After a median follow up of 36 months, mortality was 28% (17/61): among them, it was related to disease relapse/progression (35%), sepsis (29%), second tumor (18%), cerebrovascular event, respiratory insufficiency and other causes (6%). About the toxicity profile, the major toxicity was hematological with a 18% cases of WHO grade III or IV anemia, 34% neutropenia and 11% thrombocytopenia. The 10% of patients had an infective episode of WHO grade III-IV. *Conclusions.* FC chemotherapy is a useful chance for advanced untreated non follicular low-grade NHL, with an optimal ORR, CR and PFS. OS is not significantly improved in comparison with fludarabine alone or with standard therapy, even though the quality of responses was better. Infective (2 early deaths) and haematological toxicity, causing the interruption of the planned treatment in a significant subset of patients, suggest an accurate selection and a careful monitoring during the therapy.

0271

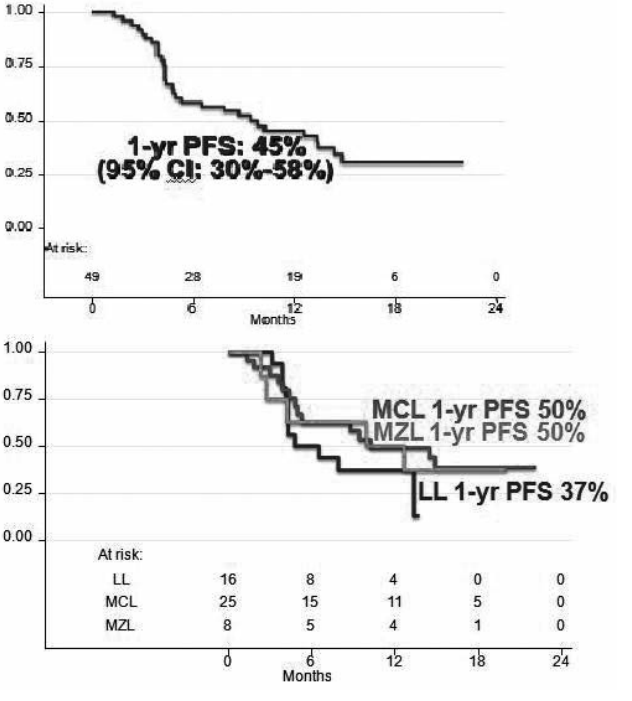
EFFICACY AND SAFETY OF BORTEZOMIB AND RITUXIMAB ASSOCIATION IN RELAPSED/REFRACTORY INDOLENT NON-FOLLICULAR AND MANTLE CELL LYMPHOMA: FINAL RESULTS OF PHASE II STUDY BY INTERGRUPPO ITALIANO LINFOMI

A Chiappella,[1] P Pregno,[1] PL Zinzani,[1] A Evangelista,[2] A Fabbri,[1] F Facchetti,[3] A Ferreri,[1] S Franceschetti,[1] R Freilone,[1] L Gargantini,[1] D Gioia,[1] AM Liberati,[1] L Orsucci,[1] L Rigacci,[1] E Russo,[1] V Stefoni,[1] A Tucci,[1] U Vitolo[1]

[1]On the behalf of Intergruppo Italiano Linfomi (IIL), Torino, Italy; [2]Unit of Cancer Epidemiology, University of Torino and CPO Piemonte, Torino, Italy; [3]Pathology Unit, Spedali Civili Hospital, Brescia, Italy

Background. Bortezomib alone or in combination with Rituximab has shown clinical benefit in treatment of Mantle Cell Lymphoma (MCL) and Marginal Zone Lymphoma (MZL). *Aims.* To evaluate safety and efficacy of Rituximab and Bortezomib combination in relapsed/refractory indolent non-follicular lymphoma and MCL not eligible to high-dose chemotherapy. Patients and *Methods.* The study was a phase II multicenter trial according to Simon's design. Inclusion criteria were: age 18-75 years, histological proven relapsed (> 1 year from the last therapy) or refractory (<1 year) indolent non-follicular (linfocytic lymphoma, LL, or MZL) and MCL after 1-4 lines of therapies. Treatment plan was: one course of four weekly intravenous bolus of 1.6 mg/sqm Bortezomib in combination with four infusion of 375 mg/sqm Rituximab followed by two courses of four weekly bolus of 1.6 mg/sqm Bortezomib. Patients with complete (CR), partial remission (PR) and stable disease at the intermediate evaluation were planned to be given three further courses with the same schedule. *Results.* From September 2006 to March 2008, 55 patients entered into the study. Histology revision was performed by three expert pathologists. Forty-nine patients fulfilled inclusion criteria and were evaluable. Clinical characteristics were: median age 68 (50-74) years; 16 LL, eight MZL, 25 MCL; 42 stage III/IV; 33 bone marrow involvement; 20 at intermediate-high/high IPI risk. Thirty-eigh patients performed > two prior lines of chemotherapy; 34 were Rituximab-pretreated; 21 refractory and 28 relapsed disease. Overall Response Rate (ORR) was 53% (CR 26.5%, PR 26.5%); no response 43% and 4% off therapy for other causes. ORR by histology was: 37% in LL, 50% in MZL and 64% in MCL. ORR was not adversely affected by Rituximab pretreatment: Rituximab-pretreated 62% and Rituximab-naïve 33%. ORR was higher in relapsed patients compared with refractory ones: 64% and 38% (p.06). With a median follow-up of one year, Overall Survival was 89% (95%CI: 75-95) and 1-year Progression free survival (PFS) was 45% (95%CI: 30-58) (Figure 1A). One-year PFS was 50% for MZL and MCL and 37% for LL (Figure 1B).

Figure 1.



A total of 233 courses were delivered with a median of 4.7 courses per patient. Thirty patients completed the treatment plan; 19 did not because of progression disease in 13, adverse events in five (one each: concomitant gastric neoplasia, neurotoxicity grade II, sepsis, pleural effusion and toxic death due to interstitial pneumonia). Grade 3-4 CTC haematological toxicity was rare: neutropenia in 5% of the courses and thrombocytopenia in <2%. Grade 3-4 CTC cumulative non-hematological toxicity was observed in 4.7% of all courses. The most frequent non-hematological toxicities were: neurotoxicity grade III in four patients, with complete recover or return to grade I in all of them. Infections were observed in eight patient with ten events: viral reactivation in four, pneumonia in three, sepsis in one and micosis in two. *Conclusions.* The combination of Rituximab and Bortezomib in weekly schedule was effective and safe in treatment of relapsed/refractory indolent and MCL. PFS was promising also in Rituximab-pretreated patients and mainly in MZL and MCL.

0272

TWO YEAR FOLLOW UP OF THE CANADIAN TOSITUMOMAB AND I131 TOSITUMOMAB (TST/I131-TST) EXPERIENCE: THE LARGEST PHASE II STUDY WITH RIT IN INDOLENT NON HODGKIN LYMPHOMA WITH PRIOR RITUXIMAB (R) TREATMENT

H Olney,[1] M Freeman,[2] J Mangel,[3] D Stewart,[4] D White,[5] G Gaudet,[6] S Vantyghem[2]

[1]Centre Hospitalier de l'Université de Montréal, Montreal, Canada; [2]GlaxoSmithKline Inc., Toronto, Canada; [3]London Health Sciences Centre, London, Canada; [4]University of Calgary and Tom Baker Cancer Centre, Calgary, Canada; [5]QEII Health Sciences Centre, Halifax, Canada; [6]Hôpital du Sacré-Coeur, Montreal, Canada

Background. Indolent NHL is characterized by relapses and remissions and tends to respond less to each successive line of therapy. Radiotherapy use in NHL is generally limited to localized disease or palliation, being more toxic as field size increases. Immunotherapy against CD20 has revolutionized NHL specifically targeting B cells. Combining these two modalities as radioimmunotherapy has been shown to be highly active but remains to be fully characterized. *Aims.* Further assess the response rate, the duration of response and toxicity to treatment with I131-T. *Methods.* A phase II open label study of TST/I131-TST was conducted at 12 Canadian centres. Patients with indolent NHL with at least two prior lines of therapy (at least one including R) who had responded to their last treatment were enrolled after obtaining informed consent from April 2004 to February 2007. *Results.* 93 patients were enrolled and included in the intent-to-treat population analysis. Median age was 59 yrs (range 32-78) and 54% were males. ECOG status was 0 in 55.9% and 1 in 37.6%. Follicular NHL was present at original diagnosis in 94.6% of the patients, 78.5% with pathologic grade 1 or 2 histology. Bone marrow involvement was documented in 25.8% of patients. The median duration of disease was 4.9 yrs (range 0.8-22.7). The median number of prior therapies was 5 (range 2-14) with 39.8% of patients enrolled within 6 months of their last therapy. 25.8% had received radiotherapy in prior treatment strategies. Over the 26 week study period, response rate was 40.9% (95% CI 30.8-51.5) including 4.3% with complete response. In 77 patients evaluable for this endpoint, the response rate was 49.4% (95% CI 37.8-61.0). With 2 years of follow up, the median duration of response was 41.4 months (95% CI 22.0-IND, range 4.2-56.4+). Median progression free survival was 12.1 months (95% CI 10.8-17.9). Median overall survival at 2 years was not reached (95% CI 33.3-IND, range 1.2-58.0+ months). There were 38 deaths, 36 of progressive disease, 1 septic shock after progression and 1 respiratory failure. Median FACT-lym scores for quality of life did not significantly decline during the study and improved by week 7 compared to baseline. While on study (to 26 weeks), treatment was well tolerated, 13 patients (14%) had at least one serious adverse event, six considered related to study medication by investigators. 98% of patients had at least one adverse event (AE), the most frequent were fatigue (49%), nausea (43%), cough (31%), headache (23%) and diarrhea (20%). 33% had a grade 3/4 AE, including neutropenia (1%/5%), anemia (3%/0%) and thrombocytopenia (0%/1%). One febrile neutropenia was observed. *Conclusions.* Treatment with TST/I131-T was associated with durable responses with no unexpected toxicities in this heavily pretreated large cohort of patients. A multi-variable model will be explored for predictors of response and other study endpoints; a preliminary stratification by factors including age (<70), number of prior therapies (<4) and size of greatest lymph node (<7 cm) identified cohorts of patients with greater response rates.

0273

OFATUMUMAB IN COMBINATION WITH CHOP (O-CHOP) ACHIEVES HIGH RESPONSE RATES IN PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA (FL) PATIENTS WITH HIGH-RISK FLIPI SCORES

S Czuczman,[1] A Viardot,[2] G Hess,[3] O Gadeberg,[4] P Hansen,[5] L Pedersen,[5] D Belada,[6] S Gregory,[7] B Pohlman,[8] J Mayer,[9] R Pytlik,[10] L Trümper,[11] I Gupta,[12] T Lin,[12] K Windfeld,[13] C Russell[13]

Background. Ofatumumab is a novel human antibody that targets a membrane-proximal epitope encompassing both the small- and large-loop on CD20, and elicits more rapid and efficient *in vitro* complement-dependent cytotoxicity and antibody-dependent cell-mediated cytotoxicity compared with rituximab. Single-agent ofatumumab has previously demonstrated clinical activity in patients with relapsed/refractory FL at doses up to 1000 mg. *Aims.* We report initial results of an open-label, randomized, two-dose, parallel-group Phase II study of ofatumumab in combination with CHOP (O-CHOP) in patients with previously untreated FL. *Methods.* A total of 59 patients with previously untreated CD20$^+$ FL (Grade 1-3, stage III-IV or bulky stage II) were randomized to ofatumumab Day 1, 500 mg (Group A) or 1000 mg (Group B); cyclophosphamide Day 3, 750 mg/m^2; doxorubicin Day 3, 50 mg/m^2; vincristine Day 3, 1.4 mg/m^2; and prednisone Days 3-7, 100 mg every 3 weeks for 6 cycles. The first ofatumumab dose was 300 mg for both groups. One patient withdrew before treatment and was excluded from analysis. The primary endpoint was overall response rate (ORR; 1999 International Working Group criteria) assessed by an Independent Endpoint Review Committee. *Results.* Twenty-nine patients were treated in each group; 93 and 100% of patients in Groups A and B, respectively, received all 6 cycles of therapy. Baseline characteristics for Group A / Group B were: median age, 55/54 years; FLIPI score 3-5, 34% / 38% of patients. ORR (95% CI) was 90% (73, 98%) in Group A and 100% (88, 100%) in Group B (Table).

Table.

Baseline characteristics and response		
Characteristic	**Group A (N=29) OFA 500 mg**	**Group B (N=29) OFA 1000 mg**
Median age (range), years	55 (25–74)	54 (33–73)

ORR, n (%) CR+CRu, n (%)	26 (90) 20 (69)	29 (100) 16 (55)
CR+CRu by FLIPI score, n (%) Low risk (0–1) Intermediate risk (2) High risk (3–5)	 4 (57) 8 (67) 8 (80)	 6 (60) 2 (25) 8 (73)
[a]At screening; [b]Omission/reduction of vincristine in 21 and 34% of patients in Groups A and B, respectively.		

Complete response (CR) + unconfirmed CR (CRu) was 69% in Group A and 55% in Group B. Overall, 16 of 21 patients (76%) with FLIPI score 3-5 attained CR/CRu. Median follow-up was 9.7 months. Ofatumumab infusion-related reactions were primarily grade 1-2 and decreased in incidence with continued therapy; 2 patients (Group B) had

grade 3 reactions during the first dose (infusion-related hypersensitivity reaction, largyngeal edema), but were able to receive subsequent doses. The most common investigator-reported grade 3-4 adverse events were leukopenia and neutropenia (31 and 28%, Group A; 28 and 17%, Group B). Incidences of grade 3-4 leukopenia and neutropenia by laboratory assessments were 83 and 90% in Group A and 72 and 90% in Group B, respectively. Grade 3-4 infections occurred in 10% of patients in Group A and 3% in Group B, with febrile neutropenia in 7 and 3% of patients, respectively. No deaths have been reported at the time of analysis. *Summary/Conclusions.* O-CHOP achieved high response rates, was effective across all FLIPI risk groups and was well tolerated with no unexpected toxicities in patients with previously untreated FL. No differences in toxicity or response were observed between the two dose groups. Longer follow-up time is needed for analysis of survival endpoints.

0274

ENZASTAURIN IN PATIENTS WITH FOLLICULAR LYMPHOMA: PRELIMINARY RESULTS OF A PHASE II STUDY

S Schwartzberg,[1] R Hermann,[2] I Flinn,[3] D Flora,[4] M Goerner,[5] A Korfel,[6] M Kneba,[7] H Salwender,[8] J Song,[9] O Hamid,[9] B Lin,[9] M Dreyling[10]

[1]The West Clinic, Memphis, USA; [2]Northwest Georgia Onc Ctrs PC, Marietta, USA; [3]Sarah Cannon Rsrch Inst, Nashville, USA; [4]OHC Inc, Crestview Hills, USA; [5]Stadt Klinikum Bielefeld, Bielefeld, Germany; [6]Charite-Universitatsmedizin, Berlin, Germany; [7]Universitaetsklinikum Schleswig-Holstein, Kiel, Germany; [8]Asklepios Klinik Altona II. Medizinische Abteilung, Hamburg, Germany; [9]Eli Lilly and Company, Indianapolis, USA; [10]Univ Hosp Grosshadern, Munich, Germany

Background. Protein kinase C beta (PKCβ) has a pivotal role in normal B-cell signaling and survival. Overexpression of PKCβ is implicated in the pathogenesis of follicular lymphoma (FL). Enzastaurin (ENZ), an oral serine/threonine kinase inhibitor, targets the PKCβ and PI3K/AKT pathways to suppress tumor cell proliferation and angiogenesis, and induce apoptosis. *Aims.* The primary objective of the study is to evaluate tumor response rate (RR) of ENZ in patients (pts) with grade 1 or 2 FL. The secondary objectives are progression-free survival, time to response, duration of response (DoR), and safety. *Methods.* This is an open-label, single-arm, phase II study of pts with histologically confirmed grade 1 or 2 and stage III or IV measurable FL. Pts were either chemonaive or had relapsed after one chemotherapy regimen or single-agent rituximab (completed ≥6 months before enrollment). Pts received 500 mg oral ENZ, once daily (1125-mg loading dose on day 1) for up to 3 yrs or until progression, withdrawal, or unacceptable toxicity occurred. *Results.* A total of 66 pts (22 males and 44 females) with a median age of 62 yrs (range, 33-82 yrs) were enrolled. According to the Follicular Lymphoma International Prognostic Index (FLIPI) score at baseline, 12.1% had low-risk disease (0-1 risk factors), 53.0% had intermediate-risk disease (2), and 34.8% had high-risk disease (3-5). Forty-six pts (70%) were chemonaive and 20 pts (30%) had one prior chemotherapy (including rituximab). As of August 2009, the median overall exposure was 10.1 months (range, 1-26.6 months). Sixty-four pts received ≥1 dose of ENZ and were evaluable for efficacy. Overall RR was 25% (1 complete response, 15 partial responses). Table 1 shows RR by FLIPI score and previous therapy.

Table 1.

	N	Responders, n (%)	95% CI
FLIPI score (risk Factors)			
Low (0-1)	8	1 (12.5)	0.3–52.7
Intermediate (2)	34	10 (29.4)	15.1–47.5
High (3-5)	22	5 (22.7)	7.8–45.4
Prior chemotherapy			
Chemonaive	44	10 (22.7)	11.5–37.8
Prior therapy	20	6 (30.0)	11.9–54.3

CI=confidence interval; N=total number of evaluable patients; n=number of patients.

A total of 25 pts (39.1%) had progressive disease (PD); 60% were progression-free for ≥12 months. The median time to response for responders was 115.5 days (range, 52-327 days). The median DoR has not been reached (range, 59-687 days; 11 pts in remission). Thirty-seven pts (56%) discontinued treatment: 3 pts (4.5%) due to adverse events, of which 2 (3%) were possibly drug-related (bronchitis and skin rash). Ten pts (15.2%) had grade 3 toxicities, one of which was study drug-related (bronchitis). There were no drug-related deaths. Twenty-nine pts (44%) continue receiving treatment. *Conclusion.* Preliminary results indicate that ENZ has clinical activity and is well tolerated in pts with grade 1 or 2 FL. Updated data will be provided at the presentation.

0275

MANAGEMENT OF RELAPSED OR REFRACTORY FOLLICULAR LYMPHOMA PATIENTS - A FRENCH PHARMACO-EPIDEMIOLOGICAL STUDY: THE OLYMPE STUDY (ML20248)

P Feugier,[1] M Maynadié,[2] P Franchi Rezgui,[3] M Hacini,[4] G Laurent,[5] E Suc,[6] O Fitoussi,[7] P Solal-Celigny,[8] G Damaj,[9] C Haioun,[10] F Lazreg,[11] D Pau,[11] G Salles,[12] P Brice[13]

[1]CHU de Nancy, Vandoeuvre les Nancy, France; [2]CHU de Dijon, Dijon, France; [3]Hôpital Saint-Louis, Paris, France; [4]Centre Hospitalier de Chambery, Chambery, France; [5]Hôpital Purpan, Toulouse, France; [6]Clinique du pont de Chaume, Montauban, France; [7]Polyclinique Bordeaux Nord Aquitaine, Bordeaux, France; [8]Clinique Victor Hugo, Le Mans, France; [9]Groupe hospitalier Sud, Amiens, France; [10]Hôpital Henri Mondor, Créteil, France; [11]Roche, Neuilly-sur-Seine, France; [12]Hôpital Lyon Sud, Pierre Bénite, France; [13]Hôpital Saint Louis, Paris, France

Background. There is no consensus on the optimal therapeutic strategy for relapsed follicular lymphoma (FL) patients. Treatment includes immuno-chemotherapy alone or followed by either Autologous Stem Cell Transplantation (ASCT), radio-immunotherapy or rituximab (R) maintenance. *Aims.* To describe, in routine practice, treatment modalities and response rates of relapsed FL in a French cohort study. *Methods.* Prospective, multicenter, observational study in patients with histologically confirmed, $CD20^+$ relapsed FL (Grade 1 to 3a) followed for up to 5 years. Eligible patients required a treatment, regardless of what they had previously received. This interim analysis focuses on induction therapy after relapse. *Results.* From January 2007 to September 2009, 260 patients with relapsed FL treated in 39 French Oncology or Hematology Centers were included in the OLYMPE study. Fourteen patients were excluded from this analysis due to either inclusion criteria violation or missing data. Median age was 61 years (range 30-87), 55.3% were male, with Ann Arbor stage I/II (20.2%) or stage III/IV (68.9%) and 62% of patients had high tumor burden according to the GELF (Groupe d'Etudes des Lymphomes Folliculaires) criteria. Most patients were in first relapse 56.9% (n=140), 22.8% (n=56) in second relapse and 20.3% (n=50) in third or more relapse. Previous treatment included rituximab with or without chemotherapy in 53% (n=131) of patients, high dose therapy with ASCT (HDT + ASCT) in 2.4% (n=6) including 1.6% (n=4) with HDT + ASCT in first line treatment. At inclusion, 94% of patients were treated with R + chemotherapy or R monotherapy. The most common chemotherapy regimens used were fludarabine-based chemotherapy (20.4%; mainly FCR 14.3%), CHOP (18.4%), platinum based chemotherapy (15.9%) and CVP (7.5%). At the end of relapse induction treatment, the overall response rate (ORR=CR+PR) was 52.4%, and complete response rate was 32% (whatever the number of prior treatment lines received), see Table 1.

Table 1.

Response rate	CR (%)	PR (%)	ORR (%)	PD/SD (%)
R+ chemotherapy (n=140)	40.7	20.0	60.7	6.4
R monotherapy (n= 52)	21.2	30.8	52.0	11.5
Chemotherapy alone (n=13)	15.4	30.8	46.2	15.4
R+ radioimmunotherapy (n=10)	40.0	10.0	50.0	10.0

Twenty patients were not evaluated at the end of the induction therapy for relapsed disease. *Conclusions*. In routine clinical practice, the most frequently prescribed induction treatment in France for relapsed FL patients is rituximab with or without chemotherapy, for both first and subsequent relapses. Even in this difficult-to-treat population, complete or partial responses were achieved in 52.4% of patients. Further follow-up is needed to assess the treatment strategies used after induction treatment (HDT + ASCT, rituximab maintenance or observation) as well as safety data.

T(14;18) IN FOLLICULAR LYMPHOMA: A REAL- TIME (PCR) FOR A REAL LIFE….?

A Janikova, A Mareckova, D Dvorakova, B Tichy, S Pospisilova, J Michalka, J Mayer

University Hospital, Brno, Czech Republic

Background. T(14;18) is a molecular marker of follicular lymphoma (FL). Polymerase chain reaction (PCR) permits detection of this specific breakpoint. The presence of t(14;18)-bearing cells is assumed to correlate with lymphoma activity. To date, however, the value of t(14;18) assessment on the initial staging and prognosis remains controversial. The quantitative analysis using real-time PCR (RQ PCR) could be more helpful. *Aims.* We performed a very complex testing of t(14;18) including quantitative analysis in blood, marrow or lymph node to assess its prognostic significance. *Methods.* Totally, 202 (160/202 stage III/IV) FL patients were tested for t(14;18) between 03/2001 and 01/2010. Initially, peripheral blood, bone marrow and lymph node tissue were tested if available. Nested PCR (for MBR and mcr) and real-time PCR (RQ PCR) in MBR+ cases were used. Blood and marrow samples were taken before and after therapy. Rituximab with chemotherapy were administered in the absolute majority of cases. *Results.* At the time of FL diagnosis/relapse (151/51), 113/202 (66%) patients were t(14;18) positive using PCR methods, but only 95/202 (47%) were MBR+. Quantitative analysis according to compartment showed the highest numbers of t(14;18) copies/106 CE (cell equivalent) in infiltrated lymph nodes (n=21; median 1.25×10^6, range 340000-8.7×10^6) compared to bone marrow (n=55; median 9800, range 0-3.6×10^6) and peripheral blood (n=58; median 2994, range 0-1.26×10^6) (P<.05). For prognosis evaluation, 75 PCR+ patients with complete molecular and clinical evaluation (median follow up 37 months; range 7-102) were analyzed according to achievement of molecular remission after therapy. Post-treatment PCR-negative subgroup (n=55) showed better prognosis vs. PCR+ subgroup (n=22) with significantly fewer clinical relapses (24% vs 55%), lymphoma-related deaths (5% vs. 40%), and longer PFS (median 21 vs. 12 months; P<012). There were no differences between subgroups in FLIPI, age, proportion of relapsed patients, stage, grade and follow-up duration. Interestingly, the post-treatment PCR- and PCR+ subgroups showed different pre-treatment numbers of t(14;18) copies/106 CE in peripheral blood with median 709 (0-650616) vs. 6870 (114-$1,2\times10^6$) copies as well as in bone marrow with median 2276 (1-451066) vs. 81414 (58-$1,05\times10^6$). These differences were statistically significant p.009 and p.005, respectively. No differences were observed in lymph node compartment. The significance of "molecular burden " before treatment in peripheral blood and/or bone marrow was confirmed by comparison of patients with "poor"and "good"clinical outcome (defined as EFS<20 vs.≥36 months). Patients with "good"outcome (n=20) showed significant lower numbers of t(14;18) copies compared with "poor"prognosis patients (n=16) in peripheral blood (P.002) and bone marrow (p.009), no differences were found in lymph node compartment. No differences in FLIPI, age, stage, grade or proportion of relapsed patients between prognostic subgroups were observed. *Conclusions.* In spite of limited utility of PCR detection of t(14;18), we conclude, that the quantity of t(14;18) in peripheral blood and/or bone marrow at diagnosis or relapse mirrors "molecular tumor burden"and seems to provide a new prognostic toll independent on FLIPI, other clinical or morphological parameters.

0277

RITUXIMAB AND CHLORAMBUCIL AS FRONT-LINE TREATMENT FOR FOLLICULAR LYMPHOMA: EXTENDED DISEASE FREE SURVIVAL WITHOUT INCREASED TOXICITY

S Bassi, S Sammassimo, F Gigli, M Negri, E Cocorocchio, A Gardellini, C Rabascio, A Calleri, G Pruneri, F Peccatori, D Laszlo, G Martinelli

European Institute of Oncology, Milan, Italy

Background. follicular lymphoma (FL) is one of the most common B-cell non-Hodgkin lymphoma (NHL) and is characterized by an indolent course with a continuous relapse pattern. The anti-CD20 monoclonal antibody Rituximab (R) in combination with chemotherapy is now considered a standard first line treatment for FL. This combination significantly improves progression-free survival (PFS), overall response rate (ORR) and complete response (CR) rate in FL compared with chemotherapy alone. *Aim.* here we report our experience with the combination of Rituximab and Chlorambucil (Chl) in untreated FL pts. *Methods.* since November 2001, 58 pts (28 male and 30 female) with FL received R-Chl as first-line treatment. Patients started with an induction phase with four weekly infusions of Rituximab at 375 mg/sqm and 6 consecutive weeks of Chl at 6 mg/sqm/daily. After restaging, all patients with stable or responsive disease proceeded to a consolidation phase with 4 monthly Rituximab infusions and 14 days of Chl each month. Median age at diagnosis was 56 years (range 29-79). Ann Arbor stage was advanced (stage III-IV) in 44 pts (76%) and 16 pts presented an extranodal localization. Only 9 patients were symptomatic. Histological grading was available in 52 cases, and was 1 in 13 pts, 2 in 33 pts and 3 in 6 pts. FLIPI was evaluable in 55 pts and 31 pts (56%) were at low risk. *Results.* after the induction phase, ORR was 98%, with 15 pts in complete remission (CR) and 42 in partial remission (PR). After the consolidation phase, 46 pts obtained a CR and 11 PR; one remained in stable disease. The mean daily dose of Chl received during the induction phase was 10 mg, while in the prolonged treatment was 8 mg. Chl dose was reduced in 25 pts (43%); however, only 13 pts (22%) had a G3-4 neutropenia, and Chl treatment was stopped in only a patient for a persistent G3 neutropenia after the first consolidation cycle. One HBsAg positive patient did not concluded the treatment because of AST/ALT elevation. With a median observation time of 31 months (range 7-129) from the diagnosis, 40 patients still in CR and 5 in PR . Ten patients (17%) relapsed, with a median time to progression of 19 months (range 7-66) and one died because of lymphoma. *Conclusions.* our preliminary results described a safe and feasible combination of immuno-chemotherapy in untreated FL pts. In terms of efficacy, our clinical results seems similar to those obtained with more aggressive therapy, but with a lower toxicity and an easier management. Our experience suggests, that the addition of Rituximab seems to delete all differences depending on the chemotherapy regimen used. Our combination with Rituximab and Chlorambucil may be considered a valid first-line therapy, especially in FL patients not eligible for more aggressive chemotherapy regimens.

0278

PRIMARY BONE MARROW MARGINAL ZONE LYMPHOMA (PBMMZL): A NEW DISEASE ENTITY?

C Kalpadakis,[1] G Pangalis,[2] S Sachanas,[3] P Korkolopoulou,[4] F Kontopidou,[2] G Levidou,[4] A Dimitrakopoulou,[2] M Angelopoulou,[2] MC Kyrtsonis,[2] E Dimitriadou,[2] S Kokoris,[2] X Yiakoumis,[3] P Tsirkinidis,[5] M Moschoyiannis,[3] D Rontoyianni,[6] P Panayiotidis,[2] H Papadaki,[1] T Vassilakopoulos[2]

[1]University of Crete, Athens, Greece; [2]Department of Haematology, University of Athens, Athens, Greece; [3]Athens Medical Center, Athens, Greece; [4]Department of Pathology, University of Athens, Athens, Greece; [5401] General Army Hospital, Athens, Greece; [6]Department of Pathology, Evangelismos Hospital, Athens, Greece

Background. The present classification of marginal zone lymphomas (MZL) is probably inadequate to describe all the clinical spectrum of the disease. *Aim.* To describe what we consider as a new marginal zone lymphoma category with primary involvement of the bone marrow and blood, without splenomegaly, lymphadenopathy or MALT involvement. *Patients and Methods.* The definition of PBMMZL was based on the following criteria: Infiltration of BM and blood by lymphoma cells with morphologic and immunophenotypic features consistent with marginal zone origin, absence of lympadenopathy, splenomegaly (by clinical and

imaging methods) or other extranodal disease localization. Between 1986-2009, among 213 patients (pts) with MZL, 23 were retrospectively recognised as fulfilling the criteria for their entry into the present analysis, thus representing 9% of the total MZL group in our Departments. *Results.* The main clinical features are presented on table 1. Circulating lymphoma cells were characterized by an heterogeneous morphology, consisting of a mixture of small lymphocytes, monocytoid and villous lymphocytes. They expressed moderate to strong CD20, more often κ light chain (70%), while they were negative for CD5 and CD10 antigens. CD11c and CD23 antigens were expressed in 43% and 48% respectively, while the expression of CD25 (17%) and CD38 (4%) were less common. A highly variable degree of BM infiltration was noted (10-90%, median 25%), while the pattern of BM infiltration was as follows: mixed 39%, nodular 35%, interstitial 13%, diffuse 9% and paratrabecular 4%. Intrasinusoidal infiltration was evident in 2 cases along with nodular infiltration. Immunohistochemistry showed strong expression of CD20 and negativity for CD10, CD5, cyclin- D1 and CD138 antigens. At diagnosis only one pt received therapy due to anemia. During follow up time 2 pts progressed, at 12 and 84 months, with increasing lymphocytosis, without evidence of splenomegaly or lymphadenopathy. These two pts were treated with rituximab and complete remission was achieved. At a median follow up time of 20 months (3-120) no deaths were recorded. *Conclusions.* We are describing a new category of MZL with primary BM involvement, which is characterized by an indolent clinical course and long survival without need of treatment in the vast majority of patients. Despite many similarities with splenic MZL, no pt in our study has so far displayed splenomegaly.

Table. Features of the 23 pts with PBMMZL at diagnosis.

Features	*No pts*	*%*
Age: Median 65y (50-83)	23	100

Background. Stage IV marginal zone B-cell lymphomas (MZLs) are present in more than one fourth of patients. But, according to previous study, they had a different prognosis between multiple mucosa-associated lymphoid tissues (MALT)-organ involved stage IV and bone marrow (BM) or nodal involved stage IV. *Aims.* In this study we conducted retrospective analyses of the clinical features and treatment outcomes of specific stage IV MZL to identify their clinical features, treatment, and prognosis. *Methods.* For analysis, between Feb. 1996 and Jun. 2009, a total of 94 patients with histologic diagnosis of stage IV-MZL from 17 different institutions in Korea were included. Stage IV was defined MZL involved (i) over 1 MALT organs (M-MZL) or (ii) BM (BM-MZL) or (iii) liver (L-MZL). *Results.* The male/female ratio of the 94 patients was 60 to 34. The median age of our subjects was 59 years (range: 12-82 years). Multiple-MALT organs involved MZL with or without lymph node (LN) was 34 patients (36.2%). BM involved stage IV MZL was 52 patients (55.3%). Median time to progression (TTP) was 2.3 years (95% CI, 2.0-2.3 years). Cause-specific overall survival (OS) was not reached median value. 5 year and 10 year OS rate were 85.2% and 80.7%, respectively. M-MZL and BM-MZL / L-MZL did not show the difference in median TTP (2.4 years versus 2.3 years, P=0.439). But, in the patients who involved LN in stage IV MZL appeared to be associated with a worse prognosis in TTP regardless of M-MZL or BM-MZL / L-MZL (P=0.010). 89 patients had treated - 2 follow up loss and 3 watchful wait. 83 patients had received chemotherapy based treatment. Out of them, CR or PR was achieved in 63 patients (75.9%). Chemotherapy treatment without operation or radiotherapy was done in 62 patients. Evenly 31 patients treated with rituximab included regimen (R+CTx) and with rituximab not included regimen (R-CTx). R+CTx had been shown better response than R-CTx (83.9% versus 54.8%, P=0.026). But, there was no difference in TTP duration (2.0 years versus 1.8 years, P=0.686). *Conclusions.* Stage IV MZL tends to be an indolent disease - characterized by prolonged survival with frequent relapses. The majority of them was controlled well with chemotherapy based treatment, and could achieve prolonged survival. LN involvement was more valuable prognostic factor than M-MZL or BM-MZL / L-MZL for TTP. Rituximab looks like contribution to better response but not in TTP. So we should consider about maintenance treatment of MZL for extend their response duration.

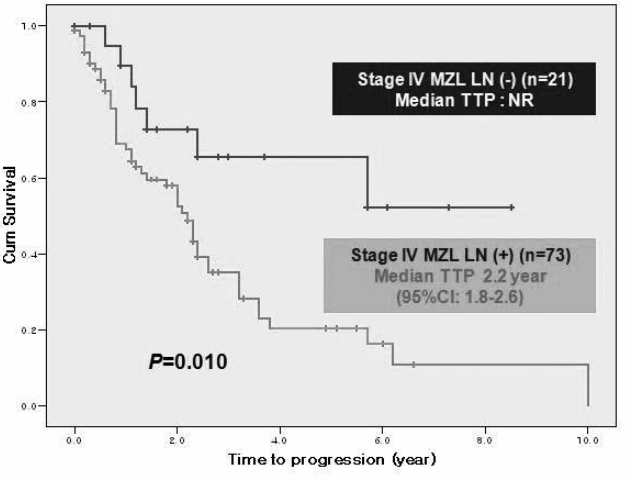

Figure. LN involvement might be a poor prognostic factor

0280

CLINICAL AND VIROLOGIC FEATURES, TREATMENT-RELATED TOXICITY AND OUTCOME OF NON-HODGKIN'S LYMPHOMAS ASSOCIATED WITH HEPATITIS C VIRUS INFECTION: A MULTICENTER ITALIAN STUDY ON 643 PATIENTS

Giovanni Battista, Turin, Italy

Background. Hepatitis C virus (HCV) has been associated with B-cell non-Hodgkin's lymphomas (NHL), especially marginal zone lymphoma (MZL) and diffuse large B cell lymphoma (DLBCL). Treatment of HCV-positive NHL is a major issue in the clinical practice: particularly, prevalence and severity of liver toxicity of (immuno)-chemotherapy are not fully elucitated. *Aims.* to analyse clinical characteristics, virological features, treatment-related hepatic toxicity and outcome of a large series of indolent and aggressive NHL associated with HCV infection. *Methods.* we studied 643 HCV-positive patients (pts) with NHL diagnosed and treated from 1993 to 2009 in 16 italian hematologic insititutions. All pts were HIV negative. *Results.* 380 cases were aggressive NHL (373 DLBCL), 263 indolent NHL (114 MZL). Features of pts are summarized in Table 1.

Table 1. Clinical and virus-specific features at presentaion in 643 patients with HCV+ NHL.

	All cases		Aggressive NHL		Indolent NHL		p
	N	%	N	%	N	%

Nine out of 38 HCV-RNA negative pts cleared HCV by means of antiviral therapy before NHL diagnosis. 587 pts received (immuno)-chemotherapy as first-line treatment. Other treatments were as follows: watch-and-wait policy in 25 pts, palliative chemotherapy in 7, splenectomy in 7, anti-HP eradicating therapy in 3 gastric MZL, anti-HCV antiviral therapy in 14 pts (7 of whom obtained both a virologic and hematologic response). Among 587 pts treated with (immuno)-chemotherapy, 369 received CHOP-like regimen (+ Rituximab in 188), 66 III generation regimen, 105 alkylators, 19 purine analogues, 9 other regimens, 19 rituximab alone. Doses of chemotherapy were reduced in 33% of pts. Among 280 pts with normal ALT at NHL diagnosis, 46 (16%) developed WHO hepatic toxicity ≥ grade 2; among 197 pts (42%) with abnormal ALT, 21 (11%) experienced ALT increase >3.5 times baseline value. Overall, severe liver toxicity developed in 67 pts (14%) (17% of aggressive NHL and 10% of indolent NHL, P=0.05). Use of Rituximab was not associated with severe liver toxicity (P=0.5). In DLBCL, R-CHOP and CHOP showed similar rates of severe hepatic toxicity (19% vs 17%, respectively; P=0.7), although R-CHOP determined higher HCV-RNA load: median increase of HCV-RNA during treatment was 3,356,300 IU/mL in R-CHOP group and 1,566,600 IU/mL in CHOP group (P=0.01). Maximum grade of liver toxicity was registered before 3rd cycle in 61% of pts treated with R-CHOP and in 30% of those treated with CHOP (P=0.008). Steroids were stopped or reduced in 100 pts (in 53 for liver toxicity). 91 pts did not complete planned therapy (22 for liver toxicity). Treatment administration was postponed at least one time in 147 pts (in 33 for liver toxicity). After a median F-UP of 2.7 years, 143 pts died (19 for liver failure). 5-yrs OS was 84% for indolent NHL and 70% for aggressive NHL. 5-yrs PFS was 38% for indolent NHL and 46% for aggressive NHL. In DLBCL, IPI and R-IPI were predictive of OS and PFS (P<0.001 for all). *Conclusions.* A significant percentage of pts with HCV-positive NHL, when treated with conventional (immuno)-chemotherapy, develop severe liver toxicity often leading to reduction of doses or interruption of treatment. In HCV-positive DLBCL, addition of rituximab to CHOP scheme does not increase hepatic toxicity; in this setting IPI and R-IPI retain prognostic value.

0281

CLINICAL FEATURES OF NON HODGKIN'S LYMPHOMAS ASSOCIATED WITH HEPATITIS C VIRUS INFECTION: STUDY OF THE 'REGISTRO LOMBARDO DEI LINFOMI HCV-POSITIVI' (LOMBARDY REGISTRY OF HCV-POSITIVE LYMPHOMAS, ITALY)

L Arcaini,[1] S Rattotti,[1] V Ferretti,[1] C Basilico,[2] A Rossi,[3] L Baldini,[4] A Ferrario,[5] A Tucci,[6] N Frungillo,[7] L Uziel,[8] A Ferreri,[9] D Laszlo,[10] M Merli,[1] A Tedeschi,[2] C Rusconi,[2] S Rizzi,[1] M Lazzarino,[1] E Morra[2]

[1]Division of Hematology, Fond. IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy; [2]Division of Hematology, Ospedale Niguarda Ca'Granda, Milano, Italy; [3]Division of Hematology, Ospedali Riuniti, Bergamo, Italy; [4]Division of Hematology, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy; [5]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy; [6]Division of Hematology, Spedali Civili, Brescia, Italy; [7]Division of Hematology, Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy; [8]Division of Hematology, Ospedale San Paolo, Milano, Italy; [9]Unit of Lymphoid Malignancies, Med. Oncology, San Raffaele H, Scientific Inst., Milano, Italy; [10]Division of Hematology, Istituto Europeo di Oncologia, Milano, Italy

Background. Hepatitis virus C (HCV) infection is a health problem all over the world. In Italy, particularly in the southern region, the infection is endemic. In Lombardia, a region of northern Italy with nearly ten millions of inhabitants, the prevalence of infected people is around 5%. In the last years, increasing evidence showed a role of HCV in the etiology of B-cell lymphomas. *Aims.* in January 2008 we launched the 'Registro Lombardo dei Linfomi HCV-positivi (Lombardy Registry of HCV-positive lymphomas, Italy), a prospective observational study, involving the Hematology Centres of "Rete Ematologica Lombarda"(REL) (Lombardia Hematology Network), with the aim to collect histological, clinical and therapeutic data of HCV-positive lymphomas in Lombardy region. This study was approved by the Regional Administration and by IRBs of participating institutions. All pts provided written informed consent. *Methods.* Since January 2008, we collected data of 140 consecutive patients (pts) with lymphoma and HCV infection diagnosed in the participating centres. *Results.* 51 were males and 89 females; median age at diagnosis was 67 years (range 32-90). Histotypes were as follows: 62 aggressive lymphoma (60 DLBCL), 40 marginal zone lymphomas (MZL) (16 splenic, 11 nodal, 13 extranodal of MALT), 14 follicular lymphoma, 3 lymphoplasmacytic lymphoma, 2 lymphocytic

lymphoma, 1 mantle cell lymphoma, 18 low-grade B-cell lymphoma NOS). Ann Arbor stage was III-IV in 82% of cases; 74 showed extranodal localizations (spleen in 29, skin in 15, salivary glands in 5, ocular adnexa in 5). ECOG score was >2 in 21. Detection of HCV positivity preceded lymphoma diagnosis in 98 pts, of whom 18 had cirrhosis; in the remaining 42 pts, the first detection of HCV-positivity and the diagnosis of lymphoma were concurrent. In 14 pts liver biopsy revealed localization of lymphoma (8 DLBCL, 3 MZL, 3 low-grade B-cell lymphoma NOS). At diagnosis of lymphoma, 110/122 (90%) pts showed a detectable HCV-RNA with prevalence of genotype 1b and 2; 4/130 pts were HbsAg positive, without active replication. AntiHBc antibodies were present in 36/106 (34%). Cryoglobulins were detected in 21 pts and a serum MC was found in 43 pts (29 IgM, 14 IgG). Cryoglobulinemia (P=0.01), serum MC (P=0.003) and autoimmunity (P=0.003) were statistically associated with indolent lymphomas. Fourteen pts with indolent lymphoma were treated with antiviral therapy only and 9 obtained regression of lymphoma. Data on chemotherapy were available for 94 pts (+ rituximab in 57). Nine pts experienced grade 3-4 WHO liver toxicity. 55 pts (67%) achieved CR, 27 (33%) PR. *Conclusions.* this prospective collection of data from a regional network confirms the association of HCV infection with diffuse large B-cell lymphoma and marginal zone lymphomas. Antiviral therapy is able to induce regression of indolent lymphoma in nearly two thirds of treated pts. These data allowed to acquire new understanding on the natural history of HCV-positive lymphomas through the integration of information among hematology centres from homogenous geographical area. It represents an epidemiological and clinical basis for studies aimed to interrupt the pathogenic cascade and to identify best treatment for HCV-driven lymphoproliferation.

0282

A PHASE II TRIAL TO INVESTIGATE THE LINK WITH INFECTIOUS AGENTS IN OCULAR ADNEXAL MARGINAL ZONE LYMPHOMA, ESPECIALLY WITH CHLAMYDIA SPECIES, AND THE ANTINEOPLASTIC EFFECTS OF DOXYCYCLINE (IELSG#27)

S Govi,[1] R Dolcetti,[2] M Ponzoni,[1] E Pasini,[2] C Doglioni,[1] F Bertoni,[3] ME Cabrera,[4] C Stelitano,[5] F Zaja,[6] C Montalban Sanz,[7] F Cavalli,[3] E Zucca,[3] A Ferreri[1]

[1]San Raffaele H Scientific Institute, Milan, Italy; [2]IRCCS National Cancer Institute, Aviano, Italy; [3]Oncologi Institute of Southern Switzerland, Bellinzona, Switzerland; [4]Hospital del Salvador, Santiago, Chile; [5]A.O. Bianchi-Melacrino-Morelli, Reggio Calabria, Italy; [6]A.O.-U. di Udine, Clinica di Ematologia, Udine, Italy; [7]Hospital Ramon y Cajal, Madrid, Spain

Background. Marginal zone B-cell lymphoma of the ocular adnexae (OAMZL) is associated with Chlamydophila psittaci (Cp) infection. The prevalence of infection has always been assessed in retrospective series, and varies around the world from 0% to 75%. Treatment with doxycycline has been associated with lymphoma regression in half of patients; prolonged contact with infected animals may determine continuous reinfection and hinder therapeutic efficacy. *Aims.* To define the prevalence of chlamydial and other infections and the eradicating and antineoplastic effects of doxycycline in OAMZL patients. *Methods.* Patients with newly diagnosed lymphoproliferative disorders of the ocular adnexae of any type were registered in an international multicenter phase II trial: patients with limited-disease (stage IEA) OAMZL and a measurable lesion were registered in the part A of the trial, received doxycycline 100 mg bid daily for 21 days and were assessable for infections prevalence, bacterial eradication and tumor response; all the others entered into the part B, were treated following the best local practice (doxycycline was an option) and were assessable for infections prevalence and eradication. The trial included molecular assessment, with different PCR protocols, of the presence of several bacteria and viruses in lymphomatous tissue, conjunctival swab, and peripheral blood mononuclear cells (PBMC). Eradication and response after doxycycline were assessed by clinical examination, conjunctival swab, PBMC sampling, and MRI of the orbits at 3 and 12 months from treatment. The primary endpoint was response rate and duration after doxycycline; the secondary endpoints were bacterial eradication, identification and geographical distribution of infectious agents, and identification of molecular factors predicting response to doxycycline. *Results.* Since October 2006 to February 2010, 49 patients were enrolled (32 in part A, 17 in part B). Hystotypes were MZL in 43 patients, pseudotumor in three, follicular lymphoma in two, and diffuse large B-cell lymphoma in one. Chlamydial infections were assessed in tumor tissue from 33 OAMZL patients and 4 non-OAMZL: Cp was detected in 27 (82%) and 3 (75%) patients, respectively. All cases were negative for C. pneumoniae and C. trachomatis. Among the 27 Cp-positive OAMZL, the microorganism was detected in 100% (n=27) of conjunctival swabs and in 78% (n=21) of PBMC samples. Swabs and PBMC were negative in Cp-negative lymphomas. Thirty-nine patients received doxycycline; bacterial eradication was assessed in 30 patients with Cp-positive swab (n=6) or Cp-positive swab and PBMC (n=24). After 3 months from antibiotics, eradication was obtained in 9/30 (30%) swabs and in 7/24 (29%) PBMC. Animal exposure (cats, birds and dogs) during treatment was not correlated with Cp eradication since 3 of the 9 eradicated patients and 6 of the 21 patients with persistent infection (Fisher exact test; P=0.99) maintained household animals during and after doxycycline treatment. Tumor response analyses will require a longer follow-up. *Conclusions.* This is the first prospective trial demonstrating that Cp is common in newly diagnosed OAMZL. Cp eradication with doxycycline failed in two thirds of patients, a feature not explained simply by animal exposure. This finding deserves to be better investigated since its potential negative effect on lymphoma regression.

0283

A PROSPECTIVE STUDY OF PREVALENCE, IMMUNOLOGIC RESPONSES AND OUTCOME OF EBV-ASSOCIATED LYMPHOMA IN THAI

U Bunworasate, P Praditsuktavorn, T Assanasen, P Hansasuta, P Lawasut, T Na Nakorn, P Rojnuckarin, T Intragumtornchai

Chulalongkorn University, Bangkok, Thailand

Background. Epstein-Barr virus (EBV) is an oncogenic virus associated with various types of lymphoma. The prevalence of EBV-associated lymphoma varies with geographic location. The role of EBV and immunologic responses to the virus and outcome in Thai patients remain unknown. Therefore, we prospectively study the prevalence, immunologic responses and outcome of EBV-associated lymphoma in Thai patients.

Table.

	1-yr Overall Survival	*P* value
B-cell NHL		
EBV-associated B-cell NHL	50%	0.018
Non-EBV-associated B-cell NHL	85.4%	
T/NK-cell NHL		
EBV-associated T/NK-cell NHL	25%	0.018
Non-EBV-associated T/NK-cell NHL	100%	
HL		
EBV-associated HL	100%	0.221
Non-EBV-associated HL	50%	

Methods. A prospective study of all newly diagnosed lymphoma in immunocompetent patients was done at King Chulalongkorn Memorial Hospital between January and October 2009. Patients who were immunocompromised or HIV-positive were excluded. *in situ* hybridization for EBV-encoded small RNA (EBER) was performed in all paraffin-embedded primary tissues; positive reaction was defined as EBER nuclear signal more than 5% of tumor cells. Blood samples were collected before starting treatment to measure cytokine (IFN-γ, IL-2) production from EBV-activated $CD8^+$ cytotoxic T lymphocytes (CTL) using enzyme-linked immunospot assay. The histopathology, EBER expression, CTL responses and patient outcome were analyzed. *Results.* There were 97 cases included in the study. EBV-associated lymphoma was detected in 5/76 (6.6%) of B-cell non-Hodgkin lymphoma (NHL) [4 diffuse large B-cell lymphoma (DLBCL), 1 Burkitt], 5/15 (33.3%) of T/NK-cell NHL [3 aggressive NK cell leukemia/lymphoma, 2 nasal-type NK/T-cell lymphoma], and 3/6 (50%) of Hodgkin lymphoma (HL) [2 mixed cellularity, 1 nodular sclerosis]. All EBV-associated T/NK-cell NHL and HL were strongly positive for EBER nuclear signal at 80-100% of tumor cells, in contrast to EBV-associated DLBCL, which had variable expression of EBER at 5-100% of tumor cells. All patients with diagnosis of aggressive NK cell leukemia/lymphoma and extranodal NK/T-cell lymphoma were EBER-positive. Among 37 patients with DLBCL, EBER was positive in 4/37 (10.8%) of cases. All EBV-associated DLBCL patients were older than 70 years old and had no CTL responses to EBV. Patients with EBV-associated DLBCL were significantly older than those with EBV-associated T/NK-cell NHL and HL (median age 75 vs. 51 vs. 43, P<0.05). None of the patients with EBV-associated HL had

CTL responses to EBV. Among 4 evaluable patients with EBV-associated T/NK-cell NHL, CTL responses to EBV were detected in 2/4 (50%) of cases. At a median follow-up of 9 months, the outcome of EBV-associated and non-EBV-associated lymphoma was summarized in the Table. *Conclusion.* Using EBER expression of more than 5% of tumor cells, our study revealed similar prevalence of EBV-associated B-cell NHL and HL but lower prevalence of EBV-associated T/NK-cell NHL, when compared to the reports from other Asian countries. Defective CTL responses to EBV might contribute to the development of lymphoma in most patients. The prognostic significance of EBV to the patient outcome needs to be confirmed with more patients and longer follow-up.

0284

CLINICAL CHARACTERISTICS, TREATMENT AND OUTCOME OF LATE POST-TRANSPLANTATION LYMPHOPROLIFERATIVE DISORDER AFTER KIDNEY TRANSPLANTATION: A MONOCENTRIC ANALYSIS OF 29 PATIENTS

F Suarez, D Michonneau, P Hirsch, R Delarue, D Anglicheau, N Brousse, D Canioni, F Martinez, R Snanoudj, C Legendre, O Hermine, MF Mamzer-Bruneel

Hopital Necker-Enfants Malades, Paris, France

Background. Adult post-transplantation lymphoproliferative disorders (PTLD) are rare and severe complications of solid organ transplantation (SOT). Early and late-onset PTLD occur during or after the first year post-SOT respectively. Compared to early-onset PTLD which usually respond to immunosuppression withdrawal, treatment of late-onset PTLD is less defined. *Aims.* To analyze the outcome of late PTLD after kidney transplantation diagnosed after 2000 in our institution. *Methods.* Clinical and histological data for 29 patients followed at our center who developed late PTLD between 1999 and 2009 after kidney transplantation were retrospectively analyzed. *Results.* 29 patients were diagnosed with a PTLD at our institution. The median interval between SOT and PTLD was 134.6 months (range 29 to 338 months). 25/29 patients (86%) had extranodal disease. Digestive tract was involved in 27.5% of patients (8/29), pulmonary localization was found in 13.7% (4/29) and central nervous system was involved in 13.7% of patients (4/29). Bone marrow involvement was found in 24.1% of patients (7/29). 19/29 patients were Ann Arbor stage III/IV (65.5%). 7% of patients had polymorphic PTLD (2/29 patients), 10% had classical Hodgkin lymphoma-type PTLD (3/29) and 83% had monomorphic PTLD (24/29). 100% of polymorphic- and 33% of monomorphic- PTLD were EBV-positive. 50% of the latter were EBV-negative and EBV status was unknown in 16.6%. 80% of monomorphic PTLD were B-cell lymphoma (19/24) and 20% were T-cell lymphomas (5/24). The majority of B-cell lymphomas were diffuse large B-cell lymphoma (89%, 17/19), 1 patient had a Burkitt lymphoma and 1 patient had an extranodal marginal zone lymphoma. All but three patients had a reduction of immune suppression: calcineurin inhibitors and antimetabolite were stopped and corticosteroids were increased. 19/29 patients (65%) received rituximab-based treatment. 4 patients (13.8%) received rituximab only and 15 (51.7%) received rituximab combined to chemotherapy. Among patients treated without rituximab, one had complete remission with decreased immune suppression, one received corticosteroid only and 8 (27%) received chemotherapy. During 28 months median follow-up (range 1 to 120 months), complete remission was obtained in 72% of cases (21/29). 2-years overall survival was 72%, 2-years progression free survival 68%. 1 patient was diagnosed for a myeloid acute leukemia 27 months after lymphoma treatment and rapidly died. Complete remission was obtained in 74% (14/19) of patients who received rituximab during treatment and in 70% of patients (7/10) who did not received rituximab. 2-year overall survival and progression-free survival were respectively 74% and 74% for patients who had rituximab, 60% and 40% for those who did not received rituximab. Kidney function was preserved in 93% cases. 2-years mean creatinine value was 1,86mg/dL (SD=0.83 mg/dL). One patient had to resume dialysis and one patient had second kidney transplantation. *Discussion/Conclusion.* This monocentric, retrospective analysis suggests improved overall survival and progression-free survival for patients who received rituximab for treatment of late PTLD after kidney transplantation. Analysis to determine impact of changes in immune suppression protocols on risk factors and outcomes of PTLD based on the comparison with a previous cohort form our center (Mamzer-Bruneel *et al*. J Clin Oncol 2000) is ongoing.

0285

HEPATITIS B REACTIVATION IN PATIENTS WITH NON HODGKIN LYMPHOMA CD20+ UNDERGOING CHEMOTHERAPY

A De Renzo,[1] M Masarone,[2] M Persico,[2] F Perna,[1] R Cuccurullo,[1] F Alfinito,[3] M Picardi,[1] L Del Vecchio,[1] S Luponio,[1] V Martinelli,[1] F Pane[1]

[1]University FedericoII Naples, Naples, Italy; [2]Hepatology, II University, Naples, Italy; [3]ItHematology Division, Naples, Italy

Background. Reactivation of HBV infection is a well-recognized complication in infected patients who undergo cytotoxic chemotherapy for cancer. The highest incidence of reactivation was reported in patients with non-Hodgkin's lymphoma (NHL) and hematopoietic stem cell transplantation. Several case reports demonstrated that severe hepatitis due to HBV reactivation after rituximab administration occurred both in hepatitis B surface antigen(HBsAg)-positive and HBsAg-negative patients. However, systematic evaluation of the relationship between HBV reactivation and rituximab is still limited. Thus, we conducted a study to investigate the relationship between rituximab-based therapy and HBV reactivation in 230 CD20-positive NHL patients at our institution. *Patients and Methods.* In our Unit, 230 CD20-positive NHL patients all newly diagnosed underwent measurement of HBsAg, anti-HBs,anti-HBc,HBeAg and anti-HBe. Patients were monitored by liver function tests during and after therapy as follows: on day 1and day 14 of each cycle, every month for a year. *Results.* 106/230 patients were HBcAb-positive. 73/106 had an aggressive lymphoma, 36 had an indolent lymphoma. HBV reactivation was observed in one patient (2,3%) who had received chemotherapy including steroid and rituximab and in 3 patients(15,7%) who had received chemotherapy including regimen with only fludarabine without rituximab (Table 1). Immediate administration of lamivudine therapy after elevation of HBV DNA level was conducted, and this resulted in reduction of it and improvement of liver function test. *Conclusions.* Rituximab plus steroid-containing regimens may increase the risk of HBV reactivation in HBsAg-negative and HBcAb-positive lymphoma patients but more attention should be paid on treatment with only fludarabine More ambitious prospective studies are required to establish clinically useful or cost-effective follow-up methods for control of HBV reactivation in lymphoma patients with occult HBV infection.

COMBINATION OF RITUXIMAB WITH CHLORAMBUCIL AS FIRST LINE TREATMENT IN PATIENTS WITH MANTLE CELL LYMPHOMA: A HIGHLY EFFECTIVE REGIMEN

S Sachanas,[1] G Pangalis,[2] T Vassilakopoulos,[2] P Korkolopoulou,[3] F Kontopidou,[2] C Athanasoulia,[2] X Yiakoumis,[1] S Masouridis,[2] C Kalpadakis,[4] M Moschoyiannis,[1] M Siakantaris,[2] P Tsirkidinis,[5] S Kokoris,[2] V Pappis,[2] M Angelopoulou[2]

[1]Athens Medical Center, Athens, Greece; [2]Department of Haematology, University of Athens, Athens, Greece; [3]Department of Pathology, University of Athens, Athens, Greece; [4]Department of Haematology, University of Crete, Heraklion, Greece; [5401] General Army Hospital, Athens, Greece

Background. Optimal treatment approach for mantle cell lymphoma (MCL) patients is not well defined. *Aim.* To present our experience on Rituximab-chlorambucil combination, a totally different therapeutic strategy of low toxicity which has been recently adopted by us, as first line treatment in patients with MCL. *Patients and Methods.* From June 2004 to August 2008 twenty consecutive patients with MCL (14 males and 6 females), except the ones with blastic variant of the disease, received the combination of Rituximab and chlorambucil as first line treatment. Patients' characteristics are shown on Table 1. Initial staging was based on the Ann Arbor system. All patients underwent bone mar-

row aspiration and biopsy as well as lower gastrointestinal tract endoscopy. IgVH analysis and FISH for the detection of t(11;14) translocation was performed at diagnosis and at reevaluation using standard techniques Response was defined using standard criteria. Further on molecular response was defined as the absence of detection of IgVH rearrangement and/or t(11;14) translocation in bone marrow/blood. Treatment schedule included an induction and a maintenance phase. At induction patients received Rituximab at a dose of 375 mg/m^2 at day 1 of each 28 day cycle. Chlorambucil was given at a fixed dose of 10mg/day for 10 consecutive days of each cycle starting the day after Rituximab administration. Patients received 8 cycles of the above combination. Thereafter chlorambucil was administered alone for 4 additional cycles. At maintenance patients in complete or partial remission after the end of induction phase received rituximab at a dose of 375 mg/m^2 every two months for 1 year. Response evaluation was assessed at the end of 8th and 12th chlorambucil cycle and at the end of maintenance phase. *Results.* After the 8th cycle 13 patients presented CR (65%) and 7 PR (35%) while after the end of induction treatment (12th cycle), CR was documented in 18 patients (90%), 1 PR (5%) and one disease progression. Overall response rate was 95%. Of the 13/18 patients in CR with demonstrable IgVH rearrangement in bone marrow at diagnosis, 12 were found to be in molecular remission. The median follow up time of our patients was 22 months (range 14-55). The 2-year progression free survival was 82%. At last follow up 16/18 pts are still in CR. Two pts in CR (11%) experienced disease relapse twenty and fourteen months after the end of induction therapy respectively. Patient in PR had stable disease until last follow up while the one with progressive disease received a fludarabine based regimen and regression of his disease was noted. In 4 younger patients in whom a molecular remission was achieved stem cell collection was performed. Treatment was well tolerated without serious haematological toxicities. *Conclusions.* The combination of Rituximab plus chlorambucil as first line treatment in MCL patients is effective inducing high response rates. Molecular remission is achievable and stem cell collection is feasible. Tolerance of treatment is excellent and all patients enjoy a high quality of life.

THE ROLE OF MANTLE CELL INTERNATIONAL PROGNOSTIC INDEX (MIPI) AS SURVIVAL PREDICTOR IN MANTLE CELL LYMPHOMA (MCL) PATIENTS TREATED WITH RITUXIMAB AND CHEMOTHERAPY

A Chiappella,[1] B Puccini,[2] M Rossi,[3] L Arcaini,[3] E Audisio,[1] I Baldi,[4] G Benevolo,[1] C Boccomini,[1] B Botto,[1] C Ciochetto,[1] F Fabbri,[5] S Ferrero,[6] C Frairia,[1] R Freilone,[1] M Ladetto,[6] D Novero,[7] M Paulli,[8] P Pregno,[1] G Priolo,[1] L Rigacci,[2] U Vitolo[1]

[1]Hematology [2], San Giovanni Battista Hospital and University, Torino, Italy; [2]Hematology, Careggi Hospital, Firenze, Italy; [3]Division of Hematology, IRCCS Policlinico San Matteo, Pavia, Italy; [4]Unit of Cancer Epidemiology, University of Torino and CPO Piemonte, Torino, Italy; [5]Hematology, University, Siena, Italy; [6]Division of Hematology, University, Torino, Italy; [7]Pathology Department, University, Torino, Italy; [8]Department of Pathology, IRCCS Policlinico San Matteo, Pavia, Italy

Background. Clinical course of MCL is unfavourable, with a pattern of continuous relapses. The recent MIPI, a clinical and biological score, defined performance-status, age, LDH and leucocyte counts as predictors of MCL outcome. Ki-67 as cell proliferation index was evaluated in biological-MIPI (MIPI-b). *Aims.* The study was a retrospective study. Primary endpoint was to tested MIPI on a retrospective group of MCL patients treated with Rituximab-chemotherapy; secondary endpoints were: to evaluate the feasibility of MIPI-b on a retrospective population and to quantify the predictive discrimination of IPI, MIPI, MIPI-b on the outcome of MCL in the Rituximab era. *Methods.* Between 1999 and 2009, 136 MCL >18 years at diagnosis consecutively treated in five Italian institutions entered into the study. Histology was centrally reviewed and Ki-67 evaluation was performed. Overall Survival (OS) and failure-free survival (FFS) curves were estimated both overall and stratified by MIPI, MIPI-b and IPI score. Differences between curves were tested using the 2-tailed log-rank test. In order to quantify the predictive discrimination of MIPI, MIPI-b and IPI scores, a Cox's model analysis and univariate logistic models (with death and failure event as binary outcomes) were fitted and the area under the receiver operating characteristic (ROC) curves (c-index) was estimated in a subgroup of 84 patients that fulfilled MIPI, MIPI-b and IPI scores. *Results.* Clinical characteristics were: median age 62 (37-84) years, 78% stage IV, 73% with bone marrow involvement, 15% with blastoid variant; median leucocyte counts at diagnosis was 7.53×10^3 (2.38-175). First-line treatments were: Rituximab with high-dose chemotherapy in 35%, Rituximab-Fludarabine based chemotherapy in 16%, Rituximab-CHOP in 37% and other Rituximab containing regimens in 12%. Ki-67 evaluation was performed in 93 patients. Patients at high-risk (HR) were 43 patients (32%) according to MIPI, 16 (12%) according to MIPI-b and 47 (35%) to IPI. With a median follow-up of 28 months, 2-year OS was 77% (95% CI:68%-84%) and 2-year FFS was 60% (95%CI: 50%-69%). Two-year OS according to MIPI and IPI were shown in Figure 1. In the subgroup of 84 patients that fulfilled MIPI, MIPI-b and IP scores an univariate logistic model and a Cox's model analysis were fitted. The c-index and Cox-index for death event were 73% and 77% for MIPI, 72% and 73% for MIPI-b, 69% and 65% for IPI respectively; the c-index and Cox-index for failure event were 66% and 72% for MIPI, 66% and 69% for MIPI-b, 66% and 64% for IPI respectively. *Conclusions.* MIPI score was confirmed as a good predictor of death event in MCL retrospective patients treated with Rituximab-chemotherapy regimens. MIPI score should predict outcome better than MIPI-b and IPI in a retrospective analysis. MIPI and MIPI-b score superiority on standard IPI should be demonstrated in prospective trials. New therapeutic strategies are warranted to improve the outcome of MCL namely in MIPI-HR group.

Background. Previous *in vivo* and *in vitro* studies have highlighted the activity of Lenalidomide (Len) in patients with relapsed or refractory mantle cell lymphoma (MCL), achieving a 53% overall response rate (ORR), which included 20% complete responses (CR) (Habermann et al. Br J Haematol. 2009) and the possible synergistic anti-proliferative effect of Dexamethasone (Dex). *Aim.* On this basis we initiated a prospective, multicenter, phase II study, to evaluate safety and efficacy of Len Dex combination for adult patients with MCL. *Methods.* Patients had to have ≥1 prior treatment regimen, and were either not eligible for, or had relapsed after, more intensive treatments including stem cell transplantation (SCT). During the induction phase (month 1 to 3), patients received Len 25 mg/day on days 1 to 21 and Dex 40 mg/day on days 1, 8, 15, 22 of a 28-day cycle (Len Dex). Patients who achieved a partial response (PR) or stable disease (SD) at the end of the induction phase continued to the consolidation phase, which consisted of treatment with Len Dex until disease progression, unacceptable toxicity, for a maximum of 12 months. Patients with a CR at the end of the induction phase, or those who achieved a CR during consolidation, received an additional 3 courses of Len Dex. The primary objective was to evaluate the ORR and CRR. *Results.* Between July 2008 and July 2009, 33 patients were enrolled on this study. Patients' median age is 68 years (range 51-80); 30 have the classic histology while 3 patients have the blastoid variant; 9 patients previously received two lines of therapy, 9 patients had three lines and 12 patients had >3 prior lines (median 3; range 1-7). Twelve patients previously underwent an autologous SCT and 7 received prior therapy with Bortezomib. At present, all patients are valuable for response to the induction phase of the study, 13 discontinued therapy prematurely, 8 completed the therapeutic program, 12 are still on therapy. Twenty-one patients responded to Len Dex (64% OR), including 4 CRs (12%); 1 patient (3%) has SD and 11 patients (33%) either had not responded or had progressed while on study. None of the CR patients had subsequent progression; among the 17 patients in PR, during consolidation therapy, 2 had subsequent progression, 2 achieved CR and 13 maintained the PR status. Most common Grade 3-4 adverse events scale of 1 to 5 were hematologic and included neutropenia (42%), thrombocytopenia (15%) and anemia (12%). Other events included 4 patients (12%) with grade 3-4 neutropenic fever and 3 patients (9%) with grade 3 bacterial pneumonia. Grade 3-4 hypotension and dispnea developed in 1 patient each, and none of the patients developed thrombo-embolic or neuropathic complications. *Conclusions.* Initial results from this study confirm the high therapeutic activity of Len in patients with relapsed and refractory MCL with a favourable safety profile; the addition of Dex does not appear to substantially improve the activity of Len in this subset but need further investigation.

Lymphoma - Clinical 2

18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY (FDG PET) RESPONSE PREDICTS SURVIVAL IN PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA

M Abdelsalam,[1] A El Weshi,[2] M Abouzied,[1] H Al Husseini,[1] H Soudy,[1] A Darwish,[1] A Mohamed,[1] A Al-Sugair,[1] Y Khafaga,[1] I Maghfoor Saad Akhtar,[1] S Akhtar[1]

[1]King Faisal Specialist Hospital, Riyadh, Saudi Arabia; [2]Centre Hospitalier Public du Cotentin, Cherbourg-Octeville, France

Background. Primary mediastinal B-cell lymphoma (PMBCL) is a distinct clinicopathological variant of large B-cell lymphoma. The optimal treatment is unknown, with some studies demonstrating favorable outcome compared to other types of diffuse large B-cell lymphoma. Role of 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) in this entity is not well reported. *Aims.* In this retrospective study, we evaluated the primary presentation, clinical characteristics, treatment outcome and impact of FDG PET on PMBCL management at our institution. *Methods.* All patients with PMBCL diagnosed and managed during 1995-2008 at our institution were identified from Oncology Data Unit. Patient's characteristics, prognostic factors, details of treatment and outcome were reviewed. *Results.* Forty-seven patients were identified. Median age was 30 years (range 18-66). There were 26 (55%) females and 21 (45%) males. Forty-two patients (89%) had stage I-II disease. Seventeen patients (36%) had ECOG performance status of >2. Bulky disease in 37 (79%) patients. All patients received CHOP (with Rituximab in nine patients) chemotherapy followed by radiation therapy in 42 (89%) patients. Complete response rate + complete response unconfirmed was 76.6%. Median follow-up was 50.5 months and median overall survival (OS) and event free survival (EFS) were not reached. Univariate analysis showed female gender, early stages and response to treatment as good prognostic factors with higher OS and EFS, while response to planned treatment was the only factor that had impact on OS in multivariate analysis in all 47 patients. Twenty-five patients had FDG PET scan after chemotherapy. On Univariate analysis FDG PET negative patients showed significant improvement in OS and EFS compared to patients who were FDG PET positive; median OS and EFS were not reached in FDG PET negative patients and they were 22.2 and 5.9 months respectively in FDG PET positive patients (P=0.002 & 0.004 respectively). On multivariate analysis, female gender (P=0.046) was the only significant factor among metabolic response (P=0.099), CT response (P=0.518), and age (P=0.231). Regardless of IPI score, patients with metabolic CR on FDG PET had an excellent OS (P=.0005) and EFS (P=0.0056) Figure attached (OS). *Conclusions.* In conclusion, Female gender carries favorable prognosis in PMBCL as reported previously in the literature. More importantly, despite having small number of patients with FDG PET, our data supports that achieving metabolic CR on FDG PET leads to significant prolongation of OS & EFS. Metabolically negative FDG PET is stronger predictor of OS and EFS compared to IPI in PMBCL.

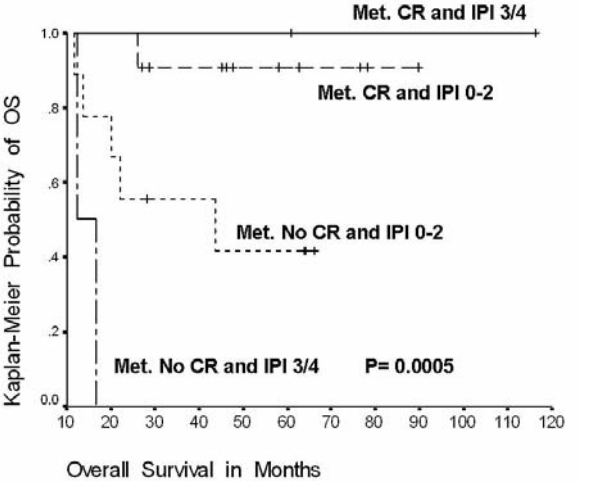

Figure.

0290

PROGNOSTIC FACTORS FOR THE OUTCOME OF PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA (PMLBCL) UNDER CHEMOTHERAPY WITH RITUXIMAB-CHOP (R-CHOP) WITH OR WITHOUT RADIOTHERAP

T Vassilakopoulos,[1] M Angelopoulou,[1] G Pangalis,[2] A Katsigiannis,[3] S Papageorgiou,[1] E Vrakidou,[4] C Poziopoulos,[5] N Constantinou,[6] P Repoussis,[7] M Dimopoulou,[8] S Kokoris,[1] M Dimou,[8] M Kyrtsonis,[1] P Panayiotidis,[1] J Dervenoulas,[1] P Roussou,[1] P Beris[1]

[1]University of Athens, Athens, Greece; [2]Athens Medical Center, Athens, Greece; [33]rd Dept of Internal Medicine,University of Athens, Athens, Greece; [4]Hygeia Hospital, Athens, Greece; [5401] General Army Hospital, Athens, Greece; [6]Theageneion Anticancer Hospital, Thessaloniki, Greece; [7]Metaxa Anticancer Hospital, Pireus, Greece; [8]Department of Haematology, University of Athens, Athens, Greece

Background. Prognostic factors have not been extensively studied in PMLBCL, obviously due to its rarity. Based on data extracted prior to the Rituximab era, the International Prognostic Index (IPI) appears to retain its prognostic significance in several but not all studies. R-CHOP provides very good results in PMLBCL, minimizing failure rates. In historical control comparisons, Rituximab-chemotherapy combinations appear to be much more efficient than the same chemotherapy alone. Thus the applicability of various prognostic factors needs to be reevaluated in the Rituximab era. *Aims.* The identification of prognostic factors for the outcome of patients with PMLBCL treated with RCHOP±Radiotherapy (RT). *Patients and Methods.* 57 patients with PMLBCL aged ≤60 years old were treated in 7 centers in Greece with RCHOP±RT (usually 6-8 cycles). The following potential prognostic factors were evaluated: Gender (female 61%), B-symptoms (39%), stage III/IV (16%), extranodal involvement (32%), performance status (PS) ≥2 (17%), LDH levels (83%), anemia (43%), leukocytosis ≥10×10^9/L (20%), lymphocytopenia <1×10^9/L (33%), ESR ≥30 mm/h (65%), albumin <4 g/dL (36%), bulky disease (≥10 cm; 60%), age-adjusted IPI (aaIPI; ≥2 in 22%). *Results.* The median age of the patients was 30 years (17-59) and the median follow-up of currently alive patients was 40 months. All 11 failures occurred within 17 months from diagnosis: There were 5 early progressions and 1 late progression (relapse), while 5 patients were considered as failures, because they were forwarded to salvage therapy or additional procedures without prior overt progression (usually due to persistent PET findings). The 3-year failure free survival (FFS) was 80±5%. With only 5 deaths recorded, the 3-year overall survival (OS) was 91%. The aaIPI identified a minority of patients (those with aaIPI ≥2; 22% of total) with a 3-year FFS of 49% vs. 90% for those with aaIPI 0-1 (P=0.001). Among its individual components, stage and PS were significant predictors of FFS (P<0.05), while LDH was of borderline significance (P=0.10). Among other potential prognostic gactors examined, only ESR ≥30 (P=0.05), bulky disease (P=0.18) and B-symptoms (P=0.19) were marginally correlated with inferior FFS. Overall survival was not predictable by any of the examined prognostic factors: 3-year OS was 92% vs. 81% for patients with aaIPI 0-1 and ≥2 respectively. *Conclusions.* RCHOP±RT provided very good results in PMLBCL with long-term FFS of 80%. Only the aaIPI was predictive of the outcome, defining a rather small subgroup of patients with a ~50% probability of failure. However, OS was not poor even in this subgroup. The low failure rate and the rarity of the disease make the cooperation between groups necessary in order to accurately define prognostic factors in PMLBCL. Elevated ESR, bulky disease and B-symptoms might add to the prediction achieved by aaIPI, but this should be further evaluated in multivariate analysis.

0291

HIV-POSITIVE PATIENTS DIAGNOSED WITH BURKITT LYMPHOMA DID NOT SHOW DIFFERENCES IN TERMS OF RESPONSE AND OUTCOME AS COMPARED WITH A COHORT OF HIV-NEGATIVE PATIENTS DIAGNOSED AT THE SAME PERIOD OF TIME

A Martínez-Trillos, G Gutiérrez-García, E Gainza, V Valera, L Colomo, J Esteve, M Rozman, M Martínez, E Campo, N Villamor, A López-Guillermo

Hospital Clínic, Barcelona, Spain

Background. Burkitt lymphoma (BL) is a highly aggressive non Hodgkin lymphoma often presenting in extranodal sites that accounts for 1-2% of all adult lymphomas in Western countries. HIV-positive patients more frequently develop BL. *Aim.* To analyze the clinical features and outcome of HIV-positive patients with BL and to compare them with the cohort of HIV-negative patients diagnosed with BL in the same period of time. *Methods.* Between 1994 and 2009, 47 patients (21 HIV-positive; 26 HIV-negative) were diagnosed with BL in a single institution, according to the WHO classification criteria. All HIV-positive patients received HAART therapy. Main clinical and evolutive variables were analyzed, including IPI. The treatment included intensive regimens in 23 cases. Rituximab was added after 2002. *Results.* Initial characteristics according the HIV-status are detailed in the Table. The median CD4 in HIV this population at the time of diagnose was 285 cells/µL (33-540). CR rate, early death rate, progression-free survival (PFS) and overall survival (OS) according to the HIV-status are listed in the table. As it can be observed, no differences were found between the two groups. Patients receiving intensive regimens showed higher OS than those with no intensive therapies (5-year OS 81 vs. 52%, respectively; P=0.009). No differences in the outcome of the patients were observed according to the rituximab treatment in either HIV-positive or HIV-negative patients. 18 patients have died after a median follow-up of 4.4 years. Causes of death included progression (4 cases), tumour lysis (1), CMV encephalitis (1) and prostate neoplasm (1) in HIV-positive patients, and progression (5), sepsis (4), liver cirrhosis (1), and complications of allogeneic transplantation (1) in HIV-negative patients. *Conclusions.* In the current series of patients diagnosed with BL the HIV-status was not relevant to predict the outcome of the patients.

Table.

Number of Patients	*HIV positive* N=21	*HIV negative* N=26
Age (median)	39 (17-59)	38 (17-9)
Gender (Male/female)	17 / 4	18 / 8
Performance status ECOG>2	48%	50%
B symptoms	61%	58%
High serum LDH (%)	76%	73%
Advance Stage (IV)	90%	62%
Extranodal involvement ≥2 sites	48%	23%
IPI Low risk Intermediate risk High risk	 19% 52% 29%	 35% 39% 27%
Treatment Rituximab regimens High Intensive regimens	 58% 52%	 30% 46%
CR rate All cases Intensive treatment	 15 (71%) 11 (92%)	 17 (64%) 9 (90%)
Early death (<4 months)	4 (19%)	5 (19%)
5-year PFS	66%	52%
5-year OS	71%	60%

0292

PHASE 1/2A STUDY OF NAVITOCLAX (ABT-263) IN RELAPSED OR REFRACTORY LYMPHOID MALIGNANCIES

H Wilson,[1] A O'Connor,[2] S Czuczman,[3] S LaCasce,[4] F Gerecitano,[5] P Leonard,[6] A Tulpule,[7] H Xiong,[8] YL Chiu,[8] T Busman,[8] H Enschede,[8] P Krivoshik,[8] H Humerickhouse[8]

[1]NCI, Bethesda, USA; [2]New York University Cancer Institute, New York, USA; [3]Roswell Park Cancer Inst., Buffalo, USA; [4]Dana Farber Cancer Institute, Boston, USA; [5]Memorial Sloan-Kettering Cancer Center, NY, USA; [6]Weill Cornell Medical College, NY, USA; [7]USC / Kenneth Norris Cancer Hospital Cancer Hospital And Research Institute, Los Angeles, USA; [8]Abbott Laboratories, Abbott Park, USA

Background. Bcl-2 family members are associated with tumor initiation and drug resistance, and are compelling therapeutic targets. Navitoclax is a novel, orally bioavailable, small molecule BH3 mimetic that binds (Ki ≤1 nM) to Bcl-2, Bcl-xL, and Bcl-w with high affinity. Navitoclax displays potent preclinical cytotoxicity (EC50 ≤1 µM) against human tumor cell lines (small cell lung carcinomas and T and B lymphoid malignancies) that express Bcl-2. Preclinical toxicities are mechanism-based, with Bcl-2, Bcl-xL and Bcl-w mediating effects on lymphocytes, platelet survival and spermatogenesis, respectively. *Aims.* The aims of this study were to assess safety/pharmacokinetics and maximum tolerated dose of ABT-263. *Methods.* Phase 1/2a single-agent international study employing a modified Fibonacci 3+3 of navitoclax in relapsed/refractory lymphoid malignancies. Subjects were dosed on

Days (d) 1-14 of a 21-d dosing cycle with 10-440 mg navitoclax, or continuous 21/21-d administration (21-d cycle) with 200-425 mg navitoclax following a 150 mg lead-in dose. Tumor responses were evaluated using the IWG criteria and NCI-WG criteria (for CLL and SLL subjects). *Results.* To date, 55 subjects (38 on a 14/21-d and 17 on a 21/21-d dosing schedule) have received navitoclax. The median subjects age was 59 y (range, 20-81). Informed consent was obtained. The PK profile of navitoclax on the 14/21-d schedule was linear and dose proportional from 10-440 mg with a terminal t½ of approximately 17 h. Platelet nadirs were transient on the 14/21-d schedule and occurred on d 3-5. Data indicates a 1-week low dose lead-in at 150 mg navitoclax followed by a 21/21-d dosing schedule minimizes platelet reduction and cycle variability. Four subjects on the 14/21-d schedule had dose-limiting toxicities (DLT); 1 at 160 mg (bronchitis), 2 at 315 mg (elevated ALT and Grade 4 Thrombocytopenia) and 1 at 440 mg (atrial fibrillation). Three subjects on the 21/21-d schedule had DLTs; 1 at 275 mg (Grade 4 thrombocytopenia) and 2 at 425 mg (Grade 3 ALT and Grade 3 GI bleed). The median progression-free survival was 88 d [95% CI: 46-171]. Of the 55 subjects enrolled, tumor regression >50% was observed in 9 subjects: 1 NK-T cell lymphoma had a 75% reduction, 1 follicular lymphoma had an unconfirmed partial response (PR) and 7 CLL/SLL had >50% reduction in lymphadenopathy; 4 additional CLL had >50% decrease in circulating lymphocytes. Of 51 subjects who discontinued therapy, 40 did so due to progressive disease, 6 due to AEs, and 5 withdrew consent. *Conclusions.* Navitoclax is well tolerated with a linear PK, with toxicity due to on-target effects and antitumor activity in subjects with relapsed or refractory lymphoid malignancies. Thrombocytopenia was predictable and manageable. One week 150 mg/d lead-in followed by continuous dosing minimizes platelet nadir and cycle variability. Based on the 21/21d continuous dosing data, the modified Fibonacci 3+3 model projection for MTD converged. To mitigate platelet nadirs and stabilize cycle variability, the phase 2 recommended dosing regimen for navitoclax is 150 mg 7-d lead-in followed by 325 mg/d continuous dosing.

0293

EFFICACY AND SAFETY OF RITUXIMAB, DEXAMETHASONE, CYTARABINE AND OXALIPLATIN (R-DHAX) IN ELDERLY PATIENTS WITH RELAPSED/REFRACTORY B CELL NON HODGKIN'S LYMPHOMA

J Lignon,[1] D Sibon,[1] I Madelaine,[1] P Brice,[1] P Franchi-Rezgui,[1] J Briere,[1] N Mounier,[2] C Gisselbrecht,[1] P Faure,[1] C Thieblemont[1]

[1]Hopital Saint Louis, Paris, France; [2]Hopital L'Archet, Nice, France

Background. Salvage therapy for elderly patients with refractory/relapsed B cell non-Hodgkin's lymphoma (NHL) is based on polychemotherapy. Several salvage regimens are based on platinum, such as R-DHAP (rituximab, dexamethasone, cytarabine and cisplatin). This regimen is usually efficient in elderly patients but produce severe myelosuppression, peripheral neuropathy, and frequent renal toxicities that often require discontinuation of the treatment. Oxaliplatin is a third generation platinum drug without renal toxicity in contrast to cisplatin. *Aim.* To assess efficacy and safety of substituting cisplatin with oxaliplatin in R-DHAP regimen. *Methods.* We retrospectively analyzed a series of 48 elderly patients with refractory/relapsed B cell NHL treated with R-DHAX regimen (rituximab 375 mg/m^2 day 1, dexamethasone 40 mg days 1-4, oxaliplatin 100 mg/m^2 day 1, cytarabine 2000 mg/m^2/every 12 hours day 2, every 21 days). Analysis was done in patients 60 to 70 years (n=30) and older than 70 years (n=18). *Results.* The most frequent histological subtypes were diffuse large B cell lymphoma (n=27) and follicular lymphoma (n=8). Eleven patients (23%) were rituximab-naive at time of R-DHAX. Performance status was good (0-1) for 40 patients (83%). Twenty four patients (50%) had an elevated LDH level. Before R-DHAX, renal function was normal in 33 patients (69%). After Cockroft calculation renal insufficiency (RI) was moderate in 14 patients (29%) and severe in 1 patient (2%). For 21 patients (44%) R-DHAX was the second line of treatment. The median number of cycles received was 3 (range 1-7). Seven patients underwent subsequently autologous stem cell transplantation. Full dose-therapy was delivered in 50% of the patients aged between 60-70 and in 28% of the patients aged 70 and above. Doses were diminished at baseline in 13 patients and during the treatment in 9 patients. Toxicities of R-DHAX are summarized in Table 1. Grade III/IV toxicities were mainly hematological, including anemia (n=7, 15%), neutropenia (n=20, 42%), and thrombocytopenia (n=24, 50%). Grade III/IV neurological peripheral toxicities were observed in 3 cases (motor neuropathy n= 3, sensitive neuropathy n=1). Those 3 patients had prior exposure to vincristin, all of them had complete recovery at discontinuation of R-DHAX. Neither renal toxicities nor degradation of previous RI were observed. Dose adjustments were made at baseline for 16 patients (previous cisplatin exposure or prevention of toxicity) and during treatment for 12 patients (hematotoxicity n=5, neurotoxicity n=6, poor performance status n=1). The overall response rate was 73% (CR + CRu n=17) for patients younger than 70 years and 72% (CR + CRu n=10) for the patients older than 70 years. The median follow-up for living patients was 27.5 months months. The two-year probability rates of OS (overall survival) and of PFS (progression free survival) were 66% and 36% respectively. Summary/*Conclusions.* R-DHAX is an efficient salvage therapy in the context of relapsed/refractory B cell lymphoma in elderly patients, and its lack of renal toxicity makes it an attractive regimen that may be used in a large group of patients. Hematotoxicity was acceptable and did not result in unexpected complications when proper dosages were administered.

Table.

	60-70 years n= 30	> 70 years n= 18
	%	%
Anemia (Hb <8 g/dL)		
- Grade III/IV	10	22

BENDAMUSTINE-R2ITUXIMAB COMBINATION TREATMENT IN RELAPSED NHL: COMBINED EXPERIENCE FROM TWO PHASE 2 TRIALS AND EXPLORATION OF RESPONSE PREDICTORS

D Kennedy,[1] M Mwamburi,[2] G Ranganathan,[2] D Mayo,[3] L Tremmel,[3] T Zaks,[3] M Rummel[4]

[1]Cephalon Inc., Frazer, USA; [2]United BioSource Corporation, Lexington, MA, USA; [3]Cephalon, Inc., Frazer, PA, USA; [4]University Hospital, Giessen, Germany

Background. Bendamustine plus rituximab (BR) is highly effective in previously treated patients with non-Hodgkin's lymphoma (NHL). Previous studies that individually evaluated the impact of BR used small sample sizes (Rummel *et al*, 2005; Robinson *et al*, 2008) without characterizing factors that influence outcomes. *Aims.* The aims of this study were to estimate the response rate and progression-free survival (PFS) based on updated data from both samples combined and to explore the predictors associated with complete response (CR) and PFS. *Methods.* Overall, 129 patients (median age, 62 years [range, 40-84], 61% male) were included in the combined analysis. Histologies included follicular (49%), mantle cell (22%), lymphoplasmacytoid (15%), small lymphocytic (8%), and marginal zone lymphoma (6%). Baseline characteristics were similar in the two studies, except that more patients in the Rummel study had stage III/IV disease and a WHO performance status ≥2. Patients were treated with bendamustine 90 mg/m^2 (30-minute intravenous infusion) on days 1 and 2 plus rituximab 375 mg/m^2 on day 1 for 4 to 6 cycles. All patients also received a single dose of rituximab 1 week before the first cycle and 4 weeks after the last cycle. We explored factors associated with (a) CR, using logistic regression modeling and (b) PFS, using Cox proportional hazard modeling. Age, gender, histological type, bone marrow involvement, spleen involvement, number of prior treatment regimens, and hematologic toxicities were reported in

a similar format across both studies. *Results.* The overall response rate (ORR) of partial response (PR) or better for BR was 91% (95% confidence interval [CI], 86%-97%), including 57% CR and 34% PR. Median follow-up time was 31.4 months, and median PFS for the combined population was 29 months (95% CI, 25-41). In the logistic regression analysis, male gender and stage IV disease were significantly associated with an inferior CR. Bone marrow involvement and spleen involvement were not significantly associated with CR. None of the predefined factors were significantly associated with PFS. Toxicity was mostly hematologic; no grade 3 or 4 toxicity was reported in the Rummel et al study population, as compared to 36% of the patients in the Robinson et al study. *Conclusions.* Pooling the data from 2 studies allowed the estimation of response rate and PFS with greater precision and facilitated the evaluation of predictors of progression in this setting. BR is a highly active regimen in previously treated NHL, demonstrating an ORR >90%. However, men and patients with stage IV disease were less likely to achieve CR. The lack of association between patient and disease characteristics and PFS during BR treatment suggests that BR is effective in inducing a response and slowing progression without strong dependence on age, histology, number of prior treatment regimens, and baseline bone marrow or spleen involvement.

0295

ANALYSIS OF A PHASE 2 STUDY OF LENALIDOMIDE AND RITUXIMAB IN RELAPSED OR REFRACTORY NON-HODGKIN'S LYMPHOMA

M Dutia,[1] I DeRoock,[2] K Chee,[3] R O'Donnell,[2] C Quirch,[2] C Reed-Pease,[2] J Tuscano[2]

[1]UC Davis Cancer Center, Sacramento, USA; [2]Hematology - Oncology, UC Davis Medical Center, Sacramento, CA, USA; [3]California Cancer Care, San Mateo, CA, USA

Background. Despite an increase in our understanding of the pathophysiology of indolent non-Hodgkin's lymphoma (NHL) and the recent advances in early-line treatment options, the optimal treatment for patients with relapsed/refractory disease has not been determined. Rituximab has demonstrated clinical benefit in combination with chemotherapy for indolent NHL, and rituximab-based chemotherapy combinations are used both in first-line and salvage therapy. The immunomodulatory agent lenalidomide has demonstrated clinical activity in the treatment of B-cell hematological malignancies. In a recently published study, lenalidomide monotherapy resulted in a >16.5-month response duration in 43 patients with relapsed/refractory indolent NHL (Witzig *et al*. JCO 2009). In lymphoma cells and in animal models, the combination of lenalidomide and rituximab (R2) has shown improved clinical activity relative to treatment with either agent alone. *Aims.* To determine the clinical benefit and safety profile of R2 combination therapy in patients with relapsed/refractory indolent NHL (off-label). *Methods.* Patients with relapsed/refractory indolent NHL with measurable disease, ≥1 prior therapy, and ECOG performance status score ≤2 provided informed consent and were enrolled. Oral lenalidomide 25 mg/day was given on days 1-21 of a 28-day cycle, and was continued until disease progression. After 2 of 4 patients developed grade 3 tumor lysis syndrome (TLS), the protocol was amended to reduce the starting dose to 20 mg/day, and prophylaxis with allopurinol was initiated. Rituximab 375 mg/m^2 IV was administered on day 15 of cycle 1, and repeated weekly for a total of 4 doses. The overall response rate (ORR) was the primary endpoint, and secondary endpoints included response duration, overall survival, progression-free survival (PFS), and safety. *Results.* 16 patients were enrolled on study and are evaluable for response assessment. The median age was 60 years (50-91), and patients had received a median of 3 prior therapies (1-11). Ten patients received ≥3 prior therapies, and were classified as heavily pretreated. The histological subtypes included 13 patients with follicular lymphoma (FL), 1 patient with small lymphocytic leukemia, and 2 with marginal zone lymphoma. Most (14/16) patients received prior rituximab, 7 patients had rituximab-refractory disease (defined as no response or response of ≤6 months after last rituximab), and 5 patients had received prior radioimmunotherapy. Responses were achieved in 14 patients (75%), 7/10 (70%) heavily pretreated patients, and 4/7 patients (57%) with rituximab-refractory disease. Notably, 85% of patients with FL responded to therapy including 38.4% of patients with a complete response (CR). Median PFS for all patients was 12 months; however, median PFS for patients who received >5 cycles has not been reached. Fatigue (13%), neutropenia (19%), lymphopenia (25%), and hyponatremia (19%) were the most common grade 3 or 4 adverse events. After prophylaxis was initiated, TLS was not observed at the 20 mg dose level. *Conclusions.* These results demonstrate that the R2 combination has significant clinical activity in patients with relapsed/refractory indolent NHL. With an ORR of 85%, patients with FL particularly benefitted from therapy. These promising results have prompted further exploration of R2 combination therapy in larger studies and in earlier lines of therapy.

0296

PLERIXAFOR AND G-CSF FOR PBSC MOBILIZATION IN POOR MOBILIZER PATIENTS WITH LYMPHOMA TREATED WITH MULTIPLE LINES OF THERAPY

L Arcaini,[1] D Laszlo,[2] S Rizzi,[1] M Balzarotti,[3] E Morello,[4] S Miqueleiz Alamos,[5] E Brusamolino,[1] L Farina,[6] M Bonfichi,[1] F Antoniazzi,[4] P Corradini,[6] G Rossi,[4] G Martinelli,[2] E Morra,[5] M Lazzarino,[1] E Todisco[7]

[1]Division of Hematology, Fond. IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy; [2]Division of Hematology, Istituto Europeo di Oncologia, Milano, Italy; [3]Division of Hematology, Istituto Humanitas, Rozzano (Milano), Italy; [4]Division of Hematology, Spedali Civili, Brescia, Italy; [5]Division of Hematology, Ospedale Niguarda Ca'Granda, Milano, Italy; [6]Division of Hematology, Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy; [7]Istituto Clinico Humanitas, Milano, Italy

Background. Peripheral blood stem cell (PBSC) mobilization is an important step in the subset of patients (pts) with non-Hodgkin's Lymphoma and Hodgkin's disease who need autologous stem cell transplantation (ASCT). However, a significant percentage of pts are unable to mobilize adequate number of PBSC after conventional stem cell mobilization programs and can not proceed to ASCT. Plerixafor (AMD3100; Mozobil), a bicyclam antagonist of the SDF-1alpha/CXCR4 complex, has been previously reported to augment PBSC collection in pts undergoing PBSC mobilization. *Aim.* To asses the efficacy of plerixafor and G-CSF in achieving the minimum required dose of CD34$^+$ cells for ASCT (2×10^6 CD34$^+$ cells/Kg) in pts with lymphoma who previously failed previous attempts of PBSC mobilization with conventional schemes of chemotherapy + G-CSF. *Methods.* 24 heavily pre-treated or treatment-refractory lymphoma pts classified as "poor mobilizers"were enrolled in a program of compassionate use of plerixafor between 2008 and 2009 in 6 italian centres of REL (Rete Ematologica Lombarda, Lombardy Hematology Network). Pts were defined as poor mobilizers when the concentration of PB CD34$^+$ cells was consistently lower than 10/μL during the recovery phase after chemotherapy and/or when the number of PBSC collected was inadequate for ASCT. *Results.* 10 pts were males and 14 were females. 21 were affected with non-Hodgkin's lymphomas (10 diffuse large B cell lymphoma, 5 follicular lymphoma, 3 mantle cell lymphoma, 1 lymphoplasmocytic lymphoma, 1 peripheral T-cell lymphoma, 1 anaplastic large cell lymphoma) and 3 with Hodgkin's disease. Median age at plerixafor treatment was 50 years (range 27-70). Median number of previous lines of therapy was 3 (range 1-5). Median number of previous attempts of mobilizations with chemotherapy + G-CSF was 2 (range 1-3) (1 attempt in 8, 2 attempts in 12, 3 attempts in 4); 3 pts had received radiotherapy, 4 radioimmunoconjugated antibodies and 3 purine analogues. Median level of CD34$^+$ cells/μL attained with 45 prior mobilization attempts with chemotherapy plus G-CSF was 5/μL. Pts received G-CSF (10 μg/kg/day) for 4 days, followed by daily plerixafor (0.24 mg/kg) plus G-CSF and apheresis for up to 4 days. Overall, plerixafor administration was safe and no serious adverse events were registered. Common plerixafor-related adverse events was ere mild nausea in 10 pts. The median number of circulating CD34$^+$ cells/μL following plerixafor was 8.5×10^6/μL (range 1.7-52 ×10^6/μL). It was more than 10×10^6/μL in 10 pts and more than 20 ×10^6/μL in 7 pts. Ten pts (42%) were able to collect the minimum required dose for ASCT (2×10^6 CD34$^+$ cells/Kg) with a median of 1 apheresis procedure (range 1-4) and 2/10 pts collected more than 4×10^6 CD34$^+$ cells/Kg. *Conclusions.* these results show that plerixafor combined with G-CSF allows collection of adequate number of PBSC in a significant proportion of poor mobilizer, heavily pre-treated pts with non-Hodgkin's lymphoma or Hodgkin's disease, who need consolidation with ASCT.

0297

A MULTICENTER TRIAL ASSESSING FEASIBILITY AND EFFICACY OF A COMBINATION OF HIGH-DOSE METHOTREXATE, CYTARABINE AND THIOTEPA IN PATIENTS WITH PRIMARY CNS LYMPHOMA: IMPACT ON OUTCOME OF CYTARABINE DOSE

G Licata,[1] M Foppoli,[1] G Corazzelli,[2] E Zucca,[3] C Stelitano,[4] F Zaja,[5] S Fava,[6] R Paolini,[7] A Franzin,[8] L Politi,[9] M Ponzoni,[10] F Caligaris-Cappio,[1] M Reni,[11] A Ferreri[11]

[1]Unit of Internal Medicine, San Raffaele H Scientific Institute, Milano, Italy; [2]Division of Hematology, Istituto Pascale, Napoli, Italy; [3]Lymphoma Unit, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland; [4]Division of Hematology, Azienda Ospedaliera di Reggio Calabria, Reggio Calabria, Italy; [5]Clinic of Haematology, University of Udine, Udine, Italy; [6]Oncology Unit, Azienda Ospedaliera di Legnano, Legnano, Italy; [7]Onco-hematology Unit, Department of Oncology, Azienda Ospedaliera di Rovigo, Rovigo, Italy; [8]Neurosurgery Unit, San Raffaele H Scientific Institute, Milano, Italy; [9]Neuroradiology Unit, San Raffaele H Scientific Institute, Milano, Italy; [10]Pathology Unit, San Raffaele H Scientific Institute, Milano, Italy; [11]Medical Oncology Unit, San Raffaele H Scientific Institute, Milano, Italy

Background. The combination of high-dose methotrexate (HD-MTX) and high-dose cytarabine (HD-araC) (experimental arm of the IELSG #20 trial) has been associated with a significantly better outcome with respect to HD-MTX alone in patients aged ≤75 years with newly diagnosed primary central nervous system lymphoma (PCNSL) [Ferreri AJM, et al. Lancet 2009; 374: 1512-20]. The addition of alkylating agents could improve MTX-araC efficacy since they are active against quiescent G0 cells and they increase cytotoxicity of antimetabolites. Thus, we conducted an exploratory trial addressing a combination (MAT regimen) of HD-MTX, HD-araC and thiotepa, an alkylating agent with excellent CNS bioavailability, in patients with PCNSL. With respect to the experimental arm of the IELSG #20 trial, araC dose was reduced from 2 g/mq to 1 g/mq to minimize the risk of toxicity. *Aims.* To assess tolerability, activity and efficacy of MAT regimen and to compare these results to those observed in the MTX/araC arm of the IELSG #20 trial. *Methods.* HIV-negative patients with newly diagnosed PCNSL, selected by using the same eligibility criteria of the IELSG #20 trial (age 18-75, ECOG-PS≤3, measurable disease), and diagnosed in five Italian and one Swiss centers during 2008 were considered. Patients received 4 courses (interval 3 weeks) of MTX 3.5 g/mq d1 + araC 1 g/mq x 2/d, d2-3 + thiotepa 30 mg/mq d4, followed by whole-brain radiotherapy (WBRT). *Results.* Twenty patients (median age 57 ys; range 42-74) were treated with MAT regimen. No significant differences in patient characteristics between the two groups were observed (Table).

Table.

	MAT (n=20)	MTX+araC (n= 39)	P (Fisher exact)
Median Age (range)	57 ys. (42-74)	59 ys (25-74)	0.98
IELSG risk			
Low	7 (35%)	10 (26%)	0.95
Intermediate	8 (40%)	24 (62%)	
High	5 (25%)	5 (13%)	
Positive CSF cytology	3 (15%)	3/34 (9%)	0.65
Ocular involvement	0 (0%)	4/35 (11%)	0.28
Toxic deaths	1 (5%)	3 (8%)	1.00
Complete remission	4 (20%)	18 (46%)	0.04
Overall response	7 (35%)	27 (69%)	0.01
Stable/Progressive disease	12 (60%)	9 (23%)	-
2-year PFS	20 ± 9%	42 ± 8%	0.03
2-yr OS	22 ± 9%	56 ± 8%	0.01

The comparison between MAT and MTX/araC regimens did not show any significant difference in terms of actually delivered courses (69% vs. 76%), chemotherapy interruptions (65% vs. 44%), dose reductions (60% vs. 44%), G4 neutropenia (85% vs. 74%), G4 thrombocytopenia (85% vs. 64%), infections (45% vs. 30%), G4 non-hematological toxicities (15% vs. 8%), and toxic deaths (5% vs. 8%). Conversely, response rates after MAT chemotherapy (CRR: 20% and ORR: 35%) were significantly lower than those reported with MTX/araC combination (Table). The seven patients who responded to MAT received consolidation WBRT, with early progressive disease (PD) in three cases and systemic dissemination in one; only four of the 12 patients with PD after MAT received WBRT, with no benefit in three of them. At a median follow-up of 20 months, 17 (85%) MAT patients experienced failure (PD, relapse, death), with a 2-yr PFS of 20±9% (Table). These results are significantly worse than those reported with MTX/araC (median f-up: 30 months). Relapse/progression involved the brain in 15 (75%) patients, meninges in one (5%) and abdominal lymphnodes in one (5%). Five patients treated with MAT and 18 treated with MTX/araC are alive, with a 2-yr OS of 22±9% and 56±8%, respectively. *Conclusions.* When compared to MTX/araC standard combination, araC dose reduction did not improve feasibility and was associated with lower efficacy, hiding a potential benefit of the addition of thiotepa in MAT regimen. Four doses of araC 2 g/mq are recommended in the upfront treatment of PCNSL.

0298

SHOULD CEREBROSPINAL FLUID ANALYSIS BE RECOMMENDED ONLY FOR HIGH RISK PATIENT WITH CENTRAL NERVOUS SYSTEM RELAPSE AS AN ESSENTIAL WORKUP IN DIFFUSE LARGE B-CELL LYMPHOMA ?

YH Choi,[1] I Na,[2] HR Lee,[2] SH Yang,[2] JK Lee,[3] SS Lee,[4] HJ Kang[2]

[1]Korea Cancer Center Hospital, Seoul, South-Korea; [2]Department of Internal Medicine, Korea Cancer Center Hospital, Seoul, South-Korea; [3]Department of Laboratory Medicine, Korea Cancer Center Hospital, Seoul, South-Korea; [4]Department of Pathology, Korea Cancer Center Hospital, Seoul, South-Korea

Background. In newly diagnosed diffuse large B-cell lymphoma (DLBCL), cerebrospinal fluid (CSF) analysis is currently recommended in patients with risk factors for central nervous system (CNS) relapse, including involvement of paranasal sinus, testis, epidural space, bone marrow or 2 or more extranodal sites. However, there is no satisfactory predicting CNS involvement at initial diagnosis. *Patients and Methods.* We analyzed CSF in 100 patients with newly diagnosed DLBCL from January 2006 to May 2009 at our institution. CSF tests were not directed based on clinical risk factors. *Results.* Among 100 patients (45 female, 55 male), 25 patients (25%) showed leptomeningeal involvement. The involvement was not associated with disease sites (nasal/paranasal sinus, testis, orbit, bone marrow) or the number of extranodal sites. International Prognostic Index score of 3 or greater was not significantly associated with leptomeningeal involvement (P=0.096). We observed no significant difference in the frequency of CNS involvement in patients with or without any of following: CNS-near sites, 2 or more extranodal sites, bone marrow or testis, advanced stage or elevated serum lactate dehydrogenase (18 of 76 (27.7%) vs 7 of 24 (29.2%), P=0.597). *Conclusions.* Our study showed that the leptomeningeal involvement at the initial diagnosis was not significantly associated with risk factors for CNS relapse. Therefore, all the patients with newly diagnosed DLBCL should be considered for CSF analysis as an essential workup in addition to criteria based on the high risks for CNS relapse. Further studies are required to confirme these findings.

0299

PHASE II STUDY OF SMILE CHEMOTHERAPY FOR NEWLY-DIAGNOSED STAGE IV, RELAPSED OR REFRACTORY EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE: NKTSG STUDY

YL Kwong,[1] M Yamaguchi,[2] Y Maeda,[3] C Hashimoto,[4] WS Kim,[5] CW Suh,[6] E Sueoka,[7] F Ishida,[8] K Izutsu,[9] R Hyo,[10] S Nakamura,[10] J Suzumiya,[11] K Oshimi,[12] R Suzuki[10]

[1]University of Hong Kong, Hong Kong, China; [2]Mie University, Tsu, Japan; [3]Okayama University, Okayama, Japan; [4]Kanagawa Cancer Center, Yokohama, Japan; [5]Samsung Medical Center, Seoul, South-Korea; [6]Asan Medical Center, Seoul, South-Korea; [7]Saga University, Saga, Japan; [8]Shinshu University, Matsumoto, Japan; [9]Kanto Medical Center NTT EC, Tokyo, Japan; [10]Nagoya University, Nagoya, Japan; [11]Shimane University, Izumo, Japan; [12]Eisai Research Institute of Boston, Andover, USA

Background. Extranodal NK/T-cell lymphoma, nasal type (ENKL) is a rare subtype of lymphoma and its standard therapy has not been established. CHOP (-like) chemotherapy has limited efficacy in ENKL, with an overall response rate (ORR) of 36% for newly-diagnosed stage IV diseases and less than 10% for relapsed or refractory diseases. Our previous phase I trial of a new chemotherapeutic regimen, SMILE [Steroid=dexamethasone 40 mg/day d2-4 IV, Methotrexate 2 g/m^2 d1

6hr IV, Ifosfamide 1.5 g/m^2 d2-4 IV, L-asparaginase 6000 U/m^2 d8,10,12,14,16,18,20 IV, and Etoposide 100 mg/m^2 d2-4 IV; every 28 days] showed promising results (Cancer Sci, 2008). *Aims.* To explore a more effective treatment for ENKL, we conducted a phase II study of SMILE chemotherapy. *Methods.* Patients with newly-diagnosed stage IV, relapsed or refractory disease after first-line chemotherapy, between 15-69 years old and with a PS of 0-2 were eligible. Primary endpoint was ORR after 2 cycles of SMILE chemotherapy, and target enrollment was 38 patients. To ameliorate myelotoxicity and based on the results of phase I study, G-CSF was started from day 6. *Results.* From July 2007 to October 2009, 39 patients were enrolled. Pt characteristics were age: 16-67 years (median 47); male:female=21:18; newly-diagnosed stage IV disease in 21; first relapse in 13; and primary refractory disease in 5. Since the first 2 patients died of grade 5 infection, we made a protocol revision stipulating awareness for infection and including lymphocyte count 500/cmm or more into the eligibility criteria. After that, no treatment-related death was observed. Twenty-nine patients (74%) completed the planned treatment. The responses were complete remission (CR) in 15, partial remission in 14, no response in 3, progressive disease in 3, and early death in 4. ORR and%CR were 74% (95% CI, 58-87) and 38%, respectively. Grade 4 neutropenia was common. Grade 4 non-hematologic toxicities were infection (n=5), hyperbilirubinemia (n=1), ALT elevation (n=2), and encephalopathy (n=1). The most common grade 3 non-hematologic toxicity was infection (41%). *Conclusions.* Our results indicate that SMILE chemotherapy is an effective treatment for newly-diagnosed stage IV, relapsed or refractory ENKL. Myelosuppression and infection during the treatment should carefully be managed.

0300

PRALATREXATE EFFICACY AND TOLERABILITY IN PATIENTS WITH RELAPSED OR REFRACTORY CUTANEOUS T-CELL LYMPHOMA (CTCL)

M Horwitz,[1] M Duvic,[2] Y Kim,[3] J Zain,[1] M Lechowiz,[4] T Koutsoukos,[5] S Fruchtman,[5] O O'Connor[6]

[1]Memorial Sloan-Kettering Cancer Center, New York, USA; [2]University of Texas MD Anderson Cancer Center, Houston, Texas, USA; [3]Stanford Cancer Center, Stanford, California, USA; [4]Emory University, Atlanta, GA, USA; [5]Allos Therapeutics, Inc, Westminster, Colorado, USA; [6]New York University Cancer Institute, NYU Langone Medical Center, New York, NY, USA

Background. Pralatrexate is a targeted antifolate designed for preferential uptake and accumulation in tumor cells, due to high affinity for reduced folate carrier and efficient polyglutamation by folypolyglutamyl synthetase. Pralatrexate was recently approved by the Food and Drug Administration for relapsed or refractory peripheral T-cell lymphoma and is currently under evaluation in other tumor types, including CTCL. PDX-010 is a dose-finding single-arm, open-label, multicenter study evaluating pralatrexate in relapsed/refractory CTCL. A dose de-escalating strategy was used to determine if an active and very low toxicity dose/schedule was achievable in this patient population. *Methods.* Eligibility included mycosis fungoides, Sézary syndrome, and primary cutaneous anaplastic large cell lymphoma, with disease progression after at least 1 prior systemic therapy and written informed consent prior to treatment. The starting dose and schedule was 30 mg/m^2 of pralatrexate by IV push weekly for 3 of 4 weeks. If toxicity as defined per protocol was observed, subsequent cohorts received reduced weekly doses (20, 15, 10 mg/m^2) and/or schedules (3/4 or 2/3 weeks). All patients received supplementation with vitamin B12 1 mg intramuscularly every 8-10 weeks and folic acid 1 mg orally QD. Response was evaluated by the modified severity weighted adjustment tool (SWAT) every 2 cycles for 6 months and then every 4 cycles. For patients with lymph node involvement, scans were completed at baseline and upon clinical response or end of treatment, whichever occurred first. *Results.* Thirty-one patients were sequentially enrolled in 6 cohorts and treated at varying doses/schedules. The optimal dose and schedule was identified as 15 mg/m^2 x 3/4 weeks, based on the tolerability and efficacy observed in the initial 6 patients (overall response rate [ORR] of 50%). The response rate (RR) for patients treated at a dose of 15 mg/m^2 x 3/4 weeks or higher was 11/18 (61%). The RR for those treated at lower dose cohorts was 1/13 (8%). The 15 mg/m^2 x 3/4 weeks cohort was expanded and 23 additional patients were treated at the optimal dose (N=29), of which 22 are currently evaluable for response. In the 47 evaluable patients across all cohorts to date, the median number of prior systemic therapies is 4 (range 1-11). Patients received pralatrexate for a median of 3 cycles (range 1-34). The ORR for all cohorts was 40% (19/47), 17 partial responses and 2 complete responses. The responding patients received a median of 4 cycles of treatment. Among evaluable patients receiving the optimal 15-mg/m^2 dose on the 3/4 week schedule, the RR was 45% (10/22). Seven patients in this cohort are on treatment and not yet evaluable. In the expanded cohort, most patients had grade 2 (6/22, 27%) or lower toxicities, with only 2 patients experiencing grade 3 mucositis, and no grade 4 toxicities were observed. Updated efficacy and safety data will be presented. *Conclusions.* Pralatrexate shows impressive activity with minimal toxicity in patients with relapsed/refractory CTCL at the identified optimal dose of 15 mg/m^2 x 3/4 week. Further follow-up is ongoing to assess final efficacy and tolerability.

0301

CLINICOPATHOLOGIC FEATURES OF AGGRESSIVE NK CELL LEUKEMIA (ANKL) - A JAPAN-KOREA MULTI-CENTER STUDY FOR ANKL -

F Ishida,[1] YH Ko,[2] WS Kim,[2] J Suzumiya,[3] Y Isobe,[4] K Oshimi,[4] S Nakamura,[5] R Suzuki[5]

[1]Shinshu University School of Medicine, Matsumoto, Japan; [2]Samsung Medical Center, Seoul, South-Korea; [3]Shimane University Hospital, Izumo, Japan; [4]Juntendo University School of Medicine, Tokyo, Japan; [5]Nagoya University School of Medicine, Nagoya, Japan

Backgrounds. Aggressive NK cell leukemia (ANKL) is a malignant disease of mature NK cells that is more common in East Asia and is often associated with EB virus. Because of its rarity, the characteristics of this disease are still largely uncertain. *Aims.* To better elucidate clinicopathologic characteristics of ANKL. *Methods.* A retrospective Japan-Korea multi-center survey of ANKL (ANKL07), was performed. Eligibility criteria are based on the diagnosis for ANKL according to the WHO classification. *Results.* 41 cases were registered from eight institutions. After central reviews, 34 cases were further analyzed, while seven cases were excluded. The main reason of exclusion was a possibility of T cell nature. Median age of the cases was 45 years old (range 16-79) with 26 males and 8 females. Four cases had a history of preceding disorders including EBV-LPD of childhood, mosquito bite hypersensitivity or EBV-associated liver damage. Of note, three female cases presented during pregnancy. Hepatosplenomegaly was recognized in 71% of the cases. Lymphadenopathy and cavity effusions were occasionally seen. Based on the central review, three types on ANKL were morphologically categorized. Type I was defined as LGL closely resembling normal LGL with slightly basophilic cytoplasm. Type III was associated with pleomorphic appearance together with basophilic cytoplasm and bizarre nucleus containing one or more nucleoli. Type II showed the intermediate morphology between type I and III. Cases having mixture of cells with type I and type III were also categorized as type II. Using this classification, there were 11, 13 and 10 cases for type I, II and III, respectively. However, no difference in clinical features except hemophagocytosis was found among the 3 types. Immunophenotypes were similar, typically, CD2$^+$, surfaceCD3$^-$, CD4$^-$, CD5$^-$, CD8$^-$, CD16+, CD56$^+$, and CD57$^-$. EBV was positive in 85% of the patients. Median survival was 51 days (range; 1-1,630). No difference of the survival was recognized among the type I, II and III. Median ratio of tumor cells in peripheral blood (PB) and bone marrow (BM) was 8% and 22%, respectively. 11 cases showed leukemic cells less than 20% both in PB and BM. The clinical characteristics and prognosis of these cases did not differ from patients with more tumor cells in PB/BM. This suggests that main infiltration sites of tumor cells are liver, spleen and BM irrespective of leukemic nature. *Summary*. These results clarify ANKL as a mature NK cell proliferative disease with heterogenous morphologies associated with EBV. ANKL shows markedly poor prognosis, regardless the PB/BM tumor burden.

0302

A NATION-WIDE SURVEY OF HTLV-1-ASSOCIATED ADULT T-CELL LEUKEMIA/LYMPHOMA IN JAPAN

Y Yamada,[1] M Soda,[2] M Iwanaga,[1] Y Koga,[1] H Hasegawa,[1] S Kamihira,[1] K Yamaguchi[3]

[1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; [2]Radiation Effects Research Foundation, Nagasaki, Japan; [3]National Institute of Infectious Diseases, Tokyo, Japan

Background. Adult T-cell leukemia/lymphoma (ATLL) is caused by the first discovered human oncogenic retrovirus, human T-cell leukemia virus type-1 (HTLV-1). The prevalence of HTLV-1 varies in different area of the world, and HTLV-1 carriers are clustered in the southwest-

ern districts of Japan, as well as among native Andeans, North Iranians, Central Africans, and African descendants in the Caribbean and South America. Clinical and laboratory features of ATLL are similar in different countries, whereas there is a significant difference in age of patients between countries. *Aims.* To show current incidence, mortality, and clinical features of patients with ATLL in Japan, and to compare the results with the results obtain from previous studies performed nationwide in Japan and report from other countries. *Methods.* A nation-wide survey of ATLL and B-cell non-Hodgkin lymphoma (B-NHL) as an internal control was performed in 2009. Questionnaires for registration were distributed to physicians in 479 hospitals having the department of hematology.*Results.* A total of 910 cases of ATLL and 7,164 cases of B-NHL, newly diagnosed from January 2006 to December 2007 (2 years), were registered from 156 hospitals. Male-female ratios were 1.16 for ATLL and 1.22 for B-NHL. Among all ATLL cases registered, 59.8% were from Kyushu, a HTLV-1 endemic area of Japan, and the ratio of ATLL to B-NHL in this area was 1 to 4, while that in Tokyo was 1 to 50. According to the classification criteria for the subtypes of ATLL, 46.7% was classified as acute type, 34.8% as lymphoma type, 10.3% as smoldering type, and 8.2% as chronic type, which results were different from those obtained from previous studies, and the ratio of acute type was decreased with an increase of lymphoma type. The more significant difference was found in age of patients. The mean age gradually increased from 58.3 years in the 5th nation-wide survey (1988-1989) to 60.3 years in the 8th nation-wide survey (1994-1995) and finally to 65.2 years in the present study (range from 19 to 94, median 67). The mean age of Japanese patients is now more than 20 years older than that reported from Jamaica and Brazil (43 years). Patients younger than 55 years, an upper age limit for allogeneic hematopoietic stem cell transplantation, are now only 19.2% of the total patients. Increase of the mean age is explained by a high HTLV-1 prevalence (>10%) in elderly people over 60 years in Japan and by a continuing development of ATLL from this large pool of HTLV-1 carriers. According to the mortality statistics from the Ministry of Health, Labor and Welfare Japan, approximately 1,000 people died annually from ATLL, which did not change in the past decade. The estimated annual incidence of ATLL calculated from the number of B-NHL as an internal control was 1,150 cases.SUMMARY: A nation-wide survey showed a change of ATLL subtypes and an increase of the age of patients, which require a change of therapeutic strategy. The incidence of ATLL in Japan was estimated to be 1,150 cases per year.

DIFFERENT PROGNOSTIC SCORES IN PERIPHERAL T-CELL LYMPHOMA (PTCL)

G Gutierrez-Garcia, A García-Herrera, A Martínez, A Martínez, E Gainza, T Cardesa, N Villamor, L Colomo, X Setoain, S Rodríguez, E Giné, E Campo, A Urbano, A López-Guillermo

Hospital Clínic, Servicio de Hematología, Barcelona, Spain

Background. PTCLs comprise a heterogeneous group of lymphoid neoplasms with poor prognosis. In contrast to aggressive B-cell lymphomas, PTCLs have not a specific clinical, immunophenotypic, genetic or gene expression signature of prognostic significance. A number of prognostic scores have been used in PTCLs, The International Prognostic Index [IPI], the Prognostic International Index [PIT], the PIT model modified by Went *et al.* [mPIT] and The International PTCL Project score [IPTCLP]. All of them have been shown to predict the outcome of the patients with PTCL. However, a systematic comparative study of all these models in a homogeneous series of patients have never been addressed before. *Aims.* to study the main clinico-biological features and outcome of patients with PTCLs from a single institution and to compare the predicitive value of different prognostic scores (IPI, PIT, mPIT IPTCLP). *Methods.* One hundred twenty one non-immunocompromised patients (73M/47F; median age, 55 years) diagnosed with PTCL according to the WHO classification, in a single institution between March 1990 and October 2008. The distribution according to the histologies was: PTCL "not other-wise specified"(PTCL-NOS) 56 (47%), anaplastic large cell lymphoma ALK$^+$ (ALCL) 21 (17%), angioimmunoblastic T-cell lymphoma (AITL) 19 (16%), NKTCL 15 (12%), hepatosplenic T-cell lymphoma (HSTL) 7 (6%) and subcutaneous panniculitis-like T-cell lymphoma (SPTCL) 3 (2%). Patients with ALK$^+$ALCL were analyzed separately because of its particular behavior. The median follow-up was 3.9 years (range, 2.8 to 5) for surviving patients, and the overall characteristics for the patients included performances status (PS) >1, 40%; stage III-IV, 81%; bone marrow (BM) infiltration 39%; any extranodal involvement, 76%; high serum LDH, 56%; platelet count <150×10^9/L, 28% and 56 (72%) patients of 78 with available data had high β2-microglobulin levels. Ninety one (91%) patients received adriamycin-containing chemotherapy, including 21 (21%) patients whom received high dose of chemotherapy and a stem cell transplantation as part of the first line therapy. The variables used to calculate the different scores were the previously established: IPI [age, performance status (PS), LDH, Ann Arbor stage and extranodal involvement], PIT [age, PS, LDH and bone marrow involvement], IPTCLP [age, PS and platelet count] and mPIT [age, PS, LDH and Ki-67 index]. The main clinico-biological and evolutive variables were analyzed. *Results.* The distribution of the patients according to the risk group, complete response rate and overall survival (OS) are detailed in Table 1.

Table 1. Complete response and overall survival according in the different scores.

Prognostic scores	*N (%)*	*CR rate (%)*	*5 year OS (%)*
Whole group	100	36	25
IPI			
Low risk	25 (25)	36	45
Low intermediate risk	23 (23)	33	28
High intermediate risk	30 (30)	17	21
High risk	22 (22)	14	0
PIT			
Low risk	16 (16)	25	75
Low intermediate risk	26 (26)	31	26
High intermediate risk	35 (35)	33	17
High risk	23 (23)	11	0
IPTCLP			
Low risk	29 (29)	31	58
Low intermediate risk	44 (44)	52	15
High intermediate risk	20 (20)	14	5
High risk	7 (7)	3	0
mPIT*			
Low risk	24 (58)	57	38
Intermediate risk	8 (20)	7	0
High risk	9 (22)	36	0

Regarding response, IPI (low vs. intermediate/high) was the best score to predict CR achievement (RR=2.45; P=0.05). IPTCLP (low vs. intermediate/high) was the best model to predict OS in a a Cox mutivariate analysis comparing the four models [IPI, PIT, IPTCLP and mPIT]

(RR=3.52 ; P<0.0001). These results were similar when only the subset of PTCL-NOS was selected. *Conclusions.* All the scores demonstrated its useful to predict the outcome of patients with PTCL, but IPTCLP demonstrated to be the most significance score to predict OS.

RETROSPECTIVE ANALYSIS FOR RISK FACTORS FOR PATIENTS WITH PERIPHERAL T-CELL LYMPHOMA IN HOKKAIDO, JAPAN

A Shigematsu,[1] N Kobayashi,[2] K Minauchi,[3] H Kobayashi,[4] A Mori,[5] N Masauzi,[6] S Umehara,[7] T Fukuhara,[8] M Kurosawa,[9] M Haseyama,[10] S Hashino,[11] M Nishio,[11] J Tanaka,[11] M Kasai,[2] M Imamura[11]

[1]Hokkaido University, Sapporo, Japan; [2]Sapporo Hokuyuu Hospital, Sapporo, Japan; [3]Sapporo City General Hospital, Sapporo, Japan; [4]Obihiro Kousei Hospital, Obihiro, Japan; [5]Aiiku Hospital, Sapporo, Japan; [6]Hakodate Municipal Hospital, Hakodate, Japan; [7]Sapporo Kousei Hospital, Sapporo, Japan; [8]Asahikawa City Hospital, Asahikawa, Japan; [9]Hokkaido Cancer Center, Sapporo, Japan; [10]Tonan Hospital, Sappro, Japan; [11]Hokkaido University Hospital, Sapporo, Japan

Background. Peripheral T-cell lymphomas (PTCLs) are heterogeneous disease with a dismal prognosis. To evaluate the incidence, treatment and prognosis of PTCLs, Hokkaido Clinical Hematology Forum conducted a multicenter retrospective survey in Hokkaido, Japan. *Patients and Methods.* Clinical data for patients with PTCLs were collected from 13 hospitals in Hokkaido, Japan, and data for patients who met the following criteria were analyzed: diagnosed between 2002 and 2008, aged more than 15 years and diagnosed as having mature T-cell neoplasms defined by the new WHO classification 3rd edition. Totally, data for 272 patients were collected and the diagnoses were adult T-cell leukemia/lymphoma (ATL, 33%), PTCL-unspecified (PTCL-u, 25%), NK-cell neoplasms (13%), angioimmunoblastic T-cell lymphoma (AITL, 13%), anaplastic large cell lymphoma (ALCL, 7%) and other subtypes (10%). After excluding patients with ATL and NK-cell tumors due to the different strategy of treatment, data for 142 patients with other subtypes of PTCLs were analyzed for characteristics and prognosis. *Results.* The median age of the patients was 67.5 years. Many patients had the following risk factors: stage III-IV (88%), high LDH (63%), B symptoms (41%) and IPI high/high-Int risk (56%). Eighty-nine percent of the patients received chemotherapy as a primary treatment and most of the patients received a CHOP-like regimen; however, 37% of them received a reduced dose due to advanced age and approximately half of the patients could not complete the treatment plan, mainly due to disease progression and complications. Overall response rate was 67.4% and CR rate was only 41.4%. In multivariate analysis, bone marrow involvement (odds ratio: 4.7) and the number of treatment cycle (<5, odds ratio: 11.1) were determined as risk factors for induction failure. In patients who achieved CR, 45.1% of the patients relapsed. Patients with ALCL who achieved CR did not relapse and patients with IPI low/low-int risk were at low risk for relapse (33% vs. high/high-int risk, 65%, P=0.03). Hematopoietic stem cell transplantation (SCT) was performed in 22 patients [autologous (auto) SCT: n=14, reduced-intensity allogeneic (allo) SCT: n=8]. Median age was younger in the allo group (49 years vs. 57 years) and other characteristics were also different in the auto group and allo group: patients with PTCL-u usually received auto-SCT, while patients with CTCL received allo-SCT, allo group had higher risk of IPI and greater chemresistance. Only one patient died after SCT. Survival of patients who received SCT was better than that of patients who did not receive SCT (P<0.01). After median follow-up of 2.8 years, 2-year overall survival rate (OS) and 2-year progression-free survival rate were 55% and 32%, respectively. Ninety-six percent of the patients died with lymphoma. B symptoms at diagnosis (HR 2.2), induction failure after primary treatment (HR: 2.9) and SCT not being performed (HR: 4.7) were revealed to be risk factors for OS by multivariate analysis. *Conclusions.* The prognosis of PTCLs is poor. Therefore, more effective regimen as a primary treatment than a CHOP-like regimen is needed, and SCT should be considered as an upfront setting for patients who are at high risk for relapse.

0305

PRALATREXATE ACTIVITY IN PATIENTS WITH RELAPSED/REFRACTORY PERIPHERAL T-CELL LYMPHOMA (PTCL): RELATIONSHIP BETWEEN RESPONSE AT CYCLE 1 AND SUBSEQUENT SURVIVAL

B Coiffier,[1] PL Zinzani,[2] C Gisselbrecht,[3] A Shustov,[4] B Pro,[5] S Horwitz,[6] E Jacobsen,[7] T Koutsoukos,[8] S Fruchtman,[8] O O'Connor[9]

[1]Centre Hospitalier Lyon-Sud, Pierre Benite, France; [2]University of Bologna, Bologna, Italy; [3]Hôpital Saint-Louis, Paris, France; [4]Seattle Cancer Care Alliance, Seattle, USA; [5]University of Texas MD Anderson Cancer Center, Houston, USA; [6]Memorial Sloan-Kettering Cancer Center, New York, USA; [7]Harvard Medical School, Boston, USA; [8]Allos Therapeutics, Inc, Westminster, USA; [9]New York University Cancer Institute, NYU Langone Medical Center, New York, USA

Background. Pralatrexate is a targeted antifolate designed for preferential uptake and accumulation in tumor cells, due to high affinity for the reduced folate carrier-1 protein and efficient polyglutamation by folypolyglutamyl synthetase. Pralatrexate was approved by the US Food and Drug Administration for the treatment of patients with relapsed/refractory PTCL based on the results of the pivotal PROPEL trial. The primary end point, objective response rate (ORR) using International Workshop Criteria, was evaluated by both independent central review (ICR) as well as by the investigator. The aim of the present analysis was to determine if responses observed early in the course of treatment are prognostic for survival. *Methods.* The relationship between tumor response and survival was tested using a landmark analysis, where patients alive and evaluated for response at the landmark time point were categorized as either having responded or not responded. The landmark time point was study day 53, which coincides approximately with the end of cycle 1. Survival was subsequently measured to the landmark and compared between categories via the Cox model. *Results.* The ORR (best response) was 29% (32/109) per ICR and 39% (43/109) per investigator assessment. By the landmark time point, there were 90 patients with an assessment per ICR, and 95 with an assessment per investigator. Of these, there were 20 responders per ICR and 33 responders per investigator. Responders and nonresponders were matched on demographics (gender, race, age, weight) and disease characteristics (mean time since diagnosis, histopathology per central review, baseline cutaneous involvement, ECOG performance status, number of prior regimens, number of prior systemic regimens). Overall survival was 14.5 months. Results of the landmark analysis are presented in Table 1. *Conclusions.* Patients treated with pralatrexate who experienced tumor response during cycle 1 had a 31% (per central review) and 54% (per investigator) reduction in risk of death. As assessed by the investigators, early responses to pralatrexate are strongly correlated with prolonged survival (P=.01) as seen from the landmark analysis.

Table 1.

	Per ICR (N = 90)		Per Investigators (N = 95)	
	Responders	Nonresponders	Responders	Nonresponders
N	20	70	33	62
Median Subsequent Survival	17.6 mos	13.4 mos	21.3 mos	8.6 mos
Hazard Ratio (95% CI)*	0.69 (0.33, 1.43)		0.46 (0.25, 0.84)	
P	.32		.01	

*Hazard ratio for risk of death subsequent to landmark responder:nonresponder.

NOVEL MECHANISM OF TRANSPLACENTAL CANCER TRANSMISSION: NATURAL-KILLER/T CELL LYMPHOMA IN THE PARATESTICULAR REGION OF AN INFANT OF MATERNAL ORIGIN

H Yagasaki,[1] E Nishikawa,[1] M Ito,[2] H Ohashi,[3] M Kato,[1] H Shichino,[1] C Chin,[1] H Mugishima[1]

[1]Nihon University, Tokyo, Japan; [2]Japanese Red Cross Nagoya First Hospital, Nagoya, Japan; [3]National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Introduction. The placental syncytiotrophoblast layer is a barrier that protects the fetus from infection and cancer metastasis. Even if mother-derived cells enter the fetus, they are usually rejected and cannot be engrafted unless the infant is immunocompromised. Materno-fetal transmission of leukemia/lymphoma is therefore extremely rare. Based on the following case findings, we propose a novel mechanism for the vertical transmission of cancer.Case report A male infant born at 30 weeks gestation weighing 1659 g maintained good health until 7 months of age. At age 8 months, his scrotum appeared enlarged and was referred to Nihon University Hospital. MRI examination revealed a testicular tumor and the infant underwent left orchiectomy. Immunohistochemical analysis of paraffin-embedded sections showed that tumor cells expressed LCA, TdT, CD3, and CD56, but not CD10, CD20, CD79a, CD34, CD68, or ALK. *in situ* hybridization analysis further revealed that the tumor cells were positive for Epstein-Barr-virus-encoded small RNA (EBER). The diagnosis was EBV-associated natural-killer (NK)/T cell lymphoma, which is a very rare histology in children. Multi-agent chemotherapy was initiated and after completing 4 courses he received cord blood transplantation. The infant's mother was a 32-year-old Japanese woman whose pregnancy was unremarkable until the 7th month of gestation. Two weeks before delivery, she was transported to Nihon University Hospital because of petechia and fever. Laboratory findings showed thrombocytopenia (68000/μL) and liver dysfunction (GOT 513 U/mL, T. Bil 6.72 mg/d, LDH 5681 U/mL). HELLP syndrome was diagnosed and emergency cesarean section was performed; however, her condition deteriorated after delivery. A bone marrow smear showed hypoplasia with large granular lymphocytes expressing cytoplasmic CD3 and CD56. Although she was treated with high-dose steroids, etoposide and cyclosporine, hepatic failure and disseminated intravascular coagulation developed and she died on postpartum day 25. Since a high EBV genome load (2.8×10^6 copies/μg DNA of peripheral $CD8^+$ lymphocytes) was detected, she was diagnosed with EBV-related NK/T cell leukemia, which is prevalent in East Asia and often fatal. Due to the similarities in disease phenotype between the mother and the infant, identification of the origin of the infant's lymphoma was attempted using two independent *Methods.* fluorescence *in situ* hybridization and microsatellite analysis. Procedures were carried out according to the Declaration of Helsinki and with the informed consent of the family. As a result, the infant's tumor cells were found to be identical to the leukemic cells of the mother.Discussion Recently, it was demonstrated that maternal leukemic cells are not rejected by an infant when they have lost non-inherited maternal HLA antigens [Isoda T, et al. PNAS; 106: 17882-5]. In our case, maternal leukemic cells most likely transmigrated into the paratesticular area where they engrafted and proliferated because the testis is a sanctuary site protected from the immuno-surveillance system. We propose that this is a novel mechanism for the vertical metastasis of cancer.

0307

LONG-TERM OUTCOME OF PATIENTS WITH PERIPHERAL T-CELL LYMPHOMA TREATED WITH FIRST-LINE INTENSIVE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION

V Prochazka,[1] T Papajik,[1] E Faber,[1] L Raida,[1] Z Rusinakova,[1] Z Kubova,[1] Z Sedova,[1] L Kucerova,[2] M Myslivecek,[3] K Indrak[1]

[1]University Hospital, Olomouc, Czech Republic; [2]Dept.of Pathology, University Hospital, Olomouc, Czech Republic; [3]PET/CT Imaging Centre, Dept. of Nuclear Medicine, Univeristy Hospital, Olomouc, Czech Republic

Background. Peripheral T-cell lymphomas (PTL) are infrequent subtypes of non-Hodgkin's lymphomas. The clinical course is aggressive, and despite anthracycline-based multiagent chemotherapy, the median survival is about 2-3 years. An optimal first-line chemotherapy protocol is not established and the role of high-dose therapy with autologous stem cell transplantation (SCT) is still unclear. *Aim.* To analyze the long-term outcome of unselected PTL patients treated with intensive first-line sequential chemotherapy with high-dose therapy and autologous transplant consolidation. *Method*. The sequential chemotherapy (SQ) protocol consists of 3 cycles of CHOEP-21-like regimen (PACEBO), 1 cycle of an ifosfamide and methotrexate-based regimen (IVAM) and a priming regimen with high-dose cytosine arabinoside (HAM). Consolidation is provided with myeloablative conditioning (BEAM 200) and autologous SCT. Here we report our experience with 29 patients with PTL. The histological subtypes were as follows: peripheral T-cell lymphoma, not otherwise specified (PTCL, NOS) n=13; anaplastic large cell lymphoma (ALCL) ALK-negative n=5; ALCL ALK-positive n=3; ALCL with an unknown ALK status n=3; angioimmunoblastic lymphoma n=1; hepatosplenic lymphoma n=1; Sézary syndrome n=1; and enteropathy-associated T-cell lymphoma (EATL) n=2. The median age at diagnosis was 48 years (29-64), most patients had advanced Ann Arbor stages (22 patients, 77%), IPI score ≥3 was found in 13 (45%) and PIT score ≥2 in 17 (59%) of the 29 patients. Twenty-six patients underwent first-line therapy according to the SQ protocol, two patients received the ProMACE-CytaBOM regimen and one patient was treated according to the modified SQ protocol. Eighteen patients received first-line high-dose therapy and autologous SCT consolidation; two patients were consolidated with allogeneic SCT in the 1st complete remission and one patient in the 1st relapse. Treatment responses were assessed according to the International Workshop Criteria (Cheson, 1999). Twelve patients with FDG-avid lymphoma were examined with integrated PET/CT at the time of diagnosis and after first-line therapy. *Results.* Nineteen (66%) patients achieved CR, 3 (10%) partial remission and 7 (24%) patients failed the procedure. The overall response rate was 76%. PET negativity (complete metabolic response) after therapy was achieved in 8/12 (75%) individuals. After a median follow-up of 55.1 months, 14 (48.3%) patients relapsed or progressed (8 PTCL NOS; 2 ALCL ALK-positive; 2 ALCL ALK-negative; 1 Sézary syndrome; 1 EATL; median time 16.1 months) and nine patients died (lymphoma progression). Eleven patients (50% of chemosensitive patients) survived more than 50 months. Three of the long-term survivors were treated with allogeneic SCT. The 2-year progression-free survival (PFS) was 52% (95%CI, 0.33-0.71); the 2-year overall survival (OS) rate reached 65% (95%CI, 0.47-0.84). PET negativity was associated with a lower probability of relapse (chi-square P=0.09). *Conclusions.* Our data show that intensive first-line therapy with etoposide-based regimens and autologous transplant consolidation may lead to long-term disease control in about a half of patients with chemosensitive PTL. Patients with partial treatment response may be treated with allogeneic stem cell transplantation. Achieving of PET negativity is probably an essential prerequisite for long-term CR.

Supported by the grants of the Czech Ministry of Education (MSM 6198959205) and Czech Ministry of Health (IGA NR/9502-3).

Myelodysplastic syndromes 1

0308

DIAGNOSTIC USE OF MULTIPARAMETER FLOW CYTOMETRY IN PATIENTS WITH SUSPECTED MYELODYSPLASTIC SYNDROME: EVALUATION OF 1013 CASES AND CORRELATION TO CYTOMORPHOLOGY, CYTOGENETIC, AND CLINICAL DATA

W Kern, C Haferlach, S Schnittger, T Haferlach

MLL Munich Leukemia Laboratory, Munich, Germany

Background. Diagnosis and classification of myelodysplastic syndromes (MDS) is based on cytomorpholgy (CM) and cytogenetics (CG). Multiparameter flow cytometry (MFC) may add important information. *Aims.* To evaluate the diagnostic role of MFC in MDS. *Methods.* We analyzed 1013 cases with suspected MDS by CM, CG, and MFC in parallel. *Results.* Cases were classified by CM as RA (n=31), RARS (n=27), RCMD (n=64), RCMD-RS (n=49), RAEB-1 (n=133), RAEB-2 (n=81), 5q- syndrome (n=24), CMML (n=65), MDS unspecified (MDS-u, n=15), MDS borderline to AML (MDS/AML, n=6), MDS/myeloproliferative neplasia overlap (MDS/MPN, n=16), suspected MDS (n=225), reactive condition (n=266), and normal findings (n=11). CG findings were normal karyotype (n=768), isolated deletion of long arm of chromosome 5 (del(5q), n=43), isolated aberrations of chromosome 7 (n=14), isolated trisomy 8 (n=30), isolated deletion of long arm of chromosome 20 (del(20q), n=21), complex aberrations (n=23), loss of Y-chromosome (n=43), other aberrations (n=71). Concordance between CM and MFC was 82.0% for diagnostic results in 788 cases with unequivocal CM. 277 of these 788 cases were classified by CM as no MDS, 13 (4.7%) of which showed MDS-typical features by MFC. Additional 225 cases showed only minor dysplastic features by CM, 51 (22.7%) of which showed clear evidence of MDS by MFC. We then focused on cytogenetically aberrant cases without unequivocal MDS by CM. In 6/12 (50.0%) cases with no MDS by CM and MDS-typical cytogenetic aberrations MFC revealed MDS characteristics. In another 11/23 (47.8%) cases with minor dysplastic features by CM and MDS-typical cytogenetic aberrations MFC revealed MDS characteristics. Furthermore, we compared blasts counts as determined by CM and MFC and found a strong correlation (P<0.001) although the mean±SD percentage was higher as determined by CM as compared to MFC (4.67±4.18 vs. 3.78±2.97). Frequencies of aberrantly expressed antigens significantly differed between cases rated by CM as MDS (median number of aberrantly expressed antigens: 3), suspected MDS (1), and no MDS (0, P<0.001). In various cases MFC identified MDS-typical aberrant antigen expression in cell compartments not rated dysplastic by CM. Particularly, aberrant antigen expression did not strongly correlate to dysgranulopoiesis by CM. Thus, in 406 cases without dysgranulopoiesis by CM dysplastic features were observed with the following frequencies: aberrant CD13/CD16 expression pattern: 104 (25.6%); aberrant CD11b/CD16 expression pattern: 62 (15.3%); CD56 expression: 38 (9.4%); CD33 negativity: 44 (10.8%); CD64 negativity: 2 (0.5%). An aberrant expression of ≥2 antigens in granulocytes was found in 16/31 (51.6%) and 15/27 (55.6%) of cases with RA and RARS, respectively. Ovedrall, spearman rank correlation confirmed a highly significant relation between the number of aberrantly expressed antigens and IPSS (r=0.409, P<0.001). In 257 cases with data on overall survival (OS) the presence of MDS-related findings (≥3 aberrantly expressed antigens, a blast count >5% in MFC, or a reduced side-scatter signal) resulted in significantly inferior 6-year-OS (68% vs. 100% P=0.008). *Conclusions.* The present analysis clearly demonstrates a diagnostic yield of MFC in addition to CM and CG in cases with suspected MDS.

0309

AN EVALUATION OF THE ASSOCIATION OF CDKN2B (P15) DNA METHYLATION WITH RESPONSE AND SURVIVAL IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (MDS) TREATED IN THE AZA-001 TRIAL

J Herman,[1] G Mufti,[2] K MacBeth,[3] J Seymour,[4] P Fenaux,[5] S Gore,[1] V Santini,[6] L Lucy,[3] C Beach[3]

[1]The Sidney Kimmel Comprehensive Cancer Center, Baltimore, USA; [2]King's College London, London, UK; [3]Celgene Corporation, San Francisco, USA; [4]Peter MacCallum Cancer Centre, East Melbourne, Australia; [5]Hopital Avicenne - Service d'hématologie clinique, Bobigny, France; [6]Azienda Ospedaliera Universitaria Careggi, Florence, Italy

Background. The phase III AZA-001 study in patients with higher-risk MDS demonstrated that treatment with azacitidine resulted in significantly improved overall survival (OS) compared with conventional care regimens (CCR) (Fenaux, Lancet Oncol, 2009;10:223). A previous study in a small number of similar risk patients showed that CDKN2B methylation status was predictive of response to azacitidine, with lower baseline methylation observed in responders vs non-responders (Raj, Leukemia, 2007;21:1937). *Aims.* We therefore sought to determine whether CDKN2B promoter DNA methylation density in bone marrow samples at baseline from patients on AZA-001 treated with azacitidine or CCR was associated with OS and response. *Methods.* The percentage of DNA methylation was determined for 18 CpG units in the CDKN2B promoter of genomic DNA isolated from 295 pre-treatment bone marrow aspirates of consenting patients using the Sequenom EpiTYPER® platform. A weighted average of methylation levels in these 18 CpG units was used to evaluate association with clinical outcome, with the number of individual CpG dinucleotides comprising each CpG unit used as the weight for that unit. Kaplan-Meier methods were used for survival estimates. Cox proportional hazards models, stratified by the randomization factors FAB subtype and international prognostic scoring system (IPSS) group, were used to estimate hazard ratios (HRs) and associated 95% confidence intervals (CIs). Adjustments were made for the following covariates: ECOG performance status, LDH, hemoglobin, number of previous red-blood-cell transfusions, and presence or absence of the cytogenetic -7/del(7q) abnormality. *Results.* (Table): In 295 patients (azacitidine [n=148] and CCR [n=147]) the median weighted average methylation density of 18 CpG units in the CDKN2B promoter DNA was 13.6% (IQR: 10.4-23.5%), ranging from 3.1 to 64.6%, and was similar between treatment arms (16.0% [IQR: 10.6-24.8%] for azacitidine and 13.1% [IQR: 10.1-21.3%] for CCR). When groups were dichotomized at the median of 13.6% methylation, there was an OS benefit for both azacitidine methylation groups (≤13.6% and >13.6%) compared with the respective methylation groups of patients treated with CCR. Relative to the low methylation group (≤13.6%) treated with CCR, the HRs for risk of death were 0.63 [95% CI: 0.39-1.01] for the azacitidine ≤13.6% group, 0.55 [95% CI 0.35-0.84] for the azacitidine >13.6% group, and 0.95 [95% CI 0.62-1.47] for the CCR >13.6% group. Additionally, there was a higher proportion of patients with hematologic response (CR+PR+HI [IWG 2000]) for both methylation groups (≤13.6% and >13.6%) treated with azacitidine compared with the respective methylation groups treated with CCR. *Summary/Conclusions.* These data show that the OS and hematologic response benefits observed with azacitidine vs CCR were independent of baseline methylation status of CDKN2B, and that a similar proportion of patients experienced increased hematologic response rates with azacitidine in each methylation group.

Table 1.

CDKN2B Methylation Weighted Average	Overall Survival			
	Deaths (n/N)	K-M Median (months)	Hazard Ratio (95%CI)	p-value

THE IMPACT OF THE DEGREE OF ANEMIA ON SURVIVAL OF PATIENTS WITH MYELODYSPLASTIC SYNDROME. A BASIS FOR PROGNOSTIC ASSESSMENT AND CLINICAL DECISION MAKING

I Ambaglio, E Travaglino, M Della Porta, C Pascutto, M Ubezio, R Invernizzi, L Malcovati, M Cazzola

Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy

Background. More than 90 percent of patients with myelodysplastic syndrome (MDS) are anemic at the time of diagnosis, while moderate

to severe anemia is observed in approximately 50 percent of cases. In MDS, low hemoglobin levels have been found to result in cardiac remodeling, and the onset of a regular transfusion requirement is associated with a higher risk of heart failure and significant worsening of survival. *Aims.* In this study we aimed at evaluating the prognostic impact of the degree of anemia in MDS patients classified according to WHO criteria, as a basis for objective prognostic assessment and clinical decision-making. *Methods.* To this purpose, we longitudinally monitored the decrease in hemoglobin (Hb) in 920 patients with MDS, followed at the Department of Hematology, S. Matteo Hospital, University of Pavia, Italy. Hb level was grouped in categories of 1 g/dL (from >13 g/dL to <8 g/dL for males and from >12 g/dL to <8 g/dL for females). Sex-specific uni- and multivariable analyses with time-dependent covariates were performed by means of Cox proportional hazards regression models. *Results.* As a first step, we performed a Cox univariate time-dependent survival analysis stratified by sex. A decrease in Hb was associated with a progressive worsening of overall survival (OS): statistical significance was obtained beginning from Hb <11 g/dL in males (HR from 5.2 to 15.7, P values from .029 to <.001) and from Hb <9 g/dL in females (HR from 6.3 to 11.8, P values from .013 to <.001). We then performed sex-specific multivariable Cox regression analyses including age, Hb categories, WHO subgroups, cytogenetic risk groups categorized according to IPSS, number of cytopenias, cardiac comorbidity as time-dependent covariates, and found a significantly higher risk for Hb <9 g/dL in males (HR 5.6, P=.018) and <8 g/dL in females (HR=5.6 P=.026). These Hb thresholds were also found to be associated with a significantly higher risk of cardiac death (HR 8.1, P=.004). Finally, we aimed at assessing whether these sex-specific Hb thresholds could be as effective as transfusion-dependency in the prognostic assessment of MDS patients. The unfavorable prognostic impact of the sex-specific Hb thresholds was comparable to that of transfusion-dependency in both univariable (HR=4.0, P<.001, and HR 4.1, P<.001, respectively) and multivariable time-dependent Cox regression (HR=2.6, P<.001, and HR=2.5, P<.001, respectively). The substantial equivalence of these two models was confirmed by the Akaike information criterion (AIC, 2967 versus 2970, respectively). Based on these results, we recalculated WPSS risk groups, using sex-specific Hb thresholds instead of red cell transfusion requirement, and obtained highly concordant risk categories (Kendall tau coefficient 0.94). Moreover, results by both Cox regression and Kaplan-Meier time-dependent analyses were superimposable. *Conclusions.* The findings of this study confirm the independent unfavorable effect of severity of anemia on survival of MDS patients. In the calculation of WPSS, the use of sex-specific Hb thresholds instead of transfusion-requirement provides a more objective score computation, and - compared to the original model - allows to identify highly concordant risk groups with similar survival and risk of leukemic progression.

EFFECT OF BASELINE EPO AND PRIOR ERYTHROPOIESIS STIMULATING AGENTS ON RBC TRANSFUSION INDEPENDENCE IN LOW-/INT-1-RISK MDS WITH DEL5Q TREATED WITH LENALIDOMIDE: A RANDOMIZED PHASE 3 STUDY (MDS-004)

P Fenaux,[1] A Giagounidis,[2] D Selleslag,[3] R Knight,[4] T Fu,[4] E Hellström-Lindberg[5]

[1]*Hopital Avicenne, Université Paris XIII, Bobigny, France;* [2]*St. Johannes Hospital, Duisburg, Germany;* [3]*AZ St-Jan Brugge AV, Brugge, Belgium;* [4]*Celgene Corporation, Summit NJ, USA;* [5]*Karolinska University Hospital Huddinge, Stockholm, Sweden*

Background. MDS patients with erythropoietin (EPO) levels >500 mIU/mL and transfusion burden ≥2 units/month have poor response to erythropoiesis stimulating agents (ESAs). The randomized, phase 3, multicenter, double-blind MDS-004 study in RBC transfusion-dependent patients with Low- or Int-1-risk MDS with del5q demonstrated that lenalidomide (LEN) 10 mg and 5 mg achieved significant RBC transfusion independence (TI) versus placebo. RBC-TI (56% versus 41%) and cytogenetic response (41% versus 17%) rates were higher with LEN 10 mg. *Aim.* This sub-analysis aims to investigate RBC-TI according to baseline EPO levels and prior ESA use in LEN-treated patients, and the effect of the LEN dose used in those patient subgroups. *Methods.* Patients who provided informed consent received LEN 10 mg (days 1-21 of a 28-day cycle) or LEN 5 mg (days 1-28 of a 28-day cycle); concomitant ESAs were prohibited. RBC-TI for ≥26 consecutive weeks was assessed according to baseline EPO levels (≤500 mIU/mL and >500 mIU/mL) and prior ESA use. *Results.* 87 patients (LEN 10 mg: n=41; LEN 5 mg: n=46) were included. Median RBC transfusion burden was 6 units/month (range 1-28). In the LEN groups combined, RBC-TI rates were similar in patients with EPO ≤500 mIU/mL (48%) versus >500 mIU/mL (51%; P=0.81) (Table 1). In patients with EPO >500 mIU/mL, the RBC-TI rate was higher with LEN 10 mg versus LEN 5 mg (76% versus 29%; P=0.0016), whereas the RBC-TI rate was similar between LEN doses in patients with EPO ≤500 mIU/mL (43% versus 54%; P=0.57). In the LEN groups combined, RBC-TI rates were lower with prior ESA (36%) versus no prior ESA (63%; P=0.01). RBC-TI rates were similar in the LEN 10 mg versus 5 mg groups in patients with prior ESA (42% versus 30%; P=0.42) and without prior ESA (76% versus 52%; P=0.12). In the LEN groups combined, RBC-TI rates in patients who had an EPO level >500 mIU/mL or received prior ESA were lower than those with EPO ≤500 mIU/mL and no prior ESA use (42% versus 80%; P=0.025). RBC-TI rates were similar with LEN 10 mg and 5 mg in patients with EPO >500 mIU/mL or who had received prior ESA (51% versus 33%; P=0.12) and in those with EPO ≤500 mIU/mL and no prior ESA (80% versus 80%; P=1.0). No differences in time to RBC-TI and duration of RBC-TI occurred according to baseline EPO level and prior ESA use, irrespective of LEN dose. *Conclusions.* LEN is effective in achieving RBC-TI regardless of baseline EPO level or prior ESA use; LEN 10 mg achieved higher RBC-TI rates than LEN 5 mg in patients with baseline EPO level >500 mIU/mL, and to a lesser extent in patients with prior ESA treatment who represent refractory populations.

Table 1.

	LEN 5 mg (n=46)	LEN 10 mg (n=41)
EPO, n (%)		
≤500	13 (28)	14 (34)
>500	24 (52)	21 (51)

MOLECULAR PATHOGENESIS OF REFRACTORY ANEMIA WITH RINGED SIDEROBLASTS

A. Liu, M Nikpour, K Högstrand, A Forsblom, M Jansson, M Karimi, A Grandien, E Hellström-Lindberg

Department of Medicine (Huddinge), Karolinska Institute, Stockholm, Sweden

Background. Refractory anaemia with ringed sideroblasts (RARS) is characterized by anaemia, erythroid apoptosis, cytochrome c release and mitochondrial ferritin accumulation. To dissect the molecular mechanisms underlying the RARS phenotype, we have determined the gene expression profiles of erythroblasts generated from normal (NBM) and RARS marrow CD34$^+$ cells. Pathway analysis showed that genes involved in apoptosis, erythroid survival and mitochondrial function were altered. *Aim.* To test the hypothesis that RARS is caused by alterations in a gene involved in cellular iron transport or possibly mitochondrial function. *Results.* We confirmed the microarray data by quantitative real-time PCR (qRT-PCR). Several erythropoiesis-associated genes were deregulated in RARS CD34$^+$ cells. ABCB7, transporting iron from mitochondria to cytosol and associated with inherited ring sideroblast formation was severely downregulated compared to normal bone marrow. Moreover, ABCB7 expression decreases dramatically in RARS progenitors undergoing erythroid differentiation, but increases with differentiation in normal bone marrow cultures. The same pattern was observed for the mitochondrial integrity gene MFN2. To study the function of candidate genes, K562 cells were employed which can be induced to erythroid differentiation by hemin treatment. The expression of ABCB7 in K562 cells by lentiviral transduction facilitated the

expression of γ-globin and glycophorin A, indicating that ABCB7 potentiated erythroid differentiation. Further, BM CD34+ cells from three RARS patient were transduced with lentiviral vectors expressing ABCB7-YFP. The transduction efficiency was tested by flow cytometry. Colony forming cell assay was initiated from day 3 cultures. The number of erythroid colonies, myeloid colonies, YFP+ erythroid, and YFP+ myeloid colonies were counted on day 14 after transduction. The number of colonies generated from mock vector-transduced cells was in comparison with that from untransduced cells, the percentage of YFP+ colonies was in consistence with that tested by flow cytometry. While colony number increased significantly from the abcb7 vector-transduced cell cultures. Interestingly, YFP+ colonies from the ABCB7 vector-transduced cell cultures increased considerably. Results indicated that upregulation of ABCB7 increased the clonogenic capacity of RARS progenitors. In addition, qRT-PCR results from day 10 cell culture samples of one RARS patient showed that upregulation of ABCB7 reduced the accumulation of mitochondrial ferritin. *Summary*. Using pathway analysis with clinical and cell biological knowledge, we can limit the number of candidate genes from the vast amount of data obtained from global gene expression analysis. With lentiviral transduction we can increase the number of genes tested on somatic hemotopoietic stem cells. In the absence of ABCB7 mutations or hypermethylation, we hypothesize that upstream mechanisms with impact on cellular iron transport may be involved in RARS pathogenesis.

DETECTION OF TP53 MUTATIONS IN LOW-RISK MYELODYSPLASTIC SYNDROMES WITH DEL(5Q) IS ASSOCIATED WITH DISEASE PROGRESSION

M Jädersten,[1] L Saft,[1] A Smith,[2] A Kulasekararaj,[2] S Pomplun,[2] R Hast,[1] A Porwit,[1] E Hellström-Lindberg,[1] G Mufti[2]

[1]Karolinska Institutet, Stockholm, Sweden; [2]King's College London School of Medicine, London, UK. Martin Jädersten and Leonie Saft contributed equally to this paper

Background. TP53 mutations have been identified as a strong prognostic marker in myelodysplastic syndromes (MDS). However, mutations have been identified preferentially in high risk MDS and often occur in conjunction with complex chromosomal abnormalities. We recently described a patient with 5q- syndrome that at time of transformation carried a del(17p) and a TP53 mutation. Intriguingly, we were able to demonstrate the mutation already two years prior to transformation. This represents a novel finding in 5q- syndrome and suggests an unrecognized heterogeneity. Therefore we hypothesize that TP53 mutated subclones at an early stage of MDS with del(5q) may be associated with an increased risk of disease progression. *Aims.* To investigate the frequency of TP53 mutations in low risk MDS with a del(5q) and to assess the association with disease progression. *Patients and Methods*. Thirty-eight sequential patients with low-risk MDS and del(5q) from the Karolinska Hospital were included (33 isolated del[5q] and 5 del[5q]+1). Nineteen patients (50%) were transfusion-dependent at time of diagnosis. Twenty-three patients (61%) received treatment with lenalidomide. All sequential bone marrow samples from diagnosis and during follow-up were reviewed and stained for p53 protein. Mutational analysis of TP53 was performed using deep sequencing in 34 patients. The Kaplan-Meier estimate and the logrank test were used for analysis of survival and disease progression.

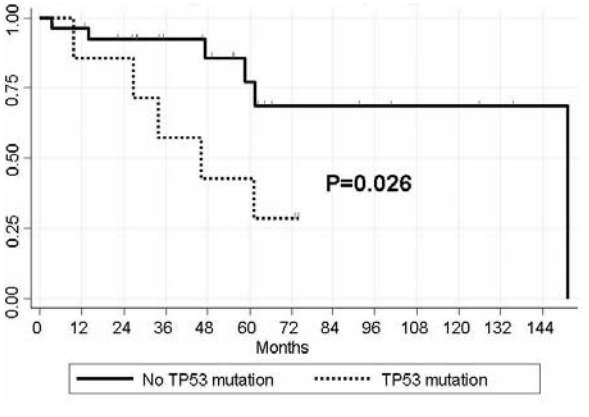

Figure 1. Probability of disease progression.

Results. The median follow-up was 48 months (interquartile range 24-66). Pre-progression TP53 mutations were found in 7 of 34 patients (21%), at levels of 3-55%. Overexpression of p53 protein was associated with the presence of TP53 mutation; 5 of 7 patients with mutated subclones showed at least 2% strongly p53 positive cells in the marrow, while none with less than 2% p53 positive cells were mutated. The presence of p53 mutation was significantly associated with disease progression (defined as a blast count above 10% or acquisition of a complex karyotype; P=0.026; Figure 1). There was no significant difference in overall survival (P=0.95). Due to the low number of mutated patients it was not possible determine any potential influence of treatment with lenalidomide on outcome. *Conclusion.* Mutations of the p53 gene at an early stage of low-risk MDS with del(5q) was associated with disease progression. If this can be confirmed in a larger cohort of patients it may constitute an important prognostic marker that could influence clinical decision making.

0314

INDEPENDENT IMPACT OF TRANSFUSION DEPENDENCY AND IRON OVERLOAD ON SURVIVAL OF PATIENTS WITH MYELODISPLASTIC SYNDROMES

M Arnan,[1] E Alonso,[2] R Tienda,[1] A Fernandez de Sevilla,[1] R Duarte[1]

[1]Catalan Institute of Oncology, Barcelona, Spain; [2]Hospital Bellvitge, Barcelona, Spain

Background. Patients with myelodysplastic syndromes (MDS), especially those with a lower-risk type of disease, are prone to developing iron overload as a result of chronic blood transfusion therapy, and also partly due to increased duodenal iron absorption induced by ineffective erythropoiesis. Transfusion dependency is clearly associated with a decreased probability of survival (Malcovati L *et al.* J Clin Oncol 2007; 25:3505). Additional recent data suggest that iron overload could also influence outcome independently fashion from transfusion dependency. *Aim.* The main aim of this study was to validate the independent prognostic value of iron overload and transfusion dependency in a relatively large single-centre series of MDS patients. *Methods.* We retrospectively analyzed the outcome of 639 patients diagnosed with *de novo* MDS according to FAB criteria between 1994 and June 2009 at the Catalan Institute of Oncology in Barcelona. Iron overload was defined as serum ferritin level >1.000 ng/mL, and transfusion dependency was defined by the WHO-based Prognostic Scoring System (WPSS). Actuarial curves of overall survival used Kaplan-Meier method and compared by log-rank test. Multivariate analysis of overall survival were performed by Cox proportional hazards regression method. *Results.* Median age at diagnosis was 71 years (range: 25-99); 410 male and 229 female. MDS subtype distribution was as follows: RA 113 (18%), RARS 91 (14%), RCMD 99 (16%), RAEB-1 126 (20%), RAEB-2 43 (7%), LAM (RAEB-t) 13 (2%), CMMoL 135 (21%), MDS-U and MDS with isolated 5q- 14 (2%).

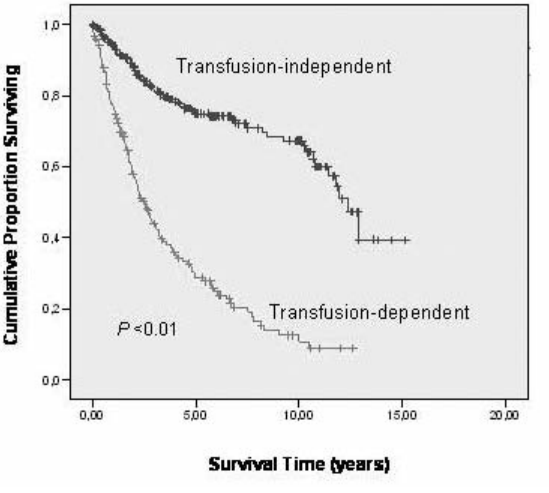

Figure 1.

The median follow-up time for these patients was 49 months (range: 8 to 182). Cytogenetic analysis was available at diagnosis for 199 (31%)

patients, in whom IPSS could be assessed (39% low risk, 42% intermediate 1, 13% intermediate 2, 6% high risk). Complete transfusion history was available for all patients. Two hundred and seventy patients (42%) were transfusion-dependent, requiring a median of 2.03 (range: 0.5-13.2) packed red blood cell monthly transfusions. Iron overload, as determined by serum ferritin level, was available in 195 patients (31%). Univariate analysis of factors influencing overall survival identified transfusion dependency, iron overload, age, karyotype risk, percentage of blasts at diagnosis, number of cytopenias, IPSS scoring system, WPSS scoring system, hemoglobin <10 g/dL and platelets <100×10^9/L as statistically significant factors (all P<0.001). Median overall survival was for transfusion-dependent patients compared with transfusion independent ones was 34 vs 56 months (P<0.001) and median survival of patients with high ferritin levels was significantly shorter than that of patients with ferritin <1.000 (34 vs 53 years; P<0.001). Multivariate analysis confirmed in our single-centre series that transfusion dependency (RR=5.8; P<0.001) and iron overload (RR=2.1; P<0.025) were strongly associated with overall survival and added independent prognostic information. *Conclusions.* Our results confirm an independent prognostic value of iron overload and transfusion dependency on overall survival in patients with MDS, and further suggest that strategies to reduce iron overload may have a positive effect on overall survival in these patients.

0315

ALLOGENEIC STEM CELL TRANSPLANTATION FOR MDS WITH BONE MARROW FIBROSIS

N Kröger,[1] T Zabelina,[1] A van Biezen,[2] R Brand,[2] T de Witte[3]

[1]*University Hospital, Hamburg, Germany;* [2]*Medical University, Leiden, Netherlands;* [3]*Medical Center, Nijmegen, Netherlands*

Background. Bone Marrow Fibrosis has an important impact on the prognosis of patients with MDS. *Aims and Methods.* We evaluate the impact of bone marrow fibrosis in 721 patients who underwent allogeneic hematopoietic stem cell transplantation (HSCT) for MDS/AML and were reported to the EBMT. *Results.* No fibrosis was noted in 483 pts, mild or moderate fibrosis in 199 pts and severe fibrosis in 39 pts. Diagnosis in the none, mild/moderate and severe fibrosis group were RA/RARS (36%, 39% and 30%), RAEB (43%, 43% and 48%) and RAEB-t (21%, 18% and 20%). Stem cell source were from related (63%, 63% and 62%) or unrelated (36%, 36% and 38%) donors. Leukocyte engraftment (>1.0×10^6/L) was observed after a median of 16, 17 and 20 days for the none, mild/moderate and severe fibrosis group, respectively (P=0.002). Incidence of acute or chronic GvHD did not differ between the groups. Non-relapse mortality at 1 year was comparable in all groups (26% vs 30% vs31%, P=0.3). Cumulative incidence of relapse at 3 years was higher in the severe fibrosis group in comparison to mild/moderate and none fibrosis group (47% vs 27% vs 28%, P=0.04), resulting in significant worse 3 year overall survival in the severe fibrosis group (21% vs 40% vs 49%, P=0.002). In a multivariate analysis severe bone marrow fibrosis remained an independent risk factor for survival (HR 1.9, P=006). Other factors for reduced survival were advanced disease at transplant (HR 1.97 P=0.005), non-CR before transplant (HR 1.88, P<0.001) and HLA-mismatch (HR 1.48, P= 0.02). I *Summary.* The negative impact of mild or moderate bone marrow fibrosis in MDS patients can be overcome by allogeneic stem cell transplantation, but severe bone marrow fibrosis remained an independent risk factor for reduced survival after transplantation.

0316

IMPACT OF LENALIDOMIDE ON HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH RBC TRANSFUSION-DEPENDENT LOW- OR INT-1-RISK MYELODYSPLASTIC SYNDROMES WITH DEL5Q: A RANDOMIZED PHASE 3 STUDY (MDS-004)

N Brandenburg,[1] T Fu,[1] D Revicki,[2] R Knight,[1] P Muus,[3] P Fenaux[4]

[1]*Celgene Corporation, Summit NJ, USA;* [2]*United BioSource Corporation, Bethesda, MD, USA;* [3]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands;* [4]*Hopital Avicenne, Université Paris XIII, Bobigny, France*

Background. In a randomized, phase 3, multicenter, double-blind study (MDS-004), lenalidomide (LEN; 5 mg and 10 mg) was generally well tolerated and resulted in significant RBC transfusion independence (TI) and cytogenetic response in patients with Low- or Int-1-risk myelodysplastic syndromes with del5q. Significant improvements in hemoglobin levels (median maximum hemoglobin increase: LEN 10 mg = 6.3 g/dL; LEN 5 mg = 5.1 g/dL) were also observed. *Aim.* To present health-related quality of life (HRQoL) analyses from the MDS-004 study. *Methods.* Patients who provided informed consent were randomized to LEN 5 mg on days 1-28 or LEN 10 mg on days 1-21, both of a 28-day cycle, or placebo. Patients with at least minor erythroid response at 16 weeks continued double-blind treatment for up to 52 weeks, until erythroid relapse or disease progression. Placebo and LEN 5 mg patients who did not respond by week 16 were considered treatment failures and could crossover to LEN 5 mg or 10 mg, respectively, in an open-label extension phase. Patient-reported HRQoL was assessed using the Functional Assessment of Cancer Therapy-Anemia (FACT-An) questionnaire. FACT-An comprises FACT-general plus additional items that assess the impact of fatigue and other anemia-related symptoms. The minimal clinically important difference in FACT-An scores is 7 points (Cella et al., J Pain Symptom Manage. 2002). FACT-An was administered at baseline, and weeks 12, 24, 36, and 48. ANOVA compared the change from baseline in FACT-An scores at week 12 in each LEN group versus placebo. Longitudinal assessment of FACT-An scores through week 48 for patients randomized to lenalidomide treatment is presented. Double-blind data are reported. *Results.* Overall, 205 patients (median age 68 y, range 36-86 y) were randomized (LEN 10 mg: n=69; LEN 5 mg: n=69; placebo: n=67) and included in the intent-to-treat analysis. FACT-An scores were available at both baseline and week 12 for 71% of randomized patients (LEN 10 mg: n=48; LEN 5 mg: n=46; placebo: n=51). Among patients with FACT-An scores at both baseline and week 12, the mean (SD) baseline FACT-An scores were 121.0 (20.1), 125.3 (23.4), and 121.3 (26.6) for the LEN 10 mg, LEN 5 mg, and placebo groups, respectively. There was a significant improvement in HRQoL with LEN 10 mg versus placebo at week 12 (mean change scores 5.2 versus -'3.3, respectively; P=0.030). The difference between LEN 5 mg versus placebo followed a similar trend (mean change scores 3.4 versus -'3.3, respectively; P=0.09). Absolute change from baseline FACT-An scores in LEN-treated patients exceeded 7 points at weeks 24, 36, and 48 (Figure). Of patients with available FACT-An scores, > 75% overall (> 90% in the LEN 10 mg group beyond week 16) achieved RBC-TI. *Conclusions.* Improvements in HRQoL, as measured by the FACT-An relative to placebo, were apparent at week 12 and were greatest in the LEN 10 mg group. Clinically relevant HRQoL improvements relative to baseline were reported in both LEN groups beyond week 12.

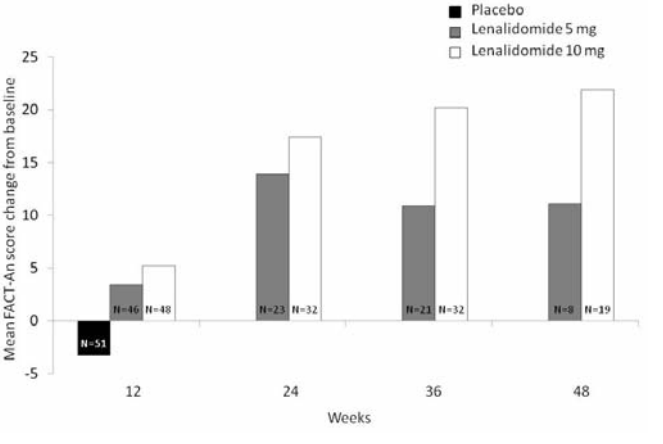

Figure.

GENE EXPRESSION ANALYSIS IN DIFFERENT HEMATOPOIETIC CELL COMPARTMENTS IDENTIFIES COMMONLY DOWN REGULATED GENES AND SUGGESTS A POSSIBLE ROLE OF AN IMPAIRED HELICASE ACTIVITY IN MDS

F Nolte,[1] O Benlasfer,[2] U Platzbecker,[3] WK Hofmann[1]

[1]*University Hospital, Mannheim, Germany;* [2]*Department of Hematology/Oncology, CBF, Charité, Berlin, Germany;* [3]*University Hospital, Department of Hematology/Oncology, Dresden, Germany*

Background. Several genetic and molecular genetic alterations have been described in myelodysplastic syndromes (MDS) but the exact underlying mechanisms remain elusive. Furthermore, gene expression analysis identified critical genes that could be involved in initiation and progression of MDS. However, whether the underlying defects affect the myeloid clone only or whether bone marrow stroma cells and

peripheral blood mononuclear cells derive from the malignant clone as well remains controversial. *Aims.* In order to further elucidate whether an underlying defect might translate into an altered gene expression pattern in different cell compartments we performed gene expression analysis on purified CD34+ bone marrow cells, bone marrow stromal cells (BMSC) and mononuclear peripheral blood cells (PB) from patients with MDS and healthy controls. *Methods.* Heparinized bone marrow samples were obtained after informed consent from 18 MDS patients (5 RA, 2 RARS, 10 RAEB and 1 RAEB-t) and 7 healthy controls. CD34+ hematopoietic progenitor cells were isolated by high gradient magnetic cell separation (Miltenyi Biotech, Bergisch Gladbach, Germany). BMSC were obtained by expansion of adherent bone marrow cells in specific cell culture. RNA was extracted from CD34+ cells, BMSC and PB using TRIzol reagent (Invitrogen, Life Technologies, Grand Island, NY) according to the manufacturer's protocol. Quality controlled RNA was hybridized according to the standard Affymetrix protocol to HG-U133 Plus 2.0 microarrays. Data analysis was performed using the Gene Spring Software version 4.0 (Silicon genetics, San Carlos, CA). Restrictions were set as follows: only genes that were 'present' in 100% of samples were used for further analyses, genes were considered as 'differentially expressed' when they showed at least 2-fold change between the different groups. Statistical significance was calculated by non-parametric t-test, with P<0.05. Gene ontology analysis was performed by using the public DAVID database and only genes that showed an enrichment score of at least 1 were considered. *Results.* Comparison of gene expression patterns in CD34+ cells, BMSC and PB from MDS patients to healthy volunteers identified 133 probe sets that were at least 2-fold downregulated in MDS. Interestingly, none were comonly upregulated in MDS in all three cell compartments. The 133 probe sets comprised of 124 genes that were further analyzed for gene ontology by using the public DAVID database. Biological functions that were most frequently affected included RNA transport as well as transcription regulation. Among these genes we identified the SMARCC1 gene exclusively being downregulated in MDS in all three cell compartments. SMARCC1 encodes for a protein which is a member of the SWI/SNF family displaying helicase and ATPase activities. These proteins are thought to regulate transcription of certain genes by altering the chromatin structure. *Summary*. In conclusion, gene expression analysis identified a possible key gene which is affected in three different cell compartments in MDS and that has been shown to play a critical role in sustaining genomic stability in human cells. Thus, impaired expression of SMARCC1 might result in an increased genomic instability, a feature which is thought to play a pivotal role in the initiation and progression of MDS.

IDH1 MUTATIONS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES ARE ASSOCIATED WITH AN UNFAVORABLE PROGNOSIS

F Thol,[1] E Weissinger,[1] J Krauter,[1] K Wagner,[1] F Damm,[1] M Wichmann,[1] G Göhring,[1] C Schumann,[2] G Bug,[3] O Ottmann,[3] WK Hofmann,[2] B Schlegelberger,[1] A Ganser,[1] M Heuser[1]

Background. Myelodysplastic syndromes (MDS) are a heterogeneous group of hematopoietic stem cell disorders with a high propensity to transform to acute myeloid leukemia (AML). The molecular changes that can lead to MDS as well as the progression to AML are still poorly understood. Heterozygous missense mutations in IDH1 at position R132 have recently been described in AML. However, the incidence of IDH1 mutations has not been reported in MDS. *Aim.* The aim of this study was to investigate the incidence and prognostic impact of IDH1 and IDH2 mutations in MDS. *Methods.* In the present study, we examined 246 patients with MDS or AML with myelodysplasia-related changes for mutations in IDH1 (R132), IDH2 (R172), and NPM1 by direct sequencing. *Results.* We found that mutations in IDH1 occur with a frequency of 3.6 and 7.5 percent in MDS (n=193) and AML with myelodysplasia-related changes (n=53), respectively. All mutations were heterozygous missense mutations, leading in the majority of MDS patients to Arg132Cys substitution. A mutation of IDH2 (R172) was identified in one AML patient, but not in MDS patients. IDH1/2 mutations were not found concurrently with NPM1 mutations in MDS patients. The presence of IDH1 mutations was associated with a shorter overall survival (HR 3.20; 95%CI 1.47-6.99). Patients with mutated IDH1 showed a higher rate of transformation into AML (67% vs 28%, P=0.04). In multivariate analysis including IDH1 mutation status, IPSS score, transfusion dependence, and karyotype, the presence of IDH1 mutation remained an independent unfavorable prognostic marker in MDS (HR 3.57; 95%CI 1.59-8.02; P=0.002). In patients with AML and a history of MDS, the mutational status of IDH1/2 had no prognostic impact on OS (HR 1.82; 95%CI 0.64-5.17; P=0.26). *Conclusions.* We have identified IDH1 mutations of amino acid 132 in 3.6 percent of MDS patients, and found a correlation of mutated IDH1 with unfavorable outcome in these patients.

FEASIBILITY OF HYPOMETHYLATING AGENTS FOLLOWED BY ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

YH Park, JH Lee, DY Kim, JH Lee, SN Lim, SD Kim, Y Choi, S Lee, KH Lee, JY Kim, YS Lee, M Seol, YA Kang, M Jeon, YJ Lee, KH Lee

Asan Medical Center, University of Ulsan College of Medicine, Seoul, South-Korea

Background. The role of hypomethylating agent therapy (HMT) as a bridging to allogeneic hematopoietic cell transplantation (HCT) in patients with myelodysplastic syndrome (MDS) still remains to be determined. *Aim.* We investigated the feasibility and clinical efficacy of HMT followed by HCT in patients with MDS at a single institute. *Methods.* Patients with MDS were treated with HMT - azacitidine (AZA; 75mg/m^2 once daily s.c. on day 1 to 7) or decitabine (DEC; 20mg/m2 once daily i.v. on day 1 to 5) every four weeks. Hematologic improvement (HI) was evaluated per each cycle and bone marrow/cytogenetic response were regularly monitored per 2-4 cycles. HCT was performed for patients in their good performance status and with available donor, irrespective of the response to HMT. *Results.* Among 75 patients who were treated with HMT between Sep. 2006 and May 2009, 19 patients of median age 47 years (range, 23-69 years) who received HCT were analyzed. Seven patients (RA: 2, RCMD: 5) were classified as low-risk and 12 patients (RAEB-1: 7, RAEB-2: 5) as high-risk, based on WHO classification at the time of HMT administration. Patients were classified by IPSS score as 'LOW' (n=2), 'INT-1' (n=8), 'INT-2 (n=6) and 'HIGH' (n=2). In terms of HMT, 9 patients were treated with DEC and 10 patients with AZA. There were no significant difference between two groups except in the median number of cycles - 3 (range, 1-6) for DEC and 5.5 (2-13) for AZA. Best response to HMT was 'CR' (11%), 'mCR' (32%), 'SD' (21%), and 'progression' (5%) for 13 evaluable patients. Six patients achieved HI (HI-P for 2, and HI-P/N for 4 patients). After the completion of HMT, there were no changes in the WHO classification compared with pre-HMT status in 15 patients (79%), one patient improved, and 3 patients (16%) progressed to acute myeloid leukemia (AML). 'Consideration of HCT' (48%) was the most common cause of HMT termination, followed by 'no effect' (26%), 'failure' (16%), and 'prolonged cytopenia' (11%). HCT was performed after the median of 7.3 months (range, 3.5-89.7 months) from the diagnosis of MDS, and 6.5 months (range, 2.1-23.9 months) from the initiation of HMT. Most of patients (95%) received non-myeloablative regimen based on fludarabine/busulfan/antithymocyte globulin as a conditioning, peripheral blood-mobilized cell (median cell number of 6.9×10^6) as stem cell source. Neutrophil/platelet engraftment were achieved in 95%/79% of patients, respectively and the number of patients who required transfusion after day 100 was 2 for RBC and 1 for platelet. Cumulative incidence rate of acute/chronic GVHD was 42%/26%, respectively. Post-HCT 2-year relapse-free survival (RFS) rate was 78% and 2-year overall survival (OS) rate was 68%. None of the clinical features associated with MDS / HMT had any significant effect on the outcome except that progression to AML during HMT did on the OS (HR 0.10, 95% CI 0.02-0.59, P=0.012). *Conclusions.* HMT followed by HCT was a feasible and effective treatment strategy for patients with MDS. Further investigations are warranted to prove the improvement of outcomes with the addition of HMT before HCT.

VASCULAR ENDOTHELIAL GROWTH FACTOR OVEREXPRESSION IN BONE MARROW CELLS FROM PATIENTS WITH MYELODYSPLASTIC SYNDROME: BIOLOGICAL AND CLINICAL RELEVANCE

R Invernizzi,[1] E Travaglino,[1] V Matti,[1] M Della Porta,[1] L Malcovati,[1] A Gallì,[1] A Filocco,[1] E Boveri,[2] V Rosti,[2] M Cazzola[1]

[1]University of Pavia, Pavia, Italy; [2]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

The expression of various angiogenesis mediators has been found to be altered in myelodysplastic syndrome (MDS) bone marrow and

abnormal angiogenesis has been implicated in the pathogenesis of the disorder. Vascular endothelial growth factor (VEGF) is one of the most important agents to stimulate angiogenesis. Intense coexpression of VEGF and receptor was detected in bone marrow immature myeloid elements from MDS patients and it was hypothesized that this angiogenic glycopeptide may have autocrine and paracrine regulatory effects on the hematopoietic system and contribute to disease progression. We analyzed by immunocytochemistry VEGF expression in bone marrow cells from 211 patients with MDS stratified according to IPSS criteria (134 low risk and 77 high risk patients), not previously treated, and 96 non hemopathic subjects. We also measured by an immunoassay VEGF bone marrow plasma levels as well as the release of VEGF in the supernatants of cell cultures from representative MDS and control cases. Our aims were to evaluate whether abnormalities in the expression of this factor were associated with relevant laboratory or clinical findings and to define their possible prognostic value; moreover, to investigate a possible correlation between VEGF expression levels and various biological parameters such as circulating endothelial cell (CEC) levels, bone marrow microvessel density, apoptosis, proliferation. VEGF was detected in most maturing myeloid cells from control samples (median 25%, IQR 14-44%). In MDS VEGF myeloid levels (median 42%, IQR 30-56%) were higher than those in controls (P<0.0001), and also many erythroblasts expressed VEGF (median 40%, IQR 13-74%). A few MDS $CD34^+$ stem cells (2-16%) expressed VEGF, whereas normal $CD34^+$ cells did not express this factor. The release of VEGF was demonstrated in all samples; VEGF levels were tendentially higher in the media conditioned by MDS mononuclear cells (median 29 pg/mL, IQR 11-77), especially from low-risk patients (median 56 pg/L, IQR 2-88), than in controls (median 9 pg/mL, IQR 0-23), and significantly higher in MDS bone marrow plasma than in normal marrow plasma (P=0.01). No significant relationship was detected between VEGF expression and CEC levels or marrow microvessel density, whereas there was a positive correlation between marrow microvessel density and CECs (P<0.001). In MDS a positive correlation between VEGF myeloid or erythroid levels and apoptotic rate (P=0.02 and P=0.04 respectively) was observed, whereas VEGF expression was independent of the proliferative rate. VEGF cell levels were unrelated to clinical or laboratory features such as age, leukocyte count, blast cell percentage or karyotype. In multivariate analysis including age, WHO subgroups and IPSS variables, myeloid VEGF levels above median values were independently associated with longer overall survival (P=0.03) and evolution-free survival (P=0.04). In conclusion, we have systematically evaluated the relation between VEGF abnormal expression profile and other biological and clinical features in MDS. Rather than stimulate angiogenesis, the production and release of this factor may influence hematopoietic cell death and contribute to ineffective hematopoiesis, possibly by a paracrine induction of inflammatory pro-apoptotic cytokines from endothelial cells and macrophages, with a potential prognostic role.

0321

TRANSFUSION INTENSITY, NOT THE CUMULATIVE NUMBER OF RED BLOOD CELL (RBC) TRANSFUSIONS, IS ASSOCIATED WITH POOR PROGNOSIS IN PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS) OR CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML)

A Pereira,[1] M Nomdedeu,[1] JL Aguilar,[1] M Belkaid,[1] A Carrió,[1] F Cobo,[2] D Costa,[1] M Rozman,[1] C Sanz,[1] B Nomdedeu[1]

[1]Hospital Clínic, Barcelona, Spain; [2]Hospital Clinic, Barcelona, Spain

Background. Previous studies have revealed an association between the cumulative number of RBC transfusions and shorter survival in patients with MDS, though the causal connection between both features has not yet been fully elucidated. *Aim.* To test three hypothetical reasons for such association: 1) the cumulative number of RBC transfusions is a confounder merely reflecting the time elapsed from diagnosis; 2) it is a surrogate for higher transfusion intensity, which in turn reflects a more severe bone marrow failure, or, alternatively, 3) it is the total amount of transfused RBC units by itself that influences on prognosis. *Methods.* Review of the transfusion history and the clinico-hematological data of 204 transfusion-dependent patients with MDS or CMML seen at our institution from 1995 to 2009. Standard statistical methods were used for survival analysis. *Results.* Median age at first transfusion was 75 (range: 16-99) years and 102 (50%) patients were females. WHO subgroups were refractory cytopenia with multilineage dysplasia (RCMD, n=96), refractory anemia with excess of blasts (RAEB, n=57), CMML (n=25), simple refractory anemia (RA, n=16), RA with ringed sideroblasts (RAS, n=7), and del5q (n=3). Karyotype was available in 175 patients (high risk: 27). At the study closing date, median follow-up from first transfusion was 1.9 years, 138 (68%) patients had died, 8 (4%) were lost to follow-up, 49 evolved into acute leukaemia (AL), and the median number of RBC units transfused per patient was 40 (range: 4-330). Out of the 204 patients, 134 received ≥25 RBC units, at which time the median follow-up from first transfusion was 10 months. Based on the WHO subgroup and cytogenetics, two prognostic groups were defined: good (RA, RAS, del5q, RCMD, with good or intermediate risk cytogenetics; median survival 3.7 years) or bad (RAEB, CMML, or high risk cytogenetics; median survival: 0.7 years). Transfusion intensity was calculated at the time of each transfusion as the number of yearly equivalent RBC units, had the patient kept being transfused at that rhythm for an entire year, and was categorized by quintiles. In order to test the study hypotheses, several nested Cox models were built to predict AL-free survival. In the basal model, the above defined poor prognosis group (hazard ratio [HR]: 2.6, 95%CI: 1.7-4.0, P<0.001) and having received ≥25 RBC units, evaluated as a time-dependent covariate (HR: 3.4, 95%CI: 2.2-5.2, P<0.001), predicted a shorter AL-free survival. Including follow-up ≥10 months from first transfusion as a time-dependent covariate had a remarkable prognostic effect (HR: 12, 95%CI: 3-50, P=0.001) but did not change the prognostic significance of having received ≥25 RBC units. In the next step, adding transfusion intensity to the basal Cox model had a significant effect on AL-free survival (HR: 1.7, 95%CI: 1.4-2.0, P<0.001) and cancelled the prognostic value of having received ≥25 RBC units (HR: 1.3, 95%CI: 0.7-2.2, P=0.33). *Conclusions.* Transfusion intensity, instead of the cumulative amount of RBC units, is the transfusion-related variable really influencing on the prognosis of patients with transfusion-dependent MDS or CMML. Transfusion seems, therefore, to be a surrogate for disease severity.

0322

MESENCHYMAL STEM CELLS FROM LOW-GRADE MDS AND HEALTHY DONORS DISPLAYED DISTINCTIVE GENE EXPRESSION PROFILE PATTERNS, WITH 5Q- SYNDROME AS AN INTERMEDIATE SUBGROUP

C Santamaria, O Lopez-Villar, S Muntión, S Carrancio, F Sánchez-Guijo, J San Miguel, MC Del Cañizo

University Hospital of Salamanca, Salamanca, Spain

Background. Currently, there is intensive research on the role of mesenchymal stem cells (MSC) in the pathophysiology of inefficient hematopoiesis. We and other groups have shown that MSC from myelodysplastic syndrome (MDS) display morphological, immunophenotypical and genomical abnormalities. However, no transcriptional analysis of MSC from MDS has been described yet. *Aim.* To compare the gene expression profile by microarray approach of MSC from 5q- syndrome, low-grade MDS and healthy controls and to establish a distinctive molecular signature between those groups. *Methods.* Fifteen samples from 5q- syndrome (n=6), other low-grade MDS ([oMDS],n=6; 3 RA, 2 RARS and 1 RCMD) and healthy donors (HD,n=3) were isolated and *in vitro* expanded following standard procedures. After the third passage, total RNA was isolated using TRIzol reagent (Invitrogen) and their integrity was confirmed by the RNA 6000 Nano kit (Agilent Technologies Inc). Labeled samples were hybridized to Affymetrix Human Gene 1.0 ST arrays (Affymetrix Inc). Using SPOTFIRE 9.1 (TIBCO Software Inc), we selected those markers with the following conditions: an ANOVA test between HD, oMDS and 5q- subgroups <0.05 and a fold change value between HD vs. oMDS+5q- >1.5, calculating the whole signature of HD/oMDS/5q- through a hierarchical clustering analysis (HCA). These selected genes were analyzed by the Ingenuity Pathway software (Ingenuity Systems®). Additionally, relative expression of several markers were confirmed by quantitative PCR using commercial TaqMan® assay (Applied Biosystems®). *Results.* Based on 190 selected probesets, we observed three main MSC subgroups in the HCA: one including all HD and three 5q- samples, a second one including the another three 5q- and one RA samples and the third one including the other MSC from low-grade MDS. Similar pattern was obtained when HCA was performed by including all probesets with an ANOVA value >1.5, independently of the fold changes between subgroups. When these 190 probes, including 153 known genes, were analyzed with the Ingenuity software, we observed several affected networks related to cellular movement, cell cycle, DNA replication, recombination, cellular assembly and organization. The main altered functions in MSC from MDS+5q- in comparison to HD were: cellular growth and proliferation, connective tissue development and function and changes in tissue morphology (quantity and density). Genes related to these processes were: ANGPT1, APC, CCND1, ENC1, IL6ST, LIFR, PIK3CA, RB1CC1, RMI1, TRPM7 (overexpressed in MSC from MDS) and BCL6,

COL14A1, DBC1, KLF4, PTGER4, PTGS2, SFRP4, SPRY2, TRIB1,WISP2 (underexpressed in MSC from MDS). Similar results were obtained when cDNA from the same MSC samples were tested with real-time PCR approach. MSC from 5q- patients showed an expression profile slightly different than low-grade MDS (i.e. higher CCND1, and lower ANGPT1, LIFR, PIK3CA, RB1CC1, SLPI and SFRP4) and resembing HD expression profile with similar ANGPT1, IL6ST, LIFR, PIK3CA, RB1CC1, RMI1, SPRY2 expression than normal controls. *Summary*. We conclude that MSC from low-grade MDS showed a distinctive gene expression profile in comparison to those from healthy donors, mainly involving signalling pathways related to proliferation, apoptosis, angiogenesis and multilineage differentiation. Additionally, MSC from 5q- syndrome displayed an intermediate profile between low-grade MDS and healthy controls.

0323

C-CBL MUTATIONS IN DE NOVO MDS AND CMML AT BOTH DIAGNOSIS AND AML TRANSFORMATION: A COMPARATIVE ANALYSIS ON 76 MATCHED PAIRED MARROW SAMPLES

LY Shih,[1] S Ogawa,[2] DC Liang,[3] M Sanada,[2] CL Lai,[4] EH Lee,[3] MC Kuo,[1] CF Huang,[1] TL Lin,[1] JH Wu[1]

[1]*Chang Gung Memorial Hospital, Taipei, Taiwan;* [2]*Cancer Genomics Project, University of Tokyo, Tokyo, Japan;* [3]*Mackay Memorial Hospital, Taipei, Taiwan;* [4]*Chang Gung University, Taoyuan, Taiwan*

Background. Somatic C-CBL mutations have been described in chronic myelomonocytic leukemia (CMML), myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) at initial diagnosis. The molecular basis of the progression of MDS or CMML to AML remained to be determined. Recent studies on C-CBL mutations in MDS or CMML were carried out either at initial presentation or only at AML transformation. The role of C-CBL mutations in MDS /CMML to AML transformation is not defined yet. *Aims.* We aimed to analyze C-CBL mutations on paired samples of MDS and CMML at both diagnosis and AML transformation to determine their roles in AML progression and also to correlate the C-CBL mutation status with clinical outcome. *Materials and Methods.* Seventy-six matched paired bone marrow samples including 47 high risk MDS (15 RAEB1, 18 RAEB2 and 14 RCMD)/AML and 29 CMML (17 CMML1 and 12 CMML2)/AML were analyzed for C-CBL mutations. Mutational analysis was performed by DHPLC and/or direct sequencing of all RT-PCR or DNA-PCR products amplified with different primer pairs covering the coding sequences of exon 7 to exon 9 of C-CBL gene. *Results.* Three (one each with RAEB1, RAEB2 and RCMD) of 47 patients with MDS had C-CBL mutations at initial diagnosis, including one homozygous mutation located in Linker region (Y371S) and another two heterozygous mutations located in the Ring finger domain (P418S and G415S). At AML transformation, all 3 patients carrying C-CBL mutations at initial presentation retained the identical C-CBL mutations and one with heterozygous G415S mutation at diagnosis exhibited homozygous pattern at AML phase. Additional 3 patients acquired heterozygous mutations (L399V, L370_Y371 insL, and C416W, respectively) during AML progression. Of the 29 patients with paired CMML/AML samples, 3 had C-CBL mutations at diagnosis, two were homozygous for I383L and I383R. The one with I383L also harbored a heterozygous Q367P mutation at diagnosis, she had a retention of the homozygous I383L but lost Q367P at AML phase. The remaining one had heterozygous G418S at both phases of disease. None of the CMML patients acquired new mutations during AML evolution. Analysis of clinicohematologic variables revealed no significant differences in age, gender, hemoglobin level, platelet count, percentage of blasts in bone marrow or blood, WHO subtype, cytogenetics or IPSS, except that C-CBL mutation-positive patients had a higher WBC count in CMML (P=0.039), but not in MDS. The mutation status did not influence outcome in terms of risk of AML transformation and overall survival in patients with MDS or CMML. *Conclusions.* Our results showed that acquisition of C-CBL mutations might occur during AML evolution in MDS, whereas C-CBL mutations were always present in both CMML and AML clones for individual patients. Clonal expansion was also observed in a subset of AML patients derived from MDS or CMML.

Supported by grants NHRI-EX99-9711SI and MMH-E-97009.

INTERIM ANALYSIS OF THE USE OF 5-AZACYTIDINE FOR TREATMENT OF MYELODYSPLASTIC SYNDROME/ACUTE MYELOID LEUKAEMIA WITH CHROMOSOME 7 OR COMPLEX CYTOGENETIC ABNORMALITIES

R Yiu, ZY Lim, AY Ho, R Ireland, J Marsh, P Pasipanodya, J Hayden, G Mufti

King's College Hospital, London, UK

Background. Chromosome 7 anomalies are well known to confer an adverse prognosis in patients with myelodysplastic syndrome (MDS). Preliminary data from various groups suggested that the use of 5-azacytidine, which is a DNA methyl transferase inhibitor, may improve clinical outcome in this group of poor risk patients. *Aims.* We report on the interim results of an open-label single-centre study designed to evaluate the clinical and haematological outcomes in MDS patients with chromosome 7 anomalies alone or with complex cytogenetic abnormalities treated with 5-azacytidine. (ClinicalTrials.gov NCT00915785). *Methods.* A total of 40 patients were enrolled in this study and received 5-azacytidine 75 mg/m^2 per day subcutaneously for 7 days with each cycle to be repeated every 28 days. Informed consents were obtained from all patients. Clinical, haematological and cytogenetic assessments were recorded and analyzed. Response criteria were based on the modified IWG response criteria for MDS. Seven of these patients received only 1 cycle of treatment and were then excluded from the final analysis. Six patients proceeded to allogeneic stem cell transplantation and their data were censored at the time of transplant. *Results.* The median age of the cohort (n=40) was 64 (range 17-82). Based on WHO classification, 1 patient had RARS, 7 had RCMD, 26 had RAEB I/II and 6 had acute myeloid leukaemia transformed from MDS. The IPSS of the cohort were Intermediate-2 (n=27) and high risk (n=13). Twelve patients had isolated chromosome 7 anomalies (including monosomy 7 and deletion of 7q) and 28 had chromosome 7 abnormalities as part of a more complex cytogenetic profile. Median number of treatment cycles delivered was 6 (range 1-21). Based on the modified IWG response criteria, 4 patients achieved complete response (CR), 6 had partial response (PR) and a further 4 had haematological improvement (HI). The overall response rate (ORR=CR+PR+HI) was 42% (5/12) for isolated chromosome 7 anomalies and 32% (9/28) for chromosome 7 with additional cytogenetic abnormalities. Complete cytogenetic response was observed in 5 patients and partial cytogenetic response in another 8 patients. The median overall survival (OS) was 10.5 months (n=33). There was no significant difference in survival between the patients with isolated chromosome 7 anomalies and those with more than one cytogenetic abnormalities (median OS: 10.5 vs 9.7 months, P=0.8). The ORR were 50% (5/10) and 39% (9/23) for these 2 groups respectively. The median OS were 12.1 months for responders and 7.9 months for non-responders (P=0.05). Total 13 patients achieved cytogenetic response and their median OS was 14.1 months compared with 8.2 months for those without any cytogenetic response (P=0.01). *Conclusions.* The interim results of this study indicate that the use of 5-azacytidine is associated with a high overall response and cytogenetic response in MDS patients with chromosome 7 abnormalities. Significantly, attainment of overall response or cytogenetic response correlates with an improved OS.

0325

HIGH FREQUENCY OF THE NQO1 C609T HOMOZYGOUS MUTANT GENOTYPE IN PATIENTS WITH MYELODYSPLASTIC SYNDROME AND ISOLATED TRISOMY 8

S Zachaki,[1] C Stavropoulou,[2] V Georgakakos,[2] H Orphanidou,[3] K Manola,[2] C Sambani[2]

[1]*NCSR Demokritos, Athens, Greece;* [2]*Laboratory of Cytogenetics, NCSR Demokritos, Aghia Paraskevi, Athens, Greece;* [3]*Health Care Unit, NCSR Demokritos, Aghia Paraskevi, Athens, Greece*

Background. Models for the pathogenesis of myelodysplastic syndromes (MDS) imply the role of cumulative genetic and xenobiotic factors in genetically predisposed individuals. The widely expressed NAD(P)H:quinone oxidoreductase 1 (NQO1) enzyme is involved in the cellular response to oxidative damage protecting cells from quinones, the ultimate toxic metabolites after exposure to benzene. The encoding gene is subject to the genetic single nucleotide polymorphism C609T, changing the aminoacid sequence (Pro187Ser), resulting in enzymatic inactivation. Individuals homozygous for the mutant allele (T/T) completely lack NQO1 activity, whereas heterozygotes

(C/T) present threefold decreased enzymatic activity. We hypothesized that the *NQO1* gene polymorphism may predispose individuals to a greater risk of MDS and/or promote specific types of chromosome aberrations in myeloid malignancies. *Aims.* To investigate the potential role of NQO1 C609T inborn polymorphism in MDS pathogenesis, we performed a case-control study analyzing the *NQO1* genotypic distribution in a large group of Greek patients with primary MDS. We next compared the genotypic frequencies in patients with isolated +8, del(5q) and -7/del(7q), since these represent the commonest unbalanced aberrations in MDS and may indicate prior exposure to xenobiotics. *Methods.* The NQO1 C609T polymorphism was investigated in 261 MDS patients and 270 matched healthy controls using a PCR-RFLP assay. It was evaluated in respect to patient characteristics, chromosome abnormalities and IPSS classification. The *NQO1* genotype was additionally investigated in 66 MDS patients carrying the recurrent unbalanced abnormalities +8, del(5q) and -7/del(7q) as sole abnormalities. *Results.* A cytogenetic result was achieved in 255 out of 261 patients at diagnosis. Among them, 103 (40.4%) showed clonal karyotypic abnormalities. The most frequently observed single abnormality was trisomy 8 (25/255, 9.8%). The distribution of the *NQO1* genotypes did not differ significantly between MDS patients and controls (homozygous wild type (C/C) 65.1 vs 61.2%; heterozygotes (C/T) 33 vs 37%; homozygous mutant (T/T) 1.9 vs 1.8%). Stratification of patients according to gender, age, cytogenetic and IPSS groups revealed no differences in the mutant (C/T and T/T) genotypic frequencies. To investigate the impact of *NQO1* polymorphism in the pathogenesis of certain recurrent karyotypic imbalances, we additionally analyzed 66 MDS patients with +8 (n=30), del(5q) (n=29) and -7/del(7q) (n=7) as sole abnormalities. We observed no differences in the frequencies of NQO1 polymorphism between patients with del(5q) and healthy controls. On the contrary, the NQO1 polymorphism was associated to an increased risk of MDS with isolated chromosome 7 abnormalities (P=0.033). Moreover, an increased frequency of the homozygous mutant genotype (T/T) was observed in patients with isolated trisomy 8, as compared to the controls (10% vs 1.8%, P=0.032). *Summary/Conclusions.* Our results show that the *NQO1* C609T polymorphism does not correlate with susceptibility to MDS. The high incidence of NQO1 mutant genotype in patients with -7/del(7q) is noteworthy, since chromosome 7 aberrations in primary MDS are indicators of previous exposure to benzene. The high frequency of the homozygous mutant genotype in our patients with isolated trisomy 8, reflecting lack of NQO1 enzyme activity, might confer a subgroup with defined prognostic significance within the heterogeneous population of +8 patients.

0326

COSTEFFECTIVENESS OF AZACITIDINE FOR THE TREATMENT OF IPSS INT-2 OR HIGH-RISK MYELODYSPLASTIC SYNDROMES IN THE UK

N Brereton,[1] A Murthy,[2] R Akehurst[3]

[1]BresMed Health Solutions, Sheffild, UK; [2]Celgene, Boudry, Switzerland; [3]University of Sheffield, Sheffield, UK

Introduction: Myelodysplastic syndromes (MDS) are fatal, progressing hematological malignancies affecting approximately 1 in 30,000 people in the UK. There is considerable unmet treatment need in patients, owing to the high morbidity, transfusion burden, risk of progression to acute myeloid leukemia (AML) and high mortality. A recently published (Fenaux *et al*, 2009) phase III, randomized, international, parallel-group, open-label trial (AZA-001) in IPSS Int-2 or High-risk patients with MDS showed a 2-fold increase in 2-year overall survival (OS) with azacitidine (AZA, 51%) compared with conventional care regimens (CCR, 26%), which comprised low-dose cytarabine (LDAC), intensive chemotherapy (IC) and best supportive care (BSC). AZA also was associated with a significantly reduced risk of progression to AML (HR: 0.50, 95% CI: 0.35-0.70) and a significant reduction in transfusion dependence compared with CCR. AZA is a cytidine nucleoside analog that appears to exert disease-modifying effects in MDS. *Aim.* The aim of this analysis was to evaluate the incremental cost-effectiveness ratio (ICER) of AZA compared with combined CCR and with LDAC, IC or BSC individually in the UK. *Methods.* A lifetime Markov cohort-based decision-analytic model was developed to examine the effect of treatment on patients with IPSS Int-2 or High-risk MDS. OS rates were extrapolated from the AZA-001 study. Health utility scores were mapped from the European Organisation for Research and Treatment of Cancer (EORTC) quality of life (QoL) scores collected during the Cancer and Leukemia Group B (CALGB) study 9221 reported elsewhere (Silverman *et al,* 2002). Resource usage was estimated from a survey of UK hematologists. The ICER assessed the incremental cost per quality-adjusted life-year (QALY) gained. A probabilistic sensitivity analysis using Monte Carlo simulation was used to evaluate uncertainty of the parameters included in the model. The analysis also includes the recent methodological guidance that has been issued by the National Institute for Health and Clinical Excellence (NICE) in the UK regarding the assessment of certain life-extending medicines. *Results.* The results show that AZA provides a significant incremental OS gain of more than 2 years versus CCR, and patients also have an improved QoL demonstrated by QALY gains of 1.68 compared with BSC, 1.83 compared with LDAC and 1.84 compared with IC. These results lead to an ICER of £37,105 per QALY compared with IC, £40,754 compared with LDAC, and £47,432 compared with BSC. Given the poor prognosis for patients with IPSS Int-2 or High-risk MDS and the ability of AZA to significantly extend OS in this population, the application of end-of-life valuation methodology as guided by NICE reduces the ICERs to £26,504 per QALY compared with IC, £29,110 compared with LDAC and £33,880 compared with BSC. Sensitivity analyses suggest that the cost-effectiveness results are significantly influenced by the choice of the parametric curve fit used to extrapolate OS, and the health utility scores. *Conclusions.* Compared with combined CCR, AZA offers an innovative, cost-effective treatment option for patients with IPSS Int-2 or High-risk MDS in the UK. Treatment with AZA significantly increases QoL in a disease with a poor prognosis and with associated morbidity.

Hematology, Bucharest, Romania; [11]Dep. Internal Medicine I, Div. Hematology & Hemostaseology, Düsseldorf, Germany; [12]CHU Purpan Pavillion de Médecines, Toulouse, France; [13]Dept of Haematology, Leeds General Infirmary, Leeds, UK

Background. To describe the demographics, the disease-management and the clinical outcome in Myelodysplastic Syndromes (MDS) a prospective, multicenter European Registry (EUMDS) for newly diagnosed IPSS low and intermediate-1 patients has been initiated under the auspices of the European LeukemiaNet. *Aims.* As data on health-related quality of life (QoL) in MDS patients are rare, the EQ-5D (European quality group 5 dimensions) descriptive system was introduced in the EUMDS evaluation. The performance status was assessed by the Karnofsky score and comorbidities at diagnosis were assessed by the Sorror index. *Methods*. In 322 out of 400 EUMDS patients analyzed so far the EQ-5D score has been applied at initial presentation. *Results.* The median age was 74 yrs (female 75.2; male 73.5) with 203 (63%) male patients. Comorbidities were detected in a substantial proportion of patients (mean Sorror score 2.4, range (0 to 11). Whereas a reduced performance status as defined by a Karnofsky Index £ 70 was detected only in 20% of MDS patients, an impaired QoL was observed in a greater proportion of patients. Using EQ-5D the dimensions mobility, self-care, usual activities and pain/discomfort were clearly age-dependent. No problem (Level 1) was detected in 80, 96, 50 and 58% of 50-59 years old persons, whereas the cohort of 70-79 years old revealed a lower percentage of 55, 80, 66 and 51% respectively. Similarly the self-reported health as assessed by a visual analogue scale (VAS) was lower in elderly patients; mean score of 74 (standard deviation (sd) 19.0) in 50-59 yrs, 73 (21.3) in 60-69 yrs, 66 (22.2) in 70-79 yrs and 62 (20.3) in 80+ yrs. Moreover, analyses revealed pronounced sex differences in distinct dimensions as no problem (Level 1) was detected in 58% male and 45% female patients in the dimensions mobility (P<0.05), in usual activities 70 vs 54% (P<0.001), in pain/discomfort 56 vs 41% (P<0.05) and in anxiety/depression 69 vs 45% (P<0.001). In contrast this effect was less pronounced in the dimension self-care as Level 1 was detected in 86% of male and 80% of female patients (ns). The EQ-5D status was reported in 10 different countries contributing to this registry. The mean

EQ- 5D VAS score was 68 (sd 21.9) and ranged from 52 (sd 16.4) in Austria to 84 (13.1) in Greece. This difference might be explained by intercountry, cross-cultural differences or differences in patient recruitment by country. *Summary/Conclusions*. This is the first prospective analysis of health-status and QoL in a large cohort of newly-diagnosed MDS patients. Relevant restrictions in self-reported health are shown in MDS patients. In the evaluation of QoL in MDS age- and gender effects as well as possible cross-cultural differences should be considered and integrated. EQ-5D value sets, representing the general population from European countries will allow comparisons to be made between the general population and patients with MDS and will contribute to understand the impact of MDS on QoL. EQ-5D will be prospectively reassessed 6-monthly in all patients continuing follow up in the registry.

0328

RED BLOOD CELL (RBC) ALLOIMMUNIZATION AFTER BLOOD TRANSFUSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS) OR CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML)

M Nomdedeu,[1] C Sanz,[1] D Abelló,[2] C Franquet,[1] F Cobo,[1] M Belkaid,[3] M Rozman,[1] JL Aguilar,[1] B Nomdedeu,[1] A Pereira[1]

[1]Hospital Clinic, Barcelona, Spain; [2]Hospital de Santa Tecla, Tarragona, Spain; [3]Universitat de Barcelona, Barcelona, Spain

Background. RBC alloimmunization is a major problem in chronically transfused patients because it exposes the blood recipient to the risk of delayed hemolytic reactions and makes it difficult to find compatible blood. *Aim.* To determine the incidence and characteristics of RBC antibodies in chronically transfused patients with MDS or CMML. *Material and Methods.* We reviewed the transfusion and clinical records of 337 patients with MDS or CMML seen at our hospital from 1990 to 2009. Patients were included if they had received ≥2 RBC transfusions, at least one month had elapsed from first to last transfusion, and no RBC antibody was detected at first transfusion. Testing for RBC antibodies was performed prior to each transfusion. For the purpose of this study only RBC antibodies of IgG class, usually of immune nature, were taken into account. Complex immunization was defined as the appearance of free autoantibody in serum or a combination of alloantibodies that decreased the probability of finding compatible blood below 3%. The cumulative incidence of RBC immunization was calculated by taking death as a competing risk. Incidence rates were compared by Poisson multivariate regression. *Results.* 272 patients met the eligibility criteria. Median age was 75 (16-99) years and 149 (55%) were males. The most frequent diagnoses were refractory cytopenia with multiliniage dysplasia (RCMD, n=85), type 2 refractory anemia with excess blasts-2 (RAEB-2, n=45), type 1 chronic myelomonocytic leukemia (CMML-1, n=37), refractory cytopenia with multiliniage dysplasia and ringed sideroblasts (RCMD-RS, n=30), and other types of MDS (n=75). Median follow-up from first transfusion was 1.4 (range: 0.1-19) years, and the median number of RBC units transfused per patient was 33 (range: 4-330). Forty-five patients formed 81 alloantibodies and 10 autoantibodies, and 11 evolved into a complex immunization. Twenty-two patients formed one antibody, 11 formed two, and 12 formed three or more antibodies. Anti-K1 and anti-E were the most frequent individual specificities (26 and 19, respectively), followed by anti-c (6) and anti-Jka (5). In 26 (59%) patients, all the alloantibodies they formed were directed against the K1 or antigens of the Rh system. In 7 out of the 10 cases with autoantibody, the latter was detected in patients already alloimmunized. The incidence rate of antibody formation was 1 per 10.5 person-years of follow-up and was not influenced by sex, age or cytologic diagnosis after adjustment for the number of transfusions. The cumulative incidence of presenting at least one antibody increased with the number of RBC transfusions; it was 14% (95%CI: 10%-19%) after 28 RBC units and reached a plateau at 19.5% (95%CI: 14%-23%) after 130 RBC units. At that time, the cumulative incidence of complex immunization was 6%. *Conclusions.* Patients with MDS and CMML exhibit a high rate of RBC immunization, which appears soon after starting on chronic transfusion support and is mostly directed against the K1 and antigens of the Rh system. It is conceivable, therefore, that transfusing these patients with extended compatibility, including the K1 and CcEe antigens, would yield a substantial reduction of the RBC alloimmunization rate.

FISH AND IMMUNOPHENOTYPE IN ELDERLY UNTREATED MULTIPLE MYELOMA PATIENTS ENTERED IN A PROSPECTIVE RANDOMIZED TRIAL OF VELCADE-MELPHALAN-PREDNISONE AND THALIDOMIDE VS VELCADE-MELPHALAN-PREDNISONE

S Caltagirone,[1] M Ruggeri,[1] M Gilestro,[1] S Aschero,[1] C Nozzoli,[2] R Ria,[2] D Rossi,[2] M Boccadoro,[1] A Palumbo,[1] P Omedè[1]

[1]A.O.U. San Giovanni Battista, Torino, Italy; [2]Italian Multiple Myeloma Network, Gimema, Italy

Background. Recurrent chromosomal abnormalities have been identified in Multiple Myeloma (MM) and these have been related to clinical course and response to therapy. Moreover, the clinical and prognostic value of immunophenotyping in MM have been demonstrated by many studies. *Aims.* To evaluate chromosomal abnormalities and immunophenotype in a large series of elderly MM patients and the correlation between different parameters in order to identify new prognostic characteristics related to response to therapy. *Methods.* Between May, 2005 and January, 2009, 511 patients aged ≥ 65 years were randomized to receive VMPT-VT (N=254) or VMP (N=257). In 336 patients FISH analysis was performed on bone marrow plasma cells (BMPC) purified using anti-CD138-coated magnetic beads. Nuclei from fixed PC were prepared for interphase FISH using standard *Methods.* DNA probes were used to detect 13q14, 12p13, 1p36 and 17p13.1 deletions; t(4;14)(p16;q32), t(14;16)(q32;q23), t(11;14)(q13;q32); 11q23 (MLL) and 1qter gains. Ploidy status was analyzed by chromosome 9,11,15 enumeration. The immunological phenotype of BMPC was assessed in 399 patients using triple or quadruple combinations of MoAbs for the detection of the following antigens: CD38, CD138, CD56, CD45, CD40, CD19, CD20, CD52, CD117, kappa/lambda. *Results.* In 90% of all patients at least one chromosomal abnormality was found. Del13 was identified in 53.9% of all patients. A significant correlation was observed between del13 and higher levels of LDH (P=0.009) and beta2-microglobulin (P=0.03), lower levels of Hgb (P=0.002) and female gender (P=0.02). Moreover, BMPC with del13 were more frequently CD45 and CD19 negative (P=0.003 and P=0.006, respectively) and correlate with delp53 and t(4;14)(P=0.005 and P=0.0002, respectively). Delp53 was found in 16.4% of all patients and no significant correlation was found according to clinical and phenotypic parameters. 18.9% of all patients showed t(4;14) and a significant correlation was found with t(14;16) (P=0.00003) and lower levels of CD117 (P=0.00001). t(14;16) was detected in 9.8% of 173 patients and showed lower expression of CD45 e CD19 (P=0.01 and P=0.02, respectively).

Table 1.

	VMPT-VT			VMP		
%	CR+VGPR	No CR+VGPR	*P* Value	CR+VGPR	No CR+VGPR	*P* Value
CD20 mean expression	8.8	16.3	0.007	10.3	18.4	0.01
CD117mean expression	17.4	25.2	0.04			ns
CD45 mean expression			ns	9.2	15.2	0.02
CD19 mean expression			ns	18.6	26.7	0.01
t(11;14)+ patients	8.6	27	0.001			ns
non-hyperdiploid patients	51.3	81.8	0.02			ns

The presence of t(11;14) was found in 16.2% of all patients and has been associated with lower levels of CRP (P=0.0002) and higher expression of CD20 (P=0.000001). Deletion of 12p13 and 1p36 was identified in 15.6% and 20.6% of 109 and 50 patients, respectively. Gain of 11q23

e 1q21 was found in 57% and 42% of 159 and 50 patients, respectively. Ploidy status was analyzed in 105 patients and 59.1% showed a non-hyperdiploid status. Significantly higher expression of CD20 was identified in patients not achieving CR+VGPR, in both VMPT-VT and VMP groups. Other phenotypic and cytogenetic features significantly correlating with response to therapy are shown in Table1. *Conclusions.* Our results indicate that: 1- Higher expression of CD20 negatively influences the response to therapy in both arms. 2- Higher expression of CD117, higher frequency of t(11;14) and non-hyperdiploid status correlate with absence of CR+VGPR only in VMPT-VT arm. 3- Higher expression of CD45 and CD19 correlates with absence of CR+VGPR only in VMP arm.

0330

ANALYSIS OF CIRCULATING MICRORNAS EXPRESSION PROFILE IN PATIENTS AFFECTED BY MULTIPLE MYELOMA AND MGUS

C Carniti, A Bermema, A Raganato, V Montefusco, M Morelli, F Spina, S Gimondi, P Corradini

Fondazione Istituto Nazionale Tumori, Milano, Italy

Background. Recent studies of microRNA (miRNA) expression profile performed on neoplastic plasmacells have demonstrated that miRNAs are involved in Multiple Myeloma (MM) pathogenesis. However to date, little is known about the role of circulating miRNAs in this malignancy. It has been shown that miRNAs circulate in a stable cell-free form in the blood-stream so that they can serve as ideal biomarkers for cancer. *Aim of the study*. To investigate the expression of miRNAs in the plasma of newly-diagnosed Myeloma patients and to detect a characteristic circulating miRNA signature to use for disease monitoring. *Methods*. We have developed a method for isolating miRNAs from blood plasma by modifying mirVana™ miRNA Isolation Kit (Ambion Inc). MicroRNAs have been isolated from peripheral blood (PB) plasma as well as from bone marrow (BM) blood plasma and CD138+ malignant plasmacells. The miRNAs expression profile has been examined using a quantitative PCR-method (TaqMan® Human microRNA cards, Applied Biosystems) that allows the analysis of 365 human miRNAs by low density array technology. Plasma samples of normal subjects have been included in the study. Relative quantification of miRNA expression has been calculated with the 2-ΔΔCt method. The data have been normalized respect to MammU6 and relative to a calibrator sample (average of normal subjects plasma samples). Differentially expressed miRNAs have been identified using "Significant Analysis of Microarrays"(SAM) algorithm, the t test and the nonparametric Wilcoxon rank sum test. The data have been analysed comparing the results with the $CD138^+$ malignant plasmacells miRNA signature reported in the literature. *Results.* We have analyzed the plasma of 10 healthy donors, 5 MGUS patients and 15 newly diagnosed myeloma patients. The miRNA expression profile observed in the peripheral blood plasma faithfully traces that of the bone marrow plasma and that of $CD138^+$ isolated plasmacells. The comparison of the miRNA expression profiles revealed a group of 47 miRNAs that are overexpressed in the plasma of patients versus healthy donors. Among these, a group of 9 miRNAs are upregulated in the plasma of both MGUS and myeloma patients, with a higher expression in the latter group. Six circulating miRNAs are specifically upregulated in MGUS patients whereas the remaining 32 miRNAs are found at high levels only in the plasma of myeloma patients but not in the MGUS group. Seven of the upregulated miRNAs detected in our study have been previously seen deregulated also in the plasmacells1. Among them, hsa-miR-191 that targets CDK6 and hsa-miR-197 that targets the tumor suppressor FUS1, are highly upregulated in the plasma of myeloma patients ($P<0.001$ and $P=0.05$ respectively). *Conclusions.* Specific miRNAs can be detected and quantified in the plasma of myeloma patients. Although very preliminary, these data suggest that the levels of differentially expressed miRNAs can significantly distinguish healthy donors from patients and MGUS from myeloma patients. This analysis could potentially represent a method to assess response to therapy in myeloma disease.

0331

MULTIPLE MYELOMA MMUNOGLOBULIN SEQUENCES SHOW NO INTRA-DISEASE CLUSTERING BUT ARE OCCASIONALLY RELATED TO REPERTOIRES FROM NORMAL LYMPHOCYTES AND OTHER B-CELL TUMORS

S Ferrero,[1] D Capello,[2] M Svaldi,[3] M Boi,[4] D Gatti,[3] D Drandi,[4] L Monitillo,[4] S Bussano,[4] S Barbiero,[4] C Lobetti Bodoni,[4] F Bertoni,[5] E Zucca,[5] V Gattei,[6] A Palumbo,[4] M Boccadoro,[4] S Cortelazzo,[3] G Gaidano,[2] M Ladetto[4]

San Giovanni Battista, Turin, Italy; [2]Division of Hematology, BRMA - Amedeo Avogadro University of Eastern Piedmont, Novara, Italy; [3]Department of Haematology and Bone Marrow Transplantation, Regional Hospital, Bozen, Italy; [4]Division of Hematology, University of Torino, A.O.U. San Giovanni Battista, Turin, Italy; [5]Lymphoma Unit, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland; [6]Clinical and Experimental Onco-Hematology Unit, Centro di Riferimento Oncologico, Aviano (PN), Italy

Background. The characterization of stereotyped immunoglobulin receptors has improved our knowledge on the antigen-driven pathogenesis of several lymphoid tumors, including chronic lymphocitic leukemia (CLL), marginal-zone lymphoma (MZL) and mantle-cell lymphoma (MCL). Multiple myeloma (MM) is a post-germinal center neoplasm no longer expressing membrane-bound immunoglobulins; however antigen stimulation might have played a role during early disease phases. Immunoglobulin heavy chain (IGH) genes have not been extensively investigated in MM, because of lack of large sequence databases. *Aims.* To address this issue, we created a database of MM sequences including our institutional records as well as sequences available from the literature. We planned a two-step analysis, characterizing first the MM repertoire and performing intra-MM clustering analysis; then comparing the MM series to a large public database of IGH sequences from neoplastic and non-neoplastic B-cells. *Patients and Methods.* 131 MM IGH genes were amplified and sequenced at our Institutions, as described (Voena *et al*., Leukemia 1997). 214 MM IGH sequences were derived from published databases (NCBI-EMBL-IMGT/LIGM-DB) for a total of 345 fully interpretable MM sequences. 28590 IGH sequences from other malignant and non-malignant B-cells were retrieved from the same public databases. All the sequences were analyzed using the IMGT database and tools (Lefranc *et al.*, Nucleic Acid Res. 2005; http://imgt.cines.fr/) to identify IGHV-D-J gene usage, to assess the somatic hypermutation (SHM) rate and to identify HCDR3. HCDR3 aminoacidic sequences were aligned together using the ClustalX 2.0 software (Larkin *et al*., Bioinformatics, 2007; http://www.clustal.org/). Subsets of stereotyped IGH receptors were defined according to Messmer *et al.* (J Exp Med., 2004) and Stamatopoulos et al. (Blood, 2007). *Results.* IGHV-D-J usage and HCDR3 lenght in MM was more in keeping with the normal B-cell repertoire compared to other lymphoid tumors, with only modest over-representation of IGHV3-9, IGHV3-21, IGHV5-51 genes and under-representation of the IGHV3-23 and IGHV4-34; 98% of MM sequences showed a SHM rate >2% with one single patient sharing 100% identity to germline. Intra-MM search for HCDR3 similarity never met minimal requirements for stereotyped receptors. When MM sequences were compared to the public database, only a minority of sequences (2.9%) clustered with those from lymphoid tumors and normal B-cells (Table 1).

Table 1.

Table 1: Mixed clusters of immunoglobulin sequences between multiple myeloma (MM) and normal or neoplastic B-cells

Source of immunoglobulin sequence	Number of sequences analyzed	Number of MM clustering with other sequences	% of present MM database clustering with other sequences	MM: probability of clustering with other sequences
Non neoplastic B-cell	24085	3 (3*)	0.9%	1.2×10^{-4}
Chronic lymphocitic leukemia	3185	5 (3*)	1.5%	1.6×10^{-3}
Marginal-zone lymphoma	195	1 (1*)	0.3%	5.1×10^{-3}
Mantle-cell lymphoma	104	0	0%	0

* Newly identified provisional clusters

Specifically two MM sequences could be assigned to previously identified CLL subsets (n.37 and n.71 according to Murray *et al*., Blood 2008). In addition, three mixed MM/CLL and one MM/MZL provisional clusters were identified. Finally three provisional clusters were found between MM and IGH sequences from normal B-cells. *Conclusions.* The

analysis of the largest currently available database of MM IGH sequences indicate the following: 1) MM IGH repertoire follows a nearly physiological distribution; 2) MM specific HCDR3 clusters do not occur to a frequency detectable with currently available databases; 3) 98% of MM sequences are not related to other "highly-clustered"lymphoproliferative disorders; 4) Occasional clustering of MM with immunoglobulin receptors from normal and (at a slightly higher frequency) neoplastic lymphocytes was noticed. In conclusion, our analysis does not support a critical role for antigen selection in the majority of MM patients.

0332

EXPRESSION OF MET MRNA AS PROGNOSTIC MARKER IN MULTIPLE MYELOMA PATIENTS TREATED WITH NOVEL DRUGS

A Rocci,[1] M Gambella,[1] L Trusolino[2], F Gay,[1] P Omedè,[1] V Magarotto,[1] A Bertotti,[2] V Montefusco,[3] C Crippa[3], F Patriarca[3], M Gilestro,[1] AM Liberati,[3] G Gaidano,[3] F Di Raimondo,[3] A Falcone[3], G Rossi,[3] D Drandi,[1] P Corradini,[3] M Ladetto,[1] P Comoglio,[2] M Boccadoro,[1] A Palumbo[1]

[1]A.O.U. San Giovanni Battista, Torino, Italy; [2]Istituto per la Ricerca e la Cura del Cancro, Università di Torino, Candiolo, Italy; [3]Italian Multiple Myeloma Network, Gimema, Italy

Background. MET is the tyrosine kinase receptor for Hepatocyte Growth Factor (HGF). Its aberrant activity has been reported in several tumors including multiple myeloma (MM) where bone marrow (BM) microenvironment produces HGF to stimulate plasma cells growth and migration. In MM cell lines, the inhibition of this pathway causes growth arrest and cell death. *Aim.* to investigate the role of MET mRNA expression as predictor of response and as prognostic marker in MM patients treated with novel agents. Patients and *Methods.* eighty four newly diagnosed MM patients have been evaluated for MET mRNA expression and HGF serum level. Fifty one patients received the PAD-MEL100-LP-L regimen (Palumbo A, JCO 2010) and 33 received nine VMP courses (Palumbo A, 2009 ASH Meeting, abs 128). On BM CD138+ cells harvested at diagnosis, MET mRNA expression has been evaluated using a quantitative Real-Time PCR. Relative quantification of MET mRNA was performed using the ΔΔCt approach. JUM2 cell line was utilized as calibrator and Gus as housekeeping gene. The cut-off value of MET mRNA was selected according to ROC analysis on samples of patients treated with PAD-MEL100-LP-L schedule (learning series) and then validated on samples of patients treated with VMP (validation series). HGF serum value has been determined using ELISA assay. *Results.* Eighty four patients (39 female/45 male) with a median age of 69 yr (range 46-86) have been evaluated. No differences in baseline albumin, β2 μg, BM plasma cell infiltration and cytogenetic abnormalities have been observed between patients with high and low MET mRNA levels.

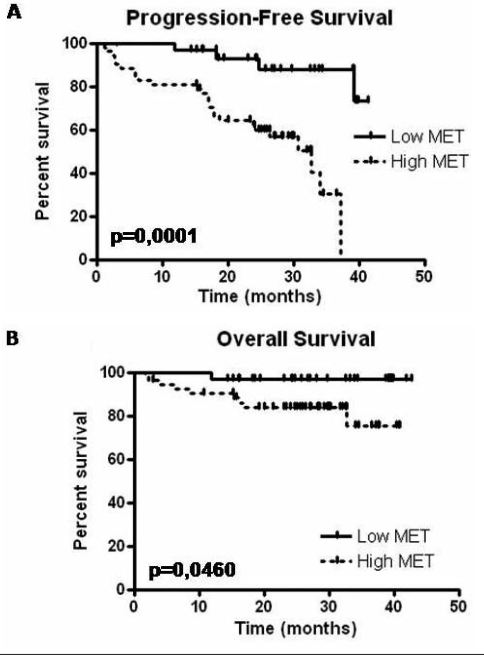

Figure 1.

Considering PAD-MEL100-LP-L patients, MET mRNA expression was significantly higher in those obtaining partial response (PR) or less, compared to patients achieving at least very good partial response (VGPR). In patients enrolled in the PAD-MEL100-LP-L trial this difference was observed after PAD-induction (median MET value 94.1 range 9.7-586.1 vs median 37.92 range 1.1-170.0, P=0.001) and was maintained after autologous bone marrow transplantation (ABMT) (median 148.6 range 27.1-586.1 vs median 65.8 range 11-466.3, P=0.007). In patients treated with VMP, MET mRNA level allowed to identify patients with differences in response rate although without reaching statistical significance. On the whole population of 84 patients, after a median follow-up of 27.7 months, the 2-year PFS in the low and in the high MET mRNA groups was 92% and 62% respectively (P=0.0001) (Figure 1A). The 2-year OS was 96.6% and 83,8% respectively (P=0.0460) (Figure 1B). The prognostic value of MET mRNA expression resulted stronger than those of β2 μg or cytogenetic abnormalities. Even a combined score of MET mRNA expression with any other biological parameter resulted less powerful compared to MET mRNA value alone. HGF serum values resulted similar in both optimal and sub-optimal responders and did not predict PFS and OS. *Conclusions.* 1) high MET mRNA expression level identifies a group of patients with suboptimal response and inferior PFS and OS in both ABMT- and non ABMT-based regimen; 2) high MET mRNA expression seems to be a hallmark of more aggressive disease thus MET can be considered a target for anti myeloma therapy.

0333

DEPLETION OF ONCOGENIC RAS ISOFORMS IMPAIRS SURVIVAL OF MULTIPLE MYELOMA (MM) INDEPENDENTLY OF AKT/PKB SIGNALING

T Steinbrunn,[1] T Stühmer,[1] M Chatterjee,[1] S Gattenlöhner,[2] H Einsele,[1] R Bargou[1]

[1]Internal Medicine II, Division of Hematology, University Hospital of Würzburg, Wuerzburg, Germany; [2]Institute of Pathology, University Hospital of Würzburg, Würzburg, Germany

Introduction: Oncogenic Ras is known to activate survival pathways in numerous cancer entities and N- or K-Ras mutations are also frequently found in MM. However, its precise role in MGUS to MM transition and tumor progression is still unclear and development of inhibitory drugs has so far not been successful, either. *Aims.* We were interested in analyzing the function of oncogenic Ras isoforms and their downstream signaling via Akt/PKB, which per se is an important survival pathway for about 50 percent of primary MM samples. *Methods.* We used shRNA expression constructs against N- or K-Ras to specifically knock down the respective Ras isoform in two N-Ras mutated, one K-Ras mutated, and two Ras wildtype MM cell lines. To control isoform specificity, we tested the shRNA effects on ectopically expressed HA-tagged Ras proteins. Transfection was performed by electroporation and subsequent enrichment through cell sorting. Signaling pathways were analyzed with Western blotting. Flow cytometry was used to measure the rate of apoptotic cells staining with Annexin-V-APC and propidium iodide. A series of different MM patient samples (n=35) were analyzed for Ras mutations by RT-PCR and were submitted to inhibition of Akt/PKB with the small molecule inhibitor Akti-1,2. Where corresponding bone marrow biopsies were available, they were screened for the presence of phosphorylated Akt by fluorescence immunohistochemistry (IHC). *Results.* Isoform-specific Ras knockdown impaired survival selectively in MM cell lines with the respective oncogenic isoform, but not in Ras wildtype cell lines. In particular, survival of the Ras wildtype AMO-1 and U266 cells remained unaffected by Ras depletion, while N-Ras knockdown induced apoptosis selectively in N-Ras mutated INA-6 and JJN-3 cells. Conversely, K-Ras mutated MM.1s cells were most responsive to knockdown of K-Ras. Phosphorylation of Akt (Ser473) was not decreased in Western blots, however. In addition, Ras mutation status in the tested primary MM samples (40% N- or K-Ras mutated) did not correlate with the presence of phosphorylated Akt as shown by IHC (60% positive), or with the sensitivity to Akti-1,2 (49% sensitive), all of which indicates that oncogenic Ras may not signal via the Akt/PKB pathway. Combined shRNA-mediated depletion of both oncogenic Ras and Akt significantly reduced the level of viability. *Conclusions.* Even though pharmacological inhibition of oncogenic Ras is currently not feasible, we show that specifically targeting oncogenic Ras isoforms impairs MM cell survival. This effect does not appear to be mediated through the Akt/PKB pathway, and constitutive Akt/PKB activation in primary MM does not appear to be a consequence of oncogenic Ras. Thus, finding ways to block oncogenic Ras function remains a therapeutically relevant scientific challenge, even more so because the combination with Akt blockade may increase the anti-myeloma effect.

0334

CENTROSOME AMPLIFICATION AS A POSSIBLE MARKER OF MYELOMA CELL PRECURSORS

F Kryukov, E Dementyeva, P Nemec, I Buresova, J Smetana, H Greslikova, R Kupska, P Kuglik, R Hajek

Babak Research Institute, Masaryk University, Brno, Czech Republic

Background Multiple myeloma (MM) is a lymphoproliferative disease characterized by the clonal expansion of neoplastic plasma cells within the bone marrow. Although PCs are recognized as fully malignant cells, the exact developmental stage at which malignant transformation occurs is still unknown. Several candidates for MM clonogenic population have been proposed; however, it is controversial whether clonogenic population is represented by B-cells or PCs, since majority of plasma cells are quiescent. In our study, centrosome amplification (CA) was chosen as potential precursor marker, reflecting mitotic disruption in carcinogenesis. *Aims.* The objective of our study was to evaluate the presence of CA in two populations of B-cell lineage - including B-cells and PCs - from MM patients and to assess whether it is associated with established prognostic factors, such as the most common chromosomal abnormalities in malignant PCs. *Methods*. Immunofluorescent labeling was used for the evaluation of centrosome amplification (CA) in B-cells ($CD19^+$) and PCs ($CD138^+$) of MM patients. Centrin (centrosome protein) copy numbers were used to define three cellular subpopulations: (1) no centrin signal (Non-CS), (2) 1-4 centrin signals (1-4CS) or (3) more than 4 signals of centrin (CA). Samples with ≥11% of B-cells or ≥10% of PCs with >4 fluorescence signals of centrin were considered CA positive. A total of 101 patients were evaluated for CA in PCs and/or B-cells, including 31 patients where both cell types were analyzed. The patient population characteristics were as follows: males/females 50/51, median age of 66 years (range, 40-92 years). Most patients had advanced stage of MM (DS II/III n = 69; ISS II/III n = 61). Interphase FISH with cytoplasmic immunoglobulin light chain staining (cIg FISH) was performed on plasma cells by well-known methods. *Results.* In our previous study, we showed the presence of centrosome amplification in B-cells of MM patients. The frequency of MM cases positive for CA was 34% (26/77) and 34% (18/53) based the analysis of PC samples and B-cell samples, respectively. Overall, 19% (6/31) of MM patients were double-positive. No significant correlation was identified between amount of CA positive PCs and B-cells ($p>0.05$). After splitting patients based on CA threshold, significant correlation was identified only in double-positive group ($r=-0,986$, $P<0.05$). Significant correlation of centrosome amplification in PCs with del(13)(q14), del(17)(p13), gain(1)(q21), or hyperdiploidy wasn't shown. But association of CA in B-cells with PCs hyperdiploidy using 4-point correlation was proven ($\phi=0.45$, $P<0.05$). *Conclusion.* In our study, we showed association of CA in B-cells with PCs hyperdiploidy. This fact relates to role of mitotic disruption in MM aneuploidy and cell carcinogenesis. In association with correlation between B-cells and PCs with CA, we suppose that B-cells with CA are part of myeloma genesis.

RESPONSE TO VELCADE-THALIDOMIDE-DEXAMETHASONE (VTD) AS INDUCTION TERAPHY IN MULTIPLE MYELOMA PATIENTS CARRYING T(4;14): ANALYSIS OF GENE EXPRESSION PROFILE

C Terragna,[1] S Durante,[1] D Remondini,[2] G Martinelli,[1] N Testoni,[1] G Marzocchi,[1] G Perrone,[1] E Zamagni,[1] P Tacchetti,[1] P Tosi,[1] L Pantani,[1] F Patriarca,[3] M Petrucci,[3] E Galli,[3] F Di Raimondo,[3] M Boccadoro,[3] P Musto,[3] M Baccarani,[1] M Cavo[1]

[1]Seràgnoli Institute of Hematology, Bologna, Italy; [2]Physics Department & CIG, Bologna, Italy; [3]GIMEMA Italian Myeloma Network, Bologna, Italy

Background. The recurrent immunoglobulin translocation t(4;14)(p16;q32) occurs in less than 20% of Multiple Myeloma (MM) patients and has been frequently associated with poor prognosis in patients treated either with conventional or high dose chemotherapy. The introduction of novel drugs, such as Thalidomide, Lenalidomide and Bortezomib, has been suggested to overcome the negative prognostic impact of high risk cytogenetic abnormalities; in particular Bortezomib has been shown to revert the negative role of the t(4,14) in MM patients. Moreover, clinical studies have shown highly heterogeneous clinical outcome in patients carrying the t(4,14), suggesting that specific biological features might define subgroups of t(4,14) positive patients. *Aim.* In the present study, newly diagnosed MM patients were analyzed by means of gene expression profiling and array-CGH experiments, in order to investigate the molecular mechanisms underlying the response to therapy in the presence or in the absence of t(4;14). *Methods.* The study was performed on a cohort of 50 patients randomly assigned to receive VTD as induction therapy in preparation for ASCT. The presence of t(4;14), del(13) and del(17) was characterize at diagnosis by FISH and/or PCR. In addition, the differential gene expression profile of CD138+ enriched plasma cells was evaluated by means of expression microarray and SNPs array using the Affymetrix platform. Expression data were analyzed by MetaCore® software and significant expression results were validated by Real-time PCR. *Results.* Eighteen out of the 50 analyzed patients carried t(4;14). Both in the positive and negative t(4;14) subgroup of patients, we didn't observe any significant clustering of gene expression based on the presence of the common chromosomal aberrations. On an intention-to-treat basis, 50% of the t(4;14) positive patients and 31% of the t(4;14) negative patients achieved at least a near CR. In both subgroups we compared the lists of genes differentially expressed in responders (R, those who achieved ≤CR or near CR) versus non responders patients (NR, those who achieved >near CR); we observed a differential expression of 2968 and 2136 genes in t(4;14) positive and t(4;14) negative patients, respectively. Moreover in R patients carrying t(4;14), a subset of genes involved in cell adhesion process (e.g. *VE-cadherin*) was significantly up-regulated, whereas the Wnt non-canonical signalling cascade resulted the pathway most affected as a consequence of the significantly down regulation of expressed genes such as *WNT10A* and *FZD7*. In the subgroup of t(4;14) negative patients, plasma cells trascriptome of R was characterized by the overexpression of genes involved in Wnt canonical (e.g. *WNT3, WNT4*) and Notch signalling pathway (e.g. *NOTCH1, NOTCH2*), and by the down regulation of pro-apoptotic genes (e.g. *CASP10*). *Conclusions.* The differential expression of genes involved in pathways controlling cell development and differentiation suggests a distinct features of the MM clone in R patients carrying t(4;14) compared to NR, and provides new insight into the biological characteristics related to the sensitivity of MM cells to treatment based on new drugs combination

EVOLUTION FROM MGUS TO MM IS CHARACTERIZED BY A CLONAL EXPANSION OF GENETICALLY ABNORMAL PLASMA CELLS

L López Corral, N Gutierrez, M Vidriales, M Mateos, R García-Sanz, J Alonso, J San Miguel

University Hospital of Salamanca, Salamanca, Spain

Background. Genetic aberrations detected in MM have also been reported in MGUS. However, the distribution of the genetic abnormalities between the asymptomatic precursors of MM, MGUS and smoldering MM (SMM), and the symptomatic MM seems to be different. *Aims.* To determine the frequency of chromosomal abnormalities and the proportion of plasma cells (PC) carrying these ones in three evolution stages of MM (MGUS, SMM and MM). *Methods.* We analyzed 88 patients with MGUS, 88 with SMM and 88 with symptomatic MM. Patients were classified into the three entities according to the IMWG (International Myeloma Working Group) criteria. PCs were purified using anti-CD138 immunobeads in all the bone marrow samples (purity was above 90% in all cases). Genetic abnormalities were evaluated by fluorescence *in situ* hybridization (FISH) with probes for IGH rearrangements, including t(4;14), t(11;14) and t(14;16), 13q14 and 17p13 deletions, and 1q21 gains. Multiparametric flow cytometry (FC) was performed for the characterization of aberrant PCs (CD38-FITC/CD56-PE/CD19-PerCP-Cy5/CD45-APC). In specific cases an additional staining for cytoplasmatic Ig light chains was used to clarify the polyclonal vs monoclonal nature of PCs. *Results.* The incidence of IGH translocations globally considered, t(4;14), 13q deletions and 1q gains was significantly higher in SMM/MM comparing to MGUS: 40/43% vs 25% for IGH translocations, 14/11% vs 4.5% for t(4;14), 39/45% vs 20% for 13q deletions and 42/53% vs 25.5% for 1q gains. In contrast, no significant differences in the frequency of specific chromosomal abnormalities were found between SMM and MM. The proportion of PC carrying any of the genetic abnormalities explored by FISH was increasing progressively from MGUS to SMM and to MM. Thus, the median percentage of PC with t(11;14) and 13q deletion was significantly lower in MGUS than in SMM, and in SMM than in MM status (38% vs 62% vs 84% and 35% vs 56% vs 77% for each abnormality respectively). Differences in the proportion of PC exhibiting the t(4;14) were also found when comparing both premalignant stages (MGUS and SMM) with MM. Furthemore, the median proportion of PC carrying 1q gains was

significantly lower in MGUS than in SMM/MM. In order to know if the increase of PC with genetic abnormalities across the evolution stages of MM was related to the less proportion of normal residual PC in MM compared to MGUS, we related the results derived from the genetic analysis by FISH with the data provided by FC. Even though the proportion of aberrant PC was lower in MGUS compared to MM, only a fraction of clonal PC in MGUS displayed the genetic abnormal clone (Figure 1). We found this same observation in SMM although in this stage the proportion of aberrant PC was similar to MM. *Summary.* Although chromosomal abnormalities recurrently found in MM were also present in MGUS, the incidence of t(4;14), 13q deletions and 1q gains was significantly higher in SMM/MM than in MGUS. Interestingly, the proportion of abnormal PCs displaying the chromosomal abnormalities was significantly increasing from MGUS to SMM and to symptomatic MM.

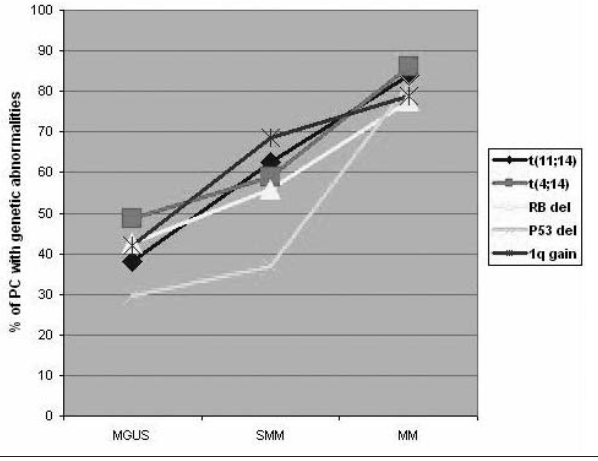

Figure 1. Median percentage of PC with genetic abnormalities.

Background. Despite the improvement in sensitivity for the identification of chromosomal aberrations by fluorescence based methods and automated analysis (Ntouroupi *et al.* Br J Cancer. 2008; Medintz *et al.* Int J Nanomedicine. 2008), a low cell number recovery may make it difficult to perform FISH detection of rearrangements involved in cancer cells. Multiple myeloma (MM), a clonal B-cell malignancy characterized by the accumulation of terminally differentiated bone marrow plasma cells (PC), represents a peculiar example because of the low infiltrate of malignant cells found in a large fraction of patients. Therefore, the manipulation and the analytical processing of PCs still represents a technological challenge and FISH detection requires purification which generally provides a limited number of PCs. *Methods.* To overcome the difficulty, we have used a novel device (microFINDTM) and tested it for FISH analyses by collecting living cells of bone marrow aspirates from MM patients. microFIND is a glass slide coated with a nanomaterial (Carbone et al. Biomaterials. 2006) that efficiently immobilizes cells (down to 4x103) inside a microchannel: a miniaturized FISH protocol (using one tenth of reagent employed in the standard protocol) is carried out and the slide evaluated by high resolution fluorescence microscopy. PCs were purified from MM bone marrow samples of 10 different patients using CD138 immunomagnetic microbeads (MidiMACS system) as previously described (Fabris *et al*. Genes Chromosomes Cancer 2005). Genetic lesions such as del(13q14), del(17p13) and the t(4;14)(p16;q32) were evaluated using commercially available kits (Abbott Chicago, IL) *Results.* When FISH results by microFINDTM and standard protocols were compared , we found a complete concordance for all tests in all cases studied. *Conclusions.* mincroFINDTM may represent a promising useful tool for the FISH analysis of genomic alterations in myeloma purified plasma cells even in case of a very limited number of available cells. Furthermore the miniaturization of the assay offers a cost saving approach, suitable for automation and throughput increase in a "chip"configuration.

IMMUNOSTIMULATORY OLIGONUCLEOTIDE METAPHASE INDUCTION IN PATIENTS WITH MULTIPLE MYELOMA: A NEW APPROACH FOR G-BANDING ANALYSIS.

F Oliveira,[1] L De Oliveira,[2] S Leite-Cueva,[3] B Pinto Simões,[2] R Passetto Falcão[1]

[1]Faculty of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil; [2]Department of Internal Medicine and Center for Research on Cell-Based Therapy, Ribeirão Preto, Brazil; [3]Departament of Genetics, Ribeirão Preto, Brazil

Background. Cytogenetic abnormalities play an important role as prognostic factors in multiple myeloma (MM). However, classical cytogenetic fail to detect these aberrations because the low mitotic index of plasma cells that reduces the availability of analyzable metaphases. The analysis of a set of subjects for the most commonly known aberrations is usually done by FISH on interphase cell. AIMS The goals of this investigation were the use of the oligonucleotide DSP30 in combination with IL-2 and IL-10, as a B-cell mitogen for cytogenetic investigation in MM and the comparison between the karyotype analyses obtained (G-banding) with FISH profile from unstimulated cells. METHODS For metaphase induction, bone marrow mononuclear cells of 27 patients, being 25 with MM and two with monoclonal gammopathy of undertemined significance (MGUS) were cultured in RPMI 1640 medium with 20% fetal calf serum in the presence of the immunostimulatory CpG-oligonucleotide DSP30 and IL-2/IL-10 for 72h. Additionally, two extra set of cell culture was performed for each patient without any stimulant agent (G-banding analysis, when possible and FISH). The FISH panel included probes for the detection of translocations involving IGH gene (14q32), gains associated to 11q23-q25 and 1q21 and deletion of 13q14. The cut off levels for IGH translocations was (>3.2%), gains of 11q23-q25 and 1q21 (2.4% and 2.7%, respectively) and deletion 13q14 (2.8%). All cut off values were established according to the FISH patterns observed in a group of 6 age and sex-matched normal control peripheral blood samples studied with the same probes. *Results.* In the cells treated with DSP30/IL-2/IL-10 it was observed that among 27 samples studied, the cytogenetic analysis was possible in 22 patients (81.4%). On the other hand, in the group without any stimulus, the cytogenetic profile was successful in 21 patients (51.8%), being 6 (42.8%) with normal karyotype and 8 with chromosomal abnormalities (57.2%). Considering the group that received stimulus, normal karyotype was found in 8 patients (31.8%) and metaphases with abnormal karyotype were seen in 14 subjects (68.2%). Among the cytogenetic profile obtained in both groups were observed aneuploidies involving the chromosomes +3, +5, +9, -13, -14, +15, +16, -18, +19, +20, -22 and structural abnormalities such as add(1)(p21), inv(3)(q21q26), del(13)(q14), add(14)(q32) and t(14;16)(q32;q23). FISH analysis performed in those patients whose bone marrow cells were not stimulated displayed the same chromosomal abnormalities as identified in the group with DSP30/IL-2/IL-10. *Conclusion.* These results indicate that the addition of the immunostimulatory oligonucleotide DSP30 in combination with IL-2 and IL-10 showed to be effective to induce cell cycle progression of MM cells *in vitro*. The limited spectrum of chromosomal abnormalities seen by using FISH analysis, with commercial probes may contribute to underestimate the cytogenetic profile in patients with MM. Thus, this new approach represents an easy and cheap method for metaphase induction in plasma cells.

ASSOCIATION OF PLASMA CELL PHENOTYPE WITH CYTOGENETIC FINDINGS IN MULTIPLE MYELOMA

L Kovarova,[1] I Buresova,[2] K Muthu Raja,[2] R Suska,[1] H Greslikova,[2] P Nemec,[2] J Smetana,[2] R Kupska,[2] M Penka,[1] P Kuglik,[2] R Hajek[1]

[1]University Hospital, Brno, Czech Republic; [2]Babak Research Institute, Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background. Multiple myeloma (MM) is characterised by presence of malignant plasma cells (PC). These PCs are phenotypically heterogeneous with presence of different cytogenetic changes. As genetic abnormalities are important prognostic indicators, surface expression of some markers could be related to patient's prognosis as well. *Aims.* To find relation between antigenic profile and cytogenetic aberrations in MM patients. *Methods.* Were done in 110 newly diagnosed untreated MM patients with median age 67 years (range 40-88 years). Bone marrow $CD38^+CD138^+$ PCs were analysed for expression of CD19, CD20, CD27, CD28, CD56 and CD117 by immunophenotyping, and PCs were considered positive for given marker when its expression on PCs was higher than 30%. Interphase fluorescent *in situ* hybridization (FISH) on separated PCs was used for analysis of del(13)(q14), del(17)(p13), t(4;14)(p16.3;q32), 1q21 gain and hyperdiploidy. *Results.* Plasma cells were detected in all patients with median 8.4% (range 0.1-75.3). Clonal $CD19^+$ PCs were found in 1 patient with del(13)(q14). Other 4 cases with $CD19^+$ PCs were phenotypically normal residual polyclonal PCs without any chromosomal abnormality. Expression of CD20 was found in 8.2% (9/110) patients and there was no significant correlation with any cytogenetic changes in $CD20^+$ and/or $CD20^-$ samples, although del(13)(q14) was found in 42.6% (43/101) of CD20 negative samples. Markers CD27 and CD28 were expressed in 31.8% (35/110) and 20.9 (23/110) patients, respectively, without differences in cytogenetic profile for CD27 and CD28 positive and/or negative cases. PCs not expressing CD56 were detected in 20.0% (22/110), and similar distribution of cytogenetic changes in CD56 positive and/or negative cases was found. Expression of CD117 was found in 31.8% (35/110) patients and this expression correlated with hyperdiploidy [51.4% vs 26.7%; P<0.05], but on the other hand, negativity for CD117 was associated with del(13)(q14) [50.7% vs 20.0%; P<0.01]. Cytogenetic analysis shown del(17)(p13) and t(4;14)(p16.3;q32) as less frequent aberrancies in MM which are not joined to specific PCs phenotype and also t(4;14) was not found in any of $CD20^+$, $CD117^+$ and CD56- cases. *Summary/Conclusions.* Plasma cells are very heterogeneous in their phenotypic and cytogenetic profiles. Our result shown CD117 (its positivity and/or negativity) as the only marker corresponding to chromosomal abnormalities, but further analysis of patients could bring some new information, especially when immunoglobulin heavy chain (IGH) translocation to other partners will be analysed.

$CD138^+$ CELL SEPARATION AFFECTS CANCER GENE EXPRESSION IN HUMAN MYELOMA CELL LINES

R Sørrig, N Hermansen, C Hother, P Gimsing

Rigshospitalet, Copenhagen, Denmark

Background and Aim. Gene expression profiling (GEP) of multiple myeloma (MM) cells is a promising means of identifying high-risk MM patients.[1-3] The analyses depend on plasma cell purification, usually by $CD138^+$ cell separation. Considering the sensitivity of gene transcription,[4] one might ask if separation distorts true *in vivo* GEP patterns. We performed a controlled study of running human myeloma cell lines (HMCL) through a standard $CD138^+$ separation procedure and comparing the resulting GEP effects. *Methods.* We grew 4 HMCLs under standard conditions: U266, INA-6, RPMI 8226, and NCI H929. We stored sample cells in a 3 mL EDTA-coated test tube and separated them, first by Ficoll® density gradient, then by automated immunomagnetic $CD138^+$ technique (StemCell Technologies). We isolated total RNA using a TRIzol® Reagent-based protocol. Using U266 as a screening model, we performed global GEP analysis using Affymetrix GeneChip® Human Gene 1.0 ST Array. Gene level summaries were extracted using RMA.[6] Differentially expressed genes were calculated using the LIMMA package[7] and Ps adjusted using Benjamini-Hochberg transformation. Sample cells showed significant changes (adj. P<0.05) in 670 genes compared to the non-separated controls. We searched for upregulated genes of myeloma and/or cancer relevance and chose *FOS* [8] (absolute fold change (abs.FC)=10.3, adj.P=0.004), *DUSP1* [9] (abs.FC=9.93, adj.P=0.0001), *NFKBIA*[10] (abs.FC=2.06, adj.P=0.002), *ATF4* [3,11] (abs.FC=1.98, adj.P=0.0007), and MIRN21 (abs.FC=4.21, adj.P=0.003)[12,13] for PCR validation. We used NCBI Primer-Blast for primer design and performed real-time quantitative PCR (qPCR) using SYBR® Green technology. The Ct files were analyzed in SAS version 9.1 on the basis of the ΔΔCt method.[14] *Results.* In all 4 HMCLs FOS and *NFKBIA* were upregulated; FOS most significantly so. Contrary to the global GEP screening, *MIRN21* was downregulated in 3 out of 4 HMCLs. Screening results for *ATF4* and *DUSP1* could not be validated by qPCR. *Conclusions.* In 4 HMCLs we verified how $CD138^+$ cell separation upregulates FOS, a transcription factor that is upregulated in several cancers,[8] and *NFKBIA*, a regulator of the NF-kappa B pathway which is most probably of clinical importance in myeloma.[10] Neither of the 2 is part of the published high-risk myeloma GEP signatures.[2,3] MIRN21 expression levels varied according to analysis method. These results have not been clinically validated. However, we encourage that the plasma cell purification method be taken into account when comparing different myeloma risk gene signatures.

THE ROLE OF HYPERPHOSPHORYLATED PARATARG-7 - THE FIRST AUTOSOMAL-DOMINANTLY INHERITED RISK FACTOR FOR HEMATOLOGICAL NEOPLASMS - IN MGUS, MULTIPLE MYELOMA AND LYMPHOMAS IN DIFFERENT ETHNICS GROUPS

S Grass,[1] KD Preuss,[1] A Wikowicz,[1] E Terpos,[2] M Dimopoulos,[2] S Treon,[3] Z Hunter,[3] S Iida,[4] A Inagaki,[4] R Ueda,[4] M Pfreundschuh[1]

[1]Jose-Carreras-Center for Immuno- and Gene Therapy, Homburg, Germany [2]University of Athens School of Medicine, Dept. of Clinical Therapeutics, Athens, Greece; [3]Bing Center for Waldenstrom's Macroglobulinemia, Dana-Farber Cancer Institute, Boston, USA; [4]Nagoya City University, Dept. Hematology, Nagoya, Japan

Background. Paratarg-7 was identified as the antigenic target of the paraproteins of 15% of IgA/IgG-MGUS and multiple myeloma (MM) and 11% of IgM-MGUS and Waldenstrom´s macroglobulinemia. We had shown that paratarg-7 was hyperphosphorylated in all patients with a paratarg-7 specific paraprotein, while pP-7 carrier state was found in only 2% of the healthy European population, thus representing a highly significant risk factor with an odds ratio of 7.9 to develop Ig/IgG-MUS and an odds ratio of 6.6 for the development for IgM-MGUS and WM (Grass et al., Lancet Oncology 2009). *Aims.* Since paratarg-7 is expressed in all tissues including peripheral blood white cells and erythrocytes, we aimed to investigate the prevalence of pP-7 in other hematological malignancies and ethnic groups. *Methods.* Lysates of peripheral blood from patients and controls were tested by gel electrophoresis and isoelectric focusing before and after phosphatase treatment. *Results.* Less Japanese IgA/IgG MGUS/MM patients had a pP-7 specific paraprotein than German patients (2/59 or 3.3%; P=0.033; χ^2-test) and the prevalence of healthy pP-7 carriers was lower (1/178) in the Japanese than in the German population (P=0.376; Fisher's exact test). However, the relative risk for pP-7 carriers to develop IgA/IgA-MGUS and MM was similar in the German and Japanese population (7.9 vs. 6.59). In order to determine whether carriers of pP-7 are at increased risk to develop hematological neoplasms other than MGUS, MM and WM, patients with DLBCL, follicular lymphoma, CLL and Hodgkin lymphoma were tested for the prevalence of pP-7. To date, no increased prevalence of pP-7 was observed in these patients. *Conclusions.* While the prevalence of the pP-7 carrier state varies between different ethnic groups, the relative risk of pP-7 to develop MGUS and MM is similar in these groups. The analysis of patients with other hematological neoplasms did not reveal an increased prevalence of pP-7 carriers among hematological diseases not associated with a paraprotein. That only MGUS/MW/MM patients who are carriers of hyperphosphorylated paratarg-7 had a paratarg-7 specific paraprotein suggests that the hyperphosphorylation of paratarg-7 induces auto-immunity and is involved in the pathogenesis of these diseases, e.g. by chronic antigenic stimulation. The identification of paratarg-7 as a frequent antigenic target enables the more detailed analysis of tumor-host interactions in these patients and its role in the pathogenesis of these diseases. Moreover, its dominant inheritance and the identification of familial cases with MGUS/MM/WM and hyperphosphorylated paratarg-7 carrier state facilitate genome-wide screens for the identification of the SNP responsible for hyperphosphorylation of this molecule.

MULTIPLE MYELOMA CELLS ANTAGONIZE HYPOXIA INDUCED CELL DEATH THROUGH UPREGULATION BCL-2 AND BCL-XL

J Hu,[1] V van Valckenborgh,[2] E Menu,[3] E de Bruyne,[2] D Xu,[2] B van Camp,[2] K Vanderkerken[2]

[1]Vrije Universiteit Brussel (VUB), Brussels, Belgium; [2]Department of Hematology and Immunology-Myeloma Center Brussels, VUB, Brussels, Belgium; [3]Department of Hematology and Immunology-Myeloma Center Brussels, VUB, Brussels, Belgium

Background. Hypoxia, a condition of decreased availability of oxygen, is major challenge for anticancer therapy. In solid tumors, hypoxia is considered as a double-edged sword: on the one hand, cells can be irreversibly injured and die under conditions of oxygen deficiency; on the other hand, cells that become adaptive to hypoxia are more resistant to apoptosis and less responsive to cancer therapy, resulting in relapse of the disease and transformation into more aggressive phenotypes. However, the oxygen level in bone marrow (BM) and the role of hypoxia in the pathogenesis of hematological malignancies such as multiple myeloma (MM) is still unclear. By staining the exogenous and endogenous hypoxia markers pimonidazole and HIF-1α in the bone marrow of naive and 5T33MM mice, we demonstrated that MM cells exist in a strong hypoxic niche. *Aims.* To investigate the mechanism of MM cells escaping from hypoxia induced cell death and anticancer therapy. *Materials and Methods.* The 5T33MM murine model, which mimicks the human MM disease closely, originated spontaneously in elderly C57BLKaLwRij mice. The 5T33vv MM cells were propagated by i.v. transfer of the diseased bone marrow into young recipients. The 5T33vv MM cells were isolated from 5T33MM bearing mice. Human and murine MM cell lines RPMI-8226, LP-1, 5T33vt were maintained in RPMI-1640 medium with 10% serum, supplemented glutamine (2 mM), and antibiotics (penicillin 100 U/mL and streptomycin 50 µg/mL). Hypoxic (1%, 0% O_2) conditions were established by culturing MM cells in a sealed chamber. Apoptosis was measured by flow cytometric analysis of Annexin V-APC/PI staining. Real-Time PCR and Western-blot were performed to the expression at both RNA and protein levels. Chromatin Immunoprecipitation (ChIP) was used to immunoprecipitate HIF1α-DNA complexes and to allow for the rapid PCR detection of HIF1α-regulated genes. *Results.* we found that hypoxia (1% O_2 and 0% O_2) can increase the expression of Bcl-2 and Bcl-xL at both mRNA and protein levels by qRT-PCR and Western blot. Stabilization of HIF1αenhances Bcl-2/Bcl-xL expression at both mRNA and protein levels in normoxic condition. In contrast, inhibition of the accumulation of HIF1α decreases Bcl-2/Bcl-xL expression in hypoxic condition. Furthermore, ChIP analysis provided proof that HIF1α can bind to the hypoxia response element (HRE) at Bcl-2 and Bcl-xL promoters. Antagonizing Bcl-2 and Bcl-xL with BH3 mimetic small-molecule inhibitor with high affinity to Bcl-2 and Bcl-xL, overcomes Bcl-2/Bcl-xL mediated MM cell apoptotic resistance to hypoxic stress both *in vitro* and *in vivo*, by increasing the expression of cleaved proapoptotic proteins caspase-3, 9 and PARP. BH3 mimetic small-molecule inhibitor in combination with a HIF1α inhibitor can synergistically induce MM cell apoptosis in hypoxic condition. *Conclusions.* (1) Bcl-2 and Bcl-xL are target genes of HIF1α: hypoxia-induced Bcl-2 and Bcl-xL gene expression is regulated via a HIF1α-mediated mechanism. (2) Hypoxia up-regulated Bcl-2 and Bcl-xL expression is associated with the resistance of MM cells to hypoxia induced cell death. Antagonizing Bcl-2 and Bcl-xL with BH3 mimetic small-molecule inhibitor or in combination with HIF1a inhibitor, synergistically overcomes Bcl-2/Bcl-xL mediated resistance to hypoxic stress.

INHIBITION OF -TORC1 AND -TORC2 REPRESENTS A NEW APPROACH IN THE TREATMENT OF MULTIPLE MYELOMA

P Maiso,[1] A Azab,[2] A Roccaro,[2] C Rommel,[3] F Azab,[2] A Sacco,[2] H Ngo,[2] Y Liu,[3] P Quang,[2] Y Zhang,[2] Y Liu,[2] B Morgan,[2] K Anderson,[2] I Ghobrial[2]

[1]Dana Farber Cancer Institute, Boston, USA; [2]Dana-Farber Cancer Institute, Boston, USA; [3]Intellikine, La Jolla, USA

Introduction: Mammalian target of rapamycin (mTOR) is a downstream serine/threonine kinase of the PI3K/Akt pathway that integrates

signals from growth factors, nutrients and stresses to regulate multiple processes, including mRNA translation, cell cycle progression and cell survival. In multiple myeloma, PI3K/Akt plays an essential role enhancing cell survival and is activated by the loss of the tumor suppressor gene PTEN and by the bone marrow microenvironment. Rapamycin analogues such as RAD001 and CCI-779 have been tested in clinical trials in MM. Their efficacy as single agents is modest, but when used in combination, they show high responses. However, total inhibition of Akt phosphorylation requires inactivation of both complexes TORC1 and TORC2. Consequently, there is a need for novel mTOR inhibitors that can target both complexes. In this study we have evaluated the activity and mechanism of action of INK128, a novel, potent, selective and orally active small molecule TORC1/2 kinase inhibitor in MM. *Methods.* The efficacy of INK128 was analyzed in eight MM cell lines (MM1S, MM1R, OPM1, OPM2, RPMI8226, U266, U266L7 and INA-6). The cytotoxicity was analyzed by means of MTT assay. Proteomic changes induced after treatment with INK128 or rapamycin were analyzed in two MM cell lines (MM1S and OPM2) with different TORC1 and TORC2 status. *Results.* We observed that INK128 fully suppressed cell viability in a dose and time dependent manner, but rapamycin reached a plateau in efficacy at±60%. The IC50 of INK128 was in the range of 7.5-30 nM in the eight cell lines tested. We checked the PI3K/Akt kinase activity and downstream signaling in all MM cell lines. MM1S showed high levels of Rictor (scaffold protein of TORC2) and p-6SR and OPM2 expressed Rictor and Raptor (scaffold protein of TORC1), alongside with high levels of p-4EBP1 and Akt kinase activity. We found that INK128 as well as rapamycin effectively suppressed phosphorylation of p6SR in both cell lines, but only INK128 was able to decrease phosphorylation of 4E-BP1, pErk and the levels of Deptor a recently described TORC1/2 interacting protein overexpressed in MM. Whereas both inhibitors had little and similar effect at 24 hour exposure, treatment of MM cells for 48 hours indicated a dose dependent increase of apoptosis much higher than rapamycin. Cleavage of PARP and Caspase-3 were found in MM cells treated with INK128 but not with rapamycin correlating with its ability to induce apoptosis. Cell cycle analysis confirmed that INK128 can cause both cell cycle arrest and death, whereas rapamycin was primarily cytostatic. Although INK128 was more potent than rapamycin to induce an effect in cell cycle progression, both drugs induced S phase decrease in all MM cell lines. INK128 displayed synergistic activity when combined with several antimyeloma agents, being most efficient in combination with dexamethasone and bortezomib. *Conclusions.* The ability of INK128 to potently induce cycle arrest and apoptosis together with its ability to augment the effect of conventional anti myeloma therapies provides the rationale for the investigation of INK128 in clinical trials for patients with MM.

THE HEAT SHOCK TRANSCRIPTION FACTOR 1 IS A NEW POTENTIAL THERAPEUTIC TARGET IN MULTIPLE MYELOMA

T Heimberger,[1] M Andrulis,[2] S Fischbach,[1] T Stühmer,[1] H Einsele,[1] R Bargou,[1] M Chatterjee[1]

[1]Internal Medicine II, Division of Hematology, University Hospital of Würzburg, Würzburg, Germany; [2]Institute of Pathology, University of Heidelberg, Germany, Heidelberg, Germany

Background. Heat shock proteins (HSPs) like Hsp90 or Hsp70 have been found overexpressed in multiple myeloma (MM). HSPs act as molecular chaperones stabilizing a multitude of oncogenic signaling proteins and thus contribute to the malignant phenotype. Physiologically, HSPs are fast up-regulated in conditions of cellular stress. Likewise, in myeloma cells an up-regulation of HSPs was observed upon treatment with therapeutic agents, such as the proteasome inhibitor bortezomib, suggesting a potential mechanism for the development of drug resistance. However, the knowledge about regulation processes within the HSP network is limited. *Aims.* We investigated the role of heat shock transcription factor 1 (HSF1), which is supposed to act as a key regulatory factor within the HSP network, for the malignant growth of MM cells. *Methods.* Expression of HSF1 *in situ* was analyzed by immunohistochemical staining in a panel of 59 bone marrow biopsies obtained from MM patients. In addition, HSF1 and HSF1-regulated HSPs were analyzed by Western blotting in primary MM cells. To evaluate the role of HSF1 for MM cell survival, knockdown of HSF1 was performed by a pSUPER-based siRNA approach. Likewise, HSP27 knockdown was analyzed. To identify HSF1-dependent genes, expression analyses using an Affymetrix GeneChip were performed after siRNA-mediated knockdown of HSF1. Furthermore, MM cell lines as well as primary MM cells were treated with the novel pharmacologic HSF1 inhibitor triptolide either alone or in combination with the novel Hsp90 inhibitor NVP-AUY922. *Results.* Whereas HSF1 was weakly expressed in normal or MGUS plasma cells, it was strongly expressed in half of the MM biopsies *in situ* and frequently overexpressed in MM cell lines *in vitro*. HSF1 knockdown by siRNA as well as treatment with the HSF1 inhibitor triptolide led to a strong induction of apoptosis in MM cells. Importantly, also primary MM cells showed apoptosis induction after triptolide treatment. This apoptotic effect of pharmacological HSF1 inhibition was significantly enhanced by the concomitant pharmacological inhibition of HSP90 with NVP-AUY922. Inhibition of HSF1 activity caused a strong reduction of basal HSP27 and minor reduction of basal HSP70 and HSP90 protein levels. Interestingly, HSF1 inhibition blocked the induction of HSP70 and HSP27 expression after treatment with NVP-AUY922. SiRNA-mediated selective knockdown of HSP27 strongly induced apoptosis. In addition to the regulation of HSPs, gene expression analysis revealed a number of additional molecular targets of HSF1 involved in apoptosis regulation. *Conclusions.* HSF1 is frequently and strongly expressed in MM cells, protects MM cells from apoptosis and regulates the level of major HSPs like HSP90 and HSP70. Our data furthermore establish an essential role of HSF1-dependent HSP27 within the HSP network in MM. Targeting HSF1 may therefore represent an attractive potential therapeutic strategy in MM, in particular in combination with HSP90 or proteasome inhibitors.

INHIBITION OF MULTIPLE MYELOMA CELL PROLIFERATION AND MAPK SIGNALING BY A DUAL PRENYLTRANSFERASE INHIBITOR

M Morgan, A Ganser, C Reuter

Hannover Medical School, Hannover, Germany

Background. Multiple myeloma (MM) is a fatal hematologic malignancy associated with disruption of Ras-to-MAP kinase (MAPK/ERK) signaling. Ras proteins require several posttranslational modifications (e.g. prenylation, proteolysis, carboxymethylation and palmitoylation) for membrane binding and full biologic activity. Thus, use of prenylation inhibitors (e.g. farnesyltransferase inhibitors = FTIs, geranylgeranyl transferase inhibitors = GGTIs) to block Ras post-translational modification and disrupt Ras signaling is one strategy to impede oncogenic Ras function *in vivo*. Since K- and N-Ras isoforms are substrates for both farnesyltransferase (FTase) and geranylgeranyltransferase I (GGTase I), it may be necessary to inhibit both prenyltransferases in order to optimize the anti-MM response. *Aims.* In this study, we used five established MM cell lines (RPMI-8226, NCI-H929, OPM-2, L-363, and U266) to investigate the anti-MM activity of the dual prenylation inhibitor (DPI) L-778,123. *Methods.* Liquid suspension MM cell cultures were treated with serial dilutions of L-778,123 (0.08-10 μM, 96 hours) and IC_{50} values were determined by proliferation assays (MTS). *RAS* mutation status was determined by direct sequencing. Apoptosis was quantified by flow cytometric analysis of DNA strand breaks labeled using the *in situ* cell death detection kit (TUNEL assay). Levels of processed and unprocessed Ras isoforms as well as activation of MAPK-1/2 were determined by Western blotting. *Results.* Three of the five MM cell lines tested contain activating *RAS* "hot-spot"mutations (RPMI-8226: K-Ras G12A; NCI-H929: N-Ras G12D; and L363: N-Ras Q61H). Additionally, OPM-2 has been reported to contain an unusual activating H-RAS mutation. DPI L-778,123 exhibited stronger growth inhibition of multiple myeloma cells which harbour activating *RAS* mutations (e.g. NCI-H929, OPM-2, RPMI-8226, L363) versus the U266 cell line which has wild-type *RAS* (IC_{50} values were 0.54 μM, 1.97 μM, 0.73 μM and 7.86 μM vs. >10 μM, respectively). Apoptosis assays revealed no induction of DNA strand breaks upon L-778,123 treatment (0.05-5 μM; 48 and 70 hours), suggesting that the L-778,123-induced anti-proliferative effects observed in MM cells are rather cytostatic than cytotoxic. Western blotting demonstrated that FTI L-778,123 blocked prenylation of Ras family proteins. H-Ras prenylation in OPM-2 cells was inhibited after 24 hours treatment with 0.05 μM L-778,123, while N-Ras prenylation in NCI-H929 was blocked with 0.25 to 1 μM of the drug. Futhermore, L-778,123 induced an accumulation of unprocessed N-Ras proteins, perhaps reflecting an important role of prenylation in Ras protein degradation. It is also interesting to note that the IC_{50} for L-778,123 in NCI-H929 cells (0.54 μM) agrees well with the concentration of drug needed to completely inhibit oncogenic N-Ras processing in this cell line (0.25-1 μM). Western blotting experiments examining activated MAPK-1/2 levels demonstrated that L-778,123 treatment elicited a concentration-dependent inhibition of Ras down-stream signaling. *Conclusions.* These findings demonstrate that the dual prenylation inhibitor L-778,123 displays anti-MM activity. Our results support that inhibition of Ras prenylation and down-stream signaling is a major mechanism

through which L-778,123 inhibits MM cell proliferation. Alternative prenylation of K- and N-Ras by GGTase I in the presence of FTIs may explain the clinically observed incomplete response to FTI treatment. As the majority of RAS mutations in multiple myeloma occur in K- and N-RAS, treatment strategies employing dual prenylation inhibitors may exhibit more potent anti-myeloma activity than those using only farnesyltransferase inhibitors.

TETRA-O-METHYL NORDIHYDROGUAIARETIC ACID (TERAMEPROCOL) INDUCES MYELOMA GROWTH ARREST AND APOPTOSIS BY INHIBITING SP1 ACTIVITY

M Fulciniti,[1] P Nanjappa,[1] S Amin,[1] T Hideshima,[1] S Rodig,[1] P Tassone,[2] K Anderson,[1] N Munshi[1]

[1]DFCI, Boston, USA; [2]UNICZ, Catanzaro, Italy

Background. Multiple Myeloma (MM) is characterized by uncontrolled proliferation of plasma cells associated with dysregulation of cell cycle checkpoint controls affecting mitosis. Terameprocol (TMP) is a novel clinically applicable site-specific transcription inhibitor that specifically competes with Sp1 for its DNA binding domains present on the promoter regions of number of cell cycle and growth control genes. TMP thus can regulate the function of cell cycle and apoptosis genes aberrantly expressed in many malignancies including MM. *Aims.* We investigated the *in vitro* and *in vivo* anti-MM activity of TMP alone and in combination with conventional and novel anti-MM agents. *Methods.* We examined the growth inhibitory effect of TMP against MM cells in the absence and in the presence of bone marrow stromal cells (BMSC) alone or in combination with dexamethasone and revlimid. Using the xenograft murine model of MM, we also analyzed the *in vivo* effect of TMP on MM cell growth. *Results.* TMP significantly inhibited MM cell growth in a dose-dependent fashion (IC_{50} between 5-20 μM at 24 hours) in a panel of MM cell lines as well as in primary patient MM cells. Longer exposure of MM cells to TMP resulted in reduction in survivin expression at both the gene and protein level, induction of apoptosis associated with caspase-3 and caspase-9 activation and PARP cleavage. TMP binds to GC-rich regions in chromatin and interferes with the transcription of genes that bear GC-rich motifs in their promoters. Inhibition of Sp1 activity is considered to be a major mechanism of the antitumor activity of TMP. We confirmed inhibition of Sp1 binding activity by TMP in MM cells using an ELISA assay specific for measuring Sp1 binding activity and using Sp1 sensitive luciferase reporter plasmid. Interestingly, Sp1 protein level in MM cells was not affected by treatment. We have observed induction of Sp1 activity in MM cells in the presence of bone marrow stromal cells (BMSC) and TMP was able to reverse this induction of Sp1 activity, inhibit MM cell adhesion to BMSC and overcome the positive effect of BMSC on MM cell growth. We have further confirmed the efficacy of TMP *in vivo* by treating nude mice bearing human myeloma xenograft with TMP and observing tumor regression and improved survival of mice. We finally examined if Terameprocol could enhance cytotoxicity induced by other therapeutic agents. We observed that treatment with dexamethasone and revlimid increased Sp1 activity in MM cells and treatment with a combination of these compounds with TMP had a synergistic effect on inhibition of Sp1 activity and MM cell growth compared to either agent alone. *Conclusions.* Our results confirm TMP as a specific Sp1 inhibitor and provide the rationale for clinical development of TMP alone and in combination with conventional and novel anti-myeloma agents.

JAK2/STAT3 PATHWAY: A NEW TARGET OF PANOBINOSTAT IN MULTIPLE MYELOMA

G Perrone,[1] E Calabrese,[2] G Gorgun,[3] D Cristea,[3] L Santo,[3] M Cavo,[1] T Hideshima,[3] K Anderson[3]

[1]Institute of Hematology and Medical Oncology Seràgnoli, Bologna, Italy; [2]Institute of Hematology, Università degli studi La Sapienza, Roma, Italy; [3]Medical Oncology, Dana Farber Cancer Institute, Boston, USA

Background. Histone deacetlyase inhibitors (HDACi) represent a novel class of therapeutic agents for the treatment of solid and hematological malignancies. In multiple myeloma (MM), preclinical and clinical studies have shown that HDACi have anti-tumor activities and exhibit a synergistic cytotoxic effect when combined with conventional and novel anti-MM agents. Besides the impact on epigenetic regulation of the transcriptome, recent studies have revealed that HDACi affect the acetylation of cytoplasmic proteins/kinases mediating major signaling cascades, including JAK2/STAT3, PI3K/AKT, ERK and NF-κB pathways. These observations suggest that the antitumor effect of HDACi may include not only their impact on the histone code and chromatin remodeling, but also the function of non-histone proteins. However, the impact of HDACi on modulation of those signaling cascades in MM cells has not yet been elucidated. *Aim.* In this study, we examined the effect of Panobinostat, a class I-HDAC inhibitor currently in phase I/II clinical trial, in modulation of major signaling cascades in MM cells. Results and *Methods.* Clinically achievable doses of panobinostat were tested on MM cell lines, (MM1S, INA6 and U266). We observed that Panobinostat *in vitro* significantly inhibits the IL6-induced JAK2/STAT3 activation in MM cells at early time point by suppressed phosphorylation of JAK2/STAT3, and by reduced DNA binding activity of STAT3. These results were further confirmed under experimental conditions where the pathway was activated (ie, co-culture of MM cells with bone marrow stromal cells). We further evaluated the effect of Panobinostat on IL-6 receptor β-subunit gp130 and observed inhibition of gp130 phosphorylation at early time points, suggesting that Panobinostat inhibits IL6R/JAK2/STAT3 pathway not only by decreasing the expression of several members of the pathway, but also by modulating the function of the IL6 receptor complex as confirmed by immunoblotting and flow cytometry analysis. In contrast, Panobinostat triggers upregulation of the MAPK pathway by inducing phosphorylation of ERK ; conversely, MEK inhibitor U0126 completely blocks panobinostat-induced ERK phosphorylation, associated with synergistic growth inhibitory effect. Importantly, Panobinostat enhanced anti-MM effect induced by other conventional and novel agents and overcame protective effect by bone marrow stromal cells. Finally, we evaluated whether Panobinostat, with or without UO126, inhibits osteoclast differentiation and found that Panobinostat and U0126 trigger synergistic inhibiton of osteoclast differentiation. *Conclusions.* Our studies therefore provide new insights on mechanisms of action of HDACi not only on MM cells, but also in their microenvironment, which can inform the design of combination therapies.

0348

GOLD COMPOUND AURANOFIN HAS CLINICAL POTENTIAL AGAINST PATIENTS WITH REFRACTORY MULTIPLE MYELOMA BY TARGETING STAT3 AND NF-κB PATHWAYS

M Sagawa,[1] A Nakaya,[2] T Tomikawa,[1] T Nemoto,[1] K Hanzawa,[1] R Watanabe,[1] M Tokuhira,[1] S Mori,[1] M Kizaki[1]

[1]Saitama Medical Center, Saitama Medical Univ., Kawagoe, Japan; [2]Keio University School of Medicine, Tokyo, Japan

Background. Multiple myeloma (MM) is a plasma cell malignancy that remains incurable despite the use of high-dose chemotherapy following stem cell transplantation. Novel therapeutic agents, such as thalidomide, bortezomib, and lenalidomide, have remarkable activity against both newly diagnosed and refractory patients with MM, but prolonged exposure may result in the development of *de novo* drug resistance. It is necessary to identify and validate novel agents with less toxicity to overcome drug resistance and to improve clinical outcome. Auranofin (AF) is a coordinated gold compound that has been widely used for the treatment of rheumatoid arthritis based on its anti-inflammatory properties through the inhibition of NF-κB activation. *Aims*. Assuming that AF has the potency to induce apoptosis in MM cells by interfering with NF-κB pathways, it may be a candidate for novel therapeutic agents. *Methods.* We here examined the efficacy and molecular mechanisms of action of AF for various MM cell lines and fresh samples from patients with MM *in vitro*. Furthermore, the clinical benefits of daily oral administration of AF (6 mg per day) in 7 patients with refractory MM with a signed informed consent were examined. *Results*. AF inhibited the growth of MM cells in a time- and dose-dependent manner with IC_{50} of 50 nM at 24 h. AF significantly induced cell cycle arrest at the G1 phase and subsequent apoptosis of MM cells, involving the activation of caspases-3, -8, and -9. AF also induced apoptosis in CD138-positive plasma cells from patients with MM. Treatment with AF inhibited the constitutive and IL-6-induced activation of STAT3, and then down-regulated the expression of Mcl-1 but not that of Bcl-2 or Bcl-xL proteins. To clarify the biological significance, Mcl-1 expression vector (pEGFP-hmcl-1) and control vector were introduced into U266 cells (designated as U266/mcl and U266/neo cells). Induction of apoptosis by AF was abrogated in U266/mcl, but not in U266/neo cells. Further, electrophoretic mobility gel shift assay demonstrated that IL-6-induced STAT3 binding activity was inhibited by the presence of AF. In addition, AF down-regulated the activation of NF-κB in an IκB-independent manner, and also inhibited DNA binding activity. Finally, since 2008, after the approval of the pro-

tocol by Ethic Committee of the Saitama Medical University, 7 patients with refractory MM were treated with oral AF 6 mg daily. The median follow-up for patients was 9 months. All 7 patients responded to AF, including one partial response and 6 stable diseases. No adverse events have been observed to date. Details of the clinical outcome will be presented. *Conclusions*. Gold compound AF inhibited constitutive activation of both STAT3 and NF-κB, resulting in the down-regulation of Mcl-1 in MM cells with clinical relevance. A low pharmacological concentration (50 nM) of AF is widely employed for the treatment of rheumatoid arthritis without any side effects; therefore, it may be used to treat MM without severe toxicity. We propose that AF may have potency as a new molecular-targeted agent for the treatment of MM.

0349

PRE-CLINICAL APPROACH OF MULTIPLE SIGNAL TRANSDUCTION PATHWAYS INHIBITION IN MULTIPLE MYELOMA

MR Ricciardi,[1] E Calabrese,[1] M Milella,[2] P Bergamo,[2] A Levi,[1] C De Benedictis,[1] R Foà,[1] A md Tafuri,[1] MT Petrucci[1]

[1]Haematology, Sapienza University of Rome, Rome, Italy; [2]Medical Oncology A, Regina Elena National Cancer Institute, Rome, Italy

Background. Multiple myeloma (MM) is a plasma cell malignancy incurable with existing conventional therapies. Advances in the understanding of the underlying molecular mechanisms of growth, progression and drug resistance of neoplastic cells has allowed the development of promising new agents that inhibit specific proteins aberrantly regulated in key signal transduction pathways. These agents have shown promising results in pre-clinical trials and some of them are currently at the early stages of clinical investigation. However, since it has become progressively more evident that inhibition of a single kinase may frequently induces escaping mechanisms in neoplastic cells trough activation of cross-talking pathways, there is a clear need to identify agents effective on inhibition of multiple targets. We already showed in *in vitro* studies on MM cell lines and primary CD138$^+$ cells from MM patients the potent growth-inhibitory effects of the specific MEK inhibitor PD0325901 and the markedly pro-apoptotic activity of the BH3-mimetic ABT-737 (kindly provided by Abbott Laboratories). In addition, the activity of Mevinolin, a mevalonate pathway inhibitor, on inducing apoptosis of MM cells by regulating different signal, including the MEK/ERK module, has been reported. *Aim.* To analyze the effects of the simultaneous inhibition of MEK/ERK, Bcl2/BclXL and mevalonate pathways on apoptosis and cell growth of MM cell lines and primary samples. *Results.* MM cell lines (KMS18, KMS27, ARH-77) were exposed to increasing concentrations of PD0325901 (1-100 nM), ABT-737 (1-100 nM) and Mevinolin (1-100 μM), alone and in combination. When used as single agents the inhibition of cell-growth was dose-dependent, while if used in combination the inhibition of cell growth was synergistically enhanced, with a combination index (CI) of 0.12 and 0.15 for the PD0325901+ABT-737 (PD-ABT) and PD0325901+Mevinolin (PD-MEV) combination, respectively. We then investigated the effects of these agents on apoptosis, demonstrating that PD0325901 as single drug mainly showed cytostatic effects without affecting apoptosis, while both ABT-737 and Mevinolin induced apoptosis only at high concentrations. The simultaneous exposure to PD0325901 with ABT-737 or Mevinolin was able to induce apoptosis at lower concentrations, showing that these pro-apoptotic interactions are highly synergistic in nature, with a CI of 0.2 (KMS18) and 0.17 (KMS27) for PD-ABT and of 0.135 (KMS18) and 0.128 (KMS27) for PD-MEV. Similarly, mitochondrial membrane depolarization was greatly induced by both combinations. SUMMARY: In conclusion, we demonstrated that the simultaneous disruption of MEK/ERK and Bcl2/BclXL or mevalonate signalling results in higher apoptosis induction and growth inhibition of MM cells, supporting the adoption of this approach based on the simultaneous multiple signal transduction pathway inhibition.

BORTEZOMIB DOWN REGULATES TELOMERASE ACTIVITY IN MULTIPLE MYELOMA - DIFFERENT LEVELS OF REGULATION IN CELLS FROM VARIOUS SOURCES - IN VITRO AND EX VIVO STUDIES

C Weiss,[1] O Uziel,[2] O Cohen,[2] O Wolach,[2] S Bulvik,[1] J Nordenberg,[2] E Beery,[2] M Lahav[2]

[1]Hematology Department, Laniado Hospital, Netanya, Israel; [2]FMRC, Rabin Medical Center, and Sackler School of Medicine, Tel Aviv University, Petah Tikva, Israel

Background. The proteasome inhibitor bortezomib is considered an effective drug in Multiple Myeloma (MM). However, its exact mechanism of action is not yet fully understood. The importance of telomerase in the biology of MM and as a prognostic factor has been clinically established, but has not been assessed in response to bortezomib. In light of common signaling pathways of bortezomib function and telomerase regulation we sought to explore the possible effect and mechanism of bortezomib on telomerase activity in MM cells. *Aims.* To characterize the effect of bortezomib on telomerase activity (TA) and its regulation in MM cell lines and in ex vivo MM cells. *Methods.* Two MM cell lines, ARP-1 and CAG and cells purified from patients' marrow were exposed to bortezomib. TA was determined by the TRAP assay. Its regulation was evaluated on the epigenetic level by assessment of the methylation status of the hTERT promoter (by bisulfite conversion assay) and on the transcriptional level by measuring the expression of the hTERT gene (by real time PCR). The binding ability of three hTERT transcription factors; SP1, c-Myc and NFκB was evaluated by the ChIP assay. Posttranslational phosphorylation of the enzyme was determined by following the phosphorylation levels of Akt and PKCα (by Western blotting). Cell proliferation was assessed by the WST-1 viability reagent. *Results.* Bortezomib inhibited telomerase activity *in vitro* in both cell lines and ex vivo cells, but in a different kinetic manner. In all cells the transcription of hTERT was inhibited by the drug. This inhibition was mediated by a decreased binding of SP-1 to its promoter while NFκB and c-Myc binding were unaffected. The methylation status of a portion of the hTERT promoter was not changed. On the posttranslational level, the phosphorylation of PKCα, the main kinase of telomerase, was decreased only in the ARP-1 cell line explaining the delayed onset of telomerase inhibition in CAG cells. *Conclusions.* This study establishes telomerase as a novel target of bortezomib in MM. The differential mechanism of inhibition (both on the level of regulation and in kinetics) in cells from different sources may indicate that similar differences between patients with MM may translate to the clinical setting as well. More studies are needed to determine whether telomerase activity in response to bortezomib may serve as prognostic factor in patients with MM.

THE HDAC INHIBITOR LBH589 ENHANCES THE ANTI-MYELOMA EFFECT OF THE IGF-1 RTK INHIBITOR PICROPODOPHYLLIN

C Fristedt,[1] M Lemaire,[2] P Agarwal,[1] E Menu,[2] E van Valckenborgh,[2] P Atadja,[3] B van Camp,[2] H Jernberg-Wiklund,[1] K Vanderkerken[2]

[1]Department of Genetics and Pathology, Uppsala, Sweden; [2]Dept. Hematology and Immunology, Brussel, Belgium; [3]Novartis Institute for Biomedical Research Cambridge, MA, USA

Our previous studies have shown that inhibition of IGF-1R pathway by picropodophyllin (PPP) can be achieved with favorable therapeutic window in multiple myeloma (MM) models *in vivo* and *in vitro*. Considering the acquirement of compensatory genetic lesions during MM progression approaches targeting single receptors are however not likely to be curative for MM. In line with this notion remaining MM cells in the *in vivo* 5TMM model eventually leads to relapse and mortality. To counteract this, we combined PPP in a combinatorial drug screen (HTS). In this approach we focused on the use of one of these candidates, the HDAC inhibitor LBH589, in combination with PPP in MM models *in vivo* and *in vitro*. The studies show that PPP and LBH589 used at suboptimal concentrations has synergistic effects in a combinatorial regimen both *in vitro* and *in vivo*. The contribution from the single drugs and the combination were monitored for apoptosis, cell cycle distribution, and the impact on downstream gene and protein expression in human and mouse MM models *in vitro*. In the RPMI8226 human MM cell line, simultaneous treatment with both compounds for 48h caused a 5-fold increase of apoptotic and late apoptotic/necrotic cells as compared to controls, while treatment with either compound alone only induced a 3-fold increase. After 24h cleavage of apoptotic proteins caspase -9, -8 and -3 could be found in RPMI8226 cells treated with both drugs individually, but in the combination we observed an additive effect on the cleavage of the active forms of caspase 8 as compared to single drug treatments. The combination of LBH589 and PPP could be monitored as an accumulation of cells in the G2/M phase, and subsequent down-regulation of cell cycle regulated proteins. The effect of both compounds on the expression of cyclin B1, -E and -D2 was additive, as demonstrated by western blot. Similar *in vitro* experiments using cells of the 5T33MM murine model confirm these data. At lower combinatorial concentrations, a significant additive reduction of VEGF secretion (56%) when compared to the single treatments (45% and 13% for LBH589 and PPP respectively) of 5T33MM cells was observed. Finally, we examined the *in vivo* effect of the combinatorial treatment using sub-optimal con-

centrations of LBH589 (2.5 mg/kg/day i.p. injection) and PPP (1,5mg/day orally) and assessed the overall survive rate using Kaplan-Meier analysis. Combined treatment resulted in a significant (P<0.03) prolonged survival (47.5 days) when compared to the control group (22 days), the LBH589-treated group (32.5 days) and the PPP-treated group (25 days). In conclusion, the results indicate an improved MM treatment opportunity in using a combination of PPP and LBH589.

0352

ACTIVATION OF INNATE IMMUNITY IN PATIENTS RECEIVING COMBINATION THERAPY WITH LENALIDOMIDE (REVLIMID), CYCLOPHOSPHAMIDE AND LOW-DOSE DEXAMETHASONE (RCD) FOR NEWLY DIAGNOSED OR RELAPSED/REFRACTORY MYELOMA

P van Heteren,[1] O Renz,[2] C Hahn-Ast,[2] A Glasmacher,[2] C Leyendecker,[2] V Janzen,[2] I Schmidt-Wolf,[2] P Brossart,[2] M von Lilienfeld-Toal[2]

[1]Uniklinik Bonn, Bonn, Germany; [2]Universitätsklinik Bonn, Bonn, Germany

Background. Lenalidomide, a derivative of thalidomide, has been reported to exert immunomodulatory activity by stimulating T cell and NK cell mediated immune response. However, the exact mode of activation is as yet unknown. The purpose of our study is to assess the effect of a combination chemotherapy including lenalidomide on NK/NKT cell numbers and expression of activating receptors (NKG2D, NKp30, NKp44 and NKp46) in patients with newly diagnosed or relapsed/refractory multiple myeloma (MM). *Patients and Methods.* Patients received lenalidomide (25 mg d1-21), dexamethasone 40 mg (d1, d8, d15, d22) and cyclophosphamide (500 mg as iv infusion d1 in cycle 1, d1 and d8 from second cycle onward). The next cycle was started on d29. Immediately before start of a cycle blood was drawn for flowcytometrical analysis of lymphocytes. *Results.* Currently, samples of 10 patients with multiple myeloma (median age 71 years, interquartile range (IQR) 68-73 years) have been analysed. In all patients RCD was administered at full dose. Five patients received RCD as first line therapy and five had relapsed/refractory MM. After a median of 2 cycles 90% of the patients achieved at least a partial remission (PR) (one minimal response, eight PR, one very good PR). In contrast to other anti-myeloma regimens the side effect profile of this combination was highly predictable, only one case of grade III neutropenia was noted. When comparing the data before start of therapy with data before the second cycle, the absolute number of lymphocytes decreased from median 1570/µL (IQR 1185-1590) to 1270/µL (IQR 1150-1825). In contrast, NK cells and NKT cells increased from 121.9/µL (IQR 117-253) to 210.9/µL (IQR 152-294, NK cells) and 88.8/µL (IQR 60-216) to 128.4/µL (IQR 32-319, NKT cells). In addition, the expression of activating receptors increased. The percentage of $NKG2D^+$ NK cells increased from 91.5% (IQR 88.6-93.5) to 93.9% (IQR 92.1-94.3) and $NKp30^+$ NK cells increased from 22.3% (IQR 16.7-40.6) to 26.6% (IQR 20.2-51.6). Also, NK cells expressing NKp44 increased significantly (median 0.115% (IQR 0.01-0.58) to 0.64% (IQR 0.3-0.97), P=0.03). In contrast, no difference was noted in NKp46 expression. Comparing NKT cells, the expression of $NKG2D^+$ increased from 74.9% (IQR 69.4-88.5) to 82.6% (IQR 75-84.2). The expression of the other markers of NKT cells remained unchanged. Updated results of a larger group of patients will be presented. *Conclusions.* These findings provide clinical data for the immunomodulatory activity of lenalidomide, which leads to an increase and activation of NK and NKT cells very early in the course of treatment and despite the concomitant application of immunosuppressive drugs.

0353

SYNERGISTIC CYTOTOXIC EFFECT OF COMBINED TREATMENT WITH NANOSIZED REALGAR PARTICLES AND SULFORAPHANE IN MULTIPLE MYELOMA CELLS IN VITRO

J Sedlak,[1] M Pastorek,[1] P Balaz,[2] D Cholujova,[1] L Hunakova,[1] J Duraj,[1] J Jakubikova[3]

[1]Cancer Research Institute SAS, Bratislava, Slovakia; [2]Institute of Geotechnics SAS, Kosice, Slovakia; [3]Dana Farber Cancer Institute, Department of Medical Oncology, Boston, USA

Background. In Western pharmacological history approximately 60 different arsenic preparations have been developed for medicinal use. Traditional Chinese medicines employ different form of mineral arsenicals (orpiment - As2S3, realgar - As4S4, and arsenolite - As2O3, arsenic trioxide) and realgar (REA) alone is included in 22 oral remedies based on Chinese Pharmacopeia Committee. Clinical use of arsenic trioxide (ATO) may be limited due to its acute toxicity as well as its association with carcinogenesis. REA is less toxic than ATO but exerts potent antileukemic activity in combination with imatinib. *Aims.* Recently we have disclosed cytotoxicity potentiation of another metal - cisplatin with synthetic isothiocyanate E4IB. Therefore the aim of present study was to characterize the cytotoxicity of REA as well as in combination with sulforaphane. *Methods.* The multiple myeloma cell lines OPM1, RPMI-LR5, and U266 were treated with different suspensions of REA particles with diameters ranging from 100 to 230 nm prepared by high-energy milling. The cell growth was tested by the MTT assay after 72 h of treatment. As some preparations of nanosized REA exerted high absorbance in MTT assay the direct cell counting with reference beads or CFSE-stained cells (x) using flow cytometry was performed. Viability (fluorescein diacetate/propidium iodide), apoptosis (Annexin-V binding) and mitochondrial potential (JC-1) were determined by standard flow cytometric assays. The CalcuSyn software was used to evaluate whether the combined sulforaphane and REA treatment was additive, synergistic or antagonistic. *Results.* Nanosized REA induced time- and concentration-dependent cell cytotoxicity with IC_{50} within the range of 0.1-0.3 microgram/mL of As. Apoptotic (Annexin-V+ PI-) and late apoptotic (Annexin-V+PI+) cells were observed as well as a decrease of mitochondrial potential. Combined treatment of cells with REA and sulforaphane resulted in enhanced cytotoxicity that was evaluated as synergistic one. *Summary*. Combined use of REA nanoparticles and sulforaphane might provide a promising therapeutic approach for multiple myeloma treatment especially in the context of low systemic damage of REA in comparison to ATO. *The support through the Agency for Science and Development (Project VVCE-0001-07), the Slovak Grant Agency (VEGA 2/0119/08 and 2/7059/27) is gratefully acknowledged.*

0354

INHIBITION OF MAGEC1/CT7 SIGNIFICANTLY DECREASED THE NUMBER OF SKO-007 CELLS IN G2 PHASE OF THE CELL CYCLE AND INCREASES THEIR SENSITIVITY TO BORTEZOMIB.

F Carvalho,[1] A Camargo,[2] E Costa,[2] J Gregório,[3] C Masotti,[2] V Andrade,[1] B Strauss,[4] O Caballero,[2] G Colleoni[1]

[1]Federal University of São Paulo, UNIFESP/EPM, São Paulo, Brazil; [2]Ludwig Institute for Cancer Research (LICR), São Paulo, Brazil; [3]Recepta Biopharma/Ludwig Institute for Cancer Research (LICR), São Paulo, Brazil; [4]Heart Institute, University of São Paulo School of Medicine, São Paulo, Brazil

Background. MAGEC1/CT7 gene encodes for a cancer testis (CT) antigen frequently expressed in multiple myeloma (MM) that may be a potential target for immunotherapy in this still incurable disease. This CT gene expression is restricted to malignant plasma cells and it has been demonstrated a positive correlation between *MAGEC1/CT7* expression and advanced stage of MM. The exact function of this protein for tumor biology is not yet understood, but same findings suggested that *MAGEC1/CT7* play pathogenic role in MM, possibly in the dysregulation of the cell cycle. *Aims.* The aims of this study were to elucidate the role of *MAGEC1/CT7* in the control of cellular proliferation, invasive potential and regulation of cell cycle of Sko-007 myeloma cell line and to evaluate the impact of this gene silencing in cells treated with the proteasome inhibitor bortezomib. *Methods.* Short hairpin RNA (shRNA) specific for *MAGEC1/CT7* was previously inserted in the pRS (pRETROSUPER) retroviral vector. The pRS-shRNA-*MAGEC1/CT7* was co-transfected with pCL-amphotropic packing vector in 293T cells to produce virus particles. Sko-007 myeloma cell line was transduced for stable expression of shRNA-MAGEC1/CT7. Downregulation of *MAGEC1/CT7* was confirmed by Western Blot and Real Time PCR (RQ-PCR). Functional studies included cell proliferation, 3H thymidine incorporation, invasion potential using Matrigel-coated Transwell filters and cell cycle analysis with bortezomib or without using propidium iodide (PI). *Results.* Sko-007 was chosen to perform the functional studies because basal *MAGEC1/CT7* gene expression level was higher in this cell line when compared with other myeloma cell lines (U266 and SK-MM-2). Sko-007shMAGEC1/CT7Δ (scramble, antisense strand deleted - GC bases) was used as control for all the experiments. *MAGEC1/CT7* expression was ~5 times lower in Sko-007sh*MAGEC1/CT7* than control cells by RQ-PCR. Western Blot showed ~80% decrease in *MAGEC1/CT7* protein expression by Sko-007shMAGE1/CT7 when compared with Sko-007shMAGEC1/CT7Δ . Our functional assays did not show any difference in cell proliferation and DNA synthesis when Sko-007sh*MAGEC1/CT7* was compared with control cells. Sko-007 cell line showed invasive potential, but no difference was observed in Sko-007sh*MAGEC1/CT7* or control cells.

Using flow cytometry analyses, we detected alterations between Sko-007sh*MAGEC1/CT7* cells and the control cells in G1 (P=0.0257), S (P=0.0058) and G2 (P=0.0088) phases. Sko-007sh*MAGEC1/CT7* population has 40% decreased in G2 phase when compared to control cells. When both inhibited and control cells were treated with 10 nM bortezomib, Sko-007sh*MAGEC1/CT7* population presented in G2 phase was more sensitive to drug (61%) than control cells (16%) (P=0.0475). *Summary/Conclusions.* Expression of *MAGEC1/CT7* mRNA could be inhibited by the shRNA strategy, although the concomitant reduction of its protein level did not seem to have an impact in cell proliferation, DNA synthesis or in invasive potential of Sko-007 MM cell line. However, the inhibition of *MAGEC1/CT7* significantly decreased the number of Sko-007sh*MAGEC1/CT7* cells in G2 phase of the cell cycle *in vitro* and these cells also appear more sensitive to bortezomib than control cells (Supported CNPq and LICR São Paulo Branch).

0355

PROTEIN PHOSPHATASE 2A AS A PROGNOSTIC MARKER OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS) AND MULTIPLE MYELOMA (MM)

S Kumeth, N Fadle, N Murawski, M Ahlgrimm, S Grass, M Pfreundschuh, KD Preuss

Saarland University Med. School, Homburg/Saar, Germany

Background. Proteinphosphatase 2A (PP2A) is a heterotrimeric holoenzyme, the activity of which is regulated by phosphorylation of tyrosine 307 of the catalytic C subunit. Since 2 bands with different signal intensities appear after isoelectric focusing (IEF), of which the upper band represents a variant of PP2A with a phosphorylation of tyrosine 307, we determined whether a correlation exists between the different PP2A states in healthy donors and MGUS/MM patients. *Methods.* Blinded samples of 169 consecutive patients and healthy donors were analyzed. Since the total amount of PP2A was similar in patients and controls, the ratio between the phosphorylated and the non-phosphorylated form could be determined by densitometry. In addition, the activity of PP2A was determined by immunoprecipitation and measurement of the phosphate turnover. *Results.* Samples of 30 consecutive MGUS and 73 MM patients as well as of 66 healthy donors were sorted by ascending ratio and plotted versus the diagnosis. MM patients had a higher ratio due to the more intense upper signal and less activity as shown by a shift to the phosphorylated variant compared to healthy donors, while in healthy controls a low ratio was associated with high activity. Results in MGUS patients were intermediate between MM patients and healthy donors. The 3 cohorts of healthy controls, MGUS and MM patients differed significantly with respect to their PP2A phosphorylation (P<0.001). There was no difference with respect to age and sex. Similarly, when selected clinical parameters, such as IgG, IgA, IgM, β2-microglobulin, total protein, albumin and creatinine of 12 MGUS/MM patients each, and 13 healthy controls were also plotted versus the ratio, no correlation with PP2A phosphorylation was found. Same was seen by analysis of patients with samples taken within 4 weeks after chemotherapy. *Conclusions.* Since the differences between healthy donors and MGUS/MM patients are significant in terms of the ratio between the two PP2A phosphorylation forms and activity of PP2A, determination of the two phosphorylation forms and PP2A activity might be helpful in the follow up of patients with MGUS who are at high risk to develop MM.

LENALIDOMIDE TREATMENT IS ABLE TO RESTORE REGULATORY T CELLS IN MULTIPLE MYELOMA PATIENTS

N Parrinello, A Chiarenza, AM Triolo, P La Cava, A Branca, O Di Bartolo, P Spina, E Spina, D Tibullo, C Giallongo, M Cavalli, A Romano, G Palumbo, F Di Raimondo

Divisione di Ematologia, Universita' di Catania, Ospedale Ferrarotto, Catania, Catania, Italy

Background. Multiple myeloma (MM) is a malignant plasma-cell proliferative disorder associated with dysfunctional T-cell responses. Lenalidomide appears to be a promising agent for the treatment of myeloma but its exact antitumor mechanism of action is unknown although an immunomodulatory effect has been postulated to be responsible for at least some of its activity. We therefore evaluated two lymphocytes subsets: the T-regs ($CD4^+/CD25^+/FOXP3^+$) and the T lymphocytes $CD3^+$ bearing $CD200^+$ (a tolerogenic molecule) in MM patients at diagnosis and we followed these population during treatment with lenalidomide and dexamethasone. *Materials and Methods.* Fifteen patients with MM (median age 54 years) received, as first line therapy, 4 cycles of lenalidomide 25 mg daily on days 1 to 21 of a 28-day cycle and dexamethasone 40 mg daily on days 1, 8, 15, 22 of each cycle. All patients were evaluable for response and toxicity. Peripheral blood mononuclear cells (PBMNc) were obtained from MM patients using density gradient centrifugation (Fycoll), at the beginning of each cycle and at the end of therapy. The absolute number of T-reg and of CD200 positive T- lymphocytes, were evaluated by cytometry. Thirty healthy subjects were used as control. *Results.* MM patients at diagnosis have a significantly lower rate of T-reg and T- lymphocytes bearing CD200+ than normal (47,2±35,5/mmc and 40,3±27,7 /mmc vs 64,2±20,9 and 75,4±47,3)(P=0,006 and P=0,02 respectively). Lenalidomide + dexa treatment resulted in an increase of both Treg cells and T-lymphocytes $/CD200^+$ already after the first cycle of treatment with a small decrease at the end of treatment. (Table 1). *Conclusions.* Our data emphasize the role of lenalidomide in modulating the endogenous tumor-specific immune response and underline the anti-myeloma activity of these new class of drugs.

Table 1.

PTS (n) 15	CD3+CD200+ /mmc	CD4+CD25+FOXP3+/mmc
Cycle	Means± SD	Means± SD
Healthy controls	75,4±47,3	64,2±20,9
Pre-therapy	40,3±27,7	47,2±35,5
Post-I Cycle	90±50*	68±31*
Post-II Cycle	83±76	74,4±40
Post-III Cycle	97,4±71*	62±36*
Post-IV Cycle	62,3±28	52,3±33
*= P < .05 by test Mann Whitney. The correlation is made with Pre-therapy.

PHASE 3B UPFRONT STUDY: INTERIM RESULTS FROM A COMMUNITY-BASED PROSPECTIVE RANDOMIZED TRIAL EVALUATING THREE BORTEZOMIB-BASED REGIMENS IN ELDERLY, NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

R Niesvizky,[1] J Reeves,[2] I Flinn,[3] N Gabrail,[4] R Rifkin,[5] V Charu,[6] B Clowney,[7] J Essell,[8] T Warr,[9] R Neuwirth,[10] D Corzo,[10] On behalf of the UPFRONT study

[1]Weill Medical College of Cornell University, New York Presbyterian Hospital, New York, USA; [2]Florida Cancer Specialists, Bonita Springs, USA; [3]Sarah Cannon Research Institute, Nashville, USA; [4]Gabrail Cancer Cener, Canton, USA; [5]Rocky Mountain Cancer Centers, US Oncology, Denver, USA; [6]Pacific Cancer Medical Center, Anaheim, USA; [7]Santee Hematology/Oncology, Sumter, USA, USA; [8]Oncology Hematology Care Inc., Cincinnati, USA; [9]Clinic Cancer Care, Great Falls, USA, USA; [10]Millennium Pharmaceuticals, Inc., Cambridge, USA, Nederland

Background. This US community-based phase 3b study compared the safety and efficacy of three bortezomib (Vc)-based regimens for multiple myeloma (MM), Vc-dexamethasone (VcD), Vc-thalidomide-dexamethasone (VcTD), and Vc-melphalan-prednisone (VcMP), in previously untreated MM patients ineligible for high-dose therapy and transplantation. A preplanned interim analysis was performed after 70 patients in each arm had had the opportunity to complete 4 cycles of therapy, with the intention of stopping enrollment in the inferior arm. An Independent Data Monitoring Committee (IDMC) reviewed all efficacy, safety, and quality-of-life data. There was no difference (≥10%) in very good partial response or better (≥VGPR) rates between any two treatment arms, and safety data were similar. The IDMC recommended continuing enrollment in all three arms, and performing a second interim analysis after longer treatment duration, the results of which are presented here. *Methods.* Patients were randomized (1:1:1) to receive 49 weeks of therapy: 24 weeks (eight 21-day cycles) of induction with VcD, VcTD, or VcMP (Vc 1.3 mg/m^2, days 1, 4, 8, 11; D 20 mg, days 1, 2, 4, 5, 8, 9, 11, 12 [Cycles 1-4], days 1, 2, 4, 5 [Cycles 5-8]; T 100 mg/d, days 1-21; M 9 mg/m^2 and P 60 mg/m^2, days 1-4, every other cycle), followed by 25 weeks (five 35-day cycles) of maintenance with Vc alone (1.6 mg/m^2, days 1, 8, 15, 22). The primary endpoint was progression-free survival. The second interim analysis was performed after 100 patients in each arm had had the opportunity to complete 8 cycles. *Results.* Patients in the VcD, VcTD, and VcMP arms had median ages of 73.5, 73, and 72 years; 85%, 63%, and 73% had ISS stage II/III MM; and 21%, 27%, and 27%, respectively, were non-Caucasian. The overall response rate (best confirmed response) was 69%, 79%, and 72% in the VcD, VcTD, and VcMP arms, respectively (including 36%, 44% and 39% ≥VGPR). In the VcD, VcTD, and VcMP arms, respectively, 69%, 82%, and 79% of patients experienced grade ≥3 adverse events (AEs), 48%, 55%, and 46% experienced serious AEs, and 26%, 42%, and 31% discontinued due to AEs. The rate of peripheral neuropathy (PN) was highest in the VcTD arm (59%, versus 41% [VcD] and 43% [VcMP]); similar trends were seen for the rate of grade ≥3 PN (25%, versus 14% and 19%, respectively). Rates of DVT were 7%, 4%, and 2% with VcD, VcTD, and VcMP, respectively. The most common AEs resulting in discontinuation (≥3 patients overall) in the VcD, VcTD, and VcMP arms were PN (8%, 18%, 17%), weakness (1%, 2%, 3%), fatigue (2%, 0, 1%), congestive heart failure (1%, 2%, 0), and pneumonia (0, 2%, 1%). *Conclusions.* All three regimens were active with well-characterized and predictable toxicities in this large, phase 3b study, which was primarily conducted in community-based oncology centers and included a high proportion of non-Caucasian patients. After both interim analyses, the efficacy and safety of the three regimens were deemed similar by the IDMC. Patients continue to be followed for assessment of progression-free survival.

0359

PROGNOSTIC IMPACT OF QUALITY OF RESPONSE IN PATIENTS WITH MULTIPLE MYELOMA RECEIVING UP-FRONT THALIDOMIDE-DEXAMETHASONE AND DOUBLE AUTOLOGOUS STEM-CELL TRANSPLANTATION (ASCT)

E Zamagni,[1] P Tacchetti,[1] C Nicci,[2] P Tosi,[1] F Patriarca,[2] F Di Raimondo,[2] M Fiacchini,[2] L Catalano,[2] C Terragna,[2] F Casulli,[2] G Marzocchi,[1] S Volpe,[2] L Masini,[2] A Ledda,[2] A Brioli,[2] N Testoni,[2] D Cangini,[2] G Perrone,[1] A Gozzetti,[2] C Califano,[2] C Cellini,[2] A Carubelli,[2] A Petrucci,[1] L Pantani,[1] G Leopardi,[2] M Offidani,[2] M Baccarani,[1] M Cavo[1]

[1]Istituto di Ematologia Seragnoli, Bologna, Italy; [2]Italian Myeloma Network Bologna 2002 Study, Bologna, Italy

Aim of the present study was to evaluate the prognostic impact of high-quality response (e.g. VGPR vs CR) in a large series of younger patients with symptomatic multiple myeloma (MM) who were planned to receive up-front thal-dex and double ASCT to support high-dose melphalan (200 mg/m^2). By study design, thal (200 mg/day) and pulsed low-dose dex (160 mg/month), were administered from the outset until the second ASCT. The analysis was performed on an intention-to-treat basis on a total of 357 patients who were followed for a median of 43 months. More than 80% of the patients were screened at diagnosis for the presence of cytogenetic abnormalities by FISH analysis. Forty-five percent of patients had del(13q), while t(4;14) and del(17p) were found in 14% and 6% of patients, respectively. The rate of at least VGPR increased from 31% after thal-dex induction therapy to 60% after the second ASCT. The final rate of immunofixation negative CR was 33% for all the patients and 44% for those who actually received double ASCT. The median duration of CR was 66 months. Median TTP and PFS were 68 and 47 months, respectively, with 5-year projected rates of 45% and 33%. The 5-year projected OS rate was 65%. Median OS after relapse or progression was 30 months, suggesting that short-term thal exposure had no adverse influence on response to subsequent salvage therapies. The quality of best response influenced clinical outcomes. In particular, patients achieving CR had significantly longer PFS and OS than patients in VGPR (PFS: median 68 vs 48 months, respectively, P=0.04; 5-year projected OS 84% vs 72%, respectively, P=0.02). Similarly, patients in VGPR had better outcomes compared with patients achieving PR (P=0.02 and P=0.04 for PFS and OS comparisons, respectively). The impact of high quality responses on PFS and OS was statistically significant also in patients with poor-risk cytogenetics, as identified by the presence of t(4;14) and/or del(17p). In particular, median PFS was 46 months for patients with at least VGPR vs 16 months for those in PR, P=0.0000. The corresponding OS values (projected at 5 years) were 75% vs 0%, P=0.0000. Patients achieving at least VGPR after thal-dex induction therapy had a significantly longer PFS in comparison with those who failed this objective (5-year projected rate: 58% vs 44%, respectively , P=0.04). In a multivariate analysis, attainment of CR and low serum beta2-m levels were the most important variables significantly extending TTP (P=0.04), PFS (P=0.000) and OS (P=0.003). In conclusion, attainment of CR and VGPR was a major determinant of favorable outcomes for patients treated with thal-dex incorporated into double ASCT. The prognostic value of the quality of response remained statistically significant even in patients with high-risk cytogenetics. Attainment of high quality response after induction therapy predicted for improved PFS.

TREATMENT WITH LENALIDOMIDE OVERCOMES THE POOR PREDICTIVE INFLUENCE OF HIGH IRF4 IN PATIENTS WITH MULTIPLE MYELOMA

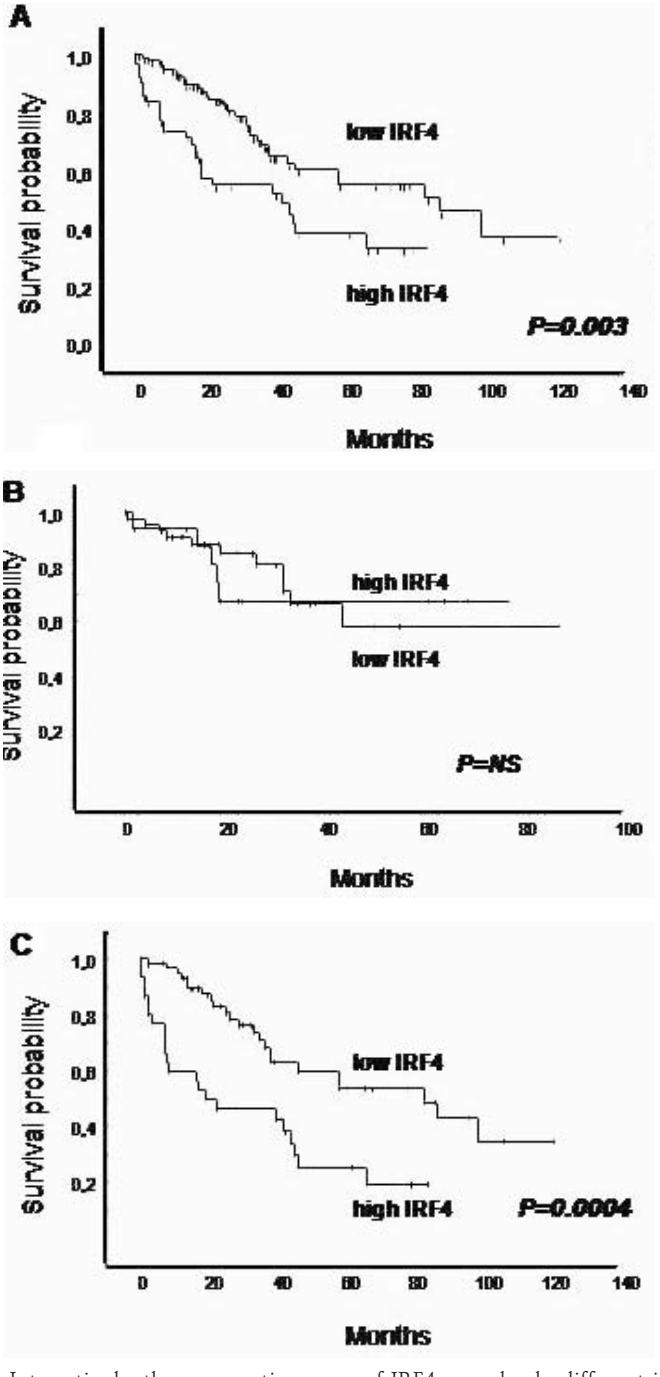
D Heintel,[1] M Schreder,[1] A Bolomsky,[1] B Hilgarth,[2] N Zojer,[1] H Gisslinger,[2] H Ludwig,[1] U Jäger[2]

[1]Wilhelminenspital, Vienna, Austria; [2]Medical University of Vienna, Vienna, Austria

Background. Interferon regulatory factor 4 (IRF4) is essential in B cell differentiation, functions as positive regulator of transcription, and depletion of IRF4 results in rapid apoptosis of myeloma cells. Previously, we have reported that high IRF4 expression in myeloma cells is associated with shortened survival. Lenalidomide exposure of myeloma cells results in significant inhibition of IRF4 and in enhanced expression of suppressor genes. However, the relationship of IRF4 expression in myeloma patient samples and clinical outcome after lenalidomide ther-

apy has not been explored until now. *Aims and Methods.* We measured IRF4 mRNA expression in bone marrow samples of 154 well characterized multiple myeloma patients (median age: 65 years, range 33-90 years) using real time PCR, and evaluated the predictive value of IRF4 in association with lenalidomide and other treatment strategies. *Results.* The median IRF4 expression of patient samples was 4.6 fold relative to normal PBMNC (range: 0.1-15343.4). Overall survival analysis confirmed previous data, showing a significantly shorter overall survival for patients with high IRF4 expression (defined as >13 fold as compared to normal PBMC), with a medium survival of 42 months in high vs. 83 months in low expressers (P=0.003, Figure 1A).

Figure 1.



Interestingly, the prognostic power of IRF4 was clearly different in patient subgroups. Sixty-four patients were treated with lenalidomide while 90 patients received other therapies including high dose therapy, bortezomib, thalidomide, alkylating agents and corticosteroids after bone marrow collection. In patients with lenalidomide therapy, there was no significant difference regarding overall survival between patients with low or high IRF4 anymore (Figure 1B). In contrast, in patients treated otherwise, high IRF4 was not only again associated with a shorter overall survival, the prognostic significance was even pronounced, with a median survival of 19 vs. 83 months (P=0.0004, Figure 1C). When patients were stratified into 4 groups according to IRF4 expression and treatment with or without lenalidomide, those with high IRF4 without lenalidomide therapy had a significantly worse prognosis, while in the other 3 groups overall survival curves were similar. In high IRF4 expressers, patients treated with lenalidomide had a significant better overall survival than those receiving other therapies (median: not reached vs. 19 months, P=0.02). In low IRF4 expressers, no difference regarding overall survival was found between patients treated with or without lenalidomide. To date, information on clinical response to lenalidomide therapy is available in 38 patients. One patient had a complete remission (CR), 3 had a near complete remission (nCR), 10 had a partial response (PR), 5 had a minimal response (MR), 6 had stable disease (SD), and 13 had progressive disease (PD). Of note, 3 of 4 patients with a CR or nCR were high IRF4 expressers, while 10 of 13 patients with PD were found in the low IRF4 group. *Summary/Conclusions.* In our study, the negative prognostic impact of high IRF4 was overcome by treatment with lenalidomide. IRF4 expression might be used as a predictive factor to optimise treatment, especially for the 30% of myeloma patients with high IRF4 expression.

Background. Bone disease is a hallmark of multiple myeloma. Occurring in the majority of myeloma patients, it is associated with bone pain, fractures, hypercalcemia and has major impacts on quality of life. In a cohort study, 16 times more fractures were observed than expected in the year before diagnosis. Before lytic lesions become apparent, a high rate of bone resorption is already existent in the majority of the patients. The standard of care in asymptomatic multiple myeloma is "wait and see". Due to their inhibitory effect on bone resorption, bisphosphonates might prevent skeletal-related events in early myeloma. Furthermore, bisphosphonates might be beneficial by interrupting the vicious cycle between osteoclast activation and myeloma progression or by other antitumor effects. *Aims.* Zoledronic acid is a third generation bisphosphonate which induces a strong inhibition of bone resorption. The present phase III study investigated the effect of intravenous treatment with zoledronic acid on progression-free survival (PFS) in patients with stage I multiple myeloma. The primary objective of the trial was PFS, secondary objectives comprised time to develop skeletal-related events and overall survival, as well as tolerability and safety of zoledronic acid. *Methods.* This prospective, randomized, open multicenter study started in 2000. PFS is calculated from start of the treatment to disease progression or death. Progression was defined as progression in stage II or III (Durie & Salmon), progression of osteolytic lesions or occurrence of skeletal-related events. Ethical approval and informed consent from all patients were obtained. It was planned to include 220 patients, but due to slow recruitment the study was prematurely terminated. 140 patients were available for analysis (71 zoledronic acid and 69 control). Patients aged > 18 years with a diagnosis of multiple myeloma according to the criteria of the British Columbia Cancer Agency (which are similar to IMWG criteria published later) and Stage I (Durie and Salmon) were enrolled in this clinical trial. Zoledronic acid (4 mg i.v.) was administered every 4 weeks. Treatment was planned to last until progression or 48 months, whatever comes first. *Results.* For the incidence of skeletal-related events, a trend favoring treatment with zoledronic acid was detected (P=0.056). Of interest, no patient in the zoledronic acid group experienced skeletal related events. Progression according to the definition of the protocol occurred in 19 patients treated with zoledronic acid and 26 patients in the control group, respectively (26.8% vs. 37.7%). Kaplan-Meier plots for progression-free survival

showed a trend favoring zoledronic acid, but the difference did not reach statistical significance (log-rank: P=0.34). *Conclusion*s. This phase III study comparing zoledronic acid with no treatment in multiple myeloma patients in stage I according to Durie & Salmon showed a trend favoring zoledronic acid in regard of both skeletal-related events and progression of multiple myeloma, although a statistical significance was not reached, possibly due to the fact that the planned sample size was not recruited.

INTERNATIONAL STAGING SYSTEM (ISS) IS A GOOD PROGNOSTIC FACTOR FOR PROGRESSION FREE SURVIVAL IN MULTIPLE MYELOMA PATIENTS WITH GOOD RESPONSE AFTER TRANSPLANT

A Corso,[1] C Crippa,[2] S Mangiacavalli,[1] AM Cafro,[3] F Cocito,[1] A Citro,[3] M Varettoni,[1] P Brasca,[3] G Rossi,[2] M Lazzarino,[1] E Morra[3]

[1]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [2]Divisione di Ematologia, Ospedali Riuniti, Brescia, Brescia, Italy[3]Division of Hematology Ospedale Niguarda Cà Granda, Milano, Milano, Italy

Background. Transplant (Tx) remains the gold-standard therapy for younger multiple myeloma (MM) patients (pts). The achievement of good quality responses (CR/VGPR) seems to be a prerequisite for longer progression free survival (PFS). However PFS could be significantly variable among patients with the same type of response (CR/VGPR/PR). No study have been performed until now exploring this aspect. *Aims.* To evaluate any correlation between baseline clinical and laboratory findings and the length of PFS within three groups of patients defined according to the type of response (CR/VGPR/PR) after Tx. *Patients and Methods.* Baseline characteristics of 443 transplanted pts were studied. VAD was used as induction in 370 pts and bortezomib plus dexamethasone in 73 pts. All pts collected stem-cells with chemotherapy plus G-CSF, and conditioning regimen included melphalan 200 mg/m^2. Pts were considered responsive when obtaining at least a PR according to IMWG criteria. The following baseline characteristics were considered for univariate and multivariate analysis: gender, age, Durie and Salmon stage, ISS, number of bone lesions (>3 or ≤3), extramedullary localizations, bone marrow plasmacytosis, haemoglobin level, hypercalcemia, creatinine level, serum and urine monoclonal component, response after induction, type of induction therapy. Type of response, PFS, and PFS in pts grouped according to response after Tx (CR, VGPR, PR) were correlated with categorical and continuous variables through Kaplan-Meyer and Cox methods. *Results.* Taken together all patients had a median follow-up of 44,8 months (1-150 months), a median OS by intention to treat of 92,5 months, and a median PFS after Tx of 24.3 months. 353/443 pts enrolled (80%) were transplanted. At the time of this analysis 25% of the pts (85/339) are free of progression. None of the baseline characteristics showed, in univariate and multivariate analysis, significant correlations either with type of response or with PFS after Tx. Better PFS was registered in pts with CR after Tx (P=0.0001). When pts were grouped according to response after Tx, median PFS were 28.6 (2-106), 22 (6-84), 18 (3-105) months for CR, VGPR, and PR respectively. In pts with CR, high ISS, low haemoglobin level and high plasmocytosis showed a statistically significant shorter PFS. In patients with VGPR, high ISS, low haemoglobin level, hypercalcemia, and high monoclonal component level were significantly correlated with shorter PFS. No significant correlations were found in PR group. *Conclusions.* Our study confirms that Tx allows long-lasting control in younger MM pts, producing in our hands a median overall survival of 92.5 months. Although the achievement of a good quality of response impacts on PFS, there is a great variability among patients with the same type of response after Tx. ISS and hemoglobin level seems to be useful in identifying patients in good response after Tx who could deserve a consolidation or a maintenance to prolong PFS.

Background. Cytogenetics and fluorescent-*in situ* hybridization (FISH) are important outcome predictors in multiple myeloma (MM). There were only few small studies that investigated prognostic implication of interphase FISH and/or conventional karyotypes in Korean MM patients. *Aims.* We investigated the incidences and prognostic significances of chromosomal abnormalities detected by interphase FISH and/or conventional karyotyping among Korean MM patients. *Methods.* We collected Korean myeloma patients' data using Korean Multiple Myeloma Registry and performed a retrospective analysis. We analyzed the impact of abnormal karyotypes and FISH anomalies on overall survival. *Results.* From 2000 to 2009, total of 789 newly diagnosed myeloma patients were enrolled in this study. Median age of patients was 62 years. Median overall survival was 68 months, and median follow up of time was 67 months. Among the patients with conventional karyotyping, 28.7% of the patients had abnormal karyotypes. Among the patients with abnormal karyotypes, 46% were hyperdiploid, and 54.0% were non-hyperdiploid. Del13q was found in 26.6% of the patients. Among the patients with interphase-FISH analysis, 23.1% were del13q, followed by t(11;14) (18.5%), t(4;14) (13.9%), del17p (12.0%) and t(14;16) (6.1%). Univariate analyses revealed that abnormal karyotypes (P<.001), del13q (P<.001) by conventional karyotyping, and del13q combined with t(4;14) (P=.019) by interphase-FISH negatively impacted the overall survival. Other genomic aberrations did not affect the overall survival. Clinical parameters that impact on overall survival were infiltration rate of plasma cells in bone marrow, serum beta2-microglobulin, creatinine, low hemoglobin, and low albumin levels. On multivariate analysis, serum creatinine (P=.006), low albumin (P<.001), and del13q by conventional karyotyping (P=.003) were independent risk factors for overall survival. *Summary/Conclusions.* Our results indicate that abnormal karyotypes, del13q by conventional karyotyping, and del13q combined with t(4;14) by interphase-FISH were negative prognostic factors for overall survival in univariate analyses. On multivariate analysis, del13q by conventional karyotyping was independent risk factor for overall survival. In future, prospective trial with laboratory standardization is needed for more reliable results from FISH and conventional karyotyping in MM patients.

0364

NEW STRATEGY FOR ALLOGENEIC PERIPHERAL BLOOD STEM CELL TRANSPLANTATION AFTER REDUCED INTENSITY CONDITIONING IN MULTIPLE MYELOMA: IFM2005-03 STUDY

M Michallet,[1] M Sobh,[1] M Mohty,[2] A Sirvent,[3] O Reman,[4] J Cornillon,[5] J El Cheickh,[6] R Tabrizi,[7] A Praire,[1] D Blaise,[6] N Milpied,[7] P Moreau,[2] J Harousseau[2]

[1]Edouard Herriot Hospital, Lyon, France; [2]Hotel Dieu Hospital, Nantes, France; [3]Archet Hospital, Nice, France; [4]Caen University Hospital, Caen, France; [5]Institut de Cancérologie de la Loire, Saint Priest en Jarez, France; [6]Institut Paoli Calmettes, Marseille, France; [7]CHU Bordeaux, Bordeaux, France

Background. The development of new agents with potent anti-tumor activity has considerably improved the survival of multiple Myeloma (MM) patients. However, allografting remains the only available curative treatment particularly for patients at high risk. *Material and Methods.* This is a prospective multicenter study for MM patients of age ≤ 65 years receiving RIC followed by allo-PBSCT after achieving at least a partial response (PR) to auto-transplantation in first line. Patients previously received induction treatment followed by Melphalan 200 mg/m^2. Patients must have an HLA identical donor either from siblings or unrelated 10/10 HLA donors, and at least one of the following poor prognostic factors (PPF): β2 microglobulin >3 mg/L, Del 13, t(4;14) and Del 17p. The conditioning regimen combined Fludarabine 30 mg/m^2/d (d-5→d-1), Busilvex IV 3,2 mg/kg/d (d-4, d-3) and ATG 2,5 mg/kg/d (d-2, d-1). By day 90 post-allograft, patients not in CR received 4 cycles of Velcade 1.3 mg/kg, and after Velcade, if the CR was not achieved, increasing doses of DLI were administered. This analysis included 12 patients, 10 males and 2 females, median age was 46 years [40-60], there were 9 IgG stageA (8κ & 1λ) and 3 IgA (1κ stage B & 2λ stage A). There were 3 patients with 1 PPF, 6 patients with 2 PPF and 3 patients with 3 PPF. *Results.* Seven patients received 4 cycles of VAD (4 patients VAD+DCEP), 2 patients received 4 cycles of Velcade + dex. and 3 patients received other combinations (1PAD, 2VAD then Velcade). After induction, 8 patients were in PR and 4 in stable disease (SD). Patients received auto-HSCT after a median time of 6.6 months [4.5-8.7] from diagnosis. All patients were in PR after auto-HSCT and before allo-PBSCT. The median number of infused CD34+ cells was 6.5×10^6/kg [2.6-13.7] from 4 identical siblings and 8 matched unrelated donors. Sex matching was: F→M:5, F→F:1, M→F: 1 and M→M:5. At D90, 3 patients were in CR and 9 patients received Velcade after absence of CR (2 VGPR and 7 PR). After Velcade, the 2 VGPR evolved to CR and patients in PR became 1 CR, 1 VGPR and 5 remained in PR). One patient in VGPR and 3 in PR received DLI after Velcade, responses were: 1 VGPR and 3 patients progressed. There were 6 acute GVHD (5 grade II and 1 grade III) and 6 chronic GVHD (5 limited and 1 extensive), all GVHD were resolved at the last follow-up. After a median follow-up of 30 months, all patients are alive [100% overall survival (O.S.)], 5 patients are in CR, 1 in VGPR, 5 in PR and one in progression without any active chronic GVHD even after DLI administration. *Conclusions.* We showed very good results due to the better conditioning with the introduction of Busilvex, also the impact of Velcade in eliminating the residual disease. According to these very promising results, we should reconsider the allo-HSCT as a first line treatment for MM especially for patients with PPF using either RIC or standard conditioning depending on age.

0365

OUTCOME OF STAGE B MULTIPLE MYELOMA UNDERGOING HIGH-DOSE THERAPY WITH AUTOTRANSPLANT

M Galli,[1] E Sabadini,[1] G Remuzzi,[1] T Barbui,[2] A Rambaldi[1]

[1]Ospedali Riuniti, Bergamo, Italy; [2]Fondazione per la Ricerca Ospedale Maggiore, Bergamo, Italy

Background. Limited information of the outcome of patients with newly diagnosed multiple myeloma (MM) presenting with serum creatinine > 2 mg/dl (stage B-MM) is available. *Aims.* In the context of an outcomes research project, we analysed the major determinants of treatment response in 71 consecutive, unselected, newly diagnosed stage B-MM patients. *Methods.* Forty-one patients (58%) were enrolled in programs of high dose chemotherapy with autologous stem cell transplant (autoTx), whereas the other 30 (42%) received non-autoTx-based treatments. Treatment allocation was based on patients' age and performance status but not on serum creatinine at diagnosis. *Results.* A the end of first-line therapy, median serum creatinine decreased from 3.75 mg/dL at diagnosis to 1.4 mg/dL, and reverted to values <2 mg/dL in 76% of patients who entered HDT with autoTx programs and in 52% of those who received non-autoTx-based treatments. However, seven of the 15 patients requiring dialysis at diagnosis remained on chronic dialysis. Age > 65 years, anemia and pre-therapy dialysis were associated with a worse outcome. The 71 stage B-MM patients had median overall survival (OS) and event-free survival (EFS) of 21 and 17 months, which decreased to 17 and 14 months for the 30 patients not eligible to HDT with autoTx programs and increased to 25 and 21 months, respectively, for the 41 patients who entered programs of HDT with autoTx. The 28 patients who received at least one autoTx procedure had median OS and EFS of 33 and 29 months, respectively. Thriteen patients received Thalidomide and/or Bortezomib during the induction phase before autoTx procedures. They enjoyed better outcomes (5-yr OS and EFS of 34% and 42%, respectively) compared to the 28 patients who did not receive either drug (5-year OS and EFS of 24% and 12%, respectively). However, these differences did not reach statistical significance. *Summary and Conclusions.* Treatment of stage B-MM improved renal function in the majority of patients, and 60% of them reached at least a partial response. AutoTx procedures were feasible in about 40% of patients, and significantly ameliorated their outcomes. However, when compared to MM patients with a normal renal function, stage B-MM patients showed a higher rate of early mortality and worse outcomes. It is, therefore, necessary to improve treatment in order to enhance response rate and reduce mortality. The incorporation of Thalidomide and, in particular, Bortezomib - which may be safely administered also in patients with severe impairment of renal function - in the first line therapies will help us to reach this goal.

0366

RANDOMIZED PHASE 2 TRIAL OF BORTEZOMIB-DEXAMETHASONE (VD) VERSUS VD PLUS CYCLOPHOSPHAMIDE OR LENALIDOMIDE IN MYELOMA PATIENTS ACHIEVING STABLE DISEASE AFTER 4 CYCLES OF VD AS SECOND-LINE TREATMENT

M Dimopoulos,[1] H Roddie,[2] M Beksac,[3] L Benboubker,[4] J de la Rubia,[5] L Casado,[6] N Allietta,[7] R Angermund,[7] T Facon[8]

[1]Alexandra Hospital, University of Athens, Athens, Greece; [2]Haematology Department, Western General Hospital, Edinburgh, UK; [3]Ankara University, Ankara, Turkey; [4]University Hospital, Tours, France; [5]Hospital La Fe, Hematology Department, Valencia, Spain; [6]Hospital Virgen de la Salud de Toledo, Hematology Department, Toledo, Spain; [7]Janssen-Cilag, Paris, France; [8]CHRU de Lille Hôpital Claude Huriez, Service des Maladies du Sang, Lille Cedex, France

Background. Bortezomib plus dexamethasone (VD) is known to be effective and well tolerated in patients with multiple myeloma (MM). As demonstrated in the frontline setting, the addition of cyclophosphamide (VCD) or lenalidomide (VRD) may lead to improved efficacy, but may be associated with increased toxicities; however, few studies have prospectively assessed VD as second-line therapy. *Aims.* This randomized, open-label, parallel-group, phase 2 study in patients with relapsed or refractory MM was designed to evaluate the safety and efficacy of an additional 4 cycles of bortezomib based therapy following 4 initial cycles of VD (Vel 1.3 mg/m^2 IV on days 1, 4, 8, and 11, and Dex 20 mg PO on days 1, 2, 4, 5, 8, 9, 11, and 12) totalling a maximum of 8 treatment cycles. *Methods.* Patients achieving at least partial response (PR) received 4 cycles of VD; patients with SD were randomised to 4 cycles of VD, VCD or VRD. Patients with progressive disease (PD) discontinued treatment. Bortezomib-naïve patients aged ≥18 years and with a KPS ≥60 were eligible; patients with grade ≥2 peripheral neuropathy (PN) were ineligible. *Results.* A total of 183 patients were enrolled; 32 had not received therapy and were excluded from the safety population (N=151). The median age at baseline was 63 years (range 34-86), 49.6% were male, 20.3% had KPS ≤70; median time from prior therapy was 14.9 months. In 92 patients, efficacy was evaluable after cycle 4. Overall response rate of 83.7% (including 10.9% CR, 25% VGPR, 47.8% PR) was observed. A further 15 (16.3%) patients had SD; 17 patients were randomized to sequential therapy. Median time to first and best response was 43 and 64 days, respectively. The glomerular filtration rate (GFR) results are shown in the Table. 54% of patients experienced grade 3/4 AEs and 36% had serious AEs. The most common grade 3/4 AEs included thrombocytopenia (13%), anemia (8%), and pneumonia (5%). AEs resulting in dose reductions/treatment stop were seen in 38%/21% of patients. Incidence of sensory PN and PN was 34% (7% grade 3/4); 76% of PN events were reversible, with resolution in 33.5% and improvement in 42.5% in a median of 241 and 55 days, respectively. *Conclusions.* This study further demonstrates that VD treat-

ment is effective and well tolerated with less than 10% of patients needing sequential therapy. Overall renal function was shown to improve with treatment. VD represents a feasible, active treatment option for patients with relapsed MM. Acknowledgments: The authors would like to thank all of the MMY-2045 study investigators.

Table. Renal function (as measured by GFR)*.

Renal function group, n†	
Baseline	121
GFR <15 mL/min	3
15–<30 mL/min	9
30–<60 mL/min	46
≥60 mL/min	63
Renal improvement by at least 1 grade, n (MM response)	12
<15 to 15–<30 mL/min	1 (1 CR)
15–<30 to 30–<60 mL/min	2 (1 VGPR, 1 PR)
30–<60 to ≥60 mL/min	9 (1 CR, 1 VGPR, 4 PR, 3 SD)

*1 patient only had a baseline GFR measurement and was not included in the renal analysis
†1 patient had no baseline GFR measurement

A PHASE III STUDY COMPARING THALIDOMIDE/CYCLOPHOSPHAMIDE/ DEXA VS THALIDOMIDE/DEXA VS THALIDOMIDE/MELPHALAN/PREDNISONE IN DE NOVO MULTIPLE MYELOMA PATIENTS NOT ELIGIBLE FOR ASCT: PRELIMINARY ANALYSIS

V Hungria,[1] E Crusoe,[2] A Maiolino,[3] R Bittencourt,[4] D Fantl,[5] A Quero,[1] AL Peres,[1] D Mercante,[3] E Miranda,[6] C Chiattone[1]

[1]Santa Casa de Misericórdia de São Paulo, Sao Paulo, Brazil; [2]Santa Casa de Misericordia de São Paulo-Pos Graduando Ciencias da Saúde- FCMSCSP, Sao Paulo, Brazil; [3]Hospital Universitario Clementino Fraga Filho-UFRJ, Rio de Janeiro, Brazil; [4]Hospital de Clinicas de Porto Alegre- UFRGS, Porto Alegre, Brazil; [5]Hospital Italiano Buenos Aires, Buenos Aires, Argentina; [6]Universidade Estadual de Campinas, Campinas, Brazil

Background. Thalidomide (Thal) is a pro-apoptotic, immunoregulatory and antiangiogenic agent for MM. Although it is used since the 90's, the optimal combined treatment remains inconclusive. *Aims.* This is a preliminary analysis of the first Latin American prospective open-label study comparing three different combinations with Thal for MM patients not eligible for autologous SCT. *Patients and Methods*. Eligible patients were randomized to one of the three arms and received nine 28-days induction cycles. All patients received Thal(100-200 mg/d) and one of the following: A- Cyclo (50 mg/d)+ Dexa (40 mg/D1-4, 15-18 in cycles 1 and 2, D1-4 in cycles 3 to 9), B- Dexa (40 mg/D1-4, 9-12, 17-20 in cycles 1,3,5,7 and 9, D1-4 in even cycles) or C- Mel (4 mg/m^2/7d)+ Pred (40 mg/m^2/7d). Thereafter, they were randomized to maintenance treatment until progression disease or unacceptable toxicity, as follows: A1-Thal (100 mg/d)+Pred (50 mg/each other day) or B1-(Thal 100 mg/d). All patients received aspirin as thromboprophylaxis and sulphatrimetroprim as prophylaxis for infection. If indicated, they received biphosphonate monthly for 24 months, and then quarterly. Before study initiation, informed consent was obtained from patients and evaluation was performed at the end of each cycle. The primary endpoint was response rate and response duration. The secondary endpoints were safety, OS and PFS. IMWG index was utilized to analyze response criteria. *Results.* Enrolment started on February 2007, and a total of 54 patients have been included. Median age at randomization was 71 (56-84) years-old, and 57% of patients were female. Durie-Salmon stages were 10% II, 84% III and ISS stages were 43% II and 33% III. Fifty-one per cent of patients presented IgG monoclonal component. After 3 cycles, 63% of patients had total objective response, 6.3% had CR, 14.9% had VGPR, and 42.5% had PR. After six cycles, total objective response was 70.2%, CR=10.6%, VGPR=19.2% and PR=40.4%. Up to present, 44.7% of patients have concluded 9 cycles with a total objective response of 90%, CR=19%, VGPR=19%, and PR=62%. The Table 1 shows the response rate of each arm and cycle (until cycle six). Progression disease was observed in one patient. Nine deaths occurred until now and 7 during induction phase, 5 of them within the first 4 months. Infection was the major cause of death. During induction, 42% of patients experienced grade 3/4 toxicity, including grade 3/4 neutropenia or infection (4 patients), neuropathy (8), and venous thrombosis (1). Dose reduction was required for 4 patients due to toxicity, but no discontinuation has occurred. The median follow-up for all patients was 226 days (11-1010) and 80% of patients are still alive. *Discussion.* This preliminary analysis suggests that Thal combinations are effective in MM patient treatment. The alkylating combination with thalidomide has demonstrated better objective response than Thal+Dexa. Toxicity was acceptable in all arms. Performance status could justify the initial mortality rate. With more patients included in this study, probably we will get to define the best Thalidomide combination for MM patients not eligible for ASCT.

We would like to thank Dr. Jesus San Miguel and Dra. Maria-Victoria Mateos who have collaborated in this study.

Background. Incorporation of novel agents has resulted in an improved response rate and reduced side effects in multiple myeloma. This has suggested the possibility of using novel agents as induction chemotherapy in patients with newly diagnosed multiple myeloma. *Aims.* We studied efficacy and safety of sequential VAD and VTD as induction chemotherapy. *Methods.* The patients were planned to receive 2 cycles of VAD and VTD. Bortezomib as a maintenance treatment was administered weekly x 4 times every 6 weeks for 4 cycles after ASCT. *Results.* A total of 71 patients were enrolled, and efficacy could be assessed in 59 patients. After 2 cycles of VAD, the RR was 67.8%. After VTD, the RR was more increased to 96.6% (CR and near CR: 27.1%). Especially, 7 patients with poor prognostic cytogenetics all responded after VTD. Autologous stem cells were successfully collected in all 52 patients with a median CD34$^+$ count of 7.12×10^6/kg (range, 1.94-44.7 ×10^6/kg), except one patient. After ASCT, 30 patients completed bortezomib maintenance, and the rate of CR and near CR was 70%. The median follow-up duration was 34.6 months, and the median time to response was 1.6 months. The median TTP and OS were not reached. *Conclusions.* The sequential VAD and VTD induction therapy in patients with newly diagnosed multiple myeloma was effective with tolerable toxicity profiles and it did not prejudice stem cell collection. VTD could have contributed to the increased RR and minimized the side effects as an induction therapy, and maintenance therapy with bortezomib maintained a very good overall response rate.

0369

EFFICACY AND SAFETY OF WEEKLY INFUSION BORTEZOMIB IN ELDERLY NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

S Bringhen,[1] M Genuardi,[1] D Rossi,[2] M Petrucci,[2] A Andriani,[2] R Rizzi,[2] G Mele,[2] G Aitoro,[2] V Mettivier,[2] O Annibali,[2] F Rossini,[2] P Gentilini,[2] V Pavone,[2] C Cellini,[2] N Giuliani,[2] A Rauco,[2] A Baraldi,[2] A Dominietto,[2] A Capaldi,[2] N Pescosta,[2] R Rizzi,[2] A Nozza,[2] A Spadano,[2] V De Stefano,[2] M Holànek,[1] G Gaidano,[2] M Boccadoro,[1] A Palumbo[1]

[1]A.O.U. San Giovanni Battista, Torino, Italy; [2]Italian Multiple Myeloma Network, Gimema, Italy

Background. Frequently observed toxicities associated with bortezomib-based therapy include peripheral neuropathy (PN), thrombocytopenia and gastrointestinal dysfunction. Bortezomib related PN is a common complication (≥G3 22%), particularly among elderly patients, it is dose related and reversible in most cases with treatment interruption and dose modifications. *Aims.* To evaluate the efficacy, the safety and the risk factors of bortezomib related adverse events, particularly PN, in patients with newly diagnosed myeloma treated with different schedules of bortezomib, in a phase III randomized study of bortezomib-melphalan- prednisone-thalidomide followed by continuous treatment with bortezomib-thalidomide (VMPT-VT) versus bortezomib-melphalan-prednisone (VMP). *Methods.* Between May, 2005 and January, 2009, 511 patients older than 65 years were randomly assigned to VMPT-VT or VMP. In the VMPT-VT arm patients received bortezomib 1.3 mg/m^2 days 1,4,8,11,22,25,29,32 in cycles 1-4 and days 1,8,22,29 in cycles 5-9; melphalan 9 mg/m^2 plus prednisone 60 mg/m^2 days 1-4 and thalidomide 50 mg days 1-42 for nine-6-week cycles, followed by VT therapy (bortezomib 1.3 mg/m^2 days 1, 15, thalidomide 50 mg/day). In the VMP arm patients received the same schedule without any further therapy. To evaluate if the treatment regimens could be further optimized by decreasing the toxicity while maintaining efficacy, in March 2007 the protocol was amended and both bortezomib schedules were reduced to once weekly infusion. *Results.* 503 patients were evaluable for safety and efficacy, 369 patients were treated with once-weekly infusion of bortezomib and 134 with twice-weekly infusion. The response rate was similar in once-weekly group as compared with twice-weekly group: ≥PR in 85% vs 86% of patients (P=.73), with a VGPR rate of 55% vs 54% (P=.84) and CR of 29% vs 35% (P=.23), respectively. There aren't differences between once-weekly and twice-weekly patients in the 3-y PFS (50% vs 47%, P=.99) and 3-y OS (88% vs 89%, P=.54). Regarding toxicity, non-hematologic grade 3 to 4 adverse events were reported in 36% of once-weekly patients and in 51% of twice-weekly patients: the reduction was significant (P=.003) and was mainly related to grade 3 or 4 sensory PN that was significantly reduced from 16% to 3% (P<.001), without any significant difference between VMPT-VT and VMP groups. In multivariate analysis the only predictive factor of lower incidence of PN (P<.0001) was the reduction of bortezomib infusion from twice to once weekly. The proportion of patients who required treatment interruption for PN was 5% in the once-weekly patients and 15% in the twice-weekly patients (P<.0001). Similarly, the proportion of patients who required bortezomib dose reduction was 24% and 54%, (P<.0001), respectively. This improvement in the discontinuation and dose reduction rate prolonged the time on therapy: the cumulative delivered bortezomib dose compared with planned dose was 40.0 mg/m^2 (46.8 mg/m^2) in once-weekly patients and 41.0 mg/m^2 (67.6 mg/m^2) in twice-weekly patients. *Conclusions.* The weekly infusion of bortezomib significantly decreased the incidence of severe PN, discontinuation rate, dose reduction rate and prolonged the time on therapy. This unprecedented improvement of safety came with no substantial reduction in terms of efficacy.

0370

OUTCOME OF ELDERLY PATIENTS 70 YEARS AND OLDER WITH NEWLY DIAGNOSED MYELOMA IN THE ECOG RANDOMIZED TRIAL OF LENALIDOMIDE/HIGH-DOSE DEXAMETHASONE (RD) VERSUS LENALIDOMIDE/LOW-DOSE DEXAMETHASONE (RD)

S Jacobus,[1] N Callander,[2] D Siegel,[3] R Abonour,[4] D David,[5] R Fonseca,[6] M Williams,[7] M Katz,[8] P Greipp,[6] V Rajkumar[6]

[1]Eastern Cooperative Oncology Group, Boston, USA; [2]University of Wisconisn, Madison, USA; [3]Hackensack University Medical Center, Hackensack, USA; [4]Indiana University, Indianapolis, USA; [5]St. Vincent's Hospital, New York, USA; [6]Mayo Clinic, Scottsdale, USA; [7]University of Virginia, Charlottesville, USA; [8]International Myeloma Foundation, North Hollywood, USA

Aim. Lenalidomide and dexamethasone is increasingly being used as frontline therapy in myeloma in elderly patients, but data on its efficacy in this cohort compared with other standard regimens is not known. The goal of this study was to determine and describe the safety and efficacy of this combination in the subset of elderly patients 70 years of age and older treated on the ECOG phase III trial of lenalidomide plus high (standard) dose dex (RD) versus lenalidomide plus low dose dex (Rd) in newly diagnosed myeloma (MM). *Methods.* The ECOG E4A03 trial enrolled 445 adult patients with newly diagnosed myeloma (median age, 65 yrs) with no age restriction, and results have been published (Lancet Oncol 2010;11:29-37). For this analysis, pts 70 years and older treated on this trial were studied. Pts in the RD arm received lenalidomide 25 mg/day PO days 1-21 every 28 days plus dex 40 mg days 1-4, 9-12, and 17-20 PO every 28 days; pts in the Rd arm received lenalidomide at the same dose plus dex 40 mg days 1, 8, 15, and 22 PO every 28 days. The primary endpoint for this analysis was overall survival at 3 years. Response and progression free survival (PFS) were studied as additional endpoints. All analyses were performed on intent to treat basis. *Results.* 147 patients ages 70 years and older (76 randomized to RD and 71 randomized to Rd) were studied. 15 patients (10%) went onto SCT. Median follow-up time is 36 months. Treatment duration was 3.9 mos (RD) and 9.7 mos (Rd), P=<0.001. The overall response rate (partial response or better) was 74% (RD=75% and Rd=74%), including 45% with very good partial response or better (RD=42% and Rd=48%). Median PFS was 22 months with Rd, and 16 months with RD, P=0.11. The 3-year overall survival rate was 66%. Overall survival in this cohort of patients 70 and older was significantly superior with lenalidomide plus low dose dex, P=0.03; 3-year overall survival 73% (Rd) versus 61% (RD). Overall survival differences persisted when survival was analyzed after excluding the 15 pts who underwent SCT (P=0.02), with corresponding 3-year survival rates of 70% with Rd and 57% with RD. Forty-eight patients have died; 23 due to disease progression, 6 cardiac causes, 6 unknown, 5 infection, 3 thrombosis/embolism, and the rest due to other causes. The rate of grade 3 or higher non-hematologic toxicities was 59% with Rd, and 78% with RD. This included deep vein thrombosis rates of 20% (Rd) and 30% (RD); corresponding rates for infections were 10% and 20%, respectively. *Conclusions.* Lenalidomide plus low-dose dexamethasone (Rd) appears to be safe and effective in elderly patients 70 years of age and older with newly diagnosed multiple myeloma, with a 3-year overall survival rate of 73%. This non-alkylator-containing oral regimen merits comparison with standard regimens such as bortezomib, melphalan, prednisone.

Background. Bortezomib plus thalidomide-dexamethasone (VTD) has demonstrated substantial activity as induction therapy in MM. Bortezomib has also shown activity in combination with cyclophosphamide-dexamethasone in treatment-naïve MM patients. While 4-drug regimens may build on efficacy of three-drug combinations, they may also be associated with increased toxicity. *Aims.* To determine whether addition of cyclophosphamide to VTD (VTDC) increases efficacy, both post-induction and following HDT-ASCT, without compromising safety. *Methods.* This randomized, phase 2, non-comparative study enrolled 98 previously-untreated, transplant-eligible MM patients (aged 18-70

years) with measurable disease. Patients received four 21-day cycles of VTD (bortezomib 1.3 mg/m^2 [days 1, 4, 8, 11]; thalidomide 100 mg daily; dexamethasone 40 mg [days 1-4, 9-12];n=49) or VTDC (VTD plus cyclophosphamide 400 mg/m^2 IV [days 1, 8];n=49), as induction therapy prior to HDT-ASCT. Patients could receive an additional 4 cycles if they became transplant-ineligible or had complete response (CR) post-induction. Responses were categorized using modified IMWG Uniform Response Criteria (stringent CR replaced by CR with normalized serum κ:λ ratio [CRflc]).The primary endpoint was combined CR rate (CRflc+CR+near-CR) post-induction. Secondary endpoints included combined CR rate post-HDT-ASCT, overall response rate (ORR: ≥partial response) post-induction and post-HDT-ASCT, time to progression (TTP), overall survival (OS), quality of life (QoL), and safety. Adverse events (AEs) were graded using NCI CTCAE v3.0. Bone marrow samples taken during suspected CR were used to assess minimal residual disease (MRD) status by flow cytometry, which may be more prognostically relevant than conventional response criteria. *Results.* In the VTD/VTDC arms, respectively, median age was 57/58 years and 18%/24% had Karnofsky performance-status ≤70%. Four VTDC patients received additional cycles of treatment. To date, 48 VTD and 35 VTDC patients have undergone HDT-ASCT. Median CD34$^+$ stem cell yields were 8.16 (VTD; n=48) and 8.13 (VTDC; n=40)×10^6/kg. Post-induction and post-HDT-ASCT response rates are shown in the table. Median TTP and OS have not been reached (median follow-up: 9.7/9.9 months). Estimated 1-year survival rate was 94% in each arm. MRD was evaluated in 23 patients in each arm during/post-induction; 17 (VTD) and 13 (VTDC) were MRD-negative. Most of these MRD-negative patients achieved combined CR (VDT n=15; VTDC n=10; per above criteria), apart from 2 VTD and 3 VTDC patients who had ≤VGPR. Post-transplant (samples collected after 40-269 days), 9 (VDT) and 3 (VTDC) additional patients became MRD-negative (all CR), thus a total of 26 (VTD; 53%) and 16 (VTDC; 33%) patients provided an MRD-negative sample during the study. Most patients experienced ≥1 treatment-emergent AE (VTD 98%, VTDC 96%), including 47% and 59% with grade ≥3 AEs. Most common non-hematologic grade ≥3 AEs (VTD/VTDC) included constipation (6%/2%), fatigue (2%/8%), and peripheral-neuropathy (10%/8%). Grade 3/4 hematologic toxicities (laboratory evaluation; VTD/VTDC) included lymphopenia (39%/78%), anemia (8%/18%), neutropenia (14%/18%), and thrombocytopenia (6%/6%). By EQ-5D and EORTC-QLQC30 QoL assessments, both treatments increased patient perceptions of health and well-being over the long-term. Summary: VTD and VTDC are both highly active induction regimens, resulting in high CR rates and MRD-negative rates. Depth of response improved post-HDT-ASCT. Although efficacy profiles were similar, rates of toxicity were higher with VTDC than VTD.

Table 1.

	N*	Combined CR (M-protein confirmed), %	Combined CR (bone marrow confirmed), %	CR^{flc}, %	≥VGPR %	ORR %
Best response post induction						
VTD	49	51	45	27	69	100
VTDC	48	44	35	27	69	96
Best response post HDT-ASCT						
VTD	38	76	58	39	87	100
VTDC	27	78	48	33	85	100

Median time to response	Time to first response, days	Time to combined CR, days
VTD	22	97
VTDC	23	139

*Response-evaluable patients
FLC = serum free light chain; VGPR = very good partial response

THE INTERNATIONAL STAGING SYSTEM FOR MULTIPLE MYELOMA REMAINS RELEVANT IN THE NOVEL AGENT ERA ONLY IN PATIENTS RELAPSING GREATER THAN 12 MONTHS FROM HEMATOPOIETIC STEM CELL TRANSPLANTATION

P Venner,[1] M Connors,[2] J Sutherland,[3] D Shepherd,[3] L Hamata,[2] Y Abou Mourad,[3] J Barnett,[3] R Broady,[3] L Forrest,[3] E Hogge,[3] H Nantel,[3] S Narayanan,[3] J Nevill,[3] J Nitta,[3] M Power,[3] L Toze,[3] A Smith,[3] W Song[3]

[1]University of British Columbia, Vancouver, Canada; [2]British Columbia Cancer Agency, Vancouver, Canada; [3]Division of Hematology, Leukemia/BMT Program, University of British Columbia, Vancouver, Canada

Background. The international staging system (ISS) for multiple myeloma (MM) has been validated as a prognostic tool based on biochemical parameters at diagnosis. At present, there is no validated model to predict response to therapy at relapse. In British Columbia the standard of care for multiple myeloma (MM) includes upfront hematopoietic stem cell transplantation (HSCT) in eligible patients. Since 2004 thalidomide, bortezomib and lenalidomide, the so called novel agents (NA) have been available for use in the relapsed setting. *Aims.* To examine whether the ISS remains relevant in predicting overall survival (OS), progression free survival (PFS) and post relapse survival (PRS) in the NA era. Whether early relapse (<12 m post SCT) further identifies high-risk disease.

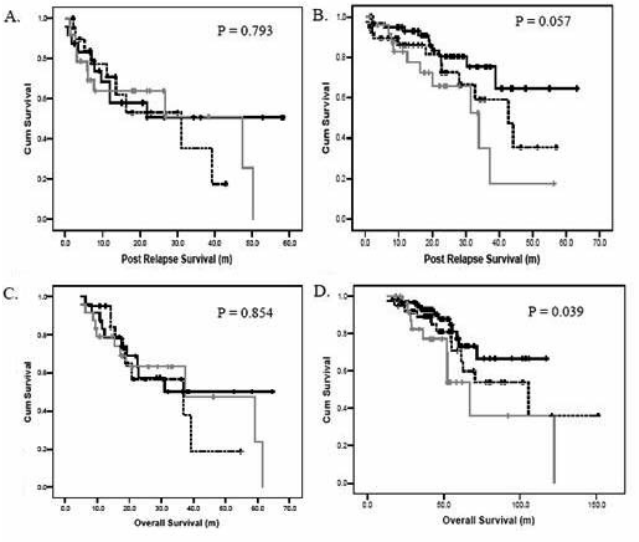

Figure 1: Kaplan-Meier curve demonstrating OA and PRS (early relapse (A and C) and late relapse (B and D)) based on ISS stage and timing of relapse. ISS 1 (—), ISS 2 (▪▪▪), ISS 3 (___).

Methods. We reviewed 230 patients with MM in our prospectively collected database treated with upfront HSCT who relapsed post January 1st, 2004. After this point NA became widely available for relapsed patients defining the NA era at our centre. 195 had complete ISS data. OS and PFS were measured in months (m) from time of HSCT. PRS was measured from the time of relapse after first SCT. The cohort was further split based on timing of relapse and assessed in terms of the ISS stages. *Results.* Median OS, PFS and PRS by ISS stage are summarized in Table 1. When separated by early and late relapse both OS (37.5 m vs. 105.5 m; P<0.001) and PRS (31.0 m vs. 42.8m; P=0.003) are significantly different. When the ISS was applied to the early and late relapsing cohort to predict PRS and OS it remained relevant only for late relapsing patients (Figure 1). This significance was also seen for OS (not shown). Lastly, patients who relapsed early had similar PRS (31.0 m vs. 34.0m; P=0.50) when compared with ISS 3 patients. *Conclusions.* From our data the ISS remains a useful tool to predict OS and PRS for patients with MM relapsing in the NA era. A subset of patients with aggressive disease will be under recognized by characteristics at diagnosis. Our data supports that early relapse is an important clinical prognostic mark-

er identifying high risk patients irrespective of baseline features defined by the ISS. Compared to those with ISS 3 disease, patients with early relapse had a similar PRS identifying a high risk cohort of patients that may warrant more aggressive post relapse therapy and consideration of enrollment in clinical trials.

0374

ELOTUZUMAB IN COMBINATION WITH BORTEZOMIB IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA WITH ONE TO THREE PRIOR THERAPIES: A PHASE 1 STUDY

J Jakubowiak,[1] D Benson,[2] W Bensinger,[3] D DiCapua Siegel,[4] T Zimmerman,[5] A Mohrbacher,[6] P Richardson,[7] D Afar,[8] A Singhal,[8] K Anderson[7]

[1]University of Michigan, Comprehensive Cancer Center, Ann Arbor, Ann Arbor, USA; [2]The Ohio State University, Columbus, USA; [3]Fred Hutchinson Cancer Research Center, Seattle, USA; [4]Hackensack University Medical Center, Hackensack, USA; [5]University of Chicago, Chicago, USA; [6]University of Southern California, Los Angeles, USA; [7]Dana-Farber Cancer Institute, Boston, USA; [8]Facet Biotech Corporation, Redwood City, USA

Background. Elotuzumab is a humanized antibody against CS1, a cell surface glycoprotein that is highly and uniformly expressed in multiple myeloma (MM). In mouse xenograft models of MM, elotuzumab demonstrated significantly enhanced antitumor activity when combined with bortezomib compared to bortezomib alone (Tai et al Blood 2008). *Aims.* This phase 1 study was designed to determine maximum tolerated dose (MTD), safety, pharmacokinetics, and response of elotuzumab in combination with bortezomib in patients (pts) with relapsed/refractory MM. *Methods.* Four escalating doses of elotuzumab (2.5-20 mg/kg) were administered on day 1 and day 11 and bortezomib (1.3 mg/m^2) on days 1, 4, 8, and 11 of each 21-day cycle. Pts with ≥ stable disease after 4 cycles continued treatment until progression. Entry criteria included age ≥18 years; confirmed MM diagnosis with 1 to 3 prior therapies (prior bortezomib use was allowed); and measurable M-protein in serum and/or urine. *Results.* Twenty-eight pts with relapsed and relapsed and refractory MM have been treated; 3 each at 2.5, 5, and 10 mg/kg and 19 at 20 mg/kg of elotuzumab, respectively. Twenty-six pts have completed data analysis, with median 3.4 years from initial MM diagnosis and median 2 prior lines of therapy. Eight pts (31%) had previously been treated with bortezomib and 9 (35%) were refractory to their last MM therapy. No dose-limiting toxicity was observed during the first treatment cycle and the MTD was not reached. Twelve serious adverse events (SAEs) were reported in 9 pts with 2 grade (G) 3 events, including chest pain and gastroenteritis, assessed as elotuzumab-related. Unrelated SAEs included G4 hypercalcemia and metabolic encephalopathy, G3 myocardial infarction, sepsis, vomiting (all 1 pt), pneumonia (2 pts), G2 dehydration, G1 ileus, and G1 incoherence. Most common adverse events included fatigue, diarrhoea, nausea, thrombocytopenia, constipation, anaemia, peripheral neuropathy, lymphopenia, neutropenia, and leukopenia. Best response (≥ MR) by the combined European Group for Blood and Marrow Transplantation and uniform criteria in 20 response evaluable pts with ≥2 treatment cycles was 60% including 40% ≥ PR. Median time-to-progression (TTP) is currently 9.6 months. Preliminary analysis of bone marrow plasma cells indicated that > PR correlates well with complete or near complete saturation of CS1 sites on MM by elotuzumab. *Summary/Conclusions.* The combination of elotuzumab with bortezomib has a manageable safety profile and encouraging activity in relapsed and refractory MM with ≥ MR in 60% of pts and a median TTP of 9.6 months. Updated safety and efficacy data will be presented at the meeting.

0375

THE IMPROVED SURVIVAL OF PATIENTS WITH MULTIPLE MYELOMA AFTER THE INTRODUCTION OF NOVEL AGENTS IS IRRESPECTIVE OF ADVANCED ISS, RENAL IMPAIRMENT OR INCREASED LDH: AN ANALYSIS ON 1501 PATIENTS

E Terpos,[1] K Zervas,[2] S Delimpasi,[2] A Parharidou,[2] N Anagnostopoulos,[2] A Zomas,[2] E Michalis,[2] A Symeonidis,[2] E Katodritou,[2] D Gika,[2] A Pouli,[2] Z Kartasis,[2] D Christoulas,[1] M Roussou,[2] E Kastritis,[1] T Economopoulos,[2] M Dimopoulos[1]

[1]University of Athens School of Medicine, Athens, Greece; [2]Greek Myeloma Study Group, Athens, Greece

Background. The introduction of novel anti-myeloma agents, such as thalidomide, bortezomib and lenalidomide has led to a substantial improvement in the overall survival (OS) of patients with multiple myeloma (MM) during the last decade. However, there is limited information for OS of specific subgroups of MM patients after the introduction of novel agents. *Aim.* The purpose of our analysis was to evaluate OS in a large number of unselected MM patients who were treated throughout Greece to define subsets of patients who were benefited the most from the administration of novel agents. *Patients/Methods.* We compared the outcome of two patient cohorts who started treatment before or after the introduction of the first novel drug, thalidomide; from 1/1/1985 till 30/9/2009, 1501 patients (841M/660F, median age 72 years) were entered into the database of the Greek Myeloma Study Group: 859 patients started treatment before 31/12/1999 (Group A) and 642 patients after 1/1/2000 (Group B), when thalidomide became available in Greece. *Results.* Patients in group A were younger (P<0.001), had less often hypercalcemia (P=0.03) and had less often advanced ISS stage (P=0.014). The majority of patients in Group B were treated upfront with novel-drug based regimens compared to only 2 (0.2%) in Group A (P<0.0001). The median follow-up of all patients was 81 months. Despite more favorable characteristics of patients in Group A, their median overall survival was 36 months compared to 50 months of patients in Group B (P<0.0001). Improved survival was observed in all ISS stages of Group B compared with the respective OS of group A: median OS for ISS-1, ISS-2 and ISS-3 was 59, 36 and 18 months, respectively for patients of group A, and 96, 49 and 32 months, respectively for patients of group B (P=0.006, 0.001 and <0.0001, for the three comparisons, respectively). The administration of novel agents improved median OS in patients with renal impairment (defined as serum creatinine ≥2 mg/dL): 28 months versus 20 months in group A (P=0.012). Similarly, the administration of novel agents improved median OS in patients with high LDH (>300 IU/L): 20 months versus 14 months in group A (P=0.048). The greatest benefit in OS by novel agents was observed in patients ≤65 years of age in whom the median OS has improved more than 2-fold in group B (96 months versus 42 months in group A, P<0.0001). The survival benefit with novel agents was also observed in patients aged 65-70 years (median OS: 60 months in group B versus 30 months in group A, P=0.001). However, in patients above the age of 70 years the administration of novel agents did not produce a significant survival advantage [median OS: 33 months in group B (n=248 patients) versus 27 months in group A (n=247 patients), P=0.001]. *Summary/Conclusions.* The introduction of novel drugs has significantly improved the outcome of MM even in patients with ISS-3, renal impairment or high LDH. The survival benefit was more pronounced in patients ≤70 years of age; thus the management of older patients needs to be improved.

0376

OUTCOME OF PATIENTS WITH MYELOMA RELAPSING AFTER IMID AND BORTEZOMIB THERAPY: A MULTICENTER STUDY FROM THE INTERNATIONAL MYELOMA FOUNDATION WORKING GROUP

K Kumar,[1] J Blade,[2] J Crowley,[3] H Goldschmidt,[4] A Hoering,[3] S Jagannath,[5] S Klein,[6] J Lahuerta,[7] J Laubach,[8] J Lee,[9] P Moreau,[10] G Morgan,[11] R Orlowski,[12] A Palumbo,[13] P Richardson,[8] J San Miguel,[14] O Sezer,[15] D Siegel,[16] P Sonneveld,[6] J Szymonifka,[17] V Rajkumar,[1] B Durie[17]

Background. Patients (pts) with multiple myeloma (MM) have increased treatment options with the advent of novel agents such as the IMiDs and bortezomib. However, the disease invariably relapses following use of these drugs and ongoing efforts are targeted to developing new agents for MM. Furthermore, the natural history of MM following the failure of these novel agents is not well understood and is critical for evaluating the potential impact of upcoming experimental therapies on outcome. *Methods.* We designed a multicenter, retrospec-

tive study that enrolled 291 pts with relapsed MM, from 14 sites (107 pts from US; 115 from Europe; and 69 from Asia). Pts were refractory to Bz, defined as no response to prior Bz-containing regimen or disease progression within 60 days of a Bz-containing regimen. Pts were also relapsed, refractory, intolerant, and/or ineligible, to treatment with an IMiD. Clinical and laboratory data from diagnosis and individual relapses were collected. The date pts satisfied the above entry criteria were defined as time zero (T0). *Results.* Median age at diagnosis was 58 years (range 30, 85) and median time from diagnosis to T0 was 3.3 years (0.18, 18.7). Median time to T0 was 4.0, 3.3, and 2.8 for US, European and Asian groups (P=0.006). Following T0, 216 (74%) pts had a treatment recorded, with 93%, 63% and 65% in the US, European and Asian groups receiving therapy respectively. Various regimens were utilized after T0 (median=1; range 0-8), with the US group receiving more regimens following T_0 compared to the other two. Minimal response or better was seen to first salvage regimen after T0 in 73 (34%) of pts; 29%, 43% and 29% in the US, Europe and Asian groups respectively. Median overall survival (OS) and event free survival from T0 were 8 mos (95% CI; 6,10) and 5 mos (95% CI; 4,5) for the entire group. Median OS was significantly longer for the US group (13 mos) compared to the European (7 mos) and the Asian (8 mos) groups(P=0.006). EFS was comparable across the groups. There were 22, 13 and 11% of pts who had a transplant after T0 in the three groups respectively. Excluding these pts, median OS was comparable across the three groups, (P=0.18) . In multivariate analysis examining factors affecting OS from T0, serum albumin, B2M and age at diagnosis were prognostically significant (P<0.05). *Conclusions.* This study confirms the poor outcome of pts once they relapse and become refractory to existing novel agents. Median OS of 8 mos and EFS of 5 mos can be used for comparing the results of ongoing clinical trials in this population. The study also serves to highlight the differences in treatment patterns, including the use of transplant later in the course of disease in US pts, as well as the trend towards the use of multiple salvage regimens, with many in the context of clinical trials.

EFFICACY AND SAFETY OF RETREATMENT WITH BORTEZOMIB IN PATIENTS WITH MULTIPLE MYELOMA: INTERIM RESULTS FROM RETRIEVE, A PROSPECTIVE INTERNATIONAL PHASE 2 STUDY

T Petrucci,[1] I Blau,[2] P Corradini,[3] M Dimopoulos,[4] J Drach,[5] P Giraldo,[6] A Teixeira,[7] M Ali,[8] R Angermund,[8] J Bladé[9]

[1]Division of Hematology,'Sapienza' University of Rome, Rome, Italy; [2]Charite, Campus Benjamin Franklin, Universitatsmedizin Berlin Med Klinik III, Berlin, Germany; [3]Istituto Nazionale Tumori, University of Milano, Milano, Italy; [4]School of Medicine, University of Athens, Athens, Greece; [5]Department of Medicine I, Medical University Vienna, Vienna, Austria; [6]Service of Hematology. Miguel Servet Universitary Hospital, Zaragoza, Spain; [7]Clinical Hematology Service, University Hospital of Coimbra (HUC), Coimbra, Portugal; [8]Janssen Cilag, Paris, France; [9]Hematology Department, Hospital Clinic, Barcelona, Spain

Background. Bortezomib retreatment has been demonstrated to be efficacious and well tolerated in patients with relapsed multiple myeloma (MM) in a number of retrospective studies and a small prospective phase 4 study. *Aims.* RETRIEVE is a large, prospective, international, open-label phase 2 study that aims to confirm the efficacy and safety of retreatment with bortezomib in MM patients who had previously responded (at least partial response [PR]) to bortezomib-based therapy as their most recent prior treatment. *Methods.* Patients had to have previously tolerated bortezomib alone or in combination and have had a treatment-free interval (TFI; time from last dose of initial bortezomib treatment to first dose of bortezomib retreatment) of ≥6 months. Patients received bortezomib at the last dose (1.0 or 1.3 mg/m^2) tolerated during initial treatment on days 1, 4, 8, and 11 for up to eight 21-day cycles, either alone or in combination with dexamethasone at the investigator's discretion. Response was assessed by European Group for Blood and Marrow Transplantation (EBMT) criteria every 6 weeks during treatment and then every 2 months until disease progression. Adverse events (AEs) were graded according to NCI CTCAE v3.0. *Results.* A total of 130 patients received at least 1 dose of bortezomib retreatment and were included in the safety population. Patients had a median age of 67 years, median time from diagnosis of MM was 4.5 years (range 0-14 years); and median number of prior therapies was 2; 15, 80, 23, and 12 patients had received 1, 2, 3, and ≥4 prior lines of therapy (including initial bortezomib therapy), respectively. Patients received a median 7.0 (range 1-8) cycles of bortezomib retreatment (23% of patients completed all 8 cycles); 72% of patients received concomitant dexamethasone. In 126 patients, the overall response rate (ORR; complete response [CR]+PR) to retreatment by best confirmed response was 39.7%; in addition, 18.3% of patients achieved minimal response (MR), to demonstrate a CR+PR+MR rate of 58%. Best response to initial bortezomib treatment was CR in 26% and PR in 74% of patients. In patients who achieved a CR or PR to initial bortezomib treatment, the ORR to bortezomib retreatment was 62.5% and 52.1%, respectively. 97.7% of patients experienced a treatment-emergent AE; 53.8% experienced a grade 3/4 AE, and 31.5% experienced a serious AE. The most common grade 3/4 AEs included thrombocytopenia (24%), neutropenia (7%), diarrhea (5.4%), and pneumonia (1.5%). The overall incidence of neuropathy was 39%, including 8.5% grade 3. Most peripheral neuropathy events were reversible; with 61% resolving within a median of 39 days. *Conclusions.* These results confirm that bortezomib retreatment is a well-tolerated, feasible and active therapeutic option in MM patients without evidence of cumulative toxicity. Acknowledgments: The authors would like to thank all of the RETRIEVE study investigators.

0378

OUTCOME OF AUTOLOGOUS STEM CELLS TRANSPLANTATION (ASCT) IN COMPARISON WITH NEW DRUG-BASED REGIMENS AS SALVAGE TREATMENT AFTER FIRST LINE THERAPY WITH SINGLE OR TANDEM ASCT IN MULTIPLE MYELOMA PATIENTS

C Crippa,[1] S Ferrari,[2] M Drera,[2] A Roccaro,[2] L Baushi,[2] F Antoniazzi,[2] G Rossi[2]

[1]Spedali Civili brescia, Brescia, Italy; [2]Spedali Civili, Brescia, Italy

Background. Multiple Myeloma (MM) remains still incurable despite the use of several new therapeutical options. High-dose melphalan+ASCT represents the standard therapy for eligible patients, although new trials are currently addressing the usefulness of ASCT in the era of novel drugs. Therapeutic options for patients relapsing after

ASCT include novel biologic agents, traditional chemotherapy and/or ASCT, but few studies about ASCT efficacy and advantage in relapse setting after single/tandem ASCT are actually available. *Aim*. We have therefore analyzed an uniform cohort of patients receiving as second line therapy new drug-based regimens or standard chemotherapy with or without further consolidation with ASCT. *Methods.* In 161 MM patients treated between 1997 and 2008 with HD-Mel and ASCT as first line therapy, relapse has occurred in 105 (65%). Females were 70 (43%), males 91 (57%), median age was 61 (range 34-75). As induction therapy before ASCT, 130 (81%) received VAD- and 31 (19%) thalidomide/bortezomib-based regimens. 85 patients (53%) received single ASCT and 76 double (47%). Second-line therapy was given to 98/105pts: 60pts (61%) received thalidomide/bortezomib-based regimens (TB group), 34pts (35%) ASCT as consolidation after thalidomide/bortezomib-based regimens (18pts) or standard chemotherapy (16pts) (ASCT group); 4pts received only standard chemotherapy and were excluded from analysis. Median follow-up from diagnosis was 56 months for both groups, range 13-148mo in TB and 17-118mo in ASCT. Baseline characteristics of the two groups, including age (median 62), were similar as well as the CR/VGPR and ORR rates obtained after first-line treatment (TB 43% and 87%; ASCT 53% and 79%, respectively). The subgroups also did not differ in median duration of first response and median time to second treatment, which were 17 and 26 months respectively, in both groups. Proportion of patients receiving a double ASCT was significantly higher in TB (47%) as compared to ASCT (9%) (P=0.03). *Results.* After second line therapy ORR (CR+VGPR+PR) was 85% in ASCT group, significantly better than TB group (49%) (P=0.0004). The second CR/VGPR rate was significantly higher after ASCT (41%) than after TB (20%) (P=0.033). Moreover, statistically significant differences in ORR were not observed in patients undergoing second-line consolidation ASCT, such as with thalidomide/bortezomib-based regimens (94%) or standard chemotherapy (75%) as reinduction (P=0.16). After a median follow-up from second-line treatment of 28 months (range 1-101mo), 2-yrs PFS was 24% after TB (median 18mo) and 36% after ASCT (median 19mo) (P=NS). 2-yrs OS was 68% (median 38mo) and 88% (median 47mo) after TB and ASCT, respectively (P=NS). Moreover, 2-yrs PFS and OS were not statistically significant different for those pts treated with new drugs as reinduction versus standard chemotherapy, in ASCT group (P=0.24). *Conclusions.* The use of ASCT as consolidation of second line treatment increased both ORR and CR/VGPR rates, independently from the type of the debulking treatment used (chemotherapy versus novel drugs), but did not significantly impact on PFS and OS when compared with second line new drugs only-based regimens. Novel drugs may be reserved for those patients not eligible for second line ASCT and preserved for effective third-line treatment in the other patients.

0379

SAFETY AND EFFICACY OF LENALIDOMIDE PLUS DEXAMETHASONE IN ELDERLY NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS 70 YEARS OF AGE AND OLDER

F Gay, S Hayman, F Buadi, K Detweiler-Short, M Lacy, S Kumar, A Dispenzieri, M Gertz, V Rajkumar

Mayo Clinic College of Medicine, Rochester, MN, USA

Background. In elderly patients with newly diagnosed multiple myeloma (MM), bortezomib-melphalan-prednisone (VMP) and melphalan-prednisone-thalidomide (MPT) are now considered the standards of care. Recently, the high efficacy and tolerability of lenalidomide plus dexamethasone (Len/dex) as initial therapy for MM was established in two randomized trials. Due to its safety profile and convenience, Len/dex is increasingly used as initial treatment in frail elderly patients, but data on the safety and efficacy in patients aged 70 and older are limited. *Aims.* To assess the efficacy and the toxicity of Len/dex combination as primary therapy in newly diagnosed elderly MM patients 70 years of age and older. *Methods.* 42 consecutive patients seen at Mayo Clinic between 2004 and 2008, aged >70 years old, who received induction treatment with Len/dex were studied in this retrospective study. Lenalidomide was given at a dose of 25 mg/day, days 1-21 on a 28-day cycle. All patients received dexamethasone, either at high-dose (n=16) (40 mg orally on days 1-4, 9-12, and 17-20) or at low-dose (n=26) (40 mg orally day 1, 8, 15, 22); each cycle was repeated every 4 weeks. Treatment was continued until progression, relapse or unacceptable toxicity, or could be stopped at the physician's discretion. Patients (n=11) were allowed to receive transplant if they wished and were deemed eligible. Outcome was analyzed on an intention-to-treat basis. Time-to-event analysis was performed using the Kaplan-Meier method. *Results.* On intention-to-treat analysis, nine of 42 (21%) patients achieved a complete response, 18 of 42 (42%) at least a very good partial response, and 34 of 42 (81%) at least a partial response. Median progression-free survival was 28 months, and the 3-year overall survival (OS) was 70%. When the analysis was restricted to patients who did not receive transplant, 3-year OS was 65%. Twenty-six (62%) of 42 patients experienced at least one grade 3 or higher extra-hematological adverse event: the most common toxicities were infections (8 patients), venous thromboembolism (7 patients) and fatigue (4 patients). Grade 3-4 hematological toxicities were reported in 11 patients, and were mainly represented by neutropenia. *Conclusions.* This cohort study shows the efficacy and tolerability of Len/dex in elderly patients with newly diagnosed MM 70 years of age and older. The 3-year OS results are comparable to those obtained with three-drug combination studies. Randomized phase III studies, comparing this non-alkylator containing regimen with alkylator-based combinations such as MPT or MPV are needed.

Background. Lenalidomide is effective for the treatment of relapsed multiple myeloma (MM), but data on long-term responses are lacking. *Aims.* This retrospective multicenter study wanted to evaluate whether long-term responders exist and which patients' characteristics may predict the long-term response. *Methods.* Patients relapsing after >/=2 chemotherapy lines receiving lenalidomide were included. Response was defined as per International Uniform Response Criteria; long-term response was defined as >/=PR lasting >/=12 months, which is beyond the median PFS of registrative studies. OS and PFS were analyzed by Kaplan-Meier, relapse incidence (RI) by Cumulative Incidence method. Multivariate analysis was performed by logistic regression. 104 patients were enrolled in 13 Italian hematology centers: 61% had IgG, 27% IgA, 12% light chain MM. Median age was 60 yrs (range 35-84). Cytogenetic analysis at diagnosis was available in 56% of the patients, and 7% of them were considered at high-risk due to the presence of 17p- deletion. Median number of previous chemotherapy was 3 (range 2-7) and included autologous transplantation (autoSCT) in 64% and allografting (alloSCT) in 13% of patients. All patients received lenalidomide for 21 every 28 days per cycle at a daily dose of 25mg (84%) or at reduced dose due to hematologic toxicity (16%). Dexamethasone was administered with lenalidomide in 98% of patients, either at low (<=160mg/cycle, 86%) or at high-dose (12%). The median number of courses per patient was 6 (range 3-72). *Results.* Median follow-up was 375 days (84-2005). The responses were: 4% sCR, 8% CR, 10% VGPR, 52% PR, 15% SD and 11% PD. All the 13 alloSCT patients responded: 7 patients with follow-up >=12 months were long-term responders. One- and 2-year OS were 78% and 67%, PFS 52% and 37%, RI 48% and 63%. OS was reduced by high-risk cytogenetics (P=0.01) and high-dose dexamethasone (P=0.05). PFS was reduced by older (>60 years) age (P=0.01) and high-dose dexamethasone (P=0.03) whereas previous alloSCT improved PFS (P=0.05). RI was higher in patients with age >60 years (P=0.01), high-risk cytogenetics (P=0.05), and receiving high-dose dexamethasone (P=0.03). AlloSCT patients had a significantly lower RI (P=0.04). Forty-two of 104 (40%) patients were long-term responders to lenalidomide. Long-term responders had significantly better OS than no long-

term responders (P<0.001). Long-term responders did not significantly differ by age, isotype, previous autoSCT, dexametasone dose and chemotherapy lines. Long-term responders included 7 alloSCT patients compared to 0 alloSCT in no long-term responders group (P=0.01). Long-term responders had a better quality of response than no long-term responders (P<0.001): 45% PR or more versus 5%. In the multivariate regression model the quality of response was confirmed as the significant predictor of long-term response (P=0.04) and reduced relapse (P=0.01). *Conclusion*s. In conclusion, 40% of MM patients treated with lenalidomide and dexamethasone were long-term responders. All the allografted patients with follow-up >/=12 months were long-term responders, suggesting and immune-mediated activity of the drug. The quality of response was the best predictor of long-term response and better survival, indicating that also in the relapse setting the therapy should be aimed at the best tumor reduction.

0381

EFFECTIVENESS AND PATTERNS OF BORTEZOMIB USE IN A REAL-LIFE SETTING: THE VESUVE COHORT STUDY

A Fourrier-Réglat,[1] O Fitoussi,[2] H Eghbali,[3] T Facon,[4] JP Fermand,[5] G Marit,[6] A Grelaud,[1] A Lemonies,[1] R Lassalle,[1] N Moore[1]

[1]Bordeaux University, Bordeaux Cedex, France; [2]Bordeaux North Polyclinique, Bordeaux, France; [3]Bergonié Institute, Bordeaux, France; [4]Lille Hospital, Lille, France; [5]Saint-Louis Hospital, Paris, France; [6]Haut-Lévèque Hospital, Bordeaux, France

Background. Targeted therapies are a very important therapeutic progress in the treatment of multiple myeloma. Bortezomib, the first proteasome inhibitor, was registered in France in April 2004 as third line treatment and in April 2005 as second line treatment. To date, no evaluation of bortezomib in a real-life setting has been conducted in France *Aims.* The VESUVE cohort study was designed to describe patterns and evaluate effectiveness of bortezomib use in a real-life setting. *Methods.* VESUVE is a national multicentre cohort study, conducted in 60 French centres that included patients initiating bortezomib from May 2004 to April 2006, using nominative pharmacy dispensations and/or preparations. Among those identified, patients treated for multiple myeloma were followed for 36 months. For each patient, demographic data, clinical characteristics of multiple myeloma, and treatment data were collected from medical files using a standardized case report form. Response was assessed by an independent committee according to adapted International Myeloma Working Group criteria. The overall survival rate from the onset of bortezomib was assessed using the Kaplan-Meier method. *Results.* A total of 798 patients were followed: mean age was 65.6 years and 53.3% were men. Immunoglobulin myeloma was reported for 83.5% of patients (56.3% IgG, 25.1% IgA), light chain for 14.9% and non-secretory for 1.6%. More than one third of patients (34.1%) had a β2-microglobulin level higher than 3.5 mg/L. Cytogenetic exams were available for 340 patients. Among them, 35.0% had a deletion of chromosome 13. Bortezomib was administered as first line treatment in 0.5% of patients, as second line in 17.7%, as third line in 33.3%, as fourth line and more in 48.5%. The median number of bortezomib cycles was 4, and 6.3% of patients completed more than eight cycles. Baseline bortezomib dose was 1.3 mg/m² for 75.7% of patients, 42.9% received bortezomib alone, 43.0% in association with dexamethasone. Response was not assessed in 79 patients (single cycle) and in 126 (missing data). They were comparable for baseline prognostic factors with the 593 evaluated patients. For the latter, the overall best response rate was 58.4% (2.2% complete, 13.2% very good partial, 43.0% partial). Disease was stable for 35.4% of patients and progressive for 6.2%. The overall survival rate from the onset of bortezomib was 61.1% at 1 year [95%CI 57.6-64.4], 42.2% at 2 years [95%CI 38.7-45.7] and 31.1% at 3 years [95%CI 27.8-34.4]. The median overall survival was 19.2 months. *Conclusions*. This observational study shows that conditions of use in a real-life setting may differ from those of the summary of product characteristics in terms of concomitant treatment or number of cycles. Nevertheless, the effectiveness was close to the efficacy reported in clinical trials.

0382

THALIDOMIDE AND DEXAMETHASONE AS SALVAGE THERAPY AT FIRST RELAPSE IN PATIENTS WITH MULTIPLE MYELOMA: ANALYSIS OF LONG-TERM CLINICAL OUTCOMES

E Zamagni,[1] A Petrucci,[1] P Tosi,[1] P Tacchetti,[1] A Brioli,[2] L Pantani,[1] G Perrone,[1] M Baccarani,[1] M Cavo[1]

[1]Istituto di Ematologia Seragnoli, Bologna, Italy; [2]Italian Myeloma Network Bologna 2002 Study, Bologna, Italy

Aim of the present analysis was to evaluate the long-term outcomes of a series of 100 patients who received thal-dex as salvage therapy at first relapse after prior ASCT or conventional chemotherapy. By study design, thal was started at the dose of 100 mg/daily for two weeks and then escalated to 200 mg/daily, provided that the initial tolerance was acceptable. Otherwise, thal was continued at the initial dose until progression. Dex was given at a monthly dose of 160 mg. The first 60 patients did not receive any thromboprophylaxis, while fixed low-dose warfarin (0.25 mg/day) was added to thal-dex in the subsequent 40 patients. Median age of the patients was 62 years. Median time from start of first-line therapy to thal-dex was 34 months. Up-front therapy for MM had included ASCT, either single (30%) or double (42%), while the remaining 28 patients had previously received conventional chemotherapy. 59% of the patients were treated with a fixed thal dose of 100 mg/daily. Overall, median duration of thal-dex therapy was 14 months. 65% of the patients stayed on treatment beyond the achievement of the best response or plateau phase; median duration of thal in these patients was 22 months (range 1-79). The most frequent adverse events were constipation (42%, grade III 8%), peripheral neuropathy (58%, grade III 5%), bradycardia (20%, grade III 0%) and skin rash (11%, grade III 1%). Venous thromboembolism was recorded in 7 patients (3 not receiving any thromboprophylaxis), at a median of 8 months (range 3-11) from the start of thal-dex therapy. The frequency of grade III neuropathy was significantly higher in patients receiving thal 200 mg/daily in comparison with those treated with 100 mg/daily (8.5% vs 1%, respectively, P=0.01). Discontinuation of thal due to toxicity was recorded in 8 patients after a median of 12 months. On an intention to treat basis, 46% of patients achieved at least a partial response at a median time of 3 months from the start of thal-dex treatment; the response rate was not significantly different between patients receiving thal 100 mg/daily and those treated with 200 mg/daily. The median duration of response (DOR) was 28 months, while the median time to next therapy was 15.5 months. With a median follow up of 25 months, median OS, TTP and PFS were 43, 22 and 21 months, respectively. TTP and PFS were significantly longer for patients responding to thal-dex therapy (TTP: 34 months vs 15 months for non-responders, P=0.005; PFS: 28 months vs 12 months for nonresponders, P=0.001, respectively). Median survival after relapse from thal-dex therapy was 26 months. In conclusion, low dose thal-dex was an effective treatment of first relapse in MM, yielding DOR, OS and EFS comparable to those reported with other novel agents when used in the same setting of patients. Low-dose thal-dex was generally well tolerated, as reflected by the long stay on treatment in the absence of progression (median: 25 months) and a low discontinuation rate (8%).

0383

POST-APPROVAL SAFETY STUDY (PASS) OF LENALIDOMIDE COMPARED WITH OTHER TREATMENTS IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: FIRST REPORT ON 518 PATIENTS

I Blau,[1] P Gimsing,[2] B Drenou,[3] L Masini,[4] H Lokhorst,[5] A Waage,[6] J De la Rubia,[7] B Andreasson,[8] J Collins,[9] M Bravo,[9] A Glasmacher,[9] N Brandenburg,[10] MT Hernandez[11]

[1]Charité, Univ., Berlin, Germany; [2]Rigshospitalet, Copenhagen, Denmark; [3]Centre Hospitalier Général, Mulhouse, France; [4]Arcispedale, Reggio Emilia, Italy; [5]UMC, Utrecht, Netherlands; [6]St. Olavs Hospital/NTNU, Trondheim, Norway; [7]Hospital de la Fe, Valencia, Spain; [8]Uddevalla Sjukhus, Uddevalla, Sweden; [9]Celgene International, Boudry, Switzerland; [10]Celgene Corporation, Summit NJ, USA; [11]Hospital Universitario de Canarias, Tenerife, Spain

Aim and *Background.* Lenalidomide plus dexamethasone was EMEA approved 2007 for the treatment of multiple myeloma (MM) patients who have received at least one prior therapy. Subsequently, an observational patient cohort study has been implemented to characterize the safety profile of lenalidomide in a normal clinical practice and to place the incidence of adverse events (AE) into context with those occurring in second line or later MM patients receiving other treat-

ments. *Methods.* Data has been collected prospectively from 518 MM patients in 117 institutions in 14 European countries. Patients had received at least one prior therapy and were commencing a new treatment in accordance with normal clinical practice with prescribed medication. No additional treatments or investigations outside of normal clinical practice were required. Data cut for this analysis was December 18th, 2009. *Results.* Of the 518 patients, 321 received lenalidomide plus dexamethasone, 105 bortezomib, 36 thalidomide, 28 other therapies and 28 had missing data. The median age of the total group was 70 years (range, 38-92), 56.9% were male. Most patients (75.4%) had a good performance status (ECOG 0-1) but 24.6% had an ECOG status of 2-4. The median number of previous treatment lines was 2 (1-6), 50.9% had two previous lines and 30.9% three or more. There were no important demographic or clinical differences in the baseline characteristics between the patient cohorts. Table 1 shows the NCI grade 3-4, AEs in the respective cohorts. 24.9% of patients in the lenalidomide cohort discontinued therapy. Patients in the lenalidomide cohort had a median Kaplan-Meier estimated treatment duration of 6.4 months. Discontinuation percentages and estimated median treatment duration for the bortezomib and thalidomide cohorts were 46.7% (3.6 months) and 41.7% (5.8 months), respectively. Primary reasons for discontinuation were adverse events (lenalidomide, 6.2%; bortezomib, 13.3%; thalidomide, 11.1%) and progression of disease (lenalidomide, 7.5%; bortezomib, 11.4%; thalidomide, 13.9%). *Conclusions.* In unselected groups of patients from normal clinical practice treated with lenalidomide, bortezomib, thalidomide or other therapies, lenalidomide demonstrates an acceptable safety profile. There are no major differences in the incidence of adverse events between lenalidomide, bortezomib and thalidomide treated patients. The overall discontinuation rate among lenalidomide-treated patients was roughly half that of patients treated with bortezomib or thalidomide, despite a longer treatment duration. Discontinuation of treatment due to adverse events or disease progression occurred less frequently in the lenalidomide cohort than in the thalidomide or bortezomib cohorts.

Events (NCI grades) (At least one event occurred)	Lenalidomide (N = 321)	Bortezomib (N = 105)	Thalidomide (N = 36)	Other Treatment (N = 28)
Event leading to death	5.0%	7.6%	5.6%	0%
Any grade 3–4 event	30.5%	33.3%	36.1%	14.3%
Drug-related grade 3–4 event	19.6%	17.1%	16.7%	7.1%
Drug-related serious event	10.6%	11.4%	11.1%	10.7%

Table 1. AEs according to NCI (v. 3) grading.

Background. Panobinostat (LBH589) is a potent pan-deacetylase inhibitor that has been shown *in vitro* to inhibit several HDAC isoenzymes including HDAC6, a key factor in both the formation of aggresomes and function of the Hsp90 chaperone protein. The combination of panobinostat and the proteasome inhibitor bortezomib has demonstrated synergistic cytotoxicity in multiple myeloma (MM) in both *in vitro* and *in vivo* studies which has been hypothesized to occur, in part, through inhibition of proteasome and aggresome function. *Aims.* The aim of this Phase IB dose-escalation study is to identify the maximum tolerated dose (MTD) of panobinostat and bortezomib when these are administered in combination in patients with relapsed or relapsed and refractory MM. *Methods.* Patients with relapsed or relapsed and refractory MM received panobinostat (p.o. thrice weekly) and bortezomib (i.v. Days 1, 4, 8, 11) on a 21-day cycle to establish the MTD of the combination. *Results.* As of Oct 9 2009, 38 patients were treated in 5 cohorts (see table). The median age of patients treated on the study was 62 years (range 46-78). Patients received a median of 2 prior therapies (range 1-7), including stem-cell transplant (n=30) and bortezomib (n=22; 13 bortezomib-refractory). No dose-limiting toxicities (DLTs) occurred in cohorts 1 and 3, 1 patient had DLT in cohort 2 (neutropenia), 4 had DLTs in cohort 4 (2 thrombocytopenia, 1 pneumonia/thrombocytopenia/neutropenia, 1 fatigue), and 1 had DLT in cohort 5 (thrombocytopenia/asthenia/dizziness). Hematologic adverse events (AEs): included Grade 3/4 thrombocytopenia (n=30), neutropenia (n=23), and anemia (n=6). Non-hematologic AEs included diarrhea (n=23), nausea (n=18), pyrexia (n=17), fatigue (n=16), and asthenia (n=13). There have been no treatment-related deaths. Responses (≥MR) were observed in 26/38 patients (68%) across all cohorts. Of note, responses were observed in 8/13 (62%) of bortezomib-refractory patients. Management of AEs, including thrombocytopenia, by dose reduction or interruption, allowed for longer treatment duration in cohort 3. Patients treated in cohort 3 also demonstrated the most favorable efficacy profile with 7/8 patients responding and no patients demonstrating progressive disease. Safety results supported the further enrolment of patients in a 6th cohort at the same dose level to confirm MTD. Altogether, these results led to the recommendation of the cohort 3 dose level for further evaluation in clinical trials, with a modified dose-schedule incorporating a week-long rest period. *Summary and Conclusions.* The combination of oral panobinostat and i.v. bortezomib has a predictable and manageable safety profile with promising activity in patients with relapsed or relapsed and refractory MM, including patients with bortezomib-refractory MM. Review of data of at least 12 evaluable patients treated at 20 mg panobinostat plus bortezomib 1.3 mg/m^2 is ongoing to confirm the MTD. This dose level, and modified schedule with panobinostat 2 weeks on and one week off will be used in phase II and III PANORAMA trials based on this combination in order to optimize therapy duration.

Cohort	**1**	**2**	**3**	**4**	**5**

0385

A PHASE I STUDY OF VORINOSTAT, LENALIDOMIDE, AND DEXAMETHASONE FOR RELAPSED AND REFRACTORY MULTPLE MYELOMA

P Richardson,[1] D Weber,[2] C Mitsiades,[1] M Dimopoulos,[3] JL Harousseau,[4] J Howe,[5] T Graef,[5] C Gause,[5] C Byrne,[6] K Anderson,[1] D Siegel[7]

[1]Dana-Farber Cancer Institute, Boston, USA; [2]MD Anderson Cancer Center, Houston, USA; [3]University of Athens School of Medicine, Athens, Greece; [4]Centre René Gauducheau, Saint Herblain, France; [5]Merck & Co., Inc., Upper Gwynedd, USA; [6]Celgene Corporation, Summit, USA; [7]Hackensack University Medical Center, Hackensack, USA

Background. Multiple myeloma (MM) is the second most common hematologic malignancy. Although novel treatment combinations have improved outcomes, new drug combinations are needed for this otherwise incurable disease. Vorinostat, an oral histone deacetylase inhibitor approved in the United States for the treatment of advanced cutaneous T-cell lymphoma, alters gene expression and protein activity, promoting MM cell death through multiple pathways. In preclinical studies, vorinostat was shown to synergistically enhance the anti-MM activity

of bortezomib and immunomodulatory and antiangiogenic drugs, including lenalidomide, with or without dexamethasone. *Aims.* The primary objective of this phase I, multicenter, open-label, investigational study was to determine the maximum tolerated dose (MTD) of vorinostat plus lenalidomide and dexamethasone in patients with relapsed or relapsed and refractory MM. Secondary objectives included determination of overall safety, tolerability, response rate, duration of response, and time-to-progression (TTP). *Methods.* Patients were enrolled sequentially into 1 of 5 escalating doses of the combination regimen using a standard 3+3 design for ≤8 cycles. Patients who tolerated the regimen and had clinical benefit were eligible for enrollment in an extension phase. Toxicity was evaluated using the National Cancer Institute CTCAE v3.0. Response was assessed using modified European Group for Blood and Marrow Transplantation criteria and International Myeloma Working Group Uniform Criteria. Safety and efficacy data were assessed with summary statistics, except for TTP, which was estimated by Kaplan-Meier method. *Results.* As of January 22 2010, 31 patients have been treated and are evaluable for safety. Most patients had received prior bortezomib (65%), thalidomide (68%), or lenalidomide (42%), with a median of 3 prior therapies (range, 1-12). Adverse events (AEs) were generally mild or moderate in severity. Common ≥grade 3 drug-related AEs (all cycles) included neutropenia (23%), thrombocytopenia (16%), diarrhea (13%), and fatigue (10%). There were 10 serious drug-related AEs among 6 patients, and 7 discontinuations due to toxicity. One dose-limiting toxicity (grade 3 diarrhea lasting >48 h) was observed at the maximum assessed dose (level 5; Table), but a MTD was not reached. There were no treatment-related deaths. Of 30 patients evaluable for response, 26 (87%) experienced at least stable disease (SD). Best responses included 2 complete (CR), 2 very good partial (VGPR), 11 partial (PR), and 4 minimal response (MR), with 7 patients achieving SD and 4 developing progressive disease, resulting in an overall response rate (ORR) (≥MR) of 63% (95% CI 44%-80%). Of 13 evaluable patients who received prior lenalidomide, SD or better was observed in 9 (69%), with 1 VGPR, 3 PR, 1 MR, and 4 SD, resulting in an ORR (≥MR) of 38% (95% CI 14%-68%). Responses proved durable, with a median TTP of 33 weeks (95% CI, 24-57 weeks). *Conclusions.* Preliminary results from this study suggest that vorinostat plus lenalidomide and dexamethasone is a convenient, effective, and generally well-tolerated oral regimen for relapsed/refractory MM. An MTD was not reached. Notable activity was observed in patients who had received prior lenalidomide, bortezomib, or thalidomide. Evaluation of this regimen in a phase II study is planned.

INTERIM ANALYSIS OF A PHASE III RANDOMIZED, DOUBLE-BLIND STUDY OF VORINOSTAT OR PLACEBO COMBINED WITH BORTEZOMIB IN RELAPSED MULTPLE MYELOMA

S Jagannath,[1] D Siegel,[2] R Hajek,[3] M Dimopoulos,[4] SS Yoon,[5] S Lonial,[6] T Graef,[7] L Lupinacci,[7] D Reiser,[7] K Anderson[8]

[1]St Vincent's Catholic Medical Center, New York, USA; [2]Hackensack University Medical Center, Hackensack, USA; [3]Faculty of Medicine MU and University Hospital Brno, Brno, Czech Republic; [4]Department of Therapeutics, University of Athens, Athens, Greece; [5]Seoul National University Hospital, Seoul, South-Korea; [6]Winship Cancer Institute, Emory University School of Medicine, Atlanta, USA; [7]Merck & Co., Inc., Upper Gwynedd, USA; [8]Dana-Farber Cancer Institute, Boston, USA

Background. Although current treatments for multiple myeloma (MM) have significantly improved initial clinical response, patients inevitably relapse and/or become refractory to approved treatments. This urgent and unmet need has stimulated the development of new targeted approaches and treatment combinations. Vorinostat, approved in the United States for the treatment of advanced cutaneous T-cell lymphoma, is a histone deacetylase (HDAC) inhibitor that alters gene expression and protein activity. The preclinical synergistic effect of vorinostat with bortezomib to inhibit aggresome formation and induce MM cell apoptosis was confirmed in phase I trials and led to a large phase III program to evaluate the clinical benefit of this drug combination for the treatment of relapsed MM. *Aims.* Vantage 088 is an ongoing, global, Phase III, randomized, double-blind study to investigate the efficacy and tolerability of vorinostat vs placebo in combination with bortezomib in relapsed MM patients. *Methods.* Patients with relapsed MM and progressive disease after 1-3 prior anti-myeloma treatments are being enrolled in this investigational study. Patients who received prior bortezomib must have had ≥minimal response on therapy and not be bortezomib-refractory. Patients receive intravenous bortezomib 1.3 mg/m^2 on days 1, 4, 8, and 11 and oral vorinostat 400 mg (or matching placebo) once daily on days 1 to 14 of each 21-day cycle. The primary endpoint is progression-free survival, with a planned accrual of 742 patients. Secondary and exploratory endpoints include tolerability, overall survival, time to progression, objective response rate, and patient-reported outcomes (PROs). Efficacy is evaluated using European Blood and Marrow Transplantation Group criteria. Instruments for PROs, including quality of life (QoL) questionnaires for cancer patients (EORTC QLQ-C30) and multiple myeloma patients (EORTC QLQ-MY20), and the EuroQol EQ-5D, are unique aspects to the study design; the use of symptom scales, including disease symptoms and side effects of treatment, coupled with QoL assessments will provide opportunities to correlate PROs with efficacy and safety data. Safety is assessed according to NCI-CTCAE, version 3.0 and clinical and laboratory safety measurements are recorded. *Results.* As of February 2009, 196 patients were enrolled (range, 1-12 cycles). The median number of prior treatments was 1.8 (range, 1-3). Safety data were collected from all patients. As of August 2009, the independent data monitoring committee (DMC) had evaluated safety data from 39 patients. Most common adverse events (AEs) included gastrointestinal (51%), hematologic (28%), and general symptoms (eg, fatigue, [26%]). Most common grade ≥3 drug-related AEs were reported in 9 patients (thrombocytopenia [27%] platelet count decrease [17%], nausea [17%]). Only 2 grade 5 AEs occurred (sepsis, renal failure/plasmacytosis; neither was treatment-related). 4 patients (10%) discontinued (AE, death, consent withdrawn, progressive disease [n=1 patient each]). The DMC recommended continuation of the study without modifications based on available safety data. *Summary/Conclusions.* This is a large international randomized trial that has passed the initial safety evaluations by DMC and is accruing patients rapidly all over the world. Updated safety data and enrollment status from the second DMC meeting held in April 2010 will be presented.

0387

COMBINED VORINOSTAT AND BORTEZOMIB IN BORTEZOMIB-REFRACTORY PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: INTERIM ANALYSIS OF A PHASE IIB STUDY

D Siegel,[1] S Jagannath,[2] S Lonial,[3] M Dimopoulos,[4] SS Yoon,[5] T Graef,[6] D Pietrangelo,[6] L Lupinacci,[6] D Reiser,[6] K Anderson[7]

[1]Hackensack University Medical Center, Hackensack, USA; [2]St Vincent's Catholic Medical Center, New York, USA; [3]Winship Cancer Institute, Emory University School of Medicine, Atlanta, USA; [4]Department of Therapeutics, University of Athens, Athens, Greece; [5]Seoul National University Hospital, Seoul, South-Korea; [6]Merck & Co., Inc., Upper Gwynedd, USA; [7]Dana-Farber Cancer Institute, Boston, USA

Background. Despite significant therapeutic advances in the treatment of multiple myeloma, a cure remains elusive and patients ultimately relapse and become refractory to available therapies. New treatments and novel treatment combinations are being assessed to address this unmet need. Vorinostat is a histone deacetylase (HDAC) inhibitor that alters gene expression and protein homeostasis. Approved in the United States for the treatment of advanced cutaneous T-cell lymphoma, vorinostat may target multiple pathways to increase myeloma cell apoptosis in combination with other small-molecule targeted therapies, such as bortezomib. In two phase I studies in relapsed/refractory (RR) MM patients, vorinostat in combination with bortezomib showed objective response rates (ORR; ≥partial response) of up to 42% in all patients, including bortezomib-refractory patients, and an overall clinical benefit up to 90%. *Aims.* Vantage 095 is an ongoing phase IIb open-label study to investigate the efficacy and tolerability of adding vorino-

stat to bortezomib in patients who are refractory to bortezomib and at least one immunomodulatory drug (IMiD) regimen and are ineligible for other approved regimens. *Methods.* Patients with RR MM who had ≥2 prior antimyeloma therapies were enrolled in this investigational study. All patients were refractory to bortezomib and relapsed, refractory, intolerant, or ineligible for other MM therapies, including IMiDs. Patients received intravenous bortezomib 1.3 mg/m^2 on days 1, 4, 8, and 11 and oral vorinostat 400 mg once daily on days 1 to 14 of each 21-day cycle. The primary endpoint is ORR with a planned accrual of 142 patients. Efficacy was evaluated using EBMT criteria. Safety was assessed according to NCI-CTCAE, version 3.0. Clinical and laboratory safety measurements were recorded. *Results.* As of February 2010, 85 patients were enrolled (range, 1-11 cycles). The median number of prior treatments was 6 (range, 2-17). Interim analysis for futility was triggered when the first 43 patients were enrolled and completed ≥3 cycles of therapy. Final adjudicated efficacy data for those 43 patients and the safety profile based on 58 patients treated at the time were reviewed by the independent data monitoring committee (DMC; data cut-off November 10, 2009). The ORR (CR+PR) was 16% (95% CI, 7-31%); minimal response and no change were observed in 5% and 51% of patients, respectively. Safety data were collected from all patients who received study drug (n=58) and were evaluated by the DMC. Fifty-three patients experienced adverse events (AEs) (most commonly including blood and lymphatic system, gastrointestinal, and general disorders). Drug-related grade ≥3 serious AEs were reported in 9 patients (most commonly thrombocytopenia [n=3], anemia [n=2], diarrhea [n=2]), one of which was grade 4 tumor lysis syndrome. No drug-related grade 5 AEs occurred. As of the data cut-off date, a total of 18 patients discontinued due to progressive disease and 7 owing to AEs. Based on passing the futility endpoint and the safety profile, the DMC recommended continuation of the study without modifications. *Summary/Conclusions.* This therapeutic regimen appears to have acceptable tolerability. Final data will confirm the potential of vorinostat combined with bortezomib in this advanced myeloma population.

0388

PX-171-006, A PHASE IB DOSE-ESCALATION STUDY OF CARFILZOMIB + LENALIDOMIDE + LOW-DOSE DEXAMETHASONE IN RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA

M Wang,[1] W Bensinger,[2] R Orlowski,[1] M Alsina,[3] T Martin,[4] S Singhal,[5] N Gabrail,[6] M Vallone,[7] M Kauffman,[7] R Niesvizky[8]

[1]University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [3]H. Lee Moffitt Cancer Center, Tampa, FL, USA; [4]University of California, San Francisco, CA, USA; [5]Northwestern University School of Medicine, Chicago, IL, USA; [6]Gabrail Cancer Center, Canton, OH, USA; [7]Onyx Pharmaceuticals, Emeryville, CA, USA; [8]Weill Cornell Medical College, New York, NY, USA

Background. Carfilzomib (CFZ) is a specific, irreversible proteasome inhibitor with promising single-agent activity in relapsed/refractory multiple myeloma (R/R MM). In previous Phase II trials, CFZ demonstrated a favorable side-effect profile with minimal myelosuppression. Lenalidomide (LEN) + dexamethasone (Dex) is a standard of care for R/R MM. In preclinical studies, LEN sensitized MM to proteasome inhibition with bortezomib (BTZ), suggesting that combination therapy may enhance clinical activity. BTZ+ LEN/Dex, while active in R/R MM, has toxicity limitations. CFZ + LEN/Dex (CRd) may provide superior activity to LEN/Dex alone. *Aims.* This open-label, Phase Ib dose-escalation study evaluates the safety, activity, and maximum recommended dose (MRD) of CRd in R/R MM. *Methods.* CRd was evaluated at 6 dose levels (≥3 subjects each). An additional ~40 patients have been enrolled in an expansion cohort at the highest dose level tolerated or the cohort 6 dose. Eligible patients include those with R/R MM following 1-3 prior therapies (including prior LEN and/or BTZ). CRd was given on 28 day cycles (C) in 6 cohorts. Primary endpoints include safety and establishment of the MRD. Additional endpoints include overall response rate (ORR) (≥ PR) as assessed by IMWG Criteria, with secondary assessment of clinical benefit response (CBR: ≥ minimal response [MR]) using EBMT Criteria. *Results.* To date, 40 patients have been enrolled in cohorts 1-6 and 40 in the cohort 6 expansion. 27/32 patients in cohorts 1-5 are evaluable for safety and 29/32 for response. Patients were heavily pre-treated; 72% received prior BTZ and 87.5% received prior LEN or thalidomide (Thal). 47% of patients were refractory to their last therapy; >84% of patients had a history of neuropathy with 67% BTZ- or Thal-related. No treatment emergent fatigue, neuropathy, or thrombotic events ≥ Grade (G) 3 were observed. Hematological AEs ≥G3 (thrombocytopenia [n=6], anemia [n=4], and neutropenia [n=6]) were reversible. 4 patients had drug-related SAEs as follows: transient G3 sinus bradycardia, G3 upper respiratory tract infection, febrile neutropenia, and G3 diarrhea + G3 urinary infection. ORR and CBR for the 29 evaluable patients are 59% and 72%, respectively. Response data is shown in the table. Initial responses improved with continued therapy, (up to 18 C). Median duration of response has not been reached (median follow-up 5.2 months). No dose-limiting toxicities or deaths attributed to study treatment have been observed. Updated data will be presented (Table). *Conclusions.* CFZ (20/27 mg/m^2) in combination with full dose LEN (25 mg) and Dex (40 mg Qwk) (CRd) is well-tolerated in patients with R/R MM, even in those with a history of neuropathy. Non-overlapping toxicity profiles of CFZ and LEN permits combination at full doses for extended durations up to 18 C. Prior therapy with BTZ or LEN and/or Thal, or disease refractory to the immediately preceding regimen did not preclude achieving CR, VGPR, PR, or MR with CRd. Based on these data, a Phase III international trial of CRd vs. Rd in relapsed MM will commence in 2010.

Background. Elotuzumab is a humanized antibody against CS1, a cell surface glycoprotein that is highly expressed in multiple myeloma (MM). Elotuzumab induces antibody-dependant cytotoxicity (ADCC) against primary MM cells in the presence of peripheral lymphocytes (PBMC). The elotuzumab-mediated ADCC is significantly enhanced when PBMC are pretreated with lenalidomide (len). In mouse xenograft MM models, elotuzumab given in combination with len demonstrated significantly enhanced antitumor activity compared to len alone. *Aims.* The study objectives evaluated the maximum tolerated dose (MTD), safety, pharmacokinetics (PK), and efficacy of elotuzumab in combination with len and low dose dexamethasone (dex). *Methods.* Elotuzumab (IV infusion) in 3 escalating dose cohorts (5, 10, and 20 mg/kg) was given weekly for the first 2 cycles and then every other week of subsequent cycles. Len (25 mg PO) was given on days 1 to 21 of each 28-day cycle. Dex was given weekly at 40 mg PO. The first 5 patients (pts) were treated for 6 months before a protocol amendment to continue treatment until progression was approved. *Results.* A total of 29 pts with a median age of 60 years were enrolled; 28 pts received elotuzumab. One pt was withdrawn from the study prior to receiving study drug due to investigator's decision. Pts had a median of 3 prior MM treatments including thalidomide (59%), bortezomib (69%), or len (21%) with 41% of pts refractory to their last MM therapy. Three pts each received 5 mg/kg and 10 mg/kg and 22 pts received 20 mg/kg of elotuzumab. No dose-limiting toxicity (DLT) was observed during dose-escalation and a MTD was not established. Two pts in the 20 mg/kg cohort discontinued due to infusion reactions, 1 grade (G) 4 hypersensitivity (related to elotuzumab) and G3 stridor (related to elotuzumab/dex). Additional unrelated SAEs (1 each) included G2 atrial fibrillation and enteritis, G3 chest pain, pneumonia, sepsis, gastrointestinal haemorrhage, febrile neutropenia, diarrhoea, atrial fibrillation, acute renal failure, and metabolic acidosis, G4 diverticular rupture, and sepsis. Common adverse

events included fatigue, diarrhoea, constipation, anaemia, neutropenia, nausea, muscle spasms, pyrexia, asthenia, and dyspnoea. The ORR by IMWG criteria in 28 treated pts was 82% (64% PR; 18% VGPR). Pts naive to len (22 pts) demonstrated ORR of 95% (73% PR; 23% VGPR). Median time-to-progression (TTP) following a median of 4.5 cycles has not yet been reached. Preliminary PK analysis suggests trough serum antibody concentrations of elotuzumab at 10 mg/kg and 20 mg/kg doses are above target levels predicted based from preclinical models. Elotuzumab dosing also resulted in complete saturation of target sites on bone marrow plasma cells. *Summary/Conclusions.* The combination of elotuzumab with len/dex has a manageable safety profile and the ORR of 82%, including 95% in len-naive patients is encouraging. A 60 pt, randomized, phase 2 expansion has been initiated to further examine the efficacy and identify the optimal dose of elotuzumab. Updated safety and efficacy data including TTP will be presented at the meeting.

A PHASE IB STUDY EVALUATING THE COMBINATION OF ORAL PANOBINOSTAT (LBH589) WITH LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA

MV Mateos,[1] A Spencer,[2] K Taylor,[3] S Lonial,[4] J De La Rubia,[5] T Facon,[6] R Bengoudifa,[7] M Klebsattel,[7] K Hazell,[7] P Bourquelot,[7] JF Rossi,[8] JL Harousseau,[9] S Jagannath,[10] J Wolf,[11] J San Miguel[1]

[1]Hospital Universitario de Salamanca, Salamanca, Spain: [2]Malignant Haematology & Stem Cell Transplantation, Alfred Hospital, Melbourne, Australia; [3]Haematology & Oncology Clinics of Australasia, Brisbane, Australia; [4]Winship Cancer Institute, Emory University, Atlanta, GA, USA; [5]Hospital Universitario La Fe, Valencia, Spain; [6]Hôpital Claude Huriez, Lille, France; [7]Novartis Pharma AG, Basel, Switzerland; [8]CHU de Montpellier, Hôpital Saint Eloi, Montpellier, France; [9]Hôpital Hôtel Dieu, Nantes, France; [10]St Vincent's Comprehensive Cancer Center, New York, NY, USA; [11]University of California San Francisco Medical Center, San Francisco, CA, USA

Background. Panobinostat (LBH589) is an orally bioavailable pan-deacetylase inhibitor targeting histone-mediated epigenetic and non-histone oncogenic pathways. The combination of panobinostat with the IMiD lenalidomide, and dexamethasone, demonstrated synergistic anti-multiple myeloma (MM) activity in preclinical models. *Aims.* This Phase IB, dose-escalation study sought to establish the maximum tolerated dose (MTD) of panobinostat in combination with lenalidomide and dexamethasone for the treatment of patients with relapsed or relapsed and refractory MM. *Methods.* Cohorts of ≥6 patients received panobinostat at one of four dose levels guided by Bayesian design (5 mg, 10 mg, 20 mg, or 25 mg; po thrice weekly every week) in combination with a single dose of lenalidomide (25 mg po days 1-21) and of dexamethasone (40 mg po days 1-4, 9-12, 17-20, cycles 1-4; days 1-4, cycle 5 onwards), in a 28-day cycle. Dose limiting toxicities (DLTs), safety, tolerability, PK/PD, and preliminary efficacy were evaluated. *Results.* As of Dec 8, 2009, 46 patients had been treated at 4 panobinostat dose levels (cohorts 1-4): 5 mg (n=8), 10 mg (n=8), 20 mg (n=21), or 25 mg (n=9). Patients received a median of 2 prior therapies (range 1-8), including bortezomib (n=28), thalidomide (n= 29), lenalidomide (n=8), and/or stem cell transplant (n=36). Over half of patients (n=25) had refractory disease. DLTs were observed in 9/36 evaluable patients (cohorts 1-4, including 3/7 patients at 25 mg panobinostat): hematologic (n=4) (thrombocytopenia, neutropenia), QTcF prolongation (n=2), atrial fibrillation (n=1), fatigue (n=1), and pneumonia (n=1). In 46 patients evaluable for safety, common adverse events (AEs) (≥20% patients) included: hematologic (Grade 3/4 thrombocytopenia [41%] or neutropenia [37%]), and gastrointestinal, or muscular. Other Grade 3/4 AEs were: fatigue/asthenia, reduced appetite, insomnia, muscle weakness/metabolic (dexamethasone-related), respiratory infection, diarrhea, and dysgeusia. Two of 7 deaths on study (respiratory insufficiency secondary to infection and febrile neutropenia with respiratory infection and sepsis) were suspected as treatment-related and occurred at the 20 mg dose. One patient had DVT. Dose adjustment frequency was comparable in lower-dose cohorts, primarily due to dexamethasone-related AEs, but increased in the 25 mg cohort (≥1 reduction in 6 patients). The MTD confirmed by the logistic Bayesian model (based over cycle 1 DLTs) was panobinostat 20 mg dose level which was expanded to include ≥12 evaluable patients. Review of tolerability over longer-term therapy is ongoing and dose recommendation for further clinical evaluation will be reviewed. Disease assessment was available for 30 patients, with responses observed in 17 (57%): 1 sCR, 1 CR, 7 VGPR, and 8 PR. Seven (23%) patients had SD, and 6 (20%) patients had PD. Of 12 patients refractory to a prior IMiD line and currently evaluable for response, 5 responded to study therapy. *Summary and Conclusions.* In this first trial evaluating the combination of oral panobinostat with lenalidomide and dexamethasone in patients with advanced MM, preliminary efficacy was very encouraging with the safety data generally consistent with previously established profile. MTD in this combination was confirmed to be 20 mg of panobinostat at this dosing regimen and schedule.

A MYC ACTIVATION SIGNATURE IS COMMON IN MM AND ASSOCIATED WITH SHORTER SURVIVAL THAT CAN BE OVERCOME BY BORTEZOMIB

WJ Chng,[1] G Huang,[1] G Mulligan,[2] P Bergsagel,[3] R Fonseca[3]

[1]National University Cancer Institute, Singapore, Singapore, Singapore; [2]Millenium Pharmaceuticals, Cambridge, USA; [3]Mayo Clinic Comprehensive Cancer Center, Scottsdale, USA

Background. We previously identified a MYC activation signature that suggests MYC activation may be an important event in the transition from monoclonal gammopathy of undetermined significance to multiple myeloma (MM). *Aims.* Study the clinical association and relevance of MYC activation in MM. *Methods.* We examined a Mayo Clinic MM cohort (n=101) treated with chemotherapy with or without stem cell transplantation that had gene expression done on Affymetrix U133A chips. We also analyzed a cohort of relapsed MM (APEX cohort) entered into a clinical trial comparing bortezomib (n=80) and dexamethasone (n=76) that had gene expression done on Affymetrix U1133A and B chip. The data was MAS5 normalized, log2 transformed and median centered for analysis. A MYC activation index (MAI) based on the median expression of genes constituting the MYC activation signature was generated. Genetic information included FISH detection of hyperdiploidy, t(11;14), t(4;14), 13 deletion, 17p13 deletion was available in the Mayo dataset. Clinical parameters including ISS stage, beta-2 microglobulin and plasma cell labeling index (PCLI) were also assessed. Association was assessed using Chi-square tests for categorical values. Comparison of continuous variables was using Mann-Whitney U Test. Survival curves were constructed using the Kaplan-Meier method and compared using log-rank test. In the Mayo cohort, overall survival (OS) was calculated from diagnosis to death. In the Apex cohort, progression free survival (PFS) and OS was calculated from trial entry to disease progression and death respectively. All patients consented to the study that was approved by the Institution Review Board of the Mayo Clinic. *Results.* In the Mayo cohort 68% had a high MAI (>1 arbitrary unit). A high MAI was associated with hyperdiploid (81% versus 62%, P=0.04), higher PCLI (median 1 versus 0.25, P=0.007), and ISS III (90% ISS III have high MAI versus 62% ISSI/II have high MAI, P=0.03). Patient with high MAI had significantly shorter survival (33 months versus 63.4 months, P=0.001). In the APEX cohort, a high MAI was associated with shorter survival compared to low MAI (16 months versus 31.9 months, P=0.01). However subgroup analysis according to treatment received showed that the prognostic impact of a high MAI is only present in patients treated with dexamethasone (9.6 months versus 36.9 months, P=0.002) but not with bortezomib (21.6 months versus 23.1 months, 0.6). We next assessed the impact of types of drug treatment within the 2 MAI categories. Response (57% versus 27%, P=0.03), PFS (6.3 months versus 2.9 months, P=0.02) and OS (21.6 months versus 9.6 months, log-rank P=0.04) was better for patients treated with bortezomib than dexamethasone in those with high MAI (37 treated with bortezomib, 28 treated with dexamethasone). However, PFS (5.6 months versus 3.4 months, P=0.34) and OS (31.9 months versus 23.1 months, P=0.4) were not different between bortezomib and dexamethasone treatment in those with low MAI (43 treated with bortezomib and 48 treated with dexamethasone). *Summary/conclusions.* MYC activation is more common in hyperdiploid MM and associated with shorter survival. This survival disadvantage seems to be overcome by bortezomib due to better response, PFS and OS.

0392

PHASE II STUDY OF CARFILZOMIB IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA AND VARYING DEGREES OF RENAL INSUFFICIENCY

R Niesvizky,[1] R Vij,[2] T Martin,[3] J Zonder,[4] K Boussina,[5] Z Wang,[5] T Woo,[5] A Wong,[5] A Badros[6]

[1]Weill Cornell Medical College, New York, NY, USA; [2]Washington University School of Medicine, St Louis, MO, USA; [3]University of California, San Francisco, CA, USA; [4]Karmanos Cancer Institute, Detroit, MI, USA; [5]Onyx Pharmaceuticals, Emeryville, CA, USA; [6]Greenebaum Cancer Center, Baltimore, MD, USA

Background. Approximately 20% of patients with newly diagnosed multiple myeloma (MM) have concomitant renal impairment (RI) and >50% will experience it during the course of their disease. RI confers shorter survival due to higher tumor burden and prevents adequate dosing of active drugs by exacerbating side effects due to reduced renal clearance. Carfilzomib (CFZ) is a novel, highly selective peptide epoxyketone proteasome inhibitor with single agent activity in relapsed and/or refractory (R/R) MM. *Aims.* In previous Phase II studies, CFZ demonstrated activity in heavily pretreated patients with R/R MM including those with moderate RI. The present study was designed to evaluate the tolerability and PK properties of CFZ in R/R MM patients with RI, including those on dialysis. *Methods.* This open-label, multicenter phase II trial enrolled R/R MM patients with varying degrees of RI who had relapsed after ≥2 prior therapies. Patients were stratified based on their degree of RI (Table).

Evaluable Patients					
Cohort	**CrCL, mL/min**	**Enrolled**	**Efficacy**	**Safety**	**PK**
Normal	80	10	10	2	4
Mild RI	50-79	9	8	8	6
Moderate RI	30-49	9	7	6	6
Severe RI	<30	9	8	4	6
On hemodialysis		2	2	2	2
Total		**39**	**22**	**35**	**24**

AE	All G (n)	G 3/4 (n)
Fatigue	14	3
Anemia	10	9
Diarrhea	9	
Nausea	8	
Constipation	7	
Thrombocytopenia	7	6
Hypokalemia	7	
Creatinine increase		4
Mental status change		3

Table 1.

Study objectives included safety, PK, pharmacodynamics (proteasome inhibition in blood and PBMC) and efficacy (overall response rate [≥PR], clinical benefit response [≥MR; CBR], stable disease [SD] ≥6 wk, duration of response, and time to progression). Patients received CFZ 15 mg/m^2 IV on days 1, 2, 8, 9, 15, and 16 every 28 days for cycle 1, with escalation to 20 mg/m^2 in cycle 2 and 27 mg/m^2 in cycle 3 and thereafter, if tolerated. After response assessment, patients failing to achieve ≥PR by cycle 2 or CR by cycle 4 could receive "low dose"dexamethasone (40 mg/week). *Results.* To date, 39 patients have been enrolled. Patients received a median of 5 prior therapies (range 2-10). All had refractory MM and 42% had progressed during their last therapy. 97% had received bortezomib; all had received ≥1 immunomodulatory agent (87% thalidomide and 95% lenalidomide); 67% had prior stem cell transplant. Thus far, 22 patients received a median of 3 C (range 1-10+); 9 have completed ≥6 C. Side effects (AEs), including Grade (G) 3/4 AEs, are presented in the table. There were no appreciable differences among the 5 cohorts in either frequency or grade of CTC-AE. No QT/QTc prolongations were seen. PK/PD were similar across all cohorts; CFZ was undetectable in plasma within 3 h (t½ = 30-60 min) and did not accumulate after 2 C. Mental status changes were all reversible; two of the 3 Grade 3/4 change in mental status were unrelated to drug and 1 resolved with drug continuation. Proteasome inhibition 1 h post-dose ranged from 75-89% at doses of 15-20 mg/m^2. The CBR was 37% (8 PRs, 5 MRs) with an additional 37% SD (n=13). Two bortezomib-refractory patients achieved PR. Seven of 18 patients received dexamethasone with 2 exhibiting improved responses (1 PR and 1 MR). *Conclusions.* Patients with MM and substantial RI can receive CFZ without dose adjustment. Toxicities are mild and manageable with no apparent effect of baseline RI on AEs. Importantly, exacerbation of pre-existing peripheral neuropathy, RI, and myelosuppression were not observed. Responses are encouraging and further evaluation of CFZ in RI patients is ongoing.

CARFILZOMIB, A NOVEL PROTEASOME INHIBITOR, EXHIBITS MINIMAL NEUROTOXIC AND PERIPHERAL NEUROPATHIC EFFECTS IN PRECLINICAL AND CLINICAL STUDIES

S Lonial,[1] S Jagannath,[2] T Martin,[3] M Wang,[4] S Singhal,[5] S Trudel,[6] M Le,[7] C Kirk,[7] S Arastu-Kapur,[7] R Vij,[8] D Siegel,[9] The MM Research Consortium[10]

[1]Winship Cancer Institute, Atlanta, GA, USA; [2]St. Vincent's Catholic Medical Center, New York, NY, USA; [3]UCSF, San Francisco, CA, USA; [4]University of Texas MD Anderson Cancer Center, Houston, TX, USA; [5]Northwestern University School of Medicine, Chicago, IL, USA [6]Princess Margaret Hospital, Toronto, Canada; [7]Onyx Pharmaceuticals, Emeryville, CA, USA; [8]Washington University School of Medicine, St. Louis, MO, USA; [9]Hackensack University Medical Center, Hackensack, NJ, USA; [10]The Multiple Myeloma Research Consortium, Norwalk, CT, USA

Background. Treatment-induced peripheral neuropathy (TIPN) can be a debilitating and therapy-limiting complication in multiple myeloma (MM). Thalidomide and bortezomib (BTZ) are two therapies frequently associated with TIPN in MM. Carfilzomib (CFZ) a novel, selective proteasome inhibitor differs from BTZ both structurally and mechanistically. Preclinically, CFZ is not associated with the off-target activities seen with BTZ (Arastu-Kapur et al, Haematologica, 2009), is active in BTZ-resistant tumor cells (Kuhn et al, Blood 2007 and Suzuki et al, Blood 2009), and is not associated with neurotoxicity in chronic animal toxicity studies. (Kirk et al, Blood 2008). *Aims.* Single-agent CFZ has demonstrated activity in relapsed or refractory (R/R) MM and does not produce dose-limiting PN. Here we compare the effects of CFZ and BTZ in an *in vitro* neurotoxicity model and report on clinical experience with CFZ from two ongoing Phase II trials. *Methods.* Proteasome inhibitor effects were measured by high content analysis of fluorescent images for cell survival (Hoechst nuclear counterstain) and neurite degeneration (FITC-mouse anti-beta-III-tubulin) in an established neurotoxicity model using differentiated SH-SY5Y neuroblastoma cells. Changes in cell morphology and cell death were captured using phase contrast imaging and both cell viability and proteasome inhibition were measured. Serine proteases with a P1 selectivity of Leu/Phe/Tyr were identified from the MEROPS (peptidase) database as potential non-proteasomal targets of CFZ and BTZ activity. *Methods.* Data from two ongoing Ph II trials of single-agent CFZ in patients with R/R MM were pooled and included past history of neuropathy, neuropathic symptoms at baseline, findings on neurological exam, and FACT-GOG/NTx scores. Adverse event (AE) data were also collected. *Results.* SH-SY5Y cells showed a 40% reduction in neurite length/cell after 24 hrs of exposure to 10 nM BTZ, compared to both CFZ- or vehicle-treated cells. However, the level of proteasomal inhibition was equivalent in CFZ and BTZ treated cells. HtrA2/Omi, a mitochondrial serine protease with a role in neuron survival was identified in the MEROPS database. HTrA2/Omi was confirmed as a non-proteasomal target of BTZ (IC_{50} = 3 nM), but not CFZ (>10 μM). *Results.* At screening, 72% of 135 patients had symptoms of PN; 81% had a history of PN attributed to their prior MM therapy. Patients received a mean of 30.4 doses (range 2-72) of CFZ and 17% were treated for over 10 mo. 10% of patients had drug-related PN (primarily Grades 1/2). Grade 3 PN was reported in only 3 (2.2%) pts; there were no reports of Grade 4 PN. No missed doses or treatment discontinuations occurred due to PN. Only 1 (<0.01%) patient was dose-reduced due to neuropathy. *Conclusions.* Contrary to BTZ, CFZ-related PN is infrequent and not a dose-limiting toxicity. *In*

vitro, BTZ potently inhibits a neuronal cell survival factor, HtrA2, and demonstrates significantly more neurotoxicity compared to CFZ despite equivalent proteasomal activity. Clinically, PN is not a treatment-limiting toxicity of CFZ. These *in vitro* and clinical data indicate that neurotoxicity occurs via a proteasome-independent mechanism and severe PN is not a class effect of proteasome inhibitors.

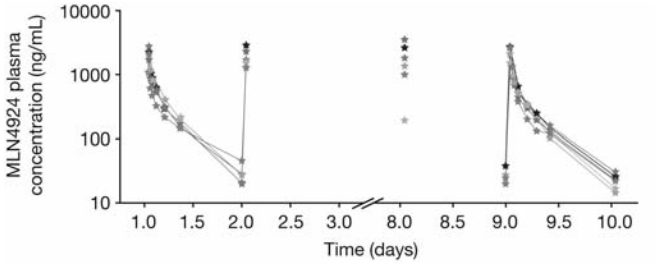
MLN4924, A NOVEL NAE INHIBITOR IN PATIENTS WITH MULTIPLE MYELOMA (MM) AND NON-HODGKIN'S LYMPHOMA (NHL): PHASE 1 DOSE-ESCALATION STUDY

J Shah,[1] A Jakubowiak,[2] O O'Connor,[3] R Orlowski,[1] M Patterson,[3] D Harvey,[4] A Berger,[5] A McDonald,[5] G Mulligan,[5] A Boral,[5] M Pickard,[5] P Smith,[5] H Kuan,[5] R Walker,[5] J Garnsey,[5] K Burke,[5] S Lonial[4]

[1]The University of Texas, M.D. Anderson Cancer Center, Houston, USA; [2]Hematology/Oncology, University of Michigan Comprehensive Cancer Center, Ann Arbour, USA; [3]Herbert Irving Comprehensive Cancer Center, Columbia University, New York, USA; [4]Winship Cancer Institute, Emory University, Atlanta, USA; [5]Millennium Pharmaceutical, Inc., Cambridge, USA

Background. MLN4924 is a first-in-class small-molecule inhibitor of NEDD8-activating enzyme (NAE). Inhibition of NAE prevents conjugation of NEDD8 to the Cullin Ring Ligases (CRLs), which inhibits proteasomal degradation of CRL substrates including proteins involved in cell cycle regulation, signal transduction (pIκBα), DNA replication (Cdt-1), and stress response (Nrf-2). *Aims.* The primary objectives of this open-label, phase-1, dose-escalation study were to determine the maximum tolerated dose (MTD) and tolerability of MLN4924, pharmacokinetics and pharmacodynamics in blood, and pharmacodynamic effects in skin. *Methods.* Patients ≥18 years with relapsed and/or refractory MM, any B or T-cell NHL, Hodgkin's lymphoma or Waldenström's macroglobulinemia after ≥2 prior lines of therapy were eligible. Escalating doses of intravenous MLN4924 (25, 50, 65, 83, 110, 147mg/m^2) were administered on days 1, 2, 8, and 9 of 21-day cycles (maximum 12 months' treatment). MTD was defined as the dose level closest to that predicted to result in dose-limiting toxicity (DLT) rate of 25%. For the pharmacodynamic analysis, peripheral blood mononuclear cells (PBMCs) and whole blood were isolated at screening, baseline, and following MLN4924 administration; skin biopsies for Cdt-1 and Nrf-2 assays were performed at baseline and after the second dose. RT-PCR was used to analyze expression of NAE-regulated genes in whole blood. *Results.* By data cut-off, 24 patients had been enrolled; median age 64 years, 63% male. Fourteen patients had MM (IgA n=4; IgG n=9; other n=1) and 10 had NHL (FL n=4; DLBCL n=2; MCL n=1; CLL/SLL n=2; lymphoplasmacytic lymphoma n=1). In MM patients, 11 had received prior autologous stem-cell transplant; all 14 patients had received previous bortezomib, 10 received prior thalidomide and 10 received prior lenalidomide.

Figure. Representative plasma PK profiles (110 mg/m^2).



Seven NHL patients received prior transplant and 10 received prior rituximab. Of the 20 DLT-evaluable patients, 4 experienced DLT: G4 febrile neutropenia (65 mg/m^2); G3 aspartate aminotransferase (AST) elevation (110 mg/m^2); G4 muscle cramps, and G2 myalgia that was considered dose limiting (both 147 mg/m^2). The MTD for this schedule was therefore determined as 110 mg/m^2. Patients received a median of 3 treatment cycles (MM=4 cycles; NHL=2). No treatment-related deaths were reported; one MM patient died due to progressive disease. Overall G≥3 AEs occurred in 54% of patients (all doses) and the most common included anemia, fatigue, increased AST, and hypophosphatemia. MLN4924 plasma concentrations declined in a multi-phasic manner after the end of infusion with relatively low pharmacokinetic variability. Pharmacokinetic profiles were similar following dosing on days 1 and 9, suggesting no readily apparent accumulation (Figure). The area under the concentration-time curve appears to increase linerarly with increasing mg/m^2. In PBMCs, NEDD8-Cullin was decreased and pIκBα expression was increased versus baseline, indicative of NAE inhibition. In whole blood, Nrf-2-regulated gene transcripts including NQO1 were increased after dosing compared to baseline. Cdt-1/Nrf-2 in skin increased above baseline following the second MLN4924 dose. Summary: MLN4924 inhibits NAE activity in blood and skin, indicating that it exerts predicted pharmacodynamic effects. Continued investigation of MLN4924 110mg/m^2 to more fully characterize safety, pharmacokinetics, and pharmacodynamics in MM and NHL is underway; two additional schedules are being investigated in subsequent patients.

JAK2V617F MUTATION PERSISTS IN BLASTS AND MATURE CELLS OF TRANSFORMED- JAK2V617F-POSITIVE-MYELOPROLIFERATIVE NEOPLASIA: A EUROPEAN LEUKEMIA NET (ENL) STUDY

CR Rinaldi,[1] P Rinaldi,[1] M Gemei,[1] F Grimaldi,[1] G Battipaglia,[1] L Del Vecchio,[1] B Martino,[2] G Specchia,[3] A Candoni,[4] L Gugliotta,[5] A Vannicchi,[6] T Barbui,[7] F Pane[1]

[1]Federico II University, Naples, Italy; [2]Ospedale di Reggio Calabria, Reggio Calabria, Italy; [3]University of Bari, Bari, Italy; [4]University of Udine, Udine, Italy; [5]Ospedale di Reggio Emilia, Reggio Emilia, Italy; [6]University of Firenze, Firenze, Italy; [7]Ospedali Riuniti di Bergamo, Bergamo, Italy

Background. Transformation to acute myeloid leukemia (AML) is a known complication of MPN but the role of JAK2V617F mutation is still undefined. In 2006, Campbell described a possible model for the development of a JAK2WT-AML in a patient with JAK2V617F-MPN and more recently, Theocharides et al. reported that in up to 53% of the patients who developed secondary AML from a JAK2-mutated MPN the mutation was no longer detectable; however the results obtained with DNA extracted from cells scraped or laser-capture-microdissected from bone marrow (BM) or peripheral blood (PB) smears, were confirmed in fresh samples only in few cases. *Aims and Methods.* In this study, we collected, by cell sorting, blast cells and mature myeloid cells (granulocytes, GRA) from whole BM aspirates of 34 newly diagnosed patients with AML secondary to MPN (18 derived from PMF; 9 from PV and 7 from ET) and analyzed the JAK2 status before and after leukemic transformation in selected cell compartments. To evaluate the modification in the JAK2 status before and during leukemic transformation we performed ASO-PCR and (QRT)-PCR assay on total BM of the MPN phase and sorted cell populations from AML phase. *Results.* At the time of MPN diagnosis, JAK2V617F was detectable in 22 of 34 patients (65%) (10 of 18 PMF; 9 of 9 PV and 3 of 7 ET). No cytogenetic abnormalities or MPL and JAK2-exone 12 mutations were detected at this stage. Median time to AML progression (TTP) was 5.09 years (yrs) (range 0.38 - 27.81). A significant difference (P=0.02) in TTP was found grouping patients according to JAK2 status during the MPN phase [JAK2WT-MPN n=12, TTP median 15.10 yrs (0.38-16.32); JAK2 mutated-MPN n=22, TTP median 4.07 yrs (0.67-27.81)]. Eight patients showed additional abnormalities involving chromosomes 1, 5, 7, 8, 9, 12, 14, 17 and 20 while no other AML-associated mutations (FLT3, NPM, CEBPA, RUNX1) were detectable at this stage. In our cohort of patients we found that JAK2V617F mutation was still present at the blast transformation in both compartments: CD34+ cells (blasts) and CD15+ cells (GRA) in 20 of 22 JAK2 mutated MPN (91%). Two of 22 patients (9%) developed JAK2V617F negative AML starting from a mutated PV with a mean TTP of 5.14 yrs. Interestingly, the WT status was confirmed in blast cells but also in GRA. Surprisingly we found a case of JAK2V617F mutated AML transforming from a WT-PMF. Also in this case the JAK2V617F positivity in the AML phase occurred in both GRA and blast compartments. No differences (P= 0.3) in the allele burden were found comparing MNCs from chronic phase with MNCs of leukemic transformations or comparing GRA with blasts in AML phase. *Conclusions.* In conclusion, these results contrast with the previous study in which the JAK2 mutation was lost in 53% of blasts during leukemia transformation. In our work, the loss of JAK2V617F mutation during AML progression is a rare event (9%). Additional studies in larger patient series and multivariate analysis are needed before a prognostic role of JAK2V617F mutation regarding time to leukemia transformation can be definitely assessed.

PROMOTER DNA HYPERMETHYLATION DISTINGUISHES VARIANTS OF JUVENILE MYELOMONOCYTIC LEUKEMIA WITH DIFFERENT PRESENTATION AND PROGNOSIS

C Flotho,[1] C Batz,[1] I Sandrock,[1] P Nöllke,[1] B Strahm,[1] H Hasle,[2] M Zecca,[3] J Starý,[4] E Bergsträsser,[5] B De Moerloose,[6] M Trebo,[7] M van den Heuvel,[8] D Wojcik,[9] F Locatelli,[3] C Niemeyer[1]

[1]University of Freiburg, Freiburg, Germany; [2]Aarhus University Hospital Skejby, Aarhus, Denmark; [3]University of Pavia, Pavia, Italy; [4]Charles University Prague, Prague, Czech Republic; [5]University Children's Hospital, Zürich, Switzerland; [6]University Hospital, Ghent, Belgium; [7]St. Anna Children's Hospital, Vienna, Austria; [8]Erasmus Medical Center, Rotterdam, Netherlands; [9]Wroclaw Medical University, Wroclaw, Poland

Promoter DNA hypermethylation contributes to the malignant phenotype in myeloproliferative neoplasms and myeloid leukemia. It is barely known whether aberrant DNA methylation also occurs in juvenile myelomonocytic leukemia (JMML), and if so, whether it is associated with clinical presentation, hematology or prognosis of the disease. We used denaturing liquid chromatography to analyze peripheral blood or bone marrow samples from 111 children with JMML and 17 healthy controls for aberrant DNA methylation at 14 candidate gene loci. All children had been enrolled in the European Working Group of MDS in Childhood (EWOG-MDS) studies 98 or 2006 with informed consent from parents or guardians. The analyses identified 4 genes with promoter DNA hypermethylation in JMML: bone morphogenetic protein 4 (BMP4) (37/111 cases), calcitonin A (*CALCA*) (38/111 cases), cyclin-dependent kinase inhibitor 2B (*CDKN2B*) (25/111 cases) and retinoic acid receptor beta (*RARB*) (18/111). The 17 controls were unmethylated at these 4 loci. We noticed that methylation in JMML did not occur with even or random distribution across samples and genes. Instead, hypermethylation was detectable at all four loci in some samples but was limited to fewer genes in others. We therefore categorized the cohort into three groups: no methylation (51/111 samples), limited methylation (1 or 2 genes; 44/111 samples) or extensive methylation (3 or 4 genes; 16/111 samples). A correlative analysis of methylation groups with clinical or hematologic features showed that extensive methylation was strongly associated with older age and elevated percentage of hemoglobin F (HbF) at diagnosis (P<0.001). A weaker correlation was seen with genetic JMML subtype (mutant *PTPN11, KRAS/NRAS, NF1,* or *CBL*) (P<0.05), with *CBL* cases largely being unmethylated. By contrast, there was no significant association between methylation and leukocyte count, absolute monocyte count, platelet count, blast percentage in blood or bone marrow or spleen size. Importantly, the presence of hypermethylation at diagnosis predicted cases with poor outcome; the 5-year overall survival (OS) in the no methylation group was 0.68 [0.53-0.82], as compared to 0.31 [0.06-0.55] in the extensive methylation group (P<0.001). Among patients receiving hematopoietic stem cell transplantation, hypermethylation characterized cases with significantly increased probability of relapse: the 5-year relapse incidence in the no versus high methylation groups was 0.17 [0.08-0.34] versus 0.57 [0.36-0.90] (P<0.001). Lineage-specific cell sorting demonstrated that aberrant methylation was restricted to clonal cell populations and could be traced back to the $CD34^+$ JMML progenitor cell compartment. This observation supports the concept that DNA methylation is associated with early pathogenetic events in JMML. Furthermore, longitudinal analyses indicated that some cases had acquired a more extensively methylated phenotype at relapse. In summary, we observed that a high-methylation phenotype characterizes an aggressive biologic variant of JMML and suggest that DNA methylation is an important molecular predictor of outcome.

0397

COMPETITIVE POTENTIAL OF JAK2-V617F STEM CELLS

L Kubovcakova, P Lundberg, H Hao-Shen, R Skoda

University Hospital Basel, Basel, Switzerland

Background. The myeloproliferative neoplasms (MPN), polycythemia vera (PV), essential thombocythemia (ET), and primary myelofibrosis (PMF), are clonal diseases caused by somatic mutations that are thought to occur at level of the hematopoietic stem cell. Based on data from mouse models, the JAK2-V617F mutation appears to be sufficient to cause MPN as a single step event, but in patients several lines of evidence indicate that additional mutations can precede the acquisition on JAK2-V617F. *Aims.* We developed a competitive repopulation assay

that allows us to assess the MPN-initiating potential of the stem cells that carry JAK2-V617F as a sole genetic alteration and clarify their proliferative and competitive abilities. *Methods.* We previously generated a Cre-LoxP inducible transgenic mouse model (FF1 mice) for the expression of human JAK-V617F. These FF1 mice have been crossed with the MxCre or SclCre mice and upon induction, the double transgenic mice primarily display a PV phenotype. Lethally irradiated wild type recipients were transplanted with a 1:1 or 1:9 mixture of total bone marrow cells from MxCre;FF1 or SclCre;FF1 mice that have been induced with polyinosine-polycytosine (pIpC) or tamoxifen, respectively, and from wild type mice that express GFP in all hematopoietic lineages (UBC-GFP). This approach allowed us to distinguish mutant (GFP negative) and wild-type (GFP positive) cells by flow cytometry and thus quantify the contribution of the JAK2-V617F cells to different lineages. *Results.* Recipients transplanted with a 1:1 ratio of mutant and wild type bone marrow cells developed a PV phenotype 4 weeks post-transplantation. At the same time we observed a replacement of wild type cells by the JAK2-V617F cells in the peripheral blood. This displacement was most rapid in erythroid lineage (>95%). After 24 weeks the hemoglobin returned to normal and the platelet counts showed a strong increase ($>5\times10^9$/L), although the percentage of JAK2-V617F positive cells remained high in all lineages. Recipients transplanted with a 1:9 ratio of mutant and wild type bone marrow also showed a PV phenotype that later switched to ET, but the timing was delayed by 8-10 weeks. Sections of the long bones and sternum revealed the presence of fibrosis in all mice transplanted with JAK2-V617F bone marrow cells in 1:1 and 1:9 ratios. When the bone marrow cells harvested during the ET phase were transplanted into secondary recipients, the PV phenotype did not reappear and the ET phenotype persisted during the entire follow-up (up to 44 weeks post transplant). The fraction of Lin-, Sca+ c-kit+ (LSK) cells was increased 8-10 fold in MxCre;FF1 mice expressing JAK2-V617F, but LSK cells from these mice induced a MPN phenotype in only a fraction of lethally irradiated recipients. *Summary.* In our transplantation model, JAK2-V617F bone marrow cells rapidly outcompeted the wild type cells when transplanted in 1:1 and 1:9 ratios and reproduced the PV phenotype of the donor mice. The LSK stem cell compartment is expanded in JAK2-V617F expressing mice, but the reconstitutive potential of these LSK cells may be diminished.

CHARACTERIZATION OF A KANK1-PDGFRB FUSION IN AN IMATINIB-RESPONSIVE MYELOPROLIFERATIVE NEOPLASM WITH SEVERE THROMBOCYTHEMIA

S Medves,[1] F Duhoux,[2] A Ferrant,[3] F Toffalini,[1] G Ameye,[2] JM Libouton,[2] H Poirel,[2] JB Demoulin[1]

[1]De Duve Institute, Brussels, Belgium; [2]Génétique Hématologique / Human Molecular Genetics (GEHU), Brussels, Belgium; [3]Cliniques Universitaires St-Luc, Brussels, Belgium

Myeloproliferative neoplasms (MPNs) are clonal stem cell disorders characterized by mature myeloid cell overproduction. Among them, essential thrombocythemia is associated in 50% of cases with the JAK2 V617F mutation. Mutations in the thrombopoietin receptor, which activates JAK2, were also found in this MPN. Here, we analyzed a patient presenting clinical features suggestive of an essential thrombocythemia but in which JAK2 V617F mutation and BCR-ABL fusion were excluded. The karyotype suggested a previously unreported t(5;9)(q32;p24) translocation. By combining fluorescence *in situ* hybridization (FISH) and PCR, we identified a KANK1-PDGFRB fusion transcript. KANK1 (also called ANKRD15) is a proposed tumor suppressor gene in renal cell carcinoma. Upon imatinib mesylate treatment (100 mg/day), the patient achieved hematological remission. The KANK1-PDGFRβ protein comprises three coiled coil domains of KANK1 fused in frame to the fifth Ig-like domain and the kinase domain of PDGFRβ. When expressed in Ba/F3 cells, the fusion protein was phosphorylated on tyrosine residues, induced the activation of STAT5 and enabled cytokine-independent cell growth like other activated PDGFRβ fusion proteins. Deletion of the fifth Ig-like domain did not affect the transforming ability of the protein, suggesting that this unusual translocation breakpoint in PDGFRB is not associated with any proliferative advantage. PDGFRβ translocation partners are characterized by the presence of dimerization domains that enable the constitutive activation of the PDGFR tyrosine kinase activity. To assess whether KANK1 coiled coil domains are implicated in KANK1-PDGFRβ transforming activity, we generated mutants in which one or more of these dimerization domains were deleted. KANK1 coiled coil domains are important but not sufficient to induce a transforming activity when fused to the PDGFRβ. This is the first report of severe thrombocythemia associated with a PDGFRB translocation, without prominent eosinophilia. This is in sharp contrast with the reported clinical features of MPNs associated with PDGFRB rearrangements, which often include eosinophilia and thrombocytopenia. Therefore, we speculate that the fusion partner KANK1 plays a role in the disease, in line with a previous report showing that it is down-regulated in JAK2 V617F-positive MPNs.

UPREGULATION OF HUMAN TRIBBLES HOMOLOGUE 3 (TRB3) BY ANAGRELIDE: A NOVEL MOLECULAR MARKER FOR THE DISCOVERY OF CANDIDATE PLATELET LOWERING AGENTS

D Erusalimsky, M Ahluwalia, H Donovan

University of Wales Institute Cardiff, Cardiff, UK

Background and Aims. TRB3, a mammalian orthologue of Drosophila Tribbles is a member of an emerging group of kinase-like proteins, increasingly implicated in the modulation of signal transduction pathways and gene transcription. TRB3 has been reported to inhibit AKT and MAP kinase cascades, both of which are involved in TPO-stimulated signalling. Accordingly, in an attempt to expand our understanding on the molecular mechanisms that regulate megakaryocytopoiesis and to clarify further how this process is affected by the platelet lowering agent anagrelide, we investigated whether this drug modulates the expression of TRB3. *Methods.* Human umbilical cord blood-derived $CD34^+$ cells were expanded in IMDM-based serum free medium supplemented with haematopoietic growth factors and then induced to undergo megakaryocytic differentiation by further culture with TPO. Relative expression levels of selected transcripts were quantified by Real Time PCR using gene-specific probes. *Results.* Culture of haematopoietic cells with TPO resulted in a time and dose-dependent decrease in the mRNA levels of TRB3, with a maximal effect (80% reduction) observed at 40 ng/mL TPO after four days incubation. Addition of anagrelide at the beginning of the differentiation period counteracted this effect of TPO, resulting in a time and dose-dependent increase of TRB3 levels (EC_{50} = 15 nM, maximal increase of ~4-fold after 8 days with 1 μM anagrelide). These changes were mirrored by reciprocal changes in the expression of the megakaryocyte-specific gene GpIIb. Anagrelide has anti-phosphodiesterase III (PDEIII) activity. However, the equipotent PDE III inhibitor cilostamide, had no discernible effect on TRB3 expression. Screening of small chemical entities for their ability to increase TRB3 mRNA expression predicted their ability to inhibit megakaryocyte development in a conventional growth assay. *Conclusions.* These findings point out to a novel mechanism for the inhibition of platelet production and suggest that TRB3 could be used as a novel marker to assist in the identification of candidate anti-megakaryocytic agents.

JAK2 V617F PROMOTES EXPRESSION OF ONCOSTATIN M (OSM) IN MYELOID PROGENITOR CELLS: A POTENTIAL LINK BETWEEN ABNORMAL JAK-SIGNALING AND BONE MARROW ANGIOGENESIS AND -FIBROSIS IN MYELOPROLIFERATIVE NEOPLASMS

G Hoermann,[1] S Cerny-Reiterer,[2] A Perne,[1] L Müllauer,[3] P Valent,[2] M Mayerhofer[1]

[1]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria; [2]Medical University of Vienna, Department of Internal Medicine I, Vienna, Austria; [3]Medical University of Vienna, Department of Pathology, Vienna, Austria

Background. Polycythemia vera, idiopathic myelofibrosis, and essential thrombocythemia are a group of myeloproliferative neoplasms (MPN) characterized by gain-of-function mutations in the Janus kinase 2 (JAK2) gene. A majority of the MPN patients carries a point mutation at codon 617 (V617F) which is located within the autoinhibitory pseudokinase domain and leads to constitutive activation of the kinase. A causal role for JAK2 in MPN has been proposed based on mouse transplantation models in which Jak2 V617F produces a condition reminiscent of MPN. Moreover, a number of *in vitro* studies have implicated the activated JAK2 mutant in cell growth and survival. However, the mechanisms driving growth and differentiation of hematopoietic cells by the JAK2 mutant remain largely unknown. It is also unclear whether JAK2 V617F contributes to the marked bone marrow microenvironment alterations, notably the increased angiogenesis and fibrosis observed in patients with MPN. Oncostatin M (OSM), a cytokine of the

IL-6 family has been implicated as a growth factor triggering the proliferation of various mesenchymal cells including endothelial cells and fibroblasts. Moreover, OSM has been described to be involved in megakaryocytic maturation and in erythropoietic differentiation. *Aims.* The aim of the current study was to investigate the expression and functional role of OSM in MPN. *Methods.* Expression of OSM in the bone marrow of MPN patients was investigated by immunohistochemistry and real time PCR. To investigate the role of JAK2 in expression of OSM, Ba/F3 cells with doxycycline-inducible expression of wild type JAK2 or JAK2 V617F were generated. In addition, the human JAK2 V617F+ cell lines HEL, SET2, and UKE1 were used. *Results.* As assessed by immunohistochemistry performed on bone marrow sections of patients with MPN (n=15), megakaryocytes and myeloid progenitors expressed the OSM protein at high levels. JAK2 V617F-positive MPN patients were found to express significantly higher OSM mRNA levels than normal bone marrow samples derived from patients undergoing lymphoma staging (Figure 1). Interestingly, expression of OSM was not increased in BCR/ABL-positive CML patients (Figure 1). In Ba/F3 cells, doxycycline-inducible expression of JAK2 V617F led to a substantial upregulation of OSM mRNA and protein levels, whereas expression of wild type JAK2 or BCR/ABL did not promote expression of OSM. Correspondingly, the JAK2 V617F-positive human cell lines HEL, SET2, and UKE1 were found to express significantly higher levels of OSM than the BCR/ABL-positive K562 cell line and knockdown of JAK2 V617F downregulated OSM expression in these cell lines. Finally, STAT5 was found to be involved in JAK2 V617F-dependent expression of OSM since RNAi knockdown of STAT5 substantially reduced OSM expression levels and a constitutively activated STAT5 mutant upregulatd OSM expression. *Conclusion.* Together, our data show that neoplastic cells in MPN express OSM in a JAK2 V617F- and STAT5-dependent manner. Whether JAK2 V617F-dependent OSM expression is involved in growth and differentiation of neoplastic cells and/or in remodelling of the bone marrow microenvironment in patients with MPN is currently under investigation.

THE ROLE OF THE JAK2 GGCC HAPLOTYPE, TET2, AND CBL IN FAMILIAL MYELOPROLIFERATIVE NEOPLAMS

D Olcaydu,[1] E Rumi,[2] A Harutyunyan,[1] F Passamonti,[2] D Pietra,[2] T Berg,[1] R Jäger,[1] T Klampfl,[1] R Kralovics,[1] M Cazzola[2]

[1]*Research Center for Molecular Medicine (CeMM) of the Austrian Academy of Science, Vienna, Austria;* [2]*Division of Hematology, Fondazione IRCCS Policlinico San Matteo, University Pavia, Pavia, Italy*

Background. Myeloproliferative neoplasms (MPN) encompass distinct hematologic malignancies that share common pathogenetic features such as the *JAK2*-V617F mutation. Recent reports showed that about 80% of *JAK2*-V617F mutations occur on a particular haplotype of the *JAK2* gene, namely the GGCC or 46/1 haplotype. It has been hypothesized that this haplotype might explain familial clustering in MPN. If this assumption is correct, higher frequency of the GGCC haplotype is expected in familial MPN when compared to sporadic cases. To test this hypothesis, we investigated the role of the GGCC haplotype in a large series of patients with familial and sporadic MPN from the same demographic area in Italy. In order to evaluate additional genetic factors that might underlie familial MPN, we examined the presence of germline *TET2* and *CBL* mutations. *Methods.* A total of 108 familial MPN patients (53 pedigrees) were identified through interview-based investigation of 960 sporadic MPN patients. The HapMap Tuscani in Italia population (TSI) was used as a demographic control. Molecular studies were performed in familial cases with available DNA from granulocytes and T lymphocytes (88 of 108) and in 123 sporadic MPN patients. A tagging single nucleotide polymorphism (SNP; rs10974944) was used for determining the *JAK2* haplotype. *Results.* Association analysis revealed a significant correlation between the occurrence of *JAK2*-V617F and the GGCC haplotype in patients with familial and sporadic MPN when compared to the TSI population. The GGCC haplotype frequency was higher in familial (0.44) and sporadic MPN patients (0.49) than in the TSI population (0.30). The risk of acquiring *JAK2*-V617F was higher for patients heterozygous or homozygous for the GGCC haplotype in familial ($P=0.0077$, OR 2.33, 95% CI 1.24-4.36) as well as sporadic MPN ($P=2.6\times10^{-05}$, OR 3.68, 95% CI 1.95-6.97) when compared to TSI. However, familial MPN did not differ significantly from sporadic MPN in disease risk conferred by the GGCC haplotype. Twelve TET2 mutations were detected in granulocytes from 11 of 88 patients. Of these, 7 were somatic TET2 mutations, whereas 5 patients displayed the same mutation in T lymphocytes: two patients carried a non-annotated SNP (P1723S), one a normal variant (V1718L) and two patients had new germline mutations (R1440Q and A241V). The TET2 R1440Q mutation was absent in the other affected member of the same pedigree, thus excluding segregation of this mutation with the disease. In case of the A241V mutation, no DNA was available from the other affected family member. No germline CBL mutations were found. *Conclusions.* Our results show no significant difference between familial and sporadic MPN in the risk of acquiring *JAK2*-V617F conferred by the GGCC haplotype. Thus, the GGCC haplotype does not explain familial clustering in MPN. Mutations in TET2 and CBL genes were recently suggested to play a role in MPN pathogenesis. However, we could not identify germline mutations that segregate with the disease phenotype. In conclusion, we could disprove the hypothesis that the *JAK2* GGCC haplotype and TET2 and CBL genes play a role in familial MPN. Thus, the genetic basis of MPN predisposition still remains to be defined.

0402

MOLECULAR MECHANISMS OF C-CBL MUTATIONS IN MYELOID NEOPLASMS

M Sanada

University of Tokyo, Tokyo, Japan

C-CBL proto-oncogene is the cellular homolog of the v-Cbl transforming gene isolated from the Cas NS-1 murine leukemia virus that causes B-cell lymphoma and myeloid leukemia in mice. Recently, we and other groups reported that c-CBL is mutated in myeloid neoplasms, especially in myelodysplastic/myeloproliferative neoplasms with acquired 11q-UPD (uniparental disomy). C-CBL is thought to be involved in the negative modulation of tyrosine kinase signaling, primarily through ubiquitin-mediated down-regulation of activated tyrosine kinases, depending on its E3 ubiquitin ligase activity. According to this functionality, C-CBL could act as a tumor suppressor, which is also supported by the fact that C-CBL null mice developed spontaneous cancers in complete penetrance. On the other hand, when transduced into NIH3T3 fibroblasts, tumor-derived C-CBL mutants thus far tested showed clear oncogenic potentials in terms of anchorage-independent growth in soft agar and tumor formation in nude mice. So to clarify the molecular mechanisms of mutant C-CBL-induced oncogenicity, we further characterized behavior of various mutants of tumor-derived C-CBL proteins. As previously reported, tumor-derived C-CBL mutants not only have defective E3 ubiquitin ligase activity but also inhibits that of wild-type C-CBL, leading to prolonged activation of receptor tyrosine kinases after ligand stimulations. C-CBL mutants that lacked their C-terminal ubiquitin associated/leucine zipper (UBA/LZ) domain were no more able to be dimerized but still showed transforming activity in NIH3T3 cells. While all tumor-derived C-CBL mutants were strongly phosphorylated, these UBA/LZ domain-deleted mutants remained to be unphosphorylated. Thus, neither dimerization nor phosphorylation seemed to be required for transforming capacity. On the other hand, when introduced a mutation that abolishes their binding to phosphorylated tyrosine kinases, these tumor-derived C-CBL mutants were no more transform NIH3T3 cells, suggesting that binding to phosphorylated tyrosine kinases are essential for their transforming capacity. Finally tumor-derived C-CBL mutants were introduced with additional mutations at tyrosine residues, Y700, 731 and 774, which are the major tyrosine phosphorylation sites in wild-type C-CBL, and were examined their effects on transforming capacity. The tumor-derived C-CBL mutants having Y700F/Y731F/Y774F still retained transforming potentials in NIH3T3 cells, although the transformation of NIH3T3 cells with

these mutants seemed to be weaker. Thus, C-terminal domains are not essential for oncogenic capacity of tumor-derived C-CBL mutants. Our results indicated that oncogenic potential of tumor-derived C-CBL mutants seemed to primarily depend on defective E3 ubiquitin ligase activity, while the impact of C-CBL's functions as a signal transducer on the transforming potentials of tumor-derived C-CBL mutants are unremarkable and could be dispensable.

TELOMERE LOSS IN PH - NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS: THE ROLE OF JAK2 V617F MUTATION ALLELE BURDEN AND THE INFLUENCE OF THE HISTORY OF THE ILLNESS

M Ruella,[1] S Salmoiraghi,[2] A Risso,[1] A Carobbio,[2] P Sivera,[3] M Mezzabotta,[3] I Ricca,[4] T Barbui,[2] C Tarella,[3] A Rambaldi[2]

[1]University of Torino, Torino, Italy; [2]Ospedali Riuniti di Bergamo, Bergamo, Italy; [3]Ematologia e Terapia Cellulari, ASO Mauriziano, Torino, Italy; [4]Medicina Interna, AO Cottolengo, Torino, Italy

Telomeres are reliable indicators of previous cell proliferation and cell ageing. A loss of telomere length (TL) has been observed in patients with Ph-negative Chronic Myeloproliferative Neoplasms (Ph-neg-CMNs) (Ferraris AM et al, Br J Haematol 2005; Bernard L et al, Leukemia 2009). This supports the possible influence of TL in the development of chronic myeloid disorders. Moreover, TL might be of prognostic relevance in these disorders. *Methods.*Peripheral blood (PB) samples were obtained from 115 Ph-neg-CMNs patients (median age 64 yrs, range 10-89): 60 had PV and 55 ET. JAK2^{V617F} mutation was present in 53 of 55 (96%) evaluable PV patients and in 29 (53%) ET patients. Sixty-five patients had been exposed for at least one year to various treatments, 61 received hydroxyurea. Forty-seven patients had never been exposed to cytotoxic drugs. Samples were obtained either at diagnosis or during follow-up. As a control, PB samples from 104 healthy age-matched subjects (median: 61 yrs, range 49-102) were analyzed as well. TL was assessed by Southern blot analysis. JAK2^{V617F} mutation was detected by ASO-PCR and digestion with BSAXI. *Results.*PV and ET patients showed individual progressive TL shortening correlated with age as observed in the healthy population. However, PV-ET patients had TL significantly shortened (6,000 bp, range: 3090-9770) compared to healthy age-matched individuals (median: 7,086 bp, range: 4926 - 10974) (Figure 1).

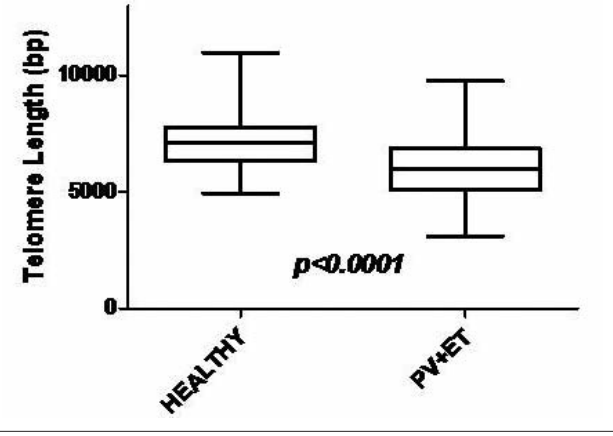

Figure 1. Comparison of TL among age-matched groups of healthy subjects, polycythemia vera patients, and essential trombocytopenia.

The most pronounced TL loss was detected in PV, with TL values significantly shorter (median TL: 5,405 bp, range: 3090 - 9570) compared to ET (median TL: 6,540 bp, range: 4,170-9,770) (P=0.0012). At univariate analysis, short TL correlated significantly with JAK2^{V617F} mutation allele burden >50% (P=0.0003). In multivariate logistic regression analysis, PV diagnosis and JAK2^{V617F} omozigosity remained independently associated with TL reduction. On the other hand, we were unable to detect any correlation between TL reductions and other clinical parameters, including sex and thrombotic complications. Disease duration had a clear impact on telomere loss, with significant differences in TL between patients with short disease duration (6,310 bp, range 3,360-9,770) compared to age-matched patients at >32 mos. since diagnosis (5,460 bp, range 3,090-9,570) (Figure 2). Accordingly, the chronic exposure to cytotoxic drugs, especially to HU, was associated with TL loss (5,941 bp range: 3,880-7,950) compared to age-matched untreated patients (6,560 bp, range: 3,430-9,570) (P=0,03). *Conclusions.* i.ET and PV are confirmed to present with TL reduction compared to the age-matched healthy population; ii.also high JAK2^{V617F} mutation burden was strongly correlated to TL loss; iii.PV has markedly shorter TL compared to ET and this likely reflects the differences in JAK2^{V617F} mutation burden between these two disorders; iv.the duration of the disease along with the need of cytotoxic treatments produce accelerated TL erosion.Although the role of the natural history of Ph-neg-CMNs may play an important role on TL shortening, the results emphasize the need of cautious use of cytotoxic drugs and raise concern about their prolonged use. Further studies are warranted to identify drugs targeting the mutated JAK2^{V617F} gene or other effective agents with reduced toxicity and low induction to cell senescence.

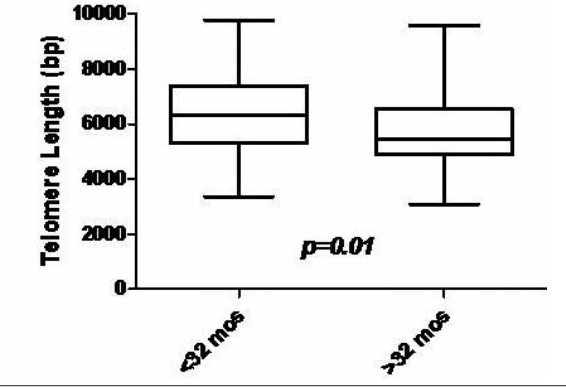

Figure 2. Differences in TL in PV-ET patients according disease duration.

0404

IDENTIFICATION OF ONCOSTATIN M AS A STAT5-DEPENDENT MEDIATOR OF BONE MARROW REMODELING IN KIT D816V-POSITIVE SYSTEMIC MASTOCYTOSIS

G Hoermann,[1] S Cerny-Reiterer,[2] A Perne,[1] L Müllauer,[3] P Valent,[2] M Mayerhofer[1]

[1]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria; [2]Medical University of Vienna, Department of Internal Medicine I, Vienna, Austria; [3]Medical University of Vienna, Department of Pathology, Vienna, Austria

Background. Systemic mastocytosis (SM) is a neoplastic disease of mast cells (MC) and their bone marrow-derived progenitors. The clinical picture in SM is variable ranging from an indolent course to highly aggressive variants with short survival. The pathologic hallmark in SM is the multifocal dense infiltrate of neoplastic MC in the bone marrow. Moreover, marked alterations of the marrow microenvironment are noticed in most patients. These include increased angiogenesis, osteosclerosis and sometimes massive fibrosis. In a majority of patients, MC display the KIT mutation D816V which leads to ligand-independent signaling of the KIT receptor. However, so far, little is known about KIT D816V-dependent expression of molecules in neoplastic MC and their role in the pathogenesis of mastocytosis. Oncostatin M (OSM) is a pleiotropic cytokine belonging to the interleukin-6 family that can elicit different biological effects depending on the disease and target cell type. OSM has been shown to act as a growth factor for mesenchymal cells including endothelial cells, fibroblasts, and osteoblasts and has recently been implicated in the generation and maintenance of a proper microenvironment in hematopoietic tissues. *Aims.* In the current study we examined expression and potential role of OSM in neoplastic mast cells. *Methods.* Expression of OSM in the bone marrow of patients with SM was determined by immunohistochemistry. To investigate the role of KIT in expression of OSM, Ba/F3 cells with doxycycline-inducible expression of wild type KIT or KIT D816V as well as the HMC-1 mast cell line were used. *Results.* As assessed by immunohistochemistry performed on bone marrow sections of patients with SM (n=18), typical spindle-shaped neoplastic MC were found to express OSM. Serial section-staining confirmed that tryptase-positive MC co-express OSM. In Ba/F3 cells, doxycycline-inducible expression of KIT D816V led to a substantial upregulation of OSM mRNA and OSM protein, whereas expression of wild type KIT did not affect expression of OSM. In addition, the KIT D816V-positive mast cell line HMC-1 was found to express OSM at high levels, whereas a KIT D816V-negative

HMC-1 subclone expressed only baseline levels of OSM. Correspondingly, the KIT D816V-targeting drug midostaurin as well as RNAi knockdown of KIT expression decreased expression of OSM. Knockdown of STAT5 expression in HMC-1 and KIT D816V-expressing Ba/F3 cells was found to substantially reduce expression of OSM whereas expression of a constitutively activated STAT5 mutant upregulated the expression of OSM. To investigate the effect of MC-derived OSM on cells of the bone marrow microenvironment, human microvascular endothelial cells, human immortalized osteoblasts, and primary human bone marrow fibroblasts were incubated with cell culture supernatants from HMC-1 cells. As assessed by 3H-thymidine incorporation assay, supernatants from KIT D816V-positive HMC-1 cells were found to stimulate growth of these cells. This growth stimulatory effect was inhibited by preincubation of supernatants with a neutralizing anti-OSM antibody. *Conclusion*. Together, our data show that neoplastic mast cells express OSM in a KIT D816V- and STAT5-dependent manner. MC-derived OSM stimulates growth of mesenchymal cells potentially involved in angiogenesis, fibrosis, and osteosclerosis in the bone marrow. Thus, OSM could represent a novel key molecule and potential target in the pathogenesis of systemic mastocytosis.

DOWNSTREAM EFFECTORS OF FIP1L1-PDGFRA AS TARGETS FOR THERAPY IN CHRONIC EOSINOPHILIC LEUKEMIA

E Lierman,[1] R Snoeckx,[2] E Stover,[3] N Berghen,[2] P Bulens,[2] P Erben,[4] A Reiter,[4] P Vandenberghe,[1] J Cools[2]

[1]Center for Human Genetics, K.U.Leuven, Leuven, Belgium; [2]Department of Molecular and Developmental Genetics, VIB, Leuven, Belgium; [3]Division of Hematology, Department of Medicine, Harvard Medical School, Boston, USA; [4]Medizinische Universitätsklinik, Universität Heidelberg, Heidelberg, Germany

Background. Chronic eosinophilic leukemia (CEL) is a rare hematological malignancy characterized by overproduction of eosinophils and is frequently caused by the FIP1L1-PDGFRA fusion gene. The small molecule tyrosine kinase inhibitor (TKI) imatinib is very active against FIP1L1-PDGFRα positive CEL, but the development of resistance, therapy related side effects and required lifelong treatment encourage the development of additional therapeutic approaches. *Objectives.* This study aimed at the identification of specific downstream effectors of FIP1L1-PDGFRα that could potentially be used as additional therapeutic targets and/or diagnostic markers in CEL. *Methods.* Gene expression patterns of untreated and TKI treated human FIP1L1-PDGFRα positive EOL-1 cells were compared. The importance of the identified genes for the proliferation and survival of EOL-1 cells was further explored using RNAi technology and specific inhibitors. In addition; their expression was examined in CEL patients. *Results.* We found 51 genes to be differentially expressed in EOL-1 cells upon treatment with both imatinib and sorafenib. Fourteen significantly up- or downregulated genes were selected and we could demonstrate a modulation of their expression by BCR-ABL1 and FLT3 kinase activity to a similar extent as in the context of FIP1L1-PDGFRα. One of these genes is CCL2 which was 100-fold upregulated downstream of FIP1L1-PDGFRα. CCL2 is a member of the CCβ subfamily of chemotactic cytokines and has a known role in cancer cell proliferation. siRNA mediated knock down of CCL2 expression as well as treatment with an anti-CCL2 neutralizing antibody significantly decreased EOL-1 cell proliferation. This antiproliferative effect on EOL-1 cells was further increased when CCL2 knock down was combined with a low nanomolar dose of imatinib. Addition of CCL2 to the culture medium abolished the siRNA mediated inhibitory effect, indicating that CCL2 production induced by FIP1L1-PDGFRα acts through an autocrine loop. Because CCL2 selectively binds to a G-coupled protein receptor CCR2, we investigated the role of CCR2 in EOL-1 cell proliferation. Blocking of the CCL2 receptor using siRNA technology or a CCR2 antagonist also inhibited EOL-1 cell growth, further demonstrating the role of CCL2 in EOL-1 cell proliferation. In PDGF stimulated NIH3T3 cells, we could confirm that CCL2 is a downstream target of PDGFRα. FIP1L1-PDGFRα positive CEL patients showed a slightly elevated CCL2 expression level compared to FIP1L1-PDGFRα negative hypereosinophilia patients. Follow up of one CEL patient documented highly increased CCL2 and CCR2 levels at time of progression towards an acute eosinophilic leukemia. *Conclusions.* Our results indicate that CCL2 production in EOL-1 cells is upregulated by FIP1L1-PDGFRα kinase activity and that CCL2 stimulates the proliferation of EOL-1 in an autocrine way. As such, CCL2 may represent a novel target for therapy in FIP1L1-PDGFRα positive CEL. Currently several CCL2 targeting compounds are already being tested for solid tumors. Further research is currently ongoing to elucidate the pathway employed by CCL2 and its receptor CCR2 to stimulate EOL-1 cell proliferation and to better characterize its function in FIP1L1-PDGFRα positive disease.

0406

FIP1L1-PDGFRA CAN CAUSE BOTH MYELOPROLIFERATIVE AND LYMPHOPROLIFERATIVE DISEASE IN MOUSE BONE MARROW TRANSPLANT MODELS

R Snoeckx, K Jacobs, J Cools

Center for Human Genetics, University of Leuven, Leuven, Belgium

Background. FIP1L1-PDGFRA is a fusion tyrosine kinase that causes chronic eosinophilic leukemia (CEL), a myeloproliferative disease that mainly affects the esoinophil lineage in humans. In mice, FIP1L1-PDGFRA has been described to lead to a myeloproliferative disease with a dramatic expansion of granulocytes ($Gr1^+/Mac1^+$). Eosinophilia was also observed in mouse models of FIP1L1-PDGFRA induced disease when FIP1L1-PDGFRA expression was combined with IL5 expression. Although FIP1L1-PDGFRA predominantly is found in patients with CEL, it has also been detected in a subset of patients with lymphoblastic T-cell lymphoma. *Aims.* We have set up mouse bone marrow transplant models to determine if FIP1L1-PDGFRA can also induce a lymphoproliferative malignancies in mice. *Methods.* Lineage depleted (Lin^-) bone marrow cells were transduced with retroviral vectors containing the FIP1L1-PDGFRA gene and a GFP reporter gene. These cells were transplanted into sublethally irradiated mice (10^6 cells/mouse). *Results.* Three weeks after transplantation, most mice developed leukocytosis mostly consisting of GFP^+ granulocytes. Despite the elevated blood counts, most animals survived and five weeks after transplantation most of the GFP^+ granulocytes had disappeared. Eleven weeks after transplantation mice developed enlarged lymph nodes, with a slightly increased GFP^+ cell population in their blood (<20%). In contrast with the earlier detected GFP^+ granulocytes, this GFP^+ population was of the lymphoid lineage. The enlarged lymph nodes contained >80% GFP^+ $CD4^+/CD8^+$ or a combination of $CD4^+/CD8^+$ and $CD4^-/CD8^+$ T-cells. In addition to the lymphomas, some animals developed splenomegaly and a lymphoproliferative phenotype with an increase of GFP^+ cells in blood and bone marrow. The GFP^+ (FIP1L1-PDGFRA+) T-cells were sensitive to sorafenib, a kinase inhibitor shown to inhibit FIP1L1-PDGFRA kinase activity, illustrating that these cells were dependent on FIP1L1-PDGFRA kinase activity for their proliferation and survival. *Conclusions.* We have shown that mice transplanted with FIP1L1-PDGFRA transduced Lin- cells can develop both myeloproliferative disease and T-cell lymphomas.

JAK2V617F ALLELE BURDEN IS ASSOCIATED WITH APOPTOSIS-RELATED GENES EXPRESSION IN ESSENTIAL THROMBOCYTHEMIA

R Tognon,[1] E Gasparotto,[1] R Neves,[1] S Kashima,[2] D Covas,[2] P Palma,[2] M Santana,[3] E Souto,[3] MA Zanichelli,[3] C Velano,[4] B Simões,[4] AM Souza,[1] F Castro[1]

[1]Faculdade de Ciências Farmacêuticas de Ribeirão Preto/University of São Paulo, Ribeirão Preto, Brazil; [2]Centro Regional de Hemoterapia de Ribeirão Preto do HCFMRP-USP, Ribeirão Preto, Brazil; [3]Hospital Brigadeiro, São Paulo, Brazil; [4]Departamento de Clínica Médica, Faculdade de Medicina de Ribeirão Preto - USP, Ribeirão Preto, Brazil

Background. Essential Thrombocythemia (ET) is a Chronic Myeloproliferative Disorder (MPD) characterized by an increase in the platelet count associated with bone marrow megakaryocyte hyperplasia. The JAK2V617F mutation is present only in 50-60% of ET patients. Therefore, the physiopathology of this disease remains unknown. It seems that apoptotic machinery deregulation contribute to ET pathogenesis. *Aims.* To determine the apoptosis-related genes expression: the anti-apoptotic a1, mcl-1, bcl-2, bcl-xL and bcl-w and the pro-apoptotic bax, bid, bik, bok, and bimEL in $CD34^+$ hematopoietic stem cells (HSC) and leukocytes from ET patient and to correlated these data with JAK2V617F allele burden. Subjects and *Methods.* We evaluated 53 controls (23 males and 30 females; mean age of 45.2 years) and 26 ET patients (5 males and 21 females; ma=60.2y). The JAK2V617F allele burden was determined by real time allelic discrimination PCR assay. Bone marrow $CD34^+$ HSC were separated using Ficoll-Hypaque protocol followed by Miltenyi CD34 isolation kit and peripheral leukocytes was obtained by Haes-Steril method. Total RNA from CD34+ HSC and leukocytes was extracted according to TrizolTM method, High Capac-

ityTM Kit was used to synthesize cDNA and apoptotic-related genes were quantified by real time PCR. The gene expression results were given as 2-ΔΔCt and statistical analyses were performed by Mann-Whitney and Spearman tests. *Results.* In CD34+ HSC, anti-apoptotic a1 and pro-apoptotic bid, bik, and bok mRNA levels were increased in ET patients (median=32.11, 4.10, 2.20 and 58.33, respectively) in comparison to controls (0.71, 1.61, 1.99, 0.73, respectively) (P<0.0001, P=0.0191, P=0.0298, P=0.0005, respectively) while pro-apoptotic bax level was found lower (0.22) than in controls (5.68) (P=0.0231). Only a1 gene expression was found elevated in ET patients´ leukocytes (14.73) compared to control group (1.93) (P=0.0015). We also found in leukocytes from ET JAK2V617F positive patients a higher bcl-2 expression (4.23) and a lower bik expression (0.71) in comparison to JAK2 negative patients (0.66, 3.23, respectively) (P=0.0388 and P=0.0274, respectively). In addition, bik expression negatively correlated with JAK2V617F allele burden (r=-0.4017; P=0.0210) in ET. *Conclusions.* CD34+ HSC and Leukocytes from ET patients present a deregulation in Bcl-2 family members´ expression. JAK2V617F mutation status and allele burden are linked to apoptosis-related gene expression. We could speculate that the alterations may contribute to ET pathogenesis. Supported by FAPESP (06/50094-8 and 08/54387-5).

A HIGHLY SENSITIVE, RAPID AND NON-PCR BASED METHOD FOR THE DETECTION OF THE JAK2V617F MUTATION IN CHRONIC MYELOPROLIFERATIVE NEOPLASMS

G Minnucci,[1] G Amicarelli,[2] S Salmoiraghi,[3] O Spinelli,[3] ML Guinea Montalvo,[3] D Adlerstein,[2] A Rambaldi[3]

[1]*Università degli Studi di Milano Bicocca, Milano, Italy;* [2]*Diasorin S.p.A, Nerviano Milano, Italy;* [3]*Ospedali Riuniti di Bergamo, Hematology Unit, Bergamo, Italy*

Background. The JAK2V617F mutation occurs at high frequency in several Ph-negative chronic myeloproliferative neoplasms (Ph-neg-CMNs), such as Polycythemia Vera (PV), Essential Thrombocythemia (ET) and Myelofibrosis (MF). The molecular analysis of this mutation is mandatory in the diagnostic work up of these diseases. *Aims.* Aim of the study is to develop a non-PCR method, based on Allele Specific-Loop mediated isothermal AMPlification (AS-LAMP), for the identification of the JAK2V617F mutation. *Methods.* We have developed a LAMP reaction which efficiently produces a large amount of amplified DNA which is both visible to the naked-eye and monitorable in Real-Time turbidimetry thanks to pyrophosphate salts produced as a result of the DNA amplification process. To ensure selectivity a Peptide Nucleic Acid (PNA) probe specific for the wild-type allele was added thus resulting in absence of normal allele amplification within the reaction time (60 minutes). The AS-LAMP assay was optimized on plasmid controls and by serial dilutions (down to 0.01%) of genomic DNA from a JAK2V617F mutated (HEL) into a JAK2 wild type (K562) cell line. *Results.* We have validated this AS-LAMP assay on DNA obtained from 105 patient samples previously analyzed by conventional Allele Specific PCR (ASO-PCR): 37 PV, 58 TE, 3 IMF, 1 post ET Acute Myeloid Leukemia (AML), 1 post PV and 1 post ET Myelofibrosis, 2 Idiopathic Erythrocytosis (IE) and 2 unclassified CMNs. All samples found positive by ASO-PCR proved also positive when tested by our AS-LAMP assay (100% concordance). When mutant DNA is present in the range of 0.1-100% in wild type DNA, we observed a linear relationship between the mutant allele burden and the amplification time. Accordingly, this assay allows the definition of an allele burden <50% or >50% ("hetero' or 'homozygosity"respectively) and selectively detects the JAK2V617F mutated DNA down to 0.05%. A comparative evaluation with commercial or published quantitative tests is ongoing and will be presented at the meeting. In addition, 6 ET and 1 IE previously found negative by ASO-PCR were found to be low-positive (≤1%) with AS-LAMP and this positivity was confirmed by sequencing analysis after PCR in presence of PNA. None of the negative controls, (1 AML, 2 Acute Lymphoblastic Leukemia, 2 Follicular Non Hodgkin's Lymphoma and 2 Chronic Lymphocytic Leukemia) gave false positive *Results.* We also tested a total of 73 DNA samples from granulocytes obtained from healthy donors: none of them proved positive for JAK2V617F. *Conclusions.* This novel non-PCR based allele-specific LAMP assay is rapid, easy to perform with limited and simple laboratory equipment. It is highly specific, sensitive and significantly increases our ability to detect a low JAK2V617F tumor allele burden. Finally, the assay allows estimation of hetero or homozigosity of the sample. For all these reasons, the AS-LAMP assay can be a valid and powerful tool in the routine molecular monitoring of these diseases.

INCREASED DKK3 PROTEIN EXPRESSION ON PLATELETS AND MEGAKARYOCYTES IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

M Medinger,[1] A Tzankov,[2] J Kern,[1] A Pircher,[1] H Ott,[3] M Hermann,[4] G Gastl,[5] G Untergasser,[1] E Gunsilius[1]

[1]*Laboratory for Tumor Biology & Angiogenesis, Innsbruck, Austria;* [2]*Institute of Pathology, University Hospital, Basel, Switzerland;* [3]*Institute of Medical and Chemical Laboratory Diagnostics (ZIMCL), Innsbruck, Austria;* [4]*KMT Laboratory, Medical University, Innsbruck, Austria;* [5]*Hematology and Oncology, Medical University, Innsbruck, Austria*

Background. Dickkopf-3 (Dkk3), a secreted member of the dickkopf protein family, has been proposed as a tumor suppressor gene and a new specific marker for tumor endothelial cells. *Aims.* Here we analyzed the expression and function of Dkk3 in platelets and megakaryocytes from healthy controls and patients with BCR-ABL1-negative myeloproliferative neoplasms (MPN). *Methods.* Dkk3 protein and gene expression in platelets was compared to endothelial and blood cell populations by ELISA, real time PCR and immunofluorescence. Moreover, megakaryocytes were isolated from bone marrow aspirates by CD61 microbeads. *Results.* Immunohistochemical studies of Dkk3 expression were performed in 30 MPN, including 10 essential thrombocythemia- (ET), 10 polycythemia vera- (PV), 10 primary myelofibrosis- (PMF), and 10 control reactive bone marrow cases. Highest amounts of Dkk3 protein were found in platelets (150±19 pg/µg total protein) compared to HUVEC (110+8 pg/µg), PBMNC (42+8.4 pg/µg), and CD14+ (15+10 pg/µg), CD8+ (4.2+2.6 pg/µg), CD4+ (3.4+2.7 pg/µg), CD19+ (6.0+8.0 pg/µg) microbead-selected cells whereas Dkk3 in CD15+ and CD235a+ (erythrocytes) cells was not detectable (Figure 1). Moreover, isolated megakaryocytes showed a strong Dkk3 gene and protein expression. By immunofluorescence, Dkk3 co-localized with VEGF in alpha granules of platelets and was released like VEGF upon stimulation with arachidonic acid, TRAP-6 (thrombin receptor activator for peptide 6) and ADP (Adenosine diphosphate). The addition of 100-10000 ng/mL recombinant Dkk3 to whole blood and platelet-rich plasma had no influence on coagulation (APTT, PT, TT) and platelet aggregation. In patients with MPN, we found significantly more Dkk3 positive megakaryocytes than in controls (ET>PV>PMF; 40+10 Dkk3-positive megakaryocytes/mm^2; 31+4; 22 + 3, respectively) compared to control cases (15+3 Dkk3-positive megakaryocytes/mm^2). In control bone marrow sections a weak Dkk3 staining of erythropoietic precursors could be shown. *Conclusions.* Based on our results we conclude that Dkk3 might play a role in the pathogenesis of MPN and plateled-derived Dkk3 released upon stimulation/aggregation like VEGF might affect blood vessel function or maturation.

COMBINED MODALITY TREATMENT WITH INTENSIFIED CHEMOTHERAPY AND DOSE-REDUCED INVOLVED FIELD RADIOTHERAPY IN PATIENTS WITH EARLY UNFAVOURABLE HODGKIN LYMPHOMA (HL): FINAL ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP (GHSG) HD11 TRIAL

A Engert,[1] P Borchmann,[2] V Diehl,[3] H Goergen,[3] H Mueller,[3] R Mueller,[1] H Eich,[1] H Mueller-Hermelink,[4] R Herrmann,[5] J Markova,[6] A Ho,[7] W Hiddemann,[8] B Doerken,[9] R Greil[10]

[1]University Hospital Cologne, Cologne, Germany; [2]University Hospital of Cologne, Cologne, Germany; [3]GHSG, University Hospital of Cologne, Cologne, Germany; [4]Dept. of Pathology, University of Wuerzburg, Wuerzburg, Germany; [5]Kantonsspital Basel, Basel, Switzerland; [6]University Hospital of Prague, Prague, Czech Republic; [7]Medical Clinic V, University of Heidelberg, Heidelberg, Germany; [8]Medical Clinic III, University Hospital Groβhadern, Munich, Germany; [9]University Hospital Berlin Charite, Berlin, Germany; [10]University of Salzburg, Salzburg, Austria

Purpose. Combined modality treatment consisting of 4 cycles of chemotherapy (CT) followed by involved field radiotherapy (IF-RT) is the standard treatment for early unfavourable HL. In our prior trial for this group of patients (HD8), overall survival (OS) and freedom from treatment failure (FFTF) at 5 years were 91% and 83%, respectively. The HD11 trial thus addressed two major questions: (1) improving outcome by intensifying CT (4xABVD vs. 4xBEACOPPbaseline; Bbas) and (2) defining the best radiation dose (30Gy vs. 20Gy IF-RT). *Patients and Methods.* Between May 1998 and January 2003, 1395 eligible patients aged 16-75 years with untreated early unfavourable stage HL (CS I, IIA with at least one of the risk factors large mediastinal mass (a), extranodal disease (b), elevated ESR (c) or ≥ 3 nodal areas (d); IIB with risk factors c and/or d) were randomized into one of the following 4 treatment arms: 4xABVD + 30Gy (A), 4xABVD + 20Gy (B), 4x Bbas + 30Gy (C) or 4x Bbas + 20Gy (D). Since there are strong indications for an interaction between CT- and RT-doses, a comparison of pooled treatment arms (A+B vs. C+D for comparison of 4xABVD vs. 4x Bbas and A+C vs. B+D for comparison of 30Gy IF-RT vs. 20Gy IF-RT) would be misleading. Therefore all treatment arms were analysed separately. *Results.* Patient characteristics were well balanced between the 4 arms (median age 33 years, 49% male, 6% stage I, 29% B-symptoms). CT- and RT-related acute toxicity occurred significantly more often in the arms with the more intensive therapy (CT: 74.1% vs. 51.8%; RT: 12.3% vs. 5.5%). The complete remission rate 3 months after end of therapy was 94.1% for the whole group and did not differ significantly between the 4 arms. The 5-year estimate of FFTF (primary endpoint) is 85.0% (OS 94.5%, PFS 86.0%). Bbas is more effective than ABVD if followed by 20Gy IF-RT (5y-FFTF difference 5.7%, 95%-CI [0.1%; 11.3%]). This effect does not exist in combination with 30Gy IF-RT (5y-FFTF difference 1.6% [-3.6%; 6.9%]). Similar results are observed for the RT-question: After 4 cycles of Bbas, 20Gy is not inferior to 30Gy (5y-FFTF difference -0.1%, 95%-CI [-5.1%; 4.9%]), whereas after 4xABVD, a relevant inferiority of 20Gy cannot be excluded (-4.0% [-9.5%; 1.4%]). *Conclusions.* A reduction of RT dose from 30Gy to 20Gy IF-RT seems to be justified only in combination with Bbas, but not with a less effective chemotherapy such as 4xABVD. Patients will benefit from an intensified CT such as Bbas only in combination with 20Gy IF-RT but not with 30Gy IF-RT.

EZH2 MUTATION IN FOLLICULAR LYMPHOMA

C O' Riain,[1] P Smith,[1] A Clear,[1] D Wrench,[1] M Gupta,[1] C Bödör,[1] A Matolcsy,[2] M Calaminici,[1] H Quentmeier,[3] H Drexler,[4] B Young,[1] J Gribben,[1] A Lister,[1] J Fitzgibbon[1]

[1]Institute of Cancer, Barts and The London School of Medicine and Dentistry, London, UK; [2]Semmelweis University,[1]st Department of Pathology and Experimental Cancer Resear, Budapest, Hungary; [3]DSMZ-Deutsche Sammlung von Mikroorganismen, und Zellkulturen GmbH, Braunschweig, Germany; [4]DSMZ-Deutsche Sammlung von Mikroorganismen, und Zellkulturen GmbH, Braunschweig, Germany

Background. Recent evidence suggests that epigenetic mechanisms are of particular importance in germinal centre B lymphomas such as Follicular Lymphoma (FL). Aberrant DNA hypermethylation occurs at 8% of promoters and is more frequent than in non-GC related lymphomas. These hypermethylated loci are enriched for stem cell targets of the EZH2, responsible for transcriptional repression via trimethylation of lysine 27 on histone H3 (H3K27me3). EZH2 has been previously linked with direct control of DNA methylation. Furthermore EZH2 has a putative role, not just in gene repression through control of global DNA and Histone methylation, but also in immunoglobulin gene rearrangement in B cell development. Mutations in the catalytic SET domain of *EZH2* were recently shown by Morin and colleagues to occur in 7% of FL suggesting that attenuated H3K27me3 repression may be an important feature of these tumours. *Aims.* In order to assess the effects of EZH2 on FL transformation (t-FL), we compared *EZH2* mutation with EZH2 and H3K27me3 expression and global methylation status in a series of 20 paired FL and t-FL cases. *Results.* DNA from these 40 samples was tested for the presence of mutation at Y641 by genomic PCR-direct sequencing. Heterozygous mutations were detected in 7 of the 20 patients (35%). Four different point mutations were identified leading to conversion of Y to either F, H, N or S. Germline controls for 4 patients all demonstrated wild-type sequence. A mutation was present in both the FL and t-FL samples of 5 patients, was restricted to the t-FL biopsy in one patient and occurred in only the FL sample of the final affected case. *EZH2* mutation at Y641 was confirmed in the DB, Karpas-422, Su-DHL-6 and WSU-DLCL2 cell lines and was identified for the first time in a further 3 lines RL, Su-DHL-4 and Su-DHL-10. Since EZH2 and DNA methyltransferases have been shown to physically interact we also compared methylation data generated using the Illumina Goldengate platform in 10 FL-tFL pairs and showed no discernible difference in DNA-methylation status between mutated and wildtype cases. EZH2 expression was also assessed by immunohistochemical tissue microarray analysis and showed no difference between wildtype and mutated cases. This was in contrast to H3K27Me3 staining which showed a heterogeneous staining pattern with some mutated cases showing a loss or reduction of expression. Summary: *EZH2* mutation is a frequent mutational event in FL-tFL (35%) and can lead to loss or reduced H3K27me3 expression. The lack of a discernible difference in DNA-methylation patterns between patients with and without mutation and the wide variation in immunohistochemical expression of H3K27me3 in FL/t-FL suggests that EZH2 mutation may exert a greater effect through altering H3K27me3 repression than through widespread alterations in global DNA methylation.

0412

IMPROVEMENT IN LIVER FUNCTION FOLLOWING ECULIZUMAB TREATMENT AVERTS NEED FOR LIVER TRANSPLANT IN A PATIENT WITH PNH AND PROGRESSIVE BUDD-CHIARI SYNDROME

A Brodsky,[1] O Mazzocchi,[1] M Volpacchio,[1] R Ventimiglia,[2] G Khursigara[2]

[1]Hospital de Clínicas José de San Martín, Buenos Aires, Argentina; [2]Alexion Pharmaceuticals, Cheshire, USA

Background. PNH is a life-threatening progressive disease that results in chronic complement-mediated hemolysis of RBCs and hyperactivation and aggregation of platelet cells. Thromboembolism (TE) accounts for 40 - 60% of deaths among PNH patients and leads to life-threatening complications including impaired hepatic function. Uncommon venous thromboses such as Budd-Chiari syndrome (BCS) and cerebral vein thrombosis (CVT) are frequent findings in PNH patients. Eculizumab inhibits chronic hemolysis and has been demonstrated to improve morbidities and to reduce the risk of thrombosis in PNH patients. *Aims.* We evaluated the response to eculizumab treatment in a 25-year-old male with PNH experiencing multiple episodes of TE, progressive BCS, and declining liver function leading to the consideration of transplantation. *History*. The patient was admitted in June 2005 with abdominal pain and distension. CT scan showed splenomegaly and liver with mottled appearance. Paracentesis recovered 2500 mL of citrinous liquid. MRI revealed BCS and thrombosis of the superior sagittal and left transverse cerebral venous sinus. Peripheral blood flow cytometry confirmed the PNH diagnosis. Despite adequate anticoagulation, the patient experienced two episodes of symptomatic suprahepatic thrombosis. BCS progressed, requiring placement of a porto-systemic shunt (TIPS) and splenic embolization to treat severe refractory thrombocytopenia. The patient experienced two TIPS thromboses, progressive liver damage, and 2 episodes of symptomatic pulmonary embolisms, despite receiving adequate anticoagulation. Given progressive deterioration of hepatic function, liver transplantation was considered. Eculizumab was initiated in January 2009 at the approved dosing regime: 600 mg every 7 days for 4 weeks, and 900 mg every 14 days from 5th week onwards.

Results. During eculizumab treatment, intravascular hemolysis (measured by LDH) decreased from an average of 2.9-fold above normal 1-2 months before eculizumab treatment to normal levels and has been maintained for one year. Platelets increased within one week of treatment and this increase has been sustained over 12 months, consistent with improvement in thromboses and hence reduction in platelet consumption. More importantly, hepatic function noticeably improved: elevated transaminases ALT and AST levels were reduced within 1 week of treatment and albumin and CHE concentrations improved to values well within the normal range, averting need for liver transplant. Portal hypertension was reduced, verified by progressive increase in the interval between paracentesis, with no additional paracenteses after 7.5 months of eculizumab treatment. No new thrombotic episodes took place during one year of treatment. Fatigue resolved completely, in spite of minimum change in anemia, allowing the patient to resume a near normal work and social life. Eculizumab has been well tolerated without adverse events. *Conclusions.* This is the first demonstration of improvement in LFT in a patient with PNH with BCS. Sustained blockade of chronic complement-mediated hemolysis with eculizumab reverted progressive systemic and hepatic venous thrombosis allowed recovery from hepatic dysfunction and thus averted the need for liver transplant, and drastically improved quality of life. These results provide solid evidence that eculizumab is the treatment of choice in patients with PNH and BCS unresponsive to anticoagulation.

Table.

Lab Value (normal range)	Days Pre-Eculizumab		Day of First Dose	Days Post-Eculizumab							
	68	33	0	7	56	112	197	239	295	323	365

PIM SERINE/THREONINE KINASES AS POTENTIAL THERAPEUTIC TARGETS IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL)

L Brault,[1] T Menter,[2] E Obermann,[2] S Thommen,[1] A Tzankov,[2] J Schwaller[3]

[1]University Hospital basel, Basel, Switzerland; [2]Institute of Pathology University Hospital Basel Schoenbeinstr. 40, Basel, Switzerland; [3]University Hospital Basel, Basel, Switzerland

Background. PIM1-3 represent a family of constitutive active serine/threonine kinases regulating cellular proliferation and survival that have been reported to be over-expressed in several human cancers. Their proto-oncogenic role has been demonstrated in several experimental lymphoma models but never systematically analyzed in primary lymphoma biopsies. *Methods.* We have studied expression of PIM1-3 by immunohistochemistry in a large cohort of well-characterized diffuse-large B-cell lymphoma (DLBCL) cases (n=101, stages I-IV, GC-DLBCL=42 as defined by the Hans algorithm), using tissue microarrays. Functional studies were performed in a panel cell lines derived from GC-type and ABC-type human DLBCLs applying previously characterized small molecule PIM inhibitors. *Results.* Whereas in most (91%) cases cytoplasmic expression of PIM1 was observed, only 12 cases showed also nuclear PIM1 staining in >50% of the tumor cells. In contrast to PIM1, we found only modest levels of PIM2 and PIM3 (>10% of the tumor cells) in most of the cases. PIM1 expression significantly correlated with activation of the signal transducers and activators of transcription (STAT3 & STAT5) as assessed by phospho-STAT staining, and with the fraction of actively proliferating cells (Ki-67, MIB1+). Nuclear expression of PIM1 expression correlated significantly with the Ann Arbor stage of the disease. Interestingly, expression of PIM2 and PIM3 correlated with the amount of tumor-infiltrating FOXP+ regulatory T-cells (Tregs). No significant correlations between PIM expression and the status of MYC-, BCL2- and BCL6-genes, EBV-association or between GC- and non-GC derivation were found. Treatment of DLBCL cell lines with two structurally different small molecule inhibitors significantly impaired cellular proliferation. *Conclusions.* Our study strongly suggests that PIM kinases are collaborating oncogenes in a significant fraction of human DLBCL associated with activation of the JAK/STAT pathway. Blocking of cellular proliferation of DLBCL cells by small molecule inhibitors implies that PIM kinases might represent rational therapeutic targets.

0414

INVOLVEMENT OF GRB2 ADAPTOR PROTEIN IN NUCLEOPHOSMIN-ANAPLASTIC LYMPHOMA KINASE (NPM-ALK) MEDIATED SIGNALING AND ANAPLASTIC LARGE CELL LYMPHOMA GROWTH

L Riera, E Lasorsa, C Ambrogio, N Surrenti, C Voena, R Chiarle

University of Torino, Torino, Italy

Background. Most Anaplastic Large Cell Lymphoma (ALCL) express oncogenic fusion proteins derived from chromosomal translocations or inversions of the Anaplastic Lymphoma Kinase (ALK) gene. Frequently ALCL carry the t(2;5) translocation, that fuses the ALK gene to the Nucleophosmin (NPM1) gene. The transforming activity mediated by NPM-ALK fusion induces different pathways that control proliferation and survival of lymphoma cells. Grb2 is an adaptor protein thought to play an important role in ALK-mediated transformation, but its interaction with NPM-ALK as well as its functions in regulating ALCL signaling pathways and cell growth have never been elucidated. *Aims.* We characterized the interaction of the adaptor protein Grb2 with NPM-ALK. In particular we focused on three aspects: the binding of Grb2 to NPM-ALK in cells, the phosphorylation of Grb2 by NPM-ALK and role of Grb2 in regulating signalling pathways and proliferation of ALCL cells. *Methods.* Human embryonal kidney cells HEK-293T were transfected with different Grb2 and/or NPM-ALK constructs and immunoprecipitation experiments and immunoblot analysis were performed. Grb2 mutated forms and all kinase mutants were generated by PCR-based mutagenesis. Inducible ALK shRNA SU-DHL-1 and TS cells were obtained by co-transduction with pLV-tTRKRAB (TTA) vector and pLVTHM vector containing the H1 promoter ALK-shRNA cassette. Inducible Grb2 shRNA TS cells were obtained by co-transduction with pLVtTRKRAB vector and pLVTHM vector containing the H1 promoter Grb2-shRNA cassette. These cells undergo NPM-ALK or Grb2 silencing when 1 μg/mL of doxycyclin is added to the medium for 72 hours. shRNA Grb2 lentiviruses were obtained by co-transfection of human HEK-293T cell line. To generate Grb2 shRNA-resistant constructs, wild-type or Y160F Grb2 were mutated in 4 bases in the sequence corresponding to the shRNA (Grb2WTINT3/4 and Grb2Y160FINT3/4). Co-culture experiments and proliferation studies were performed. *Results.* In this study we demonstrate that Grb2 binds to active NPM-ALK and is phosphorylated in human ALCL cells. We identified Y160 as major phosphorylation site of Grb2 by NPM-ALK. We found that Y160 of Grb2 is phosphorylated also by other oncogenic fusion tyrosine kinases such as TPR-MET, BCR-ABL and TEL-JAK2, as well as by wild-type receptor tyrosine kinases (RTK), such as ALK and MET. Further, we show that NPM-ALK combined mutations in Y152-156, Y567 and P415-417 almost completely abrogated Grb2 binding and Y160 phosphorylation. Finally, shRNA knock-down experiments showed that Grb2 is essential for the activation of SHP2 in ALCL and is required for sustained ALCL cell growth. *Conclusions.* The down-modulation of Grb2 in ALCL cells strongly impaired cell proliferation, thus suggesting that Grb2 is fundamental for the full activation of a signalling cascade that involves Shc and SHP2 and assures an optimal proliferation of lymphoma cells. Thus, Grb2 could represent a potential target to control cell proliferation in NPM-ALK mediated lymphomas.

A C-MYC INDUCED GENE EXPRESSION SIGNATURE IN HUMAN GERMINAL CENTER B CELLS PREDICTS SUBTYPES OF AGGRESSIVE NON-HODGKIN LYMPHOMA

A Schrader,[1] S Bentink,[2] R Spang,[3] D Lenze,[4] M Hummel,[4] M Kuo,[5] J Arrand,[6] P Murray,[6] L Trümper,[1] D Kube,[1] M Vockerodt[6]

[1]Georg-August University, Göttingen, Göttingen, Germany; [2]Dana-Farber Cancer Institute, Boston, USA; [3]University of Regensburg, Regensburg, Germany; [4]Charité Berlin, Berlin, Germany; [5]Birmingham Children's Hospital, Birmingham, UK; [6]University of Birmingham, Birmingham, UK

Background. Aggressive Non-Hodgkin Lymphoma (aNHL) are a heterogenous group of malignancies derived from germinal centre B (GC

B) cells. Burkitt's lymphoma (BL) is the most homogeneous aNHL entity, characterized by an aberrant expression of the proto-oncogene c-Myc. Recently BL was defined by a specific gene expression signature including c-Myc as one hallmark. Despite an abundant number of cell line investigations and murine models, there is a lack of experimental systems to investigate the role of c-Myc for the transformation of human GC B cells. Therefore we expressed c-Myc in primary tonsillar GC B-cells and monitored expression changes using microarray gene expression profiling. *Aims.* We performed analyses integrating expression profiles from clinical lymphoma samples pointing us to potential mechanisms of disease initiation and progression. Furthermore we asked whether these changes permit to further subgroup aNHL. *Materials and Methods.* Purified human tonsillar CD10+ GC B cells were transfected with a c-Myc expression plasmid (treatment) or empty vector (control). mRNAs from 8 independent treatment-control pairs (8 human tonsils) were was subjected to gene expression profiling (Affymetrix® U133 plus2.0). Gene set enrichment analysis (GSEA) and bioinformatics integration of two large clinical lymphoma micorarray data sets were used to generate a c-Myc gene expression signature. *Results.* Microarray profiled genes were ranked by concordance of their expression levels with those of c Myc in both tonsillar B cells and tumors. Gene set enrichment analysis revealed a strong enrichment of c Myc target genes and a depletion of CD40/NF-κB pathway targets. We defined the c-Myc signature comprising the top c-Myc responding genes as c Myc index. This index stratifies aNHL patients based on the expression of the c-Myc signature genes. The signature is consistently expressed in BL, while its expression varies in DLBCL. In two independent clinical DLBCL microarray data sets the presence of high c-Myc index is significantly associated with a shorter overall survival. *Conclusions.* Our approach integrates two important aspects of cancer research; intervention in experimental model systems and observation on tumor samples. Mimicking aberrant c-Myc expression in GC B cells provided us with insights into downstream molecular pathways affected, confirmed BL as unique disease entity, and yielded a novel prognostic stratification of DLBCL.

0416

EBV-POSITIVE DLBCL OF THE ELDERLY IS A DISTINCT CLINICO-BIOLOGICAL ENTITY WITH POOR OUTCOME IN CHOP-R TREATED PATIENTS

M Gandhi, C Keane, J Nourse, K Jones, N Ross, E Han, D Nguyen-Van

Queensland Institue of Medical Research, Brisbane, Australia

Background. Diffuse Large B-cell Lymphoma is the commonest aggressive lymphoma. Epstein-Barr virus-positive DLBCL of the elderly (EBV+ DLBCL) is a provisional sub-type predominantly described in Asian populations. *Aims.* Data on EBV$^+$ DLBCL's response to the gold-standard regimen cyclophosphamide, doxorubicin, vincristine, prednisolone with rituximab (CHOP-R) is limited. Detailed studies of biological determinants have not been performed. Our aim was to determine incidence, obtain CHOP-R survival data, and to study viral and biological characteristics of EBV$^+$ DLBCL in an unselected Australian population. *Methods*. We analysed a consecutive cohort of DLBCL patients drawn over a 6 year period. Cases tested were chosen on the availability of tissue but were otherwise unselected. Survival curves were generated, and detailed assays of gene expression, methylation, tissue microarray, DNA sequencing and EBV-specific T-cell immunity were performed. *Results.* In 121 DLBCL cases in immunocompetent Australian patients, we found 9.1% were EBV$^+$, exclusively in those aged over 50 years (11.3% in the over 50 year-old DLBCL population). The majority of patients were Caucasian. In the over 50's receiving CHOP-R, EBV$^+$ DLBCL demonstrated strikingly inferior event-free (P=0.0002) and overall survival versus EBV- DLBCL (P=0.0368), with EBV-positivity an adverse risk factor by multivariate analysis (P=0.017). Previous evidence inferred from EBNA-2 protein expression suggested type II latency was restricted to the immuno-subdominant EBNA1, LMP1 and LMP2 in 70% of cases, with only 30% showing the EBV (type III) latency pattern seen in PTLD. Our data show these inferences are mistaken. Unexpectedly and in contrast to EBV$^+$ DLBCL occurring in the context of immunosuppression (EBV$^+$ DLBCL-PTLD), it displayed a novel type II/III EBV-latency profile, with up-regulation of EBNA3 but down-regulation of EBNA2. As opposed to latency type III, the major EBV-latency promoter C was consistently hyper-methylated. Polymorphisms in regions encoding for known CD8$^+$ T-cell epitopes were observed in the immuno-subdominant EBV proteins EBNA1 and LMP1, but not the immuno-dominant EBNA3. EBV-specific effector T-cells against multiple EBV-latent proteins could be expanded from baseline peripheral blood. *Conclusions.* EBV$^+$DLBCL is clinically and biologically distinct from EBV- DLBCL and EBV$^+$ DLBCL-PTLD. The poor response of EBV$^+$ DLBCL to CHOP-R indicates new approaches targeting the virus are warranted. Our in depth characterization of EBV viral transcription, promoter methylation, viral polymorphism and EBV-specific effector T-cell immunity is likely to have important therapeutic implications. The role of targeted antiviral immunotherapies and/or EBV lytic-induction strategies should be explored.

0417

DETAILED MOLECULAR ANALYSIS OF CLONAL TCRA AND TCRB GENE REARRANGEMENTS IN SÉZARY SYNDROME REVEALS A RESTRICTED TCR REPERTOIRE

Y Sandberg,[1] L van der Fits,[2] D Tielemans,[1] W Zoutman,[2] N Darzentas,[3] I Wolvers-Tettero,[1] M Vermeer,[2] A Langerak[1]

[1]Erasmus Medical Center Rotterdam, Rotterdam, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Center for Research and Technology Hellas, Thessaloniki, Greece

Background. Sézary syndrome is a rare form of cutaneous T-cell lymphoma (CTCL) characterized by the triad of erytroderma, lymphadenopathy and the presence of malignant T-cells in the peripheral blood (PB). The T-cells are clonal in nature as evidenced by clonally rearranged T-cell receptor (TCR) genes. The vast majority of cases are CD3$^+$/CD4$^+$/TCRαβ$^+$. Although the pathogenesis of CTCL remains unknown, there is evidence for involvement of chronic antigenic stimulation in driving T-cell expansion. The complementarity determining region 3 (CDR3) region of the TCR molecule has the highest antigenic specificity and directly binds to the antigenic peptide in the context of HLA. Detailed molecular characterization of Vα- and Vβ CDR3 regions of a large cohort of patients with Sézary syndrome has not been performed and may contribute to the understanding of the etiology of this disorder. *Aims.* To define TCR clonotypes and to establish the preferential usage of specific TCR-Vα and Vβ families in Sézary syndrome. In addition, we aimed to obtain more insight in the pathogenesis by analysis of CDR3 sequences of *TCRA* and *TCRB* genes *Materials and Methods.* In the present study we evaluated the immunophenotypical and molecular data of a series of 28 patients diagnosed with Sézary syndrome with a high tumorload in PB. We performed detailed immunophenotypical analysis using a T-cell antigen panel and a Vβ antibody (Ab) panel. BIOMED-2 PCR-based GeneScan and sequence analysis of *TCRB* gene rearrangements was performed in all PB samples. *TCRA* gene rearrangements were analyzed using a novel multiplex RT-PCR approach. *Results.* A dominant Vβ protein was detected in 7 out of 11 cases. One case demonstrated dual Ab reactivity whereas no Ab reactivity was detected in 3 cases. Clonal *TCRA* and *TCRB* gene rearrangements were detected in all cases. Sequence analysis of clonally rearranged *TCRB* genes showed overrepresentation of Vβ13, Vβ21 and Vβ22 as compared to healthy controls. No shared/restricted CDR3 motifs could be detected. The Vβ-Jβ2/Vβ-Jβ1 ratio in our series of patients was 1.3, which still clearly differs from the overrepresentation of the Jβ2 gene segment in the PB TCR repertoire of healthy adults (Vβ-Jβ2/Vβ-Jβ1 ratio of 2.6). There was no common Vα gene segment usage and our study did not show identical *TCRA* CDR3 amino acid motifs. *Conclusions.* Based on their immunophenotypic and immunogenotypic features, TCR clonotypes demonstrate heterogeneity. The lack of clearly shared CDR3 motifs of *TCRA* and *TCRB* genes indicate that a single common antigen is not involved in the pathogenesis of Sézary syndrome. Nevertheless, the overrepresentation of Jβ gene segment usage and some Vβ gene segments does reveal a restricted TCR repertoire, which might reflect other, yet to be identified TCR clonotypes, that could be present in a larger cohort of patients.

0418

INDUCTION OF CELL DEATH IN ADULT T-CELL LEUKEMIA CELL LINES BY SURVIVIN-RESPONSIVE CONDITIONALLY REPLICATING ADENOVIRUSES.

S Suzuki,[1] H Kofune,[1] K Uozumi,[1] Y White,[1] M Yoshimitsu,[1] T Kozako,[2] K Kosai,[3] N Arima[1]

[1]Center for Chronic Viral Diseases, Kagoshima Univ Grad School of Med and Dent, Kagoshima, Japan; [2]Faculty of Pharmaceutical Sciences, Fukuoka University, Fukuoka, Japan; [3]Dept of Gene Ther & Regenerat Med, Kagoshima Univ Grad School of Med & Dent Sci, Kagoshima, Japan

Background. Adult T-cell leukemia (ATL) is an aggressive peripheral T-cell neoplasm that develops after long-term infection with the human

T-cell leukemia virus type I (HTLV-1). Although there has been recent progress in chemotherapy for ATL, the prognosis for patients with ATL is still poor. On the other hand, survivin-responsive conditionally replicating adenoviruses (Surv.CRAs) in which expression of the adenoviral early region 1A (E1A) gene is regulated by the survivin promoter, has been demonstrated to treat a variety of cancers in which surviving is upregulated. *Aims.* Because survivin was also overexpressed in ATL, we examined ATL-selective replication and induction of cell death by Surv.CRAs at the possibility of the clinical application in the future. *Methods.* Six cell lines; 2 ATL cell lines and 3 HTLV-1 infected T-cell lines established from patients in our laboratory and MT-2, were tested. As a negative control, activated peripheral blood lymphocytes (PBLs) of healthy subjects were used. These cells were infected with either E1-deleted replication-defective adenoviruses expressing beta-galactosidase (LacZ) for analyzing gene transduction efficiencies and promoter activities or Surv.CRAs expressing enhanced fluorescent green protein (EGFP) for ATL-specific viral replication and therapeutic efficiencies at a various multiplicity of infection. Promoter activity was measured using the galactosidase enzyme reporter assay. The expression of the coxsackie and adenovirus receptor (CAR), important for cell infection by adenoviruses, was tested by flow cytometric analysis. Viral replication was assessed based on percentage of EGFP-positive cells. The cell viability was determined using a colorimetric assay. *Results.* The survivin promoter was strongly activated in 6 cell lines, both ATL cell lines and HTLV-1 infected T-cell lines. Moreover, the expression of CAR was highly upregulated in these cell lines. In contrast, weak activation of the survivin promoter and low expression of CAR were observed in activated PBLs of healthy subjects. Surv.CRAs efficiently replicated and potently induced cell death in 5 out of 6 cell lines compared to minimal viral replication in normal activated PBLs, in which there was no significant cytotoxicity. Although over-expression of survivin in ATL contributes significantly to apoptosis resistance against conventional chemotherapy, the higher activity of survivin promoter in both ATL cell lines and HTLV-1 infected T-cell lines serves as a potential therapeutic target for survivin-dependent apoptosis induction by Surv.CRAs. Unlike the high CAR expression and strong survivin promoter activation, characterizing the other cell lines, only one HTLV-1 infected T-cell line exhibited resistance to Surv.CRA treatment. This unique cell line may of interest in seeking to elucidate the mechanism of resistance to Surv CRAs. *Conclusions*. This is the first report demonstrating that Surv.CRAs form an attractive potential antileukemic agent that could efficaciously and specifically treat ATL.

0419

MIRNAS EXPRESSION PATTERN IN GASTRIC MALT LYMPHOMA

A Pons,[1] A Salar,[2] B Sánchez-González,[2] S Pairet,[2] R Longarón,[2] M Garcia-Garcia,[2] E Gimeno,[2] A Seoane,[2] C Besses,[2] S Serrano,[2] B Bellosillo[2]

[1]Hospital del Mar (FIMIM), Barcelona, Spain; [2]Hospital del Mar, Barcelona, Spain

Background. MicroRNAs are short non-coding RNA sequences that regulate target genes by inducing translational inhibition and cleavage of targeted transcripts. To date, microRNA have been implicated in development, cell differentiation, apoptosis and proliferation. However, their role in gastric MALT lymphoma remains unknown. *Aim.* To analyze the expression pattern of miRNA in patients with gastric MALT lymphoma. 2- to find a distinctive signature according to the presence or absence of the t(11;18)(q21;q21) API/MALT translocation. *Material and Methods.* Total RNA was extracted from gastric biopsies from 9 patients with MALT lymphoma and 2 with chronic gastritis with the Kit MirVanaTM (Applied Biosystems). Median age of patients was 63 years (range, 32-85), the Ann Arbor stage was 44% stage I, 22% stage II and 22% stage IV and the translocation t(11;18)(q21;q21) was present in 5 patients (56%). miRNA expression was profiled in 384 miRNA via Taqman Low Density Array in ABI PRISM 7900. Expression data was normalized with RNU48 and relative quantification was calculated with the 2- Ct method. The data were presented as log10 of relative quantity of target miRNA. Median of chronic gastritis was used as calibrator for all samples. Data were analyzed by means of Significant Analysis of MicroArrays (SAM), Prediction Analysis of MicroArrays (PAM) and Class Comparison methods using BRB array tools version 3.7.0 and TIGR multiexperiment viewer version 4.3. *Results.* We identified genes that were differentially expressed among the two groups using a random-variance t-test, with a median false discovery rate (FDR) of 10%. We found a group of 5 miRNA (miR-142-3p, miR-594, miR-489, miR-222 and miR-429) overexpressed in gastric MALT lymphoma with respect to chronic gastritis (P<0.001). When we compared miRNA differentially expressed between translocation t(11;18) carriers and non carriers, we found also a group of 9 miRNA with a P<0.05 and a FDR of 10%. Comparing the relative expression levels (2-ΔΔCt) according to Ann Arbor stage, we found a significantly higher level expression of miR-203 and miR-555 in both stages I and II with respect to stage IV. *Conclusions.* Our results suggest specific expression profiles of some miRNA in gastric MALT lymphoma. In addition, several of the miRNA differentially expressed allow us to discriminate cases according to API/MALT translocation and also according to Ann Arbor stage.

SNP RS6457327 ON CHROMOSOME 6P PREDICTS TRANSFORMATION OF FOLLICULAR LYMPHOMA

J Wrench,[1] C Skibola,[2] J Matthews,[3] JB Cazier,[4] S Iqbal,[1] E Carlotti,[1] M Calaminici,[1] A Davies,[5] S Montoto,[1] J Gribben,[1] A Lister,[1] J Fitzgibbon[1]

[1]Barts and the London School of Medicine, Queen Mary University London, London, UK; [2]Division of Environmental Health Sciences, University of California, Berkeley, USA; [3]Data Management Unit, Department of Haemato-oncology, St Bartholomew's Hospital, London, UK; [4]The Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, UK; [5]Cancer Sciences Division, Somers Cancer Research Building, Southampton, UK

Background. A genome-wide association study (GWAS) recently identified a 26kb region on chromosome 6p21.33 as a genetic risk locus for follicular lymphoma (FL) (Skibola et al, Nature Genetics 2009). The variant allele of a single nucleotide polymorphism (SNP), rs6457327 (involving C>A), associated with reduced FL risk which was validated in four independent FL case-control studies from North America and Germany ($P=4.7\times10^{-11}$ across a total of 645 FL cases and 3377 controls). It is not known if this locus is relevant in established disease. *Aims.* This study sought to determine if rs6457327 is associated with FL risk in the United Kingdom (UK) population and whether it impacts on disease outcome. *Methods.* Germline DNA from 221 FL cases was genotyped for rs6457327 by allelic discrimination polymerase chain reaction (AD-PCR) in a retrospective single centre study of patients treated at St Bartholomew's Hospital between 1977 and 2005. Direct sequence analysis showed complete concordance with AD-PCR genotypes on a validation subset constituting 10% of the samples tested. The significance of differences between groups was determined using 2-by-2 tables, crude odds ratios (OR), 95% confidence intervals (CI) and 2-tailed p values (Fisher's exact test). Survival analysis was performed using Kaplan-Meier survival function with log rank test for equality of survival. *Results.* Comparison of rs6457327 genotypes for the study population to those of a UK control population, obtained from the Wellcome Trust Case Control Consortium (n = 2937), demonstrated a significantly reduced risk of FL for cases carrying AA (OR = 0.47, 95% CI = 0.27-0.79, P=0.003) or AA/AC (OR = 0.73, 95% CI = 0.55-0.97, P=0.02) as opposed to the CC genotype. The minor allele frequencies within the study cohort (0.32) and WTCCC control set (0.38) showed similar distribution to case (0.31) and control (0.38) populations from the GWAS study. Although rs6457327 genotype showed no association with overall survival or event free survival in FL, disease transformation occurred more frequently in the presence of the minor allele, AA and AC versus CC (odds ratio = 2.2, 95% CI = 1.2-4.1; P=0.007). Moreover, the minor allele was also associated with shorter time to transformation (P=0.01) (Figure 1).

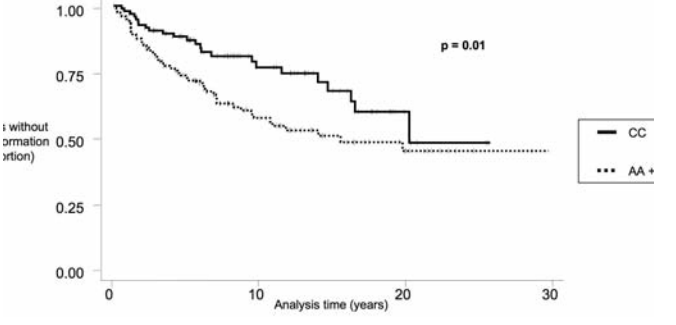

Figure 1. rs6457327 genotype and time to transformation.

Summary/Conclusions. This study confirms a previous report that

found a reduced risk of FL associated with the minor allele for rs6457327 located on chromosome 6p21.33 and demonstrates for the first time that rs6457327 predicts disease transformation. This SNP is located 6 kb telomeric to C6orf15, the only gene located within the 26 kb risk locus. A mouse homologue of this gene has recently been identified as an extra-cellular matrix protein termed emprin. The role of C6orf15 in FL and its transformation is currently under investigation.

0421

CIRCULATING MIR-92A LEVEL IS A NOVEL BIOMARKER FOR MONITORING PATIENTS WITH NON-HODGKIN'S LYMPHOMA

S Yoshizawa, K Ohyashiki, T Umezu, M Kurada, J Ohyashiki

Tokyo Medical University, Tokyo, Japan

Backgrounds: The miR 17-92 cluster is a polycistronic miRNA gene and is important in immune cell development and tumorigenesis in lymphoid tissue. Recent studies have demonstrated that circulating miRNAs are detectable in the plasma in various cancer patients. Therefore, the deviations of certain miRNAs detected in plasma of lymphoma patients could be a useful and non-invasive marker to detect cancer development. *Aims.* To evaluate the clinical relevance of the miR-92a in plasma obtained from non-Hodgkin's lymphoma patients. *Methods.* We evaluated plasma miR-92a value (miR-92a/miR-638) using qRT-PCR, in 108 patients with non-Hodgkin's lymphoma, consisting of 66 patients with diffuse large B cell lymphoma (DLBCL), 28 patients with follicular lymphoma (FL), and 14 patients with T-cell lymphoma, at various clinical phases, and compared results with healthy subjects. This study was approved by the institutional review board of Tokyo Medical University (no. 930: approved on June 24, 2008). Total RNA in plasma was extracted as we have previously reported (Tanaka *et al. PLoS One* 4:e5532, 2009). MicroRNAs were quantified by TaqMan® MicroRNA Assays (Applied Biosystems), using microRNA specific stem-loop primers (has-miR-92a, 000431; has-miR-638, 001582; Applied Biosystems). The miR-92a expression was normalized to miR-638 expression. The miR-638 was selected because of its lack of expression variability in plasma. Relative expression was caliculated using the comparative Ct method. *Results.* Plasma miR-92a values in non-Hodgkin's lymphoma were extremely low, compared to healthy subjects (P<0.0001), irrespective of lymphoma sub-type. The expression level of plasma miR-92a in patients with DLBCL was approximately 10% lower than that obtained from healthy volunteers (0.05027±0.01118 versus 0.8355±0.4018: P<0.0001). Of the DLBCL patients, the plasma miR-92a level did not differ according to clinical stage, however, Stage IV patients showed significantly decreased plasma miR-92a levels compared with Stages I to III patients (P<0.0001). Plasma miR-92a in DLBCL patients in complete response (CR) increased significantly compared with the diagnosis level (P<0.0001), but no significant difference was found when compared with healthy individuals (P=0.1167). In the relapse phase, plasma miR-92a levels again decreased and these levels were similar to those at diagnosis (P=0.6936). Similarly, a significantly low level of plasma miR-92a was noted in patients with FL at the time of diagnosis (0.02187±0.01022 versus 0.8355±0.4018: P). It normalized after obtaining CR, and again decreased in the relapse phase. Interestingly, plasma miR-92a level in patients classified as CR uncertain (CRu) tended to decrease compared to that of CR (0.1980±0.07881 in CRu versus 0.5915±0.1881 in CR) (P = 0.0913). The fluctuation pattern of plasma miR-92a detection levels in relation to clinical status in T-cell lymphoma was similar to those of DLBCL or FL. Extremely low levels of the miR-92a value by the qRT-PCR method were found, compared with normal subjects (0.08870±0.06845 versus 0.8355±0.4018: P<0.0001). *Conclusions.* The plasma miR-92a value could be a novel biomarker for monitoring lymphoma patients, especially in those with indolent lymphoma.

0422

CHARACTERIZATION OF COPY-NUMBER ABERRATIONS IN MANTLE CELL LYMPHOMA WITH HIGH-RESOLUTION GENOMIC ARRAYS: CORRELATION WITH GENOMIC COMPLEXITY AND THE PROLIFERATION GENE EXPRESSION SIGNATURE

M Halldorsdottir,[1] B Sander,[2] H Göransson,[1] A Isaksson,[1] M Mansouri,[1] R Rosenquist,[1] H Ehrencrona[3]

[1]Uppsala University, Uppsala, Sweden; [2]Karolinska Institute, Huddinge, Sweden; [3]Lund University Hospital, Lund, Sweden

Background. Mantle cell lymphoma (MCLs) represents a clinically aggressive lymphoma with a poor prognosis. Genetically it is characterized by the t(11;14)(q13;32) translocation and numerous recurrent secondary copy-number aberrations (CNAs). Gene expression profiling studies have defined a proliferation gene expression signature (PS) where high proliferation scores predict shorter survival. *Aims.* To study CNAs and copy-number neutral loss of heterozygosity (CNN-LOH) in MCL and to correlate specific CNAs with the PS score, genomic complexity and survival. *Methods.* Thirty-one primary MCL cases were investigated using a high-density single nucleotide polymorphism (SNP) array (Affymetrix™ GeneChip® Mapping 250K arrays). Quality control, genotype calling, and probe level normalization were done using the Affymetrix GeneChip® Genotyping Analysis Software (GTYPE) 4.1. Subsequent copy number analysis was performed using the Nexus software from Biodiscovery. Gene expression profiling was performed with Affymetrix™ expression arrays, and the PS score was calculated using the expression levels of 20 proliferation-associated genes as previously described. PS below or above the median (0.99) was considered low or high, respectively. *Results.* The majority of recurrent CNAs identified in this study had previously been described in MCL, and include losses at 1p (55%), 11q (55%), 17p (29%), 9q (29%), 8p (29%), 9p (26%), 6q (23%) and gains at 3q (39%), 8q (26%), 15q (23%), 18q (23%). However, several novel recurrent CNAs were identified, including losses at 10q (13%), 14q (23%), 18p (13%), 20q (16%) and 22q (16%). Notably, the loss at 20q13.2 targeted the SALL4 gene in 4/5 cases. Novel gains were identified at 12p (13%), 16q (13%), 18p (13%) and 22q (13%). Interestingly, some CNAs were associated with increased genomic complexity, for instance, 8p loss correlated with increased average number of CNA regardless of size (P <0.001), whereas losses at 13q and 17p were associated only with increased CNAs >5 Mb (P<0.001 and P=0.03). Furthermore, gains at 7p correlated with high PS score (P=0.02), as did losses at 9q (P=0.037). There were four recurrent chromosomal regions affected by CNN LOH; two at 12q, one at 19p and one at 22q, each identified in two cases. Large 13q losses correlated with improved survival (P<0.05) as did losses at 19p (P<0.05), while gains at 19p tended to correlate with inferior survival (P=0.07). Summary: This high-resolution genomic analysis identified novel recurrent CNAs and CNN-LOH regions and found that several common secondary CNAs correlated with genomic complexity (losses at 8p, 13q, 17p), or proliferation status (7p gains and 9q losses).

0423

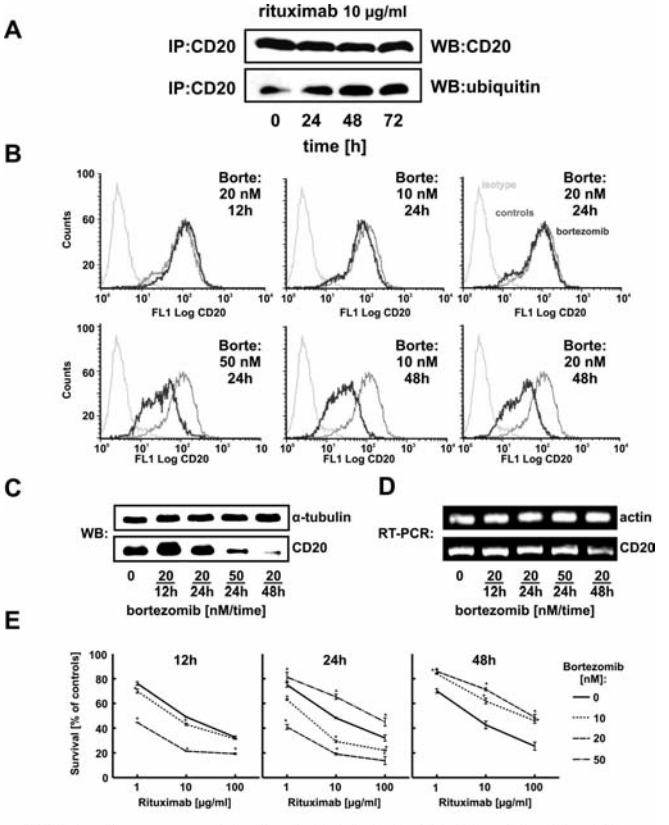
BORTEZOMIB MODULATES SURFACE CD20 IN B-CELL MALIGNANCIES AND AFFECTS RITUXIMAB-MEDIATED COMPLEMENT-DEPENDENT CYTOTOXICITY

M Winiarska,[1] J Bil,[2] K Bojarczuk,[1] D Nowis,[1] J Golab[1]

[1]Medical University of Warsaw, Warsaw, Poland; [2]Central Clinical Hospital of the Ministry of Interior and Administration, Warsaw, Poland

Background. The mechanism of resistance to rituximab therapy is not fully elucidated and still little is known about the molecular regulation of CD20 levels. The decreased surface CD20 levels were recently demonstrated in rituximab-resistant cell lines that also exhibited upregulation of the components of the ubiquitin-proteasome system (UPS). *Aim.* We decide to investigate in more detail the role of UPS system in regulation of CD20 levels and the influence of proteasome inhibition on rituximab-mediated CDC and ADCC against CD20-positive B-cell lymphomas. *Methods.* Rituximab-mediated cytotoxicity (R-CDC) was determined with MTT assay. CD20positive B-cell lymphomas and primary cells from patients, pretreated with proteasome inhibitors, were incubated with rituximab and 10% human serum. CD20 surface levels, as well as other surface antigens, were detected with fluorochrome - conjugated antibodies in flow cytometer. Total CD20 protein levels were assayed with Western blotting, the expression of CD20 gene was determined with RT-PCR. The ubiquitination of CD20 protein was assessed with Western blotting after immunoprecipitation with anti-CD20 antibody. The ubiquitination of membrane CD20 protein was performed as described above, preceeded by biotinylation of surface proteins. Autophagy detection was performed with acridine orange staining, bafilomycin A1 was used as an inhibitor of lysosomal/autophagosomal pathway of protein degradation. *Results.* We observed that CD20 molecule is ubiquitinated in lymphoma cells and that rituximab binding increases its ubiquitination. However, inhibition of the UPS was not associated with up-regulation of surface CD20 levels although it significantly increased its ubiquitination. Inhibition of proteasome activity resulted in bi-modal regulation of CD20 levels. Short-term (24h) incubation of Raji cells with 10 or 20 nM bortezomib did not change CD20 levels, but sensitized $CD20^+$ lymphoma cells to R-CDC (50% of survival in control cells, 20% of survival in bortezomib-pretreated cells). Prolonged (48h) incubation with 20 nM bortezomib, or

incubation with 50 nM bortezomib for 24h led to a significant decrease in surface CD20 levels as well as R-CDC (50% of survival in control cells, 80% of survival in bortezomib-pretreated cells). Bortezomib-mediated modulation of CD20 levels was also observed in primary tumor cells. The unexpected finding of decreased levels of CD20 and increased levels of its ubiquitination in bortezomib-treated cells indicates that ubiquitination might also label proteins for degradation by another proteolytic system. Indeed, we have observed induction of autophagy upon treatment with bortezomib. Also, bafilomycin A1 partly restored CD20 levels in bortezomib-treated cells. *Summary/conclusions.* Our results for the first time report that CD20 is ubiquitinated in tumor cells. These studies indicate that CD20 levels are regulated by two proteolytic systems and that the use of proteasome inhibitors might be associated with unexpected negative influence on R-CDC.



(A) Raji cells were exposed to 10 µg/ml rituximab for 24h, 48h or 72h, after which protein lysates were prepared. CD20 antigen was immunoprecipitated from probes with protein G bead slurry and subjected to Western blot analysis. Blots were sequentially probed (after stripping) with anti-ubiquitin and anti-CD20 antibodies. **(B)** Raji cells were incubated with either diluent or bortezomib (10-50 nM) for 12h, 24h or 48h. Then, cells were incubated with saturating amounts of FITC-conjugated mAb against CD20 for 30 min on ice in the dark and analyzed in a FACSCalibur. **(C)** CD20 protein levels in Raji cells incubated with either diluent or 20 and 50 nM bortezomib for 12h, 24h or 48h were assayed with Western blotting. **(D)** CD20 mRNA levels in Raji cells incubated with either diluent or 20 and 50 nM bortezomib for 12h, 24h or 48h were assayed with RT-PCR. **(E)** Raji cells were incubated with either diluent or bortezomib at 10, 20 or 50 nM concentration for 12h, 24h or 48h. Then cells were incubated for 1h with serial dilutions (from 1 to 100 µg/ml) of rituximab in the presence of 10% human AB serum as a complement source. Cell viability was measured with a MTT assay. The survival of cells is presented as percentage of corresponding diluent- or bortezomib-pretreated cells without rituximab.

ANALYSIS OF IMMUNOGLOBULIN HEAVY CHAIN VARIABLE GENES IN BURKITT LYMPHOMA UNCOVERS AN ANTIGEN ROLE IN LYMPHOMAGENESIS

MJ Baptista,[1] M Crespo,[2] E Calpe,[3] C Codony,[3] E Fernandez,[4] L Colomo,[4] TM Cardesa-Salzmann,[5] P Abrisqueta,[2] E Montserrat,[3] F Bosch[2]

[1]Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain; [2]Department of Hematology, Hospital Vall d'Hebron, Barcelona, Spain; [3]Institut of Hematology and Oncology, Department of Hematology, Hospital Clinic,, Barcelona, Spain; [4]Department of Pathology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain; [5]Department of Pediatric Oncology, Hospital Sant Joan de Déu, University of Barce, Barcelona, Spain

Burkitt lymphomas are aggressive neoplams derived from germinal center B cells. Analysis of nucleotide sequences of immunoglobulin heavy chain variable (IGHV) gene can provide insight into the stage of B cell development at which clonal expansion occurs in B cell tumours. The relationship of ZAP-70 expression and IGHV mutational status in CLL and the finding of ZAP-70 expression in some Burkitt lymphomas (BL) prompted us to analyze ZAP-70 expression in BL cells and to seek for a relationship with IGHV repertoire, somatic hypermutation (SHM) status, and intraclonal diversity (ID). We analyzed 14 BL cases of which 4 were HIV-BL and 3 were pediatric-BL. Other 13 pediatric-BL are currently under analysis. Clonality was assessed by GeneScan fragment analysis of PCR products of independent IGHV subgroups (FR1 and IGHJ-consensus primers, BIOMED-2 protocol). Another PCR was performed with the leader IGHV clonal subgroup primer and IGHC or IGHJ-consensus primer (BIOMED-2 protocol). This product was further cloned into pCRII vector and introduced into competent bacterial cells. At least 10 clones were sequenced in 2 separate reactions. Sequencing analysis and alignments were performed with the use of IMGT/V-QUEST tool. ZAP-70 expression was assessed by means of flow cytometry and QRT-PCR. The majority of cases (78.6% n=11) had mutated IGHV genes (<98% germline identity (GI)). Only 1 BL case (7.1%) presented unmutated IGHV gene (100% GI), whereas 14.3% of cases (n=2) had IGHV genes with borderline/minimally mutated status (98-99.9% GI). ZAP-70 expression was found in 78.5% of cases (n=11), hence, there was no relationship between ZAP-70 expression and mutational status of the IGHV genes. Although the number of BL was small, we observed biased use of IGHV4-39 and IGHV3-30 (35.7%), as previously reported by Trautmann et al (ASH 2009). Pediatric-BL presented a low mutational load (98% mean GI) compared to other BL (94.7% mean GI). Stereotyped aminoacid changes were detected in 57.1% of the studied BL (n=8). They were identified in cases that use IGHV4-39 and IGHV3-30 genes but also in cases with different IGHV genes and even subgroups. These shared replacement mutations strongly indicate the influence of a common antigen in the SHM process of the immunoglobulins in BL. Ongoing SHM leads to ID and reflects the persistence of antigen encounter in the germinal center reaction. For ID evaluation, only confirmed mutations, mutations observed more than once in the clones of the same BL case, were considered. ID was present in 57.1% of the 14 BL cases studied (n=8). More, all HIV-BL and all ZAP-70 negative BL showed ID being reasonable to speculate that BL cells of these particular groups are continually being stimulated by an antigen. To conclude, in BL the high IGHV mutational load observed and the evidence of ID suggested that antigen selection pressure must be involved in the malignant transformation. Moreover, the biased use of certain IGHV genes and the observed stereotyped aminoacid changes pointed that particular antigens must be implicated in BL development by stimulating proliferation of B cells that express surface immunoglobulin encoded by certain IGHV genes.

NON-IG MEDIATED ABERRATIONS OF FOXP1 IN HUMAN B CELL LYMPHOMA

L Rouhigharabaei,[1] T Tousseyn,[2] E Haralambieva,[3] B Maes,[4] C Vicente,[2] P Vandenberghe,[2] C de Wolf-Peeters,[2] J Cools,[1] I Wlodarska[2]

[1]Catholic University Leuven, VIB, Leuven, Belgium; [2]Catholic University Leuven, Leuven, Belgium; [3]University of Wuerzburg, Wuerzburg, Germany; [4]Virga Jesse Hospital, Hasselt, Belgium

Background. The FOXP1 forkhead transcription factor is targeted by rare but recurrent translocations in B-NHL, particularly marginal zone lymphoma (MZL) and diffuse large B-cell lymphoma (DLBCL). The

most common is IGH-mediated t(3;14)(p14;q32) resulting in deregulation of FOXP1 transcription by regulatory sequences of IGH. Several translocations of FOXP1 involving non-IG loci have been described, but remain uncharacterized at the molecular level. *Aims.* This study aimed at genetic and molecular characterization of non-IG FOXP1 aberrations identified in 4 lymphoma cases. *Methods.* FISH with a panel of BAC probes was applied to map the affected breakpoints at 3p14/FOXP1 and 2q36, 3q11-q13 and 10q24. Expression of FOXP1 mRNA was analyzed by quantitative RT-PCR (QRT-PCR) with primers specific for exons 5-6, 7-8, 11-12, 14-15 and 17-18. Expression of FOXP1 protein was demonstrated by immunohistochemistry (IHC) with the JC12 antibody. *Results.* All 4 cases showed an aberrant expression of FOXP1 protein by IHC. Three of them displayed various 3p14 aberrations including t(2;3)(q36;p14) (C1) (MZL), inv(3)(p14;q11) (C2) (MZL) and t(3;10)(p14;q24) (C3) (CLL in Richter transformation). In one case of DLBCL (C4) a non-IG t(FOXP1) was detected by interphase FISH. In contrast to lymphomas with t(3;14) showing the 3p14 breakpoints in the 5'end of FOXP1, all cases with non-IG FOXP1 rearrangements displayed breakpoints in the 3'end of the gene. The reciprocal breakpoints were mapped within AP1S3 at 2q36 (C1), in a region at 3q11 lacking known genes (C2) and close to NFKB2 at 10q24 (C3). In C1, AP1S3 has an opposite transcriptional orientation to FOXP1, which precludes the role of its 5' promoter in deregulation of FOXP1. Also the mechanism of FOXP1 overexpression in C2 with inv(3) affecting no known gene locus at 3q11 remains unknown. To check the hypothesis that non-IG translocations of FOXP1 result in an aberrant expression of variant FOXP1 transcripts, we performed exon-specific QRT-PCR analysis of two available cases (C2 and C4). As controls, we analyzed 2 cases with t(3;14) and 6 cases of DLBCL/MZL expressing FOXP1 but lacking FOXP1 rearrangements. These studies showed that both cases with t(3;14) expressed all analyzed coding exons (6-17) while cases with non-IGH translocations of FOXP1, as well as FOXP1$^+$ DLBCL/MZL cases expressed sequences coded by exons 7-17, but not of exon 6. *Conclusions*. Our study demonstrates that the 3p14 breakpoints of non-IG FOXP1 rearrangements in lymphoma are clustered in the 3'end of the gene. Consequently, these aberrations result in expression of variant FOXP1 transcripts, likely encoding N-terminally truncated proteins, similar to potentially oncogenic smaller FOXP1 isoforms recently identified in ABC-DLBCL cell lines and primary DLBCLs. Which transcriptional regulatory elements are engaged to aberrantly express variant FOXP1 transcripts in these peculiar non-IG FOXP1 aberrations warrants further studies.

NK CELL BINDING AND INDUCTION OF POTENT NK CELL-MEDIATED ADCC BY OFATUMUMAB, A NEW HUMAN CD20 MONOCLONAL ANTIBODY

J Beurskens,[1] W Mackus,[1] P Engelberts,[1] S Miller,[2] S Speller,[3] L Chamberlain,[3] B Davis,[4] S McHugh,[4] E Bullmore,[4] C Cox,[5] J Bakker,[1] J van de Winkel,[1] P Parren,[1] J Craigen[3]

[1]Genmab, Utrecht, Netherlands; [2]BioPharm R&D, GSK, Stevenage, UK; [3]Discovery Analytics, GSK, Harlow, UK; [4]Clinical Unit, ACCI, GSK, Cambridge, UK; [5]Genetics, GSK, Harlow, UK

Background. Immunotherapy with the CD20 monoclonal antibody (mAb) rituximab is part of the standard treatment for B-cell malignancies such as follicular lymphoma. Antibody-dependent cytotoxicity (ADCC) is postulated to be a key *in vivo* mechanism of action of CD20 mAb, given differences in response to rituximab based on the Fc receptor (FcγRIIIa) polymorphism. The FcγRIIIa 158V/V allotype is associated with a better response to rituximab relative to the 158F/F allotype. Ofatumumab is a new human mAb targeting a membrane-proximal epitope encompassing both the small and large loop of CD20, and has been shown to induce rapid and efficient killing of tumor cells via complement-dependent cytotoxicity. *Aims.* To investigate the ability of ofatumumab and rituximab in inducing ADCC by NK cells from FcγRIIIa 158V and 158F homozygous donors. *Methods.* Following informed consent, blood was drawn from healthy volunteers homozygous for FcγRIIIa 158V (n=10) or 158F (n=10), from a pool of donors matched for age, sex and race. Using purified NK cells, Fc-mediated antibody binding and ADCC were assessed in a blinded study. Glycan profiling was performed for ofatumumab and rituximab by HPAEC-PAD analysis. MAb binding was measured by flow cytometry in a competition binding assay in which binding of FITC-labelled CD16 mAb 3G8 was blocked by the binding of ofatumumab or rituximab. ADCC was assessed by measuring Europium release from the B-cell line ARH77 target cells upon incubation with a concentration curve of ofatumumab or rituximab in the presence of NK effector cells (effector:target ratio 5:1). Statistical analysis was performed using a non-linear mixed effect model fitting sigmoidal concentration-responses curves to data from each donor for each antibody. The model provided estimates of mean EC50 for each antibody and donor group, and allowed differences between these means to be tested for statistical significance. *Results.* Monomeric ofatumumab bound more strongly to NK cells expressing FcγRIIIa 158 V/V than FcγRIIIa 158 F/F (Table). The approximately 4.4-fold difference in affinity was statistically significant (P<0.0001). A similar 4.2-fold difference between the allotypes (P<0.0001) was found for rituximab. Rituximab bound 1.4 fold less tightly to both FcγRIIIa allotypes than ofatumumab (P<0.0001; Table). Ofatumumab induced potent NK-mediated ADCC with both FcγRIIIa 158V/V- as well as 158 F/F-expressing NK cells (Table). The observed 2.7-fold difference in potency was significant (P=0.0002). Higher concentrations of rituximab compared to ofatumumab were required to induce ADCC by NK cells obtained from both types of donors. This 1.8-fold difference in ADCC potency between ofatumumab and rituximab was statistically significant (P≤0.001; Table). *Summary/Conclusions.* Expected differences in affinity for the 158V and 158F allotypes of FcγRIIIa were observed for both ofatumumab and rituximab. These differences correlated with a stronger ADCC by FcγRIIIa 158V/V compared to 158F/F-expressing NK cells. Notably, ofatumumab induced ADCC more potently than rituximab for both Fc receptor allotypes. Ofatumumab binds CD20 stably and at a distinct membrane-proximal epitope compared to rituximab. Our data suggest that these binding characteristics may positively impact ofatumumab's ability to direct killing of tumor cells via ADCC.

Table

NK cell binding, mean EC50 (95% CI), ng/mL			
Allotypes	Ofatumumab	Rituximab	p value*

A MEMBRANE-ASSOCIATED MUCIN MUC1 IS OVEREXPRESSED IN ADULT T-CELL LEUKEMIA/LYMPHOMA CELLS AND CONTRIBUTES TO ANTI-APOPTOTIC PROPERTIES

H Hasegawa,[1] Y Yamada,[1] S Yonezawa,[2] A Osaka,[1] D Sasaki,[1] K Tsukasaki,[1] Y Miyazaki,[1] S Kamihira[1]

[1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; [2]Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan

Mucins are high molecular weight glycoprotein expressed at the luminal surface of a variety of reproductive tract epithelia. MUC1 represents a type I transmembrane glycoprotein and often becomes highly overexpressed in epithelial cancer cells and a limited types of hematological malignant cells such as myeloma cells. Adult T-cell Leukemia (ATL) is an aggressive neoplasm etiologically associated with human T-cell lymphotropic virus type-1 (HTLV-1). ATL is sub-classified into 4 clinical subtypes of acute, chronic, smoldering and lymphoma and is known to have the diversity in clinico-pathological features. Since ATL cells frequently show multi-organ invasions and are resistant to anticancer therapies, we analyzed the expression profiles and the functions of MUC1 on ATL cells. We first analyzed quantitative mRNA expression of MUC1 in various hematological cell lines: 8 ATL-related, 2 T-cell leukemia, 5 B-cell lineage, and 3 myeloid leukemia. All of ATL-related cell lines had quite high levels of MUC1 mRNA compare to the other cell lines. In primary ATL cells, acute-type (n=52) and chronic-type (n=12) ATL cases had significantly higher levels of MUC1 mRNA (P<0.01) compared with PBMC's from healthy donors (n=10). Flowcytometric analysis confirmed that ATL-related cell lines and primary ATL cells had high levels of MUC1 protein. Clinical observations in epithelial cancers have demonstrated that high MUC1 expressions are indica-

tive of an aggressive stage in tumor progression and poor survival. Meanwhile, the effect of MUC1 on tumor growth has not been clearly demonstrated. We assessed prognosis between high MUC1 mRNA expression cases and low cases of acute-type ATL. Despite the tendency that high MUC1 mRNA expression cases had poor prognosis, there was no significant difference. Of note, many of ATL-related cell lines proliferate showing auto-aggregation. Among them, we focused on KK1 and KOB cells with high levels of MUC1 expression and performed knockdown experiment of MUC1 by siRNA. After 96 hours incubation, cell growth of si-MUC1 cells was repressed in comparison with si-control cells. Next, we investigated the pattern of aggregation in KK1 and KOB cells. Interestingly, si-MUC1 cells significantly reduced aggregation after 72hours incubation in comparison with si-control cells, suggesting that MUC1 expression is a key molecule for cell aggregation. We previously found that ATL cells are resistant to TRAIL though they had death-receptors and we further investigated whether MUC1 contribute to the inhibition of apoptosis. After treatment with TRAIL for 24 hours Annexin-V positive cells of si-control cells were about 20% which increased in si-MUC1 cells to 42% in the KK1 cells. Similar effects were also observed in KOB cells. In addition, when we used a more potent apoptosis inducer MG132, si-MUC1 cells also increased the percentage of annexin-V positive cells in these cells. Consequently, we found for the first time that ATL cells had unusually high levels of MUC1 as leukemia cells. si-RNA experiments unexpectedly revealed that MUC1 contributes to the cell aggregation in a certain types of ATL cells. Furthermore, MUC1 play a role in the resistance of apoptosis in ATL cells. These findings may contribute to discover unknown function of MUC1 in leukemia cells.

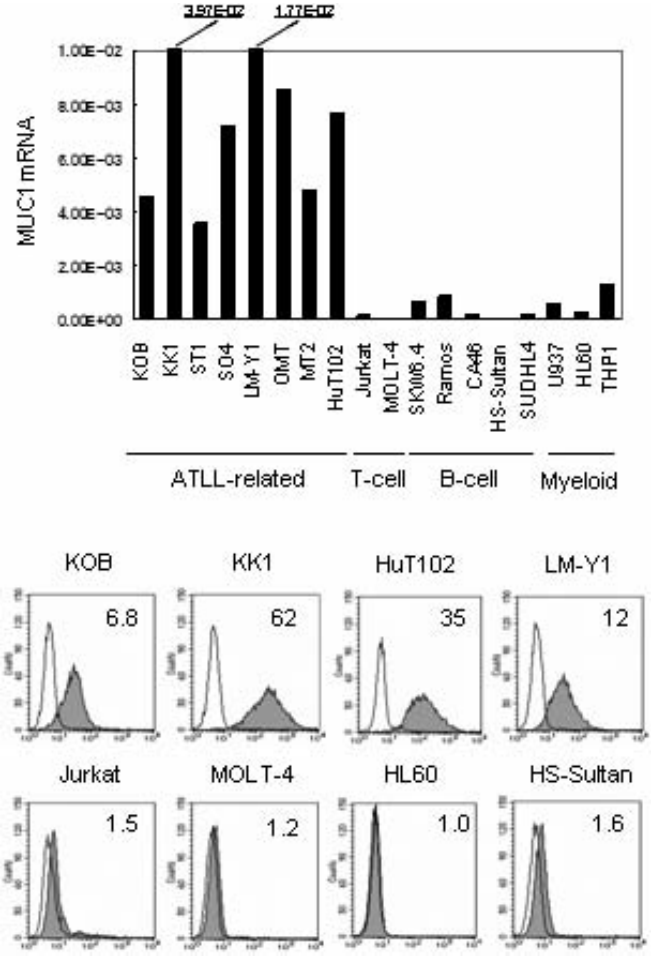

Figure. MUC1 expression in ATL cells.

NON-HODGKIN LYMPHOMA SUBTYPES CLASSIFICATION USING FOCUSED MICROARRAY

B Tichy, J Supikova, K Stano-Kozubik, D Salek, A Janikova, I Vasova, J Mayer, S Pospisilova

University Hospital Brno and Medical Faculty Masaryk University, Brno, Czech Republic

Background. Non-Hodgkin lymphomas (NHL) represent a heterogeneous group of lymphoproliferative disorders with highly variable clinical course and outcome. In some cases, current diagnostic methods based on histopathology and immunohistochemistry may be insufficient for exact tumor classification and subjectively influenced by pathologist's experience. The genome-wide transcriptional profiling was reported to accurately define the biological phenotype of the tumor. *Aims.* We have designed a novel focused oligonucleotide microarray targeted at molecular diagnostic and prognostication of lymphoproliferative disorders, particularly non-Hodgkin lymphomas. We have used the Nearest Shrunken Centroid (NSC) supervised classification algorithm (Tibshirani 2002) to test the utility of the microarray for the classification of NHLs *Methods*. The microarray based on inkjet in-situ synthesis technology contains more than 15.000 specific long-oligonucleotide probes for approximately 4.000 genes selected with emphasis on their role in lymphoproliferations as well as in crucial biological processes such as apoptosis or cell cycle control. Majority of the genes is represented by more than one distinct probe. *Results.* The classification algorithm was applied to the set of 78 NHL samples representing 3 major NHL subtypes - Follicular Lymphoma (FL), n=42, Diffuse Large B-cell Lymphoma (DLBCL), n=21 and Mantle Cell Lymphoma (MCL), n=15. For the classification the samples were randomly assigned into training and test set - 60% of samples of each NHL subtype were used to train the algorithm. The classification was performed 20 times to investigate the influence of random sampling.The NSC classification algorithm combines both gene selection and sample classification processes. For the 20 runs the best results were obtained for classifiers consisting of approximately 200 probes (median 189) translating to approximately 100 genes. The proportion of missclassified test set cases varied between 10% and 30% (median 17%), for the whole dataset the missclassification rate varied between 18% and 38% (median 27%). Most of the errors applied to wrong classification of DLBCL and FL cases, only two MCL samples were wrongly classified (in 50% and 15% of algorithm runs) both cyclin D1 negative/weak cases. *Summary*. We demonstrated successful application of gene expression based disease classification using focused microarray. The redundancy in probe coverage emerged to be an important benefit of our microarray design thus partially solving the pitfalls with probe designing such as SNPs, alternative splicing or hybridization thermodynamics. This also enhances the comparability to other microarray platforms. Our observation shows large influence of sample selection on the classification algorithm performance especially when dealing with smaller datasets. Despite the low number of cases certain NHL subtypes (MCL) can be distinguished with high confidency and even cases with aberrant phenotype could have been correctly classified.

FCGRIIIA RECEPTOR GENOTYPE DOES NOT INFLUENCE AN OUTCOME IN PATIENTS WITH FOLLICULAR LYMPHOMA TREATED WITH RISK-ADAPTED IMMUNOCHEMOTHERAPY

V Prochazka,[1] T Papajik,[1] L Raida,[1] Z Kubova,[1] E Faber,[1] K Indrak,[1] M Jarosova,[1] M Divoka,[2] J Gazdova,[2] Z Sedova,[1] L Kucerova[3]

[1]University Hospital, Olomouc, Czech Republic; [2]Molecular Genetics Lab., Dept. of Hemato-oncology, University Hospital, Olomouc, Czech Republic; [3]Dept.of Pathology, University Hospital, Olomouc, Czech Republic

Background. Antibody (rituximab) dependent cellular cytotoxicity is a key mechanism in killing $CD20^+$ lymphoma cells. FCGR3A-158 V/F gene polymorphism results in expression of 3 variants of the FcgammaI-

IIa receptor (FCGRIIIA) on cytotoxic lymphocytes with different receptor affinity. Some studies with follicular lymphoma (FL) patients treated with immunochemotherapy demonstrated better outcomes of patients with the V/V or F/V genotypes over the F/F genotype. The role of FCGR3A-158 V/F gene polymorphism in patients treated with a risk-adapted approach has not been studied yet. *Aim.* To assess whether the FCGRIIIA receptor genotype influences the treatment response quality and outcome in patients with FL treated with risk-adapted immunochemotherapy. *Methods.* We studied 102 patients with newly diagnosed FL (grades I-IIIa) who fulfilled the GELF criteria. The median age was 52 years (31-84); 92% of the patients had advanced (III/IV) clinical stages and 56% had bulky (>7 cm) disease. The FLIPI scores were as follows: low 18.9%, intermediate 33.7% and high 47.4%. Ninety-four patients had detectable bcl-2/IgH rearrangement in bone marrow and/or peripheral blood. The front-line treatment was stratified according to the commonly used risk factors (FLIPI, beta-2-m and s-TK levels, bulky disease) into 3 treatment groups: (1) patients with FLIPI 0-1 treated with (R)-CHOP (51%), (2) patients under 60 (65) years of age with intermediate-risk disease (FLIPI 2) indicated for an intensive protocol (ProMACE-CytaBOM or sequential chemotherapy) (21%), and (3) patients under 60 (65) years with high-risk disease (FLIPI ≥3) treated with intensive chemotherapy plus autologous stem cell transplantation (BEAM) (28%). Rituximab was added to front-line chemotherapy in 59% of the patients. Genotyping of the FCGR3A-158 V/F gene was performed using PCR followed by allele-specific restriction enzyme digestion. *Results.* Generally, complete remission (CR) or unconfirmed CR was achieved in 85% of the patients, 11% had partial remission and 4% stable disease. Molecular CR (CRm) was achieved in 67.4% of 86 evaluable patients. After a median follow-up of 52 months, 57% of the patients are still in the 1st CR, 30% relapsed or progressed and 13% of the patients died. Overall survival (OS) at 5 years reached 84% (95% CI 0.74-0.93); event-free survival (EFS) at 5 years was 58% (95% CI 0.45-0.71). The frequencies of FcgammaRIIIa-158 V/V, V/F and F/F were 8%, 50% and 42%, respectively. The FLIPI score distribution was not different in F/F patients as compared to V/F+V/V carriers (chi-square, P=0.7). The treatment modalities (treatment arm or rituximab administration) had the same distribution in V/V+V/F vs F/F patients (chi-square, P=0.38 and P=0.52, respectively). The CRm rates were similar in both subgroups of V/V+V/F vs F/F patients (chi-square, P=0.92). Survival curves for OS and EFS were not significantly different when comparing the subgroups of V/V+V/F vs F/F patients (P=0.28 and P=0.57, respectively). Summary: We found no difference in the quality of treatment response or survival after front-line immunochemotherapy between FCGRIIIA subgroups. Risk-adapted intensive immunochemotherapy overcomes the negative prognostic impact of the FCGRIIIA receptor genotype. The following question is whether patients with the F/F genotype will have the same benefit from rituximab maintenance treatment. *Acknowledgements.* MSM6198959205

PCR DETECTION OF NON-MTC T(11;14) TRANSLOCATIONS IN MANTLE CELL LYMPHOMA

B Tichy, J Supikova, A Mareckova, H Skuhrova-Francova, D Salek, I Vasova, J Mayer, S Pospisilova

University Hospital Brno and Medical Faculty Masaryk University, Brno, Czech Republic

Background. The translocation t(11;14) (q13;q32) is the major cytogenetic hallmark of Mantle Cell Lymphoma (MCL). This translocation juxtaposes an immunoglobulin heavy chain gene (*IGH*) transcriptional enhancer on chromosome 14q32 to the protooncogene *CCND1* encoding cyclin D1 on chromosome 11q13. The translocation could be detected either by FISH or PCR. The PCR method is especially suitable for samples with low tumor load, however it is hampered by the scattering of 11q13 breakpoints. Current PCR methods are designed for detection of breakpoints clustered in Major Translocation Cluster (MTC) on 11q13 that can be found at approximately 40% of cases only. *Aims.* We have designed a set of multiplex long-range PCR assays to extend the t(11;14) detection rate at DNA level and allow the use of this tumor specific marker for monitoring of circulating lymphoma cells by real-time PCR. *Methods.* primers were designed to tile the region of approximately 400kb centromeric of *CCND1* gene at chromosome 11 and were combined with single primer designed for chromosome 14 into the set of multiplex long-range PCR assays. The first set of PCR assays was designed redundantly - in positive cases up to three different products in different PCR assays should be obtained. Second set of primers was designed to shorten the PCR amplicon and enable rapid sequencing of the breakpoint region. *Results.* For initial testing we have used 16 DNA samples obtained from lymphnode biopsies which were PCR negative for MTC breakpoints. FISH t(11;14) assay was accomplished in 7 (44%) of these samples yielding positive result in all of them.The breakpoint region was succesfully amplified in 11 (69%) and sequenced in 7 (44%) of the 16 samples. We have obtained 3 amplicons in 2 (18%), 2 amplicons in 7 (64%) and single amplicon in 2 (18%) cases. The breakpoints on chromosome 11 were scattered over the region of approx. 200kb centromeric of the *CCND1* gene. In the set of sequenced samples *IGHJ6* gene was used in 3 (43%), *IGHJ4* gene in 3 (43%) and *IGHJ3* gene in 1 (14%) case. Of the 7 FISH analysed cases amplification product was obtained in 4 (57%) of them. The breakpoint can be detected at dilution at least 1:100 as determined by serial dilution of positive DNA. *Summary.* We have demonstrated our method for multiplex long-range PCR detection of t(11;14) can increase the overall PCR detection rate to approximately 80%. It still remains lower compared to FISH assay but the PCR method could be succesfuly used even in samples with low tumor load such as periferal blood or bone marrow.

FEASIBILITY AND SAFETY REDUCING COLONY-STIMULATING FACTORS (G-CSF) IN DOSE DENSE R-CHOP THERAPY

G Antognoli, L Rigacci, B Puccini, R Alterini, V Carrai, A Bosi

Hematology Department, Florence, Italy

Background Reducing the cycle length from 3 to 2 weeks (CHOP21 vs CHOP14) in treatment of aggressive non Hodgkin lymphoma (NHL) has been demonstrated to increase OS in young patients with good prognosis, OS and EFS in elderly patients. In these studies use of G-CSF was for 10 days (from +4 to +13). Employment of G-CSF is recommended by ASCO guidelines 2006 because it allows to respect the programmed bi-weekly chemoimmunotherapy and reduce the risk of febrile neutropenia when it's equal or greater than 20%. *Aims.* In this prospective study we evaluate the feasibility of growth factors' reduction during treatment of NHL. Our aim was to demonstrate that less number of vials of G-CSF don't significantly increase the risk of haematological toxicity and infection even if we use a dose-dense chemotherapy. *Methods.* From June 2002 to July 2009 we included 89 patients with a newly diagnosed non Hodgkin lymphoma (87% diffuse large B-cell lymphoma; 10% follicular lymphoma grade IIIb; 3% other types of NHL). The median age was 62 years (range 26-75) and 32% of patients had an high-intermediate or high IPI. Patients were treated with immunochemotherapy every 14 days: rituximab on day 1 and CHOP on day 2 followed by G-CSF (lenograstim). In first ten patients we used 7 vials of G-CSF (from +5 to +11) after each cycle of chemotherapy. According to well-tolerance of treatment we prospectively decided to administer 5 vials of G-CSF(from +7 to +11). Evaluation of therapy's tolerance was made with cell blood counts at the beginning of each cycle. Further reduction of vials, at least 3 for cycle, was accepted if patients reached a number of leucocytes over 20.000/mmc. *Results.* We used a median of 25 vials of G-CSF (range 10-35) for each patient that correspond to 5 vials for each cycle (range 0-10). Due to occurrence of severe adverse events (neutropenia, piastrinopenia , infective episodes and mucositis) therapy was delayed in 21% of patients and 3 patients switched to R-CHOP21 scheduling because of poor tolerance of dose-dense chemotherapy. Eighty-six patients out 89 (96.6%) completed treatment: incidence of neutropenia grade 3-4 was 15%, trombocitopenia grade 3-4 2%, febrile episodes 10% and hospedalization in 5.6% of patients. Leucocyte nadir was 3500/mmc (400-8400), anemia nadir was 11 gr/dL (5,8-15,5) and thrombocytopenia 146.000/mmc (43000-328000). We evaluated response to therapy in 89 patients who completed the programmed scheduling R-CHOP14: complete remission rate was 87.2% with an overall response rate of 96.5%. Overall survival was 84% after a median follow-up period of 25 months (range 4-90). *Conclusion.*s Dose-dense therapy was well tolerated by modulating, according to leucocyte count, G-CSF administration and reducing the number of G-CSF's vials from 10 to 5 for cycle. The rate of neutropenia and febrile episodes were not different from those reported by literature. The be-weekly scheduling was respected in the majority of patients even if we used a less number of vials.

0432

DEPLETION OF TUMOR CELLS AND T REG CELLS AFTER TREATMENT IN GASTRIC MALT LYMPHOMA

A Antonio, M García, B Bellosillo, B Sánchez-González, L Martínez, A Ferrer, E Gimeno, F Solé, C Besses, S Serrano, A Salar

Hospital del Mar, Barcelona, Spain

Background. The tumor microenvironment of follicular lymphoma and diffuse large B-cell lymphoma has been shown to play a critical role in the biology of these diseases. The clinical significance of T regulatory cells infiltrating B-cell lymphomas has been highlighted by immunohistochemistry studies demonstrating that an increased infiltration by FOXP3$^+$ cells correlates with an inferior outcome. However, the significance of the presence of T reg cells (FOXP3$^+$) in MALT lymphoma of the stomach remains unknown. *Aim.* To study by immunohistochemistry the presence of T reg cells in the microenviroment of gastric MALT (gMALT) lymphomas at the time of diagnosis and during follow-up, and to evaluate their possible impact in outcome. *Patients and Methods.* Patients were included in the study if they had gastric MALT lymphoma diagnosed according to the 2008 WHO criteria and diagnostic paraffin-embedded blocks were available for review. Thirty two patients met the criteria for inclusion in the study. As controls we used 7 gastric diffuse large B-cell lymphomas with MALT areas (gDLBCL) and 12 with chronic gastritis (5 pts H. pylori negative and 7 pts H. pylori positive). Sections were immunostained for CD20, CD3, CD4, CD8, CD68, FOXP3, PD-1, bcl-10 and Ki*67*. t(11;18) was studied by FISH and/or PCR and t(1;14) by FISH. Clonality study of the B cell receptor was done according to the BIOMED-2 protocol. The number of CD20+ tumor cells and FOXP3$^+$ infiltrating cells was quantified using a micrometric ocular (WPK 10 x mn) that has a 10 mm linear scale divided to 100 parts. *Results.* The median age was 63 y (range 32-83) with 50% being male. Stage: I in 65%, II in 25% and IV in 10%; B-symptoms in 6%. Translocation t(11;18) was present in 9 (28%) pts with gMALT; 2 additional gMALT cases had strong nuclear expression of BCL-10 without t(11;18) or t(1;14). At diagnosis, the mean (± standard deviation) number of CD20$^+$ tumor cells was different between patients with gMALT (674±234 cells/cm^2) and gDLBCL (499±221; P=0.078) or chronic gastritis (304±197; P<0.0001). The mean (± SD) number of FOXP3$^+$ infiltrating cells was different between patients with gMALT (30±30 cells/cm^2) and gDLBCL (12±8; P=0.008) but not with chronic gastritis (36±40; P=0.605). The mean number of CD20$^+$ tumor cells and FOXP3+ infiltrating cells was similar between gMALT with or without t(11;18). In five cases, treatment was not available or not given. Number of treatment analyzed for gMALT was 35, since 4 and 1 pts received treatment twice or 3 times, respectively. Treatment regimens included: eradication therapy (n=10); single or combined agent chemotherapy without rituximab (n=5); rituximab alone or CHOP-like with rituximab (n=4); fludarabine (n=8); fludarabine or bendamustine with rituximab (n=8). All but 1 case with t(11;18) was treated with eradication therapy alone. The first response evaluation was done 1-2 months after finishing treatment and showed an overall clinical response rate of 82% (CR 77%); persistence of residual disease by histology or molecular (IGHV) studies was seen in 29% and 56%, respectively. Elderly patients and those with nuclear expression of Bcl-10 responded worse (P=0.062 and P=0.004). The number of CD20$^+$ or FOXP3$^+$ cells at diagnosis did not have any influence in clinical, histological o molecular response. Overall, the mean (±SD) CD20$^+$ tumor cells and FOXP3$^+$ infiltrating cells was significantly reduced after treatment (729±210 vs 290±352; P<0.0001; 32±41 vs 18±36; P=0.016, respectively). The decrease of CD20$^+$ and FOXP3$^+$ cells was observed in the same pattern in cases with or without nuclear expression of Bcl-10.The mean number of CD20$^+$ tumor cells and FOXP3$^+$ infiltrating cells significantly decreased in responders (P<0.001 and P=0.031, respectively) but not in non responders (P=0.27 and P=0.25). Treatment with fludarabine or bendamustine with or without rituximab induced a more profound depletion in the number of CD20$^+$ cells in comparison with the other treatments (9-fold vs 2-fold reduction), but the average reduction of FOXP3$^+$cell was similar with all types of treatment (2-fold). *Conclusions.* The number of CD20$^+$ tumor cells in gMALT lymphoma is greater than in chronic gastritis or gDLBCL, while the number of FOXP3$^+$ infiltrating cells is similar between gMALT and chronic gastritis. Reduction of both CD20$^+$ cells and FOXP3$^+$ cells is seen in responding patients after all types of treatment. However, regimens with fludarabine or bendamustine with or without rituximab result in deeper reduction of CD20$^+$ tumor cells while infiltrating FOXP3$^+$ cells are moderately reduced. The value of monitoring CD20$^+$ and FOXP3$^+$ during follow-up is under analysis.

0433

ANTITUMOR EFFECT OF CELECOXIB AND A NON COX-2 INHIBITOR DERIVATIVE IN DIFFUSE LARGE B CELL LYMPHOMA

R Bosch,[1] I Casanova,[1] R Diéguez,[1] M Gómez,[1] M Parreño,[1] MV Céspedes,[1] J Sierra,[2] R Mangues[1]

[1]Institut de Recerca Hospital Sant Pau, Barcelona, Spain; [2]Hospital de Sant Pau, Barcelona, Spain

Background. Diffuse large B-cell lymphoma (DLBCL) is the most common of the aggressive non-Hodgkin's lymphomas. Lymphoma progression depends on survival signals mediated by a functional B cell receptor (BCR). BCR activation leads to the activation of some of the main focal adhesion proteins. Celecoxib, a selective cyclooxygenase-2 (COX-2) inhibitor, has demonstrated antineoplastic effect in combination with other drugs in patients with aggressive lymphomas. E7123 is a new synthetic derivative of celecoxib lacking COX-2-inhibitory function. *Aims.* To evaluate the antitumor activity of E7123, a celecoxib derivative, and its mechanism of action, including the involvement of focal adhesion proteins, in human DLBCL cell lines. *Material and Methods.* We used seven human DLBCL established cell lines. Antitumor activity was evaluated measuring cell metabolic capacity (viability) using the XTT test. To evaluate apoptotic induction by celecoxib or E7123, we performed nuclear staining with the Hoescht dye. We analyzed the alteration of the focal adhesion proteins and the activation of caspases by Western Blot. Subcellular distribution of p130Cas was analyzed by immunofluorescence. *Results.* Celecoxib and E7123 inhibit the viability of the DLBCL cell lines in a concentration-dependent manner. E7123 shows higher levels of cytotoxicity than celecoxib (IC_{50}= 13-17 μM and 44-63 μM, respectively), after 4 hours exposure. Both drugs induce the proteolysis of the focal adhesion protein p130Cas and the nuclear traslocation of its 31 KDa fragment. Moreover, E7123 inhibits the activation of other focal adhesion proteins such as FAK, PYK2, LYN and AKT. In addition, E7123 induces caspase-independent cell death associated with mitochondrial release of AIF. *Conclusions.* E7123 shows higher antitumor effect than celecoxib in DLBCL cells. This compound does not inhibit COX-2; thus, it may not induce the cardiovascular toxicity associated with the clinical use of COX-2 inhibitors. This is the first time that apoptosis through focal adhesion deregulation has been reported in DLBCL. Moreover, E7123 induces caspase-independent cell death, a mechanism not described among current DLBCL therapeutics. Based on these results, we are carrying out *in vivo* studies to continue the development of this drug as a potential new treatment in diffuse large B cell lymphoma.

SPECIFIC EFFECTS EXERTED BY B-LYMPHOPROLIFERATIVE DISEASES ON PERIPHERAL TLYMPHOCYTES PROTEIN EXPRESSION

MC Cox, M Borro, G Gentile, O De Luca, MA Aloe Spiriti, MS Torre, C Tatarelli, V Naso, L Aimati, B Veggia, G Antolino, B Monarca, M Simmaco

A.O. Sant'Andrea, La Sapienza University, Rome, Italy

Background. B-lymphoproliferative diseases represent a wide range of neoplastic syndromes: Hodgkin's lymphoma, aggressive and indolent lymphoma, chronic lymphocytic leukemia, plasma cell dyscrasias. Various studies describe alteration of T-cells in patients affected by such diseases (1-4) arising a great interest about the regulatory function of T-lymphocytes on B-cells pathologies. In our laboratory, we have previously demonstrated that T-lymphocytes and/or their subpopulations from peripheral blood may represent molecular sensors to be used for the evaluation of gene expression modification in physiological and pathological conditions,providing a unique and easily available biological model for integrated studies of gene expression in humans *Aims.* Here we report on the proteome profile of peripheral T-cells in patients affected by B-lymphoproliferative diseases at the onset. *Methods Subjects.* Twelve patients (4 females and 8 males, mean age 59±15) with various lymphoproliferative malignancies were selected for this study by the Haematology division of the Azienda Ospedaliera Sant'Andrea, Sapienza University of Rome, Italy. Among these, 4 were affected by diffuse_large-B-cell-lymphoma (DLBCL); 3 by follicular lymphoma (FL); 3 by classical Hodgkin's lymphoma (CHL); 2 by chronic lymphocytic leukemia (CLL). Informed consent was obtained by all patients. *Samples.* T cells were then isolated by negative selection (mean purity ≥95%) using a magnetic beads system (Pan T Cell Isolation Kit II, human, Miltenyi Biotec, Auburn, CA) and Protein separation was car-

ried out after cell lysing . Two-dimensional (2D) gel electrophoresis and MALDI-ToF mass spectrometry were used for protein separation and identification. *Interaction network analysis.* Protein-protein interaction analysis was performed using STRING (Search Tool for the Retrieval of Interacting Genes/Proteins) software version 8.1 (6). The database was queried using only experimental data as prediction method and limiting the search to no more than 100 molecular interactors, with a required minimum confidence score of 0.4 (medium level). *Hierarchical clustering of proteomic data.* Unsupervised analysis of proteomic data was performed by the GeneSpring GX 7.3 expression analysis software (Agilent Technologies). For each analysed patient, the average quantisation of spot values inside its replicate group, reported as the ratio to the average of the control replicate group, was imported as expression data. Analysis included T-cell proteome profiles of: 12 B-lymphoproliferative disorders, 10 polycystic ovary syndrome (PCO), 5 congenital adrenal hyperplasia (CAH), 2 monoclonal gammopathy of undetermined significance (MGUS), healthy subjects (single sample representative of ten pooled control subjects, as described above). Clustering was performed according to an average linkage algorithm using the following parameters: similarity measure by Pearson correlation, similar branches merged with a separation ratio of 1, minimum distance 0,001. *Results.* The analysis of the proteome profile of peripheral T-cells of patients affected by B-lymphoproliferative diseases reveals decreased levels of profilin-1 and cofilin-1 and increased levels of coronin1A and prohibitin, compared with healthy controls. The protein-protein interaction network of these proteins was studied, highlighting the actin cytoskeleton regulation as the main biological process involved in peripheral T-cells of such patients. Unsupervised cluster analysis of protein expression data shows that the recorded alteration of T-cell proteome was specifically induced by B-cells pathologies. *Discussion.* Peripheral T-lymphocytes represents easily available living biosensors, and proteins whose expression level changes significantly in specific pathological states might represent new molecular markers for follow-up testing of the disease state. All patients enrolled in this study were at the on-set of the disease, and the identified proteins differentially expressed can be regarded as markers of T-cell activation, according to many recent works reporting alterations of T-cells functionality, number and functional class balance in B-lymphoproliferative disorders (35-39). We believe it is interesting to evaluate the potential prognostic and/or diagnostic value of monitoring the expression level of these factors during the therapy.

ABNORMAL T-CELL RECEPTOR REPERTOIRE PATTERN AND REGULATORY T CELL DISTRIBUTION IN PATIENTS WITH NON HODGKIN LYMPHOMA

F Fozza, S Contini, P Virdis, A Galleu, S Bonfigli, M Careddu, D Giannico, M Longinotti

University of Sassari, Sassari, Italy

Background. Although most non Hodgkin lymphomas (NHL) take origin from the B-cell lineage, several studies suggest that any impairment involving the different branches of the immune system may play a role in their pathogenesis. Moreover the cross-talk among lymphoma cells and other cell types, such as for instance T-lymphocytes and antigen presenting cells, within the peritumoral microenvironment seem to deeply influence the onset and evolution of NHL. *Aims.* In order to explore the possible impact that the degree of activation of the T-cell immune system and the balance among different T-cell populations may have on the NHL pathogenesis, we analysed the T-cell receptor (TCR) repertoire and the distribution of different T-cell subsets -including regulatory T-cells (Treg)- in patients with NHL. *Methods.* Our study was based on a flow cytometric analysis performed on the peripheral blood of 8 patients (4 with indolent NHL and 4 with diffuse large B-cell lymphoma, DLBCL) and 15 age-matched controls. We first determined the frequency of $CD3^+$, $CD4^+$, $CD8^+$ and $CD16^-56^+$ T-cells. Treg were then identified by considering the $CD4^+$ cell fraction characterised by a very high (>2 log) expression of CD25 and by a very low (<2 log) expression of CD127, as well as by determining the expression of FoxP3 and CD152. TCR repertoire analysis was based on a panel of 24 beta variable (BV) family-specific antibodies, combined in groups of 3, one antibody being conjugated to FITC, another to PE, and the third to FITC/PE. Costaining was performed with anti-CD4/anti-CD8 PerCp. A BV expansion was defined as any value of BV family expression higher than the mean + 3 standard deviations calculated in normal controls. *Results.* We first showed that patients had reduced frequencies of $CD8^+$ cells (mean 21% vs 33%) and $CD16^+$ $CD56^+$ natural killer cells (11% vs 22%) when compared with normal controls, while $CD3^+$ and $CD4^+$ frequencies were similar. Patients also showed a higher frequency of Treg than controls (mean 2.68% vs 1.14%), although this increase was mainly confined to patients with DLBCL (mean 3.64%) rather than in patients with indolent NHL (mean 1.57%). Finally we determined the frequency of expanded T-cell subpopulations expressing the same TCR BV subfamilies, showing in patients and controls a similar frequency of expansions in $CD4^+$ cells (1% vs1%), besides an increased frequency of $CD8^+$ expansions in patients (4% vs 2%). When we looked at the possible influence of several disease-related factors, such as WHO lymphoma subtype, IPI score, presence of constitutional symptoms, bone marrow involvement and stage, only a diagnosis of DLBCL rather than indolent NHL was specifically associated with an increased frequency of $CD8^+$ lymphocyte expansions (5% vs 1%). *Summary/Conclusions.* Our preliminary data suggest that the T-cell branch of the immune system in patients with NHL show features which can be distinguished from those observed in normal controls. In particular, NHL patients seem to show an increased degree of activation of the TCR repertoire along with a higher frequency of Treg, which are both even more pronounced in patients with aggressive NHL.

LIMITED NUMBER OF GENES DISTINGUISHES BETWEEN GERMINAL CENTRE-LIKE AND NONGERMINAL CENTRE-LIKE DIFFUSE LARGE B CELL LYMPHOMA

H Votavova,[1] K Forsterova,[1] V Campr,[2] J Stritesky,[1] Z Velenska,[1] R Pytlik,[1] B Prochazka,[3] M Trneny[4]

[1]Charles University General Hospital, Prague, Czech Republic; [2]Motol University Hospital, Prague, Czech Republic; [3]National Institute of Public Health, Prague, Czech Republic; [4]Charles University in Prague, Prague, Czech Republic

Background. Diffuse large B-cell lymphoma (DLBCL) was divided into GC- (germinal centre), non-GC (non-germinal centre) and PMBL (primary mediastinal B cell lymphoma) subtypes using microarray technique. The subtypes differ in their gene expression and patients' prognosis. GC-like and nonGC-like DLBCLs were distinguished by immunohistochemistry (IHC) using CD10, Bcl6 and MUM1 proteins. IHC algorithm is less precise than gene expression and some cases remain unclassified because of borderline positivity of IHC staining. *Aims.* Our aims were to define limited number of genes significantly differentially expressed between GC- and nonGC-like DLBCLs. These genes could improve DLBCL classification. Further, we want to confirm that formalin-fixed, paraffin embedded (FFPE) tissue is material suitable for gene expression analysis. *Methods*. RNA was successfully isolated from 99% of obtained paraffin blocks. 60 patients with verified DLBCL were included. Gene expression was performed on RNA isolated from FFPE tissue and RTqPCR and $\Delta\Delta$ CT methods were used. Expression of Ki67, cyclin A2, Bcl2, MME/CD10, LMO2, CD44 a MUM1/IRF4 genes was analyzed. IHC was performed on parafin slides and DLBCL were divided into GC-like and nonGC-like groups using the algorithm by Hans et al. *Results.* 58% of included patients had nonGC-like disease. GC-like DLBCLs showed higher expression of genes LMO2 (P=0.001) and MME/CD10 (P<0.001). NonGC-like tumors showed higher expression of IRF4/MUM1 (P<0.001) and Bcl2 gene (P=0.022). In comparison to published microarray data, Ki67, CCNA2 and CD44 genes did not show different expression between GC- and nonCG-like groups when RTqPCR was performed. With obtained data discrimination function was used to generate a formula assigning new patients to GC- or nonGC-like DLBCL groups. Eight IHC borderline cases were analyzed with the formula, 5/8 (62%) were assigned as nonGC-like DLBCLs. The group of patients will be extended and clinical data will be analyzed. *Summary/Conclusions* Gene expression of MME/CD10, LMO2, Bcl2 and IRF4/MUM1 genes significantly differs between GC-like and nonGC-like DLBCL tumors. These findings can be used to improve DLBCL classification especially in IHC borderline cases. Different expression of Ki67, CCNA2 and CD44 genes found with microarray techniques was not confirmed with RTqPCR. Archive material can be successfully used for gene expression analyses. *This work was supported by Ministry of Education, Youth and Sports, Czech Republic [Grant MSMT 0021620808] and by Ministry of Health, Czech Republic [Grant NS9791-4/2008].*

TARGETING INTEGRIN/CD49D/VLA-4 WITH NATALIZUMAB CAN INHIBIT ADHESION OF MALIGNANT B CELLS AND SENSITIZE THEM TO CHEMOIMMUNOTHERAPY

M Mraz,[1] C Zent,[1] A Church,[1] D Jelinek,[2] X Wu,[2] S Pospisilova,[3] S Ansell,[1] A Novak,[1] T Witzig,[1] G Nowakowski[1]

[1]Division of Hematology, Mayo Clinic, Rochester, USA; [2]Immunology, Mayo Clinic, Rochester, USA; [3]Center of Molecular Biology and Gene Therapy, University Hospital Brno, Brno, Czech Republic

Background. Compelling evidence suggests that signals from the microenvironment of the bone marrow (BM) and lymph nodes (LN) are involved in lymphoma and CLL drug resistance. The homing of malignant B cells to LN/BM leads to adhesion, mediated by molecules such as VLA-4 (CD49d) and provides pro-survival signals for malignant B cells. VLA-4 binds fibronectin and VCAM-1 and is strongly expressed on primary lymphoma cells (FL, DLBCL,MCL) and in a subset of aggressive CLL cells. Disrupting the VLA-4 dependent adhesion and signaling is a potential strategy to overcome cell adhesion-mediated drug resistance (CAM-DR). Recently, a humanized monoclonal antibody natalizumab (Biogen-Idec) targeting CD49d/VLA-4 was approved for use in Crohn's disease and multiple sclerosis, and could thus be potentially introduced into cancer therapy if proven to be effective. *Aims.* We hypothesize that natalizumab can overcome CAM-DR by disrupting VLA-4 mediated adhesion and pro-survival signaling. *Methods.* VLA-4 expressing cell lines Karpas-422, Granta-519, and MEC-1, and primary lymphoma and CLL cells were used in this study. The ability of natalizumab to disrupt cell adhesion was assessed by adding natalizumab (10 ug/mL) to adherent cells cultivated on a fibronectin coated surface. For apoptosis studies, cells were pre-incubated with various concentrations of the active metabolite of fludarabine (F-ara-A, Sigma-Aldrich), rituximab (Genentech) and natalizumab and plated on a plastic, fibronectin coated surface, or confluent HS-5 stromal cells (HS-5 cells express fibronectin and VCAM-1). The viability of cells was assessed at different time points by flow cytometry (Annexin V/PI) and/or direct cell counting of cells stained with Trypan blue (Countess Automated Cell Counter, Invitrogen). For confocal microscopy, natalizumab and rituximab were labeled with Alexa 488/568 (Alexa Fluor Antibody Labeling Kit, Invitrogen). *Results.* Natalizumab significantly inhibited the adhesion of malignant B cells to fibronectin (90% reduction in the number of adherent cells, $P<0.005$). Importantly, natalizumab itself had no effect on the viability or proliferation of cell lines or primary lymphoma/CLL cells. Adhesion to stromal cells (HS-5) provided significant protection from F-ara-A induced apoptosis ($P<0.01$). Natalizumab reduced the protective effect of stroma by ~30% ($P<0.05$) and had no effect on fludarabine treated cells cultured in non-adherent conditions (plastic surface). Interestingly, natalizumab enhanced rituximab induced apoptosis in cells cultured on plastic, suggesting that an adhesion-independent mechanism may also play a role in the synergy between rituximab and natalizumab. Moreover, natalizumab's influence on rituximab efficacy was evident in rituximab induced complement lysis assays. Similar data were obtained for several tested primary lymphoma/CLL samples. We observed co-localization of fluorescent labeled rituximab and natalizumab on the surface of malignant B cells, suggesting that natalizumab may affect rituximab binding and cell membrane distribution. *Summary*. We have demonstrated that the adhesion mediated resistance of malignant B cells to fludarabine can be successfully overcome by targeting CD49d/VLA-4 with natalizumab. We have also shown that cell adhesion can mediate resistance to rituximab, and that natalizumab enhances rituximab cytotoxicity. Our results provide a strong rationale for the development of clinical trial(s) combining natalizumab with chemoimmunotherapy in the treatment of lymphomas/CLL.

NODAL AND NON-NODAL MANTLE CELL LYMPHOMAS DISPLAY A DIFFERENT GENOMIC PROFILE AND IGHV MUTATIONAL STATUS

I Del Giudice,[1] M Messina,[1] S Chiaretti,[1] S Santangelo,[1]S Tavolaro,[1] MS De Propris,[1] M Nanni,[1] E Pescarmona,[2] F Mancini,[1] A Pulsoni,[1] E Russo,[1] E Cavalieri,[1] E Finolezzi,[1] A Cuneo,[3] F Mauro,[1]A Guarini,[1] R Foà[1]

[1]Department of Cellular Biotechnologies and Hematology, "Sapienza" University, Ro, Rome, Italy; [2]Anatomia e Istologia Patologica, "Sapienza" University, Rome, Italy; [3]Hematology Section, St. Anna University Hospital, University of Ferrara, Ferrara, Italy

Background. Mantle cell lymphoma (MCL) bears the worst prognosis among B-cell non Hodgkin lymphomas, with a median survival of 3 years. Cases with leukemic MCL and splenomegaly without adenopathies may have a more indolent course when compared to patients with predominantly nodal disease. This difference is associated with a higher rate of mutated immunoglobulin heavy chain variable region (IGHV) genes and a less frequent expression of CD38. *Aims*. We investigated the gene expression profile of a cohort of leukemic nodal and non-nodal MCL to gain insights into the biologic features of these subgroups. *Methods*. Sixteen peripheral blood samples with >75% of clonal B-lymphocytes from untreated patients affected by MCL were evaluated by HGU133 Plus 2.0 arrays (Affymetrix). Diagnosis of MCL was supported in all cases by t(11;14)(q13;q32) and/or cyclin D1 detection. Statistical analysis, performed using the dChip software, was based on unsupervised and supervised approaches. Functional annotation and enrichment analyses were performed by DAVID and FATIGO softwares. IGHV sequencing followed ERIC recommendations. *Results.* Median age was 69 years; 10 patients (62%) were males; the median lymphocyte count was 12.3×10^9/L (4.9-140.1). Twelve cases showed splenomegaly at presentation; 9 (56%) had palpable and/or deep lymphadenopathies (nodal group), while the remaining patients had no nodes (n=7, non-nodal group). IGHV mutational status, evaluable in 15 patients, proved unmutated in all nodal MCL (one third displayed IGHV3-21 gene) and mutated in all non-nodal MCL. CD38 was positive in 8/9 nodal and 1/5 non-nodal evaluable cases. T-test selected 389 differentially expressed genes and segregated samples in 2 clusters corresponding to nodal and non-nodal groups; non-nodal MCL appeared more homogeneous than nodal cases, that grouped into 2 subclusters; one included the three IGHV3-21 cases. In the nodal group, 291 genes were up-regulated and the gene categories over-represented were: apoptosis (p-value=8.5E-03), DNA repair/response to DNA damage (p-value=7.5E-02) and, to a lesser extent, cell proliferation (P=7.9E-02). Notably, a conspicuous number of up-regulated genes were related to TP53-pathway (MDM4, TP53INP1, ZNF148). In the non-nodal group, 98 genes were up-regulated with a prevalence of the lymphocyte activation terms (P=2.8E-04). Similarly, some genes that play a role in NFKB-pathway were up-regulated: MALT1, typically altered in MALT lymphoma; TNFRSF13B that regulates B-cell homeostasis; PRDX4 and FLNA that positively regulate NFKB-pathway. It is worth mentioning that BIC was over-expressed in this series. BIC processing can generate miR155, highly expressed in Hodgkin's lymphoma, diffuse large B-cell lymphomas and chronic lymphocytic leukemia. Interestingly, the comparison between the two gene lists by FATIGO highlighted a prevalence (P=9.36E-01) of genes involved in cell adhesion (IGAE, EZR, PCDH9) in the nodal group. Given the perfect overlap between clinical presentation and IGHV sequencing, these results reflect also the differences between mutated and unmutated MCL. *Conclusions.* These findings contribute to dissect the molecular mechanisms underlying the different clinical presentation of non-nodal MCL, characterized by mutated IGHV, up-regulation of lymphocyte activation genes and down-regulation of cell adhesion genes, and offer the rationale to explore their apparent different prognosis and improve the clinical management in a broadened cohort of patients.

LFB-R603 A THERAPEUTIC CD20 ANTIBODY MEDIATES A SUPERIOR ANTITUMORAL EFFICACY IN NON-HODGKING LYMPHOMA XENOGRAFT MODEL AND B-CELL DEPLETION IN CYNOMOLGUS MONKEYS

C Dumontet,[1] S Herveau,[1] C Tournebize,[1] JL Meterreau,[2] I Esteves,[2] B Fournès,[2] F Dhainaut,[2] B Bodenant,[2] B Picot,[2] P Azam,[2] N Khandoudi,[2] M Salcedo[2]

[1]INSERM, Lyon, France; [2]LFB Biotech, Les Ulis, France

Background. LFB-R603 is an anti-CD20 antibody, characterized by a specific glycosylation pattern containing a high percentage of non fucosylated antibodies molecules at the Fc site. This pattern of glycosylation increases the affinity of antibodies for human Fc ∘ RIIIa resulting in an increased antibody dependent cell-mediated cytotoxicity (ADCC) by human Fc ∘ RIIIa-expressing effector cells. This antibody is currently in phase I clinical trial in B-CLL patients and its use may be expanded to other lymphoproliferative diseases such as non hodgkins lymphoma (NHL). *Aims.* The main objective was to study the antitumoral efficacy of LFB-R603 in comparison with rituximab in a model of human follicular NHL grown as a xenotransplant in mice. In addition this study aimed to compare the ability of LFB-R603 and rituximab to deplete normal B cells in cynomolgus monkeys. *Methods.* RL cells, derived from a patient with transformed NHL were implanted subcutaneously in SCID mice. When tumors became palpable mice were randomized to receive LFB-R603 (4 weekly intravenous injections at dose levels of 10, 30 and 100 mg/kg) or rituximab (4 weekly intravenous injections at dose levels of 30 or 100 mg/kg). In a separate experiment antibodies (30 or 60 mg/kg) were administered in combination with cyclophosphamide (50 mg/kg, intraperitoneal injection) for a total of 4 injections. Tumor volumes and weight were monitored twice weekly. Depletion of non-malignant B cells by LFB-R603 was also studied in cynomolgus monkeys. Monkeys were intravenously injected once a day for 4 consecutive days at different doses: 0.012, 0.03, 0.06, 0.12 and 0.3 mg/kg for LFB-R603 and 0.06, 0.2, 0.3, 0.6 mg/kg for RTX. B-cell depletion was measured in the peripheral blood by flow cytometry. Cynomolgus B cell depletion was also evaluated during toxicological study. In this study 0.3, 10 and 100 mg/kg of LFB-R603 were administrated and B-cell depletion was also measured in lymphoid organs. *Results.* We found that LFB-R603 displayed a dose-related antitumor activity in the RL model. Furthermore LFB-R603 possessed greater antitumoral activity than rituximab in the RL model at doses of 60 and 100 mg/kg. We also observed additive cytotoxicity of cyclophosphamide and LFB-R603 against RL xenografts. In cynomolgus monkeys dose-dependent B-cell depletion was observed in peripheral blood with both antibodies. However, the total dose required for 50% depletion calculated from the dose-effect curve showed that LFB-R603 activity was almost 6 times higher than that of rituximab. On day 15 after administration of LFB-R603 at 0.3, 10 and 100 mg/kg a marked dose-dependent reduction of B-cells was observed in lymphatic tissue (axillary lymph nodes, femoral bone marrow and spleen). This effect was reversible as for the highest dose tested analysis of B-cell depletion 113 days after treatment showed the reconstitution of the B-cell population in lymphatic tissue. *Summary and Conclusions.* Compared to rituximab LFB-R603 showed a superior efficacy in a NHL xenograft model and in B-cell depletion studies performed in cynomolgus monkeys. Moreover, an antitumoral additive effect was observed with cyclophosphamide. These results suggest that LFB-R603 possesses anti-NHL activity *in vivo*, can be combined with cyclophosphamide and may be superior to rituximab.

0439

ELIGLUSTAT TARTRATE, AN INVESTIGATIONAL ORAL THERAPY FOR GAUCHER DISEASE TYPE 1: PHASE 2 RESULTS AFTER 2 YEARS

E Lukina,[1] J Peterschmitt,[2] N Watman,[3] E Arreguin,[4] G Pastores,[5] M Iastrebner,[6] M Dragosky,[6] H Rosenbaum,[7] M Phillips,[8] M Kaper,[2] T Singh,[2] AC Puga[2]

[1]Russian Academy of Medical Sciences, Moscow, Russian Federation; [2]Genzyme Corporation, Cambridge, USA; [3]Hospital Ramos Mejia, Buenos Aires, Argentina; [4]Instituto Mexicano del Seguro Social Hospital de Especialidades, Col. La Raza, Mexico; [5]New York University, New York, USA; [6]Instituto Argentino de Diagnostico y Tratamiento, Buenos Aires, Argentina; [7]Rambam Medical Center, Haifa, Israel; [8]Sha'are Zedek Medical Center, Jerusalem, Israel

Background. Gaucher disease type 1 (GD1), an inherited lysosomal storage disorder, is characterized by a deficiency of acid β-glucosidase and accumulation of glucosylceramide in lysosomes causing organomegaly, thrombocytopenia, anemia, and bone disease. Eliglustat tartrate (formerly Genz-112638) is a novel, oral, small molecule inhibitor of glucosylceramide synthase under development for the treatment of GD1. *Aim.* To describe efficacy and safety observations in GD1 patients after 2 years of treatment with eliglustat tartrate. *Methods.* This is an ongoing, open-label, uncontrolled, multicenter, Phase 2 clinical trial of eliglustat tartrate (50 or 100 mg bid, depending on plasma level of drug) in 26 previously untreated adults with GD1. All patients had to have splenomegaly with thrombocytopenia and/or anemia. Efficacy results included changes from baseline in spleen and liver volumes, hemoglobin and platelet levels, bone mineral density, and other skeletal findings. Hematologic and visceral parameters were assessed every 3 to 6 months; MRI, DXA, and X-rays were performed yearly and reviewed centrally. Achievement of Gaucher disease therapeutic goals for anemia, thrombocytopenia, and organomegaly also was assessed at 2 years. *Results.* Two-year treatment results (mean changes from baseline±SD) are available in up to 20 patients. Hemoglobin level increased by 2.1±1.5 g/dL (11.2±1.6 to 13.3±1.5 g/dL), and platelet count increased by 81.5±56.0%, from 67,900±20,900/mm3 to 119,200±42,400/mm3. Spleen volume (as multiples of normal, MN) decreased by 52.4±10.7%, and liver volume (MN) decreased by 23.9±12.8%. Through 2 years, no bone crises or reductions in mobility were reported. Femur MRI showed improved dark marrow signal in 8 patients and stable findings in the remaining 10 patients with available data. There were no new lytic lesions or bone infarcts. At 2 years, all 9 existing lytic lesions remained stable; of 7 existing infarcts, 1 was improved and 6 remained stable. Mean lumbar spine bone mineral density improved throughout the study period. At 2 years, there was a mean improvement in DXA Z-score of 0.60±0.69 (P=0.0033; n=16) over baseline (-1.34±1.02) and a similar mean improvement in DXA T-score of 0.56±0.78 (P=0.0115; n=16) over baseline (-1.69±1.07). Data for achievement of therapeutic goals will also be presented. Eliglustat tartrate was well tolerated in this trial up to 2 years. Most adverse events (AEs) were mild and unrelated to treatment. The most common AEs reported during 2 years were viral infections (6 patients), and urinary tract infections, increased blood pressure, and abdominal pain (3 patients each). Eight drug-related AEs, all mild, occurred in 6 patients. *Summary/Conclusions.* Eliglustat tartrate has shown promising efficacy as an oral therapy for GD1. After 2 years, patients with GD1 treated with eliglustat tartrate continued to show improvements in hematologic, visceral, and bone parameters with a safety profile that supports ongoing treatment. Two controlled Phase 3 studies"'1 in untreated patients and another in treated and stabilized patients"'are currently underway.

HDAC INHIBITORS SYNERGISTICALLY ENHANCE APO866 ACTIVITY IN HUMAN LEUKEMIA CELLS: EVIDENCE FOR CONVERGING MECHANISMS OF SIRT1 INHIBITION

M Cea,[1] A Cagnetta,[1] A Garuti,[1] G Cirmena,[1] I Rocco,[1] C Palermo,[1] D Soncini,[1] I Caffa,[1] G Zoppoli,[2] I Pierri,[1] M Gobbi,[1] A Ballestrero,[1] A Nencioni,[1] F Patrone[1]

[1]University of Genoa, Genoa, Italy; [2]National Institutes of Health, Bethesda, USA

Background. Cancer cells invariably exhibit aberrant histone deacetylase (HDAC) activity leading to changes in chromatine structure, altered gene expression, poor differentiation, impaired apoptosis and increased proliferation. Accordingly, virtually all the HDAC inhibitors currently available show some degree of antitumor activity in preclinical cancer models and several of these compounds are currently under investigation or already approved for the treatment of human malignancies. Furthermore Nampt (nicotinamide phosphoribosyltransferase) inhibitors such as APO866 deplete intracellular NAD^+ stores and hold promise in the treatment of hematological malignancies. Sirtuins are a large family of deacetylases characterized by a unique, NAD^+-dependent enzymatic mechanism. Recent evidence points to an emerging role for sirtuins in carcinogenesis. We have explored the combination of traditional HDAC inhibitors with the sirtuin inhibitors in leukemic cells. *Methods.* Different leukemia cell lines (Jurkat, U936 and 697) were used. Primary leukemic cells were obtained from patients with B-CLL (n=40) and AML (n=10). Cell viability was assessed by propidium iodide staining and flow cytometry. Cell signaling and apoptotic pathways were determined by Western Blot. Mitochondrial transmembrane potential (m) and intracellular NAD^+ contents were determined by tetramethylrhodamine and HPLC, respectively. The intracellular detection of Bax lev-

els was analyzed by flow cytometriy. The role of caspase activity in the cytotoxic activity was assessed using the caspase inhibitors Z-VAD-FMK (pan-caspase inhibitor). Retroviral transgenesis was performed to engineer leukemia cells to stably express a dominant negative catalytically inactive SIRT1 isoform (H363Y) or the respective empty vector. Determination of the synergistic effect of drugs combination was calculated using the CalcuSyn software based on the Chou-Talalay method. *Results.* In leukemia cells, Nampt inhibitor APO866, which reduces intracellular NAD^+ levels, synergistically increased HDAC inhibitors mediated cytotoxicity. Among the NAD^+-dependent enzymes, we subsequently identified the sirtuin family of deacetylases as involved in this interaction, since sirtuin inhibitors, but not PARP inhibitors or CD38 genetic ablation, recreate the observed synergistic lethality. As a biochemical substrate for this interaction, we found that HDAC inhibitors downregulate SIRT1 at the posttranscriptional level, thereby increasing leukemia cell susceptibility to sirtuin inhibitors. Indeed, in the presence of the dominant negative SIRT1 isoform, leukaemia cells were more efficiently killed by APO866, and sirtuin inhibitors, confirming that pre-existing SIRT1 downregulation is a condition whereupon the activity of the sirtuin inhibitors is enhanced. Moreover, HDAC inhibitors lead to Bax upregulation and cooperated with sirtuin inhibitors to promote m dissipation. Remarkably, in healthy cells, including peripheral blood mononuclear cells, normal $CD34^+$ progenitor cells and fibroblasts, HDAC inhibitors and sirtuin inhibitors were poorly active and failed to show any cooperation, suggesting a cancer-specific mode of action. *Conclusions.* Our data indicate a specific requirement by leukemia cells for sustained sirtuin activity when classical HDACs are inhibited. In the light of these results, combined HDAC and sirtuin inhibition could potentially be advised as a therapeutic strategy for human leukemias.

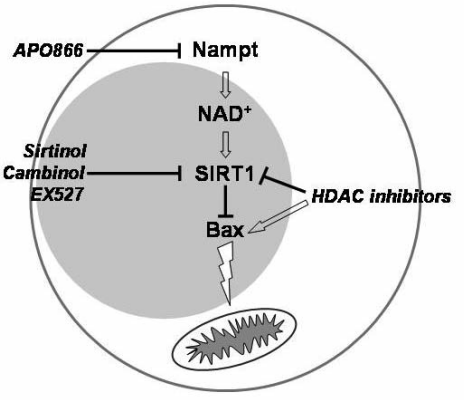

Figure. Mechanisms for the synergistic interaction.

THE ANTITUMOR ACTIVITY OF MLN9708 IN GENETICALLY ENGINEERED MOUSE MODELS OF PLASMA CELL MALIGNANCY

E Kupperman,[1] E Lee,[1] M Fitzgerald,[1] R Liu,[1] J Terkelsen,[1] D Bradley,[1] B Bannerman,[1] T Babcock,[1] L Hu,[2] J Hynes,[2] V Neppalli,[2] M Pickard,[1] Z Li,[1] O Tayber,[1] P Li,[1] M Silva,[1] A Berger,[1] L Silverman,[1] M Manfredi,[1] B van Ness,[3] S Janz[2]

[1]Millennium Pharmaceuticals, Inc., Cambridge, USA; [2]The University of Iowa Carver College of Medicine, Iowa City, USA; [3]Institute of Human Genetics, University of Minnesota, Minneapolis, USA

Background. The proteasome inhibitor VELCADE® (bortezomib) is a critical component of the chemotherapeutic strategy in treating multiple myeloma, a plasma cell malignancy (PCM). While genetically engineered mouse models (GEMMs) of cancer often accurately recapitulate their human disease counterparts, their usage in drug discovery settings have been very limited. *Aim.* Here we described the antitumor activity of a second generation proteasome inhibitor MLN9708 in the iMycCα/Bcl-XL GEMMs of PCM, in which neoplastic plasma cell development is driven by enforced expression of the Myc and Bcl-XL transgenes. *Methods.* MLN9708 immediately hydrolyzes to MLN2238, the biologically active form, upon exposure to aqueous solutions or plasma; MLN2238 was used for all preclinical studies below. We have previously demonstrated that double transgenic $iMyc^{C\alpha}$/Bcl-X_L (C57BL6/FVB) mice develop *de novo* PCM with short onset (135 days) and full penetrance (100%). We have derived a plasma cell tumor (PCT) cell line, called DP54, from the bone marrow of a syngeneic mouse previously inoculated with an $iMyc^{C\alpha}$/Bcl-X_L tumor. DP54 PCT cells were stably transfected with the firefly luciferase gene, clonally isolated, and designated as DP54-Luc cells. Nine-week-old $iMyc^{C\alpha}$/Bcl-X_L (C57BL6/FVB) mice were untreated or treated with bortezomib (1.2 mg/kg intravenously [IV] twice weekly [BIW]) or MLN2238 (18 mg/kg IV BIW) for 6 consecutive weeks and monitored for tumor-free survival for an additional 25 weeks. To establish disseminated and intraosseous mouse models of $iMyc^{C\alpha}$/Bcl-X_L PCM, freshly dissociated DP54-Luc cells were aseptically injected into the lateral tail veins and the bone marrow space of the upper right tibia, respectively, of immunocompromised mice. Once tumor growth was established, mice were randomized and treated with vehicle (5%HPbCD), bortezomib (0.8 mg/kg IV BIW) or MLN2238 (13 mg/kg IV BIW) for 3-4 consecutive weeks. The doses used represent the maximum tolerated dose for each drug treatment in each mouse strain. *Results.* In the $iMyc^{C\alpha}$/Bcl-X_L GEMM of *de novo* PCM, treatment with bortezomib and MLN2238 significantly prolonged tumor-free survival (+27 and +36 days, respectively; $P<0.0001$) and decreased plasma immunoglobulin levels compared to untreated controls. In the disseminated and intraosseous mouse models of $iMyc^{C\alpha}$/Bcl-X_L PCM, treatment with bortezomib and MLN2238 significantly reduced disease burden as measured by IVIS® bioluminescent imaging. *Summary/Conclusions.* GEMMs of cancer have often been viewed as promising alternatives to traditional subcutaneous xenograft models, yet data in which to support their wider use in drug discovery settings are sparse. Here we demonstrated that carefully implemented GEMM studies can be integrated as an important part of the drug-discovery paradigm. MLN9708 is currently in human clinical development for both hematologic and solid tumor indications.

ACTIVATION OF TOLL-LIKE RECEPTORS WITH THE ANTI-MALARIAL MEFLOQUINE INDUCES CELL DEATH IN LEUKEMIA CELLS

M Sukhai, X Li, XM Wang, R Hurren, M Gronda, H Sun, S Chow, R Bremner, D Hedley, A. Schimmer

University Health Network, Toronto, Canada

Background. Off patent drugs with previously unrecognized anti-leukemia activity can be rapidly repurposed for this new indication, given their prior safety and toxicity testing. *Aims.* We identified mefloquine, a quinoline licensed in oral formulation for the treatment and prophylaxis of malaria, as having potential anti-cancer activity, and sought to characterize its anti-leukemia properties. Methods and *Results.* We demonstrated that mefloquine decreased the viability of 9/9 leukemia cell lines with LD50~5.0 uM. Mefloquine reduced the viability of 6/6 primary AML blast samples, isolated from the peripheral blood of AML patients, with LD50 <5 uM, concentrations that appear pharmacologically achievable in patients. In contrast, it was significantly less cytotoxic to normal hematopoietic cells (LD50 > 40 uM). Given its *in vitro* activity, we evaluated the effects of oral mefloquine in mouse xenograft models of leukemia. Sublethally irradiated SCID mice were injected subcutaneously with OCI-AML2 or K562 human leukemia cells or MDAY-D2 murine leukemia cells, and treated with 50 mg/kg mefloquine, or vehicle alone, by oral gavage. Oral mefloquine decreased tumor weight and volume in all 3 mouse models without toxicity at pharmacologically relevant doses. To determine the mechanism by which mefloquine induces cell death in leukemia cells, we performed gene expression oligonucleotide array analysis of OCI-AML2 cells treated with mefloquine. At times preceding cell death, mefloquine altered the expression of genes associated with Toll-like receptor (TLR) and interferon response pathways. For example, we detected up-regulation of STAT1 and its downstream targets, additional TLR targets IRF1, IRF7 and IL-8, as well as NF-κB targets. Gene expression changes were validated by Q-RT-PCR, and NF-κB activity was confirmed with an ELISA-based DNA binding assay. In contrast, changes in TLR targets were not detected in normal dendritic cells resistant to mefloquine-induced cell death. Activation of TLR signaling and up-regulation of STAT1 can increase reactive oxygen species (ROS) generation. Therefore, we measured ROS generation after mefloquine treatment and demonstrated that mefloquine increased ROS production in leukemia cells, at times preceding and concentrations associated with cell death. Increased ROS production was functionally important for mefloquine-induced cell death, as blocking ROS production with N-acetyl-L-cysteine (NAC) abrogated mefloquine-induced cell death. However, NAC did not prevent up-regulation of STAT1, demonstrating that changes in STAT1 are upstream of ROS generation. To determine whether STAT1 signaling

is also functionally important for mefloquine-induced cell death, we evaluated mefloqine in 2fTGH bladder cancer cells and the U4A mutant line with a deficiency in JAK1 that is necessary for STAT1 activation. Compared to wild-type, JAK1 deficient cells were more resistant to mefloquine-induced cell death and had impaired upregulation of ROS after mefloquine treatment. Finally, we demonstrated that simultaneous knockdown of the TLR adapter proteins MyD88 and TRIF1 with siRNA abrogated mefloquine-induced cell death as well as mefloquine-induced ROS production. *Summary/Conclusions.* Our data demonstrate that mefloquine induces cell death in leukemia cells through its ability to activate multiple TLRs. Thus, this work highlights a new therapeutic strategy for leukemia. In addition, mefloquine could be rapidly advanced into clinical trial for patients with refractory leukemia.

COMPARATIVE STUDIES BETWEEN ERYTHROPOIETIN (EPO) AND PBI-1402, A NEW ERYTHROPOIESIS-STIMULATING AGENT (ESA), ON MURINE CANCER MODELS

L Gagnon, F Sarra-Bournet, L Geerts, K Hince, M Lagraoui, B Grouix, P Laurin, C Penney

ProMetic BioSciences Inc., Laval, Canada

Background. PBI-1402 is a first-in-class novel orally active compound which reduces the need for transfusion and increases hemoglobin (Hb) level and red blood cell count (RBC) in chemotherapy-induced anemia (CIA) patients. PBI-1402 promotes the production of erythrocytes by a mechanism of action which is distinct from erythropoietin (EPO). This mechanism involves differentiation of earlier progenitor stem cells (CFU-GEMM) than those affected by EPO (BFU-E, CFU-E). *Aim.* The objective of this study was to compare the effect of PBI-1402 and EPO on modulation of tumor growth. *Methods.* The effect of administration of PBI-1402 (200 mg/kg, oral, once a day) or EPO (200 or 2000 U/kg, s.c. injection, twice a week) was studied in a subcutaneous syngeneic murine P815 mastocytoma model. Tumor growth, metastasis, serum nitric oxide (NO) and hematocrit (Ht) were assessed. The effect of PBI-1402 (200 mg/kg, oral, once a day) and EPO (200 U/kg, s.c.) in combination with gemcitabine (50 mg/kg, i.p., once a week) was also studied in a subcutaneous syngeneic murine Lewis Lung (LL-2) cancer model. *Results.* These tumors express both PBI-1402 and EPO receptors on their cell surface. P815 tumor growth is rapid and metastasizes to the liver. Inflammation is also associated with P815 tumor growth. Oral administration of PBI-1402 significantly reduced tumor growth (Treated/Control (T/C): 37%) and tumor invasion as demonstrated by a 33% reduction of mice with liver metastasis. In comparison, EPO had no effect (200 U/kg, equivalent dose used in CKD treatment). However, high dose EPO (2000 U/kg, equivalent dose used in human cancer treatment) exacerbated tumor growth (T/C: 135%). Both doses of EPO induced a significant ($P<0.01$) increase in the percentage of mice with liver metastasis (2X, 200 U/kg, and 3X, 2000 U/kg) compared to control. PBI-1402 treatment had no effect on NO and Ht. However, treatment with high dose EPO significantly increased ($P<0.05$) NO and Ht level. The effect of PBI-1402 or EPO (200 U/kg) alone or in combination with gemcitabine was also studied in LL-2 cancer. Mice treated with PBI-1402 or EPO or gemcitabine alone had a T/C of 94%, 121% and 72%, respectively. Mice treated with a combination of gemcitabine plus PBI-1402 displayed a significant (synergistic) reduction of tumor growth (T/C: 33%). Mice that received gemcitabine plus EPO (T/C: 68%) did not show improvement compared to gemcitabine alone. *Conclusions.* These results suggest that oral treatment of PBI-1402 may inhibit growth and metastasis of cancer cells. They also suggest synergistic activity when used as adjuvant to chemotherapy. In contrast to EPO, PBI-1402 may offer the advantage of reducing tumor growth and metastasis while preventing anemia induced by chemotherapy.

THE REGENERATION PROCESS AFTER G-CSF-MOBILIZATION IN LIVER FIBROSIS IS MEDIATED BY BONE-MARROW DERIVED AND ENDOGENOUS STEM CELLS

E Tsolaki,[1] E Yannaki,[1] E Athanasiou,[1] N Zogas,[1] G Karponi,[1] M Yiangou,[2] A Anagnostopoulos[1]

[1]G.Papanicolaou Hospital, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, Thessaloniki, Greece

Recent studies have demonstrated that bone marrow (bm) cells could potentially give rise to mature hepatocytes. We have previously shown that G-CSF accelerates the recovery process in an acute liver injury model predominantly by triggering endogenous repair mechanisms and G-CSF-mobilized hematopoietic stem cells (HSCs) produce a lasting amelioration of alcoholic cirrhosis in a pilot clinical study. Given that, we investigated the contribution of bm-derived and endogenous liver stem cells (oval cells) in the regeneration process of the chronically injured liver after G-CSF mobilization by tracking the origin of cells reconstituting liver after injury. GFP mice were used as bm donors for transplantation into lethally irradiated C57Bl6 recipients. After predominant donor chimerism was determined by flow cytometry (FCM) in peripheral blood (PB) of transplanted mice, recipients were injected with 1,5ml/kg CCl4 twice a week to produce chronic liver damage. After 2 months of CCl4 treatment, G-CSF was administered intraperitoneally at 250μg/kg/day for 7 days. Control mice received no G-CSF-treatment. Lin-sca-1+c-kit+ (LSK) cells in PB were measured by FCM to determine the successful mobilization of HSCs. Hepatic fibrosis was estimated by Gomori and Masson histostains using a five scale grading system (0-IV) and by immunohistochemistry for a-sma+ cells which represent activated hepatic stellate cells producing collagen. Immunohistochemistry in liver sections for ck19, FVIII and ki67 was used to detect hepatic stem cells, to evaluate the degree of angiogenesis and to estimate the proliferation status in each condition, respectively. Double immunofluoresence for GFP/ ck8,18 and GFP/ ck19 was used to detect bm-derived mature hepatocytes (GFP^+/ $ck8,18^+$) or endogenous liver stem cells ($GFP^-/ck19^+$). Similarly, double immunofluoresence for GFP/ki-67 was used to distinguish donor-origin proliferating cells ($GFP^+/ki67^+$) from endogenous proliferating cells ($GFP^-/ki67^+$). In $CCl4^+$G-CSF-treated mice, hepatic parenchyma maintained a rather normal architecture with limited fibrosis in contrast to extensive fibrosis seen in liver sections of CCl4-treated animals. A regeneration process was evident in both groups with increased liver mitotic activity (ki-67 positivity) in the $CCl4^+$G-CSF group. In particular, G-CSF increased the fraction of bm-derived proliferating cells ($GFP^+/ki67^+$) and more significantly the fraction of endogenous regenerating cells ($GFP^-/ki67^+$). Likewise, higher numbers of both bm-derived mature hepatocytes (GFP^+/ $ck8,18^+$) as well as *in situ* hepatic stem cells ($GFP^-/ck19^+$) could be detected in G-CSF-treated than in control group. In addition, well-shaped and dense vessels were detected in liver sections of G-CSF-treated mice accompanied by increased presence of FVIII+cells in contrast to the disorganized liver microvascular network of control mice. G-CSF attenuates liver fibrosis and facilitates hepatic regeneration by both bm-derived hepatocytes and *in situ* proliferating hepatic stem cells as well as induction of angiogenesis.

0445

METHIONINE-INDUCED HYPERHOMOCYSTEINEMIA REVERTS FIBRINOLYTIC PATHWAY ABERRATIONS IN A MURINE MODEL OF ACUTE PROMYELOCYTIC LEUKEMIA

R Jacomo, B Santana-Lemos, AS Lima, AP Lima, P Assis, L Oliveira, A Garcia, L Pontes, MC Pintao, R Falcao, E Rego

Faculdade de Medicina de Ribeirão Preto, Ribeirao Preto, Brazil

Background. A major component in Acute Promyelocytic Leukemia (APL) coagulation abnormality is a hyperfibrinolytic state that may be related to a high expression of Annexin II, a receptor for both tPA and plasminogen. We previously confirmed that hCG-PML-RARα leukemic mice had a higher expression of Annexin II and higher tPA levels. Homociyteine can block tPA to Annexin II linkage at a concentration of 11 μM and hyperhomocysteinemia can be induced through oral methionine supplementation. *Aims.* We proposed to block tPA linkage site in Annexin II through methionine-induced hyperhomocysteinemia in a murine model of APL (hCG-PML-RARα). *Methods.* A bone marrow transplant leukemia model was used with cells from leukemic hCG-MPL-RARα transplanted to wild type littermates after 200-cGy irradiation. One group received no treatment (LEU), one was treated with oral methionine (MET) 200 mg/Kg (q4h, 3 doses) on day 21 and another one received LCKLSL peptide (PEP), which inhibits Annexin II - tPA linkage. Four hours after peptide administration or last dose of methionine, plasma was collected from inferior vena cava after sodium citrate infusion. We also cloned Annexin II into Pichia methanolica and protein expression was confirmed by western blot followed by protein purification in nickel affinity column. Two groups of wild type mice were infused with 10 μg/Kg Annexin II. Group ANX received no further treatment and group ANXMET received oral methionine 200 mg/Kg. Tissue plasminogen activator (tPA) and plasmin levels were measured by ELISA method. *Results.* The administration of both methionine and LCKLSL peptide reduced tPA levels in leukemic mice (Group LEU: 12.14%, Group MET: 10.54% and Group PEP 11.1% -

P<0.01). In animals infused with Annexin II there was a reduction in tPA levels in methionine treated mice (ANX: 11,63%, ANXMET: 11.03% - P<0.01) which was confirmed by Plasmin levels (ANX: 302 mg/Kg, ANXMET: 235.16 mg/Kg - P<0.001). *Conclusions.* Methionine-induced hiperhomocysteinemia lowers tPA to normal leves in this model of acute promyelocytic leukemia. The same effect was observed with LCKLSL peptide, which binds to Annexin II in the same site as homocysteine, confirming the pathway of inhibition. Furthermore, in Annexin II infused mice, administration of methionine also reverted tPA and plasmin levels to normal. We conclude that methionine- induced hyperhomocysteinemia may be a approach to control APL coagulopathy.

IDENTIFICATION OF POLO-LIKE KINASE-1 (PLK-1) AS A NOVEL DRUG TARGET IN NEOPLASTIC MAST CELLS IN SYSTEMIC MASTOCYTOSIS

B Peter,[1] K Gleixner,[1] S Cerny-Reiterer,[1] H Herrmann,[2] E Hadzijusufovic,[1] V Ferenc,[1] V Winter,[1] K Schuch,[1] W Willmann,[3] W Pickl,[1] P Valent[1]

[1]Medical University of Vienna, Vienna, Austria; [2]Ludwig Boltzmann Cluster Oncology, Vienna, Austria; [3]University of Veterinary Medicine of Vienna, Vienna, Austria

Systemic mastocytosis (SM) is a myeloid neoplasm characterized by abnormal growth and accumulation of mast cells (MC) in internal organs. In most patients, the D816V-mutated variant of KIT that confers resistance against several kinase inhibitors, is detectable. In aggressive SM or mast cell leukemia (MCL) the response to conventional drugs is poor and the prognosis is grave. Therefore current research is attempting to identify novel drug targets in neoplastic MC. Polo-like kinase 1 (Plk-1) is a serine/threonine kinase that plays an essential role in mitosis and has recently been introduced as a new target in myeloid leukemias. We analyzed the expression and function of Plk-1 in neoplastic human MC in patients with SM (ISM, n=27; ASM, n=3, MCL, n=2). As assessed by immunostaining, primary neoplastic MC were found to display activated/phosphorylated Plk-1 (pPlk-1) in all patients examined. The human MC leukemia cell line HMC-1 was also found to exhibit pPlk-1. In addition, we found that primary neoplastic MC as well as HMC-1 cells express Plk-1 mRNA. A Plk-1-specific siRNA induced apoptosis in neoplastic MC, whereas no effect was seen with a control siRNA. As assessed by 3H-thymidine uptake, the Plk-1-targeting drug BI 2536 was found to inhibit proliferation in HMC-1 cells (IC_{50} 5-10 nM) and in canine mastocytoma C2 cells (IC_{50} 10-50 nM). The effect of BI 2536 was seen in both subclones of HMC-1, i.e. in HMC-1.1 cells harbouring KIT G560V but not KIT D816V, and in HMC-1.2 cells exhibiting KIT G560V as well as KIT D816V, with comparable IC_{50} values. Moreover, BI 2536 was found to inhibit the proliferation of primary neoplastic MC. The growth-inhibitory effects of BI 2536 on MC were found to be associated with mitotic arrest and G2-M cell cycle arrest as well as consecutive apoptosis. In consecutive experiments, we found that pPlk-1 is expressed in neoplastic MC independent of KIT D816V. We therefore also asked whether combined targeting of KIT D816V and Plk-1 would lead to synergistic drug-effects. In these experiments, BI 2536 was found to synergize with midostaurin (PKC412) in counteracting the proliferation of HMC-1 cells, C2 cells, and primary neoplastic MC. In conclusion, our data show that activated Plk-1 is expressed in neoplastic MC in SM. Targeting of Plk-1 in neoplastic MC may be an attractive pharmacologic concept in advanced SM.

0447

PIFITHRIN μ ACTIVATES THE UNFOLDED PROTEIN RESPONSE IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

A Steele,[1] A Prentice,[2] A Hoffbrand,[2] K Cwynarski,[2] R Wickremasinghe[2]

[1]University College London, London, UK; [2]Royal Free and UCL Medical School, London, UK

Introduction: Deletion or mutation of p53 genes identify a poor prognosis group of patients with chronic lymphocytic leukemia (CLL). The p53 protein plays a key role in inducing apoptosis of CLL cells in response to treatment with conventional cytotoxic drugs, therefore it is important to identify novel agents which kill CLL cells by p53-independent mechanisms. We have shown that pifithrin μ (PFTμ; 2-phenylethynesulfonamide) induces selective, p53-independent apoptosis of CLL cells (Steele et al: Blood 114:1217; 2009). Although apoptosis induction by this agent apparently correlated with upregulation of the pro-apoptotic Noxa protein, the mechanism of Noxa induction was not clarified. Recent studies have shown that PFTμ is an inhibitor of the chaperone protein Hsp70 (Leu *et al*. Mol Cell 36:15; 2009), which acts to maintain cytosolic proteins in a correctly folded state. In contrast, inhibition of chaperones within the endoplasmic reticulum (ER) results in accumulation of unfolded proteins within this compartment and consequent activation of a subset of specific intracellular pathways known as the unfolded protein response (UPR). These pathways are initiated by the activation of protein kinases IRE-1α and PERK. Under normal conditions these enzymes are supressed via binding to the ER chaperone BiP. An increase in unfolded proteins within the ER sequesters BiP, thereby allowing activation of IRE-1α and subsequently of the JNK kinase. PERK is activated in an analogous manner, resulting in the phosphorylation of the transcription factor eIF2α, resulting in striking changes in the pattern of protein translation. Here we describe studies consistent with the interpretation that the PFTμ toxicity is dependent on its ability to induce the UPR via inhibition of BiP. *Aim.* To determine whether induction of the UPR by PFTμ may contribute to its ability to induce apoptosis of CLL cells. *Methods.* CLL cells were isolated and cultured *in vitro*. Molecular responses to treatment with PFTμ and/or other agents were investigated primarily by western blotting. *Results.* Treatment of CLL cells with 10-20 μM PFTμ induced phosphorylation of JNK and its target c-JUN, which are downstream of the UPR signalling protein IRE-1α. PFTμ also induced phosphorylation of eIF2α, a target of PERK. The ER chaperone BiP was elevated in response to PFTμ, reinforcing the conclusion that this agent induced the UPR. However, the cytosolic chaperones Hsp70 and Hsp40 were also elevated, consistent with an inhibition of cytosolic chaperones in addition to ER chaperones. N-acetylcysteine, a scavenger of reactive oxygen species which relieves ER stress, blocked apoptosis induction by PFTμ and also blocked induction of UPR pathways. *Conclusions.* These data suggest that PFTμ induces ER stress and the UPR signaling pathway, in addition to inhibition of cytotsolic chaperone mechanisms. This dual mode of action suggests that PFTμ may prove to be of value as a p53-independent therapeutic agent for CLL. Since eIF2α phosphorylation has been shown to augment Noxa expression (Fribley et al: J Biol Chem 281: 31440; 2006), further studies are being carried out determine whether this mechanisms represents a major route for apoptosis induction by PFTμ.

0448

ICL670 AS A THERAPEUTIC AGENT AGAINST MANTLE CELL LYMPHOMA

G Granot,[1] L Vazana-Barad,[2] R Mor-Tzuntz,[1] G Granot,[1] M Dreyling,[3] I Nathan,[2] O Shpilberg[4]

[1]Felsenstein Medical Research Center, Beilinson Hospital, Tel Aviv University, Petah Tikva, Israel; [2]Institute of Hematology, Faculty of Health Sciences, Ben-Gurion University, Beer Sheva, Israel; [3]Department of Internal Medicine [3], Klinikum der Universität, Campus Grosshadern, München, Germany; [4]Felsenstein Medical Research Center, Institute of Hematology, Beilinson Hospital, Petah Tikva, Israel

Background. Mantle cell lymphoma (MCL) is recognized as a distinct form of B-cell non-Hodgkin's lymphoma characterized by the t(11;14)(q13;q32) translocation, resulting in cyclin D1 overexpression. MCL is considered one of the most aggressive lymphoid neoplasms and one of the most challenging lymphomas to treat. To date, there is no accepted standard therapy for MCL. Several approaches including conventional chemotherapy with and without stem cell transplantation have failed to produce durable remissions for most patients. Therefore, more effective novel therapies are needed. The increasing understanding of the pathobiology of this disease enables educated use of molecular target-based therapies. In this respect, iron chelators, like ICL670, have previously been shown to exhibit antiproliferative properties. However, their effect on MCL cells has never been investigated. *Aims.* Our main goal is to study the antiproliferative effect of the iron chelator ICL670 and to reveal the biochemical mechanisms accountable for its effect in MCL cell lines. *Methods.* The effect of ICL670 was examined using the MCL cell lines: HBL-2, JEKO-1 and Granta 519. The effect of ICL670 on cell survival was assessed by XTT proliferation assay. ICL670-induced apoptosis was examined using acridine orange/ethidium bromide and Annexin V-FITC staining and analyzed by fluorescent microscope and by FACS, respectively. The biochemical mechanism involved in the ICL670-induced apoptosis was analyzed using western blot and immunoprecipitation. *Results.* The growth inhi-

bition effect of ICL670 on HBL-2 cells was determined by the XTT proliferation assay. A 50% reduction (IC_{50}) in cell viability was observed following treatment with 5.74 μM ICL670. Clinical use of ICL670 indicates that this agent is safe for human use. In agreement, we showed that normal lymphocytic cells were less sensitive to ICL670 than the MCL cell lines. We also showed that ICL670 induces apoptosis which is mediated by the upregulation of caspase-3. Analysis of the biochemical mechanism involved in the apoptosis induced by ICL670 revealed that ICL670 leads to a decrease in cyclin D1 protein levels. After incubating the cells in cycloheximide we observed that ICL670 exposure results in accelerated cyclin D1 degradation. Furthermore, pre-treatment with the proteasome inhibitor, bortezomib, followed by ICL670 exposure, resulted in complete inhibition of cyclin D1 downregulation, suggesting a role of the proteasome in cycline D1 degradation. We also demonstrated down regulation of phosphor-Rb (Ser780) expression which results in increasing levels of the E2F/Rb complex. These data indicate that the activity of the cyclin D1/cdk 4 complex is reduced following exposure to ICL670. Finally, we found that the cyclin D1 downregulation and the induction of apoptosis observed following ICL670 treatment are probably dependent on the iron chelating abilities of ICL670. *Conclusions.* We have demonstrated that the iron chelator ICL670 induces caspases-3 dependent apoptosis in MCL cell lines. The effect of ICL670 is associated with cyclin D1 downregulation and increased E2F/RB complex formation. Because iron is known to play an essential role in controlling cell proliferation, the present data indicate that ICL670, by inhibiting cyclin D1, may constitute a promising adjuvant therapeutic molecule in the strategy for MCL treatment.

THE FIRST-IN-CLASS SMALL MOLECULE INHIBITOR OF NEDD8-ACTIVATING ENZYME (NAE), MLN4924, INDUCES STABLE DISEASE REGRESSION IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA (AML)

J Carew,[1] R Swords,[1] K Kelly,[1] P Smith,[2] J Garnsey,[2] D Mahalingam,[1] E Medina,[1] M O'Dwyer,[3] K Oberheu,[1] S Nawrocki,[1] F Giles[1]

[1]CTRC at UTHSCSA, San Antonio, USA; [2]Millennium Pharmaceuticals, Cambridge, USA; [3]University College Hospital, Galway, Ireland

Background. The majority of patients diagnosed with acute myeloid leukemia (AML) are more than 60 years of age and their long-term prognosis is dismal. Pre-existing myelodysplasia, multidrug resistance, and co-existing morbidities limit therapeutic options for many patients. Novel approaches are urgently needed to improve clinical outcomes. Protein homeostasis is an important regulator of the biology of cancer cells. The NEDD8-activating enzyme (NAE) has been identified as an essential regulator of the ubiquitin-like molecule, NEDD8, which post-translationally directs the specificity of cullin-dependent E3 ubiquitin ligases. The cullins control the timely ubiquitination and subsequent degradation of many proteins with important roles in cell cycle progression, DNA damage, stress responses, and signal transduction. We hypothesized that disrupting NEDD8-mediated control of protein turnover would inhibit proliferation and induce cell death. We tested this hypothesis by investigating the preclinical anti-leukemia activity of MLN4924, a novel first-in-class small molecule inhibitor of the NEDD8-activating enzyme. *Aims.* To determine the preclinical activity of MLN4924 in AML. To elucidate the mechanism of action of MLN4924 in AML cells. *Results.* Nanomolar concentrations of MLN4924 (mean IC_{50} = 211 nM) selectively and potently inhibited the *in vitro* growth and survival of MOLM-13, PL-21, MV4-11 and HL-60 cells and primary AML cells from patients with different clinical and molecular features. MLN4924 treatment also dramatically disrupted colony formation and led to a dose-dependent induction of apoptosis. Co-culturing AML cells with human stromal cells did not significantly impact the pro-apoptotic activity of MLN4924. This indicates that MLN4924 can overcome the survival advantage provided by stroma. Similarly, MV4-11 cells with and without stable shRNA-mediated knockdown of FLT3 expression responded equally to treatment with MLN4924. This suggests that MLN4924 may be an effective agent for patients with FLT3 ITD and/or activating mutations in FLT3, which are associated with inferior outcomes to conventional induction therapy. Inhibition of NAE activity with MLN4924 produced a time-dependent decrease in the levels of NEDDylated cullins leading to stabilization of cullin-dependent substrates (p27, CDT-1, NRF-2, and phopsho-IκBα) and activation of the DNA damage sensor, CHK1. Treatment with MLN4924 resulted in decreased NFκB DNA-binding activity and reduced expression of key NFκB targets. Treatment with MLN4924 led to a significant increase in reactive oxygen species (ROS) generation. The antioxidant N-acetyl-cysteine significantly blunted apoptosis indicating that ROS production is an important event in MLN4924-induced cell death. The *in vivo* anticancer activity of MLN4924 was evaluated by administering MLN4924 or vehicle control to mice implanted with HL-60 xenografts. MLN4924 treatment led to a dose-dependent decrease in disease burden and 10/10 animals in the groups treated with 60 and 90 mg/kg experienced stable regressions. Analysis of specimens collected from animals following administration of a single dose of MLN4924 demonstrated *in vivo* inhibition of cullin NEDDylation and accumulation of phospho-IκBα. *Conclusions.* MLN4924 is a very promising novel inhibitor of NAE that has potent preclinical activity and has advanced into a Phase I clinical trial for the treatment of AML.

IMMUNOTHERAPY OF RECURRENT B-CELL MALIGNANCIES IN ADULT AND PAEDIATRIC PATIENTS WITH FBTA05, A TRIFUNCTIONAL ANTIBODY (ANTI-CD3 X ANTI-CD20) AND ALLOGENEIC DONOR LYMPHOCYTE INFUSION

R Buhmann,[1] M Stanglmaier,[2] F Schuster,[3] B Simoes,[1] H Menzel,[4] P Ruf,[5] C Peschel,[4] H Lindhofer,[2] A Borkhardt,[3] HJ Kolb[1]

[1]Helmholtz Center Munich, Munich, Germany; [2]Trion Research GmbH, Munich, Germany; [3]Department of Paediatric Oncology, Haematology and Immunology, Duesseldorf, Germany; [4]Medical Clinic III, Klinikum rechts der Isar, TU, Munich, Germany; [5]TRION Research GmbH, Munich, Germany

Background. Donor lymphocyte infusion (DLI) after allogeneic stem cell transplantation (allo-SCT) displayed limited use in recurrent B-cell malignancies in paediatric and adult patients. *Objective*. Here we studied whether FBTA05, a novel trifunctional bispecific antibody targeting CD20 on lymphoma cells and CD3 on T cells, could augment graft-versus-leukaemia/lymphoma (GvL) effects while reducing the risk of undesirable reactivity against normal host cells. *Method/Study-Design*. In compassionate use, 2 children (high-grade non-Hodgkin´s lymphoma (HG-NHL)) and 8 adults (four patients with HG-NHL and four patients with p53-mutated chronic lymphocytic leukaemia (CLL)) refractory to standard therapy were treated with escalating doses of FBTA05 (range 10-2,000 microgram) and DLI after allo-SCT. *Results.* With respect to the adult patients, three out of the four CLL cases showed a prompt but transient clinical and haematological response. In one patient with HG-NHL a halt in progression for almost 4 months could be observed. In one of the children an ongoing (7 month) response, characterized by a complete disappearance of the mediastinal tumour bulk could be observed. In both, children and adults, side effects (fever, chills and bone pain) were tolerable and appeared at antibody dose levels between 40 and 200 μg. Moreover, none of the responders evaluable for graft-versus-host disease (GvHD) (survival >100 days following DLI) revealed clinical signs of active GvHD although repeated applications of DLIs up to 1×10^8 T cells/kg body weight were performed. The cytokine profile was characterized by transiently increased release of IL-6, IL-8 and IL-10. Plasma concentrations of FBTA05 reflected differences in treatment, but strictly correlated with the corresponding dosing schedules. The highest plasma concentration of FBTA05 with 0.38 microgram/mL was detectable after application of 2,000 microgram FBTA05 accompanied by the rapid clearance of antibodies within few days. So far no significant correlation with tumour burden or disease activity could be established. *Summary/Conclusions.* In summary, FBTA05 induced prompt anti-tumour responses in treatment-refractory patients. Moreover, the absence of GvHD after repeated courses of DLI indicated the potency of FBTA05 to redirect the graft-related allogeneic response towards lymphoma cells. Based on these encouraging results, a clinical phase I/II dose-escalation study of FBTA05 in combination with DLI in adult patients with CD20-positive low and high grade B-cell lymphoma after allo-SCT is now initiated.

0451

NOVEL ANTI-CD20 MONOCLONAL ANTIBODY WITH HIGH ADCC ACTIVITY AGAINST LOW DENSITY CD20-EXPRESSING TARGETS

M Salcedo, C De Romeuf, N Fournier

LFB Biotechnologies, Courtaboeuf, France

Background. LFB-R603 is an IgG1 anti-CD20 with increased antibody depending cell cytotoxicity (ADCC) activity via improved IgG1 binding to CD16 due to its glycosylation pattern. *Aims.* This study aimed to study the ability of LFB-R603 to mediate effective killing of targets bearing very low density of CD20 target molecules at the cell surface after

engagement of a limited effector cell number. *Methods.* We investigated the relationship between enhanced ADCC induced by LFB-R603 and antigen density on target cells using either Raji tumor cell line cells, CD20-transfected JY5 cells (JY E5.1 cells) or B-CLL patient-derived B cells bearing around 500 000, 100 000 or 20 000 CD20 molecules per cell respectively. We further investigated the impact of effector cell (E) number on ADCC mediated by LFB- R603 or rituximab of the target Raji cell (T). ADCC experiments were performed at two different E/T ratios, 5/1 and 50/1. *Results.* Results showed that LFB-R603 is able to mediate high ADCC of JY E5.1 as well as patient-derived B-CLL cells while rituximab could only mediate weak ADCC of the same targets. EC50 of lysis mediated by LFB-R603 was reached at a concentration of 0.93 ng/mL for Raji cells, 3.8 ng/mL for JY E5.1 cells and 5 ng/mL for patient derived B-CLL cells. The amount of rituximab needed to reach these levels of lysis (LFB-R603 EC50 levels) was 35 ng/mL for Raji cells, 525 ng/mL for JY E5.1 cells and >5000 ng/mL for patient-derived B-CLL cells, showing that lysis mediated by rituximab is much more sensitive to antigen density on target cells than lysis mediated by LFB-R603. We showed that maximum lysis values were 20% lower at 5/1 ratio compared to 50/1 ratio for both LFB-R603 or rituximab. However, the amount of LFB-R603 needed to reach EC50 of lysis at both 5/1 and 50/1 E/T ratios was lower than that of rituximab (LFB-R603 EC50 5/1=0.16 ng/mL, 50/1=0.14 ng/mL; rituximab EC50 5/1=2.15 ng/mL, 50/1=7.27 ng/mL). *Summary and Conclusions.* Our data showed that LFB-R603 was able to mediate high ADCC of target cells expressing low CD20 density in contrast to rituximab and that LFB-R603-mediated killing at low E/T ratio was more effective than rituximab-mediated one.

INTRAFISTULAR INJECTION OF AUTOLOGOUS BONE MARROW-DERIVED MESENCHYMAL STROMAL CELLS FOR THE TREATMENT OF REFRACTORY PERIANAL CROHN'S DISEASE

M Mantelli,[1] ME Bernardo,[1] V Achille,[2] MA Avanzini,[1] R Ciccocioppo,[3] A Sgarella,[4] ML Russo,[3] F Bonetti,[1] M Scabini,[5] C Perotti,[6] R Maccario,[1] G Corazza,[3] F Locatelli[7]

[1]Oncoematologia Pediatrica, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy; [2]Unità Epidemiologia Clinica, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy; [3]Clinica Medica I, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy; [4]Chirurgia Epatopancreatica, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy, [5]Servizio di Diagnostica per Immagini, Fondazione IRCCS Policlinico S.Matteo, Pavia, Italy; [6]Servizio Immuno-Trasfusionale, Fondazione IRCCS Policlinico S.Matteo, Pavia, Italy; [7]Ospedale Bambin Gesù, Roma, Italy

Fistulas are an invalidating, often difficult to treat, complication of patients with Crohn's disease (CD), a disabling, chronic, relapsing inflammatory enteropathy caused by dysregulation of the immune tolerance towards intestinal bacteria in genetically susceptible individuals. Mesenchymal stromal cells (MSC) have been proved to be endowed with relevant immunomodulatory properties and represent a promising tool in therapeutic approaches of regenerative medicine, as well as in immune-mediated diseases. MSC administered either intravenously infused or locally injected into colon tissue surrounding mucosal lesions proved to be of benefit in an experimental murine model of CD. Moreover, local injection of autologous, adipose tissue-derived, MSC has been already employed in clinical practice to treat complex perianal fistulas of cryptoglandular origin or associated with CD, with promising results. We investigated the feasibility, safety and efficacy of local injection of autologous bone marrow (BM)-derived MSCs for refractory CD fistulas. MSCs were isolated and expanded ex vivo in the presence of platelet lysate from BM of 12 patients (7 males, median age 33 yrs, range 16-59). Patients received intrafistular injection of MSCs scheduled every 4 weeks (median 4 infusions) and were monitored at time of each injection, and 1, 3, 6, 12 months after the last treatment. The cytokine profile of MSCs and their ability to influence apoptosis of mucosal T cells obtained from involved and uninvolved colonic areas were also analyzed. MSC expansion was successful in all patients and no adverse event was recorded during and up to 12 months after treatment. Intrafistular injection of MSCs was effective in inducing sustained closure of fistulas, with the appearance of regenerative tissue along the tracks. In particular, 7 patients (70%) benefited from complete and sustained healing of fistula tracks, while three had partial response. All patients showed a significant reduction of both CD Activity Index (pre- and post-treatment median values: 294 SD 49 and 99 SD 32 at 6 months after the last infusion; P<0.001) and Perianal Disease Activity Index (pre- and post-treatment median values: 13.0 SD 2.2 and 4.5 SD 2.4 at 6 months after the last infusion; P<0.001) reaching disease remission usually after the second procedure. The immunephenotype of circulating T lymphocytes showed progressive increase of the number of $CD4^+CD25^{bright}FoxP3^+$ cells, which became significant (P<0.01) after the second procedure and remained stable up to 6 months after the last infusion. No modification of serum cytokines was observed at any time point. MSCs caused a sort of block of the rates of both apoptotic and living cells when incubated with T lymphocytes from diseased mucosa, whilst critically increased the apoptotic rate when incubated with T lymphocytes from apparently healthy mucosa. We speculated that a number of locally injected MSC might be able to circulate in blood and/or lymphatic stream and to reach lymph node germinal centres, thus influencing T cell differentiation. These observations highlight crucial points related to MSC distribution and homing, which deserve further investigations. Local injection of autologous BM-derived MSCs appeared feasible, safe and successful in treating fistulas associated with CD.

0453

GA101 IS A HIGHLY EFFICACIOUS TYPE II ANTI-CD20 MONOCLONAL ANTIBODY THAT INDUCES DIRECT CELL DEATH BUT LOW COMPLEMENT MEDIATED CYTOTOXICITY IN B-CLL WHOLE BLOOD ASSAYS

L Bologna,[1] J Golay,[1] E Gotti,[1] A Rambaldi,[2] T Intermesoli,[2] M Introna[1]

[1]Laboratory of Cellular Therapy G.Lanzani, Bergamo, Italy; [2]USC Hematology Ospedali riuniti di Bergamo, Bergamo, Italy

Background. Understanding the mechanism of action *in vivo* of therapeutic MAbs is fundamental to improve their efficacy. Unconjugated antibodies currently investigated for the treatment of B-chronic lymphocytic leukemia include anti-CD52 alemtuzumab, anti-CD20 rituximab and more recently third generation glycoengineered anti-CD20 antibody GA101. *Aim*. We have set up a whole blood assay using B-CLL samples with the view of :1) having a rapid assay to test the efficacy of novel antibodies against B-CLL or normal B cells in the circulation, 2) having a tool to dissect the role of different mechanisms of target cell killing by MAbs in a context as unmanipulated as possible. *Methods.* B-CLL whole blood samples in citrate (0.1M) were incubated for various times with alemtuzumab, rituximab or GA101 and/or blocking anti-C5 antibody Eculizumab. Death of $CD19^+$ B-CLL was measured by FACS analysis. *Results.* We first demonstrated that direct cell death, complement mediated cytotoxicity (CDC) and phagocytosis induced by different MAbs were not significantly inhibited by citrate used at the standard concentration for anti-coagulant activity (0.1 M). We then compared the efficacy and mechansim of action of alemtuzumab, rituximab and GA101. Alemtuzumab efficiently lysed B-CLL targets with maximal lysis reached already at 1-4 hours with 10 μg/mL antibody (62%). Rituximab instead induced more limited cell death (21%) with maximal lysis only at 24 hours. Lysis by both alemtuzumab and rituximab was fully complement dependent since it was inhibited by at least 90% in presence of excess blocking anti-C5 antibody eculizumab. Interestingly GA101 killed B-CLL targets with more rapid kinetics than rituximab with 19.2.% vs 23.5% cell death at 4 and 24 hours, respectively, compared to 7.9% and 21.4% for rituximab. Lysis by both Rituximab and GA101 correlated directly with CD20 expression levels (R^2=0.88 and 0.85, respectively). GA101 required at least 10 times higher concentrations than rituximab to induce equivalent complement activation, and lysis of B-CLL in whole blood was due to complement for only 50-65%. Indeed GA101 induced direct cell death of purified B-CLL or B lymphoma cell lines in addition to CDC, and this cell death involved the lysosomal pathway. Both rituximab and GA101 showed in contrast the same efficiency in phagocytosis assays but phagocytosis was low in whole blood due to excess human immunogloulins.*Conclusions.* We conclude that the major activity of alemtuzumab and rituximab in the circulation is through complement. In contrast GA101 induces both CDC and direct cell death in an additive manner. The latter may explain the major efficacy of GA101 with respect to rituximab against B-CLL samples in whole blood assays.

0454

SELECTIVE INHIBITION OF THE CHYMOTRYPSIN-LIKE ACTIVITY OF IMMUNOPROTEASOME AND CONSTITUTIVE PROTEASOME REPRESENTS A VALID ANTI-TUMOR STRATEGY IN WALDENSTROM MACROGLOBULINEMIA (WM)

A Roccaro,[1] A Sacco,[2] M Aujay,[3] T Ngo,[2] F Azab,[2] A Azab,[2] P Quang,[2] P Maiso,[2] S Demo,[3] G Rossi,[1] M Ghobrial[2]

[1]Spedali Civili di Brescia, Brescia, Italy; [2]Dana-Farber Cancer Institute, Boston, USA; [3]Onyx Pharmaceuticals, Emeryville, CA, USA

Background. Selective inhibition of chymotrypsin-like (CT-L) activity of constitutive-(c20S) and immuno-(i20S) proteasome represents a successful strategy to induce anti-neoplastic effect in malignancies. We therefore studied ONX0912, a novel selective, irreversible inhibitor of CT-L activity of i20S and c20S. *Aims.* To evaluate the distribution of i20s and c20S in WM primary cells as compared to the related normal cellular counterpart. To evaluate the role of selective inhibition of CT-L activity of i20s and c20s as an anti-tumor strategy in WM. *Methods.* WM and IgM-secreting-low-grade-lymphoma-cell lines; bone-marrow (BM)-primary CD19$^+$cells and BM stromal cells (BMSC) were used. Expression of i20S and c20S subunits (beta1/beta2/beta5; LMP2/MECL1/LMP7) were detected in primary WM cells and cell lines by an ELISA-based-assay. Cytotoxicity/DNA synthesis/cell cycle/apoptosis were measured by thymidine uptake/MTT/PI staining/flow cytometry analysis/DNA fragmentation, respectively. NF-kB activity has been evaluated using a DNA-binding ELISA-based assay. Cell signaling and apoptotic pathways were determined by Western-Blot. Determination of the additive or synergistic effect of drugs combination was calculated using the Chou-Talalay-method (CalcuSyn-software). *Results.* Primary BM-derived WM cells present with higher expression of immunoproteasome as compared to the constitutive-proteasome. ONX0912 inhibited the C-L activity of both the immunoproteasome and the constitutive-proteasome, leading to induction of toxicity in primary WM cells; as well as to apoptosis in a caspase-dependent and -independent-manner, as shown by activation of c-jun-N-terminal-kinase; inhibition of NF-kB; and initiation of the unfolded-protein-response. PR-047 induced cytotoxicity and inhibited DNA synthesis in primary WM cells; IgM-secreting-low-grade-lymphoma cells; and exerted cytotoxicity even in the context of BM milieu, by inhibiting BMSCs-induced Akt- and ERK-phosphorylation in WM cells. Moreover, combination of ONX0912 and bortezomib induced synergistic cytotoxicity in WM cells, as shown by enhanced caspases-, PARP-cleavage; and NF-KB-inhibition. *Conclusion*. These findings suggest that targeting i20S and c20S CT-L activity by ONX0912 represent a valid anti-tumor therapy in WM.

0455

FONDAPARINUX VERSUS ENOXAPARIN TREATMENT IN WOMEN WITH INFERTILITY OR PREGNANCY LOSS

E Winger, J Reed

Laboratory for Reproductive Medicine & Immunology, San Francisco, USA

Background. Unexplained miscarriage and infertility affect approximately 6% of couples trying to start a family. Immunologic and clotting disorders have been reported in many of these patients. Enoxaparin has been a preferred anticoagulant therapy due to its relative safety and effectiveness in pregnancy. However, it requires more frequent dosing compared with newer anticoagulants such as fondaparinux. *Aims.* We compared the pregnancy success rates and safety parameters of fondaparinux versus enoxaparin, combined with immunotherapy, in patients with a history of miscarriage and/or infertility and coagulation defects. *Methods.* A total of 126 pregnancies in patients with a history of miscarriage and/or infertility were retrospectively evaluated. Of these, 63 pregnancies used fondaparinux 2.5 mg daily and 63 pregnancies used enoxaparin 30 mg twice daily. The treatment groups were similar in terms of maternal age (37.1±4.3 versus 36.8±4.5 years), the number of previous miscarriages (2.2±1.8 versus 2.4±1.8 losses), and maternal immunologic and thrombophilic status. Elevated antiphospholipid antibodies were present in 41% (26/63) of patients administered fondaparinux and 43% (27/63) of patients administered enoxaparin. Elevated NK cytotoxicity (K562 killing at an effector: target ratio of 50:1) was present in 44% (28/63) of patients administered fondaparinux and 52% (33/63) of patients administered enoxaparin. Inherited thrombophilia (polymorphism of one or more of the following genes: heterozygous or homozygous factor V Leiden R506Q, prothrombin G20210A, or plasminogen activator inhibitor 4G/5G; homozygous methylene tetrahydrofolate reductase (MTHFR) C677T; or compound heterozygous MTHFR C677T/A1298C) was present in 63% (40/63) of patients administered fondaparinux and 73% (46/63) of patients administered enoxaparin. The most common immunotherapy protocol used in the two groups was IVIG [(87% (55/63) versus 81%(51/63)] and corticosteroid [57%(36/63) versus 75%(47/63]. Informed consent was obtained by all patients for off label use of relevant drugs. The study was approved by the Institutional Review Board (WIRB Study Number 1094182). Patient confidentiality was strictly maintained. *Results.* The pregnancy success rate was 67% (42/63) for patients receiving fondaparinux and 67% (42/63) for patients receiving enoxaparin. No difference was detected in birth weight (2.8±0.7 and 3.0±0.8 kg, respectively) or gestational age at delivery (37.7±2.3 and 38.1±2.8 weeks, respectively). Vaginal bleeding occurred in 14% (9/63) of fondaparinux-treated patients and 17% (11/63) of enoxaparin-treated patients (P=0.81), typically between 7 and 9 weeks of gestation. No birth defects, severe bleeding-related complications, or serious allergic reactions were observed. *Summary/Conclusions.* In women with miscarriage and /or infertility treated with a combination of immunotherapies and anticoagulants, fondaparinux is well-tolerated and enables successful pregnancy outcomes at a rate comparable with that of enoxaparin therapy. Because fondaparinux also offers more convenient once-daily dosing and, in previous studies, fewer side effects than enoxaparin, we propose that fondaparinux may offer an attractive therapeutic alternative to enoxaparin in immune-treated pregnancy. Although equivalent outcomes were observed in our analysis, a larger study is required to achieve statistical power.

0456

PRECLINICAL EVALUATION OF CPX-351 LIPOSOME INJECTION IN COMBINATION WITH CLOFARABINE AND HYPOMETHYLATING AGENTS

D Mayer, J Udechukwu, Y Fan, O Harasym

Celator Pharmaceuticals, Vancouver, Canada

Background. We have shown that delivering synergistic cytarabine (Cyt):daunorubicin (Daun) drug ratios *in vivo* using nano-scale liposomes (CPX-351 Liposome Injection) provides dramatic efficacy improvements compared to the free drug cocktail in a wide range of preclinical leukemia models. Clinically, CPX-351 is being developed with the intent to replace conventional "7+3"Cyt:Daun therapy. Given the limited success in the clinic to combine newly developed agents for hematological malignancies with 7+3 Cyt:Daun, we examined whether CPX-351 could provide an enhanced therapeutic outcome in combination with purine antimetabolites such as clofarabine and hypomethylating agents such as azacytidine using a bone marrow-engrafting acute leukemia xenograft model. *Aim.* To determine the therapeutic benefits of combining CPX-351 with recently approved hematological malignancy drugs. *Methods.* The maximum tolerated dose (MTD) of individual drugs as well as drug combinations was determined in non-tumor bearing mice using a Q2Dx3 iv dosing schedule for CPX-351 as well as free Cyt:Daun cocktail and QDx5 ip dosing of clofarabine and hypomethylating agents. Antileukemic efficacy was determined at MTD doses for the drug combinations compared to the individual components in Rag-2M mice bearing bone marrow-engrafted CCRF-CEM human leukemia with treatment starting 21 days after leukemia cell inoculation. Therapeutic activity was determined by monitoring treatment-induced increases in life span compared to saline-treated control mice. *Results.* Combining clofarabine and azacytidine with free Cyt:Daun cocktail required a 2-fold dose reduction of Cyt:Daun (from the MTD in the absence of the added agents) in order to avoid mortality and achieve tolerable weight loss. Under these conditions, the combination treatments utilizing free drug cocktail provided minimal increase in life span (ILS) compared to the individual treatment components and absolute antileukemic activity was modest (ILS values of 24% and 27% for free drug cocktail treatments combined with clofarabine and azacytidine, respectively). Although these agents also caused the need for dose reductions when combined with CPX-351, the degree of therapeutic improvement for the combination treatment was improved over the individual components and absolute anti-leukemic activities of CPX-351-containing combinations was significantly greater than those achieved for combinations utilizing the Cyt:Daun cocktail. This effect was most pronounced for CPX-351 combined with azacytidine (ILS values of 47% and 62% for combinations containing clofarabine and azacytidine, respectively). *Conclusions.* CPX-351 was designed to enhance the antitumor efficacy of cytarabine:daunorubicin combination therapy by encapsulating both agents within a drug carrier that maintains the synergistic 5:1 molar ratio for extended times after injection. This agent

may also enhance therapeutic activity when used in combination with recently approved hematological malignancy drugs such as clofarabine and hypomethylating agents compared to combinations of these new agents with conventional Cyt:Daun therapy.

0457

THE NOVEL DNA INTERCALATOR AMONAFIDE (AS1413), DISRUPTS THE CELL CYCLE BY MECHANISMS DISTINCT FROM THOSE OF TOPO II INHIBITORS DAUNORUBICIN AND ETOPOSIDE

S Sederovich,[1] D Jones,[1] A Ajami,[2] F McLaughlin[1]

[1]Antisoma Research Limited, Welwyn Garden City, UK; [2]Antisoma Inc, Cambridge, MA, USA

Background. Amonafide-L-malate (amonafide, AS1413) is a novel DNA intercalator that induces apoptosis through mechanisms involving Topoisomerase II. Previous studies have indicated that amonafide has a number of important properties that differ from those of classical TopoII poisons: 1. Amonafide is not a substrate for Pgp, MRP-1 or BCRP, resistance mechanisms that may contribute to treatment failure with classical TopoII inhibitors. 2. Amonafide is a non-quinodal napthylamide derivative, which is structurally unrelated to anthracycline or anthracenedione classes of antileukemic agents. It therefore lacks the redox and free radical reactive pharmacophores associated with the cardiotoxicity of the anthracyclines. 3. While amonafide exerts cell killing by acting on the Topoisomerase II cycle, it does not form cleavable complexes. Further work on elucidating the action of amonafide on the Topoisomerase II cell cycle is outlined here. *Results.* Cell cycle analysis was performed on the AML cell lines Thp1 and KG1. Cells were exposed to AS1413, etoposide or daunorubicin at IC_{50} doses for 24 hours (etoposide and daunorubicin) or 48 hours (amonafide). Amonafide exposure resulted in a G2/M cell cycle arrest. Further analysis of the G2/M checkpoint by microscopic analysis of metaphase spreads from cells exposed to IC_{50} levels of amonafide showed that approximately 10% of the cells were arrested in metaphase (with chromosomes clearly visible), a higher proportion than seen in untreated cells. Furthermore, there was evidence for DNA bridge formation between cells which were not fully divided, indicating inhibition in metaphase. In contrast, etoposide treatment resulted in a G2/M arrest, with no cells visible in metaphase. Daunorubicin exhibited a G1/S arrest; while this was unexpected, the mechanism of action of daunorubicin has been shown to be less cell cycle specific, so this effect may be specific for the cell lines tested here. Again, no cells were arrested in metaphase. Cell cycle regulators such as p21 were up-regulated to a greater extent after exposure to amonafide than after etoposide or daunorubicin treatment. Further investigation of pharmacodynamic markers indicative of AS1413 clinical activity will be carried out. *Conclusions.* Amonafide has shown activity in AML, a setting where anthracyclines are currently used. The findings outlined here and the other distinctive properties of amonafide, notably evasion of multi-drug resistance mechanisms, suggest that amonafide could offer a clinical profile distinct from that of classical TopoII poisons. The value of replacing an anthracycline with amonafide is currently being tested in a large randomised phase III trial comparing amonafide plus cytarabine with daunorubicin plus cytarabine in patients with secondary AML.

0458

LONG-TERM RESULTS OF 2-CHLORDEOXYADENOSINE AND CYTOSINE ARABINOSIDE COMBINATION THERAPY IN PEDIATRIC PATIENTS WITH REFRACTORY LANGERHANS CELL HISTIOCYTOSIS.

G Solopova,[1] V Sunsova,[1] D Baidildina,[1] A Khachatryan,[2] V Goronkova,[1] A Novichkova,[1] A Maschan,[1] A Maschan[1]

[1]Federal clinical research center for pediatric hematology, oncology and immunol, Moscom, Russian Federation; [2]Federal Clinical Research Center for Pediatric Hematology, Oncology and Immunol, Moscom, Russian Federation

Background Langerhans cell histiocytosis (LCH) is a rare disease which results from clonal proliferation of pathologic Langerhans cells. Overall prognosis varies from favorable to grim depending on risk organ (RO+: liver, spleen, bone marrow and lungs) involvement and early response to therapy. Standard therapy of multisystem (MS) LCH is based on vinblastin and prednisone combination. According to recent international trials, overall survival in patients with RO involvement is 69%, and in non-responders to initial treatment - less than 20%. Since 1994 2-Chlorodeoxyadenosine (2-CdA) was reported to be effective in refractory and relapsed forms of LCH. Effect in patients with risk organ involvement is limited. 2CdA is a purine analog with established activity in hairy cell leukemia and acute myeloid leukemia. *in vitro* studies demonstrated synergism of 2-CdA and cytosine arabinoside (AraC). *Aim.* The aim was to evaluate response rate, long-term results and toxicity of combination 2-CdA + AraC therapy in patients with RO+ LCH refractory to standard treatment. *Methods*. Seven patients (6 boys and 1 girl) with RO+ LCH, refractory to initial treatment, were enrolled between 2001 and 2006. Median age at disease presentation was 11,3 months (1 month - 2,4 year). Six patients were treated with LCH II protocol and 1 patient with LCH I protocol as initial therapy. After 6 weeks of therapy disease progression was documented in 5 patients and stable active disease in two. Combined 2CdA+AraC therapy was started after 6 weeks of standard therapy in 4 patients, 11 weeks - in 1 patient. Two patients received 2CdA+AraC after several courses of multi-agent chemotherapy. Therapy details are presented in Table 1. *Results.* Transient stabilization of disease (improvement of hepatosplenomegaly, lymphadenopathy and skin rash) with subsequent fulminant progression and death was seen in 2 patients. Five patients achieved non-active disease status. Four of them had complete response. One developed cirrhosis as permanent consequence of disease. This patient died of bleeding from esophageal varices. Median interval from first line treatment start to 2CdA+AraC therapy was 60 days (37-138 days). In non-survivors there was a tendency for longer delay of salvage therapy (median 87 days vs 41 days, P=.0571. At last follow-up (median 6 years, range 3.7-7.3 years) 4 patients are alive with complete resolution of disease manifestations. No reactivations and no permanent consequences were observed. One patient has viral hepatitis C. Acute toxicity included in all cases CTC grade IV neutropenia, thrombocytopenia and anemia and life-treating infections that universally required inpatient care. No long-term toxicity was observed. *Conclusions*. 2CdA+AraC combination therapy demonstrates significant activity in refractory RO+ LCH. Earlier application may give greater chance for cure. This therapy should be provided in centers able to provide high quality AML-type supportive care.

Table 1.

№	Initial treatment	Status at 6 weeks	Therapy details	Status at the end of treatment	Status at last follow-up
1	LCH I	Progression	2CdA 5 mg/m^2/day N5, AraC 200 mg/m^2/day N5 - 2 courses	Progression	Death, disease progression
2	LCH II	Progression	2CdA 7 mg/m^2/day N5, Dauno 45 mg/m^2/day N3; 2CdA 7 mg/m^2/day N5, AraC 1000 mg/m^2/day N5; 2CdA 7 mg/m^2/day N5, AraC 1000 mg/m^2/day N5 + Ida 8 mg/m^2/day N3	Complete response	Alive
3	LCH II	Progression	2CdA 8 mg/m^2/day N5, AraC 1000 mg/m^2/day N5 – 4 courses	Complete response	Alive Hepatitis C
4	LCH II	Active disease	2CdA 8 mg/m^2/day N5, AraC 1000 mg/m^2/day N5 – 3 courses	Complete response	Alive
5	LCH II	Progression	2CdA 9 mg/m^2/day N5, AraC 1000 mg/m^2/day N5 – 3 courses (+ Dauno 45 mg/m^2/day N2 in course 3)	Progression	Death, disease progression
6	LCH II	Active disease	2CdA 6 mg/m^2/day N5, AraC 1000 mg/m^2/day N5 – 3 courses	Non-active desease Hepatic cirrhosis	Death, upper GI bleeding
7	LCH II	Progression	2CdA 6 mg/m^2/day N5, AraC 1000 mg/m^2/day N5 – 3 courses	Complete response	Alive

THE IMPACT OF A TREATMENT FREE INTERVAL ON MULTIPLE MYELOMA PATIENTS QUALITY OF LIFE: A UK CROSS-SECTIONAL OBSERVATIONAL SURVEY

S Acaster,[1] S Gaugris,[2] A Lloyd,[1] G Velikova[3]

[1]Oxford Outcomes, Oxford, UK; [2]Janssen-Cilag Ltd, High Wycombe, UK; [3]St James's Institute of Oncology, Leeds, UK

Background. Multiple myeloma patients may experience a period of remission following their first line therapy. The degree to which this period is treatment-free will be dependent on the chemotherapy regimen received and whether a maintenance therapy was administered. However, the impact of a treatment free interval on patients' health related quality of life (HRQoL) is currently unclear. *Aim.* The aims of this study were to assess if a) during the treatment free interval (TFI) patients have higher HRQoL vs. during treatment phases; b) the length of the TFI is associated with better HRQoL. *Method.* A cross-sectional postal survey was undertaken. Patient demographics, current myeloma treatment phase and treatment details were collected. HRQoL was assessed using the EORTC QLQ-C30 (cancer specific), the MY-20 (multiple myeloma specific), and the EQ-5D (generic). Participants were identified by Myeloma UK who sent the survey to patients listed on their database (n=605). The TFI data was analysed using ordinary least square regressions; an unadjusted critical alpha of 0.05 was used given the exploratory nature of the study. The EQ-5D utility and VAS scores and each functional domain of the EORTC QLQ C30 and MY20 were included as dependent variables. In order to address the aims of the study two sets of regression analyses were conducted; one with comparative treatment phases as the predictors (1st TFI vs. first line therapy, 1st TFI vs. second line therapy and 1st TFI vs. later stage) and the other with TFI length as the predictor. *Results.* The survey response rate was 67%. Out of the 402 responses received, 370 were eligible for analysis, based on the provision of current treatment stage data. Out of the 370 patients, 12 were in first line therapy, 177 in their 1st TFI, 59 in second line and 122 in later phases of myeloma treatment. Statistically significant differences were found in favour of the 1st TFI versus the first line treatment for the EQ-5D-VAS and two domains of the EORTC QLQ-C30. Being in a 1st TFI relative to the second line treatment phase or the later phases was also significantly associated with higher HRQoL as assessed by numerous domains of the EORTC QLQ-C30, the MY-20 and the EQ-5D, with some indication that this difference was greater in later treatment phases (Table 1). A longer TFI was significantly associated with better 'physical' and 'role' functioning on EORTC QLQ C30, 'future perspectives' and 'body image' domains of the MY20 and the EQ-5D derived utility value. *Conclusion*. This survey found that both being in a TFI and experiencing a longer TFI were significantly associated with higher QoL as measured by some domains of the EORTC QLQ C30, MY20 and EQ-5D. Given these findings and the limitations associated with cross sectional studies, longitudinal observational studies are needed to further explore the QoL benefit associated with a treatment free interval.

Cuore, Rome, Italy; [8]Innsbruck University Hospital, Innsbruck, Austria; [9]AZ Saint-Jan AV, Brugge, Belgium; [10]University of Freiburg, Freiburg, Germany: [11]Hospital Casa Sollievo della Sofferenza, S. Giovanni Rotondo, Italy; [12]Purpan Hospital, Toulouse, France; [13]Kunming Medical University, Kunming, China; [14]University of Bari, Bari, Italy; [15]National Taiwan University, Taipei, Taiwan; [16]CHC - Centre Hospitalier Chrétien, Liege, Belgium

Background. Improving quality of life (QoL) and alleviating symptoms are the major goals of treatment in patients with myelodysplasia (MDS). However, empirically-based information about these patients' QoL and experienced symptoms is lacking. There is a pressing need to gain insight into the disease burden and the health status areas that are of major concern to better inform patients and to eventually support medical decision making. *Aims.* To compare the mean pretreatment QoL and symptom scores of patients with high-risk MDS with population-based reference values and to compare the mean pretreatment QoL and symptom scores between high-risk MDS patients differing in age, gender and risk. *Methods.* Newly diagnosed patients with intermediate-2 or high-risk IPSS score are recruited in an international prospective observational study involving 15 countries and 41 centers. Patients were classified according to the WHO histology classification and a number of socio-demographic, clinical and laboratory variables were collected prior to treatment. These included: comorbidity, performance status, platelets, hemoglobin, neutrophils, white blood cell counts, and transfusion dependency. To date, 70 patients are enrolled. QoL and symptoms were measured in the hospital using the EORTC QLQ-C30. Its standardized scores range from 0-100, with higher scores representing higher levels of functioning or higher levels of symptoms. This questionnaire has undergone rigorous linguistic cross-cultural validation and was available for all patients in the appropriate language. Mean QoL and symptom scores were compared to general population reference values, adjusted for age and gender. Statistical comparisons were adjusted for multiple testing. Differences in mean scores were expressed in Cohen effect sizes (ES; with 0.2, 0.5, and 0.8 indicating small, medium, and large ES, respectively) and clinical significance (at least 10-point difference). *Results.* Median age of patients was 73 years (45% female and 55% male) and 86% was diagnosed with IPSS int-2 risk score and 14% with IPSS high risk score. Most patients were classified as WHO, RAEB-2 (69%). When compared to general population reference values, all functioning and symptom scores indicated statistically significant impairment (P<0.01). Physical and social functioning were the most impaired functional domains with ES of 0.7. These differences were also clinically meaningful with a mean difference of 11 and 13 points, respectively. Symptoms mostly impaired were fatigue (ES= 0.9), constipation (ES=0.9) and appetite loss (ES= 1.2) all showing clinical relevance (13 to 20 points difference). No major differences were found in QoL profiles and symptoms between male and female. Older patients (< 73 versus >73 years) had clinically significant worse health outcomes only as for physical functioning and constipation. Patients classified as high-risk IPSS had a clinically significant worse profile than those with int-2 risk score mainly in terms of appetite loss and fatigue (mean scores: 23 versus 44 and 40 versus 65 respectively). *Conclusions.* Patients with MDS report a seriously impaired QoL and a high symptom burden, even prior to treatment. This knowledge can alert clinicians to better identify and treat key QoL and symptoms, particularly fatigue, constipation and appetite loss. We continue accruing patients to obtain a larger sample size to further investigate and confirm these findings.

0461

HEALTH RELATED QUALITY OF LIFE IN YOUNG HAEMOPHILIA PATIENTS FROM 9 EUROPEAN COUNTRIES IN THEIR TRANSITION FROM ADOLESCENCE TO ADULTHOOD - THE HYQOL-EUROPE STUDY

S Von Mackensen,[1] R Klamroth,[2] A Gringeri[3]

[1]Institute of Medical Psychology, Hamburg, Germany; [2]Haemophilia and Haemostaseology Centre, Vivantes Clinics Friedrichshain, Berlin, Germany; [3]A. Bianchi Bonomi Haemophilia and Thrombosis Centre, University of Milan, Milan, Italy

Background. Adolescents and young adults with haemophilia are concerned by maturation and aspects such as transition from adolescence to adulthood and independence and problems related to self-management of treatment and integration in job and adult life. Their health-related quality of life (HRQoL) is not only influenced by the disease and its treatment, but also by educational, vocational and relational changes associated with transition from adolescence to adulthood. *Aims.* The HyQoL-Europe - 'Helixate treated young Haemophiliacs' Quality of Life' Study was designed to provide a deeper insight into HRQoL in order to evaluate the role of transitional events and impact on haemophilia treatment. HRQoL and psychosocial determinants such as sexuality, religious beliefs, physical activity and adherence to treatment in haemophilic adolescents and adults will be assessed. Moreover, the study will identify key transitional life events that might have an impact on HRQoL such as living situation, partnership and professional situation. *Methods.* In this prospective, longitudinal, multicenter, non-interventional study 150 patients aged 14-35 years, affected by moderate or severe haemophilia A using Helixate from 9 European countries are enrolled. HRQoL is assessed by means of generic (SF-36, EQ-5D) and disease-specific (Haemo-QoL, Haem-A-QoL) questionnaires; physical functioning (HEP-Test-Q) and activity level (short EPIC Norfolk index) are evaluated with validated instruments. In addition psychosocial determinants such as sexuality, religious/spiritual beliefs, etc. are assessed with ad-hoc developed questionnaires. Clinical data are collected by physicians on bleeding history, treatment modalities, orthopaedic status, etc. by means of a modular constructed medical documentation. All evaluations will be carried out at baseline and yearly for 3 years. Differences in HRQoL will be estimated across countries or project regions and between different patient groups (e.g., adolescents vs. adults, family status, personal life circumstances, etc.). *Results.* 9 countries from 3 regions in Europe have been identified capturing different socio-economic situations and cultural aspects allowing a variety of different transitional situations (Regions: I: Germany, Austria, Switzerland, II: France, Belgium, Netherlands, III: Greece, Italy, Spain). So far, 6 patients have been enrolled from Italy. *Conclusions.* The HyQoL-Europe Study together with its sister project in Canada are the first studies looking at the crucial period of transition in the life of young haemophilia patients.

0462

DEVELOPMENT AND VALIDATION OF A HAEMOPHILIA-SPECIFIC QUESTIONNAIRE FOR THE ASSESSMENT OF HEALTH-RELATED QUALITY OF LIFE IN ELDERLY HAEMOPHILIACS (HAEM-A-QOLELDERLY)

S Von Mackensen,[1] A Gringeri,[2] SM Simona,[2] P Mannucci[2]

[1]Institute of Medical Psychology, Hamburg, Germany; [2]A. Bianchi Bonomi Haemophilia and Thrombosis Centre, University of Milan, Milan, Italy

Rationale. Life expectancy of people with haemophilia (PWH) has increased enormously over the last 3 decades resulting in more PWHs reaching an old age. This is due to the improvement of haemophilia care, however, only few information are available on how this impacts on patients' well-being and health-related quality of life (HRQoL). For the adequate assessment of HRQoL standardised and validated instruments are necessary. Only one geriatric-specific HRQoL instrument is available for elderly people (WHOQOL-OLD), but no haemophilia-specific instrument exist for elderly haemophilia patients. In the frame of a retrospective case-control study the first haemophilia-specific HRQoL questionnaire for elderly patients was developed and validated. *Methods.* The validated disease-specific Haem-A-QoL questionnaire for the assessment of HRQoL in adult haemophilia patients was adapted for elderly patients (Haem-A-QoLElderly), since not all domains were applicable for elderly persons (such as work, family planning). Focus groups with physicians and with elderly haemophilia patients were conducted. Statements of these focus groups were content analysed and additional aspects were formulated as items and included in the existing version of the Haem-A-QoL. The pre-final version of the Haem-A-QoLElderly consisted of 106 items on a five-point Likert scale pertaining to 14 dimensions (physical health, feeling, view, family, friends, perceived support, others, sport/leisure time, work, dealing, treatment, centre, future, sexuality) and one total score. The Haem-A-QoLElderly was filled in by haemophilia patients ≥65 years and psychometrically tested for reliability (Cronbach's alpha, test-retest-reliability) and validity. Convergent validity was determined by means of the Pearson correlation coefficients comparing the Haem-A-QoLElderly scales with the generic EQ-5D, WHOQOL-BREF and WHOQOL-OLD. Discriminant validity was tested for clinical subgroups such as invalidity, orthopaedic status, viral infections and number of bleeds. *Results.* 39 haemophilia patients with a median age of 68 years (65-78) filled in the Haem-A-QoLElderly, representing 84.6% of all severely affected elderly haemophilia patients registered in Italy. 85% had haemophilia A, 21% received prophylactic treatment and 37% reported chronic pain. In average 8.6 joint bleeds were reported in the past 12 months. Patients suffered from viral infections (87% chronic hepatitis C, 13% HIV) and inhibitors (13%) and impairments were found in their orthopaedic joint status (OJS: M=19.8+15.2). Psychometric analyses showed that the newly developed Haem-A-QoLElderly has good values for internal consistency ranging from Cronbach's α=.647-.931 for the subscales and for the total score α=.964. Haem-A-QoLElderly showed good discriminant validity for invalidity, orthopaedic joint status, number of bleeds and chronic pain. The final questionnaire consists of 63 items pertaining to 11 dimensions. Elderly patients were mainly impaired in the dimension 'sport' (M=59.01+32.6), 'physical health' (M=49.72+31.0) and 'view of themselves' (M=49.30+27.3). In a linear regression model including infections, no of total bleeds, invalidity, OJS, marital status and depression 65.3% of the variance in Haem-A-QoLElderly could be explained only by depression. *Conclusions.* It could be demonstrated that the Haem-A-QoLElderly is a reliable and valid instrument for the assessment of HRQoL in elderly haemophilia patients. Since depression has the greatest impact on HRQoL compared to other predictors, special care should be provided to this patient population.

0463

ASSESSING SYMPTOMS IN HEMATOLOGY FROM THE PATIENTS' PERSPECTIVE: FEASIBILITY OF A PATIENT REPORTED INSTRUMENT IN CLINICAL RESEARCH

C Cartoni,[1] F Efficace,[2] A Tendas,[3] P Niscola,[4] G Brunetti,[5] MG Marini,[6] L Reale,[6] C Minotti,[7] P Finsinger,[7] MG Loglisci,[7] V Federico,[7] E Meloni,[8] F Mandelli[9]

[1]Policlinico Umberto I, Sapienza University, Rome, Rome, Italy; [2]Gimema, Rome, Italy; [3]Hematolology, S. Eugenio Hospital, Rome, Italy; [4]Hematology, S.Eugenio Hospital, Rome, Italy; [5]Hematology, Policlinico Umberto I - Sapienza University, Rome, Italy; [6]Fondazione ISTUD, Milan, Italy; [7]Hematology, Policlinico Umberto I, - Sapienza University, Rome, Italy; [8]Italian Association against Leukemias, Lymphoma and Myeloma (AIL), Rome, Italy; [9]GIMEMA, Rome, Italy

Background. Patient Reported Outcome (PRO) assessments introduce the patient's perspective into the clinical research process via standardized and methodologically sound self-report questionnaires. Appropriate PRO instrument selection, however, require careful attention of a number of issues (e.g. disease stage and phase of treatment, concerns about respondent burden and feasibility and sensitivity of the measure being used). *Aims.* To investigate the feasibility and sensitivity of a validated cancer patient-reported symptom tool (MD Anderson Symptom Inventory-MDASI) in patients with hematologic malignancies. To investigate pattern of symptoms prevalence of patients in curative phase or palliative phase of treatment. *Methods.* Patients with various hematological diseases are being enrolled in a prospective study comparing a number of outcomes between those followed in a hospital-based setting versus an home-care-based program. A number of socio demographic and clinical laboratory data are collected including: comorbidity, functional independence (ADL scale), neutrophils, white and red blood cell counts and haemoglobin level. To date a total of 86 patients have been included. Patient symptoms are being measured with the MDASI which consists of 19 items (i.e. 13 items assessing symptom severity and 6 items assessing symptoms interference with various aspects of the patient's life). Items are rated on a numeric rating scale from 0 to 10, with the higher scores indicating a higher level of symptoms or a higher symptom interference. The symptom items were classified according to the following scores: mild (1-4), moderate (5-6) and severe (7-10). Descriptive statistics and linear regression analy-

ses were used. All statistical comparisons were adjusted for multiple testing. *Results.* Baseline data are available for 86 patients (26% curative phase and 74% palliative phase). Mean age was 65 years with 48% being female and 52% male. The majority of patients were diagnosed with acute myeloid leukemia (42%), non Hodgkin lymphoma (20%) and myelodysplastic syndromes (10%). Accuracy of questionnaire completion was optimal with more than 80% of patients completing all items. The percentage of missing items was low ranging between 1% to 5% (symptom interference with work activity). The top three moderate to severe symptoms in terms of prevalence in patients in palliative phase of treatment were: fatigue (80%), dry mouth (57%) and distress (54%). In patients undergoing curative treatment top three moderate to severe symptoms were: fatigue (50%), lack of appetite (46%) and nausea (38%). Details on mean symptom scores for both patient populations are reported in Figure 1 suggesting also the MDASI being able to discriminate different profiles in haematological patients based on type of treatment (curative vs. palliative). Except for lack of appetite, vomiting and nausea, all mean scores were statistically significant different at (P<0.05). Means of symptom interference for those in curative and palliative phase of treatment were 4 (SD=2.5) and 6.6 (SD=2.5) respectively, indicating symptoms severity having a higher impact on patients' life undergoing palliative treatments. *Conclusions.* The results suggest the MDASI being a feasible tool that can be successfully implemented in haematological research; it is sensitive to different populations undergoing various treatments. Regardless of patients' stage, fatigue is the most relevant symptom identified by this measure.

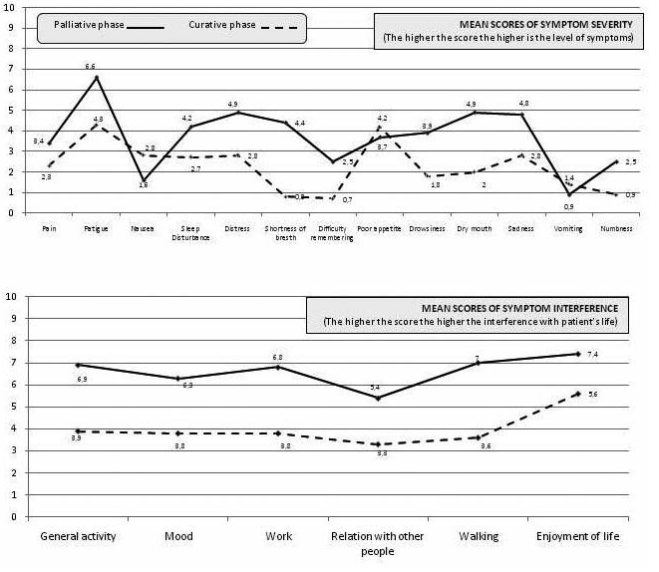

Figure 1. MDASI: symptom burden of patients in palliative or curative phase of treament.

0464

EFFECTS OF DIFFERENT TREATMENTS ON GERIATRIC ASSESSMENT AND QUALITY OF LIFE PARAMETERS IN ELDERLY MDS/AML PATIENTS

B Deschler, G Ihorst, M Lübbert

University Freiburg, Freiburg, Germany

Background Treatment allocation of elderly patients (pts) with MDS/AML to either intensive or non-intensive approaches remains difficult. In order to optimally inform the pt about different treatment options, it is essential to obtain insight into the possible development of dependence, frailty, depression and quality of life (QOL) during/after treatment. Geriatric and QOL assessment is an in-depth evaluation permitting to objectify a number of these variables. Very little is known about the development of subjective and objective parameters relevant to elderly pts under different treatment options. Aims. To study the development of parameters of a geriatric and QOL assessment in pts with MDS/AML ≥60 years over a period of 6 months under three different therapeutic approaches. *Methods.* The study cohort included all pts >/= 60 years with the initial diagnosis of MDS/AML (2004-2008) at the University Hospital Freiburg for treatment initiation. The instruments applied included those recommended for a comprehensive geriatric assessment (ADL; IADL, Comorbidities (HCT-CI), 'timed up and go test', Mini Mental State Examination (MMSE), Geriatric Depression Scale (GDS)) as well as performance status (Karnofsky Index) (PS) and items of the QOL questionnaire EORTC C-30 (global QOL, fatigue). A first assessment was performed at time of respective treatment start. To avoid attrition, only data of 119 surviving pts were evaluated for descriptive statistics, calculation of relevant deterioration/improvement in follow-up parameters and comparison between treatment groups best supportive care (BSC), hypomethylating agents (HA) and induction chemotherapy (IC). *Results.* Follow-up assessments were conducted after a median of 140 days of treatment:15.1% (n=18) BSC, 30.2% (n=36) HA and 54.6% (n=65) IC. Median age was 74.5 yrs (range 64-83), 72.5 yrs (62-82) 67 yrs (60-77) for BSC, HA and IC groups, respectively. AML (WHO) was evident in 88 (73.9%) pts. Significant differences between the following baseline parameters could be detected between treatment groups: PS BSC 73.9±13.3, HA 82.4±12, PS IC 74.9±10.6 (P=0.0093), HCT-CI BSC 3±2.3, HA 1.7±1.5 and IC 2.7±2.1 (P=0.032). At follow-up, global QOL and fatigue showed a marked improvement in 31.2% of BSC, 41.6% of HA and 39.7% of IC pts and in 50% of BSC, 44.4% of HA and 53.9% of IC pts, respectively. About 1/3 of all pts experienced a deterioration/decrease in these parameters regardless of treatment. Geriatric assessment detected new dependencies (ADL/IADL) in 11.7-32.3% of pts, while depression and cognitive changes became obvious in 4.7-24.2% of pts. PS decreased in 37.5% of BSC, 49.9% of HA and 35.4% of IC pts. *Summary/Conclusions* Geriatric and QOL assessment evokes awareness of relevant changes in elderly MDS/AML pts that might otherwise be unnoticed. Parallel to the occurrence of new dependencies and impairments that became apparent to very similar degrees in surviving pts across all treatment groups, global QOL deteriorated in 1/3 of pts. Focused interventions according to the results of repeat geriatric and QOL assessments may ameliorate impairments and dependencies.

DEVELOPMENT AND FEASIBILITY OF A PATIENT-REPORTED SYMPTOM CHECKLIST FOR CHRONIC MYELOID LEUKEMIA PATIENTS

F Efficace,[1] M Breccia,[2] M Baccarani,[3] G Alimena,[2] G Lambertenghi Deliliers,[4] G Specchia,[5] F Cottone,[1] M Vignetti,[1] F Mandelli[1]

[1]Italian Group for Adult Hematologic Diseases (GIMEMA), Rome, Italy; [2]University of Rome La Sapienza, Rome, Italy; [3]University of Bologna, Bologna, Italy; [4]University of Milan, MIlan, Italy; [5]University of Bari, Bari, Italy

Background. Patient Reported Outcome (PRO) instruments are now crucial to evaluate overall treatment effectiveness in oncology. While, these are broadly available for several cancer populations, there is lack of tools for patients with hematologic malignancies. Particularly, no PRO instrument exist for CML patients. *Aims.* To report early development of a brief patient-reported symptom measure to be used with CML patients undergoing treatment with Imatinib (IM) and evaluate patients' acceptance and feasibility in clinical research. *Methods.* This development followed various steps. Preliminary literature search was carried out to identify relevant issues for this patient population using several electronic databases (i.e. MEDLINE, EMBASE, CINAHL and PSYCHINFO). The list of potential issues/themes generated from the literature search was then presented to health care professionals (including clinicians and research nurses) for feedback on appropriateness of content and breadth of coverage. The list was also pilot tested on a small sample of CML patients for further refinement and issues were then operationalised into questions. Item response were designed as a 4 point Likert scale ranging from 'not at all' to 'very much' with standardized scores ranging between 0 and 100 (i.e. higher scores indicating higher symptom intensity). This checklist was then administered to a larger sample of patients in treatment with IM as part of a study investigating a number of health outcomes. Descriptive statistics were used for the sociodemographic and clinical data to characterize the sample. Distribution of missing values was investigated and Pearson's correlation coefficients between items were calculated. Discriminant validity was assessed by comparing sub-samples that were expected to differ in their symptomatology. Statistical comparisons were adjusted for multiple testing. *Results.* The literature search yielded some 300 potential articles that were independently scrutinized by two authors. Only 12 articles dealt with PRO issues in CML patients, thus additional literature dealing with IM toxicity was searched. Feedback for relevance ensuring content validity was received from 10 healthcare professionals and 11 CML patients. The list was eventually reduced to 9 key items. Analysis was then undertaken on a sample of 249 CML patients with a median age of 56 years (62% male and38% female). The large major-

ity (78%) in treatment with IM at a dose of 400 mg. Fatigue, muscle cramps and edema had the highest mean scores being 41 (SD=27), 39.6 (SD=27) and 34 (SD=29) respectively. Patients' acceptance was optimal with missing items ranging from 0 to 1.2%. Out of 36 possible correlations among the checklist items: 81% were weak (r<0.40); 19% moderate (r=0.40-0.60) and none was strong. The checklist was able to discriminate between gender, showing significant worse scores for female in all symptoms except for diarrhea and skin problems (P<0.05). The checklist was also able to capture statistically significant different profiles (P<0.05) for patients with associated co-morbidity. *Conclusions.* The use of this 9 items checklist is feasible in CML patients and it targets important side effects of IM treatment. Further development is ongoing in a larger international setting within the EORTC Quality of Life Group to eventually devise an EORTC CML questionnaire.

0466

RISK FACTORS FOR INEFFECTIVE COPING IN ACUTE LEUKEMIA PATIENTS

A Parvu,[1] L Petrov[2]

[1]Oncological Institute Cluj-Napoca, Cluj-Napoca, Romania; [2]University of Medicine and Pharmacy, Cluj-Napoca, Romania

Background. Coping with cancer, in general, and acute leukemia, in particular represents a dynamic process influenced by medical, psychological and social issues. Many psychooncologists emphasize that some patients adapt better than others and psychosocial support services cannnot yet be offered to every patient. For this reason it is important to determine wich patient is at greatest risk of developing adjustment problems in order to offer them psychological support. *Aims.* Identification of risk factors for developing an ineffective coping in acute leukemia patients *Methods.* We have interviewed 100 acute leukemia patients in various disease stages and various therapeutically steps treated in the Hematology Department Clinic, Cluj-Napoca during November 2007-May 2009. Patient interviews were conducted using a questionnaire divided in an introductory part (consisting in obtaining informed consent and explaining the reason of the intervew) and 10 specific sections. The following topics were pursued: analysis of the way the diagnosis was communicated and the patient`s psychological reaction to diagnosis; the five-stage process of coping with the malignant diagnosis (denial, anger, bargaining, depression, acceptance); identification of factors with a facilitating effect in overcoming an ineffective coping and developing an effective coping; interval from diagnosis to acceptance; the level of acceptance; evaluation of patient internal and external resources; understanding different types of coping with malignant disease symptoms and therapy side effects; coping with substitution therapy with blood and blood products; coping with death of a fellow patient; taking self-blame for the disease; disease effect on patient's life on a personal, family, professional and social level; family behavior regarding the disease; self-assessment of coping. Based on the interviews, we evaluate the efficiency of coping (from a psychosocial counselor's and a haematologist's perspective) and the statistical significance of correlations between coping and 25 other variables (such as patient personality traits, patient`s demographic characteristics, disease-related and treatment-related issues, diagnosis communication, diagnosis acceptance, time passed to diagnosis acceptance, isolation in hospital, patient's psychological resources, selfblaming for the disease and others). Data was analyzed using SPSS. Statistical significance for various qualitative variables association was evaluated using the Pearson's chi-square test and Fisher Freeman-Halton's exact test in cases when at least 20% of the expected count less than 5. The study has the agreement of Ethic Committee of the Medicine and Pharmacy University Cluj-Napoca, Romania. *Results.* Risk factors for inefficient coping in acute leukemia patients are: lack of sense of humor (OR=12.6, 95% CI: 1.45-109.39); lack of fighting spirit (OR=23.33, 95% CI: 3.94-138.098). Inefficient coping in acute leukemia patients is statistically significant associated with; lack of sense of humor (P=0.008<0.05, statistically significant); lack of fighting spirit (P=0.0005<0.05, statistically significant); hopelessness/ helplessness (P=0.00031<0.05, statistically significant); low acceptance of diagnosis, i.e. values between 4 and 6 on a 1 to 10 scale (F=7.13, P=0.019<0.05, statistically significant) *Conclusions.* Analising 25 factors, only lack of humor and lack of fighting spirit representing risk factors for inefficient coping, so that these patients should benefit of targeted and individualised psychological support.

0467

STUDY OF EFFECTIVENESS RECOMBINANT HUMAN ERYTHROPOIETIN IN LYMPHOPROLIFERATIVE DISORDERS PATIENTS WITH ANEMIA

N Romanenko, K Abdulkadyrov

Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background. Anemia in patients with lymphoproliferative disorders is a frequent symptom and can influence the efficacy of antitumor chemotherapy, survival rate and overall quality of life (QoL). Red blood cell (RBC) transfusions are routinely used to treat anemia, while recombinant human erythropoietin (rHuEPO) treatment has been shown to significantly increase hemoglobin (Hb), reduce the number of RBC transfusions and improve QoL in patients with chemotherapy induced anemia. *Aims.* This study was find out the effectiveness Recombinant Human Erythropoietin in lymphoproliferative disorders patients with anemia and improving QoL. *Methods.* There were done this interventional prospective study to investigate the effectiveness of rHuEPO (epoetin alpha) on Hb concentration, RBC count and QoL in patients (n=27) with low-grade non-Hodgkin's lymphoma (n=7), chronic lymphocytic leukemia (n=8) and multiple myeloma (n=12). The median age of patients was 65.5 years (range 24-80). Recombinant human erythropoietin alpha was injected subcutaneously on 10.000IU 3 times a week. Before start of rHuEPO treatment all patients have being received two or more cycles of chemotherapy. The target Hb level was 12 g/dL and planned duration of treatment with rHuEPO within 16 weeks. QoL was assessed using the FACT-Anemia (FACT-An) questionnaire. *Results.* Mean baseline Hb concentration was 8.21±1.96 g/dL and RBC count was $2.63\pm0.68\times10^{12}$/L. The period of rHuEPO-therapy was from 6 to 16 weeks (mean 10±4 weeks and median follow-up of 9 weeks). During the study period, the Hb concentration and RBC count increased from baseline to 10.67±2.82 g/dL (P<0.02) and $3.38\pm0.98\times10^{12}$/L (P<0.01), respectively. An Hb increase >1 g/dL was observed in 17 patients (63%), while a non-response was observed in 37%. 4 patients (15%) needed the dose increase (from 10.000IU to 20.000IU), but only in 1 patient (4%) was positive response (Hb concentration increased on 3,4 g/dL during 16weeks). FACT-An demonstrated that rHuEPO-therapy reduced symptoms such as: fatigue, force and physical efficiency, depression, drowsiness, giddiness, headaches, pain in thorax and dyspnea. On a scale from 0 to 4 points, the symptoms reduced from 1.70±0.88 to 1.27±0.83 indicating an improvement in QoL in the study patients (P<0.05). We disclosed arterial hypertension (increasing 20 mm/Hg or more) in 6 patients with positive response (22.2%) and 1 case in non-response patients (3.7%) on rHuEPO-treatment. But this adverse event was controlled by administration of antihypertensive therapy and in 1 case by withdrawal of rHuEPO-treatment. Hb levels and arterial pressure were monitored weekly. *Conclusions.* The study has shown that rHuEPO is effective at increasing Hb and improving QoL in a small group of anemic patients with lymphoproliferative disorders.

0468

COMPARISON OF SYMPTOM BURDEN (PAIN, ANXIETY, DEPRESSION) IN PATIENTS WITH LEUKEMIA VERSUS PATIENTS WITH SOLID TUMORS AT DIAGNOSIS: IDEAL CUT-OFF POINTS FOR SCREENING BY ESAS

M Luppi,[1] R Zanin,[2] M Morselli,[2] E Bandieri,[3] A Berti,[2] L Galli,[2] C Del Giovane,[2] R D'Amico,[2] F Forghieri,[2] M Maccaferri,[2] L Potenza,[2] F Narni,[2] L Buonaccorso,[3] D Bolognesi,[3] A Pietramaggiori,[4] F Artioli,[4] M Romero,[5] G Tognoni,[5] P Conte,[2] C Ripamonti,[6] E Bruera,[7] G Torelli[2]

[1]University of Modena and Reggio Emilia, Modena, Italy; [2]Azienda Ospedaliera Universitaria Policlinico, Modena, Italy; [3]Palliative Care Unit. Azienda USL, Modena, Italy; [4]Oncologic Day Hospital, Mirandola, Modena, Italy; [5]Centro Studi SIFO, Consorzio Mario Negri SUD Santa Maria Imbaro, Chieti, Italy; [6]Supportive Care in Cancer Unit. IRCCS Foundation, National Cancer Institute, Milano, Italy; [7]MD Anderson Cancer Center, Houston, USA

Background. Contrary to what is generally accepted, not only solid cancer but also leukaemia patients may suffer from physical pain and emotional distress since diagnosis and during all phases of the disease (Morselli et al., Leu Res 2010 34:e67-8). *Aim*. We prospectively reviewed data by Hospital Anxiety and Depression Scale (HADS), Edmonton Symptoms Assessment System (ESAS), and Numerical Rating Scale (NRS) of ESAS, to compare the frequency and burden of physical pain, emotional distress and other symptoms, in patients with leukaemia, since diagnosis, during the neutropenia phase (+15), and at discharge,

during the various clinical phases (induction, subsequent consolidation, and autologous and allogeneic bone marrow-BM-/peripheral blood stem cell-PBSC- transplantation procedure), as well as in patients with non haematologic cancers, evaluated at diagnosis, as controls. *Patients and Methods.* 81 patients with acute leukaemia (66 myeloid and 15 lymphoblastic; 55 male, 26 female; median age 59 years-range 21-79-) and 118 patients with solid cancer; 51 female, 67 male; median age 65 years-range 42-84-) were enrolled. The diagnosis of depression and/or anxiety and moderate/severe depression and/or anxiety were made when patients scored 8 or more, and 11 or more in HADS questionnaire, respectively. The sensitivity, specificity, positive and negative predictive values for ESAS were calculated. *Results.* According to the HADS score, during the induction phase, depression was reported in 25.7%, 37.3% and 26.9% of the patients, at diagnosis (time 0), at +15 and at discharge, respectively, while anxiety in 32.4%, 36.9%, 30.8% of the cases, at the same time intervals, respectively. Depression was reported in 31.1% while anxiety in 35.6% of all questionnaires, respectively, collected from patients at all time intervals during all clinical phases. According to the NRS score, during the induction phase, mild pain was reported in 36%, 30%, and 15% of the cases, at diagnosis, at +15 and at discharge, respectively, being moderate to severe pain reported in 14%, 18% and 6% of the cases, at the same three time intervals, respectively. A cut off of 2 out of 10 or more in the ESAS gave a sensitivity of 71% and 95% with a specificity of 76% and 69% for depression and moderate/severe depression, respectively, when questionnaires during the induction phase were considered, while a sensitivity of 60% and 78% with a specificity of 70% and 67%, when questionnaires at all time intervals, during all clinical phases were considered. A cut off of 3 or more in the ESAS gave a sensitivity of 73% and 86% with a specificity of 84% and 75% for anxiety and moderate/severe anxiety, respectively when questionnaires during the induction phase were considered, while a sensitivity of 51% and 74% with a specificity of 84% and 78% for anxiety and moderate/severe anxiety, respectively, when questionnaires at all time intervals, during all clinical phases were considered. Symptom severity appeared similar (pain, anxiety, depression and dyspnea) or even higher (fatigue, nausea, drowsiness, appetite, well-being, sleep) in leukaemia compared with solid cancer patients at diagnosis. *Conclusions*.We propose the first ideal cut-off points of ESAS for screening of depression and anxiety in leukaemia patients at diagnosis and during all clinical phases, out of the palliative care.

0469

SINGLE DOSE PALONOSETRON IN PREVENTING CHEMOTHERAPY-INDUCED NAUSEA AND VOMITING IN PATIENTS WITH HODGKIN LYMPHOMA RECEIVING ABVD REGIMEN

L Rigacci, C Landi, JP Caruso, R Alterini, V Carrai, A Bosi

Azienda Ospedaliera Careggi, Florence, Italy

Background. Chemotherapy-induced nausea and vomiting (CINV) is associated with a significant deterioration in quality of life. The ABVD regimen (Adriamycin, Bleomycin, Vinblastine and Dacarbazine) is considered the standard of care for first line Hodgkin Lymphoma and patients treated with this regimen have a high risk of CINV. *Aims.* The aim of our study was to evaluate the efficacy of a new agent, palonosetron, in Hodgkin's lymphoma patients treated with ABVD regimen. Palonosetron is a second-generation 5-HT3 receptor antagonist (5HT3RA) with a longer half-life and a higher binding affinity than old 5-HT3RA. *Methods.* All patients were treated with palonosetron 0.25 mg i.v. and dexamethasone 8 mg i.v. prior chemotherapy administration. Complete Response (CR: no vomiting and no rescue therapy), during the overall phase (0-120 hours) of the first ABVD cycle, was the primary endpoint. Emesis-free and use of rescue medication rates, during the acute (0-24 hrs) and overall phases, were the secondary endpoints. Incidence of nausea according Likert scale was evaluated during the study observation period. Two ABVD cycles were evaluated. *Results.* From January 2008 to February 2009 36 patients were enrolled, most of the patients were male (63.9%) and young (median age 33.5). All patients received study treatment during the first cycle of ABVD, while 9 of them changed antiemetic prophylaxis at the second cycle. The primary endpoint (CR 0-120 hours) was achieved by 55.6% of patients. Most of the patients didn't experience emesis during the overall phase of the first (86.1%) and the second (85.2%) ABVD cycle. 61.1% and 88.9% of patients didn't use rescue medication during the first and the second ABVD cycles respectively. Administration of palonosetron was well tolerated and the most common adverse events were transient constipation and headache as expected. *Conclusions.* In conclusion our study demonstrated that a single dose palonosetron (0.25 mg) and a single dose dexamethasone (8 mg) on day 1 was effective in preventing CINV in Hodgkin Lymphoma patients treated with ABVD regimen.

0470

USE OF CHEMOTHERAPY, IMMUNOTHERAPY AND SUPPORTIVE CARE IN THE END OF LIFE OF PATIENTS TREATED FOR B-CELL DIFFUSE LARGE CELL LYMPHOMA IN A SINGLE INSTITUTION: RETROSPECTIVE ANALYSIS OF A COHORT OF 410 PATIENTS AND TRENDS ACCORDING TO THE TIME PERIOD

J Sebban, B Favier, T Gargi, P Rey, I Domnisoru, O Derbel, Y Devaux, G Chvetzoff, C Carcel, P Biron, H Ghesquieres

Centre Leon Berard, Lyon, France

Background. Despite major improvement in the outcome of diffuse large B cell lymphoma (DLBCL), some patients will die from direct evolution of the disease. Adequate timing for cessation of aggressive care is difficult to establish. *Aims.* To document in a cohort of patients treated in a single institution for DLBCL, the management during the last month of life. *Patients and methods*. From 1996 to 2008, 410 pts older than18 years have been referred in our institution for first line therapy of DLBCL. Patients with primary cerebral lymphoma and seropositive for HIV were excluded.. Median age was 64 years. With a median follow-up of 60 months, 5-year overall survival and 5-year EFS were respectively 67% and 61%.132 pts died including 81 pts from terminal evolution of the lymphoma, 27 pts from toxic deaths in first line, 9 pts from other solid tumours (8) or myelodysplasic syndromes (1), and 15 pts from other or unknown causes. We have analyzed these 81 pts died from direct evolution of the disease and their management in the endlife according 2 time periods for initial diagnosis 1996-2002 (cohort 1) and 2003-2008 (2003-2008). *Results.* Median age at diagnosis was 69.5 years (24-89) and median age at death was 70 years (25-90). 53% of pts were stage IV and 50% had IPI>= 3. Median time between diagnosis and death was 13 months (1.5-106). Forty% of pts died in our institution, 25% died in a homecare setting, 6% in an intensive care unit and 29% in other institutions mainly in palliative care units with a similar repartition of death place according to the time period. Except for the use of Rituximab, there were no significant differences in the endlife management of these patients. A pharmacoeconomic evaluation will be reported. *Conclusion.* This is the first study reporting the incidence of 'aggressive care"the last month of life of patients with evolutive DLCBL.Prognostic factors are needed in order to better predict risks and benefits of subsequent therapy in order to avoid useless and expensive treatments and to optimize resources for palliative care.

Table.

		Total	cohort 1	cohort 2
		81	42	39
Number of chemotherapy regimen:				
	0-2	44	21	23
	3	23	13	10
	> 3	14	8	6
Median time from last chemotherapy to death (day)		38	35	48
% of pts receiving Rituximab at least one time		60%	33%	92%
% of pts receiving chemotherapy last month		40%	33%	45%
% of pts receiving Rituximab last month		14%	2%	26%
%of pts receiving platelets last month		20%	21%	18%
% of pts receiving erythocytes last month		26%	24%	28%
% of pts receiving morphine last month		59%	55%	67%
% of pts receiving antibiotics last month		27%	33%	21%

THE VALUE OF PATIENT ASSOCIATIONS IN HEMATOLOGY CLINICAL RESEARCH: CHALLENGES AND PRELIMINARY RESULTS OF A JOINT STUDY INVESTIGATING HEALTH OUTCOMES IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA.

F Efficace,[1] M Baccarani,[2] M Vignetti,[1] P Fazi,[1] M Breccia,[3] G Alimena,[3] G Lambertenghi Deliliers,[4] G Specchia,[5] E Meloni,[6] F Mandelli[1]

[1]Italian Group for Adult Hematologic Diseases (GIMEMA), Rome, Italy; [2]University of Bologna, Bologna, Italy; [3]University of Rome La Sapienza, Rome, Italy; [4]University of Milan, MIlan, Italy; [5]University of Bari, Bari, Italy; [6]Italian Association against Leukemias, Lymphoma and Myeloma (AIL), Rome, Italy

Background. Involving patient associations and advocacy groups in cancer research and healthcare planning is now regarded as key issue, but there is lack of evidence in hematology research. *Aims.* To describe methods, challenges and preliminary results of a joint quality of life

(QoL)-based study between a research organization and a national patient association (i.e. the Italian Association against Leukemias, Lymphoma and Myeloma-AIL). *Methods.* Patients with CML in treatment with Imatinib (IM) for at least three years were approached and invited by their treating physicians (i.e. investigators) in the Hospital. All consenting patients were then handed over a QoL Survey Packet with the request to completing it at home and send it back with a pre-paid reply envelope. AIL voluntaries involvement was expected to maximize patients compliance in returning the Survey and provide logistic support to the conduct of study. Participating local AIL-based branches were located in the same cities of research centers, whereas possible, and a responsible AIL representative, in each branch, was appointed to collaborate with local investigators. Prior to study initiation, an educational session describing research protocol, study purposes and logistics was organized providing all actors involved (investigators and AIL representatives) standardized working guidelines. At study closure, an ad hoc survey was completed by all AIL representatives. The survey covered a number of areas including: socio-demographics, challenges encountered in terms of relationships with investigators and related logistical barriers and level of satisfaction for being involved in the study. *Results.* Twenty-six research centers throughout Italy participated in the study and 473 patients were enrolled between March to December 2009. Patients' compliance in returning valid QoL Survey Packet was 94% which is particularly high compared to similar research settings in terms of study design and patient population (i.e. mid to long term survivors). Twenty-three AIL representatives were involved: 3 male (13%) and 20 female (87%). 43% had high school diploma and 57% had a university degree and nearly all (95%) have never participated in previous collaborative studies. As concern the topics addressed during the "educational session", organized prior to study start, these were rated as "very relevant"for study purposes by 68% of participants; all of them (100%) found working guidelines as "very helpful". Frequency distribution to the question: "to what extent this research experience was gratifying to you?"was as follow: not at all (0), a little bit (4%), somewhat (41%), quite a bit (45%) and very much (9%). All of them would participate again in similar studies and 75% would be happy to play even a more active role in future studies dealing with QoL issues. Nearly all (95%) believed the optimal patients' compliance rate achieved was, to some extent, attributable to their collaboration in this research. Only 35% judged their contribution in reducing investigators' workload being minimal. *Conclusions.* Patient associations can potentially be of great value in QoL-based studies in hematology, providing tasks are clearly defined a priori. Future experiences are encouraged to provide additional data in this area.

0472

INVESTIGATION OF PSYCHIATRIC FACTORS AFFECTING COMPLIANCE OF TRANSFUSION DEPENDENT THALASSAEMIA PATIENTS WITH IRON CHELATING AGENTS, DESFEROXAMINE, DEFERIPRONE AND DEFERASIROX

S Fragatou,[1] I Tsourveloudis,[2] M Fragatou,[1] P Paterakis[1]

[1]Dromokaiteio Hospital, Athens, Greece; [2]Thalassaemia Unit G.Gennimatas Hospital, Athens, Greece

Introduction: Transfusion-dependent thalassaemia patients' compliance with iron chelation therapy is the determining factor for complication-free survival and better quality of life. It is known that depression seriously influences compliance with therapy; however, depression potentially covers other psychiatric factors negatively affecting compliance, such as affective disorders, behavioural disorders, paranoid ideation or psychotic symptomatology. *Objective.* To investigate the potential existence of psychiatric factors which could hide under depression and contribute to poor compliance, in patients following different iron chelation regimens: Desferoxamine (DFO), Deferiprone (DFP) or Deferasirox (DFX) monotherapy, and combination therapy with DFO and DFP. *Patients and Methods.* 47 patients, 21 males and 26 females, mean age 38 years (range 27-56) from one thalassaemia unit were enrolled in the study. Patients fell into four groups according to iron chelation regimen: Group A, 14p receiving DFO (40 mg/kg x 24h x 6 days/week); Group B, 11p formerly DFO, switched to DFP (75 mg/kg/day); Group C, 11p on combined treatment with DFO (40 mg/kg x 24h x 4 days/week) and DFP (75 mg/kg/day); and Group D, 11p switched from DFO or DFP to DFX (30 mg/kg/day). Each patient was interviewed by the same doctor. Compliance was estimated by the compliance index. Psychiatric parameters were evaluated by the Brief Psychiatric Rating Scale (BPRS), a simple and reliable tool for recording certain psychiatric symptoms. Total BPRS score ≤40 indicates no serious psychopathology. Psychological support was provided by experienced staff of the clinic, while psychiatric treatment protocols did not change during the study. *Results.* Compliance differed significantly between groups (P=0.003) and was best in Group D (DFX). BPRS score > 40 was detected in 87% of all patients in the study. Psychotic behavior was observed in one patient, who did not comply with parenteral or oral chelation treatment. A high rate of depression (85%) was found. Anxiety disorders, panic attacks, paranoid ideation and inappropriate affect associated with medium and poor compliance were recorded in high percentages in Groups A, B, and C. However patients in Group D (DFX) who all had excellent compliance, showed rates of depression (77%), anxiety (91%), panic attacks (91%), hypomania (45%), paranoid ideation (45%) and inappropriate affect (55%) as high as or higher than other groups (Table 1). *Conclusions.* This study showed that thalassaemia patients had serious psychopathological characteristics underlying depression, potentially affecting their compliance with iron chelation therapy. However, these parameters did not negatively influence compliance with a specific regimen. Severe depression associated with poor compliance might mean masked suicide attempts. Further studies in a larger sample will be required to elucidate association between the occurrence of psychiatric factors and the treatment regimen.

Table 1. Psychopathology by compliance with iron chelation therapy.

	Group/Iron chelation treatment

NEW INSTRUMENT FOR COMPREHENSIVE SYMPTOM PROFILE ASSESSMENT IN PATIENTS WITH MALIGNANT LYMPHOMAS: APPLICABILITY AND CHARACTERISTICS

A Novik,[1] T Ionova,[2] S Kalyadina,[2] D Fedorenko,[1] N Mochkin,[1] K Kurbatova,[2] T Nikitina,[2] G Gorodokin[3]

[1]National Pirogov Medical Surgical Center, Moscow, Russian Federation; [2]Multinational Center of Quality of Life Research, Saint-Petersburg, Russian Federation; [3]New Jersey Center for Quality of Life and Health Outcome Research, New Jersey, USA

Comprehensive symptom assessment before and during treatment in lymphoma patients is worthwhile. We aimed to develop a new symptom assessment tool - Comprehensive Symptom Profile in Lymphoma Patients (CSP-Lym) and test its applicability in this patient population. CSP-Lym is being developed to assess the severity of 45 symptoms specific for lymphoma patients. It consists of numerical rating scales, scored from "0"(no symptom) to "10"(most expressed symptom). Thirteen clusters of symptoms have been identified, which were clinically relevant and increased the practicability of the tool. Applicability of CSP-Lym with preliminary analysis of psychometric properties was tested in a pilot study. Thirty one patients with different types of malignant lymphomas (Stage - II-IV) were included in the study: Non-Hodgkin's lymphoma - 8; Hodgkin's lymphoma - 23. Mean age was 34 years old; male/female distribution -14/17. The utility of CSP-Lym was demonstrated: all the items were easy for the patients to read and understand; the data produced by the tool were clear for interpretation by physicians and were used by them in clinical decision making. Reliability of CSP-Lym was satisfactory (Chronbach's alpha coefficient varied from 0.60 to 0.98). The construct validity of CSP-Lym was proved by factor analysis and "known-group"comparison. Statistically significant differences (P<0.05) in symptom severity were found in the groups with different patient status. Sensitivity to changes was demonstrated by comparison of symptom severity before and after treatment. Thus,

CSP-Lym is an appropriate and practical tool to assess the symptom severity in lymphoma patients. The utility of the questionnaire was shown; preliminary psychometric properties appeared to be satisfactory. Further studies are needed before the wide-spread use of CSP-Lym in clinical practice and clinical trials.

0474

GERMAN G-DRG LUMP SUM SYSTEM IS CAPABLE TO RECOVER THE TREATMENT COSTS OF PATIENTS (PTS) WITH ACUTE MYELOID LEUKEMIA (AML) RECEIVING S-HAM INDUCTION CHEMOTHERAPY (CTX) - BUT NOT FOR NON-RESPONDERS

M Krych, A Reuter, J Braess, H Ostermann

Klinikum der Universitaet Muenchen, Muenchen, Germany

*Background.*Sequential CTX with high dose cytarabin and mitoxantrone (S-HAM) as induction treatment under evaluation in phase III trials and might become one new standard of care for patients with de-novo AML. The regimen was shown to shorten the duration of critical neutropenia by 14 days as compared to standard double induction, which might have an impact on hospital costs as well. In Germany inpatient treatment is remunerated by DRG lump sums based on national average costs for AML patients receiving double-induction chemotherapy (G-DRG R60A). However hospitals report that the individual treatment costs show a high variance and little is known about the variables responsible for cost differences or whether the G-DRG lump sum compensations are cost covering. *Aims.*By comparing the costs and the revenues for AML treatment of all pts treated with S-HAM in a five year period we wanted to identify predictive clinical parameters for high expenditures and evaluate the ability of G-DRG lump sum system to bear the costs of a very complex treatment such as induction CTX. *Methods.*This is a single institution cost-benefit-analysis in a large referral university hospital consecutively analyzing 77 pts with AML receiving S-HAM from 2004-2008. Revenues were retrieved from hospital bills. Costs where valued from hospital perspective and transferred in a two dimensional 110-field cost-unit accounting matrix for each patient. Univariate and multivariate analyses were run to identify diagnoses and clinical procedures to be discriminators for cost-benefit-differences. *Results.*Median length of hospitalization was 47 days and mean *per diem* costs were 0,864€. Mean revenues were 44,6T€ (range 16,3T€;148,2T€) and mean costs were 45,7T€ (range 10T,5€; 173,4T€). DRG remuneration was almost cost covering for the cohort (total loss -83,9 T€) but not less then 32 pts showed a negative cost-benefit-ratio (mean loss -15,0T€). 41 pts showed a positive cost-benefit-ratio (mean win 9,7 T€). Cost-Benefit-ratio was not different with respect to age (P=0.31), survival (P=0.08), mechanical ventilation (P=0.26) or the use of pretended high cost drugs like antifungal agents (P=0.70). However non-responders (P=0.02) and patients requiring intensive care in general (P=0.03) where significantly at higher risk for insufficient financial recovery. *Summary/Conclusions.*G-DRG lump sum system is capable to recover the treatment costs of AML S-HAM CTX but a high individual financial risk remains. Non-responders are the patient group with the highest difference between allocated costs and retrieved revenues.

0475

KOBRA - A NEW AUTOMATICALLY GENERATED SCORING SYSTEM IS PREDICTIVE FOR TREATMENT COSTS OF PATIENTS (PTS) WITH ACUTE MYELOID LEUKAEMIA (AML) RECEIVING S-HAM INDUCTION CHEMOTHERAPY (CTX)

M Krych, A Reuter, E Hoster, H Ostermann, J Braess

Klinikum der Universitaet Muenchen, Muenchen, Germany

*Background.*Sequential CTX with high dose cytarabin and mitoxantrone (S-HAM) was shown to be highly effective as induction treatment in a phase II study and is therefore currently being evaluated in a phase III trial for patients with *de novo* AML. Many studies in health economics use *per diem* rates to estimate the costs of inpatient treatment. Cost estimates are often based on experts' opinions and rest rarely on real life data. It remains unclear if the *per diem* rates can be used in a complex setting like induction CTX of AML patients or if more sophisticated scores are mandatory. If more complex scores would be necessary for cost prediction an automated generation of these scores would be desirable. *Aims.*We calculated real life costs for AML patients and compared *per diem* rates with scoring systems based on TISS and SAPS. We established a predictive score system based on electronically available laboratory data. We presumed that laboratory values that are characteristic for organ dysfunctions might be the best discriminators for costs. *Methods.*The study was a single institution retrospective chart review in a large referral university hospital analyzing 60 pts with AML receiving S-HAM from 2004-2008. Costs where valued from hospital perspective and transferred in a two dimensional 110-field cost-unit accounting matrix for each patient. TISS-28, TISS-10 and SAPS scores where assessed by hospital chart abstraction for each day of treatment. KOBRA score was established by daily ranking of laboratory values 4 predefined classes scored with 0;1,2;4 points per day for CRP, leucocytes, thrombocytes, creatinine and bilirubin for each patient and day. When missing, the newest available value was used. *Results.*The use of *per diem* rates (860 €/ day) showed an apparent correlation (r^2=0.53) but a better correlation could be achieved with daily SAPS-2 and daily TISS28 score (r^2=0.77). KOBRA score (142€/ point) was reliably predictive for treatment costs (r^2=0.67). *Summary/Conclusions.*Treatment costs strongly correlate with diagnostic and therapeutic sores, with TISS-28 supposing to be one of the most predictive. The KOBRA score can be generated automatically and thus can be used as a pragmatic and effective predictor for treatment costs in clinical and economical trials.

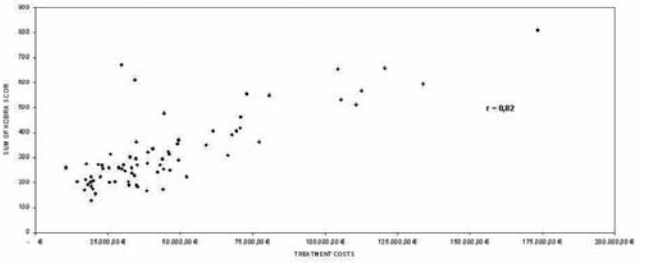

Figure. Correlation between KOBRA and TREATMENT COSTS

COMPLETE RESPONSE AND SURVIVAL OUTCOMES WITH BORTEZOMIB-MELPHALAN-PREDNISONE: AN INDIRECT COMPARISON VERSUS THALIDOMIDE-BASED REGIMEN FOR THE FRONT LINE TREATMENT OF MULTIPLE MYELOMA

J Jansen,[1] S Gaugris,[2] M Spencer,[2] B Austen[3]

[1]Mapi Values, Boston, USA; [2]Janssen-Cilag Ltd, High Wycombe, UK; [3]University Hospital of Wales, Cardiff, UK

Background. Melphalan and Prednisone (MP) has been considered a standard of care for front line treatment for multiple myeloma (MM) patients that are not eligible for high-dose chemotherapy and autologous stem cell transplant. Both Bortezomib-Melphalan-Prednisone (VMP) and Melphalan-Prednisone-Thalidomide (MPT) combinations have been approved in Europe in this patient group. Thalidomide with Cyclophosphamide and Dexamethasone attenuated (CTDa) is a regimen commonly used in clinical practice in the UK. There has been no head-to-head trial directly comparing VMP to MPT and CTDa. *Aim.* To compare the efficacy of VMP with MPT and CTDa as front line treatment of MM in patients non eligible for transplant via an indirect comparison. *Methods.* Seven randomized controlled trials investigating the efficacy of MPT (3 published articles, 2 abstracts comprising 1495 patients), VMP (1 published article, 682 patients) and CTDa (abstract, 523 patients) relative to MP were identified through a systematic literature review up to May 2009. Endpoints of interest were complete response (CR), overall survival (OS) and progression free survival (PFS). The relative efficacy estimates of MPT versus MP as obtained from the MPT-MP trials were combined using meta-analytic techniques and simultaneously indirectly compared with the relative efficacy of VMP versus MP and CTDa versus MP. Published Kaplan Meier curves were digitally scanned to reconstruct life tables and facilitate the analyses for OS up to 48 months and PFS up to 30 months. This adjusted indirect comparison was performed with Bayesian fixed (CR) and random effects models (OS, PFS). As compared to frequentist approach, Bayesian meta-analysis offers a more informative summary of the likely value of efficacy after observing the data and allows for direct probabilistic inferences. *Results.* Our indirect analysis demonstrated that patients treated with VMP were more than two times as likely to achieve a CR compared to patients treated with MPT (Relative Risk=2.64; 95% CrI: 1.32-5.10). The relative risk for VMP versus CTDa was 1.57 (95% CrI: 0.74-3.33). Both VMP and MPT were superior to MP

for PFS (HR=0.49, 95% CrI 0.35-0.68 and HR=0.65, 95%CrI 0.55-0.78 respectively) and OS (HR=0.68, 95% CrI 0.51-0.89 and HR=0.83, 95%CrI 0.71-0.97, respectively) (Table 1); the indirect comparison of VMP versus MPT resulted in a hazard ratio (HR) of 0.75 (95%CrI 0.52-1.09) for PFS and a HR of 0.81 (95%CrI 0.59-1.12) for OS, indicating a trend towards improved survival outcomes with the VMP combination. The HR for CTDa versus MP was 0.92 (95%CrI 0.67-1.28) for PFS; the indirect comparison results in a HR of 0.54 (95% CrI 0.33-0.84) for VMP versus CTDa. The probability of superiority of VMP over MPT was 93% for PFS and 72% for OS. *Conclusions.* This indirect comparison of VMP versus MPT as front line treatment in myeloma patients not eligible for transplant has shown that VMP results in a twofold higher CR rate than MPT. This translates into a trend towards improved progression and survival outcomes with VMP versus MPT. The indirect comparison of VMP versus CTDa results in a superior PFS and a trend towards improved OS with VMP.

Table 1. Hazard ratios for overall suvival.

Randomised clinical trials	Overall Survival as reported in individual trial HR (95% CI)	Overall Survival as estimated with piece-wise constant hazard model HR (95% CrI)	
		Individual trial	*Meta-analysis*
		VMP vs. MP

ECONOMIC EVALUATION OF CASPOFUNGIN VERSUS LIPOSOMAL AMPHOTERICIN B FOR EMPIRICAL ANTIFUNGAL THERAPY IN PATIENTS WITH PERSISTENT FEVER AND NEUTROPENIA IN SWEDEN

J Lundberg,[1] S Naik,[2] R Kumar,[3] J Sjolin,[4], J Jansen[2]

[1]MSD Sweden, Sollentuna, Sweden; [2]Mapi Values, Boston, MA, USA; [3]Merck & Co., Inc., Whitehouse Station, NJ, USA; [4]Department of Medical Sciences, Infectious Diseases, Uppsala University Hospita, Uppsala, Sweden

Background. Prolonged neutropenia in patients undergoing major cancer chemotherapy increases the risk of infection. Liposomal amphotericin B has frequently been used for empirical antifungal therapy in patients with neutropenia and persistent fever despite antimicrobial treatment. In a randomized, double-blind, multinational trial, caspofungin was found to be as effective as liposomal amphotericin B and generally better tolerated. Costs for the empirical antifungal therapy associated with caspofungin and liposomal amphotericin B, respectively, might differ and incremental cost-effectiveness ratios for caspofungin versus liposomal amphotericin B in Sweden remain to be explored. *Aims.* The aim of this study was to evaluate the cost-effectiveness of caspofungin versus liposomal amphotericin B for empirical antifungal therapy in patients with persistent fever and neutropenia in Sweden. *Methods.* A decision-analytic model was constructed to evaluate the cost-effectiveness of caspofungin versus liposomal amphotericin B. Model outcomes included life years lost (LYL), quality adjusted life years (QALYs) lost, expected antifungal drug costs, expected other medical costs (hospitalization costs and drug costs for adverse events), and expected overall costs. Incremental outcomes, defined as the differences between the two treatment arms, were then calculated for QALYs saved, life years saved and incremental costs to ultimately establish incremental cost-effectiveness ratios. Efficacy and tolerability data were based on additional analysis of a randomized, double-blind multinational trial. Information on life expectancy, medical resource use and costs were gathered from the literature and expert opinion. Probabilistic sensitivity analysis was used to incorporate uncertainty in the model. Results are reported as point estimates with uncertainty reflected by the 2.5th and 97.5th percentile of the uncertainty distribution. *Results.* The caspofungin total treatment costs amounted to €22,948 (95% uncertainty interval 22,125; 23,813) whereas the liposomal amphotericin B treatment cost amounted to €26,684 (25,815; 27,555), a difference of €3,736 (3,077; 4,318). Treatment with caspofungin resulted in 0.25 (0.01; 0.55) QALYs saved in comparison to treatment with liposomal amphotericin B. In Figure 1 the uncertainty of the QALYs and cost estimates for caspofungin relative to liposomal amphotericin B are presented. Taking into account the uncertainty in the results, there is a >95% probability that caspofungin is economically dominant, i.e. cost saving and QALY saving. *Conclusions.* Given the underlying assumptions and data used, our evaluation demonstrates that caspofungin is cost-effective compared to liposomal amphotericin B for empirical antifungal therapy in patients with persistent fever and neutropenia in Sweden.

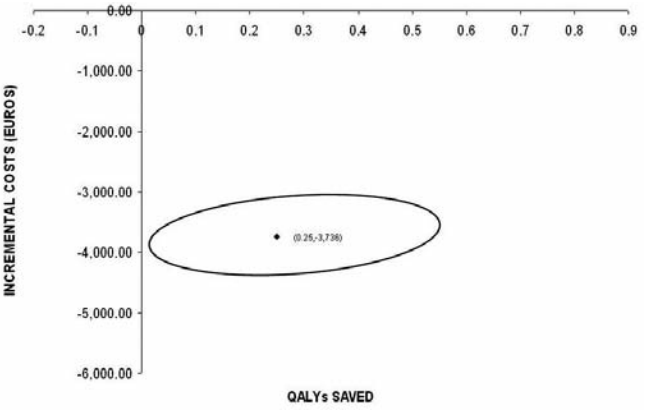

Figure 1. Cost effectiveness plane (incremental costs vs. quality adjusted life years (QAl, Ys) saved with caspofungin relative to liposomal amphotericin B).

NEED OF RECONSIDERATION OF MOBILIZATION STRATEGY IN AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA: RESULTS OF THE POSITIVE IMPACT OF HIGH NUMBER OF CD34+ INFUSED CELLS

M Michallet,[1] M Sobh,[1] F Nicolini,[2] N Raus,[1] F Barraco,[1] G Cannas,[1] Y Chelghoum,[1] G Clapsisson,[1] X Thomas,[1] H Labussiere,[1] S Duscastelle-Lepretre[1]

[1]Edouard Herriot Hospital, Lyon, France; [2]Hopital Edouard Herriot, Lyon, France

Background. Autologous Stem Cell Transplantation (ASCT) with Peripheral Blood Stem Cells (PBSC) is widely used in first line treatment for Multiple Myeloma (MM) patients. The rapidity and stability of cell engraftment may correlate with the number of CD34+ cells in the autograft. However, the impact of this number on hematologic recovery and long term outcomes is not very well defined yet. Having a higher number of collected CD34+ cells seems to be a very important and accessible objective in 2010 (availability of mobilization agents), also it has in the same time cost and efficacy results. *Material and Methods.* This study concerned 130 MM patients who underwent ASCT in our center between years 2000 and 2007. There were 79 M and 51 F with a median age of 56.8 years (34-72). At diagnosis there were 71 IgG (49κ, 22λ), 26 IgA (15κ,11λ), 2 IgD (1κ, 1λ), 27 light chain (18κ,9λ), 2 plasma cell leukemia and 2 nonsecretory. There were 11 patients in stage I (10A and 1B), 12 IIA, 96 III(75A and 21B) and 11 not classified. At diagnosis, 24 patients had del(13), and 65 had high levels of β2microglobulin. The median interval between diagnosis and ASCT was 7.8 months (3.5-131). Before transplantation, all patients received G-CSF 5µg/kg/day, PBSC were mobilized in steady state in 135 cases, 62 after G-CSF + cyclo. As conditioning, all pts received Mel. alone. Sixty six patients received a single ASCT and 64 patients received 2 ASCT in a double ASCT program. After transplantation, there were 2 graft failure, 40% of patients received red blood cell transfusions, and 64% received platelet transfusions. The median number of days with neutrophils <0.5G/L was 6 (0-33) and with platelets <20G/L was 17 (2-104). The median length of hospitalization for auto transplantation was 18 days (14-54). *Aim.* To assess the impact of the infused CD34+ cells number, we have analyzed 2 groups: group 1 (n=86) for ASCT with a number of CD34+ ≤3×10^6/kg and group 2 (n=107) for ASCT with a number of

$CD34^+$ >3×10^6/kg. For cost analysis, data were collected regarding the mobilisation and harvest of PBSC, and the graft period until hospital discharge. *Results.* We found a high significant impact of the high number of infused $CD34^+$(group 2) on platelets recovery (P=0.002), a trend for the high number of infused $CD34^+$ cells (group2) on leukocyte recovery O.R= 0.748 [0.5-1.0] (P=0.0568) and a high significant impact of the same group on neutrophils recovery O.R= 0.670 [0.5-0.9] (P=0.009). The multivariate analysis using Cox model showed a significant impact only of poor prognostic factors on overall survival O.R.= 7.94 [1.0-59.2] (P=0.04) and also on progression free survival (PFS) O.R.= 2.55 [1.1-5.7] (P=0.024). *Conclusions.* High level of infused CD34+ appeared to be very optimal for hematological recovery after ATSC in MM, without any significant impact on O.S and PFS. Our study showed that a high number of $CD34^+$ cells number had an important economical impact including a total cost saving of 1500 euros (P=0.03).

COST-EFFECTIVENESS OF TREATMENT WITH RITUXIMAB IN PREVIOUSLY UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA IN ROMANIA

A Lupu,[2] S Baculea,[1] B Pana,[3] P Radu,[3] C Kalfas,[1] S Baculea,[1] M Szkultecka-Debek[4]

[1]Roche Romania SRL, Bucharest, Romania; [2]Coltea Clinical Hospital, Bucharest, Romania; [3]Panmedica SRL, Bucharest, Romania; [4]Roche Polska Sp z.o.o, Warzaw, Poland

Background. First-line treatment with rituximab in combination with fludarabine and cyclophosphamide (R-FC) compared with FC alone in patients with untreated CLL has shown to increase PFS and reduce the risk of progression or death. *Aims.* To evaluate the long-term outcomes and cost-effectiveness of R-FC versus FC from the Romanian National Health Insurance House perspective. *Methods.* A three health states transition Markov model (progression-free survival, progression and death) was developed. Patient level data was obtained from the ML17102 study (CLL-8) evaluating progression-free survival (PFS) and overall survival (OS) in patients with previously untreated CLL. PFS was modeled using a Weibull function. An equal risk of death for R-FC and FC patients following disease progression was assumed; OS was modeled as a Markov process with a constant rate of death, obtained by modeling post-progression to death as a single population. All-cause mortality was obtained from Romanian life-tables. Time horizon considered is 15 years. Utility values were drawn from published sources. Direct costs considered were drug acquisition, drug administration, adverse events and supportive care costs. Unit cost values were used from published sources in Romania. Costs were discounted by 5%, outcomes by 0%. Sensitivity analyses were performed. *Results.* This analysis showed that for each treatment where R-FC is used instead of FC, the additional cost per patient would be on average 15,313 Euro. Benefit to the patient would be 1.008 QALY, on average, for a 15 years time horizon. The additional cost per QALY gained for R-FC over FC would be 15,191 Euro. *Conclusion.* This study confirms the long-term clinical and economic benefits of adding rituximab to FC in patients with CLL in Romania.

NEONATAL SCREENING OF NEWBORNS: TARGETED VERSUS UNIVERSAL APPROACH AS A COST EFFECTIVE STRATEGY

S AlMadhani,[1] S Alkindi,[2] A Pathare,[2] S AlZadjali,[2] R Misquith,[2] D Gravell,[2] H Al-Haddabi,[2] R Krishnamoorthy[3]

[1]Sohar Hospital, Sohar, Oman; [2]Sultan Qaboos University, Muscat, Oman; [3]INSERM, U763, Paris, France

Background. Hemoglobinopathies are quite common in the ethnically diverse Omani subjects and represent a major public health concern. Disease-oriented specific prevention and control programs are mandatory and particularly relevant in the context of the high consanguinity rates in this population. High performance liquid chromatography [HPLC] is a powerful tool to screen newborns for haemoglobinopathies. Neonatal screening includes cord blood samples collection, screening and follow up of all newborns with abnormal results. *Aims.* The study aimed at establishing neonatal cord blood screening in the Sultanate of Oman to determine the prevalence of haemoglobinopathies and recommend a cost-effective strategy to the health authorities. *Methods.* A total of 7837 consecutive cord blood samples were screened for the presence of the underlying haemoglobinopathies by HPLC using Biorad Variant II program between April 2005 & March 2007. Complete blood counts [CBC] were also obtained on Cell Dyn 4000 automated blood cell counter. All samples were then processed to isolate and store mononuclear leukocytes for subsequent confirmatory molecular diagnostics. *Results.* The findings indicated a 48.5% incidence of α-thalassaemia, based on significant amounts of Hb Barts on HPLC and low mean cell volume [MCV] & mean cell haemoglobin [MCH] on the CBC. Amongst the α-globin-related abnormalities, the overall incidence of other haemoglobinopathies was 9.5% (4.8% sickle cell trait, 2.6% β-thal trait, 0.9% Hb E trait, 0.8% Hb D trait, 0.08% Hb C trait, 0.3% sickle cell disease and 0.08% homozygous β-thalassemia). *Summary/Conclusions.* The significantly high incidence of haemoglobinopathies amongst the newborns in the Sultanate of Oman emphasizes the value of neonatal cord blood screening to be implemented as the first step in the national strategy towards the management of haemoglobinopathies including early diagnosis, comprehensive clinical care and counseling of the affected families. The results of this large study indicate that using HPLC & CBC[<2 USD/sample] and prescreening of parents to select only abnormal samples for neonatal cord blood screening <10% samples] can be recommended as a highly cost-effective method targeted to screen only the abnormal samples (Figure).

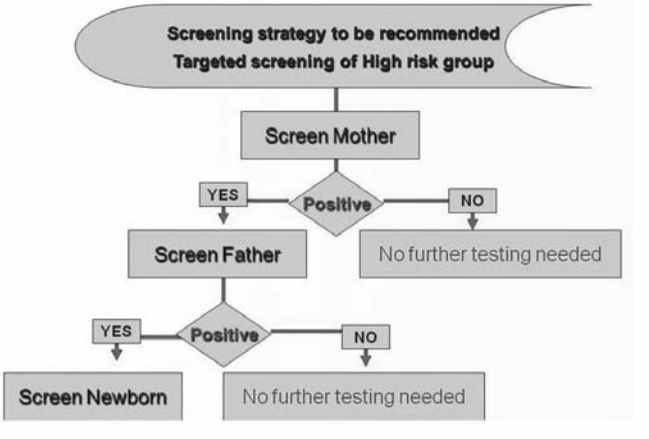

Figure. Approach to Targeted Newborn screening

DO WE NEED EDUCATION PROGRAMS ABOUT IRON DEFICIENCY ANEMIA (IDA)?

P Duska,[1] A Duletic Nacinovic,[1] T Batinac,[1] T Valkovic,[1] I Host,[1] R Dintinjana Dobrila,[1] Z Itkovic Zuckerman[2]

[1]Clinical Hospital Center Rijeka, Hreljin, Croatia; [2]Phaculty of Phylosophy, Zadar, Croatia

Background. Iron deficiency anemia (IDA) is the most common form of anemia, but usually it is not an end diagnosis, and requires complete work-up until the clarification of underlying cause . We felt that in our center to many missdiagnosed or not completely diagnosed patients have been sent to Hematologist without proper evaluation for IDA. So we tried to explore this impression and improve management of these patients. *Aims.* We evaluated influence of continuing medical education of general practitioners on managing the patients with IDA. *Methods.* During three years long, prospective study, altogether 1586 patients (983 in initial and 603 in final group) were referred to Hematology Outpatient Clinic, Rijeka University Hospital Center, Croatia due to diagnosis of IDA.They were examined by clinical hematologist during the first visit and follow up period. Patients were questioned by the means of questionnaire and complete laboratory analyses were performed in order to: evaluate physical condition and laboratory findings, to assess duration of anemia, possible other specialists' consultation, iron supplementation therapy, and finally, determine the type of anemia present. Initial group of 983 patients was examined during one year period. Following the education campaign the same parameters were analyzed in comparable (final) group of 603 patients during next one year period. *Results.* Following the education, the number of patients referred to Outpatient Clinic due to diagnosis of IDA was significantly decreased from 983 (61.97%) to 603 (38.02%) (P<0.05) as was the number of patients referred as having IDA but finally established to have a different type of anemia, from 661 (97.24%) to 149 (24.71%)(P<0.001). The number of patients started on iron supplementation therapy before establishing the type of anemia was significantly decreased from 543 (55.24%) to 76 (12.60%) (P<0.001) as well as duration of iron supplementation therapy administered in these cases (21±9.8 vs 6±8.7 weeks) (P<0.001). We have detected a significant decrease in: time necessary for definitive diagnosis (49±19.2 vs 28±9.1 weeks) (P<0.001), number of visits to other specialists (2.9±1.35 vs 1.1±0.94) (P<0.05), duration of anemia before treatment initialization (41±29.8 vs 26±18.7 weeks) (P<0.001). Average hemoglobin (Hg) level in patients referred to hematologist was significantly lower following education (98.9±15.5 vs 82.6±14.2) (P<0.05). *Conclusions.* Continuing medical education of primary care physicians has significant role in diagnosis and treatment of patients with IDA. Education programs result in benefits for the patients and physicians.

ALLELIC DISTRIBUTION AND GEOGRAPHICAL CLUSTERING OF SEC23B MUTATIONS IN CDA II PATIENTS FROM ITALY

R Russo, MR Esposito, A Gambale, A Iolascon

Ceinge Biotecnologie Avanzate S.c.a.r.l., Napoli, Italy

Background. The Congenital Dyserythropoietic Anemia type II (CDA II) is an autosomal recessive disorder characterized by an impaired differentiation-proliferation pathway of the erythroid lineage. The vast majority of CDA II cases are associated with mutations in the SEC23B gene, codifying a component of the cytoplasmic coat protein (COP)II complex, involved in the anterograde transport of correctly folded protein from the endoplasmic reticulum towards the Golgi. Until now, 63 unrelated cases from CDA II International Registry have been described (Schwarz, 2009; Bianchi, 2009; Iolascon, 2009). Among them, 31 cases had Italian origin with 15 different mutations. *Aims.* To characterize the allelic distribution and geographical clustering in Italian country of SEC23B gene mutations. *Methods.* Fifty-four CDA II independent cases from the Italian Registry were included in this study, of which 13 still unpublished. All exons, flanking splice junctions, 5'- and 3'-untranslated regions of the SEC23B gene were amplified to perform mutational screening. Italian country was divided into North, Middle, South in order to assess the geographical clustering and the allelic frequencies of the mutations in each region. *Results.* Overall we found 26 different mutations, of which 11 resulted novel. They included 12 missense, 6 nonsense, 4 frameshift and 4 splice site mutations. The most representative missense mutations were E109K (31%) and R14W (26%): these data substantially confirm the E109K as the most frequent mutation, as observed previously (Iolascon, 2009). Nevertheless, R14W mutation showed an higher frequency when compared to those calculated from International Registry (26% vs 17%). When we analyzed the geographical distribution in Italian country we observed two peaks of elevated frequency for E109K substitution: one in South (42.9%) and another in North (20.8%) Italy. Instead, R14W mutation showed a progressive reduction of frequency from North to South Italy. *Summary/conclusions.* Here, we described 11 novel mutations in CDA II Italian patients. We also characterized the allelic distribution in Italian country of SEC23B gene mutations and we defined the two most frequent mutations in CDA II patients from Italy, confirming previously described data. Moreover, the study of geographical distribution could be useful for the understanding of migration within the Italian peninsula.

IN VITRO COMPLEMENT PROTEIN 5 (C5) BLOCKADE RECAPITULATES THE COMPLEMENT PROTEIN 3 (C3) BINDING TO GPI-NEGATIVE ERYTHROCYTES OBSERVED IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) PATIENTS ON ECULIZUMAB

M Sica,[1] C Pascariello,[2] T Rondelli,[1] A Risitano,[3] R Notaro[1]

[1]Core Research Laboratory - Istituto Toscano Tumori, Firenze, Italy; [2]Department of Hematology, Federico II University, Napoli, Italy; [3]Department of Biochemistry and Medical Biotechnologies, Federico II University, Napoli, Italy

Background. C5 blockade by the monoclonal antibody eculizumab produces significant clinical improvement in most PNH patients by preventing intravascular hemolysis. However, in almost all PNH patients on eculizumab a proportion of GPI-negative (GPI-neg) red blood cells (RBC) become coated with C3 ($C3^+$), and thus potential prey to phagocytosis by macrophages. In most cases this phenomenon has relatively little clinical relevance; however, in some patients it may limit the clinical benefit from eculizumab. *Aims.* To investigate mechanism and modalities of C3 binding to RBCs of PNH patients on eculizumab. *Methods*. We have set up an *in vitro* model of the above *in vivo* phenomenon by incubating RBCs from PNH patients with AB0-compatible sera from either healthy subjects or PNH patients on eculizumab. In these sera complement alternative pathway is activated by either acidification or spontaneous 'tick-over' only. At serial time points C3 binding was assessed by flow cytometry. *Results.* In untreated PNH patients there was no evidence of C3 binding on either normal or GPI-neg RBCs (Figure 1A). The same was true when RBCs from untreated PNH patients (n=11) were incubated with acidified sera from healthy subjects. However, when RBCs from untreated PNH patients were incubated with acidified sera from patients on eculizumab, we observed in

every case the appearance of a population of C3+ GPI-neg RBCs (Figure 1B). Just as in PNH patients on eculizumab, this population coexists with a population of GPI-neg RBCs without C3 and with a population of normal RBCs, none of which became C3+. The percentage of C3+ GPI-neg RBCs increased with time from 6±2% at 1 hour to 64±15% at 24 hours. In the presence of 1.25 mM MgCl2 the proportion of C3+ GPI-neg RBCs increased further, in some cases up to nearly 100%. Also with RBCs from PNH patients on eculizumab upon incubation with acidified sera virtually all GPI-neg RBCs eventually became C3+. Serum acidification *in vitro* produces discrete GPI-neg RBCs hemolysis (20-70%) whereas intravascular hemolysis, usually, is not observed *in vivo* in PNH patients on eculizumab. In order to mimic more physiological conditions, we next investigated the effects of spontaneous complement activation. Under these conditions, not surprisingly, hemolysis of GPI-neg RBCs in sera from patients on eculizumab was negligible (0-10% at 5 days); however, even under these very mild complement activation conditions, C3 binding on GPI-neg RBCs was still substantial (Figure 1C): 20±18% at 3 days and 29±23% at 5 days. *Conclusions.* We have reproduced *in vitro* the C3 binding on GPI-neg RBCs observed in PNH patients on eculizumab. The *in vitro* kinetics of C3 binding suggests that the two populations of GPI-neg RBCs (with and without C3 binding), observed both *in vivo* and *in vitro*, do not result from intrinsically different properties of RBCs, but rather from how long they have been exposed to activated complement. A discrete population of C3+ GPI-neg RBCs is produced only when C5 is blocked by eculizumab, strongly supporting the notion that it results from a specific interaction between eculizumab C5 blockade and GPI-neg RBCs.

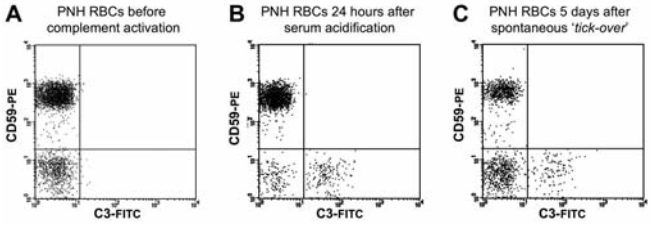

Figure 1. C3 binding on PNH red blood cells after in vitro C5 blockade.

RIBOSOMAL DEFICIENCIES CAUSE TRANSLATIONAL DEREGULATION OF GENES CRUCIAL FOR ERYTHROPOIESIS

R Horos,[1] H IJspeert,[1] E Taskesen,[1] D Pospisilova,[2] M Von Lindern[1]

[1]Erasmus University Medical Center, Rotterdam, Netherlands; [2]Pediatrics, Palacky University Hospital, Olomouc, Czech Republic

Background. Diamond Blackfan Anemia (DBA) is a rare congenital pure red cell aplasia in which mutations in distinct ribosomal proteins (RPs) for small (40S) and large (60S) subunit have been identified in over 54% of patients. It remains elusive why loss of such ubiquitously expressed proteins causes a distinct erythroid phenotype. *Aims.* Previously, we showed that selective translation of transcripts with a complex RNA structure in the 5'untranslated region (5'UTR) is crucial in Stem Cell Factor (SCF) dependent expansion of the early erythroid compartment. Transcripts such as Immunoglobulin binding protein 1 (Igbp1) are actively recruited into translating polyribosomes upon SCF signaling which activates the PI3K-mTOR pathway leading to release of eukaryote initiation factor 4E (eIF4E), a limiting factor for assembly of the scanning complex. We therefore investigated if polysome recruitment of specific mRNAs is affected in erythroblasts deficient for RPs. *Methods.* Mouse primary erythroblasts derived from p53-deficient and wild-type (wt) fetal livers were cultured in presence of erythropoietin, SCF and dexamethasone under serum free conditions. Knockdown of RPs was achieved using lentivirus-delivered shRNA followed by analysis of subpolysomal and polysome-bound RNA by sucrose gradient centrifugation. Subpolysomal and polysome-bound RNA fractions from 3 independent experiments were used for expression profiling. The ratio of polysome association was calculated per gene for each experiment and datasets from wt, scrambled shRNA treated, Rps19 and Rpl11 deficient conditions were compared using F-test with random variance model (P<0.0005). *Results.* Downregulation of either Rps19 or Rpl11 resulted in reduced proliferation and inhibition of differentiation in comparison to control cells. Cells showed a specific reduction of the 40S and 60S ribosomal subunit upon knock down of Rps19 and Rpl11, respectively. Ratios comparisons revealed that SCF-dependent transcripts were found enriched in polyribosomes, whereas a set of mRNAs, including Fxc1 (fractured callus expressed-1), Bag-1 (Bcl2-associated athanogene 1), Csde1 (cold shock domain containing E1) and Cdc25B (cell division cycle homolog B) were lost from translating polyribosomes upon RP deficiency. We next analyzed selective translation of some of these genes in erythroblasts from DBA patients. Erythroblasts could be cultured from peripheral blood of DBA patients although expansion potential of the cultures was decreased compared to control cultures. Protein expression of identified target genes (CSDE1, CDC25B) was down regulated in erythroblasts derived from DBA patients as compared to controls, whereas their transcript level on total mRNA remained unchanged, indicating a specific translation defect. Further investigation showed that loss of Csde1 perturbed cell cycle progression and erythroid differentiation. *Summary.* In conclusion, we identified transcripts whose translation is selectively affected in RP deficient erythroblasts cultured from mouse fetal livers or DBA patients. We propose that the erythroid phenotype in DBA patients is caused by defective translation of a specific set of mRNAs that are essential for erythroid development.

THE SFLT-1 TO PLGF RATIO IS IMPAIRED IN PATIENTS WITH THALASSEMIA AND SICKLE CELL DISEASE

I Papassotiriou,[1] A Kouraklis-Symeonidis,[2] F Apostolakou,[3] V Ladis,[4] A Kattamis[4]

[1]Aghia Sophia Children's Hospital, Athens, Greece; [2]Hematology Division, Department of Internal Medicine, Patras University, Patras, Greece; [3]Department of Clinical Biochemistry, Aghia Sophia Children's Hospital, Athens, Greece; [4]First Department of Pediatrics, Athens University Medical School, Athens, Greece

Background. Placental growth factor (PlGF) is a member of the vascular endothelial growth factor family and is associated with inflammation and with pathologic angiogenesis. PlGF is released from marrow erythroid cells. Serum PlGF concentrations have been reported to be elevated in patients with sickle cell disease. The fms-like tyrosine kinase-1 or sFlt-1 is a soluble form of vascular endothelial growth factor receptor-1 (VEGF-R1), which binds to and sequesters circulating free vascular endothelial growth factor (VEGF) and free PlGF, thereby neutralizing their pro-angiogenic effects. PlGF and VEGFR-1 are key molecules in regulating the angiogenic switch during pathological conditions maintaining the proangio-and anti-angiogenic balance. Perturbations of this balance leads to various degree of endothelial dysfunction, a common pathology in patients with hemoglobinopathies and specifically induce pulmonary hypertension (PHT). In this study we assessed the PlGF and sFlt-1 levels in patients with hemoglobinopathies at steady state. *Patients and Methods.* One hundred twenty three patients with hemoglobinopathies and 20 apparently healthy individuals were included in the study divided in groups as follows: Group A: 38 patients with thalassemia intermedia; Group B: 41 patients with transfusion-dependent beta-thalassemia; Group C: 33 patients with beta-thalassemia/sickle cell disease (SCD) Group D: 11 patients with beta-thallassemia and clinical evidence of PHT, and; Group E: 20 individuals served as control group In patients and controls we performed measurements of PlGF and sFlt-1 with fully automated electrochemiluminescence assays using the immunochemistry autoanalyzer Roche cobas e411. This method provides rapid and reliable assessments and follow-up of patients any time in the day compared to immunoenzymatic assays. *Results.* We found that: a) serum PlGF levels were increased in all groups of patients compared to controls (42.7±19.9 pg/mL, 49.9±23.4 pg/mL, 27.5±9.4 pg/mL, 58.1±27.6 pg/mL for group A, B, C and D, respectively vs 17.1±3.9 pg/mL for control group, P<0.001), b) serum sFlt-1 levels were also increased in all groups of patients compared to controls (89.3±18.3 pg/mL, 90.2±24.0 pg/mL, 89.4±15.3 pg/mL, 117.2±43.5 pg/mL, respectively vs 76.7±11.1 pg/mL, P<0.001 for control group and c) sFlt-1 to PlGF ratio was decreased in all groups of patients compared to controls (2.4±0.9, 2.2±1.2, 3.5±1.0, 2.2±0.8, respectively vs 4.7±1.1 for control group, P<0.001. The most significant changes were found in patients with PHT. *Conclusions.* These findings indicate that patients with thalassemia syndromes and SCD appear to have increased degree of angiogenesis, which is more pronounced in patients with thalassemia compared to patients with SCD and markedly increased in patients with PHT. The decreased sFlt-1/PlGF ratio in almost all patients suggest that the proangio-and anti-angiogenic system is shifted towards to proangiogenic state, providing evidence that patients with hemoglobinopathies even in the steady phase have altered angiogenic state and

low-grade inflammation. The results are in accordance to those published earlier for SCD (Blood, 2008;112:856-865.), where the authors demonstrated that PlGF levels were intrinsically elevated due to the increased red cell turnover and may contribute to inflammation and PHT seen in the disease.

0486

PREFERENTIAL PATTERNS OF MYOCARDIAL IRON OVERLOAD BY MULTISLICE MULTIECHO T2* CMR IN THALASSEMIA MAJOR PATIENTS

A Meloni,[1] V Positano,[1] A Pepe,[1] G Rossi,[2] MC Dell'Amico,[1] C Salvatori,[1] P Keilberg,[1] A Filosa,[3] G Sallustio,[4] M Midiri,[5] D D'Ascola,[6] MF Santarelli,[1] M Lombardi[1]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]Epidemiology and Biostatistics Unit, Institute of Clinical Physiology, CNR, Pisa, Italy; [3]UOC Pediatria, DH Talassemia, Cardarelli Hospital, Napoli, Italy; [4]Radiology Department, John Paul II Catholic University, Campobasso, Italy; [5]Department of Radiology, University of Palermo, Palermo, Italy; [6]U.O. Microcitemie, A.O. Bianchi-Melacrino-Morelli, Reggio Calabria, Italy

Background. T2* multislice multiecho cardiac magnetic resonance (CMR) technique has permitted quantification of myocardial iron overload (MIO) by a segmental approach. Little is known in the literature about patterns of iron store in hemochromatosis. *Aims.* Our study aimed to investigate myocardial iron overload in thalassemia major (TM) patients by segmental T2* CMR technique, in order to determine if there were preferential patterns of iron deposit. *Methods.* Five hundred and nineteen TM patients underwent CMR. Three parallel short-axis views (basal, medium, and apical) of the left ventricle were obtained by a T2* gradient-echo multiecho sequence. The images were analyzed using a previously validated, custom-written software (HIPPO-MIOT IFC-CNR®). The myocardium was automatically segmented into a 16-segment standardized LV model and the T2* value on each segment was calculated. The global T2* value averaged over all 16 segmental T2* values, as well as the mean values over the basal, middle, and apical slices were automatically provided. The T2* value in the mid-ventricular septum was evaluated by averaging the T2* values in segments 8 and 9. Four different main circumferential regions were defined by averaging the corresponding segmental T2* values: anterior (segments 1,7,13), septal (segments 2,3,8,9,14), inferior (segments 4,10,15) and lateral (segments 5,6,11,12,16). *Results.* Two-hundred and twenty-nine patients showed global T2* value < 26 ms, corresponding to significant global heart iron overload [4]. The analysis was focused on this patient population, subsequently divided into two groups: severe iron overload (N = 83, global T2* < 10 ms) and mild-moderate iron overload (N =146, global T2* between 10 and 26 ms). For each group, segments were sorted by mean T2* value. Segment order was significantly preserved between the two groups (r = 0.91, P<0.0001). Significant circumferential variability was found in patients with overall heart iron overload as well as in both groups (P<0.0001). The mean T2* value over the anterior region was significantly lower than the mean T2* values over the other regions and the mean T2* over the inferior region was significantly lower than the T2* values over the septal and lateral regions. This pattern was preserved within each single slice. We found a significantly higher T2* value in the basal slice versus the medium and apical slices in patients with severe iron overload. *Conclusions.* A preferential pattern of iron store in anterior and inferior regions appears to be present in TM patients with severe and mild-moderate iron overload. The preserved pattern between the groups prevents attributing this datum to additive susceptibility artefacts, which are negligible in heavily iron-loaded patients. A segmental T2* CMR approach could identify early iron deposit, useful for tailoring chelation therapy and preventing myocardial dysfunction in the clinical setting.

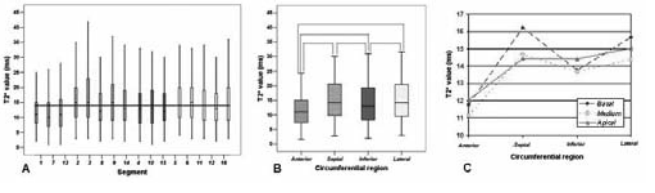

Figure 1. CMR data in patients with global heart T2* <26 ms.

CORRELATIONS BETWEEN PANCREATIC IRON BURDEN AND HEART IRON OVERLOAD AND FUNCTION BY MRI IN A LARGE COHORT OF THALASSEMIA MAJOR PATIENTS

A Pepe,[1] A Meloni,[1] V Positano,[1] M Missere,[2] MC Dell'Amico,[1] B Favilli,[1] MC Rizzello,[3] L Sardella,[4] G Sallustio,[2] M Lombardi,[1] G Restaino[2]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]Catholic University of the Sacred Heart, Department of Radiology, Campobasso, Italy; [3]Ospedale Sant'Eugenio Papa - Centro Talassemie, Roma, Italy; [4]A.S.L. BA - Osp. Di Venere, Bari, Italy

Background. The leading cause of death in thalassemia major (TM) is heart failure, but impairment of the pancreatic function is common. Multiecho T2* magnetic resonance imaging (MRI) is a well established technique for heart and liver iron overload assessment. *Aims.* Aim of our study was to investigate using quantitative MRI the correlation between heart iron overload and function with pancreatic siderosis in TM patients. *Methods.* We studied 147 TM patients (233 males, age 31±9 years) enrolled in the Myocardial Iron Overload in Thalassemia network. Myocardial iron overload was measured by T2* multislice multiecho technique. Biventricular function parameters were quantitatively evaluated by cine images. Pancreatic iron burden was measured using a T2* gradient-echo multiecho sequence. *Results.* Significant positive correlations were found between the pancreatic T2* values and the global heart T2* values (r=0.44, P<0.0001) and the number of segments with normal T2*. A normal pancreatic T2* value (≥26 ms) showed a negative predictive value of 100% for cardiac iron. Pancreatic T2* values were positively related with left ventricular (r=0.21, P=0.028) (Fig) and right ventricular (r=0.23, P=0.015) ejection fractions. *Conclusions.* Pancreatic iron overload is positively correlated to myocardial iron overload and negatively correlated to bi-ventricular systolic function. Pancreas T2* had a powerful predictor for heart iron burden. Thus, staging abdominal and cardiac MRI could significantly reduce need for sedation in young patients, costs and magnet time, particularly in countries where the cardiac MRI availability is difficult.

CHRONIC COLD AGGLUTININ DISEASE: HIGH RESPONSE RATES AND DURABLE REMISSIONS AFTER FLUDARABINE AND RITUXIMAB COMBINATION THERAPY

S Berentsen,[1] G Tjonnfjord[2]

[1]Department of Medicine, Haugesund Hospital, Haugesund, Norway; [2]Department of Medicine, Oslo University Hospital, Oslo, Norway

Background. Chronic cold agglutinin disease (CAD) is a subtype of cold-antibody autoimmune hemolytic anemia. A clonal lymphoproliferative bone marrow disorder is present in most, if not all patients traditionally classified as having 'primary' CAD. Treatment with rituximab is the only established drug therapy, leading to partial response (PR) in 45-60% of the patients, while complete responses (CR) are rare. The median response duration is only 11 months. *Aim.* We wanted to improve on these results by studying the potential of fludarabine and rituximab combination therapy, and we present here the preliminary findings. *Method.* We performed a prospective, uncontrolled multi-center trial. After informed consent had been obtained, eligible patients received infusions of rituximab, 375 mg/m^2 day 1, 29, 57 and 85; and fludarabine orally, 40 mg/m^2 day 1-5, 29-34, 57-51 and 85-89. Responses were assessed according to previously published, strict definitions, and adverse events were recorded. *Results.* 29 patients were treated, 12 men and 17 women, with a median age of 73 years (range, 39-87). Median hemoglobin level was 8.7 g/dL (range, 5.4-15.6; two non-anemic patients being treated because of disabling circulatory symptoms).

Median IgM concentration was 2.8 g/L (0.94-19.2); cold agglutinin titer, 1024 (64-64000); and cellular kappa/lambda ratio in bone marrow aspirates, 8.4 (3.5-800). Lymphoplasmacytic lymphoma or marginal zone lymphoma was found in bone marrow biopsy specimens in 59%. Following therapy, we observed an overall response rate of 77%, including 5 CR (19% of evaluable patients) and 15 (58%) PR. Six patients (23%) were non-responders, while response evaluation is still pending in 3. Among 9 patients who had previously received rituximab single agent therapy without response, 1 achieved CR and 4 PR following the combination therapy. Median time to response was 4 months (1-6). Median increase in hemoglobin level was 2.5 g/dL (-1.2 - +5.7) in the total cohort and 3.0 g/dL among the responders. Serum IgM concentrations decreased by median 66% of pretreatment levels. At a median follow-up of 30 months (range, 2-66) after achieving remission, the median and even the lower tertile of response duration has not yet been reached (range, 6 - >66 months). Grade III or IV toxicity occurred in 11 patients (38%) including grade IV adverse effects in 5 (17%). *Conclusions.* Fludarabine and rituximab combination therapy is very efficient in patients with CAD, leading to high response rates as well as durable remissions. For the first time, we report a considerable number of CRs after therapy for CAD; and remissions have been achieved in patients who did not respond to previous single agent therapy with rituximab. Toxicity is more prevalent as compared to rituximab monotherapy, and we have not studied the long-term effects of fludarabine in this patient group. Some caution should probably be exerted in the youngest as well as the oldest and most frail patients. It remains to be established whether the fludarabine-rituximab combination should be considered first-line or an efficient second-line therapy in patients with CAD requiring pharmacologic treatment.

0489

HYPOXIA CAUSES SIGNIFICANT AUTONOMIC DYSREGULATION AND SIGHS CAUSE VASO CONSTRICTION IN PATIENTS WTIH SICKLE CELL ANEMIA: A POSSIBLE LINK BETWEEN PULMONARY PATHOLOGY AND VASO OCCLUSIVE CRISIS

D Coates,[1] S Sangkatumvong,[2] R Kato,[1] J Detterich,[1] A Bush,[1] H Meiselman,[3] M Khoo[2]

[1]Childrens Hospital Los Angeles, USC School of Medicine, Los Angeles, USA; [2]USC Deptartment of Biomedical Engineering, Los Angeles, Ca, USA; [3]USC Keck School of Medine, Los Angeles, Ca, USA

Background. Nighttime hypoxia predicts stroke and crisis frequency in subjects with sickle cell disease (SCD) suggesting a role for sleep disordered breathing and recurrent hypoxia in the pathophysiology of SCD. *Aims.* Determine the mechanism by which transient hypoxia modulates microvascular blood flow in subjects with SCD. *Methods.* Using an ethics committee approved protocol; we established a method to induce a single episode of hypoxia that mimicked those occurring naturally during sleep. To accomplish this, we exposed normal and SCD subjects who had continual monitoring of electrocardiogram, tidal volume, oxygen saturation, and microvascular blood flow to five breaths of pure nitrogen. An autoregressive model was used to examine autonomic balance derived from heart rate variability (HRV) measurements and we used standard statistical methods to study the relation of sighs seen in the tidal volume tracing (Vt) to episodes of marked decrease in microvascular perfusion. The high frequency component of the HRV signal reflects parasympathetic nervous system tone. *Results.* 8 SCD subjects and 9 normal controls were studied. In a total of 27 experiments in SCD subjects with two hypoxic exposures, there were no severe adverse events. The nadir of the SaO2 was 80% of baseline in SCD and 85% in normals. Microvascular blood flow was measured by laser-Doppler flowmetry and did not decrease in response to the hypoxia, as we had expected. However, we did note a significant change in the heart rate in SCD subjects that was not seen in normals. We also noted periodic transient episodes of marked vaso-constriction commonly in SCD subjects and rarely in normals. Because of the heart rate changes we examined respiratory corrected heart rate variability and found significant loss of the parasympathetic component of the cardiac autonomic balance in response to hypoxia in SCD but not in normal subjects. The periodic drops in perfusion were associated with deeper breaths (sighs) seen in the tidal volume recording. The odds ratio for a sigh causing vasoconstriction was 1750 P<.001 indicating that sighs induce vaso constriction in SCD and normals. However, there is a 77% probability that a sigh will cause vaso constriction in SCD compared to only 14% in normal subjects (P<.008). *Summary.* Subjects with SCD have significant loss of heart rate variability in response to transient hypoxia indicating severe autonomic deregulation. Furthermore, sighs cause transient neurally- mediated vaso constriction and this effect is significantly enhanced in SCD subjects. Vaso constriction results in retention of red cells in the microvasculature increasing the likelihood that sickling will occur before the rbc exit into larger vessels. Thus the rigid SRBC become lodged in the microvascularture resulting in vasoocclusion. These data suggest that the association of sickle crisis with sleep disordered breathing and asthma may be mediated through a mechanically sensed autonomic /neural transmitted vaso-constriction leading to SRBC retention in the microvasculature and subsequent vaso-occlusion rather than by a direct effect of hypoxia on HbS as the initiating event in vaso-occlusion.

0490

A NOVEL MUTATION IN INTESTINAL ISOFORM OF DIVALENT METAL TRANSPORTER 1 (DMT1-1A)

L De Falco,[1] I Andolfo,[1] F Di Noce,[2] PD Beneitez,[3] A Iolascon[1]

[1]Ceinge, Advanced Biotechnologies, Naples, Italy; [2]Ceinge, Advanced Biotechnologie, Naples, Italy; [3]Unitat Eritropatologia, Lab Clinics Hosp Vall d'Hebron, Val d'Hebron, Barcelona, Spain

Background. Divalent metal transporter 1 (DMT1) mediates apical iron uptake into duodenal enterocytes and also transfers iron from the endosome into the cytosol after cellular uptake via the transferrin receptor. Mutations in DMT1 cause systemic iron deficiency and microcytic anemia. The three patients with DMT1 mutations described so far developed highly transferrin saturation and mildly elevated serum ferritin, despite liver iron overload. Anemia is present from the birth. The molecular defect is common to intestinal and erythroid isoforms, which could explain the elevated transferrin saturation and the microcytosis. Four DMT1 isoforms exist resulting from mRNA transcripts that vary both at their 5' ends (starting in exon 1A or exon 1B) and at their 3' ends giving rise to mRNAs containing (+) or lacking (-) the 3' IRE (iron-responsive element). Exon 1A is located 1.9 kb upstream of the first exon ("1B") of the previously characterized human DMT1 and is followed by a consensus splice sequence. The exon 1A is spliced directly to exon 2. The 1B isoform is ubiquitous, whereas the 1A isoform is tissue-specific, predominantly in the duodenum and kidney. Here, we report a novel DMT1 variant with a mutation in 1A isoform due to A>T transition at nucleotide position 652 of Ensembl sequence ENSG00000110911. *Case Report.*, This 55-'years-'old Caucasian female with unrelated parents was admitted to our hospital for mild anemia and microcytosis (Figure 1). We observed a mild hypochromic microcytic anemia with a hemoglobin level of 9 g/dL, a mean cell volume (MCV) of 56 fL, and a mean hemoglobin concentration (MCH) of 30.9 pg, the reticulocyte count was $69\times10^3/\mu L$. Transferrin saturation was elevated (129%) as well as ferritin levels and soluble transferrin receptor values. There were no alterations in hemoglobin electrophoresis and there was no enzymatic defect. *Results.* Sequencing of the exons and exon-intron boundaries of the DMT1 gene revealed the proband compound heterozygote for c.GGC723>GTC, also described in literature, and a novel A>T substitution in intron 1A at position 1 following the acceptor splice site. The latter could lead to splicing alterations as verify by in silico and *in vitro* tools and not affect the mRNA expression of DMT1. *Conclusions.*The DMT1 1A mutation has an homozygote expression in enterocytes, otherwise there is no expression of this isoform in hepatic or erythroid cells. Compound heterozygote condition is present only in enterocytes, where we hyphotize that the exon 8 G>T transition causes a functional alteration while mutation in DMT1 1A causes a reduction of protein expression.

EXPRESSION OF MICRORNAS IN RETICULOCYTES FROM BETA THALASSEMIA INTERMEDIA PATIENTS

R Ferreira,[1] MA Bezerra,[2] A Araujo,[3] D Albuquerque,[2] F Ferreira[1]

[1]Unicamp, Campinas, Brazil; [2]UNICAMP, Campinas, Brazil; [3]Hematology and Hemotherapy Center of Pernambuco, Recife, Brazil

MicroRNAs (miRNAs) represent a novel class of endogenous non-coding RNAs of approximately 20-22 nucleotides. In mammalian cells, miRNAs negatively regulate gene expression by inhibiting translation of target RNAs or degrading messenger RNAs. In normal erythropoiesis, microRNAs play a very important role because they regulate differentiation in most stages. There is an increasing number of studies demonstrating the function of these non-coding RNAs in the pathogenesis and prognosis of erythropoietic disorders, including thalassemias. Beta-Thalassemia (BT) is an inherited hematologic disease caused by reduced or absent synthesis of beta globin chain, leading to a relative excess of alpha globin chains. This imbalance causes hemolysis and impair erythropoiesis. The aim of this study was to analyze the expression profile of miRNAs 24, 144, 155, 210, 221, 222, 223 and 451 in beta-thalassemia intermedia patients. Reticulocytes were separated from peripheral blood samples of control subjects (n≥9) and from untransfused BT IVS-I-6 (T C) homozygous patients without HU therapy (n≥9). Samples from spherocytosis patients with reticulocytosis and synthesis of normal globin chains were also included to confirm miRNA expression profile (data not show). Extraction of miRNA, transcription to cDNAs and Real Time PCR were performed to analyze miRNAs expression, using U47 and RNU6B as endogenous controls. The statistical analyzes showed that the expression levels of the miRNAs 24, 144, 155, 210, 221, 222, 223 and 451 were significantly lower in BT patients compared to control subjects (mean 0.0009 vs 0.193, P=0.030; 0.034 vs 0.357, P=0.04; 0.073 vs 0.736 , P=0.0106; 0.029 vs 0.222, P=0.0244; 0.029 vs 0.556, P=0.0001; 0.048 vs 0.358, P=0.0106; 0.045 vs 0.198, P=0.0056; 0.029 vs 0.169, P=0.0160, respectively). These miRNAs were previously described to act in different stages of normal erythropoiesis. When up-regulated, miRNAs 144 and 451 promotes erythroid maturation and synthesis of hemoglobin, while the miRNA 210 acts in erythroid differentiation. In this study, the low expression of these miRNAs suggests their involving at latest maturation in BT. The interaction between miRNAs 451 and 155 demonstrates that overexpression of miRNA 451 promotes decrease in expression of miRNA 155. However, the data presented in this report shows low expression of both microRNAs. Downregulation of miRNAs 24, 221, 222 and 223 results in erythroid maturation; although this study as shown that the expression profile of these miRNAs was lower in BT, the pathways from which they draw the erythroid differentiation is not clear. This is the first report of miRNAs expression involved in reticulocytes of beta-thalassemia intermedia patients. These results suggest the importance of miRNAs molecular pathways in the BT patient's erythropoiesis which may contribute to the understanding of this pathophysiology.

ACE-536, A MODIFIED TYPE II ACTIVIN RECEPTOR INCREASES RED BLOOD CELLS IN VIVO BY PROMOTING MATURATION OF LATE STAGE ERYTHROBLASTS

K Kumar, R Suragani, C Cadena, M Mitchell, S Sako, D Davies, T Tomkinson, U Ucran, G Grinberg, U Underwood, P Pearsall, S Seehra

Acceleron Pharma, Cambridge, USA

Anemia is a common debilitating complication associated with diseases such as chronic kidney disease and cancer chemotherapy. Currently, administration of recombinant erythropoietin (EPO) represents the most common treatment for anemia. However, a significant number of people remain hypo or non-responsive to EPO treatment. Several members of the TGFβ super family have demonstrated a role in erythropoiesis. We developed a soluble receptor Fc fusion chimera of a modified form of activin receptor IIB (ACE-536) and studied its effect on erythropoiesis. *In vivo* subcutaneous administration of ACE-536 (10 mg/kg subcutaneously, twice weekly) in C57BL/6 mice twice weekly resulted in a significant increase in hematocrit, hemoglobin and red blood cells (RBC count) compared to a vehicle group after 4 days, although these parameters were already significantly increased 24 hours post treatment. These observations were evident in the presence of an EPO neutralizing antibody suggesting that EPO is not directing the initial RBC response. No changes in red blood cell half life were noted in mice treated with ACE-536. Differentiation profiling of bone marrow and Splenic erythroblasts by flow cytometric analysis revealed that ACE-536 promotes faster maturation of erythroblasts. ACE-536 treatment for 72 hours resulted in a decrease in basophilic erythroblasts and an increase in subsequent late stage poly, ortho chromatophilic and reticulocytes in bone marrow and spleen compared to the TBS treated mice. ACE-536 (10 mg/kg) treatment of Sprague Dawley rats (N=4) increased the rate of reticulocyte formation compared to the vehicle group, but did not alter the rate of reticulocyte maturation in the peripheral blood. Furthermore, ACE-536 (10 mg/kg) treatment together with recombinant human EPO (1800 units/kg) for 72 hours increased RBC, hematocrit and hemoglobin by 23% over TBS treated vehicle group and significantly enhanced the effects compared to EPO treatment alone. Consistent with its role in proliferation, EPO treatment increased the splenic basophilic erythroblast formation. However, ACE-536 treatment with EPO significantly promoted maturation of basophilic erythroblasts demonstrating a novel mechanism during erythroid differentiation. This novel mechanism of ACE-536 offers the opportunity for a new treatment for anemia with a safety and efficacy profile that may be distinct from EPO.

EVALUATION OF ERYTHROPOIESIS AND IRON METABOLISM IN RESPONSE TO ERYTHROPOIETIN INJECTIONS IN A MOUSE MODEL OF GENERALIZED INFLAMMATION AND ANEMIA

S Millot,[1] S Lasocki,[1] V Andrieu,[1] P Letteron,[1] I De Domenico,[2] C Beaumont,[1] S Millot[1]

[1]INSERM U773, Paris, France; [2]Department of Medicine, University of Utah, Salt lake city, USA

Background. Several factors contribute to the development of anemia of chronic disease (ACD), such as an impaired proliferation of erythroid progenitors, reduced red blood cell (RBC) half life, a blunted erythropoietin response and dysregulation of iron homeostasis. Pro-inflammatory cytokines play a major role in the onset of anemia. In mouse, acute anemia stimulates BMP4 expression in the spleen and induces the proliferation of BMP4-responsive stress erythroid progenitors allowing rapid recovery from anemia. The effect of inflammation on this stress erythropoiesis is not known. *Aims.* to explore erythropoiesis and iron metabolism in a mouse model of chronic inflammation and to assess the efficacy of Epo injections in correcting the ACD. *Methods.* Mice (C57BL/6) received a single intraperitoneal injection of Zymosan at day 1 (Z1) and were analyzed at Z2, Z5, Z12 and Z17. Epo injections in inflammed mice were performed on four consecutive days starting at Z5. Double Ter119/CD71 labelling was used to analyze erythroblast differentiation by FACS, in bone marrow and spleen. Spleen BMP4 expression was followed by RT-qPCR and immunohistochemistry. Haematological parameters were recorded and RBCs survival was evaluated. Serum hepcidin concentrations and macrophage ferroportin expression were assessed. *Results.* Zymosan-induced inflammation lead to a long-lasting anemia with reduced number of RBCs and low Hb levels (10 g/dL). We found that the Zymosan injection shortened RBCs survival. Furthermore, bone marrow erythropoiesis was fully suppressed with an increase in the percentage of apoptotic $Ter119^+$ cells and it did not respond to Epo injections. In the spleen, inflammation only moderately stimulated the percentage of erythroblasts. However, Epo injections led to a 10-fold increase in immature erythroblasts one day after the final Epo injection, followed three days later by a similar increase in the proportion of mature erythroblasts. Epo also induced a significant increase in BMP4 expression in spleen macrophages. Serum hepcidin levels were dramatically elevated in inflammed mice and ferroportin expression in spleen macrophages was repressed. However, Epo injections decreased hepcidin concentrations but the response was delayed as compared to control mice. Ferroportin expression increased concomitantly. Nine days after the final injection, Epo had allowed a partial correction of the anemia(Hb=11.2 g/dL as compared to 14 g/dL in controls). *Conclusions.* These results highlight the differences between bone marrow and spleen erythropoiesis. They also show that Epo injections in mouse can partially correct the ACD by stimulating spleen stress erythropoiesis and progressively decreasing hepcidin expression and suggest that Epo favours iron mobilization from tissue iron stores, despite the presence of inflammation.

0494

ANALYSIS OF SEVEN RIBOSOMAL PROTEIN GENES IN ITALIAN DIAMOND BLACKFAN ANEMIA PATIENTS

U Ramenghi,[1] P Quarello,[2] E Garelli,[2] A Carando,[2] A Lorenzati,[2] G Ansaldi,[2] M Davitto,[2] I Boria,[3] A Aspesi,[3] I Dianzani[3]

[1]University of Torino, Torino, Italy; [2]Department of Pediatrics, University of Torino, Torino, Italy; [3]University of Eastern Piedmont, Department of Medical Sciences, Novara, Italy

Background. Diamond Blackfan anemia (DBA; MIM 205900) is a rare, pure red cell aplasia of childhood due to an intrinsic defect in erythropoietic progenitors. Somatic malformations are present in about 40% of patients. For about 10 years, RPS19 was the only gene found mutated in DBA patients and its mutations accounted for 25% of cases. In the last four years, however, heterozygous mutations in several genes (RPS24, RPS17, RPL35A, RPL5, RPL11, RPS7) encoding for ribosomal proteins (RP) of either the small or the large ribosomal subunit have been reported. Recently, Doherty et al. (Am J Hum Genet, 2010), described the involvement of two other genes, RPS10 and RPS26, in about 10% of DBA patients.*Aims.* To characterize 135 Italian DBA patients for mutations in seven genes, all encoding for RPs. *Methods*. We sequenced exons, intron-exon boundaries of RPS19 in 135 Italian unrelated DBA patients and RPS24, RPL35A, RPL5, RPL11 genes in 96 patients with no mutations in RPS19. So far RPS26 and RPS10 genes have been sequenced in 23/68 patients not mutated in other RP genes; sequencing of these two genes in the remaining 45 is ongoing. One hundred normal chromosomes were studied for each identified DNA change to rule out polymorphisms. *Results.* The analysis of In the Italian DBA cohort demonstrated 39/135 mutations in RPS19 gene (29%), 14/135 (10%) and 12/135 (9%) mutations in RPL5 and RPL11 genes. Only 2/135 (1.5%) patients showed mutations in RPS24. No mutations were found in RPL35A. Regarding the last two genes identified, we found 3 heterozygous mutations in RPS26 and one in RPS10. The first one is a missense mutation (c.3G>A) involving the first ATG codon. The second mutation is a deletion of 4 bp in exon 3 with the creation of a premature stop codon and the third is a mutation at donor splice site of intron 1. A missense mutation with substitution of Treonine with Isoleucine at codon 138 was found in RPS10 gene. All mutations but one were new mutations (i.e. not yet described in the literature). All RPS10 and RPS26 mutations were *de novo*. No malformation was present in these patients. All RPS26 mutated patients were unresponsive to steroid therapy and transfusion dependent. *Conclusions.* Overall, mutations in 5 RP genes (RPS19, RPL5, RPL11, RPS10 and RPS26) account for more than 50% of all DBA cases. RPL5 and RPL11 are associated with hand and cleft malformations. No correlation was found between somatic malformations and RPS26 mutations. We observed a severe phenotype in term of transfusion dependence among RPS26 patients.

ERYTHROPHAGOCYTOSIS BY ANGIOGENIC ENDOTHELIAL CELLS IS ENHANCED BY LOSS OF ERYTHROCYTE DEFORMABILITY

M Fens,[1] G Storm,[2] R Pelgrim,[2] A Ultee,[2] A Byrne,[3] C Gaillard,[4] W van Solinge,[1] R Schiffelers[2]

[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]Utrecht University, Utrecht, Netherlands; [3]Royal College of Surgeons, Dublin, Ireland; [4]Meander Medical Center, Amersfoort, Netherlands

Objective. Angiogenic endothelial cells can function as phagocytes and phagocytosis is initiated via the opsonin lactadherin. In this study, we examined the interaction between lactadherin-opsonized erythrocytes with reduced deformability and angiogenic endothelium, as loss of deformability is characteristic for suicidal and aged erythrocytes. *Methods.* We used the RGD-modified erythrocyte model and investigated the deformability parameter by cross-linking erythrocyte membranes, through treatment with glutaraldehyde (GA). Association *in vitro* with primary endothelial cells was detected by flow cytometry and visualized by light, fluorescent and electron microscopy. Involvement of two crucial factors in phagocytosis, αv-integrins and Rho GTPase family member Rac1 was studied using siRNA technology. Modified erythrocytes were administered *in vivo* into tumor-bearing mice to detect phagocytosis by endothelial cells. *Results.* GA-treated (rigid) RGD-modified erythrocytes showed a strongly enhanced endothelial cell association compared to flexible RGD-modified erythrocytes. Knockdown by siRNA lipoplexes of αv-integrins and Rac1, confirmed classical tethering and internalization of rigid RGD-erythrocytes. Upon *in vivo* administration, tumor endothelium showed pronounced erythrophagocytosis. *Conclusion.* The pronounced phagocytosis of opsonized erythrocytes with reduced deformability by angiogenic growth factor-activated endothelial cells (Figure 1), evoke new insights in endothelial cell function and suggest a role for these endothelial cells in (haematological) disorders because of their capacity to clear disordered erythrocytes.

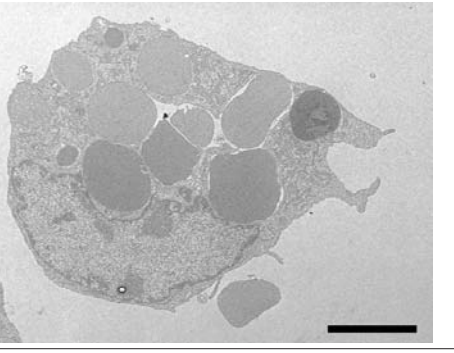

Figure 1 Pronounced erythrophagocytosis by HUVEC.

MYOCARDIAL FIBROSIS BY DELAYED ENHANCEMENT CARDIOVASCULAR MAGNETIC RESONANCE AND HCV INFECTION IN THALASSEMIA MAJOR PATIENTS

A Pepe,[1] A Meloni,[1] Z Borsellino,[2] MC Dell'Amico,[1] C Borgna-Pignatti,[3] A Maggio,[4] V Positano,[1] E Cracolici,[5] M Lombardi,[1] M Capra[2]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy;[2]P.O. G. Di Cristina, ARNAS Civico, Palermo, Italy; [3]University of Ferrara, Department of Clinical and Experimental Medicine, Ferrara, Italy; [4]Ematologia II con Talassemia, „V. Cervello„ Hospital, Palermo, Italy; [5]Department of Radiology, University of Palermo, Palermo, Italy

Background. Delayed enhancement (DE) cardiac magnetic resonance (CMR) technique is the only validated non-invasive approach for detecting myocardial fibrosis. In thalassemia major (TM), myocardial fibrosis has been detected using the DE technique and a positive correlation with anti-HCV antibodies has been described. However, HCV-induced cardiomyopathy is still controversial. *Aims.* The aim of our study was to verify a possible correlation between myocardial fibrosis detected by DE CMR and chronic HCV infection in a large retrospective cohort of TM patients. *Methods.* We analysed 434 TM patients (233 males, mean age 31±9 years) consecutively enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) study. DE images were acquired to detect myocardial fibrosis. HCV-RNA tests were sensitive to detect more than 50 copies/mL. *Results.* Ninety out of 434 TM patients (21%) were found to have myocardial fibrosis by DE CMR technique. There was a significant correlation between the presence of myocardial fibrosis and the HCV-RNA positive patients plus the patients with a previous diagnosis of chronic hepatitis C (CHC) treated by alpha-interferon (P=0.026). *Conclusions.* Our finding supports the hypothesis that HCV infection can be involved in the pathogenesis of myocardial fibrosis in the multitransfused TM patients, who could therefore benefit from therapeutic interventions directed towards the eradication of HCV.

EVALUATION OF TINF2 AND SBDS GENE MUTATIONS AND SCREENING TELOMERE LENGTH IN ADULT JAPANESE PATIENTS WITH ACQUIRED BONE MARROW FAILURE SYNDROMES

J Takeuchi,[1] H Yamaguchi,[1] K Inokuchi,[1] H Tamai,[1] Y Mitamura,[1] F Kosaka,[1] H Ly,[2] K Dan[1]

[1]Division of Hematology, Department of Internal Medicine, Nippon Medical School, Tokyo, Japan; [2]Department of Pathology and Laboratory Medicine, Emory University, Atlanta, USA

Background and *Aims.* We have recently shown that some patients with cryptic and late on set Dyskeratosis Congenita (DKC) patients among those with acquired aplastic anemia (AA) or myelodysplasia syndrome (MDS) have short telomeres due to mutation in the telomerase gene component TERC or TERT. In addition, several recent studies showed heterozygous mutations of the telomere maintenance associated genes TINF2 and SBDS in 1-5% of patients with acquired AA. The largest controlled epidemiologic study reported that the incidence of AA in the West is 2 per million per year and is about 2- to 3-fold higher in Asia. The analysis of the TINF2 and SBDS genes among adult Asian populations with AA and MDS, to the best of our knowledge, had never been done. Therefore, we carried out an investigation to determine whether mutations in these genes can be found in adult Japanese patients with acquired BMFS. Clinically it is very important to identify these patients with shortened telomeres and pathogenic mutations of telomere associated genes, because these patients will likely exhibit refractoriness to conventional immunosuppressive therapy (IST). Moreover, previous report revealed that non-responders of IST showed shorter telomeres than responders in AA patients. Therefore, in this study, we also evaluated telomere length in peripheral blood from patients at the time of diagnosis with AA to clarify its usefulness in treatment strategies. *Methods.* We screened the entire coding region of the SBDS gene and exon 6 of TINF2 by direct sequence. We used Southern blot analysis to measure the length of telomeres in peripheral blood from AA and BMF patients with mutations in telomere associated genes. *Results.* Among 120 Japanese patients with acquired bone marrow failure syndromes (BMFS), we identified two patients (1.7%) with TINF2 heterozygous mutations (P283H and the novel n865-866 dinucleotide CC deletion), and one patient (0.8%) with SBDS heterozygous mutation (intervening sequence (IVS)+2T/C mutation at intron 2). Both patients with TINF2 mutation show extremely short telomeres as compared to healthy age-matched controls, but the patient with the SBDS mutation did not show obvious short telomere. These patients had no evidence of clinical histories and physical anomalies of DKC or Shwachman-Diamond syndrome. The two patients with TINF2 mutations were diagnosed with severe AA, and did not show any clinical response to immunosuppressive therapy. Age-adjusted telomere length did not significantly differ between non-responders of IST (n=10) and responders (n=16) (P=0.488), but those with mutations of telomere associated genes (n=3) were significantly shorter than those without mutations (P=0.017). *Conclusions.* These findings revealed for the first time that mutations in TINF2 and SBDS genes indeed occur in Asian BMFS patients, and screening telomere length is useful for detecting cryptic DKC, but not for predicting responses to IST among BMFS patients.

CONTINUED IMPROVEMENT IN CARDIAC T2* WITH DEFERASIROX TREATMENT OVER 2 YEARS: RESULTS FROM THE EXTENSION OF EPIC CARDIAC SUBSTUDY IN BETA-THALASSAEMIA PATIENTS WITH MYOCARDIAL SIDEROSIS

D Pennell,[1] J Porter,[2] M Cappellini,[3] LL Chan,[4] A El-Beshlawy,[5] Y Aydinok,[6] H Ibrahim,[7] CK Li,[8] V Viprakasit,[9] M Elalfy,[10] A Kattamis,[11] G Smith,[1] D Habr,[12] B Roubert,[13] A Taher[14]

[1]Royal Brompton Hospital, London, UK; [2]University College London, London, UK; [3]Universitá di Milano, Policlinico Foundation IRCCS, Milan, Italy; [4]University Malaya Medical Centre, Kuala Lumpur, Malaysia; [5]Cairo University, Cairo, Egypt; [6]Ege University Medical Faculty, Izmir, Turkey; [7]Hospital Kuala Lumpur, Kuala Lumpur, Malaysia; [8]Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong, Hong Kong; [9]Department of Pediatrics, Siriraj Hospital, Mahidol University Bangkoknoi, Bangkok, Thailand; [10]Ain Shams University, Cairo, Egypt; [11]First Dept of Pediatrics, University of Athens, Athens, Greece; [12]Novartis Pharmaceuticals, East Hanover, NJ, USA; [13]Novartis Pharma AG, Basel, Switzerland;[14]American University of Beirut, Beirut, Lebanon

Background. The efficacy of chelation in reducing cardiac iron in β-thalassaemia patients has been demonstrated using myocardial T2* in several prospective clinical trials of up to 1 year. Since T2* normalization may take several years, longer-term efficacy and safety assessments are required. In the cardiac substudy of the EPIC trial, patients have now received deferasirox for up to 2 years in an extension study. *Aims.* To evaluate the efficacy and safety of deferasirox in removing myocardial iron in heavily transfused β-thalassaemia patients over 2 years. *Methods.* Eligible patients were aged ≥10 years with myocardial T2* >5-<20 ms (indicating cardiac siderosis) by cardiovascular magnetic resonance (CMR), left ventricular ejection fraction (LVEF) ≥56%, serum ferritin (SF) >2500 ng/mL, MR (R2) liver iron concentration (LIC) >10 mg Fe/g dry weight (dw), and a lifetime minimum of 50 transfused blood units. Deferasirox was initiated at 30 and increased to 40 mg/kg/day by the time patients entered the extension. Dose decreases were allowed for safety reasons. Primary endpoint was change in myocardial T2* from baseline to 2 years. *Results.* 101 patients entered the extension study. Baseline myocardial T2* was >5-<10 ms in 39 patients (38.6%) and 10-<20 ms in 62 (61.4%); geometric means were 7.3 ms and 14.6 ms, respectively. Mean deferasirox dose increased from 33.1±3.7 in the core study to 36.1±7.7 mg/kg/day during the extension. After 2 years, myocardial T2* significantly increased from a geometric mean baseline of 11.2 to 15.7 ms (P<0.001). Significant increases also occurred in patients with baseline T2* >5-<10 and 10-<20 ms (Figure).

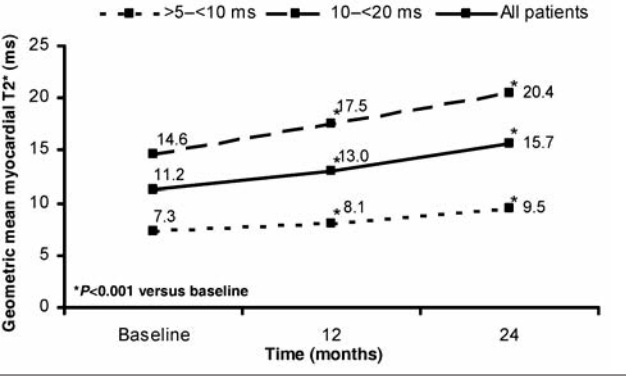

Figure. Geomatric mean myocardial T2* over 2 years.

56.7% of patients with mild-to-moderate baseline cardiac siderosis (10-<20 ms) normalized (≥20 ms) after 2 years; 43% of patients with severe baseline cardiac siderosis (>5-<10 ms) improved to 10-<20 ms. LVEF remained stable. RVEF improved from baseline over 2 years (P<0.001). Both mean LIC (-10.7±12.8 mg Fe/g dw) and median SF (-2343 ng/mL) were reduced significantly from baseline (P<0.001). 86/101 patients (85.2%) completed 2 years. Reasons for discontinuation were: unsatisfactory therapeutic effect (n=7), consent withdrawal (n=4), protocol violation (n=1), lost to follow-up (n=1), abnormal test procedure (decreased T2*; n=1) and abnormal laboratory value (increased urinary protein:creatinine ratio; n=1); no deaths were reported. Investigator-assessed drug-related AEs (≥5%), including increased serum creatinine (SCr), rash and increased alanine aminotransferase (ALT), did not increase in the extension relative to the core study. Three patients dur-

ing the core and one during the extension had increased SCr >33% above baseline and upper limit of normal (ULN) on two consecutive visits. Two patients during the core and two during the extension had increased ALT >10xULN on two consecutive visits; levels were >ULN at baseline in all patients. *Conclusions.* This is the first large prospective study to report 2-year data on cardiac iron removal for any chelator. Continued therapy with deferasirox (30-40 mg/kg/day) removed cardiac iron in β-thalassaemia patients with mild-to-moderate and severe cardiac siderosis and was well tolerated. Normal cardiac function was maintained with decreased hepatic and total body iron burden.

0499

SIMULATION OF THE STRUCTURE, FUNCTION AND MOLECULAR DYNAMICS OF HB S-SÃO PAULO [BETA 6 (A3) GLU TO VAL; BETA 65 (E5) LYS TO GLU] - A NEW VARIANT OF HUMAN HEMOGLOBIN

MF Sonati,[1] S Jorge,[2] E Kimura,[2] D Oliveira,[2] L Caire,[3] L Martinez,[3] C Suemasu,[2] F Costa,[2] M Skaf[3]

[1]State University of Campinas-UNICAMP, School of Medical Sciences, Campinas, Brazil; [2]School of Medical Sciences - State University of Campinas, Campinas, Brazil; [3]Institute of Chemistry - State University of Campinas, Campinas, Brazil

Background. Hemoglobin (Hb) S [beta 6 (A3) Glu to Val], present in patients with sickle cell disease, is the most studied hemoglobin structural variant. Concomitant aminoacid replacements that reduce the affinity of the hemoglobin for O2 may lead to desoxi-HbS polymerization and hemolysis to simple carriers. *Aim.* We describe here a new beta chain variant that has a Lysine (Lys) to Glutamic acid (Glu) substitution at position 65 in addition to the Glu to Valine (Val) substitution at position 6. The presence of glutamic acid at position 65 seems to be responsible for the reduced O2 affinity showed by the total hemolysate in absence of organic phosphates. Because of the origin of its carrier, this variant was called HbS-São Paulo. Patient, Methods and *Results.* The proband, an 18-month-old male, had the following hematological parameters: RBC= 3.73×10^6/mm^3, Hb= 8.9 g/dL, Ht= 29.2%, MCV= 78.3 fL, MCH= 23.9 pg, RDW= 18.5%, and reticulocytes= 1.51%. His mother was heterozygous for HbS (AS); his father was not available for studies. Alkaline electrophoresis revealed a band that is faster than Hb A, although acidic electrophoresis, isoelectric focusing and the ID-sickle cell test were compatible with the presence of HbS in heterozygosis. Cation exchange High Performance Liquid Chromatography (HPLC) revealed this anomalous fraction, which had a distinct elution time and represented 29.6% of the total hemoglobin (at the D peak window). Reverse Phase-HPLC showed a mutated beta chain (11.47%), which eluted more slowly than the native beta one. Stability tests were slightly positive, except for the Heinz body test, which was negative. Beta gene sequencing identified two different mutations that were responsible for the Glu to Val and Lys to Glu substitutions; these corresponded to the 6th (GAG to GTG) and 65th (AAG to GAG) codons of the beta chain, respectively. The function of the total stripped hemolysate in the absence and presence of IHP (Inositol Hexaphosphoric acid) was evaluated by the method described by Rossi-Fanelli and Antonini (1958) using a pH between 6.5 and 8.5 and showed a reduced Bohr effect and affinity of hemoglobin for O2 in the stripped state without IHP despite the presence of 12.3% Hb F. To obtain insights into this decreased oxygen affinity, computational models of the double mutant structure were produced from the native structure using the NAMD simulation package and CHARMM parameters, as shown in Figure 1.

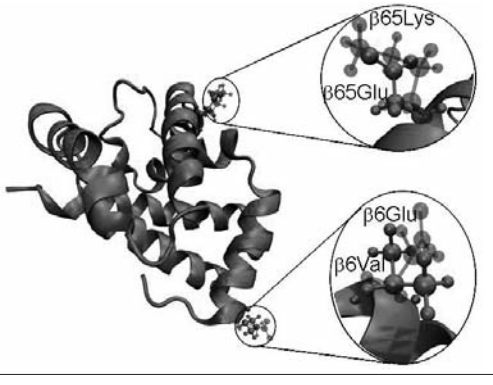

Figure 1. Double mutant of the β-blobin. Structures with transparent representation correspond the native rsidues, which ere sustituted.

Structural analysis revealed that the substitution of Lys65 by a negatively charged glutamic acid may perturb the binding of oxygen by introducing a torsional restraint on the E helix. This torsion seems to impair the entry and exit of oxygen from the heme pocket. *Conclusions.* This event could favor the desoxi-Hb conformation, as demonstrated in the functional tests, and facilitate polymerization of the variant caused by the substitution Glu to Val at position 6 of the beta-chain. *Financial support: FAPESP and CNPq / Brazil.*

0500

CRYPTIC SPLICING SITE USAGE LEADS TO TRUNCATED TMPRSS6 AND IS RESPONSIBLE OF IRON REFRACTORY IRON DEFICIENCY ANAEMIA (IRIDA) IN AN ITALIAN FAMILY

I Tchou, M Neerman-Arbez, P Beris

Centre Medical Universitaire,, Geneva, Switzerland

Background. Iron Refractory Iron Deficiency Anaemia (IRIDA) is an autosomal recessive disease characterised by 1) congenital hypochromic, microcytic anaemia; 2) low MCV (mean corpuscular volume); 3) low serum iron and low transferrin saturation; 4) normal ferritin or ferritin levels in the lower limits of the normal; 5) no response to oral iron treatment and incomplete response to iv iron administration; 6) inappropriately high levels of hepcidin. IRIDA has recently been shown to be caused by mutations in the TMPRSS6 gene, which encodes a type II transmembrane serine protease called matriptase-2 and which is predominantly expressed in the liver. Matriptase-2 (Tmprss6) is the sole protein which can reduce hepcidin expression and hepcidin plays a key role in iron homeostasis. Recently, patients with TMPRSS6 mutations and suffering from IRIDA have been reported. *Aims.* We described a male born in 1955 of Italian origin suffering from IRIDA. He presented microcytic anaemia (64fl) with low serum iron (3 mmol/L) and transferrin saturation (5%) and normal ferritin values (68 mg/L). His hepcidin expression was 9.8 nM (M: 5.8±2.8 nM). This value is inconsistent with the low serum iron of the patient and indicates impaired hepcidin regulation (no hepcidin inhibition in the presence of iron deficiency). This finding reinforced the hypothesis of IRIDA and motivated the sequencing of TMPRSS6. DNA analysis of this patient showed a homozygous G to C mutation in the last nucleotide of exon 15. We made the hypothesis that this mutation is responsible for abnormal splicing. To prove this we analysed matriptase-2 mRNA extracted from peripheral blood cells, since recently it was shown that this protein is expressed at low levels in these cells. *Methods.* DNA was extracted from peripheral blood cells according to standard techniques. All TMPRSS6 coding regions and intron-exon boundaries were sequenced as described by Finberg et al. Nat Genet 2008. mRNA was obtained from peripheral blood cells and converted to cDNA using Superscript II (Invitrogen) and we analysed it for TMPRSS6 expression. A couple of primer in exons 14 and 16 was used to amplify a normal product at 558nt. *Results.* In our patient a smaller aberrant splice transcript was produced. Sequencing analysis showed that another splice donor site was used and led to a novel mRNA with a deletion of 112nt in exon 15. This deletion induces a frameshift leading to a premature stop corresponding to a truncated protein of 595 amino acids instead of the normal one of 811AA. Furthermore this truncated protein has an abnormal carboxy terminus concerning the 16 amino acids before the stop codon. This mutation deletes the serine protease domain of the matriptase-2. *Conclusions.* We have demonstrated that a single mutation in the last nucleotide of exon 15 of the TMPRSS6 gene by activating a cryptic splicing site, is responsible of novel mRNA characterised by a deletion of 112nt. This mutation introduces a frameshift with as a consequence the synthesis of an abnormal protein missing the serine protease domain. This molecular pathology is responsible of IRIDA.

DEVELOPMENT OF LIVER FIBROSIS/CIRRHOSIS IN ADULT HCV POSITIVE THALASSEMIA MAJOR PATIENTS

L Pancini,[1] I Motta,[1] E Cassinerio,[1] G Graziadei,[1] F Brevi,[1] L Zanaboni,[1] MD Cappellini[2]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Department of Internal Medicine, University of Milan, Milan, Italy

Background. It has been shown that iron and HCV infection in patients with thalassemia major (TM) are independent but mutually reinforcing risk factors for the development of liver fibrosis and cirrhosis, with a reciprocal multiplicative effect. *Aim.* The aim of this study was to evaluate the prevalence of HCV infections and iron-related liver disease in

a cohort of adult TM patients in a single care center. *Design and Methods.* We performed a retrospective analysis in a cohort of 132 transfusion dependent TM patients (80 female/52 male, aged 35±6.6 years) followed from 1997 to 2008 (mean 10±3 years) at Hereditary Anemia Center, University of Milan. All patients underwent regular blood transfusions with mean pre-transfusion hemoglobin values 9.3±0.3 g/dL and they were treated with iron chelation therapy. Five patients were lost during follow-up (3 died for liver disease, 2 for cardiovascular disease). To evaluate iron overload we monitored serum ferritin levels. Liver fibrosis was estimated by Transient Elastography (TE); TE thresholds related to Ishak fibrosis score (S) were considered: >7.9 kPa for S≥3; >10.3 kPa for S≥4; >12.0 kPa for S≥ 5. *Results.* Of 132 patients, 111(84%) were anti HCV positive of whom 71(64%) had chronic active hepatitis C because of persistently RNA positive. Liver fibrosis evaluated by TE showed higher values among anti HCV positive patients than negative patients (10.2 vs 4.7 kPa; P=0.0001), and considering patients with TE values >12 KPa, the 80% (8/10) were RNA positive. To investigate the role of iron overload and HCV infection in developing liver damage, all patients were divided in 6 groups based on HCV RNA positivity/negativity and serum ferritin levels (<1000 ng/mL, 1000-2500 ng/mL, >2500 ng/mL). In patients with serum ferritin levels <2500 ng/mL HCV RNA positive group showed significant higher levels of ALT compared to HCV RNA negative (serum ferritin levels <1000 ng/mL P=0.007; serum ferritin levels 1000-2500 ng/mL P=0.005); while HCV RNA positive patients with serum ferritin levels >2500 ng/mL had increased ALT levels but not statistically significant compared to HCV RNA negative. TE values in HCV RNA positive patients were respectively 7 kPa in patients with ferritin<1000 ng/mL and 9.6 kPa in patients with ferritin between 1000 and 2500 ng/mL. So far 25 (35,3%) RNA positive patients underwent antiviral treatment and a sustained viral response was observed only in 8/25 (31%) patients. Among RNA positive we observed 4/71 (5.6%) cases of hepatocellular carcinoma (HCC) in patient aged 45±5 years, a number significantly higher than HCV RNA positive non Thalassemia population of similar age; no one of them underwent antiviral treatment. *Conclusions.* Although chronic active infection plays a main role in developing liver fibrosis, the highest stage of fibrosis were observed in HCV RNA positive patients and with severe iron overload. These data confirm that HCV infection and iron overload are synergistic risk factors in developing fibrosis and cirrhosis that may lead to HCC. Thus it's mandatory to consider antiviral treatment in HCV positive TM patients.

0502

MOLECULAR ANALYSIS IN FAMILIAL CONGENITAL ERYTHROCYTOSIS: NOVEL MUTATIONS IN EPOR AND VHL GENES

H Almeida,[1] C Bento,[1] F Pierdomenico,[1] L Relvas,[1] U Rebelo,[1] F Lago,[2] A Herrera Diaz-Aguado,[3] R Ornelas,[4] R Costa,[5] ML Ribeiro[1]

[1]Centro Hospitalar de Coimbra, Coimbra, Portugal; [2]Hospital Teresa Herrera, A Coruña, Spain; [3]Hospital Universitario Virgen del Rocio, Sevilla, Spain; [4]Hospital Distrital Faro, Faro, Portugal; [5]Unidade Oncológica, Hospital Barreiro, Barreiro, Portugal

Background. Congenital erythrocytosis results from 1) inherited intrinsic defects in red blood cell precursors that cause increased responsiveness to EPO due to a mutation in EPO receptor gene (EPOR); 2) inherited defects in hypoxia sensing pathway due to mutation in the Von Hippel-Lindau gene (VHL), in the prolyl hydroxylase domain 2 gene (PHD2) or in the hypoxia-inducible factors gene (HIF); 3) high affinity hemoglobin variants; 4) 2,3-difosfogliceratomutase (DPGM) enzyme deficiency. The inheritance is autosomic: dominant for high-affinity Hb and EPOR mutations and recessive for DPGM, VHL and PHD2 gene mutations. Conversely, in a great number of congenital erythrocytosis the underlying defect remains unknown. *Aims.* To characterise the molecular basis of the erythrocytosis in a group of patients studied in our laboratory. *Methodology.* We studied 61 subjects, from 40 different families, with erythrocytosis. Patients were either regularly followed in our Haematology clinic or referred from other Centres. Non haematological causes associated with erythrocytosis were excluded. Laboratory testing was guided by the clinical history and EPO levels and included: exclusion of JAK2 V617F mutation by ASO-PCR, Hb analysis by high-performance liquid chromatography, DPGM activity quantification and HBB, HBA, VHL, EPOR (exons 7- 8), DPGM and PHD2 genes sequencing. *Results.* In this study we identified: in 15 subjects (11 families) eight different high-affinity Hb variants; in 10 subjects (4 families) three different mutations in the exon 8 EPOR gene; in 1 patient a homozygous missense mutation in the exon 3 VHL gene. One of the EPOR mutations, a mutation in CD487 (AAC-AGC) was already reported, the other two are novel mutations in exon 8: a nonsense 2 base pair deletion (-TC) starting in nucleotide 5997, resulting in a premature stop codon and a misense CD 437 (CGT-CAT) mutation. In the VHL gene a novel misense mutation, CD196 (AAA-GAA) in homozygote state was detected in a Spanish woman, with consanguineous parents. *Conclusions.* We were able to identify the congenital erythrocytosis molecular aetiology in 16/40 unrelated families (26/61 subjects). The presence of a high-affinity Hb variant was the commonest cause (11 families). Two novel mutations in EPOR and one in VHL, were identified. None of the subjects showed mutations in DPGM or PHD2 genes. In the remaining 24 families the erythrocytosis genetic underlying defect(s) remain elusive, needing further investigations.

Epidemiologia, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy

Background. Conventional therapy of warm autoimmune haemolytic anaemia (WAIHA) include administration of corticosteroids and immunosuppressive agents, or splenectomy, whereas no effective treatment exists for cold hemagglutinin disease (CHD). A substantial proportion of patients with WAIHA do not respond to or relapse after corticosteroid therapy and may experience clinically relevant side effects. Favorable responses to rituximab at standard doses (375 mg/m^2 weekly for 4-6 courses) have been reported in both WAIHA and CHD, idiopathic or secondary, as well as in other autoimmune diseases, such as rheumatoid arthritis and primary immune thrombocytopenia. Recently, low dose (LD)-rituximab (100 mg fixed dose weekly for 4 courses) has been proven effective in patients with autoimmune cytopenias, particularly immune thrombocytopenia. *Aims.* To evaluate the safety, activity and the duration of the response of LD-rituximab associated with standard oral prednisone (PDN) as first line therapy in newly diagnosed WAIHA and CHD, and as second line therapy in WAIHA relapsed after standard oral PDN. *Methods.* In this single-arm prospective pilot study, LD-rituximab was administered at 100 mg fixed dose weekly on days +7, +14, +21, +28 along with standard oral PDN (1 mg/kg/die p.o. from day +1 to + 30, followed by quick tapering: 10 mg/week until 0.5/mg/kg/die, then 5 mg/week until stop). Complete and partial initial responses (iCR and iPR) were defined as Hb > 12 g/dL and > 10 g/dL at month +2 from the beginning of therapy, respectively; sustained response (SR) was defined as Hb > 10 g/dL at month +6 and +12, in the absence of any treatment. *Results.* Seventeen patients (10 female, 6 male; median age 51 yrs, range 28-72) were enrolled after informed consent. An iCR and iPR were observed in 10 (59%) and 4 (24%) out of 17 patients, respectively; the median Hb level increased from 9.2 g/dL (range 4.4-12.3) at enrolment to 12.4 g/dL (range 9.1-15.3) at month +2. A SR at month +6 was observed in 12 out of 12 evaluable patients, and in the first 6 patients enrolled at month +12. One patient relapsed at month +16 and was retreated with the same protocol with iPR at month +18, and another patient at month +7, again treated with iPR at month +9. No side effects or serious adverse events were observed. For 9 relapsed AIHA patients laboratory data (Hb, LDH, reticulocytes) and steroid administration were available before LD-rituximab treatment: a lower cumulative dose (roughly 50%) of steroid was administered to patients during LD-rituximab study compared with previous therapy, without significant differences in the general trend of Hb, LDH, and reticulocytes. These preliminary results seem to indicate that the addition of LD-rituximab to standard corticosteroid therapy is a feasible and active treatment in AIHA. Data on SR are intriguing, particularly regarding the possible steroid sparing effect of LD-rituximab, but need to be confirmed in larger survey and after longer follow up.

BLOOD TRANSFUSION USAGE AMONG PATIENTS WITH SICKLE CELL DISEASE - A SINGLE INSTITUTION EXPERIENCE OVER TEN YEARS

E Drasar,[1] N Igbineweka,[1] N Vasavda,[1] M Awogbade,[2] M Allman,[2] A Mijovic,[2] SL Thein[1]

[1]Kings College, London, UK; [2]King's College Hospital, London, UK

Background. A major option in the treatment of sickle cell disease (SCD) is the transfusion of red blood cells on a chronic or intermittent basis. Long term or life-long transfusion for primary or secondary prevention of stroke is recommended (Adams *et al.*, 1998, Adams and Brambilla, 2005, Lusher *et al.*, 1976) but in recent years there has been expanding usage of blood transfusion with no clear evidence base. *Aims.* To examine the trend in blood usage among adult patients with SCD in a single institution. *Method.* The study includes adult patients (over 16 years of age) attending King's college Hospital (KCH), London, over a ten year period between 1st of January 2000 to 31st of December 2009. A total of 659 patients were identified from matching the KCH SCD database with in- and outpatients attendance. We then used this list to interrogate PathNet and WinPath (transfusion databases) and KCH electronic patient record (EPR) system for details of blood issued including indications for transfusion, number of units and method of transfusion.

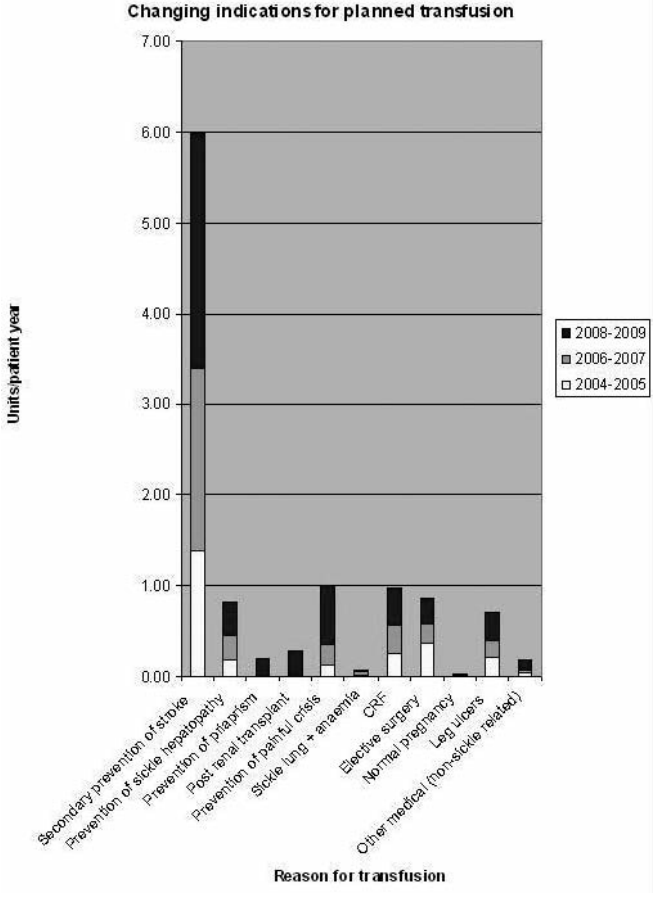

Figure 1. Changing indications for planned transfusions.

Results. The KCH cohort of SCD increased from 313 patients per year to 435 patients per year from 2000 to 2009 but the proportion of genotypes has remained stable during this time (mean%= HbSS 64%, HbSC 28%, SB+ 5%, SBo 3%). During this time period 44% of the patients were transfused at least one unit of blood. Although HbSS patients comprised 64% of the cohort they used 84% of all blood transfused. Further, 93% of all blood transfused was given to only 9% of patients thus defining this group as having a relatively more severe phenotype. The percentage of patients transfused each year has increased from 16% in 2000 to 19% in 2009, and mean units per patient increased significantly (P<0.005) from 12 (95% CI 7.6 to 16.2) to 21 (95% CI 15.7 to 25.9). Increase in blood use is most marked between 2005 and 2009 and is due to increased exchange transfusion, the majority for secondary prevention of stroke. Indications for planned transfusion have also expanded in our cohort (Figure 1). *Summary.* Blood use in the Kings sickle cell disease population has increased in the past ten years due to increase in exchange transfusion and expanding indications such as preventive therapy for sickle hepatopathy, priapism and control of acute pain (failed hydroxycarbamide therapy). The majority of blood is given to a small proportion of patients with severe disease; further evidence of the remarkable variation in disease severity.

HIGH PREVALENCE AND MORTALITY ASSOCIATED WITH THROMBOEMBOLISM IN ASIAN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH)

JW Lee,[1] JH Jang,[2] JH Lee,[3] SS Yoon,[4] JS Kim,[5] YK Kim,[6] DY Cho,[7] SK Sohn,[8] JS Chung[9]

[1]Seoul St. Mary Hospital, Seoul, South-Korea; [2]Samsumg Medical Center, Seoul, South-Korea; [3]Asan Medical Center, Seoul, South-Korea; [4]Seoul National University Hospital, Seoul, South-Korea; [5]Severance Hospital, Seoul, South-Korea; [6]Chonnam National University Hospital, Kwangju, South-Korea; [7]Chungnam National University Hospital, Daejeon, South-Korea; [8]Kyungpook National University Hospital, Daegu, South-Korea; [9]Pusan National University Hospital, Pusan, South-Korea

Introduction. PNH is a hematopoietic stem cell disorder in which uncontrolled activation of the terminal complement system leads to significant ischemic morbidities with shortened lifespan. Life-threatening thromboembolism (TE) is the most feared complication of PNH, accounting for up to 40-67% of patient deaths. It is estimated that 40% of PNH patients experience a clinically evident TE and 60% of patients without clinically diagnosed TE demonstrate TE by high-sensitivity MRI, indicating the ongoing thrombotic risk in most patients with PNH. *Aims.* To understand the impact of TE in Asian patients with PNH, we retrospectively analyzed medical charts of 286 PNH patients from national data registry in South Korea over the last 41 years.

Table.

Predictor of Mortality	Odds ratio; P value*
TE	Odds ratio 7.0; P<0.0001
Abdominal Pain	Odds ratio 2.2;P=0.046
Predictor of TE	**Odds ratio; P value***
Abdominal Pain	Odds ratio 3.6; P=0.0004;
Chest Pain	Odds ratio 2.6; P=0.024
Dyspnea	Odds ratio 2.4; P=0.015
Hemoglobinuria	Odds ratio 2.1; P=0.046
Sites of Thromboembolism Events	**% of Total TE**
Venous TE	**60 %**
Deep vein thrombosis	18%
Mesenteric/visceral vein	12%
Pulmonary embolism	10%
Hepatic portal vein	8%
Renal vein thrombosis	6%
Dermal	1.5%
Gangrene	1.5%
Cerebral venous occlusion	1.5%
RUL infarction	1.5%
Arterial TE	**39%**
Cerebral arterial occlusion	15.0%
Coronary arterial occlusion	13.0%
Myocardial infarction	(7.5%)
Unstable angina	(4.5%)
Mesenteric/visceral artery	9.5%
Retinal artery obstruction	1.5%

*Fisher exact test was used

Results. Patient ages ranged from 8 to 88 years (median 37 years), median PNH duration was 7.8 years (1 month to 41 years), and median PNH granulocyte clone size was 49%. History of another bone marrow disorder (BMD was observed in 45% of patients. TE was a strong predictor of mortality (P<0.0001; odds ratio 6.99; 95% CI 3.2 - 15.2) and accounted for 46% of patient deaths. TE was reported in 15% (43/286) of patients, of which 40% (17/43) had > 2 recorded TEs. Median age at first TE was 40 years. The likelihood of a TE was unrelated to the presence of another BMD; 40% of TE patients had BMD vs 60% of non-TE patients had BMD. TE likelihood was not influenced by granulocyte clone size: median clone size was 52% in patients with TE, 20% of patients with TE had clone size <30%, and clone size was 50% in patients without TE. TE manifested at both venous (60%) and arterial (39%) sites. Specific venous sites include DVT (18%), mesenteric/visceral vein (12%), PE (10%), hepatic portal vein (8%), and renal vein thrombosis (6%). Arterial sites were particularly common: cerebral arterial occlusion (15%), coronary artery (13%), and mesenteric/visceral artery (9.5%). The presence of abdominal pain is a significant predictor of TE (Odds ratio 3.6, 95% CI 1.8-7.4, P=0.0004) and mortality (Odds ratio 2.2, 95% CI 1.0 - 4.5, P=0.046). Additionally, dyspnea (Odds ratio 2.4, 95% CI 1.2 - 4.6, P=0.015), hemoglobinuria (Odds ratio 2.1, 95% CI 1.0 - 4.2, P=0.046), and chest pain (Odds ratio 2.6, 95% CI 1.2 - 6.0, P=0.024) were also significant predictors for TE. TE is an important signal to test for PNH. TE was reported in 21% (9/43) of patients before the diagnosis of PNH and in 21% (9/43) of TE patients within 1 month of diagnosis. *Conclusions.* These data indicate that the prevalence and impact of TE in Asian patients with PNH is similar to that in other populations. TE occurs in young patients, in venous sites and is particularly prominent in arterial locations. TE risk appears to be strong across the spectrum of granulocyte clone sizes and the presence of concomitant BMD does not diminish the risk for TE. Abdominal pain is strongly associated with TE in Asian patients. Most importantly, TE is a significant contributor to early mortality in Asian PNH patients.

CLINICAL SYMPTOMS OF HEMOLYSIS ARE PREDICTIVE OF DISEASE BURDEN AND MORTALITY IN ASIAN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH)

JW Lee,[1] JH Jang,[2] JH Lee,[3] SS Yoon,[4] JS Kim,[5] YK Kim,[6] DY Cho,[7] SK Sohn,[8] JS Chung[9]

[1]Seoul St. Mary Hospital, Seoul, South-Korea; [2]Samsumg Medical Center, Seoul, South-Korea; [3]Asan Medical Center, Seoul, South-Korea; [4]Seoul National University Hospital, Seoul, South-Korea; [5]Severance Hospital, Seoul, South-Korea; [6]Chonnam National University Hospital, Kwangju, South-Korea; [7]Chungnam National University Hospital, Daejeon, South-Korea; [8]Kyungpook National University Hospital, Daegu, South-Korea; [9]Pusan National University Hospital, Pusan, South-Korea

Background. PNH is a progressive and life-threatening disease characterized by chronic complement-mediated hemolysis. The progressive morbidities and mortality associated with PNH, including life-threatening thromboembolism (TE), renal dysfunction, pulmonary hypertension, disabling fatigue, abdominal pain and dysphagia, lead to diminished quality of life. Failure to recognize the clinical consequences of chronic hemolysis results in delayed diagnosis and, more importantly, in progressive morbidities and disease burden. The frequency and type of clinical symptoms, and the relation of these symptoms to severe morbidities and early mortality has not been previously examined in Asian PNH patients. *Aims/Methods.* To describe the clinical manifestations and disease burden of Asian PNH patients, we retrospectively analyzed medical records 286 PNH patients from national data registry in South Korea. *Results.* The median patient age was 37 years (range: 8 to 88 years) and PNH duration was 7.8 years. At diagnosis median PNH granulocyte clone was 49% and LDH was 3.9-fold above upper limit of normal (ULN). Forty-five percent (45%) of patients had history of concomitant bone marrow disorder. Median platelet count was 99×10^9/L and median ANC was 1.2×10^9/L, 21% with ANC $<1.0\times10^9$/L (with mean LDH 3.8 fold above ULN). Corticosteroids were employed in 78% and immunosuppressive treatments (ATG or CsA) in 20% of patients. Fatigue was common and reported in 76% of patients. TE was detected in 15% of patients, 21% before the diagnosis of PNH. TE was a strong predictor of mortality (P<0.0001; odds ratio 6.99; 95% CI 3.2-15.2), yet only 14% of patients were treated with antithrombotics. Late-stage kidney disease (medical diagnosis of renal impairment or documented GFR <60 mL/min/1.73 m^2) was somewhat more common than observed in Western studies and observed in 27% (36/133) of evaluable Asian patients following diagnosis. Impaired hepatic function was reported in 6% of patients, 47% after the diagnosis of PNH diagnosis. Pain was reported by 58% of patients. Medical intervention for pain was required in 47% of these patients: NSAIDs (38%), opioids (18%). Abdominal pain was reported in 46% of patients and treatment accounted for 75% of the total opioid use. Abdominal pain was a strong marker for clinical TE: 72% of patients with TE had evidence of abdominal pain. Abdominal pain significantly predicted TE (Odds ratio 3.6, 95% CI 1.8-7.4, P=0.0004) and mortality (Odds ratio 2.2, 95% CI 1.0-4.5, P=0.046). Clinical symptoms of PHT were prominent (41% of patients): shortness of breath (36%) and chest pain (12%). Furthermore, chest pain also was a significant predictor of TE (Odds ratio 2.7, 95% CI 1.2-.2, P=0.024); 29% of patients with chest pain had a TE. *Conclusions.* These data demonstrate that Asian PNH patients frequently suffer disabling symptoms and progressive disease burden including late stage kidney disease, liver dysfunction, and symptoms of PHT. Moreover, prominent symptoms such as abdominal pain and chest pain are predictors of TE. Finally, TE is a strong predictor of mortality in Asian patients. Despite medical intervention with supportive care, including 78% corticosteroid use, patients continued to demonstrate disabling symptoms, progressive complications and early mortality.

Table.

Major Symptoms of PNH	Percent of Patients
Thromboembolism	15%
Late-stage kidney disease (after diagnosis)	27%
Impaired hepatic function	6%
Pain	58%
Abdominal pain	46%
Hemoglobinuria	58%
Symptoms of pulmonary hypertension (PHT)	
Shortness of breath	36%
Chest pain	12%
Medical Treatments	
Non-specific Immunosuppressive treatment	
Corticosteroids	78%
Other immunosuppressants (CsA or ATG)	20%
Treatment or prevention of TE	
Antithrombotic medication (warfarin, heparin)	14%
Treatment of pain	
Anti-inflammatory medication	38%
Opioid medication	18%
Treatment of abdominal pain	
NSAID or opioid medications	40%

ERYTHROCYTOSIS ASSOCIATED WITH A NOVEL MISSENSE MUTATION IN THE HIF2A GENE

R van Wijk,[1] S Sutherland,[2] W van Solinge,[1] A van Wesel,[1] E Huizinga,[1] M Percy,[3] M Bierings,[1] F Lee[2]

[1]University Medical Center Utrecht, Utrecht, Netherlands; 2niversity of Pennsylvania School of Medicine, Philadelphia, United States of America; [3]Belfast City Hospital, Belfast, Northern Ireland

Background. Erythropoietin (EPO) is the central regulator of red blood cell mass. The EPO gene is regulated by the key transcription factor Hypoxia Inducible Factor (HIF) which is composed of an oxygen-sensitive α subunit (HIF-1α, HIF-2α, or HIF-3α) and an oxygen-insensitive β subunit. In this pathway, Prolyl Hydroxylase Domain protein 2 (PHD2) hydroxylates two prolyl residues in HIF-α, which in turn promotes HIF-α degradation by the von Hippel Lindau tumor suppressor (VHL) protein. Erythrocytosis is an uncommon disorder characterized by abnormally elevated red cell mass. Some cases can be attributed to mutations in proteins of the oxygen-sensing pathway that regulates HIF such as VHL and PHD2. Recently, studies have shown that mutations in the HIF2A gene comprise a third cause of erythrocytosis attributable to defects in the oxygen-sensing pathway. These studies implicate HIF-2α as the central HIF-α isoform regulating EPO in human adults. All reported HIF2A gene mutations to date affect residues that are C-terminal to the primary hydroxylation site in HIF-2α, Pro531. They variably affect the interaction with PHD2 and/or VHL. These mutations, while affecting different proteins in the oxygen-sensing pathway, all lead to aberrant upregulation of HIF-2α. *Aims.*We describe a patient with a novel HIF2A mutation associated with erythrocytosis. This mutation is predicted to result in a seemingly conservative p.Asp539Glu amino acid substitution. Notably, this is perhaps the most subtle mutation thus far described. *Methods.* The patient is a 17-year old girl of North African ancestry with elevated hemoglobin levels and red blood cell counts, respectively 17.7 g/dL and 6.3×10^{12}/L. The inappropriately high level of EPO (25 IU/L) together with the absence of any pulmonary, cardial, or renal abnormalities suggested a genetic cause of secondary erythrocytosis. Therefore, the genes encoding hemoglobin, bisphosphoglyceratemutase, PHD2, VHL, and HIF-2α were investigated by DNA sequence analysis. *In vitro* PHD2 binding assays were performed employing in vitro translated GAL4-HIF-2α fusion proteins and recombinant PHD2. VHL binding assays were performed by assessing the capacity of hydroxyprolated HIF-2α peptide to compete with hydroxyprolated HIF-1α binding for in vitro translated VHL. Hydroxyproline-531-substituted wild type or Asp539Glu HIF-2α peptides as well as N-terminal biotinylated Hyp-564 HIF-1α peptide were commercially obtained. *Results.* DNA sequence analysis showed no abnormalities other than a novel heterozygous missense mutation in HIF2A, predicting a Asp539Glu substitution at residue 539. *In vitro* PHD2 binding assays showed that wild type HIF-2α binds with easily detectable affinity to PHD2 whereas the p.Asp539Glu mutation weakens this interaction. In addition, VHL binding assays showed that VHL binds with high affinity to Hyp-HIF-1α with wild type Hyp-HIF-2α acting as an effective competitor. The p.Asp539Glu mutation diminishes the capacity of the Hyp-HIF-2α peptide to compete for VHL binding. *Summary/conclusions*. We conclude that the p.Asp539Glu mutation impairs the interaction of HIF-2α with both PHD2 and VHL. This is similar to most HIF-2α mutations studied to date. These findings support the notion that HIF-2α is the critical isoform regulating EPO in human adults and indicate that a seemingly conservative substitution is sufficient to disrupt this pathway.

SUPERIOR GRAFT-VERSUS-LEUKEMIA EFFECT ASSOCIATED WITH TRANSPLANTATION OF HLA-MISMATCHED/HAPLO-IDENTICAL COMPARED WITH HLA-IDENTICAL SIBLING DONOR GRAFTS FOR PATIENTS WITH HIGH RISK ACUTE LEUKEMIA

Y Wang,[1] XJ Huang,[2] LP Xu,[2] DH Liu,[2] KY Liu,[2] H Chen,[2] YH Chen,[2] W Han,[2] XH Zhang,[2] HX Shi,[2] FR Wang,[2] JZ Wang,[2] Y Chen,[2] T Zhao,[2] YY Zhang[2]

[1]Peking University People's Hospital,Institute of Hematology, Beijing, China, Beijing, China

Background Great progress has been made in haploidentical donor (HID) hematopoietic stem cell transplantation (HSCT). over the past 20 years, and it has become a feasible option for leukemia patients without a HLA-identical sibling donor (ISD), especially with high-risk features. It has been speculated that HID HSCT may potentially exert a strong GVL effect, but there have been no comparative clinical studies to confirm this hypothesis. *Aims.* The purpose of this non-randomized, single-center study was to comparatively analyze transplantation outcomes in a consecutive series of high-risk acute leukemia patients who underwent HSCT from either HID or ISD without *in vitro* T cell depletion (TCD) at our institute. *Methods.* The study was approved by the Institutional Review Board of the Peking University Institute of Hematology. All included patients were informed and signed an informed consent form. Consecutive patients with high-risk acute leukemia (patients in CR3 or beyond, non-remission, or CR1 with high-risk cytogenetics, such as t (4; 11) or t (9; 22), n=117) receiving HSCT from either an ISD (n=36) or a HID (n=81) between January 2005 and April 2009 were enrolled. If a matched sibling donor was unavailable as a first treatment option, patients without a suitable closely HLA-matched unrelated donor, or whose disease status left insufficient time for an unrelated donor search, were eligible for HID HSCT. The conditioning therapy for the HID group consisted of a modified BUCY2 plus ATG (thymoglobulin), while patients in the ISD group received modified BUCY2 without ATG.

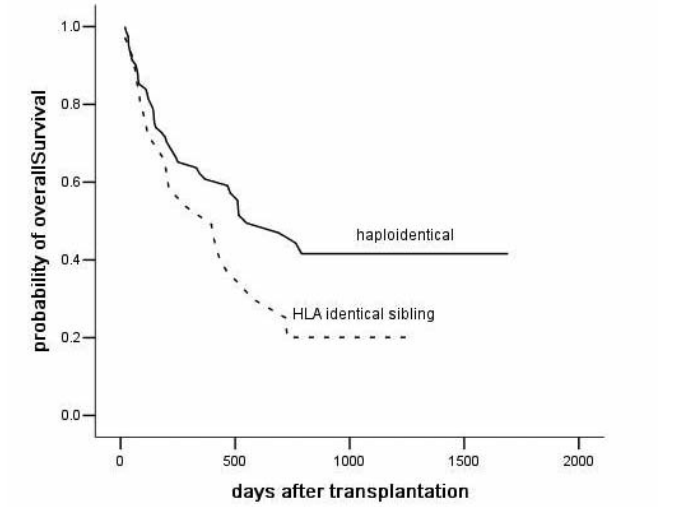

Figure. Probability of OS after ISD or HID HSCT

Results. Full engraftment was achieved in 98% patients in the HID group and 97% in the ISD group. Patients engrafted to absolute neutrophil counts exceeding 0.5×10^9/L at a median time of 13 days in the HID group and 16 days in the ISD group (P=.061). The cumulative incidences of grades II-IV acute GVHD in the HID and ISD cohorts were 49% and 24%, respectively (P=.014), with a relative risk (RR) of 2.99 (95% CI, 1.25-7.21) (P=.014). The 2-year cumulative incidences of chronic GVHD in the HID and ISD cohorts were 62% and 39%, respectively (P=.11), with a relative risk (RR) of 1.52 (0.69-3.34) (P=.30). The 2-year cumulative incidence of relapse was significantly lower in HID (26%) than in ISD patients (49%) (P = .008) with RR = 0.21 (0.08-0.53) (P=.001). The 2-year cumulative incidence of non-relapse mortality was comparable in recipients of HID (34%) and ISD grafts (38%) (P=.85).

The 3-year probability of overall survival was higher in HID patients (42%) than in ISD (20%) (P=.048) patients. The 3-year LFS in the HID group was 42% versus 15% in the ISD group (P =.029). *Summary/Conclusions* The current study showed that lower relapse rate, similar engraftment rate, and higher survival probability was achieved with HID patients than with ISD patients. The results suggest that HID HSCT might achieve a better anti-leukemia effect for high-risk acute leukemia patients.

MONITORING OF WT1 EXPRESSION IN PB AND CD34+ DONOR CHIMERISM OF BM PREDICT EARLY RELAPSE IN AML AND MDS PATIENTS AFTER HEMATOPOIETIC CELL TRANSPLANTATION WITH REDUCED INTENSITY CONDITIONING

T Lange,[1] M Hubmann,[2] R Burkhardt,[3] G Franke,[2] M Cross,[2] M Scholz,[4] S Leiblein,[2] HK Al-Ali,[2] J Edelmann,[5] J Thiery,[3] D Niederwieser[2]

[1]University of Leipzig, Leipzig, Germany; [2]Department of Hematology and Oncology, University of Leipzig, Leipzig, Germany; [3]Department of Clinical Chemistry and Molecular Diagnostics, Leipzig, Germany; [4]Institute for Medical Informatics, Statistics and Epidemiology, Leipzig, Germany; [5]Institute for Forensic Medicine, Leipzig, Germany

*Background.*HCT following reduced intensity conditioning (RIC) relies mainly on immunological effects for disease control. The early detection and quantification of minimal residual disease and the timely adjustment of immune suppression are therefore particularly important in this setting. *Aims.* Since appropriate disease-specific gene markers are not always available in patients with acute myeloid leukemia (AML) or myelodysblastic syndrome (MDS), the potential of both donor chimerism and Wilms Tumor gene 1 (WT1) expression to provide quantification of MRD was investigated. *Patients and Methods.* Eighty eight consecutive patients with AML (n=68) and intermediate/high-risk MDS (n=20) were analyzed. Patients were 61 (median; range 22-74) years old and in CR1 (n=41), CR2 (n=25), or more advanced disease status (n=22). Grafts were obtained either from related (n=22) or unrelated (n=66) donors. Conditioning regimens consisted of fludarabine 30 mg/kg BW day -4 to -2 (n=84) and total body irradiation with 2 Gy at day 0 (n=88), and post-transplant immunosuppression employed cyclosporin A and mycophenolate mofetil. Total donor chimerism (TDC, n=86 patients, 221 samples), CD34+-chimerism (n=86, 196 samples) and disease-specific molecular markers detected by FISH (DSM, n=38, 70 samples) were all determined prospectively from bone marrow (BM) samples at baseline and on days +28, +56 and +84 post-transplant. WT1 expression was analyzed retrospectively by RT-PCR from stored peripheral blood (PB) samples (n=86, 260) from the same time points. *Results.* With a median follow-up of 12.3 (range 1.3-64.9) months, 32 (37.2%) patients relapsed (defined by BM blasts >5%). Since complete results from all techniques were available up to day 84, we analyzed the diagnostic power of all methods to predict hematological relapse one month in advance up until the fourth month after HCT (n=21 patients, 24%, 66% of all relapses). First, we estimated the value of the three different prospective MRD techniques (DSM, TDC and CD34+ chimerism) using Receiver Operating Curves (ROC). Relapse was predicted 1 month in advance by a decrease of $CD34^+$-chimerism of ≥ 5% [P= 0.001, area under the curve (AUC) = 0.895], but not by TDC or DSM. The cut-off value of 5% decrease in $CD34^+$ chimerism in a one month period achieved a sensitivity of 71% and specificity of 91%. In comparison, WT1 expression was similarly associated with a pending relapse (P< 0.0001, AUC = 0.855). The optimal cut-off value of 24 WT-1 copies per 10000 ABL copies was assessed by ROC and resulted in a sensitivity of 79% and specificity of 89%. In a logistic regression model, we estimated the ratios of the odds of relapsing within the next month. WT1 achieved a higher odds ratio (27.6/1) than $CD34^+$ chimerism (23.9/1). Combining both techniques yielded a specificity of 98% and an odds ratio of 61/1. *Conclusions.* WT1 expression in PB and $CD34^+$ chimerism in BM are superior to full donor chimerism and disease-specific markers determined by FISH in predicting relapse

0509

STABLE VESSEL GENERATION TROUGH APPLICATION OF BLOOD-DERIVED ENDOTHELIAL COLONY FORMING PROGENITOR CELLS (ECFCS) AND MESENCHYMAL STROMAL / STEM CELLS (MSCS)

A Reinisch, N Hofmann, A Obenauf, K Karl, E Rohde, K Schallmoser, D Thaler, M Frühwirth, K Flicker, W Linkesch, M Speicher, D Strunk

Medical University of Graz, Graz, Austria

ECFCs have recently been described as vascular progenitor cells with robust proliferative potential and vessel-forming capacity. This study was performed to establish conditions for the generation of stable vessels by ECFC/MSC-cotransplantation. MSCs were propagated as previously described. ECFCs were isolated with a novel recovery strategy and propagated under animal protein-free culture conditions with pooled human platelet lysate (pHPL) replacing fetal bovine serum (FBS). ECFC long-term proliferation potential was monitored and phenotype was analyzed by flow-cytometry and immune- cytochemistry. Functionality was studied during vascular network assembly *in vitro* and in human vessel formation in immune-deficient mice *in vivo*. Genomic stability was assayed with chromosome G-banding and array-comparative genomic hybridization (array-CGH). Additionally we compared telomere-length and telomerase-activity of ECFCs at different time points of culture with flow-fluorescence *in situ* hybridization (Flow-FISH) and telomere repeat amplification protocol-assay (TRAP). A mean of four ECFC colonies/mL of peripheral blood could be recovered. The progeny of these cultures could be expanded to mean $1.5\pm0.5\times10^8$ ECFCs within 11-25 days. ECFC purity, immune phenotype and sustained proliferation potential for >30 population doublings with preserved progenitor hierarchy could be confirmed following analysis. Karyotyping and array-CGH revealed genomic stability. Large-scale expanded ECFCs functioned even after cryopreservation to form complex vascular networks *in vitro* and assembled stable $CD31^+$/$Vimentin^+$/von Willebrand factor+ human vessels when transplanted with MSCs *in vivo*. Direct connection to murine circulation of the developed human vessels was indicated by a rich content of $Ter119^+$ murine erythrocytes. This demonstrates that ECFC/MSC-cotransplantation results in generation of functional and stable human vessels. The procedure should help to set a new standard for the study of therapeutic applicability and risk profile of vessel-forming ECFC-based investigational new drugs.

A NEW PRE-TRANSPLANT PREDICTIVE MODEL FOR EVENT FREE SURVIVAL INCORPORATING FUNCTIONAL IMAGING USING FDG-PET IN LYMPHOMA PATIENTS UNDERGOING HDC & ASCT

S Akhtar, A Al-Sugair, M Abuzaid, Y Al Kadhi, M Dingle, M Abdelsalam, H Soudy, A Mohamed, A Darwish, M Nabil, I Maghfoor Saad Akhtar

King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia

Background. There are emerging data indicating poor outcome in diffuse large cell lymphoma (DLCL) and Hodgkin's Lymphoma (HL) patients with positive 18F-fluorodeoxyglucose positron emission tomography ((FDG-PET) before HDC ASCT. Large studies to evaluate various prognostic factors along with FDG-PET in this setting are very limited. *Aims.* This study evaluates the impact of PDG-PET among other prognostic / predictive factors. We also constructed a predictive model based on pre transplant FDG-PET results and other factors for post HDC ASCT residual / progressive disease and relapse in patients with DLCL and HL undergoing HDC ASCT. *Methods.* From 2003 to September 2009, 215 consecutive patients with HL and DLCL underwent HDC ASCT. Of these, 127 patients had FDG-PET after salvage chemotherapy / prior to HDC ASCT. ESHAP was used as salvage chemotherapy, responding DLCL or responding / stable HL patients had BEAM as HDC. Patient had CT scan and FDG-PET before starting ESHAP, after 2-3 cycles of ESHAP / prior to HDC ASCT and 100 days post ASCT. FDG-PET "positive study" was defined as study showing evidence of disease and "negative study" as no evidence of disease. Disease specific (DS) event is defined as presence of persistent disease, progression or relapsed disease after ASCT. DS event free survival (DS-EFS) was calculated from day 0. Logistic regression (univariate analysis) was used to identify the significance of various factors at relapse / progression on DS-EFS (gender, histology, prior XRT, age at ASCT 30 vs > 30, LDH, PS 0,1 vs higher, B symptoms, spleen involvement, CT positive vs negative, extranodal involvement, stage I-II vs III-IV, bulky disease, mediastinal involvement, refractory vs relapsed, FDG-PET positive vs negative. Factors with P=< 0.1 were selected for multivariate analysis. Each

patient was scored with 0, 1, 2 or 3 depending upon the number of significant risk factors identified. DS-EFS was calculated using Kaplan-Meier Method and comparison between groups using log-rank test. *Results.* There were 73 (58%) male and 54 (42%) female: DLCL: 34 (27%) and HL: 93 (73%). Relapsed: 59 (46%), refractory 68 (54%). Median age at ASCT was 28 years (14 to 63). Median follow-up of all patients from ASCT is 18 months (1.2 to 83 months); alive patients 21 months. Mmultivariate analysis showed FDG-PET positive (P=0.0001), mediastinal involvement (P=0.008) and refractory disease (P=0.04) as significant factors. As of February 28, 2010, of these 127 patients, 45 (35%) had a DS-EFS event, DS-EFS is 65%. DS-EFS for PET negative vs. positive patient is 72% vs. 40% at 36 months (P=0.0001). DS-EFS for patients with score 0 (100%), score 1 (66%), score 2 (51%) and score 3 (26%) showing a very significant impact (P=<0.0000) ((survival graph). *Conclusions.* Prior to HDC ASCT, FDG - PET scan result is the most important predictor of DS-EFS among mediastinal involvement and refractory disease. Based on these factors, a score can be used to predict treatment failure in these patients. Higher score indicates increasing risk of residual disease / progression or relapse. These patients are potential candidate for more aggressive and experimental therapies.

INDUCTION OF GVHD BY HEMATOPOIESIS-SPECIFIC T CELLS MAY OCCUR DURING AN ONGOING PROFOUND GVL REACTION DUE TO ICAM-1 MEDIATED INDUCTION OF COLLATERAL DAMAGE

B van der Zouwen, A Kruisselbrink, P von dem Borne, J Falkenburg, I Jedema

Leiden University Medical Center, Leiden, Netherlands

Graft versus host disease (GvHD) after allogeneic stem cell transplantation (SCT) may occur when donor T cells respond to antigens specifically expressed on cells of the recipient, such as minor histocompatibility antigens (mHags). It has been hypothesized that ubiquitously expressed mHags, like HY and ADIR-1F may be targets for both GvHD and graft versus leukemia (GvL), whereas hematopoiesis-restricted mHags such as HA-1 may give rise to a more specific GvL effect without GvHD. However, it has been reported that mismatching for HA-1 is correlated with the development of GvHD. In addition, there is clinical evidence that the presence of a high tumor load leading to a profound GvL reaction may be associated with the induction of GvHD. Based on these observations, we hypothesized that hematopoiesis-restricted T cells may have the capacity to induce collateral damage to surrounding non-hematopoietic tissues during an ongoing profound immune response against hematopoietic cells of the patient. To test this hypothesis we investigated in-vitro whether mHag-specific cytotoxic T lymphocytes (CTLs), in the presence of mHag positive hematopoietic targets, could lead to lysis of surrounding mHag-negative primary human fibroblasts in a 4, 8 and 20hrs chromium release assay. No damage to fibroblasts occurred under steady state conditions. However, in a pro-inflammatory environment mimicked by IFNg pretreatment of fibroblasts, HA-1-specific CTLs optimally activated by HA-1 positive EBV-LCL (S/R ratio 10/1), exerted 40% (25-60%) bystander cytotoxicity to the surrounding fibroblasts at a 10/1 T cell/fibroblast-ratio after 20 hrs. T cell activation was required for the induction of this collateral damage since no bystander kill was observed when HA-1-specific CTLs were exposed to HA-1 negative EBV-LCL. Using a transwell system we demonstrated that this bystander kill was not mediated by soluble factors like cytokines, since direct T cell-fibroblast interaction was required. To investigate how mHag-specific CTLs could interact with the mHag negative fibroblasts we used imaging techniques using fluorescent microscopy. As expected no strong association of mHag-specific CTLs with mHag negative fibroblasts was observed under steady state conditions. However, under pro-inflammatory conditions a firm attachment of mHag-specific CTLs to fibroblasts was seen in the absence of specific peptide/MHC recognition. Since ICAM-1 was significantly upregulated on the fibroblasts after IFNg pre-treatment, we analyzed the requirement of ICAM-1 expression by transduction of ICAM-1 into fibroblasts. This enforced expression of ICAM-1 appeared to be sufficient to achieve the firm T cell-fibroblast interactions and allowed the mHag-specific T cells to induce collateral damage even without IFNg pretreatment. In conclusion, these data indicate that hematopoiesis-specific T cells, activated during a profound GvL immune response may create a pro-inflammatory environment, which allows them to attach to surrounding non-hematopoietic tissues in the absence of expression of relevant peptide/MHC complexes, resulting in the induction of collateral damage.

PLASMA BRAIN NATRIURETIC PEPTIDE PREDICTS HEPATIC VENO-OCCLUSIVE DISEASE AND MORTALITY IN ALLOGENEIC STEM CELL TRANSPLANTATION

Y Nannya, K Kataoka, H Iwata, S Seo, K Kumano, T Takahashi, R Nagai, M Kurokawa

Tokyo University, Tokyo, Japan

Background. Hepatic veno-occlusive disease (VOD) is a life-threatening complication after hematopoietic stem cell transplantation (HSCT) and featured with unexplained fluid retention, jaundice, and right hypochondrial pain with hepatomegaly. Because brain natriuretic peptide (BNP) is a 32-amino-acid neurohormone synthesized in ventricular myocardium and secreted in response to volume expansion, we hypothesized that plasma BNP concentrations indicate onset and/or severity of VOD and serve as a prognostic marker after HSCT. *Methods.* We retrospectively analyzed the association of plasma BNP with the onset of VOD and early mortality after allogeneic HSCT in 33 consecutive adult patients who underwent allogeneic HSCT at our institution between February 2008 and February 2009. Plasma BNP concentrations were measured once before transplantation for routine workup and weekly after transplantation, using fluorescence enzyme immunoassay. The diagnosis of VOD was based on modified Seattle criteria and the severity of VOD was defined according to the established criteria. *Results.* A total of 12 (36.3%) patients developed VOD (mild to moderate in 6 and severe in 6) between 1 and 15 days (median, 9.5 days) after transplantation. Plasma BNP concentrations were similar before and on day 0 between patients with and without VOD, but significantly increased on day 7 and later in those with VOD. Peak plasma BNP concentrations before engraftment in patients with VOD were significantly elevated compared with those without (median values, 1686.9 pg/mL vs. 87.6 pg/mL; P=0.01). Among patients with VOD, peak BNP was associated with its severity (3678.0 pg/mL in severe VOD vs. 525.1 pg/mL in mild to moderate VOD; P=0.02). We investigated the impact of plasma BNP on early mortality using peak plasma BNP concentrations before day 14 because most patients presented VOD before day 14. ROC curve analysis showed a BNP cutoff value of ≥380 pg/mL could effectively differentiate nonsurvivors from survivors at day 100, with a sensitivity of 85.7% and a specificity of 84.6%. We investigated the associations between plasma BNP concentrations and these conditions because plasma BNP concentrations can be increased in various diseases including heart failure and sepsis. However, there was no significant correlation between peak BNP concentration before engraftment and documented infection (P=0.72). With respect to cardiac function, pretransplant left ventricular ejection fraction (LVEF) showed no correlation with peak plasma BNP concentrations before engraftment (r=-0.09; P=0.63). In 6 patients whose peak BNP concentrations were ≥ 1000 pg/mL, cardiac performance was normal or slightly reduced (LVEF ≥50%) in 4 patients and moderately deteriorated (LVEF 30 - 50%) in 2 patients when they had peak plasma BNP concentrations. *Conclusions.* We found plasma BNP concentrations are elevated in patients with VOD and associated with the severity of VOD and mortality at day 100, irrespective of pretransplant cardiac function and coexistence of documented infection. These findings suggested plasma BNP may represent a prognostic marker of VOD and could offer a valuable tool toward therapeutic interventions.

OUTCOME OF PEDIATRIC CD3/CD19 DEPLETED HEMATOPOIETIC STEM CELL TRANSPLANTS IN A SINGLE UK CENTER

D O'Connor,[1] H Kaur,[1] G Turner,[2] P Davies,[1] P Darbyshire,[1] M Velangi,[1] S Lawson[1]

[1]Birmingham Children's Hospital, Birmingham, UK; [2]Birmingham NHSBT Centre, Birmingham, UK

Background. T-cell depletion for allogeneic hematopoietic stem cell transplantation (HSCT), via graft manipulation, commonly involves CD34+ cell selection, rendering the graft deplete of CD34- cells. However, studies have suggested that cells lost through this method, particularly natural killer (NK) cells, play an important role in engraftment, immune reconstitution and the graft versus leukemia (GvL) effect. In response to this an alternative selection method has been developed involving $CD3^+/CD19^+$ cell depletion, thus retaining CD34- progenitors, NK cells and dendritic cells. *Aims.* This study reports a retrospective comparison of 59 $CD34^+$-selected pediatric HSCT's and 40 $CD3^+/CD19^+$ depleted pediatric HSCT's, in terms of engraftment, immune reconstitution and outcome. It is the first study to provide outcome data for patients receiving CD3+/CD19+ depleted grafts from both matched unrelated and haploidentical donors. *Methods*. All patients who underwent allogeneic HSCT at Birmingham Children's Hospital between January 2001 and October 2009 were identified retrospectively from local databases. Graft manipulation prior to April 2006 was $CD34^+$ selected; from May 2006 onwards grafts were $CD3^+/CD19^+$ depleted. All manipulated grafts were included in this study for analysis. Repeat transplants in single patients were excluded. *Results.* The study included 59 patients in the CD34 group and 40 patients in the CD3/19 group (median age 7 vs. 9 years), who underwent HSCT's for a variety of malignant and non-malignant diseases. The CD34 group included 6 matched related, 29 matched unrelated and 24 haploidentical transplants, whilst the CD3/CD19 group included 6 matched related, 23 matched unrelated and 11 haploidentical transplants. Groups were comparable based on age, diagnosis and graft type. Median follow up was 67 months in the CD34 group and 28 months in the CD3/CD19 group. Rejection rates were similar in the two groups, with 4 primary graft failures in each (P=0.826). Time to neutrophil engraftment (absolute neutrophil count>0.5×10^9/L) was identical, with a median of 12 days, but time to platelet engraftment (platelet count>50×10^9/L) was significantly shorter in the CD3/CD19 group (18 vs. 15 days, P=0.010). Time to immune reconstitution (CD3>0.3×10^9/L) was similar in the CD34 and CD3/CD19 groups (85 days vs. 100 days, P=0.269). Transplant related mortality under 100 days was similar (12% vs. 15%, P=0.650). There was significantly more acute graft versus host disease (GvHD) in the CD3/CD19 group (35% vs 55%, P=0.009) but no difference in chronic GvHD, veno-occlusive disease, or viral infection. Significantly, Kaplan Meier estimation of patients with malignant disease showed no difference in relapse rates between the two groups (28% vs 44%, Log Rank P=0.235). *Summary/Conclusions* In keeping with previous evidence there was a significant reduction in time to platelet engraftment in the CD3/CD19 group. However, we could not demonstrate a significant improvement in neutrophil engraftment or immune reconstitution. As expected higher rates of acute GVHD were seen in the CD3/CD19 group but this did not translate into improved relapse free survival. A randomized controlled trial is therefore necessary to further define the role of CD3/CD19 depletion in pediatric HSCT.

EFFECT OF DONOR REGULATORY T CELLS ON CMV-SPECIFIC CD8+ T LYMPHOCYTES RECONSTITUTION AND ACUTE GVHD AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

D Pastore, M Delia, A Mestice, P Carluccio, A Ricco, A Russo Rossi, R Angarano, C Longo, N Sgherza, M Leo, V Liso, G Specchia

Hematology-University of Bari, Bari, Italy

Backgound. Regulatory T-cells (T reg,$CD4^+CD25^{high}Foxp3^+$) are important regulators of allo-reactivity and may therefore represent an important predictor for the risk of acute graft versus-host disease (aGvHD) and immune reconstitution after allogeneic peripheral stem cell transplantation (allo-PBSCT). *Patients and Methods.* To determine the clinical significance of T regs in peripheral stem cell grafts, we analyzed 34 myeloablative alloPBSCT and correlated the T regs in the donor graft with the aGvHD incidence and immunological recovery (evaluated on recovery of CMV-specific $CD8^+$ T lymphocytes by tetramer analysis). We used fluorochrome-conjugated tetrameric complexes of HLA-A101, HLA-A201, HLA-B702, HLA-B801, HLA B3501 to monitor recovery of CMV-specific $CD8^+$ according to the patient's HLA. Patients were transplanted with unmanipulated peripheral blood stem cells from an HLA identical related donor (n=29) or an HLA identical unrelated donor (n=5). Median age was 32 years (range (r) 18-58); diagnoses were acute myeloid leukaemia (n=31) and acute lymphoblastic leukaemia (n=3). The median T regs dose administered was 5×10^6/Kg (r:1-20).The patients were divided into a high T regs group (T regs>5×10^6/Kg, n=14) and a low T regs group (T regs<5×10^6/Kg, n=20) according to the number of T regs in the grafts. *Results.* Median CMV-specific $CD8^+$ T lymphocytes were significantly higher in patients with high than with low T regs in the graft at 1(2 cells/mmc vs 0, P<.001), 2(6 cells/mmc vs1, P<.001), and 3(15 cells/mmc vs 3, P<.001) months. During the three months after transplantation, CMV infection/disease was observed in 2/13 (15%) patients with high T regs and in 12/20(60%) patients with low T regs (P=.015). Moreover, the median recovery of T regs after transplantation was significantly higher in patients with high T than with low T regs in the grafts at 2 (15 cells/mmc vs 6, P<.001) and 3 months(23 cells/mmc vs 8, P<.001). The incidence of aGvHD (grade II-IV) in the high infused T regs group was lower than in the low T regs group (1/13 or 7% vs 11/20 or 55%, P=.009). *Conclusions.* We suggest that there is a good correlation between the number of T regs in the graft and the incidence of aGvHD after myeloablative allo-PBSCT. T regs mediate protective effects against aGvHD and the maintenance of an optimal microenviroment for the reconstitution of functional immunity. Our results support further consideration of T regs immunotherapy for clinical alloSCT.

0515

IMPACT OF CYCLOSPORINE LEVELS ON THE DEVELOPMENT OF ACUTE GRAFT VERSUS HOST DISEASE IN THE REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION SETTING

I García Cadenas, D Valcarcel, J Piñana, R Martino, P Barba, S Novelli, A Sureda, J Briones, J Delgado, M Granell, L Facchini, A Kerguelen, S Brunet, J Sierra

Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background. Previous studies have supported that high serum cyclosporine (CsA) levels in the early phase after transplantation could result in a lower incidence of acute graft versus host disease (aGVHD) after myeloablative allogeneic stem cell transplantation (allo-SCT). If this finding also applies to reduced intensity allo-SCT (allo-RIC) has not been reported. *Aims.* The aim of the study was to analyze the impact of CsA levels in the development of grade 2-4 aGVHD (2-4 aGVHD) in the setting of allo-RIC in the first four weeks after transplantation. *Methods.* This study analyzes 134 consecutive patients [56 (41,8%) women], median age 53 (17-69) years old, who underwent HLA-identical sibling allo-RIC at a single institution. RIC included fludarabine 150 mg/m^2 plus busulphan (Bu) 10 mg/kg (for myeloid malignancies n=44 and PNH n=1) or melphalan (Mel) 70-140 mg/m^2 (lymphoid malignancies n=88 and aplastic anemia n=1). GVHD prophylaxis was based on CsA plus methotrexate (MTX) (n=113) or mychopenolate mofetil (MMF) (n=21). CsA levels were measured at least twice weekly during the first four weeks (or until discharge) and the dose was adjusted to maintain blood levels between 200 and 300 ng/mL. *Results.* As the use of MTX vs MMF and Bu vs Mel did not impact on the incidence of grades 2-4aGVHD patients were analyzed together. The median blood concentrations of CsA at 1st, 2nd, 3rd and 4th weeks after allo-SCT were 138 (range: 10-444), 214 (range:60-656), 247 (range: 53-586) and 224 ng/mL (range: 49-670) respectively. Forty patients (29,9%) developed grade 2-4 aGVHD for a cumulative incidence of 32% (95% CI 25-42%) at a median of 34 (range:18-137) days after allo-SCT. One hundred and seven (80%), 44 (33%), 25 (19%) and 19 (14%) of patients had levels below 150 ng/mL in the 1st, 2nd, 3rd and 4th week respectively. In univariate analysis the variables associated with a higher incidence of 2-4 aGVHD were: donor-recipient sex (female to male) P=0,05, CsA mean levels in the 3rd week (P=0.011), CsA levels below 150 ng/mL in the 3rd week (P=0,001) and CsA levels below 150 ng/mL in the 4th week (P=0,013). In multivariate analysis, the only significant variables associated with higher 2-4 aGVHD were CsA levels below 150 ng/mL in the 3rd (RR 2,6 (95% CI 1,2-5,6) P=0.014) and 4th weeks (RR 2.3 (95% CI 1-5.3) P=0.05). *Conclusions.* In the RIC setting, CsA level below 150 ng/mL in the third and/or fourth weeks after SCT is associated with a high risk of developing 2-4 aGVHD.

0516

THE ABSENCE OF KIR ACTIVATING RECEPTORS IN DONOR NATURAL KILLER CELLS INCREASES THE RISK OF ACUTE GVHD IN UNRELATED HEMATOPOIETIC STEM CELL TRANSPLANTATION

R Littera,[1] S Aresu,[2] N Orrù,[3] A Ventrella,[3] B Casula,[3] M Arras,[2] P Paganelli,[2] M Simbula,[2] G Caocci,[2] D Lisini,[4] S Nesci,[5] C Giardini,[5] F Locatelli,[4] C Carcassi,[3] G La Nasa[2]

[1]Azienda USL8 - R. Binaghi Hospital, Cagliari, Italy; [2]CTMO Binaghi Hospital, Cagliari, Italy; [3]Cattedra di Genetica Medica,Università di Cagliari, Cagliari, Italy; [4]Oncoematologia pediatrica, Policlinico S.Matteo, Pavia, Italy; [5]Centro trapianti midollo osseo di Muraglia, Ospedale S.Salvatore, Pesaro, Italy

Background. NK cells exert their activity through interaction of Killer cell immunoglobulin-like receptors (KIRs) with specific ligands on the surface of target cells. Many of the KIRs recognize human leukocyte antigen (HLA) class I molecules. Two broad haplotypes of KIR genes have been defined. The A haplotype is characterised by the presence of a single activating KIR gene (2DS4), whereas the B haplotype is characterised by two or more activating KIR genes (2DS1, 2DS2, 2DS3, 2DS5 e 3DS1).). About 80% of homozygotes for KIR haplotype A carry the KIR2DS4*003 allele which is not expressed. *Aims.* The aim of this study was to evaluate whether the presence of the KIR2DS4*003 allele (not expressed) on donor KIR haplotype A could affect the outcome of unrelated hematopoietic stem cell transplantation (HSCT). *Methods.* We analyzed the KIR genotype profiles in 93 patients and their donors following allogeneic HSCT for thalassemia. All donor/recipient pairs were identical at molecular level for the HLA Class I and Class II loci. We also determined the allelic specificities of the activating KIR 2DS4 (*001, *002, *003). The conditioning regimen was the same in all patients. *Results and conclusions*. Out of transplanted patients, 70 are alive and well (disease-free survival 75%), 11 rejected and 12 died. Twenty-six patients (26/93-28%) developed acute graft-versus-host disease (aGVHD). In 9 of these patients, aGVHD was grade III-IV. Patients transplanted from donors with NK cells lacking activating KIRs (homozygous for KIR2DS4*003 which is not expressed) had a higher risk of developing aGVHD, particularly severe grade III-IV aGVHD (HR= 14.8; 95% CI: 2.8 - 78.5; P<.001). Overall, our findings suggest that the KIR gene profile and 2DS4 KIR expression should be included among the parameters used to predict the risk for severe aGVHD following unrelated HSCT.

0517

BETA-2 MICROGLOBULIN (B2M) IS A RELIABLE UNBIASED PREDICTOR MARKER FOR OUTCOME IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AFTER ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT)

C Moreno,[1] J Delgado,[2] M Rovira,[3] L Facchini,[2] J Esteve,[3] C Martinez,[3] G Ferrer,[3] R Martino,[2] J Sierra,[2] E Montserrat[4]

[1]Hospital Clinic, Barcelona, Spain; [2]Department of Hematology. Hospital Santa Creu i Sant Pau, Barcelona, Spain; [3]Department of Hematology. Hospital Clinic, Barcelona, Spain; [4]Department of Hematology. Hospital Clinic. University of Barcelona, Barcelona, Spain

Background. Allo-SCT is the only treatment able to cure a fraction of patients with CLL. Advanced stage, extensive prior therapy, lack of response to therapy, and T cell depletion of the graft are considered to have a negative impact on outcome after allo-SCT. Nevertheless, to date there are no conclusive prognostic factors analysis to identify subgroup of patients who are most likely to benefit from being allografted. B2M has important prognostic value in patients treated with chemoimmunotherapy but has been scarcely investigated in the context of allo-SCT. Aims/*Methods.* We investigated the influence of prognostic factors including B2M in 50 patients who received an allo-SCT (32 non-myeloablative,18 myeloablative) in two institutions, between 1991 and 2008. Median age was 51 (29-63). Interval between diagnosis and SCT was 46 months (6-129). Median number of prior therapies, 3 (1-7). Eight patients had previously received an autologous SCT (auto-SCT). Most patients had adverse biologic features (high ZAP-70 expression, unmutated IGHV, poor cytogenetics). Serum B2M levels were ≥ 3.0 mg/L in 14 out of 48 patients prior to transplant. 48% of patients were refractory to fludarabine. Creatinine levels were normal. *Results.* Median follow-up after transplantation was 7 years (1.8-17). The relapse risk (RR) at 5 and 10 years was 15% (CI, 1-29) and 38% (CI, 11-65), respectively. At one and 10 years the non-relapse mortality (NRM) was 38% (95% CI, 25-51) and 43% (95% CI, 29-57). Five and 10-year progression free survival (PFS), event free survival (EFS) and overall survival (OS) were 85% (CI, 72-99) and 62% (CI, 35-89), 45% (CI, 30-60) and 32% (CI, 16-49), and 51% (CI, 37-65) and 48% (CI, 33-62). In the univariate analysis, factors associated with a higher NRM were prior auto-SCT (P=0.001), number of prior therapies (≤2 vs. >3) (P=0.04) and serum B2M levels (>3 mg/L) at the time of SCT (P<0.001). Time from diagnosis to SCT (>3 years) was associated with EFS (P=0.029) and high B2M levels (P<0.001), prior autologous SCT (P<0.001 and P=0.001), and number of prior therapies (≤ 2 vs. >3) (P=0.008 and P=0.023) were associated with both EFS and OS. In the multivariate analysis, prior auto-SCT was associated with EFS (RR=3, CI: 1.2-8.2; P=0.02) and OS (RR=3, CI: 1.1-7.7; P=0.03) whereas pretransplant B2M levels were an independent factor for NRM (RR=6.80; CI: 2.7-17), EFS (RR= 3.3; CI: 1.5-7.5; P=0.003) and OS (RR=4.4; CI: 1.9-10.3; P=0.001). Furthermore, B2M remained the strongest prognostic factor associated with outcome when the analysis was restricted to patients who received a non-myeloablative SCT. In contrast, other well known prognostic variables were not associated with outcome. *Summary.* Although B2M correlates with chemorefractory disease, this study indicates that, B2M is a strong predictor factor for outcome in CLL patients submitted to allo-SCT. Thus, whereas the diagnosis of refractory disease relies on criteria not always easy to be assessed (i.e, prior therapies, sites with remaining disease and their evaluation methods - clinical or imaging studies), B2M seems to be a reliable predictor factor of clinical outcome of patients with CLL receiving an allograft.

0518

EARLY VS CONVENTIONAL/LATE AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN MULTIPLE SCLEROSIS: LESSONS LEARNED OVER THE PAST TEN YEARS OF RUSSIAN-AMERICAN COOPERATION

Y Shevchenko,[1] A Novik,[1] A Kuznetsov,[1] V Melnichenko,[1] D Fedorenko,[1] T Ionova,[1] A Kartashov,[1] K Kurbatova,[1] G Gorodokin[2]

[1]National Pirogov Medical Surgical Center, Moscow, Russian Federation; [2]New Jersey Center for Quality of Life and Health Outcome Research, New Jersey, USA

High dose immunosuppressive therapy with autologous hematopoietic stem cell transplantation (HDIT+AHSCT) is a new and promising therapy for severe autoimmune diseases which has been used with increasing frequency as a therapeutic option for multiple sclerosis (MS) during the last decade. Among a number of unclear questions is the timing for transplantation in MS patients. According to our concept there are 3 strategies of HDIT+AHSCT depending on terms of disease process: early (EDSS 1.5-3.0), conventional (EDSS 3.5-6.5) and late (EDSS 7.0-8.5). We aimed to study treatment outcomes in MS patients after early, conventional/late HDIT+AHSCT. 164 MS patients (secondary progressive - 57, primary progressive - 29, progressive-relapsing - 5, relapsing-remitting - 73) were included in this study (mean age - 33.0; male/female - 66/98). 72 patients underwent early transplantation, 84 - conventional, 8 - late transplantation. Median EDSS at baseline - 4.0. The mean follow-up duration - 22.9 months (range 6 - 128). Median follow-up duration - 20.6 months (range 6 - 128). Neurological evaluation was performed at baseline, at discharge, at 3, 6, 9, 12 months, and every 6 months thereafter. Transplantation procedure was well tolerated by the patients with no transplant-related deaths. The efficacy analysis was performed in 129 patients with the follow-up at least 6 months: 56 patients after early and 73 patients after conventional/late HDIT+AHSCT. At 6 months after transplantation the following distribution of patients according to the clinical response was observed: 26 patients (46%) achieved improvement and 30 patients (54%) stabilization after early transplantation; 35 patients (48%) demonstrated improvement, 37 patients (51%) - stabilization, and 1 patient (1%) - disease progression after conventional/late transplantation. At 12 months post transplant in the group of conventional/late HDIT+AHSCT one more patient progressed. No progression was registered in the group of early transplantation. At long-term follow-up (median - 24.7 months) after early HDIT+AHSCT improvement was observed in 17 (65%) patients, stabilization in 8 (31%), and progression in 1 (1%) patient. After conventional/late HDIT+AHSCT 20 (57%) patients improved, 11 (31%) were stable, and 4 (12%) progressed. No active, new or enlarging lesions were registered on MRI in patients without disease progression. Thus, HDIT+AHSCT appears to be a safe and effective treatment for MS. Early HDIT+AHSCT results in better treatment outcomes as compared to conventional/late transplantation. Further studies should be done to establish the best timing for HDIT+AHSCT.

EFFICACY OF PLERIXAFOR PLUS G-CSF FOR STEM CELL MOBILISATION IN PATIENTS WITH MULTIPLE MYELOMA OR LYMPHOMA WHO HAVE FAILED PRIOR MOBILISATION - A NAMED PATIENT PROGRAM [NPP] EVALUATION

F Apperley,[1] G Cook,[2] A Pagliuca,[3] K Stringaris,[1] K Douglas,[4] A Pozo,[5] K Wilson,[6] J Davies[7]

[1]Imperial College London, London, United Kingdom; [2]St James University Hospital, London, United Kingdom; [3]Kings College Hospital, London, United Kingdom; [4]Gartnaval General Hospital, Glasgow, United Kingdom; [5]Addebrooks Hospital, Cambridge, United Kingdom; [6]University Hospital of Wales, Cardiff, United Kingdom; [7]Western General Hospital, Edinburgh, UK

Background. Growth factors alone or in combination with chemotherapy fail to mobilise adequate hematopoietic stem cells (HSC) for autologous transplantation in a substantial number of patients with multiple myeloma (MM) or lymphoma. Plerixafor, a CXCR4 receptor antagonist, was recently approved in Europe in combination with G-CSF for HSC collection in poor mobilisers. *Aims.* To evaluate the efficacy of mobilisation with plerixafor plus G-CSF in patients with MM or lymphoma who had failed prior mobilisation with G-CSF±chemotherapy. *Methods.* This was a retrospective analysis of patients in the NPP from 32 sites in the United Kingdom. Patients received G-CSF (10 µg/kg) each morning for 4 days. On the evening of Day 4, patients received plerixafor (0.24 mg/kg) by subcutaneous injection. On the morning of Day 5, G-CSF administration was followed by apheresis, occurring approximately 10 hours after plerixafor administration. Repeated administration of G-CSF and plerixafor was committed for up to 4 consecutive days, until adequate numbers of HSC were or were not collected.

Table. Summary of findings.

	MM n=84	NHL n=70	HD n=10	Other n= 2	Total n=166
Patients collecting >2 x 10^6 CD34+ cells/kg on Day 1 (%)	35 (41.6)	10 (14.3)	4 (40)	1 (50)	50 (30.1)
Patients collecting >2 x 10^6 CD34+ cells/kg in all apheresis days (%)	65 (77.4)	38 (54.3)	5 (50)	2 (100)	110 (66.3)
Patients who proceeded to transplantation, N (%)	63 (75)	36 (51.4)	7* (70)	1 (50)	107 (64.5)
Patients who achieved successful neutrophil engraftment (%)	62/63 (98.4)	35/36 (97.2)	7/7 (100)	0 (0)	104/107 (97.2)

**2 patients did not mobilize > 2 million CD34+ cells but proceeded to transplantation with cells pooled from other mobilisation attempts.*

Results. Of 253 patient requests complete data were available for 166 patients (MM, n=84, NHL, n=70, HD, n=10, other, n=2). The median age was 61 years (range, 24-70) and 89 (54%) patients were male. All patients had received chemotherapy (ranging from 1-9 regimens) prior to the remobilisation attempt with plerixafor; 46 patients had also received prior radiotherapy. Prior mobilisation history was available for 165 patients and included G-CSF alone in 22 (13%) patients, G-CSF plus chemotherapy in 125 (76%) patients, and both in 18 (11%) patients. The median peripheral blood $CD34^+$ cell count prior to plerixafor, available for 22 patients, was 5.5 $CD34^+$ cells/µL. Mobilisation with plerixafor plus G-CSF resulted in collection of the minimum target cell yield (>2×10^6 $CD34^+$ cells/kg) in 110 (66.3%) patients. The median number of apheresis days for all patients was 2 (range, 1-4). Of 166 patients, 107 (64.5%) proceeded to transplant. The median number of infused $CD34^+$ cells was 3.02×10^6 $CD34^+$ cells/kg (range, 1.6-8.8) The median time to neutrophil engraftment in 104 patients (MM, n=62, lymphoma, n=42) was 14 days(range, 11-32). Data on platelet engraftment were not collected. Follow up post transplant was available for 71 patients; at the date of last follow up 44 patients were in complete remission and 27 patients were in partial remission. There were 18 deaths (MM, n=5, lymphoma, n=13) in the total cohort of 166 patients (causes of death were disease progression, n=12; sepsis, n=2; and 1 each of gastrointestinal hemorrhage, pneumonitis, infective endocarditis, and cause unknown.) None of the deaths was deemed to be plerixafor-related. *Conclusions.* Mobilization with plerixafor + G-CSF achieved the target cell collection of 2×10^6 $CD34^+$ cells/kg in 110 (66.3%) of 166 patients who had failed prior mobilisation. To date 107 patients have been able to proceed to transplantation whereas this was not possible previously. These data are consistent with the US compassionate use program (Calandra 2007 BMT), further supporting the value of adding the CXCR4 antagonist plerixafor + G-CSF as a mobilisation agent.

MONITORING OF MINIMAL RESIDUAL DISEASE BY QUANTITATIVE WT1 GENE EXPRESSION FOLLOWING REDUCE INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA.

A Candoni, E Toffoletti, R Gallina, E Simeone, M Chiozzotto, S Volpetti, R Fanin

Division of Hematology and BMT, Udine, Italy

WT1 is well-known to be a panleukemic marker that is expressed in 90% of acute myeloid leukemias (AML). Quantification of WT gene expression in bone marrow (BM) samples may be useful as a marker of minimal residual disease (MRD) during and after treatment for early prediction of relapse. We evaluated the validity of this AML-MRD marker after Reduce Intensity Conditioning (RIC) allogeneic Stem Cell Transplantation (SCT). The quantitative assessment of WT1 expression by Real-Time Quantitative PCR (RQ-PCR) was measured in 25 AML patients (pts) at diagnosis, at the time of RIC-SCT and after transplant at precise time points. All cases showed high WT1 levels at diagnosis with a mean of 4895 (SD 4462) and a median of 3679 (range 454-16853) copies WT1/104 ABL. At transplant 18/25 pts (72%) were in Complete cytologic Remission (CcR) and 7/25 (28%) had refractory AML. At the pre-SCT evaluation, bone marrow (BM) samples from pts transplanted in CcR showed significantly lower WT1 expression levels compared to the samples from pts with refractory AML (P=0.002). Median follow up after RIC-SCT was 18 months (range 2-54). On 18 pts transplanted in CcR, those (17/18) who maintained CcR after RIC-SCT displayed WT1 copy numbers persistently low during all the follow-up period. In patients who received RIC-SCT with active disease obtaining a sustained CcR after transplant (3/25), WT1 levels decreased to normal range in the first two months after RIC-SCT and remained low through the entire study period. All pts who relapsed after RIC-SCT (4/25) had a high WT1 copy number before the cytologic relapse. In 50% of these cases, an increase in WT1 expression was documented before molecular chimerism decreasing. With this experience, taking into account the limited number of pts, we confirmed a concordance between WT1 expression levels (measured by RQ-PCR at precise and sequential time points) and status of AML before and after RIC-SCT and we found a concordance between WT1 expression levels and hematopoietic chimerism status. Our data suggest that, in the RIC-SCT setting, the sequential and quantitative analysis of WT1 may be useful as a leukemia marker for monitoring MRD and as a predictor of overt AML cytologic relapse

THERAPEUTIC POTENTIAL OF GAMMA DELTA T CELLS IN CONTROLLING CMV AND LEUKEMIA AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

S van Dorp, S Kersting, F Pietersma, S Hol, S Heijhuurs, V Marcu-Malina, D van Baarle, J Kuball

UMC Utrecht, Utrecht, Netherlands

Background. Allogeneic stem cell transplantation (allo-SCT) is substantially hampered by GvHD, infections like CMV and relapse of disease. Gamma delta T cells (gdT cells) seem to be important in virus control but also in malignancy control by MHC independent recognition of antigens up regulated on stressed cells, however they do not mediate GvHD. In particular CMV infections are associated with an increased expansion of gdT cells, expressing the Vd1 chain. *Aims.* We investigated frequency and function of gdT cells after allo-SCT in order to assess their therapeutic potential. *Methods.*PBMCs at time points within 3 months after allo-SCT of 17 patients were sampled. CMV viral load was monitored by real-time PCR. Phenotype and frequency of gdT cells and alpha beta T cells (abT cells) were analyzed by flow cytometry. Two patients with CMV reactivation were selected and gdT

cells were isolated and expanded from time points before, during and after CMV reactivation. Two patients without CMV reactivation were used as controls. Frequency and clonality of $Vd1^+$, $Vd2^+$ and $Vd3^+$ gdT cells were measured with spectratyping. The reactivity against CMV AD169 infected fibroblasts, uninfected fibroblasts and primary AML blasts of $Vd2^-$ and $Vd2^+$ gdT cells was tested using an IFN-g ELISPOT. *Results.* We observed an increased polyclonal expansion of $Vd1^+$ gdT-cells after allo-SCT in patients during CMV reactivation and contraction after resolution as assessed by flow cytometry and spectratyping. Furthermore $Vd1^+$ but not $Vd2^+$ T-cells from these patients reacted against CMV AD169 infected fibroblasts, but not against uninfected fibroblasts. This suggests that $Vd1^+$ gdT-cells have the potential to dampen CMV infection after allo-SCT. Moreover, following pp65-reactive abT cells in HLA-$A2^+$ patients indicated that $Vd1^+$ gdT cells precede an abT-cell response. Finally, selectively $Vd2^+$ gdT cells had the potential to recognize primary leukemic blasts, but only in the presence of pamidronate, a phospho-antigen stimulating agent. *Conclusion.* GdT cells are present in patients after allo-SCT, have the potential to eradicate CMV infected fibroblasts and maybe the potential to spread an immune response to abT cells. Furthermore $Vd2^+$ gdT cells have the potential to recognize primary AML blasts. This strongly supports the idea to explore gdT cells as cell population for immune interventions after allo-SCT and the application of pamidronate post allo-SCT in patients suffering from AML.

QUANTITATIVE MONITORING OF WT1 GENE EXPRESSION IN PERIPHERAL BLOOD AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA - AN USEFUL TOOL FOR EARLY DETECTION OF MINIMAL RESIDUAL DISEASE

J Polák, V Válková, A Vítek, H Hájková, M Marková, C Sálek, P Cetkovsky

Institute of Haematology and Blood Transfusion, Prague [2], Czech Republic

Background. WT1 has been found overexpressed in the majority of patients with acute myeloid leukemia. *Aims.* Monitoring of the WT1 expression in peripheral blood (PB) may be useful as a marker of minimal residual disease (MRD) and may predict the relapse of AML after allogeneic stem cell transplantation (alloSCT). *Methods.* The quantitative expression of WT1 was measured in 40 patients with AML transplanted between 14.4.2005 and 18.11.2009. In 8 patients we had not data before alloSCT, three patients had not WT1 overexpression at diagnosis. For more precise analysis, we included a total of 29 patients (12 males, 17 females) who had significant WT1 overexpression at diagnosis or at relapse before alloSCT. The ELN recommended RQ-RT-PCR protocol was used for WT1 monitoring. *Results.* Overall 26 patients were transplanted in CR (5xCR1, 4xCR1 MRD+, 11xCR1 after second line treatment, 6xCR2), 3 patients were transplanted with active disease. Median follow-up after alloSCT was 17 months (range; 2-56). The level of WT1 expression correlated with attained or maintained CR in 19/27 patients. Eight (28%) patients relapsed after alloSCT after previous achievement of CR and all of them had an increase of WT1 expression at /or before relapse. Two patients transplanted with active disease died of progression without any response. At last follow-up: overall 6 patients died, 5 of relapse or progression, 1 of NRM. Four patients are treated for relapse and 19 patients remain in CR. In all cases, the increased WT1 expression correlated well with morphological examination, flow cytometry, chimerism and specific fusion genes. Moreover, in 4 cases, increased WT1 expression detected impending relapse sooner than chimerism , flow cytometry and morphological examination with median of 1 month (range 0,6-2,3) In 2 patients with the presence of specific fusion genes, their kinetics in relapse fully correlated with the WT1 kinetics. *Conclusions.* In our experience, there was a clear concordance between WT1 expression levels and AML status before and after alloSCT. WT1 could be useful as a non-specific leukemia marker for monitoring MRD and as a predictor of clinical relapse of AML. Monitoring of WT1 gene is probably most appropriate for patients transplanted in remission, where the increase in WT1 expression may signal a relapse in advance of standard investigative *Methods.* Based on these results, patients with increased WT1 levels after alloSCT and without graft vs. host disease may be candidates for immunosuppression tapering or DLI therapy .

CIK CELLS AND MESENCHYMAL STROMAL CELLS: A 'DANGEROUS' RELATIONSHIP

K Chieregato, S Castegnaro, D Madeo, F Rodeghiero

San Bortolo Hospital, Vicenza, Italy

Background. Human mesenchymal stromal cells (MSCs) are multipotent cells possessing: self-renewal capacity; long term viability; multilineage potential and immunomodulatory properties. Cytokine-induced killer cells (CIK) are $CD3^+CD56^+$ T cells with natural killer-like cytotoxic activity against tumour cells of several lineages *in vitro*. *Aims.* In view of the potential role of MSCs and CIK cells in the immunotherapy of tumours, we explored the possible interactions between these two cell types. *Methods.* At the end of passage 3, umbilical cord-derived MSCs (UC-MSCs), cultured in DMEM supplemented with FBS (10%) and blocked with Mitomycin C (10 µg/mL), were co-cultured, at different ratios, with a constant number (1000000) of expanded CIK cells isolated from human peripheral blood of five healthy donors using Ficoll, and then stimulated with INFγ, OKT3 and IL2 for 14 days (UC-MSCs:CIK ratios: 1:1, 1:2, 1:4, 1:10, 1:20 and 0:1000000). The experiments were performed with the two cell types in contact or separated by trans-well membrane. After six days, CIK cells were gently resuspended, counted in a Burker chamber and tested for cytotoxic activity. UC-MSCs, exposed or not at CIK cells, were fixed, stained with haematoxylin-eosin and observed at microscopy. Residual cytotoxic activity of CIK cells was evaluated and quantified measuring the fluorescence of Calcein-AM released by K562, a chronic myeloid leukemia cell line, co-cultured for four hours with CIK cells at the following K562:CIK ratios: 1:1, 1:2, 1:4, 1:10, 1:20. *Results.* The apoptotic effect of UC-MSCs on CIK cells or vice versa was related to their ratio. At 1:1 ratio CIK reduction caused by UC-MSCs was of 88.4±4.4%; this percentage decreased in the presence of a diminishing number of mesenchymal cells (Figure 1A). On the other hand, decreasing their ratios, UC-MSCs were susceptible to lysis by CIK cells; at 1:20 ratio they were no more microscopically detectable (Figure 1B). Also CIK cells cytolytic activity against K562 was inversely proportional to UC-MSCs:CIK ratio, that is their cytotoxic effect increased when CIK were co-cultured in the presence of an decreased number of mesenchymal cells (Figure 1A line). All these apoptotic effects were related to cell contact; in fact they disappeared when the two cell lines were separated by trans-well membrane. *Conclusions.* These results should be taken into account when evaluating the combination of the two cell types in novel therapeutic strategies designed to improve engraftment, to suppress graft versus host disease or to exploit the effect of CIK-mediated graft versus leukemia. They suggest, for a future clinical application, to infuse before MSCs to support hematopoiesis and then CIK cells to kill residual neoplastic cells.

Figure 1. A. Reduction of CIK cells at different UC-MSC:CIK ratio (*** p<0.001; ** p<0.01 compared to CIK reduction at 1:20 ratio. n=5). CIK residual cytolytic effect against K562 after co-culture with mesenchymal cells (data referred to UC-MSCs:CIK ratio 1:1. Line). **B.** Haematoxilin-eosin stain showed that CIK cells were capable of killing MSC (magnification 100x).

SIGNIFICANT REDUCTION OF MORBIDITY AND MORTALITY OF EARLY CMV DISEASE AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION BY PRE-EMPTIVE THERAPY WITH ANTI-VIRAL DRUGS AND CMV CYTOTOXIC T LYMPHOCYTES

L Lu,[1] T Wu,[1] XY Cao,[1] JB Wang,[1] Y Sun,[1] YL Zhao,[1] CR Tong,[1] LJ Chang,[2] DP Lu[1]

[1]*Beijing Daopei Hospital, Beijing, China;* [2]*University of Florida, Gainesville, Florida, USA*

Background. CMV disease is one of main causes of death after allogeneic hematopoietic cell transplantation (allo-HCT), especially from alternative donors. It is important to initiate pre-emptive therapy for CMV viremia since CMV disease usually has poor response to anti-viral medicines. *Aim.* In present clinical study, morbidity and mortality of CMV disease after pre-emptive therapy with anti-viral drugs and CMV specific cytotoxic T lymphocytes (CMV-CTLs) in allo-HCT recipients were investigated. *Methods.* From January 2007 to January 2009, total 334 patients who received allo-HCT were studied (matched sibling 100, unrelated 88, haploidentical146). The median age was 35 years (range, 5 to 55 years). Conditioning regimens were myeloablative with BUCY or CYTBI. ATG was added in unrelated and haploidentical transplants. CMV serological status of both donor and recipient before transplant was screened by ELISA. Plasma CMV DNA was monitored 1 to 2 times weekly with real time quantitative polymerase chain reaction (RQ-PCR). Ganciclovir was used for 8 days during conditioning. Either Ganciclovir or Foscarnet was used as front-line pre-emptive therapy when plasma CMV DNA turned to positive. Combination of Ganciclovir and Foscarnet or CMV-CTLs were administrated if the patients failed to front-line pre-emptive therapy. *Results.* Almost all recipients (100%) and donors (100%) were CMV serological positive. Overall 100-day cumulative incidence of CMV viremia was 69.1% (231/334) with median time of day 33 (range, day 11 to 79). Much lower incidence of CMV viremia was found in matched sibling transplant (33.3%) compared with unrelated (88.6%) and haploidentical (82.1%) transplants (P<0.001). Total 29.4% (68/231) patients received combined anti-viral medicines and 12.1% (28/231) patients were managed with CMV-CTLs with median cell dose 1.87×10^5 /kg (range, 2.4 103to 8.0×10^6/kg). CMV DNA became negative in 93.9% (217/231) patients after pre-emptive therapy. Fourteen patients developed CMV disease (enteritis 12 cases, interstitial pneumonia 1 case, encephalitis 1 case), which was much less than our historical control (Dao-Pei LU, *et al.* Blood 2006;107:3065). Overall 100-day cumulative incidence of CMV disease was only 3.8% although 70.1% patients underwent allo-HCT from either unrelated or haploidentical donors. There were no statistical difference in the incidences of CMV disease among transplants from matched sibling (3.0%), unrelated (4.5%), haploidentical (4.1%) donors (P=0.214). Only 5 patients died of CMV disease(they are all enteritis). No significant difference on 2-year overall survival was seen in patients with or without CMV disease (70.5% vs. 66.0%, P=0.397). Univariate and multivariate analysis showed that alternative donors and gradeII~IV acute GVHD were the risk factors for CMV reactivation. *Conclusions.* Viremia which is determined by RQ-PCR guided pre-emptive therapy with anti-viral medicines and CMV-CTLs significant reduces morbidity and mortality of early CMV disease in allo-HCT patients, even in the setting from alternative donors.

CLINICAL OUTCOMES PREDICTION FOR NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS TREATED WITH THALIDOMIDE-DEXAMETHASONE AND AUTOLOGOUS STEM CELL TRANSPLANTATION BY 8-GENE SIGNATURE OF CD138+ PLASMA CELLS

C Terragna,[1] D Remondini,[2] G Martinelli,[1] P Tosi,[1] E Zamagni,[1] P Tacchetti,[1] G Perrone,[1] A Brioli,[1] M Ceccolini,[3] N Testoni,[1] G Marzocchi,[1] G Castellani,[2] S Durante,[1] F Di Raimondo,[3] F Patriarca,[3] L Catalano,[3] L Masini,[3] A Ledda,[3] E Angelucci,[3] P Galieni,[3] A Gozzetti,[3] M Baccarani,[1] M Cavo[1]

[1]*Seràgnoli Institute of Hematology, Bologna, Italy;* [2]*Physics Department & CIG, Bologna, Italy;* [3]*GIMEMA Italian Myeloma Network, Bologna, Italy*

Background. Efficacy of Thalidomide-dexamethasone (TD) as induction therapy in preparation for autologous stem cell transplantation (ASCT) in multiple myeloma provided the basis for the design of the phase II "Bologna 2002"study incorporating TD into double autotransplantation as up-front therapy for younger patients (pts) with newly diagnosed disease. *Aim.* We performed a molecular study aimed at identifying a gene expression profile (GEP) signature predictive of attainment of at least near complete response (nCR) to TD and subsequent autotransplantation. *Methods.* For this purpose, we analyzed bone marrow samples obtained at diagnosis from 112 pts who received TD before double ASCT. The differential gene expression of $CD138^+$ enriched plasma cells was evaluated by means of expression microarray using the Affymetrix platform. Significant expression results were validated by Real-time PCR. *Results.* Two subsequent study phases were planned. Firstly, a GEP supervised analysis was performed on a training set of 32 pts, allowing to identify 157 probe sets differentially expressed (P<0.05) in pts with at least nCR (e.g. responders) versus those who failed at least nCR (e.g. non responders) to TD induction therapy. Most of the 157 genes resulted down expressed in responder pts and were mainly involved in cell cycle and apoptosis regulation. In particular, signaling pathways which might be affected by the de-regulated expression of genes in responding pts, are the MAPK signaling pathway (Ppp3r1, PRKY, PRKX, FAS, ATF2, MAP4K3 and DUSP4), the Wnt signaling pathway (Ppp3r1, PRKY, PRKX and CCND2) and the p53 pathway (CCND2, FAS, CCNDE and MDM2).In the second phase of the study, we generated an 8-gene GEP signature which predicted at diagnosis the probability to achieve at least a nCR after TD induction therapy. The performance of this assay was subsequently validated by Real-time PCR in a training set of 80 pts: 36 pts were predicted as responders to TD , whereas 44 as non responders. The post autotransplantation outcome was analyzed according to Real-time expression results. On an intention-to-treat basis, the rate of CR, either immunofixation negative or positive, was 51.4% among CR-predicted ps and 23% (P=0-001) in the subgroup of 44 NR-predicted pts. The 65-months probability of OS for CR-predicted pts was 72% as compared to 41% for those who were predicted to be NR (P=0.03). The projected rates of TTP and PFS at 55 months for CR-predicted and NR-predicted pts were 69% vs. 34% (P=0.003) and 55% vs. 19% (P=0.01), respectively. *Conclusions.* These results can be an important first step to identify at diagnosis those pts who are more likely to respond favorably to a particular treatment strategy.

MICRORNAS CHANGES OCCUR IN MULTIPLE MYELOMA CELLS IN THE CONTEXT OF BONE MARROW MILIEU

A Roccaro,[1] A Sacco,[2] A Azab,[2] F Azab,[2] T Ngo,[2] P Quang,[2] P Maiso,[2] G Rossi,[1] M Ghobrial[2]

[1]*Spedali Civili di Brescia, Brescia, Italy;* [2]*Dana-Farber Cancer Institute, Boston, USA*

Introduction. It has been previously demonstrated that primary multiple myeloma (MM) cells are characterized by a specific microRNA (miRNA) signature compared to the related normal plasmacell counter-

part; and that miRNAs play a crucial role in regulating MM pathogenesis. Nevertheless, miRNA changes that occur in MM cells in the context of the bone marrow microenvironment have not been previously examined. *Aims.* To evaluate miRNA signature in MM clonal plasmacells. To evaluate the role of bone marrow microenvironment in regulating miRNA signature in MM clonal plasmacells. *Methods.* miRNA expression profiling has been performed on MM cell lines (MM.1S, RPMI) either alone or in co-culture with bone marrow stromal cells (BMSCs); MM primary CD138$^+$ bone marrow-derived CD138$^+$cells; healthy subjects bone marrow-derived CD138$^+$ cells. *in vitro* and *in vivo* functional studies were performed on miRNA-15a- and -16-1-precursors-transfected MM cells. Effect of miRNA-15a and -16-1 on signaling cascades have been evaluated by western blot and immunofluorescence. *in vivo* MM cell growth has been evaluated by either using an *in vivo* imaging model or bioluminescence. Angiogenesis has been studied both *in vitro* and *in vivo* using the chorioallantoic membrane model. *Results*. miRNA-15a and -16-1 are down-regulated in MM cells as compared to normal cells. Precursor-miRNA-15a- and -16-1-transfected cells showed decreased DNA synthesis; decreased cyclinD1/cyclinD3/cdk6/pRb protein expression; phase G1 cell cycle arrest; as compared to either scramble probe-transfected or not transfected MM cells. Moreover, transfected cells showed inhibition of NFkB pathway as shown by reduced p65-/p50-/p52-NFkB activities; downregulation of p-p65/p50/p52 nuclear protein level; upregulation of phospho-IkB in the cytoplasm; and inhibited translocation of p-p65 from the cytolplasm to the nucleus. Similarly, inhibition of MM cell growth was confirmed *in vivo*; and anti-angiogenic properties of miRNA-15a and -16-1 were validated both *in vitro* and *in vivo*. miRNA profiling of MM cells cultured with primary BMSCs (MM+BMSC system) differs from MM cells which were not grown in contact with primary BMSCs (MM cells alone). Specifically, we observed increased expression of miRNA-450/-432*/-299-5p/-409-3p/-29b/-542-5p/-184/-517*/-218/128b/-142-5p/-211 (P<0.05) in MM cells obtained from the MM+BMSC system, compared to MM cells alone. Stem-loop qRT-PCR was performed on matched samples and showed expression patterns similar to those observed in miRNA analysis. Predicted human miRNA gene targets of the increased miRNAs included negative regulators of NFkB, PI3K/Akt/mTOR, and MAPK/ERK signaling pathways (PTEN/KSR2/TWEAK/DUSP); as well as tumor suppressors (MCC/TSSC1/TUSC1/FBW7/RHOBTB), pro-apoptotic factors and cyclin-dependent kinases inhibitors. *Summary.* These data demonstrate that miRNAs play an important role in MM pathogenesis by regulating plasmacell tumor clone growth; and that bone marrow stromal cells exert a modulatory effect on miRNA profiling in MM cells, which results in promoting MM cell growth and inducing MM cell survival.

GENETIC VARIATIONS ASSOCIATED WITH TREATMENT RESPONSE, PROGRESSION FREE SURVIVAL AND OVERALL SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA IN THE HOVON 50/GMMG-HD3 TRIALS

S Corthals,[1] H Lokhorst,[2] Y de Knegt,[1] B van der Holt,[1] H Goldschmidt,[3] D Hose,[3] U Bertsch,[3] S Zweegman,[4] E Vellenga,[2] B Durie,[5] B van Ness,[6] P Sonneveld[1]

[1]Erasmus University Medical Center, Rotterdam, Netherlands; [2]University Medical Center, Utrecht, Netherlands; [3]University of Heidelberg, Heidelberg, Germany; [4]VU University Medical Center, Amsterdam, Netherlands; [5]Cedars Sinai Cancer Center, Los Angeles, USA; [6]University of Minnesota, Minneapolis, USA

Background. Thalidomide improves overall response and quality of response before and after high dose melphalan in patients with multiple myeloma (MM). In addition, it prolongs progression free survival (PFS), but not overall survival (OS), due to inferior survival from relapse. Genetic instability and clinical variables (ISS) are prognostic variables for outcome. Little attention has been given to structural host factors as additional markers to predict treatment response and survival. Single nucleotide polymorphisms (SNPs) may influence may influence the individual response to treatment and could therefore act as an independent class of predictors. *Aims.* The aim of this study was first to determine if genetic variations are associated with response to therapy and survival in patients with multiple myeloma and second to analyse these effects in thalidomide based versus traditional vincristine/adriamycin/dexamethasone (VAD) based induction treatment. *Methods*. We collected peripheral white blood cell DNA from 532 MM patients included in the Dutch-German HOVON-50/GMMG-HD3 clinical trials comparing 3 cycles of VAD, to thalidomide 200 mg orally, days 1 to 28 plus adriamycin and dexamethasone (TAD) as induction regimens (Lokhorst HM. *et al.*, Blood. 2010 Feb 11;115:1113-20). Genetic variations were analyzed using a custom-built molecular inversion probe (MIP) based SNP chip, designed by 'Bank on a Cure' (BOAC), containing 3404 SNPs selected in "functional regions"within 983 genes representing cellular functions and pathways that may influence disease response, toxicities, complications, and survival. A Cochran-Armitage trend test was performed to determine SNP associations with response to therapy, PFS and OS for VAD and TAD treated patients separately using the program PLINK. To account for multiple testing we carried out label swapping procedures. *Results.* The results of the SNP association analyses for response to TAD and VAD treatment both show associations with the ADME genes (drug absorption, distribution, metabolism, and excretion) ABCC1 and ABCC2. In addition, only TAD response is associated with ABCB11 (P=.002) and ABCC4 (P=.01). Inflammatory genes are associated with TAD response, whereas genes involved in cell death are associated with VAD response. In TAD treated patients, significant associations for both PFS and OS were observed with SNPs located in the DNA repair genes LIG3 (P=.003 and P= .002 respectively) and SHFM1 and the inflammatory genes TNF, SELE (P= .002 and P=.03 respectively) and F13A1. Furthermore, SNPs associated with PFS were located in the ADME genes CYP39A1 (P=.002), ABCC2 (P=.002) and CYP2F1. *Summary/Conclusions.* In this study we identified SNPs which were associated with treatment response, overall and progression free survival in multiple myeloma patients receiving TAD or VAD induction treatment. These results indicate that variations in drug metabolism, inflammatory response and DNA repair are crucial in treatment outcome. We conclude that SNPs contribute to treatment outcome and survival.

This investigation was supported by the Dutch clinical trial group HOVON, by Erasmus MC and by the International Myeloma Foundation.

THE CLINICAL AND BIOLOGICAL SIGNIFICANCE OF THE IMMUNOPHENOTYPIC ASSESSMENT OF CD81 IN MULTIPLE MYELOMA CLONAL PLASMA CELLS

B Paiva,[1] M Vidriales,[2] N Gutierrez,[2] M Montalban,[3] A Oriol,[4] J Martinez,[3] M Mateos,[2] L Lopez-Corral,[2] J Perez,[2] M Sarasquete,[2] J Laraña,[5] F De Arriba,[6] L Palomera,[7] M Echebeste,[8] M Terol,[9] R De Paz,[10] A Martin,[11] J Hernandez,[12] Y Gonzalez,[13] R Martinez,[14] J Blade,[15] J Lahuerta,[3] J San Miguel[2]

[1]Hospital Universitario Salamanca, Salamanca, Spain; [2]Hospital Universitario de Salamanca, Centro de Investigación del Cáncer, Salamanca, Spain; [3]Hospital [12] de Octubre, Madrid, Spain; [4]Hospital Universitari Germans Trias i Pujol, Badalona, Spain;[5]Hospital Ramon y Cajal, Madrid, Spain; [6]Hospital Morales Meseguer, Murcia, Spain; [7]Hospital Lozano Blesa, Zaragoza, Spain; [8]Hospital de Donostia, San Sebastian, Spain; [9]Hospital Clínico de Valencia, Valencia, Spain; [10]Hospital Universitario La Paz, Madrid, Spain; [11]Hospital Virgen de la Concha, Zamora, Spain; [12]Hospital General de Segovia, Segovia, Spain; [13]Hospital Josep Trueta, Girona, Spain; [14]Hospital San Carlos, Madrid, Spain; [15]Hospital Clínic, IDIBAPS, Barcelona, Spain

Background. Although CD19 is typically down regulated in myelomatous plasma cells (MM-PC), we have recently shown that a minority of multiple myeloma (MM) patients (4%) express this marker at diagnosis, which correlates with adverse outcome. The CD19 expression is thought to be regulated by CD81, a tetraspanin involved in mechanisms of cell proliferation. However, phenotypic or genomic studies of CD81 expression in MM are scanty, and its potential prognostic value remains unknown. *Aims.* To assess the frequency and the prognostic value of the immunophenotypic detection of CD81 surface expression in MM-PC of smoldering and symptomatic MM patients at diagnosis. *Methods.* A total of newly diagnosed 36 smoldering MM (SMM) patients and 229 symptomatic MM patients were included in this study, the latter group uniformly treated according to the Spanish GEM05>65y protocol. Expression of CD81 on MM-PC was assessed by multiparameter flow cytometry (MFC), staining BM samples using a four-color direct immunofluorescence technique that allowed the identification of MM-PC as well as CD81 surface expression. In a subset of patients (18 SMM, 23 MM) mRNA gene expression profiling (GEP) was performed on immunomagnetically enriched MM-PC. *Results.* MFC studies detected positive staining for CD81 in MM-PC of 15/36 (42%) SMM and 90/229 (39%) MM patients. Interestingly, both SMM and MM CD81$^+$ cases showed a higher frequency of CD19 expression on MM-PC compared to CD81- cases (13% vs. 0%, P=.08 and 7% vs. 1%, P=.01; respectively), in line with the regulatory role of CD81 over CD19. Concerning GEP analysis, we found a significantly (P=.003) lower relative expression of CD81 mRNA in MM-PC of SMM (6.8) and MM (6.7) patients compared to normal PC (9.3), which could explain, at least in part, the absence of CD81 on MM-PC surface in ≈half of myeloma cases. Accordingly, we found a signifi-

cant correlation between GEP and MFC expression of CD81 (r=.743; P<.001), and CD81+ SMM and MM patients showed higher levels of relative expression of CD81 mRNA compared to CD81- cases (7.5 vs. 6.6, P=.03 and 7.4 vs. 6.7, P=.04, respectively). No significant differences were found in baseline characteristics of CD81- vs. CD81+ SMM or MM patients, except for the% of MM-PC in S-phase (0.8 vs. 1.4, P=.09 and 0.9 vs. 1.4, P=.003 for SMM and MM, respectively). Finally, CD81+ SMM patients had a shorter time to progression to symptomatic disease than CD81- cases (NR vs. 25 months, P=.04, Figure A); and also CD81+ MM showed significantly lower response rates (complete remission: 8% vs. 26%, P=.01), progression-free (23 months vs. NR, P=.001, Figure B) and overall survival (P=.03, Figure C) than CD81- cases. In MM patients, a multivariate analysis identified two baseline variables with independent prognostic value for PFS: highly abnormal sFLC ratios (<0.02 or >10;HR=3.0;P=.008) and CD81+ expression (HR=2.2; P=.02) , whereas for OS only CD81+ expression (HR=2.3;P=.05) was selected. *Conclusions.* Our findings uncover the existence of a phenotypic/genomic correlation of CD81 expression in MM-PC, which correlated with an adverse outcome in SMM and MM, supporting the clinical relevance of baseline routine BM evaluation by MFC in myeloma.

DEVELOPMENT OF PERIPHERAL NEUROPATHY IN MULTIPLE MYELOMA PATIENTS; INCIDENCE, MOLECULAR CHARACTERIZATION AND EFFECT ON RESPONSE IN BORTEZOMIB VS CONVENTIONAL TREATMENT

A Broyl,[1] S Corthals,[1] Y De Knegt,[1] B van der Holt,[1] H Goldschmidt,[2] H Lokhorst,[3] B Durie,[4] B Van Ness,[5] P Sonneveld[1]

[1]Erasmusmc, Rotterdam, Netherlands; [2]University of Heidelberg, Heidelberg, Germany; [3]University Medical Center, Utrecht, Netherlands; [4]Cedars Sinai Cancer Center, Los Angeles, USA; [5]University of Minnesota, Minneapolis, USA

Background. The proteasome inhibitor bortezomib has demonstrated high antitumor activity in multiple myeloma (MM). Bortezomib induced peripheral neuropathy (BiPN) is a major dose-limiting toxicity. Chemotherapy induced peripheral neuropathy has also been described with thalidomide and vincristine in MM. The exact mechanisms of both BiPN and vincristine induced peripheral neuropathy (ViPN) are not fully understood. *Aims.* The aim of this study was to gain more insight in the mechanism underlying BiPN and ViPN in MM patients and to identify differences in incidence and to unravel underlying molecular characteristics. In addition we evaluated the association of BiPN with response to therapy. *Methods.* Genetic variation associated with BiPN or ViPN was analyzed using a custom-built molecular inversion probe (MIP) based single nucleotide polymorphism (SNP) chip, designed by 'Bank on a Cure' (BOAC), containing 3404 SNPs selected in "functional regions"within 983 genes representing cellular functions and pathways that may influence disease response, toxicities, complications, and survival. MM samples were taken from the Dutch-German HOVON-65/GMMG-HD4 clinical trial comparing standard induction treatment with vincristine combination (VAD) to bortezomib combination (PAD) prior to high" dose therapy (HDT) and stem cell transplantation. For BiPN 51 cases and 80 controls and for ViPN 20 cases and 107 controls were included in a SNP association analysis. Samples from 329 MM patients from this trial were analyzed for tumor gene expression using U133 2.0 arrays to gain more insight in the characteristics of myeloma plasma cells at baseline which could play a role in the development of BiPN or ViPN, and to differentiate between early or later development of BiPN. Cox regression analysis with BiPN as a time-dependent covariate was used to analyze the prognostic value of BiPN on achieving at least a very good partial response (VGPR). *Results.* The observed associated SNPs with BiPN differ considerably from those associated with ViPN. SNPs associated with BiPN were located in the DNA repair genes BRCA1 and ERCC4 (P=.0004) and in inflammatory genes F2 and F13A1. SNPs associated with ViPN were mainly located in genes involved in cell death such as JUN (P=.001) and the metabolism genes ABCC4 (P=.008) and FMO3. The genetic profile of myeloma plasma cells from patients developing BiPN included genes involved in immune cell trafficking, such as PIK3CG, MFHAS1, SOX8, RAPH1 and CKM1 (FDR<.05). Upregulated genes in patients with ViPN included interferon induced genes, such as IFIT2, IFIT3, CXCL10 (FDR<.05), and the inflammatory gene TNFSF13B (FDR<.05). BiPN grade 2-4 was observed in 27% of patients during induction treatment and was significantly associated with achievement of VGPR and CR with PAD, hazard ratio (HR)=1.42, 95% CI=1.03-1.97 (P=.033). *Summary/Conclusions.* In this study we showed unique genetic associations for BiPN and ViPN, indicating different mechanisms may be involved in the development of BiPN and ViPN. Development of grade 2-4 BiPN was significantly associated with achievement of VGPR and CR on induction with 3 cycles of PAD. Our results contribute to a better understanding of the mechanisms underlying BiPN and ViPN and differences between these two types of peripheral neuropathy.

Thrombosis and Bleeding

PREVALENCE AND DETERMINANTS OF BLEEDING IN SEVERE VON WILLEBRAND DISEASE TYPE 3: RESULTS OF RETRO/PROSPECTIVE STUDIES IN A COHORT OF 105/52 ITALIAN PATIENTS

A Federici,[1] A Iorio,[2] G Castaman,[3] MG Mazzucconi,[4] M Morfini,[5] A Rocino,[6] M Schiavoni,[7] P Mannucci[1]

[1]University of Milan, Milan, Italy; [2]University of Perugia, Perugia, Italy; [3]Division of Hematology, Vicenza, Italy; [4]University of Rome, Rome, Italy; [5]Careggi Hospital, Firenze, Italy; [6]Pellegrini Hospital, Napoli, Italy; [7]Hemophilia Center, Bari, Italy

Background. von Willebrand disease type 3 (VWD3) is due to virtually complete deficiency of the von Willebrand factor (VWF) and, for this reason, has been also described as "severe VWD". Although rare (1-5 cases per million population), VWD3 is of major interest because of its severe clinical presentation, the need for replacement therapy with VWF/FVIII concentrates and the risk of occurrence of anti-VWF inhibitors after the infusion of VWF/FVIII concentrates. *Aims.* and design of the study: to determine the prevalence and determinants of bleedings requiring therapy with VWF/FVIII concentrates in VWD3 patients, data were collected from the Italian registry on Hemophilia and Allied Disorders . Some of these VWD3 patients were then followed up for one year by six Italian Centers and prospective data on number, type and management of bleeding episodes were analyzed. *Patients and Methods.* VWD3 patients were diagnosed when VWF antigen was undetectable and factor VIII (FVIII) levels were reduced in plasma. Bleeding severity score (BSS) was calculated at enrollment. Gene deletions and mutations were searched for in all available DNA. Bleeding-free survival was computed with the Kaplan-Meier method and a Cox's proportional hazard model was used to calculate the risk of bleeding (hazard ratio = HR). *Results.* In the Italian registry, 105 VWD3 patients (5.7%) were identified among the 1850 VWD (Italian prevalence=1.75 per million). The entire cohort of VWD3 was characterized by the following demographic, clinical and laboratory parameters (median, range): gender (M/F)= 50/55; age=37 (3-65); BSS=18 (3-35); FVIII= 4 (2-18); anti-VWF inhibitors= 7 cases (6.7%) from 3 families. Molecular diagnosis was available in 65/105 cases with the following gene defects (pt-n): large deletion (7); small deletions and insertions (23); nonsense (9); splice site (8) and missense mutations (17). Mucosal bleedings (64%) were more frequent than hematomas and hemarthrosis (24%). At the time of the enrollment in the registry 95/105 (91%) VWD3 had been already exposed to VWF/FVIII concentrates because of bleeding and/or minor or major surgeries. In the prospective study, 52 VWD3 patients could be enrolled and 46 (88%) were treated in a year for 118 bleeding episodes and 27 minor or major surgeries. BSS>10 (6.8, 3.8-12.3) and FVIII<10U/dL (4.1, 2.4-7) were significantly associated with high risk of bleeding. The bleeding-free survival at one year calculated according to values of BSS and FVIII levels showed 4 different KM curves with the following *Results.* 89% (BSS=5-10&FVIII>10U/dL); 64%(BSS>10&FVIII=5-10U/dL); 59% (BSS=5-10&FVIII<10U/dL); 18% (BSS>10&FVIII<5U/dL). VWD3 patients were given 192 injections of VWF/FVIII concentrates for bleeding and surgeries. Patients with anti-VWF inhibitors were off therapy during this follow-up. *Conclusions.* these retro/prospective studies performed for the first time in a relative large cohort of patients show that also VWD3 can be very heterogeneous. BSS and FVIII levels are good predictors of bleeding. Multicenter studies with larger number of cases should be organized to identify additional modifiers of bleeding risk in VWD3

PLATELET DYSFUNCTION AND MDS FEATURES DUE TO NOVEL SOMATIC GATA1 MUTATION

K Freson,[1] L de Waele,[2] P Vandenberghe,[3] R de Vos,[4] P Vyas,[5] C van Geet[2]

[1]University of Leuven, Leuven, Belgium; [2]Department of Pediatrics, Leuven, Belgium; [3]Center for Human Genetics, LEuven, Belgium; [4]Department of Pathology, Leuven, Belgium; [5]Weatherall Institute of Molecular Medicine, university of Oxford, Oxford, UK

Background. Germline exon 4 mutations in the N-terminal zinc finger (N-finger) of GATA1 cause X-linked dyserythropoiesis with macrothrombocytopenia, while a germline splicing mutation in exon 2 leads to congenital neutropenia and anemia due to exclusive expression of GATA1s, the short isoform of GATA1. Acquired GATA1 exon 2 splicing mutations occur in both transient myeloproliferative disorder (TMD) and acute megakaryoblastic leukemia (AMKL) in Down syndrome patients. *Aims.* In the present study, we describe the functional characteristics of a somatic GATA1 mutation (E200G) in a boy with a lifelong history of bleeding problems, anemia, neutropenia, severe bone pains and hepatosplenomegaly, and bilineage dysplasia in the bone marrow. *Methods.* Platelet morphology and function was studied. Different *in vitro* and ex vivo experiments were applied to study the functional effect of the GATA1-E200G mutation. *Results.* The patient has a clinical bleeding problem, an increased Ivy bleeding time and a prolongation of the PFA100 occlusion time. Electron microscopy revealed normal sized platelets with few dense granules. Platelet ATP secretion and aggregation were decreased. The a to g substitution was found in GATA1 mRNA (exon 4) from platelets and bone marrow mononuclear cells, and in genomic DNA from purified myeloid progenitors, but not lymphoid progenitors, lymphocytes and fibroblasts. This GATA1-E200G mutation affects a highly conserved residue at the beginning of the N-finger, but does not perturb DNA binding to GATA sites and partially reduces its interaction with FOG1. In addition, the mutation is located at the exonic splice site and is associated with alternative splicing and reduced GATA1 protein levels in *in vitro* differentiated megakaryocytes from $CD34^+$ hematopoietic stem cells isolated from peripheral blood of the patient and a control subject. *Conclusions.* This study expands the GATA1 phenotype-genotype spectrum with the development of MDS and platelet dysfunction due to a somatic GATA1 splice mutation.

ANNEXIN II IS OVER EXPRESSED IN HCG-PML-RARα LEUKEMIC MICE AND IS ASSOCIATED WITH HIGHER LEVELS OF TISSUE PLASMINOGEN ACTIVATOR (TPA)

R Jacomo, B Santana-Lemos, AS Lima, P Assis, AP Lima, L Oliveira, A Garcia, MC Pintao, L Pontes, R Falcao, E Rego

Faculdade de Medicina de Ribeirão Preto, Ribeirao Preto, Brazil

Background. Acute Promyelocytic Leukemia (APL) is frequently associated with a coagulation abnormality that is the main cause of morbidity in this disease. At least three components can be indentified: activation of coagulation cascade, proteolysis and fibrinolysis. Annexin II, a receptor for both tissue plasminogen activator (tPA) and plasminogen has been shown to be over expressed in human APL and may be involved in fibrinolytic abnormalities. The murine model of APL (hCG-PML-RARα) evolves to acute leukemia in about 15%, and cells from leukemic mice can be transplanted. Few is known from coagulation in this model and plasmine activator Inhibitor (PAI) and tumor necrosis factor α (TNFα) appear to be elevated. *Aims.* We aimed to compare Annexin II expression in a murine transplant model of APL as well as plasmine and tPA plasmatic levels. *Methods.* We studied two groups of wild type mice that received each 200-cGy irradiation followed by infusion of 2×10^6 cells from bone marrow of wild type animal (group Wild) or from a leukemic hCG-PML-RARα animal (group Leu). On day 21 after transplantation the animals were sedated with tribhromoethanol followed by inferior vena cava infusion of sodium citrate and blood collection. Plasma was separated and analyzed for tPA and plasmine by ELISA method. Cells from experimental animals bone marrow was obtained through infusion of RPMI in large bones and analyzed by flow cytometry to quantify Annexin II and CD117 expression. We used Mean Fluorescence Channel (MFC) ratio and D value (Kolmogorov-Smirnov statistics) to estimate Annexin II expression. *Results.* Mean MFC ratio was 1,038 in group Wild and 1,702 in group LEU (P<0,001) and D value was 0,0938 and 0,9380 (P<0.001), respectively. D value in CD117 positive cells was also different between groups (0,1163 in group Wild and 0,396 in group Leu). We also observed a correlation (Pearson coefficient: 0,734- P=0.001) between CD117 positive Cells and Annexin II expression. tPA levels were elevated in Leu group (12,14% versus 10,71%, P<0.001) but no difference was observed in plasmine levels (233,4 mg versus 233,8 mg). There was also a correlation between Annexin II expression (both MFC ratio and D value) and tPA values (Pearson coefficient=0.913 for MFC ratio and 0,833 for D - P<0.001). *Conclusions.* We confirmed that, similar to human APL, bone marrow cells from hCG-PML-RARα leukemic mice over express Annexin II. We also observed higher levels of tPA, but no difference was seen in plasmine levels, which may be due to its half-life. The correlation of Annexin II and tPA levels suggests that this protein may actually be involved in fybrinolytic abnormalities seen in APL. This murine model is adequate to explore Annexin II and fibrinolytic pathways interactions.

0533

FREQUENCY, TYPES AND MANAGEMENT OF BLEEDING EPISODES IN ACQUIRED VON WILLEBRAND SYNDROME: A FIVE-YEAR PROSPECTIVE STUDY IN A COHORT OF 18 PATIENTS WITH CHRONIC LYMPHO-MYELOPROLIFERATIVE DISORDERS (LPD/MPD)

A Federici, F Rezzonico, P Bucciarelli, A Artoni, G Cozzi, MT Canciani

University of Milan, Milan, Italy

Background. Acquired von Willebrand Syndrome (AVWS) is a rare bleeding disorder with laboratory findings similar to those of inherited VWD. Actual prevalence, frequency and types of bleedings of patients with AVWS are unknown because large prospective studies are not available. AVWS is frequently associated with monoclonal gammopathy of uncertain significance (MGUS) or Essential Thombocythemia (ET). *Aims.* To determine frequency and types of bleeding episodes which might need therapeutic interventions we have prospectively followed-up for five years our cohort of AVWS *Patients and Methods.* 18 patients were enrolled in the study on January 2005 with diagnosis of AVWS performed according to the criteria of ISTH-SSC. A bleeding severity score (BSS) was calculated after exposing patients at enrollment to a detailed questionnaire. Bleeding time (BT) and VWF activities were measured in all cases while platelet nucleotides only in ET. Bleeding-free survival was computed with the Kaplan-Meier method. Types and number of treatments needed to manage bleeding were also recorded. *Results.* AVWS associated with MGUS (n=10) showed higher mean values of BSS than those (n=8) with ET (15 versus 6) in agreement with lower mean levels of VWF:RCo (8 versus 35 U/dL) and FVIII (12 versus 65 U/dL). Among the 8 cases with ET, BSS was relatively higher when low VWF:RCo levels were associated with lower platelet nucleotides. BT was moderately prolonged, with values of 16 (MGUS) and 12 (ET) min. The bleeding-free survival at five year calculated according to MGUS and ET was 20% and 50%, respectively. Mucosal (n=36) and non-mucosal (n=23) bleeds in MGUS (case n=8) or ET (case n=4) were treated with DDAVP (n=38), VWF concentrates (n=43), IVIg (n=26), rFVIIa (n=12). *Conclusions.* Patients with AVWS associated with MGUS/ET can show severe bleeding requiring intensive treatment. An early correct diagnosis should improve morbidity and mortality of these patients.

0534

IDIOPATHIC VEIN THROMBOSIS: IDENTIFICATION OF POPULATIONS AT DIFFERENT RISK OF RELAPSE FOLLOWING ORAL ANTICOAGULANT TREATMENT. THE RESULTS OF THE 'EXTENDED-DACUS STUDY'

S Siragusa,[1] A Malato,[1] G Saccullo,[1] L Lo Coco,[1] A Iorio,[2] A Tuttolomondo,[1] A Pinto,[1] A Casuccio,[1] V Abbadessa,[1] G Mariani[3]

[1]*University of Palermo, Palermo, Italy;* [2]*University of Perugia, Perugia, Italy;* [3]*Unirsity of l'Aquila, L'Aquila, Italy*

Background. The safest duration of anticoagulation, after the first episode of idiopathic Deep Vein Thrombosis (DVT), is unknown. *Aims.* We evaluated, in a prospective management study, the optimal Vitamin K-Antagonist (VKA) duration with reference to the risk of thrombosis relapse according to Residual Vein Thrombosis (RVT). *Methods.* Patients with a first idiopathic DVT were evaluated for the presence of RVT after 3 months of VKA; subsequent thrombosis and/or bleeding events were recorded during treatment and during the one-year follow-up after VKA withdrawal.

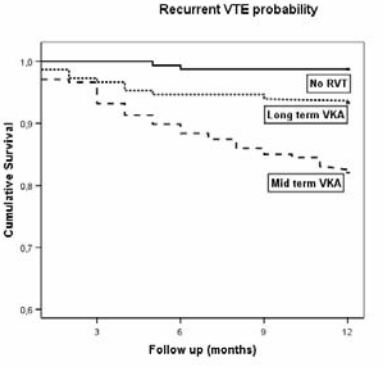

Figure 1. Kaplan-Meier curves of recurrent VTE after VKA sus.

Results. In 29.9% of patients, no RVT was found after 3 months of therapy and VKA was stopped; the remaining patients received anticoagulants for additional 15 or 21 months. Among the RVT-negative group, the incidence of recurrent VTE and major bleeding was 1.2% (2/164) and 0. Among the RVT-positive groups, the incidence of thrombosis was 7% (27/384) while on anticoagulation. After VKA withdrawal, the incidence of recurrences was 17.9% in the mid-term and 6.7% in the long-term group (Figure 1). Major bleeding was observed in 1% (4/384) of the cases. *Conclusions.* Our results indicate that in patients without RVT, a short VKA treatment is sufficient; in those with persisting RVT, treatment duration extended to 2 years substantially reduces but not abolishes, the risk of thrombosis recurrence.

Myelodysplastic syndromes

Background. The IPSS-Score, published by Greenberg et al. (1997), defines the gold standard in risk stratification of patients with MDS. Since its implementation in 1997 based on 816 patients with primary MDS, the knowledge concerning the prognostic impact of distinct abnormalities increased extensively. *Aims.* The present study proposes a new and comprehensive cytogenetic scoring system based on an international data collection originating from the German-Austrian (GA)-, the International Risk analysis workshop (IMRAW)-, the Spanish Cytogenetics working group (GCECGH) and the International Cytogenetics Working Group of the MDS Foundation (ICWG). *Methods.* Inclusion criteria were defined as follows: Primary MDS, age >=16, and bone marrow blasts <=30%. Regarding therapy, exclusively patients with supportive care were included. Based on these criteria, 955 patients were excluded resulting in 2901 patients available for final analysis. Univariate and multivariate analysis concerning overall survival (OS) and AML-transformation (AML-t) was performed. Age, gender, bone marrow blast count, number of peripheral cytopenias, center and year of diagnosis were included in the multivariate model. OS and AML-t in distinct cytogenetic abnormalities was only calculated when the abnormality occurred as an isolated aberration with a minimal frequency of n=10. Median observation time was 19.0 (0.1-326) months. Clinical follow-up was performed until April 2009. *Results.* In total, 20 cytogenetic subgroups were included, allowing the prognostic classification of 92% of all patients. Abnormalities were grouped as normal (n=1543, 53.2% of all cases), single (1 abnormality), double (2 abnormalities) or complex (>=3 abnormalities). Single abnormalities found were: der(1;7) (10, 0.4%); der(3)(q21)/der(3)(q26) (10, 0.4%); del(5q) (180, 6.4%); -7/7q- (60, 2.1%); +8 (133, 4.8%); del(11q) (20, 0.7%); del(12p) (18, 0.6%); i(17q)(11, 0.4%); +19 (10, 0.4%); del(20q) (48, 1.7%); +21 (10, 0.4%); -Y (60, 2.1%) and any other single (154, 5.5%). Double abnormalities were stratified into 3 subgroups: double including del(5q) (45, 1.6%); double including -7/7q- (31; 1.1%) and any other double (98, 3.4%). Complex karyotypes were sub-divided into 2 groups: Karyotypes with 3 abnormalities (60, 2.1%) vs. >3 abnormalities (196, 7.0%). 21 pts. (0.7%) displayed cytogenetically unrelated clones. According to OS and AML-t, abnormalities were classified to 5 prognostic subgroups: very good (del(11q), -Y), good (normal, der (1;7), del(5q), del(12p), del(20q), double incl. del(5q)); intermediate (-7/7q-, +8, i(17q), +19, +21, any other single, any other double, independent clones); poor (der(3)(q21)/der(3)(q26), double incl. -7/7q-, complex 3 abnormalities) and very poor (complex >3 abnormalities). Median survival was 60.8 months for very good (n=80), 48.5 months for good (n=1844), 24.0 months for intermediate (n=578), 14.0 months for poor (n=101) and 5.7 months for very poor (n=196); P<0.0001. Multivariate analysis resulted in a Hazard Ratio of 1.0 for very good (reference category), 2.1 for good, 3.4 for intermediate, 6.0 for poor and 9.3 for very poor concerning OS (p <0.0001). *Summary/Conclusions.* We were able to generate a solid database for a revised cytogenetic scoring system, which can serve as the cytogenetic model for the upcoming revision of the IPSS. *Acknowledgements.* The authors like to thank the MDS-Foundation for its support.

DETECTION OF RARE ABNORMALITIES AND KARYOTYPE EVOLUTION IN MDS PATIENTS FROM PERIPHERAL BLOOD: FIRST RESULTS FROM THE MULTICENTER GERMAN PROSPECTIVE DIAGNOSTIC CD34+FISH-STUDY

F Braulke,[1] J Schanz,[1] S Detken,[2] J Seraphin,[2] M Metz,[2] T Brümmendorf,[3] K Goetze,[4] U Platzbecker,[5] L Truemper,[1] D Haase[1]

[1]University Medicine, Goettingen, Germany; [2]Onkologische Gemeinschaftspraxis, Northeim, Germany; [3]Dep. Hematology and Oncology, University of Aachen, Aachen, Germany; [4]Dep. Hematology and Oncology, Tech. University of Munich, Munich, Germany; [5]Dep. Hematology and Oncology, University of Dresden, Dresden, Germany

Background. In myelodysplastic syndromes (MDS) chromosomal aberrations can be detected in 50-80% of patients (pts). They play an important role for pathogenesis, prognosis, diagnosis and, more recently for treatment allocations. The acquisition of clonal abnormalities in pts with initially normal karyotype, the expansion of an aberrant cell clone with a given anomaly or the occurrence of new, secondary abnormalities are called karyotype evolution (KE). A model of stepwise cytogenetic changes is proposed, but only a few systematic studies had focused on this phenomenon. In MDS most chromosomal anomalies detected by banding analyses of bone marrow (bm) metaphases are provable by fluorescence *in situ* hybridisation (FISH) of bm as well as by enriched $CD34^+$ stem cells from peripheral blood (pb). *Aims.* In a multicenter German diagnostic study we analyse immunomagnetically enriched circulating $CD34^+$ cells in MDS pts by FISH using 2 different FISH probe panels for initial screening and sequential follow-up measurements to detect chromosomal aberrations in pb and follow the clone size during therapy. Methods CD34+ stem cells from pb are enriched by immunomagnetic cell sorting (MACS®) and analysed by FISH afterward using a "Superpanel"(D7/CEP7, EGR1, CEP8, CEP XY, D20, p53, IGH/BCL2, TEL/AML1, RB1, MLL, 1p36/1q25, CSF1R, all Abbott® Products) for initial screening, after 12 and 24 months and in every case of suspected disease progression and a "Standardpanel"(EGR1, D7/CEP7, CEP8, p53, D20, TEL/AML1, CEP X/Y) every 2 months during the first year and every 3 months during the second year. *Results.* After 17 months of study time 142 pts (78 m, 64 f) with suspected or cytomorphologically proven MDS from 10 German centres of haematology/oncology are included in our study: With regard to age, gender distribution and MDS subtypes the study cohort is representative for the disease. The median follow-up time is 4.6 months (1-15 months). In 77 pts (54%) chromosomal aberration were detected by FISH of circulating $CD34^+$ cells: 43 pts (56%) with one isolated anomaly, 15 pts (19%) with 2 anomalies, 10 pts (13%) with 3 aberrations and 9 pts (12%) with more than 3 anomalies. In decreasing frequency we detected del(5q) (n=37), del(7q)/-7 (n=25), allelic loss of TP32 (n=12), del(12p) (n=11) and del(20q) (n=10) as the most commen aberrations. In 12 pts of 99 with at least 2 analyses (12%) KE could be detected by FISH from pb. In 5/12 cases KE was followed by cytomorphological progression to higher stages of MDS. Discussion KE is a known phenomenon in MDS suspected to lead to increased chromosomal instability and a stepwise progression of the disease. The frequency of KE in our cohort is comparable to other studies published in literature. Our results show that close-meshed sequential FISH analyses of circulating $CD34^+$ cells are a feasible and sensitive method to monitor MDS pts. KE can be diagnosed early in the course of disease, so it might help to learn more about rare abnormalities and clonal evolution in MDS.

PROLIFERATIVE AND APOPTOTIC SIGNALLING IN BONE MARROW CELL SUBPOPULATIONS OF MYELODYSPLASTIC SYNDROMES PATIENTS USING FLOW-CYTOMETRY TECHNIQUE

E Spinelli, R Caporale, F Buchi, A Gozzini, A Sanna, E Masala, F Sassolini, A Bosi, V Santini

FU Hematology, University of Florence, Florence, Italy, Florence, Italy

Background. Myelodysplastic syndromes (MDS) are heterogeneous clonal diseases characterised by cytopenias as a result of ineffective

hemopoiesis. Development of effective treatments has been mainly impaired by limited insights into MDS pathogenesis. Moreover, little is known about signal transduction pathways altered MDS cells. *Aims and Methods.* We have devised a multiparameter flow-cytometry method of signal transduction pathways analysis allowing rapid and specific separate evaluation in specific cellular subpopulations of MDS bone marrow cells. Cells were fixed with formaldehyde and permeabilized with methanol, then stained with APC anti-human CD34, PE anti-human CD71, PerCP anti-human CD45 and Alexa-Fluor488 anti-STAT5 (pY694), Alexa-Fluor488 anti-ERK1/2 (pT202/pY204), Alexa-Fluor488 anti-p38 (pT180/pY182) and Alexa-Fluor488 anti-cleaved caspase-3 (D175). Samples were analysed on a cytometer with 6 color laser. We studied in 60 MDS cases phosphorylation of ERK1/2 and p38 MAP kinases, phosphorylation of signal transducer and activator of trascription (STAT)5 and proteolitic activation of caspase-3 in bone marrow mononuclear cell subpopulations $CD34^+$, $CD45^+$ and $CD71^+CD45^-$ and compared with normal bone marrow cells. We performed the analysis before and after erythropoietin (EPO) and granulocyte colony stimulating factor (G-CSF) stimulation. *Results.* Baseline activation of MAPK phospho-proteins, STAT5 and caspase-3 was variable among MDS cases and among distinct cellular subpopulations. Non-parametric Wilcoxon test indicated that STAT5 was significantly activated in all $CD34^+$, $CD45^+$ and $CD71^+CD45^-$ MDS cells compared with cells from normal controls while caspase-3 was activated in $CD34^+$ and $CD45^+$ MDS cells. By the Kruskal-Wallis test we observed that refractory anemia (RA) and refractory anemia with excess of blasts-1 (RAEB-1) were more prevalently affected by this phenomenon. G-CSF stimulation activated STAT5 in $CD34^+$ from MDS and normal controls, without significant differences. EPO stimulation failed to induce STAT5 activation in $CD71^+CD45^-$ cell subpopulation of 22/36 MDS cases while it was effective in normal cells and in 14/36 $CD71^+CD45^-$ MDS cells. Non-parametric Wilcoxon test showed that STAT5 activation induced by EPO in $CD71^+CD45^-$ MDS cells was significantly lower than in normal cells. Evaluation of EPO response *in vivo* (Hb increase > 2 g/dL without transfusions after 8 weeks of EPO treatment) has shown that in 20/22 cases it correlated with *in vitro* EPO dependent STAT5 activation (Spearman's rho=0.62 and P=0.002). *Conclusions.* Signal transduction pathways may be analysed separately in specific subpopulations of MDS marrow cells. Our study indicates that different subpopulations ($CD34^+$, $CD45^+$, $CD71^+CD45^-$) show diverse pathway activations and diverse apoptosis pattern. Response to growth factors is also restricted to specific cellular subpopulations.

0538

AZACITIDINE TREATMENT PATTERNS, HEMATOLOGIC IMPROVEMENT, AND TOLERABILITY IN A LARGE GROUP OF ELDERLY PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS) IN THE AVIDA REGISTRY TREATED IN A COMMUNITY SETTING

R Komrokji,[1] A List,[1] M Sekeres,[2] M Narang,[3] A Swern,[4] K Sullivan,[4] T Street,[4] D Grinblatt[5]

[1]Moffitt Cancer Center, Tampa, USA; [2]Cleveland Clinic Taussig Cancer Institute, Cleveland, USA; [3]Alliance Hematology Oncology, Westminster, USA; [4]Celgene Corporation, Summit, USA; [5]NorthShore University HealthSystem, Evanston, USA

Background. Treatment decisions for elderly patients with MDS remain challenging, with little clinical data from controlled studies for guidance. Elderly patients are typically under-represented in clinical trials, although in higher-risk MDS patients ≥75 years of age in the AZA-001 study (N=87), azacitidine (AZA) was shown to significantly prolong survival compared with conventional care regimens (Seymour, Blood 2008:A3629). AVIDA is a large, prospective, US, community-based registry of patients treated with AZA. This registry includes the largest cohort of lower-risk (IPSS risk Low or Int-1) MDS patients treated with AZA. *Aims.* We evaluated AZA treatment patterns, hematologic improvement (HI), and tolerability in patients aged ≥75 years in the AVIDA registry. *Methods.* These interim data were collected between Oct 2006 and Nov 2009. Data were collected at registry entry, then quarterly, via electronic data capture. Treating physicians decided AZA dose, dosing schedule, and treatment duration. Reported AZA dosing schedules included 7 consecutive days, 5-2-2 (5 dosing days, 2-day break, 2 additional dosing days), and 5 consecutive days. HI and transfusion independence (TI) were assessed centrally using IWG 2000 criteria. Adverse events (AEs) were graded per NCI-CTCAE v3.0. *Results.* 434 patients ranging in age from 29 to 91 years were in the registry at the time of this analysis, Nov 12, 2009. Of them, 226 (52%) were age ≥75 years (mean [±SE] 80.8±0.3), half of whom (n=128, 57%) were ≥80 years of age. For these 226 patients, average time since MDS diagnosis was 15.3±2.0 months, 76% had baseline ECOG performance status 0-1 and 24% had ECOG PS ≥2, and of patients with IPSS data, 68% had lower-risk (IPSS 0-1) and 32% had higher-risk (IPSS ≥1.5) MDS. Patients received a median of 4 AZA cycles (range 1-24), with 38% receiving at least 6 cycles with a median follow-up of 5.0 (range: 0.03-25.0) months. Half of all treatment cycles (51%) were administered ≤28 days after the previous cycle, 29% occurred at 29-35 days, and 19% occurred at ≥36 days. For patients with available data, the most common route of AZA administration was intravenous (59%) vs subcutaneous (41%). More than half of patients (53%) received a 5-day AZA course, 16% received 5-2-2 dosing, and 13% received 7 consecutive day dosing. Approximately two-thirds of patients achieved HI or RBC TI (Table). Grade 3-4 hematologic AEs included neutropenia (14%), anemia (12%), and thrombocytopenia (12%); most occurred during cycles 1-2 and decreased in frequency thereafter. Grade 3-4 infections occurred in 13% of patients and predominately included pneumonia (5%). Patients <75 years of age had comparable effectiveness (Table) and safety outcomes. *Conclusions.* These AVIDA registry data, from the largest cohort of lower-risk MDS patients treated with AZA, show that among patients aged ≥75 years, AZA is preferentially dosed on a 5-day schedule, with approximately half of all AZA cycles administered without delay. These results also validate the effectiveness of AZA in patients with lower- or higher-risk MDS aged ≥75 years treated in a community setting, and demonstrate that AZA yields high rates of HI and RBC TI and is generally well-tolerated.

Table.

IWG-2000 Response	Patients receiving AZA Age ≥75 years (N=197*)	Patients Receiving AZA Age <75 years (N=185*)
Hematologic Improvement†		
Any HI	118/194 (61%)	98/174 (56%)
HI-Erythroid (Major)	82/181 (45%)	76/163 (47%)
HI-Platelet (Major)	51/117 (44%)	37/101 (37%)
HI-Neutrophil (Major)	19/98 (19%)	19/111 (17%)
Transfusion Independence‡		
Red blood cells	69/103 (67%)	60/92 (65%)
Platelets	19/26 (73%)	18/30 (60%)

*Ongoing patients with <56 days on-study were not eligible for analysis
†Individual cell line denominators include only patients eligible for improvement
‡ Denominators include only patients who were baseline transfusion-dependent (ie, received at least 1 transfusion in the 56 days prior to the start of AZA dosing).

Background. JMML and CMML are rare myeloproliferative and myelodysplastic neoplasms occurring at both ends of life, in infancy and in the elderly respectively. They share several diagnostic criteria. *Aims.* In order to better understand the pathophysiological relationship between JMML and CMML, we screened mutations of genes recently involved in CMML in a series of patients with JMML. *Methods.* 65 JMML have been studied. Mutations in *NRAS, KRAS, NF1* or *PTPN11* were present in 17%, 15%, 5% and 45% of cases respectively. The presence of germline mutations has been verified using fibroblasts as a source of constitutional DNA. Mutations in CBL (*c-CBL*), ASXL1, AML1 (*RUNX1*), and *TET2* have been screened by direct bi-directional sequencing. *JAK2*^{V617F} has been searched by TaqMan® probe hybridization. 51 JMML have been studied by SNP-array (Affymetrix SNP 6.0). *Results.* The mutation frequency in genes associated with JMML (*RAS, PTPN11* and *NF1*) or CMML (*CBL, ASXL1, AML1* and *TET2*), has been assessed in 65

patients with JMML and compared with that reported in CMML. Homozygous mutations of CBL associated with 11q23-qter copy neutral loss of heterozygosity were found in 4 out of 65 patients (6%). None of these patients had mutation in *RAS, PTPN11 or NF1*. A p.F418L substitution was found in one case and a p.Y371H substitution in the 3 others. These 3 latter patients presented with mild developmental anomalies, which led us to suspect the presence of an underlying genetic condition. A germline heterozygous mutation of CBL was found in these three patients. The mutation was *de novo* in 2 patients and inherited from the father in the third case. Two heterozygous mutations of *ASXL1*, p.G645VfsX58 and p.G646WfsX12 were found in 2 out of 65 patients (3%). Both mutations lead to a truncated *ASXL1* protein, which is removed from its PHD finger at the C-terminal extremity. These mutations have been identified in 2 patients older than 4 years at diagnosis and carrying a mutation in *NRAS* or *PTPN11*. No mutation in *TET2, AML1*, and *JAK2*^{V617F} genes was found in our series of JMML although these genes are mutated in 42%, 26% and 7% of CMML respectively. SNP-array pangenomic analysis did not show any abnormalities at these loci in JMML. *Summary/Conclusions.* JMML and CMML present mutations in CBL but substitutions found in JMML seem to be specific and are germline in a subset of children, thus defining a new predisposing syndrome to JMML. Among the various genes recently implicated in CMML, only *ASXL1* was found mutated in JMML. *ASXL1* belongs to the polycomb family gene and is a regulator of chromatin remodeling. Frameshift mutations lead to a truncated protein, which compromise the function of the associated chromatin modifiers. *ASXL1* mutations may be associated with JMML progression rather than initiation. In conclusion, the pattern of genetic lesions observed in JMML differs from that of CMML and confirms the crucial role of RAS and growth factor signaling deregulation in JMML.

Istituto Scientifico San Raffaele, Milano, Italy

Background. In Chronic Lymphocytic Leukemia (CLL) the relationships between cell accumulation within lymphoid organs and proliferation are not elucidated, and the mechanisms regulating CLL cell migration and re-circulation between peripheral blood and the lymphoid tissues are poorly characterized. Our previous studies demonstrated that Hematopoietic cell specific Lyn substrate 1 (HS1), a pivotal molecule in the signal transduction pathway triggered by the B-cell receptor, is a potential prognostic marker in CLL and interacts with several cytoskeletal components. Even though HS1 function in normal and leukemic B cells is poorly defined, both our data and the dissection of the protein structure prompted us to hypothesize an actin-binding activity as well as a potential role in cytoskeletal organization. *Aims.* Given the role played by the cytoskeleton in controlling cellular shape, mobility and homing, we hypothesized that HS1 could be potentially relevant in the regulation of CLL cells infiltration into lymphoid tissues and re-circulation between peripheral blood and tissues. *Methods.* To study HS1 function, we silenced its expression in a CLL cell line (MEC1) using an RNA Interference approach, and we utilized B lymphocytes from HS1 Knockout (KO) mice. Both cell types were then studied for their migration, adhesion, actin-polymerization and aggregation capacity by *in vitro* and *in vivo* assays. *Results.* In both cellular systems HS1-deficient B cells were severely impaired in their spontaneous migration and adhesion capacity. A decrease in F-actin polymerization and an increased homotypic aggregation ability were also evident in cells lacking HS1. Moreover, in the absence of HS1, B cells failed to form acto-myosin complexes and showed a defect in actin distribution and filopodia formation. To test *in vivo* HS1 function, we injected MEC1 cells silenced for HS1 subcutaneously in Rag2-/-γc-/- mice and observed that cells lacking HS1 spread and localize preferentially in the bone marrow (BM) and in the lymph nodes as compared to control cells. To further investigate HS1 role in the onset and progression of CLL, we crossed HS1 KO mice with Eμ-TCL1 transgenic animals (CLL mouse model). The HS1 KO/TCL-1 transgenic mice showed an earlier disease onset and a preferential accumulation of leukemic cells in the BM where they are usually observed only at low frequencies in the Eμ-TCL1 mouse. *Conclusions.* These findings suggest that HS1 has an important role in controlling cell migration and tissue invasion by leukemic B cells, likely through its involvement in cytoskeleton organization. This points at HS1 as a potential target for development of novel cancer treatments aimed at interfering with tissue infiltration and invasion.

Background. A fraction of CLL transforms to Richter syndrome (RS),

generally represented by diffuse large B-cell lymphoma (DLBCL). Knowledge of the genetic lesions driving RS transformation is scant. Aim. We aimed at exploring the pattern and prognostic impact of RS molecular lesions. *Methods.* Upon pathological review, all RS (n=81) were classified as DLBCL. Candidate genetic lesions were selected among those recurrently affecting *de novo* DLBCL and CLL. Mutational analysis of TNFAIP3/A20, CARD11, BLIMP1, CD79A/CD79B, EZH2, BCL6, c-MYC, PAX5, TTF, PIM1 and TP53 was performed by Sanger sequencing. Probes used for FISH were: i) LSI13, LSID13S319, CEP12, LSIp53, LSIATM, LSI IGH/BCL2, LSI BCL6, LSI IGH/c-MYC/CEP8, c-MYC breakapart, LSI N-MYC; BCL3 split signal; iii) 6q21/alpha-satellite; iv) BAC clones 373L24-rel and 440P05-BCL11A. Clonal relationship between CLL and RS was assessed by immunoglobulin gene analysis. Informed consent was obtained. *Results.* MUM1 was expressed in 77.3% RS, BCL6 in 25.4%, CD10 in 5.6%. IG were unmutated in 65.4% cases. TP53 mutations occurred in 28/80 (35.0%) RS, CARD11 mutations in 5.3%, BCL6-intron1 mutations in 7.1%, c-MYC mutations in 3.6%, PIM1 mutations in 10.7%, PAX5 mutations in 7.1%, and TTF mutations in 14.3%. Mutations of TNFAIP3/A20, BLIMP1, BCL6-exon1, CD79A/CD79B, and EZH2 were consistently absent in RS. c-MYC activation occurred in 25.9% RS (translocation: 13.8%; amplification: 12.1%), BCL2 amplification in 10.5%, BCL6 amplification in 7.0%, and BCL6 translocation in 1.8%. 17p13 deletion occurred in 27.1% RS, 11q22-q23 deletion in 16.0%, +12 in 12.1%, 13q14 deletion (MIR15/16B) in 13.7%, 6q21 deletion in 8.3%, MYCN amplification in 3.8%, and BCL3 translocation in 2.1%. TP53 disruption by mutation and/or deletion occurred in 48.3% cases.

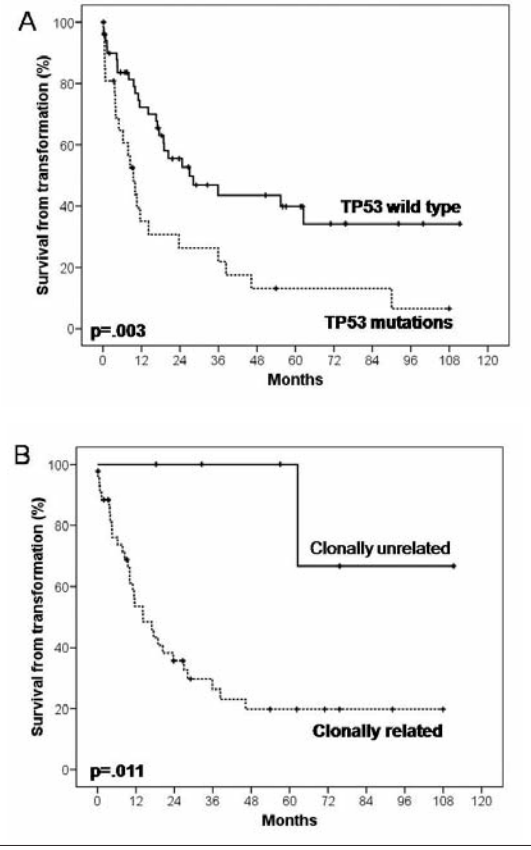

Figure 1.

Analysis of paired clonally related CLL/RS showed that TP53 disruption, c-MYC activation and CARD11 mutations are acquired at transformation. We then investigated the impact of molecular lesions on RS survival. At diagnosis, 64.1% RS were older than 60 years, 35.9% showed ECOG PS >1, 75.6% Binet stage B-C, 93.6% Ann Arbor stage III-IV, 43.6% B symptoms, 44.9% tumor size >5 cm, 30.8% involvement of >1 extranodal site, 62.5% LDH elevation, 69.2% Hb <11 g/dL, and 30.8% platelets $<100+10^9$/L. Biological variables associated with poor RS survival were TP53 mutation (P=.003), del17p13 (P<.001), and MUM1 expression (P=.047) (Figure 1A). Multivariate analysis selected TP53 mutations (HR:1.86 P=.040) as an independent predictor of RS survival along with ECOG PS (P=.001), tumor size (P=.001), and platelet count (P=.049). Clonally unrelated RS (7/81; 8.6%) differed from clonally related RS (45/81; 55.6%) because of lower prevalence of MUM 1 expression (33.3% vs 82.2%; P=.010) and TP53 mutations (0 vs 47.7%; P=.033). This difference translates into longer survival of clonally unrelated RS compared to clonally related RS (5-years survival: 66.7% vs 19.8%; P=.011) (Figure 1B). *Conclusions.* This study documents that: i) the genetic pattern of RS differs from that of *de novo* DLBCL; ii) TP53 disruption and c-MYC activation are the most frequent RS genetic lesions; iii) TP53 mutations are an independent prognostic factor in RS; iv) clonally unrelated RS are biologically and clinically distinct from clonally related RS.

SELECTIVE INHIBITORS OF THE SPLEEN TYROSINE KINASE BLOCK CELL SURVIVAL AND MIGRATION IN CHRONIC LYMPHOCYTIC LEUKEMIA

J Hoellenriegel,[1] G Coffey,[2] U Sinha,[2] A Pandey,[2] W Wierda,[1] M Keating,[1] J Burger[1]

[1]MD Anderson Cancer Center, Houston, USA; [2]Portola Pharmaceuticals, South San Francisco, USA

Background. There is growing evidence suggesting that B-cell receptor (BCR) signaling plays an important role in the pathogenesis of chronic lymphocytic leukemia (CLL). BCR signaling in CLL cells activates the spleen tyrosine kinase (Syk), which leads to a number of downstream events that promote cell survival. Therefore, disrupting BCR-induced signaling by inhibiting Syk represents a novel therapeutic approach in CLL. A recent clinical trial indicated that inhibition of the Syk by R788 (fostamatinib disodium, FosD) is effective in patients with CLL and other B cell malignancies. R788 is a relatively selective Syk inhibitor, but also displays activity against Flt3, Jak, and Lck. *Aims.* Since Syk has been implicated in CLL cell activation, migration and survival, the present study was designed to determine the effects of BCR stimulation and its inhibition with two selective Syk inhibitors. *Results.* Pre-treatment with selective Syk inhibitors (P142-76 and P505-15) and a Syk/JAK inhibitor (P420-89), abrogated the increased CLL cell migration and survival of CLL cells in response to BCR engagement. Activation of the BCR with polyclonal goat F(ab')2 fragments to human IgM significantly increased CLL cell viability compared to control, and this pro-survival effect of BCR triggering was abrogated by treatment with the Syk inhibitors P142-76 and P505-15. The mean relative CLL cell viability at 48 hours was decreased to 78±4% (P142-76), 62±5% (P505-15) or 50%±4.5% (P420-89) of controls (100%; data are means±SEM, n=19). Furthermore we found that the inhibitors induce apoptosis in CLL cells in co-culture with nurselike cells (NLC), indicating that Syk inhibition antagonizes microenvironment-derived survival signals from NLC.

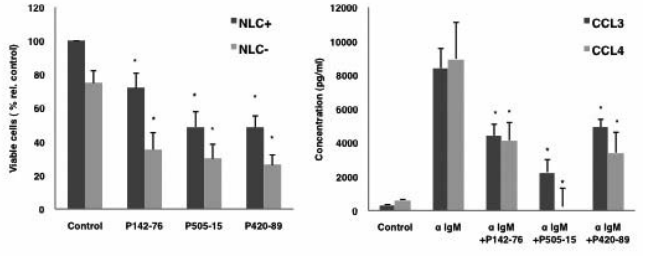

Figure. Syk inhibitors block BCR-induced CLL cell survival.

As shown in Figure A, the selective Syk inhibitor P505-15 significantly reduced CLL cell viability in NLC co-cultures from 84.4± 5% to 46±8% at 48 hours and the Syk/JAK inhibitor P420-89 to 52± 6% (mean ± SEM, n=6,*P<0.05). We recently reported that BCR triggering enhances CLL cell chemotaxis toward CXCL12 and CXCL13 (Blood 114:1029-37, 2009). To determine the effects of the selective Syk inhibitors on chemotaxis, CLL cells were incubated with anti-IgM with or without the Syk inhibitors before the chemotaxis assay. The selective Syk inhibitor P505-15 decreased chemotaxis toward CXCL12 and CXCL13 to levels that were 49.5% ± 5% or 32.8±6% of respective controls. Engagement of BCR induces the secretion of the chemokines CCL3 and CCL4 by CLL cells, which was almost completely abrogated by inhibiting Syk. As displayed in Figure B, BCR triggering induced CCL3 supernatant levels of 8400 pg/mL ± 1166 pg/mL and CCL4 levels of 8959 pg/mL ± 2147 pg/mL (mean ± SEM, n=5). Preincubation with P505-15 significantly reduced the levels of these chemokines to 2263 pg/mL ± 744 pg/mL (CCL3) and to 2250 pg/mL ± 1093 pg/mL (CCL4), respectively (mean ± SEM, n=5, *P< 0.05). This inhibition of CCL3/4 secretion could also be

demonstrated in CLL cocultures with NLC. *Conclusion*. In this study we demonstrate that inhibition of Syk with selective, small molecule inhibitors is highly effective in disrupting different BCR-derived responses. Specifically, these selective inhibitors antagonize CLL cell survival after BCR triggering, and in suspension- and NLC-cultures. Moreover, they inhibit CLL cell migration towards the chemokines CXCL12 and CXCL13. Also, they inhibit BCR- and NLC-induced secretion of the chemokines CCL3 and CCL4 by CLL cells. These results support the future therapeutic development of these selective Syk inhibitors in patients with CLL.

0543

IMPACT OF TP53 MUTATIONS ON OUTCOME: RESULTS FROM THE CLL8 TRIAL (FC VS. R-FC) OF THE GCLLSG

T Zenz,[1] P Hoth,[1] R Busch,[2] H Helfrich,[1] D Winkler,[1] A Bühler,[1] N Patten,[3] N Truong,[3] L Wu,[3] G Fingerle-Rowson,[4] K Fischer,[4] A Fink,[4] U Jäger,[5] S Böttcher,[6] M Kneba,[6] M Wenger,[7] M Mendila,[7] M Hallek,[4] H Döhner,[1] S Stilgenbauer[1]

[1]University of Ulm, Ulm, Germany; [2]Technical University Munich, Munich, Germany; [3]Roche Molecular Systems, Pleasanton, USA; [4]University of Cologne, Cologne, Germany; [5]University of Vienna, Vienna, Austria; [6]University Hospital Schleswig Holstein, Kiel, Germany; [7]Pharmaceuticals Division, Hoffmann-La Roche, Basel, Switzerland

There is growing evidence that TP53 mutations are associated with poor survival in CLL. There are limited prospective trial data on treatment effects of chemoimmunotherapy in CLL with and without TP53 mutation. The current study set out to define the impact of TP53 mutation in patients treated with FC or R-FC in the CLL8 trial. Analysis of TP53 mutation status by microarray-based re-sequencing assay (Amplichip p53 assay in development by Roche Molecular Systems) and confirmatory direct DNA sequencing were performed in a central reference laboratory. Samples were available for 628 (76.9%) patients at study entry and this cohort was representative of the full trial population regarding other baseline prognostic factors and demographics. In addition, 94 follow-up samples of 89 patients at relapse were available. The incidence of the TP53 mutations was 11.9% (71/628; 41 in FC arm, 30 in R-FC arm). Forty-two of 51 patients (82.4%) with 17p deletion had a TP53 mutation. 5% of patients without 17p deletion (28/553) had a TP53 mutation. Patients with TP53 mutation showed lower complete response (CR) and overall response (OR) rates as compared to the group without TP53 mutation (6.9 vs. 36.4% and 62.1% vs. 95.3% (P<0.001). Lower response rates were observed for the TP53 mutation groups in both arms (FC and R-FC): CR (3.2% and 11.1%), CR+PR (51.6% and 74.1%). Response rates for patients without TP53 mutation were 24.2% (CR (FC)) and 92.2% ORR (FC) vs. 47.8 (CR R-FC arm) and 98.2% (ORR R-FC). Median progression free survival (PFS) was significantly shorter for patients with TP53 mutations (12.3 months vs. 45 months) (HR: 4.4 (3.29-5.87) P<0.001). Median PFS was better for patients in the R-FC group in the TP53 mutated subgroup (FC 12.1 / R-FC 15.4 months; HR 0.53 (0.31-0.9) P=0.019). Patients with TP53 mutation showed a median OS of 39.3 months whereas median OS was not reached in all other patients (HR 6.01 (4.08-8.87) P<0.001).

Table. Impact of treatment arm and genetic factors on overall survival in CLL patients treated with FC/R-FC (CLL8 trial).

	p=	lower CI (95%)	upper CI (95%)	HR
R-FC	0.019	.432	.927	0.633
IGHV unmutated	0.035	1.035	2.576	1.632
TP53 Mutation	0.002	1.415	4.905	2.634
17p deletion	0.0002	1.831	6.780	3.523

Multivariate analysis was performed by Cox regression including age, stage, treatment arms, IGHV status, genomic aberrations and TP53 mutation. Regarding PFS (n=567), independent prognostic factors were 17p- (HR: 3.6; P<.001), TP53 mutation (HR: 2.2; P<.001), unmutated IGHV (HR: 1.7, P<.001), age (HR: 1.4; P<.001), and R-FC (HR: 0.52; P<.001). Regarding OS (n=580), 17p- (HR: 3.5; P<.001), TP53 mutation (HR: 2.6: P<.001), unmutated IGHV (HR: 1.6; P=.035), and R-FC (HR: 0.6; P=0.019) were identified as independent factors. The analysis of follow-up samples (n=94; collected a median of 1028 days after the initial sample (range 97-1963)) showed an incidence of TP53 mutation of 26.6% (25 / 94). All 17 cases with TP53 mutation before treatment and available follow-up sample, showed the same mutation. Eight follow-up samples showed a TP53 mutation that was not present initially (10.5%; 8/76 samples tested). In conclusion, 17p deletion and TP53 mutation (independent of 17p deletion) are powerful and independent prognostic markers after 1st line FC and R-FC treatment in CLL. When considering the genetic profile in a multivariate model including these, R-FC improves PFS and OS compared to FC in CLL.

HUMAN LEUKOCYTE ANTIGEN MATCHING AND CONDITIONING IMPACT ON LONG-TERM TRANSPLANT OUTCOME AFTER ALLOGENEIC HSCT FOR CHRONIC LYMPHOCYTIC LEUKEMIA: STUDY FROM THE EBMT REGISTRY

M Michallet,[1] M Sobh,[1] D Milligan,[2] S Morisset,[1] D Niederweiser,[3] V Koza,[4] T Ruutu,[5] N Russell,[6] L Verdonck,[7] N Dhedin,[8] A Vitek,[9] M Boogaerts,[10] L Vindelov,[11] J Finke,[12] V Dubois,[1] A van Biezen,[13] R Brand,[13] P Dreger[14]

[1]Edouard Herriot Hospital, Lyon, France; [2]Birmingham Heartlands Hospital, Birmingham, UK; [3]University of Leipzig, Leipzig, Germany; [4]University Hospital Pilsen, Pilsen, Czech Republic; [5]Helsinki University Central Hospital, Helsinki, Finland; [6]Nottingham University Hospital, Nottingham, UK; [7]University Medical Centre, Utrecht, Utrecht, Netherlands; [8]Hôpital Pitié-Salpêtrière, Paris, France; [9]Institute of Hematology and Blood Transfusion, Prague, Czech Republic; [10]University hospital of Leuven, Leuven, Belgium; [11]Rigshospitalet, Copenhagen, Denmark; [12]University Medical Center Freiburg, Freiburg, Germany; [13]Leiden University Medical Centre, Leiden, Netherlands; [14]University Hospital Heidelberg, Heidelberg, Germany

Background. The outcomes of related and unrelated donor hematopoietic stem cell transplantations (HSCT) are strongly affected by the degree of human leukocyte antigen (HLA) matching between the transplant recipient and the donor or cord blood unit. HLA matching plays an important role in engraftment, incidence and severity of graft-versus-host disease (GVHD) and also in overall survival; although this factor is still not validated yet in many hematological malignancies. Objective: To evaluate the impact of HLA matching and difference in matching degree among transplants from unrelated donors (UD) on different outcomes in chronic lymphocytic leukemia (CLL). *Materials and Methods.* we have analyzed 370 CLL patients who underwent allogeneic hematopoietic stem cell transplantation (HSCT) as reported to the EBMT registry between 1995 and 2007. There were 198 HLA-identical siblings and among transplants from UD, there were 31 well matched in high resolution (WMUD), and 141 mismatched (MM) including 30 matched in low resolution. Regarding conditioning, 266 (72%) were RIC and 104 (28%) standard. *Results.* After multivariate adjustment for possible confounders, there was no difference in overall survival (OS) between HLA-identical siblings [5 years OS=55% (48-64)] and WMUD [5 years OS=59% (41-84)] P=0.82. In contrast, OS was significantly worse for MM [5 years OS=37% (29-48) P=0.005] due to a significant excess of transplant related mortality (TRM). Conditioning intensity (RIC) had no significant impact on OS [HR=1.19 (0.78-1.81) P=0.4], relapse [HR=1.69 (0.83-3.44) P=0.14] and TRM [HR=1.01 (0.62-1.64) P=0.9]. *Conclusions.* Our findings support the use of WMUD as equivalent alternative to HLA-matched sibling donors for allogeneic HSCT in CLL, and justify further exploration of RIC in this disease.

Acute myeloid leukemia - Clinical

OUTCOME OF PATIENTS WITH NEWLY DIAGNOSED ACUTE PROMYELOCYTIC LEUKEMIA (APL) TREATED WITH THE COMBINATION OF ALL-TRANS RETINOIC ACID (ATRA), ARSENIC TRIOXIDE (ATO), WITH OR WITHOUT GEMTUZUMAB OZOGAMICIN (GO)

F Ravandi, J Cortes, S Faderl, S O'Brien, S Pierce, M Brandt, G Garcia-Manero, H Kantarjian

University of Texas - M. D. Anderson Cancer Center, Houston, USA

Background. With the introduction of arsenic trioxide (ATO) as an effective treatment for relapsed acute promyelocytic leukemia (APL), its potential role earlier in the course of treatment is increasingly under investigation. *Aims.* We examined the outcome of patients with newly diagnosed acute promyelocytic leukemia (APL) treated with all-trans-retinoic acid (ATRA) and arsenic trioxide (ATO) with or without gemtuzumab ozogamicin (GO) but without traditional cytotoxic chemotherapy in induction or consolidation. *Methods and patients*. From July 2002 to December 2009, 92 patients with newly diagnosed APL with performance status (PS) ≤2 were treated with a combination of ATRA plus ATO in two studies. All patients signed an approved informed consent form before participation. The first cohort of 47 patients received ATRA (45 mg/m^2 daily) and ATO (0.15 mg/kg daily beginning on day 10 of ATRA). High-risk patients (White blood cell count [WBC] ≥10×10^9/L) received GO 9 mg/m^2 on the first day of induction. From July 2007, the second cohort of 45 patients received ATRA (45 mg/m^2 daily) and ATO (0.15 mg/kg daily) concomitantly on day one of induction. They also received GO 9 mg/m^2 on day 1, if high risk, and any time during induction if the WBC rose to > 30×10^9/L (and more recently if > 10×10^9/L). Consolidation was with 4 courses of ATO administered daily for 5 days/week for 4 weeks every other month as well as ATRA 2 weeks on/2 weeks off for a total of 28 weeks after CR. Monitoring for PML-RARA fusion gene using reverse transcriptase-polymerase chain reaction (RT-PCR) was conducted after induction and throughout consolidation and follow up. If confirmed RT-PCR positive, GO 9 mg/m^2 would be administered with ATRA and ATO every 4-5 weeks (based on recovery of counts) until negative. The median age for the 92 patients was 46 years (range, 14-81 years). Their median presenting WBC was 2.7×10^9/L (0.4-131.4×10^9/L) and their median platelet count was 36×10^9/L (range, 7-261×10^9/L). Sixty four (70%) had low risk and 28 (30%) high risk disease (based only on the presentation WBC < or ≥ 10.0×10^9/L). *Results.* Overall, 90 patients (98%) achieved complete remission (CR) and 2 died at induction. With a median follow-up of 25 months (range, 3 to 99 months), 83 patients remain alive. The estimated 5-year survival rate is 90% and only 5 of the patients achieving a CR (6%) have relapsed. The median overall, relapse-free and event-free survival has not been reached (Figure 1). Two late deaths (beyond 75 months) were in CR and from unrelated cancers. *Conclusions.* The combination of ATRA and ATO (with or without GO) as initial therapy for APL is highly effective and safe; it can potentially substitute chemotherapy containing regimens in high and low risk patients.

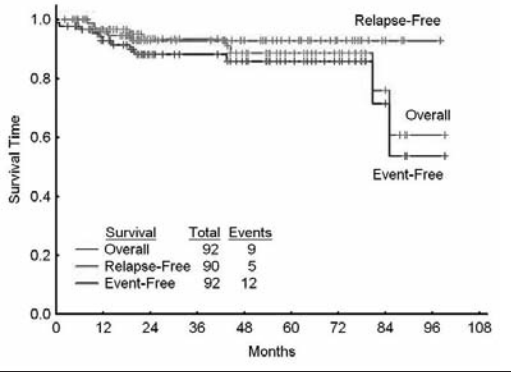

Figure 1. Overall, relapse-free and event-free survival

LONG-TERM OUTCOME OF AML PATIENTS ACCORDING TO THE NEW GENETIC RISK CLASSIFICATION OF THE EUROPEAN LEUKEMIANET RECOMMENDATIONS: EVALUATION OF THE PROPOSED REPORTING SYSTEM IN A COHORT OF 1507 PATIENTS

C Röllig,[1] C Thiede,[1] W Aulitzky,[2] M Bornhäuser,[1] H Bodenstein,[3] R Stuhlmann,[4] M Kramer,[1] B Mohr,[1] F Stölzel,[1] M von Bonin,[1] H Wandt,[5] G Ehninger,[1] M Schaich[1]

[1]Universitätsklinikum Dresden, Dresden, Germany; [2]Robert-Bosch-Krankenhaus, Stuttgart, Germany; [3]Klinikum Minden, Minden, Germany; [4]Asklepios Klinik St. Georg, Hamburg, Germany; [5]Klinikum Nord, Medizinische Klinik 5, Nürnberg, Germany

Background. Among several prognostic factors in patients with Acute Myeloid Leukemia (AML), cytogenetic aberrations have the strongest impact on prognosis. Whilst there is consensus on classification and prognostic value of favorable risk (FR) and adverse risk (AR) aberrations, most patients display neither favorable nor adverse genetic features, therefore creating a large and heterogeneous group of intermediate risk (IR). Based on literature review and expert consensus, the authors of the recently published European LeukemiaNet (ELN) recommendations on diagnosis and management of AML proposed a subdivision of the IR group into an Intermediate-I group (normal karyotype with absent NPM+/FLT3-ITD- and absent CEBPA+) and a less favorable Intermediate-II group. *Aims.* To assess the prognostic value of the new ELN reporting system for correlation between cytogenetic and molecular genetic data, and clinical data, in a large cohort of patients. *Methods*. Complete data for classification were available for 1507 of 1916 patients treated in the AML96 trial between 1996 and 2004. Patients were assigned to the proposed genetic groups from the ELN recommendations and survival analyses were performed using the Kaplan-Meier method and log-rank tests for significance testing. *Results.* Assignment to risk groups resulted in roughly equal patient numbers in all four genetic groups with 21-29% of all patients per group. The median age of all patients was 59 years (range, 15-87). After a median follow-up time of 7.9 years, significant differences in the probability of relapse (PR) were observed between all groups. The median time to relapse (TTR) in the IR-I, IR-II and AR groups was 1.1, 2.1 and 0.6 years, respectively (p=0.012). The median TTR for the FR group was not reached. Similar effects were observed for disease-free survival (DFS). Separate analyses in the age groups ≤60 years and >60 years revealed that the described differences between IR-I and IR-II were caused by marked effects in the young age group while in elderly patients no difference between IR-I and IR-II were observed. The median overall survival (OS) in all patients was 1.0 year. The median OS was significantly different between the FR group (3.3 years) and the AR group (0.6 years), while there was no difference in OS between the two IR groups (1.1 years each). *Summary/Conclusions.* In our cohort, the ELN classification resulted in significant differences between all four risk groups in terms of PR, TTP and DFS, particularly in younger AML patients. Interestingly, patients in IR-I have a higher risk of relapse than in IR-II, which is most likely due to the presence of FLT3-ITD+ in IR-I. The ELN classification therefore seems to mirror variations in AML biology. Noteworthy, no differences were noted between the IR-I and IR-II groups regarding OS. This may be due to the risk-adjusted treatment approaches applied in the AML96 trial, in which autologous and allogeneic transplantation were applied whenever possible in the IR group. Additional prognostic factors and on-treatment evaluations are desirable for the prediction of OS in the group without favorable or adverse genetic features and for elderly AML patients.

0547

FACTORS DETERMINING CLINICAL RESPONSE TO 5'-AZACITDINE AND SODIUM VALPROATE COMBINATION THERAPY IN PATIENTS WITH HIGH RISK ACUTE MYELOID LEUKAEMIA AND MYELODYSPLASIA

C Craddock,[1] S Siddique,[2] T McSkeane,[1] M Griffiths,[3] S Pillai,[1] J Cavenagh,[4] P Vyas[5]

[1]Queen Elizabeth Hospital, Birmingham, UK; [2]Centre for Clinial Haematology, Queen Elizabeth Hospital, Birmingham, UK; [3]West Midlands Regional Genetics Laboratory, Birmingham, UK; [4]St Bartholomew's Hospital, London, UK; [5]Institute of Molecular Medicine, Oxford, UK

Background. Demethylating agents and histone deacetylase inhibitors represent important new treatment options in high risk acute myeloid leukaemia (AML) and myelodysplasia (MDS). However the optimal combination of these agents remains to be determined. *Aims.* We therefore evaluated the clinical activity of a novel combination of the demethylating agent 5'-azacitidine (AZA) and the histone deacetylase inhibitor sodium valproate (VAL) with the aim of identifying factors predicting clinical outcome. *Methods.* 71 patients with high risk AML or MDS received treatment with AZA (75 mg/m^2 x 7 days per 28 day cycle) and continuously administered VAL (1-2.5 g daily as tolerated). Patients also received continuous all trans retinoic acid and theophylline. All patients gave informed consent and the clinical trial was approved by the Research Ethics Committee. Clinical responses were assessed using Cheson criteria. Patients achieving a complete remission (CR) or partial response (PR (defined as >50% reduction in bone marrow blasts)) after six cycles continued trial therapies until loss of response. 59 patients commencing treatment had AML (43 relapsed/ refractory disease, 16 untreated) and 12 high risk MDS by IPSS criteria. The median patient age was 66 years (range 32-85). Cytogenetic data was available for all patients: 76% patients were standard, 24% poor and 1% good risk according to MRC criteria. *Results.* A total of 47 patients received 1 or more cycles of AZA. The most common Grade 3-4 non-haematological toxicities were febrile episodes (44%), fatigue (31%) and diarrhoea (13%). Major clinical responses (CR or PR) were observed in 27 (38%) patients. 13 (18%) patients achieved CR or CR with incomplete count recovery (CRi) and 14 (20%) a PR. The median time to achievement of maximal response was 3 cycles. Response duration ranged from 29-799 days. The 1 year overall survival (OS) was 59% (95% CI: 42-73%). The liklihood of achieving a major clinical response (CR or PR) was higher in patients with previously untreated disease in univariate and multivariate analysis. Improved OS was associated with a lower percentage of blasts at the commencement of therapy and the presence of previously untreated disease in univariate analysis. Age, cytogenetic classification and performance status did not impact on the liklihood of achieving a major clinical response or OS. *Conclusions.* These data demonstrate significant clinical activity of AZA and continuously administered VAL in elderly patients with high risk AML and MDS. Importantly clinical activity was not influenced by cytogenetic subgroup or patient age. The liklihood of achieving a major clinical response was higher in patients with no history of prior exposure to chemotherapy emphasising the importance of early deployment of these agents.

0548

LOW DOSE GEMTUZUMAB OZOGAMICIN PLUS FLUDARABINE, CYTARABINE, IDARUBICIN (GO-FLAI) AS INDUCTION THERAPY IN CD33-POSITIVE ACUTE MYELOID LEUKEMIA (AML) PATIENTS YOUNGER THAN 65 YEARS. INTERIM RESULTS FROM A PHASE III MULTICENTER PROSPECTIVE CLINICAL TRIAL (MYFLAI07-NCT.00909168).

A Candoni,[1] G Martinelli,[2] F Gherlinzoni,[3] C Papayanidis,[2] I Iacobucci,[2] M Gottardi,[3] G Visani,[4] E Simeone,[1] S Paolini,[2] B Lama,[2] A Michelutti,[1] A Isidori,[4] P Piccaluga,[2] G Sparaventi,[4] M Malagola,[5] D Russo,[5] M Baccarani,[2] R Fanin[1]

[1]Division of Hematology and BMT, Udine, Italy; [2]Institute of Hematology and Oncology A and L Seragnoli, University of Bologna, Italy; [3]Division of Hematology, Ca Foncello Hospital, Treviso, Italy; [4]Division of Hematology and BMT Center, San Salvatore Hospital, Pesaro, Italy; [5]Chair of Hematology and BMT unit, University of Brescia, Italy

Introduction. We report the interim results from a phase III multicenter clinical trial combining low dose of Gemtuzumab-ozogamicin (GO) with FLAI regimen (Fludarabine, Cytarabine, Idarubicin) as Induction chemotherapy in AML patients younger than 65 years (eudract: 2007-005248-26; ClinicalTrials.gov NCT00909168). *Patients and Methods.* Primary endpoints: Feasibility, Efficacy (CR, PR rate) and Toxicity of GO-FLAI; overall survival (OS) and disease free survival (DFS). Secondary endpoints: Evaluation of Minimal Residual Disease by WT1 (and other biologic markers) expression and monitoring. Feasibility and outcome of consolidation with BMT. One hundred and eighteen consecutive AML patients were included. All patients were younger than 65 with a median age of 51 years (range, 18-65) and CD33 expression exceeded 20% in all cases. The M/F ratio was 58/60, and 80/118 (68%) of patients were poor-risk at diagnosis. The induction regimen (GO-FLAI) included fludarabine (30 mg/sqm) and Ara-C (2 g/sqm) on days 1-5, idarubicin (10 mg/sqm) on days 1, 3, and 5 and GO (3 mg/sqm) on day 6. Hematopoietic stem cell transplant (HSCT) was planned for all high risk AML patients in first complete remission (CR) after consolidation with intermediate doses of Ara-C and idarubicin (ID-AC and IDA). Cytogenetic, multidrug-resistance phenotype, FLT3 and NPM mutation status, WT1 quantitative expression analyses, were performed at diagnosis in all patients. Quantitative WT1 gene expression (with RQ-PCR technique validated by Leukemia Net), cytogenetic (in positive cases) and specific molecular marker analyses were performed after induction to detect and follow Minimal Residual Disease. *Results.* Patients were evaluated for response rate, treatment-related adverse events, OS and DFS. After induction with GO-FLAI, CR rate was 81% (95 of 117 evaluable pts); four patients achieved partial remission (PR) and 15/117 were resistant (Overall response rate was 85%). There were only 3 cases of death during induction (DDI 3%). The haematological and extra haematological toxicity of GO-FLAI was manageable and will be reported in detail; 55% of patients experienced transient and reversible GO infusion-related adverse events (especially fever and chills), but no cases of veno-occlusive disease occurred during chemotherapy or after allogeneic SCT. In the setting of patients who achieved a cytological CR after GO-FLAI, the mean of WT1 copies dropped from 8178±10040/104ABL (at diagnosis) to 185±225 copies/104ABL after induction therapy [P<0.05]. After a median follow-up of 16 months (range 1-50), 88/118 (75%) patients are alive (83/88 in CR). The probability of 2-year OS and DFS were 74% and 70%. Allogeneic and Autologus SCT was performed in 65 (55%) and 19 (16%) patients, respectively. *Conclusions.* The interim results of this trial confirm that GO-FLAI is an effective and well tolerated induction regimen for CD33 positive AML patients younger than 65 years, with a high complete response rate (81%), good disease debulking, favourable safety profile and low DDI (3%), allowing consolidation therapy with SCT early and in a high proportion of cases (84/118, 71%).

0549

A PHASE II MULTICENTRE STUDY WITH ELACYTARABINE IN LATE STAGE ACUTE MYELOID LEUKAEMIA

S O'Brien,[1] D Rizzieri,[2] N Vey,[3] F Ravandi,[1] U Krug,[4] M Sekeres,[5] M Dennis,[6] A Venditti,[7] T Jacobsen,[8] B Nilsson,[8] F Giles[9]

[1]University of Texas MD Anderson Cancer Center, Houston, USA; [2]Duke Univ. Med. Ctr., Cellular Therapy, Durham, NC, USA; [3]Institut Paoli-Calmettes Centre Régional de Lutte Contre le Cancer, Marseille, France; [4]University of Münster, Dept. of Internal Medicine, Hematology/Oncology, Münster, Germany; [5]Cleveland Clinic, Taussig Cancer Inst., Hematologic Oncology and Blood Disorders, Cleveland, OH, USA; [6]Christie Hospital NHS Trust, Department of Haematology, Manchester, UK; [7]University Tor Vergata, Hematology, Roma, Italy; [8]Clavis Pharma ASA, Oslo, Norway; [9]The Inst. for Drug Development, CTRC at the Univ.of Texas Health Science Center, San Antonio, TX, USA

Background. Elacytarabine (CP-4055; 5'-O-(trans-9"-octadecenoyl)-1-β-D-arabinofuranosyl cytosine) is a novel cytotoxic nucleoside analogue with similar mechanisms of action to cytarabine, but unlike cytarabine it is independent of nucleoside transporters (e.g. human Equilibrative Nucleoside Transporter 1 (hENT1)) for cellular uptake. *Aims.* To assess the efficacy and safety of elacytarabine monotherapy when given to patients (pts) with late stage acute myeloid leukemia (AML). *Methods.* An open, multicenter study of elacytarabine, enrolling consenting adult pts with PS 0-2, who had received 2 previous chemotherapy regimens and who had refractory/relapsed AML. CR after first salvage therapy lasted < 6 months. Study drug was administered at 2,000 mg/m^2 as a continuous IV infusion (CIV) d1-5 q3w. CR+CRp and overall survival were compared with a historical material of AML patients receiving second salvage therapy (Giles et al, Cancer 2005;104: 547-54) . The population was matched for 6 adverse prognostic factors (adv fact), identified in the historical material, and put into 4 risk groups based on the number of adv fact; low risk group, 1-2 adv fact; intermediate 1: 3 adv fact , intermediate 2: 4 adv fact, high risk group: 5-6 adv fact. An Independent Data Monitoring Committee (IDMC) evaluated the results for futility and toxicity after every 20-pt cohort. Pts were followed for relapse and survival for at least 6 months. Toxicity was graded according to NCI CTCAE v3.0. *Results.* Sixty-one pts (40 male and 21 female) with late stage AML and a median age of 58 years (range 25-82) were enrolled between April'08 and March'09 and received at least one course of elacytarabine. Fifty-three pts had PS 0-1 and 8 had PS 2. The adverse prognostic factors included: duration of CR1< 12 months (43 pts), duration of CR2< 6 months (61), second salvage therapy not including SCT (61), non-inversion16 AML (50), platelet count <50×10^9/L (40), WBC>50×10^9/L (10). Two pts were in the low risk group, 9 pts in the intermediate 1, 20 pts in the intermediate 2 and 30 pts were in the high risk group. Twelve pts had received previous stem cell transplantation (SCT). Nine pts attained CR/CRp, 5 CR and 4 CRp, representing a remission rate of 14.8% vs 2.5% in the historical control (P< 0.0001). The median overall survival was 5.3 months (160 days; range 8 - 411+ days), 3 times that of the historical control of 1.5 months. The 6 month survival rate was 44%. Ten pts were referred to SCT post treatment, including, but not limited to pts in CR. Side effects were predictable and manageable. The most frequently reported related adverse events grade ≥ 3 (CTCAE v3.0) were thrombocytopenia, leucopenia, neutropenia, febrile neutropenia, anemia and lymphopenia. The 30 day all cause mortality following treatment was only 13% vs. 25% in the historical control. *Conclusions.* In this study, elacytarabine showed promising activity, remission rate and overall survival, and manageable side effects in late stage AML patients. A randomized phase III study is planned to further elucidate the effect of elacytarabine in relapsed AML.

Acute lymphoblastic leukemia - Biology

CLONAL GENETIC EVOLUTION IN HUMAN ACUTE LYMPHOBLASTIC LEUKEMIA TRANSPLANTED INTO IMMUNE-DEFICIENT MICE

E Clappier,[1] B Gerby,[1] S Quentin,[2] F Touzri,[2] A Baruchel,[2] P Ballerini,[3] F Pflumio,[1] J Soulier[2]

[1]CEA, Fontenay-aux-Roses, France; [2]Hopital Saint-Louis, Paris, France; [3]Hopital Trousseau, Paris, France

Background. Cancer stem cells are believed to represent a distinct subpopulation of tumor cells with self-renewal capacity. The concept of cancer stem cells has come from pioneering studies on acute myeloid leukemias which have defined a subset of cells, named the NOD-SCID-leukemia initiating cells (LIC), characterized by their ability to initiate the disease when transplanted into immune-deficient mice. The cellular characteristics of cancer stem cells are thought to be due to an epigenetic state reminiscent of that of normal stem cells. These characteristics confer a particular resistance to drugs, implying that cancer stem cells are involved in the persistence of tumor cells during treatment and subsequent relapse. *Aims.* Genetic heterogeneity and clonal evolution is another aspect of cancer biology. As it has been shown to occur frequently in acute lymphoblastic leukemia, we hypothesized that it might contribute to leukemia initiation in immune-deficient mice. We aimed to test this hypothesis by comparing the genetic alterations of human primary leukemias and corresponding xenografted leukemias. *Methods* A series of 18 human T-cell acute lymphoblastic leukemias (T-ALL) was successfully engrafted into NOD-SCID or NOD-SCID-IL2Rγ-/- mice. High-density array-CGH was used to compare the pattern of copy number alterations (CNAs) of paired diagnosis and engrafted T-ALL samples. Several CNAs were precisely mapped to sequence the breakpoint junctions and perform specific backtracking by Q-PCR. Re-sequencing of PTEN, WT1, NOTCH1 and FBXW7 genes was performed. *Results.* In 10 out of 18 cases, we found at least one new CNA in engrafted leukemic samples compared to the corresponding diagnostic sample. Strikingly, these CNAs frequently targeted well-known oncogenes or tumor suppressor genes, such as PTEN (n=2 cases), MYC, CDKN2A/p16/ARF, WT1 and LEU2. Moreover, additional mutations in PTEN (n=3) and FBXW7 (n=2) as well as different profiles of NOTCH1 mutations (n=4) were identified between diagnostic and engrafted samples. Backtracking these genomic abnormalities in diagnostic samples showed that they were already present but in a minor subclone, ranging between 0.01 to 6% of the leukemic cells. In some cases, analysis of CNAs profiles demonstrated that the engrafted leukemic clone did not directly derive from the major clone present in the diagnostic sample, but from a common ancestral clone. *Conclusions* These results demonstrate a clonal genetic evolution during leukemia re-initiation from leukemic cells transplanted into immune-deficient mice. The frequent targeting of cancer genes, including genes involved in self-renewal by genomic abnormalities identified in engrafted cells, and their pre-existence in minor leukemic sub-clones at diagnosis suggest that a selection process has occurred. That implies that subclonal oncogenic alterations may participate in the LIC phenotype. These findings have important implications for the cancer stem cell biology.

NEXT GENERATION TRANSCRIPTOME RESEQUENCING IDENTIFIES NOVEL POINT MUTATIONS, GENE EXPRESSION AND ALTERNATIVE SPLICING PROFILES IN BCR-ABL1 POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

I Iacobucci,[1] A Ferrarini,[2] M Sazzini,[3] A Lonetti,[1] E Giacomelli,[2] L Xumerle,[4] A Ferrari,[1] C Papayannidis,[1] S Paolini,[1] D Cilloni,[5] MC Abbenante,[1] V Guadaguolo,[1] A Vitale,[6] F Pane,[7] S Soverini,[1] M Baccarani,[1] M Delledonne,[2] G Martinelli[1]

[1]Institute of Hematology Seràgnoli, Bologna, Italy; [2]Department of Biotechnology, University of Verona, Verona, Italy; [3]Department of Evolutionary Biology Laboratory of Molecular Anthropology, University of Bologna, Italy; [4]Dept. of Mother and Child, Biology and Genetics, Section Biology and Genetics, University of Verona, Italy; [5]Dept. of Clinical and Biological Sciences, University at Orbassano, Turin, Italy; [6]Dept. of Cellular Biotechnologies and Hematology, Sapienza University of Rome, Rome, Italy; [7]Ceinge-Advanced Biotechnology, University of Naples Federico II, Naples, Italy

Background. Although the pathogenesis of BCR-ABL1+ ALL is main-

ly related to the expression of BCR-ABL1, additional genetic lesions are supposed to be involved in its development and progression. *Aim.* In order to define the full repertoire of leukemia-related mutations, changes in expression profiles and alternative splicing (AS) events, the leukemia transcriptome of a BCR-ABL1+ ALL patient at diagnosis and relapse was sequenced using a Whole Transcriptome Sequencing (RNA-Seq) approach. The selected cases had previously been profiled by high-resolution SNP and gene expression arrays and candidate gene resequencing. *Methods.* Poly(A) RNA from blast cells was used to prepare cDNA libraries for Illumina/Solexa Genome Analyzer. Obtained sequence reads were mapped to the human genome reference sequence (UCSC hg18) to identify single nucleotide variants (SNVs). Reads that showed no match were mapped to a dataset of all possible splice junctions created in silico to identify AS events. The number of reads corresponding to RNA from known exons was also estimated and a normalized measure of gene expression level (RPKM) was computed. *Results.* RNA-seq analysis generated 13.9 and 15.8 million reads from *de novo* and relapsed ALL samples, most of which successfully mapped to the reference sequence of the human genome. With the exclusion of the T315I mutation in the BCR-ABL kinase domain, seven novel missense mutations were detected after applying stringent criteria to reduce the SNV discovery false positive rate and validating novel substitutions with genomic DNA Sanger sequencing: 4 were exclusively found in the primary ALL sample and affected genes involved in metabolic processes (DPEP1, ZC3H12D, TMEM46) or transport (MVP); 3 missense mutations specific to the relapse sample affected genes involved in cell cycle regulation (CDC2L1) and catalytic activity (CTSZ, CXorf21). Differences in mutational patterns suggest that the leukemia clone from which relapsed cells have been developed was not the predominant one at diagnosis and that relapse specific variants were mutations probably acquired during Ph+ ALL progression. Moreover, 4,334 and 3,651 primary ALL and relapse isoforms with at least one AS event were identified. An average of 1.5 and 1.3 AS per isoform was estimated. The well-known alternatively spliced IKZF1 gene was also detected. Finally, a detailed gene expression profile was obtained indicating that more than 60% of annotated human genes were transcribed in leukemia cells in both diagnosis and relapse phases. Approximately 23% of genes were up-regulated at relapse with respect to diagnosis. Many of these genes affect cell cycle progression (AURORA A, SURVIVIN, PLK1, CDK1, Cyclin A, Cyclin B), suggesting that the loss of cell cycle control and the subsequent increased proliferation play a role in disease progression. Conversely, only 9% of active genes in both samples were down-regulated at relapse with respect to diagnosis. *Conclusions.* Discovery of novel missense mutations, as well as exhaustive alternative splicing and gene expression profiles were achieved for the first time for a BCR-ABL1+ positive ALL demonstrating that RNA-Seq is a suitable approach for identifying a wide spectrum of genetic alterations. MIRNA-155 TARGETS BCL6 AND HDAC4 IN A MURINE B-CELL LEUKEMIA MODEL: A PARADIGM SHIFT IN THE ONCOGENIC MECHANISMS OF MICRORNAS

S Shukhinder, S Costinean, R Neinast, M Parthum, C Croce, R Garzon

The Ohio State university, Columbus, USA

Background. MicroRNAs (miRNAs), are non-coding RNAs with key regulatory roles in hematopoiesis. Earlier studies showed that miR-155 is over-expressed in several lymphoid and myeloid malignancies. Over-expressing miR-155 in mouse B cells has been shown to induce pre-B cell proliferation followed by high-grade B-cell lymphoma. It is thought that miR-155 exerts its oncogenic activity by targeting directly or indirectly tumor suppressor genes, such as SHIP-1. Despite these advances, further research is needed to uncover the molecular mechanism responsible for miR-155 induced leukemogenesis. *Aims.* Here, we attempt to further characterize the mechanisms by which miR-155 contributes to leukemogenesis by performing genomic wide mRNA gene expression analysis in B cells from the transgenic (TG) miR-155 mice. *Methods.* B cells were isolated from spleens of TG and wild type (WT) mice using MACS B cell isolation kit. Total RNA isolated with Trizol was hybridized into the Affymetrix microarray Chip (mouse 4302 Arrays). Data were normalized using GC-RMA (BRB Array tools). Univariate analysis (Class comparison) was performed to compare TG (n=4) Vs. WT (n=4) samples. Luciferase assay, western blots and qRT-PCR were used to validate miRNA targets. *Results.* We identified 544 genes (229 up and 315 down) differentially expressed in the TG with respect to the WT samples ($P<0.01$, $FDR<0.01$). Interestingly, we observed that the oncogene B cell leukemia 6 (BCL-6) was down regulated two-fold in the miR-155 TG B cells. These results were validated by RT-PCR and immunoblotting. To investigate whether miR-155 targets directly BCL-6, we examined its 3' untranslated region (UTR) for miR-155 binding sites. Although there were two possible miR-155 binding sites in BCL-6 3' UTR, there was no interaction between the BCL-6 3'UTR luciferase reporter and miR-155. Since BCL-6 has been shown to be regulated by acetylation, we reasoned that miR-155 was regulating BCL-6 by increasing BCL6 acetylation and thus degradation by the proteosome. Indeed, immunoprecipitated Bcl6 from total splenocytes of TG mice had increased levels of acetylated versus total Bcl6 as compared to WT control mice. We further identified that histone deacetylase 4 (HDAC4), mRNA and protein expression levels were lower in the miR-155 TG B cells (50% reduction, respectively) and that HDAC4 is a direct target of miR-155 (luciferase assays). Since HDAC4 de-acetylate non histone proteins as well, we reasoned that miR-155-dependent HDAC4 repression resulted in increased BCL-6 acetylation and degradation. Finally, microarray expression of BCL6 targets in the TG samples revealed that three known BCL-6 targets (Chemokine Ligand 3/CCL3, Cyclin D1/ccnd1 and Inhibitor of differentiation/Id2) were significantly up-regulated (6-fold, 3-fold, and 4-fold, respectively) in TG samples with respect to WT. *Conclusions.* Our results indicate that an oncogenic miRNA, like miR-155 targets surprisingly two oncogenes; BCL-6 and HDAC4 and unblock the expression of their targets. This findings enlighten about the complex interplay between tumor suppressor and oncogene pathways affected by a single gene, that when over-expressed results in leukemia. This is a shift in the paradigm of typical oncogenic miRNAs mechanisms, whereby they can act, not only by targeting tumor suppressors but also oncogenes.

LOSS OF THE TUMOR SUPPRESSOR GENE CDKN2A/ARF BY GENOMIC DELETIONS IS A FREQUENT EVENT IN ADULT BCR-ABL1 POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS AND CONTRIBUTES TO DISEASE PROGRESSION

I Iacobucci,[1] A Ferrari,[1] A Lonetti,[1] C Papayannidis,[1] V Guadaguolo,[1] C Storlazzi,[2] E Ottaviani,[1] MC Abbenante,[1] S Paolini,[1] S Parisi,[1] D Cilloni,[3] S Soverini,[1] F Pane,[4] A Vitale,[5] B Lama,[1] R Foà,[5] M Baccarani,[1] G Martinelli[1]

[1]Institute of Hematology Seràgnoli, Bologna, Italy; [2]Department of Genetics and Microbiology, University of Bari, Bari, Italy; [3]Dept. of Clinical and Biological Sciences, University at Orbassano, Turin, Italy; [4]Ceinge-Advanced Biotechnology, University of Naples Federico II, Naples, Italy; [5]Dept. of Cellular Biotechnologies and Hematology, Sapienza University of Rome, Rome, Italy

Background. The chromosome 9p21 locus contains the 40-kb region encoding the p16/CDKN2A (cyclin-dependent kinase inhibitor 2a) tumor suppressor gene and two other related genes, p14/ARF and p15/CDKN2B, all of which encode critical factors for the regulation of cell cycle and/or apoptosis. This locus is a major target in the pathogenesis of a number of human tumors and its inactivation has been also documented in childhood ALL. *Patients and Methods.* In order to assess whether and how it is inactivated in adult BCR-ABL1-positive ALL, we studied 112 adult patients: 78 (70%) were *de novo* ALL, 15 (13%) were unpaired relapsed cases and 19 (17%) were paired relapsed cases. Their median age was 53 years (range: 18-76) and their median blast percentage was 90% (range, 18-99). Affymetrix single nucleotide polymorphism (SNP) arrays (GeneChip® Human Mapping 250K NspI and Genome-Wide Human SNP 6.0) were used to identify at a high resolution copy number changes on 9p21. PCR amplification and mutation screening of all exons by cloning and subsequent sequencing were also performed. *Results.* SNP array analysis revealed CDKN2A/ARF and CDKN2B genomic alterations in 33% and 24% of diagnosed patients, respectively. Deletions were in the majority of cases bi-allelic (73% vs 27%) and had a mean size of 100.8 kb (range, 27 kb-300 kb), ranging from 21.82 Mb to 22.12 Mb. In 70% of cases, deletions were limited to CDKN2A/CDKN2B genes, whereas in 30% they also affected neighbour genes and/or the entire chromosome 9. FISH analysis was performed using three different BAC clones, but since they overlooked microdeletions we only appreciated a mild fluorescent signal reduction. In order to assess whether CDKN2A loss is responsible for progression, 34 patients were analyzed at the time of relapse and a significant increase in the detection rate of CDKN2A/ARF loss (53%) compared to diagnosis ($P=0.04$) was found. In contrast, CDKN2B deletions were found to be not significantly different between diagnosis and relapse (41% vs 24%, $P=0.07$). To assess whether deletions affected CDKN2A/ARF transcript levels, we used the Fluidigm Dynamic Array real-time qPCR assay (Flu-

idigm Corporation, South San Francisco, CA) which enables to perform TaqMan nano-reactions at high sensitivity. This analysis showed that deletions in the 9p21 locus led to a strong down-regulation at the transcript level of CDKN2A/ARF (P=0.0005). Finally, the mutation screening of all exons showed that the 9p21 locus is rarely affected by point mutations, since we only identified the D146N and the R128 in the exon 2 of CDKN2A/ARF and the P83 silent mutation in the exon 2 of CDKN2B gene. These mutations were mutually exclusive and were found in only single cases. *Conclusions.* Loss of the tumor suppressor gene CDKN2A/ARF by genomic deletions is a frequent event in adult Ph+ ALL and it is involved in disease progression. PARALOG 4 GENES HOXA4 AND HOXB4 INDUCE A STRONG EXPANSION OF B-CELL PROGENITORS IN VITRO IN THE CONTEXT OF E2A-PBX

M Fournier, M Hassawi, H Frison, CE Lebert-Ghali, E Shestakova, J Bijl

Centre de Recherche Hopital Maisonneuve-Rosemont, Montreal, Canada

The oncogene E2A-PBX1 is the result of a translocation fusing the N-terminal of E2A, containing two activation domains, to the C-terminal of PBX1, a co-factor of the clustered homeobox (HOX) gene proteins. The homeotic cooperative motif (HCM) of PBX is still present in the fusion protein, and biochemical studies have shown that HOX proteins can indeed bind to E2A-PBX1. Moreover, structure function studies demonstrated that the HOX binding motif fused to the E2A activation domains is sufficient to induce cellular transformation. It has thus been suggested that deregulation of the HOX-PBX transcriptional network contributes to the oncogenic properties of E2A-PBX. Previously, we have generated a transgenic mouse model for pre-B ALL induced by E2A-PBX1a and identified HoxA cluster genes as candidate collaborators to E2A-PBX1 in leukemia induction using a proviral insertional mutagenesis screen. Retroviral insertions in the HoxA locus caused the expression of the majority of the HoxA cluster genes (Hoxa3-Hoxa10). Furthermore, we showed that a Hox gene, Hoxb4, genetically interacts with E2A-PBX1 in the induction of leukemia in a murine acute T cell leukemia model. To further investigate the role of Hox genes in E2A-PBX induced B-cell leukemia the expression of HoxA genes was first analysed in E2A-PBX1 primary mouse B-cell leukemias. Except for Hoxa13 the expression of HoxA genes was 100-800 folds higher in B-ALL samples derived from E2A-PBX1/CD3-/- transgenic mice than those derived from MMLV injected mice. In particular the expression of Hoxa4 and -a11 was very high reaching levels of >10000 copies per 25ng RNA. The expression of HoxA genes in B-cells (B220+) isolated from healthy 3-4 months old E2A-PBX1 transgenic mice was comparable to levels measured in control littermates. These data suggest that the activation of HoxA genes is critical in the oncogenic transformation by E2A-PBX1. Hoxb4 and Hoxa4 (unpublished) can expand very early myeloid progenitors and hematopoietic stem cell (HSC). However, it is less clear whether these Hox genes have such a direct effect on B-cell progenitors. To study whether Hox genes expand B-cell progenitors in the context of E2A-PBX1, B-cell cultures were initiated with sorted B220 cells derived from transgenic and control mice and cells were transduced with retroviral vectors for Hoxa4-GFP, Hoxb4-GFP or control-GFP after one week. E2A-PBX1 pro-B cell cultures expressing Hoxa4 and -b4 had grown slightly four days post-transduction (1.2 x and 1.1x, respectively, while cell numbers had decreased in the culture transduced with the control vector (2.7x). B-CFC assays showed that the growth of the E2A-PBX1 B-cell cultures in the presence of Hoxa4 or Hoxb4 was supported by a 4-fold and 3.3-fold expansion of B-cell progenitors. Interestingly, Hoxb4 overexpression in wild type B-cell cultures could not reverse the decline of the B-cell cultures (Hoxa4 not done). Thus the potent expansion of B-CFC by Hoxa4 and Hoxb4 in the presence of E2A-PBX1 only strongly suggests that these genes collaborate with E2A-PBX1 in B-cell leukemogenesis. Currently, we are investigating whether Hoxa4 or -b4 can accelerate B-ALL caused by E2A-PBX1.

MICRORNA-DEPENDENT MODULATION OF HISTONE ACETYLATION IN WALDENSTROM'S MACROGLOBULINEMIA

A Roccaro,[1] A Sacco,[2] A Azab,[2] F Azab,[2] T Ngo,[2] P Maiso,[2] G Rossi,[1] M Ghobrial[2]

[1]Spedali Civili di Brescia, Brescia, Italy; [2]Dana-Farber Cancer Institute, Boston, USA

Introduction. Epigenetic regulation of gene-expression, including histone-acetylation, is commonly deregulated in many malignancies leading to aberrant transcription, but microRNA (miRNA)-dependent modulation of histone-acetylation in Waldenstrom's Macroglobulinemia (WM) has not been evaluated yet. *Aims.* To evaluate the histone acetylation status in primary WM cells. To evaluate the role of miRNA9* and miRNA-206 in regulating histone acetylation in WM. 3) To delineate the functional role of miRNA-dependent inhibition of HDAC activity in WM. *Methods.* miRNA- and gene-expression-profiling have been performed on bone-marrow-derived-CD19$^+$ WM cells, compared to their normal cellular counterparts. Data were validated by stem-loop-qRT-PCR. Functional studies were performed on precursor-miRNA-9* and anti-miRNA-206-transfected-WM cells. Effect on signaling cascades have been evaluated by western-blot and immunofluorescence. DNA-proliferation/cytotoxicity/cell cycle/apoptosis were assessed by thymidine incorporation/MTT/PI/Apo2.7 staining, respectively. *Results.* WM cells present with a miRNA signature characterized by increased expression of miRNA-206 and decreased expression of miRNA-9* (ANOVA;P< 0.01). Predicted targets for miRNA-206 and -9* included histone-deacetylases (HDAC4;HDAC5) and -acetyltransferases (Myst3). We first demonstrated that primary WM cells are characterized by unbalanced expression of HDACs and HATs at gene level, responsible for decreased acetylated-histone-H3 and -H4, at protein level and increased HDAC activity. miRNA-206 and -9* played a functional role in regulating histone-acetylation and HDAC activity in WM cells, based on their ability to target HDACs and HATs; leading to induction of toxicity in precursor-miRNA-9*- or anti-miRNA-206-transfected cells, as shown by reduced proliferation rate, cell cycle arrest, induction of apoptosis, supported by PARP-, caspase-8-, caspase-9-cleavage. In addition, miRNA-9* induced autophagy in WM cells by modulating Rab7 and LC3B. *Conclusion*. These findings confirm that histone-modifying genes and HDAC activity are de-regulated in WM cells, partially driven by aberrant expression of miRNA-206 and -9* in the tumor clone; and provide the basis for miRNA-based-targeted therapies in WM.

0556

PRIMARY WALDESNTROM MACROGLOBULINEMIA (WM) CELLS HARBOR CONSTITUTIVE ACTIVATION OF PI3K/AKT AND MTOR PATHWAYS

A Roccaro

Spedali Civili di Brescia, Brescia, Italy

Background. The PI3K/Akt and mTOR pathways play a pivotal role in initiation and progression of malignancies. Therefore, it is critical to examine therapeutic agents that explicitly target these pathways, in tumors that harbor activation of PI3K/Akt/mTOR pathway, such as WM. *Aims.* To evaluate expression level of PI3K/Akt and mTOR in primary WM cells. To evaluate the anti-tumor activity of dual PI3K/Akt and mTOR inhibitor in WM cells in the context of bone marrow milieu. *Methods.* Primary-CD19$^+$ bone-marrow(BM)-derived WM cells; BM stromal cells; WM and IgM secreting low-grade lymphoma cell lines; primary normal CD19$^+$ peripheral-blood-derived (CD19$^+$PB) cells were used. Gene-expression and microRNA-profiling have been performed. Cytotoxicity/DNA synthesis/cell cycle/apoptosis were measured by thymidine uptake/MTT/PI staining/Apo2.7 and flow cytometry analysis, respectively. Cell signaling and apoptotic pathways were delineated by Western Blot and immunofluorescence. *in vivo* homing has been assessed by *in vivo* flow cytometry. *Results.* Primary BM-derived-WM cells present with lower expression of PTEN; higher expression of pospho(p)-Akt, p-mTOR, rictor, raptor, as compared to normal CD19$^+$PB cells. Moreover, microRNA-542-3p and -494 are highly expressed in primary WM cells as compared to normal CD19$^+$PB cells (P<.01); and they both target PTEN, suggesting their role in inhibiting PTEN expression. We tested the dual PI3K/Akt and mTOR inhibitor NVP-BEZ235, which induced cytotoxicity and inhibited DNA synthesis in primary WM cells,

and in IgM-secreting-cell-lines; without cytotoxicity on CD19+PB cells. NVP-BEZ235 inhibited p-Akt/p-mTOR; and downstream-Akt-targeted-proteins (GSK3a/b;p-S6R;p-p70S6). NVP-BEZ235 also inhibited Akt and mTOR *in vitro* kinase activities; as well as rictor and raptor, thus abrogating the rictor-induced-Akt-phosphorylation in WM cells. NVP-BEZ235 also induced significant cytotoxicity in WM cells through targeting forkhead-box-transcription-factors. Finally, NVP-BEZ235 targeted WM cells in the context of BM microenvironment by inhibiting migration, adhesion *in vitro* and homing *in vivo*. *Conclusion*. These studies therefore show that WM cells harbor activation of the PI3K/Akt/mTOR cascades; and dual targeting of the PI3K/Akt/mTOR pathways represents a promising therapy for WM.

Background and Aims. The GELA sponsored intergroup PRIMA Phase III study was designed to investigate 2-years of rituximab (R) maintenance in follicular lymphoma (FL) patients responding to first line immunochemotherapy, consisting of either 8 cycles of R-CVP, or 6 cycles of R-CHOP or R-FCM (plus 2 additional rituximab infusions) according to each participating centre's pre-specified choice. Patient eligibility criteria included: untreated FL (except grade 3B) in adults requiring treatment for high tumor burden (as defined in Salles et al, Blood 2008). *Methods.* From December 2004 until April 2007, 1217 patients from 25 countries (223 centres) consented to participate in the study. Complete data were available for 1193 patients with the following pre-induction characteristics: median age 56 years [range 22-87]; 52% male; 90% Ann Arbor stage III-IV; 56% bone marrow involvement; 4% ECOG performance status >1; 33% B symptoms; 34% elevated LDH; 32% β2-microglobulin >3mg/L; FLIPI score 0-1 (21%), FLIPI 2 (36%), FLIPI 3-5 (43%). Patients received induction immunochemotherapy with R-CHOP (75%), R-CVP (22%) or R-FCM (3%). Response status at the time of randomization was CR=39%; CRu=32% and PR=28% (others 1%). 1018 eligible patients responding to induction therapy were randomized (stratified by regimen and response to induction) to observation or R-maintenance, 375 mg/m^2 i.v. every 8 weeks for 2 years. *Results.* At the planned interim analysis (ITT: 513 observation, 505 rituximab maintenance), after a median follow-up of 25 months from randomization, a significant (stratified log-rank, P<.0001) improvement in PFS (the primary endpoint) was observed in the rituximab maintenance arm (2-year PFS= 82%; 95%CI [78-86%] compared to 66% [61-70%] in the observation arm; hazard ratio (HR)=0.50; 95%CI [0.39-0.64]). An independent review of response and progression validated the significant benefit observed in the R-maintenance arm. Prespecified exploratory analyses confirmed the overall significant PFS benefit among sub-groups for age (<60 and >60), FLIPI score and response after induction. Time to next anti-lymphoma treatment (HR=0.58 [0.44-0.77]) and time to next chemotherapy (HR=0.60 [0.44-0.81]) were also significantly improved. Response status at the end of maintenance or observation was better in the R-maintenance arm (CR/CRu 67% versus 48%, respectively). No major differences were observed in quality of life assessments scores (FACT-G and EORTC QLQ-C30 scales) between the two arms. At the time of data cut-off, only 34 patients (3.3%) had died and longer follow-up is required to evaluate the effects of rituximab maintenance on overall survival in this study. The most common AEs were infections (22% observation, 37% R-maintenance). Grade 3-4 AEs were reported in 16% (observation) and 22% (R-maintenance) of patients (with neutropenia 1% vs. 4%; and infections 1% vs. 4%, respectively). *Conclusions.* The PRIMA study demonstrates that 2 years of rituximab maintenance therapy after immunochemotherapy as first line treatment for FL results in a significant improvement in patient outcome with acceptable toxicity. In FL patients in need of treatment, 2-year rituximab maintenance after immunochemotherapy should now be considered as a new standard of care.

Background. GA101 is the first fully humanized and glycoengineered type II monoclonal anti-CD20 antibody with Phase I results (NHL/CLL) previously reported (Salles, ASH 2008, 2009; Cartron, EHA 2009; Morschhauser, ASH 2009; Sehn, ASH 2009). *Methods.* 40 patients (all signed informed consent) were randomized to receive GA101 in a low-dose (LD, n=18) or a high dose (HD, n=22) cohort. GA101 was given on d1, d8, d22 and q21 days for total of 9 infusions (6 months). In the LD cohort, GA101 was given 400mg all infusions; in the HD cohort, d1 and d8 at 1600mg and 800mg thereafter. Primary endpoint was response rate, with secondary endpoints of safety and pharmacokinetics. *Results.* Patients (Table 1) were heavily pre-treated (median 4 prior therapies) with 60% of patients not responding to or relapsing within six months after a previous rituximab-containing regimen (rituximab refractory). There were no significant differences in demographics and baseline tumour burden between the two cohorts. 75% of patients completed all scheduled 9 infusions. GA101 was well tolerated in both cohorts with the most common AEs being infusion related reactions (LD 72%, HD 73% of patients), mostly of G1-2. 11 patients experienced at least one SAE, with 5 related to GA101 (LD n=1, HD n=4). During treatment, related G3-4 hematological AEs were transient neutropenia (n=3 in HD) and thrombocytopenia (n=1 in HD), four patients experienced at least one G3-4 Infection (LD n=1, HD n=3). GA101 pharmacokinetics was

similar to rituximab, characterized by two clearance components, one linear and one time-dependent saturable component consistent with target-mediated disposition. 38/40 patients were evaluable for end of treatment response (EOR), evaluated 4 weeks after last infusion, 44 weeks after treatment start. EOR was 17% (3 PR, 6 SD, 7 PD, 2 UNK) in the LD cohort, and 55% (2 CR, 10 PR, 6 SD, 4 PD) in the HD cohort. Of note, 7/24 rituximab-refractory patients (6 HD, 1 LD) responded, with 4 in HD and 1 in LD with an ongoing response. An additional refractory patient in the HD cohort with SD at EOT converted to PR post-treatment. Responses occurred across all FcγIIIR genotypes in both cohorts: of 3 responders in LD, 2 patients with F/F genotype, other unknown; of 12 responders in HD; 5 F/F, 7 F/V. *Conclusion.* In this group of heavily pre-treated iNHL patients, single-agent GA101 was safe with a high response rate in HD cohort (55%), and responses also observed in rituximab-refractory patients (HD 55% [6/11]), supporting a possible dose-response relationship.

CD3/CD19 BISPECIFIC BITE® ANTIBODY BLINATUMOMAB TREATMENT OF NON-HODGKIN LYMPHOMA (NHL) PATIENTS: 60 µG/M²/D BY CONTINUOUS INFUSION IS TOLERABLE AND RESULTS IN DURABLE RESPONSES

M Goebeler,[1] A Viardot,[2] R Noppeney,[3] S Knop,[1] M Topp,[1] D Nagorsen,[4] G Zugmaier,[5] M Klinger,[5] M Schmidt,[5] P Klappers,[5] P Kufer,[5] H Einsele,[1] R Bargou[1]

Blinatumomab is a CD19/CD3-bispecific antibody construct of the bispecific T cell engager (BiTE®) class that induces cytotoxic T effector memory cells to kill CD19 expressing malignant B cells. We have previously reported that blinatumomab could be delivered by continuous intravenous (CIV) infusion over 4-8 weeks at doses that depleted peripheral B cells and induced a proliferation of T effector cells. Initial infusion doses of 90 µg/m²/d exceeded the maximal tolerable dose. Here, we update the results of an ongoing phase 1 trial of patients with relapsed indolent NHL treated at a dose of 60 µg/m²/d for 4-8-weeks by CIV infusion with single-agent blinatumomab. In total, 14 patients with mainly follicular or mantle cell subtypes were treated at 60 µg/m²/d during the first treatment cycle. 13/13 evaluable patients showed an objective response (9 PR and 4 CR). As of February 2010, response duration was up to 27+ months. Median follow-up for response duration was 13 months with 8 out of 13 responses ongoing. The single patient that was not evaluable for response experienced a fully reversible, neurological adverse events leading to early discontinuation of treatment. Of the 13 responders, five patients had adverse events leading to discontinuation which were all fully reversible (one port infection and four neurological symptoms). A predictive biomarker, low peripheral blood B:T cell ratio, identified patients with a higher frequency of reversible neurological adverse events. Therefore, we implemented a lower initial dose for 1-2 weeks (5 and/or 15 µg/m²/d, n=5 patients) followed by a maintenance dose of 60 µg/m²/d. A lower starting dose appeared to substantially ameliorate initial adverse events to an extent that treatment could be continued without interruption. Taken together, our data confirm high single-agent activity of 60 µg/m²/d blinatumomab infused for 4-8 weeks with long lasting remissions and a favorable risk/benefit profile. Evaluation of safety and clinical efficacy in other subtypes of NHL and a uniform dose schedule is ongoing.

DASATINIB COMPARED TO IMATINIB IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC-PHASE CHRONIC MYELOGENOUS LEUKEMIA (CML-CP): RESULTS FROM THE RANDOMIZED PHASE 3 DASISION TRIA

M Baccarani,[1] N Shah,[2] H Kantarjian,[3] J Cortes,[3] S Shah,[4] M Ayala,[5] B Moiraghi,[6] J Mayer,[7] M Bradley-Garelik,[8] C Zhu,[8] A Hochhaus[9]

Ramos Mejia, Buenos Aires, Argentina; [7]University Hospital Brno, Brno, Czech Republic; [8]Bristol-Myers Squibb, Wallingford, USA; [9]Universitätsklinikum Jena, Jena, Germany

Background. Dasatinib is a highly potent BCR-ABL kinase inhibitor. Once daily dasatinib induces rapid, durable complete cytogenetic response (CCyR) in a substantial proportion of patients with imatinib resistance, suboptimal response, or intolerance. Of patients with newly diagnosed CML-CP, a significant proportion fails to achieve an optimal response with imatinib. Lack of CCyR by 12 months is associated with decreased long-term progression-free survival (PFS). *Aims.* The DASISION trial compares the efficacy and safety of dasatinib to that of imatinib as first-line treatment of CML-CP. Results after a minimum follow-up of 12 months are presented. *Methods.* 519 adults with Ph^+ CML-CP stratified by Hasford scores were randomized to receive dasatinib 100 mg once daily (n=259) or imatinib 400 mg once daily (n=260). The primary endpoint was rate of confirmed CCyR (cCCyR; CCyR on 2 consecutive assessments; any # of metaphases) by 12 months. Other endpoints were rates of and times to CCyR and major molecular response (MMR; ≤0.1% BCR-ABL transcripts on the International Scale).

Table. EHA Dasatinib table.

n (%)	Dasatinib	Imatinib	P
CCyR ≥20 metaphases			
3 months	140 (54)	80 (31)	
6 months	189 (73)	154 (59)	
9 months	203 (78)	174 (67)	
12 months	216 (83)	186 (72)	0.0011
MMR			
3 months	21(8)	1 (<1)	
6 months	70 (27)	21(8)	
9 months	101 (39)	48 (18)	
12 months	119 (46)	73 (28)	<0.0001

Results. Baseline patient characteristics were well balanced across arms. Median treatment duration was 14 months for each drug. 85% of patients on dasatinib and 81% on imatinib remained on study; 5% and 4.3% discontinued for adverse drug reactions (ADR), respectively. Median dose intensity was 99 mg/day for dasatinib and 400 mg/day for imatinib. The cCCyR rate was superior for dasatinib vs. imatinib (77% vs. 66%, P=0.0067). Both CCyR and MMR rates by 12 months (Table) were higher for dasatinib vs. imatinib (CCyR: 83% vs. 72%; MMR: 46% vs. 28%). MMR was obtained significantly faster with dasatinib than with imatinib (HR 2.0, P<0.0001), as was CCyR (HR 1.5, P<0.0001). Rates of CCyR and MMR were higher for dasatinib than for imatinib across all Hasford risk groups. Rates of transformation to accelerated phase or blast crisis were 1.9% for dasatinib and 3.5% for imatinib. Grade 3/4 cytopenias were as follows (dasatinib vs. imatinib): anemia (10% vs. 7%), neutropenia (21% vs. 20%) and thrombocytopenia (19% vs. 10%); 4 patients on dasatinib and 3 on imatinib discontinued treatment due to drug-related cytopenias. Thirteen patients (5%) on dasatinib and 12 (5%) on imatinib experienced gastrointestinal or other bleeding. Non-hematologic ADRs (all grades) occurring in ≥10% of patients (dasatinib vs. imatinib) included fluid retention (19% vs. 42%; including pleural effusion, all grade 1 or 2, 10% vs. 0%), nausea (8% vs. 20%), vomiting (5% vs. 10%), myalgia (6% vs. 12%), muscle inflammation (4% vs. 17%) and rash (11% vs. 17%). *Summary/Conclusions.* Dasatinib once daily resulted in significantly higher and faster rates of CCyR and MMR than imatinib. Overall, both treatments were well tolerated. Given the strong predictive value of 12-month CCyR and MMR for long-term PFS, dasatinib as initial therapy may improve long-term outcomes in patients with newly diagnosed CML-CP.

VITAMIN D RECEPTOR IS ESSENTIAL FOR NEURONAL CONTROL OF HEMATOPOIETIC STEM CELL NICHE

Y Kawamori,[1] Y Katayama,[1] N Asada,[1] K Minagawa,[1] M Sato,[1] A Okamura,[1] M Shimoyama,[1] K Nakagawa,[2] T Okano,[2] M Tanimoto,[3] S Kato,[4] T Matsui[1]

Hematopoietic stem/progenitor cells (HSPCs) are released from the bone marrow (BM) to the circulation by granulocyte-colony stimulating factor (G-CSF) via sympathetic nervous system (SNS)-mediated osteoblast suppression (Katayama *et al*. Cell 2006). Because the orientation of HSPCs in their osteoblastic niche is reported to be guided by $[Ca^{2+}]$, we speculated a co-operation between calcium regulating hormones (CRHs) and SNS to regulate HSPC trafficking. In this study, we found that vitamin D receptor (VDR), the receptor for a major CRH $1,25(OH)_2D_3$, is essential for G-CSF-induced osteoblast suppression via β2-adrenergic signals and for subsequent HSPC mobilization. G-CSF failed to mobilize HPCs (75% reduction assessed by CFU-Cs, n=7, P<0.001) and HSCs (95% reduction assessed by competitive repopulating units at 6 months posttransplant, n=5, P<0.05) in *Vdr*-/- mice. Similar results were obtained from animals grown on high calcium diet in which the major phenotype of VDR deficiency, the rickets type II, was restored. Reciprocal BM transplantation models revealed that this impaired mobilization originated from the defect in microenvironment but not in hematopoietic cells. Despite the highly impaired mobilization, mRNA and protein levels of BM CXCL12 were drastically down-regulated after G-CSF-treatment even in *Vdr*-/- mice, suggesting a possibility that the decrease of CXCL12 level in the BM is not enough or not fundamental for G-CSF-induced mobilization. It is well known that osteocalcin is produced by mature osteoblasts and its level in circulation is decreased during G-CSF-induced mobilization. Plasma osteocalcin levels in steady-state were similar between *Vdr*+/+ and *Vdr*-/- littermates. Following G-CSF-treatment, it was significantly decreased in *Vdr*+/+ mice (29% reduction, n=6, P<0.05) whereas no reduction was observed in Vdr-/- littermates. The number of stretched/spindle shaped (Type III and IV mature) osteoblasts evaluated by histomorphometry was markedly decreased (63% reduction, n=4, P<0.05) in Vdr+/+ mice after G-CSF-treatment whereas it was remained unchanged in Vdr-/- littermates. These data suggest that activity and the number of mature osteoblasts are not decreased by G-CSF in the absence of VDR. Next we assessed the connection between sympathetic stimuli and VDR in mature osteoblasts. Injection of pan-β adrenergic receptor (AR) agonist isoprenaline into normal mice induced rapid increase of Vdr mRNA in the BM in two hours (7.6 fold, n=6, P<0.001). Single dose of G-CSF also induced significant increase of Vdr mRNA in the BM in three hours (1.3 fold, n=4-5, P<0.01). We also evaluated the alterations of VDR at protein and mRNA levels in mature osteoblasts by β-agonists *in vitro*. Isoprenaline-treatment induced great increase of VDR protein and mRNA in MC3T3-E1 and primary calvarial osteoblasts in two hours (mRNA: 7.5-7.8 fold, n=3, P<0.05) and β2-selective agonist clenbuterol displayed similar or more efficient VDR induction, suggesting that the role of VDR in osteoblastic niche is likely inducible by β2-AR signaling. Collectively, our results demonstrate a novel function of active vitamin D3 as a critical mediator of neuronal control of HSPC trafficking and how it contributes to brain-bone-blood integration in an unanticipated way distinct from other classical CRHs.
