JUNE 9 - 12, 2011

ABSTRACT BOOK

ISSN 0390-6078

The abstract book of the 16th Congress of the European Hematology Association is published as a supplement of Haematologica/the Hematology Journal in one volume per year.

All business correspondence and purchase and reprint requests should be addressed either to Haematologica Journal Office, via Giuseppe Belli 4, 27100 Pavia, Italy; phone: +39 0382 27129; fax: +39 0382 394705; e-mail: office@haematologica.org or to the European Hematology Association, Koninginnegracht 12b, 2514 AA The Hague, The Netherlands; phone: +31 (0)70 345 55 63; fax: + 31 (0)70 392 36 63; e-mail: info@ehaweb.org.

The Abstract book is available both at http://www.haematologica.org and http://www.ehaweb.org

16th CONGRESS
JUNE 9-12, 2011
LONDON

Word of welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to present the Abstract Book of the 16th Congress of EHA.

The Scientific Program Committee has compiled an interesting program of Simultaneous Sessions and Poster Sessions from almost 2,000 submitted abstracts. Please join our expert moderators for a walk along the posters in your field of interest on Friday and Saturday. The six best abstracts have been selected for presentation during the Presidential Symposium on Saturday, June 11.

On behalf of the EHA Board, the committees and all the people involved in this year's EHA congress, we thank you for coming to London and hope that this Abstract Book will provide you with an important reference source of recent advances in hematology research.

RESEQUENING OF 97 ONCOGENES AND CANDIDATE ONCOGENES IDENTIFIES TYK2 MUTATIONS IN T-ALL

V Gianfelici,[1] K De Keersmaecker,[1] Z Kalender,[2] E Geerdens,[1] R Vandepoel,[1] M Porcu,[3] A Uyttebroeck,[4] J Cloos,[5] P Vandenberghe,[6] S Aerts,[6] J Cools[1]

Background. T-cell acute lymphoblastic leukemia (T-ALL) is a malignancy of T-cell precursors that mainly occurs in children and adolescents. Optimization of chemotherapy regimens has resulted in improved responses with cure rates up to 75% in children. However, the current therapies are very toxic and cure rates rapidly decline in older patients, indicating the need for better and less toxic therapies. *Aims.* To discover new mutations that are implicated in the pathogenesis of T-ALL, we sequenced the coding regions of 97 genes in T-ALL cell lines and T-ALL samples. *Methods.* We captured all exons of 97 genes (known and candidate oncogenes/tumor suppressor genes) and subsequently sequenced these exons using 454 sequencing technology. In addition, all exons of the TYK2 gene were sequenced according to the Sanger method in diagnostic samples of 96 T-ALL patients; 54 acute myeloid leukemia (AML) and 53 B-ALL patients. Identified point mutations were cloned and introduced into Ba/F3 (IL3 dependent B-cells) and MOHITO (IL7 dependent T-cells) cells for assessment of transforming capacity, autophosphorylation and activation of downstream signaling pathways. *Results.* Resequencing of these 97 genes in T-ALL cell lines and primary T-ALL cases identified mutations in known T-ALL associated oncogenes such as NOTCH1, FBXW7, PHF6, HRAS/NRAS/KRAS, PTEN, TP53, NF1, as well as novel mutations in genes encoding tyrosine kinases (IGF1R, TYK2) and negative regulators of signaling such as tyrosine phosphatases (PTPRC) and sprouty related proteins (SPREDs). Remarkably, T-ALL cell lines were characterized by frequent mutation of TYK2 (6 of 18 T-ALL cell lines), a JAK kinase family member. While previous studies have described JAK1, JAK2, and JAK3 mutations in ALL patients, TYK2 mutations were previously not described in leukemia. Sequence analysis of TYK2 in primary patient samples identified TYK2 mutations in 2 of 97 T-ALL cases and 1 of 54 AML, but none of 53 B-ALL. Expression of TYK2 mutants in Ba/F3 and MOHITO cells conferred factor-independent growth, with some mutations being significantly more transforming than wild type TYK2, which by itself also transformed these lymphoid cell lines. Western blot analysis showed constitutive phosphorylation of TYK2, and also of JAK1 and STAT3, indicating that TYK2 mutants signal through JAK1 and STAT3. Overall, mutations in JAK1, JAK2, JAK3 and TYK2 were identified in approximately 15% of T-ALL cases. *Conclusion.* In addition to JAK1, JAK2 and JAK3 mutations, our data show that activating TYK2 mutations can also occur in acute leukemia. TYK2 mutations result in constitutive activation of the TYK2/JAK1/STAT3 pathway and represent an attractive new molecular target for JAK kinase inhibitors. These data show that the entire JAK kinase family can be mutated in acute leukemia, and warrant further clinical trials with JAK inhibitors for treatment of patients with JAK1, JAK2, JAK3 or TYK2 mutation.

PTEN/AKT PATHWAY MUTATIONS ARE RECIPROCAL TO NOTCH1-ACTIVATING MUTATIONS IN PEDIATRIC T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL)

L Zuurbier,[1] M Vuerhard,[1] C Kooi,[1] W Smits,[1] J Buijs-Gladdines,[1] M Horstmann,[2] V De Haas,[3] R Pieters,[1] J Meijerink[1]

[1]*ErasmusMC/Sophia Children's Hospital, Rotterdam, Netherlands*
[2]*Co-operative Study Group for Childhood Acute Lymphoblastic Leukemia (COALL), Hamburg, Germany*
[3]*Dutch Childhood Oncology Group (DCOG), Den Haag, Netherlands*

PTEN-inactivating mutations that affect the PI3K/AKT pathway are often found in T-cell Acute Lymphoblastic Leukemia (T-ALL). To investigate the incidence of the PTEN/AKT pathway aberrations in pediatric T-ALL, we retrospectively determined the incidence of PTEN, PI3K and AKT mutations in 142 pediatric T-ALL patients treated according to the Dutch DCOG or German COALL protocols. Using PCR-sequencing and array-CGH techniques, PTEN mutations/deletions were detected in 13% of the patients. In addition, we found three patients, of which one also carried a PTEN mutation, having aberrant PTEN splice products. Another 2% of the patients carried an AKT mutation, whereas no PI3K mutations were identified. Using reverse-phase protein microarray analysis (RPMA), we demonstrated that PTEN protein expression was absent in PTEN-mutated or PTEN-deleted patients or patients with aberrant splicing, with the exception of one patient that carried a PTEN missense mutation. We also identified two T-ALL cases that lacked PTEN protein expression in the absence of PTEN mutations, defective splicing or for differential PTEN promoter hypermethylation in these patients. Therefore, 18% of the patients had PTEN or AKT aberrations in total. PTEN or AKT mutations (PTEN/AKT) were especially observed in TAL or LMO¬-rearranged T-ALL patients (p=0.007), but not in HOX-rearranged cases (p=0.003). PTEN/AKT mutations followed a pattern that seems reciprocal to the presence of NOTCH-activating mutations; they hardly co-express NOTCH1-activating mutations and PTEN/AKT-mutated cells express low protein levels of activated NOTCH1, cMYC and MUSASHI. This indicates that PTEN/AKT mutations are not simply secondary events following NOTCH1/FBXW7 mutations such as initially reported1. This also explains γ-secretase inhibitor insensitivity of PTEN-mutated cell lines, rather than acquired resistance as consequence of oncogenic addiction switch1. Survival rates for PTEN/AKT patients seemed comparable to wild-type patients (5-yrs DFS DCOG WT 71±6% vs PTEN/AKT 60±16%, COALL WT 78±6% vs PTEN/AKT 57±15%). However, when NOTCH1/FBXW7-mutated patients (associated with poor survival rates in DCOG and COALL cohorts) were separated from the wild-type group, the presence for NOTCH1/FBXW7 or PTEN/AKT mutations was associated with poor outcome, whereas the disease-free survival rate for wild-type patients was nearly 100% (5-yrs DFS DCOG+COALL WT 92±6% vs PTEN/AKT/NOTCH1 65±5%, p=0.005).

Background. Being a strong prognostic factor in acute lymphoblastic leukaemia (ALL), minimal residual disease (MRD) evaluation is now used for treatment stratification. Two methods are currently used: quantitation of Ig/TCR clonal rearrangements using allele-specific quantitative PCR (IG/TCR-QPCR) and multidimensional flow cytometry (FC). Ig/TCR-QPCR is now standardised and quality control rounds organised by the EuroMRD consortium ensure that results are comparable between participating labs. Such a standardisation process must be set up for FC. Moreover, whether FC can reach Ig/TCR-QPCR performance in routine ALL follow-up monitoring is still questionable. *Methods.* In the multicenter STIC 2006 program, MRD measurements were performed prospectively using IG/TCR-QPCR (4 EuroMRD labs) and FC (8 labs) in 598 follow up samples from 238 patients treated for a BCR-ABL negative ALL (136 adults ALL and 102 high-risk childhood ALL); 153 had BCP-ALL and 85 had T-ALL. Both techniques were performed on the same bone marrow sample. Ig/TCR-QPCR was performed following EuroMRD guidelines. FC was performed on fresh cells. Similar antibody panels, antibody clones and gating strategies were used with 4-color (39%) or 5/7-color (61%). FC-MRD positivity was defined as a cluster of more than 10 events displaying the leukaemia-associated immunophenotype (LAP) among at least 105 total events to reach a 10^{-4} (0.01%) sensitivity. Ig/TCR and LAP markers were considered suitable when allowing MRD detection with a sensitivity of at least 10^{-4}. *Results.* Six FC quality controls were run by sending mock MRD samples (fresh ALL cells spiked into normal bone marrow cells) to all FC laboratories. Among 45 measurements by the 8 labs, false positivity was observed in 2 cases and negativity in none. Ninety percent of positive results were clustered within half-a-log. In addition, a subset of FC data files (n=141) was reviewed collectively. The consensus conclusion (< or ≥10^{-4}) differed from the local centre result in 19/141 (13%) cases and were kept for further analyses. At least one suitable Ig/TCR marker was identified at diagnosis in 214/238 (90%) patients and a suitable LAP in 223/238 (94%) patients. All patients could be monitored using at least one method. Tandem MRD measurement by QPCR and FC was evaluable in 518/598 (87%) samples. The MRD conclusion (< or ≥ 10^{-4}) was identical in 495/518 samples (96%). However, in 73/518 (14%) samples, MRD was detectable with QPCR but not with FC. In 63 of these 73, PCR-MRD was positive not quantifiable (<10^{-4}). When positive ≥10^{-4}, FC and PCR MRD results were correlated (n=109; Spearman coefficient, r2: 0.87, p<0.0001) but clustered within half-a-log in only 69% of cases. In particular, QPCR provided significantly higher MRD results than FC in the 38 adult post-induction samples (median QPCR/FC-MRD ratio=2.0, p<0.03, Mann-Whitney test). *Discussion/Conclusion.* This study shows that multicenter MRD study by FC is feasible. Standardisation has, however, to be improved, in particular for homogenous data interpretation. Results obtained using QPCR and FC are generally similar, but the impact of discrepant positive results, which are apparently not random, needs to be elucidated and, although complementary, these approaches cannot yet be considered interchangeable.

0004

IDENTIFICATION OF NEW PROGNOSTIC FACTORS PREDICTIVE OF EXTRAMEDULLARY RELAPSE IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

Background. Extramedullary (EM) involvement is defined as leukemic infiltration in EM sites like the central nervous system (CNS), testis, gut or skin. EM involvement at diagnosis is rare (1-4%) in childhood acute lymphoblastic leukemia (ALL) patients, but is more frequent at relapse (~40%). We hypothesized that: 1. migration of ALL cells to EM locations is an active process mediated by molecules present on or in the ALL cells, and 2. at diagnosis a (sub)population of ALL cells with migratory capacity is already present in the bone marrow (BM) and/or peripheral blood (PB). *Aim.* The aim of this study is to find cellular and molecular targets that allow the early identification of ALL patients at risk of an EM relapse. *Methods.* RNA was extracted from ALL cells derived from cerebrospinal fluid (CSF; n=5) or testis (n=8) or isolated from BM after FACS sorting on B-cell precursor (BCP)-ALL cells (>95% pure; n=24). Gene expression profiling was performed using Affymetrix protocols. Protein expression was determined by flowcytometry and ELISA. *Results.* Using Principal Component Analysis or hierarchical clustering, a clear separation between BM-derived and CSF- or testis-derived ALL samples was found. 1238 and 3501 genes were differentially expressed between CSF- and BM-derived BCP-ALL cells and testis- and BM-derived BCP-ALL cells, respectively (FDR≤0.01; fold change (FC)>1.5). Top lists of genes were generated based on differential expression and biological relevance (genes involved in cell adhesion, chemotaxis, or migration). Two of these genes were already analyzed in more detail: 1. SPP1 (mean FC=69, p=5E-10), known to be involved in cell migration and adhesion, and 2. LEPROTL1 (mean FC=5.9, p=3E-5), with unknown function. Increased mRNA expression of both genes was confirmed by RQ-PCR. SPP1 protein expression was not increased in CSF-derived BCP-ALL cells (n=4) compared to BM-derived BCP-ALL cells (n=28). The absence of intracellular SPP1 may partly be explained by secretion, since significantly increased soluble SPP1 levels were found in ALL-positive compared to ALL-negative CSF samples. Protein expression of LEPROTL1 and other top-ranked genes is currently being evaluated on CSF- and testis-derived ALL cells. Diagnostic BM cells from four BCP-ALL patients with isolated CNS relapse were analyzed for (sub)populations of ALL cells with increased SPP1 and/or LEPROTL1 expression. Clear subpopulations of ALL cells (~0.2%) with high LEPROTL1 or SPP1 expression were present in 2/4 and 0/4 patients, respectively, suggesting that LEPROTL1, but not SPP1 may be of prognostic value for the prediction of an (isolated) CNS relapse. *Summary/Conclusions.* EM-ALL cells and BM-derived BCP-ALL cells show distinct gene expression profiles. The presence of a small subpopulation of ALL cells with an EM signature at diagnosis may predict EM relapse. Prospective flowcytometric analysis of LEPROTL1 and other top-ranked genes in BM cells from newly diagnosed ALL patients, combined with a long-term follow-up, is ongoing to evaluate the prognostic significance of these markers. In future, the identification of proteins involved in CNS localization may contribute to the design of targeted therapies for both prophylactic treatment in patients at high risk of EM-ALL and therapeutic intervention in case of CNS relapse.

0005

THE RS564398, A POLYMORPHISM IN 'THE ANTISENSE NON-CODING RNA IN THE INK4 LOCUS', ANRIL, IS ASSOCIATED TO PHILADELPHIA POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) SUSCEPTIBILITY

Introduction. Little is known about alterations of cyclin dependent kinase inhibitors p15INK4B, p16INK4A and p14ARF due to single nucleotide polymorphisms (SNPs) located within the CDKN2A/B genes and/or neighbouring loci. In order to investigate the potential involvement of such common DNA sequence variants in leukemia susceptibility, an association study was performed. *Methods.* 23 SNPs spanning the MTAP, CDKN2A/B and CDKN2BAS loci, as well as relative intergenic regions were genotyped in a case-control cohort made up of 149 leukemia patients, including Philadelphia positive (Ph+) ALL and acute myeloid leukemia (AML) samples, and 183 healthy controls. 6 SNPs were selected on the basis of their previous association with several diseases, such as coronary artery disease (rs2891168, rs518394, rs564398, rs10757278), type 2 diabetes mellitus (rs564398), frailty (rs2811712). The remaining 17 SNPs were selected to deepen the SNPs coverage for the examined region. Genotyping was performed using

iPLEX Gold technology and MassARRAY high-throughput DNA analysis with Matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectrometry (Sequenom, Inc., San Diego, CA). *Results.* A total of 17 SNPs, spanning the 9p genomic interval that encompasses the MTAP, CDKN2A/B and CDKN2BAS loci, were successfully genotyped and used for investigating their potential associations with the leukemia phenotypes. Five SNPs (rs1012713, rs10965179, rs34011899, rs3731232, rs3218010) with MAF <0.05 in cases and controls, as well as one SNP (rs3931609) showing >20% missing call rates, were instead excluded from the association analysis and potential population stratification affecting the control sample was ruled out as its genotypes distribution satisfies the Hardy-Weinberg equilibrium criterion. Among the 17 SNPs, rs564398, mapping to the CDKN2BAS locus (exon 2) that encodes for ANRIL antisense non-coding RNA, showed a statistically significant correlation with the ALL phenotype, with a risk pattern that was compatible with an overdominant model of disease susceptibility and a OR of 2 (95% CI, 1.20 to 3.33; p= 7.1 x 10-3). *Conclusions*. Since a co-ordinated regulation of ANRIL and p14/ARF, p16/CDKN2A, p15/CDKN2B transcription has been already observed in both physiologic and pathologic conditions, we hypothesized that rs564398 association reflects a condition of high linkage disequilibrium between such polymorphism and a causative variant that is able to alter CDKN2A/B expression profiles by changing ANRIL dosage, thus leading to abnormal proliferative boosts and consequent increased ALL susceptibility. Recently, the rs564398 has been demonstrated by Cunnington M.S. *et al*. (2010) to alter ANRIL expression leading in turn to a deregulation of CDKN2A/B genes. Supported by European LeukemiaNet, AIL, AIRC, FIRB 2006, Ateneo RFO grants, Project of integrated program (PIO), PRIN 2008, Programma di Ricerca Regione - Università 2007 - 2009.

Background and Aims. The reciprocal translocation t(12;21) (p13;q22) is the most common structural chromosomal alteration in pediatric cancer as it occurs in approximately 25% of B-cell precursor acute lymphoblastic leukaemias (ALL). The resulting chimeric transcription factor TEL-AML1 is expected to function in a dominant-negative fashion. Here, we aimed to identify direct target genes of TEL-AML1 using an inducible TEL-AML1 system in combination with a novel TEL-AML1 antibody recognising the fusion site between the two proteins. *Methods.* We applied several state-of-the-art genome-wide screening methods, namely ChIP-on-chip, gene expression arrays and stable isotope labeling by amino acids in cell culture (SILAC). The large, highly complex data sets were inter-correlated in order to unveil global biological processes affected by TEL-AML1 expression. We used an inducible murine pro B-cell system developed from the BA/F3 cell line (provided by A. M. Ford & Mel Greaves, London) expressing TEL-AML1 in presence of mifepristone. Furthermore, we performed gene expression analysis using mouse genome arrays and protein profiling with SILAC followed by mass spectrometrical identification of expressed peptids. *Results.* Matching results from ChIP and gene expression studies revealed 202 putative target genes directly regulated by TEL-AML1 (125 upregulated, 77 downregulated). From these direct DNA and mRNA targets, eight were subsequently also detected in the SILAC experiments (two upregulated, six downregulated): RIKEN cDNA 9030617O03 gene, *klc4*, *pdlim5*, *rsl1d1*, *gnb2l1*, *hist1h4h*, *ints2*, *metap2*. The clustering of affected biological processes regarding GO terms disclosed several distinct pathways like signal transduction, protein modification and localisation as well as processes involved in regulation of transcription and RNA metabolism. As 67% of the genes corresponding to 'regulation of transcription' (e.g. *snip1*, *rai1*) were found to be downregulated and 83% of those targets corresponding to 'negative regulation of transcription' (e. g. *hdac5*, *zfhx3*, *foxp1*) showed an upregulated expression, this observation comes up to the expectation that TEL-AML1 mainly acts as a transcriptional repressor. Just as most of the genes (78%) involved in 'RNA metabolic processes' (e. g. *ftsj3*, *elac2*), target genes playing a role in 'proteolysis' (e. g. *metap2*, *bace1*, *senp3*) or 'intracellular signaling pathways' (e. g. *gnb2l1*, *rab7l1*) were mainly found to be downregulated as a consequence of TEL-AML1 expression by 75% and 67%, respectively. By contrast, 67% of the demonstrated target genes involved in 'protein modification processes' (e. g. *dusp7*, *prkd2*, *snrk*) showed an upregulation. *Summary and Conclusions.* Our data show that TEL-AML1 expression has an effect on many different biological processes, mostly represented by both up- and downregulated genes. Altogether, our findings show that TEL-AML1 acts as a repressor of transcription and that it also contributes to altered protein localisation and signal transduction. As no target gene commonly known for its oncogenic potential was found to be a direct target of TEL-AML1 in our experiments, one could assume that the observed alterations do not promote onset of overt leukaemia in affected cells by themselves. The altered expression of the eight genes found by ChIP-on-chip, gene expression and protein profiling will be subjected to further investigations in primary material from TEL-AML1-positive patients.

[2]*Sir James Spence Institute, Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom*

Background. Survival rates in childhood ALL are now in the region of 90%, however treatment outcomes in certain cytogenetic subgroups remain poor. The translocation, t(17;19)(q22;p13), is a rare cytogenetic abnormality, which occurs in less than 1% of childhood acute lymphoblastic leukemia (ALL) and is associated with a very poor prognosis and chemotherapy resistance. Understanding the mechanisms of resistance in these patients is therefore a priority. *Aims.* It has been assumed that following relapse, ALL cells will divide more rapidly than at presentation. In order to test this hypothesis, we have developed an animal model of competitive repopulation using paired samples from presentation and relapse from a case of t(17;19) positive ALL. *Methods.* Leukemic cells from a child with t(17;19) positive ALL obtained at presentation and at relapse were analysed for copy number variations using the Affymetrix Genome-Wide Human SNP Array 6.0 (SNP6.0) platform. Deletion of the NR3C1 gene (glucocorticoid receptor) on chromosome 5 was detected at relapse but not at presentation. This was confirmed by fluorescence *in situ* hybridisation (FISH). Cells were separately transplanted via intrafemoral injection into immunocompromised NOD/scid IL2Rγnull (NSG) female mice. Human blasts recovered from primary transplantations were subsequently used for secondary transplantation in mixed populations with ratios of presentation to relapse cells of 10:0, 9:1, 7:3, 5:5, 3:7, 1:9 and 0:10. Engraftment and progression of disease were assessed by flow cytometry at the terminal timepoint. The percentages of presentation and relapse cells which engrafted in these mice were determined using FISH for *NR3C1* deletion. The expression levels of glucocorticoid receptor (NR3C1) in the harvested leukemic cells were determined by real-time quantitative PCR. *Results.* Microarray analysis identified a deleted region of chromosome 5 involving the NR3C1 gene in cells obtained at relapse but not at presentation. Without treatment, those mice transplanted with relapse cells survived significantly longer than those transplanted with presentation cells (p=0.005), while the survival rates of mixed cells fell between the two curves. All engrafted mice presented with an enlarged spleen indicating leukemic infiltration. This was confirmed by flow cytometry, which identified t(17;19) cells with CD19+/CD10+/CD34- immunophenotype among those isolated from bone marrow (85-92%) and spleen (64-90%). FISH analysis showed that the percentages of presentation cells which engrafted in the mice with mixed populations were always higher than the ratios initially transplanted. Real-time PCR analysis confirmed that the levels of NR3C1 from all ratios of mixed cells represented the level of the presentation cells only. Repopulation experiments are currently being repeated with mice treated with Dexamethasone. *Conclusions.* In this study we observed that in t(17;19) positive ALL, without treatment, presentation cells outgrew cells obtained at relapse regardless of the ratio of cells initially transplanted. It is anticipated that, on treatment, relapse cells will outgrow those obtained at presentation, due to deletion of the glucocorticoid receptor, which would render cells insensitive to steroid treatment.

0008

SEQUENCE OF MUTATIONAL EVENTS AND CLONAL ARCHITECTURE IN BCR-ABL POSITIVE ACUTE LYMPHOBLASTIC LEUKAEMIA

M Carnicer, F van Delft, L Kearney, M Greaves

Institute of Cancer Research, Sutton, United Kingdom

Background. Intra-clonal genetic diversity is a hallmark feature of cancer and provides the substrate for sub-clonal selection, progression and therapeutic resistance. We recently demonstrated a variegated genetic architecture in the blast cells and leukaemia-propagating ('stem') cells of childhood *ETV6-RUNX1*-positive acute lymphoblastic leukaemia (ALL by single cell analysis with multi-colour FISH probes (Anderson *et al*., Nature 469: 356-361, 2011). *Aims.* In the present study, we aimed to determine whether this genetic diversity also applies to high risk ALL with *BCR-ABL* fusion. *Methods.*We used multiplexed FISH analysis of single cells using probes labelled with five distinct fluorochromes. We screened diagnostic blast cells samples from 8 *BCR-ABL*-positive cases for deletion of *IKAROS* (IKZF1), *CDKN2A/p16* and *PAX5*. The application of multiple FISH probes allowed us to score all cells (200 per patient sample) simultaneously for the *BCR-ABL* fusion (and multiple copies of the fusion), and one or two copy deletions of *IKZF1*, *PAX5* and *CDKN2A*. *Results.* The genetic classification of individual cells allowed a designation of sub-clones and the assembly of putative ancestral trees. Four of the eight cases screened had concurrent *IKZF1*, *PAX5* and *CDKN2A* deletions and in two of these we could distinguish the order acquisition of the deletions. In one case the *IKZF1* and *CDKN2A* and *PAX5* deletions arose independently in different sub-clones; i.e. *IKZF1* was deleted first in one subclone and *CDKN2A* first in another sub-clone. In the second case the *CDKN2A* deletion arose subclonally to both the Ikaros and *PAX5* deletions. We also studied one patient with matched diagnosis and relapse samples available. Comparison of SNP array data at diagnosis versus relapse revealed that different (or reiterated) *CDKN2A*, *PAX5* and *IKZF1* deletions were involved. We developed probes specific for the different genomic regions involved in the two distinctive *IKZF1* deletions (diagnosis versus relapse). FISH analysis then allowed us to identify clonal substructure at diagnosis, including a minor sub-clone (1%) with the genotype of the dominant clone seen in relapse. *Summary/Conclusions.* These results indicate that the sub-clonal architecture in BCR-ABL positive ALL is genetically diverse. The common CNA are acquired in no preferential order, and CNA involving the same gene can arise independently in different sub-clones. An important prediction derived from this pattern of sub-clonal architecture is that the leukaemia propagating cells in *BCR-ABL* ALL should themselves be genetically diverse. We plan to perform *in vivo* transplantation experiments in NOD/SCID/γ^{null} mice with leukaemic cells from patients for whom we find clonal heterogeneity. Regenerated leukaemias will be re-transplanted and the subsequent leukaemias analysed by both SNP arrays and multi-colour FISH to compare genetic diversity of stem cell output as previously with *ETV6-RUNX1*+ cases. We anticipate that these data will allow us to conclude that genetic diversity of leukemic stem cells is a consistent feature of both low and high risk ALL.

0009

MTORC2 PLAYS A DISTINCT ROLE IN MEDIATING ANTI-PROLIFERATIVE AND PRO-APOPTOTIC EFFECTS OF INHIBITORS OF THE PI3K/AKT/MTOR CASCADE IN LONG-TERM CULTURED PRIMARY ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) CELLS

S Badura, T Tesanovic, H Pfeifer, C Hohnloser, M Liebermann, H Serve, M Ruthardt, O Ottmann

Goethe University Frankfurt, Frankfurt, Germany

Background. The PI3K/AKT/mTOR pathway is considered as a downstream signaling pathway of the bcr abl oncogene that is the hallmark of Philadelphia chromosome positive (Ph+) acute lymphoblastic leukemia (Ph+ ALL) and of CML. Activation of the PI3K signaling pathway has been suggested to play a role in resistance of Ph+ ALL to tyrosine kinase inhibitors (TKI) that target BCR ABL kinase activity. Its role in Ph neg. ALL has not been clearly established. mTOR is a kinase and catalytic subunit of the two complexes mTORC1 and mTORC2. Whereas mTORC1 predominantly controls cell growth, mTORC2 appears to mediate cell proliferation and cell survival. mTORC1 phosphorylates the translational regulators S6K1 and 4E-BP1. The central role of mTORC1 regulation in oncogenic PI3K signaling provides strong rationale for targeting mTORC1 in cancer, but mTORC1-dependent negative feedback loops mitigate the effectiveness. mTORC2 phosphorylates AKT on a regulatory site required for maximal AKT kinase activity. This prompted rationale to develop mTOR inhibitors that target both complexes. *Aims.* To establish the role of components of the PI3K/AKT/mTOR signaling pathway in different subtypes of ALL to overcome resistance to TKI. *Methods.* The effects of selective inhibitors of PI3K (NVP-BKM120) and mTORC1 (RAD001) and of dual PI3K/mTORC1/C2 inhibitors (NVP-BEZ235 & NVP-BGT226) on long-term serum-free cultures of primary human Ph+ (n=6) and Ph neg. (n=6) B-precursor ALL cells were analysed. All inhibitors were kindly provided by Novartis, Basel, Switzerland. Cell proliferation and apoptosis were monitored by XTT-assays and FACS analysis using annexin V/propidium iodide. Phosphorylation of the proteins 4E-BP1 (Thr37/46) & S6 Ribosomal Protein (Ser235/236) downstream of mTORC1 was assessed by Western Blotting. *Results.* The dual PI3K/mTORC1/2 inhibitors (NVP-BEZ235 & NVP-BGT226) were more potent in inhibition of cell proliferation and induction of apoptosis in Ph+ and Ph neg. ALL than the selective PI3K and mTORC1 inhibitors alone. The anti-proliferative and pro-apoptotic effects of these inhibitors were independent of bcr-abl and partial resistance to 1st and 2nd generation TKI. Comparison of the effect of selective PI3K and mTOR inhibitors on mTOR signaling revealed differential regulation of S6 and 4E-BP1. Whereas selective inhibition of PI3K and mTORC1 by BKM120 and RAD001, respectively, resulted in dephosphorylation only of the S6 protein, combined inhibition of PI3K and mTORC1 was associated primarily with a decrease of S6 phosphorylation and only minor dephosphorylation of 4E-BP1. Conversely, exposure to the dual PI3K/mTORC1/C2 inhibitors resulted in nearly complete dephosphorylation of both S6 and 4E-BP1. *Summary/Conclusions.* Our observation that compounds inhibiting PI3K/mTORC1/2 have significantly greater growth inhibitory and pro-apoptotic effects than selective inhibition of PI3K and mTORC1 support a functional role of mTORC2 in survival and growth of B-precursor ALL cells. Our data indicate that mTORC2 contributes substantially to regulation of the downstream target 4E-BP1 by mTORC1 in ALL. Combined targeting of these complexes may provide a novel therapeutic approach for both Ph+ ALL resistant to ABL TKI and Ph neg. ALL.

Histone deacetylases (HDACs) have been identified as therapeutic targets due to their regulatory function in chromatin structure and organization. Here we analyzed the therapeutic effect of LBH589, a class I-II HDAC inhibitor, in acute lymphoblastic leukemia (ALL). *In vitro*, LBH589 induced dose-dependent antiproliferative and apoptotic effects, which were associated with increased H3 and H4 histone acetylation. Intravenous (i.v.) administration of LBH589 in immunodeficient BALB/c-RAG2-/-γc-/- mice in which human-derived T and B-ALL cell lines were injected induced a significant reduction in tumor growth. Using primary ALL cells, a xenograft model of human leukemia in BALB/c-RAG2-/-γc-/- mice was established, allowing continuous passages of transplanted cells to several mouse generations. Treatment of mice engrafted with T or B-ALL cells with LBH589 induced an *in vivo* increase in the acetylation of H3 and H4, which was accompanied with prolongued survival of LBH589-treated mice in comparison with those receiving Vincristine and Dexametasone. Notably, the therapeutic efficacy of LBH589 was significantly enhanced in combination with Vincristine and Dexametasone. Our results demonstrate the therapeutic activity of LBH589 in combination with standard chemotherapy in pre-clinical models of ALL and suggest that this combination may be of clinical value in the treatment of patients with ALL.

0011

THE INSULIN RECEPTOR SUBSTRATE 4 GENE IS MUTATED IN PAEDIATRIC T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

K Karrman, M Isaksson, K Paulsson, B Johansson

Clinical Genetics, Lund, Sweden

Background. The cytogenetic hallmark of T-cell acute lymphoblastic leukaemia (T-ALL) is the presence of rearrangements involving the T-cell receptor (TCR) loci, mainly *TRA@/TRD@* at 14q11 and *TRB@* at 7q34, that dysregulate a variety of genes with oncogenetic potential. Several genes involved in TCR translocations have also been shown to be targeted by alternative mechanisms. *NOTCH1* is the most pertinent example of this. This gene was initially shown to be rearranged by the rare t(7;9)(q34;q34), but is now known to harbour activating mutations in the majority of T-ALL cases. Thus, mutation analysis of an infrequent TCR target may well reveal that it plays a greater role in T-ALL development than surmised based on the incidence of the translocation alone. *Aims.* We recently reported a novel translocation - t(X;7)(q22;q34) - in a paediatric T-ALL and showed that it results in overexpression of the insulin receptor substrate 4 (*IRS4*) gene. We speculated that this gene could be mutated in additional cases, akin to what has been reported for *NOTCH1*. In the present study, we have therefore sequenced IRS4 in paediatric T-ALL samples. *Methods.* The patients (n = 21) with T-ALL represents 78% (21/27) of all T-ALL (<18 years) diagnosed in Lund and Linköping 1990-2007 and comprises all cases from which DNA from diagnostic samples was available. The IRS4 gene at Xq22.3 consists of only one exon (3,881 bp; NM_003604.2), which was amplified by nested extra long polymerase chain reaction (Applied Biosystems, Foster City, CA, USA). Sequencing of the antisense strand of *IRS4* was carried out by the GATC sequencing service (Konstanz, Germany). The sequences were analysed using the Mutation Surveyor software (Softgenetics LLC, State College, PA, USA). *Results.* The entire *IRS4* gene was successfully sequenced in all 21 cases, of which 19 displayed a sequence matching the reference (NM_003604.2). Two cases had sequences that deviated from the reference but which have not been reported as polymorphisms, suggesting that they were mutations. Case 3 displayed an in-frame 594 bp deletion - c.105_698del (NM_003604.2); p.24_221del (NP_003595.1) indicated in figure 1A with a dotted line. Unfortunately, no remission sample was available to ascertain whether this deletion was acquired or constitutional. The found deletion results in the removal of the pleckstrin homology domain represented by a black box in figure 1B whereas the blue box indicates the segment reported as a copy number variation in Yoruba Nigerians (http://projects.tcag.ca/variation/). The pleckstrin homology domain is functionally important and well conserved among the IRS proteins. Case 8 harboured a missense mutation - c.670C>A (NM_003604.2); p.Pro213Thr (NP_003595.1), the position is marked by a red asterisk in figure 1B and 1C. The mutation was not found in either a remission or a relapse sample. Threonine residues have occasionally been reported to be phosphorylated in IRS proteins resulting in inhibition of the IRS activity. *Summary.* We have for the first time identified *IRS4* mutations in T-ALL. Whether such mutations confer a specific biological or clinical impact remain to be investigated in larger patient cohorts.

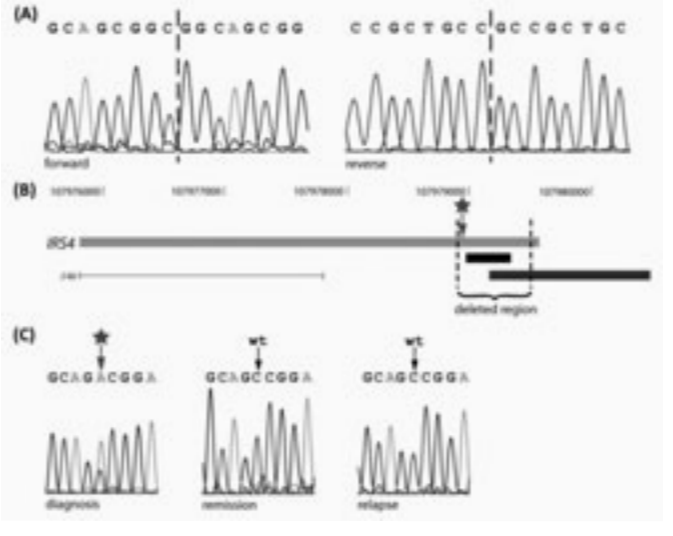

Figure 1.

0012

DISTINCT ACCESSIBILITY OF TLX1 AND LMO2 BREAKPOINT SITES MODULATES INVOLVEMENT IN T-CELL RECEPTOR (TCR)-ASSOCIATED TRANSLOCATION FORMATION

N Larmonie, A van der Spek, J van Dongen, A Langerak

ErasmusMC, Rotterdam, Netherlands

Background. T-cell receptor (TCR) translocations are a genetic hallmark of T-cell acute lymphoblastic leukemia (T-ALL). Two well known TCR translocation partners, *LMO2* and *TLX1*, have shown to be recurrently involved in these translocations, and are therefore considered to be more prone to the induction of DNA double-strand breaks (DSB) at time of V(D)J recombination. LMO2 and TLX1 are respectively regarded as "Type 1"and "Type 2"translocation models. *LMO2* translocations mostly involve RAG mediated DSB inductions due to the presence of a cryptic recombination signal sequence (cRSS), while the cause of *TLX1* DSB induction is unknown. We hypothesize that chromatin modulation during thymocyte development renders DNA vulnerable to DSB induction. This vulnerability is thought to facilitate both "Type 1 and "Type 2"translocations during V(D)J recombination. *Aims.* We aimed to determine the accessibility of *LMO2* and *TLX1* at breakpoint sites (BPS) during thymocyte development. We did this in order to assess whether there is a correlation between accessibility of BPS during thymocyte development and the involvement of these sites in translocations. *Methods.* We isolated DNA of thymocyte subsets by FAIRE (Formaldehyde Assisted Isolation of Regulatory Elements) to quantitatively determine nucleosome occupancy throughout thymocyte development at TCR-associated BPS. Furthermore, we isolated thymocyte DNA to determine the methylation status of these BPS by means of bisulfite sequencing. Obtained data were correlated to the thymocyte developmental stages at which TCR loci are rearranged and to the occurrence of involvement of the BPS in translocations. *Results.* Our findings show some level of nucleosome depletion at oncogene BPS, with no clear increase in accessibility at a particular thymocyte developmental stage. Nucleosome enrichment levels correlate to the methylation status of the BPS within the *LMO2* locus. However, the *LMO2* translocation hotspot, at which a functional cRSS is located, is hardly nucleosome depleted and is mostly hypermethylated. In contrast, all *TLX1* analyzed BPS were mostly hypomethylated, with only the *TLX1* translocation hotspot showing high levels of nucleosome depletion. *Conclusions.* Nucleosome depletion combined with a hypomethylated status seems to renders BPS within the *TLX1* translocation hotspot more prone to involvement in TCR-associated translocations. The *LMO2* translocation hotspot is hardly accessible during thymocyte development, perhaps an indication that another type of accessibility is needed for RAG targeting. No clear chromatin modulation at the *LMO2* and *TLX1* locus is seen during thymocyte development. This implies that other conditions are imperative in driving the occurrence of T-ALL related translocations in specific thymocyte stages.

0013

IS IMATINIB-RESISTANCE IN BCR-ABL1-POSITIVE LEUKEMIA DUE TO LOSS OF PTEN AND/OR ACTIVATING PIK3CA MUTATIONS?

H Quentmeier, S Nagel, S Eberth, J Romani, M Zaborski, R MacLeod, H Drexler

DSMZ, Braunschweig, Germany

Background. The *BCR-ABL1* translocation occurs in 95% of cases with chronic myeloid leukemia (CML) and in 25% of cases with acute lymphoblastic leukemia (ALL). Tyrosine kinase inhibitors (TKI) - routinely administered in CML - are not equally effective for treating ALL. Causes for imatinib-resistance are: (i) the development of clones carrying mutations in the kinase domain of *BCR-ABL1*, (ii) low intracellular drug levels caused by disordered influx and efflux transport, (iii) overexpression of *BCR-ABL1*, and (iv) activation of alternative signalling pathways by oncogenic enzymes like *SRC* kinases. Many studies performed to elucidate imatinib-resistance make use of cells ectopically expressing *BCR-ABL1* or of cell lines which gained resistance after chronic exposure to rising drug concentrations. *Aims.* To find models for TKI-resistance, we analyzed nineteen *BCR-ABL1*-positive cell lines and found that five cell lines (KCL-22, MHH-TALL1, NALM-1, SD-1, SUP-B15) were resistant to imatinib and nilotinib. We set out to investigate whether these cell lines displayed the known molecular causes for TKI-resistance. *Methods.* TKI-reistance was determined by [3H]-thymidine uptake and annexin-V binding assays. Activity of signal transduction pathways was tested by Western blot analysis

using antibodies against phosphorylated *BCR-ABL1* targets. Mutational analysis of the *BCR-ABL1* kinase domain, of *PIK3CA* and of *PTEN* were performed by DNA sequencing. *Results.* None of the resistant cell lines carried mutations in the kinase domain of *BCR-ABL1* or other molecular aberrations previously mentioned in the context of TKI-resistance. The cell lines dephosphorylate the BCR-ABL1 downstream targets ERK1/2 and STAT5 after treatment with imatinib, while PI3K/AKT/mTOR activity remains unaffected. Treatment with AKT1 inhibitors promoted dephosphorylation of the mTOR target RPS6 and induced apoptosis. Cell line KCL-22 carried a PI3Kalpha E545G mutation, a site critical for the constitutive activation of the enzyme, indicating that mutations in the *PI3K* itself may be responsible for imatinib-resistance. Not only oncogenes, but also loss of tumor suppressor genes can activate oncogenic pathways. Accordingly, the T-ALL cell line MHH-TALL1 was found to carry a missense mutation in the PI3K-counteracting phosphatase *PTEN* leading to truncation of the protein after amino acid 241. Quantitative genomic PCR analysis revealed that the second *PTEN* allele was deleted in this cell line. *Summary/Conclusions.* 5/19 *BCR-ABL1*-positive cell lines tested were TKI-resistant. All imatinib-resistant cell lines were responsive to TKI regarding the *BCR-ABL1*-downstream targets STAT-5 and ERK1/2, but resistant with respect to the PI3K/AKT1 pathway. One of the resistant cell lines (KCL-22) carried a PI3Kalpha E545G mutation, a second (MHH-TALL1) did not express the full-length version of the PI3K-counteracting tumor suppressor gene *PTEN*. Either aberration might be responsible for the constitutive PI3K activity, and thus also be responsible for TKI-resistance. Our results highlight the importance of the PI3K in imatinib-resistance.

0014

FREQUENT METHYLATION AND DECREASED EXPRESSION OF THE RIZ1 GENE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA OF T CELL PHENOTYPE

H Shimura,[1] N Mori,[1] YH Wang,[1] M Okada,[2] T Motoji[1]

[1]*Tokyo Women's Medical University, Tokyo, Japan*
[2]*Chromosome Laboratory, Shiseikai Daini Hospital, Tokyo, Japan*

Background. Retinoblastoma protein-interacting zinc finger gene, *RIZ1* has characteristics of a negative regulator of tumorigenesis and is considered to be a tumor suppressor gene. The *RIZ1* gene is inactivated in various tumors by hypermethylation, and epigenetic silencing is the common process behind RIZ1 inactivation. In hematological malignancies, *RIZ1* expression was found to be significantly decreased in leukemia cell lines, primary samples from acute myeloid leukemia and chronic myelogenous leukemia during the transformation from chronic phase to blastic crisis. However, the role of the *RIZ1* gene has not been well examined in adult acute lymphoblastic leukemia (ALL). *Aims.* The aims of this study are to assess the *RIZ1* expression and altered methylation status in adult ALL and to determine the association between these features and clinical characteristics of the patients. *Methods.* We examined expression of the *RIZ1* gene by quantitative real-time reverse transcription-polymerase chain reaction (PCR) analysis and performed methylation-specific PCR on the *RIZ1* gene in newly diagnosed 73 adult ALL patients (62 B-ALL and 11 T-ALL). Normal bone marrow cells (n=10), normal lymphocytes (n=3) and lymphoid cell lines (n=4) were also examined. Characteristics of the patients including age, sex, phenotype of ALL, WBC counts, LDH at the diagnosis, karyotype and response to induction chemotherapies were also investigated. MOLT-4 cells that have the *RIZ1* methylation were treated with DNA methyltransferase inhibitor, 5-Aza-dC. *Results. RIZ1* expressions of 67 ALL (mean 1.043) were decreased compared with those of normal bone marrow mononuclear cells (mean 1.471) (P = 0.030). The *RIZ1* expressions in the T-ALL patients (mean 0.606) were lower than those in the B-ALL patients (mean 1.145) (P = 0.045), although the expressions in normal T-cells (mean 6.933) were higher than those in normal B-cells (mean 3.229). The expression was not associated with other clinical characteristics. Methylation of the *RIZ1* promoter was detected in 11 of the 71 patients (15.5%) while it was absent in healthy controls. The *RIZ1* methylation was accompanied with decrease of *RIZ1* mRNA levels among 9 of the 11 methylation-positive patients (81.8%), although there was no difference in the expressions between methylation-positive (mean 0.818) and -negative patients (mean 1.114) (P = 0.151). *RIZ1* methylation was more frequent in T-ALL (63.6%) than in B-ALL (5.0%) (P < 0.0001), and more frequent in Philadelphia chromosome (Ph)-negative ALL (23.3%) than in Ph-positive ALL (3.7%) (P = 0.027). We found no correlations between the methylation status and other clinical characteristics. 5-Aza-dC treatment of MOLT-4 cells induced demethylation of the *RIZ1* promoter and suppression of cell proliferation and viability in a dose- and time-dependent manner. Restoration of the *RIZ1* expression was induced in the cells treated with a high concentration of 5-Aza-dC. *Summary/Conclusions. RIZ1* expression is decreased in adult ALL. Decreased expression and methylation of the *RIZ1* gene are frequent in T-ALL. 5-Aza-dC treatment of MOLT-4 cells induced demethylation of the *RIZ1* promoter and restoration of the *RIZ1* expression. These results suggest that *RIZ1* is inactivated in adult ALL and this inactivation is associated with methylation in T cell phenotype.

0015

GERMLINE GENOMIC VARIATIONS AT IKZF1, ARID5B, AND CEBPE GENES FOR THE PREDICTION OF DEVELOPING CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA IN KOREA

DK Han,[1] HN Kim,[2] MH Shin,[3] M Ishimae,[4] M Eguchi,[4] E Ishii,[4] HJ Baek,[1] SJ Park,[1] HJ Kim,[2] H Kook,[1] TJ Hwang[1]

[1]*Chonnam National University Hwasun Hospital, Hwasun, South-Korea*
[2]*Genome Research Center for Hematopoietic Diseases, Chonnam National University H, Hwasun, South-Korea*
[3]*Department of Preventive Medicine, Chonnam National University Medical School, Gwangju, South-Korea*
[4]*Department of Pediatrics, Ehime University Graduate School of Medicine, Toon, Japan*

Background. Recent western studies have showed the implication of the germline genomic variations in IKZF1 gene at 7p12.2, ARID5B gene at 10q21.2, and CEBPE gene at 14q11.2 on the risk of childhood acute lymphoblastic leukemia (ALL); the most significant association was observed in the single nucleotide polymorphism (SNP) rs4132601 which located at 3' region of the IKZF1. IKZF1 plays an important role in lymphocyte differentiation, proliferation and function, ARID5B in embryogenesis and growth regulation, and CEBPE in regulation of myelopoiesis. Genomic variants in these genes are therefore considered to be involved in transcriptional regulation and differentiation of B cell progenitors. However, there have been no reports on the role of germline variations in leukemogenesis of childhood ALL in Asian countries. *Aims.* The aim of this study is to show the impact of these genetic variants on childhood ALL in Korea. *Methods.* To examine the association between genetic variations (IKZF1 rs4132601, ARID5B rs7089424, and CEBPE rs2239633) and the risk of childhood ALL, we here analyzed 228 children with ALL and 508 healthy individuals in Korea. *Results.* In ARID5B rs7089424, TG and GG genotypes were significantly associated with a risk for ALL (odds ratio [OR], 1.63; 95% confidential interval [CI], 1.07-2.48; P=0.02 for TG genotype, OR, 2.69; 95% CI, 1.42-5.07; P=0.002 for GG genotype). The allele incidence of ARID5B rs7089424 was also significantly associated with a risk for ALL (OR, 1.66; 95% CI, 1.24-2.22; P=0.0006). CEBPE rs2239633 TT genotype showed a significant association with a decreased risk for ALL (OR, 0.54; 95% CI, 0.33-0.90; P=0.02 for TT genotype). The allele incidence of CEBPE rs2239633 was also associated with a decreased risk for ALL (OR, 0.77; 95% CI, 0.61-0.97; P=0.02). There was no significant association between IKZF1 rs4132601 polymorphism and a risk for ALL in this study. *Conclusions.* These results suggest that genomic variations of ARID5B and CEBPE may play an important role in the risk for childhood ALL in Korea, compared with findings from western countries showing a significant relation between IKZF1 and childhood ALL. Several factors should be considered to explain a discrepancy between our results and the previous studies, which include different genotype frequencies in polymorphisms and varied susceptibility to ALL in different ethnic groups. Further studies incorporating larger number of cases and analyzing other SNPs or other Asian countries are warranted in childhood ALL.

0016

PARALLEL SAMPLING OF BONE MARROW AND PERIPHERAL BLOOD IS ADVISED FOR THE MOLECULAR EVALUATION OF MINIMAL RESIDUAL DISEASE IN BOTH B AND T LINEAGE ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

O Spinelli,[1] M Tosi,[1] B Peruta,[1] ML Guinea Montalvo,[1] T Intermesoli,[1] E Oldani,[1] E Angelucci,[2] G Rossi,[3] D Mattei,[4] AM Scattolin,[5] S Cortelazzo,[6] E Pogliani,[7] R Bassan,[8] A Rambaldi[8]

Background. An accurate detection of minimal residual disease has become a crucial tool to evaluate prognosis and therapeutic strategies both in childhood and adult patients with acute lymphoblastic leukaemia (ALL). The need of repeated (BM) sampling during the clinical course can be problematic for many patients. Preliminary results obtained in children showed that BM sampling can not be replaced by PB in B precursor ALL, but could be considered for T-ALL. Here we report our comparative analysis performed in a large prospective study performed in adult B and T ALL. *Material and Methods.* One hundred and seven adult patients (73 B-precursor ALL and 34 T lineage ALL) enrolled 2 consecutive clinical trials launched by NILG, were monitored for molecular MRD in BM and PB. Two informative Ig or TCR derived molecular probes (with a sensitivity ranging from 10-3 to 10-5) were used in 77 patients (51 B-precursor and 26 T-ALL) while only one probe was available for 30 (22 B-precursor and 8 T-ALL). A paired BM/PB analysis was conducted on 721 paired samples (500 from B and 221 from T-ALL) by real-time quantitative PCR (RQ-PCR). *Results.* In T-ALL 132 out of 221 paired samples obtained during follow-up proved negative both in the BM and PB whereas a positive MRD was found in at least one sample of the remaining 89 paired analyses. Among these latter samples, a positive MRD was detected in both BM and PB with comparable levels of residual disease in 47 paired samples (53%), while the amount of detectable disease was remarkable different (from 1 to 2 log) in 23 pairs (26%). In 8 paired samples (9%) MRD proved positive only in the BM while in 11 (12%) only in the PB. In B precursor ALL 200 out of 500 paired samples showed a measurable MRD level in the BM and/or PB (figure 1 panel A). In 46 paired samples (23%) the amount of MRD was similar in BM and PB while in 72 (36%) MRD was significantly higher (up to 3 log difference) in the BM compared to PB. In only one case (0.8%) a higher MRD level was detected in PB. In 66 paired samples (33%) MRD was detectable only in the BM and in several of these cases the amount of residual disease could be as high as 10-2. In 16 pairs (8%) only the PB proved positive but at very low levels (usually ≤ 10-4) (figure 1 panel B). *Conclusion.* Although MRD detection on BM samples is more sensitive compared to PB, in both B and T lineage ALL. However, in some T-ALL cases, the PB may provide discordant and informative results. All in all, our results suggest that either in B precursor ALL as well as in T-ALL, an MRD evaluation must be always performed on BM but preferably, PB samples should be tested in parallel.

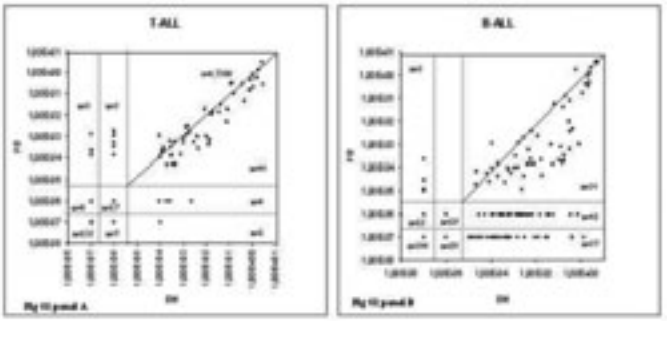

Figure 1. MRD levels in paired BM and PB samples.

[2]*Hematology Department. Hospital General, Alicante, Spain*
[3]*Hematology Department. Hospital Universitari Germans Trias i Pujol, Badalona, Spain*
[4]*Department of Clinical Analysis. Hospital Universitario La Fe, Valencia, Spain*

Background. Except for the known adverse prognosis of Ph+ ALL, few other cytogenetic and molecular markers are used in the clinical practice for adult ALL. Microdeletions of genes involved in B lymphopoiesis and cell-cycle regulation, such as *CDKN2A*, *PAX5*, *IKZF1*, *ETV6*, *RB1* and *EBF1*, have been reported as a highly frequent event in pediatric ALL, but the frequency of this findings and its prognostic implication in adulthood are still uncertain. *Aims.* To identify the frequency of deletions in these genes and their relationship with clinical data and prognosis in an adult cohort of Ph- ALL patients. *Methods.* We studied 67 patients diagnosed with Ph- ALL with available DNA sample collected at diagnosis. Median age was 38 years (range 15 - 85) and leukocyte count 16.8 x 10^9/L (range 1-371). Nucleic acids were extracted from bone marrow aspirate using standard procedures. We performed Multiplex Ligation Probe Amplification (MLPA), a multiplex PCR based technique that allows comparative quantification of multiple sites, using the SALSA MLPA kit P335-A1 (MRC-Holland, Amsterdam, The Netherlands), that contains, among others, probes for *CDKN2A*, *PAX5*, *IKZF1*, *ETV6*, *RB1* and *EBF1*. The PCR products were separated by capillary electrophoresis on an ABIPRISM 310 DNA Analyzer (Applied Biosystems). Data were analyzed using GeneMapper software v3.2 (Applied Biosystems) and relative copy number was obtained after normalization of peaks against controls. Values below 0.7 indicated loss and over 1.3 indicated gain. *Results.* Forty-one (61%) patients showed abnormalities in at least one of these genes. The most common deletions were found in *CDKN2A* (33%) and *IKZF1* (22%), but were also frequent in *ETV6* (16%), *PAX5* (14%), *RB1* (14%), *EBF1* (11%) and *BTG1* (6%). Deletion of *CDKN2A* were related to leukocyte count >50 x 10^9/L (P = .042) and *ETV6* deletion (P <.001). No other gene microdeletions were significantly associated with any clinical or biological characteristic. Multivariate analysis for overall survival including all significant variables in the univariate analysis (leukocyte count, age, karyotype, *CDKN2A*, *ETV6* and *PAX5* deletions) showed as independent variables: age >50 years [HR 4.3 (CI 95% 1.7 - 10.6); P = .001], *PAX5* deletions [HR 3.5 (CI 95% 1.0 - 11.8); P = .043] and leukocyte count >50 x 109/L [HR 3.1 (CI 95% 1.1 - 9); P = .035]. Similarly, multivariate analyses for relapse free survival showed *ETV6* deletions as the only independent risk factor for relapse [HR 5.2 (CI 95% 1.7 - 16.2); P = .004]. We could not confirm a negative effect of *IKZF1* deletions in our series. *Conclusions.* This study shows the high incidence of deletions in genes of cell-cycle and B-lymphopoiesis in adult Ph- ALL. In particular, deletions of *PAX5* and *ETV6* could be of interest for risk assessment.

DASATINIB SHOWS ANTI-LEUKEMIC ACTIVITY IN E2A-PBX1-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

T Tesanovic,[1] S Badura,[2] B Nijmeijer,[3] M Ruthardt,[2] O Ottmann[2]

[1]*Universitätsklinikum Frankfurt, Frankfurt am Main, Germany*
[2]*Department of Hematology/Oncology, University of Frankfurt, Frankfurt am Main, Germany*
[3]*Department of Hematology, Leiden University Medical Center, Leiden, Netherlands*

Background. Chromosomal translocations that activate specific genes are a defining characteristic of human leukemias and of acute lymphoblastic leukemia in particular. The t(1;19) (q23;p12.3) chromosomal translocation, leading to the production of the E2A/PBX1 fusion transcript, is a rare but still one of the most recurring translocations in pe-

diatric ALL, with an overall frequency of 5% to 6%. The rearrangement fuses 5' exons encoding the transactivation domain of the E2A transcription factor gene to 3' exons ecoding the putative DNA-binding region of the homeobox gene, PBX1. The role of E2A-PBX1 in the development of acute leukemia has not been established. *Aims.* The aim of this study is to investigate potential anti-leukemic activity of the tyrosine kinase inhibitor (TKI) dasatinib in long-term cultured primary human E2A-PBX1-positive ALL cells and in E2A-PBX1-positive cell lines. Dasatinib is a multikinase inhibitor with potent activity against BCR-ABL (IC50<1 nM) and Src Family Kinases (IC50 of 0.2 and 1.1 nM) that has been approved for the treatment of patients with CML and Philadelphia-chromosome-positive acute lymphoblastic leukemia. *Methods.* To investigate the anti-leukemic activity of dasatinib, we screened E2A-PBX1-positive cell lines as well as long-term cultured human acute lymphoblastic leukemia cells established recently (Nijmeijer *et al*. 2009). The long-term *in vitro* proliferating cells phenotypically strongly resemble the initial cell population and have a largely identical karyotype. The effect of TKIs on proliferation of ALL cells was determined by the XTT-assay according to standard protocol. Cells incubated without drugs are used as controls and dasatinib is added at serial dilutions to allow IC50-calculations. The effect of TKI treatment on induction of apoptosis was determined by annexin V/propidium iodide staining and analysed by FACS. cDNAs encoding pE2A-PBX1 for expression in Ba/F3 cells were cloned from E2A-PBX1-positive long-term cultured ALL cells by RT-PCR and confirmed by sequencing. The construct were subcloned into pENTR.1A ("Gateway"recombination system-Invitrogen) for further transfer into expression vectors. For retroviral transduction we used retroviral vectors based on the PINCO vector, which harbours the green fluorescence protein (GFP) as reporter. *Results.* Dasatinib strongly (80%) inhibited cell proliferation of all E2A-PBX1-positive ALL cells tested in this study. The anti-proliferative effect was observed at concentrations up to 1µM with IC50-concentrations ranging from 25-50 nM. In contrast, IC50-concentrations were below 5 nM in BCR-ABL-positive ALL cells. Treatment with the kinase inhibitor imatinib and the second-generation BCR-ABL inhibitor nilotinib did not inhibit the proliferation of E2A-PBX1-positive cells. Exposure of E2A-PBX1-positive cells to dasatinib up to a concentration of 1 µM for 72 hours did not led to a significant induction of apoptosis (<20%) compared to a 20-70% apoptosis rate in BCR-ABL-positive ALL cells. Analysis of the anti-leukemic effect of dasatinib on Ba/F3 cells transfected with a plasmid that confers expression of E2A-PBX1 is ongoing. *Conclusion.* Exploration of the tyrosin kinase inhibitor dasatinib as a novel therapeutic approach to E2A-PBX1-positive ALL appears warranted based on its consistent profound growth inhibitory effect on E2A-PBX1 expressing cells.

0019

DNA DAMAGE-INDUCED POSTTRANSLATIONAL MODIFICATIONS OF P53 DECREASED UPON ACTIVATION OF CAMP SIGNALING IN PRE-B ALL CELLS

A Kazemi, M Safa

Tehran University of Medical Sciences, Tehran, Iran

Background. The p53 tumor suppressor protein is a potent roadblock to tumor development. Cells that are insulted by chemotherapeutic DNA-damaging agents or other forms of stress stabilize the p53 protein by phosphorylation or other modifications. Stabilized p53 accumulates in the nucleus to regulate the expression of numerous pro-apoptotic genes. *Aims.* The aim of this study was to evaluate the effect of activation of cAMP signaling system on post-translational modifications of p53 in pre-B ALL cells upon exposure to chemotherapeutic drugs. *Methods.* Cultured pre-B ALL NALM-6 cells were exposed to doxorubicin in the presence or absence of cAMP-increasing agents forskolin/IBMX for 24h and then cells were subjected to apoptosis analysis by flow cytometry. Western blot method was used to analyze phosphorylation and acetylation state of p53 protein, total p53, and the levels of other proteins which were involved in doxorubicin-induced apoptosis. Real-time PCR was performed to analyze the expression levels of p53 and p53 target genes. *Results.* These results indicate that elevation of cAMP in B cell precursor acute lymphoblastic leukemia (BCP-ALL) cells harboring wild-type p53 profoundly inhibit the apoptotic response to doxorubicin. We further demonstrate that elevated cAMP levels repressed DNA damage-induced p53 protein phosphorylation, acetylation, and accumulation in NALM-6 cells. Increased cAMP levels also shifted the ratio of the death promoter to death repressor genes via alteration of Bcl-2 and Bax proteins expression. Whereas elevated cAMP was able to decrease doxorubicin-induced gene expression levels of p53 target genes, it had no effect on p53 mRNA steady-state levels. *Summary/Conclusions.* In conclusion, recognition that elevated cAMP levels may abrogate p53-dependent apoptosis carries clinical implications for patients with wild-type p53 leukemia cells undergoing curative antineoplastic therapy, because a large number of common agents modulate cAMP metabolism.

B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA NEGATIVE FOR CD38: A SUBSET OF PATIENTS WITH DISTINCT BIOLOGICAL AND PROGNOSTIC FEATURES?

T Martin-Santos,[1] L Gonzalez-del-Castillo,[1] A Lemes,[2] T Molero,[2] C Sanchez,[2] C Rodriguez-Medina,[2] J Bosch,[3] R Lopez-Almaraz,[1] B Soria,[1] M Brito,[1] L Hernandez-Nieto,[1] JM Raya[1]

[1]*Hospital Universitario de Canarias, La Laguna, Spain*
[2]*Hospital Dr. Negrin, Las Palmas, Spain*
[3]*Hospital Insular, Las Palmas, Spain*

Background. It is known that CD38 expression is associated with poor prognosis in patients with chronic lymphocytic leukaemia; however, its significance is unclear in other lymphoid malignancies. Although some authors have suggested that the negativity of the blasts for CD38 is correlated with a worse prognosis in patients with B-cell acute lymphoblastic leukaemia (B-ALL), it has yet to be clarified. *Aims.* The purpose of this study was to evaluate the main characteristics of patients with B-ALL according to CD38 expression. *Methods.*We analyzed the features at diagnosis and the evolution of 44 patients with B ALL treated at two hospitals in our community over the past ten years. The group consisted of 17 pediatric patients (age below 18 years) and 27 adults, with a median age of 26.5 years (range 2-75) and women 54%. Recorded data included morphology, laboratory findings, immunophenotype, cytogenetics and FISH, clinical features, treatment approach, follow-up and survival. Statistic analysis was performed using SPSS software, and relations between variables were studied using the Fischer exact test (categorical) and the Mann Whitney U test (continuous). *Results.* In 33 patients lymphoblasts were positive for CD38, while eleven did not express this cell surface marker. When compared with CD38 positive B-ALL group, the blasts of patients negative for CD38 were more frequently CD34, KOR-SA and CD13 positive (p=0.05, p=0.013 and p=0.049, respectively), and CD20 and CD22 negative (p=0.014 and p=0.05). Of note, 86% of patients lacking CD38 presented with BCR-ABL1 fusion gene, and only 14% in the CD38 positive group (p=0.001). Although overall survivals were similar, mortality tended to be higher among the CD38 negative B-ALL cases (p=0.058). Finally, there was not correlation between CD38 expression and age, sex, extramedullary involvement, lymphadenopathy, hepatosplenomegaly, blood cell counts, serum lactate dehydrogenase, morphology of lymphoblasts, bone marrow aspirate findings, other recurrent genetic abnormalities different to BCR-ABL1, minimal residual disease status evaluated by flow cytometry, chemotherapy regimens, hematopoietic stem cell transplantation, disease-free survival and overall survival. *Conclusions.* Although further studies involving a larger number of cases are certainly needed, these preliminary results show that: 1) Phenotypically, the absence of CD38 is associated with positive expression for CD34, KOR-SA and CD13, and negative for CD20 and CD22. 2) CD38 negative B-ALL seems to correlate strongly with the presence of BCR-ABL1. 3) Mortality tends to be higher among this subgroup of patients. These findings lead us to consider the possibility that CD38 negative B-ALL patients constitute a subgroup of B-ALL with different biological characteristics and prognosis.

0021

WHOLE GENOME DNA MICROARRAY ANALYSIS OF ADOLESCENT/YOUNG ADULT T-ALL

C Furness, F van Delft, S Colman, M Greaves

Institute of Cancer Research, Surrey, United Kingdom

Background. Outcomes for adolescent/young adults (AYAs) with ALL have improved in recent years with incorporation of this age group into paediatric protocols. However, event free survival for those aged over ten years remains inferior to their younger counterparts and the biological basis behind this difference is poorly understood. Possible explanations include a higher proportion of poor risk cytogenetic abnormalities in the AYA group, poor compliance with treatment or novel genetic aberrations specific to this adolescent group. This is par-

ticularly relevant to T-ALL where up to 40% of patients have no detectable cytogenetic abnormality. In recent years whole genome microarray analysis has improved our understanding of T-ALL pathogenesis with the identification of multiple novel copy number alterations (CNA). We applied this technology to testing the hypothesis that AYA ALL has a unique genetic profile. *Aims.* Our aim was to perform whole genome copy number analysis in a cohort of AYA T-ALL patients to determine the frequency of known genetic aberrations in our cohort compared to previous paediatric studies and to determine the presence of any novel copy number alterations (defined as recurrent CNA present in two or more samples in our cohort and not described in previous series of T-ALL). *Methods.* Diagnostic DNA from 25 AYA T-ALL patients (age 10 - 25 years) was subjected to copy number analysis using the Affymetrix SNP Array 6.0 platform, and CNAG 3.3.0.0 software for data analysis. Each CNA was classified as a passenger or driver: CNAs were classified as passengers if they were a known variant present in healthy controls or if they had no known/postulated role in oncogenesis. CNAs were classified as drivers if they were recurrent changes or if they had a known/postulated role (e.g known oncogene from another malignancy) in leukaemogenesis. *Results.* The mean number of drivers was 3.8 and the median was 3 (range 1 - 9). Frequency of known CNA in AYA T-ALL in our series was similar to paediatric studies with deletion of p16 again playing a pivotal role. Frequencies of deletion of 1p33, 11p13, 9q34.11-34.13 (leading to upregulation of TAL1, LMO2 and HOXA respectively) and deletion/gain of LEF1, MYB and PTEN were similar to previous paediatric references (see Table 1). A number of individual samples had copy number changes in genes usually associated with other haematological malignancies including loss of ARHGAP26 (JMML) and loss of DLEU2 (CLL). Potential novel areas of recurrent CNA identified included gain of 1p22.3 and deletion of 3q12.2. *Conclusions.* Copy number 'drivers' in our AYA T-ALL cohort were surprisingly similar to the paediatric population. However, the hypothesis that AYA T-ALL represents an independent group at a molecular genetic level cannot be rejected without expansion of this approach to sequence based mutations and cryptic translocations (undetectable by microarray). Gain of 1p22.3 in 12% samples implicated CLCA4, a chloride channel as warranting further study, and deletion of 3q12.2 in 8% of the samples is of interest as this corresponds to a partial deletion of the TFG gene previously implicated in oncogenic rearrangements in anaplastic lymphoma.

Table 1.

Frequency of Known Copy Number Alterations in AYA T-ALL Cohort

Cytoband	Gain/Loss	Gene (s)	AYA T-ALL % Frequency	Historical % Frequency in Paediatric Population (Reference)
9p21.3	Loss	CDKN2A/B	72 %	70% (Van Vlierberghe et al, 2008)
1p33	Loss	SIL, TAL1	24 %	25% (Van der Burg et al, 2002)
10q23.3	Loss	PTEN	12 %	8.5% (Gutierrez et al, 2009)
6q22 - q23	Gain	MYB	12 %	8% (Remke et al, 2009)
9q34.11 - 34.13	Loss	SET-NUP214	4 %	3% (Van Vlierberghe et al, 2008)
4q23 - 4q25	Loss	LEF1	4 %	11% (Gutierrez et al, 2010)
11p13	Loss	LMO2	4 %	3% (Van Vlierberghe et al, 2008)
9q34	Gain	ABL1	0 %	5% (Hagemeijer and Graux, 2010)
17q11.2	Loss	NF1	0 %	2.9% (Balgobind et al, 2008)
Xq26.3	Loss	PHF6	0 %	3% (Van Vlierberghe et al, 2010)

0022

CLINICAL IMPACT OF NOTCH1 AND FBXW7 MUTATIONS AND FLASH DELETION IN PEDIATRIC T LYMPHOBLASTIC LYMPHOMA

C Callens,[1] F Baleydier,[2] E Lengline,[1] R Ben Abdelali,[1] C Persiaux,[1] Y Bertrand,[2] V Asnafi,[1] E Macintyre[1]

[1]*Hôpital Necker, Paris, France*
[2]*Hospices civils de Lyon, Lyon, France*

Background. Lymphoblastic T-cell lymphoma (T-LBL) and T-cell acute lymphoblastic leukemia (T-ALL) are lymphoid neoplasms characterized by the proliferation of malignant T lymphoblasts arrested at early stages of maturation. They differ by the extent of bone marrow involvement, which is <25% in T-LBL. Since they share several biological characteristics, including cytology and immunophenotype they tend to both be treated on T-ALL protocols. Relapsed patients with either disease do badly, but the time to relapse tends to be shorter in T-LBL than in T-ALL and the sites of relapses differ. Identification of biological criteria associated with high risk disease is therefore important. In pediatric T-ALL protocols, the measurement of the kinetics of leukemia clearance during early induction is widely used for individual risk based stratification. This approach cannot be extrapolated easily to T-LBL, although detection of submicroscopic bone-marrow involvement (also called minimal disseminate disease or MDD) by flow cytometry or molecular quantification of TCR rearrangements has been associated with unfavourable EFS. NOTCH1 and FBXW7 (N/F) mutations occur in >50% of all childhood T-ALL patients and have previously been associated with a favorable prognostic in several protocols but not all. To date, few data are available on the frequency and the prognostic value associated with N/F mutational status in T-LBL. Chromosome 6q deletion (del6q) has been suggested by Burkhardt *et al.* to identify a poor prognostic group of T-LBL. *Aims.* Monitoring of MDD remains a late criteria for therapeutic adjustment, justifying the identification of molecular poor prognostic markers at diagnosis which would facilitate early therapeutic stratification. In this study, we determined the frequency and the prognostic value of N/F mutations and FLASH deletion at 6q in a homogenous cohort of 47 pediatric T-LBL. *Methods.* tumoral samples were obtained at diagnosis from lymph nodes (n=8), pleural effusions (n=30), mediatinum (n=7) or tissue biopsies (n=2). N/F mutations were identified by direct sequencing and allelic dosage was used to detect FLASH deletions. *Results.* NOTCH1 and/or FBXW7 mutations (N/F^{mut})were found in 24 of 47 T-LBL, when they identified a group with superior prognosis considering the EFS (p=0.01). NOTCH1 mutations were found in 45% (21/47) and FBXW7 mutations in 13% (6/45) of T-LBL. FLASH monoallelic deletions were observed in 20% (9/46) of T-LBL, similar to the previously published incidence of del6q (19%). We observed no biallelic FLASH deletions. The majority of patients with FLASH deletion were not mutated for NOTCH1 or FBXW7 (N/F^{wt})(7/9) but this was not statistically significant. To date, 9 patients from the cohort had a clinical event: 1 with NOTCH1 mutation without FLASH deletion, 4 with FLASH deletion without N/F^{mut} and 4 with neither FLASH deletion nor N/F^{mut}. *Conclusion.* FLASH genetic dosage represent a simple alternative to LOH or CGH to identify T-LBL with del6q. FLASH deletions do not appear to accentuate the bad prognosis of N/F^{wt} T-LBL. Given that FLASH deletion is found preferentially in N/F^{wt} cases it is possible that its poor prognosis reflects the absence of N/F^{mut}, rather than being directly related to the del6q.

0023

IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA THE RISK EFFECT OF NQO1 C609T POLYMORPHISM AND THE PROTECTIVE EFFECT OF MTHFR A1298C POLYMORPHISM NEUTRALIZE EACH OTHER

G Ebid,[1] M Kamel,[1] M Rong[2]

[1]*National Cancer Institute, Cairo University, Cairo, Egypt*
[2]*Kfshrc, Reyadah, Saudi Arabia*

Background. Xenobiotic-metabolizing enzymes constitute an important line of defense against a variety of carcinogens. Many are polymorphic, constituting the basis for the wide inter-individual variation in metabolic capacity and possibly a source of variation in the susceptibility to chemical-induced carcinogenesis. *Aims.* The aim of this study was to determine the existence of any association between the genetic polymorphisms of NQO1 C609T & MTHFR C677T & A1298C, and altered risk for pediatric ALL. *Methods.* A total of 91 patients and 311 controls were genotyped by means PCR-RFLP-based assays. Mutated alleles comprising NQO1 C609T & MTHFR C677T & A1298C were analyzed along with the wild-type alleles. *Results.* The frequency of NQO1 609CT heterozygous genotype was 42(46.7 %) among patients compared to 87 (30.2%) among controls; the difference was found to be statistically significant (P. value = 0.003, O.R=2.214 & 95% C.I =1.343 - 3.649). The frequency of the NQO1 609TT homozygous genotype was 8 (8.6 %) among patients compared to 13 (4.5 %) among controls; the difference was found to be statistically insignificant (P. value = 0.04, O.R=2.822& 95% C.I =1.099 - 7.248). this results pointed to 2.2 folds and 2.8 fold increased risk of ALL for both heterozygous and homozygous respectively. MTHFR A1298C heterozygous genotype was significant higher in the control group 140 (45%) however in ALL group 22 (25%) (P = 0.001, OR =0.382 and95% C.I =0.222 - 0.658. this results pointed to 2.6 folds of protective effect among the control group. The frequency of the MTHFR1298AC heterozygous and NQO1 609CT heterozygous, i.e. (ACCT) genotype was 8 (9.5 %) among patients compared to 40 (14.0 %) among controls; the difference was found to be statistically insignificant (P. value = 0.280). also the frequency of combined genotype MTHFR1298AC heterozygous and NQO1 609TT homozygous (ACTT) was 2 (2.4 %) among patients compared to 7 (2.5 %) among controls; the 2 figures are comparable (P. value = 0.969) (Table 50). The protective effect of MTHFR 1298AC allele and the risk effect of NQO1 C609T neutralize each other. *Summary*

and Conclusion. on a separate analysis the NQO1 609Ct&TT associated with increased risk of pediatric ALL while MTHFR 1298AC associated with protective effect. On combined analysis, both effete neutralize each other.

0024

MUTATION OF THE RECEPTOR TYROSINE PHOSPHATASE PTPRC (CD45) IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

M Porcu,[1] V Gianfelici,[2] M Kleppe,[2] J Soulier,[3] V Asnafi,[4] E Macintyre,[4] A Uyttebroeck,[5] P Vandenberghe,[6] J Cools[2]

Background. Deregulated tyrosine kinase signaling is an important factor that contributes to the enhanced proliferation and survival of leukemic cells. In T-cell acute lymphoblastic leukemia (T-ALL), activation of tyrosine kinases (ABL1, JAK1, LCK, FLT3) has been reported in approximately 20% of patients. Additionally, our group recently reported deletions of the tyrosine phosphatase PTPN2 in 6% of T-ALL cases. Loss of PTPN2 was shown to potentiate oncogenic kinases as well as influence response to kinase inhibitor treatment. *Aims.* It can be expected that additional tyrosine kinases and phosphatases remain to be discovered that play a prominent role in the pathogenesis of T-ALL. To identify novel therapeutic tyrosine kinase targets in T-ALL, we screened a panel of 10 T-ALL cell lines with an siRNA library targeting the human tyrosine kinome. *Results.* Our siRNA screen successfully identified known critical tyrosine kinases in three control leukemia cell lines (NUP214-ABL1 in ALL-SIL cells, FIP1L1-PDGFRA in EOL-1 cells, and LCK in HSB-2 cells), establishing it as a reliable tool for target identification. Furthermore, our screen identified several critical tyrosine kinases in other T-ALL cell lines, including LCK (in three cell lines), NTRK2, and JAK1 (each in one cell line). We identified and confirmed JAK1 to be an essential kinase for the proliferation of DND41 cells. The JAK1 gene itself was not mutated in DND41, but we identified a heterozygous nonsense mutation in the PTPRC gene. PTPRC encodes the tyrosine phosphatase CD45, a known negative regulator of JAK kinases. In functional assays in T-cell lines, siRNA mediated knockdown of CD45 indeed caused increased JAK/STAT signaling downstream of cytokine receptors. Sequence analysis of PTPRC subsequently identified missense and nonsense mutations in 3 of 15 T-ALL cell lines and 5 of 65 primary T-ALL cases at diagnosis. *Conclusion.* Our data demonstrate that siRNA screens can identify tyrosine kinases that are essential for the proliferation of T-ALL cells. Based on these results, we identified loss-of-function mutations in the receptor tyrosine phosphatase CD45 (PTPRC). Our data provide genetic and functional evidence for a tumor suppressor function for CD45.

0025

C-JUN PROMOTES BCR-ABL INDUCED LYMPHOID LEUKEMIA BY INHIBITING METHYLATION OF THE 5' REGION OF CDK6

K Kollmann,[1] G Heller,[2] R Ott,[3] M Bilban,[4] W Warsch,[3] M Malumbres,[5] V Sexl[1]

Background. The transcription factor c-JUN and its upstream kinase JNK1 have been implicated in BCR-ABL induced leukemogenesis. JNK1 has been shown to regulate BCL2 expression thereby altering leukemogenesis, but the impact of c-JUN remained unclear. *Aims.* In this study we show that JNK1 and c-JUN promote leukemogenesis via separate pathways, since lack of c-JUN impairs proliferation of p185BCR-ABL transformed cells without affecting viability. *Methods/Results.* The decreased proliferation of c-Jun cells is associated with the loss of cyclin dependent kinase 6 (CDK6) expression. In c-Jun cells CDK6 expression becomes down-regulated upon BCR-ABL induced transformation which correlates with CpG island methylation within the 5' region of Cdk6. We verified the impact of Cdk6 deficiency by using Cdk6-/- mice that developed BCR-ABL induced B-lymphoid leukemia with significantly increased latency and an attenuated disease phenotype. In addition we show that re-expression of CDK6 in BCR-ABL transformed c-Jun cells reconstitutes proliferation and tumor formation in Nu/Nu mice. *Summary.* In summary, our study reveals a novel function for the AP-1 transcription factor c-JUN in leukemogenesis by antagonizing promoter methylation. Moreover, we identify CDK6 as relevant and critical target of AP-1 regulated DNA methylation upon BCR-ABL induced transformation, thereby accelerating leukemogenesis.

SMALL SOMATIC MUTATIONS IN ACUTE PROMYELOCYTIC LEUKEMIA (APL) IDENTIFIED BY EXOME SEQUENCING

P Greif,[1] M Yaghmaie,[2] N Konstandin,[1] K Alimoghaddam,[2] A Ghavamzadeh,[2] A Hauser,[1] A Graf,[1] S Krebs,[1] H Blum,[1] S Bohlander[1]

[1]*Universität München, München, Germany*
[2]*Tehran University of Medical Sciences, Tehran, Iran*

The t(15;17) translocation which results in the PML/RARA fusion is the disease defining lesion in nearly all cases of acute promyelocytic leukemia (APL). Despite the importance of the PML/RARA fusion for the pathogenesis of APL it is most likely not sufficient to cause leukemia alone. For example, collaborating mutations affecting the FLT3 receptor tyrosine kinase are found in about 20-30% of APL patients. To screen systematically for additional mutations, we performed whole exome sequencing of 3 APL patients. Thereby, we generated at least 5 Gbp of exome sequence for each of the APL samples and for each of the corresponding remission samples. This allowed us to cover at least 80% of RefSeq coding exon positions with a minimum read depth of 10 and at least 75% of RefSeq coding exon positions with minimum read depth of 20. By comparing the APL exome sequence with the remission exome sequence, we screened for small APL-specific genetic variants. We were able to confirm 3 to 5 somatic mutations per patient by Sanger sequencing. These APL specific mutations affected not only known mutational targets in leukemia, such as WT1 and KRAS, but also genes with potential implications in leukomogenesis, such as LYN, encoding a kinase which acts downstream of FLT3, and a novel homeobox gene. Our findings demonstrate that exome sequencing is an efficient method to screen for leukemia specific point mutations and small indels that may collaborate with the PML/RARA fusion during the onset and progression of APL.

HIGHLY EXPRESSED MIR-125B AND LET-7C FORM ONE POTENTIAL MECHANISM TO EVADE THE GROWTH INHIBITION OF TGF? IN ACUTE MEGAKARYOBLASTIC LEUKEMIA OF DOWN SYNDROME PATIENTS

M Rasche, S Emmrich, K Reinhardt, D Reinhardt, JH Klusmann

Hannover Medical School, Hannover, Germany

Background. TGFβ has been shown to play a crucial role in cancer development through its function as a tumor suppressor. Via the SMAD-signaling pathway it regulates apopotosis as well as differentiation. In hematopoiesis TGFβ is mainly known through its inhibitory effects on proliferation. Children and neonates with Down syndrome (DS; i.e. trisomy 21) are highly predisposed to develop acute megakaryoblastic leukemia (ML-DS) and the antecedent transient leukemia (TL-DS). Significantly increased levels of TGFβ in the amniotic fluid of DS-pregnancies and the secretion of TGFβ through the leukemic megakaryoblasts are suggestive for a pivotal escape mechanism of the leukemic cells to evade the growth inhibition of TGFβ. The molecular mechanism of this disruption of the TGFβ pathway have still to be elucidated in ML-DS. Especially the role of the highly expressed chromosome 21 (hsa21)-encoded miRNAs miR125b-2, miR99a and let-7c in this TGFβ escape mechanism of ML-DS cells remains unknown. *Aims.* Here, we studied the function of hsa21-encoded miRNAs miR-125b-2, miR-99a and let-7c in TGFβ signaling. We hypothesized a putative role of these miRNAs in DS leukemogensis by suppressing its inhibitory effects allowing ML-DS-blasts to grow under high TGFβ conditions. *Methods.* We employed pathway-specific in silico target prediction (Diana mirPath and miRGen), followed by *in vitro* studies to assess the response of various cell lines to TGFβ and by functional validation in lentivirally transduced cell lines. *Results.* Two independent target prediction algorithms showed in silico enrichement of TGFβ pathway components in the potential targetome of the Hsa21 encoded miRNAs, especially miR-125b-2 and let-7c. We addressed our attention to identify the key factors of the disruption of the TGFβ signaling, which seems to be negatively regulated through the miRNAs. Consistent with these data we found decreased mRNA levels for SMAD3 (~10fold in ML-DS cell lines compared to K562 cells exhibiting low endogenous hsa21 miRNA expression), for TGFBR1(~ 5fold compared to K562) and for SMAD2 and SMAD4. Next, we assessed the viability of amongst others leukemic cell lines with known TGFβ-escape mechanisms, ML-DS and non DS-AMKL cell lines with various levels of miRNA expression under a wide range of TGFβ concentrations . These studies gave high indices that the TGFβ resistance is caused by miR-125b-2 or let-7c. Thus, we focussed on two TGFβ-responder cell lines, NB4 (FAB-classification M3) and MV4:11 (FAB-classification M5). Overexpression in NB4 and MV4:11 with decreased basic levels of these essential miRNAs conferred a stronger survival (up to 1.4fold increase of viable cells after 5 days of TGFβ-incubation relative to controls) under high TGFβ concentration. *Summary.* Our data revealed the connection between the phenotypic non-responder morphology of the ML-DS blasts and miRNA expression levels. We could demonstrate the interplay of miR-125b-2, let-7c and TGFβ signaling showing the morphological change of high sensitive cell lines into more resistant cell lines through overexpression of miR-125b-2 in MV4:11 and through overexpression of miR-125b-2 and let-7c in NB4 cells.

HIGH-THROUGHPUT CLONAL SEQUENCING OF SMALL RNA TRANSCRIPTOME IN ACUTE MYELOID LEUKAEMIA CHARACTERISED HUNDRED OF NOVEL SMALL RNA MOLECULES

S Debernardi, J Wang, J Marzec, F Manodoro, C Mein, A Curtotti, B Young

Queen Mary University of London/Barts Cancer Institute, London, United Kingdom

Background. Despite many years of clinical research into the treatment of acute myeloid leukaemia (AML), there is still a real need for new therapeutic targets. Because of their regulatory role in gene expression, microRNAs (miRNAs) and other small non-coding (snc)RNAs could potentially be exploited in clinical treatment regimes. However, a deeper understanding of their role in AML needs to enable this. It was recently established by real-time PCR that the expression level of miRNAs provides molecular signatures characteristic of the major translocation-mediated gene fusion events in AML. However the results were restricted to a fraction of known miRNAs. *Aims*. This study aims to systematically characterise the whole small RNA transcriptome in AML. This includes the quantification and the discovery of novel tumour associated miRNAs and sncRNA species, including edited molecules, relevant to the occurrence, development and management of the disease. *Methods.* We report the results of high-throughput clonal sequencing (Solexa-Illumina) of 38 libraries of size-fractionated RNA obtained from 36 cytogenetically and clinically distinct cases of AML and 2 normal bone marrow from healthy donors. Sequences were aligned to the genome of reference (NCBI36/hg18) and to miRNA and sncRNA databases (MiRBase and fRNAdb) using Novoalign. A location was recorded where >=2 reads mapped in any sample. The distribution of sncRNAs and miRNAs was determined for each sample. MiRDeep and snoSeeker were used to identify potential novel miRNA and small nucleolar RNA (snoRNA) candidates, respectively. *Results.* We detected the expression of 765 known miRNAs and 684 uniquely located species of sncRNAs, including small nuclear (sn)RNAs, piwiRNAs, Y-RNAs, and small nucleolar (sno)RNAs. MiRNAs and other sncRNAs accounted for 53.8% and 21% of total reads, respectively. Alignment of the sequence to the hairpin miRNA database confirmed the presence of 144 miRNA star (*) not yet reported in the miRBase database. Approximately 3.7% of total reads were from unknown tags and were investigated for novel miRNA and sncRNA species. A total of 575 potential miRNA candidate hairpins were identified. Of these, 126 were located in exonic regions of the genome. We also identified 37 C/D Box and 51 H/ACA Box, potential novel snoRNAs. In general, the novel sncRNAs were expressed at a low level compared with the already known molecules. ANOVA test applied to the 38 AML samples in order to find miRNAs with statistically significant differences in expression level among the major cytogenetic groups identified 177 miRNAs passing a 0.5% false discovery rate (FDR) filter. These included 70% of miRNAs at 14q32 imprinted region in t(15;17) AMLs. *Summary/Conclusions.* High-throughput sequencing revealed a complex distribution of small non-coding RNAs, including the detection of new hairpin molecules, in cancer cells. Also it provided the small RNA expression pattern in AML. Further investigations, especially in the role of snoRNAs, may uncover novel aspects of the disease aetiology.

[9]*Inserm U1016 CNRS UMR 8104, University Paris Descartes, Paris, France*
[10]*Service de Maladies du Sang, CHU d'Angers, Angers, France*

Background. TET2 mutations were recently involved in 20-26% of MDS, in 12% of MPN and in 10-17% of AML. The impact of TET2 mutations is not fully examined in secondary AML (SA) which encompass myelodysplasia-related changes (MRC) AML and therapy-related (TR) AML according to the WHO classification *Methods.* In this study, we have collected bone marrow samples from 247 patients at diagnosis identified as SA. We have determined the status of TET2 gene together with other genes frequently mutated in AML (IDH1, IDH2, NPM1, FLT-3, N and K-RAS, c-KIT). *Results.* The cohort of 247 samples was subdivided in 201 MRC AML and in 46 TR AML. A normal karyotype (NK) was found in 70 patients (39.5%). 69 abnormalities of the TET2 sequence were found and dispatched among 49 patients corresponding to 19.8% of patients with at least one TET2 mutation. TET2 mutations are significantly more frequent in MRC AML (22.3%) than in TR AML (8.7%) (P=0.03). The SA patients harbouring a TET2 mutation are significantly older and present higher levels of hemoglobin and leukocyte, involving monocytes, than unmutated patients. They also exhibit a significant lower MCV and platelets count. Percentage of blasts in the bone marrow is similar in the two groups. These particular modifications of the biological parameters are observed independently of the presence of a normal karyotype. A NK is present in 51% of TET2 mutated patients and in 23% of unmutated patients, indicating that TET2 mutations are strongly associated with NK (P<0.001). By contrast, 57% of unmutated patients versus 29% of TET2 mutated patients have a complex karyotype. IDH mutations (~14% of the whole cohort) are not mutually exclusive of TET2 mutations. No statistical association can be found between TET2 mutations and NPM1, FLT-3, N and K-RAS mutations. There is a slight increase of c-KIT mutations in the TET2 mutated group as described in mastocytosis. In 158 patients receiving intensive chemotherapy at diagnosis, the complete remission rate and the overall survival are identical in the TET2 mutated and unmutated groups. *Conclusion.* TET2 mutated SA at diagnosis present particular clinical and biological characteristics but no association with markers of poor prognosis as complex karyotype or FLT-3 mutations. TET2 mutations have no impact on survival.

0030

DELETION OF THE TUMOR SUPPRESSOR GENE NF1 OCCURS IN 5% OF MYELOID MALIGNANCIES AND IS ACCOMPANIED BY A MUTATION IN THE REMAINING ALLELE IN 56% OF CASES

C Hepperger, V Grossmann, A Kohlmann, S Schindela, W Kern, S Schnittger, T Haferlach, C Haferlach

MLL Muenchner Leukaemie Labor, Muenchen, Germany

Background. Alterations of the RAS pathway play an important role in the pathogenesis of myeloid malignancies and occur either by activating mutations in RAS itself or by mutations in genes involved in RAS-dependent pathways such as FLT3, KIT or CBL. The NF1 gene encodes neurofibromin 1 and is a negative regulator of RAS signaling. *Aims/Methods.* In order to analyze the role of NF1 in adult AML, we first evaluated NF1 gene expression in 272 AML using microarrays (HG-U133 Plus 2.0, Affymetrix, Santa Clara, USA). These included cases with t(15;17) (n=15), t(8;21) (n=16), inv(16) (n=7), t(11q23)/MLL-rearrangement (n=10), inv(3)/t(3;3) (n=3), complex karyotype (n=47), normal karyotype (n=97), and with various other genetic abnormalities (n=77). *Results.* The median NF1 expression intensity was 131.6. 68 cases showed an expression intensity of NF1 below 98.6 (first quartile, low expression group). In this cohort cases with t(8;21) (n=10) or complex karyotype (n=18) were over-represented (Chi-square: p<0.0001 and p=0.021, respectively), while cases with normal karyotype (n=16) were under-represented (Chi-square: p=0.016). Low NF1 expression could be due to a deletion of one NF1 gene copy. Therefore, we performed FISH analysis using a NF1-probe in 54/68 of cases with low NF1 expression with available material. In 11/54 of these cases (20.4%) a NF1 deletion was identified by FISH. Chromosome banding analysis in the 11 cases with NF1 deletion revealed a complex karyotype (n=7, one of theses cases with inv(3)), a normal karyotype (n=2), an inv(3) (n=1), and a 5q-deletion accompanied by +21 (n=1), respectively. To further investigate the incidence of NF1 deletion in myeloid malignancies 889 additional patients were analyzed by FISH for NF1 deletion. A heterozygous NF1 deletion was observed in 46/889 (5.2%) patients. In detail, 23/315 (7.3%) de novo AML, 3/72 (4.2%) s-AML, 4/25 (16%) t-AML, 7/176 (4.0%) CMML, 2/165 (1.2%) MDS, and 7/136 (5.1%) MPN showed NF1 deletions. Chromosome banding analysis in the NF1-deleted cases revealed a normal karyotype (6/509; 1.2%), an inv(16)/t(16;16) (6/37; 16.2%), an inv(3)/t(3;3) (3/27; 11.1%), a complex karyotype (n=19/62; 30.6%) or other abnormalities (12/162; 7.4%). The frequency of NF1 deletions was remarkably high in patients with inv(16)/t(16;16) and inv(3)/t(3;3) (6/37 cases (16.2%) and 3/27 cases (11.1%), respectively), both subgroups are known to be associated with NRAS mutations. The frequency of NF1 deletions in patients with complex karyotype was 30.6% (19/62) and in patients with normal karyotype 1.2% (6/509). Further, next-generation deep-sequencing (454 Life Sciences, Branford, CT) was used to study molecular NF1-mutations in 32 patients with NF1 deletions. In 18 cases (56.3%) a NF1 mutation was detected. *Conclusions.* NF1 deletions occur in 7.3% of de novo AML, 4% of CMML, 1.2% of MDS and 5.1% of MPN and therefore are a frequent and important alternative genetic mechanism for activating the RAS pathway in adult myeloid malignancies. Furthermore, in 58% of cases with NF1 deletion as detected by FISH a NF1 mutation was observed in the remaining allele. Future studies are necessary to determine the prognostic impact of NF1 deficiency either caused by downregulation, deletion and/or mutation in the various subtypes of myeloid malignancies.

0031

NPM1 DELETION/HAPLOINSUFFICIENCY IS A FEATURE OF MYELOID LEUKEMIAS WITH HIGH RISK CYTOGENETICS

Background. We previously identified heterozygous *NPM1* exon 12 somatic mutations in approximately 60% of adult acute myeloid leukemia (AML) with normal karyotype (NEJM 2005). The unmutated allele was never deleted in AML mutated cases. *NPM1* haplo-insufficiency leads to genomic instability and causes bone marrow dysplasia in mice (Nature 2005). *NPM1* maps at human chromosome 5q35. *Aims.* To investigate *NPM1* haploinsufficiency in human myeloid leukemias with complete or partial loss of chromosome 5 (-5/5q-). *Methods.* A total of 213 bone marrow or peripheral blood samples were studied from 120 females and 93 males (age range 9-94) with myeloid leukemias and -5/5q- or not. Findings from 145 cases have already been published (PLoS One 2010). The other 68 cases [39 myelodysplastic syndrome (MDS), 27 AML, and 2 primary myelofibrosis (PMF)] belong to a consecutive prospective series of cases that were analyzed in our laboratory from January 1st 2007 to January 31st 2011. Cytogenetically, 65/213 cases had isolated 5q-; 127 cases had a -5/5q- plus one or more changes; 21 cases had a complex karyotype without -5/5q-. To investigate *NPM1*/5q35 we used interphase FISH with clone RP11-117L6 encompassing the entire gene. *TP53*, *ATM*, and *XRCC2* deletions were investigated by FISH with RP11-199F11 clone, LSI p53/LSI ATM (Vysis, Abbott), and CTD-2326K14. In 31 retrospective cases with *NPM1* deletion exon 12 mutations of the residual allele were investigated by direct sequencing. *Results. NPM1* heterozygous deletion was found in 58 cases: 56/127 (44%) with non isolated -5/5q- and 2/65 (3%) with isolated 5q- (P=0.000). According to *NPM1* status, cases with non-iso-

lated -5/5q- were grouped as NPM1+/- and NPM1+/+. A diploid karyotype was present in 2/56 NPM1+/- (3.5%) and in 23/71 NPM1+/+ (32.3%) (P<0.001). Significantly more monosomies were found in the NPM1+/- subgroup (median: 3, range: 0-9 vs median: 2, range:0-7) (P=0.009). Gross chromosomal changes, i.e. markers, rings, and double minutes, were found in 43/56 NPM1+/- (76.7%) and in 33/71 NPM1+/+ (46.4%) (P=0.0005). Distribution of events involving *TP53*/17p13, *ATM*/11q23 or *XRCC2*/7q36 was not significantly different in NPM1+/+ and NPM1+/- subgroups. No cryptic deletion emerged in cases with complex karyotype without -5/5q-. *Summary/Conclusions. NPM1* deletion/haploinsufficiency clearly emerged as a feature of over 40% of human myeloid leukemias associated with high risk cytogenetics including -5/5q-., with the incidence reaching 41.9% in the prospective series of 68 cases. NPM1+/- cases showed a significantly higher prevalence of monosomies and gross chromosomal changes, suggesting that in humans, as in mice, *NPM1* haploinsufficiency was related to genomic instability independently of TP53. AML/MDS associated with *NPM1* deletion/haploinsufficiency are strikingly different from the karyotypically stable, low-risk AML associated with *NPM1* heterozygous mutations. Accordingly *NPM1* sequence mutation and deletion are mutually exclusive.

REACTIVATING PP2A BY FTY720 AS A NOVEL THERAPY FOR AML WITH C-KIT TYROSINE KINASE DOMAIN MUTATION

Y Yang, S Huang, X Li, Q Huang

Union hospital, Wuhan, China

Background. C-KIT is a type 3 receptor tyrosine kinase. Its tyrosine kinase domain (TKD) mutations are associated with poor prognosis in acute myeloid leukemia (AML). The most frequently occurred C-KIT/TKD mutation in AML is D816V. Protein phosphatase 2A (PP2A) is a human tumor suppressor and its dysfunction might contribute to malignant cell behavior. As far as we know, PP2A activity status in AML subgroups harboring C-KIT/TKD mutation has not been demonstrated. FTY720 shows promising preclinical activity in patients with refractory CML, while its role in C-KIT/TKD AML remains to be elucidated. *Aims.* To investigate PP2A statues in C-KIT/TKD AML and develop FTY720 as a novel therapy for C-KIT/TKD AML. *Methods.* Eight AML patients harboring C-KIT/D816V and twelve AML patients harboring wide-type C-KIT (C-KIT/WT) were recruited and informed consent at Union hospital of Wuhan in this study. Real-time quantitative PCR was used to identify C-KIT/WT and C-KIT/D816V. PP2A activity in the peripheral blood mononuclear cell of patients was assayed with a PP2A Immunoprecipitation Phosphatase Assay Kit. Furthermore, primary AML cells and cell lines were treated with FTY720 alone or combined with specific PP2A inhibitor okadaic acid (OA) in culture. Cell growth was assessed using the CCK8 Kit. Cell apoptosis was analyzed by flow cytometry after dual staining with annexin V/ propidium iodide. Western blotting was used to analyze the protein changes. All experiments were repeated three times. Statistical analysis was performed using SPSS 17.0. *Results.* PP2A activity was significantly decreased in AML subgroups harboring C-KIT/D816V mutation compared with C-KIT/WT AML (P = 0.043). In addition, FTY720 induced toxicity in all AML cells, including Kasumi-1, HL60 harboring C-KIT/WT and primary cells from AML patients in a time- and dose-dependent manner. PP2A inhibitor OA rescued these cells from FTY720-induced apoptosis. Furthermore, Increased PP2A activity was detected after FTY720 treatment. When cells were pretreated with OA, PP2A activity was partially rescued. Finally, PP2A expression remained unchanged after FTY720 treatment. Our results strongly suggested that FTY720-induced cytotoxicity was mediated by PP2A activation without altering its expression. Interestingly, it was observed that cells harboring C-KIT/TKD mutation were more sensitive to this agent (IC50: 13.5 μM VS 20 μM, P< 0.05). *Conclusions.* From the standpoint of prevalence, PP2A activity is decreased in patients with C-KIT/TKD AML. Our study also provides evidence for the PP2A-dependent toxicity of FTY720 in AML cells, and these effects of FTY720 appear to be most marked in C-KIT/TKD AML where conventional chemotherapeutic approaches are most likely to fail. The significant preclinical efficacy of FTY720 indicates that it may be valuable therapeutic agents for refractory C-KIT/TKD AML.

GLOBAL DNA METHYLATION ANALYSIS OF ACUTE MYELOID LEUKAEMIA REVEALS LEUKAEMIA-SPECIFIC AND SUBTYPE-SPECIFIC PATTERNS ASSOCIATED WITH GENE PROMOTERS, CPG ISLANDS AND REPEAT ELEMENTS

M Saied,[1] S Khaled,[1] T Down,[2] J Marzec,[1] S Derbernardi,[1] M Raghavan,[1] B Young[1]

[1]*Barts Cancer Institute, London, United Kingdom*
[2]*Thomas Down, Cambridge, United Kingdom*

Methylated DNA immunoprecipitation followed by high-throughput sequencing (MeDIP-seq) of 12 acute myeloid leukaemia and 4 normal bone marrows has been performed. An ethical approval has been obtained for this study. This revealed 18,081 regions of the genome that exhibit differential levels of methylation between leukaemia and normal bone marrow ($p < 0.05$). Such differentially methylated regions (DMRs) included not only certain gene promoters, gene bodies, CpG islands, CpG island shores but also members of the LINE and SINE repeat families. The majority of regions exhibited hypermethylation in leukaemia, with a smaller number exhibiting leukaemia associated demethylation. The gene promoters methylated in leukaemia included previously identified genes e.g. MYOD1, ID4, DCC but also revealed potentially important novel methylation targets e.g. DPP6, CASP7, TERT. The following karyotypic AML subtypes were included in the analysis t(8;21), t(15;17), +8 and normal karyotype. It was also possible to identify regions exhibiting strong subtype specificity, including certain gene promoters, gene bodies, CpG islands, CpG island shores especially in t(8;21) subtype. Additionally clear subtype specificity was found in the methylation of members of the LINE and SINE repeats families. Confirmation of these data was obtained by pyrosequencing analysis of chosen regions in 63 additional AML samples. Gene expression profiles were available for certain of the AMLs analysed by MeDIP-seq. We were therefore able to demonstrate negative correlation between gene expression and corresponding methylation of promoter, CpG islands and CpG island shores (1-3KB from transcriptional start site) in a direct manner ($p < 0.0001$). However, gene body methylation was insignificant to corresponding gene expression. Furthermore, we were able to demonstrate significantly different promoter methylation levels for genes up and down regulated in t(8;21) and normal karyotype AMLs ($p = 0.005$, $p = 0.044$ respectively). Interestingly, however, there was no significant difference in methylation levels for such genes in our t(15;17) AMLs.

[3]*Central Institute for Experimental animals, Kawasaki, Japan*

Background. Acute Myeloid Leukemia (AML) is a heterogeneous disease associated with various genetic and epigenetic abnormalities. It is characterized by the uncontrolled proliferation of myeloid blast cells blocked in their differentiation. Epigenetic abnormalities are reversible in contrast to genetic abnormalities, which are irreversible. Agreeing on these concepts it was argued that epigenetic targeting possibly would bring back the malignancy to a more normal state. 5-azacytidine (5AZA, DNA methyl transferases inhibitor) and valproic acid (VPA, Histone deacetylases inhibitor) are among the various pharmacological drugs used as epigenetic modifiers in clinics to treat AML. Based on these reports, we hypothesized that combining these drugs along with a differentiating and apoptotic agent ATRA may have good therapeutic effects in all AML subtypes including ATRA resistant AML. *Aims.* Establishment of a preclinical model for the validation of drugs in targeted therapy of AML. *Methods.* Blood and bone marrow samples from patients were collected after informed consent was obtained. CD3 negative cells were transplanted through retro-orbital sinus into male NOD/shi-SCID IL2Rg-/- (NOG) mice. AZA and VPA was injected daily for 7days and on day 8 ATRA pellet was implanted and monitored foe 21days after that mice were sacrificed. The cells were collected from bone marrow and spleen along with blood from untreated and treated mice for various assays (QRTPCR, MGG staining, immunophenotyping, FISH, culture in semisolid medium and secondary transplantation). *Results.* Treatment of xenotransplanted mice (FAB: M2, M3 and M5) with the combination AZA, VPA and ATRA, results in the progressive elimination of leukemic cells from the mice environment although. This effect is related to the differentiation of abnormal leukemic human cells, as the remaining human cells after the treatment were mature and differentiated. In case of Acute promyelocytic leukemia (APL) there was decrease in the PML-RAR transcript after treatment, clearly indicated the decrease in the leukemic blast in the mice. In addition, the treatment also leads to the elimination of leukemic stem cells as no secondary engraftment was obtained whereas the hCD45 cells from the untreated mice were successfully grafted in the 2nd generation of mice. Interestingly, with the decrease in human cells in the treated mice, there was a restoration of the mouse hematopoiesis suggesting that there is no toxic effect of the drug combination on normal hematopoiesis and the hematopoietic microenvironment. *Conclusion.* This is a useful tool to validate the real effectiveness and the presence of leukemic initiating cells after treatment. These results also show that as in a human setting an efficient therapeutic effect of this drug combination may be obtained in xenotransplanted mice. Thus provides an appropriate system to study and optimize drugs before entering to clinics. Email: patelsatyananda@gmail.com

DNMT3A MUTATIONS IN INTERMEDIATE-RISK ACUTE MYELOID LEUKEMIA

J Markova,[1] P Michkova,[1] K Michalova,[2] P Cetkovsky,[1] J Schwarz[1]

[1]*Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic*
[2]*Center of Oncocytogenetics, General University Hospital, Prague 2, Czech Republic*

Background and Aims. Recently, mutations in *DNMT3A* gene were found to cause worse survival of patients with AML. We attempted to test their impact in our patient cohort. *Patients and methods.* 163 AML patients with an intermediate-risk cytogenetic profile, diagnosed between years 1999 and 2008, were screened for the presence of mutations in *DNMT3A* gene. The male/female ratio was 74/89. The median age at diagnosis was 56.1 (18.2-81.7) years and the initial median WBC count was 23.5 x 10^9/L (0.7-483.7). RT-PCR followed by direct sequencing (exons 11-26) was used to test the presence of *DNMT3A* mutations. *Results.* 44 patients out of 163 (27.0%) carried a mutation in *DNMT3A* gene. 28 of them had a single nucleotide change at codon Arg882 (21 had Arg882His, 6 Arg882Cys and 1 had Arg882Ser). 11 patients had another missense mutation while the remaining 5 carried various frameshift mutations. The incidence of mutations was slightly higher among female patients (30.3% vs. 23.0%) and was independent of the age of patients. According to the FAB classification, *DNMT3A* mutations were most frequently present at subtypes M1 (14/37; 37.8%) and M4 (11/35; 31.4%), on the other hand, none of 9 patients with M5 subtype harbored the mutation. Occurrence of *DNMT3A* mutations was associated with the presence of *FLT3*/ITD (P=0.012). Patients with *DNMT3A* mutation had significantly higher initial WBC counts than those without it (47.5 vs. 14.6 x 10^9/L; P=0.005). This was even more evident in patients with single nucleotide change at codon Arg882 (78.7 vs. 14.6 x 10^9/L; P=0.0004). There was no difference between mutated and unmutated group in reaching complete remission (CR) (52.3% vs. 54.6%; P=0.395). Patients with any change of codon Arg882 more easily reached CR than those with any other *DNMT3A* mutation (57.1% vs. 43.8%; P=0.196). The CR rate within the *DNMT3A*-mutated group was unfavorably affected by the presence of *FLT3*/ITD (62.5% vs. 40.0%; P=0.068). Patients positive for *DNMT3A* mutation significantly more often suffered a relapse (60.0% vs. 40.8%; P=0.049). Among mutated patients, cases with Arg882 aberration relapsed less often than patients with any other mutation (33.3% vs. 57.1%; P=0.124). The overall survival (OS) was not affected by *DNMT3A* mutations (10.9 months in mutated vs. 13.6 in unmutated cases; P=0.386). Within the group of *FLT3*/ITD positive cases, *DNMT3A* mutations caused shorter OS (6.09 vs. 10.24 months; P=0.090). When *DNMT3A*-mutated cases were analyzed with respect to the *FLT3*/ITD status, those carrying both of these aberrations had significantly shorter OS than *FLT3*/ITD negative ones (6.09 vs. 18.87 months; P=0.002). Out of 20 patients harboring both of these mutations only one is still alive. Hematopoietic stem cell transplantation (HSCT) could salvage *DNMT3A*-mutated patients: 5/11 patients survive at 2 years post HSCT. *Conclusions.* We have confirmed high incidence of *DNMT3A* mutations in patients with AML with an intermediate cytogenetic risk. Patients with any mutation in *DNMT3A* gene tend to relapse more often than negative cases. Double-mutated (*FLT3*/ITD+*DNMT3A*) patients have a very poor prognosis. Patients with AML harboring *DNMT3A* mutation may benefit from HSCT.

[2]*Inserm U848, Villejuif, France*
[3]*Hopital Avicenne, Bobigny, France*

Background. Deregulated signalling via the transcription factor FOXO3a correlates with a poor prognosis in AML (Kornblau, Clin Cancer Res. 2010) most likely due to its aberrant nuclear localisation and subsequent loss of transcriptional activity. We here tested the capacity of hypomethylating agents to "correct"the pathogenetic events and correlated it with their established ability to induce apoptosis and cell cycle arrest. *Methods.* MDS (MOLM-13)- and AML- (HL-60)-derived cell lines were incubated with AZA (0,2-2µM) and DAC (0,2-2µM). The capacity of those drugs to induce apoptosis (DiOC6(3)/PI), cell cycle arrest (PI) and their impact on the expression level (immunoblot) and subcellular localization (immunoflourescence) of DDR-related proteins were concomitantly assessed. Functional relevance was determined by co-incubation with biochemical inhibitors of ATM (KU-55933), ATM/ATR (caffeine), Chk-1 (UCN-01), and Chk-2 (NSC-109555). Most important findings were recapitulated on MDS patient cells (n=7) after selection for CD34-positivity. *Results.* As previously described, both drugs induced dose- and time-dependent apoptosis and cell cycle arrest in G2/M. Noteworthy, DAC exhibit a higher capacity to induce to induce G2/M-arrest than AZA (G2/M-increase at 48h DEC: 20%). Most importantly, this increased anti-proliferative capacity was accompanied by an earlier and more efficient activation of FOXO3a (as demonstrated by a decreased phosphorylation on Ser253) and a concomitant nuclear translocation of non-phosphorylated FOXO3a. Noteworthy, this cytoplasmic-nuclear shift of FOXO3a was recapitulated in patient-derived cells responding to hypomethylating agents. Although the here assessed cohort of patients was small, the degree of Foxo3a translocation tended to augment with increased *in vitro* sensitivity to hypomethylating agents. Most importantly, in myeloid cell lines nuclear translocation of FOXO3a was accompanied by upregulation of its transcriptional

targets known to confer G2/M-arrest (p21, p27) as well as apoptosis (PUMA). To delineate the functional consequences of these observations, we recapitulated experiments in myeloid cell lines in the presence of biochemical cell cycle inhibitors. We thus show that both agents increase activation of the checkpoint-kinases-1 and -2 (phosphorylation of Chk-1-Ser317 and Chk-2-Ser68) as well as their downstream target γ-H2AX (phosphorylation on Ser139). Inhibition of ATM-mediated signalling by KU-55933 or ATM/ATR-mediated signalling by caffeine had little to no impact on AZA/DAC-induced apoptosis or inhibition of cell cycle progression, whereas inhibition of Chk-1 by UCN-01 (and to a lesser degree inhibition of Chk-2 by NSC-109555) abrogated G2/M-arrest induced by hypomethylating agents. *Conclusions.* We showed that hypomethylating agents can correct aberrant signaling pathways in MDS/AML, notably by "correcting"aberrant cytoplasmic localization of FOXO3a thereby (re-)establishing its function as a transcriptional regulator of cell-cycle-arresting and apoptosis-inducing molecules.

Background. Acute myeloid leukaemia (AML) arises from myeloid progenitor cells that are arrested at early stages of differentiation. It is a cytogenetically heterogeneous disorder with acquired recurrent chromosomal alterations detected in about 55% of adult patients, such as translocations, inversions, deletions, trisomies, and monosomies. In the remaining 45% of cases of normal karyotype AML, a number of novel molecular abnormalities have been described, such as the internal tandem duplication (ITD) or mutation (D835) of FLT3 gene, mutations of NPM1 gene, mutation of CEBPA gene and partial tandem duplication of the MLL gene. Several studies have shown that genome-wide gene expression profiling can clearly distinguish the major cytogenetic groups, so providing a better understanding of the underlying disease biology. Despite this progress, focusing on known genes will likely not suffice to uncover the molecular puzzle of AML. The integration of a whole genome approach including non-coding RNAs may lead to an improved understanding of AML biology. MicroRNAs (miRNAs) are a class of small noncoding RNAs that negatively regulate protein expression of specific mRNA by either translational inhibition or mRNAs degradation. There are several indications that miRNAs might be a new class of genes involved in human cancer and has been observed that distinct patterns of miRNA expression reflect different developmental lineage and different genetic categories of AML. I an our previous work we performed quantitative real-time RT-PCR to study the expression of 365 known human miRNA in a cohort of 29 primary selected AML characterized by common cytogenetic and molecular alterations and we identified distinctive miRNA expression patterns in some genetic groups. *Aims and Results.* According to the recent literature we found a strong up-regulation of mir-155 in normal kariotype AML carrying FLT3 mutations (Cammarata G. *et al.*, AJH 2010); so we decide to investigate expression levels of this miRNA in a larger cohort of 47 FLT3 AML patients (42 ITD and 5 D835) and 50 AML of other genetic categories. We found a 37,259 fold up-regulation of mir-155 in the first group compared to the second (P<0,0001). Several studies demonstrated that miR-155 directly repressed a broad range of target mRNAs implicated in myeloid hyperplasia and/or hematopoiesis. Using available prediction target algorithms we selected hypothetical mir-155 regulated genes such as PU.1 and CEBPβ, both genes codify for lineage specific transcription factors, indispensable for normal myeloid development. In the same cohort of 97 patients we found an inverse correlation between mir-155 expression levels and its predicted targets: PU.1 (Fold=0,471; P=0,005), CEBPβ (Fold=0,414; P=0,008). *Conclusions.* Based upon our current study, miR-155 appears to play a role in malignant haematopoiesis targeting the expression of central myeloid specific transcription factors that may contribute to block differentiation. Future functional analysis will clarify better the role of mir-155 in AML genesis and its molecular mechanism in the inhibition of myeloid differentiation

TRANSCRIPTOME-WIDE IDENTIFICATION OF RNA-BINDING PARTNERS OF THE FUS PROTEIN CRITICALLY INVOLVED IN LEUKEMOGENESIS BY THE CHROMOSOMAL TRANSLOCATION T(16;21)

I Spitzer,[1] E Larsson,[2] C Sander,[2] A Borkhardt,[1] T Tuschl[3]

[1]*Heinrich Heine University, Duesseldorf, Germany*
[2]*MSKCC / Computational Biology Center, New York, United States of America*
[3]*The Rockefeller University, New York, United States of America*

Background. The translocation t(16;21)(p11;q22) is a recurrent primary abnormality in acute myeloid leukemia (AML), joining the two proteins FUS and ERG. The FUS-ERG fusion gene occurs in 1% of AMLs and is known to be associated with young age at diagnosis and poor prognosis. *Aims.* The biological mechanism by which these oncogenes disrupt the physiological developmental program during leukemogenesis is poorly understood. While most molecular studies have focused on the fusion protein, less effort has been dedicated to the analysis of the function of wild-type FUS. Gene expression in eukaryotes is extensively controlled at the post-transcriptional level by RNA-binding proteins (RBPs) modulating the maturation, stability, transport, editing and translation of RNA transcripts. FUS represents one of the rare examples of an RBP known to be altered in AML. We thus aimed to establish the role of FUS to better understand the impact of the loss of one of its alleles in FUS-ERG positive AMLs. *Methods.* We recently developed a crosslinking technology termed PAR-CLIP (photoactivatable ribonucleoside-enhanced crosslinking and immunoprecipitation) for the transcriptome-wide identification of RBP binding sites by incorporation of the photoreactive nucleoside 4-thiouridine into mRNA of cultured cells. Using next-generation sequencing, this allows mapping the exact crosslink sites thus gaining insight into the RNA-recognition elements (RREs), the bound mRNA targets and thus the function of the studied RBP. *Results.* We have employed the PAR-CLIP method for FUS. The roughly 2,000,000 generated mRNA reads gave rise to around 30,000 clusters containing at least five reads and meeting our stringent quality criteria. We found that nuclear localized FUS predominantly binds intronic RNA segments. We identified and biochemically validated the RRE of FUS, which consists of a stem-loop opened by a non-Watson-Crick U-pyrimidine base pair and an A immediately 3' to the mispaired U in the loop region. Knockdown of FUS, despite its previously proposed function, did not significantly impact splice regulation nor alter mRNA stability in a binding-site-dependent manner. We are currently in the process of analyzing previously published genes known to be dysregulated in FUS-ERG AMLs to address the question whether FUS down regulation contributes to their dysregulation. Examples include RUNX1, CDK1, CSF3R, CD56, IL2RA and IL3RA. Additionally, we will generate expression profiles of FUS-ERG AMLs to correlate changes to our knockdown data. *Summary/Conclusions.* We did not find evidence of a suggested role of FUS in splicing regulation. Instead, its abundant, ubiquitous expression suggests a more general function in supporting basic nuclear RNA processing functions. This might implicate that the inactivation of one FUS allele amplifies the oncogenic effect of the FUS-ERG fusion, or that it possibly contributes additional oncogenic activity. Future research should not solely focus on the gain-of-function effects of the FUS-ERG fusion but rather follow a dual approach in also considering the loss-of-function effects of wild-type FUS. The latter approach can lead to the design of new inhibitors, such as RNA decoys containing a high affinity ligand for the RBP, or may identify downstream regulatory targets or pathways contributing to leukemogenesis. jessica.spitzer@med.uni-duesseldorf.de

HEAT SHOCK PROTEINS EXPRESSION PROFILE FOR AML PATIENTS REVELS A DISTINCT SIGNATURE STRONGLY ASSOCIATED WITH FLT3 MUTATION STATUS- CONSEQUENCES AND POTENTIALS FOR PHARMACOLOGICAL INTERVENTION

H Reikvam,[1] E Ersvær,[1] R Hovland,[2] K Petersen,[3] J Skavland,[4] K Hatfield,[4] Ø Bruserud[4]

[1]*Institute of Medicine, University of Bergen, Bergen, Norway*
[2]*Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway*
[3]*Department of Bioinformatics, University of Bergen, Bergen, Norway*
[4]*Institute of medicine, University of Bergen, Bergen, Norway*

Background. Acute myelogenous leukemia (AML) is a heterogeneous malignancy characterized by bone marrow accumulation of immature leukemic cells. Even though the AML cell biology has been extensively

characterized, this has not translated into new therapeutic strategies with major improvements in overall disease-free survival. Heat shock proteins (HSPs) exhibit sophisticated cellular protection mechanisms, acting as molecular chaperones that prevent the formation of protein aggregates and assist proteins in their folding to native structures. HSPs are important for the regulation and remodeling of several proteins involved in leukemogensis (e.g. several transcription factors and kinases), and especially inhibition of HSP90 now emerges as a promising therapeutic strategy. *Aims.* We hypothesized that the HSPs level varies between AML patients, and that this variation can be used for subclassification of patients with regard to responsiveness to targeted therapy. The aim of the present study was to quantify the HSP levels for a large cohort of AML patients, and to compare HSP levels and the effect of the HSP90 inhibitor 17-dimethylaminoethylamino-17-demethoxygeldanamycin (17-DMAG) in these patients. *Methods.* We included 75 consecutive patients. AML cells were isolated by density gradient separation and contained at least 95% leukemia blasts. Cell lysates were prepared from cryopreserved cells and protein levels of HSP27 (phosphor-Ser 15, phspho-Ser82), HSP40, HSP60, HSP70 and HSP90 determined by multiplex immunoassay for flow cytometric analyzes. The levels were compared with clinical and biological patient characteristics by using robust bioinformaticals tools including hierarchical clustering analyses. Functional characterization of 17-DMAG effects on AML cells included regulation of apoptosis, proliferation and release of angioregulatory cytokines. *Results.* AML cells derived from various patients differed in the expression level of different HSPs, and patients could be divided into two major clusters with low (cluster I) and high (cluster II) HSP levels. The two clusters did not differ with regard to AML etiology (de novo vs. secondary/relapse), differentiation (FAB classification, expression of CD34), cytogenetics or frequency of NPM1 mutations. In contrast, the frequency of FLT3 mutation was significantly higher in the high-HSP cluster II, thus the HSP levels are generally higher in primary AML cells with chemoresistant FLT3 mutations (p=0.0002). HSP90 inhibition showed a stronger proapoptotic effect in FLT3-ITD positive patients, whereas HSP90 inhibition had a strong antiproliferative and antiangiogenic effect in all the identified patient clusters. *Summary/Conclusions.* The HSP expression profile of primary human AML cells varies between patients, and especially patients with FLT3 mutations have special high intracellular protein levels of HSP. This is consistent with the hypothesis that HSP90 stabilizes this important oncogenic kinase. These differences may (i) be important for the responses to conventional chemotherapy and HSP90 inhibitors, or (ii) be used to identified patients with a high susceptibility to HSP90 inhibition.

DIFFERENTIAL GENE EXPRESSION IN CYTOGENETICALLY NORMAL AML WITH RUNX1 MUTATIONS IS CHARACTERIZED BY HIGH EXPRESSION OF DNTT (DEOXYNUCLEOTIDYLTRANSFERASE, TERMINAL)

P Greif,[1] N Konstandin,[1] T Herold,[1] K Metzeler,[1] P Pasalic,[1] V Jurinovic,[1] A Dufour,[1] K Spiekermann,[1] J Braess,[1] MC Sauerland,[2] B Wörmann,[3] T Büchner,[2] W Hiddemann,[1] S Bohlander[1]

[3]*Hämatoonkologische Schwerpunktpraxis, Bremen, Germany*

The AML1/RUNX1 gene is a frequent mutational target in myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML). We have screened 95 cytogenetically normal AML (CN-AML) patients for RUNX1 mutations by capillary sequencing of genomic DNA. This led to the identification of 9 patients with RUNX1 mutations (9,5%). While RUNX1 mutations were significantly associated with older age, male sex, MLL-PTD mutations and poor clinical outcome, an inverse correlation with NPM1 mutations was observed. Patients with RUNX1 mutations showed a unique gene expression pattern with differential expression of 55 genes. The most significantly upregulated gene in RUNX1 mutation positive CN-AML was DNTT (deoxynucleotidyltransferase, terminal) which was previously shown to be associated with poor prognosis in AML (Venditti el., Leukemia, 1998). DNTT plays a role in early lymphoid differentiation where it generates antigen receptor diversity by synthesizing non-germ line elements (N-regions) at the junctions of rearranged Ig heavy chain and T cell receptor gene segments. Thus, high expression of DNTT in RUNX1 mutated AML might indicate abortive lymphoid differentiation during leukemogenesis in these patients. Interestingly, 21 out of 55 differentially expressed genes were reported to be also deregulated in RUNX1 mutated AML M0 (Silva *et al*., Blood, 2009) indicating that the expression of these genes is very likely to be influenced by RUNX1 mutations. These findings provide insights into the pathogenesis of RUNX1 mutation positive AML and may contribute to the identification of novel diagnostic markers and targets for therapy.

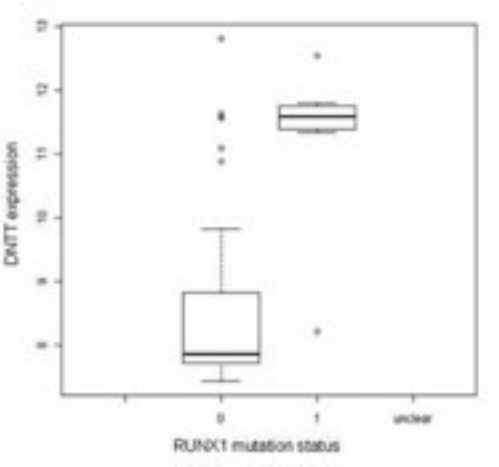

Figure 1. DNTT-Expression in RUNX1 wt vs RUNX1 mutated AML.

0041

THE DEACETYLASE INHIBITORS DACINOSTAT AND VORINOSTAT INHIBIT SELF-RENEWAL AND REPOPULATION CAPACITY OF AML1/ETO- AND PLZF/RARA-EXPRESSING MURINE STEM CELLS

A Romanski, K Schwarz, A Vogel, J Roos, C Oancea, M Keller, S Wietbrauk, H Serve, M Ruthardt, G Bug

Klinikum der Johann Wolfgang Goethe Universität, Frankefurt, Germany

Background. Deacetylase inhibitors (DACi) are promising drugs leading to growth inhibition, cell cycle arrest, premature senescence and apoptosis in malignant cells. In acute myeloid leukemia, the most primitive population of leukemic stem and progenitor cells (LSC) are thought to account for relapses of the disease. As the efficacy of a DACi therapy depends on its capacity to eradicate the LSC compartment, we aimed to study function and gene expression in response to DACi treatment. *Aims.* Aim of our study was 1) to analyze the impact of an *in vitro* treatment with various DACi on the proliferation and self-renewing capacity of normal and leukemic stem cells and 2) to assess DACi-induced regulation of genes involved in survival of leukemic progenitor cells. *Methods.* Murine Sca1+/lin- hematopoietic stem cells (HSC) were retrovirally infected with AML1/ETO and PLZF/RARα known to induce an acute leukemia in C57BL/6N mice. Serial replating and day 12 spleen colony-forming unit assays (CFU-S) were performed to assess the impact of DACi on the functional capacity of LSC. For gene expression studies PLZF/RARα-, AML1/ETO- and mock-transduced 32D cells were analysed by Westernblot after treatment with valproic acid (VPA, 150µg/ml), dacinostat (2.5-20nM) or vorinostat (1 or 2µM). *Results.* Sca+/lin- HSC carrying AML1/ETO or PLZF/RARα had a serial replating capacity far exceeding that of mock infected controls (at least 6 vs. 2 rounds of plating, resp.). Of note, continuous presence of DACi in the methylcellulose resulted in a progressive loss of colony forming cells suggesting exhaustion of leukemic progenitors over time. The repopulation capacity of mock- as well as AML1/ETO- or PLZF/RARα-transduced HSC was analysed after a 7-day culture period in presence of cytokines +/- DACi. Compared to control cultures, the class I DACi VPA induced an up to 3-fold expansion whereas the more potent class I/II DACi dacinostat and vorinostat lead to a considerable cell loss by at least one log. When all the progeny grown were injected into lethally irradiated mice, the sparse dacinostat- and vorinostat-treated cells gave rise to a significantly lower number of spleen colonies compared to only cytokine-or VPA-treated controls (n=3 independent experiments). In the spleen of mice transplanted with AML1-ETO and PLZF-RARα-transduced HSC, oncogene expression was detected by qPCR. Dacinostat seemed to exert a deleterious effect on LIC, as we failed to detect an AML1/ETO- or PLZF/RARα-signal. VPA turned out to be effective in PLZF/RARα-, but not AML1/ETO-positive LIC and vorinostat gave conflicting results. In mock transfected Sca+/lin- HSC, dacinostat and vorinostat seemed to damage normal committed progenitor cells as measured by serial replating, but largely

spare the repopulating stem cell fraction responsible for establishing CFU-S. VPA significantly enhanced spleen colony formation as previously reported. Westernblot of PLZF-RARα- AML1-ETO- and Mock-infected 32D cells showed a concentration-dependent downregulation of Bmi-1 and c-myc after treatment with VPA, dacinostat and vorinostat which may have contributed to vanishing of leukemic progenitors. *Conclusion.* In summary, our data suggest that in contrast to the class I DACi VPA the potent class I/II DACi dacinostat and vorinostat inhibit both proliferation and self-renewal of LIC.

0042

THERAPEUTIC POTENTIAL OF TARGETING KEY HOXA-TALE GENES IN AML

J Dickson, K O'Hagan, D Finnegan, MF McMullin, K Mills, T Lappin, A Thompson

Queen's University Belfast, Belfast, United Kingdom

Background. HOX genes are master regulators of hematopoietic stem and progenitor cell (HSPC) development. HOX interaction with TALE (PBX or MEIS) proteins is pivotal to their function. The prevailing hypothesis is that HOX/TALE expression underlies HSPC self-renewal while dysregulated HOX/TALE expression underpins maintenance of the leukemia initiating cell. Gene expression profiling studies support this hypothesis and highlight the importance of the HOXA cluster and TALE genes in hematopoiesis and leukemogenesis. HOXA6 and HOXA9 form part of the leukemia-associated 'HOX code' identified from human samples and murine models of this disease. *Aims.* To identify and therapeutically target the AML-associated HOXA-TALE axis in intermediate subtype human AML. *Methods.* HOXA cluster and leukemia-associated TALE gene expression was evaluated in 145 favourable and intermediate AML patient samples by Affymetrix microarray and expression of the significantly different genes were confirmed by RQ-PCR assays in an independent patient cohort. Immunoprecipitation assays were used to identify HOXA-TALE protein interactions using tags in overexpressing fibroblasts and endogenous interactions were determined AML cells. HOXA/TALE was transiently silenced using Nucleofection or viruses to package and deliver shRNA to OCI AML3 (NPM1-mut) and U937 (NPM1-WT) AML cells. Viability was assessed using CellTiter-Glo® and direct cell counting whilst cell death was determined using the Caspase-Glo®assay. The proportion of cells within specific phases of cell cycle was established using FACS and propidium iodide staining. Cell responses were examined following target gene knockdown alone or in combination with chemotherapy (Cytarabine or Mylotarg). Furthermore altered gene expression was examined using the Roche AmpliChip containing 1500 leukemia-associated probesets. *Results.* HOXA1-A2, A4-A10, PBX3 and MEIS1 displayed differential ($p \leq 0.01$) expression between favourable and intermediate AML groups and confirmed an association of HOXA/TALE with nucleophosmin gene mutations (NPM1-mut) recently identified as a favourable prognostic marker in AML. HOXA-PBX3-MEIS1 protein interactions were identified in AML cell lines suggesting functional relevance of these complexes for which silencing may alter cell survival. HOXA9 is an established oncogene and HOXA6 was identified as the most consistently and highly expressed 'HOX code' gene in 318 AML samples by microarray thus these HOXA and their TALE partners were selected for further study. Specific shRNAs were transiently transfected into OCI AML3 and U937 cells and knockdown was validated by RQ-PCR and western blotting where compatible antibodies were available. Preliminary data indicate that HOXA6, HOXA9, MEIS1 and combined HOXA6/HOXA9 silencing greatly reduced cell growth compared to controls and was additive with chemotherapies at IC50 values used in treatment of AML. Furthermore altered expression of cell cycle-associated and adhesion-associated genes was identified in the HOXA knockdown cells by microarray. *Summary.* HOXA/TALE knockdown impairs growth and sensitises cells to chemotherapy independently of NPM1 mutation status. *Conclusion.* These findings suggest silencing of clinically significant HOXA cluster genes and their critical co-factors or modulation of downstream pathways could offer a novel strategy in the treatment of AML.

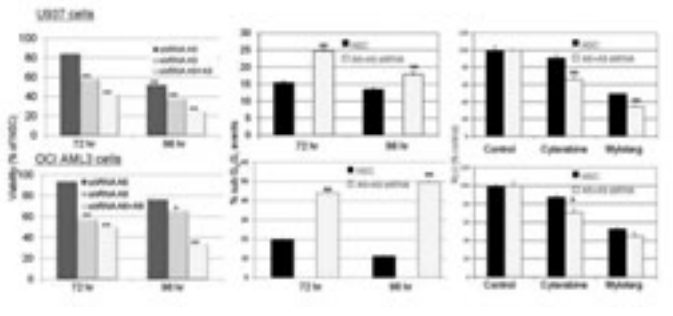

Figure 1. Reduced HoxA6/A9 +chemotherapy reduces cell growth.

0043

THE ROLE OF CYSTEINE PROTEASES IN PAEDIATRIC LEUKAEMIA

J Fisher, S Prall, F Ponthan, O Heidenreich

University of Newcastle upon Tyne, Newcastle, United Kingdom

Background. Calpains and cathepsins are cysteine proteases known to be expressed in ALL and AML. We have previously shown that treatment with Calpain Inhibitor III (*MDL28170*) reduces cell viability and clonogenicity in a dose-dependent manner, demonstrating a more potent effect in cells carrying the AML1/MTG8 fusion gene (Kasumi-1) than in another M2 cell line (HL-60) lacking this translocation. *MDL28170* also inhibits Cathepsin B and Cathepsin L. These lysosomal enzymes are both involved in the regulation of apoptosis, cell adhesion and cell cycle control. They are highly expressed in many malignant cell types and their secretion has been identified as being an important mediator of solid tumour invasion and metastasis. The intracellular roles of these cathepsins and their effects in leukaemia are less well understood. *Aims.* We aimed to identify which calpains and cathepsins are important in leukaemic maintenance and to functionally analyse their roles. We aim to test and validate these proteases as potential drug targets. *Methods.* Specific inhibitors of cathepsin B (*CA074Me*), Cathepsin L (*Cathepsin L inhibitor 3*) and Calpain 1&2 (*PD150606*) were chosen in addition to *MDL28170* which inhibits all of the above proteases. Knockdown of cysteine protease expression was achieved using siRNA and confirmed using RTPCR and Western Blot. Cell-cycle analysis and apoptosis assays were also performed in the presence of the inhibitors. LD50 was determined using the WST-1 cell viability assay in t(8:21)(q22;q22) positive and negative cell lines, including some bearing the t(4;11) poor prognostic marker. The effects on clonogenicity of the inhibitors and of cysteine protease knockdown using siRNA were assessed. *Results.* Calpain and cathepsin inhibition has a dose-dependent cytotoxic effect in the AML and ALL cell lines tested. The effects of simultaneous calpain, cathepsin B and cathepsin L inhibition using *MDL28170* are more pronounced than those seen when inhibitors meant to target specific cysteine proteases are used. Cathepsin inhibitors have a greater cytotoxic effect than calpain inhibitors. *MDL28170*, *CA074Me* and *Cathepsin L Inhibitor 3* have a greater effect on Kasumi-1 clonogenicity than calpain inhibition in isolation using *PD150606*. Knockdown of the calpain small subunit and Calpain-2 using siRNA also reduced clonogenicity of Kasumi-1 cells by up to 80%. *Summary/Conclusions.* In summary, we show that calpains are important mediators of leukaemic maintenance and clonogenicity. In addition, Cathepsins B and L are play a role in proliferation, clonogenicity and survival of AML1/MTG8 expressing cell lines and other leukaemic populations. Further functional analysis is ongoing to examine the potential links between these pathways.

ROLE OF DEATH CELL-RECEPTORS PATHWAY IN APOPTOSIS INDUCED BY THE HISTONE DEACETYLASE INHIBITOR SODIUM BUTYRATE IN NPM1-MUTATED AML CELLS

MP Martelli, I Gionfriddo, F Cecchetti, R Rossi, F Mezzasoma, V Pettirossi, B Falini

Hematology, Perugia, Italy

AML carrying NPM1 mutations [Falini B *et al.*, NEJM 2005;352:254-266] accounts for about one-third of adult AML, shows distinctive biological and clinical features [Falini B *et al.*, Blood 2007;109:874-885] and has been included as a provisional entity in the 2008 World Health Organization (WHO) classification of myeloid neoplasms. In spite of the relatively good prognosis of NPM1-mutated AML, there are still cases that show poorer outcome, especially those associated with FLT3-ITD mutation and elderly patient population. Therefore new therapeutic strategies need to be explored. Here, we investigated the effect of sodium butyrate, a short-chain fatty acid which has long been known to be a histone deacetylase inhibitor (HDACi) able to induce maturation in normal and tumor cells, in cellular models of NPM1-mutated

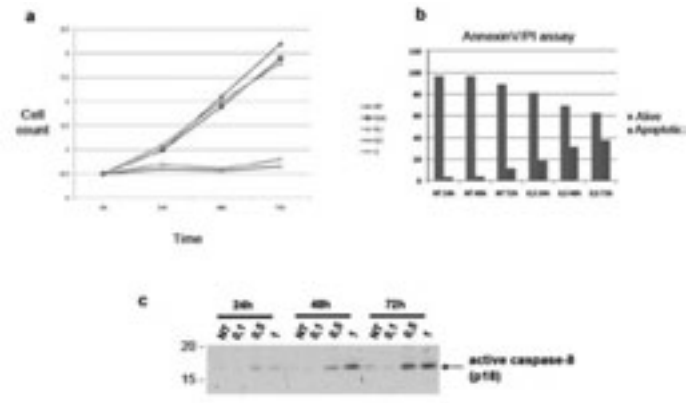

Figure 1.

AML: i) the OCI/AML3 cell line, previously identified as a human AML cell line carrying cytoplasmic mutated NPM1 in the absence of FLT3-ITD; ii) primary AML cells originated from a patient with NPM1-mutated AML bearing FLT3-ITD mutation (MONT1) and propagated as cell line in NOD/SCID mice; and iii) primary AML cells from 4 NPM1-mutated AML patients at diagnosis. In either cell lines or patients' primary AML cells carrying NPM1 mutation, but not in the U937 or OCI/AML2 cell lines (not harboring NPM1 gene mutation) used as control, growth arrest and pro-apoptotic effects were evident after 24 hrs and marked after 48 hrs of treatment with doses of drug of 0.5-1 mM (Figure 1a and b). In particular, no signs of differentiation were evident at morphological examination of treated cells. Interestingly, induction of apoptosis was associated with activation of caspase-8 (Figure 1c), suggesting involvement of the death cell receptors pathway. Indeed, flow cytometric analysis showed increased expression of TRAIL-receptor DR5 upon drug treatment. Moreover, concomitant treatment with a specific caspase-8 inhibitor prevented cell growth arrest and markedly reduced apoptosis. Levels of either NPM1 mutant or wild-type protein did not appear significantly affected by treatment with sodium butyrate. Further studies are needed to further characterise the molecular mechanisms of sodium butyrate-induced apoptosis in NPM1-mutated AML cells.

2(β-PIPERIDINO-ETHYL)9-HYDROXYELLIPTICINIUM BICHLORIDE (ELP10) EXHIBITS ANTI-LEUKEMIC ACTIVITY IN VITRO AND IN VIVO

S Boehrer,[1] S Lebel-Binay,[2] F Pitre,[2] JL Labernardière,[2] S Thepot,[3] E Lainey,[3] C Bouteloup,[3] M Sebert,[3] L Ades,[1] C Gardin,[1] C Auclair,[2] P Fenaux,[1] G Kroemer[3]

[1]*Hôpital Avicenne, Bobigny, France*
[2]*BioalliancePharma, Paris, France*
[3]*INSERM 848, Villejuif, France*

Background. ELP10 is a 9-hydroxyellipticine derivative namely 2(β-piperidino ethyl)9-hydroxyellipticinium-bichloride. Since it was developed as an anti-cancer agent, we here assessed its anti-neoplastic efficacy with particular emphasis on its anti-leukemic activity in MDS and AML. *Methods.* To delineate the anti-neoplastic activity of ELP10, a screening of 68 NCI-listed malignant cell lines was carried out. The IC50 was confirmed by retesting the drug impact on 32 selected cell lines (solid tumors, and leukemia cell lines) by employing a sulforhodamine B (SRB) assay. The exact dose-and time-dependency of ELP10's anti-leukemic efficacy in AML-/MDS-derived cell lines was determined by assessment of apoptosis (by staining with DioC23/PI and FACS quantification at 24h, 48h and 72h) and cell cycle progression (PI staining and FACS quantification at 24h and 48h) on MDS/AML-derived cell lines (KG-1, KG-1a, HL-60, MOLM-13, Kasumi-1). Finally, ELP10's anti-leukemic efficacy *in vivo* was characterized in Balb/c mice injected intraperitoneally with L1210 or P388 murine leukemia cells and treated with increasing dosages of ELP10 (ranging from 1,6mg/kg to 50mg/kg). *Results.* In the NCI cell line bank ELP10 exhibited anti-neoplastic activity in a large series of cell lines representative of solid tumors as well as leukemias. The anti-neoplastic activity was highest in cell line models of acute leukemia, notably of AML-derived cell lines, which exhibited the lowest IC50. Confirmatory experiments in a broad spectrum of MDS- and AML-derived cell lines established ELP10's ability to induce time-and dose-dependent induction of apoptosis and cell cycle arrest in G2/M. Apoptosis- and/or cell cycle-arresting effects of ELP10 were observed - albeit to a different degree - in all tested myeloid cell lines, thus 72h of incubation of HL-60- or Kasumi-1 cells with 1μM ELP10 induced apoptosis in about 50% of cells, and increased G2/M-arrest by about 40% (24h) of cells. Finally, in Balb/c mice, ELP10 increased life-span by about 50% in P388-grafted mice, and by about 30% (low dose ELP10) to 90% (high dose ELP10) in L1210-grafted mice. *Conclusions.* These studies provide evidence for an *in vitro* and *in vivo* anti-leukemic activity of ELP10, especially in AML- and MDS-derived cells, even at low dose levels.

0046

FUNCTIONAL CHARACTERIZATION OF THE PROMOTER REGION OF EVI1 IN ACUTE MYELOID LEUKEMIA

M Maicas Irigaray, I Vazquez, A García-Sanchez, N Marcotegui, L Urquiza, X Cortes, C Vicente, MD Odero

CIMA, Pamplona, Spain

The EVI1 gene (3q26) codes for a transcription factor with important roles in development and leukemogenesis. Aberrant expression of EVI1 has been reported in patients with 3q26 rearrangements; however, about 9-20% of acute myeloid leukemia cases with no 3q abnormalities overexpress EVI1, and this is also associated with an unfavorable outcome. These rearrangements were the only known mechanism that led to EVI1 overexpression; although recently it has been described that MLL fusion proteins selectively activate EVI1 in HSC-derived MLL leukemic cells. Our aim was to functionally characterize the promoter region of the human EVI1 gene, and to identify transcription factors involved in its regulation. *Material and Methods*. Bioinformatic analysis, validation by chromatin immunoprecipitation (ChIP), siRNA analysis, and luciferase assays. *Results.* To determine the minimal promoter region, we generated seven 5'-truncation constructs of the EVI1 promoter upstream of the luciferase reporter gene. These constructs were transfected into HEK293T, HEL, HEPG2 and A549 cell lines. These experiments revealed that a 318bp region retains more than the 50% of the full length construct activity. To identify the upstream regulatory factors in this EVI1 minimal promoter region, we examined the 318bp sequence using MATCH, TFSEARCH and MatInspector softwares. Site-directed mutagenesis allowed us to define the contribution of the hypothetical binding sites found. Tansfection of the mutated constructs in the HEK293T and A549 cell lines showed a marked decrease in the promoter activity when the ELK1 and RUNX1 binding sites were mutated. ChIP in HEL and HEK293T cell lines demonstrated that ELK1 and RUNX1 bind to the proximal promoter region of EVI1. Moreover, knockdown of RUNX1 and ELK1 by siRNA caused decrease of EVI1, demonstrating their involvement in the transcriptional regulation of EVI1. Taking together, this approach allowed us to identify a functional region of 318bp in the proximal promoter region of EVI1, with several binding sites for transcription factors with important roles in hematopoiesis. These results also showed that RUNX1 and ELK1 regulate the transcription of EVI1. Further studies to confirm the role of the transcription factors RUNX1 and ELK1 in acute myeloid leukemia cases with overexpression of EVI1 are in progress. E-mail address: mmaicas@alumni.unav.es

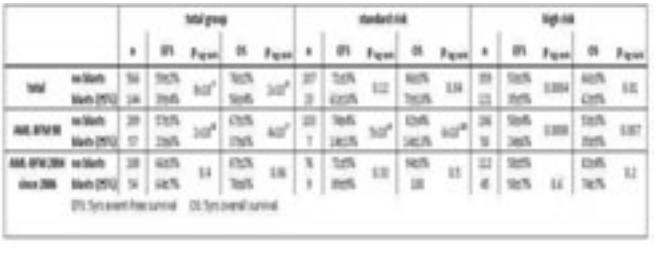
STRATIFICATION ACCORDING TO TREATMENT RESPONSE IMPROVED OUTCOME IN CHILDHOOD ACUTE MYELOID LEUKEMIA

J Ohlendorf,[1] C Von Neuhoff,[1] E Creutzig,[1] M Zimmermann,[1] A Sander,[1] U Creutzig,[2] D Reinhardt[1]

[1]*Hannover Medical School, Hannover, Germany*
[2]*University Childrens Hospital Muenster, Muenster, Germany*

Background. Treatment response is generally considered as prognostic factor; however, studies of minimal residual disease did not confirm independent significance.[1] Since 2006 the AML-BFM study group stratified poor responders after 1st and 2nd induction to intensified therapy, either an additional element or eligiblility for allogeneic matched donor stem cell transplantation (SCT). *Patients and Methods.* Sevenhundred-ten children from the German AML- BFM trials 98 (n=346) and 2004 (n=364) were included. Excluded were children with acute promyeloblastic leukemia (n=39), myeloid leukemia of Down syndrome (n=122), early death (n=35) or incomplete data (n=89). 230 children (32%) were treated in the SR-group* and 480 in the HR-group (68%). Complete remission (CR) was determined after induction, late complete remission (LCR) at the end of intensive therapy. Bone marrow smears were centrally analyzed during treatment. Immunophenotyping was performed to confirm the morphology results. In a 4-color approach, the following antibodies were used: CD33, CD34, CD2, CD7, CD56, CD15, CD117, CD123, CD13, and CD19. *Results.* A good correlation was found between morphology and immunophenotyping (coefficient Pearson 0.86). In 28% of the patients regenerating blasts could be distinguished from malignant blasts. Persistence of blasts was detected in 144 patients (20%); 53 patients showed more than 5% blasts (SR n=13, 2%, HR n=40, 5%) and 90 children more than 10% of blasts (SR n=13, 2%, HR n=77, 11%). Whereas in Study 98 only 13%of the SR patients were shifted to HR therapy, since 2006 it increased to 21%. In the HR patients with persistent blasts, SCT in 1st CR or PR increased from 22 to 33%. Vice versa, in patients without detectable blasts after 1st induction the frequency of SCT decreased from 9% to 6%. Overall, blasts persistence after 1st induction was associated with an impaired event-free and overall-survival (EFS 39±4% vs. 59±2% $p_{log\ rank}$ 8x10-7; OS 56±4% vs. 76±2% $p_{log\ rank}$ $8x10^{-7}$). This was mainly an effect by the HR-group (EFS 35±5% vs. 53±3% $p_{log\ rank}$ 0.0004; SR: EFS 61±10% vs. 71±3% $p_{log\ rank}$ 0.12). Since 2006, the prognostic significance of "blasts after 1st induction"was lost (table 1).

Table 1.



Analyzing the effect of further therapy including SCT in patients with blasts after 1st induction, in study 98 36 out of 55 patients (65%) achieved CR and 41 (75%) LCR. This significantly improved in study 2004 (CR 71%, LCR 88% and since 2006 (CR 78%, LCR 95%, p=0.007). In conclusion, using treatment response for stratification, EFS and OS could be improved in childhood AML.

Background. Panobinostat is an oral pan-deacetylase inhibitor that increases acetylation of proteins involved in cancer cell growth and survival. Preclinical studies demonstrated that panobinostat potentiates the activity of cytarabine (ara-C) and fludarabine and has synergistic activity in combination with doxorubicin in acute myeloid leukemia (AML) cells. Single-agent panobinostat has demonstrated complete responses (CR) in patients with AML in a previous phase I trial. AML is associated with poor prognosis, particularly in patients with relapsed or refractory disease. The addition of panobinostat to a chemotherapeutic regimen that is active in patients with AML who have relapsed or are refractory to prior induction therapy has the potential to improve therapeutic outcomes in this setting. *Aims.* The primary objective of this phase Ib, multicenter, open-label study is to determine the maximum tolerated dose (MTD) of panobinostat in combination with fixed dose ara-C and mitoxantrone in patients with relapsed or refractory AML by determining the incidence of dose-limiting toxicities (DLTs) within the first cycle. Secondary and exploratory objectives include safety and anti-leukemic activity. *Methods.* The study is comprised of 3 parts: 1) dose escalation to determine the MTD of panobinostat in combination with ara-C and mitoxantrone, 2) dose expansion to assess safety and preliminary activity at the MTD, and 3) optional dose extension to assess safety of single-agent panobinostat in responding patients who are not eligible for other therapies. Panobinostat was orally administered (20 mg starting dose) thrice weekly on days 1, 3, 5, 8, 10, and 12, in combination with intravenous ara-C (1 g/m^2) on days 1-6, and intravenous mitoxantrone (5 mg/m^2) on days 1-5 of a 28-day cycle. Patients receive a maximum of 3 cycles of combination therapy. Patients who are eligible for optional dose extension received single-agent panobinostat (60 mg thrice weekly). *Results.* As of February 14, 2011, 29 patients have been treated, 5 in cohort 1 (20 mg panobinostat), 7 in cohort 2 (30 mg panobinostat), 10 in cohort 3 (40 mg panobinostat) and 7 in cohort 4 (50 mg panobinostat). Safety and efficacy analyses are available for these patients. The median age was 53 years (range 19-72). All patients received prior ara-C. One DLT was observed (sepsis and tachyarrhythmia) at 40 mg panobinostat. Adverse events (AEs) were observed in 24 patients (83%). Frequent hematologic AEs included thrombocytopenia and febrile neutropenia (45% each), anemia (31%), leukopenia (27%), and neutropenia (24%). Frequent non-hematologic AEs included: nausea (69%), diarrhea (59%), vomiting (55%), decreased appetite and hypokalemia (48% each), fatigue and pyrexia (45% each). The most frequent grade 3/4 AEs were febrile neutropenia (45%) and thrombocytopenia (41%). Encouraging clinical efficacy was observed in 15 patients (52% ≥ partial response [PR]; 8 CR, 3 CR with incomplete blood count recovery, and 4 PR), particularly at higher doses of panobinostat. *Summary/Conclusions.* The combination of panobinostat with ara-C and mitoxantrone showed no unexpected toxicities with promising activity in patients with relapsed or refractory AML. The MTD has not been reached, and the study is ongoing at the 60 mg cohort of the dose-escalation phase.

Prognosis of AML patients with unfavorable cytogenetic features is poor with reported long term survival of approximately 20% despite the use of alloHSCT. So far, any modifications of induction chemotherapy did not result in improved survival. Between 2004-2008 the Polish Adult Leukemia Group conducted a randomized trial comparing standard induction (daunorubicin 60 mg/m2 for 3 days + AraC 200 mg/m2 for 7 days, DA) with the same regimen combined with either cladribine 5 mg/m2 on days 1-5 (DAC) or fludarabine 25 mg/m2 on days 1-5 (DAF). Inform consent was obtained. The goal of the current analysis was to evaluate if the addition of purine analogue affects outcome in a cohort of patients with high-risk karyotype, as defined according to SWAG criteria. Among 652 patients with newly diagnosed AML included in the PALG DAC vs. DAF vs. DA study, 111 presented with unfavorable karyotype. The median age was 50 (19-60) years. 35 patients were randomly assigned to DA arm, 35 to DAC, and 41 do DAF. In the respective study groups the rate of CR was 37%, 60%, and 54% (DA vs. DAC+DAF, p=0.05). Among CR patients 41% received consolidation followed by alloHSCT from either HLA-matched related or unrelated donor (DA, 23%, DAC 48%, DAF 45%). With the median follow-up of 2.8 yaers the 3-years probability of the overall survival was 20% for DA arm, 36% for DAC and 37% for DAF (DA vs. DAC+DAF, p=0.01) (see: figure). Leukemia-free survival equaled 45%, 31% and 56%, respectively (p=NS). No significant differeneces could be demonstrated with regard to remission duration and non-relapse mortality. All three regimens were characterized by comparable hematological and non-hematological toxicity. We conclude that the addition of purine analogue either cladribine or fludarabine to standard induction regimen based on daunorubicin combined with AraC is associated with improved survival of patients with newly diagnosed AML and high-risk karyotype. The advantage is mainly a consequence of increased rate of complete remission.

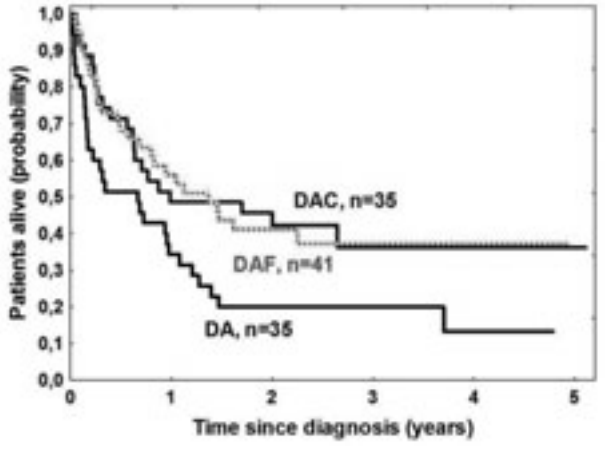

Figure 1.

[5]*CHU Lille, Lille, France*
[6]*Saint Louis, Paris, France*
[7]*Hôpital Avicenne, Bobigny, France*

Background. Older patients with AML in first relapse are frequently targeted for new drug evaluation. There are, however, few published data on their optimal management and current outcome. *Aim.* We performed an analysis of 393 patients aged 50y+ (median, 64y) with AML in first relapse after prospective inclusion in ALFA-9801/9803 trials (232/161). *Patients.* At relapse, median CR1 duration was 9 months (1-69); median WBC was 3.4 x 109/L; ECOG-PS was 2+ in 28% of the patients. Only 12 patients relapsed after HSCT. Diagnosis cytogenetics was: CBF, 16 (4%); intermediate, 240 (61%) including 173 normal karyotype (NK); adverse, 76 (19%); and not done 61 (16%). Twenty-nine of the 174 patients tested at diagnosis had FLT3-ITD (17%), while incidences of NPM1, double CEBPA, IDH1, IDH2, or WT1 mutation were 24%, 2%, 9%, 10%, and 2%, respectively. Among 86 NK-AML patients tested, 24 had a favorable genotype (NPM1 or double CEBPA without FLT3-ITD). *Results.* By physician choice, salvage was intensive chemotherapy (ICTx) in 209 (53%), low-dose cytarabine (LDAC) in 48 (12%), best supportive care (BSC) in 124 (32%), and unknown in 12 (3%) patients. Overall, CR2 rate was 30% with a significant impact of CR2 on post-relapse survival (median PRS, 16 vs 4 months; P<0.001). Duration of CR1 (<6m, 29%; 6-12m, 37%; >12m 34%) strongly influenced CR2 rate (12 vs 32 vs 47%; P<0.001) and PRS (4 vs 7 vs 11

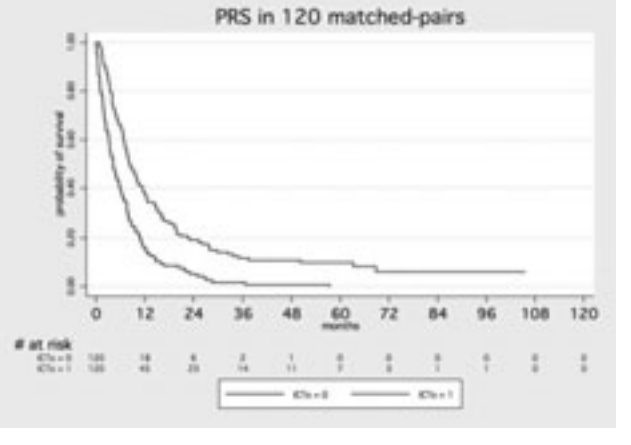

Figure 1. Post relapse Survival in 120 matched pairs.

months; P<0.001). As also expected, patients with CBF-AML had higher CR2 rate (69 vs 27%, P<0.001) and longer PRS (16 vs 6 months, P=0.02). They were not included in subsequent analyses. In patients tested, FLT3-ITD predicted shorter PRS (3 vs 7 months, P=0.03). Patients with NK-AML and favorable genotype had similar CR2 rate and PRS than other patients with normal, or intermediate, or even unfavorable karyotype. In multivariate analysis, CR1<12m (HR, 1.8; P<0.001), ECOG-PS 2+ (HR, 2.0; P<0.001), age (P=0.001), and WBC (P=0.03) predicted shorter PRS, while adverse cytogenetics and FLT3-ITD did not. Patients who received ICTx displayed higher CR2 rate (52 vs 4%, P<0.001) and longer PRS (9.5 vs 4 months, P<0.001) than LDAC/BSC patients, without significant difference in PRS between LDAC and BSC (5 vs 3 months). When ICTx vs LDAC/BSC was added in the multivariate model, ICTx (HR, 0.5; P<0.001), CR1 <12m (HR, 1.7; P<0.001), ECOG-PS 2+ (HR, 1.8; P<0.001), and WBC (P=0.006) but not age remained significant, suggesting younger age was an important decision criteria for ICTx. To further evaluate the role of intensive salvage, we performed a one-to-one matching based on the propensity score for ICTx vs LDAC/BSC calculated with the following variables: age, ECOG-PS, WBC, CR1 duration, prior HSCT, and intermediate versus adverse cytogenetics. In 120 matched-pairs, ICTx was strongly associated with longer PRS (8.1 vs 4.2 months; HR, 0.50; P<0.001). *Conclusion.* These results confirm the value of favorable cytogenetics and CR1 duration as important prognostic factors in older patients with AML in first relapse. Awaiting new effective therapies, they also indicate that ICTx salvage should be proposed each time the patient status allows it.

0051

CD34+ PEAK IN PERIPHERAL BLOOD DURING MOBILIZATION IS AN INDEPENDENT PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA PATIENTS IN 1ST CR TREATED WITH ALLOGENEIC OR AUTOLOGOUS TRANSPLANTATION

G Milone,[1] M Poidomani,[2] S Leotta,[2] A Privitera,[2] S Mercurio,[2] MA Romeo,[1] G Sortino[1]

[1]*Ospedale Ferrarotto, Catania, Italy*
[2]*BMT Program, Catania, Italy*

Ninety-six AML patients in 1st complete remission (CR) were evaluated for peak CD34+ cell levels in peripheral blood (PB) during PBSC mobilization and harvest. Distribution of CD34+ cell peaks was determined and cases were grouped on the basis of 50th and 75th percentile: Group A, those having a CD34 peak ≤70 × 109/L (n.48); Group B, those having a CD34+ cell peak between 70 and 183 × 109/L (n.24); Group C, those having a CD34+ peak >183 x 109/L (n.24). Irrespectively of post remissional treatment received, Group A had a disease free survival (DFS) of 73%, Group B a DFS of 51% and Group C of 30% (P=0.0003). In intermediate cytogenetic risk stratum, those patients treated by autologous transplantation had a DFS of 68%, 33% and 14% in groups A, B and C, respectively, (P=0.01) while after allogeneic transplantation DFS was 87% in Group A+B versus 50% in Group C,(P=0.009). Peak of CD34 in PB was selected by multivariate stepwise analysis as independent predictor for DFS while harvested number of CD34 cells and infused CD34 cell were not entered the model. Others factors important in univariate analysis were age, cytogenetic risk, FAB classification and FLT3-ITD. Peak of CD34+ cells in PB was predictor for DFS also when these factors were considered in multivariate Cox proportional hazard analysis. In conclusion peak of CD34+ cells reached after 1st consolidation cycle is a simple and reliable prognostic factors. Its clinical value should further studied and compared to others known predictors of prognosis.

Background. Recent studies on adolescents and young adults undergoing treatment for acute lymphoblastic leukemia (ALL) have shown promising results for implementation of more intensive pediatric treatment protocols in the adult setting. The comparison of treatment outcomes in young acute myeloid leukemia (AML) patients has not yet been studied as extensively. *Aim.* To investigate disease characteristics, treatment and outcome for adolescents and young adults treated for AML according to pediatric and adult protocols within the Nordic countries. *Patients/Methods.* A mainly population-based retrospective survey of all patients aged 10-18 years diagnosed with AML, according to the WHO-classification, at pediatric clinics in Denmark, Finland, Iceland, Norway and Denmark 1993-2009 and all patients 15-30 years diagnosed in adult clinics in Denmark 2000-2009, Sweden 1997-2009 and a majority of the Norwegian patients diagnosed 1996-2008 were investigated. All FAB-classes were included. Secondary leukemias and patients with Down syndrome were excluded. *Results.* 166 patients aged 10-18 years (median 13 years) with de novo AML treated according to the NOPHO 1993 and 2004 protocols were compared with 253 patients 15-30 years (median 24 years) treated in adult centres according to different national or regional guidelines. The incidence of de novo AML 2000-2009 was 5.5 per million inhabitants in the age group 10-14 years, 5.9 in 15-18 years old, and 6.2 in 19-30 years old in Sweden, the corresponding figures for Denmark were 3.9, 7.7 and 7.9, respectively. The disease characteristics differed regarding the frequency of acute

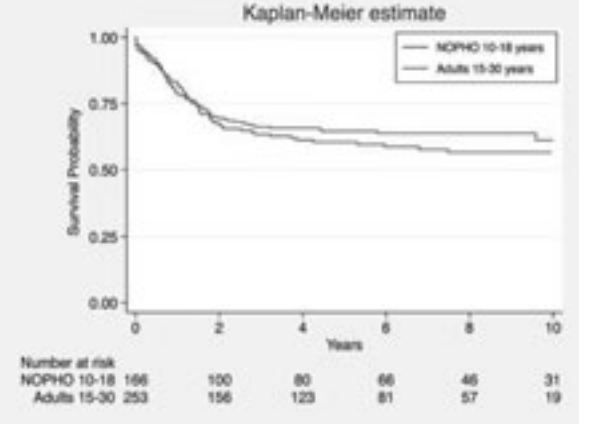

Figure 1.

promyelocytic leukemia (APL) and cytogenetic features between the cohorts. APL was more common in the adult cohort, 19.8% of adult leukemias compared to 5.4 % in the pediatric cohort. Core binding factor (CBF) leukemia was more common in the pediatric cohort 21% versus 14.2 % in the adults. Total favorable cytogenetics (defined as t(15;17), inv(16), and t(8;21)) were thus more frequent in the adult cohort with 33.2% versus 26.5%. The MLL-rearrangements, t(9;11) and 11q23, were more frequent in the pediatric cohort, 9.6%, than in the adult cohort with 6.0%. Overall survival (OS) at 5 years was similar for the pediatric and adult cohorts, 60.4% (52.2-67.7%) vs. 64.6% (58.1-70.3%). OS at 5 years excluding APL-patients was almost identical, 60.3 % (51.9-67.8%) vs.59.9% (52.4-66.5%). OS at 5 years was better, but not significantly so, for female than for male AML-patients in both cohorts; in the pediatric cohort 65.3% (59.0-75.5%) vs. 56.8% (45.8-66.4%) and in the adult cohort, 70.6% (61.6-77.9%) vs. 58.2% (48.6-66.7%). *Conclusion.* Differences in disease biology with less APL, more CBF-leukemia and more MLL-leukemia in the pediatric patients were found. No difference in outcome for AML patients aged 10-30 years, treated either in pediatric protocols or adult national/regional guidelines, was found. Age could not be shown to be an independent prognostic marker in this mainly population-based material from the Nordic countries.

0053

THE ADDITION OF LOW DOSE GEMTUZUMAB OZOGAMICIN TO INDUCTION, CONSOLIDATION AND MAINTENANCE THERAPY OF ELDERLY PATIENTS WITH NON M3 AML: UPDATE OF GENOA EXPERIENCE AND ANALYSIS OF PROGNOSTIC FACTORS

M Clavio, F Cruciani, L Vignolo, F Ballerini, C Ghiggi, L Mitscheunig, E De Astis, C Marani, P Minetto, N Colombo, R Grasso, A Ghiso, M Bergamaschi, M Miglino, G Pica, F Galaverna, S Aquino, L Canepa, A Carella, M Gobbi

Clinica Ematologica, Genova, Italy

Background. Elderly AML patients and patients with AML evolved from MDS or therapy related (sAML) display a very poor prognosis. We showed that adding low dose gemtuzumab ozogamicin (GO) to fludarabine, Ara-C and anthracycline (MY-FLAI3) may improve DFS and OS without increasing toxicity compared to a historical cohort of patients treated with fludarabine, Ara-C and idarubicin (FLAI), (Clavio 2007). *Aims.* We updated our experience and reviewed the prognostic impact of cytogenetics and molecular biology (mutations of FLT3 and NPM genes and expression of WT1 and BAALC genes) at diagnosis. *Patients and Methods.* Eighty-five consecutive CD33+ AML patients (≥ 60 years) were treated between May 2004 and June 2010. The median age was 68 years (60-82), the karyotype was unfavourable in 21 patients (25%), intermediate in 63 (74%) and favourable in 1 (1%). Twenty-eight patients had secondary AML (33%). The induction therapy consisted of Fludarabine 25 mg /sqm, Ara-C 1 g /sqm, idarubicin 5 mg / sqm, all for 3 days, followed by GO 3 mg / sqm at day 4. Complete responders received the same regimen as consolidation therapy and started a twelve-month maintenance therapy consisting in alternating GO (3 mg/sqm) with chemotherapy (Cytarabine, 1 g /sqm every 12 hours for three times), every 3 months. *Results.* Neutrophil (N > 0.5 x 109 / l) and platelet (Plt > 25 x 109 / l) recovery required a median of 15 days (range 10-26) and 16 days (range 7-30) from the end of therapy, respectively. There were four early deaths during induction (5%). Twenty-six major infectious complications were recorded (sepsis in 15 patients, pneumonia in 3, aspergillosis in 5, other infections in 2). Non-haematological toxicity was very mild. In particular, none of the patients experienced grade 3 or 4 hepatic toxicity. Forty-seven patients (55%) achieved a complete remission (CR) (seven after a second induction course). No clinical or molecular parameters were significantly associated with CR rate, whereas complete remission rate was 64% and 28% in good-intermediate /poor karyotype patients, respectively (p 0.03). Median duration of CR and OS were 9 months (range 1-70) and 12 months (range 1-72), respectively; 36-month projected EFS and OS were 12% and 18%, respectively. Cox regression analysis disclosed that good-intermediate karyotype patients had a better EFS (p 0.006) and OS (p 0.002) compared to those with poor risk cytogenetics. Patients with denovo AML had a better EFS compared to patients with sAML (p 0.029). Among molecular markers only BAALC expression < 1000 affected OS, although with borderline statistical significance (p 0.05). *Conclusions.* The addition of low dose GO to induction, consolidation and maintenance therapy is well tolerated and associated with a good antileukemic activity. In elderly AML patients treated with MY-FLAI classical prognostic factors such as karyotype and clinical history (de novo vs secondary disease) appear to be more important than molecular markers.

Background. Epidemiological and clinical information on blastic plasmacytoid dendritic cell leukemia (BPDCL) are rarely reported. *Aims.* To evaluate in patients (pts) with BPDCL the clinical features, the prognostic factors, and the efficacy of treatments. *Methods.* A multicenter retrospective cohort study was carried out between January 2005 and December 2010 in 26 Italian hematology divisions. *Results.* According to WHO-2008 classification, a total of 42 evaluable cases of BPDCL were collected (M/F 31/11; median age 57 y.o., range 20-81). At diagnosis the median values of hemoglobin, white blood cell count, and platelet counts were 5.2 g/dL (range 4.5-16.6), 2.1 x 10^9/L (range 0.3-54.1), 27 x 10^9/L (range 8-428), respectively. The median bone marrow infiltration was 90%. In 92% of cases constitutional symptoms (fever, fatigue, weight loss) were present, while only 3 were asymptomatic; 33 pts (78%) had peculiar skin lesions, while lymph node and/or spleen involvements were documented in 22 (52%). Extramedullary disease was described in 5 cases and included: CNS (3), nasal cavities (1), and pleural fluid (1). In 22 pts (52%) cytogenetic study was performed, revealing an unfavourable karyotype in 9 (40%), in 6 characterized by complex chromosome aberrations. Molecular biology studies were performed in 10 pts, showing in 3 the FLT-3 ITD mutation. Forty pts received an acute leukemia-like induction therapy (2 died early, receiving only palliative treatments), that consisted of antracycline and cytarabine or equivalent (AML-like regimen) in 29 (72%), and of dexamethasone, vincristine, cyclophosphamide, metotrexate (ALL-like regimen) in 11 (28%); 1 pt received in addition radiotherapy for cutaneous localizations. Nine pts (22%) underwent allo-HSCT as part of first-line (2) or salvage treatment (7). A complete (CR) or partial remission (PR) after induction therapy was achieved in 19 (45%) and 6 pts (14%) respectively (overall response rate 59%). It were registered 8 CR and 2 PR after ALL-like regimen, and 11 CR e 4 PR after AML-like regimen, with a significant advantage for ALL-like chemotherapy (p=0.04). The median overall survival (OS) was 8 months (range 0.2-60); 22 months (range 2-31) and 8 months (range 0.2-60) in pts received ALL-like regimen and AML-like regimen respectively (p=0.05). In HSCT-pts the median OS were 31 months (range 3-60), with a significant advantage with respect to non-transplanted pts (median 6 months, range 0.2-26, p=0.004). In pts obtaining a complete remission, the median disease free survival was 9 months (range 3-60); among them 18 pts relapsed, after a median time to diagnosis of 4 months (range 1-9). As for the transplanted pts, 4 was still alive in CR at last follow up. The overall mortality rate was 43% at 6 months and 73% at 12 months. *Summary/Conclusions.* BPDCL is a

rare hematopoietic neoplasia, preferentially involving skin, bone marrow, and lymph nodes, characterized by a poor prognosis. Initial response to acute leukemia-like chemotherapy is good, but relapse occurred very rapidly after a median time of only 4 months; allo-HSCT performed in first remission may lead to long-term survivor and disease control in selected cases, but more data are needed to confirm these preliminary results.

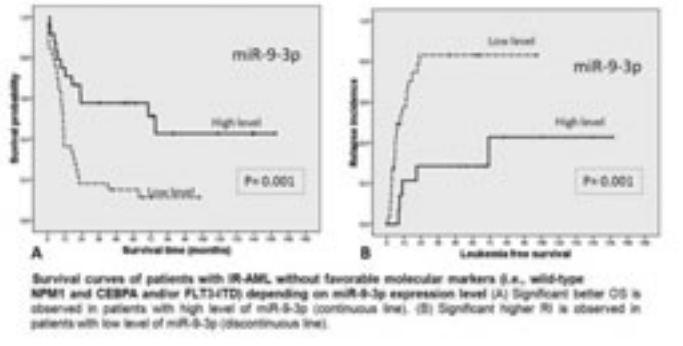
0055

THE EXPRESSION PATTERN OF MICRORNAS (MIRNA) MIGHT ADD RELEVANT PROGNOSTIC INFORMATION TO MOLECULAR CATEGORIZATION OF INTERMEDIATE RISK CYTOGENETIC ACUTE MYELOID LEUKEMIA

M Díaz-Beyá,[1] A Navarro,[2] T Diaz,[2] M Pratcorona,[3] M Rozman,[4] M Monzo,[2] J Esteve[3]

[1]*Hospital Clinic Barcelona, Barcelona, Spain*
[2]*Molecular Oncology and Embryology Laboratory, Human Anatomy Unit, Barcelona, Spain*
[3]*Hematology Department, IDIBAPS, Hospital Clinic, Barcelona, Spain*
[4]*Hematopathology Unit, IDIBAPS, Barcelona, Spain*

Background. The prognosis of AML patients within the intermediate cytogenetics category is mainly determined by the mutational status of some relevant genes, such as NPM1 mutations (NPMmut), or biallelic CEBPA mutations (CEBPAmut), associated with a favorable outcome, and with the presence of FLT3 internal tandem duplication (FLT3-ITD), which correlates with an adverse prognosis. Nonetheless, additional biological features such as miRNA expression pattern might contribute to refine prognosis and guide therapy in this setting. *Aim.* To investigate whether miRNA expression is associated with molecular characteristics and clinical outcome in intermediate-risk AML patients (IR-AML). *Methods.* We have analyzed samples from 85 IR-AML patients (median age, 52 [range, 18-71]; 52% males) who received intensive therapy from 1994 to 2009. Forty-three patients (51%) harbored NPMmut, 37 (44%) harbored FLT3-ITD (including 23 with NPMmut), and 11 (13%) harbored CEBPAmut, including 7 with biallelic mutations. The expression of 670 mature miRNAs was analyzed by multiplex Real Time PCR using TaqMan Human MicroRNA Arrays (Applied Biosystems). All PCR reactions were performed using an ABI 7900 HT sequence detection system. miRNA expression data was analyzed by the $2^{-\Delta\Delta}$Ct method, using RNU48 as endogenous control. Statistical analysis was performed with BRB Array Tools, SPSS version 15.0.1 and R software version 2.9.0. *Results.* Supervised analysis by means of t-test based on multiplex permutations (class comparisons analysis, p<0.001) revealed a distinctive miRNA signature in patients with NPMmut, with overexpression of miR-10a, miR-10a*, miR-10b and miR-196b, and downregulation of miR-126, miR126*, miR-424, miR-424* and miR-335, as well as patients with biallelic CEBPAmut, characterized by downregulation of miR-196b and upregulation of miR-181a. Response rate in this series of patients was 84%, with 5-year survival of 43±11% and relapse incidence (RI) of 55±14%. Multivariate analysis for survival identified age, absence of NPMmut, and FLT3-ITD as unfavorable variables together with low expression of miR-9-3p (p<0.001; HR=3.3, 95% CI: 1.7-6.4), and increased level of let-7a* (p=0.026; HR=5.1, 95% CI: 1.21-21.5) and miR-196b (p=0.056; HR=7.27, CI: 0.95-55.6). Concerning risk of relapse, the absence of NPMmut, FLT3-ITD and increasing leukocyte count were associated with a higher RI. Remarkably, decreased miR-9-3p expression (p=0.011; HR=3.3, 95% CI: 1.3-8.2) and miR-135a (p=0.02; HR=4.2, 95% CI: 1.2-14.2), together with higher levels of miR-23a* (p<0.001; HR=6.2, 95% CI: 2.61-14.7) were independently associated with a higher relapse risk. Of note, a decreased miR-9-3p level retained its adverse prognosis value in the subgroup of patients without favorable molecular markers (i.e., wild-type NPM1 and CEBPA and/or FLT3-ITD;p=0.001, see figure). On the contrary, let-7a* levels segregated subgroups of patients in the category of favorable genotype (i.e., mutated NPM1 without FLT3-ITD p=0.027). *Conclusions.* In this series of patients of intermediate-risk cytogenetic AML, measurement of expression levels of several miRNAs such as miR-9-3p, miR-135a, let-7a* or miR-23a* showed independent prognostic value, and might contribute to predict the outcome within specific molecular subgroups. Nonetheless, confirmation of the prognostic impact of these miRNAs and investigation of possible underlying mechanisms account for this effect require future studies.



Survival curves of patients with IR-AML without favorable molecular markers (i.e., wild-type NPM1 and CEBPA and/or FLT3-ITD) depending on miR-9-3p expression level (A) Significant better OS is observed in patients with high level of miR-9-3p (continuous line). (B) Significant higher RI is observed in patients with low level of miR-9-3p (discontinuous line).

Figure 1.

0056

EFFICACY OF HISTAMINE DIHYDROCHLORIDE AND INTERLEUKIN-2 IN MORPHOLOGIC SUBTYPES OF ACUTE MYELOID LEUKEMIA

B Thoren,[1] J Aurelius,[1] M Brune,[1] M Hansson,[2] A Martner,[1] L Palmqvist,[1] J Rowe,[3] K Hellstrand[1]

[1]*University of Gothenburg, Gothenburg, Sweden*
[2]*Lund University, Lund, Sweden*
[3]*Department of Hematology and Bone Marrow Transplantation, Rambam Medical Center, Haifa, Israel*

Background. The combination of histamine dihydrochloride (HDC) and low-dose interleukin-2 (IL-2) was recently approved in Europe as relapse-preventive immunotherapy in acute myeloid leukemia (AML). HDC has been shown to block the formation of immunosuppressive oxygen radicals in normal myeloid cells that express a radical-generating NADPH oxidase and histamine H2 receptors (H_2R). HDC thus preserves anti-leukemic functions of natural killer cells and cytotoxic T cells. *Aims.* 1) To investigate the expression of NADPH oxidase components and H_2R on leukemic cells in morphologic subtypes of newly diagnosed AML. 2) To determine the outcome of HDC/IL-2 immunotherapy in morphologic subtypes of AML. *Methods.* Flow cytometry was employed to screen freshly recovered leukemic cells from the blood or bone marrow of patients with morphologic subtypes of newly diagnosed AML and to monitor the expression of H_2Rs and the NADPH oxidase component gp91phox. Leukemia-free survival (LFS) was determined in patients receiving HDC/IL-2 or no treatment (control) in a phase III trial as described in detail elsewhere (Brune *et al.*, Blood 108:88-96). *Results.* H_2R and gp91phox were commonly co-expressed in a fraction (10-60%) of malignant cells recovered from patients with AML of M4 and M5 FAB classes. In contrast, H_2R or gp91phox were undetectable on leukemic cells from patients with FAB/M2 AML. In line with these findings, a post-hoc efficacy analysis of a phase III trial using HDC/IL-2 in AML revealed that patients with FAB/M2 AML in first CR did not benefit from HDC/IL-2 immunotherapy, even when the analysis was carried out in patients with a strong overall benefit of HDC/IL-2 (age <60, p>0.7, HR=1.14, n=41). In contrast, corresponding HDC/IL-2-treated patients with non-M2 AML displayed significantly higher LFS than control patients (52 vs. 23 % LFS at 3 years, p<0.001, HR=0.43, CI: 0.27-0.69, n=113). The LFS benefit was pronounced in patients with M4 or M5 AML (63 vs. 27 % at 3 years, p<0.01, HR=0.37, CI: 0.18-0.75, n=58). *Summary and Conclusions.* These finding imply that HDC/IL-2 immunotherapy predominantly targets monocytic forms of AML, which may be explained by co-expression of histamine receptors and gp91phox on leukemic cells of the monocyte lineage.

0057

RASGRP1/APTX RATIO STRONGLY CORRELATES WITH CLINICAL RESPONSE AND SURVIVAL IN AML PATIENTS TREATED WITH TIPIFARNIB-BORTEZOMIB COMBINATION

G Martinelli,[1] S Paolini,[1] C Papayannidis,[1] S Parisi,[1] I Iacobucci,[1] A Curti,[1] D Cilloni,[2] G Saglio,[2] A Candoni,[3] M Baccarani[1]

[1]*Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy*
[2]*Internal Medicine and Hematology, Università di Torino, Torino, Italy*
[3]*Clinica Ematologica, Azienda Ospedaliero-Universitaria di Udine, Udine, Italy*

Background. We conducted a phase I-II study aiming to assess efficacy and toxicity of tipifarnib-bortezomib treatment in elderly AML patients. RASGRP1/APTX genetic ratio, which is associated with treatment response in patients treated with tipifarnib alone, was tested.

Methods. Eighty patients were enrolled with secondary-AML: 14 had high risk cytogenetics; 42 were previously untreated. Seventy-five patients were treated. *Results.* Nine patients achieved complete remission (CR), 1 patient obtained a partial response (PR) and in 2 cases an hematological improvement (HI) was documented for an overall response rate (ORR) of 19%. Median time to response was 112 days, corresponding to 4 cycles (range 2-14). Marrow response (CR+PR) was significantly associated with overall survival (OS) (p<0.0001). RASGRP1/APTX was evaluated before treatment initiation on bone marrow (BM), peripheral blood (PB) or both. The median RASGRP/APTX value on BM was 15.3 (15-19.8) in responder patients and 2.2 (0.5-25.9) in non responders, respectively (p=0.00006). Its median value on PB was 31.6 (19.3-35.5) in responders and 6.4 (0.5-27.1) in non responders, respectively (p=0.00001). Interestingly, no marrow responses were recorded in patients with marrow RASGRP1/APTX ratio <8, while the response rate was 43% [how many were CR?] in patients with RASGRP1/APTX >8 (p<0.0001). Finally, RASGRP1/APTX levels significantly correlated with OS (p=0.001) with a median OS of 490 days and 162 days in patients with RASGRP1/APTX >8 and <8 respectively. *Conclusion*. We conclude that the clinical efficacy of the combination of tipifarnib and bortezomib was evident. We confirmed that the RASGPR1/APTX BM or PB level is an effective predictor of response and survival and our now studying the response of such patients to tipifarnib, alone.

DNMT3A EXON 23 MUTATIONS IN ACUTE MYELOID LEUKEMIA: A SINGLE CENTER EXPERIENCE

C Recher, O LaRochelle, S Bertoli, F Vergez, V Mansat- De Mas, C Demur, F Huguet, A Huynh, E Delabesse

CHU de Toulouse, Toulouse, France

Background. It has been recently shown that DNMT3A mutations are recurrent in patients with intermediate-risk cytogenetic AML and are associated with a poor outcome (Ley T *et al.*, NEJM, 2010). We have assessed the clinical characteristics and prognostic impact of DNMT3A exon 23 mutations (DNMT3Am) in a series of 210 patients treated at the Hematology department of Toulouse, France. *Aims.* To assess the prognosis impact of DNMT3Am in AML patients treated with intensive chemotherapy. *Methods.* We used a real-time High Resolution Melting (HRM) polymerase chain reaction (PCR) to identify a somatic mutation in the exon 23 of DNMT3A. Positive cases detected by the HRM analysis were sequenced to confirm the mutation. FLT3 and NPM mutations were assessed by multiplex PCR and capillary electrophoresis. We used samples from 210 AML patients (65y or younger) stored at the HIMIP cell bank in Toulouse University Hospital. Patients were treated by a "3+7"induction chemotherapy (between 01/2000 and 12/2009). Responding patients with HLA-identical sibling were allocated to allogeneic stem cell transplantation (allo-SCT) in first CR, others to autologous-SCT or high dose Ara-C. Study endpoints: complete response rate, cumulative incidence of relapse, disease-free and overall survival. *Results.* DNMT3Am were detected in 39 patients (18.6%): 17 males, median age 47y (20-62), median WBC 36.8 G/L (1.2-253), platelets (58 g/L, 8-814), FAB M1/2 (31%), M4/5 (62%), normal karyotype 25/38 (66%), intermediate Ka 37/38 (97%). As compared with DNMT3A exon 23 wild type (wt), DNMT3Am were significantly associated with both FLT3-ITD (17 FLT3-ITD out of 38 DNMT3Am, p=0.007) and NPM1 mutations (21 NPM1c/26, p<0.0001). Analysis of therapeutic outcome was performed only for patients with intermediate cytogenetic risk (n=180). The complete response rate was 31/37 (84%) in the DNMT3Am group vs 115/143 (80%) in the DNMT3Awt group (p=0.65). In CR patients, allo-SCT was performed in 37 (DNMT3Awt) and 15 (DNMT3Am) patients, respectively. With a median follow up of 24 months, we did not detect any impact of DNMT3A mutation on DFS (DNMT3Awt, median: 19.1 vs 94.7 months, DNMT3Am, p=0.15), CIR (DNMT3Awt, median: 22.8 vs 94.7 months, DNMT3Am, p=0.42) and OS (DNMT3Awt, 26.3 vs 99.9 months, DNMT3Am, p=0.3). In this series, the only significant prognostic factor for DFS and OS was NPM1 mutation. Although we did not find any impact of DNMT3Am in FLT3-ITD patients, DNMT3Am could worsen the outcome of NPM1m/FLTwt patients. Furthermore, in patients who received allo-SCT, there was a trend for improved DFS and OS in DNMT3Am patients (medians not reached) as compared with DNMT3Awt patients (median DFS, 28.4 months; median OS, 104.1 months) but the difference did not reach statistical significance. *Summary / Conclusions.* The mutation of DNMT3A exon 23 had no clear prognostic impact in AML with intermediate-risk cytogenetics. However, the favorable outcome of DNMT3Am patients after allo-SCT suggests that this therapeutic strategy could erase the prognostic impact of DNMT3A mutations. Many more patients are needed to determine if DNMT3Am could help in the refinement of therapeutic decision for patients with a favorable molecular risk (NPM1m/FLT3wt).

0059

DEVELOPING DIGITAL MRNA COUNTING AS A NEW TECHNIQUE FOR ACUTE LEUKEMIA DIAGNOSIS

Introduction. The diagnosis of malignant hematological diseases has become increasingly complex during the last decades. It is based on the interpretation of results from different laboratory analyses, which range from microscopy to gene expression profiling. Recently, a new method for the analysis of mRNA phenotypes has been developed, the nCounter technology (Nanostring® Technologies), which allows for the quantification of hundreds of mRNA molecules in biological samples. We evaluated this technique in a Swiss multi-center study on samples from acute leukemia (AL) patients. *Material and Methods.* Peripheral blood (PB) and bone marrow (BM) samples were obtained from healthy controls (5 PB, 11 BM) and from patients with AL and various other hematological diseases (38 AML, 8 ALL, 2 CML, 3 CLL, 3 MDS), and referred to the Geneva Haematology Service. 43 AL samples were obtained from other Swiss Centers. For each patient a hematological work-up was performed, including a detailed flow cytometric analysis. Leftover material was used for the quantification of a set of 85 different mRNAs using the nCounter technology. Initially, 100 ng of purified RNA from each sample were hybridized with probes specific for the corresponding 85 surface antigens, and every specific hybridization product was then quantified. Subsequently, we exploited one of the many advantages of the nCounter technology, namely the fact that crude RNA without any enzymatic treatment is hybridized, and thus used total cell lysates in the hybridization. Correlation coefficients were calculated for the most relevant 18 antigens using mRNA values (number of molecules/sample) and values obtained from flow cytometry (% of positive cells/sample, in comparison to isotype controls). *Results.* mRNA and protein profiles were established for normal PB and BM samples. Relative signal intensities and expression patterns of the various surface antigens were similar to those described in the literature and found in previously performed Affymetrix microarray analyses. Acute leukemia samples were analyzed with this validated set of antigens and the Spearman Correlation Coefficients for nCounter and flow cytometry results calculated, based on >1600 comparisons. Highly significant values between 0.4 and 0.9 were found for the 18 antigens tested. A second correlation analysis performed on a sample basis and specifically on the blast population resulted in concordant results between flow cytometry and nCounter in 54 - 100% of the antigens tested, depending on the number of blasts present and the type of leukemia (AML versus ALL). Discordant results could be attributed mainly to samples with mRNA expression but lacking expression of the corresponding protein on the cell surface, and to myeloid antigens with an already high mRNA and protein expression in normal non-leukemic samples. *Conclusion.* The nCounter allows the fast and easy establishment of a mRNA profile from hematological samples. Correlation between the values for mRNA quantity obtained by this technique and protein expression, as measured by flow cytometry, is excellent for most of the antigens tested. Potential advantages of this new technology in the diagnosis of

AL, especially of rare AL cases and in MPAL (mixed phenotype acute leukemia), will be discussed.

[3]*National Taipei College of Nursing, Taipei, Taiwan*

Background. Acute myeloid leukemia (AML) represents a clinically and biologically heterogeneous malignancy with uncontrolled proliferation of hematopoietic precursors. Although the majority (70-80%) of AML patients achieve a complete remission (CR) after induction chemotherapy, about a half of these patients relapse with a gravid prognosis. However, the genetic alterations at relapse have not been extensively studied. *Aims.* In this study, we aimed to compared the genetic aberrations between AML at diagnosis and at relapse to determine their roles in AML development and disease progression. *Methods and Materials.* Comparison of genetic alterations, including Class I mutations, such as mutations of *N-RAS, K-RAS, PTPN11, JAK-2, KIT* tyrosine kinase domain of FLT3 (*FLT3/TKD*) and internal tandem duplication of FLT3 (*FLT3/ITD*) and Class II mutations, such as mutations of *CEBPA, AML1/RUNX1,* and partial tandem duplication (PTD) of MLL as well as *NPM1* and *WT1* mutations, at relapse with those at diagnosis was performed in paired samples from 118 patients with de novo AML. *Results.* One hundred and one (85.6%) patients had at least one molecular gene mutation and 56 (47.5%) had at least two mutations at diagnosis. At relapse, 85 (72%) out of the 118 patients had at least one molecular gene mutation, and 40 patients (33.9%) had two or more mutations. Among the patients with gene mutations, concurrent Class I and Class II or Class I and *NPM1* mutations, which behave more like Class II mutations, could be demonstrated in 46.5% (47/101) at diagnosis and in 38.8% (33/85) at relapse. Mutational shifts occurred in 55 patients (46.6%). Class I mutations, which activate signal transduction, were lost more frequently (around 50%) at relapse than Class II mutations, which perturb transcription factors. Genetic evolution with acquisition of novel mutations at relapse were identified in 14 individuals (11.9 %), all involving Class I or *WT1* mutations, but not Class II or *NPM1* mutation. The patients with genetic alterations at relapse had poorer overall survival. Stepwise Cox proportional hazards modeling showed that presences of *FLT3/ITD*, *WT1*, *KIT* or *MLL/PTD* at relapse were independent poor prognostic factors. *Conclusions.* The findings from this study support the two-hit theory not only in the development but also in the progression of AML. The fact that Class I mutations are frequently lost and can be acquired at relapse, in contrast to Class II mutations or *NPM1* mutation, suggests that Class II and *NPM1* mutations may play a role as the first hit in the leukemogenesis, while Class I mutations act as the second hit. In addition, genetic alterations at relapse can predict the clinical outcome.

[5]*Division of Pediatric Hematology and Oncology, Medical University of Graz, Graz, Austria*
[6]*Institute of Human Genetics, Medical University of Graz, Graz, Austria*

Background. Therapy-related myeloid neoplasms (t-MNs) are severe long-term sequelae of cytotoxic treatments for a primary, often malignant disorder accounting for 10% of all MDS/AML cases. Increasing evidence from animal and human studies pinpoints a strong influence of genetic predisposition in the pathogenesis of these secondary malignancies. *Aims.* Cases with t-MNs frequently exhibit a remarkable family history of cancer. We therefore hypothesized that cancer predisposition syndromes are prevalent in this cohort of patients and aimed at identifying germ-line mutations in respective candidate genes. *Methods.* A "nuclear pedigree"consisting of all first- and second degree relatives was obtained from 51 adult and pediatric index patients with t-MNs and evaluated for cancer predisposition syndromes according to established criteria. In conspicuous cases, genomic DNA from cultured skin fibroblasts of t-MN patients was analyzed for deleterious germ-line mutations by PCR and direct sequencing as well as for large genomic rearrangements by MLPA. Mutations and genetic variants were classified according to public databases. Deleterious heterozygous germ-line mutations were further assessed for loss of the wildtype allele in CD34+ sorted leukemic cells by PCR, direct sequencing and SNP/CNV microarrays (Affymetrix GeneChip Human Mapping SNP 6.0 arrays), respectively. *Results.* Twenty-five of 51 (49%) patients with t-MNs had a hematological malignancy and 26 (51%) a solid tumor as primary disease. Non-Hodgkin's lymphoma (29%), breast cancer (BC) (25%) and sarcoma (8%) were the most frequent primary neoplasms found in more than 60% of all patients. Six pedigrees indicated a hereditary breast and ovarian cancer syndrome and ten a Li-Fraumeni (LF) or LF-like syndrome initiating a search for *BRCA1*, *BRCA2*, *BARD1* and *TP53* germ-line mutations, respectively. Deleterious, heterozygous germ-line mutations were found in 5/51 (9.8%) individuals: two in *BRCA1* (c.5251C>T, p.R1751*; c.3112G>T, p.E1038*), one in *BARD1* (c.1670G>C, p.C557S) and two in *TP53* (c.1146delA, p.K382fs*40; c.849-852insGGCG, p.R283fs*22). The *TP53* mutations have not been described previously. Both, *BRCA1* c.3112G>T and *TP53* c.849-852insGGCG germ-line mutations showed homozygosity in sorted CD34+ leukemic cells and SNP/CNV microarray analysis revealed loss of the wild-type allele in either case. *Conclusion.* Given the estimate that approximately 5% of cancers arise in the context of hereditary cancer predisposition syndromes, deleterious germ-line mutations are found with increasing prevalence in this cohort of t-MN patients. Preliminary data indicate that these mutations contribute to therapy-related leukemogenesis. Furthermore, our data may have clinical implications with respect to genetic counseling of these patients and their relatives.

0062

EXPRESSION PATTERN OF WT1 ISOFORMS IN PATIENTS WITH CHILDHOOD AML

K Kramarzova,[1] L Boublikova,[1] A Willasch,[2] T Lopotova,[3] J Stary,[1] K Machova-Polakova,[3] J Trka[1]

[1]*Charles University in Prague, 2nd School of Medicine, Prague, Czech Republic*
[2]*Department of Paediatric Haematooncology and Haemostaseology, Goethe University, Frankfurt am Main, Germany*
[3]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic*

Background. Wilm's tumour gene 1 (WT1) is overexpressed in a large proportion of acute leukaemias and other haematological malignancies. It has been demonstrated that WT1 protein is produced in more than 36 different isoforms. These variants have distinct, partially overlapping functions and their ratio is supposed to influence the final effect of WT1. However, only limited information on WT1 isoforms has been published so far and the relevance of their expression pattern remains unclear. *Aims.* We determined the expression pattern of four WT1 isoforms characterized by the presence or absence of exon 5 and KTS insert (A[-/-], B[+/-], C[-/+], D[+/+]) in childhood AML using a specific qPCR system. *Methods.* We designed a unique qPCR system for detection and quantification of 4 major WT1 isoforms and verified the sensitivity, specifity and reproducibility of the results in extensive testing. With this assay we analysed WT1 isoforms expression pattern in 7 leukemic cell lines (Kasumi-1, MV4;11, NB-4, REH, NALM6, UOCB6, RS4;11), diagnostic bone marrow samples of 64 children with AML and 26 healthy controls. *Results.* We found an excellent correlation between the total WT1 expression and the sum of WT1 isoforms levels (rho=0,973, p<0.0001). Analysis showed diverse expression patterns of WT1 isoforms in the particular leukemic cell lines (p<0.0001). Interestingly, we found a similar pattern of WT1 isoforms in cell lines with MLL/AF4 rearrangement, independent of the lineage (myeloid - MV4;11 and lymphoid - RS4;11). The analysis of healthy controls (bone marrow or peripheral stem cells) failed to define the physiological ratio of WT1 isoforms. Very low levels of total WT1 in these samples precluded detection of WT1 isoforms since we reached the limit of the sensitivity of qPCR method (as defined by limiting dilution experiments). For the same reason of very low total WT1 levels, 11 patients (mostly AML M5) were excluded from the further analyses. Rather surprisingly, in all analysed patient diagnostic samples (N=53) a uniform WT1 isoforms expression pattern was present (A<C<B<D) with

Exon5[+] variants overexpression. We observed a trend to a higher level of isoform C in M1 and M3 patients and PML/RARa+ patients (Kruskal-Wallis p=0.0307 and p=0.0063, respectively). *Conclusion.* This is the first report of the analysis of WT1 isoforms expression pattern in childhood AML using a unique qPCR method for the detection of WT1 variants. Although the ratio of WT1 isoforms may vary in different tissues and cell lines, our data suggest that the WT1 isoforms expression pattern is rather uniform in paediatric AML, with predominant expression of Exon5[+] isoforms and possible variations in isoform C levels depending on the morphological and genetic characteristics. Careful pre-analytical testing of the detection system parameters suggests the technical limitations in detection of WT1 isoforms in samples with very low total WT1 levels. Therefore, the previously reported differences in WT1 isoforms ratio between normal bone marrow and AML samples should be interpreted with caution.

LEVEL OF MINIMAL RESIDUAL DISEASE (MRD) AND WHITE BLOOD CELL COUNT (WBCC) DISCRIMINATE CATEGORIES OF PATIENTS WITH DIFFERENT OUCOME AMONG ADULTS WITH FAVOURABLE-RISK ACUTE MYELOID LEUKEMIA

L Maurillo, F Buccisano, MI Del Principe, C Sarlo, M Cefalo, L Ottaviani, C Ditto, G De Angelis, F Duranti, F Lo Coco, W Arcese, S Amadori, A Venditti

Policlinico Tor Vergata, Rome, Italy

Background. Core binding factor acute myeloid leukaemia (CBF-AML) and AML with mutated Nucleophosmin (NPM) without FLT3-ITD mutation are currently regarded as favourable-risk AML. Recent findings suggest a biological and prognostic heterogeneity of this AML subgroup, particularly of CBF-AML. *Aims.* The aim of our study was to assess whether MRD detection was able to identify patients with increased risk of relapse. *Material and Methods.* MRD was determined by multiparametric flow cytometry (MPFC) on bone marrow (BM) samples collected at the end of consolidation therapy. The threshold for MRD negativity was set below the level of 3.5x10e-4 residual leukemic cells. We evaluated 59 patients with de novo AML, enrolled sequentially in AML10/AML12 (n=48) and AML17 (n=11) EORTC/GIMEMA randomized trials between 1995 and 2007. In AML10/AML12 protocols, patients aged ≤ 60years received induction treatment that combined standard or high dose of cytarabine (ARA-C), according to randomization, etoposide, and anthracycline. As consolidation, all patients received intermediate dose of ARA-C and anthracycline. Thereafter, those with an HLA-compatible sibling were allografted. Patients without a donor underwent autologous stem cell transplantation (AuSCT). Patients aged > 60 years (AML17) received mitoxantrone, ARA-C, and etoposide and 2 cycles of a consolidation program consisting of idarubicin, cytarabine, and etoposide. All patients were randomized before induction, to receive or not, gemtuzumab ozogamicin, repeated on day 1 of each consolidation cycle. Median age was 48 yrs (range 18-75), 11 patients were older than 60 years, 36 were males and 23 females and 48 (81%) had white blood cell count (WBCc) <50 x 10e-9/L. Twenty-nine CBF-AML [21 with t(8;21) and 8 with inv(16)] and 30 NPM-AML were evaluated. Overall 24 patients (41%) relapsed, 3 NPM-AML patients experienced an early relapse after consolidation therapy. After first consolidation, 21 patients underwent AuSCT, 13 AlloSCT and 23 did not received any transplant procedure: 11 because of age, the remainders due to refusal or medical reasons (2 of 12 were consolidated with high dose ARA-C). *Results.* MRD positive status after consolidation (MRDpos) and WBCc ≥50 x 10e-9/L were significantly associated to relapse (p=0.017 and 0.0001, respectively). At 4 years, DFS for patients MRDneg vs MRDpos and with WBCc <50 vs ≥ 50 x 10e-9/L was 70% vs 44% and 59% vs 21% (p=0.018 and 0.011, respectively). Accordingly, cumulative incidence of relapse (CIR) at 4 years for patients MRDneg vs MRDpos and with WBCc <50 vs ≥ 50 x 10e-9/L was 21% vs 55% and 33% vs 83% (p= 0.005 and <0.001, respectively). Therefore, we identified 3 different groups of patients based on the combination of MRD status after consolidation and WBCc. At 4 years, DFS for MRDneg/WBCc<50 x 10e-9/L, MRDpos/WBCc<50 x 10e-9/L and MRDposWBCc≥50 x 10e-9/L was 77%, 49% and 15%, respectively (p=0.001) and CIR at 4 years was 12%, 47% and 90% (p<0.0001). *Conclusions.* Combined evaluation of WBCc and post-consolidation MRD status enables identification of patients at higher risk of relapse in spite of a favorable risk genetics/cytogenetics profile for whom intensification by AlloSCT should be considered.

0064

TREATMENT OF MOLECULAR RELAPSE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

M Toskova, Z Racil, D Dvorakova, M Bajerova, J Prochazkova, J Mayer

University Hospital Brno, Brno, Czech Republic

Background. Evidence for beneficial effect of minimal residual disease (MRD) monitoring and early intervention (=pre-emptive therapy) in non-APL acute myeloid leukemia (AML) pts. are very limited. *Aims.* To assess usefulness, efficacy and toxicity of various treatment regiments in the therapy of molecular relapse in non-APL AML patients. *Methods.* We have performed a retrospective analysis of molecular relapses in AML pts. with molecular target (RUNX1-RUNX1T1, CBFB-MYH11, MLL fusion and NPM1) and its treatments. RQ-PCR was used for the MRD monitoring. Molecular relapse was defined as confirmed reappearance of the fusion transcript or mutated gene detection or its 10-fold increase in pts. with persistent positivity and corresponding bone marrow cytology, immunophenotype and cytogenetic analysis remained negative. *Results.* In the study period 1/1/2003 - 31/12/2010 we have treated 30 molecular relapses in 19 pts. Median follow up was 24 months (range 8-95 months). The median time from the end of previous therapy to molecular relapse was 5.6 months (range 0.3-31 months) - for RUNX1-RUNX1T1 positive patients 5 months, for CBFB-MYH11 pts. 4 months, for patients with MLL fusion 9.5 months and 6 months for patients with NPM1 mutation. Following pre-emptive treatment regimens were used: conventional chemotherapy ("5+2"like regimens) (20% of relapses), clofarabine (30%), gentuzumab ozogamicine - GO (17%) and immunomodulation after allogeneic hematopoietic stem cell transplantation - allo HSCT (30%). The overall response rate was 66% (CMoR - 53%, PMoR - 13%, SD - 13%, progression - 20%). The highest response rate was achieved with clofarabine - 88% (CMoR - 66%, PMoR - 12%, SD - 0%, progression - 22%) and conventional chemotherapy - 84% (CMoR - 50%, PMoR - 34%, SD - 16%, progression - 0%). The response rate for GO was 60% and for immunomodulation after HSCT 44%. We observed neutropenia and thrombocytopenia gr. III-IV (according to CTCAE 4.0) in 100% cases treated with clofarabine, conventional chemotherapy or GO and only in 11% and 0% respectively in patients after immunomodulation after HSCT. Severe complications occured in 17% cases treated with conventional chemotherapy (one death for toxicity) and in 11% cases treated with clofarabine, but not in patients treated with GO or immunomodulation. 30% of patients underwent allo HSCT. New relapse during follow up period was observed in 58% with median 7 months (range 3-18 months). However only 50% (8/16) of cases that achieved CMoR after treatment of molecular relapse relapsed in follow up period; in opposite 100% (3/3) patient with only PMoR after treatment of initial relapse relapsed in follow up period. One-year disease free survival was 56%, one-year overall survival was 74%. *Summary/Conclusions.* Our study has shown feasibility of MRD monitoring and pre-emptive strategy using molecular targets in non-APL AML pts. This approach had reasonable toxicity. Different pre-emptive treatment strategies led to response in 2/3 of molecular relapses and clofarabine led to the highest % of CMoR (66%). However, even using allo HSCT as the part of molecular relapse treatment, in 58% of responders new relapse occurred with median of 7 months.

0065

AGE-DEPENDENT ANALYSIS OF THE PROGNOSTIC IMPACT OF MINIMAL RESIDUAL DISEASE (MRD) IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA

F Buccisano, L Maurillo, MI Del Principe, C Sarlo, M Cefalo, L Ottaviani, C Ditto, F Duranti, G Del Poeta, F Lo Coco, S Amadori, A Venditti

Fondazione Policlinico Tor Vergata, Rome, Italy

Background. Although the therapy of acute myeloid leukemia (AML) has witnessed remarkable progress over the last 2-3 decades in, two thirds of young adults still die of their disease. In older adults, who represent the majority of patients with AML, the results are even more unsatisfactory. In fact, while 40-50% can achieve a complete remission (CR), less than 10% are long-term survivors. Based on this, age is universally recognized as a pivotal prognosticator affecting outcome and treatment choice. In consecutive series of adult patients with de novo AML, we have repeatedly demonstrated the prognostic role of (MRD) detection, by flow cytometry. In particular, we have found that a level

of MRD ≥ 3.5x10e-4 leukemic cells at the end of consolidation is associated with a relapse rate of 70-80%. *Aims.* In the present study we evaluated whether the prognostic impact of MRD assessment after consolidation remained unaltered even in age-stratified (< 60 and > 60 years) populations of adult patients with de novo AML. *Methods.* For the purpose of this study, we analyzed 128 young adults (median age 46, range 18-60) and 55 elderly adults (median age 67, range 61-78). All patients under study, achieved CR after induction therapy of EORTC/GIMEMA protocols AML10, LAM99P and AML12 (for patients < 60 years) or AML13, AML15A and AML17 (for patients > 60 years). The two cohorts were well balanced in terms of frequency of FLT3-ITD and NPM1 mutated cases. A lower frequency of good-risk karyotypes was observed in elderly vs young patients (4% vs 20%, p=0.014). *Results.* The frequency of MRD negative measurements was lower among elderly patients as compared to the younger ones [7 (13%) vs 42 (33%), p=0.005]. Among 48 MRD positive elderly, 40 (83%) have relapsed and 8 (17%) have not; among 7 MRD negative, 4 (57%) have relapsed and 3 (43%) have not. Overall survival (OS) and disease free survival (DFS) were significantly longer for patients who were MRD negative at the post-consolidation time-point (p<0.001 for both comparisons). On the opposite, among 86 MRD positive younger patients, 51 (59%) experienced a relapse and 35 (41%) did not whereas among 42 MRD negative, 11 (26%) have relapsed and 31 (74%) are in continuous remission (p<0.001). OS and DFS were significantly longer for patients who were MRD negative at the post-consolidation time-point (p<0.001 and p=0.002, respectively). Cumulative incidence of relapse (CIR) was significantly lower for the MRD negative group both in elderly (57% vs. 88%, p<0.001) and younger patients (30% vs. 70%, p=0.002). *Conclusions.* in elderly adults, flow-cytometric MRD negativity defines a subgroup of patients with a CIR that is significantly lower than that of MRD positive patients (57% vs 88%, p=0.002). Nonetheless, elderly patients infrequently become MRD negative 13% vs 33%, p=0.005 and, even when MRD negativity is obtained, the rate of relapse doubles that of the younger counterpart (57% vs 26%, p=0.005), confirming that age represents by itself a poor-risk features in AML.

0066

THE IMPACT OF PRIOR HYPOMETHYLATING AGENT TREATMENT AMONG SECONDARY AML PATIENTS TREATED WITH CPX-351 OR 7+3 CHEMOTHERAPY

J Lancet,[1] J Cortes,[2] T Kovacsovics,[3] D Hogge,[4] J Kolitz,[5] M Tallman,[6] M Chiarella,[7] A Louie,[7] E Feldman[8]

[6]*Memorial Sloan-Kettering Cancer Center, New York, United States of America*
[7]*Celator Pharmaceuticals, Princeton, United States of America*
[8]*Weill Cornell Medical College, New York, United States of America*

Background. CPX-351 encapsulates cytarabine and daunorubicin at a 5:1 molar ratio predicted *in vitro* to maximize synergy. CPX-351 liposomes accumulate within bone marrow with preferential uptake by leukemia cells followed by intracellular release of drug. Multiple CRs in advanced AML patients in Phase I led to a randomized Phase 2b study comparing CPX-351 (85 pts) vs. standard cytarabine + daunorubicin (7+3) (41 pts) for untreated older patients with AML. CPX-351 showed improvement in CR + CRi rate, 60 day mortality, EFS and OS. Significant improvement in OS was observed among 51 (40%) patients entered with secondary AML (prior antecedent hematologic disorders (AHD): MDS, MPN, CMMoL, and treatment related AML. Previously treated patients with AHD, particularly prior hypomethylating agent therapy for MDS, identifies a subgroup with poor outcomes. Further analyses were performed to see whether the apparent improvement in outcomes following CPX-351 treatment of secondary AML patients might extend to patients with prior hypomethylating agent treatment. *Aims.* To evaluate the impact of prior hypomethylating agent therapy on the outcome of AML induction treatment with CPX-351 compared to 7+3. *Methods.* Previously untreated de novo or secondary AML patients, aged 60-75, PS= 0-2, S_{Cr} <2.0 mg/dL, total bilirubin <2.0 mg/dL, ALT/AST <3 x ULN, and LVEF >50%, were eligible. Patients were randomized 2:1 to receive up to 2 induction and 2 consolidation courses of CPX-351 (100 u/m^2; d1, 3, 5; 90 min infusion, 1 unit= 1 mg cytarabine + 0.44 mg daunorubicin) or standard 7+3 treatment (cytarabine 100 mg/m^2/d CI x 7d and daunorubicin 60 mg/m^2 d1, 2, 3). Consolidation with hematopoietic stem cell transplantation (HSCT) was permitted. Endpoints included: CR + CRi rate (1° endpoint) and duration, EFS, aplasia rate, survival at 1-year, and death at day 30 and 60. *Results.* This analysis focuses on the group of secondary AML patients randomized to CPX-351 (32 pts) and 7+3 (19 pts), analyzing the impact of prior hypomethylating agent treatment. Twenty (39%) of 51 patients with secondary AML included in this study received prior hypomethylating agents. Three patients on CPX-351 and 2 on 7+3 had prior treatment with other agents and are not included in the table. Prior treatment with hypomethylating agents was associated with reduced response rate, EFS and proportion alive at 1 year. With small numbers of secondary AML patients CPX-351 treatment was associated with improved outcomes. *Summary/Conclusions.* Newly diagnosed secondary AML patients treated with CPX-351 demonstrated higher response (CR + CRi) rate, lower induction mortality, improved EFS, and improved survival (p=0.01) compared to 7+3 chemotherapy. Prior hypomethylating therapy diminished treatment efficacy in both arms of the study, but CPX-351 treatment was associated with improved response and survival in this poor prognosis group.

Table 1.

0067

THE PROGNOSTIC IMPACT OF GERMLINE 46/1 HAPLOTYPE OF JANUS KINASE 2 IN CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA

S Nahajevszky,[1] H Andrikovics,[2] A Batai,[1] A Bors,[1] J Csomor,[1] L Gopcsa,[1] M Koszarska,[2] A Kozma,[1] N Lovas,[1] S Lueff,[1] Z Matrai,[1] N Meggyesi,[2] A Sipos,[1] A Szilvasi,[2] A Varkonyi,[1] E Adam,[1] A Tordai,[2] T Masszi[1]

[1]*St. Istvan and St. Laszlo Hospital, Budapest, Hungary*
[2]*Hungarian National Blood Transfusion Service, Budapest, Hungary*

Background. Risk stratification according to acquired genetic alterations received increasing attention in acute myeloid leukemia (AML) in recent years, although current prognostic factors are not sufficient to accurately predict outcome especially in AML with normal karyotype (NK-AML). Inherited polymorphisms are also candidates for the explanation of the heterogeneous prognosis. Germline Janus kinase 2 (JAK2) haplotype designated as 46/1 haplotype was reported to be associated with an inherited predisposition to JAK2 V617F positive and negative myeloproliferative neoplasm, and also to NK-AML. *Aims.* The aim of this study is to assess the prognostic impact of 46/1 haplotype on disease characteristics (age at disease onset, history of AML, morphology, associations with cytogenetic and molecular genetic alterations) and treatment outcome (complete remission and relapse rate, disease free survival [DFS] and overall survival [OS]) in AML. *Methods.* JAK2 rs12343867 SNP tagging 46/1 haplotype was genotyped by LightCycler technology applying melting curve analysis with the hybridization probe detection format in 176 patients with AML diagnosed consecutively in a single center. The participants signed informed consents, and the study was approved by the Institutional Ethics Committee. *Results.* The allele C of JAK2 rs12343867 co segregates with the 46/1 haplotype, while allele T of rs12343867 is linked to the wild type haplotype.46/1 haplotype carrier frequency was similar in de novo and in myelodysplasia- or therapy-related AML subgroups. Distribution of morphological subtypes were different between haplotype-carriers and non carriers (p=0.047). There were considerably more FAB M2 morphological

cases within 46/1 non-carriers vs. carriers [17% (15/87 TT) vs. 6% (5/89 TC and CC), p=0.018], while myelomonocytoid and monocytoid variations were more frequent in 46/1 haplotype carriers [32% (28/87 TT) vs. 55% (49/89 TC and CC), p=0.003]. Similar distribution was observed in case of NK-AML. There was a tendency of increased 46/1 haplotype carrier frequency in NK-AML compared to AML with abnormal karyotypes [58% vs. 44%, p=0.069, OR (95%CI): 1.79 (0.98-3.26)]. FLT3 ITD and NPM1 mutation distribution was equal in 46/1 carriers and non-carriers. Considerably higher remission rate (94% vs. 79%, p=0.064) and fewer deaths in complete remission or in aplasia caused by infections (24% vs. 47%, p=0.038) were observed in 46/1 non-carriers compared to 46/1 haplotype carriers. SNP rs12343867 had no prognostic impact in the entire AML group, where age, karyotype, NPM1-FLT3 ITD combined mutation status were independent prognostic factors. C allele carriership of the SNP 12343867 was an independent adverse prognostic factor for DFS [HR (95%CI): 1.88 (1.07-3.29), p=0.028] and OS [HR (95%CI): 1.88 (1.07-3.29), p=0.027] in NK-AML. *Conclusions.* JAK2 46/1 haplotype may be a novel, independent unfavorable risk factor in NK-AML.

MLN4924 A NOVEL INVESTIGATIONAL NEDD8-ACTIVATING ENZYME (NAE) INHIBITOR, IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) OR HIGH-GRADE MYELODYSPLASTIC SYNDROMES (MDS): RESULTS FROM A PHASE 1 STUDY

H Erba,[1] R Swords,[2] D DeAngelo,[3] D Bixby,[1] M Pickard,[4] G Mulligan,[4] S Kuan,[4] P Smith,[4] B Dezube,[4] F Giles,[2] B Medeiros[5]

[2]*Cancer Therapy and Research Center at the University of Texas, San Antonio, TX, United States of America*
[3]*Dana-Farber Cancer Institute, Boston, MA, United States of America*
[4]*Millennium Pharmaceuticals, Inc, Cambridge, MA, United States of America*
[5]*Stanford Comprehensive Cancer Center, Stanford, CA, United States of America*

Background. NAE regulates the NEDD8 conjugation pathway and is required for the activity of cullin-RING E3 ligases (CRLs), which control degradation of substrates involved in cell-cycle regulation, signal transduction, DNA replication, and stress response, including proteins important for AML cell survival. Inhibition of NAE with MLN4924, a novel, investigational, first-in-class small molecule NAE inhibitor, results in accumulation of CRL substrates and leads to apoptosis, as demonstrated in AML preclinical models. *Aims.* The primary objectives of this multicenter study were to evaluate the safety and tolerability of MLN4924, and to establish the MTD and the recommended phase 2 dose of MLN4924 in patients with AML and high-grade MDS. Secondary objectives included a preliminary assessment of efficacy, and analysis of pharmacokinetics and pharmacodynamics. *Methods.* Patients aged ≥18 years, with ECOG performance status 0-2, who had AML or high-grade MDS and were not candidates for potentially curative therapy, received MLN4924 as a 60-minute IV infusion on days 1, 3, and 5 of a 21-day cycle for ≤12 months or until documented disease progression. Dose escalation from 25 mg/m^2 proceeded using a standard '3+3' escalation method. Informed consent was obtained. *Results.* Twenty-nine patients (19 males, 28 AML, 1 MDS) were treated, including 3, 4, 5, 13, and 4 at dose levels of 25, 33, 44, 59, and 78 mg/m^2, respectively. Median age was 57.7 years (range 20-84 years); by cytogenetics, 1, 6, and 12 patients had good-risk, intermediate-risk, and poor-risk disease. Seven patients have received ≥6 cycles; 4 remain on treatment. Two DLTs, multi-organ failure and reversible ALT elevation, were reported at the 78 mg/m^2 dose level. Accrual has been completed and the MTD has been established as 59 mg/m^2. The most common treatment-emergent grade ≥3 AEs were febrile neutropenia (n=9, 31%), elevated ALT/AST (n=5, 17%), thrombocytopenia (n=4, 14%), and pneumonia (n=3, 10%). Four patients achieved a CR. A 29-year-old woman with relapsed AML following allogeneic SCT achieved CR after Cycle 1 (25 mg/m^2) before developing PD during Cycle 8. An 82-year-old man with high-risk azacitidine-refractory MDS that evolved into AML had a PR in Cycle 8 and a CRi in Cycle 10 (33 mg/m^2), becoming transfusion-independent before progressing after Cycle 12. A 71-year-old man with de-novo AML refractory to standard cytarabine plus daunorubicin induction achieved CRi during Cycle 1 (44 mg/m^2); the patient has reduced transfusion dependence in Cycle 15. A 51-year-old man with refractory AML following allogeneic SCT achieved a marrow CRi after Cycle 1 (59 mg/m^2). Plasma $AUC_{0\text{-}24hr}$ of MLN4924 increased linearly with increasing dose from 25-44 mg/m^2 after Cycle 1 Day 1 dosing in 9 evaluable patients. MLN4924 exerted predicted pharmacodynamic effects in peripheral blood and bone marrow, including increased transcription of the targets of CRL substrates in blood and the formation of MLN4924-NEDD8 adduct in bone marrow. *Conclusions.* NAE inhibition by MLN4924 demonstrates evidence of anti-tumor activity in patients with AML. MLN4924 appears generally well tolerated. Pharmacodynamic analyses show anticipated effects of tumor target inhibition. Further dosing schedules are being investigated to enable higher doses and greater MLN4924 exposure.

IDENTIFICATION OF A SUBSET OF AML CASES WITH CYTOPLASMIC NPM1 LOCALIZATION WITHOUT DETECTABLE KNOWN NPM1 MUTATIONS

C Woolthuis, A Mulder, R Verkaik-Schakel, S Rosati, A Diepstra, JJ Schuringa, E Vellenga, P Kluin, G Huls

University Medical Center Groningen, Groningen, Netherlands

Background. Mutation of the nucleophosmin gene (NPM1) is detected in about 30% of all patients with acute myeloid leukemia (AML). AML with mutated NPM1 shows distinctive biological and clinical features and is a provisional entity in the 2008 WHO classification. One of the important clinical features of NPM1-mutated AML is its favorable prognosis in the absence of FLT3-ITD. Mutation of NPM1 leads to aberrant accumulation of nucleophosmin in the cytoplasm of leukemic cells. This feature is often used to examine the presence of an NPM1 mutation in AML blasts by immunohistochemistry (IHC). *Aim.* To evaluate the sensitivity and specificity of NPM1 IHC in predicting NPM1 mutation status. *Methods.* Immunohistochemical stainings of decalcified bone marrow biopsies derived from AML patients were performed with a Benchmark XT. Slides were incubated with 1:50 diluted supernatant of the biotinylated anti-NPM1 antibody. Streptavidin with multimer horse radish peroxidase (HRP) and color development was carried out using DAB as a chromogen. NPM1 mutation analysis was performed by cDNA fragment analysis with a fluorescent labeled forward primer. For sequencing of the NPM1 gene RT-PCR was performed and PCR products were sequenced. *Results.* A total of 119 patients diagnosed with AML in the University Medical Center Groningen from 2005 to 2010, excluding those with favorable cytogenetic abnormalities, were analyzed in this study. The mean age was 57 years (range 17 to 81 yr) and 52% was female. Cytogenetics revealed that 65 patients (55%) had a normal karyotype and 26 (22%) had an unfavorable karyotype. An internal tandem duplication of the FLT3 gene (FLT3-ITD) was found in 23% of cases. Screening for NPM1 mutations by fragment analysis revealed mutated NPM1 in 34 out of 119 patients (29%). Screening for NPM1 mutations by IHC revealed cytoplasmic NPM in 33 out of 119 patients (28%) of these cases (Table 1). However, 5 cases had mutant NPM1 by fragment analysis but nuclear localization of NPM1 by IHC, and, reversibly, 4 cases had no NPM1 mutation detected by fragment analysis but cytoplasmic localization of NPM1 by IHC. Additional sequencing of exons 9 and 11 of the NPM1 gene of the latter cases did not reveal mutations at these sites. Consequently, in this study considering fragment mutation analysis as a gold standard, the positive predictive value of cytoplasmic NPM1 was 89% and the negative predictive value was 94%. The sensitivity of the IHC analysis was 85% with a specificity of 95%. In addition, we performed quantitative RT-PCR studies of several HOX genes, MEIS1, PBX3, BAALC and MN1. The cases with nuclear staining of NPM1 by IHC but a NPM1 mutation by fragment analysis showed a gene-expression profile as expected for NPM1 mutated AML. Interestingly, also the gene-expression patterns of the AML cases with cytoplasmic NPM1 by IHC but no known NPM1 mutation closely resembled those of mutated NPM1 controls. *Conclusion.* In this study, cytoplasmic localization of NPM1 by immunohistochemistry often but not always predicted mutation of the NPM1 gene. However, discrepant cases with cytoplasmic expression without detectable mutations may represent a distinct subgroup.

Table 1.

MODULATION OF IMMUNE RESPONSES TO SELF AND NON-SELF ANTIGEN BY ACTIVATED PLATELETS IN VITRO

S Gudbrandsdottir,[1] HC Hasselbalch,[1] C Nielsen[2]

[1]*Copenhagen University Hospital Roskilde, Roskilde, Denmark*
[2]*Institute for Inflammation Research, Copenhagen University Hosp Rigshospitalet, Copenhagen, Denmark*

Background. Platelets are abundantly present in the circulation, and activated platelets may have a role in regulating immune responses. Recent studies have indicated that activated platelets may stimulate maturation of monocyte-derived dendritic cells and regulate B-cell activity via shedding of soluble and platelet-derived microparticle bound CD40L. The impact of platelets on T-cell function is largely unknown, however. *Aims.* In this study we examined how activated platelets influence the cytokine production and CD4+ T-cell proliferation elicited by self- and non-self antigens in cultures of mononuclear cells (MNCs) from healthy donors. *Methods.* MNCs were isolated from 10 healthy donors (3 females, mean age 38 years, SD ± 16 years) and labelled with carboxyfluorescein succinimidyl ester (CFSE). Platelets were isolated by centrifugation and activated by thrombin-receptor activating protein (TRAP). The MNCs were cultured in media containing autologous serum and stimulated with tetanus toxoid (TT), thyreoglobulin (Tg), autologous platelets (plts) or combinations of TT + plts or Tg + plts. Platelets were added to the cultures in concentrations ranging from 0.5 - 3.4 x1010/L. Culture supernatants were harvested at day 1 and analysed for Th1/Th2 cytokine production. CD4+ T cell proliferation was measured at day 7 by flow cytometry. MNCs and platelets from 10 healthy donors (5 females, mean age 23 years, SD ± 10 years) were subsequently isolated and stimulated correspondingly, but were harvested after 16 hours for analysis of IL-10 secretion. *Results.* Addition of activated platelets caused an increased production of IL-10 in MNC cultures stimulated with Tg (p=0.0005), and reduced the production of TNF-a (p=0.0237). In cultures stimulated with TT, addition of activated platelets resulted in an increased production of IL-6 (p= 0.012). IL-10 secretion assays revealed a significant higher percentage of IL-10 producing CD4+ T cells in cultures stimulated with Tg in presence of platelets compared to cultures containing platelets alone (p=0.045)(Fig. 1A, horizontal bars represent means). Moreover, activated platelets inhibited both the Tg- and the TT-induced proliferation of CD4+ cells (p=0.002 and p=0.037, respectively) (Fig. 1B, horizontal bars represent means). *Conclusion.* Addition of activated autologous platelets to MNC cultures increases the IL-10 production by i.a. CD4+ T cells and, accordingly, inhibits the proliferation of CD4+ T cells elicited by the self-antigen Tg *in vitro*. Inhibition of the CD4+ T-cell proliferation elicited by the foreign antigen TT was also observed. The results of this study suggest that platelets may have a role in regulating the adaptive immune system.

TWO NOVEL VON WILLEBRAND FACTOR GENE MUTATIONS THAT RESULT IN A UNUSUAL TYPE 2N VWD WITH DEFECTIVE MULTIMERISATION AND REDUCED VWF LEVEL

P Bignell,[1] D Keeling,[2] A Goodeve[3]

[1]*Molecular Haematology, Oxford, United Kingdom*
[2]*Oxford Haemophilia and Thrombosis Centre, Oxford, United Kingdom*
[3]*Sheffield Molecular Genetics Service, Sheffield Children's Hospital, Sheffield, United Kingdom*

VWD is a congenital bleeding disorder which results from quantitative or qualitative defects of von Willebrand factor (VWF). It is the most common inherited bleeding disorder in humans with a prevalence ranging from 3-4 /100,000 to 1.3% of the population. The current classification of VWD consists of 6 distinct types. Types 1 and 3 result in a quantitative VWF deficiency, whilst the 4 type 2 variants cause qualitative VWF defects. Type 2N defect result from defective VWF binding to F8 and consequently low levels of circulating F8. Inheritance is autosomal recessive. In this report our non consangious Asian family had significantly reduced levels of plasma VWF and lacked high molecular weight multimers. Analysis of the VWF gene sequence in DNA from affected members of the family detected 2 novel mutations. See tables 1 and 2. Type 2N mutations are normally found in regions essential for F8 binding, either the D' (amino acids 769-865) and D3 (amino acids 866 to 1244) domains. Mainly exons 18-20 with a few outside this. The novel exon 19 mutation, c.2546 G>T, p.C849F, this is a non conservative change in the D' region of VWF, responsible for binding to F8. Additionally, similar loss/gain of cysteine residues have previously been associated with reduce/absent high molecular weight multimers in individuals with type 2N VWD. This mutation is consistent with a contribution to the diagnosis of type 2N VWD. A second variant is expected to contribute to the reduced VWF level seen in this family. The novel c.8155+6 T>A mutation in intron 50 of the VWF gene. The sequence change has not been reported but a c.8155+6T>C mutation affecting the same nucleotide, has been reported to lead to skipping of exon 50 of the VWF gene. In silico splice site predictions also indicate a deleterious effect on splicing of the c.8155+6T>A sequence change. The three affected children have 2 novel mutations that are consistent with the diagnosis of Type 2N VWD with absent high molecular weight multimers. Whereas mum is a carrier of the type 2N mutation and dad is a carrier of the intron 50 mutation.

Table 1.

POLYMORPHISMS IN IMMUNE RESPONSE GENES IN SEVERE HAEMOPHILIA A PATIENTS WITH INHIBITORS IN INDIA

P Pinto, K Ghosh, B Kulkarni, S Shetty

National Institute of Immunohaematology (ICMR), Mumbai, India, Mumbai, India

Background. The development of alloantibodies or 'FVIII inhibitors' to infused FVIII, is perhaps the most serious complication of FVIII replacement therapy. It leads to a considerable increase in mortality and cost of management of bleeds among these patients. In developing countries such as India, where resources are limited, an increased incidence of post-operative inhibitor development has been reported, which usually proves disastrous during this critical time of wound healing. A number of genetic and non-genetic risk factors have been implicated, but there is no data on the predisposing risk factors for inhibitor development in Indian haemophilia A patients. *Aims.* We studied polymorphisms in the *IL1β, IL4, IL10, CTLA-4* and *TNFA* genes, in 100 Indian severe hemophilia A patients, i.e. 40 inhibitor positive patients (and also 20 inhibitor concordant or discordant haemophilic family members), and 40 inhibitor negative control patients, to attempt to find a marker for the differential immune response to FVIII. The polymorphisms selected for study have been shown to influence antibody production in various autoimmune disorders, and some are reported to be associated with FVIII inhibitors in other populations. *Methods.* The *IL1β* rs1143634 C/T and *IL4* rs2243250 C/T single nucleotide polymorphisms (SNPs); as well as the *CTLA-4* rs5742909 C/T and rs231775 A/G SNPs, were analysed by the PCR-RFLP technique. Six *TNFA* SNPs; rs1800629 G/A, rs361525 A/G, rs1800630 C/A, rs4248158 C/T, rs1799724 C/T, and rs3093662 G/A were also studied in these patients by DNA sequencing. Cost-effective and quicker allele-specific PCRs have been designed to analyze the *TNFA* rs1799724 C/T and rs3093662 G/A SNPs. Genotyping for the *IL10* promoter dinucleotide microsatellite, *IL10G*, was carried out using a 6-FAM fluorescent labeled forward primer and GeneMapper analysis software (v.4.0). *Results.* The 'C/T' genotype of the *TNFA* rs1799724 C/T polymorphism was found to be significantly higher in inhibitor positive patients (OR: 4.645, P:0.0228, 95%CI:1.200-17.982; Fisher's exact test). The other cytokine related gene polymorphisms showed no strong association, in contrast to reports on the association of certain polymorphisms with inhibitors in other populations. *Summary/Conclusions.* This is the first report from India on the association of polymorphisms in immune response genes with inhibitors in severe haemophilia A patients. These findings could influence the study of other immune response gene polymorphisms as well as other genetic risk factors of inhibitor development. This could provide useful insights into the immune response to FVIII in inhibitor positive haemophilia A patients, and possibly influence the timely prediction and prevention or treatment of FVIII antibodies.

0073

A RARE CASE OF COMBINED INHERITED DYSFIBRINOGENEMIA AND FACTOR VII DEFICIENCY FROM MUTATIONS IN THE FGB AND F7 GENES

HI Woo,[1] IA Park,[2] KO Lee,[2] SH Kim,[1] HJ Kim[1]

[1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South-Korea*

[2]*Samsung Biomedical Research Institute, Samsung Medical Center, Seoul, South-Korea*

Background. Dysfibrinogenemia and factor (F)VII deficiency are autosomally inherited rare coagulation disorders. The genetic backgrounds of the disorders are mutations in the fibrinogen Aα (*FGA*), Bβ (*FGB*) or γ (*FGG*) gene and *F7* gene, respectively. Clinical manifestations of both disorders are variable from asymptomatic form to life-threatening hemorrhage. *Aims.* We herein report the first genetically confirmed case of dysfibrinogenemia combined with FVII deficiency. *Methods.* The patient was a 51-year-old man referred for prolonged PT that was accidentally detected on preoperative screening. Past medical history revealed no history of bleeding tendency even on several surgeries to treat hemorrhoid, injured intervertebral disks of the lumbar spine, and sprain of right rotator cuff. Routine coagulation studies revealed prolonged prothrombin time (PT) at INR 1.31-1.35, marginally prolonged activated partial thromboplastin time (aPTT) at 41.2 sec (reference range, 29.1-41.9 sec), prolonged thrombin time (TT) at 42.2 sec (14.3-16.5 sec), and decreased fibrinogen level at 57 mg/dL (182-380 mg/dL, Clauss method). Special coagulation tests revealed a decreased FVII activity at 44% (68-149%). On suspicion of dysfibrinogenemia and hereditary factor VII deficiency, direct sequencing analyses were performed for *FGA*, *FGB*, *FGG* and *F7* genes. *Results.* The patient was found to be heterozygous for a point mutation in exon 8 of *FGB*, replacing the last stop codon to tryptophan (c.1475A>G, p.X492TrpextX13). The mutation was previously reported in dysfibrinogenemia (Fibrinogen Magdeburg II). In addition, the patient was heterozygous for a known missense mutation in exon 6 of *F7* (c.466G>A, p.Gly156Ser). Collectively, the patient was confirmed to have dysfibrinogenemia and heterozygous FVII deficiency by molecular genetic studies. *Summary/Conclusions.* To our knowledge, the present patient is the first genetically confirmed case of dysfibrinogenemia and factor VII deficiency. It was suggested that these autosomally inherited coagulation disorders might not be very rare and have potentially been underdiagnosed in Koreans.

0074

HYPOFIBRINOGENEMIA ASSOCIATED WITH A MUTATION IN THE BETAC-DOMAIN OF FIBRINOGEN

R Kotlin, K Zichova, J Suttnar, P Salaj, J Dyr

Institute of Hematology and Blood Trasfusion, Prague 2, Czech Republic

Background. Fibrinogen, a 340 kDa glycoprotein, is composed of three sets of different polypeptide chains termed Aα, Bβ, and γ. It plays a crucial role in hemostasis and other physiological processes. Hypofibrinogenemia is characterized by a low fibrinogen level and bleeding tendencies may occur. *Aims.* The aim of the study was to characterize pathological preoperative coagulation findings in a patient with decreased both functional and total fibrinogen level. *Methods.* Routine coagulation testing was performed on STA-R coagulation analyzer (Diagnostica Stago). Both, fibrin polymerization and fibrinolysis were measured by turbidimetrical method at 350 nm after addition of human thrombin to the patient`s plasma. Kinetics of fibrinopeptide release was measured by RP-HPLC method. Gene sequencing was performed by a Sanger method. Scanning electron microscopy (SEM) was performed on VEGA Plus TS 5135 electron microscope (Tescan sro). *Results.* The patient presented with a low fibrinogen level as determined by both Clauss and immunoturbidimetric method and did not indicate any haemorrhagic or thrombotic complications. Both fibrin polymerization and fibrinolysis were found to be normal. Proteomics studies did not show any evidence of the mutant chain in the patient's plasma. DNA analysis revealed a heterozygous point mutation Bβ Asn381Lys. The mutation is situated approximately in the middle of the βC-domain. Molecular modeling revealed no stable rotamer of the mutated fibrinogen. The replacement of neutral charged asparagine residue by the positively charged lysine residue presumably changes the conformation of its neighborhood, which is unallowable for a correct Bβ chain assembly and subsequent fibrinogen folding. Aberrantly folded molecules may be then either degraded or stored by hepatocytes; and the mutated molecules are not present in the circulation. There is no evidence of a liver disease in the patient so we presume that misfolded molecules are rather degraded than stored by hepatocytes. *Conclusion.* The mutation found in the patient may be the direct cause of hypofibrinogenemia. E-mail: kotlinr@uhkt.cz

SYSTEMATIC REVIEW OF PHARMACOKINETIC OF FACTOR IX

B Polack,[1] JM Scherrmann,[2] Z Tellier[3]

[1]*CHU Grenoble, Grenoble, France*

[2]*Descartes and Diderot Universities, Paris, France*

[3]*LFB Biomédicaments, Les Ulis, France*

Background. The substitutive therapy of hemophilia B relies approximately for half on recombinant and the other half on plasma derived products, on a worldwide basis. More than 10 years after the first marketing authorization of recombinant factor IX (rFIX), the quantities used have more than doubled without significant change in therapeutic practices. It seems that the number of patients treated cannot explain such a difference *Aims.* . It raises the question of real pharmacokinetic equivalence or not between plasma-derived products and the recombinant one. Indeed, in 2003 Kisker *et al.* already suggested that, based on pharmacokinetics modelisation, therapy using rFIX may be more expensive.

This prompted us to review all available data. *Methods.* Systematic review of PubMed indexed literature has been performed, leading to the identification of 51 studies. 7 studies on animals and 2 on continuous infusion were not integrated, yielding to 42 analysed studies. Among these studies only 15 (36%) were in accordance with international sampling recommendations and 19 (45%) were conformed to recommendations of doses for injection. Concerning recovery (IU/dl/IU/kg), only 20/42 were considered as methodologically acceptable with data available for 26 studies . *Results.* Recovery data indicate for plasma-derived FIX (pdFIX) 1.17 ± 28 vs rFIX 0.81 ± 0.14 showing a significant advantage for pdFIX (p<0.0001). Only 4 paired studies were available, showing also a very clear difference between 1.41 ± 0.33 for pdFIX and 0.82 ± 0.05 for rFIX p=0.03. The comparison of clearance (ml.h-1.kg-1) could be achieved among 22 studies for pdFIX and only 3 studies for rFIX, showing also a significant difference: 5.6 ± 1.9 for pdFIX and 8.5 ± 4.5 for rFIX with p<0.05. *Conclusion.* These data may explain why lower quantities may be enough for treating hemophilia B patients when using pdFIX as previously suggested.

0076

MARKERS OF COAGULATION ACTIVATION AND ENHANCED FIBRINOLYSIS IN GAUCHER TYPE 1 PATIENTS: EFFECTS OF ENZYME REPLACEMENT THERAPY

M Mitrovic,[1] Z Sumarac,[2] D Antic,[1] A Bogdanovic,[1] I Elezovic,[1] N Suvajdzic[1]

[1]*Clinics of Hematology CCS, Belgrade, Serbia*
[2]*Institute of Medical Biochemistry, CCS, Belgrade, Serbia*

Background. Low-grade coagulation activation and enhanced fibrinolysis have been reported in Gaucher patients (GP). Data concerning the effects of enzyme replacement therapy (ERT) on that aspect of Gaucher disease are rare and controversial. *Aim.* To assess the parameters of coagulation and fibrinolysis activation in our GP and the impact of ERT on them. *Methods.* From 2005 to 2008, 21 Serbian treatment-naive type 1 GP (M/F 11/10; median age 37 years, range 2-74; splenectomized 8/21) were studied. Chitotriosidase activity (CA) was measured by spectrofluometry method. Spleen volume (SV) was assessed with CT. Fibrinogen was measured according to standard methods. Plasminogen, protein C (PC), antithrombin (AT) and plasminogen activator inhibitor (PAI) were measured using spectrophotometric assay. Thrombin-antithrombin complexes (TAT), prothrombin fragments (F1+2) and D-dimer were measured by ELISA. All GP were treated with ERT (Imiglucerase). Haemostatic parameters were assessed after 6, 12 and 24 months (ERT6, 12, 24). *Results.* Pre-treatment: Mean values of markers of coagulation activation (TAT and F1+2) and mean value of marker of enhanced fibrinolysis (D-dimer) were elevated although disseminated intravascular coagulation (DIC) was not registered (DIC score: mean 2, range 0-4),Table 1. A significant positive correlation between CA and D-dimer (p=0.047) as well as a significant inverse correlation between CA and PC level (p=-0.048) were registered. Non-splenectomized GP had significantly reduced AT and PC level compared to the splenectomized ones (p=0.0285 and p=0.0599). After ERT: CA and SV significantly decreased during ERT (p=0.0001). Fibrinogen (p=0.001), TAT (p=0.0001), F1+2 (p=0.0001) and D-dimer (p=0.05) significantly decreased while PC (p=0.006) and PAI (p=0.02) significantly increased at ERT12 and remained unchanged at ERT24. At ERT24 the mean D-dimer was still elevated while the mean TAT and F1+2 remained in normal.ranges. *Conclusion.* Our results suggest that a significant number of our GP had ongonig low-grade coagulation activation and enhanced fibrinolysis without an overt DIC, which might contribute to the bleeding tendency of GP. D-dimer and PC levels corelated with total CA and SV suggesting a relationship beetwen Gaucher cells burden and deriving pronflamatory cytokines on one side and coagulation activation on the other side. ERT significantly decreased the level of coagulation activation and enhanced fibrinolysis.

Table 1. Markers of coagulation activation and fibrinolysis.

Parameter	Normal range	N° pts with abnormal values	Mean ERT_0	Mean ERT_6	Mean ERT_{12}	Mean ERT_{24}	N° of pts with abnormal values

RARE COAGULATION DISORDERS: A STUDY OF 70 CASES IN THE EGYPTIAN POPULATION

M Abdelwahab, N Kaddah

Cairo University Pediatric Hospital, Cairo, Egypt

Background. Few Rare Bleeding Disorders registries (RBD) exist, none in Africa.Rare coagulation defects, such as factor (F)I, FII, FV, FV +FVIII, FVII, FX, FXI and FXIII deficiencies are transmitted as autosomal recessive traits with more prevalence in Muslim countries where consanguineous marriages are frequent.However, epidemiological information on the real distribution of these deficiencies is still limited and consequently when compared with the common bleeding disorders, most of these rare disorders are not well characterized clinically and do not have well-established treatment strategies.The clinical data of some big rare coagulation disorders registries such as the Italian, Iranian and North American have been reported.Only several small scale studies have been reported in Africa with none to date in the Egyptian population. *Aim.* To compare the clinical spectrum of some RBD in Egypt with other published data and to see if they behave differently in a population with many historical ethnic variations. *Methods.* A local hospital registry was started and patients were studied over 3 years.Assessment included detailed bleeding history, diagnostic events,clinical manifestations and treatment recieved. FX and FV deficiencies were classified according to the North American Rare Bleeding Disorders Registry and FVII deficiency according to the severity scoring system. Treatment was provided according to UKHCDO guidelines in view of resource constraint and patient's previous bleeding history. *Results.* We report the full clinical data of 70 patients, 61.4 % males and 38.6% females with the vast majority the offspring of consanguineous marriages .Afibrinogenemia is the most prevalent constituting 28.6% of the rare coagulation disorders, FV deficiency(10 homozygous and one heterozygous) constituting 15.7% and 20% of patients had FVII deficiency (6 severe, 7mild and 1moderate) .FX deficiency (11homozygous and 2heterozygous) was reported in 18.6% and FXIII deficiency in 11.4%. One patient had combined FV and FVIII deficiency and 3had FII deficiency. Intracranial hemorrhage occurred in 10% of our study group, joint bleeds in 12.9%, muscle bleeds in 7.1%, oral bleeding in 48.6%, epistaxis in 50%, bleeding per rectum in 17.1%, hematuria in 7.1%, post-circumcision bleeding in 14.3% and umbilical bleeding in 30% mainly in afibrinogenemia patients. Most patients received on demand therapy usually on initial presentation and 5 are on prophylactic therapy. *Conclusions.* The prevalence of these rare coagulation deficiencies and bleeding symptoms is different in the Egyptian population than elsewhere and so further studies including bigger numbers of patients could serve as an important source for clinicians in different parts of the world in view of rarity of these conditions.

CARDIAC RESYNCHRONIZATION THERAPY DEVICE IMPLANTATION OR REPLACEMENT IN PATIENTS ON ORAL ANTICOAGULATION TREATMENT. EFFICACY AND SAFETY OF A REDUCED-DOSE PROGRAM

P Machado, L Perez-Hernandez, A Rodriguez-Gonzalez, J Ferrer, P Pecos, R Diaz-Rodriguez, S Lakhwani, L Morabito, F Marrero, A Lara, F Bosa, JM Raya

Hospital Universitario de Canarias, La Laguna, Spain

Background. Many patients who require cardiac resynchronization therapy (CRT) are on oral anticoagulant therapy (OAT). Current guidelines recommend discontinuation of OAT and the initiation of anticoagulant 'bridging' therapy with heparin during these procedures. But some patients may be exposed to bleeding and/or thromboembolic complications. *Aims.* Our purpose was to evaluated the efficacy and the safety of CRT-device (CRT-D) implantation or replacement without interruption of OAT, applying a dose reduction program. *Methods.*A group of patients attending the Cardiology Department with an indication of CRT that were previously on chronic oral anticoagulation, was prospectively

analyzed. We collected their main baseline characteristics: age, sex, previous clinical history, blood cell counts, biochemistry (including renal function parameters), OAT indication, and concomitant use of antiplatelet drug. The type (implantation or replacement) and duration of the procedure, and the type of CRT-device, were also recorded. We established the hemorrhagic-thrombotic risk of each patient. We applied a dose adjustment of the OAT to achieve, just the day of surgery, an internacional normalized ratio (INR) between 1.5 and 2.0 for patients at low risk of thrombosis, and about 2.0 in case of high risk. Among others, the incidence of bleeding and thrombotic complications was analyzed. For statistical analysis, we used the Fischer's exact test for qualitative variables and the Mann-Whitney test for quantitative variables. *Results.* A total of 31 consecutive patients (mean age 73 years, range 36-90, males 24) were enrolled: 14 cases of CRT-D replacements (13 pacemakers and 1 defibrillator) and 17 CRT-D implantations (13 pacemakers, 3 re-synchronizers and one defibrillator). The mean time spent in the procedure was 53 minutes (range 15-150). In 18 patients (58%) the indication for OAT was a permanent or paroxysmal atrial fibrillation, and in six (19%) a mechanical valve prosthesis. A high bleeding risk was established in 19% of patients and a medium-high thrombotic risk in 52%. Five patients (16%) were carriers of coronary stent and six patients (19%) were also taking antiplatelet agents. The mean INR value on the day of surgery was 1.76 ± 0.34. Peri-procedure, 5 patients (16%) had complications: four cases of mild-moderate hematomas and one mild thrombotic complication. Forty-five days after the procedure, all complications had resolved. The baseline conditions of the patients associated with a higher rate of complications were a terminal renal failure status (p=0.037) and a prosthetic mechanical valve (p = 0.06). *Conclusions.* Our findings suggest that implantation/replacement of a CRT-D with a dose reduction of AOT constitutes an effective and safe alternative to interruption or routine "bridging"therapy. Complications were rare and never serious in our series, and the patients at increased risk were those with advanced renal failure or mechanical valve prostheses. Further studies involving a larger number of cases are needed to confirm these preliminary results.

0079

ASSOCIATION BETWEEN LEPTIN LEVELS AND BONE DISEASE IN HEMOPHILIAC PATIENTS

P Anagnostis,[1] S Vakalopoulou,[2] M Charizopoulou,[3] E Kazantzidou,[4] T Chrysopoulou,[4] E Moka,[2] V Zournatzi,[3] V Garipidou[2]

[1]*Aristotle University of Thessaloniki, Thessaloniki, Greece*
[2]*Division of Hematology, 2nd Propedeutic Department of Internal Medicine, Thessaloniki, Greece*
[3]*Aristotle University, Thessaloniki, Greece*
[4]*Radiology Department, Hippokration Hospital, Thessaloniki, Greece*

Background. Hemophilia A and B has been associated with increased prevalence of osteopenia or osteoporosis. Leptin may play a key role in the pathogenesis of osteoporosis. *Aims.* The purpose of the present study was to investigate serum leptin levels in hemophiliac patients with or without bone disease. *Methods.* 81 male patients (73 with hemophilia A, 8 with hemophilia B) aged 45.4±15 years were screened. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry (DXA) in lumbar spine (LS), femoral neck (FN) and total hip (TH). *Results.* Low bone mass was diagnosed in 20 patients (24.7%). The mean leptin levels in the whole cohort were 9.26 ± 9.89 ng/ml (range 0.05-51.97), being 12.61 ± 11.05 ng/ml (range 3.15-44.72) in patients with low bone mass (n=20) and 8.16 ± 9.32 ng/ml (range 0.05-51.97) in those with normal BMD (n=61). Serum leptin concentrations were strongly associated with body weight (rs = 0.457, P = 0.0001) and body-mass index (BMI) (rs = 0.491, P = 0.0001). In unadjusted analysis leptin was inversely associated with BMD in LS (rs = -0.255, P = 0.023), but not in FN and TH (rs = -0.205, P = 0.068 and rs = -0.191, P = 0.090, respectively). However, after adjusting for BMI and body weight, leptin was inversely associated with BMD in FN (F1,76 = 7.727, P = 0.007, β = -0.371, ΔR2 = 0.089) and TH (F1,76 = 4.533, P = 0.036, β = -0.290, ΔR2 = 0.054), but not in LS (F1,75 = 2.076, P = 0.154, β = -0.202, ΔR2 = 0.026). No association was found between age, presence of HBV, HCV or HIV infection or alkaline phosphatase and leptin levels. No association was also found between the severity of arthropathy (assessed by Pettersson score for knees and ankles: rs = 0.120, P = 0.334, rs = 0.110, P = 0.375, respectively and with Arnold-Hilgartner classification system: rs = 0.092, P = 0.461, rs = 0.226, P =0.066, respectively) and leptin levels. *Conclusions.* Our study showed a negative correlation between circulating leptin and BMD in patients with hemophilia A or B independently of body weight and BMI.

THE CYCLIN-DEPENDENT KINASE INHIBITOR CR8 INDUCES APOPTOSIS IN PROLIFERATING CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

M Michie,[1] M McCaig,[1] H Wheadon,[1] T Leach,[2] L Meijer,[3] E Cosimo[1]

[1]*University of Glasgow, Glasgow, United Kingdom*
[2]*West of Scotland Cancer Centre, Gartnavel General Hospital, Glasgow, United Kingdom*
[3]*Protein Phosphorylation & Human Disease, CNRS, Station Biologique, Roscoff, France*

Background. Chronic lymphocytic leukemia (CLL) is the most common adult leukemia in the Western world, and follows a heterogeneous clinical course. The finding that CLL patients with undetectable minimal residual disease (MRD) post-treatment possess a survival advantage has prompted the development of novel agents for incorporation into clinical trials, with the aim of eradicating MRD. *Aim.* To determine whether a novel cyclin-dependent kinase inhibitor (CKI) CR8 can overcome pro-survival and pro-proliferative signals induced in the tumor microenvironment, thus promoting apoptosis in CLL cells. *Methods.* Peripheral blood samples were obtained, after informed consent, from patients with a clinically confirmed diagnosis of CLL. The effect of CR8 treatment on CLL cells was determined by culturing them either in isolation, or by co-culturing on the mouse fibroblast cell line NT-L, or NT-L cells transfected with CD154 *in vitro*, to replicate *in vivo* survival- or proliferation-promoting environments, respectively. Flow cytometry, Western blotting and quantitative-PCR were performed to eludicate the mechanism utilised by CR8 to induce CLL cell apoptosis. *Results.* Our research demonstrates that the CKI CR8 (a novel derivative of roscovitine) is 100-fold more potent at inducing apoptosis in primary CLL cells than roscovitine in isolated culture (EC_{50}: 0.14 µM and 14.99 µM, respectively). Treatment of distinct CLL prognostic subsets with 100 nM CR8 revealed that cells isolated from previously-treated patients with more advanced disease were significantly less sensitive to CR8 than cells derived from untreated patients. While there was a trend towards reduced CR8 sensitivity in samples exhibiting poor prognostic markers (ZAP-70+, 11q/17p cytogenetic abnormalities), this did not reach significance. Importantly, 85% apoptosis was noted in all CLL subgroups upon treatment with 300 nM CR8. While *in vitro* co-culture systems that mimic the *in vivo* microenvironment of CLL proliferation centres rendered CLL cells resistant to fludarabine, CR8 was capable of inducing apoptosis, targeting actively proliferating CLL cells, albeit at a reduced potency compared with cells treated in isolated culture. Moreover, CR8 reduced the ability of cells to proliferate, causing a block at the G_1 phase of the cell cycle. CR8-induced apoptosis in CLL cells was mediated, at least in part, by an inhibition in expression of the anti-apoptotic proteins XIAP, Bcl-xL and Mcl-1. Indeed, reduced expression of XIAP and Mcl-1 was likely due to the ability of CR8 to inhibit CDK7 and CDK9 activities, both of which control transcription. Interestingly, we identified a non-dividing population of CLL cells resistant to CR8, when cultured in a pro-proliferative environment. *Summary*. These studies demonstrate that the novel CKI CR8 overcomes pro-survival and -proliferative signals to induce apoptosis, but reveal a discrete population of chemo-resistant cells that may be responsible for MRD in CLL patients.

FC GAMMA RECEPTOR IIB ON HUMAN B CELLS PROMOTES RITUXIMAB INTERNALISATION AND REDUCES CLINICAL EFFICACY

S Lim, A Vaughan, R French, S Beers, H Chan, E Williams, S Dixon, N Potter, C Mockridge, M Ashton-Key, K Cox, A Davies, D Oscier, P Johnson, M Glennie, M Cragg

University of Southampton, Southampton, United Kingdom

Background. The anti-CD20 monoclonal antibody (mAb) rituximab is invaluable in the treatment of B-cell neoplasms, but resistance remains a significant problem. Anti-CD20 mAb can be classified as type I (rituximab, ofatumumab) or type II (tositumomab, GA101) according to their activities in various *in vitro* effector assays. We recently reported that type I mAb, unlike type II, are internalised from the surface of normal and malignant B cells. Such internalisation is important because

it consumes mAb and reduces therapeutic efficacy. Here, we report that the inhibitory Fc gamma receptor (FcγRIIb) on target B-cells is a key regulator of this process *Aims.* The aim of the study is to uncover the mechanism behind the internalisation of rituximab. *Methods.* Internalisation of anti-CD20 mAb in primary tumour material was analysed using an *in vitro* flow cytometry-based fluorescence quenching assay. Western blotting and confocal microscopy were used to elucidate the events post-internalisation. *Results.* Rapid internalisation was particularly evident in most cases of chronic lymphocytic leukaemia and mantle cell lymphoma (MCL), but not from the majority of follicular or diffuse large B-cell lymphoma samples, possibly explaining their differing clinical responses to rituximab. Within each disease, the speed and extent of internalisation was heterogeneous. Internalisation of rituximab correlated strongly with FcγRIIb expression on tumour cells regardless of lymphoma subtype. Transfection of FcγRIIb converted FcγRIIb- Ramos cells into rapid internalisers in a dose-dependent manner. Internalisation also resulted in reduced macrophage phagocytosis of mAb-coated targets and could be inhibited by blocking FcγRIIb. Internalisation was largely cell-intrinsic, independent of contact with other FcγRIIb-expressing cells, in a process wherein FcγRIIb was phosphorylated and internalised along with CD20 and mAb prior to lysosomal degradation. This data is supported by clinical results showing that high FcγRIIb expression predicted less durable responses following rituximab-containing regimens in a small cohort of MCL patients. *Summary/conclusions.* High FcγRIIb expression provides a potential biomarker of response to rituximab-containing therapy and may identify patients for which treatment with type II anti-CD20 mAb may be preferable.

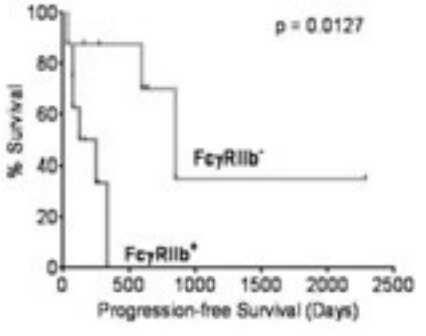

Figure 1. PFS of MCL patients by FcgRIIb expression.

MONOALLELIC EXPRESSION OF THE CANDIDATE TUMOR SUPPRESSOR GENE C13ORF1 IDENTIFIED BY PROMOTER-RESTRICTED H3K4ME2

D Mertens,[1] A Philippen,[1] M Ruppel,[2] H Döhner,[1] P Lichter,[2] S Stilgenbauer[1]

[2]*DKFZ, Heidelberg, Germany*

Monoallelic expression is a mechanism of gene regulation especially relevant in the context of tumor suppressor genes (TSG), where inactivation of the single expressed copy can lead to a complete loss of tumor suppressive function. Monoallelic gene expression has been proposed to correlate with promoter-restricted enrichment of dimethylated lysine 4 of histone H3 (H3K4me2). We used this epigenetic mark to predict monoallelic expression of candidate tumor suppressor genes in a critical region in chromosomal band 13q14.3 telomeric to RB1 that is recurrently deleted in tumors. While the biallelically expressed gene KPNA3 and the monoallelically expressed candidate tumor suppressor gene RFP2 localized in 13q14.3 showed no promoter-restricted enrichment of H3K4me2, the monoallelically expressed candidate tumor suppressor ncRNA genes DLEU1 and DLEU2 carry significantly more H3K4me2 marks in their promoters compared to their first exons. Interestingly, based on the promoter-restricted enrichment of H3K4me2 in peripheral blood mononuclear cells, we identified the potential tumor suppressor gene C13ORF1 to be also monoallelically expressed in a parent-of-origin independent manner. We suggest that this gene might be involved in the pathomechanism of chronic lymphocytic leukemia (CLL), where more than 50% of patients display loss of one allele in the leukemic cells and where monoallelic expression will at least in a subset of patients cause a complete loss of C13ORF1 function.

B-cell chronic lymphocytic leukaemia (CLL) is characterised by clinical and biological heterogeneity. Its pathogenesis remains largely unknown and it is unclear which genes are involved in disease maintenance and progression. Next generation sequencing technology has the ability to analyse the whole genome for sequence variations and is a sensitive tool to elucidate the complexity of cancer genomes. We therefore performed whole genome sequencing (WGS) on 2 patients with relapsed/refractory CLL and identified multiple protein code changing mutations. The aim of the present study was to validate our findings in a larger cohort of CLL patients. *Methods.* Discovery WGS was carried out to an average of >30-fold depth on blood samples of 2 patients plus matched germline buccal swab controls. Sequencing employed SBSv5 chemistry on the HiSeq2000 instrument. Paired 100-base reads were aligned to the human reference GRCh37.1/hg19 and candidate single nucleotide variants (SNVs), insertions, deletions and copy number variants (CNVs) were detected in both genomes. Potential candidate mutations were selected on the basis of: (1) functional annotations, (2) predicted impact on protein function using SIFT and Polyphen analysis, and (3) high-resolution SNP array data on a large cohort of CLL patients which identified copy number alterations (CNAs) affecting genomic regions in the potential candidates affected by targeted re-sequencing. Next, 40 CLL patients with treatment naïve or relapsed/refractory CLL were selected and subjected to capillary sequencing of the coding exons of candidate mutations. *Results.* WGS of 2 CLL patients revealed on average 20 non-synonymous, nonsense or frame-shift mutations per patient. Of the genes selected, many are involved in cancer pathways (eg MEK1, ASXL1, FAT3, NRG3) or are important in B-cell development or regulation of the innate immune response (ADAD1, SAMHD1, BCL2L13). Besides, we identified mutations in wnt pathway members. *Conclusions.* WGS has the potential to efficiently detect mutations in promising candidate genes involved in CLL pathogenesis. Work is ongoing to elucidate the frequency and dynamics of these mutations in a larger cohort of patients to provide insights into understanding CLL biology and help direct future therapeutic options.

IMPACT OF THE MEVALONATE PATHWAY AND HIF/PGP AXIS IN MODULATING MULTIDRUG-RESISTANCE IN UNMUTATED CLL CELLS

M Coscia,[1] M Rigoni,[2] C Riganti,[1] I Campia,[1] C Vitale,[2] S Peola,[2] V Griggio,[2] B Castella,[2] P Sciancalepore,[2] D Drandi,[2] M Ladetto,[2] M Boccadoro,[2] A Bosia,[1] M Massaia[2]

[1]*Università di Torino, Torino, Italy*
[2]*Dip. Medicina e Oncologia Sperimentale, Sez. Ematologia, Università di Torino, Torino, Italy*

Background. The mutational status of the tumor immunoglobulin heavy chain variable region (IGHV) is a very reliable prognosticator in chronic lymphocytic leukemia (CLL): patients with unmutated (UM) IGHV have a worse prognosis than patients with mutated (M) IGHV. The tumor microenvironment actively supports the survival and *in vivo* accumulation of CLL cells and confer a multidrug resistance (MDR) phenotype to CLL B cells. MDR is due to the over-expression of membrane transporters, like P-glycoprotein (Pgp), which actively extrudes

several anticancer drugs. The activity of Pgp is under the positive control of the transcription factor Hypoxia-Inducible-Factor-1-alfa (HIF-1α), which is in turn activated by Ras/Rho-dependent signaling. A low mevalonate pathway activity, is known to be associated to a reduced production of isoprenylated small G-proteins, which are crucial factors for Pgp activity. Little is known on the role of metabolic and molecular pathways regulating chemoresistance in CLL cells. *Aim.* The aim of this study was to investigate the role of metabolic and signaling pathways involved in MDR modulation in M and UM CLL cells, in order to identify specific targets of therapeutic interventions. *Methods.* M and UM CLL cells negatively selected by magnetic beads isolation were cultured in standard medium in the presence or in the absence of murine stromal cells (M2-10B4) and CLL-derived bone marrow stromal cells (BMSC). The Mevalonate pathway activity was measured by cells radiolabelling with [14C]-mevalonic acid, lipid extraction and thin layer chromatography. RhoA/Ras isoprenylation, ERK1/2, Akt activity and HIF-1 phosphorylation were detected by Western blot. Pgp expression was measured by Real Time-PCR and Western Blot and its activity was evaluated by measuring the efflux of rhodamine 123. The Cytotoxicity induced by Doxo was analysed by annexin V and propidium iodide (PI) staining. *Results.* UM CLL cells showed a significantly more active Mev pathway than M CLL cells. The higher levels of Mev pathway activity were associated to a higher expression of Ras/Rho and to a higher activity of downstream kinases Akt and ERK1/2. This higher activity of ERK/Akt pathway was paralleled by a higher expression of phosphorylated HIF-1α, which is a potent inducer of mdr1/Pgp gene. As expected, UM CLL cells displayed higher levels of mdr1 mRNA expression, lower accumulation of intracellular Doxo and higher *in vitro* viability upon Doxo exposure. BMSCs induced the upregulation of Rho/Rho Kinase and Pgp proteins in UM CLL cells, protecting them from Doxo-induced cytotoxicity. Targeting of the Mev pathway by Zoledronic acid determined a significant reduction of the Rho/Rho kinase and Pgp activity, and abrogated BMSCs-mediated chemoresistance. *Conclusions.* Our data demonstrate that Hif/Pgp axis is more active in UM CLL cells compared to M CLL cells, leading to higher levels of chemoresistance. Specific targeting of the Mevalonate pathway and/or downstream signalling pathways may represent a promising strategy of therapeutic intervention.

0086

PI3-K-ALPHA ISOFORM AS A POTENTIAL TARGET FOR THERAPY IN CHRONIC LYMPHOCYTIC LEUKEMIA

S Schnabl, M Hilgarth, R Hubmann, D Demirtas, P Ponath, E Brynzak, M Reiter, J Schwarzmeier, C Zielinski, U Jaeger, M Shehata

Medical University of Vienna, Vienna, Austria

Background. There is evidence on the involvement of PI3-K/Akt pathway in the pathophysiology of CLL. We have recently shown that this pathway is activated *in vivo* and *in vitro* upon the interaction between CLL cells and primary bone marrow stromal cells (BMSC). Several inhibitors of this pathway has been tested and few such as PI3-K-delta inhibitor is already in clinical evaluation. However, the pattern of expression of different PI3-K isoforms and the significance of selective targeting of other isoforms remains to be explored. *Aims.* The aim of this study is to evaluate the expression of the four isoforms of PI3-K-p110 catalytic subunit (alpha, beta, gamma and delta) and to test the *in vitro* response of CLL cells to pan- and isoform-selective inhibitors of the PI3-K. *Methods.* Peripheral blood mononuclear cells of 15 CLL patients and 7 healthy individuals were analysed for the expression of the four isoforms of PI3-K-p110 at the mRNA and protein levels. The effect of pan-PI3-K inhibitors (Wortmannin, LY-294002 and PI-103) and PI3-K-isoform inhibitors against alpha, beta and gamma isoforms on cell viability was valuated. Overall cell viability was estimated by annexin V/PI staining, FACS analysis and MTT assays. Selective effect on cellular subpopulations was evaluated by flowcytometry using antibodies against CD3, CD14 and CD19 in combination with 7AAD. The effect of the inhibitors on the phosphorylation of the downstream targets Akt and PTEN was evaluated by western blotting. *Results.* RT-PCR analysis demonstrated the expression of the four PI3-K-p110 isoforms (alpha, beta, gamma and delta) in CLL samples. The mRNA expression was higher in CLL samples compared to healthy individuals. Western blot experiments confirmed that CLL cells express all four PI3-K-p110 isoforms at higher levels in comparison to healthy persons. Intracellular staining using isoform-specific antibodies demonstrated that more than 50% of the leukemic cells (CD19+/CD5+) were positive for p110 isoforms compared to less than 30% of CD19+ cells of healthy individuals. Exposure of CLL cells to pan- and isoform specific PI3-K inhibitors showed a significant induction of apoptosis with variable potency. PI3-K-p110-alpha selective inhibitor (morpholino-thienopyridine compound) was most effective at nanomolar concentrations with IC50 ranging between 10-20 nM with maximum effect at 40 nM concentration. This was followed by p110-beta inhibitor (morpholino-pyrimidinone/TGX-221) and p110-gamma inhibitor (thiazolidinedione compound). Co-culture experiments showed that p110-alpha inhibitor is most effective in inhibiting the supportive effect of BMSC. The induction of apoptosis was accompanied by dephosphorylation of Akt at Thr308 leading to Akt inactivation. This was also associated with dephosphorylation of PTEN at amino acid residues Ser380 consistent with the activation of PTEN phosphatase function. *Conclusion.* CLL cells express all four PI3-K-p110 isoforms at the mRNA and protein at higher levels than samples of healthy individuals. Targeting the PI3K pathway with alpha isoform-specific inhibitors significantly induces apoptosis in CLL cells and overcome the supportive effect of BMSC. These data confirm the value of PI3-K as a potential target for therapy in CLL and point to the significance of targeting the PI3K-p110 alpha isoform in particular.

Background. In chronic lymphocytic leukemia (CLL), a fraction of cases carries highly homologous "stereotyped"B-cell receptors (BCR) characterized by non-random combinations of immunoglobulin heavy-chain variable (IGHV) genes and heavy-chain complementarity determining region-3 (HCDR3). *Aim.* We performed sequencing analysis to characterize IGHV regions in a large panel of CLL patients investigated by a multicenter Italian study group and investigated possible correlations between stereotyped HCDR3 subsets and IGHV usage or biological/molecular and clinical features. *Methods.*The analysis of stereotyped subsets was performed based on previously reported criteria (Stamatopoulos *et al*. Blood 2007; Murray *et al*. Blood 2008; and Bomben *et al*. BJH 2008). A pair-wise alignment of sequences was adopted in order to discover novel potential subsets (HCDR3 identity > 60%). Evaluation of the time to first treatment (TTFT) was performed only in Binet A patients. *Results.* A total of 1382 CLL patients were investigated for productive IGHV-D-J rearranged sequences; twenty-two carried a double in-frame rearrangement. Based on the 98% homology criteria, 504/1404 sequences (35.9%) were classified as unmutated (UM). Stereotyped HCDR3 sequences were found in 28.6% (402/1404) of the patients, 66.6% (268) of which were UM; the most recurrent stereotyped subsets identified in our panel were #1 (39 cases), #7 (30), #4 (27), #3 (16), #9 (14) and #2 (14). Of note, the global alignment procedures within our dataset sequences allowed to identify 31 new putative subsets in 65 patients. Concerning the correlations between the most recurrent stereotyped subsets and genomic aberrations we found that (i) subset #1 (IGHV1-5-7/IGHD6-19/IGHJ4) was significantly associated with del(17)(p13); (ii) subsets #8 (IGHV4-39/IGHD6-13/IGHJ5) and #10 (IGHV 4-39 or IGHV2-5/IGHD2-2/IGHJ6) with trisomy 12;(iii) subset #4 (IGHV4-34) with a favorable cytogenetic profile. Despite previous reports (Marincevic *et al*. Haematologica 2010) we did not observe the presence of del(11q)(23) in all the cases (9 pts) included in subset #2 (IGHV3-21). Of clinical relevance, we found that subset #1 patients showed a significantly reduced TTFT compared to all UM patients, UM not stereotyped patients or UM patients with the same heterogeneous IGHV genes. Concerning previous reports, we confirmed the more unfavorable clinical course of subset #2 but not the difference in disease progression between subset #5 (IGHV1-69/IGHD3-10/IGHJ6), not stereo-

typed IGHV1-69 and subset #3 (IGHV1-69/IGHD2-2/IGHJ6) patients. *Conclusion.* Our findings suggest that distinct stereotyped BCRs in CLL are characterized by specific cytogenetic profiles and clinical course. In particular, we found a significant prognostic relevance of subset #1 in the context of UM CLL patients that would be validated in larger prospective series of patients.

NURSE-LIKE CELLS SHOW DEREGULATED EXPRESSION OF GENES INVOLVED IN IMMUNOCOMPETENCE

D Mertens, N Bhattacharya, I Idler, S Diener, T Zenz, H Döhner, S Stilgenbauer

University of Ulm, Ulm, Germany

Chronic lymphocytic leukemia (CLL) cells convert CD14+ cells from patients into "nurse-like"cells (NLCs). CLL cells can also convert CD14+ peripheral blood mononuclear cells (PBMCs) from healthy donors into cells with morphological similarities to NLCs (CD14CLL-cells). However it is unclear whether this conversion process is only induced by CLL cells. We show that CD14+ PBMCs from healthy donors can also be converted into differentiated cells (CD14B-cells) by non-malignant B-cells. Intriguingly, non-malignant CD19-sorted B-cells were also able to differentiate CD14+ PBMCs from healthy donors into cells (CD14B-cells) that support survival similar to NLC and CD14CLL-cells. Moreover, gene expression levels of survival-associated genes like APRIL, BAFF and PECAM1 were comparable in all three differentiated cell types (NLC, CD14CLL- and CD14B-cells). In order to identify changes specifically induced by CLL cells, we compared gene expression profiles of NLCs, CD14CLL-cells and CD14B-cells. CD14+ cells cultured with CLL cells were more similar to NLCs than those cultured with non-malignant B-cells. The most significant changes induced by CLL cells were deregulation of the antigen presentation pathway and of genes related to immunity. NLCs had reduced levels of lysozyme activity, CD74 and HLA-DR *in-vitro* while expression of inhibitory FcGR2B was increased. These findings suggest an impaired immunocompetence of NLCs which, if found in-vivo, could contribute to the immunodeficiency in CLL patients.

Background/Aims. Determine if SNP random bead-arrays (Illumina, using oligonucleotides probes immobilized onto beads, that correspond to Single-Nucleotide Polymorphisms along the human genome) are more sensitive than Interphase Fluorescence In Situ Hybridization (I-FISH) or Conventional metaphase Cytogenetics (CC) to detect specific chromosomal abnormalities associated with prognosis in B-CLL, e.g. deletions at 17p, 11q, 13q and trisomy 12. *Methods.* A blood sample from 24 patients with B-CLL at diagnosis was analysed simultaneously by I-FISH, CC and SNP bead-array. FISH: LSI p53, ATM and CEP12 Single Color Probes (Abbott) were used, to detect del(17p13.1), del(11q22.3) and tri12, respectively. For detection of del(13q14.3), we tested in parallel the LSI D13S319 (~130 kb) Single Color (Abbott) and 13q14.3 (~400 kb)/ 13qter Dual Color probes (Cytocell). In normal lymphocytes, an average of 6% nuclei showed a loss of signal (truncated nuclei or random colocalized signals), and the cut-off to ascertain a chromosomal deletion was defined over 10% (m+3SD) CC: blood lymphocytes are cultivated for 72 hours with immunostimulants (DSP30 and IL-2) SNP: DNA (200 ng) was hybridized on the Illumina HumanCNV370 BeadChips (~373,397 markers; 4.9 kb median marker spacing; mean 7.8 kb). *Results.* FISH identified del(13q) (13-95% of nuclei, m=47%), del(11q) (35-54%) and tri12 (25-49%) in 18 (75%) [including 2 biallelic deletions], 3 (12.5%) and 4 cases (17%) respectively (5 cases presented associated abnormalities). SNP-arrays detected all of those abnormalities [del(13q), size: 0.49-33 Mb; del(11q), 35-42 Mb], with signals intensity correlating with percentage of FISH-positive nuclei. Moreover, SNP-arrays showed 4 del(13q) detected neither by the FISH probes used (>150 kb) nor by CC: cryptic deletions (39-82 kb) located at 13q14.3 (n=2) or q14.1 (n=1); 30 Mb deletion (13q13-q22) undetected by I-FISH (2% of nuclei with loss of signal, low clonal infiltration) (n=1). In that case, a biallelic deletion (20% nuclei) was detected by FISH performed 6 months later. In one case with del(13q) and tri12 (~25% of nuclei by FISH), an additional del(11q) was detected by CC (5/24 mitoses) and SNP-array (38 Mb, including ATM). In addition, SNP-arrays enabled to define more precisely the size and location of the abnormalities. For example, in 4 cases with del(13q) detected by FISH, SNP-arrays showed coexistence of several clones with variable sizes. No del(17p) was detected. Only one of the 24 cases (37% of CLL cells) was negative by FISH, CC and SNP-array, for the loci studied. *Summary/Conclusions.* The SNP random bead-array platform is more sensitive than molecular or conventional cytogenetics techniques. In our study, 92% (22/24) B-CLL cases presented with del(13q) at diagnosis. We report the best resolution (deletion of 39 kb) described. Higher density SNP-arrays (> 5 million markers) may be used to improve sensitivity, and closely determine involved genes. Our study confirms usefulness of SNP bead-arrays for prognostic evaluation in B-CLL, and sensitivity (abnormality detected in 2% of tumoral cells). This could allow to define a more homogeneous set of patients for prospective therapy trials.

We have recently reported that chronic lymphocytic leukemic (CLL) cells express the hepatocyte growth factor (HGF) receptor c-MET, a tyrosine kinase, at high levels. HGF is a pleiotropic cytokine that may induce survival, proliferation, adhesion and migration of malignant cells. We demonstrated that mesenchymal cells (MSC) producing HGF in elevated quantities, such as bone marrow stromal cells (BMSC) or trabecular bone marrow cells (TBMC) or an osteoblast-like cell line, protect CLL cells from spontaneous apoptosis, when co-cultured *in vitro* and we suggested that HGF may contribute to the enhancement of CLL survival in the bone marrrow microenvironment. In agreement with this observation recombinant human HGF, exogenously added in cultures *in vitro*, also induced increased viability of CLL cells.In order to clarify and confirm the critical role played by HGF in MSC/CLL crosstalk we utilized a neutralizing anti-HGF antibody, or a c-MET inhibitor, in functional studies and further silenced HGF secretion by siRNA in mesenchymal cells. Moreover through western blot and cyto-fluorographic analysis we studied the activation of signaling molecules potentially induced by CLL/MSC co-cultures or HGF treatment of leukemic B cells . We demonstrated a significant inhibition of the prolonged survival of CLL cells by the use of an anti-HGF neutralizing antibody or of the c-MET inhibitor SU11274 in experiments where CLL cells were co-cultured with different mesenchymal cell lineages. Silencing of HGF production by siRNA significantly reduced the anti-apoptotic effect induced by the osteoblast-like cell line MG63 in co-culture experiments. We further observed that co-culture of CLL cells with conditioned media from BMSC or MG63, or their treatment with recombinant HGF induced phosphorylation of STAT3 in TYR705 after 10-40 min. A putative role played by pSTAT3 in CLL survival by MSC co-culture or HGF treatment was further confirmed by blocking CLL cells viability with a STAT3 inhibitor.Our data underlines a pivotal role of HGF in prolonging CLL cells survival and potentially in contributing to apoptosis resistance of the leukemic B cell clone at the level of particular bone marrow niches. Molecules involved in the HGF/c-MET signaling pathway(s) may be further forseen as possibile therapeutical targets in the treatment of chronic lymphocytic leukemia.

HETEROGENEOUS FUNCTIONAL OUTCOMES AFTER TOLL-LIKE RECEPTOR STIMULATION IN DIFFERENT SUBGROUPS OF CHRONIC LYMPHOCYTIC LEUKEMIA ARE UNDERLINED BY DISTINCT TRANSCRIPTIONAL PROGRAMS

S Ntoufa,[1] N Papakonstantinou,[2] A Anagnostopoulos,[2] V Aleporou-Marinou,[1] F Caligaris-Cappio,[3] C Belessi,[4] P Ghia,[3] M Muzio,[3] K Stamatopoulos[2]

[4]*Nikea General Hospital, Athens, Greece*

We have recently reported that subgroups of patients with chronic lymphocytic leukemia (CLL) defined by distinctive molecular characteristics of the clonotypic B cell receptors (BcRs) exhibit distinct expression profiles of the Toll-like receptor (TLR) signaling pathway-associated genes as well as differential outcomes after TLR stimulation. The aim of this study was to investigate whether specific TLR-induced transcriptional modulation is observed and if it may be implicated in differential functional effects. To this end we analyzed 4 CLL cases each belonging to stereotyped subset #1 (unmutated IGHV1/5/7-IGKV1(D)-39 BcRs) or #4 (mutated IGHV4-34/IGKV2-30 BcRs). We selected these particular cases prompted by our recent finding of subset-biased response patterns to certain TLR ligands; in particular, imiquimod (ligand for TLR7) was active in subset #1 and induced CD25 expression while Pam3CSK4 (ligand for the TLR1/2 heterodimer) was active in subset #4 and induced CD86 expression. In addition, we included in the analysis 3 cases utilizing the IGHV4-34 gene, in mutated albeit non-stereotyped rearrangements (non #4). In order to study transcriptional changes, we negatively selected CD19+ B lymphocytes and stimulated the cells with specific TLR ligands. The gene expression profile of the TLR signaling pathway (overall, 83 genes) was determined by the RT² Profiler® PCR Array kit (PAHS-018A array, SABiosciences) in CLL cells unstimulated or stimulated with TLR ligands for 24 hours. Stimulation of TLR7 with imiquimod in subset #1 cases led to a specific transcriptional program characterized by significant changes of only a few genes with up-regulation of HSPD1 and TNF and down-regulation of HMGB1, MAP2K3 and IFNG mRNA levels. In stark contrast, stimulation of TLR1/2 with Pam3CSK4 in subset #4 cases affected the expression of a much greater number of genes. The effect was uniform in that all genes with significant changes showed down-regulated mRNA levels. Notably, the genes with altered expression include receptors, adaptors, effectors and NFκB/ MAPK signaling molecules which are all critical for TLR signaling; this suggests that a negative feedback loop may occur in this subset. Finally, in non #4 cases, which are generally non responsive to TLR1/2 stimulation, we observed that HSPD1, IL6, MAP2K4, MAP4K4, NFKB2, SARM1, TICAM2, TLR6 and TLR9 were up-regulated, while only SIGIRR, a negative regulator of the TLR signaling pathway, was down-regulated. In conclusion, the TLR pathway is competent for signaling in CLL with subset-biased functional outcomes; specifically, distinct transcriptional programs are activated by different TLR that may regulate TLR responsiveness and/or tolerance to additional TLR ligands.

Background. IGHV1-69/51p1 identifies ~30% unmutated CLL (U-CLL) and has a marked restriction in the HCDR3, with ~50% assigned to subsets with stereotypic patterns. The most representative pattern is subset-6 (>1% of all CLL), including virtually identical HCDR3s encoded by IGHV1-69, IGHD3-16 in reading-frame 2 (RF2), and IGHJ3. In healthy individuals, ~20% circulating naïve B-cells using IGHV1-69/IGHJ6 combinations have stereotypic patterns similar to U-CLL, suggesting tumor origin from the natural naïve B-cells. If U-CLL using different IGHV1-69/IGHJ combinations (including those assigned to subset 6) also derive from a similar repertoire is unknown. *Aims.* The aims of the present study were i) to detect stereotypic patterns using IGHV1-69/J3 rearrangements in the circulating B-cells of healthy donors and ii) to identify any counterparts of the unusually highly conserved subset-6 sequence in the normal blood. *Methods.* The functional IGHV1-69/D/J3 nucleotide sequences (n=165) derived from 7 healthy individuals were aligned to IMGT sequence directory (http://imgt.cines.fr/) and analyzed for IG usage. The derived HCDR3 amino acid (AA) sequences were aligned to those from a pre-established reference database of IGHV1-69+ve CLLs (n=654, including 78 IGHV1-69/J3 rearrangements) and to each other, and analyzed for identity with public and new CLL subsets, in concordance with established criteria. *Results.* One-hundred-forty-five normal rearrangements (87,9%) were unmutated and 20 (12,1%) were mutated, similarly to CLL (66/78 [84,6%] U-CLL and 12/78 [15,4%] M-CLL, p=.5). Frequencies of IGHD genes of IGHV1-69/J3 normal B-cells were significantly different from those of IGHV1-69/J3 CLL (p<.001). In particular IGHD3-16 frequency was markedly lower in normal (7/165, 4,2%) than in CLL (41/78, 52,6%, p<.001). IGHD3-16 was in RF2 less frequently in normal (5/7, 71,4%) than in CLL (39/41, 95,1%, p<.029). Stereotypic IGHV1-69/J3 patterns were found in 62/165 normal (37,6%) and 51/78 CLL (65,4%, p<.001). Remarkably, none of the normal stereotypes associated with the CLL stereotypes and viceversa. None of the normal IGHV1-69/D3-16/J3 rearrangements were assigned to subsets while CLL IGHV1-69/D3-16/J3 rearrangements were assigned to subset-6 in almost all circumstances (39/41, 95,1%, p<.001). A seminested PCR with a subset-6 specific degenerate primer was used to extract IGHV1-69/D3-16/J3 rearrangements assignable to subset-6 from the naïve B-cell repertoire. We identified 46 unique sequences and 10 clonal expansions from 114 clones, giving a total of 56 sequences with different HCDR3. Thirty-eight CLL subset-6 HCDR3 derived-AA sequences were available for comparison. All CLL used a common CAR(GGxYD) motif at codons 107-111 comprising the V-N1-D joining region). By sequence logo analysis, it emerged that the GGxYD motif was completely disrupted and never repeated in any individual normal B-cell. Disruption was also in terms of length of the N1 junction (5-15 AA in normal vs constantly 5 AA in CLL). *Summary/Conclusions*. These data suggest existence of CLL-specific motifs in the N1 junction region of subset-6-associated HCDR3, that are not found among circulating naive B-cells. This unusual feature of a highly frequent (>1%) HCDR3 motif in CLL is the most representative example of HCDR3 selection by "antigen" in CLL. One important question is to search the antigen or autoantigen that provides this CLL-specific driving force.

0093

THE MIR-17~92 CLUSTER FAMILY DETERMINES THE RESPONSIVENESS OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS TO TOLL-LIKE RECEPTOR 9 TRIGGERING

R Bomben

Centro di Riferimento Oncologico, Aviano, Italy

Background. Chronic lymphocytic leukemia (CLL) cells expressing unmutated (UM) IGHV, a phenotype associated with aggressive clinical courses, can be more efficiently induced to proliferate by stimulating Toll-like Receptor 9 (TLR9) with unmethylated CpG oligonucleotides (CpG) than mutated (M) CLL cells. MicroRNA (miRNAs) are 18- to 22-nucleotide-long non-coding RNA molecules that regulate gene expression and play a key role in several biological process including oncogenesis. *Aim:* Elucidating miRNAs involvement in regulating activation/proliferation processes of CLL cells. *Methods:* Freshly-isolated negatively-selected CLL cells from 17 CLL patients (9 UM and 8 M) were stimulated with CpG (18 hours) or left unstimulated. miRNA and Gene Expression Profiling (GEP) were performed with Agilent Technologies. In-silico prediction of miRNAs modulation was made analyzing GEP data by the T-REX and GSEA software; validations were performed by qRT-PCRs. *Results:* miRNA profiling and GEP were separately evaluated in UM and M-CLL. In UM-CLL, 21 miRNAs resulted up-regulated and 3 down-regulated upon CpG stimulation. GEP data analysis selected 30 significant miRNAs, upregulated in CpG-stimulated cells, as allegedly responsible for GEP perturbation, of which 3 of them (miR-17, miR-20a, and miR-20b) in common with the miRNA signature of CpG-stimulated cells. These 3 miRNAs and additional 4 miRNAs

(miR-17*, miR-18a, miR-19b-1* and miR-92a-1*) again comprised in the miRNA signature, all belonged to the miR-17~92 cluster, a well-known miRNA cluster over-expressed in a variety of B-cell lymphomas. The GEP of CpG-stimulated UM-CLL cells included genes involved in cell cycle regulation and NF-kappaB cascade, in agreement with the proliferative effect of CpG in UM-CLL cells. In particular, among these genes: i) E2F5, TP53INP1, TRIM8, and ZBTB4, all target of miR-17, were downregulated in CpG-stimulated cells and knocked-out upon miR-17 transfection in six primary UM-CLL cells; ii) the miR-17 gene regulator MYC and the MYC target genes CAD, PGK1 and TFAM were upregulated in CpG-stimulated UM-CLL cells. Time-course experiments using primary UM-CLL cells showed that MYC and miR-17 were both upregulated upon CpG stimulation although follow different kinetics. In M-CLL cells no miRNA was differentially expressed between CpG-stimulated and unstimulated CLL cells. Despite this, in a hierarchical cluster driven by the UM-CLL microRNA signature, 4/8 M-CLL cases showed a microRNA profile similar to that of UM-CLL, including the increase of miR-17~92 cluster. In agreement with this data, the same 4 M-CLL clustered "near"to UM-CLL cells in a hierarchical cluster made using the GEP data of UM-CLL cells ("CpG-responder"M-CLL). Consistently, in these "CpG-responder"M-CLL, MYC gene resulted upregulated along with two (CAD and PGK1) MYC target genes. *Conclusion:* Altogether, our data suggest that TLR9 triggering is able to elicit a complete response which includes upregulation of MYC, miRNAs from the miR-17~92 cluster family and specific gene targets for these miRNAs both in UM-CLL cells and a subset of M-CLL.

[4]*Department of Pathology and Diagnostics, University of Verona, Verona, Italy*

Background. In the microenvironments where B-CLL develops, complex molecular networks propagate signals that confer growth advantage to CLL. Within this context, interplaying between TNF superfamily members and their cognate receptors has been shown to play a relevant role in controlling B-CLL growth and survival. TNF-like protein 1A (TL1A) is a recently discovered member of the TNF superfamily expressed on various cell types, including macrophages, dendritic cells, and endothelial cells. The TL1A cognate receptor, death receptor 3 (DR3), is a member of the TNF receptor superfamily expressed on various cell types, including activated T cells and macrophages. TL1A-DR3 interactions have been shown to modulate immune and inflammatory functions. So far, the expression of DR3 on B-lineage cells as well as possible roles of TL1A-DR3 interplaying in CLL biology has not been explored. *Aims.* The objective of the study was to investigate DR3 expression and function(s) in B-CLL. *Methods.* B cells were purified from PBMC of 23 B-CLL patients and 13 healthy donors by negative selection with magnetic beads. DR3 surface expression was measured by flow cytometry at baseline and various time points following stimulation with F(ab')2 anti-human IgM conjugated to latex microspheres. DR3 mRNA was detected by quantitative RT-PCR. Phosphorylation states of NF-kappaB, Erk1/2, and TBK1 were measured by using phospho-specific antibodies and flow cytometry in basal condition and following DR stimulation of cells with agonistic antibody at different time points (15, 30, 60, 180 minutes). *Results.* Although both healthy and CLL B cells did not express DR3 in basal conditions, stimulation of B cell receptor (BCR) induced a statistically significant increase of DR surface expression in healthy as well as malignant B cells ($p<0.001$ for both cells). Time course analysis showed that DR3 expression peaked at 24 hour after stimulation. DR3 expression was confirmed also at the mRNA level. Time course analysis showed that DR3 mRNA in B-CLL cells peaked at 2.5 hour following anti-IgM stimulation (4-fold change with respect to basal conditions). Anti-IgM-induced DR3 expression levels were significantly higher in B-CLL cells if compared with healthy B cells ($p<0.05$). Interestingly, when B-CLL patients were stratified by IGVH mutational status, anti-IgM-induced DR3 expression levels were significantly higher in B-CLL cells harboring unmutated IGVH genes compared with cells with mutated IGVH genes. To assess whether the anti-IgM-induced DR3 molecule was functionally active in B-CLL cells, we examined the ability of DR3 to trigger phosphorylation events in biologically relevant signaling nodes (i.e. Erk1/2, NF-kappaB, and TBK1) by stimulating cells with anti-DR3 agonistic antibodies. Phospho-specific flow cytometry analysis showed that DR3 engagement induced phosphorylation of Erk1/2 but not NF-kappaB or TBK1. *Conclusions.* We described for the first time the expression of functional DR3 molecules in B-lineage cells activated by BCR stimulation in healthy and pathological cells (i.e. B-CLL cells). The findings that anti-IgM-induced DR3 expression was higher in B-CLL cells if compared with healthy B cells and that, among B-CLL patients, this expression was higher in cells with unmutated IGVH genes, suggest that DR3 stimulation may have a role in B-CLL pathogenesis.

[4]*Papanicolaou Hospital, Thessaloniki, Greece*

Background. We previously demonstrated that the phosphorylation status of Hematopoietic cell specific Lyn substrate 1 (HS1) i) is a potential prognostic marker as CLL patients whose leukemic cells carry phosphorylated HS1 have a better prognosis than patients with the hyper-phosphorylated form; ii) in the CLL-prone Eμ-TCL1 transgenic mouse is a pivotal molecule in the signal transduction pathway triggered by the B-cell receptor (BCR), serving as a central interactor of several cytoskeletal components and being involved in tissue trafficking and homing and iii) has a profound effect on the development and progression of murine CLL suggesting that the hyper-phosphorylation of HS1 leads to its inactivation rather that activation. *Aims.* Given the role played by HS1 in BCR signalling and cell migration, we decided to dissect the signalling pathway and the migratory capacity of CLL cells presenting a differential phosphorylation status of HS1. *Methods.* We started by taking advantage of the CLL cell line MEC1 where we silenced the expression of HS1 and dissected the signalling pathway by Western Blot and Immunoprecipitation. We then utilized primary CLL cells to validate the results. Finally we investigated *in vivo* the migration of human leukemic cells labeled with different concentrations of CFSE and injected intravenously into Rag2-/-γc-/- recipient mice. *Results.* In the HS1-silenced MEC1 cell line we found that the phosphorylation status of several BCR signalling molecules, including Lyn Kinase, SHP phosphatase, ERK kinase and the cytoskeletal-related proteins Vav, Rac and HIP-55, is directly affected by the absence of HS1. We confirmed a similar pattern of modifications in primary cells from 25 patients who had a different phosphorylation status of HS1. These findings indicate that the pattern of HS1 phosphorylation is associated with a specific biochemical signature characterized by the loss of phosphorylation in several BCR downstream signalling molecules. We then investigated the homing ability of CLL cells from patients showing different HS1 levels of phosphorylation. CLL cells purified from 8 patients were paired into 4 couples according to their HS1 phosphorylation status. Each couple included a case with phosphorylated HS1 and a case with hyper-phosphorylated HS1 CLL cells. In 3/4 couples of differentially phosphorylated paired patients, CLL cells with phosphorylated HS1 had a consistent homing rate to the spleen while CLL cells with hyper-phosphorylated HS1 had a preferential homing to the BM. This observation indicates a correlation between the status of HS1 phosphorylation and the propensity of human CLL cells to accumulate in the bone marrow *in vivo*. *Conclusions.* These findings strengthen our previous observation that HS1 phosphorylation has an important role in controlling cell migration and homing of leukemic B cells, likely through its involvement in cytoskeleton organization and BCR signalling. Accordingly our future plans are: i) to increase the number of patients studied in order to detect potential correlations between signalling results, clinical behaviour and biological prognostic factors and ii) to identify novel intracellular HS1 partners to explore the possibility that the phosphorylation of HS1 may be modulated for therapeutic purposes.

0097

PROGRAMMED DEATH-1 IS A NOVEL IMMUNOTOLERANT MOLECULE EXPRESSED ON LEUKEMIC B CELLS IN CHRONIC LYMPHOCYTIC LEUKEMIA

K Giannopoulos, M Grzywnowicz, J Zaleska, T Tomczak, P Wlasiuk, A Bojarska-Junak, A Dmoszynska

Medical University of Lublin, Lublin, Poland

Background. Programmed death-1 (PD-1) molecule is an immunoreceptor, which through a interaction with its ligand (PD-L1), controls peripheral tolerance by limiting activation, development and effector function of T lymphocytes. PD-1/PD-L1 pathway was found to be one of the potential tumor escape mechanism from the immunosurveillance and PD-1 expression was described on exhausted T lymphocytes. *Aim.* We assessed a mRNA level and surface expression of PD-1 and PD-L1 in CLL patients since the aberrant expression of PD-1 might represent a novel target on the lymphocytic B-cells. It might also define possible prognostic markers. *Patients and Methods.* Quantitative reverse transcriptase PCR was performed for the PD-1 transcript with four splicing variants as well as for PD-L1 and one splicing variant in 43 CLL patients and 10 healthy volunteers (HVs). For characterization of the surface expression of PD-1 and PD-L1 on leukemic B-cells in a group of 33 CLL patients and 10 HVs magnetic separation followed by five parameter flow cytometric analysis was used. *Results.* The median level of PD-1 transcripts in CLL patients was higher in comparison with HVs (p=0.006). Additionally, expression of truncated PD-1 splicing variant lacing of exons 2, 3 and 4 was lower in CLL patients compared with HVs (p=0.0465). No difference of PD-L1 expression between CLL patients and HVs on mRNA level was observed. The expression of a non-functional splicing variant lacking exon 2 was elevated in CLL patients compared with HVs (p=0.008). In flow cytometric analysis, we confirmed the presence of PD-1 and PD-L1 on the CLL cells surface. Notably, both PD-1 and its ligand were expressed on the same CLL cells. Mean fluorescence intensity (MFI) was higher among CLL patients in comparison with HVs (13.34 vs. 4.9, p<0.001). There was no difference in MFI levels of PD-L1 between CLL patients and HVs. Significantly higher MFI levels of PD-L1 were observed in early stage CLL patients (13,34 vs 4,9, in stage A and stage C according to Binet classification, respectively). There was no difference in time to progression and overall survival in groups of patients characterized by low and high PD-1 and PD-1L expression. *Conclusions.* PD-1, which is expressed both on mRNA and cell surface levels in CLL cells might represent a novel immunotolerant molecule involved in the pathomechanism of disease, as well as provide a novel target for future therapies.

Background. Bendamustine (Ben) and alemtuzumab (Cam) are shown to be effective in relapsed/refractory CLL. Both agents exhibit an individual, unique mechanism of action. Therefore, a synergistic or additive effect might be expected when used in combination. *Aim.* We designed a multicentric, single arm, dose escalation study to determine maximum tolerated dose (MTD) and efficacy of Ben Cam combination in refractory/relapsed CLL. *Methods.* Previously treated CLL pts requiring therapy were enrolled. A stepwise dose escalation exploring MTD has been evaluated. Starting dosages were: Ben 50 mg/m2 d 1,2 and Cam 20 mg sc d 1-3. If MTD was not reached within the 1st cohort, the 2nd cohort received an increased dose of Cam 30 mg with a subsequent further increase of Ben 70 mg/m2 if MTD was not reached. Treatment was repeated every 28 d up to 4 cycles. Based on phase I (12 pts) results, MTD were Ben 70 mg/m2d 1,2 and Cam 30 mg sc d 1-3. *Results.* Overall, 29 pts have been enrolled in the study from July 2008 to October 2010. Median age was 69 y (range 54-82). 45% were Binet C; refractory pts represented 24% of our population. Median prior regimens were 2 (1-6), 76% received previously fludarabine based regimens, and 55% monoclonal antibodies (rituximab 34,5%, alemtuzumab 14%, both 7%). Biological characteristics are shown in the table. The 29 pts received overall 104 courses, median 4 (2-4). Response is available in 23 pts, pending in 6. Response rate was 61%, including 26% CRs and 35% PRs. Disease progression during treatment was observed in 17% of cases. Grade III-IV haematological toxicity consisted of: neutropenia 36% of courses, anemia 7%, thrombocytopenia 9%. FUO developed in 19% of cycles; 6 major infections (2 sepsis, 3 pneumonia, 1 enteritis) were observed. CMV reactivation occurred in 10 pts: no CMV disease was recorded. Extra-hematological toxicity was mild. *Conclusion.* Results from the interim analysis of this new, 4-weekly dosing Ben Cam regimen suggest that combination therapy with Bendamustine and Alemtuzumab is feasible, safe, and effective in treating patients with relapsed and refractory CLL. Major treatment toxicities were myelosuppression and manageable infections. No toxic deaths were recorded while on treatment.

[7]*Institut Paoli Calmettes, Marseille, France*

Aims and Methods. To evaluate the efficacy and toxicity of RIC regimen including fludara. and TBI with the introduction of rituximab for allo-HSCT, we conducted a prospective study for CLL patients aged < 65 years in stage B or C in response after a salvage treatment, having a HLA identical sibling donor. The conditioning included: rituximab 375 mg/m on day-5, fludarabin e 30 mg/m from day-4 to day-2, TBI 2grays on day0 and rituximab 500 mg/m on day 1 and day 8. Forty patients were included, 34 (85%) males and 6 females, median age 54 years (35-65), 38 (95%) in B stage and 2 in stage C. Among 23 explored for cytogenetics, 8 were abnormal. Before transplantation, 17 patients received 2 lines treatment, 10 three lines, 13 5 lines. At time of allograft, 7 (17%) patients were CR, 29 (73%) in PR and 4 (10%) < PR, 59% were sex-mismatched. For ABO matching, 68% were compatible, 19% major incomp. & 13% minor incopm. The median interval diagnosis-allo-HSCT was 58 months (6-177). Seven (17%) patients did not receive rituximab during conditioning because the protocol did not include it at the beginning and has been amended later. *Results.* Thirty-nine (98%) patients engrafted with a median time to neutrophils recovery of 20 days (11-70), 79% of patients reached a total donor chimerism at day 90. Seventeen patients developed aGVHD grade II (8 grII, 8 grIII & 1 grIV) with a cumulative incidence at 3 months of 44% (36-52). The cumulative incidence of cGVHD was, at 12 months: 29% (21-36) for lim. and ext.; at 18 months: 32% (24-40) lim. and 42% (34-50) ext. After a median follow-up of 28 months (3-71), the median OS was not reached with 5-years probability of 55%(41-74). The median time of EFS was 30 months (15 - 70) with a 5-years probability of 46%(33-66). The cumulative incidence of relapse at 1 and 3 years was 17% (11-23) and 22% (15-29) respectively. The cumulative incidence TRM at 1 and 3 years was 10% (5-15) and 27% (20-35) respectively. At the last follow-up, 17 patients died, 6 due to relapse and 11 due to TRM. The multivariate analysis showed a positive impact of rituximab on OS and EFS [HR=0.1 [0-0.6] p=0.02 & HR=0.1[0-0.4] p=0.035 respectively. *Conclusion.* The introduction of rituximab allowed a better outcome especially a significant reduction of incidence and severity of acute GVHD. Nevertheless there was still a high incidence of cGVHD, leading us to propose either to increase the number of rituximab injections after allo-HSCT, or to test Fludarabine/busilvex/ATG associated to rituximab.

Background. Obinutuzumab (GA101) is the first type II, glycoengineered, humanized monoclonal anti-CD20 antibody to enter clinical trials. In a phase I study (BO20999), GA101 was administered as monotherapy to 13 patients (400-2000mg) with relapsed/refractory CLL, with GA101 given on Days 1, 8 and 22 and q21 (total of 9 infusions). End of treatment response (EOR) was 62% (8/13, all PR) (Cartron, EHA 2009, Morschhauser, ASH 2009). *Methods.* In the phase II part of BO20999, twenty patients with relapsed/refractory CLL received 1000mg GA101 monotherapy administered (flat dose) on Days 1, 8, 15 and 22 and q21 (total of 10 infusions). Primary endpoint was EOR with responses based on combined CT-scan and hematology results (IWCLL criteria, 2008). *Results.* GA101 was well tolerated with the most common AE being infusion related reactions (19/20 patients, grade 1,2: n=13, grade 3 n=5, grade 4 n=1), mainly during the first infusion. Thirteen patients completed all scheduled cycles. Reasons for 7 early withdrawals were: AEs [3], insufficient response [2], patient choice [1], protocol violation [1]). Most common related grade 3/4 hematological toxicities were neutropenia (n=4) and thrombocytopenia (n=2). There was one patient who developed febrile neutropenia (resolved without sequelae). Baseline characteristics and response are shown in Table 1.

Table 1. BO20999 - Phase I & II CLL baseline demog.

Patients median (range)	Phase I (n=13)	Phase II (n=20)
Age	64 (46-81)	62.5 (36-81)
Male/Female	9/4	12/8
Prior therapy	3 (1-8)	3 (1-7)
Prior rituximab	62% (8/13)	95% (19/20)
Prior stem cell transplant	15% (2/13)	20% (4/20)
Baseline SPD	2,124mm² (1,068-26,732)	3,138mm² (330-6,399)
Lymph nodes ≥5cm	31% (4/13)	35% (7/20)
Lymphocytes (x10⁹)	50.5 (5-153)	69 (0.6-134)
Platelets (x10⁹)	190 (93-356)	120 (39-246)
Hemoglobin (g/dL)	12.6 (9.4-14.9)	12.2 (9.6-15.8)
Cytogenetics		
Chromosomal aberrations	n=8: 17p (n=2), 11q (n=1), 13q (n=1), 8+12 (n=2), normal (n=3)	n=8: 13q (n=1), 11q (n=3), normal (n=1)
IgV_H status	n=8: mutated (n=2), unmutated (n=7)	n=5: mutated (n=3), unmutated (n=2)
FISH	n=8: mutated (n=1), unmutated (n=7)	n=14: mutated (n=5), unmutated (n=9)
Response		
End of Treatment	62% (8 PR, 4 SD, 1 PD)	25% (4 PR, 5 SD, 7 PD, 4 non-evaluable)
End of treatment median lymphocytes (x 10⁹/L)	1.0 (0.4-1.4)	0.8 (0.2-1.9)

Compared to the patient population in the previously reported phase I part of the study, patients had a higher tumor load with a median sum of product of diameter (SPD) of 2124 mm² (1,068-26,732mm²) for the phase I patients, compared with 3138 mm² (330-6,399 mm²) for the phase II patients. Based on 16 patients evaluable by combined CT-scan and hematology results, EOR was 25% (4 PR, 5 SD, 7 PD). Importantly, peripheral B-cell depletion for all patients was rapid following the first infusion of GA101, with all patients achieving B-cell levels below 4000/ul within one week of treatment, levels which were sustained during the treatment period, confirming the same observation reported in the phase I study. Of note, baseline tumour burden (TB) may be an important co-variate impacting patient response in the monotherapy setting in heavily pre-treated patients. Of the 4 PR patients, three had

baseline TB ranging from 1383-1989mm². Of the 6 patients with disease progression and 6 patients with stable disease, baseline TB ranged from 3004-5943 mm² and 2410-6266 mm² respectively, suggesting that those patients with baseline TB approximately >2400 mm², may not respond to the antibody when given as monotherapy, although all patients achieved impressive and sustained peripheral B-cell depletion. This is also supported in the phase I results, with 6 of the 8 responding patients having baseline TB ranging from 1068-2029 mm². This important data supports combination with chemotherapy in patients to maximize the clinical potential of GA101 in CLL to overcome lymphadenopathy. *Conclusion.* These phase II results indicate that GA101 has promising single agent activity in a heavily pre-treated patient population and will continue to be evaluated as a single-agent and in addition, the 1000mg dose is currently being investigated in combination with chemotherapy in a first line, phase III CLL trial (CLL-11).

Background. Refractoriness to fludarabine-based chemo-immunotherapy is associated to poor prognosis in chronic lymphocytic leukemia (CLL). Alemtuzumab has been shown to be effective in this category of patients although associated with relevant toxicity in terms of infections. *Aim.* We evaluated efficacy and safety of alemtuzumab subcutaneously administered at lower dose in a cohort of fludarabine-refractory CLL patients. *Methods.* Thirty-nine fludarabine-refractory patients have been enrolled at our center and treated with subcutaneous alemtuzumab. Patients received 10 mg of alemtuzumab three times weekly for 18 weeks. In 18 randomly selected patients, after obtaining lymphocyte count reduction of 1 Log, the antibody was then administered once weekly at the dose of 30 mg. Biological prognostic markers were tested in 33 patients, including CD38 and ZAP70 expression by flow-cytometry, FISH panel for del(17)(p13), del(11)(q22), trisomy 12 and del(13)(q14); IGHV mutational status was available in 10 patients. *Results.* Median age was 64 years (range 48-82 years) with 31% of the patients older than 70 years. The patient population was characterized by high-risk biologic disease profile as shown by the incidence of del(17p) (18%), del(11q) (27%), unmutated IGHV (80%), CD38+ (48%) and ZAP70+ (55%). Median previous therapy lines were 3 (1-6); twenty-one were pre-treated with FC(R). Low-dose alemtuzumab yielded a 44% (95%CI 23.0-64.2%) overall response rate (ORR) whereas complete remission (CR) was obtained in 3 patients (8%; 95%CI 0-21.1%). Two of the three patients in CR resulted MRD negative. Median overall survival (OS) and progression free survival (PFS) were 29.1 months (95%CI 21.7-39.0) and 10.3 months (95%CI 8.3-16.2), respectively. Both PFS (p<.0001) and OS (p=.04) were significantly longer in responding versus non-responding patients. Treatment was well tolerated: all and 3-4 grade non-CMV infection were 46% and 7%, respectively. CMV reactivation occurred in 27% of the patients, showing only one case of disease. Moreover, no death occurred during therapy. No significant difference both in terms of safety and efficacy was observed in elderly (>70 years) patients and between the two different schedules evaluated. *Conclusion.* Our data indicate that low dose alemtuzumab is safe and effective in this setting of poor prognosis CLL patients. Efficacy results appear to be similar to those obtained with standard treatment, while toxicity is significantly lower. This data question the use of standard dose alemtuzumab in frail or elderly patients and provide evidence for an equally effective and more practical one-weekly alemtuzumab schedule.

Background. The coexistence of CLL and myeloproliferative neoplasms (MPN) has been sporadically reported in the literature, but only as single cases: overall, 25 cases of CLL/chronic myeloid leukemia (CML), 18 of CLL/polycitemia vera (PV), 12 of CLL/essential thrombocythemia (ET) and only one case of CLL/primary myelofibrosis (PMF). *Aims.* We investigated the clinico-biological characteristics of CLL/monoclonal B-cell lymphocytosis (MBL), the timing of onset of the two diseases, the familiar predisposition to CLL/MBL, the role of chemotherapy for MPN on the course of CLL itself. We present data from the largest series of concomitant CLL/MBL and MPN so far reported. *Methods.* We retrospectively analyzed 46 patients affected by CLL/MBL and a concomitant MPN, diagnosed between August 1985 and May 2010. Data were collected from the CLL archives of 15 Italian centers on behalf of the GIMEMA chronic lymphoproliferative disorders Working Party: 30 were males, 16 females, with a median age at CLL/MBL diagnosis of 71 years. *Results.* Eight patients were classified as MBL, while 38 suffered from CLL. With regard to MBL, a diagnosis of MPN (2 ET, 2 PV, 2 PMF, 1 CML, 1 MPN/MDS) was made simultaneously in 5 patients and later during the follow-up in 3. None has so far progressed to an overt CLL; one patient died of an extrahematological cause. All 38 CLL patients were in Binet stage A at diagnosis. The diagnosis of MPN (16 ET, 8 PV, 8 CML, 4 PMF and 2 MPN/MDS) preceded that of CLL in 15 cases, was simultaneous in 7 and developed subsequently in 16. Six patients have so far received chemotherapy for progressive CLL (2 before, 1 simultaneous and 3 subsequent to the diagnosis of MPN). Six of the CLL patients have died after a median follow-up of 64.5 months; none of them experienced a progression of CLL requiring chemotherapy. The causes of death were never related to the MPN or to the lymphoproliferative disorder. MPN chemotherapy did not influence the course of the lymphoproliferative disorder; indeed, the lymphocyte count remained stable after 3, 6 and 12 months from MPN treatment. The biological prognostic parameters - IGHV (70% mutated), CD38 (78.5% negative), Zap-70 (71% negative) and del 17p or del11q (positive in only 7% of cases) - confirmed the clinical data indicative of a low risk CLL. Only one patient had a brother affected by CLL. *Conclusions.* Patients with a concomitant CLL/MBL and MPN usually have an indolent lymphoproliferative disorder with good clinico-biological prognostic features. None of the MBL patients have evolved into an overt CLL; only 6 stage A patients have experienced progressive disease requiring chemotherapy. Seven patients have died for causes not related to the lymphoproliferative disease nor to the MPN. Treatment for MPN or CLL did not influence the course of the other condition, suggesting that the occurrence of the MPN is not due to a leukemogenic effect of prior chemotherapy, but possibly to an immunodeficiency status associated to CLL.

UPDATED RESULTS OF A SCREENING PROCESS FOR DATA QUALITY IMPROVEMENT WITHIN THE CLL10-TRIAL OF THE GERMAN CLL STUDY GROUP

A Westermann,[1] P Cramer,[1] AM Fink,[1] R Meister-Paetz,[1] S Frohs,[1] B Eichhorst,[1] K Fischer,[1] KA Kreuzer,[1] S Stilgenbauer,[2] M Hallek[1]

[1]*University Hospital Cologne, Cologne, Germany*
[2]*University Hospital Ulm, Ulm, Germany*

Background and Aims. The clinical course of chronic lymphocytic leukemia (CLL) is extremely variable, depending on different prognostic factors especially high risk cytogenetics. Moreover, the patient (pt) population in CLL is quite heterogenic, due to different physical conditions and the burden of comorbidity because of the broad age spectrum observed in this disease. Protocol violations are a frequent problem in clinical trials. Primarily in order to enhance patient safety, but also to describe the patient population more precisely and to increase the data quality, the GCLLSG implemented a central screening process prior to randomisation. *Patients and Methods.* The CLL10-study is an international multicenter phase III trial comparing FCR and BR in patients (pts) with low comorbidity score, normal renal function and with advanced CLL requiring treatment, that was initiated in September 2008. Pts with del(17p) were excluded and are treated in a separate protocol for very high risk pts. Central laboratory testing for immunophenotyping, cytogenetics and other prognostic parameters, as well as a medical review of all data, especially those regarding response assessments and safety data, are well established means of quality control in GCLLSG-trials. The CLL10-study is the first GCLLSG-study with a screening process prior to the randomisation. Blood samples from all patients are sent to the central laboratories for testing of cytogenetics and immunophenotyping to confirm the diagnosis of CLL and to exclude del(17p). In addition, the pt's comorbid conditions and renal function are evaluated by checking the CIRS-Score and concomitant medication and by recalculating the creatinine-clearance. Moreover, the need of treatment according to the recently published guidelines by Hallek *et al*. is reassessed by one of the GCLLSG study physicians. *Results.* Until February, 28th 2011, 582 pts were screened for participation in the CLL10-trial. The median number of included pts is 3 pts per center. 17,9% (104) of the 582 pts were not eligible for randomisation, either due to violation of the inclusion-/ exclusion-criteria (95; 92,3%) or due to physician or pts wish (9). Thirty-five pts were not eligible because of concomitant diseases or comorbid conditions, including twenty-eight pts with an impaired renal function and five pts with an active secondary neoplasia. Twenty pts had to be excluded because of a del(17p-), eight pts were pretreated, in fifteen cases the diagnosis of CLL was not confirmed by the central immunophenotyping and in twelve cases the absolute leukocyte counts were <5000/µ (small lymphocytic lymphoma). Five pts were not in need of treatment according to the recently published guidelines. At the beginning of the trial, the percentage of screening failures was around 25% in January 2009 and decreased to 18% in February 2011. *Conclusions.* The high rate of screening failures underlines the importance of quality assurance in clinical trials not only to achieve comparability and transferability of results, but also for better patient-security. The decline in the rate of screening failures could be the result of a learning process. Moreover, these data show that central laboratory diagnostic for immunophenotyping and prognostic factors is essential in CLL.

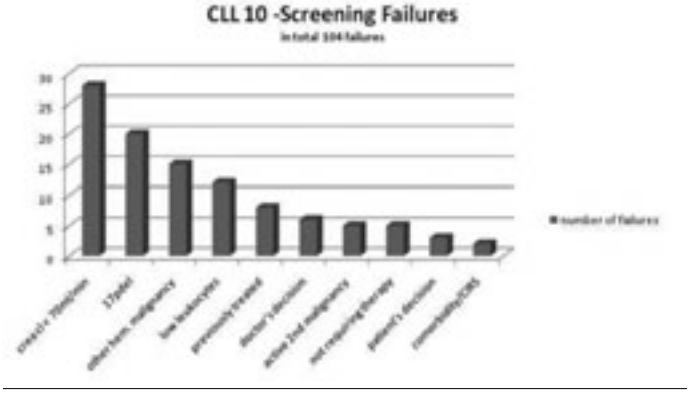

Figure 1. CLL10 Screening Failures.

[5]*Hospital, Pelhrimov, Czech Republic*

Background. Combination of fludarabine, cyclophosphamide and rituximab (FCR) is currently considered the treatment of choice in physically fit patients (pts) with chronic lymphocytic leukemia (CLL). However, many patients cannot tolerate this aggresive treatment because of advanced age and/or serious comorbid conditions. For these patients, chlorambucil has remained so far the standard of treatment. Low-dose fludarabine-based regimens have recently demonstrated promising results in small studies. *Aims.* to assess efficacy and safety of low-dose FCR regimen used in elderly/comorbid patients with CLL. *Patients and Methods.* Between March 2009 and December 2010, we treated 93 pts with active disease (CLL, n=88, SLL, n=5, males, 59%, median age, 70 years [range, 58-83], median Cumulative Illness Rating Score 4 [range, 0-10]) by low-dose FCR at fourteen centers cooperating within Czech CLL Study Group. Dose reduction of chemotherapy was as follows: fludarabine to 50% (12 mg/m2 i.v. or 20 mg/m2 orally on Days 1-3), cyclophosphamide to 60% (150mg/m2 i.v./p.o. D1-3). The dose of rituximab was standard (375mg/m2 in 1st cycle, 500mg/m2 from 2nd cycle). Treatment was repeated every 4 weeks. Antimicrobial prophylaxis with sulfamethoxazol/trimethoprim and aciclovir or equivalents was recommended. Fifty-six per cent of pts were treated in first line, remaining 44% had relapsed/refractory disease. Advanced Rai stages (III/IV) were present in 62% pts; 40% had bulky disease. IgVH genes were unmutated in 74%; according to hierarchical model, del 11q was present in 32% and del 17p in 5%. *Results.* Based on intention-to-treat principle, the overall response/complete response rate (including clinical CR and CR with incomplete blood count recovery) was 71/39% in first-line treatment and 63/27% in relapse; 18% of pts are still on treatment. Data on PFS/OS are not available yet. Serious (CTC grade III/IV) neutropenia occurred in 54%, thrombocytopenia in 13% and anemia in 11% of pts. Serious infections were diagnosed in 13% of pts. *Conclusions.* Treatment of elderly/comorbid CLL/SLL patients with low-dose FCR demonstrated promising results. Toxicity was acceptable and manageable. Updated results will be presented. Supported by research project MZO 00179906 from Ministry of Health, Czech Republic.

Background. Alemtuzumab has shown significant activity in chronic lymphocytic leukemia (CLL). However its use has been associated to profound immune suppression leading to high rates of severe infec-

tions. We have previously reported that alemtuzumab given at lower doses may be equally effective and less toxic in refractory CLL. *Aim.* We conducted a multicenter retrospective study on the routine clinical use of low-dose alemtuzumab in relapsed/refractory CLL. *Methods.* One hundred and eight patients from 11 Italian centers were included in the analysis. Low-dose alemtuzumab was defined as a total weekly dose <45 mg and a cumulative dose <600 mg up to eighteen weeks of therapy; both subcutaneous (SC) and intravenous (IV) administrations were allowed. The other inclusion criterion was that patients had to be treated with at least one previous line not containing alemtuzumab as single agent or in combination. Biological prognostic factors including CD38 and ZAP70 expression, as well as FISH analysis were available for 97 patients; the IGHV mutational status was known for 49 patients. *Results.* Median age was 68 years (range 40-84). No patients had an ECOG PS >2. Fifty patients (46%) were in Binet stage C, the median WBC count was 54.900/mmc (2.100-288.000), while bulky lymph nodes (>5 cm) were present in 17 patients. Forty-three patients (44%) showed an unfavorable cytogenetic profile, including 27 patients with del(17p) and 18 patients carrying del(11q); CD38 and ZAP70 were expressed by 47 and 48 patients, respectively; 33 of the 49 patients studied (67%) were characterized by an unmutated IGHV configuration. The median number of previous lines of therapy was 2 (1-6); 75% of patients were previously exposed to chlorambucil (60% being refractory) and 60% to fludarabine (74% being refractory). Different treatment schedules of alemtuzumab were employed; most patients (92%) received a weekly dose of 30 mg either divided into three 10 mg administrations (51%) or given as a single dose (41%). In 14 cases, alemtuzumab was given IV. The overall response rate (ORR) was 56%, including 22% of CRs. After a median follow-up of 42.2 months (2.1-91.9), the median OS and PFS were 39 months (95% CI 29.8-58.4) and 19.4 months (95% CI 15.9-23.6), respectively. In univariate analysis, response was inversely associated to lymph node (p=.01) and spleen (p=.02) size, fludarabine-refractoriness (p=.01), previous treatment lines (p=.01), presence of del(11q) (p=.009). Presence of del(17p) was not associated to a worse outcome. Response occurred regardless of the cumulative dose of alemtuzumab administered, both in the whole cohort and in the biologically-determined high risk subsets of patients. Hematologic toxicities were frequent but manageable: grade 3-4 neutropenia, thrombocytopenia and anemia were reported in 29%, 6% and 6% of patients, respectively. Severe (grade 3-4) infections occurred in 7 patients (7%) during therapy. CMV reactivation was documented in 37 patients (34%), with only one case of CMV infection. *Conclusions.* This retrospective analysis shows that alemtuzumab given at lower doses is a valid and currently used therapeutic option for the treatment of relapsed/refractory CLL, in particular in elderly and frail patients.

RITUXIMAB AND SUBCUTANEOUS CLADRIBINE: CLINICAL RESULTS OF AN EXTENDED COHORT OF CHRONIC LYMPHOCYTIC LEUKAEMIA PATIENTS

P Bertazzoni, F Gigli, A Gardellini, D Radice, M Negri, A Calleri, G Gregato, S Bassi, D Laszlo, S Liptrott, L Preda, G Martinelli

European Institute of Oncology, Milan, Italy

Background. Rituximab in combination with purine analogue is a well established treatment for chronic lymphocytic leukaemia (CLL). Recently we published preliminary results on CLL patients using subcutaneous cladribine in combination with rituximab. *Aims.* Here we report updated results on 67 patients with active CLL or small lymphocytic lymphoma (SLL) treated with this combination treatment. *Methods.* Sixty-seven patients with active CLL or small lymphocytic lymphoma (SLL) received rituximab 375 mg/mq on day 1 and cladribine 0.1 mg/kg subcutaneously on days 2-6. The treatment was repeated every 4 weeks for a total of four cycles. Response to treatment was evaluated according to NCI-WG updated guidelines for patients with CLL and with Cheson criteria for SLL patients. *Results.* Forty-five patients were previously untreated. The median age was 63 (32-78). 2-microglobulin was abnormal in 54% of patients at baseline. 25% of patients presented multiple genetic alterations at FISH analysis and 66% of patients showed a ZAP-70 positivity. Sixty-five patients were evaluable for response. The overall response rate was 86% (45% CR and 41% PR), with 44% of untreated patients and 41% of pre-treated patients achieving a CR. Thirteen patients achieved a clinical remission in the absence of minimal residual disease. The median follow up was 27.6 months. The median time to treatment failure (TTF) was 36.7 months. There was a statistically significant difference in terms of duration of response between untreated and pre-treated patients (TTF respectively: 52 vs 23 months, p=0.065). Patients achieving a CR had a longer response duration than patients with PR (TTF respectively: not reached vs 23 months, p=0.025). Low serum lactate dehydrogenase levels and 2-microglobulin levels at baseline and a normal CT scan at the end of therapy (independent of response) did not influence TTF. Ten patients developed severe neutropenia (grade 3-4). Thrombocytopenia grade 3 was observed in one patient and anemia grade 2 in one patient. Five pts developed pneumonia, rapidly resolved without serious consequences. One patient developed febrile neutropenia with diarrhoea (Salmonella positivity). In 3 patients we observed cutaneous toxicity with resolution after the use of oral steroids. *Conclusions.* Our data confirm that combination therapy with R-cladribine is an effective and safe treatment for patients with CLL and SLL achieving results similar to those reported with more aggressive regimens.

Background. Hairy cell leukaemia (HCL) is a rare indolent lymphoproliferative disorder characterised by infiltration of the bone marrow, liver and spleen by malignant B-cell with hairlike cytoplasmic projections (HC). Purine analogues are highly effective in HCL with overall responses in more than 85%. However, HCL patients are projected to progress in their life-span or, in a minority are refractory. *Aims.* To investigate the long-term outcome for patients with HCL treated with purine analogues, to compare efficacy of pentostatin and cladribine (in the absence of any randomised controlled trials) and to identify factors associated with response, or relapse. *Methods.*We reviewed clinical and laboratories dates retrospectively from 75 patients, initially treated with pentostatin or cladribine, to investigate the current long-term outlook. Patients entering the study received pentostatin 4 mgr/m2/15 days or cladribine (by different schedules) as a single course. Minimal residual disease (MRD) was studied by flow cytometric immunophenotyping in peripheral blood (PB) and bone marrow (BM). Efficacy endpoints were response to therapy, treatment free interval (TFI) and overall survival (OS). TFI was measured in all patients from treatment initiation to time of new treatment requirement. OS was measured from therapy initiation to death or last follow-up. We studied risk factors associated of response and relapse. Analysis was performed using the SPSSv15.1 software package. *Results.* Of 75 patients, 54 were males (72%). Median values and range were: age 54 years (31-82), haemoglobin 11,2 g/dL (4,1-15,8), platelets 73x109/L (13-267), WBC 2,7x109/L (0,7-20), %HC in BM 36 (5-90) and size spleen 15cm (12-33) without significant differences between two groups of treatments. Twenty one patients received pentostatin and 54 cladribine for first line therapy. The median follow-up was 156 months (4-393) for pentostatin group and 65 months (3-191) for cladribine group. The overall response rate was 100%. The complete remission (CR) rate was 95,2% with pentostatin and 90,7% with cladribine. The median numbers of pentostatin injections required to achieve CR were 7 (2-14). In 5 patients treated with cladribine who still remained in partial remission (PR), was administrated a second cycle of cladribine which led to a CR in 4 patients. MRD was positive in 52,4% of pentostatin patients and 33,3% of cladribine patients. Twenty patients relapsed: 47,6% patients treated with pentostatin and 18,5% of those who received cladribine. By univariate analysis risk factors of relapse were: Hb (P=0,001), %HC in BM (P=0,013) and size spleen (P=0,003). Cox multivariate analysis revealed Hb and splenomegaly as independent risk factors of relapse.

By Kaplan-Maier estimates the median TFI was 96 months in pentostatin, and 144 in cladribine patients; 95 months in MRD+, and 216 in MRD- patients. *Conclusions.* Although both agents are effective in HCL, the results are better for cladribine than pentostatin respect rate of relapse, TFI and MRD. Haemoglobin levels and splenomegaly are confirmed as independent risk factors of treatment failure and rapid progression. The relation between MRD+ and shorter TFI suggests the convenience to add treatment, like Rituximab, to obtain MRD negative response.

0109

SMALL LYMPHOCYTIC LYMPHOMA (SLL) AND CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): A SINGLE DISEASE WITH SIMILAR PROGNOSIS?

L Dang,[1] B Stamatopoulos,[1] P Heimann,[1] M Vaes,[1] R Dewind,[1] L Lagneaux,[1] B Cantinieaux,[2] N Meuleman,[1] D Bron[1]

[1]*Institut Jules Bordet, Brussels, Belgium*
[2]*Hôpital St Pierre, Brussels, Belgium*

Introduction. Small lymphocytic lymphoma (SLL) is a mature (peripheral) B-cell neoplasm characterized by a progressive accumulation of monoclonal B lymphocytes. It is considered to be identical to chronic lymphocytic leukemia (CLL) with similar pathologic and immunophenotypic features . Distinction is usually made based upon clinical presentation) and an arbitrary cut-off of 5x109/L lymphocytosis. *Objectives.* To perform a retrospective analysis of patients (pts) with CLL/SLL with emphasis on cytogenetic data and clinical outcome. *Patients and Methods.* We retrospectively reviewed our database of 201 SLL/CLL patients registered between 1980 and 2010. Two pts were excluded because of the diagnosis of Monoclonal Benign Lymphocytosis (MBL). All these pts fulfilled the diagnostic criteria for CLL/SLL i.e. > 5x109/L peripheral blood lymphocytes co-expressing CD5/CD19, CD23 and low levels of surface immunoglobulin by flow cytometry (B-CLL pts) or a typical immunohistochemistry on lymphnode biopsy showing diffusely effaced nodal architecture with an infiltrate composed of mostly mature-appearing, small lymphocytes with <5x109/L lymphocytes (SLL pts). A bone marrow aspirate and/or biopsy was performed in all pts. Mantle cell lymphoma, hairy cell leukemia, follicular lymphoma or Richter' syndrome were excluded. Caryotypic or FISH analysis was available in 45% of the pts. *Results.* Data are available on 196 pts (101 CLL Stage A, 41 CLL stage B, 27 CLL Stage C, and 27 SLL) 65% males with a median age of 65.4 years old. Overal survival(OS)/5 years was respectively 83.95%, 78.05%, 50.05%, 77.61% for Stage A-, B-, C- CLL and SLL. Imunophenotypic analysis (CD5, CD23, CD19, FMC7, ZAP70) was very similar in the four groups. CD38 expression appears to be lower in SLL but the size of the group does not allow any statistical comparison. This contrasts with the published data that Adherence to the stroma increases CD38 expression. Mutational status of the IgVH was rarely performed in our population of SLL but mutated and unmutated status are observed . Cytogenetic analysis was performed in 20 out of 27 SLL and only 3/20(15%) had 13q deletion whereas 7/20 (35%) pts had a poor prognostic caryotype (17p del or 11q del). Therapeutic approaches varied considerably; a majority of the SLL pts were treated by "lymphoma"regimens but fludarabine-based protocols became more frequently used in recent years. *Conclusion*. SLL and B-CLL are very similar in terms of phenotype and histology. OS of SLL is equivalent to OS of stage B CLL and should thus be managed such as progressing stage B-CLL taking into account the somewhat higher incidence of17p del.

0110

PHASE I-II STUDY OF BORTEZOMIB IN COMBINATION WITH R-HCVAD AND R-METHOTREXATE/ CYTARABINE (R-MA) IN UNTREATED MANTLE CELL LYMPHOMA (MCL)

J Romaguera,[1] M Wang,[1] F Hagemeister,[1] P Weaver,[1] K Hartig,[1] M Fanale,[1] L Fayad,[1] A Younes,[1] A Rodriguez,[1] N Fowler,[1] R Orlowski,[1] T Feldman,[2] N Wagner-Bartak,[1] P Ford,[2] J Smith,[2] M Ekaney,[2] A Mato,[2] M Valentinetti,[2] L Kwak,[1] A Goy[2]

[1]*MD Anderson Cancer Center, Houston, United States of America*
[2]*Hackensack University Medical Center, Mackensack, United States of America*

Although 87% of patients with advanced MCL achieve a CR with R-HCVAD/R-MA, patients still relapse over time, especially in those > 65 yrs of age, who have a median time to failure free survival of 3 years. Bortezomib (B) has 31% single agent response rate in relapsed/refractory MCL and synergizes *in vitro* with many of the drugs in the above regimen. A phase I study of BR-HCVAD/BR-MA did not show increased toxicity (Br. J. Haem. August 2010) and resulted in an elected dose of 1.3 mg/m2 bortezomib. We present preliminary data on the phase II study. Thirty-two patients have been entered, and their clinical presentation is shown in table 1.

Table 1. Patient characteristics.

Number patients 32
Median age (range) 64 (39-75)
Male 22 (69%)
Blastoid variant 1 (3%)
Ann Arbor stage IV 32 (100%)
Median ß2 microglobulin (range) 3 (1.59-9.7)
MIPI score low, int, high 37%, 44%, 19%
Ki-67 (17 pts) < 20, 21-40, > 40 46%, 35%, 18%

All 23 evaluable pts for response have responded: 12 have finished treatment (3-8 cycles, median of 6), of whom 9 have achieved a CR and 3 patients achieved a partial response. These 3 patients were responding but had delays in recovery of platelet counts and either were removed from study as per protocol guidelines (2 pts, ages 52 and 54 years, both with MIPI score of 3) or progressed while awaiting recovery (1 pt, 65 yrs old, MIPI score 5). At a median follow up of 5 months only this last patient has relapsed/progressed while on the study. When combining Phase I and II patients who received a similar dose of bortezomib of 1.3 mg/m2 and completed therapy (20 patients), 100% of the patients have responded, 89 % have achieved a CR, and only one has progressed with a median follow up of 12 months for the combined group. Grade 3-4 toxicity was mainly hematologic, as expected, and one patient died from neutropenic infection with methicillin-resistant staphylococcus aureus bacteremia. She did not have prolonged neutropenia. Seven patients went off study due to delayed recovery of counts, usually after cycles 3-5, five of them after achieved a CR (currently all five remaining in CR). There was no grade 2-4 neuropathy. In conclusion, this phase II portion of the study demonstrates continued high rates of complete remission. The study is currently accruing and updated information will be presented at the time of the symposium.

0111

SIMPLE CLINICAL AND LABORATORY FEATURES HAVE PROGNOSTIC VALUE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AND 17P DELETION

Background. Patients with chronic lymphocytic leukemia (CLL) whose tumor cells harbor a 17p deletion are considered to have a dismal prognosis. The disease is usually refractory to conventional chemotherapy and risky therapeutic approaches, such as allogeneic hematopoietic cell transplantation, are generally recommended for younger patients. However, there is a degree of clinical heterogeneity within 17p-deleted CLL patients, as a significant proportion of patients remain asymptomatic for prolonged periods of time. Furthermore, 17p deletions can be detected at diagnosis (de novo) but can also be acquired during the evolution of the disease (acquired), particularly in patients who have received chemotherapy. *Aims.* To further define the prognostic profile of CLL patients with either de novo or acquired 17p deletions. *Methods.* Clinical and laboratory data were collected from 207 CLL patients at the time the 17p deletion was detected. All patients had interphase fluorescent in-situ hybridization (FISH) tests performed using probes specific to *TP53* (17p13.1), *ATM* (11q22.3), *D13S319*

(13q14.3) and the centromeric region of chromosome 12 (12p11.1-q11). Minimum data required were age, sex, Binet stage, lymphocyte count, presence of B symptoms, date of FISH analysis, percentage of cells with 17p deletion, time to first therapy (if required) and last follow-up visit. A significant proportion of patients also had information on IGHV status, CD38 and ZAP-70 expression and beta$_2$-microglobulin serum concentration. *Results.* We identified 103 (51%) patients with de novo and 64 (32%) patients with acquired 17p deletions (i.e. not present at CLL diagnosis). In 35 (17%) patients, FISH results were only available after therapy. Sixty-four percent were male and 36% female. Median age was 68 (range 22-99) years and Binet stage was B or C in 56% of patients. Additional FISH abnormalities were detected in 49% (13q-), 17% (+12) and 13% (11q-) of patients. CD38 and ZAP-70 expression was positive in 45% and 43% of patients, respectively, while the IGHV gene was unmutated in 66% of them. Median overall survival (OS) from FISH diagnosis was 37 months for the entire cohort. By univariate analysis, OS was significantly shorter in patients older than 65 years (P = 0.008), with B symptoms (P < 0.001), an acquired 17p deletion (P = 0.023), a beta$_2$-microglobulin concentration higher than 2.5 mg/l (P = 0.002), more than 20% of cells with deletion (P < 0.001) and Binet stage B or C (P = 0.002). Cox regression analysis revealed that four variables had independent prognostic value: Binet stage (P = 0.037), B symptoms (P = 0.003), age (P = 0.017) and percentage of cells with deletion (P = 0.016). *Conclusions.* The prognosis of CLL patients with a 17p deletion is modulated by simple and widely available clinical and laboratory features such as Binet stage and the presence of B symptoms. Patients with acquired deletions had a shorter median OS compared to those with de novo deletions (32 vs 39 months, P = 0.023), but only by univariate analysis. These factors could help clinicians when deciding the most appropriate therapeutic approach for an individual patient.

The multicenter CLL2O trial aims at achieving a higher remission rate in "ultra-high risk"CLL [17p- and/or Fludarabine(F)- or Bendamustine (Benda)-refractory] by adding high-dose dexamethasone to alemtuzumab and prolongation of remission duration and survival by alemtuzumab maintenance or allogeneic stem cell transplantation (SCT). Ninety [F-/Benda-refractory (n=40); 17p- without prior therapy (n=31) and 17p- in relapse (n=19)] enrolled pts were analysed for TP53 mutations. We used DHPLC to screen for TP53 mutations (Exons 4-10). Aberrant DHPLC profiles lead to sequencing of the respective amplicons. In addition, detailed characterization of prognostic markers and clinical features were performed. Median follow up time was 5.32 months. The incidence of the TP53 mutations was 75.5 % (68/90). For 81 of 90 patients FISH data was available: Fifty-nine of 65 patients (90.8 %) with 17p- had a TP53 mutation. The 16 F-/Benda-refractory pts without 17p- showed the following genetic features: TP53 mutation 3/16 (18.7%); 11q- 6/16 (37.5%); 13q- single 3/16 (18.7%); no abnormality 2/16 (12.5%); other chromosomal aberrations 2/16 (12.5%) and unmutated IGHV-status 12/16 (75%). In the 17p- 1stline cohort, 25 of 31 pts (80.6%) also had a TP53 mutation. All 19 relapsed pts with 17p- showed a TP53 mutation (100%). In the F-/Benda-refractory cohort 60% (24/40) had a TP53 mutation. Four of 11 pts analysed over time (2 to 6 years between analyses) acquired TP53 mutations. All of them received cytotoxic therapy before the acquisition of TP53 mutation. Five of the remaining 7 pts already had a TP53 mutation at first analysis with 3 showing increase in TP53 mutated clone size. IGHV-status was available for 82/90 patients. The vast majority 72/82 (87%) exhibited an unmutated IGHV-status with no differential distribution among TP53 mutated and TP53 wild type pts (TP53 WT). There was no significant difference between the TP53 mutated and unmutated subgroup concerning the distribution of the following markers and clinical features: gender, age, WBC, B-symptoms, ECOG performance status, ß2-microglobulin and thymidine kinase. Response data was available for 57 pts. There was no significant difference for complete and overall response rate (ORR) between TP53 WT and TP53 mutated pts. [CR: TP53 WT 0/15 (0%) vs. TP53 mutated 6/42 (14.2%) p-value: 0.3245; ORR: TP53 WT 10/15 (66.6%) vs. TP53 mutated 35/42 (83.3%) p-value: 0.2669]. For the 90 evaluated patients median progression free survival (PFS) was 13.9 months and median overall survival (OS) was 17.7 months. No significant difference in PFS between the TP53 mutated and TP53 WT subgroup was detected (TP53 WT: 8.8 months vs. TP53 mutated: 13.9 months; p-value: 0.801). OS was similar in both subgroups with 18.7 months for TP53 WT and 17.7 months for TP53 mutated cases. In conclusion we show a high incidence of TP53 mutations in this "ultra-high risk"CLL cohort. This data, showing no significant difference between TP53 mutated and unmutated cases in clinical endpoints, suggests that the CLL2O treatment algorithm might be an effective strategy for TP53 mutated cases and can overcome their refractoriness to therapy. Refractory pts without detectable TP53 alterations are of importance for further studies.

[5]*Rabin Medical Center, Petah-Tikva, Israel*

Spontaneous regression in CLL is characterized by documented decrease in tumor burden not related to specific treatments. Cases of CLL regression have been occasionally documented. In the data of the Medical Research Council CLL trials, Thomas *et al.* reported a series of 10 patients who showed spontaneous remission out of 2370 (0.42%) registered cases (Br J Haematol, 2002, 116, 341). Recently Del Giudice *et al.* reported also the clinical and biological features (Blood, 2009, 114, 668) in 9 cases and found an overexpression of VH 3-30 and DICER gene by micro-RNA. An Editorial on this issue emphasized this 'unfolding CLL mystery' (Montserrat E). We analyzed the incidence of hematological remission in a large group of patients included in the Registry of the Israeli Study Group on CLL. Out of 1296 patients registered with CLL, 21 patients (1.6%) experienced spontaneous remission during the course of their disease. There were 10 women and 11 men, with median age at diagnosis of 69 years (range, 46-87). All but one were diagnosed in clinical Binet stage A, the remainder had en-

larged spleen compatible to stage Binet B. On flow cytometry, the median CD19/CD5 antigen coexpression on circulating CLL lymphocytes was 50%. Serum b2-microglobulin values were normal and mildly elevated in two patients; in these early stages no additional prognostic parameters were evaluated. The median follow-up period was 12 years (3-23 years). The regression was noted after a median of 8 years (range 1-22 years) of the follow-up. The maximal median lymphocyte count during the course of CLL was 15x109/l (9-75) and at regression dropped down to 2.3x109/l (1.2-4.7). The median CD19/CD5 antigen coexpression at regression was 28% (range, 17-37%). Distribution of T-cell subset during regression didn't reveal significant changes. A possible association of this phenomenon in CLL with infection, smallpox vaccination or development of second malignancy has been previously suggested. In order to search associated diseases or events that may explain changes in the hematological condition, we reviewed medical reports of the patients. Eight patients suffered from recurrent infections, which required multiple hospitalizations and antibiotic treatments. One another patient developed ischemic heart disease and was treated by verapamil. This drug by itself was found to induce apoptosis in CLL (Berrebi *et al.*, Leukemia, 1994, 8, 2214). One patient developed the regression three years after being treated for autoimmune hemolytic anemia. Two patients had hypothyroidism treated with eltroxin. Finally, three patients showed hematological improvement while developed solid tumors (brain, lung and nasopharynx). In 7 patients no concomitant diseases at time of regression were documented. In conclusion, spontaneous remission in CLL is a rare phenomenon developed usually in early stage with no bad biological prognostic factors. Concurrent disorders such as infections and/ or second malignancy may contribute to decrease CLL clone.

0114

ANALYSES OF PARAMETERS WITH INFLUENCE ON RATE AND DURATION OF RESPONSE AFTER THE FIRST-LINE TREATMENT OF PATIENTS WITH HAIRY CELL LEUKEMIA

D Lekovic, M Gotic, D Tomin, G Jankovic, V Novakovic, N Kraguljac, M Perunicic, B Mihaljevic

Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. For many years the first line treatment for hairy cell leukemia (HCL) were splenectomy and alpha interferon (INF-α). Major breakthrough in the treatment of HCL has appeared with introduction of purine analogs, which improved the long-term outcome. It seems that the dilema about the first line treatment was solved but there are still patients (pts) with HCL who need to receive more than one treatment for inducing the long-lasting clinical remission. *Aim.* The aim of our retrospective study was to identify the clinical and laboratory parameters which have influence on response rate after the first-line treatment of pts with HCL. *Patients and Methods.* We analysed 102 HCL pts who were diagnosed and treated in our clinic from January 1993 to December 2009, with a median follow-up of 87 months. We compared age, clinical and laboratory parameters, immunohistological characteristics of bone-marrow (BM) with response rate to therapy. Two groups of HCL pts were divided according to number of treatment-lines received to achieve remission: Group A included 48 pts who received the first and only-line treatment, Group B included 50 relapsed pts treated with 2 to 6 lines. Four pts were followed up only, without any treatment. In Group A: 38 pts received 2-chlorodeoxyadenosine (2-CDA), 4 INF-α and 6 had splenectomy, resulting in 77.1% CR, 16.7% PR and 4.2% non-response (NR). In Group B: 16 pts received 2-CDA, 1 deoxycoformycin, 12 INF-α and 21 had splenectomy resulting in 18% CR, 70% PR and 12% NR. Median duration of response in Group A was 49 months while in a Group B was 11 months ($p<0.001$). *Results.* Median age in Group A was 56 (M/F=41/7) while in Group B was 50 (M/F=42/8) ($p=0.01$). According to laboratory parameters, pts in Group B had significantly lower hemoglobin level (Hb≤120g/L) than pts in Group A (Hb>120g/l) ($p=0.01$). Number of leukocytes, platelets and the presence of lymphadenopathy and hepatomegaly were not statistically different between analysed groups. Patients in Group B had the statistically larger diameter of the spleen (≥15cm) than the pts in Group A (<15cm) ($p=0.023$). A statistically significant difference in response rate was recorded for 2 of 5 BM parameters tested: infiltration >50% hairy cells (HC) and degree of fibrosis >II/III. Patients in Group B had the statistically higher BM infiltration with HC ($p=0.027$) and larger degree of fibrosis ($p=0.045$) than pts in Group A. Patients in Group A treated with 2-CDA had the significantly higher CR rate than pts in Group B ($p<0.001$). *Conclusions.* Our data indicate that Hb <120g/L, spleen size>15cm, BM infiltration >50%HC, fibrosis >II/III have unfavorable prognostic value for the rate and duration of response. Patients with these parameters as the reflection of the larger tumor burden have to receive more than one treatment lines. Additional research of biological parameters in HCL is needed to determine the optimal treatment strategy for this disorder.

0115

SERUM HSP 70 ANTIBODIES AS AN INDICATOR FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKAEMIA PATIENTS

J Piszcz, E Cichocka, L Bolkun, K Mazgajska-Barczyk, A Kulczynska, J Kloczko

Medical University of Bialystok, Bialystok, Poland

Background. Chronic lymphocytic leukaemia (CLL) is the most common form of adult leukaemia in Western countries. The diagnosis is often accidental and there is no indication for early intervention. The current recommendation to start treatment includes disease-related symptoms, massive and/or progressive hepatosplenomegaly or lymphadenopathy, increasing bone marrow failure, autoimmune disease, and recurrent infections. The early treatment may be considered only in patients with unfavourable prognostic factors at the diagnosis. Heat shock proteins (HSPs) are molecular chaperones involved in a number of cellular functions in stress conditions. It is well established that leukemic cells may express HSPs including HSP70 on their surface. It has also been suggested that an increased surface expression of heat shock proteins on apoptotic tumour cells results in the generation of potent antitumour T-cell responses. Anti HSP70 antibodies are known to play a role in immunological and neoplastic processes. However their significance in CLL has not been well documented. *Aims.* The aim of our study was the assessment of the anti HSP70 antibody concentration in the patients with CLL. *Material and Methods.* The studied group consists of 38 newly diagnosed CLL patients (aged 46-74), males and females in equal proportion. The patients were in A-C stages of CLL according to Binet scale. Twenty two of studied individuals required chemotherapy. Quantitative determination of anti-human HSP70 antibodies in the serum was done using commercial test (anti HSP70 Elisa Kits, Stressgen). The results are presented as mean ± SEM. Statistical analysis was done using Shapiro-Wilk, Mann-Whitney and Spearman's tests. *Results.* The levels of anti HSP70 antibodies were significantly lower in the group of patients that required chemotherapy in comparison to those in whom "watch and wait"strategy was applied (61.17±12.6ng/ml vs.118.86±27.8ng/ml; $p<0.04$). There was no association between the levels of antibodies and the stage of the disease. The study showed no correlations between anti HSP 70 antibody concentration and other parameters such as age, gender and some prognostic factors (LDH, ß2-microglobulin). *Conclusions.* The assessment of low anti HSP70 antibody concentrations in CLL patients may support other clinical and laboratory features that indicate starting of chemotherapy in this cohort. Further studies are required to elucidate the role of anti HSP70 antibodies as a prognostic marker in CLL patients.

Chronic myeloid leukemia - Biology

0116

EVI1-REARRANGEMENTS AND HIGH EVI1 EXPRESSION ARE FREQUENT IN CHRONIC MYELOID LEUKEMIA (CML) IN BLAST CRISIS (BC)

V Grossmann, A Kohlmann, M Zenger, S Schnittger, W Kern, T Haferlach, C Haferlach

MLL Munich Leukemia Laboratory, Munich, Germany

Blast crisis (BC) is the terminal phase of chronic myeloid leukemia (CML). Activation processes of oncogenic factors and/or mutations leading to loss of function of tumor suppressor genes in hematopoietic stem cells are involved in disease progression. MECOM (MDS1 and EVI1 complex), located on chromosome band 3q26, functions as oncogene by transcriptional regulation binding to DNA sequences in the promoter region of target genes and further interacts with epigenetic regulators, e.g. DNMT3A. An elevated EVI1 expression is observed in myeloid malignancies with 3q26 rearrangements, some t(11q23)/MLL-rearrangements, monosomy 7/7q-, and also in a subset of acute myeloid leukemia (AML) with normal karyotype or other chromosomal abnormalities. Elevated EVI1 expression is associated with poor prognosis in CML and AML. In AML, elevated EVI1 expression has been described in the subset with 3q26/EVI1-rearrangements (1% frequency; Grimwade *et al*. 2010). Here, we studied a cohort of 34 BC-CML (21 myeloid; 8 lymphoid; 4 not specified). All patients had been thoroughly characterized by cytogenetics and FISH to identify EVI1-rearrangements. The proportion of EVI1-rearrangements (inv(3)(q21q26) n=3; t(3;21)(q26;q22) n=2; t(3;11)(q26;q23) n=1; other 3q26 rearrangements n=2) detectable in this cohort was remarkably high with 23.5% (8/34 cases). Of note, two EVI1-rearrangements were cytogenetically cryptic and therefore only detectable by FISH analysis. Next, we investigated the EVI1 expression using a quantitative real-time RT-PCR assay (LightCycler®, Roche Diagnostics, Mannheim, Germany). The expression of MDS-EVI1/EVI1 was normalized against the expression of the control gene ABL1 (values are given as % MDS-EVI1/EVI1/ABL1). In our BC-CML cohort, the median EVI1 expression was 16.5, ranging from 0-107.6 (no RNA available in 4 cases). EVI1-expression was significantly higher in cases with EVI1-rearrangement (8/34 cases) compared to patients without rearrangement; median expression 40.4 (range: 18.5-93.3) vs. 9.1 (range: 0-107.6; p=0.003). Interestingly, in both patients with lymphoid BC a high EVI1 expression with a ratio of 29.0 was detected. Subsequently, patients with detectable EVI1 expression (22/30) were further investigated for possible t(11q23)/MLL-rearrangements using FISH. However, we did not detect any t(11q23)/MLL abnormality in this subgroup. In addition, WT1 mutations were detected in 6/34 patients (17.6%). The frequency was significantly higher in patients with EVI1-rearrangement (4/8; 50%) compared to those without (2/26; 7.7% p=0.02). Of note, we sequenced ASXL1, CBL, CEBPA, IDH1, IDH2, IKZF1, KRAS, NRAS, NPM1, TET2, TP53 and investigated the BCR-ABL1 ratio for the complete cohort. Besides EVI1-rearrangement no correlation between an elevated EVI1 expression and any other molecular or cytogenetic marker was observed. Limited on cases without MLL- and EVI1-rearrangements (n=26), the median EVI1 expression in BC-CML patients was comparable to AML patients, based on a cohort of 260 AML cases we previously studied (mean 14.7 vs. 9.9, p=n.s.). Moreover, for patients with EVI1-rearrangements (n=8) the EVI1 expression in BC-CML is similar to patients harboring an AML with EVI1-rearrangement (n=57) (mean 49.1 vs. 175.3, p=n.s.). In conclusion, we demonstrated that EVI1-rearrangements occurred with a high incidence of 23.5% and both translocation and overexpression of EVI1 may play a central pathogenetic role in BC-CML. Further analyses are warranted to assess the clinical impact of these findings.

0117

THE OLIGOMERIZATION AND DC2 DOMAINS OF THE BCR PROTEIN MODULATE ITS SUBCELLULAR LOCALIZATION AND REGULATE BCR-ABL TRANSFORMING ACTIVITY

P Vigneri, M Massimino, C Romano, P Buffa, A Fidilio, L Manzella

University of Catania, Catania, Italy

Background. The Breakpoint Cluster Region (BCR) protein is implicated in the pathogenesis of Chronic Myeloid Leukemia (CML) as its N-terminus portion is fused in frame with most of the ABL sequence, generating the BCR-ABL chimaeric oncoprotein. To date, the intracellular localization of BCR is still controversial as previous evidence has suggested that BCR binds to heterochromatin, implying a nuclear localization. However, further results assigned BCR exclusively to the cell cytoplasm. *Aims.* To investigate the mechanisms regulating the subcellular localization of BCR and to determine if and how they modulate the localization and function of BCR-ABL. *Methods.* Computational analyses recognized two putative Nuclear Localization Signals (NLS) and a Nuclear Export Signal (NES) in BCR. The functional activity of these domains was assessed by generating GFP-fusion constructs and by determining their intracellular distribution by immunofluorescence (IF) and fractionation experiments. Multiple BCR and BCR-ABL deletion mutants were then transiently expressed in HeLa cells or in the mouse pro-B BaF3 cell line and their intracellular localization was determined by IF. BaF3 cells expressing different BCR-ABL mutants were cultured in liquid media (in the absence of IL-3) or in soft agar to investigate their transforming ability. The proliferative potential of each BCR-ABL construct was also ascertained *"ex vivo"* after lentiviral expression in CD34-positive cells. *Results.* Both NLSs directed GFP in the nuclear compartment, while the NES favored its cytoplasmic localization. The latter effect was abolished after treatment with the exportin-1 inhibitor Leptomycin B (LMB). Despite these findings, wild-type BCR was an exclusively cytoplasmic protein because of a lack of nuclear import. However, removal of the N-terminus oligomerization domain (OD), of the C-terminus Protein Kinase C conserved region 2 (DC2) and of the Rho-GAP domain generated a construct displaying strong nuclear staining that was further increased by LMB. As the OD and part of the DC2 are preserved in BCR-ABL, we wanted to establish if these domains contributed to the subcellular localization of the oncoprotein. To this end, we generated a ΔDO-ΔDC2 BCR-ABL mutant and its kinase-proficient counterpart ΔDO-ΔDC2 BCR-ABLP1124L. Each construct was transiently expressed both in HeLa and in BaF3 cells but failed to relocalize to the nucleus. Interestingly, both mutants were devoid of transforming activity as confirmed by expression in CD34-positive progenitors. *Conclusions.* Our results have identified two putative NLS and one potential NES in the BCR sequence. The NLSs are functionally/structurally inhibited by the OD, DC2 and Rho-GAP domains of BCR, causing its cytoplasmic localization. Deletion of the OD and DC2 regions in BCR-ABL fails to relocalize the oncoprotein to the nuclear compartment, regardless of its catalytic activity. However, a kinase-proficient ΔDO-ΔDC2 BCR-ABL does not display transforming potential, suggesting that the DC2 domain plays a pivotal role for BCR-ABL-dependent oncogenic activity.

0118

TRITERPENOID CDDO-ME IS HIGHLY SYNERGISTIC WITH THE HO-1 INHIBITOR SMA-ZNPP IN IMATINIB-RESISTANT CML CELLS

K Gleixner,[1] H Herrmann,[1] K Blatt,[1] K Schuch,[1] W Pickl,[1] M Konopleva,[2] M Andreeff,[2] P Valent[1]

[1]*Medical University of Vienna, Vienna, Austria*
[2]*University of Texas MD Anderson Cancer Center, Houston, United States of America*

Background. In chronic myeloid leukemia (CML), resistance against one or more tyrosine kinase inhibitors (TKI) may develop during therapy, often because of BCR/ABL1 mutations. Novel therapeutic strategies and drugs are required to overcome TKI-resistance and to achieve long term remission in these patients. CDDO-Me is an oleanane triterpenoid that has been described to suppress survival of neoplastic cells in various tumors and leukemias by targeting several pro-survival factors including mTOR, Akt, and STAT3, and by inducing ROS-generation and thereby apoptosis. However, not all survival pathways may be suppressed by CDDO-Me. Notably, recent data suggest that exposure of leukemic cells to CDDO-Me results in a pronounced increase in heme-oxygenase-1 (HO-1), a major survival and resistance factor in CML. *Aims.* The aim of this study was to explore whether CDDO-Me exerts effects on imatinib-resistant leukemic cells carrying BCR/ABL1 mutations, and to learn whether the HO-1 inhibitor SMA-ZnPP would synergize with CDDO-Me in producing growth inhibition and apoptosis in CML cells. *Methods and Results.* As assessed by 3H-thymidine uptake, CDDO-Me was found to inhibit the proliferation of the CML cell line K562 as well as Ba/F3 cells transfected with drug-resistant mutants of BCR/ABL (T315I, E255K, Y253F, H396P) with reasonable IC50 values (0.1-0.5 μM). Growth-inhibition was accompanied by apoptosis as assessed by combined AnnexinV/PI staining. Next, we examined the effects of CDDO-Me on primary CML cells isolated from 12 CML patients in chronic phase, including 4

patients who had developed resistance against two or more TKI. CDDO-Me was found to inhibit proliferation of leukemic cells in all patients tested, with IC50 values ranging between <0.1 and 0.5 μM. No differences in IC50 values were observed between TKI-naïve and TKI-resistant CML cells. Since BCR/ABL-targeting TKI or other drugs, when used as single agents, usually fail to induce long-term remission in advanced CML, drug combinations are currently being tested preclinically and in clinical trials. In this study, we applied the combination CDDO-Me+SMA-ZnPP and found that this combination is highly synergistic in producing growth inhibition in K562 cells and primary CML cells isolated from imatinib-naïv and imatinib-resistant patients, including one patient in whom BCR/ABL T315I was detected. We also examined whether CDDO-Me would exert synergistic effects on CML cells when combined with BCR/ABL TKI. We therefore applied the combinations CDDO-Me+dasatinib and CDDO-Me+nilotinib in K562 cells. Both combinations were found to synergize in producing growth inhibition. *Conclusions.* CDDO-Me inhibits the proliferation of imatinib-resistant BCR/ABL+ cell lines and of primary CML cells isolated from untreated and TKI-resistant patients, including cells carrying the BCR/ABL mutant T315I. Our data also show that CDDO-Me and BCR/ABL TKI synergize in producing growth inhibition in CML cells. Synergistic drug interactions were also observed with CDDO-Me+SMA-ZnPP which may be explained by the HO-1-inducing effect of CDDO-Me.

0119

IS P210 PHILADELPHIA POSITIVE-ACUTE LYMPHOBLASTIC LEUKEMIA A LYMPHOBLASTIC CRISIS OF LATENT CHRONIC MYELOID LEUKEMIA?

N Takahashi,[1] M Suzuki,[2] Y Shinohara,[1] T Akagi,[3] K Tajima,[4] E Omoto,[5] H Noji,[6] K Murai,[7] H Tsujimura,[8] Y Tamai,[9] Y Wano,[10] Y Tomiya,[11] F Nakamura,[12] K Sawada,[1] H Harigae[2]

[12]*Tenri Hospital, Tenri, Japan*

Background. The Philadelphia (Ph) chromosome is a hallmark cytogenetic abnormality in chronic myeloid leukemia (CML), and is also present in ~25% of adult acute lymphoblastic leukemia (ALL). Although the p210 BCR/ABL isoform is predominant among CML patients, about 50% of adult Ph+ALL have p210 and the remainder harbor the p190 isoform. If left untreated, CML invariably progresses to a blastic phase, which is typically of myeloid lineage. However, in ~30% of CML cases the blasts are of lymphoid lineage. In the absence of documented chronic phase CML, this lymphoblastic presentation poses a diagnostic challenge to differentiate from de novo Ph+ALL. Neutrophil-FISH (N-FISH) using peripheral blood cells for CML diagnosis and/or to monitor imatinib response is widely available in Japan. Importantly, N-FISH also identifies the Ph chromosome lineage to neutrophils in some patients with ALL. *Aims and Methods.* To assess the clinical differences between p210- and p190-ALL, a retrospective chart review was performed for cases of Ph+ALL in the Tohoku Hematology Forum study group between October 2000 and September 2010. Eighty one Japanese patients with Ph+ALL were enrolled in this study. The data reviewed included diagnosis, treatment, hematologic parameters, cytogenetic characteristics, and clinical outcome. N-FISH was performed at the time of diagnosis in 24 cases (p210, n=11; p190, n=13). *Results.* No definite clinical differences were identified between p210-ALL (n=25) and p190-ALL (n=56). However, similar to what is observed in CML, N-FISH identified BCR-ABL positive neutrophils in 91% (10 of 11) of p210-ALL (average 74.4%). In contrast, BCR-ABL positive neutrophils were only found in 38% (5 of 13) of p190-ALL (average 61.3%) which was statistically different than p210-ALL (p=0.008 by Fisher's test). All Ph+ALL cases were then subdivided based on N-FISH results: "*secondary* ALL", with Ph chromosome myeloid lineage involvement (n=15); and "*de novo* ALL", without myeloid lineage involvement (n=9). Using this classification, additional features were identified that significantly differed between the two subgroups (secondary ALL vs. de novo ALL): laboratory parameters (platelets: 95x10(3)/μl vs. 26x10(3)/μl, p=0.005; basophils: 0.56% vs. 0%, p=0.041), immunophenotypes (CD13+: 12/15 vs. 2/9, p=0.005; CD33+: 11/15 vs. 1/9, p=0.003), and percentage of residual normal clones (6/15 vs. 8/8, p=0.005). *Conclusion.* N-FISH revealed myeloid lineage involvement in "*secondary* ALL", which was largely comprised of p210-ALL cases. As this group resembled CML in several other clinical features, these data suggest that "*secondary* ALL"may represent CML presenting in lymphoblastic crisis. During a latent phase prior to the clinical onset of CML, Ph chromosome patients could acquire genetic abnormalities to transform to lymphoblastic crisis. Despite the great advances in CML treatment with the development of imatinib and other tyrosine kinase inhibitors, the latent phase of CML is still poorly understood and may have the potential to progress to p210-ALL in addition to clinically overt CML.

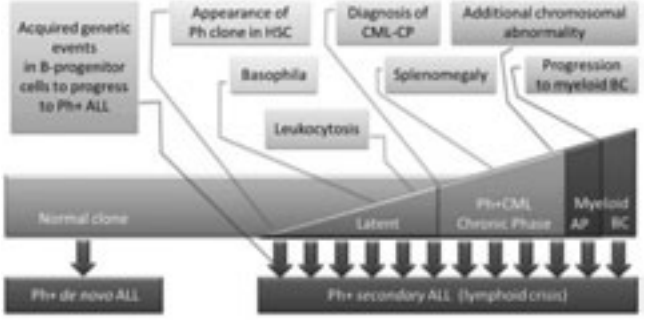

Figure 1. Ph+ secondary ALL and Ph+ latent CML.

REGULATION OF CELL CYCLE IN PRIMITIVE CHRONIC MYELOID LEUKAEMIA (CML) VS NORMAL STEM CELLS

F Pellicano,[1] L Hopcroft,[1] M Aspinall-O'Dea,[2] S Graham,[1] G Graham,[1] A Whetton,[2] M Girolami,[3] T Holyoake[1]

[1]*University of Glasgow, Glasgow, United Kingdom*
[2]*University of Manchester, Manchester, United Kingdom*
[3]*UCL, London, United Kingdom*

Background. Chronic myeloid leukaemia (CML) is a clonal haemopoietic stem cell (HSC) disorder associated with the Ph chromosome and BCR-ABL oncogene, encoding a constitutively active tyrosine kinase. *Aims.* We hypothesise that the resistance of CML stem cells to chemotherapy is dependent on pathways that are deregulated in malignancy, offering the possibility of developing therapeutic approaches that are selective for leukaemic versus (vs) normal HSC. *Methods.* We have investigated the transcriptional differences between quiescent (G0) normal and CML stem cells by carrying out RNA and miRNA profiling. Biochemical analysis was carried out by flow cytometry and western blotting. *Results.* G0 CD34+ haemopoietic cells were isolated from normal controls and patient samples and gene profiling revealed differences in the expression of cell cycle genes, including CDC20, CHEK1, CDKN3, CDC27, CDC2, CDC6 and Cyclin B2. Interestingly, E2F1, the communal transcription factor for all the genes we found differentially expressed, was abnormally regulated in CML and it is likely that, together with is regulator Rb, E2F1 is a key player in modulating CML stem cell quiescence. E2F1 was upregulated in CML CD34+ cells compared to normal, at both the protein and mRNA level. Furthermore, its activation in these cells was confirmed by the high level of phosphorylated Rb. To understand if miRNAs have a role in CML stem cell survival and in particular in the regulation of the E2F1/Rb pathway, we carried out miRNA arrays. CD34+38- cells isolated from normal and patient samples were used to perform genome-wide miRNA expression profiling (LC Sciences www.lcsciences.com). Initial data analysis has provided several potential candidates which are under investigation. *Summary/Conclusions.* These data suggest that the E2F1/Rb signalling pathway may have a role CML stem/progenitor cells cycle status and contribute to the understanding of CML stem cell quiescence, suggesting new strategies to target CML stem/progenitor cells by preventing or reversing these effects. In addition, enhanced knowledge of the survival pathways that are operative within CML stem cells, which may lead to eradication of this critical population, would be of relevance to other forms of cancer.

0121

REDUCED EXPRESSION OF THE LTB4 MEMBRANE RECEPTOR BLT1 EXPLAINS ALOX5 DOWN-REGULATION IN NEWLY DIAGNOSED CML PATIENTS

M Lucas, R Harris, E McDonald, A Giannoudis, A Holcroft, R Fowler, R Clark

University of Liverpool, Liverpool, United Kingdom

Background. Alox5 has been reported to be upregulated in mouse leukaemic stem cells (LSC), and this is not inhibited by imatinib. Furthermore, mice transplanted with Alox5 deficient BCR-ABL1+ bone marrow cells were resistant to the induction of chronic myeloid leukaemia (CML).(1) Alox5 deficiency was found to have no effect on BCR-ABL negative cells. This suggests that Alox5 is important in LSC growth and is essential for the development of CML. *Aim.* To investigate the role of Alox5 in imatinib treated CML patients. *Methods.* Functional Alox5 was assessed using an LTB4 ELISA and Alox5 mRNA determined via a TaqMan gene expression assay. BLT1 protein levels were assessed by cell surface FACS analysis. *Results.* Alox5 expression was measured in 27 chronic phase patients at diagnosis and at 3, 6 and 12 months following imatinib treatment. At diagnosis Alox5 expression in all patients was below that seen in samples from normal controls. On treatment initiation Alox5 levels increased to normal values in all patients except those who were destined to progress to blast crisis (BC) where levels remained low. All increases in Alox5 levels were statistically significant, diagnosis and 3 months (p=0.003), 6 months (p=<0.001), and 12 months (p=0.024) in patients who subsequently achieve a CCR. Plasma LTB4 levels were utilised as a measure of Alox5 function. In all CML patients LTB4 levels were higher than that measured in samples from normal controls, and all patient levels increased further on imatinib treatment. Levels in BC were always higher compared to chronic phase. These data in clinical material are in conflict with previously published work utilising a mouse model, since we find that LTB4 levels are increased despite low Alox5 expression. To investigate this further we undertook determination of LTB4 receptor (BLT1) levels. BLT1 surface expression was found to be extremely low in newly diagnosed chronic phase CML patients. BLT1 protein in newly diagnosed patients was significantly lower than the level observed in patients responding to tyrosine kinase inhibitor (TKI) treatment (defined as a BCR-ABL1 ratio 1-10%) and those patients who achieved a CCR (p=0.004 and p=<0.0001 respectively). *Conclusion.* Alox5 expression is low and LTB4 levels are high in CML patients at diagnosis. This is likely the result of increased negative regulation of Alox5 via the arachidonic acid pathway intermediates (5-HEPTE and LTA4) and a lack of positive feedback through LTB4 due to the reduced expression of the BLT1 receptor. Clearly different pathways of Alox5 regulation exists between the CML mouse model and patients which should be considered when translating findings from the mouse model to a clinical setting.

0122

DYSREGULATION OF THE TUMOUR SUPPRESSOR PTEN IN CHRONIC MYELOID LEUKAEMIA

G Gareth, J Alonso, B Bak, S Hill, L Soriano, M Daghistani, J Sorouri-Khorashad, M Alikian, AC Lim, A Ibrahim, H De Lavallade, A Reid, D Marin, J Apperley, L Foroni

Imperial College London, London, United Kingdom

Background. Chronic Myeloid Leukaemia (CML) is a myeloproliferative disorder characterised by the BCR-ABL1 fusion oncogene. Despite the uniformity of causation and therapeutic modality (Imatinib), patients exhibit heterogeneity in their response. PTEN (Phosphatase and Tensin Homolog) is a tumour suppressor gene, which codes for a phosphatase antagonist of the PI3K/AKT mitogenic axis. Down-regulation or loss of PTEN, through mutations, deletions and epigenetic silencing, has been described in many malignancies and is linked to disease progression. Although PTEN is known to be down-regulated in CML, the mechanism of repression is yet to be fully elucidated, but both promoter hypermethylation and dysregulation of the pseudogene PTENP1, which acts as a decoy for suppressive microRNAs, have been implicated. *Aims.* To investigate whether CpG hypermethylation and/or changes in PTENP1 pseudogene expression contribute to the down-regulation of PTEN in diagnostic CML, and to correlate expression with patient Sokal score and 12mth clinical response. *Methods.* Peripheral blood lysates from 32 chronic-phase CML patients at diagnosis and 30 normal volunteers were used to isolate DNA and mRNA. The DNA was bisulfite treated and used for High Resolution Melt analysis (HRM) and Pyrosequencing CpG methylation studies. Two CpG island were interrogated for methylation: one residing in the 5' UTR of PTEN by HRM, and the other 1.4kb upstream of exon 1 by Pyrosequencing. The mRNA was converted to cDNA and used for qPCR gene expression studies. The qPCR employed primers specific for PTEN and PTENP1, with B2M as the endogenous control. Expression levels were given as delta-CT relative expression ratios (RER). 16 CML samples were classified by Sokal score (low, intermediate & high risk) and by 12mth response to Imatinib (400mg/day), defined by attainment of complete cytogenetic response (CCyR). *Results.* PTEN was shown to be significantly under-expressed in CML compared with Normal samples (median RER 0.31 and 1.69, respectively; p<0.001); whereas PTENP1 was conversely expressed (RER 2.06 and 0.62; p=0.0013). Patients with a high Sokal score had a significantly higher PTEN expression than those in the low risk group (1.04 and 0.52, respectively; p<0.05), but there was no difference for PTENP1. There was also no significant difference in expression for either gene between the 12mth optimal and suboptimal response groups. Neither HRM nor pyrosequencing showed any evidence of CpG hypermethylation in any of the patient samples. *Summary/Conclusions.* Although loss of PTEN is known to be a marker of disease progression in many tumour types, in CML the dynamic appears to be more complex. It was consistently down-regulated at diagnosis, but patients with high-risk Sokal scores showed a higher relative expression; although caution must be taken when drawing conclusions from such a relatively small sample number. In addition, the pseudogene PTENP1 was found to be over-expressed in CML, weakening the case for its role as a decoy for suppressive microRNA as a mechanism in PTEN dysregulation. The epigenetic assays performed found no evidence of promoter hypermethylation, suggesting that PTEN down-regulation in CML occurs via a yet to be elucidated mechanism.

SHEPHERDIN-DEPENDENT SUPPRESSION OF SURVIVIN INDUCED BY A BCR- ABL/JAK2/STAT3 PATHWAY SENSITIZES IMATINIB RESISTANT CML CELLS TO DIFFERENT DRUGS

S Stella,[1] E Tirrò,[1] E Conte,[1] L Manzella,[1] D Altieri,[2] P Vigneri[1]

[1]*University of Catania, Catania, Italy*
[2]*University of Massachusetts Medical School, Department of Cancer Biology, Boston, United States of America*

Background. The BCR-ABL oncoprotein of Chronic Myelogenous Leukemia (CML) displays exclusive cytoplasmatic localization and constitutive tyrosine kinase activity leading to the activation of different pathways that favor cell proliferation and survival. Treatment of CML cells with Imatinib Mesylate (IM) suppresses BCR-ABL kinase activity reverting the anti-apoptotic phenotype of the leukemic cells. Survivin (SVV) is a member of the inhibitor of apoptosis proteins that is expressed in most forms of human cancer causing reduced sensibility to multiple death stimuli. *Aims.* To ascertain the signaling pathway(s) triggered by the BCR-ABL kinase to induce SVV expression and determine whether reduced SVV levels increase the anti-proliferative activity of different cytotoxic compounds on IM-resistant CML cells. *Methods*. Lysates from K562, KCL22, KYO-1 and LAMA 84 CML cell lines exposed to IM, PD98059, LY294002, AG490 or incubated with siRNAs against JAK2 or antisense oligonucleotides against STAT3 were employed to identify BCR-ABL-dependent signaling pathways responsible for SVV induction. Viability of IM-resistant cells was assessed using the ATPlite luminescence assay and/or Annexin V-FITC/PI staining after SVV silencing or incubation with the peptidomimetic Shepherdin in association with IM, hydroxyurea (HU), Cytosine Arabinoside (Ara-C) or Doxorubicin. *Results.* Inactivation of BCR-ABL catalytic activity decreased SVV levels confirming that, in CML cells, SVV expression relies on BCR-ABL constitutive tyrosine kinase activity. BCR-ABL-mediated up-regulation of SVV involved the JAK2/STAT3 pathway since silencing of either JAK2 or STAT3 caused a consistent reduction of SVV. In cells unresponsive to IM, SVV silencing failed to restore sensitivity to the drug, indicating that SVV is not directly involved in the development of IM resistance. Cell lines unresponsive to IM because of point mutations in the BCR-ABL kinase domain were highly responsive to HU after down-regulation of SVV. However, this was not the case in cells failing IM because of BCR-ABL gene amplification. Finally, incubation of IM-resistant cells with cell-permeable Shepherdin, a peptidomimetic compound that down-regulates SVV expression by preventing its interaction with heat shock protein 90, enhanced cell death induced by IM, HU, Ara-C and Doxorubicin. *Conclu-*

sions. BCR-ABL kinase activity induces SVV expression in CML cells via the JAK2/STAT3 signaling pathway. Suppression of SVV fails to resensitize resistant cells to IM. However, the combination of Shepherdin with different cytotoxic drugs significantly increases the activity of these compounds on cells unresponsive to IM because of point mutations (including T315I) in the BCR-ABL catalytic domain.

PROTEIN SIGNALLING TRIGGERED BY IMATINIB AND DASATINIB IN THE MYELOID BLASTIC CRISIS OF CML: AN IN VITRO PROTEOMIC AND PHOSPHOPROTEOMIC STUDY

A Romano,[1] C Romano,[2] F Stagno,[2] A Cupri,[2] F Di Raimondo,[2] L Liotta,[1] V Espina,[1] P Vigneri[2]

[1]*George Mason University, Manassas, United States of America*
[2]*Department of Clinical and Molecular Bio-Medicine, Section of Hematology, Oncolo, Catania, Italy*

Background. Imatinib resistance (IM-R) developing in approximately 30% of Chronic Myeloid Leukemia (CML) patients (pts) recognizes both BCR-ABL-dependent and BCR-ABL-independent mechanisms. The former include point mutations in the BCR-ABL kinase domain and amplification of the BCR-ABL gene locus while the latter are still poorly understood, probably involving improper activation/inactivation of BCR-ABL-independent signaling pathways. *Aims.* We describe preliminary results of a study employing immortalized CML cells - either sensitive or resistant to IM - to perform Reverse Phase Protein Micro-Arrays (RPMAs) aimed at characterizing the proteomic profiles of these cell lines and at identifying BCR-ABL-independent pathways that contribute to the development of IM-resistant CML. *Methods.* RPMA is a reproducible, high-throughput system for protein signaling pathway profiling. The phosphorylation state of kinase-associated therapeutic targets provides direct information regarding the target and off-target effects of different drug treatments. Human CML cell lines, sensitive (K562S, LAMA84S) and resistant (K562R, LAMA84R) to Imatinib, were incubated with IM 1uM, Dasatinib (DAS) 1uM or LY-294002 10uM (LY) used as a control. After 2 or 12 hours, cells were placed in a preservative that suppresses fluctuations in kinase pathway proteins. RPMAs were used to quantitatively map 45 cell signaling pathway endpoints, including autophagy, DNA repair systems, DNA damage and transcriptional factors crucial for CML. *Results.* Previous evidence has demonstrated that K562R are unresponsive to IM because of unknown BCR-ABL-independent mechanisms, while LAMA84R display BCR-ABL genomic amplification. Compared to their sensitive counterpart, K562R exhibited a paradoxical reduction in BCR-ABL signaling at BCR(Y177), CRKL(Y207), ERK(T202/Y204) and Cofilin(D59), associated with over-expression of autophagy markers (ATG5 and LC3B). Conversely, LAMA84R presented increased BCR-ABL signaling at BCR(Y177), CRKL(Y207) and ERK(T202/Y204). In drug treatment endpoints, DAS was confirmed stronger than IM in abrogating BCR-ABL auto-phosphorylation on BCR(Y177). We found HDAC3 induction in both K562R and LAMA84R and this event was positively associated with increased expression of c-MYC and NUMB and higher phosphorylation on mTOR(S2445), pRb(S608), CHK1(S345), FOXO1(T24), FOXO3a(T32), but not on BCR(Y177) or c-ABL(Y245). *Conclusions.* Taken together, our data confirm the value of the RPMA assay to investigate improperly activated pathways that could identify one or more potential targets for future treatment strategies of IM-resistant pts.

0125

INHIBITION OF THE PTP1B PHOSPHATASE MEDIATES UBIQUITINATION AND DEGRADATION OF BCR-ABL

G Cotter

University College Cork, Cork, Ireland

Background. Chronic myelogenous leukemia (CML) is a myeloproliferative disorder characterized at the molecular level by the expression of Bcr-abl, a chimeric protein with deregulated tyrosine kinase activity. Expression of this oncogene is associated with an increase in activity of the PI3k/Akt kinase driven pathway which in turn contributes to tumour cell survival. The protein tyrosine phosphatase 1B (PTP1B) is upregulated in Bcr-abl expressing cells suggesting a regulatory link between the two proteins. In addition a direct interaction between these two proteins has been demonstrated, but the function of this interaction is unknown. *Aims.* The aim of this piece of research work is to investigate at a molecular level why and how Bcr-abl interacts with PTP1B and how this might affect tumour cell survival. *Methods.* TonB.210 cells kindly provided by Dr. George Daley (MIT, Cambridge, MA, USA) contain a Doxycycline responsive promoter whereby Bcr-abl p210 can be conditionally induced when incubated with the antibiotic. For PTP1B inhibition, cells were treated with 1 g/ml DOX for 48 hours and 35 M 3-(3,5-Dibromo-4-hydroxy-benzoyl)-2-ethyl-benzofuran-6-sulfonicacid-(4-(thiazol-2-ylsulfanyl)-phenyl)-amide (PTP1B inhibitor or PTP1B). Western blotting was carried out to look at Bcr-abl and PTP1B protein expression levels. siRNA, Negative Control #1 siRNA and two Silencer® pre-designed siRNA (Ambion, Warrington, UK) were used for silencing PTP1B over a 24/48 h incubation period. The siRNA chosen for PTP1B were #1 siRNA ID:s72430 and #2 siRNA ID:s72431. The sequences are available from the manufacturer website. Confocal microscopy was used to look at where in the cell Bcr-abl degradation occurred. 2D-SDS-PAGE was used to look at the phosphorylation status of Bcr-abl. *Results.* We describe a novel mechanism by which the phosphatase PTP1B is required for Brc-abl protein stability. When TonB.210 cells were treated with increasing concentrations of the PTP1B inhibitor or siRNA to PTP1B there was almost a complete loss of Bcr-abl expression at the protein level. A dose of 35 µM of the PTP1B inhibitor for 2 hours was optimal for reducing Bcr-abl protein levels. A similar result was demonstrated when siRNA to PTP1B was used over a 24/48 hour period. RT-PCR analysis demonstrated that there was no effect at the RNA level indicting that the loss of Bcr-abl was the result of protein degradation. Subsequent western blotting demonstrated that this loss is the result of Bcr-abl ubiquitination. Degradation occurs via a lysosomal pathway rather than the proteosome since the proteosomal inhibitor Lactacystin had no effect. Confocal microscopy confirmed this. 2D-SDS-PAGE demonstrated that the constant removal of a phospho group from Bcr-abl by an active PTP1B was necessary to maintain its stability. When PTP1B was inhibited or knocked down by siRNA Bcr-abl remained phosphorylated and this triggered its ubquitination and degradation. *Conclusions.* In this work, we describe a novel mechanism by which Bcr-Abl is stabilized by PTP1B. These results suggest that inhibition of PTP1B may be a useful strategy to explore in the development of novel therapeutic agents for the treatment of CML.

STATINS CAN POTENTIATE ANTILEUKEMIC EFFECT OF IMATINIB THROUGH THE INHIBITION OF ABCB1 AND ABCG2 ACTIVITY

E Glodkowska-Mrówka,[1] P Mrówka,[1] M Winiarska,[1] G Basak,[1] J Niesiobedzka-Krezel,[1] I Seferynska,[2] T Stoklosa[1]

[1]*Medical University of Warsaw, Warsaw, Poland*
[2]*Institute of Hematology and Blood Transfusion, Warsaw, Poland*

Background. Despite clinical success of imatinib in the majority of patients, development of resistance becomes relevant clinical problem. Variations of intracellular concentration of tyrosine kinase inhibitors, dependable on the activity of drug transporters, are among major mechanisms responsible for development of resistance in the absence of BCR/ABL mutations. Intracellular concentration of imatinib results from the balance of drug influx mediated mainly by OCT-1 transporter and drug efflux mediated by ABC transporters. According to the recent knowledge, in clinical settings imatinib is a substrate of ABCB1 and ABCG2 transporters. Strong evidence suggest that agents modulating membrane cholesterol level, e.g. statins, are able to change conformation of membrane-bound drug transporters and increase intracellular imatinib concentration. *Aim of the study.* Potentiation of antileukemic activity of imatinib in cell lines transformed with BCR/ABL-1 oncoprotein and primary human CML CD34+ cells employing statins. *Methods.* The following cells were used in the study: primary CD34+ cells obtained after informed consent from the patients with CML as well as from healthy blood donors; cell lines: K-562, 32Dcl3 wild type and BCR/ABL-transformed. ABC transporters activity was evaluated using specific fluorescent substrates: BODIPY-prazosin (for ABCG2) and rhodamine 123 (for ABCB1) while direct imatinib efflux studies were performed using 14C-labelled drug. Imatinib-mediated cytotoxicity was analyzed using cell viability and apoptosis assays (XTT and propidium iodide staining). Clonogenic assay after drug treatment was performed. Expression of BCR/ABL-dependent proteins was assessed . *Results.* Cytometric analysis of ABC transporters activity has shown that lovastatin significantly decreased the activity of ABCB1 and ABCG2-mediated efflux capacity. The effect was completely reversed by the addition of cholesterol. It was observed both for stable cell lines and primary CD34+ CML cells. These results were confirmed using radiolabeled 14C-imatinib concentration measurement after incubations with

statins. Statins caused at least 2-fold increase in intracellular imatinib concentration in cell lines and primary CML CD34+ cells, including cells obtained from patients clinically resistant to imatinib with no detectable ABL kinase domain mutations (Figure 1). We did not observe changes in initial influx of the drug between statin-treated and control cells. Interestingly, statins did not influence the expression of ABC transporters. Lovastatin enhanced cytotoxicity of imatinib in BCR/ABL-positive cell lines and CML CD34+ primary cells as compared to wild-type counterparts and cells obtained from the healthy donors respectively. Similar effects were observed for other members of statin family. Flow cytometry analysis after propidium iodide staining revealed that co-treatment induced cell cycle arrest and increased percentage of apoptotic leukemic cells in comparison to imatinib alone. Lovastatin also increased imatinib-induced reduction of the phosphorylated form of the adaptor protein CrkL, which serves as a marker for efficient BCR/ABL kinase inhibition in both stable cell lines and primary CML CD34+ cells. *Conclusions.* Our results indicate that statins may enhance therapeutic efficacy of imatinib through the inhibition of drug efflux mediated by ABCB1 and ABCG2 transporters and may become potent treatment modality for the patients resistant to imatinib without mutations in BCR/ABL kinase domain.

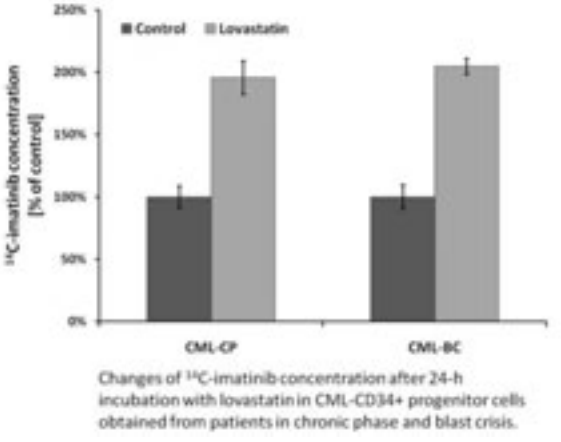

Figure 1. 14C-imatinib concentration after statins.

OVER-EXPRESSED NUCLEOPHOSMIN/ B23 AND NUCLEOLIN C23 PREDICTED DISEASE PROGRESSION IN CHRONIC MYELOID LEUKEMIA

J Hu,[1] M Lin,[2] T Liu,[2] J Li,[2] B Chen,[2] Y Chen[2]

[1]*Fujian Institue of Hematology, Fujian Medical University Union Hospital, Fuzhou, China*
[2]*Fujian Institute of Hematology, Fujian Medical University Union Hospital, Fuzhou, China*

Background and Aims. Nucleophosmin/ B23 NPM B23), or NPM1,also termed NO38 or numatrin, is an acidic nucleolar protein which belongs to the nucleoplasmin/nucleophosmin family of nuclear chaperones. B23 interacts with nucleolin C23, both are multifunctional nucleolar proteins and play important role in various aspects of ribosome biogenesis from transcription regulation to the assembly of pre-ribosomal particles. Compared to C23, NPM is much more investigated for its relation to cancer. The deletion and translocation of NPM gene have been observed in hematological malignancies. NPM1 mutations occur specifically in about 30% of adult de novo AML. However, NPM1 mutation and B23 protein expression were rarely reported in CML. Our previous study showed that proteins B23 and C23 were over-expressed in relapased/refractory acute leukemia patients. *Methods.* In order to investigate their clinical significances in CML, B23 and C23 expressions were detected by western blot and RQ-PCR in leukemia cell lines K562, K562/ADR (adriamycin-resistant K562), KG01 (imatinib-resistant K562) and 139 CML patients, including 106 chronic phase(CP), 13 accelerated phase(AP) and 20 blast crisis(BC). *Results.* Compared to healthy control samples, which showed no expressions of these 2 proteins, leukemic cell lines revealed an obvious up-regulation of B23 and C23. Moreover, significantly higher expressions of B23 and C23 were found in 2 resistant cell lines compared to the parent K562 cells. In primary CML samples, much higher expressions of B23 and C23 were noted in CML-BC than in CML-AP and CML-CP, which were 75%(15/20), 7.7%(1/13) and 12.3%(13/106) respectively. The concomitant expression of B23 and C23, both positive or negative, was noted in 96%(133/139) patients. No NPM1 mutations were found from 20 CML samples (10 B23+ and 10 B23-), which were not consistent to B23 protein expressions. B23 and C23 positivity significantly correlated with shorter OS and poorer prognosis. One patient became B23 positive as disease progressed from CP to BC. *Conclusions.* It could be concluded that B23 and C23 may be prognostic indicators for CML and be useful in predicting progression of CML. Further investigation is needed to explore their involved mechanisms in progression of CML.

0128

THE ROLE OF SPARC IN CHRONIC MYELOID LEUKEMIA

D Tibullo, C Giallongo, P La Cava, D Tibullo, A Branca, I Barbagallo, N Parrinello, F Stagno, A Romano, G Palumbo, F Di Raimondo

University of Catania, Catania, Italy

Background. Secreted protein acid and rich in cysteine (SPARC/osteonectin/BM-40) is a multifunctional matricellular glycoprotein with counter-adesive properties and effects on cell shape, proliferation, cell cycle and angiogenesis. In some types of cancer, SPARC correlates with poor prognosis (melanoma, glioma, prostate and breast cancer), while in others the protein functions as a tumor suppressor (ovarian, pancreatic and colorectal cancers). Studies of SPARC in hematopoietic malignancies resulted in conflicting reports about its role as a tumor suppressor (5q¬-MDS and AML with rearrangement of the MLL gene) or promoter (multiple myeloma and plasmacytoma). In chronic myeloid leukemia (CML) a recent study indicates that intracellular SPARC may be involved in resistance to imatinib (IM) *Aims.* Inhibition of BCR/ABL by IM results in a G1 cell cycle arrest mediated by PI3K pathway. It has been reported that PI3K inhibitors synergize with IM, increasing apoptosis of CML cells. Because SPARC affects PI3K/AKT, we focused on its potential role as tumor suppressor protein in CML cells. *Methods and Results*. By using qRT-PCR and western blot analysis, we demonstrated that SPARC was downregulated in CML cells from peripheral blood of 35 patients at diagnosis in respect to healthy controls ($p<0.001$ as mRNA and $p<0.05$ as protein). Ten patients were evaluated during IM treatment and in all patients a significant increase in SPARC mRNA and protein expression was recorded already at 3 months of treatment and this increase was maintained at least through the 12th month of therapy, when all patients were in complete cytogenetic remission ($p<0.01$ as mRNA and $p<0.001$ as protein). In one patient, discontinuation of IM at the 12th month, resulted in a significant reductionof SPARC protein level that increased again after IM was restarted. Analysis of SPARC serum levels by ELISA showed that, in CML patients, SPARC resulted decreased compared to healthy donors at diagnosis ($p<0.01$) but it progressively increased, reaching its peak at 18th months of IM treatment ($p<0.001$). We also incubated K562 with human recombinant SPARC for 2 days and then with IM for 24 h. Cell proliferation was evaluated after 72 h by ATP-lite: a cytotoxicity of 18±3,2% and 29±1,6% vs untreated cells was recorded with SPARC and IM alone respectively; their association induced a reduction of cell viability of 37,5±3,7%. After 96 h the combination SPARC/IM resulted more effective than IM alone with an increase of cytotoxicity of 16,5±3% ($p<0.01$ vs IM alone). Flow cytometry analysis revealed an accumulation of K562 cells in G0/G1 after 24 h exposition to IM alone (15±1,7% vs untreated cells; $p<0.01$) or SPARC alone (14,5±4,1%; $p<0.01$) while SPARC/IM combination showed an additive effect (26,5±3,3%; $p<0.001$). *Conclusion.* SPARC production is downregulated in CML cells. Treatment of IM induces overproduction of SPARC by normal PBMC. *In vitro*, SPARC induces a G0/G1 cell cycle arrest thus reducing the growth rate of K562 cells and increasing their sensitivity to IM. In conclusion, we found that exogenous SPARC has an antiproliferative effect on BCR/ABL positive cells.

0129

IMATINIB HAS THE POTENTIAL TO EXERT ITS ANTILEUKEMIA EFFECTS BY DOWN-REGULATING HERG1 K+ CHANNELS IN CHRONIC MYLEOGENOUS LEUKEMIA

F Fang, H Li, K Liang, Y Du, D Guo, S Huang

Center for Stem Cell Research and Application, Wuhan, China

Background. Imatinib (STI571, Gleevec), a powerful protein tyrosine kinase (PTK) inhibitor, is the current first-line therapy for all newly diagnosed chronic myeloid leukemia (CML). Studies aimed at deci-

phering the mechanism of imatinib anti-leukemic activity have focused on inhibited PTKs activity, such as Abl, c-Kit, and the platelet-derived growth factor receptors. Indeed, in addition to the mediation of cellular events such as cell proliferation, differentiation, embryonic development, metabolism, and oncogenesis, PTKs also regulate a large number of ion channels. Increasing evidence suggests that PTK inhibitors alter the activity of a large number of voltage-dependent ion channels. *Aims.* hERG1 K+ channels are highly expressed in leukemia cells and appear of exceptional importance in favoring leukemogenesis, while the effect of imatinib on hERG1 K+ channels in CML has not been well characterized. The present study explored a possible regulatory effect of imatinib upon hERG1 K+ channels as a mean to uncover new molecular events involved in the antileukemia activity of this PTK inhibitor in CML. *Methods.* Real-time PCR, flow cytometry analysis and the whole-cell patch clamp technique were used to analyze effects of imatinib on hERG1 K+ channels. The hERG1 K+ channels inhibitor was used to detect whether hERG1 K+ channels act a potential target for imatinib-induced antileukemia effects in primary CML cells and Bcr-Abl-positive K562 cells. *Results.* Present data demonstrated that hERG1 was highly detected in K562 cells and primary CML cells. K562 cells cultured with imatinib (5 μM), the expression of hERG1 mRNA and protein were down-regulated by (67.9 ± 19.2) % and (64.3 ± 12.4) %, separately. Furthermore, current recordings of HEK293T cells transiently transfected with herg showed that imatinib markedly reduced the step hERG currents amplitude to (45.7 ± 2.5) % (n = 6) of control at 10 mV, and peak tail currents amplitude to (25.8 ± 3.1) % (n = 6) of control at 20 mV. Unexpected, imatinib failed to alter the voltage-dependence of hERG channel activation. The consequent pathophysiological effects of suppressing hERG1 K+ channels by imatinib illustrated that cells pretreated with imatinib in the present of 1 μM E-4031, a specific hERG1 K+ channels inhibitor, which achieved 1.9-fold higher the inhibition of proliferation and 1.3-fold stronger induction of apoptosis than that of cells treated with imatinib. Moreover, the synergistic effects of E-4031 and imatinib on the suppression VEGF secretion and NF-κB activation were observed. When treated with imatinib in the present of E-4031, the expression of VEGF mRNA was significantly reduced by 60%. The mean VEGF concentration in culture supernatants from cells treated with imatinib combined with E-4031 was 199.9 ± 101.5 ng/L per 10*6* cells, which was 1.6-fold higher inhibition efficiency than that of cells treated with imatinib. *Conclusions.* Our data demonstrate that imatinib down-regulates hERG1 K+ channels currents, which involves in imatinib-induced antileukemia effects in CML. These findings reveal a novel potential molecular mechanism of antileukemic activities by imatinib, which independent of targeting on the Bcr-Abl pathway.

[7]*Department of Hematology/Oncology "L. and A. Seràgnoli", Bologna, Italy*

Background. The oncogenic transformation of Chronic Myeloid Leukemia (CML) cell of origin has been associated to an increased glucose metabolism, where the glycolytic pyruvate is directed away from the mitocondria, converted into lactate and secreted from the cell. This metabolic conversion is termed aerobic glycolysis, or Warburg effect and very essentially, it serves to support the tumor cell proliferation, by providing nucleotides, aminoacids and lipids enough to replicate all of cellular content. CML patients are historically stratified according to their Sokal risk score, which for more than 30 years has been regarded as the most significant prognostic factor in this hematological malignancies. The putative genetic and/or genomic basis driving this stratification are still not known. *Aim.* Here we present data obtained from GEP experiments aimed at the identification of genes and pathways able to predict and/or to elucidate the onset of the disease and the disease course in CP-CML pts by analyzing the transcriptome of the CD34+ cell fractions obtained at diagnosis from a cohort of high and non-high Sokal risk CML patients. *Patients and Methods.* Overall, 67 patients with previously untreated CML in chronic phase (CP) entered the study; all of them have been enrolled in GIMEMA CML protocols and provided highly enriched CD34+ cell fractions from peripheral blood. Gene expression profiling (GEP) was performed, in order to identify genes most significantly and most differentially expressed between high and non-high Sokal risk patients. All other cases were used in Real-time experiments, in order to validate the GEP data. *Results.* By GEP, 82 probe-sets, corresponding to 78 genes resulted significantly differentially expressed between high and non-high Sokal risk patients in a supervised analysis of gene profiles. A gene enrichment analysis of this profile showed that genes involved in hypoxia and oxidative stress resulted significantly overexpressed in the comparison between high and non-high risk patients. Particularly interesting resulted a significantly higher expression in high Sokal risk patients of FBP1 (fructose 1,6 bisphosphatase), a key-enzyme of gluconeogenesis, together with a significant over-expression of genes coding for enzyme involved in gluthatione biosynthesis (FBP1,GSTM3,SEPP1). These data suggest that CD34+ cells obtained from high Sokal risk patients might exhibit an unexpected moderation of the glycolytic flux, mainly due to the over-expression of FBP1, which might cause a re-direction of the pathway into the pentose phosphate shunt. Moreover, we validated by Real-time the de-regulated expression of these genes in a different set of newly diagnosed CP-CML patients, thus confirming that they are differentially expressed between high and non-high risk patients and we found that HIF1α, which is a gene that may be involved in the metabolic reprogramming, is indeed deregulated in our system. Overall, our data demonstrate for the first time, that the expression at diagnosis of sugar metabolic enzymes, might drive the evolutive Sokal risk of CML patients.

0131

EVI-1 GENE OVER-EXPRESSION: A POSSIBLE MECHANISM OF THROMBOCYTOSIS AT CHRONIC MYELOID LEUKEMIA ONSET

G Balatzenko, V Hristchev, A Lilova, G Mihailov, M Guenova

National Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background. A considerable proportion of chronic myelogenous leukemia (CML) patients are characterized by elevated platelet counts at diagnosis. The underlying mechanisms are still poorly understood. Besides, thrombocytosis in acute leukemias has been recently linked with structural abnormalities of the short arm of chromosome 3, where EVI-1 gene maps. Activation of the EVI-1 oncogene has been reported in acute myeloid leukemia, CML in blast crisis, and less commonly, in chronic-phase CML patients. *Aim.* To investigate EVI-1 overexpression [EVI-1(+)] in chronic phase (CP) CML patients with extreme thrombocytosis in comparison to patients with normal or moderately elevated values as well as to patients with essential thrombocytemia (ET). *Materials and Methods.* In total, 21 patients with BCR-ABL-positive CP-CML and platelet counts above 1000x10^9/L (ranging 1000-2644x10^9/L) were studied for EVI-1 over-expression by reverse transcription polymerase chain reaction (RT-PCR) and the results were compared to a group of 22 BCR-ABL-positive CP-CML patients with platelet counts ranging 209-833x10^9/L. A group of 15 patients with ET, including 6 cases positive for JAK2 V617F mutation, were also included. Major clinical and laboratory variables, as well as the BCR-ABL type of transcripts were analysed. *Results.* In total, 21 patients with CP-CML were found to be EVI-1(+). The incidence of EVI-1 overexpression was significantly higher in CML patients with thrombocytosis >1000x10^9/l where it was found in 16/21 cases (76,2%) compared to 5/22 (22,7%) in CML patients with lower platelet counts (Fisher's Exact Test, p=0.001). No association between EVI-1 gene status with basic laboratory features such as leukocyte counts, hemoglobin levels, and age nor with the BCR-ABL type of transcripts was found. However, even in the whole CP-CML group, the platelet counts in EVI-1(+) patients was significantly higher compared to the EVI-1(-) cases (mean 1192.9±542.4x10^9/L vs 708.1±551.9x10^9/L; Pearson Chi square, p=0.006). Interestingly, none of the 15 ET patients (0%) had detectable EVI-1 mRNA levels. *Conclusions.* Until recently the EVI-1 gene over-expression was considered as a marker of disease progression. Up to our knowledge the present study provides for the first time additional evidence that the oncogene might play a role in the pathogenetic mechanisms of thrombocytosis in CML patients that differ from the involved pathways in ET.

Background/Aims. MicroRNAs (miRNAs) are short non-coding regulatory RNAs that control gene expression at the post-transcriptional level. Deregulation of miRNA expression has been discovered in a variety of tumors and it is now clear that they contribute to cancer development and progression. Chronic myeloid leukemia (CML) is an extensively studied neoplasms. The hallmark of CML is the Philadelphia chromosome, created by the t(9;22)(q34;q11) translocation, resulting in the formation of the bcr-abl oncogene, which codes for a deregulated tyrosine kinase. Imatinib, a Bcr-Abl inhibitor, selectively induces apoptosis of Bcr-Abl+ cells and is successful in treating CML patients. One major obstacle to imatinib-based therapies is imatinib resistance. In an attempt to override resistance, second-generation inhibitors, such as dasatinib were developed. Dasatinib is a multikinase inhibitor targeting Bcr-Abl and Src kinases and inhibiting most imatinib-resistant mutants. Our objective is to decipher an miRNA expression signature associated with CML and to determine potential target genes and signaling pathways affected by these signature miRNAs. *Methods.* Global miRNA expression profiling was performed with miRNA-based microarrays. Analysis was performed using Partek Genomics Suite and validation was done by Taqman-miRNA. Bioinformatics was performed using: Target Scan, Ingenuity Pathway Analysis, KEGG pathway database. *Results.* We analyzed the miRNAs expression profile of K562 cells in reference to a pool of healthy blood. We also looked into the expression profile of K562 cells treated with imatinib or dasatinib. With the aid of unsupervised hierarchical clustering we found that healthy blood samples were clustered separately from K562 cells. Untreated K562 cells were clustered separately from treated ones and imatinib treated cells were clustered closely to those treated with dasatinib. Seventy-five miRNAs were downregulated and 35 upregulated in K562 cells as compared to healthy blood. Seventeen miRNAs were upregulated and 21 were downregulated following imatinib or dasatinib treatments. Following miRNA real-time PCR validation, we focused on 8 statistically significant differentially expressed miRNAs: 7 were downregulated (miR-31, miR-34a, miR-143, miR-145, miR-155, miR-196b, miR-564) and one was upregulated (miR-128) in K562 cells. MiR-128 was downregulated following imatinib and dasatinib treatments. MiR-564 was upregulation following imatinib treatment. The expression of the remaining 6 miRNAs was not altered following either drug treatment. We next analyzed predicted targets and affected pathways of the 8 deregulated miRNAs using Target Scan and Ingenuity Pathway Analysis. Reassuringly, the analysis identified cancer, and specifically CML, as the main disease associated with these 8 miRNAs. MAPK, TGF-β and Wnt were the main molecular signaling pathways related with these expression patterns. Utilizing Venn diagrams we found appreciable overlap between the CML-related miRNAs and the MAPK and TGF-β-related miRNAs. *Conclusions.* Our data suggest that our identified miRNAs might offer a pivotal role in CML. Nevertheless, while these data point to a central disease, the precise molecular pathway/s targeted by these miRNAs is variable implying a high level of complexity of miRNA target selection and regulation. These deregulated miRNAs highlight new candidate gene targets allowing for a better understanding of the molecular mechanism underlying the development of CML, and propose possible new avenues for therapeutic treatment.

Background. Real-time quantitative PCR (RQ-PCR) measurement of BCR-ABL transcripts in blood is a key tool for disease monitoring in Chronic Myeloid Leukemia (CML). Achieving major molecular response (MMR), i.e. a BCR-ABL load below 0.1% on the International Scale (IS), is now the main treatment objective with tyrosine kinase inhibitors, highlighting the need for more accurate and precise measurement methods. Recently, calibrated reference materials (CRM) have been developed and validated under the WHO umbrella, allowing for a simpler international standardization of BCR-ABL quantification. However, these CRM are a limited resource and their availability is restricted to manufacturers of secondary reference materials. In this context, Ipsogen developed an IS-MMR RNA strictly calibrated on the CRM, intended to be used as an intra-run calibrator for BCR-ABL/ABL conversion on IS. *Aims.* This study aimed at evaluating inter-laboratory variability when using a kit containing the IS-MMR RNA sample compared to in-house methods before and after conversion to the IS with laboratory-specific conversion factors (CF). *Methods.* Fourteen laboratories participated in the study. Analyses were run blindly on 8 test RNA samples provided by Ipsogen, previously calibrated on the IS, and corresponding to 7 BCR-ABL levels (5 below 1%, one above 10%) and a negative sample.

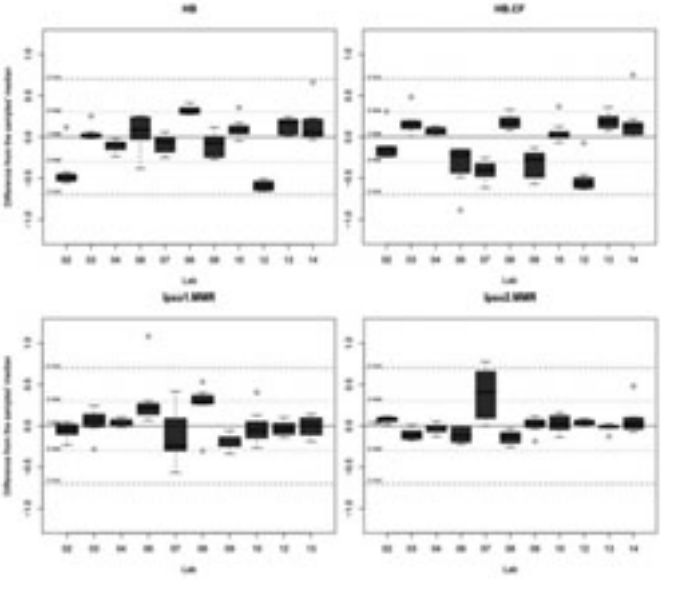

Figure 1.

A high positive control (HC) was also provided and included in each run. Each laboratory performed 2 runs with the BCR-ABL IS-MMR kit (Ipsogen) following the kit package insert instructions, and 1 run with their validated in-house method. Eleven laboratories had a CF, and were able to report home-brew results before (HB) or after (HB-CF) conversion to the IS. Four different real-time instruments were used. *Results.* Technical failure rate with the kit was low: 18 missing measures (7.1%), corresponding to two runs 1 failed in lab 5 and 14. Lab 7 reported a technical problem on its real-time instrument during the kit experiments, but results were not discarded. Inter-laboratory comparison was evaluated on fold-changes, taking the median values observed among laboratories as reference (see figure). On 81 common interpretable measures assessed in 10 laboratories on BCR-ABL positive samples, 85% and 94% of BCR-ABL/ABL% IS obtained with the kit (for run 1 and 2, respectively) were within the 2-fold interval, compared to 74% with HB and only 69% with HB-CF (p=0.00026). Values obtained with the kit were consistent with expected values and HB results, whereas HB-CF median values were systematically below the BCR-ABL/ABL% IS median values obtained with the kit. Kit results were consistent between runs, with 97% overall agreement on MMR prediction. *Conclusions.* In this study, the IS-MMR kit significantly improved inter-laboratory variability compared to HB-CF. With HB methods, laboratory-specific CF did not reduce inter-laboratory variability and even led to an underestimation of BCR-ABL values. Routine practice use of secondary reference materials calibrated on the WHO CRM should therefore be a simple and effective approach to standardise BCR-ABL quantification.

Various techniques have been employed to detect BCR-ABL1 kinase domain (KD) mutations in patients with chronic myeloid leukemia (CML) resistant to imatinib or second generation tyrosine kinase inhibitors (TKI). This variation may at least partially explain the different frequencies of mutations that have been reported. Standardized techniques and protocols for the detection of BCR-ABL1 KD mutations will be necessary in the future to obtain comparable mutation results within clinical studies. The first objective of this study conducted within the EUTOS (European Treatment and Outcome Study) for CML program was to record the mutation analysis techniques and protocols that are used for routine diagnostics by 24 national reference laboratories in 20 European countries, 9 of whom perform regular mutation analyses as a central laboratory for national or international clinical trials. Most laboratories (n=13; 54%) perform 1-10 mutation tests per month (range <1 to >100) and use published protocols for nested RT-PCR from peripheral blood or bone marrow leukocytes. Failure to amplify BCR-ABL1 mRNA at low BCR-ABL1 transcript levels was reported to be the most common PCR related difficulty in 16 (67%) laboratories. Sanger sequencing is applied for routine BCR-ABL1 KD mutation analysis in 23 (96%) laboratories. Additional screening techniques (e.g. D-HPLC, HRM) or more sensitive detection methods (e.g. ASO-PCR, pyrosequencing) are used routinely by eight laboratories each, respectively. Quantitative mutation analysis is performed routinely in 9 (38%) laboratories. The second objective of this study was to evaluate the techniques by analysis of blinded samples containing various BCR-ABL1 KD mutations. Twenty blinded cDNA samples were sent out on dry ice to each participating laboratory (total of 480 samples). Seventeen Ba/F3BCR-ABL cell lines harboring various BCR-ABL1 KD mutations were mixed with non-mutated Ba/F3BCR-ABL to produce dilutions ranging from 1% to 100% of mutant alleles. Three samples were non-mutated Ba/F3BCR-ABL only and were used as negative controls. The three non-mutated samples were identified cor-

rectly in 71/72 (99%) tests. For the 17 mutated samples, 240/408 (59%) samples were identified correctly. For further analysis, those samples with high (≥20%; n=11) and low (≤10%; n=6) levels of mutation were distinguished. For the high level samples 224/264 (85%) tests were reported correctly. Of the incorrect results, 28 were scored as negative and 12 were false positives. For the low level samples, 16/144 (11%) tests correctly identified the mutation. Most (127/144; 88%) were reported as undetectable and a false positive result was reported in one case. We conclude that Sanger sequencing is the most frequently applied technique for routine analysis of BCR-ABL1 KD mutations in CML in Europe. In general it reliably identifies mutations when the proportion of mutant alleles comprise 20% or more. Nevertheless, false negative and false positive results were reported in a substantial proportion of samples with ≥20% mutation level (40/264, 15%). For mutations that are present at 10% or less mutant alleles, routine methods mainly failed to identify mutations. This study indicates that further work is needed to establish reliable tests to identify BCR-ABL1 KD mutations in CML on TKI therapy.

Background. Nilotinib is a potent and selective BCR-ABL inhibitor. The phase 3 ENESTnd trial demonstrated superior efficacy of nilotinib vs imatinib, with higher and faster molecular responses. After a median of 24 months, the rates of progression to accelerated-blastic phase (ABP) were 0.7% and 1.1% with nilotinib 300mg and 400mg BID, respectively, significantly lower compared to imatinib (4.2%). Nilotinib has been approved for the frontline treatment of Ph+ CML. With imatinib 400mg (IRIS trial), the rate of any event and of progression to ABP were higher during the first 3 years. Consequently, a confirmation of the durability of responses to nilotinib beyond 3 years is extremely important. *Aims.* To evaluate the response and the outcome of patients treated for 3 years with nilotinib 400mg BID as frontline therapy. *Methods.* A multicentre phase 2 trial was conducted by the GIMEMA CML WP (ClinicalTrials.gov.NCT00481052). Minimum 36-month follow-up data for all patients will be presented. Definitions: Major Molecular Response (MMR): BCR-ABL/ABL ratio <0,1%IS; Complete Molecular Response (CMR): undetectable transcript levels with ≥10,000 ABL transcripts; failures: according to the revised ELN recommendations; events: failures and treatment discontinuation for any reason. All the analysis has been made according to the intention-to-treat principle. *Results.* 73 patients enrolled: median age 51 years; 45% low, 41% intermediate and 14% high Sokal risk. The cumulative incidence of CCgR by 12 months was 100%. CCgR at each milestone: 78%, 96%, 96%, 95%, 92% at 3, 6, 12, 18 and 24 months, respectively. The overall estimated probability of MMR was 97%, while the rates of MMR at 3, 6, 12, 18 and 24 months were 52%, 66%, 85%, 81% and 82%, respectively. The overall estimated probability of CMR was 79% at 30 months, while the rates of CMR at 12 and 24 months were 12% and 27%, respectively. No patient achieving a MMR progressed to ABP. Over 3 years of observation, only one patient progressed to ABP, at 6 months, and subsequently died (high Sokal risk, T315I mutation). AEs were mostly grade 1 or 2 and manageable with appropriate dose adaptations. During the first 12 months, the mean daily dose was 600-800mg in 74% of patients. Nilotinib last daily dose was as follows: 800mg in 46 (63%) patients, 600mg in 3 (4%) patients and 400mg in 18 (25%). Six permanent discontinuations: 2/6 deaths (1:ABP, 1: mental deterioration and starvation, unrelated to study drug). 3/6, recurrent episodes of amylase and/or lipase increase (no pancreatitis) and 1/6, atrial fibrillation (other epysodes before nilotinib): 2 patients are currently on imatinib second-line and 2 on dasatinib third-line. With a median follow-up of 39 months, the estimated probability of overall survival, progression-free survival and failure-free survival was 97%, the estimated probability of event-free survival was 91%. *Conclusions.* The rate of failures was very low during the first 3 years. Responses remain stable. The high rates of responses achieved during the first 12 months are being translated into optimal outcome for most of patients.

Background. For almost 10 years, the BCR-ABL inhibitor imatinib was the standard first-line treatment for CML-CP. Dasatinib, a more potent BCR-ABL inhibitor, is an approved therapy for patients with imatinib-resistant or imatinib-intolerant CML or newly diagnosed CML-CP. The recommended dosing regimen is dasatinib 100 mg once daily (QD), based on results from the CA180-034 dose-optimization study in patients with CML-CP and resistance or intolerance to prior imatinib therapy. The CA180-034 trial provides the longest follow-up of patients with CML-CP treated with a newer BCR-ABL inhibitor. *Aims.* To investigate the long-term efficacy and safety/tolerability of dasatinib 100 mg QD in patients with CML-CP and resistance or intolerance to prior imatinib therapy. *Methods.* Details of the study design and endpoints have been published (Shah *et al*. J Clin Oncol, 2008; 26: 3204-12). Patients (n=670) provided informed consent and were randomized using a 2x2 factorial design to one of four dasatinib dosing regimens: 100 mg QD, 50 mg twice daily (BID), 140 mg QD, or 70 mg BID. *Results.* After a minimum follow-up of 4 years, 251 (37%) patients remained on dasatinib treatment. More patients in the dasatinib 100 mg QD arm (45%) remained on treatment compared with the other three arms (33-37%). For patients randomized to dasatinib 100 mg QD (n=167), the 4-year rate of progression free survival (PFS) was 66%, overall survival (OS) was 82%, and 4% of patients had transformed to accelerated or blast phase while on treatment. In the dasatinib 100 mg QD arm, 4-year PFS rates were 93% and 87% in patients who had achieved a complete cytogenetic response (with or without a major molecular response) at 6 and 12 months, respectively. For dasatinib 100 mg QD, 4-year cumulative rates of nonhematologic adverse events (AEs) of any grade included headache (33%), diarrhea (28%), fatigue (25%), and pleural effusion (24%). Most nonhematologic AEs first occurred within 24 months of starting treatment. Grade 3/4 hematologic AEs usually first occurred within the first 12 months of treatment and included neutropenia (36%) and thrombocytopenia (24%). Dose modifications or changes to the dosing schedule were permitted for managing AEs. At the last available follow-up across the four treatment arms, 178 (71%) patients were on a QD dosing schedule, of which 107 (60%) patients were taking ≥100 mg QD. 44% of patients switched

from BID to QD dosing. Five-year follow-up will be presented. *Conclusions.* In the CA180-034 study, the majority of patients who remain on study are on a QD dosing schedule after 4 years of dasatinib treatment. Continued follow-up of patients with CML-CP receiving dasatinib following prior imatinib therapy further demonstrates the durable efficacy and acceptable tolerability and safety profile of long-term dasatinib 100 mg QD treatment.

Background. We have previously demonstrated excellent results from the TIDEL-II trial, using sequential therapy (imatinib [IM] then nilotinib [NIL]) in de novo chronic phase CML (CML-CP) patients. Here, we present longer term results (median follow-up of 24 months). *Aim.* To optimise molecular outcome and survival in treatment naïve CML-CP patients by selective dose escalation of imatinib and early switching to nilotinib based on imatinib blood level and early treatment response. *Method.* 105 patients entered the first cohort of this open label multicentre prospective trial, conducted through the ALLG. Therapy starts with IM at 600mg/d. Patients with IM trough level <1000ng/mL on day 22 and those failing to achieve molecular goals (BCR-ABL RQ-PCR of 10%, 1% and 0.1% IS at 3, 6 and 12 months respectively) had their IM dose escalated to 800mg/d. Patients were switched pre-emptively to nilotinib for a) failure to achieve molecular goals 3 months after dose escalation; b) loss of response or c) IM intolerance (Grade III/IV or persistent Grade II non-haematological toxicity). *Results.* The median follow-up is 24 months (range: 15-29). The confirmed MMR & CMR rate was 65% and 12% at 12 months respectively (ITT). Two patients progressed to AP/BC, both had kinase domain mutations (one T315I amongst others, the other H396P). There were two deaths, one from disease progression and one following a myocardial infarct. Seventeen patients withdrew from the study (16%). In total, six patients developed mutations (6%), two with T315I (5 patients on IM at the time mutations were detected). All three patients who experienced disease progression or T315I mutation had PCR >1% at 3 months. One, six and 11 patients dose escalated from IM600mg/d to IM800mg/d for suboptimal responses at 3, 6 and 12 months respectively; 5/7 patients who dose escalated at 3 and 6 months met their goals after 3 months, although two of these patients subsequently failed their 12 month time point. In all, 11/18 (61%) met treatment goals within 3 months of dose escalation. Thirty-seven patients failed to achieve confirmed MMR by 12 months, (5 had withdrawn before that time point). Thirty-two remained on trial with a median additional follow up of 12 months, 10 of whom achieved confirmed MMR (31%) subsequently. Of the 22 patients who did not achieve MMR, seven had withdrawn (1 BC transformation, 1 T315I mutation, 5 for other reasons); the remaining 15 all have RQ-PCR between 0.1% and 1%. *Conclusions.* Selective dose escalation of IM for patients who failed to achieve adequate drug levels or treatment milestones, with pre-emptive switching to nilotinib, is a successful therapeutic strategy in treatment naïve CML-CP patients, with excellent 12 month MMR rates. For those who failed to reach MMR at 12 months, even though a majority have sustained RQ-PCR between 0.1-1%, achieving MMR in the subsequent 12 months is difficult. The TIDEL-II approach has highlighted the problems in achieving a deeper response in this group of patients and the importance of early disease control.

Background. The achievement of a molecular response level of 10% BCR-ABL IS (International Scale) or deeper after three months of imatinib treatment has been shown to be associated with a favorable outcome in terms of failure free survival according to European LeukemiaNet (ELN) definitions and progression free survival (Hanfstein *et al.*, Blood. ASH Annual Meeting Abstracts;116:360). With the availability of potent second generation tyrosine kinase inhibitors (TKI) for upfront treatment of CML, the early identification of patients at risk under imatinib is crucial for clinical decision making and patients' outcome. According to ELN recommendations (Baccarani *et al.,* JCO 2009) patients are considered treatment failures if they lack a complete hematologic remission (CHR) after three months of imatinib treatment. If no cytogenetic response is observed after three months (No CgR, Ph+ metaphases >95%) patients are considered suboptimal responders. Molecular landmarks offering guidance in the interpretation of three month BCR-ABL levels are lacking up to now. *Aims.* We sought to compare the predictive significance of early molecular, cytogenetic and hematologic landmarks to evaluate new and established response criteria in a large data set. METHODS: In the randomized German CML Study IV n=949 patients were treated with an imatinib based therapy consisting of standard dose imatinib (400 mg/d, n=265), high dose imatinib (800 mg/d, n=260) and combinations of standard dose imatinib with low dose cytarabine (n=138) or interferon alpha (n=286). BCR-ABL IS was determined by quantitative RT-PCR. The type of BCR-ABL transcript (b2a2, n=424; b3a2, n=464; b2a2 and b3a2, n=148) was defined by multiplex PCR. Patients with atypical BCR-ABL transcripts were excluded from the analysis. Cytogenetic response was determined by G-banding metaphase analyses. Disease progression was defined by the incidence of accelerated phase, blastic phase or death on an intention-to-treat basis. In total 49 progressions were observed after a median of 22 months (range 1-70), 37 patients died. 441 patients were evaluable for hematologic, 423 for cytogenetic and 570 for molecular prediction after three months. Log-rank tests were used to analyze Kaplan-Meier plots. *Results.* Treatment failure after three months defined by the lack of CHR (n=94) did not prove to be predictive for disease progression (p>0.5). Suboptimal response defined as no CgR (n=23) showed a trend to significance (p=0.0558). In contrast, the 10% BCR-ABL IS landmark separated a high risk group (n=161) with a 17% risk for disease progression after 7 years from a low risk group with a 4% risk (Kaplan-Meier estimate, p=0.0156). The lack of a partial cytogenetic remission (Lack of PCgR, Ph+ metaphases >35%) is suited as a cutoff level as well (p=0.0367). *Conclusions.* After three months of imatinib treatment high risk patients can be identified by a BCR-ABL of 10% or more, whereas the lack of a complete hematologic remission is of no prognostic relevance.

Background. Nilotinib is approved for the treatment of patients with newly diagnosed Ph+ CML in chronic phase (CML-CP), and Ph+ CML-CP and accelerated phase (AP) resistant or intolerant to imatinib. *Aims.* To evaluate the population pharmacokinetics (PK) of nilotinib and its relationship with safety and efficacy in patients with imatinib-resistant or -intolerant CML. *Methods*. Population PK was assessed by non-linear mixed effects modeling, including 495 CML patients in CP (n = 235), AP (n = 135), or blast crisis (BC, n = 125) who had nilotinib PK data available. Exposure-efficacy analysis was performed in CML-CP patients, where the efficacy measures included complete cytogenetic response (CCyR) at 12 and 24 months, major molecular response (MMR) at 12 and 24 months, time to CCyR, time to MMR, and time to progression (TTP, defined as time from study entry to discontinuation due to disease progression or death). Baseline prognostic risk score (0 to 2) was investigated as a covariate in the exposure-efficacy analysis: 0 if hemoglobin > 120 g/L, basophils < 4%, and no insensitive mutation; 1 if missing 1 criterion; 2 if missing 2 or 3 criteria (Kantarjian *et al.*, ASH 2009). The relationship between nilotinib C_{min}, UGT genotype, and total bilirubin levels over 24 months was assessed in all patients. *Results.* Nilotinib dose intensity and PK were similar in all phases of CML. Baseline demographics did not significantly affect nilotinib PK. Patients with lower nilotinib dose and C_{min} (Q1) tended to have lower CCyR at 12 months, lower MMR at 12 and 24 months, longer time to CCyR and MMR, and shorter TTP than patients with higher nilotinib dose and C_{min} (Q2-Q4, Table).

Table 1.

	Nilotinib Response According to C_{min}* With Corresponding Dose†				P	
	Q1	Q2	Q3	Q4	Overall	Q1 vs Q2-Q4
Response **Median Dose, mg**						
CCyR at 12 mo, % Dose n = 89	39 469	68 717	68 780	59 800	.15‡	.053‡
CCyR at 24 mo, % Dose n = 56	71 426	83 735	71 799	75 800	.89‡	1.0‡
MMR at 12 mo, % Dose n = 92	28 486	37 721	56 798	39 800	.24‡	.22‡
MMR at 24 mo, % Dose n = 52	50 607	50 753	60 789	77 800	.47‡	.66‡
Time to CCyR, months Dose n = 163	26 429	20 754	18 798	19 800	.079§	.010§
Time to MMR, months Dose n = 158	31 413	24 697	23 799	24 800	.089§	.012§
TTP, months Dose n = 157	23 408	28 764	31 788	27 800	.037§	.009§

*Model-based daily C_{min} averaged to time of assessment.
†Total daily dose averaged to time of assessment.
‡Chi-square.
§Log-rank.

Baseline prognostic risk score also significantly affected TTP (27.9 and 18.7 months for scores 0-1 vs 2). Nilotinib C_{min} and UGT genotype were significantly associated with the occurrence of bilirubin abnormalities (both $P < .1$). The occurrence of grade 3/4 bilirubin abnormalities was 6%, 10%, 10%, and 14% in patients with nilotinib C_{min} in Q1 (< 429 ng/ml, n = 124), Q2 (429 - < 615 ng/mL, n = 123), Q3 (615 - < 850 ng/mL, n = 123), and Q4 (≥ 850 ng/mL, n = 123), respectively, and 6%, 12%, and 48% for patients with TA(6)/TA(6), TA(6)/TA(7), and TA(7)/TA(7) UGT genotypes, respectively. *Conclusions.* Patients with lower nilotinib dose, lower C_{min}, and higher baseline prognostic risk showed a higher risk of progression and a trend of poorer response. Nilotinib C_{min} was also significantly associated with total bilirubin elevation. However, the ultimate impact of such an association on patient outcomes might be limited, since bilirubin elevations were reversible and the observed hyperbilirubinemia was clinically manageable in patients receiving nilotinib therapy. The present analysis suggests that adherence to nilotinib dose in order to maintain sufficient C_{min} is important in maximizing the clinical efficacy of nilotinib.

LYMPHOCYTE MOBILIZATION AFTER DASATINIB INTAKE IS CORRELATED WITH PLASMATIC LEVEL OF DASATINIB AND MAY INFLUENCE MOLECULAR RESPONSE IN CP-CML PATIENTS RECEIVING DASATINIB AS SECOND LINE THERAPY

P Rousselot,[1] A Talbot,[1] S Mustjoki,[2] V Raggueneau,[1] J Bories,[3] M Noguera,[3] S Bouchet,[4] JM Cayuela,[3] M Spentchian,[1] M Molimard,[4] K Porkka,[2] P Rousselot[1]

[3]*Hôpital Saint-Louis, Paris, France*
[4]*CHU and University of Bordeaux, Bordeaux, France*

Background. Lymphocytes mobilization after dasatinib intake has been recently reported (S Mustjoki at al., ASH Annual Meeting Abstracts; 116: 1204). The clinical significance of this phenomenon is not clearly established. We aimed to describe lymphocytes mobilization in Chronic Phase Chronic Myelogenous Leukemia (CP-CML) patients receiving dasatinib as a second line therapy. *Patients and Methods.* CP-CML patients from two institutions and receiving dasatinib were prospectively proposed to perform a WBC and a platelets analysis before (H0) and 2 hours (H2) after dasatinib intake. Dasatinib plasmatic levels were determined on the same time points (Cmin and C2hours). BCR-ABL/ABL IS ratio was determined during the same period of time. *Results.* 40 CP-CML patients were analysed and we report here the data on the first 28 patients studied. Median age was 59.6y (27-90) and sex ratio (M/F) was 1.5. The Sokal risk group was low in 45%, intermediate in 25% and high in 30% of the patients. 48% of the patients received dasatinib after imatinib failure and 52% after imatinib intolerance. The median duration of dasatinib before the lymphocytes analysis was 29 months (0.4-68). The median lymphocytes count values at H0 was 1.27 G/L and 2.6 G/L at H2 (paired t-test $p<0.001$). Surprisingly, a transient decrease in the platelets counts was observed between H0 and H2 (195.5 G/L versus 167.5 G/L, paired t-test $p<0.001$). This was associated with a transient increased of the occlusion time. The magnitude of lymphocytes mobilization (H2/H0) was 1.82 fold in median (1-3.56). We next analyzed if the lymphocytes increment was linked to pharmacokinetic (PK) values. No correlation was found with the Cmin. However, a positive correlation was demonstrated with the 2 hours plasmatic level of dasatinib ($r^2=0.5736$, $p=0.0011$). We then compared the magnitude of lymphocytes mobilization in patients with or without major molecular response (MMR). A significant association was found between high levels of mobilization and MMR ($p=0.047$). A phenotypic analysis was conducted in 7 patients. Despite a pan lymphocytes mobilization, a preferential increased in the CD3-/CD16/56+ and in the CD3-/CD57+ lymphocytes populations was observed (1.83 and 2.94 fold in median respectively). Of note, large granular lymphocytes was reported in only 2 patients and no patient had an absolute lymphocytosis at H0, suggesting that lymphocytes mobilization could be an independent phenomenon. *Conclusion.* We have demonstrated that lymphocyte mobilization could be observed in virtually all patients receiving dasatinib in the absence of an absolute lymphocytosis. We also confirm that lymphocytes mobilization is driven by dasatinib PK and report for the first time a link between lymphocytes mobilization and MMR. More patients will be presented and we are currently analysing lymphocytes mobilization in our first line patients included in the OPTIM dasatinib French trial.

0141

MOLECULAR RESPONSE <1% BCR-ABL (IS) AT 12 MONTHS IS ASSOCIATED WITH IMPROVED OVERALL AND PROGRESSION-FREE SURVIVAL AND REPRESENTS A SUPERIOR PREDICTOR THAN COMPLETE CYTOGENETIC REMISSION

M Müller,[1] A Hochhaus,[2] M Lauseker,[3] S Jung-Munkwitz,[1] M Pfirrmann,[3] A Leitner,[1] S Krause,[4] N Pletsch,[1] B Hanfstein,[1] P Erben,[1] A Gratwohl,[5] J Hasford,[3] R Hehlmann,[1] S Saussele[1]

[1]*Medizinische Fakultät Mannheim, Universität Heidelberg, Mannheim, Germany*
[2]*Universitätsklinikum, Klinik für Innere Medizin II, Jena, Germany*
[3]*Institut für Medizinische Informationsverarbeitung (IBE), LMU, Munich, Germany*
[4]*Universitätsklinikum, Medizinische Klinik 5, Erlangen, Germany*
[5]*Universitätsspital Basel, Basel, Switzerland*

Background. The prognostic relevance of major molecular remission (MMR, <=0.1% BCR-ABL according International Scale, IS) for survival on imatinib-based treatment has remained uncertain. Gold standard is complete cytogenetic remission in spite of its limited sensitivity, the need for bone marrow. Standardization of PCR, definition of a uniform reporting system, and harmonization of laboratories using conversion factors to account for differences of methods and reagents have changed the situation in Europe. *Aims.* To determine the degree of molecular response after 12 months of imatinib-based treatment and its impact on overall and progression-free (PFS) survival. *Methods.* 848 out of 1014 patients within the CML-Study IV (randomized comparison of imatinib 800 mg vs 400 mg vs 400 mg + IFN) were eligible for evaluation since 12 month molecular data was available. Patients (61% male) have been recruited between July 2002 and April 2009, the median age was 54 years (range 16-84), and the median observation time was 40 months (minimum 12). Landmark analyses at 12 months and log-rank tests were performed. *Results.* 341 patients (40%) achieved a BCR-ABL expression <=0.1% (MMR), 240 patients (28%) between 0.1% and 1% and 267 patients (31%) >1% by 12 months. Independent of treatment approach, the groups of patients achieving MMR and 0.1%-<1% at 12 months showed significantly higher PFS (97% vs 95% vs 87% at 5 years, p=0.0023) and better overall survival (97% vs 96% vs 88% at 5 years, p=0.0011) compared to the group with >1% BCR-ABL by 12 months. Applying a landmark analysis at 12 months depending on the achievement of complete cytogenetic remission (CCyR) revealed less pronounced differences in overall survival (96% vs 91% at 5 years, p=0.015) than using the molecular predictor. *Conclusions.* Faster and deeper response to imatinib-based treatment by 12 months revealed to be associated with improved PFS and overall survival. The critical cutoff level seems to be 1% BCR-ABL IS which is supposed to closely correlate with complete cytogenetic remission. Furthermore, RQ-PCR from peripheral blood is more precise and better tolerable than cytogenetics from bone marrow.

0142

DETECTION AND PROLIFERATION KINETICS OF SUBCLONES CARRYING POINT MUTATIONS IN THE BCR-ABL1 TYROSINE KINASE DOMAIN IN CML PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS

T Lion,[1] S Preuner,[1] R Kastner,[1] G Mitterbauer,[2] C Mannhalter,[2] S Herndlhofer,[3] W Sperr,[3] P Valent,[3] T Lion[1]

[1]*Children's Cancer Research Institute, Vienna, Austria*
[2]*KIMCL, Vienna, Austria*
[3]*MUV-Div Hematology, Vienna, Austria*

Background. Point mutations in the BCR-ABL1 tyrosine kinase domain (TKD) are an important mechanism of resistance to treatment with tyrosine kinase inhibitors (TKIs). However, detection of mutant subclones may not always permit reliable assessment of imminent resistant disease because various mutations may be biologically neutral, and even subclones carrying mutations known to confer TKI resistance can disappear spontaneously. *Aims.* We have addressed the question whether quantitative monitoring of mutant subclones during treatment would facilitate timely identification and surveillance of resistant disease. *Methods.* A ligase-dependent (LD) PCR technique permitting sensitive detection and quantitative monitoring of point-mutated subclones was employed (Preuner *et al*. Leukemia 2008). The LD-PCR approach displays a detection limit ≥1%, and permits reproducible assessment of changes in the size of mutant subclones exceeding ±5%. We have investigated prospectively collected, serial PB specimens derived from CML patients displaying a variety of mutations including M244V, L248V, G250E, E255K, T315I, F317L-A/G, M351T, and F359V, and monitored the proliferation kinetics during the course of treatment. *Results.* Different mutant subclones appeared sequentially in individual patients upon changes of treatment. The appearance of new mutant subclones at a level detectable by LD-PCR has occasionally occurred within a few weeks after initiation of treatment with a TKI, but the time span until mutant leukemic cells became the dominant BCR-ABL1 positive clone was variable, ranging between 1-18 months after first detection. Expanding mutant clones could be documented even in the presence of decreasing BCR-ABL1 transcripts, and occasionally preceded the subsequent rise in BCR-ABL1 transcript levels by several weeks. Therapy-independent disappearance of a subclone carrying the T315I mutation, and the response of other mutant subclones to treatment could be documented by the quantitative LD-PCR approach. *Conclusions.* Our observations of multiple expanding mutant subclones in individual patients support the notion of non-linear, branching clonal architecture. The biological behavior of mutant subclones *in vivo* does not necessarily reflect the observations of sensitivity and resistance to TKIs made *in vitro*. Point mutations in the BCR-ABL1 TKD with expected sensitivity to certain TKIs may be markers of subclones displaying independent mechanisms of resistance. Quantitative monitoring of mutant subclones during treatment with TKIs provides information on their actual responsiveness to therapy and the imminent onset of resistant disease. Judicious implementation of quantitative diagnostic approaches such as the LD-PCR technique in the surveillance of CML patients can improve our current options for timely treatment decisions, and may help optimizing disease management in patients displaying point mutations in the BCR-ABL1 TKD or other sites of potential relevance.

Background. Bosutinib is an orally active, dual Src/Abl tyrosine kinase inhibitor (TKI) with minimal inhibitory activity against PDGFR or c-kit. *Aim.* This open-label, phase 1/2 trial evaluated the safety and efficacy of bosutinib as third-line therapy in patients with Philadelphia chromosome-positive chronic phase chronic myeloid leukemia (CP CML). *Methods.* After informed consent was obtained, adults (aged ≥18 years) with prior imatinib failure who were dasatinib-resistant (n = 37), dasatinib-intolerant (n = 50), or nilotinib-resistant (n = 27) received daily oral bosutinib starting from 400 to 600 mg/day. *Results.* Of the 114 third-line CP CML patients enrolled, 45% were male, the median age was 56 years (range, 20-79 years), and the median time from CML diagnosis was 6.3 years (range, 0.6-18.3 years). Median follow-up was 26.4 months (range, 0.3-54.0 months), and the median bosutinib dose was 476 mg/day (range, 185-563 mg/day). Non-hematologic treatment-emergent adverse events (TEAEs) seen in ≥20% of patients (all grades/grade ≥3) included diarrhea (83%/9%), nausea (46%/1%), vomiting (40%/1%), rash (27%/4%), headache (25%3%), fatigue (21%/1%), and abdominal pain (20%/1%). The incidence of TEAEs was similar for dasatinib-resistant, dasatinib-intolerant, and nilotinib-resistant patients. Gastrointestinal events were predominantly grade

1/2, early in onset, and usually subsided within a month. Two dasatinib-intolerant patients had grade 3 pleural effusions; both patients had these events on prior dasatinib and were grade 1 on study entry. No grade 3/4 QTc prolongation was observed. Grade ≥3 laboratory abnormalities (≥10% of patients) included thrombocytopenia (26%), neutropenia (18%), and hypermagnesemia (12%). Of 82 (73%) evaluable patients achieving complete hematologic response (CHR; Table), 34 (41%) retained their response and are still on therapy. Of 31 (32%) evaluable patients achieving major cytogenetic response (MCyR), 12 (39%) retained their response and are still on therapy; 21 (22%) patients achieved complete response (CCyR). Major molecular response (MMR) was achieved in 21 (22%) of evaluable patients. MCyR and CHR were observed across 11 different Bcr-Abl kinase domain mutations, but not T315I. *Summary/Conclusions.* Third-line bosutinib therapy demonstrated acceptable toxicity and promising activity, emphasizing the therapeutic potential of bosutinib in CP CML patients with resistance or intolerance to other second-generation TKIs.

Table 1.

n/n evaluable (%)	Imatinib failure+ dasatinib resistance	Imatinib failure+ dasatinib intolerance	Imatinib failure+ nilotinib resistance
CHR	23/37 (62)	39/49 (80)	20/26 (77)
MCyR	11/35 (31)	13/37 (35)	7/24 (29)
CCyR	4/35 (11)	12/37 (32)	5/24 (21)
MMR	3/32 (9)	17/46 (37)	1/19 (5)

Background. The median age of Chronic Myeloid Leukemia (CML) patients is around 60 years and age is still considered an important prognostic factor, included in Sokal and EURO risk scores. With IM, this negative impact of age has been partially reappraised, at least in late chronic phase (CP). However, only limited data about the long term outcome are available for elderly patients treated in early CP; moreover, the allocation of elderly patients to IM, in particular within clinical trials, is still an important issue. *Aim*. To evaluate the long term outcome of elderly patients treated frontline with IM. *Methods*. We analyzed the relationship between age and outcome in 559 early CP CML patients, enrolled in 3 prospective clinical trials of GIMEMA CML-WP (Clin. Trials Gov. NCT00514488 and NCT00510926), treated with IM. The median follow-up was 60 months (range 1-83 months). Older patients (≥ 65 years old) were 115 (21%). Events were defined as: treatment failure or permanent discontinuation of IM for any reason; treatment failures were defined according to the updated European LeukemiaNet (ELN) recommendations; progression to accelerated/blast phase was defined according to ELN criteria. *Results*. The hematologic, cytogenetic, and molecular response rates observed in the 2 age groups were similar. The cumulative incidence of complete cytogenetic response (CCyR) and major molecular response (MMR) were 87% (100/115) and 85% (98/115) vs. 88% (391/444) and 85% (377/444), in older and younger patients, respectively. CCyR at 6, 12, and 18 months were 79/115 (69%), 90/115 (78%), and 85/115 (74%) in older patients, respectively, and 299/444 (67%), 343/444 (77%), and 346/444 (78%) in younger ones, respectively; MMR at 6, 12, and 18 months were 54/115 (47%), 67/115 (58%), and 65/115 (57%) in older patients, respectively, and 215/444 (48%), 262/444 (59%), and 278/444 (63%) in younger ones, respectively; all the differences were not significant. Regarding the long term outcome, the estimated 6-year EFS (55% vs. 67%, p = 0.006), FFS (62% vs. 78%, p=0.009), PFS (75% vs. 90%, p=0.0001) and OS (78% vs. 92%, p<0.0001) were all significantly worse in the older age group. Importantly, the analysis of the causes of death showed that in older patients more deaths in complete hematologic response (CHR) (unrelated to CML progression) have been recorded: 17/115 (15%) and 15/444 (3%) for older and younger patients, respectively (p<0.0001). On the other hand, deaths due to progression of CML were 6/115 (5%) and 15/444 (3%), for older and younger patients, respectively (p = 0.4). The analysis of the estimated 6-year EFS, FFS, PFS, and OS, censoring deaths unrelated to CML progression (all in CHR), showed that there was no longer any significant difference between the 2 age groups. *Conclusion*. These data show that response to IM was not affected by age and that the mortality rate linked to CML is similar in both age groups. Therefore older age must not be a limitation for treating patients with IM and for enrolling them in clinical trials.

0145

NILOTINIB IS ASSOCIATED WITH FEWER TREATMENT FAILURES AND SUBOPTIMAL RESPONSES VS IMATINIB IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): RESULTS FROM ENESTND

G Saglio,[1] A Hochhaus,[2] F Guilhot,[3] N Gattermann,[4] M Wang,[5] C De Souza,[6] R Blakesley,[7] N Gallagher,[8] A Hoenekopp,[8] H Kantarjian,[9] R Larson,[10] T Hughes[11]

Background. The ENESTnd trial established the superiority of the tyrosine kinase inhibitor (TKI) nilotinib over imatinib in newly diagnosed patients with Philadelphia chromosome-positive (Ph+) CML-CP. *Aims.* We sought to investigate the frequency of suboptimal response (SoR) and treatment failure (TF) on ENESTnd with 24 months' follow-up. Also, the outcome of the imatinib-treated patients after dose escalation following SoR/TF is presented. *Methods.* 846 patients with newly-diagnosed Ph+ CML-CP were randomized to nilotinib 300 mg twice daily (BID) (n = 282), nilotinib 400 mg BID (n = 281), or imatinib 400 mg once daily (QD) (n = 283). An escalation in dose to 400 mg BID was permitted in patients on the imatinib arm who had a SoR or TF, using the European LeukemiaNet (ELN) criteria originally defined for patients treated with imatinib 400 mg QD. Dose escalation of nilotinib or crossover was not permitted. *Results.* Patients on both nilotinib doses had lower rates of SoR and TF by each ELN milestone, and higher rates of optimal response (Table). The rates of SoR observed on all arms at 18 months were primarily due to lack of major molecular response (MMR) at 18 months. Among patients randomized to imatinib, 82 (29%) patients received dose escala-

tion to 400 mg BID for SoR or TF after a median of 14 months of treatment with imatinib 400 mg QD. Median time on treatment after dose escalation among these patients was 9 months (range 0.2 - 28.2). Subsequent to dose escalation, 21 (26%) patients achieved MMR; 14 (17%) patients achieved CCyR without MMR, and 47 (57%) patients had no improvement in responses after dose escalation. After dose escalation, 36 (44%) patients had dose reductions / interruptions. A total of 37 (45%) patients discontinued treatment subsequent to imatinib dose escalation: 23 (28%) due to SoR or TF, 6 (7%) due to intolerance, 3 (4%) due to disease progression, and 5 (6%) due to other reasons. *Conclusions.* Frontline therapy with nilotinib offers improvement over the standard of care imatinib 400 mg QD in terms of less frequent SoR and TF. Favorable long-term outcomes are unlikely in patients with TF, and may be less likely in patients with SoR than in optimal responders. Dose escalation was not an effective strategy to overcome SoR/TF on imatinib, as approximately three quarters of these patients failed to achieve MMR after dose escalation, and nearly half had dose reductions/interruptions and discontinued treatment. Using 2009 ELN criteria, nilotinib frontline therapy (especially 300 mg BID) appears to be more effective than imatinib frontline therapy, even with imatinib optimization by dose escalation.

Table 1.

Response, %	Nilotinib 300 mg BID (n = 282)	Nilotinib 400 mg BID (n = 281)	Imatinib 400 mg QD (n = 283)
By 6 months			
Optimal	71	68	62

Background. Bosutinib is an orally active, dual Src/Abl tyrosine kinase inhibitor (TKI) with minimal inhibitory activity against PDGFR or c-kit. *Aims.* This open-label, phase 1/2 study evaluated the efficacy and safety of bosutinib as second-line therapy in patients with Philadelphia chromosome-positive CP CML. *Methods.* After collection of informed consent, adults (aged ≥18 years) with resistance (n = 200) or intolerance (n = 88) to imatinib received daily oral bosutinib starting from 400 to 600 mg/day. *Results.* Of 288 CP patients enrolled, 53% were male, median age was 53 years (range, 18-91 years), and median time from CML diagnosis was 3.6 years (range, 0.1-15.1 years). Median follow-up was 2.5 years (range, 0.1-5.0 years), with 49% of imatinib-resistant and 47% of imatinib-intolerant patients still receiving treatment. Median bosutinib dose was 485 mg/day (range, 128-600 mg/day). Of 172 (86%) imatinib-resistant and 75 (85%) imatinib-intolerant patients achieving complete hematologic response (CHR), respectively, 69% and 81% retained their response as of the data cutoff. In the evaluable population, of 101 (54%) imatinib-resistant and 39 (49%) imatinib-intolerant patients achieving major cytogenetic response (MCyR), respectively, 68% and 90% retained their response as of the data cutoff. Of patients who had not previously achieved MCyR on imatinib, 45% and 28% achieved MCyR and CCyR, respectively, on bosutinib (Table). Complete cytogenetic response (CCyR) was achieved by 42% and 43% of imatinib-resistant and imatinib-intolerant patients, respectively. Among patients who achieved CCyR, major molecular and complete molecular (undetectable Bcr-Abl transcripts) responses, respectively, were observed in 69% and 52% of evaluable imatinib-resistant and 73% and 68% of evaluable imatinib-intolerant patients. MCyR and CHR were observed across 25 different Bcr-Abl kinase domain mutations, but not T315I. Grade ≥3 non-hematologic treatment-emergent adverse events (TEAEs) seen in ≥2% of patients were diarrhea (9%), rash (9%), and vomiting (3%). Diarrhea was predominantly grade 1/2, early in onset, and usually subsided within a month. Grade 3/4 lab abnormalities (≥10%) included thrombocytopenia (24%), neutropenia (17%), anemia (13%), hypermagnesemia (11%), and alanine transaminase elevation (10%). Overall, dose reductions and interruptions were required by 47% and 67% of patients, respectively; 12% of patients' dose escalated to bosutinib 600 mg/day. TEAEs led to treatment discontinuation in 17% of imatinib-resistant and 33% of imatinib-intolerant patients. Limited cross-intolerance between bosutinib and imatinib was observed: 8% of patients with imatinib intolerance re-experienced the same grade ≥3 AE on bosutinib and 11% discontinued bosutinib due to the same AE. Four of 32 patients with imatinib intolerance related to myelosuppression experienced grade ≥3 myelosuppression on bosutinib, and 3 of 10 patients with imatinib intolerance related to rash experienced a grade ≥3 rash on bosutinib; no patient with imatinib intolerance related to gastrointestinal events, edema, fatigue, hepatobiliary disorders, or muscle spasms experienced these grade ≥3 events on bosutinib. *Summary/Conclusions.* Bosutinib demonstrated promising activity as second-line therapy, with responses observed irrespective of prior response to imatinib. Bosutinib was also associated with an acceptable toxicity profile, with limited cross-intolerance. These results emphasize the therapeutic potential of bosutinib in patients with CP CML following imatinib failure.

Table 1.

n/n evaluable (%)	Imatinib-resistant (n = 200)	Imatinib-intolerant (n = 88)	Total (N = 288)
Hematologic response			
CHR	172/199 (86)	75/88 (85)	247/287 (86)
CHR in patients without baseline CHR	76/100 (76)	34/41 (83)	110/141 (78)
Cytogenetic response			
MCyR	101/156 (54)	39/80 (49)	140/266 (53)
CCyR	79/186 (42)	34/80 (43)	113/266 (42)
MCyR by best prior cytogenetic response to imatinib*			
MCyR on imatinib	64/80 (80)	28/39 (72)	92/119 (77)
No MCyR on imatinib	45/106 (46)	9/24 (38)	58/130 (45)
CCyR by best prior cytogenetic response to imatinib*			
MCyR on imatinib	59/80 (74)	27/39 (69)	86/119 (72)
No MCyR on imatinib	30/106 (28)	6/24 (25)	36/130 (28)

*Analysis is based on all treated patients with available data for best cytogenetic response to imatinib.

[5]*Universitaetsmedizin, Mannheim, Germany*
[6]*Institut f. Medizinische Informationsverarbeitung (IBE), LMU, Munich, Germany*

Background. The prognostic impact of cytogenetic findings in addition to the translocation t(9;22)(q34;q11) or the variant translocation

t(v;22) at diagnosis of chronic myeloid leukemia (CML) is conflicting. *Patients and Methods.* We used baseline and outcome data of 1030 patients (pts) (608 male, 422 female, median age 53, range 16-88) with chronic phase CML randomized to the German CML-Study IV (imatinib [IM] 800 mg [n=265] vs IM 400 mg [n=254] vs IM 400 mg + IFN [n=281] vs IM 400 mg after IFN failure [n=108] vs IM 400 mg + AraC [n=122]). We sought to investigate the impact of additional clonal cytogenetic findings at diagnosis on time to complete cytogenetic remission (CCR), as an accepted prognostic marker. Cytogenetic analysis was performed after 24- and/or 48 h culture on G-banded metaphases. If appropriate, fluorescent-in-situ-hybridization (FISH) was used in addition. *Results.* In total, at diagnosis 912/1030 pts (89%) had the translocation t(9;22)(q34;q11), 60/1030 pts (5.9%) showed a variant translocation t(v;22). 58/1030 (5.6%) had additional clonal cytogenetic findings [56 pts in addition to the translocation t(9;22) and 2 pts in addition to a variant translocation t(v;22)]. Out of these 30/1030 pts (2.9%) lacked the Y chromosome (-Y) and 28/1030 pts (2.7%) had additional numerical or structural aberrations except -Y. Median age, sex and treatment were similarly distributed except for -Y male pts who were older. For pts with the translocation t(9;22), with variant translocations t(v;22) and with the translocation t(9;22)(q34;q11)/t(v;22) with additional clonal chromosomal changes other than -Y, median time (years) to CCR was 0.98, 0.84 and 1.92. When comparing the groups "translocation t(9;22)"and "t(9;22)/t(v;22) with additional chromosomal findings other than -Y"and when comparing the groups "variant translocations t(v;22)"and "translocation t(9;22)/t(v;22) with additional chromosomal findings other than -Y"over the entire period of time, time to CCR was significantly shorter in the group "translocation t(9;22)"respectively "variant translocation t(v;22)"($p < 0.001$). No difference regarding time to CCR was seen when comparing the groups "translocation t(9;22)"and "t(v;22)"or the groups "translocation t(9;22)"and "-Y". *Conclusion.* We conclude that additional clonal cytogenetic findings at diagnosis have an impact on time to CCR and possibly on prognosis.

[8]*Ural State Medical Academy, Ekaterinburg, Russian Federation*

Background. Approximately 1% of the CML patients do not have t(9;22)(q34;q11) detectable by conventional cytogenetics, but carry *BCR-ABL* fusion gene revealed by fluorescence in situ hybridization (FISH) and/or reverse-transcriptase PCR (RT-PCR). Imatinib efficacy in this group of patients remains unclear. *Aim.* To define FISH patterns and imatinib treatment efficacy in Ph-negative BCR-ABL-positive CML patients. *Methods.* Initial diagnostics including chromosome banding analysis (CBA) and RT-PCR was done in 531 primary CML patients. CBA was performed after 24 hours culture. G-banding was performed by a trypsin-Giemsa method. Karyotypes were described according to ISCN (2005). At least 20 metaphases for each sample were analyzed. In Ph-negative patients who had *BCR-ABL* transcript FISH assay using Dual-Colour Dual-Fusion *BCR-ABL* Translocation Probe (Abbott, USA) was applied on at least 200 interphase nuclei (I-FISH) and on all available metaphases. CBA and FISH were performed at the time of diagnostics and every 6 months of imatinib treatment. Quantitative measurement of *BCR-ABL/ABL* transcripts ratio by real-time quantitative PCR (RQ-PCR) was done every 3-6 months. Detection of point mutations in the BCR-ABL tyrosine kinase domain was performed by direct sequencing of RT-PCR products. Compete cytogenetics response (CCgR) was assumed as ≤ 1% of FISH-positive nuclei (N. Testoni, Blood, 2009) Event-free survival (EFS) was calculated in respect of intention-to-treat and defined as the time from imatinib beginning until any of the following events occurred: any sign of treatment failure (according to the European LeukemiaNet criteria (M. Baccarani *et al.*, JCO, 2009)), progression to AP/BC or death of any reason. *Results.* Normal karyotype was detected in 12 newly diagnosed CML patients (2.3%). However, all of them harboured *BCR-ABL* fusion gene revealed by FISH and RT-PCR. Ph-negative group included 2 males and 10 females with median age of 51 years and median follow-up of 39-months. 4 patients had e13a2 transcript variant, 8 patients - e14a2. Three different FISH patterns were indentified (table).

Table 1.

D-FISH pattern	Chromosome localization of signals			Number of cases	Interpretation
	Fusion	Red	Green		
2R1G1F	1F(22)	1R (9) 1R (9)	1G (22)	9	Cryptic insertion of *ABL* into *BCR* gene on chromosome 22
1R2G1F	1F (9)	1R (9)	1G (22) 1G (22)	2	Cryptic insertion of *BCR* into *ABL* gene on chromosome 9
1R1G1F	1F(22)	1R (9)	1G (22)	1	Loss of *ASS*, 5'*ABL* and 3'*BCR* genes on chromosome 9

7 of 12 patients received imatinib treatment. 6 of 7 patients achieved complete hematological response at 3 months. Median number of *BCR-ABL*-positive nuclei at 12 months was 22% (range 1-50%), at 18 months - 40% (range 0-92%). Only 1 patient had CCgR (assessed by I-FISH) by 18 months. One patient progressed to AP and died subsequently. None of patients had BCR-ABL mutations. EFS in Ph-negative CML patients treated by imatinib was significantly lower than in 244 Ph-positive ones, for whom long-term follow-up data was available: 0.14±0.13 vs 0.62±0.03 (p=0.007), while overall survival was comparable in both groups: 0.83±0.15 vs 0.85±0.02% (p=0.88). *Conclusions.* Our data suggests that main mechanisms of fusion gene formation in Ph-negative CML are cryptic insertions of *ABL* into *BCR*, or vice versa. In our series treatment outcome in this group was significantly worse in comparison with Ph-positive CML patients. Resistance in observed group seems to have BCR-ABL-independent mechanisms, because of lack of BCR-ABL mutations, duplication or amplification. Absence of response criteria for data obtained by I-FISH assay hampered to refer such patients to treatment failure earlier than 18 months.

0149

CHRONIC PHASE CML PATIENTS ON TYROSINE KINASE INHIBITORS HAVE A POLYFUNCTIONAL CELLULAR IMMUNE RESPONSE AGAINST INFLUENZA BUT AN IMPAIRED IGM HUMORAL RESPONSE AGAINST PNEUMOCOCCUS AFTER VACCINATION

H de Lavallade,[1] M Hart,[2] T Sekine,[2] I Gabriel,[2] W Kelleher,[2] A Alsuliman,[2] A Khoder,[2] K Stringaris,[2] J Khorashad,[2] D Milojkovic,[2] L Foroni,[2] A Chaidos,[2] A Ibrahim,[2] J Goldman,[2] J Apperley,[2] D Marin,[2] K Rezvani[2]

[1]*Imperial College London, London, United Kingdom*
[2]*Imperial College, London, United Kingdom*

The tyrosine kinase inhibitors (TKI) imatinib, nilotinib and dasatinib are remarkably effective as single-agent treatments for chronic myeloid leukaemia (CML) in chronic phase (CP). However little is known of their potential impact on the immune system; this is of particular interest in terms of the long-term effects of TKI on tumour immune surveillance and susceptibility to infections. To date there are no human *in vivo* studies to assess how these molecular-targeted drugs affect immune function in patients and data from *in vitro* and animal studies with imatinib have been contradictory, ranging from impaired antigen-specific T-cell response to enhanced stimulation of tolerant T cells. Few data are available to assess potential immunomodulatory effects of the second-generation TKIs nilotinib and dasatinib. The aim of this study was to prospectively analyze humoral and cellular immune responses to vaccination against influenza virus (Flu) and Pneumococcus in CP-CML patients treated with imatinib, dasatinib or nilotinib compared to healthy controls. Fifty CP-CML patients on standard dose TKIs (IM, n=22; dasatinib, n=15; nilotinib, n=13) and 15 healthy controls were vaccinated against Flu (Influenza vaccine Ph. Eur. 2008/2009, CSL biotherapies) and pneumococcus (Pneumovax II, Sanofi Pasteur MSD). Samples were collected before and 1 and 3 months post-vaccination. We analyzed the immunological T-cell response to influenza virus both quantitatively and qualitatively using flow cytometry for intracellular TNF-α, IFN-γ, IL-2 and the cytotoxicity marker CD107a. Titers of IgM and IgG anti-pneumococcal were determined using ELISA, and the proportion of B-

cell subsets (IgM memory and switched memory B-cells) were measured using flow cytometry. CD8 and CD4 T-cell responses to Flu vaccination were not significantly different between patients and controls: after vaccination, T cell responses against Flu were detected in 18/35 patients on TKI and 9/11 healthy control. Polyfunctional T cells were detected in 6/10 evaluable patients and 4/8 healthy controls. In contrast a significantly lower proportion of patients mounted an anti-pneumococcal IgM response at 4 weeks post vaccination (defined as IgM serum titer >80 U/ml and 4-fold increase in titer from baseline) compared to healthy controls (20/45 versus 11/12 respectively, p=0.004). The median frequency of IgM memory B cells in controls was 13.9% (range 7.06 to 18.45); the frequency of IgM memory B cells in CML patients on TKI was below this range in 17 of 36 (Fisher exact test, p=0.004). Overall, T and B cell responses to vaccination were not significantly different when comparing patients on imatinib, dasatinib and nilotinib although the relatively small number of patients in each group precludes any definitive conclusions. These data have significant implications for the use of TKI together with immunotherapy, and in patients receiving vaccination against infectious agents. Contrary to some *in vitro* studies, TKI do not appear to impair the cellular immune response to viruses *in vivo*. However we found that compared to controls, CML patients on TKI have an impaired IgM antibody response to pneumococcus, associated with a selective reduction in the IgM memory B cell subset. We are currently investigating the mechanism underlying this observation.

0150

RECOMMENDATIONS TO MEET THE NEW STATISTICAL CHALLENGES ARISING FROM EFFICACY ENDPOINTS BEYOND OVERALL SURVIVAL IN CLINICAL TRIALS ON CHRONIC MYELOID LEUKEMIA

M Pfirrmann,[1] A Hochhaus,[2] M Lauseker,[1] S Saussele,[3] R Hehlmann,[3] J Hasford[1]

[1]*Ludwig Maximilian University, Munich, Germany*
[2]*Department of Hematology / Oncology, University Hospital Jena, Jena, Germany*
[3]*III. Medical Clinic, Medical Faculty Mannheim of the University of Heidelberg, Mannheim, Germany*

Background. Overall survival (OS) used to be the primary endpoint for efficacy evaluation of treatments in chronic myeloid leukemia (CML). However, due to the success of tyrosine kinase inhibitors, the mortality is low and possible significant differences between treatments will not be observed for a long time. There is the need to arrive at insights on therapeutic improvement earlier on. Thus, remission parameters regarded as surrogate markers for OS are considered, either as new primary endpoints by themselves or as part of a composite endpoint. *Aims.* To master the new statistical challenges, we suggest recommendations for sound statistical analyses of efficacy parameters in CML. *Methods.* For "time-to-first-remission"endpoints (first complete cytogenetic remission, first major (or complete) molecular remission), Kaplan-Meier analysis may not to be applied. Methodological issues also with regard to composite endpoints are discussed. *Results.* A prerequisite for Kaplan-Meier analysis is "non-informative censoring", i.e. the event of interest might be observed in the future. With the competing event "death before a possible observation of a first remission"this prerequisite is no longer met, instead the probability of a later first remission is reduced to zero. Erroneous censoring of competing risks leads to systematically overestimated probabilities of observing the event of interest. The appropriate approach to estimate these probabilities is the calculation of the cumulative incidence function (CIF). However, the date of first remission is hardly known exactly and its detection depends on protocol compliance. Differences in evaluation frequencies may lead to a seriously biased effect size between two randomized treatments. A composite endpoint "failure-free survival (FFS)"might be defined as survival until one of the following events is observed: Failure of achievement or loss of a certain remission status, severe toxicity, disease progression, or death. The last two events are usually summarized as progression-free (PFS), the last three events as event-free survival (EFS). With FFS, missing-value problems regarding the events linked to insufficient remission are likely and the wide range of failure causes implies difficulties with respect to interpretation. In contrast to severe toxicity, progression, or death, remission failures alone are much less critical events. *Conclusions.* For above reasons, we do not recommend to use time to (a certain level of) remission (TTR) or complex composite endpoints as the primary endpoint of a clinical trial. Despite delayed discovery times, TTR analysis remains a useful tool to support judgment on the velocity of drug response and on the time until a certain remission should be waited for. If established as a surrogate marker for OS, the remission status at such a time could be chosen as primary endpoint. In accordance with accuracy and ease of interpretation, the order of preference for time-to-event endpoints is "overall survival", progression-free"and "event-free survival". Still, the chance to identify essential treatment differences earlier due to a higher number of failures could speak for EFS where the severity of possible events is reasonably comparable. If regarded as (secondary) endpoints, TTR parameters and composite endpoints demand analysis of all (competing) events and caution with outcome interpretation.

0151

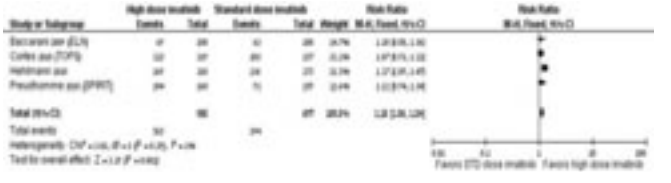
THE EFFICACY AND SAFETY OF HIGHER DOSES OF IMATINIB FOR THE TREATMENT OF NEWLY DIAGNOSED, PREVIOUSLY UNTREATED CHRONIC MYELOID LEUKEMIA PATIENTS IN CHRONIC PHASE - SYSTEMATIC REVIEW AND META-ANALYSIS

A Gafter-Gvili,[1] A Leader,[2] R Gurion,[1] L Vidal,[1] R Ram,[1] A Shacham-Abulafia,[1] I Ben-Bassat,[1] M Lishner,[2] O Shpilberg,[1] P Raanani[1]

[1]*Rabin Medical Center, Petah-Tikva, Israel*
[2]*Meir Medical Center, Kfar-Saba, Israel*

Background. Imatinib at a dose of 400mg daily is considered frontline treatment in chronic phase (CP) chronic myeloid leukemia (CML). Doses of 600mg or 800mg daily have proven efficacy in the accelerated phase or in the event of unsatisfactory response to standard dose imatinib. Recent randomized controlled trials of standard dose versus higher doses of imatinib as first-line treatment for CP-CML have demonstrated conflicting results regarding treatment outcomes. *Aims.* We aimed to evaluate the efficacy and safety of higher doses of imatinib (≥ 600mg daily) compared with standard doses (400mg daily) for newly diagnosed, previously untreated CP-CML patients. *Methods.* Systematic review and meta-analysis of randomized controlled trials comparing frontline treatment with single agent imatinib 400mg daily vs. higher doses (≥ 600mg daily) in patients with CP-CML. The Cochrane Library, MEDLINE, conference proceedings and references were searched until February 2011. Two reviewers appraised the quality of trials and extracted data. Outcomes assessed were: Complete cytogenetic response (CCyR) and major molecular response (MMolR) at 12 months; progression to accelerated phase (AP) / blastic crisis (BC); all-cause mortality at the end of follow-up; adverse events at 12 months. Relative risks (RR) were estimated and pooled. *Results.* Our search yielded four trials, published between the years 2009-2010 and randomizing 1645 patients. Three trials compared the standard dose of 400 mg daily with 800mg daily and one with 600mg daily. Three trials included patients of all Sokal risk scores, while one trial included only high risk Sokal score patients. The median actual dose of imatinib in the high dose arm trials ranged from 590mg to 720mg. *Efficacy analysis*: CCyR at 12 months was improved in the high dose imatinib arm (RR 1.15, 95% CI 1.06-1.24, 4 trials, figure). High dose imatinib also improved MMolR at 12 months (RR 1.36, 95% CI 1.08-1.70, 4 trials). However, there was no difference in all-cause mortality (RR 0.79, 95% CI 0.52-1.22, 3 trials) or progression to AP/BC (RR 0.83, 95% CI 0.45-1.50, 3 trials) at the end of follow-up. *Safety analysis*: Adverse events requiring discontinuation were more common in the high dose imatinib arm (RR 1.98, 95% CI 1.20-3.26, 3 trials), as were grade III/IV neutropenia, thrombocytopenia and edema: RR 1.57, 95% CI 1.15-2.14 (3 trials), RR 1.91, 95% CI 1.28-2.93 (3 trials) and RR 2.44, 95% CI 1.21-4.92 (2 trials), respectively. There was no difference in grade III/IV anemia or myalgias. *Conclusions.* Higher doses of imatinib significantly improved CCyR and MMolR, as compared to standard dose imatinib. There was no difference in all-cause mortality or progression to AC/BC, although this should be taken with reservation due to the short time of follow-up. Moreover, higher doses were associated with greater toxicity. Thus, there is currently insufficient evidence to support the routine use of higher imatinib doses as frontline treatment for CP-CML. Extended follow-up is needed to evaluate if the superior CCyR and MMolR with higher doses of imatinib will translate to long-term clinical benefit.

Table 1. Complete cytogenetic response at 12 months.



0152

THE PREVIOUS RESPONSE TO IMATINIB IS THE MAIN PREDICTOR OF CCYR ACHIEVEMENT ON SECOND LINE TKI TREATMENT

A Zaritskey,[1] V Shuvaev,[2] A Abdulkadyrova,[2] E Usacheva,[2] V Udalieva,[2] I Zotova,[2] I Martinkevitch,[2] E Machulaitene,[3] N Ilina,[4] E Koryagina,[4] E Goryunova,[1] E Sbityakova,[1] N Lazorko,[1] E Lomaia,[1] K Abdulkadyrov[2]

[2]*Russian Research Institution of Hematology and Transfusiology, St-Petersburg, Russian Federation*
[3]*St-Petersburg Pavlov's State Medical University, St-Petersburg, Russian Federation*
[4]*City Hospital #15, St-Petersburg, Russian Federation*

Background. New tyrosine-kynase inhibitors (TKI) is the best possibility to overcome the imatinib resistance in patients with chronic myeloid leukemia (CML). Still we need more data to predict TKI's efficacy for appropriate choose treatment strategy. *Aims.* The aim of the study was to evaluate several prognostic markers of new TKI's efficacy in imatinib resistant patients. *Patients and Methods.* 47 imatinib-resistant pts (male:female ratio 21:26) with chronic phase of CML were analyzed retrospectively. Patients were treated with nilotinib (34 pts) or dasatinib (13 pts) since 2005 to 2010 with median follow-up on new TKIs 16,4 mos (3-66 mos). The median imatinib pretreatment time was 27 mos (2-83 mos). The median follow-up duration from the diagnosis was 45 mos (8-190 mos). The median age at the beginning of new TKIs - 50,4 years (26-84). There were 11, 17, 14 pts with low, intermediate and high Sokal risk, respectively (among 42 evaluable patients). *Results* Probability of CCyR achievement was 65 % (the rate 51,1% (23/45)). It was significantly higher among secondary than in primary resistant patients: 81% (rate 66,7% (10/15)) vs 50% (rate 39,3% (11/28)), p=0,045. It also depends on the best cytogenetic response (0-65% vs >65% Ph-positive cells) during imatinib treatment: 73% (rate 67,9% (19/28)) and 41% (rate 25% (4/16)), p=0,02. The probability of CCyR was higher in pts with complete hematologic response (CHR) at the start of 2nd TKI treatment: 78% (rate 66.7% (20/30)) with CHR vs 18% (rate 2/14)) without CHR, p=0,01. It also was relatively, but not significantly higher in low+intermediate than in high Sokal risk groups: 80% (rate 63% (17/27)) vs 50% (rate 38,5% (5/13)), respectively, p=0,101. In multivariant analysis (Cox regression) the significance of CHR and best CyR were confirmed, p<0,05. During 2nd line TKI treatment time to partial CyR predicted CCyR achievement - the probability of CCyR was 93% (rate 17/19 - 89.5%)) vs 83% (5/6 - 83.3%) in patients with PCyR achieved before or later 6 mos, respectively, p=0,022. Probability of CCyR loss was 10% (rate 9,1% (2/22)), we failed to reveal any factors, influencing it. Probability of progression-free survival (PFS) by 5,5 years was - 88% (progression rate - 4,3% (2/47)). It was better in patients with low and intermediate than in high Sokal risk group: 100% (progression rate 0/29) vs 68% (rate 15,8% (2/13)), p=0,048. Probability of survival from the start of TKI2 by 5,5 years was 92% (death rate 4,3% (2/47)) (only CML-related deaths were considered). The probability of survival among patients with low+intermediate Sokal risk score was 100% (death rate 0/29) and 67% (death rate 15,4% (2/13)) among high risk patients, p=0,046. Other factors didn't influence the patient's overall or progression free survival. The therapy was stopped in 21 patients: 16 due to resistance, 5 due to intolerance. *Conclusion.* Previous efficacy of imatinib and stable CHR at the start of therapy, but not Sokal risks, appear to be the main predictors of CCyR on 2nd TKI treatment. Only Sokal risk groups influenced overall and progression free survival in our cohort of patients.

0153

DYNAMICS OF MOLECULAR RESPONSE TO STANDARD-DOSE IMATINIB IN NEW CP CHRONIC MYELOID LEUKEMIA PATIENTS AFTER ACHIEVING CMR4.0

SY Choi,[1] HG Goh,[2] D Kim,[2] SH Kim,[2] J Lee,[2] EJ Jang,[2] JH Bang,[2] SM Oh,[2] WJ Song,[2] DW Kim[2]

[1]*The Catholic University of Korea, Seoul, South-Korea*
[2]*Seoul, South-Korea*

Background. Imatinib has been the standard therapy in CML patients, and sustained undetectable BCR-ABL using real time quantitative polymerase chain reaction (RQ-PCR) is often referred to as complete molecular response (CMR). With prolonged imatinib therapy, the numbers of patients with CMR are increasing, and an estimated 40% of chronic phase (CP) CML patients will achieve CMR after 5 years on imatinib therapy. However, the degree of CMR might be different in each laboratory depending on the sensitivity of RQ-PCR assays, and it is important to confirm what level of sensitivity is necessary to determine the stability of patients on therapy. Although the significance of achievement of major molecular response (MMR) has been extensively studies in the previous studies, according to our knowledge, significance of achievement of CMR has not been determined yet. *Aims.* In this study, we investigated the dynamics of molecular response to imatinib after achieving $CMR^{4.0}$ in CP CML patients, and investigated their current clinical status to determine whether the achievement of $CMR^{4.0}$ represents the level of stability in patients on imatinib therapy. *Methods.* Fifty three patients who achieved $CMR^{4.0}$ with imatinib therapy after diagnosed as new CP CML in Seoul St. Mary's Hospital from 15Aug 2001 to 18 Dec 2009 were monitored by RQ-PCR assay at regular intervals to evaluate the molecular response. Patients' median age was 43 (range 17 - 68) and median follow-up duration were 71.9 months (range 9.7 - 108.8 months) after commencing imatinib and 19.6 months (range 2.8 - 88.8 months) after achieving $CMR^{4.0}$. Molecular response was expressed as a ratio of BCR-ABL to ABL% according to the international scale (IS), and $CMR^{4.0}$, $CMR^{4.5}$ and $CMR^{5.0}$ are defined as 4-log, 4.5-log and 5-log reductions from the baseline, respectively. *Results.* With the estimated detection limit of 5.0 logs below the standardized baseline in our RQ-PCR assay, we could discriminate $CMR^{4.0}$, $CMR^{4.5}$ and $CMR^{5.0}$, and different dynamics of molecular responses were demonstrated in each group as shown in Table 1.

Table 1. Molecular dynamics after achieving CMR4.0.

Dynamics of molecular response	Patient grouping according to the degree of CMR		
	Group 1 $CMR^{4.0}$, but not $CMR^{4.5}$ (N = 9)	Group 2 $CMR^{4.5}$, but not $CMR^{5.0}$ (N = 13)	Group 3 $CMR^{5.0}$ (N = 31)
Undetectable BCR-ABL levels N (%)	0 (0)	0 (0)	21 (67.7)
Decreasing BCR-ABL levels N (%)	2 (22.2)	6 (46.2)	0 (0)
Fluctuation under CMR level N (%)	6 (66.7)	4 (30.8)	0 (0)
Fluctuation across CMR level N (%)	1 (11.1)	3 (23.1)	7 (22.6)
MMR, but loss of CMR* N (%)	0 (0)	0 (0)	3 (9.7)

* CMR is defined differently in each group: 4-log, 4.5-log and 5-log reduction from the baseline in group 1, 2 and 3, respectively

Among 53 patients with $CMR^{4.0}$, 9 patients achieved $CMR^{4.0}$, but not $CMR^{4.5}$ (Group 1), 13 patients achieved $CMR^{4.5}$, but not $CMR^{5.0}$ (Group 2), and 31 patients obtained $CMR^{5.0}$ (Group 3). All patients have maintained complete hematologic response (CHR), complete cytogenetic response (CCyR) and MMR without disease progression, and survival rate was 98.1% (52/53) with 1 patient died from complications after SCT. Although 7 patients showed fluctuating BCR-ABL levels under/across $CMR^{4.0}$ levels, all of them maintained $CMR^{4.0}$ without further progression to advanced disease. *Conclusions.* Although different molecular dynamics were observed after achieving $CMR^{4.0}$, this study demonstrates that the achievement of $CMR^{4.0}$ represents a stable level where the risk of progression including loss of MMR is extremely low. Analysis of molecular dynamics after achieving $CMR^{4.0}$ examined here can be extended to expand our understanding of molecular profiles in CML patients through clinical application in a larger cohort with longer follow-up. With further follow-up, other possible significances of achieving CMR could be determined.

0154

THE EFFECT OF COMPLETE MOLECULAR RESPONSE ON PROGRESSION-FREE SURVIVAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA RECEIVING IMATINIB MESYLATE

I Kaygusuz, T Toptas, B Kantarcioglu, G Yilmaz, C Adiguzel, E Eksioglu-Demiralp, T Firatli-Tuglular, M Bayik

Marmara University Hospital, Division of Hematology, Istanbul, Turkey

Background. Achievement of major molecular response (MMR) at 18th month and stable or improving MMR anytime during the treatment of chronic myeloid leukemia (CML) were defined as optimal re-

sponse by the European LeukemiaNet (ELN) based on previous studies. Importance of MMR is obvious. However, results of studies regarding the prognostic significance of complete molecular response (CMR) are conflicting. *Aims.* To investigate the effect of CMR achieved by imatinib mesylate (IM) on progression-free survival (PFS) in patients with CML. Secondary aim of the study was to compare disease outcomes in BCR-ABL positive and negative patients with MMR. *Methods.* Data from 106 CML patients receiving imatinib mesylate therapy were evaluated retrospectively. Of those, 35 patients were excluded because MMR could not be achieved. Demographic and clinical data of the remaining 71 patients are shown in Table 1. Remission definition and cytogenetic and molecular monitoring during the treatment was performed in accordance with the criteria of the ELN. CMR was defined as no detection of BCR-ABL by two consecutive polymerase chain reaction analyses at least three months apart. Any treatment failure was defined as progression. PFS was estimated as the time elapsed from the beginning of the treatment until the progression or last contact. Overall survival (OS) was calculated as the time between the beginning of the treatment until death or last contact. Demographic data were compared by descriptive statistics, $\chi 2$, Student's t-test, and Mann Whitney U tests. Survival analyses and curves were performed by log-rank test and Kaplan-Meier method, respectively. *Results.* CMR was obtained in 59 out of 71 (83.1%) patients with MMR. Median PFS was not reached in both BCR-ABL positive and negative groups. 3-year PFS was 74.1% and 89.8% for BCR-ABL PCR positive and negative patients, respectively (p=0.3). Only one patient has died among 71 patients. 3-year OS was 100% vs. 97.1% for BCR-ABL PCR negative and positive patients, respectively (p=0.7). There were no differences between groups regarding disease outcomes including treatment failure, disease transformation, and death (Table 2). *Conclusions.* Although this is a retrospective study including only a limited number of patients with CMR, our results show that achieving CMR in patients with CML has no effect on either PFS or disease outcomes. CMR should not be an essential goal in the treatment of CML patients.

SERUM SCLEROSTIN CORRELATES WITH BONE MINERAL DENSITY IN PATIENTS WITH THALASSEMIA MAJOR AND OSTEOPOROSIS; IMPLICATIONS INTO THE MANAGEMENT OF THALASSEMIA-RELATED OSTEOPOROSIS

E Voskaridou,[1] D Christoulas,[2] A Papatheodorou,[3] A Anastasilakis,[4] C Bratengeier,[5] D Kaliontzi,[1] S Polyzos,[6] E Plata,[1] E Terpos[2]

[1]*Laikon General Hospital, Athens, Greece*

[3]*251 General Air Force Hospital, Athens, Greece*
[4]*424 General Military Hospital, Thessaloniki, Greece*
[5]*Biomarker Design Forschungs GmbH, Vienna, Austria*
[6]*Aristotle University of Thessaloniki School of Medicine, Thessaloniki, Greece*

Background. Osteoporosis represents an important cause of morbidity in adult patients with thalassemia major (TM). Its pathogenesis includes increased osteoclast activity and osteoblast deregulation. Osteocyte is a key cell for the control of bone remodeling. Sclerostin is a secreted inhibitor of the wingless-type and integrase 1 (Wnt) canonical pathway which is produced by osteocytes and has inhibitory effects on osteoblasts. *Aims.* The aim of this study was to evaluate the circulating levels of sclerostin in patients with TM-related osteoporosis and explore possible correlations with clinical and laboratory data. *Methods.* Sixty-six patients with TM-related osteoporosis were studied. These patients were blindly randomized to receive zoledronic acid (ZOL) at a dose of 4 mg, iv, every 6 months (n=23) or every 3 months (n=21), or to receive placebo every 3 months (n=22) for a 12-month period. Bone mineral density (BMD) of the lumbar spine (L1-L4), femoral neck (FN) and distal radius (R) was determined using DXA before and 12 months post-ZOL treatment. Circulating sclerostin was measured in the serum of all patients at baseline and after 12 months of therapy, using an ELISA methodology (Biomedica Medizinprodukte, Vienna, Austria), along with a series of serum bone indices: i) bone resorption markers [C-terminal telopeptide of collagen type-1 (CTX) and tartrate resistant-acid phosphatase (TRACP-5b)]; ii) bone formation markers [bone-alkaline phosphatase (bALP), osteocalcin and C-terminal propeptide of collagen type-I (CICP)]; iii) osteoclast regulators [RANKL, osteoprotegerin (OPG) and osteopontin] and iv) dickkopf-1 (Dkk-1), another inhibitor of Wnt signaling. The above bone markers were also evaluated in 30, age- and gender-matched, healthy controls, while sclerostin was also measured in 62 women with post-menopausal osteoporosis. *Results.* At baseline, patients with TM had elevated circulating levels of sclerostin (median: 605 pg/mL, range: 22-1227 pg/mL) compared to healthy controls (250 pg/mL, 0-720 pg/mL, p<0.001) and reduced levels of sclerostin compared with postmenopausal women with osteoporosis (840 pg/mL, 181-1704 pg/mL, p<0.001). TM patients had also increased values of CTX (p<0.001), Dkk-1 (p<0.001), bALP (p<0.001), CICP (p=0.003), TRACP-5b (p<0.01), and sRANKL/OPG ratio (p=0.001). Sclerostin levels correlated with BMD in all studied sites L1-L4 (r=0.454, p<0.001), R (r=0.324, p=0.01) and FN (r=0.268, p=0.035). Similar results were obtained for post-menopausal women with osteoporosis for L1-L4 BMD (r=0.501, p<0.001). The other Wnt inhibitor, Dkk-1 also correlated with BMD of L1-L4 (r=-0.290, p=0.022) and R (r=-0.415, p=0.001). Patients who received ZOL did not alter their sclerostin levels after 12 months of therapy, but reduced their circulating Dkk-1 (from 39.6±16.6 to 28.9±16.3 pmol/L, p=0.004). In contrast, placebo group patients showed an increase of sclerostin levels (p=0.01) and a borderline increase of Dkk-1 (p=0.08). *Summary/Conclusions.* These results suggest that circulating sclerostin is elevated in TM patients with osteoporosis and correlated with their BMD. Furthermore, the high Dkk-1 serum levels and their association with BMD support the notion of a disrupted Wnt signaling in patients with TM-related osteoporosis which leads to osteoblast deregulation. These findings give the rationale for the use of novel drugs targeting sclerostin and Dkk-1 in TM patients with osteoporosis.

LIVER IRON CONCENTRATION AND MORBIDITY IN PATIENTS WITH THALASSEMIA INTERMEDIA

K Musallam,[1] J Wood,[2] M Cappellini,[3] I Motta,[3] H Tamim,[1] A Taher[1]

[1]*American University of Beirut Medical Center, Beirut, Lebanon*
[2]*Children's Hospital Los Angeles, Los Angeles, CA, United States of America*
[3]*University of Milan, Milan, Italy*

Background. Patients with thalassemia intermedia (TI) can have significant iron overload, irrespective of transfusion status, secondary to increased intestinal iron absorption. Correlation between serum ferritin levels ≥ 1000 ng/ml and the rate of clinical complications in TI has been studied; however, data on the effect of elevated liver iron concentration (LIC) on morbidity is lacking. *Aims.* To evaluate the association between LIC and several morbidities in patients with TI. *Methods.* A retrospective study of 168 TI patients treated at two centers in Beirut, Lebanon and Milan, Italy; for whom an LIC measurement was available. None of the patients were receiving iron chelation therapy. Data on demographics (age and gender), splenectomy status, transfusion status, and presence of clinical complications were retrieved. Mean values of SF, fetal (HbF) and total hemoglobin (Hb) levels, as well as platelet and nucleated red blood cell (NRBC) counts were retrieved. For LIC, direct determination of iron burden was performed using R2 MRI in Lebanon and T2* MRI in Italy using established methodology. *Results.* The mean age was 35.2 ± 12.6 years with 42.9% being males. A total of 121 (72%) patients were splenectomized and 44 (26.2%) were transfusion independent. The mean LIC was 8.4 ± 6.7 mg Fe/g dry weight (dw). On bivariate analysis, mean LIC values were significantly higher in patients with leg ulcers (P<0.05), thrombosis (P<0.01), pulmonary hypertension (P<0.001), abnormal liver function (P<0.001), hypothyroidism (P<0.05), osteoporosis (P<0.001), and hypogonadism (P<0.001) than those without. On multivariate logistic regression analysis, after adjusting for age, gender, splenectomy status, transfusion status, and laboratory indices, a 1-mg Fe/g dw increase in LIC was independently associated with higher odds of thrombosis (AOR: 1.12, 95% CI: 1.05-1.20), pulmonary hypertension (AOR: 1.08, 95% CI: 1.02-1.14), hypothyroidism (AOR: 1.05, 95% CI: 1.01-1.11), osteoporosis (AOR: 1.08, 95% CI: 1.02-1.14), and hypogonadism (AOR: 1.10, 95% CI: 1.03-1.16). *Summary/Conclusions.* Elevated LIC is associated with vascular and endocrine complications in patients with TI.

0157

EVALUATING PLATELET FUNCTION IN PATIENTS WITH THALASSEMIA USING THE PFA-100 SYSTEM; THE EFFECT OF CHELATION TREATMENT

A Kattamis,[1] P Delaporta,[1] K Stokidis,[1] I Papassotiriou,[1] T Petropoulou,[1] H Platokouki[2]

[1]*National and Kapodistrian University of Athens, Athens, Greece*
[2]*Hemostasis Hemophilia Unit, Agia Sofia Children's Hospital, Athens, Greece*

Background. Patients with thalassemia are at increased risk for developing thromboembolic events. Prophylactic use of aspirin, though widely adopted in these patients, is mainly based on theoretical *Background.* Furthermore, the effect of iron chelation therapy in platelet aggregation is not known. *Aim.* To evaluate the use of a screening method for platelet function in patients with thalassemia and to assess how the results of the method are affected by iron chelation therapy. *Methods.* Samples from the patients, after informed consent was obtained, were evaluated using the PFA-100 platelet function analyzer (Dade Behring Inc. Deerfield, IL, USA). This instrument uses small membranes coated with either collagen and epinephrine (Col/Epi) or collagen and ADP (Col/ADP). Blood samples pass through the membranes at a high shear rate, simulating the *in vivo* hemodynamics in the small capillaries. The PFA test is considered a rapid, accurate screening test to measure both platelet adhesion and aggregation (primary hemostasis). Sixteen patients (10 females, mean age: 33 ± 6.4 years) followed in our unit with either thalassemia major (12 patients) or thalassemia intermedia (4 patients) were included in the study. Patients were on chelation treatment with either desferioxamine (DFO) (2 patients), deferiprone (5 patients) or combination therapy of DFO and deferiprone (5 patients). Fourteen patients underwent a 2nd evaluation, 2-4 weeks after starting or switching chelation therapy to deferasirox. *Results.* Mean PFA-100 levels at the first evaluation were 114.9 ± 13.3sec, which were within the reported reference values. There were no differences in regards to gender or type of thalassemia. After initiation of therapy with deferasirox there was a significant increase in the PFA-100 levels from a mean value of 113 ±12.9sec to 132.6 ± 23.1 (p<0.05). In 6 of these patients the Col/Epi closure time was longer than the reference value with 4 of these 6 patients showing also prolongation of the Col/ADP closure time, indicating a more profound effect on platelet function. The prolongation of Col/Epi closure time parallels the changes in renal function, a well described phenomenon observed during treatment with deferasirox (p<0.05) *Conclusions.* A significant change was noted in the results of the PFA-100 evaluation after initiation of treatment with deferasirox. A possible mechanism for this phenomenon may be the inhibition of the heme-containing enzyme cyclooxygenase of the platelets, which produces thromboxane A2 from arachidonic acid, a potent regulator of platelets aggregation. This observation may have significant clinical applications for in patients receiving deferasirox. Toxicity from the chelator may be prevented by avoiding other drugs which have similar effect to platelets aggregation. Moreover, the need for concomitant antithrombotic prophylaxis with aspirin needs to be reconsidered. Larger long-term studies are required to validate these observations.

[7]*Università Cattolica del Sacro Cuore, Campobasso, Italy*

Background. Renal dysfunction has been reported in adult subjects with thalassemia major (TM) since 1975. One of the main cause is the iron overload consequent to regular transfusions. Multiecho T2* MRI is a well-established technique for cardiac and hepatic iron overload assessment, but there very few report concerning the kidneys. *Aims.* The aims of this study were to describe the T2* values of the kidneys in patients with TM, to investigate the correlation between renal and myocardial or hepatic siderosis and biventricular cardiac function. *Methods.* 119 TM patients (58 men, 30.7 ± 8.2 years) enrolled in the Myocardial Iron Overload (MIOT) networks underwent MRI. For the measurement of iron overload, multiecho T2* sequences were used. The left ventricle was segmented into a 16-segments standardized model and the T2* value on each segment was calculated as well as the global value. In the liver, the T2* value was assessed in a single region of interest (ROI) in a homogeneous area of the parenchyma. For each kidney, T2* values were calculated in three different ROIs and were averaged to obtain a representative value for the kidney. The mean T2* value over the kidneys was also calculated. Cine images were obtained to quantify biventricular morphological and functional parameters in a standard way. *Results.* T2* values in the right kidney were significant lower than in the left kidney (40.3±11.9 ms vs 44.1±12.7 ms, P<0.0001). The mean T2* value over the kidneys was 42.2±11.9 ms and 40 patients (33.6%) had a pathological value (T2*<36 ms, lower limit of normal evaluated on 20 healthy subjects). The mean T2* value did not show a significant difference amongst men ad women (43.2±11.7 ms versus 41.3±12.1 ms, P=0.378). The mean T2* values increased with age in a significant manner (r=0.321, P<0.0001). There was a significant negative correlation between serum ferritin levels and mean renal T2* values (r=-0.446, P<0.0001, figure 1 left).

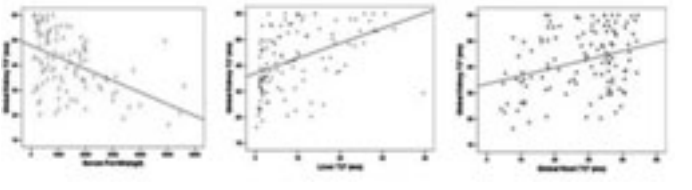

Figure 1.

Significant positive correlations of the mean T2* values were demonstrated for liver (r=0.511, P<0.0001, figure 1 center) and global heart (r=0.262, P=0.004, figure 1 right) T2* values. No correlation was found between renal iron overload and bi-ventricular function parameters. *Conclusions.* Systemic T2* differences between left and right kidneys were found, with significant lower values in the right one. Mean T2* value increased with age. We confirmed that kidney iron deposition was not very common in TM, but it was correlated with iron deposition in liver and heart.

SAFE AND EFFICIENT CHELATION BY DEFERASIROX IN THALASSEMIA MAJOR PATIENTS WITH LOW LIVER IRON CONCENTRATIONS

R Grosse,[1] A Jarisch,[2] J Yamamura,[1] G Janka,[1] P Nielsen,[1] R Fischer[1]

[1]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
[2]*Johann-Wolfgang-Goethe University, Frankefurt, Germany*

Background. Chelation treatment of iron overload due to chronic blood (RBC) transfusions has dramatically improved life experience, morbidity and mortality in Thalassemia major (TM) patients. Different treatment regimen are used, especially for chronically transfused patients with low or even normal liver iron concentration. *Aims.* We wanted to study the efficiency and safety of iron chelation therapy with Deferasirox (DSX) in TM patients with normal or low liver iron concentration (LIC) and chronic blood transfusion. *Methods.* This study included regularly transfused TM patients who were on iron chelation treatment with low liver iron overload. Inclusion criteria were LIC < 1200 µg/g-liver wet weight (conversion factor 6 for mg/g-dry wgt). Liver iron measurements by SQUID biomagnetic susceptometry (BLS) and/or MRI-R2 were performed in intervals of 6 to 12 months. For each measurement interval, the ratio of daily iron influx and DSX dose rate was calculated. This represents the equilibrium molar efficacy for iron balance. *Results.* Nineteen TM patients (9 females, mean age 14 y) were treated with DSX (median dose 19 mg/kg/d, range: 2 - 38 mg/kg/d) for 6 to 71 months. In all TM patients no severe side effects were observed and creatinine was in the normal range of < 0.9 mg/dl throughout the treatment with DSX. Median RBC transfusion rate was 8500 ml/y, equivalent to about 2 erythrocyte concentrates per 3 weeks and a daily iron influx of 16.2 mg/d. The median LIC was 778 µg/g-liver wet weight (range: 460 - 1122 µg/g). From baseline treatment interval to the endpoint of treatment observation, liver iron decreased by 124 - 4689 µg/g-liver, and serum ferritin decreased by -596 to 8283 µg/l. For all measurement intervals, molar chelation efficacies between 18 % and 56 % were calculated at equilibrium with a median efficacy of 31 % (interquartile range = 16 %). This agrees with molar efficacies of DSX reported earlier but for relatively higher LIC and chelation doses (Blood 2005; 106(11):#2690 and Blood 2007; 110(11):#2776). *Conclusion.* Iron chelation therapy with DSX enables TM patients to stay on a relatively low iron burden, however, it is necessary to find a balance between the continuous iron accumulation from RBC transfusions and the toxicity of iron chelation therapy. Under these circumstances iron chelation therapy with DSX in TM patients with normal to low liver iron overload is safe, and does not result in increased creatinine levels or severe side effects and is as efficient as in patients with high liver iron overload.

Background. Heart failure remains the main cause of mortality in thalassemia major (TM). Magnetic Resonance Imaging (MRI) by the T2* approach is the unique non invasive technique for highly reproducible quantifications of myocardial iron burden and is the gold standard for quantifying biventricular function parameters. It is important to determine the appropriate age to start MRI screening, because its high cost and no large availability. Few data are available in the literature. *Aims.* The aim of this study was to address this issue in a cohort of paediatric patients selected from a large TM population homogenous for geographical origin and treatment approach. *Methods.* We studied retrospectively 72 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network with an age < 18 years (47 males, 4.2-17.9 years old, mean age 13.0±3.7 years). Myocardial iron overload (MIO) was measured by T2* multislice multiecho technique. Biventricular function parameters were quantitatively evaluated by cine images. *Results.* The global heart T2* value was 29±11 ms. No MIO was detected in the 33% of the patients; 44% of the patients showed a heterogeneous MIO with a global T2*value ≥ 20 ms; 10% showed a heterogeneous MIO with a T2* global value < 20 ms and 13% had a homogeneous MIO. No significant correlation was found between global heart T2* value and age. OR for a global heart T2* < 20 ms was 1.13 (P = 0.18) per year. The global heart T2* value did not show significant differences according to the sex (male 30.2±11.0 ms versus female 28.7±11.8 ms, P=0.568). None of patients with an abnormal global heart T2* value (<20 ms) was under 8 years of age. Global heart T2* value was negatively correlated with mean serum ferritin levels. OR for high serum ferritin levels (≥ 1500 ng/ml) was 8.4 (1.01-69.37 OR 95%CI) for abnormal global heart T2* values (<20 ms). The global heart T2* value did not show a significant difference with respect to the chelation therapy (P=0.322). No significant correlations were found between the global heart T2* values and the bi-atrial areas or the left ventricular (LV) and right ventricular (RV) morphological and functional parameters. Five patients showed a LV ejection fraction (EF) < 57% and one patient showed a RV EF < 52%. None of them was under 8 years of age. *Conclusion.* The MRI screening for both iron overload and function assessment can be started for TM patients at the age of 8 years. At this age not sedation is generally needed. If the availability of cardiac MRI is low, the serum ferritin levels can be used as a discriminating factor.

Background. The gradient echo multiecho T2* MRI technique is the most robust method for the sensitive and reproducible quantification of iron overload in transfusion dependent patients. The 1.5T MRI scanner is generally used in the clinical arena. However, given that 3T scanners are becoming largely widespread, there is a growing need to assess the practicality of evaluating MIO at 3T. *Aims.* This study aimed to establish the relationship between T2* values at 3T and 1.5T over the range of clinical interest of tissue iron concentrations. *Methods.* 38 transfusion-dependent patients (22 males, 36±7 years) were scanned at 1.5T and 3T. In the liver the T2* value was determined over a circular region of interest. For the heart, the T2* value on each of the 16 segments was calculated as well as the global value. The relationship between R2* (1000/T2*) values at 3T and 1.5T is expected to be linear and can be approximated as: (R2*3T=aR2*1.5T + I) Eq.1, so the relationship was found out in terms of R2* values. T2* values were transformed into their reciprocal R2*. The R2* values at 3T were plotted versus the correspondent values at 1.5T. The data were fitted to a straight line, of which the slope and the y-intercept were extracted. In the clinical practice is most common to use T2* values as measure of iron overload. So, the T2* values at 3T were expressed as a function of the values at 1.5T by inverting both the members of the equation 1. *Results.* Figure 1A shows the liver R2* values at 3T plotted against the corresponding values at 1.5T. At very high iron tissue concentrations the T2* assessment is lacking of precision because technical constraints, so the patients with a R2* value at 1.5 T greater than 1000 Hz were excluded from the fitting (cross-shaped marker). The line of best

fit had a slope of 1.917±0.061 and an intercept of -9.145±13.083 Hz. The R-squared value for the fit was 0.973. Figure 1B shows the global heart R2* values at 3T plotted against the corresponding values at 1.5T for the patients. The line of best fit for the patients had a slope of 1.961±0.053 and an intercept of -17.570±3.160 Hz. The R-squared value for the fit was 0.975. The fit was performed even for all the segmental T2* values. The line of the best fit had a slope of 2.008 ± 0.043 and an intercept of -19.205 ± 2.787 Hz. The R-squared value for the fit was 0.784. Specific conversion formulas for liver and global heart T2* values at 3T vs T2* at 1.5T are indicated in Figure 1C. *Conclusion.* For both liver and heart, the R2* values at 3T were about twice that at 1.5 T with an intercept depending on the non-iron component of the tissue. A conversion formula between T2* values at 3T and 1.5T was introduced and it may be used in the clinical arena by the centers that use 3T scanners.

Background. The multislice multiecho T2* Cardiovascular Magnetic Resonance (CMR) technique allows to detect different patterns of myocardial iron overload (MIO). *Aims.* The aim of this study was to verify the risk of biventricular dysfunction related to different patterns of MIO in a large cohort of thalassemia major (TM) patients. *Methods.* 1135 TM patients (538 M, 30±19 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network underwent CMR . For the assessment of MIO, three short-axis views of the left ventricle (LV) were acquired and the myocardium was segmented into 16-segments standardized LV model. The T2* value on each segment was calculated as well as the global T2* value. Biventricular function parameters were quantitatively evaluated by cine images. *Results.* Four groups of patients were identified: homogeneous MIO (all segments with T2*<20 ms) (N=173), heterogeneous MIO (some segments with T2*≥20 ms and other segments with T2*<20 ms) and global heart T2*<20 ms (N=160), heterogeneous MIO and global heart T2*≥20 ms (N=33) and no MIO (all segments with T2*≥20 ms) (N=465). The LV ejection fraction (EF) was significant different among the groups (P<0.0001) (Figure 1, top). Odds Ratio for LV dysfunction (LV EF<57%) was 4.8 (3.1-7.3 OR 95%CI; P<0.0001) for patients with homogeneous MIO vs patients with no MIO and 1.9 (1.2-3.2 OR 95%CI; P=0.007) for patients with heterogeneous MIO and global heart T2*<20 vs patients with no MIO. The right ventricular (RV) EF was significant different among the groups (P<0.0001) (Figure 1, bottom). Odds Ratio for RV dysfunction (RV EF<55%) was 2.1 (1.4-3.2 OR 95%CI; P=0.001) for patients with homogeneous MIO vs patients with no MIO. *Conclusions.* Biventricular dysfunction is correlated with MIO distribution decreasing from the patients with homogeneous MIO to the patients with no MIO. Homogeneous MIO and heterogeneous MIO with a global heart T2*<20 predicts a significantly higher risk to develop cardiac dysfunction suggesting an intensive chelation therapy in this group of patients.

THYROID DYSFUNCTION IN PEDIATRIC EGYPTIAN THALASSEMICS: WHAT ABOUT IODINE DEFICIENCY?

A ElBeshlawy, L Fawaz, M Hamdy, A Sabry, W Mohamed, A Kamel

Faculty of Medicine Cairo University, Giza, Egypt

Introduction. Primary hypothyroidism is one of the most frequent endocrinal complications observed in patients suffering from thalassemia (10-50%). Long standing anemia, hypoxia and hemosiderosis were proposed as a cause. Iodine deficiency is an important contributing factor for hypothyroidism. Iodine deficiency is not uncommon among Egyptian children, its contribution to hypothyroidism in thalassemia major patients was not studied. The urinary iodine concentration is the most useful test for assessing iodine nutrition in populations. The aim of the present study was to assess the thyroid hormones and the urinary iodine level in Egyptian thalassemic pediatric patients. *Study design.* Sixty thalassemia patients (31 males, 29 females), mean age 14.4±3.83 years) followed up at the hematology clinic were randomly selected to participate in this study together with thirty six age and sex matched controls after the parents gave their consent. All patients were subjected to thorough clinical examination. Serum evaluation of T3, T4, TSH and urinary iodine. *Results.* A highly significant difference was observed in urinary iodine, T3, T4 and TSH between the thalassemic and the control groups (P<0.001). T3 was low in 81.7% (n=49), T4 in 68.3% (n=41) while TSH was elevated in 81.7% (n=49) of the patients. Overt hypothyroidism (low T4 and elevated TSH >10 uIU/ml) was present in 45% (n=27)of the patients, while all controls were euthyroid with normal urinary iodine. Severe iodine deficiency was present in 15% (n=9), moderate deficiency in 45%(n=27) and mild deficiency in 40% (n=24) of the patients . Thyroid function tests results varied among these groups of iodine deficiency. A negative correlation was found between urinary iodine and both serum ferritin and TSH (r=-0.413, P<0.001, and r=0.881, P< 0.001 respectively) and both serum ferritin and age (r=0.355, P<0.001, r=0.491, P<0.001). *Conclusion.* Correction or supplementation of iodine to thalassemia patients may have a role in prevention or correction of hypothyroidism in thalassemia patients especially in areas where iodine deficiency is common like Egypt.

Background. No prospective data are available about the efficacy of deferasirox versus deferiprone and desferrioxamine in monotherapy. *Aims.* Our study aimed to prospectively assess the efficacy of deferasirox versus deferiprone and desferrioxamine in monotherapy in a large cohort of thalassemia major (TM) patients by quantitative Magnetic Resonance (MR). *Methods.* Among the 1135 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network we selected those with an MR follow up study at 18±3 months who had been received one chelator alone between the 2 MR scans, We identified three groups of patients: 80 treated with DFX, 39 with DFP and 74 with DFO. Iron overload was measured by T2* multiecho technique. Biventricular function parameters were quantitatively evaluated by cine images. *Results.* Excellent/good levels of compliance were similar in the DFX (98.8%) vs DFP (94.9%) and DFO (95.9%) groups. The percentage of patients who maintained a normal global heart T2* value (≥20 ms) was comparable for DFX (98.1%) vs DFP (100%) and DFO (98.1%) groups. The percentage of patients that maintained a normal left ventricular ejection fraction (LVEF>57%) was significantly lower in DFX (75.8%) versus DFP group (100%) (P=0.002), but no versus DFO group (83.1%). Among the patients with myocardial iron overload at baseline, in all three groups there was a significant improvement in the global heart T2* value (DFX: +3.5±4.7 ms P=0.001, DFP: +8.8±8.6 ms P=0.015 and DFO: 3.7±5.5 ms P=0.001) and a reduction in the number of pathological segments (DFX: -2.4±3.8 P=0.003, DFP: -6.0±5.6 ms P=0.012 and DFO: -2.9±3.7 ms P=0.001).

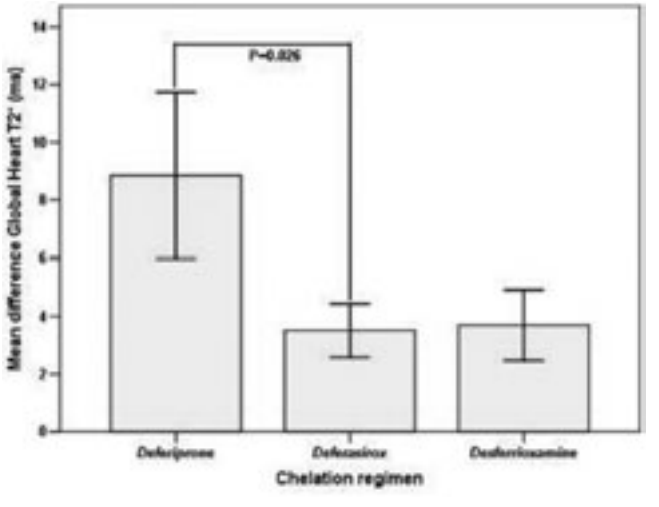

Figure 1.

Only in the DFP group there was a significant improvement in left and right ventricular ejection functions (+5.0±6.4% P=0.045 and +6.8±3.7% P=0.001, respectively). The improvement in the global heart T2* was significantly lower in the DFX versus the DFP group (P=0.026, see figure), but it was not significantly different in the DFX versus the DFO group. The improvement in the LVEF and in the RVEF was higher in the DFP group than in the DFX group at the limit of the significance (P=0.066 and P=0.062, respectively); it was comparable between DFX and DFO groups. Among the patients with hepatic iron at baseline (T2*<9.2 ms) the changes were not significantly different in DFX versus the other groups. *Conclusions.* Prospectively in a large clinical setting of TM patients, DFX monotherapy was significantly less effective than DFP in improving myocardial siderosis and in maintaining a normal left ventricular ejection fraction.

0165

THE PALATABILITY AND TOLERABILITY OF DEFERASIROX TAKEN WITH DIFFERENT LIQUIDS OR FOOD

S Goldberg,[1] P Giardina,[2] J Cain,[3] D Chirnomas,[4] J Esposito,[5] C Paley,[5] E Vichinsky[6]

[1]*John Theurer Cancer Center of Hackensack University Medical Center, Hackensack, United States of America*

[5]*Novartis Pharmaceuticals Corporation, East Hanover, United States of America*
[6]*Children's Hospital and Research Center Oakland, Oakland, United States of America*

Background. Deferasirox is an oral iron chelator indicated for the treatment of transfusional hemosiderosis in patients aged ≥2 years. The recommended mode of administration is to be taken on an empty stomach in water, apple juice or orange juice ≥30 minutes before food. Post-marketing reports have noted discontinuation or reduced compliance of deferasirox secondary to palatability and gastrointestinal adverse events. Registration trials with deferasirox did not evaluate food combinations to maintain predictable plasma levels since single dose pharmacokinetic studies suggested that bioavailability was increased by food. *Aims.* Assess palatability and tolerability of deferasirox when taken with meals, various liquids, and crushed and added to food. *Methods.* A single-arm, open-label, multi-center study (NCT00845871) enrolling patients with transfusional hemosiderosis (minimum entry serum ferritin ≥500 µg/L) aged ≥2 years with thalassemia major, sickle cell disease, low or intermediate-1 risk MDS or other anemias, who were on, starting, or resuming treatment with deferasirox. The study began with a 1-month run-in phase with deferasirox dosed according to prescribing information, followed by a 3-month assessment phase where subjects chose each week from 5 options: with/without meals; morning/evening; crushed and added to soft food/liquid of choice. Palatability was assessed with a Five-Point Facial Hedonic Scale with additional questions capturing GI effects. *Results.* Sixty-five patients were enrolled (Table 1).

Table 1.

Summary of underlying hematological disorder, serum ferritin, and patients with GI events by age

Category	Age ≥2 to <10 years (n=10)	Age 10 to <60 years (n=44)	Age ≥60 years (n=11)	Total (N=65)
Median age, years (range)	6.0 (3–9)	17.5 (10–48)	74.0 (60–83)	18.0 (3–83)
Hematological condition				
Sickle cell disease, n (%)	3 (30)	22 (50)	0	25 (38.5)
Thalassemia major, n (%)	5 (50)	15 (34.1)	0	20 (30.8)
Myelodysplastic syndrome, n (%)	0	0	9 (81.8)	9 (13.8)
Other anemia, n (%)	2 (20)	7 (15.9)	2 (18.2)	11 (16.9)
Serum ferritin				
Median baseline[a], µg/L (range)	2680 (800–6880)	2200.5 (560–8660)	4[illegible] ([illegible])	
Median end-of-study[b], µg/L (range)	2442.5 (1234–5340)	1968 (440–8040)	3670 (1677–6040)	
Patients with GI events during run-in phase (n=62; by age group: n=9/43/10, respectively)				
Diarrhea, n	1	9	5	15
Abdominal pain, n	1	6	1	8
Nausea, n	0	5	4	9
Vomiting, n	0	2	2	4
Patients with GI events during assessment phase (N=65)				
Diarrhea, n	1	3	3	7
Abdominal pain, n	3	9	2	14
Nausea, n	1	4	2	7
Vomiting, n	0	4	2	6

[a] 68% of patients received deferasirox prior to study; [b] 4 months of treatment

Palatability ratings improved with the introduction of food. The mean percentage of weeks that each patient rated a mode as "dislike extremely"or "somewhat dislike"was lower during the assessment phase as compared to the run-in phase. No particular mode was clearly more palatable than others. The most popular soft foods chosen were apple sauce and yogurt; the most popular liquids chosen were orange and apple juice. An age effect was observed for GI disturbances during the (fasting) run-in phase with older subjects (≥60) reporting higher rates of nausea (40% versus 9.6%, P=0.04) and diarrhea (50% versus 19%, P=0.09) compared to younger subjects. Gastrointestinal adverse events decreased with the addition of food. There were 46 occurrences of diarrhea in 15 patients (n=62) during run-in versus 29 occurrences in 7 patients (n=65) during assessment (P=0.08 by patients); there were 2 patients with diarrhea in both the run-in and assessment phases. Most diarrheal events occurred ≤2 hours after dose. The rates of other GI events in the run-in versus assessment phases included: 54 versus 47 abdominal pain events; 31 versus 23 nausea events; and 10 versus 15 vomiting events. There were no marked differences in renal or liver function tests between phases. *Conclusions.* Administration of deferasirox with food was rated by patients as more palatable and appeared to lessen GI adverse events. This study suggests that the addition of food may improve the palatability and tolerability of deferasirox among those experiencing difficulties with the approved dosing schedule. Further evaluations of safety and the effect of food on pharmacokinetics at steady state are required.

[2]*Thalassemia Center, Makarion Hospital, Nicosia, Cyprus*
[3]*"Karamandanion" Children's Hospital, Patras, Greece*
[4]*Laboratory of General Biology, University of Patras Medical School, Patras, Greece*

Bakground/Aims. Homozygous beta-thalassemia has been considered a hypercoagulable state, particularly following splenectomy. However, few large series of patients have been reported, describing the frequency of thrombotic complications in this group of diseases. We herein present our experience on venous and arterial thrombotic events, encountered among a large group of 538 thalassemic patients and investigate the relevant risk factors. *Patients and Methods.* Medical records of all thalassemic patients of three Thalasemia Units were studied, and all venous and arterial thromboembolic events were collected and analyzed. Three hundred and sixty-one patients (67.1%) had thalassemia major (TM), 168 (31.2%) had thalassemia intermedia (TI), and 9 had Hemoglobin (Hb) H disease (1.7%). In this population the prevalence of thromboembolic events was analyzed, in relation to disease genotype, patient's age, frequency of transfusions, serum ferritin levels, type of iron chelation, the presence of HCV infection, adequacy of hepatic function, history of previous splenectomy, Hb levels, MCV, platelet count, mean platelet volume (MPV), presence of nucleated red blood cells (RBC), total serum globulin levels, and the presence of FV Leiden-, FIIG20210A-, beta-Fibrinogen-455G=>A-, FXIII-, MTHFRC667T and MTHRF1298CT mutations, which have been associated with a hereditary thrombophilic state. *Results.* Totally, 17 (3.2%) venous and 7 (1.3%) arterial thromboembolic events were recorded. In particular, there were 7 episodes of portal vein thrombosis, 4 of pulmonary embolism, 4 of pulmonary hypertension, 3 of central venous catheter thrombosis, extended to left atrium, 3 of deep vein thrombosis (DVT) and 3 ischemic cerebral attacks. The frequencies of thrombophilic mutations in the studied population were: 2.5% for FV Leiden, 1.7% for FII G20210A and 7.1% for MTHFR C667T polymorphism homozygocity. These mutations were not related to any increase in the incidence of thrombosis in patients with TM and TI. Statistical analysis of the remaining parameters studied, revealed that genotype IVSI-6, and previous splenectomy were independent risk factors for the appearance of both, venous and arterial thrombosis. The prevalence of venous thrombosis in TM and TI were 2.49% and 7.7% respectively, whereas that of arterial thrombosis was estimated at 0% for TM and 4.2% for TI. By removing central venous catheter events the prevalence of venous thrombosis in TM was calculated 1.66%. Fourteen of the 17 venous thrombotic episodes and all arterial thrombotic events occurred in splenectomized patients. These events occurred 8 days to 45 years post-splenectomy. Platelet count at the onset of thrombotic event ranged between 250 and 1400x103/μl, but was not a significant factor for the event. TI patients with a thrombotic episode were sporadically transfused, while they were splenectomised due to severe hypersplenism. *Conclusions.* TI patients exhibit substantially higher risk for both, venous and arterial thrombosis as compared to TM patients. Splenectomy and disease genotype, associated with an intermediate phenotype were shown to be the major contributing factors for thrombosis. For TI patients, not regularly transfused, the presence of abnormal and of nucleated RBCs in circulation and endothelial damage are considered major factors contributing to thrombosis.

0167

NEW INSIGHTS ON β-THALASSEMIA IN GAZA: HIGH FREQUENCY AND MILDER PHENOTYPE AMONG IVS1-1 HOMOZYGOUS PATIENTS WITH HIGH LEVELS OF FETAL HEMOGLOBIN

H Ghoti,[1] D Filon,[2] H Abed,[3] H Jeadi,[4] R Rusrus,[4] E Rachmilewitz[1]

[1]*Edith Wolfson Medical Center, Holon, Israel*
[2]*Hadassah Hebrew University Medical Center, Jerusalem, Israel*
[3]*Netherlands*
[4]*European Hospital of Gaza, Gaza, Palestinian Territory*

Background. Beta thalassemia is a very common disease in the Gaza strip. The rate of carriership is estimated to be 4.3% and there are around 300 homozygous patients treated by transfusions. Premarital screening is being implemented since 2000 and this is the only mean of prevention as prenatal diagnosis is not performed routinely. The aim of the present study is to understand better the correlation between genotype and phenotype in the thalassemic population of Gaza. *Patients and Methods.* Peripheral blood samples were obtained from 82 patients with β thalassemia major from 54 families, after signing an informed consent. Analysis of β-globin mutations and XmnI polymorphism were carried out using PCR followed by either Allele Specific Oligonucleotide hybridization, sequencing and endonuclease restriction. *Results.* Thirteen different mutations have been identified, which have been previously describes in Mediterranean populations. However, the distribution of the mutated alleles among the patients in Gaza is quite unique. The most common mutation was IVS1-1 G-A, which was prevalent in 31.5% of the thalassemic alleles. The IVS1-110 mutation, which is the most frequent mutation in the Eastern Mediterranean as well as in other Arab countries, was found in 25% of alleles. In addition, the mutations of IVS1-6, Frameshift 5, Nonsense 39, IVS1-(-1) were found among 9%, 8%, 7% and 6% of the chromosomes respectively. Two rare mutations were also found. The novel Poly A mutation AATAAA- A——-, which was reported previously only in Gaza, was found in an additional family. In addition, the 25 bp deletion which is prevalent in the Arab Golf countries, mostly in Bahrain, was first diagnosed in a Palestinian family. Fifteen patients were homozygotes for IVS1-1 and 20 were homozygotes for IVS1-110 mutations. The homozygotes for IVS1-1 mutation required less blood, since they consumed only 13 packed red cell units a year while those with IVS1-110 consumed 24 blood units a year ($p<0.00001$). Their mean hemoglobin level was 8.3gr/dl and 7.68gr/dl (Figure A,B) respectively, and there was no significant difference in age or gender distribution between these two groups. The reason for the difference in blood requirements between the 2 groups are over expression of fetal hemoglobin (HbF): The mean HbF level was 46% in the homozygotes for IVS 1-1 and 6% for those with IVS 1-110 ($p<0.0001$) (Figure C). The XmnI polymorphism at the gamma globin gene, which is known to be associated with elevated HbF levels, was found in 7 out of 15 IVS1-1 patients. The XmnI positive patients had HbF level of 76.86% compared to 18.76% ($p<0.0001$). *Conclusion.* The distribution of β-thalassemia among patients in Gaza is unique with a highest frequency of IVS1-1 mutation which is a βo mutation resulting in severe β thalassemia major. Counter to expectation, these patients required less blood transfusions, due to persistent production of HbF. The association between IVS 1-1 mutation with high expression of HbF has not been previously described.

MATERNAL AND FETAL COMPLICATIONS IN THALASSEMIA MAJOR: OUTCOMES FROM A 10 YEAR STUDY AT MOUNT SINAI HOSPITAL IN TORONTO, CANADA

R Ward,[1] E Warner,[1] M Sermer[2]

[1]*University Health Network/University of Toronto, Toronto, Canada*
[2]*Mount Sinai Hospital/University of Toronto, Toronto, Canada*

Background. Thalassemia major is an inherited disorder of ineffective erythropoiesis, resulting from severely defective or absent production of beta globin chains. Lifelong chronic transfusion support leads to iron overload, affecting the pituitary-gonadal axis as well as cardiac and hepatic siderosis. With advances in the detection of iron overload and improved chelation therapy, it has been increasingly possible for women to successfully undergo pregnancy. This is the first centre in North America to date that has studied pregnancy outcomes in this population. *Aims.* To identify maternal and fetal complications in pregnant women with Beta Thalassemia Major, with reference to the Ontario population. *Methods.* A retrospective study of consecutive deliveries of thalassemia major patients at Mount Sinai Hospital Special Pregnancy Program, from September 2000 through December 2010 was conducted. Maternal demographics, pregnancy complications including transfusions, mode of delivery, apgar scores and fetal complications were recorded. Patients were identified from the Special Pregnancy Database and the Delivery Databases of Mt. Sinai Hospital. Electronic patient records from the Toronto General Hospital and Mt.Sinai Hospital paper charts were reviewed. *Results.* A total of 44 women were identified. There were 41 singleton and 2 sets of twin live birth deliveries and 1 neonatal death. Median maternal age was 32(range 21 to 41) years with a median gestational age of 38.5 (range 27 to 41) weeks. Only 15% of women delivered before 37 weeks. For 56% of women it was their first live birth. 39% of deliveries were by C-section. One mother developed mitral regurgitation during the pregnancy. Gestational diabetes developed in 9% and pregnancy induced hypertension (PIH) in 2/44 (4.5%) There were no cases of intra-uterine growth retardation. Median birth weight was 3158 (930-4860). 13% of neonates were born less than 2.5 kg. Mean apgar scores at 1 and 5 minutes were 8.3 ± 1.5 and 9.0 ± 0.2 respectively. There were no fetal anomalies. *Summary/Conclusions.* Although the C-section rate was higher than the 2005/2006 Ontario rate of 28% it was at the lower end of the reported range in Thalassemia, of 26-93%. This relatively low C section rate probably reflects optimal transfusion support and suppression of marrow expansion, preserving normal pelvic anatomy. Preterm labour and neonates with a low birth weight were higher than the 2005/ 2006 Ontario rates of 8.6% and 7% respectively. Gestational diabetes was higher than the 4% found in the Ontario data, indicating pituitary and pancreatic iron deposition. Other maternal and fetal outcomes in our study did not differ from averages for healthy women. Pregnancy outcomes in women with thalassemia major are excellent if care is provided by an experienced multidisciplinary team including hematologists and high risk pregnancy obstetricians.

0169

RELATIONSHIP BETWEEN SERUM FERRITIN AND LIVER IRON CONCENTRATION IN HEMOGLOBIN E THALASSEMIA

T St Pierre,[1] N Olivieri,[2] V Thayalasuthan,[2] G Muraca,[2] D Weatherall,[3] C Kim,[2] A Premawardhena,[4] A Perera,[5] A O'Donnell[3]

[1]*The University of Western Australia, Crawley, Australia*
[2]*University Health Network, Toronto, Canada*
[3]*Weatherall Institute of Molecular Medicine, Oxford, United Kingdom*
[4]*University of Kelaniya, Ragama, Sri Lanka*
[5]*National Thalassaemia Centre, Kurunegala, Sri Lanka*

Background. Hemoglobin E thalassemia, the most common form of severe thalassemia worldwide, is associated with body iron loading even in the absence of frequent transfusions. *Aims.* The aim of the study was to determine the degree of relationship between serum ferritin and liver iron concentration in hemoglobin E thalassemia patients. *Methods.* Approvals were obtained from the human research ethics committees at The University of Kelaniya, The University of Western Australia, and the University Health Network, Toronto. Informed consent was obtained from all subjects. Hemoglobin E thalassemia subjects were recruited from the National Thalassaemia Centre, Kurunegala, Sri Lanka. Patients were then categorized into to two groups (1) those who had received less than or equal to 20 transfusions lifelong (N=25) and (2) those who had received more than 20 transfusions lifelong (N=61). LIC was measured for all subjects using spin density projection assisted R2-MRI (FerriScan®). *Results.* The mean age of subjects was 27.3 ± 16.1 [range 7.8 to 57.4] years for group 1 and 23.5 ± 10.1 [range 8.3 to 60.2] years for group 2. The figure shows the relationships between serum ferritin and LIC for groups 1 and 2. Solid lines are linear regression fits to the data; gradient 29.9 (± standard error 10.1) ng ferritin/L per mg Fe/g dw for group 1 and gradient 71.0 (± standard error 15.1) ng ferritin/L per mg Fe/g dw for group 2. Dashed lines represent the 95% confidence bands of the line of best fit. For group 1, there was a weak (r^2=0.28) but significant (p=0.007) correlation between serum ferritin and LIC. For group 2, there was also a weak (r^2=0.27) but significant (p< 0.0001) correlation with LIC. However, for both groups the 95% prediction intervals for LIC for a given serum ferritin were so broad as to make serum ferritin of little clinical value in determining liver iron loading. For example, a serum ferritin of 1500 ng/L was associated with 95% prediction intervals of LIC of 21.2 to 83.1 mg Fe/g dw (group 1) and 0.3 to 13.2 mg Fe/g dw (group 2). *Conclusions.* Serum ferritin measurements have limited clinical value for assessing the degree of iron loading of patients with hemoglobin E thalassemia.

PUBERTAL EVALUATION OF FEMALES AND MALES WITH B-THALASSEMIC MAJOR IN RELATION TO CHELATION REGIMEN

M El Alfy, I Ragab, I Abdeen, M El Tobgy, E Abdel-Aziz, H ElSedfy

Ain Shams University, Cairo, Egypt

While transfusion and iron chelation therapy have increased longevity of patients with beta-thalassemia major (BTM), yet puberty disorders and infertility have become more apparent. *Aim of the study.* To evaluate the prevalence of delayed puberty and the pituitary gonadal axis in transfusion-dependent BTM patients in relation to chelation type and degree of iron overload. Also, to assess the spermatogenic function in pubertal males with BTM males. *Patients and Methods.* A two year prospective study of 93 regularly transfused thalassemics; 42 males and 51 females; 14 years and above. Sixty-Two (66.7%) were on deferiprone (DFP), 21 (24%) on desferrioxamine (DFO), and 10(9.3%) on combination DFO & DFP. At study entry, after baseline compliance analysis, endocrinal evaluation were performed. Those with delayed and arrested puberty were tested for pituitary -testicular axis and pituitary-ovarian function by gonadotrophin-releasing hormone (GnRH) and human chorionic gonadotropin (HCG) tests. Spermiograms were done for pubertal males. Patients with delayed puberty with good pituitary and gonadal responses were shifted to combined chelation therapy, and yearly pubertal assessment and spermiogram for pubertal males. *Results.* Median age was 20 years, Thirteen male patients (30.9%) had normal puberty; they were on either DFP 7(53.8%), DFO 2(15.4%) or combination 4(30.8%), while twenty- nine (69%) had puberty disorder (21 on DFP, 8 on DFO); Out of non pubertal males; 13(44.8%) had good pituitary and testicular response to LHRH stimulation. Forty seven % of studied females had pubertal disorders; delayed puberty (13.7%), primary amenorrhea (17.6%) or secondary amenorrhea (15.7%) and 75% of the delayed puberty were on DFO alone. During two years follow-up using intensive combination chelation therapy(DFP + DFO), 7 of good pituitary responders males progressed to puberty and six females had reversal of their hypogonadism (24.9%).Total sperm count and sperm motility were decreased in 4 (25%) and 6 (35.3%) patients respectively. In conclusion, The risk of hypogonadism in B-TM patients remained high. Intensive combination chelation for 2 years lead to better sexual development in both sexes.

Background. T2* Magnetic Resonance Imaging (MRI) technique allows noninvasive quantification of organ-specific iron burden, playing a key role in the management of thalassemia major (TM) patients. There are few data on the incidence of heart failure and arrhythmias in TM patients according to baseline T2* values. *Aims.* The aim of this study was to establish prospectively the risk of cardiac complications in a large cohort of well-treated TM patients. *Methods.* We considered 527 TM patients (252 males, mean age 30±9 years) for who clinical data relative to a period of 5 years after the first MRI were collected in a central data base. At time of the first scan mean ferritin levels were1653±1559 ng/l, global heart was 27±13 ms, and excellent/good level of compliance were present in the 96% of the study population. *Results.* At 5 years of follow-up, we recorded 24 cardiac events: 4 episodes of cardiac failure, 15 of arrhythmia, 1 of pulmonary hypertension and 4 of other cardiac complications. The majority of these events (21/24) happened within the first 24 months subsequent to the MRI, so we considered this follow-up period. At the first MRI scan, in patients with cardiac complications the global heart T2* was 22.5 ±12.4 ms. In comparison with global heart T2* values ≥20 ms, there was not a significantly increased risk of cardiac complications associated with global heart T2* values <20 ms (HR= 2.028 P=0.09). In the heart failure patients the global heart T2* was 19±12 ms. In comparison with global heart T2* values ≥20 ms, there was not a significantly increased risk of heart failure associated with global heart T2* values <20 ms (HR=1.9 P=0.524) or <10 ms (HR=2.6 P=0.443). In the arrhythmic patients the global heart T2* was 25±13 ms. In comparison with global heart T2* values ≥20 ms, there was not a significantly increased risk of arrhythmia associated with global heart T2* values <20 ms (HR=2.1 P=0.179) or <10 ms (HR=0.8 P=0.824). During the follow up changes in the chelation therapy (type and/or dose-frequencies) were found in > 25% of the study population. *Conclusion.* We detected very few cardiac events, almost all concentrated in the first 24 months. In a large cohort of well-treated TM patients heart T2* lost its power in predicting cardiac events probably due to a patient-specific adjustment of the chelation therapy MRI-guided.

Background. No data are available in literature about possible different changes in cardiac and hepatic iron and in cardiac function in thalassemia major (TM) patients treated with sequential deferipron-desferrioxamine (DFP-DFO) versus deferasirox (DFX). Magnetic Resonance (MR) is the unique non invasive suitable technique to evaluated quantitatively this issue. *Aims.* Our aim was to prospectively assess the efficacy of the DFP-DFO vs DFX in a large cohort of TM patients by quantitative MR. *Methods.* Among the first 1135 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, 392 patients performed a MR follow up study at 18±3 months according to the protocol. We evaluated prospectively 35 patients treated with DFP-DFO versus 80 patients treated with DFX between the 2 MR scans. Cardiac iron was evaluated by T2* multiecho multislice technique. Biventricular function parameters were quantitatively evaluated by cine images. Liver iron was measured by T2* multiecho technique. *Results.* Excellent/good levels of compliance were similar in the two groups (DFP-DFO 97.1% vs DFX 98.8%; P=0.544). Among the patients with no significant myocardial iron overload (MIO) at baseline (global heart T2*≥20 ms), there were no significant differences between groups to maintain the patients without myocardial iron overload (DFP-DFO 96% vs DFX 98%; P=0.536). Among the patients with MIO at baseline, in both groups there was a significant improvement in the global heart T2* value (DFP-DFO: 4.8±3.9 ms P=0.004 and DFX: 3.5±4.7 P=0.001) and a significant reduction in the number of pathological segments (DFP-DFO: -3.2±3.8 P=0.026 and DFX: -2.4±3.8 P=0.003). Only in sequential group there was a significant increment in the left and right ventricular ejection fractions (4.3±5.1% P=0.035 and 6.7±6.6% P=0.017, respectively). The improvement in the global heart T2* was not significantly different between groups. The improvement in the left as well in the right ventricular ejection fractions was significantly different between groups (P=0.009 and P=0.015, respectively) (Figure 1). Among the patients with hepatic iron at baseline (T2*<9.2 ms), only in the DFX group there was a significant improvement in the liver T2* value (2.6±5.3 ms P=0.001). The changes in liver T2* were significantly higher in DFX group than in DFP-DFO (0.5±2.0 ms) group (P=0.030). *Conclusions.* Prospectively no significant differences on cardiac iron were found between TM patients treated with sequential DFP-DFO and TM patients treated with DFX, although the DFP-DFO was significantly more effective in improving biventricular function. DFX was significantly more effective in reducing hepatic siderosis.

Clinical thrombosis

0173

SELECTION CRITERIA OF PATIENTS WITH VENOUS THROMBOEMBOLISM FOR LABORATORY INVESTIGATION OF INHERITED THROMBOPHILIA

E Rossi, T Za, A Ciminello, S Betti, G Leone, V De Stefano

Institute of Hematology, Catholic University, Rome, Italy

Background. Laboratory investigation for inherited thrombophilia is warranted in young patients, especially those with severe venous thromboembolism (VTE) occurred spontaneously or recurrently. Investigation of older patients is discouraged, especially when events are mild or provoked. Such policy could miss a number of carriers, leaving undiagnosed their kindreds. *Aims.* To investigate whether clinical parameters are predictive of the presence of inherited thrombophilia in VTE patients. *Patients and Methods.* We analyzed the files of 1,835 patients referred to our Thrombosis Center between 1996 and 2009. The median age at the first VTE was 37 years (range 0-89); 736 were males (40.1%). Patients were stratified according to family history of VTE, age of first VTE (<45 years), type of first VTE (defined severe for proximal DVT and/or pulmonary embolism and mild for distal DVT or superficial vein thrombosis), circumstances of first VTE (unprovoked or provoked), history of recurrent VTE. Multiple regression was carried out labelling as dependent variable diagnosis of overall thrombophilia or severe thrombophilia (antithrombin or protein C or protein S deficiency, homozygous or multiple defects, n=211) or mild thrombophilia (heterozygous factor V Leiden or prothrombin G20210A, n=415). *Results.* Diagnosis of overall thrombophilia was associated with family history (p=0.005), severity of VTE (p=0.008) and recurrent events (p<0.0001); the aforementioned criteria were all absent only in 8% of patients with thrombophilia. Among patients with thrombophilia 30% had clinical onset >45 years, 62% had a first provoked VTE, and 11% had both. Severe thrombophilia was associated with family history (p=0.02), first unprovoked VTE (p=0.015) and recurrent events (p=0.04). Mild thrombophilia was associated with family history (p=0.05), severity of VTE (p=0.03) and recurrent events (p<0.0001). *Conclusions.* Family history, clinical severity and recurrence of VTE are strong predictors of inherited thrombophilia, and at least one of these parameters is present in more than 90% of cases. Selection of the patients to be investigated according only to age and/or circumstances of the first VTE could miss diagnosis of thrombophilia in a relevant number of cases.

0174

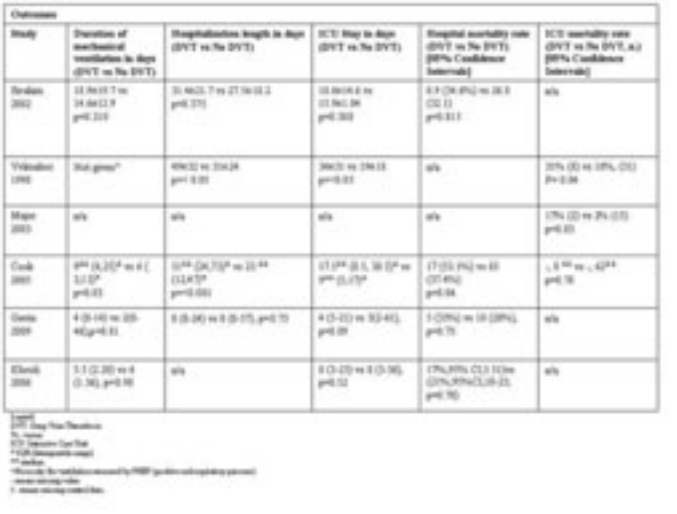
THE IMPACT OF VENOUS THROMBOEMBOLISM IN CRITICALLY ILL PATIENTS: A META-ANALYSIS OF MAJOR CLINICAL OUTCOMES

A Malato,[1] F Dentali,[2] F Fabbiano,[3] G Saccullo,[4] S Siragusa[4]

[1]*Policlinico Universitario di Palermo,Istituto di Ematologia, Palermo, Italy*
[2]*Università dell'Insubria,Varese, Varese, Italy*
[3]*Ospedali Riuniti Villa Sofia-Cervello, Sofia-Cervello, Italy*
[4]*Istituto di Ematologia,Policlinico Universitario di Palermo, Palermo, Italy*

Background. Critically ill patients are at high risk of developing venous thromboembolism (VTE) during their stay in the intensive care unit (ICU) because of premorbid medical and surgical conditions. The clinical consequences of Deep Vein Thrombosis (DVT) have the potential to be serious yet are frequently unrecognized in the Intensive Care Unit (ICU). In contrast to the extensive documentation on the short and long-term outcomes of patients with DVT evaluated in other clinical settings, little is known about the clinical course of this disease in the ICU setting. We hypothesized that both undetected and clinically evident VTE would affect the prognosis of critically ill patients. *Purpose.* To systematically review whether a diagnosis of DVT in critically ill patients affects clinically important outcomes including length of stay, duration of mechanical ventilation and mortality. *Material and Methods.* MEDLINE and EMBASE databases were searched up to June 2010. Two reviewers performed study selection independently. Studies were selected if evaluate one or more of the following outcomes: hospital and ICU mortality, duration of patient stay in hospital and in ICU, and duration of mechanical ventilation. Two investigators independently extracted and reviewed data from each study; including study and patient characteristics and outcomes. Association between DVT and hospital and ICU mortality, and the mean difference of duration of patient stay in hospital and in ICU, and duration of mechanical ventilation in patients with and without DVT were calculated using a random-effects model (DerSimonan and Laird method). Pooled results are reported as relative risk (RR) and mean difference and are presented with 95% confidence interval (CI) and with 2-sided P values. A P value of .05 or less was considered statistically significant. Statistical heterogeneity was evaluated using the I2 statistic, which assesses the appropriateness of pooling the individual study results [22]. The I2 value provides an estimate of the amount of variance across studies due to heterogeneity rather than chance. Cohen's Kappa for inter-rater agreement was used to assess inter-rater reliability. *Results.* Six studies for a total of 1518 patients were included in the systematic review. Patients diagnosed with DVT compared to those without DVT had increased ICU and hospital stay (7.3 days (95% CI 1.4 to 13.2; P= 0.02) and 16.5 days (95% CI 1.51 to 30.59; P= 0.03), respectively. Duration of mechanical ventilation appeared to be increased in patients with DVT although this difference was not statistically significant (weighted mean difference: 3.41 days 95 % CI -1.12 to 7.94; P=0.14). Patients diagnosed with DVT also had a marginally significant increase in the RR of hospital mortality (RR 1.31 95%CI,0.99 to 1.74,P=0.06), and a non statistically significant increase in the RR of ICU mortality (RR 1.96; 95% CI 0.74 to 5.19; P = 0.17). *Conclusions.* A diagnosis of DVT upon ICU admission appears to affect clinically important outcomes including length of ICU and hospital stay and hospital mortality. Further research involving larger prospective study designs are warranted.

Table 1.



0175

VENOUS THROMBOEMBOLISM IN ADOLESCENTS WITH CANCER - A SINGLE CENTRE EXPERIENCE

P Kumar, S George, C Crehan, S Stoneham

University College London Hospital, London, United Kingdom

Background. The association between cancer and venous thromboembolism (VTE) is well documented with a reported incidence of 4.1% from a large adult series. Risk factors for thrombosis include the underlying neoplasm and its therapy, patient age, other predisposing medical conditions and immobilization. Younger age is considered protective. The presence of central venous catheters (CVC) is perhaps the single most important predisposing factor in the development of VTE in children. The British Committee for Standards in Haematology (BCSH) has recently released a guideline on the prevention, investigation and management of VTE in children below 16 years of age. In March 2010 the NICE VTE thromboprophylaxis guidelines for adults aged 18 and above were introduced. Our adolescent unit treats approximately 72 teenagers (aged 13-19) with cancer each year; most of whom have CVCs inserted to facilitate treatment. There is a paucity of evidence for the risk of developing a VTE across this specific age range and lack of clarity in recommendations for patients between 16-18 years of age. This has prompted an evaluation of the VTE episodes in our unit and to audit our procedure against both current national guidelines. *Aims.* 1) To identify incidence of VTE in an adolescent cancer population and any specific patient characteristics and risk factors. 2) Audit our population and current practice

against both sets of guidance. 3) Confirm our diagnostic methods and treatment follow national guidelines. *Methods.* Retrospective casenote review of all adolescents with cancer diagnosed between 2005 and 2010 who developed a clinically significant VTE during treatment. Patient records were cross referenced with pharmacy records of patients treated with dalteparin (treatment of choice in our unit). Data were collated on a proforma and entered onto an electronic database. *Results.* 483 patients were treated in our unit between 2005 and 2010. 50/483 developed VTE during the course of their treatment (11.6%). 29/50 episodes were in girls, and 21/50 in boys. At least 21 VTE were line-associated. 7 patients had sagittal sinus thromboses of which 5 were contemporaneous to L-asparaginase. L-asparaginase administration was also associated with 11 other VTE (line-related, lower limb DVT and PE). Other notable risk factors include immobility due to surgery in 4 patients. Of note, one patient who was appropriately risk assessed pre-surgery (managed with graduated compression stockings and dalteparin) subsequently developed a line-associated VTE. There was a high degree of compliance with diagnostic techniques and therapy as recommended by both the BCSH and NICE guidelines. *Summary/Conclusions.* Adolescents with cancer are at significant risk of developing VTE; in particular female patients with indwelling CVCs. Our incidence of VTE is higher than reported in adult patients with a cancer diagnosis. At the very least, all adolescent patients should be screened using the NICE guidelines. However, further analysis of risk factors and morbidity will help develop tailored recommendations for this specific patient population. <br type='_moz' />

SUCCESSFUL IMLPLEMENTATION OF AN ELECTRONIC (COMPUTER BASED) MODEL OF MANDATORY RISK ASSESSMENT FOR VENOUS THROMBOEMBOLISM IN PATIENTS ADMITTED TO A MEDIUM SIZED GENERAL HOSPITAL

N Ahmad, N Ford, P Paul, R Kanji, D Fudulu

Burton Hospitals NHS FT, Burton on Trent, United Kingdom

Background. Venous thrombo-embolism (VTE) amongst the hospitalised patients is a serious and prevalent problem jeopardizing patient safety. Most consensus based guidelines on this subject highlight the need for recognising and identifying the individuals at risk. The process of risk assessment allows the health care providers to take appropriate preventive measures e.g. administration of prophylactic doses of Enoxaparin. The success of the risk assessment process itself depends on awareness amongst the health providers about this issue. This is best achieved by putting in place a system of alerts, reminders and mandatory intervention. *Aim.* Over the last 3 years, we developed and implemented a computer based electronic model of mandatory assessment for the risk of VTE in all adult patients admitted to our hospital. *Methods.* Using the fully integrated Electronic Patient Record system, a computer program was developed to introduce VTE risk assessment as a step in the admission process. This program also provided electronic reminders to the health care staff to perform the VTE risk assessment and prescribe thrombo-prophylaxis. As an electronic tool it makes auditing easy and accurate and enables the clinical leadership to address areas with lesser compliance. We have now analysed our VTE risk assessment and thrombo-prophylaxis data for the last 33 months and our results show evidence that electronic models of VTE risk assessment is practically possible and effective. *Results.* Before the introduction of our VTE risk assessment tool, there was no formal process of risk assessment. The tool raised the profile of VTE risk assessment throughout the hospital and there was a rapid and significant increase in the number of patients having formal VTE risk assessment. In the last 3 months we have achieved a hospital wide average of 95.6% of adult in-patients being assessed for the risk of VTE. Prior to the implementation of risk assessment, the only measure of VTE prevention was prescribing rates for Enoxaparin prophylaxis. Our data shows that before the implementation of the tool, an average of 26% of all adult in-patients received thrombo-prophylaxis. The use of this tool has improved the thrombo-prophylaxis by about 10%. Nevertheless, the data shows that there still is a gap between the number of patients assessed and those prescribed thrombo-prophylaxis. In the last three months we achieved VTE risk assessment in over 95% of patients admitted, demonstrating 51.6% at risk of VTE, but only 35% received Enoxaparin. *Summary/Conclusions.* Risk assessment for VTE is an essential step for reducing hospital acquired thrombosis and enhancing patient safety. Our data shows that an electronic model of VTE risk assessment is easy to implement and successful in achieving high rates of assessment. However, the prescription of thrombo-prophylaxis lags behind and this needs to be studied further. In the recent years, the focus has been on the need for accurate risk assessment. Now that computer based systems make that achievable, is it time to shift our focus to practical implementation of thrombo-prophylaxis?

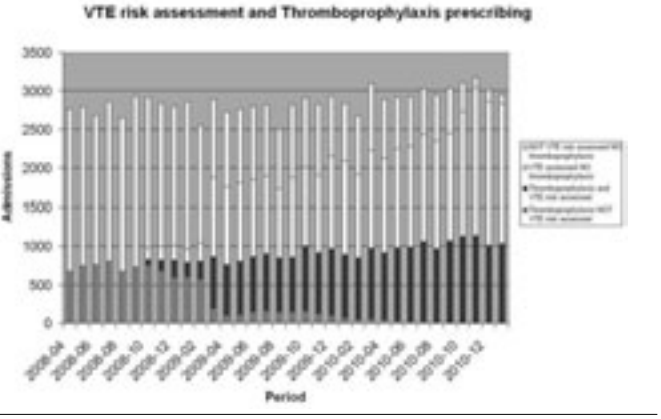

Figure 1. Summary snap shot of our data.

0177

THE RISK OF VENOTHROMBOEMBOLISM (VTE) AMONG ASIAN PATIENTS (PTS) WITH LYMPHOPROLIFERATIVE DISORDERS (LPD) RECEIVING IMMUNOMODULATORY AGENTS (IMIDS) IS LOWER, BUT CORRELATES WITH CUMULATIVE EXPOSURE

L Kam,[1] J Ng,[1] H Leong,[1] S Han,[2] Y Lee,[1] S Gopal,[1] W Hwang,[1] L Ang,[1] T Goh,[1] L Lee,[1] C Tan[1]

[1]*Haematology, Singapore General Hospital, Singapore, Singapore*
[2]*Christ's College, Cambridge University, Cambridge, United Kingdom*

Background. In contrast to western populations, the risk of VTE in Asian pts with LPD receiving IMIDS including thalidomide and lenalidomide is unknown. With limited evidence postulating a negligible risk, VTE prophylaxis is commonly omitted. *Aims.* We sought to evaluate the incidence and risk factors of VTE in our LPD pts exposed to IMIDS, and explore the role of anti-platelet agents (APA) in the prevention of VTE. *Methods.* From the comprehensive multiple myeloma (MM) and non-Hodgkin's lymphoma (NHL) registry maintained in a tertiary institution, newly diagnosed pts from 2000 to 2009 with an objectively confirmed diagnosis of VTE were identified. Their characteristics and exposure to IMIDS and APA were compared against other pts in the registry. Thalidomide and lenalidomide were available for treatment of LPD from 2003 and 2008 respectively. Cumulative thalidomide exposure is measured in milligrams- week (mg-wk) [dose x duration]. Thromboprophylaxis with warfarin or heparin was not mandated in this patient population receiving MM treatment. *Results.* Among 731 consecutive LPD pts (320 MM and 411 NHL) entered into the registry, and prospectively followed, 239 pts (33% overall, 72% in MM and 2% in NHL) have been exposed to IMIDS, and 17 developed VTE event (7.1%). All VTE events were reported in MM pts only. Risk of VTE was not associated with pt (gender, ethnicity, age) or disease (stage, tumor burden, immunoglobulin subtype) characteristics at presentation. The median time to VTE was 16 months (range, 2 -134) from the time of MM diagnosis. Five patients developed VTE during induction treatment, while 12 developed VTE post-induction (maintenance or relapse)($P<0.001$). Among pts exposed to thalidomide (N=235), the median cumulative dose was 3750 mg-week (range, 100 -37,100). VTE risk was 3.4% for cumulative dose less than 3750 mg-wk, compared with 10.5% for patents receiving more than 3750 mg-wk ($P=0.03$). Among 239 pts with complete medication records available, 72 received APA (aspirin, ticlopidine, clopidogrel) indicated for other co-morbidities while receiving IMIDS. Interestingly, there was a near significant trend of a higher VTE risk for patients receiving concomitant APA (11.1%) compared with those who did not (4.8%) ($P=0.07$). *Conclusions.* Although VTE risk in Asian pts receiving IMIDS is lower compared with Western literature, it still confers a significant morbidity risk. Events appear to occur later in the course of the disease and were significantly influenced by the cumulative exposure to IMIDS. Concomitant use of an APA did not preclude the risk of developing VTE. Perhaps, the co-morbidities which indicated the use of APA could be risk factors for VTE. As IMIDS have become an integral part of MM treatment, and the survival of MM patients have improved, an optimal strategy for prophylaxis needs to be defined and validated, since duration of IMID use tends to be longer in MM pts.

0178

THE CLINICAL SIGNIFICANCE OF JAK2V617F MUTATION FOR PHILADELPHIA-NEGATIVE CHRONIC MYELOPROLIFERATIVE DISEASES IN PATIENTS WITH SPLANCHNIC VEIN THROMBOSIS

I Yonal,[1] B Pinarbasi,[2] F Hindilerden,[3] V Hancer,[4] M Nalcaci,[1] S Kaymakoglu,[5] R Diz-Kucukkaya[4]

[1]*Istanbul University Istanbul Medical Faculty, Division of Hematology, Istanbul, Turkey*
[2]*Istanbul University Istanbul Medical Faculty,Division of Gastroenterohepatology, Istanbul, Turkey*
[3]*Istanbul Bilim University, Division of Hematolgy, Istanbul, Turkey*
[4]*Istanbul Bilim University, Division of Hematology, Istanbul, Turkey*
[5]*Istanbul University Istanbul Medical Faculty, Division of Gastroenterohepatology, Istanbul, Turkey*

Background. Polycythemia vera (PV), essential thrombocythemia (ET) and idiopathic myelofibrosis (IMF), collectively known as Philadelphia-negative (Ph-negative) chronic myeloproliferative diseases (MPDs) represent commonest causes of splanchnic vein thrombosis (SVT), including Budd-Chiari syndrome (BCS) and portal vein thrombosis (PVT). JAK2V617F mutation has been demonstrated in most Ph-negative chronic MPDs. High prevalence of JAK2V617F mutation in SVT reported in recent studies raised suspicion of an underlying MPD. *Aims.* We assessed the diagnostic value of JAK2V617F mutation in 68 patients with SVT (42 PVT, 19 BCS, 7 combined PVT and BCS) under follow up at outpatients clinics of Hematology and Gastroenterohepatology Departments of Istanbul Faculty of Medicine between years 2007 and 2010. *Methods.* Patients with SVT presenting with portal hypertension with/without cirrhosis were enrolled. Screening was performed for prothrombotic states, including genotyping for factor V Leiden, factor II, protein C, protein S, and antithrombin deficiencies, homocysteinemia and antiphospholipid antibodies. JAK2V617F mutation was detected by fluorescent resonance energy transfer probes and LightCycler techniques. Genotype assessment was based on melting curve analysis. *Results.* Patient features with respect to JAK2V617F mutation status are demonstrated in Table 1.

Table 1. Patient features regarding JAK2V617F status in SVT.

All patients	Without JAK2V617F, n=39 (mean [SD])	With JAK2V617F, n=29 (mean [SD])	P
Age, y	42 [12.5]	45 [12.7]	0.398
Women, %	22 (56.4%)	19 (65.5%)	0.611
Hemoglobin, g/dl	12.2 [2.3]	12.8 [2.8]	0.312
Hematocrit, %	36.6 [7.18]	38.8 [8.46]	0.263
WBC count, /mm³	5803 [3114]	10525 [6547]	0.001
Platelet count, /mm³	179333 [153921]	369103 [300724]	0.004
LDH, U/L	431 [184.5]	523 [229.1]	0.08
Cirrhosis, %	21 (53.8%)	14 (48.3%)	0.834
Pro-thrombotic states ,%	15 (38.5%)	5 (17.2%)	0.103
Combined thrombosis ,%	2 (5.1%)	5 (17.2%)	0.127
Essential thrombocythemia ,%	1(2.6%)	5 (17.2%)	0.016
Polycythemia vera ,%	1(2.6%)	8 (27.6%)	0.002

JAK2V617F mutation was present in 42.1% of patients with BCS, 38.1 % of PVT and 71.4% of combined PVT and BCS. Thirteen of 15 (86.6%) with overt MPD and 16 of 53 (30.1%) without overt MPD (patients with either normal blood counts or cytopenias), including 6 of 16 with BCS (37.5%), 7 of 33 with PVT (21.2%) and 3 of 4 with combined BCS and PVT (75%) possessed JAK2V617F mutation. JAK2V617F was associated with significantly higher platelet and leukocyte counts (Table 1). Most patients with JAK2V617F mutation had peripheral blood cell counts within normal range except for higher mean values for leukocytes (10525/mm3 (SD 6547). There was a trend for higher LDH levels in JAK2V617F mutation carriers than in noncarriers (mean 523 U/L (SD 229.1), mean 431 U/L (SD 184.5), respectively; p=0.08). There was a significant positive correlation between JAK2V617F mutation status and leukocyte and platelet counts (r=0.445 and r=0.384, respectively). Receiver Operating Characteristic (ROC) curve analysis determined a platelet count of 190000/mm3 (area under curve; AUC=0.724, p=0.002) and a leukocyte count of 8150/mm3 (AUC=0.76, p=0.001) as best cutt-off values for highest sensitivity and specificity ratios of JAK2V617F mutation in SVT. No relationship was observed between prothrombotic risk factors, and JAK2V617F status, sites of thrombosis (PVT or BCS), presence of combined thrombosis and Hb, Htc, platelet and leukocyte counts. *Conclusions.* Signs of myeloproliferation may not be evident on peripheral blood if SVT is accompained by portal hypertension and a hypersplenic state. In our study, despite absence of overt signs of MPH, a substantial proportion of patients with SVT were shown to carry the JAK2V617F mutation. We found no relationship between prothrombotic risk factors and JAK2V617F status, site of thrombosis and presence of combined thrombosis. Our experience confirms that simple and rapid JAK2V617F testing on peripheral blood represents a key element of diagnosis of latent MPD in SVT.

0179

CLINICAL PHENOTYPE IN CONGENITAL ANTITHROMBIN DEFICIENCY

T Prigancova, A Batorova, D Jankovicova

National Hemophilia Centre, Bratislava, Slovakia

Backround. Antithrombin (AT) is a potent inactivator of thrombin and factor Xa and the major inhibitor of blood coagulation. Inherited AT deficiency is considered as the strongest genetic factor increasing the risk of thrombosis 20-50 fold. The prevalence of heterozygous AT deficiency in general population ranges between 0.02% and 0.3%, its proportion among the patients with venous thrombosis (VT) and pulmonary embolism (PE) is about 5%. AT level may be detected by functional and immunologic assays, however, the reduction of functional activity is more predictive for the risk of thrombosis. At least 70% of a normal functional level is essential to ensure effective hemostasis control. Most patients with congenital AT deficiency have AT levels between 40% and 60%. Wehether the risk for thrombosis correlates with the severity of AT decrease is still not clear. *Methods.* We present the clinical phenotype in 37 patients with inherited AT deficiency (22F/15M) with a mean age of 41 yrs (range 9-65 yrs) and mean AT activity of 51±9%. The diagnosis was based on repeated AT testing (chromogenic assay Anrithrombin Berichrom, Siemens) and exclusion of acquired causes of AT decrease. The prevalence, type and recurrence of thrombosis, age at first thrombosis, concomitant risk factors and the need for sustained anticoagulation therapy were evaluated with regard to gender and antithrombin levels of 30-40% and >40%. *Results.* The prevalence of VTE and PE in entire patient group was 28/37 (76%) and 10/37(27%), respectively. The first episode occured at mean age of 29 yrs. Four patients had symptoms of ischemic stroke and two sinus venous thrombosis. Nine patients with AT of 36-66% were asymptomatic at the diagnosis in age 22-57 yrs. In symptomatic women (n=16) and men (n=12) the age at the first episode was 24 yrs (2 weeks-46 yrs) and 33 yrs (18-52 yrs), respectively. PE was more frequent in women (43% v.s. 25%; RR:1.72), while recurrent VT was present in 50% men and only 25% of women; RR:2.0. In men 75% episodes of VTE were idiopatic, while in 81% women concomitant risk factor was present, represented mostly by oral contraceptives (31%) and pregnancy (31%). The frequency of VTE family history was equal in both groups (75%), however, genetic markers were negative in all but one patient heterozygous for FVLeiden. Interestingly, there was no difference between the two patient's groups with AT≤40% (n=10) and AT>40% (n=27) in the prevalence of the VTE (80% v.s. 74%) or recurrent VT (20% v.s. 30%). However, albeit non-significantly, the incidence of PE and continuous warfarin use were higher in patients with AT≤40% than in the other ones: 40% v.s. 22% and 50% v.s 37%, respectively. *Conclusion.* Our results demostrate inherited AT deficiency to be a strong risk factor of VTE. In our cohort oral contraceptives and pregnancy were cause of an earlier VT manifestation in young women than men. Despite the rarity of the disorder appropriate diagnostic and preventive measures should be taken in all persons with a strong family history of VTE, in pregnancy or before contraceptives prescription in particular.

UPPER EXTREMITY DEEP VENOUS THROMBOSIS AND THROMBOPHILIA

F Gabriel,[1] O Portolés,[2] M Labiós,[3] M Ferreiro,[4] M Morales,[5] A Ruíz,[6] D Nauffal,[7] R Group[8]

[1]*Hospital Clínico Universitario de Valencia. Servicio de Medicina Interna, Valencia, Spain*
[2]*Fac. Medicina. Dep. Medicina Preventiva y Salud Pública. Universidad de Valencia, Valencia, Spain*
[3]*Hospital Clínico Universitario de Valencia. Servicio. Medicina Interna, Valencia, Spain*
[4]*Hospital de Pontevendra. Servicio de hematología, Pontevedra, Spain*
[5]*Hospital del Tajo. Servicio de Medicina Interna, Madrid, Spain*
[6]*Hospital Universitario Joan XXIII, Tarragona, Spain*
[7]*Hospital Universitario La Fe. Servicio de Neumología, Valencia, Spain*
[8]*Valencia, Spain*

Background. Deep venous thrombosis (DVT) is much less common in the upper than in lower extremity. Furthermore, there is limited information on risk factors for and the prognosis of upper extremity (UE) DVT in general population. Our aim was to study the contribution of genetic and acquired thrombophilic defects to the appearance of acute episode of UEDVT, either isolated or associated with pulmonary embolism (PE). *Materials and Methods.* By December 2008, 4503 patients objectively diagnosed with venous thromboembolism (VTE) on whom a thrombophilia study was carried out had included in RIETE (Registro Informatizado de la Enfermedad Tromboembólica), is an ongoing, international multicenter, observational registry of consecutive patients with symptomatic, objectively confirmed, acute VTE. Thrombophilia screening included: tests for antithrombin (AT), protein C (PC) and protein S (PS) deficiencies, factor V Leiden (FVL) and prothrombin G20210A (PTG20210A) mutations, resistance to activated protein C (APC-R), hyperhomocysteinemia, and antiphospholipid sindrome (APS). Odds ratios (OR) and 95% confidence intervals (CI) were calculated using unconditional logistic regression. *Results.* The mean age of our population was 43 ±18 years. 1852 patients (41%) presented positive results. 3.9% suffered UEDVT, and 0.3% UEDVT+PE. The risk of suffering UE-DVT or UEDVT+PE was calculated according to thrombophilia factors which, following adjustment for chronic lung diseases, chronic heart failure, abnormal creatinine levels, post-operative, immobility, cancer, prior VTE, journeys longer than 6 hours over three preceding weeks, oestrogen therapy during two previous months, legs varicosities, body mass index, and idiopathic VTE. There were not association between any of the trombophilic defects studied and UEDVT or UEDVT+PE (OR: 0.5; CI 95% 0.2 -1.2) and (OR: 1; CI 95 % 0.1-8.2), respectively. *Conclusions.* AT, PC and PS deficiencies, FVL and PTG20210A mutations, APC-R, hyperhomocysteinemia, and APS carriers there are not risk developing UEDVT or UEDVT+PE. From our results thrombophilia study in patients with UEDVT would not be recommended.

0181

FACTOR VIII LEVELS AND RISK OF RECURRENCE OF VENOUS THROMBOEMBOLISM

A Godoy Molias,[1] C Aguilar Franco,[1] JF Lucía Cuesta,[2] F Sevil Puras,[1] J Lao Romera,[2] MV Faura Pestiño[1]

[1]*Hospital Santa Bárbara, Soria, Spain*
[2]*Hospital Universitario Miguel Servet, Zaragoza, Spain*

Background. Patients presenting with a first episode of venous thromboembolism (VTE) have a well known risk of thrombotic recurrence potentially resulting in significant both morbidity and mortality rates. The role played by the different thrombophilic markers, and in particular elevation of factor VIII plasma levels, remains controversial. *Aims.* The main goal of the current study was to evaluate the possible existence of a correlation between elevated factor VIII levels and recurrence of a first episode of VTE. *Methods.* We carried out a retrospective observational study including 220 patients from our healthcare area with a diagnosis of a first episode of VTE from 1998 to 2010. Patients with coexistent active malignancy, chronic liver disease or chronic renal failure were excluded from the study. Overall 151 patients were eligible for evaluation. Both demographic and clinical features were recorded; these included age, sex, number of thrombotic episodes, type of VTE episode and number of patients who suffered subsequent thrombotic recurrence. Factor VIII measurement was performed in citrated plasma by coagulometric method using factor VIII deficient plasma from Stago (STA Factor VIII, Diagnostica Stago, Asniéres sur Seine, France) and an STA-R coagulometer (Diagnostica Stago). FVIII levels above 150 IU/dL were considered as elevated (normal range 55-150 IU/dL) *Results.* Median age of patients enrolled at diagnosis of the first thrombotic event was 45 years (range 9-80). Eighty three of them (55%) were men and 68 (45%) women. Median number of thrombotic episodes was 1 (range 1-4). The first episode of VTE was a distal deep venous thrombosis (DVT) in 83 cases (55%), a proximal DVT in 34 (22.5%), a pulmonary embolism in 23 (15.2%), a cerebral venous thrombosis in 7 (4.6%) and a mesenteric venous thrombosis in 4 (2.6%). Median factor VIII levels of the whole series of patients was 147.5 IU/dL (range 11-300 IU/dL). Out of 151 patients eligible for FVIII measurement 45 (29.8%) suffered thrombotic recurrence. Twenty seven out of 69 (39.1%) subjects who showed initially elevated FVIII levels (>150 IU/dL) presented with recurrent VTE versus 18 out of 82 (21.95%) of those whose FVIII plasma concentrations were within the normal range (p=0.021). *Summary/Conclusions.* Our findings confirm the statistically significant association existing between elevated FVIII plasma levels and thrombotic recurrence in patients with a previous episode of VTE. Inclusion of FVIII measurement in the routine thrombophilia screening is thus mandatory in order to identify this subset of patients. Whether such individuals are candidates to long term anticoagulant treatment on the basis of this higher risk of VTE recurrence remains unclear and future trials addressing this issue are warranted. email-address: anagodoy1006@hotmail.com

0182

ANTIPHOSPHOLIPID ANTIBODIES IN PEDIATRIC PATIENTS WITH SYSTEMIC LUPUS ERYTHREMATOSUS-LONG TERM CLINICAL AND LABORATORY FOLLOWUP STATUS STUDY

S Naseem, J Ahluwalia, S Singh, D Suri, S Bose, A Rawat

Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background. Anti-phospholipid antibodies (APLA) have been reported in 38-87% patients with pediatric systemic lupus erythrematosus (p-SLE). Although studies have analyzed the frequency of APLA in p-SLE patients, there are limited studies on long term follow up of p-SLE patients and their APLA status. In a previous study (Rheumatol Int 2005: 25:530-535), we analyzed 27 p-SLE patients for the prevalence of APLA; in the present study we further reviewed the APLA status and its relation with clinical outcome of this cohort of patients for a further 7 years followup period. *Aim.* To evaluate long term prevalence of APLA in p-SLE and its correlation with clinical outcome. *Methods.* Twenty seven p-SLE patients were tested for APLA and their clinical status was followed up. APLA testing included: i) lupus anticoagulant (LA) [by kaolin clotting time, diluted Russell viper venom time (LA Screen and LA Confirm, Dade Behring) and STACLOT-LA kit] ii) anticardiolipin antibodies (ACA)-IgG, IgM and iii) anti-β2 glycoprotein-1 (β2 GP1) antibodies-IgG, IgM (Orgentec GmBH by ELISA). Criteria for defining antiphospholipid syndrome (APS) was as outlined previously (Miyakis S, *et al*. J Thromb Haemost 2006; 4: 295-306). Patients with active disease were managed with high-doses corticosteroids along with cyclophosphamide in addition to hydroxychloroquine. Children in remission were receiving maintenance doses of prednisolone and/or hydroxychloroquine. *Results.* Out of the initial cohort of 27 patients, followup APLA testing was available in 21 patients. Six patients in whom no followup APLA testing was available included -1 patient who had died at the time of previous study, 3 who were lost to followup and 2 who died shortly after study. Therefore the present study analyzed 21 p-SLE patients for their follow up APLA and clinical status. These patients were tested for APLA on 49 occasions in further 7 year followup period. Seven (33.3%) of these 21 patients were never positive for any of the APLA, 5 (23.8%) were positive for APLA only once, 9 (42.9%) were positive for APLA intermittently. Most common APLA positivity was for LA seen in 7 (33.3%) patients. IgG and IgM ACA was positive in 3 (14.3%) patients each. Anti-β2 GP1 antibodies were tested in 11 patients on followup, of which 3 (27.3%) showed positivity. In all, 4 (19%) patients showed positivity for more than 1 APLA. Out of these 21 patients, 3 (14.3%) patients had thrombosis and all 3 patients were positive for APLA, 1 for IgG and IgM ACA and 2 for LA. Two of these fulfilled the criteria for APS. There were 2 fatalities in this cohort while on followup, both of these had thrombosis and were positive for APLA. *Conclusion.* Pediatric patients with SLE on treatment frequently test positive for APLA. Thrombosis ending fatally was infrequent in this cohort, however, when present was associated with APLA positivity. On the other hand presence or persistence of these antibodies was not always associated with thrombosis. Our

study suggests that p-SLE children should be tested routinely for APLA, as this would identify patients with an increased risk for thrombotic manifestations. email: shanonaseem@yahoo.co.in

0183

IMPROVING ADHERENCE TO VTE (VENOUS THROMBOEMBOLISM) PROPHYLAXIS

D Warcel, H Jones, S Pomfret, K Antrobus, O Turan

Barts and the London, London, United Kingdom

VTE (venous thromboembolism) is estimated to cause 60,000 deaths per annum in the UK. Hospital in-patients have many risk factors for VTE, such as acute illness, reduced mobility or surgery. As a result, NICE guidelines and government CQUIN targets aim to nationally reduce the morbidity and mortality associated with in-patient VTE through mechanical and pharmaceutical prophylaxis following focused risk assessment. This formed the initiative behind our study into improving education and awareness of VTE prophylaxis. Our aim was to assess and improve local trust adherence to VTE prophylaxis. Based in a major hospital in Central London, we set out to identify the barriers that needed to be addressed in order to improve compliance, and to implement changes that would raise awareness and reinforce the importance of VTE prophylaxis. By auditing inpatient populations on two separate occasions we were able to assess changes in compliance over a period of 6 months. Initially we ran a baseline audit to assess compliance prior to any awareness programme. Between audits, we ran a trust wide education programme: the introduction of a VTE risk assessment proforma and specialised drug charts, and creating new hospital guidelines. Flowcharts for prophylaxis were displayed around the trust to aid staff. We then reaudited to assess whether compliance had improved. Our audit standard was the NICE venous thromboprophylaxis guideline CG92 (2010) and excluded patients in ITU, obstetrics and gynaecology, and paediatrics.

Figure 1. Flowchart.

Our audit tool was an amended version of the Department of Health VTE audit tool designed locally. The audits ran as a 'snap-shot' of the hospital with all eligible wards being audited within a few days, in January and July 2010. Audit 1 (January 2010) n = 250; Male to female ratio = 1.05:1; 64% aged greater than 60 years, 26% aged between 40-60 years; 11% with no risk factors, 35% with one risk factor and 54% with two or more risk factors. 13% of patients contraindicated for pharmaceutical prophylaxis. Audit 2 (July 2010) n=242; Male to female ratio = 0.9:1; 61% aged greater than 60 years, 23% aged between 40-60 years; 13% with no risk factors, 26% with one risk factor and 60% with two or more risk factors. 4% of patients contraindicated for pharmaceutical prophylaxis. Initially no standardised risk assessment on admission, 28% completed forms after education programme. Initial VTE prophylaxis prescribed for 49% of eligible patients, climbing to 74% after education programme. A concentrated education programme clearly improves compliance of VTE prophylaxis. However, it is a danger that without continued efforts, VTE prophylaxis and risk assessment can be overlooked. CQUIN targets of 90% are imposed on all NHS trusts for VTE prophylaxis and risk assessment, and it is likely some trusts will struggle without an awareness programme. Electronic patient records would increase the ability to not only audit VTE prophylaxis but also act as a reminder to risk assess accordingly for patients. Ideas for future development would be formal teaching at compulsory induction sessions for new employees and assigning a specialist nurse role in the trust.

0184

ANTITHROMBOTIC THERAPY IN NON-NEOPLASTIC CHRONIC PORTAL VENOUS THROMBOSIS IN CIRRHOSIS: RECANALIZATION AND LIVER FUNCTION EVALUATION

L Bento de Miguel,[1] A Rodriguez-Huerta,[2] C Pascual,[2] G Pérez-Rus,[2] I Gonzalez-Gascón y Marín,[2] F Carretero,[2] M Infante,[2] A Roldán,[2] V Catalina,[2] I Yepes,[2] M Kwon,[2] JL Díez-Martín[2]

[1]*H. Gregorio Marañón, Madrid, Spain*
[2]*H.G.U. Gregorio Marañón, Madrid, Spain*

Introduction. Non-neoplastic chronic portal vein thrombosis (PVT) is a frecuent diagnosis in the course of liver cirrhosis, with reported prevalences of 0.6% to 15,8%. PVT can motivate life-threatening complications due to worsening portal hypertension, so anticoagulation therapy is challenging in these patients. OBJECTIVE: To analyze the response to antithrombotic therapy and changes in liver function tests in 28 patients with chronic PVT associated with cirrhosis. *Patients and Methods.* 28 consecutive patients with liver cirrhosis and chronic PVT were treated with antithrombotic therapy from 2004 to 2009. Hepatocellular carcinoma and known thrombophilic risks were ruled out. Therapy consisted in 15 days of therapeutic doses of low molecular weight heparin (LMWH) (enoxaparin) adjusted according to baseline coagulability (Table 1), followed by either prophylactic doses (40mg/day) of LMWH or acenocoumarol (target INR 2-3), during 6 months. Response was evaluated after 6 months.

Table 1.

Range of baseline coagulation study and adjusted therapeutic doses of LMWH. N: Normal range; LH: Low hypocoagulability; MH: Moderate hypocoagulability; MSH: Moderate-Severe hypocoagulability.

Test	N	LH	MH	MSH
Platelet count /mm³	> 120000	80000-120000	50000-80000	30000-50000
INR	< 1.4	1.4-1.8	1.8-2.2	1.8-2.2
APTT sec.	< 37	37-40	40-45	40-45
Fibrinogen mg/dl	> 200	150-200	100-150	100-150
LMWH doses	1mg/kg/12h	0.75mg/kg/12h	0.5mg/kg/12h	1mg/kg/24h

If recanalization was complete, therapy was suspended. If recanalization was partial or no recanalization was observed, therapy was continued until response. RESULTS: From the 28 patients studied, 19 (68%) were males with a median age of 53 years (range 35-77). Cirrhosis was due to alcoholism (25%), virus (54%), mixed in 1 patient and other causes in 3 patients. PVT involved the portal trunk and/or branches in 19/28 (68%) patients, mesenteric vein in 2 patients and portal trunk and/or branches, mesenteric and/or splenic vein thrombosis coexisted in 7 patients. 19/28 (68%) of the patients had moderate or moderate-severe hypocoagulability range. Complete and partial thrombosis was seen in 18 and 10 patients at diagnosis, respectively.

From the 28 patients, 18 (64%) responded to antithrombotic therapy after 6 months, with a complete recanalization in 13 patients 13/18 (72%) and partial in 5/18 patients (28%). None of the 28 patients presented hemorrhagic complications and none showed platelets counts below baseline values. 17 from the 18 patients who responded, showed altered liver function tests before therapy. After 6 months, 8/17 (47%) improved liver function (only one patient had received antiviral therapy). After a median follow up of 42 months (range 7-67), 15/18 (83%) patients continued showing complete or partial response while 3 patients progressed. Of note, 3 patients of this group could proceed to further liver transplantation. *Conclusions*: Antithrombotic therapy in chronic PVT in cirrhotic patients resulted in a high response rate (64%) in our study, with a complete recanalization in 72% of the cases. Adjusted dose scheme according to level of hypocoagulability seems to be effective and safe, since 63% of the subgroups of moderate and moderate-severe hypocoagulability responded with no haemorrhagic complications.

THROMBOPHILIC FACTORS IN IDIOPATHIC GANGRENE OF LIMBS

J Ahluwalia, S Naseem, S Singh, R Das, M Sachdeva, N Varma, S Varma

Dept. of Hematology, PGIMER, Sector 12, Chandigarh, India

Background. Gangrene of limbs result from thrombotic occlusion of peripheral arteries. Most commonly gangrene occurs because of alteration in the hemostatic balance, caused by hypercoagulability which is out of proportion to the response of fibrinolytic system of the body. Such a hypercoagulable or thrombophilic state resulting in gangrene is usually secondary to septicaemia, autoimmune conditions, vasculitides, measles, chickenpox, malignancy, ergotism, protein C, protein S or antithrombin deficiency. However, gangrene of limbs has been reported in patients without any underlying obvious primary etiology. We describe here the laboratory profile of thrombophilic factors in patients with idiopathic gangrene of limbs. *Aim.* To study the role of inherited and acquired thromobophilic factors in patients with idiopathic gangrene of limbs and to determine differences between adults and pediatric cases, if any. *Methodology.* We analyzed and compared thrombophilic factors in 22 patients with idiopathic gangrene of limbs, who presented at our centre over a 9 year period (January 2002- January 2011). The parameters which were studied include- factor V leiden mutation (FVL), protein C levels (PC), protein S levels (PS), antithrombin levels (AT), anticardiolipin antibodies (ACA) and lupus anticoagulant (LA). Patients were tested for these factors after 6 weeks of the acute event/or after 4 weeks of cessation oral anticoagulant therapy. PC, PS, AT were tested on automated coagulation analyser STA Compact (Stago Diagnostica), ACA with a commercial ELISA kit (Organtec GmBH), LA by screen and confirm kits (Dade Behring) and FVL by method described by Bertina *et al. Results.* During the study period 2700 patients with thrombosis were referred to laboratory for workup of thrombophilic factors, of which 62 patients (2.3%) had idiopathic gangrene of limbs. Complete data for all the above parameters was available in 22 cases, which were included in the present study for analysis of thrombophilic factors. In the 22 cases analyzed, male: female ratio was 1:1 with mean age of 20 years (range= 27 day- 49 years). Among these 22 patients, 14 (63.6%) were children (1 was a neonate) and 8 (36.7%) were adults. In this cohort, none of the patients had FVL mutation, PC or AT deficiency. 4 children had 1 or more underlying thrombophilic factors .ACA positivity, transient LA positivity and Protein S deficiency were present in a single case each. One patient tested positive for both LA and ACA. Among the adult patients, however only patient had Protein S deficiency. This patient also had a history of recurrent stroke. *Conclusion.* Our results show that idiopathic gangrene of limbs is an uncommon condition. Overall, testing for the above parameters would contribute to underlying etiology in only 23% patients. Acquired risk factors were slightly more common in this study population. Significant differences could not be established between adults and pediatric patients due to limited sample size. Alternative factors including fibrinolytic parameters and platelet activation markers need to be evaluated in this setting of idiopathic gangrene of limbs, as these might be indicative of underlying etiology.

0186

RANDOMIZED COMPARISON OF THE DAWN AC COMPUTER PROGRAM AND A SIMPLE MANUAL NOMOGRAM FOR QUALITY OF WARFARIN DOSING

L Hubers,[1] R Nieuwlaat,[1] A Spyropoulos,[2] A Stehouwer,[1] H van Spall,[1] J Eikelboom,[1] S Schulman,[2] S Connolly[1]

[1]*Population Health Research Institute, Hamilton ON, Canada*
[2]*McMaster University, Hamilton, ON, Canada*

Background. In patients receiving warfarin, the quality of anticoagulant control as measured by the time-in-therapeutic range (TTR) for the International Normalized Ratio (INR) is a key determinant of risk for thromboembolic and bleeding events. Computer programs can assist physicians in optimizing TTR, but are expensive. *Aim.* The purpose of this study was to determine whether a computer system (DAWN AC) was non-inferior to a two-step manual nomogram used in a hospital anticoagulation clinic, for quality of warfarin dosing. *Methods.* Patients receiving warfarin maintenance therapy with target INR range 2-3 in the anticoagulation clinic were randomized to management with the newly acquired DAWN AC computer system or the clinic's standard of care, a simple manual dosing nomogram. After an initial run-in phase, study data collection started on February 1st 2010 and was completed on August 8th 2010. Primary outcome was the mean TTR calculated by the Rosendaal linear interpolation method. The non-inferiority margin was set at 4.5% lower TTR for DAWN AC compared with the nomogram. Approval from the Research Ethics Board of Hamilton Health Sciences was obtained and no patient informed consent was required. *Results.* Of the 1,298 patients initially randomized, 1,127 were still managed by the clinic after the run-in phase and entered the study on February 1st; 564 were managed with DAWN AC, and 563 with the manual nomogram. The mean age of study patients was 69 ± 14 years and 62% were male. Main indications for anticoagulation were atrial fibrillation (48%) and prosthetic heart valves (25%). Mean follow-up was 172 days, encompassing 8,344 INR values and 155,041 patient days. Adherence to recommended warfarin doses was higher in the DAWN AC than in the nomogram group (99 vs. 90%; p<0.0001), and the average interval between consecutive INR measurements was similar in the two groups (21 ± 12 vs. 21 ± 13 days; p=0.1987). In the primary analysis, mean TTR in the DAWN AC group was non-inferior to mean TTR in the nomogram group (71.0% ± 23.3 vs. 71.9% ± 22.9; non-inferiority p=0.0052). The effect of DAWN AC vs. nomogram on TTR was compared among subgroups for age, gender, warfarin pill size and primary indication and no significant interactions were found. *Conclusions.* Among patients receiving warfarin maintenance therapy with a target INR of 2-3 in an anticoagulation clinic, quality of anticoagulant control with the DAWN AC computer program was non-inferior to a simple two-step manual dosing nomogram. The nomogram could be a useful dosing tool for physicians without access to a computerized warfarin dosing system.

0187

MOTOR DISABILITY IN PATIENTS ON ORAL ANTICOAGULANT THERAPY (OAT): PRELIMINARY RESULTS FROM AN ITALIAN EPIDEMIOLOGICAL STUDY

L Scaramucci,[1] A Tendas,[1] F Bondanini,[2] M Giovannini,[1] M Palombi,[1] L Cupelli,[1] P Niscola,[1] A Perrotti,[1] P De Fabritiis[1]

[1]*S. Eugenio Hospital, Hematology, Rome, Italy*
[2]*Laboratory Medicine, 'Sandro Pertini' Hospital, Rome, Italy*

Background. OAT is chronically administered to prevent thrombotic events in a broad group of diseases having a narrow therapeutic range to balance the risk of hemorrhage and thrombosis, thus requiring a close monitoring of prothrombin time (PT) and the international normalized ratio (INR). Although PT/INR can be tested by a healthcare professional or by the patients (pts) themselves, the majority of pts are usually followed by an hematological specialized center for both analysis and OAT management, thus resulting in the need of hospital visits and in complex burden of problem related to frailty and several degree of disability afflicting OAT pts. Although these concerns are commonly observed in the daily clinical practice, the incidence of disability in OAT pts is unknown. *Aims and Methods.* In order to address this issue, we performed a cross-sectional evaluation of the motor disability (MD) in a group of consecutive outpatients on OAT, by handling in a MD assessment questionnaire at the moment of therapy schedule delivering. MD was assessed using Barthel Index (BI), which was used as basic ADL ability scale, and was classified as mild

(BI>66%), moderate (BI: 33-66%) and severe (BI<33%). *Results.* There were 122 patients (73 male); median age was of 71 (27-91) years. Disability was present in 37/122 (30%) patients; mild in 27%, moderate in 2% and severe in 1% of patients, respectively. The frequency of BI items reduction revealed that bladder function and complex activities are the most frequently impaired basic ADL in OAT pts (mean item reduction: bladder -14%, ascending and descending stairs -11%, bathing -8%, dressing -6%). *Conclusions.* Although preliminary and related to a limited series of patients, our data provide new insights on a neglected issue in OAT pts, such as disability. Indeed, MD is a frequent feature, but extended data analysis is required to achieve a better understanding about the disablement process, onset, causes, related risk factors and progression. A targeted rehabilitative approach to prevent and treat disability may lead to positive effects on both patient's quality of life and caregiver work-load. Home care management for MD affected OAT pts may be a suitable option, but requires a trained healthcare professionals team and adequate resources.

PRELIMINARY RESULTS OF OUR STUDY DOES NOT SUPPORT THE ASSUMPTION THAT FREQUENCIES OF THROMBOPHILIA CAUSES ARE DIFFERENT BETWEEN EARLY AND LATE LOSSES IN CASES WITH RECURRENT PREGNANCY LOSS

C Beyan, K Kaptan, A Ifran

Gulhane Military Medical Academy, Ankara, Turkey

Background. Recurrent pregnancy loss (RPL) is defined by two or more failed pregnancies according to American Society for Reproductive Medicine. There is a large and contradictory literature on the association between maternal inherited thrombophilia and RPL occurring in the first trimester. Evaluation for an inherited thrombophilia should be considered in cases of RPL after nine weeks associated with evidence of placental ischemia and infarction and maternal vessel thrombosis. *Aims.* The purpose of our study is to compare the frequencies of hereditary thrombophilia factors among cases who had pregnancy loss before 10th week of gestation and after in Turkish RPL cases. *Methods.* Sixty three cases included in study whose ages range between 28,43 ± 3,88 years (mean ± standart deviation) (21-37 years). Cases with genital anatomical or chromosomal anomalies were excluded. All cases were investigated for activated protein C resistance, factor V Leiden and prothrombin gene 20210GA polymorphisms, antithrombin, protein C and S deficiencies. The number of losses were between 2 to 5 (median 2). Thirteen cases explained that thay had at least one healthy childbirth (secondary RPL). *Results.* According to our findings, 33,3% of RPL cases had at least one thrombophilia factor. The frequencies of thrombophilia causes in RPL cases and their comparisons according to whether they were early or late losses were shown in table. *Summary/Conclusions*. Preliminary results of our study support that the frequencies of thrombophilia causes are not different between cases who had early or late RPL. Studies larger and evaluating abortus materials histopathologically are needed to support our findings opposite to suggestion that early RPL cases are not subject to investigate for thrombophilia factors.

Table 1. Thrombophilia factors in RPL cases.

Cause	All Frequency (%)	Early RPL (n= 39)	Late RPL (n= 24)	p value
Activated protein C resistance (<120 seconds)	17,3% (9/52) (5,8% F V Leiden negative)	20,0% (7/35)	11,8% (2/17)	0,376
Factor V Leiden gene	9,7% (6/62) (1,6% homozygous)	10,2% (4/39)	8,7% (2/23)	0,607
Prothrombin gene 20210GA	3,4% (2/59)	2,6% (1/38)	4,8% (1/21)	0,589
Antithrombin deficiency (<80%)	1,6% (1/63)	0,0% (0/39)	4,2% (1/24)	0,381
Protein C deficiency (<70%)	1,7% (1/58)	2,7% (1/37)	0,0% (0/21)	0,638
Protein S deficiency (<60%)	14,3% (9/63)	10,2% (4/39)	20,8% (5/24)	0,212
At least one cause	33,3% (21/63)	33,3% (13/39)	33,3% (8/24)	0,611

ARE JAK2 MUTATION AND PAI -1 POLYMORPHISM RISK FACTORS FOR VASCULAR EVENTS IN ET PATIENTS?

B Sokolowska,[1] K Bykowska,[2] A Nowaczynska,[1] S Chocholska,[1] E Mendek-Czajkowska,[2] A Walter-Croneck,[1] M Kowalska,[3] T Gromek,[1] K Wejksza,[4] M Kandefer-Szerszen,[4] J Windyga,[2] K Warzocha,[2] A Dmoszynska[1]

[1]*Medical University, Lublin, Poland*
[2]*Institute of Hematology and Blood Transfusion, Warszawa, Poland*
[3]*The Children's Hospital of Philadelphia, Philadelphia, United States of America*
[4]*Virology and Immunology, University of Marie Curie- Sklodowska, Lublin, Poland*

Background. The treatment of ET patients focuses mainly on lowering the risk and incidence of thrombotic and haemorrhagic complications. The tyrosine kinase activating JAK2 V617F point mutation has been found in 50% of Essential Thrombocythemia (ET)patients and the relationship between the occurance of this mutation and thrombotic events has been widely suggested. Additionally, it has recently been found that a 4G/5G polymorphism located in the promotor region of plasminogen activator inhibitor -1(PAI-1) can also be a risk factor for deep vein thrombosis, a complication often observed in ET patients. *Aim.* In this study we tried to identify the most important risk factors for vascular events based on evaluation of pathogenetic and prothrombotic mutations as well as hemostatic risk factors . *Methods.* We have examined 106 patients with ET (80 females and 26 males, mean age 54(23-82)).The control group (CG) consisted of 20 healthy persons: 6 males and 14 females (mean age 41(31-54)). We searched for JAK2V617F, Factor V Leiden, G20210A prothrombin gene, MTHFR C667T gene mutations and PAI-1 polimorphism. We also evaluated plasma levels of: factors I, VIII, XII, AT, protein C and S and serum levels of: homocysteine, folic acid, witamin B12 . *Results.* The JAK2 V617F point mutation was detected in 48 (45,28%) ET patients. In ET patients with JAK2 point mutation compared to ET patients without JAK2 mutation, the higher levels of:red blood cells(RBC), white blood cells(WBC), hemoglobin (HGB)and hematocrit (HCT) were found. The results were as follows: RBC: median 4.77 T/l; P25-75%, 4.46-5.26 and 4.22T/l,3.8-4.52,p<0.001, WBC: median 8.5G/l,P25-75%,6.8-9.9 and 7.2G/l,5.7-8.7,p<0.05, HGB: median 14.2g%,P25-75%,13.5-15.0 and 13.0g%,11.8-3.9,p<0.001,HCT:median 41.5%,P25-75%,38.7-45.6 and 37.5%,34.0-40.2,p<0.001 respectively. JAK2 positive patients had lower CRP and free protein S levels compare to JAK2 negative ones (CRP: median 1.5 P25-75%,0.7-2.1 and 2.0; 1.75-2.45mg/l, p<0.05 and protein S: median 78.25%,P25-75%,72.4-94.65 and 90.96%,79.7-103.0, p <0.05). In 21(19.8%) patients from ET group 37 thrombotic complications occurred and in 22(20.75%)ET patients bleeding episodes were noticed. 14(32.56%)patients with thrombotic complications were JAK2 positive, while only 5(11.63%) patients with bleeding episodes were JAK2 positive. The difference beetween these group was statistically significant (p<0.05). In JAK2 positive patients thrombotic episodes were found more often, while JAK2 negative patients were more prone to bleeding complications. The hiperhomocysteinemia was detected in 41(38.7%) of ET patients. The median homocysteine level was higher in ET patients compared to CG (11.10; P25-75%,8.74-13.20and 9.21,7.94-10.60umol/l, <0.05).What is more, the folic acid level was lower in ET patients compared to patients from CG (median 7.96,P25-75%,5.16-10.8 and 12.6,9.03.18.8 ng/ml, p<0.001).In ET group PAI-1 4G/4G polimorphism was found in 34(32.08%)persons while 4G/5G polimorphism was detected in 42 persons (39.62%).These mutations were present in the same proportions in patients with thrombotic and bleeding complications. *Conclusions.* The pathogenetic JAK2 point mutation seems to be also a thrombotic risk factor in ET patients. Higher RBC, HGB, WBC, HCT levels observed in JAK2 positive patients may aggravate the thrombotic risk. Hiperhomocysteinemia observed in ET patients may be due to lower folic acid level. PAI-1 polimorphism seems not to be a risk factor for thrombotic and bleeding complications.

0190

INHERITED THROMBOPHILIA MUTATION ASSOCIATIONS: A THOUSAND VARIABLES, ONE CLINICAL DECISION - CAN CURRENT GUIDELINES ADEQUATELY REPRESENT THE REAL POPULATION?

M Pereira, G Marques, M Lourenço, G Ribeiro

Coimbra University Hospitals, Coimbra, Portugal

Background. Inherited thrombophilias are mutations with a Mendelian transmission that predispose carriers to a variably increased risk of venous or arterial thromboembolism. Commercially available testing kits include several such mutations, the clinical applicability of some being unproven. While the higher-risk mutations are associated with published risk-benefit analyses that clearly favour primary or secondary prophylaxis, other mutations confer a small increase in thrombotic risk that does not balance the increased bleeding risk of prophylaxis. Still other mutations carry a theoretically increased risk which has yet to be demonstrated in robust clinical series. The coexpression of more than one high-risk mutation facilitates the clinical decision to introduce prophylaxis, as the risk-benefit balance further shifts towards anticoagulation or antiaggregation; however, decisions become increasingly subjective as the number of low-risk or unproved-risk mutations increases, increasing with it the perceived theoretical thromboembolic risk. *Aims.* To determine the frequency of hereditary thrombophilia mutation associations in a sample of patients, to characterize the clinical difficulties of deciding whether or not to institute prophylaxis. *Methods.* We reviewed all requests for molecular biology analysis of inherited thrombophilias, from patients with thromboembolic events, obstetric complications or familial thrombosis, received in our center between June 2005 (introduction of the strip-assay currently used) and January 2011, containing complete results for Factor V Leiden (FVL), Factor V HR2 Haplotype (FVHR2), Prothrombin G20210A, Beta-Fibrinogen 455 G>A, Plasminogen Activator Inhibitor 1 4G/5G and 5,10-Methylenetetrahydrofolate Reductase (MTFHR) C677T and A1298C, as well as levels of Antithrombin (AT) and Proteins C (PC) and S (PS). *Results.* We identified 2048 individual patients fulfilling the inclusion criteria; 27 (1.3%) had no alterations in the parameters analyzed; 537 (26.2%) were high-risk patients with homozygosity for FVL or deficiencies of AT, PC or PS (irrespective of other mutations), and 7 (0.3%) were heterozygous for both FVL and FVHR2 (irrespective of other mutations). Single heterozygous mutations were found in 142 (6.9%), while 72 (3.5%) carried single homozygous mutations (excluding FVL), of whom 49 (2.4%) were homozygous for a MTHFR mutation. Considering coexpression of low-risk mutations, 587 (28.7%) expressed two mutations, 469 (22.9%) expressed three, 182 (8.9%) expressed four, 23 (1.1%) expressed five and 2 (0.1%) expressed six. *Conclusions.* In this series we identified only 1.3% of patients with neither mutations in the strip-assay kit used, nor deficiencies of AT, PC and PS. A total of 26.5% presented with high-risk mutations which are well characterized in the literature, while 10.4% had low-risk mutations which are also well described. However, the majority of patients (51.6%) presented with two or three simultaneous low-risk mutations and a significant number (10.1%) with four or more mutations. This study highlights that fact that, though published series focus on individual mutations, the majority of patients have complex associations of low-risk mutations, the interaction of which is not well understood. Due to the number of mathematical combinations possible (over 1200), relevant cohorts analyzing the thrombotic risk of each are impossible to obtain. Current recommendations need to take into account this grey area, and further define guidelines for anticoagulation and antiaggregation.

Cytogenetics and molecular diagnostics

[5]*Department of Internal Medicine III, University of Munich, Munich, Germany*
[6]*Department of Internal Medicine I, University of Saarland, Homburg, Germany*

Background. Acute promyelocytic leukemia (APL) characterized by the translocation t(15;17)(q22;q12), resulting in the fusion gene *PML-RARA*, is a distinct subset of acute myeloid leukemia. Since the introduction of all-trans retinoic acid (ATRA) this AML subgroup has a favourable prognosis. *Aims.* To evaluate the incidence of additional chromosomal and molecular abnormalities in APL patients. *Methods.* The study included 106 adult APL patients (median age, 45.5 years; range 18-72 years) entered on 2 protocols (APL95 and AML HD98B) of the German-Austrian AML Study Group (AMLSG) between 1995 and 2004. All patients were treated with ATRA in combination with intensive chemotherapy. Beside cytogenetic analysis, we evaluated the mutational statues of *ASXL1*, *CEBPA*, *DNMT3A*, *FLT3* internal tandem duplication (ITD), *FLT3* tyrosine kinase domain (TKD), *IDH1*, *IDH2*, *MLL*, *NPM1*, *NRAS*, *RUNX1* and *TET2*. *Results.* Median follow up for survival was 6.5 years. In 36 of the 106 patients (34%), at least one additional chromosomal abnormality was detected. The most common secondary chromosomal abnormalities were trisomy 8 in 33% (n=12) and chromosome 7 abnormalities in 19% (n=7), including deletions of the long arm (del(7q), n=6) as well as one balanced translocation t(2;7)(p21;q22). Additional abnormalities affected chromosome 17 in 14% (n=5) of the patients, including isochromosomes (n=3), derivative chromosomes (n=2) and one deletion of the short arm of chromosome 17 (del(17p)). Activating *FLT3* mutations were the most frequent secondary molecular abnormalities with 38% for *FLT3*-ITD and 14% for *FLT3*-TKD. At least one activating *FLT3* mutation was identified in 48% of the patients. In trend, activating *FLT3* mutations were inversely correlated with secondary chromosomal abnormalities (p=0.08). All other gene mutations occurred in a very low frequency, *ASXL1* mutation in 1.5%, monoallelic *CEBPA* mutation in 1.5%, *DNMT3A* in 1.8%, *IDH1* in 1%, *NRAS* in 5% and *TET2* in 4%. None of the patients harboured *IDH2*, *MLL*, *NPM1* or *RUNX1* mutations. Patients with activating *FLT3* mutations had a higher frequency of additional gene mutations (17%) versus those without (5%). Overall survival (OS) after 6 years was 71% (95%-CI 63-81%) for the whole cohort. A significant inferior survival was observed in patients with at least one gene mutation (n=46) versus in those without (n=45) (p=0.05). If presence or absence of secondary cytogenetic abnormalities were combined with presence or absence of at least one gene mutation, three risk groups with significantly different survival could be defined: A, absence of secondary cytogenetic abnormalities and gene mutations; B, presence of secondary cytogenetic abnormalities or gene mutations; C, presence of secondary cytogenetic abnormalities as well as gene mutations. OS rates at 6 years were 84%, 64% and 46% for group A, B and C, respectively. A Cox regression model on OS revealed higher age (HR for a difference of 10 years, 1.38, p=0.04), WBC above 10/nl (HR, 2.6, p=0.03) and cytogenetic/molecular risk group (HR for change from A to B or B to C, 2.1, p=0.03) as unfavourable prognostic variables. *Conclusions.* In our study on 106 APL patients secondary chromosomal abnormalities and concurrent gene mutations had an adverse impact on outcome.

Background. Molecular monitoring of BCR-ABL1 transcripts by real-time quantitative (RQ)-PCR is an integral part of the management of patients with chronic myeloid leukaemia. Sequential BCR-ABL1 transcript results demonstrate the kinetics of response to tyrosine kinase inhibitor (TKI) therapy, correlate with progression free survival and can indicate impending loss of response. Inter-laboratory standardisation is necessary to provide consistent interpretation of patient results allowing therapeutic decisions and accurate comparison of clinical trial data. To date, standardisation to the International Scale (IS) has required sample exchanges with a national or international reference laboratory in order to establish and validate a methodology specific conversion factor (CF). Current methods for BCR-ABL1 RQ-PCR require time consuming preparatory, analysis and reporting steps. Automated and standardised BCR-ABL1 quantitation platforms would negate the requirement for a relatively labour-intensive, manual methodology and significantly improve turn around times enabling prompt clinical decisions. *Aims.* To evaluate the performance, in the diagnostic and residual disease settings, of the automated, cartridge-based Xpert BCR-ABL Monitor/GeneXpert (Cepheid), a rapid, closed-system, nested real-time PCR assay requiring minimal pre- and post-analytical manipulations. This evaluation was implemented as part of the ongoing All Ireland Co-operative Oncology Research Group (ICORG) 0802 trial: a phase 2, multi-centre study of nilotinib 300mg twice daily as first line treatment of newly diagnosed, Ph-positive, chronic phase CML (ClinicalTrials.gov NCT00809211). *Methods.* Paired, peripheral blood analyses of 36 evaluable CML patients were performed at diagnosis and at 128 subsequent three-monthly timepoints. BCR-ABL1/ABL1 measurements were performed on all samples by RQ-PCR methodologies aligned to IS and by the Xpert BCR-ABL Monitor system. *Results.* At diagnosis both techniques had comparable results in 35/36 (97.2%) samples: IS, median BCR-ABL1/ABL1 41.0% (range 15.0->100.0%, non-linear >10%); Xpert BCR-ABL Monitor, median BCR-ABL1/ABL1 44.0% (range 16.0-100.0%) in patients expressing e13a2 or e14a2 BCR-ABL1 transcripts. The automated system was unable to identify and quantify e19a2 BCR-ABL1 transcripts in one patient. For follow up samples, the failure rate of the manual methodology was 4.7% (n=6). In the 122 paired analyses, correlation between methodologies, without automated system IS conversion, over a five log range (IS BCR-ABL1/ABL1 100-0.001%) was favourable (r2=0.845) with a progressive decline in correlation noted with each decreasing log IS BCR-ABL1/ABL1 level. Analysis at clinically relevant levels revealed no significant difference between the Xpert BCR-ABL Monitor and IS RQ-PCR in identifying major molecular responses (44.3% vs 41.8%) although a trend was apparent for the automated system to overestimate complete molecular responses (≤0.001 IS RQ-PCR) when compared with IS RQ-PCR (10.7% vs 4.9%). *Summary.* The Xpert BCR-ABL Monitor is capable of providing rapid (<2 hours) quantitative BCR-ABL1/ABL1 results with standardised kit reagents that require minimal pre-analytical steps thus significantly reducing potential contamination while maintaining maximal amplification efficiency. The system performs well in the diagnostic and residual disease settings but would not obviate the requirement for RNA isolation for identification of variant BCR-ABL1 species or acquired resistance-associated mutations. A reagent lot-specific IS CF would enhance applicability in monitoring TKI therapy with confirmation required by IS RQ-PCR for clinically relevant molecular responses.

Background. In recent years, the discovery of new genetic lesions such as mutations of JAK2 and TET2 genes has provided crucial insight to understand the molecular pathogenesis of chronic myeloproliferative neoplasms (MPNs). Nonetheless, the underlying genetic lesion remains unknown in many cases and this represents a major obstacle to define the most appropriate treatment in many patients. High throughput transcriptome sequencing and Single Nucleotide Polymorphism (SNP) analysis may represent a rapid and widely applicable tool to identify genetic lesions in these patients. By this approach, cryptic genetic lesions can be identified and at least in some cases, this may offer the possibility to apply new molecular targeted therapies. *Patients and Methods.* In 1997 a diagnosis of atypical Ph-, chronic MPN was posed to a 63 years old woman who was followed-up and treated with hydroxyurea only when indicated to control excessive leukocytosis and splenomegaly. The cytogenetic analysis performed at diagnosis and repeated in year 2009, showed a normal karyotype and the molecular analysis (FISH and RT-PCR) repeatedly proved negative for BCR-ABL p210, p190 and p230. Whole transcriptome sequencing (RNAseq) and SNP analysis were performed on peripheral blood granulocytes derived RNA and DNA using an Illumina or Affymetrix Platform, respectively. SNP analysis was also performed on DNA derived from purified CD3 positive T-lymphocytes to discriminate individual variations from neoplasm-associated genotype alterations. The identified chimeric fusion gene was validated with FISH, RT-PCR and conventional sequencing. Imatinib was administered at 400mg/die and the fusion transcript monitored with RQ-PCR during treatment. *Results.* The parallel SNP analysis performed on peripheral blood CD3+ T lymphocytes as well as on granulocytes allowed to demonstrate on these latter cells only, the presence of a deletion on the long arm of chromosome 9 and a duplicated region on the short arm of chromosome 12. The simultaneous RNAseq unveiled the presence of an ETV6/ABL chimeric fusion transcript as the only fusion gene emerging among a huge amount of potentially interesting results. RT-PCR and direct sequencing of the PCR product confirmed the presence of a fusion between ETV6 exon 5 and ABL exon 2. FISH analysis with fluorescent molecular probes encompassing ETV6 and ABL genes showed the co localization of the two probes on chromosome 9 thus confirming the presence of a cryptic translocation, as previously described in some cases of ETV6-ABL fusions. Due to the reported sensitivity of ETV6-ABL positive diseases to TKI, Imatinib was given to the patient at 400 mg/die. A rapid and complete normalization of blood counts and splenomegaly was documented in less than 2 weeks; the molecular monitoring of response is currently ongoing by sequential RQ-PCR analysis of the fusion transcript. *Conclusion.* Our results underline the clinical utility of high throughput whole transcriptome sequencing to identify cryptic genetic lesions in patients with a normal karyotype. This approach can lead to tailored, effective treatments.

[4]*III. Medizinische Klinik, Universitätsmedizin Mannheim, Mannheim, Germany*

Background. Identification of fusion genes with involvement of the platelet derived growth factor receptor alpha or beta (PDGFRA or

PDGFRB) in eosinophilia-associated myeloproliferative neoplasms (Eos-MPN) is challenging due to the presence of multiple partner genes with heterogeneous breakpoints. However, accurate detection of these fusions is important for clinical management as they are associated with excellent response to imatinib mesylate. *Aims.* To develop quantitative real time PCR (RQ-PCR) assays to detect clinically significant overexpression of the 3'-region of PDGFRA and PDGFRB that may be indicative of an underlying gene fusion. Six RQ-PCR assays were designed for each gene; three assays 3' to known breakpoints and three assays 5' to known breakpoints. Where no fusion transcript is present, normal PDGFRA and PDGFRB expression (relative to the control gene assays) should be observed for all assays. However, when a fusion transcript is present the three assays 3' to the breakpoint region may detect overexpression compared to the three assays 5' to the breakpoint region. *Methods.* Using the BioMark real-time PCR system and 48.48 Dynamic Array (Fluidigm) we tested pre-amplified cDNA from haematologically normal controls (n=16), samples from patients with unexplained eosinophilia that had previously tested negative for PDGFRA (n=12) or PDGFRB (n=3) fusions using conventional assays and samples with known PDGFRA (n=11) or PDGFRB (n=4) fusions. PDGFRA and PDGFRB expression was analysed using 6 RQ-PCR assays per gene and control gene assays for ABL1, BCR and GUSB. The 48.48 dynamic array allowed 2304 real time PCRs to be performed in one run enabling 48 samples to be analysed simultaneously in triplicate using 16 RQ-PCR assays. *Results.* Median Ct values were used to calculate the delta-delta Ct value for each assay and each sample using ABL1, BCR or GUSB as a reference. These data were then normalised to the expression level observed in the calibrator sample (normal human leukocytes). The difference between the median expression calculated for the assays 5' and 3' to known breakpoints was used to determine the relative overexpression of the 3' end of PDGFRA or PDGFRB. The median relative overexpression was 44.3 fold (PDGFRA, $p<0.0001$) for samples with PDGFRA fusions and 59.3 fold (PDGFRB, $p=0.003$) for samples with PDGFRB fusions compared with 0.66 fold (PDGFRA) and -0.06 fold (PDGFRB) in normal controls relative to ABL1. No significant overexpression of the 3' end of the genes was found in the patients with unexplained eosinophilia when compared to normal controls (PDGFRA, $p=0.186$; PDGFRB, $p=0.401$). Statistically significant overexpression was observed in cases with known PDGFRA and PDGFRB fusions compared to normal when the data were analysed using BCR and GUSB as reference genes. *Conclusions.* This simple, rapid and high throughput screen can be used to detect clinically significant overexpression of PDGFRA and PDGFRB in Eos-MPN. The flexible nature of the dynamic array means that further assays could be designed to facilitate high throughput screening for other gene fusions in haematological malignancies.

GENOMIC PROFILING USING SNP-BASED MICROARRAYS AS A DIAGNOSTIC TOOL IN ACUTE LYMPHOBLASTIC LEUKEMIA

A Simons, M Stevens-Kroef, N ElIdrissi-Zaynoun, D Olde Weghuis, E Waanders, R Kuiper, A Geurts van Kessel, P Hoogerbrugge, S van Gessel

Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background. In acute lymphoblastic leukemia (ALL) specific chromosomal abnormalities provide important diagnostic and prognostic information. In recent years, it has become clear that ALL cells also frequently harbor relevant disease related submicroscopic chromosomal abnormalities (Kuiper *et al.* Leukemia 2007, 21, 1258-1266; Mullighan *et al.*, Nature 2007, 446, 758-764). Although conventional karyotyping is generally considered as the gold standard in the genetic diagnosis of ALL, this method is limited by its low success rate due to an inadequate metaphase yield and/or a poor banding quality, and its inherent capacity to detect only those copy number changes that are large enough to be microscopically visible (5-10 Mb in size). Implementation of genome-wide high-resolution copy number profiling using genomic microarrays in routine diagnostics would significantly improve the detection of clinically relevant abnormalities and, at the same time, would overcome the above mentioned limitation of karyotyping, since no culturing of the clinical samples is required. *Aims.* We explored whether microarray-based genomic profiling would be feasible as an alternative method to detect diagnostic and prognostic relevant genomic copy number aberrations (CNAs) in a routine clinical diagnostic setting. In addition, we aimed to develop a practical workflow for fast, objective and routine interpretation of CNAs obtained by microarray-based genomic profiling, thereby facilitating its application in a routine clinical diagnostic setting. *Methods.* We performed both conventional cytogenetic analysis and microarray-based genomic profiling, using the 250K Affymetrix® GeneChips arrays, of 60 ALL cases and subsequently compared conventional karyotypes with microarray-deduced copy number profiles. *Results.* Microarray-based genomic profiling resulted in a CNA detection rate of 93%, whereas for conventional karyotyping this was 61%. In addition, many small (< 5 Mb) genetic lesions were encountered using the microarray platform. Many of these, sometimes focal, lesions harbor clinically relevant ALL-related genes such as CDKN2A/B, ETV6, PAX5 and IKZF1. *Summary/Conclusions.* We conclude that microarray-based genomic profiling serves as a robust tool in the genetic diagnosis of ALL. In addition, it outreaches conventional karyotyping in CNA detection, both in terms of sensitivity and specificity. Since balanced chromosomal abnormalities were not identified, it is recommended to apply FISH and/or other targeted methods for the detection of translocations with a known diagnostic and/or prognostic impact (e.g. t(9;22)/BCR-ABL1).

PAX5 DELETION IS COMMON AND CONCURRENTLY OCCURS WITH CDKN2A DELETION IN B LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA

M Kim,[1] JE Choi,[2] CJ She,[1] SM Hwang,[1] HY Shin,[1] HS Ahn,[1] SS Yoon,[1] BK Kim,[1] MH Park,[1] DS Lee[1]

[1]*Seoul National University Hospital, Seoul, South-Korea*
[2]*Korea University Anam Hospital, Seoul, South-Korea*

Background and Aims. The *PAX5* is essential in normal B-cell lymphopoiesis and deregulation of *PAX5* function is believed to contribute to leukemogenesis in B-ALL. Although the common cytogenetic changes in ALL may serve as diagnostic and prognostic markers, they are detectable at only low rates in ALL. In this study, we investigated the clinical utility of *PAX5* deletion in childhood and adult B-ALL. *Methods.* We performed a comprehensive study using FISH, G-banding and IHC, to identify *PAX5* deletion and immunoexpression in 102 *CD19+* clinical B-ALL cases (79 children and 33 adults) and investigated its relationship with common cytogenetic changes including *BCR-ABL1, ETV6-RUNX1* and *MLL* rearrangements, and *CDKN2A* deletion. *Results.* The incidences of translocations and deletions were 2.5% and 10.0% in 33 children, and 0.0% and 18.2% in adults, respectively. The incidence of *PAX5* deletion was higher than those of *BCR-ABL1* (8.9%) or *MLL* rearrangements (5.1%) in children and than that of *MLL* rearrangement (3.1%) in adults. Most of patients with *PAX5* deletion (83.3% of children and 100.0% of adults with *PAX5* deletion) had concurrent *CDKN2A* deletion. *PAX5* deletions were detected both in patients with positive and negative *PAX5* immunoexpression. *Conclusions.* In this study, we found that *PAX5* is a common target in leukemogenesis of B-ALL along with *CDKN2A*. Owing to its frequent deletion in B-ALL, *PAX5* could be used as one of the cytogenetic markers in diagnosis and monitoring of the disease. No correlation between immunoexpression of *PAX5* and deletion of *PAX5* suggests allele-specific regulation and haploinsufficiency of *PAX5*. As a marker for minimal residual disease, early relapse or response to therapy, *PAX5* appears to be more widely applicable than BCR-ABL1 or MLL rearrangment in B-ALL.

SENSITIVE AND QUANTITATIVE DETECTION OF LOW LEVEL KIT D816V MUTATION IN PATIENTS WITH SYSTEMIC MASTOCYTOSIS USING A NANOFLUIDIC DIGITAL PCR ARRAY

E White,[1] D Scott,[2] V Hall,[1] K Waghorn,[3] R Sanders,[2] C Foy,[2] N Cross[1]

[1]*National Genetics Reference Laboratory (Wessex), Salisbury, United Kingdom*
[2]*LGC, Queens Road, Teddington, United Kingdom*
[3]*Wessex Regional Genetics Laboratory, Salisbury, United Kingdom*

Background. Systemic mastocytosis (SM) is characterised by the abnormal proliferation and accumulation of clonally derived mast cells and is classified as a myeloproliferative neoplasm (MPN). The acquired activating point mutation 2447 A>T (D816V) in exon 17 of KIT can be detected in 80 - 95% of patients with adult onset SM. Because of its transforming activity, D816V is considered to play a primary role in SM and is included in the consensus WHO SM classification criteria. Development of a sensitive assay for detection of KIT D816V is important diagnostically and also has predictive significance since the mutation confers resistance to the kinase inhibitor imatinib mesylate. *Aims.* Analysis of D816V in SM is challenging as clonally derived cells are often patchily distributed in the bone marrow (BM) and absent or present only at very low level in peripheral blood (PB. Techniques such as direct sequencing are only able to detect mutational loads >20% and therefore we aimed to develop an assay to facilitate low level, quantitative detection of the mutated allele. *Methods.* A mutation specific digital PCR assay was developed for sensitive detection and quantification of D816V using the Fluidigm Biomark real time PCR system and BioMark digital array. DNA samples from putative SM cases (n=24) and normal controls (n=12) were analysed in a blinded fashion for the presence of the D816V mutation and results were compared to those obtained using an allele-specific competitive blocker (ACB) PCR assay. Analysis of serial dilutions of the HMC-1 cell line (50% - 0.01% D816V) were tested to determine the limit of detection of the assay. *Results.* Testing of patient DNA by digital PCR showed 97% concordance with the ACB PCR results with the levels of quantification ranging from 0.01% - 37.9%. One case was found to be negative by ACB PCR but showed amplification in 3 reaction chambers in the digital PCR assay (mutational load of 0.01%). Amplification of D816V was not observed in normal control samples (n=12) or negative control panels demonstrating that the assay is highly specific for the mutated allele and that no amplification occurs from the wild type allele. Testing of HMC-1 cell line DNA serially diluted in DNA extracted from normal peripheral blood determined that the lowest limit of detection of the digital PCR assay was 0.01% compared to 0.1% for the ACB PCR. *Conclusions*. The nanofluidic digital PCR array used in conjunction with a novel mutation specific real time PCR assay allowed sensitive detection and quantification of KIT D816V to 0.01% in genomic DNA samples. The use of the digital array enables enhanced detection of rare mutated alleles in a high background of wild type DNA as the sample is partitioned prior to amplification. The detection sensitivity of 0.01% is greater than that achieved using any other methodology published to date. This enhanced sensitivity may increase the detection of D816V in samples with low mast cell content helping to improve the diagnosis and clinical management of patients with SM.

THE FREQUENCY AND IMPLICATION OF GENE MUTATIONS INVOLVING RECEPTOR TYROSINE KINASES AND RAS PATHWAYS IN CHILDHOOD ACUTE MYELOID LEUKEMIA WITH FOUR MAJOR RECURRENT GENETIC ABNORMALITIES

DC Liang,[1] LY Shih,[2] CP Yang,[3] IJ Hung,[3] TH Jaing,[3] HC Liu,[1] TC Yeh,[1] SH Chen,[3] JY Hou,[1] CL Lai,[4] TH Lin[4]

[1]*Mackay Memorial Hospital, Taipei, Taiwan*
[2]*Chang Gung Memorial Hospital and Chang Gung University, Taipei, Taiwan*
[3]*Chang Gung Children's Hospital, Taoyuan, Taiwan*
[4]*Chang Gung University, Taoyuan, Taiwan*

Background. Two-hit model of leukemogenesis has been proposed for acute myeloid leukemia (AML). Recurrent chromosomal translocations of t(8;21), inv(16), t(15;17), and *MLL* rearrangements are considered class II mutations. The implication of class I mutations in childhood AML with the 4 major recurrent genetic abnormalities is not clear. *Aims.* We sought to determine the frequencies of class I mutations involving receptor tyrosine kinases (RTK)/JAK2/RAS signaling pathways in childhood AML with the 4 major recurrent genetic abnormalities and to assess their prognostic impact. *Methods.* Two hundred and one consecutive patients with childhood AML were diagnosed between 1996 and 2010. Ninety-nine patients had the 4 major recurrent genetic abnormalities which were detected by cytogenetic analysis and/or RT-PCR. *MLL* gene rearrangement was first screened by cytogenetic, Southern blot or FISH analysis, followed by RT-PCR to detect common *MLL* fusion transcripts and cDNA panhandle PCR to identify the rare *MLL* partner genes. Class I gene mutations, including *FLT3*/ITD, *FLT3*/TKD, *C-KIT*, and *C-FMS* (RTKs); *N-RAS*, *K-RAS*, and *PTPN11* (RAS pathway); and *JAK2*V617F, were examined. Mutational analyses were performed by DNA/cDNA PCR followed by direct sequencing for genes of RTKs and RAS pathways, and allele-specific PCR for *JAK2*V617F. Fifty-seven patients treated with Taiwan Pediatric Oncology Group APL and AML 97A (for non-APL) protocols were analyzed for the prognostic impact of gene mutations. *Results.* The frequencies of gene mutations in each genetic subtype of AML are shown in Table.1.

Table 1.

The frequencies of gene mutations in each genetic subgroup of childhood AML

Genetic subgroup	Pt no.	FLT3/ITD	FLT3/TKD	C-KIT	C-FMS	JAK2V617F	N-RAS	K-RAS	PTPN11
t(15;17)	18	4	4	0	0	0	0	1	1
t(8;21)	39	0	0	15	0	3	0	3	0
inv(16)	17	0	1	7	0	1	4	1	0
11q23-abn	27	0	4	0	2	0	3	3	1

Mutations involving RTKs/ JAK2/ RAS pathways occurred in 51.3 % of t(8;21)AML, 70.6% of inv(16), 62.5% of t(15;17) and 40.7% of *MLL* translocations. Taken together, 53.5 % of patients had class I gene mutations; 38% for RTKs, 17% for RAS pathway and 3% for JAK2V617F, in the whole cohort of AML patients carrying 4 major recurrent genetic abnormalities; 5 of them had multiple gene mutations. The 5-year event free survival (EFS) of 57 patients was 72±6% (mean±S.E.), 92% for patients with t(15;17), 70% for inv(16), 68% for t(8;21), and 62% for *MLL* rearrangement (P= 0.2). The 5-year overall survival (OS) of the whole group was 72%, 90% for t(15;17), 78% for inv(16), 68% for t(8;21), and 67% for *MLL* rearrangement. Comparison of 5-year EFS or OS between gene mutation-positive and mutation-negative patients in each genetic subtype of AML showed that neither gene mutation of RTKs nor gene mutation of RAS pathway had a significant influence on outcomes. *Conclusions.* Our results showed that 53.5% of pediatric AML with the 4 major recurrent genetic abnormalities harbored mutated genes involving RTK/JAK2/RAS pathways but presence of gene mutations did not have influence on outcomes.

MOLECULAR DETECTION OF CIRCULATING SEZARY CELLS IN PATIENTS WITH MYCOSIS FUNGOIDES: COULD IT PREDICT A FUTURE DEVELOPMENT OF SECONDARY SEZARY SYNDROME? A SINGLE MEDICAL CENTER EXPERIENCE

E Wang, C Hutchinson, J Papalas, F Wang, S Sebastian, M Datto

Duke University Medical Center, Durham, United States of America

Background. Mycosis fungoides (MF) is a primary cutaneous T-cell lymphoma and its prognosis heavily depends on clinical stage. While the majority of patients with early-stage disease have an excellent prognosis with life expectance similar to normal population, few cases progress to secondary Sezary syndrome (sSS), which carries a dismal clinical outcome. An early detection of sSS is crucial for clinical decision making, but a reliable test is currently not available. *Aims.* To investigate the PCR detection of blood T-cell receptor gamma gene (TCRG) rearrangement in patients with MF and its role in predicting clinical outcome with a special focus on cases with B0-1 of blood staging. *Method.* After the institutional approval of the study, 135 cases of MF/SS were identified in our medical informatics system. The clinical staging, skin histology, circulating Sezary cell count, flow cytometric analysis of blood sample and PCR detection of TCRG rearrangement in skin and blood specimens were retrospectively analyzed. Kaplan-Meier survival analysis was performed to study the follow up evaluations and patients' survivals. *Results.* Of 135 total cases, 74 (54.8%) are male and

61 (45.2%) are female. The median age is 60 years with range of 21-93. Fifteen cases (11.1%) fulfilled the diagnosis of SS and 120 were MF. The initial clinical staging includes T1 in 79 (58.5%), T2 in 41 (30.4%), and T3/T4 in 15 (11.1%) cases. In addition, 7 (5.2%) cases were staged as N1-N3 or Nx. No one showed evidence of visceral organ involvement (M0) at initial presentation. At the initial evaluation of blood, the median of Sezary-like cells is 4% of total lymphocytes with range from 0% to 70%. By flow cytometry, the median of percent CD4+/CD7- T-cells is 3.8 with range of 0-83, and the median for CD4+CD26- T-cells is 5.6 with range of 0-87. The median CD4:CD8 ratio is 2.1 with a range of 0.5-50. Of 131 cases with PCR/TCRG performed on blood, 44 (33.6%) are positive for clonal TCRG rearrangement and 87 (66.4%) are negative. When stratified by the diagnoses, the patients with MF showed a 26.5% (31/117) positive rate for blood T-cell clone, of which approximately 50% (10/20) had identical T-cell clone in skin. Follow up evaluation showed conversion into sSS in 50% (5/10) of the cases with positive blood T-cell clone (MF-1) (estimated mean interval=41.8 months) in comparison to none in the cases without (MF-2) (0/31) (P<0.0001) (Figure 1A). Interestingly, 4 of 5 cases with sSS had an identical T-cell clone in skin, while the remaining case did not have the test performed on skin for clonal comparison. Kaplan-Meier survival analysis demonstrated a poor clinical outcome in the group with blood T-cell clone in comparison with the one without in overall survival (P<0.0001) (Figure 1B1) and progression free survival (P<0.0001; HR=22.6) (Figure 1B2). *Conclusion.* The findings suggest a role of molecular detection of blood T-cell clone in predicting sSS. Due to amplification of non-neoplastic T-cell expansion in significant cases, comparison of blood T-cell clone with skin may have a confirmatory value for defining the clonal nature.

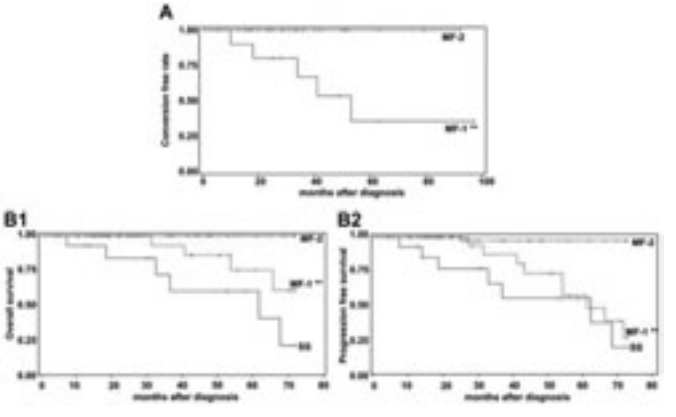

Figure 1. Kaplan-Meier survival analyses.

BCR-ABL QUANTITATION: TO IS OR NOT TO IS, THAT IS THE QUESTION?

R Clark, A Jack, L Holden, D Barnett, J Reilly

UK NEQAS LI, Sheffield, United Kingdom

Reverse-transcription real-time quantitative polymerase chain reaction (RQ-PCR) measurement of BCR-ABL oncogene expression is now a routine monitoring strategy for tyrosine kinase inhibitor (TKI) treated chronic myeloid leukemia. A major molecular response of at least a 3-log reduction in BCR-ABL expression is associated with favorable progression to disease free survival. Data from our UK NEQAS LI BCR-ABL quantitation programme has shown that there is an average 105% inter laboratory CV (range 78%-130%). Recently, to overcome this problem, a new International Scale (IS) for BCR-ABL measurement has been proposed. The aim of this study was to determine whether the use of the IS significantly reduces this variability and allows inter-laboratory comparison. UK NEQAS LI issued samples to over 100 laboratories worldwide for BCR-ABL quantitation. The consensus median (calculated from results returned) and delta values (difference between an individual laboratory's result and the median) were determined for each pre- and post- conversion percentage BCR-ABL/control gene result. This approach allowed us to determine whether IS conversion brought individual laboratory results closer to, or further, from the median value. Following analysis of 122 returned results from 8 different samples, it was apparent that many laboratories were inappropriately converting to IS values when BCR-ABL/control gene values were greater than 10% (note IS has not been validated for levels >10% due to the non- linearity of the BCR-ABL1 and ABL control gene relationship). For samples with a consensus median <10%, the number of results that moved closer to the median, post conversion, was 57% (n=33), whilst unexpectedly 43% (n=25) moved away, a fact that may relate to the failure to validate local conversion factors, as recommended by Branford *et al.* (2008).[1] In conclusion, this study has shown that the use of the IS has not reduced inter-laboratory variability but it has highlighted the need for further education and guidance on conversion factor determination/usage and IS application. Future development of reference reagents should help and hopefully lead to better internal quality control systems and facilitate comparative inter-laboratory studies.

HIGH-RESOLUTION COPY NUMBER ARRAY IN THE MOLECULAR CYTOGENETIC DIAGNOSTICS OF PEDIATRIC MALIGNANT HEMATOLOGICAL DISORDERS

I Ögärd,[1] C Wikhager,[1] T Martinsson,[1] J Abrahamsson,[2] L Palmqvist,[1] H Sjögren[1]

[1]*Institute of Biomedicine, Göteborg, Sweden*
[2]*Department of Pediatrics, The Queen Silvia Children's Hospital, Göteborg, Sweden*

Background and Aim. The importance of genetic characterization with cytogenetic and molecular genetics methods is well established in the diagnosis, prognosis prediction and determination of therapy in the management of malignant hematological disorders. The methods used today have limited detection sensitivity and resolution but are also relatively expensive. In order to validate the use of a genome-wide high resolution DNA copy number analysis in combination with conventional cytogenetic and molecular cytogenetic analysis, a high-density oligonucleotide based single nucleotide polymorphisms (SNP) array was performed on pediatric hematological malignancies. *Material and methods.* Bone marrow aspirates were consecutively collected from 56 children referred for diagnosis and treatment at The Queen Silvia Children's Hospital during the years 2006 to 2009. All patients were diagnosed with malignant hematopoietic disorders, including 24 patients with precursor B lymphoblastic leukemia (B-ALL), 11 with T-cell acute lymphoblastic leukemia (T-ALL), 15 with acute myeloid leukemia (AML), two with myelodysplastic syndrome (MDS), two with chronic myeloid leukemia (CML), one with acute promyelocytic leukemia (APL) and one with Burkitt lymphoma (BL). Genetic alterations were investigated with molecular allelokaryotyping (Human Mapping 250K Nsp Array) in combination with conventional and spectral karyotyping (SKY), flourescence in situ hybridization (FISH) analysis. *Results.* A total of nine balanced reciprocal translocations, 36 unbalanced translocations, 12 deletions and one inversion were detected by G-banding and/or SKY. FISH and RT-PCR confirmed all the known balanced translocations and the inversion. Eleven of the karyotypes in the material were complex, including four B-ALL, three T-ALL and four AML patients. The array analysis identified gains, losses and CNN-LOH in all the acute leukemia types, except for in the APL. The SNP information showed different patterns in the different leukemia entities. Gains dominated the B-ALL patients and losses the T-ALL and AML patients. Nearly all of the CNN-LOH was detected in the T-ALL patients. The SNP array was particularly helpful in detecting additional chromosome aberrations in the B- and T-ALL patients. The SNP array revealed the exact breakpoints in the unbalanced structural aberrations and small deletions were discovered. For example, loss of CDKN2A (9p21) was detected in four T-ALL patients but the array revealed ten losses. Also, the array verifies unbalanced structural rearrangements as well as confirming the balanced. None of the balanced translocations were identified by the array and small pathological clones detected by conven-

tional cytogenetics and /or FISH were not detected as the proportion of these cells was too small. *Conclusions.* Here, we conclude that the addition of SNP array based karyotyping combined with conventional cytogenetics improve the genetic characterization of pediatric hematological malignancies. The two techniques enhance the cytogenetic image and should not be contrasted as they meet distinct important roles. Since balanced translocation cannot be detected with the currently used SNP-arrays and tumor specific translocations are very important diagnostic and prognostic indicators we suggest that SNP-based array is a valuable adjuvant tool in the cytogenetic diagnostics of pediatric leukemias but cannot replace currently used techniques, i.e. G-banding and FISH.

HSP 90 AS A POSSIBLE INDICATOR OF DISEASE DETERIORATION IN CHRONIC MYELOID LEUKEMIA

M Zackova, T Lopotova, D Mouckova, Z Ondrackova, H Klamova, J Moravcova

Inst. of Hematology and Blood Transfusion, Prague, Czech Republic

Heat shock proteins 90 and 70 (HSP 90 and 70) are chaperones important for stability of various proteins. One of their client proteins is BCR-ABL kinase, fusion protein playing a crucial role in chronic myeloid leukemia (CML). The BCR-ABL/HSP90 complex stabilizes BCR-ABL kinase and decreases cell sensitivity to apoptosis (Shiotsu Y. Blood 2000; 96:2284-2291, Wu, L.X. Leukemia 2008; 22:1402-1409,). Moreover Src kinases and other proteins playing role in CML resistance to therapy are also clients of HSPs 90 and 70. The aim of our study was to find out whether the increasing levels of HSP90 and HSP70 might be associated with resistance to therapy and disease progression. We tested the expression levels of HSP90 and HSP70 in 41 CML patients with various responses to imatinib both on protein (western blots) and mRNA levels (real-time PCR). Eight more patients were examined during the course of therapy and development of resistance. Eight healthy donors and K562 cell lines were used as controls. By western blot analyses we found that the expression levels of Hsp70 did not markedly changed between different responses to therapy, between different disease stages or even between CML patients and healthy subjects. On the other hand, we found high variability in HSP90 protein levels. Patients at diagnosis and patients in good response to therapy (major molecular response) had low expression levels of HSP90 which were very similar to the HSP90 levels in healthy individuals. Patients in hematological relapse and in advanced CML phases (AP/BC) exhibited overexpression of HSP90. Very high HSP90 expression levels were also found in cell lines derived from CML blast crisis. Results indicate that HSP90 protein level well correlates with the disease status. In patients where the HSP90 protein expression was measured in course of disease, the increase of HSP90 level preceded relapse by 2 month at least. Thus the increasing HSP90 level seems to signalize arising resistance to therapy and disease progression. The amount of HSP90 also well correlated with the BCR-ABL transcript level in most cases. The only discordance was in samples from CML diagnosis, where BCR-ABL transcript level was high while HSP90 level was very low. This suggests different intensity of HSP90 action at CML diagnosis and blast crisis. In the same samples we also tested HSP90 expression on mRNA level by real-time RT-PCR. We quantified expression of two HSP90 isoforms - alpha and beta. The mRNA profiles showed high similarity with data obtained from western blot analyses. The analyses showed that increase in HSP90 levels associated with disease deterioration is probably mainly represented by HSP90beta isoform. These results suggest that HSP90 expression at protein as well as mRNA level may be an additional indicator of disease deterioration, a risk factor of poor therapy response. The advantage of such a non-specific general marker is in the possibility of monitoring the leukemic burden independently of the mechanism of developing resistance.

POLYPLOIDY DETECTION DURING CYTOGENETIC INVESTIGATION OF BONE MARROW FOR THE ASSESSMENT OF THE COURSE OF SOME HEMATOLOGICAL MALIGNANCIES

Y Lozynskyy,[1] M Lozynska,[2] Y Vyhovska,[1] Z Maslyak[1]

[1]*Institute of Blood Pathology, Lviv, Ukraine*
[2]*Institute of Hereditary Pathology, Lviv, Ukraine*

Background. Polyploid metaphases are frequent findings during convenient cytogenetic investigation of bone marrow aspirate from patients with different hematological malignancies. However, they aren't recognized in most cases as a pathological feature, referring polyploid metaphases to the signs of normal megakaryocytes presence in the specimen. Nevertheless, endomitotic events in megakaryocytes are rare phenomena in normal bone marrow, as well as spontaneous polyploidization of hemopoetic cells, and contribute approximately 1% of endomitotic events at the same time in short cultures. *The aim of the Study.* was to evaluate the occurrence and the role of ploidy shift in dividing cells from the cytogenetic samples of bone marrow aspirate from patients with myeloid malignancies. *Materials and Methods.* The cytogenetic study was carried out for bone marrow aspirates from 76 patients: 35 of them had chronic myelogeneous leukemia (CML), 2 had primary myelofibrosis (PM) and 39 suffered from different forms of myelodysplastic syndromes (MDS). The standard 48h-method of cell cultivation was used. Karyotype analysis was performed using G-method of differential staining. Up to 25 metaphases were analysed from every aspirate. *Results.* olyploid metaphases was observed in 14 (35.9%) patients with MDS, and appeared in all cases as a mosaic feature (4.2-50.0% of whole amount of metaphases, in a given patient). Polyploidy as the only variation of karyotype was diagnosed in 6 patients; the other 8 had additional chromosome abnormalities. Polyploid cells were clonal in 3 (7.7%) patients with MDS, and constituted 12.5-50.0% of cytogenetically visible cell population of the specimen. The increased ploidy varied from 3n to 13n, but the most frequent (92.8%) were tetraploids in different proportions. Polyploid metaphases (tetraploids alone or in combination with triploids in 1 patient) were detected in 7 (20.0%) of CML patients and constituted 5.0-40.0% of all metaphases. Polyploids appeared after the beginning of treatment in 2 patients with CML, and were the sole change in the karyotypes, while the Ph-chromosome was already cytogenetically undetectable. Both 2 patients with PM had abnormal polyploid metaphases: 2 neartriploid clones in one patient and 2 variants of neartetraploids in another. *Conclusions.* The primary mutations in myeloid malignancies occur in multipotent cells-progenitors, which mean that such mutations could cause effect on both myeloid, erythroid and megakaryocytic lines. So, the explanation of an increased ploidy in the considerable amount of bone marrow cells may be a presence of pathologically changed megakaryocytes with increased endomitotic activity, which indirectly depict retention of residual malignant clone, even if proliferating blasts are eliminated. The other possibility is that discovered polyploids, especially those detected as a clonal change are blasts. Previous reports have shown that polyploid cells have decreased availability to proliferate. This could result in a small amount of polyploid blast cells during cytogenetic investigation. So, polyploid metaphases should be carefully detected, even if discovered in only one copy per sample, because such finding may show the presence of the residual pathological clone with low proliferative index, availability of several copies of oncogenes and enhanced heterochromatinization, which could cause together higher tolerance for injurious effects of antineoplastic agents.

0205

MUTATIONS OF NPM1, FLT3-ITD/TKD AND CEBPA IS VERY RARE IN MYELOID SARCOMA - FROM AN EVALUATION OF THE DIAGNOSTIC UTILITY OF CYTOGENETIC AND MOLECULAR GENETIC STUDIES IN ISOLATED MYELOID SARCOMA

M Han,[1] M Kim,[1] CW Kim,[1] JS Ahn,[2] HN Kim,[2] HJ Kim,[2] DS Lee[1]

[1]*Seoul National University Hospital, Seoul, South-Korea*
[2]*Chonnam National University Hwasun Hospital, Hwasun-gun, Chonnam-do, South-Korea*

Background. Myeloid sarcoma (MS), an AML equivalent, refers to one or more tumor masses consisting of myeloid blasts occurring at an anatomical site other than the bone marrow (BM). MS is very rare consisting of 3-5% of AML, showing worse prognosis than other AMLs. Common chromosomal abnormalities in MS include *MLL* or *ETV6-RUNX1* rearrangement, monosomy 7 and trisomy 8. Few studies have

studied the incidence of mutations of *NPM1, FLT3* or *CEBPA* - the good prognosis factors of AML - in MS. The cytogenetic and the molecular genetic abnormalities were investigated using G-banding, FISH and mutation analysis. *Aims.* We identified the incidence of recurrent genetic changes of AML in MS and evaluated the diagnostic utility of cytogenetic and molecular genetic studies in detecting BM involvement of MS without morphological evidence. *Methods.* Fourteen cases (1.8%) of MS were selected based on pathological diagnosis out of 784 AML patients Seoul National University Hospital between Jan 1997 and Oct 2010. Serial specimens of primary tissue of MS and BM at diagnosis and in disease monitoring were included in the study. Interphase FISH technique was used to detect *ETV6-RUNX1, CBFB-MYH11, PML-RARA, MLL* or *BCR-ABL1* rearrangements on tissue and BM specimens. G-banding was performed on the BM specimen. Mutation studies including *NPM1, FLT3-ITD/TKD* and *CEBPA* mutation were also performed on tissue and BM specimens. *Results.* The incidence of MS was 1.8% (14/784, 5 males and 9 females, median age 31.1 years ranging from 1 month to 67 years). Most of them (85.7%, 12/14 patients) were presented as isolated MS without BM involvement at initial diagnosis. Affected sites include gingiva, neck lymph node, small bowel, abdominal wall, mediastinal lymph node, retromolar area, palate, uterus, supraclavicular lymph node, and buttock. Out of 12 with isolated MS, 6 patients developed BM involvement during the treatment (median interval, 5.3 months ranging from 2.7 to 14.0 months). Among 12 with isolated MS, 2 had *MLL* rearrangement, and one had *CBFB-MYH11*. The other 9 showed normal karyotype. In one patient with isolated MS, MLL rearrangement was observed in both the tissue of MS (abdominal wall, 91.0% of all nucleated cells in iFISH) and the BM section (5.0%) at the initial diagnosis, without the morphological evidence of BM involvement. The morphological evidence of BM involvement developed in 4 months with additional gain of 1q. Patients who developed BM involvement of GS during treatment showed *MLL* or *CBF-MYH11* rearrangement in both tissue and BM (2 cases), complex translocations involving chromosome 5, 4, 12, 15, 17 and 21, and loss of 7q- (2 cases). All 12 cases showed wild type of *NPM1, FLT3-ITD/TKD* and *CEBPA* genes. *Conclusions.* We confirmed that *MLL* and *CBF-MYH11* is relatively common cytogenetic abnormalities in MS. The mutations of *NPM1, FLT3-ITD/TKD* and *CEBPA* genes were not observed in MS in this study, which might be associated with the poor prognosis of MS than other AMLs. Our result suggests the potential diagnostic utility of cytogenetic/molecular genetic studies in detecting the occult BM involvement of MS without definite morphological evidence.

0206

MONITORING OF TOTAL WT1 EXPRESSION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML): WT1 AS A HELPFUL MARKER BESIDES BCR-ABL

T Lopotová, M Žácková, H Klamová, J Moravcová

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

WT1 encodes for a transcriptional regulator which behaves as an oncogene in leukemias. Although the mechanism of WT1 oncogenic behaviour has not yet been uncovered, WT1 expression is already used as a marker for monitoring minimal residual disease of patients with acute myeloid leukemia. Concerning CML, there is still very limited information about WT1 expression, most of the studies focused on WT1 expression significance for early prediction of relapses following allogenic stem cell transplantation. Now, it is of interest whether monitoring of WT1 expression might be useful also for patients on tyrosin kinase inhibitors. In our study, we focused on WT1 expression in CML patients on imatinib. Altogether, we have examined 35 patients during the course of imatinib therapy: 4 patients exhibited optimal response, 8 suboptimal response and 23 therapy failure. Twenty % of those patients relapsed and the remaining patients stayed without relapse for more than 30 months (45,5 months in median). Real-time PCR was used according to Cilloni *et al*., 2004, B2M was applied as control gene. Predictive value of WT1 expression for development of haematological relapse was compared with that of BCR-ABL transcript and mutations in the BCR-ABL kinase domain. Before upcoming haematological relapse, WT1 expression was increased in about 60% of patients more expressively and in about 45% of patients even in median 2,3 months earlier as compared to BCR-ABL expression. As compared to BCR-ABL mutation analyses, WT1 increase predicted relapse earlier in about one third of patients. According to our experience, CML patients exhibiting suboptimal response and therapy failure represent a highly heterogenic group in terms of relapse emergence during the course of therapy. In our patients cohort, there were 70 % of suboptimal responders and 30 % of patients in therapy failure who did not relapse for more than 30 month of therapy despite of high levels of BCR-ABL (10 to 100%). Interestingly, exact WT1 levels even in the 12th month of therapy corresponded to relapses emergence during further course of the disease. Expression levels higher that 0,1 meant 90% probability of relapse. Taken together, our data indicate that WT1 might be a very useful marker for both relapses prediction during the course of therapy and patients stratification according to risk of relapse at the beginning of treatment. Monitoring of WT1 expression might be thus of advantage both for improving CML therapy outcomes and for further investigation of mechanism underlying different responses to therapy.

Background. In acute myeloid leukemia (AML) the presence or absence of cytogenetic abnormalities allows the identification of favorable, intermediate and unfavorable subgroups. However, besides these specific subgroups, little it is known about the genetic variations influencing specific drug-related phenotypes. *Aims.* To perform an exploratory pharmacogenomic study that relates genetic variations in multidrug enzymes and transporters genes with the efficacy and toxicity to treatment. *Patients and Methods.* We analyzed 94 CD33-positive AML patients younger than 65 previously untreated and enrolled in a phase III multicenter clinical trial combining low dose of Gemtuzumab-ozogamicin (GO) with FLAI regimen (Fludarabine, Cytarabine, Idarubicin) as Induction chemotherapy (eudract: 2007-005248-26; ClinicalTrials.gov NCT00909168). The induction regimen (GO-FLAI) included fludarabine (25 mg/sqm) and Ara-C (2 g/sqm) on days 1-5, idarubicin (10 mg/sqm) on days 1, 3, and 5 and GO (3 mg/sqm) on day 6. Hematopoietic stem cell transplant was planned for all high risk AML patients in first complete remission (CR) after consolidation with intermediate doses of Ara-C and idarubicin. Cytogenetics, multidrug-resistance phenotype, FLT3 and NPM mutation status, as well as WT1 quantitative expression analyses were performed at diagnosis in all patients. Furthermore, high-resolution single nucleotide polymorphism (SNP) array analysis (Affymetrix, Inc. Santa Clara, CA, USA) was also performed. The allele frequencies of 1936 genetic variations of 225 absorption, distribution, metabolism and excretion were assessed using the new Affymetrix drug-metabolizing enzyme and transport (DMET Plus) genotyping platform (Affymetrix). All statistical analyses were performed using the R package 2.11.1. *Results.* Of the 94 patients, genotype results were evaluable for 91 cases. The median call rate was 99.48 (range, 96.32-100). Three samples were run in duplicate and results with "passed call rate"were compared across all the polymorphic sites, showing a repeatability of 99.99%. In an initial screening procedure, we tested the association among SNPs and response to the induction cycle (FLAI + Gemtuzumab-Ozogamicin). Therefore, the genotyping profile of 80 patients in complete (85%) and partial (3%) remission was compared to that of patients (12%) with no response. We found a highly significant difference ($p < 0.001$) in the allele frequency of 2 variants, in complete linkage disequilibrium, in the alcohol dehydrogenase enzyme (ADH1A). These variants were not associated with high risk AML, FLT3 and NPM1 mutations, but strongly influenced response to the induction phase also in a multivariate analysis. Since genetic polymorphisms may influence the toxicity of chemotherapy drugs, we stratified SNPs according to liver toxicity and a significant difference in the allele frequency of a member of the cytochrome P450 family which is involved in the alcohol metabolism (CYP2E1) was found to be associated with a grade I/II liver toxicity. *Conclusions.* A pharmacogenomic panel made up of 1 gene (ADH1A) associated with clinical outcome and 1 gene (CYP2E1) associated with toxicity was for the first time identified in AML patients younger than 65 years treated with a combination of GO and FLAI regimen.

CELLULAR INHIBITOR OF PROTEIN PHOSPHATASE 2A DETERMINES BORTEZOMIB-INDUCED APOPTOSIS IN ACUTE LEUKEMIA CELLS

CY Liu,[1] CW Shiau,[2] HY Kuo,[2] HP Huang,[3] MH Chen,[1] CH Tzeng,[1] KF Chen[3]

[1]*Taipei Veterans General Hospital, Taipei, Taiwan*
[2]*Institute of Biopharmaceutical Sciences, National Yang-Ming University, Taipei, Taiwan*
[3]*National Taiwan University Hospital, Taipei, Taiwan*

Background. Bortezomib has excellent antitumor activity against multiple myeloma and mantle cell lymphoma via its proteasome inhibition. The multiple cellular targets affected by proteasome inhibition implicate the potential role of bortezomib in enhancing antitumor activities in other hematological malignancies, despite that currently bortezomib is only approved in mantle cell lymphoma and multiple myeloma. Our previous study has shown that down-regulation of phospho-Akt (p-Akt) plays a key role in determining the sensitivity of hepatocellular carcinoma cells to bortezomib-induced apoptosis. *Aims.* In this study we aimed to examine the antitumor activity of bortezomib and to further explore the mechanism by which bortezomib induces apoptosis in acute leukemia cells, particularly focusing on target(s) regulating p-Akt (such as protein phosphatase(s)). *Methods.* Several acute leukemia cell lines were used for *in vitro* studies. Apoptosis was examined by both flow cytometry and Western blot. Signal transduction pathways in cells were assessed by Western Blot. Gene silencing was done by small interference RNA (siRNA). *Results.* We demonstrated bortezomib differentially induced apoptosis in acute leukemia cells (Fig 1b and 1c). Importantly, bortezomib showed the similar inhibition of the proteasome activity in both sensitive and resistant cells, suggesting that bortezomib-induced apoptotic effect may be independent of its proteasome inhibitory effect (Fig 1d). Furthermore, we found that a novel oncoprotein, cancerous inhibitor of pro-

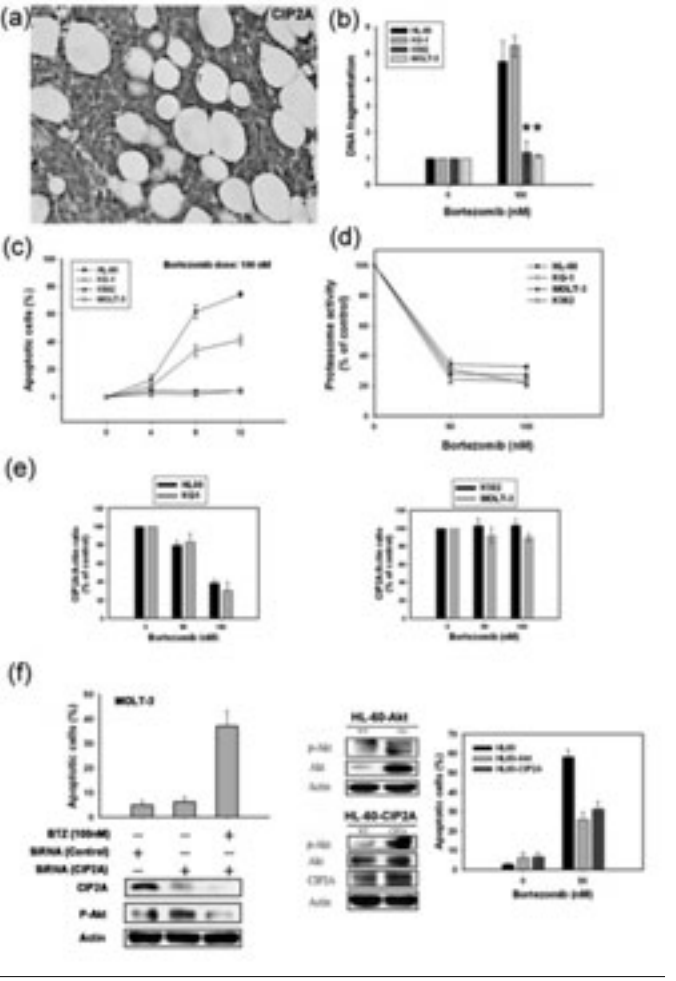

Figure 1. CIP2A in acute leukemia.

tein phosphatase 2A (CIP2A), a cellular inhibitor of protein phosphatase 2A (PP2A), mediated this apoptotic effect of bortezomib in acute leukemia cells. CIP2A expression is readily demonstrated in acute leukemic blasts (Fig. 1a). In accordance to our previous study on bortezomib, we showed bortezomib increases PP2A activity in sensitive acute leukemia cells (HL-60 and KG-1), but not in resistant ones (MOLT-3 and K562). We validated that bortezomib's down-regulation of CIP2A and p-Akt correlates with its drug sensitivity. Over-expression of CIP2A or Akt in HL-60 cells protected cells from bortezomib-induced apoptosis, and down-regulation of CIP2A by siRNA overcame the apoptotic resistance to bortezomib in MOLT-3 cells (Fig 1e and 1f). Furthermore, we indicated that CIP2A negatively regulates Akt-related PP2A activity. Importantly, bortezomib exerts *in vivo* antitumor activity in HL-60 xenografted tumors (in nude mice), but not in CIP2A overexpressed HL-60 tumors. Interestingly, HL-60 cells with ectopic CIP2A expression had increased cell proliferation and DNA synthesis, as well as a more rapid xenografted tumor growth. *Summary.* In conclusion, this study has identified CIP2A as a major molecular determinant of bortezomib's sensitivity on acute leukemia cells and that CIP2A may play an important role in leukemia biology. It is also implicated that focusing on interaction of oncoprotein and phosphatase and kinases could be a novel anti-leukemia strategy.

THE MULTI-KINASE INHIBITOR TG02 DOWNREGULATES MCL-1 IN AML CELLS AND PREFERENTIALLY TARGETS CD34+CD38-CD123+ CELLS FROM SAMPLES WITH AN INTERNAL TANDEM DUPLICATION OF FLT3

M Pallis,[1] F Burrows,[2] M Jawad,[3] N Yu,[3] C Seedhouse,[3] N Russell[3]

[1]*Nottingham University Hospitals, Nottingham, United Kingdom*
[2]*Tragara Pharmaceuticals, San Diego, United States of America*
[3]*University of Nottingham, Nottingham, United Kingdom*

Background. In clinical trials, FLT3 inhibitors are reported to kill circulating AML blasts, but the bone marrow is protected. We have previously reported that niche-like conditions (fibronectin and a cytokine cocktail) significantly reduced the *in vitro* toxicity of the FLT3 inhibitor AG1296 to AML cells. Moreover, the toxicity of AG1296 to the quiescent, stem-cell-enriched leukaemic CD34+CD38-CD123+ subset was completely abolished under niche-like conditions. The novel multi-kinase inhibitor TG02 has selectivity against cell cycle and transcriptional CDKs and JAK2 as well as FLT3. TG02 has efficacy in *in vivo* models and induces apoptosis in primary AML cells including CD34+CD38-CD123+ cells. We have now evaluated the impact of FLT3 internal tandem duplications (ITDs) on the *in vitro* toxicity of TG02 under niche-like conditions. FLT3 ITDs are associated with over-expression of the survival molecule Mcl-1, particularly in the leukaemic stem cell compartment. We have therefore investigated the impact of TG02 on Mcl-1. *Methods.* The 48 hour toxicity of TG02 to primary AML blasts and to the MOLM13 cell line, which harbours a FLT3 internal tandem duplication (ITD), were studied by flow cytometric viable cell enumeration. Mcl-1, phosphorylated (active) STAT5 and phosphorylated RNA polymerase II serine 2 (RP2) were measured by flow cytometry. Phosphoproteome analysis was performed with a kit from R&D Systems. Phosphorylated p38 was measured by Western blotting. *Results.* In a cohort of eight FLT3-ITD and twelve FLT3-wildtype samples examined under niche-like conditions, 100 nM TG02 induced median decreases of 37% in bulk cells and 33% in CD34+CD38- CD123+ cells, whereas AG1296 (5μM) induced a median 20% decrease in bulk cells but no reduction in CD34+CD38- CD123+ cells. Cells with a FLT3 ITD were preferentially targeted by TG02 (p=0.05 for bulk cells and P=0.002 for CD34+CD38-CD123+ cells). TG02 might target Mcl-1 through inhibition of JAK/STAT pathways and/or through CDK9-mediated inhibition of RP2. In MOLM13 cells, a 20 hour incubation with 100 nM TG02 inhibited active RP2 to 4% of control values, and Mcl-1 protein was decreased by 73%, but STAT5 activity was not reduced. On treating primary AML samples with TG02, we found inhibition of STAT5 activity in the absence, but not the presence, of supportive niche-like conditions. However, RP2 is strongly inhibited by TG02 in primary samples, even in the presence of niche-like conditions and Mcl-1 protein expression is decreased, suggesting a role for CDK9 inhibition. Additionally, signalling through the stress kinase p38 is strongly inhibited by TG02, which may induce other changes in apoptotic regulatory circuits. These are currently under investigation. *Conclusion* . Under niche-like conditions TGO2 is able to target CD34+CD38-CD123+ AML cells, as well as bulk AML cells, particularly in samples characterised by a FLT3 ITD. TG02 toxicity in AML is associated with inactivation of RNA Polymerase II and p38 and downregulation of Mcl-1.

0210

POLYMORPHISM Q141K OF ABCG2 PROTEIN IS ASSOCIATED WITH POOR OUTCOME IN ACUTE MYELOID LEUKEMIA PATIENTS RECEIVING IDARUBICIN-BASED CHEMOTHERAPY

M Tiribelli,[1] D Fabbro,[2] A Michelutti,[1] A Franzoni,[2] M Cavallin,[1] A Pianta,[2] A Geromin,[1] R Fanin,[1] G Damante,[2] D Damiani[1]

[1]*Division of Hematology and BMT, Udine, Italy*
[2]*Institute of Genetics, Udine, Italy*

Background. Single nucleotide polymorphisms (SNPs) in drug metabolism and transporters genes can explain the large inter-individual variability in response to therapy. Among naturally occurring SNPs reported in ABCG2 protein, a member of ABC transporter protein recently associated with negative prognosis in acute myeloid leukemia (AML), the Q141K variant is the most frequent in Caucasian population. Data from *in vitro* studies suggest that this polymorphism affects the protein function. modifying the resistance profile of many anticancer agents such as mitoxantrone, daunorubicin, topotecan and SN-38. However, *in vivo* effects are still largely unknown. *Aims.* We evaluated the prevalence of Q141K ABCG2 protein in a series of patients with AML referred to the Division of Hematology of Udine for diagnosis and/or therapy, with the purpose to assess its potential impact on response to chemotherapy. *Methods.* A total of 163 consecutive patients with non-promyelocytic AML were included in the study. ABCG2 expression was evaluated by flow cytometry; ABCG2 mRNA expression was normalized to the simultaneously analyzed GAPDH gene (assays on demand Applied Biosystems: ABCG2 Hs00184979 m1 and GAPDH Hs9999905 m1,). ABCG2 sequence was evaluated by the TaqMan SNP Q141K genotyping Assay (Applied Biosystems, C_15854163_70). One hundred twenty two of 163 patients received chemotherapy according to the Institutional protocol; induction regimen included fludarabine in all cases and idarubicin was the only anthracycline used through all the therapeutic program. *Results.* Q141K ABCG2 was detected in 29/163 (17.8%) patients, a percentage comparable to what is reported by the literature in Caucasian ethnicity. Membrane protein expression was variable among mutated patients: 18/29 (62%) overexpressed ABCG2. Seventy two out of the 122 (59%) treated patients responded to therapy, irrespectively of ABCG2 expression or protein polymorphism. Complete remission was affected by age, CD34 and CD56 expression. Relapse occurred in 27/72 (52%) patients; relapse risk was affected by ABCG2 overexpression, CD34 positivity and CD56 expression. Considering the whole population, a trend of a shorter leukemia free survival (LFS) was observed in patients with Q141K variant, but the difference did not reach statistical significance. However, stratifying patients in three groups, by high or low ABCG2 expression and by presence of Q141K polymorphism (regardless of ABCG2 expression intensity), we observed a significantly higher relapse probability in mutated patients, whose LFS was comparable to those with ABCG2 over-expression (chi squared 8.7; p=0.019). Median survival was 16 months (95% CI: 11-31 months). Overall survival (OS) was affected by age, CD34 and high ABCG2 expression. Again no differences were observed between wild type or mutated protein if the whole population was considered, but a significantly worse survival in Q141K group emerged after stratification in three groups (chi squared 6.8; p=0.032). High ABCG2 expression, Q141K polymorphisms, age and CD34 positivity maintained their negative impact also in multivariate analysis. *Summary/Conclusions.* This is the first observation of the negative impact of Q141K ABCG2 polymorphism on leukemia outcome. If confirmed in larger studies, our data suggest that patients-tailored post induction therapy should be planned in presence of Q141K ABCG2, including drugs not affected or positively affected by the mutated protein.

0211

REGULATION OF CYP3A4 AT NFSE IN HEMATOPOIETIC CELLS INVOLVES RNA AND EF1A

S Cohen, S Haim, T David-Kalish, E Malik, D Rund

Hadassah University Hospital, Jerusalem, Israel

Background. CYP3A4 is the most abundantly expressed hepatic cytochrome P450 and significantly contributes to drug metabolism, with substantial intra- and inter-individual variability. Its regulatory mechanisms are still enigmatic, with complex interactions in the 5'-flanking region. An A to G substitution in the nifedipine responsive element (NFSE) of the CYP3A4 promoter (termed CYP3A4*1B) is associated with a lower incidence of pediatric (Felix, PNAS, 1998) and adult (Rund, Leukemia, 2003) therapy-related AML. Previous studies by

others demonstrated binding of nuclear proteins at NFSE in hepatic cells and we have found such binding in hematopoietic cell lines and primary AML patient cells. NFSE regulation appears to be stress-responsive (heat shock) (David-Kalish, 2005). *Aims.* 1. To analyze expression of wild type and polymorphic NFSE sequences in hematopoietic cells. 2. To identify the proteins which differentially bind to the wild type and polymorphic sequences. 3. To determine if these proteins are regulated by stress (such as heat and chemotherapy), possibly via HSR1, an RNA molecule that activates stress response genes such as HSF-1. *Methods.* We constructed luciferase reporter plasmids (pGLE vector) driven by the CYP3A4 promoter, using polymorphic and wild type sequences. These plasmids were transfected into hematopoietic cell lines: K562 (CML blast crisis), CCRF (T cell ALL) and KG1a (myeloid leukemia). HepG2 (hepatoma) served as a control. In addition, electrophoretic mobility shift assays (EMSA) were performed using nuclear extracts from various cells using radiolabelled probes corresponding to the wild type and polymorphic sequences. A streptavidin-biotin system was used to isolate the proteins binding at NFSE. *Results.* CYP3A4 reporter gene studies demonstrated 20-30% lower activity in KG1a, CCRF and K562 using the polymorphic compared to the wild type sequence while HepG2 showed higher activity with the wild type. The results for HepG2 confirmed results reported by Rebbeck (2003). EMSA demonstrated NFSE binding using nuclear extracts from CCRF which increased following heat shock. In CCRF-Actinomycin resistant cells, the heat shock effect was stronger. The streptavidin-biotin system demonstrated that the DNA binding complex at NFSE was present in the same elution fractions containing HSF-1. Mass spectrometry demonstrated elongation factor 1a (EF1a). EF1a is known to be activated by an RNA molecule (Shamovsky 2006). Treatment with RNase enhanced binding to NFSE, suggesting that RNA interferes with binding of nuclear proteins to the CYP3A4 promoter. Addition of EF1a antibodies to nuclear extracts increased binding. NFSE complex formation was further enhanced when RNase and anti-EF1a were used together. The influence of RNase on the signal of the complex using the polymorphic NFSE probe was greater than its effect on NFSE wild type. Additional factor(s) may facilitate(s) assembly of the complex. The ALIBaBa database of transacting factors states high homology of the 5'11bp-NFSE-9bp 3' region with the consensus binding site of C/EBPb. C/EBPb itself was found involved indirectly, reducing the strength of the complex, possibly by binding to the C/EBPb element, found upstream to NFSE. *Conclusions.* Regulation of CYP3A4 at NFSE in hematopoietic cells appears to be stress-responsive, involving RNA as well as EF1a, not previously reported for other CYP genes.

INTERACTION OF THE COMMON HOCT1 M420DEL AND M408V SNPS IS CRITICAL IN PREDICTING CLINICAL OUTCOME IN IMATINIB TREATED CHRONIC MYELOID LEUKAEMIA

A Giannoudis,[1] L Wang,[1] G Xinarianos,[1] S Pushpakom,[1] T Liloglou,[1] E Zhang,[1] G Austin,[1] T Holyoake,[2] L Foroni,[3] M Müller,[4] M Pirmohamed,[1] R Clark[1]

[1]*University of Liverpool, Liverpool, United Kingdom*
[2]*University of Glasgow, Glasgow, United Kingdom*
[3]*Hammersmith Hospital, London, United Kingdom*
[4]*University of Heidelberg, Mannheim, Germany*

Background. The human organic cation transporter 1 (hOCT1) is responsible for the uptake of imatinib into chronic myeloid leukaemia (CML) cells. Its expression level and functional activity are powerful predictors of the clinical response to imatinib (Wang *et al.,* Clin. Pharm. Therapeut. 2008, White *et al.,* Blood 2007). Several single nucleotide polymorphisms (SNPs) in hOCT1 affect its expression and transport activity, contributing to inter-individual variation in clinical response. SNPs in hOCT1, particularly M420del (c.1260del, allele frequency 18.5% in European-Americans), can affect the action and pharmacokinetics of metformin, an anti-diabetic drug and a well known hOCT1 substrate (Shu *et al.,* Clin. Pharm. Therapeut. 2008). In addition, M408V is another common hOCT1 SNP with allelic frequency approximately 59.8% in European-Americans. *Aim.* Firstly to analyse the uptake activities of the common hOCT1 variants M420del and M408V in a CML cell line model and secondly to investigate the effect of these SNPs on the clinical response to imatinib treatment in a large cohort of newly diagnosed CML patients. *Methods.* KCL22 CML cells were selected for hOCT1-transfection due to their low basal hOCT1 expression. The specific SNPs were introduced to the pcDNA-hOCT1 plasmid by site-directed mutagenesis. Stably transformed cell lines with various combinations of M420del and M408V SNPs were generated. The uptake of 14C-radiolabelled imatinib into different cells was measured by scintillation counter. Genomic DNA samples were prepared from peripheral blood from 182 newly diagnosed chronic phase CML patients prior to imatinib therapy. Genotyping for the M420del and M408V SNP was performed by pyrosequencing and Sequenom MALDI-TOF Mass ARRAY. *Results.* Cell lines carrying the hOCT1 M420del and M408 showed a significant decrease in imatinib uptake compared with wild-type KCL22 cells with undeleted M420 and M408 (p=0.001). Conversely, KCL22 cells with undeleted M420 and V408 had an increased imatinib uptake compared with cells with undeleted M420 and M408 (p=0.05). In KCL22 cells with both M420del and V408, uptake did not differ from the wild type cells. These data imply that both M420del and M408V play a role in the uptake of imatinib by hOCT1 transporter, whereby M420del decreases uptake and V408 increases it. In clinical samples from 182 cases of newly diagnosed CML patients treated with imatinib, patients who carried the M420del allele (n=53) had a greater probability of imatinib resistance requiring a change of therapy (p=0.034) and treatment failure (i.e. resistance + intolerance; p=0.024, Kaplan-Meier log-rank test) than patients with undeleted M420. Patients carrying both M420del and M408 alleles (n=43) had a greater probability of imatinib resistance requiring a change of treatment (p=0.025) and treatment failure (p=0.014). However, patients with both M420del and V408 had comparable times to treatment failure to patients with undeleted M420 and M408 demonstrating that V408 can reverse the adverse effect of M420del. *Summary/Conclusions.* This study provides evidence on the functional significance of both M420del and M408V polymorphisms in hOCT1. It also demonstrates the importance of SNP interactions in determining clinical outcome. These SNPs may have potential use for patient-specific therapy in newly diagnosed chronic phase CML.

PREDICTION OF IMATINIB THERAPY RESPONSE: A ROLE OF INTRACELLULAR TRANSPORTERS HOCT-1 AND ABCB1

F Rázga,[1] Z Racil,[1] L Buresova,[2] K Machova Polakova,[3] H Klamova,[3] D Zackova,[1] D Dvorakova,[1] P Cetkovsky,[3] J Mayer[1]

[1]*Faculty Hospital Brno, Brno, Czech Republic*
[2]*Institute of Biostatistics and Analyses Masaryk University, Brno, Czech Republic, Brno, Czech Republic*
[3]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic, Prague, Czech Republic*

Background. The role of intracellular IMA transport in overall resistance and in treatment outcome prediction have been intensively studied since main influx (hOCT-1) and efflux (ABCB1) transport proteins have been described. Several studies that correlate the pretreatment activity/mRNA expression of IMA transporters with subsequent therapy response have been reported to date. However, different cell populations from patients who received various degree of pretreatment were used for these analyses. Therefore, several biases in the results and their interpretation may arise. *Aims.* In this report we demonstrate that the composition of analyzed material at the time of testing (i.e. percentage of different cell types) has critical impact on the resultant activity/mRNA expression of these transporters, and therefore it can significantly affect the overall correlation and data interpretation. *Methods.* We analyzed the differences in *hOCT-1* and *ABCB1* mRNA expression measured in peripheral blood (PB) leukocytes (LEU), polymorphonuclear cells (PMNC) and mononuclear cells (MNC) of PB LEU obtained from healthy volunteers and patients with *de novo* CML. Additionally, we analyzed the changes in *hOCT-1* expression during the first six months of IMA therapy and the relationship between the percentage of individual cells that comprise the total LEU count and *hOCT-1* and *ABCB1* mRNA expression assessed from the total LEU. Finally, we investigated the predictive value of the pretreatment mRNA expression levels of *hOCT-1* and *ABCB1* in selected cell populations with regard to the therapy response at six and twelve months of IMA therapy. *Results.* The *hOCT1* mRNA expression was significantly higher in PB PMNC compared to MNC. Expression in each analyzed group of cells was always significantly lower in IMA naïve *de novo* CML patients compared to healthy volunteers. This difference disappeared after the initiation of IMA therapy, suggesting that CML tumor burden and the degree of pretreatment at the time of monitoring were both influencing factors. Moreover we found the statistically significant relationship between *hOCT-1* mRNA expression and the percentage of immature myeloid cells as well as BCR/ABL transcript levels in PB (both as indirect markers of tumor burden). Considering *ABCB1* expression, it was significantly higher in MNC compare to PMNC. Similarly to *hOCT-1*, a

correlation with percentage of immature myeloid cell was obtained. All these results suggest that both *hOCT-1* and *ABCB1* mRNA expression level used as a prognostic factor should always be assessed in relation to the cell type in which expression was measured. Finally, regarding the therapy response prediction, no statistically significant relationship between the pretreatment levels of *hOCT-1* or *ABCB1* mRNA expression in different cell populations and therapy response, have been observed. *Conclusion.* The observed cell type dependence, tumor burden dependence, and other pre-analytical and analytical biases found in recent literature lead to the conclusion that the desired stratification of CML patients into responders/non-responders prior to IMA therapy is hardly to obtain and these parameters are not suitable for routine clinical practice.

0214

P-GLYCOPROTEIN AND BREAST CANCER RESISTANCE PROTEIN IN ACUTE MYELOID LEUKAEMIA CELLS TREATED WITH THE AURORA-B KINASE INHIBITOR BARASERTIB-HQPA

M Grundy, M Pallis, N Russell, C Seedhouse

Nottingham University Hospitals, Nottingham, United Kingdom

Background. Aurora kinases play an essential role in orchestrating chromosome alignment, segregation and cytokinesis during mitotic progression, with both aurora-A and B frequently over-expressed in a variety of human malignancies. Over-expression of the ABC drug transporter proteins P-glycoprotein (Pgp) and Breast cancer resistance protein (BCRP) is a major obstacle for chemotherapy in many tumour types with Pgp conferring particularly poor prognosis in acute myeloid leukaemia (AML). Barasertib-hQPA is a highly selective inhibitor of aurora-B kinase that has shown tumouricidal activity against a range tumour cell lines including those of leukaemic AML origin. *Aims.* Using leukaemic cell lines and primary samples we aim to investigate the specificity of barasertib-hQPA with particular reference to their ABC transporter status. *Methods.* We analysed response in a panel of leukaemic cell lines and 37 primary AML samples by measuring phosphoHistone H3 (pHH3) expression, the biomarker for barasertib-hQPA activity. *Results.* In this study we report the creation of the cell line OCI-AML3DNR, which over-expresses Pgp but not BCRP or multidrug resistance-associated protein (MRP), through prolonged treatment of OCI-AML3 cells with daunorubicin. We demonstrate that Pgp (OCI-AML3DNR and KG-1a) and BCRP (OCI-AML6.2) expressing AML cell lines are less sensitive to barasertib-hQPA induced pHH3 inhibition and subsequent loss of viability compared to transporter negative cell lines. We also show that barasertib-hQPA resistance in these cell lines can be reversed using known Pgp and BCRP inhibitors. We report that barasertib-hQPA is not an inhibitor of Pgp or BCRP, but by using 14[C]-barasertib-hQPA that it is effluxed by these transporters. We measured Pgp and BCRP expression in 37 primary AML samples. 9/37 (24.3%) were positive for Pgp and 9/35 (25.7%) were positive for BCRP with a significant correlation (p=0.008) seen for co-expression. By measuring pHH3 expression in AML samples cultured for 1 hour with or without barasertib-hQPA we determined that Pgp and BCRP positive primary samples were less sensitive to barasertib-hQPA induced pHH3 inhibition (p=<0.001) than transporter negative samples. However, we found that IC50 inhibition of pHH3 by barasertib-hQPA was achieved in 94.6% of these samples after 1 hour drug treatment, in contrast to the resistance seen in the cell lines. *Conclusions.* We conclude that monitoring of Pgp, BCRP status and pHH3 down-regulation should be considered in patients treated with barasertib in order to establish whether transporter-mediated efflux is sufficient to adversely impact on the efficacy of the agent.

0215

THE ABCC3 EFFLUX TRANSPORTER CAN PREDICT CLINICAL OUTCOME IN CML PATIENTS AND IS AN IMPORTANT DETERMINANT OF DRUG FAILURE

A Giannoudis, A Davies, R Harris, C Lucas, S Francis, M Pirmohamed, R Clark

University of Liverpool, Liverpool, United Kingdom

Background. Imatinib is a substrate for the ABC efflux transporters ABCB1 (MDR1) and ABCG2 (BCRP), whereas its uptake into the cells is highly dependent on the expression and/or the activity of the influx transporter SLC22A1 (OCT1). A recent study by Hu *et al*. (Clin. Cancer Res, 2008) showed that SLC22A1 expression was interrelated with the expression of ABCB1, ABCC3, ABCC4, ABCG2 and OATP1A2. Thus, they suggested that SLC22A1 expression may be a composite surrogate for expression of other transporters relevant to the intracellular uptake and retention of imatinib. *Aim.* To assess a panel of organic anion/cation and ABC transporters in CML patients to determine their contribution to the cellular transport of imatinib and to relate findings to the eventual patient outcome. *Materials and Methods.* Peripheral blood leukocytes were collected from 4 normal individuals and 48 newly diagnosed CML chronic phase patients prior to imatinib treatment, and 12 months after initiation of therapy. All CML cases were positive for the t(9;22) translocation at diagnosis and were classified into three response groups following 12 months of imatinib treatment; R (responders, complete cytogenetic response), NR (non-responder, complete haematological but no cytogenetic response) and blast crisis (BC). The TaqMan low density array (TLDA) and single TaqMan gene expression assays were used. The relative expression level of a particular gene of a given sample was calculated by the Comparative Ct method. KCL22, K562, KYO1 and Lama84 CML cell lines were included as controls. *Results.* A significant positive correlation was shown to exist between SLC22A1 (OCT1) and SLC22A4 (r=0.74, Sign at 0.000), ABCC3 (r=0.6, Sign at 0.000), SLCO3A1 (r=0.68, Sign at 0.000), SLCO1A2 (r=0.53, Sign at 0.000), SLC22A5 (r=0.48, Sign at 0.001), and ABCB1 (r=0.48, Sign at 0.001). Clinically, of the influx transporters, only SCL22A4 appeared to be important (but not to statistically significant levels R vs NR/BC p=0.059), while for the efflux transporters ABCC3 appeared to be more important than ABCB1 (R vs NR p=0.016; R vs BC p=0.027, respectively). Additionally, when patients' SLC22A1, ABCB1 and ABCC3 mRNA levels were compared it was apparent that patients with high ABCC3 expression were failing treatment irrespective of SLC22A1 expression levels. *Summary/Conclusions.* Our data clearly demonstrate the importance of the ABCC3 efflux transporter in imatinib treated CML patients and propose its potential use as a prediction marker of treatment failure. We are testing this idea within a larger clinical cohort as well as against the clinical response with other TKIs.

0216

MOLECULAR MECHANISMS OF NILOTINIB RESISTANCE AND REVERSAL OF RESISTANCE IN CHRONIC MYELOID LEUKEMIA CELLS

Y Baran,[1] A Camgoz,[1] A Ural,[2] F Avcu[2]

[1]*Izmir Institute of Technology, Izmir, Turkey*
[2]*Gulhane Medical School, Department of Hematology, Ankara, Turkey*

Background. Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells, arising from a reciprocal translocation between long arms of chromosomes 9 and 22, known as the Philadelphia chromosome. This translocation causes a juxtaposition of ABL and BCR genes, resulting in a BCR-ABL fusion gene. Nilotinib disrupts the ATP-binding pocket of BCR/ABL oncoprotein and inhibits interaction, and thus, phosphorylation with the target proteins. However, despite high rates of hematologic and cytogenetic responses, intrinsic or acquired nilotinib resistance is still the main problem for the treatment of chronic myeloid leukemia patients. *Aims.* In this study we aimed to develop a nilotinib resistance cell line, to examine the molecular mechanisms of nilotinib resistance. Furthermore, we aimed to reverse nilotinib resistance by modulating bioactives phingolipids metabolism with using glucosyle ceramide synthase (GCS) and sphingosine kinase-1 (SK-1) inhibitors. *Methods.* Human Antiproliferative effects of nilotinib on K562 and 50 nM nilotinib-resistant K562 (K562/NIL-50) cells were determined by XTT cell proliferation assay. Changes in caspase-3 enzyme activity and mitochondrial membrane potential were determined by caspase-3 colorimetric assay kit and JC-1 mitochondrial membrane potential detection kit, respectively. Expression levels of Bcr/Abl, apoptosis related genes (bcl-2, bcl-xl, bax, caspase-3), ceramide synthase genes (CerS1-6), GSS and SK-1, drug transporter genes (mdr1, mrp1, bcrp, lrp) and Beta-actin as an internal positive control were assed by RT-PCR. *Results.* IC50 values of nilotinib were calculated as 42 and 385 nM for K562 and K562/NIL-50 cells, respectively indicating that K562/NIL-50 cells gain about 10-fold resistance to nilotinib as compared to parental K562 cells. Apoptotic mechanisms were repressed in K562/NIL-50 cells as determined by decrease in caspase-3 enzyme activity and increases in mitochondrial membrane potential. Expression levels of Bcr-Abl gene were upregulated in K562/NIL-50 cells as compared to parental sensitive cells. Nucleotide sequence analyses of ABL kinase gene revealed that there was no mutation in nilotinib binding site of BCR/ABL oncogene in resistant cells. There was also an increase in expression levels of MRP1 gene in resistant cells. Besides, apoptotic Bax and CerS1 genes were downregulated and

antiapoptotic GCS and SK-1 genes were upregulated in K562/NIL-50 cells. Inhibition of GCS and SK-1 by chemical inhibitors sensitized K562/NIL-50 cells to nilotinib as determined by cell proliferation and apoptosis analyses. *Summary/Conclusions.* Determination of genetics mechanisms of cellular resistance in response to nilotinib is very important. In conclusion, we determined mechanisms involved in nilotinib-resistance in CML cells. Our results also demonstrated that targeting antiapoptotic GCS and SK-1 genes, besides inhibition of BCR-ABL by nilotinib, may be a good way of treatment of CML.

0217

PHARMACOGENETICS IN CHRONIC MYELOID LEUKEMIA TREATMENT: A TOOL TO PREDICT THERAPY OUTCOME TO IMATINIB TREATMENT?

L Campiotti,[1] M Ferrari,[1] E Orlandi,[2] M Boni,[2] B Rocca,[2] L Appio,[1] F Passamonti,[1] C Terrasanta,[1] F Marino,[1] M Cosentino[1]

[1]*University of Insubria, Varese, Italy*
[2]*Irccs Foundation Policlinico San Matteo, Pavia, Italy*

Background. Imatinib mesylate (IM) is a selective tyrosine kinase inhibitor, that has achieved successful treatment outcomes and improved the life quality of chronic myeloid leukemia (CML) patients. However, some of the patients fail to achieve optimal response, and a substantial proportion of patients develop resistance to IM. Several determinants were known to be associated with the pharmacokinetics of imatinib with respect to absorption, distribution, and metabolism, influencing the systemic level or intracellular concentration of imatinib which might affect response to therapy. IM is a substrate for the adenosine triphosphate binding cassette (ABC) transporters, ABCB1 and ABCG2, whereas the active uptake of IM into cells is mediated by the human organic cationic transporter-1 (OCT1; SLC22A1). Also, IM is metabolized through first-pass drug metabolism by the cytochrome P450 - CYP1A2, CYP2C9, CYP2D6, CYP3A4 and CYP3A5. Genetic variations affecting genes involved in IM transport and metabolisms, however, role of single nucleotide polymorphisms (SNPs) in predicting therapy outcome remains to be established. *Aims.* The aim of present work is to correlate response to imatinib therapy in CML patients with common SNPs, alone or in combinations, in genes involved in pharmacokinetics of these drugs. *Methods.* We evaluated imatinib efficacy as: (a) molecular response: complete (CMoR; defined as disappearance of detectable BCR/ABL fusion gene transcripts by quantitative PCR) / major (MMoR; defined as =3 log reduction of BCR/ABL fusion gene transcripts) / absent (AMoR) after 18 moth treatment (b) cytogenetic response: complete (CCyR; 0% Ph+ cells in marrow by conventional cytogenetics) / partial (PCyR; 0-35% Ph+ cells in marrow) after 12 moth treatment. We analyzed 10 candidate gene SNPs: in 3 genes associated with imatinib transport (ABCB1, ABCG2 involved in drug extrusion and SLC22A1 involved in imatinib cell uptake) and 4 genes associated with drug metabolism (CYP1A2, CYP2C9, and CYP3A5). Genotyping was performed by Real Time PCR using TaqMan probe. ABCB1 phenotype was defined according to specific SNPs combinations as follow: Low Transporters (LT): patients carriers at least 3 polymorphic alleles; Intermediate Transporters (IT): patients carriers 2 polymorphic alleles and Extensive Transporters (ET): patients carriers no more that 1 polymorphic allele. *Results.* So far, 57 patients with CML treated with imatinib were enrolled: 11 (3M/8F; age 54±10 years achieved CMoR, 24 (14M/10F; age 54±17 years) MMoR and 22 (7M/15F; age 58±16) AmoR 51 patients (22M/29F; 55±15 years) shown CCyR and 6 (2M/4F; 56±16 years) PCyR. Cytogenetic response was not associated with genetic profile. However SNPs in ABCG2 (rs2231137), and in SLC22A1 (rs683369), but not in ABCB1 and cytochrome, were significantly associated with molecular response. Moreover, 4 (37%) patients with CMoM had ABCB1 LT phenotype, while only 2 (9%) patients with AMoR were LT, (CHI^2 test: P = 0.045). *Conclusions.* Preliminary results showed that the treatment outcomes, especially for molecular response, of imatinib therapy could be predicted using a novel, multiple candidate gene approach based on the pharmacogenetics of IM.

0218

ASPIRIN RESISTANCE IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

N Candeo, S Vettore, F Tezza, I Bertozzi, ML Randi
University of Study of Padua, Padova, Italy

Background. Low-dose aspirin (100mg/die) improves the survival of patients with cardiovascular events; however, about 25% of the patients treated with aspirin present thromboembolic complications (aspirin resistance). Pharmacological resistance is defined as the inability of aspirin to inhibit platelet aggregation and thromboxane production. Patients affected by myeloproliferative neoplasms (MPN) are at risk for thromboembolic complications and low-dose aspirin are effective also in these patients in reducing their thromboembolic risk. At present, few is known about aspirin resistance in this set of patients. *Aims.* This study explores pharmacological aspirin resistance in patients with MPN, in particular with polycythemia vera (PV) and essential thrombocythemia (ET), evaluated with platelet aggregation and serum thromboxane (TxB2) assay. *Patients and Methods.* We studied 123 MPN patients (41 PV and 82 ET), 83 were treated with aspirin (100mg/die) (MPN-ASA) and 40 were not (MPN-basal). PV and ET were diagnosed in agreement with WHO criteria. As controls we studied 50 patients treated with aspirin (100mg/die) for secondary prevention of thrombosis (Controls-ASA) and 42 healthy subjects (Controls). Platelet aggregation under 1 mM arachidonic acid (AA) stimulus was evaluated with Born's method. Serum thromboxane B2 (TxB2) was measured with ELISA assay (Thromboxane B2 Express EIA kit-monoclonal, Cayman Chemical Company; USA). Comparison between categorical variables was performed by $\chi 2$test and the threshold of serum TxB2 has been defined with ROC curve considering Controls and Controls-ASA TxB2 levels and obtaining a cut-off value of TxB2 to define the "aspirin resistance". *Results.* All Controls-ASA (100%) had suppressed AA-aggregation (<10%), while 22 MPN-ASA (26.5%) had not (80 ± 16%). No statistical difference was found in serum TxB2 between Controls and MPN basal or between the MPN-ASA and Controls-ASA. TxB2 production was significantly reduced in Controls-ASA compared to Controls ($p < 0.0001$) as well as in MPN-ASA compared to MPN-basal ($p = 0.04$); however, MPN-ASA had significantly higher levels of TxB2 than Controls-ASA ($p < 0.0001$).

	Platelets $x10^9$/L	TxB2 pg/mL	TxB2 pg x 10^{-8} plts
Controls (42)	229±73	36451±5754	25085±6788
MPN basal (22)	584±120	45058±32515	32099±6650
Controls-ASA (21)	236±90	1095±170	441±65
MPN- ASA (77)	614±323	5759±2881	1432±194

Serum TxB2 948 pg/plts x 10-8 was the cut-off limit to distinguish patients with a reduced suppression of TxB2 by aspirin (aspirin resistant). None of Controls and MPN-basal had a TxB2 value lower than 948 pg/plts x 10-8, while 2 (9.5%) Controls-ASA and 37 MPN-ASA (48%) were "aspirin resistant". 18 MPN-ASA (25%) had both an AA-aggregation > 10% pattern and a reduced suppression of serum TxB2 production, despite the use of aspirin. *Conclusions.* Pharmacological aspirin resistance occurs more frequently in MPN patients than in general population. Platelet aggregation can identify aspirin resistance in about 25% of MPN patients while an incomplete inhibition of serum TxB2 identify aspirin resistance in about 50% of MPN patients.

0219

RELATIONSHIP BETWEEN METHYLENETETRAHYDROFOLATE REDUCTASE POLYMORPHISMS (C677T AND A1298C) AND METHOTREXATE METABOLISM AND TOXICITY

B Perez Lasala, C Wandosell Jurado, L Ruiz Trujillo, P Loeches Jiménez, T Parra Cid, D De Miguel Llorente

Hospital universitario de Guadalajara, Guadalajara, Spain

Background. Pharmacogenetic is a promising tool for therapy personalization because there are several single nucleotide polymorphisms (SNPs) that can give rise to differing responses to drugs. Methotrexate (MTX) is a structural analogue of folic acid that blocks the enzyme dihydrofolate reductase, inhibiting purine metabolism and causing elevated homocysteine levels and in several cases, toxicity. The enzyme methylenetetrahydrofolate reductase (MTHFR) catalyses the irreversible conversion of 5,10-methylene tetrahydrofolate to 5-methyl tetrahydrofolate. Both C677T and A1298C MTHFR polymorphisms lead to decreased MTHFR activity and consecuently, to increased levels of blood homocysteine. *Aims.* Analyse the relationship between the presence of A1289C and C677T MTHFR polymorphisms and the metabolism and the toxicity caused by the MTX administration to haematologic patients. *Materials and Methods.* All included patients were treated according to standardized protocols (HD-MTX). We evaluated 67 MTX infusion courses administered to 17 subjects, aged 17 to 65 years (mean: 45 years). Five out of these patients were affected with ALL, 11 with NHL and 1 with myeloma. MTX concentrations were determined at 12, 36 and 60 hours post-drug infusion, and after, every 24 hours until undetectable MTX levels. We used a Dimension RXL

(Siemens). Delayed elimination was defined as MTX levels ≥ 1.0 mM at 36h or MTX levels ≥ 0.2 mM at 60 h. We applied the following hepatic toxicity definition: ALT levels higher than 200 U/L in any of measures obtained using a Dimension RxL. Genomic DNA was extracted from 200 mL EDTA-stabilized blood using the DNA kit Blood-Spin UltraCleanTM (MoBio). Using TaqMan technology in a real-time PCR platform (ABI Prism 7000, AB), allelic discrimination was applied for the MTHFR C677T and A1298C polymorphisms. Primers and fluorencence probes were designed by AB and the PCR cycling conditions were the 'universal amplification conditions'. *Results.* In our population, 11.1% of subjects were carriers of a wild genotype respect to MTHFR C677T and A1298C polymorphisms. Heterozygosity for C677T and A1298C were found in 33.3% and 11.1%, and homozygosity in 5.5% and 5.5% of patients, respectively. Moreover, we identified 27.8% of subjects with a heterozygous mixed genotype. The elimination rate of MTX was normal in 40 courses for 8 patients, while 27 courses of the remaining 9 patients met the criteria to be classified as delayed elimination. Relative risk (RR) for delayed elimination of heterozygous and homozygous respect to the other genotypes, was 2.2. Three out of 5 with ALT values exceeding 200U/L, were homozygous or mixed heterozygotes; RR for elevated ALT calculated for this group compared with the remaining patients was 2.1. RR for hepatotoxicity in patients with delayed elimination compared to patients with normal elimination was 1.3. *Conclusions.* Our results show that there are a relationship between the genotypic characteristics (C677T and A1298C MTHFR polymorphisms) and the response to MTX therapy, measured as drug elimination rate and of hepatic toxicity. We suggest that the genotyping of these polymorphisms is convenient to identify and monitor subjects with high risk of toxicity following administration of this therapy.

0220

ANALYSES OF MACROMOLECULES IN NILOTINIB RESISTANCE BY FOURIER TRANSFORM INFRARED SPECTROSCOPY

Y Baran,[1] A Camgoz,[1] C Ceylan[2]

[1]*Izmir Institute of Technology, Izmir, Turkey*
[2]*Izmir Institute of Technology, Department of Food Engineering, Izmir, Turkey*

Background. Nilotinib is a very efficient tyrosine kinase inhibitor used for the treatment of chronic myeloid leukemia. Although very high hematologic and cytogenetic responses were obtained for nilotinib, resistance to nilotinib observed in the beginning or during the treatment is the major problem in treatment of chronic myeloid leukemia patients. Fourier transform infrared spectroscopy is used to monitor molecular changes since it is a rapid, sensitive and nondestructive method which is widely used in the analysis of biological systems in any physical state. The method requires only minute amounts of samples and allows analysis of the data with many different digital manipulations. It is a valuable analytical technique in detecting the changes in the cellular components such as lipids, proteins, carbohydrates and nucleic acids in the level of functional groups simultaneously. The technique both qualitatively and quantitatively evaluates shifts in peak positions and changes in bandwidths and in intensities of the bands to obtain structural and functional information about the systems analyzed. In addition, FTIR spectroscopy provides information about the amount and chemical and physical nature of the groups in close vicinity. *Aims.* In the present work we examined the changes in macromolecules in nilotinib resistant K562 cells at the molecular level using Fourier transform infrared (FT-IR) spectroscopy. *Methods.* Human K562 CML cells were exposed to step-wise increasing concentrations of nilotinib, and subclones of K562 cells resistant to 50 nM nilotinib were generated and referred to as K562/NIL-50 cells. Antiproliferative effects of nilotinib were determined by XTT cell proliferation assay. Changes in macromolecules in parental and resistant cells were studied by FT-IR spectroscopy. *Results.* IC50 values of nilotinib were calculated as 42 and 385 nM for K562 and K562/NIL-50 cells, respectively. Nilotinib resistance caused significant changes which mainly indicated that the level of glycogen increased, the membrane/lipid order increased, the total amount of lipids did not change significantly but the relative proportion of cholesterol and triglycerides changed considerably and, the transcriptional status increased along with higher metabolic turn-over as revealed by the FT-IR spectra. In addition, changes in the proteome and structural changes in both proteins and nucleus were observed in the K562/NIL-50 cells. *Summary/Conclusions.* All these results indicate that changes in macromolecules may be an important regulator of nilotinib resistance. FT-IR technique provides a method for analyzing drug resistance related structural changes in leukemia and other cancer types.

Immune thrombocytopenia

A PHASE II 6-MONTH EXTENSION STUDY OF THE EFFICACY, SAFETY AND TOLERABILITY OF E5501 (AKR501) IN SUBJECTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP)

J Bussel,[1] Y Zhang,[2] S Tang,[2] J McIntosh,[2] D Kuter[3]

[1]*Weill Cornell Medical College, New York, United States of America*
[2]*Eisai Inc., New Jersey, United States of America*
[3]*Harvard Medical School, Boston, United States of America*

Background. E5501 (AKR501) is a thrombopoietin (TPO) receptor agonist. In a previous 28-day, multicenter, randomized, double-blind, placebo-controlled Phase II study (501-CL-003), E5501 (once-daily) was well tolerated and, at higher dose, effective at increasing platelet counts in subjects with relapsed or refractory chronic immune thrombocytopenia (cITP). *Aim.* To evaluate the long-term efficacy, safety and tolerability of E5501 in subjects with relapsed or refractory cITP, in a 6-month extension study to 501-CL-003. *Methods.* Sixty four subjects entered the prior 28-day double-blind study randomized to treatment with placebo or E5501 (2.5, 5, 10, 20 mg). The 53 subjects who completed the study (501-CL-003) were enrolled in this multicenter, parallel-group, Phase II, 6-month extension study (501-CL-004) from 17 US centers. Subjects were classified as either previous responders or non-responders at Day 28 of 501-CL-003. Response was defined as an increase in platelet count by a minimum of 20 $x10^9$/L above baseline and a count of ≥50 $x10^9$/L at Day 28. In 501-CL-004, previous responders (n=25) continued to receive their E5501 blinded dose (2.5, n=2; 5, n=6; 10, n=7; 20 mg, n=10). Previous non-responders (n=28) received open-label 10 mg E5501 once-daily. In both groups, dose was titrated upwards in 10-mg increments every 14 days depending on subject response (to a maximum dose in non-responders, of 40 mg once daily; and in responders, blinded dose plus 20 mg once daily) for 24 weeks, followed by a 4-week follow-up period. Concomitant medication dose reduction/discontinuation was permitted based on platelet response. Safety and tolerability of E5501 were evaluated in all 64 subjects who had been treated with E5501 in both CL-003 and CL-004. Efficacy was evaluated in the 53 subjects who were treated with E5501 for an additional 6 months based on platelet counts. Efficacy endpoints included the proportion of patients who achieved, without rescue medication, a durable platelet response, defined as a response-level platelet count at least 75% of the time at ≥3 platelet count assessments during the last 14 weeks of the treatment period. The number and percentage of subjects who achieved a platelet response at

Table 1.

Proportion of subjects who achieved response-level platelet count by study visit

Time point in Study 501-CL-004	Responders (n=25) with response-level platelet count n (%)	Nonresponders (n=28) with response-level platelet count n (%)	E5501 Total (n=53)
Week 2	19 (86.4)	15 (53.6)	34 (68.0)
Week 4	19 (79.2)	12 (44.4)	31 (60.8)
Week 8	19 (90.5)	12 (46.2)	31 (66.0)
Week 12	12 (85.7)	13 (65.0)	25 (73.5)
Week 16	9 (81.8)	8 (47.1)	17 (60.7)
Week 20	9 (90.0)	8 (66.7)	17 (77.3)
Week 24	17 (81.0)	12 (70.6)	29 (76.3)

Table 2.

Serious treatment-emergent adverse events (TEAEs)

Serious adverse event	Subjects n (%)
Thrombocytopenia	5 (7.8)
ITP	1 (1.6)
Leukocytosis	1 (1.6)
Mitral valve incompetence	1 (1.6)
Myocardial infarction	1 (1.6)
Retinal artery occlusion	1 (1.6)
Vomiting	2 (3.1)
Diarrhea	1 (1.6)
Gastritis hemorrhagic	1 (1.6)
Nausea	1 (1.6)
Chest pain	1 (1.6)
Pyrexia	1 (1.6)
Pneumonia	1 (1.6)
Platelet count decreased	1 (1.6)
Back pain	1 (1.6)
Cerebrovascular accident	1 (1.6)
Hemorrhage intracranial	1 (1.6)
Lethargy	1 (1.6)
Transient ischemic attack	1 (1.6)
Hypotension	1 (1.6)
Pelvic venous thrombosis	1 (1.6)

each study visit were also evaluated. *Results.* A durable platelet response was achieved in 52.8% of all subjects, and this response rate ranged from 35.7% among previous non-responders in the CL-003 study up to 72% among previous responders. The platelet response rate ranged from approximately 60% to 80% at on-therapy visits, and was higher in previous responders than previous non-responders at all assessment timepoints during the study (Table 1). Among subjects using steroids, 54.2% decreased their use by >50%, including 33.3% who discontinued their use permanently. All 64 subjects experienced ≥1 treatment-emergent AE (TEAE); most were mild and transient, and resolved completely. The most common TEAEs were fatigue (37.5%), headache (32.8%) and epistaxis (25%). TEAEs leading to study discontinuation were reported in 10/64 (15.6%) subjects. Serious TEAEs were reported in 12/64 (18.8%) subjects (Table 2); only 4 (6.3%) were considered treatment-related. *Conclusion.* This study demonstrates a durable platelet response to long-term E5501 treatment in subjects with relapsed or refractory cITP.

Background. Rozrolimupab is a recombinant antibody mixture of 25 fully human monoclonal antibodies, designed to capture the natural diversity of the human antibody response to RhD as a modern counterpart to the plasma-derived anti-RhD immunoglobulins currently used in the treatment of ITP. *Aims.* To investigate the safety and efficacy of a single dose of rozrolimupab in RhD positive, non-splenectomized patients with ITP. *Methods.* Following informed consent patients were enrolled in this dose escalation (75 µg/kg - 350 µg/kg), multicentre, open label trial. Inclusion criteria included confirmed presence of thrombocytopenia with two individual pre-dosing platelet counts of < 30 x 109. The patients received a single iv dose of rozrolimupab, were followed for 6 weeks and evaluated for safety and efficacy. Response was defined as platelet count ≥ 30 x109/L and increase in platelet count from baseline by > 20 x 109/L at 7 days after dosing. *Results.* Four dose groups comprising 36 patients have been evaluated so far: 75 µg/kg (11 patients), 100 µg/kg (10 patients), 125 µg/kg (10 patients) and 150 µg/kg (5 patients). The four cohorts differed in a number of baseline characteristics including distribution by sex (3, 9, 6 and 4 females), median platelet count before trial entry (15, 26, 16 and 22 x 109/L) and median time from first ITP diagnosis (68, 20, 5 and 8 months). In the individual dose groups, up to 70% of patients responded including one of the seven patients who had baseline platelet counts below 10 x109/L. All reported adverse drug reactions (E=20), except for a severe event of headache in the 100 µg/kg dose group, were of mild or moderate intensity. The reactions included pyrexia (E=2), decreased haemoglobin (E=2) and more frequent (E=6) events of headache. Laboratory data showed that haemoglobin values decreased in all patients indicating biological activity but generally, the values reverted towards baseline during the course of the trial. Three patients had a haemoglobin decrease of ≥ 2 g/dL; the biggest drop (3.1 g/dL) was categorized as a serious adverse event possibly related to rozrolimupab. The event was mild and not associated with serious bleeding and the patient recovered without receiving treatment. *Conclusions.* Rozrolimupab is well tolerated with no unexpected toxicities and shows preliminary signs of clinical activity. Beneficial effect of this agent in patients with ITP should be further evaluated.

Background. Romiplostim is recommended for second- and third-line treatment of chronic ITP in adults. This study, conducted in Europe, North America and Australia, investigated romiplostim in adults with ITP of varying duration and severity. *Aims.* To expand the understanding of the safety and efficacy of romiplostim in adult ITP patients. *Methods.* Eligibility criteria were broad: patients ≥18 years of age, who had received prior ITP therapies (current amendment: ≥1, previous amendments: ≥3), with low platelet counts (current amendment: ≤ 30 x 10^9/L, previous amendments: ≤10, ≤20 x 10^9/L) or uncontrolled bleeding. The only excluded comorbidities were: hematological malignancy, myeloproliferative neoplasms, MDS and bone marrow stem cell disorder. Romiplostim was initiated at 1 µg/kg/week, with dose adjustments allowed to maintain platelet counts ≥50 x 10^9/L. Patients could continue on study until they had access to commercially available romiplostim. Rescue medications were allowed at any time; concurrent ITP therapies could be reduced when platelet counts were > 50 x 10^9/L. Primary endpoint was incidence of adverse events (AEs) and antibody formation. Secondary endpoint was platelet response, defined as either (1) doubling of baseline count and ≥50 x 10^9/L or (2) ≥20 x 10^9/L increase from baseline. *Results.* As of April 2009, 235 patients had enrolled and received at least one dose of romiplostim. Of these, 77% remained on study (121/235) or had completed the study (61/235); 23% (53/235) had

Table 1. Adverse events - Subject incidence.

		N=235 n (%)
All events		198 (84)
Most common events	*Headache, Fatigue, Arthralgia, Nausea, Contusion, Epistaxis, Diarrhoea*	66 (28), 53 (23), 45 (19), 38 (16), 37 (16), 37 (16), 35 (15)
Serious events		62 (26)
Treatment-related events		104 (44)
Serious, treatment-related events		8 (3)
Key events of interest	*Thrombotic/thromboembolic*	14 (6)
	Thrombocytosis	7 (3)
	Hemorrhage events	91 (39)
	Bone marrow fibrosis/reticulin	3 (1)

withdrawn, with withdrawn consent the most common reason (10/235 [4%]). Median (Q1, Q3) time from ITP diagnosis was 4.7 (1.2, 12.2) years, with 60% of patients splenectomised and 38% receiving baseline concurrent ITP therapies. Median (range) baseline platelet count was 12.0 (1.0-170.0) x 10^9/L. Median (Q1, Q3) treatment duration was 18 (7, 39) weeks (maximum 201 weeks), with a total of 7288 subject-weeks on study. Incidence and type of AEs were consistent with previous studies. Nine patients died; 2 deaths (haemolysis, aplastic anemia) were considered treatment-related. One event of mild (1+) reticulin fibrosis, occurring 3 weeks after last romiplostim dose, was considered serious and treatment-related. No neutralizing antibodies to romiplostim or TPO, or hematopoieitic malignancies or MDS events were reported. Approximately 90% of patients achieved each of the platelet response definitions [(1): 86%; (2): 91%]; median (Q1, Q3) time to response was 1 [(1): (1, 4); (2): (1, 2)] weeks for both. *Summary/Conclusions.* The data are similar to that reported for previous romiplostim studies, with romiplostim able to safely induce a rapid platelet response in adult ITP patients with low platelet counts or bleeding symptoms. Romiplostim is an important, well-tolerated, treatment option for adult ITP patients, which significantly increases and maintains platelet counts.

0224

BONE MARROW FIBROSIS, IMMUNOPHENOTYPING AND CYTOGENETICS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP) TREATED WITH THROMBOPOIETIC AGENTS

W Ghanima, L Boiocchi, J Geyer, S Barsam, S Barsam, O Orazi, J Bussel

Weill Cornell Medical College, New York, United States of America

Background. ITP is characterized by accelerated platelet destruction and suboptimal platelet production. Thrombopoietin receptor agonists (Tpo-RA) increase platelet counts in ITP through stimulation of thrombopoietin receptors. While an acceptable safety profile has been demonstrated for these agents, an important area of concern is bone marrow (BM) fibrosis, which has been reported in a few patients treated with these agents. The relation between megakaryocyte stimulation and fibrosis has been proved in animal models and is apparently mediated by cytokines. *Aims.* This study aimed to determine the extent of bone marrow fibrosis, immunophenotypic abnormalities and chromosomal aberrations in ITP patients on treatment with Tpo-RA. *Methods.* This retrospective study included ITP patients receiving treatment with Tpo-RA at the Platelet Disorders Center, The New York Presbyterian Hospital (NYPH), USA, having at least one BM biopsy (BMB) performed prior to or during treatment with Tpo-RA. All BMB and aspirates were performed as part of the standard follow-up practice of patients on Tpo-RA. BM morphology, cytogenetic and flow-cytometric (FCM) examinations were performed in the Pathology Department of NYPH. Histological sections were stained with H&E, Gomori stain for reticulin and trichrome stain for collagen; fibrosis was graded according to the European Consensus Classification into 4 grades. *Results.* 77 BMB were available from 49 ITP patients (median age 50 years; 29 females 59%) treated with various thrombopoietic agents (see table). Ten patients had a pre-treatment BMB, of whom eight had on-treatment biopsies. The grade of reticulin in these eight increased from grade MF-0 to MF-1 in 5 patients, decreased from MF-1 to MF-0 in one patient and remained unchanged (MF-1) in two, after initiation of Tpo-RA. Median time from Tpo-RA initiation to first BMB was 1.3 years (IQR 1.0-1.8). Thirty-eight of 45 patients (85%) had greater than MF-0; of these 4 (9%) had MF-2 and 3. Median duration of treatment to second BMB in 16 patients was 3.0 years (IQR 2.3-4.3). From first to second BMB, reticulin grading increased by at least one grade in 6, remained unchanged in 8, and decreased in 2 with ongoing treatment with Tpo-RA. Out of all on-treatment biopsies, 10 patients had BMB with grade 2 or (one) 3 MF-grade. Cytogenetic analysis was performed in 50 of the BM examinations; 2 had abnormal karyotypes (see table). All 36 FCM revealed normal immunophenotypes. *Summary/Conclusions.* At a median duration of 1.3 years on treatment with Tpo-RA the proportion of patients having reticulin deposition in their marrows was 85%, which appears to be higher than that reported in the literature in ITP patients unexposed to Tpo-RA (40%) (Ettrup *et al.* Am J Hematol. 2010; 85:930-934) and in pretreatment BMB in this material (50%). Further increment in reticulin was observed in >30% of patients who continued treatment. No serious cytogenetic of immunophenotypic abnormalities emerged during treatment with Tpo-RA. Based on these results, regular follow-up with BM biopsies is recommended during treatment with Tpo-RA.

Table 1. Pre- and on-treatment bone marrow examinations.

Pre- and on Treatment Bone marrow examinations					
	Pre-	On-treatment			
	BM	1st BM	2nd BM	3rd BM	4th BM
BM biopsy (n)	10	45	16	4	1
MF-0	5 (50%)	7 (15%)	1 (8%)	-	-
MF-1	5 (50%)	34 (76%)	9 (56%)	4 (100%)	1
MF-2	-	3 (7%)	6 (38%)	-	
MF-3	-	1 (2%)	-	-	-
Trichrome (n +/-)	0/8	1/41	0/9	0/3	0/1
Cytogenetic (n +/-)	-	2*/30	0/14	0/3	0/1
FCM (n +/-)	-	0/22	0/12	0/1	0/1

* Cytogenetic abberations were: 45,X,-Y[15]/46,XY[5] in an 80 years old male- a finding commonly associated with aging; 46,X,i(X)(q10)c[13]/45,Xc[7] in a female with Turner Syndrome.

[7]*Dalhousie University, Halifax, Canada*
[8]*University of British Columbia, Vancouver, Canada*
[9]*University of Ottawa, Ottawa, Canada*
[10]*University of Toronto, Toronto, Canada*

Background. Early treatment with rituximab for patients with immune thrombocytopenia (ITP) may improve rates of disease remission; however, the feasibility of conducting a blinded randomized trial to address this question is not known. *Aims.* 1) To estimate event-free survival with rituximab added to standard ITP therapy; 2) To determine the feasibility of a blinded, randomized trial of rituximab in ITP. *Methods.* We performed a randomized, double-blind, concealed, placebo-controlled pilot trial in non-splenectomized patients with newly-diagnosed or relapsed ITP in 7 centres in Canada. Patients were randomly assigned to receive rituximab or placebo infusion adminis-

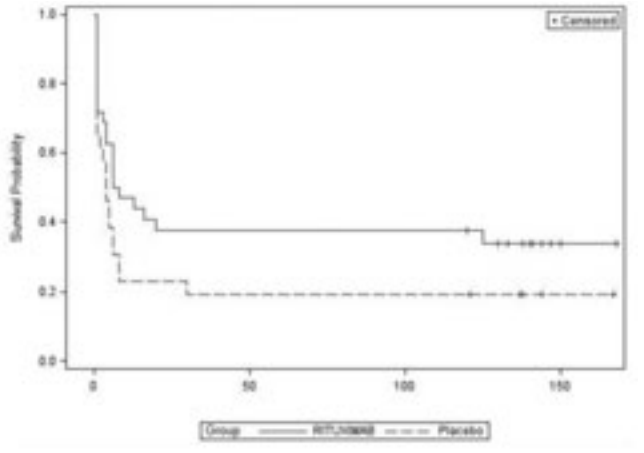

Figure 1. 6-month event-free survival (LogRank= 2.4; p= 0.1).

tered weekly for 4 consecutive weeks. Patients were 18 years of age or older, had primary ITP, a platelet count below 30 x10^9/L and had begun standard therapy chosen at the discretion of their physician. The efficacy outcome was 6-month event-free survival, where an event was any platelet count below 50 x10^9/L, the need for rescue treatment or grade 2 bleeding (Page *et al.* 2007) occurring after standard therapy was discontinued. Feasibility outcomes were rate of recruitment, protocol adherence and blinding integrity. Analysis was by intention-to-treat. *Results.* 33 patients were assigned to rituximab and 27 to placebo. All patients received standard ITP therapy consisting mostly of corticosteroids and/or intravenous immune globulin. Two patients (1 in each group) were lost to follow-up before receiving a single study infusion. Median age was 40 years [interquartile range (IQR), 30.5 - 59.0] and 58% were female. Median baseline platelet count was 15 x10^9/L (IQR, 9 - 23) and patients had ITP for a median of 1 year (IQR, 0 - 3.5) prior to randomization. Event-free survival at 6 months was 11/32 (34.4%; 95% CI 17.9 - 50.8%) in the rituximab group and 5/26 (19.2%; 95% CI 4.1 - 34.4%) in the placebo group (odds ratio= 2.2, 95% CI 0.7 - 7.4) (Figure). Fewer patients in the rituximab group had any platelet count below 50 x10^9/L [17/32 (53.1%) vs. 16/26 (61.5%)] or needed rescue treatment [14/32 (43.8%) vs. 17/26 (65.4%)] during the 6-month follow up period (differences were not statistically significant). Rates of grade 2 bleeding were similar between groups [7/32 (21.9%) vs. 6/26 (23.3%)]. Adverse events in rituximab-treated patients were minor. Recruitment was slow because 53 patients refused to participate and 13 failed screening. Refusals were mostly due to concerns about side effects of rituximab or an unwillingness to receive placebo. Blinding integrity was maintained for research staff after the administration of 4 study infusions; however, patients were able to infer group assignment more accurately than what could be attributable to chance. *Conclusions/Summary.* This study demonstrates promising effects of early rituximab administration on avoidance of thrombocytopenia and on the need for rescue treatment when given in conjunction with standard ITP therapy. A larger randomized trial of upfront rituximab for ITP powered on efficacy endpoints may be feasible; however, the widespread use of rituxamb in practice and difficulties in maintaining patient blinding would require careful consideration.

Funded by Hoffmann-LaRoche. All patients provided informed consent. ITP is not a licensed indication for rituximab.

0226

MARKERS FOR CHRONICITY IN IMMUNE THROMBOCYTOPENIA OF CHILDHOOD

H Platokouki, M Vranou, H Pergantou, P Xafaki, S Aronis

"Aghia Sophia" Children's Hospital, Athens, Greece

Background. Immune Thrombocytopenia (ITP), the term currently used for idiopathic or immune thrombocytopenic purpura, is known as a haemorrhagic state from Hippocrates's ages and myriads of studies have been published on it; however, there are still unanswered questions regarding diagnosis, clinical expression and therapeutic management, mainly based on the unavailability of markers that could predict a chronic course for ITP in children. *Aim.* To point out whether any differences in clinical or laboratory data at the onset of the disease between acute and chronic cases could predict the form of ITP. *Methods.* Data from the files of 795 children with ITP, followed up during a 30 years period (1974-2005), were retrospectively logged in a computerized program for statistical evaluation. Duration of thrombocytopenia (TP) <6 or >6 months was characterized as acute (aITP) or chronic (cITP) ITP. *Results.* A total of 728 children with ITP were included in the study; 60.6% had aITP, 32.8% cITP, 6.6% recurrent ITP. Children with a preceding viral infection or vaccination had a 2.4-fold and 2.5-fold probability, respectively, to run aITP versus cITP (CI 1.691-3.414, p< 0.01 and CI 1.181-5.171, p=0.013, respectively). In cITP, 55.2% were females (p< 0.01). Children with bleeding manifestations at the onset of ITP had almost 8.5-fold probability to have aITP [OR 8.38 (CI 5.14-13.64, p <0.001)]. Furthermore, although not all of the patients with severe TP (platelet count <5x109/L) bled, the probability of children with severe TP and hemorrhage to have aITP was twice as high (OR 1.92) than that of patients with severe TP without bleeding (p<0.05). Regarding therapeutic management, aITP patients who had received no therapy at the onset of the disease were more likely not to need therapy during the course of ITP [OR 2.97 (CI 1.75-5.05)]. On the contrary, cITP patients who had required therapeutic intervention at the onset of ITP had a 3-fold probability to receive additional treatment during the course of ITP [OR 2.946 (CI 1.540-5.636), p<0.01]. Recovered cITP patients had a lower platelet count at the onset of the disease in comparison to non-recovered patients (p=0.009). Splenectomy was applied in 15% of cITP children. Prior to splenectomy, children had bleeding manifestations twice as frequently than non splenectomized patients (p< 0.01), whereas therapeutic intervention was required 4 times more often than in non splenectomized children (p<0.01). Nevertheless, in non splenectomized children, TP at the onset of ITP was more profound than in splenectomized cITP cases (mean platelet count: 12 vs 28 x109/L, respectively). Finally, in multiple regression analysis, a higher probability for cITP was revealed in the absence of all three: preceding viral infection, vaccination and bleeding at the onset of the disease, in comparison to aITP (45.4% vs 25.1% of cases, respectively, p<0.05). *Conclusion.* Preceding viral infection, vaccination, severe thrombocytopenia coupled with bleeding manifestations at the onset of ITP were found to be involved in aITP. In contrast, the absence of any previous history related to ITP, mild clinical presentation and female predominance could be associated with cITP in childhood. Presenting author's email: eplatokouki@paidon-agiasofia.gr

SPLENECTOMY IN IMMUNE THROMBOCYTOPENIA: RESULTS OF 73 CASES WITH A MEDIAN FOLLOW-UP OF 22 YEARS

N Vianelli, F Palandri, N Polverelli, L Catani, D Sollazzo, M Baccarani

Department of Hematology and Clinical Oncology "L. and A. Seràgnoli", Bologna, Italy

Background. Splenectomy is still acknowledged as the gold-standard treatment of refractory immune thrombocytopenia (ITP). Recently, new medical therapies (anti-CD20 and thrombopoietin mimetics) have entered into clinical practice, encouraging a generalized tendency to delay splenectomy. Consequently, the importance to define the efficacy and safety of splenectomy in the long-term is substantial. *Patients and Methods.* We retrospectively analyzed the data of 73 ITP patients who underwent laparotomic splenectomy between 1963 and 1998 and have now a minimum follow-up of 10 years (median, 22 years; range, 10-47). *Results.* Overall, 73 ITP patients followed at our institution have now a minimum observation time of 10 years after splenectomy. Sixty-six percent were women; median time from diagnosis to splenectomy was 13 months (range, 0-254) and median age at splenectomy was 35 years (range, 6-65, with 12 patients younger than 16). Nine patients (12%) underwent splenectomy front-line; the other patients were splenectomized after failure of at least one course of medical therapy (prednisone alone or in combination with azatioprine and/or immunoglobulin). Overall, 66 patients (90%) achieved a complete response (platelet >100x109/L) after splenectomy and in 44 cases (66%), the response was stable at last contact. Twenty-two patients (33%) lost the response during the follow-up. Nine patients (41%) experienced a very early relapse (within 30 days from splenectomy), while in the remaining 13 patients, relapse occurred after a median time of 40 months (range, 4-256), for a relapse-free survival of 64% at 20 years (Figure 1). Three patients (4%) achieved a response (platelet count >50x109/L), while 4 patients (6%) were refractory. Overall, 25 patients (34%) needed further treatment after surgery. At last contact, 57 patients (78%) were in complete response (13 of whom, thanks to medical treatment post-splenectomy), 3 patients were in response and 13 patients had a platelet count <50x109/L. Eight patients (11%) remained in

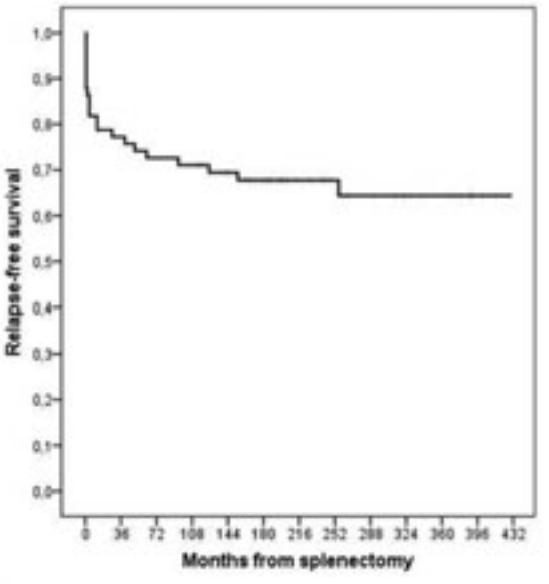

Figure 1. Relapse-free survival.

on-demand steroid therapy after a median time of 12 years (range, 3-24) from splenectomy. Forty-two hemorrhagic events (7 of which grade 3-4 WHO) were observed in 17 patients (23%), after a median time of 83 months. Fourteen patients (19%) experienced one or more infectious episodes after surgery, which were severe (pulmonary) in 9 cases and were observed late in the follow-up (median time from splenectomy to the event, 16.7 years, range 2.8-21.7). Nine patients died for causes unrelated to ITP (median age, 74 years; range 43-85). *Conclusions.* Splenectomy confirmed to induce a stable remission in 66% of ITP patients in the long-term. Relapse rate was higher in the first months, with sporadic relapses occurring even 20 years after surgery. The incidence of late severe infectious complications was not negligible, probably due to the fact that most patients did not receive prophylactic vaccinations.

0228

PREVALENCE OF DIAGNOSED ADULT IMMUNE THROMBOCYTOPENIA IN THE UNITED KINGDOM

D Bennett, M Hodgson, A Shukla, J Logie

GlaxoSmithKline, Philadelphia, United States of America

Background. Primary immune thrombocytopenia (ITP) is an autoimmune disorder most commonly characterized by decreased platelet count (< 100 × 10^9/L) resulting from autoantibody-mediated, peripheral platelet destruction and suboptimal platelet production. Data regarding prevalence of ITP are scant, and are derived mostly from North American and European population-based analyses. *Aims.* The aims of this study were to 1) estimate the unadjusted overall, age- and gender-specific prevalence of diagnosed adult (>=18 years of age) ITP in the General Practice Research Database (GPRD) in United Kingdom (UK) from January 1, 1992 to December 31, 2009 (18 year prevalence) and 2) estimate the overall age- and gender-adjusted prevalence (per 100,000) of diagnosed adult ITP adjusted to the 2009 UK population. *Methods.* This was a retrospective study using observational data from the GPRD, an electronic medical records database in the UK. Data from the GRPD are drawn from the computer systems of a representative sample of general practices throughout the UK and currently include information regarding diagnoses, prescriptions, referrals, outcomes and laboratory results, together with basic demographic information for approximately 6.4 million patients from over 480 centers. The GPRD is an excellent resource for estimating the prevalence of ITP because its population-based and representative of the age, sex and geographic regions of the UK. Prevalence of ITP was generated by accruing cases of adult ITP from 1992 through 2009 (unadjusted prevalence), then applying age- and gender-specific prevalence to the 2009 UK population (adjusted prevalence).Prevalent cases included all adult individuals (male and female) with at least one diagnostic code for ITP identified by the OXMIS and Read codes (42P2.11; D313.12; D313000; D313012; 2871C) in their medical records, enrolled any time in the 18 year study period (Jan 1, 1992- Dec 31, 2009), and with at least one year of prior up-to-standard follow-up in the GPRD. The overall prevalence (per 100,000 patients) of ITP the GPRD in 1992-2009 was calculated as the total number of identified adult ITP cases between January 1, 1992 and December 31, 2009, divided by all adults in the GPRD database. The age- and gender-specific prevalence was calculated using the same methodology. Confidence intervals (CIs) were calculated based on the binomial distribution. *Results.* The study results are presented in the Table. ITP prevalence was lower in adults aged 18-49 years of age than in older adults 50-64 years of age or 65+ years of age. Prevalence was higher among females vs. males. As expected due to the aging of the population, prevalence in the GPRD rose over time. *Summary/Conclusions.* This recent analysis of the general practice in UK provides most robust prevalence estimates of diagnosed ITP among adults. Prevalence of ITP was higher in older females and gradually increased over years in the GPRD.

Table 1. GPRD ITP prevalence.

Population	Prevalence per 100,000 patients	95% CI
Overall, unadjusted	50.3	48.5, 52.1
Overall, age-gender adjusted	50.0	49.2, 50.9
Ages 18-49	30.1	28.3, 31.9
Ages 50-64	58.2	53.9, 62.6
Ages 65+	93.8	88.8, 98.8
Females	59.3	56.6, 62.0
Males	40.7	38.4, 43.0
Year 1992	16.2	13.7, 19.0
Year 2000	36.7	34.5, 39.3
Year 2008	56.0	53.5, 58.8

Background. Chronic ITP is characterized by increased platelet destruction and decreased platelet production. The peptibody romiplostim increases platelet counts by binding to and activating downstream signaling of the thrombopoietin receptor. *Aims.* To examine the safety and efficacy of long-term romiplostim use in Japanese patients with chronic ITP. *Methods.* Patients from a phase 2 open-label study and a phase 3 randomized study could choose to enroll in an open-label extension study. If patients enrolled within 12 weeks of the previous study and had a platelet increase ≥20x10^9/L from baseline once during the 13-week treatment period in the previous study, the romi-

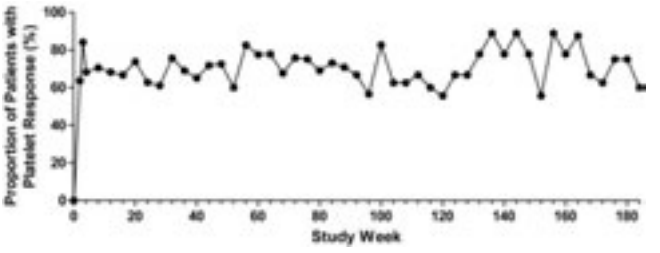

Figure 1.

plostim dose remained the same. Otherwise, the initial dose was 3 μg/kg romiplostim per week, which could be titrated up to 10 μg/kg to maintain platelet counts between 50-200x10^9/L. *Results.* As of April 2010, 44 patients had enrolled; 71% women, median (min, max) age of 55.5 (25, 81) years. At data cutoff, 5 patients (11%) discontinued study drug due to patient request (2), administrative decision (2), or other (1). The median (Q1, Q3) treatment duration was 100 (70, 113) weeks (maximum 184 weeks), and the median (Q1, Q3) average weekly dose was 3.8 (2.0, 6.4) μg/kg. The most frequent adverse events were nasopharyngitis (2.1/100 patient-weeks), headache (0.7/100 patient-weeks), back pain (0.3/100 patient-weeks), contusion (0.3/100 patient-weeks), and malaise (0.3/100 patient-weeks). Nine patients (21%) had a total of 14 serious adverse events (0.31/100 patient-weeks); the only one considered treatment-related was mouth hemorrhage. There were no life-threatening adverse events, and no patients died or withdrew from the study due to adverse events. A total of 50 hemorrhagic adverse events were reported in 20 patients (46%), with 3 patients (7%) having serious hemorrhagic adverse events, one patient with epistaxis and hemorrhagic anemia, one with melena and subcutaneous hematoma, and one with mouth hemorrhage. The most common hemorrhagic adverse events were contusion (0.3/100 patient weeks), epistaxis (0.2/100 patient-weeks), purpura (0.1/100 patient-weeks), and conjunctival hemorrhage (0.1/100 patient-weeks). No events were observed of hematopoietic malignancy, myelodysplastic syndrome, thrombocytosis, or bone marrow reticulin/collagen fibrosis (bone marrow biopsies were performed at investigator discretion). The only thromboembolic event was a serious adverse event of transient ischemic attack, which was not considered treatment-related. No patients tested positive for neutralizing antibodies to romiplostim or to TPO. Ninety-six percent of patients had a platelet response (doubling of platelet count and platelet count ≥50x10^9/L). Median platelet count was ≥50x10^9/L from Week 2 onwards. Of the 25 patients receiving concurrent ITP therapy at baseline, all reduced or discontinued the therapy: 11 with >25% reduction in ≥1 concurrent therapy, 5 with >50% reduction in ≥1 concurrent therapy, and 9 discontinued all concurrent therapies. Nine patients (21%) received rescue medications. *Summary/Conclusions.* Administration of romiplostim for up to 3.5 years was well tolerated in Japanese patients with chronic ITP with a platelet response that was maintained during this long-term extension study. The reported incidence of adverse events was similar to that seen in other romiplostim studies and did not increase over time. No new safety concerns were identified.

Background. Primary immune thrombocytopenia (ITP) affects a heterogeneous group of patients, whose initial diagnosis is often difficult and entails the exclusion of other diseases. Although ITP has been a well-known hematologic disorder for more than two centuries, some aspects regarding the etiologic factors, clinical behaviour or efficacy of the most frequently used treatments still remain unclear or even unknown. *Aims.* To describe the clinical characteristics of patients with ITP, compare with the available clinical evidence and define their therapeutic management and response. *Methods.* This is a Spanish multicentre observational epidemiological study in patients with recently diagnosed ITP. Patients were followed every 6 months for 1 year. Results from interim analysis of data between baseline and month 6 are presented. *Results.* The database was locked on 25 January 2011, with a deviation from the planned recruitment of +4.5%. A total of 315 patients from 98 Spanish hospitals were evaluated, with a median age of 53 years (range 27.4-73.8). Platelets at baseline: 11x109(range 4-28)/L. The most commonly performed diagnostic tests included: antibody testing (hepatitis B serology, 90.8% [10.3% positive]; hepatitis C serology, 90.1% [3% positive]; antinuclear antibodies, 78.2% [13.8% positives]; antiphospholipid antibodies, 49.3% [4.7% positives]; antiplatelet antibody, 20.3% [6.1% positives]), bone marrow study (38.7% [1.7% abnormal]), and H. pylori determination (35.7% [9.7% positive]). Clinical manifestations were observed in 235 patients, which were mainly skin bleeding (86%), oral mucosa bleeding (37.9%) and epistaxis (23.8%). Two hundred seventy-seven patients received first-line treatment. Most frequent first-line treatments were: corticosteroids (48.1%), corticosteroids+IV immunoglobulin (39.8%) and IV immunoglobulin alone (7.5%). Response was evaluated in 173 patients, with an 89% response rate. Data at month 6 were available in 132 patients. Median platelet counts at month 6 was 121x109(range 67-217)/L. At this time, only 13 patients experienced clinical manifestations: skin bleeding (69.2%), oral mucosa bleeding (38.5%) and metrorrhagia (23.1%). Thirty-seven patients underwent a second-line treatment. Mean time between lines was 26.5±50.8 days. The most frequent second-line treatments included rituximab (24.3%), romiplostim (18.9%) and corticosteroids (10.8%). The data was insufficient to assess the response. Splenectomy occurrence was observed in later lines. *Conclusion.* This interim analysis, which includes a greater recruitment than expected, shows heterogeneity in diagnostic procedures to exclude secondary etiology in patients with thrombocytopenia among the participating hospitals. Moreover, although the first-line treatment was homogeneous and showed a remarkable response rate, the second-line treatments seem not to be universally accepted. Further analyses will confirm that more homogeneous protocols are needed for the management of ITP patients.

THE COMBINATION OF THREE DEXAMETHASONE CYCLES AND RITUXIMAB YIELDS HIGH RESPONSE RATE IN PREVIOUSLY TREATED IMMUNE THROMBOCYTOPENIA (ITP)

W Ghanima, R Elstrom, J Bussel

Weill Cornell Medical College, New York, United States of America

Introduction. ITP is characterised by an immune-mediated destruction of platelets and impaired platelet production. The aim of treating ITP is to achieve sustained elevation of platelet counts (PC). Both dexamthason and rituximab are effective in elevating PC and are widely used in the treatment of ITP. Sustained response rates (RR) achieved by multiple cycles of dexamethasone given upfront looked superior to single cycle (85 % vs 45%), while RR for rituximab in previously treated patients is about 60% with 40 % of complete responses (CR). Recently up-front treatment rituximab plus one cycle of dexamethasone was shown to be superior to dexamethasone alone with respective RR of 63% vs 36% at 6 months (Zaja *et al.,* Blood, 2010). The combination of multiple cycles of dexamethasone and rituximab in previously treated ITP has not been reported previously. *Aims.* This pilot study aimed to determine the efficacy and safety of combining three cycles of dexamethasone to rituximab in previously treated patients with ITP. *Methods.* A retrospective study that enrolled patients with persistent, chronic or refractory ITP who were intended to be treated with the combination of 4 weekly rituximab infusions (375mg/m2) plus 3 dexamethasone cycles (40 mg or adjusted for weight on days 1-4, 15-18, and 29-32). The primary endpoint was CR (platelet count >100x109/L) at last follow-up; secondary endpoints were RR (platelet 30-100 x109/L with at least doubling of baseline PC) and safety defined number of greater > grade 2 adverse events (AE) during first 6 months of treatment. The study was approved by the IRB at Weill Cornell Medical College. *Results.* The table shows characteristics of 21 patients treated with rituximab and dexamethasone (R&D). Median duration of follow-up from first rituximab infusion was 6 months (IQR 4.9-8.5). Median pre-treatment and post-treatment PC registered at last follow-up were 35 X 109/L (IQR

Table 1. Patients' charachteristics.

Patients' Characteristics	
	N=21
Median age in years (IQR)	20 (13-39)
Female gender	14 (66%)
Median number of previous treatments (R)	2 (1-6)*
Median duration of ITP in years (IQR)	3.6 (0.6-6)
Treatment	**Number of patients**
Number of Rituximab infusions	4 in 19; 3 in 1; 2 in 1
Number of Dexamethsone cycles	3 in 15; 2 in 4; 1 in 2

*Only one patient was splenectomized. R= Range; IQR= interquartile range

20-49) and 133 X 109/L (IQR 35-277) respectively. At the last follow-up, 11 patients (52%; 95%CI 30-74) were in CR and 2 (9.5%; 95%CI 1-30) were in PR resulting in total RR of 62% (95%CI 38-82). There was no statistical difference in the CR rates in relation to the disease duration of <1 or> 1 year. During the first 6 months, four grade-3 and one grade-4 AE's occurred three patients. In addition 11 bleeding episodes were recorded in four patients, three of whom were non-responders. *Summary/Conclusion.* In previously treated patients with persistent, chronic and refractory ITP, the suggested combination yielded CR rate of 52%, which is comparable to that reported in previously untreated patients by Zaja *et al*. Four grade 3/4 AE occurred in 2 (10%) patients. 75% of the patient adhered to the designated treatment regimen. The retrospective nature, small sample and short follow-up are the main limitations of this trial. In conclusion, a regimen of rituximab and three 4-days cycles of dexamethasone appears effective, safe and tolerable. This combination merits further exploration in a prospective clinical trial.

0232

EVALUATION OF BASELINE LABORATORY PARAMETERS POTENTIALLY ASSOCIATED WITH THROMBOEMBOLIC EVENTS IN PATIENTS WITH CHRONIC ITP ENROLLED IN A CLINICAL TRIAL OF ELTROMBOPAG

T Shamsi,[1] R Wong,[2] A Giagounidis,[3] K Bakshi,[4] A Brainsky[4]

[1]*National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan*
[2]*Prince of Wales Hospital, Hong Kong, China*
[3]*St. Johannes Hospital Duisburg, Duisburg, Germany*
[4]*GlaxoSmithKline, Collegeville, United States of America*

Background. It has been proposed that immune thrombocytopenia (ITP) may have pro-thrombotic characteristics and low platelet counts may prevent a higher incidence of thrombotic events (TEEs).[1-3] In the UK General Practice Research Database, incidence rates for TEEs were 1.35/100 patient years (PYs) (95% CI [0.99, 1.79]) for patients with ITP vs 1.16/100 PYs (95% CI [0.99, 1.35]) in patients without ITP.1 Similar results were found in a US claims database study.[4] Despite increasing acceptance of this premise, the reason why patients with ITP are prone to thrombotic events is not well understood. *Aim.* To describe the frequency of potential laboratory predictors of thrombophilia in patients with chronic ITP. *Method.* Adult patients with chronic ITP[5] were enrolled in a phase 4, open-label, 2-year study to evaluate potential changes from baseline in bone marrow reticulin, associated to long-term treatment with eltrombopag. Patients with a prior history of a TEE and ≥2 risk factors for thrombosis were not eligible for the study. A "thrombophilia panel"collected at baseline comprised multiple known or suspected laboratory predictors of thrombosis. Patients could not have been treated with a TPO-R agonist in the 6 months prior to enrollment. All patients provided signed informed consent prior to study initiation. *Results.* In this ongoing study, baseline thrombophilia panels were available for 80 patients as of the date of this evaluation (Feb 2011). Mean age was 41 years; 70% (n=56) were female; mean BMI was 24.9 (range, 15.5-40.5). The median time since ITP diagnosis was 4 years (range, 0.2-45.7 years). 5/80 patients had prior exposure to eltrombopag. Most patients did not report a family or personal history of TEEs (n=75). Five patients reported clinical risk factors potentially associated with thromboembolic events (atrial fibrillation [n=1], arterial HTN [n=3]), and cardiac insufficiency [n=1]). The majority of tests in the thrombophilia panel were normal; however, many patients (Table 1) had abnormal levels of well known or suspected predictors of thrombosis or markers or activation of the coagulation cascade: ß2-Glycoprotein 1 (22/80), d-dimer (29/80), Factor VIII (46/80), Lupus anticoagulant (15/80), and Protein S activity (decreased, 14/80). Two patients in the study reported a TEE: 1 DVT (study day 31) and 1 infective thrombophlebitis requiring anticoagulation (study day 27). Both patients had baseline increases in d-dimer, Factor VIII, and Lupus anticoagulant (detected and confirmed). *Summary/Conclusions.* To our knowledge this is the only published report of a thrombophilia profile in a cohort of patients with chronic ITP. The multiple baseline abnormalities in possible predictors of thrombophilia may support the theory that ITP is a pro-thrombotic disease. The potential correlation of such abnormalities with TEEs will be the topic of further reports as the study progresses.

Table 1.

Patients with Abnormalities in the Thrombophilia Panel

	N (%)
Total patients	80 (100)
≥1 abnormality	69 (86)
1 abnormality	16 (20)
2 abnormalities	15 (19)
3 abnormalities	14 (18)
4 abnormalities	11 (14)
5 abnormalities	5 (6)
6 abnormalities	6 (8)
7 abnormalities	2 (3)

THE CLINICAL SIGNIFICANCE OF DETECTION OF CIRCULATING B CELLS SECRETING PLATELET-SPECIFIC ANTIBODY AND PLATELET GLYCOPROTEIN IIB/IIIA IN THE PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA

JF Chen, Y Yang, C Chang, F Feng, JQ Liu

The Second Hospital of Shanxi Medical University, Taiyuan, China

Background. Primary immune thrombocytopenia (ITP), is characterized by a low platelet count, which is the result of both increased platelet destruction and insufficient platelet production. The development of autoantibodies against platelet glycoproteins remains central in the pathophysiology of ITP, The diagnosis of ITP is still a puzzle problem. *Aims.* Througn detecting the circulating B cells secreting platelet-specific antibody, the platelet glycoprotein IIb/IIIa and platelet-specific antibody in patients ITP, evaluate their roles in the diagnosis of ITP and their clinical significance. *Methods.* The frequencies of circulating B cells secreting platelet-specific antibody, the positive rate of platelet glycoprotein IIb/IIIa and platelet-specific antibody in 64 ITP patients 33 non-immune thrombocytopenia patients and 31 healthy controls were measured with ELISPOT,MAIPA and FCM respectively. *Results* Compared with the controls and non-immune thrombocytopenia patients, the frequencies of circulating B cells secreting platelet-specific antibody and the positive rate of platelet glycoprotein IIb/IIIa in ITP patients were significantly increased and notably decreased, respectively(P 0.05). The ELISPOT and FCM had a sensitivity of 70.69% 58.7% a specificity of 90.91% 93.8% for the diagnosis of ITP, the sensitivity were higher than that of modified MAIPA's (43.10%) P 0.05 . However there was no apparent difference of ELISPOT and FCM for the diagnosis of ITP patients P 0.05). *Conclusion.* Detecting the frequencies of Circulating B Cells Secreting Platelet-Specific Antibody and the platelet glycoprotein IIb/IIIa in the patients with idiopathic thrombocytopenic purpura, which can reflect the pathogenesis of idiopathic thrombocytopenic purpura and have higher sensitivity and specificity than modified MAIPA, could be able to improve the diagnosis and guide clinical therapy in some degree.

0234

CYTOKINES AND CHEMOKINES IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (ITP) TREATED WITH TPO-RECEPTORAGONISTS (TPO-RA) COMPARED TO HEALTHY CONTROLS

S Gudbrandsdottir,[1] W Ghamima,[2] X Feng,[3] HC Hasselbalch,[1] J Bussel[2]

[1]*Copenhagen University Hospital Roskilde, Roskilde, Denmark*
[2]*Dept of Pediatric Hematology/Oncology, Weill Cornell Medical College, New York, United States of America*
[3]*Hematology Branch, NHLBI, NIH, Maryland, United States of America*

Background. Thrombopoietin receptor agonists (TPO-ra) are new treatment modalities for chronic ITP, exerting their effect by stimulating platelet production. Treatment with TPO-ra has been preliminarily shown to increase suppressive activity of regulatory T-cells, but much remains to be learned about the influence of TPO-ra on the immune system. *Aims.* In this study, the production of a panel of inflammatory cytokines and chemokines in chronic ITP patients treated with TPO-ra was investigated and compared to healthy controls. *Methods.* Cytokines and chemokines in EDTA-plasma samples from 22 ITP patients treated with TPO-ra (16 females, median age 51 years, IQR 33-58 years, median platelet counts $59x10^9$/L, IQR 30-$100x10^9$/L) and 7 healthy controls (2 females, median age 35 years, IQR 21-38 years) were analysed by immuno-bead-based multiplex assay. *Results.* Elevated levels of soluble CD40 ligand (sCD40L) (median 411 vs. 222 pg/mL, p=0.003), tumor necrosis factor alpha (TNFα) (median 4.0 vs. 0 pg/mL, p=0.000), interleukin-1-receptor antagonist (IL-1ra) (median 915 vs. 325 pg/mL, p=0.001), chemokine (C-X-C motif) ligand 10 (CXCL10) (median 55 vs. 16 pg/mL. p=0.000), CXCL11 (median 52 vs. 23 pg/mL, p=0.000), chemokine (C -C motif) ligand 4 (CCL4) (median 30 vs. 8 pg/mL, p=0.008) and IL-8 (median 3.6 vs. 1.7 pg/mL, p=0.016) were found in ITP patients, with no differences in IL-6, CCL-2 or CCL5. However, a positive correlation between the increase from pre-treatment to on-treatment platelet counts and levels of CCL5 was observed (p=0.01). Correspondingly, a negative correlation between the increase in platelet counts and levels of CXCL10 (p=0.047) was observed. No other correlation between increase in platelet counts and cytokine levels were detected in this series. We also found a 3-fold increase in the median ratio of the Th1-associated chemokine CXCL10 compared to the Th2-associated chemokine CCL2 (median ratio 0.56 vs. 0.19, p = 0.001). *Summary and Conclusion.* The inflammatory mediators sCD40L, CXCL10, CXCL11, CCL4 were significantly increased as compared to healthy controls. This was also observed for TNFα and IL-8, although concentrations were low. CCL5 and IL-6, often associated with acute inflammatory reactions, were not elevated in this series. However, levels of CCL5 correlated to the increased platelet counts following TPO-ra treatment. Increased CXCL10/CCL2 ratio have previously been reported in treatment-naïve ITP patients, and is associated with a Th1-predominant active immune response. In our series, ITP patients had higher CXCL10/CCL2 ratios than healthy controls, despite succesfull treatment with TPO-agonists. Interestingly, levels of CXCL10 inversely correlated to the increase in platelet counts obtained by treatment with TPO-ra. Platelets are associated with inflammatory processes involving both the innate and the adaptive immune compartment. It can be hypothesized that TPO-agonists, i.e. by increasing platelet production, exert a larger than expected effect on the immune compartment in these patients. In this study, we found elevated levels of a range of inflammatory mediators in TPO treated ITP patients compared to healthy controls. Further studies are needed to fully understand the apparent influence of TPO agonists on the immune system in patients with ITP.

ROMIPLOSTIM THERAPY IN CHILDREN WITH REFRACTORY CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA

G Mokhtar

Ain Shams University, Cairo, Egypt

Background. Romiplostim, a thrombopoiesis-stimulating peptibody, represents a new therapeutic option in adult refractory chronic immune thrombocytopenic purpura (ITP).There are lacking studies about romiplostim use in pediatric chronic ITP. *Aim.* This study aimed to assess the short term efficacy and safety of romiplostim in children with refractory chronic ITP. METHODS:Eight patients with chronic ITP refractory to standard lines of therapy were recruited from the Pediatric Hematology Unit, Children's Hospital, Ain Shams University, Cairo, Egypt. One patient was initially excluded because of increased bone marrow reticulin.Therapy was initiated in 7 patients, aged 3.4 years-15.2 years(median 5.5 years),and the disease duration ranged from 13 months-7.3 years (median 2.4 years), none was splenectomized. Romiplostim dose was started as 1µgm/kg/week and dose was escalated by 1 µgm/kg/week according to platelet count. The duration of therapy varied between 1 week to 22 weeks (median 12 weeks). *Results*. Results revealed that 4 out of the 7 patients achieved variable response. Four patients demonstrated rapid increase in platelets counts when pulse steroid therapy was added, achieving rapid control of serious bleeding in three patients. Most reported adverse events were mild and transient including acute nasopharyngitis in 2 patients, epistaxis in 1 patient, but one patient developed moderately severe wheezy chest necessitating hospitalization. *Conclusions.* These results revealed variable response rate in children with chronic ITP to romiplostim therapy; addition of steroids especially in emergency bleeding situations could potentiate romiplostim thrombopoietic effect even in patients initially refractory to steroids. Romiplostim safety and efficacy in pediatric ITP needs further long-term studies.

MORTALITY DURING CLINICAL STUDIES OF ELTROMBOPAG IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA

N Cooper,[1] I Pabinger,[2] C Bailey,[3] K Bakshi,[3] A Brainsky[3]

[1]*Hammersmith Hospital, Imperial Health Care NHS Trust, London, United Kingdom*
[2]*Medizinische Universitaet Wien, Vienna, Austria*
[3]*GlaxoSmithKline, Collegeville, United States of America*

Background. Disease- and treatment-related mortality in adult patients with chronic immune thrombocytopenia (ITP) is the subject of ongoing investigation. Reports suggest a rate of 0.3%-12%,[1] increasing to 8%-16% in patients with refractory disease[2] and to 15.7% for refractory patients following splenectomy failure.[3] Cohen reported an incidence of fatal bleeding events of 0.0162-0.0389/patient year (PY); life expectancy was reduced for patients with persistent thrombocytopenia and for older patients, with 5-year rates of fatal bleeding events of 2% and 47.8% for patients <40 years and >60 years, respectively.[4] Similar findings were reported by Portielje, who noted that the most common causes of death were bleeding and infection in almost equal proportions.[5] Eltrombopag is an oral thrombopoietin receptor agonist approved for chronic ITP. *Aim.* To describe mortality in adult patients with chronic ITP in eltrombopag clinical studies. *Methods.* Mortality among 494 adult patients with chronic ITP exposed to placebo or eltrombopag were analyzed from 5 clinical trials: two 6-week, placebo-controlled studies (TRA100773A/B: eltrombopag, n=164; placebo, n=67); RAISE, a 6-month, placebo-controlled, phase 3 study (eltrombopag, n=135; placebo, n=62); REPEAT, an open-label study of 66 patients treated intermittently with eltrombopag in three 6-week cycles; and EXTEND, an ongoing extension study with 299 patients from prior eltrombopag trials receiving eltrombopag for up to 3 years. *Results.* Eight patients (1.6%) have died (eltrombopag, n=7; placebo, n=1), with an overall exposure period of 584.4 PYs for eltrombopag and 35 PYs for placebo. The overall mortality rate for patients who died on therapy or within the subsequent 8 weeks was 0.0077/PY (95% CI 0.0025, 0.018). Two patients died 107 and 199 days following the last dose of study medication and were excluded from the calculation. Of the 8 patients who died, 5 were from EXTEND, and 1 each were from TRA100773A, RAISE, and REPEAT. Ages ranged from 40-77 years, with 3 patients >60 years. The deaths were not considered by investigators to

Table 1.

Causes of Death in Patients Exposed to Eltrombopag

Study	Age	Gender	Cause of Death	Study Drug	Exposure (Days)	Time from Last Dose to Death (Days)
TRA100773A	66	M	Cardiac failure - respiratory failure	Eltrombopag	21	5
RAISE	43	F	Brain stem hemorrhage	Placebo	7	2
REPEAT	71	M	Pancreatic cancer	Eltrombopag	126	199
EXTEND	56	F	Motor vehicle accident	Eltrombopag	86	On treatment
EXTEND	44	M	Hypovolemic shock/GI hemorrhage	Eltrombopag	46	55
EXTEND	59	F	Unknown (autopsy not performed; investigator opinion: Acute brain hemorrhage vs. myocardial infarction vs. arrhythmia and cardiac arrest vs. sepsis in a patient with fever on steroids)	Eltrombopag	529	On treatment
EXTEND	40	F	Subarachnoid hemorrhage	Eltrombopag	412	107
EXTEND	77	F	Multiple organ failure/pulmonary sepsis	Eltrombopag	218	42

GI, gastrointestinal.

be related to study medication. Fatal hemorrhage occurred in 3/494 patients: two, treated with eltrombopag, had never achieved a response and died 55 and 107 days following their last dose of eltrombopag; a third patient, treated with placebo, died of an intracranial hemorrhage. Other deaths include one each of cardiorespiratory failure, multi-organ failure, motor vehicle accident, pancreatic cancer, and unknown (died at home with no autopsy). *Conclusions.* No discernible pattern in cause of death is apparent, other than fatalities due to bleeding events in patients with persistently low platelet counts. The mortality rate across the eltrombopag trials is lower than that reported in the literature. These data need to be interpreted cautiously as patients enrolled in clinical trials are subjected to specific monitoring schemes not necessarily implemented in clinical practice.

SUSTAINED HEMOSTATIC PLATELET COUNTS IN ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) FOLLOWING CESSATION OF ROMIPLOSTIM - FOUR EUROPEAN CASE STUDIES

A Newland,[1] L Cervinek,[2] J Eggermann,[3] F Lefrere,[4] G Kreuzbauer[5]

[1]*Royal London Hospital, London, United Kingdom*
[2]*University Hospital, Brno, Czech Republic*
[3]*University Clinic, Ulm, Germany*
[4]*Necker Hospital, Paris, France*
[5]*Amgen (Europe) GmbH, Zug, Switzerland*

Background. Romiplostim is recommended for second- and third-line treatment of chronic ITP in adults. While often perceived as a chronic, long-term treatment, previous data suggest some patients maintain hemostatic platelet counts when treatment stops. *Aims.* To describe individual cases of patients maintaining hemostatic platelet counts following cessation of romiplostim. *Methods.* We describe four patients with long-term (6-49 years), chronic ITP, and refractory to previous treatment options, including splenectomy, corticosteroids, IVIg, anti-D and rituximab. All received romiplostim in clinical trials, initiated at 1-3 µg/kg/week and with dose adjustments allowed to maintain platelet counts above 50 x 10^9/L. Romiplostim was withheld when counts rose above a pre-specified threshold (400 or 450 x 10^9/L), and reinitiated at a lower dose when counts fell below 200 x 10^9/L. Following completion of the relevant trial, patients were managed as per routine clinical practice. *Results.* Patient 1 completed a 24-week trial, during which platelets counts increased to normal levels. Following cessation of romiplostim, counts fell slightly and a single dose of IVIg was administered. Thereafter, hemostatic platelet counts were maintained without any ITP therapy for over 4 years. Patient 2 experienced high platelet counts after 8 weeks of dose titration, and romiplostim was withheld for 11 weeks. Following a single count <200 x 10^9/L and one dose of romiplostim 3 µg/kg, counts were again high and romiplostim was withheld for the remaining 7 months of the study. Thereafter, hemostatic platelet counts were maintained without any ITP therapy for 2 years, until death from ventricular fibrillation. Patient 3 experienced highly variable platelet counts, with romiplostim withheld on several occasions due to high values. After 3 years dosing at 1 µg/kg/week, counts remained >200 x 10^9/L and romiplostim was withheld for the remaining 3 months of the study. Patient 4 experienced a high platelet count after 1 year of romiplostim treatment and romiplostim was withheld. At the last recorded contact, patients 1, 2 and 4 had maintained platelet counts >50 x 10^9/L for 9 months-4.5 years in the absence of any ITP therapy or bleeding episodes. *Summary/Conclusions.* Dose adjustment rules allow romiplostim to be discontinued when hemostatic platelet counts are reached. This report of sustained hemostatic counts following romiplostim cessation provides evidence that romiplostim can be a short-term treatment in some adult ITP patients, including those with long-term, chronic disease. While the exact incidence of such cases is unknown, additional anecdotal evidence may provide more insight.

Table 1. Patient data.

Patient	1	2	3	4
Age (yrs) / sex	49/female	73/male	69/female	65/female

INTRAMUSCULAR USE OF ANTI-D GAMMAGLOBULIN IN PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA: A SINGLE CENTER EXPERIENCE

T Martin-Santos, S Iraheta, JM Raya, M Rodriguez-Salazar, M Fernandez, C Stoica, B Gonzalez-Gonzalez, L Gonzalez-del-Castillo, R Diaz-Rodriguez, L Hernandez-Nieto, M Hernandez-Garcia

Hospital Universitario de Canarias, La Laguna, Spain

Background. Treatment guidelines support the intravenous administration of anti-D gammaglobulin as an option in Rh positive patients with a diagnosis of immune thrombocytopenic purpura (ITP). However, in Spain this drug is only available for intramuscular (IM) injection. This is the reason why we used the anti-D immunoglobulin intramuscularly in our patients. *Aims.* In this study we show our experience with IM anti-D gammaglobulin, when indicated, in the treatment of ITP patients. Our purpose was to evaluate the efficacy and safety of this therapeutic option. *Methods.*We have analyzed 41 patients with ITP treated with IM anti-D gammaglobulin in our institution over the past 20 years. The unitary dose was 900 micrograms repeated on days 1, 2 and 4 as the initial dose (loading dose). After one week, another loading dose was administered if necessary, and eventually further single doses as maintenance. The current consensus guidelines published in 2009 by the IWG were used to asses the response to treatment, especially the time to achieve a response and a complete response, and the number of doses required to obtain them. *Results.* Thirty of 41 patients were evaluable (median age 47 years, range 16-85; 19 women and 11 men). The exclusion criteria were a diagnosis other than ITP or the discontinuation of treatment before completing at least one loading dose. In most cases, anti-D gammaglobulin was administered as second or third line treatment, with median prior lines 2 (range 0-4). Corticosteroids were the initial therapy in 28 patients, most often associated with intravenous immunoglobulins (17 cases). The indications for starting anti-D were: relapse after other lines of treatment in 14 patients (47%), refractoriness to initial therapy in six cases (20%), and as maintenance approach in eight (27%). One patient received anti-D as first line therapy and another one because of toxicity to previous treatments. The mean platelet count before starting anti-D was 67 x 109/L. The number of patients who achieved complete response criteria (platelet count > 100 x 109/L) was 23 (77%), while two patients failed to reach it. Complete response criteria were not applicable in five cases because the initial platelet count was above 100 x 109/L. No adverse effects related to drug (especially any bleeding complication associated with the intramuscular route of administration) were registered. *Conclusions.* Although current guidelines do not include the IM administration of anti-D gammaglobulin, our experience demonstrates that this is an effective, safe, and economical option, with the added advantage of an outpatient administration.

THE INTERNATIONAL MULTICENTRIC COOPERATION CYTOGENETIC SCORING SYSTEM EFFECTIVELY PREDICTS DISEASE OUTCOME IN DE NOVO MDS

P Bernasconi,[1] C Klersy,[2] M Boni,[1] I Dambruoso,[1] R Zappatore,[1] P Cavigliano,[1] I Giardini,[1] B Rocca,[1] C Calvello,[1] M Caresana[1]

[1]*Division of Hematology, Foundation IRCCS Policlinico San Matteo, Pavia, Italy*
[2]*Scientific Direction Clin Epidemiology & Biometry Service Found IRCCS S Matteo, Pavia, Italy*

Background. In 2010 an International Multicentric Cooperation proposed a new, comprehensive cytogenetic scoring system for primary MDS (Haase *et al.,* EHA 2010). *Aims.* The present study was aimed at assessing whether this new cytogenetic scoring system could improve the prognostic stratification of 631 consecutive de novo MDS patients, who were observed in the period January 1990-January 2010. *Methods*. Inclusion criteria were: primary MDS, age >=16 years, bone marrow blast cell percentage <20%, supportive therapy only. Univariate and multivariate analyses concerning overall survival (OS) and MDS/AML progression were performed. Median follow-up was 19.6 months (mo.) (Inter-quartile range, IQR, 7.3-46.3). At the time of the analysis 160 pts (25.3%) had died after a median follow-up of 18.7 mo. (IQR 8.4-38.1) and 137 pts (21.7%) had experienced MDS/AML progression after a median time of 14.6 mo. (IQR 5.9-34.2). *Results.* There were 249 females and 382 males whose median age was 65.3 yrs (IQR 56.6-72.5). According to WHO 70 pts (11.1%) were RARS, 122 (19,3%) RA, 25 (3,9%) RCMD with ringed sideroblasts (RCMDS), 149 (23,6%) RCMD, 38 (6,0%) 5q- syndrome, 9 (1,4%) unclassifiable MDS (u-MDS), 102 (16,1%) RAEB-1 and 116 (18,4%) RAEB-2. According to IPPS 177 pts (28,1%) were low-risk, 255 (40,4%) int-1 risk, 139 (22%) int-2 risk and 60 (9,5%) high-risk. Three-hundreds fifty-three (55.9%) pts presented an abnormal karyotype: 260 (41.2%) carried a single chromosomal defect, 46 (7,3%) carried two defects and 47 (7,4%) >=three defects. Based on the new cytogenetic scoring system, 14 pts (3,8%) were considered very good risk, 392 (62,1%) good risk, 162 (25,6%) intermediate risk, 29 (4,6%) high-risk and 34 (5,3%) very high-risk. Two-years OS was 91.0% (95% CI: 50.8-98.7) for the very good-risk category, 87.0% (95% CI: 82.7-90.6) for the good-risk category, 72.0% (95% CI: 63.2-80.0) for the intermediate-risk category, 54.8% (95% CI: 29.7-74.1) for the high-risk category and 9.4 % (95% CI: 0.6-32.9) for the very high-risk category (p<0.0001). Multivariate analysis, which compared each category to the very-good, resulted in a Hazard Ratio of 1.7 for the good-risk category; 2.8 for the intermediate-risk category; 4.0 for the poor-risk category and 16.3 for the very-poor risk category (p<0.0001). Two-years PFI was 90.9% (95% CI: 50.8-98.6) for the very good-risk category, 79.0% (95% CI: 74.0-83.3) for the good-risk category, 54.7% (95% CI: 45.3-63.2) for the intermediate-risk category, 46.1% (95% CI: 22.7-66.7) for the high-risk category; no patient of the very high-risk category was surviving at this time (p<0.0001). Multivariate analysis resulted in a Hazard Ratio of 2.0 for the good-risk category; 3.9 for the intermediate-risk category; 4.4 for the poor-risk category and 15.5 for the very-poor risk category (p<0.0001). Six multivariate models were compared by means of Akaike Information Criterion (AIC). To predict OS, the best models included age, peripheral cytopenias, WHO classification, and either new cytogenetic categories or number of chromosomal abnormalities (AIC=1631 and 1622); to predict PFI, the best models included the same variables (AIC=2454 and 2448). *Conclusion.* The new cytogenetic scoring system is effective in improving the prognostic stratification of pts with de novo MDS.

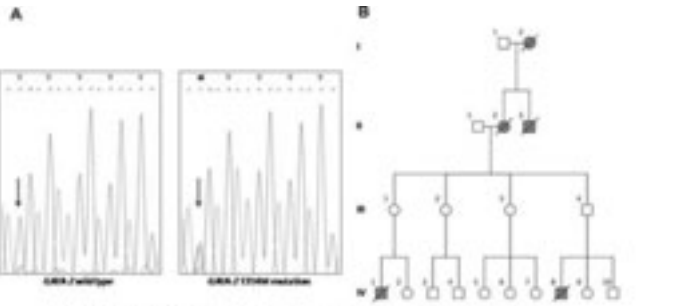
GERM-LINE GATA2 T354M MUTATION IN FAMILIAL MDS WITH MONOSOMY 7 SYNDROME WITH RAPID ONSET AND POOR SURVIVAL

J Owen,[1] C Bödör,[2] A Charazac,[2] S Iqbal,[2] M Smith,[2] J Cavenagh,[2] J Fitzgibbon[2]

[1]*University of Calgary, Calgary, Canada*
[2]*Centre for Haemato-Oncology, London, United Kingdom*

Background. While the majority of MDS/AML cases are sporadic, rare familial cases occur and have provided insight into the molecular basis of leukemogenesis. The best defined familial MDS/AML syndromes result from inherited mutations in *RUNX1* or *CEBPA*. More recently, a novel germline mutation in *GATA2* was reported. *Methods.* Individuals from families with ≥ 1 first-degree relative with MDS/AML were selected for investigation. Informed consent was obtained. Genomic DNA was used to PCR amplify exon 5 of the *GATA2* gene, sequencing performed by bidirectional Sanger sequencing, with mutations confirmed from 2 independent PCR amplicons. *Results.* Individuals from 6 families with a history of familial MDS/AML and wildtype *RUNX1* and *CEBPA* were investigated. A *GATA2* T354M mutation (Figure 1A) was observed in samples (2 tumour, 1 remission) from 2 first-degree cousins in a single pedigree. This same missense mutation was reported by Scott *et al.* in 3 of 4 previously described pedigrees and was not observed in 268 sporadic MDS/AML samples (ASH LBA-3). Material was not available from other family members. Figure 1B demonstrates the genogram. The proband IV-1, presented at age 23 with cytopenias and no past medical history. A bone marrow biopsy demonstrated trilineage dysplasia with 17% myeloblasts, consistent with a diagnosis of RAEB. Cytogenetic analysis demonstrated isolated monosomy 7. He underwent chemotherapy and obtained a CR but with persistence of dysplasia. The bone marrow at CR revealed normal cytogenetics. Seven months later, he relapsed with re-emergence of the monosomy 7 clone, and died early of transplant-related complications following a haplo-identical transplant. IV-8, the first cousin of IV-1, presented 1 week after his cousin at age 19 and was similarly diagnosed with RAEB and monosomy 7. His bone marrow revealed 7% myeloblasts and monosomy 7. He underwent a haplo-identical HSCT but died from relapsed disease. None of the individuals in the preceding generation have hematological abnormalities. The *GATA2* mutation was observed in MDS samples from IV-1 and IV-8 and was absent from the remission sample of IV-1. The presence of this presumed germline mutation suggests that III-1 and III-V are asymptomatic obligate carriers who have avoided development of MDS, confirming that the *GATA2* mutation is not sufficient alone to cause overt MDS/AML. This was also a feature of previous *GATA2* pedigrees. Monosomy 7 in association with pure familial MDS/AML has been previously reported in more than 12 pedigrees and typically presents at young age with autosomal dominant transmission. Non-preferential deletion of parental chromosomes has been demonstrated in several sibling pairs suggesting that the predisposing locus is not located on chromosome 7. The presence of monosomy 7 in both affected individuals suggests that germline *GATA2* mutations may be a cause of the "Familial MDS with monosomy 7 syndrome". *Conclusions.* These findings confirm the recent report that germline *GATA2* mutations predispose to familial MDS/AML and that outcomes after diagnosis of MDS/AML are uniformly poor in these patients. Our investigations also suggest that monosomy 7 may be a recurrent cytogenetic abnormality in these families, providing the necessary 'second hit' for development of overt MDS/AML.



A Illustrated is the GATA-2 T354 mutation and the corresponding wild-type sequence. The change of the ACG codon to ATG leads to a threonine (T) – methionine (M) substitution at the protein level. B. Genogram for GATA2-mutated pedigree. The squares denote males and circles denote females. The grey boxes mark the individuals with a history of MDS or AML.

REPRODUCIBILITY OF THE WHO 2008 CLASSIFICATION FOR MYELODYSPLASTIC SYNDROMES

L Senent,[1] L Arenillas,[2] L Florensa,[2] E Luño[3]

[1]*Servicio de Hematología. Hospital Universitario La Fe, Valencia, Spain*
[2]*Laboratorio de Citología Hematológica. Servicio de Patología. Hospital del Mar, Barcelona, Spain*
[3]*Servicio de Hematología. Hospital Universitario Central de Asturias, Oviedo, Spain*

Background. Myelodysplastic syndromes (MDS) are a group of clonal hematologic neoplasms with different risk for progression to acute leukemia and survival. The current 2008 WHO classification for MDS

was built in an attempt to improve the prognostic value of the previous FAB classification. The 2008 WHO classification is based on the percentage of blast cells in bone marrow (BM) and peripheral blood (PB), the type and degree of dysplasia, the proportion of ring sideroblasts, and number of cytopenias. However, the reproducibility of WHO classification is still unclear. The aim of this study was to analyze the interobserver concordance between four experienced morphologists from three different centers and to define potential diagnostic difficulties. *Methods.* Smears from PB and BM samples (stained by May Grunwald-Giemsa and iron) from 50 patients with well established diagnosis of MDS were blindly analyzed by 4 observers. The assessment of myelodysplasia and blast cell enumeration was performed as recommended by WHO guidelines (Swerdlow *et al.*, 2008). The degree of correlation between observers in the percentages of blast cells in BM and PB and ring sideroblasts was analyzed by Pearson correlation and inter-observer agreement index in the diagnostic morphological subtype (7 categories) and degree of dysplasia (3 categories; <10%, 10 - 39%, ≥ 40%) was studied by using the generalized kappa statistic for multiple raters. *Results.* The degree of correlation between observers for the proportion of blast cells in BM (R, .44 - .89; *P*, .002 - <.0001) and PB (R, .31 - .72; *P*, .03 - <.0001) and ring sideroblasts in BM (R, .77 - .94; *P*, <.0001) was statistically significant in all instances. The kappa coefficient for dysgranulopoiesis, erythroid, and megakaryocyte dysplasia was .40, .18, and .41 respectively. The kappa value for morphological subtype was .39, ranging from .17 for refractory cytopenia with unilineage dysplasia to .66 for mixed MDS/myeloproliferative disorders (chronic mylomonocytic leukemia subtype). *Conclusions.* These results suggest that there is a good correlation between observers in quantification of the percentage of blast cells in PB and BM and ring sideroblasts in BM. Second, the degree of concordance in the assessment of dysplastic changes is adequate for the granulocytic and megakaryocytic lineages but inadequate for erythroid lineage. However, the apparently accurate concordance for most parameters evaluated did not translate in a good agreement in the final diagnosis classification for several subtypes. This absence of agreement could be due to the arbitrary cut off points in the percentage of blast cells and dysplastic features that determine the different subtypes.

0242

ANTI-LEUKEMIC EFFICACY OF THE EGFR-INHIBITOR ERLOTINIB IN MDS/AML IS AT LEAST PARTIALLY CONVEYED BY OFF-TARGET EFFECTS ON THE SRC-KINASE LYN

S Boehrer,[1] E Lainey,[2] S Thepot,[2] M Sebert,[2] L Ades,[1] C Gardin,[1] P Fenaux,[1] G Kroemer[2]

[1]*Hôpital Avicenne, Bobigny, France*
[2]*INSERM 848, Villejuif, France*

Background. The EGFR-inhibitor erlotinib (Erlo), currently evaluated in phase-I/II clinical studies (NCT00977548, NCT01085838), demonstrated acceptable toxicity and anti-leukemic efficacy in higher risk MDS patients having failed hypomethylating agents (Komrokji *et al*., abstract 1854, ASH 2010). Nevertheless, due to the EGFR-negativity of these entities, the molecular determinants conveying erlotinib's off-target effects remain to be defined (Boehrer, Blood, 2009). *Methods.* Hypothesizing that erlotinib functions by inhibiting one or several tyrosine kinases (TK) deregulated in MDS/AML (notably Lyn and Syk), we incubated erlotinib-sensitive KG-1 cells with biochemical inhibitors (+/-erlotinib) of individual kinases (PP2, Piceatannol, BAY61-3606), and quantified the phosphorylation/activation status by immunoblot and flourocytometric analysis. Biological consequences were determined by evaluation of apoptosis (DioC3(6)/PI staining), cell cycle progression (PI staining), and autophagy (by LCII/I quantification using immunoblot and immunoflourescence analysis, as well as electron microscopy, EM). Erlo's impact on colony-forming capacity was evaluated in patient-derived MDS-/AML cells (n=5). *Results.* Erlotinib decreased aberrant activation of the TK Lyn in KG-1 cells and patient-derived AML-cells. In addition, biochemical inhibition of Lyn (by PP2) recapitulated erlotinib-induced anti-proliferative effects, i.e. 10μM of PPI induced the same degree of G1-arrest at 24h as 10μM of erlotinib (+10% as compared to controls). The observation that this anti-proliferative effect was not increased by concomitant incubation of KG-1 cells with PP2 and Erlo indicates that both drugs work by employing the same pathway. In contrast, none of the Syk-inhibitors (Piceatannol, 10μM and BAY 61-3606, 50nM) had an effect on cell cycle progression. Whereas Lyn-inhibition alone (by PP2) did not induce apoptosis in KG-1 cells, it considerably increased apoptosis upon combination with Erlo, providing evidence that anti-proliferative and pro-apoptotic effects of erlotinib are conveyed by different signaling pathways. Assessment of phosphorylation status confirmed that PP2 (but not Piceatannol or BAY 61-3606) diminished aberrant activation of Lyn to the same degree as erlotinib, and that this dephosphorylation was not increased by concomitant incubation with both drugs. Since the critical role of aberrant activation of Lyn and subsequent deregulation of mTOR signaling has been previously identified in AML (Dos Santos *et al*., Blood, 2008), we next tested if correction of Lyn activation by Erlo also impacts on mTOR-signaling: 4h of incubation with Erlo indeed significantly diminished phosphorylation of the mTOR-targets p-p70S6K(Thr389) and p-4E-PB1(Thr70). Assessment of LC3-II, as well as the cytoplasmic accumulation of autophagosomes and autolysosomes, both correlates of autophagy, provide evidence that erlotinib's inhibition of aberrant mTOR-signaling results in autophagy. Finally, we confirmed the antiproliferative activity of Erlo by demonstrating its capacity to decrease colony growth of patient-derived CD34-positive myeloblasts *Conclusions.* These results provide evidence that anti-proliferative effects of Erlo in EGFR-negative blasts are obtained by antagonizing aberrant Lyn-activation, therefore providing a mechanistic explanation for the therapeutic benefit of Erlo in high-risk MDS patients. In addition, we provide further evidence that the biological effects (notably on cell cycle progression and apoptosis) elicited by Erlo are conveyed by different signaling pathways.

ACTIVATION OF COMPENSATORY PATHWAYS ARE RESPONSIBLE OF AML SECONDARY TO HIGH-RISK MDS TREATED WITH 5-AZACYTIDINE

A Romano,[1] C Giallongo,[2] A La Branca,[2] N Parrinello,[2] C Vetro,[2] G Palumbo,[2] F Di Raimondo,[2] L Liotta,[1] V Espina[1]

[1]*George Mason University, Manassas, United States of America*
[2]*Department of Clinical and Molecular Bio-Medicine, Section of Hematology, Oncolo, Catania, Italy*

Background. Approximately one-third of Myelodysplastic syndromes (MDS) patients progresses to acute myeloid leukemia. Several studies have shown increased rates of programmed cell death (apoptosis) in marrow cells of patients with low grade/early stage MDS, and a changing interplay of pro-apoptotic and anti-apoptotic signals is central to disease progression. 5-azacytidine (5-AZA) is a DNA methyltransferase inhibitor used in treatment of high-risk MDS. A large clinical trial showed its beneficial in achieving better clinical outcomes and quality of life when compared to supportive care. Despite 5-AZA can delay the progression of MDS to acute myeloid leukemia (AML), by preventing the inactivation of tumor suppressor genes, high-risk MDS mortality for progression to AML is still too high. *Methods.* We analyzed 17 patients affected of high risk MDS, treated for 4 months with 5-azacytidine (median age 71 years, M/F=12/5). In 5 cases the sample after 4 cycles of therapy was matched to the sample collected before the therapy start. Bone marrow mononuclear cells were obtained using density gradient centrifugation (Fycoll) under sterile conditions, at the beginning of treatment and after 4 cycles of therapy. All samples were lysed at the same time into 40 uL of lysis buffer containing a 1:1 mixture of 2x Tris-Glycine SDS sample buffer (Invitrogen Life Technologies) and Tissue Protein Extraction Reagent (Pierce) plus 1.0% betamercaptoethanol for 5 min at 100oC. Reverse-phase protein microarray (RPMA) is a reproducible, high-throughput system for protein signal pathway profiling. RPMA were used to quantitatively map 45 cell signaling pathway endpoints, including survival, proliferation, drug resistance, apoptosis, and autophagy. *Results.* All patients were evaluable for response one month after the 4th cycle. 2 patients were refractory, progressing to AML under treatment, 1 progressed with a concomitant monoclonal gammopathy, and 1 was a late responder (documented response after 7cycles). 5/35 protein endpoints were linked together in the induction of a compensatory pathway induced after the treatment with 5-azacytidine, independently from the quality of achieved response. PLC-y-1-Tyr783 (p=0.0017), and its upstream SrcTyr416 (p=0.002) and downstream target STAT5Tyr694 (p=0.0017) were increased, without affecting proliferative pathways, such as AKT activation status on Ser473 and Thr308 or mTORSer2448. Comparing pool of samples at diagnosis with the pool of samples after 4 cycles we found an increase of the three main proteins considered markers of autophagy: ATG5 (p<0.0001), Beclin 1 (p=0.0056) and LC3B (p=0.0124), independently from the achieved quality of response. The activation occurred downstream mTOR pathway, since mTORSer2448, AktSer473, AktThr308, ERKThr202Tyr204 were not affected. *Conclusion.* We identified at protein level two compensatory pathways induced by

5-azacytidine. Since STAT5 is involved also in the transcriptional regulation of H3/H4, herein we provide the molecular rationale for the development of a combination based upon 5-azacytidine+ inhibitors of HDAC. Similarly, autophagy activation can be considered an escape pathway of survival in neoplastic cells. The observation that 5-azacytidine does not affect proliferative pathways, identified as new potential target in acute myeloid leukemia, suggests the need to combine 5-azacytidine to anti-proliferative agents, such as Rapamycin or RAD001, in order to target proliferation of neoplastic cells.

[3]*Anatomy Department, University of Florence, Florence, Italy*
[4]*FU Hematology,University of Florence, Florence, Italy*

Background. The implication of the Wnt pathway in self-renewal and proliferation of hematopoietic stem and progenitor cells suggests its involvement in the pathogenesis of haematopoietic neoplasias. This signalling cascade is controlled by different Wnt antagonists that interfere with ligand-receptor activating interactions. Among them, members of the DKK and sFRP family, whose activation induces the accumulation of non-phosphorylated β-catenin (NPBC) in the cell nucleus. Interestingly, aberrant methylation of these Wnt antagonists has been demonstrated in some haematological malignancies (acute myeloid leukemia and chronic myeloid leukemia). *Objectives.* 1. To study the methylation status of the Wnt antagonists: sFRP1, sFRP2, sFRP4, sFRP5 and DKK1 in primary MDS cells 2. To evaluate the correlation between methylation of Wnt antagonist and activation of the Wnt pathway, analyzing the expression of NPBC using bone marrow MDS cells before and after treatment with azacytidine (AZA). *Methods.* We studied bone marrow cells from 24 patients diagnosed with MDS according to the WHO classification: 10 RCMD, 5 RAEB-1, 3 RA and 6 RARS. Median age was 73 yr and M/F was14/24. After bisulphite treatment, methylation was evaluated by methylation specific PCR (MSP) using primers specific for the methylated and unmethylated alleles of the genes. Bone marrow cells of MDS patients were grown in RPMI 1640 medium supplemented with FBS and treated with AZA 1μM during 48 hours. Expression of β-catenin was studied by confocal microscopy using antibodies against total β-catenin and NPBC. *Results.* Hypermethylation of the gene promoters was observed for all Wnt antagonist genes. Among the 24 cases, methylation frequencies were as follows: 75% sFRP2, 75% DKK1, 61% sFRP1, 29% sFRP5 and 16% sFRP4. Most MDS patients (92%) showed methylation of at least one gene, ranging from one to 5 methylated genes. Bone marrow cells of the MDS cases with sFRP2 and sFRP2 together with sFRP4 methylated, respectively, were cultured *in vitro*. After AZA treatment, a reduction of DNA methylation level of sFRP2 and sFRP4 was observed, indicating the decrease on the. Additionally, confocal microscopy showed a reduction of NPBC in the cell nucleus, clearly indicating that inactivation of the Wnt pathway was provoked by the treatment with AZA. *Conclusion.* Hypermethylation of Wnt antagonists is a frequent event in MDS and seems to be associated with activation of the Wnt pathway, as demonstrated by the relocation of NPBC in the cell compartments after AZA treatment.

[5]*Servicio de Hematología. Hospital San Jorge, Huesca, Spain*
[6]*Servicio de Hematología. Hospital Rio Hortega, Valladolid, Spain*

Background. Information concerning the cell cycle distribution of different bone marrow (BM) cell compartments in myelodysplastic syndromes (MDS) remains limited and most studies reported have either been restricted to the overall BM cellularity or to the CD34+ BM cell subset. *Aims.* In the present study, we provide a comprehensive analysis of the cell cycle distribution of different BM hematopoietic cell compartments in a series of 117 MDS patients at different disease stages versus both normal and cytopenia-associated reactive BM. *Methods.* The proliferation index (PI; S+G2/M phase cells) was analyzed among the BM compartments of CD34+ hematopoietic progenitor and precursor cells (HPC), maturing neutrophils, maturing monocytes, mature lymphocytes, eosinophils and nucleated red blood cells (NRBC) from a cohort of 117 patients with MDS and 94 normal (n=47) and cytopenia-associated reactive BM samples (n=47), using multicolor flow cytometry immunophenotyping and the DRAQ5 DNA-dye. *Results.* Overall, our results show similar proliferation profiles in normal (n=47) vs reactive (n=47) BM, except for a slightly decreased PI among non-lymphoid CD34+ HPC (p=0.02), and a higher PI among CD13hi/CD11b+ neutrophils and monocytic cells in the latter group (p=0.03). Regarding MDS, significantly different proliferation profiles were detected in low- vs high-risk MDS. Overall, abnormally increased PI were found among low-risk MDS patients for the non-lymphoid CD34+ HPC (p 0.001), maturing and mature neutrophils (p 0.005) and NRBC (p=0.01); conversely, high-risk MDS cases showed lower PI for the non-lymphoid CD34+HPC (p<0.001), the more immature neutrophil compartments (p 0.004), monocytic cells (p≤0.05) and NRBC (p<0.001). Upon grouping patients according to their PI, a clear association was observed between a lower PI of the non-lymphoid CD34+ HPC (PI: <10% vs ≥10%) and other adverse disease features: >2 cytopenias (79% of cases vs 56%; p=0.03), thrombocytopenia (71% vs 35%; p=0.004) and increased LDH serum levels (57% vs 11%; <0.001). Similarly, a lower NRBC PI (<24% vs ≥24%) in MDS was associated to detection of >2 cytopenias (86% vs 53%; p=0.03), thrombocytopenia (86% vs 30%; p<0.001), increased LDH serum levels (46% vs 17%; p=0.05), anemia (86% vs 53%; p=0.03), transfusion dependence (90% vs 28%; p=0.001) and transformation into acute leukemia (41% vs 9%; p=0.01). Interestingly, those subjects with intermediate/poor cytogenetics according to the IPSS displayed an abnormally increased PI of CD13hi/CD11b+ neutrophils (3.5±3.4% vs 1.3±1%; p=0.005) associated with a lower PI of NRBC (24±5% vs 31±9%; p=0.004) and eosinophils (5±4% vs 6±5.5%; p=0.004) vs cases with normal or favourable karyotypes. From the prognostic point of view, assessment of the PI of NRBC emerged as an independent prognostic factor for overall patient survival. *Summary*. The assessment of the PI of different compartments of BM cells from patients with MDS revealed differential proliferation profiles in low vs high-grade MDS which might contribute to the prognostic stratification of the disease.

[3]*Divisione di Medicina, Macerata, Italy*
[4]*Divisione di Oncologia, Camerino, Italy*

Background. Epigenetic aberrations are now well recognized as very frequent and also as early events in the process of malignant transformation. It is very often reported that gene-specific hypermethylation occurs in the context of global hypomethylation. The clinical responses of MDS to drugs that reverse aberrant hypermethylation, such as 5-aza-2-deoxycytidine and 5-azacytidine, suggest that aberrant hypermethylation plays a causative role. *Aims.* We investigated global DNA methylation by immunohistochemistry in bone marrow trephine biopsy specimens in a cohort of 132 MDS patients comprising all subgroups. Results were compared to an age-matched control group of 47 healthy subjects and to a group of de novo (36) and secondary (20) AML patients. We applied a double staining procedure to discriminate the cell lineage of positive cells. *Methods.* Immunohistochemistry was performed on paraffin-embedded sections using anti-5-methylcytosine/5mc antibody. Scoring of immunohistochemistry was evaluated with a four-points scale for both the number of positive tumor cells and their intensity of immunoreactivity. Double immunostainings were performed on histological section for nuclear 5-methylcytosine/5mc and one of four cytoplasmic/cell membrane markers (CD34 for precursors, MPO for myeloid cells, Glycophorin-C for erythroid cells, Factor VIII for megakaryocytes) by using EnVision® G|2 Doublestain System,

Rabbit/Mouse (Dakocytomation): cells showing double stainings showed brown nuclei and red cytoplasms or cell membranes. *Results.* Normal bone marrows showed a low number of cells reactive for 5mc: with double stainings they were recognised as intermediate myeloid MPO-reactive and early erythroid glycophorin-C-reactive precursors accounting for less than 10% of the entire series. Segmented and polymorphonucleated granulocytes and orthochromatic erythroblasts were not stained with 5mc. CD34+ precursors with double stainings were hardly visualised in sections. Compared to normal bone marrows, MDS and AML cases showed respectively a moderate and a marked increase of positivity for 5mc. Primary AML were characterized by the highest percentage of 5mc+/CD34+ and 5mc+/MPO+ cells, including also more mature cells like segmented granulocytes and bands; 5mc+/glycophorin-C+ cells were few in this group of cases. Secondary AML showed a percentage of 5mc+/MPO+ and 5mc+/glycophorin-C+ cells and 5mc+/CD34+ cells higher than MDS cases and lower than primary AML. Unilineage and multilineage MDS without excess of blasts showed a mild increase of 5mc+/MPO+ and a significant increase of 5mc+/glycophorin-C+ precursors compared to normal bone marrows. MDS with excess of blasts exhibited a slight increase of 5mc+/CD34+ precursors compared to MDS without blasts and normal bone marrows. Differences were statistically significant between AML and MDS cases and between AML and normal marrows. In MDS the 5mc+/CD34+ and 5mc+/MPO+ percentage correlated significantly with the risk score according to the International Prognostic Scoring System. Factor VIII+ megakaryocytes were frequently reactive for 5mc in all conditions and we were not able to find any difference among different groups of patients. *Summary.* These results may provide a molecular explanation for the success in treating MDS patients with hypomethylation-inducing agents. Future studies have to analyse whether the determination of global methylation levels may serve as a new predictive marker for therapy response.

[2]*Hematology - University of Bari, Bari, Italy*

Background. Myelodysplastic syndromes (MDSs) are a heterogeneous group of hematopoietic stem cell disorders characterized by ineffective hematopoiesis and a propensity to progress into acute myeloid leukemia. In de novo MDS, chromosomal lesions consist mainly of unbalanced rearrangements and numerical defects whereas balanced structural rearrangements are rare, being observed in fewer than 5% of patients and their prognostic impact remains unknown. *Aims.* We aimed to characterize the t(3;11)(q13;q14) rearrangement in MDS at the genomic, molecular and functional level. *Methods.* One-hundred and fifteen MDS patients at diagnosis were analyzed by conventional cytogenetic analysis. FISH analyses were performed using BAC and fosmid probes selected according to the University of California Santa Cruz database (http://genome.ucsc.edu/). Quantitative real-time PCR (qRT-PCR) experiments were performed using the ABI Prism 7300 Sequence Detection System. Statistical analysis of the relative expression results was performed with the Relative expression software tool (REST). *Results.* Two (1.7%) cases showed a t(3;11)(q13;q14) translocation. FISH experiments detected the presence of the same breakpoints in both patients. UCSC database querying showed that no known gene was located on the chromosome 11 breakpoint, whereas 3 genes (CD86, ILDR1, and CASR) with known function were mapped next to the chromosome 3 breakpoint. qRT-PCR experiments showed ILDR1 upregulation in the patients by a mean factor of 13.775 (p=0.02). Bioinformatic analysis of the chromosome 11 breakpoint region showed the presence of a promoter (892+)#2 and a CpG island (CpG 172) at a distance of about 220 Kb from the breakpoint region. *Conclusions.* We reported a novel t(3;11)(q13;q14) rearrangement associated with overexpression of the immunoglobulin-like domain-containing receptor (ILDR1) gene in MDS patients. We hypothesize that the gene upregulation could be mediated by the juxtaposition of regulatory elements next to the ILDR1 gene as a consequence of the chromosomal translocation. ILDR1 expression has been related to the development and/or progression of cancer, as it has been detected in the transformation of a low grade follicular lymphoma to a high-grade diffuse large B cell lymphoma. The question whether there is a functional link between the clinical features and the ILDR1 gene dysregulation and whether it may have a potential prognostic significance in MDS remains to be established.

0248

UP-REGULATION OF SUBSET OF MIRNAS LOCATED IN 14Q32 DOMAIN IN CD34+ BONE MARROW CELLS FROM PATIENTS WITH MYELODYSPLASTIC SYNDROME

Z Krejcik, M Dostalova Merkerova, H Votavova, M Belickova, A Vasikova, J Cermak

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background. MicroRNAs (miRNAs) are small non-coding RNAs functioning as key regulators of many cellular processes including hematopoiesis. Differential miRNA expression patterns and a number of causative aberrations in miRNA genes have been detected in various pathological processes originating from hematopoietic stem cells. However, limited information is available regarding the importance of miRNAs for the development and progression of myelodysplastic syndrome (MDS), a heterogeneous group of clonal preleukemic conditions with high risk of transformation into secondary acute myeloid leukemia (AML). Recently, 46 potential miRNA genes located in the human imprinted 14q32 domain were suggested to play a role in various developmental or oncogenic processes, including AML. *Aims.* To expand the understanding of MDS etiology, here we focused on miRNA expression levels of 14q32 miRNA domain in patients with MDS using microarray techniques. *Methods.* Expression levels of miRNAs were measured in CD34+ bone marrow cells of 39 patients with MDS and AML evolved from MDS using human v2 MicroRNA Expression Profiling Kit (Illumina), and obtained data were compared with the group of 6 samples of healthy donors. Presence of cryptic chromosomal aberrations was tested in 23 MDS patients by the whole genome SNP-array (HumanCytoSNP-12 BeadChip; Illumina). All tested subjects signed the informed consent and the Institutional Review Board approved the study. *Results.* We defined a set of 9 miRNAs (miR-299-3p, miR-299-5p, miR-323-3p, miR-370, miR-409-3p, miR-431, miR-432, miR-494 and miR-654-5p) within 14q32.2 region significantly ($p<0.001$) upregulated in patients compared to controls; additionally, all miRNAs of this cluster whose expression was detected in our array experiment (n=35) displayed higher expression in patients compared to controls (24 miRNAs (i.e. miR-127) reached $p<0.01$, the others (n=11) displayed apparent but statistically non-significant increase in approx. 80% of patients). To examine a presence of some cryptic chromosomal aberrations (copy number variation (CNV) and uniparental disomy (UDP)) in this region which could be responsible for increased miRNA expressions, we applied SNP-microarray based karyotyping but there was no evidence for the chromosomal defect in this region; this rather suggest change in the methylation or acetylation status of the region or aberrant characteristics of some transcriptional regulator. *Conclusions.* Several publications suggested implication of miRNA members of 14q32 cluster in various developmental or oncogenic processes regarding mainly brain, placenta, and gastrointestinal tract tissues (e.g. miR-370 or miR-494). Interestingly, miR-127, another up-regulated member of 14q32 miRNA cluster, is involved in B-cell differentiation process through post-transcriptional regulation of BLIMP1 and XBP1; moreover, we detected negative association of another miR-127 target, BCL6, in MDS patients. Proto-oncogene BCL6, mediating aberrant cell survival, functions as a transcriptional regulator required for B- and T-lymphocyte terminal differentiation. The over-expression of miR-127 may thus represent a key event in lymphomagenesis by blocking the B-cell differentiation process. In the context of MDS, over-expression of miR-127 may be associated with previously documented down-regulation of genes involved in B-cell lineage differentiation. This is an early report describing distinctive miRNA expression profiles in 14q32 miRNA cluster in MDS CD34+ cells, likely reflecting the disease-specific regulation.

ABERRANT BNIP3 EXPRESSION IN MDS CELLS: A POSSIBLE DECITABINE TARGET

M Lazarini, J Machado-Neto, A Duarte, K Barcellos, F Costa, F Traina, S Olalla Saad

Hemocentro-Unicamp, Instituto Nacional de Ciência e Tecnologia do Sangue, Campinas, Brazil

Introduction. Myelodysplastic syndrome (MDS) encompasses a group of clonal hematopoietic stem cell disorders characterized by in-

Table 1.

Patient characteristics

	Low Risk (n°)	High Risk (n°)
FAB	RA (14) RARS (7) LMMC (1)	RAEB (9) RAEBt (3)
WHO	RCUD (1) RARS (7) RCMD (12) MDS 5q (1)	RAEB-1 (6) RAEB-2 (3) AML with myelodysplasia-related changes* (3)
IPSS	Low (10) Int-1 (16)	Int-2 (5) High (1)
Cytopenia	0 (4) 1 (11)	2 (12) 3 (7)

FAB: French-American-British; RA, Refractory Anemia; RARS, Refractory Anemia with Ringed Sideroblasts; RAEB, Refractory Anemia with Excess of Blasts; RAEBt, Refractory Anemia with Excess of Blasts in transformation; WHO, World Health Organization; RCUD, Refractory Cytopenia with Unilineage Dysplasia; RCMD, Refractory Cytopenia with Multilineage Dysplasia; RAEB-1, Refractory Anemia with Excess Blast-1; RAEB-2, Refractory Anemia with Excess Blast-2; AML, Acute myeloid leukemia. IPSS, International Prognostic Score System; INT-1: Intermediate-1; INT-2: Intermediate-2.
* Excluded from the WHO classification analysis.

effective hematopoiesis and a tendency to progress towards acute myeloid leukemia (AML). MDS progression is characterized by changes in protein functions that confer the ability of proliferation, impaired cell differentiation and decrease in apoptosis. BNIP3 is a hypoxia-induced enhancer of cell death and is associated with various tumors. BNIP3 expression is reduced in hematopoietic cell lines and primary leukemia cells and this result was associated to aberrant methylation and histone deacetylation of the transcription start site. BNIP3 expression is also reduced in myeloproliferative neoplasia, indicating that BNIP3 may play a role in the disturbed apoptosis observed in these diseases. Furthermore, BNIP3 was related to the regulation of erythrocyte production through modulation of apoptosis. Nevertheless, there are as yet no studies of the expression or function of BNIP3 in MDS. *Aims.* The aim of the present study was to characterize *BNIP3* expression levels in bone marrow cells from MDS and AML patients and normal donors, and the expression levels of *BNIP3* in MDS cells submitted to treatment with 5-aza-2'-deoxycytidine (DAC). Moreover, we evaluated the expression levels of *BNIP3* transcripts during erythroid differentiation of $CD34^+$ cells from normal donors and MDS patients. *Methods.* Bone marrow aspirates were obtained from thirty-four patients with MDS and twenty-eight patients with AML. Samples were collected from patients at the time of diagnosis. Twenty samples from normal donors were used as controls. MDS patients were grouped in low-risk and high-risk according to FAB, WHO and IPSS (Table 1). Gene expression was evaluated by quantitative PCR in total cells. Mononuclear cells from four MDS patients were isolated with Ficoll Hypaque density gradients and treated with 5μM DAC for seventy-two hours. Erythroid-differentiation was performed in $CD34^+$ bone marrow cells from 4 normal donors and 4 MDS patients. *Results.* We observed a significant decrease in *BNIP3* expression of AML and MDS cells compared with normal hematopoietic cells (0.52 [5.27-0.00]; 0.52 [5.25-0.02] versus 1.09 [6.04-0.18], respectively; $p<0.05$). In MDS, *BNIP3* expression was lower in both low-risk and high-risk patients according to FAB and WHO classification, IPSS and number of cytopenias, when compared to normal subjects. Interestingly, among the mononuclear cells submitted to DAC treatment, *BNIP3* expression was increased by three fold after DAC exposure in the cells from the two patients that showed lower *BNIP3* expression. *BNIP3* expression was not modulated during erythroid differentiation in normal and MDS cells. *Conclusion.* The downregulation of *BNIP3* in MDS cells may play a role in the dysregulation of apoptosis in hematopoetic cells leading to ineffective hematopoiesis. The increase in *BNIP3* expression after DAC treatment indicates that this gene may be epigenetically inactivated by methylation in this disease and might be a target for DAC treatment. Although it is difficult to explain the pathophysiology of the MDS only by *BNIP3* gene modulation, the study of different pathways is important in order to identity new prognostic markers or therapeutic targets in this disease.

Myelodysplastic Syndromes (MDS) are clonal disorders. However, whether the transforming event occurs in a myeloid committed cell or in earlier progenitor (stem cell?) it is still not ascertained. Evidence have been accumulated in both senses, but certainly, MDS initiating cells must be capable of sufficient repopulating capacity to perpetuate the disease. *Objectives.* To evaluate the repopulating ability of hypoxia selected cells in primary MDS bone marrow cultures and characterize the "stemness"of MDS maintaining cells. We evaluated 12 patients with different WHO subtypes of MDS (RCMD 5, RAEB-I 3, RAEB-II 3, 1 RA) . Mononuclear bone marrow cells were isolated after gradient centrifugation and grown in RPMI 1640 medium supplemented with 20% FBS and a cocktail of cytokines (TPO, FLT3-L, SCF,IL-3). Cells were incubated and selected in Ruskin Concept 400 anaerobic incubator, in severe hypoxia conditions by flushing with a performed gas mixture (0,3 % O2, 5%CO2, 95% N2). Cells were cultured under hypoxic conditions for 10-13 days (LC1), daily counted (Trypan blue) and then recovered from culture. The stem and progenitor cell potential of these cultures at different times of incubation was explored by transferring cells to growth-permissive secondary cultures in normoxia (LC2), with SCF, G-CSF, IL-6, IL-3, according to the Culture-Repopulating Ability assay methodology (Leukemia, 14:735-9, 2000). The phenotype of hypoxia selected cells was evaluated by determining the expression of CD34,CD38,CD117,CD133 and the frequency of early progenitor cells CD34posCD38negCD133 positive was compared to that present before hypoxic culture and to the Culture-Repopulating ability. Colony forming ability in semisolid medium was also evaluated in parallel in the presence of the same cytokine cocktail. The hypoxic culture system allowed selection of a minute cell population: in 12/12 cases viable cell number was decreased of one log after 10-13 days. In one case we observed, after hypoxia selection, a reduction of CD34 positive cells (0,15% against 9,44%). This population was enriched with CD 133 positive cells (91,8% against 83% before selection), and CD38positive cells were also increased (77% against 45%).Only 2/10 cases showed a significant repopulating ability at day 17 of LC2. In the other 10/10 cases, repopulating ability was apparently absent. Surprisingly, MDS cases presenting blasts in the bone marrow did not show more repopulating cells after selective hypoxic conditions. Although our results are preliminary, we demonstrate that it is possible to select by severe hypoxic conditions primary MDS progenitor cells endowed with repopulating ability. Further characterization (phenotypic and molecular) of these selected progenitors will allow a deeper insight into the biology of this heterogenous group of diseases.

UNSUSPECTED CHROMOSOMAL LESIONS ARE REVEALED BY FISH IN KARYOTYPICALLY NORMAL MDS PATIENTS

P Bernasconi, I Dambruoso, M Boni, P Cavigliano, R Zappatore, I Giardini, B Rocca, C Calvello, M Caresana

Division of Hematology, Foundation IRCCS Policlinico San Matteo, Pavia, Italy

Background. In MDS the cytogenetic pattern is the most important parameter to predict overall survival (OS) and the risk of MDS/AML evolution, but 40-50% of patients are not informative being chromosomally normal. *Aims.* Our study evaluated whether probes derived from aCGH studies were truly able to unmask cryptic lesions in chromosomally normal MDS patients and influenced OS and disease evolution. *Methods.* The 73 chromosomally normal MDS patients analysed came to our observation in the period January 2005-December 2010. They were twenty-five females and forty-eight males, their median age was 64 years (range 22-77). According to WHO classification, 5 patients were classified as RARS, 27 as RA, 5 as RCMD, 22 as RAEB-1 and 14 as RAEB-2. Considering IPSS score, 24 patients were considered low-risk, 28 intermediate-1 risk and 15 intermediate-2 risk and 6 as high-risk. Median follow-up was 21 months (range 1-66). At the time of the study no patient has died. Overall, 9 transformed into a more advanced MDS subtype and 11 into AML. FISH probes were chosen based on the frequency of their involvement and their Mb position (UCSC genome browser on Human Mar. 2003 assembly). They were obtained from BACPAC Resources Center at C.H.O.R.I. (Oakland, USA), labelled and

applied as previously described. We used the following probes: RP11-912d8 (19q13.2); RP11-196p12 (17q11.2); RP11-269c4 (14q12); RP11-351o1 (10q21.3); RP11-144g6 (10q11.2); RP11-122a11 (7q34); RP11-951k18 (5q13.1); RP11-100m20 (4p14); RP11-544h14 (2q33). For i-FISH, cut-off values, obtained from the analysis of 300 nuclei from ten normal samples, were fixed at 10%. Results An abnormal FISH pattern was revealed in 26 patients (35.6%). A single defect was revealed in 19 patients (73.0%) and more than two defects in 7 (26.9). Sixteen patients (61.5%) presented a 19q13.2 deletion, 7 (26.9%) a deletion of band 14q13.2, 4 (15.4%) a deletion of band 17q11.2, 4 (15.4%) a deletion of band 5q13.1-q13.2, 4 (15.4%) a deletion of band 4p14, 3 (11.5%) a deletion of band 10q11.22, 3 (11.5%) a deletion of band 7q34, 2 (7.7%) a deletion of band 10q21.3 and one a deletion of band 2q33.1-q33.2. An abnormal FISH pattern was observed in 1/5 RARS, in 7/27 (25.9%) RA, in 3/5 RCMD, in 8/22 (36.4%) RAEB-1 and in 7/14 (50%) RAEB-2. Considering the IPSS, at least one defect was observed in 4/24 (16.6%) low-risk, in 12/28 (42.8%) intermediate-1 risk and in 7/15 (46.6%) intermediate-2 risk 3/6 (50%) high-risk patients. Disease evolution occurred in 2 RA patients, in 3 RAEB-1 and in 4 RAEB-2 patients with an abnormal FISH pattern. Seven of these patients presented at least two chromosomal deletions. In contrast, disease evolution occurred in one RARS, in two RA, 3 RAEB-1 and in 5 RAEB-2 with a normal FISH pattern. In conclusion our data suggest that FISH: i) reveals novel unsuspected chromosomal lesions in about 36% of chromosomally normal MDS patients; ii) these chromosomal lesions mostly consist in gains/losses, whereas balanced rearrangements are very rare; iii) an abnormal FISH pattern with more than two deletions seems to correlate with disease progression.

Background. Overexpression of death receptor Fas and its ligand FasL, plays a major role in the activation of extrinsic pathway of apoptosis in MDS. TNF-a, a potent activator of the NFκB pathway, upregulates Fas in normal myeloid cells. FAS gene expression is controlled by NFκB in T cells and hepatocytes, while FasL is regulated by FOXO3A which nuclear translocation is inhibited by NFkB. *Aims.* This study aims at investigating the role of NFkB in the regulation of Fas and FasL in MDS/AML cells. *Methods.* Localization of p65 NFkB subunit by IF and WB on nuclear fractions, FAS transcript by RT-PCR and Fas and FasL proteins by flow cytometry were analyzed in P39 and HL-60 cell lines and in bone marrow-derived MDS/AML mononuclear (n=11) or CD34+ cells (n=3) maintained in culture with FLT3-L, TPO, IL-6, SCF. Binding of p65 NFkB subunit to the FAS promoter was evidenced *in vitro* by pull-down of p65-transfected 293T cells on 5'biotinylated-oligonucleotides mimicking consensus NFkB sequences of FAS promoter and *in vivo* by ChIP. NF-kB pathway was inhibited by the IKKa inhibitor BAY11-7082 (5 µM) or lentiviral expression of IkSR, a non-degradable form of IkBa. *Results.* The P39 cell line which exhibits a strong expression of the p65 NFkB subunit in the nucleus, express Fas at plasma membrane. Fas is inducible in HL-60 cells treated with TNF-a, which provoked p65 nuclear translocation. Apoptosis of MDS/AML CD45lo/CD34+ blasts is significantly lower than in earlyMDS. p65 is in the nucleus of 60 -100% MDS/AML mononuclear or CD34+ cells and this correlates with the lack of FasL and the expression of Fas at plasma membrane. *In vitro*, p65 is trapped on the 4 NFkB sequences of the FAS promoter by oligoprecipitation. *In vivo*, we demonstrate by ChIP that p65 is able to bind to the FAS promoter in myeloid cells. BAY11-7082 decreases nuclear expression of p65 NFkB subunit and expression of Fas transcript and protein in P39 cell line and MDS/AML mononuclear or CD34+ cells. In 4 MDS cases, lentiviral expression of IkSR in CD34+ cells both inhibits the nuclear expression of p65 and the expression of Fas in the GFP+ cell population corresponding to infected cells. *Conclusion.* NFkB pathway is implicated in the regulation of Fas expression in MDS/AML cells. Induction of Fas together with downregulation of FasL lead to the inhibition of Fas-dependent apoptosis, a mechanism by which NFkB may contribute to the progression of the disease.

[3]*University of Pavia, Pavia, Italy*

Background. WHO proposal for myelodysplastic syndrome (MDS) classification introduced uni- versus multilineage dysplasia as a diagnostic criterion in MDS with <5% bone marrow (BM) blasts, increasing the prognostic value of this classification. Cytopenias generally correspond to dysplasia, but discordance may be present. However, a structured and reproducible approach for the precise recognition of BM dysplasia is still missing, and the relationship between cytopenia and dysplasia needs to be clarified. *Aims*. The aims of this study were to identify a panel of reproducible morphological criteria associated with MDS useful for a correct application of WHO classification and to evaluate the prognostic relevance of the single morphological abnormalities and of the total lineage dysplasia as well as of the degree of dysplasia. *Methods*. We retrospectively examined the cytological features of BM smears from 429 MDS patients previously classified according to FAB criteria, 214 patients with hyporegenerative anemia and 74 healthy subjects. By counting 100 cells for the erythroid and granulocytic lineages and at least 20 megakaryocytes and classifying them for their dysplastic changes, a panel of dysplastic features showing a better sensitivity and specifity for MDS identification was developed. The morphological panel including 26 dysplastic features (12 erythroid, 8 granulocytic and 6 megakaryocytic) was employed, in association with the evaluation of blast and sideroblast percentages, to reclassify MDS patients by 2008 revised WHO proposal using the 10% threshold to record dysplasia in the erythroid and granulocytic lineages and the 25% threshold for dysmegakaryopoiesis, with a between-investigators and within-investigator agreement of 92% and 95% respectively. *Results*. Three hundred and one MDS cases were correctly reclassified, 45 were unclassifiable for inadequate BM smears and 83 belonged to other hematopoietic neoplasms. On univariate analysis, increase of BM blasts, multilineage dysplasia and two or more cytopenias were associated with worse outcome but multivariate analysis failed to confirm the prognostic value of cytopenias. In MDS without an increase of BM blasts, Kaplan Meier estimates of overall survival (OS) and leukemia-free survival (LFS) showed that all patients with multilineage dysplasia had a significantly worse outcome, independently of the number of cytopenias (P=0.03 and P=0.0005 respectively). Some morphological abnormalities, i.e. erythroblast irregular nuclear edges or multinuclearity, granulocyte hypo-agranularity, small binucleated megakaryocytes, were associated with poor outcome, and total granulocytic or megakaryocytic dysplasia showed a significant independent unfavorable prognostic value (P=0.0004 and P<0.0001 respectively). Also the degree of granulocytic or megakaryocytic dysplasia, estimated based on percentage of dysplastic cells, was found to have a significant effect on OS (P=0.002 and P=0.0003 respectively). *Conclusions*. The definition of BM dysplasia with a standardized morphological panel that improves the objectivity and reproducibility of microscopic analysis is useful for a correct application of WHO classification as well as for the differential diagnosis between MDS and other cytopenias. Our data confirm the significance of multilineage dysplasia correlation with high-grade MDS. Prognostic systems including the evaluation of the degree of BM dysplasia should be adopted for clinical decision-making and selection of MDS patients for new effective targeted therapies.

Background. PNH is a chronic, life-threatening disease associated with increased risk of thrombosis (TE), end organ damage, often poor quality of life, with premature mortality. TE accounts for 40-67% of PNH-related-deaths; anticoagulation (AC) management may not be effective in PNH, as TE rates in AC-treated PNH patients remain elevated. The complement inhibitor eculizumab reduces chronic hemolysis rapidly and significantly; it also leads to reductions in TE events pulmonary hypertension and improvements in chronic kidney disease (CKD) and quality of life. *Methods.* All patients (N=195) in the PNH eculizumab clinical trials and subsequent Extension studies were evaluated for safety, sustained outcomes, and patient survival. Median age was 40 yrs, 54% female, 29% with history of aplastic anemia and 1.5% with history of myelodysplasia. TE was reported in 32% (63/195) of patients prior to eculizumab treatment. *Results.* Median eculizumab treatment duration was 29 mo (1-66;IQR:23-32m); total eculizumab exposure was 467.1 patient-years. LDH was rapidly and significantly reduced from baseline of 2,293U/L (~10x ULN) to 310U/L post 1 month treatment (P<0.0001) and was sustained through 36 months (P<0.0001). TEs were significantly reduced from 52 pre-treatment to 10 trial events by matched-time analysis (P<0.0005). Of the 7/195 patients who experienced a TE, 5 had history of TE and 2 were concomitantly treated with AC. Of patients treated with AC, 58/98 experienced at least 1 TE prior to treatment. In 11 patients who discontinued AC while on eculizumab, no TEs were reported during or following AC discontinuation. Chronic Kidney Disease (CKD) was reduced from 69% at baseline to 31% (n=29) 36 months post-treatment. Significant increases in hemoglobin were sustained over 36 months treatment (mean increase over baseline at 36 months: 9.5g/L; P<0.0001; range: -31,68), despite significant and sustained reductions in transfusion requirements. Of the 87/195 patients receiving at least 36 months of eculizumab, 29% (25/87) became transfusion independent and maintained transfusion independence for the entire treatment period. Eculizumab was well tolerated; 90% (175/195) of patients completed the parent and extension trials. Twenty patients (10%) did not complete the trial including 9 patients following a reported adverse event (AE). In 16 week follow-up, TE was reported in 3 of these 20 patients, including 1 death. Most AEs (91%) were mild or moderate in severity. There were 2 cases of meningococcal sepsis; both were successfully treated without sequelae. There were 4 patient deaths: 3 not related and 1 possibly related to eculizumab, per investigator. Kaplan-Meier analysis (fig.1) showed probability of overall survival was 97.64% at 3 years and was maintained through 5.5 years of ongoing treatment. Patient survival compares favorably to a predicted survival rate previously reported in historical controls of 65% at 5 years. *Conclusion.* Long term reduction of chronic hemolysis in PNH patients treated with eculizumab is associated with significant improvements in the incidence of TE, CKD, and other PNH-associated symptoms. Long term treatment with eculizumab also results in a high probability of survival, which is maintained over 5.5 years of ongoing treatment.

[4]*Department of Clinical and Experimental Medicine, Second University of Naples, Naples, Italy*

Background. Immunosuppression (IS) is a worthy treatment option for patients suffering from aplastic anemia (AA) or other lineage-specific immune-mediated marrow failure, such as pure red or white cell aplasias (PRCA and PWCA). *Aims.* We have previously described results from a pilot phase II prospective trial (NCT00895739) investigating the anti-CD52 monoclonal antibody alemtuzumab in combination with low-dose cyclosporine A (CyA; Risitano, BJH 2010;148:791). Here we report the long-term follow up of the study. *Methods.* Twenty-eight patients were enrolled in the study: 13 SAA, 13 PRCA and 2 PWCA; 15 (6 SAA, 9 PRCA and 1 PWCA) had not received any previous IS. Median age was 51 years (range 25-87). The patients received alemtuzumab as subcutaneous injection of 3-10-30-30-(30) mg (total dose 103 mg for SAA, 73 mg for PRCA and PWCA), in consecutive days, followed by oral CyA 1 mg/kg). Given the major concerns about infectious risk, all patients received adequate prophylaxis, including valganciclovir (for 3 months) and bactrim. *Results.* All patients completed the treatment without serious adverse events; lymphocyte depletion was immediate and complete in all patients, with delayed immune reconstitution (especially for CD4+ T-cells). With a median follow up of 33 months, infectious events were infrequent and clinically mild, with exception of 1 fatal sepsis and 1 progressive multifocal leukoencephalopathy (PML, occurring in a PRCA patient relapsed with metastatic thymic carcinoma, during salvage chemotherapy). No CMV disease nor EBV-related disease or lymphoproliferative disorder was observed, even if 5 patients developed asymptomatic CMV reactivation (promptly cleared by pre-emptive valganciclovir). The response rates were 77% (38.5% CR) in AA and 84.5% (61.5% CR) in PRCA patients; both PWCA achieved long-lasting CR. Current stable remission were achieved in 38.5% of AA and 23% of PRCA; the majority of long-term responders have received an additional dose of alemtuzumab to sustain the hematological response. Long-term treatment failures were due to refractory relapses (15% for AA and 7.5% for PRCA) or to clonal evolution (15% for AA, both myelodysplastic syndromes with chromosome 7 abnormalities, and 23% for PRCA, with 2 acute megakaryoblastic leukemia and 1 5q- syndrome). Overall survival in AA was 72%, even due to effective salvage therapies; all deaths were due to refractory disease. Unexpectedly, overall survival was only 20% in PRCA; the causes of death were disease evolution (3 leukemias and 1 AA), PRCA-associated morbidities (1 thymoma complicated with PML, 1 refractory connective tissue disease) or unrelated cardiovascular comorbidities. *Conclusions.* Long-term follow up of patients treated with alemtuzumab confirms that this agent has a remarkable efficacy for the treatment of immune-mediated bone marrow failures, with response rates comparable to that of standard IS. Treatment-related long-term toxicity was acceptable, with a low risk of infectious complications; as with standard IS, late treatment failures were mainly due to relapse (alternative maintenance strategies might be considered) or clonal evolution. Even in consideration of the recent data showing the inferiority of rabbit ATG (Scheinberg, ASH 2010;116:LBA-4), our results suggest that alemtuzumab is a worthy alternative to standard IST by horse ATG, possibly deserving appropriate head-to-head comparison.

PROGNOSTIC VALUE OF IRON PARAMETERS AT DIAGNOSIS IN MYELODYSPLASTIC SYNDROME PATIENTS: ANALYSIS OF 643 PATIENTS FROM THE PIEDMONT MDS REGISTRY

E Messa,[1] D Gioia,[2] B Allione,[2] C Bertassello,[2] M Bonferroni,[2] G Cametti,[2] D Cilloni,[2] G Ciravegna,[2] E Crisà,[2] D Ferrero,[2] R Freilone,[2] M Lunghi,[2] F Marmont,[2] B Pollio,[2] F Salvi,[2] A Tonso,[2] G Saglio,[2] A Levis[2]

[1]*Ospedale SS Antonio e Biagio, Alessandria, Italy*
[2]*Piedmont MDS Registry, Italy*

Background. The role of serum ferritin (SF) value as prognostic factor in patients affected by myelodysplastic syndrome (MDS) is still controversial. Increased SF levels mainly due to transfusion requirement has been associated with lower overall survival (OS) (Malcovati, 2007) and increased risk of leukemic transformation (Sanz, ASH 2008; de Swart ASH 2010). Conversely, Park and colleagues (ASH 2010) failed to identify a negative prognostic value of SF higher than 300 ng/mL at baseline in a cohort of low risk untransfused MDS patients. Little is known about the impact on survival of other iron parameters such as transferrin saturation (TS). *Aims.* We evaluated the prognostic significance of SF and TS at diagnosis in MDS patients analyzing data collected in the MDS Piedmont Registry. *Methods.* Data from 1558 patients from 37 centres included from 1999 to 2010 were analyzed. We evaluated OS according to iron parameters including the following variables: haemoglobin (Hb), neutrophils and platelets counts, IPSS, serum EPO (sEPO), C reactive protein (CRP), comorbidities, age, cytogenetic risk, transfusion dependence (TD), first line treatment. *Results.* SF at diagnosis was available in 643 patients (274 females, 369 males), who are the object of the present analysis. Median age was 74 (range 25-106). WHO classification was as follows: 177 RA (with 16 of them classified as 5q- syndrome), 46 RARS, 96 RAEB-1, 148 RCMD, 49 MDS-U, 1 atypic cronic myeloid leukemia, 86 RAEB-2. In addition 30 CMML and 10 RAEB-t registered before 2003 according to FAB classification were included. IPSS stratification was as follows: 15% low risk, 47% Int-1, 15% Int-2 and 23% high risk. Median Hb value was 9,5 g/dL (range 2,8-17; mean 9,8), median SF was 282 ng/mL (range 1-3496; mean 396), median TS was 36% (range 2,1-100; mean 43,5). In univariate analysis, SF >500 ng/mL was positively associated with increased TS (>45%) (p=0,001) and with male gender. Furthermore, increased TS was positively associated with increased sEPO (p=0,004) but negatively with CRP levels. OS by Kaplan-Meyer method was analyzed according to basal SF and TS values in the whole population. No statistically significant difference was found in OS of MDS patients according to SF lower or higher than 500 ng/mL also in the subgroup of non TD patients. Conversely, patients with TS <45% showed worse outcome in the whole population (p= 0,007) and in the non TD group (p=0,014). The prognostic significance of TS is confirmed in the group non TD low and Int-1 IPSS patients: median OS of 40 vs. 53 months (p=0,02). *Conclusions.* In our cohort of 643 patients from the MDS Piedmont Registry, increased SF >500 ng/mL at baseline does not impact on OS, conversely transferring saturation lower than 45% is strongly associated with worse OS in low risk non TD patients. Further evaluations of comorbidities, chronic inflammation and oxidative stress parameters should be evaluated in order to clarify the meaning of our findings.

0257

VALIDATION OF A FLOW CYTOMETRIC SCORING SYSTEM FOR THE PROGNOSTICATION OF THE MYELODYSPLASTIC SYNDROMES; A RETROSPECTIVE COHORT STUDY

C Alhan, T Westers, C Cali, G Ossenkoppele, A van de Loosdrecht

VU University Medical Center, VU Institute for Cancer and Immunology (V-ICI), Amsterdam, Netherlands

The International Prognostic Scoring System (IPSS) and WHO-based prognostic scoring system provide prognostic information in myelodysplastic syndromes (MDS). However, even if patients are allocated in the same risk category their clinical course remains heterogeneous. Previous studies demonstrated that flow cytometry (FC) and specifically a flow cytometric scoring system (FCSS) is emerging as a valuable technique for predicting outcome in MDS. The FCSS is a scoring system that allows for a numerical display of immunophenotypic aberrancies in the (im)mature myelo-monocytic lineage (Wells, Blood 2003). Scores are generated by enumerating abnormalities; high scores reflect high number of aberrancies. The current study aimed to validate the FCSS for identification of prognostic subgroups in MDS. We analyzed aberrancies in (im)mature myelo-monocytic cells by FC in BM of 107 MDS patients, including 48 MDS patients from a previous cohort. The diagnoses according to WHO 2001 classification were RA(RS) n=20, RCMD(RS) n=60, RAEB-1 n=14, RAEB-2 n=13 and age-matched healthy volunteers (n=39) were included. The FCSS in RA(RS) (median=3, range 1-6) patients was significantly higher compared with healthy controls (median=1, range 0-2, p<0.001). In contrast to our previous results the FCSS for RA(RS) and RCMD(RS) patients did not differ. This is a remarkable finding, since by morphology RA(RS) patients show only unilineage dysplasia, in contrast to flow cytometric findings, where 85% of the RA(RS) patients had two or more aberrancies in the (im)mature myelomonocytic compartment. Patients with a high FCSS experienced a significantly worse overall survival (OS) compared with patients with an intermediate FCSS (p=0.001, median OS 28 and 89 months, respectively). Remarkably, the FCSS was not correlated with IPSS cytogenetic risk categories low, intermediate and poor. However, within the good risk category according to IPSS, the FCSS identified different prognostic subgroups. Patients with good cytogenetics and a high FCSS have a worse OS compared to those with intermediate FCSS (p=0.001, median OS 39 and 164 months, respectively). Transfusion data was available in 77 patients. Interestingly, the majority of MDS patients who were transfusion dependent or progressed into AML, had aberrant expression of CD5, CD7 and/or CD56 on myeloid progenitors compared with patients without aberrant marker expression (50% vs 24%, respectively; p=0.012). In conclusion, the FCSS and detection of aberrant myeloid progenitors can provide refined prognostication within currently used classification and prognostication systems. The FCSS can identify patients at risk for transfusion dependency and adverse clinical outcome, independent of current classification systems.

0258

FMNL1 EXPRESSION IN CELLS OF MDS PATIENTS AND THEIR CD4:CD8 T-CELL RATIOS

M Lopes,[1] F Traina,[1] P De Melo Campos,[1] S Medina,[1] J Machado-Neto,[1] F Costa,[1] I Lorand-Metze,[1] S Olalla Saad,[1] P Favaro[2]

[1]*Hemocentro-Unicamp, Instituto Nacional de Ciência e Tecnologia do Sangue, Campinas, Brazil*
[2]*Department of Biological Sciences, Federal University of Sao Paulo, Diadema, Brazil*

Background. Myelodysplastic syndromes (MDS) are a heterogeneous group of disorders characterized by impaired peripheral blood cell production and a tendency to develop leukemia. Evidences have shown that T-cell mediated marrow suppression is the cause of the cytopenia in approximately 20-30% of MDS patients. Human FMNL1 belongs to a conserved family of formin-related proteins, and is restrictedly expressed in hematopoietic cells, including lymphocytes, and overexpressed in chronic lymphocytic leukemia and lymphoma samples as well as in malignant cell lines. Moreover, FMNL1 participates in the regulation of the cytoskeleton in activated T lymphocytes and in the control of the polarization of centromeres, required for the cytotoxic function of these cells. *Aims.* Characterize *FMNL1* expression in peripheral blood $CD3^+$ lymphocytes and in total bone marrow cells of patients with MDS and normal donors; compare *FMNL1* expression levels among low-risk, high-risk MDS (according to FAB classification and number of cytopenias) and normal donor cells; correlate the CD4:CD8 T-cell ratios of patients with the three disease classifications (FAB, WHO and IPSS) and number of cytopenias. *Methods.* A total of seventy-one patients with a diagnosis of MDS, receiving no treatment, were included in the study; twenty-two samples from normal donors were used as controls. Patients were grouped into low-risk and high-risk disease, according to FAB, WHO, IPSS and number of cytopenias (Table 1). This study was approved by the National Ethical Committee Board, with the signed informed consent of all patients. *FMNL1* expression levels from $CD3^+$ cells (obtained by Ficoll-Hypaque followed by magnetic selection) or total bone marrow cells were determined by quantitative PCR (q-PCR). $CD3^+$ cell counts and CD4:CD8 ratio was determined by flow cytometry. *Results. FMNL1* expression was significantly higher in MDS $CD3^+$ peripheral lymphocytes when compared with normal donor cells (P=0.01), although there was no change in $CD3^+$ cell number between those two groups. In the bone marrow samples, *FMNL1* expression was higher in low-risk compared to high-risk MDS according to FAB (P=0.07) and number of cytopenias (P=0.01). CD4:CD8 T-cell ratios were significantly higher in high-risk MDS group when compared to normal donor cells according to FAB, WHO and IPSS classification (P<0.01), and this is due to a tendency of decrease in the number of $CD8^+$ cells in the peripheral lymphocyte pool of those patients. Interestingly, we observed a higher CD4:CD8 ratio in MDS high-risk group when compared with the low-risk group, based on

Table 1.

Patient characteristics

	Low Risk (BM/CD3+)	High Risk (BM/CD3+)
FAB	RA (18/22) RARS (04/04)	RAEB (11/06) RAEBt (06/00)
WHO	RCUD (05/07) RARS (01/02) RCMD (15/16)	RAEB-1 (09/05) RAEB-2 (06/02) AML with myelodysplasia-related changes* (3/0)
IPSS	Low (09/14) Int-1 (20/15)	Int-2 (08/02) High (02/00)
Cytopenia	0 (04/05) 1 (13/11)	2 (14/14) 3 (07/02)

BM: Bone marrow; FAB: French-American-British; RA: Refractory Anemia; RARS: Refractory Anemia with Ringed Sideroblasts; RAEB: Refractory Anemia with Excess of Blasts; RAEBt: Refractory Anemia with Excess of Blasts in transformation; WHO: World Health Organization; RCUD: Refractory Cytopenia with Unilineage Dysplasia; RCMD: Refractory Cytopenia with Multilineage Dysplasia; RAEB-1: Refractory Anemia with Excess Blast-1; RAEB-2: Refractory Anemia with Excess Blast-2; AML: Acute myeloid leukemia; IPSS: International Prognostic Score System; INT-1: Intermediate-1; INT-2: Intermediate-2.
* Excluded from the WHO classification analysis.

the number of cytopenias (although not statistically significant). *Conclusions.* During the early stages of MDS, one mechanism contributing to hypercellular marrow and peripheral blood cytopenia is the significant increase of apoptosis in haematopoietic cells. The higher expression of *FMNL1* in MDS $CD3^+$ lymphocytes and bone marrow cells may be related to clonal or oligo-clonal T cell activation, since FMNL1 is important for the cytotoxic function of these cells. The CD4:CD8 imbalance could reflect an alteration in the immune regulation, which could contribute to the cytopenia in some MDS patients. Further studies are required to test these hypotheses. Supported by FAPESP, CNPq and INCT do Sangue.

THE PRESENCE OF ABERRANT MYELOID PROGENITORS PREDICTS OVERALL SURVIVAL IN INTERMEDIATE-2 AND HIGH RISK MYELODYSPLASTIC SYNDROMES UPON TREATMENT WITH AZACITIDINE

C Alhan,[1] T Westers,[1] C Eeltink,[1] C Cali,[1] G Huls,[2] G Ossenkoppele,[1] A van de Loosdrecht[1]

[1]*VU University Medical Center, VU Institute for Cancer and Immunology (V-ICI), Amsterdam, Netherlands*
[2]*University of Groningen and University Medical Center Groningen, Groningen, Netherlands*

One of the major challenges in MDS is the prognostication and selection of the most suitable therapeutic options. Flow cytometric analysis of bone marrow cells in low and int-1 risk MDS patients can identify distinct subgroups within validated risk groups and predict response to growth factor treatment. (Westers *et al*., Blood 2010) In this study we investigate the predictive value of flow cytometry (FC) for prognosis and selection of int-2 and high risk MDS patients for response to azacitidine. Bone marrow aspirates were analyzed by FC in 25 constitutive MDS patients before treatment and after every third cycle of azacitidine. A flow score was calculated using the flow cytometric scoring system (FCSS; Wells *et al*., Blood 2003). The FCSS is a scoring system that allows for a numerical display of immunophenotypic aberrancies in (im)mature myelo-monocytic cells (0-1 no flow cytometric dysplasia, 2-3 mild dysplasia, ≥4 severe dysplasia); e.g. high scores (≥4) reflect a high number of aberrancies. Response was evaluated using IWG-2006 criteria. The WHO 2008 categories were 2 RCMD, 3 RAEB-1, 9 RAEB-2, 7 AML with multilineage dysplasia and 4 CMML. Flow cytometric follow up was available in 17 patients. Median follow up time after initiation of the first cycle was 9.6 months. Four patients achieved complete remission (CR), 7 stable disease (SD) and 6 had progressive disease (PD). The median FCSS at baseline was 7 (range: 3-8). Patients who achieved CR showed a significant decrease in the FCSS after 3 cycles as compared to patients with SD and PD (median FCSS 1.5, 5 (p=0.009) and 6.5 (p=0.003), respectively). At baseline, 16/25 patients had aberrant marker expression (AME) (i.e. CD5, CD7, CD11b and/or CD56) on myeloid progenitors and/or monocytes. These patients had significantly worse overall survival as compared to patients without AME (p=0.004; relative risk (RR) of death in patients with AME was 6 times higher than without AME). Absence of AME in patients with SD was strongly associated with erythroid response (HI-E). Our data indicate that patients with SD and AME are less likely to show HI-E upon azacitidine treatment (RR=4). In conclusion, persistent high FCSS during treatment and/or presence of AME at baseline is of prognostic value and identifies int-2 and high risk MDS patients who are unlikely to achieve CR or HI-E and with worse overall survival as compared to patients without AME.

CLINICAL CHARACTERISTICS OF THERAPY-RELATED MYELODYSPLASTIC SYNDROME

H Kim,[1] JH Park,[1] G Garcia-Manero[2]

[1]*Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, South-Korea*
[2]*The University of Texas MD Anderson Cancer Center, Houston, United States of America*

We identified 438 patients who have had one or more malignancies prior to the diagnosis of MDS evaluated at MDACC between 1997 and 2007. To select therapy-related myelodysplastic syndrome (Tx-MDS), we removed patients who have diagnosed as MDS by FAB classification but have not included in WHO classification, and we selected patients who have undergone chemotherapy (CTx) and/or radiation therapy (RTx) for prior malignancies (Fig 1). Finally 281 patients were included for the analysis of Tx-MDS. Male sex was 165 (58.7%) and median age at diagnosis of MDS was 66.2 years (range 13.4-89.4). Patients were classified by WHO classification as follows: RA (n=63, 22.4%), RARS (n=29, 10.3%), RCMD/RCMD-RS (22, 7.9%), RAEB-1 (n=90, 32.0%), RAEB-2 (n=67, 23.8%), MDSu (n=10, 3.6%). IPSS was low in 30 (11%) patients, INT-1 in 87 (31.0%) patients, INT-2 in 120 (42.7%) patients and high in 35 (12.5%) patients. The most common cytogenetic abnormality was -5 and/or -7 (n=149, 53.1%). Seventy five patients (26.7%) were diploid. Prior cancers included: head and neck (n=7, 2.5%), thyroid (n=3, 1.1%), lung (n=7, 2.5%), breast (n=32, 11.4%), gastrointestinal (n=13, 4.6%), prostate (n=34, 12.1%), other genitourinary or gynecological (n=16, 5.7%), melanoma/skin cancers (n=5, 1.8%), sarcomas (n=8, 2.8%), other solid cancers (n=2, 0.7%), lymphoma (n=102, 36.3%), CML/CLL (n=6, 2.1%), AML/ALL (n=5, 1.8%), multiple myeloma (n=11, 3.9%) and multiple cancers (n=30, 10.7%). Prior Tx was CTx only (n=107, 38.1%), RTx only (n=73, 26.0%) or both CTx and RTx (n=101, 35.9%). The treatments of Tx-MDS were categorized as follows: supportive care/cytokine therapy in 126 (44.8%); non-cytotoxic drugs in 77 (27.4%); cytotoxic chemotherapy in 65 (23.1%); hematopoietic stem cell transplantation (HSCT) in 13 (4.6%). A total of 54 patients had received HSCT (autologous, n=52 (18.5%); allogeneic, n=2 (0.7%)). Univariate analyses for survival revealed that presence of hepatomeglay (no hepatomegaly vs. hepatomegaly; p=0.023), cytogenetics (8+, 20q-, Y-, normal vs. others; p<0.001), types of MDS by WHO classification (RA, RCMD, MDSu vs.

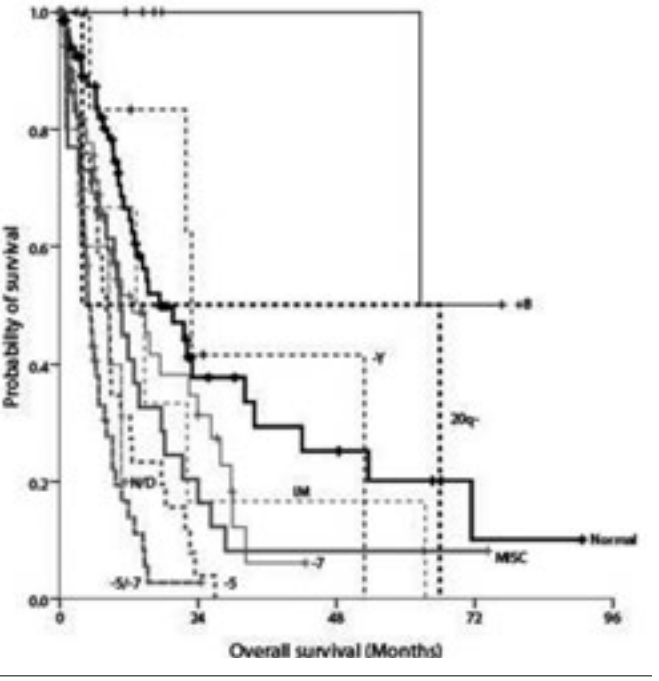

Figure 1. Overall survival by chromosomal abnormalities.

others; p<0.001), time from Tx to MDS (≤5 vs. >5Y; p=0.027), number of line(s) of therapy (1 vs. ≥2; p=0.011), serum albumin (≥4 vs. <4g/dL; p=0.005), serum beta2 microglobulin (≤3 vs. >3mg/L; p=0.015), serum creatitine (≤1 vs. >1mg/dL; p=0.061), ECOG performance status (0-1 vs. ≥2; p<0.001) as significant. Age (≤65 vs. >65; p=0.109), sex (male vs. female; p=0.862), prior Tx (CTx vs. RTx only; p=0.471), prior malignancies (hematological vs. solid cancer; p=0.650), prior lymphoma (lymphoma vs. non-lymphoma; p=0.958), prior HSCT (ASCT vs. alloHSCT vs. none; p=0.691) and serum ferritin level (≤600 vs. >600ng/mL; p=0.420) were not significant. The events of leukemic evolution were not consistent with the risk groups: 3 (10.1%) in low, 12 (13.5%) in INT-1, 9 (8.3%) in INT-2 and 9 (25.0%) in high by IPSS. High risk group in IPSS showed high possibility of leukemic evolution (p=0.039).

CYTOGENETIC CHARACTERISTIC OF MYELODYSPLASTIC SYNDROME IN HUMAN IMMUNODEFICIENCY VIRUS INFFECTED PATIENTS: HIGH INCIDENCE OF POOR PROGNOSTIC KARYOTYPE AND CHROMOSOME 7 ABNORMALITIES

K Takahashi,[1] M Yabe,[2] S Kato,[3] I Shapira,[1] M Varma[2]

[1]*Beth Israel Medical Center, New York, United States of America*
[2]*St.Lukes-Roosevelt Hospital Center, New York, United States of America*
[3]*University of San Diego, San Diego, United States of America*

Background. Human Immunodeficiency Virus (HIV) infection can often cause myelodysplastic features in bone marrow. However bona fide myelodysplastic syndrome (MDS) is not common in this population. Data are lacking whether HIV associated MDS has distinct clinical features from non-HIV MDS. *Aims.* The aim of this study was to compare the clinical characteristics of HIV associated MDS and non-HIV MDS. *Methods.* This is the retrospective cohort study with 91 patients who were diagnosed with MDS in our allied three teaching hospitals in New York City from 2005 to 2010. Their clinical history, pathological data, cytogenetic studies, and laboratory data were obtained through electronic medical records. HIV diagnosis was confirmed based on serological testing of enzyme-linked immunosorbent assay (ELISA) with Western Blot confirmation as well as HIV-1/2 viral PCR. MDS diagnosis was confirmed with bone marrow morphology, laboratory data and cytogenetic studies and was classified both according to the French-American-British (FAB) classification and World Health Organization (WHO) criteria. Research protocol was approved by our Institutional Review Board. *Results.* Within the cohort of 91 patients with MDS, 9 patients carried diagnosis of HIV and 82 patients were non-HIV. Karyotype abnormalities were more associated with HIV related MDS (88% vs 39% p <0.01). Additionally, poor prognostic karyotype abnormalities were more associated with HIV related MDS according to the International Prognostic Scoring System (IPSS) (66% vs 16%, p<0.01). Number 7 chromosome abnormalities which are also considered to be poor prognostic marker, was highly involved in HIV related MDS cohort (77% vs 15.6%, p<0.01). Within the cases of HIV related MDS, 8 out of 9 patients had a follow up data. Their median survival after diagnosis of MDS was 9.3 months and rate of transformation to acute leukemia was 62.5% (n=5). Median survival after transformation was 3.6 months. *Conclusions.* HIV related MDS has higher incidence of poor prognostic karyotype abnormalities compared to non-HIV MDS cohort and has high rate of transformation and poor survival. This result suggests that HIV infection itself, antiretroviral therapy, or immunodeficiency state might be associated with clonal mutagenesis in bone marrow.

0262

THE QUANTITY OF P15INK4B METHYLATION IS LOWER IN PEDIATRIC MDS THAN IN ADULTS, BUT CORRELATES WITH BONE MARROW BLAST PERCENTAGE AND SURVIVAL

M Kim,[1] H Kook,[2] DK Han,[2] P Hyeon Jin,[3] K Hyoung Jin,[1] HY Shin,[1] HS Ahn,[1] KC Lee,[4] KS Lee,[5] SK Park,[6] JY Lim,[7] HK Kim,[1] L Dong Soon[1]

Background. The inactivation by promoter hypermethylation of *p15INK4b* is believed to contribute to the initiation and progression of MDS in adults. Contrary to demonstrated benefits of demethylating agent in adults, the use of demethylating agent has not been reported for childhood MDS. *Aims.* To evaluate the potential of the use of demethylating agent in childhood MDS, we performed a quantitative analysis on *p15INK4b* promoter methylation. *Methods.* The study included 41 childhood MDS (22 RCC, 14 RAEB and 5 JMMoL) and12 healthy bone marrow donors as controls. Pyrosequencing was performed using PSQ96MA system (Biotage, Uppsala, Sweden). The mean % of methylated cytosine (methylation level: MtL) in childhood MDS was compared with that of adult MDS in the previous study. *Results.* The MtL of *p15INK4b* was lower in children than in adults both in control group (1.62% vs. 4.30%, p=0.001) and in MDS group (2.57% vs. 8.76%, p=0.001). The childhood MDS patients with >5% BM blasts showed higher MtL than those with <5% BM blasts (3.28% vs. 1.92%, p=0.098). MtL>2.50% was a poor prognostic factor in childhood MDS (p=0.075, univariate analysis). *Conclusions.* To our knowledge, this is the first study which quantitatively analyzed *p15INK4b* methylation in childhood MDS. In conclusion, the methylation quantity of p15INK4b of children is lower than that of adults both in controls and in MDS patients. The methylation quantity of *p15INK4b* of children MDS is higher than that of normals. The high methylation quantity of p15INK4b is associated with BM blasts and shorter mean survival in childhood MDS.

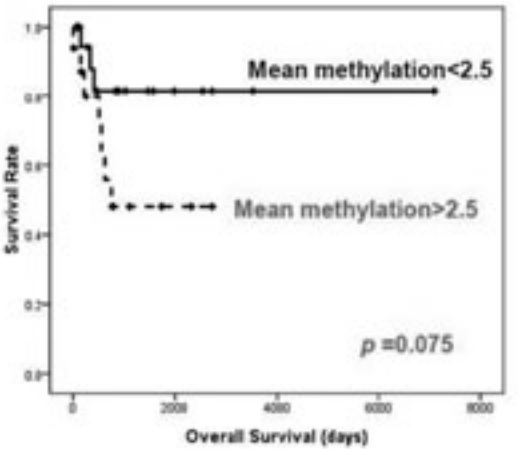

Figure 1. Prognostic impact of p15INK4b methylation.

Background. Refractory cytopenia in childhood (RCC) is the most common subtype of pediatric myelodysplastic syndrome (MDS). In

addition to allogeneic hematopoietic stem cell transplantation (HSCT), immunosuppressive therapy (IST) has recently been introduced as a treatment modality. *Aims.* Because horse anti-thymocyte globulin (h-ATG) is currently not available in Europe, rabbit ATG (r-ATG) is widely used. However, the information on the efficacy of rabbit ATG in IST is limited. Here we report the results of IST with ATG and cyclosporine A (CSA) in patients (pts) with RCC, comparing r-ATG and h-ATG. *Patients.* Ninety-one pts (52 boys /39 girls) with RCC were given IST as first line treatment between 1999 and 2009. At diagnosis, the median age was 9.8 (1.2-18.1) years. The median absolute neutrophil count (ANC) was 315 (0-3038) x109/L. 77 pts were transfusions dependent for platelets and 66 for red cells. Bone marrow cellularity was low in 78 pts and normo/hypercellular in 8 pts. Cytogenetic analysis revealed a normal karyotype in 49 pts, an abnormal clone in 3 pts and no result in 39 pts. IST was started at a median of 67 (0-472) days after diagnosis. Fifty-four pts was given Thymoglobulin® (r-ATG group), 33 pts Lymphoglobulin® (h-ATG group), and 4 pts others. There were no statistical differences in patient characteristics listed above between r- ATG and h-ATG groups. Since 2007 h-ATG has been replaced by r-ATG. *Results.* 57 (63 %) pts responded to IST at 6 months (complete response =normal blood count (CR): n=6, partial response (PR): n=51), with no difference between r-ATG and h-ATG (57.6% vs. 68.5%, respectively, p=n.s.). There were also no differences in response rate according to age, days between diagnosis and IST, and ANC at IST. Clonal evolution occurred in 6 pts (5 pts in r-ATG-, 1 pt in h-ATG-groups; cumulative incidence at 5 years =10.2%), 3/6 pts developed -7 or 7q- aberrations Seven responders experienced recurrent disease (2 pts: r-ATG, 5 pt: h-ATG groups). One child (h-ATG) developed clinical PNH. Thirty-five pts received HSCT as the second line therapy. The overall survivals (OS) were 85.1% in r-ATG group (at 3 yrs) and 91.2% in h-ATG group (at 5 yrs), and the failure free survivals (FFS) were 41.2% in r-ATG group (at 3 yrs) and 43.6 in h-ATG group (at 5 yrs) (p=n.s.), respectively. The median follow-up after ATG was 510 days (105-1095) in r-ATG group and 1476 days (14-3672) in h-ATG group. *Summary.* In this selected patient population with RCC, about 60% of pts responded to IST. This finding suggests that the immune system plays the key role in the pathophysiology of bone marrow failure in some pts with RCC. There was no difference in response rate between r-ATG and h-ATG groups. Although the follow-up time is shorter in the r-ATG group, there were also no differences in OS and FFS between 2 groups. These results justify the further application of r-ATG in the treatment of RCC.

0264

THE QUANTITY OF CLONAL CELLS DETECTED BY CONVENTIONAL CYTOGENETIC ANALYSIS CORRELATES WITH BONE MARROW BLASTS AND LEUKEMIA FREE SURVIVAL IN MYELODYSPLASTIC SYNDROMES

M Kim, S Chung, CJ She, SS Yoon, BK Kim, HK Kim, DS Lee

Seoul National University Hospital, Seoul, South-Korea

Backgrounds. Most researches studied clonal chromosomal abnormalities in MDS focusing on the relationship between the presence or absence of abnormality of certain chromosome and the prognosis of MDS. However, little has been known about the utility of the quantitative result of clonality studies in clinical practice. *Aims.* This study investigated the novel roles of CCA and FISH results in predicting outcome of MDS patients. The results of CCA and FISH were compared both in qualitative and in quantitative aspects. We analyzed the prognostic significance of the quantity of clonal cells in CCA or FISH in MDS. *Methods.* We performed the quantitative and qualitative analyses of conventional cytogenetic analysis (CCA) and interphase FISH (iFISH) results in 129 MDS patients, and investigated their unknown roles in predicting prognosis. *Results.* The abnormalities of -5/5q, -7/7q, +8, -20q and +1q were detected in 13.2%, 14.0%, 19.4%, 7.0% and 7.8%, respectively. iFISH detected occult abnormalities in 18.6% (24/129), changing IPSS grouping in 4.9% (6/129). The proportion of clonal cells for each chromosome of CCA did not correlate with the result of iFISH (Δ, from 0.580 to 0.778). The clonal cell percentage in CCA was higher in patients with >5% bone marrow blasts than those with <5% (37.4% vs. 24.4%, p=0.066). Multivariate analysis showed that high proportion of clonal cells in CCA analysis is an independent prognostic factor for progression free survival into AML in MDS (p=0.059). *Conclusions.* iFISH is advantageous in identifying cryptic cytogenetic abnormalities, and can change the IPSS risk grouping. We showed the quantity of clonal cells detected in CCA correlates with the bone marrow blast percentage, and the progression free survival into AML, suggesting the novel diagnostic utility of CCA in MDS.

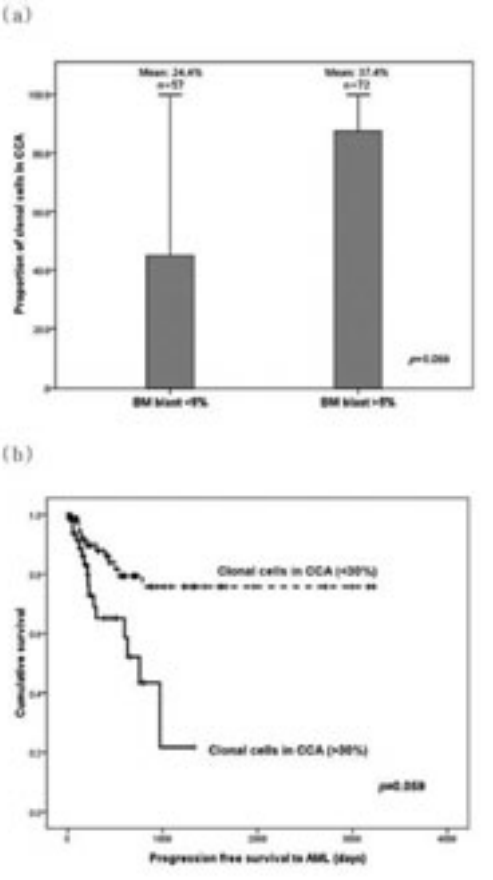

Figure 1. Prognostic impact of the proportion of clonal cell.

0265

ALLOGENEIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH MYELODYSPLASTIC SYNROME; REVISITING THE NEED FOR PRE-TRANSPLANT INDUCTION THERAPY

A Shimoni, N Shem-Tov, Y Volchek, R Yerushalmi, A Nagler

Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background. Allogeneic stem-cell transplantation (SCT) is potentially curative therapy for myelodysplastic syndrome (MDS). SCT in MDS patients who are often elderly and heavily transfused may be associated with high incidence of non-relapse mortality (NRM). Reduced-intensity conditioning (RIC) may reduced NRM, but may be associated with increased relapse rate, such that the optimal conditioning regimen is unknown. Similarly, the need for induction chemotherapy prior to SCT is controversial. *Aims.* To determine the conditioning regimen with best outcome in previously untreated MDS. *Methods.* We retrospectively analyzed SCT outcomes in 82 patients with MDS given allogeneic SCT in a single institution over 11 years. Patients were not given any prior therapy for remission induction. Younger patients in good medical condition were given standard myeloablative conditioning (MAC) consisting of busulfan and cyclophospahmide. Older patients in good medical condition or patients with relative contraindications for MAC were given reduced-toxicity myeloablative conditioning (RTC) consisting of fludarabine and myeloablative doses of busulfan (total 12.8 mg/kg) or treosulfan (36 gr/m2). Patients considered to have absolute contraindication for MAC were given RIC consisting of fludarabine and reduced-dose busufan (6.4 mg/kg). *Results.* Median patient age was 58 years (21-73). The donor was matched sibling (n=42) or matched unrelated (n=40). The conditioning regimen was MAC (n=14), RTC (n=52) or RIC (n=16). IPSS score at SCT was intermediate-1 (n=29), intermediate-2 (n=33) and high (n=20). Thirty-nine patients had >10% marrow blasts at SCT and 23 had poor-risk cytogenetics. With median follow-up of 25 months (1 month-11 years), 37 patients are alive; 27 died of NRM and 18 of relapse. The estimated 5-year overall survival (OS) was 38% (95CI, 22-47). The cumulative incidence of NRM and relapse mortality was 35% and 27%, respectively. 5-yr OS was 29%, 49% and 18% after MAC, RTC and RIC,

respectively (p=0.04 for RTC vs. others). Multivariate analysis identified RTC as a favorable prognostic factor, HR 0.4 (0.2-0.9, p=0.04). Age, gender, donor type, IPSS, blast excess and cytogenetics were not predictive. MAC and unrelated donor were predicting factors for NRM with HR 2.3 (p=0.06) and 2.4 (p=0.05), respectively. NRM was 50% after MAC vs. 39% and 30 after RIC and RTC. RIC predicted for increased relapse risk, 44% Vs 22% in the other regimens, HR 2.8 (p=0.06). We compared these outcomes to a separate group of 39 patients with AML that was secondary to MDS who were given induction chemotherapy and transplanted after achieving CR1. 5-year OS after SCT was 51% (95CI, 33-68). *Conclusions.* RTC is associated with optimal results in untreated MDS. MAC may be associated with excessive NRM, while RIC may result in excessive relapse rate. Although not a direct comparison, patients with secondary AML transplanted in CR1 had similar outcome as MDS patients (including with excess blasts) transplanted upfront with RTC. Considering that only a fraction of MDS patients will achieve CR1 with induction chemotherapy and some will not be able to proceed to SCT due to treatment complications, this suggests that prior induction chemotherapy may not be needed when using upfront SCT with RTC.

Background and Aims. Hypocellular myelodysplastic syndrome (MDS) comprised approximately 10-20% of total MDS cases. The difference in clinical features and prognosis between hypocellular MDS and other cellular MDS remains uncertain. Therefore, we conducted this study to define the characteristics and prognostic factors of Korean hypocellular MDS patients. *Methods.* We collected clinical and laboratory data from web-based Korean MDS registry (www.mdsregistry.or.kr). A total of 1274 evaluable MDS patients, who were diagnosed between the years 1993 and 2010, form 28 Korean hospitals were registered in Korean MDS Registry. Hypocellularity was defined as less than 30% of cellularity in patients <70 years, and <20% in patients 70 years or older in the bone marrow biopsy specimen. *Results.* We identified 146 (15.0%) patients with hypocellular MDS from 973 adult primary MDS patients according to the WHO classification criteria. Median age, gender, performance status, Hgb, transfusion dependency, bone marrow blast percentage, and karyotype did not differ between two groups. However, hypocellular MDS patients were more neutropenic (median ANC 0.9x109/L vs. 1.19x109/L, p=0.001) and thrombocytopenic (61x109/L vs. 72x109/L, p=0.013). There was no difference in estimated overall survival between the hypocellular and the normo/hypercellular MDS (40.7 months vs. 38.0 months, P=0.471) with the median follow-up length of 12. 2 months. 7.5% of hypocellular MDS patients and 10.2% of normo/hypercellular MDS patients transformed to AML (p=0.368). Time to AML transformation was 9.1 and 10.1 month, respectively (p=0.707). To define prognostic factors in the hypocellular MDS series, we performed univariate and multivariate analysis. At univariate analysis, the factors associated with a poor overall survival were age (≥60), thrombocytopenia (<50x109/L), neutropenia (<0.5x109/L), transfusion dependency and high LDH (≥600 IU/L). Using the Cox proportional hazard regression model, neutropenia, transfusion dependency and high LDH were independent, statistically significant, prognostic indicators. *Conclusions.* Hypocellular MDS had similar clinical features and survival compared to normo/hypercellular MDS. However, hypocellular MDS patients had a different pattern from those of normo/hypercellular MDS regarding prognostic factors.

0267

A 5-DAY OUTPATIENT REGIMEN OF 5-AZACITIDINE IS WELL-TOLERATED AND EFFECTIVE FOR HIGH-RISK MYELODYSPLASTIC SYNDROME AND ACUTE MYELOID LEUKEMIA PATIENTS UNSUITABLE FOR AGGRESSIVE CHEMOTHERAPY

M O'Reilly,[1] C McHale,[2] A Almazmi,[1] A Hameed,[3] N O'Connell,[2] P Murphy,[1] J Quinn,[1] P Thornton,[3] P O'Gorman,[3] H Frankova,[4] J Sargent,[4] J McHugh,[2] P Evans,[2] H Enright[2]

[1]*Beaumont Hospital, Dublin, Ireland*
[2]*Adelaide and Meath Hospital, Dublin, Ireland*
[3]*Mater Hospital, Dublin, Ireland*
[4]*Letterkenny Hospital, Letterkenny, Ireland*

Background. Azacitidine has been established as an effective agent for patients with myelodysplastic syndrome (MDS), with prolongation of survival and delayed progression to Acute Myeloid Leukemia (AML). Patients with AML who are unsuitable for aggressive therapy or those with refractory disease may also benefit from therapy with this agent. Azacitidine is usually delivered according to a 7-day regimen, which may be difficult to deliver in the day ward setting. *Aims.* To examine the use of azacitidine delivered as a five-day regimen in patients with high risk MDS and AML patients not suitable for intensive chemotherapy (off-label use of azacitidine). *Methods.* We report the use of a 5-day regimen of azacitidine in 70 patients with MDS (n=34) or AML (n=36) in 4 centres in Ireland. Patients received azacitidine 75mg or 100mg/m^2/day subcutaneously or intravenously for 5 days in a day-ward setting. Cycles were given at 28-day intervals and continued until disease progression. *Results.* Of the 70 patients treated 48 were male and 22 female. Median age at time of treatment was 71 years (range 36-89 years). MDS patients included 14 with RAEB-2, 9 with RAEB-1, and 7 with CMML. Others included RCMD (n=2), RARS (n=1) and MDS/MPD (n=1). Most patients had an IPSS of Int-1, Int-2 or High. Patients received a median of 7 cycles of therapy (range 2-29). Twelve patients (35%) had partial remission with a 50% reduction in bone marrow blasts or change to a lower grade of MDS, 19 (56%) had haematological improvement (as assessed by IWG criteria, Cheson B *et al.*, Blood 2006), and 5 had stable disease. Nine red cell transfusion-dependent patients became transfusion-independent. Five patients requiring platelet transfusion prior to therapy became platelet transfusion-independent. 17 patients (50%) remain alive and 17 have died. Median survival was 10 months (range 1-35 months). Of 7 patients with CMML, 4 patients had prolonged survival >20 months. AML patients (n=36) included 18 with de novo AML and 15 with AML secondary to MDS (data not available for 3 patients). Most patients had received prior intensive AML induction chemotherapy but were unsuitable for further intensive therapy due to age, infection or comorbidities, had primary refractory AML or relapsed AML. Eight patients received azacitidine as primary therapy for AML. Median survival in this very poor prognosis AML group was 5 months (range 1-14 months). 50% had stable disease during treatment. Of 22 patients who had > 4 cycles of therapy, median survival was 10 months (range 5-14 months). *Conclusions.* Azacitidine was well-tolerated and effective in both MDS and AML patients, with many remaining transfusion independent. In the poor-prognosis AML group, there was significant reduction in in-patient admissions, compared to the use of intensive chemotherapy. A 5-day regimen of azacitidine, conveniently delivered in the day ward or outpatient setting, is effective in high-risk MDS and offers a well-tolerated palliative out-patient therapy for patients with very poor prognosis AML.

CLINICAL AND BIOLOGICAL ROLE OF VASCULAR ENDOTHELIAL GROWTH FACTOR AND ITS RECEPTORS IN MYELODYSPLASTIC SYNDROMES

V Valeria, N Fracchiolla, U Gianelli, F Savi, C Vener, M Sciumè, G Reda, A Cortelezzi

Ospedale Maggiore Policlinico, Milan, Italy

Background. The angiogenesis mediators are altered in myelodysplastic syndromes (MDS) and abnormal angiogenesis is implicated in

the pathogenesis of these disorders. VEGF is the most important pro-angiogenetic factor and exerts its biologic effects by interaction with its specific receptors i.e. VEGF-R1 and VEGF-R2. The VEGF/receptor signaling system is involved in the regulation of angiogenesis and hematopoiesis, the former through a paracrine loop and the latter through an autocrin loop. *Aims.* We analyzed bone marrow (BM) immunohistochemical expression of VEGF-Rs and VEGF in MDS patients. Furthermore, we investigated if these parameters had an impact on patient clinical outcome, in order to define their potential prognostic value. *Methods.* Study population included 79 MDS patients, categorized according to WHO 2008 classification and stratified in prognostic categories by means of IPSS and the WPSS systems, and 20 age-matched normal controls (NC). Bone marrow VEGF (and VEGF-Rs) expression was correlated to BM cellularity through an index (i): [(% of BM cellularity x %VEGF-positive cells)/10^4]. *Results.* VEGF had a weak cytoplasmic expression in BM pro-erythroblasts, whereas normoblasts were not immunoreactive. In the myeloid lineage, VEGF expression was more intense in immature cells. VEGFi was higher in MDS in comparison to NCs (Mann-Whitney U-test, p=.006) and was evenly distributed among the different IPSS and WPSS categories. VEGF-R1 had a moderate cytoplasmic expression in myeloid precursors, at all stages of differentiation. VEGF-R1i was higher in MDSs than in NCs (Mann-Whitney U-test, p=.05). VEGF-R1i significantly differed among IPSS and WPSS prognostic classes (Kruskal-Wallis analysis, p=.04 and p=.003). VEGF-R2i was expressed in myeloid precursors with a moderate cytoplasmic positivity. Myeloid mature cells were not immunoreactive. There were no difference in VEGF-R2i in MDSs as compared to NCs. In MDSs, both VEGF-R1i and VEGF-R2i directly correlated with VEGFi (Spearman test, r=.64; p<.0001 and r=.47, p<.0001, respectively). Considering the 75° percentiles of VEGFi and VEGF-R1i values, Low and High VEGFi and VEGF-R1i classes could be determined. Low-VEGFi patients had a longer LFS (Kaplan-Meyer, p=.006) and a significant better OS (Kaplan-Meyer, p=.03) compared with High-VEGFi. Similarly, Low-VEGF-R1i had a longer LFS (Kaplan-Meyer, p<.001) and a better OS (Kaplan-Meyer, p<.001), compared to High-VEGF-R1i patients. Nevertheless, in a multivariable analysis stratified by IPSS, VEGFi and VEGF-R1i did not retain a significant effect on both OS and LFS. No significant correlation between VEGF-R2i and clinical variables was found. *Summary/Conclusions.* The enhanced cytoplasmic expression of both VEGF-R1 and VEGF in BM of MDS patients and their prognostic impact on LFS and OS, although in univariate analysis, may suggest the hypothesis of an intracrine loop that may provide a growth advantage to neoplastic cells. Further studies, integrated with molecular approaches, will be needed to verify the role and the alterations of the VEGF/ VEGF-receptors pathway in these neoplasms.

Background. Reports of haematologic responses associated with iron chelation therapy in transfusion-dependent patients with MDS are emerging, although the mechanism by which these occur has yet to be elucidated. Not all patients have shown such haematologic improvements; hence it is important to determine factors that may be associated with this response. *Aims.* To evaluate change in serum ferritin and labile plasma iron (LPI) as potential predictors of haematologic responses to deferasirox in a *post-hoc* analysis of transfusion-dependent MDS patients enrolled in the 1-year prospective EPIC study. *Methods.*

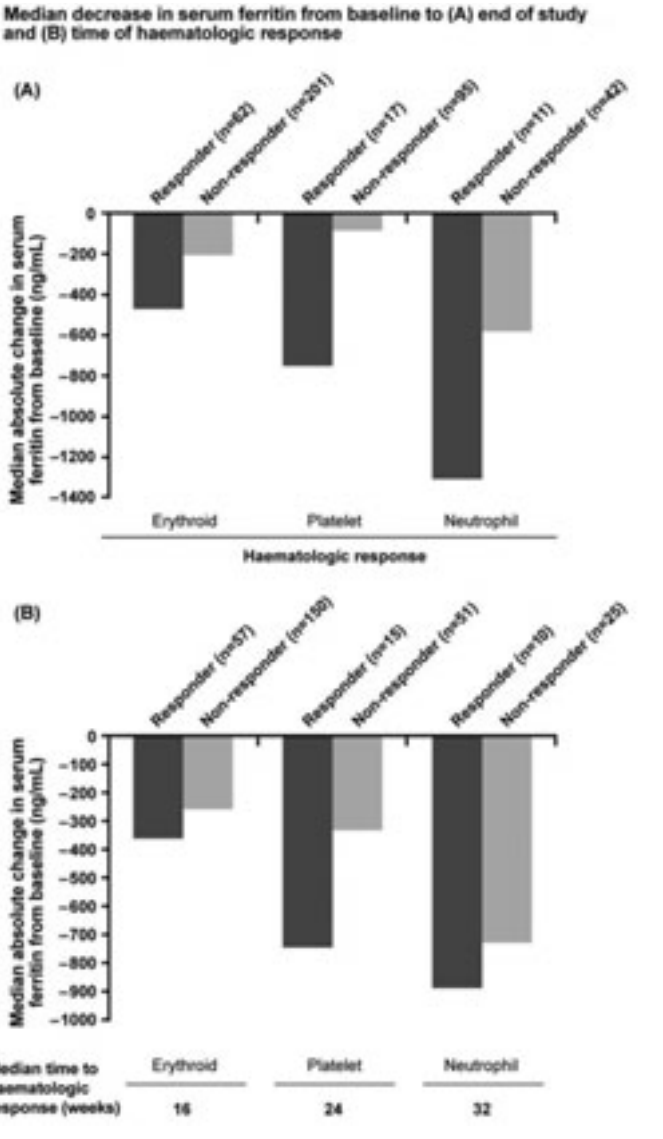

Figure 1.

Details of study design and inclusion/exclusion criteria for EPIC have previously been described (Gattermann *et al. Leuk Res* 2010). Recommended initial deferasirox dose was 20 mg/kg/day with dose adjustments of 5-10 mg/kg/day up to 40 mg/kg/day. MDS patients with haemoglobin (Hb) <11 g/dL or red blood cell (RBC) transfusion requirements >4 units/8 weeks and not receiving erythropoietin were eligible for erythroid response analysis. Patients with platelet counts <100 x 10^9/L or platelet-transfusion dependence, and absolute neutrophil counts <1.0 x 10^9/L and not receiving granulocyte colony-stimulating factor or granulocyte macrophage colony-stimulating factor were selected for the assessment of platelet and neutrophil responses, respectively. Erythroid response: Hb increase ≥1.5 g/dL or reduction in transfusion requirements of ≥4 RBC transfusions/8 weeks. Platelet response: increase ≥30 x 10^9/L for patients with >20 x 10^9/L platelets or increase from <20 x 10^9/L to >20 x 10^9/L and by at least 100%. Neutrophil response: ≥100% increase and absolute increase >0.5 x 10^9/L. All responses to last ≥8 weeks (IWG 2006 criteria [Cheson *et al. Blood* 2006]). Changes in serum ferritin and LPI over time were assessed for haematologic responders and non-responders. *Results.* 279, 121 and 56 patients were included in erythroid, platelet and neutrophil response analyses, respectively. Erythroid responses were observed in 22.6% (63/279) of patients. Median time to response was 109 days. Platelet and neutrophil responses were observed in 14.0% (17/121) of patients after a median of 169 days and 19.6% (11/56) of patients after a median of 226 days, respectively. Median baseline serum ferritin levels were comparable among responders and non-responders (erythroid analysis: 3129 vs 2679 ng/mL; platelet analysis: 3228 vs 3383 ng/mL; neutrophil analysis: 2946 vs 3043 ng/mL). Median absolute change in

serum ferritin from baseline was greater in the haematologic responders compared with non-responders at end of study [Figure (A)] and at the time of haematologic response [Figure (B)], but the differences were not statistically significant. Mean pre-administration LPI levels were high at baseline (>0.4 µmol/L), but were reduced to below this threshold with deferasirox from week 12 onwards; the extent of LPI change did not differ between haematologic responders and non-responders. *Summary/Conclusions.* Deferasirox is associated with improvements in haematologic parameters in some MDS patients. Change in serum ferritin was more pronounced in haematologic responders, suggesting that the serum ferritin decrease could play a role. However LPI did not appear to be related to the haematologic response seen with deferasirox. Additional factors influencing haematologic responses and the mechanisms behind these responses need further investigation.

Background. The Erythropoiesis-Stimulating Agents (ESAs) remain the gold standard treatment of anemia in Low Risk MDS. This study was performed in order to evaluate the efficacy, safety and response prognostic factors of ESAs treatment and to correlate response to IPSS and WPSS. *Patients and methods.* From January 2002 to December 2009 a total of 582 MDS patients from 11 Hematologic Centers of the Roman Group of Myelodysplasies (GROM) were retrospectively evaluated. Diagnosis was made according to FAB and WHO Criteria; response was evaluated using IWG Criteria (2006). Patients were divided in Low Risk group (LR) including Low and Int-1 IPSS, and High Risk group (HR) including Int-2 and High IPSS. As for WPSS, patients were stratified as LR (WPSS very low and Low), Intermediate (IR, WPSS Intermediate), and HR (WPSS High and very High). *Results.* Among 311/582 (53,4%) patients who received ESAs only 117 (37.7%) were fully evaluatble. Of these 117, 3 patients (2,5%) who received ESAs 80.000 UI weekly, presented adverse events (1 deep venous thrombosis, 1 phlebitis and 1 hypertensive crisis); all of them were Low Risk. Therapy was discontinued by1 patient. Overall response rate was 63,2% (n=74), a Major and minor Haematological response was observed in 49 patients (41,8%) and 25 patients (21,4%) respectively. No significant statistical differences were found between ESA dosage 40.000 UI vs 80.000 UI. Of 74 responders 70 were LR (95%) and 4 were HR (5%) according to IPSS, whereas 58 were LR (78%), 10 IR (13,5%) and 6 HR (8%) according to WPSS. After a median time of 9,4 months (range 0,7-42,4 mo) 15 patients (20,2%) lost the response (12 pts LR and 3 HR). In our study predicting factors of response were: Haemoglobin and serum EPO dosage at diagnosis and ESAs initiation, serum ferritin at diagnosis and number of RBC transfusions within 2 months before starting ESA treatment. The analysis of prognostic score by IPSS revealed that 109/117 (93%) were LR and 70/109 (64.2%) were responsive to ESAs treatment. A total of 12/70 (17%) responding patients relapsed after a median time of 10 months. Among 8 HR patients 4 (50%) were responsive to treatment, of these and 3 (70%) lacked response after a median time of 4.6 months (range 2,4-7,2 mo). Using WPSS, 84 patients (71,8%) resulted LR, 20 (17,1%) INT and 13 (11.1%) patients HR. Response was obtained respectively in 58/84 LR (69%), 10/20 IR (50%) and 6/13 (49%) HR patient. *Conclusions.* our study demonstrate the safety of ESAs therapy, corroborate (uphold) predicting factors of response already reported and confirm the efficacy of ESAs in LR MDS moreover in HR MDS ESAs are able to obtain a response in about 50% of patients. Prospective studies are needed to validate these retrospective results.

Introduction. PNH is a chronic and progressive disease characterized by chronic complement mediated hemolysis leading to significant ischemic morbidities, end organ damage and shortened lifespan. It has been reported that renal failure accounts for 8-18% of PNH related deaths. The proposed complement mediated mechanism is multifactorial that includes development of renal-mircothombi, ischemia, hemosiderin deposition due to high levels of free hemoglobin, and vasoconstriction of renal arteries reducing eGFR. *Aims.* To understand the impact of late stage renal impairment in patients with PNH, defined as history of acute renal failure or reported eGFR<60 ml/min/1.73m2, we retrospectively analyzed medical charts of 301 PNH patients from national data registry in South Korea over the last 41 years. *Results.* Patient ages ranged from 8 to 88 years (median 37 years), median PNH duration was 7.6 years (1 month to 41 years), and median PNH granulocyte clone size was 49% and median LDH was 4 fold above normal. Approximately 16% (50/301) of patients had a history or presence of late stage renal impairment, similar to the reported 20.5% of PNH patients with CKD 3-5 in the eculizumab clinical study (N=195). Median age of patients with late stage renal impairment was 38 years, and median granulocyte clone was 34%. Patients with renal impairment accounted for 35% of patient deaths. Using a multivariate regression analysis renal impairment was a strong predictor of mortality ($p<0.0001$; odds ratio 3.1; 95% CI 1.15 - 8.18). Patients with renal impairment had a significantly worse overall survival with a hazard ratio of 2.53 (95% CI (1.35, 4.74); P=0.003) compared to PNH patient with no late stage renal impairment. Renal impairment was reported equally in PNH patients with (48%) or without (52%) a bone marrow disorder. *Conclusion.* Late stage renal impairment in patients with PNH is underappreciated. These data establish renal impairment as a risk factor of early mortality in PNH patients.

TREATMENT OF INTERMEDIATE AND HIGH RISK MYELODYSPLASTIC SYNDROMES(MDS) WITH AZACYTIDINE. THE HELLENIC EXPERIENCE

V Pappa,[1] D Vasilatou,[1] S Papageorgiou,[1] A Symeonidis,[2] P Lampropoulou,[2] H Papadaki,[2] M Ximeri,[2] A Galanopoulos,[2] N Anagnostopoulos,[2] H Bouronikou,[2] P Matsouka,[2] J Kotsianidis,[2] K Tsatalas,[2] E Vervessou,[2] M Dimou,[2] J Meletis,[2] A Zomas,[2] P Karmas,[2] H Poulakidas,[2] T Economopoulos,[1] J Dervenoulas[1]

[1]*Attikon University General Hospital, Athens, Greece*
[2]*Hellenic MDS Study Group, Athens, Greece*

Background. Myelodysplastic syndromes constitute an heterogenous group of clonal hemopoetic disorders characterized by ineffective hemopoiesis and frequent evolution to acute leukemia. Azacytidine is a hypomethylating agent with significant efficacy and already approved for the treatment of MDS. *Aim.* The aim of this retrospective analysis was the investigation of the efficacy of azacytidine in a group of patients with intermediate and high risk MDS *Methods.* 114 patients (37 female, 77 male) with a median age of 70 years (47-85) were included, Azacytidine was administered at the dose of 75mg/m2 SC for 7 days every 28 days. Response to treatment was evaluated according to the International Working Group (IWG) criteria for MDS. Patients were

classified accoding to FAB as follows RA n=15, RAEB n=67, RAEB-t n=16, AML n=6, RARS n=5, CMML n=5 and according to WHO as:RA n=3, RCMD n=8, RCMD-RS n=3, RARS n=2, RAEB-I n=32, RAEB-II n=44, AML n=17. The IPSS was int-1 n=38, int-2 n=48, high n=26 and the WPSS, low n=5, intermediate n=14, high n=63, very high n=24. 65% of the patients were previously treated. 68% of the patients were RBC and 19% PLT transfusion dependent. *Results.* The median time to therapy initiation since diagnosis was 8 months (0-114), while the median number of cycles administered was 5(1-34). The median time to best response was 3 months (0.5-17) and 4 cycles (1-18). 17.5% of patients achieved CR, 14.6% PR,13.6% HI with an overall response rate of 45.7% while 46.6% had SD and 7.8% PD. The median duration of response was 4 months (4-23). Improvement in WPSS was observed in 17.5%, no change in 32.5% and deterioration in 8.8%.The improvement in WPSS observed after treatment was statistically significant (p=0.011)Toxicity was acceptable with localized skin reaction in all cases, hematologic toxicity grade II-IV in 72,respiratory tract infections in 22, and neutropenic fever in 6 cases. Loss of response was observed in 38% whereas in 26% of cases a stable response was observed. 28.3% and 27.3% of patients who were RBC and PLT transfusion dependent respectively, became transfusion independent . Overall 26% of patients experienced transformation to AML within a median time of 9 months post treatment (1-90). 60.5% (69/114) patients remain alive, with an overall mortality rate of 37.7%. No significant association was observed between response to treatment and baseline clinical characteristics, prior therapy, transfusion dependencey, and time to treatment onset since diagnosis.On the opposite patients who responded to treatment or had a stable disease had a significantly lower percentage of transformation to AML compared to patients with stable disease (p=0.002). Moreover transformation to AML positively correlated with lower neutrophil (p=0.004) and platelet counts (p=0.011), higher bone marrow blasts at baseline (p<0.0001), and with FAB, WHO and IPSS high risk categories. *Conclusions.* Azacytidine is a safe and effective treatment for intermediate and high risk MDS with an overall response rate of 45.7%. A significant improvement of WPSS score was observed following treatment while the risk of transformation to AML was significantly reduced in responding as well as patients with stable disease.

0273

CLINICAL HETEROGENEITY AND OUTCOMES OF UNRELATED BONE MARROW TRANSPLANTATION IN 3 JAPANESE CHILDREN WITH FAMILIAL PLATELET DISORDER WITH PREDISPOSITION TO ACUTE MYELOGENOUS LEUKEMIA

H Yagasaki, M Kato, H Shichino, M Chin, H Mugishima

Nihon University, Tokyo, Japan

Background. Familial platelet disorder with predisposition to acute myelogenous leukemia (FPD/AML) is an autosomal dominant disorder characterized by thrombocytopenia and high risk for developing leukemia. Heterozygous germ-line mutations in *RUNX1* have been identified in at least 32 FPD/AML families. As a contribution to the literature on this rare disorder, we present here the clinical courses and genetic studies in 2 Japanese families with FPD/AML. Case report: The proband of family I, who presented with isolated thrombocytopenia at the age of 1 year and was suspected of having moderate immune thrombocytopenic purpura (ITP), developed severe thrombocytopenia at the age of 7 years. Bone marrow findings showed features of myelodysplastic syndrome (MDS): presence of micromegakaryocytes and up to 14% of myeloblasts. Eight months later, he developed pancytopenia and was diagnosed with overt leukemia. Cytogenetic analysis showed normal karyotype and the immunophenotype of the blasts was CD7+, 13+, 33+ and 34+ and HLA-DR+. He received 3 courses of intensive chemotherapy. Because he did not achieve complete remission, he underwent unrelated donor marrow transplantation (UR-BMT), but relapsed 18 months later. At the age of 10 years, he underwent a second UR-BMT on relapse. The patient is still in remission 3 years later. The 3-year older sister of the proband also presented with moderate isolated thrombocytopenia at the age of 1 year and developed severe thrombocytopenia at the age of 11 years. Bone marrow findings showed features of ITP; increased numbers of immature megakaryocytes without blasts. Two years later, platelet number decreased below $2.0x10^4/\mu l$, and megakaryocytes disappeared in the bone marrow. This finding was quite different from the previous one. Cytogenetic analysis showed normal karyotype. Finally, she was diagnosed with MDS and received a successful UR-BMT at age 14 years. The patient is alive and well 1.5 years later. In contrast, their father has presented with only mild isolated thrombocytopenia ($13.5x10^4/\mu l$ at age 36 years and $12.5x10^4/\mu l$ at 48 years). The proband of family II, who presented with moderate isolated thrombocytopenia at the age of 2 years, developed chronic myelomonocytic leukemia at age 9 years. She received a successful UR-BMT at age 12 years. The patient is alive and well 2 years later. The 2-year older sister of the proband also has a 10-year history of moderate isolated thrombocytopenia from the age of 1 year ($8.5x10^4/\mu l$ at age 16 years) without bleeding tendency. Their father died of MDS at age 43 years. Sequencing analyses of *RUNX1* revealed a heterozygous mutation in each family. Discussion: Clinical courses vary among FPD/AML patients within the same family. Our findings support the clinical heterogeneity of the disease as reported by other investigators. Because bone marrow findings in the early phase of FPD/AML mimic that in ITP, genetic analysis of *RUNX1* is necessary to screen for FPD/AML. Finally, we consider that early indication of stem cell transplantation (SCT) leads to better outcome although the optimal conditioning regimen remains to be determined.

CONSTITUTIVE ACTIVE FIBROBLAST GROWTH FACTOR RECEPTOR 3 (FGFR3) WITH LYS650GLU MUTATION ENHANCES THE BORTEZOMIB SENSITIVITY IN PLASMA CELL MALIGNANCY

M Otsuka,[1] M Mizuki,[1] J Fujita,[1] S Kang,[2] Y Kanakura[1]

[1]*Osaka University Graduate School of Medicine, Osaka, Japan*
[2]*Emory University School of Medicine, Atlanta, United States of America*

Background. The t(4;14)(p16.3;q32.3) translocation occurs in 15-25 % of multiple myeloma (MM) patients and leads to the deregulation of fibroblast growth factor receptor 3 (FGFR3) gene. This results in ectopic expression of FGFR3, which promotes the proliferation and survival in myeloma cells. Clinical data indicate that patients with this translocation demonstrate resistance to conventional chemotherapy and early progression after a response occurs, leading to poor prognosis. Activating mutations of FGFR3, such as Lys650Glu (K650E) and Tyr373Cys (Y373C) have been identified in MM patients with t(4;14), who show more aggressive clinical course. Recently, it is reported that bortezomib is able to overcome the poor prognosis associated with t(4;14) or FGFR3 expression. Therefore, we are interested in the bortezomib-sensitivity of malignant plasma cell possessing FGFR3 and its mutation *Aims.* This study investigated whether FGFR3 and its mutations are associated with the cytotoxic effect of bortezomib in malignant plasma cells. *Methods.* Human plasmacytoma cell line, FR4 and human myeloma cell line, RPMI8226 were transfected with the plasmid encoding a full length of FGFR3 cDNA of wild type (WT), K650E and Y373C mutations. Cell apoptosis assays were performed in these cells after exposure to bortezomib. The localization of the FGFR3 receptors in the cells was observed by immunocytochemical analysis, and the induction of endoplasmic reticulum (ER) stress protein was compared between each type of cells after bortezomib treatment. Furthermore, we observed the alteration of bortezomib sensitivity by co-treatment with tunicamycin or cycloheximide. *Results.* FR4 cells with FGFR3 K650E showed enhanced sensitivity to bortezomib, as compared to FR4 cells with mock, FGFR3 WT or FGFR3 Y373C. Similar results were obtained when RPMI8226 cells were used in place of FR4 cells. According to the immunocytochemical analysis of FR4 cells, FGFR3 K650E mutant was preferentially localized in the ER and constitutively activated, whereas FGFR3 WT or FGFR3 Y373C receptors existed on the cell surface and the former was activated only after the stimulation by the FGF ligand. These results indicated that the FGFR3 K650E receptor accumulated and activated in the ER, aberrantly. Transcriptional up-regulation of ER stress proteins, such as BiP, Edem1 and CHOP were observed by real-time PCR after treatment with bortezomib. As a result, BiP, Edem1 and CHOP were strongly induced by bortezomib in FR4 cells, the magnitude of which were significantly increased in FR4 K650E transfected cells. The combination of bortezomib and ER stressor, tunicamycin, enhanced the cytotoxicity of bortezomib, resulting in the comparable apoptosis in each cell. In contrast, ameliorating ER stress with cycloheximide reversed the cytotoxicity activity of bortezomib, leading to similar survival of each cell type. These results suggested that increased ER stress is associated with the enhanced sensitivity of FGFR3 K650E expressing cells to bortezomib. *Summary/Conclusions.* This study indicated that FGFR3 with K650E mutation showed aberrant ER localization and enhanced the bortezomib-sensitivity in malignant plasma cells via ER stress pathways.

0275

IGH TRANSLOCATION AND DEL(13Q14) ARE FREQUENTLY ABSENT IN THE ANCESTRAL PLASMA CELL CLONE IN MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

M Schmidt-Hieber,[1] M Gutiérrez,[2] M Pérez-Andrés,[2] B Paiva,[2] A Rasillo,[2] M Tabernero,[2] J Sayagués,[2] A Lopez,[2] P Carrasco,[2] M Sanchez,[2] N Gutierrez,[2] J San Miguel,[2] A Orfao[2]

[1]*Charite Campus Benjamin Franklin, Berlin, Germany*
[2]*University of Salamanca, Salamanca, Spain*

Background. Previous cytogenetic studies in multiple myeloma (MM) and monoclonal gammopathy of undetermined significance (MGUS) have been mainly done in whole bone marrow or CD138+ microbead-sorted plasma cells (PC) and suggested that both entities typically share karyotypic patterns, where IGH translocations and to a lesser extent del(13q14) frequently are primary oncogenetic events. However, also the technique of PC sorting by CD138+ microbeads is hampered in several aspects such as CD138 expression by normal and reactive PC as well as coexistence of CD138+ and CD138- clonal PC in monoclonal gammopathies. In addition, rapid loss of CD138 by apoptotic PC and insufficient purity are among the principal limitations of this technique. *Aims.* We analyzed 208 patients with MM (n=148) and MGUS (n=60) for the presence of different cytogenetic abnormalities - e.g. t(14q32), del(13q14) and del(17p13) - using highly purified flow cytometry-sorted clonal PC to get more insights in patterns of cytogenetic abnormalities and intratumoral clonal evolution profiles. *Methods.* Immunophenotyping of normal and clonal PC was carried out using multiparameter flow cytometry and clonal PC were sorted according to their specific immunophenotype with a ≥98% median purity using a FACSAria II cell sorter. Cytogenetic abnormalities were assessed by multicolor interphase fluorescence in situ hybridization using purified clonal PC. *Results.* Del(13q14), del(17p13) and t(14q32) were significant more frequent among MM than MGUS patients (55%, 11%, 42% vs. 22%, 0%, 22%), whereas del(13q14) in conjunction with t(14q32) was a common finding in MM but not in MGUS (26% vs. 3%, p<0.001). The presence of 2 or more cytogenetically different clones was more frequently observed in MM than in MGUS patients (64% vs. 37%, p<0.001). A primary clonal PC clone (ancestral tumor cell clone) without any cytogenetic abnormality for all probes tested was detected in 49% and 73% of MM and MGUS cases, respectively (p=0.002). Even more interestingly, t(14q32) and del(13q14) arose as a non-primary clone in 24% and 43% of MM vs. 62% and 38% of MGUS patients carrying the respective cytogenetic alteration (p=0.02 and p>0.05). Acquisition of cytogenetic abnormalities occurred stepwise in MM and MGUS, both groups frequently showing different cytogenetic evolution profiles when other cytogenetic variables such as DNA ploidy status, deletions/gains of IGH, FGFR3, CCND1 and MAF, were additionally considered in their respective chronological sequences of acquisition. *Summary/Conclusions.* Overall, our results indicate that acquisition of cytogenetic abnormalities may occur stepwise in different types of monoclonal gammopathy. In contrast to the general belief, IGH translocations and del(13q14) are present in only part of all clonal PC in a significant proportion of MGUS and MM cases once evaluated at the intratumoral cell level.

Background. High dose therapy (HDT) followed by autologous stem cell transplantation (ASCT) is currently the most widely accepted approach in newly diagnosed myeloma patients who are considered fit enough to undergo the procedure; however, almost all patients will eventually relapse with a median progression free survival (PFS) of 2 to 3 years. As PFS is the most robust predictor for overall survival (OS) in myeloma patients, it is important to identify those who are likely to relapse early from ASCT, so that additional treatment could be given to modify the outcome. *Aims.* This study aims to examine the molecular basis of HDT resistance and to develop a predictive signature for patients at high risk of early relapse following ASCT. *Methods.* Gene expression profiling (GEP) data is available in 80 newly diagnosed myeloma patients who underwent front-line ASCT following induction therapy after informed consent. PFS was calculated from the date of HDT to the date of progression, with those dying without evidence of relapse censored at the time of death. OS was defined as the time from HDT to the date of death from any cause. Univariate Cox analyses were conducted on PFS to identify significant genes associated with early relapse with multiple testing adjustment. The independence of the genes from other prognostic factors was tested using multivariate Cox regression. *Results.* Nine genes were identified as being associated with early relapse after ASCT, among which five were on chromosome X. Three of the five chromosome X genes belong to the cancer/testis gene family which has been shown to be prognostic in myeloma patients. NUDT11 has been reported to be involved in vesicle trafficking, DNA repair and apoptosis, and has been linked to drug resistance in some cancer types. The identified chromosome X genes were also significantly associated with shorter OS in our dataset,

which is independent from any other known prognostic factors such as β2m, alb, delp53, gain1q and adverse chr14 translocations identified by FISH ($p < 0.05$). The prognostic value of the genes identified was also validated in an external cohort of patients treated with ASCT. *Conclusion.* By analyzing GEP data we identified genes significantly associated with high risk of early relapse following ASCT, most of which mapped to chromosome X. Upon further investigation, theses genes could give insight into the biology underlying HDT resistance. The development of a predictive signature based on the identified genes is currently undergoing and will be presented at the conference.

Background. The Hedgehog (Hh)-pathway is required for cell-fate determination during the embryos life, cell growth and differentiation in the adult organism. In mature tissues it regulates tissue homeostasis and repair and, in those tissues undergoing constant renewal as skin, colon, liver and blood it is also implicated in maintaining a stem/progenitor cell compartment. In this context, it is easy to understand how Hh-pathway deregulation may cause development defects during the embryos life, while leads to tumorigenesis during the adult life for a stem cell pool expansion or for onset, within more differentiated cells, of mutations affecting the normal growth-regulatory mechanisms. We already showed that an aspect of plasma cells (PCs) malignant transformation is the aberrant expression of developmental genes as those of Wnt- and Hh-pathways. Several evidences support a role of Hh-signaling in regulating a stem cell niche also in Multiple Myeloma (MM) and in modulating clinical response to conventional and novel therapeutic agents. Indeed, Hh-ligands produced by mice-derived Bone Marrow Stromal Cells (BMSCs) have been recently identified as new soluble factors supporting growth and survival of human primary CD19+ lymphoma and CD138+ MM cells demonstrating a role of Hh-pathway also in lymphoma and in MM terminally differentiated cells. Finally, we recently showed ciliary proteins over-expression as a possible cause of constitutive and non canonical Hh-pathway activation suggesting a cilia-dependent mode of Hh-signaling in MM. *Aims.* Here our aim was to demonstrate that Hh pathway plays a role in cancer formation and survival also in MM. *Methods and Results*. First we evaluated the Hh-genes expression in CD138+ PCs isolated from BM aspirate of 4 healthy persons, 12 MGUS, 132 MM and 9 PCL patients using oligonucleotide microarrays analysis. As compared with CD138+ cells isolated from healthy persons, we found that PCs from MGUS and MM patients express significantly higher levels of Hh-genes suggesting that Hh-pathway activation might play a role in MM disease initiation and pathogenesis. Conversely the down-regulated Hh-genes expression observed in PCL, a more advanced and BM-independent disease, suggests a role for stroma-derived Hh-signals in triggering a paracrine Hh-activity in MM. We also demonstrated a Smoothened (Smo)-dependent Hh-signaling showing that NVP-LDE225, a novel synthetic Smo-inhibitor (Novartis), affected MM cells viability, as assessed by MTT, inducing specific down-regulation of Gli1 and Ptch1, hallmarks of Hh-activity, as demonstrated by western blotting analysis. Additionally we detected, by immunofluorescence, an unexpected nuclear localization of Gli1 which is completely abrogated by Forskolin, a Gli1 modulating compound, demonstrating Smo-independent mechanisms leading to Hh-activation in MM. Finally we found that MM patient-derived bone-marrow stromal cells (BMSCs) were source of Shh-ligand although they showed resistance to Hh-inhibitor probably due to defective Smo expression as well as Ptch1 up-regulation. *In vivo* studies showed little antitumor efficacy of NVP-LDE225 as single agent that significantly increased when combined with proteasome inhibitor Bortezomib. *Conclusions*. All together our data demonstrate canonical as well as non canonical Hh-pathway activation in MM and provide the rationale for further investigations and for using Hh-inhibitors to improve MM patient outcome.

Background. The combined use of microarray technologies and bioinformatics analysis has improved our understanding of biological complexity of multiple myeloma (MM). In contrast, the application of the same technology in attempt to predict clinical outcome has been less successful with the identification of heterogeneous molecular signatures. *Aim.* This approach was aimed at the identification of robust and reproducible signatures associated with prognosis across independent datasets. *Methods.* We have reconstructed gene regulatory networks in a panel of 1883 samples from MM patients profiled on Affymetrix platform, derived from seven publicly available gene expression sets. The transcriptional networks were reconstructed using ARACNe (Algorithm for the Reconstruction of Accurate Cellular Networks). Critical analysis of network components was applied to identify genes playing an essential role in transcriptional networks, which are conserved between datasets, and proportional hazard models were used to evaluate the association of each gene with outcome. The correlation with overall survival was tested in three of the seven datasets for which clinical data were available. *Results.* The network critical analysis revealed that i) *CCND1* and *CCND2* were the most critical genes; ii) among the top critical genes *CCND2*, *AIF1* and *BLNK* had the largest number of connections shared among the datasets; and iii) robust gene signatures with prognostic power were derived from the most critical transcripts and from shared primary neighbors of the most connected nodes. In particular, a "critical-gene"model, comprising *FAM53B*, *KIF21B*, *WHSC1* and *TMPO*, and a "neighbor-gene"model, comprising *BLNK* shared neighbors *CSGALNACT1* and *SLC7A7*, predicted survival in all datasets with follow-up information. *Conclusions.* The reconstruction of gene regulatory networks in a large panel of primary tumors suggested novel molecular mechanisms central to MM biology and identified specific genes with prognostic importance.

Background. Hsp90, a central chaperone molecule involved in the maturation and folding of several cellular client proteins, is essential for malignant plasma cell survival. Hsp90 inactivation in multiple myeloma (MM) cells has been shown to cause perturbation of the ER stress/unfolded protein response (UPR), eventually triggering the apoptotic cascades. Protein kinase CK2 is an important regulator of Hsp90 activity phosphorylating the Hsp90 cochaperone Cdc37 stabilizing a macromolecular complex containing Hsp90, Cdc37 and client proteins. We previously described that CK2 is over-expressed in a fraction of MM patients and is an essential MM pro-survival molecule. Currently, phase I clinical trials are ongoing with Hsp90 inhibitors and orally available ATP-competitive CK2 specific inhibitors. *Aims.* We have here investigated the role of CK2 in the ER stress/UPR pathways and in Hsp90

inhibition-induced apoptosis in MM cells. We analyzed CK2 activity upon ER stress and the consequences of the effects of CK2 inhibition/silencing on ER stress induced-apoptosis triggered by chemicals and Hsp90 inhibitors. *Methods.* MM cell lines, human bone marrow stromal cells and plasma cells from patients were exposed to geldanamycin or 17-AAG (17-(demethoxy)-17-allylamino geldanamycin) (Hsp90 inhiibtors) and CK2 inhibitors K27 and CX4945. RNA interference was used to silence the CK2 catalytic α subunit. Thapsigargin and Tunicamycin were used to trigger ER stress. Annexin V and propidium iodide staining and analysis of PARP cleavage were employed to assess cell growth and viability. UPR related signaling pathways were studied with western blot and real time-polymerase chain reaction analysis. *Results.* Down-regulation of the catalytic CK2α subunit with chemical inhibitors or RNA interference resulted in modifications of the main UPR regulating signaling cascades: a reduction of IRE1α protein levels; a reduction of BiP/GRP78 chaperone protein levels; an increase of PERK activity and phospho eIF2α levels. CK2 partly localized to the ER and the ER-stressor Thapsigargin triggered its kinase activity. CK2 inactivation enhanced Thapsigargin-induced apoptosis and opposed CHOP/GADD153 and IRE1α rise. Treatment of CK2-inhibited/silenced MM cells geldanamycin or 17-AAG resulted in a much more pronounced reduction of IRE1α protein levels; a marked inhibition of GA or 17-AAG-triggered BiP/GRP78 protein level raise; a more evident increase of eIF2α phosphorylation. Of note, CK2 plus Hsp90 inhibition was followed by apoptotic cell death to a much greater extent than that obtained with the single inhibition of the two molecules. Noteworthy, these effects were also reproduced upon modelling the MM bone marrow microenvironment by co-culturing MM cells with BM stromal cells and on plasma cells isolated from MM patients. Mechanistically, we demonstrated that CK2 inhibition leads to a reduction of IRE1α/HSP90/CDC37 complexes in MM cells, a phenomenon that could justify the reduced IRE1α half-life in MM cells. *Summary/Conclusions.* These data highlight the importance of CK2 in tuning HSP90 function and the ER stress/UPR cascades in MM cells. In view of the very recent development of phase I clinical trials with both CK2 inhibitors and Hsp90 inhibitors as anti-MM agents, our results might provide useful insights to better set the groundwork in designing novel combination treatments for this disease.

INITIATING ROLE OF RECURRENT IGH TRANSLOCATIONS DURING THE ONCOGENESIS OF PLASMA CELL MYELOMA IS QUESTIONABLE IN A NOT NEGLIGIBLE SUBSET OF CASES

D Alpar, Z Nagy, B Kajtar, D Feller, P Jakso, M David, S Kosztolanyi, J Hermesz, L Kereskai, L Pajor

University of Pecs, Pécs, Hungary

Background. Only indirect evidence is available regarding the exact temporal sequence of cytogenetic aberrations during the oncogenesis of plasma cell myeloma (PCM). *Aims.* In this study, the correlation of cytogenetic changes to each other and the incidence of abnormalities within the purified plasma cell population were analyzed by interphase fluorescence in situ hybridization (FISH). Combined FISH analysis was applied in order to get direct evidence regarding cytogenetic evolution of PCM. *Methods.* We investigated diagnostic bone marrow specimens from 185 patients with PCM. Ethical Committee approval and written informed consent from the patients has been obtained. Aspirated plasma cells were purified with immunomagnetic cell separation using CD56 and CD138 antibodies. FISH probes were used for the detection of monosomy or deletion of chromosome 13 (Δ13), deletion of *p53* gene and the most frequent recurrent immunoglobulin heavy-chain gene (*IGH*) translocations: *IGH/FGFR3*, *IGH/CCND1* and *IGH/c-MAF*. After initial screening, patients' samples with more than one specific aberrations were chosen for the combined FISH analysis which was performed using motorized microscopy. *Results.* The Δ13, *p53* deletion and *IGH* disruption were found in 47.2, 7.5 and 58.9% of cases, respectively. Incidences of *IGH/FGFR3*, *IGH/CCND1* and *IGH/c-MAF* aberrations within the *IGH* positive group were 22.6, 21.7 and 6.6%, respectively. 25 cases harboring at least two specifically identified aberrations were found. Performing combined FISH analysis on these samples, more than one abnormal cell clones suggesting clonal evolution were observed in 16% of cases. The Δ13 was preceded by the *IGH/FGFR3* and *IGH/c-MAF* translocations. Deletion of *p53* gene was a secondary aberration compared to the Δ13 and the *IGH/CCND1* translocation. Interestingly, in 25% of *IGH* positive cases examined by combined FISH analysis the recurrent *IGH* translocations were presented only in a subset of purified plasma cells. Subsequently, we extended our observation to all 185 patients screened in this study. In 21.8% of cases harboring specifically identified recurrent *IGH* translocation (*IGH/FGFR3* 20.0%, *IGH/CCND1* 16.7% and *IGH/c-MAF* 28.6%) the aberration was presented in less than two-thirds of purified plasma cell population. The presence of more than one *IGH* translocations was excludable in these cases. *Conclusions.* Combined FISH analysis addressing the issue of clonal evolution of structural cytogenetic aberrations in patients with PCM has not been published yet; therefore our results not only support the current model of the oncogenesis of PCM, but provide the first direct evidence at single cell level. Other workgroups investigating patients with MGUS and smoldering myeloma have also found that sometimes recurrent *IGH* translocations are present in a subset of plasma cells. In these early lesions, the presence of normal plasma cells may confound results, since the count of abnormal plasma cells is relatively low. However, it is widely recognized that this diluting effect of normal plasma cells is negligible at the time of diagnosis of PCM. Consequently, our results suggest that recurrent *IGH* translocations investigated in this study are not primary events at least in approximately one-fifth of cases. Contact: donat.alpar@kk.pte.hu

AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA: IMPACT OF SINGLE NUCLEOTIDE POLYMORPHISMS (SNP) IN GENES INVOLVED IN INFLAMASSOME AND MIRNA NETWORK IN SURVIVAL AND PROGRESSION

C Fernández de Larrea,[1] A Navarro,[2] T Díaz,[2] MT Cibeira,[1] B Martin,[1] N Tovar,[1] L Rosiñol,[1] M Rovira,[1] M Rozman,[1] A Urbano,[1] M Monzó,[2] J Bladé[1]

[1]*Hospital Clínic, Barcelona, Spain*
[2]*University of Barcelona, Barcelona, Spain*

Background. Polymorphisms (SNPs) in proteins involved in cytosolic macrocomplex with regulatory functions in the immune system have previously shown to have prognostic impact after stem cell transplantation. Otherwise, SNPs in miRNA proteins pathway and in the target genes binding sites (miR-SNPs) have been observed with different prognostic implications in some tumors. However, data in multiple myeloma (MM) has ever been reported. *Patients and Methods.* One hundred and thirty seven patients with chemosensitive MM (73M/64F, median age 55 years) intensified with autologous stem cell transplantation (ASCT) have been studied in one institution. The patients achieved at least a minimal response after one (117) or two (20) induction regimens prior to ASCT. The genes (SNPs) evaluated in genomic DNA by allelic discrimination (TaqMan assays) were NLRP2 (rs1043684), NLRP3 (rs10925027), ATBF1 (rs7193297) and EP300 (rs20551) for innate immune system, and KRT81 (rs3660), AFF1 (rs17703261), FAM179b (rs1053667) and XPO5 (rs11077) for miR-SNPs. *Results.* Overall survival (OS) was significantly longer in patients with SNPs in KRT81 (rs3660; p=0.029), NLRP2 (rs1043684; p=0.053) and XPO5 (rs11077; p=0.012)(Figure). A correlation of this latter polymorphism in XPO5 with progression-free survival (PFS) was also observed (p=0.013). This miR-SNP retained its prognostic impact on PFS and OS when a Cox

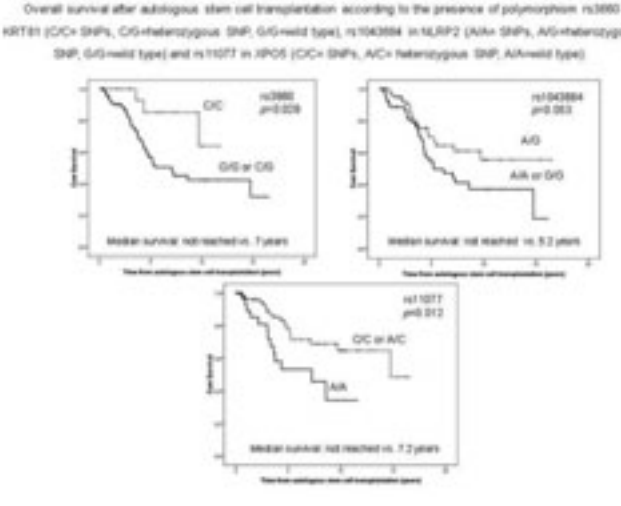

Figure 1.

multivariate regression analysis, including age, international staging system and immunoglobulin isotype, was performed (p=0.028 and p=0.014, respectively) There was a trend toward a longer PFS for miR-SNP in KRT81 (p=0.17), but not for NLRP2. EP300 (rs20551) SNP was associated with higher incidence of implant syndrome (42% vs. 12%, p=0.015). No other associations with prognosis or toxicities were observed in the remaining SNPs. *Conclusion.* Among the immune system genes, only NLRP2 was associated with longer OS in this ASCT series, as previously reported in the allogeneic SCT setting. EP300 is the first genomic risk factor associated with the development of implant syndrome. Concerning to the miRNA network, this is the first report in haematological malignancies that a miR-SNP in a keratin gene (KRT81), target of diverse myeloma-miRNA clusters and relevant in the structural cytoplasm framework, has been associated with prognosis. Moreover, a miR-SNP in XPO5 was significantly associated with longer PFS and OS in our study. This gene, exportin 5, mediates pre-miRNA nuclear export. This SNP could modify the miRNome of the cell, with a miRNA-target disturbance due to a global impairment of mature miRNAs. Further studies on proliferation and miRNA interaction are encouraged.

0283

THE EFFECT OF LENALIDOMIDE AND DEXAMETHASONE COMBINATION ON BONE REMODELING OF RELAPSED/REFRACTORY MYELOMA: FINAL RESULTS OF TWO STUDIES OF THE GREEK MYELOMA STUDY GROUP WITH 205 PATIENTS

E Terpos,[1] D Christoulas,[1] E Katodritou,[2] E Kastritis,[1] MC Kyrtsonis,[2] A Papatheodorou,[2] S Delimpasi,[2] E Michalis,[2] M Migkou,[2] X Papanikolaou,[2] M Gkotzamanidou,[1] E Koulieris,[2] M Gavriatopoulou,[1] Z Kartasis,[2] P Repousis,[2] K Zervas,[2] MA Dimopoulos[1]

[1]*University of Athens School of Medicine, Athens, Greece*
[2]*Greek Myeloma Study Group, Athens, Greece*

Background. Lenalidomide plus dexamethasone (RD) is very effective for the management of refractory/relapsed multiple myeloma (MM). However, there is limited information for the effect of RD on bone remodeling of MM patients. *Aims.* We performed both a retrospective analysis and a prospective study to evaluate the effect of RD regimen on bone remodeling in relapsed/refractory MM. *Methods.* Firstly, we evaluated 106 consecutive patients (54M/52F; median age 68 years) who received lenalidomide at the standard dose of 25mg PO daily (or adjusted to creatinine clearance) on days 1-21 of a 28-day cycle in combination with dexamethasone at a dose of 40mg PO on days 1- 4 and 15-18 for the first four cycles and only on days 1-4 thereafter. All patients were under zoledronic acid both pre- and during treatment period. The following serum indices of bone metabolism were measured on day 1/cycle 1, and then on day 28 of cycles 3 and 6: (i) osteoblast inhibitor dickkopf-1 (Dkk-1); (ii) osteoclast regulators: sRANKL and osteoprotegerin (OPG); (iii) bone resorption markers: CTX and TRACP-5b; and (iv) bone formation markers: bone-specific alkaline phosphatase (bALP) and osteocalcin (OC). These markers were also evaluated in 44 healthy controls of similar gender and age. Then, to confirm the results of the retrospective analysis, we scheduled a prospective study in which 99 patients received either RD (n=50) or VRD (bortezomib+RD, n=49), based on previous peripheral neuropathy status. The above bone markers were measured on day 1/cycle 1 and on day 28 (for RD) and 21 (for VRD) of cycles 3 and 6. Radiological skeletal survey was performed at baseline, after 6 cycles of therapy and then as needed, while patients were assessed for skeletal-related events (SREs) throughout the period of the study. *Results.* In the retrospective analysis, before RD, myeloma patients had increased serum Dkk-1, sRANKL, and bone resorption markers and reduced OC and bALP compared to controls. The objective response rate was 55%. RD produced a reduction of CTX and sRANKL/OPG only in responders, with no effect on bone formation. In the prospective study, VRD reduced Dkk-1 and increased OC after 3 cycles, while it reduced sRANKL/OPG and increased bALP after 6 cycles. These changes were irrespective of treatment response which was similar among treatment arms (63%). In VRD, % Dkk-1 reduction strongly correlated with % increase of bALP. RD reduced CTX only in responders, while it increased Dkk-1; however, responders had a median increase of 9% while non-responders of 91%. No SREs were observed in the VRD arm while two patients treated with RD who had not responded to therapy developed a vertebral pathological fracture. *Summary/Conclusions.* RD regimen reduces bone resorption only in responding patients with relapsed/refractory myeloma but has no effect on bone formation, possibly due to the presence of high dose dexamethasone and to the enhancement of Dkk-1 expression by lenalidomide. On the contrary, VRD enhances bone formation, at least partially due to a significant reduction of Dkk-1, reflecting the strong anabolic effect of bortezomib in MM patients.

0284

INHIBITION OF PROTEIN KINASE CK2 ENHANCES THE CYTOTOXIC EFFECTS OF BORTEZOMIB ON MULTIPLE MYELOMA CELLS

F Piazza,[1] S Manni,[1] A Brancalion,[1] L Quotti Tubi,[1] L Pavan,[2] C Gurrieri,[1] G Semenzato[1]

[1]*University of Padua, Padua, Italy*
[2]*Department of Hematology, University of Padova, Padova, Italy*

Background. Multiple Myeloma (MM) cells are exquisitely sensitive to the cytotoxic effects of proteasome inhibitors (PI). Bortezomib (BZ) is a first-in class PI currently widely used in the therapy of MM patients. BZ causes MM cell apoptosis through different mechanisms which are only partially known. The pro-survival protein kinase CK2 has been implicated in human cancer and phase I clinical trials are ongoing utilizing oral ATP-competitive CK2 inhibitors in MM and other tumors. *Aims.* In this study we have investigated the role of CK2 in the regulation of BZ-induced MM cell death. We aimed to assess apoptosis and proliferation of MM cells exposed to BZ and CK2 inhibitors. We investigated pro-survival signaling pathways associated with MM cell resistance to BZ and chemotherapy. *Methods.* MM cell lines, human bone marrow stromal cells and freshly isolated plasma cells from patients were cultured and exposed to BZ and the CK2 inhibitors K27 and CX4945. Cell growth and viability was assessed upon the different treatments by annexin V and propidium iodide staining, MTT-assays, evaluation of mitochondrial potential depolarization and FACS analysis of cell cycle. Survival signaling pathways were studied with WB analysis and RT-PCR. *Results.* BZ-induced apoptosis and cell cycle arrest were significantly increased by the simultaneous inhibition of CK2. This effect was observed both in MM cell lines grown in suspension, in a model of bone marrow microenvironment as well as in malignant plasma cells isolated from MM patients. Mitochondrial membrane potential measurements revealed that CK2 inhibition enhanced BZ-triggered intrinsic apoptotic cell death. Also, CK2 inhibition together with BZ treatment was associated with reduced MM cell proliferation, as shown by cell cycle analysis with propidium iodide staining. We observed that unwanted side effects of BZ treatment were the activation of the MM growth-promoting NF-κB and STAT3 signaling pathways and the rise in the levels of the unfolded protein response-associated kinase IRE1α. These changes could lend MM cells the ability to escape the cytotoxic effects of BZ. Oppositely, CK2 inhibition was associated with a strong reduction of phopspho-p65 NF-κB, phospho-STAT3 and IRE1α levels in MM cells. Remarkably, the simultaneous treatment of BZ with CK2 inhibitors was accompanied with a significant reduction of BZ-triggered p65 NF-κB and STAT3 activation and we found that CK2 inhibition was also able to hamper the BZ-induced rise in IRE1α levels. *Summary/Conclusions.* These results indicate that protein kinase CK2 can antagonize BZ-induced apoptosis and regulates critical signaling pathways in MM cells, such as the NF-κB and STAT3 cascades. Our findings indicate that CK2 inhibition could represent a rational therapeutic strategy to be tested in designing novel BZ-based anti-MM combination therapies.

0285

USE OF SPECIFIC IMMUNOGLOBULIN HEAVY/LIGHT CHAINS PAIRS FOR THE DIAGNOSTIC AND FOLLOW-UP OF MULTIPLE MYELOMA PATIENTS: NORMAL RANGES AND ASSAY UTILITY

C Bermudo Guitarte,[1] N Barbosa de Carvalho,[2] J de Veas Silva,[1] S Cánovas,[1] M Campos[2]

[1]*Hosiptal Univ. Virgen Macarena, Sevilla, Spain*
[2]*The Binding Site, Barcelona, Spain*

Background. Multiple myeloma (MM) is a B cell disorder and is characterized in most of the cases by the production a monoclonal protein (MP). The detection and quantification of the MP by serum protein electrophoresis is the most used technique for the screening of monoclonal gammopathies. However, this can often be difficult, especially in cases where the paraprotein is of low amount and in cases where the band is masked by other proteins. Immunofixation (IFE) improves sensitivity to the detection protocol but it is not a quantitative method, therefore not suitable for the follow-up. More accurate methods could benefit the patient in several ways: by avoiding problems related to a delayed diagnostic; and by allowing a closer monitoring of the applied therapy, and by doing so helping in treatment decisions such as when

2 - Serum free light chains plus Hevylite (2010) 4th Edition

Normal HLC ranges from a Spanish population and comparison to previously described ranges.

an adjustment is required or when avoiding undesired secondary effects that therapies can cause. A new assay (HevyliteTM - The Binding Site) is now available that allows the quantification of specific heavy chain/light chain pairs (HLC) (IgAk, IgAλ, IgGk, IgGλ, IgMk, IgMλ) and it is our aim to determine normal ranges in healthy individuals considering that the use of HLC ratios (HLCr) will help us improve the diagnostic and follow-up of monoclonal gammopathies. *Methods.* We measured HLC and immunoglobulin's (Igs) G and A concentrations in blood donor sera by turbidimetry (SPA+ - The Binding Site). 37 myeloma samples of treated and untreated patients (16 IgA MM + 19 IgG MM + 2 MM IgM), together with 4 MGUS, 1 Hodgking Lymphoma and 1 Mielodisplasic syndrome were analyzed. In addition, SPE and IFE were performed for all the samples *Results.* Normal HLC ranges were calculated (Table 1) and were found to be in agreement with the ranges previously published. There was a good correlation between the summation of HLC K + λ and the values of total Igs (tIgs) (tIgA vs HLC IgA, r2 =0,91; tIgG vs HLC, IgG r2 =0,91). Regarding the sensitivity of the assay for the identification of pathological cases, 13/16 IgA and 15/19 IgG patients presented altered HLCr. Interestingly, patients who presented normal HLCr for both IgA and IgG were in complete response with negative IFE. The 2/2 IgM, 3/4 MGUS patients, 1/1 Hodgking Lymphoma and 1/1 Mielodisplasic syndrome presented normal HLCr. *Conclusion.* HLC assays allowed the determination (typing and quantification) of specific individual immunoglobulin heavy/light chains concentrations and the respective ratios. Due to the higher sensitivity, HLCr could be a more sensible tool for quantitatively monitoring treatment response since altered ratios were observed in patients during complete response. It seems to present an enormous potential for the identification and the follow-up of patients with very low monoclonal components or in cases where it is difficult to identify a monoclonal protein hidden by other proteins.

[2]*Department of Biological Sciences, Federal University of Sao Paulo, Diadema, Brazil*

Background. Ankyrin-repeat-containing proteins regulate multiple cellular functions including transcription, cell cycle and cell survival. Ankyrin repeat and KH domain-containing protein 1 (ANKHD1) is one such protein ubiquitously expressed in normal human tissues and has a varied and high expression in cancer, including acute leukemias. Multiple myeloma (MM) is a plasma cell malignancy preliminary localized in the bone marrow and characterized by its capacity to disseminate. Previous study by our group showed that ANKHD1 is highly expressed in plasma cells of MM patients compared with normal individuals; however its role in the development of MM is still undetermined. *Aim.* The present study was aimed to study the expression of ANKHD1 mRNA and protein in a panel of multiple myeloma cell lines. In addition we used lentiviral mediated RNA interference technique to down regulate the expression of ANKHD1 gene in human myeloma cell line U266 and studied its effect on apoptosis, proliferation and cell cycle. *Methods.* MM cell lines U266, MM1S, MM1R and RPMI 8266 were used. ANKHD1 mRNA and protein expression were evaluated using real time RT-PCR and Western Blot. Localization of ANKHD1 in cells were analysed by laser confocal microscopy. Specific shRNA-expressing lentiviral vector to ANKHD1 or LacZ gene (control) was designed and used for transduction in U266 cell line. Quantitative PCR (q-PCR) and Western blot analysis were performed to determine the inhibition of ANKHD1 expression. After 48 hours of culture, proliferation was analyzed by MTT assays, apoptosis by Anexin-V and propidium iodide (PI), cell cycle by incubation with PI and RNase A buffer and flow cytometry. *Results.* ANKHD1 mRNA and protein was found to be highly expressed in all MM cell lines as evident by q-PCR and Western blot when compared to K652, a leukemia cell line (positive control). Confocal microscopy showed ANKHD1 to be predominantly localized in cytoplasm of MM cell lines. Lentiviral mediated ANKHD1 shRNA downregulated ANKHD1 mRNA expression and protein level significantly, with a downregulation of 88% and 92%, respectively when compared with control cells (P<0.0001). MTT assays showed that the proliferation was significantly reduced by 70% in ANKHD1 knockdown cells when compared with control cells (P<0.0001). Cell cycle analysis showed an increase of cells in S phase (59.3±1.5 versus 49.4±2.4; P<0.0001) in ANKHD1 knockdown cells as compared to control cells. However, annexin-V analysis showed no significant increase in apoptosis of cells on silencing ANKHD1 expression. *Conclusion.* ANKHD1 is highly expressed in all MM cell lines studied and is predominantly localized in the cytoplasm. Downregulation of ANKHD1 in MM cell line U266, effectively caused decrease in cell proliferation and increase in S phase cells suggesting that ANKHD1 plays a role in cell proliferation and in the accumulation of S phase cells. Further studies are being carried out to elucidate the underlying mechanisms.

[4]*Departamento de Biotecnología. Instituto de Higiene.Facultad de Medicina, Montevideo, Uruguay*

Background. Interleukin-6 (IL-6) is a key molecule in the pathogenesis of multiple myeloma (MM), resulting in myeloma cell proliferation.[1] Overexpression of IL-6 receptor (IL6R) in MM cells is being studied as a molecular target for imaging as well as for treatment. Tocilizumab, a humanized anti IL6R monoclonal antibody has been conjugated with ^{99m}Tc through HYNIC showing good stability *in vitro* and *in vivo*.[2] Conjugation of ^{99m}Tc-Tocilizumab by means of tricarbonyl could be a suitable option as imaging agent in MM, with the advantage of not requiring derivatization previous to its labeling. *Aims.* Development of 99mTc(CO)3-Tocilizumab. Evaluation as imaging agent in MM. *Methods.* 1ml of 99mTc-pertechnetate solution was added to the IsoLink carbonyl labeling agent (Mallinckrodt). 1 mg Tocilizumab (Roche) was incubated with 1mL $[^{99m}Tc(CO)_3(OH2)_3]^+$ at pH 7, during 45 min at 37°C. Radiochemical purity was controlled by chromatographic systems: ITLC/NaCl 0.9%, Whatman 1MM/MEK, ITLC in BSA/EtOH-NH3-H2O (2:1:5) as stationary and mobile phase and by HPLC using size exclusion column and a phosphate buffer 0,01 M, pH7 isocratic gradient as mobile phase at 1ml/min. Stability of $^{99m}Tc(CO)_3$-Tocilizumab was evaluated in PBS and challenged with hystidine for 24 h. Binding studies to U266 MM cells were performed incubating 200000 cpm of the conjugate with 1000000 cells in 1ml culture medium at 30, 60 and 120 min. Specificity of binding was supported by competition experiments using unlabeled antibody. Tocilizumab was derivatized with FITC and purified by PD10 column. Laser scanning confocal microscopy was done with an excitation/emission wavelength of 488/530 nm. Fluorescent images were obtained. Atomic force microscopy imaging of U266 cells were done. Biodistribution studies were performed at 24 h in CD1 normal mice (n=3). Each mice was in-

jected with 37 MBq of $^{99m}Tc(CO)_3$-Tocilizumab and sacrificed 24 h after injection. Organs of interest were collected. *Results.* Radiochemical purity was 91.0 ± 1.1% and 93,5 ± 0.5% at 1 and 2 h respectively, remaining stable at 24 h, showing no significant transchelation. Competition experiments using cold antibody showed a reduction in binding to U266 cells superior to 50%, confirming the specificity of binding. Confocal microscopy proved the ability of the fluorescent antibody to recognize the IL6R in U266 myeloma cells. Biodistribution at 24 h showed blood (4.2) %act/g, liver (3.4) %act/g, kidney (1.2)%act/g and spleen (1.1) %act/g uptake with hepatic and renal elimination. *Conclusion.* Tocilizumab was easily labeled to 99mTc through tricarbonyl with good stability, radiochemical purity and specificity. These results were similar results to those obtained in its conjugation through HYNIC (2). $^{99m}Tc(CO)_3$-Tocilizumab may be a useful imaging agent in MM.

EXTRACELLULAR MATRIX REMODELING AND STROMAL CELL-DERIVED TUMOR PROMOTION IN THE BONE MARROW REFLECT THE PROGRESSION OF MGUS TO MULTIPLE MYELOMA

J Drach, A Slany, V Haudek-Prinz, J Griss, T Mohr, A Meshcheryakova, C Zielinski, C Gerner

Medical University of Vienna, Comprehensive Cancer Center, Vienna, Austria

Background. The pathogenesis of multiple myeloma (MM) is regarded as a multistep process, in which an asymptomatic stage of MGUS precedes virtually all cases of MM. Molecular events leading to transition from MGUS to MM are still poorly defined. Genetically, MGUS plasma cells resemble MM plasma cells in many features, and the clinically apparent step-wise progression of MGUS to MM is poorly reflected by genetic aberrations. *Aims.* We hypothesized that the bone marrow microenvironment is critically involved in the pathogenesis of monoclonal gammopathies. Therefore, we performed a comparative proteome profiling study and investigated the contribution of bone marrow fibroblast precursor cells to disease progression in MM. *Methods.* Primary bone marrow fibroblasts from patients with MGUS and MM were compared to control fibroblasts obtained from hip replacement surgery. Primary cells were cultured for 3 to 5 passages, characterized by immunophenotyping (FACS analysis), fractionated into cytoplasmic, nucleic and secreted protein fractions and then analyzed using shotgun proteomics. Confirmatory experiments were performed using Western blotting. *Results.* Strikingly, a group of extracellular matrix (ECM) proteins, ECM receptors and ECM-modulating enzymes was found to be progressively up-regulated from controls to MGUS and to MM. These proteins include laminin 8, lysyl hydroxylase 2, nidogen-2, integrin alpha-5, macrophage mannose receptor 2, PAI-1 and MMP-2. Additionally, the growth factors periostin and stem cell growth factor as well as PDGF-receptor beta showed a similar progression-related pattern. *Conclusion.* Our results indicate that ECM remodeling and stromal cell-derived tumor promotion in the bone marrow takes place already at the level of MGUS and becomes even more pronounced in MM. Thus, for the first time, marker proteins could be identified indicating a step-wise progression from MGUS to MM.

[3]*Department of Haematology, Royal Free Hospital, London, United Kingdom*
[4]*Alexandra Hospital, University of Athens, School of Medicine, Athens, Greece*

Background. Natural killer (NK) cells are cytotoxic lymphocytes able to kill tumor cells and virus-infected cells. Human resting NK cells can be activated by co-culture with NK-resistant CTV-1 cells. These tumor-activated cells (TaNK) are cytotoxic to a range of NK-resistant tumor cells *in vitro*. This potential, has not been explored in multiple myeloma (MM). *Aim.* The current study was design to assess the relative function *in vitro* of NK and TaNK cells from MM patients compared to normal controls in the lysis of tumor cell- lines and freshly isolated autologous and allogeneic MM cells. In addition we explored whether the ability to generate TaNK cells *in vitro* correlates with patients' characteristics, including the disease status and treatment, including novel agents. *Methods.* Freshly isolated CD56+ NK cells from normal donors and 21 MM patients, separated with CD56 immunomagnetic Microbeads were co-incubated with CTV-1 cells or lysates there from, overnight at 37oC, 5% CO2, to generate TaNK cells. For the cytotoxicity assay, the erythroleukemia cell-line K562 with known sensitivity to NK lysis was used as a positive control, the Burkitt's lymphoma cell-line Raji, known to be refractory to NK lysis was used as a negative control of NK killing. The Myeloma cell-line U266 as well as freshly isolated bone marrow (BM) autologous and allogeneic CD138+ plasma cells from MM patients were used to evaluate the sensitivity of plasma cells to MM patients' NK and TaNK lysis. Cytotoxicity was measured in a 4-h assay. Loss of membrane integrity was measured by ingress of To-Pro-3 iodide as determined by flow cytometry. Bone marrow plasma cells, were acquired after electronic gating on the CD138(+) cells, and the mean proportion of CD138 positive/To-Pro 3 iodide- positive cells from the samples was determined. *Background.* Target-cell death was determined from cells incubated in the absence of effector cells and the "percent lysis - CD138+"was calculated by subtraction of the background cell death. To determine the specificity of malignant plasma cell lysis, CD138-ve cells were gated in the same analysis and the "percent lysis - control cells"determined as above. This was subtracted from the "percent lysis - CD138+"to give a "percent specific lysis". *Results.* We have demonstrated that TaNK cells from MM patients lyse several myeloma targets, including autologous and allogeneic CD138+ myeloma cells whilst sparing CD138-ve BM cells. Myeloma patients' TaNK-induced lysis of the U266 cell-line was significantly higher compared to normal controls (median specific lysis 79.1% vs 69.5%) (p=0.003). In addition, TaNKs induced substantial lysis of autologous and allogeneic CD138+ myeloma cells (median specific lysis 52.5% and 37.4%, respectively). The percentage of specific lysis did not correlate with important disease characteristics, (ISS, age, high-risk cytogenetics), nor with the disease status and anti-myeloma treatment, including novel agents and dexamethasone. *Summary/Conclusions.* Tumor-primed NK cells are able to induce substantial lysis of myeloma targets including autologous and allogeneic CD138+ myeloma plasma cells and could be an additional therapeutic approach in MM, particularly in the era of novel agents.

ANALYSIS OF SHELTERIN COMPONENTS MRNA EXPRESSION IN MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE. CORRELATION WITH CLINICAL CHARACTERISTICS

J Panero,[1] D Fantl,[2] J Arbelbide,[2] I Slavutsky[1]

[1]*Academia Nacional de Medicina, Buenos Aires, Argentina*
[2]*Hospital Italiano, Buenos Aires, Argentina*

Background. Shelterin is the mayor protein complex (TRF1, TRF2, TIN2, POT1, TPP1 and RAP1) bound to mammalian telomeres, involved in telomere length (TL) regulation and chromosome ends protection. Previous data from our group have provided the first evidence of modifications in the mRNA expression of TRF1 and TRF2 in plasma cell disorders (Panero *et al.,* Mol Med 2010). *Aim.* The aim of the present study was to evaluate the participation of the other four members of the shelterin complex: TIN2, POT1, TPP1 and RAP1, in patients with multiple myeloma (MM) and monoclonal gammopathy of undetermined significance (MGUS). Results were correlated with TRF1, TRF2 and hTERT (telomerase catalytic subunit) expression, and TL. Clinicopathological characteristics of patients were also evaluated. *Methods.* Bone marrow samples from 145 patients: 77 with MM (35 males; mean age: 68 years; range: 30-87 years; 35.5% ISS stage 3) and 68 with MGUS (29 males; mean age: 69.1 years; range: 39-88 years) and, 15 normal controls were studied. All patients gave informed consent and the study was approved by the local Ethics Committee. Real-Time Quantitative PCR was used to quantify gene expression and TL measurements were performed by Terminal Restriction Fragments. For statistical analysis, Mann-Whitney test, Kendal coefficient and receiver operating characteristic (ROC) were used. *Results.* Differences in the

Table 1.

Analysis of telomere-associated genes expression and mean TL according to hTERT groups in patients with multiple myeloma (MM) and monoclonal gammopathy of undetermined significance (MGUS).

Groups (n)	Telomeric genes (ΔΔCt)							TRF (kb)
	hTERT	TRF1	TRF2	TIN2	POT1	TPP1	RAP1	(ΔΔCt)
MM								
GA (48)	0.32±0.04	0.29±0.10	0.07±0.01	2.05±0.2*	0.05±0.01*	0.54±0.05	0.24±0.02*	7.02±0.38
GB (30)	6.08±1.04*	0.20±0.03	0.12±0.02*	2.54±0.31	0.06±0.01	0.84±0.09*	0.37±0.07	5.36±0.35*
MGUS								
GA (53)	0.28±0.05	0.41±0.08	0.04±0.003	1.36±0.12	0.016±0.001	0.45±0.05	0.19±0.04	7.33±0.42
GB (15)	4.47±0.8*	0.23±0.04	0.07±0.02	2.10±0.32	0.019±0.006	0.41±0.08**	0.24±0.06	6.83±0.81

Significant difference in MM of group B (GB) with respect to group A (GA): *p<0.01.
Significant difference in GB between MGUS and MM: **p<0.001.
Significant difference in GA between MGUS and MM: p<0.01

mean mRNA levels of telomere-associated genes in patients with respect to normal controls were observed (p<0.04). The comparison between both entities showed higher POT1 (p=0.0007), RAP1 (p=0.02), TPP1 (p=0.03) and TIN2 (p=0.003) mRNA levels in MM with respect to MGUS patients. In both pathologies an up-regulation of hTERT and a positive association with RAP1 and TPP1 (p<0.0002) were found. For a better analysis, patients were divided into two groups according to hTERT levels using ROC curves: hTERT mRNA levels <1.08 (Group A; GA) and >1.08 (Group B; GB). Table 1 shows the global analysis of all shelterin genes, hTERT and TL. In both entities, an increased gene expression in GB with respect to GA, with significant differences in MM for TPP1 and TRF2 as well as shorter TL (p<0.01) was observed. TPP1 also showed significant differences between GBs from MM and MGUS (p=0.003). Higher levels of RAP1 (p=0.009), POT1 (p=0.002) and TIN2 (p=0.01) in GAs from MM and MGUS were also found. In MM, the analysis of clinical characteristics showed a negative association between hemoglobin and POT1 and RAP1 expression (p<0.03), while the percentage of bone marrow infiltration was positively correlated with POT1 and TPP1 mRNA levels (p=0.03). RAP1 expression was also positively associated with calcium and creatinine levels (p<0.001). Although non-significant, a shorter overall survival in MM patients of GB compared to GA was observed. *Conclusion.* Our findings show a global modification in the expression of telomere-associated genes in MM and MGUS, suggesting that the up-regulation of most of the shelterin components may contribute to the stabilisation of short telomeres by delaying/repressing the telomere damage signals, contributing to the development and/or progression of the disease.

CLONALITY ASSESSMENT USING 8-COLOR FLOW CYTOMETRY

L Kovarova,[1] T Varmuzova,[2] P Zarbochova,[2] K Muthu Raja,[2] R Suska,[1] J Stossova,[2] M Penka,[1] R Hajek[2]

[1]*University Hospital, Brno, Czech Republic*
[2]*Babak Research Institute, Masaryk University, Brno, Czech Republic*

Background. Monoclonal gammopathies (MG) are characterised by presence of different numbers of clonal plasma cells (PC), lower in monoclonal gammopathy of undetermined significance (MGUS) and higher in multiple myeloma (MM). Discrimination between normal polyclonal PC (N-PC) and abnormal clonal PC (A-PC) is important in time of diagnosis and especially after treatment (transplantation etc.). Expression of surface markers CD19 and CD56 on PCs is widely used for this discrimination, but unfortunately in some cases is not enough sufficient. *Aims.* Verification and validation of 8-color flow cytometry protocol for clonality assessment of PC and B cell subsets in MGs. *Methods.* Analyses of 22 MG patients in various stages of diagnosis and treatment were done (14 newly diagnosed MGUS/MM, 6 treated MM and 3 relapsed/progressed MM patients). Combination of CD38/CD138/CD19/CD56/CD45/CD27/ck-appa/clambda was used to detect clonality of PCs subpopulations, mature B cells and memory B cells by flow cytometry. *Results.* There was found 0.4% (0.04-13.40) [median (min-max)] of $CD38^+CD138^+$ PCs in bone marrow. Only N-PCs ($CD19^+CD56^-$ PCs) were found in 4 patients (2 new diagnoses, 1 progression and 1 post-treatment) and only clonal A-PCs ($CD19^-CD56^{+/-}$ PCs) were found in 3 patients (1 new diagnosis, 1 progression and 1 post-treatment). Remaining cases were characterized by mixture of N-PCs and A-PCs, but detailed analysis of PC subpopulations using cytoplasmic kappa/lambda expression shown that not all $CD19^-$ PCs and/or $CD56^+$ PCs are clonal as was expected. This detailed analysis could be very useful in minimal residual disease (MRD) monitoring. Simultaneous analysis showed presence of clonal mature B cells and clonal memory B cells as well in 5 cases (4 new diagnoses and 1 post-treatment), so presence of lymphoproliferation should be verified in these patients. *Summary/Conclusions.* Analysis using combination of surface and intracellular markers in 8-color setting can improve detection even small clone of pathological PCs and together with B cell assessment can be very important for determination of diagnosis and monitoring after treatment.

CENTROSOME ASSOCIATED GENES IN MULTIPLE MYELOMA

F Kryukov, P Nemec, E Dementyeva, S Sevcikova, M Almasi, J Smetana, P Kuglik, R Hajek

Masaryk University, Brno, Czech Republic

Background. Multiple myeloma (MM) is a lymphoproliferative disease characterized by clonal expansion of neoplastic plasma cells within the bone marrow. The genome of malignant plasma cells is extremely unstable characterized by a complex combination of structural and numerical abnormalities. It is suggested that centrosome abnormalities, of which centrosome amplification is the most prominent, occur early in MM pathogenesis and increase with disease progression. Centrosome amplification is therefore associated with deregulation of cell cycle, mitosis, DNA repair and proliferation. *Aims.* The objective of our study was to evaluate changes in expression profile of genes involved in centrosome structure/function in MM with known role in oncogenesis. *Methods.* 57 patients were evaluated by gene expression profiling of PCs. CD138+ cells were separated by MACS. Total RNA was transcribed into cDNA (Ambion WT Sense Target assay), labeled and hybridized to the Affymetrix GeneChip Human Gene ST 1.0 array according to a manufacture protocol. Acquisition of Affymetrix array images, RMA normalization algorithm and hierarchical clustering algo-

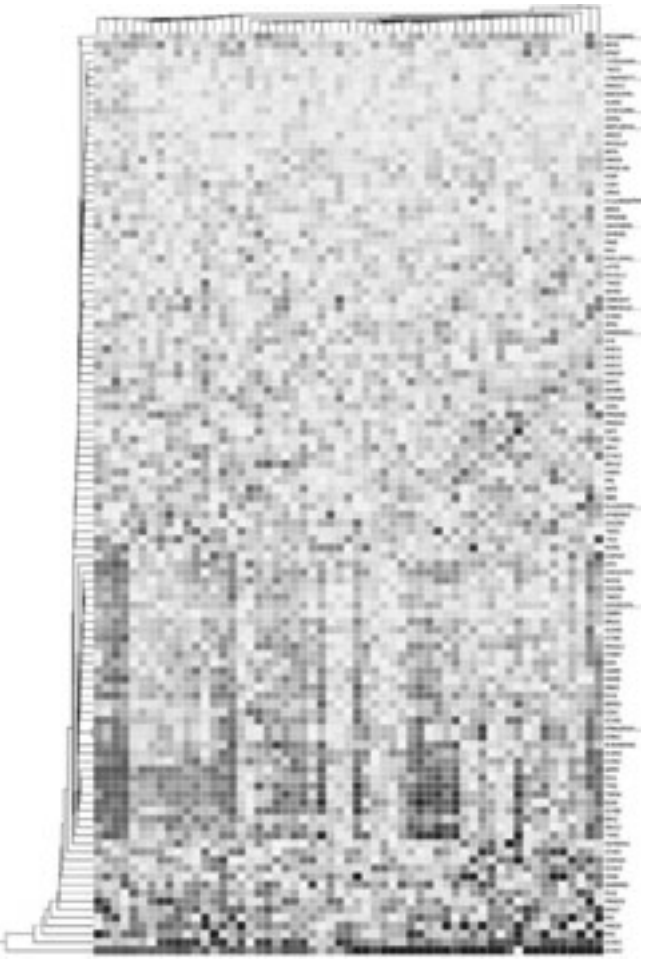

Figure 1.

rithm with Euclidean similarity measure were performed using appropriate software. 100 genes were selected for clustering. All of these genes are known to be involved in regulation of centrosome duplication and function with known role in oncogenesis. *Results.* We have found one distinct cluster of 36 genes. Based on ontology, the following gene groups can be distinguished: genes associated with cell-cycle, including CDK1 and CDK2 families, E2F and Plk families AURKA and NEK2; kinetochore and microtubule attachment genes (AURKB, BIRC5, CENP family); mitotic checkpoint genes presented by BUB1 and MUD2 families; DNA damage checkpoint genes presented with centrosome amplification supressors, integrity and reduplicate regulators (RAD51, XRCC2, MSH2, CHEK1) and structural genes presented with TUBG1. The rest of genes from revealed cluster (HMMR, TACC3, TOP2A, BRCA1 and BARD1) are also closely functionally connected with mentioned gene groups. *Conclusions.* In our study, we showed distinct cluster of 36 mitotic genes involved in centrosome abnormality in MM. Similarity of expression profile in revealed cluster gives us the possibility to suspect that these genes are involved in MM cell oncogenesis as a whole complex. This fact needs more detailed investigation and in our futher work we anticipate new insights into pathogenesis and possible crucial role of centrosome abnormalities in myeloma malignancy.

CANCER-TESTIS ANTIGENS OF THE MAGE FAMILY INDUCE SPONTANEOUS HUMORAL RESPONSES IN PATIENTS WITH MULTIPLE MYELOMA

Y Cao, T Luetkens, K Bartels, S Kobold, Y Hildebrandt, N Lajmi, H Reinhard, J Templin, M Meyer, N Kröger, C Bokemeyer, D Atanackovic

University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background. We have previously shown that cancer-testis (CT) antigens are specifically expressed in the bone marrow (BM)-infiltrating plasma cells of patients with multiple myeloma (MM) and that certain members of the MAGE family are the CT genes most commonly detected in MM. In addition MAGE genes, such as MAGE-C1/CT7, MAGE-C2/CT10 and MAGE-A3, seem to independently promote the progression of MM. *Aims.* In this study, we investigated for the first time the occurrence of spontaneous humoral responses against these promising targets for the antigen-specific therapy of MM. *Methods.* Peripheral blood (PB; N=1347) plasma samples from 225 MM patients and PB samples from 97 healthy donors were screened for antibody responses against MAGE-A1, MAGE-A3, MAGE-A8, MAGE-A11, and MAGE-C2/CT10 by ELISA and western blot. A B cell ELISPOT assay was applied to determine the number of CT antigen-specific memory B cells in the PB of MM patients. *Results.* MAGE-A11-, MAGE-A1-, MAGE-A8-, and MAGE-A3-specific antibody responses occurred in 17 (7.6%), 5 (2.2%), 4 (1.7%), and 3 (1.3%) MM patients respectively, at least once throughout the course of their disease. The most commonly detectable humoral responses were directed against MAGE-C2/CT10 being present in 33 (15%) of MM patients. In agreement with this finding, we were also able to demonstrate for the first time the presence of MAGE-C2/CT10-specific memory B cells in the PB of MM patients by ELISPOT. In a western blot analysis, spontaneous MAGE-C2/CT10-specific immune responses in the patients were found to be highly specific for both natural and recombinant protein. Epitope mapping in an ELISA using overlapping MAGEC2/CT10 20mer peptides further showed that antibody responses were restricted to regions of the full-length protein spanning amino acids 40-60, 160-180, 180-200, and 270-290. MAGEC2/CT10-specific antibodies consisted mainly of IgG2 and to a lesser extent of IgG1, IgG3 and IgG4 subtypes. *Conclusions.* Cancer-testis antigens of the MAGE family, especially MAGE-C2/CT10, are capable of inducing spontaneous humoral response in MM patients. These antigens represent promising targets for the antigen-specific immunotherapy of MM but might also be of use as diagnostic and/or prognostic parameters for myeloma represent potential targets for immunotherapy in patients with multiple myeloma, vaccination targeting this kind of antigen could remarkably enhance the corresponding response.

Background. The combination of Melphalan-Prednisone-Lenalidomide (MPR) has shown promising results in elderly newly diagnosed myeloma patients. In young myeloma patients, low-dose chemotherapy (induction) precedes high-dose chemotherapy (autologous transplantation consolidation). This approach reduces tumor mass, with few side effects, before achieving the maximum cyto-reduction with transplantation consolidation. The same approach has been designed for the elderly patients: lenalidomide plus corticosteroids precedes consolidation with MPR. *Aims.* To evaluate the safety and efficacy of Lenalidomide-Prednisone (RP) as induction, followed by Melphalan-Prednisone-Lenalidomide (MPR) as consolidation and RP as maintenance in elderly myeloma patients. *Methods.* Unfit patients with newly diagnosed symptomatic myeloma older than 65 years were enrolled in a two-stage phase II clinical trial designed according to Bryant and Day method. No exclusion criteria were included in the protocol, to avoid the selection of fit elderly subjects only. Patients with low blood count, abnormal performance status, hepatic, renal, cardiac or pulmonary functions were enrolled. Patients received 4 RP courses (Lenalidomide 25 mg/day for 21 days for 4 cycles, plus Prednisone 50 mg three times/week for 4 months) followed by 6 MPR cycles (Melphalan 2 mg and Prednisone 50 mg three times/week for 6 months plus Lenalidomide 10-15 mg/day for 21 days for 6 cycles) and maintenance with RP (Lenalidomide 10 mg/day for 21 days and Prednisone 25 mg three times a week until PD). Two different dose-levels of Lenalidomide were tested in combination with MP: 15 mg (dose-level 1) and 10 mg (dose-level 2). Each cohort included 12 patients, with additional 22 patients enrolled at dose-level 2. *Results.* Forty-six patients (median age 75, range 65-88) were enrolled. Forty-four patients were evaluable after a median follow-up of 13.3 months. During RP induction, the most frequent grade 4 hematological adverse events were neutropenia (7%) and anemia (2 %), no grade 4 thrombocytopenia was observed. During MPR consolidation no increase in grade 4 adverse events was registered, incidence of neutropenia was 11%, while no grade 4 anemia and thrombocytopenia were observed. Non-hematological toxicities were more frequent during RP cycles and reduced during MPR cycles (cutaneous rash and infections). Discontinuation rate was higher during induction (14% vs 5%). After RP induction, at least partial response (PR) rate was 73%, at least very good partial response (VGPR) was 16%. During MPR consolidation, PR rate increase to 78%, including 24% of patients who achieved at least a VGPR. CONCLUSION: Induction with RP followed by consolidation with MPR showed a manageable safety profile with a reduced the risk of severe haematological toxicity in unfit elderly myeloma patients.

Background. Carfilzomib, a novel epoxyketone that specifically and irreversibly inhibits the proteasome, has shown promising single-agent activity in relapsed/refractory multiple myeloma (R/R MM) with a favorable side-effect profile and minimal myelosuppression. Lenalidomide with low-dose dexamethasone (Rd) is a standard of care for patients with relapsed MM. In preclinical studies, lenalidomide sensitized MM to bortezomib, suggesting that combination therapy with these complementary agents may enhance clinical activity. Although the clinical utility of bortezomib/Rd is limited by toxicity, the combination of carfilzomib with lenalidomide and dexamethasone (CRd) may be similarly efficacious and prove to be more tolerable. *Aims.* This phase 1b/2 study evaluated the maximum tolerated dose (MTD) of CRd in patients with relapsed or refractory MM. The safety and antimyeloma activity of the highest dose was further assessed in an expanded cohort. *Methods.* Eligible patients included those with relapsed or refractory MM following 1-3 prior therapies (including prior lenalidomide and/or bortezomib). CRd was given on 28-day cycles to 6 cohorts in a 3+3 dose-escalation design. The dosing cycle included carfilzomib on days 1, 2, 8, 9, 15, and 16; lenalidomide on days 1-21, and dexamethasone on days 1, 8, 15, and 22 (Table). An additional ~40 patients enrolled in an expansion cohort at the highest dose level. Primary endpoints included safety and establishment of the MTD. Grading of adverse events (AEs) was performed according to NCI CTC v3.0. Additional endpoints included overall response rate (ORR, including partial response or better) as assessed by IMWG criteria, with secondary assessment of clinical benefit response (CBR, minimal response or better) using EBMT criteria. *Results.* Approximately 75% of the patients enrolled were previously treated with bortezomib. MTD was not reached. Eighty-one patients (50 at the highest dose) were response-evaluable. Initial responses generally occurred within the first 2 cycles and improved with continuing therapy. Responses were observed at all dose levels (Table). As of December 2010, median duration of response has not been reached (>14 mo). Patients have continued on therapy for up to 28 months, and prolonged administration has not resulted in any unexpected toxicities. Most AEs were reversible and manageable. AEs ≥ Grade 3 were primarily hematologic, including neutropenia, thrombocytopenia, and anemia. Twelve patients discontinued treatment due to AEs. *Conclusions.* The combination of full-dose carfilzomib (20 or 27 mg/m^2) with Rd was well-tolerated in MM patients who had received 1-3 prior treatment regimens, including bortezomib or immunomodulators. At the highest dose tested ORR was 78%, and prolonged administration led to no new or overlapping toxicities. CRd is being directly compared to Rd in patients with relapsed MM in ASPIRE, an ongoing phase 3 open-label, international, multicenter trial.

AN ABNORMAL NON-HYPERDIPLOID KARYOTYPE IN MULTIPLE MYELOMA PREDICTS FOR AN ADVERSE OUTCOME AFTER HIGH DOSE THERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANATATION (HDT/ASCT)

D Tan,[1] Y Loh,[1] C Diong,[1] M Poon,[2] Y Linn,[1] LK Tan,[2] YT Goh,[1] LP Koh,[2] W Hwang,[1] WJ Chng[2]

[1]*Singapore General Hospital, Singapore, Singapore*
[2]*National University Hospital of Singapore, Singapore, Singapore*

Background. Despite routine HDT/ASCT in younger patients (pts), a huge heterogeneity in overall survival (OS) outcomes is still observed. This relates to the underlying biological heterogeneity of MM. We evaluate the impact of pre-transplant characteristics and the eventual post-transplant response on the OS of pts who underwent HDT/ASCT in 2 major transplant centers in Singapore. We sought to identify important prognostic factors that may predict clinical outcomes in the era of novel therapy. *Methods.* 122 of 483 newly diagnosed MM pts were enrolled to our HDT/ASCT programme from 1999 to 2009. Pt and disease characteristics including age, gender, cytogenetics, ISS staging, induction therapy, bortezomib exposure and the eventual post-transplant response were evaluated. For induction therapy, pts received VAD chemotherapy and thalidomide/dexamethasone (TD) before and from 2004 respectively. Bortezomib was available for treatment of relapsed MM and induction treatment of high-risk MM from 2005. All pts received cyclophosphamide 4g/m2 as mobilization followed by peripheral blood stem-cell collection prompted by G-CSF. HDT/ASCT entailed conditioning with melphalan 200mg/m2. Response was defined according to IMWG uniform criteria. *Results.* The median age of all pts was 55 years. 22%, 43% and 35% of patients presented with ISS stage I, II and III disease respectively. Metaphase cytogenetics detected abnormalities in 44% of pts (hypodiploidy [16%], hyperdiploidy [22%], pseudodiploidy [4%] and near tetradiploidy [3%]). For MM subtypes: IgA 13%, IgG 34%, IgD 1%, and light chain MM 7%. Interphase FISH for high-risk markers [deletion17p, t(4;14), t(14;16)] was positive in 12/52 pts (23%) diagnosed after 2005. For induction, 40% received VAD, while 40% and 20% received TD and bortezomib-based combination respectively. At a median follow-up of 3 years, 65 pts (53%) have been exposed to bortezomib (31% in frontline and 69% at relapse). Overall, the median OS is 8.3 years. Median OS for pts with ISS stage I, II, and III were not reached, 8.1 and 5.1 years respectively (p=0.09). The median OS for pts with diploid, hyperdiploid and non-hyperdiploid karyotype were not reached, 5.1 and 2.8 respectively (p<0.001). When this analysis was further stratified by bortezomib exposure (non-exposed, frontline or relapse), the impact of cytogenetics was no longer apparent only among the group of pts who received frontline bortezomib induction. There was a non-significant trend for longer OS among pts attaining at least a very good partial response (≥VGPR) (9.5

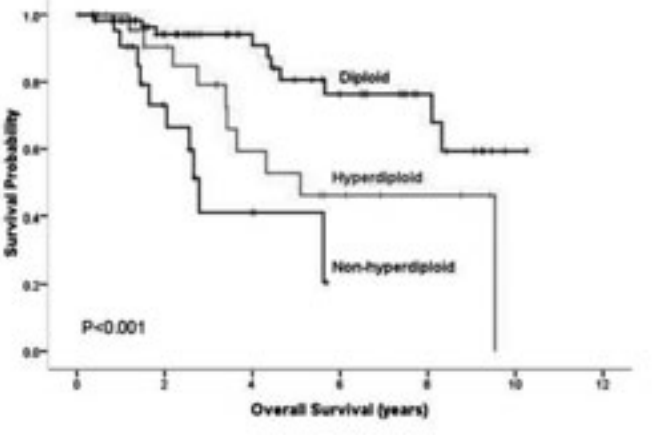

Figure 1. Overall survival by metaphase cytogenetics (N=122).

years vs 8.1 years, p=0.15). On Cox regression multivariate analysis, the presence of a non-hyperdiploid karyotype emerged as the single most adverse prognostic indicator after HDT/ASCT (hazard ratio 4.1, 95% CI 1.2, 14.0, p=0.03). *Conclusion.* Our study suggests that while HDT/ASCT may prolong the OS of transplant-eligible pts, it is still unable to overcome adverse cytogenetics detected on conventional metaphase karyotyping. Upfront bortezomib combination prior to HDT/ASCT rather than sequential use at relapse should be considered in this group of pts. Although the attainment of ≥VGPR post-HDT/ASCT has been reported as an important surrogate marker of better prognosis, it does not appear to confer any benefit for pts with a non-hyperdiploid karyotype.

A NOVEL ESTIMATED GFR FORMULA, BASED ON CYSTATIN-C, INDEPENDENTLY PREDICTS FOR SURVIVAL IN PATIENTS WITH NEWLY-DIAGNOSED, SYMPTOMATIC, MULTIPLE MYELOMA: RESULTS IN 157 PATIENTS

MA Dimopoulos,[1] E Kastritis,[2] E Katodritou,[2] D Christoulas,[2] M Gkotzamanidou,[2] S Delimpasi,[2] E Michalis,[2] M Roussou,[2] A Zomas,[2] A Pouli,[2] Z Kartasis,[2] J Meletis,[2] K Zervas,[2] E Terpos[2]

[1]*University of Athens School of Medicine, Athens, Greece*
[2]*Greek Myeloma Study Group, Athens, Greece*

Background. Renal impairment (RI) is a common complication of multiple myeloma (MM). Cystatin-C (Cys-C) is considered as a sensitive marker of glomerular filtration rate (GFR). A recent study in >3,400 patients with chronic kidney disease (CKD) showed that estimating GFR (eGFR) based on serum creatinine(sCr), Cys-C, age, gender and race (eGFR/Cys/Cr) provides the most accurate GFR estimates: eGFR=177.6 x Scr-0.65 x CysC-0.57 x age-0.20 x (0.82 if female) x (1.11 if black). However, this new formula has not been evaluated in MM. *Aim.* The aim of this study was to evaluate eGFR/Cys/Cr in newly-diagnosed MM patients, compare it with eGFR assessed by MDRD equation and explore possible correlations with clinical data, including survival. *Methods.* We studied 157 newly-diagnosed, symptomatic, MM patients (87M/70F, median age 68 years) before any kind of therapy and evaluated both eGFR/Cys/Cr and eGFR/MDRD. Serum Cys-C was determined by particle enhanced immunonephelometry (Dade Behring, Liederbach, Germany). *Results.* Serum Cys-C was increased in MM patients compared to 52 controls [median: 1.01 mg/L vs. 0.72 mg/L, p<0.0001] and was significantly correlated to sCr (R2=0.497, p<0.001) and beta2-microglobulin (R2=0.42, p<0.001). Median values of eGFR/Cys/Cr (68.7 ml/min/1.73m2) were not different compared with those of eGFR/MDRD (66.1 ml/min/1.73m2). There was also no difference in terms of number of patients with RI of different stages between the two estimates (39% of patients had CKD 3-5 by the MDRD equation and 41% by the eGFR/Cys/Cr equation). However, in 15% of patients, there was a difference in CKD staging according to the two methods: 13 (8%) patients were CKD 3-5 by eGFR/Cys/Cr but CKD 1-2 by eGFR/MDRD, while 10 (6%) were CKD 1-2 by eGFR/Cys/Cr but CKD 3-5 by eGFR/MDRD. eGFR/Cys/Cr was correlated with ISS (p<0.001). The median survival was 48 months (median follow-up: 20 months). In the univariate analysis, CKD 3-5 assessed by eGFR/Cys/Cr (HR:2.93, p<0.001) was a stronger prognostic factor than CKD 3-5 assessed by eGFR/MDRD (HR:1.85, p=0.018). Elevated LDH, ISS stage, bone disease and myeloma subtype (light chain only MM vs. others) were also associated with survival in the univariate analysis. In ISS-2, eGFR/Cys/Cr could identify a subgroup of patients with poor survival: 19 patients with eGFR/Cys/Cr <68.7 ml/min/1.73m2 had a median survival of 23.9 months, while the median survival of all other (n=32) has not been reached (p=0.003). However, eGFR/MDRD, either by using the median as a cutoff or by using the CKD stage, could not discriminate prognostic groups within ISS-2. In a multivariate analysis eGFR/Cys/Cr was the strongest prognostic factor for survival, either as continuous variable (HR 0.986; p=0.004) or as a dichotomous at median (HR:0.380, p=0.01); other factors included bone disease (HR 2.220; p=0.018) and LDH (HR 2.782; p=0.025). *Summary/Conclusions.* These results suggest that eGFR/Cys/Cr estimates RI comparable to eGFR/MDRD. However, only eGFR/Cys/Cr strongly correlates with survival, while it could identify a subgroup of patients with ISS-2 disease with poor outcome. This may be due to the better reflection of both renal function and tumor burden by eGFR/Cys/Cr, as Cys-C is also overproduced by myeloma cells.

Background. The ongoing community-based phase 3b UPFRONT study compares the safety and efficacy of three bortezomib (Vc)-based regimens, Vc-dexamethasone (VcD), Vc-thalidomide-dexamethasone (VcTD), and Vc-melphalan-prednisone (VcMP), followed by Vc maintenance therapy, in previously untreated, transplant-ineligible MM patients. *Aims.* To measure changes in patient-reported QoL during Vc-based induction and maintenance. *Methods.* Patients with symptomatic, measurable MM were randomized (1:1:1) to receive 49 weeks of treatment; eight 3-week induction cycles with VcD, VcTD, or VcMP followed by five 5-week maintenance cycles with single-agent Vc. All patients provided written consent. Adverse events (AEs) were graded by NCI-CTCAE v3.0. Responses were assessed according to IMWG criteria. Patient QoL was recorded using the EORTC QLQ-C30 questionnaire, which assesses global health status, multiple function scores and symptom scores including fatigue, nausea and vomiting, pain, dyspnea, insomnia, appetite loss, constipation, diarrhea, and financial difficulties. Patients completed the questionnaire at baseline, on day 1 of every odd-numbered cycle, at the end-of-treatment visit, and every 12 weeks thereafter. Data were analyzed after 300 patients, 100 per arm, had the opportunity to undergo all 13 treatment cycles. Data imputation was used for patients who died within a year of randomization with missing QoL assessments assigned the worst possible score of zero. Changes in mean global health status scores from baseline, within and between treatment arms, were calculated. Observed data were further analyzed using a linear mixed effect model; a sensitivity analysis using last observation carried forward was also performed. *Results.* Patient baseline characteristics were well balanced across the treatment arms, as reported previously (Niesvizky, ASH 2010). Patients received a median of 9 (VcD), 6 (VcTD), and 7 (VcMP) treatment cycles; 56%, 33%, and 43% of patients, respectively, received Vc maintenance. After 13 cycles, re-

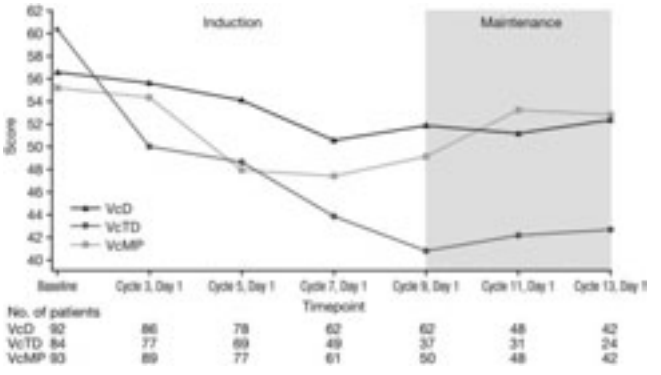

Figure 1. Mean observed global health status score by arm.

sponse rates were 71% (VcD), 79% (VcTD), and 73% (VcMP); ≥VGPR rates were 39%, 47% and 44%, respectively. Rates of grade ≥3 AEs after 13 cycles were 74% (VcD), 86% (VcTD), and 80% (VcMP); serious AEs were highest for VcTD (61% vs 57% VcD and 51% VcMP), as was the rate of discontinuation due to AEs (41% vs 29% VcD and 35% VcMP). QoL assessments were available at baseline and ≥1 post-baseline time point for 80% (VcD), 67% (VcTD), and 80% (VcMP) of patients. The observed data indicate that all treatment groups experienced a downward trend in mean global health status score until cycle 7 or 8, followed by an increase or stabilization by the end of treatment (Figure); there were no differences between treatment arms. Symptom scores changed very little during induction with all Vc-based regimens, with moderate improvements seen during maintenance, except for nausea/vomiting and diarrhea. *Conclusions.* The trends to decreased QoL score seen during Vc-based induction may reflect the onset of treatment-associated AEs. Post-induction increases in QoL may reflect the positive impact of achieving a response and the limited toxicity profile associated with Vc maintenance. Patients continue to be followed for QoL assessment and long-term outcomes.

Background. The impact of cytogenetic abnormalities on the response to therapies and survival in patients with multiple myeloma (MM) is well-established in the literature. Bortezomib, alone or in combination with other agents, may overcome the adverse impact of several common unfavorable cytogenetic features. Additionally, responses with lenalidomide (LEN)/dexamethasone and pomalidomide have been reported in patients with unfavorable cytogenetics. Carfilzomib is a novel, highly selective epoxyketone proteasome inhibitor that produces durable single-agent activity in patients with R/R MM. *Aims.* The objective of this analysis was to evaluate the influence of cytogenetics in a large phase 2b study (PX-171-003-A1) of single-agent carfilzomib in patients with R/R MM. *Methods.* 229 of 266 patients enrolled (86%) were response-evaluable and had available metaphase cytogenetics and/or fluorescence in situ hybridization (FISH) analyses for adverse cytogenetics defined per mSMART criteria (hypodiploidy, chromosome 13 deletions, del 17p13, t(4:14), and t(14;16) chromosomal abnormalities). Metaphase data were available for 200 patients (75%), FISH data for 205 patients (77%). All patients received carfilzomib at 20 mg/m^2 IV on days 1, 2, 8, 9, 15, and 16 in a 28-day cycle (C) in C1 followed by 27 mg/m^2 in each C thereafter for up to 12 C. Patients who completed 12 C of therapy were eligible to continue carfilzomib on extension study PX-171-010. Responses were assessed and confirmed by an Independent Review Committee. Overall response rate (ORR) was defined as ≥PR by International Myeloma Working Group criteria, and clinical benefit response (CBR) was defined as ≥MR by European Group for Blood and Marrow Transplantation criteria. *Results.* Patients had disease that was relapsed after ≥2 treatment regimens including bortezomib and either thalidomide or lenalidomide, and were refractory to their most recent regimen. Patients in this heavily pre-treated population had received a median of 13 prior anti-myeloma drugs and a median of 5 prior treatment regimens. Patients had previously received treatment with bortezomib (99.6%), thalidomide (74%), lenalidomide (93%), and stem cell transplantation (72%). 71 of 229 patients (31%) had ≥1 cytogenetic abnormality. Of these, 47/71 (66%) had abnormalities detected via metaphase cytogenetics, 44 (62%) by FISH, and 20 (28%) by both methods. The presence of deletion 13 or hypodiploidy by cytogenetics or del17p13, t(4;14), or t(14;16) by FISH did not significantly impact the ORR. Specifically, 28% of patients with ≥1 abnormality responded compared to 24% with none. The CBR was also unaffected at 32% versus 37% for patients with ≥1 and no abnormalities, respectively. For patients with ≥1 abnormality, the median duration of response (DOR) was 6 months (95% CI, 4-10) compared with a DOR of 8 months (95% CI, 6-11) in patients with no abnormalities. *Conclusions.* Carfilzomib demonstrated durable and comparable activity in patients with R/R MM in both the absence and presence of cytogenetic abnormalities including hypodiploidy, chromosome 13 deletions, del 17p13, t(4:14), or t(14;16). The results of the present study suggest that durable responses to carfilzomib can be achieved in heavily pretreated patients and these responses are not influenced by poor prognostic cytogenetic features.

Background. The selective, epoxyketone proteasome inhibitor carfilzomib produces potent, sustained proteasome inhibition while lacking many of the off-target activities associated with bortezomib. Carfilzomib produces durable single-agent activity in patients with relapsed/refractory multiple myeloma (R/R MM) who have received multiple prior therapies, as well as in patients with advanced-stage disease or significant comorbidities. PX-171-004 is an ongoing phase 2 study of single-agent carfilzomib in patients with relapsed or refractory MM following 1-3 prior therapies. *Aims.* Here we present updated data on the bortezomib-naïve patients treated on study. *Methods.* Patients received either 20 mg/m^2 for all treatment cycles (Cohort 1) or a stepped-up dose-escalating regimen of 20 mg/m^2 for Cycle 1 and 27 mg/m^2 for all treatment cycles thereafter (Cohort 2). Carfilzomib was administered on days 1, 2, 8, 9, 15, and 16 of every 28-day cycle, for a maximum of 12 cycles. The primary endpoint was the overall response rate (ORR; CR + VGPR + PR) determined according to the International Myeloma Working Group Uniform Response Criteria. Secondary endpoints included the clinical benefit response (CBR; ORR + MR) rate, time to progression (TTP), duration of response (DOR), and safety. *Results.* 123 of 125 enrolled bortezomib-naïve patients were evaluable for response. Prior therapies included thalidomide (58%), lenalidomide (59%), alkylating agents (82%), and stem cell transplant (73%). 44 patients had disease refractory to the most recent therapy. A median TTP of 8.3 months and a median DOR of 13.1 months were observed for Cohort 1. The median TTP and DOR for Cohort 2 have not been reached. The most common treatment-emergent adverse events (AEs), regardless of relationship to carfilzomib, were fatigue (60%), nausea (45%), anemia (40%), and dyspnea (36%). These were primarily ≤ Grade 2 in severity. The most common Grade 3/4 AEs were anemia (13%), lymphopenia (13%), pneumonia (13%), neutropenia (12%), and thrombocytopenia (11%). Treatment-emergent peripheral neuropathy (PN) was infrequent (18%) and mild. Only 1 case of Grade 3 PN (0.8%) was observed. Overall, 49 patients (~40%) completed 12 cycles (~1 yr) and 38 patients (29%) continued to receive carfilzomib therapy on extension protocol PX-171-010, including 11 patients from bortezomib-naïve Cohort 1 and 27 patients from bortezomib-naïve Cohort 2. Significantly, no cumulative toxicities have been noted. *Conclusions.* Single-agent carfilzomib achieves high response rates in bortezomib-naïve patients with relapsed myeloma, with minimal neuropathy. At the recommended phase 3 dose of carfilzomib, the 53% ORR is noteworthy for a single-agent regimen for patients with myeloma who had received 1-3 prior regimens for MM. Moreover, prolonged carfilzomib treatment is well-tolerated, with ~40% of patients completing 12 cycles and 29% continuing treatment beyond 1 year.

Table 1.

Best response	Cohort 1 N=59 20 mg/m^2 n (%)	Cohort 2 N=64 20/27 mg/m^2 n (%)

Background. MLN9708 is an investigational, orally bioavailable, potent, reversible, and specific 20S proteasome inhibitor. MLN9708 is active in solid tumor and hematologic xenograft models. IV and oral formulations are in phase 1 trials. *Aim.* Two studies of oral MLN9708 are ongoing to assess its safety, maximum tolerated dose (MTD), pharmacokinetics (PK), and anti-tumor activity in patients with relapsed/refractory multiple myeloma (MM). *Methods.* Adults with MM after ≥2 prior therapies, which must have included bortezomib, thalidomide/lenalidomide, and corticosteroids, were eligible. Patients provided informed consent. Patients received MLN9708 on days 1, 4, 8, 11 of 21-day cycles (twice-weekly [TW]) or days 1, 8, 15 of 28-day cycles (weekly [W]). Dose-escalation proceeded from 0.24 mg/m^2 using a standard 3+3 schema based on the occurrence of dose-limiting toxicities (DLTs) in cycle 1. Adverse events (AEs) were graded by NCI-CTCAE v3. PK samples were collected after single and multiple doses for both schedules. Response was assessed by modified EBMT criteria. *Results.* To date, 26 patients (16 male, median age 64.8 years [range 50-83]) have received MLN9708 TW at 0.24, 0.48, 0.8, 1.2 (each n=3), 1.68 (n=4), 2.0 (n=7), and 2.23 mg/m^2 (n=4), and 22 patients (12 male, median age 63.5 years [range 40-76]) have received MLN9708 W at 0.24, 0.48, 0.8, 1.2 (each n=3), 1.68 (n=4), 2.23, and 2.97 mg/m^2 (each n=3). Patients received medians of 4 cycles (range 1-12+) on the TW and 2 cycles (range 1-8+) on the W schedules; 9 and 8 patients remain on treatment, respectively. Safety data are shown in the Table. The MTD for MLN9708 TW was established as 2.0 mg/m^2 and MTD on the W schedule has not yet been reached. All-cause grade 3/4 AEs on the TW schedule included thrombocytopenia (n=6), neutropenia (n=2), and non-cardiac chest pain (n=2) and on the W schedule included

Table 1.

	MLN9708 TW (n=26)	MLN9708 W (n=22)
DLTs	Grade 3 rash, Grade 4 thrombocytopenia (both at 2.23 mg/m²)	0
MTD	2.0 mg/m²	Not reached (escalated to 2.97 mg/m²)
All-cause common AEs, % Fatigue Diarrhea Nausea	 42 42 31	 41 27 27
All-cause grade ≥3 AEs, %	50	14
Drug-related grade ≥3 AEs, %	35	0
Serious AEs, % (all unrelated)	35	9
Discontinuations due to AEs, n	0	1
On-study deaths, n	1 (unrelated)	0

syncope, pathologic fracture, and musculoskeletal pain (each n=1). Baseline grade 1 neuropathy was present in all patients reporting treatment-emergent neuropathy (peripheral [PN] or sensory [PSN]) or paresthesia (P). With TW dosing, 6 patients had grade 1 PN/P and 1 had a grade 2 event (unrelated). With W dosing, one grade 2 and three grade 1 PSN/P events were seen. For both TW and W schedules, MLN9708 was absorbed rapidly with T_{max} of ~0.5-2.0 hr and terminal half-life of ~5-7 days. Steady-state was not achieved following Day 11 dose for TW and Day 15 dose for W dosing. Exposures appeared to increase proportionally with increasing dose from 0.8 to 1.68 mg/m^2. With TW dosing, 1 patient receiving 1.2 mg/m^2 achieved a partial response in cycle 5, which was maintained through cycle 11+; 16 had stable disease, of whom 5 have received ≥8 cycles. With W dosing, 3 patients have reported stable disease to date. Response evaluation is ongoing in both studies. *Conclusions.* These data suggest oral MLN9708 is generally well tolerated and has early signs of activity. W dosing appears to enable delivery of higher MLN9708 doses. Combination trials guided by these data are ongoing.

Background. Carfilzomib (CFZ) is a novel, highly selective proteasome inhibitor that differs from BTZ both structurally and mechanistically. CFZ does not cause cumulative toxicity (including neurotoxicity) in long-term (6-9 month) chronic animal toxicology studies. Phase 2 clinical trials of single-agent CFZ in MM demonstrated durable responses in patients with relapsed and relapsed/refractory (R/R) multiple myeloma (MM), including patients with pre-existing peripheral neuropathy and substantial renal dysfunction. *Aims.* Here we report on the updated clinical experience with long-term treatment (>12 cycles) with carfilzomib in patients with MM. *Methods.* Patients treated in phase 1 or 2 MM trials were eligible to enroll in an extension study after 12 cycles. Patients initially received carfilzomib on Days 1, 2, 8, 9, 15, and 16 of every 28-day cycle. The dosing frequency could be reduced to alternate weeks (ie, Days 1, 2, 15, and 16). Dose increases up to a maximum of 56 mg/m^2 were also permitted. Depending upon the time of administration from the patients' original study, IV carfilzomib was administered over a period of either 10 minutes or 30 minutes. In selected patients, a second anti-myeloma agent was added. Patients continued treatment until evidence of progressive disease or unacceptable toxicity, or individual withdrawal of consent. *Results.* As of 31 January 2011, 78 patients with MM had enrolled. The relative proportion of patients rolling over was highest from the 2 phase 2 trials: 29/266 patients (11%) from 003-A1 (R/R MM pts) and 38/129 patients (29%) from 004 (bortezomib-naïve, 1-3 prior regimens). Sixty-one MM patients (78%) remain on study and are receiving a median dose of 27 mg/m^2 (range: 15-56 mg/m^2). The median total duration of treatment (original study + extension study) is 18 months. 29 patients remain on their original dosing schedule, and 21 patients are receiving the intermittent dosing schedule. The longest total duration of treatment is >30 months. 13 patients are off-study due to progressive disease, 1 patient was removed at the investigator's discretion, and 1 patient withdrew consent. 2 patients had dose reductions due to toxicity, and there have been no withdrawals due to toxicity. 15 patients had their doses of carfilzomib increased, 2 patients added lenalidomide, and 4 patients added 40 mg/wk dexamethasone. Clinically significant cumulative toxicities were not observed. *Conclusions.* CFZ can be safely administered to patients with MM for extended therapy using the either the original dosing schedule or an intermittent schedule. The maintenance carfilzomib treatment regimen sustains disease control and provides excellent long-term tolerability.

EFFICACY AND SAFETY OF LENALIDOMIDE IN COMBINATION WITH LOW DOSE DEXAMETHASONE (LD) AS FIRST LINE TREATMENT OF PRIMARY PLASMA CELL LEUKEMIA (PPCL)

P Musto,[1] F D'Auria,[1] MT Petrucci,[2] T Caravita,[2] F Di Raimondo,[2] A Falcone,[2] F Morabito,[2] M Offidani,[2] N Filardi,[2] V Callea,[2] A Levi,[2] A Zonno,[1] E Zifarone,[1] V Santopietro,[1] G Pietrantuono,[1] M Martorelli,[1] O Villani,[1] R Guariglia,[1] G Mansueto,[1] R Le Rose,[1] K Todoerti,[2] S Bringhen,[3] F Gay,[2] M Cavo,[2] M Boccadoro,[2] P Omedè,[2] A Neri,[2] A Palumbo[2]

[1]*IRCCS, Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, Italy*
[2]*GIMEMA Multiple Myeloma Working Party and Italian Multiple Myeloma Network, Rome, Italy*
[3]*Division of Hematology, University of Torino, AOU S. Giovanni Battista, Torino, Italy*

Background. PPCL is an aggressive, rare variant of multiple myeloma, whose prognosis is usually poor. Lenalidomide is an IMiD®-immunomodulatory agent with proven efficacy in multiple myeloma. There are some sporadic reports of PPCL treated with lenalidomide as salvage therapy, but no data are currently available on the use of this drug as first line therapy. *Aims.* On March, 2009, we started the first multicenter pilot study aiming to evaluate safety and antitumor activity of LD in previously untreated PPCL. *Methods.* Newly diagnosed patients received lenalidomide at a dose of 25 mg/d for 21 days and oral dexamethasone at a dose of 40 mg on days 1, 8, 15, and 22 for each 28-day cycle. After 4 cycles, responding patients not eligible for stem cell transplantation (SCT) continued until 8 cycles of full-dose LD, if tolerated, followed by a maintenance dose of single agent lenalidomide equal to 10 mg/d on days 1-21 of each 28-day cycle. Patients responding after 4 cycles and eligible for SCT proceeded according to single Centre transplant policy. Patients not responding after 4 cycles or progressing during treatment were considered off-study. The primary endpoint was early response rate according to International Uniform Criteria. The secondary endpoints were PFS, OS, safety, and percentage of eligible patients able to undergo autologous or allogeneic SCT. Biological markers (cytoge-

netics, SNP and GEP studies) were also evaluated (results reported in a different abstract). Appropriate dose reductions, contraception methods and anti-thrombotic prophylaxis were applied. *Results.* According to the Simon Optimal Two-Stage Adaptive Design, twenty out of 22 planned patients have been so far enrolled (M/F 11/9; median age 66 years, range 45-81). Circulating plasma cells ranged from 655 to 70.000 x 10e9/l. Moderate renal failure, increased LDH and extramedullary disease occurred in 35%, 55% and 30% of patients, respectively. Hb was < 10 g/dl in 14 patients (70%), while platelet count was < 50 x 10e9/l in 5 patients (25%). Cytogenetic abnormalities were frequently combined in complex karyotypes and detected in 15 out of 17 (88.2%) analyzed patients: there were 12 del13, eight del17, four t(11;14), seven t(14;16) and one t(4;14). With a median follow-up of 14 months, eleven out of 18 evaluable patients achieved at least PR (61.1%), with 39% of patients achieving at least VGPR on intention-to-treat analysis. Causes of early interruption were progressive disease (four patients), adverse events (one acute renal insufficiency, one Stevens-Johnson's syndrome), one death in PR due to causes unrelated to treatment or disease. Grade 3-4 hematological and non hematological toxicities occurred in 29.4% and 35.2% of patients, respectively. Dose adjustment was required in 11/18 patients (61%), including those with initial renal failure. One-year OS and PFS were 77% and 50%, respectively. Four out of 6 eligible patients underwent autologous SCT (one patient refused, one patient failed to collect PBSC): to-date, all transplanted patients are alive in remission phase. *Conclusions.* LD is a promising initial therapy for PPCL, which can rapidly control the disease in the majority of cases, allowing following single patient-adapted therapeutic strategies.

0304

REAL-LIFE DATA ON THE CURRENT APPROACH TO OLDER PATIENTS WITH MULTIPLE MYELOMA

F Ferrara,[1] B Pocali,[2] F Pollio,[2] P Caraffa,[3] L Corvatta,[3] M Catarini,[4] M Offidani[3]

[1]*AORN Antonio Cardarelli, Napoli, Italy*
[2]*Divisione di Ematologia e Trapianto, Ospedale Cardarelli, Napoli, Italy*
[3]*Clinica di Ematologia, Azienda Ospedaliero-Universitaria Ospedali Riuniti, Ancona, Italy*
[4]*Divisione Medicina Ospedale Macerata, Macerata, Italy*

Background. The combination melphalan-prednisone (MP) has represented the standard of care for older patients with multiple myeloma (MM). The introduction of new agents has challenged the role of MP and led to new standards of care, even in aged individuals. All randomized studies comparing MP with MP plus thalidomide (MPT) showed advantage in progression free survival for MPT; in addition, in two of these studies a survival advantage was recorded. More recently, superiority versus MP was also demonstrated for the combination of MP plus bortezomib (MPV). Accordingly, the combination of MP with a new agent is the current standard of care in MM of the elderly. While in the daily practice a proportion of aged patients still receive MP treatment, the real number of them and exact reasons accounting for suboptimal therapy are unknown. *Aims.* In this study, we retrospectively analyzed a consecutive series of 237 patients with MM aged over 65 years, with the aim of assessing the number of patients who did not received a 3-drug regimen and the causes of suboptimal treatment. *Methods.* From 2008 to 2010, 237 patients over 65 years were diagnosed at our institutions. The median age was 74 years and all of them had symptomatic disease requiring treatment. Twenty-five patients (12%), all aged 66-70 years, who received autologous stem cell transplantation were excluded from the analysis. Among the remaining 212, 47 patients received MP (22%), 102 MPT (48%) and 63 (30%) MPV. Among MPT and MPV patients, 66 % were accrued into prospective clinical trials; conversely, no patients within the MP subgroup were judged as eligible for any trial (p >0.001). The median age was 77 years for the MP patient subgroup, as opposed to 71 for MPV and 73 for MPT; the difference was statistically significant between MP and MPV (p=0.004) as well as between MP and MPT (p=0.007), while it was not significant between MPV and MPT (p=.14). The median number of comorbidities requiring specific treatment was 3 (range 1-5) in the MP subgroup as opposed to 1 in the MPT (range 0-1) and 0 (range 0-1) in the MPV subsets. Once again, differences between MP and MPT (p=0.03) and between MP and MPV (p=0.01) were statistically significant. The main criteria for the selection between MPT and MPV were distance from hospital, ability of the patients to travel and the period of observation (more patients received MPV after the registration as first line). *Conclusions.* We conclude that 22% of older MM patients receive suboptimal therapy, i.e. the old MP combination. More advanced median age and number of severe comorbidities requiring specific treatment account for the therapeutic selection. Among patients treated with current standard of care, the choice between MPV and MPT is strictly related to the ability of patients to travel as well as to distance from the hematological institution. Of note, most of data refer to specialized hematological institutions; it is conceivable that in non hematological wards, the percentage of exclusion from the current standard of care can be higher.

0305

BORTEZOMIB-BENDAMUSTINE-DEXAMETHASONE FOR TREATMENT OF RELAPSED/REFRACTORY MYELOMA

H Ludwig,[1] H Kasparu,[2] H Gisslinger,[3] J Thaler,[4] R Greil,[5] L Pour,[6] C Leitgeb,[1] M Schreder,[1] N Zojer,[1] Z Adam[6]

[1]*Wilhelminenspital, Vienna, Austria*

[3]*University Hospital Vienna, Vienna, Austria*
[4]*Hospital Wels-Grieskirchen, Wels, Austria*
[5]*Hospital Salzburg, Salzburg, Austria*
[6]*University Hospital Brno, Brno, Czech Republic*

Background. Bendamustine, an alkylating agent with purine analogue like activities and non-cross resistance with several other alkylators, exerts significant activity when combined with the proteasome inhibitor bortezomib. In addition, evidence has been created for a favorable risk/benefit ratio for the triple combination of bendamustine -bortezomib - dexamethasone. *Aims.* In this ongoing phase II trial we evaluate the efficacy of the triple combination in patients with relapsed/refractory myeloma. *Methods.* Up to now 21 patients with relapsed/refractory multiple myeloma have been enrolled. Informed consent was obtained from all patients. Median age at baseline was 62 years (range 46-86), male/female: 8/13. Data documentation is available for 20 patients: ISS stage I: 5, stage II: 7, stage III: 8. 13 patients presented ECOG performance status 2, 7 patients with ECOG 1. Twelve patients had 1-2, 6 patients 3-4, and 2 patients >4 previous treatment lines. 13 of 20 patients had previously been exposed to bortezomib. Treatment regimen: Bendamustine 70 mg/m2 day 1+4, Bortezomib 1.3 mg/m2 days 1, 4, 8 and 11, Dexamethasone 20 mg on days 1, 4, 8 and 11, repeated every 4 weeks. Treatment should be applied for a maximum of 8 cycles; in case of no response or stable disease (SD) after 4 cycles, patients should be switched to another therapy. *Results.* Responses are presently evaluable in 12 patients (≥ 2 cycles completed and fully documented). 2 patients completed 7, 6, 3 and 2 cycles, respectively; 3 patients received 4 cycles and in 1 patient 5 cycles were applied. ORR (CR + nCR + PR + MR) was 66.6% with 1 patient achieving CR (8.3%), 4 nCR (33.3%), 1 PR (8.3%), and 2 MR (16.6%), respectively. Median time to response was 87 days. Responses were observed in 5 (62.5%) of 8 patients previously exposed to bortezomib therapy. In 17 fully documented patients the following grade 3/4 toxicities were observed: thrombopenia in 8 (47.0%), anemia in 4 (23.5%), herpes zoster in 3 (17.6%), and acute renal impairment in 2 (11.8%) patients, respectively. Grade 3/4 diarrhea, constipation, and sepsis were seen in 1 (5.9%) patient each. Interestingly, grade 3/4 leukopenia was noted in 1 (5.9%) patient only, while up to now no grade 3/4 polyneuropathy has been observed. *Conclusions.* The BBD combination exerts significant activity (ORR: 66.6%) in pretreated patients with relapsed/refractory myeloma. Re-induction of response was noted in 5/8 patients previously exposed to bortezomib. The regimen was well tolerated with grade 3/4 thrombopenia being the most frequently (47%) observed side effect. Updated results will be presented at the meeting.

0306

LENALIDOMIDE-DEXAMETHASONE (LD) AS TREATMENT OF ACUTE CAST NEPHROPATHY-INDUCED RENAL FAILURE (ARF) IN MULTIPLE MYELOMA (MM). A PHASE II STUDY

H Ludwig,[1] I Spicka,[2] J Thaler,[3] R Greil,[4] A Lang,[5] E Müldür,[1] A Weiβmann,[1] N Zojer,[1] Z Adam[6]

[1]*Wilhelminenspital, Vienna, Austria*
[2]*Charles University, Prague, Czech Republic*
[3]*Hospital Wels-Grieskirchen, Wels, Austria*
[4]*Hospital Salzburg, Salzburg, Austria*
[5]*LKH Feldkirch, Feldkirch, Austria*
[6]*University Hospital Brno, Brno, Czech Republic*

Background. Light chain-induced renal failure is a severe complication of MM associated with increased risk of infections, dependency on

chronic hemodialysis and shortened survival. Reversal of renal impairment requires immediate installment of effective anti-myeloma therapy and rapid reduction of the pathogenic light chains. *Aims.* To prospectively evaluate the efficacy of Lenalidomide (L)-Dexamethasone (D) in restoring renal function and tumor control in patients with light chain-induced acute renal failure (LC-ARF). *Patients and Methods.* 21 patients with LC-ARF as formerly defined (JCO 2010) have been identified for this trial and informed consent was obtained from all patients; 1 patient died before first study medication and for 2 patients data are not available as yet. Lenalidomide was given from d 1-21 with dose adaptation according to GFR. Dexamethasone 40 mg was administered on d 1-4, 9-12, 17-20 during cycle 1; thereafter 1x/week. Cycles were repeated q 4 weeks. *Results.* Baseline data are available for 18 pts at present: Median age: 68 years (range: 47-87 years), male/female: 8/10, 17 patients presented with ISS stage III (1 data missing). 17 (94.4%) presented with de novo MM and 1 (5.5%) with previously treated, but relapsing disease; median GFR 21.2 ml/min (range 6.1 - 27.6 ml/min). ECOG performance status was 0 in 6 patients, 1 in 4 pts, 2 in 5 pts, 3 in 1 pt and 4 in 2 pts. Presently, 12 patients are evaluable for response (completed ≥2 cycles and fully documented). 6 patients completed all 9 cycles, 2 patients 6 cycles and 1 patient each completed 7, 5, 3 and 2 cycles. nCR was achieved in 7 (58.3%), VGPR in 1 (8.3%), PR in 1 (8.3%), and MR in 3 (25.0%) patients, respectively. yielding a nCR-PR rate of 75%. Median time to tumor response was 129 days. Renal response was assessed as formerly defined (JCO 2010). 2 patients achieved CRrenal and 6 PR/MRrenal, respectively, yielding an ORRrenal in 8 (61.5%) of the evaluable pts. Median time to best renal response was 147 days. 3 of 8 dialysis dependent patients became dialysis independent. Median GFR of evaluable patients increased from 14.7 (range 6.1 - 27.6 ml/min) at baseline to a median best GFR of 28.9 ml/min (range 11.3 - 74.0 ml/min). In 7 patients with nCR median GFR improved from 9.4 to 30.6 (11.3 - 74 ml/min). In 5 patients with VGPR/PR/MR median GFR increased from 14.7 to 26.0 (16.8 - 40.7 ml/min). Full documentation of adverse events is presently available in 16 patients. 2 patients died due to infection (12.5%). Grade 3/4 anemia, thrombopenia and leucopenia, were seen in 9 (56.2%), 2 (12.5%), and 1 (6.25%) patients, respectively. Other common grade 3/4 toxicities were infection 5 (31.2%), and cardiac dysfunction 3 (18.8%). Exanthema, pulmonary embolism, macula edema, and fatigue were seen in 1 patient each (6.25%). *Conclusions.* LD showed significant anti-myeloma activity and improved renal function in 62% of this high risk population. The LD regimen with the dose of lenalidomide adjusted according to GFR was well tolerated. Updated results will be presented.

0307

BORTEZOMIB-BASED THERAPY OVERCOMES THE PROGNOSTIC ROLE OF ISS SCORE IN MULTIPLE MYELOMA PATIENTS NOT ELIGIBLE FOR TRANSPLANT

A Corso,[1] F Di Raimondo,[2] S Mangiacavalli,[1] R Ria,[3] M Offidani,[4] C Pascutto,[1] G Gaidano,[5] M Boccadoro,[6] M Cazzola,[1] A Palumbo[6]

[6]*Hematology Division, AOU S.Giovanni Battista, University of Torino, Torino, Italy*

Background. Novel agents had considerably changed the outcome in multiple myeloma (MM) patients not eligible for transplant. The achievement of a CR correlates with long-term progression free survival (PFS) even in this setting. PFS could be significantly variable in patients with the same type of response. Among baseline prognostic factors, ISS seems to maintain its role even in patients treated upfront with novel agents. *Aims.* We explore the role of ISS in predicting the length of progression free survival (PFS) in MM patients not eligible for transplant stratified according to response. *Methods.* We retrospectively reviewed the records of 511 patients enrolled in the controlled multicenter phase III GIMEMA trial VMPT-VT vs VMP (Palumbo *et al.*, JCO 28:5101-5109, 2010). Patients were randomly assigned to received 9 VMPT cycle (bortezomib +melphalan+prednisone+thalidomide) followed by VT maintenance (bortezomib+thalidomide) for 2 years (or until progression) (VMPT-VT arm, 254 patients) or 9 cycle of VMP (bortezomib+melphalan+prednisone) without maintenance (VMP arm, 257 patients). The study was performed according to the Declaration of Helsinki, and approved by the ethics committee of each participating institution. Response to therapy was defined according to EBMT criteria. Patients were considered responsive (ORR) when obtaining at least a PR. *Results.* ISS distribution was balanced in the two arms (p=0.40) with 19%/39%/23% and 22%/34%/22% of patients with ISS 3/2/1 in VMPT-VT and VMP arm respectively. ORR was 89% (CR 38%, VGPR 21%, PR30%) in VMPT-VT arm vs 81% (CR 24%, VGPR 26%, PR 31%) in VMP arm (p=0.01). Longer PFS was observed in patients obtaining a CR with no statistical difference between patients with VGPR and PR both in VMPT-VT and VMP arm (p=0.35 and p=0.33 respectively). The prognostic role of ISS on PFS was evaluated in the whole population and after stratification according to response and study arm. In univariate analysis ISS showed no significant impact on PFS (p=0.9). In patients reaching a CR, ISS showed no significant correlation with PFS in both treatment arm (p=0.8 and p=0.6 in VMPT-VT and VMP arm respectively). In patients with less than a CR (VGPR/PR) low ISS (1) was associated with better PFS, only in patients in VMP arm (p=0.04), without significant correlation for patients with similar response enrolled in VMPT-VT arm (p=0.18). *Conclusions.* In MM patients not eligible to transplant, the prognostic role of ISS is overcome by bortezomib-based treatment. In patients with less than a CR, ISS have a negative prognostic impact on PFS only in those who do not receive a maintenance.

Background. Carfilzomib is a novel, highly selective epoxyketone proteasome inhibitor in development for treatment of MM. Single-agent carfilzomib has demonstrated durable activity in patients with R/R MM in phase 1 and 2 studies. *Aims.* Here we report on clinical experience with single-agent carfilzomib in the open-label, single-arm phase 2 PX-171-003-A1 trial in patients with multiply-relapsed and refractory MM, including those patients with Grade (G) 1/2 peripheral neuropathy (PN) at study entry. *Methods.* Patients must have received ≥2 prior therapies including bortezomib, either thalidomide or lenalidomide, and an alkylating agent. Patients received carfilzomib at 20 mg/m^2 on a QDx2 schedule (Days 1, 2, 8, 9, 15, and 16 every 28 days) in cycle (C) 1 and were dose escalated to 27 mg/m^2 on the same schedule thereafter for up to 12 C. Patients completing 12 C were eli-

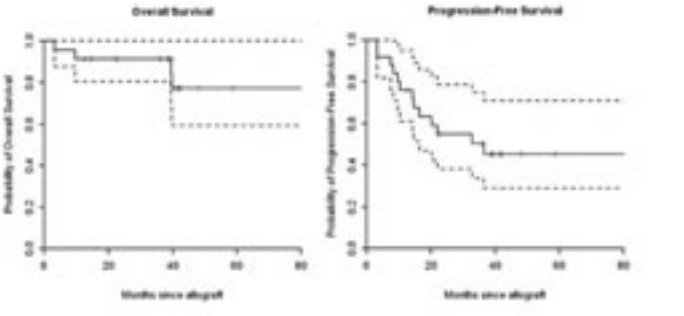

Figure 1.

gible to enter an extension study (PX-171-010). Responses and progression were determined according to the International Myeloma Working Group (IMWG) criteria and were assessed and confirmed by an Independent Review Committee (IRC). The primary endpoint was overall response rate (ORR) (≥ partial response [PR]). Secondary endpoints included: clinical benefit response (CBR) (ORR + Minimal response [MR]), duration of response for ≥PR (DOR), overall survival (OS), time to progression (TTP), progression-free survival (PFS), and safety. PN history, ISS/Durie-Salmon staging, and prior treatment history were collected for all patients for subset analyses. Newly incident PN or worsening PN were monitored by prospective neurologic exams every 2 C. *Results.* Of 266 patients enrolled, 257 were response-evaluable as detailed in the table below. The ORR was 24% with a median DOR of 7.4 months (range 6.2-10.3). 202 of 257 patients (79%) had G1/2 PN at baseline and achieved an ORR of 24%, with a median DOR of 7.4 months (95% CI 5.6-9.2). The OS for all patients was 15.5 months (95% CI 12.7-19.0). The most common treatment-emergent adverse events (AEs) ≥G3 regardless of relationship to study drug were predominantly hematologic and included thrombocytopenia (22%), anemia (20%), lymphopenia (10%), pneumonia (8%), neutropenia (8%), fatigue (7%), hyponatremia (5%), and hypercalcemia (5%). New-onset PN was infrequent and PN ≥G3 was reported in only 2 patients (0.97%). 27 patients completed 12C and continued on extension protocol PX-171-010. Additional subset analysis and updated long-term follow-up data will be presented. *Conclusions.* Single-agent carfilzomib achieved significant durable responses in patients with R/R MM whose disease had relapsed after all available therapies including bortezomib and immunomodulatory agents, including patients with active G1/2 PN at study entry. Carfilzomib was well-tolerated, and AEs were clinically manageable with no new, unexpected, or cumulative toxicities, allowing prolonged single-agent dosing for disease control. Notably, PN had no impact on depth or durability of responses, or on the tolerability of carfilzomib in these heavily-pretreated patients. Importantly, exacerbation of pre-existing PN was uncommon. The CBR and median DOR achieved with this steroid-sparing regimen establish the potential of carfilzomib to offer substantial clinical benefit to patients with relapsed or refractory disease.

Material and Methods. This study concerned MM patients (pts) prospectively allocated to receive a tandem auto-allo-HSCT for being of bad prognosis. They received RIC followed by allo-HSCT after achieving at least a PR to auto-HSCT. RIC regimen in majority combined Fluda. 30mg/m²/d (d-5[ARROWRIGHT]d-1), Busilvex IV 3.2mg/kg/d (d-4, d-3) and ATG 2.5mg/kg/d (d-2, d-1). This analysis included 25 pts, 18 males and 7 females, median age 51 years [28-67], there were 15 IgG, 6 IgA and 4 light chains MM, 14 pts had del13, 7 had del17 and 17 had high level of beta2µ; 7 pts had the 3 factors combined and 6 pts had 2 factors combined. For induction therapy, 16 pts received VAD and 9 patients received Vel.D. Pts received auto-HSCT after a median time of 5.5 months [3.6-15.3] from diagnosis. All pts were in PR after auto-HSCT and before allo-HSCT. Allografts came from 16 identical siblings, 8 matched (10/10) and 1 mismatched (9/10) unrelated donors. *Results.* At Day 90, 10 pts were in CR, 15<CR among them 9 received Velcade, 6 received other treatments including DLI. There were 8 acute GVHD (7 grade II and 1 grade III) and 11 chronic GVHD (3 lim. and 8 ext.). At the last follow-up, 10 pts were in durable CR1 post allo-HSCT. After a median follow-up of 40 months [3-125], the median OS was not reached with a 6 years probability of 70% [53-95], the median PFS was 36 months [16-125], with a 6 years probability of 45% [29-71], TRM was 8% at 2 years and reached 12% at 4 years. *Conclusion.* According to these very promising results, we should reconsider the allo-HSCT as a first line treatment for MM especially for pts with poor prognostic factors. The development of novel reduced-intensity preparative regimens, pre- and post-transplantation strategies enhancing the graft-versus-myeloma effect are the important key issues for the future. RIC Allo-HSCT should be optimized rather than replaced.

0310

EVALUATION OF 18F- FDG PET/ CT AND 99MTC- MIBI SCINTIGRAPHY IN PATIENTS WITH MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNKNOWN SIGNIFICANCE: COMPARISON OF METHODS

J Bacovsky

University Hospital, Olomouc, Czech Republic

Newer imaging modalities, such as 18F- FDG PET/ CT and 99mTc-MIBI scintigraphy, have been recently introduced to assess the aktivity and extent of disease in patients with multiple myeloma (MM) and gammopathy of undetermined signifi cance (MGUS). *The aim* of our study was to compare the impact of these imaging modalities in the evaluation of MM and MGUS patients. *Materials and Methods.* A total of 101 patients with MM (81 patients) and MGUS (20 patients) were enrolled in the study (21 newly diagnosed and 44 relapsed patients with symptomatic MM, 16 with asymptomatic MM and 20 with MGUS). All patients were without therapy and underwent 18F- FDG PET/ CT and 99mTc- MIBI scintigraphy within a maximum interval of 14 days. The scans were classifi ed as normal (N), diff use (D), and focal or combined (F- FD) pattern. *Results.* There was no signifi cant diff erence in the detection of newly diagnosed MM and relapsed patients between the compared methods. 18F- FDG PET/ CT performed better than 99mTc-MIBI scintigraphy in the detection of focal lesions ($p < 0.039$), whereas 99mTc- MIBI scintigraphy was superior in the visualization of diff use disease ($p = 0.042$). 18F- FDG PET/ CT visualised signifi cantly more focal lesions than 99mTc- MIBI scintigraphy ($p = 0.002$), both generally in the cohort and when comparing the number of focal lesions per patient. Both the imaging modalities singly or in combination infl uenced the subsequent clinical management in 17% of patients. In our study, 18F- FDG PET/ CT predicted asymptomatic MM and MGUS transformatio ninto more aggressive forms with the necessity to start therapy more often than 99mTc- MIBI scintigraphy. *Conclusion.* 18F- FDG PET/ CT appeared to be a better imaging technique than 99mTc- MIBI scintigraphy in the detection of focal lesions in patients with symptomatic MM.99mTc- MIBI was superior in the visualization of diff use disease. On the other hand, despite its limited capacity in detecting focal lesions, 99mTc- MIBI scintigraphy still remains the most rapid and inexpensive technique for whole- body evaluation and may be an alternative option when a PET/ CT facility is not available.

Background. We know the changes in bone remodeling markers and cytokines related to bone disease in Multiple Myeloma (MM) patients treated with different drugs (chemotherapy, Bortezomib, Lenalidomide,..), but so far this subject is not studied in smoldering MM (sMM) patients. *Aims.* To analyze sequential changes of serum bone parameters in sMM at high risk of progression treated with Lenalidomide and Dexamethasone. *Material and Methods.* A phase III trial has been conducted by the Spanish Myeloma Group (GEM), in which sMM patients at high-risk of progression were randomized to receive Len-dex (9 cycles) as induction followed by a maintenance phase with Len alone vs. no treatment in order to evaluate whether the early treatment prolongs the time to progression (TTP) to symptomatic disease. In the serum of this patients, we analyzed one bone resorption marker (C-Terminal telopeptide (Ctx)), one bone formation marker (bone alkaline phosphatase (bAP)) and some cytokines related to bone disease pathogenesis in MM (Macrophage inflammatory protein 1-alpha (MIP-1alpha), sRANKL, osteoprotegerin (OPG) and DKK1) before the start of treatment, after 3 and 9 cycles. *Results.* We analyzed these parameters in 33 patients in the treatment group who achieved at least partial remission, (20 of them underwent sequential analysis of the parameters above. The only two parameters that showed significant sequential changes in this subset of patients were DKK1 and OPG. In the case of DKK1, was a significant decrease of the same after 3 months of treatment (mean ± SD: 35.46 ± 26.9 (at baseline) to 20.80 ± 13.21 (after 3 cycles) ($p = 0.007$)), which stabilized after 9 cycles (22.17 ± 13.06). The OPG showed late decrease (6.28 ± 3.07 (at baseline) to 5.10 ± 2.37 (after 9 cycles) ($p = 0.013$)). *Summary.* The decrease in DKK1 has been described in patients with MM. It has been postulated to be due to the reduction of malignant plasma cells, which would also explain the decline in our patients after 3 cycles of treatment. The stabilization of DKK1 levels after 9 cycles could be explained because in patients with low tumor mass, tumor control could be done especially in the first cycles. The OPG is produced by osteoblasts and mesenchymal cells, so the late fall of OPG observed in our study would imply a decrease in the synthesis and osteoblastic activity, which could be due to the action of Dexamethasone.

Granted by Celgene Laboratories.

0312

NOVEL AGENTS ARE BENEFICIAL FOR REAL LIFE PATIENTS WITH MULTIPLE MYELOMA NOT ELIGIBLE FOR HIGH DOSE TREATMENT

J Liwing,[1] K Uttervall,[2] P Näsman,[3] J Aschan,[1] J Andreasson,[4] A Gruber,[2] H Nahi[2]

[1]*Janssen AB, Sollentuna, Sweden*
[2]*Karolinska, Stockholm, Sweden*
[3]*Center for Safety Research, KTH, Stockholm, Sweden*
[4]*Södersjukhuset, Stockholm, Sweden*

*Background.*High dose treatment (HDT) in Multiple Myeloma (MM) has been shown to be superior to standard chemotherapy. However, a large amount of patients are not eligible for HDT. Evaluating real life outcome in those patients is important to understand prognostic factors. *Aim.* Evaluate real life responses, time to progression (TTP), time to next therapy (TTNT) and overall survival (OS) and prognostic power of patient variables in real life non-HDT patients with MM. *Methods.* All non-HDT patients, n=269, diagnosed with MM between Jan 2000 and Jul 2010 at Karolinska Huddinge and Jan 2005 and Jul 2010 at Karolinska Solna were included. Near complete response (nCR) was defined as an immeasurable M-protein by standard electrophoresis. Very good partial response (VGPR), partial response (PR), no response (NR) and TTP were defined according to IMW criteria. Standard statistical methods were used. *Results.* The median age was 72 years and 51% male. Baseline median creatinine was 98 µmol/L, albumin 33 g/L, hemoglobin 110 g/L and β2-microglobulin 3.8 mg/l. The median number of treatment lines was 2. 58% of the patients were given at least 2 treatment lines and only 34% 3 or more. The response distribution nCR/VGPR/PR/NR was 15/16/29/40 in 1st line, 13/9/23/55 in 2nd line. nCR in the 1st line implied a 43% probability to receive a ≥VGPR and 26% probability to receive an nCR in 2nd line. NR in the 1st line implied a 58% probability to receive a NR in the 2nd line. Logistic regression analysis shows that the patients receiving novel agents (Bortezomib, Lenalidomide, Thalidomide) in 1st line had a higher probability of achieving nCR. Baseline creatinine values, β2-microglobulin and most likely also albumin and hemoglobin, seem to be of importance for the response. The median TTP/TTNT was 248/301 days in the 1st line 176/187 in 2nd line and 180/210 in 3rd line. There was a significant trend of increasing TTP/TTNT in 1st line depending on the increased depth of the response with TTP/TTNT for nCR of 423/481 days, VGPR 289/376 days, PR 269/376 days and NR 190/176. Kaplan-Mayer analysis shows that the use of novel agents in 1st line predicted a longer TTP. Median OS was 3.6 years 95% CI [2.9;4.2] with 44% censored. The median OS for patients with 1st line best response nCR was 4.9 years, VGPR 3.9 years, PR 4.0 years and NR 1.9 years. There is a correlation between TTP in 1st line and increased OS. Kaplan-Mayer analysis shows that use of novel agents in the 1st line predicted a longer OS, median 5.1 years vs. 2.8 years. Baseline patient variables that showed to have significant importance for OS were creatinine, albumin, hemoglobin and β2-microglobulin. *Summary.* Patients receiving 2nd and 3rd line treatment were declining rapidly. Receiving a nCR in 1st line seems to be very important. Receiving a VGPR or PR seems to give similar results, less good than nCR but better than NR. Variables of importance are creatinine, albumin and hemoglobin. The use of novel agents improves response, TTP and OS.

0313

A COMPARISON OF REDUCED-INTENSITY CONDITIONING FOR ALLOGRAFTING (RICT) FOLLOWING AUTOGRAFTING (ASCT) VERSUS DOUBLE AUTOGRAFTING FOR NEWLY MULTIPLE MYELOMA (MM) PATIENTS. TEN YEARS EXPERIENCE

A Carella, G Catania, G Pica, G Beltrami, M Spriano

Azienda Ospedaliera Universitaria San Martino, Genoa, Italy

Background. Multiple Myeloma (MM) is the most frequent indication for autografting (ASCT). ASCT represents the most effective palliation for these patients. Even the double ASCT where there is demonstrated good long-term control in a minority of patients do not appear to result in cure of disease. Myeloablative AlloSCT is penalized by excessive transplant-related mortality (TRM) and toxicity. The introduction of reduced-intensity conditioning for allografting (RICT) has renewed interest in the use of AlloSCT for MM. *Aims.* Recent studies have reported encouraging results with tandem ASCT followed shortly thereafter by RICT in MM patients as compared to ASCT or myeloablative AlloSCT alone. Here we present an update at 10 years of the results

achieved in our Unit in patients receiving double ASCT compared to patients receiving tandem ASCT/RICT. *Methods.* We enrolled 132 consecutive patients 65 years of age or younger with stage II or III myeloma. One hundred seven patients had siblings and 93 patients and their siblings underwent HLA typing. Thirty-four of them had an HLA-identical sibling. All patients were initially treated with induction chemotherapy consisting of 3-4 courses of VAD regimen or modifications of VAD regimen. Soon after, peripheral blood stem cells (PBSC) were collected after 3-4 gr of cyclophosphamide per square meter of body surface are. G-CSF was given 4-5 days after chemotherapy. Daily aphereses was continued until at least >3x10^6 CD34 cells/kg were collected. After the first ASCT, patients who had an available HLA-identical sibling donor were offered RICT. Patients without an HLA-identical sibling donor underwent a second ASCT. The conditioning regimen of ASCT-1 and ASCT-2 consisted of melphalan 200 mg/m^2 infused over 30 minutes. The RICT consisted of fludarabine 30 mg/m^2 daily for 3 days and TBI (2 Gy or melphalan 70 mg/m^2). Graft-versus-host prophylaxis consisted of cyclosporine A and short-course methotrexate. *Results.* The rate of CR was significantly higher in RICT arm (RICT: 54,1%; ASCT: 28,5%). At December 2010 9 (37,5%) of 24 patients who received RICT and 4 (11,1%) of 35 patients who received double ASCT were in continuous CR after a median of 57 months (range, 14-88 months) and 56 months (range, 28-70 months), respectively. Thirteen (54,1%) patients in the ASCT/RICT group and 12 (34,2%) in the double ASCT were alive at a median of 104 months (range, 45-124 months) and 65 months, respectively. The cumulative incidence rate of acute and chronic GVHD after RICT was 41% and 54%. In the RICT arm, 12 patients died of: extensive chronic GVHD (4 patients), progressive disease, (5 patients) and cGVHD and infections (3 patients). At December 2010, 13 patients in RICT and 12 patients in double ASCT are alive after a median of 104 mo. (range, 45-124) and 62 mo. (range, 20-118), respectively. *Conclusions.* this update retrospective analyses suggests that ASCT/RICT may be able to reduce the incidence of disease progression.

0314

A PHASE IB STUDY OF ORAL PANOBINOSTAT PLUS INTRAVENOUS BORTEZOMIB IN RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS AT THE EXPANSION PHASE

J San Miguel,[1] P Richardson,[2] O Sezer,[3] A Günther,[4] D Siegel,[5] J Bladé,[6] R LeBlanc,[7] H Sutherland,[8] MV Mateos,[1] M Gramatzki,[4] K Hazell,[9] BR Bengoudifa,[9] P Bourquelot,[9] K Anderson[2]

Background. Panobinostat is an oral pan-deacetylase inhibitor (pan-DACi) that increases acetylation of proteins involved in multiple oncogenic pathways. In preclinical studies, panobinostat has demonstrated synergistic activity in combination with bortezomib which may occur through inhibition of the aggresome and proteasome pathways causing an accumulation of intracellular misfolded cytotoxic proteins leading to multiple myeloma (MM) cell apoptosis. *Aims.* This phase Ib study sought to identify the maximum tolerated dose (MTD) of the combination of panobinostat and bortezomib in patients with relapsed or relapsed and refractory MM. Safety and efficacy was further evaluated in an expansion phase using a modified dosing schedule of panobinostat at the MTD of the combination. *Methods.* This study completed enrollment (N = 62) in December 2010 with 47 patients in the dose escalation phase and 15 patients in the dose expansion phase. In the dose escalation phase, panobinostat was administered orally thrice weekly in combination with bortezomib (intravenous, days 1, 4, 8, 11) in 21-day cycles. Dexamethasone was to be added in case of suboptimal response from cycle 2 onwards (n = 16 patients). The MTD was determined to be 20 mg panobinostat plus 1.3 mg/m^2 bortezomib. In the expansion phase, 15 patients received the MTD of panobinostat plus bortezomib, with a modified panobinostat schedule (2 weeks on, 1 week off) and dexamethasone was introduced for all patients, from cycle 2 onwards allowing time for pharmacokinetic analysis of panobinostat and of bortezomib before as well as after introduction of dexamethasone. This dosing schedule was evaluated in an effort to increase tolerability and maximize therapy duration and is identical to the schedule in the ongoing phase II and III PANORAMA trials. *Results.* Patients in the dose-escalation phase received a median of 2 (1-10) prior therapies with 28 having received prior bortezomib and 15 refractory to last bortezomib based therapy (12 progressing under or within 60 days of this therapy). Responses of ≥ minor response (MR) were observed in 36/47 (76%) dose-escalation patients and 10/15 (66%) patients with bortezomib-refractory MM (Table 1). The ≥ partial response (PR) rate was 64% (30/47) and 40% (6/15) among patients with bortezomib-refractory MM. Response assessments are also available at this early cut-off date, for 12/15 patients in the dose-expansion phase with ≥ PR observed in 9/12 patients (75%) including 1/4 bortezomib-refractory patients. Safety data was available for all 62 patients and common grade 3/4 adverse events included thrombocytopenia (n = 47), neutropenia (n = 33), asthenia (n = 13), and anemia (n = 10), with no treatment-related mortality. *Summary/Conclusions.* The combination of panobinostat and bortezomib has a predictable and manageable safety profile with promising activity in advanced MM including in patients with bortezomib-refractory MM. Updated data from the dose-expansion phase will be presented.

Table 1.

Best Response by Cohort

Treatment Phase	Dose Escalation (n = 47, 15 bortezomib-refractory)												Dose Expansion (n = 15, 4 bortezomib-refractory)	
Cohort	1		2		3		4		5		6		7

NF-E2 OVER-EXPRESSION ALTERS ERYTHROCYTE MEMBRANE STRUCTURE LEADING TO PREMATURE DESTRUCTION IN A TRANSGENIC MOUSE MODEL

M Gothwal, A Gründer, H Pahl

University Hospital Freiburg, Freiburg, Germany

Background. We have previously demonstrated that the transcription factor nuclear factor erythroid-2 (NF-E2) is overexpressed in MPN patients, irrespective of the presence of the JAK2V617F mutation.[1,2] In order to investigate the role of NF-E2 overexpression in the pathophysiology of MPN, we have engineered a transgenic mouse model overexpressing NF-E2 specifically in haematopoietic cells. While this model recapitulates many features of MPN including thrombocytosis, leucocytosis, characteristic BM morphology, and transformation to acute leukaemia,[3,4] surprisingly the mice do not display polycythemia. However, spleens of NF-E2 tg mice show a large increase in iron containing histiocytes, indicating increased red cell destruction. NF-E2 has previously been implicated in the transcriptional regulation of several erythrocyte membrane structural genes, as well as in globin gene expression.[5,6] We therefore tested the hypothesis that NF-E2 overexpression leads to an alteration in erythrocyte membrane structure and physiology, promoting destruction of RBCs in our tg mouse model. *Aims.* To elucidate the effect of NF-E2 overexpression on the RBC phenotype in a novel mouse model of MPN. *Methods.* Two independent transgenic mouse lines were generated which overexpress human NF-E2 under the control of the hematopoietic specific vav-promoter.[3,7] Expression of RBC structural genes as well as of α and β globin was quantified by q-RT-PCR from mouse bone marrow of NF-E2 tg mice and wt littermates. Osmotic fragility assays were performed as previously described.[8] *Results.* NF-E2 tg mice showed a significantly increased expression of several structural erythroid membrane components: Erythroid Protein band 4.1 (Epb4.1, p=0.002 for wt vs tg, n≥15), Alpha Spectrin (p=0.009) and Band3 (Slc4a1, Solute carrier family 4 anion exchanger 1, p=0.03). In contrast, four other structural genes tested (Ankyrin-1, Beta-Adducin, Erythroid Protein band 4.2 and Dematin) were not significantly different between wt and tg animals. The expression of both α and β globin was elevated in the bone marrow of transgenic animals (p=0.03 and p=0.02, respectively). Because β globin expression was increased to a greater extent than α globin, the α/β globin ratio in tg animals fell to 0.69 compared to 0.91 in wt littermates (p=0.006). In addition, the osmotic fragility of NF-E2 tg RBCs was reduced (0.45% NaCl, p=0.01 and 0.5% NaCl, p=0.02), indicating increased rigidity. *Summary/Conclusions.* In NF-E2 tg mice abnormally increased expression of erythrocyte structural protein genes renders erythrocytes more rigid and, by inference, less flexible. We therefore propose that these abnormal RBCs are subject to premature phagocytosis in the spleen. In addition, the disbalance between a and b globin expression in erythrocytes from NF-E2 overexpressiong tg mice contributes to their early destruction. To substantiate this conclusion, *in vivo* RBC turnover measurements, which are currently ongoing, will be presented.

BONE MARROW STROMA-MEDIATED PARACINE INHIBITION OF RUXOLITINIB (INCB018424)-INDUCED APOPTOSIS OF JAK2V617F MUTATED CELLS: PROTECTIVE EFFECT OF MPN PATIENT-DRIVED BUT NOT HEALTHY DONNOR-DERIVED STROMA

T Manshouri,[1] Z Estrov,[1] L Knez,[1] C Creighton,[2] H Kantarjian,[1] S Verstovsek[1]

Myeloproliferative neoplasms (MPNs) are a class of stem cell-derived hematologic malignancies, characterized by an expansion of one or more myeloid lineage with resulting bone marrow (BM) hypercellularity. Because BM cells of most patients with MPN carry a gain-of-function mutation in the Janus kinase-2 gene (JAK2V617F) that contributes to the pathophysiology of the disease, several inhibitors of JAK2 have been developed and their activity has been tested in clinical trials. We have recently reported that Ruxolitinib (INCB018424), an oral inhibitor of JAK1 and JAK2, induced marked and durable clinical benefits in patients with primary myelofibrosis (Verstovesk S *et al*. N Engl J Med 12:1117, 2010). Ruxolitinib induced a dose-dependent suppression of phosphorylated signal transducer and activator of transcription 3 (STAT3), a marker of JAK signaling, however only a mean maximal suppression of 13% from baseline of the JAK2V617F allele burden was seen after 12 cycles of therapy. Therefore, we hypothesized that extracellular signals negate the effects of JAK2 inhibitors. To test our hypothesis, we designed co-culture experiments to test the interaction between the JAK2V617F mutated cells and their BM stromal microenvironment. Ruxolitinib inhibited the proliferation and induced marked apoptosis of the human JAK2V617F mutated SET2 (IC50 56nM) and UKE-1 (IC50 329nM), but not of the JAK2-wild type human mast MHC1.1 and MHC1.2 cells. However, the anti-proliferative effect of ruxolitinib was markedly attenuated when JAK2V617F mutated cells were co-cultured with either primary patient or immortalized patient derived human BM mesenchymal stromal cells (MSC). Specifically, co-culturing JAK2V617F-positive cells with TM-R1 MSC from the myelofibrosis patient hampered the anti-proliferative and pro-apoptotic effect of ruxolitinib and inhibited its ability to dephosphorylate STAT3 and STAT5. However when JAK2V617F-positive cells were co-cultured with MSC from healthy donors the protective effect was not observed. Subsequent experiment demonstrated that protective effect by TM-R1 MSC was due to a paracrine secretion of cytokines, since the effect was observed even when JAK2V617F-positive cells were cultured with MSC separated by micropore filters. Cytokine profile of supernatants from co-cultures of TM-R1 MSC with JAK2V617F-positive cells differed from those of supernatants from co-cultures of normal MSC with JAK2V617F -positive cells (with or without ruxolitinib). Interleukin (IL)-6 was elevated in both co-cultures whereas basic fibroblast growth factor (b-FGF-basic p= 1.05E-17) and CXCL10/IP10 (p= 2.19E-4) were significantly lower in normal MSC/JAK2V617F supernatants. Using neutralizing antibodies against IL6, b-FGF, and CXCL10/IP10, or using shRNA to down-regulate their mRNAs, we blocked the protective effect of TM-R1 MSC. Our results suggest that marrow stroma secreted cytokines play a significant role in protecting JAK2V617F-positive cells from JAK2 inhibitor therapy, thus highlighting the role of the microenvironment not only in the pathogenesis of MPNs but also in the resistance to JAK2-directed therapies.

Background. Recent reports have shown complete or major molecular remission in patients with polycythemia vera after long-term treatment with the immunomodulating agent, interferon-alpha2 (IFN-alpha2). Accordingly, there are reasons to believe that the immune system is a key player in eradicating the JAK2-mutated clone in these patients. Foxp3+ regulatory T cells play a pivotal role in maintaining immune homeostasis and importantly preventing immune reactivity to self antigens. However, their suppressive activity can compromise an

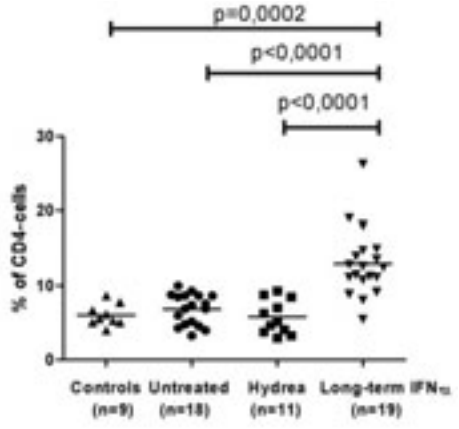

Figure 1. Frequency of CD25+Foxp3+-cells in CMPN patients.

effective anti-tumor immune response and high frequencies of regulatory T cells (Treg) in peripheral blood have been reported in both hematological and solid cancers. Foxp3 is the most specific marker of a regulatory phenotype, but cytokine-producing non-suppressive effector T cells (Teff) can transiently express Foxp3 upon activation. *Aims.* We have analyzed the frequency, phenotype and function of circulating CD4+CD25+Foxp3+ T cells in patients with chronic myeloproliferative neoplasms (CMPNs) treated with IFN-alpha2, hydroxyurea or untreated patients. *Methods.* 48 patients (19 women, 29 men; median-age 61, range 43-83 years) with a diagnosis of PV (n=31), ET(n=13) or PMF(n=4) according to the World Health Organisation (WHO) classification were included in this study. 18 patients were untreated, 11 patients treated with hydroxyurea and 19 patients were treated with pegylated IFN-alpha2 long term (>1 year; mean 40 months). Nine healthy subjects were used as controls (6 women, 3 men; median-age 63 years). Peripheral blood mononuclear cells were isolated and frozen using standard procedures. Flowcytometric analysis was performed after surface and intracellular staining with the following antibodies: APC-Cy7 anti-CD3, PerCP anti-CD4 FITC anti-CD127, APC anti-CD25, PE-Cy7 anti-CD45RA and PE anti-Foxp3. *Results.* We have analyzed the frequency of circulating CD25+Foxp3+ T cells in the CD4+lymphoid compartment of patients with CMPNs. Surprisingly, we found that patients on long-term IFN-alpha treatment had a marked increase in circulating CD4+CD25+Foxp3+ T cells (12,98%;CI 10,78-15,18%) when compared to healthy subjects (6,06%;CI 4,93-7,19%), untreated patients (6,87%;CI 5,84-7,37%) or patients treated with hydroxyurea (5,83%; CI 4,28-7,37%), P<0,0001. Results are given as mean with 95% confidence intervals. When distinguishing phenotypically between activated Tregs and Teff using CD45RA and Foxp3 expression, we found a significant expansion of both subpopulations in patients treated with IFN-alpha compared to other patient categories or healthy subjects (Tregs: P<0,0001; Teff: P=0,001). *Summary.* To date, IFN-alpha is the only therapy which is able to induce minimal residual disease with low-burden JAK2 V617F. We believe that immunological mechanisms are key factors in eradicating JAK2-mutated cells during IFN-alpha treatment. For the first time, we have shown a marked CD4+ T cell response in these patients, and further studies are ongoing to elucidate immunological responses triggered by IFN-alpha. In perspective, we hope to bring more focus on the potential benefit of immunotherapy as frontline treatment in JAK2-positive CMPNs.

Background. Little is known about Mesenchymal Stem Cells (MSC) derived from the bone marrow (BM) of patients with chronic myeloproliferative neoplasms (MPNs). It has been shown that MSCs from MPN patients with JAK2V617F positive hematopoiesis never harbor the mutation and their immunophenotype is similar to that of MSCs derived from healthy donors (HD). Previous data from our group, obtained by array-comparative genomic hybridization, have documented that recurrent cytogenetic abnormalities in *in vitro* expanded MSCs from MPN patients are present only at late passages (P). However, the possibility that MSCs from MPN patients can be clonal has been never thoroughly investigated. *Aims.* We have studied clonality and loss of heterozygosity (LOH) in *ex vivo* expanded BM-derived MSCs of MPN patients both at early and at late P. The study was approved by the institutional review board of the IRCCS Policlinico S. Matteo Foundation, and all patients gave written informed consent. *Methods.* Nine patients (3 males and 6 females) were studied: 6 patients were affected from Primary Myelofibrosis (PMF), 2 from Essential Thrombocythemia (ET), 1 from Polycthemia Vera (PV); 8 healthy, age matched individuals served as controls. MSCs were isolated and expanded *ex vivo*, according to standard protocols from BM biopsies. DNA was extracted by commercial kit from MSCs both at early (P2-P3), intermediate (P4-P8) and late passages (> P9). Clonality was assessed by the human androgen receptor assay (HUMARA) and LOH was investigated by PCR-based analysis of selected polymorphic microsatellite markers. Results. Four out of 6 female patients were heterozygous at the locus for HUMARA. Of them, 1 (a JAK2V617F positive ET) showed a skewed pattern of X-chromosome inactivation in MSCs at P2, indicating the presence of a clonal population of MSCs at the beginning of the culture. A second JAK2V617F positive ET patient had skewed X-chromosome inactivation at P12. Assessment of X-chromosome inactivation of MSCs at P3 of this patient is ongoing. The remaining 2 patients (both affected from PMF) showed a polyclonal pattern of X-chromosome inactivation. Microsatellite analysis was performed in 2 male patients (1 PV and 1 PMF, both with JAK2V617F positive hematopoiesis): 10% of MSC showed allelic loss at P3; the proportion of cells with LOH progressively increased at P7 and P13, reaching 90% and 100%, respectively. As expected, in all cases JAK2V617F mutation was not detectable and telomerase activity was found at low levels, as in HD-MSCs. Neither skewed X-chromosome inactivation nor LOH were observed in HD-MSCs both at early and at late P. Conclusion. Taken together, our data indicate that a clonal population of MSCs with genetic abnormalities is detectable in *in vitro* culture already at early passages, suggesting that small clones of mutated MSCs can expand in the bone marrow of MPN patients. Further studies are warranted to assess whether these MSCs can contribute to the pathogenesis of MPNs. (486/500).

Background. Polycythemia vera (PV) is a clonal disorder resulting in a multipotent hematopoietic progenitor cell that causes the accumulation of morphologically normal red cells, white cells, platelets, and their progenitors in the absence of a definable stimulus. Until now many aspects of physiopathology remains unclear and no effective treatment for curing or prevention of disease progress exists. Deregulation of apoptotic machinery might have a role in PV physiopathology. Entirely understanding of apoptotic machinery and its regulation by potential modulation of the microRNA in PV patients cells might unveil novel targets, which may be translated into novel therapies. *Aims.* To quantify the miR-26a, miR21, miR29c, miR-130b and let-7d, expression in Polycythemia Vera (PV) patients and to correlate the data with the expression of target genes. *Subjects and Methods.* 13 PV patients (6 males and 7 females with a mean age of 58.46y) and 13 healthy subjects (6 males and 7 females, m=57.6y). Peripheral leukocytes were obtained by Haes-Steril method, total RNA was extracted according to Trizol® method and High Capacity® Kit was used to synthesize cDNA. Quantification of apoptomirs and its target genes was performed by real time PCR and results were given as $2^{-\Delta\Delta Ct}$. Statistical

analyses were performed by Mann-Whitney tests. *Results.* miR26a, miR21, miR29c, miR130b and let7-d levels were increased in PV (median=4.01; 7.961; 2.135; 2.52 and 8.47; respectively) patients in comparison to controls (m=1.33, 1.19, 1.292; 1.05; 1.64) (p=0.0005; p<0.0001; p=0.0017; p=0.0177 and p<0,0001; respectively). In adition we detected the deregulated expression of *mcl*-1 (m= 2.80), bcl-2 (m= 0.10) anti-apoptotic and *bax* pro-apoptotic (m= 0.28) when compared to controls (m= 0,855; m=1.32 and m= 1.422, respectively) (p= 0.0076, p=0.002 and p=0.0052; respectively). These data suggest that *bcl*-2 expression may be regulated by the miR 21. *Conclusions.* The results indicate that peripheral blood cells patients with polycythemia vera have some microRNA signatures and genes expression distinct from those reported in literature and suggests the potential new targets and pathways that might be modulating apoptosis process and acting in physiopathology of PV.

Background. The JAK2V617F mutation, occuring in variable frequency in 50% of Primary Myelofibrosis (PMF) patients, has been used as a prognostic marker for several years. Even though JAK2V617F has been detected in terminally differentiated or CD34+ circulating cells in PMF patient peripheral blood, its contribution to the outgrowth of the malignant clone has not been elucidated yet. Characterization of JAK2V617F+ circulating primitive stem cells may shed light on our understanding of PMF pathophysiology. *Aim.* To identify the prime stem cell compartment responsible for PMF development, by investigating the clonogenic potential of CD133+ cell populations derived from peripheral blood of PMF patients and by assessing their JAK2V617 mutational burden variability. *Method.* CD133+ peripheral blood circulating cells were isolated from JAK2V617F+ PMF patients and cultured in liquid media supplemented to induce endothelial and hematopoietic differentiation. CD133+ expanded cells were also assessed for clonogenic potential in semisolid media enriched with various growth factors. Outgrown colonies were morphologically characterized, isolated and tested for JAK2V617F allele burden by real time PCR. *Results.* Purified CD133+/CD45+ stem cells derived from PMF patient peripheral blood were positive for the JAK2V617F mutation and expanded in suspension cultures supplemented with differentiation-inducing growth factors. Differentiation induced cultures of isolated CD133+ exhibited two different phenotypes. CD133+ cells expanded under presence of VEGF or G-CSF were found positive when immunostained for endothelial or hematopoietic lineage markers, respectively. RT-PCR analysis for JAK2V617F allele burden in isolated colonies outgrown from individual CD133+ cells indicated variability within progeny that is, differentiated into endothelial or diverge hematopoietic lineages. JAK2V617F allele burden analysis of various hematopoietic and endothelial colonies indicated heterozygotic mutational status to occur mostly in the endothelial and macrophage colonies, while homozygotic in more committed hematopoietic progenitors. *Conclusions.* Our data suggest that: (i) JAK2V617F mutation can occur early in the stem cell compartment of PMF patients contributing to extended genetic instability of one or more malignant clones. (ii) These JAK2V617F+ / CD133+ malignant clones are likely to derive from bipotent cells in the stem cell compartment that are able to differentiate into both hematopoietic and endothelial lineages. *In vitro* evidence indicates that PMF develops from acquired mutations of a stem cell population with hemangioblastic potential.

[3]*Chang Gung Memorial Hospital, Taipei, Taiwan*

Background. RUNX1 is an essential transcription factor for normal hematopoiesis. We have observed a high mutation frequency (37%) of RUNX1 gene in chronic myelomonocytic leukemia (CMML) whereas the mutation status did not correlate with the clinicohematological features (Leukemia, 2009, 23: 1426-1431). The implication of biological functions of RUNX1 mutants and the disease progression remains to be determined. *Aims.* We aimed to study the biological effects of the RUNX1 mutants and to correlate the functions of mutants to sAML progression and survival. *Methods.* Bone marrow samples from 93 patients with CMML were analyzed for RUNX1 mutations. Mutational analysis of RUNX1 was performed by RT-PCR amplification of whole coding region of RUNX1 followed by sequencing of the PCR products. Each mutation was reconfirmed by PCR with alternative primers. Expression plasmids of wild-type RUNX1 and the mutants were constructed and applied for functional studies of the mutants. Immunoprecipitation followed by Western blotting was performed to confirm the interaction between RUNX1 mutants and CBFβ. Transactivation activities of RUNX1 mutants were examined by luciferase reporter assay. Mutation frequency of RUNX1 and transactivity of the RUNX1 mutants were correlated to sAML transformation of the patients. *Results.* Thirty-four mutations of RUNX1 were identified in 32 patients. Six RUNX1 mutants were homozygous. Seventeen of 32 RUNX1 mutation-positive patients (53%) progressed to sAML compared with 21 of 61 RUNX1 mutation-negative patients (34%) (P=0.081). There was no significant difference in the overall survival between RUNX1 mutation-positive and mutation-negative patients (median survival 11.5 and 13.4 months, respectively, P=0.180). Functional study revealed that RUNX1 mutants of C72W, S114L and P398L which retained more than 70% transactivities of wild-type RUNX1 were designated as high activity mutants; S195fsX209, G324fsX565, M341fsX569, S268fsX578, P332fsX573 and F369fsX572 which exhibited only 40% to 70% transactivities were designated as the medium activity mutants; H78Q, W79R, R80L, N109K, R139G, R177X, R293X, L71fsX94 and I150fsX185 which exhibited less than 40% transactivities were designated as low activity mutants. Patients with lower transactivation activity mutants had a higher risk of sAML transformation (P=0.003) and a shorter time to sAML transformation (P=0.044) whereas the transactivity did not influence the overall survival (P=0.722). *Conclusions.* Our results showed that RUNX1 activity was a determinant factor for the progression of CMML to sAML; lower transactivity mutants were associated with a higher risk and rapid progression to sAML.

Background. Megakaryopoiesis is a multiple stage differentiation process under the control of thrombopoietin (TPO). Megakaryocytic precursors proliferate, switch to polyploidization and stop DNA replication before terminal differentiation leading to platelet shedding. We reported that UT7 cells genetically modified to over-express the TPO receptor MPL (UT7-MPL) respond to TPO by inducing senescence and that a similar process occurs in normal megakaryocytes. In contrast, megakaryocytes from primary myelofibrosis (PMF) patients lack these senescence markers, suggesting that an escape from the senescence-like signaling pathways could participate in the abnormal megakaryocytic proliferation observed in myeloproliferative neoplasms (MPNs). *Aims.* The aim of our work was to study the involvement of MPL

and/or the associated protein kinase JAK2 expression deregulation in this escape. *Materials and Methods.* We selected 5 UT7-MPL cell clones for their ability to escape from TPO-induced cellular senescence (ie these clones proliferate in presence of TPO). To study megakaryopoiesis *in vitro*, CD34+ cells were cultured in serum-free medium supplemented with TPO. Platelets were isolated from normal, essential thrombocythemia (ET) and PMF patients. The mRNA and protein expression levels of MPL and JAK2 were examined in the different cell lines, primary CD34+ cells and platelets by TaqMan and Western Blot, respectively. Cell signaling was studied by Western Blot. *Results and Discussion.* TPO-induced signaling was stronger in UT7-MPL cells compared to the 5 derived clones, as determined by Western blotting for the phosphorylated forms of various key TPO/MPL downstream molecules. This correlated with MPL and/or JAK2 expression, decreased in the different clones. Accordingly, we over-expressed either MPL or JAK2 in these clones, and recovered the TPO-induced proliferation arrest and expression of the senescence markers. Thus, cellular response to TPO depends on the MPL/JAK2 protein expression levels. A weak signaling is proliferative and a strong signaling induces a growth arrest and cellular senescence. Moreover, we observed a progressive and continuous increase of MPL and JAK2 protein expressions during normal megakaryopoiesis. We then hypothesized that megakaryopoiesis could be regulated by MPL and JAK2 expression levels, allowing the transition from a weak TPO-induced proliferative signal in immature cells expressing few MPL/JAK2 to a strong signaling (due to a high MPL/JAK2 expression in more engaged cells) inducing a proliferation arrest and megakaryocytic maturation. Interestingly, MPL and JAK2 expressions were lower in platelets from ET and PMF patients compared to normal platelets confirming previous data on MPL level in MPN. Based on these results, we propose that the decrease in MPL and/or JAK2 protein expression may be involved in MPN abnormal megakaryocytic proliferation, by extending the proliferative signal in immature cells, resulting in the amplification of the progenitor cell compartment. This protein expression decrease could be a shared consequence between different events leading to a myeloproliferation. *Conclusion.* We show that MPL and JAK2 protein expressions are decreased in MPNs megakaryocytic cells and hypothesize that this down-regulation could be involved in the abnormal cellular proliferation characterizing MPNs.

Background. The germline constitutive JAK2 haplotype, called GGCC or 46/1, is a susceptibility factor for BCR-ABL negative classic myeloproliferative neoplasms (MPNs). The mechanisms linking this haplotype and the acquired MPN remains unclear. Splanchnic vein thrombosis (SVT) is variably associated with MPNs, occurring either during the course of well defined MPNs, or as the event leading to the diagnosis of MPN. *Aim.* In this study we sought to clarify the potential role of 46/1 haplotype in the etiology of SVT. The study was approved by the institutional review board of the IRCCS Policlinico S. Matteo Foundation, and all patients gave written consent. *Methods.* Screening for the 46/1 haplotype was performed by assessing the tag SNP rs12343867 that is in complete linkage disequilibrium with this haplotype. This SNP consists in a T to C shift, with the C allele associated with the 46/1 haplotype. Analysis was performed both by a PCR reaction followed by restriction-enzyme digestion and using a commercially available RT-PCR SNP genotyping assay. The chi-square or Fisher's exact test were used in the statistical analysis; P values <0.05 were considered significant. Results. One-hundred-sixty-four subjects with SVT were studied. In 56 of them (11 with a Budd-Chiari syndrome and 45 with portal vein thrombosis) a diagnosis of MPN was excluded. One-hundred-eight patients (32 ET, 29 fibrotic and 26 pre-fibrotic PMF, 21 unclassified MPNs) received a diagnosis of MPN-associated SVT. Fifty-six healthy subjects served as controls (CTRLs). Patients with SVT but no MPN had a C allele frequency not different from that of CTRLs (0.241 vs 0.267, p=0.6453), and the genotypic frequencies reflected this similarity. SVT-associated MPN patients as a whole had a C allele frequency significantly increased compared to CTRLs (0.440 vs 0.267, p=0.0023). This difference was principally due to an excess in V617F positive cases (p=0.0001), whereas the 46/1 haplotype was not over-represented in V617F-negative cases vs CTRLs (p=0.847). Accordingly, the JAK2 mutated patients had the highest frequency of CC genotype. SVT-associated ET and PMF (prefibrotic and fibrotic type) showed a significant increase of C allele frequency compared to CTRLs, whereas SVT-associated unclassifiable MPNs did not (0.381, p=0.1720). Moreover, the 46/1 haplotype was overexpressed in JAK2V617F-negative patients with ET (frequency=0.363), and prefibrotic PMF (0.300) but not PMF-fibrotic type (0.187) or unclassifiable MPN (0.250). These differences, however, were not statistically significant, likely due to the small number of subjects considered. These latter results are in agreement with published data showing that patients with a proven JAK2V617F-negative MPN and Budd-Chiari syndrome showed increased frequency of the 46/1 haplotype. Conclusion. In summary, our observations exclude the hypothesis that the 46/1 haplotype confers susceptibility neither to SVT, nor to vein thrombosis. Rather, we suggest that the 46/1 haplotype confers susceptibility to JAK2 mutation positive MPNs presenting with SVT.

DIFFERENTIAL GENE EXPRESSION PROFILE RELATED TO LEUKOCYTOSIS IN JAK2 V617F POSITIVE POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

E Albizua,[1] M Gallardo,[2] S Barrio,[2] I Rapado,[2] A Jimenez,[2] R Ayala,[2] E Puigdecanet,[3] B Blanca Espinet,[3] L Florensa,,[3] C Besses,[4] J Martínez-López[2]

[4]*Hospital del Mar, Barcelona, Spain*

Background. Recognized risk factors to thrombosis in classic chronic BCR/ABL negative myeloproliferative neoplasms (MPN) are age at diagnosis (over sixty) and previous events of thrombosis. Recently, two additional risk factors seem to play a key role in pathogenesis of thrombosis. Leukocyte (white Blood cells, WBC) count -in addition to JAK2V617F point mutation status and allele burden- has been identified as a probable independent predictor of major thrombosis in both essential thrombocythemia (ET) and polycythemia vera (PV). However, whether leukocytosis should be simply considered a marker for vascular disease or whether elevated WBC levels actually contribute directly to causing such disorders is presently matter of many studies, to be corroborated by prospective studies as well as JAK2 V617F (De Stefano *et al.*, Am J Hematol. 2010). *Aims.* We aimed to analyze the differential gene expression profile of JAK2 V617F positive PV and ET, with and without leukocytosis (threshold, WBC>11 X109/L) before and after treatment with Hydroxyurea (HU). We hoped to identify underlying molecular alterations related with leukocytes, platelets activation and /or endothelium adhesion that may contribute to thrombosis. *Methods.* Twenty-one PV (10 with treatment, 11 at diagnosis), and 28 ET (16 with treatment, 12 at diagnosis) were included in the study. cDNA of granulocytes from venous peripheral blood was extracted. Low-density quantitative real time PCR array (LDA) was performed on selected genes from a previous microarray analysis (E Albizua *et al.*, Ann Hematol. 2011 Feb 18). Statistical analyses of data were performed using the non-parametric Wilcoxon analysis. Statistical significance was considered when P value was under 0.05. *Results.* Thirty genes were significantly over-expressed in ET and PV with leukocytosis at diagnosis compared to those with normal leukocytes. Among them are to be outlined genes involved in leukocytes activation, and endothelium adhesion - CD44 (P=0.016) and SELL (P=0.009)-,other genes playing key roles as transcription factors - LYN, (P=0.04) -, in MAP kinase (MAPK) signaling pathways - RAF1(P=0.01) MAP2K1 (P=0.031), MAPK14(P=0.009) -, in other proliferative pathways - JUN (P=0.013), IGF1R (P=0.004), - as tyrosine kinases - BTK (P=0.028) -, and in regulation of hematopoietic cell differentiation and development of lymphocytes - IKZF1(P=0.000). Interestingly, overexpression of these genes disappeared after treatment with HU. *Conclusions.* Neutrophil activation correlated with activation of both endothelial cells and the coagulation cascade is a well known phenomenon in ET and PV as well as that white cells contribute to the procoagulant response at sites of vascular injury (Bouchard *et al*. Curr Opin Hematol,2001; Falanga *et al.*, Blood 2000). Our results suggest an association between leukocytosis and a group of genes involved in activation of leucocytes, and endothelium adhesion, that could contribute to the underlying molecular mechanism to thrombosis in PV and ET. In addition, genes playing key role as transcription factors and in proliferative pathways are over-expressed in PV and ET with leukocytosis at diagnosis, that may participate to thrombosis as well.In addition, disappear-

ance of over-expression of these genes after treatment with HU could give additional molecular support to the antithrombotic effect of HU (Brun *et al.*, Pharmacogenomics J. 2003).

ASXL1 MUTATIONS IN PRIMARY AND SECONDARY MYELOFIBROSIS

C Ricci, O Spinelli, S Salmoiraghi, G Finazzi, A Carobbio, A Rambaldi

Ospedali Riuniti di Bergamo, Bergamo, Italy

Background. In patients with Myelofibrosis (MF), beyond the presence of the JAK2V617F mutation, additional genetic lesions have been recently identified, including ASXL1 truncating mutations, that might be relevant for the development of this disease. *Aims.* To elucidate the role of ASXL1 mutations in the molecular pathogenesis of primary MF (PMF), and their contribution to the disease progression from Polycythemia Vera (PV) and Essential Thrombocythemia (ET) to MF. *Methods.* We analyzed 43 PMF and 22 secondary MF patients (13 post-PV and 9 post-ET) by direct DNA sequencing of six amplicons encompassing ASXL1 exon 12 (~3 kb). For 10 PMF, paired DNA samples were screened at diagnosis and during follow-up. The same sequential study was performed in 6 PV and 5 ET before and after disease progression to MF. The DNA from 10 PV and 10 ET at diagnosis was also sequenced in parallel. *Results.* Overall, 19 distinct ASXL1 mutations (10 frameshift, 8 nonsense and 1 missense) were identified in 28/65 (43%) MF patients: 23/43 (53%) with PMF and 5/22 (23%) with secondary MF (3 post-PV and 2 post-ET). In contrast, ASXL1 mutations were rarely detectable at diagnosis in ET patients (0/10) and PV (only 1 out of 10). Notably, analysis of paired CD3+ T lymphocytes purified in parallel from the peripheral blood of 9 PMF and 5 secondary MF confirmed that all lesions were restricted to the neoplastic clone only. In PMF patients, ASXL1 mutations were identified at diagnosis in 18/36 (50%) cases and during the course of the disease in 11/16 (69%). In one patient two distinct ASXL1 mutations were detected at diagnosis, while in another case an additional aberration was acquired during the follow-up. Analysis of paired diagnosis/follow-up samples in PMF documented the presence of the same ASXL1 mutation at diagnosis and during follow-up in 6 out of 10 patients (60%); in one patient the mutation occurred during follow-up, while in three patients mutations were never detectable. No correlation was found between ASXL1 mutations and the presence of the JAK2V617F allele. In post-PV/ET MF, the analysis performed on paired samples collected during the course of the disease showed that ASXL1 mutations were subsequently acquired during the course of the disease in 3 out of 4 informative cases. *Conclusions.* ASXL1 mutations are frequently detectable in MF, albeit more commonly in primary compared to secondary cases, whereas they are rather uncommon in PV and ET at diagnosis. In secondary MF, ASXL1 mutations may possibly contribute to the molecular progression of the dis.

Background. PRV-1, a molecular marker for Myeloproliferative Neoplasms (MPN), is a cell surface receptor expressed in blood cells, which is involved in cell signaling proliferation process. Essential Thrombocythemia (ET) and Primary Myelofibrosis (PMF) are MPN characterized by accumulation of myeloid cells in peripheral blood and bone marrow hyperplasia. Apoptosis process deregulation may be linked to the cell accumulation and, therefore, to the MPN physiopathology. *Aims.* 1) To determine *PRV-1* gene expression in CD34$^+$ cells and leukocytes from ET and PMF patients; 2) To correlate these results with extrinsic apoptosis pathway related gene *c-flip*, *fas*, *fasL*, *dr4*, *dr5* and *TRAIL* expression and with JAK2V617F mutation allele burden. *Subjects and Methods.* This study analyzed CD34$^+$ cells and leukocytes from 22 ET patients (5 males and 17 females; mean age(ma)=58.4 years), 12 MF patients (9 males and 3 females; ma=61.6y) and 44 controls (20 males and 24 females; ma of 43.5 y) as control group. The JAK2V617F allele burden was determined by real time allelic discrimination PCR assay. Ficoll-Hypaque protocol and Miltenyi CD34 isolation kit were used to obtain bone marrow CD34$^+$ HSC whereas leukocytes were obtained by Haes-Steril method. Total RNA was extracted and cDNA synthesized by reverse transcription using High Capacity® Kit. Gene expression was quantified by real time PCR, the results were given as fold change ($2^{-\Delta\Delta Ct}$) and statistical analyses were performed by Mann-Whitney and Spearman tests. *Results.* There was no significant difference in *PRV-1* expression in CD34$^+$ cells from control, ET and PMF groups (p>0.05). However, *PRV-1* expression was increased in ET and MF leukocytes (median= 2.33 and 4.40, respectively) compared to control (m=0.91) (p=0.014; p=0.002, respectively). Regarding JAK2V617F mutation, *PRV-1* expression in leukocytes from ET and PMF patients and JAK2V617F allele burden showed a positive correlation (r=0.420; p=0.026; r=0.537, p=0.047, respectively). Considering that *TRAIL* expression was decreased in ET and PMF leukocyte (m=0.30, m=0.49) in comparison to control (m=1.6) (p=0.0004; p=0.029), it was interesting to emphasize that we found a negative correlation between *PRV-1* and *TRAIL* expression in ET leukocytes (r=-0.6228, p=0.001). *Conclusions. PRV-1* overexpression is associated with apoptosis related gene expression *TRAIL*, a relevant molecule in death receptor pathway and a potential therapeutic target in neoplasms. These results indicate that *TRAIL* deregulated expression and *PRV-1* overexpression may contribute to the myeloaccumulation and to the physiopathology of the Myeloproliferative Neoplasms.

[4]*University of Navarra, Pamplona, Spain*

Background. The JAK2/STAT5 signalling pathway transduces signals from many cytokines and growth factors, and promotes essential hematopoietic events such as proliferation, cell migration and apoptosis. This pathway is frequently altered in chronic myeloproliferative neoplasms (MPNs) with activating mutations in *JAK2*. However, one *JAK2* mutation (V617F) leads to the development of MPNs with distinct phenotypic features. Some explanations have been proposed to account for this fact (such as V617F allele burden, other mutations in *JAK2* or mutations in *TET2* and other genes), but none of them fully explains the phenotypic differences observed in this group of diseases. This suggests that there might be other genes transcriptionally regulated by STAT5 that could contribute to the phenotypic variability of chronic MPNs. *Methods.* We performed a genome-wide search for the presence of STAT5-binding sites in human promoters. Affymetrix Exon 1.0 Arrays (Affymetrix Inc, Santa Clara, CA) were used to search for genes differentially expressed after activation of the JAK2/STAT5 pathway in cell lines. We validated expression changes by qRT-PCR. Cell lines used: - M07e, a myeloid cell line in which the JAK2/STAT5 pathway can be induced by IL-3 and inhibited by a specific inhibitor (STAT5 inhibitor, Cat. No. 573108, Calbiochem, San Diego, CA, USA). - HEL, a human erythroleukemia cell line that harbors the V617F activating mutation in *JAK2* gene. - SET-2, a cell line originally derived from a patient with essential thrombocytemia at megakaryoblastic transformation, heterozygous for the V617F mutation in *JAK2*. In HEL and SET-2 cells, JAK2/STAT5 pathway was inhibited by the JAK2 inhibitor AG490 (from the tyrphostin family of tyrosine kinase inhibitors, Cat. No. 658401 Calbiochem, San Diego, CA, USA). To confirm whether STAT5 binds to putative binding sites in the promoter of specific genes, we measured binding by chromatin immunoprecipitation (ChIP) with a specific STAT5 antibody and qPCR, so as to compare the amount of DNA bound by STAT5 before and after IL3-mediated induction of the pathway in M07e cells. We obtained peripheral blood samples from patients with chronic MPNs and measured the expression of *LIF* and *OSM* by qRT-PCR. *Results.* Bioinformatic analyses predicted STAT5-binding sites in the promoter of Leukemia Inhibitory Factor (*LIF*). ChIP experiments confirmed binding of STAT5 to one of these motifs in response to IL-3 mediated activation of the pathway.

Moreover, *LIF* expression was significantly upregulated by IL-3 in M07e cells and this was reversed by treatment with a specific STAT5 inhibitor. Treatment of HEL and SET-2 cell lines with a JAK2 inhibitor downregulated *LIF* expression. These results confirm that *LIF* behaves as a direct transcriptional target of STAT5. Finally, MPN patients showed significantly increased expression levels of *LIF* as compared with healthy donors. The finding of *LIF* as a novel STAT5-regulated gene might help to understand STAT5-mediated oncogenesis.

Background. Polycythemia vera (PV) is a clonal hematopoietic stem cell malignance characterized by an accumulation of mature myeloid cells in bone marrow and peripheral blood. A specific point mutation in the Janus kinase 2 gene (JAK2V617F) has been identified in more than 90% of patients with PV however many aspects of pathogenesis and the description of diagnostic markers remains unclear. Apoptosis deregulation may play a role in PV physiopathology and we speculate that galectin-1 interferes in the apoptotic pathway of PV patients' myeloid cells. Galectin-1 may interact with proteins from Bcl-2 family, leading to apoptosis. The potential regulation of apoptotic machinery by this lectin in PV patients cells might emerge as novel target for therapy manipulation or as a possible diagnostic marker for PV. *Aims.* 1) To quantify *galectin-1* and genes from Bcl-2 family expression in $CD34^+$ hematopoietic stem cells in PV patients and controls; 2) To correlate the results of *galectin-1* expression and apoptosis-related genes and JAK2V617F allele burden. *Methods.* Bone marrow $CD34^+$ cells from 20 PV patients (9 males and 11 females with a mean age of 62,25y) and 15 healthy subjects (9 males and 6 females, m=29,73y). $CD34^+$ cells were enriched by using the MACS (magnetically activated cell sorting) CD34 isolation kit (Miltenyi Biotec). Total RNA was extracted according to Trizol® method and the High Capacity® Kit was used to synthesize cDNA. The expression of *galectin-1* and apoptosis-related genes was performed by real time PCR. The JAK2V617F mutation and the allele burden were conducted by real time allelic discrimination PCR. The gene expression results were given as $2^{-\Delta\Delta Ct}$. Statistical analyses were carried out by Mann-Whitney and Spearman tests. *Results. Galectin-1* mRNA levels in $CD34^+$ bone marrow cells were decreased in PV patients (median=0.6) in comparison to controls (m=1.0, p=0.017). Pro-apoptotic *bax* (m= 0.09) and the anti-apoptotic *mcl-1* (m=3.74) expression were different from controls (m= 1.049, m=1.415; respectively) (p= 0.027, p= 0.027; respectively). *Galectin-1* expression correlated with the expression of pro-apoptotic gene *bax* (r= 0.46; p= 0.032). The *bax* expression also correlated with JAK2V617F mutation allele burden (r=-0,46; p=0,036). *Conclusions.* Apoptosis impairment in myeloid cells from PV patients may be linked to low levels of *galectin-1* and *bax* pro-apoptotic mRNA and to the overexpression of *mcl-1* anti-apoptotic gene. These findings highlight the potential participation of galectin-1 in the physiopathology of PV, suggesting an interaction of this lectin with Bcl-2 family members in PV.

NO EVIDENCE THAT MPL, NPM1 OR FLT3 CONSTITUTIONAL HAPLOTYPES PREDISPOSE TO THE ACQUISITION OF ACQUIRED MUTATIONS IN MYELOID DISORDERS

A Jones,[1] S Schnittger,[2] A Vannucchi,[3] W Tapper,[1] N Cross[1]

[1]*University of Southampton, Salisbury, United Kingdom*
[2]*Munich Leukemia Laboratory, Munich, Germany*
[3]*Unità Funzionale di Ematologia, University of Florence, Florence, Italy*

Background. We and others have previously shown that the constitutional JAK2 46/1 haplotype predisposes to the acquisition of JAK2 V617F in myeloproliferative neoplasms, and to a lesser extent it also predisposes to the acquisition of JAK2 exon 12 and MPL mutations. It is not known whether this association between germline and somatically acquired factors reflects something unique about the JAK2 locus, or whether other acquired driver mutations in cancer also arise on specific inherited haplotypes. *Aims.* To investigate the relationship between acquired mutations and haplotypes in MPL, FLT3 and NPM1 in MPN and AML. *Methods.* For each gene, regions of low genetic recombination were determined firstly by visual inspection of HapMap data and then minimal regions of high linkage disequilibrium were selected for detailed analysis using the programs LDMapper and PHASE along with SNP data generated by the Welcome Trust Case Control Consortium (WTCCC) from normal blood donors. From the list of haplotypes generated, a minimal number of SNPs for each gene locus was identified that could capture at least 85% of the genetic variation in that region. Pyrosequencing, a technique that provides a quantitative readout of SNP allele ratios, was used for genotyping and also detected allele skewing of heterozygous SNPs bought about by acquired uniparental disomy at 1p (MPL) or 13q (FLT3). For cases carrying homozygous MPL W515X and FLT3-ITD mutations, haplotypes associated with mutant alleles could be determined. Allele frequencies of patient subgroups were compared to data from either the WTCCC UK blood donor cohort (n=1500), the 'German Kooperative Gesundheitsforschung in der Augsburg' cohort (KORA; n=1805), and the Italian 'Invecchiare in Chianti' cohort (inCHIANTI; n=1200) depending on the ethinicity of the patient population. The allele frequencies of each patient subgroup were compared to controls using Fisher's exact test (2-tailed). *Results.* There were no significant deviations from the expected allele frequencies of matched control populations for three MPL SNPs genotyped in 139 cases with a diagnosis of MPL W515X positive MPN. Likewise, for the 96 cases with a diagnosis of AML carrying a mutation in NPM1, there were no significant differences in allele frequency for two SNPs in NPM1. For FLT3, a total of three SNPs were genotyped in 144 AML cases (FLT3-ITD; n=91, FLT3-TKD; n=43, FLT3-ITD and TKD; n=10), but again there were no statistically significant deviations from allele frequencies found in matched controls. *Summary.* These findings show myeloid-specific mutations in MPL, FLT3 and NPM1 appear to arise randomly on different haplotypes. Whilst this does not preclude the possibility that somatic mutations in other genes might occur preferentially on particular haplotypes, it does suggest that the association between JAK2 46/1 and somatically acquired mutations in JAK2 and MPL is not a general phenomenon.

Background. The MPN&MPNr-EuroNet network, created in 2009, is supported by the European program COST (CoOperation in Science and Technology). It is open to all colleagues active in the fields of myeloproliferative neoplasms (MPN) and related hereditary diseases (MPNr: hereditary erythrocytosis and thrombocytosis). *Aims.* To facilitate and improve the diagnosis of MPN and hereditary erythrocytosis and thrombocytosis in Europe. *Methods.* MPN&MPNr-EuroNet has formed 4 working groups (WG): WG 1 focuses on JAK2-mutated MPN; WG 2 is dedicated to thrombocythemia and myelofibroses without mutation of JAK2 and includes subgroups specialized in hereditary thrombocy-

tosis and in histopathology; WG 3 is dedicated to hereditary erythrocytosis; WG 4 is responsible for scientific cooperation and the diffusion of scientific knowledge. *Results.* During the first year of activity of MPN&MPNr-EuroNet, colleagues from 17 countries participated in the four WG, resulting in the achievements listed below. WG 1: determination of the best JAK2V617F assays, a joint MPN&MPNr-EuroNet/LeukemiaNet project; on-going study of MPN cases with low JAK2V617F burden; on-going study of MPN cases with multiple JAK2 mutation; WG 2: list of laboratories responsible for the diagnosis of MPL and THPO mutations in Europe; first international quality test of the detection of MPL mutations; on-going study of new THPO and MPL mutations in cases of hereditary thrombocytosis (HT); on-going study of the histopathology of MPN without mutation of JAK2 and of HT; WG 3: list of laboratories responsible for the diagnosis of hereditary erythrocytosis (HE) in Europe; consensus on a diagnostic algorithm for the diagnosis of HE; close interaction with COST Action TD0901 - HypoxiaNet - to facilitate discovery of new genes of interest for the diagnosis of HE; exchange of positive control samples for the main mutations responsible for HE; WG 4: MPN&MPNr-EuroNet's website (www.mpneuronet.eu); organization of two annual meetings (2011 meetings: April 6-8, La Baule, France; Sept. 14-16, Münich, Germany); support for short term scientific missions for exchange between participating institutions; and creation of two annual training schools: a spring training school dedicated to the molecular detection of JAK2 and MPL mutations (Nîmes, France), and a fall training school dedicated to hereditary erythrocytosis (Coimbra, Portugal). *Summary/Conclusions.* MPN&MPNr-EuroNet will enable European researchers to define new diagnostic tools and exchange technologies. MPN&MPNr-EuroNet is open to all interested physicians and scientists and we invite new members to join us. Scholarships are available to finance participation to meetings and training schools, and to facilitate exchanges between participating institutions (see www.mpneuronet.eu).

Background. Several hypotheses have tried to explain how a unique mutation is related to three different phenotypes in myeloproliferative neoplasms (MPN). Metalloproteases are a group of proteins involved in matrix remodelling, migration and differentiation processes. Our group has found differential expression of Matrix metalloproteinase-14 (MMP14) and CD44 in PV and ET JAK2V617F positive samples (E. Albizua *et al.*, Ann Hematol. 2011Feb). *Aims.* To analyze the phenotypic divergence between PV and ET by proteomic screening, and validation of previously MMP14 and CD44 gene expression results by protein expression analysis and cultures methods, with the objectives of identifying alternative routes for targeted therapy. *Methods.* Fifty-nine MPN were included in the study: 24 PV, 24 ET and 11 PMF. An additional 24 healthy donors were used as controls. Granulocytes from whole venous peripheral blood were isolated and the corresponding cytosolic protein fraction was extracted. PV and ET cytosolic proteomes were analyzed using 2D-DIGE gels followed by MALDI-TOFTOF mass spectrometry analysis of the spots of interest. Results were analyzed with DeCyder v7.0 (GE) and Mascot software. Leukocytes were obtained and analyzed by flow cytometry (FCM) using anti-MMP14, anti-CD44 and anti-CD45 antibodies (BD). Bone marrow biopsies were selected to perform immunohistochemistry (IHC) with anti-MMP14 and anti-CD44 antibodies (R&D). Finally a culture study was performed. Mononuclear cells from patients were extracted and seeded in Methocult with IL-3, SCF and EPO (Stem Cell). MMP14 was inhibited by the drug Marimastat at 100µM, 50µM and 10µM (TOCRIS); and CD44, with anti-CD44 antibody at 10mg/ml, 1mg/ml and 0.1mg/ml. Results were analyzed by BFU-E count, viability study by trypan blue and FCM employing antibodies anti-CD45, anti-CD71, anti-CD44, anti-MMP14 and Annexin (BD). The Mann-Whitney non-parametrical statistical hypothesis test was used to assess the statistical significance of our results. *Results.* 2D-DIGE analysis found 50 spots with statistically significant differences

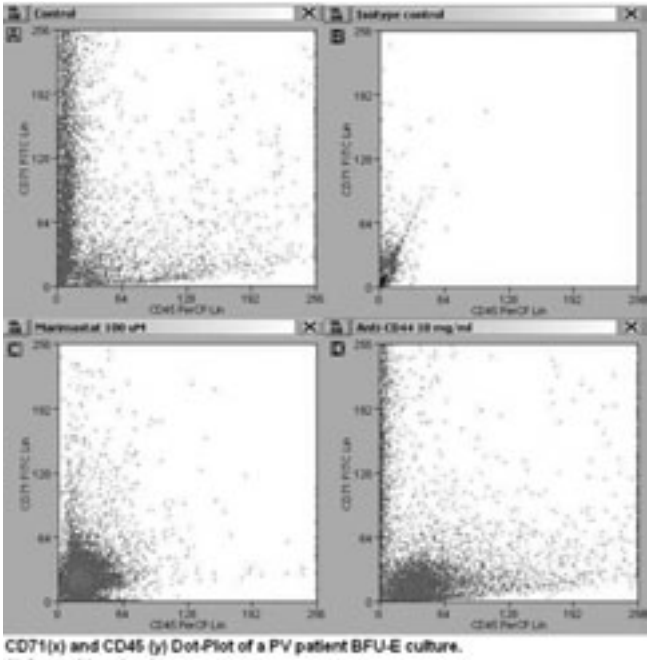

Figure 1. FCM dot-plot of PV patient BFU-E culture.

in protein expression between PV and ET samples. Three spots were especially interesting in the context of our model. These corresponded to HSPA1A, a chaperone related with GATA-1 and erythroid differentiation. FCM of the granulocytes showed over-expression of CD44 in PV population versus ET (P=0.004). FCM CD44 results were confirmed by bone marrow biopsies IHC in granulocytes (P=0.039); IHC also showed MMP14 differential expression between ET, PMF or PV compared to healthy biopsies in megakaryocites, over-expressed in MPN. However, ET and PV did not show MMP14 differential expression. Significant differences of inhibition BFU-E growth and cell proliferation were found between treatment groups (Marimastat -100µM and 50µM- and anti-CD44 -10mg/ml and 1mg/ml-) versus group without treatment (P=0.05 and P=0.037 respectively). FCM of BFU-E cultures pointed to a significant decrease of CD71 (erythroid) and increase of CD45 (leukocyte-common antigen) with both treatments. *Conclusions.* Our results suggest that MMP14 and CD44 could play a role in erythroid and myeloid differentiation. Differences between ET and PV may be caused by both molecules which may contribute to phenotypic divergence. Our results suggest that MMP14 and CD44 could be future therapeutic targets. Other molecules that could contribute to phenotypic divergence, such as chaperone HSPA1A, are under study.

JAK1 AND STAT3 LOW MRNA EXPRESSION IS ASSOCIATED TO RESPONSIVENESS TO IFN-α THERAPY OF ESSENTIAL THROMBOCYTHEMIA

N Pugliese, C Quintarelli, B De Angelis, N Esposito, A Gravetti, V Martinelli, F Pane

Federico II University of Naples, Naples, Italy

Background. Interferon-α (IFN-α) is a useful and nonleukemogenic treatment of ET, able to normalize platelet counts in 80% of treated patients, to induce molecular response and to keep patient off therapy. This cytokine suppresses megakaryocyte (MK) formation of both murine and human marrow cells by inhibition of TPO induced MK growth. IFN-α is a type I IFN and its receptor is associated with Janus kinase proteins, Tyk2 and Jak1. IFN binding to this receptor results in tyrosine cross-phosphorylation and auto-phosphorylation of the JAKs proteins. These phoshothyrosines recruit STAT proteins whose phosphorylation and activation are in turn regulated by Jak1 and Tyk2. The STATs activated in response to type I IFNs include STAT1, STAT2, STAT3 and STAT5; these initiate transcription of SOCSs proteins,

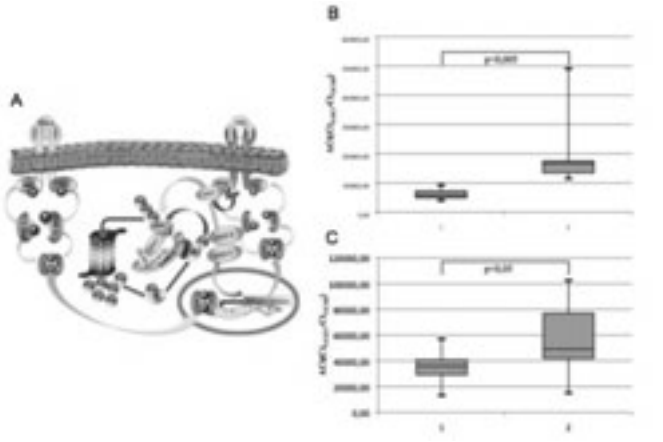

Figure 1. JAK1 and STAT3 mRNA expression is lower in IFN-α r.

whose role is to extinguish cytokine signaling by inhibition of JAKs. The SOCSs KIR blocks JAK kinase-activity directly, instead, the SOCS-box motif promotes the polyubiquitination and proteasomal degradation of SOCS binding partners, like Jak2. In summary, IFN-α induces SOCS expression which inhibits TPO mediated signaling through Jak2 double inhibition. This allows IFN-α and the TPO pathway to cross-talks by means of the JAK-STAT-SOCS cascade. *Aims.* In order to predict IFN treatment responsiveness, we evaluated the expression of specific genes involved in the IFN-α receptor pathway, which signal cross-talks with the JAK-STAT pathway under the TPO receptor. In particular we evaluated the mRNA expression of JAK1, TYK2, STAT1, STAT3, SOCS1 and SOCS3. *Methods.* Among the 60 IFN-α treated patients we considered eligible the 21 who had not received previous therapy and were treated with the same schedule (IFN-α-2b 3 million units 3 times a week for at least 6 months). Informed consent for the study was obtained from all patients. Two patient groups were selected on the basis of clinical response to therapy: Responders (R) (n=12) achieved a reduction of platelet count below 400x109/L, whereas the No Responders (NR) (n=9) group failed to show this hematological response. Target genes mRNA expression was explored by RT q-PCR, using SYBR Green detection, on bone marrow samples. Data were normalized as follows: [mRNA normalized copy number (NCN)= mRNA target gene/mRNA GUSB*104]. Methylation-specific PCR was performed to investigate the methylation status of the promoter regions of the SOCS3 genes. *Results.* STAT3 expression showed a significant lower levels in R in relation to NR (p=0,01); JAK1 expression also was lower in BM cells from R compared with NR (p=0,0008). No differences were found for other gene expressions and for the methylation of SOCS3 promoter between R and NR. Response was not influenced by age (p=0,06), gender (p=0,37), baseline values of hematocrit (p=0,57), platelet (p=0,52), WBC (p=0,08), spleen volume (p=0,09), JAK2V617F mutation (p=0,33). *Conclusions.* JAK1 and STAT3 gene expression may be used as predictor marker of response to IFN-α in ET patients. Thus, patients with low levels of JAK1 and STAT3 mRNA could be also candidate for lower IFN-α doses, which are better tolerated. Moreover, patients with JAK1 mRNA increased levels could be addressed for JAK1/JAK2 inhibitors therapy.

0334

JAK2V617F ALLELE BURDEN IS A CONTRIBUTING FACTOR IN PROTHROMBOTIC MECHANISMS ACTIVATION

M Coucelo, G Caetano, T Sevivas, M Duarte, C Menezes, C Bento, M Ribeiro

Centro Hospitalar de Coimbra, EPE, Coimbra, Portugal

Introduction. Myeloproliferative neoplasms (MPN) are associated with thrombohemorragic diathesis which, in some extent, can be consequence of platelet and leukocyte activation. Different groups suggested an association between JAK2V617F mutation and thrombosis in MPN patients. *Objective.* Evaluate haemostatic activation parameters and their relationship with JAK2V617F allele burden and thrombosis in a group of PV and ET patients. *Methods.* 28 PV and 46 ET patients (median age 65 and 75y, respectively) and a control group of 47 healthy volunteers (median age 30y) were studied. All patients are clinically stable and under HU treatment. With patients' informed written consent, aspirin was withdrawn for 10 days prior the studies. Using flow cytometry we evaluated: platelet P-selectin (CD62P) and granulophysin (CD63), platelet dense granules (mepacrine uptake/release test), platelet-leukocyte aggregates (PLA), leukocyte CD11b and monocyte Tissue Factor (TF) expression. JAK2V617F allele was quantified by Allele Specific qRT-PCR (JAK2MutaQuant, Ipsogen). Presence of MPL exon 10 mutations were screened by SSCP and identified by direct sequencing. *Results/Discussion.* 28 PV (100%) and 28 ET (61%) with JAK2V617F mutation and 1 ET with MPL W515L mutation; 7 PV and 16 ET patients had thrombosis at diagnosis. All patients have increased baseline CD62P and CD63 expressions ($p<0.01$), increased response to arachidonic acid ($p<0.01$) and diminished response to TRAP6 stimulation ($p<0.01$); 77% of PV and 50% of ET present a storage pool disease. Leukocyte CD11b and monocyte TF expressions were increased in all patients ($p<0.01$). PLA were found increased in all patients ($p<0.01$) vs controls, nevertheless platelet-neutrophil (PMN) aggregates were significantly increased in ET vs PV ($p<0.01$). Patients with JAK2V617F>50% present a significantly increase of CD11b expression and platelet-PMN aggregates comparing to JAK2V617F<50% ($p<0.01$). PV patients present increased levels of TF when comparing with ET ($p<0.01$), and was higher in PV JAK2V617F>50% ($p<0.01$). In ET JAK2V617F mutation was statistically correlated with thrombosis and with JAK2V617F allele >50% (no association in PV). Regarding the allele burden and platelet function studies no association was found (p=ns). These results show, with statistically significance, that PV and ET patients have circulating activated platelets and leukocytes and increased PLA. Activation parameters were higher in patients with JAK2V617F allele burden >50% comparing to those with JAK2V617F<50%, which is consistent with the influence of JAK2V617F allele burden in leukocyte activation. *Conclusions.* Our data demonstrate that JAK2V617F mutation drives mechanisms that favor thrombosis, namely, neutrophil and monocyte activation, increased monocyte TF expression and platelet-leukocyte aggregates.

C-CBL MUTATIONS IN V617FJAK2 POSITIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

P Aranaz, C Hurtado, I Erquiaga, I Cristóbal, MJ Calasanz, F Novo, M García-Delgado, JL Vizmanos

University of Navarra, Pamplona, Spain

Background. BCR-ABL1 negative chronic myeloproliferative neoplasms (CMPNs) are a heterogeneous group of clonal hematological malignancies. The most frequent aberration is V617FJAK2, present in most of PV and over 50% of ET and MF. In last years, different groups have described mutations in other genes as C-CBL (Casitas B-lineage Lymphoma), that encodes for an E3 ubiquitin ligase involved in negative regulation of several tyrosine-kinases, as EGFR, FGFR or SYK. These mutations are present in different myeloproliferative neoplasms, especially in CMML and JMML, often in patients negative for other frequent mutations as V617FJAK2. Several groups have demonstrated that mutations in the RING finger domain of C-CBL result in deregulation of downstream targets of this protein. *Methods.* We have used dHPLC to detect sequence mutations on samples from 377 BCR-ABL1 negative CMPN patients (145 V617FJAK2 negatives and 232 positives) and 20 samples from healthy individuals as controls. We analyzed the proliferative response induced by the C-CBL mutants in 32D cell line, previously transfected with FLT3 in four independent experiments, using the CellTiter 96® AQueous Non-Radioactive Cell Proliferation Assay. *Results.* We have found five mutations in C-CBL in six patients, four of them non-described previously. Three of these mutations were located in the RING finger domain, but two were found in the proline-rich domain (one of them was recurrent). All the mutations promoted a significant increase in the rate of proliferation induced by cytokines. Three of the mutations (two of the RING finger and one in proline-rich region) were found in four V617FJAK2 positive patients. *Conclusion.* Our results suggest that mutations in C-CBL and JAK2 genes are not exclusive events. In addition, proline-rich region mutants can induce the same proliferative effect than RING finger domain mutants, so this region of C-CBL must also be considered for mutation analysis of this gene in CMPN. This work has been funded with the help of the Spanish Ministry of Science and Innovation (SAF 2007-62473), the PIUNA Program of the University of Navarra and the Caja Navarra Foundation through the Program "You choose, you decide" (Project 10830). PA has a predoctoral grant from the Government of Navarra.

Background. The mammalian target of rapamycin (mTOR) is a serine/threonine kinase that functions as a key regulator of cell growth, protein translation and metabolism. Consistent with its role as a growth-promoting factor, numerous studies have found increased mTOR signaling in a broad spectrum of human cancers. Essential thrombocythemia (ET) and myelofibrosis (MF) are BCR-ABL-negative chronic myeloproliferative disorders characterized by megakaryocytic bone marrow hyperplasia and a sustained elevation of platelet number with a tendency for thrombosis and hemorrhage. However, the molecular mechanisms underlying the pathogenesis of these diseases are still poorly understood, delaying the development of effective targeted treatments. *Aims.* To evaluate phospho-mTOR expression in megakaryocytic cultures derived from the peripheral blood of healthy individuals or from patients diagnosed with ET or MF. *Methods.* We have developed a liquid megakaryocytic (MK) unilineage system that reproduces, *ex vivo*, all the stages of megakaryopoiesis generating morphologically and functionally mature platelets. Human CD34-positive cells were purified by positive selection. Unilineage MK differentiation was induced in each sample (healthy individuals and ET or MF patients) by cultivating CD34-positive cells for 14 days in the presence of thrombopoietin. Purity of the selected population was evaluated immediately after purification and during MK differentiation (days 0, 3 e 12) by flow-cytometry using anti-CD34 and anti-CD61 antibodies and morphological analysis after May-Grünwald-Giemsa staining. Phospho-mTOR expression was analyzed on day 3 and 12 of the differentiation process by flow-cytometry, immunofluorescence and immunohistochemistry (carried out on slides from 35 bone marrow samples: 14 ET and 21 MF patients). *Results.* mTOR activation was increased during MK differentiation in both ET and MF patients compared to healthy donors where mTOR staining was barely detectable. Immunohistochemical analysis of phospho-mTOR confirmed high expression levels in ET and MF patients in contrast with the negative staining observed in healthy individuals. *Conclusions.* Taken together, our data suggest that induction of the mTOR pathway is involved in the MK differentiation of samples derived from ET and MF patients. Our findings suggest that mTOR could represent an attractive molecular target for the treatment of ET and MF patients failing previous lines of treatment.

Background. Essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF) are haematopoietic stem cell neoplasms, in which the JAK2 V617F mutation is observed in >95% of PV patients and in about 50 % of patients with ET and PMF. All diseases may be associated with autoimmune or chronic inflammatory disorders. Gene-expression profiling studies have yielded divergent results which might be explained by different platforms used and differences in the cell types being profiled (granulocytes, CD34+ cells) and their origin (bone marrow samples, peripheral blood). Aberrant expression of genes involved in inflammatory responses has also been reported, mainly being performed on granulocytes or CD34+ cells. *Aims.* In order to achieve a "global"characterization of aberrant genes of significance for inflammation and immune function, we have performed gene expression profiling of whole blood to obtain an integrated transcriptional signature of cells involved in inflammation, immune surveillance and function. *Methods.* Gene expression microarray studies have been performed on control subjects (n = 21) and patients with ET (n = 16), PV (n = 36), and PMF (n = 9). Patients on interferon-alpha therapy were excluded from the study. Gene expression profiles were generated using Affymetrix HG-U133 2.0 Plus microarrays recognizing 54,675 probe sets (38,500 genes). Total RNA was purified from whole blood and amplified to biotin-labeled RNA and hybridized to microarray chips. *Results.* We identified 23,657, 25,567, and 17,417 probe sets which were significantly differentially expressed between controls and patients with ET, PV, and PMF, respectively (false discovery rate (FDR) adjusted p values < 0.05). 122 genes involved in inflammation and immune regulation were studied and 52, 73, and 60 were significantly deregulated in ET, PV and PMF, respectively. A total of 98 genes were significantly upregulated. The most significantly upregulated genes included in ET patients CCL7, CCL25, FGB, and ITGB3, in PV patients CCR1, CXCL10, IL1R1, and ORM1, and in PMF patients C5, CXCL2 CXCL3, ORM1, PTX3, and VEGFA. In the whole group of patients, 87 genes were significantly downregulated. The C5 and IL5 genes were progressively and significantly upregulated in patients with ET, PV, and PMF, whereas the genes, CCR3, CCR6, CCR9, CD40LG IL10RA, and SELPLG were progressively and significantly downregulated from ET over PV to PMF, respectively. *Summary/Conclusions.* Our findings of significantly deregulated genes involved in inflammation and immunoregulation with progressive deregulation for particular genes from ET, over PV to PMF may reflect chronic inflammation to be of pathogenetic importance for the progression of these neoplasms towards the myelofibrotic endstage. In this context, the aberrant inflammatory and immunoregulatory pathways may be deregulated as part of the clonal evolution. Irrespective of the underlying mechanisms, the deregulated (upregulated or downregulated) genes may drive clonal myeloproliferation. It is intriguing to consider if chronic inflammation or a chronic aberrant autoimmune process might also elicit clonal evolution and the emergence of a myeloproliferative neoplasm. If so, the abnormal immune homeostasis may be involved in the progression of the disease consequent to defective immune surveillance.

THE ACTIVATING G537R MUTATION IN HIF2-ALPHA IS ASSOCIATED WITH IN VITRO HYPERSENSITIVITY OF ERYTHROID PROGENITORS TO ERYTHROPOIETIN

J Kucerova,[1] D Pospisilova,[2] M Horvathova,[1] J Nausova,[1] V Divoky[1]

[1]*Faculty of Medicine Palacky University, Olomouc, Czech Republic*
[2]*University Hospital Olomouc, Olomouc, Czech Republic*

Background. Polycythemias/erythrocytoses in childhood are rare and may be a result of various pathophysiological conditions. Primary polycythemias were reported in children with acquired mutations in JAK2 and with congenital mutations in erythropoietin receptor (EPOR). Recessive mutations in gene encoding von Hippel-Lindau (VHL) protein lead to polycythemia, which exhibits features of both primary and secondary. Recently described polycythemic patients with mutations in PHD2 and HIF2-alpha (HIF2A), were reported to have elevated serum EPO levels; the information on *in vitro* sensitivity of erythroid progenitors to EPO is missing or not complete. *Aims.* We aim to characterize, at cellular and molecular level, selected pediatric patients diagnosed with polycythemia in Czech Republic (1990 - 2010). Part of this cohort (6 patients) was previously presented.[1] *Patients and Methods.* We studied a group of 9 children diagnosed at the centers of Pediatric Hemato-Oncology in Czech Republic with signs of primary polycythemia. Their hemoglobin levels at the time of diagnosis were in the range of 18-22.3 g/dL. Four patients were clinically asymptomatic, five patients had plethora. Hematopoietic colony assay was used to determine *in vitro* sensitivity of erythroid progeni-

tors to EPO. Mutation analysis of known candidate genes was performed and included sequencing of JAK2 exons 12 and 14, EPOR exons 7 and 8, HIF2A and HIF1A exon 12 and all exons of VHL and PHD2. *Results.* All patients exhibited *in vitro* hypersensitivity of erythroid progenitors to EPO, seven samples were also positive for the growth of endogenous erythroid colonies (EECs). A known heterozygous 5967insT mutation in EPOR[2] was found in two unrelated patients; this result was already presented.[1] Recently, we detected another previously reported mutation, heterozygous 1609G>A substitution which changes glycine 537 for arginine in HIF2A,[3] in the other two unrelated and clinically asymptomatic patients. The erythroid progenitors of both were *in vitro* hypersensitive to EPO, one was also EEC-positive. Surprisingly, their EPO levels were not elevated, however only one single measurement for each from two different biochemical laboratories is available. Therefore EPO levels need to be re-evaluated in one center using another rigorous measurement. The remaining five patients were negative for a mutation in all analyzed genes. *Conclusions.* We present a group of pediatric patients with primary polycythemia, and mild clinical sings in 5/9 of the cases. The disease causing mutation was detected in 4/9 patients. The presence of the same G537R mutation in two our patients in combination with independent cases reported by others confirm the suggested mutational hotspot in HIF2A gene. We show for the first time that in addition to VHL-associated polycythemia also erythroid progenitors of patients with HIF2A mutation are *in vitro* hypersensitive to EPO. We hypothesize that endogenous erythroid EPO production is stimulated by this activating G537R HIF2A mutation leading to augmented activation of EPO/EPOR pathway and excessive erythroid proliferation.

ANALYSIS OF THE MUTATIONAL STATUS OF IL-3, IL-5 AND GM-CSF RECEPTORS IN CHRONIC MYELOPROLIFERATIVE NEOPLASMS

I Erquiaga,[1] C Hurtado,[1] P Aranaz,[1] I Migueliz,[1] E Olavarria,[2] JL Vizmanos[1]

[1]*Universidad de Navarra, Pamplona, Spain*
[2]*Hospital de Navarra, Pamplona, Spain*

Background. Over the last few years several genetic aberrations have been described to be the cause of some cases of chronic myeloproliferative neoplasms (CMPNs). Among these aberrations V617F mutation in JAK2 is the most frequent one, having been found in 55% of ETs, almost 100% of PVs and 65% of IMFs. In spite of these findings, an important number of CMPNs still have an unknown molecular origin. *Aims.* Current knowledge of CMPNs has revealed the importance of JAK2 and the JAK/STAT pathway in these diseases. This encouraged our team to study cytokine receptors signaling through JAK/STAT pathway. We focused our work in the screening for mutations on the genes coding for the receptors for interleukin (IL)-3, IL-5 and GM-CSF. *Methods.* We analyzed a series of DNA samples from 44 patients with *BCR-ABL1* and V617F*JAK2* negative CMPNs. We used denaturing High Performance Liquid Chromatography to carry out a screening for mutations on the coding exons of genes *IL3RA*, *IL5RA*, *CSF2RA* and *CSF2RB*. Samples with an elution profile different to a healthy control were sequenced. For the exons with alterations the study was extended to other series of CMPNs patients, either V617F*JAK2* positive or negative, and a longer series of samples from healthy donors was analyzed for the recurrent ones. No matched sample from other tissue was initially available in any case. *Results.* We found nine sequence changes not previously described as mutations nor polymorphisms in dbSNP or 1000genomes.org in *CSF2RB*, *CSF2RA* and *IL3RA*. Five were found in *CSF2RB* (p.D312N, p.A328T, p.P509S, p.P513L, and p.R517C); three in *CSF2RA* (p.R164Q, p.P166S and p.Y167D); and one in *IL3RA* (p.W226X). R164Q in *CSF2RA* was found to be recurrent as it appeared in nine patients, but also in three healthy donors. In one case with R164Q*CSF2RA* a buccal swab sample was found to carry the same sequence change, showing that it was germinal. In addition, D312N in *CSF2RB* and Y167D in *CSF2RA* appeared in one healthy donor each. *Summary.* We have found some sequence changes in the genes we studied. Three cases (R164Q and Y167D in *CSF2RA*, and D312N in *CSF2RB*) were also present on healthy samples. These changes seem to be rare variants, although they could contribute to the effect of other mutations. For the six remaining cases the analysis of 20 control samples was negative. These sequence variants (1.10% (4/362) in *CSF2RB*, 0.55% (1/183) in *CSF2RA*, and 0.64% (1/156) in *IL3RA* in V617F*JAK2* negative CMPNs patients) could be rare variants or singletons but could also be oncogenic mutations. In fact, random mutagenesis experiments have shown an oncogenic effect for some *CSF2RB* mutations. In addition, W226X, found in *IL3RA* produces a truncated protein. We are currently studying the impact of the sequence changes we found on cell cultures. Anyway mutations in these genes, if existing, would be infrequent events in these diseases. Although considering all our data, almost 2% of CMPNs cases show alterations in these genes.

Non-Hodgkin lymphoma - Biology

CD20 DIRECTS CELL POSITIONING IN SECONDARY LYMPHOID ORGANS

T van Meerten,[1] R van Rijn,[2] A Martens,[1] A Hagenbeek,[1] T Mutis[1]

[1]*University Medical Center Utrecht, Utrecht, Netherlands*
[2]*Erasmus Medical Center, Rotterdam, Netherlands*

Background. Human CD20 is a B cell restricted transmembrane molecule and the most successful monoclonal antibody targeted antigen, used worldwide to treat patients with B cell non-Hodgkin's Lymphoma (B-NHL). Unfortunately, the majority of B-NHL patients develops resistance to anti-CD20 therapy, resulting in relapse of the disease. Anti-CD20 antibody resistance is poorly understood and a current focus of investigation. Antibody resistance may be related to the interaction of CD20 with tumor cells and the microenvironment. However, although the CD20 molecule was discovered 30 years ago, its exact function is still unknown. *Aim.* The aim of this study is to gain insight in the role of the CD20 molecule in relation to the microenvironment. *Methods.* To explore the function of CD20, we used a system that isolates human CD20 from other B cell surface molecules by retrovirally transferring the human CD20 gene into normal human T cells. Then these CD20-positive T cells were used in *in vivo* mouse models and in *in vitro* functionality assays. *Results.* Initial *in vitro* assays comparing peptide-specific CD20-positive T cell clones with nontransduced parental clones demonstrated no altered proliferative activity or cytokine production associated with CD20 transduction. We then injected a T cell population containing 20% CD20-positive T cells into immune deficient RAG2-/-γc-/- mice (n=10) to compare the distribution of the cells into the organs with the distribution of normal human T cells (control mice n= 10) and human B cells (control mice n=5). Immunohistochemical staining of the organs revealed a remarkable phenomenon in all 10 spleens of the mice that received the transduced T cells: while normal T cells were scattered throughout the spleen, the CD20-positive T cells had positioned themselves periarteriolar in the same way as the human B cells do (figure 1).

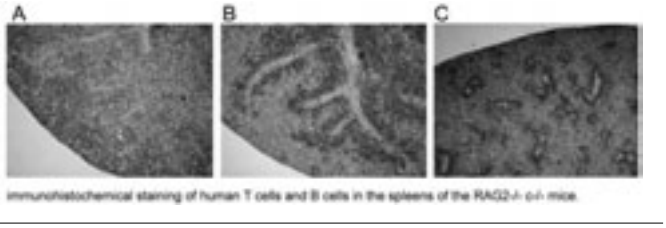

Figure 1.

In the other organs, like the gut, liver and lungs, in contrast, the distribution of the CD20-positive T cells did not differ from the normal T cells. To confirm the hypothesis that the migration capacity of T cells is altered following expression of the CD20 molecule, we studied the influence of CD20 expression on T cells in *in vitro* transwell migration assays. In these assays CD20-positive T cells exhibited a 50% decreased migration capacity towards stroma cells compared to the normal T cells (p=0.0075). *Summary/Conclusions.* These data demonstrate that the CD20 molecule directs the positioning of cells in secondary lymphoid organs. This indicates that CD20 holds back further migration of the cells in order to take a periarteriolar position, which may be the optimal site for the physiological (T cell independent) B cell antigen recognition. These findings help to understand the role of CD20-positive cells in their microenvironment, which opens up new ways to conquer anti-CD20 antibody resistance in the treatment of B-NHL.

CD137 EXPRESSION IS INDUCED BY EPSTEIN-BARR VIRUS (EBV) INFECTION AND ACTIVATES NF-?B CONTRIBUTING TO THE DEVELOPMENT OF EBV-POSITIVE T/NK-CELL LYMPHOPROLIFERATIVE DISEASE

A Arai,[1] M Yoshimori,[1] KI Imadome,[2] L Wang,[1] T Fukuda,[1] T Koyama,[1] S Fujiwara,[2] O Miura[1]

[1]*Tokyo Medical and Dental University, Tokyo, Japan*
[2]*National Research Institute for Child Health and Development, Tokyo, Japan*

Background. There are EBV-positive T/NK-cell lymphoproliferative diseases (EBV-T/NK-LPD), such as extranodal NK/T-cell lymphoma nasal type (ENKL), aggressive NK-cell leukemia, and chronic active EBV infection (CAEBV). In these diseases clonally proliferating cells are EBV-positive T or NK cells and it has been suspected that EBV may contribute to the development of these disorders. However, why and how EBV infects T or NK cells, whether EBV itself induces these malignancies, and the mechanism of action responsible for these malignancies have not been clarified to date. *Aims.* To clarify the molecular mechanism underlying the development of EBV-T/NK-LPD, we focused on costimulatory receptor CD137, which is expressed on the surface of activated T cells and plays a pivotal role in their proliferation, survival, and differentiation. *Methods.* Four EBV-positive T and NK cell lines, SNT8, SNK6, SNT15 and SNT16, were obtained for examination. These cell lines had been established from primary lesions of ENKL patients (SNT8 and SNK6) and peripheral blood of CAEBV patients (SNT15, 16). Clinical samples were obtained from CAEBV patients, diagnosed according to the criteria suggested by Okano M. *et al.* (Am J Hematol 80:64-9, 2005). To detect and isolate EBV-infected cells, T and NK cells were separated using magnetic beads from peripheral blood mononuclear cells. *CD137* gene and protein expression were analyzed by RT-PCR and flow cytometry respectively. For *in vitro* EBV infection, EBV was prepared from the culture medium of B95-8 cells and added to MOLT4 cells as previously described (PNAS 100:7836-40, 2003). NF-κB activation was examined by western blotting and electrophoretic mobility shift assay. Apoptotic cells were detected by $DiOC_6$ staining. The study was approved by the ethical committee and written informed consent was obtained from each patient. *Results.* We detected significantly high expression of *CD137* gene and protein in four EBV-infected T or NK cell lines compared to EBV-negative T and NK cell lines. *In vitro* EBV infection of MOLT4 cells resulted in induction of endogenous CD137 expression. Transient expression assay demonstrated that the EBV-encoded protein, LMP1, induced endogenous *CD137* gene expression. Next we validated the results using clinical samples. Sixteen patients (aged 8-72 years; 6 males, 10 females; infected cell types CD4: 4, CD8: 5, γδ: 1, and CD56: 6) were diagnosed with CAEBV. EBV-infected T or NK cells derived from these patients revealed significantly higher *CD137* gene expression than cells from healthy donors. CD137 protein expression was also upregulated in peripheral mononuclear cells from CAEBV patients in the presence of Interleukin-2, but not in cells from healthy donors. VP16-induced apoptosis of these cells was significantly suppressed through the stimulation of CD137 on the cell surface by the human CD137L stably expressed on Chinese Hamster Ovary cells. Moreover, NF-κB activation downstream of CD137 was shown. *Summary.* These results indicate that upregulation of CD137 expression by EBV in T/NK cells induces the anti-apoptotic intracellular signaling pathway through NF-κB activation and may contribute to the development of EBV-T/NK-LPD.

DEREGULATION OF MULTIPLE CHEMOKINE RECEPTORS DURING GASTRIC MALT LYMPHOMAGENESIS - MALIGNANT TRANSFORMATION IS ACCOMPANIED BY LOSS OF CXCR4-SDF-1? SIGNALLING

A Deutsch,[1] E Steinbauer,[2] N Hofmann,[1] D Strunk,[1] W Linkesch,[1] C Beham-Schmid,[1] H Schaider,[3] P Neumeister[1]

[1]*Internal Medicine, Graz, Austria*
[2]*Pathology, Graz, Austria*
[3]*Tumor Biology Unit, Department of Dermatology, Graz, Austria*

Background. Chemokine receptors play a crucial rule in development and progression of lymphoid neoplasms. *Aims and Methods.* Because the chemokine receptor expression profile in gastric MALT lymphoma is unknown, we performed an expression analyses of 19 chemokine receptors on gastric tissue samples derived from Helicobacter pylori (HP) associated gastritis, gastric MALT lymphoma and extranodal diffuse large B cell lymphoma (eDLBCL) originating from MALT lymphoma

(transformed MALT lymphoma) by using a semi-quantitative RT PCR approach. In addition five chemokine receptors (CCR8, CCR9, CXCR4, CXCR6, CXCR7) and the CXCR4 ligand SDF-1α were analysed by immunohistochemistry. *Results.* In the model of the stepwise development from a non-neoplastic lesion to the HP associated gastritis, we observed a de novo expression of CCR7, CXCR4, CXCR5 and CXCR7 and a loss of XCR1. Following malignant transformation from HP to MALT lymphoma, an up-regulation of CCR7 and CXCR7, de novo expression of CXCR3 and a loss of CXCR4 were detected. Additionally, we showed that the chemokine receptor expression profile of gastric MALT lymphomas differs substantially compared to eDBLCL with a higher expression of CCR1, CCR5, CCR7, CCR8, CXCR3, CXCR6 and CXCR7 and de novo expression of CCR9 and XCR1 in eDLBCL. Continuous expression of all B-cell homeostatic chemokine receptors was found in both lymphoma entities except for CXCR4, which was entirely lacking following transformation to MALT lymphoma. SDF-1α expression, the ligand for CXCR4 and CXCR7, was found in epithelial, endothelial and dendritic cells, macrophages, in lymphoma cells of gastric MALT lymphomas and with a significant higher number of positive lymphoma cells in eDLBCL. Comparing CXCR4 expression between gastric MALT lymphoma and nodal marginal B cell lymphoma and between gastric eDLBCL and nodal DLBCL, CXCR4 mRNA transcripts were exclusively found in nodal lymphomas. Furthermore, the proliferation rate of gastric MALT lymphomas and gastric eDLBCLs correlated with expression of CCR9 and CXCR7. *Conclusions.* Our results support a model of a stepwise progression of gastric MALT lymphoma from a non neoplastic event to HP associated gastritis, to MALT lymphoma, and finally to overt eDLBCL, is guided by differentially expressed B-cell homeostatic and activation-dependent chemokine receptors.

JUNCTIONAL ADHESION MOLECULE C (JAM-C) INFLUENCES SELECTIVELY THE HOMING OF NORMAL AND MALIGNANT B-CELLS TO DIFFERENT LYMPHOID ORGANS

C Doñate,[1] C Ody,[2] T Mckee,[3] S Ruault-Jungblut,[4] V Laplana,[4] B Lee,[2] B Imhof,[2] T Matthes[4]

[1]*University Hospital of Geneva, Geneva, Switzerland*
[2]*Department of Pathology, University Medical Center, Geneva, Switzerland*
[3]*Clinical Pathology Service, University Hospital, Geneva, Switzerland*
[4]*Hematology service, University Hospital, Geneva, Switzerland*

Background. Homing of malignant B-cells to bone marrow (BM) and secondary lymphoid organs is of critical importance in disease progression of lymphoproliferative syndromes. Junctional adhesion molecule C (JAM-C) is an adhesion molecule with restricted expression to precise differentiation stages in B-cell maturation, allowing a clear classification into two types of B-cell malignancies: JAM-C positive lymphomas, with supposed origin in the marginal zone, and JAM-C negative lymphomas, with supposed origin in the germinal center. In the current study, we investigated the role of JAM-C in the proliferation and migration of normal and malignant B-cells. *Methods.* Human B-cells from tonsils and from peripheral blood of healthy donors and lymphoma patients were activated *in vitro* with interleukins (IL-2, IL-4, IL-10) and CD40L, with or without JAM-C antibodies, then proliferation and JAM-C expression were assessed by flow cytometry. To study the role of JAM-C in B-cell migration, B-cells were injected i.v. into NOD/SCID mice and homing of cells to lymphoid organs (BM, spleen, lymph nodes) was analyzed one hour later by flow cytometry and immunohistochemistry. In parallel experiments, B-cells were incubated with anti-JAM-C, anti-VLA4 or combinations of both antibodies prior to injection into mice. *Results.* Activation of B-cells led to a 50% decrease in JAM-C expression and incubation with anti-JAM-C antibodies significantly reduced proliferation of normal and malignant JAM-C pos B-cells by 33%. *In vivo* studies demonstrated that JAM-C pos B-cells from mantle cell lymphoma and marginal zone lymphoma have a reduced capacity to home to lymph nodes (decrease of 77% in number of cells compared to normal B-cells). Furthermore, blocking JAM-C with anti-JAM-C antibodies reduced the homing of normal and lymphoma JAM-C pos B-cells to BM and spleen by 50-60%. This contrasted to the reduced homing of B-cells into BM and lymph nodes but not into spleen when the cells were incubated with anti-VLA4 antibodies prior to injection. Interestingly, combination of both antibodies resulted in inhibited homing into the three lymphoid organs. *Conclusion.* Our results show for the first time a functional role of JAM-C in B cell proliferation and in the homing to lymphoid organs. Targeting JAM-C could thus constitute a new therapeutic strategy, with JAM-C blocking as a treatment to prevent lymphoma cells from reaching supportive microenvironments in BM and spleen.

DEEP SEQUENCING REVEALS A COMPLEX PATTERN OF CLONALITY IN FOLLICULAR LYMPHOMA BY ANALYSIS OF THE HEAVY CHAIN OF THE IMMUNOGLOBULIN GENE IN DIFFERENT TUMOR SUB-POPULATIONS

E Carlotti,[1] G Rosignoli,[1] A Sangaralingam,[1] T Chaplin,[1] S Iqbal,[1] J Matthews,[1] M Calaminici,[1] B Young,[1] T Lister,[1] P Campbell,[2] J Gribben[1]

[1]*Barts Cancer Institute (BCI) a CR-UK Centre of Excellence Queen Mary University, London, United Kingdom*
[2]*Cancer Genome Project, Wellcome Trust Sanger Institute, Hinxton, United Kingdom*

Background. We previously demonstrated the existence of a common progenitor cell (CPC) linking follicular lymphoma (FL) and transformed FL (t-FL) by analyzing the somatic mutation (SHM) of the heavy chain of the immunoglobulin gene (IgH-VH). *Aims.* We investigated IgH-VH using the Roche 454 GS FLX Titanium platform and DNA extracted from flow-sorted subpopulations, corresponding to 4 stages of B-cell maturation (i.e. pro/pre germinal centre (PP-GC), centroblasts (CB), centrocytes (CC) and memory enriched (ME)) in sequential biopsies from lymphoma cases showing a pattern of direct or divergent evolution, in order to determine the full extent of clonal diversity in FL and identify compartment specific changes that could explain these two models of progression. *Methods.* 20-45 ng of DNA (approximately 3500-7000 cells) from 7 lymph nodes cells suspension (6 FL/1 t-FL) corresponding to 3 patients (2 having a pattern of direct and 1 of divergent evolution) and 24 samples from the corresponding flow-sorted subpopulations, were investigated. The subpopulations were purified using IgD, CD38, CD10 and CXCR4 cell surface markers. Amplicons were prepared using IgH-VH3 primers (known to detect the tumor clone) modified with unique tags and the germline IgH from A375β6 melanoma cell line as control. Libraries were pooled and sequenced, twice, in both the directions. *Results.* We generated 937,000 high quality reads (average per library: 26,000; range 17,647 - 57,848). Among the sequences, tumor related sequences were 52%-77% in total biopsies and 9%-75% in subpopulations. The majority were identical to the major clone, except for the PP-GC and ME populations. A complex degree of clonality was observed, with the number of haplotypes ranging from 11 (in a ME sample) to 221 (in a CC) and many clones detected at a frequency <0.001. Most haplotypes were closely related to the major clone (only 2-3 different SHM) and typically showed a more mutated IgH-VH locus. Comparison of the samples from patients with a direct and divergent evolution did not show any difference regarding the number of haplotypes, level and type of SHM. In the samples from the patient with a CPC pattern it was possible to identify reads identical to the 2 major clones (each having 8 and 22 unique SHMs) in the other total biopsy and selected subpopulations, at frequencies from 0.02 to 0.0009. Sequences similar to the predicted CPC were not detected, suggesting that or is absent or it exists at a level below the assay's sensitivity. *Summary/Conclusions.* The investigation of the IgH-VH SHM in FL subpopulations using GS FLX Titanium platform unravels an unexpected complex level of clonality; the haplotypes' analysis shows a high variability among the different subpopulations, independently of the inferred model of evolution. This variability is more related to the individual than to the samples and similar profiles are observed when biopsies from the same patient are considered. Further investigation of the relationship and the maturation of these clones will better highlight the evolution of these FL clones.

0345

THE KINETICS OF SYSTEMIC CELLULAR IMMUNOSUPPRESSION IN PATIENTS WITH POOR-RISK DIFFUSE LARGE B-CELL LYMPHOMA DURING TREATMENT WITH 'CHOP-R': A PROSPECTIVE STUDY FROM THE ALLG

M Gandhi,[1] M Hertzberg,[2] E Han,[1] C Keane,[1] A Lopez,[1] K Radford,[3] J Seymour,[4] D Gill,[5] F Vari[1]

[1]*QIMR, Brisbane, Australia*
[2]*Westmead Hospital, Sydney, Australia*
[3]*Mater Medical Research Institute, Brisbane, Australia*
[4]*Peter MacCallum Cancer Institute, Melbourne, Australia*
[5]*Princess Alexandra Hospital, Brisbane, Australia*

Background. The immune system plays a pivotal role in the pathogenesis of lymphoma. Within the malignant lymph node, a variety of mech-

anisms have been identified by which the lymphomatous B-cell evades the host immune response. Conversely, the mechanism(s) by which systemic immunosuppression is mediated are poorly understood. Consistent with previous reports, in 122 consecutive patients with diffuse large B-cell lymphoma (DLBCL) treated with rituximab-CHOP therapy (median follow-up 31 mo.), lymphopenia (≤650mm3/L) was an adverse prognostic factor independent of IPI (p=0.03). Understanding the biology underpinning this observation is a pre-requisite to developing novel immunotherapeutic strategies in DLBCL. *Aim.* To perform a highly-detailed prospective functional characterisation of systemic cellular immunosuppression in DLBCL. *Method.* We collected 30mls peripheral blood in twenty-three HIV- patients with newly diagnosed poor-risk DLBCL (mean age =53 years, range32-71, 2F:M13). Poor-risk was defined as IPI>1 and/or bulky (≥7.5cm) disease. Serial samples were taken at specified time-points: prior to therapy ('baseline') and twenty-one days after cycle four CHOP-R therapy ('interim'). All patients received pegylated G-CSF at day +2. 20 age-matched healthy controls were used for comparison. All participants provided informed consent. The study was performed by the Australasian Leukaemia Lymphoma Group. *Results.* In patients with DLBCL, at baseline (versus controls) circulating CD3+ T-cells but not CD19+ B-cells are decreased. This was due to lower CD4+ counts (p<0.001) with normal CD8+ T-cells and CD3-CD56+ NK-cells. Interim CD4+ T-cells remained reduced. To put this into context, we quantified conventional cellular immune evasion mechanisms. However, we observed no difference in patient levels of either CD4+CD127-CD25hi regulatory T-cells or CD14-HLADR-CD33+ myeloid derived suppressor cells. By contrast, CD14+ monocytes were strikingly elevated in patients at baseline relative to control subjects (p<0.0001). In paired analysis, levels of monocytes rose further at interim. However, the surface marker composition of circulating monocytes markedly changed, with total CD14+HLA-DR-/lo monocytes increased at baseline compared to interim. A paired comparison of CD14+HLA-DRhi / CD14+HLA-DR-/lo monocytes between baseline and interim showed the ratio to be higher in baseline patient samples (p<0.01). The CD14+HLA-DR-/lo phenotype is a newly identified monocyte subset proposed to mediate systemic immunosuppression, including modulating lymphocyte proliferation, effector T-cell activity, and impairing responsiveness to anti-tumour vaccines. As circulating monocytes can differentiate into dendritic cells (DC) *in-vivo*, (and serve as a reservoir of DC for immunomodulation), we quantified the numbers of mature monocyte derived DC (moDC) that differentiate from adherent PBMC. Concordant with the decline in CD14+HLA-DR-/lo monocytes, *in-vitro* differentiation to moDC was improved at interim relative to baseline. *Summary.* There is growing interest in stimulating host immunity in poor-risk DLBCL. The optimal timing of immunomodulation is unknown, but will be influenced by circulating effector cells, immunosuppressive monocytes, and the timing of concurrent therapy. To our knowledge we present the first study outlining the kinetics of lymphocyte subsets and CD14+HLA-DR-/lo monocytes in DLBCL. We show that CD14+HLA-DR-/lo monocytes are elevated at baseline but normalize after 4 cycles of CHOP-R. CD14+HLA-DR-/lo monocytes appear inversely proportional to CD4+ T-cells, and have reduced ability to differentiate into moDCs.

[4]*Dipartimento di Scienze e Tecnologie Biomediche, Università degli Studi di Udine, Udine, Italy*

Background. Splenic marginal zone lymphoma (SMZL) is an indolent mature B-cell malignancy. However, nearly one-third of patients display a rapidly progressive disease and a dismal outcome. Risk stratification has been recently proposed based on the assessment of clinical and laboratory parameters on diagnosis. Biological prognostic factors are still lacking and their identification might prove of great value for identifying patients at high risk of unfavorable disease. In SMZL, bone marrow (BM) infiltration is almost invariably observed on diagnosis and the BM microenvironment may play an important role in the disease progression. *Aims.* Aim of this study was to characterize the BM microenvironment associated with SMZL infiltrates in order to identify

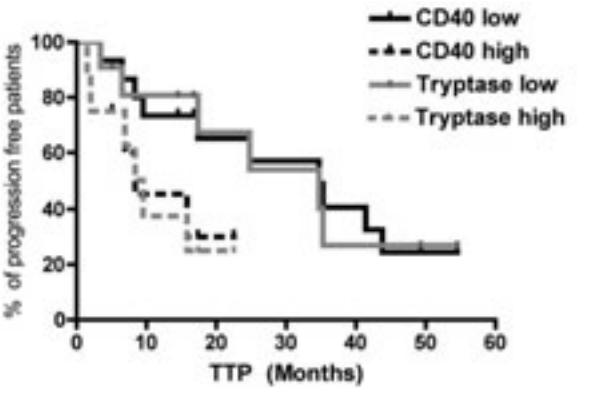

Figure 1.

potential influences of the stroma on the biology and natural history of this lymphoma. *Methods.* Routinely processed BM biopsies (BMB) of thirty-five consecutive cases of SMZL diagnosed at our Institution between 2001 and 2010 were collected. All patients had a BMB at the time of diagnosis. Besides the expression of CD20, CD3, CD5, CD43, CD23, bcl-2 and bcl-6, density and distribution of stromal elements were immunohistochemically evaluated on BMBs by semiquantitative analysis of the markers CD10 (adventitial reticular cells), CD31 (blood vessels), and CD40 (activated stromal cells and endothelia). Moreover, the amount of immune cells infiltrating the SMZL lymphoid aggregates was estimated by counting the number of CD68+ (macrophages), DC-Sign+ (myeloid DCs), CD4+ (Th cells), and tryptase+ cells (mast cells). Time to progression (TTP) was used as clinical endpoint. TTP was calculated as the time interval between diagnosis and progressive disease (PD). PD was defined either as an increase in size of previously documented disease greater than 25%, or as the appearance of disease at any new site or even the shift to a more aggressive histotype. *Results.* We found a significant correlation between the amount of infiltrating tryptase+ mast cells and TTP (Fig. 1). Patients with elevated numbers (above mean value) of mast cells (41.4%) had a mean TTP of 11.1 months, as compared with patients with low mast cell numbers (58.6%) that showed a TTP of 30.8 months (p=0.05). A strong positive correlation was observed between CD40 stromal expression and the number of tryptase+ mast cells (p=0.0001). Multivariate analysis was performed including, along with tested immunohistochemical variables, clinical and laboratory features of the SMZL prognostic score system, such as hemoglobin, LDH, and albumin levels. Notably, Cox proportional hazard revealed that the amount of tryptase+ mast cells populating SMZL BM infiltrates, and CD40 expression in the BM stroma were significant and independent predictors of a shorter TTP (p=0.05; p=0.03) in our SMZL patients. *Conclusions.* Here we demonstrated that BM microenvironment-related features, namely the presence of tryptase+ mast cells and CD40 stromal expression, could have a role in determining prognosis of SMZL patients. Our preliminary results point out a possible functional link between mast cells and BM stromal cells that may impact on neoplastic clone survival and proliferation. Further investigations will address the functional significance of such interactions.

0347

MANTLE CELL LYMPHOMA: USING THE TRANSCRIPTION FACTOR SOX11 AS BIOMARKER FOR MCL VIA A HIGHLY SENSITIVE AND SPECIFIC QPCR ASSAY

K Hornung Hamborg, H Bentzen, C Nyvold

Aarhus University Hospital, Aarhus, Denmark

Background. In both leukemia and malignant lymphomas balanced chromosomal translocation are seen as tumor markers in a significant part of the patients. These translocations characterize the molecular phenotype of the disease, which provides for a mean to diagnose accurately using PCR and can be used as biomarkers to determine minimal residual disease (MRD) using real-time quantitative PCR (qPCR). MRD quantification with markers specific for the malignant cells makes more risk based treatment strategies possible. The translocation t(11;14) is the hallmark of Mantle cell lymphoma (MCL) and results in cyclin D1 (CCND1) overexpression but it only gives limited information on the course of MCL. Some patients suffer an aggressive course with large tumor burdens while other resembles CLL, which may not require treatment. The gene encoding the transcription factor SOX11 was in

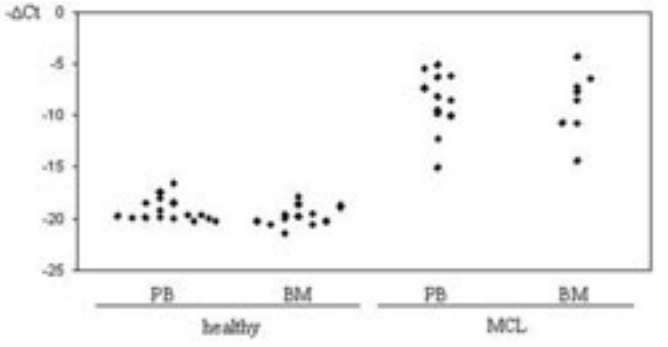

Figure 1. SOX11 expression.

1995 described to play a part in CNS development and later as a potential tumor marker for MCL as it is overexpressed in this subset of hematological malignancy and the SOX 11 expression seems to give information on the clinical and biological behavior in MCL. *Aims.* We wished to establish a very sensitive and specific qPCR assay for detection and quantification of SOX11 mRNA in order to use this gene as biomarker for MCL. As SOX11 is an intronless gene the challenging task was to establish a sensitive and specific qPCR assay without the risk of contamination from genomic DNA (gDNA). Furthermore we wished to compare the expression patterns of SOX11 and CCND1 in a cohort of MCL patients. *Methods.* Mononuclear cells were obtained from peripheral blood (PB) and bone marrow (BM) samples from healthy individuals and diagnostic PB and BM samples from MCL patients. The cell line Granta 519 was used as positive control for SOX11 and CCND1 expression. Total RNA was prepared and cDNA was synthesized using anchored oligo(dT) primers avoiding amplification of gDNA in the downstream qPCR. We overcame the risk of gDNA contamination by the design of a polyA specific reverse primer together with an LNA modified TaqMan probe ensuring efficient amplification and detection of SOX11 cDNA. GUS and B2M were used as control genes. *Results.* We find a highly significant differences in expression of SOX11 between healthy individuals and MCL patients (PB: $p<10^{-4}$, BM: $p=10^{-4}$, calculated using Wilcoxon rank-sum test). Figure 1 depicts the SOX11 expression levels in healthy individuals and diagnostic MCL PB and BM evaluated as -ØCt (ØCt = Ct(SOX11)-(average Ct control genes)) with an assay sensitivity of 10^{-4}. Ct = 40 was used as cut off between SOX11 negative and positive samples. *Conclusions.* A highly sensitive and specific qPCR assay without risk of contaminating gDNA was established enabling SOX11 to be used as biomarker for following MRD in MCL. This potent qPCR assay will be used in the ongoing longitudinal study of MRD in MCL patients in order to demonstrate a connection between treatment response and load of MRD in the heterogeneous group of MCL patients.

0348

ROLE OF GLYCOLYSIS IN THE PATHOGENESIS OF NON-HODGKIN LYMPHOMA

T Wang,[1] YY Pang,[1] JH Zhong,[1] F Li,[2] XF Han,[1] L Zhong,[1] HH Huang,[1] H Zhong,[1] F Gonzalez,[2] FY Chen[1]

[1]*Shanghai Jiao Tong University School of Medicine, Shanghai, China*
[2]*Lab of Metabolism, National Cancer Institute, National Institutes of Health, Bethesda, United States of America*

Background. Non-Hodgkin lymphoma is a set of heterogeneous diseases with different pathology and malignant behaviors, varied a lot from indolent to aggressive, and chemosensitive to chemoresistant, thereby highlighting the importance of determine the underlying molecular mechanisms and biomarkers for the evaluation of treatment efficacy and prognosis. *Aims.* To investigate the relationship between metabolomic, biologic, and genomic phenotypes of Non-Hodgkin lymphoma, identify the pathogenesis biomarker and the corresponding mechanism, and provide a target for therapy. *Methods.* C57BL/6Nr mice were administered either corn oil or the environmental carcinogen dibenzo-[a,l]pyrene (DB[a,l]P) via gavage to establish the lymphoma-bearing mouse models. Tumors were developed in various organs including liver, spleen, lymphnode, thymus, small intestine, mammary gland, ovary, kidney and bone marrow, demonstrated by histopathology and immunohistochemistry. Urine and serum samples were collected and metabolomic analysis was performed using Ultra Performance Liquid Chromatography coupled to Time-of-Flight Mass Spectrometry (UPLC- QTOFMS). Biomarker extraction was undertaken using SIMCA-P+ and Random Forests. Non-

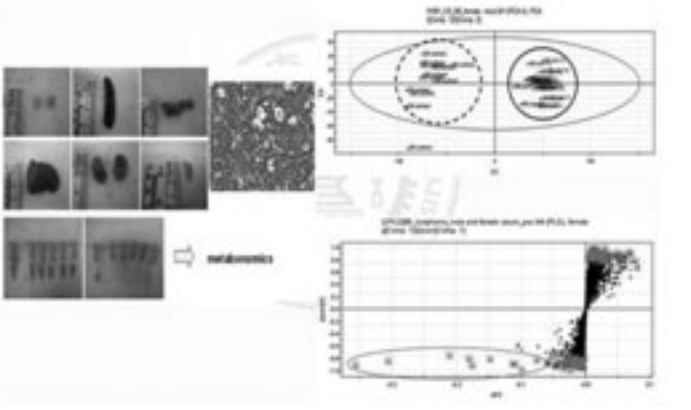

Figure 1. Metabolomics study of lymphoma-bearing mice.

Hodgkin lymphoma cell lines Namalwa, Raji, SU-DHL-4 and Jeko-1 cells were maintained. Cell proliferation and cytotoxicity were detected using Cell Counting Kit-8. Real-time PCR were performed to determine the molecular mechanisms. *Results.* Principal Component Analysis (PCA) revealed good separation of lymphoma and control groups, and biomarkers contributed to the separation were identified as metabolites of energy metabolism, especially the glycolysis pathway. The abnormal accumulation of lactate, final product of the glycolysis pathway under hypoxia, and succinate, the intermediate metabolite of mitochondrial tricarboxylic acid cycle, suggested the activation of glycolysis and dysfunction of mitochondrial respiration. Real-time PCR demonstrated a significant upregulation of glycolysis enzyme genes including hexokinase 1, glucose-6-phosphate isomerase, phosphofructokinase, aldolase A, fructose-bisphosphate, riosephosphate isomerase 1, glyceraldehyde-3-phosphate dehydrogenase, phosphoglycerate kinase 1, phosphoglycerate mutase 1, enolase 1, pyruvate kinase, and lactate dehydrogenase A genes in lymphoma cell lines. Furthermore, the upregulation levels were positive correlated with the malignant behaviors of those cell lines as Namalwa > Raji > SU-DHL-4 > Jeko-1 cells. Glycolysis inhibitor 2-Deoxyglucose (2-DG) exhibited cytotoxic effect in Namalwa cells, together with a significant decrease in the production of lactate and transcription of glycolysis enzyme genes, suggesting glycolysis as a target for lymphoma therapy. Summary/conclusions: In the present study, metabolomic analysis clearly distinguished lymphoma-bearing mice from control mice. The underlying mechanisms of the fundamental metabolic alteration were identified as an activation of glycolysis in the lymphoma cells, resulting in the consumption of more glucose to get sufficient ATP supply for their active proliferation. Inhibition of glycolysis may have potential therapeutic implications due to the preferential killing of lymphoma cells. Further metabolomic studies using human biofluid samples are needed to determine whether those markers would have clinical utilities.

0349

ACTIVATION AND STABILIZATION OF P53 BY NUTLIN-3A LEADS TO DOWNREGULATION OF HSP90 AND SYNERGISTIC EFFECTS WITH 17-AAG IN ANAPLASTIC LARGE CELL LYMPHOMA

G Rassidakis,[1] K Psatha,[1] A Antonoglou,[1] E Drakos,[2] V Atsaves,[1] T Vassilakopoulos,[1] P Panayiotidis,[1] E Patsouris,[1] M Aivaliotis,[3] G Rassidakis[1]

[1]*National and Kapodistrian University of Athens, Athens, Greece*
[2]*University of Crete, Heraklion, Greece*
[3]*Laboratory of Proteomics FORTH, Heraklion, Greece*

Background. The tumor suppressor gene p53 is frequently expressed but rarely mutated in ALK+ anaplastic large cell lymphoma (ALCL) (Rassidakis *et al*, Leukemia 2005, 19:1663), an aggressive type of T-non Hodgkin lymphoma. Recently, a small molecule that functions as a potent Mdm2 inhibitor, nutlin-3a, has been developed, which disrupts the interaction between p53 and Mdm2 resulting in stabilization and activation of p53. In a recent study, we showed that nutlin-3a induces cell cycle arrest and apoptosis through activation of p53 in ALK+ ALCL cells carrying wild -type (wt) (SUPM2) or mutated (mt) but partially functional p53 gene (DEL) (Drakos *et al*, Leukemia 2009, 23:2290). *Aim.* The aim of the study was to identify the proteomic profile of ALK+ ALCL before and after stabilization and activation of wild-type (wt) p53. *Methods.* Mass spectrometry-based proteomics were used to identify the proteomic profile of ALK+ALCL cell lines before and after treatment with

nutlin-3a in an effort to uncover new targets of activated p53 protein in our *in vitro* system. Cell viability and proliferation assays were performed. Expression levels of proteins were analyzed by Western blot. *Results.* Our preliminary proteomic data revealed that Hsp90 protein levels were significantly decreased following nutlin 3a treatment in SUP-M2 and DEL. This finding was confirmed using Western blot analysis and whole lysates of the same ALK+ ALCL cell lines. Combined treatment of ALK+ALCL cells with nutlin-3a and 17-AAG, a potent inhibitor of Hsp90, which is already used in investigational clinical trials in patients with aggressive lymphomas, resulted in significant decrease of cell viability assessed by trypan blue exclusion assay. In addition, proliferation of viable cells assessed by MTS assay and total cell numbers was substantially reduced following nutlin 3a treatment in these ALK+ ALCL cell lines. Analysis of these data also demonstrated synergistic effects in cell death and proliferation of cells treated with nutlin-3a and 17-AAG as compared with the results for each agent alone. *Conclusions.* Our preclinical findings support the rationale for combined use of targeted therapies such as nutlin 3a and 17-AAG in aggressive lymphoma types.

0350

ANALYSIS OF T-CELL SUBSETS BY FLOW CYTOMETRY IN LYMPH NODE BIOPSIES IDENTIFIES PATIENTS WITH GOOD PROGNOSIS IN FOLLICULAR LYMPHOMA (FL)

A Martinez-Trillos, N Villamor, G Gutierrez, J Carreras, E Gine, G Ghita, A Martinez, L Colomo, M Aymerich, E Campo, A Lopez-Guillermo

Hospital Clinic de Barcelona, Barcelona, Spain

Background. Tumor microenvironment plays an important role in the outcome of the patients with FL. By gene expression and immunohistochemistry, an increase in macrophages has been associated with poor outcome, whilst an increase in T-cells is associated with better prognosis. The quantification of immunohistochemical staining is time consuming and poorly standardized. The use of flow cytometry could help in identifying the different groups of risk in FL patients. *Patients and Methods.* Lymph nodes at diagnosis from 73 patients (35M/38F, median age 59, range 29 to 81) with FL were processed by standard flow cytometry. The percentage of CD3, CD4, CD8, CD57, and germinal center (GC) CD4 cells (CD4+CD57+), as well as the ratio B/T, CD4/CD8, CD4/CD3, CD8/CD3 and GC-CD4/CD4 were correlated with the main initial features and the clinical outcome of the patients. Histological grade 1 and 2 was observed in 58 patients, grade 3a in 12 and grade 3b in 1. Low-risk FLIPI was observed in 52%. 61 patients have received polychemotherapy, including rituximab in 36. After a median follow-up of 6 years, 23 patients have died, with a 5-year overall survival (OS) of 76%. *Results.* The mean (±SD) percentage of B-cells, CD3, CD4, CD8 and GC-CD4 was 59.7% (±15.1), 35.2% (±15.4), 26.4% (±12.3), 8.7% (±5.5), and 3.6% (±2.9), respectively. Age >60 years was associated with higher percent of CD3, CD8 cells and higher CD3/B-cell ratio. Grade 3 histology was associated with higher CD3 and CD8 cells and lower CD4/CD8 than grades 1 and 2. Response to treatment was not related to lymphocyte subpopulations. FLIPI, among other clinical variables, was able to predict OS. Patients with a CD4/CD8 ratio 4.4 had better OS than the remainder (5-year OS: 100% vs. 68%, respectively; p=0.01). Patients with high GC-CD4/CD4 ratio (0.19) showed a better OS than the others (5-year OS: 100% vs. 65%, respectively; p=0.02). A multivariate analysis identified GC-CD4/CD4 (p=0.03), CD4/CD8 (p=0.01) and FLIPI (p=0.04) as the most important variables to predict OS. *Conclusion.* flow cytometry allows the identification of a microenvironment pattern associated with good prognosis in patients with FL.

[3]*Department of Pathology, UZ Leuven, Leuven, Belgium*
[4]*Department of Hematology, UZ Leuven, Leuven, Belgium*

Background. Splenic marginal zone lymphoma (SMZL) is a rare low-grade B-cell lymphoma that has been recognized as a separate entity in the WHO classification. Chromosomal abnormalities are present in more than 70% of cases, most frequently gains of 3q and 12q, and loss of 7q sequences. In rare SMZL cases, immunoglobulin (*IG*)-mediated translocations affecting *BCL6*/3q27, *MUM1*/6p25, *PAX5*/9p13 and *BCL3*/19q13 have been described. We have collected four cases of SMZL characterized by del(7q) and t(*IGH*), either in the stem line, or in a subclone. In one of these cases, occurrence of the t(*IGH*) coincided with clinical progression of the disorder. *Aims.* Our project aims to identify partner genes affected by t(*IGH*) in SMZL and to unravel their role in the pathogenesis/progression of these disorders. *Methods.* Fluorescence *in situ* hybridization (FISH) with a set of probes for candidate partner genes was applied. In one case with unbalanced t(*IGH*), additional array comparative genomic hybridization (aCGH) analysis was performed with the Agilent 244K platform. Transcript levels of candidate genes were analyzed by QRT-PCR. *Results.* All four presented SMZL cases showed del(7q) and one of the following translocations: t(6;14)(q23;q32) (case 1), der(14)t(14;18)(q12;q32) (case 2), t(14;19)(q32;q13) (case 3) and an unknown t(*IGH*) detected by interphase FISH (case 4). FISH with probes for 7q and *IGH* was performed to determine the prevalence of both aberrations in each sample. The t(6;14) of case 1 was absent in the diagnostic sample, but appeared as a subclonal aberration at the time of clinical progression. FISH mapped the 6q23 breakpoint in the region of *MYB*. The unbalanced t(14;18) of case 2 showed a breakpoint centromeric to *BCL2* and *MALT1*. FISH and aCGH analysis narrowed down the breakpoint to the region harboring *DCC*, *MBD2* and *TCF4*. Further molecular studies of both cases are ongoing. The t(14;19) of case 3 showed involvement of *BCL3*, and in case 4 a normal FISH status of the candidate partner genes *BCL3*, *BCL6*, *MYB* and *PAX5* was found. *Conclusion.* Our preliminary data suggest that *IGH* translocations are recurrent secondary events acquired during the clinical course of SMZL. These translocations target miscellaneous partner genes, including *BCL3* and *MYB*. *MYB* is a proto-oncogene that encodes a transcription factor important for lineage commitment, proliferation and differentiation of hematopoietic progenitor cells. So far, involvement of *MYB* in the pathogenesis of B-cell malignancies has not been reported.

COMPARISON OF FLOW CYTOMETRY AND BONE MARROW BIOPSY IN THE DETECTION OF LYMPHOID INFILTRATION IN NON-HODGKIN'S LYMPHOMAS

L López-Anglada,[1] A Duque,[1] A García-Mateo,[2] JJ Pérez,[1] M González,[1] D Caballero,[1] MT Villaescusa,[1] I Córdoba,[1] M Cabrero,[1] E Pérez,[1] J Labrador,[1] T Flores,[1] N Puig,[1] A Martín,[1] M Díez-Campelo,[1] A Orfao,[3] J San Miguel,[1] MB Vidriales[1]

[1]*Hospital Clínico Universitario, Salamanca, Spain*
[2]*Hospital General de Segovia, Segovia, Spain*
[3]*Universidad de Salamanca, Salamanca, Spain*

Background. Bone marrow biopsy (BMB) is mandatory for non-Hodgkin's lymphoma's (NHL) staging, being also useful for assessing treatment response and for re-staging in relapse. Immunophenotypical analysis by multiparametric flow cytometry (MFC) has been increasingly used in hematological malignancies due to its high applicability and sensitivity at diagnosis and for detection of minimal residual disease (MRD). However, the use of MFC in the routine clinical settings for NHL staging is not yet well established. *Aims.* To compare the value of trephine biopsies (BMB) and multiparametric flow cytometry (MFC) in the assessment of bone marrow infiltration in NHL. *Methods.* 494 diagnostic (n=282) and follow up (n=212) specimens, simultaneously analysed by BMB and MFC, from non Hodgkin's lymphomas (NHL) patients were included in the study. Most patients (87%) had B-cell NHL: diffuse large B cell lymphoma (DLBCL) 35% (n=172), follicular lymphoma (FL) 27% (n=135), mantle cell lymphoma (ML) 10% (n=49), marginal zone lymphoma (MZL) 9,7% (n=48), Burkitt's lymphoma (BL) 2.2% (n=11), small lymphocytic lymphoma (LLC/SLL) 1.8% (n=9) and lymphoplasmacytic lymphoma (LPL) 1.4% (n=7); the rest of cases (12.8%) were classified as T/NK lymphomas (T/NK NHL). BMB infiltration was categorized as nodular, interstitial, mixed and diffuse. Selected panels of monoclonal antibodies were used for MFC study, using four-colour direct immunofluorescence technique and according to previously well described methods, aimed to identify and characterize B and/or T cells in BM. *Results.* Concordant results between BMB and MFC were found in 396 samples (80%), being both techniques negative in 83% (330/396) and positive in 17% (66/396) of cases. Discrepant results were found in 98 cases (20%), with a similar distribution among cases BMB+MFC- (42%; 41/98 cases) and BMB-MFC+ (58%; 57/98 cases). Considering histology, discrepant results were found more frequently in T/NK NHL (33%; 21/63 cases) in which MFC

was a little more sensitive than BMB, since 62% of discrepant cases (13/21) corresponded to BMB-MFC+ cases, whereas 38% (8/21) corresponded to BMB+/MFC- cases. In ML 20% were discrepant cases (10/49), also being MFC more sensitive than BMB (90% of discrepant cases were BMB-/MFC+). In MZL 23% (11/48) cases were discrepant, with a similar frequency of cases BMB-MFC+ (45%) and BMB+MFC- (55%). In FL and DLBCL discrepancies were more uncommon, with 17% (23/135 cases) and 15% (26/172 cases) of discrepancy, respectively. In FL, BMB was lightly more sensitive than MFC (13/23 -56%- being BMB+MFC-), and, by contrast, in DLBCL MFC was more sensitive (15/26 -58%- being BO-MFC+). Although with low number of cases, all discrepancies in LPL (2/7) were BMB+CMF- whereas in BL (2/11) and LLC/SLL (3/9) all discrepancies were BMB-MFC+. *Summary/Conclusions.* According with our results, we can conclude that MFC can detect a subgroup of patients with bone marrow involvement in which BMB is negative. Therefore both techniques complement each other and both should be used for the detection of bone marrow infiltration in B cell disorders.

[2]*Charite, Berlin, Germany*
[3]*Institute of Human Genetics, Poznan, Poland*

The genetic background of Sezary syndrome, a disseminated form of cutaneous T-cell lymphomas (CTCL), is still a matter of discussion. To unravel genetic imbalances, high density comparative genome hybridization was performed on leukemia samples derived from 12 patients. We identified bi- and monoallelic deletions of the tumor necrosis factor alpha induced protein 3 gene (TNFAIP3; A20) in a high proportion of SS patients as well as biallelic A20 deletion in the SS-derived cell line SeAx. Furthermore, we demonstrate that inhibition of A20 activates the NF-κB pathway thereby increasing the proliferation of normal T lymphocytes. On the other hand, the reconstitution of A20 expression slowed down the cell cycle in SeAx cells. Recently A20 inactivation has been reported in various B-cell lymphomas. In this study we show that A20 is also a putative tumor suppressor in the T-cell malignancy - Sézary syndrome.

PATIENTS WITH B-CELL NON HODGKIN LYMPHOMA SHOW INCREASED FREQUENCIES OF REGULATORY T CELLS AND CD8+ T-CELL EXPANSIONS

C Fozza, S Contini, P Virdis, A Galleu, M Careddu, D Giannico, S Bonfigli, M Longinotti

University of Sassari, Sassari, Italy

Background. Although most non Hodgkin lymphomas (NHL) take origin from the B-cell lineage, several studies suggest that any impairment involving the different branches of the immune system may play a role in their pathogenesis. Moreover the cross-talk among lymphoma cells and other cell types, such as for instance T-lymphocytes and antigen presenting cells, within the peritumoral microenvironment seem to deeply influence the onset and evolution of NHL. *Aim.* In order to explore the possible impact that the degree of activation of the T-cell immune system and the balance among different T-cell populations may have on the NHL pathogenesis, we analysed the T-cell receptor (TCR) repertoire and the distribution of different T-cell subsets -including regulatory T-cells (Treg)- in patients with NHL. *Methods.* Our study was based on a flow cytometric analysis performed on the peripheral blood of 15 patients (6 with indolent NHL and 9 with diffuse large B-cell lymphoma, DLBCL) and 15 age-matched controls. We first determined the frequency of CD3+, CD4+, CD8+ and CD16-56+ T-cells. Treg were then identified by considering the CD4+ cell fraction characterised by a very high (>2 log) expression of CD25 and by a very low (<2 log) expression of CD127, as well as by determining the expression of FoxP3 and CD152. TCR repertoire analysis was based on a panel of 24 beta variable (BV) family-specific antibodies. A BV expansion was defined as any value of BV family expression higher than the mean + 3 standard deviations calculated in normal controls. *Results.* We first showed that patients had reduced frequencies of CD16+ CD56+ natural killer cells (14% vs 21%) when compared with normal controls, while CD3+, CD4+ and CD8+ frequencies were similar. Patients also showed a higher frequency of Treg than controls (mean 2.35% vs 1.14%), although this increase was mainly confined to patients with DLBCL (mean 2.79%) rather than in patients with indolent NHL (mean 1.70%). Finally we determined the frequency of expanded T-cell subpopulations expressing the same TCR BV subfamilies, showing in patients and controls a similar frequency of expansions in CD4+ cells (1,3% vs 1,5%), besides an increased frequency of CD8+ expansions in patients (5,7% vs 3,2%). When we looked at the possible influence of several disease-related factors, such as WHO lymphoma subtype, IPI score, presence of constitutional symptoms, bone marrow involvement and stage, only a diagnosis of DLBCL rather than indolent NHL was associated with a trend towards an increased frequency of CD8+ lymphocyte expansions (6,2% vs 4,8%). *Conclusions.* Our preliminary data suggest that the T-cell branch of the immune system in patients with NHL show features which can be distinguished from those observed in normal controls. In particular, NHL patients seem to show an increased degree of activation of the TCR repertoire along with a higher frequency of Treg, which are both even more pronounced in patients with aggressive NHL.

0355

PRIMARY EFFUSION LYMPHOMA CELL ADHESION TO EXTRACELLULAR MATRIX PROTEINS

E Boulanger, P Binkley, SJ Gao

UTHSCSA, San Antonio, United States of America

Background. Primary effusion lymphoma (PEL) is a KSHV-associated B-cell non-Hodgkin lymphoma developing as malignant effusions in serosal cavities. The extracellular matrix (ECM) of serosal cavities contains type IV collagen, fibronectin (FN) and laminin (LN). *Aims.* To investigate the ability of PEL cells to adhere to ECM proteins and to identify the integrin receptors mediating cell-ECM interactions. *Methods.* The expression pattern of integrins was determined in eight PEL cell lines using membrane immunostaining and flow cytometry analyses. Their ability to attach to human ECM proteins versus human serum albumin used as control was assessed in cell-ECM adhesion assays, with or without preincubation with specific blocking monoclonal antibodies to various integrin subunits or isotype-matched immunoglobulins, and competing RGD peptides. *Results.* All PEL cell lines were found to express CD29/β1 and CD49f/α6 integrins. All but one (ISI-1) were found to be CD49d/α4-positive. CD49b/α2, CD49c/α3, CD49e/α5, α9β1, CD104/β4 and αVβ3 were found to be expressed in three (BBG-1, BCP-1, CRO-AP/3), two (BCP-1, ISI-1), five (BC-1, BCBL-1, BCP-1, HBL-6, ISI-1), four (BC-1, BC-3, CRO-AP/3, ISI-1), five (BC-1, BC-3, BCP-1, CRO-AP/3, ISI-1) and four cell lines (BC-1, BC-3, CRO-AP/3, ISI-1), respectively. All PEL cell lines were found to lack expression of CD49a/α1 and CD18/β2. Cell-ECM adhesion assays showed a significant binding of BC-3 (11.23 ± 6.09%), CRO-AP/3 (14.20 ± 0.93%) and BCP-1 (28.14 ± 15.66%) to FN, and a significant binding of BC-3 (12.67 ± 3.12%), BBG-1 (21.66 ± 8.35%) and ISI-1 (30.94 ± 9.02%) to LN. BCBL-1, BC-1 and HBL-6 did not show any significant attachment to ECM proteins. No significant binding to type IV collagen was observed. LN binding was reduced by 62% for BBG-1 (8.57 ± 5.76%, P=0.002), 55% for BC-3 (5.71 ± 2.16%, P=0.02), and 76% for ISI-1 (7.50 ± 4.64%, P=0.009) by anti-CD29/β1 mAb, and by 78% for BBG-1 (4.82 ± 2.24%, P=0.01), 59% for BC-3 (5.16 ± 4.64%, P=0.02) and 50% for

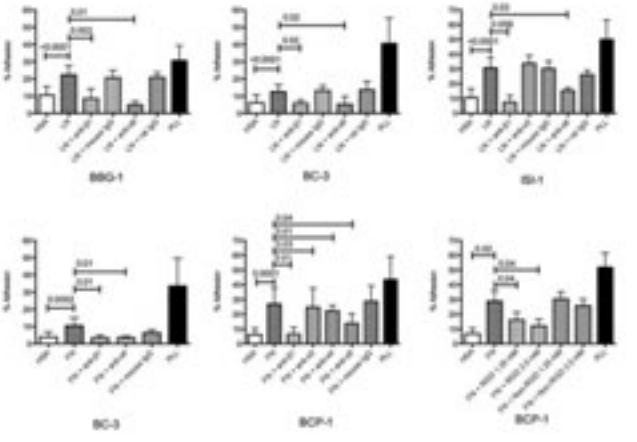

Figure 1.

ISI-1 (15.31 ± 2.09%, P=0.03) by anti-CD49f/α6 mAb. Incubation with anti-CD49c/α3, anti-α9β1, anti-αVβ3 and anti-CD104/β4 mAbs did not inhibit PEL cell adhesion to LN. FN binding was reduced by 68% for BC-3 (3.33 ± 1.70%, P=0.01) and 76% for BCP-1 (6.49 ± 4.62%, P=0.01) by anti-CD29/β1. BC-3 adhesion to FN was also reduced by 67% (3.49 ± 1.04%, P=0.01) by anti-CD49d/α4, whereas BCP-1 adhesion to FN was moderately although significantly reduced by anti-CD49c/α3 (24.76 ± 13.06%, P=0.03), anti-CD49d/α4 (22.23 ± 3.80%, P=0.01) and anti-CD49e/α5 (13.76 ± 6.64%, P=0.04) mAbs, with 8%, 18% and 49% inhibition, respectively. Moreover, competing RGD peptides significantly reduced BCP-1 attachment to FN, in a dose-dependent manner, suggesting a predominant involvement of α5β1/VLA-5. *Conclusions.* All PEL cell lines express the LN receptor α6β1/VLA-6 and at least one FN receptor, mostly α4β1/VLA-4. BBG-1, BC-3 and ISI-1 cell attachment to LN is predominantly α6β1/VLA-6-dependent. BC-3 binding to FN is mostly α4β1/VLA-4-dependent, whereas BCP-1 binding to FN is mediated by α3β1/VLA-3, α4β1/VLA-4 and α5β1/VLA-5, with a predominant involvement of α5β1/VLA-5. These integrin receptors may represent interesting targets for the development of novel therapeutic strategies for patients with PEL.

0356

HANS' CLASSIFIER IN PATIENTS TREATED WITH DOSE ADJUSTED EPOCH-R (DAEPOCH-R) FOR ADVANCED DIFFUSE LARGE CELL B LYMPHOMA (DLBCL)

J Bergua, L Ferrando, F Ibañez, H Fernandez-Leyva, J Prieto, C Cabrera-Silva, H Bañas, F Carnicero, ML Bengochea, MJ Arcos-Carmona, N Bermejo, MJ Garcia-Blanco, C Martín-Aguilera

Hospital San Pedro de Alcántara, Cáceres, Spain

Purpose. Analysis of the Progression Free Survival (EFS) and overall survival (OS) of diffuse large cell B lymphoma treated with R-EPOCH utilizing Han's classifier. *Material and Methods.* We use R-EPOCH as described by Wilson *et al*.[1] No radiation therapy was applied over bulky disease. We included only patients diagnosed of diffuse with a IPI score higher than 3 or IPI adjusted<65 higher than 2. Han's classifier was applied as reported by Hans *et al*.[2] Cases were considered positive for CD10,BCL6 and MUM when the number of cells stained were higher than 30% of the tumor cells. Cases were classified as Germinal centre when CD10 was positive, or if CD10- cases when BCL6+ and MUM1- concurrently. *Patients.* 33 Patients were treated with R-EPOCH. Median age was 55 (28-77); 15 patients (45%)were older than 60 year old. 20 patients (60%) were male. Ann Arbor stage was: IIB: 2 patients; IIIA:, IIIB: 2, IV: 28. Median LHD was 811 (256-5413 u.i/L; normal 480 u.i/L). Median Beta 2 microglobulin was 3.07 (1,3-7,3 mg/dl; control 2). Adjuted age IPI (aaIPI) mean was 3,55; IPI mean was 4,03. *Results.* Median follow-up is 28 months (1.4- 73.3). 26 patients are alive. Treatment outcomes were: 27 achieved CR; 1 uCR; 3 (9%) patients were resistant or progressed during treatment. Three patients died during treatment. 5 patients relapsed at a median follow-up of 7.5 months (6-40,867). Median OS or EFS have not been reached. OS at 5 years was 72% and EFS was 60.58%. Three relapsed/resistant patients were successfully salvaged with Autologous stem-cell transplantation, one patient obtained complete response with R-ESHAP. Bcl6 were positive in 95% of the cases; Bcl2 in 55%; CD10 in 25%; MUM-1 in 75%. 33% of the patients were Germinal-Center type according to Han's classifier. In univariate analysis only high LDH was correlate with poor outcome (p=0.05). We have not found correlation with outcome with age, beta-2-microglobulin, stage and expression of bcl-2, bcl-6, MUM1 and Hans classifier. *Conclusion.* DA EPOCH-R overcomes poor prognosis derived from biological markers, including Bcl6. We not confirm the negative impact of Bcl-6 negativity observed by Wilson *et al*1. Our results compared favorably to R-CHOP or R-CHOP plus transplant in high risk DLCBL. These results are even better than the results obtained by Wilson *et al* in patients with worse prognosis1 and confirms the results of Garcia-Suarez *et al*.[3]

MANTLE CELL LYMPHOMA CELLS EXPRESS B7 FAMILY MOLECULES AND B7-H1 EXPRESSION ARE UP-REGULATED AFTER INTERFERON-GAMMA AND LPS EXPOSURE VIA MEK-DEPENDENT PATHWAY IN MANTLE CELL LYMPHOMA CELLS

Z Cai,[1] L Wang,[1] J Qian,[2] H Bao,[1] Y Yang,[1] Y Zhao,[1] D He,[1] P Lu,[1] Y Li,[1] L Yang,[1] M Wang,[2] Q Yi[2]

[1]*The First Affiliated Hospital, Zhejiang University, Hangzhou, China*
[2]*MD Anderson Cancer Center, Houston, United States of America*

Background. Mantle cell lymphoma (MCL) is a distinct subtype of B-cell non-Hodgkin lymphomas characterized by a specific t(11;14)(q13;q32) translocation, causing over-expression of cyclin D1. Recent studies demonstrated that B7 family molecules were not only expressed on antigen presenting cells but also on various hematopoietic malignancies and solid tumors, and may play important roles in tumor immunology. Many cytokines could upregulate the expression of B7 molecules, however, the molecular mechanism of regulating expressions of B7 molecules in mantle cell lymphoma are still unknown. *Aims.* We detect the expression of B7 family molecules in mantle cell lymphoma cells and investigate the expression of B7 family molecules in mantle cell lymphoma cells after interferon-gamma and LPS exposure and study the cell signaling pathway involved. *Methods.* RNA isolation, RT-PCR, quantitative real-time polymerase chain reaction, Flow cytometry, Cellular lysate preparation, Western blot analysis and Signal transduction analyses. *Results.* RT-PCR and flow cytometry demonstrated that MCL patients and cell lines express B7 family molecules. After interferon-gamma and LPS stimulation, B7-H1 expression were upregulated detected by flow cytometry in MCL patients and cell lines. When we knocked down TLR4, LPS stimulation did not up-regulate B7-H1 expression. Pretreatment and coincubation of MCL cells with the MEK1/2 inhibitor UO126 reduced interferon-gamma and LPS induced B7-H1 expression, indicating that the MEK pathway was crucial for B7-H1 expression in MCL cells. To confirm that LPS and interferon-gamma induced B7-H1 expression through a MEK pathway in MCL cells, we stimulated MCL cells with LPS or interferon-gamma and analyzed the phosphorylation of ERK1/2 at different time. ERK1/2 phosphorylation were significantly up-regulated following LPS or interferon-gamma treatment. We confirmed that pretreatment of the cells with MEK inhibitor U0126 inhibited LPS or interferon-gamma induced phosphorylation of ERK1/2. *Summary/Conclusions.* In conclusion,

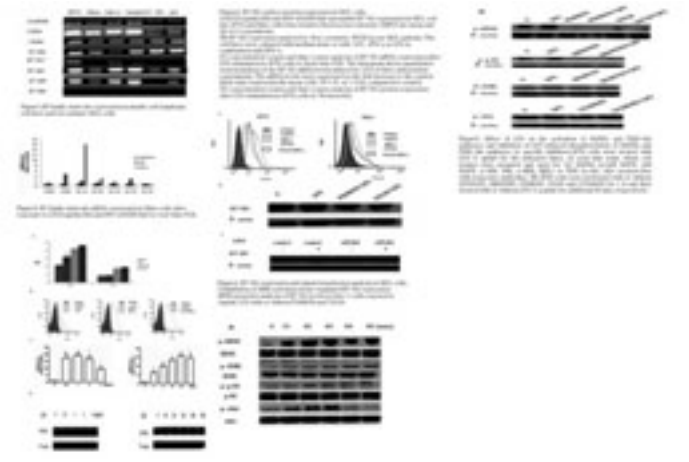

Figure.

our study demonstrated that mantle cell lymphoma cells express B7 family molecules. B7-H1 expression were up-regulated after interferon-gamma and LPS exposure via MEK-dependent pathwaysin MCL cells.

DECREASED NUMBER OF CIRCULATING T REGULATORY CELLS AMONG PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B CELL LYMPHOMA

J Nieckula,[1] M Glowala-Kosinska,[1] A Chwieduk,[1]
M Sadus-Wojciechowska,[1] S Grosicki,[2] Z Krawczyk,[1]
E Nowara,[1] S Giebel[1]

[1]*Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland*
[2]*Hospital, Chorzow, Poland*

Introduction. T regulatory cells (Tregs) are a subset of lymphocytes contributing to immune evasion by maliganacies. However, in contrast to solid tumors their role in promoting diffuse large B cell lymphoma (DLBCL) has not been clearly established. So far the presence of Tregs was demonstrated in involved tissues with conflicting results with regard to prognosis. The goal of our study was to prospectively analyze the number of Tregs in peripheral blood of patients with newly diagnosed DLBCL. Results were correlated with clinical characteristics. *Methods.* Blood samples from 19 patients with median age of 58,5 (22-79) years were collected and analyzed with the use of multiparameter flow cytometry for the presence of CD3+CD25+FoxP3+ (phenotype of "natural"Tregs) cells including subtypes characterised by expression of CD45RA (naïve Tregs), HLA-DR (marker of activation), CTLA4 (marker of costimulation), CD39 (selectin P), CD62L (marker of homing to inflamed regions). Results were compared with those achieved for 12 healthy individuals. *Results.* The absolute number of circulating Tregs, including both Tregs expressing CD45RA and CD45RA-negative was significantly lower among patients compared to controls (Table 1). The same was found for subpopulations of HLA-DR+ and CD62+ Tregs. The proportion of CD45RA+ cells among Tregs was also reduced for DLBCL group. Among patients with DLBCL the number of circulating Tregs was higher for patients in good performance status (ECOG=0) compared to those with ECOG=1 or 2: 46 (23-107) x10e6/L vs. 10 (4-48) x10e6/L, p=0.004.The number of Tregs did not correlate with age, LDH level, clinical stage, or the presence of general symptoms. *Conclusions.* The number of circulating Tregs is significantly decreased in patients with DLBCL. The reduction is associated with poorer performance status. Our observations together with previously published studies suggest that Tregs migrate from peripheral blood to involved areas and therefore may play a role in the pathogenesis of DLBCL.

Table 1.

Subpopulation	DLBCL n=19	Controls N=12	p
CD4+CD25+FoxP3+ (x10e6/l)	19 (4-107)	44 (19-104)	0.02
CD45RA (% Treg)	18 (7-60)	37 (13-56)	0.04
CD4+CD25+FoxP3+CD45RA+ (x10e6/l)	3 (0-28)	12 (4-52)	0.004
CD4+CD25+FoxP3+CD45RA- (x10e6/l)	17 (2-88)	30 (10-52)	0.04
HLA-DR+ (% Treg)	27 (8-63)	25 (14-49)	0.76
CD4+CD25+FoxP3+HLA-DR+ (x10e6/l)	5 (1-35)	11 (5-30)	0.03
CD39+ (% Treg)	60 (8-89)	45 (25-63)	0.16
CD4+CD25+FoxP3+CD39+ (x10e6/l)	7 (1-79)	17 (8-48)	0.06

[4]*Department of Medicine and Biosystemic Science, Kyushu Uninersity, Fukuoka, Japan*
[5]*Department of Medicine, Kurume University School of Medicine, Kurume, Japan*

Background. The heterogeneity of diffuse large B-cell lymphoma (DLBCL) has prompted the search for new markers that can accurately separate prognostic risk groups. We previously showed in multivariate analysis that high Skp2 expression by immunohistochemical method was a strong predictor of poor outcome in DLBCL. To better characterize the molecular mechanisms, we performed the DNA microarray study on DLBCL patients. *Material and Methods.* To investigate which genes are aberrantly expressed in DLBCL cells, we performed cDNA microarrays and compared gene expression profiling of either group with high (n=4) or low Skp2 DLBCL cells (n=4). *Results.* We selected 633 genes, 311 upregulated and 322 downregulated, which showed significant differences with a P-value of <0.01 (lima). IPA (Ingenuity pathway analysis) showed clearly the network composed of cell cycle regulators, which mediate cell cycle progression during the G1/S checkpoint. A computer-assisted approach was used to procure specific molecular signalling pathways that were aberrantly expressed in DLBCL cells. Several genes related to cyclins and cell cycle regulation and to the MAPK, JAK/Stat, WNT, tumor growth factor β and Myc mediated apoptosis signalling pathways were altered in DLBCL cells when compared with Skp2 levels. In addition, MTA3 (Metastasis -associated protein 3), which was direct corepressor WNT4 pathway, was a high average increase (1.16-lima/fold change, respectively) in high Skp2 DLBCL. MTA3 are reportedly highly expressed in high-growth fraction lymphomas, such as Burkitt Lymphoma, DLBCL. *Conclusion.* These genes may play a significant role in the pathogenesis of DLBCL and deserve further investigation as candidates for new therapeutic targets.

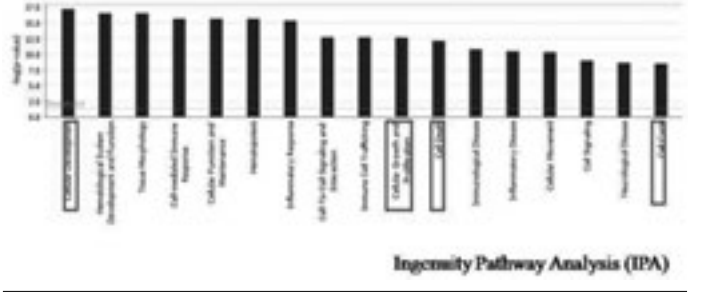

Figure 1. Functional classification (High Skp2 vs Low Skp2).

Chemokines - chemokine receptors (CRs) signal transduction network controls the proper function of the immune system. Previously we have identified the cluster of CR genes that includes CCR1 and CCR2, on human 3p21.31 within the malignancy-related chromosome

instability region (MCIR). Genes within MCIR are often silenced in cancer cells by DNA rearrangements and/or by epigenetic mechanisms (methylation). This 3p21.3 region was the most frequently deleted (LOH was detected in 83% of informative cases) in human solid tumors from different tissues (576 tumors from 10 tissues were analyzed) (Petursdottir *et al*., 2004). EBV is associated with endemic Burkitt's lymphoma (BL) and post-transplant lymphoproliferative disease. EBV infection leads to B-cell activation and transformation. Upon infection viral proteins induce interferon pathway, cell-surface adhesion molecules, activation antigens, chemokines and CRs (CCR6, CCR10, and CCR7). The aim of this study was to examine expression of CCR1 and CCR2 in long-time cultivated CD10+ B-cell lines both, EBV-negative (EBV-) and EBV-positive (EBV+), and also in peripheral blood (PB) circulating CD10+ B-cell subset of primary patients (prior specified diagnosis and treatment) with B-cell lymphoproliferative disorder (LPD). Twenty three B-cell lines (18 BLs (11 EBV+ and 7 EBV-), 3 PB B-cell lymphomas (BcL), and 2 diffuse histiocytic lymphomas (DHL)) were assayed by duplex RT-PCR for CRs (CCR1, CCR2, CCR5) from 3p21.31 region, CXCR4, CD markers (CD10, CD30, CD34, CD38, CD77), and EBV genes (EBNA1, EBNA2, LMP1) as well. Eleven cell lines (all BL) that transcribed CCR1 (among them 7 transcribed also CCR2), and PB of 8 patients were analyzed by polychromatic flow cytometry (FC), using monoclonal antibodies CD19-PerCP-Cy5.5, CD10-PE, CD191-Alexa-Fluor647 and CD192-Alexa-Fluor647. All cell lines were negative for CD34 and CCR5 transcripts, and were positive for CXCR4 transcript. In all 12 EBV- cell lines CCR2 transcript was not found, but CCR1 transcript was detected in two. On the contrary, among 11 EBV+ cell lines seven were CCR2-transcript positive and nine were CCR1-transcript positive. Notably that by polychromatic FC CCR2 was only found in about 10% of cells in 3 EBV+ cell lines, but CCR1 was present in the range of 4 - 36% in 9 out of the 11 EBV+ and in the range of 6 - 10% in two EBV-cell lines. In 8 samples of primary patients with CD10+ B-cell LPD CCR1 and CCR2 were observed on PB circulating CD10+ B-cell subset in the range of 98 - 100% and 76 - 99% respectively. Our results tentatively suggest that the lack of CCR2 in PB circulating CD10+ B-cell subset might be associated with progression of immature B-cell malignancy. Obviously, further extensive studies are necessary for the verification of our hypothesis. Petursdottir *et al*., Genes Chromosomes Cancer, 2004; 41:232-242.

Non-Hodgkin lymphoma - Clinical 1

Background. In patients with FL, quality of response to first-line therapy has been linked with improved survival. Additional active treatment options are required for patients with relapsed FL to improve outcomes. Rituximab is approved for relapsed/refractory FL; bortezomib has shown activity alone and in combination with rituximab in relapsed FL. The international, multicenter, phase 3 LYM3001 study compared bortezomib-rituximab with rituximab alone in patients with rituximab-naïve/-sensitive relapsed FL. *Aims.* This analysis was conducted to determine the impact of quality of response to treatment on outcomes. *Methods.* Patients with grade 1/2 measurable, relapsed FL (time to progression[TTP] ≥6 months for prior rituximab-containing therapy) were randomized (1:1) to five 35-day cycles of bortezomib (1.6 mg/m^2, days 1, 8, 15, 22, all cycles) plus rituximab (375 mg/m^2, days 1, 8, 15, 22, cycle 1, and day 1, cycles 2-5), or rituximab alone. All patients provided written informed consent. The primary endpoint was progression-free survival (PFS). Response/progression were assessed by an independent radiology committee using modified International Workshop Response Criteria. PFS, duration of response (DOR), TTP, time to next lymphoma treatment (TTNT), and treatment-free interval (TFI) were assessed in patients achieving complete response (CR)/unconfirmed CR (CRu) (verified by bone marrow and lactate dehydrogenase), partial response (PR), or no response (NR). *Results.* A total of 676 patients were enrolled to receive bortezomib-rituximab (n=336) or rituximab alone (n=340). Baseline characteristics were generally well balanced between arms; median age was 57 (range 24-83)/57 (range 21-84) years, 51%/40% were male, 41%/41% had high (≥3) FLIPI score, and 43%/44% had received prior rituximab in the bortezomib-rituximab/rituximab arms. After a median follow-up of 33.9 months, median PFS was 12.8 months with bortezomib-rituximab versus 11.0 months with rituximab (HR 0.822, p=0.039); overall response rates (CR/CRu+PR) were 63% versus 49% (p<0.001), including 25% versus 18% CR/CRu. In both arms, PFS was significantly longer in patients who achieved CR/CRu versus PR versus NR (bortezomib-rituximab: 32.6, 13.6, 4.5 months, respectively; rituximab: 33.2, 14.1, 4.7 months; p≤0.001 for all comparisons). Similarly, higher quality of response was associated with longer DOR, TTP, TTNT, and TFI in both treatment arms. Median DOR was 16.0 and 13.8 months, with 50%/32% of patients in the bortezomib-rituximab arm and 38%/23% in the rituximab arm having responses durable for 6/12 months. Median TTP was 13.3 versus 11.3 months (HR 0.808, p=0.027), median TTNT was 23.0 versus 17.7 months (HR 0.799, p=0.024), median TFI was 17.7 versus 13.0 months, and 1-year OS rate was 90.1% versus 90.5%, with bortezomib-rituximab versus rituximab. In the bortezomib-rituximab and rituximab arms, 46%/21% of patients had grade

≥3 adverse events (AEs), 18%/11% had serious AEs, and 17%/1% had peripheral neuropathy (3% and 0% grade ≥3), respectively. *Conclusions.* Bortezomib-rituximab resulted in improvements in PFS, response rates, DOR, and other outcomes compared with rituximab alone, with acceptable additional toxicity. Achievement of CR/CRu versus PR versus NR was associated with greater clinical benefit in both arms. The longer PFS/TTNT in the bortezomib-rituximab arm was driven by the additional responses with bortezomib-rituximab, which were as meaningful as those on rituximab alone.

BENDAMUSTINE FOR PATIENTS WITH INDOLENT LYMPHOMA - A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS (RCT)

L Vidal,[1] A Gafter-Gvili,[2] R Gurion,[2] P Raanani,[2] M Dreyling,[3] O Shpilberg[2]

[1]*Beilinson Medical Center, Davidoff Cancer Center, Petah Tikva, Israel*
[2]*Rabin Medical Center, Davidoff Cancer Center, Petah Tikva, Israel*
[3]*Department of Internal Medicine III, University Hospital Munich-Grosshadern, Munich, Germany*

Background. Survival of patients with indolent lymphoma has improved in the recent decade. While it is clear that the addition of rituximab to induction chemotherapy improves survival of these patients, it is unclear which is the best chemotherapy to combine with rituximab. None of the chemotherapy regimens that had been compared in randomized controlled trials (RCTs), were superior in terms of overall survival (OS). A number of RCTs have examined the effect of bendamustine in patients with indolent lymphoma. Progression free survival (PFS) was similar or prolonged with bendamustine compared to other chemotherapy and an OS benefit has not been shown. *Aims.* We performed a systematic review and meta-analysis to evaluate the effect of bendamustine on the OS of patients with indolent lymphoma. *Methods.* We included RCTs that compared bendamustine to other chemotherapy regimens for patients with indolent lymphoma. In December 2010 we searched The Cochrane Library, MEDLINE, LILACS, conference proceedings, and databases of ongoing trials. The primary outcome was all cause mortality. Relative risk (RR) for dichotomous data and hazard ratio (HR) for time to event data were estimated and pooled. *Results.* We identified 4 trials, conducted between the years 1994 and 2010 randomizing 1251 adult patients with a mean/median age of 58 - 68. The rate of patients with follicular lymphoma ranged between 40% to 52%, and mantle cell lymphoma 20% to 22% in the 3 trials that included patients with those types of lymphoma. One trial included only patients with chronic lymphocytic leukemia (CLL). The comparisons were between bendamustine, vincristine, prednisone to cyclophosphamide, vincristine, prednisone (COP); bendamustine-rituximab to cyclophosphamide, adriamycin, vincristine, prednisone, rituximab (RCHOP); bendamustine-rituximab to fludarabine-rituximab; and bendamustine to chlorambucil. Patients treated with bendamustine had an improved OS compared to controls, RR for death 0.80; 95% CI 0.67 - 0.97, I2 = 0 (Figure). After excluding the trial with only CLL patients the RR is 0.82; 95% CI 0.67 - 1.01. PFS was improved with bendamustine, HR 0.47; 95% CI 0.39 - 0.57. The rate of complete remission improved with bendamustine compared to controls, RR 2.31; 95% CI 1.07 - 4.96, random effects model, I2 = 88%. The rate of grade 3/4 adverse events was unaffected RR 1.21; 95% CI 0.99 - 1.48. *Conclusions.* This meta-analysis shows for the first time that bendamustine improves OS and PFS of patients with indolent lymphoma and CLL compared to other chemotherapy. These results should be interpreted cautiously due to the wide clinical heterogeneity of patients and treatments. Further trials of a more homogenous group should be performed to explore the role of bendamustine in various lymphoproliferative neoplasms.

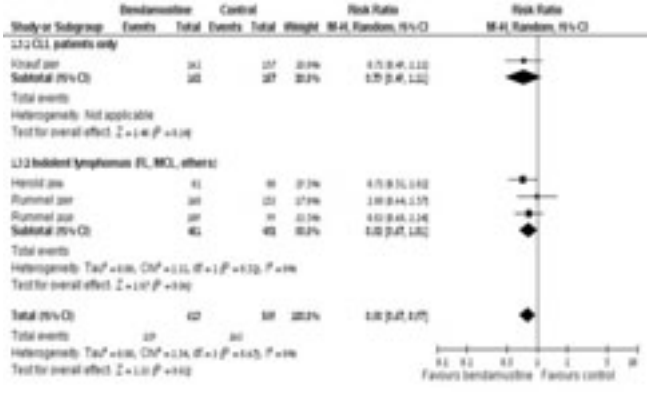

Figure 1. All cause mortality in patients with indolent lymphoma treated with bendamustine compared to other chemotherapy. CI = confidence interval; CLL = chronic lymphatic leukemia; FL = follicular lymphoma; MCL = mantle cell lymphoma.

[4]*Hematology Department, Centre Hospitalier Lyon-Sud,, Pierre-Benite, France*

Background. It is well documented that objective response rate (ORR) and progression-free survival (PFS) decrease with each subsequent chemotherapy regimen in the treatment of most cancers, a hallmark of acquired drug resistance. Although not reported, this trend often defines the natural history of patients with PTCL. The most common first-line treatment in PTCL is cyclophosphamide/doxorubicin/vincristine/prednisone (CHOP); however, despite high response rates, most patients progress within 6 to 12 months and require further salvage systemic therapy. Pralatrexate (FOLOTYN®) was granted accelerated approval in the United States for the treatment of relapsed/refractory PTCL based on results of the pivotal PROPEL study. As part of patients' medical history, data were collected on the ORR and PFS documented in previous therapies. Patients had a median of 3 prior therapies (range, 1-12). *Aims.* This retrospective analysis was conducted to evaluate whether progressive resistance was observed in patients with relapsed/refractory PTCL and to assess activity of pralatrexate compared with patients' previous treatments. *Methods.* Using investigator assessment of response, analyses were conducted according to the patients' number of prior systemic therapies. PFS and ORR for pralatrexate were compared with PFS and ORR for the most recent therapy prior to pralatrexate (-1); PFS and ORR of the most recent prior therapy (-1) were compared with those of the second prior therapy (-2); and PFS and ORR of second prior therapy (-2) were compared with the third therapy prior to pralatrexate (-3). *Results.* Results indicated a trend of reduced PFS and ORR with prior successive therapies, which appeared to be reversed by pralatrexate. Of the 109 evaluable patients in the PROPEL study, all had ≥1 prior therapy. For example, for the 57 patients who had ≥3 prior therapies in the -3 versus -2 analyses, the hazard ratio (HR) was 0.660, median PFS was 213.5 days, and ORR was 56% for the -3 therapy, compared with a PFS of 140 days and ORR of 33% for -2 therapy. These same patients had a further decrease in median PFS and ORR (95 days and 30%, respectively) with their -1 therapy. The trend was reversed with pralatrexate, which produced a median PFS of 134 days and ORR of 40% (Figure). Similarly, for the 86 patients who had ≥2 prior therapies in the -2 versus -1 analysis, the HR was 0.785, median PFS was 144 days, and ORR was 38%. In the full population of 109 patients with ≥1 prior therapy, the HR further increased to 1.051 for the -1 prior therapy when compared with pralatrexate; median PFS

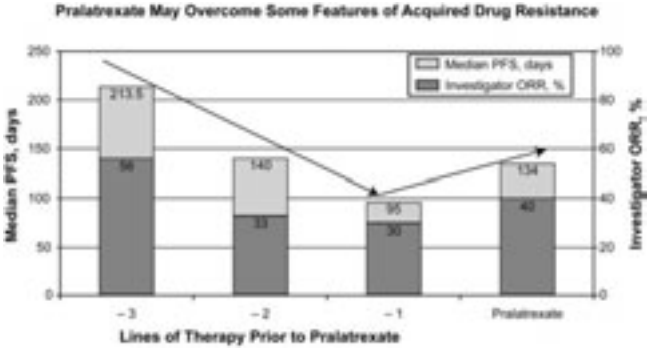

Figure 1.

was 114 days and ORR was 38% with the immediately previous line of therapy, as compared with a median PFS of 121 days and ORR of 39% for pralatrexate. *Conclusions.* This analysis demonstrated that patients with PTCL exhibit progressive resistance to treatment in which outcomes worsened with successive therapy. This trend was reversed with pralatrexate. Pralatrexate demonstrated higher responses and longer PFS than would be expected in a later line of therapy, thus reversing the trend of progressive resistance.

0364

DICE AS SALVAGE TREATMENT IN PATIENTS WITH RELAPSED OR REFRACTORY EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE

Y Guo, XJ Ma, Z Xia, K Xue, B Wang, X Hong

Fudan University Shanghai Cancer Center, Shanghai, China

Background and Aims. Recently, non-anthracycline-based chemotherapy was shown to be effective in extranodal NK/T-cell lymphoma, nasal type. Thus, a prospective phase II study was conducted in our institution to evaluate the efficacy and safety of DICE regimen in patients with untreated or relapsed disease. Here, we reported the treatment outcomes of DICE in the salvage setting. *Methods.* Thirty-eight patients with relapsed or refractory extranodal NK/T-cell lymphoma, nasal type were enrolled and received DICE (dexamethasone 40 mg, ifosfamide 1200 mg/m^2, cisplatin 20 mg/m^2 and etoposide 75 mg/m^2 on days 1 to 4) as salvage treatment. After chemotherapy, radiotherapy could be considered for patients with localized stage or residue disease if possible. *Results.* The median age of the patients was 38 years (range, 21 to 79). Other major patient characteristics were shown in Table 1. Of the 18 patients with stage IV disease, skin involvement was most frequent and developed in 10 patients (55.6%). In terms of prior treatment, 27 patients (71.1%) received radiotherapy and 31 patients (81.6%) had chemotherapy exposure which was mostly anthracycline-based (77.4%). The median cycles of DICE was four (range, 1 to 6). Twenty-one patients responded to DICE with an overall response rate of 55.3%. The complete and partial response rates were 23.7% and 31.6%, respectively. Radiotherapy was given to 13 patients with localized stage or residue disease after chemotherapy. Among 11 patients of them, who did not achieve complete response with chemotherapy, 6 patients (54.5%) were rendered disease-free by radiotherapy. Hematological toxicities were remarkable, but easily managed including dose-reduction in 17 patients (44.7%). All patients experienced grade 3/4 neutropenia and 10 patients (26.3%) had grade 3 neutropenic fever. The grade 3 and 4 anemia rates were 10.5% and 7.9%, respectively. Seven patients (18.4%) experienced grade 3 thrombocytopenia. Grade 3/4 non-hematological toxicities were uncommon except nausea/vomiting. There was no chemotherapy-related death. With a median follow-up time of 22 months (95% CI, 8.4 to 35.2), 17 patients died and 7 of them were complicated by hemophagocytic syndrome. Two-year progression-free and overall survival (OS) rates were 42.9% and 58.7%, respectively. Sub-group analysis demonstrated that chemo-sensitivity significantly correlated with survival. Two-year OS rates for patients with complete response, partial response and no response were 77.8%, 66.7% and 35.3% (P = 0.019). Through multi-variate analysis, response status after chemotherapy was also found to be the sole independent prognostic factor (RR 1.74, 95% CI 1.15 - 2.62; P = 0.009). *Conclusions.* In the present study, DICE was proved to be effective with manageable toxicities in patients with relapsed or refractory extranodal NK/T-cell lymphoma, nasal type. Response after chemotherapy had a significant impact on survival outcome. Efforts need to be done in an attempt to improve chemo-sensitivity which might be achieved by integrating novel agents with DICE. e-mail address: medoncol@gmail.com (Ye Guo, MD).

LONG-TERM FOLLOW-UP OF RITUXIMAB AND INFUSIONAL CYCLOPHOSPHAMIDE, DOXORUBICIN, AND ETOPOSIDE (CDE) IN COMBINATION WITH HAART IN HIV-RELATED NON-HODGKIN'S LYMPHOMAS (NHL)

M Spina,[1] M Spina,[1] U Jaeger,[2] JA Sparano,[3] R Talamini,[1] G Rossi,[4] E Vaccher,[1] U Tirelli[1]

[1]*National Cancer Institute, Aviano (PN), Italy*
[2]*University of Vienna, Wien, Austria*
[3]*Montefiore Medical Center, New York, United States of America*
[4]*Spedali Civili, Brescia, Italy*

Background. The combination of Rituximab plus chemotherapy (CT) is more effective than CT alone in the treatment of high grade NHL. *Objective.* To report the long-term follow-up of CDE plus Rituximab in HIV-NHL. *Methods.* In June 1998, we started a phase II study using infusional CDE (Cyclophosphamide 187.5 mg/m2/day, Doxorubicin 12.5 mg/m2/day and Etoposide 60 mg/m2/day) administered by continuous intravenous infusion for 4 days every 4 weeks and Rituximab 375 mg/m2 i.v. on day 1. HAART was given concomitantly with CT. *Results.* Seventy-four patients (pts) have been enrolled. The median CD4+ cell count was 161 (range 3-691) and the median Performance Status was 1 (range 0-3). Diffuse large B-cell NHL was diagnosed in 72% of pts and Burkitt in 28%. Seventy per cent of pts had advanced stage (III-IV) disease and 57% of pts had an age-adjusted international prognostic index >2. Fifty-two out of 74 pts (70%) achieved a complete remission (CR), 4/74 (5%) had a partial remission and 18 pts progressed. With a median follow-up of 61 months, only 17% of CRs have relapsed and 41/74 pts are alive. The overall survival, disease free survival and time to treatment failure (TTF) at 5 years were 56%, 81% and 52%, respectively. Four cases of secondary tumours have been observed. No case of late pulmonary or cardiac toxicity has been reported. *Conclusions.* The combination of Rituximab and CDE in HIV-NHL treated concomitantly with HAART is very active. CR rate (70%) and TTF at 5 years (52%) are comparable to those observed in high grade NHL of the general population. Our data confirm that in HAART era a high proportion of HIV-NHL can be cured.

Background. Bcl-2 family proteins are associated with tumor initiation and are frequently over-expressed in lymphomas. Navitoclax, a novel, oral, small molecule BH3 mimetic with clinical activity in lymphoid malignancies, binds with high affinity (Ki ≤1 nM) and inhibits Bcl-2, Bcl-Xl and Bcl-w, which regulate survival of lymphocytes, platelets and spermatocytes. *Methods.* This is a phase 2a safety-expansion portion of a phase 1/2a, single-agent, international study of patients with relapsed/refractory lymphoid malignancies, ≥1 prior chemotherapy regimen and ECOG status ≤1. The Phase 1 results have been reported previously. Following a 7 to 14-day lead-in dose-titration of 150 mg/day oral navitoclax, patients with platelet count ≥50,000/mm^3 proceeded to

21/21-day continuous dosing at 250 mg/day on C1D1 followed by possible dose titration to 325 mg/day, based on safety data from the initial 11 patients. Safety, efficacy, and pharmacokinetics (PK) were evaluated in Arm A (relapsed/refractory follicular lymphoma [FL]) and Arm B (other indolent B-cell lymphoid malignancies). Preliminary efficacy analyses included tumor response (IWG, NCI-WG criteria) and progression-free survival (PFS). Adverse events (AEs) were graded by NCI CTCAE v3. *Results.* Twenty-six patients (median age 62 years, range 42-86) are enrolled in the phase 2a study. Eleven patients enrolled on Arm A (FL), and 15 on Arm B (CLL [6], SLL [2], mantle-cell lymphoma [2], lymphoplasmacytic lymphoma [2], marginal-zone lymphoma [1], low-grade B-cell lymphoma nos [1], and transformed prolymphocytic leukemia [1]). Tumor response for patients in Arm A: 1 CRu, 4 SD, 4 PD, 2 incomplete data; and in Arm B: 6 PR, 6 SD, 1 PD and 2 incomplete data. For CLL/SLL patients in Arm B, 4 had PR (2 nodular), 2 SD, 1 PD; 1 incomplete data; and 7 had >50% reduction in absolute lymphocyte count. Overall 7 (27%) patients had objective responses. Median PFS [95% CI] for all patients was 6.4 months [3.1, not reached (NR)]; Arm A 3.0 months [1.5, 3.8]; and Arm B 6.4 months [NR, NR]. The most common navitoclax-related AEs (any grade) were diarrhea (81%), nausea (50%), and thrombocytopenia (42%); the most common Grade 3/4 AE was thrombocytopenia (31%). Two patients had serious AEs: bacterial sepsis, tumor lysis (1 each), and 7 patients had AEs (mainly thrombocytopenia) leading to dose reduction. Navitoclax exposure appeared consistent across cycles. *Conclusions.* Navitoclax was reasonably well tolerated with most toxicity due to on-target effects. Thrombocytopenia was predictable and manageable. Following a lead-in dose of 150 mg/day oral navitoclax, patients with platelet counts ≥50,000/mm^3 proceeded to 21/21-day continuous dosing at 250 mg/day on C1D1 followed by possible dose titration to 325 mg. As observed in the phase 1 study, CLL/SLL showed the best tumor responses. In other tumor types, navitoclax should be tested in combination with other agents.

Background. AME-133v is a humanized monoclonal antibody that via Fc engineering has greater CD20 affinity and antibody-dependent cell-mediated cytotoxicity (ADCC) potency than rituximab *in vitro*. A Phase 2 study was conducted to assess the safety and efficacy of AME-133v in patients with previously treated follicular lymphoma (FL) who expressed a low affinity variant of FcγRIIIa. The Phase 1 dose-escalation component of a Phase 1/2 clinical trial of AME-133v at doses ranging from 2 - 375 mg/m2 demonstrated that AME-133v was safe and tolerable at all dose levels tested, and 375 mg/m2 was chosen for further assessment. *Aims.* The aims of the Phase 2 component of this study were to determine the safety and tolerability of four, weekly infusions of AME-133v at 375 mg/m2, and to determine the pharmacokinetic (PK) profile, objective response rate, and duration of response in patients who are F-carriers in one or both alleles that encode amino acid position 158 of the FcγRIIIa gene. *Methods.* After obtaining informed consent, 50 patients were enrolled in the Phase 2 study. Based on the Phase 1 dose escalation results, AME-133v was administered at the highest previously tested dose of 375 mg/m2 intravenously every week for 4 weeks. Six patients were treated at 375 mg/m2 during dose-escalation and are included in this analysis as pre-specified in the protocol. Safety, PK, response, and progression free survival were assessed. Response was also assessed by an independent central reviewer. *Results.* The median age was 61 (39-83) years and the median number of prior therapies was 2 (1 - 9). The majority of patients (54%) received prior rituximab [(median number of doses was 8 (0-24)]. There were 22 patients with V/F- and 28 with F/F FcγRIIIa alleles. Forty-nine patients reported mostly Grade 1/2 adverse events (AEs) with the most common related AEs being chills, fatigue, nausea, and pyrexia. Grade 3/4/5 AEs were observed in 13 patients and SAEs were reported by 11 patients. Possibly related SAEs included neutropenia, abdominal pain, nausea, vomiting, and aspiration pneumonia. Three patients discontinued the study due to AEs and four patients experienced a dose-limiting toxicity (DLT). Two patients died during the study; one due to life-threatening oesophageal achalasia and one due to aspiration pneumonia. Investigator-assessed responses were observed in 15 (30%) patients, including 4CRs and 3 CRus. The centrally assessed response rate was 32%. The median progression free survival (PFS) was 38.3 weeks as assessed by the investigators. The pharmacokinetic profile of AME-133v was similar to rituximab. Lymphocyte subset analysis showed a significant and selective reduction of B-cells during and after AME-133v treatment. *Summary/Conclusions.* AME-133v was safe and well tolerated at the recommended Phase 2 dose of 375 mg/m2. Clinical responses, including 14% with CR/CRu, were observed. These data demonstrate that AME-133 is active in previously-treated FL patients who are F-carriers at amino acid position 158 in the FcγRIIIa gene.

0368

INTERIM RESULTS FROM A PHASE IB STUDY OF THE ANTI-CD20 ANTIBODY OBINUTUZUMAB (GA101) IN COMBINATION WITH FC OR CHOP IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA (FL)

A Davies,[1] J Radford,[2] G Cartron,[3] F Morschhauser,[4] G Salles,[5] R Marcus,[6] M Wenger,[7] E Asikanius,[7] E Wassner Fritch,[7] U Vitolo[8]

[5]*CH Lyon-Sud, Lyon, France*
[6]*King's College Hospital, London, United Kingdom*
[7]*F Hoffman-La Roche, Basel, Switzerland*
[8]*Azienda Ospedaliera, Torino, Italy*

Background. Obinutuzumab (GA101) is the first type II, glycoengineered, humanized monoclonal anti-CD20 antibody. Phase II Single-agent results in FL have previously been reported (Salles, ASH 2010) *Methods.* 56 patients with relapsed or refractory FL received either 4-6. cycles of G-FC q28d (n=28) or 6-8 cycles of G-CHOP q21d (n=28). Patients in each chemotherapy arm were randomized between two doses of GA101, either 400 mg on Days 1, 8, of cycle 1 and 400 mg for subsequent cycles or 1600 mg GA101 on Days 1, 8, of cycle 1 and 800 mg for subsequent cycles. Responding patients were then offered maintenance treatment with GA101 at the randomized dose received previously, on a 3 monthly schedule for a maximum of 2 years or until progression. All patients gave informed consent. The primary objective was to investigate the safety of GA101 in combination with chemotherapy. Preliminary efficacy data was a secondary/exploratory objective (end of treatment response assessed according to Cheson *et al*. 1999 criteria, but CRu downgraded to PR). *Results.* Patients baseline characteristics are reported in Table 1. At this interim analysis, all 28 G-FC patients and 17 of 28 G-CHOP patients had completed induction treatment. Incidence, as well as severity of AEs, was similar in both treatment dose groups. The most common adverse events (AE) during induction treatment were infusion related reactions (IRR); 64% and 79% of the patients for G-CHOP and G-FC respectively, mainly during the first infusion. Seven percent of the patients in both arms experienced Grade 3 / 4 IRR, all during first infusion. Currently no patient has withdrawn from G-CHOP, 22/28 patients completed all scheduled cycles on G-FC. Reasons for 6 early withdrawals in the G-FC arm were: AEs (n=5) and insufficient response (n=1). Grade 3/4 toxicities included neutropenia (n=10 and n=14), infections (n=4 and n=5) for G-CHOP and G-FC patients respectively. Two deaths were reported on G-FC arm, secondary to progression in one patient and from underlying Parkinson's disease in the other. Of 181 doses of G-CHOP, 6 doses in 5 patients were delayed for an AE (3 doses by 2 weeks, 3 doses by 1 week). Vincristine was reduced for neuropathy in 5 patients, and one patient each had a reduction of prednisone, cyclophosphamide, and cyclophosphamide/doxorubicin. Of the 137 doses of G-FC delivered, 10 doses in 9 patients were delayed for an AE (5 doses by 2 weeks, and another 5 by 1 week), 7 of these patients also had a dose

Table 1.

Characteristic	CHOP (n=28)	FC (n=28)
Age, median (range)	62.5 (32–75)	61.0 (45–77)
Clinical stage at progression I-II/III-IV, n (%)	9 (32%)/9 (68%)	5 (18%)/23 (82%)
FLIPI, n (%) Low Intermediate High	8 (29%) 15 (54%) 5 (18%)	8 (29%) 7 (25%) 13 (46%)
Prior treatment lines, median (range)	1.0 (1–3)	2.0 (1–7)
Prior rituximab treatment lines, median (range)	1.0 (0–2)	1.0 (0–3)
Bone marrow involvement, n (%	7 (25%)	7 (26%)*
Bulky >7cm, n (%)	9 (32%)	5 (18%)

* Bone marrow results available for n = 27

reduction, and an additional 3 patients had a dose reduction only. At the time of interim analysis, end of treatment response were 94% (8 CR, 8 PR) in G-CHOP arm and 93% (14 CR and 12 PR) in G-FC arm. *Conclusion.* These preliminary results indicate that G-CHOP and G-FC combinations may be delivered safely and are highly effective treatments in patients with relapsed FL. Importantly, G-CHOP can be delivered at the pre-specified three-weekly intervals without need for dose reductions or delays. GA101 is now being investigated in first-line patients in combination with CHOP and bendamustine.

0369

RESOLUTION OF MALIGNANT CUTANEOUS LESIONS WITH BRENTUXIMAB VEDOTIN (SGN-35) IN PATIENTS WITH RELAPSED OR REFRACTORY SYSTEMIC ANAPLASTIC LARGE CELL LYMPHOMA

R Advani,[1] M Fanale,[2] P Brice,[3] J Rosenblatt,[4] R Elstrom,[5] A Evens,[6] T Illidge,[7] G Verhoef,[8] Y Yang,[9] D Kennedy,[9] B Pro[10]

[10]*Fox Chase Cancer Center, Philadelphia, United States of America*

Background. Brentuximab vedotin (SGN-35) is an anti-CD30 antibody conjugated to the highly potent antimicrotubule agent, monomethyl auristatin E (MMAE), by a plasma-stable linker. Brentuximab vedotin binds to CD30 on the cell surface, internalizes, and releases MMAE inside the cell via lysosomal degradation. Binding of MMAE to tubulin disrupts the microtubule network within the cell, induces cell cycle arrest, and results in apoptotic death of the CD30-expressing tumor cell. In a phase 2 study of brentuximab vedotin in 58 patients with relapsed or refractory systemic anaplastic large cell lymphoma (sALCL), an objective response rate of 86% was observed by independent review. *Aims.* To describe the experience with brentuximab vedotin in relapsed or refractory sALCL patients with malignant cutaneous lesions who participated in a phase 2, single-arm, multicenter study. *Methods.* Brentuximab vedotin 1.8 mg/kg was administered every 3 weeks as a 30 minute outpatient IV infusion for up to 16 cycles of treatment. Informed consent was obtained for all patients. Determination of antitumor efficacy was based on objective response assessments by an independent review facility according to the Revised Response Criteria for Malignant Lymphoma (Cheson 2007). Resolution of cutaneous lesions was assessed by the investigator. *Results.* 15 patients with relapsed or refractory sALCL who participated in the phase 2 study had malignant cutaneous lesions at baseline. Among these patients, the median age was 57 years (range 33-70), and ECOG performance status was 0 or 1. Median number of prior therapies was 2 (range 1-5) and 4 patients (27%) had an autologous stem cell transplant prior to the study. The majority of patients (80%) had ALK-negative disease. Complete resolution of malignant cutaneous lesions was achieved in 93% of patients (14 of 15) with a median time to resolution of all lesions of 4.9 weeks (range 2.6-36). Objective responses were achieved by all patients (12 CR, 3 PR). Median duration of objective response was not reached (range 0.3+ to 45.3+ weeks). At the time of the analysis, the median follow up in the study was approximately 6 months. Patients received a median 7 cycles of treatment (range 1-16), with 4 remaining on treatment at the time of the analysis. The most common adverse events (≥30%) of any grade among the 15 patients were diarrhea, pyrexia, constipation, nausea, peripheral sensory neuropathy, and decreased appetite. Adverse events ≥ Grade 3 that occurred in more than 1 patient were neutropenia (4 patients), anemia, diarrhea, and thrombocytopenia (2 patients each). *Summary/Conclusions.* In a phase 2 trial of brentuximab vedotin in relapsed or refractory sALCL, local and systemic responses were observed among 15 patients who had malignant cutaneous lesions at baseline: 93% of patients had complete resolution of cutaneous lesions and 100% had objective responses. Adverse events were manageable, and the safety profile was comparable to that observed among patients without cutaneous involvement. These results warrant further study of brentuximab vedotin in patients with CD30-positive cutaneous and systemic lymphomas. A trial of brentuximab vedotin in patients with CD30-positive cutaneous T-cell lymphomas (CTCL) is planned.

0370

PHASE II STUDY OF INTRATHECAL LONG ACTING LIPOSOMAL CYTARABINE IN THE PROPHYLAXIS OF LYMPHOMATOUS MENINGITIS IN HIV-RELATED NON-HODGKIN'S LYMPHOMA

M Spina,[1] F Martellotta,[1] M Berretta,[1] E Zanet,[1] A Lleshi,[1] V Canzonieri,[1] P Bulian,[1] M Bibas,[2] A Antinori,[2] L Uziel,[3] A Manna,[4] A Carbone,[1] U Tirelli[1]

[1]*National Cancer Institute, Aviano (PN), Italy*
[2]*National Institute for Infectious Diseases L. Spallanzani, Rome, Italy*
[3]*San Paolo Hospital, Milano, Italy*
[4]*Sant'Andrea Hospital, La Spezia, Italy*

Background. Around 5% of patients (pts) with aggressive non-Hodgkin's lymphoma (NHL) develop central nervous system (CNS) progression or relapse during the course of their disease. Pts with HIV-related NHL often develop CNS progression despite the use of adequate prophylaxis. Liposomal cytarabine has show a significant activity in lymphomatous meningitis but there are limited data in the prophylactic setting. *Methods.* Since May 2006, we are running a prospective phase II study of intrathecal liposomal cytarabine at the dose of 50 mg in 48 pts with HIV-NHL with the aim to evaluate the feasibility and activity of this drug in the prevention of lymphomatous meningitis. *Results.* Forty-two pts were males and the median age was 44 years (range 18-69). As far as the histological subtype of NHL, 47% of pts had a diffuse large B-cell (DLBC) NHL and 40% Burkitt NHL. Stage III-IV was diagnosed in 80% of ps and 68% of DLBC were age-adjusted IPI 2 or more. An extranodal involvement was diagnosed in 70% of pts (gastrointestinal 30%, bone 27%, spleen 10%, liver 22%, bone marrow 17%). Liposomal cytarabine was well tolerated with headache grade I to III being the most frequent side effect in only 32% of pts. Less common toxicity (all grade I) included cortical changes (4%), fever (2%), vomiting (2%), hypertension (2%), chills (2%). With a median follow up of 15.5 months only one pt (2%) with Burkitt lymphoma developed a combined systemic and meningeal relapse. Moreover, in our experience previously the present study, we used methotrexate as practical use in 426 HIV-NHL with a meningeal progression or relapse of 14% (p=0.09). The use of a liposomal formulation allowed to significantly reducing the number of lumbar injections in comparison to the standard schedules (approximately of 50%) with an improvement of quality of life of pts and with a reduction of professional exposure risk for health care staff. *Conclusions.* In this first prospective study on prophylaxis of lymphomatous meningitis in HIV-NHL reported in the literature, liposomal cytarabine seems safe and active and it reduces of approximately 50% the number of lumbar punctures and exposure risk for health staff as well.

0371

LENALIDOMIDE PLUS RITUXIMAB-CHOP21 IS SAFE AND EFFECTIVE IN ELDERLY UNTREATED DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): RESULTS OF PHASE I PART OF REAL07 TRIAL OF ITALIAN LYMPHOMA FOUNDATION (FIL)

U Vitolo, A Chiappella, A Carella, I Baldi, B Botto, G Ciccone, A Congiu, G Gaidano, P De Masi, M Ladetto, A Levis, AM Liberati, V Pavone, S Perticone, A Tucci, M Zanni, G Rossi

On the behalf of FIL, Hematology 2, AOU San Giovanni Battista, Torino, Italy

Background. R-CHOP21 is the standard treatment in newly diagnosed DLBCL of the elderly, however 30-40% of the patients failed.

Lenalidomide monotherapy in relapsed/refractory DLBCL was tested, with promising results; preclinical studies demonstrated a synergism with Rituximab. On these basis, FIL is running a prospective multicenter dose finding phase I-II trial with the aim to evaluate toxicity and efficacy of Lenalidomide plus R-CHOP21 (LR-CHOP21) for elderly untreated DLBCL patients (clinicaltrials.gov, NCT00907348). The primary end-point for the phase I was to define the Dose Limiting Toxicity (DLT), the maximum dose inducing any grade ≥ 3 non-hematologic toxicity, or a > 15 days delay of planned cycle. *Patients and Methods.* Inclusion criteria were: age 60-80; untreated CD20+ DLBCL; Ann Arbor stage II/III/IV; International Prognostic Index (IPI) at low-intermediate/intermediate-high/high (LI/IH/H) risk. Treatment plan was: 6 R-CHOP21 every three weeks in association with Lenalidomide for days 1-14 at the established dose level. Phase I was planned to define the Maximum Tolerated Dose (MTD), that is the dose that achieves a DLT in 33% or less patients; evaluation was planned after three LR-CHOP21. The study was designed with the Continual Reassessment Method (CRM), a Bayesian memory design that uses, as dose allocation rule of the sequentially incoming patients, the re-estimated probability of toxicity based on the results obtained for the patients already observed. Four doses of Lenalidomide were tested: 5, 10, 15 and 20 mg. At the end of each cohort, the dose level associated with an updated DLT probability closest to 33% was recommended to be administered to the next cohort. Results. From May 2008 to February 2010, 21 patients were enrolled in the phase I part of the study. Clinical characteristics were: median age 68 (61-77); stage III/IV 81%; PS > 1 81%; IH/H IPI risk 52/24%. Patient allocation by Lenalidomide dose (on days 1-14 of each LR-CHOP21 courses) was: 5 mg/day in nobody, 10 mg/day in nine patients, 15 mg/day in nine and 20 mg/day in three. DLTs in the first three courses of LR-CHOP21 were recorded in seven patients; according to CRM, these events determined Lenalidomide 15 mg/die as the MTD in association to R-CHOP21. Of 115 LR-CHOP21 courses performed in the series of 21 patients, hematological toxicity was mild: grade III/IV thrombocytopenia occurred in 10% of courses, anemia in 4% and neutropenia in 28%. Extra-hematological toxicities were moderate: grade IV increase of CPK in one patient, grade III cardiac in one, grade III neurological in three and grade III infections in four (two pneumonias, one febrile neutropenia with diarrhea and one diarrhea). At the end of six LR-CHOP21, complete remission was achieved in 76% patients. *Conclusions.* MTD for Lenalidomide in association to R-CHOP21 is Lenalidomide 15 mg, administered on days 1-14 of each courses. LR-CHOP21 is safe and feasible in elderly DLBCL, with promising preliminary efficacy results. The ongoing phase II part of the trial is aimed to test the efficacy of 15 mg of Lenalidomide in association with R-CHOP21.

0372

PRIMARY MEDIASTINAL LARGE B CELL LYMPHOMA (PMBL). LONG TERM RESULTS AND LATE TOXICITY IN PATIENTS TREATED WITH MACOP-B WITH OR WITHOUT RITUXIMAB PLUS INVOLVED MEDIASTINAL RADIATION THERAPY

E Finolezzi,[1] A Di Rocco,[1] V De Sanctis,[2] A Fama,[1] L Grapulin,[1] R Foà,[1] M Martelli[1]

[1]*Hematology University of Rome Sapienza, Rome, Italy*
[2]*Radiotherapy University of Rome Sapienza, Rome, Italy*

Background. Primary mediastinal large B cell lymphoma is a distinct subtype of diffuse large B cell lymphomas that is more common in younger females. The combination of chemotherapy (CHT) together with involved field radiation therapy (IFRT) is considered the standard treatment. In the pre-Rituximab era third generation regimens such as MACOP-B have improved survival in PMBL patients (pts) over CHOP, but the introduction of Rituximab has abrogated this difference. The real need of consolidation mediastinal IFRT is still debated in view of the risk of secondary cancers and cardiac complications. We report the long-term results on a large series of PMBL pts treated at a single center. *Method.* 107 patients (pts) with PMBL were treated between June 1991 and September 2006 at our institute; 80 pts had stage II and 27 stage IIE-IV; 75% had elevated LDH; bulky disease was present in 95 pts including 58 (55%) with clinical evidence of superior vena cava obstruction. Median age was 34 yrs (15-61) and 71% were females. The aaIPI score was 0-1 in 60 pts and 2-3 in 47. Ninety-two pts were treated with the standard MACOP-B regimen and 15 pts with a Rituximab/MACOP-B regimen since March 2004. Overall, 101/107 pts (94%) received IFRT at a dose of 30-36 Gy. The response was evaluated in all pts at the end of CHT and of IFRT. *Results.* At the end of the program, a CR/CRu was obtained in 76 pts (71%), a PR in 23(21%), NR 1(1%),while 7 pts were not evaluable (6 pts received an early intensification for progressive disease and 1 died for CHT related toxicity). At the end of the program: 14 PR pts obtained a CR/CRu after IFRT with an overall CR/CRu rate of 89%; 9 pts relapsed within 10 months and 4 of them died of progressive disease. After a median follow-up of 111 months (1-238) the 10-yrs OS, PFS and EFS were 88%, 85% and 83% respectively. No statistically significant difference in terms of PFS and OS and toxicity was recorded for pts treated with or without Rituximab. Patients with an IPI 0-1 had a significantly better PFS (p=0.020) and OS (p= 0.015). In our cohort of pts, 1/107 developed a secondary cancer (acute myeloid leukemia) after 164 months from the end of therapy and no breast cancer occurred. Four of 107 pts presented late severe cardiotoxicity (3 congestive heart failures and 1 arhythmic sudden death). *Conclusions.* This is the largest reported series of pts with PMBL treated with a uniform strategy at a single center. MACOP-B +/- Rituximab plus IFRT is highly effective and devoid of severe long-term toxicities. Future randomized trials should evaluate the real need of a mediastinal IFRT in pts who obtain a PET-negative CR after a R-chemotherapy regimen to reduce unexpected late toxicities.

0373

CLINICAL AND PROGNOSTIC SIGNIFICANCE OF APOPTOTIC PROFILE IN PATIENTS WITH NEWLY DIAGNOSED NODAL DIFFUSE LARGE B CELL LYMPHOMA (DLBCL)

O Markovic,[1] D Marisavljevic,[1] B Mihaljevic,[2] V Cemerikic,[3] M Perunicic-Jovanovic,[2] A Savic,[4] M Todorovic,[2] A Vidovic,[2] R Zivkovic[1]

[1]*Clinical Center "Bezanijska Kosa", Belgrade, Serbia*
[2]*Institute of Hematology, KCS, Belgrade, Serbia*
[3]*Beolab, Belgrade, Serbia*
[4]*Clinic of Hematology, KCV, Belgrade, Serbia*

Background. Apoptosis-related proteins might play an important role in the pathogenesis of lymphoma and sensibility to chemotherapy in patients with non-Hodgkin's lymphoma (NHL). Aim of our study was to analyzed the relationship between expression of two proapoptotic (CD95, caspase 3) and four antiapoptotic proteins (c-FLIP, bcl-2, survivin and XIAP) and clinical outcome of nodal DLBCL patients. *Methods.* We have analyzed lymph node biopsy specimens obtained from 78 patients with newly diagnosed nodal DLBCL. The expression of apoptotic parameters was analyzed using the standard imunohistochemical method (antibodies against caspase 3, CD95, c-FLIP, XIAP, survivin and bcl-2) on formalin-fixed and routinely processed paraffin-embedded lymph node specimens. The expression of immunohistochemical parameters has been evaluated semiquantitavely as a percentage of tumor cells. *Results.* Caspase 3, CD95, c-FLIP, survivin, XIAP and bcl-2 immunoexpression has been found in 48(61.5%), 39(50%), 45(57.7%), 41(52.6%), 43(55.12%) and 39(50.0%) patients, respectively. The therapy response was achieved in 53(67.9%) patients. Besides numerous clinical parameters survivin and XIAP positivity along with CD95 negativity were found to be unfavorable factors for therapy response and shorter survival in univariate analysis. According to this finding, an "apoptotic score"which includes unfavorable apoptotic parameters has been defined. In multivariate analysis only IPI and apoptotic score remained independent prognostic predictors for the chance to reach the complete remission (p=0.003 and p=0.044, respectively) and longer overall survival (p=0.002 and p=0.046, respectively). Significantly the better response to immunochemotherapy in comparison to chemotherapy has been achieved in patients with expression of caspase 3, c-FLIP and survivin and in patients without the immunoexpression of XIAP. In addition, immunochemotherapy was superior to chemotherapy in both bcl-2 positive and bcl-2 negative patients. *Conclusion.* The results of this study showed that the disregulation of apoptosis can appear on different places of apoptotic cascade in DLBCL. Apoptotic score is more useful tool in predicting therapy response and overall survival of patients with DLBCL than single apoptotic parameters and along with IPI could help to identify a high risk group of newly diagnosed nodal DLBCL.

0374

PATIENT-REPORTED OUTCOMES DURING AND FOLLOWING TREATMENT WITH BORTEZOMIB PLUS RITUXIMAB OR RITUXIMAB ALONE IN PATIENTS WITH RELAPSED FOLLICULAR LYMPHOMA (FL): RESULTS FROM A PHASE 3 STUDY

M Rothman,[1] L Pei,[2] R Ganguly,[2] P Theocharous,[2] Y Elsayed,[2] E Zhu,[2] DL Esseltine,[3] B Coiffier[4]

[1]*GSM&MA, Washington, United States of America*
[2]*Janssen Research & Development, Raritan, NJ, United States of America*
[3]*Millennium Pharmaceuticals Inc., Cambridge, MA, United States of America*
[4]*Hematology Service, Hospices Civils de Lyon, Lyon, France*

Background. FL, an indolent, incurable non-Hodgkin's lymphoma subtype, can adversely affect patients' health status, thus adversely affecting patient-reported outcome (PRO) scores on these measures. An important aim of treatment is to maintain patients' functional status through active treatment options offering improved outcomes with favorable toxicity profiles. Bortezomib-rituximab resulted in improved progression-free survival, response rates, and other long-term outcomes versus rituximab alone in patients with relapsed FL in the international, multicenter, phase 3 LYM3001 study. Assessment of PROs was an exploratory endpoint. *Aims.* To evaluate changes from baseline in PRO scores during/following treatment with bortezomib-rituximab or rituximab using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30). *Methods.* Patients were randomized to receive five 5-week cycles of bortezomib-rituximab (N=336) or rituximab (N=340), as previously described (Coiffier *et al*, ASH 2010). All patients provided written informed consent. The primary endpoint for the PRO analyses was the Global Health Status (GHS) subscale of EORTC QLQ-C30; other endpoints included the other subscales, comprising five functional scales, three symptom scales, and six single items. Patients completed EORTC QLQ-C30 at baseline, on day 1 of each cycle, at the end-of-treatment visit, and every 10 weeks post-treatment/pre-progressive disease (PD). *Results.* 333 and 335 patients in the bortezomib-rituximab and rituximab arms, respectively, provided evaluable EORTC QLQ-C30 data at baseline; as expected, these numbers decreased over time, to 293/289 at the end of treatment, and 23/21 at end of data collection. At baseline, observed mean GHS scores were 62.94 and 63.11 in the bortezomib-rituximab and rituximab arms, respectively; changes are shown in the figure. For analyses of changes from baseline and comparisons between arms, a joint modeling approach was used to address the potential issue of non-random missing values; values deviate from observed means due to incorporation of informative dropout and repeated measures. For bortezomib-rituximab, mean GHS was not statistically different from baseline through week 25 (end of treatment) and statistically improved at weeks 30-120; mean changes ranged from 3.57 at week 30 (mean 66.02) to 6.55 at week 80 (mean 69.00). With rituximab, mean GHS was statistically improved from baseline at weeks 5-120; mean changes ranged from 1.93 at week 5 (mean 64.92) to 7.91 at week 70 (mean 70.89). Between-group comparisons showed significantly lower mean scores with bortezomib-rituximab versus rituximab at weeks 10 (mean change -0.69 vs 2.78), 15 (mean change -1.44 vs 2.75) and 20 (mean change -1.98 vs 1.95); from week 25 there were no significant differences between arms. Changes from baseline and differences between arms were generally not sufficiently large to be considered clinically meaningful (≥5 points). Findings for changes in functional scores were similar to those for GHS. Minimal differences between arms in symptoms and side-effect scales were consistent with the adverse event profile of bortezomib. *Conclusions.* Rituximab resulted in slightly better PRO scores compared with bortezomib-rituximab during treatment, reflecting additional adverse events associated with bortezomib. However, post-treatment/pre-PD scores were similar between arms and slightly higher compared to baseline. Differences/changes from baseline were not clinically significant.

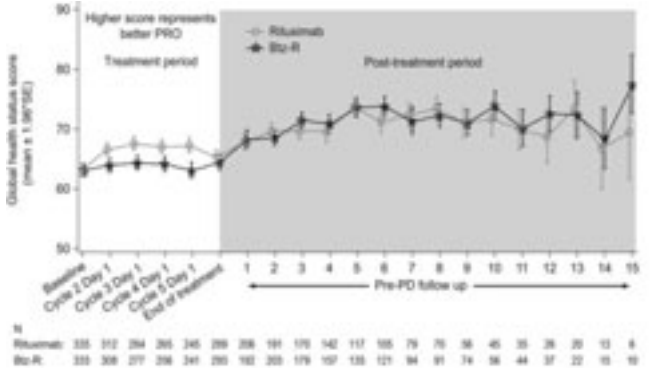

Figure 1.

0375

COMPREHENSIVE GERIATRIC ASSESSMENT-ADAPTED CHEMOTHERAPY IN ELDERLY PATIENTS (> 70 YEARS) WITH DIFFUSE LARGE B-CELL NON-HODGKIN'S LYMPHOMA (DLBCL): FINAL RESULTS AND LONG TERM FOLLOW-UP

M Spina,[1] U Tirelli,[1] L Fratino,[1] M Balzarotti,[2] L Uziel,[3] A Giacalone,[1] A Ferreri,[4] A Santoro,[2] M Spina[1]

[1]*National Cancer Institute, Aviano (PN), Italy*
[2]*Humanitas Institute, Rozzano, Italy*
[3]*San Paolo Hospital, Milano, Italy*
[4]*San Raffaele Hospital, Milano, Italy*

Background. R-CHOP is the standard treatment for elderly patients (pts) with DLBCL. Many pts aged 70 years (yrs) or more are unable to receive R-CHOP and the majority of them are excluded from clinical trials. Comprehensive geriatric assessment (CGA) is a useful instrument to predict the clinical outcome of elderly pts with cancer. Within the GOL (Gruppo Oncoematologico Linfomi) we started a phase II study aiming to evaluate feasibility and activity of a CGA-driven chemotherapy for elderly pts with DLBCL. *Material and Methods.* Pts with no comorbidity received CHOP/R-CHOP; pts with mild cardiopathy received epirubicin instead of doxorubicin; in pts with moderate/severe cardiopathy the use of anthracyclines was omitted; pts with diabetes did not receive prednisone; in pts with neuropathy vincristine was omitted. The dosage of chemotherapy was decided according to CGA: pts with a good score (ADL=6 and IADL>6) received full doses of CT; pts with an intermediate score (ADL=5 and IADL>4) received 75% of the dose; pts with a poor score (ADL<5 and IADL<5) received 50% of the dose. *Results.* One hundred pts (41 males and 59 females) have been treated. The median age was 75 yrs and stages III-IV were diagnosed in 51% of pts. Sixty-one percent of pts received full doses of CT; 25% received 75% of dose and 14% received 50% reduced dose; 86% of pts received an anthracycline and 54% rituximab. Toxicity was quite acceptable. Grade 3-4 neutropenia was observed in 30% of pts, mucositis in 12%, and peripheral neuropathy in 9%. Four toxic deaths were observed. Overall, 81% of pts achieved complete remission; with a median follow-up of 50 months, 20% of them have relapsed. The 5 yr-OS, DFS, EFS are 58%, 78% and 50%. It is remarkable that the 5-year specific survival is 72%. *Conclusions.* Our results demonstrate that a CGA-driven approach is feasible in elderly pts with DLBCL. This strategy allows offering a curative approach to all pts with aggressive NHL, avoiding to under treating pts with a potentially cured disease or over treat pts with severe comorbidities.

0376

A NEW PROGNOSTIC SCORING MODEL FOR PERIPHERAL T-CELL LYMPHOMA, NOT OTHERWISE SPECIFIED

K Sato,[1] Y Torimoto,[1] Y Kohgo,[1] T Fukuhara[2]

[1]*Asahikawa Medical University, Asahikawa, Japan*
[2]*Hokkaido Hematology Study Group, Sapporo, Japan*

Background. Peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS) comprises a clinically and histopathologically heterogeneous group of lymphomas which do not fit into the definition of any other identified subtype of PTCLs. Most of the cases are characterized by aggressive behavior and a dismal prognosis. *Aim.* To assess the clinical backgrounds and the prognosis of PTCL-NOS patients, the Hokkaido Hematology Study Group (HHSG) conducted a multicenter retrospective survey in Hokkaido, Japan. *Methods.* We reviewed 508 mature T-cell and NK-cell neoplasms diagnosed according to the 4th edition of the WHO Classification of Tumours of Haematopoietic and Lymphoid Tissues at the HHSG, which includes 30 hematology/oncology or pediatrics departments of 23 institutes, from

January 2002 to December 2009. One hundred seven (21%) PTCL-NOS patients were extracted and further analyzed with regard to their clinical backgrounds, treatments, remission or relapse rates, survival, and prognostic factors. The overall survival (OS) and progression free survival (PFS) were estimated using the Kaplan-Meier method and compared by a log-rank test. The risk factors at diagnosis for OS were evaluated either in a univariate analysis by the chi-squared test, or in a multivariate analysis by the Cox proportional hazards model. *Results.* The median follow-up of the patients was 24 months (range 1-95). The patients included 70 males and 37 females with a median age of 67 years (range 9-94). Chemotherapy (ChT) was selected in 90% (96/107) patients as the primary treatment. CHOP-like regimens were chosen for 91% (86/96) of patients as the primary ChT. A total of 48 (52%) of the 92 evaluable patients achieved a CR after the primary treatment, in which 46% (22/48) relapsed. The estimated 5 year-OS and -PFS of all patients was 35%, and 28%, respectively. The risk factors at diagnosis accosiated with OS by the univariate analysis were age>60 (p=0.027), presence of B-symptom (p=0.006), an advanced clinical stage (p=0.002), a high LDH level (p=0.007), sIL2R>3000U/ml (p=0.001), platelets<10x10^4/μl (p=0.002), lymphopenia (p=0.040), bulky disease (p=0.042), and bone marrow involvement (p=0.013). Extranodal involvement sites>1 (p=0.116) and a poor perfomance status (p=0.119) were not significant risk factors for a deceased OS. In a multivariate analysis, three independent risk factors for OS bulky disease (hazard ratio; HR=5.324, p=0.019), age>60 (HR=3.015, p=0.025), and platelets<10x10^4/μl (HR=3.999, p=0.036), were identified. Three risk groups for OS were defined by the numbers of these 3 risk factors: score 0, low risk; score 1, intermediate risk; score 2-3, high risk. The OS curves of the PTCL-NOS patients were more significantly stratified into three risk groups by using our scoring model (p=0.0005, Figure 1), compared to the results obtained by using the prognostic index for the PTCL-unspecified (PIT) scoring model (p=0.019). *Conclusions.* We demonstrated that the OS for PTCL-NOS patients was clearly stratified into 3 risk groups according to new prognostic scoring model by using three risk factors; bulky disease, age>60, and thrombocytopenia. Although further verfication by a prospective analysis is needed, these findings may provide valuable information to help predict the prognosis or to select effective therapeutic strategies for PTCL-NOS patients.

0377

COMPARISON OF PROGNOSTIC MODELS FOR PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA: THE NEED FOR A REVISION IN THE RITUXIMAB ERA

YC Huang, YB Yu, HJ Lu, CY Liu, CJ Liu, JT Pai, YC Hong, HW Teng, LT Hsiao, TC Chao, JP Gau, JH Liu, HC Hsu, TJ Chiou, PM Chen, CH Tzeng

Taipei Veterans General Hospital, Taipei, Taiwan

Background. Several revisions of International prognostic index (IPI) have been proposed for patients with diffuse large B cell lymphoma (DLBCL) after the introduction of rituximab. Expanding evidence suggests that baseline absolute lymphocyte count (ALC) is also an independent factor for outcome prediction. *Aims.* We investigated the optimal prognostic model for these patients in the rituximab era. *Methods.* The study enrolled 274 consecutive patients with DLBCL receiving first-line CHOP-based chemotherapy with rituximab between 2003 and 2009. Five factors within IPI and ALC were entered for Cox regression analysis. Overall survival (OS) was calculated for different risk groups of models. Efficacy of models was compared by the value of Akaike information criterion (AIC). *Results.* Revised IPI (R-IPI) and ALC/R-IPI, but not IPI, were informative to discriminate between different risk groups of patients with DLBCL. In multivariate analysis for individual factors of the prognostic models, however, only performance status > 1 [odds ratio (OR) 3.59], Ann Arbor stage III or IV (OR 2.24), and ALC less than 1x109/L (OR 2.75) remained their significance. A modified score based on the three factors divided patients into four risk groups and the 5-year OS rate was 81%, 74%, 36%, and 9% respectively. By comparing AIC values in the Cox proportional hazards analysis, the modified 3-factor model had superior prognostic value followed by ALC/R-IPI, R-IPI and IPI scores. *Conclusions.* Addition of the novel factor, ALC, interacts with other established factors in outcome prediction for DLBCL. Development of a new score is needed for a better risk stratification in the rituximab era and would be helpful in the design of future clinical trials. The proposed 3-factor model should be validated in large scale studies.

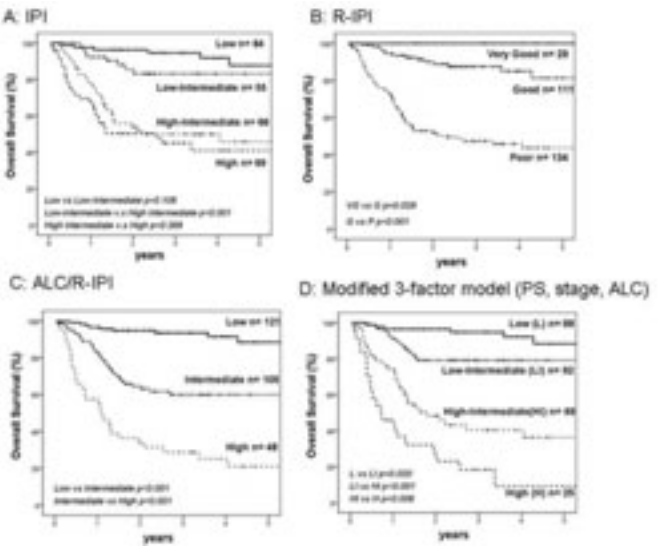

Figure 1. Overall survival by four prognostic models.

R-CHOP21 VS R-CHOP14 IN 200 DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: RESULTS FROM A RETROSPECTIVE STUDY

L Rigacci,[1] A Fabbri,[2] B Puccini,[1] A Pietrini,[2] L Iovino,[1] R Dottori,[3] G Bartalucci,[2] F Lauria,[2] A Bosi[1]

[1]*Azienda Ospedaliero Universitaria Careggi, Florence, Italy*
[2]*Azienda Ospedaliero Universitaria Le Scotte, Siena, Italy*
[3]*La Misericordia Hospital, Grosseto, Italy*

Background. Diffuse large B cell lymphoma (DLBCL) is one of the most common types of non-Hodgkin's lymphoma. R-CHOP21 (C21) is considered the standard therapy but a large number of studies tested R-CHOP14 (C14). *Aims.* The aim of our study was to evaluate retrospectively a cohort of patients (pts) treated with C21 or C14. *Methods.* All pts with diagnosis of DLBCL or follicular grade IIIb lymphoma, treated with curative intent were accrued. *Results.* From january 2002 to december 2009, 99 pts were treated with C21 and 101 were treated with C14. The two cohorts of pts were balanced for all clinical characteristics a part for age (<65 or >64 years) with more aged pts in C21 arm (p 0.002) and Beta2 mycroglobulin value (evaluable in 137 patients) with more pathologic values in C21 arm (0.007). After induction therapy 158 pts (79%) obtained a complete remission: 76/99 (77%) after C21 and 82/101 (81%) after C14. After a median period of observation of 31 months 23 pts relapsed, 8 (11%) in the C21 arm and 15 (18%) in the C14 arm. Considering the two therapies, C21 vs C14, no differences were reported in OS, PFS and DFS: 61% vs 68%, 59% vs 58% and 74% vs 61% respectively. In univariate analysis OS was lower in older pts (p: 0.02), advanced stage (p:0.02), symptomatic disease (p:0.05), elevated LDH (p: 0.001), bone marrow infiltration (p: 0.02) and intermediate or high risk IPI (p: 0.000); PFS was lower in advanced stage (p: 0.002), symptomatic disease (p: 0.009), elevated LDH (p: 0.001), bone marrow infiltration (p: 0.001) and intermediate high risk IPI (p: 0.000). In multivariate analysis OS was significantly better in low-intermediate IPI risk pts (p:0.000) and in pts treated with C14 (p:0.02); the PFS was better in low-intermediate IPI risk pts (p:0.000). Considering only pts with low or low-intermediate IPI we observed that OS was significantly superior in the group treated with C14 (90% vs 64% p:0.03), moreover in young pts (< 65 years) OS was better in pts treated with C14 (81% vs 58% p:0.05). As expected hematological grade III/IV toxicity was more frequent in pts treated with C14, all pts but three (3%) completed the therapy without delay or dose reduction. No differences in extra-hematological toxicity were observed. *Conclusions.* In conclusion our results confirm that C14 do not improve the results of the standard C21 in the whole lymphoma population but in a subset of pts, young and low/intermediate risk pts, the C14 scheme semms to improve the OS. Further prospective randomized studies are needed to verify this preliminary observations.

0379

HIGH RESPONSE RATE IN SPLENIC MARGINAL ZONE LYMPHOMA IN PATIENTS TREATED WITH RITUXIMAB, EITHER AS MONOTHERAPY OR IN COMBINATION WITH CHEMOTHERAPY

A Marin-Niebla,[1] P Batty,[1] M Else,[1] F De la Cruz,[2] E Rios Herranz,[3] D Catovsky,[1] C Dearden,[1] E Matutes[1]

[1]*Royal Marsden Hospital/Institute of Cancer Research, London, United Kingdom*
[2]*Hospital Virgen del Rocio, Sevilla, Spain*
[3]*Hospital Ntra Sra de Valme, Sevilla, Spain*

Background. Splenic marginal zone lymphoma (SMZL) is an uncommon indolent B-cell non-Hodgkin's lymphoma usually presenting with marked splenomegaly and bone marrow (BM) and/or peripheral blood (PB) involvement. Splenectomy has been the treatment of choice in symptomatic patients. Systemic treatment is required in patients with widespread disease, who are at high risk from surgery, or who have relapsed after splenectomy. Rituximab has shown encouraging results in SMZL, with sustained responses. *Aims.* To assess, retrospectively, response to treatment, toxicity and survival after rituximab in SMZL. *Methods.* Twenty-nine patients from two different centers, diagnosed with SMZL between 1982 and 2011, received one or more treatments with rituximab. Eighteen patients received rituximab alone and 20 combined with chemotherapy. Thus 9 patients received each of these sequentially, to improve response, with or without interim relapse. The median age at diagnosis was 62 years (range 37-89 years); the male:female ratio was 2:3; B symptoms were present in 12 patients; ECOG performance status was 0-2 in 28/29 patients. All presented with splenomegaly, with involvement of the BM in 27 patients, PB in 24, lymph nodes in 11 and extranodal involvement in 7 patients. Diagnosis was made according to the WHO 2008 classification by spleen histology (n=12), BM histology (n=19), PB morphology (n=12) and immunophenotype (n=13). Rituximab monotherapy was administered at 375 mg/m2/weekly x4 weeks. In combination with fludarabine-based regimens (n=14), or other regimens including CHOP (n=6), rituximab was administered on day 1 of each cycle. Responses were assessed according to the Response Criteria Guidelines for SMZL (Matutes, Leukemia 2008). Toxicity was graded according to the CTCAE v3.0. The Fisher exact test was used to compare best responses between groups. Survival was estimated using the Kaplan-Meier method. *Results.* All patients responded to rituximab monotherapy and/or to a combination treatment. At least one complete response (CR) was achieved in 20/29 patients (69%). This compares with a CR in only 4/17 (24%) of these same patients after any prior therapy (p=0.005): 11 patients had received splenectomy, with or without chemotherapy and 6 had received chemotherapy only. There was no difference in the CR rate between rituximab monotherapy (71%) versus rituximab combinations (68%). The most common adverse event was grade 3-4 neutropenia (n=7, 24%). Two patients had grade 3-4 infections. Anemia (n=3) and thrombocytopenia (n=2) were grade 1-2 only. Four cases presented with histological transformation prior to rituximab, all achieving CR with rituximab combination therapy. After a median follow-up of 24 months from rituximab treatment (range 4-102 months), the median overall survival was not yet reached. Survival at 2 years after rituximab was 100%. Only one death, due to lung cancer, occurred at 48 months follow-up. *Conclusions.* In patients with SMZL, the CR rate after rituximab, either alone or in combination with chemotherapy, was significantly better than the CR rate after other prior treatments in the same patients, with manageable toxicity. No difference in the CR rate between rituximab monotherapy or combination therapy was observed. Rituximab, with or without splenectomy, should be considered in the therapeutic scenario of SMZL.

0380

SALVAGE CHEMOTHERAPY WITH RITUXIMAB, IFOSFAMIDE AND ETOPOSIDE (R-IE) IN PATIENTS WITH PRIMARY CNS LYMPHOMA RELAPSED OR REFRACTORY TO HIGH-DOSE METHOTREXATE-BASED CHEMOTHERAPY

E Marturano,[1] G Licata,[1] G Donadoni,[1] A Zanoni,[1] M Frezzato,[2] L Uziel,[3] F Vianello,[4] C Stelitano,[5] M Sorarù,[6] A Ferrari,[7] F Ilariucci,[8] I Proserpio,[9] S Mappa,[1] P Vezzulli,[1] M Reni,[1] A Ferreri[1]

[3]*S. Paolo Hospital, Milan, Italy*
[4]*Universitary Hospital, Padova, Italy*
[5]*Melacrino Morelli Hospital, Reggio Calabria, Italy*
[6]*Hospital of Camposampiero, Padova, Italy*
[7]*S. Andrea Hospital, Rome, Italy*
[8]*S. Maria Nuova Hospital, Reggio Emilia, Italy*
[9]*Hospital - Fondazione Macchi, Varese, Italy*

Background. Conventional upfront high-dose methotrexate (HD-MTX)-based chemotherapy ± radiotherapy is associated with a high complete remission rate in immunocompetent patients with primary CNS lymphoma (PCNSL); however, 35-60% of responsive patients experience relapse within a few months and an additional 10-15% is refractory to primary chemotherapy. Often, salvage therapy results in a second remission with consequent symptomatic and survival improvement; however, only a few active drugs suitable for salvage therapy exist and studies addressing new drugs and combinations in relapsing patients should be encouraged. Thus, patients with PCNSL relapsed or refractory to HD-MTX/HD-cytarabine-based chemotherapy ± radiotherapy were treated with a combination of rituximab, ifosfamide and etoposide (R-IE regimen) at nine Italian centres. The choice of the drugs was based on their capability to cross the blood-brain barrier and their efficacy to treat extra-CNS aggressive lymphomas. *Aims.* To evaluate feasibility and activity of R-IE chemoimmunotherapy regimen in patients with relapsed or refractory PCNSL. *Methods.* HIV-negative patients with ≤75 years old, ECOG PS ≤3 with PCNSL relapsed or refractory to HD-MTX/HD-cytarabine-based chemotherapy ± radiotherapy were considered. R-IE regimen consisted of four courses of rituximab 375 mg/m^2 day 0; ifosfamide 2 g/m^2/d days 1-3; etoposide 250 mg/m^2 day 1. *Results.* Twenty patients (median age 60 ys, range 39-71; M/F ratio: 1.2) were treated with R-IE, as second-line treatment in 15 patients, as third line in three and as fourth line in two patients. Thirteen patients had refractory PCNSL (progressed during previous treatment) and seven had relapsing disease. Ten patients had received whole-brain radiotherapy as part of previous treatments. Fifty-one (64%) of the 80 planned courses were actually delivered. R-IE was interrupted in 14 patients due to lymphoma progression (n=12), toxicity (n=1) and patient's refusal (n=1); treatment is ongoing in one patient. G4 hematologic toxicity (neutropenia 50%; thrombocytopenia 25%; anemia 15%) was common but manageable; no G4-nonhematologic toxicity was observed; one patient died of pulmonary aspergillosis. Response after R-IE was complete in six patients and partial in one (ORR= 35%; 95%CI: 14%-56%), with a median response duration of 11+ months (4+ - 19+). Five responsive patients successfully collected autologous stem cells after the 2nd course of R-IE, and three of them received consolidation with BCNU 400 mg/m2 day -6, thiotepa 5 mg/kg days -5 -4 and ASCT day 0. At a median follow-up of 11 months, no responder experienced relapse, while 12 patients experienced lymphoma progression, with a 2-yr PFS of 23% ± 11%. Nine patients are alive, nine died of lymphoma, one of pulmonary aspergillosis and one patient died of neurological impairment while in remission, with a 2-yr OS of 30% ±12%. The number of previous lines of treatment, prior irradiation and relapsed or refractory disease did not influence response nor survival rates. *Conclusions.* R-IE is a feasible and active combination for patients with relapsed or refractory PCNSL. This regimen allowed autologous stem cell collection, and consolidation with high-dose chemotherapy supported by ASCT resulted in long-term remission.

0381

WEEKLY INFUSION OF RITUXIMAB AND BORTEZOMIB IS EFFECTIVE AND SAFE IN RELAPSED/REFRACTORY INDOLENT AND MANTLE CELL LYMPHOMA: LONG TERM ANALYSIS OF A PHASE II TRIAL OF ITALIAN LYMPHOMA FOUNDATION (FIL)

A Chiappella, P Pregno, PL Zinzani, A De Renzo, A Evangelista, A Fabbri, A Ferreri, S Franceschetti, R Freilone, D Gioia, AM Liberati, D Novero, L Orsucci, L Rigacci, D Rota-Scalabrini, C Rusconi, E Russo, F Saccona, G Specchia, V Stefoni, A Tucci, F Zaja, U Vitolo

On the behalf of FIL, Hematology 2, AOU San Giovanni Battista, Torino, Italy

Background. Gene-profiling studies demonstrated a constitutive activation of the NFκB signalling pathway in Mantle Cell Lymphoma (MCL) and Marginal Zone Lymphoma (MZL). Bortezomib, an inhibitor of the proteasome, is effective in relapsed MCL and it is synergistic with Rituximab to enhance apoptosis and NFkB depletion. On these basis, the FIL conducted a phase II multicenter study aimed to evaluate safety and efficacy of Bortezomib in association with Rituximab in relapsed/refractory non-follicular Lymphoma (Linfocytic, LL and MZL) and MCL, not eligible to high dose chemotherapy with stem cell transplantation. *Patients and Methods.* The study was a prospective phase II non randomized trial, designed on Simon two-stage Optimal Design. Primary end-point was to obtain an Overall Response Rate (ORR) > 40%. A central histological revision was planned in all the patients at the enrollment. Inclusion criteria were: 18-75 years, relapsed/refractory LL, MZL, MCL after 1-4 lines. Treatment schedule was: one course of 1.6 mg/sqm Bortezomib in combination with standard 375 mg/sqm Rituximab on days 1, 8, 15, 22 followed by two courses of four weekly intravenous bolus of Bortezomib alone; patients with complete (CR), partial remission and stable disease at the intermediate evaluation were planned to be given three further courses with the same schedule. Results. From September 2006 to March 2008, 55 patients were enrolled and six were excluded at central histological revision. Clinical characteristics were: median age 68 (50-74); 16 LL, 8 MZL, 25 MCL; 42 stage III/IV; 33 bone marrow involvement. Thirty-eight patients were at third or fourth relapses, 34 Rituximab pretreated; 21 had refractory disease. ORR was 53% (CR 26.5%); no response was 43% and 4% off therapy. ORRs by clinical subgroup were: LL 37%, MZL 50%, MCL 64%; Rituximab pretreated 62%, Rituximab naïve 33%; relapsed 64% and refractory 38%. With a median follow-up of 26 months, median Overall Survival was not reached and median Progression Free Survival (PFS) was 9.9 months (95% CI: 4.8 - 18.3). Median PFS by histology was: 4.8 (95% CI: 4.1 - 8.9) for LL, 18.3 (95% CI: 5.3 - 29.9) for MCL and 9.9 months (95% CI: 2.4 - not reached) for MZL. Thirty patients completed the treatment and 233 courses were delivered (median: 4.7 courses/patient); 19 patients did not because of no response in 13, adverse events in five, with only one toxic death due to interstitial pneumonia. Of 233 courses performed, hematological toxicity was rare: grade III/IV neutropenia in 5% and thrombocytopenia in < 2% of all courses. Grade III/IV CTC non-hematological toxicities were: neurotoxicity grade III in four patients (all completely recovered) and infections in eight patients (viral reactivation, bacterial pneumonia and micosis). *Conclusions.* Weekly infusion of Bortezomib in combination with Rituximab is effective and safe in relapsed/refractory indolent and MCL, also in Rituximab pretreated patients. Data demonstrated that this schedule is effective mainly in MZL and MCL.

Novel therapeutics, targeted therapies and gene therapy

PGP IS EXPRESSED IN MESENCHYMAL STEM CELLS AND CAN BE IMPLEMENTED FOR THEIR ISOLATION

H Galski, I Bar, A Nagler

Chaim Sheba Medical Center, Tel Hashomer, Israel

Background. Human mesenchymal stem cells (MSCs) are multipotent stem cells that can differentiate *in vitro* and *in vivo* into various cell types. Therefore, MSCs exhibit high potential for therapeutic applications. MSCs are found in various tissues, including bone marrow (BM) and umbilical cord blood (UCB). AIMS. It is commonly accepted that BM- and UCB-derived plastic- adherent cells (mesenchymal-like stem cells) are very heterogeneous, comprising only a small subset of authentic stem cells. These cells are currently identified through a combination of poorly defined physical, phenotypic and functional properties. Thus a more comprehensive view of the MSCs identity and characteristics is urgently needed. METHODS. UCB and BM-derived mononuclear cells were grown in culture for 1 week. The plastic adherent cells were detached by EDTA. Cells were labeled with anti-CD105-APC and with MRK16 antibody against Pgp and secondary rabbit anti- mouse antibody PE. The CD105/Pgp subsets were sorted by Fluorescence-activated cell sorter. These subsets were analyzed for: (1) formation of Colony Forming Unit-Fibroblasts (CFU-Fs); (2) expression of a panel of surface markers of MSCs and lack of expression of hematopoietic markers; and (3) differentiation potential toward osteocytes and adipocytes under specific *in vitro* differentiating conditions. RESULTS. In this study, we demonstrate that a MSCs from human UCB and BM can be identified and isolated based on a single known surface antigen (e.g., CD105) and coexpression of the ABC transporter P-glycoprotein (Pgp). Among the plastic adherent MSCs-like cells, only the CD105+/Pgp+ subset demonstrates all the criteria for MSCs. These include long survival; fibroblast-like (CFU-F) morphology; expression of a panel of MSCs positive markers (CD105, CD44, CD49a, CD73, CD90, CD271) but not expression of the hematopoietic stem cells' markers (CD45, CD34). Moreover, only the CD105+/Pgp+ cells can differentiate into osteogenic and adipogenic cells in the presence of specific supplements. Upon these differentiation pathways, the Pgp is down regulated, suggesting that Pgp is a novel marker for identifying MSCs. Functional blocking of Pgp activity by Pgp-specific inhibitor augment the adipogenic differentiation pathway of the MSCs but has apparently no effect on the osteogenic differentiation pathway. CONCLUSIONS. This study indicates that overexpression of Pgp is characteristics for genuine MSCs and can be utilized to isolate the relatively small subset of multipotent MSCs from the heterogeneous adherent cell populations of BM and UCB.

ENHANCED ADHESION & MIGRATION AND INDUCTION OF PYK2 COMPLEX FOMATION IN NB4 AND K562 CELLS FOLLOWING ATRA AND IMATINIB TREATMENT

A Ovcharenko,[1] G Granot,[1] O Shpilberg,[2] P Raanani[2]

[1]*Felsenstein Medical Research Center, Petah Tikva, Israel*
[2]*Felsenstein Medical Research Center and the Institute of Hematology, Tel Aviv, Israel*

Background/Aims. All-trans-retinoic-acid (ATRA) and imatinib (IM) are targeted therapies used for acute promyelocytic leukemia (APL) and chronic myeloid leukemia (CML), respectively. Despite improved prognosis, ATRA and IM administration has been associated with extramedullary disease (EMD) occurrence. We postulate that, like in the metastatic processes, changes in migration and adherence potential may enable leukemic cells to inhabit extramedullary sites. Focal adhesion complexes linking between extracellular matrix and the cell cytoskeleton are likely to play an important role in these processes. Pyk2 is a tyrosine kinase highly expressed in hematopoietic cells. Proteins such as paxillin, talin, vinculin, etc, interact with Pyk2 creating the "Pyk2 associated signaling complex"at focal adhesion sites. These complexes participate in adhesion and migration processes and may be involved in EMD development. Our objectives are to identify the molecular changes associated with ATRA and IM administration, define their

effect on adhesion and migration ability and to establish the role of these changes in treatment-associated EMD. *Methods.* We studied the effect of ATRA and IM on NB4 and K562 cells by combining adhesion/migration assays, microarray analysis, RT-PCR, Western blots and siRNA experiments. *Results.* 30-40% of ATRA-treated NB4 cells and IM-treated K562 cells adhered to fibronectin as opposed to untreated cells having no adhesion ability. NB4 cells adhered to FN even 5 days after ATRA withdrawal. In addition, we found a 2.4-7.6-fold increase in the migration ability of NB4 and K562 cells following ATRA and IM treatment, respectively as compared to untreated cells. A microarray screen revealed alteration in the expression of many migration/adhesion related genes (pyk2, paxillin, integrin β2 and β7) following ATRA treatment. Following processing of the microarray results and relying on the decision to focus on the "Pyk2 associated signaling complex, we continued our studies on 3 of the most relevant proteins in this complex: Pyk2, paxillin and integrin β2. We found that the mRNA and protein levels of these 3 key proteins are elevated following cellular exposure to ATRA. Moreover, Pyk2, paxillin and integrin β2 were found to be activated in response to ATRA treatment as seen by an increased phosphorylation levels or by the unveiling of activation-specific epitopes. Pyk2 activation is known to lead to the recruitment of paxillin and vinculin to Pyk2 located at focal adhesion sites. We observed an ATRA-dependent increase of Pyk2-paxillin and Pyk2-vinculin complex formation in our cells. In order to prove that Pyk2 is essential for ATRA-induced NB4 cell adhesion/migration, pyk2 expression was knockdown by siRNA. The adhesion and migration ability of si-pyk2 infected NB4 cells was found to be inferior to that of the parental NB4 cells. *Conclusions.* ATRA and IM induce NB4 and K562 cell adhesion and migration accompanied by increased phosphorylation and activation of Pyk2 and of additional focal adhesion proteins in these cells. We also discovered that Pyk2 is one of the key proteins regulating ATRA-induced cell migration and adhesion. Collectively our data suggest a critical role of Pyk2 in adhesion and migration initiated by various targeted therapies and a possible role in EMD development.

CD38-SPECIFIC ANTIBODY DARATUMUMAB SYNERGIZES WITH NOVEL AGENTS LENALIDOMIDE AND/OR BORTEZOMIB TO IMPROVE THE ANTI-MYELOMA EFFECT EVEN IN LENALIDOMIDE/ BORTEZOMIB REFRACTORY PATIENTS

T Mutis,[1] M de Weers,[2] M van der Veer,[1] B van Kessel,[1] J Bakker,[2] S Wittebol,[3] P Parren,[2] H Lokhorst[1]

[1]*UMC Utrecht, Utrecht, Netherlands*
[2]*Genmab, Utrecht, Utrecht, Netherlands*
[3]*Meander Medical Center, Amersfoort, Netherlands*

Background. Multiple myeloma (MM) is a yet incurable malignancy of antibody-producing clonal plasma cells. Recently, significant progress has been made in MM treatment using novel immunomodulating agents such as lenalidomide (LEN) and bortezomib (BORT). Daratumumab (DARA) is a first-in-class human therapeutic CD38-specific antibody with broad-spectrum killing activity. Set out to further improve MM therapy by combining DARA with novel MM therapeutics, we have already shown the significant improvement of *in vitro* MM cell lysis by combining DARA with LEN. *Methods.* In *ex vivo* assays, which allow us to address killing of MM cells in bone marrow aspirates isolated from MM patients, we now explored the impact of combining DARA with LEN+BORT and with two recently introduced triple combination therapies: RDV (LEN+BORT+ Dexamethason) and MPV (Melphalan+ prednisone + BORT). *Results.* Addition of DARA to the combination of LEN and BORT significantly exceeded the effectiveness of the LEN-BORT treatment alone ($P<0.001$). Specifically, we observed a remarkable synergy between DARA and LEN/BORT in samples which responded poorly to LEN+BORT, including those samples obtained from 5 patients refractory to BORT and/or LEN. Furthermore, when combined with RVD and MPV, DARA almost doubled MM cell killing, especially in the low-dose range of the cocktails. *Conclusion.* Our results illustrate that treatment of MM with DARA in combination with novel multidrug therapies bears great promise.

0385

ELIGLUSTAT, AN INVESTIGATIONAL ORAL THERAPY FOR GAUCHER DISEASE TYPE 1: PHASE 2 RESULTS AFTER 3 YEARS

E Lukina,[1] N Watman,[2] E Avila Arreguin,[3] G Pastores,[4] M Iastrebner,[5] M Dragosky,[5] H Rosenbaum,[6] M Phillips,[7] R Aguzzi,[8] D Bertin-Millet,[8] AC Puga,[8] J Peterschmitt[8]

Background. Gaucher disease type 1 (GD1) is an inherited lysosomal storage disorder caused by deficient activity of acid β-glucosidase, a key enzyme in the degradation of sphingolipids. In GD1 patients, accumulation of glucosylceramide occurs primarily in tissue macrophages and leads to clinical manifestations, including thrombocytopenia, anemia, hepatosplenomegaly, and bone disease. Eliglustat, a novel ceramide analog that is a potent and specific inhibitor of glucosylceramide synthase, is under development as an oral substrate reduction therapy for GD1. *Aim.* To report long-term efficacy and safety results of eliglustat in GD1 patients. *Methods.* This ongoing, open-label, uncontrolled, multicenter, Phase 2 clinical trial of eliglustat (50 or 100 mg bid, depending on plasma trough levels) enrolled 26 previously untreated adults with GD1. Patients had to have splenomegaly with thrombocytopenia and/or anemia. The main efficacy outcomes included mean changes (± SD) from baseline in hemoglobin and platelet levels, spleen and liver volumes, and bone mineral density (BMD); the percentage of patients achieving therapeutic goals for anemia, thrombocytopenia, splenomegaly, and hepatomegaly (Pastores, *Semin Hematol*. 2004); and descriptive changes in skeletal lesions, infarcts, and femur dark marrow (reflecting marrow infiltration by Gaucher cells). Hematology, organ volumes, and biomarkers were assessed every 3-6 months. MRI, DXA, and X-rays were performed yearly and reviewed centrally. *Results.* Nineteen patients have completed 3 years of treatment, and 7 patients have discontinued the trial. After 3 years, hemoglobin increased by 2.6±1.39 g/dL (11.3±1.63 to 13.8±1.37 g/dL) and platelet count increased by 91±65.9% (70,000±21,700/mm^3 to 126,800±40,500/mm^3). Spleen volume (multiples of normal, MN) decreased by 61±12.2% and liver volume (MN) decreased by 29±15.8%. Most patients met long-term therapeutic goals for hemoglobin (100%), spleen volume (100%), liver volume (89%), and platelets (63%), and all patients met ≥3 therapeutic goals at 3 years. In 15 patients with evaluable DXA results at all timepoints, lumbar spine BMD increased by 0.6±0.69 Z-score and 0.6±0.94 T-score. Femur dark marrow was reduced (56%, 10/18) or stable (44%, 8/18) in18 patients with findings at baseline. No bone crises or reductions in mobility occurred. There were no new lytic lesions, bone infarcts, fractures, or areas of osteonecrosis, and no worsening of pre-existing lytic lesions (8 patients) or bone infarcts (7 patients); 1 patient had worsening osteonecrosis noted retrospectively at baseline. Plasma GL-1 levels normalized, and median chitotriosidase and CCL-18 decreased by 80% and 73%, respectively. Eliglustat was well tolerated. Most adverse events (AEs) were mild (74%) and unrelated (95%) to treatment. The most common AEs were viral infections (6 patients); urinary and upper respiratory tract infections (4 patients each); and headache, increased blood pressure, abdominal pain, and diarrhea (3 patients each). Eight drug-related AEs, all mild, occurred in 6 patients. *Summary/Conclusions.* Eliglustat is a potential promising oral substrate reduction therapy for GD1. Clinically meaningful improvements have been observed in hematologic, visceral, and bone parameters, and most patients have met long-term therapeutic goals by 3 years. Eliglustat has been well tolerated and has led to the initiation of 3 international Phase 3 studies, which are actively enrolling patients.

0386

SIRT1: A NOVEL THERAPEUTIC TARGET IN ACUTE MYELOID LEUKEMIA

T Nawrocki,[1] M Espitia,[1] K Kelly,[1] S Padmanabhan,[1] J Esquivel,[1] C Santoyo,[1] G Bornmann,[2] J Carew[1]

[1]*CTRC Institute for Drug Development, San Antonio, United States of America*
[2]*MD Anderson Cancer Center, Houston, United States of America*

Background. Acute myeloid leukemia (AML) is one of the most prevalent forms of adult leukemia with very few long-term survivors. Novel approaches are urgently needed to improve clinical outcomes for patients. A better understanding of the factors that control AML pathogenesis will reveal new therapeutic targets and may offer an opportunity to improve patient survivorship. The sirtuin deacetylases (SIRTs) are a family of histone deacetylases (HDACs) with important roles in the regulation of genes that are essential for longevity, cell growth, tumor suppression, and apoptosis. Dysregulation of SIRT expression has been reported in several forms of cancer and could contribute to disease progression and drug resistance by increasing the lifespan and survival capacity of malignant cells. We hypothesize that SIRT1 is a critical regulator of the survival of AML cells and can be targeted for therapeutic benefit. *Aims.* (1) To elucidate the role SIRT1 in the growth and survival of AML cells. (2) To investigate the mechanism of action of the small molecule SIRT inhibitor tenovin-6 in preclinical models of AML. *Methods.* We tested our hypothesis in human AML cell lines, primary patient specimens and mouse models of AML. *Results.* We assayed the expression levels of SIRT1 and the related factor SIRT2 in normal mononuclear, a panel of human AML cell lines, and primary blasts patients with AML by quantitative RT-PCR and Western blotting. Our results showed that SIRT1 was expressed at significantly higher levels in all AML cell lines and primary AML blasts as compared with normal controls. In contrast, SIRT2 was expressed at very low levels in the majority of the samples analyzed. Although a number of HDAC inhibitors have been clinically investigated for cancer therapy, none of these drugs have significant inhibitory effects against the Class III HDACs (SIRTs). Therefore, the therapeutic potential of disrupting SIRT activity as an anticancer strategy remains to be rigorously investigated. Tenovin-6 is a novel small molecule inhibitor of SIRT activity. Treatment with tenovin-6 caused a dose-dependent reduction in AML cell viability and clonogenic survival and triggered apoptotic cell death. The tumor suppressor p53 is a SIRT1-regulated gene with a critical role in the cellular response to many classes of anticancer agents and its inactivation contributes to disease progression and drug resistance. Increased SIRT1 activity has been proposed as one mechanism by which cancer cells eliminate p53 function through chromatin silencing. Tenovin-6 treatment caused a dose-dependent accumulation of acetylated p53 in AML cells and increased expression of both p21 and PUMA. Targeted knockdown of PUMA with shRNA revealed that PUMA is a critical regulator of the pro-apoptotic effects of tenovin-6. Administration of tenovin-6 to mice was well-tolerated and led to a significant reduction in disease burden. *Conclusions.* SIRT1 is a very promising novel therapeutic target in AML. Further investigation aimed to elucidate the safety, efficacy, and mechanism of action of tenovin-6 is warranted.

0387

TARGETING PLK1 ACTIVITY WITH THE INVESTIGATIONAL DRUG TAK960 SIGNIFICANTLY PROLONGS SURVIVAL IN PRECLINICAL MODELS OF AML

J Rowe,[1] M Hasegawa,[2] K Kelly,[1] T Satou,[2] Y Hikichi,[2] S Padmanabhan,[1] J Esquivel,[1] C Santoyo,[1] K Kuida,[3] S Nawrocki,[1] J Carew[1]

[1]*CTRC Institute Drug Development, San Antonio, United States of America*
[2]*Takeda Pharmaceutical Company Limited, Tsukuba, Japan*
[3]*Millennium Pharmaceuticals, Inc., Cambridge, United States of America*

Background. Acute myeloid leukemia (AML) primarily affects elderly patients that have a reduced ability to tolerate intensive chemotherapy. Novel targeted agents offer an opportunity to achieve better therapeutic selectivity and improve clinical outcomes for patients with AML. Polo-like kinase-1 (PLK1) is a serine-threonine kinase that functions as an essential regulator of mitosis. Overexpression of PLK1 is a frequent event in cancer and is correlated with a poor prognosis. Its intrinsic overexpression in malignant cells and critical role in cell cycle regulation make PLK1 an attractive target for therapeutic inhibition. TAK960 is a novel small molecule inhibitor of PLK1 that has entered Phase I clinical trials. We hypothesized that inhibition of PLK1 would disrupt cell cycle progression, diminish AML cell viability, induce apoptosis, and anatagonize *in vivo* leukemia pathogenesis. *Aims.* (1) To investigate the preclinical activity of TAK960 in preclinical models of AML. (2) To elucidate the mechanism of action of TAK960. *Methods.* The preclinical activity of TAK960 was investigated in human AML cell lines and disseminated and subcutaneous mouse models of AML. *Results.* Treatment with TAK960 potently disrupted the viability of a panel of 8 human AML cell lines. Acute exposure to TAK960 severely impaired the ability of AML cells to form colonies. Analysis of the effects of TAK960 on cell cycle progression demonstrated that TAK960 caused a substantial accumulation of cells with G2/M DNA content. TAK960 treatment led to the dose-dependent induction of apoptosis. Kinetic analyses revealed that cell cycle disruption occurred prior to the onset of apoptosis. We established a disseminated mouse xenograft model of AML with luciferase-expressing human AML cells to investigate the *in vivo* activity of TAK960. Administration of TAK960 to mice was well-tolerated, diminished the numbers of leukemic blasts in the bone marrow, and significantly prolonged animal survival. Analysis of specimens from mice treated with revealed a pharmacodynamic signature consistent with PLK1 inhibition. The *in vivo* efficacy of TAK960 was also evaluated in the subcutaneous MOLM-13 AML xenograft model. Administration of TAK960 significantly inhibited the growth of MOLM-13 tumors, disrupted cell proliferation and led to the induction of AML cell apoptosis. *Conclusions.* TAK960 is a very promising novel PLK1 inhibitor that has potent activity in preclinical models of AML. Further investigation aimed to elucidate the safety, efficacy, and mechanism of action of TAK960 is warranted.

0388

CARFILZOMIB-DEPENDENT SELECTIVE INHIBITION OF CHYMOTRYPSIN-LIKE ACTIVITY OF THE PROTEASOME LEADS TO IN VITRO AND IN VIVO ANTI-TUMOR EFFECT IN WALDENSTROM MACROGLOBULINEMIA

M Aldo, A Sacco, P Maiso, AK Azab, Y Zhang, Y Liu, F Azab, H Ngo, P Quang, C Issa, I Ghobrial

Dana-Farber Cancer Institute, Boston, United States of America

Background. Selective inhibition of chymotrypsin-like (CT-L) activity of constitutive-(c20S) and immuno-(i20S) proteasome leads to a significant anti-neoplastic effect in a wide spectrum of hematologic tumors. Preclinical evaluation of new proteasome inhibitors with a more targeted inhibition of clonal cells is needed in order to increase efficacy and improve patient outcome. We evaluated the anti-tumor activity of Carfilzomib, a novel selective, irreversible peptide epoxyketone inhibitor of the CT-L activity of i20S and c20S, in WM.selective chymotrypsin-like (CT-L) proteasome inhibitor in WM, both *in vitro* and *in vivo*. *Aims.* 1) To evaluate the distribution of i20s and c20S in WM primary cells as compared to the related normal cellular counterpart. 2) To evaluate the anti-tumor properties of Carfilzomib in WM, both *in vitro* and *in vivo*. *Methods.* Primary WM cells were obtained from bone marrow (BM) of WM patients (CD19+ microbead selection). WM and IgM secreting low-grade lymphoma cell lines were used. Level of imunoproteasome (i20S) and constitutive proteasome (c20S) subunits were detected by an ELISA-based assay. Cytotoxicity, DNA synthesis were measured by MTT and thymidine uptake, respectively. Cell signaling and apoptotic pathways were determined by Western Blot. Effect of Carfilzomib on paracrine WM cell growth in the BM has been evaluated by looking at adhesion, migration and co-colture of WM cells with primary BM stromal cells (BMSCs). Drug synergism was calculated using CalcuSyn software. *In vivo* studies were perfomed using BCWM.1-GFP+/Luc+ cells injected into SCID mice, treated intra-venously with either Carfilzomib or vehicle. Detection of Carfilzomib-induced apoptosis has been validated *ex vivo* using WM cells isolated from BM of SCID mice treated with either vehicle or Carfilzomib. Measurement of human IgM has been performed on serum obtained from treated mice. *Results.* Primary WM cells which are characterized by higher expression of the i20S subunits as compared to c20S subunits, and they contain a higher i20S content as compared to normal CD19+ B-cells. Carfilzomib inhibited the CT-L activity of both i20S (LMP7) and c20S (β5) in primary WM cells, leading to inhibition of proliferation and induction of cytotoxicity; supported by increased PARP-, caspase-9-, -8 and -3-cleavage, as well as induced activation of c-jun-N-terminal kinase and ER-stress in a dose-dependent manner. Carfilzomib targeted WM cells even in the context of BM milieu, where inhibition of adhesion and migration were observed, together with inhibition of WM growth even in presence of BMSCs. Combination of carfilzomib and bortezomib induced synergistic cytotoxicity in WM

cells, as shown by enhanced PARP-, caspase-9- and -3-cleavage; and synergy in inhibiting the CT-L activity of the i20S and c20S. Antitumor activity of Carfilzomib has been validated *in vivo*, where carfilzomib-treated mice presented with a significant lower number of tumor cells (P<.05); increased percentage of apoptotic WM cells (P<.05); and reduced serum IgM levels (P<.05), as compared to control mice. *Summary.* These findings demonstrate for the first time that Carfilzomib targets WM cells both *in vitro* and *in vivo*, due to its anti-CT-L activity of both i20S and c20S proteasome, providing the framework for testing this compound in this disease.

TREATMENT OF B-CELL MALIGNANCIES WITH EPRATUZUMAB ANTI-CD22-SN-38 CONJUGATES ALONE AND COMBINED WITH VELTUZUMAB ANTI-CD20 ANTIBODY THERAPY

M Sharkey,[1] V Govindan,[2] M Cardillo,[2] D Goldenberg[1]

[1]*Center for Molecular Medicine and Immunology, Belleville, United States of America*

[2]*Immunomedics, Inc., Morris Plains, United States of America*

Background. Many B-cell malignancies are responsive to antibody therapy, but more often, antibody therapy is combined with chemotherapy to optimize response. We developed procedures for coupling antibodies to SN-38, a highly potent topoisomerase I inhibitor that is the active component of the prodrug irinotecan. SN-38-conjugates of humanized antibodies epratuzumab anti-CD22 (Emab-SN-38) and veltuzumab anti-CD20 (Vmab-SN-38) were evaluated separately, and Emab-SN-38 was tested in combination with unconjugated Vmab. *Methods.* Emab and Vmab were conjugated with 6 moles of SN-38. The linker used in the preparation of these conjugates allows the SN-38 to be released slowly, with *in vitro* stability studies in human serum estimating that about 50% of the SN-38 is released within 1 to 1.5 days. With this type of linkage antibodies that are not internalized (i.e., Vmab), as well as internalizing antibodies (Emab), can be effective. *In vitro* and *in vivo* studies were performed to assess the activity of the conjugates against several B-cell lymphoma and leukemia cell lines. *In vivo* studies also examined combination therapy with Emab-SN-38 and unconjugated Vmab. *Results. In vitro* studies in 5 B-cell lymphoma cells lines (Daudi, Raji, Ramos, WSU-FSCCL, Jeko-1) and 4 acute lymphoblastic lymphoma cell lines (697, REH, MN-60, and RS4;11) expressing varying amounts of CD22 and CD20 determined by FACScan analysis, showed an IC50 ranging from 0.5 to 10 nM, confirming potent activity of each conjugate. Potency was not correlated to antigen content. Nude mice bearing SC Ramos human lymphoma had significant, yet similar anti-tumor activity, with both conjugates (0.25 and 0.5 mg of each conjugate given twice weekly for 4 weeks). No toxicity is seen at these dose levels, with mice able to tolerate a cumulative dose of the conjugate as high as 60 mg. The Emab-SN-38 conjugate was examined further, since this provided an opportunity for it to be combined with effective unconjugated Vmab therapy without competing for the same target antigen. Selective targeting of the Emab-SN-38 was demonstrated against a control, non-targeting, IgG-SN-38 conjugate. In the WSU-FSCCL human follicular B-cell lymphoma IV model, with treatment initiated 5 days after implantation, the median survival for untreated animals was 42 d (0/10 surviving at 160 d), increasing to 91 d (2/10 surviving at 160 days) for unconjugated Vmab-treated animals. Emab-SN-38-treated animals had a median survival of 63d (0/10 surviving after 160 d), but when combined with Vmab, the median survival had not been reached at 160 d, with 6/10 surviving. Animals treated with a non-targeting IgG-SN-38 conjugate alone or combined with Vmab had a median survival of 63 d (0/10) and 91 d (2/10). The Emab-SN-38 conjugate combined with Vmab was significantly better than all treatment or control groups ($P \leq 0.05$). Similar enhancements were found in SC Ramos. *Conclusion.* Even at non-toxic dose levels, the Emab-SN-38 conjugate is a potent therapeutic, but responses could be enhanced significantly when combined with anti-CD20 immunotherapy. These data indicate Emab-SN-38 should be evaluated clinically alone and in combination with Vmab therapy.

0390

COMBINED THERAPY WITH BONE MARROW-DERIVED ENDOTHELIAL PROGENITOR CELLS AND SONIC HEDGEHOG IMPROVES ANGIOGENESIS AND MYOGENESIS IN AN EXPERIMENTAL MODEL OF MUSCULAR DYSTROPHY

M Palladino,[1] I Gatto,[1] V Neri,[1] S Straino,[2] R Smith,[3] M Capogrossi,[2] R Pola,[1] G Leone[1]

[1]*Catholic University of the Sacred Heart, Rome, Italy*

[2]*IDI-IRCCS Institute, Rome, Italy*

[3]*St Elizabeth's Medical Center, Tufts University School of Medicine, Boston, MA, United States of America*

Recent work demonstrates that vascular abnormalities are required for, and an essential cause of, muscle damage in Duchenne muscular dystrophy (DMD). Dystrophin is physiologically expressed in endothelial cells (ECs) and dystrophin-lacking ECs have significant impairment of flow-induced dilatation. It has been proposed that organ damage in DMD might be aggravated by such a defective arterial response to flow. These data suggest that increasing the vasculature in DMD may ameliorate the histological and functional phenotypes associated with this disease and indicate that, for an effective therapy of DMD, both the muscle and the vasculature need to be addressed. The bone marrow (BM) is an important source of ECs. In DMD, regenerative mechanisms, including angiogenesis, are constantly activated to contrast muscle degeneration, thus in this disease the contribution of BM-derived ECs to the process of regeneration might be substantial. We have recently demonstrated that Sonic hedgehog (Shh) gene therapy has angiogenic and myogenic potentials in the setting of ischemia. We investigated the hypothesis that combining Shh gene therapy with the administration of BM-derived endothelial progenitor cells (EPCs) increases angiogenesis and myogenesis in an experimental model of DMD. EPCs were obtained from the BM of 8-week-old C57BL/6J mice. We constructed a 4,878-bp plasmid containing the 600bp amino terminal domain coding sequence of human Shh. Unilateral hind-limb ischemia was created in 6 months-old mdx mice, the murine equivalent of DMD in humans. Each group was injected with either 1) PBS, 2) phShh (200 μg/mouse), or 3) phShh (200 μg/mouse) + EPCs (1×106 cells/mouse). Blood flow was measured in ischemic and contralateral hind-limbs by laser Doppler perfusion imaging at days 0, 7, 14, 21, and 28 after ischemia. At day 28, mice were sacrificed and adductor muscles were used to assess muscle weight, capillary density, and number of regenerating myofibers. At day 28 after ischemia, blood perfusion ratio between the ischemic and the contralateral leg was higher in EPCs+Shh-treated mice (0.86±0.07), and in Shh-treated mice (0.82±0.11) compared to control mice (0.70±0.04; p=0.01, p=ns). Capillary density was significantly higher in the in EPCs+Shh-treated muscle (106±31.8), and in Shh-treated muscle (86.4±30.3) compared to controls (68.2±17.7; p=0.0002, p=0.02). There was a significant increase in the muscle weight of mice treated with EPCs+Shh, and Shh versus controls (0.25±0.01, 0.29±0.03 vs 0.20±0.01 grams; p=0.005, p=0.004). The number of regenerating myofibers was significantly higher in the EPCs+Shh-treated muscle (44.6±10.75), and in Shh-treated muscle (52.03±29.38) compared to controls (30.5±8.8; p=0.00006, p=0.004) (Figure 1).

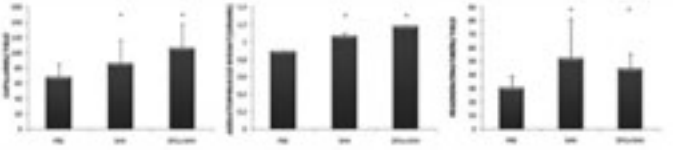

Figure 1.

In summary, Shh gene therapy had significant beneficial effects on blood perfusion ratio, capillary density, muscle weight, and number of regenerating myofibers, compared to PBS. These beneficial effects were further increased by combined therapy with Shh and BM-derived EPCs. Our results show that EPCs implantation combined with transfer of the human Shh gene improves angiogenesis in ischemic muscles of dystrophic mice. Further, this combined therapy enhances muscle mass and increases the number of regenerating myofibers in the mdx muscle. These findings represent a possible tool for future cell and gene therapy applications in DMD disease or other muscular dystrophies.

0391

A TARGETED THERAPY (AVL-292) FOR BRUTON'S TYROSINE KINASE IN B-CELL MALIGNANCIES

J Singh,[1] E Evans,[1] R Karp,[1] R Tester,[1] M Sheets,[1] S Aslanian,[1] T St. Martin,[1] M Nacht,[1] Z Zhu,[1] P Chaturvedi,[1] J Burger,[2] P Ponader,[2] R Petter,[1] W Westlin[1]

[1]*Avila Therapeutics, Waltham, United States of America*
[2]*MD Anderson, Houston, United States of America*

Background. Targeted therapies that suppress B cell receptor (BCR) signaling have emerged as promising agents in the treatment of B cell malignancies. Bruton's tyrosine kinase (Btk) plays a crucial role in promoting B cell proliferation and survival through participation in the BCR signaling pathway and represents a promising new drug target. *Aims.* - Demonstrate the utility of a potent and selective inhibitor of Btk in B cell malignancies. - Investigate effects of clinical candidate, AVL-292, on the survival and BCR activation of primary CLL cells cultured with Nurse-like cells (NLC). - Determine, in a clinical setting, the minimum AVL-292 dose necessary for maximal Btk target site occupancy utilizing a novel translational medicine approach. *Methods.* B lymphocyte cell signaling: Human naïve, primary B cells or cultured Ramos human Burkitt's lymphoma cells were incubated with compound for 1 hour followed by BCR stimulation with -IgM. Antibodies used for immunoblot analysis include P-PLC 2, Btk and P-Btk. B Cell Proliferation: Human B cells were incubated with compound and anti-IgM for 56 h at 37 C and measured for 3H-thymidine incorporation. Btk target occupancy: Cell lysates were incubated with the biotinylated covalent probe for one hour to detect free, unbound Btk. Lysates were then added to a streptavidin-coated plate to capture probe-bound Btk, followed by detection with an anti-Btk antibody. *Results.* AVL-292 is an orally active highly selective small molecule covalent Btk inhibitor that potently silences Btk enzymatic activity (IC50 < 0.5nM) and inhibits primary B cell proliferation and activation (EC50 1-10nM). AVL-292 inhibits proliferation of multiple lymphoma cell lines which are dependent upon BCR signaling. AVL-292 also reduces survival and markers of BCR activation, such as CCL3 and CCL4 cytokine production, of primary CLL cells cultured with NLC. We have developed a covalent probe assay that enables direct measurement of Btk target site occupancy and can be used to correlate target site occupancy with activity of AVL-292 *in vitro* and *in vivo*. Recent completion of an innovative human clinical trial with AVL-292 has delivered important insights into dose-dependent Btk target site occupancy with AVL-292 determined using the covalent probe assay. An AVL-292 dose achieving maximal Btk target site occupancy was identified and the measured rate of Btk protein resynthesis in human subjects supports a once daily dosing schedule. *Summary/Conclusions.* Targeted covalent drug design has enabled the discovery and early clinical development of a potent and highly selective inhibitor of Btk, AVL-292, and supports Btk as an exciting new target for B cell malignancies. These data demonstrate that specific targeting of Btk inhibits growth of B cell lymphoma cell lines as well as the survival of primary CLL cells in the presence of nurse-like cell support. The covalent mechanism of action of AVL-292 can deliver translational pharmacodynamic information early in clinical drug development and has facilitated the rational selection of dose and dose schedule to maximize patient benefit in clinical trials studying B cell malignancies.

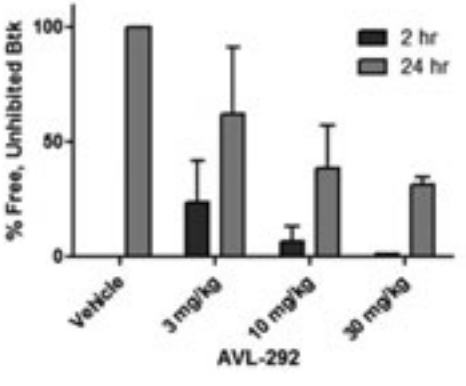

Figure 1. Btk target occupancy *in vivo.*

RAPID TREATMENT OF SYMPTOMS OF TTP IN A BABOON MODEL

J Roodt[1] & H Feys,[2] H Mottl,[3] S Hou,[3] S Lamprecht,[4] W van Rensburg,[4] H Deckmyn,[2] K Vanhoorelbeke[2]

[1]*National Health Laboratory Services, Bloemfontein, South Africa*
[2]*Laboratory for Thrombosis Research, Katholieke Universiteit Leuven, Kortrijk, Belgium*
[3]*Glenmark Pharmacutical S.A., La Chaux-de-Fonds, Switzerland*
[4]*University of the Free State, Bloemfontein, South Africa*

Background. Thrombotic thrombocytopenic purpura (TTP) is characterized by hemolytic anemia and thrombocytopenia, with or without signs and symptoms of ischemic organ dysfunction. TTP has been associated with accumulation of ultra large von Willebrand Factor (ULVWF) due to deficiencies in the VWF cleaving protease ADAMTS13. These ULVWF multimers spontaneously interact with platelets in the microcirculation and promote the formation of platelet thrombi resulting in life-threatening microthrombosis. Recently, we have shown that all the clinical features of TTP can be induced in baboons by infusion of an inhibitory anti-ADAMTS13 antibody (3H9). TTP is currently treated by plasma exchange or plasma infusion. As spontaneous binding of platelets to the ULVWF molecules is responsible for the pathology, inhibiting the binding of platelets to ULVWF might be a good alternative treatment for TTP. *Aim.* To test whether GBR 600, an inhibitory anti-VWF-A1 domain monoclonal antibody previously shown to be safe and effective in preventing arterial thrombosis in a modified Folts model in baboons, will prevent and treat the symptoms of TTP in a baboon TTP model. *Methods.* Eight baboons were given 3H9 at 48 hour intervals to induce TTP for either 5 (n=3, prevention group) or 11 days (n=5, prevention group and control group). In the prevention group, baboons received in parallel a daily injection of GBR 600 (5 days) to see if this could prevent onset of TTP. In the treatment group (n=3), baboons received a daily injection of GBR 600 from the fifth day on to see if this would treat the symptoms of TTP. The baboons in the control group (n=2) did not receive GBR600. Platelet count, haemoglobin concentration and % circulating schistocytes were monitored at regular intervals. *Results.* As previously reported, injection of 3H9 in baboons gradually induced thrombocytopenia reaching platelet counts of less than 30X10^9/l at day 4 in the control and treatment groups. Interestingly however, thrombocytopenia could be prevented when GBR600 was administered starting at day 1 of the 3H9 injections (prevention group). The platelet count in the treatment group showed a steady increase from day 6 and returned to the baseline value in 72 hours after first injection of GBR 600. Haemoglobin concentration did not change significantly in the prevention group and decreased steadily in the control group for the duration of the study. In the treatment group there was a steady decrease in heamoglobin until day 6 after which it stabilized and started increasing from day 8. Prominent schistocytosis was seen in the control and treatment groups. *Summary.* In this study we showed that inhibition of platelet binding to ULVWF can effectively prevent the onset of TTP as well as rapidly invert ongoing symptoms of TTP on the background of fully inhibited ADAMTS13.

0393

THE INVESTIGATIONAL NOVEL MULTI-TARGETED AURORA B KINASE INHIBITOR TAK901 HAS POTENT ACTIVITY IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA

T Nawrocki,[1] R de Jong,[2] K Kelly,[1] T Satou,[3] A Romanelli,[4] J Esquivel,[1] C Santoyo,[1] S Padmanabhan,[1] M Hasegawa,[3] J Carew[1]

[1]*CTRC Institute for Drug Development, San Antonio, United States of America*
[2]*Takeda San Diego, Inc., San Diego, United States of America*
[3]*Takeda Pharmaceutical Company Limited, Tsukuba, Japan*
[4]*Millennium Pharmaceuticals, Inc., Cambridge, United States of America*

Background. The majority of patients diagnosed with acute myeloid leukemia (AML) are more than 60 years of age and their long-term prognosis is dismal. Pre-existing myelodysplasia, multidrug resistance, and co-existing morbidities limit therapeutic options for many patients. Novel approaches are urgently needed to improve clinical outcomes. The Aurora kinases (A, B, and C) are critical regulators of several events during mitosis. The overexpression of Aurora kinases in AML and other forms of cancer contributes to genetic instability, disease progression, and drug resistance. TAK901 is an investigational novel small molecule Aurora B kinase inhibitor with effects against a number of other

kinases with important roles in cancer that is being evaluated in Phase I trials. We hypothesized that simultaneously targeting Aurora B and other oncogenic kinases with TAK901 would disrupt cell cycle kinetics, inhibit proliferation, and induce AML cell death. *Aims.* (1) To determine the preclinical activity of TAK901 in AML. (2) To elucidate the mechanism of action of TAK901 in AML cells. *Methods.* Human AML cell lines and disseminated and subcutaneous mouse models of AML were utilized to investigate the preclinical activity of TAK901. *Results.* TAK901 potently diminished the growth and clonogenic survival of a panel of 8 AML cell lines. Treatment with TAK901 disrupted cell cycle kinetics leading to an accumulation of aneuploid cells, which occurred prior to the onset of apoptosis. A disseminated xenograft mouse model of AML was established using luciferase-expressing MV4-11 cell to investigate the *in vivo* anti-leukemic activity of TAK901. Administration of TAK901 to mice was well-tolerated and led to a highly significant increase in survival that was superior to what was achieved with the standard agent cytarabine. TAK901 induced AML cell apoptosis (active caspase-3) *in vivo* and dramatically diminished the phosphorylation of histone H3 in a manner consistent with Aurora B inhibition. Notably, TAK901 inhibited the infiltration of leukemic cells into the spleen and disrupted homing of AML cells to the bone marrow. The activity of TAK901 was also evaluated in the MOLM-13 subcutaneous AML xenograft model. Administration of TA901 to mice bearing MOLM-13 tumors inhibited AML cell proliferation, induced apoptosis and led to disease regression. *Conclusions.* TAK901 is a novel multi-targeted Aurora B inhibitor that has preclinical activity in AML models and warrants further investigation.

SAFETY AND TOXICITY OF INTRATHECAL LIPOSOMAL CYTARABINE FOR TREATING CENTRAL NERVOUS SYSTEM (CNS) RELAPSE IN PEDIATRIC ACUTE LEUKEMIA: A MULTICENTER RETROSPECTIVE STUDY

R Parasole,[1] F Petruzziello,[1] C Messina,[2] A Pession,[3] E Barisone,[4] F Locatelli,[5] C Concetta,[6] AM Testi,[7] S Varotto,[2] W Morello,[3] M Calvillo,[6] M Berger,[4] G Menna,[1] V Poggi[1]

[5]*University of Pavia and Bambin Gesù Hospital, Pavia-Rome, Italy*
[6]*"G. Gaslini" Research Institute, Genoa, Italy*
[7]*"La Sapienza" University of Rome, Rome, Italy*

Background. The treatment of Central Nervous System (CNS) relapse in pediatric acute Leukemia (AL) remains a challenging clinical problem. Liposomal Cytarabine (DepoCyte) is a new intrathecal (IT) formulation characterized by the slow-release of free Cytarabine into the cerebrospinal fluid (CSF), resulting in longer drug exposure and a possibly higher leukemic response rate. Severe neurotoxicity has been reported during DepoCyte treatment. *Aims.* We retrospectively evaluated the safety profile of IT DepoCyte in a cohort of 26 pediatric AL patients with CNS relapse. *Methods.* Between May 2005 and August 2010 twenty-six patients (18 males, 8 females; 21 ALL and 5 AML; age at diagnosis 0.6-17 years; age at treatment 0.8-18 years) with CNS relapsing AL were treated with IT DepoCyte at dosages ranging from 20 to 50 mg/dose depending on age, in seven Italian Pediatric Hemato-Oncology Association (AIEOP) centers. Patients concomitantly received oral administration of Dexamethasone (DEXA) at a dosage of 0.2 mg/kg twice a day for 5 days, associated with IT DEXA in eleven children. Twenty three out of 26 patients were simultaneously treated with systemic chemotherapy. Concurrent high dose cytarabine or methotrexate was administered to 20 of these patients. DepoCyte was started upon CNS relapse and was administered every 15 days regardless of aplastic phase and underlying chemotherapy until CSF negativity in two consecutive lumbar punctures. Table I summarizes the clinical characteristics of patients. DepoCyte treatment was discontinued when neurotoxicity appeared or in the presence of severe adverse events. Toxicity was evaluated according to the National Cancer Institute Criteria. *Results.* 23 out of 26 patients (88.5%) achieved complete CSF remission and the remaining 3 presented partial remission (CSF negativity with persistence of neuroradiological findings of cerebral localization). The median number of administered doses was 4 (range 2-9), with CSF negativity after a median of three IT administrations. Neurological toxicity > grade 3 was observed in 3 patients (11.5%); one patient experienced posterior reversible encephalopathy syndrome, the second had strabismus and clonus in the lower right limb and the third had partial seizures after CNS hemorrhagic stroke during the aplastic phase. Two of these 3 patients resumed DepoCyte after CNS event resolution without complications. We observed mild headache < grade 2 in 4 other patients. No permanent sequelae were observed. Two patients died of sepsis during treatment and 2 died from transplant-related complications; 8 died of non-CNS disease progression. Fourteen patients are currently alive in complete remission. *Conclusion.* The use of IT liposomal Cytarabine in the Italian experience showed acceptable tolerability and reasonable efficacy in the majority of patients. The frequency of neurological side effects was similar to what has been observed following other types of IT treatment. Despite its potential neurotoxicity, DepoCyte represents an interesting formulation since it reduces the frequency and total number of IT administrations. These characteristics associated with efficacy can improve compliance and quality of life in young patients. Further prospective studies on larger pediatric series are needed to confirm our observations and define optimal dosage and best timing administration of the drug in the pediatric setting.

Table 1.

Clinical characteristics of the Patients

Characteristic	No.
Gender:	
Male/Female	18/8
Median age at diagnosis (yrs) (range)	7 (0.6-17)
Median age at DepoCyte treatment (yrs) (range)	10 (0.8-18)
Underlying neurological disease	1
Diagnosis:	
Acute Lymphoblastic Leukemia	21
Acute Myeloid Leukemia	5
N. of CNS relapse at DepoCyte treatment:	
First relapse	12
Second relapse	7
a Third relapse	6
Resistance	1
Tipe of relapse:	
Isolated CNS relapse	21
Combined relapse	5
Median DepoCyte administration	4 (2-9)
Dose Level per patients:	
20 mg	3
25 mg	3
35 mg	14
50 mg	6
CNS response (%):	
Complete response	23 (88.5)
Partial response	3 (11.5)
Neurological toxicity ≥ grade 3 (%)	3 (11)
Posterior reversible encephalopathy syndrome	1
Strabismus and clonie at right inferior limbs	1
Partial seizures after CNS hemorrhagic stroke	1
Toxicity < grade 3:	
Headache grade I/II	4
Irritability	3
Fever	2
Concurrent HD-MTX/ARA-C	20
Outcome:	
Death from sepsis	2
Death from TRM	2
DOD	8
Alive in CR	14
Median follow-up from DepoCyte therapy (mts) (range)	7 (2-37)

CNS: central nervous system; HD-MTX/ARA-C: high dose Methotrexate/ Cytarabine; yrs: years; mts: months; CR: complete remission; TRM: transplant related mortality; DOD: died of disease

PRECLINICAL EVALUATION OF CPX-351 LIPOSOME INJECTION IN A GENETICALLY ENGINEERED MOUSE (GEM) MODEL OF DRUG RESISTANT HUMAN ACUTE MYELOGENOUS LEUKEMIA (AML)

O Harasym,[1] W Zhao,[2] D Mayer,[1] S Lowe[2]

[1]*Celator Pharmaceuticals Corp., Vancouver, Canada*
[2]*Cold Spring Harbor Laboratory, Cold Spring Harbor, United States of America*

Background. CPX-351 Liposome Injection is a nano-scale liposomal formulation that contains a synergistic 5:1 molar ratio of cytarabine (Cyt) and daunorubicin (Daun). Previous preclinical studies revealed that CPX-351 provides dramatic efficacy improvements compared to free drugs in a range of syngeneic and xenograft leukemia models.

Clinically, CPX-351 is being developed to replace conventional Cyt plus Daun therapy ("7+3"). A recent Phase II trial in newly diagnosed elderly AML patients treated with CPX-351 demonstrated improved outcomes over conventional "7+3"treatment with the largest improvements occurring in high-risk AML patients including CRs in patients that failed to respond to 7+3 prior to crossing over to CPX-351 treatment. Here we compare the therapeutic effects of CPX-351 and conventional Cyt:anthracycline in a GEM model exhibiting a genetic makeup common in refractory human AML to better understand the basis of the different responses observed between these two treatments. *Aim.* Assess the therapeutic activity of CPX-351 in a GEM leukemia model which reflects the genetics and pathology of refractory human AML. *Methods.* Luciferase expressing AML cells were implanted in C57/BL6 mice, cells were prepared from AML mice induced by MLL/AF9 + Nras oncogene. Mice were monitored for bioluminescence signal every 4 days, starting 10 days after implant. Upon detection of a bioluminescent signal (pelvis, tail, femurs, hepatosplenic infiltration) treatments were initiated with CPX-351 (Q2D x3) or a cocktail of free Cyt (QD x5) and doxorubicin (QD x3). A no-treatment group served as control. Therapeutic activity was monitored by imaging before treatment, after last treatment, and 4 days after last treatment. Histopathological analysis of peripheral blood (May-Grunwald-Giesma) and mouse survival were also monitored. *Results.* Mice inoculated with refractory AML cells were treated once a bioluminescent signal indicative of leukemia cell engraftment was observed. Overall, more pronounced leukemia reduction (reduced bioluminescence) and survival was observed following CPX-351 treatment than was observed with free drug treatment. Images from mice that received no treatment displayed widely disseminated leukemia. Similar images of disseminated disease were observed in the free drug arm; however the extent and intensity required an additional 4 days to develop (8 days from treatment initiation) and only 3 mice survived. In contrast all 5 mice treated with CPX-351 were alive 8 days after treatment initiation and showed reduced bioluminescence than mice treated with free drugs. Peripheral blood smears obtained 3 days after treatment and on the day of euthanasia exhibited reduced leukemia cell burden. The resulting decrease in leukemia led to a statistically significant increase in 50% median survival when comparing the treatment arms. While the treatment-induced increase in lifespan (ILS) for the free drug cocktail was minimal (14%), CPX-351 significantly increased the ILS to 57%. *Conclusions.* CPX-351 was designed to enhance the efficacy of Cyt:Daun therapy by encapsulating both agents within a drug carrier that maintains the synergistic 5:1 molar ratio for extended times. Here preclinical data indicated that CPX-351 treatment of a model with a common genetic translocation for refractory human AML resulted in decreased leukemia burden and improved survival when compared to free drug treatment.

Background. Atypical hemolytic uremic syndrome (aHUS) is a rare, life-threatening disease characterized by systemic thrombotic microangiopathy (TMA) due to chronic, uncontrolled terminal complement activation. Systemic TMA manifests as endothelial damage, hemolytic anemia and platelet consumption, leading to multi-organ damage or failure. Many patients receive chronic plasma exchange/infusion therapy, but despite this, still have persistent TMA and poor outcomes - 60% develop end-stage renal disease or die within 1 year of diagnosis. In prospective clinical trials of adult and adolescent aHUS patients, the complement C5 inhibitor eculizumab controlled the TMA process, prevented and/or reversed kidney damage and reduced plasma exchange/infusion requirements. *Aims.* To assess efficacy and safety of eculizumab for treatment of aHUS outside of clinical trials. *Methods.*

Table 1.

Baseline Characteristics*	n=15
Platelet count <150×10⁹/L, n (%)	7 (47)
eGFR <30mL/min/1.73m², n (%)	3 (20)
Serum LDH >ULN, n (%)	10 (67)
Median (range) duration of current aHUS clinical manifestation, days	36 (2, 481)
Median (range) number of PE/PI sessions in week before eculizumab	4 (0, 7)
Identified complement regulatory factor mutation, n (%)	7 (47)
Efficacy Outcomes During Eculizumab Treatment[†]	
Platelet normalization (>150x10⁹/L), n (%)	
All patients	14 (93)
Patients with abnormal platelet count at baseline	6/7 (86)
Hemoglobin improvement ≥20g/L, n (%)	8 (53)
eGFR improvement ≥15mL/min/1.73m², n (%)	8 (53)
Complete TMA response (platelet count/LDH normalization plus ≥25% serum creatinine reduction), n (%)	7 (50)[‡,¶]
TMA event-free status attained (stable platelets, no PE/PI or dialysis), n (%)	12 (80)
Mean (SD) TMA intervention rate (PE/PI or dialysis events/patient/day)	
Pretreatment period	0.67 (0.63)
Treatment period	0.01[¶] (0.02)

eGFR=estimated glomerular filtration rate; LDH=lactate dehydrogenase; ULN=upper limit of normal.
*One patient received eculizumab to prevent TMA in a kidney graft, thus having normal biological parameters at baseline. [†]Intent-to-treat population (n=15). [‡]N=14. [¶]P<0.0001 vs pretreatment period (sign-rank test).

We conducted a retrospective data collection analysis of 30 aHUS patients receiving ≥1 eculizumab dose outside of clinical trials between 2007 and 2009. This report presents efficacy and safety outcomes for the 15 pediatric patients aged <12 years (<2 y [n=5]; 2-4 y [n=3]; 5-11 y [n=7]). *Results.* Baseline data and eculizumab efficacy outcomes for the 15 pediatric patients are presented (Table). Eculizumab efficacy was similar across the 3 age groups. Eculizumab safety in these pediatric patients was similar to eculizumab safety in adult and adolescent patients evaluated in clinical trials. *Conclusions.* In this medical practice setting, results for pediatric aHUS patients are consistent with results from adult and adolescent controlled trials in demonstrating that eculizumab treatment is well tolerated and can control TMA, improve kidney function and reduce need for plasma exchange/infusion, thus showing the promising potential of eculizumab as a new standard of care for aHUS.

FETAL HEMOGLOBIN INDUCTION BY A NEW HISTONE DEACETYLASE INHIBITOR

L Ronzoni,[1] G Fossati,[2] M Baroni,[2] A Cattaneo,[1] A Colancecco,[1] M Forino,[2] D Modena,[2] M Moras,[2] M Cappellini[1]

[1]*Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy*
[2]*Italfarmaco SpA Preclinical Research Centre, Milan, Italy*

Background. Induction of fetal hemoglobin (HbF) remains a promising therapeutic approach for the treatment of β-thalassemia and sickle cell disease, since HbF can substantially ameliorate the clinical symptoms of these genetic disorders. Several pharmacologic agents, such as hydroxyurea, 5-deoxyazacytidine, butyrate and trichostatin A have been shown to induce γ-globin activity. However, the therapeutic use of these products is limited due to their relatively weak and variable efficacy, their cytotoxicity and possible long-term side effects. Thus, more effective agents that can induce higher HbF levels with lower toxicity are needed. One candidate group of substances with high therapeutic potential are the histone deacetylase inhibitors (HDIs), which through decondensation of chromatin structure can lead to reactivation of gene expression. *Aims.* To investigate the effects of a new histone deacetylase inhibitor (HDACi) on erythropoiesis and hemoglobin synthesis. *Methods.* An *in vitro* erythropoiesis model derived from human CD34+ progenitors cells from normal donors was used. HDACi effects on cell growth and viability, on erythroid differentiation and on HbF induction was investigated. *Results.* HDACi reduced cell growth and delay erythroid differentiation in a dose-dependent manner; concentration higher than 50nM significantly decreased the percentage of GPA+ and CD71+ cells and of mature orthochromatic erythroblasts and increased the percentage of immature proerythroblasts. Lower concentration (1-50nM) didn't affect cells proliferation and maturation (table 1). HDACi positively affected hemoglobin production, increasing the γ/γ+β globin gene ratio and the HbF percentage. The increase observed with concen-

Table 1.

	Cell growth (10^6)	GPA+ Cells (%)	CD71+ Cells (%)	% Proerythroblasts	% Orthochromatic e.	% HbF/HbT	γ/γ+β ratio	BCL11A
Control	3,2	76,2	73,3	13	42	2,8	0,5	1
1nM	2,5	88,8	70,7	14	45	2,7	0,5	0,8
10nM	2,8	57,3	85,8	21	35	5,4	0,6	0,7
50nM	1,7	33,4	57,3	36	6	8,8	0,8	0,3
150nM	0,8	28,7	52,7	88	0		1	0,25

tration higher than 50nM could be related to the inhibitory effect on erythroid differentiation, so to the presence of an higher percentage of immature erythroblasts physiologically expressing higher levels of HbF. On the contrary, the increase observed with HDACi 10nM seem to be due to a specific effect of the drug on γ-gene transcription, probably mediated by a decrease in the expression of BCL11A, a known repressor of γ-globin gene. The HDACi 10nM efficacy in inducing HbF was similar to that of butyrate and hydroxyurea, already used in clinical trials. *Conclusions.* HDACi 10nM may improve erythropoiesis and increase the ratio of fetal to adult haemoglobin, although total Hb doesn't increase. Its HbF inducing activity compare favourably with those of known HbF inducer but, unlike these, without affecting cell viability and differentiation. These findings support the evaluation of HDACi as new candidate molecule for hemoglobinophaties treatment.

0398

KNOCK-DOWN OF MLL/AF4 AND AML1/MTG8 AFFECTS PROLIFERATION AND DIFFERENTIATION OF AML AND ALL CELLS AND IMPAIRS CLONOGENICITY

F Ponthan, H McNeill, O Heidenreich

Newcastle University, Newcastle upon Tyne, United Kingdom

Background. MLL/AF4 and AML1/MTG8 are two fusion genes most frequently found in infant acute lymphoblastic leukaemia (ALL) and acute myeloid leukaemia (AML), respectively. We have previously shown that transient siRNA mediated knock-down of MLL/AF4 and AML/MTG8 impairs proliferation and clonogenicity *in vitro* and causes a significant increase in median survival in a xeno-transplantation model. *Aims.* We aim to investigate the role of MLL/AF4 and AML1/MTG8 in leukaemic maintenance and progression of established decease *in vivo*. We used a constitutive and an inducible lentiviral shRNA expression system to determine the effects of knock-down of MLL/AF4 in the t(4;11)-positive SEM cell line and of AML1/MTG8 in the t(8;21)-positive human leukaemic cell line Kasumi-1. *Methods.* shRNA cassettes specifically targeting the MLL/AF4 and the AML1/MTG8 fusion were either cloned into the pHR'SINcPPT-SEW GFP expressing lentiviral transfer vector where the shRNA is constitutively expressed or into the pTRIPZ vector where shRNA expression and RFP expression are both induced by doxocycline. SEM and Kasumi-1 cells were transduced with lentiviral particles produced in 293T cells and the transduction efficiency was determined by quantifying GFP or RFP positive cells, respectively, using flow cytometry. Knock-down and expression of known targets of the fusion genes were verified at both the RNA and protein level by qPCR and western blotting respectively. Cell growth was monitored by cell counts and colony formation assays including replating experiments were preformed. Immunodeficient NSG mice were transplanted by intrafemoral injection followed by monitoring of disease progression using bioluminescence. *Results.* More than 95% of SEM and kasumi-1 cells were transduced with pHR'shMLL/AF4 and pHR'shAML1/MTG8 3 days after transduction but decreased to 90% after 30 days in culture. We confirmed that kasumi-1 cells transduced with pHR'shAML1/MTG8 had decreased expression levels of AML1/MTG8 at protein and RNA levels associated with decreased expression of CD34, increased levels of IGFBP7 and an impaired clonogenicity. SEM cells transduced with pHR'shMLL/AF4 showed decreased expression of MLL/AF4 with concomitant decreased expression of HOXA7. The inducible shRNA expression systems showed similar results for both cell lines; however the transduction efficiencies were considerably lower compared to the constitutively expressed shRNA experiments. Currently, we are examining the *in vivo* consequences of fusion gene knockdown in our murine xeno-transplantation model. *Conclusions.* shRNA knock-down of MLL/AF4 and AML1/MTG8 with either the constitutive or the inducible systems led to decreased proliferation and impaired clonogenicity and affected genes associated with differentiation. However the effects were delayed compared to transient siRNA knock-down. Further optimisation of the inducible shRNA system is warranted before *in vivo* experiments can be initiated. frida.ponthan@ncl.ac.uk

0399

TARGETING NAD+ SALVAGE PATHWAY IS A NOVEL THERAPEUTIC STRATEGY IN MULTIPLE MYELOMA

M Cea,[1] A Cagnetta,[1] T Yu-Tzu,[1] M Fulciniti,[1] F Cottini,[1] M Gobbi,[2] A Nencioni,[2] F Patrone,[2] K Anderson[1]

[1]*Dana Farber Cancer Institute, Boston, United States of America*
[2]*Universita di Genova, Genova, Italy*

Background. Nicotinamide adenine dinucleotide (NAD+) is a coenzyme crucially involved in several cellular functions. During the neoplastic transformation, nicotinamide phosphoribosyltransferase (NAMPTase), a key enzyme involved in NAD+ biosynthesis, performs an important role since becomes upregulated to compensate for increased metabolic demands. Therefore, drugs capable to inhibit this enzyme, such as APO866, are under investigation for their potential as anticancer therapeutics. In this study we aimed to investigate the role of NAD+ in Multiple Myeloma (MM) by the activity and mechanism of action of the selective Nampt (the rate-limiting enzyme in the NAD+salvage pathway) inhibitor APO866. *Methods.* a panel of 14 MM cell lines, both sensitive as well as resistant to conventional chemotherapy, were used. Additionally 5 samples from peripheral blood of healthy donors were collected. 5x104 cells/well were plated in 96 well plates and treated with increasing concentrations of APO866 (range 10-9-10-6 M). Viability was assessed at 96 h from the beginning of the treatment by propidium iodide exclusion using a FACS CantoII. In selected cases, Annexin-V/propidium iodide staining was done to detect early- vs. late-apoptotic leukemia cells in response to treatment. Proliferation assays were performed using thymidine incorporation. Intracellular NAD+ content was measured using a biochemical assay; the characterization of cell death was performed by pan-caspase inhibitor (zVAD-fmk), the caspase 9 and 8 specific inhibitors (to value apoptosis) and chemical modulators such as wortmannin, LY294002, 3methyladenine and bafilomycin A1 (to assess autophagy). *Results.* We found maximal cytotoxicity of APO866 against MM cell lines, with an IC50 values ranging from 3-30nM at 96h. Remarkably, in healthy leukocytes, APO866 was poorly active and failed to show any cytotoxic effect, indicating an increased reliance on these enzymes'activity by MM cells. Tritiated thymidine uptake assay confirmed the antiproliferative effects of APO866 in MM. Also the intracellular NAD+ levels lowered in the treatment with APO866 at 24 and 48 hours. A strongly expression of Nampt was revealed by western-blot analysis in all the cell lines analyzed. The AnnexinV/PI analysis confirmed APO866's ability to induce apoptosis in a dose- and time-dependent fashion. Interestingly Nampt inhibitor showed anti-myeloma activity even in the presence of interleukin-6 and insulin-like growth factor-1, confirming its ability to overcome the proliferative advantage conferred by this cytokines. Mechanistic studies, showed that APO866 cell death occurred in the absence of caspase activation. Furthermore, autophagy inhibitors reduced APO866 cytotoxic activity. *Conclusion.* our preliminary data show the efficacy of Nampt inhibitor in MM cell lines,at nanomolar concentrations. Ongoing mechanistic and *in vivo* studies will delineate the role of NAD+ and in MM and better define Nampt inhibitors for clinical development in MM.

0400

PLUMBAGIN ENHANCES TRAIL-INDUCED APOPTOSIS OF HUMAN LEUKEMIC KASUMI-1 CELLS THROUGH UP-REGULATION OF DR5 EXPRESSION, ACTIVATION OF CASPASE-8 AND INHIBITION OF CFLIP

LG Liu

Shanghai Fifth People's Hospital, Fudan University, Shanghai, China

*Background.*Although the patients with t (8; 21) acute myeloid leukemia (AML) have a favorable prognosis when compared with other non-t (15; 17) AML patients, only approximately 50% patients with this relatively favorable subtype are still alive at 5 years and refractory/relapse is still a tough problem in clinical. So the approach of finding new agents and/or methods is important. *Aims.*To investigate the effect of plumbagin alone,TRAIL alone and combination plumbagin with tumor necrosis factor"related apoptosis inducing ligand (TRAIL) induced apoptosis on leukemic Kasumi-1 cells and its mechenisms. *Methods.* Kasumi 1 cells were treated with plumbagin alone, rsTRAIL alone at different concentration, rsTRAIL combining with plumbagin. Cell proliferation was analyzed by CCK-8 assay.

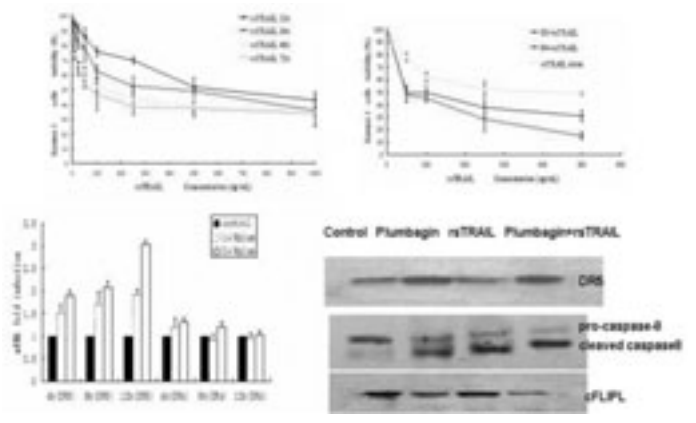

Figure 1.

Apoptosis was studied independently through Annexin /PI double staining by flow cytometry and TUNEL staining The expression of DR4 and DR5 at mRNA lever was detected by real-time PCR. The expression of signal transduction proteins, such as DR5, caspase-3, caspase-8, caspasep-9, Bid, Bax and c-FLIP was detected by Western blotting. 4. *Results.*Both rsTRAIL and plumbagin could induce the apoptosis of Kasumi-1, and rsTRAIL-induced apopotosis of Kasumi-1 could be enhanced by plumbagin. The ratios of annexin V positive Kasumi-1 cells were 27.7±2.9 %, 25.6±3.1 % and (52.1±3.3 % in 100 ng/m1 rsTRAIL groups, 2μmol/Lol/L plumbagin and the combination of the two agents group respectively, and the combination group was significantly higher than the group of rsTRAIL or plumbagin alone. TUNEL assay demonstrated that the number of apoptotic cells in groups of plumbagin combining with rsTRAIL were higher than the groups of rsTRAIL or plumbagin alone. Plumbagin could up-regulate the expression of DR5 at mRNA levels in Kasumi-1 cells by real-time PCR assay, and up-regulation of DR5, activation of caspase-8 and down-regulation of c-FLIP at protein level could be detected in plumbagin-alone and the combination with rsTRAIL groups. *Conclusions.*Plumbagin can enhance TRAIL induced apoptosis of Kasumi-1 cells, and the mechanism is involving in the upregulation of DR5, activation of caspase-8 and the degradation of c-FLIP.

0401

IRON CHELATING AGENTS HAVE ANTI-LEUKEMIC EFFECT ON SECONDARY IRON OVERLOADED LEUKEMIA MOUSE MODEL

DC Jeong,[1] PS Jang,[2] JW Lee,[3] NG Chung,[3] B Cho,[3] HK Kim[3]

[1]*Incheon St. Mary's Hosp, College of Medicine, The Catholic University of Korea, Incheon, South-Korea*

[2]*Uijeongbu St. Mary's Hosp.,College of Medicine, The Catholic University of Korea, Uijeongbu, South-Korea*

[3]*Seoul St. Mary's Hosp., College of Medicine, The Catholic University of Korea, Seoul, South-Korea*

Background. The patients with hematologic diseases receive multiple transfusions due to disease characteristics or treatments. In addition to the removal of iron, iron chelating agents (ICA) have several biological effects, including immunosuppression and changes in cell metabolism. *Aims.* We investigated the anti-tumor activity of ICA in an animal leukemia model with secondary iron overload (SIO). *Methods.* We used 5 week-old male BDF1 ($H2^{b/d}$) mice, and leukemia or lymphoma cell lines (A20, L1210, EL4) of B and T lymphoblast origin. The cell viability of cell lines was assessed in 48 hour culture under the various ICA concentrations with or without ferric chloride by CCK8 method. Also, we performed apoptosis analysis using flow cytometry. All mice were injected subcutaneously with L1210 cells in the right flank area, and measured for tumor mass and weight 3 times a week. All mice except control group received iron dextran (10 mg/day) intraperitoneally for 20 days for SIO from day 7 of tumor injection. Deferrioxamine (DFO) was injected intraperitoneally in dose of 40 mg/kg/day for 6 days, and deferasirox (DFX) orally administered at 20 mg/kg/day for 15 days from day 28 of tumor inoculation, respectively. We assessed tumor iron content (TIC), liver iron content (LIC), tumor size, and survival. *Results.* The viability of A20 and L1210 decreased more than that of EL4 under the ICA. The viability of L1210 under DFX decreased more than that under DFO in therapeutic concentrations ($P<0.01$). The percentage of apoptosis was dependent on the concentration of DFO and DFX, although there was more apoptosis in DFX treated group than in DFO group ($P<0.01$). The expressions of Fas on L1210 did not change according to ICA concentration. Sizes of tumor mass between groups were not different until ICA administration ($P>0.05$). However, tumor grew rapidly in untreated groups (control and SIO) but slowly in ICA treated groups (DFO and DFX) ($P<0.01$). LIC and TIC in SIO were higher than in ICA treated groups. Survival was higher in SIO+DFX ($P<0.01$) but shorter in SIO+DFO ($P<0.01$). *Conclusion.* ICA may have concentration-dependent anti-tumor activity. In SIO with tumor, DFX may result in survival benefit and decreased iron content. We concluded that ICA might be a candidate for anti-tumor treatment along with chemotherapy in leukemia patients who have received multiple transfusions.

0402

A DRUG REPROFILING STRATEGY IDENTIFIES THE ANTI-HELMINTIC NICLOSAMIDE AND VALPROATE (VAN) AS AN EFFECTIVE NOVEL ANTI-MYELOMA COMBINATION THERAPY THAT ALSO REDUCES FREE LIGHT CHAIN PRODUCTION

L Khanim, B Merrick, H Giles, M Jankute, M Bunce, T Drayson

University of Birmingham, Birmingham, United Kingdom

Background and Aims. Our *in vitro* and *in vivo* studies have shown that rational drug redeployment (drug reprofiling) can be used successfully to develop novel therapies for haematological tumours and bring significant clinical benefit. In this study, we have investigated a similar drug redeployment approach for multiple myeloma (MM). MM is a malignancy of differentiated B cells characterised by >10% neoplastic plasma cells in the bone marrow, monoclonal immunoglobulin (whole and/or free light chain;FLC) in serum/urine, lytic bone lesions and fractures, anaemia and immunodeficiency. Many patients also develop renal impairment (RI), predominantly caused by elevated nephrotoxic FLC secreted by the malignant plasma cell clone. Despite advancements in therapy and improvement in survival times, particularly for younger patients, MM remains incurable. Relapse with resistant disease is a major cause of death. Furthermore, current intensive treatments are associated with significant toxicity and are not suitable for many MM patients especially the high proportion that are >70yrs. Hence novel therapies with low associated toxicities are urgently needed. The aim of this work was to identify drug combinations for MM using a screen of clinically available safe drugs. *Methods.* A panel of 100 off-patent oral drugs with low toxicity profiles, at drug concentrations consistent with peak serum concentrations achievable for routine clinical indications, were screened against MM cell lines. Cell number was assessed using Alamar Blue assays. Actions of drugs were investigated using flow cytometry assays for apoptosis (annexin V/PI, Caspatag), reactive oxygen species, cell cycle, and mitochondrial membrane depolarisation. Immunoblotting and/or immunofluorescence were used to measure LC3-II levels, and levels/localisation of components of NF-kB pathway. FLC protein was measured using luminex and flow cytometry and mRNA levels using quantitative real-time PCR. *Results.* The screen identified several drugs with anti-MM activity including valproate (already under investigation in myeloma) and niclosamide a broad spectrum anti-helminthic. The combination of niclosamide and valproate (VaN) exhibited greater anti- MM activity against cell lines and primary MM cells than either agent alone and, at least *in vitro*, out-performed the current anti-myeloma chemotherapy combinations of cyclophosphamide/thalidomide/dexamethasone (CTD) or melphalan/prednisolone (MP). Importantly, normal donor haemopoietic progenitor cells were significantly less sensitive to the treatments. Niclosamide treatment of myeloma cells was associated with the generation of mitochondrial superoxide (Mitosox) which was enhanced with the addition of valproate. Treatment with niclosamide was accompanied by rapid depolarisation of mitochondrial membranes as measured by TMRE and JC-1 staining. Cell death was associated with markers of apoptosis, annexin-V positivity and caspase activation. Individually, niclosamide induced markers of autophagy and valproate induced a G1 cell cycle arrest. Furthermore, sub-lethal doses of niclosamide reduced FLC protein secretion from MM cell lines, and some primary MMs. In some, but not all cases, reduced FLC protein secretion was associated with reduction in FLC mRNA transcription most likely through inhibition of NF-kB activity. *Summary.* This study has identified a potent novel combination of off-patent drugs with low associated toxicities which have anti-myeloma activity. Niclosamide, by inhibiting production of FLC, has further potential in light chain mediated diseases including primary amyloidosis.

INHIBITION OF MTOR WITH EVEROLIMUS (RAD001) AND SILENCING BY VASCULAR ENDOTHELIAL CELL GROWTH FACTOR SPECIFIC SIRNA INDUCES ADDITIVE ANTITUMOR ACTIVITY IN MULTIPLE MYELOMA CELLS

M Koldehoff, A Elmaagacli, D Beelen

Medical School of University of Duisburg-Essen, Essen, Germany

Background. Angiogenesis plays an important role in the pathogenesis and progression in multiple myeloma (MM). MM cells secrete vascular endothelial growth factor (VEGF), which further promotes proliferation of the tumor cells. Several RNA interference (RNAi) methodologies are rapidly being established and hold promise to specifically inhibit gene expression in mammals. RNAi is the sequence-specific, posttranscription gene silencing methods initiated by double-stranded RNAs, which are homologous to the gene being suppressed. Mammalian target of rapamycin (mTOR) is an essential part of tumour growth being capable of integrating proliferative, antiapoptotic and angiogenic signalling by connecting VEGF, hypoxia-inducible factor 1 (HIF-1) and HER family receptors. Several reports have demonstrated the anti-tumor activity of everolimus (RAD001), an mTOR inhibitor, in a variety of cancers, including various leukemias and lymphomas. *Aims.* Therefore, we evaluated the anti-myeloma effect of VEGF siRNA silencing in MM cells and whether it can be augmented by the additional application of everolimus. *Methods and Results.* After transfection with VEGF siRNA we observed a reduction of VEGF expression in all studied cell lines: OPM-2, RPMI-8226, INA-6, Jurkat, Raji and Karpas-299, as well as in cells of MM- and lymphoma patients. Next, using the MM cell line OPM-2 we studied the time courses of VEGF siRNA transfection in order to investigate the knock-down efficiency of VEGF expression. The efficiency of VEGF siRNA transfection in treated OPM-2 cells showed a reduction of 75.5% VEGF protein levels after 24 h compared to the untreated OPM-2 cells ($p<0.001$). Further, VEGF siRNA both significantly induced apoptosis and inhibited proliferation in OPM-2 cells ($p<0.001$), RPMI-8226 ($p<0.001$), and in INA-6 ($p<0.01$) versus controls. To assess whether everolimus treatment of OPM-2 and RPMI-8226 affects the viability of these cells, cells were treated with various doses (1-20 nM) of everolimus for 24 hours, harvested, and analyzed for cell viability by MTT assay. Everolimus significantly decreased the viability of OPM-2 cells (IC50 = 1.9 nM) and of RPMI-8226 cells (IC50 = 2.1 nM), respectively. Everolimus and siRNA both together might to reduce the VEGF gene expression up to 33% ($p<0.001$) compare to siRNA VEGF (61%) alone or everolimus alone (39%), that demonstrated additive effects of everolimus and siRNA. *Conclusions.* These findings suggest that mTOR inhibition and silencing by VEGF specific siRNA may be associated with an additive antitumor activity and might be a suitable target for new therapeutic strategies using RNA interference in MM.

DRUG REPROFILING IN SUB-SAHARAN AFRICA; IDENTIFICATION OF ZINC AND COLCHICINE (ZAC) AS POTENTIAL AFFORDABLE NON-TOXIC THERAPY FOR ENDEMIC BURKITT'S LYMPHOMA

L Khanim, M Bunce, T Drayson

University of Birmingham, Birmingham, United Kingdom

Background. Burkitt's lymphoma (BL) is a high-grade B-cell Non-Hodgkin's Lymphoma (NHL) with one of the fastest doubling time amongst human tumours. Occurring most frequently in children in areas with holoendemic and hyperendemic malaria, endemic BL (eBL) accounts for ~50% of all childhood malignancies in sub-Saharan Africa. Although intensive chemotherapy is highly effective against BL with potential cure rates of ≥85% the financial implications of high-intensity regimens including the cost of drugs, transfusions, and intensive supportive medical care preclude their use in many developing countries for the majority of patients. Low-dose chemotherapy combinations based on cyclophosphamide costing <US$50 per patient have managed to achieve ~50% 1year disease free survival in eBL (95% chance of a cure). However there is a desperate need for effective, affordable, non-myeloablative therapies. *Aim.* The aim of this study was to identify novel treatments for BL by screening off-patent, non-toxic, non-myeloablative, oral drugs for anti-BL activity. *Methods.* A panel of 100 off-patent drugs at concentrations consistent with peak serum concentrations achievable during their routine clinical indications were screened against 8 BL cell lines. Cell number was assessed using Alamar Blue assay. Actions of selected drugs were investigated using flow cytometry based assays for apoptosis (annexin V/PI, Caspatag), reactive oxygen species (ROS) and cell cycle. Normal donor bone marrow samples were treated and viability assessed using immunophenotyping and flow cytometry. *Results.* The drug screen performed using peak serum drug concentrations identified colchicine and zinc as having potent anti-BL activity against 8 BL cell lines. Colchicine, a microtubule destabilising agent, induced potent G2/M cell cycle arrest by 48hrs to a similar extent as vincristine, a commonly used microtubule destabilising chemotherapeutic which has significant associated toxicities. Colchicine treatment was then followed by rapid cell death with markers of apoptosis including annexin V positivity and caspase activation. Zinc treatment also induced a rapid cell death, within 24hrs for most BL cell lines. Dose titrations of zinc and colchicine demonstrated that each agent had potency at concentrations easily achievable using routine clinical doses. Cross-titration experiments highlighted additive effects of the combination (zinc and colchicine; ZaC) in some of the BL cell lines tested. Importantly, neither agent, either alone or in combination, impacted upon the survival of normal donor CD34+ve haemopoietic progenitors. *Summary.* This study has identified that a novel combination of zinc and colchicine (ZaC) has potent anti-BL activity. Importantly, neither agent affected the survival of haemopoietic progenitor cells indicating that ZaC therapy is unlikely to be myeloablative. This is supported by an absence of toxicities associated with long-term clinical use of each agent e.g. months/years treatment of paediatric Familial Mediterranean Fever demonstrate colchicine to be safe in children. Zinc supplementation is known to be safe and interestingly, the vast majority of BL patients will be zinc-deficient as a result of malnutrition. Individually, each agent was potent at killing BL cell lines and additive actions of the combination were observed in some of the lines. These data indicate that ZaC is an effective, affordable, therapeutic option for endemic BL.

PRALATREXATE SELECTIVELY INDUCES APOPTOSIS AND SYNERGIZES WITH BEXAROTENE THROUGH UP-REGULATION OF P53/BAX/PUMA IN CUTANEOUS T-CELL LYMPHOMA CELLS

CL Zhang, X Zhang, S Rangwala, M Duvic

The University of Texas MD Anderson Cancer Center, Houston, United States of America

Background. Pralatrexate (PDX), a targeted antifolate, was designed for preferential uptake and accumulation in tumor cells based on its high affinity for reduced folate carrier-1 and efficient polyglutamation by folypolyglutamyl synthetase. PDX is approved by the United States FDA for relapsed or refractory peripheral T-cell lymphoma, and has demonstrated activity in a Phase I study in cutaneous T-cell lymphoma (CTCL). Bexarotene (BEX), approved for treatment of CTCL, is an RXR-selective retinoid, and thus of interest to study in combination with PDX. *Aims.* In this study, we investigated the therapeutic mechanisms of PDX and whether combination with BEX has synergistic anti-tumor effects in CTCL. *Methods.* Cell viability was examined by MTS assay and apoptosis by FACS analysis. Expression of apoptosis-associated proteins was analyzed by Western blotting. *Results.* PDX (1-5 nM for 24 and 48 hrs) decreased cell viability and induced apoptosis in a time- and dose-dependent manner in four CTCL cell lines (MJ, Hut78, HH, and HH/VOR). PDX (1-5 nM for 48 hrs) also caused significantly more apoptosis of $CD4^+$ T cells from six Sézary syndrome (SS) patients with high percentages (74-96%) of circulating $CD4^+CD26^-$ T cells compared to $CD4^+$ T cells from three healthy donors ($p < 0.05$). Moreover, PDX at low dose (2 nM) combined with BEX (10 μM) induced up to 12-fold increase in apoptosis compared to either drug alone in all four CTCL cell lines and in SS patients' $CD4^+$ T cells. Additionally, PDX combined with BEX synergistically increased the tumor suppressor p53, and the p53-regulated pro-apoptosis proteins, Bax, and PUMA. *Conclusions.* Our results show that PDX at low nanomolar concentrations selectively induces apoptosis in CTCL cell lines and SS patients' $CD4^+$ T cells, and PDX in combination with BEX exerts a synergistic pro-apoptosis effect through up-regulation of p53/Bax/PUMA in CTCL. These findings support the ongoing phase I clinical trial of PDX/BEX and provide the rationale for future studies of this combination in CTCL patients.

DNA-DEPENDENT PROTEIN KINASE AS A PROMISING MOLECULAR TARGET FOR THE TREATMENT OF ADULT T-CELL LEUKEMIA-LYMPHOMA

T Hisatomi

Saga University, Saga, Japan

The DNA repair system is a promising target for sensitization and overcoming drug resistance on cancer treatment. Since the cells that genetically too unstable will die, a treatment that blocks a particular DNA repair system can induce apoptotic cell death on cancer cells but not on normal cells. We recently found that high expression of catalytic subunit of DNA-dependent protein kinase (DNA-PKcs) was observed in adult T-cell leukemia-lymphoma (ATL) cells. In addition, a new chemotherapeutic drug NK314 possessing inhibitory activity for both topoisomerase II and DNA-PK potently inhibited the growth of various ATL cell lines. According to the results, we designed combination treatment with various DNA-PK inhibitors and chemotherapeutic agents. NU7026, a DNA-PK inhibitor, enhanced the anti-cancer activity of etoposide. Such enhancement of cell growth inhibition by DNA-PK inhibitors was not observed in DNA-PK deficient cancer cell line, M059J cells. These results suggested that DNA-PK is a promising target molecule for ATL. We also identified that hnRNP B1, a RNA binding protein, directly bound with DNA-PK complex and inhibited DNA-PK activity in lymphoid malignant cells. Since hnRNP B1 is overexpressed in a population of ATL cells, hnRNP B1 can be a prediction marker for response to combination therapy with DNA-PK inhibitors and chemoradiotherapy.

ENUCLEATION OF HUMAN ERYTHROBLASTS IS AN ACTOMYOSIN-DEPENDENT PROCESS FOLLOWING NUCLEAR POLARIZATION

K Ubukawa,[1] YM Guo,[1] M Hirokawa,[1] Y Michishita,[1] M Nara,[1] H Tagawa,[1] N Takahashi,[1] A Komatsuda,[1] W Nunomura,[2] Y Takakuwa,[2] K Sawada[1]

[1]*Akita University Graduate School of Medicine, Akita, Japan*
[2]*Tokyo Women's Medical University, Department of Biochemistry, Tokyo, Japan*

Backgrounds. During erythropoiesis, stem cells undergo lineage specific commitment and generate erythroid progenitor cells through cellular division events including nuclear (mitosis) and cytoplasmic (cytokinesis) division. In terminally differentiated erythroblasts, the centrally located nucleus becomes eccentrically located in the cytoplasm via a process known as polarization, and is expelled via a process termed enucleation, becoming reticulocytes and subsequently mature erythrocytes. Enucleation of erythroblasts is thought to occur through a process similar to cytokinesis. However, little is known in regards to how the process of enucleation differs from conventional cytokinetic processes as well as to the precise role of non-muscle myosin II in enucleation. *Aim.* The aim of this study is to investigate how the process of enucleation differs from conventional cytokinetic processes, and to elucidate the role of cytoskeletal modifiers during each step of enucleation in human erythroblasts. *Methods.* We investigated the role of cytoskeletal modifiers during conventional cell division of early-stage erythroid cells such as colony-forming unit-erythroid (CFU-E), and compared their roles with that during each step of enucleation in human erythroblasts. For this purpose, highly purified human CD34+ cells were induced to differentiate to the level of CFU-E, and to the level of terminally differentiated erythroblasts that undergo enucleation. Since the efficacy of inhibitors for cell division often varies depending on the species of the cell observed, the immortality of the cells and their redundancy in the cells themselves, efficient inhibitors of cell division in human CFU-E were selected, and then examined the effects of these inhibitors on nuclear polarization and enucleation events. *Results.* We selected blebbistatin, an inhibitor of non-muscle myosin II ATPase, cytokalasin D, an inhibitor of actin polymerization, NSC23766, an inhibitor of Rac 1 GTPases, Y27632, an inhibitor of ROCK, colchicine and vinblastine, inhibitors for microtubules, and monastrol, an inhibitor of the mitotic kinesin Eg5, as efficient inhibitors for CFU-E cell division. When these inhibitors were applied to terminally differentiated erythroblasts, blebbistatin, cytochalasin D increased the number of cells with a polarized nucleus accompanied with a complete block of enucleation. NSC23766 and Y23766 appeared to increase cells with nuclei positioned in the center of the cytoplasm, and caused an immediate and complete inhibition of enucleation. Colchicine, vinblastin and monastrol did not increase cells with a polarized nucleus and did not inhibit enucleation. The degree of the increase in reticulocytes during the initial 24 h was similar to that of cells with a polarized nucleus. *Conclusion.* This study shows that the inhibition of non-muscle myosin II ATPase and ROCK completely blocked enucleation of human erythroblasts, demonstrating for the first time that non-muscle myosin II is required for human erythroblast enucleation. We also suggest that tubulin, kinesin, Rac GTPases and ROCK may be involved in nuclear polarization that is required just prior to enucleation. It is anticipated that these advances will enable the definition of defects in enucleation of erythroblasts in inherited and acquired red cell disorders, and in bone marrow failure syndromes.

GENE EXPRESSION PROFILE ANALYSIS IN HEREDITARY PERSISTENCE OF FETAL HEMOGLOBIN (BRAZILIAN TYPE): IDENTIFICATION OF TARGET GENES THAT COULD BE RELATED TO HEMOGLOBIN SWITCHING

F Roversi,[1] A Cunha,[2] A Brugnerotto,[1] R Ferreira,[1] C Lanaro,[1] D Albuquerque,[1] F Costa[1]

[1]*UNICAMP, Campinas, Brazil*
[2]*UFSCAR, São Carlos, Brazil*

Hereditary Persistence of Fetal Hemoglobin (HPFH) is a heterogeneous and benign group of genetic disorders characterized by an abnormal switching from fetal to adult hemoglobin, resulting in increased fetal hemoglobin (HbF) levels at the adult stage The reactivation of HbF

is an important therapeutic option in patients with hemoglobin disorders, since it inhibits the polymerization of sickle hemoglobin. The non deletional Brazilian type HPFH (BHPFH), a C[ARROWRIGHT]G mutation at -195 position of the A gamma globin gene, was first identified in 1990, but the underlying mechanism of upregulation of fetal hemoglobin is still unclear. In order to elucidate how this point mutation leads to an altered gene expression pattern, the aim of this study was to identify genes that are differentially expressed in reticulocytes of BHPFH subjects and of control subjects using Suppression Subtractive Hybridization Library (SSH). Real Time PCR (RT-PCR) was used for posterior validation. Total mRNAs extracted from reticulocytes isolated from peripheral blood samples were used for the construction of the SSH, a PCR-based method for cDNA subtraction libraries. Genes appearing only in one of the libraries were considered as overexpressed. A total of 57 overexpressed genes were identified in the normal library, while 59 genes were overexpressed in the BHPFH cDNA library. Differentially expressed genes included transcription factors (KLF1, NFIA, FOXP1), transcription coregulators (MKRN1, NCOA4), genes involved in GTPase regulation (HOOK3, RASA1, DOCK8) and erythroblast differentiation (FOXO3a) genes. Genes involved in chromatin organization (MIER1, PPP1R10, WHSC1, MORF4L1) were mostly upregulated in control subjects. Six genes (KLF, FOXO3a, HOOK3, MKRN1, MIER1, PPM1a) were chosen for individual analysis by RT-PCR. Lower expression of KLF1, HOOK3, MIER1 genes and higher expression of FOXO3a, MKRN1 and PPM1a were found in BHPFH subjects, when compared to control subjects. Interestingly, KLF1, a gene encoding a transcription factor that regulates the developmental gamma-to-beta globin switch, was highly expressed in control subjects, and a DNA-protein array confirmed increased activity of the KLF1 protein in erythroid cells of controls subjects compared to BHPFH. These results suggest that, in BHPFH, the maintenance of fetal hemoglobin levels is associated with low KLF1 activity. Our data also suggest for the first time that other genes such as MKRN1, FOXO3a, PPM1A and HOOK3 may play a role in globin gene regulation, gamma gene expression and augmentation of HbF levels, representing novel pathways involved in erythroid cells control of hemoglobin switching to be studied.

Support by FAPESP and CNPq.

HYDROXYUREA REDUCES THE HYPERCOAGULABLE STATE OF PATIENTS WITH SICKLE CELL ANEMIA

MP Colella, J Machado-Neto, S Quaino, N Conran, F Costa, JM Annichino-Bizzacchi, S Saad, E de Paula, F Traina

State University of Campinas (Unicamp), Campinas, Brazil

Background. Nearly every element of hemostasis is altered towards the pro-coagulant state in sickle cell anemia (SCA), and thus, an increased rate of thrombotic complications is observed. A major therapeutic approach in these patients is hydroxyurea, which is capable of reducing vaso-occlusive complications and the hemolytic anemia. *Aims.* To evaluate the effect of hydroxyurea in the hypercoagulable state of patients with SCA; the expression of tissue factor (TF), the physiological initiator of coagulation, and the plasma thrombin-antithrombin complex (TAT), a marker of coagulation activation. *Methods.* This study was conducted on a cohort of 34 SCA adult patients (genotype SS) followed at a Sickle Cell Disease University Clinic, and 22 healthy controls. The SCA patients were all in steady state and 21 of them were on hydroxyurea therapy. Informed consent was obtained from all patients included in the study. We studied the mRNA expression of *TF* in total leukocytes through quantitative PCR (qPCR) and TF protein expression in monocytes by flow cytometry. Plasma TAT levels were measured by ELISA (Enzygnost TAT micro, Siemens). Statistical analyses were done using Mann-Whitney U test and Spearman correlation test. *Results.* Patients with SCA had higher levels of leukocyte *TF* relative gene expression in comparison to healthy controls (4.8 vs 1.3; p=0,0006). Hydroxyurea was effective in significantly reducing this expression, among patients with SCA, the *TF* mRNA levels were significantly lower in patients on hydroxyurea therapy in comparison to those not on hydroxyurea (2.7 vs 8.4; p=0.0083). These results were confirmed by the flow cytometry experiments. Levels of fetal hemoglobin showed a strong negative correlation with the relative quantification of *TF* mRNA (r=-0.5339; p=0.010). *TF* expression also correlated with some hemolysis markers such as hemoglobin concentration (r=-0.6744; p=0.0002) and hematocrit (r=-0.5739;p=0.0034), but surprisingly not with lactate dehydrogenase, reticulocyte count and bilirubin. There was a significant positive correlation between *TF* expression and leukocyte, monocyte and neutrophil counts. (r=0.41, p=0.045; r= 0.54, p=0.006 and r=0.46, p=0.021, respectively). Levels of TAT (ug/L) were significantly higher in SCA patients in comparison to controls (12.1 vs 0.7; p<0.0001), and therapy with hydroxyurea was also able to significantly reduce these levels (9.1 vs 17.0; p=0.0160), further demonstrating the inhibitory effect of hydroxyurea on coagulation activation. *Conclusions.* We demonstrated that hydroxyurea is capable of inhibiting *TF* gene expression in leukocytes of patients with SCA and also of reducing plasma levels of TAT, a marker of coagulation activation. These results clearly indicate that therapy with hydroxyurea modulates the hypercoagulability state encountered in SCA.

KLF1 GENE MUTATIONS ARE ASSOCIATED WITH HEREDITARY PERSISTENCE OF FETAL HEMOGLOBIN AND DECREASED KLF1 AND BCL11A GENE EXPRESSION LEVELS

M Radmilovic,[1] J Borg,[2] N Tosic,[1] T Karan-Djurasevic,[1] M Stojiljkovic Petrovic,[1] B Zukic,[1] V Spasovski,[1] G Nikcevic,[1] G Patrinos,[3] S Pavlovic[1]

[1]*Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia*
[2]*Lab. of Mol Genetics, Depart of Physiology and Biochemistry, University of Malta, Msida, Malta*
[3]*University of Patras, Department of Pharmacy, University Campus, Patras, Greece*

Background. Hereditary persistence of fetal hemoglobin (HPFH) is characterized by persistent high levels of fetal hemoglobin (HbF) in adults. Several genetic factors that control HbF levels in adults have already been identified (HBB, HBS1L-MYB, BCL11A genes), while others remain elusive. Recent studies have reported mutations within the KLF1 gene, leading to high levels of HbF in adults. Elevated HbF levels may ameliorate the clinical phenotype of beta-thalassemia. *Aim.* The aim of this study was to investigate the possible correlation between mutations within the KLF1 gene and its expression levels in Serbian patients with high levels of HbF, who were shown to be negative for mutations in the γ-globin genes. *Methods.* Mutation screening in the KLF1, HBB, HBG1 and HBG2 genes was done using PCR and direct resequencing. KLF1 and BCL11A gene expression levels were quantified by RQ-PCR method, using SYBR Green chemistry. GAPDH gene served as an internal control. Relative quantification analysis was performed using comparative Ct method (2-ddCt), where ddCt = dCt (sample) - dCt (healthy (median)). *Results.* Three adult patients presented with high levels of HbF (11-17.7%) and with no mutations in the HBB, HBG1 and HBG2 genes, were analyzed for the presence of mutations in the KLF1 gene. Sequencing analysis revealed the presence of two mutations, namely p.S102P and p.F182L, within exon 2 of the KLF1 gene. One patient (HbF=12%), homozygous for the p.S102P mutation was also shown to be heterozygous for p.F182L mutation. The other two patients (HbF11% and HbF17.7%) were heterozygous for p. S102P mutation only. However, in healthy Serbian controls none of these mutations were detected. RQ-PCR analysis in the patient, homozygous for p.S102P mutation and heterozygous for p.F182L mutation, showed that KLF1 gene expression levels were more than 60% lower than in healthy controls, while BCL11A gene expression levels in this patient were 45% lower compared to healthy controls. *Conclusion.* Our study showed the presence of mutations within the KLF1 gene in patients with elevated HbF levels. We propose that these mutations, in single or compound heterozygosity, influence KLF1 and BCL11A gene expression, which, in turn, affects transcription of the γ-globin genes and, hence, HbF production.

0411

VARIANTS IN GENETIC MODIFIERS OF BETA-THALASSEMIA CAN HELP TO PREDICT CLINICAL SEVERITY

C Badens,[1] P Joly,[2] I Agouti,[3] I Thuret,[4] A Francina,[5] A Loundou,[6] S Pissard[7]

[6]*Unite d'aide methologique à la recherche clinique, faculté de médecine, Marseille, France*
[7]*Laboratoire de genetique moleculaire, hopital H. Mondor, Creteil, France*

Background. Patients with beta-thalassemia display large variability in disease severity and are usually classified into thalassemia major

(TM) or intermedia (TI) according to clinical criteria. The major determinant of the severity is the degree of beta-globin chain deficit resulting from the nature of the beta-thalassemia mutations. Other genetic modifiers, affecting the degree of alpha and non alpha-globin chain imbalance, also impact the phenotypic severity: an associated alpha-thalassemia minimizes the excess of alpha-globin chains and tends to produce a less severe condition. An increased residual level of HbF in adult life is also a major amelioration determinant. Three major HbF Quantitative Trait Loci (QTL) have been identified so far. The so-called -158 C>T XmnI SNP, is located in the fetal Ggamma-globin gene promoter. The two others are located in the BCL11A and in the HBSB1L-cMYB inter-region. Some particular tag-SNPs in these regions are associated with high HbF levels in healthy adults and in Thalassemia patients. *Aims.* In this study, we investigated the effect that these SNPs might exert in combination with beta and alpha-thalassemia genotypes on beta-thalassemia severity. *Method.* A cohort of 101 affected patients, included in the French National Registry for Thalassemia, were classified into TM (n=69) or TI (n=32) according to clinical data. All patients were genotyped for (i) beta-thalassemia mutations, (ii) the XmnI SNP, (iii) the -3.7 kb alpha-thal deletion, (iv) the tag-SNP rs 11886868 in BCL11A exon 2 and (v) the tag-SNP rs9399137 in the HBSB1L-cMYB inter-region. Univariate and multivariate analyses were performed to study the risk of TI associated with the presence of favourable alleles. *Results.* As expected, univariate analysis showed that beta-thalassemia mutations and XmnI -158 C>T SNP have the strongest effect on severity. Multivariate analysis performed with the 5 modifiers indicated that presence or absence of these favourable alleles could predict the type of Thalassemia in 83.8% of the cases (major type: 92.2%; intermedia type: 69%). The predictions made from the beta-thalassemia mutations and the XmnI SNP alone were significantly improved by the adjustment with the 3 other modifiers, moving from 75.2% to 83.8% (p<0.001). In order to test an easy-to-use prediction tool, we calculated a 'score variable' defined as the number of favourable alleles carried by each patient. Following this simple scoring, all patients with score 0 were TM (96% with score 0 or 1) whereas all patients with score 5 or 6 were TI. When considering only the beta0/beta0 patients, the scores ranged between 0 and 5 and became informative for all patients: more than 95% patients with a score between 0 and 2 were TM; more than 95% patients with a score between 3 and 5 were TI. *Conclusion.* In this study, we showed that predictions based on genetic modifiers can predict the major or intermedia type of beta-thalassemia, even in cohorts of patients with various beta-globin genotypes (up to 30 different mutations in our series). If further validated, this prediction tool of severity may have implications for genetic counselling but also for decisions regarding therapeutic options such as HSC transplantation.

TELOMERASE ACTIVITY IS USEFUL FOR THE SCREENING OF CRYPTIC AND LATE ONSET DYSKERATOSIS CONGENITA AND THE EVALUATION OF THE TREATMENT RESPONSE TO ANABOLIC STEROIDS FOR THEIR BONE MARROW FAILURE

J Takeuchi, H Yamaguchi, H Tamai, Y Mitamura, F Kosaka, K Inokuchi, K Dan

Division of Hematology, Department of Internal Medicine, Nippon Medical School, Tokyo, Japan

Background and Aims. We have recently shown that some patients with cryptic and late onset Dyskeratosis Congenita (DKC) among those with acquired aplastic anemia (AA) or myelodysplasia syndrome have short telomeres due to mutation in the components of telomere-associated genes such as *TERC*, *TERT* or *TINF2*. Clinically it is very important to identify cryptic and late onset DKC patients, because these patients will exhibit refractoriness to conventional immunosuppressive therapy (IST) for their bone marrow failure. Several groups, including our own (15th. Congress of European Hematology Association, 2009, Barcelona, Spain), revealed telomere length in peripheral blood was useful in the screening of these patients, but some patients with telomere-associated gene mutation did not have short telomere. The reasons of normal telomere length in these patients might be that aging and accelerated generation were insufficient. Moreover, recent study reported that the androgen, sex steroid hormone, induced hematopoiesis by activating telomerase in hematopoietic cells. In this study, we evaluated telomerase activity in peripheral blood from patients with DKC and AA patients to clarify its usefulness in diagnosis and the evaluation of the treatment response to anabolic steroid. *Methods.* We analyzed telomerase activity in peripheral blood from one DKC, three cryptic DKCs, 15 AA patients, and 30 healthy controls. Telomerase activity of the cellular extract from 2×10^4 peripheral mononuclear cells was assayed using the TRAPeze Telomerase Detection Kit. We analyzed the entire coding region of each telomere-associated genes by direct sequence, and measured the length of telomeres in peripheral blood by Southern blot analysis. *Results.* Telomerase activity of DKC and cryptic DKC patients were significantly lower than healthy controls (16.3 TPG unite vs 86 TPG unite, p=0.011). Telomerase activity did not significantly differ between AA patients and healthy controls (77.3 TPG unite vs 86 TPG unite, p=0.323). However we identified two AA patients who showed obviously lower telomerase activity (33 and 44 TPG unite) than healthy controls. One of these AA patients showed shortened telomere (4.2kb) without mutations of telomere associated genes. These AA patients with lower telomerase activity did not responded to IST, and may have unknown mutations of telomere associated genes. Next, we analyzed the relationship between telomerase activity and the clinical responses to anabolic steroid in one DKC, two cryptic DKCs, and 3 AA patients who were refractory to IST. The anabolic steroid significantly increased telomerase activity in DKC patient (from 15.7 to 54 TPG unite, p=0.002) and tended to increase telomerase activity in cryptic DKC patients (from 21 to 42 TPG unite, p=0.061) and AA patients (from 77 to 93 TPG unite, p=0.052). Clinically, a slight increase of hemoglobin (from 9.8 to 10.9 g/dl) was found in DKC patient, but no obvious increase in hemoglobin was seen in other patients. *Conclusions.* These findings revealed that the assay of telomerase activity is useful for screening cryptic DKC, but that longer follow-up may be necessary to evaluate clinical response to anabolic steroid.

Background. Cobalamin (or vitamin B12) is important to the normal production of thymidilate, and its deficiency may prevent normal DNA synthesis in bone marrow precursors causing megaloblastic anemia. Ineffective erythropoiesis is a hallmark of this condition and high levels of lactate dehydrogenase (LDH) with mild unconjugated hyperbilirubinemia due to intramedullary hemolysis have been described. Inherited hemoglobinopathies such as the thalassemia syndromes also present with ineffective erythropoiesis, and recent studies have shown that erythroblasts in the ineffective bone marrow produce large amounts of Growth Differentiation Factor 15 (GDF-15), a potent downregulator of hepcidin, resulting in increased iron uptake and consequent iron overload. *Aims.* To determine GDF-15 plasmatic levels in patients with megaloblastic anemia, and correlate with iron homeostasis and hematological parameters during the normalization of erythropoiesis after cobalamin replenishment. *Methods.* We selected patients with proven cobalamin deficiency anemia, as confirmed by a typical blood smear (macro-ovalocytes, neutrophil hypersegmentation), low serum cobalamin (<200pg/mL) along with normal serum folate levels and characteristic clinical presentation (anemia with or without neurological symptoms). Peripheral blood samples were collected upon informed consent at diagnosis, 7 days after daily 5mg intramuscular cyanocobalamin treatment and after complete normalization of hematological parameters. Ferritin, transferrin saturation and LDH levels were determined by routine laboratory methods. GDF-15 plasmatic levels were determined by ELISA assay. *Results.* Fourteen patients were enrolled with symptomatic cobalamin deficiency between August 2009 and September 2010 (10 male/4 female, age range 28-80 years old). Results are expressed as mean±SEM. Mean cobalamin levels at diagnosis were 81.5±14.1pg/mL. Mean serum ferritin levels and transferrin saturation were in the normal range, 227.2±41.4 ng/mL and 32.9±5.0%, respectively. As expected, mean hemoglobin (Hb) levels increased with treatment (8.75±0.41 g/dL at diagnosis (D0), 10.64±0.54 g/dL after 7 days of treatment (D7) and 13.02±0.45 g/dL after normalization (DN), p<0.0001). Mean corpuscular volume decreased with treatment (114.4±2.5 fL (D0), 110.1±2.6 fL (D7) and 91.4±2.3fL (DN), p=0.0005). GDF-15 levels were 8057±2215pg/mL at D0 (range 1933-23483) and decreased significantly to 1047±164 pg/mL (D7) and 876±205 pg/mL (DN) (p=0.0039) after adequate treatment. There was

significant correlation between GDF-15 levels and Hb levels (r^2=0.34, p<0.0001), but not between GDF-15 and LDH levels (p=0.45). *Conclusions.* Treatment with cyanocobalamin restored normal erythropoiesis while decreasing GDF-15 levels to baseline levels before normalization of hematological parameters. The lack of correlation with LDH levels, unspecifically produced in increased cell proliferation, is consistent with reports that only more immature erythroblasts produce large amounts of GDF-15. While immunity-driven overproduction of GDF-15 has been reported in anemia of chronic disease not primarily affecting iron homeostasis, and erythropoiesis-driven high GDF-15 levels in thalassemia have been linked to iron overload, there was no association between ineffective erythropoiesis and spontaneous iron overload in cobalamin deficiency. This suggests that long periods of time of exposure to increased GDF-15 levels may be needed for iron overload to take place in this setting. The pathophysiological role of the iron regulatory effect of GDF-15 in megaloblastic anemias should be further investigated.

ALTERATIONS IN CELL TURNOVER AND PRO-APOPTOTIC SERUM FACTORS MAY MODULATE NEUTROPHIL NUMBERS IN SICKLE CELL DISEASE

C Almeida,[1] ME Favero,[2] S Saad,[3] F Costa,[3] N Conran[3]

[1]*Unicamp, Campinas, Brazil*
[2]*Hemocenter - Unicamp, Campinas, Brazil*
[3]*Instituto Nacional de Ciência e Tecnologia do Sangue - University of Campinas, Campinas, Brazil*

Background. Leukocytes are known to exacerbate inflammatory and vaso-occlusive processes in sickle cell disease (SCD) by adhering to the vascular endothelium and participating in inflammatory mechanisms. The relevance of neutrophil death to inflammatory disease pathogenesis is recognized, since alterations in leukocyte apoptotic processes may affect cellular function and inflammatory processes. *Aim.* Since previous data indicate an inhibition of neutrophil apoptotic pathways in SCD, the present study investigated whether alterations in SCD neutrophil (SCDneu) death pathways are the result of a shift in cell turnover and/or whether factors present in SCD serum (ser) influence this process. *Methods.* The maturity of circulating neutrophils from healthy control (CON) and SCD individuals was determined immunophenotypically. Serum factors affecting neutrophil apoptosis (determined by annexin-V binding) were analyzed by culturing (16h, 37°C) control neutrophils (CONneu) with pooled serum (10%v/v) from CON, SCD and SCDHU (SCD patients on hydroxyurea therapy) individuals. *Results.* Immunophenotypic characterization indicated an increase in immature neutrophils in the circulation of SCD individuals (0.22±0.05; 0.6±0.09% CD13-/CD45+ cells; for CONneu and SCDneu respectively, n≥8; P<0.01) although no differences in the presence of mature circulating neutrophils were observed (41.2±4.6; 41.1±3.3% CD13+/CD45+ cells; for CONneu and SCDneu respectively, n≥9; P>0.05). Whilst SCDneu cultured in the presence of CONserum presented delayed apoptosis compared to CONneu (41.6±4.2; 54.0±2.9% AnnexinV binding; respectively; n≥13; P<0.05), unexpectedly, the culture of CONneu with SCDser significantly augmented apoptosis (56.5±5.4%; n=8) compared to CONneu cultured with CONser (44.4±4.2%; P<0.0001; n=8) or SCDHUser (45.1±4.8%; P<0.0001; n=8; compared to SCD; Annexin V binding). Caspase-9 activity was also significantly increased when CONneu were cultured for 16h in SCDser, compared to CONser (0.025±0.003; 0.016±0.002 OD; n≥12; P<0.01, respectively). However, caspase-9 gene expression was not different between the groups (data not shown). Incubation of neutrophils with serums in the presence of the programmed necrosis inhibitor, Necrostatin (10μM), reduced death cell independently of serum type (2.2±0.3; 0.6±0.06% propidium iodide staining; P<0.001 for CONser; 2.9±0.5; 1.1±0.2%; P<0.001 for SCDser; 2.1±0.3; 0.9±0.1%; P<0.01 for SCDHUser without or with Necrostatin, respectively; n=7), although non-necroptotic death of CONneu incubated with SCDser was significantly higher than for CONneu incubated with CONser (1.1±0.2; 0.6±0.06%; PI positive cells; n=7; P<0.01). *Conclusions.* Characterization of circulating neutrophils demonstrated a higher incidence of immature cells in SCD individuals, indicating a shift in cell turnover and/or earlier release of leukocytes from the bone marrow. While SCDneu appear to demonstrate an increase in cell survival, the serum of SCD individuals seems to contain pro-apoptotic factors, as indicated by the stimulation of phosphatidylserine presentation and caspase-9 induction in leukocytes incubated with SCD serum. Necroptosis may contribute slightly to neutrophil cell death, independently of serum type, although apoptotic cell death seems to be increased by SCD serum. Data indicate that alterations in cell turnover or emigration from bone marrow may contribute to elevate leukocyte number and delay cell death in SCD; however cell death may be subject to modulation by a complex balance of both anti- and pro-apoptotic factors contained in the serum of SCD individuals.

EYA3 SILENCING PROMOTES MODIFICATIONS IN THE EXPRESSION PATTERN OF GLOBINS GENES, HBF AND APOPTOSIS LEVELS SUGGESTING ITS PARTICIPATION IN ERYTHROID DIFFERENTIATION

D Branco,[1] A Cunha,[2] S Gambero,[1] D Albuquerque,[1] C Lanaro,[1] F Costa[1]

[1]*UNICAMP, Campinas, Brazil*
[2]*UFSCAR, São Carlos, Brazil*

Background. Erythroid differentiation is a dynamic process in which a pluripotent stem cell undergoes a series of developmental changes that commit it to a specific lineage. These alterations involve changes in gene expression profiles. Previous results using SAGE identified 93 differentially-expressed genes during erythroid development. One of these genes, EYA3, a homologue gene of Eyes Absent 3 in Drosophila, is a transcription cofactor with intrinsic phosphatase activity and its expression was observed to be high at the end of CD34+ differentiation and in human bone marrow. *Aim.* Evaluate effects of EYA3 gene silencing in the K562 (erythroleukemia cell) line after hemin induction, such as modifications of globins gene expression, apoptosis and fetal Hemoglobin (HbF) expression. Furthermore, we evaluated EYA3 gene expression using CD34+ cells and reticulocytes from sickle cell disease (SCD) patients, compared to a control group. *Methods.* Two different cultures from human K562 cells (1x10^{5}cells/mL in DMEM, 10% FBS, penicillin/streptomycin, 5% CO_2, 37°C) were transfected with control or EYA3 knockdown lentivirus (MOI=1.0). After proliferation and selection of positive cells with puromicin (2.0 ug/mL), cells were treated with 30μM hemin and collected after 0, 24, 48, 72 and 96h for gene expression and flow cytometry analysis. CD34+ hematopoietic cells from 4 control individuals were proliferated and differentiated into late stage erythroblasts. EYA3, α, β and γ-globin gene expression was analyzed by qRT-PCR and quantified using the Gnorm program. HbF expression and apoptosis were evaluated by flow cytometry. *Results.* Analysis of α, β and γ-globin gene expression shows that these genes are downregulated in K562 culture cells knockdowned for EYA3 compared with a control culture at 0, 24, 48, 72 and 96h after hemin addition (see Table, ***p<0.0001 and **p<0.001, n=2). HbF expression was downregulated at 48h after hemin addition in silenced cultures (541.6±77.3; 277.3±7.6, for Control and siRNA respectively, p<0.001, n=2). Finally, apoptosis levels were found increased at 24, 48 and 72h after hemin addition (C24h: 8.76±0.075, siRNA24h: 14±0.04, C48h: 8.47±0.21, siRNA48h: 11.07±0.24, C72h: 8.62±0.3, siRNA72h: 10.94±0.58, p<0.0001, except for C72h vs siRNA72h, p<0.05, n=2) in EYA3 knockdowned culture compared to levels obtained in control K562 culture. Evaluation of EYA3-gene expression using CD34+ primary culture showed that the expression of this gene increases during erythroid differentiation (day 7: 0.98±0.03; day 10: 1.37±0.5; day 13:

Table 1.

		0h	24h	48h	72h	96h
α-globin	Control	0.97 ±0.03	1.02 ±0.06	1.33 ±0.08	0.9 ±0.2	1.6 ±0.1
	siRNA	0.077 ±0.005 ***	0.084 ±0.005 ***	0.23 ±0.03 ***	0.44 ±0.02 ***	0.36 ±0.02 ***
β-globin	Control	0.9 ±0.01	1.83 ±0.2	1.4 ±0.04	1.4 ±0.08	1,7 ±0.03
	siRNA	0.17 ±0.1 **	0.07 ±0.007 ***	0.06 ±0.001 ***	0.09 ±0.01 ***	0.14 ±0.03 ***
γ-globin	Control	1.03 ±0.03	1.53 ±0.2	1.4 ±0.02	1.7 ±0.03	1,7 ±0.03
	siRNA	0.2 ±0.008 ***	0.23 ±0.001 ***	0.33 ±0.05 ***	0.43 ±0.02 ***	0.43 ±0.08 ***

1.94±0.41), although this increase is not statically significant. Conversely, analysis of EYA3 expression using reticulocytes shows that this gene is downregulated in SCD patients (0.3±0.06) compared to the control group (1.18±0.17, p<0.05, n=8). However, no statistical difference for SCD patients on HU therapy was observed (data not shown). *Conclusions.* These results show modifications in the expression pattern of globins genes and HbF as well as modifications of apoptosis levels in K562 EYA3 knockdowned culture cells. Additionally, EYA3 gene expression in primary culture seems to be increased during erythroid differentiation and also modified in reticulocytes of SCD patients, suggesting that EYA3 may participate in the erythroid differentiation process.

RELEVANCE OF SERUM LEVELS AND TISSUE EXPRESSIONS OF FIBROSIS MARKERS IN THE EVOLUTION AND REVERSAL OF LIVER FIBROSIS IN PATIENTS WITH BETA THALASSEMIA MAJOR TREATED WITH DEFERASIROX

Y Aydinok,[1] D Nart,[1] Z Karakas,[2] I Sasmaz,[3] D Canatan,[4] L Agaoglu,[2] Y Kilinc,[3] A Canatar,[5] O Arikan Ocak,[5] E Alnigenis,[5] C Arikan[1]

[4]*Suleyman Demirel University Medical Faculty, Isparta, Turkey*
[5]*Novartis Pharma AG, Istanbul, Turkey*

Background. Iron overload in beta thalassaemia major (TM) enhances oxidative stress within the liver which is associated with the development of fibrosis that may progress to cirrhosis. The interactions between various resident hepatic cell populations and immune cells that lead to the establishment of fibrosis are complex and little information is available with respect to the possible alterations in serum levels and tissue expressions of fibrosis markers and contribution to the liver fibrosis in TM. *Methods.* This study was run in Turkey following the completion of the ICL670A0107E extension. TM patients who completed core phase and continued with deferasirox or switched to deferasirox during 4 year extension were included after consenting for participation in this locally run study. Liver biopsy specimens and simultaneously collected frozen serum samples of those patients was used. Serum concentrations of tenascin, collagen IV, tissue inhibitors of metalloproteinase (TIMP-1), and matrix metalloproteinase (MMP-1) levels were measured with enzyme-linked immunoassay kits. Liver iron concentrations (LIC) were measured by AAS. Fibrosis stage and inflammation grade were assessed in a blinded fashion by a single pathologist according to the Ishak (score 0-6, grade 0-18) system and iron stained and staged according to the Sciott (0-4x3). Paraffin sections from formalin fixed material were immunostained with antibodies against alfa-SMA, Collagen-4, TIMP-1 and MMP-1. The intensity of immunostaining in entire representative slides was semiquantitatively graded from 0 to 4. *Results.* A total of 198 liver biopsy specimens and serum samples from 66 patients who received deferasirox (n=41) since the core study and switched to deferasirox (n=25) after 1 year and completed 4 year extension study were included. LIC was correlated with liver fibrosis and inflammation (p=0.000). LIC significantly decreased from baseline (21.2±1.6) at 1sty (14.6±1.2) and the EOS (9.4 ±1.0) (p<0.001) while mean fibrosis score did not differ significantly. However, fibrosis scores decreased significantly by decrease in LIC (p=0.018). Decrease in hepatocyte iron rather than kuppfer or portal iron was related with decrease in fibrosis during Deferasirox therapy up to 5 years (p=0.012). Although, there was a highly significant correlation between LIC and iron deposition in hepatocytes, kuppfer cells and portal field (p=0.000), fibrosis was only correlated with hepatocytes and portal iron. Serum collagen4 and TIMP-1 were correlated with LIC (p=0.0002, p=0.004) but not with the stage of fibrosis. However, portal expression of collagen4 and TIMP-1 were correlated with fibrosis stage (p=0.009, p=0.02). Portal aSMA showed a significant correlation with fibrosis (p=0.001) and changes in portal aSMA was correlated with changes of fibrosis from baseline at 5 years (p=0.04). During treatment all serum fibrosis markers decreased significantly compared to baseline (p=0.000). However, only decrease in TIMP-1 was significantly correlated with decrease in portal iron at tissue level (p=0.04). *Conclusions.* This study first revealed the role of HSC activation leading TIMP-1 upregulation and consequently collagen deposition in the progress of fibrosis in patients with TM. Deferasirox chelation can effectively reduce liver iron burden and help to resolution of fibrosis by blocking HSC activation.

TIMP-1 BALANCE EFFECT ON ELEVATED MMP-9 IN PATIENTS WITH THALASSEMIA MAJOR AND OSTEOPOROSIS

E Voskaridou,[1] D Christoulas,[2] A Papatheodorou,[3] E Plata,[1] E Terpos[2]

[1]*Laikon General Hospital, Athens, Greece*
[2]*University of Athens School of Medicine, Athens, Greece*
[3]*251 General Air Force Hospital, Athens, Greece*

Background. Tissue inhibitors of metalloproteinases (TIMPs) are endogenous inhibitors of metalloproteinase activities that primarily modulate matrix metalloproteinase (MMP) activity and suppress extracellular matrix turnover. TIMP-1 binds to the hemopexin domain of proMMP-9, but not other pro-MMPs. TIMP-1 also binds to the catalytic domain of all soluble activated MMPs and inhibits their enzymatic activity. Osteoporosis represents a major cause of morbidity in patients with thalassemia major (TM). *Aims.* The aim of the study was to evaluate the serum levels of TIMP-1 and MMP-9 in patients with TM-related osteoporosis and explore possible correlations with bone remodeling and bone mineral density (BMD). *Methods.* Twenty-two patients with thalassemia-induced osteoporosis (10M/12F; median age 42 years) were studied. Patients were blindly randomized to receive zoledronic acid at a dose of 4 mg, iv, in 15 min infusion, every 6 months (n=16) or to receive placebo every 6 months (n=6) for a period of one year. All patients were under oral calcium (500 mg) administration during the treatment period. TIMP-1 and MMP-9 were measured at baseline and after 12 months of therapy using ELISA methodology (Oncogene Science/ Siemens HealthCare Diagnostics, Cambridge, MA, USA and R&D Systems, Minneapolis, MN, USA, respectively) along with a series of serum bone remodeling indices: i) bone resorption markers [C-telopeptide of type-I collagen (CTX), tartrate-resistant acid phosphatase isoform-5b (TRACP-5b)], ii) bone formation markers [bone-alkaline phosphatase (bALP), osteocalcin, and C-terminal propeptide of collagen type-I (CICP)], and iii) osteoclast regulators [receptor activator of nuclear factor-kappa B ligand (RANKL), osteoprotegerin (OPG), and osteopontin]. BMD of the lumbar spine (L1-L4), femoral neck (FN) and wrist (W) was determined using DXA, before and 12 months after treatment. The above bone markers were also evaluated in 30, age- and gender-matched, healthy controls. *Results.* At baseline, six patients (3M/3F; 27%) had elevated values of TIMP-1 (upper normal limit 459 ng/ml for males and 374 ng/ml for women). Furthermore, TM patients had increased values of MMP-9 (median and range: 628 ng/ml, 289-911 ng/ml versus 312 ng/ml, 113-514 ng/ml; p<0.001), CTX (p<0.001), bALP (p<0.001), CICP (p=0.003), sRANKL (p=0.02), and OPG (p=0.001) compared with controls. TIMP-1 serum levels correlated with OPG (r=0.461, p=0.031), sRANKL/OPG ratio (r=-0.483, p=0.023), bALP (r=0.490, p=0.021) and OPN levels (r=0.533, p=0.013). Patients with elevated values of TIMP-1 had increased L1-L4 z-score (median: -1.65, range: -2.5 to -1.5) compared to patients with normal values (median: -2.65, range: -4.4 to -1.2; p=0.042). MMP-9 correlated with CTX (r=0.476, p=0.03) and TIMP-1 (r=-0.445, p=0.041). Administration of zoledronic acid did not alter serum levels of TIMP-1 or MMP-9, although these patients experienced an increase of BMD in all measured sites. *Summary/Conclusions.* TIMP-1 serum levels are elevated in approximately 25% of patients with TM-related osteoporosis and associated with BMD. This increase may reflect a balance effect on the increased MMP-9 activity present in this condition. Larger studies will reveal if high TIMP-1 protects TM-induced bone loss and reveal MMP-9 as possible target for development of novel drugs against TM-induced osteoporosis.

Background. Recent studies have demonstrated the role of high adenosine levels in priapism episodes in a mouse model of sickle cell disease (SCD). Interestingly, in addition to priapism, altered adenosine signaling (through four distinct receptors; A1, A2a, A2b and A3) has been implicated in several physiopathological processes that are asso-

ciated to distinct clinical features observed in patients with SCD. Moreover, adenosine levels are partially controlled by its conversion into inosine, carried by the enzyme Adenosine Deaminase (ADA). Although SCD is characterized by a single base substitution resulting in a mutated β-globin (HbS), a broad spectrum of clinical manifestations and severity are observed in the patients. This variability reflects the distinct genetic background of these patients. *Aims.* To evaluate the potential association of selected single nucleotide polimorphisms (SNPs), present in adenosine receptors and ADA genes, with clinical manifestations observed in SCD patients. *Methods.* DNA was extracted from peripheral blood samples collected from a total of 230 patients with Sickle Cell Disease (SS and Sβ), being assisted in the Regional Blood Center (HCFMRP-USP). Samples were obtained after informed consent, following a protocol approved by the local ethics committee. Three SNPs were evaluated. The SNPs in the ADORA1 (C/T aleles, rs1685103) and ADORA3 (G/T alleles, rs35511654) genes were evaluated by Real Time PCR using TaqMan probes and primer, the SNP 968 G>T and 1007 C>T in the ADORA2B gene were identified and evaluated by sequencing, the SNP ADA*2 (Asp8Asn; G22A, GeneBank M13792) in the ADA gene was evaluated by restriction fragment length polymorphism (RFLP). The main clinical manifestations evaluated, and the age cutoff for inclusion in the study, were: were acute chest syndrome (ACS), pulmonary hypertension (PH; >10 years old), priapism (>15 years old male patients), bone disorders such as osteopenia and osteoporosis (BD; >13 years old), and stroke (>5 years old). The software GENEPOP 3.4 was used to test for Hardy-Weinberg equilibrium and a Fisher exact test was carried to identify potential associations between polymorphisms and the clinical manifestations considered. Haplotype studies and corresponding statistical analysis (Tukey test) were carried using the softwares Arlequim (v3.1) and SAS (v9.13), respectively. Results. Significant differences were found for the 1007 C>T SNP of the ADORA2B gene, with patients in the group with acute chest syndrome showing an increased frequency of the T allele (p=0.032). For this same SNP a significant higher frequencies where of genotypes C/C and C/T were found among patients with BD (p=0.013). For the SNP 968 G>T, we found a significant higher frequency of patients with the G/G genotype among patients with BD (p=0.0043). Haplotype studies, revealed a significant association with the manifestation of distinct clinical features, including, priapism, stroke and ACS. Summary. Our results indicate that distinct genes related to adenosine signaling may play a role as modifiers of severity in sickle cell disease.

[5]*Department of Medical Genetics, Athens University Medical School, Athens, Greece*

Background. Continuous Reactive Oxygen Species (ROS) production in individuals with Sickle Cell Disease (SCD) may alter their overall redox status and cause tissue damage. The aim of this study was to evaluate oxidative stress in patients with SCD. *Patients and Methods.* A total of 40 patients with SCD and 25 apparently healthy volunteers (control group) were enrolled in the study. Components of glutathione system (GSHtotal GSSG and GSHreduced, vitamins A, C, and E, and malondialdehyde were determined with reverse-phase HPLC, non-transferrin bound iron (NTBI) was assessed with atomic absorption spectroscopy using graphite furnace, superoxide dismutase (SOD), glutathione reductase (GR) and glutathione peroxidase (GPx) activities were determined spectrophotometrically in red cell lysates, nitric oxide (NO) was detected colorimetrically, while FORT (free oxygen radicals test) and FORD (free oxygen radicals defense) using colorimetric assays. *Results.* NTBI values as well as the lipid peroxidation marker MDA were significantly higher in patients with SCD compared to controls, ($p<0.001$ and $p<0.001$, respectively. Impairment of the glutathione system indicated by reduced GSHtotal levels in patients with SCD compared to controls (748.9 ± 135.9 vs 1125 ± 180.0 μmol/L, respectively, $p<0.001$). Similarly, GSHreduced levels were significantly decreased in patients with SCD compared to controls (517.7 ± 133.3 vs 810.0 ± 245.0 μmol/L, respectively, $p<0.001$), while GSSG levels were lower in patients with SCD compared to controls ($p<0.001$). In terms of overall glutathione system function expressed as percentage of GSSG/GSHtotal, this ratio is significantly increased in patients with SCD compared to controls ($p<0.001$). Furthermore, patients with SCD have significantly higher total NO levels compared to controls, ($p<0.001$). FORT levels were significantly higher patients with SCD compared to controls, ($p<0.001$), while FORD levels were significantly lower in the patients with SCD compared to controls, ($p<0.02$). Red cells antioxidant enzymes GPx and SOD, were significantly higher in patients with SCD compared to controls, ($p<0.001$ and $p<0.05$, respectively), while no significance different was observed for GR ($p>0.6$). The above reported observations consisted with the significantly lower plasma concentrations of the antioxidant Vitamins A, E and C found in patients with SCD compared to controls, ($p<0.01$, $p<0.01$ and $p<0.001$, respectively). *Conclusion.* Since oxidative stress seems to play a major role in SCD, the development of novel therapies founded on free radical biology appears imperative. Hemolysis and oxidative stress are only partially reduced by blood apheresis and hydroxyurea therapy, and in our SCD group seems to play no significant role. Newer therapeutic agents that can target oxidative stress, such as NADPH oxidase inhibitors, NO based therapeutics, anti-inflammatory agents and antioxidants supplementation may constitute valuable means for improved manifestations and outcome.

TUMOR NECROSIS FACTOR POLYMORPHISMS IN PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANAEMIA

M Pavkovic,[1] T Sotirova,[1] S Trpkovska-Terzieva,[1] A Dimovski,[2] M Spiroski,[3] O Karanfilski,[1] L Cevreska,[1] A Stojanovic[1]

[1]*Department of Hematology, Skopje, Macedonia*
[2]*Faculty od Pharmacy, Skopje, Macedonia*
[3]*Institute for Immunobiology and Human Genetics, Skopje, Macedonia*

Background. Tumor necrosis factor (TNF) is a multifactorial cytokine that is secreted by monocytes (TNF-α) or lymphocytes (TNF-β). TNF cytokines have numerous immunoregulatory effects as well as potent proinflammatory effects, and they are implicated in many inflammatory and autoimmune diseases, like inflammatory bowel disease, rheumatoid arthritis, systemic lupus erythematosus, immune thrombocytopenia, etc. Autoimmune hemolytic anemia (AIHA) is a second most common autoimmune blood disorders. AIHA may occur as primary (idiopathic) or secondary to other lymphoproliferative or immune disease. The etiology of AIHA remains unclear, but both genetic and environmental factors are thought to play role in the development of the disease. *Aims.* The aim of our study was to investigate a possible association of some single nucleotide polymorphisms (SNP) in genes for tumor necrosis factor beta (TNF-β +252 G/A) and tumor necrosis factor alpha (TNF-α -308 G/A) with autoimmune hemolytic anemia. *Methods.* We have analyzed 60 adult patients with AIHA; 30 patients with idiopathic AIHA and 30 patients with secondary AIHA and chronic lymphocytic leukemia (CLL). Controls were 120 healthy individuals and 100 CLL patients without AIHA. DNA was isolated from peripheral blood mononuclear cells with standard phenol-chloroform extraction. Genotyping was performed by using PCR and RFLP methods. The distribution of genotypes and allele frequencies were compared between patients and controls using a chi-squared test or Fisher's exact test. *Results.* Our results demonstrated that the G allele of the TNF-β (+252 G/A) was significantly more frequent among the patients with AIHA (n=60; G/G=14, A/G=23, A/A=23) compared to controls (n=120 G/G=16, A/G=35, A/A=69), p=0.043. This difference was even more significant when only CLL patients were compared between them (CLL with AIHA n=30; G/G=8, A/G=12, A/A=10 versus CLL without AIHA n=100; G/G=10, A/G=31, A/A=59), p=0.018. We found that the A allele of the TNF-α (-308 G/A) was also more common in patients with AIHA (n=60; G/G=33, A/G=22, A/A=5) than in controls (n=120; G/G=95, A/G=23, A/A=2), p=0.002. This difference was most striking when only CLL patients were compared between them (CLL with AIHA n=30; G/G=15, A/G=12, A/A=3 versus CLL without AIHA n=100; G/G=82, A/G=17, A/A=1), p=0.0006. There was no significant difference in genotype distributions between CLL patients without AIHA and healthy control individuals for both genes

(p=0.74 for TNF-β and p=0.83 for TNF-α). *Conclusion.* The obtained data indicate that the G allele of TNF-β (+252) and A allele of TNF-α (-308 G/A), which are both associated with increased TNF production and secretion, are more frequent in patients with AIHA than in controls, especially in the group of CLL patients with AIHA. These results implicate that these two polymorphisms may predispose to the development of autoimmune hemolytic anemia, especially in the group of patients with CLL.

Hereditary Spherocytosis (HS) is the most common non-immune hemolytic anemia in individuals of northern European ancestry (1/2000). In a previous study, we showed that high levels of erythropoietin (EPO) were not able to induce a proportional reticulocyte production in moderate HS patients that was observed in mild HS (Rocha S, Br J Haematol, 2005, 131, 534-542). In the present study, our aim was to evaluate the relationship between that erythropoietic disturbance and inflammation, in the clinical outcome of HS (mild, moderate and severe HS). We studied 82 unsplenectomized HS Portuguese patients, presenting mild (n=49), moderate (n=27) and severe (n= 6) HS. We evaluated plasma levels of EPO, soluble transferrin receptor (sTfR), iron, transferrin, ferritin, folic acid, vitamin B12, C-reactive protein (CRP), granulocyte-monocyte colony stimulating factor (GM-CSF), tumor necrosis factor (TNF)-α, interferon (IFN)-γ, elastase and lactoferrin; determined reticulocyte count and the total and differential leukocyte counts, and calculated the reticulocyte production index (RPI). Mild HS patients showed a rise in EPO, sTfR, reticulocytes and RPI, reflecting a compensated hemolysis, and positive statistical significant correlations between EPO and sTfR, reticulocytes and RPI, were observed. In moderate and severe HS, in spite of significantly higher EPO, sTfR, reticulocytes and RPI than mild HS, these correlations were not observed. For all patients iron stores, folic acid and vitamin B12 were within normal values or were slightly higher. HS patients presented a low grade inflammation that was particularly enhanced in severe HS, as shown by the highest median levels of GM-CSF, CRP, TNF-α, IFN-γ and elastase and the lowest levels of iron and lactoferrin. Our data show HS as a disease linked to enhanced erythropoiesis that in the more severe forms (moderate and severe) is disturbed. Inflammation may contribute, at least in part, to that disturbance, especially in the severe cases of HS. This study was supported by a PhD grant (SFRH/BD/22442/2005) attributed to S.Rocha by FCT and FSE.

MLPA ANALYSIS OF BETA GLOBIN GENE CLUSTER: DETECTION OF 41 ALTERATIONS (INCLUDING FIVE NOVEL DELETIONS) IN SPANISH POPULATION

P Ropero, J Martínez-Nieto, F De la Fuente-Gonzalo, L Vinuesa, H Monfredini, F González, A Villegas, J Díaz-Mediavilla

Hospital Clinico San Carlos, Madrid, Spain

Background. Genetic alterations in the beta globin cluster can lead to a variety of diseases such as High Persistence of Fetal Hemoglobin (HPFH), deltabeta thalassemia (β thal), beta thalassemia (β thal), and more. Sequencing the globin genes is the more suitable method for the identification of point mutations or small deletions. However, large deletions are common cause of disease, due to the elimination of entire genes or regulatory elements dispersed in the beta cluster. There are PCR methods designed to detect nothing but a few of this known deletions. Thus, those screening techniques can not be used in the search

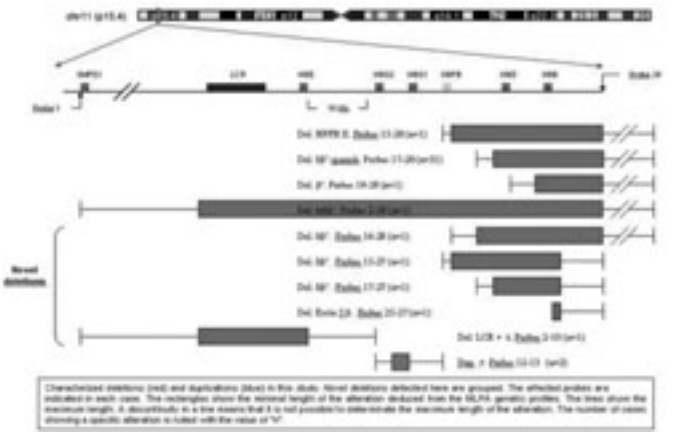

Figure 1.

of novel alterations and the molecular diagnosis becomes difficult in a considerable proportion of the cases. Recently, the development of the Multiplex Ligation-dependent Probe Amplification (MLPA) technique has solved this problem, and now it is possible a quick identification of any copy number variation in the beta globin cluster. *Aim.* This is a descriptive work showing the results of the analysis by MLPA method of cases suspected to carry an alteration in the beta globin cluster. *Methods.* This study included 66 patients with a phenotype of HPFH, βthal or β thal. The existence of point mutations or small deletions/duplications in the β gene was ruled out by sequencing. The MLPA technique is based on the quantitative amplification and a subsequently fragment analysis of multiple probes hybridized across a region of interest. This method allows for a genetic profile showing the copy number variation of those targets. A deletion is detected when a reduction of the amount of amplified product of several consecutive probes is observed in the genome. Here we used a commercial kit (MLPA kit P102-B1 HBB, MRC-Holland) that contains 28 probes designed to detect copy number changes in the beta cluster, from LCR to 10Kb downstream of β globin gene, spanning more than 80Kb. *Results.* Sixty-three percent of the patients are carriers for an alteration that can satisfactorily explain theirs clinical manifestations. A total of 41 chromosomes contain a deletion or duplication in the βcluster. Ten different genetic alterations have been detected in this study; five of them has not been previously described in scientific publications and are novel. Twenty-five patients have shown a normal genetic profile. The alteration most frequently found is the (β)° Spanish deletion. A total of 31 patients are heterozygote carriers for this deletion. Duplication in the region of gamma genes has been found in two cases. All the other alterations detected here have been found in only one case (detailed view in figure 1). Finally, we are currently designing long range PCRs for the identification of the breakpoints of the novel deletions mentioned above. *Conclusions.* Almost all the deletions detected have been found in only one case. The results support the idea of the existence of a high molecular heterogeneity for the alterations in the β cluster. Within this scenario, MLPA analysis means an improvement of the molecular diagnosis and the genetic counseling applied to this group of diseases.

Stem cell transplantation - Clinical 1

Background. Disease relapse is the most frequent cause of treatment failure following allogeneic haematopoietic cell transplantation (allo-HCT), and carries a very poor prognosis. A second allo-HCT may be the only curative option for the majority of these patients. Patient and transplant factors that may associate with the outcome of a second allo-HCT are required for clinical-decision making in such high-risk patients. *Aims and Methods.* We performed a retrospective analysis of adult patients receiving a second allo-HCT for disease relapse after a prior allo-HCT reported by GETH centres. Our aim is to analyze our experience in this setting, and to identify factors associated with patient outcome. *Results.* We present data on 66 patients who underwent a second allo-HCT for disease relapse in Spain between 1990 and 2010 (median year 2003), with a median follow-up for survivors of 63 months (3-224): median age 38 years (range 14-69); 35 male and 31 female; initial diagnosis AML 25 patients, ALL 13 patients, MDS/MPD 11 patients, CML 11 patients, lymphoprolipherative disorder 6 patients; 23 (35%) cases of myeloablative conditioning. Donors were related in 55 cases. Also, 11 second allo-HCT were performed with new donors different from the donors in the previous allo-HCT. Only 4 cases had T-cell depletion. Median time from the first to the second allo-HCT was 21 months (1-170). The cumulative incidence of non-relapse mortality was 26.2%. The median overall survival (OS) was 315 days (95% CI, 176 - 454), with an OS at 1, 3 and 5 years of 38%, 31% and 31%, respectively. OS survival was significantly better in patients who underwent second allo-HCT with low disease burden (complete response, good partial response, or chronic phase; 61% at 1 year, 51% at 3 years) than in patients in active relapse or progression (22% at 1 year, 17% at 3 years; p<0.001). Patients who relapsed early after the first allo-HCT and required a second allo-HCT <1 year after first HCT also had a poorer outcome (OS 17% at 1 year, 9% at 3 years) than those having the second allo-HCT 1 year or longer after the first one (50% at 1 year, 43 at 3 years; p<0.001). Time to second allo-HCT and disease status also associated with the probability of progression free survival in this series (p<0.001 and p=0.002, respectively). Type of donor (related versus unrelated and new donor versus same donor) and type of conditioning (myeloablative versus non-myeloablative) had no statistically significant association with patient outcome. *Conclusions.* The experience from GETH reported here shows that over 30% of patients who relapse after an allo-HCT can achieve long-term survival of 5 or more years following a second allo-HCT. Also, our data suggest that disease status at HCT and time to relapse between first and second HCT are two significant prognostic factors for survival outcome. The indication of a second allo-HCT should be thoroughly discussed for individual cases with early relapse and active disease. Donor type does not appear to influence the outcome.

0424

PRIOR MALIGNANT COMORBIDITY: RISK FACTOR FOR ALLOGENEIC STEM CELL TRANSPLANTATION?

M Stadler, E Dammann, S Buchholz, H Diedrich, M Varvenne, L Hambach, C Koenecke, E Weissinger, J Krauter, A Ganser

Hannover Medical School, Hannover, Germany

Background. Prior malignancies are considered important comorbidities for patients undergoing allogeneic hematopoietic stem cell transplantation (HSCT). In the widely used Charlson's Comorbidity Score and Sorror's Hematopoietic Cell Transplantation Comorbidity Index, prior malignancies are being attributed high risk rankings. *Aims.* We evaluated the impact of prior malignant comorbidities on the outcome of allogeneic HSCT for hematologic diseases in a large, independent patient cohort. *Patients.* From 1995 to 2010, 800 patients received allogeneic HSCTs at our institution. 283 patients had de novo acute myeloid leukemia (AML), 156 myelodysplasia or secondary AML, 114 acute lymphoblastic leukemia, 111 myeloproliferative disorders, 102 lymphomas, 2 solid tumors, and 32 nonmalignant hematological diseases. 340 were females and 460 males, with a median age of 47 years (range: 16 to 72). *Results.* 57 of 800 patients (7%) had suffered from other malignancies before their current hematologic disease. Prior malignancies included breast cancer (n = 19), lymphomas (n = 15), cancers of the uro-genital tract (13), gastro-intestinal cancers (n = 5), malignant melanomas (n= 3), thyroid cancers (n = 2), among others. 2 of 57 patients had two different malignant comorbidities before allogeneic HSCT. Prior malignancies had required systemic (n = 44) or only local treatment (n = 15, including 4 carcinomas-in-situ). At the time of allogeneic HSCT, prior malignancies were in complete (n = 57) or partial (n = 2) remission with a median follow-up of 6.2 years (range, 0.4 to 39.7). 4 of 57 patients (7%) relapsed with their prior malignancies after a median of 11.4 years (range, 3.7 to 29): two patients with late metastases after adjuvant therapy of breast cancer are still receiving hormonal treatment, whereas two patients with locally controlled carcinoma-in-situ of the larynx and malignant melanoma, respectively, died of cancer recurrence. Compared with the entire cohort, patients with prior malignancies were predominantly female, older, and more likely to have received reduced intensity conditioning, but otherwise similar regarding diagnoses, risk status, and remission, as well as donor, gender, and cytomegalovirus match. With 2 years of median follow-up (range: 0 to 12.4), their overall (OS) and disease-free survival (DFS) as well as non-relapse mortality were not different from those of the entire cohort. In multivariate analysis, prior malignancies had no prognostic impact; instead, significant factors for DFS were myeloablative conditioning (p = 0.010; Hazard Ratio, HR, 1.29), hematologic diagnosis (p = 0.002, HR 1.39), and remission status before HSCT (p < 0.001; HR 2.13), whereas for OS only hematologic diagnosis (p < 0.001; HR 1.61) and remission status before HSCT (p < 0.001; HR 2.10) remained significant. *Conclusions.* Patients with prior malignant comorbidities represent a small, but relevant subgroup of allogeneic HSCT candidates, whose transplant outcomes do not appear to be significantly impaired. To refine existing comorbidity indices in that respect, much larger databases are likely required.

0425

INCREASED INCIDENCE OF ACUTE GRAFT-VERSUS-HOST DISEASE IN CHILDREN WITH THALASSEMIA FOLLOWING HLA-IDENTICAL SIBLING BONE MARROW TRANSPLANTS WITH HIGH CD3+ AND CD34+ CELL DOSES

J Gaziev,[1] M Marziali,[1] A Isgrò,[1] MD Simone,[1] P Sodani,[1] N Daniele,[2] C Gallucci,[1] M Andreani,[1] G Del Proposto,[2] G Adorno,[2] K Paciaroni,[1] A Lanti,[2] M Testi,[1] G De Angelis,[1] A Roveda,[1] C Alfieri,[1] F Torelli,[1] G Lucarelli[1]

[1]*Mediterranean Institute of Hematology, Rome, Italy*
[2]*Servizio di Immunoematologia e Medicina Trasfusionale. Policlinico Tor Vergata, Rome, Italy*

Background. It is generally accepted that children are at less risk for GVHD than adults, however its incidence is still significant especially when using alternative donors. Few studies have examined the impact of T cells in the graft on acute GVHD (aGVHD) after HLA-identical sibling BMT in adults with controversial results. Pediatric transplant recipients differ from adults regarding cell dose in the harvested bone marrow: the donor who is likely close in age, usually younger, tend to have a rich harvest leading to the infusion of a higher number of nucle-

ated cells. Therefore, we hypothesized that the impact of graft composition on acute GVHD in children undergoing BMT could be different and a threshold dose of cells that affects GVHD can be defined. This is the first study prospectively evaluating the impact of the CD3+ and CD34+ cell doses infused on GVHD in children undergoing HLA-identical sibling BMT for nonmalignant diseases to date. *Aims.* Assessing the impact of graft composition on aGVHD in children underwent HLA-identical BMT from sibling donors. *Methods.* Between 2004 and 2010, 92 patients with median age of 8 years (range, 1.6-17) were given a bone marrow graft for thalassemia. The preparatory regimens for class 1 and class 2 patients (n=49) consisted of BUCY200 ± thiotepa, and for class 3 patients (n=43) of BUCY160 ± thiotepa (preceded by cytoreduction/immunosuppression with hydroxyurea, azathioprine and fludarabine). From June 2006 onwards, all patients were given targeted i.v.Busilvex (Pierre Fabre Medicament, France). As GVHD prophylaxis patients received CSA, a short course of MTX and methylprednisolone. *Results.* The median of 4.6x 108/kg (range 1.3-10.8) total nucleated cells (TNC), 7.2x106/kg (range 0.8-35) CD34+ cells, and 55.3x106/kg (range 3.8-208) of CD3+ cells were infused. There was a weak correlation (Spearman's test) between CD34+ and CD3+ cell doses (ρ=.35, p=.001). Cumulative incidence of grade 2-4 and 3-4 aGVHD was 35% (95% CI: 25-44) and 9% (95% CI 4-16), respectively. In univariate analysis only CD3+ and CD34+ cell doses above or equal to the median were significantly associated with grade 2-4 aGVHD (49% vs 20%; p=.005 and 46% vs 23%; p=.021, respectively). Multivariate analysis confirmed that high CD3+ (HR, 4.6; p=.010) and CD34+ (HR, 4.3; p=.011) cell doses were major risk factors for grade 2-4 aGVHD. We further examined the effect of CD3+ and CD34+ cell doses on aGVHD using quartile cutoff points and found a minimum threshold for CD3+ (4-38x106/kg) and CD34+ (0.8-4x 106/kg) cells above which the incidence of grade 2-4 aGVHD is significantly increased (8% to 38%-54% and 5% to 41%, respectively). Cumulative incidence of extensive cGVHD was 10% (95% CI 5-18). *Conclusion.* This study for the first time demonstrated that high doses of CD3+ and CD34+ cells within the graft are risk factors for grade 2-4 aGVHD in children with thalassemia undergoing HLA-identical BMT, and defined a minimum threshold dose for these cells above which the incidence of aGVHD significantly increases. These data indicate that patients receiving CD3+ and CD34+ cell doses beyond minimum threshold should be given additional immunosuppressive agents.

0426

THE RISK FACTORS FOR EBV VIREMIA EARLY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

L Yue, W Tong, C Xing-Yu, W Jing-Bo, Z Yan-LI, S Yuan, D Wang-Ming, J Shu-Quan, Y Yu-Ming, T Chun-Rong, L Dao-Pei

Beijing Dao Pei Hospital, Beijing, China

Objective. To identify the risk factors for Epstein-Barr Virus (EBV) viremia early after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Patients and *Methods.* Between January 2007 and January 2009, total 277 patients after allo-HSCT (haploidentical 116, unrelated 75, matched sibling 86) with continuous monitoring plasma EBV-DNA were studied. Conditioning regimens were BUCY/Flu or CY/Flu TBI mainly. ATG was added in both haploidentical and unrelated donor transplants. Cyclosporine, methotrexate and mycophenolate mofetil were employed for GVHD prophylaxis. Serum EBV status of donor and recipient pre-HSCT was determined by ELISA. The levels of plasma EBV-DNA were monitored with real-time quantitative polymerase chain reaction (RQ-PCR) 1 to 2 times weekly in the first 3 months after allo-HSCT. EBV viremia was diagnosed when plasma EBV-DNA was more than 5 x 102 copies/ml but without symptoms. Acyclovir (10mg/kg or 500mg/m2 iv q8h) was administrated for pre-emptive therapy and immnuo-suppressants were decreased if possible. *Results.* Total 33 patients (11.9%) developed EBV viremia with the median time at day 44 (day 19 to day 84). The incidences of EBV viremia were 15.5%, 20.0%, 0% in haploidentical, unrelated, matched sibling transplant, respectively. There was no significant difference on the incidences of EBV viremia between haploidentical and unrelated transplants (p=0.09), but much less EBV viremia was seen in matched sibling transplant (p=0.001). Twenty of 33 patients with EBV viremia (60.6%) had complete response to the pre-emptive therapy with acyclovir. The median time to reach plasma EBV-DNA negative was 11 days (4 to 56 days). The median duration of pre-emptive therapy was 21 days (14 to 60 days). Both univariate and multivariate analysis indicated that haploidentical and unrelated transplants, acute GVHD were the risk factors for EBV viremia. Two-year overall survival in the patients with EBV viremia was significantly lower than that without EBV viremia (54.2% vs. 72.1%, p=0.006). *Conclusions.* Our large clinical study has demonstrated that it is not necessary to monitor plasma EBV-DNA in matched sibling transplant. The incidences of EBV viremia are similar between haploidentical and unrelated transplants. Majority of patients with EBV viremia benefits from the pre-emptive therapy with acyclovir. Haploidentical and unrelated transplants, acute GVHD are the risk factors for EBV viremia early after allo-HSCT which has negative impact on survival.

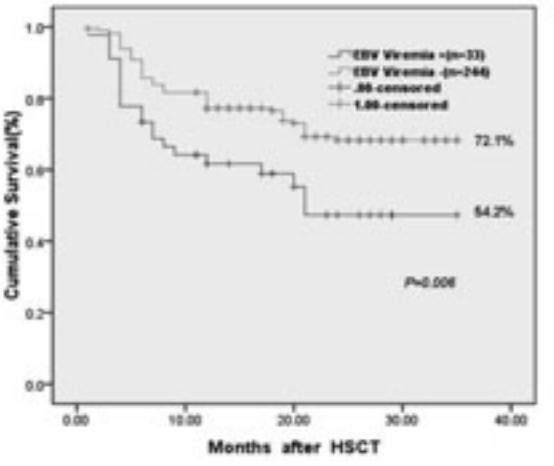

Figure 1.

0427

PROGNOSTIC RELEVANCE OF MINIMAL RESIDUAL DISEASE (MRD) PRIOR TO AUTOLOGOUS TRANSPLANTATION ON LONG-TERM FOLLOW-UP IN ACUTE MYELOID LEUKEMIA (AML). ON BEHALF OF ROME TRANSPLANT NETWORK (RTN)

A Chierichini,[1] B Anaclerico,[1] L Maurillo,[2] A Venditti,[2] R Cerretti,[2] S Angelini,[2] T Dentamaro,[3] B Neri,[3] M D'Andrea,[4] L Dessanti,[4] P De Fabritiis,[3] MC Petti,[4] L Annino,[1] W Arcese[2]

[1]*Azienda Ospedaliera S.Giovanni Addolorata, Rome, Italy*
[2]*Haematology University Tor Vergata, Rome, Italy*
[3]*Haematology S.Eugenio Hospital, Rome, Italy*
[4]*Haematology Istituto regina Elena, Rome, Italy*

Background. autologous stem cell transplantation (ASCT) is currently considered a therapeutic option improving outcome of patients with acute myeloid leukemia (AML). Up to now, it is controversial in which risk patient subgroup it may play a role as post-consolidation therapy. Therefore, risk assessment should be integrated with other parameters to point out this issue. *Aim.* in order to evaluate the prognostic significance of MRD prior to ASCT, its value detected by flow-cytometry (FMC) has been retrospectively analyzed in AML patients followed on a long-term follow-up.. *Patients and Methods.* 89 AML pts with median age of 50 years (range 20-75) undergoing ASCT (June 1995-October 2009) in four Institutions participating to the Rome Transplant Network (RTN), a metropolitan transplant network, have been analyzed. The cytogenetic risk groups were distributed as follows: 46 (63%) intermediate, 12 favourable, 15 adverse; 7 (12%) pts were Flt3-ITD positive. Patients received ASCT in first CR after standard induction- consolidation chemotherapy according to AML EORTC-GIMEMA trials. Bone marrow MRD by FMC was determined prior to ASCT using a cut-off level of 3.5x10-4 leukemic cells. MRD was available in 58 pts, of whom 22 were MRD negative and 36 MRD positive. Fifty-seven out of 89 pts received Bu-Cy conditioning regimen, the others BEAM/BEAM-like regimens. Median CD34+ collected by aphaeresis was 4.57 x106 /Kg (range 0.5-76) and median CD 34+ infused was 4.43 x106 /Kg (range 0.5-26.76). *Results.* at 12 years, overall survival (OS) risk of relapse (RR) and disease free survival (DFS) are, respectively, 54%, 32% and 53% for MDR negative pts, which are significantly better than 20%, 81% and 13% respectively calculated for MRD positive pts. The p-value of DSF (p=0.028), RR (p=0.008), OS (p=0.084) is statistically significant (see Figure 1). The risk assessment at diagnosis has not been considered in these curves. *Comments.* MRD assessment detected by FMC before ASCT has a high prognostic value in term of DFS, RR and OS for pts with CR1 AML and should be considered in the choice

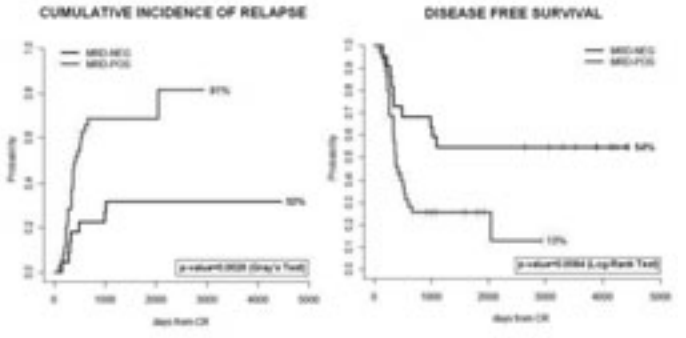

Figure 1.

of the most appropriate transplant approach after consolidation therapy.

A PROSPECTIVE RANDOMIZED TRIAL COMPARING PHLEBOTOMY AND DEFERASIROX FOR THE TREATMENT OF IRON OVERLOAD IN PAEDIATRIC THALASSEMIA MAJOR PATIENTS CURED BY STEM CELL TRANSPLANTATION: 6-MONTH FOLLOW-UP

A Inati,[1] E Khoriaty,[1] N Sbeiti,[2] S Koussa,[3] T Abi Nasr,[3] K Musallam,[4] A Taher[4]

[1]*Rafik Hariri University Hospital, Beirut, Lebanon*
[2]*Zahraa University Hospital, Beirut, Lebanon*
[3]*Chronic Care Centre, Hazmieh, Lebanon*
[4]*Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon*

Background. Patients with β-thalassaemia major who have undergone curative haematopoietic stem cell transplantation (SCT) are at increased risk of iron overload because of previous transfusion therapy. There are limited data on post-SCT iron removal achieved with phlebotomy or iron chelators. *Aims.* To compare efficacy, safety and convenience of phlebotomy versus deferasirox for the treatment of iron overload in children with thalassaemia major after allogeneic SCT. *Methods.* Study LB03T is an ongoing prospective, 1-year, randomized trial in paediatric patients with thalassaemia major who have undergone allogeneic SCT. Chelation-naïve, hepatitis B- and C-negative patients aged 2-<18 years with iron overload (serum ferritin ≥500ng/mL on ≥2 monthly occasions, and liver iron concentration [LIC] >3mg Fe/g dry weight [dw] determined by MRI) were eligible. Patients were randomized to phlebotomy (6mL/kg blood/2 weeks) or deferasirox (10mg/kg/day starting dose; 5mg/kg/day adjustments up to a dose of 20mg/kg/day according to 3-monthly ferritin trends were allowed). Compliance with phlebotomy was determined by the ratio of phlebotomy performed over planned phlebotomy; compliance with deferasirox was determined by missed tablet counting. *Results.* 28 patients were enrolled and randomized to phlebotomy or deferasirox. Two patients randomized to phlebotomy refused treatment. Baseline parameters for 26 patients were comparable between treatment groups (Table). Mean patient age: 12.6 years; mean follow-up: 6.8 months. For patients with serum ferritin <1000ng/mL at baseline, the efficacy of deferasirox at 10mg/kg/day and phlebotomy was similar (Table); for patients with serum ferritin ≥1000ng/mL, the absolute median change was non-significantly greater with phlebotomy. For TIBC, the increase with deferasirox was significantly greater than with phlebotomy in all groups. The absolute mean decrease in haemoglobin was -0.12 and -0.59g/dL (P=0.027) for the deferasirox and phlebotomy groups, respectively. Two patients reported treatment-related adverse events (AEs) with deferasirox (skin rash [n=1] and mild nausea/flatulence [n=1]) and four reported difficulty with phlebotomy (difficult veins [n=3], distress [n=1]). Compliance was excellent for 11 (91.7%) and 12 (85.7%); good for 1 (8.3%) and 1 (7.1%) and poor in 0 and 1 (7.1%) patients in the deferasirox and phlebotomy groups, respectively. Parents of 13/14 children randomized to phlebotomy voiced their wish for their children to receive deferasirox because of pain, risk of anaemia and longer/more frequent hospital visits (missing school days for the child and work days for parents) associated with phlebotomy. Parents of 1/14 were content with phlebotomy because of concerns over possible AEs with deferasirox. *Summary/Conclusions.* For post-haematopoietic SCT patients with serum ferritin <1000ng/mL, phlebotomy and deferasirox (10 mg/kg/day) were equally effective in ferritin reduction; in patients with serum ferritin ≥1000ng/mL, phlebotomy reduced serum ferritin to a greater extent (difference did not reach significance between treatment groups). This highlights that a starting dose of 10mg/kg/day may not be sufficient to reduce iron loading in such patients, and that earlier and appropriate dose adjustments should be carried out. Deferasirox increased TIBC to a more statistically significant extent than phlebotomy. Deferasirox was well tolerated; the majority of parents with children receiving phlebotomy noted a desire to switch to deferasirox.

Table 1.

Baseline and efficacy assessments

Parameter	Deferasirox (n=12)	Phlebotomy (n=14)	*P*-value

EPIDERMAL LANGERHANS CELLS IN THE CONTEXT OF FULL AND REDUCED INTENSITY CONDITIONING

T Schmitt, K Schneiker, D Wolff, K Bender, D Strand, EM Wagner, J Hemmerling, M Theobald, W Herr, R Meyer

University Medical Center, Mainz, Germany

The interaction of residing host-derived dendritic cells (DC) and donor T cells is a crucial step in the induction of acute graft versus host disease (GVHD). In particular, epidermal Langerhans cells (LC) of the recipient persist after allogeneic hematopoietic stem cell transplantation (HSCT). Allo-reactive T cells mediate GVHD but also promote the switch from host to donor LC. We investigated on the LC chimerism early after transplantation in patients who had been treated with a reduced intensity conditioning (Fludarabine / Melphalan) combined with *in vivo* T-cell depletion mediated by high-dose alemtuzumab (100mg) prior to HSCT. In addition, we compared the impact of this conditioning regimen on LC-density with that of a 12Gy total body irradiation (TBI)-based full intensity conditioning regimen. Epidermal skin layers were prepared from 6 mm punch biopsies and split for further immunofluorescent staining as well as for the generation of single cell suspensions. CD1a/MHC-class II-positive LC were analyzed and subsequently sorted by flow cytometry. LC frequency among the isolated epidermal cells was analyzed by flow cytometry prior to conditioning, on the day of transplantation as well as on day +20. In addition, LC density was semiquantitatively assessed by confocal laser-microscopy on stained epidermal sheets. Donor chimerism was measured by STR-based assays on LC isolated on day + 20. Despite of a low LC-density on day +20 compared to that before transplantation, LC could be isolated in 51/52 patients. The numbers of isolated cells ranged from 2 to >1000. In samples with >300 isolated cells, these were re-analyzed by flow-cytometry and showed a purity of >90%. Chimerism analyses led to valid results in 39 samples. Of 19 patients who suffered from an

early GVHD after transplantation, 10 patients (53%) had predominantly donor-derived LC as early as day +20 after HSCT. In contrast, of 20 patients without primary GVHD, only 3 (15%) predominantly had donor-derived LC. The 20 patients without GVHD subsequently received prophylactic CD8-depleted donor-lymphocyte infusions (DLI). DLI induced acute GVHD in 11 patients, but we did not find a correlation between day +20 LC chimerism and the incidence of DLI-associated GVHD. The relative LC-density, calculated as the quotient of LC frequency among epidermal cells before and after conditioning was 60% (+/-30%) after Flu/Mel/Alemtuzumab (n=5) and 6% (+/-3.5%) TBI-based conditioning (n=4). These results were confirmed by manual counting of LC in stained epidermal sheets. We have established a sensitive method enabling us to investigate LC chimerism and follow LC chimerism prospectively. Early after SCT following a Flu/Mel/Alemtuzumab conditioning, the majority of patients still have predominantly host-derived LC. However, the predominant donor-LC chimerism in patients with primary GVHD on day +20 supports the hypothesis that persisting LC are relevant targets of allo-reactive T cells in acute GVHD. In addition, first data in a small series of patients point towards an impact of the conditioning regimen on LC density. Further studies will focus on the persistence of host-LC particularly after reduced intensity conditioning and might lead to DC-depleting strategies to further reduce the rate of acute GVHD in this setting.

[6]*Hospital Universitario. Centro en Red de Medicina Regenerativa CyL.Tercel, Salamanca, Spain*

Background. Several clinical trials have reported the evaluation of the therapeutic potential of mesenchymal stem cell (MSC) infusion for the treatment of acute graft-versus-host disease (GVHD), but information from the chronic GVHD setting is far more limited. Most clinical trials use MSC generated in medium with fetal calf serum (FCS). However, FCS is an undesirable source of xenogeneic antigens and bears the risk of transmitting animal viral, prion and zoonose contaminations. Platelet (PL) lysate and human serum (HS) have been proposed as an alternative, although only one study has evaluated the efficacy of these approaches in the clinical setting. *Aim.* In the current trial we have evaluated the feasibility and efficacy of the infusion of MSC expanded using HS for the treatment of refractory acute or chronic GVHD. *Methods.* Overall, 28 expansions were started. MSC were expanded from donor's bone marrow. Culture medium was enriched with HS from the MSC donor, and PL was added in cases of slow growth. Ten patients received MSC for the treatment of refractory or relapsed acute GVHD. Two patients received MSC as the second-line, five as the third-line and three as ≥ the fourth-line of treatment. Eight patients received MSC for the treatment of chronic GVHD. Four received MSC as second-line and four as third-or-more-line treatment. None of the patients receiving MSC as a second-line treatment had previously responded. *Results.* In 22 of the expansions, the minimum number of > 1x106 MSC/kg were obtained after a median of 26 days. After the addition of PL only one case did not reached this number of cells so this procedure yielded enough cells in most cases. In ten cases cells were not infused either because of patient's death prior to expansion due to GVHD or due to response to the previous line. Regarding patients treated for aGVHD, one obtained complete remission (CR), six had a partial response (PR), and three patients did not respond. In the subset receiving MSC for the treatment of cGVHD: one obtained CR, three had PR and four did not respond. No adverse events could be directly attributed to the MSC. *Conclusions.* The current study is the first clinical trial evaluating the feasibility and safety of MSC expanded *in vitro* using HS with PL for the treatment of heavily treated patients of both acute and chronic GVHD. In conclusion the present study shows that the use of MSC is safe and feasible in such patients. Moreover in it is the first clinical trial showing promising results in chronic GVHD.

EXTRACORPOREAL PHOTOPHERESIS (ECP) AND RITUXIMAB (RTX) FOR THE TREATMENT OF STEROID REFRACTORY GRAFT VERSUS HOST DISEASE (SR-GVHD)

R Cekauskiene, L Kryzauskaite, A Griskevicius, K Sinkevic, R Matuzeviciene, T Zvirblis, I Trociukas, L Griskevicius

Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania

Background. Treatment options for SR-GVHD after allogeneic stem cell transplantation (alloSCT) are unsatisfactory. ECP has immunomodulating effect mainly on T cells and has been used for the treatment of SR-GVHD with encouraging results. Rtx targeting B cells showed efficacy in SR-GVHD. We present a retrospective analysis of ECP and Rtx combination targeting two pathogenetic GVHD treads T and B cells used in our center to treat SR-GVHD after alloSCT. *Aims.* To determine the clinical benefit of ECP and Rtx combination in SR-GVHD in terms of clinical response rate (CRR) and site using the National Institutes of Health consensus criteria. To evaluate lymphocyte subpopulations as prognostic markers of response. *Methods.* Patients with acute or chronic GVHD, refractory to steroids, received ECP plus Rtx (off label use) as add-on to steroids ± imumosuppressive agents. 12 ECP cycles (each consisting of two procedures on two consecutive days) were given by weekly schedule followed by monthly ECP for up to 16 cycles. 1 g of Rtx was given after 1st and 3rd and optionally after 9th and 11th ECP cycles. Evaluations were performed after 6, 12, 14 and 16 ECP cycles. *Results.* 10 patients with aGVHD (2 - grade II; 8 - grade III-IV) and 9 with cGVHD (3 - moderate, 6 - severe) received ECP + Rtx. The median observation time was 4.5 months (range: 1-28). The median number of ECP cycles was 14 (range: 5-16). 13 patients are alive (7 patients completed treatment schedule, 6 are ongoing) and 6 died before the treatment had been completed. Clinical response was achieved in 16 patients (84%) with complete remission (CR) in 7 (37%) and partial remission (PR) in 9 (47%). 3 (16%) patients were non responders (NR). 3 (33%) cGVHD patients achieved CR, 5 (56%) achieved PR, one (11%) did not respond. The best response in cGVHD patients was observed in skin and mouth (100% CRR; 83% and 85% CR). CRR in other sites were: gastrointestinal tract (GI) (100% CRR; 43% CR), eyes (33% CRR; 33% CR) and liver (66% CRR; 0% CR). 4 (40%) aGVHD patients achieved CR, 4 (40%) had PR and 2 (20%) were NR. aGVHD response by site was: skin (71% CRR; 57% CR), GI (78% CRR; 44% CR). Treatment was well tolerated with no procedure related serious adverse events. 3 patients experienced hypocalcaemic reactions during ECP, 1 nausea, 1 vomiting and 1 fever were recorded. Immunosuppression was reduced in 10 and discontinued in 1 patient at first evaluation (after 6 ECP cycles) and further reduced in 2 and discontinued in 3 patients. The median survival was 10 months (1.5-19; CI 95%). One year survival was 44%. The causes of death were infections in 5 patients and intracranial hemorrhage in 1 patient. One patient had no GVHD at the time of death, 2 had minimally active GVHD and 3 had active GVHD (all NR). None of the lymphocyte subpopulations (CD3+ CD4+, CD3+ CD8+, NK cells, Treg) significantly predicted response to treatment. *Conclusion.* ECP and Rtx treatment is feasible and effective in SR-GVHD.

IMPACT OF THE NEW ANTI-MYELOMA DRUGS ON OUTCOME OF ALLOGENEIC STEM-CELL TRANSPLANTATION WITH REDUCED-INTENSITY CONDITIONING IN PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA

J Elcheikh, R Crocchiolo, JM Boher, S Furst, C Faucher, L Castagna, A Granata, C Oudin, D Coso, R Bouabdallah, AM Stoppa, D Blaise

Institut Paoli Calmettes Marseille, Marseille, France

Introduction. The increasing use of the novel agents lenalinomide and bortezomib to treat multiple myeloma (MM) has contributed to higher complete remission (CR) rates and longer overall (OS) and event free survival (EFS). We set out to assess the impact of these drugs on the outcome of high-risk MM patients treated with allogeneic stem-cell transplantation (allo-SCT) after reduced-intensity conditioning (RIC) over the last 10 years. *Methods.*This retrospective study compared 45 patients (group1) transplanted in our centre between January 1999 and January 2006 and who had not received either novel agent prior to transplant (as induction or relapse therapy) with 34 patients (group 2) transplanted between January 2006 and june 2010 who received either one or both drugs before allo-SCT. *Results.* The median time between diagnosis and Allo-SCT was 37 months (6-161) and 41 months (9-145)

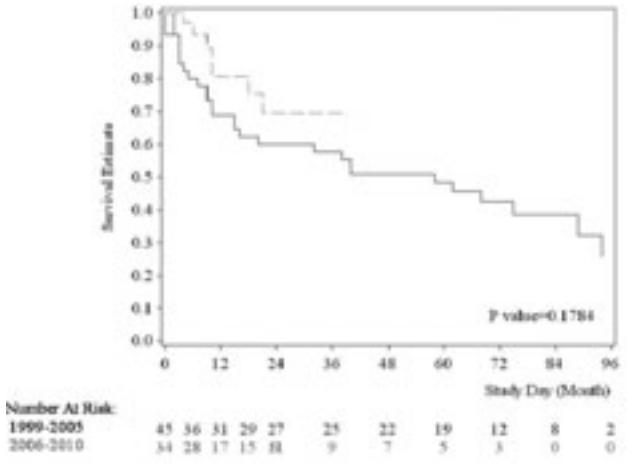

Figure 1. OS.

in the two groups respectively. The median follow-up after transplant was 45 (2-127) and 16 (3-39) months in the first and second group respectively.The cumulative incidence of acute graft versus-host disease (GVHD) was significantly higher before 2006 (47% vs 24%; p=0.0584). The cumulative incidence of chronic GVHD was also different (56% vs 30%; p=0.0241). The estimated probability of non relapse mortality (NRM) at day 100 was 12% in the first group vs 0 % in the second group transplanted after 2006. The one and two years NRM was 18% vs 23% (p =0,537). The overall survival (OS) at two years was 60% vs 70% in the first and second group respectively (p=0.1784). The progression-free survivals (PFS) was significantly different at 2 years, 45% before 2006 compared to 65% after 2006 (p=0,056). The PFS median not reached in the second group compared to 22 months before 2006 (p=0.1811). *Conclusion.* We documented a lower incidence of acute GVHD and NRM associated with a higher CR rate as well as significantly improved survival and relapse incidence since the introduction of novel reduced-intensity preparative regimens and peri- and post-transplantation strategies.. These results suggest that enhancing the graft-versus-myeloma effect is of key importance for managing high-risk MM patients.

EARLY PERIPHERAL BLOOD AND T CELLS CHIMERISM DYNAMICS AFTER SINGLE CORD BLOOD TRANSPLANTATION WITH CO-INFUSION OF CD34+ CELLS FROM A THIRD PARTY DONOR PREDICTS CB GRAFT FAILURE

M Kwon, C Martinez-Laperche, P Balsalobre, D Serrano, J Gayoso, JL Díez-Martín, I Buno

Hospital Gral. Univ. Gregorio Marañon, Madrid, Spain

Background. Umbilical cord blood (CB) transplant from unrelated donors has been increasingly used as an alternative stem cell source for patients with hematological malignancies lacking HLA-matched adult donors. The co-infusion of mobilized and selected CD34+ cells from a non-HLA-identical donor (dual transplant) has shown to reduce the period of postransplant neutropenia and related early morbidity and mortality of single CB transplantation. The aim of this study was to analyze the predictive value of early postransplant peripheral blood (PB) and T lymphocytes (TL) chimerism analysis after dual transplant regarding CB engraftment or failure. *Patients and Methods.* 15 patients with high risk disease underwent 16 dual transplants between 2004 and 2011. Chimerism analysis was performerd weekly after graft infusion until complete chimerism was achieved by STR-PCR (AmpFlSTR SGM Plus; Applied Biosystems) in PB and TL purified using immunomagnetic technology (CD3+, Miltenyi Biotec). Complete chimerism (CC) was defined as <1% recipient in PB and <5% in leukocyte lineages (95% purity of enriched samples). *Results.* From the 16 transplants, 12 (Figure 1a-l) showed engraftment (>500 TNC) in a median of 16 days (11-28) reaching full CB chimerism in a median of 24 days. Early postransplant PB chimerism analysis showed increasing percentages of CB cells in 8 cases (Figure 1a-h). Only 2 cases showed low (<15%) percentages of CB cells in the first sample (day +14), although both showed an increase in the second determination (day +21). In the remaining 4 cases the proportion of CB cells remained stable or slightly

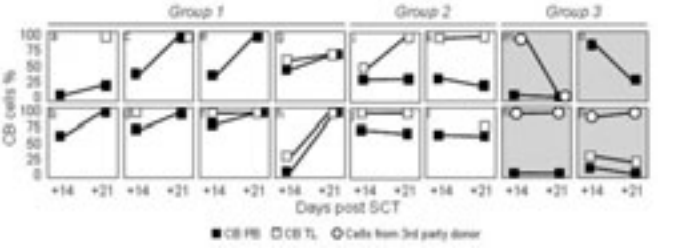

Figure 1.

decreased from day +14 to day +21 (Figure 1i-l), however TL chimerism showed a significant increase or remained near 100% CB cells in both determinations. On the other hand, 4 out of the 16 transplants experienced primary CB graft failure (Figure 1m-p). Three of them showed low percentages of CB cells in PB (<15%) on day +14 with a further decrease in the second sample. The fourth case showed an initial high proportion of PB CB cells with a significant decrease in the following sample (TL chimerism not available). *Conclusions.* Early postransplant chimerism dynamics in PB and TL can predict CB engraftment or failure in dual transplants. Initial low percentages of CB cells in PB without an increase within the first month post-transplant as well as a decrease in the proportion of PB CB cells without an increase in TL, seem to correlate with CB failure. Therefore, an early significant proportion of CB in TL associates with CB engraftment irrespectively of the dynamics of chimerism in PB.

0434

TREATMENT OF STEROID RESISTANT GRADE II TO IV ACUTE GVHD BY INFUSION OF MESENCHYMAL STROMA CELLS EXPANDED WITH HUMAN PLASMA AND PLATELET LYSATE - A PHASE I/II STUDY

L te Boome, C Lindemans, I Slaper-Cortenbach, H Rozenmuller, E Petersen, M Bierings, J Boelens, N Wulffraat, J Kuball

UMCU, Utrecht, Netherlands

Introduction. For numerous malignant and non-malignant hematological diseases allogeneic hematopoietic stem cell transplantation (HSCT) is the only curative therapy. Despite multiple improvements in the last decade in the field of HSCT, acute graft versus host disease (aGVHD) remains a life-threatening complication and reduces substantially efficacy of HSCT. In particular, the outcome of patients with severe steroid-resistant aGVHD is very poor. Therefore, it remains important to search for new therapeutic strategies for the treatment of aGVHD. *Objective.* Feasibility of the generation and efficacy of mesenchymal stroma cells (MSCs) generated with fetal calf serum (FCS) has been suggested recently. However, FCS is a putative source of prions and virus transmission. Therefore, the feasibility of the generation of MSCs expanded with human plasma and platelet lysate (hPPL) was tested as well as the feasibility and safety of the application of hPPL-MSCs in patients with steroid-refractory aGVHD. *Method.* In an open-label, non-randomized prospective phase I/II study MSCs were extracted from the bone marrow of healthy volunteers, expanded with hPPL, and stored. Patients with steroid-refractory aGVHD grade II to IV were treated with ~2x106/kg hPPL-MSC. Response rate, transplantation-related deaths, and other adverse events were assessed for up to 12 months after the last infusion of the cells. *Results.* Between January 2009 and December 2010, 20 patients were included, 2 patients drop out, and 18 patient were available for further analysis: 5 children and 13 adults. Median age was 32.5 years (range 1.3-65.9). Organs involved in aGVHD were the skin (67%), the gastro-intestinal tract (83%) and the liver (28%). Overall grade was II for 4 (22%), III for 13 (72%), and IV for 1(6%) patients. 1 patient received one infusion, all other patients received two or more infusions. No patient had side-effects during or immediately after infusions of the hPPL-MSC. Median follow-up was 5.5 months (range 0.33-12). Complete overall response was observed in 11 patients (61%) after a median of 65 days (range 10-184 days). The overall survival was significantly better in responders when compared to non-responders (p <0.001). Of the 11 patients who reached a CR, 8 patients relapsed approximately 2 months after reaching CR (median 59 days, range: 1-244). Three children relapsed with clinical signs of an allo-immune-lung, auto-immune-cytopenia or limited cGVHD and all 5 adults relapsed with GVHD of the gut (median 98 days after reaching CR, range: 35-302 days). However, GVHD of the gut was then again sensitive to steroids. Overall, 7 patients died, 4 due to progression of

aGVHD, 1 patient due to abdominal bleeding and 2 due to sepsis. *Conclusion.* Generation and infusion of hPPL-MSCs in steroid-resistant aGVHD grade II- IV is feasible, safe and very effective. In addition, also patients who initially responded to hPPL-MSCs but develop later a relapse of aGVHD during tapering or cessation of immunosuppressive drugs become again sensitive to the treatment with steroids.

0435

ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION WITH RIC CONDITIONING IN PATIENTS WITH HIGH RISK MULTIPLE MYELOMA: COMPARATIVE ANALYSIS OF OUTCOMES BETWEEN UNRELATED AND RELATED DONOR

J Elcheikh, S Furst, AM Stoppa, R Crocchiolo, L Castagna, C Faucher, A Granata, C Oudin, P Ladaique, C Lemarie, B Calmels, C Chabannon, D Blaise

Institut Paoli Calmettes Marseille, Marseille, France

The purpose of this study was to assess the results of allogeneic stem cell transplantation (Allo-SCT) after reduced-intensity conditioning (RIC) from an unrelated donor in patients with high-risk multiple myeloma (MM) in a single centre. From January 2007 to January 2010 we transplanted 33 consecutive patients with MM. *Methods.* Thirteen (39%) (Group 1) and 20 patients (61%) (Group 2) had unrelated and related donor respectively. The median age was 48 years (39-63) in the first group and 56 years (40-67) in the second group.Thirty two patients (97%) received one or more autologous transplantation. The disease status at transplantation was [Complete Remission (CR) or VGPR in (15%) vs (40%); Partial remission (PR) in (77%) vs (55%); progression or refractory disease in (8%) vs (5%)] in the first and second group respectively (p=0.1770). stem cell source was peripheral blood steam cells (PBSC) in all patients in the related donor group and in 10 patients (77%) in the second group, the other 2 patients (15%) received marrow and one patient (8%) received cord blood cells. Twenty five patients (Group 1: N=4 (31%); Group 2: N=4 (20%) were treated with a RIC based on Fludarabine (30mg/m²/d x 5); Busulfan (4 mg/kg/d p.o. or 3.2 mg/kg/d IV over 2 to 3 days) and rabbit ATG (2.5 mg/kg/d x 2). *Results.*The median follow-up was 17 months (4-39). None of our patient experienced a graft rejection. The cumulative incidence of grade II-III acute graft versus-host disease (GVHD) was higher (38%) for the unrelated donor vs (15%) for the related donor (p= 0.12). The cumulative incidence of chronic GVHD was no different between the first and second group (31% vs 30% respectively).The estimated probability of non-relapse mortality (NRM) at day 100 was 0% in the two groups. At two-year the NRM probabilities was lower in the unrelated group 14% vs 24% in the related group (p =0,477). Also at 2 years, patients receiving unrelated transplantation had superior overall and progression-free survivals, 83% and 65% respectively compared to patients with related donor transplantation, 67% and 36% (p= 0.241). The incidence of acute GVHD, OS, PFS and NRM were not significantly different between the two groups. *Conclusion.* in patients with high risk multiple myeloma; RIC Allo-SCT with unrelated donor, is feasible and effective treatment with low non-relapse mortality, high complete remission rates and prolonged disease-free survival. This procedure seems to be comparable to those of HLA-identical siblings.

[14]*Jichi Medical School, Tochigi, Japan*

Background. No standard of care for PRCA following allogeneic hematopoietic stem cell transplantation (HSCT) from major ABO-incompatible donors has been established. *Aims.* The primary objective of the present study was to learn the efficacy and long-term outcome of intervention for post-transplant PRCA. *Methods.* The present study was conducted as a retrospective observational study and approved by the IRB and the Japan Society for Hematopoietic Cell Transplantation. The patient cohort was selected from the registry database of the Transplant Registry Unified Management Program (TRUMP) that covered both adult and pediatric transplantation using all kinds of graft sources in Japan. One-hundred forty-five recipients who achieved engraftment with delayed recovery of erythropoiesis and survived >6 months after transplant without disease relapse were selected from 2,846 records of major ABO-incompatible allogeneic transplantation during 2003 to 2007. The questionnaires were sent to the transplant centers and the response rate was 68.3% (99/145 recipients). Forty-eight recipients were identified as having PRCA, and then the detailed transplant data of 46 out of those 48 recipients could be collected. *Results.* The grafts were bone marrow and blood stem cells in 33 and 13 patients, respectively. No patient with PRCA was reported after cord blood transplantation. Donors were related in 24 patients, and unrelated in 22. Incompatible hemagglutinins were anti-A in 28 patients, anti-B in 12, and both in 6. Treatment of PRCA except for transfusion was performed in 22 patients (intervention group) but not in other 24 patients (non-intervention group). Response to the primary treatment was observed in 2 out of 8 patients who had been rapidly tapered calcineurin inhibitors (2CR), and 6 out of 12 patients receiving corticosteroid (5CR, 1PR). None of the patients receiving rituximab (n=1) or erythropoietin (n=1) responded. Secondary therapy including rituximab, additional immunosuppressants, or DLI was given in 8 patients with 50% response rate. Overall response rate of intervention was 54.5%. Four out of 10 patients who did not show any responses to intervention spontaneously became transfusion-independent. Days from the diagnosis of PRCA to recover reticulocytes >1% and cumulative doses of RBC transfusion during the period were not significantly different between the two groups. Incompatible hemagglutinin titers at diagnosis of PRCA were not different, either. Strikingly, the Kaplan-Meyer estimate of the survival demonstrated the inferior survival of the intervention group (log-rank 0.001). Eleven and 2 deaths were observed in the intervention and the non-intervention groups, respectively. Infections accounted for the death of 7 patients in the intervention group. Univariate analysis indentified the 5 variables influencing the OS, and

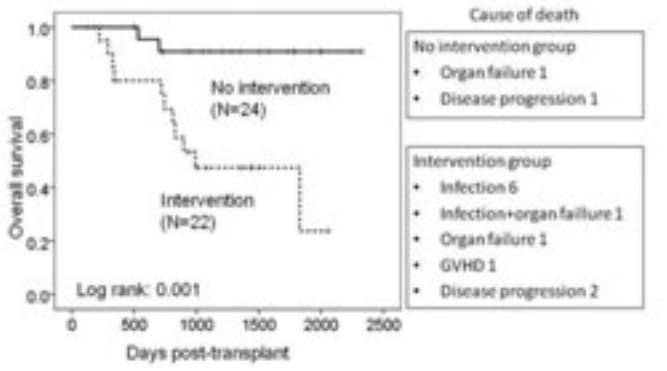

Figure 1. Overall survival of post-transplant PRCA.

Cox regression analysis revealed that the intervention for PRCA remained as the only factor negatively affecting OS (p=0.040). Matched pair analysis using the non-PRCA cohort as a control showed the marginal probability of difference (log-rank 0.114), possibly because of the limited number of patients. *Summary/Conclusion.* The present study suggests that the intervention for PRCA may adversely affect the outcome of the patients. Prospective cohort study or randomized controlled trial should be encouraged to explore the role for intervention of PRCA following major ABO-incompatible HSCT.

0437

REDUCED INTENSITY ALLOGENEIC TRANSPLANTATION IN YOUNG PATIENTS WITH VERY HIGH RISK ACUTE LYMPHOBLASTIC LEUKEMIA (VHR ALL)

E Semenova, N Stancheva, A Alyanskiy, E Babenko, L Zubarovskaya, B Afanasyev

Pavlov State Medical University, Saint Petersburg, Russian Federation

Backround. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) with reduced intensity conditioning regimens (RIC) has become a well-established approach in adult patients with hematologic malignancies. The role of this type conditioning in pediatric cancer has yet to be defined. The aim: to compare efficacy of reduced intensity conditioning (RIC) and myeloablative conditioning (MAC) for allo-HSCT in children and adolescents suffering from VHR ALL. *Patients and Methods.* 98 ALL patients (pts) from 1 till 21 y.o. (mediana 12 y.o.) were underwent allo-HSCT between 12/2000 and 12/2010. Indication for allo-HSCT in children and adolescents was VHR ALL: late responder on chemotherapy (induction failure), poor-risk cytogenetics (t(9:22), t(4:11)) and MRD(>10 -2), infants with 11q23 rearrangement, short first remission, primary resistance or resistant relapse. RIC allo-HSCT performed in 28 pts (RIC- group): 16 pts in I or II complete remission (CR), 12 pts were in resistant relapse. Indication for RIC allo-HSCT was poor performance status, organ dysfunction due to previous therapy or infection complication at the moment of allo-HSCT. MAC was used in 70 pts (MAC-group): 42 pts were in I and II CR at the moment of HSCT, 28 pts were III and IV CR or in resistant relapse. RIC consisted of Flu 150 mg/m2/d + Mel (140 mg/m2/d)±ATG or Flu 150 mg/m2/d + Bu 8 mg/kg±ATG; MAC consisted of Bu 16 mg/kg (or Treo 36-48 mg/m2) +Cy 120 mg/kg ±ATG. Allo-HSCT from matched related donor was performed in 27 pts (RIC, n=6), from matched unrelated donor - in 71 pts (RIC, n=22). *Results.* (tab 1,2): In RIC-group granulocyte's engraftment >=0,5x109/l was on D+18 (in ranges D+13-31). For pts in I or II CR at RIC allo-HSCT 9 of 16 are alive. Overall 7-years survival (OS) and disease-free survival (DFS) were 50% and 46%, corresp. Five pts died within 100 days: infection (1), aGVHD (4). Relapse occurred in 3 pts (19%), 2 relapsed pts achieved CR after chemotherapy+DLI in 1st ptn and immunosuppression withdrawal in 2nd ptn, one ptn died due to relapse in 5 months. CR was achieved in 5 of 12 pts after alloHSCT at resistant relapse. But 1-year OS was 0%. Patients died from infection (3), aGVHD (1), and disease progression (7). MAC-group: granulocyte's engraftment >=0,5x109/l was on D+21 (in ranges D+10-49). Eighteen of 42 pts are in CR after MAC allo-HSCT in I or II CR. Overall 7-years survival (OS) and DFS were 51% and 44%, corresp. 11 pts relapsed after MAC allo-HSCT (28%), but 2 of them achieved CR after chetmotherapy+DLI. Ten pts died from relapse, aGVHD-5; infection -2; transplant related toxicity -2, non-engraftment - 1. Five from 28 pts after MAC alloHSCT in relapse either III or IV CR are in CR (1-104 months; mediana 44 months). Other pts died - relapse (13), infection (7), aGVHD (3). *Conclusion.* RIC allo-HSCT of VHR ALL in CR pts ≤ 21 yo is effective and comparable with MAC allo-HSCT. These results make new approaches for pts in VHR ALL in CR, indicate sensitivity to immunoadoptive therapy and produce the base for clinical trials.

Table 1. Table 2.

Outcomes after allo-HSCT

Complication after allo-HSCT

Condition regimen	Status at the moment of allo-HSCT (n)	Relapse n(%)	TRM n(%)	7-OS	7-EFS
RIC	I or II CR 16	3(19)	5(30)	50%	46%
	Relapse 12	6(50)	4(36)	0	0
MAC	I or II CR 42	11(26)	10(24)	51%	44%
	Relapse 28	13(46)	10(50)	14%	14%

	RIC (%)	MAC (%)
Acute GVHD grade 1-4	55	53
Chronic GVHD	78	54
infection	62	84
non-hematological toxicity	31	54
hemorrhagic	13	75

Background. Plerixafor the major inhibitor of the α chemokine CXCL12 receptor has been largely used in the context of hematopoietic stem and progenitor cells mobilisation (HSPC) since its approval in 2009 in Europe. In France, its main indication remains for poor mobilizers patients with lymphoma and or myeloma. *Aims and Methods.* We retrospectively reviewed the data collection of 65 patients assigned to autologous stem cells transplantation (ASCT) and who underwent their apheresis at the French Blood Institute between 2008 and 2010. All patients who received Granulocyte-colony stimulating factor (G-CSF: 10 micrograms/kg/dose subcutaneously daily x 4 days) during mobilisation attempt + Plerixafor (0,24 mg/kg/dose subcutaneously daily, after at least the fourth dose of G-CSF) were evaluated. Additional doses of G-CSF and Plerixafor for subsequent apheresis sessions were administered using a COBE Spectra separator. *Results.* Baseline characteristics of the patients were: median age = 57 yrs (range, 12-67); sex ratio M/F =1,3; haematological malignancies = 58; non-haematological malignancies = 7; 3 patients received high dose cyclophosphamide during mobilisation setting; median lines of chemotherapy = 2 (range, 1-6). Plerixafor was well tolerated and no severe side effects reported. Patients had a median of 2 mobilisation attempts (range, 0-4). Sixty three percent of patients achieved the aim of ≥ 2x106 CD34+ cells/kg collection after a median number of apheresis sessions of 2 (range, 1-3). The median level of CD34+ cells in the peripheral blood (pCD34+) at day 1 of apheresis after Plerixafor injection was 19/µl (range, 0-145), 7,3 hours (range, 4,3-11,5) prior to apheresis. The median yield of CD34+ cells was 1,8x106/kg (0,1-16,5) after the first session of apheresis (Table 1). Interestingly, Plerixafor could lead 58 % of patients

Table 1.

Characteristics of patients and collection

No of Patients	65
Diagnosis (Myeloma/non Hodgkin Lymphoma/Hodgkin Lymphoma/Chronic Lymphocytic Lymphoma and Waldenström/ Non-hematologic Malignancies)	15/32/6/5/7
Median Weight (range) kg	70 (16-125)
Median sessions of apheresis (range)	2 (1-3)
Median Doses of G-CSF (range) µg/kg	10 (6-16.8)
Median Total blood volume processed at first apheresis (range) Liters	10,4 (4,4-20,5)
Median CD34+cells x10^6/kg collected at day 1 of apheresis (range)	1.8 (0.1-16.5)
Median CD34+cells x10^6/kg collected at day 2 of apheresis (range)	1.1 (0.3-4.6)
Median Total CD34+cells x10^6/kg collected (range)	2.66 (0.7-5.7)

to a pCD34+ level ≥ 20 /µl and collection of ≥ 3x106 CD34+cells/kg during only 1 session of apheresis. Moreover, the median level of pCD34+ available for 21 patients among the 65 before and after injection of Plerixafor was 4/µl (range, 0-16) and 12,5/µl (range, 0-97) respectively after a 3,2-median fold expansion (range, 0-16,2). At the day of analysis, twenty patients had already undergone ASCT with successful engraftment. *Summary.* Mobilisation with G-CSF + Plerixafor is an excellent strategy in the context of heavily pre-treated patients with haematological and extra haematological malignancies, can lead to early collection of HSPC and requires close collaboration between clinicians and physicians collection facilities. Further leg of this analysis will evaluate the data of patients harvested with Plerixafor + chemotherapy during neutrophil recovery and engrafment data after ASCT.

THE PRESENCE OF CIRCULATING ANTI-PR1 AND ANTI-SURV SPECIFIC CD8+ LYMPHOCYTES POST ALLOGENEIC STEM CELL TRANSPLANTION IS ASSOCIATED TO MORE FAVORABLE OUTCOME

J Serrano López, D Tallón-Pérez, C Martinez-Losada, J Serrano, C Martín, R Rojas, F Martínez, J Garcia-Castellanos, G Rodriguez-García, A Rodriguez-Villa, J Casaño, A Torres-Gomez

University Hospital Reina Sofia, Córdoba, Spain

Background and Aims. Allogeneic stem cell transplantation (allo-SCT) is a potentially curative treatment option for patients with hematological disorders. Alloreactive donor-derived T lymphocytes exert a benefitial graft-verus-leukemia (GVL) effect through the recognition of leukemia-restricted (or preferentially expressed) antigens as Wilms tumor protein (WT1), survivin (SURV) or proteinase (PR1). Current research in transplant immunology focouses in enhacing GVL while preventing the deleterious graft-versus-host disease (GVHD) that could be achieved by manipulating donor-derived antigen-specific T-populations. In this study we sought the presence of peripheral blood leukemia-associated antigen-specific CD8+ T-lymphocytes and the impact on outcome post-allo-SCT. *Methods.* 54 consecutive HLA*0201 patients undergoing conventional myeloablative (n=32) or non-myeloablative (n=22) allo-SCT as treatment of hematological disorders were included. Donor was an HLA-identical sibling in 46 cases (80.5%) and unrelated in 8 cases (14.5%). Stem cell source included mobilized peripheral blood (n=22), bone marrow (n=25) and umbilical cord blood (n=7). Twenty-nine patients received rabitt antithymocyte globulin at 6-8mg/kg. Wiht a median follow up was 27.5 months (range 2-88) four patients had relapsed 9-14 months after allo-SCT. We used four color multiparametric flow cytometry in a FACSCanto II adquiring at least 5 x105 viable (Propidium Iodide low) lymphoid gated events, stained with MnAbs: CD8-FITC and CD3PE/APC. To identify leukemia-antigen specific CD8 lymphocytes we used APC or PE conjugated class I HLA*0201 pentamers (Proimmune) against the following nonapeptides: Proteinase 1:VLQELNVTV; WT1:RMFPNAPYL and SURV:ELTLGEFLKL. Fuctional assesment of CD8+ was perfomed by intraccellular IFN- detection using 1x106 PBMCs stimulated with or without SURV, PR1 and WT1 synthetic peptides (10µg). After one hour in culture 10µg/ml breferdin A was added. As negative controls we used PE/APC labelled HLA-A-0201 negative control pentamer and as positive control we used CMVpp65/HLA-A0201. *Results.* Donor-derived CD8+ lymphocytes against PR1, WT1 and SURV were detected in periheral blood samples in 56.4%, 47.5% y 37.1% of recruited patients respectively. Median percentage of anti-PR1 was 0.051% (range:0.001-0.367% over CD3+CD8+ events), 0.03% for WT1(range:0.001-0.457%) and 0.020% for SURV(range:0.001-0.250). Detection of leukemia-antigen specific CD8+ lymphocytes was not significantly associated with clinical variables such as conditioning regimen (conventional or non-myeloablative), age donor, alloSCT source. The presence of anti-PR1 specific CD8+ lymphocytes was significantly more frequent in patients grafted with an HLA-identical sibling donor (P<0.01), and in patients not receving ATG (P=0.05). In addiction, the presence of circulating anti-SURV specific CD8+ lymphocytes was more frequently found in patients developing GVHD post-allo-SCT(P=0.043). Detection of circulating anti-PR1 and anti-SURV specific CD8+ lymphotes was associated with less mortality rate (P<0.01 and P<0.01 respectively). In the univariate analysis we found that overall survival and event free survival was significatly better in patients with anti-PR1 and anti-SURV specific circulating CD8+ lymphocytes (P<0.01 and P=0.024, respectively). *Conclusions.* Multiparametric flow cytometry is a useful tool to detect and quatify rare donor-derived CD8+ lymphocytes specific for leukemia-associated antigens as PR1, WT1 or SURV. The presence of anti-PR1 and anti-SURV specific CD8+ lymphocytes in peripheral blood is associated with a better survival and this finding could be related to an increased immunosurveillance against residual tumor cells in allo-SCT.

0440

SEQUENTIAL STRATEGY OF REDUCED-INTENSITY ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION (IDA-FLAG-MELPHALAN) FOR PATIENTS WITH PRIMARY REFRACTORY OR RELAPSED ACUTE MYELOID LEUKEMIA

M Nomdedeu, M Pratcorona, M Díaz-Beyá, M Rovira, C Martinez, F Fernández-Avilés, L Rosiñol, G Gutiérrez, E Carreras, A Urbano-Ispizua, J Esteve

Hospital Clinic, IDIBAPS, Barcelona, Spain

Background. The prognosis of patients with acute myeloid leukemia (AML) failing to frontline therapy remains poor, with allogeneic hematopoietic stem-cell transplantation (alloHSCT) arising as the only option with long-term curative potential. Nonetheless, only a minority of such patients ultimately undergo alloHSCT after salvage therapy. Sequential strategies are aimed to integrate a cytoreductive phase followed by reduced intensity conditioning in a sole procedure, in order to increase the proportion of patients who might benefit from the alloreactive graft-versus-leukemia effect. *Aim.* To compare the outcome of a series of patients with primary refractory (Ref) or relapsed (Rel) AML treated according to a sequential protocol with a group of patients receiving conventional salvage chemotherapy in a single institution. *Patients and Methods.* In 2005 we designed a sequential protocol based on a cytoreductive phase with the IDA-FLAG regimen (days -11 to -7) followed by melphalan (70 mg/m2 x days -3 & -2) for patients with Rel or Ref AML not considered candidates to a myeloablative alloHSCT, due to age >50 and/or previous transplantation. The outcome of these patients (SEQ arm) was compared with a cohort of Ref/Rel AML patients from our center consecutively treated since 1998 with a standard approach (CONV arm), consisting of 1-2 cycles of IDA-FLAG followed by alloHSCT in responding patients. *Results.* Overall, 22 patients (age: 52, 29-65; 50% male) included in the SEQ arm were compared to 51 patients (age: 48, 22-68; 53% male) treated according to CONV strategy. Within SEQ arm, a higher proportion of patients were diagnosed of secondary AML (36 vs. 8%, p=0.005), received more lines of previous therapy (≥2: 45 vs. 6%, p<0.001), and had previously undergone HSCT (41 vs. 4%, p<0.001), whereas the CONV arm contained a higher proportion of Ref AML (59 vs. 27%, p=0.013). The SEQ strategy was followed by a high immediate antileukemic response (complete response at day +30, 95 vs. 45% after CONV arm, p<.001). Of note, only 38% of patients in CONV arm finally received an alloHSCT. Among patients achieving CR after salvage therapy, cumulative incidence of relapse at 2-yr was 31% (95% CI: 15-67%) and 45% (95% CI:29-72%) in the SEQ and CONV arms, respectively. Moreover,

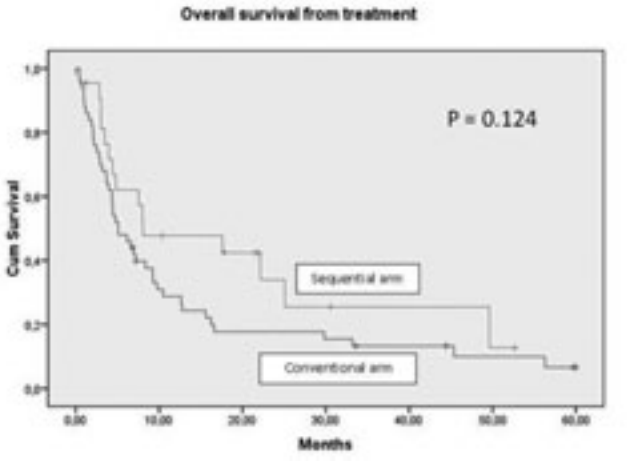

Figure 1.

non-relapse mortality (NRM) at 2-yr was 41% (95% CI: 24-71%) and 31% (95% CI:17-58%) after SEQ and CONV strategy, respectively. As a result, overall survival at 2-year after salvage therapy was 34±12% and 18±6% for patients treated according to SEQ strategy and CONV arm, respectively, without achieving statistical significance (p=0.12, see figure). *Conclusions.* Despite a remarkable antileukemic effect, the herein described sequential strategy did not result into a survival benefit over a standard salvage strategy, probably due to high non-relapse mortality. Further strategies aimed to diminish toxicity and relapse after allogeneic are warranted to improve the overall results of sequential strategies for the management of refractory and relapsed AML.

0441

HIGH DOSE THERAPY AND AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN RELAPSED/PRIMARY REFRACTORY HODGKIN LYMPHOMA PATIENTS: OUTCOME AND PROGNOSTIC FACTORS. EXPERIENCE FROM TWO GREEK CENTERS

[3]*Athens Medical Center, Athens, Greece*
[4]*University of Crete, Heraklion, Greece*
[5]*251 General Air Force Hospital, Athens, Greece*

Background. High dose therapy and autologous hematopoietic stem cell transplantation (HDT/ASCT) is considered the standard of care for patients with relapsed or primary refractory Hodgkin lymphoma (HL). *Aims.* To analyze the prognostic factors and outcome of HDT/ASCT in 142 patients with primary refractory/relapsed HL from two transplantation centers. *Methods.* 142 patients from the Department of Hematology and the 2nd Department of Propaedeutic Internal Medicine of the University of Athens were studied. Progression free survival (PFS) was calculated from ASCT to relapse/progression or death and overall survival (OS) from ASCT to death from any cause. *Results.* Median age at HDT/ASCT was 30 years (17-66) and 56% were male. At diagnosis 8%, 46%, 22% and 24% of the patients had clinical stage I, II, III and IV respectively, 43% had B symptoms, 31% bulky disease, 86% were initially treated with ABVD, while 39% received additional radiotherapy. At relapse/progression 14%, 43%, 5% and 38% of the patients had clinical stage I, II, III and IV respectively, 19% B symptoms, 10% bulky disease and 41% extranodal disease. Forty-three % of them were treated with HDT/ASCT for 1st relapse, 11% for multiple relapses and 46% for primary refractory disease. After the last salvage chemotherapy and just prior to HDT/ASCT, 33% were in complete remission, 44% in partial remission and 23% were chemorefractory. At a median follow-up of 45 months (2-173), 5-year PFS was 50%, while OS at 5 and 10 years was 81% and 72% respectively. Chemoresistance before HDT/ASCT ($p<0.0001$), bulky disease ($p<0.02$) and B symptoms at relapse ($p<0.002$) proved to be poor prognostic factors for PFS. Thus, 5 year PFS was 56% for chemosensitive patients vs 21% for chemorefractory ones, respectively. Moreover, patients who were transplanted due to multiple relapses had a better outcome compared to others ($p<0.05$). Chemoresistance ($p<0.0001$), bulky disease ($p<0.0001$) and B symptoms at relapse ($p<0.0003$) were found statistically significant for OS, as well. In addition, age ≥ 45 years proved an unfavorable prognostic parameter for OS ($p<0.01$). Multivariate analysis documented the independent prognostic value of chemosensitivity and B symptoms for PFS and OS. Age was also an independent prognostic factor for OS. *Conclusions.* HDT/ASCT may cure half of the patients with relapsed or primary refractory HL. Chemorefractory patients and those with bulky disease and B symptoms at relapse or progression have a dismal outcome.

0442

AUTOLOGOUS STEM CELL TRANSPLANTATION AS A CONSOLIDATION TREATMENT FOR MANTLE CELL LYMPHOMA

M Badior, I Carvalhais, A Carneiro, F Principe, JE Guimarães

Hospital de São João - EPE, Porto, Portugal

Background. Mantle cell lymphoma (MCL) is an aggressive subtype of B-cell non-Hodgkin lymphoma with poor prognosis and a reported median overall survival (OS) of 3 to 6 years. In an attempt to improve the prognosis of these patients, several therapeutic strategies have been tested, before and after introduction of monoclonal antibodies but there is no consensus about the choice first line therapy. However, a consistent number of studies show that high-dose chemotherapy followed by autologous stem cell transplantation (ASCT) increases relapse free survival (RFS) of MCL patients. *Aim.* To analyse retrospectively the role of ASCT (with BEAM conditioning) as consolidation for newly diagnosed MCL patients. *Materials and Methods.* We analysed 23 patients with confirmed diagnosis of MCL that have been submitted to ASCT between 1999 and 2010 in our institution. We included patients treated with different induction chemotherapy regimens. We collected data related to sex, age, stage of the disease, response to induction chemotherapy, evaluation at day +100 after transplant and RFS and OS were calculated. *Results.* Male sex was predominant (82.6%), median age was 58 years (42-67). All patients were in advanced stage disease: 91.3% in stage IV and 78.3% with leukemic expression. Eight patients were treated upfront with CHOP+/-R (x6) and 13 with Hiper-C-VAD+/-R (x4). One patient was treated with R-FC and another with FCM followed by 6x R-CHOP. Fifteen patients (65.2%) attained complete remission (CR) after the induction courses in which are included 12 of 13 patients treated with Hiper-C-VAD; eight patients only achieved partial response after induction but one of these obtained a CR after R-ESHAP. In total, 16 patients (69.6%) were in CR at the time of transplant. CR rate at day +100 after ASCT increased to 86.9%. The median RFS was 58 months and the median OS was 79 months. With a median time of follow-up of 3 years and 7 months, there are 71.4% patients alive. Of these patients, 2 have relapsed so far. There was not any transplant related mortality (TRM) in this series. *Conclusions.* Our retrospective analysis suggests that ASCT as a consolidation therapy in MCL patients is a safe, effective and well tolerated therapeutic option, in patients under 65 years. In our study, median OS and RFS of patients that were submitted to ASCT was not reached yet. Until the last follow-up, only 1 patient treated with R-Hyper-CVAD followed by ASCT relapsed. These results emphasize a role for Hyper-C-VAD induction followed by ASCT as frontline management of MCL patients.

Stem cell transplantation - Experimental & clinical

0443

PALONOSETRON + APREPITANT VERSUS GRANISETRON FOR PREVENTION OF NAUSEA AND VOMITING IN PATIENTS RECEIVING HIGH DOSE CONDITIONING CHEMOTHERAPY REGIMENS PRIOR TO STEM CELL TRANSPLANTATION (HSCT)

J López Jiménez,[1] E Martín,[1] L Vázquez,[2] R Carrión,[3] D Serrano,[3] A Bermúdez,[4] M Canales,[5] C Fernández,[6] G Fernández[7]

[1]*Hospital Ramón y Cajal, Madrid, Spain*

[3]*Hospital Gregorio Marañón, Madrid, Spain*
[4]*Hospital Marqués de Valdecilla, Santander, Spain*
[5]*Hospital La Paz, Madrid, Spain*
[6]*Hospital Clínico de San Carlos, Madrid, Spain*
[7]*Former Position MSD Medical Department, Madrid, Spain*

Background. Nausea and vomiting (CINV) in patients receiving high-dose, multiday conditioning regimens prior to stem cell transplantation is particularly common (55-100% of patients) and troublesome, especially in the delayed phase (beginning 24 hours after the start of conditioning). Newer antiemetics (palonosetron and aprepitant) appear to significantly reduce acute and delayed CINV as compared to the classic setrons; however, few studies have prospectively evaluated the efficacy of these drugs in this challenging setting. *Aims.* To assess whether palonosetron (0.25 mg iv every 48 h) administered in combination with aprepitant (125 mg on day 1 followed by 80 mg each of the remaining days) during the conditioning period (duration 5-6 days) improved control of CINV compared with daily granisetron (3 mg iv). *Methods.* This was a prospective, multicenter, randomized, stratified (by conditioning regimen), double-blind study. Patients received either BEAM (78%), BUCY (17%), or CBV/Cy-TBI (5%) as the conditioning regimen prior to HSCT. The primary efficacy endpoint was complete response (defined as no emesis and no use of rescue medication); secondary endpoints included evaluation of emesis and nausea throughout the conditioning period. Adverse events were also assessed. *Results.* Sixty consenting patients were included in the study (n = 31 palonosetron + aprepitant; n = 29 granisetron). The mean age was 39.5 ± 20 years; 50% were women; 53% were being treated for non-Hodgkin lymphoma, 27% for E. Hodgkin's and 12% for AML. 94% of HSCT were autologous. There were no between-group differences in variables that could potentially influence emesis (sex, previous chemotherapy or CINV, and regular intake of alcohol). Significantly more patients in the palonosetron + aprepitant group versus the granisetron group had a complete response during the acute (0-24h; 92.3% vs 67.9%, respectively), delayed (24-120h; 61.5% vs 28.6%) and overall (0-120h; 61.5% vs 28.6%) periods. In addition, palonosetron + aprepitant significantly reduced the proportion of patients with emesis during the acute, delayed and overall periods and showed a trend toward a reduction in percent of patients with significant nausea during the delayed period (see Table). There were no significant differences between the groups in adverse events or in the times of graft infection / severe infections. *Conclusion.* The combination of palonosetron + aprepitant was well tolerated with superior protection from nausea and vomiting compared with granisetron in patients receiving multiday highly emetogenic conditioning chemotherapy regimens prior to HSCT.

Table 1.

Efficacy Endpoints (Palonosetron + Aprepitant vs Granisetron): % of Patients						
	Acute (0-24h)		Delayed (24-120h)		Overall (0-120h)	
	P + A	G	P + A	G	P + A	G
Complete Response	92.3%*	67.9%	61.5%*	28.6%	61.5%*	28.6%

Background. Iron overload is an adverse prognostic factor in patients undergoing allogeneic hematopoietic stem cell transplantation (allo-SCT). Hepcidin, a peptide hormone produced by the liver, plays a central role in the regulation of iron homeostasis. We previously reported that elevated pre-transplant serum hepcidin levels were significantly associated with a higher incidence of early bacterial infection independent of ferritin levels (Kanda *et al.*, BBMT 2009). *Aim.* To investigate the association between pre-transplant serum hepcidin levels and clinical outcomes of allo-SCT. *Methods.* We retrospectively studied 100 patients (age, 17-64 years; median age, 48.5 years) who underwent their first allo-SCT for hematologic malignancies at our institution between July 2006 and December 2010. Written informed consent was obtained from all patients. The primary diseases were myeloid (n = 66) and lymphoid malignancies (n = 34). Serum hepcidin-25 levels prior to the administration of conditioning regimen were measured using a liquid chromatography-tandem mass spectrometry-based assay system. The primary endpoint was overall survival after allo-SCT, and the secondary endpoints were the cumulative incidence of acute and chronic graft-versus-host disease (GVHD), transplant-related mortality (TRM), and relapse. Factors evaluated in the analysis included the recipient's age, sex, diagnosis, disease status, source of stem cells, conditioning regimen, GVHD prophylaxis, serum hepcidin levels, ferritin levels, and C-reactive protein (CRP) levels. *Results.* The median hepcidin level of the patients was 29.3 ng/mL (range, 0.4-371 ng/mL; normal level, 22.2 ± 12.3 ng/mL). There was a weak correlation between hepcidin and ferritin levels (r = 0.217, $P = 0.030$). These patients were divided into 2 groups: the low-hepcidin group (<30 ng/mL, n = 50) and the high-hepcidin group (≥30 ng/mL, n = 50). Ferritin levels were higher in the high-hepcidin group than in the low-hepcidin group ($P < 0.001$). Patients in the high-hepcidin group had a significantly inferior overall survival at 2 years than those in the low-hepcidin group (49% vs. 69%, $P = 0.044$) (Figure), although the association was not significant in the multivariate analysis. Older age, high ferritin levels, and high CRP levels were significantly associated with lower overall survival rate in the multivariate analysis. A trend toward a higher incidence of grade 3-4 acute GVHD was observed in the high-hepcidin group (16% vs. 4%, $P = 0.078$). The incidences of chronic GVHD, TRM, and relapse were not different between the 2 groups. *Conclusions.* In the present study, elevated pre-transplant hepcidin levels were associated

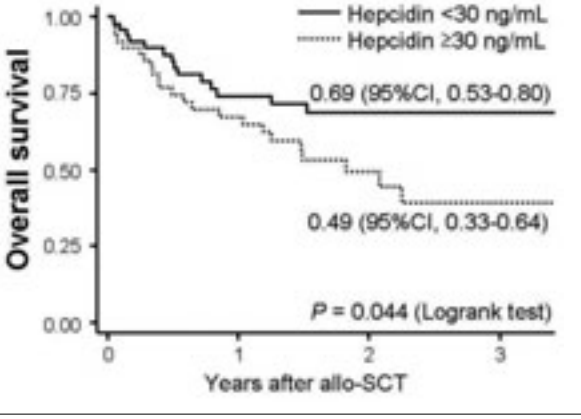

Figure 1.

with an inferior overall survival in the univariate analysis, but not in the multivariate analysis. Our data confirmed that elevated ferritin and CRP levels were strong adverse prognostic factors for survival, as many other studies have shown. In addition, we observed a tendency toward a higher incidence of grade 3-4 acute GVHD in the high-hepcidin group. Larger studies are necessary to elucidate the association between hepcidin levels and acute GVHD.

[2]*Blood Transfusion Unit, University of Padova, Padova, Italy*

Background. Acute graft-versus-host disease (aGVHD) is a major cause of morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HSCT). Glucocorticoids are the standard treatment for aGVHD. Patients who fail to respond to this first-line therapy have a poor prognosis, with high transplant-related mortality due to GVHD itself and to it's treatment complications such as opportunistic infections. Extracorporeal photopheresis (ECP) has been shown to be effective for patients with GVHD not responsive to conventional therapeutic approaches. We report our experience on ECP treatment in pediatric patients affected by aGVHD. *Aims.* To evaluate the efficacy of extracorporeal photopheresis for the treatment of steroid-refractory or steroid-dependent aGVHD in pediatric patients. *Methods.* From 1997 to 2009, 49 children (32 males, 17 females) with steroid-refractory or dependent aGVHD have been treated with ECP. Patients underwent HSCT for ALL (n=25), AML (n=15), NHL (n=4), CML (n=3) or other non-malignant diseases (n=2). The median age at ECP was 8.7 years (range: 0.95-18.7) and the median body weight was 29 Kg (range: 7-98). The stem cell sources were unrelated donors (n=32), siblings (n=11), cord blood (n=5) or haploidentical donor (n=1). The overall clinical stage of aGVHD was grade II (n= 24), grade III (n=13) and grade IV (n= 12). Cutaneous GVHD was diagnosed in 44 children, liver and gastro-intestinal tract involvement in 11 and in 43 children respectively. ECP was started after a median interval from HSCT of 42.5 days (range: 13-91) and after a median time from aGVHD onset of 28.5 days (range: 4-91). A Hickman-Broviac double-lumen central venous line was used in all patients. The median duration of treatment was 4.6 months (range: 0.5-10.2), with a median number of 10 cycles (range: 3-45). ECP was performed using the on-line technique (n=17) or using off- line technique (n=32). *Results.* 34 patients (69.4%) survived while 15 died (30.6%), due to relapse of the underlying disease (n=9), GVHD (n=3), CMV-related interstitial pneumonia (n=2) or encephalopathy (n=1). Among the 34 patients who survived, a complete, partial, or no response to ECP was seen in 79%, 0%, and 21% of patients with aGVHD II respectively, in 69%, 15% and 16% of patients with aGVHD III, and in 50%, 33% and 17% of those with GVHD IV respectively. A complete response of aGVHD manifestations of skin, gut and liver was observed in 75%, 74%, 91% of patients respectively. *Conclusions.* Our results confirm the efficacy of ECP in the treatment of steroid resistant or dependent aGVHD in pediatric patients. Moreover, for all skin, gut and liver, a good response to ECP was found.

Diamond-Blackfan anemia (DBA) is a clinically and genetically heterogeneous condition characterized by pro-apoptotic hematopoiesis, congenital anomalies and predisposition to cancer. Cord blood (CB) stem cell transplantation is becoming an effective cure for DBA patients, especially if HLA-identical sibling donors are available. In transplantation setting, in addition to Major Histocompatibility Complex antigens (HLA), minor Histocompatibility Antigens (mHAgs) may affect the outcome in terms of engraftment, rejection and Graft versus Host Disease (GvHD). In HLA-identical sibling transplantation, mHAgs mismatches can stimulate T-cell activation, leading to specific alloreactivity against donor's or recipient's antigens, consequently supporting rejection or GvHD, respectively. We considered four DBA patients and their HLA-identical (HLA-A, -B, -DRB1) CB sibling donors to investigate the role of 12 polymorphic mHAg: HA-1, HA-2, HA-3, HA-8, HB-1, ACC-1, ACC-2, CD31 (codons 125, 563 and 670), CD62L (codons 206 and 213), PANE-1, UGT2B17, SP110 (mHA Minitray kit, University Clinic Heidelberg, Germany), and HY. The patients' characteristics and the cell dose of CB grafts are shown in the table. All patients reached full chimerism, and no-one experienced graft failure. At present, they are all alive and disease-free. Considering the two directions of mHAg mismatches (GvHD: donor versus recipient; rejection: recipient versus donor), we investigated the mHAgs-mismatching-grade in all patients with respect to GvHD, neutrophil and platelet recovery times. The only patient (D) who experienced aGvHD showed no mHAg mismatches in GvHD direction, while the other ones, with no signs of aGvHD, showed at least three mismatches in GvHD direction (see the graph). Moreover, going from patient A to patient D, the mHAg-mismatching-grade increases in rejection direction, as well as platelet recovery time augments (21 to 44 days), whereas the mHAg-mismatching-grade in GvHD direction decreases. Despite this kind of sample (homogeneous for HLA-identity, non-malignant condition, conditioning regimen and GvHD prophylaxis) could be suitable to investigate the mHAg effect on CB transplantation, its size is restricted. However, we put forward a few hypotheses. Data regarding patient D seem to be in contradiction with the classical histocompatibility assumption, which predicts GvHD according to HLA disparities in GvHD direction. Moreover, patient D received Treosulfan-based conditioning regimen, which is reported to be less toxic than Busulfan. At most, Treosulfan may help to overcome the mHAg-mismatching-grade in rejection direction, as it is associated to excellent engraftment results. Therefore, trying to explain the occurrence of aGvHD in patient D, the involvement of an autologous-GvHD syndrome can be reasonably hypothesized. Recent studies in human and animal models highlighted that an autoimmune syndrome can occur after bone marrow transplantation (BMT) between identical twins, or even after autologous BMT, and this syndrome seems to be pathologically identical to the GvHD after allogeneic BMT. Autologous-GvHD is a special autoaggression syndrome which may cause the exacerbation of GvHD. Two major factors may induct an autologous-GvHD: the failure to re-establish peripheral self-tolerance and the disruption of thymic-de-

Table 1.

Characteristics of DBA patients and cell dose of cord blood grafts				
Patient	A	B	C	D
Age at transplant (years)	2.02	9.03	11.03	8
Body weight (kg)	12	36.5	32	25
Conditioning regimen	BU+TT+FLU	BU+TT+FLU	BU+TT+FLU	TT+TREO+FLU
TBI	NO	NO	NO	NO
GvHD prophylaxis	Cs-A	Cs-A	Cs-A	Cs-A
NC infused (x10e7/Kg)	10.00	2.8	3	3.2
Neutrophils recovery day	11	15	15	14

EFFICACY OF MOBILIZATION WITH PLERIXAFOR IN PATIENTS FAILING A PREVIOUS MOBILIZATION ATTEMPT AND AS FIRST-LINE MOBILIZING THERAPY IN PATIENTS AFFECTED BY MULTIPLE MYELOMA

D Laszlo, G Andreola, A Babic, C Rabascio, M Negri, G Martinelli

IEO, Milan, Italy

Peripheral blood stem cells (PBSC) represent a well established viable alternative to bone marrow as a source of hematopoietic stem and progenitor cells for autologous transplantation, a standard approach for treatment of different hematological malignancies. A dose of 2.0x10E6 CD34+cells/kg is generally considered sufficient to allow a successful engraftment after high-dose chemotherapy. Nonetheless a high fraction of patients (pts) ranging from 11 to 53% will fail mobilization of stem cells and won't be able to benefit from autologous stem cell transplantation (ASCT). Plerixafor (AMD 3100) a bicyclam antagonist of the SDF-1 alpha/CXCR4 complex, has been previously reported to improve PBSC collection in pts undergoing PBSC mobilization. From April 2009 to February 2010, a total of 13 patients affected by hematological malignancies (5 Hodgkin Lymphoma, 5 Non-Hodgking Lymphoma, 3 Multiple Myeloma) who had already failed a previous mobilizing attempt, underwent stimulation with plerixafor at a standard dose after receiving G-CSF for 4 days in order to mobilize PBSC; other 6 patients who had never been mobilized before, received the same stimulation therapy following immunomodulatory drugs containing induction chemotherapy for multiple myeloma (MM). Pts characteristics were the following: 15 were female, 4 were male, median age was 53 years (27-70); median number of previous lines of therapy was 2 (1-7) and 4 pts had received radiotherapy. Overall plerixafor administration was safe and no serious adverse events were reported. The median number of circulating CD34+ cells/μl following plerixafor was 22 (11-138). All 19 patients were able to collect the minimum required dose for ASCT in a median number of procedures of 1 (1-3); median numbers of CD34+ cells collected was 2.5x10E6/kg; notably the 6 patients affected by MM, stimulated with plerixafor upfront were able to collect in a single procedure the target CD34+ dose to be used for a tandem transplant. At the time of the analysis, 13 of the 19 pts had already undergone ASCT: 13/13 engrafted with a median time to ANC≥500/ul of 12 days and to a PLT≥20000 of 16 days. We conclude that mobilization with plerixafor is safe and effective being able to rescue patients who failed a previous mobilizing attempt and likely being an effective mobilization strategy for pts with MM who need to collect a greater number of CD34+ cells/kg for a tandem transplant.

MYELOABLATIVE CONDITIONING FOLLOWED BY UNMANIPULATED HAPLO-MISMATCHED MARROW FOR ADVANCED HEMATOLOGIC MALIGNANCIES

A Bacigalupo,[1] AM Raiola,[2] MT Van Lint[2]

[1]*Ospedale San Martino, Genova, Italy*
[2]*Divisione Ematologia, Genova, Italy*

Background. Haplomismatched marrow has been grafted successfully following a non myeloablative conditioning (NMA) and high dose cyclophosphamide (HDCY) post-transplant. HDCY is capable of preventing acute graft versus host disease (GvHD), despite the HLA mismatched haplotype (Luznick *et al*, BBMT 2008) *Aim of the study.* In this study we tested whether HDCY could also prevent aGvHD in a setting of myeloablative conditioning regimen. *Methods.* Patients were prepared with Fludarabine 50 mg/m^2/day x3, i.v. Busulfan 3.2 mg/kg/day x3; Thiotepa 5 mg/kg/dayx2. HDCY was given at 50 mg/kg day+3, day+5 Cyclosporin and mycophenolate were given from day -1. One patient was prepared with FLU-TBI. Marrow was harvested from haplo-mismatched family members according to standard procedures. *Results.* We have grafted 16 patients with leukemia beyond second remission: the diagnosis was AML (n=4), ALL (n=2), CML (n=2), lymphoma (n=3), myelofibrosis (n=1), myelodisplasia (n=3). Three patients were receiving a second allogeneic transplant. The median marrow cell dose given was 4.2x10^8/kg (range 2.7-7.8). Median day to 0.5x10^9/L neutrophils was day+20 (13-30). Two patients died of hemorrhage before day 7. Of the 14 evaluable patients all engrafted with 100% donor chimerism by day +30. Hematologic recovery was complete in all patients. GvHD was scored as grade I in 7 patients and grade II in one patient. No patients developed grade III-IV GvHD: CMV and EBV infections were not a problem in this initial series of patients. Transplant related mortality was seen in 4 patients (25%). 3 patients died of leukemia relapse. 11/16 patients survive (68%) 30-280 days post transplant. *Conclusions.* This initial series of patients suggests that (a) haplo mismatched unmanipulated marrow can be grafted after myeloablative conditioning; (b) hematologic recovery is reliable and complete (c) transplant mortality acceptable for a group of advanced patients and (d) most importantly transplants can be organized in useful time for advanced leukemia.

0449

HIGH BASELINE BAALC EXPRESSION AT DIAGNOSIS PREDICTS POOR POST TRANSPLANT OUTCOME IN PATIENTS WITH CORE BINDING FACTOR POSITIVE ACUTE MYELOID LEUKEMIA

HJ Kim,[1] SA Yahng,[1] SE Lee,[2] KS Eom,[3] JW Lee,[4] WS Min,[5] CW Park[6]

[1]*The Catholic University of Korea, Seoul, South-Korea*
[2]*Sung-Eun, Seoul, South-Korea*
[3]*Ki-Sung, Seoul, South-Korea*
[4]*Jong-Wook, Seoul, South-Korea*
[5]*Woo-Sung, Seoul, South-Korea*
[6]*Chong-Won, Seoul, South-Korea*

Background. High BAALC transcripts are associated with unfavorable outcome in newly diagnosed acute myeloid leukemia (AML) patients. *Aims.* We analyzed BAALC gene expression in patients with core binding factor (CBF) positive AML undergoing hematopoietic stem cell transplantation (HSCT) in order to assess whether this prognostic impact parallels with the post-transplantation outcome. *Methods.* Among fifty three consecutive adult patients diagnosed as CBF-AML between January 2008 and June 2010 in Catholic Blood and Marrow Transplantation Center, quantification of BAALC transcripts by real-time quantitative PCR in diagnostic bone marrow (BM) as well as assessments of FLT3, NPM1 and c-kit mutation status were performed in 41 patients. We retrospectively analyzed the treatment outcome on 31 CBF-AML patients who completed induction chemotherapy and received stem cell transplantation. *Results.* The median age at diagnosis was 45 years (range, 16-61). The median number of BAALC transcripts measured on diagnostic BM of available 41 samples were 62.293 (range, 9.587 - 497.4). All patients (n=31) achieved complete remission (CR) after 1 cycle of induction chemotherapy and remained so by the time of transplantation. The median BAALC transcript level after achieving CR reduced to 2.171(range, 0.251-31.604). At the time of transplantation after 1 or 2 courses of consolidation chemotherapy, the median transcript level was 1.1705(range, 0.291-34.174). Six patients (19%) had complex karyotype and c-kit mutation was detected in 11 patients while NPM in two patients. FLT 3 was negative in all patients. Thirteen patients (42%) received autologous stem cell transplantation while the remaining 18 patients underwent allogeneic HSCT; myeloablative and reduced intensity conditioning in 14 and 4 patients, respectively. The median follow-up duration of survivors was 12.25 months (range, 1.54-23.13). The estimated 1-year overall survival and disease-free survival of all patients were 68.7% (±10) and 65.9 % (±10), respectively. The 1-year cumulative incidence of treatment related mortality was 15.34% (±7.3) while that of relapse was 10.55% (±5.8). When the baseline BAALC transcript levels were dichotomized into high and low levels, as high level being upper third quartile, the higher level group had significant poor results in 1-year cumulative incidence of relapse.(4.3 % vs 37.5%, p-value=0.012). *Conclusions.* CBF-AML patients expressing high BAALC RNA levels at diagnosis had significantly higher risk of relapse after undergoing transplantation.

ALLOGENEIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH MULTIPLE MYELOMA AT RELAPSE: A SINGLE CENTRE EXPERIENCE

B Mohty, A Ben Aissa, A Casini, E Levrat, M Bernimoulin, M Nagy, Y Tirefort, PY Dietrich, K Samii, T Matthes, Y Chalandon

Hopital Universitaire de Geneve, Geneva, Switzerland

Background. The survival of patients with multiple myeloma (MM) has considerably improved over the past decade. Although allogeneic stem cell transplantion (allo-HSCT) may provide a curative option, its place in the therapeutic armamentarium has been very controversial.

Aims. We here report the clinical outcomes of patients with MM allografted at the Geneva University Hospital between 1988 and 2010. *Methods.* 23 patients (15 males and 7 females) were included in this retrospective analysis. Their median age at transplantation was 48 (range, 24-57) years and the median interval from diagnosis to allo-HSCT was 18 (range, 5-78) months. Sixteen (70%) patients had IgG, 3 (13%) IgD, 1 (4%) IgA and 3 (13%) light chains MM. Almost all patients (91%) were Salmon-Durie stage III and 12 patients (52%) were ISS stage III. Cytogenetics data were not available for this analysis. Most of the patients (n=18, 80%) were allografted at relapse: 11 (48%) at 1st, 4 (17%) at 2nd and 3 (13%) at 3rd relapse. The median number of chemotherapy lines prior to allo-HSCT was 2 (range, 1-4). Thirteen (56%) patients had received novel drugs and 14 (60%) had undergone an autologous transplantation prior to allo-HSCT. *Results.* Almost all patients (n=20, 87%) were transplanted with an HLA identical sibling donor. Twelve (52%) patients received a myeloablative (MAC) and 11 (48%) a reduced intensity (RIC) conditioning regimen. T-cell depletion of the graft was performed in 15 (65%) cases. At time of allo-HSCT, 9 (40%) patients were in CR/VGPR and 13 (60%) in PR/SD (1 missing). The median follow-up was 48 (range, 9-128) months. After allo-HSCT, 20 (92%) patients reached CR/VGPR. The incidence of acute grade>2 and chronic GvHD were 30% (SE + /- 20%) and 57% (SE +/- 22%), respectively. The incidence of transplant-related mortality (TRM) was 23% (SE +/- 20%). At 5 years, the progression free (PFS) and overall survival (OS) were 34% (SE +/-21%) and 59% (SE +/- 23%), respectively. We found no impact of chronic GVHD, conditioning regimen intensity, T-cell depetion and the number of prior treatment lines on PFS and OS. *Conclusion.* Although few patients were included in this study to allow a reliable estimation of clinical outcomes, our series suggest that high-risk patients may substantially benefit from allo-HSCT at relapse. Still, chronic GVHD and transplant related mortaliy remain the major limitations that likely compromise the allo-HSCT risk-benefit balance

0451

PLASMA HUMAN HERPESVIRUS 6 (HHV-6) DNA LOADS AND INTERLEUKIN-6 CONCENTRATION AS FACTORS IN THE DEVELOPMENT OF HHV-6 ENCEPHALITIS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

K Takano,[1] T Satou,[1] M Ogata,[1] J Ikewaki,[1] K Kohno,[1] Y Miyazaki,[2] E Ohtsuka,[2] Y Saburi,[2] J Kadota[1]

[1]*Oita University Faculty of Medicine, Yufu, Japan*
[2]*Oita Prefectural Hospital, Oita, Japan*

Background. Reactivation of human herpesvirus 6 (HHV-6) is associated with the development of encephalitis after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Recently, a surprisingly high incidence of HHV-6 encephalitis (5-12%) has been reported from many Japanese transplant units. Little is known about the pathogenesis of HHV-6 encephalitis. Several reports have shown that most HHV-6 encephalitis develops after an episode of pre-engraftment immune reaction or engraftment syndrome. Such findings suggest hypercytokinemia may play a role in the progression to encephalitis. *Aims.* To determine the roles of both HHV-6 and cytokines in the pathogenesis of HHV-6 encephalitis, we analyzed the kinetics of HHV-6 DNA and 17 kinds of cytokines and chemokines after allo-HSCT. *Methods.* This retrospective analysis involved 100 consecutive patients who received allo-HSCT in Oita University Hospital and Oita Prefectural Hospital. Among these, 6 patients (6%) developed HHV-6 encephalitis. HHV-6 DNA levels and concentrations of cytokines and chemokines in weekly collected plasma were evaluated until 70 days and 28 days after HSCT, respectively. HHV-6 DNA in plasma was quantified using real-time PCR and cytokine concentrations were quantified using ELISA. Measured cytokines were IL-1beta, L-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-17, G-CSF, GM-CSF, interferon-gamma, MCP-1, MIP-1beta, and TNF-alpha. All study protocols were approved by the ethics committee of the Faculty of Medicine at Oita University, and written informed consent was obtained from each patient. *Results.* According to Kaplan-Meier analysis, the cumulative rate of positive results for plasma HHV-6 DNA by day 70 was 62.7%. Conversion of HHV-6 DNA concentrated around 3-4 weeks after HSCT. Median (range) peak HHV-6 DNA levels in 6 patients with HHV-6 encephalitis and 94 patients without HHV-6 encephalitis were 104,397 copies/ml (20,647-208,614 copies/ml) and 382 copies/ml (0-417,829 copies/ml), respectively (P = 0.0004). None of the 74 patients whose peak HHV-6 DNA was <10,000 copies/ml developed HHV-6 encephalitis, while 6 of 26 patients (23%) with peak HHV-6 DNA ≥10,000 copies/ml developed HHV-6 encephalitis. Examination of plasma cytokines concentrations showed that peak concentrations of IL-6, IL-8, IL-10, IL-13, MCP-1, and MIP1beta were significantly higher in patients who developed HHV-6 encephalitis than in patients who did not. In particular, IL-6 concentration was very high in patients who developed HHV-6 encephalitis (median, 1215 pg/ml *versus* 70.1 pg/ml, P = 0.0007). None of the 68 patients whose peak IL-6 concentration was less than double the median (155 pg/ml) developed HHV-6 encephalitis, while 6 of 32 patients (19%) with peak IL-6 concentration more than double the median developed HHV-6 encephalitis. Among the 6 patients who developed HHV-6 encephalitis, central nervous system dysfunction developed concomitant to peak HHV-6 DNA in each patient. Plasma IL-6 concentration peaked 1 week before the development of HHV-6 encephalitis in 5 patients and at the time of developing HHV-6 encephalitis in 1 patient. *Discussion.* Increased IL-6 before the development of HHV-6 encephalitis suggests the involvement of increased IL-6 production in the pathogenesis of HHV-6 encephalitis. Control of inflammatory conditions before engraftment may prevent the development of HHV-6 encephalitis.

0452

AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) FOR RELAPSED OR REFRACTORY HODGKIN'S LYMPHOMA (HL): A SINGLE-CENTER EXPERIENCE

D Dujmovic, I Aurer, D Nemet, S Bašic Kinda, I Radman, D Sertic, R Serventi-Seiwerth, M Mrsic, F Šantek, S Dotlic, B Josip, B Labar

UHC Zagreb, Zagreb, Croatia

Background. Relapsing patients with HL are usually treated with intensive chemotherapy and ASCT since mid 1990s. Pretransplant cytoreductive chemotherapy regimens and supportive care changed during this period but it is not known whether this affects outcome. *Aims.* Analyze outcome of relapsing / refractory HL patients treated with ASCT in a single center between 1994 and 2010. Identify variables affecting outcome. *Methods.* Retrospective study performed by chart review. All patients received supportive care standard at the time of transplantation; pretransplant cytoreductive therapy varied, but all were conditioned using BEAM or BEAC. Areas not in CR prior to transplantation were irradiated after hematological recovery. *Results.* During this period 87 patients, 52 men and 35 women, 15-55 years old (median 30) with relapsed / refractory HL were autografted at our institution. Thirty-one were refractory, 26 in early relapse, 25 in late relapse and 5 had multiple relapses prior to transplantation. Sixty patients had nodular sclerosis, 22 mixed cellularity, 2 lymphocyte predominant HL and in 3 the type was unknown. With a median follow-up of 34 months 3-year and 5- year overall survival (OS) of the entire cohort are 78% and 66% and event-free survival (EFS) 66% and 60% respectively (Fig). HL type, response to last previous treatment (refractory vs. early relapse vs. late relapse vs. multiple relapses), pretransplant therapy (miniBEAM vs. DHAP vs. high-dose ifosfamide and mi-

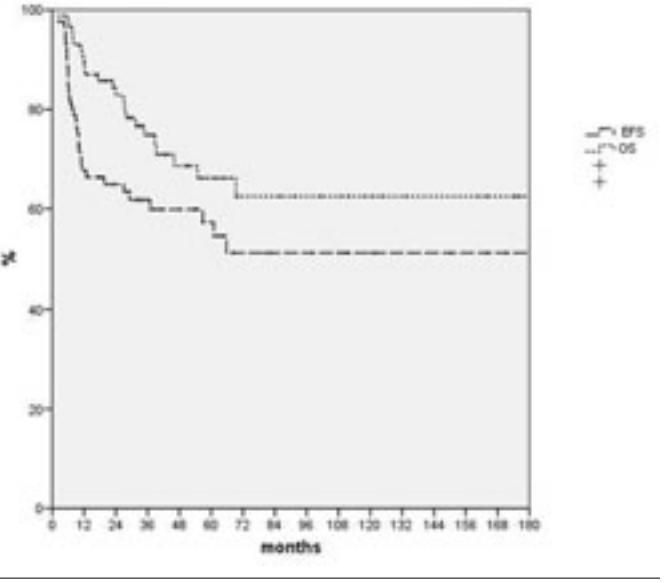

Figure 1.

toxantrone) and date of transplantation did not affect outcome. Older age at transplantation was a negative prognostic factor for OS but not EFS. The only statistically significant prognostic factor that we were able to identify was response to pretransplant cytoreductive therapy. In the group transplanted in CR, 3-year OS was 87% and EFS 85%, in PR 80% and 63%, in stable disease 52% and 20% and in progressive disease 25% and 25% respectively. This difference is highly statistically significant (p<0,001, log-rank test). *Conclusions.* Outcome of autografted HL patients has not changed significantly in the last 15 years. Sixty percent of these patients remain long-term free of their cancer. In our experience, response to pretransplant cytoreductive chemotherapy is a more important prognostic factor than response to last previous treatment.

0453

GASTROINTESTINAL SYMPTOMS FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION: MYCOPHENOLATE MOFETIL OR GRAFT-VERSUS-HOST-DISEASE?

A Klijn, M de Gast, O Visser, E Barbé, J Janssen

VU University Medical Center, Amsterdam, Netherlands

Background. Gastrointestinal (GI) complications occur frequently after allogeneic stem cell transplantation (alloSCT). Difficulties in confirming a diagnosis could emerge when mycophenolate mofetil (MMF) is used as part of the GVHD prophylaxis regimen, as it may cause gastrointestinal toxicity mimicking graft-versus-host-disease (GVHD). Currently, dose reduction or even discontinuation of MMF is the only way to clarify the origin of gastrointestinal symptoms, though this could be dangerous if GVHD is the cause of symptoms. Furthermore, there may be an increased risk of graft rejection associated with premature discontinuation of MMF. *Aim.* The aim of this study is finding markers that enable to differentiate between gastrointestinal symptoms as caused either by MMF or by GVHD. This would prevent unnecessary discontinuation of MMF in patients that suffer from GI GVHD and would better guide physicians in establishing which patients may require MMF discontinuation. *Methods.* All stored gastric and colonic biopsy specimens at the department of clinical pathology, that were taken between 2004 and 2009, of patients who suffered from GI symptoms and had received MMF after allogeneic SCT were reviewed. Additionally, clinical data were retrieved by review of medical records. Biopsies were scored for apoptosis, crypt cell destruction, inflammation of the lamina propria and denudation of the mucosal wall. Together these parameters constituted the histological grade of gastrointestinal damage. Clinical features contained clinical grade of GVHD, temporal relations between start of MMF and occurrence of symptoms, the effect of interruption of MMF and the final clinical diagnosis. *Results.* Biopsies of 54 patients were available. In 16 patients (29,6%) the gastrointestinal symptoms were assigned to MMF, in 34 patients (63%) to GVHD and in four patients (7,4%) to infection. Based on a 7-level scale scoring epithelial apoptosis (no apoptosis=0, none-minor=1, minor=2, minor-intermediate=3, intermediate=4, minor-severe=5, intermediate-severe=6 and severe=7) the mean score (SD) in the MMF group was 3,31 (1,78) and in the GVHD group 4,47 (1,88). This difference was statistically significant (p=0,047). No other significant differences were revealed by review of the histological specimens. *Summary/conclusions.* In almost 30% of patients who had histological evidence of gastrointestinal damage, the symptoms were designated as MMF-induced. Histological differentiation between gastrointestinal toxicity due to either MMF or GVHD may be supported by scoring the grade of epithelial apoptosis, which could therefore be important in deciding whether to stop MMF or not.

BK-RELATED HAEMORRHAGIC CYSTITIS IN ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANT: A SINGLE CENTER EXPERIENCE

A Rivera Ginés, R Ríos Tamayo, F López Jiménez, E López Fernández, A Romero Aguilar, M Jurado Chacón

University Hospital "Virgen de las Nieves", Granada, Spain

Background. Haemorrhagic cystitis (HC) is considered a primary manifestation of BK virus (BKV) infection in patients undergoing allogeneic haematopoietic stem cell transplantation (allo-SCT). Roughly 50-100 % of all allo-SCT recipients develop BK viruria, while only 5-40 % progress to HC, which is associated with significant morbidity and mortality. *Aims.* To evaluate the incidence, associated risk factors and clinical impact of HC in a single centre series during a three-year period (2008-2010). *Methods.* All consecutive Allo-SCT performed at our unit during the period of study were evaluated prospectively for HC. All patients received the same graft-versus-host-disease (GVHD) prophylaxis. BK viruria and BK virus load in plasma were systematically recorded, along with a set of clinical variables: age, sex, underlying diagnosis, type of donor, source of stem cells, conditioning regimen, presence of symptoms, grade of GVHD, HIV status and absolute neutrophil count. Samples of urine and plasma were tested for BKV by PCR. Kaplan-Meier method was used for survival analysis, and log-tank test for differences in overall survival (OS). Statistical analysis were performed with SPSS v 15.0 package. *Results.* 37 patients had an allo-SCT during the period of study, four of them were HIV positive. The median age was 41 (17-63), 24 men (64.9 %) and 13 women (35.1 %). 13 patients (35.1 %) developed HC between 4 and 115 days after allo-SCT: 10 of 24 men (41.6 %) and 3 of 13 women (23 %); only one of the 13 HC patients was HIV positive; 3 of 5 (60%) had grade ≥3 and 10 of 32 (31.2%) ≤ 2 GVHD; 3 of 14 (21.4 %) and 10 of 23 (43.5 %) had a related o unrelated donor, respectively. 4 patients had only dysuria while 20 patients had no genitourinary symptons. A significative BK viruria presented in 10/20 (50 %) in asymptomatic group, 3 of 4 (75 %) in de group of dysuria and 12 of 13 (92.3 %) in the HC group. Median survival (see figure 1) was 12.3 months (2.7-21.8) and 8.2 (1.9-14.5) in the non-HC and HC groups, respectively (p=0.113). *Conclusions.* HC is a serious and frequent event in the Allo-SCT setting. We confirm a tendency to HC in patients with unrelated donors and severe GVHD. Every effort should be made to minimize this complication in order to improve transplant-related mortality.

Background. Acute Graft Versus Host Disease (aGVHD) is one of the major causes of morbidity and mortality in the first 100 days after Allogeneic Hematopoietic Stem Cell Transplantation (HSCT). It can occur, despite aggressive immunosuppressive prophylaxis, even when the donor is a "perfectly"matched (HLA-identical) sibling, suggesting that the risk of developing this complication does not only depend on HLA matching. Many recent studies have reported the association between inflammatory cytokine gene polymorphisms and the occurrence of aGVHD in transplanted adults, but few data are available about the pediatric population. *Aims.* The aim of this study is to analyze the association between a wide panel of inflammatory gene polymorphisms and the occurrence of aGVHD in a setting of pediatric HSCT from HLA-

GVHD: graft-versus-host disease; MTX: methotrexate; CsA: cyclosporine A; ATG: anti-thymocyte globulin; TCD: T-cell depletion; ALL: acute lymphoblastic leukemia; AML: acute myeloid leukemia; SAA: severe aplastic anemia; NBL: neuroblastoma; NHL: non-hodgkin lymphoma; ES: Ewing sarcoma; RMS: rhabdomyosarcoma; HL: hodgkin lymphoma; MDS: myelodisplastic syndrome; JMML: juvenile myelomonocytic leukemia; HLH: hemophagocytic lymphohistiocytosis; WT: Wilms tumour; MFD: matched family donor; MUD: matched unrelated donor; MMD: mismatched donor.

matched family and unrelated donors (MFD and MUD). *Methods.* The study population consisted of 136 children who underwent HSCT at the Pediatric Hematology-Oncology of the Bologna University between 1995 and 2010 and their respective donors. Patient (pts) and donors characteristics are resumed in Table 1. Genotypes of 38 single nucleotide polymorphisms (SNPs) in 19 immunoregulatory genes known to be related to GVHD onset risk (ESR1, FAS, FCGR2A, IL1A, IL1B, IL2, IL6, IL10, IL10RB, IL18, MBL2, MTHFR, NOD2, TGFB1, TGFBR2, TLR4, TNF, TNFRSF1B and VDR) were determined by the Sequenom MassARRAY system. Results were checked for Hardy Weinberg equilibrium and filtered to exclude SNPs with minor allele frequency < 0.15. Association with aGVHD was analysed in a case-control study format by Chi-square statistics, with OR ±95%CI estimation, using SNPator package (http://www.snpator.org). *Results.* aGVHD (grade I-IV) was observed in 17/44 (38%) pts and 53/92 (57%) receiving a MFD and a MUD respectively. In the whole cohort of pts we found statistically significant associations between recipient IL10 592A and 819T single nucleotide polymorphisms (SNPs) (P=0.02, OR 2.1, CI: 1.10-4.08) and donor TNF +488C (P=0.03, OR 1.86, CI: 1.03-3.37) with grade I-IV aGVHD. The same association between recipient -592A and -819T polymorphisms of the IL10 gene was confirmed even in the sole MFD cohort (P=0.04, OR 2.94, CI: 1.01-8.57). In this latter cohort also donor -889C SNP of IL1A was associated with aGVHD grade I-IV (P=0.04, OR 2.76, CI: 1.03-7.40). Regarding the MUD cohort, a statistically significant association with grade I-IV aGVHD was observed for donor IL1B 3954T and donor and recipient TNF+488C and -857C (P=0.01, OR 3.03, CI: 1.25-7.36; P=0.003, OR 3.29, CI: 1.45-7.49; P=0.01, OR 2.87, CI: 1.23-6.66, respectively). *Conclusions.* Polymorphisms in genes of clear importance in the regulation of the inflammatory response such as TNF, IL1A, IL1B and IL10 play a crucial role in the risk of developing aGVHD in the pediatric population. In particular in the setting of HSCT from MFD, where a perfect high resolution HLA-matching is warranty, IL10 gene SNPs in the recipient can predispose to the risk of developing aGVHD.

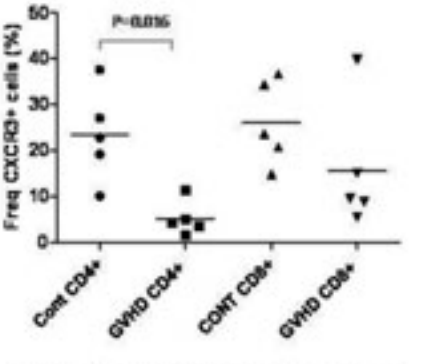
CXCL10 CONTRIBUTES TO THE PATHOGENESIS OF CHRONIC SKIN GVHD BY RECRUITING CXCR3+ T CELLS

J Croudace,[1] R Malladi,[2] S Nagra,[2] C Craddock,[2] P Moss[3]

[1]*University of Birmingham, Birmingham, United Kingdom*
[2]*Centre for Clinical Haematology, Queen Elizabeth Hospital, Birmingham, United Kingdom*
[3]*School of Cancer Sciences, University of Birmingham, Birmingham, United Kingdom*

Background. Chronic Graft versus host disease (cGVHD) remains a major cause of morbidity and mortality following allogeneic stem cell transplantation (SCT), affects up to 60% of patients who survive 100 days post transplant and significantly impacts upon quality of life. Novel therapies for the treatment of cGVHD are required. The chemokine-receptor axis represents an important mechanism by which lymphocytes traffic to target organs and we therefore wished to explore this pathway in the pathogenesis of chronic GVHD. *Aims.* The study aimed to identify key chemokines associated with the pathogenesis of tissue-specific cGVHD post allogeneic SCT and to determine whether they represent potential therapeutic targets. *Methods.* Patients were recruited onto the study following informed consent prior to undergoing allogeneic SCT. Peripheral blood samples were taken both pre and post transplantation. Additional blood and fresh skin biopsy samples were also received at the time of skin cGVHD. A panel of cytokines and chemokines were analysed by luminex technology in the serum of patients at the time of chronic disease (n=40), and compared to those who did not develop clinical evidence of chronic GVHD (n=18). Equal proportions of patients who underwent sibling and MUD allografts, and who underwent myeloablative and nonmyeloablative allografts were included. Patients included in the cohort had evidence of cGVHD of tissues including the skin, gut, liver, oral and ocular mucosa and the lungs. In addition chemokine receptor expression was then assessed in both the peripheral blood and tissues using 9 colour flow cytometry and immunohistochemistry. *Results.* The CXCR3 specific chemokines CXCL9, 10 and 11 were found to be significantly associated with chronic GVHD of the oral mucosa, skin and eye, and with pulmonary cGVHD respectively, being elevated in the serum of patients at the time of cGVHD. In particular CXCL10 was elevated from approximately 170pg/ml to 350pg/ml in both skin and ocular disease ($p<0.05$). CD4+ CXCR3+ T cells were reduced in the peripheral blood of patients with skin disease from approximately 23% of CD4+ T cells in control patients to just 5% in patients with skin cGVHD (p=0.02, n=5). Levels of both CD4+ and CXCR3+ T cells were also elevated in the skin of patients with cGVHD with CD4+ cells being increased from approximately 16% (n=7) of the T cell population to 38% (n=8) and CXCR3+ cells from 50% to 63% of the T cell population. The nature of conditioning and transplant did not appear to affect the levels of CXCL10 in the serum of patients post 100 days post SCT, and regulatory T cell populations in the peripheral blood expressing



A role for CXCL10/CXCR3 in chronic GVHD pathogenesis; Reduced peripheral blood frequencies of CD4+ CXCR3+ T cells as identified by flow cytometry in patients with chronic skin GVHD compared to patients post SCT without cGVHD.

Figure 1.

CXCR3 were not significantly reduced. *Summary/Conclusions.* The data suggests that CXCL9-11 are associated with cGVHD, and that elevated levels of CXCL10 may result in the migration of effector T cell populations from the blood to the skin where they can cause tissue damage. CXCL10 thus represents a specific chemokine which could be targeted to both prevent or treat the symptoms of cGVHD of the skin.

[4]*Experimental Pathology Dept. University of Bologna, Bologna, Italy*

Background. Busulfan is the most widely used drug for allogeneic conditioning regimens. Busulfan metabolism depends on liver glutathion (GSH) availability. A number of loci controls liver GSH synthesis and consumption, occurring during drug conjugation and oxidative stress response. *Aims.*The impact of polymorphisms at loci involved in GSH balancing on overall survival (OS) and transplant related mortality (TRM) was tested. *Methods.* Here we report on a study population of 331 consecutive patients who received an allogeneic HSCT for haematological malignancies at Institute of Hematology "Seràgnoli"from 2004 onwards. 185 patients received busulfan in the conditioning regimen, mostly at myeloablative intensity, while 146 received a TBI based regimen or a reduced intensity conditioning regimen non busulfan-based; clinical variables were similarly distributed in the two groups. A total of 35 polymorphisms (32 SNPs and 3 insertion/deletions) at 15 candidate genes were analysed by high throughput mass array Sequenom TM platform or by DHPLC. *Results.* We found that a C to G rs2180314 SNP at Glutahione Transferase A2 (GSTA2) locus (Codon 112 which leads to a Ser to Thr aminoacidic transition) impacts OS and TRM in the whole population (CC vs G-carriers: HR=1.604, 95%CI=1.081-2.381, p=0.019 for OS and HR=1.992, 95%CI=1.100-3.609, p=0.023 for TRM). Such an effect was particularly evident in patients who received busulfan (CC vs G-carriers: HR=2.438, 95%CI=1.446-4.108, p=0.0008 for OS and HR=4.580, 95%CI=2.005-10.461, p=0.0003 for TRM). No effect was present in the group not receiving busulfan. The polymorphism at microsomial GST-1 promoter (rs7970208) also affects OS and TRM, although to a lesser extent (AA vs G-carriers: HR=1.405, 95%CI=1.076-1.835, p=0.012 for TRM and HR=1.255, 95%CI =1.050-1.499, p=0.012 for OS). *Summary/Conclusions.* These data point out that genetic variability at loci controlling GSH balancing may affect allogeneic HSCT outcome in busulfan treated patients. These data could be validated on patients populations belonging to controlled clinical trials with the aim to predict toxicity after allogeneic HSCT.

GPI-ANCHOR NEGATIVE MEMORY T CELLS IN PATIENTS AFTER ALEMTUZUMAB-MEDIATED T-CELL DEPLETED HEMATOPOIETIC STEM CELL TRANSPLANTATION

EM Wagner, C Götze, A Lay, M Sommer, M Theobald, W Herr, R Meyer

University Medical Center of the Johannes Gutenberg-University, Mainz, Germany

The anti-CD52 antibody is frequently used in allogeneic hematopoietic stem cell transplantation (HSCT) for *in vivo* T cell depletion (TCD). We have recently shown that CD52 negative donor T-cells reconstitute in patients after HSCT following alemtuzumab-mediated TCD. These T cells persist for years in the peripheral blood. We have also demonstrated that the application of donor lymphocyte infusion (DLI) has the capacity to replenish the CD52-positive T cell compartment. By staining with a fluorescent aerolysin, we have demonstrated that the lack of CD52 expression originates from a loss of glycosyl-phosphatidyl-inositol (GPI) anchors in the T-cell membrane. GPI-anchor negative T cells revealed an altered antigen specific function compared to GPI-anchor positive T cells: They secreted less IFN gamma in response to CMV peptides and allogeneic stimuli. They also showed a decreased lytic response and proliferative capacity. We further stained peripheral blood T-cells from 12 patients of different age with the surface markers CD45RA, CD45RO, CD62L and CCR7 to differentiate memory and naïve CD4 and CD8 T cells. Early after transplantation, the T cells were only of memory phenotype reflecting the proliferation of graft-derived memory T cells. The expression of CD45RO, CD62L or CCR7 did not differ between GPI-anchor positive and negative T cell subpopulations. In many patients, we detected CD45RA-positive naïve T cells later after transplantation even though the time of reconstituting naïve T cells strongly differed between individual patients. The newly reconstituting naïve T cells were always GPI-anchor positive. At the same time, GPI-anchor negative cells were still present among memory T cells. Our data promote the hypothesis, that graft derived GPI-anchor negative memory T cells persist and proliferate in patients following alemtuzumab-mediated T-cell depletion in the context of allogeneic HSCT. The GPI-anchor negative T cells present with an altered antigen specific T cell function. We hypothesize that naturally occurring GPI-anchor negative T cell sub-populations expand under the selective pressure of the anti-CD52 antibody alemtuzumab. These T cells persist for years by homeostatic proliferation. In those patients, were naïve T cells reconstitute from the stem cell compartment, the new naïve T cells are GPI-anchor positive. Since GPI-anchor negative T cells are functionally altered, prophylactic DLI application might help to bridge the state of impaired T cell function through provision of GPI-anchor positive memory T cells.

GENETIC VARIABILITY IN INNATE IMMUNE GENES (NLRP2, NLRP3, TGFB1) IMPACT THE ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) CLINICAL OUTCOME AND INFLUENCE THE INFLAMMATORY CYTOKINE PROFILE PRODUCTION

B Martin,[1] D Rodriguez,[1] D Romero,[1] M Suarez-Lledo,[1] G Gutierrez,[1] F Fernández,[1] C Martinez,[1] M Rovira,[1] R Cardesa,[2] I Espigado,[2] M Carmona,[2] A Urbano-Ispizua[1]

[1]*Hospital Clinic/IDIBAPS, Barcelona, Spain*
[2]*Hospital Universitario Virgen del Rocio, Seville, Spain*

Background. Graft versus leukemia effect (GvL) is the main advantage in the allogeneic stem cell transplantation (allo-SCT) setting. However in spite of this, the inflammatory response due to the conditioning regimen and the graft versus host disease (GvHD) are responsible for the transplant related mortality (TRM) incidence. Previous results by our group have shown variants of innate immune genes associated with GVHD, with the incidence of leukemic relapse, and with TRM after allo-SCT. We speculated that the effect of these polymorphisms of innate immune genes was due to an influence on the inflammatory cytokine profile production. *Aims.* To determine the inflammatory cytokine profile in healthy individuals harbouring single nucleotide polymorphisms (SNPs) in genes involved in innate immunity (*NLRP3*, *NLRP2*, *TGFB1*, *IRF3*) which were previously associated with the incidence of relapse, TRM and chronic GvHD in a series of HLA-identical sibling allo-SCT (n=198). *Methods.* Study population for the functional studies consisted of 120 healthy donors. Peripheral blood (PB) was stimulated with phytohaemagglutinin (PHA), incubated overnight at 37°C, and serum was collected by centrifugation 15 min at 2,500 RCF. ELISA was performed to determine the IFN-γ production, whereas IFN-α, IL12, IL13, IL15 and IL17 production were determined using the Human Cytokine II 5-Plex (Invitrogen). *Results.* CC recessive gene variant in rs10925027 in donor in *NLRP3*, associated with lower relapse incidence, was responsible for higher IFN-γ (103 *vs* 171 pg/mL, p=0.029) and lower IL12 (52 *vs* 89 pg/mL, p=0.05) production in healthy individuals. GG dominant variant in rs1043684 in donor in *NLRP2*, associated with higher TRM, was responsible for higher IL12, IL-13 and IL17 production in healthy donors (85 *vs* 88 *vs* 47 pg/mL, p=0.04; 128 *vs* 72 *vs* 43 pg/mL, p=0.038; and 84 *vs* 60 *vs* 47 pg/mL, p=0.04, respectively). Finally, GG recessive gene variant in rs2282790 in donor in *TGFB1*, associated with higher incidence of cGvHD, was responsible for higher IFN-γ production (116 *vs* 116 *vs* 131 pg/mL, p=0.049). *Conclusions.* SNPs in rs1043684 in *NLRP2*, causing high levels of inflammatory cytokines correlate with higher TRM, whereas SNPs in rs10925027 in *NLRP3* and in rs2282790 in *TGFB1* causing high levels of IFN-γ correlate with lower relapse and higher cGVHD incidence. These gene variants could be used as predictors of development of cGVHD and inflammatory complications after allo-SCT.

0460

THE ROLE OF HISTONE DEACETYLASE INHIBITORS IN HEMATOPOIETIC STEM CELL EXPANSION

R van Os, M Walasek, S Olthof, A Dethmers-Ausema, M Ritsema, G de Haan

University Medical Center Groningen, Groningen, Netherlands

Histone deacetylase inhibitors (HDIs) are a new class of potential anticancer agents that are also active against leukemic cell lines and primary leukemia cells. The list of this class of drugs is growing and several are now in phase I/II clinical trials. Although the mechanism of action of HDIs on cancer cells may include enhancement of apoptosis, induction of cell cycle arrest and promotion of cellular differentiation, the exact mechanism is not known. Interestingly, researchers have found that in *ex vivo* expansion cultures addition of HDIs to the cultures delayed differentiation and enhanced stem cell numbers. Therefore, we investigated the effect of HDIs and other small molecules on normal hematopoietic stem cells in expansion cultures. To study this, we used a differentiation model where murine Lin-Sca-1+c-kit+ (LSK) cells are forced to differentiate in response to SCF and GM-CSF. It was found that Valproic Acid (VPA), together with LiCl, delayed hematopoietic stem cell (HSC) differentiation. Morphology and several *in vitro* and *in vivo* assays suggested that VPA and LiCl synergistically delayed or prevented differentiation and this was found also on the level of gene expression. Li did not significantly change gene expression during 7 days of culture, VPA affected expression of approximately 100 genes and the combination lead to altered expression of more than 300 genes. The transcriptional program associated with multilineage differentiation has been affected. Moreover, the combination of VPA and Li enhanced the expression of multipotency- associated genes but reduced the expression of differentiation- associated genes. Our preliminary data also suggest that VPA delayed myeloid and lymphoid differentiation, whereas it enhanced erythroid differentiation. We further investigated whether other HDIs were able to modulate GM-CSF-induced differentiation. Therefore, we have chosen 6 different HDIs, VPA, sodium butyrate, trichostatin A (TSA), suberoylanilide hydroxamic acid (SAHA), MS-275 and apicidin and compared their effects. All HDIs influenced cell growth, stem cell phenotype and delayed stem cell differentiation in a dose-dependent manner. Strikingly, expression of the mouse stem cell antigen (Sca)-1 could be upregulated by HDIs and this correlated with an increase in progenitor cell function. Progenitor cells were found to be an important target cell for HDI action because they increased their proliferative capacity in colony and single cell assays. This research implies that HDIs may be used to improve HSC expansion protocols by delaying differentiation and enhancing the potency of hematopoietic progenitors.

REGULATORY T CELLS USE AN IL-10 INDEPENDENT, CAMP DEPENDENT PATHWAY TO SUPPRESS GRAFT-VERSUS-HOST DISEASE

M Weber,[1] C Lupp,[1] P Stein,[1] T Bopp,[1] T Wehler,[2] E Schmitt,[1] H Schild,[1] M Radsak[2]

[1]*Johannes Gutenberg-University Medical Center, Mainz, Germany*
[2]*Johannes Gutenberg-University Medical Center III. Dept. Medicine, Mainz, Germany*

Allogenic hematopoetic stem cell transplantation (HSCT) is a common curative treatment option for many hematological malignancies. Graft-versus-host disease (GvHD) is a significant contributor to morbidity and mortality after HSCT. A possibility to control GvHD is the use of regulatory FoxP3+ CD4+ T cells (Treg) which are able to suppress conventional T cell activation. We used an acute MHC mismatch mouse model to analyze Treg dependent mechanisms of GvHD amelioration transplanting BALB/c recipients with bone marrow and CD90.2+ T cells from C57BL/6 donors. The resulting severe GvHD was strongly attenuated by cotransfer of donor Treg cells. By *in vivo* studies with IL-10-/- donor and recipient mice we show an important role for IL-10 in moderating GvHD. Following *in vitro* studies adressing the suppressive mechanisms used by Treg reveal that this suppression occurs independent of Treg derived IL-10. In this case Treg cells utilize gap junction intercellular communication (GJIC) to suppress allogenic dendritic cell activation. Inhibition of the cAMP degradating enzyme phosphodiesterase 4 (PDE4) by the drug Rolipram leads to enhanced suppressive capacities of Treg cells suggesting an important role for cyclic adenosine monophosphate (cAMP). In conclusion, we demonstrate important yet distinct roles for IL-10 and Treg cells in suppressing GvHD: Treg mediated suppression of GvHD is IL-10 independent, but contact dependent and can be modulated by drugs modulating cAMP metabolism. Our results may provide the basis for an advanced understanding of the role Treg cells play and pave the way for combined cellular and drug therapies to overcome current limitations of allogenic HSCT. THE PHENOTYPICALLY NAIVE T CELL SUBSET OF HEALTHY DONORS CAN BE USED TO EXPAND ACUTE MYELOID LEUKEMIA-REACTIVE CD4+ T CELLS IN VITRO

Y Eichinger,[1] E Distler,[2] E Schnürer,[2] M Theobald,[2] W Herr[2]

[1]*University Medical Center of Johannes Gutenberg-University Mainz, Mainz, Germany*
[2]*University Medical Center of Johannes Gutenberg-University, Mainz, Germany*

Background. In allogeneic hematopoietic stem cell transplantation (allo-HSCT), donor-derived T lymphocytes recognize leukemia-associated and minor histocompatibility antigens (mHag) on recipient leukemia cells, thereby mediating the graft-versus-leukemia (GvL) effect. Here, previous research has mainly focused on CD8+ cytotoxic T cells as GvL effectors. Other studies have demonstrated that CD4+ T cells are not only required to provide help for CD8 responses, but can exhibit direct cytolytic reactivity against leukemia cells. Furthermore, leukemia-reactive CD4+ T cells have been isolated from allo-HSCT patients upon GvL responses, and were successfully used to identify HLA class II-restricted mHag. *Aim.* We aimed at extending our recently developed protocol for CD8+ T cells (Distler *et al*., Exp Hematol 2008; Albrecht *et al*., Cancer Immunol Immmunother 2011) to the *in vitro* generation and expansion of acute myeloid leukemia (AML)-reactive CD4+ T cells from the naive donor T cell repertoire. *Methods.* Naive CD4+ T cells were isolated from PBMC of healthy donors either immunomagnetically (Naive CD4 T Cell Isolation Kit, Miltenyi Biotec) or by FACS sorting according to expression of CD45RA. T cells were stimulated in 96-well mini-mixed lymphocyte-leukemia cultures ("mini"-MLLC) with HLA-DR and -DQ matched irradiated AML blasts isolated from patients at initial diagnosis. AML blasts were pre-cultured overnight in medium only, or for 4 days in medium supplemented with IL-4, GM-CSF, SCF and TNF-α to improve the antigen-presenting cell phenotype. After 2 weekly re-stimulations with AML blasts, mini-MLLCs were screened in split-well IFN-γ ELISpot assays for reactivity against stimulator cells. Leukemia-reactive populations were expanded by further re-stimulations with AML blasts and were characterized for cytokine production, HLA restriction, cytolytic activity, and T cell receptor (TCR) Vβ chain usage. *Results.* In 2 out of 3 AML patient/donor pairs with full HLA-DR and -DQ match several CD4+ T cell populations with strong and persistent AML reactivity could be expanded to cell numbers exceeding >108. Reactivity of these T cells was restricted by HLA-DR, -DQ or -DP alleles as determined by using specific HLA blocking antibodies in IFN-γ ELISpot assays. Since HLA-DP was not yet typed, we cannot exclude allo-HLA-DP mismatch reactivity for HLA-DP-restricted T cell populations. T cells recognized either solely AML blasts, or also EBV-transformed B cells of patient origin in IFN- ELISpot assays. Donor-derived EBV-B cells or K562 cells were not recognized. Chromium-release assays showed that CD4+ T cells lysed primary AML blasts only at moderate levels. Leukemia-reactive CD4+ T cell populations expressed either TCRs with Vβ chains of a single family, indicating clonality, or were oligoclonal with up to 4 different TCR Vβ chains. *Summary/Conclusions.* We show herein that leukemia-reactive CD4+ T cells can be readily isolated and expanded from naive precursors of HLA class II-matched healthy individuals by *in vitro* stimulations with primary AML blasts. Our current effort is to optimize the protocol in further patient/donor combinations. We also plan to investigate the *in vivo* behavior of AML-reactive CD4+ T cells in immunodeficient NOD/SCID-IL2R (null) mice. Moreover, well-expanded leukemia-reactive CD4+ T cell clones can be used to identify potential target antigens for AML immunotherapy.

COMBINATION CELL THERAPY OF EX-VIVO EXPANDED REGULATORY T CELLS AND HUMAN ADIPOSE TISSUE-DERIVED MSCS EFFECTIVELY INHIBITS ACUTE GRAFT-VERSUS-HOST DISEASE IN MURINE MODEL

SG Cho,[1] JY Lim,[2] E Jeon,[2] HS Park,[2] MJ Park,[2] GI Lim,[2] ML Cho,[2] SW Yang,[3] SE Lee,[3] JW Park[3]

[3]*The Catholic University of Korea, Seoul, South-Korea*

Background. Graft-versus-host disease (GVHD) remains the major barrier to the success of allogeneic hematopoietic stem cell transplantation (HSCT). The immunomodulatory effects of MSCs have been proposed as a promising treatment for acute GVHD as well as experimental encephalomyelitis and diabetes. However, the specific mechanisms involved in the immunoregulatory activity of MSCs remain unknown. Although the therapeutic effects of MSCs have varied in preclinical models those were closely related to the involvement of CD4+CD25+Foxp3+ regulatory T cells (Tregs) regardless of antigen specificity. Our previous study showed a negative effect of single infusion of MSCs on a murine model of collagen-induced arthritis (CIA) because MSCs alone did not prevent proinflammatory cytokines. Therefore, the combination cell therapy of *ex-vivo* expanded Tregs and MSCs may be expected synergistically to inhibit acute GVHD in allogeneic HSCT. *Aims.* The present study is aimed to evaluate the therapeutic efficacy of combination cell therapy of *ex-vivo* expanded regulatory T cells and human adipose tissue-derived mesenchymal stem cells (hAd-MSCs) to prevent acute GVHD in murine model. *Methods.* To obtain Treg cells, isolated CD4+ T cells from recipients (BALB/c) were cultured with anti-CD3 (1 ug/ml), anti-CD28 (1 ug/ml), human recombinant transforming growth factor (5 ng/ml) and all-trans retinal (1 uM) for 3 days. In murine models of GVHD, lethally irradiated BALB/c mice are transplanted C57BL/6 BM cells on day 0. Following transplantation, recipients after given once a week 4 times combination of hAd-MSCs (RNLBIO, Seoul, Korea) and Tregs or a single hAd-MSCs injection. All animals were monitored for survival and clinical signs of GVHD. *Results.* The results showed that combination cell therapy of hAd-MSCs and Tregs can act remarkably protected recipients from lethal GVHD and prevented severe tissue damage after allogeneic BM transplantation. A single infusion of hAd-MSCs was less effective than those in preventing GVHD. These therapeutic effects were associated with an increase of Th2 and Tregs for suppressive effect against activated T cells, and decrease of Th1 and Th17 cells. *Conclusions.* These data indicate that combination cell therapy of *ex-vivo* expanded regulatory T cells and hAd-MSCs effectively inhibits acute graft-versus-host disease in murine model. In addition, the results of the ongoing clinical trials will properly assess the therapeutic potential of hAd-MSCs and Tregs.

Background. Multiple myeloma (MM) is characterised by accumulation of malignant plasma cells (PC) in the bone marrow (BM). Although it is well established that acquired genetic events in co-operation with the tumour microenvironment activate proliferation and survival pathways thus driving tumour growth, the identity and functional properties of the myeloma propagating cells have been a matter of controversy. *Aims.* To establish the phenotypic diversity in MM and study its functional and clinical significance *ex vivo* and *in vivo*. *Methods.* Multicolour flow-cytometric analysis and sorting were performed on BM and peripheral blood samples using LSRFortessa and FACSAriaII sorter respectively. Clonotypic cells, bearing the patient-specific IgH CDR3 area were quantified within sorted cellular compartments using a highly sensitive genomic DNA Taqman qPCR. Flow-cytometry cell cycle analysis was performed after DAPI staining, while transcription factor mRNA levels were measured by qPCR. For *in vivo* assays, 8-10-week old NOD/SCID/IL-2Rγ-/- (NSG) mice were transplanted with highly purified primary myeloma cell populations. *Results.* Using flow-sorting combined with IgH CDR3 qPCR in a cohort of 30 patients, we established that the immunophenotypic diversity of the clonotypic fractions in MM comprises a hierarchy of at least 5 different populations that display incremental frequency and follow normal late B cell development: CD19+CD27+/-IgD-CD38-CD138- resting memory B cells, CD19+CD27+/-IgD-CD319+CD38++CD138- plasmablasts (PB), a novel CD19-CD38+CD56+CD319+CD138- fraction we termed pre-plasma cells (PPC), and CD19-CD56+CD38+CD319+CD138low and CD138hi PC. Although these clonotypic fractions are morphologically diverse with PPC resembling small lymphocytes, they all share the same oncogenic chromosomal aberrancies that define malignant PC. To test their tumour-propagating potential, highly purified CD138hi PC and PPC were transferred to NSG mice. Both fractions engrafted in the BM and, remarkably, both recapitulated the original, patient BM CD19- hierarchy of CD138low and CD138hi PC as well as PPC suggesting that PC and PPC represent two dynamic and interchangeable phenotypic states of the same cell. Strikingly, engraftment in the spleen and liver of NSG mice preferentially comprised PPC suggesting the presence of a specialised PPC niche in 2o lymphoid organs. These differences were also underpinned by absent or very low expression of Pax-5 mRNA in CD138low/hi PC but its higher expression in PPC and the extramedullary clonotypic fractions, both in patients and NSG mice. To explore the clinical significance of the functional relationship between PC and PPC, we compared their frequency at diagnosis and after treatment in the same 8 patients. We found that while PC frequency was reduced by ~30-fold after treatment, PPC frequency was reduced by only ~4-fold suggesting that PPC are relatively chemoresistant *in vivo*. Consistent with this, PPC were considerably more quiescent than PC. *Conclusions.* The cellular diversity of MM is more extensive than previously recognised and is organised in a dynamic phenotypic and functional hierarchy (memory B cell»PB»PPC"PC138lo"PC138hi). Both PC and the novel PPC fraction display myeloma propagating activity but PPC are more quiescent and chemoresistant *in vivo* than PC and are preferentially present in extramedullary niches. These findings have profound implications for treatment, monitoring disease status and development of new therapeutic strategies in MM.

Background. Multiple myeloma (MM) is a clonal proliferation of malignant plasma cells (PCs) characterized by a marked genomic instability. Plasma cell leukemia (PCL) is an aggressive malignancy that can occur directly (primary, pPCL) or progress from intramedullary MM (secondary, sPCL). Genome-wide studies in PCL are still limited. *Aims.* To provide insights into the genetic lesions and altered molecular pathways characterizing Plasma Cell Leukemia. *Methods.* Highly purified PCs from 54 newly diagnosed MM, 16 untreated pPCL and 6 sPCL patients were characterized for the main chromosomal aberrations by FISH. pPCL cases were recruited in a multicenter GIMEMA clinical trial testing the lenalidomide/low dose dexamethasone combination. Gene expression profiles were generated on Gene 1.0 ST array (Affymetrix) in the complete dataset. Thirty-five MMs and 13 pPCLs were profiled for global miRNA expression on miRNA Microarray V2 (Agilent). Genome-wide DNA profiles of 13 pPCLs were obtained using the 250K Nsp SNP array (Affymetrix); copy number values were inferred through circularly binary segmentation and FISH-based normalization procedures. *Results.* Unsupervised analyses of gene and miRNA expression profiles grouped most of PCLs and MMs into two distinct branches partly according to the major IgH chromosomal translocations. Supervised analysis evidenced 237 differentially expressed genes in PCLs versus MMs, of which 155 positively modulated genes were enriched in cytoskeleton organization, cell adhesion, migration categories and partly (24%) associated to invasion and metastasis processes. As compared to pPCL, in sPCLs we evidenced the overexpression of transcripts mainly concerned in mitosis, spindle organization and chromosome segregation. Thirty upregulated and 21 downregulated miRNAs were identified in pPCLs vs MMs. Some of the overexpressed miRNAs in PCL samples may have a particular importance in the context of B cell dyscrasias as demonstrated by their involvement in B cell development, lymphoproliferative disorders or in sustaining growth of MM cell lines. The genotyping analysis and FISH concordantly detected 13q deletion in 77% and 17p deletion in 58% of cases. The most recurrent copy number alteration specifically identified by SNP-array was 1q gain (61.5%); in addition, losses involving chromosomes 1p (39%), 8p (31%), 14q (39%), 16q (39%) and gains affecting 7q (31%) and 19p (31%) and one amplification at 17q21 (46%) were detected. One case displayed a near tetraploid karyotype and, interestingly, another showed a hyperdiploid pattern. A correlation between the expression levels and the occurrence of allelic imbalances was identified for 199 genes mainly localized in the previously described altered regions. The same integrative approach applied on miRNA expression evidenced 23 miRNAs mostly mapping to chromosomes 1p (22%), 13q (26%) and 19 (22%). These results highlighted a wide gene-dosage effect suggesting that genomic structural abnormalities in pPCL closely reflect expression imbalances. *Conclusions.* Integrative genomics approach in PCL patients allowed the identification of specific gene and miRNA signatures, altered molecular pathways and novel genetic lesions potentially involved in more aggressive forms of PC dyscrasia.

[3]*Massachusetts General Hospital, Boston, United States of America*

Background. Mammalian target of rapamycin (mTOR) is a downstream serine/threonine kinase of the PI3K/Akt pathway that integrates signals from the tumor microenvironment such as cytokines and growth factors, nutrients and stresses to regulate multiple cellular processes, including translation, autophagy, metabolism, growth, motility and survival. Mechanistically, mTOR operates in two distinct multi-protein complexes, TORC1 (Raptor) and TORC2 (Rictor). Activation of TORC1 leads to the phosphorylation of p70S6 kinase and 4E-BP1, while activation of TORC2 regulates phosphorylation of Akt and other AGC kinases. In multiple myeloma (MM), PI3K/Akt plays an essential role enhancing cell growth and survival and is activated by the loss of the tumor suppressor gene PTEN and by the bone marrow microenvironment. Rapamycin analogues have been tested in clinical trials in MM and their efficacy as single agents is modest. Inhibition of Akt and 4E-BP1 signaling requires inactivation of both complexes TORC1 and TORC2. Consequently, there is a need for novel inhibitors that can target mTOR in both signaling complexes. *Aims.* Evaluate the role of TORC1 and TORC2 in MM and the activity and mechanism of action of INK128, a novel and selective TORC1/2 kinase inhibitor. *Methods.* MM cell lines and BM samples from MM patients. The mechanism of action was investigated by MTT, Annexin V, cell cycle analysis, Western-blotting and siRNA assays. For the *in vivo* analyses, OPM2 cells were injected into the tail vein of 30 SCID mice, the percentage of CD138+ cells and the effect in homing were detected by *in vitro* and *in vivo* flow cytometry, respectively. Nanofluidic proteomic immunoassays were performed in selected tumors. *Results.* We examined the protein expression levels of both mTOR complexes and their downstream effectors in MM cells from patients and cell lines. mTOR, Akt, pS6R and 4E-BP1 are constitutively activated in all samples, and the activity was independent of the expression levels of Deptor, Rictor and Raptor. The IC50 of INK128 was in the range of 7.5-30 nM in the eight cell lines tested. Similar results were observed in freshly isolated plasma cells from MM patients. In the bone marrow microenvironment context, INK128 inhibited the proliferation of MM cells and decreased the p4E-BP1 induction. INK128 also showed a significantly greater effect inhibiting cell adhesion to BMSCs and HUVECs compared to rapamycin. These results are in concordance with our *in vivo* homing studies using *in vivo* flow cytometry showing that inhibition of both TORC1 and TORC2 had a significant effect in delaying homing of MM cells to the BM compared with the inhibition of only TORC1. Moreover, oral daily treatment with INK128 highly decreased the percentage of CD138+ tumor plasma cells in mice implanted with OPM2, reduced the levels of p-Akt and p-4EBP1, and induced apoptosis upon treatment. In conclusion, our results show that TORC1/TORC2 and its downstream targets are major regulators of cell cycle, apoptosis and adhesion of MM cells. These results suggest that dual targeting of TORC1 and TORC2 by active-site mTOR inhibitors offers a novel therapeutic approach disrupting the interaction of MM cells with the BM microenvironment.

BKT140 IS A NOVEL CXCR4 ANTAGONIST WITH A POTENT STEM CELL MOBILIZATION CAPACITY AND THE ABILITY TO INDUCE MULTIPLE MYELOMA APOPTOTIC CELL DEATH

A Peled,[1] K Beider,[2] M Abraham,[3] H Wald,[3] I Avivi,[4] J Rowe,[4] I Hardan,[2] E Galun,[1] O Eizenberg,[3] A Shimoni,[3] A Nagler[2]

[4]*Rambam Medical Center and Technion, Haifa, Israel*

Background. CXCR4-CXCL12 interaction is involved in the retention of normal hematopoietic stem cells (HSCs) in the bone marrow (BM) niches, as well as in localization and adhesion of multiple myeloma (MM) tumor cells to the BM microenvironment. Therefore, blocking CXCR4 may result in mobilization of HSCs and may influence the biology of MM and the disease course. BKT140 is a high affinity CXCR4

inhibitor. The possible usage of BKT140 for mobilization of normal HSCs and as anti-MM compound was evaluated in patients with MM. *Results.* In pre-clinical study, we demonstrated that the CXCR4 antagonist BKT140 but not AMD3100 exhibited a CXCR4-dependent cytotoxicity toward MM cells. BKT140 induced apoptotic cell death of MM *in vitro*, demonstrating increased phosphatidylserine externalization, decreased mitochondrial membrane potential, caspase-3 activation, sub-G1 arrest, and DNA double-stranded breaks. *In vivo*, subcutaneous injections of BKT140 significantly reduced, in a dose-dependent manner, the growth of MM xenografts. Tumors from animals treated with BKT140 were smaller in size and weights, had larger necrotic areas and high apoptotic scores ($p<0.01$). Further, we conducted a phase I/IIa clinical study administrating BKT140 to 16 MM patients (pts), assessing toxicity, mobilization of CD34+ cells, pharmacokinetic (PK), pharmacodynamic and its effect on CD138+ MM cells. BKT140 was administrated at escalated doses (30,100,300,900 μg/kg) following high-dose cyclophosphamide (Cy) (2 g/m2) and G-CSF (5 μg/kg). G-CSF was started on day 5 post Cy and BKT140 was injected subcutaneously once on day 10. BKT140 demonstrated low toxicity and short PK profile. Preliminary results show that BKT140 administration resulted in a significant dose-dependent increase in PB CD34+ cells as well as neutrophils, monocytes and lymphocytes, compared to the Cy/G-CSF individual pt baseline. The mean absolute PB CD34+ cells mobilized following BKT140 administration was 6.6, 7.5, 11.2 and 20.6 x106/kg for the 4 BKT140 administered doses, respectively. Moreover, the number of aphaereses was reduced from 2.5 to 1 procedure at the lowest (30 and 100 μg/kg) and highest (300,900 μg/kg) BKT140 doses, respectively. BKT140 at the highest doses reduced the number of PB CD138+ cells in PB in 3/7 pts with baseline CD138+ cells in their blood, while BKT140 at the lower doses increased the number of circulating CD138+ cells. The BKT140 mobilized grafts were used for AutoSCT in 15 MM pts following 200 mg/m2 melphalan conditioning. Pts received an average of 5.3x106 CD34+ cells/kg. All pts demonstrated rapid engraftment. The median day for neutrophil (>500/mm3) and platelet (>20,000/mm3, >50,000/mm3,) recovery was day 11 (range, 0-13), day 11 (range, 0-14), and day 14 (range, 0-23), respectively. *Conclusions.* BKT140 demonstrated potent anti-MM effect *in vitro* and *in vivo* in mouse xenograft model. Furthermore, first human phase I/IIa clinical trial in MM pts showed that BKT140 can be safely administrated with minimal toxicity and side effects. BKT140 significantly increased HSC mobilization and at higher doses reduced days of aphaeresis. In addition, at higher doses BKT140 released MM cells from the BM to the circulation. Additional studies are warranted to further evaluate the effect of BKT140 as an anti-MM agent.

Background. The incorporation of high-dose therapy/autologous-stem-cell-transplantation (HDT/ASCT) and novel agents for the treatment of young multiple myeloma (MM) patients have markedly improved response rates, particularly the achievement of complete response (CR), and survival. The association between higher CR rates and extended survival is unquestionable, but the clinical course of MM patients achieving CR is still heterogeneous; some patients die from disease progression within few months, whereas others live for over 10 years. *Aims.* To identify prognostic parameters for the prediction of early disease progression in patients achieving CR after HDT/ASCT. *Methods.* A total of 241 patients achieving CR at day+100 after HDT/ASCT are the focus of this study. Patients were included in two consecutive GEM/PETHEMA trials: GEM2000 (VBMCP/VBAD, n=140) and GEM2005<65y (Thalidomide/Dexamethasone, n=20; Bortezomib/Thalidomide/Dexamethasone, n=46; VBMCP/VBAD with Bortezomib in the two final cycles, n=35). All cases were referred for minimal residual disease (MRD) assessment by multiparameter flow cytometry (MFC) at day+100 after HDT/ASCT; baseline FISH analysis were available in 110 of the 241 patients. *Results.* Time-to progression (TTP; median, 71 months) and overall survival (OS; 73% at 5-years) of these 241 patients were, as expected, superior than those of the whole series (TTP: median, 52 months; OS: 66% at 5-years). Multivariate analysis including those variables with significant influence in the univariate analysis showed that the best combination of independent predictive parameters for TTP were: MRD status by MFC (P=.007, HR=9.004), FISH cytogenetics (high- vs. standard-risk; P=.009, HR=9.081), and percentage of plasma cells in S-phase (>2%; P=.013; HR=7.094); in turn, for OS MRD status by MFC (P=.001; HR=7.730), FISH cytogenetics (P=.011; HR=5.062) and age (<60 vs. ≥60 years; P=.027, HR=3.420) were selected. We further investigated which parameters could help to identify those cases showing early progressive disease. Of the 241 patients, 30 (12%) progressed within one year after HDT/ASCT. This subgroup of patients showed significantly increased frequency of baseline anemia (48% vs. 26%, P=.013), ISS stage 2 or 3 (86% vs. 55%, P=.003), high-risk cytogenetics (40% vs. 10%, P=.005) and persistent MRD detected by MFC (63% vs. 32%, P=.001). By multivariate analysis, only MRD status by MFC (P=.005, HR=4.686) and FISH cytogenetics (P=.005, HR=4.528) were selected as independent prognostic factors for predicting progressive disease during 1-year after HDT/ASCT. Based on the variables with independent predictive value for early disease progression (MRD status by MFC and FISH cytogenetics), we established a predictive index by assigning 1 point for each adverse factor. Accordingly, 3 risk groups of patients in CR were defined, with significantly different (P<.001) rates of disease progression within one year after HDT/ASCT for patients with no risk factors (4 progressions of 58 cases, 7%), cases with 1 risk factor (9 progressions of 45 cases, 20%), and patients with both risk factors (7 progressions of 7 cases, 100%). *Conclusions.* Patients with high-risk cytogenetics and persistent MRD after HDT/ASCT do not sustain the CR and are candidates for experimental consolidation treatments.

Acute myeloid leukemia - Clinical 1

A VALIDATED DIAGNOSTIC MICROARRAY FOR NEWLY DIAGNOSED ADULT AML PATIENTS

E van Beers,[1] L de Best,[1] M van Vliet,[1] J Brand,[1] P Burgmer,[1] L de Quartel,[1] B Dumee,[1] A Provoost,[1] P Valk,[1] R Delwel,[1] L Bullinger,[2] P van de Spek,[1] H Viëtor,[1] H Döhner,[2] B Löwenberg[1]

[1]*Skyline Diagnostics, Rotterdam, Netherlands*
[2]*Depart. of Medicine, Oncology, Rheumatology, Infectious Diseases, Univ. of Ulm, Ulm, Germany*

Background. In newly diagnosed acute myeloid leukemia (AML) gene expression (RNA) profiling (GEP)[1] on Affymetrix GeneChips identifies homogeneous clusters that correlate with all favorable cytogenetic subtypes t(15;17), t(8;21) and inv(16)/t(16;16) and favourable CEBPA gene double mutants.[2] GEP can also detect NPM1 type A/B/D by RNA genotyping with specifically designed probes on the microarray and it can assess the expression levels of individual transcripts with demonstrated prognostic significance (e.g. EVI1 and BAALC RNA expression). *Aims.* We set out to develop and validate an *in vitro* diagnostic microarray for use in diagnostics of newly diagnosed adult AML. *Methods.* A custom Affymetrix microarray, the AMLprofiler, was produced that contains a combination of generic and specially designed probes. The array was tested following hybridisation of 261 AML training cases. Next, the AMLprofiler was evaluated in an independent cohort of 267 unselected newly diagnosed cases of AML (Erasmus University Medical Center & University Ulm). *Results.* During validation in 267 independent cases the AMLprofiler identified 18/17 inv(16), 7/7 t(15;17) and 16/16 t(8;21) AML's and 70/71 NPM1A/B/D cases. There was one false-positive inv(16) namely a t(11;16) translocation concurrent with MYH11 overexpression, suggesting involvement of the 16p13.1 breakpoint like in bona fide inv(16) or t(16;16) which has been infrequently reported in secondary AML. There was 1 false-negative case of NPM1 type-D, which prompted a retraining of the algorithm and subsequently required independent re-validation. This re-validation detected 68/66 NPM1 type AB/D mutants in 143 Normal Karyotype AML cases. One of the two latter false-positive cases carried a non-AD type mutation which is clinically indistinguishable from D mutations. The EVI1 and BAALC cut points were validated according $p < 0.05$ in the logrank test for OS between high versus low expressing intermediate cytogenetic risk cases. *Summary/Conclusions.* We report the development of an AML gene expression RNA microarray for diagnostic use that can be applied by physicians in their own laboratories, to detect core binding AML, PML, NPM1 A/B/D mutant, CEBPA double mutant, high EVI1 and low BAALC AML cases for diagnostic use.

Background. Prognosis among older patients (pts) with relapsed or refractory (R/R) acute myelogenous leukemia (AML) is dismal with median survival of 4.7 months (mos) (Rowe, Blood 2005 106: Abstract 546). For these patients, attainment of a complete remission (CR) is often considered the first treatment objective. Since remission status at the time of hematopoietic stem cell transplantation (HSCT), the only curative approach in R/R AML, is an important predictor of long term outcomes, new agents to increase complete remission rates prior to transplant are needed. *Aim.* Phase III study designed to evaluate the efficacy and safety of clofarabine (CLO) in combination with cytarabine (ara-C) compared to ara-C alone in older adult pts with R/R AML. *Methods.* This prospective, randomized, double-blind, placebo-controlled trial included pts ≥55 yrs with relapsed or refractory AML. Randomization to CLO+ara-C or placebo+ara-C was stratified by duration of remission following the first pre-study induction regimen [REF: refractory or CR1 <6 mos; REL: CR1 ≥6 mos]. Patients received CLO (40

mg/m^2 IV) or placebo followed by ara-C 1 g/m^2 IV daily x5 days. The primary endpoint was overall survival (OS). Select secondary endpoints included overall remission rate (ORR=CR+CRi), event-free survival (EFS) and safety; exploratory endpoints included HSCT rates. *Results.* Of the 320 pts with confirmed AML, 162 were randomized to CLO+ara-C and 158 to ara-C alone. The median age was 67 yrs (range: 55-86). Overall, 45% were primary refractory to their initial induction therapy and 49% had adverse cytogenetics. Although there was no difference in OS, CLO+ara-C demonstrated statistical significance across secondary efficacy endpoints, including doubling of remission rates and 37% improvement in EFS [HR: 0.63] (Table 1). Overall the number of patients who underwent HSCT was similar between the 2 arms; 21% in the CLO+ara-C arm vs 19% ara-C alone arms. However, a higher proportion of patients in the CLO+ara-C arm underwent HSCT while in remission from their study treatment (16% vs 9%). Overall 30-day mortality was 16% and 5% in the CLO+ara-C and ara-C alone arms, respectively. Serious adverse events (SAE) occurred in 60% of the CLO+ara-C and 49% of the ara-C alone pts. Serious infections occurred in 38% vs 22% of pts, respectively. The most frequent (≥5%) non-infectious SAE included febrile neutropenia (16% vs 12%) and pyrexia (4% vs 6%). Grade 3 or higher infections occurred in 65% vs 48% of pts, respectively. Grade 3 or higher non-infectious AEs occurring in ≥10% of pts in either arm included febrile neutropenia (47% vs 34%), hypokalemia (18% vs 10%), thrombocytopenia (16% vs 17%), anemia (13% vs 8%), neutropenia (11% vs 9%), increased AST (11% vs 2%) and increased ALT (10% vs 3%). *Summary/Conclusions.* While OS did not differ between arms, CLO+ara-C significantly improved response rates and EFS and allowed more patients to proceed to transplant in remission from study treatment compared to ara-C alone. Study follow-up continues and the role of clofarabine in the treatment of adult patients with AML continues to be investigated in randomized studies by cooperative groups.

HIGH EXPRESSION OF THE BRCA1 COMPLEX MEMBER BRE PREDICTS FAVORABLE PROGNOSIS IN ACUTE MYELOID LEUKEMIA, ESPECIALLY AMONG MLL-AF9 POSITIVE LEUKEMIA

A van der Reijden,[1] S Noordermeer,[1] M Sanders,[2] C Gilissen,[1] E Tönnissen,[1] A Van der Heijden,[1] J Jansen,[1] P Valk[2]

[1]*RUNMC, Nijmegen, Netherlands*
[2]*EUMCR, Rotterdam, Netherlands*

Background and Aims. Acute myeloid leukemia is a heterogeneous disease. Several recurrent genetic mutations that contribute to disease pathogenesis have an impact on disease outcome. Therefore, treatment strategies are influenced by the presence of mutations that have prognostic impact. Because deregulated expression levels of genes, like EVI1, also correlate significantly with disease outcome, the type of treatment is also influenced based on expression levels of individual genes. However, it is still not possible to classify all patients based on currently known aberrations. Changes in protein ubiquitination have recently been identified to contribute to the pathogenesis of acute myeloid leukemia (AML). To identify new prognostic factors in AML, we studied whether changes in expression of over 1600 ubiquitination-related genes correlated with clinical outcome in 525 adult AML patients. *Methods and Results.* Gene expression from 525 cases with AML, for whom written informed consent was obtained, was analyzed using Affymetrix HG-U133 plus 2.0 arrays. To study the correlation between expression changes of ubiquitination-related genes and overall survival (OS) the Cox proportional hazard model was used. In addition, we performed analyses to identify genes that showed altered expression in a small subset of patients (so called outlier expression) that correlated with survival. A differential expression of 9 genes was found to correlate with OS. Subsequent multivariate analyses identified the level of expression of five of these nine genes (BRE, DNMT3B, EVI1, RNF168 and ZAP) as independent prognostic factors for overall survival. Outlier high expression of one of these genes, BRE, was observed in 3% of the patients and predicted a favorable overall and event free survival (5-year overall survival of 57%). Importantly, high BRE expression was mutually exclusive with FLT3 ITD, CEBPA mutations, EVI1 over-expression, and favorable karyotypes. In contrast, high BRE expression co-occurred strongly with FAB M5 morphology and MLL-AF9 fusions. Strikingly, within the group of MLL-AF9 positive patients, high BRE expression predicted superior survival, while lack of high BRE expression predicted extremely poor survival (5-year overall survival of 80% vs 0%, respectively, p=0.0002). Finally, unsupervised gene expression profiling showed that 86% of the patients with high BRE expression were confined to a previously unrecognized cluster. *Conclusion.* We conclude that high BRE expression defines a novel good risk group among adult AML. This work contributes to further risk stratification and sub-classification of AML and may contribute to individualized treatment strategies.

[5]*University Hospital Hamburg-Eppendorf, Hamburg, Germany*
[6]*Krankenhaus Siloah, Hannover, Germany*
[7]*Klinikum Lüdenscheid, Lüdenscheid, Germany*

Background. Acute myeloid leukemia (AML) is a heterogeneous neoplasm of the hematopoietic stem cell caused by mutations, deregulated gene expression and epigenetic modifications of genes leading to decreased differentiation of hematopoietic progenitor cells and increased proliferation. Recently, mutations in DNMT3A have been identified to occur in AML. *Aims.* The aim of this study was to analyze the frequency and prognostic significance of DNMT3A mutations in a large cohort of uniformly treated, well characterized AML patients. *Methods.* A total of 489 AML patients younger than 60 years were examined for DNMT3A mutations by direct sequencing. The prognostic impact of DNMT3A mutations was evaluated in the context of other clinical prognostic markers and genetic risk factors (cytogenetic risk group; mutations in NPM1, FLT3, CEBPA, IDH1, IDH2, MLL1, NRAS, WT1, and WT1 SNPrs16754; expression levels of BAALC, ERG, EVI1, MLL5, MN1 and WT1). *Results.* DNMT3A mutations were found in 87 out of 489 patients (17.8 %). The highest mutation frequency was found in cytogenetically normal (CN-) AML (71 of 261 patients, 27.2 %). Patients with DNMT3A mutations were found be older, had higher WBC and platelet counts and more often had a normal karyotype. Additionally, patients with mutated DNMT3A were also more likely to have mutations in NPM1, FLT3, and IDH1 genes, and had higher MLL5 expression levels when compared to patients with wildtype DNMT3A. Multivariate analysis demonstrated that DNMT3A mutations independently predicted a shorter overall survival (OS) (HR 1.59; 95% CI 1.15-2.21; P=.005), but were not associated with relapse-free survival (RFS) or complete remission (CR) rate when the entire patient cohort was considered. In CN-AML patients, DNMT3A mutations independently predicted shorter OS (HR 2.46; 95% CI 1.58-3.83; P<.001) and lower CR rate (OR 0.42; 95% CI 0.21-0.84; P=.015), but not RFS (P=.32). Additionally, within CN-AML patients, DNMT3A mutations had an unfavorable effect on OS, RFS, and CR rate in NPM1/FLT3ITD high risk but not in low risk patients. *Conclusion.* DNMT3A mutations are among the most frequent mutations in younger AML patients, and are associated with an unfavorable prognosis.

NPM1 MONITORING ENABLES EARLY DETECTION OF IMPENDING RELAPSE IN ACUTE MYELOID LEUKEMIA FOLLOWING CONVENTIONAL CHEMOTHERAPY AND POST ALLOGENEIC STEM CELL TRANSPLANTATION

N Shayegi, M Kramer, M Bornhäuser, M Schaich, J Schetelig, U Platzbecker, C Röllig, G Ehninger, C Thiede

Universitätsklinik Dresden, Dresden, Germany

Background. Relapse of disease remains the major reason for treatment failure in patients with acute myeloid leukemia (AML), even after allogeneic stem transplantation (SCT). Early detection of relapse using molecular techniques could enable early preemptive therapy, but so far, the number of suitable markers is limited. More recently, mutations of the nucleophosmin gene (NPM1) have been described. These mutations are amongst the most common changes in adult AML and have shown potential for minimal residual disease (MRD) detection. However, only few studies on NPM1-based MRD detection have been published. *Aim.* In this study we investigated the suitability of NPM1 as MRD-marker in a large cohort of AML-patients. *Methods.* 184 NPM1-

mutant AML patients (pts) (median age 53.5 yrs. (range, 21-81 yrs.)), treated in protocols of the Study Alliance Leukemia (SAL) were prospectively monitored. We developed an optimized assay for the sensitive cDNA based detection of the three most common NPM1-mutations using a Real-Time-Q-PCR with locked-nucleic acid (LNA) containing primer-probe designs. The threshold for molecular relapse (mol-Rel) was defined as a 10-fold increase of NPM1 transcript level compared to the lowest level achieved or levels with greater than 1%. Molecular non or partial responder were defined as cases without a significant decrease of NPM1 transcript levels or levels > 1% after completion of the first line therapy. *Results.* We studied 184 patients having one of the three most common NPM1-mutations, A (N=156), B (N=17) and D (N=11). A total of 1661 samples (978 BM; 683 PBL) were analyzed, the median number of samples per patient was 7 (range, 3-55), the median molecular follow-up was 453 days (99-1703 days). 65 patients (35.3%) had undergone SCT (12 auto SCT, 53 allo SCT), an FLT3-ITD mutation was present in 68 pts. (37%). According to our criteria, 18 pts were defined as molecular non-responders and none of them achieved durable CR. In 28 pts with hematological relapse (hem-rel) and sufficient molecular follow-up, the rise of MRD preceded the hem-rel by a median of 66 days (range, 0-313 days). Out of 121 pts without mol-rel only one patient relapsed ($p < 0.001$). In a subgroup of 117 patients with available NPM-data in remission generalized linear models were fitted to model the risk of relapse in a defined time span. In a second step ROC-analyses were performed to identify MRD-ranges with different relapse risks. *Conclusions.* In conclusion, our data indicate that NPM1 mutations can serve as markers for MRD monitoring allowing early detection of recurrent disease in a considerable proportion of AML patients. Increasing NPM1 transcript level could trigger preemptive intervention using DLI after allogeneic SCT or targeted therapy within prospective clinical trial.

Non-Hodgkin Lymphoma - From biology to therapy

MICRORNAS PLAY A PIVOTAL ROLE IN REGULATING WALDENASTROM'S MACROGLOBULINEMIA BIOLOGY

M Aldo, A Sacco, P Maiso, AK Azab, Y Zhang, Y Liu, F Azab, H Ngo, P Quang, C Issa, I Ghobrial

Dana-Farber Cancer Institute, Boston, United States of America

Background. Waldenstrom's Macroglobulinemia (WM) is a low-grade lymphoproliferative disorder characterized by the presence of a lymphoplasmacytic infiltrate in the bone marrow and serum monoclonal immunoglobulin M. Cytogenetic and molecular studies on gene expression analysis at the mRNA level have demonstrated minimal changes in WM cells. Therefore, multi-level characterization of this disease at genetic and epigenetic levels is required to improve our understanding of the underlying molecular changes that lead to the initiation and progression of this disease. We have therefore evaluated how microRNA (miRNA) aberrations may possible modulate WM biology both *in vitro* and *in vivo*. *Aims.* 1) To determine miRNA profiling in primary WM cells. 2) To evaluate the functional role of miRNA-155 and -9* in regulating WM biology both *in vitro* an *in vivo*. *Methods.* miRNA- and gene-expression-profiling have been performed on bone-marrow-derived-CD19+ WM cells, compared to their normal cellular counterparts. Data were validated by stem-loop-qRT-PCR. *In vitro* and *in vivo* functional studies were performed on precursor-anti-miRNA-155 and precursot-miRNA-9*-transfected-WM cells. Effect on signaling cascades have been evaluated by western-blot and immunofluorescence. DNA-proliferation, cytotoxicity, cell cycle, apoptosis were assessed by thymidine incorporation, MTT, PI, Apo2.7 staining, respectively. GFP+ WM cells were transfected using either control-probe or miRNA-155 knockdown probe, and then injected in mice 24 hours after transfection: *in vivo* confocal imaging has been performed. *Results.* WM cells present with a miRNA signature characterized by increased expression of miRNA-155 and decreased expression of miRNA-9* (ANOVA;$P< 0.01$). Potential microRNA-155 target genes were identified using gene-expression-profiling and included genes involved in cell cycle progression, adhesion, and migration. Predicted miRNA-9* included histone-deacetylases (HDAC4; HDAC5) and -acetyltransferases (Myst3). We found that miRNA-155 regulates proliferation and growth of WM cells *in vitro* and *in vivo* by inhibiting signaling cascades including MAPK/ERK, PI3/AKT and NF-kB pathways. In addition, we demonstrated that primary WM cells are characterized by unbalanced expression of HDACs and HATs at gene level, responsible for decreased acetylated-histone-H3 and -H4, at protein level and increased HDAC activity. miRNA-9* played a functional role in regulating histone-acetylation and HDAC activity in WM cells, based on their ability to target HDACs and HATs; leading to induction of toxicity in precursor-miRNA-9*-transfected cells, as shown by reduced proliferation rate, cell cycle arrest, induction of apoptosis, supported by PARP-, caspase-8-, caspase-9-cleavage. In addition, miRNA-9* induced autophagy in WM cells by modulating Rab7 and LC3B. *Conclusion.* These *in vitro* and *in vivo* findings confirm that miRNA-155 and -9* are crucial regulators of WM pathogenesis; and provide the basis for miRNA-based-therapeutical strategies in this disease.

0475

DEPLETION OF TUMOUR ASSOCIATED MACROPHAGES SIGNIFICANTLY RETARDS THE PROGRESSION OF AN AGGRESSIVE AND CHEMORESISTANT MODEL OF B-CELL NON HODGKIN LYMPHOMA

L Hallam,[1] J Candido,[1] E Maniati,[1] R Thompson,[1] N Van Rooijen,[2] T Hagemann,[1] J Gribben[1]

[1]*Barts Cancer Institute, London, United Kingdom*
[2]*Department of Molecular Cell Biology, Amsterdam, Netherlands*

Background. A large number of infiltrating tumour associated macrophages (TAM) is associated with a poor prognosis in many cancers. *In vitro* studies have established the diversity and plasticity of macrophages, such that they may exhibit classically activated (M1) or alternatively activated (M2) phenotypes. In models of non-lymphoid malignancies, TAM exhibit pro-tumoural features approximating an M2 phenotype. In Non Hodgkin Lymphomas (NHL) there are conflicting reports of the clinical significance of TAM

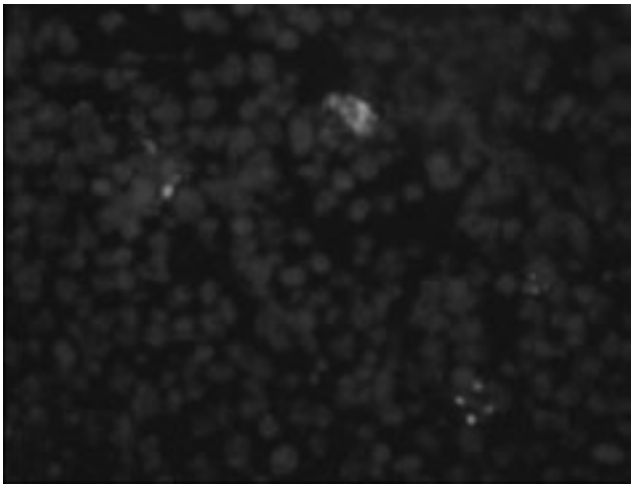

Figure 1. Fluoresecent labeled adoptively transferred BMDM.

numbers. Gene expression analysis of whole lymph node biopsy specimens in Follicular Lymphoma and Diffuse Large B-Cell Lymphoma suggest that macrophage activity might be associated with a poor prognosis. We are testing the hypothesis that TAM play an important role in the progression of NHL, and might therefore constitute a rational and effective therapeutic target. *Aims.* To investigate tumour-macrophage interactions by manipulating TAM numbers and phenotype in a transplantable mouse lymphoma with a view to providing a rationale for further investigation of the therapeutic potential of manipulating TAM in human B-NHL. *Methods.* As a model system to study B-NHL we used a mature B-cell lymphoma arising in Eμ-myc/bcl-2 transgenic mice, which, when intravenously injected into healthy C57BL/6 mice produced a disseminated lymphoma. Macrophage depletion was achieved by intravenous injection of liposomes containing dichloromethylene-diphosphonate (Liposomal Clodronate). A variety of schedules of delivering Liposomal Clodronate were employed to establish the nature and amplitude of effects on progression of lymphoma. Subsequent studies employed macrophage depletion with Liposomal Clodronate combined with adoptive transfer of syngeneic BM derived macrophages (BMDM), *in vitro* polarized to M1 and M2 phenotypes. More specific targeting of TAM, and relative sparing of physiological monocytes and resident tissue macrophages, was attempted by pharmacological inhibition of monocyte recruitment. This strategy was used against growing lymphomas, and in lymphomas relapsing after chemotherapy. Lymphoma growth was assessed by measuring lymph node weight, and cross-sectional area in tissue sections. Gene expression changes in whole lymph nodes with and without lymphoma, and following interventions to manipulate macrophage populations, were determined by real-time PCR. Changes to the cellular composition of the immune microenvironment were assessed by FACS analysis of single-cell suspensions of lymph nodes, and by immunohistochemistry. Circulating monocyte populations and serum cytokine levels were measured by FACS analysis and ELISA, respectively. *Results.* Intravenous delivery of Liposomal Clodronate in mice injected with Eμ-myc/bcl-2 lymphoma successfully depleted macrophages in the bone marrow, lymph nodes, and spleen, and significantly reduced lymphoma mass compared to vehicle controls (29.7%↓). We observed a dose-response reduction in lymphoma growth in Liposomal Clodronate treated animals. Adoptive transfer of M1-polarized BMDM also attenuated lymphoma growth (37.3%↓). Moreover, it resulted in further attenuation of lymphoma growth in mice previously treated with Liposomal Clodronate (47.1%↓). Pharmacological inhibition of macrophage recruitment resulted in reduced lymphoma growth in otherwise untreated lymphomas (19.7%↓), as well as in lymphomas relapsing following cytotoxic chemotherapy, whilst not depleting the circulating monocyte pool. *Summary/Conclusions.* Our *in vivo* studies support a crucial relationship between macrophage numbers/ phenotype, and lymphoma progression. Therefore, targeting TAM provides a very attractive therapeutic opportunity in human B-lymphomas.

0476

TARGETING THE CD20 AND CXCR4 PATHWAYS IN NON HODGKIN LYMPHOMA (NHL) WITH ANTI CD20 AND CXCR4 ANTAGONIST

K Beider,[1] E Ribakovsky,[1] M Abraham,[2] H Wald,[2] O Eizenberg,[2] A Avigdor,[1] A Peled,[3] A Nagler[1]

[1]*Chaim Sheba Medical Center, Ramat-Gan, Israel*
[2]*Biokine Therapeutics Ltd., Science Park, Ness Ziona, Israel*
[3]*Goldyne Savad Institute of Gene Therapy, Hebrew University Hospital, Jerusalem, Israel*

Background. Non Hodgkin's lymphoma (NHL) derives from the neoplastic transformation of lymphocytes at different stages of differentiation and may show systemic, nodal and extranodal localization in different sites, including bone marrow. Rituximab is anti-CD20 monoclonal antibody which is widely used in treatment of B-cell malignancies. The overall survival rates of patients with B cell lymphoma improved with rituximab treatment, but the relapsed/refractory rates are still high. Chemokine receptor CXCR4 and its ligand CXCL12 are critically involved in the survival and trafficking of normal and malignant B lymphocytes. The interaction of malignant B cells with stromal cells via CXCR4/CXCL12 signaling may induce chemo-resistance. Therefore, blockade of CXCR4/CXCL12 signaling may antagonize the survival and spreading of lymphoma cells and restore their chemo-sensitivity. *Results.* We evaluated the effect of CXCR4-specific antagonist BKT140 on lymphoma cell growth and rituximab-induced cytotoxicity *in vitro* and *in vivo*. We found that *in vitro* treatment with BKT140 antagonist directly inhibited the cell growth and induced cell death of CD20-expressing lymphoma cell lines and primary lymphoma cells from patients with bone marrow involvement. Combination of BKT140 with rituximab significantly increased the cytotoxic effect (apoptosis) against the lymphoma cells in a dose-dependent manner. We found that rituximab induced CXCR4 expression in lymphoma cell lines and primary lymphoma cells, both on mRNA and cell-surface levels, suggesting the possible interaction between CD20 and CXCR4 pathways in NHL and providing the rationale for CXCR4 targeting in combination with rituximab treatment. To further explore the effect of BKT140 on NHL, we established a xenograft model of B-cell lymphoma with bone marrow involvement in mice. Human CXCR4-expressing B NHL cell line, BL-2, was subcutaneously implanted into NOD/SCID mice and developed aggressive local tumors which specifically spread to the bone marrow. Following the tumor establishment, mice were injected subcutaneously with BKT140, rituximab or with combination of both reagents. BKT140 reduced the local tumor progression of BL-2 generated tumors. Moreover, BKT140 treatment significantly reduced the number of BL-2 tumor cells in the BM by 76% ($p<0.01$) compared to control, and promoted their apoptosis within bone marrow microenvironment. *In vivo* treatment of established bone marrow tumors with BKT140 together with rituximab increased the anti lymphoma effect of rituximab. *Conclusions.* Taking together, these results demonstrate potent anti-lymphoma effect of CXCR4-specific antagonist BKT140 *in vitro* and *in vivo*, suggest the possible interaction between CD20 and CXCR4 pathways in NHL, and provide the rational basis for the development of novel combined CXCR4-targeted therapies for refractory NHL.

0477

CROSSLINKING CD74 AND CD20 WITH NOVEL BISPECIFIC ANTI-CD74/CD20 ANTIBODIES INDUCES POTENT CYTOTOXICITY IN MANTLE CELL LYMPHOMA LINES

P Gupta,[1] T Cardillo,[1] E Rossi,[1] CH Chang,[1] D Goldenberg[2]

[1]*Immunomedics Inc., Morris Plains, United States of America*
[2]*Garden State Cancer Center, Morris Plains, United States of America*

Background. Mantle cell lymphoma (MCL) is an aggressive form of B-cell lymphoma with poor prognosis. The combination of chemotherapy with rituximab increases the overall survival, but the disease relapses in virtually all patients. At present, there is no cure for MCL; thus novel treatments are desirable. The anti-CD20 rituximab or veltuzumab is moderately effective against MCL lines *in vitro* only in the presence of a crosslinking antibody and the observed cytotoxicity can be enhanced with the addition of the anti-CD74 milatuzumab. *Aims.* To determine whether bispecific anti-CD20/CD74 antibodies are more potent against MCL than their parental antibodies alone or in combination. *Methods.* Hexavalent antibodies (HexAbs) comprising four Fabs of one specificity linked to a full IgG of the same or a different specificity can be successfully prepared by the Dock-and-Lock (DNL)

method to retain the binding activity of each constitutive Fab. Cognate CH3-AD2-IgG and CH1-DDD2-Fab modules were generated and combined under mild redox conditions to produce 74-(20)-(20), comprising four Fabs of veltuzumab linked to milatuzumab, and 20-(74)-(74), comprising four Fabs of milatuzumab linked to veltuzumab. The *in vitro* activities of 74-(20)-(20) and 20-(74)-(74) were assessed in three MCL lines (JeKo-1, Mino, and Granta-519) for growth inhibition by cell proliferation assay and for apoptosis by annexin binding assay and the results compared with the monospecific counterparts of 74-(74)-(74) and 20-(20)-(20). In addition, the effects on human B cells and growth of JeKo-1 cells in whole blood were analyzed *ex vivo*. *Results.* Each HexAb was shown to be homogeneous, with >95% purity by size-exclusion HPLC and SDS-PAGE. Both 20-(74)-(74) and 74-(20)-(20) potently inhibited the growth of JeKo-1, Mino and Granta-519 cells at 10 nM. In contrast, neither parental antibody, alone or in combination, nor the two monospecific counterparts, 74-(74)-(74) and 20-(20)-(20), inhibited the growth of JeKo-1 under the same conditions, suggesting the requirement of heteromerization of CD74 and CD20 for the observed cytotoxicity. The two anti-CD20/CD74 HexAbs also induced 25-30% apoptosis in Jeko-1, compared to 10-12% apoptosis with parental IgG, alone or in combination, and similar results were observed in clinical samples obtained from MCL patients. Additional studies revealed that the bispecific HexAbs, but not the parental mAbs, induced strong homotypic adhesion, pronounced phosphorylation of ERKs and JNKs, and reduction of the anti-apoptotic protein Bcl-xl in target cells. Although both bispecific HexAbs were capable of depleting human B cells *ex vivo*, only 20-(74)-(74) inhibited the growth of JeKo-1 cells in blood. We also found that 20-(74)-(74) had a higher antibody-dependent cellular cytotoxicity than 74-(20)-(20), but neither showed complement-dependent toxicity. The *in vivo* efficacy of 20-(74)-(74), given 370 μg twice a week for two weeks, was demonstrated in nude mice bearing JeKo-1 xenografts, resulting in 56% increase in median survival as compared to saline control mice (P<0.0001). *Conclusions.* The promising results obtained for 20-(74)-(74) against MCL lines and patient samples warrant its further preclinical evaluation as potential therapeutic against MCL and B-cell lymphomas that are refractory or poorly responsive to anti-CD20 or anti-CD22 antibodies.

Centre Henri Becquerel, Rouen, France

Background. In addition to the molecular classification, [18F]-Fluorodeoxyglucose positron emission tomography (FDG-PET) imaging is essential to optimise initial staging or to predict prognosis of DLBCL. *Aims.* The aim of the study was to assess the relationship between cell of origin (COO) classification and PET scan features in DLBCL. *Methods.* Fifty seven cases treated by CHOP/CHOP-like+R were retrospectively analysed (median age = 65y, aaIPI 0-1 = 30%, 2-3 =70%). PET scan results at diagnosis (SUVmax), following 3/4 cycles of chemotherapy (interim PET) and at the end of treatment (final PET) were correlated to molecular features. Expression profile of 18 genes related to GCB/ABC signatures and 5 genes coding for glucose transporters (GLUT) was determined from frozen tissues using an Illumina platform and DASL technology (cDNA-mediated Annealing, Selection, Ligation and extension). Phenotypes were also assessed by immunohistochemistry (IHC) according to Hans algorithm. *Results.* Gene expression profiling classified 30 DLBCL in the GCB subtype (2-year PFS=76%) and 27 in the ABC subtype (2-year PFS=51%, p=0.03), giving a concordance rate of 77% with IHC. Expression of GLUT2 was significantly higher in DLBCL with SUVmax ≥ third quartile, regardless the GCB/ABC subtype. At base-line, SUVmax was higher in the GCB subtype as compared to the ABC subtype (p = 0.029) but was not predictive of the outcome. Interim and final FDG-PET (negative / positive) were highly predictive of the prognosis. Using semi-quantitative assessment of SUV decrease at interim PET (SUV) fast (n=36) and slow (n=9) responders (SUV ≥ or < 70%) were defined. In multivariate analysis, GCB/ABC(OR=5.1), aaIPI(OR=7.1) and slow/fast responses (OR=0.1) were independently correlated with PFS and OS. Using the GCB/ABC classification and interim PET, we identified patients with a very favourable outcome (2-year OS/PFS = 100%) characterized by a GCB phenotype and a fast metabolic response. Conversely, in the GCB group (defined by DASL or IHC), slow responders display a very poor prognosis (2-year OS=33%). Similarly, DLBCL with fast metabolic responses but belonging to the ABC subtype displayed an unfavourable outcome (2-year OS = 57%). *Conclusion.* Molecular classification according to COO and interim TEP scan are two strong and independent prognostic factors in DLBCL that should be incorporated in future clinical trials to tailor therapeutic strategies.

Introduction. Partial (del(7q)) or total monosomy 7 (-7) is one of the most frequent cytogenetic abnormalities in MDS, occurring as an isolated anomaly in about 5% of abnormal cases in patients (pts) with primary MDS. The IPSS defines any abnormality of chromosome 7 as unfavourable and classifies them, combined with complex abnormalities, into the poor risk cytogenetic subgroup. However, in previous publications from other groups, the prognosis of isolated -7/del(7q) was described as intermediate. The aim of the present study was to re-analyze the prognostic impact of -7/del(7q) as a single anomaly based on a large, international MDS database. *Materials and Methods.* 2901 Patients derived from the international MDS database were screened for monosomy 7. This large international data collection contains patients with MDS, originating from the German-Austrian (GA)-, the International MDS Risk Analysis Workshop (IMRAW), the Spanish Cytogenetic Working group (GCECGH) and the International Cytogenetics Working Group of the MDS Foundation (ICWG). Only patients with primary MDS, age >=16, and bone marrow blasts <=30%, treated with supportive care exclusively, were considered for the analysis. Uni- and multivariate analyses were performed for overall survival (OS) and risk of AML-transformation (AML-t). In multivariate analysis, site, age, gender, bone marrow blast count, date of first diagnosis and number of peripheral cytopenias were defined as co-variables. *Results.* In total, 59 patients (2.1% of all pts/4.6% of abnormal cases) with monosomy 7 were identified (del(7q): n=13; -7: n=46). The median age of these patients was 66.1 years, which is significantly lower compared to patients without monosomy 7 (70.0 years; p<0.01; t-test, 2-sided). Regarding peripheral blood count, the mean hemoglobin in -7/del(7q) pts (9.2 g/dl) as well as ANC (1.7*10^3/ul) did not differ significantly as compared to pts without -7/del(7q) whereas the platelet count in pts with -7/del(7q) was significantly lower (82*103/ul vs. 125*10^3/ul; p<0.01). The median overall survival in -7/del(7q) pts was 16.0 (95% CI 14.0-21.4) months and the Hazard ratio (HR; as compared to a normal karyotype with a median survival of 47.4 (44.0-53.4) months as the reference category) was 1.6 (1.1-2.3; <0.01). Regarding the risk of AML-transformation, the median time to AML was 42.2 (14.4-not reached) months and the HR 1.7 (0.9-3.2; p<0.01). In comparison, this differed significantly from the median survival- (p<0.0001) and time to AML-transformation (p=0.027) for complex abnormalities, which are included with -7/del(7q) in the poor risk IPSS cytogenetic subgroup and were 5.7 (4.7-6.8) and 8.2 (6.4-14.0) months, respectively. The HR for complex abnormalities was 4.3 (3.4-5.4; p<0.01) for OS and 5.2 (3.8-7.5; p<0.01) for AML-transformation. *Conclusions.* The re-analysis of -7/del(7q), based on the largest MDS patient cohort yet published, confirms that the prognostic impact of an isolated total or partial monosomy 7 for overall survival as well as the risk of AML-transformation is not as poor as defined in the IPSS and significantly different from complex abnormalities. This finding is anticipated to be considered in the upcoming revision of the IPSS.

A RANDOMIZED TRIAL OF HORSE VERSUS RABBIT ANTITHYMOCYTE GLOBULIN IN SEVERE ACQUIRED APLASTIC ANEMIA

P Scheinberg, O Nunez, B Weinstein, P Scheinberg, C Wu, N Young

National Heart, Lung, and Blood Institute, Bethesda, United States of America

In patients with severe aplastic anemia (SAA) who are not candidates for stem cell transplantation, immunosuppressive therapy with horse anti-thymocyte globulin (ATG; ATGAM®) plus cyclosporine (CsA) is standard. In comparison to horse ATG, rabbit ATG (Thymoglobulin®) is more potent and has distinct biological effects on the immune system. Thymoglobulin is preferred to ATGAM in some clinical settings, as in the prevention and treatment of kidney allograft rejection. In patients with refractory and relapsed SAA, rabbit ATG used as salvage therapy improves hematopoiesis. We hypothesized that rabbit ATG would be a superior regimen compared to horse ATG as first therapy in SAA. To test this hypothesis, we conducted a prospective randomized study comparing horse ATG/CsA and rabbit ATG/CsA in treatment-naïve SAA (registered at www.clinicaltrials.gov as NCT00260689). Informed consent was obtained according to a protocol approved by the Institutional Review Board of the National Heart, Lung, and Blood Institute. Consecutive patients with SAA who required initial immunosuppressive therapy were eligible; all were enrolled from December 2005 to July 2010 and treated at the National Institutes of Health in Bethesda. The primary endpoint was hematologic response at 6 months, which has been shown to strongly correlate with long-term survival (JAMA 289: 1130, 2003). The current study was powered to detect a 25% difference between arms at a 5% significance level and with 80% power. A total of 120 patients (ages 2-78 years) were randomized between horse and rabbit ATG (60 in each arm). Median follow-up for surviving patients was 891 days (range, 185-1852). All patients are evaluable for the primary endpoint. Demographics and clinical features were well matched between the two groups. The hematologic response rate at 6 months for horse ATG was 68% (95% CI, 56%-80%) and for rabbit ATG 37% (95% CI, 24%-49%; p<0.001). (Almost all patients in both arms had shown response by 3 months: horse ATG 37/60 [62%] and rabbit ATG 20/60 [33%].) Hematologic response rates for horse ATG are similar to our reported experience (Blood 108: 2509, 2006). Despite relatively short follow-up, relapse and clonal evolution to date have occurred with similar frequency; 9 relapses (among 41 responders) and 9 clonal evolutions have been observed in the horse ATG arm, and 2 relapses (among 22 responders) and 7 evolutions in the rabbit ATG group. There have been 4 deaths in the horse ATG arm and 14 in the rabbit ATG arm, resulting in different survival proportions for the two regimens mainly due to high-risk therapies required in patients who failed initial immunosuppression (see Figure). We infer from our results that rabbit ATG/CsA is markedly inferior to horse ATG/CsA as first treatment in SAA, as measured by the critical parameter of early hematologic response. Horse ATG is presently not available in Europe, Japan and South America, and therefore these data have immediate implications for the treatment of SAA worldwide, as well as to the mechanism of action of polyclonal antisera in general and in particular in this disease.

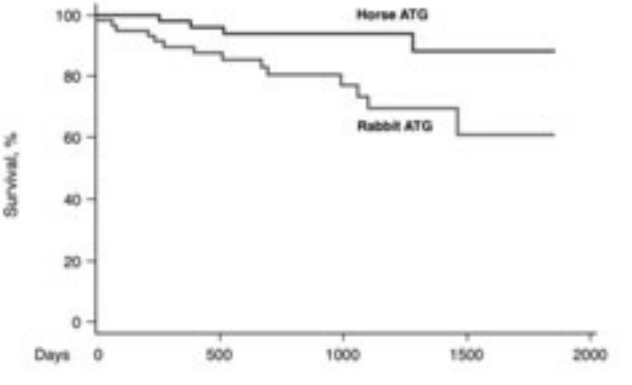

Figure 1. Overall survival for horse and rabbit ATG.

[6]*Celgene Corporation, Summit (NJ), United States of America*
[7]*Hopital Avicenne, Bobigny, France*

Background. Most studies evaluating prognosis in MDS have focused on untreated patients from all subgroups. Higher transfusion burden and bone marrow blast percentage, and complex cytogenetics at baseline have been associated with reduced OS and increased AML progression in MDS patients (Greenberg P, *et al*. Blood. 1997;89:2079-88; Malcovati L, *et al*. J Clin Oncol. 2007;25:3503-10). Evaluation of predictive factors specific to disease-modifying drugs such as LEN, and to MDS subtypes such as Low-/Int-1-risk groups with del(5q) is needed. *Aim.* To identify predictive factors for OS and AML progression in RBC-transfusion dependent patients with IPSS-defined Low-/Int-1-risk MDS with del(5q), treated with LEN in 2 multicenter trials"[1]MDS-003 (phase 2 single-arm) and MDS-004 (phase 3 randomized, double-blind). *Methods.* Patients who provided informed consent received LEN 5 mg on days 1-28, or 10 mg either on days 1-21 or 1-28 of 28-day cycles. Cox proportional hazards models assessed the impact of baseline characteristics and RBC-transfusion independence (TI) for ≥26 weeks, on OS and time to AML progression (calculated from study entry/randomization); RBC-TI for ≥26 weeks was included as a time-dependent covariate. Once potentially significant risk factors were identified, a multivariate model simultaneously determined the most important prognostic variables using a backward elimination variable-selection approach. The Table shows the univariate model with individual variables and the final model based on backward model selection. *Results.* From the 2 studies, 286 LEN-treated patients were included in the intent-to-treat population. Median age was 69 years (range 36-95); 70% of patients were female; 70% had isolated del(5q) and 26% had del(5q) plus ≥1 additional abnormality; 31%, 42%, and 6% had IPSS-defined Low-, Int-1-, and Int-2-/High-risk MDS, respectively. FAB subtypes were: 63% RA/RARS; 19% RAEB/CMML; and 19% other/missing. At baseline, median transfusion burden was 6 units/8 weeks (range 1-25) and median platelet count was 235×10^9/L (range, 14-1401). Median follow-up duration for OS was 38.4 months (range, 0.3-81.9) in MDS-003 and 36.1 months (range, 0.4-59.4) in MDS-004. Results of the Cox proportional hazards model are in the Table. Achieving RBC-TI for ≥26 weeks and higher baseline platelet counts were associated with significantly reduced relative risks of death (64% and 13% reductions per platelet count increase of 100×10^9/L, respectively). Additionally, significant increases in the relative risk of death were reported with RAEB/CMML (63% increase), higher transfusion burden (6% increase per 1 unit/8 weeks), and older age (5% increase per year) at baseline. Higher transfusion burden and del(5q) plus ≥1 additional abnormality were associated with significantly increased relative risks of AML progression. *Summary.* In LEN-treated patients with Low-/Int-1-risk MDS with del(5q), higher baseline transfusion burden was associated with an increased relative risk of AML progression and death. Older age and RAEB/CMML at baseline were associated with reduced OS, whereas del(5q) plus ≥1 additional abnormality was associated with an increased risk of AML progression. Achievement of RBC-TI for ≥26 weeks and higher baseline platelet counts were associated with significantly increased OS in this large patient cohort, confirming the findings in previous, smaller-scale studies.

Table 1.

Variables*	HR Univariate Model (Individual Variable)		HR Final Model	
	OS	AML Progression	OS	AML Progression
Age, years	1.0358 P < 0.001	0.9915 P = 0.451	1.0468 P < 0.001

A GENE EXPRESSION BASED RISK SCORE IN MDS PATIENTS PREDICTS AML TRANSFORMATION

M Heuser,[1] F Thol,[1] A Sonntag,[1] F Damm,[1] E Weissinger,[1] J Krauter,[1] K Wagner,[1] M Morgan,[1] M Wichmann,[1] G Göhring,[1] G Bug,[2] O Ottmann,[2] WK Hofmann,[3] B Schlegelberger,[1] T Haferlach,[4] K Mills,[5] A Ganser[1]

[2]*University of Frankfurt, Frankfurt, Germany*
[3]*University Hospital Mannheim, Mannheim, Germany*
[4]*Munich Leukemia Laboratory, Munich, Germany*
[5]*Queen's University Belfast, Belfast, United Kingdom*

Background. High expression levels of MN1, ERG, BAALC and EVI1 have been found to be associated with an adverse outcome in patients with acute myeloid leukemia (AML). Whether expression levels of these genes also have a prognostic influence in myelodysplastic syndromes (MDS) remains unknown. *Aims.* The aim of this study was to develop a scoring system that is predictive for progression of MDS to AML based on gene expression levels of MN1, ERG, BAALC and EVI1 in patients with MDS. *Patients and Methods.* MN1, ERG, BAALC and EVI1 transcript levels were analyzed by quantitative RT-PCR in 140 MDS patients and assessed for their prognostic significance in the context of other clinical and molecular markers. Expression data of the four genes were combined in an additive score, which was validated in an independent patient cohort of 110 MDS patients. *Results.* Patients with high compared to low expression of the individual genes MN1, ERG, BAALC or EVI1 expression showed a significantly worse overall survival (OS, P=.001; P<.001, P<.001, and P=.044, respectively) and shorter time to AML progression (MN1, ERG, and BAALC, P<.001, EVI1, P=.001). Multivariate analysis revealed that a high 4-gene expression score, defined as expression above the median of at least two of the four genes predicted a significantly shorter OS (HR 2.29, 95%CI 1.29-4.08, P=.005) and time to AML progression (HR 4.83, 95%CI 2.01-11.57, P<.001) compared to a low 4-gene expression score, independent of karyotype, transfusion dependence, percentage of bone marrow blasts, ASXL1, and IDH mutation status. In a validation cohort of 110 MDS patients, a high 4-gene expression score predicted shorter OS (HR 1.77; 95%CI 1.04-3.0, P=.034) and time to AML progression (HR 3.0, 95%CI 1.17-7.65, P=.022). *Conclusion.* A high 4-gene expression score is an unfavorable prognostic marker in MDS and is associated with a high risk for progression to AML. This prognostic marker may become useful for risk and treatment stratification.

BONE MARROW RESPONSE AND OVERALL SURVIVAL IN ON 01910.NA TREATED PATIENTS WITH REFRACTORY ANEMIA AND EXCESS BLASTS WHO FAILED PRIOR HYPOMETHYLATING THERAPY

L Silverman,[1] A Raza,[2] M Olnes,[3] P Greenberg,[4] F Wilhelm[5]

[1]*Mount Sinai Medical Center, New York, United States of America*
[2]*Columbia University Medical Center, New York, United States of America*
[3]*National Heart, Lung and Blood Institute, Bethesda, MD, United States of America*
[4]*Stanford University Cancer Center, Stanford, CA, United States of America*
[5]*Onconova Therapeutics Inc., Pennington, NJ, United States of America*

Background. ON 01910.Na is a new potent and selective mitotic inhibitor which inhibits the cell cycle progression at the G2/M interface, as well as the alpha and beta subunits of PI3-Kinase resulting in reduced levels of Cyclin D, C-myc and other regulatory proteins. It is also selective in cancer cells vs. normal cells. *Methods.* We analyzed bone marrow (BM) response and overall survival (OS) in 31 patients (pts) with refractory anemia with excess blasts (RAEB) -1,- 2 or -t, previously treated with azacitidine or decitabine who signed informed consent and were enrolled in 4 independent clinical trials. Pts received ON 01910.Na administered as a continuous intravenous infusion (CIV) from 2 to 6 days weekly or every other week (wk) with BM response initially assessed per protocol by wk 4 or 8 and every 8 wks thereafter. *Results.* Median OS was 36 wks and reached 49 wks in patients treated with ON 01910.Na 1800 mg dosing per 24h over 3-day infusions every other wk. A BM complete response (CR) (>50% decrease from baseline BM blast and decrease below 5% for at least 4 wks, per MDS IWG 2006 criteria) or a > 50% decrease of BM blasts was documented in 13/24 (54%) treated pts with at least one follow-up BM evaluation (green line) and was associated with a 44-wk median overall survival (OS) by the method of Kaplan-Meier (Fig. 1). Patients with stable disease (N=9; orange line) had a 40-wk median OS. Two patients progressed (median OS=16 wks; brown line) and 7 were not assessed (median OS=7 wks; blue line). Five pts had complete BM response and 5 patients had a hematological improvement (IWG 2006). Best results were found with 3-day infusions. Overall, ON 01910.Na infusions were well tolerated and no myelotoxicity was found when analyzing bone marrow cellularity. *Conclusion.* The median survival of MDS pts who failed to respond to prior treatment with azacitidine or decitabine has been reported to be approximately 4 to 6 months. These results and the apparent predictive value of BM response to ON 01910.Na for estimating overall survival of these patients have led to the initiation of a randomized survival trial of ON 01910.Na 3-day infusions vs. best supportive care in RAEB 1,2,t pts who failed or progressed after receiving hypomethylating agents.

Background. In ENESTnd, nilotinib has demonstrated superior efficacy to imatinib in patients with newly-diagnosed Philadelphia chromosome-positive (Ph+) CML-CP at 12 and 18 months. *Aims.* Here, we report results with a minimum patient follow-up of 24 months. *Methods.* 846 patients with newly-diagnosed Ph+ CML-CP were randomized to nilotinib 300 mg twice daily (BID) (n = 282), nilotinib 400 mg BID (n = 281), or imatinib 400 mg once daily (n = 283). Major molecular response (MMR; ≤ 0.1% BCR-ABL^{IS}) and complete molecular response (CMR^{4}, ≤ 0.01%^{IS}; CMR$^{4.5}$, ≤ 0.0032%^{IS}) by 24 months, time to progression to accelerated phase/blast crisis (AP/BC) on treatment, progression-free survival (PFS) on treatment, and overall survival (OS) were measured. *Results.* Significantly higher rates of MMR by 24 months were reported for both doses of nilotinib (71% and 67% on nilotinib 300 mg and 400 mg BID, respectively) compared with imatinib (44%, $P < .0001$ for each comparison) (Table). Rates of MMR were superior

* Cochran-Mantel-Haenszel test stratified by Sokal vs imatinib.
** Log-rank test stratified by Sokal vs imatinib.

for nilotinib at both doses (vs imatinib) regardless of Sokal risk score. Rates of CCyR by 24 months were also significantly higher on both nilotinib arms (87%, 85%) vs imatinib (77%; *P* = .0018 and .0160 for comparison with nilotinib 300 mg BID and 400 mg BID, respectively). Rates of CMR[4] and CMR[4.5] at any time were significantly higher for both doses of nilotinib vs imatinib (CMR[4]: 44%, 36%, and 20% for nilotinib 300 mg and 400 mg BID and imatinib, respectively, *P* < .0001 for both; CMR[4.5]: 26%, 21%, and 10%, *P* < .0001 and .0004 for nilotinib 300 mg BID and 400 mg BID vs imatinib, respectively). Progressions to AP/BC (without clonal evolution) continued to be less frequent on nilotinib, occurring in 2, 3, and 12 patients on the nilotinib 300 mg BID, 400 mg BID, and imatinib arms, respectively. At 24 months, OS remained similar in all groups, but there were fewer CML-related deaths on both nilotinib 300 (n = 5) and 400 mg BID (n = 3) vs imatinib (n = 10). Twice as many patients had emergent BCR-ABL mutations on imatinib (n = 20) vs nilotinib (n = 10 and 8 for 300 mg BID and 400 mg BID, respectively) and mutations were more frequent in patients with high or intermediate Sokal risk. Overall, 72 (26%), 61 (22%), and 92 (33%) of patients in the nilotinib 300 mg and 400 mg BID and imatinib arms, respectively, discontinued treatment. Both drugs were well tolerated, with the fewest discontinuations due to adverse events/laboratory abnormalities in the nilotinib 300 mg BID arm (9% vs 13% and 10% for the nilotinib 400 mg BID and imatinib arms, respectively). There has been no change in the safety profile of nilotinib in the second year of treatment. *Conclusions.* With a minimum follow up of 24 months, nilotinib continues to demonstrate superior molecular responses and improved disease control compared with imatinib. These data continue to support nilotinib as a potential new standard of care in newly-diagnosed patients with Ph+ CML-CP.

Background. Bosutinib is an orally active, dual Src/Abl tyrosine kinase inhibitor with minimal inhibitory activity against PDGFR or c-kit. *Aim.* The phase 3 BELA study compared bosutinib with imatinib in patients with newly diagnosed Philadelphia chromosome positive (Ph+) chronic phase chronic myeloid leukemia (CP CML). *Methods.* Patients (N = 502) with Ph+ CP CML stratified by Sokal score and region were randomized to oral bosutinib 500 mg/day (n = 250) or imatinib 400 mg/day (n = 252). Study design and endpoints have been described (Gambacorti, ASH 2010). Safety analyses included all treated patients; efficacy analyses included all randomized patients (intent-to-treat [ITT] population). *Results.* Median treatment duration was 16.6 months for bosutinib and 16.8 months for imatinib; 69% and 78% of patients, respectively, were still receiving therapy. Common treatment-emergent adverse events (TEAEs; ≥20% of patients) observed with bosutinib and imatinib, respectively, were diarrhea (68%, 22%), vomiting (31%, 14%), nausea (31%, 35%), rash (21%, 16%), and muscle cramps (4%, 20%). Pleural effusions were seen in 3% of bosutinib patients (no imatinib patients). Grade ≥3 TEAEs (≥2% of patients) seen with bosutinib were diarrhea (10%), vomiting (3%), pneumonia (3%), and dyspnea (2%). Median cumulative duration of diarrhea was 33 days for bosutinib and 17 days for imatinib. Grade ≥3 laboratory abnormalities (≥10% of patients) with bosutinib and imatinib, respectively, were elevated alanine aminotransferase (23%, 3%), thrombocytopenia (14%, 14%), elevated aspartate aminotransferase (11%, 3%), neutropenia (9%, 21%), and hypophosphatemia (4%, 17%). Twenty-two percent of bosutinib patients and 6% of imatinib patients discontinued due to AEs. Deaths occurred in 4 (1.6%) bosutinib patients and 12 (4.8%) imatinib patients; overall, 81% of these died from disease progression, with CML-unrelated deaths reported for only 1 bosutinib patient and 2 imatinib patients. In efficacy analyses, complete cytogenetic response (CCyR) rates for bosutinib and imatinib, respectively, at 1 year were 70% and 68% for the ITT population, and 78% and 68% for the evaluable population (P = 0.026). Cumulative CCyR rates by 1 year were 79% (bosutinib) and 75% (imatinib). Major molecular response (MMR) rates at 1 year were higher for bosutinib versus imatinib (39% vs 26%; P = 0.002), as were cumulative MMR rates by 1 year (47% vs 32%; P <0.001). Time to CCyR and MMR were significantly shorter with bosutinib (P <0.001 for both). Transformation to accelerated/blast phase occurred in 4 (2%) patients on bosutinib and 10 (4%) patients on imatinib (P = 0.053). Treatment failures were reduced in the bosutinib group compared with the imatinib group (3% vs 10%; P <0.001). Event-free survival rates were similar between groups (92% for bosutinib and 90% for imatinib). *Summary/Conclusions.* Safety and efficacy were consistent with previously reported results. Bosutinib had a distinct and acceptable toxicity profile. Bosutinib showed a significantly higher MMR rate at 1 year, significantly faster times to CCyR and MMR, and a borderline significantly lower transformation rate versus imatinib. In conclusion, bosutinib may provide a new therapeutic option in patients with newly diagnosed Ph+ CP CML. Data for the 18-month follow-up will be presented.

Background. Over the years, Bcr-Abl kinase domain (KD) mutation analysis has more and more extensively been applied in Ph+ patients receiving tyrosine kinase inhibitors (TKIs). *Aims.* We reviewed the database recording the mutation analyses performed in our laboratory from January 2004 to January 2011 in order to: i) assess how the clinical relevance of mutations (overall and individually) has changed from the imatinib to the 2nd-generation TKI era; ii) understand how the role of mutation analysis in routine clinical management of patients has evolved over time; iii) elucidate how frequently physicians may expect to find mutations in specific settings. *Methods.* 3285 bcr-Abl KD mutation analyses were performed by D-HPLC and/or direct sequencing; 1439 patients were analyzed (CML, n=1275; Ph+ ALL, n=164). *Results.* Since 2006, mutation analysis of CP-CML patients on imatinib has usually been triggered by failure or suboptimal response according to ELN definitions. Only 41/142 (29%) failures and 19/222 (10%) suboptimal responses we analyzed harbored mutations; the likelihood of mutation detection varied across different subcategories. In particular, no mutations were detected in any of the 42 CCyR patients who failed to achieve MMR at 18 months. Over time, more and more physicians asked for mutation analysis of their CP-CML patients because of a Bcr-Abl transcript increase at a single RQ-PCR test; mutations were detected in 0/26 patients who experienced <1-log increase without MMR loss, 0/41 patients who experienced ≥1-log increase without MMR loss, 1/36 (3%) patients who experienced <1-log increase with loss of MMR and 2/41 (5%) patients who experienced ≥1-log increase with loss of MMR but not CCyR. The 25 additional patients analyzed after a transcript increase confirmed by two subsequent RQ-PCR assess-

ments were negative as well. Among imatinib-resistant CML patients receiving a 2nd-generation TKI (dasatinib, nilotinib) 38 analyses were triggered by provisional ELN criteria for failure or suboptimal response; again, failures were more frequently associated with mutations (57%) than suboptimal responses (21%). In addition, 71% of patients who lost a previously achieved response (HR or CyR) were positive for mutations. The ten most frequent mutations conferring resistance to dasatinib/nilotinib in CML and Ph+ ALL included T315I (30.3%), F317L (16.2%), Y253H (16.2%), F359V (7.1%), V299L (7.1%), E255K (6.1%), E255V (5.1%), F359I (4%), T315A (3%), F359C (2%) - detected either alone (56% of patients), or combined (29%), or together with other mutations (15%). Some physicians ask for mutations analysis of their newly diagnosed, TKI-naïve patients - mutations were detected in 1/58 CP CML, 3/12 BC CML and 3/60 Ph+ ALL patients. *Summary.* Bcr-Abl KD mutations contribute differently to different types of 'resistance', and this happens both in the setting of imatinib first-line and in the setting of 2nd-generation TKIs second-line - although the mutation frequency is, overall, higher in the latter. In CP CML patients on imatinib who show Bcr-Abl transcript increase, only loss of MMR is a reasonable trigger for mutation analysis - although <3% of molecular suboptimal responders can be expected to harbour mutations. Prevalence of individual mutations is changing. Additional analyses will be presented.

Acknowledgments: Supported by ELN, AIL, PRIN.

Background. Chronic myeloid leukemia (CML) is characterized by the BCR-ABL fusion gene. Different types of BCR-ABL transcripts can be found, due to different genomic breakpoints and alternative splicing. The most frequent transcripts are the e13a2 (b2a2) and the e14a2 (b3a2). Occasionally, both transcripts may be present. In the imainib (IM) era, few data about the prognostic significance of the transcript type are available, particularly in the setting of early chronic phase (ECP): one study suggested that patients with the b2a2 transcript may be more sensitive to IM (de Lemos *et al*. Genet Mol Res 2005), while two larger studies suggested that patients with b3a2 transcript may have better responses to IM (Vega-Ruiz *et al*. ASH 2007; Lucas *et al*. Haematologica 2009). No systematic evaluations in large prospective clinical trials have been performed. *Aims.* To investigate the influence of the BCR-ABL transcript type on the responses and the outcome of ECP CML treated with IM. *Methods.* Analysis of 3 concurrent clinical trials of the GIMEMA CML WP (Clin Trials Gov. NCT00514488, NCT00510926 and observational trial CML/023). Response monitoring: conventional cytogenetic examination (bone marrow) and Q-PCR (peripheral blood). Definitions: Major Molecular Response (MMR): BCR-ABL/ABL ratio <0.1% (International Scale); failures: revised European LeukemiaNet criteria (Baccarani *et al*. J Clin Oncol 2009); events: failure or treatment discontinuation for any reason. All the calculations have been made according to the intention-to-treat principle. *Results.* 559 consecutive ECP CML patients were enrolled. Patients expressing rare transcript types (e1a2 and e19a2) and patients with both b2a2 and b3a2 transcripts were excluded: 493 out of 559 patients were evaluable, 203 (41%) with b2a2 transcript and 290 with b3a2 transcript (59%). The 2 groups were comparable (no significant differences in sex, age, Sokal/Hasford score distribution, clonal chromosomal abnormalities in Ph+ cells), except for the proportion of patients treated with IM 800 mg/daily: 20% and 28% (p=0.034) in patients with b2a2 and b3a2, respectively. The median observation time was 60 months. In patients with b2a2 and b3a2 transcript, the observed 12-months CCgR rates were 75% and 79%, respectively, with a cumulative CCgR incidence of 89% and 88%, respectively (no significant differences). The time to MMR was significantly shorter for patients with b3a2 transcript and the overall estimated probability of MMR was significantly lower for patients with b2a2 transcript (85% vs 90%, p<0.001, fig.1). The probability of Overall Survival (OS), Progression-Free Survival (PFS), Failure-Free Survival (FFS) and Event-Free Survival (EFS) was 86% and 91% (p=0.064), 82% and 90% (p=0.027), 70% and 76% (p=0.095), 58% and 70% (p=0.027) in patients with b2a2 and b3a2 transcript, respectively (fig. 1). *Summary/Conclusions.* In patients with b2a2 and b3a2 transcript the CCgR rates were comparable, but the overall estimated probability of MMR was significantly lower for patients with b2a2 transcript. OS, PFS, FFS, and EFS were uniformly lower in patients with b2a2 transcript (PFS and EFS: p< 0.05).The b2a2 transcript is a candidate adverse prognostic factor in ECP CML patients treated with IM frontline.

CANCEROUS INHIBITOR OF PP2A (CIP2A) AT DIAGNOSIS OF CHRONIC MYELOID LEUKAEMIA IS A CRITICAL DETERMINANT OF DISEASE PROGRESSION

M Lucas,[1] R Harris,[1] A Giannoudis,[1] M Copland,[2] R Slupsky,[1] R Clark[1]

[1]*University of Liverpool, Liverpool, United Kingdom*
[2]*Paul O'Gorman Leukaemia Research Centre, Gartnavel General Hospital, Glasgow, United Kingdom*

Background. Prospective identification of patients whose chronic myeloid leukaemia (CML) will progress to blast crisis is currently not possible. PP2A is a phosphatase and tumour suppressor which regulates cell proliferation, differentiation and survival. Cancerous inhibitor of PP2A (CIP2A) is a recently described novel inhibitor of PP2A with an unknown biological role in CML. *Aims.* The aim of this study was to investigate the role played by CIP2A in CML and whether PP2A, or its inhibitors CIP2A and SET, could predict clinical outcome. *Methods.* In 31 newly diagnosed chronic phase patients PP2A, phosphorylated PP2A (as a measure of PP2A activity) and CIP2A proteins were assessed by flow cytometry at diagnosis and following 12 months of treatment, or at transformation. TaqMan gene expression assays were used to measure PP2A and CIP2A gene expression, and CIP2A siRNA was transfected into K562 cells. Results were analysed in patients stratified according to their eventual clinical outcome - cytogenetic responders (CCR), Non-responders (No-CCR) and blast crisis (BC). *Results.* PP2A is functionally inactive in MNC and CD34+ cells taken at diagnosis in patients destined to progress to BC compared to those patients who

achieve a CCR. With SET, protein levels were significantly higher at diagnosis in the CCR and No-CCR groups compared to normal values (p=0.001 and p=0.01 respectively), but in patients who subsequently progressed to BC there was a trend for lower SET levels - suggesting that SET was not solely responsible for inhibiting PP2A in destined to progress into BC. At diagnosis of CML, patients who later progress to BC have significantly higher levels of CIP2A protein (p=<0.0001) than patients who do not progress. There was no correlation between CIP2A levels and patients' Sokal score. CIP2A protein was not suppressed by imatinib treatment *in vivo*. During disease progression, CIP2A protein levels increased further, suggesting that PP2A function is increasingly impaired in these patients. Chronic phase patients who have high CIP2A protein at diagnosis have a 100% probability of progressing to BC - with the mean time to progression being 13 months. Knockdown of CIP2A resulted in increased PP2A activity and decreased BCR-ABL1 tyrosine kinase activity. mRNA expression of CIP2A, SET and PP2A had no prognostic value. These data show that two mechanisms control PP2A activity in CML. In patients who clinically respond well SET appears to be the controlling inhibitor, while in patients who progress to BC PP2A activity appears to be impaired predominantly by CIP2A. Importantly these two signalling mechanisms can be detected at diagnosis. *Summary/Conclusion.* CIP2A is a prospective biomarker of BC in CML and may be a useful therapeutic target.

Background and Aims. Chromosomal translocations involving the immunoglobulin heavy chain gene (IGH) locus play a pivotal role in the pathogenesis of human B-cell malignancies. IGH translocation brings target genes positioned on different chromosome loci into close apposition with transcription elements within the IGH locus, resulting in deregulated expression of the target genes. We previously reported an insertion of microRNA125b1 (hearafter,miR125b1) into the IGH locus in a patient with B-cell precursor acute lymphoblastic leukemia (BCP-ALL). Other groups identified fusion sequences of IGH and miR125b1 from t(11;14)(q24;q32) indicating that chromosome translocation involving IGH and miR125b1 loci is a recurrent event in human BCP-ALL However, *in vivo* oncogensis of miR125b in B-cells have not been fully understood. To confirm that deregulated expression of miR125b by IGH regulatory elements induces B-cell tumor, we generated transgenic mouse (Emu/miR125b1 TG mouse) mimicking the t(11;14)(q24;q32). *Methods.* The transgene consisted of human intronic enhancer of IGH

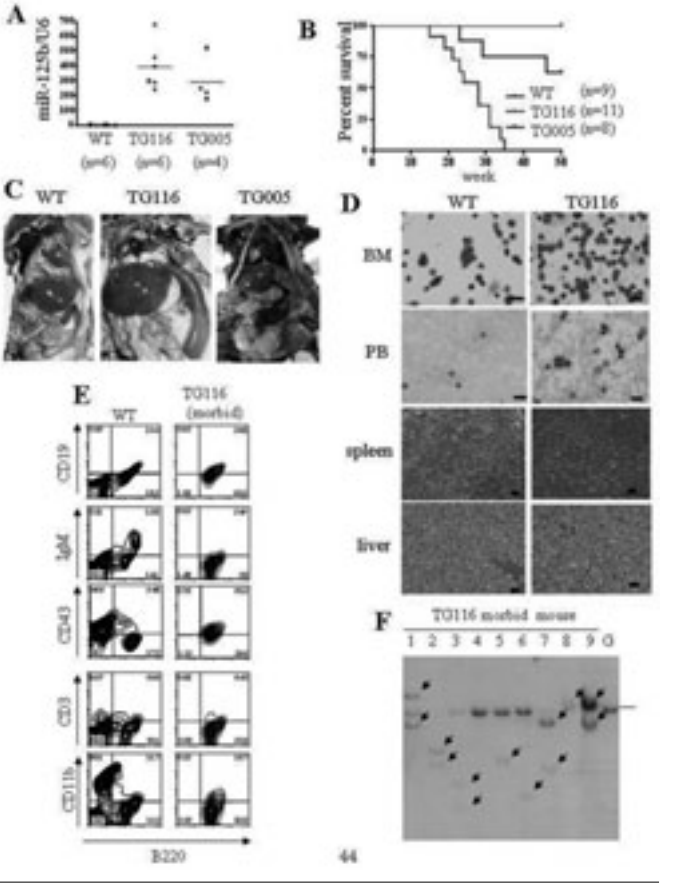

Figure 1.

(Emu), mouse VH promoter, and rat beta-globin including mouse genomic sequence containing pre-miR125b. Two stable Emu/miR125b1 mice (TG116 and TG005) were established and subsequently examined in morphologic, phenotypic and genotypic characteristics. We performed a bioinformatics search using Targetscan for candidate targets of the miR125b. MiR125b expression was analyzed in various hematological tumor samples using qRT-PCR. *Results.* Both TG mice developed lethal B-cell malignancies. Most tumor cells of the morbid TG116 mice were B220+/CD19+/IgM-/CD43+ B-cells; whereas those of the morbid TG005 mice were B220+/CD19+/IgM+/CD43- B-cells with clonal B-cell proliferation as shown by Southern blot analysis. We found several molecules for the target of miR125b, such as BAK1, which has been previously reported as a candidate. Among them, we focused on trp53inp1, a pro-apoptotic gene. MiR125b binds to tpr53inp1 3'UTR with seed sequence and B-cells obtained from the TG116 mice tended to reduce trp53inp1 at the mRNA and protein levels compared to WT mice. 32Dcl3 cells overexpressing miR125b or B-cells of TG116 became resistant to apoptosis induced by cytokine depletion or serum starvation, respectively. Of clinical relevance, overexpression of miR125b was found in various human hematological tumors including B-ALL, AML and MDS, especially in BCR/ABL positive B cell leukemia (four out of eight BCR/ABL positive ALL and one B-lymphoid crisis from CML). *Conclusion.* Deregulated expression of miR125b controlled by IGH regulatory elements causes BCP-ALL in TG mice. The phenotype of the tumor cells seen in the TG mice was similar to those of human disease. MiR125b binds to trp53inp1 and its overexpression is suggested to confer anti-apoptotic characteristics on cells. Overexpression of miR125b might be associated to BCP-ALL derived from BCR/ABL hematopoietic clone.

CLONAL SELECTION IN XENOGRAFTED HUMAN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA RECAPITULATES GAIN OF MALIGNANCY AT RELAPSE

E Clappier,[1] B Gerby,[2] F Sigaux,[3] M Delord,[3] F Touzri,[3] L Hernandez,[3] P Ballerini,[2] A Baruchel,[1] F Pflumio,[2] J Soulier[3]

[1]*Robert Debré Hospital, Paris, France*
[2]*LSHL, IRCM, CEA, Fontenay-aux-Roses, France*
[3]*Hopital Saint-Louis, INSERM U944, Paris, France*

Background. Despite major therapeutic improvements, a fraction of patients with acute lymphoblastic leukemia (ALL) still relapse and experience eventual refractory leukemia, pointing to the need for relevant preclinical models to design new therapeutic strategies. Genomic studies in human ALL have revealed intra-clonal heterogeneity at diagnosis and clonal evolution at relapse, suggesting that genetic subclones with distinct functional properties may preferentially contribute to tumor progression. *Aims.* Primary human ALL cells can be transplanted and expanded into immunodeficient mice, leading to xenograft human leukemia. We hypothesized that re-initiation of leukemia in mice could favor clonal evolution similarly to relapse in patients. We aimed to use xenograft to investigate the genomic and functional mechanisms of tumor progression in T-ALL patients. *Methods.* A series of 26 diagnosis T-ALL samples was transplanted into immunodeficient mice (NOD/Scid or NSG), and paired xenograft and diagnosis T-ALL samples were compared by high-density DNA arrays and oncogene resequencing. For 8 patients, relapse samples could also be analyzed. Large scale gene-expression profiling, lentiviral-mediated shRNA knockdown in patient's primary leukemic cells followed by competitive *in vivo* experiments, and *in vitro* assays for drugs response were performed to analyze functional features of clonal selection in xenograft leukemias. *Results.* We show that leukemia in recipient mice frequently re-initiated from minor subclones pre-existing at diagnosis and bearing additional genomic lesions of human cancer genes like PTEN, MYC, MYB, WT1, CDKN2A, and NOTCH1, reminiscent of clonal selection towards relapse in patients. Gene-expression profiling identified a robust signature of cell cycle and mitosis in the xenograft leukemia samples compared with the corresponding diagnosis samples. Importantly, Gene Set Enrichment Analysis (GSEA) found that this signature was also highly enriched in the cells at relapse in two independent series of human ALLs. Mimicking the effect of an additional genomic lesion in patient's primary leukemia cells by shRNA-mediated knock-down conferred a selective advantage in competitive engraftment experiments, demonstrating that these lesions can be drivers of increased leukemia-initiating activity. Finally, xenograft leukemia cells had an overall diminished sensitivity to glucocorticoids and gamma-secretase inhibitor. *Summary/Conclusions.* The establishment of human T-ALL in immunodeficient mouse is associated with the selection and expansion of a more aggressive leukemia with enhanced proliferation, recapitulating the process of leukemia progression in patients. This approach using leukemia xenotransplantation shed light on the mechanisms underlying tumor progression and should contribute to the design of novel strategies to prevent or treat T-ALL relapse in patients. Finally, these results suggest that genetic heterogeneity of ALL and subsequent clonal selection in immunodeficient mouse have to be considered when characterizing human ALL leukemic stem cells.

MUTATION OF THE HEDGEHOG PATHWAY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

D Pauwels,[1] I Lahortiga,[1] Z Kalender,[2] K De Keersmaecker,[1] N Mentens,[1] A Uyttebroeck,[3] S Aerts,[2] P Vandenberghe,[2] J Cools[1]

[1]*Center for Human Genetics, K.U.Leuven, VIB Leuven, Leuven, Belgium*
[2]*Center for Human Genetics, K.U.Leuven, Leuven, Belgium*
[3]*Pediatric Hemato-oncology, University Hospitals Leuven, Leuven, Belgium*

Background. The Hedgehog (HH) signaling pathway plays an important role in cell growth and differentiation and is involved in the development of many tissues, including T cell development. Based on this important function, it is not surprising that several human diseases are caused by mutation in components of the HH pathway. Many studies have revealed mutation of this pathway in basal cell carcinoma, medulloblastoma, and other cancers. Also in chronic myeloid leukemia stem cells, activation of the HH pathway was suggested, but mutation in HH pathway components have not been identified in hematological malignancies. *Aims.* Upon mutation analysis of 97 candidate oncogenes in T-cell Acute Lymphoblastic Leukemia (T-ALL), we identified PTCH1 (patched) mutations in several T-ALL cell lines (see abstract by V. Gianfelici *et al.*). The aim of this project was to confirm the involvement of the HH pathway in the pathogenesis of T-ALL and to determine the sensitivity of T-ALL cell lines to HH pathway inhibitors. *Methods.* We performed a mutation analysis of the different HH components in 17 T-ALL cell lines and 57 T-ALL patients. In addition, we treated a set of T-ALL cell lines with 4 different HH antagonists (Cyclopamine, GDC-0449, GANT61 and Itraconazole) and tested the effect on proliferation, cell cycle and apoptosis. *Results.* Sequence analysis of PTCH1, PTCH2, SMO, SUFU, GLI1 and GLI3 revealed a number of mutations in at least one of these genes in 9/17 (53 %) cell lines and 9/57 (15%) primary T-ALL samples. In agreement with this, T-ALL cell lines showed sensitivity to HH pathway antagonists. Itraconazole, a natural antifungal triazole, that was recently discovered as a new inhibitor of the HH pathway was identified as the most potent HH inhibitor in T-ALL cell lines with IC50 values below 500 nM. Apart from a reduction of the proliferation, it also induced apoptosis and blocked the cell cycle. *Conclusion.* Our data demonstrate an important role of the HH pathway in the pathogenesis of T-ALL, and show potent inhibitory activity of HH pathway inhibitors on T-ALL cell proliferation and survival.

0492

THE ERYTHROPOIETIN RECEPTOR (EPOR) IS DEREGULATED BY ETV6-RUNX1 (TEL-AML1) IN EARLY B LINEAGE PROGENITOR CELLS

M Ford, T Torrano Moya, E Procter, E Cardus, F Greaves

The Institute of Cancer Research, Sutton, United Kingdom

Background. ETV6-RUNX1 (TEL-AML1) fusion is a pre-natal and initiating event in childhood acute lymphoblastic leukaemia (ALL). The erythropoietin receptor gene (EPOR) is consistently highly expressed ectopically in TEL-AML1+ ALL but any role in leukemogenesis driven by TEL-AML1 remains to be confirmed. *Aims.* To assess the impact of TEL-AML1 expression on candidate 'pre-leukaemic' stem cells and to demonstrate the presence of functional, ligand binding EPOR on TEL-AML1+ ALL cells that may provide these cells with a survival signal. *Methods.* Biotinylated erythropoietin (EPO) and flow analysis were used to assess cell surface EPOR protein levels. Quantitative PCR, ChIP, luciferase reporter assays and EMSA showed that TEL-AML1 directly regulates EPOR. Standard tissue culture techniques were used to show cell survival in the presence of EPO alone and western blot to assess the mechanism of cell signalling. *Results.* Biotinylated EPO and flow analysis showed that the pre-B ALL TEL-AML1+ cell line REH has higher levels of EPOR than similar non-TEL-AML1 cell lines. A "blind screen"of CD19+ cells isolated from 10 patients with pre-B ALL, identified five patients with high expression of ligand-binding EPOR, four of which were subsequently identified as TEL-AML1+. The inducible

expression of TEL-AML1 in lymphoid BaF3 cells, or its constitutive expression in a murine transgenic model was sufficient to increase expression of EPOR. EMSA and ChIP experiments within the EPOR promoter confirmed occupancy of AML1 consensus binding sites by TEL-AML1 and luciferase reporter assays in the presence of the fusion protein showed up-regulation of EPOR promoter activity. Given the proposed pro-survival properties of EPO on non-erythroid cells, we asked if the observed increase in expression of the EPOR could correlate with increased cell survival in the presence of EPO. Cell survival experiments including growth curves, propidium iodode staining and analysis of anti-apoptotic gene markers revealed that IL3-dependent cells expressing TEL-AML1 showed a prolonged survival in the presence of EPO alone. Turning off TEL-AML1 in these cells resulted in cell death even in the presence of EPO, suggesting that this effect is a consequence of TEL-AML1 expression alone. Signalling through EPOR in the presence of EPO was confirmed by phosophorylation analysis of JAK and AKT pathways, analysis of STAT5B activity and the concomitant up-regulation of BCL-XL. EPOR functionality in the presence of EPO was also demonstrated in TEL-AML1+ patient cells. In our model of human pre-leukemia, normal human CD34+ cord blood cells were transduced *in vitro* with a lentivirus capable of expressing both TEL-AML1 and GFP and cells were 'primed' for pre-B lineage commitment. These TEL-AML1+ cells also showed increased levels of functional cell surface EPOR and activated survival gene targets - again suggesting a role for enhanced cell survival through the EPO-EPOR axis. *Summary.* These data support the contention that TEL-AML1 directly activates ectopic expression of a functional EPOR, which provides cell survival signals that contribute critically to persistence of the pre-malignant clone in patients.

[4]*INSERM U563, Toulouse, France*

Background. T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive malignancy of thymocytes. In order to comprehensively assess the action of microRNAs (miRNAs) in T-ALL, we compared miRNA expression patterns in 50 human T-ALL samples and 5 distinct subsets of normal developing T-cell progenitors with an unbiased miRNA library screen followed by computational target identification and functional assessment of the most relevant candidate miRNAs in a murine T-ALL model. *Methods.* Using high-throughput quantitative stem-loop RT-PCR, 430 miRNAs were profiled in a T-ALL patient cohort including 12 HOXA, 15 TAL/LMO, 10 TLX3 and 5 TLX1 rearranged patient samples as well as in 5 different subsets of sorted T-cell populations from human thymus. An unbiased miRNA library screen was performed in myc-transduced MEFs, based upon rescue for myc-induced apoptosis, followed by validation for individual miRNAs in FL5-12 lymphocytes and an *in vivo* NOTCH1-sensitized murine T-ALL model. *Results.* A total of ten miRNAs were highly expressed in the entire cohort of T-ALLs, i.e. miR-223, miR-19b, miR-20a, miR-92, miR-142-3p, miR-150, miR-93, miR-26a, miR-16 and miR-342. High expression of this subset of 10 miRNAs was confirmed in a series of 18 T-ALL cell lines. Cross-comparison with the miRNA library screen allowed the identification of five T-ALL promoting miRNAs (miR-19b, miR-20a, miR-26a, miR-92 and miR-223). Remarkably, these miRNAs produce overlapping and cooperative effects on validated target genes with known tumor suppressor function in T-ALL, including IKAROS (IKZF1), PTEN, BIM, PHF6, NF1 and FBXW7. In addition, specific sets of differentially expressed miRNAs were delineated for each of the genetic T-ALL subgroups. Finally, the current mRNA/miRNA profiles also provide insight into key regulatory events controlling normal T-cell development. *Conclusion.* A comprehensive and unbiased analysis of miRNA action in T-ALL and normal developing thymocytes reveals a cooperative role for a small set of miRNAs in suppression of key T-ALL suppressor genes, identifies miRNA signatures in genetic T-ALL subgroups and provides insights into miRNA controlled regulation of thymocyte maturation.

Background. Immunomodulator drugs (IMiDs) are new and very promising oral agents in Multiple Myeloma (MM); however, IMiDs are also associated with an increased risk of thromboembolism events (TE) which necessitates routine prophylaxis. Controversies remain regarding the best choice of TE prophylaxis in MM patients treated with IMiDs-based therapy and the criteria for the TE risk definition. *Aims.* We designed a large multicentre observational study aimed at prospectively evaluate the incidence and risk factors of venous thromboembolisms associated with IMiDs [either lenalidomide (Len) or thalidomide (Thal)] therapy in MM. *Methods.* A total of 519 patients with MM treated with IMiDs-based therapy at first to third line of therapy were included in this study. VTE prophylaxis was recommended to start prior to start IMiDs, the choice was left at the discretion of the investigator. Patients gave written informed consent according to the declaration of Helsinki. Various patient characteristics were recorded, such as age, sex, criteria of vascular complications, including adjuvant treatment and previous history of vascular complications. The physicians were to record the risk of VTE occurrence, based on guidelines and their own appreciation of the risk. Occurrence of any thrombosis event (either venous or arterial) was to be recorded along with the descriptive characteristics of the event, how the event was managed and the outcome of the patient. The data were collected at entry in the study, and then at 4 and 12 months. *Results.* Out of the 519 patients, 35.66% had Thal-based and 64.34% had Len-based therapy. Overall, median age was 71, with 65% >65 years old and sex ratio was 249 male/268 female, similar in the 2 groups (data missing for n=2). One hundred and eighty patients were in first line therapy, 169 in second line therapy and 153 in third line therapy (data missing for n=17). Patients were treated with VTE prophylaxis as follow (data missing for n=8); 293 (57.34%) aspirin, 91 (17.81%) LWMH and 46 (9.00%) vitamin K antagonists. Surprisingly, 16% had no VTE prophylaxis. Aspirin was primarily administered in 70% of low risk patients and 58% of moderate risk patients, and LWMH in 46% of high risk patients along with 20% aspirin. Investigators recorded 17 (3. 5%) VTE at 4 months. Of the VTE, 50% of the patients had aspirin and 20% had LWMH. Interestingly, patients with VTE in the aspirin group were considered low risk, and patients in the LWMH group were considered high risk. The occurrence of VTE was unrelated to the IMiD-based therapy and the line of therapy. None of the patients with PE had LWMH. *Conclusion.* VTE is low in IMiDs-based treated MM patients upon VTE prophylaxis. However, despite VTE prophylaxis, we observed occurrence of VTE, not related to the VTE risk stratification recommended in guidelines. It is therefore needed to determine risk factors of VTE upon VTE prophylaxis. Final results will be proposed with updated results at EHA 2011.

Type and duration of anticoagulation is still matter of debate in cancer patients with acute Deep Vein Thrombosis (DVT) of the lower limbs. Residual Vein Thrombosis (RVT) has been proven to be effective for assessing the optimal duration of oral anticoagulants in non cancer patients (Siragusa S *et al* Blood 2008:112:511-5). In the present study we evaluate the role of a RVT-based management of anticoagulation with Low-Molecular Weight Heparin in cancer patients with acute DVT. *Materials and Methods.* Patients with active cancer and a first episode of DVT were treated with LMWH for 6 months (the first month at full dosage followed by dose reduction of 25% in the next 5 months). At the end of treatment, they were managed according to RVT findings: those with RVT were randomized to continue anticoagulants for 6 additional months (Group A1) or to stop it (Group A2), while patients without RVT stopped LMWH (Group B). Outcomes were recurrent venous thromboembolism and/or major bleeding; patients were followed up for one year after LMWH discontinuation. *Results.* Over a period of 36 months, 409 patients were evaluated; 62 were excluded (refusal, need for continuing anticoagulation, etc). In total, 347 were included in the study (Table 1). RVT was detected in 242 (69.7%) patients; recurrent events occurred in 21.9% of those randomized to discontinue and 14.2% of those who continued LMWH. In patients without RVT (105, 30.3%), recurrent events occurred in 3 cases (2.8%) (Table 2 and Figure 1). The adjusted Hazard Ratio (HR) for age and sex between RVT groups (Group A2 vs A1) was 1.58 (95% confidence interval [CI], 0.85-2.93; P=.145). The adjusted HR between group A1 versus RVT-negative group (B) was 4.54 (CI 2.3-6.66; P =.028). Five major bleeding events occurred in Group A1 and two events both in Group A2 and B (Table 2). Overall, 89 (25.6%) patients died due to cancer progression after a median follow-up of 10.2 months after heparin withdrawn. *Conclusions.* The Cancer DACUS is the first ever study evaluating an individual marker for assessing duration of anticoagulation in active cancer population. Final results of the study show that absence of RVT identifies a group of patients at low risk for recurrent thrombosis who can safely stop LMWH after 6 months.

THROMBIN GENERATION AND PROANGIOGENIC PROPERTIES OF BREAST CANCER CELLS ARE MODULATED BY HEPARINS

E Diani, M Marchetti, A Vignoli, A Falanga

Ospedali Riuniti di Bergamo, Bergamo, Italy

Background. Breast cancer is the most frequent solid tumor among women and is associated to an increased thrombotic risk during antitumor treatments. Tumor cell-associated procoagulant activity contributes to the thrombotic risk and to the disease progression in cancer patients. Reducing tumor procoagulant activity may improve the outcome of the disease. In this setting, low molecular weight heparins (LMWH) have shown a beneficial effect on both thrombosis rate and survival from cancer. *Aim.* In this study we investigated whether two LMWH (i.e. dalteparin, mean MW 6.0 KDa and bemiparin, mean MW 2.6 KDa) and unfractioned heparin (UFH, mean MW 15 KDa) might affect the thrombin generation potential (TG) and the proangiogenic activity of the breast cancer cells. *Methods.* MDA.MB.231 breast cancer cells were lysed (150,000 cells/ml) by 3 cycles of freezing and thawing and TG was evaluated by the Calibrated Automated Thrombogram (CAT) and compared to the activity of a standard TF preparation (i.e. 1 and 5 pM, Thrombinoscope). Parameters evaluated were: time to generate thrombin (Lagtime, min), endogenous thrombin potential (ETP, nM*min), peak height (Peak, nM) and time to reach the peak (ttPeak, min). The inhibition capacity of heparins was evaluated after addition of increasing concentrations of these drugs (from 0.01 to 1 IU/ml) to the experimental system. The anti-angiogenic activity of heparins was evaluated as the capacity of these agents to inhibit endothelial cells capillary-like tube formation in Matrigel. Specifically, endothelial cells (HMEC-1) were incubated for 24 hours with MDA.MB.231 conditioned medium in the presence or absence of heparins (from 0.01 to 1IU/ml), and the total length of the network formed was measured. *Results.* MDA.MB.231 showed a high TG, with values comparable to those obtained with 5pM standard TF. Heparins significantly and dose-dependently reduced the breast cancer cell-induced TG. Among the different TG parameters, ETP and Peak were the most affected by heparins. Particularly, at 0.4 IU/ml concentration, TG was completely inhibited by UFH, while ETP and Peak were reduced by 60% and 80% by dalteparin, and 30% and 50% by bemiparin, respectively. All the heparins studied also reduced in a dose dependent way the proangiogenic activity of tumor cells in the Matrigel assay. Starting from a concentration of 0.1 IU/ml, a significant ($p<0.05$) reduction of capillary network formation was observed with all the three heparins. The pattern of inhibition was the opposite of that of TG, i.e. 100% for bemiparin, 75% for dalteparin and 35% with UFH, showing an inverse relation with the heparin molecular weights. *Conclusion.* The effect of LMWH on the control of two crucial steps of breast cancer invasiveness, i.e.TG and the proangiogenic capacity, supports the role of these agents as adjuvant therapy for cancer treatment.

Background. Thalidomide-based regimens are associated with an increased incidence of thrombosis in newly diagnosed myeloma (MM) patients. Preliminary studies on MM patients treated with a combination of lenalidomide (R) plus dexamethasone have shown an increased risk (between 11% and 75%) of thromboembolic events as well. *Aims.* In a prospective, multicenter phase III trial (RV-MM-PI-209) newly diagnosed patients were treated with lenalidomide and low-dose dexamethasone (Rd) induction and subsequently randomized to receive consolidation with lenalidomide + melphalan + prednisone (MPR) or high dose melphalan (MEL200). In this substudy, we compared the efficacy and safety of aspirin (ASA) or low-molecular weight heparin (LMWH) as thromboprophylaxis in newly diagnosed MM patients younger than 65 yrs during Rd induction and MPR consolidation. Primary end-points were incidence of venous thromboembolism (VTE), acute cardiovascular events, sudden death, major and minor bleeding. *Methods.* a total of 402 transplantation candidates received four 28-day cycles of lenalidomide (25 mg d 1-21) and low-dose dexamethasone (40 mg d 1,8,15,22) (Rd) as induction and randomized to consolidation with six 28-day cycles of melphalan (0,18 mg/Kg days 1-4), prednisone (2 mg/Kg days 1-4) and lenalidomide (10 mg days 1-21) (N=202) or tandem melphalan 200 mg/mq with stem-cell support (N=200). A total of 342 patients without clinical indication or contraindication for a specific antiplatelet or anticoagulant therapy, were enrolled in this substudy and randomly assigned to receive Aspirin 100 mg/d (N=176) or Enoxaparin 40 mg/d (N=166) during induction with Rd and consolidation with MPR. *Results.* patient characteristics and distribution of major risk factors were similar in the two groups. During induction, the overall incidence of any 3-4 thrombotic events was 2,27% in the ASA group and 1,20% in the LMWH group (p=0.685). Deep vein thrombosis were equally distributed in the two groups (1.13% Vs 1.20%, p=0.466), while pulmonary embolism was observed only in the ASA group (1.70%). Compared with LMWH, the absolute risk difference was +0.5% (95%CI=-2.5 to 3.5, p=0,605) in the ASA group. All thromboembolic events occur in early phase of treatment (median 1,3 months). Only 1% of minor bleeding was detected in the LMWH group and no cardiovascular events were observed. During MPR consolidation only one thrombotic event was seen in the LMWH group. *Conclusion.* our data indicate a low overall incidence of thrombotic events in all groups. Both ASA and LMWH show similar safety and efficacy in reducing thromboembolic events in newly diagnosed multiple myeloma patients treated with lenalidomide-based regimens.

0498

TIMING OF TISSUE FACTOR (TF) MRNA AND HYPERCOAGULABILITY DOWNREGULATION BY ALL-TRANS-RETINOIC ACID (ATRA) IN ACUTE PROMYELOCYTIC LEUKEMIA (APL)

C Tartari,[1] L Russo,[1] M Marchetti,[1] E Di Bona,[2] A Rambaldi,[1] F Lo Coco,[3] A Falanga[1]

[1]*Ospedali Riuniti di Bergamo, Bergamo, Italy*
[2]*Ospedale S. Bortolo, Vicenza, Italy*
[3]*Università Tor Vergata, Roma, Italy*

Background. Among the mechanisms responsible for intravascular clotting activation in APL, a key role is played by the procoagulant activities, including TF expressed by the promyelocytic blasts. Differentiating therapy with ATRA or Arsenic Trioxide (ATO) achieves 90% complete remission rate and corrects the hyperactivity of the coagulation and fibrinolytic systems. The beneficial effects on the coagulopathy are at least in part due to the capacity of ATRA and ATO to downregulate TF expression in APL cells. However, it is not known whether the persistence of TF mRNA expression in peripheral APL cells might be a marker of hypercoagulability in these patients. *Aim.* In this study we evaluated the levels of TF mRNA in peripheral mononuclear cells (PBMC) obtained from 9 APL patients: 4 treated with ATRA+Idarubicin (IDA) and 5 treated with ATRA+ATO. *Results.* of TF mRNA were correlated to the plasma levels of thrombin antithrombin complexes (TAT), as an index of thrombin formation and inhibition, and of activated factor VII-Antithrombin complex (FVIIa-AT), as an index of TF exposure and inhibition on blast cells. Five healthy subjects acted as the control group. *Methods*. Blood samples were obtained at the onset of the disease (T0) and after 7 (T1), 14 (T2) and 28 (T3) days of treatment. PBMC were isolated from whole blood and TF mRNA was assessed using real time-polymerase chain reaction. Results were normalized versus T0. Platelet-free plasma was obtained by two serial centrifugations (both 4,000rpm for 15 min) of citrated whole blood. ELISA methods were used for the measurement of plasma levels of TAT (Siemens) and FVIIa-AT complexes (STAGO). *Results.* The levels of TF mRNA of APL PBMC were significantly elevated at the onset of the disease compared to controls ($p<0.05$). In patients treated with ATRA+IDA the levels of TF mRNA decreased by 68% at T1, by 70% at T2 and by 90% at T3; similar reductions were observed in patients treated with ATRA+ATO, i.e. 64% at T1, 83% at T2 and 82% at T3. Plasma concentration of TAT complex of APL patients significantly decreased ($p<0.05$) from T0 (48.9±6.43 mg/L) to T3 (8.13±0.92 mg/L). Similarly, plasma concentration of FVIIa-AT significantly decreased from T0 (287.10±36.51 pM) to T3 (168.31±16.62 pM). The statistical analysis revealed significant correlations between TF mRNA and TAT at T1 and T3 (ATRA+IDA: T1 R2=0.691; T3 R2=0.927; ATRA+ATO: T1 R2=0.685) and between TF mRNA and FVIIa-AT at T1 and T2 (ATRA+IDA: T1 R2=0.767; T2 R2=0.672; ATRA+ATO T1 R2=0.828; T2 R2=0.817). *Summary/Conclusions.* Our results show that TF expression is elevated in PBMC of APL patients at the onset of the disease and is downregulated either by ATRA+IDA or ATRA+ATO treatment following a similar pattern of reduction. The significant correlation between TF mRNA reduction and the decrease of the two markers of hemostatic system activation (TAT and FVIIa-AT) suggests that TF mRNA as a useful surrogate marker of hypercoagulation in multicenter studies.

Experimental stem cell transplantation

0499

REGULATION OF ACUTE GRAFT VERSUS HOST DISEASE BY MICRORNAS

P Ranganathan,[1] C Heaphy,[1] N Stauffer,[1] S Costinean,[1] R Santhanam,[1] S Sandhu,[1] J Nuovo,[1] G He,[1] M Hamadani,[2] G Hadley,[1] G Marcucci,[1] C Croce,[1] S Devine,[1] R Garzon[1]

[1]*The Ohio State University, Columbus, United States of America*
[2]*West Virginia University, Morgantown, United States of America*

Background. Acute Graft-Versus-Host disease (aGVHD) is a frequent complication of allogeneic bone marrow transplantation (BMT) in which donor T cells destroy HLA mismatched host tissues. Recent studies indicate that microRNA (miR)-155 is induced upon CD4+ cell activation and promotes Th1 differentiation. *Aims.* Based on the importance of T cells in aGVHD pathogenesis and the regulation of immune responses by miR-155, here we propose to investigate whether miR-155 expression is deregulated in donor T cells during aGVHD and whether miR-155 is involved in the modulation of this process. *Methods*. We used a MHC mismatched BMT aGVHD model in which spleen cells (20X106) and T cell depleted bone marrow (t-BM;5X106) from C57BL/6 (B6) donors were transferred i.v. into lethally irradiated B6D2F1 recipient mice. Control groups included mice that received t-BM only or received no cell infusion. CD4+CD62L- effector cells were isolated from the spleen, RNA extracted and miR-155 expression measured by qRT-PCR. *Results.* CD4+CD62L- cells isolated from mice with aGVHD exhibited increased miR-155 expression with respect to the same cell populations obtained from the t-BM only group (4 fold increase, $p<0.001$). To confirm that a causal relationship exists between miR-155 and aGVHD severity, we repeated the MHC mismatched murine experiment using B6 mice deficient for miR-155 expression as donors. Mice receiving donor spleen cells from BIC/miR-155 KO mice exhibited dramatically lower mean GVHD scores and improved survival compared to those receiving WT spleen cells (87% vs. 13% of mice alive at 70 days, respectively; $p<0.001$). GVHD histological scores in the spleen, liver or gut were remarkably lower in recipients from miR-155 KO (none grade III-IV). Overall survival, GVHD scores and histological GHVD findings were similar between miR-155 KO and WT t-BM only group. Mice receiving miR-155 KO spleen cells also had significantly lower TNF-α levels than WT controls (14 pg/ml vs. 48 pg/ml, $p=0.005$). To further establish the regulatory role of miR-155 in aGVHD, we generated a transgenic mouse that over-expresses miR-155 in T cells under the LCK promoter (B6 LCK-miR-155). Using splenocytes from LCK-miR-155 TG mice we performed the mismatched MHC experiments as described previously. Recipients of miR-155 over-expressing splenocytes developed hyper-acute GVHD (confirmed by pathology) and died shortly after transplant (within 2-3 weeks), while recipients of WT cells developed lethal aGVHD significantly later ($p=0.03$). Relevant to human aGVHD, we measured miR-155 expression in the colon tissues of aGVHD patients (n=5) or controls (n=4) using DIG-tagged anti-miR-155 LNA and found a dramatic up-regulation of miR-155 in the mucosa of aGVHD patients, while it was negative in healthy controls. Finally, we performed the B6 into F1 MHC-mismatched transplants as described and treated 6 mice with antisense miR-155 (LNA anti-155) and 6 mice with a scrambled control (n=6) 5 mg/kg twice a week (I.V) x 2 weeks starting at day+7. The mice that received LNA anti-155 showed higher survival rate compared to mice that received the scramble control ($p<0.03$). *Conclusions.* Collectively, our data indicate that miR-155 modulates aGVHD, and thus point to miR-155 as a potential target for therapeutic intervention for aGVHD.

0500

IKAROS-NOTCH SIGNALING IN HOST ANTIGEN PRESENTING CELLS REGULATES EXPERIMENTAL GRAFT-VERSUS-HOST DISEASE (GVHD) AND GRAFT-VERSUS-LEUKEMIA (GVL) RESPONSES

T Toubai,[1] Y Sun,[1] I Tawara,[1] C Malter,[1] R Evers,[1] E Nieves,[1] C Liu,[2] I Maillard,[3] S Winandy,[4] P Reddy[1]

[1]*University of Michigan Comprehensive Cancer Center, Ann Arbor, United States of America*

[3]*University of Michigan, Ann Arbor, United States of America*
[4]*Univerisity of Boston School of Medicine, Boston, United States of America*

Background. Host antigen presenting cells (APCs) are necessary for induction of graft-versus-host (GVH) responses. But the APC autonomous molecular mechanisms that are critical for modulation of GVH are not known. Because Ikaros (Ik) is known to negatively regulate certain dendritic cell (DC) responses (the most potent APCs), we hypothesized that its deficiency in host APCs will reduce GVHD. *Methods and Results.* We generated [B6[ARROWRIGHT]B6] and [Ik-/-B6[ARROWRIGHT]B6] chimeras and utilized them as recipients in C3H.SW B6 model of acute GVHD. The [Ik-/-B6 [ARROWRIGHT] B6] animals showed significantly worse survival, GVHD specific clinical severity and histopathological damage than the allogeneic [B6[ARROWRIGHT] B6] animals ($P < 0.001$). *In vitro*, CFSE and annexin labeling studies demonstrated that Ik-/-DCs caused greater proliferation without altering the rate of apoptosis. To characterize the molecular mechanisms we evaluated the role of putative molecular targets of Ikaros, the Notch signaling pathway. Ik-/- DCs, at steady state, showed an increase in the expression of several Notch target genes such as Hes-1, Hex-1, etc. Blockade of Notch signaling with γ-secretase inhibitor (DAPT) mitigated the enhanced allo-stimulatory capacity of the Ik-/-DCs *in vitro* and decrease donor T cell expansion and improved body weight loss *in vivo*. We next hypothesized that given the enhanced GVHD response that was associated with increased proliferation and preserved cytotoxicity of allo-T cells, the GVL response will also be enhanced in the recipients with Ik-/- APCs. Unexpectedly, the [B6[ARROWRIGHT] B6] and [Ik-/-B6 [ARROWRIGHT] B6] chimeras when transplanted with tumor cells demonstrated equivalent GVL responses despite greater severity of GVHD. *Conclusions.* Together our data demonstrate differential regulation of GVHD and GVL at the level of host APCs and show a role for a novel molecular pathway, the Ik-Notch axis, in the host APCs as an important modulator of GVH responses.

ANALYSIS OF MIIRNA EXPRESSION PROFILE AFTER HAEMATOPOIETIC STEM CELL TRANSPLANTATION: A PROMISING TOOL FOR PREDICTING ACUTE GVHD

C Carniti,[1] S Gimondi,[2] A Bermema,[2] M Morelli,[2] A Vendramin,[2] E Biganzoli,[2] P Corradini[2]

[1]*Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy*
[2]*Fondazione IRCCS Istituto Nazionale Tumori and University of Milan, Milano, Italy*

Background. Allogeneic haemopoietic-stem-cell transplantation (HSCT) is the treatment of choice for many malignant and non-malignant disorders. Despite the recent advances in post-transplant immunosuppressive therapy, Graft-versus-Host Disease (GVHD) still represents the major life-threatening complication. Recent studies have indicated that microRNAs (miRNAs) circulate in a stable, cell-free form in the bloodstream and that the abundance of specific miRNAs in plasma or serum can serve as biomarkers of cancer and other diseases. *Aim.* This study was aimed at the prospective analysis of miRNA expression profile in the plasma of allo-transplanted patients in order to detect specific miRNAs with predictive role for acute GVHD (aGVHD). *Methods.* After informed consent, we collected plasma samples from 10 healthy donors and 22 patients (median age: 59 and 41 years) who received unmanipulated HSCT (18 from Matched Unrelated Donors and 4 from HLA-matched siblings). Blood samples were collected weekly after HSCT and patients were monitored to assess aGVHD onset. Three of 22 patients developed intestinal GVHD (grade 2) while 9 of 22 patients developed cutaneous GVHD (grade 2-3). MicroRNAs were isolated from the plasma of patients using a modified mirVana® miRNA Isolation Kit (Ambion Inc). The miRNA expression profile was examined using a quantitative PCR-method (TaqMan ® Human microRNA

Cards, Applied Biosystems) that allows the analysis of 384 human miRNAs by low density array technology. The results obtained were subsequently validated with specific miRNA Single Assays (Applied Biosystems). Hsa-miR-16 was used for data normalization due to its stability in all the samples analyzed. Relative quantification of miRNA expression was calculated with the $2^{-\Delta\Delta Ct}$ method. Cluster analysis was performed using an agglomerative hierarchical algorithm with average linkage as a distance measure. Differential miRNA expression profile was investigated with the Mann-Whitney test. *Results.* Circulating miRNAs are detectable and amplified in all samples analyzed. Unsupervised hierarchical clustering of miRNAs present before the onset of GVHD, showed that specific circulating miRNA expression signatures discriminate between patients who will develop GVHD from those who will not. By comparing the miRNA expression profiles of GVHD patients and non-GVHD patients, we identified a group of 13 miRNAs upregulated in the plasma of GVHD patients ($p<0.05$). We then aimed at assessing whether this 13-miRNA panel provided information regarding the involvement of specific target organs. MiR-194 and miR-367 are overexpressed in patients developing intestinal GVHD ($p<0.05$). Of interest, both miRNAs are implicated in the differentiation of the gastrointestinal epithelium. A significant upregulation of miR-203 was observed prior to the onset of cutaneous aGVHD ($p<0.001$). The involvement of miR-203 in cutaneous aGVHD is supported by recent papers demonstrating that it targets p63, a protein required for keratinocytes differentiation, and SOCS3, a protein involved in the pathogenesis of GVHD (Hill *et al*. Blood, 2010). *Conclusions.* Our results demonstrate that the analysis of miRNA expression profile after HSCT is a promising tool for predicting aGVHD onset. Significantly higher plasma levels of miR-203 characterize patients who will develop skin-only GVHD whereas an upregulation of plasma levels of miR-194 and miR-367 may be used to predict the risk of developing intestinal aGVHD.

Background. Allogeneic bone marrow transplantation (BMT) is a curative treatment modality for hematopoietic malignancies such as acute and chronic leukemias and lymphomas. Mature donor T cells in the allograft support engraftment, promote early T cell immunity of the recipient and mediate the graft-versus-leukemia (GVL) effect. However, these donor T cells are also responsible for the induction of graft-versus-host disease (GVHD) by attacking recipient tissue such as liver, skin, and bowel leading to significant morbidity and mortality. While depletion of mature T cells from the allogeneic donor graft significantly reduces the risk of GVHD it also abrogates the beneficial effect of GVL and delays immune reconstitution of the host, thereby supporting opportunistic infections. *Aims.* A major challenge in allogeneic BM transplantation is the identification of T cell subpopulations mediating the GVT-effect in the absence of GVHD induction. *Methods.* By repetitive alloantigen stimulation we established alloantigen-specific $CD8^+$ cytotoxic T cells (CTLs) with highly efficient cytotoxicity towards alloantigen-expressing target cells. In two MHC-mismatched BM transplantation models where induction of lethal GVHD is either dependent on the presence of $CD4^+$ or $CD8^+$ T cells we tested the effects of these *in vitro*-generated alloantigen-specific CTLs on GVHD induction and GVT-effect. *Results. In vitro*-derived CTLs exhibited an effector/memory phenotype and showed strong cytotoxicity towards alloantigen-expressing target cells *in vitro*. However, these alloantigen-specific CTLs did not induce GVHD in both MHC-mismatched BM transplantation models. They did not induce the expression of GVHD-associated cytokines IFN-gamma, and TNF-alpha in transplanted recipient mice. No clinical or histological signs of GVHD were detected and CTL-transplanted mice exhibited a survival rate above 90%. Inability to induce GVHD was not due to a decreased survival or impaired effector function of CTLs *in vivo* since they lysed antigen-expressing target cells *in vitro* when re-isolated fourteen days after transplantation. Also a five-fold increase in the number of transplanted CTLs could not induce GVHD. In contrast to alloantigen-activated CTLs, transplantation of unstimulated $CD8^+$ T cells, which were not primed for the alloantigen *in vitro*, induced severe, lethal GVHD in both transplantation models. Surprisingly, alloantigen-specific CTLs efficiently eradicated Bcr-Abl transformed B cell leukemias or mastocytomas showing that they maintain their GVT-reactivity. *Summary/Conclusions.* To our knowledge we show for the first time in a $CD4^+$ and $CD8^+$ T cell-dependent MHC-mismatched BMT model that *in vitro*-generated alloantigen-specific CTLs do not induce GVHD but mediate an efficient anti-tumor effect indicating that adoptive transfer of such effector cells might provide a treatment strategy for tumor eradication in the context of allogeneic BMT in the absence of GVHD-induction. Testing CTLs in a chimeric human/mouse xenogeneic GVHD model will further elucidate whether this stimulation protocol might be applicable in the clinic.

LOOKING FOR MOST SUITABLE CELLS FOR T-CELL RECEPTOR RNA TRANSFER - MEMORY T CELLS OFFER CONSIDERABLE ADVANTAGES

S Thomas, S Klobuch, M Theobald, W Herr

University Medical Center of Johannes Gutenberg-University Mainz, Mainz, Germany

Background. Reactivation of latent Cytomegalovirus (CMV) infection is a common and sometimes life-threatening complication following allogeneic hematopoietic stem cell transplantation (HSCT). Long-term virus control requires the re-establishment of protective antiviral T-cell immunity in the host. The latter is challenging, particularly if the donor is CMV-negative and thus, no CMV-reactive T cells are being transferred to recipient during HSCT. *Aims.* Grafting nonreactive T cells of CMV-negative donors by virus-antigen specific T-cell receptors (TCR) may be an efficient means to transfer CMV specific T-cell function into HSCT recipients. To overcome the limitations of vector-based gene transfer that hamper clinical translation, we used *in vitro* transcribed RNA encoding CMV-specific TCR for electroporation of non-reactive human T cells. Due to the instability of the introduced RNA molecules, repetitive administration of TCR redirected T cells appears mandatory. However, this approach might be hampered by the induction of serious alloreactivity through the repeated transfer of polyclonal donor T cells with unknown endogenous specificity. To address this concern, our study aimed at the analysis of the CMV-specific as well as allo-HLA-reactive effector potential of different naive and memory T-cell populations. *Methods/Results.* We have reprogrammed T cells of CMV-negative donors with human TCR RNA recognizing the immunodominant HLA-A*0201-binding epitope 495-503 derived from the CMV pp65 protein. This procedure resulted in transient expression of the introduced TCR for up to one week. To compare different T-cell populations with regard to their alloreactive potential, we generated TCRpp65 transfected pure naive and memory T-cell subsets. The latter have been reported to induce less alloreactivity due to a more restricted endogenous TCR repertoire. Although both naive and memory T-cell subsets showed comparable expression of TCRpp65, memory $CD8^+$ T cells mediated superior cytotoxicity and IFN-γ production against CMV-infected fibroblasts for up to one week. Alternatively, we generated EBV/HLA-A*0201 peptide-specific T-cell lines and transfected them with TCRpp65 RNA to obtain EBV/CMV-bispecific T cells. As with TCR redirected memory T-cell subsets, EBV/CMV-bispecific $CD8^+$ T cells showed strong reactivity against CMV-infected fibroblasts for up to one week without hampering the endogenous EBV peptide-specific effector function. To analyze the allo-HLA-reactivity of the naive, memory and EBV-specific T-cell populations, we assayed their IFN-γ-secretion upon stimulation with different HLA-mismatched donor EBV-transformed B cells (EBV-LCL) as well as CD40 ligand activated B-cells. Although we tested only a small panel of 6 HLA-mismatched donors, alloreactivity was solely mediated by T-cell populations of naive phenotype. Moreover, no differences were obtained with either TCRpp65 RNA transfected or untransfected T cells, assuming that mixed dimer formation between introduced and naturally expressed TCR chains did not induce additional allo-HLA-reactivity in our studies. *Summary.* Our data demonstrate that memory T-cell populations from CMV-negative donors can be easily redirected with TCRpp65 RNA, thereby gaining CMV-specific T-cell effector function for a considerable time period. Due to their decreased alloreactivity, we believe that TCRpp65 RNA redirected memory T-cell populations have the potential to be further developed as a therapeutic 'off-the-shelf' reagent for CMV-positive patients who undergo allogeneic HSCT from CMV-negative donors.

Background. R-CHOP induction is considered the standard regimen for elderly patients with mantle cell lymphoma (MCL), but remissions are of short duration. Maintenance with interferon-alfa has been suggested to be effective, but side effects were serious. Rituximab seemed a promising candidate for improvement. *Aims.* In the European MCL Elderly trial we studied different induction regimens as well as the role of maintenance therapy. Here, the results of the maintenance are reported. *Methods.* Eight countries participated in this trial. Patients >60 yrs not eligible for high dose therapy with stage II-IV MCL were included. Initially, patients were randomized between 8 cycles of 3-weekly R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) or 6 cycles of 4-weekly R-FC (rituximab, fludarabin, cyclophosphamide). Subsequently, patients in complete or partial remission (CR, CRunconfirmed or PR) underwent a second randomization between maintenance with rituximab 375 mg/m^2 every 2 months or interferon-alfa 2a or 2b (IFN) (regular IFN weekly 3x3 MIU or pegylated IFN 1x1 μg/kg). Second randomization was stratified for induction regimen, study group, age, international prognostic index (IPI) and response (CR/CRu vs PR). Both maintenance regimens were continued until progression. *Results.* Randomization was closed Oct 2010. Out of 308 responding patients randomized for maintenance, data from 223 patients are currently evaluable. Median age was 70 yrs, 68% male, 79% stage IV, 48% intermediate and 43% high risk MIPI. Sixty-one percent of patients had a CR/CRu upon induction therapy. Fifty-eight percent had received R-CHOP induction. After a median follow-up of 30 months, patients randomized for rituximab maintenance had a significantly longer remission duration compared to IFN (51 vs 24 months; p=0.0117; HR 0.56; 0.36-0.88). Overall survival (OS) was not different between both arms. However, the subcohort R-CHOP-treated patients appeared to show an advantage after rituximab maintenance (3-yr OS 85% vs 70% after IFN; p=0.0375). Hematologic grade 3-4 toxicity was higher in the IFN arm (leukocytopenia 36% vs 17%; thrombocytopenia 16% vs 7%); non-hematologic grade 3-4 toxicity was rare, except for infections (7% IFN; 7% rituximab). R-FC followed by rituximab resulted in the highest infection rate (all grades 48% vs 30%). Sixty-one percent of patients on IFN stopped maintenance - although not progressive vs 30% on rituximab. Patients in CR/CRu or PR after induction who did not receive any maintenance for various reasons, mainly based upon patient's decisions or ongoing cytopenia after induction (n = 106) had a poor outcome (median remission duration 26 months; 3-yrs OS 52%). *Conclusions.* Rituximab maintenance after R-CHOP induction should be considered the new standard for elderly patients with MCL, to which new regimens should be compared.

Background. Dysregulated JAK-STAT signaling is a key feature in myelofibrosis, which is characterized by splenomegaly, debilitating symptoms, cytopenias and shortened survival. There are currently no effective drug therapies for myelofibrosis. Ruxolitinib is a selective JAK1 and JAK2 inhibitor with demonstrated clinical activity in myelofibrosis. *Aims.* COMFORT-I was designed to determine the safety and efficacy of ruxolitinib relative to placebo in patients with myelofibrosis. *Methods.* All study participants signed informed consent. Patients with intermediate-2 or high-risk myelofibrosis were randomized to start placebo or ruxolitinib at a dose of 15 or 20 mg PO BID depending on baseline platelet count (100-200 × 10^9/L or >200 × 10^9/L, respectively). The dose was optimized for efficacy and safety during treatment. The primary endpoint was the proportion of patients with ≥35% reduction in spleen volume at week 24 of therapy, assessed by blinded central review of spleen MRI or CT. Secondary endpoints were durability of spleen response, changes in symptom burden as assessed daily by the modified Myelofibrosis Symptom Assessment Form (MFSAF) v2.0, and survival. Additional exploratory endpoints included change in quality of life (QoL) measured by the EORTC-QLQ-C30, fatigue measured with the PROMIS Fatigue Scale, molecular and serum biomarkers, and transfusion dependence. *Results.* 309 patients were randomized: 155 to ruxolitinib and 154 to placebo. Median follow-up was 32.2 weeks. The proportion of patients with ≥35% reduction in spleen volume at 24 weeks was 41.9% vs 0.7% (ruxolitinib vs placebo, p<0.0001). Median duration of response has not been reached. At week 24, the proportion of patients with ≥50% improvement in symptom score was 45.9% vs 5.3% (ruxolitinib vs placebo, p< 0.0001) and the mean percent change in total symptom score was an improvement of 46.1% vs a worsening of 41.8% (ruxolitinib vs placebo, p<0.0001). There were 10 vs 14 deaths (ruxolitinib vs placebo, HR 0.67, p=0.33). Improvement in symptoms was rapid, with the majority of patients showing significant benefit within the first 4 weeks. Changes in both QoL and fatigue mirrored changes in the modified MFSAF v2.0 symptom score over time, and all showed improvement relative to placebo regardless of changes in hemoglobin. The most common AEs of any grade seen in >20% of patients on either arm of the study were (ruxolitinib vs placebo) abdominal pain (10.3% vs 41.1%), thrombocytopenia (34.2% vs 9.3%), fatigue (25.2% vs 33.8%), anemia (31% vs 13.9%), diarrhea (23.2% vs 21.2%), and peripheral edema (18.7% vs 22.5%). Anemia and thrombocytopenia were manageable and rarely (0.6% ruxolitinib vs 0.7% placebo, each) led to withdrawal from the study. *Summary/Conclusion.* In this study, ruxolitinib demonstrated

marked clinical benefits in spleen size, debilitating symptoms, and QoL that were rapid in onset and sustained. Anemia and thrombocytopenia were among the most common AEs but they were manageable, as demonstrated by the low withdrawal rate due to these events. The overall safety profile relative to placebo in myelofibrosis was acceptable.

DYNAMIC MUTATION PROFILES OF LEUKAEMIC CELL POPULATIONS IN RESPONSE TO TREATMENT ARE REVEALED BY GENOME-WIDE SEQUENCING OF SEQUENTIAL SAMPLES FROM PATIENTS WITH B-CLL

A Schuh,[1] D Bentley,[2] J Taylor,[3] A Timbs,[4] R Clifford,[4] A Burns,[4] J Becq,[2] M Ross,[2] S Humphray,[2] R Grocock,[2] Z Kingsbury,[2] D McBride,[2] L Murray[2]

[4]*Oxford BRC Haemato-molecular Diagnostic Service, Oxford, United Kingdom*

B-cell chronic lymphocytic leukaemia (B-CLL) is the most common leukaemia in the Western World. It is characterized by clinical and biological heterogeneity and a chronic relapsing course making it an ideal model to study the molecular events underlying relapse and the development of treatment resistance. Whole genome sequencing (WGS) has the potential to identify molecular pathways perturbed in cancer. However, the clinical significance of this information is not clear. Our aim was therefore to (1) establish the molecular profiles of sequential samples from patients with B-CLL at every relapse using WGS and (2) correlate findings with clinical outcome. Patients undergoing multiple rounds of treatment including second-generation monoclonal antibody treatment were selected for study. WGS was carried out to an average of >30-fold depth on each of five sequential peripheral blood samples per patient plus matched germline buccal swab controls. Sequencing employed SBSv5 chemistry on the HiSeq2000 instrument. Paired 100-base reads were aligned to the human reference GRCh37.1/hg19 and candidate single nucleotide variants (SNVs), insertions, deletions and copy number variants (CNVs) were detected in all genomes. Candidate somatic variants were called in each tumour sample by subtraction of all germ-line variants (i.e. those present in the matched normal sample for the individual). Somatic variants were clustered based on the profiles of allele frequency along the time-course of the entire tumour set within an individual. Targeted deep sequencing (TDS) of amplicons containing selected non-synonymous SNVs was carried out to a depth of ~10-50,000-fold and mutant allele frequencies were calculated by establishing the fraction of reads containing the mutant allele. An average of 4,600 mutations per sample were identified in each patient. On average, just 20 mutations were non-synonymous, nonse<<nse or frameshift mutations. On the basis of their varying mutant frequency profiles over time, the mutations could be clustered into up to 4 classes depending on patient: (I) those that disappear after treatment with purine analogues; (II) those that are present throughout the course of the disease and therefore resistant to treatment; (III) those that are initially detected at low frequency and then expand (Class III); and (IV) those not detected until later stages. So far, the data suggest that Class I and Class II sub-clones are characterized by mutations in pathways regulating innate immune responses and apoptosis (eg ADAD1, SAMHD1, BCL2L13) whereas Class III and IV sub-clones carry mutations in general cancer pathways (eg MEK1, ASXL1, FAT3, NRG3). *Conclusions.* This is the first sequential WGS analysis of B-CLL samples. We reveal that the molecular composition of this leukaemia alters with treatment. We identify mutations that are eradicated by or resistant to treatment including mutations important in regulation of innate immune response and cancer progression. These findings and the results of ongoing studies of other B-CLL cases will direct future clinical trials and therapeutic decisions.

Background. Genome-wide association meta-analysis studies (GWAS) have identified over 100 independent genetic loci associated with blood cell indices, including volume and count of platelets and erythrocytes. *Aims.* Although several of these loci encode known regulators of haematopoiesis the mechanism by which the majority of sequence variants exert their effect on blood cell formation remains elusive. *Methods.* A recent meta-analysis of the GWAS in 68,000 individuals of European ancestry has identified 68 genomic loci (53 new) associated with platelet count and volume. Here we demonstrate a functional validation for five of these novel loci in *Danio rerio* by the means of gene silencing. *Results.* Our experiments in *Tg(cd41:EGFP)* transgenic fish reveal important functions for genes encoding guanine nucleotide exchange factors *(arhgef3)*, tropomyosins *(tpma)* and previously uncharacterised transcriptional regulators (*rnf145* and *jmjd1c*), in regulating thrombopoiesis. In addition, lineage relatedness of megakaryocytes and erythrocytes prompted us to explore the putative role of these genes in erythropoiesis and silencing of all five genes but tpma (transcription of its human homologue *TPM1* in blood is restricted to megakaryocytes) also exerted an effect on primitive erythropoiesis. The silencing of *arhgef3* on erythropoiesis was the most profound and this prompted further detailed studies. Examination of peripheral blood from *arhgef3* morpholino (MO) injected zebrafish embryos revealed microcytic and hypochromic erythrocytes, a classic feature of iron deficiency. Anemia was rescued by intracellular supplementation of iron to *arhgef3* MO injected embryos, demonstrating that *arhgef3* depleted erythroid cells, once provided with intracellular iron are fully capable of haemoglobinisation. Disruption of the arhgef3 target, RhoA, also produced severe anemia, which was again rescued by iron injection. Moreover, silencing of ARHGEF3 expression in the erythromyeloblastoid cell line K562 revealed that the uptake of transferrin, the main blood plasma protein for iron transport, was severely impaired. *Conclusions.* Taken together, this is the first study to provide evidence for ARHGEF3 being a regulator of transferrin and iron uptake in erythroid cells, through activation of RhoA. Taken together, our findings demonstrate the value of pursuing GWAS signals as a new and exciting forward genetics approach in identifying novel regulatory molecules and signalling pathways in haematopoiesis.

Background. High-dose chemotherapy with haemopoietic stem-cell improves quality of response and survival in multiple myeloma (MM).The introduction of novel agents questions the role of autologous stem-cell transplantation (ASCT). *Aims.* to compare in a prospective randomized study conventional chemotherapy plus novel agents (MPR) with tandem high-dose melphalan (MEL200) and ASCT in newly diagnosed MM patients younger than 65 years. *Methods.* All patients (N=402) received four 28-day cycles of lenalidomide (25 mg, d1-21) and low-dose dexamethasone (40 mg, d1,8,15,22) (Rd) as induction. Patients (N=202) were then randomized to MPR [six 28-day cycles of melphalan (0.18 mg/kg d1-4), prednisone (2 mg/kg d1-4) and lenalidomide (10 mg d1-21); pts (N=200)] or MEL200 [tandem melphalan 200 mg/m2 with stem-cell support]. All patients enrolled were stratified according to International Staging System (ISS) (stages 1 and 2 vs stage 3) and age (<60 vs >60 years). Primary end point was PFS. Data were analyzed in intention-to-treat. *Results.* Response rates were similar in the two groups (MPR vs MEL200): >VGPR (60% vs 58%, p=0.24) and CR (20% vs. 25%, p=0.49). After a median follow-up of 20 months, the 18-months PFS was 68% in MPR and 78% in MEL200 (HR=0.58, p=0.006). CR prolonged the 18-months PFS in the MPR (90% vs 66%) and in the MEL200 group (87% vs 76%). The 18-months OS was similar (91% vs 95%, p=0.073). In the MPR and MEL200 groups, G3-4 neutropenia was 55% vs 89% (p <.001); G3-4 infections were 0% vs 17% (p <.001); G3-4 gastrointestinal toxicity was 0% vs 21% (p<.001); second tumors were 0.005% in both arms. DVT was 2.44% vs 1.13% (p=0.43). *Conclusions.* PFS was significantly prolonged in MEL200 group compared to MPR, although toxicities were significantly higher. This is the first report showing a PFS advantage for ASCT in comparison with combinations including novel agents. At present OS is not significantly different in the two groups.

0509

BRAF MUTATIONS IN HAIRY CELL LEUKEMIA

Background. Hairy cell leukemia (HCL) is a well defined clinico-pathological entity whose underlying genetic lesion is still obscure. *Methods.* We searched for HCL-associated mutations by massively parallel sequencing of the whole exome of leukemic and matched normal mononuclear cells purified from the peripheral blood of one patient with HCL. *Results.* Whole exome sequencing identified 5 missense somatic clonal mutations that were confirmed at Sanger sequencing, including a heterozygous V600E mutation involving the BRAF gene. Since the BRAF V600E mutation is oncogenic in other tumors, further analyses were focused on this genetic lesion. Sanger sequencing detected mutated BRAF in 46/46 additional HCL patients (47/47 including the index case; 100%). None of the 193 peripheral B-cell lymphomas/leukemias other than HCL that were investigated carried the BRAF V600E mutation, including 36 cases of splenic marginal zone lymphomas and unclassifiable splenic lymphomas/leukemias. Immunohistological and Western blot studies showed that HCL cells express phospho-MEK and phospho-ERK (the downstream targets of the BRAF kinase), indicating a constitutive activation of the RAF-MEK-ERK mitogen-activated protein kinase pathway in HCL. *In vitro* incubation of BRAF-mutated primary leukemic cells from 5 HCL patients with PLX-4720, a specific inhibitor of active BRAF, led to marked decrease of phosphorylated ERK and MEK. *Conclusions.* The BRAF V600E mutation was present in all HCL patients investigated. This finding may have relevant implications for the pathogenesis, diagnosis and targeted therapy of this hematological disorder (Funded by the Associazione Italiana Ricerca Cancro and others).

First line therapy in Multiple Myeloma

We prospectively compared thalidomide-dexamethasone (TD) with bortezomib plus TD (VTD) as induction therapy before, and consolidation therapy after, double autologous stem-cell transplantation (ASCT) in patients with newly diagnosed multiple myeloma (MM). 474 patients randomized to the VTD (n=236) or TD (n=238) arm were analyzed on an intention-to-treat basis. After three 21-d cycles of induction therapy, the rate of complete response (CR) plus near CR (nCR), the primary study endpoint, was threefold higher with VTD compared to TD (31% vs 11%, respectively; p<0.0001). Post-ASCT consolidation therapy comprised two 35-d cycles of either VTD (V, 1.3 mg/m2 once-weekly; T, 100 mg/d through d 1 to 70; D, 320 mg/cycle) or TD (same doses as in VTD), according to the initial randomization. After consolidation therapy, the rate of CR-nCR, a secondary study endpoint, was 62% in the VTD and 45% in the TD arm (p=0.0002). A per-protocol analysis of 323 patients who actually received VTD (n=161) or TD consolidation therapy (n=162) was performed to evaluate the activity and toxicities of the two regimens. McNemar test results showed that VTD consolidation significantly increased the rate of CR (p=0.005) and CR-nCR (p=0.01), an objective failed by TD consolidation (p=0.07 and p=0.2 for upgraded CR and CR-nCR rates, respectively). Overall, the probability to upgrade high-quality response from less than CR before consolidation to CR after consolidation was twofold higher with VTD compared to TD (11% vs 6%, respectively). Non hematologic grade 3-4 adverse events were 11% with VTD and 10% with TD, including peripheral neuropathy (1% vs 0%, respectively) and skin rash (0.6% in each of the two treatment arms). Dose adherence of study drugs was very close to that planned; in particular, patients in the VTD arm received 93% of planned doses of bortezomib and thalidomide, while the corresponding value for thalidomide in the TD arm was 97%. In a substudy, post-consolidation molecular detection of minimal residual disease (MRD) was evaluated by means of patient-specific primers. VTD consolidation significantly increased the rate of molecular negativity, up to the 64% value (p=0.007 using the McNemar test), a benefit not seen with TD consolidation (48% of molecular negativity; p=0.06). Quantitative analysis of MRD after the 2 planned cycles of VTD consolidation therapy showed a 5-log reduction in residual clonal cells. By the opposite, consolidation therapy with TD yielded a 1 log reduction in MRD. Attainment of molecular negativity after consolidation therapy was a strong predictor of favourable clinical outcomes. In particular, the 3-year estimate of progression-free survival was as high as 89% for patients with undetectable MRD after consolidation therapy, while the corresponding value for patients with molecular positivity was 47%% (p=0.04). It is concluded that VTD consolidation was more effective than TD in upgrading the rate of high-quality responses and yielding unprecedented high rate of molecular remission, in excess of 60%. Achievement of molecular negativity favourably affected clinical outcomes and should be the primary goal of ASCT incorporating the novel agents.

[4]*HOVON, Rotterdam, Netherlands*
[5]*GMMG, Study Group, Germany*

Background. Chromosomal aberrations are important prognostic parameters in multiple myeloma (MM). By using interphase fluorescent *in situ* hybridization (FISH) on CD138-enriched plasma cells, specific changes in interphase cells can be detected, overcoming the lack of dividing cells required for conventional cytogenetics. *Aims.* We evaluated the association of FISH results and outcome of a subgroup of patients (pts) within the HOVON-65/GMMG-HD4 trial, a prospective, randomized phase III trial for pts with newly diagnosed MM stage II or III according to Salmon & Durie up to 65 years. *Methods.* Pts were randomized to receive three cycles of VAD (arm A; vincristine, adriamycin, dexamethasone) or PAD (arm B; bortezomib, adriamycin, dexamethasone). All pts received one or two cycles of high dose melphalan (200 mg/m²) with autologous stem cell transplantation followed by maintenance therapy with thalidomide 50 mg daily (arm A) or bortezomib 1.3 mg/m2 once every 2 weeks (arm B), respectively, for a maximum of 2 years. Sites in Germany, the Netherlands and Belgium participated in this trial (n=833 pts). For the German pts (GMMG, n=399) FISH was performed in a single laboratory prior to start of treatment. Cytospins of CD138 purified plasma cells were subjected to FISH with two-color probe sets for the detection of numerical changes for the following chromosome regions: 1q21/8p21, 6q21/15q22, 9q34/22q11, 11q23/13q14, and 17p13/19q13, as well as for the translocations t(4;14), t(11;14), and t(14;16). *Results.* For this analysis, FISH results from 354 (89%) of all GMMG pts were available (n=182 in arm A; n=172 in arm B). For all pts the median follow-up time from randomization was 38.9 months (mo.). The most pronounced impact on prognosis was seen for t(4;14), del13q14, del17p13, and gain1q21, each significantly associated with poor prognosis with respect to progression free survival (PFS) and overall survival (OS). However, deletion of chromosome 13q as exclusive chromosomal aberration without the presence of del(17p) and t(4;14) indicates no impact on outcome. A multivariable Cox PH Model identified t(4;14), del17p13, gain1q21, and ISS III as independent factors for PFS and OS. When comparing pts in the two arms for PFS and OS, we found that bortezomib-based treatment improves significantly the outcome in myeloma patients with del(17p) (3yr-PFS rates: A: 16%, B: 27%, p=0.030; 3yr-OS rates: A: 17%, B: 69%, p=0.014). Patients with t(4;14) or gain1q21 showed also a favourable outcome in arm B, although this difference was not of statistical significance. A multivariable Cox PH Model showed that t(4;14), del17p13, and gain1q21 are independent factors for PFS and OS in arm A, whereas only t(4;14) were of borderline significance for OS in arm B (p=0.049). *Conclusions.* Our analysis confirms the significant negative prognostic impact of del17p13, t(4;14) and gain 1q21 on PFS and OS for pts with newly diagnosed MM. All patients with high-risk chromosomal aberrations benefit at least in part from bortezomib-based treatment. The negative impact of del17p13 on PFS and OS could be significantly improved by the bortezomib-based treatment, suggesting that long-term administration of bortezomib should be considered as a standard of care for these patients.

[3]*Hematologic Clinic, Dpt Clinical and Morphological Research, Udine, Italy*
[4]*Institute of Nuclear Medicine, S. Maria della Misericordia Hospital, Udine, Italy*

Background. 18F-FDG PET/CT has been reported to be a careful technique for a widespread screening of myelomatous lesions at the onset of MM. Moreover, FDG-PET has been identified as a valuable methods to carefully monitor response and predict clinical outcomes in various tumors, particularly in lymphoma. The incorporation of novel agents into ASCT allowed the achievement of unprecedented high rates of complete response (CR) in young multiple myeloma (MM) patients. Availability of new techniques to identify minimal residual disease (MRD), such as multiparametric flow cytometry or molecular biology, led to the demonstration of a correlation between the depth of response and prognosis. *Aims.* Aim of the present study was to prospectively analyze the prognostic relevance of PET/CT negativity after induction and ASCT in 192 newly diagnosed MM patients. *Methods.* By study design, all patients were studied with 18F-FDG PET/CT at baseline, after induction treatment, after ASCT, once/year during post-ASCT follow-up and at the time of relapse. Bone marrow involvement was described as negative, diffuse or focal. The number of focal lesions (FL), as well as size and associated standardized uptake values (SUV) were recorded. Extramedullary disease (EMD), if present, was described by location, size, number and SUV. *Results.* Twenty four percent of the patients had a negative PET/CT scan at diagnosis. Among PET/CT-positive patients, 44% showed ≥ 3 focal lesions (FLs), 46% had SUV values > 4.2 and in 6% EMD could be detected. These 3 variables adversely affected 4-year estimates of PFS and OS. Thirty seven percent of the patients were negative after induction, while PET/CT was negative in 65% after 3 months from ASCT. Persistence of severe FDG uptake (SUVmax still > 4.2) after induction predicted for shorter PFS at 4 years (P= 0.004). Complete FDG suppression post-ASCT conferred superior PFS and OS in comparison with persistence of FDG uptake. In particular, 4-year estimates of PFS and OS for negative patients were 66% and 89%, respectively, as compared to 45% and 65% for positive patients (P 0.02 both for PFS and OS). In multivariate analysis, both severe PET/CT involvement at diagnosis (SUV > 4.2 and/or EMD) and persistence of FDG uptake after ASCT were independent predictors of worst PFS (SUV > 4.2= HR: 2.0, 95%CI: 1.13-3.72; EMD= HR: 15.0, 4.0-55.8; FDG uptake after ASCT= HR: 2.12, 1.19-3.77) and OS (EMD= HR: 6.99, 2.28-21.46; FDG uptake after ASCT= HR: 3.57, 1.03-12.39). *Conclusions.* These results provide demonstration that PET/CT at diagnosis and after treatment is a reliable tool for predicting prognosis in autografted MM patients and to identify patients at different risk of progression. In particular, post-ASCT complete FDG suppression is associated with extended PFS and OS. Based on these data, aims to evaluate MRD should include also imaging techniques such as PET/CT.

[10]*Western General Hospital, Edinburgh, United Kingdom*
[11]*Royal Devon and Exeter Hospital, Exeter, United Kingdom*
[12]*University of Newcastle, Newcastle-upon-Tyne, United Kingdom*

Background. A key feature of MM is related organ or tissue impairment (ROTI), manifest as CRAB: hypercalcemia, renal impairment, anemia, bone lesions and infection. In the Medical Research Council (MRC) Myeloma IX study, ZOL significantly improved overall and progression-free survival versus CLO in patients undergoing initial therapy for MM (hazard ration [HR] = 0.84, *P* = .0118 for survival; HR = 0.88, *P* = .0179 for progression-free survival; Morgan *et al*. *Lancet*. 2010), but the effects on CRAB have not been reported. *Aims.* These exploratory analyses investigated whether ZOL provided benefits beyond CLO for CRAB in the Myeloma IX study. Both agents are indicated for the prevention of skeletal complications from MM in the United Kingdom; prevention of CRAB is, therefore, off label. *Methods.* Patients newly diagnosed with MM were assigned either to intensive or non-intensive treatment pathways and randomized to CVAD vs CTD or to MP vs CTDa, respectively. Within each treatment arm, patients were randomized to intravenous ZOL (4 mg q3-4wk, adjusted based on renal function) or oral CLO (1,600 mg/d), each of which was continued at least until disease progression. Safety was assessed by continuous adverse event monitoring and standard laboratory and imaging evaluations. All patients provided informed written consent. *Results.* Among the intent-to-treat population (N = 1,960), at a median follow-up 3.7 years, a total of 104 new osteolytic lesions were reported in 95 (9.7%) CLO-treated patients compared with only 53 new osteolytic lesions in 46 (4.7%) ZOL-treated patients (*P* < .0001). Overall, more patients treated with ZOL versus CLO had complete or very-good partial responses (*P* = .018 for the non-intensive pathway). During the first 3 months on study, 16 (1.6%) CLO-treated but no ZOL-treated patients died of renal failure (*P* < .0001), and 42 (4.3%) CLO-treated and 27 (2.8%) ZOL-treated patients died of infections (*P* = .08). During the course of the study, 47 (4.8%) CLO- and 43 (4.4%) ZOL-treated patients died of renal failure (*P* = .67). In the same time period 123 (12.6%) CLO- and 92 (9.4%) ZOL-treated patients died of infections related to MM or its treatment (*P* = .025). In each group, 28 (2.9%) patients had hypercalcemia, reported as a serious adverse event (SAE) for 6 (0.6%) per group (*P* = .99). A pre-specified univariate Mantel-Haenszel test identified no statistically significant between-group differences in hypercalcemia (*P* = 0.99). There was no difference in time to hypercalcemia with ZOL versus CLO (*P* = .60). Recovery data were only available for 9 of the hypercalcemia SAEs, and showed complete resolution for 4 patients per group and death for 1 patient on CLO. A total of 18 (1.8%) ZOL- and 19 (1.8%) CLO-treated patients developed grade 3 or 4 anemia. Summary/conclusions: Consistent with previous reports of objective treatment benefits with ZOL versus CLO in patients receiving initial treatment for MM, ZOL also reduced the incidence and severity of some ROTI compared with CLO, especially early in the course of treatment in the Myeloma IX study.

0514

INCIDENCE OF SECOND PRIMARY MALIGNANCY (SPM) IN MELPHALAN-PREDNISONE-LENALIDOMIDE COMBINATION FOLLOWED BY LENALIDOMIDE MAINTENANCE (MPR-R) IN NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) PATIENTS = 65 YEARS

[6]*Sapienza University of Rome, Rome, Italy*
[7]*Celgene Corporation, Summit, United States of America*
[8]*University of Athens School of Medicine, Alexandra Hospital, Athens, Greece*

Background. MM patients have an 8-10 fold higher risk of developing acute myeloid leukemia (AML) than the general population. Among persons ≥ 65 years, incidence rate (IR) of invasive cancer is 2.1 per 100 person-years. MM-015 compared continued MPR-R vs fixed-duration melphalan and prednisone (MP) or melphalan, prednisone, and lenalidomide (MPR) in transplant-ineligible patients ≥ 65 years. *Aim.* MM-015 is a phase 3 trial comparing MPR-R vs MP or MPR in transplant-ineligible patients aged ≥ 65 years. This post hoc analysis evaluated IRs for SPMs and risks of SPM relative to progression risk. *Methods.* Potential SPMs were identified (non-melanoma skin cancers excluded). IRs per 100 person-years were calculated for AML and solid tumor malignancies. Progression-free survival (PFS) and relative hazard of progression in MPR-R vs MP were contrasted against an event-free survival (EFS) model that considered SPM an event. *Results.* As of February 11, 2011, the total number of SPM cases during active treatment and extended follow-up was 7/150 in the MPR-R arm, 8/152 in MPR, and 2/153 in the MP arm. Median onset of SPM was 28.2 months (range 2.4-42.5). These include 5 hematologic SPMs in the MPR-R arm (IR: 1.44; 3 AML, 1 T-cell acute lymphoblastic syndrome [ALL], 1 myelodysplastic syndrome [MDS]), 4 in MPR (IR: 1.17; 2 AML, 2 MDS), and 0 in the MP arm (IR: 0). These also include 2 solid tumor SPMs in the MPR-R arm (IR: 0.58), 4 in the MPR arm (IR: 1.17), and 2 in the MP arm (IR: 0.56). A total of 11 patients had adverse complex karyotype of bone marrow plasma cells at diagnosis of MM; all were randomized to receive lenalidomide (MPR-R or MPR arms). Of these, 3 developed AML and 2 developed MDS. Solid tumors were of heterogeneous tumor types. No B-cell malignancies were reported. In addition, 2 cases of AML and 4 solid tumors been reported after February 11, 2011 in the MPR-R/MPR arms as well as 1 case of MDS and 1 solid tumor in MP arm. Continued therapy with lenalidomide in the MPR-R arm provided sustained disease control. Median PFS of MPR-R vs MP was 31 months vs 13 months (P < .001; median follow-up: 25 months), with a 60% reduction in the relative risk of progression (hazard ratio [HR] = 0.395; P<.0001). The benefit of lenalidomide treatment was preserved when SPMs were added as events to the PFS analysis (HR = 0.408; P < .0001). *Conclusions.* An imbalance in the incidence of AML/MDS was observed in MPR/MPR-R vs MP, although the incidence was low (3.6% vs 0.7%, respectively); with 5 of 11 adverse complex karyotype patients developing AML/MDS. Solid tumor IRs were also low. Lenalidomide maintenance significantly reduced the risk of progression. Importantly, SPMs did not impact PFS when added as an event. Longer follow-up will further characterize SPM risk in newly diagnosed MM patients receiving lenalidomide and melphalan.

[4]*Pathology Department, Hospital del Mar,, Barcelona, Spain*
[5]*Hematopathology Section, Laboratory of Pathology, Hospital Clinic, IDIBAPS, Barcelona, Spain*

Background. Standard cytotoxic chemotherapy for cHL has changed little in 30 years; the treatment for patients with relapsed or refractory disease remains challenging and novel agents are under development. JAK/STAT constitutive activation plays an important role in the pathogenesis of cHL. Lestaurtinib is an orally bioavailable multikinase inhibitor that has recently been shown to inhibit JAK2 in myeloproliferative disorders. Its potential role in cHL therapy is unknown. *Aims.* Firstly, to analyze the *in vitro* effectiveness of Lestaurtinib in five cHL cell lines and its role in the JAK2/STAT5 signaling pathway. Secondly, to analyze for the first time the effect of Lestaurtinib in lymph nodes from cHL patients by flow cytometry. *Methods.* Five cHL cell lines, L-428, L-1236, L-540, HDLM-2 and HD-MY-Z were assayed for proliferation and apoptosis after 48h of treatment with Lestaurtinib or DMSO (control). Cell growth was determined using CellTiter 96 AQueous One Solution Cell Proliferation Assay and apoptosis was measured using CaspaseGlo 3/7 kit (Promega). After 1 hour of incubation with Lestaurtinib, the levels of the JAK2 pathway proteins, JAK2, phospho-JAK2 (Tyr1007/1008), STAT5, phospho-STAT5 (Tyr694), STAT3 and phospho-STAT3 (Tyr705), were analyzed by Western Blot. BCL-xL mRNA levels were quantified using TaqMan Gene Expression assays (Applied Biosystems). cHL patients were diagnosed at the Haematology Department from the University Hospital del Mar, Barcelona. Median age was 29 (range 24-43); 3 were nodular sclerosis and one lymphocyte-rich subtype. All patients were EBV- and 2 were stage IIA and 2 stage IIIA. By flow cytometry, we evaluated 750,000 cells from lymph nodes cultured for 24 hours with 300nM of Lestaurtinib or DMSO. Hodgkin Reed-Sternberg (HRS) cells were gated by the expression of CD40-PE-Cy5, CD95-Pacific Blue and CD30-PE, and the absence of CD3-APC-Cy7 (BD Bioscience). Viability was analyzed using FITC AnnexinV (BD Bioscience). Samples were analyzed on a FACS CANTO II (Becton Dickinson). *Results.* At 48h, a dose-dependent cell growth inhibition (23-66% at 300nM) and apoptotic increment (10-64% at 300nM) were observed in all cell lines. Moreover, Lestaurtinib inhibited JAK2, STAT5 and STAT3 phosphorylation and reduced the mRNA expression of its downstream antiapoptotic target Bcl-xL. Additionally, we have analyzed the effect of Lestaurtinib in lymph nodes from four cHL patients. We have evaluated the effect of treatment with 300nM of Lestaurtinib in the subpopulation of lymph node cells CD30+, CD40+, CD95+ and CD3-, which contain HRS cells. After 24h, cell viability had decreased in three of the four cases by 22%, 35% and 24% versus control cells. In the non-responder patient, we increased the treatment dose to 1μM and then we observed a reduction in cell viability by 12%. In order to shed light on the potential toxicity of Lestaurtinib, we have also analyzed cell viability in lymph node CD3+ cells after treatment with 300nM of Lestaurtinib and observed no decrease of viability (mean versus control=100.5%; range: 90%-119%). *Summary/Conclusions.* Our findings provide, for the first time, a molecular rationale for testing JAK2 inhibitors, specifically Lestaurtinib, in HL patients.

LONG TERM FOLLOW-UP OF PATIENTS TREATED WITH INVOLVED-FIELD COMPARED WITH EXTENDED-FIELD RADIOTHERAPY AFTER CHEMOTHERAPY FOR HODGKIN'S LYMPHOMA: 10 YEAR-ANALYSIS OF THE HD8 TRIAL OF THE GHSG

S Sasse,[1] B Klimm,[2] H Görgen,[2] A Lohri,[2] P Koch,[2] M Wilhelm,[2] G Trenn,[2] J Finke,[2] R Müller,[2] V Diehl,[2] H Eich,[2] P Borchmann,[2] A Engert[2]

[1]*University Hospital of Cologne, Cologne, Germany*
[2]*German Hodgkin Study Group, Cologne, Germany*

Background/Aims. In the HD8 trial of the German Hodgkin Study Group (GHSG), we investigated whether radiotherapy (RT) can be reduced without loss of efficacy from extended field (EF) to involved field (IF) after four cycles of chemotherapy. The current 10 year follow-up analysis was conducted to assess the influence of the two modalities with regard to long-term outcome rates and toxicities including secondary malignancies. *Methods.* Between 1993 and 1998, patients with newly diagnosed early-stage unfavorable HL were randomized to receive four cycles of chemotherapy followed by either RT of 30 Gy EF + 10 Gy to bulky disease (arm A) or 30 Gy IF + 10 Gy to bulky disease (arm B). Of 1,204 patients randomly assigned to treatment, 1064 patients were informative and eligible for the arm comparison (532 patients in each treatment arm; drop-outs before RT excluded). *Results.* Patients demographics and clinical characteristics were well balanced between the two treatment arms. The median observation time was 114 months. Survival rates at 10 years after start of radiotherapy revealed no differences for arms A and B with respect to freedom from treatment failure (FFTF; 79.8% and 79.7%), progression free survival (PFS; 79.8% and 80.0%) and overall survival (OS; 86.4% and 87.3%). Non-inferiority of the experimental arm (IF-RT) was proven with statistical significance for the primary endpoint FFTF (95%CI for HR 0.72-1.25). However, patients 60 years or older had an inferior outcome when treated with EF-RT compared with IF-RT. Acute toxicity from radiotherapy including nausea, leucopenia, thrombocytopenia, gastrointestinal and pharyngeal toxicity were more frequent in the EF arm. A total of 15% of patients in arm A and 12.2% of patients in arm B died; causes of deaths were mainly secondary malignancies (5.3% vs. 3.4%), HL (3.2% vs. 3.4%), and cardiovascular disease (1.7% vs. 2.1%). Interestingly, there were more secondary malignancies (n=58 vs. n= 45), especially AMLs (n=11 vs. n=4) after combined modality treatment including EF-RT than IF-RT. However, longer follow-up is needed for statistic significance and evaluation of other long-term side effects. *Summary/Conclusions.* Radiotherapy volume size reduction from EF to IF after chemotherapy does not result in inferior long-term outcome and produces less acute and long-term toxicities in patients with early-stage unfavorable HL.

Background. Panobinostat is an oral pan-deacetylase inhibitor (pan-DACi). TARC (thymus and activation-regulated chemokine) production by Hodgkin lymphoma Reed-Sternberg cells drives intra-tumoral accumulation of reactive cells. TARC levels have been studied in relation to DACi in Hodgkin lymphoma cell lines and are known to reflect disease activity in patients. In a pivotal Hodgkin lymphoma study, panobinostat achieved durable responses in heavily pretreated relapsed/refractory patients after autologous stem cell transplant (ASCT). *Aims.* This prospective analysis was conducted to evaluate TARC as a biomarker for disease activity and to explore the correlation with the response and progression of patients with relapsed/refractory Hodgkin lymphoma following ASCT treated with panobinostat. *Methods.*

Baseline and Cycle 1 Day 15 TARC Data by Best Overall Response

	CR n=5	PR n=31	SD n=70	PD n=14	Unknown n=9
Baseline					
n	n=4	n=25	n=62	n=12	n=6
Median, pg/mL	1122	2089	1479	1318	955
IQR*	568-2188	1288-2951	708-2951	1202-2884	513-1950
Cycle 1 Day 15					
n	n=3	n=25	n=51	n=10	n=4
% of baseline	72%	78%	90%	100%	90%
IQR*	58%-92%	71%-98%	87%-98%	95%-101%	79%-101%

*IQR, interquartile range (interval between 25th and 75th percentile).

Figure 1.

Panobinostat was administered 40 mg three times per week, every week in 21-day cycles. Response was assessed every 2 cycles by CT/MRI scan. Blood was collected at screening, days 5, 8, and 15 of cycle 1, day 1 of cycles 2-4, and end of treatment. Milliplex Map Human Cytokine/Chemokine panel II (Millipore) was used to analyze TARC. *Results.* A total of 129 patients were enrolled and treated, and 36 responses were seen (5 complete [CR], 31 partial [PR]). Stable disease (SD) was observed in 70 patients (for a disease control rate [CR+PR+SD] of 82%), and 14 patients had progressive disease (PD). Samples were collected from 117 patients for analysis. Statistical analysis showed that baseline TARC levels were in similar range across patients with CR, PR, SD, and PD (see table). Reduction of TARC on treatment was observed as early as cycle 1 day 8. Percent change, calculated as the geometric mean ratio of TARC levels at cycle 1 day 15 to baseline, showed a reduction of TARC level to 72% in CR, 78% in PR, 90% in SD, and no change in PD patients. Patients with more than the median TARC reduction (high reduction) were at less risk of progression compared to patients with less than the median of TARC reduction (low reduction); hazard ratio 2.27 [95% CI; 1.30, 3.98]. Median progression-free survival (PFS) in the high-reduction group was 9.9 months vs 4.9 months for the low-reduction group. At cycle 1 day 15, the hazard ratio of PFS for each 1-log reduction in TARC from baseline was 0.44 (95% CI; 0.23, 0.83). Similar trends were observed at other time points. *Summary/Conclusions.* Early TARC reduction was observed post-panobinostat treatment in Hodgkin lymphoma patients with disease control. The level of TARC reduction at cycle 1 day 15 was highest in patients achieving CR and PR, providing further evidence to support the mechanism of action of DACi in Hodgkin lymphoma. Further analysis is ongoing to correlate changes in TARC vs time to response and target lesion reduction, and these updated results may support TARC as a potential biomarker for monitoring Hodgkin lymphoma response to panobinostat.

[5]*University of Miami, Sylvester Comprehensive Cancer Center, Miami, United States of America*
[6]*Seattle Genetics, Inc., Bothell, United States of America*

Background. Brentuximab vedotin (SGN-35) is an anti-CD30 antibody conjugated to the highly potent antimicrotubule agent, monomethyl auristatin E (MMAE), by a plasma-stable linker. Brentuximab vedotin binds to CD30 on the cell surface, internalizes, and releases MMAE inside the cell via lysosomal degradation. Binding of MMAE to tubulin disrupts the microtubule network, induces cell cycle arrest, and results in apoptotic death of the CD30-expressing tumor cell. Brentuximab vedotin induced durable objective responses in association with manage-

able adverse events in patients with relapsed or refractory HL after ASCT (Chen *et al*., ASH 2010). *Aims.* To characterize the safety and efficacy of brentuximab vedotin in a population of patients with relapsed or refractory HL who refused or were ineligible for ASCT ("pre-ASCT"patients). *Methods.* Pre-ASCT patients were enrolled per study entry criteria in 2 phase 1 multicenter studies. In Study SG035-0001, patients received brentuximab vedotin IV q3 weeks at: 0.1, 0.2, 0.6, and 1.2 mg/kg (1 patient each); 1.8 mg/kg (2 patients); and 2.7 mg/kg (4 patients). In Study SG035-0002, patients received brentuximab vedotin IV q1 week, 3 out of 4 weeks, at: 0.4 mg/kg (2 patients), 0.8 mg/kg (1 patient), 1.0 mg/kg (3 patients), 1.2 mg/kg (1 patient), and 1.4 mg/kg (3 patients). Informed consent was obtained for all patients. *Results.* Twenty pre-ASCT patients were enrolled across the 2 studies. The median age was 31.5 years (range, 12-87), 65% were male, baseline ECOG performance status was 0 (50%), 1 (30%) or 2 (20%). The median number of prior systemic chemotherapy regimens was 3 (range, 1-7), and 45% of patients had received prior radiotherapy. Relative to the post-ASCT population, a higher proportion of pre-ASCT patients had primary refractory disease and were refractory to their most recent prior therapy. The incidence of bone marrow involvement and baseline B symptoms was also higher in the pre-ASCT population. Adverse events (AEs) of any grade in ≥25% of patients were fatigue, nausea, pyrexia, diarrhea, vomiting, back pain, decreased appetite, anemia, night sweats, and weight decreased. Eleven of 20 patients (55%) experienced AEs with a maximum severity of Grade 3 and treatment-related serious AEs were reported in 3 patients (15%). No deaths occurred within 30 days of the last dose of brentuximab vedotin. Objective responses (Cheson 2007) were observed in 6 of the 20 pre-ASCT patients (30%); 2 CR and 4 PR. Median duration of objective response could not be estimated because only 1 of the 6 patients had disease progression or death by the time of study closure. Censored response duration in the remaining 5 responders ranged from 29.6+ to 60.1+ weeks. *Summary/Conclusions.* Brentuximab vedotin was associated with manageable adverse events in a population of patients with relapsed or refractory HL who refused or were ineligible for ASCT, with a safety profile comparable to that observed in post-ASCT patients. The demonstration of objective responses suggests that anti-tumor activity is not limited to patients who received brentuximab vedotin after ASCT and warrants further studies in earlier lines of therapy.

Background. The outcome of patients (pts) with HIV-HL has improved since the introduction of highly active antiretroviral therapy (HAART). However, standard therapy for HIV-HL has not been defined. *Aims.* The current trial was initiated to investigate a risk adapted treatment strategy in pts with HIV-HL as established in HIV-negative pts with HL. *Methods.* Pts. were planned to receive 2x ABVD + 30 Gy involved field (IF) radiation for early stage (ES) favourable HL (stage I/II without risk factors), 4x BEACOPP baseline + 30 Gy IF for ES unfavourable HL (extranodal involvement, large mediastinal mass, ≥ 3 lymph node areas involved), and 6-8 x BEACOPP baseline for advanced stage HL. BEACOPP should be replaced by ABVD in pts with far advanced HIV-infection. HAART was given concomitantly with chemotherapy. The primary endpoint was tolerability and treatment related mortality. Secondary endpoints include event free survival (EFS) and overall survival (OS). *Results.* From 03/2004 to 12/2010 105 pts (8 females) were included in the trial. 23/105 pts (22%) had ES favourable HL, 14 (13%) ES unfavourable HL, and 68 (65%) advanced stage HL. B-symptoms were present in 69 pts (66%) and the mixed cellularity subtype was found in 63 pts (60%). 28 pts (27%) had a prior AIDS defining illness. The median CD4 count at HL diagnosis was 223/µl (range 7-967) and 57 pts (54%) had an HIV-viral load below the detection limit. The median time from HIV diagnosis to HL diagnosis was 5.8 yrs (range 0 - 26). In advanced stage HL grade 3/4 toxicity occurred in 13/13 pts under ABVD and 45/60 pts (75%) under BEACOPP with non haematological toxicity being more frequently observed under BEACOPP than under ABVD (48% vs. 39%). 5 pts died of neutropenic sepsis after the 1st, 7th (n=2) and 8th cycle of BEACOPP, and after 1 cycle of ABVD, respectively. So far response data are available from 101 pts. After a median follow-up of 23.1 months 20/21 pts (95%) with ES favourable HL and 13/13 pts (100%) with ES unfavourable HL achieved a CR/CRu. In pts with advanced HL the CR/CRu rate was 87% (58/67). Of 6 pts with relapsed/refractory HL 2 received an autologous stem cell transplant resulting in a 2nd remission and 4 pts died of progressive disease. 10 of 105 pts (9.5%) have died. Apart from neutropenic sepsis causes of death were progressive HL (n=4) and progressive HIV-infection (PML, n=1). The 2-year OS of the entire study population is 90.6% without significant differences between early, intermediate and advance stage HL. However, pts with both, advanced HL and advanced HIV-infection had a significantly worse OS (p=0.023). *Conclusions.* In pts with HIV-HL risk-adapted CT and concomitant HAART is feasible and effective. However, pts must closely be monitored for neutropenic infections. These data suggest that the prognosis of HIV-HD may approach results achieved in the HIV-negative population with HL.

Background/Aims. The success of tyrosine kinase inhibitors (TKIs) depends on the addiction of Philadelphia-positive (Ph+) CML progenitors to BCR-ABL1 kinase activity. However, CML quiescent hematopoietic stem cells (HSC) are TKI-resistant and represent an active disease reservoir. We hypothesize that this innate drug-resistance depends on inhibition of the tumor suppressor protein phosphatase 2A (PP2A). PP2A can be reactivated by FTY720, a drug that targets CML but not normal progenitors. Here we investigated the mechanism controlling survival/self-renewal of quiescent leukemic HSCs and their sensitivity to PP2A-activating drugs. *Methods.* HSCs from CML (n=68) and healthy (n=12) donors were FACS-isolated, and the biologic importance of PP2A inhibition and pharmacologic PP2A activation on their survival/self-renewal was assessed by BM serial transplantation; CFSE and Annexin-V staining; LTC-IC and CFC/replating assays; lentiviral shRNA/cDNA-transduction; LEF/TCF and proximity-ligation assays; Western blot, confocal microscopy and FACS analyses. *Results.* We observed increased BCR-ABL1 expression with impaired kinase activity in quiescent CML HSCs, in which BCR-ABL1 per se is required for induction of JAK2 that subsequently activated beta-catenin and inhibited PP2A. In fact, PP2A was suppressed in CML but not normal CD34+/CD38-/CD90+ HSCs. FTY720 and/or its non-immunosuppressive (S)-FTY720-OMe derivative markedly reduced survival and self-renewal of CML but not normal quiescent HSCs through BCR-ABL1 kinase-independent and PP2A-mediated JAK2 and beta-catenin inhibition. Importantly, FTY720 also strongly diminished BCR-ABL1+ LT-HSC frequency in serial BM transplantation assays. *Conclusions.* The pharmacologic targeting of the newly-identified BCR-ABL1 kinase-independent JAK2/ -catenin interplay in quiescent HSCs with FTY720 and its derivatives, might lead to cessation of lifelong patient dependence on TKIs.

0521

COMBINATION OF THE HEDGEHOG PATHWAY INHIBITOR LDE225 AND NILOTINIB TARGETS THE LEUKEMIC STEM CELL POPULATION IN CHRONIC MYELOID LEUKAEMIA

A David,[1] B Zhang,[2] Y Ho,[2] S Buonamici,[3] P Manley,[3] T Holyoake,[1] R Bhatia,[2] M Copland[1]

[1]*Paul O Gorman Leukaemia Research Centre, Glasgow, United Kingdom*
[2]*City of Hope National Medical Center, Duarte, United States of America*
[3]*Novartis Pharma AG, Basel, Switzerland*

Background. Although effective in inducing cytogenetic and molecular remission in chronic myeloid leukaemia (CML), tyrosine kinase inhibitors do not eliminate leukaemia stem cells (LSC), potentially resulting in relapse/progression. Therefore alternative strategies are required for eradication of CML LSC. The Hedgehog (Hh) pathway, a developmental pathway regulating stem cell fate, is active in BCR-ABL+ LSC and contributes to CML LSC maintenance via up-regulation of Smoothened (SMO). Thus inhibition of SMO may specifically target CML LSC. *Aim.* To assess the effect of LDE225 - a clinical grade SMO inhibitor (Novartis) - alone and in combination with nilotinib in chronic phase (CP)-CML. *Methods.* Baseline global gene expression was assessed in primitive CD34+ normal and CP-CML cells using the HuGene 1.0 ST array and Taqman® qRT-PCR. CD34+ primary CP-CML cells were cultured in the presence of LDE225±nilotinib prior to analysis, inoculation into colony forming cell assays (CFC) or long-term culture initiating cell assays (LTC-IC) or transplantation into NOD-SCID γ-chain (NSG) mice. The Scl-tTa-BCR-ABL murine model of CP-CML was used to assess effects of *in vivo* treatment with LDE225 (80mg/kg/day) ±nilotinib (50mg/kg/day) or vehicle over 21 days (Koschmieder *et al*; Blood 2005;105:324-334). *Results.* We detected differential expression of key Hh elements and targets between primitive CD34+ normal and CP-CML cells. Furthermore, Hh targets (Gli1 and Ptch2) in CD34+ CP-CML cells were inhibited following 72 hours exposure to LDE225. Increasing concentrations of LDE225 (1nM-1μM) had no effect on viability, proliferation or cell cycle status on primary $CD34^+$ CP-CML cells compared to untreated controls. LDE225 did not affect CFC readout after 14 days, however, we noted a significant reduction in secondary colony formation following re-plating after exposure to LDE225 (50nM LDE225; 62% $p<0.02$) alone or combined with nilotinib (LDE225 10nM & nilotinib 5μM; 73% $p<0.03$). LDE225 also reduced the LTC-IC recovery of CD34+ CP-CML cells compared to untreated controls (40%; $p<0.03$) and combination treatment (LDE225 10nM & nilotinib 5μM) resulted in significantly reduced LTC-IC frequency versus nilotinib alone (85%; $p=0.007$). $CD34^+$ CP-CML cells, exposed to 10nM LDE225, 5μM nilotinib or combination for 72 hours were transplanted into NSG mice. Combination treatment reduced engraftment of CML $CD45^+$, $CD34^+/45^+$ and CFC compared with control ($p=0.06$ / $p=0.02$ / $p=0.005$ respectively). FISH demonstrated a 1.3-fold and 1.8-fold reduction in engrafted leukaemic cells with nilotinib and LDE225 respectively but a 6-fold reduction following combination treatment. LDE225±nilotinib did not affect engraftment of normal $CD34^+$ cells. In the Scl-tTa-BCR-ABL murine model of CML, LDE225±nilotinib reduced the number of splenic $Lin^-Sca\text{-}1^+Kit^+Flt3^-CD150^+CD48^-$ (LT-HSC) cells ($p<0.01$) compared to control, but did not affect bone marrow (BM) LT-HSC. Nilotinib did not reduce LT-HSC numbers in spleen or BM. Mice treated with combination therapy demonstrated enhanced post-treatment survival compared with other experimental arms. Secondary transplantation experiments indicated that recipients of BM or splenic cells from combination treated mice had a reduced incidence of leukaemogenesis. *Conclusion.* LDE225 targets CP-CML LSC *in vitro* and in a murine model of CML. LDE225 combined with nilotinib represents a promising novel strategy for eradicating the LSC population in CP-CML patients.

0522

ENHANCED EXPRESSION OF THE HEDGEHOG PATHWAY TARGET GENE PTCH1 PREDICTS INFERIOR RESPONSE TO IMATINIB IN CHRONIC MYELOID LEUKEMIA

M Daghistani, J Khorashad, D Milojkovic, A Ibrahim, P May, G Gerrard, J Goldman, J Apperley, L Foroni, D Marin, A Reid

Imperial College London, London, United Kingdom

Background. Tyrosine kinase inhibitors (TKI) for chronic myeloid leukemia have yielded great success. However, BCR-ABL1-positive leukemic stem cells (LSCs) can persist despite lifelong TKI therapy and are believed to be a source of disease relapse and eventual progression. Recent studies indicate that activity of the Hedgehog (Hh) signaling pathway is crucial for survival of LSCs in CML. The level of Hh activity can be quantified via expression of its downstream target genes GLI1 and PTCH1. *Aims.* The aim of this study was to investigate the range of expression of PTCH1 in CML patients at diagnosis and to compare expression of PTCH1, and thus the level of Hh activity, to clinical outcome. *Methods.* Real-time quantitative PCR was used to measure PTCH1 expression in relation to a housekeeping gene (GUSB). RQ-PCR was performed on cDNA samples from peripheral blood granulocytes taken from 85 unselected CML patients at the time of diagnosis. Imatinib was given as a first line therapy for patients in chronic phase. A second cohort of 31 CML patients was identified for validation of clinical associations. Probabilities of OS, PFS and EFS were calculated using the Kaplan-Meier method. A receiver operating characteristic (ROC) curve method was used to calculate a threshold for poor response. *Results.* The median level of PTCH1 expression relative to GUSB was 3x10-4 (range 0 to 3.76x10-1). Importantly, the 59 patients with low expression of PTCH1 at diagnosis (calculated as on or below the 59th percentile of the expression range) had a superior seven year probability of CCyR, MMR, EFS, PFS and OS than the 26 patients with high expres-

sion; namely 94.9% vs 65.4% (p=0.007), 72.0% vs 23.7%, (p=0.0007), 84.1% vs 39.8 (p< 0.0001), 93.1 vs 53.2 (p< 0.0001) and 97.4% vs 58.9% (p< 0.0001). The expression of PTCH1 considered as a continuous variable was also predictive for the achievement of CCyR (RR= 0.68, p=0.01), MMR 0.49, p=0.004), EFS (RR= 0.56, p<0.0001), PFS (RR= 0.67, p=0.001) and OS (RR= 0.76, p=0.006). Expression of PTCH1 was an independent predictor for OS, PFS and CCyR and its predictive value was independent of Sokal score. The CD34 count in the bone trephine and the percentage of blast in peripheral blood at diagnosis was also comparable between patients with low (3.9% and 2.8%) and high (4.9% and 2.7%) PTCH1 expression (p=0.72 and p=0.88 respectively). The predictive value of PTCH1 expression was validated in an independent cohort of 31 patients. *Summary.* Our data suggest that PTCH1 has significant potential in predicting response to imatinib therapy in CML. The inter-patient variability of Hh activity in granulocytes may reflect similarly variable activity of this pathway in CML HSCs. This is supported by the observation that BCR-ABL1 increases Hh signaling in progenitor cells and stem cells to a comparable degree relative to normal counterparts. Variability in Hh pathway activity in CML HSCs therefore represents a plausible mechanism by which the CML clone in some patients may escape the inhibitory effects of imatinib to become a source of frank relapse.

0523

CANCEROUS INHIBITOR OF PP2A (CIP2A) INHIBITS PP2A AND STABILISES PIM1 AND C-MYC IN CML LEADING TO BLAST CRISIS

M Lucas,[1] R Harris,[1] A Giannoudis,[1] M Copland,[2] R Slupsky,[1] R Clark[1]

[1]*University of Liverpool, Liverpool, United Kingdom*
[2]*Paul O'Gorman Leukaemia Research Centre, Gartnavel General Hospital, Glasgow, United Kingdom*

Background. BCR-ABL1 tyrosine kinase activity induces and maintains chronic myeloid leukaemia (CML), but the molecular factors that contribute to disease progression are not well understood. PP2A is a phosphatase which regulates cell proliferation, differentiation and survival. Disease progression in CML is associated with inhibition of PP2A activity. In MNC and CD34+ cells taken at diagnosis from patients destined to progress to blast crisis (BC), we have shown that CIP2A functionally inhibits PP2A, and that levels of CIP2A detected in diagnostic samples can prospectively predict disease progression. We have also shown that 1) CIP2A is not suppressed by imatinib treatment and 2) CIP2A levels rise as patients progress into BC, further suppressing PP2A activity. As CIP2A levels rise BCR-ABL1 tyrosine kinase activity increases. *Aim.* The aim of this study was to investigate the mechanism by which CIP2A predisposes patients to disease progression. *Methods.* CIP2A, PP2A, pY^{307}-PP2A and PIM1 proteins were assessed by flow cytometry in 31 newly diagnosed chronic phase patients. c-Myc and pS^{62}-c-Myc were assessed by ELISA. CIP2A siRNA was transfected into K562 cells. Results were analysed in patients stratified according to their eventual clinical outcome - cytogenetic responders (CCR), Non-responders (No-CCR) and blast crisis (BC). *Results.* Phosphorylation of c-Myc on serine 62 stabilises c-Myc from degradation. MNC from chronic phase patients destined to progress to BC demonstrate significantly higher pS^{62}-Myc and c-Myc levels than in those patients who do not progress (p=0.04, p=0.002 respectively) suggesting high c-Myc levels indicate a high risk of disease progression. PP2A is the major phosphatase that dephosphorylates and destabilises Myc, so high levels of Myc support the observation of PP2A activity inhibition. siRNA knockdown of CIP2A restored PP2A activity and decreased pS^{62}-Myc levels and BCR-ABL1 tyrosine kinase activity. PIM1 phosphorylates and stabilises c-Myc; PIM1 is also a target for PP2A. PIM1 was elevated in CD34+ cells from patients destined to progress to BC compared to CCR and No-CCR patients. Analysis undertaken in K562 cells revealed that activation of PP2A, either by addition of the PP2A activators forskolin and FTY720 or by inhibition of CIP2A by imatinib, also decreased PIM1 levels. These data further support PP2A activity suppression in CD34+ cells of patients at high risk of developing BC. *Conclusion.* We show here firstly that pY^{307}-PP2A (inactivity), PIM1 and pS^{62}-Myc levels correspond with high levels of CIP2A and secondly that CIP2A siRNA knockdown restores PP2A function, and decreases BCR-ABL1 and c-Myc activities. Our data suggest that CIP2A predisposes patients to disease progression by inhibiting PP2A leading to the stabilisation of PIM1 and stabilisation and increased activity of c-Myc. C-Myc via its role in cell cycle promotion and increased cellular proliferation may then contribute to disease progression by promoting aneuploidy as a result of deregulated cell division and increased mismatch repair.

0524

THE PROPORTION OF LEUKEMIC STEM CELLS (PH+ CD34+CD38-) IN BONE MARROW OF NEWLY DIAGNOSED PATIENTS WITH CML CORRELATES WITH EARLY CYTOGENETIC AND MOLECULAR RESPONSE TO IMATINIB OR DASATINIB

Background. In vitro studies have suggested that CML stem cells are resistant to bcr-abl inhibitors. However, no prospective clinical studies have evaluated their effect on leukemic stem cells in patients. In addition, the prognostic value of leukemic stem cell burden at diagnosis is unknown. *Aims.* To analyze the proportion of Ph^+ putative leukemia stem cells in CML patients at diagnosis and during imatinib or dasatinib treatment (TKI therapy), and correlate the leukemic stem cell burden with disease eradication kinetics and early treatment response. *Patients and Methods.* 42 newly diagnosed chronic phase CML patients within the Nordic countries were enrolled in a Phase II study (NordCML006) comparing the effect of dasatinib 100 mg (n=21) to imatinib 400 mg (n=21) at the stem cell level. Ph+ candidate leukemic stem cells were analyzed at 0, 1, 3, and 6 months after start of therapy. After pre-selection of CD34+ cells from BM aspirates, the cells were fractionated into CD38 positive ($CD34^+CD38^+$) and negative ($CD34^+CD38^-$) pools with sorting flow cytometer. The proportion of Ph^+ cells in different fractions was determined by interphase FISH for *BCR-ABL1*. *Results.* Measurement of Ph+ stem cells was feasible in most patients at all time-points. The median percentage of Ph^+ cells at diagnosis was significantly lower in $CD34^+CD38^-$ fraction when compared to $CD34^+CD38^+$ fraction or to unfractionated BM (79%, range 0.6-100%; 96%, 50-100%; and 96%, 57-100%, respectively, p=0.0001, n=41). During TKI therapy, the proportion of Ph^+ cells decreased rapidly in both stem cell fractions. At 1 month, the median proportion of Ph^+ cells was 14% and 56% in $CD34^+CD38^-$ and $CD34^+CD38^+$ fractions, respectively compared to 71% in whole BM (p=0.0002, n=36). At 3 month, the respective numbers were 0.18%, 0.19% and 0.80% (p=0.03, n=27).The proportion of Ph^+ cells in the $CD34^+CD38^{neg}$ fraction at diagnosis correlated with high leukocyte count (r=0.50, p<0.001), enlarged spleen (r=0.43, p=0.0055), high blood blast percentage (r=0.57, p=0.0001) and low hemoglobin concentration (r=-0.44, p=0.004). Pre-treatment leukemic stem cell burden also correlated with cytogenetic response during TKI therapy at 1, 3 and 6 months time-points (r=0.67, p<0.0001; r=0.52, p=0.0017; r=0.43, p=0.015, respectively). Patients who achieved MMR at 6 months time-point (n=17) had significantly lower proportion of Ph^+ $CD34^+CD38^-$ cells at diagnosis compared to patients without MMR (n=21) at 6 months (70% vs. 89%, p=0.03). Grade ≥2 hematological adverse effects were more common during first 3 months of therapy in patients with high leukemic stem cell burden at diagnosis (55% vs. 19%, p=0.02). *Conclusions.* Our results indicate that the proportion of Ph^+ stem cells at diagnosis is a key biological marker and correlates with cytogenetic and molecular response as well as hematological toxicity within first 6 months of treatment. Successful TKI therapy rapidly eliminated most Ph^+ cells from the stem cell compartments *in vivo*. The effect of therapy by the treatment arm will be analyzed when all patients have reached the primary endpoint at 6 months time-point.

Platelets and bleeding disorders

A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE II TRIAL ON THE EFFICACY, SAFETY AND TOLERABILITY OF E5501 (AKR501) IN SUBJECTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP)

J Bussel,[1] Y Zhang,[2] S Tang,[2] J McIntosh,[2] D Kuter[3]

[1]*Weill Cornell Medical College, New York, United States of America*
[2]*Eisai Inc., New Jersey, United States of America*
[3]*Harvard Medical School, Boston, United States of America*

Background. Thrombopoietin (TPO) receptor agonists mimic TPO, the endogenous platelet production regulator, and have demonstrated efficacy in randomized controlled trials in chronic immune thrombocytopenia (cITP) patients who relapsed after first- and/or second-line agents. *Aims.* E5501 (previously AKR501) is a novel, orally-active, once-a-day TPO agonist which increased platelet counts in healthy volunteers. This study investigated the efficacy and safety of E5501 in subjects with cITP. *Methods.* This was a Phase II, multicenter, randomized, double-blind, placebo-controlled, dose-ranging, parallel group 4-week study (501-CL-003). Subjects had cITP that was refractory to, or had relapsed after, at least one prior therapy, and had a baseline platelet count of <30 x10^9/L, or <50 x10^9/L if they were on stable corticosteroid therapy. Sixty-four subjects were enrolled and randomized in the ratio 3:3:3:3:1 respectively to E5501 (2.5, 5, 10 or 20 mg) or placebo, administered orally, once daily for 28 days. Response was assessed by weekly platelet count and the primary endpoint was responder rate at Day 28, with responders defined as having a platelet count ≥50 x10^9/L that had risen by ≥20 x10^9/L above baseline. *Results.* A dose-dependent increase in responder rate at Day 28 was observed among subjects receiving E5501 (Table 1). Responder rate at Day 28 was significantly higher in the E5501 20 mg group (80.0%) than the placebo group (0%; p=0.0036) and the E5501 2.5 mg group (13.3%; p=0.0007). Median platelet counts at Day 28, and change above baseline, increased dose dependently in subjects receiving E5501 (Table 2). In the E5501 20 mg group, 93.3% of subjects achieved early response (by Day 7; Table 3). For subjects achieving early response with E5501 20 mg, 76.9% maintained platelet response up to Day 28. None of the subjects receiving E5501 2.5 mg achieved and maintained response. None of the 5 placebo-treated subjects demonstrated response at any point. A similar proportion of treatment-emergent adverse events (TEAEs) occurred in all dose groups. Most TEAEs were mild and transient, with fatigue (20.3%), headache (20.3%) and epistaxis (15.3%) the only TEAEs that occurred in ≥10% of E5501-treated subjects. Overall few AEs led to dose interruption or treatment discontinuation in the study, and there was no clear dose relationship in the incidence of these events. Two subjects (1 each in the 5-mg and 10-mg dose groups) withdrew due to a drug-related AE (musculoskeletal chest pain [5 mg]; myocardial infarction, transient ischemic attack, and retinal artery occlusion [10 mg]); and 2 subjects [20 mg] withdrew due to increased platelet counts (≥500,000/mm^3). Three subjects reported 3 additional serious TEAEs unrelated to study drug: 1 pneumonia by the previously mentioned subject in the 10 mg dose group and 2 occurred in 2 subjects in the 2.5-mg dose group. *Conclusion.* E5501 was effective in increasing platelet counts in subjects with cITP at doses of 5, 10, and 20 mg daily, was well tolerated and had an acceptable safety profile. These data support continued development of E5501 as an effective treatment in patients with cITP.

A FAMILY WITH TYPE 2M VWD WITH NORMAL VWF:RCO BUT REDUCED VWF:CB DUE TO A M1761K MUTATION IN THE A3 DOMAIN

P Bignell,[1] J Beavis,[2] R Marr,[2] K Sukhu,[2] D Keeling[2]

[1]*Molecular Haematology, Oxford, United Kingdom*
[2]*Oxford Haemophilia and Thrombosis Centre, Oxford, United Kingdom*

Type 2 VWD is characterised by a qualitative defect in VWF and is diagnosed by demonstration of a discrepancy between circulating plasma levels of VWF and its functional activity. Type 2 VWD is subdivided into types 2A, 2B, 2M and 2N. Type 2A and 2M variants show decreased platelet binding but type 2A VWD is also associated with an absence of high molecular weight multimers. Type 2B variants have increased affinity for platelet glycoprotein 1b. Type 2N VWD refers to variants with a decreased affinity for F8. A 17-year-old presented with menorrhagia, Fe deficiency, epistaxis and bruising (bleeding score 5). Both her sisters and mother had menorrhagia and bruising, one sister had nose bleeds and the mother had a PPH (bleeding scores 2, 3 and 4). The principal detectable abnormality was defective collagen binding. Genetic analysis showed the mutation c.5282 T>A, p.M1761K in the A3 domain of VWF. All have the same mutation, normal RIPA and normal multimers. The table shows the results including VWF:CB measured by two different kits. Four previous mutations with this phenotype have been described S1731T, W1745C, S1783A, H1786D. Our novel mutation was picked up by the Corgenix assay (equine type III collagen) but not by the Technozym assay (pepsin-digested human type III collagen) which demonstrates that this sub-type of type 2M VWD will be missed if VWF:CB assays are not performed and that different assays may differ in their sensitivities. The 1994 definition of type 2M VWD depended on "decreased platelet-dependent function"which defined patients with VWF GPIb binding site defects who have reduced VWF:RCo. This family would have remained unclassified. In the recently updated ISTH SSC VWD classification isolated collagen binding defects are included within the 2M subgroup. Impairment of VWF-dependent platelet adhesion to the endothelium in type 2M VWD occurs in the presence of a full range of VWF multimers. This is a key characteristic of the 2M subtype. There are 3 important differences with the 2M group. 1. 2M mutations are clustered in the A1 domain (residues 1260-1471) of VWF, whereas these mutations af-

fecting collagen binding are found in A3. 2. 2M is characterised by impaired binding to platelet GpIbα, demonstrated by reduced ratio of RCo:Ag. 3. A clinically important feature of the 2M phenotype is it tends to be associated with poor functional response to DDAVP. VWF secreted in response to DDVAP continued to show a qualitative defect in collagen binding demonstrated by persistence of the abnormal CB:Ag ratio. In addition to measuring GP1bα-dependent function using riscocetin cofactor activity (VWF:RCo), it is recommended that collagen binding activity (VWF:CB) is analysed in the subclassification of type 2 VWD. Mutations in the A3 domain of VWF causing reduction in collagen binding, independent of multimer composition may cause clinically significant bleeding symptoms.

[8]*Interlakes Oncology and Hematology, Rochester, NY, United States of America*
[9]*Immunomedics, Morris Plains, NJ, United States of America*

Background. Subcutaneous (SC) injections of veltuzumab, a 2nd-generation humanized anti-CD20 monoclonal antibody with structure-function differences from rituximab, may offer potential benefits to both patients and the healthcare system. *Aims.* A multicenter, phase I/II study to evaluate SC veltuzumab in adults with primary ITP who failed ≥1 standard therapy and presented with platelets ≤30K/μL, but without major bleeding. *Methods.* All patients received 2 doses of veltuzumab 2 weeks apart (without steroids), initially administered IV, but then by SC injection after a higher concentration formulation became available. By recent international working group categories, efficacy was evaluated separately for patients with newly-diagnosed or persistent disease (≤1 year duration) compared to patients with chronic disease (>1 year), with best responses (on at least 2 occasions, one week apart) classified as complete (CR, >150K/μL), partial (PR, 50-150K/μL), or minor (MR, 30-50K/μL). Adverse events (AEs) and safety laboratories were evaluated by NCI CTC v3 toxicity grades. Other evaluations included circulating B-cell levels (CD19), veltuzumab serum levels, and human anti-veltuzumab antibody (HAHA) titers. *Results.* Of 36 patients now entered, 7 received IV veltuzumab doses of 80 (N=3), 120 (N=3), or 200 mg (N=1), and 29 received SC doses of 80 (N=9), 160 (N=5), or 320 mg (N=15). One patient had a Grade 3 infusion reaction after receiving ~100 mg veltuzumab at first IV dose. Otherwise veltuzumab was well tolerated with a limited number of AEs (All Grade 1-2 transient infusion/injection reactions) and no other safety issues. Of 8 patients (5 female/3 male; median 55-years old) with ITP ≤1 year and treated with steroids and/or immunoglobulins, 7 (88%) achieved an objective response (OR: CR+PR+MR), including 3 (38%) CRs. Of 28 patients (16 female/12 male; median 53-years old) with ITP > 1 year (13 with 5 - 31 years) and additional therapies [splenectomy (N=8), azathioprine (N=8), rituximab (N=6), tpo-receptor agonists (N=5), chemotherapy (N=4)], 17 (61%) still achieved ORs, including CRs in 4 (14%) patients with ITP for 1.4, 2.0, 2.4 and 25 years. ORs and CRs occurred with both SC and IV administrations, and across all dose levels. The CRs were durable, with median relapse-free survival currently 1.2 years (0.3 - 1.9 yr) and 5/7 CRs still continuing. Most PRs and MRs relapsed before 6 months, and of 7 patients then retreated, most obtained responses comparable to their initial response. B cells were depleted rapidly with both IV and SC dosing with recovery starting 12 to 16 months after treatment. Compared to IV dosing, SC veltuzumab had slower release over several days with lower serum levels, but comparable availability/exposure. Four patients developed low-level HAHA titers of uncertain clinical significance. *Conclusions.* Low-dose SC veltuzumab was convenient, well tolerated and with promising activity in relapsed ITP. With only 2 SC doses, patients with limited disease duration of ≤1 year achieved high rates of objective responses [88%], including 38% durable CR's. In patients with longer-standing disease, CRs occurred less frequently, but there was activity [61% ORs], and more extended dosing SC regimens may be required in this more refractory population.

Background. Acquired haemophilia A (AHA) is an autoimmune disease characterised by development of an autoantibody to factor VIII (FVIII). Immunosuppression to eradicate the inhibitor should start as soon as the diagnosis has been made to reduce the time patients are at risk of bleeding. If presenting characteristics could be used to predict the likelihood of inhibitor eradication it might be possible to improve treatment. To increase knowledge of AHA the European Acquired Haemophilia Registry was established and collected data on 501 patients from 12 countries. *Aim.* Investigate whether presenting characteristics could be used to predict inhibitor eradication. *Methods.* A subset of 240 patients was eligible for analysis. The patients included were from countries that had no restrictions on entry and on whom outcome data were available. Inhibitor eradication was defined as FVIII >70IU/dL and inhibitor negative. The baseline model included age, gender and underlying aetiology (autoimmune, pregnancy, malignancy or idiopathic). To investigate the potential clinical utility of presenting FVIII level and inhibitor titre; survival c-index derived from a Cox model, net reclassificaction improvement (NRI) and integrated discrimination improvement (IDI) were calculated. The IDI is a measure of how much a parameter (FVIII, inhibitor titre or both) improves the overall predictive value of the model for inhibitor eradication compared to the baseline model, whereas the NRI measures the improvement in prediction according to pre-specified cut offs of risk. *Results.* 156/240 (65%) patients achieved remission after first line immunosuppression after a median (IQR) 35 (19-77) days. The underlying aetiology and gender were not significantly associated with time to inhibitor eradication on Cox regression modelling but age was borderline significant: hazard ratio (HR) (95% CI) 1.02 (1.0-1.03), P<0.03. Using Cox regression modelling, an inhibitor titre <16 BU/mL (the median inhibitor titre of the cohort) HR 1.57 (1.10-2.23), P<0.02 and higher FVIII level at presentation (analysed as a continuous variable) HR 1.06 (1.02-1.101), P<0.001 were both associated with faster inhibitor eradiation. Compared to the baseline model (age, gender and aetiology), adding

inhibitor titre <16 BU/mL resulted in a survival c-index (95% CI) of 0.62 (0.58-0.67), P=0.0006. The NRI for inhibitor titre <16BU/mL was 15.75%, P=0.14 and the IDI was 3.38%, P<0.005. FVIII level at presentation resulted in survival c-index 0.61 (0.56-0.66), P<0.02, NRI 16.48%, P=0.08 and IDI of 2.94%, P<0.005. Combining both inhibitor titre <16BU/mL and FVIII level gave a survival c-index 0.64 (0.59-0.69), P<0.001, NRI 16.48%, P=0.06 and IDI 4.56%, P<0.001 for the time to inhibitor eradication. *Conclusions.* These data are the first demonstration that inhibitor titre and FVIII level at diagnosis provide time dependent prognostic information about the likelihood of inhibitor eradication. The results may be useful for improving the understanding of the biology of AHA. Whether this information will be clinically useful is not known. It is possible, however, that patients presenting with high titre inhibitors and low FVIII levels may benefit from more intensive immunosuppressive regimens but this will required further study. The results further highlight the value of high quality registry data for the investigation of rare diseases.

[5]*Hemophilia Center, Bari, Italy*
[6]*A. B. Bonomi Hemophilia Thrombosis Center, Milan, Italy*

Background. von Willebrand disease (VWD) is the most common inherited bleeding disorder and is due to quantitative and/or qualitative defects of von Willebrand factor (VWF). Despite the improved knowledge of this disorder, no data on the incidence and determinants of bleeding requiring specific treatments are available up to now. Aims and design of the study: To determine the incidence and determinants of bleeding requiring therapy with DDAVP and/or VWF/FVIII concentrates in patients with VWD, a national registry (RENAWI) was organized to collect detailed retrospective information. Patients included in RENAWI were then followed up for one year and prospective data on number, type and management of bleeding episodes were analyzed. *Methods.* All patients were diagnosed following recommendations of the ISTH-SSC-SC on VWF, with bleeding score (BS) calculated at enrollment. Diagnosis of VWD was confirmed by the coordinating center using multimeric analysis in plasma and mutations of VWF gene. For different risk categories, the incidence of bleeding (mucosal and non-mucosal) was calculated. Bleeding-free survival was computed with the Kaplan-Meier method, and a Cox's proportional hazard model was builded to calculate the risk of bleeding [expressed as hazard ratio (HR)] associated with different determinants, adjusted for the effect of the other variables. *Results.* In the prospective study based on 797/1,234 (65%) cases of the registry (VWD1=57%, VWD2A=8%, VWD2B=7%; VWD2M=21%; VWD3=6%), 147/797 (18%) were treated in a year for 318 bleeding episodes and 87 minor or major surgeries. At univariate analysis, the determinants significantly associated with a high risk of bleeding were: BS>10 [HR=6.72 (95%CI: 3.74-12.07)], bleeding time>20 min [HR=5.66 (3.19-10.02)], VWF:RCo<10 U/dL [HR=3.26 (1.76-6.04)], and FVIII:C<20 U/dL (HR=4.20 (2.43-7.26)]. Including all the variables in a Cox's proportional hazard model, BSS was the most significant determinant of bleeding [HR=5.26 (2.64-10.44)]. The probability of being free from bleeding at one year was significantly lower in VWD3 (49%) than in VWD1 (95%) and VWD2 (90%) patients. Those with both VWF:RCo>30 U/dL and FVIII:C>40 U/dL always showed BS<5 and the lowest incidence of bleeding. A total of 292 DDAVP injections were used to manage bleeding and surgeries in VWD1 (65%) and VWD2 (35%) patients, and 452 administrations of VWF/FVIII concentrates were used to treat bleeding and to manage surgeries in VWD3 (75%), VWD2 (34%) and VWD1 (15%). *Conclusions.* This prospective study confirms that BS is an important clinical predictive factor for bleeding and for the need of treatment. In cases with VWF:RCo>30 U/dL and FVIII:C>40 U/dL bleedings are very rare, in agreement with their relatively low BS.

Improving outcome in chronic lymphocytic leukemia

RITUXIMAB THERAPY OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS IN REMISSION

P Zagoskina,[1] V Demyanova,[2] E Zotina,[2] I Grishina[2]

[1]*Kirov scientific research institute of hematology and blood transfusion of FMBA, Kirov, Russian Federation*
[2]*Kirov Scientific Research Institute of Hematology and Blood Transfusion of FMBA, Kirov, Russian Federation*

The application of the combination of rituximab with a fludarabine-containing chemotherapy regimen in recent years has significantly improved the results of overall and disease-free survival of patients with chronic lymphocytic leukemia (CLL). *Aim.* To study the efficiency of maintenance with rituximab after induction chemotherapy or immuno-chemotherapy in CLL patients. *Materials and Methods.* The study included 213 patients in remission. The age of patients ranged from 34 to 76 years (median, 59 years). Remission was induced after a RFC program in 117 patients and FC in 96 patients. Complete remission (CR) was observed in 121 (57%) patients, and partial remission (PR) in 92 (43%). The patients were randomly assigned to either observation (133 patients) or supporting rituximab therapy in the form of 4 weekly injections (375 mg/m2) every 6 months over 2 years (60 patients). *Results.* The patients treated with a RFC regimen with subsequent rituximab maintenance had a significantly lower frequency of relapse and death compared to the observation group ($\chi2$=10.749, p=0.001 and $\chi2$=5.877, p=0.015, respectively). Analyzing these indicators in patients treated with an FC regimen we also see the advantage of maintenance therapy in relation to the observation group ($\chi2$=49.896, p=0.0001 and $\chi2$=9.985, p=0.002, respectively). Comparative analysis of progression free survival (PFS) of CLL patients who received various regimens revealed a significant difference. Thus, in patients who completed the program followed by RFC and supporting rituximab therapy, the median PFS was achieved, while in patients without supporting rituximab therapy it was 42 months (p=0.009). The related indicators of patients receiving the combination of FC with further supporting rituximab therapy differed significantly: their median PFS was not achieved in contrast to patients in the monitoring group, whose PFS was 24 months (p=0.001). During the period of supporting rituximab therapy no additional toxicity was observed. *Conclusion.* The results of our study confirm the role of rituximab therapy in CLL remission maintenance.

The treatment target of chronic lymphocytic leukemia (CLL) is the attainment of an optimal disease control combining chemotherapy with monoclonal antibodies. This approach may produce complete molecular remissions and longer response duration (RD), remaining often a minimal residual disease (MRD). We treated in first line 138 CLL symptomatic patients (pts), after informed consent, median age 63 years, with six monthly courses of intravenous (25 mg/sqm) or oral (30-40 mg/sqm) fludarabine and then, after a median time of 30 days, with four weekly doses (375 mg/sqm) of rituximab (rtx). Fourteen pts had a modified low Rai stage, 121 an intermediate stage and 3 a high stage. We defined as high risk pts having at least two of these markers: unmutated IgVH, CD38>30%, ZAP-70>20%, intermediate/unfavorable cytogenetics (trisomy 12 or del11q or del17p). For MRD flow cytometric study, the threshold was set at >1% CD19+CD5+CD79b+/- bone marrow (BM) CLL cells. Based on NCI criteria 106/138 (77%) pts

achieved a complete remission (CR), 26/138 (19%) a partial remission (PR) and 6/138 (4%) stable disease or progression. Phenotypic CR (CD19+CD5+CD79b- BM cells <1%) was achieved in 80/138 (58%) CLL pts. Interestingly, MRD+ pts showed a significant shorter overall survival (OS) in comparison with MRD- pts (24% vs 72% at 16 years, P=0.00016). During the induction and consolidation/maintenance, 13 pts underwent grade 2-3 (WHO) infective lung toxicity and 2 pts progressed towards Richter's syndrome. Hematologic toxicity was mild including mainly neutropenia (grade 3 and/or 4 in 60 pts) and thrombocytopenia (grade 3 and/or 4 in 8 pts). Fifty-seven pts (43%) either in CR with B-CLL BM cells >1% (MRD+, n=15 pts) or in CR MRD negative, but developing MRD positivity within 2 years after induction (n=24 pts) or in PR (n=18 pts), underwent consolidation and maintenance therapy with four monthly cycles of rtx at 375 mg/sqm followed by twelve monthly low doses of rtx (150 mg/sqm). The median follow-up duration was 59 months. Noteworthy, both persistently MRD negative (>2 years) pts (n=52) and pts undergoing consolidation/maintenance therapy (n=57) showed a longer RD vs MRD+ not consolidated pts (n=22) [76% vs 57% vs 0% at 5 years; P<0.0001]. Equally, OS was shorter in MRD+ not consolidated pts in comparison with the other two subsets (0% vs 61% vs 97% at 15 years; P=0.03). Moreover, ZAP-70+ or unmutated IgVH pts revealed shorter RD (17% vs 53% at 16 years, P=0.001; 16% vs 53% at 6.5 years, P<0.0001). Importantly, within the high risk subset (n=59), pts in persistent phenotypic CR (n=20) and consolidated pts (n=20) showed a longer RD (90% vs 61% vs 0% at 2.5 years, P=0.0009) vs MRD+ not consolidated pts (n=13). In multivariate analysis, consolidation/maintenance (P<0.0001) and biologic risk classes (P=0.001 and P<0.0001) were confirmed as independent prognosticators with regard to RD and OS. Therefore, persistent MRD negativity and/or rituximab consolidation/maintenance therapy improve RD and OS in CLL, also within the high risk subset, and important biological markers such as ZAP-70 and IgVH mutational status retain their prognostic impact with regard to the clinical outcome.

Background. The addition of rituximab to fludarabine-cyclophosphamide (R-FC) significantly improves outcome in CLL patients (pts). Myelotoxicity and immunosuppression represent an important limitation for the use of R-FC in elderly patients who frequently show impaired performance status and multiple comorbidities. *Aims.* This study was designed to determine whether the CLB-R combination is a feasible and beneficial first-line treatment for elderly CLL patients and to define the role of maintenance with R. *Methods.* Between October 2008 and January 2010, 97 elderly patients with untreated CLL requiring therapy according to the IWCLL criteria were enrolled. Written informed consent was obtained from all patients. CLB was administered every 28 days up to 8 courses at a dose of 8 mg/m^2/day on days 1-7 combined with 375 mg/m^2 R for cycle 3 and 500 mg/m^2 for cycles 4-8. Responsive patients were subsequently randomized to receive R maintenance every 2 months for 2 years or clinical observation. At baseline, blood samples were analyzed for FISH, IGHV mutational status, p53 mutation, and Zap-70 and CD38 expression. Minimal residual disease (MRD) was evaluated by flow cytometry and PCR on CR patients. The primary endpoint was the overall response rate (ORR) at the end of the induction phase on an intention-to-treat (ITT) population (all enrolled patients who received at least 1 R dose). *Results.* Eighty-five patients from 19 Italian centers were evaluable on an ITT basis. Median age was 70.0 years (range 61-84). Overall, 52.9% of patients were ≥70 years. One or more comorbidities were recorded at baseline in 47.1% of cases. Binet's stage was A in 25.9% of cases, B in 57.6% and C in 16.5%. Trisomy 12, deletion 13q, deletion 11q and deletion 17 were found in 26.5%, 48.2%, 19.3% and 4.8% of cases, respectively. p53 mutations were recorded in 4.8% of patients. Fifty-eight percent were IGHV unmutated, 41% CD38+ and 75.9% Zap-70+. The ORR was 81.2% (69 pts). CR, confirmed by CT scan, was found in 16.5% of pts (14 pts), CRi in 2.4% (2 pts), nPR 2.4% (2 pts) and PR in 60% (51 pts). In the 14 CR cases, MRD evaluated by flow cytometry in blood and marrow was negative in 2; no patient was PCR negative. A treatment failure was recorded in 18.8% of cases (16 pts): PD 3.5% (3 pts), SD 4.7% (4 pts) and lack of response assessment 10.6% due to early treatment withdrawal (9 pts: investigator's decision, 2; treatment-related AEs, 4; treatment-unrelated AEs, 3). Twenty SAEs were recorded in 17 patients: 5 (4 pts) related to CLB only, 3 (3 pts: pleural effusion, 1; anemia, 1; neutropenia, 1) related to CLB-R and 12 (12 pts) treatment-unrelated. The most common hematologic toxicity was neutropenia (grade III-IV: 13.5% of patients, 7.4% of episodes and 2.9% of cycles). The median number of administered CLB-R cycles in patients <80 years was 6. A dose reduction of CLB was required in 7.8% of cycles, mainly for myelotoxicity. *Conclusions.* This study shows that R-CLB is an active and well tolerated front-line regimen for elderly CLL patients.

Background. Remission duration in chronic lymphocytic leukaemia (CLL) depends on the level of minimal residual disease (MRD). Conversion from MRD positive to negative should prolong remissions and survival. Several small studies have reported alemtuzumab consolidation following chemotherapy but with concerns over toxicity; primarily due to immune suppression and infections. Dose and interval between prior chemotherapy and alemtuzumab appear critical. *Aims.* Phase II trial designed to assess the efficacy and toxicity of alemtuzumab consolidation post-chemotherapy. *Methods.* The alemtuzumab was administered at 30mg subcutaneously 3 times a week for 6 weeks followed by marrow assessment. MRD negative patients and non-responders stopped therapy; MRD positive patients with a significant response continued therapy for a further 6 weeks. MRD was assessed in blood and marrow using multi-parameter flow cytometry with a 0.01% detection limit. All patients received PCP prophylaxis and aciclovir as well as CMV-PCR monitoring. *Results.* 47 patients re-

ceived alemtuzumab (median age 58yrs [40-77] and 35 [74.5%] males). There was a median of 2 prior therapies (range 1 to 4) with 46 patients receiving fludarabine combinations and 9 rituximab-containing combinations. There were a total of 22 SAE's in 17(36.2%) patients with 2(4.3%) treatment related deaths (EBV-LPD and parainfluenza). G-CSF was given when the neutrophil count fell below 1 x 10^9/l, and 27(58%) patients required G-CSF during or after alemtuzumab. Positive CMV PCRs were detected in 21(45%) patients, all of whom were successfully treated with pre-emptive antiviral therapy. 13/23(56%) patients in partial remission achieved a CR three months after alemtuzumab. 39/47 (83%) patients had MRD negative marrows at the end of alemtuzumab, 7 (15%) remained MRD positive and 1 (2%) was not evaluable. Six months after alemtuzumab, 18/39(46%) MRD negative patients became MRD positive in the blood (although all except 2 with low CLL levels (<0.1x10^9/l), and 20/39(51.0%) patients remained MRD negative. Of these, 15/16 (94%) remained MRD negative at 12 months. Therefore MRD negativity in blood at 6 months predicts for persistent MRD negativity better than the marrow assessment at the end of therapy. 6/9 patients receiving 12 weeks of alemtuzumab became MRD negative, but only 1(17%) responder remained MRD negative in the blood at 6 months. In contrast, of the 33 MRD negative patients after 6 weeks of treatment, 19(58%) remained MRD negative at 6 months. The 24 month PFS after start of alemtuzumab consolidation is 82% for all patients and 85% for those who achieved MRD negativity. Of the 18 MRD negative patients 6 months after alemtuzumab, after median follow-up of 21 months from treatment, only one patient has progressed clinically at 38 months. *Conclusion.* Consolidation with alemtuzumab is associated with largely manageable mainly infectious toxicities. 43% of patients were MRD negative 6 months following alemtuzumab consolidation which justifies the continued investigation of this approach in CLL primarily within a clinical trial setting with appropriate monitoring of patients. To this end we plan a randomized Phase III trial of consolidation with alemtuzumab compared to observation (the CLARET study).

Background. Despite available, effective treatments, most patients with CLL will experience multiple relapses and become refractory to standard therapy. Bcl-2 is universally over-expressed in CLL cells, thus suppression of Bcl-2 is an attractive therapeutic target. Navitoclax, a novel BH3 mimetic, binds with high affinity (Ki ≤1nM) and inhibits multiple anti-apoptotic Bcl-2 family proteins. Our earlier phase-I trial established that single-agent navitoclax 250mg/day achieved predicted pharmacokinetic (PK) parameters, was well tolerated and provided a signal of activity in previously treated patients with relapsed/refractory CLL, justifying phase-II evaluation at this dose. *Methods.* This multicenter international trial assessed safety, efficacy, and PK of oral navitoclax in patients with relapsed/refractory CLL, ECOG status ≤1, platelets ≥75,000/mm^3, who had received ≤5 prior regimens. Patients from the phase-I study were excluded. Following a 7-day lead-in at 100mg/day, navitoclax was dosed at 250mg/day on a 21-day cycle (C) until PD or intolerable toxicity. Preliminary efficacy endpoints included tumor response (NCI-WG 1996) and PFS. Disease was assessed at end of C2 and C4, every 4 cycles through C20, and every 8 subsequent cycles. Adverse events (AE) were graded by NCI CTCAE V3. *Results.* Thirty-one patients, median age 70y (range 44-82), were enrolled; 7/19 with available data were fludarabine-refractory. Median (range) number of prior therapies was 2.5 (1-6). So far, 13 patients have cytogenetic data; 9 were high-risk (5 with 11q-, 2 with 17p-, and 2 with both); 4 had neither deletion. Median time on study is 5.6 months (3.8-14.5+) with 10 patients still receiving drug. Twenty-six patients are evaluable for response (5 too early); 10 (38%) PR, 14 (54%) SD, 2 (8%) PD. Median PFS [95% CI] for 29 patients was 8.7 months [6.0, not reached]. By serial CT 12 (46%) patients had >50% nodal regression. Of 27 patients with baseline lymphocytosis, 24 (89%) had ≥50% reduction (median reduction 78.4%). Seventeen patients (55%) had bulky disease (adenopathy >5 cm); of the 13 evaluable all showed anti-tumor activity: 6 with PR and 7 with SD. PK analysis of trough concentrations suggested consistent exposure across cycles. The most common navitoclax-related AEs (all grades) were diarrhea (57%) and nausea (43%), both most likely attributable to the formulation; Grade 3/4 AEs included thrombocytopenia (27%) and neutropenia (17%). One patient each had a serious, navitoclax-related AE: pyrexia (Grade 1/2), tumor-lysis syndrome (Grade 3), dizziness (Grade 1/2). Three patients had AEs leading to discontinuation, and 9 leading to dose reduction, mainly thrombocytopenia. Nineteen patients discontinued: 6 due to PD, 6 due to AEs, 5 withdrew consent, and 2 due to other reasons (lack of response, investigator decision based on low-trending platelets). Two of 4 patients with 17p- achieved PR; patients with 11q- (n=5) appeared to have favorable outcome vs patients with 17p- (n=4) or with normal cytogenetics (n=4) (PFS 183 days vs not reached, p=0.0376). *Conclusions.* These data confirm that navitoclax has an acceptable safety profile at 250mg/day and significant anti-tumor activity in patients with heavily pre-treated CLL, including those with 17p- and other high-risk cytogenetic characteristics. Updated results will be presented.

THE CGMP PATHWAY AS A DRUG TARGET FOR THE REDUCTION OF VASO-OCCLUSION IN SICKLE CELL ANEMIA MICE: ACUTE EFFECTS OF HYDROXYUREA AND A PHOSPHODIESTERASE 9 INHIBITOR

C Almeida,[1] C Scheiermann,[2] J Jang,[3] C Prophete,[2] F Costa,[4] P Frenette,[5] N Conran[4]

[4]*Instituto Nacional de Ciência e Tecnologia do Sangue - University of Campinas, Campinas, Brazil*
[5]*Albert Einstein College of Medicine and Mount Sinai School of Medicine, New York, United States of America*

Background. Modulation in the levels of the second messenger cyclic guanosine monophosphate (cGMP) downstream in the nitric oxide (NO) pathway, represents a possible therapeutic approach for sickle cell disease (SCD). Up-regulation of cGMP-dependent signaling may induce γ-globin production in erythroid-lineage cells and *in vitro* experiments demonstrate a reduction in the adhesive properties of leukocytes following activation of this pathway. Evidence indicates that hydroxyurea (HU) may act as a donor of NO *in vivo*; in addition, recent data suggest that the cGMP degrading enzyme, phosphodiesterase 9 (PDE9), may be highly expressed in hematopoietic cells, possibly providing a cell-specific drug target. *Aim.* Since leukocyte adhesion to the vessel wall plays a crucial role in vaso-occlusion initiation, we investigated the effects of the acute administration of HU and a PDE9-inhibiting agent, BAY73-6691, on a humanized model of sickle cell vaso-occlusion. *Methods.* Fully chimeric male sickle cell mice (SCD mice), produced by transplanting the bone marrow of Berkeley SCD mice to lethally irradiated C57BL/6 animals, were utilized for intravital microscopy at 3-5 months post-transplantation. An inflammatory process was induced in mice by TNF-α injection (0.5 μg i.p.); mice were concurrently treated with BAY73-6691 (3 mg/Kg i.v.) or HU (100 mg/Kg i.v.) or both drugs or vehicle. At 2.5h after TNF-α administration, venules of the cremaster muscle were videotaped continuously for 1 min. Leukocyte rolling, adhesion and extravasation were monitored and analyzed for 45 minutes after surgery. *Results.* SCD mice (N=4) treated with hydroxyurea and BAY73-6691 demonstrated increased leukocyte rolling (36.9±8.2; 14.1±3.9 leuk/min, for HU+BAY73-6691 and vehicle control, respectively, $p<0.05$). Reduced leukocyte adhesion to the vessel wall was observed in the treated groups (3.7±0.4; 3.7±0.7; 1.6±0.1; 6.0±0.3 leuk/100μm, for HU; BAY73-6691; HU+BAY73-6691 and vehicle control, respectively, $p<0.0001$; $n \geq 4$). Cell extravasation was also decreased in all three groups (2.0±0.2; 1.1±0.1; 1.3±0.2; 3.2±0.4 leuk/100x50μm^2, for HU; BAY73-6691; HU+BAY73-6691 and vehicle control respectively, $p<0.0001$; $n\geq4$). Additionally, administration of BAY73-6691 or HU+BAY73-6691 decreased RBC-leukocyte interactions (0.3±0.06; 0.2±0.09; 0.7±0.14 RBC-leukocyte interactions/min, for BAY73-6691; HU+BAY73-6691 and vehicle control respectively, $p<0.05$). Surprisingly, the combination of drugs significantly prolonged the survival of SCD mice after TNF-α ($p<0.05$; $n\geq5$). In C57BL/6 mice, where HU and BAY73-6691 also reversed TNF-α-induced alterations in leukocyte parameters, ODQ (guanylate cyclase inhibitor; 15mg/Kg i.v.) was able to revert the effects of HU on leukocyte adhesion (3.2±0.2; 9.4±0.7 leuk/100μm, for HU and ODQ+HU, respectively, $p<0.0001$; $n\geq4$). Similarly, when C57BL/6 mice were treated with KT5823 (protein-kinase-G inhibitor; 1mg/Kg i.v.) and BAY73-6691, the reduction in leukocyte adhesion was reversed (3.3±0.3; 8.8±0.8 leuk/100μm, for BAY73-6691 and KT5823+BAY73-6691, respectively, $p<0.0001$; $n\geq4$). *Conclusions.* These results suggest that drugs that target the NO/cGMP pathway may reduce vaso-occlusive processes and increase survival, at least in SCD mice. Importantly, HU, thought to have NO donating properties, when administered acutely, was seen to significantly alter leukocyte properties in the SCD mouse, demonstrating that this drug could have immediate beneficial effects that are independent of its fetal hemoglobin-elevating properties. Furthermore BAY73-6691, a tissue-specific drug, when combined with HU amplifies the beneficial effects observed on the vaso-occlusion process.

[6]*Novartis Pharmaceuticals, East Hanover, United States of America*
[7]*American University of Beirut, Beirut, Lebanon*

Background. Patients with forms of non-transfusion-dependent thalassaemia (NTDT), such as β-thalassaemia intermedia, milder forms of haemoglobin (Hb)E/β-thalassaemia and HbH α-thalassaemia, have little or no requirement for transfusions, but may still develop iron overload as a consequence of increased gastrointestinal iron absorption secondary to ineffective erythropoiesis. Factors determining the distribution of iron in NTDT are not completely understood. The prospective, randomized, double-blind, placebo-controlled Phase II clinical trial of deferasirox (THALASSA) enrolled 166 patients with NTDT and iron overload. Laboratory parameters prior to treatment initiation are analyzed. *Aims.* To assess the interrelationships between the key components of the NTDT phenotype, namely anaemia, ineffective erythropoiesis and iron overload. *Methods.* Patients aged ≥10 years with NTDT, liver iron concentration (LIC) ≥5 mg Fe/g dry weight (dw) and serum ferritin (SF) levels >300 ng/mL were enrolled into the study. Exclusion criteria included: anticipated requirements for regular transfusion during the study period, transfusion within 6 months or chelation therapy within 1 month prior to study entry, HbS variants of thalassaemia and impaired renal or liver function. Correlations were assessed by simple linear regression model. *Results.* Of 166 patients randomized, mean age was 32.1 ± 12.0 years and 53.6% were male. Most had β-thalassaemia intermedia (57.2%) or HbE/β-thalassaemia (29.5%), while the remaining 13.3% had HbH α-thalassaemia. 53.0% of patients were splenectomized. Patients generally had received little or no transfusion on a regular basis; 21 patients (12.7%) were not transfused at all. The randomized patients were anaemic (median Hb 8.1, range 4.5-14.0 g/dL) and iron-overloaded; the latter being reflected by increased SF (median 992, range 304-6419 ng/mL), LIC (median 12.1, range 2.6-49.1 mg Fe/g dw), transferrin saturation (TSAT; median 90.8, range 24-100%) and non-transferrin-bound iron (NTBI; median 2.2, range -3.2 to 8.5 μmol/L). There was a significant correlation between SF and LIC, which confirmed previous reports (Taher *et al*. *Haematologica* 2008). The patients showed increased levels of serum erythropoietin (EPO; median 101.0, range 18.3-3405.0 U/L), soluble transferrin receptor (sTfR; median 28.8, range 8.3-64.3 mg/L) and growth differentiation factor 15 (GDF15; median 9179, range 689-53,730 ng/L); the latter two are markers of ineffective erythropoiesis. sTfR showed a significant inverse correlation with Hb and a significant positive correlation with EPO, while GDF15 correlated significantly with sTfR and EPO. NTBI correlated significantly with TSAT, SF and LIC. A weaker but significant correlation was also found between NTBI and sTfR. Statistics for all correlations are presented in the Table. Interrelationships of underlying disease, age and previous therapy with the indices of iron metabolism and erythropoiesis will also be analyzed. *Conclusions.* Non-transfused or infrequently transfused NTDT patients develop significant

Table 1.

Statistics for correlation analyses

Correlation	*R*	*P*-value
SF and LIC	0.64	<0.0001
NTBI and TSAT	0.84	<0.0001
NTBI and SF	0.39	<0.0001
NTBI and LIC	0.35	<0.0001
NTBI and sTfR	0.20	0.0133
sTfR and Hb	–0.48	<0.0001
sTfR and EPO	0.24	0.0021
GDF15 and sTfR	0.32	<0.0001
GDF15 and EPO	0.47	<0.0001

iron overload as assessed by LIC and SF in parallel with increments in TSAT and NTBI, the latter of which is the source of potentially toxic free iron. Increased levels of NTBI result from both significant iron overload and ineffective erythropoiesis, two key components of the NTDT phenotype.

0537

RISK OF ACUTE ISCHAEMIC STROKE (AIS) IN CHILDREN WITH SICKLE CELL DISEASE (SCD) SCREENED WITH TRANSCRANIAL DOPPLER (TCD) PRE- AND POST-STOP PROTOCOL IMPLEMENTATION

P Telfer,[1] B Kaya,[2] C Abdulla,[3] S Whitmarsh,[4] N Gadong,[5] B Van Meijgaarden,[6] C Hemmaway,[7] J Evanson,[1] F Kirkham[8]

[8]*Institute of Child Health, University College London, London, United Kingdom*

Background. The STOP trial, published in 1998, showed that regular transfusion of children with SCD and abnormal TCD velocities reduced the risk of AIS by about 90%. *Aims.* To assess the long-term results of TCD screening +/- early transfusion of children with abnormal TCD in a non-trial setting. *Methods.* We compared two cohorts of children followed in our network. Cohort 1 children were first screened with TCD between 1991 and 2000. Recomendations for transfusion were made in a joint haematology/neurology specialist clinic on the basis of symptoms and signs of ischaemia. Cohort 2 children were first screened after 1/1/2001 and were routinely offered transfusion for primary AIS prophylaxis if found to have abnormal TCD. All children had a diagnosis of HbSS or HbS/beta thalassaemia. Those with previous stroke were excluded. Scans were done by PT,FK, BK and CA, using non-imaging equipment. Classification of abnormal scan required Vmax>200cms/sec on two occasions. Stroke was diagnosed by standard clinical criteria and confirmed by cerebral MRI. Follow-up for both cohorts continued either until censorship date of 28/2/2011, death or transfer to a different adult clinic at age 16. Kaplan Meier survivorship and Cox proportional Hazards modelling were used for data analysis. *Results.* 537 children had a total of 1548 scans. Cohort 1 consisted of 81, and Cohort 2 of 456 children. Average age at first scan was 7.2 years and did not differ between the two cohorts. The majority of children continued adult follow-up in our unit after the age of 16. Doppler categories at first scan were: Standard 78%; Conditional 12%; Abnormal 3%; Low velocity/asymmetric 1%; inadequate 6%. There was a significant difference in doppler categorization at first scan between the two cohorts, with relatively more conditional scans and less abnormal in Cohort 2. During follow-up, a total of 41 (7.6%) children developed abnormal Doppler. The risk of abnormal Doppler at 5,10, and 15 yrs of age was 2%, 8% and 12%. 5 (6.2%) in Cohort 1 developed abnormal TCD, and only one was transfused prospectively compared to 36 (7.9%) in cohort 2, the majority progressing from conditional to abnormal. 35 of these were transfused prospectively. There were a total of 11 (2%) AIS events, 5 (6%) in Cohort 1 and 6 (1.3%) in Cohort 2. The probability of remaining free of AIS at ages 5,10,15 and 20 years for Cohort 1 100%; 96.3%; 93.7% and 91.9%. For Cohort 2 they were 99.8%; 99.4%; 98.3%; 93.6% (Figure). There was a trend to reduced risk of AIS in Cohort 2, although this did not reach statistical significance (p=0.09) due to the small numbers with AIS. *Conclusions.* We showed a lower percentage developing abnormal TCD than previously described. Transfusion is generally accepted by parents of children with abnormal TCD. AIS rate is only 1.7% at age 15 in those managed according to the STOP protocol, but is not completely prevented. There is some evidence for an advantage in prospective transfusion over transfusion based on clinical assessment in these children.

[8]*FFTA, Rosny-sous-Bois, France*
[9]*FFPJP, Marseille, France*

Background. Iron is essential to erythropoiesis and muscular metabolism. High levels sport is associated with a lower iron biodisponibility due to malabsorption, sequestration, or loss excess (sweat, microhemorrhage, hemolysis) that may impair athlete performance. Recently, the increase of hepcidin synthesis during sport training has been shown to lower iron bioavailability. Strong experimental evidence suggests that hemochromatosis associated to HFE mutation is due to a decrease in hepcidin production. Therefore, HFE mutations may counterbalance the decrease of iron avaibility and as such may improve performance in high level athletes. *Aim.* To assess HFE mutations frequency in elite athletes and its impact on sport performance. *Methods.* We performed a prevalence study of HFE gene mutations in sportsmen of four top level French teams, practicing aerobic (Group 1, n=95: nordic ski, rowing), anaerobic (Group 2, n=34: judo), and non energetic (Group 3, n=41: petanque), compared to control subjects, matched by geographic origin, age, and gender (n=219). High level performance can be assessed through the titles and podiums collected during international competitions (continental or world championships and olympic games). In group 1, we compared athletes, who reached the three best places (international podium group: IPG, n=17) to those who did not succeed to reach this level (no international podium group, NPG, n=60). According to the Necker hospital Ethics committee, sport and control subjects have been screened for 18 haemochromatosis linked gene mutation. Test strip containing allele-specific oligonucleotide probes immobilized are realized according to haemochromatosis strip assay kit protocol (Haemochromatosis StripAssay Atm, Vienna Lab Diagnostics GmbH). We used logistic regressions to test the relative frequency of the mutations in athletes compared to the control group, and expressed as odds-ratio. *Results.* Among HFE mutations, H63D was found in 106 cases (27.0%), C282Y in 28 cases (7.2%), S65C in 11 cases (2.8%) and H63H in 1 case only (0.3%). Among them, 92% were heterozygotic. In energetic sports, the frequency of any mutation was superior to the control (Group 1: OR1=1.97, p=0.008, Group 2: OR2=3.85, p=0.003). In contrast, a non significant difference was found in the non energetic Group 3: OR3=1.12, p=NS). In the international podium group, the frequency of any mutation was even larger: among Group 1 athletes, the HFE mutation frequency was 13.3 higher in the subgroup with international titles as compared to the NPG (p=0.0001). The higher frequency of HFE mutations was found in both genders, with a tendency toward higher OR in women (OR1: 3.33 vs 1.37, OR2: 3.92 vs 2.51, ORIPG=17.3 vs 12.6, for women and men respectively). *Conclusion.* This study demonstrates that HFE frequency is significantly larger in French athletes of high energetic sports and strongly correlated with international top performance. During evolution, these genotypes altering a major protein

of iron, red cell and muscle metabolism may have been selected, in the heterozygotic form, due to their large impact on phenotypes ie. energy performance under extreme physiological constraint. Genetic studies in high level sport might reveal such associations.

[4]*Molecular Medicine Branch, NIDDK, National Institutes of Health, Bethesda, United States of America*

The pattern of changes in human globin gene expression during development has been well studied. To study the contributions of other genes and pathways to these processes, we have used oligonucleotide microarray and real-time quantitative PCR technologies to examine gene expression modulation in human erythroid progenitor cells of various tissues during ontogeny. Human hematopoietic CD34+ progenitor cells were isolated from fetal liver (FL), cord blood (CB), adult bone marrow (BM), peripheral blood (PB) and G-CSF stimulated mobilized PB (mPB), and then differentiated *in vitro* into erythroid progenitor cells (EPC) by cocktail of cytokines including erythropoietin. We found that cell growth capacity was most abundant in FL and CB-derived cells. The EPC were sorted as 100% CD71+. During ontogeny, beta-globin gene expression reached maximum levels in cells of adult blood origin (176 fmol per microgram of RNA). For the period of early *in vitro* erythropoiesis culture, gamma-globin gene expression was consistently up-regulated in CB-derived cells (60 fmol). In microarray studies, a total of 3917 genes were persistently expressed in mPB, 3844 in CB, 1770 in BM, 1755 in FL and 1325 genes in PB-derived EPC. A total of 994 common genes were identified in majority of samples of EPC derived from previously mentioned tissues through ontogeny. The common genes related to the hematological system development were further assessed. During gamma-globin induction, we identified G protein-related genes that were activated via the JAK-STAT (SOCS1, HSD3B1), MAP kinase (SERBP1, JUN, MAX) and NO/cGMP (PRPF18) signaling pathways. This study correlates in EPC changes in the expression of globin genes with variations in other genes expression during ontogeny, with the accent on G protein-coupled receptor signaling pathways.

KNOCK IN OF HUMAN NPM1 MUTATION A BLOCKS MEGAKARYOCYTIC DIFFERENTIATION IN A MOUSE MODEL

P Sportoletti, E Varasano, R Rossi, D Cecchini, I Gionfriddo, E Tiacci, N Bolli, MP Martelli, F Falzetti, B Falini

Hematology and Clinical Immunology, Perugia, Italy

Background. NPM1 mutation (NPMc+), the most frequent genetic alteration in Acute Myeloid Leukemia (AML), accounts for about 30% of all AMLs. Despite the progress in the diagnosis and in the clinical and biological characterization of NPM1-mutated AML, little is known about NPMc+ role in leukemogenesis *in vivo*. Recently, a transgenic mouse model showed NPMc+ was implicated in abnormal myelopoiesis but not progression towards leukemia (Cheng, Sportoletti *et al*., Blood 2010). Thus, more sophisticated gene-targeting approaches are needed to model human NPMc+ AML in mice and to study NPMc+ role in leukemia development *in vivo*. *Aims.* To investigate the *in vivo* role of NPMc+ in hematopoiesis and leukemia we generated a knock-in mouse model that conditionally expresses human NPMc+ cDNA. *Methods.* The model was generated by targeted insertion of human NPMc+ cDNA into the Rosa26 locus via homologous recombination in embryonic stem cells. NPMc+ mutants were crossed with Mx1-Cre transgenic mice to restrict expression of the conditional allele in hematopoietic progenitors. In progeny 1) RT-PCR examined NPMc+ transgene expression; 2) Western blot on cellular fractions determined NPMc+ protein localization using an anti-NPMc+ antibody 3) FACS analysis determined phenotype in bone marrow (BM) cells. *Results.* In NPMc+Mx1Cre+ mice RT-PCR detected NPMc+ transgene mRNA in peripheral blood, spleen and BM cells. After Cre induction transgene expression was maintained for 1-year (latest observation). Western blot detected NPMc+ protein in peripheral blood, spleen and BM cells and demonstrated the NPMc+ mutant localized in the BM cell cytoplasm. Strikingly, compared with NPMc+MxCre- controls, platelet counts were significantly lower while white blood cells counts and hemoglobin levels were not. Platelets were one-half of the control count in mutants harboring one conditional allele and one-quarter in homozygous NPMc+ knock-in mice. To investigate whether the low platelet count was due to abnormal hematopoiesis, 2 months after Cre induction we analyzed BM cells from NPMc+MX1Cre+ mice. Compared with controls, CD41+ cells were double in number ($p<0.05$) while serum TPO levels were identical. Lin-Kit+Sca-1-CD150+CD41+ megakaryocytic progenitors (MkPs) were increased 2-fold ($p<0.001$), suggesting NPMc+ expression leads to an expansion of immature megakaryocytes. Interestingly, immunohistochemistry on BM trephines from patients with NPMc+ AML detected megakaryocyte expansion in some. No significant differences emerged in total BM cellularity, in Lin-Kit+Sca-1+ cells or Lin-Kit+Sca-1-CD41-CD150+FcγR-CD105lo erythromegakaryocytic progenitor cells. The splenic CD41+ cell count and the spleen/body weight ratio were higher ($p<0.05$ for both). Since miR-10a down-regulation was recently hypothesized to unblock target genes involved in megakaryocytic differentiation, we evaluated miR-10a expression in BM cells. Compared with controls, mi-R10a was significantly up-regulated, suggesting the increase in MkPs was related to a differentiation blockage. MiR-10a up-regulation was associated with increased expression of HOXB4 and HOXB5 genes in which cluster miR-10a is embedded. Similar findings have already been described in human NPMc+ AML. There was no leukemic evolution after 1 year follow-up. *Summary.* These results demonstrate that NPMc+ expression impedes megakaryocyte maturation by blocking differentiation. This new mouse model is expected to aid understanding of the molecular and genetic background to NPMc+ AML.

[7]*University of Goettingen, Goettingen, Germany*

Background. Alteration of DNA methylation is a hallmark of epigenetic modification in human cancers. A gene family of *DNA methyltransferases* (*DNMT*), *DNMT3A*, *DNMT3B* and *DNMT1B*, catalysing the addition of a methyl group to the cytosine residue of CpG dinucleotides affect promoter methylation status and therefore gene expression. Using a next generation sequencing approach a frameshift mutation of *DNMT3A* has been detected in an AML case. Subsequent sequencing analysis in an independent cohort of 288 AML patients (pts) revealed *DNMT3A* mutations in 22% of the pts; *DNMT3A* mutations were associated with intermediate-risk cytogenetics and poor outcome. *Aims.* To evaluate frequency and clinical impact of *DNMT3A* mutations in younger (16 to 60 years of age) adult AML pts who were treated within the AML HD98A study. *Methods.* *DNMT3A* mutation screening was performed in 687 AML (de novo AML, n=631; s-AML, n=22; t-AML, n=31) using a DNA-based PCR assay for all coding exons (1 to 23) followed by direct sequencing. The median follow-up was 6.46 years. *Results.* *DNMT3A* mutations were found with an overall incidence of 18% (125/687), with two AML exhibiting two mutations. 109 mutations were located in the MTase domain clustering at amino acid R882 (77%). All mutations were heterozygous. *DNMT3A* sequence alterations included 7 frameshift, 3 nonsense and 117 missense mutations. Pts with *DNMT3A* mutations were significantly older (P=.009), had higher white blood cell and platelet counts (P<.001, P<.001, respectively) and higher LDH serum levels (P=.002). There was no correlation with respect to type of AML (P=.21). DNMT3A mutations were significantly associated with cytogenetically normal AML (CN-AML, P<.001), while an inverse correlation was found for AML with t(8;21), inv(16), t(15;17), t(11q23), and complex karyotype (P=.02; P=.009; P<.001; P=.005 and P=.006, respectively). Correlations with other molecular markers (*NPM1*, *CEBPA*, activating FLT3, *IDH1/2* and *TET2* mutation) revealed a significant association with *NPM1* (P<.001), *FLT3*-ITD (P=.01) and *IDH1/2* (P<.001) mutations and in trend an inverse correlation with *CEBPA* mutations (P=.08). *DNMT3A* mutation status did not impact cumulative incidence of relapse (CIR) and overall survival (OS) in the whole AML cohort (P=.49; P=.28, respectively) as well as in the subgroup of CN-AML (P=.78; P=.65, respectively). We next performed subgroup analysis in CN-AML according to the *NPM1*/*FLT3*-ITD genotypes. *DNMT3A* mutations had no impact in pts with the genotype *NPM1*-mutated/*FLT3*-ITD-negative [CIR (P=.99); OS (P=.56)], while in pts with all other genotypes (*NPM1*-wildtype/*FLT3*-ITD-positive, *NPM1*-wildtype/*FLT3*-ITD-negative, *NPM1*-mutated/*FLT3*-ITD-positive) *DNMT3A* mutations were associated with inferior OS and in trend inferior CIR (P=.01, and P=.06, respectively). *Conclusions.* We confirm that *DNMT3A* mutations are frequent genetic aberrations in AML, associated with normal karyotype, and *NPM1*, *FLT3*-ITD and *IDH* mutations. Our data suggest a negative prognostic impact in molecular high-risk CN-AML, however, these data need to be validated in larger patient cohorts.

0542

MODELING RUNX1 BIALLELIC MUTATIONS ASSOCIATED WITH AML-M0 AND AML-FPD IN MICE REVEALS IMPORTANCE OF RESIDUAL RUNX1 FUNCTION

E Stocking,[1] K Schulz,[1] K Behrens,[1] B Niebuhr,[1] J Cammenga[2]

[1]*Heinrich-Pette-Institute, Hamburg, Germany*
[2]*2Lund Strategic Center for Stem Cell Biology and Cell Therapy, Lund University H, Lund, Sweden*

Disruption of the RUNX1 gene is one of the most common aberrations found in myeloid leukemia. The most common disruptions are chromosomal translocations, but intragenic mutations are found at a high incidence in minimally differentiated AML (AML-M0) and in AML secondary to familial platelet disorder (AML-FPD). The majority of these mutations impact the conserved Runt domain, specifically disrupting the DNA-binding (DB) interface, while other mutations are predicted to be null alleles, due to complete deletion or frameshifts leading to premature stop codons. Interestingly, although monoallelic RUNX1 germline mutations have been reported in 27/28 families reported with FDP, recent evidence demonstrates that patients developing AML have acquired mutations in the second RUNX1 allele. Similarly, the AML-M0 subtype also shows a high incidence of biallelic RUNX1 mutations (circa 25%). In both cases, trisomy 13 (correlating with high FLT3 expression) or FLT3 activating mutations (FLT3-ITD) are common secondary mutations. Earlier work by us and others have shown that either functional inactivation of the Runx1 gene or expression of DB-RUNX1 mutants leads to increased self-renewal capacity of myeloid progenitors *in vitro*. We thus predicted that either null or DB mutations may disrupt a critical 'gatekeeper' function of this gene, permitting the accumulation of secondary mutations (e.g. FLT3 activation) that lead to an overt leukemia. In a study to test our hypothesis, constitutively active FLT3-ITD alone or together with RUNX1-DB was introduced into hematopoietic progenitors from Runx1 deficient, heterozygous, or wildtype mice. These studies showed that in the C57Bl/6 mouse background, activated FLT3-ITD most readily induces a T-cell thymoma. Neither Runx1 inactivation nor coexpression of RUNX1-DB shifted the disease spectrum to myeloid neoplasia. However, together, FLT3-ITD, Runx1 deletion, and RUNX1-DB led to a rapid and fatal myeloid disorder with left-shifted myelopoiesis. These results support a tumor suppressor function for wildtype RUNX1 - but indicate that RUNX1 DB mutants have retained important Runx1 oncogenic activity, which cooperates with loss of wild-type Runx1 in disease progression. Important signaling pathways differentially regulated by wildtype and DB RUNX1 will be discussed. These results help explain the significance of the specific mutations in the DNA-binding interface and the high incidence of biallelic mutations in AML-M0 and AML-FPD.

0543

OVEREXPRESSION OF SET IS A RECURRENT EVENT ASSOCIATED WITH POOR OUTCOME THAT CONTRIBUTES TO PP2A INHIBITION IN ACUTE MYELOID LEUKEMIA

I Cristóbal, L García-Ortí, C Cirauqui, MA García-Sanchez, X Cortés, MM Alonso, MJ Calasanz, MD Odero

CIMA, University of Navarra, Pamplona, Spain

Protein phosphatase 2A (PP2A) is a tumor suppressor reported as a potential therapeutic target in chronic and acute leukemias. The protein SET (I2PP2A/TAF-Iβ), a potent PP2A inhibitor, has been implicated in many cell processes and signaling pathways. Moreover, SET has been described as an oncogene that is overexpressed in several neoplasms, including chronic myeloid leukemia, where it correlates with the activity of BCR/ABL, leading to PP2A inhibition. We previously described how SETBP1 in AML cells protects SET from protease cleavage, leading to PP2A inhibition, Moreover, we observed a recurrent PP2A inactivation in AML, and noted that PP2A activation impairs cell proliferation in AML cells. In addition, we postulated that SET deregulation could be one mechanism contributing to the inhibition of PP2A in AML. In order to study whether SET was deregulated in AML, we first analyzed its levels in 13 AML cell lines, observing SET overexpression at both mRNA and protein levels. Prevalence of SET overexpression in AML patients at diagnosis was 28% (60/214), and was associated with SETBP1 ($p<0.01$) and EVI1 overexpression ($p=0.02$). Interestingly, patients with SET overexpression had worse overall survival ($p<0.01$) and event free survival ($p<0.01$). We next confirmed SET overexpression at protein level in a series of 16 patients with AML at diagnosis. We found increased levels of SET protein in 9 out of 16 cases (56.2%), although only 6 of these cases had SET overexpression by real-time RT-PCR (QRT-PCR), which indicates that SET overexpression is a recurrent event in AML that could be underestimated by QRT-PCR. It has been demonstrated that SET upregulation, and the resulting PP2A inhibition, is critical in BCR/ABL-positive cells to fulfill its tumorigenic potential. Analysis by MTS assay showed that ectopic expression of SET restores proliferation in AML cells ectopically expressing PP2A. When we investigated the molecular mechanisms involved in SET deregulation in AML, we observed that activation of PP2A leads to reduced SET levels. Therefore, we postulated that the inhibited status of PP2A could contribute to deregulate SET in AML cells. Moreover, analysis of the SET proximal promoter identified hypothetical binding-sites for transcription factors such as AP-1, GATA1, and EVI1. In our series of AML patients, SET and EVI1 overexpression were associated, suggesting that EVI1 could regulate SET. ChIP showed that EVI1 binds the SET promoter; however, we detected no differences in the luciferase assay, sug-

gesting that EVI1 could regulate SET indirectly. In summary, we demonstrate that SET overexpression is a recurrent molecular event associated with poor outcome in AML, which promotes cell proliferation and restores the reduced cell viability induced after PP2A overexpression. Moreover, PP2A activation status could be involved in the regulation of SET. Altogether, SET overexpression could differentiate a subgroup of patients with poor prognosis who could be treated with PP2A activators in future clinical trials. e-mail address: icristobal@alumni.unav.es

SLEEPING BEAUTY DRIVEN LEUKAEMOGENESIS FOLLOWS AN ACCELERATED DARWINIAN-LIKE EVOLUTION IN A MOUSE MODEL OF NPM1C+ ACUTE MYELOID LEUKAEMIA

S Grove, J Cooper, S Rice, R Rad, A Bradley, G Vassiliou

Wellcome Trust Sanger Institute, Cambridgeshire, United Kingdom

Heterozygous somatic mutations in NPM1, the gene for Nucleophosmin, are the commonest group of mutations in acute myeloid leukaemia (AML). We recently described a humanised mouse model of these mutations, in which one third of mice with conditional activation of a humanised Npm1c knock-in allele, Npm1flox-cA, developed late-onset AML. The same model was subjected to insertional mutagenesis with Sleeping Beauty, through the mobilisation of 80 copies of the novel transposon GrOnc, from a resident locus on mouse chromosome 19. Rapid onset AML developed in 80% of these mice in association with recurrent insertions in many known and novel leukaemia genes including Csf2, Flt3 and Nup98 (Vassiliou *et al*, Nature Genetics 2011 - In Press). Here we report the findings from a similar but novel model mobilising 15 copies of GrOnc from mouse chromosome 16 (Figure 1a). Common integration sites (CISs) from the analysis of 40 leukaemias showed a striking overlap with CISs identified in the aforementioned study, confirming the strong cooperativity of such insertions with Npm1c (Figure 1b). To understand the molecular basis of leukaemogenesis in this model, fortnightly blood samples were taken from 12 of these mice from the time of activation of the SB transposase (via Mx1-Cre) to the onset of frank leukaemia. Additionally, single-cell derived leukaemic blast colonies were generated and analysed. Leukaemia onset was sudden and could not be predicted in advance from FBC parameters (Figure 1c). A subset of transposon integrations were found to occur early and persist over several months during leukaemia development (Figure 1d). Large numbers of transposon integrations (50-200) were identified within each tumour, however only a small number of these were common to multiple single cell colonies generated from the same tumour. Similarly only a few integrations persisted on serial transplantation of tumour cells. These results reveal that transposon mobilisation continues throughout leukaemia evolution leading to the development of multiple sub-clones within these neoplasms. Our data suggest that only a subset of the integrations identified in leukaemia samples behave as "driver"mutations, whilst most insertions are "passengers". Continued mobilisation of transposons from these passenger sites occurs without loss of proliferative potential. By contrast, mobilisation of driver insertions in host cells is immediately selected against. Our findings validate the critical pathways able to cooperate with Npm1c in leukaemogenesis, whilst also giving important novel insights into the way Sleeping Beauty operates in carcinogenesis and highlighting critical differences to retroviral mutagenesis. We are currently applying these insights to improve recognition of leukaemic "drivers"and to develop novel applications, such as the identification of genetic pathways able to overcome inhibition of leukaemic growth by anti-leukaemic drugs.

During the last decade high-dose immunosuppressive therapy with autologous hematopoietic stem cell transplantation (HDIT+AHSCT) has been used with increasing frequency as a therapeutic option for MS patients. The major treatment outcomes for MS patients are disease-progressive free period and improvement of patient's quality of life (QoL). We aimed to study safety and treatment outcomes in MS patients after HDIT+AHSCT. 191 patients with MS (secondary progressive - 84, primary progressive - 28, progressive-relapsing - 5 and relapsing-remitting - 74) from 6 clinical centers were included in this study. Mean age - 34.0, range: 17-55; male/female - 78/113. BEAM or BEAM-like conditioning regimens were used in 182 patients, and Fludara - in 9 patients. Median EDSS at base-line was 4.5 (range 1.5 - 8.5). The median follow-up duration was 29 months (range 1.5 - 128). QoL was assessed using the generic questionnaire SF-36. QoL assessment and neurological examination were performed at baseline, at discharge, at 3, 6, 9, 12 months, and every 6 months thereafter. For treatment outcomes clinical response and QoL response rates were evaluated at 6, 12, 24 months after HDIT+AHSCT and at longer-term follow-up. QoL treatment response was classified as improvement, stabilization or worsening. In the vast majority of cases the mobilization and transplantation procedures were well tolerated. One case of death at early posttransplant period was registered - a female patient died on day +8 from sepsis with multiple organ failure. The efficacy analysis was performed in 121 patients who had follow-up for at least 12 months (median follow-up duration - 36.5 months). At long-term follow-up overall treatment response in terms of neurological improvement (n=49) or stabilization (n=46) was observed in 79% of patients. 26 (21%) patients progressed at different time-points after AHSCT. One patient died after disease progression at 3 years posttransplant. QoL treatment response was evaluated in 73 patients. At 6 months after HDIT+AHSCT significant improvement of all the scales of SF-36 except pain and role emotional functioning as compared with base-line was demonstrated ($p<0.05$). At longer term follow-up further QoL improvement was found. At 6 months post-transplant QoL improvement was achieved in 52% of patients, QoL stabilization - in 36%, and QoL worsening - in 12% of patients. At 12 months post-transplant the vast majority of patients (92%) were either stable or improved. At long-term follow-up QoL improvement was registered in 44%, QoL stabilization - in 40% of patients, and QoL worsening - in 16% of patients. This study provides ample evidence in support of HDCT+AHSCT efficacy in MS patients both in terms of clinical and QoL response rates. Further studies should be done to investigate clinical and patient-reported outcomes of HDCT+ASCT in MS patients to better define treatment results.

[8]*Ospedale Civile di Pescara, Pescara, Italy*

Background. Allogeneic stem cell transplantation (alloSCT) with a reduced-intensity conditioning (RIC) is an effective salvage therapy for relapsed lymphomas. However, in the last GITMO RIC-alloSCT trial we observed an incidence of grade II-IV acute graft-versus-host disease (GVHD) of 35% (Leukemia 2007). The present GITMO study is a prospective multicenter phase II trial designed for patients affected by CD20 positive lymphomas. It increases the thiotepa dose of 20%, and incorporates high-dose Rituximab (R) in a RIC regimen to improve the outcome and possibly modulate the incidence of acute GVHD. *Aims.* Primary end-point was 1-year progression-free survival; secondary endpoints were non-relapse mortality and incidence of acute and chronic GVHD. *Methods.* Fifty-two patients were enrolled so far in the study and 34 are evaluable for preliminary analysis. Treatment plan consisted of high-dose R (500 mg/m2 on day -6) followed by a RIC regimen containing thiotepa (12 mg/kg), fludarabine (60 mg/kg) and cyclophosphamide (60 mg/kg). Graft-versus-host disease (GVHD) prophylaxis included cyclosporine and mini-methotrexate; ATG was added to the patients allografted from class I antigen mismatched sibling or unrelated donors. Histopathological subtypes included aggressive (n=11 diffuse large B-cell lymphomas, n=5 mantle cell lymphomas) and indolent lymphomas (n=10 follicular lymphomas, n=8 small lymphocytic/chronic lymphocytic leukemia). Patients were allografted from matched related siblings (n=23) or alternative donors (n=11). All the patients had chemosensitive disease (38% in complete remission) and 16 (47%) failed a previous autoSCT. *Results.* The median follow-up is 1 year (range, 180-1000 days). The cumulative incidence (CI) of non-relapse mortality (NRM) was 9% at 1 year. In total only 5 of 34 patients had acute GVHD (n=4 grade II, n=1 grade III) with an estimated CI of 17% at 100 days. Only 25 patients are evaluable for chronic GVHD with an estimated CI of 41% at 1 year (n=8 limited, n=2 extensive). Infections after engraftment requiring hospitalization or intravenous treatment occurred in 15 patients (44%). Preliminary data on immune-reconstitution showed absence of circulating CD19 B cells at 6 months after allograft. The CI of relapse was 19% and 31% at 6 months and 1 year, respectively. In the indolent and aggressive groups, OS estimates were 88% (95%CI, 60% to 97%) and 59%(95CI, 31% to 78%) and PFS estimates were 63% (95%CI, 32% to 83%) and 55% (95% CI, 28% to 75%), respectively. *Conclusions.* The present data suggest that the administration of high-dose R is feasible and causes an unexpected reduction of the incidence of acute GVHD (only 1 case had GVHD grade III) without increasing the NRM and the incidence of severe infections complications. Complete data evaluating the effects of R on immune reconstitution are ongoing.

IMMUNE-ABLATIVE REGIMEN FOLLOWED BY AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR NEWLY-DIAGNOSED TYPE I DIABETIS

J Hu,[1] WQ Gu,[2] N Ning,[2] T Tang,[1] W Wang[1]

[1]*Shanghai Institute of Hematology, Shanghai, China*
[2]*Department of Endocrinology, Rui Jin Hospital, Shanghai, China*

Background. Patients with Type one diabetis mellitus (DM) is mostly juvenile, insulin-dependent and associated with auto-immune-mediated in nature. *Aim.* To determine the safety and efficacy of immune-ablative regimen followed by autologous hematopoietic stem cell transplantation (Auto-HSCT) in newly-onset type 1 DM patients. *Methods.* We conducted a prospective clincial trial in newly-diagnosed type 1 DM patients(NCT00807651). All patients received cyclophosphamide (200mg/kg) and ATG (4.5mg/kg) followed by infusion of autologous mobilized peripheral hematopoietic stem cells. Monitoring of serum hemoglobin A1c, C-peptide levels and anti-glutamic acid decarboxylase antibody (GAD) titers was carried out before and after auto-HSCT. *Results.* A total of 18 patients were enrolled with a median average age of 18 (range, 15~23). The median follow-up was 414 days (range, 140~750). Among these patients, 12 (67%) patients achieved full stop of insulin with a median of 6 weeks (range 2~21) after HSCT. Four cases eventually resumed the insulin therapy all triggered by mild illness (common cold). With the last follow-up, 44.4% (8/18) remained free of insulin therapy, and the other patients acheived reduction of insulin dose on an average of 67.3% ± 22.4%. All 18 patients achieved a singificant decrease of GAD level and among them 6 (33.3%) became negative. Fasting C peptide and postprandial 2 hour C peptide levels increased significantly after HSCT and the C peptide area under the curve (AUCC) increased remarkably and can maintain for more than 1 year. During the transplantation treatment process, all patients had varying degrees of gastrointestinal reactions, hair loss, fever and bone marrow suppression. Five patients must received supportive blood transfusion. No severe adverse event involving the heart, liver, kidney and other or-

gans was documented. *Conclusion.* AutoHSCT for the treatment of newly-onset type 1 diabetes is feasible and effecitve. Large scale clinical trial with long-term followed-up are warranted.

Background. In Europe, plerixafor + G CSF is approved for mobilisation of haematopoietic stem cells (HSC) for autologous HSC transplantation (auto-HSCT) in patients with lymphoma and multiple myeloma (MM) whose cells mobilise poorly. *Aims.* We report preliminary results from the PREDICT study, a multicentre, open label, single arm study conducted in Europe to further assess the safety and efficacy of plerixafor + G-CSF for front-line mobilisation in patients with lymphoma or MM. *Methods.* Adult patients with non Hodgkin's lymphoma (NHL), Hodgkin's disease (HD), or MM who required auto-HSCT, in first or second complete or partial response were eligible; those with prior allogeneic or >1 prior auto-HSCT were excluded. All patients provided informed consent. Patients received G CSF (10µg/kg/day) subcutaneously (SQ) for 4 days; on the evening of Day 4 they received plerixafor (0.24 mg/kg SQ). Patients underwent apheresis on Day 5 after an AM dose of G CSF, 10-11 hours after plerixafor. Plerixafor, G CSF and apheresis were continued for up to 5 days. The primary study objective was to confirm the safety of mobilisation with plerixafor. Secondary objectives included assessment of efficacy (apheresis yield; time to engraftment). *Results.* 118 patients (MM=90; NHL=25; HD=3) were mobilized with plerixafor + G-CSF (Table 1; data for HD patients not included). Treatment-emergent plerixafor-related adverse events (AEs) occurring from the first G-CSF dose up to 30 days after the last plerixafor dose or the first dose of myeloablative chemotherapy, whichever occurred first (period 1) were reported in 18 pts. Most AEs occurred within 1 hour post-injection, were grade 1 or 2 in severity and included gastrointestinal disorders or injection-site reactions. There were three grade 3 related AEs: myocardial infarction (MI; occurred 19 days after first plerixafor dose; n=1), injection-site reaction (n=1) and asymptomatic leucocytosis (n=1; baseline WBC=8.9x 10^9/L; WBC on apheresis Day1=71.4x10^9/L). 3 patients reported drug-related serious AEs in period 1: disease recurrence, hypomagnesaemia (occurred 2 days post-apheresis) and the abovementioned MI. At a median follow-up of 1 year, there were 4 unrelated deaths due to relapse (n=1), liver failure likely due to disease relapse (n=1), cardiorespiratory failure (n=1) and sepsis (n=1). The minimum cell yield (≥2x10^6 CD34+ cells/kg) was harvested in 98% MM and 80% NHL patients in a median of 1 apheresis. The optimum cell dose (≥5x10^6 CD34+ cells/kg) was harvested in 92% MM and 48% NHL patients (few NHL patients close to collecting 5x10^6 cells elected not to complete all protocol-specified aphereses). Eighty-four (93%) MM and 19 (76%) NHL patients were transplanted. All patients with available data (75 MM and 17 NHL patients) engrafted; median time to neutrophil and platelet engraftment was 14 and 18 days in MM patients and 17 and 19 days in NHL patients. *Conclusions.* In this prospective, multi-center European study, mobilisation with plerixafor + G-CSF allowed the majority of patients with MM or NHL to undergo transplant with minimal toxicity, providing further data supporting the safety and efficacy of plerixafor + G-CSF for front-line mobilisation in patients with NHL or MM.

Table 1. Patient characteristics and outcomes.

	MM (n=90)	NHL (n=25)

AZACITIDINE CAN PREVENT OR DELAY RELAPSE OF PATIENTS WITH MDS OR AML AND MINIMAL RESIDUAL DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: FINAL RESULTS OF THE RELAZA1 TRIAL

U Platzbecker, M Wermke, J Radke, A Kiani, F Seltmann, C Röllig, M Von Bonin, B Mohr, U Oelschlägel, J Schetelig, G Ehninger, M Bornhäuser, C Thiede

Medizinische Klinik und Poliklinik I, Dresden, Germany

Background. Relapse is one of the major challenges in the care of patients (pts) with MDS or AML undergoing allogeneic hematopoietic stem cell transplantation (HSCT). However, relapse can be predicted by monitoring minimal residual disease (MRD). In case of CD34-expression on the leukemic clone, a sensitive chimerism analysis in sorted CD34+ peripheral blood (PB) cells correlates with MRD levels. If CD34+ donor cells drop below 80%, relapse is almost inevitable within a median of 60 days even in the presence of interventions like immediate cessation of immunosuppression or the administration of DLI. However, both approaches often result in clinically significant GVHD. *Aims.* The aim of this prospective phase II clinical trial was to evaluate the efficacy of azacitidine (AZA) to treat MRD as defined by a decreasing CD34-donor chimerism, and thus prevent hematological relapse in pts with CD34+ AML or MDS after allogeneic HSCT. *Methods.* A total of 59 pts with CD34+ MDS (n=5) or AML (n=54) were prospectively screened after HSCT for a decreasing chimerism of donor CD34+ cells. In case of increasing MRD heralding imminent relapse, AZA was given at a dose of 75mg/m^2/d s.c. day 1-7. A total of 4 cycles every 28 days were allowed. Pts showing either insufficient CD34-chimerism response, i.e. an increase but below 80%, or again decreased below the cut-off were eligible for a second treatment phase. *Results.* At a median of 169 days after HSCT, 20 out of 59 pts screened entered the treatment phase of the study with a median of 25% (range 0-79%) CD34+ donor cells in the PB. However, a complete overall and T-cell donor chimerism in the PB as well as less than 5% marrow blasts were documented in all pts before AZA treatment. Median age of the treated population was 58 years (20 - 74 years). Two out of 20 pts had already undergone a 2nd transplant because of relapse. During preemptive AZA treatment reversible neutropenia grade 3/4 occurred in 80% of the pts whereas thrombocytopenia grade 3/4 was observed in 65% of them. Four out of 20 pts (20%) relapsed during the first 4 cycles (between cycle 2 and 4). Of the remaining pts, ten (50%) showed a complete clearance of MRD which was sustained in four of them. In an additional six pts (30%) MRD was stable during the first 4 cycles in the absence of hematological relapse. The latter as well as those pts with later drop of CD34+ DC <80% after initial response were eligible for subsequent AZA cycles. In fact, 11 pts (55%) received a median of 4 (range 1-11) additional cycles. Overall, hematological relapse occurred in a total of 13 pts (65%) but was prolonged by a median of 6 months compared to our previous experiences with DLI or cessation of immunosuppression only. *Summary/Conclusions.* Preemptive treatment of MRD with AZA can prevent or at least delay hematological relapse in pts with advanced MDS or AML and MRD after allogeneic HSCT.

Background/Aims. Clinical risk stratification fails to predict relapse in many patients with ALL (acute lymphoblastic leukemia), causing undertreatment with chemotherapy and overtreatment with stem cell transplantation (SCT) in trials with a risk-oriented design. We used MRD (minimal residual disease) as leading predictive factor for relapse and key decisional tool for allocation to SCT or chemotherapy (Blood 2009;113:4153). Here we provide the final study update in a larger cohort of patients, excluding Ph+/t(4;11)+ ALL (eligible to SCT regardless of MRD). *Methods.* Details of induction/consolidation and molecular MRD study were reported. Risk class was defined standard (SR-B: pre-B, WBC <30; SR-T: cortical T, WBC <100) or high (HR, others). Bone marrow MRD was assessed after chemotherapy blocks 3,5,7 (weeks 10,16,22) using 1 or 2 patient-specific probe(s) with sensitivity >10-4. MRD negativity (Mneg) was defined by w16 levels <10-4 and negative w22. Postconsolidation was maintenance in Mneg, SCT (family-related/unrelated) in Mpos, autologous stem cell-supported hypercycles (H/C) plus maintenance in Mpos without donor, or was driven by risk class when missing MRD analysis. *Results.* 237 out of 278 patients (median age 35 years [range 16-68], SR 138, HR 129, unknown 11) entered CR (85%), and 179 (75.5%) had at least one sensitive probe. 178 completed consolidation (75.1%) while 94 did not because of relapse (15.6%), early SCT (6.7%) and toxicity. Median and 5-year survival rates of CR patients were 3.1 years and 45%. 134 patients completed the MRD study (75.2%). 75 (56%) were MRDneg with no difference among SR-B (59%), HR-B (51%), SR-T (64%), HR-T (47%). MRD analysis reclassified 40% of SR patients (30/75 Mpos) and 50% of HR patients (28/56 Mneg). Most MRD-studied patients received the planned chemotherapy (69/75 Mneg, 92%) and SCT or H/C (42/59 Mpos, 71%). By treatment intention, incidence of relapse (any site), treatment-related mortality (TRM), and 5-year survival and disease-free survival (DFS) rates were 33%, 0%, 76%, 65% in Mneg patients, compared to 58%, 19%, 33%, 22% in Mpos patients (all P's=0.0000). In Mneg group, relapse rate was unrelated to number of probes (one vs. two, P=0.46) and initial risk classification (SR vs. HR, P=0.53). In Mpos group, relapse rate was lower in patients receiving H/C therapy (10/17, 58%) or allogeneic SCT (8/25, 32%, P=0.026 vs. H/C) compared to others (16/17, 94%, P=0.000). Moreover, 5-year survival was improved after H/C or SCT, from 12% in 17 untreated patients to 41% (n=42, P=0.005), and finally allogeneic SCT proved superior to H/C therapy (survival 49% vs. 20% [P=0.06], DFS 42% vs. 14% [P=0.032]). *Conclusions.* The simplified two-step approach chosen for MRD analysis in this study (w16 and w22, from middle to end of consolidation) led to refine risk classification in 40-50% of patients, identified the majority of those curable by chemotherapy without TRM and independently of risk class and probe number (Mneg), and documented the substantial relevance of allogeneic SCT against chemoresistant ALL (MRDpos). Being at moderate risk of relapse, MRDneg patients must be monitored closely during maintenance.

DESIGN AND VALIDATION OF A PROGNOSTIC INDEX SCORE FOR PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) BASED ON CLINICAL AND EPIGENETIC DATA

V Martín Palanco,[1] A Torres-Gomez,[2] P Gomez,[2] I Badell,[3] J Nomdedeu,[3] J Roman-Gomez[1]

[1]*HUR Sofía IMIBIC, Córdoba, Spain*
[2]*HUR Sofia, Cordoba, Spain*
[3]*Hospital Sant Pau, Barcelona, Spain*

Introduction. Despite major improvements achieved in the treatment of childhood ALL, significant challenges still remain. Traditional risk factors have proven to be important in predicting patient outcome, but more than half of dismal events still occur in non high risk patients. If identified early, these patients may benefit from an intensified treatment. However, current strategies fail to identify these patients and indicate the need for new prognostic markers. *Material and Methods.* We analyzed 245 patients with de novo ALL divided into training and validation cohorts. The training cohort consisted of 165 patients from the PETHEMA Spanish group. The validation cohort comprised 80 patients from SHOP Spanish group trials. Protocols were approved by the IRB of the involved institutions and written informed consent was provided. We studied the methylation profile of 50 genes (36 cancer-related genes and 14 microRNAs) belonging to pathways involved in cell transformation in the training cohort by MSP (Methylation-specific PCR) in order to design a Prognosis Index Score (PIS). Univariate and multivariable analyses were performed using the Cox proportion hazards model. The multivariable analyses were undertaken with both forward and backward stepwise procedures for identifying the independent prognostic variables. The model results were used to define levels of risk for survival. *Results.* Promoter methylation of 27 genes was found in at least 20% of the patients, and these genes were selected for further analysis. In the univariate analysis, methylation of 16 genes was associated ($P \leq 0.1$) with shorter OS. In multivariate analysis, methylation of 6/16 genes remained as independent predictors of OS (hsa-mir-124-1, hsa-mir-196-2, Wnt5a, Reprimo, Wif1 and Lats1). ALL patients were classified into two different methylation phenotype (MP) groups: MP-negative (no methylated genes) and MP-positive (at least, one methylated gene). In addition, univariate analysis revealed four clinical variables (WBC count, presence of TEL-AML1, age at diagnosis and immunological phenotype) and the MP that were significantly associated with OS. However, multivariate analysis showed that only three of these variables were independently associated with survival (age, MP and immunophenotype) and they were used to design a model to predict an individual patient's risk of OS. The index score was defined as the sum of the number of risk factors present with each risk factor receiving a value of 1 except for MP status, which was scored as 2 for MP-positive patients. Patients could receive a score from 0 to 4 and they could be grouped as low risk (score 0-1, n=46), intermediate risk (score 2, n=72), high risk (score 3, n=39) or very high risk (score 4, n=8). The mean survivals for these groups were 202.6, 150.2, 80.3 and 33.3 months, respectively, (P<0.0001). These four groups also showed distinctive differences in, relapse rate, mortality rate and DFS. Results were validated in an independent cohort of 80 patients. *Conclusion.* We have created a new prognostic score for ALL children that integrates for the first time, traditional parameters and epigenetic data. Our scoring system stratifies patients into 4 groups at very different risk of death after treatment.

Background. Relapsed/refractory B-precursor ALL is an aggressive malignant disease with a dismal prognosis and therapy is an unmet medical need. 80-90% of adults with relapsed ALL die from their disease or adverse effects of therapy. CD19 is the most frequently expressed B-cell differentiation antigen and can be targeted by blinatumomab, a member of a novel class of T-cell engaging, bispecific single-chain antibodies called BiTE antibodies. We initiated an open-label multi-centre exploratory Phase 2 study in collaboration with the German Multicenter Study Group for Adult Lymphoblastic Leukemia (GMALL) in order to determine the efficacy and safety of blinatumomab in adult patients with relapsed/refractory B-precursor ALL. *Methods.* The primary endpoint is complete remission (CR) rate with hematological recovery. Secondary end-points are minimal residual disease (MRD) response rate (defined by an MRD level below the quantitative detection limit of 10e-4), time to hematological relapse and overall survival. Eligible patients must have B-precursor ALL relapsed after at least induction and consolidation or primary refractory disease. Prior allogeneic HSCT is permitted. Patients with Ph-positive ALL have to be ineligible for tyrosine kinase inhibitors. Blinatumomab is administered as a 4-week continuous intravenous infusion followed by a 2-week treatment-free period. Responders may receive up to 3 additional cycles. The first cohort of five evaluable patients received a dose of 15 μg/m²/d. A second cohort receives 5 μg/m²/d for the first 7 days of the first cycle followed by 15 μg/m²/d for the remaining 3 weeks of the cycle and the following cycles. A risk-benefit assessment will determine which of the dose levels will be evaluated in the second stage enrolling 10 additional patients. *Results.* Seven patients have been treated in the first cohort. Their age ranged from 18 to 77 years. Four of the five evaluable patients had a reduction of bone marrow blasts < 5% within the first cycle two with CR and two with a complete remission with only partial hematologic recovery (CRh*). To date, three also have an elimination of MRD below quantitative detection limit within the first 2 cycles. One responder had an extra-medullary relapse during the third cycle of treatment. The most common adverse events were fever and chills. Two patients were not evaluable for response assessment as they had to permanently discontinue treatment without completion of the first cycle due to adverse events. One non evaluable patient with high leukemic burden had a completely reversible SAE of cytokine release syndrome (CRS). Subsequent patients with high leukemia burden were managed by pre-treatment with dexamethasone and/or cyclophosphamide, and no further treatment discontinuations due to CRS were observed. The second non evaluable patient had treatment discontinued due to a completely reversible CNS event of encephalopathy and disorientation. Despite a limited course of treatment, this patient showed an elimination of MRD below quantitative detection limit. Recruitment of the second cohort receiving a low initial dose of blinatumumab is ongoing, *Conclusion.* These initial data show that blinatumomab elicits pronounced anti-leukemic activity in patients with relapsed/refractory ALL and support further evaluation in this patient population.

Background. The prognostic significance of CD20 expression in B-cell precursor acute lymphoblastic leukemia (BCP-ALL) has been investigated in children and adults and its role is still under debate. The first study addressing the prognostic relevance of CD20 in adults was carried out by Thomas *et al* (Blood 2009); CD20 positivity (i.e. more than 20% of positive ALL cells) was associated with worse disease-free survival (DFS) and overall survival (OS), and this effect appeared unrelated to age. The French group (Maury *et al*, Haematologica 2010) documented a significant prognostic impact of CD20 only in patients with white blood cell (WBC) count above 30 x 10⁹/L. Conversely, Chang *et al* (Haematologica 2010) did not detect any prognostic relevance of CD20. *Aims.* The aim of our study was to correlate CD20 expression with clinical-biological characteristics and outcome in Philadelphia-negative (Ph-) BCP-ALL patients prospectively treated within the multicenter NILG 09-2000 study (Bassan *et al*, Blood 2009), designed to orientate post-remission strategy upon minimal residual disease (MRD) assessment. *Methods.* Immunophenotyping was performed according to the general recommendations from European Group for the Immunological characterization of Leukemias (EGIL). Phenotypic data were expressed as the percentage of CD20 positive cells on whole leukemic population; we considered 20% as the threshold for positivity. *Results*. From March 2000 to September 2008, 172 Ph- BCP-ALL were enrolled in the study. Median age was 37 years (range 16-68); median WBC was 10 x 10⁹/L (0.5-730). According to EGIL classification, BCP-ALL diagnoses were B-I 50, B-II 96, and B-III 26. Fifty-two (30.2%) patients resulted CD20-positive. The CD20-positive group showed

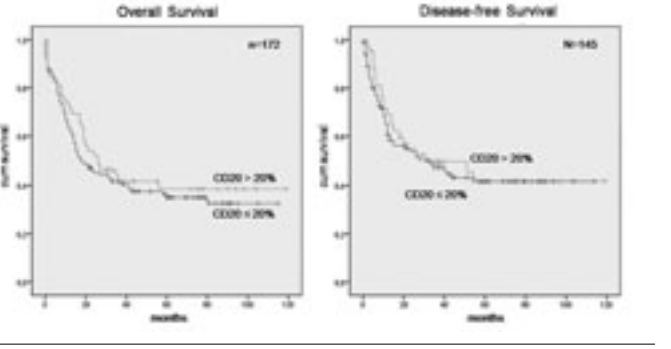

Figure 1.

higher frequency of B-II phenotype (77.0% vs. 33.3%; p<0.0001), and higher incidence of splenomegaly (53.8% vs 35.0%, p=0.067) and hepatomegaly (46.2% vs 25.8%, p=0.014), while no other difference was detected with regard to demographic and diagnostic characteristics. As regards treatment, no difference emerged between the two groups with respect to complete remission rate, MRD response, DFS and OS (Figure 1). Moreover, we searched for an impact of CD20 expression within specific patient and disease subgroups: age, WBC count and EGIL classification were not associated with CD20 positivity and CD20 expression did not affect outcome in any of these subsets. Exclusion of t(4;11)+ ALL from analysis did not alter these results. *Summary/conclusions*. Our study failed to demonstrate a prognostic significance for CD20 expression in BCP-ALL. The discrepancy between our data and others might be related to differences in study design and therapeutic strategy, herein MRD-oriented, that could have resulted in abrogation of the pejorative prognostic effect by CD20. Nonetheless, independently of these considerations, CD20 antigen remains a useful therapeutic target to improve outcome further in CD20+ ALL.

Background. Most minimal residual disease (MRD)-directed treatment interventions in current treatment protocols for acute lymphoblastic leukemia are based on bone marrow testing, which is a consequence of previous reports showing the superiority of bone marrow (BM) over peripheral blood (PB) as an investigational material. Those studies typically did not explore the prognostic impact of peripheral blood involvement and lacked samples from very early time points of induction treatment. *Aims.* To compare MRD levels in BM vs. PB at early time points of treatment and to evaluate their impact on prognosis. *Design and Methods.* In this study, we analyzed 398 pairs of simultaneously taken blood and marrow follow-up samples from 95 children with B-cell precursor acute lymphoblastic leukemia during ALL IC-BFM 2002 treatment using immunoglobulin and T-cell receptor gene rearrangement testing at diagnosis (n=93), day 8 (n=83) and day 15 (d15, n=78) of induction, the end of induction phase 1 - day 33 (n=53), preconsolidation - week 12 (n=47), prior to maintenance therapy (n=6), and at the end of maintenance therapy (n=38). *Results.* Also at early treatment time points, we confirmed the previously published poor correlation between MRD in BM and PB, with BM-MRD being higher than PB-MRD in most samples (BM/PB: median 7.9, range 0.04-8 293). Higher PB involvement at diagnosis was associated with higher WBC (p=0.003), enlargement of the spleen (p=0.0004) and of the liver (p=0.05). No obvious difference has been observed between PB-MRD levels regarding immunophenotype or genetic subtype including Ikaros gene status, except for the fact that hyperdiploid leukemias had a trend towards lower d15 PB-MRD values than other patients excluding TEL/AML1 cases (p=0.057). At day 15, PB-MRD lower than 10-4 was achieved in 45% of patients and was associated with an excellent five-year relapse-free survival (100% vs. 69±7 %; p=0.0003). PB-MRD subgroups (high-risk, HR:≥10-2, intermediate-risk, IR:<10-2 and ≥10-4, standard-risk, SR:<10-4) correlated with d15 BM-MRD based stratification proposed for BFM protocols (HR:≥10-1, IR:<10-1 and ≥10-3, SR:<10-3), but the risk groups did not match completely. Together, day 15 BM- and PB-MRD identified a larger low-risk group with no relapse (49% of patients) than BM alone. However, a larger study would be needed to assess if PB-MRD could also improve the identification of HR patients, if combined with BM testing. No other treatment time point was predictive of outcome regarding PB, except for a trend at day 8 (p=0.057). *Conclusions.* PB-MRD at d15 identified a large group of patients with an excellent prognosis on BFM-based protocol. When combined with BM-MRD, it could further refine the risk group stratification based on d15, which is currently limited mainly to flow cytometric MRD testing.

Background. Results of adult acute lymphoblastic leukemia (ALL) treatment have improved in recent years. In spite of this, ALL relapse remains challenging as only a minority of patients are cured. *Aims.* The aim of this population-based study was to assess results of reinduction treatment and allogeneic stem cell transplantation (SCT) in Swedish patients diagnosed with first ALL relapse 2003-2007. *Methods.* 76 patients with ALL relapse (Burkitt leukemia excluded) 2003-2007 were prospectively reported to The Swedish Adult Acute Leukemia Registry. Informed consent was obtained from all patients. Missing data were complemented retrospectively. The national guidelines recommended retreatment with initial therapy (ABCDV) for late relapses and two alternatives for early relapses, FLAG-Asp (Fludarabine 30 mg/m2 i.v., Ara-C 2000 mg/m2 i.v. on days 1-5 and PEG-Asparaginase 500 E/m2 i.v. on days 2 and 16) and MEA (Mitoxantrone 12 mg/m2 i.v., Etoposide 100 mg/m2 i.v. and Ara-C 1000 mg/m2 b.i.d. i.v. on days 1-4). For most relapsing patients not transplanted in first remission (CR1) the aim was to perform allogeneic SCT in second remission (CR2). *Results.* For all relapsing patients median age at initial diagnosis was 40 years (range 15-65). Median time from diagnosis to relapse was 13 months (2-116). Median overall survival (OS) after relapse was 8 months (0.5-96). OS at 1 year was 38%, 2 years 25% and 5 years 14%. Five patients (7%) given palliative treatment at relapse were excluded from further analyses. 37/71 patients (52%) given intensive salvage treatment achieved CR2 after the first reinduction course. Additionally, 13 patients reached CR2 after a second course. MEA and FLAG-Asp gave CR2 in 6/9 (67%) and 10/16 (63%) patients respectively. Three patients died of toxicity / infection after reinduction without reaching CR2. Allogeneic SCT in CR2 was performed in 29 patients (sibling-14, unrelated-14, cord blood-1) of whom 19 were under 35 years at diagnosis. Multivariate analysis for OS after relapse (Table1)

Table 1.

	All patients (N=66), missing values: site of relapse (N=5)			*Patients not transplanted in CR1 (N=54)*		
	N	HR-OS (95%CI)		N	HR-OS (95%CI)	
Age at diagnosis *35-65 vs 15-35 years*	37/29	3.6 (1.8-7.2)	**p<0.001**	28/26	3.8 (1.7-8.6)	**P=0.001**
Time diagnosis to relapse *<18 vs >18 months*	35/31	2.2 (1.2-4.0)	**p=0.012**	29/25	3.4 (1.6-7.6)	**P=0.002**
Site of relapse *Extramedullary +/- BM vs sole BM*	14/52	0.6 (0.3-1.2)	p=0.157	10/44	0.3 (0.1-0.8)	**p=0.017**
Treatment after relapse						
Allo-SCT in CR2	29	1.0	**p<0.001**	29	1.0	**p<0.001**
No allo-SCT in CR2	19	1.5 (0.7-2.9)	p=0.267	10	3.1 (1.2-7.5)	**p=0.015**
CR2 not achieved	18	5.6 (2.7-11.4)	**p<0.001**	15	4.9 (2.2-10.8)	**p<0.001**

identified age over 35 years and time to relapse <18 months as significant negative prognostic factors. For patients not transplanted in CR1, treatment with allogeneic SCT in CR2 was favourable compared to CR2 achievement without subsequent transplantation. Unexpectedly, sole bone marrow relapse was a negative factor compared to extramedullary +/- bone marrow relapse. Eleven patients, all under 35 years at diagnosis, are still alive at median 63 months (46-96) after relapse. Ten of these received allogeneic and one autologous SCT in CR2. All 10 patients over 35 years who received allogeneic SCT in CR2 died, as did all patients treated solely with chemotherapy. *Summary/Conclusions.* Both MEA and FLAG-Asp appear effective as reinduction therapies. Of our patients under 35 years treated with allogeneic SCT in CR2, 10/19 (53%) have sustained survival. However, in older and most of the early relapsing patients, outcome was poor. Prevention of relapses is paramount, and new salvage treatments are urgently needed. piotr.kozlowski@orebroll.se

Background. Infants' ALL still remain a disease with poor outcome due to the early recurrence and treatment-related mortality. Recently developed ATRA containing MLL-Baby protocol-ATRA(+) treatment approach-is intended to overcome high early relapses rate without additional treatment toxicity. *Aims.* To perform comparative analysis of treatment results in patients from ATRA(+) group and patients treated by standard chemotherapy alone-ATRA(-) treatment approach. *Methods.* From July 2003 till November 2010 ninety-nine infants younger 365 days with ALL were non-randomly allocated either to ATRA(+) schedule-66 pts. or to ATRA(-) schedule-standard chemotherapy, mainly ALL-MB protocol, - 33 pts. Treatment approaches have been chosen under the decision of treating clinics. Both ATRA(-) and ATRA(+) groups of pts. were similar by initial characteristics: median age 6 (range 1-11) and 6 (range 0-11) months (p=0.99); sex-m/f ratio 12/21 and 24/42 (p=0.82); WBC - 96 (range 0.7-940) and 70 (range 1.6-2058) per µl (p=0.99); initial CNS involvement: 4 and 14 pts. (p=0,4), immunophenotype: BCPI - in 30.8% pts. and 52.3% pts.(p=0.1), BCPII - 34.6% pts. and 29.2% pts. (p=0,8), BCPIII - 26.9% pts. and 13.8% pts. (p=0.23); biphenotype: 0 and 1,5% pts. (p=0.63); AUL: 0 and 1.5% pts. (p=0.63); TIII - 3,8% pts. and 0 (p=0.63); TIV - 3.8% pts. and 1,5% pts. (p=0.91)respectively. MLL rearrangements were detected in 45 (68.2%) among 66 pts. allocated to ATRA(+) and in 15 (53.6%) among 28 examined pts. allocated to ATRA(-) regimen. More than half of MLL-positive pts. had t(4;11): 23 out of 45 pts. from ATRA(+) group and 8 out of 15 pts. from ATRA(-)group, respectively. *Results.* We did not observe any significant difference in induction deaths: 5 (15.1%) vs. 5(7.6%), p=0.43 in ATRA(-) and ATRA(+) groups; CR rates: 28(84.9%) out of 33 pts. vs. 59(89.4%) out of 66 pts., p=0.74; remission deaths: 0 vs. 6(10.1%), p=0.83 respectively; but proportion of relapses remains different: 16(57.1%)from 28 pts. in ATRA(-)group vs. 11(18.6%) out of 59 pts. in ATRA(+)group, p=0.0001. Probability of RFS - 0.74±0.06 vs. 0.37±0.09, p=0.008; cumulative incidence of relapse - 0.62±0.01 vs. 0.25±0.004, p=0.01 in ATRA(-) and ATRA(+) groups correspondingly. Univariant analysis identified the following parameters to have a significant negative impact on EFS-age younger 6 months (p=0,0001); MLL rearrangements (p=0,018) and treatment without ATRA (p=0,04). Multivariant Cox regression analysis confirmed the significant negative value on EFS age younger 6 months with Hazard Ratio 2,550(95%CI 1.272-5.112) p=0,008 and ATRA(-) treatment apptroach-HR 2.017 (95%CI 1.072-3.796) p=0.03. *Conclusion.* Our data demonstrates that ATRA based approach could be treatment of choice in infants with ALL.

Background/Aims. In acute lymphoblastic leukemia (ALL) an early reduction of minimal residual disease (MRD) <10-4 confers a significant survival advantage. Since 2008 we adopted a T-ALL regimen including methotrexate (MTX) infusions at 5 g/m2. Obtaining a high rate of early molecular remissions was a major study endpoint, to improve survival also in comparison to an historical control series. *Methods.* Program N-10 consisted of 5 standard chemotherapy blocks alternating with 3 MTX blocks at 5 g/m2 (24-h infusion, folinic acid rescue 6-hourly from h 42 to a level <0.25 micromol/L; age >55 years: MTX 1.5 g/m2). This schedule targeted an *in vivo* MTX concentration of ~65-70 micromol/L, in keeping with the concept of lineage-targeted MTX developed at St. Jude's Hospital. A concurrent molecular evaluation of bone marrow MRD was performed to optimize risk stratification and related therapeutic decisions. Early treatment consisted of pre-phase (PDN/CY), cycle 1 (VCR/IDR/DEX/ASP), cycle 2 (VCR/IDR/CY/DEX/AraC/6MP) and cycle 3 (MTX/HD-AraC), plus day +30 and +70 MRD analysis. Cycles 4 and 6 were like 2, 5 and 7 like 3 (no. 5 with ASP instead of HD-AraC), and 8 like 1. Risk classes were standard (SR: thymic CD1a+ and WBC <100; CR cycle 1) and high (HR: others). Allo-SCT was prescribed to HR patients, and to SR patients with MRD >10-4 on day +70 and/or positive at later time-points. Auto-SCT followed by maintenance could be used as an alternative. SR MRD negative patients were submitted to maintenance. *Results.* All 24 evaluable patients (median age 40 years [range 17-65], SR 10, HR 14) entered CR (100%), 23 after N-10 induction and one refractory to cycle 1 after Clofarabine/AraC. Twenty patients are alive in CR1 (83%), 4 relapsed (17%) and one died in CR after SCT. With a maximum follow-up of 3 years, 2-year overall and disease-free survival are 74%. The associated MRD response was highly favorable. Day +30 MRD was negative in 62.5% (5/8) and 33% (3/9) of evaluable SR and HR patients, respectively, and <10-4 in 2 other patients, for a major postinduction response of 75% in SR and 44% in HR. Post-MTX day +70 MRD was negative in 80% (8/10) and 67% (6/9) of SR and HR patients, respectively, and <10-4 in 2 other patients, for a major post-consolidation response of 90% in SR and 78% in HR. MTX plasma determinations at 8-h and 24-h from start of infusion were available from 37 5 g/m2 blocks administered to 19 patients, and were generally close to stated therapeutic target (8-h, mean: 78.1 [21.6]; median: 75 [44-120]; 24-h, mean: 76.9 [22.5]; median 84 [27.6-124]). Extrahematologic grade III-IV toxicity was occasional (liver: 5.4%, gastrointestinal 8%, metabolic 2.7%) and transient in nature. *Conclusions.* Protocol N-10, introducing for the first time in adult ALL 5 g/m2 MTX infusions, was feasible and highly active in adult T-ALL. Compared to the results from a previous study (protocol N-9: 84 patients, CR 85%), day +70 MRD response and 2-year survival are being improved (MRD negative 74% vs 58%; survival 74% vs. 41%, P=.046).
