Background. Mature B-ALL (acute lymphoblastic leukemia) and Burkitt lymphoma are characterized by high cell proliferation, aggressive clinical behavior and poor prognosis unless a highly specific treatment is used. The German Multicenter Study Group for Adult ALL (GMALL) recently introduced a short intensive chemotherapy program in combination with rituximab to improve results in B-ALL and Burkitt lymphoma (Hoelzer *et al*, ASH 2007, abstr 518). The Northern Italy Leukemia Group (NILG) adopted the same protocol to treat >100 patients since 2002. *Aims.* To evaluate efficacy, toxicity and long-term results obtained with this regimen in a prospective cohort of unselected patients with B-ALL and Burkitt lymphoma. *Methods.* Treatment consisted of six chemotherapy courses (4 courses in stage I-II disease without mediastinal or extranodal involvement) plus Rituximab (R) 375 mg/m2 for 6-8 total doses, and local radiotherapy (mediastinal or CNS involvement, or residual tumor). Treatment plan was as follow: prednisone-cyclophosphamide prephase —> R+course A (dexamethasone, vincristine, ifosphamide, HD-methotrexate, teniposide [or etoposide], Ara-C,intrathecal therapy) —> R+course B (dexamethasone, vincristine, cyclophosphamide, HD-methotrexate, adriamycin, intrathecal therapy) —> R+course C(dexamethasone, vindesine, HD-methotrexate, etoposide, HD-Ara-C) —> R+A —> R+B —> R+C. Patients aged >55 years received only courses A and B but not C and lower dose methotrexate (0.5 instead of 1.5 g/m2). *Results.* Between December 2002 and June 2010, 106 patients were enrolled. Fifty patients had B-ALL and 56 Burkitt lymphoma (stage III-IV 28%, bulky 47%, extranodal involvement 64%). Median age was 47 years (range 17-78), 60% were male, 31% were >55 years, 16 (15%) were HIV+, 35% had an ECOG PS > 2, and 79% an elevated LDH. Eighty-three patients (78%) achieved CR, 8 had refractory disease and 15 died early (10 by infection, 3 hemorrhage, 2 other) (Table). No statistically significant difference in CR rate was observed between HIV negative and positive patients (80% vs. 69%, p=0.3). Sixty-eight patients (64%) received the whole treatment program. At a median follow-up of 3 years, 65 patients (61%) are alive in CR1, 20 (19%) died of treatment complications (TRM) and 11 developed recurrent disease (3 BM, 1 CNS, 1 BM + CNS, 6 nodal). Projected 5-year OS and DFS were 62% and 75%, respectively, with significant differences in favor of patients aged <55 years (Table). Other clinical indicators that significantly affected OS and DFS were an elevated serum LDH (P=0.03) and an ECOG PS > 2 (P=0.003). *Conclusions.* The short intensive German chemotherapy/rituximab regimen was confirmed effective for the management of adult patients with B-ALL and Burkitt lymphoma up to an age of 55 years (75% projected alive at 5 years). In the older age group, the lower cure rate (37% at 5 years) was equally related to TRM (mainly caused by infection) and progressive disease.

Table 1.

	Age (years)	no.	CR no. (%)	OS (5 years)	DFS (5 years)	Failures, no.
B-ALL	≤55	32	27 (84)	75% (P=0.001)	85% (P=0.01)	disease, 7 TRM, 2
	>55	18	12 (67)	33%	50%	disease, 4 TRM, 8
Burkitt lymphoma	≤55	41	33 (80)	76% (P=0.03)	83% (P=0.09)	disease, 4 TRM, 7 secondary AML, 1
	>55	15	11 (73)	40%	55%	disease, 4 TRM, 3 late death, 1

0559

RAPID ADVERSE OUTCOME IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND A MIXED 3 REPEATS/ 4 REPEATS IN THE ENHANCER REGION OF THE 5'-UNTRANSLATED REGION OF THE THYMYDILATE SYNTHASE GENE

PT Vu Hoang

UCL, Brussels, Belgium

Background. Several cohort studies have investigated the relationship between thymidylate synthase (TS) genotype, expression and survival in children with cancer. A high level of TS expression is correlated with poor prognosis in paediatric patients with acute lymphoblastic leukemia (ALL). While polymorphic tandem repeats in the TS enhancer region (TSER) of the 5'Untranslated Region (5' UTR) has been shown to impact on TS expression, it is reported that the TSER3R/TSER3R genotype increases the resistance to methotrexate (MTX) and is associated with a higher risk of relapse after chemotherapy. *Aim.* The goal of this preliminary study was to compare the TSER genotype prevalence in a cohort of Belgian and Vietnamese ALL children. *Material and Methods.* Blood Samples from Belgian (n=114) and Vietnamese (n=115) ALL children were collected in Saint-Luc Hospital (UCL, Brussels, Belgium) and Blood Transfusion - Hematology Hospital (PNT Medical University, Ho Chi Minh city, Vietnam) in accordance with a protocol approved by the local ethics committees. Genomic DNA was obtained from whole blood. It was extracted with BioRobot EZ1 (Qiagen, Hilden, Germany) using a DNA (EZ1 DNA Blood 350 µl/kit (48) and EZ1 DNA buffy coat card) according to the manufacturer's instructions. Purified DNA was quantified using NanoDrop ND1000® spectrophotometer (Nanodrop Technologies, Inc. Wilmington, DE, US) and stored at -20°c prior to subsequent molecular analysis. DNA samples were amplified by polymerase chain reaction for the TSER. The DNA fragments were run in a 2.5% agarose gel with ethidium bromide and visualized on a UV transilluminator. Sequencing analysis was performed in the validation phase as well as as a confirmation in case of unusual genotype (3R, 4R). DNAs from anonymous African patients (n=50) were used as a control for interethnic differences in the prevalence of TSER genotypes. *Results.* The distribution of TS genotype in the patient and DNA control groups is given in Table 1. Interethnic differences are highly significant (Fisher exact test, p<0.0001). Two leukemic children respectively of African and Vietnamese ancestry were found with the rare 3R/4R TS genotype. Both had a poor therapeutic outcome after chemotherapy: a 15-year-old African girl was indeed unsuccessfully treated with the FRALLE-2000 group T chemotherapy after presenting with an undifferentiated acute leukemia. The patient died during the consolidation phase of ELAM-02 chemotherapy; a 18-month-old Vietnamese boy who presented with ALL-L2 was unsuccessfully treated with FRALLE 2000 group B1 chemotherapy (including MTX). Extramedullary (Central Nervous System) relapse was diagnosed 29 days after starting the intensification phase. Up to now, the patient has undergone 4 successive relapses and has never achieved remission. *Conclusions.* The 3R/4R TS genotype was found in one Vietnamese and one African ALL children but not in the Caucasian cohort. Nevertheless, this genotype seems to be associated with a very bad outcome and chemoresistance in carriers. Further investigations are now pursued on Vietnamese and African cohort to assess their TSER genotypic status and response to therapy.

Table 1.

	TSER genotypes in ALL children		
	Vietnamese	Belgian	African DNA controles
	n=115	n=114	n=50

CD20+ PROGNOSTIC SIGNIFICANCE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

P Carluccio, M Delia, D Pastore, A Mestice, A Ricco, V Fesce, G Nardelli, G Specchia

Hematology - University of Bari, Bari, Italy

Background. The prognostic significance of CD20 expression in Acute Lymphoblastic Leukemia (ALL) blasts is still a matter of debate in adult ALL patients. These patients' outcome has been considered up to now to be variously affected both by non homogeneous chemotherapy approaches and by different biological parameters. *Aim.* Aim of our study was to evaluate the prognostic impact of CD20 expression in 119 adult ALL patients (<60 yy), diagnosed according to the FAB/WHO classification and homogeneously treated between 1996 and 2009. *Patients and Methods.* Cut-off for CD20+ expression was 20%. All patients were treated according to the 0496 Gimema Protocol (Prednisone, Vincristine, Daunolastine, Asparaginase). Patients median age was 32 years (r 15-60). *Results*. The median age of patients expressing CD20 (CD20+: 54 pts) was higher than of CD20- patients (42 vs 26, p=0.039), while there were no differences regarding white blood cells, platelets, percentage of peripheral and bone marrow blasts cells, recurrent genetic abnormalities (t(9;22), t(4;11), t(8;14)). CD20+ patients showed a lower incidence of myeloid antigen expression (CD13 and/or CD33, p.0.04), but this was not confirmed in CD20+Ph- patients. There was no correlation between Ph+ (40 pts) and CD20+ and the outcome was independent of CD20 expression. In the Ph- group (85 pts), Disease free survival (DFS, p=.9) and Overall survival (OS, p=.24) did not seem to be affected by CD20 expression. *Conclusions.* Taken together, our data seem to suggest that CD20+ ALL adult patients are older and have a lower expression of myeloid antigens, but these data are uncorrelated with OS and DFS. Although our patients sample was a homogeneous study cohort for age and treatmen, further large case series are needed to evaluate the true prognostic impact of CD20 expression in adult ALL patients and the role of CD20 antibodies therapy.

0561

EFFECT OF PREVENTIVE ANTITHROMBOTIC MEASURES ON THROMBOTIC RISK IN ADULT PATIENTS TREATED FOR ACUTE LYMPHOBLASTIC LEUKEMIA

M Lauw,[1] B van der Holt,[2] S Middeldorp,[1] B Biemond[1]

[1]*Academic Medical Center, Amsterdam, Amsterdam, Netherlands*
[2]*HOVON Data Center, Erasmus University Medical Center, Rotterdam, Netherlands*

Background. Treatment of acute lymphoblastic leukemia (ALL) is frequently complicated by venous thromboembolism (VTE). The reported incidence varies from 2% to 37%. The highest VTE risk arises in the first treatment weeks, while the value of preventive measures is not clear yet and standardized prevention protocols are lacking. *Aims.* To assess the effect of various preventive antithrombotic protocols on the VTE risk in adult patients during treatment for ALL. *Methods.* 240 patients aged 16-59 years with newly diagnosed ALL were treated on the same anti-leukemic protocol, containing L-asparaginase in the first induction cycle, in a Dutch-Belgian multicenter study from 1999 to 2005. All VTE complications during protocol were recorded. VTE prophylaxis differed between centers (no prophylaxis, frozen plasma (FP), antithrombin (AT)). We retrospectively analyzed the various preventive antithrombotic protocols during the first ALL induction cycle to assess their effect on the risk of VTE, using available patient records. Informed consent was obtained for this analysis. *Results.* 36 of 240 patients (15.0%; 95% CI 10.5-19.5) experienced VTE during protocol (10 sagittal sinus, 20 upper limb (90% central venous catheter-related), 4 deep-vein thromboses of the leg, 2 pulmonary embolisms). In 25 patients VTE occurred during the first induction cycle. Prophylactic FP compared to no VTE prevention reduced the VTE risk in the first induction cycle by nearly three-quarters (RR 0.3; 95% CI 0.1-0.5; see Table). Since prophylactic AT was only rarely given in two centers, its effect could not be properly assessed. Low-molecular-weight heparin (LMWH) was not used as regular VTE prophylaxis during this study. *Conclusions.* The reduced VTE risk with prophylactic FP during adult ALL induction therapy could be explained by a FP-induced increase of AT, in contrast with previous studies that showed a negligible benefit of FP, a skewed ratio of FP protocols between centers, or another more obscure manner of FP-induced anticoagulation. Moreover, this was a retrospective quasi-randomized (by treatment center) observation. The effect of FP or other preventive VTE measures during adult ALL treatment should be confirmed by a randomized controlled study.

Table 1. Frozen plasma protocols.

ALL treatment centers with frozen plasma protocols		
Treatment center	Total number of included patients	Number of patients with VTE in first induction cycle
Protocol FP +		
1	38	1
2	30	3
3	26	1
4	22	2
5	18	1
6	14	1

MIXED PHENOTYPE ACUTE LEUKEMIA (MPAL) ACCORDING TO THE WHO 2008 CLASSIFICATION-REPORT OF 17 CASES

M Bogunovic, N Kraguljac- Kurtovic, A Bogdanovic, M Perunicic, V Djordjevic, V Lazarevic, V Novakovic, D Lekovic, M Colovic, G Jankovic, N Suvajdzic, M Gotic, A Vidovic, D Tomin, I Elezovic, B Mihaljevic

Clinical Center of Serbia, Beograd, Serbia

Background. Biphenotypic acute leukemias are rare leukemias and account less than 4% of acute leukemias, characterized by coexpression of lymphoid and myeloid markers on the same leukemic cells. The diagnostic criteria until now were based on the scoring sistem proposed by EGIL, that was adopted by the WHO 2001 classification. The most recent edition of the WHO classification (2008) has established and published new criteria for the diagnosis of BAL, which is now termed mixed phenotype acute leukemia (MPAL).The WHO definition of MPAL is based on the expression of strictly specific T lymphoid (cytoplasmic CD3) and myeloid (MPO) antigens, shown by either flow cytometry or cytochemistry, and/or evidence of monocytic differentiation; for B -cell lineage strong expression of CD 19 together with another B-cell associated marker or, in cases with weak CD 19, the expression of at least three B- lineage markers. *Aim.* to describe clinical features and treatment response in 17 cases of MPAL. *Methods.* We studied 896 adult patients with de novo acute leukemia, selected from clinical archives (1999-2010), and described clinical features, morphology and cytochemistry according to the French-American-British (FAB) criteria, immunophenotypic characteristics (by flow cytometry and immunocytochemistry), and cytogenetics by conventional karyotypic studies and molecular analysis in 17 MPAL. Patients were treated according to the national protocols for ALL or AML. *Results.* The final dg of MPAL fulfilled 17/896 (1,9%) patients. There were 10 male and 7 female, median age 45 (range 18-61). Morphology was consistent with ALL (65%) and AML (35%). Immunophenotyping disclosed B/myeloid variant (11/896, 1,2%pts.),T/myeloid (5/896, 0,6%pts),and rare B/T (1/896, 0,1%pts.)variant. All studied patients expressed HLA-DR and/or CD 34 Ags. Cytogenetics were available in all patients and evidenced t(9;22)(12%), in 1pts. associated to complex karyotypic changes, complex (23,5%),abberant (23,5%) or normal (35%)karyotypes. 12% patients had not metaphases. 5 patients received ALL therapy, 10 patients

AML therapy, two patients a combination of therapy. ALL treatment induced a response in 40% patients, AML treatment in 40% patients; one patient responded to the combination of therapy. 15 (88 %) patients died, 7(41%) of resistant/relapsed disease.Two patients (12%) received high dose therapy for AML followed by BMT and PBSCT, obtained CR and still surviving. Overall median survival was 13,6 months and 12% of the patients are alive (1 and 11 years). *Conclusions.* Our results confirm a poor prognosis of MPAL.There are no uniform criteria about type of treatment in this rare disease. Adults patients should be considered for stem cell transplantation in first remission.

0563

PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE DETECTED BY PCR FOR FUSION GENE TRANSCRIPTS IN INFANTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED BY MLL-BABY PROTOCOL

G Tsaur,[1] A Popov,[1] T Nasedkina,[2] O Kalennik,[2] A Kustanovich,[3] O Aleinikova,[3] T Riger,[1] A Ivanova,[1] O Streneva,[1] E Shorikov,[1] A Solodovnikov,[4] L Saveliev,[4] L Fechina[1]

[1]*Regional Children's Hospital 1, Research Institute of Medical Cell Technologies, Ekaterinburg, Russian Federation*
[2]*Engelgardt Institute of Molecular Biology, Moscow, Russian Federation*
[3]*National Research Center for Pediatric Oncology and Hematology, Minsk, Belarus*
[4]*Ural State Medical Academy, Ekaterinburg, Russian Federation*

Background. Prognostic significance of minimal residual disease (MRD) in acute lymphoblastic leukemia (ALL) was shown within several treatment regimens. Majority of infants with ALL carry *MLL* rearrangements, so in this group MRD monitoring by detection of fusion gene transcripts (FGt) could be fast, easy and cost-effective approach. MLL-Baby treatment protocol is successfully applied for infant ALL within Russian Federation and Republic of Belarus (L. Fechina *et al*, ASH 2007 #2828). In this treatment approach conventional chemotherapy is augmented by administration of all-trans retinoic acid (ATRA). *Aim.* To evaluate the prognostic significance of MRD detected by PCR for FGt in *MLL*-rearranged infant ALL, enrolled into MLL-Baby study. *Methods.* 23 infants with defined FGt who had at least 4 available follow-up samples were included in the current study. Median of follow-up period was 30 months (range 7-90 months). Presence of *MLL* rearrangements was detected by nested reverse-transcriptase PCR (RT-PCR), FISH and confirmed by long-distance inverse PCR (C. Meyer *et al*, 2005). MRD detection in bone marrow (BM) was performed by both real-time quantitative PCR and qualitative nested RT-PCR as previously described (N. Palisgaard *et al*., 1998, J. Gabert *et al*, 2003). MRD-negativity was defined as absence of FGt in both assays with sensitivity 1E-05. Among 23 infants there were 13 *MLL-AF4*-positive patients, 4 *MLL-MLLT10*-positive patients, 3 *MLL-EPS15*-positive patients, 2 *MLL-MLLT1*-positive patients and one *MLL-MLLT3*-positive patient. BM samples were obtained at the time of diagnostics, on day 15 of remission induction (time point 1 (TP 1)), at the end of remission induction (TP2) and after each ATRA course (TP3-TP9). Event-free survival (EFS) was calculated. Informed consent was obtained in all cases. *Results.* According to the qualitative MRD results patients were divided into MRD-positive and MRD-negative categories. All pts were MRD-positive at TP1. At TP2 3 patients became MRD-negative. At TP3 other 5 patients converted to MRD-negativity. By TP4 18 patients were MRD-negative, while FGt was detected in 5 patients. 2 patients became MRD-negative before protocol II (at TP9), while 3 patients never achieved MRD-negativity. Retrospectively all patients were referred to 3 groups in respect of MRD status at TP3 and TP4. The MRD-low risk group included 8 patients who were MRD-negative at both TPs. The MRD-intermediate risk group consisted of 10 patients who were MRD-positive at TP3 but MRD-negative at TP4. 5 patients remaining MRD-positive at TP4 were referred to MRD-high risk group. Outcomes in these three groups were significantly different. EFS was 1.00 in MRD-low risk group, 0.70±0.14 in MRD-intermediate risk group and 0.20±0.17 in MRD-high risk group (log-rank p for trend 0.002). *Conclusions.* MRD monitoring by FGt measurements has significant prognostic value in infants with *MLL*-rearranged ALL treated by MLL-Baby protocol. Consideration of MRD status at TP3 and TP4 allows dividing patients into 3 groups with different outcomes. These data could be implemented into the patients' stratification in MLL-Baby trial, when more patients will available for the analysis.

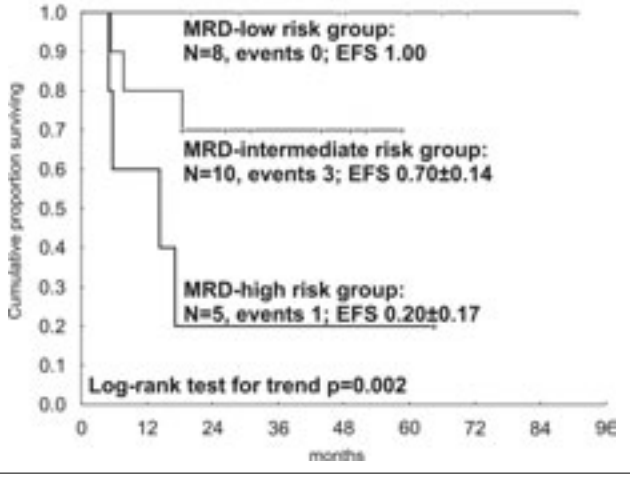

Figure 1. Event-free survival for MRD-defined risk group.

0564

THYROID DYSFUNCTION IN LONG-TERM SURVIVORS OF ACUTE LYMPHOBLASTIC LEUKEMIA: EXPERIENCE OF A SINGLE ITALIAN PEDIATRIC INSTITUTION

F Petruzziello, A Mangione, R Parasole, S Di Maio, A Misuraca, G Pollio, S Buffardi, G Loffredo, F Cecere, T Ferrara, V Poggi

Santobono-Pausilipon Children Hospital, Naples, Italy

Background. The risk of thyroid dysfunction increases in childhood survivors of acute lymphoblastic leukemia (ALL) treated with cranial or craniospinal radiotherapy, due to disruption of the hypothalamic-pituitary axis or direct injury to the thyroid gland. There are few reports in the literature on the contribution of chemotherapy to the development of central hypothyroidism in childhood cancer survivors. Previous studies, with small numbers of survivors and limited follow-up post-treatment, have reported no significant thyroid dysfunction in childhood ALL survivors treated with chemotherapy alone. *Aim.* We retrospectively evaluated the incidence of thyroid dysfunction in 280 childhood long survivors with ALL treated according to the protocols of the Italian Association of Pediatric Hemato-Oncology (AIEOP). *Methods.* From June 1986 to January 2011, two hundred and eighty patients (145 males and 135 females) survivors of ALL were followed in a single pediatric Hemato-Oncology Institution. Two hundred and thirty-eight children were treated with chemotherapy alone and 42 received also cranial/craniospinal radiotherapy. All patients annually underwent thyroid echography and blood measurement of free FT4, FT3, TSH, anti-thyroperoxidase and anti-thyroglobulin antibodies. All thyroid nodules exceeding 1,5 centimetres were aspirated and cytologically analyzed. *Results.* In our series of 280 patients, the mean age at outcome assessment was 7 years (range, 4 to 30 years) and the average follow-up duration from completion of therapy to last survey was 8.6 years (range, 1 to 24 years). No patients treated with radiotherapy experienced thyreopathy. Nine (2 males and 7 females) out of 238 patients (3,7%), treated with chemotherapy alone, reported thyroid dysfunction. Five survivors developed one or more thyroid nodules without lost of gland function (only one with thyroperoxidase and thyroglobulin antibodies). The fine needle aspirate cytology resulted negative for neoplasms. Subclinical hypothyroidism was observed in two patients. One patient developed autoimmune hypothyroidism and started thyroid replacement therapy while another reported autoimmune hyperthyroidism treated with methimazole. In only one patient, familiar anamnesis was positive for thyreopathy. The mean time to thyroid dysfunc-

Table 1.

Clinical characteristics of patients

Pt	Sex	Age at diagnosis (yrs, mos)	Age at stop therapy (yrs, mos)	Thyreopathy	Thyroid antibodies	Thyroid function	Time to event from stop therapy (yrs)	Age at event (yrs, mos)	Need for therapy	Familiarity
1	F	8 yrs	10 yrs	Thyroid nodules	Yes	Normal	5 yrs	15 yrs	No	No
2	F	6 yrs 5 mos	8 yrs 5mos	Hypothyroidism	Yes	Altered	1 yrs	9 yrs 5 mos	Yes	No
3	F	2 yrs 5 mos	4 yrs 5 mos	Thyroid nodule	No	Normal	3 yrs	7 yrs 5 mos	No	Yes
4	F	9 yrs 5 mos	11 yrs 5 mos	Thyroid nodule	No	Normal	4 yrs	15 yrs 5 mos	No	Adopted

Abbreviations: Pt: patient; yrs: years; mos: months

tion after stop-therapy was 4.5 years (range, 1 to12 years); the mean age at the event was 12.3 years (range, 6.9 to 22 years). Table I resumes the clinical characteristics of survivors with thyreopathy. *Conclusion.* In our experience, the incidence of thyroid dysfunction in long survival pediatric ALL treated with chemotherapy alone results comparable to that reported in literature after cranial or craniospinal radiotherapy. The more frequent thyroid abnormalities observed were thyroid nodules without gland failure. The short series of radiotherapy-treated survivors do not allow a correct evaluation of thyreopathy incidence in this group of patients. We believe that childhood leukemic survivors require lifelong surveillance after completion of chemotherapy, for an early recognition and prompt treatment of late thyreopathy.

0565

USE OF CLOFARABINE IN CHILDREN WITH RELAPSED/REFRACTORY ACUTE LEAUKAEMIAS; THE LARGEST SINGLE UK CENTRE EXPERIENCE

J Motwani, P Darbyshire, S Lawson, M Velangi, M Williams

Birmingham Children's Hospital, Birmingham, United Kingdom

Acute leukaemia is the most common cause of malignancy in children less than 18 years. Advances in effective treatment options have improved outcomes in recent years such that 5-year survival rates now approach 85% for ALL and 50-60% for AML. Despite these advances, approximately 20% of children with ALL experience relapse, which remains the leading cause of treatment failure (Pui & Evans, 2006). Prognosis remains poor for children who experience relapses or are refractory to front line therapy. The safety and efficacy of the combination clofarabine/cyclophosphamide/etoposide was assessed retrospectively in children with relapsed or refractory acute lymphoblastic leukaemia (ALL) or acute myeloid leukaemia (AML) or non-Hodgkin's Lymphoama (T-NHL). In this single centre experience we describe 14 children (10 males, 4 females) (median age 14 years, range 3-18 years) with either relapsed/refractory ALL (n=8), AML(n = 5) or T-NHL (n =1), who received clofarabine in combination with cyclophosphamide and etoposide .7 children received doses of clofarabine 40 mg/m2, cyclophosphamide 440mg/m2 and etoposide 100mg/m2 for 5 days,(doses as per CLO218 Hijiya *et al*) and 7 received doses of clofarabine 40 mg/m2, cyclophosphamide 300mg/m2, etoposide 150mg/m2 for 5 days, 3 along with dexamethasone. (Doses from High Risk modification arm of MRCUKALLR3). Informed consent was obtained from all families. Of the 8 children with underlying ALL, 7 (87.5%) achieved complete morphological remission. 1 who had bulky extramedullary disease achieved good partial response. 5 of the 8 children have received a haemopoietic stem cell transplant (HSCT) (62.5%). 2 children are currently awaiting HSCT. 1 child could not receive HSCT due to invasive fungal infection. 1 child, with T-NHL, achieved remission and received HSCT. Of the 5 children with underlying had AML, 3(60%) achieved morphological remission and received HSCT. 1 child died soon after chemotherapy due to multiorgan failure, and hence response could not be asessed.1 child received this combination chemotherapy for post HSCT relapse, and did not respond. The most common adverse events were febrile neutropenia, mucositis and reversible liver toxicity; no case of liver veno-occlusive disease was reported. Heavily pre-treated children had more side effects. These data suggest that the clofarabine/cyclophosphamide/etoposide regimen is reasonably well tolerated and can induce clinical response in a relevant proportion of children with refractory/multiple relapsed ALL and AML. Good supportive care with prophylactic antifungal and anti-PCP agents is important. (pnemocystis carinii).

0566

PROGNOSTIC IMPACT OF CD20 EXPRESSION IN ADULTS WITH DE NOVO PRECURSOR B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

C Moreira, A Espírito-Santo, N Domingues, I Moreira, I Oliveira, A Martins, L Viterbo, M Marques, G Martins, JM Mariz

Instituto Português Oncologia Porto, Porto, Portugal

Background. In the last decades, we observed an improvement in treatment outcome of adult *de novo* acute lymphoblastic leukemia (ALL) brought mainly by intensive chemotherapy and increased use of allogeneic hematopoietic stem cell transplant (HSCT). The addiction of tyrosine kinase inhibitors to chemotherapy, for patients with Philadelphia-chromossome (Ph) positive ALL, significantly improved outcome. However, the incidence of relapse is still high in these patients. CD20 is a cell surface marker expressed in the majority of mature B-ALL blast cells, but expressed in only 40% of precursor B-cell ALL blast cells. Recently, a few studies have been published suggesting a worse outcome associated with CD20 expression in adult ALL. *Aim.* To evaluate the prognostic impact of CD20 expression in adults diagnosed with de novo precursor B-cell ALL. *Methods.* From 1997 to 2009, we diagnosed 147 new cases of ALL and lymphoblastic lymphoma. Fifty-four patients met criteria of inclusion in this report (diagnosis of Burkitt-type ALL, T-cell ALL and lymphoblastic lymphoma were excluded). Statistical analysis was performed with SPSS®Statistics v18. *Results.* Fifty-four patients were diagnosed with precursor B-cell ALL (57.4% males; median age of 49 years, range 14-79) and were treated in first-line with Hyper-CVAD (n=44; 7 of these associated Imatinib for Ph-positive ALL), Linker Protocol (n=2), BF12 (n=2; younger patients presenting with complex karyotype), ALL-BFM90 (n=2; less than 21 years old) and vincristine plus dexamethasone (n=4; above 70 years old). Allogeneic HSCT was performed in 15 patients. Nineteen patients expressed CD20 at a level of at least 20%. Distribution of pretreatment characteristics such as age, gender, performance status, leukocyte count, FAB subtype, LDH, CNS involvement at diagnosis and presence of Philadelphia chromosome was similar by CD20 status. First-line therapy was equality distributed between both groups. Complete response rate was similar irrespective of CD20 status (85.3% in CD20-negative vs. 84.2% in CD20-positive). There was a higher incidence of disease recurrence in the CD20-negative group (51.4% vs. 36.9%, p=0.3) and CD20-positive patients had better overall survival (OS, 39.4 months vs. 22 months, p=0.51) and disease-free survival (DFS, 72 months vs. 26.3 months, p=0.41), but this did not reach statistical significance. The median time to relapse was 11.7 months in the CD20-negative group and 16.9 months in the CD20-positive group (p=0.7). Analyzing only the subset of patients treated with Hyper-CVAD, we obtained similar results. Multivariate analysis of pretreatment characteristics was also performed; the only independent prognostic factor was the presence of Philadelphia chromosome which was associated with a worse outcome (p=0.006). There was no difference in median OS or DFS in both CD20 positive and negative Philadelphia ALL, although at 3 years, CD20-positive patients had better OS (29% vs. 9%, p=0.53) and DFS (33% vs. 13%, p=0.52). *Conclusions.* Although none of the results was statistically significant, we observed a trend towards a better outcome associated with the presence of CD20 in adults with *de novo* precursor B-cell ALL, even in Philadelphia positive patients. Further investigation is needed to clarify the role of CD20 as a prognostic factor in adult ALL.

0567

ASSESSMENT OF ENDOCRINOLOGIC AND CARDIOLOGIC LATE EFFECTS AMONG SURVIVORS OF CHILDHOOD LEUKEMIA

H Oren

Dokuz Eylül University Faculty of Medicine, Izmir, Turkey

Background. Survival rates for childhood acute leukemia have significantly improved and late effects of therapy have been important in follow-up of survivors. *Aims.* The objective of this study is to identify the endocrinologic and cardiologic late effects of acute leukemia patients treated in our pediatric hematology unit. *Methods.* Patients treated for leukemia with BFM protocols after at least five years of diagnosis were included in the study. Endocrinologic late effecs (growth failure, obesity, insulin resistance, dyslipidemia, thyroid gland disorders such as hypothyroidism, osteopenia/osteoporosis, pubertal disorders) and cardiologic late effects (cardiac toxicity, hypertension) were evaluated. The study group was evaluated with anthropometric measurements, body mass index, laboratory testing of fasting glucose, insulin, serum lipids and thyroid functions. Pubertal stage was determined by using the Tanner criteria. Bone mineral densities were measured by DEXA (dual-energy X-ray absorptiometry). Blood pressures were noted. Evaluation of cardiac systolic and diastolic functions were performed using standard M-mode echocardiography and tissue doppler imaging. *Results.* Of 43 acute leukemia survivors with a median age of 15 (range; 7-30 years), 23 (54%) were females and 20 (46%) were males. Five (12%) of the patients had acute myeloid leukemia and 38 (88%) of them had acute lymphoblastic leukemia. They had been off therapy for an average of eight years (range; 5-17 years, SD 3.4 years). At least one adverse event occured in 25 (58%) of the 43 survivors, with 10 of them (23%) having multiple problems. Six (14%) of the survivors were obese and 10 (23%) of them were overweight. Subjects who were overweigth or obese at the time of diagnosis and at the end of therapy were more likely to be overweight or obese at last follow-up. Overweight and obesity were more frequently determined in patients who were younger than six years of age at the the time of diagnosis. Insulin resistance was observed in nine (20%) subjects. Insulin resistance was more frequently seen in

subjects who are overweight or obese and who have family history of type 2 DM. Hyperlipidemia was detected in eight (18%) of the 43 survivors. Premature telarche was detected in one (2%) subject. None of the patients had short stature. Hypothyroidism was observed in one (2%) survivor. Two (5%) survivors had osteopenia. Avascular necrosis of femur head occurred in two (5%) survivors. Cardiovascular abnormalities occurred in one (2%) of the subjects with hypertension and cardiac diastolic dysfunction. No statistically significant difference was determined for the distribution of late effects between subjects who received cranial radiotherapy or not. *Conclusions.* In our study at least one adverse event occured in most of the cases. Acute leukemia survivors should be followed up for the endocrinologic and cardiologic late effects with concerning sex, age at diagnosis and contents of the therapy.

0568

THE PROGNOSTIC IMPACT OF METHYLATED P15 AND P73 GENES IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

T Abdel Hamid, G Mossallam, M Sherisher

National Cancer Institute- Egypt, Cairo, Egypt

Background. Aberrant methylation of promoter-associated CpG islands is an epigenetic modification of DNA that plays an important role in leukemia pathogenesis. This phenomenon is frequently observed in ALL and results in the functional inactivation of its associated genes. The aim of this study was to investigate the frequency and prognostic impact of methylated p15 and p73 genes in adult acute lymphoblastic leukemia patients. *Patients and Method.* The study included 51 newly diagnosed adult ALL patients who presented to the Medical Oncology Department of the National Cancer Institute - Cairo University in the period from January 2008 to May 2009. Written consent was obtained from all patients. Eligible patients were adult up to the age of 50 years with adequate organ function and performance status. Mature B phenotype cases were excluded. Risk stratification based on age, initial total leucocytes count, immunophenotyping, cytogenetic and complete remission rate at 4 weeks were performed at diagnosis. The treatment plan was risk adapted, standard versus high and very high risks with more intensified treatment for the high and very high risk patients. Methylation-specific polymerase chain reaction was used to analyze methylation of the p15 and p73 genes. *Results.* We included 30 males and 21females, their median age was 23years. Precursor B phenotype was detected in 37 patients while T phenotype in 14 cases. Overall risk stratification showed 18 standard (35.3%), 27 high (52.9%) and 6 very high (11.8%) risk patients. The methylation frequencies of p15 and p73 at diagnosis were 41.2% and 27.5%, respectively. Concomitant methylation was detected in 14%. The CR rate was 80.4%. No association was encountered between CR rate and methylation of a single gene, however, concomitant methylation of p15 and p73 was associated with significant lower rate of CR compared to patients without methylation (57% versus 90%), p=0.008.The median survival of the standard risk patients was significantly longer than those of the high and very high risk group (15.8 versus 7 months respectively, p = 0.03). The p15 methylation status did not affect the overall survival but the p73 methylation was associated with poorer overall survival and the difference was near significant (p = 0.059). The survival benefit was significant for patient without methylation compared to patients with methylation of p15, p73 or both genes (p = 0.047). At 12 months, The LFS of the whole group was 67.4%. The leukemia free survival was not affected by the methylation status of a single gene p15 or p73. But it was worse in patients who have methylation of p15, p73 or both genes when compared to patients without methylation (p = 0.08). In conclusion, aberrant p73 promoter methylation is a potential prognostic factor. P15 methylation is frequent in Egyptian adult ALL patients, its concomitant methylation with p73 is of poor prognostic significance. Identification of these molecular targets results in improved risk assessment and accordingly selection of appropriate therapy.

APPLICABILITY OF NG2 FOR FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE MONITORING IN INFANTS WITH MLL-REARRANGED ACUTE LYMPHOBLASTIC LEUKEMIA

A Popov,[1] T Verzhbitskaya,[1] G Tsaur,[1] E Shorikov,[1] L Saveliev,[2] L Fechina[1]

[1]*Regional Children's Hospital / Research Institute of Medical Cell Technologies, Ekaterinburg, Russian Federation*

[2]*Ural State Medical Academy, Ekaterinburg, Russian Federation*

Background. In spite of great progress in flow cytometric minimal residual disease (MRD) detection in ALL patients in last two decades, new leukemia-associated markers searching is still a demanding task. Neuroglycan-2 (NG2), known to be expressed by leukemic blasts in patients with *MLL*-rearranged ALL, could be a valuable tumor-specific marker for MRD monitoring. Applicability of any leukemia-associated antigen for MRD detection depends on heterogeneity of its expression by tumor cells' population and on its expression modulation during treatment. *Aim.* We analyzed NG2 applicability for MRD monitoring in *MLL*-rearranged infants' ALL. *Methods.* NG2 expression and percentage of NG2-positive cells were assessed in 65 bone marrow samples from 15 infants with *MLL*-rearranged ALL: 12 samples were obtained at diagnosis, 15 - during remission induction, 18 - at post-induction follow-up, 6 - in relapses and 14 - during relapses treatment. MRD detection was performed by multicolor flow cytometry. NG2 expression was assessed by 7.1-PE antibody (Beckman Coulter, US). For comparison reasons mean fluorescence intensity (MFI) values were converted to molecular equivalent of soluble fluorochrome (MESF) units. *Results.* At the time of initial diagnostics NG2-positive cells' percentage varied from 20.60% to 95.80% (median 63.75%). Only in two patients nearly all leukemic blasts expressed NG2. NG2 MESF values at diagnosis were significantly higher comparing to post induction follow-up, relapses and relapses during treatment (p=0.0245, p=0.0032, p=0.0001 respectively). No difference in MESF values in diagnosis and remission induction was found (p=0.7551). NG2 expression in remission induction samples was also significantly higher than in later time-points and relapses (p=0.0053, p=0.004, p=0.0084 respectively). Distribution of NG2-positive cells number in tumor cells' population presented the similar differences. NG2 was heterogeneously expressed by leukemic cells' population (range 0.00%-96.80%) also in the follow-up samples. MRD values detected by standard approach were significantly higher than number of residual cells calculated according to NG2-positivity (p<0.0001). We also found no correlation between NG2 expression level and normalized copy numbers of fusion genes, measured by quantitative real-time PCR. Thus, due to leukemic population heterogeneity and significant treatment-induced downexpression NG2 cannot be applied for MRD gating, although it could be useful for previously gated cells' population description, especially in samples with low MRD-positivity. *Conclusion.* Due to leukemic population heterogeneity and significant treatment-related downexpression NG2 cannot be used as a single marker for MRD detection in infants with *MLL*-rearranged ALL. Nevertheless NG2 could be helpful as tumor-specific marker in combination with other antigens.

EVALUATION OF ESSENTIAL STEPS TO PROMOTE ADHERENCE TO CYTOTOXIC DRUGS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

L Sherief, E A Khalek, A Gharib, H Shawky

University, Zagazig, Egypt

Background. Drug adherence is important for successful therapy in children with Acute Lymphoblastic Leukemia (ALL). Poor adherence to cytotoxic drug can cause relapse of the disease, increase therapeutic costs and may lead to death. *Aim.* Evaluation of adherence to medication in leukemic children in Egypt and identify possible steps to promote adherence in these children. *Methods.* study included children with ALL in complete remission at the maintenance phase of chemotherapy and taken 6-Mercaptopurine daily oral dose. Evaluation was done through specific questionnaire to the patients or his care giver which included details about the child, his family, his illness and details about the medication given and its circumstances. Also, determination of 6- mercaptopurine (6MP) metabolites was done for all children using thin layer chromatography in red cells. *Results.* forty three children with ALL were included in this study, 22 males and 21 females with age ranged from 19 months to 12 years. Non adherence was detected by 6-MP level in 32.5% of cases, -ve results obtained in 9 patients (20.9%) and very low levels (< 4.5 ng) in 5 patients (11.6%), and 58.1% detected by the questionnaire. Non adherence was significantly associated with low educational level (76%), 30.7 % of the non adherent children belong to a lower socio economic class, forgetfulness is the main cause of non adherence (46.2%), followed by refusal of the child to take the medicine (23%) other causes include negligence 11.5% and drug unavailability (11.5%). Mothers were the caregivers in 93 % of our patients, all well knows about the illness of their children and the consequence of stopping 6 MP, all were satisfied with the instructions for treatment, and for follow-up, although 51.1% found the cost to come to the hospital high and 48.8% find the time spent in each visit long. Age, sex, number of family members was not significant association. *Conclusion.* Results suggest that non adherence is mainly in-

fluenced by the educational level of the family and the low socio-economic condition More efforts should focus on methods of assessment and prediction of adherence to medicine especially in children with cancer and studying steps to promote such adherence, further study of this problem is needed urgently especially with the more usage of oral antineoplastic drugs.

THROMBOTIC COMPLICATIONS IN ADULT PATIENTS WITH ACUTE LEUKEMIA: A SINGLE CENTER EXPERIENCE IN MÉXICO. INCIDENCE, RISK FACTORS AND SURVIVAL

E Crespo, P Guzman, A Rosas, J Zepeda

Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background. Acute leukemias are hematopoietic malignancies that may be accompanied by abnormalities in hemostasis. Thrombotic complications are the second leading cause of death in patients with cancer, and the pathogenesis is multifactorial. The use of catheters, surgery, prolonged immobilization, the start of chemotherapy (including L-asparaginase), among others, are all risk factors involved in the incidence of thrombosis. *Objectives.* To describe clinical characteristics, frequency of thrombotic events, risk factors and survival of adults with acute leukemia treated at the Instituto Nacional de Ciencias Médicas y Nutrición, "Salvador Zubirán", Mexico City. *Methods.* A retrospective cohort of adult patients, diagnosed with acute leukemia in a specialized center, from October 2003 to December 2009. Analysis of thrombotic events, frequencies and proportions, survival curves by Kaplan-Meier, univariate and multivariate analysis were performed to determine the risk of thrombosis. Informed consent was not required. *Results.* We analyzed 181 patients with a median age of 33 years, 44.2% were women and 55.8% were male. The most common subtype was acute lymphoid leukemia (ALL) with 45.8%, being phenotype B the most frequent with 87.95%. Fifteen cases with thrombosis (8.3%) were documented, of which 53.3% were related to the use of a catheter, followed by DVT in 26.7%, acute myocardial infarction (AMI)/ischemic stroke in 13.3% and PE in 6.7%. Doppler ultrasound was the preferred diagnostic tool in 80% of cases, and the median time to develop thrombosis was 92 days, with 33.3% of events occurring during the first 30 days of diagnosis. L-asparaginase was administered in 11% of the patients, and only in 3 cases of this group (1.6%) an episode of thrombosis was also recorded. With regard to mortality, of the 15 patients with thrombosis, 27% were alive without evidence of disease at last follow-up, and 73% had died, being disease progression (48% of cases) the most common cause of death. We did not find recurrent episodes of thrombosis, and none of the events had an impact on mortality. There were no risk factors related to thrombosis in our study. The median overall survival was 349 days (range 257 to 440 days), with a follow-up of 3.5 years. *Conclusions.* The present study confirms that the incidence of thrombosis in this mexican adult population is comparable to that reported around the globe. However, only a third of these cases were diagnosed during the first month, contrary to what has been published in recent series. And, although catheter-related thrombosis was the most frequent event in this group, our study did not confirm that this or any other factor (age, subtype of leukemia, type of chemotherapy, platelet count or WBC at diagnosis) were associated with an increased risk of thrombosis or that the thrombosis per se could be considered a negative prognostic factor regarding overall survival.

PULMONARY COMPLICATIONS IN SURVIVORS OF CHILDHOOD HEMATOLOGICAL MALIGNANCIES:SINGLE CENTER EXPERIENCE

A Tantawy,[1] N El Barbary,[2] A El Sharkawy,[2] N Mohamed,[2] S Ezz-Elarab[3]

[1]*Faculty of Medicine, Ain Shams University, Cairo, Egypt*
[2]*Faculty of Medicine, Ain Shams University, Cairo, Egypt*
[3]*Ain Shams University Hospitals, Cairo, Egypt*

Background. Children treated for cancer face the risk of complications later in life, including pulmonary dysfunction. *Aim of study.* To evaluate the frequency and severity of pulmonary complications in survivors of childhood leukemia and lymphoma treated with chemotherapy alone or combined with radiotherapy. *Methods.* 70 childhood cancer survivors (44 males and 26 females) were enrolled in this study after parental consent.They included survivors of acute lymphoblastic leukemia (n=25), acute myeloid leukemia (n=5), Hodgkin disease (n=20) and non Hodgkin lymphoma (n=20).Their age at diagnosis varied between 1-14 years (median 4 years), and their age at evaluation varied between 3-25 years (median 10 years). Exclusion criteria included the presence of primary or secondary disease in the thorax, recent major surgery, previous thoracic surgery, known major non neoplastic lung disease, bone marrow or stem cell transplantation. Patients having evidence of chest infection at time of evaluation were temporarily excluded till at least four weeks after resolution of infection.Pulmonary complications were assessed through history taking, chest examination, high resolution computed tomography (HRCT) chest, and pulmonary function testing (PFTs). *Results.*Although most survivors had no clinical pulmonary compromise,40% had abnormal PFTs including: (14.3%) obstructive pattern, (5.7%) restrictive pattern and (20%) mixed pattern. There was no difference in PFTs between the groups in relation to malignancy diagnosis(P=0.37). Significant pulmonary dysfunction was seen in children older than 10 years of age at evaluation (P=0.003). Duration since completion of therapy was not signicantly related to PFTs in multivariate analysis. Patients treated with combined chemotherapy and radiotherapy showed higher percentage of complications (72.7%) compared to those treated with chemotherapy alone (25%) (P=0.001). Cumulative dose of Bleomycin caused significant abnormal PFTs compared to other chemotherapeutic agents (P=0.04),whereas administration of methotrexate was a significant factor related to pulmonary dysfunction(p=0.002). Only male patients who received combined therapy showed higher frequency of both restrictive and obstructive lung disease, abnormal respiratory reactance and peripheral airway disease when compared to chemotherapy only group (P=0.007, P=0.04, P=0.002, P=0.003, P=0.05 respectively), there was no significant difference in female patients. Survivors with abnormal CT chest findings (n=14) had lower FVC%, FEV1% and PEF% when compared to individuals with normal CT (P=0.001, P <0.001, P=0.001 respectively). *Conclusion.* Subclinical pulmonary function abnormalities are found in survivors of childhood hematological malignancies previously treated and off therapy .Pulmonary dysfunction is more evident with combined chemotherapy and radiotherapy. Bleomycin and methotrexate are the most incriminated chemotherapeutic agents,and males are at higher risk than females. Specific and extended follow up is warranted especially in the presence of risk factors or previously detected pulmonary problems.

DO NATURAL KILLER CELL KILLER IMMUNOGLOBULIN-LIKE RECEPTOR GROUP GENETICS AFFECT RISK OF ACUTE MYELOID LEUKAEMIA DEVELOPMENT AND TREATMENT OUTCOME?

K Stringaris,[1] J Barrett,[2] R Hills,[3] D Linch,[4] R Sergeant,[1] K Rezvani,[1] J Apperley[1]

[1]*Imperial College London, London, United Kingdom*
[2]*Hematology Branch, NHLBI, National Institutes of Health, Bethesda, United States of America*

[4]*UCL Cancer Institute, University College London, London, United Kingdom*

Characterising natural killer cell (NK) reactivity using Killer Immunoglobulin-like Receptor (KIR) genetics has proven useful in predicting outcome of haematological malignancy after stem cell transplantation (SCT). We recently showed that stem cell donors with the activatory NK receptors KIR 2DS1, 3DS1 and the co-inherited 2DL5a, were associated with less relapse following T-deplete SCT for de novo Acute Myeloid Leukaemia (AML) but not other haematological malignancy. Interestingly, this effect was not seen in secondary AML. To investigate whether KIR genetics also affect AML biology outside the context of SCT, we performed KIR genotyping on DNA obtained at diagnosis from patients enrolled on the Medical Research Council (MRC) AML 10 and 15 trials. Patients received four courses of chemotherapy according to MRC protocols. KIR genes were identified using Qiagen© SSP PCR KIR genotyping kits. The frequency of KIR genes in 469 de novo and 38 secondary AML patients was compared to the gene distribution in a normal control population of 246 donors. HLA typing for KIR ligands (Cw, Bw, A3, A11) in AML patients was performed and combined with KIR genotype data to identify individuals missing an HLA ligand for their inhibitory KIR. In de novo AML, the KIR gene frequency did not differ significantly from the normal control population. However, in secondary AML (related to prior therapy, MDS or MPD), the frequency of the activating KIR 2DS2 was significantly lower (26%) than in normal controls (44%) or de novo AML (51%) (p=0.004). The activatory KIR haplotype B was also less common in individuals with therapy-related AML than in those without therapy-related AML (27% v 67%, p=0.005). In contrast to our previous findings in AML SCT, the activatory KIR 2DS1, 3DS1 and the coinherited 2DL5a, were not associated with improved outcome after chemotherapy for either de novo or secondary AML. HLA typing data for KIR ligands and KIR genotype data was combined in a model to predict those with the most activatory NK populations. The results of this analysis of KIR frequencies and HLA groups together in AML patients will be presented.

Background. Germ line loss of function SPRED1mutations are associated to Legius syndrom (LS), an autosomal dominant condition characterized by café au lait macules, freckling and sometimes Noonan-like appereance or learning difficulties. SPRED 1 is a member of Sprouty/Spred family of membrane associated negative regulators of ERK activation. SPRED1specifically inhibits MAPKs signaling by suppressing RAF phosphorylation and activation. We preaviously reported a case of AML in a 11-month old boy with SPRED1 germline mutation. *Aims.* We sought further explore the possible involvement of SPRED1 alterations in paediatric leukemia. *Methods.* We performed whole gene SPRED1 mutation screening at genomic and RNA levels as described (Passmant 2009) in 210 leukemia diagnostic samples: 67 AML, 140 Lymphoblastic Acute Leukemias (ALL), and ten Juvenile MyeloMonocytic Leukemia, JMML. AML samples were screened for NRAS, Ki-RAS, PTPN11, B-RAF1, FLT3-ITD, gene mutations. SPRED1 expression level was quantified by RQ-RT-PCR in diagnostic leukemic (32 AML, 54 ALL, 5 JMML) and in paired normal bone marrow samples obtained at the complete remission (CR), (32: 28 AML and 2 ALL). Physiological level of SPRED1 expression was determined in normal hematopoietic cells (10 healthy donors Bone Marrow, BM, one CD34+ sample, one thymus and 5 blood mononuclear cells). SPRED1, ERK1/2 and MEK protein expression and phosphorylation were evaluated by Western Blot and IHC on normal (BM, AML samples at CR) and pathological samples (AML at the diagnosis). *Results.* Three novel SPRED1 heterozygous nucleotide variations were identified in two B-ALL and one AML: one isosemantic transition c.674C>T, and two missense mutations: c.124G>A (p.Val42Ile) and c.1089A >G (pIle363Met). These nucleotide variations were confirmed in leukemia RNA at the time of diagnosis and in the remission BM. Patients did not have phenotypic features of Legius syndrome or other NF1 like diseases. SPRED1 expression was significantly decreased in AML compared to ALL (p<10-3) and normal hematopoietic samples (p <10-5). SPRED 1 expression levels varied among AML samples from 10-1 to 10-3 fold the amount measured in the normal BM. Lowest levels were correlated to FLT3 ITD mutations (p = 0.008) and highest with N-RAS mutations (p= 0.013). In AML -paired complete remission samples SPRED1 expression rose to a level similar to those of normal BM. This normalization of SPRED1 expression was correlated to the decrease of MEK/ERK protein expression and phosphorylation. *Conclusions.* SPRED1 mutations are rare in paediatric leukemia. The three novel variations described are germline mutations not associated to any characteristic feature of Legius syndrome. SPRED1 expression is strongly inhibited in the vast majority of AML both at transcript and protein levels. The loss of SPRED1 protein contributes to the loss of inhibition of MEK and ERK activation and to the increase of phospho-ERK1/2 et phosphor-MEK. This is the first observation of a role of SPRED1 gene in the signalling RAS-dependent cascade in children AML.

SMALL SUBPOPULATIONS OF NG2 EXPRESSING BLASTS IN THE CONTEXT OF A PANMYELOID IMMUNOPHENOTYPE PREDICT FOR INVERSION INV(16) IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

U Oelschlaegel, B Mohr, M Bornhäuser, M Kramer, M Schaich, C Röllig, G Ehninger, C Thiede

University Hospital Dresden, Dresden, Germany

Background. Individualized treatment is currently developed in the context of AML therapy. As a first step into this direction, treatment stratification based on cytogenetic or molecular aberrations is implicated in many current treatment protocols. Cytogenetic or molecular testing of reciprocal translocations is still the basis of this approach, but takes at least one or two days to be assessed. Flow cytometry is a standard procedure performed in the diagnostic workup of patients with AML. Recent work has shown that flow cytometric immunophenotyping allows for rapid prediction of several important cytogenetic or molecular aberrations, e.g. t(8;21), 11q23, or *mNPM1* gene. *Aim.* The aim of the present study was to identify an immunophenotypic pattern predicting the presence of inv(16) in AML patients. *Methods.* An 8-color approach (until 2006 3-color) was performed for diagnosing AML. Therefore, a FACS-Canto II (until 2006 FACS-Calibur; BD Biosciences) was used. 1,421 AML patients treated in different multicenter studies of the SAL study group were included. The NG2 monoclonal antibody (moAB 7.1, Beckman Coulter) has been used to predict the presence of aberrations at chromosome 11q23 (MLL gene) in AML and ALL, but no association was reported for inv(16) so far. The inv(16) and/or *CBFβ-MYH11* was detected in 85 patients using FISH as well as PCR. *Results.* As a first step, the panmyeloid antigen expression (CD13+CD33+CD117+cyMPO+CD34+), CD14, or aberrant CD2 expression was shown to reach only a moderate sensitivity or specificity: 100%/71%, 59%/92%, and 28%/98%. Second, we discovered that the consideration of a low NG2 expression (1%-19%) as a unique marker was already highly sensitive and specific

(80%/95%) in predicting inv(16). The combination of NG2 and pan-myeloid antigen expression only increased specificity to 99%. Finally, an integrated antigen pattern using NG2 expression plus all the above mentioned phenotypic characteristics lead to a sensitivity and specificity of 95% and 96%, respectively. Two of the 4 false negative patients showed a complex karyotype including trisomy 8. Three of those 4 patients did not achieve a CR, were MRD positive after induction therapy, or relapsed later. *Conclusions.* Using the immunophenotypic characteristics described above it was possible to predict the presence of inv(16) in AML with a high sensitivity and specificity of at least 95%. Since inv(16) is sometimes hard to assess in standard metaphase preparations and requires secondary confirmation using FISH or PCR assays, flow cytometry might provide a fast and reliable screening method for rapid risk-based treatment stratification.

0576

FREQUENCY AND PROGNOSTIC SIGNIFICANCE OF MONOSOMAL KARYOTYPE IN ACUTE MYELOID LEUKEMIA

A Voutiadou, G Papaioannou, M Gaitatzi, O Asteriou, Z Lazarou, C Lalayanni, C Vadikoliou, A Anagnostopoulos, A Athanasiadou

G. Papanicolaou Hospital, Thessaloniki, Greece

Monosomal karyotype (MK), defined as 2 or more monosomies, or a single monosomy in the presence of structural abnormalities, has recently been reported as identifying a distinct subset of acute myeloid leukemia (AML) with an extremely poor prognosis. We retrospectively evaluated all AML cases with MK diagnosed in our Department over a period of 13 years and explored potential associations with clinicobiological features and outcome. Overall, karyotypic data obtained from conventional cytogenetic analysis of unstimulated bone marrow cells were available in 549 AML cases. In our series, MK was found at a frequency of 11.3% (62/549 cases), similar to what has been reported recently in an independent patient cohort. Ninety-two percent (57/62) of MK cases were found to have a complex karyotype. Additionally, 98% (61/62) of MK cases were assigned to the unfavorable cytogenetic risk category. The median age of MK cases was 60.5 (range, 18-88) years. MK increased with age, being present in 5.5% of cases below the age of 30 but in 15% of those over age 60 (X2-test: P=0.022). Of 51 cases with available data, 24 (47%) concerned secondary AML, whereas the remaining 27 cases (53%) were de novo AML. At diagnosis, the median white blood cell count of MK cases was 3.25x109/l (range, 0.7-82) and the median LDH value 349 IU (range, 100-3360). For statistical purposes, MK cases were compared to a group of 51 AML cases with unfavorable karyotypic profile yet without MK (UWMK) who were treated with similar, "3+7"based regimens. Complete remission rates after induction treatment were 37% in UWMK patients versus 27% in those with MK (P=0.33). The median overall survival (OS) of UMWK patients was 15 months versus only 6.5 months in those with MK, with 3-year OS rates of 16% and 8%, respectively MK (P =0.003). Thus, MK defines a sizeable subset of patients with unfavorable cytogenetics, often with secondary AML and advanced age, who have a particularly poor prognosis even when compared to other cases with an unfavourable cytogenetic risk profile.

COMPARISON OF PROGNOSTIC MARKES IN ACUTE MYELOID LEUKEMIA EXCLUDING PROMYELOCYTIC LEUKEMIA

M Mello, D Albuquerque, K Albanez, R Adam, F Pereira-Cunha, K Pagnano, F Costa, K Metze, I Lorand-Metze

University of Campinas - UNICAMP, Campinas, Brazil

Background. Recently, several cytogenetic and molecular features, such as FLT3 alterations and NPM1 gene mutation, have been described in acute myeloid leukemia (AML). On the other hand, variables of nuclear chromatin texture have been described as independent risk factors in several malignancies (ALL, melanoma, multiple myeloma). *Aims.* Analyze the correlations of molecular features, morphometric characteristics and methylation and compare the influence on overall survival in adult patients with AML. *Methods.* Diagnosis was made by bone marrow (BM) cytology and karyotype, and cases were classified by WHO criteria. Cases of promyelocytic leukemia were excluded. We examined mutations of FLT3 and NPM1, besides methylation of p15, p16, p57, p73 and ER. Blasts from the diagnostic BM cytology were digitalized and interactively segmented. We studied nuclear texture variables derived from the co-occurrence matrix and fractal dimension. We compared the influence on overall survival of cytogenetic, molecular and nuclear texture features on overall survival of the patients. *Results.* We studied 86 cases of AML. Median age: 54 years. PB leukocytes: 30.0x10^9/l. In 61 cases the karyotype was available: 6 had a low risk karyotype, 34 had a normal, 4 had an otherwise intermediary risk and 17 a high risk karyotype. FLT3-TKD mutation was found in 8.2%, FLT3-ITD in 23.5% and 29.4% had NPM1 mutation (44.0% of these had also FLT3-ITD). p15 was methylated in 26.7%, p16 in 11.6%, p57 in 1.2%, p73 in 23.3% and ER in 3.5% of the patients. Blast nuclei of AML without maturation showed higher entropy (p=0.008), contrast (p=0.024), energy (p=0.049) and diagonal moment (p=0.016) and lower a second angular moment (p=0.008). In the univariate Cox analysis were significant: PB leukocytes (p=0.09), FLT3-ITD mutation (p=0.09), local homogeneity (p=0.1), cluster prominence (p=0.08) and "goodness of fit"($R^2$45) of the chromatin fractal dimension according to Minkowski (p=0.07). In multivariate analysis the FLT3-ITD mutation (p=0.001) and $R^2$45 (p=0.025) were independent factors of poor and good prognosis, respectively. Karyotype alone had no influence on survival. *Conclusions.* In our study, FLT3-ITD and chromatin fractal characteristics were more important risk factors for overall survival than karyotype and gene methylation status.

LAG3 (LYMPHOCYTE-ACTIVATION GENE 3) IS AFFECTED BY DNA HYPERMETHYLATION IN AML AND MDS PATIENTS

H Hajkova

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

LAG3 (lymphocyte-activation gene 3) is involved in T-cell regulation as an activator of antigen-presenting cells through MHC class II signaling, leading to increased antigen-specific T-cell responses *in vivo*. The aim of this study was to identify T-cell regulation genes, which are influenced by DNA methylation. *LAG3* is one of these genes, which inactivation through aberrant DNA methylation could contribute to the ability of cancer cells to escape the control of immune system (IS). Mononuclear cells (MNC) from peripheral blood or bone marrow of 10 de novo AML patients at diagnosis (age 42-65, median 58), 8 MDS patients (age 60-85, median 65) and 4 healthy donors (age 42-55, median 49) were subjected to methylation analysis. Informed consent from all AML and MDS patients were obtained. Besides *LAG3* other 23 genes involved in T-cell regulation were studied using methylation-restriction endonucleases followed by RQ-PCR. Bisulfite sequencing was used to validate these results and to extend number of examined samples. Levels of *LAG3* gene expression were measured by TaqMan gene expression assay. The restriction-based methylation analyses showed hypermethylation of 7 genes in AML and 6 genes in MDS patients. *LAG3* is one of the most promising. Frequency of hypermethylation of this gene was as follows: 5/10 AML and 3/8 MDS patients compared with 0/4 healthy donor samples. Further we made bisulfite sequencing that confirmed the same DNA methylation frequency of *LAG3* gene in other 8 AML patients. By both methods we examined DNA methylation status of *LAG3* gene in altogether 18 AML patients. We also performed gene expression profiling of *LAG3* on the subset of 19 AML patients at diagnosis and 11 healthy controls. We have found significant downregulation of its expression in AML patients at diagnosis. Our data suggest that hypermethylation of *LAG3* could play a role during process of leukemogenesis and contribute to molecular mechanisms of escape from immunological surveillance. It is a very promising gene to further evaluate its potential prognostic impact on disease outcome.

This study is part of the COST Action BM0801 (EuGESMA) and is supported by OC10042 and IHBT00023736. *hajkova@uhkt.cz*

Acute promyelocytic leukemia is characterized by the chromosomal translocation t(15;17), resulting in the formation of PML-RARA gene.

Animal models have shown although this fusion protein is necessary it is not sufficient for leukemia development. We generated FISH probes by sequence independent amplification for chromosomal regions which have been described as altered in APL patients. The following loci were used to analyze a series of 23 APL patient samples after obtaining the inform concent:TP53, MYC, CDKN2A, CDKN1B, RB1, RASA3, NF1, hTERT, ERG, ABCB1 and the region between PML and telomere of chromosome 15. We detected regions which are well-known to be amplified like 8q24 or deleted like 17p13 in APL, along with others like 15q24.1-qter which may harbor novel tumor suppressor gene. Deletions were detected in CDKN2A locus (30% cases), CDKN1B (26% cases), RB1 (26% cases), P53 (17% cases), ABCB1 (43% cases), PML-TEL (22%cases) and hTERT (30%cases). Duplications were also detected in MYC (13% cases), ERG (4%), NF1 (4%), and PML-TEL(4%). Our FISH assay confirmed the accuracy by which DNA copy numbers were detected by BAC array CGH in these tumor suppressors and oncogenes loci in different studies.Taken together, these results suggest that the PML/RARA fusion gene needs several other cooperating genetic lesions to cause APL.

[2]*University of Oslo, Oslo, Norway*

Valproic acid (VPA) has been introduced for relapsed advance Acute Myeloid Leukemia (AML) in clinical trials. Only a subset of patients respond to this treatment. Using the Brown Norwegian Myeloid Leukemia rat as model of progressive disease under VPA therapy, we screened the phosphoproteome for molecular targets of VPA. The preclinical rat model Brown Norwegian Myeloid Leukemia (BNML) was treated with 170 mg/kg VPA twice-daily, demonstrating significant increases in survival in comparison to controls ($p = 0.004$). To screen for molecular targets of VPA in this highly responsive model, phosphoproteome analysis was performed by difference gel electrophoresis (DIGE) separation and subsequent differential gel software analysis. Phosphoproteins were isolated from leukemic blasts in the spleen prior to harvesting by immobilized metal ion affinity chromatograpy (IMAC) and identification via Orbitrap mass-spectrometry. Seven of the phosphoproteins found to be significantly differentially expressed in VPA treated BNML rats compared to controls, were investigated for functionality. This was performed by RNAi in Bristol N2 strain of C. elegans at larval stage L1, 24 hours prior to exposure to 15 mM VPA for 72 hours. 4 of 7 gene knock-downs resulted in larval developmental arrest, defined as synthetic lethality. To investigate whether this lethality was a result from apoptosis the CED-1::GFP transgenic reporter assay was employed to quantify germline cell death following RNAi depletion and VPA exposure. Results showed increased numbers of apoptotic corpses by all genes examined. Knock-down of the 4 candidate genes in the transgenic cep-1::CED-1::GFP expressing C. elegans p53 ortholog, CEP-1, resulted in increased basal level of germline apoptosis independent of CEP-1. This suggests that a similar combinational treatment of AML patients might be benefitial, regardless of p53 status. Human AML cell line MOLM-13 was co-treated with VPA and a small molecule inhibitor against prospective target ACTB, cytochalasin B, to test this hypothesis. Inhibition of actin polymerization resulted in increased apoptosis and decreased proliferation when supplemented by VPA, as determined by DNA specific staining with Hoechst and WST-1 colorimetric assay respectively. Results indicate combination of such drugs may be beneficial in treatment of AML. Further, we used a chemical genetics synthetic lethal RNAi screen in Caenorhabditis elegans to a) explore the mechanisms of VPA regulated phosphoproteins, b) unravel why a subset of primary AML cells proliferate after treatment with VPA, c) find novel interactors of VPA by exploring chromatin associated genes, and d) find new targets for combination treatment with VPA. Indeed, we were able to discover novel genes, which increased the effect of VPA *in vitro*, in all screens. Interestingly, we identified 15 genes involved in suppression of VPA amongst the chromatin associated genes. Especially the enhancer of VPA SERBP1 (phosphoprotein screen), and suppressor UTX (chromatin gene screen) were of interest. UTX is shown to be somatically mutated in several cancers. We conclude that novel therapeutic targets can be targeted to increase the efficacy of VPA in AML.

Background. AML is a clinically and biologically heterogeneous disease entity that constitutes 15% to 20% of childhood leukemia. Historically, treatment of AML has been ineffective but identification of disease subgroups and risk stratified treatment based on genetic markers and treatment response has improved prognosis over the last decades. Apart from cytogenetic aberrations, additional genetic markers have been identified as possible prognostic markers, including the mutation status of the *FLT3*, *NPM1*, *CEBPA* and *WT1* genes as well as gene expression levels of *ERG*, *MN1* and *BAALC*. The prognostic significance of mutations in *FLT3*, *NPM1*, *CEBPA* and *WT1* has been thoroughly studied in adult AML but there are also many studies performed on childhood AML. However, gene expression of *ERG*, *MN1* and *BAALC* and their prognostic relevance in pediatric AML have to our knowledge not been studied. Furthermore, most studies have not investigated all

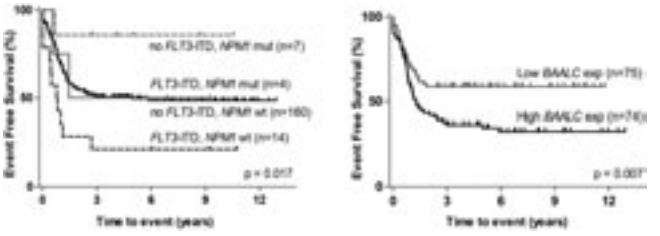

Figure 1. Kaplan-Meier curves.

these genetic markers in relation to each other and most studies have only focused on normal karyotype AML (CN-AML). *Aim.* To perform a thorough evaluation of *FLT3*, *NPM1*, *CEBPA* and *WT1* gene mutations as well as *ERG*, *MN1*, *BAALC*, *FLT3* and *WT1* gene expression as prognostic markers in pediatric AML, all treated within the same NOPHO protocols, and compare their prognostic strength in relation to each other. *Method.* The presence of *FLT3*, *NPM1*, *CEBPA* and *WT1* gene mutations and gene expression levels of *ERG*, *MN1*, *BAALC*, *FLT3* and *WT1* were investigated in 213 pediatric AML samples collected at diagnosis. All patients were enrolled in the NOPHO 1993 or NOPHO 2004 protocols. *Results.* The following results were obtained. 1) *FLT3*-ITD, *NPM1*, *CEBPA* and *WT1* mutations were most common in CN-AML pediatric AML and they commonly co-existed. 2) The presence of *FLT3*-ITD in the absence of *NPM1* mutation was associated with significantly shorter event free survival (EFS), see K-M curve. 3) The presence of an *NPM1* mutation in the absence of an *FLT3*-ITD correlated with improved EFS (see K-M curve) and the presence of an *NPM1* mutation was associated with a better overall survival (OS) in patients with normal karyotype (p=0.038). 4) No significant correlation with survival was found for *FLT3*-TKD, *CEBPA* or *WT1* gene mutations. 5) Gene expression levels of *ERG*, *MN1* and *BAALC* displayed a strong positive correlation with each other. 6) High levels of *ERG* and *BAALC* transcripts at diagnosis were associated with a significant shorter EFS (*ERG* p=0.002 and *BAALC* see graph). 7) No significant correlation with survival was found for *MN1*, *FLT3* or *WT1* gene expression. 8) In multivariate analysis, the presence of *FLT3*-ITD and high *BAALC* gene expression were independent markers for lower EFS. *Conclusions.* We can therefore conclude that analyzing the mutational status of *FLT3* and *NPM1* at diagnosis is important for correct prognostic stratification of pediatric AML patients and that determining the *ERG* and *BAALC* gene expression levels can add valuable information.

0582

ROLE OF SERINE339 IN CXCR4-MEDIATED MIGRATION, HOMING AND ENGRAFTMENT OF LEUKEMIC CELLS

L Brault,[1] S Thommen,[1] A Tzankov,[2] J Schwaller[1]

[1]*University Hospital Basel, Basel, Switzerland*
[2]*Institut of Pathology, Basel, Switzerland*

Background. The CXCR4 chemokine receptor is a major regulator of cell migration, and its overexpression has been associated with a poor prognosis notably in acute myeloid leukemia (AML). We have recently shown that the PIM1 serine/threonine kinase mediates phosphorylation of the serine residue 339 in the intracellular C-terminal tail of the receptor that interferes with CXCR4 receptor recycling and signaling. *Aim.* To study the role of Ser339 phosphorylation in CXCR4 mediated homing and migration, we stably expressed wildtype CXCR4 (WT) or CXCR4 mutants that abrogate phosphorylation (S339A) or imitate constitutive phosphorylation (S339E) in Kasumi-1 human AML cells lacking endogenous CXCR4 expression. *Methods.* The impact of these mutations on CXCR4 function was studied by measuring receptor internalization/recycling and downstream signals by cellular imaging, flow cytrometry and Transwell migration assay. *Results*. In the presence of the ligand (CXCL12), both the normal and mutated receptors were internalized. Recycling of the receptors was observed for all variants with a slight but significant increased recycling capacity of the S339E variant. Expression of both CXCR4 mutants resulted in enhanced ERK activation when compared to the WT receptor. Intracellular calcium efflux upon ligand binding was markedly affected by the mutations: expression of CXCR4-S339A resulted in an increased efflux whereas expression of CXCR4-S339E was associated with decreased efflux when compared to WT CXCR4. Functionally, expression of WT or mutant CXCR4 was able to restore migration capacity towards CXCL12. Expression of the mutant receptors resulted in increased chemotaxis associated with increased chemokinesis (random migration capacity). Transplantation experiments in NOD-SCID-IL2 -/- (NSG) mice allowed addressing the role of Ser339 in homing and engraftment. In contrast to mock-transduced cells, Kasumi-1 cells expressing WT CXCR4 showed efficient bone marrow homing and engraftment measured 24 hours and 7 days after transplantation. Interestingly, cells expressing the CXCR4-S339A or CXCR4-S339E mutant showed a significantly impaired homing and engraftment capacity. However, long-term expansion (measured 7 weeks post transplant) of grafted cells from the epiphyseal area to the diaphysis of the long bones was observed for all variants, suggesting that CXCR4-S339 may play a prominent role during the process of homing and engraftment in the bone marrow rather than during expansion of the leukemic cells. Homing and engraftment was mostly directed to the bone marrow with only sporadic presence of cells in other CXCL12 expressing organs such as the spleen, the liver, or the meningeal space. Interestingly, *in vitro* adhesion and detachment assays revealed that cells expressing the CXCR4 mutants showed an increased adhesion capacity that correlated with their chemotactic potential. In addition, they displayed significantly reduced detachment properties when compared to cells expressing CXCR4-WT supporting the reduced homing capacity observed *in vivo*. *Conclusions.* Our data suggest that Ser339 phosphorylation is likely to act as an important fine-tuning mechanism for CXCR4-mediated adhesion, homing and migration of leukemic cells. Targeted interference with phosphorylation of Ser339 may therefore constitute a novel strategy to therapeutically control CXCR4 functions in normal and malignant cells.

0583

SEQUENTIAL GENOMIC PROFILING IDENTIFIES POTENTIAL DRIVER ABERRATIONS IN ACUTE MYELOID LEUKEMIA FOLLOWING MYELODYSPLASTIC SYNDROME

G Rücker, J Gohlke, C Blersch, L Bullinger, S Kayser, R Schlenk, H Döhner, K Döhner

University Hospital of Ulm, Ulm, Germany

Background. Myelodysplastic syndromes (MDS) are clonal stem cell disorders characterized by ineffective hematopoiesis leading to peripheral cytopenia. MDS patients exhibit an increased risk of progression towards secondary acute myeloid leukemia (sAML) with poor prognosis. The mechanisms underlying transformation from MDS to sAML are largely unknown. *Aims.* To identify genetic lesions that are associated with leukemogenesis we performed sequential genome-wide human single-nucleotide polymorphism (SNP) array 6.0 profiling in 32 MDS [WHO categories: RA (n=3), RCMD (n=10), RAEB-I (n=5), RAEB-II (n=8), CMML-2 (n=1), not classified (n=5)] and the corresponding sAML samples. *Results.* In total, 22 (69%) patients acquired additional genomic aberrations (copy number alterations [CNA] and/or uniparental disomies [UPD]) at diagnosis of sAML as compared to the corresponding MDS sample. The most frequent acquired numerical aberration was trisomy 8 (n=6) followed by monosomy 7 (n=3); recurrent submicroscopic losses were identified at 17q11.2 (n=6) encompassing *NF1*, and at 21q22.12 (n=2) including *RUNX1*; of note, biallelic 17q11.2 and 21q22.12 losses were detected in one sAML each. Acquired UPD were detected in 6 (19%) cases affecting the following chromosomal regions: 1p (n=1), 11q (n=1), 13q (n=1), 20q (n=1), and 21q (n=2). Paired sequencing of candidate genes in 1p and 13q revealed UPD related homozygous mutation patterns for pre-existing heterozygous *NRAS* (p.G12S; chromosomal band 1p13.2) and *FLT3* (internal tandem duplication; 13q12.2) mutations in the corresponding sAML cases. Paired sequencing analysis of candidate genes known to be mutated in AML (*NPM1*, *TP53*) revealed that in both *NPM1* mutated sAML cases the mutation was already present at the time of MDS (RCMD each) diagnosis suggesting NPM1 mutations to be an early event in malignant myeloid transformation. In contrast, we also observed the acquisition of novel mutations during transformation. For example, a case initially diagnosed as RCMD with 5q- acquired a $TP53^{V173M}$ mutation during transformation to sAML with complex karyotype. Further analyses of candidate genes with potential leukemogenic relevance, in particular those mapping to 11q (*MLL*, *CBL*) and 21q (*RUNX1*) are currently underway. On the other hand, genomic profiling of one sAML case following 5'-azacitidine treatment of RAEB-II identified a normal genomic status in 11q and 13q, two regions found to be gained in the corresponding MDS sample. This suggests that these aberrations are not necessarily linked to transformation, and that distinct pre-existing clones might be selected by treatment for progression to AML. *Summary/Conclusions.* In our study more than two thirds of MDS cases ac-

quired additional genetic abnormalities during progression to sAML. Homozygous mutation patterns of known oncogenes, such as *NRAS* and *FLT3*, as well as complete loss of tumor suppressor genes or transcription factors, such as *NF1* and *RUNX1*, seem to play an important role in disease progression. Novel molecular analyses like next generation sequencing will facilitate to disclose additional genomic/genetic aberrations involved in this multistep process.

0584

GENOME-WIDE ANALYSIS OF REVERSIBLE EPIGENETIC ALTERATIONS MEDIATED BY RUNX1/ETO

A Ptasinska,[1] S Assi,[2] S James,[1] M Hoogenkamp,[1] P Cockerill,[1] D Westhead,[2] O Heidenreich,[3] C Bonifer[1]

[1]*Leeds Institute of Molecular Medicine, Leeds, United Kingdom*
[2]*Institute of Molecular and Cellular Biology, Leeds, United Kingdom*
[3]*Newcastle University Northern Institute for Cancer Research, Newcastle, United Kingdom*

The reciprocal translocation of chromosomes 8 and 21, t(8;21), results in the formation of the RUNX1/ETO fusion gene that initiates acute myeloid leukaemia by recruiting co-repressor complexes to DNA. RUNX1/ETO interferes with the function of its wild-type counterpart, RUNX1, by directly targeting RUNX1 binding sites. However, the expression of RUNX1/ETO alone does not result in leukaemia and requires secondary mutations and currently it is unclear to which extent the precise epigenotype of t(8;21) cell depends on the presence of the original tumorigenic stimulus. The main purpuse of our study was to (i) identify RUNX1/ETO bound target regions, (ii) determine the chromatin structure of RUNX1/ETO target regions and (iii) most and foremost investigate to which extent these features can be reprogrammed by the selective removal of RUNX1/ETO. To this end, we used a combination of small interfering RNA-mediated RUNX1/ETO depletion, DNaseI accessibility studies, genome-wide chromatin immunoprecipitation (ChIP-seq) and expression profiling in t(8;21) carrying cell lines and cells from patients. RUNX1/ETO was found to co-localize with RUNX1, demonstrating that the fusion protein follows the binding pattern of the wild type protein but does not function primarily by displacing it. We also demonstrate that the RUNX1 binding profile and the sequence composition of RUNX1 binding cis-regulatory elements in t(8;21) and non-t(8;21) leukaemic cells is different. Integrated analysis of gene expression profiles and the RUNX1/ETO ChIP-seq readout showed that genes containing RUNX1/ETO binding sites are mostly up regulated by RUNX1/ETO knockdown. Depletion of RUNX1/ETO resulted in decreased expression of early myeloid progenitor antigens and increased expression of genes typical for differentiated myeloid cells, such as SPI.1, c-FMS, C/EBPalpha, BPI as well as the antiproliferative genes IGFBP7 and SLA. We also show that depletion of RUNX1/ETO leads to an increase of H3K9 Acetylation and RNA Polymerase II at RUNX1/ETO bound genes. Finally we demonstrate that the level of DNA-methylation is inversely correlated with the level of gene expression, DNAseI accessibility, H3K9Ac and H2AZ recruitment. However, even prolonged RUNX1/ETO depletion does not significantly influence DNA methylation, indicating that the relief of epigenetic silencing of tumour suppressor genes requires additional therapeutic strategies.

0585

CO-INHIBITION OF MDM2 AND HDAC SYNERGISTICALLY ACTIVATE P53 MEDIATED APOPTOSIS IN ACUTE MYELOID LEUKEMIA *IN VITRO* AND *IN VIVO*

T Gjertsen, I Haaland, G Venås, R Forthun, S Huseby, G Gausdal, S Knappskog, D Micklem, Ø Bruserud, J Lorens, E McCormack

University of Bergen, Bergen, Norway

Although TP53 mutations are rare in acute myeloid leukemia (AML), wild-type p53 function is habitually annulled through over expression of MDM2 or through various mechanisms including epigenetic silencing via histone deacetylases (HDACs). We hypothesized that binary antagonism of MDM2 and HDACs, with nutlin-3 and valproic acid would additively inhibit growth in leukemic cells expressing wild-type TP53 and induce p53-mediated apoptosis. *In vitro* studies with the combination demonstrated synergistic induction of apoptosis in AML cell lines and patient cells. Mechanisms included massive induction of p53, acetylated p53 and p53 target genes in comparison to either agent alone. The inhibitory effect of the combinational therapy upon proliferation was correlated to the clinical parameters of the patients, where CD34

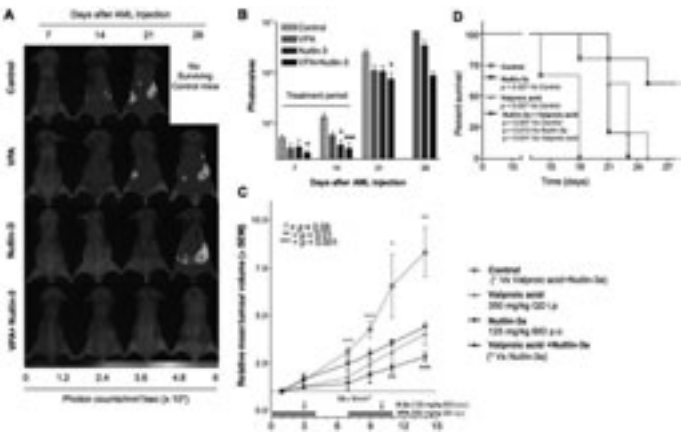

Figure 1.

negative patient samples demonstrated significantly better response in comparison to CD34 positive samples. To evaluate the combination *in vivo*, we developed an orthotopic, NOD/SCID IL2rγnull xenograft model of MOLM-13 (AML FAB M5a; wt TP53) expressing firefly luciferase. Survival analysis and bioluminescent imaging demonstrated the superior *in vivo* efficacy of the dual inhibition of MDM2 and HDAC in comparison to controls. Our results suggest the concomitant targeting of MDM2-p53 and HDAC inhibition, may be an effective therapeutic strategy for the treatment of AML.

0586

ACUTE MYELOID LEUKEMIA INDUCES BONE MARROW FAILURE BY INDUCING DORMANCY IN NORMAL HEMATOPOIETIC STEM CELLS

F Miraki-Moud,[1] E Griessinger,[2] J Gribben,[1] D Bonnet,[2] D Taussig[1]

[1]*Barts Cancer Institute, London, United Kingdom*
[2]*London Research Institute, London, United Kingdom*

Background. Bone marrow failure (reduced production of neutrophils, platelets and erythrocytes) is an important cause of morbidity and mortality in acute myeloid leukemia (AML). We have previously shown that normal hematopoietic stem cells (HSCs) are relatively preserved in AML while normal progenitors and differentiated blood cells are reduced indicating a block in differentiation of HSCs (Haematologica 2010; 95, suppl.2, Abstract 0031). *Aim.* Understand how AML induces a block in differentiation of normal HSCs. *Patients and Methods.*Primary samples were obtained from patients attending St Bartholomew's Hospital, London following informed consent. Controls were untreated patients with a normal blood count and marrow examination with a non-leukemia diagnosis. 1. Cell cycle analysis of HSCs. We have previously shown that the CD34+ compartment of some AMLs (termed CD34- negative AML) is normal and contains normal stem-progenitor cells. The cell cycle status of residual HSCs (CD34+ CD38- cells) in bone marrow from patients with CD34-negative AML and controls was examined using the Ki67 assay. In addition, the proliferation of HSCs in the bone marrow of NOD/SCID/Interleukin 2 receptor gamma chain null mice transplanted with human AML cells (or controls) was assessed using the BRDU assay. 2. *In vitro* co-culture assay. To investigate whether the effect of AML on HSCs is dependent on cell-cell contact or due to secretion factors from AML, we cultured AML cells and

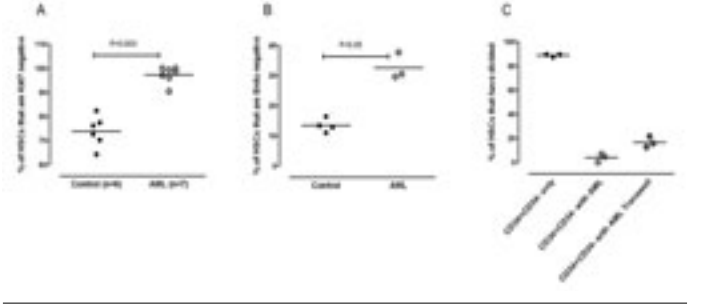

Figure 1.

normal HSCs (CD34+ CD38- cells) together or separated by a porous membrane (0.4 micron pore size to prevent cell contact). MS-5 stromal cells were used to support the AML and HSCs. Division of the HSCs was monitored using BRDU assay. *Results.* 1. HSCs are inappropriately quiescent in the context of AML. Normal HSCs in bone marrow from AML patients were more quiescent compared to HSCs in the control group (Figure 1A). Normal HSCs were shown to divide less in mice transplanted with AML than controls using BRDU assay (Figure 1B). 2. AML secretes a soluble factor that induces quiescence in normal HSCs. Normal CD34+CD38- cells divided less when cultured with AML than alone (Figure 1C). AML reduced division in normal CD34+ CD38- cells even when they are not in direct contact with HSCs (Figure 1C) suggesting a soluble factor is responsible. *Conclusion.* AML induces bone marrow failure by increasing quiescence in normal HSCs. This quiescence is inappropriate given the hematopoietic stress that would be expected to induce HSC cycling. This process appears to be mediated by a soluble factor. We are currently trying to identify this factor.

0587

MIR-34B HYPERMETHYLATION AND CREB OVEREXPRESSION MAY IDENTIFY MDS THAT EVOLVED TO AML

M Pigazzi,[1] E Manara,[2] E Baron,[2] A Beghin,[2] C Tregnago,[2] S Bresolin,[2] T TeKronnie,[2] K Sakamoto,[3] G Basso[2]

[1]*University of Padova-Città della Speranza, Padova, Italy*
[2]*University of Padova-Pediatrics Dpt, Padova, Italy*
[3]*David Geffen School of Medicine at UCLA, Los Angeles, United States of America*

Background. The cAMP response element binding protein (CREB) has been shown to be over-expressed in acute leukemia promoting abnormal proliferation, cell cycle progression, and clonogenic potential *in vitro* and *in vivo*. CREB has been previously reported to be a direct target of the microRNA, miR-34b. Low expression of miR-34b in myeloid leukemia cell lines was demonstrated to be due to hypermethylation of its promoter region. *Aim.* Our aim is to study *in vivo* the role of miR-34b in leukemogenesis. *Methods and Results.* HL-60 and K562 cell lines has been transfected with lentivirus for stable expression of MiR-34b and monitored for reduced expression of CREB. The transfected cell lines were transplanted in NOD-SCID mice and in flank tumor mice models. A decreased CREB expression was confirmed, whereas engraftment and disease progression *in vivo* were reduced by miR-34b expression. These results confirmed an important tumor-suppressor function for MiR-34b in AML. Mir-34b expression was monitored by RQ-PCR in a large cohort of 113 patients affected by de novo AML, and in 49 pediatric patients with diagnoses of myelodysplastic syndrome or myeloproliferative disorder (MDS/JMML). The distribution of MiR-34b expression in 113 AML patients at diagnosis was significantly downregulated (RQ = 0.176) with respect to healthy bone marrow CD19-CD3-sorted population (RQ = 1). MDS/JMML patients presented higher levels of MiR-34b (RQ = 5.5) compared to AML at diagnosis (RQ = 1). Methylation Specific-PCR revealed 65.5 % (74/113) of AML patients to be methylated at the miR-34b promoter region. Methylated AML patients had lower MiR-34b expression (RQ = 0.075), with respect to the unmethylated patients (RQ = 0.373). Moreover, CREB protein expression correlated to the methylation status of the MiR-34b promoter region in AML. By contrast, all healthy samples and the 49 MDS/JMML specimens never show methylation at the miR-34b promoter region. CREB protein expression was not detectable in MDS/JMML patients with MiR-34b promoter hypomethylation. These results indicated that methylation of the MiR-34b/c region is a tumor-specific phenomenon and that MiR-34b controls CREB protein expression. We examined the DNA of 3 MDS patients who evolved to AML. Results showed that the MiR-34b promoter was exclusively methylated in the onset of AML, together with a decrease of MiR-34b expression levels (RQmean-MDS = 0.41 vs RQmean-AML = 0.26). We used RNA to study changes in gene expression profiles from MDS to AML using GeneChip HG U133 Plus 2.0 on 4 paired patient samples. Supervised analysis of gene expression profiles identified 11 differentially overexpressed CREB-target genes (PRKACB, FDX1, NRXN2, PROSC, ADAM10, RAB7L1, NPR3, ITM2C, LATS2, CDK6 and HOXA7 ($p < 0.001$) between the MDS stage and the evolution to AML. Unsupervised hierarchical clustering analysis using these 11 genes divided the 4 pairs into two separated groups, revealing CREB over-expression and activation of the CREB pathway a feature of disease progression from MDS to AML. *Conclusion.* We consider MiR-34b promoter hypermethylation to be a critical early event for the onset of AML through the activation of the CREB pathway.

T(6;11)(Q27;Q23)MLL/AF6 ENHANCES RAS PATHWAY WEAKENING AF6 FUNCTION IN MYELOID CELLS

M Pigazzi,[1] E Manara,[2] E Baron,[2] A Beghin,[2] C Tregnago,[2] G Basso[2]

[1]*University of Padova-Città della Speranza, Padova, Italy*
[2]*University of Padova-Pediatrics Dpt, Padova, Italy*

Background. Chromosomal rearrangements involving the human MLL gene at 11q23 are associated with the development of acute leukemias, and have been related to different outcome depending on the MLL translocation partner. The t(6;11)(q27;q23) translocation is characterized by MLL/AF6 expression, known to be a bad prognostic marker in pediatric acute myeloid leukaemia (AML). AF6 is a cytoplasmic protein that can bind RAS through its Ras Association (RA) domain, sequestering and therefore inactivating its GTP-bound active form. The exact function of the MLL/AF6 chimera and its role in the tumorigenic mechanism is still unclear.*Aim.* Here we focus on unravelling the process of leukemogenesis activated by MLL/AF6 fusion gene. *Methods.* Immunofluorescence experiment are performed to detect the localization of AF6 and RAS in healthy primary culture or in t(6;11) cell lines such as ML-2 and SHI-1. Transfection experiment are achieved to knock down AF6 or MLL/AF6 expression. Real time PCR and western blot analysis show the extent of the knockdown and the effect on downstream targets. Pathway inhibition assays confirm the important involvement of the RAS pathway in this MLL/AF6 translocated myeloid leukemia. *Results.* Results show the cytoplasmic co-localization and the interaction of AF6 and RAS in healthy bone marrow cells. This binding is demonstrated to reduced RAS-GTP levels. AF6 silencing in healthy bone marrow cells induces an increase in the expression of RAS pathway proteins by western blot, demonstrating that AF6 is crucial in maintaining the homeostasis of RAS active form and consequently of its targets. In MLL-leukemia, the chimera MLL-AF6 is found into nucleous promoting the sequestration of the cytoplasmic AF6 into the nucleus as well. RAS-GTP levels were high. The silencing of the chimera in ML-2 and SHI-1, by RNA interference, shows a change in AF6 sub-cellular localization. In fact, AF6 returns in the cytoplasm and co-localize with RAS, decreasing the availability of RAS-GTP active form. Effects on the downstream pathway, after MLL/AF6 silencing, such as increase in the phosphorilation of RAF, MEK, ERK is also evident. The implication of the RAS via in t(6;11)(q27;q23) AML cells is further confirmed by using specific RAS pathway inhibitors (PD98059 and U0126). After drugs administration ML2 and SHI1 cell lines, significatively increase cell mortality and decrease colony formation capability, at the same extent as seen after MLL/AF6 silencing. *Conclusions.* We assume that AF6 is a cytoplasmic protein that interacts with RAS-GTP in healthy bone marrow cells, preventing an over-activation of its downstream signalling pathway. In t(6;11)-MLL/AF6 translocated AML cells, the chimera promotes AF6 removal from the cytoplasm and its reclusion into the nucleus, thereby preventing its interaction with RAS and its normal function within the hematopoietic cells. These results suggest one possible mechanism by which MLL/AF6 acts in AML to be further investigated.

HIGH-THROUGHPUT BISULFITE AMPLICON SEQUENCING OF THE 14Q32 IMPRINTED DOMAIN IDENTIFIES DNA METHYLATION SIGNATURES IN ACUTE MYELOID LEUKAEMIA

F Manodoro, J Marzec, T Chaplin, J Wang, B Young, S Debernardi

Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Several studies have shown that aberrant epigenetic programming, including DNA methylation, plays a role in tumorigenesis. We have previously reported that in Acute Myeloid Leukaemia (AML) a subset of miRNAs clustered in 14q32 imprinted domain show a differential expression in cytogenetically distinct subtypes of AML. The domain harbours differentially methylated regions (DMRs) that regulate the expression of the encompassed genes and several binding sites for CTCF, an enhancer blocking protein, whose binding to DNA is inhibited by methylation. Hypermethylation of CTCF binding sites prevents the activity of the protein and correlates with overexpression of regulated genes.The aim of this study is to determine whether a change of DNA methylation pattern at 14q32 may occur in AML thus affecting the expression of genes and miRNAs regulated by imprinting.Bisulfite amplicon sequencing with Roche 454 GS FLX Titanium has been performed to analyse the DNA methylation pattern of 7 CTCF binding sites and surrounding sequences located at 14q32. The

region spanning 8 kb and overlapping the promoter of the gene MEG3, includes also the MEG3-DMR and 2 CpG islands. Twenty-four AML patients, including 14 cases with t(15;17) and 3 cases with t(8;21) translocations, 3 cases with inversion (inv16) and 4 normal karyotype (NK) have been selected for the study. Remission samples for patients with t(15;17) and NK, 4 normal bone marrow from healthy donors and 2 non-infiltrated bone marrow from Non-Hodgkin Lymphoma patients, were included in the analysis as controls. High-throughput sequencing of 8 amplicons ranging from 347 bp to 492 bp generated over 600.000 reads with an average sequence depth of 615 reads per amplicon. A total of 160 CpG-dinucleotides have been analysed with an average of 20 CpGs per amplicon.Unsupervised hierarchical cluster analysis showed distinctive DNA methylation signatures associated with cytogenetically different subclasses of AML. Notably, DNA methylation in 14q32 segregates leukaemia's diagnostic specimens from remission and normal bone marrow samples. The analysis segregates also CpGs belonging to the same amplicon, suggesting that CpG methylation is non-randomly distributed in the area. AMLs displayed hypermethylation as compared to controls, with a prominent signature in AML with t(15;17). No significant differences were detected between normal bone marrow and remission samples. Statistical analysis with ANOVA showed that 89 CpGs, distributed in 5 regions, were differentially methylated (p-value < 0.05) among all cases. In particular, 5 of 20 CpGs embedded in 3 CTCF binding sites, were highly methylated in patients with t(15;17) as compared to controls. This pattern is consistent with miRNAs overexpression in AML with t(15;17) previously described. A highly distinctive methylation profile was detected in a region with all 33 CpGs exceeding the significance threshold (p < 0.05).This study shows that changes in 14q32 DNA methylation profile occur in cytogenetically distinct subclasses of AML. It is likely that alteration of DNA methylation in this region could determine miRNAs deregulation.

PRAME-INDUCED INHIBITION OF RETINOIC ACID RECEPTOR SIGNALING-MEDIATED DIFFERENTIATION IN AML CAN BE OVERCOME BY HIGH-DOSE ATRA

L Bullinger,[1] R Schlenk,[1] M Götz,[1] U Botzenhardt,[1] S Hofmann,[1] A Babiak,[1] Z Lu,[1] V Schneider,[1] K Döhner,[1] M Schmitt,[2] H Döhner,[1] J Greiner[1]

[1]*University of Ulm, Ulm, Germany*
[2]*University of Rostock, Rostock, Germany*

Background. In acute myeloid leukemia (AML) without retinoic acid receptor (RAR) rearrangement the effect of all-trans retinoic acid (ATRA) is still poorly understood besides a previously discovered correlation with NPM1 mutation in cytogenetically normal AML. Recently, the leukemia-associated antigen PRAME has been shown to be a dominant repressor of retinoic acid receptor (RAR) signaling in the presence of ATRA. *Aims.* Within this study, we now wanted to focus our efforts on further investigating the impact of PRAME expression on the response to ATRA treatment in AML. *Methods.* We profiled gene expression in diagnostic AML samples (n=88) derived from our AML HD98B trial for AML patients older than 60 years, in which ATRA was administered in addition to intensive chemotherapy. Gene expression findings were then further investigated in leukemia cell line models by shRNA based PRAME knock-down in PRAME-expressing cells (K562, THP-1) and PRAME knock-in in PRAME-negative cell lines (KG-1, OCI-AML2). *Results.* Profiling gene expression revealed a PRAME-associated gene expression pattern consisting of 1051 genes (ClassComparison analysis, P<0.05), which was significantly enriched for genes involved in the retinoic acid metabolic process as determined by DAVID functional annotation analysis. In AML cell line models we could demonstrate that cell proliferation and differentiation in PRAME-negative versus -positive cell lines were different. While in PRAME-negative AML cells a reduction of the proliferation rate from 49% to 23% was observed at low ATRA concentrations (10e-8mol/l), increasing ATRA levels could not further decrease proliferation (23% at 10e-5mol/l). In PRAME-positive cells increasing ATRA concentrations were associated with a continuous decrease in the proliferation rate (26% at 10e-8mol/l and 6.5% at 10e-5mol/l, respectively) and increase in differentiated, CD66b expressing cells (from 1.5% at 10e-8mol/l to 5% at 10e-5mol/l). shRNA-mediated knock-down of PRAME increased the ATRA-induced differentiation >4fold and overexpression of PRAME in negative cell lines reduced the expression of CD66b ~2fold. In line, our primary AML patient data also suggests that the repressor activity of high PRAME levels can be overcome by ATRA treatment in addition to conventional chemotherapy as determined by a trend towards better outcome in ATRA-treated PRAME-positive cases (p=0.11, log rank test). *Summary/Conclusions:* In PRAME-positive cells PRAME may block differentiation and increase proliferation via blocking RAR-signaling, which might be overcome with ATRA. Thus, in addition to its immunological role, PRAME expression seems to be involved in leukemic cell growth and impaired differentiation, and might represent a marker, which can be targeted by both ATRA-treatment and immunotherapeutic approaches in AML.

ACETYLATION OF MYELOID-SPECIFIC TRANSCRIPTION FACTORS DURING ATRA-DEPENDET MYELOID DIFFERENTION OF THE NB4 AND HL-60 CELL LINES

M Klimiankou, I Kuznetsova, K Welte, J Skokowa

Hannover Medical School, Hannover, Germany

Previously, we identified a new signaling pathway operating during G-CSF-triggered granulocytic differentiation. We found that G-CSF activates synthesis of the enzyme Nicotinamide Phosphorybosyltransferase (Nampt) which converted nicotinamide into NAD+ with followed activation of NAD+-dependent protein deacetylase SIRT1. We also found that SIRT1 binds to and activates myeloid-specific transcription factors C/EBPα and C/EBPβ. However, mechanisms and functional outcomes of acetylation/deacetylation of myeloid-specific transcription factors are not fully understood. In the present work we aimed to analyse whether myeloid transcription factors, C/EBPα, C/EBPβ and PU.1 could be acetylated and if SIRT1 is involved in this process. We treated two promyelocytic cell lines, NB4 and HL60, with ATRA for 2 days and studied acetylation status as well as intracellular localization of above mentioned transcription factors. We found, that all three proteins were acetylated in both cell lines. In NB4 cells, acetylated C/EBPα was localized predominantly in the nucleus and its localization was not changed after stimulation with ATRA. Acetylated PU.1 was found in both nucleus and cytoplasm and ATRA treatment led to a slight increase in cytoplasmic acetylated PU.1 protein. C/EBPβ was only weakly acetylated and localized predominantly in the cytoplasm in untreated and ATRA treated cells. In HL-60 cells, acetylated C/EBPα protein was localized in the cytoplasm and was translocated into the nucleus after treatment with ATRA. Acetylated PU.1 protein was found in both cytoplasm and nucleus and incubation with ATRA resulted in slight increase of acetylated PU.1. C/EBPß was weakly acetylated in control and ATRA-treated cells. We also found that all three transcription factors interacted with SIRT1. In both cell lines, C/EBPα:SIRT1 as well as C/EBPβ:SIRT1 protein complexes were detected in the cytoplasm and in the nucleus and ATRA treatment led to nuclear import of these complexes. Contrary, PU.1:SIRT1 complexes were localized exclusively in the cytoplasm independent of ATRA treatment. Differences in the intracellular localization of acetylated PU.1 and C/EBPα transcription factors could be explained by the reciprocal feedback inhibition of C/EBPα and PU.1 for terminal granulocytic vs monocytic differentiation. Since granulocytic differentiation requires C/EBPα and monocytic PU.1. However, exact effects of the acetylation/deacetylation of myeloid transcription factors have to be analyzed more in the details.

EXPRESSION OF DIFFERENTIATION-DEFECTIVE ISOFORM IV OF G-CSFR IS NOT AFFECTED IN MYELOID CELLS OF CN PATIENTS

J Skokowa,[1] M Reuter,[2] S Ehlers,[2] C Zeidler,[2] M Germeshausen,[2] K Welte[2]

[1]*Hannover Medical School, Hannover, Germany*
[2]*MHH, Hannover, Germany*

Severe congenital neutropenia (CN) is a preleukemic syndrome with a cumulative incidence to develop acute myeloid leukemia (AML) or myelodysplastic syndrome (MDS) of ca. 20 %. More than 80 % of CN patients who developed leukemia have acquired mutations in the gene encoding granulocyte-colony stimulating factor receptor (G-CSFR). Moreover, CN patients, who required doses of G-CSF higher than 8 ug/kg/d for treatment, have a higher incidence of AML/MDS, in comparison to patients with lower G-CSF doses. Therefore, we assume that aberrant G-CSFR signaling pathway could be involved in the leukemogenic transformation in CN patients. Previously, it has been shown that elevated expression of the isoform IV of G-CSFR in standard risk AML patients who received G-CSF therapy was correlated

with increased 5-year cumulative relapse incidence, in comparison to AML patients who did not receive G-CSF. Isoform IV of the G-CSFR has the membrane proximal tail responsible for proliferative functions, but replaces the carboxy-terminal region critical for maturation with a novel sequence, ablating its ability to drive neutrophilic differentiation. In the present study we aimed to compare the expression levels of isoform IV and isoform I in myeloid cells of CN patients, CyN patients and healthy individuals. We analysed 22 CN patients (7 with ELA2 mutations, 7 with HAX1 mutations and 8 patients with unknown genetic defects), 4 CyN patients and 10 healthy individuals. We found that in healthy individuals expression levels of isoform I of G-CSFR were more than 200 (78-264) fold higher than of isoform IV. There were no significant differences in the expression ratio of isoform I to isoform IV between CN patients (median=348.7), CyN patients (median=429.7) and healthy individuals (median=199.0). There were also no differences between CN patients with different genotypes. Only one patient developed leukemia and revealed a ratio of 175. We therefore hypothesize that the expression of Isoform IV is not involved in the underlying disorder of congenital neutropenia.

Acute myeloid leukemia - Clinical 2

High risk myelodysplasia (MDS) and acute myeloid leukaemia (AML) with associated chromosomal changes involving chromosome 5, especially as part of a complex karyotype, rarely has a durable response to cytotoxic chemotherapy. Conversely MDS patients with an isolated deletion of the long arm of chromosome 5 (del5q) frequently have a dramatic response to immunomodulatory therapy with lenalidomide. We therefore conducted a phase 2 non randomised study between August 2009 and May 2010 to assess the safety, tolerability and efficacy of lenalidomide monotherapy, followed by lenalidomide with intensive chemotherapy in patients with primary/relapsed/refractory high risk MDS or AML with abnormalities of chromosome 5. The initial lenalidomide monotherapy consisted of 10mg daily days 1-21 of a 28 day cycle. If a complete response was achieved this was consolidated with combination ADE (3+3+5 -days)- cytarabine 100mg/m2 BD, daunorubicin 50mg/m2 OD, etoposide 100mg/m2 OD) and with same dosing of lenalidomide, if a partial response was achieved a further cycle of lenalidomide monotherapy was administered, if progressing then combination induction chemotherapy with ADE (10+3+5) and lenalidomide was administered. Informed consent was obtained from 14 patients, median age 66 (range 40-75). 4 had high risk MDS, 10 had AML. 9 had primary, 3 relapsed and 2 refractory disease. Karyotypic abnormalities consisted of del5q alone in 2 and del5q with additional abnormalities in12. All 14 patients received the initial lenalidomide monotherapy and 9 patients received combination therapy. 1 patient had only monotherapy. 4 patients discontinued the study. The primary endpoints were early death rate (EDR), the proportion of patients recovering their platelets and surviving 42 days post combination chemotherapy and response rate. Stopping rules were set for review after 10 patients had received combination chemotherapy. 3 patients died during the initial monotherapy, an early death rate of 27%, with no patients with blasts >5% achieving a remission. 1 patient with blasts <5% achieved CR after 2 cycles and continues on maintenance therapy. Of the 9 patients who received combination therapy 4 achieved CR/CRp (44%) 2 patients achieved PR (22%), for an ORR of 66%. 2 patients successfully underwent allogeneic transplantation following achievement of remission. 15 SAE's were reported, which consisted primarily of haematological toxicity, grade 3 ALT rise (22%) and venous thrombo-embolism (11%). In view of the unacceptable EDR and lack of response to monotherapy the trial was halted for consideration of amendment and simultaneous review of data for the 9 patients who had received combination chemotherapy. There were no early deaths with combination therapy, however 7 had failed to achieve platelet recovery and the stopping rule was activated. In conclusion Lenalidomide monotherapy at a dose of 10mg daily is ineffective as induction therapy in MDS/AML patients with increased marrow blasts. Lenalidomide combined with ADE chemotherapy has predictable toxicity and has efficacy even in this particularly adverse patient cohort which warrants further investigation.

0594

OUTCOME OF RELAPSE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA (AML)

R Devillier, R Crocchiolo, A Etienne, T Prebet, A Charbonnier, S Fürst, J El Cheikh, E D'Incan, J Rey, C Faucher, D Blaise, N Vey

Institut Paoli Calmettes, Marseille, France

Background. 20% to 30% of AML patients relapse after allo-SCT. For these patients there is no standard therapy. They may receive intensive salvage, donor lymphocyte infusion (DLI) or palliative chemotherapy. Recently, new agents such as lenalidomide showed promising activity. We retrospectively analyse the outcome of 51 patients from our Institution who relapsed from AML following allo SCT. *Methods.* We selected patients with a diagnosis of AML according to WHO criteria who received allo-SCT and relapsed between Jan 2000 and Oct 2010 from our database. Primary endpoint was response rate and duration after salvage treatment. Secondary end points were the overall survival (OS) and relapse free survival (RFS) for responsive patients. At relapse, patients received either curative (anthracycline and/or high dose cytarabine and/or gemtuzumab) or non curative salvage (low dose cytarabine and/or and/or Azacytidine oral chemotherapy or best supportive care (BSC)). OS was calculated from the date of relapse. *Results.* Initial patients characteristics included: median age=48 years [range: 16-69], favourable-risk (n=1; 2%) intermediate-risk (n=29; 57%) or poor-risk cytogenetics (n=18; 35%). Thirty four patients (67%) had been transplanted in complete remission (31 [61%] in CR1 and 3 [6%] in CR2), and 17 (33%) with refractory disease. The conditioning regimen was myeloablative (MAC) and reduced intensity (RIC) for 9 (18%) and 42 (82%) patients respectively. Thirty patients (59%) received an allograft from matched related donor (MRD), 8 (16%) from matched unrelated donor (MUD), 12 (23%) from cord bloods and 1 (2%) from haplomismatch donor. Median time from SCT to relapse was 3.9 months [0.8-90], 29 patients (57%) relapsed <6 months after SCT. Twenty two patients (43%) received curative salvage treatment, 22 (43%) non intensive chemotherapy and 7 (14%) BSC. Among the 22 patients who received intensive salvage therapy, 16 achieved CR (72%). There were 2 (9%) toxic deaths related to high dose chemotherapy and 1 patient died from extensive chronic graft-versus-host disease after a DLI. With a median follow up at 13 months [3-33], the median RFS was 5.4 months. The overall median survival (OS) was 3.4 months. Factors influencing survival were: treatment (curative vs non curative: median OS= 6.7 vs 1.8 months, p=0.015), time between allo SCT and relapse (>6 months versus <6 months, median OS= 7.7 months versus 1.9 respectively; p=0.009). Disease characteristics (cytogenetics, WHO classification) and status before graft did not significantly impact the OS. *Conclusions.* Our results confirm that the prognosis of the patients who relapse after allo SCT is very poor with a median 3.4 months survival underlining the need for new therapies. Initial CR and salvage treatment significantly affect survival after relapse. In a selected group of 43% of patients who relapsed after allo SCT and received intensive chemotherapy, 72% achieved CR and survived significantly longer.

CONTINUOUS SEQUENTIAL INFUSION OF FLUDARABINE AND CYTARABINE FOR ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) AND LOW BONE MARROW (BM) BLAST COUNT (20-30%)

F Ferrara,[1] S Palmieri,[2] G Mele,[2] T Izzo,[2] C Criscuolo,[2] A Carbone,[2] P Angelillo,[2] C Riccardi[2]

[1]*AORN Antonio Cardarelli, Napoli, Italy*

[2]*Divisione di Ematologia e Trapianto, Ospedale Cardarelli, Napoli, Italy*

Background. According to WHO classification, the presence in the BM of 20 % or more blast cell is required for diagnosis of AML. Notwithstanding, the same WHO panel suggested that the 20% blast threshold is not a mandate to treat the patient as having AML, in that therapeutic decisions must always be based on the clinical situation after all information is considered. Accordingly, the treatment of these patients, namely in the elderly, is controversial. *Aims.* To investigate in a phase II trial the efficacy and toxicity of a regimen including fludarabine (F) and ARA-C (CI-FLA) in a series of 40 untreated patients aged more than 60 years with 20-30% BM blast count. A comparison with 100 patients with higher BM blast percentage uniformly treated in the same period is also presented. *Methods.* F at loading dose of 10 mg/sqm over 15 min at day 0, and after three hours and half ARA-C at a loading dose of 390 mg/sqm over 3 hours were given; then, F (20 mg/sqm/ci/24 hours for a total of 72 hours) and ARA-C (1440 mg/sqm/ci/24 hours for a total of 96 hours) were started. G-CSF was added at day +15 at a dose of 5 microg/kg. Patients achieving CR were programmed to receive a reduced course of CI-FLA, followed by G-CSF from day 15 to mobilize CD34+ cells and perform autologous stem cell transplantation (ASCT). Between June 2001 and October 2010, 40 out of 140 patients (28%) were found with 20-30% BM blast count. Median age was 67 years (61-81). Cytogenetic analysis was successful in 38 patients (95%) and showed normal karyotype (intermediate) in 24 patients (63%), while 14 patients (37%) had different chromosomal abnormalities and were classified as unfavourable. *Results.* Overall, 27 patients (67%) achieved CR. There were 5 induction deaths (12%), while 8 patients (20%) were refractory to induction treatment. The median number of days to neutrophil >0.5x10E9/l and platelet >20x10E9/l was 19 (7-34) and 20 (9-38), respectively. Documented infections occurred in 5 cases (12%). Twenty-two patients (81% of remitters) were eligible for consolidation and monitorized for mobilization of CD34+ cells, collection being successful in 15 of them (68%). Median number of CD34+ cells/kg collected was 6.8x10E6 (2.5-40.3), median number of apheresis being 2 (1-2). Thirteen patients (32% of the whole population) received ASCT. Median disease free survival (DFS) and overall survival were 9 and 10 months, respectively. Survival at 5 years is projected to 23%. The only parameter significantly related to DFS duration was the presence of unfavorable cytogenetics. In particular, DFS was 29 months for patients with diploid karyotype as opposed to 7 months for those with adverse one (p:0.001). Finally no difference was found with patients with > 30 % BM blast count as to CR achievement and duration, toxicity and overall survival. *Conclusions.* CI-FLA is effective and well-tolerated in elderly patients with low blast count AML. Therapeutic results are encouraging as to CR achievement and ASCT feasibility; however best results are achievable in the subgroup of patients with diploid karyotype.

0596

A HYPERTENSIVE PEAK SIGNIFICANTLY PRECEDES THE OCCURRENCE OF DIFFERENTIATION SYNDROME (DS) IN APL PATIENTS TREATED WITH AIDA BASED REGIMEN

R Jeddi, H Ghédira, R Ben Amor, Y Ben Abdennebi, K Kacem, M Zarrouk, H Ben Neji, L Aissaoui, R Ben Lakhal, H Ben Abid, Z Belhadjali, B Meddeb

Aziza Othmana University Hospital, Tunis, Tunisia

Background. Cardiovascular manifestations observed during DS, a life threatening side effect of ATRA, include hypotension, weight gain and pericardial effusion. The observation that several APL patients develop a hypertensive peak before the occurrence of DS led us to investigate its predictive value for such complication. *Patients.* 51 pts (31 female, 20 male) with genetically confirmed APL were treated with the Spanish PETHEMA LPA99 trial between 2004 and 2010. Median age was 40 years (range, 7-71). 2 pts (4%), 31 pts (61%) and 18 pts (35%), respectively, were Sanz's low, intermediate and high risk score. Additional cytogenetic abnormalities were observed in 39% of the pts. Median body mass index (BMI) was 24 kg/m^2 (range, 14-40). 43 pts achieved CR (86%). DS prophylaxis included prednisone 0.5 mg/kg from d1 to d15 in high risk pts (WBC >10 G/l). *Results.* According to Frankel's criteria 16 pts (32%) developed DS. Median time to onset of DS was 15 days (range, 2-29).Weight gain, pericardial effusion and hypotension were noted respectively in 50%, 37.5% and 18.7% of pts who developed DS. A hypertensive peak was observed 24 to 96 hours (median 36) before DS in 7 (43.7%) of the pts who developed this complication, of whom only one had a history of hypertension. Systolic and diastolic blood pressure values varied from 160 to 260 mmHg and 95 to 110 mmHg, respectively. 4 pts died from DS. By univariate analysis, age ≥ 40 (P=0.034), BMI ≥ 30 (P=0.009), baseline WBC ≥ 10G/l (P=0.034), serum creatinine >1.4mg (P<0.001) and absence of additional cytogenetic abnormalities (P=0.009) were associated with DS. A hypertensive peak was seen in 43.7% of the patients who developed DS compared to 11.7% of those without DS (P=0.011). Occurrence of a hypertensive peak was independent from the use of steroid prophylaxis (P=0.45), but was significantly associated with high BMI (P=0.003). *Conclusion.* Hypertensive peaks during induction treatment of APL may have a predictive value on the occurrence of DS.

VALUE OF NPM GENE MUTATIONS IN RESPONSE ASSESSMENT AND MINIMAL RESIDUAL DISEASE EVALUATION IN DENOVO CYTOGENETICALLY NORMAL NPM+ AML

M Clavio, C Marani, N Colombo, M Miglino, R Grasso, A Kunkl, D Testa, F Ballerini, F Cruciani, G Pica, F Galaverna, E De Astis, C Ghiggi, L Vignolo, A Carella, M Gobbi

Clinica Ematologica, Genova, Italy

Background. In normal karyotype AML patients the presence of Nucleophosmin (NPM) gene mutations at diagnosis is considered a good prognostic marker and FLT3 ITD negative NPM+ patients are not anymore considered for allogeneic tranplant in first complete haeamatological remission (CR). For minimal residual disease (MRD) evaluation the study of NPM gene mutations is not routinely performed and WT1 gene expression is considered the standard method for all patients. *Aims.* We evaluated NPM gene mutations as a possible indicator of quality of response and as marker of minimal residual disease (MRD), in comparison with WT1. *Patients and Methods.* One-hundred-fifty-eight bone marrow samples of twenty-four consecutive normal karyotype NPM+ denovo AML patients (median age 54 years) treated between May 2004 and June 2010 and achieving CR after two courses of conventional chemotherapy were studied. Follow-up analyses were censorized at the time of allogeneic transplantation or at the last bone marrow evaluation. A four-color flow cytometer was used to perform immunophenotype (IF). FLT3 ITD were performed according to the international standards of quality. NPM A and B DNA mutations and WT1 expression were studied by a quantitative Real Time PCR. *Results.* In 19 out of 22 patients in whom IF was done at response evaluation the flow cytometric analyses did not detect the clonal population observed at diagnosis (immunophenotypic CR, 86%). In 12/24 patients samples were negative for NPM mutations (molecular CR, 50%). Relapses in molecular CR patients and in those with persistence of NPM mutations were 5/12 (42%) and 11/12 (92%), respectively ($p < 0.05$). Patients with the first two consecutive NPM negative samples had a lower relapse rate compared to the other patients [3/11 (27%) vs 12/13 (92%); $p < 0.01$]. FLT3 ITD was detected in 8 patients. Five of them relapsed (median DFS 6 months, range 1-8), 3 are still in molecular CR (median DFS 21 months, range 8-69). In the follow up study of 15 patients who achieved a molecular CR the reappearance of NPM mutations was followed by haematological relapse in 8/9 patients (89%) with a median interval of 3,5 months (range 1-6 months). In 4 of these 8 NPM+ patients WT1 expression and IF were normal at the time of NPM gene evaluation. The median interval between WT1 increase and haematological relapse was 1 month (range 0-4). The median DFS in the 9 patients who achieved two consecutive negative NPM determinations and those who did not (15 patients) were 17 months (range 6-69 months) and 7.5 months (range 0-12 months), respectively. *Conclusions.* our preliminary analysis shows that the achievement of at least two consecutive negative NPM determinations is associated with prolonged haematological remissions. In the follow up of molecular CR patients the reappearance of NPM gene mutations is almost always followed by clinical relapse and may be considered an earlier relapse-marker than WT1 increase. Monitoring NPM gene mutations at response evaluation and in the follow up might help in defining subgroups of patients with high relapse risk and therefore likely to benefit of an early allogeneic transplant.

ACUTE MYELOID LEUKEMIA PATIENTS WITH HIGHER BONE MARROW DENDRITIC CELL LEVELS IN COMPLETE REMISSION HAVE SUPERIOR DISEASE FREE SURVIVAL

R Derolf,[1] E Laane,[2] E Björklund,[3] M Björkholm,[4] A Porwit[3]

[1]*Karolinska Institutet, Stockholm, Sweden*

[4]*Dept of Medicine, Karolinska Instituet, Stockholm, Sweden*

Background. Dendritic cells (DC) are unique lineage-negative antigen-presenting leukocytes which play a critical role in the regulation of the adaptive immune response. There is limited information on a potential association between bone marrow (BM) DC levels and minimal residual disease (MRD) status and outcome in patients with acute myeloid leukemia (AML). *Aims.* To establish levels of DC at AML diagnosis and during follow-up and relate the findings to the presence of MRD and disease free survival (DFS). *Methods.* Fifty-six out of 62 AML patients (≤ 65 years; 90%) achieved complete remission (CR) following intensive chemotherapy treatment at Karolinska University Hospital 2002-2006. Immunophenotyping by four-color flow cytometry (FC) on BM was performed at diagnosis to determine DC levels and aberrant blast features for MRD follow-up. Plasmacytoid DC (pDC) and myeloid DC (mDC) were identified by lin-/HLA-DR+/CD123+ and lin-/HLA-DR+/CD11c+ phenotypes, respectively and expressed as percentage of the total nucleated BM cell count. DC and MRD levels were assessed at CR (n=51) and after completion chemotherapy (n=26). A hospital control group (n=10) was used to determine reference DC levels in BM. Median follow-up time for patients alive was 78 months. *Results.* In the control group the median levels of pDC and mDC were 0.10% (range 0.02-0.27%) and 0.07% (range 0.02-0.19%), respectively. At AML diagnosis (n=62), pDC (median 0.00; range 0.00-1.2%) and mDC (median 0.00; range 0.00-0.8%) could be detected in only 15 and 17 patients, respectively. In all but two patients, DC levels increased at CR with median levels of pDC 0.16% (range 0-1.16%) and mDC 0.09% (range 0-1.36%). At the end of treatment the levels had in-

Table 1.

Levels of dendritic cells expressed as percentage of the total bone marrow cell count in AML patients at diagnosis, complete remission, follow-up, and relapse and in hospital controls

		p(DC) median	p(DC) range	m(DC) median	m(DC) range
AML patients	Diagnosis (n=62)	0.00	0.00-1.20	0.00	0.00-0.80
	CR (n=51)	0.16	0.00-1.16	0.09	0.00-1.36
	Post cons (n=26)	0.28	0.02-0.84	0.14	0.02-0.27
	Relapse (n=20)	0.05	0.00-0.65	0.03	0.00-0.37
Hospital controls	(n=10)	0.10	0.02-0.27	0.07	0.02-0.19

creased further, median pDC 0.28% (range 0.02-0.84%) and median mDC 0.14% (range 0.02-0.27). Patients with higher levels (defined as above the median value) of pDC at CR and after consolidation chemotherapy had longer DFS than patients with lower values, 22.5 vs. 11.5 months. No difference in DFS was observed in relation to mDC at CR (12.5 vs. 14 months) but patients with higher mDC after completion of consolidation chemotherapy had superior DFS (40 vs. 22.5 months). The number of patients with allogeneic SCT in first CR did not differ between the groups. MRD levels above 0.01-0.1% (depending on the sensitivity of the analysis) were detected in 80% of patients at CR and 35% at the end of post consolidation treatment. There was no significant association between DC levels and presence of MRD. Among 30 patients with relapse, DC levels were measured in 20 patients and were found to be almost as low as at diagnosis; median pDC 0.05% (range 0-0.65%), median mDC 0.03% (range 0-0.37%). *Summary/Conclusions.* No DC were seen in BM at AML diagnosis but both pDC and mDC regenerated after CR, sometimes to much higher levels by comparison to those in control patients. DC diminished again at relapse. Patients with higher levels of DC at CR and after completion of chemotherapy seem to have superior DFS. There was no correlation between MRD and DC levels. asa.derolf@karolinska.se

FLUDARABINE, CYTARABINE, IDARUBICIN AND ETOPOSIDE (FLAIE) SCHEDULE IS SAFE AND ACTIVE FOR YOUNG PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA: RESULTS OF A MULTICENTRIC PHASE III ITALIAN STUDY

C Papayannidis,[1] I Iacobucci,[1] A Candoni,[2] MC Abbenante,[1] S Paolini,[1] M Malagola,[3] E Ottaviani,[1] A Lonetti,[1] A Curti,[1] S Parisi,[1] N Testoni,[1] B Lama,[1] M Baccarani,[1] G Martinelli[1]

[1]*Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy*
[2]*Division of Hematology and BMT, Udine, Udine, Italy*
[3]*Chair of Hematology and BMT unit, University Of Brescia, Brescia, Italy*

Background. Fludarabine plus Cytarabine and Idarubicine (FLAI) was proved to be an effective and well tollerated induction regimen for treatment of acute myeloid leukaemia (AML). The trial objective was to assess the efficacy of Etoposide when used in combination with FLAI schedule. *Design and Methods.* We retrospectively report clinical outcome results of 101 newly diagnosed and younger than 60 years AML patients (median age 46 years, range 18-60 years) treated in a Phase III clinical trial, with FLAIE induction chemotherapy, including Etoposide to the FLAI schedule. Induction consisted of Fludarabine 25mg/m2/day on days 1-5, Idarubicin 6 mg/m2/day on days 1, 3 and 5, Cytarabine 2 g/m2 infused in 4 h, daily on days1-5 and Etoposide 100 mg/m2/day on day 1-5. After induction, all the patients underwent consolidation with Cytarabine (2 g /sqm i.v. infusion on days 1-5) and Idarubicin (12 mg/ sqm i.v. infusion on days 1, 3 and 5). All the patients shared the same strategy for intensification, that was allogenic or autologous stem cell transplantation. After consolidation, maintenance treatment with Cytarabine was given to patients who obtained a complete remission but who could not undergo allogenic or autologous stem cell transplantation. More than half of the patients had abnormal karyotypes. Molecular analysis at diagnosis for the more frequent abnormalities was performed. Duration of CR and overall survival was estimated according to the Kaplan-Meier method. The CR duration was dated from start of CR to first evidence of recurrence. *Results.* After informed consent was obtained, the patient received a single induction course of FLAIE; 73 pts obtained a CR (72.2%) and 8 pts a CRp (7.9%) for an overall response rate of 80.2%. Fifteen patients (14.9%) had resistant disease, and 5 (4.9%) died during induction. After a median follow-up of 33 months, 75 patients (76%) are in continuous CR. The median CR duration and OS were 45 and 55 months, respectively. 11 pts underwent ABMT and 44 a BMT. Relapses were more frequent in patients who were not submitted to allogenic stem cell transplantation. Of the 55 transplanted patients, 28 (51.9%; 1 with chromosome 7 abnormality), were alive in CR after a median follow up of 10 months (range, 2 to 45 months) after transplantation, 14 (25.9%) relapsed (median DFS 4 months), and 13 (24%) died in CR or CRp of transplant related complications. The most common grade 3 adverse events included gastro-intestinal toxicities(i.e. nausea, vomiting, mucositis and diarrhoea), liver dysfunction, and skin rash. *Conclusion.* The combination of etoposide to FLAI is safe and active. Further studies exploring different dosing and scheduling are warranted, particularly in patients with poor-risk AML.

PRETREATMENT RISK FACTORS AND IMPORTANCE OF COMORBIDITY FOR OVERALL SURVIVAL, COMPLETE REMISSION AND EARLY DEATH IN PATIENTS WITH ACUTE MYELOD LEUKEMIA

I Djunic,[1] M Virijevic,[1] A Novkovic,[2] V Djurasinovic,[1] N Colovic,[3] A Vidovic,[3] N Suvajdzic-Vukovic,[3] D Tomin[3]

[3]*Clinical for Hematology, Clinical Center of Srerbia, Shool of Medicine, Belgrade, Serbia*

Background. The prognosis and clinical course of acute myeloid leukemia (AML) differs among patients depending on specific the features of the disease, such as cytogenetics, white blood cell (WBC) count and serum lactate-dehydrogenase (LDH) level. Moreover, patient-related factors including age, performance status and pre- or coexisting diseases (comorbidity) are of prognostic importance, too. *Aims.* The aims of this study were to determine the pretreatment risk factors for overall survival (OS), rate of complete remission (CR) and early death in patients with AML, as well as to estimate the influence of comorbidity on patients' outcome. *Methods.* This single-center study involved 145 patients with nonpromyelocytic AML with 58-month follow-up. The following parameters were estimated as the risk factors for OS, CR and early death: age, WBC (<30x109/L vs ≥30x109/L), level of serum lactate dehydrogenase (LDH) more than 1.5 x upper limit of normal and expression of CD34 antigen on leukemic blasts (<10% vs ≥10%). Performance status evaluated by Eastern Cooperative Oncology Group, ranged 0-4 (<1 vs ≥2). Cytogenetic risk group was assessed by recommendation of European LeukemiaNet: favorable, intermediate-I, intermediate-II and adverse group. Comorbidities were evaluated by using the hematopoietic cell transplantation-specific comorbidity index (HCT-CI). Patients treated by Medical Research Council 12. The risk factors were identified using the univariate and multivariate analysis. *Results.* The median patients' age was 55.6 years, range 18-79 years. The most significant risk factor for poor OS was the adverse cytogenetics: p=0.008, relative risk (RR)=1.406 (95% CI 1.092-1.810). The age ≥55 years indicated to be the most significant risk factor for poor rate of CR: p=0.001, RR=0.214 (95% CI 0.111-0.413). The most significant factor for early death was the HCT-CI ≥3: p=0.001, RR=0.357 (95% CI 0.202-0.630). The significant cut-off age for poor OS and CR was ≥55. The incidence of HCT-CI≥3 was significantly increased in patients with age of ≥55 years than in patients under age 55 (p<0.001). Half of the patients aged ≥55 years had HCT-CI≥3, other half of the patients aged <55 years had HCT-CI=0. Infection as a comorbidity had an impact on HCT-CI score (according HCT-CI definition) in most of patients (91.7%) with the age of <55 years. We estimated the risk factors for both of these groups. The most significant risk factor for OS in the group under age 55 was adverse cytogenetics: p<0.001, RR=1.731 (95% CI 1.239-2.342), while in the group with age ≥.55 years it was HCT-CI≥3: p=0.008, RR =1.195 (95% CI 1,011-1,412). In the group aged <55 years, the most significant factor for poor CR rate and for early death: p=0.007, RR=0.063 (95% CI 0.008-0.471) was infection as a comorbidity: p=0.005, RR=3.125 (95% CI 1.410-6.928), while in patients with age ≥55 years it was elevated serum LDH level for CR: p=0.049, RR=0.27, (95% CI 0.0784-0.9968) and leukocytosis: p=0.007, RR=1.0098 (95% CI 1.0027-1.0170) for early death. *Conclusions.* This study identified the pretreatment risk factors for OS, CR and early death in patients with AML. Comorbidity, evaluated by HCT-CI has important influence on OS and early death in these patients.

Introduction. Acute Myeloid Leukemia (AML) in the elderly is difficult to treat. Azacytidine has been shown to improve survival in patients (pts) with myelodysplastic syndromes. We present results of a phase II trial treating elderly or frail AML pts with azacytidine. *Methods*. AML pts unfit for intensive chemotherapy, with a WHO performance status ≤ 3 were eligible. Trial therapy consisted of azacytidine 100 mg/m2 injected subcutaneously on 5 consecutive days every 28 days for up to 6 cycles stopping at 6 cycles if no hematological improvement (HI) was observed, stopping early in case of progression or complications, and continuing beyond 6 months for responding pts. The primary endpoint was complete (CR) or partial remission(PR) within 6 months. *Results*. Between September 2008 and January 2010, 45 evaluable pts across 10 Swiss centers were accrued with a median follow-up of 11 months (95% confidence interval (C.I.) [9.3, 13.5]). 27 (60%) were male, median age was 74 (55-86) years and 35 (79%) had performance status 0-1. Pts received a median of 3 (1-14) cycles. Treatment was terminated because of lack of response after 6 cycles in 3 pts and earlier in 37 pts (disease progression in 12, toxicity in 4, patient refusal in 2, death with leukemia in 11 and poor performance status in 3, other in 5). Five pts remain on therapy. The median hospital stay in 27 pts admitted during the first treatment cycle was 13 days (1-30). Adverse events of grade III or higher most frequently reported were constitutional or hematologic, i.e. fatigue in 6, febrile neutropenia in 18, infections in 16, dyspnea in 7, thromboembolic complications in 2, hemorrhage in 5 and retinal detachment in 5. Among all 45 pts, 8 (18%,95% C.I.: 8-32%.) achieved CR/Cri, 6 (13%) HI and 15 (33%) stable disease within 6 months. Up to now 35 (78%) died. Median overall survival was 6 months. Age, gender and cytogenetic risk group had no significant impact on response, but there was a borderline association when pts were grouped by blast count (> or ≤ 30%, p=0.08). *Conclusions*. The current results show that the modified azacytidine schedule is a feasible option for elderly or frail AML pts in an outpatient setting with moderate, mainly hematologic, toxicity and response in a substantial proportion of pts, although the predetermined level of expected efficacy was not reached.

0602

LOW-DOSE LENALIDOMIDE COUPLED WITH LOW-DOSE CYTARABINE INDUCES COMPLETE REMISSION OF ELDERLY ACUTE MYELOID LEUKEMIA PATIENTS WITH UNFAVORABLE CITOGENETICS: PRELIMINARY RESULTS OF A PHASE II STUDY

G Visani,[1] F Ferrara,[2] F Di Raimondo,[3] MR Caraci,[3] S Barulli,[1] B Guiducci,[1] F Loscocco,[1] G Sparaventi,[1] A Isidori[1]

[1]*Hematology and Stem Cell Transplant Center, Pesaro, Italy*
[2]*Hematology, Cardarelli Hospital, Napoli, Italy*
[3]*Hematology, Catania University, Catania, Italy*

Background. Elderly acute myeloid leukemia (AML) patients frequently fail chemotherapy. Median survival does not usually exceed few months. Recently, two groups demonstrated the efficacy of high-dose lenalidomide (50 mg/day, days 1-28). However, no reports demonstrated the efficacy of low-dose lenalidomide in combination with other drugs. *Aims*. we designed a phase II study to assess the antitumor efficacy of the combination regimen with low-dose lenalidomide and low-dose cytarabine in patients with AML aged >70 years. The primary endpoint of the study was to determine the complete response (CR) rate according to SWOG criteria. *Methods*. Sixteen patients (median age 76 years, range: 70-80) were consecutively enrolled in the study. Median white blood cell count at diagnosis was 7.5 $x10^9$/l (range: 0.59-44$x10^9$/l), whereas median haemoglobin was 9.4 g/dl and median platelet count was 44$x10^9$/l. Two out of sixteen patients had a normal karyotype, whereas 14/16 presented with an intermediate or unfavourable karyotype. Twelve patients had a de novo AML, whereas 4 patients had a secondary AML (2 after MDS, 1 after CMPD, 1 after myelofibrosis). All patients received low-dose lenalidomide (10 mg/day orally, days 1-21) and low-dose cytarabine (20mg twice day subcutaneously, days 1-15). Therapy was repeated every 6 weeks, up to 6 cycles The study was registered at EMEA with the EUDRACT no 2008-006790-33, and is still recruiting patients. All patients gave written informed consent. *Results*. Two out of 16 patients are still receiving induction therapy, and are not evaluable for response. Five out of 16 patients died in aplasia while receiving the first induction cycle of therapy, and are not evaluable for response. Nine patients received at least one cycle of therapy and are evaluable for response. Among these patients, 4/9 (44%) cleared peripheral blood blasts at the end of the second week of the first cycle, with recovery of normal WBC, hemoglobin and platelets values after a median of 36 days (range: 31-42) from the start of chemotherapy. Three out of 4 responding patients are still in morphologic, cytogenetic and FISH CR after 11, 10 and 8 months from the start of therapy, respectively. The remaining patient died after receiving the third cycle of therapy while in CR due to a multi organ failure after an infectious complication. The other 5 patients who completed at least one cycle of therapy did not respond at all and rapidly died due to progressive disease. At present, 3/16 patients are alive in continuous CR, 2/16 are alive with active disease, 2/16 are too early and 8/16 died either in aplasia (5) or in progressive disease (3). Notably, all responding patients presented at diagnosis patients with low blast count and unfavorable cytogenetics. *Conclusions*. low-dose lenalidomide has clinical activity, when coupled with low-dose cytarabine, in an extremely poor-prognosis subset of AML patients. *Acknowledgements*. Celgene is gratefully acknowledged for providing Lenalidomide for the patients. The study was supported in part by AIL Pesaro Onlus.

FENOTIPING ANALYSIS OF NK CELL AT DIAGNOSIS OF ACUTE MYELOID LEUKEMIA (AML): CLINICAL CORRELATION WITH OUTCOME

B Sanchez-Correa,[1] J Bergua,[2] I Gayoso,[1] MJ Arcos-Carmona,[2] ML Bengochea,[2] J Casado,[1] S Morgado,[1] H Bañas,[2] H Fernandez-Leyva,[2] F Ibañez,[2] R Tarazona[1]

[1]*Departamiento Inmunología. Facultad de Veterinaria, Cáceres, Spain*
[2]*Hospital San Pedro de Alcántara, Cáceres, Spain*

Purpose. To study the expression of NKp30, NKp46, DNAm ad NCR fenotype in NK cells of patients with Acute Myeloid Leukaemia (AML) at diagnosis and their correlation with survival (OS) and relapse free survival (RFS). We decided not perform analysis of APL patients because all them are alive and in remission (PETHEMA LPA 2005 protocol). *Patients*. 48 patients diagnosed of AML from 2006 to 2010 were included. The median age is 65 year (21-87); a 60% of the patients are male. The FAB categories were: M0:8; M1: 4, M2:7;M3: 7; M4: 6; M5: 15, M6:1. Karyotype were: Good risk: 10 (22%); Intermediate: 19(43%); High risk: 15 (34%). White blood counts were 16X109/L (1,2-339x109/L); median bone marrow blast was 55% (21%-98%). 30 patients were treated according to LMA-2007 PETHEMA protocol (induction protocol Cytarabine 200 mg/m2 x7 days and Idarrubicine 12mg/m2x3 days; 10 patients were treated previously to LMA2007 with the same induction schedule, consolidation and 2 cycles of Ara C intensification (only normal Karyotypes and high-risk patients were submitted to allogenic bone marrow transplantation). Only one patient was treated with Azacitidine. *Methods*. NK cells from patients with AML were sorted in FACS. Expression of NK markers such as DNAM-1, NKP 46, NKp30, NCR phenotype were perfomerd against control of similar age. We also tested the effect of age in expression of DNAM-1 on NK cells comparing with normal controls (n=21). We tested also the expression of DNAM-ligands on AML blasts CD112 and CD155 and the correlation with DNAM-1 in NK cells. *Results*. Expression of DNAM-1, NCRs, NKp46 and NKp30 on NK cells in patients <65 was decreased compared with age-matched controls (p<0.04). Older patients differ only in NKp46 expression (p<0.03). It was a significant inverse correlation between DNAM-1 expression on NK cells and CD112 in AML blasts. DNAM-1 on NK cells is down regulated after co-culture with AML blasts expression DNAM-ligands. Nowadays, 14 of the 48 patients are alive. The median OS is 13,467 months. The median RFS was 50.966 months. In univariate analysis, OS was correlated

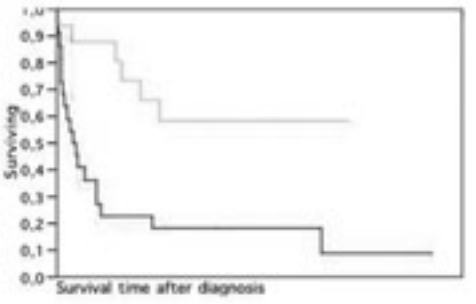

Figure 1.

with age>65 (Long-rank test: p<.0002); expression of NKp-46 (p<0.00160), NCR phenotype (Long-ran p<0,0112); expression of DNAM-1 (p<0,0297). Multivariate analysis was performed and only age (p=0,0001) and NKp-46 (p=0.05) was correlated with OS. This results point out NKp-46 in NK populations of AML patients at diagnosis as an independent factor of OS.

0604

DAY 14 BONE MARROW RESULT HAS LOW POSITIVE PREDICTIVE VALUE FOR REMISSION FAILURE IN ACUTE MYELOID LEUKEMIA

A Macdonald,[1] R Juskevicius,[2] S Couban,[1] N Sparavalo,[1] M Almohammadi,[1] M Alzahrani[1]

[1]*QEII Health Sciences Centre, Halifax, Canada*
[2]*East Carolina University, Greenville, NC, United States of America*

Background. The initial objective of induction therapy for patients with acute myeloid leukemia (AML) is to achieve a complete remission (CR). The conventional measure of response following induction chemotherapy is the percentage of myeloblasts on a bone marrow biopsy (BMB) performed 28 days after chemotherapy. Previous studies have suggested persistent leukemia on a BMB at day 14 (D14-BMB) is significant, and some protocols recommend immediate further treatment when persistent myeloblasts are present on D14-BMB. *Aims*. At our centre, we routinely perform D14-BMB, with the intent to immediately administer further chemotherapy if persistent myeloblasts are found. The aims of this study are to assess our adherence to this strategy, and to assess how the results of D14-BMB impact on treatment outcome. *Methods*. This was a retrospective review of consecutive patients with a new diagnosis of AML treated at our centre between 1993 and 2007. Patients were included if they had induction chemotherapy and had D14-BMB. Through chart review, their subsequent course was determined, including any therapy prior to Day 28, and subsequent bone marrow biopsy results. *Results*. There were 129 patients who had induction therapy for AML and had a D14-BMB. Forty two (32.5%) had residual leukemia on day 14, defined by myeloblasts >4%; of these, 17 had immediate reinduction chemotherapy, 5 patients were changed to supportive care, and 20 had no further action until a repeat BMB was performed at time of peripheral blood count recovery. The CR rate on the recovery or day 28 marrow for the whole group was 67.4%. The CR rate for patients with residual leukemia on day 14 was 45.2%. For patients who had additional chemotherapy after day 14 it was 47% versus 55% for patient with persistent leukemia on day 14 who had no additional chemotherapy. The CR rate for patients who had no residual leukemia on day 14 was 82.4%. For the entire group, the results of the D14-BMB resulted in any intervention in 17% of patients. The finding of a positive D14-BMB resulted in any intervention in 52% of patients. The positive predictive value of the presence of myeloblasts >4% on the day 14 BMB, in patients receiving no further action until repeat BMB at peripheral blood count recovery, was only 45%. The negative predictive value for the finding of no residual leukemia on day 14 BMB was 78%. *Conclusions.* These data confirm that the day 14 BMB result is an important prognostic factor for remission status at day 28. However, nearly half of the patients with persistent myeloblasts on day 14 BMB had no further treatment until a repeat BMB was done around day 28, and over half of these patients were in remission on day 28. In our hands, the day 14 marrow has prognostic significance but low utility in altering treatment during the induction phase of patients with AML.

[3]*St James' Hospital, Dublin, Ireland*
[4]*Beaumont Hospital, Dublin, Ireland*
[5]*Midlands Regional Hospital, Tullamore, Tullamore, Ireland*
[6]*Midwestern Regional Hospital, Limerick, Limerick, Ireland*

Background. Development of acute myeloid leukemia (AML) in elderly patients is considered a condition with a very poor prognosis. Standard treatment with low-dose cytarabine has few responses in high-risk patients and only an 18% overall response rate (ORR). Clofarabine is a second-generation purine nucleoside analogue which has activity versus AML and may produce improved responses especially in high-risk groups. *Aims*. We aim to examine the outcome of elderly patients, not fit for intensive therapy, treated with clofarabine as an initial, single agent therapy. *Methods*. This is a retrospective study of patients diagnosed with AML and treated first line with single agent clofarabine across five centers in Ireland. These patients were considered unsuitable for higher intensity treatment due to age or performance status. *Results*. A total of 24 patients were treated in 5 Irish centers between July 2007 and June 2010. 83% were males. The median age at the commencement of treatment was 74 years (range 64-80) and 79% of patients (n=19) were >70 years. Of the patients for whom analysis at diagnosis was available, 60% (9/15) had a poor risk genetic profile according to WHO classification. Patients received a median of 2 cycles of clofarabine treatment (range 1-3). 83% of patients (n=20) were treated with 20mg/m^2 for 5 days per cycle, the remainder received 30mg/m^2 for their first cycle. The overall response rate was 54% (n=13). Complete remission rate was 29% (n=7), with 8% of patients (n=2) having a complete response without count recovery. The principle adverse event was neutropenic sepsis and the 30-day mortality rate was 25%. The 6-month mortality rate was 62% and the 12-month mortality rate was 89%. The overall median time of survival was 16.5 weeks (range 1-384).In those who responded it was 39 weeks (range 6.5-384 weeks) and of non-responders was 4 weeks (range 1-20). Median survival in patients > 70 years was 17 weeks (range 1-130 weeks, mean 25.5 weeks). *Conclusion*. Clofarabine as a single agent was associated with promising activity in a poor risk group of elderly AML patients with predominantly poor risk cytogenetics with a CR/CRi of 37%. Unfortunately these responses were not durable with only 11% of patients alive at 12 months. Despite a possible improvement in response rates with new agents such as Clofarabine, the optimal post-remission strategy for these patients remains a major challenge and requires further studies.

0606

THE PREDICTIVE VALUE OF HEMATOPOIETIC CELL TRANSPLANTATION COMORBIDITY INDEX FOR EARLY DEATH AND SURVIVAL IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA

A Savic, V Kvrgic, I Urosevic, N Rajic, I Milosevic, I Savic, N Vaisavljevic, S Popovic

Clinical Center of Vojvodina, Novi Sad, Serbia

Background. The Hematopoietic cell transplantation comorbidity index (HCTCI) predicts non-relapse mortality and overall survival (OS) after stem cell transplantation. HCTCI score is predictive of early death and survival in elderly patients with acute myeloid leukemia (AML). *Aims*. The aim of this study was to determine the prognostic role of HCTCI for early death and OS in adult AML patients of all ages. *Methods*. In the single-center, retrospective study, we analyzed the outcome of 233 AML patients aged >=18 years (excluding promyelocytic AML) treated between 1993 and 2010. Eighty three percent of patients received chemotherapy. The rest of patients (17%) died before treatment (median survival 5 days, range 3-17 days) and they make a part of early death group (38%). Comorbidities were evaluated by using the Hematopoietic cell transplantation comorbidity index (HCTCI). *Results*. The median patients age was 57,3 years, ranged 18-85. Elderly population (above 60 years) makes 46% (107 Pts.) of entire group. The patient population was divided into those with HCTCI scores of 0 (low score), 1 or 2 (intermediate), or 3 and more (high score) according to original

description of the HCTCI scoring system. Forty eight per cent of patients had low HCTCI scores of 0, 24% had intermediate scores of 1-2 and 28% high scores of 3 or more. Early death rates in the three groups defined as death before specific treatment or within 30 days from time of commencing induction treatment were 30,6%, 42% and 69% respectively (Chi-Square P <0.00001). The significant difference in early death rates was present in subgroup analysis in elderly patients (>60 years, p<0.00001) as well as in younger patients (<60 years, p<0.05). When we compared all patients in early death with other patients the significantly higher WBC number (p<0.001), and HCTCI score (p<0.001) were found. OS was a median of 7,5 months in patients with a low HCTCI score of 0, 4,5 months in those with an intermediate score of 1-2, and 0,6 months in those with a high score 3 and more (p<0.001). In subgroup analysis, HCTCI score influence survival in elderly patients (p<0.01). In patients younger than 60 years there was significantly shorter survival in high HCTCI score group (0,77 months) comparing with low HCTCI score group (9,4 months) (p = 0.03327) but not in other comparisons. *Summary/Conclusions*. The results from this study indicated that HCTCI score is predictive of early death in adult patients with AML and overall survival in elderly patients with AML. High HCTCI score also predicts shorter survival in younger patients with AML.

0607

IMPACT OF FLUDARABINE-BASED INDUCTION THERAPY ON CLINICAL OUTCOME OF CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA (CN-AML) WITH FLT3-ITD AND/OR NPM1 MUTATION

M Tiribelli,[1] M Miglino,[2] D Fabbro,[3] A Franzoni,[3] A Pianta,[3] A Michelutti,[1] M Cavallin,[1] R Gallina,[1] N Colombo,[2] R Grasso,[2] M Clavio,[2] G Damante,[3] M Gobbi,[2] A Geromin,[1] R Fanin,[1] D Damiani[1]

[1]*Division of Hematology and BMT, Udine, Italy*
[2]*Division of Hematology - AOU S. Martino, Genoa, Italy*
[3]*Institute of Genetics, Udine, Italy*

Background. Cytogenetically normal acute myeloid leukemia (CN-AML) defines a clinical entity with an heterogeneous outcome, as 5-year survival rates range from 24 to 42%. In this patients, accounting for about 45% of total AML cases, many important prognostic factors have been identified in the last years. Among these, mutations of FLT3 and NPM1 genes are the most widely studied. Fludarabine-based induction therapy displayed interesting results in AML, with high rates of complete remission (CR). However, no specific data are available about fludarabine effect on the outcome of CN-AML patients according to specific molecular "signature". *Aims*. To assess the impact of molecular abnormalities in CN-AML patients treated with fludarabine, we analyzed 137 patients treated with a fludarabine-based induction therapy, evaluated response according to internal tandem duplication (ITD) in FLT3 gene and/or nucleophosmin (NPM1) mutation. *Methods.* One hundred thirty seven patients with CN-AML and assessed for FLT3-ITD and NPM1 mutations were included in the study. All patients received fludarabine as a part of induction course, according to the institutional protocols. Patients considered at high risk of relapse for disease characteristics at diagnosis or poor response to induction therapy were considered candidate to allogeneic stem cell transplantation (SCT); in transplanted patients, survival was censored at the time of SCT. *Results.* Median age of patients (73 males and 64 females) was 54 years (range: 20-79), with 61 (44.5%) aged more than 55. Hyperleukocytosis (WBC > 30 x 10^9/L) and CD34 positivity were present in 50 (36.5%) and 54 (39.5%) cases, respectively. FLT3-ITD was detected in 44/137 (32%) patients. No association was found between FLT3 status and age, FAB subtype or CD34 expression, but FLT3+ patients had significantly higher WBC count (50 ± 75 x 10^9/L vs 42 ± 74 x 10^9/L, p=0.03). NPM1 mutation was studied in 100/137 (73%) cases and detected in 41/100 (41%) patients. NPM1 mutation was found in 17/32 (53%) FLT3+ patients and in 24/68 (35%) FLT3- ones (χ^2=2.17, p=0.14). All patients were evaluable for response to therapy. CR was achieved in 100/137 (73%) cases, and was affected only by age and CD34 positivity, while no correlation was found with WBC count, FLT3 and NPM1 mutations. Leukemia free survival (LFS) was significantly shorter in FLT3-ITD+ patients compared to un-mutated ones (11 vs 28 months, p=0.05), and in CD34 positive cases (10 vs 22 months, p=0.02). No differences were found considering WBC, age and NPM1 status. Overall survival (OS) was worse in elderly patients (p=0.001) and CD34+ cases (p=0.002), while FLT3 and NPM1 mutations did not have a significant impact. Considering survival by the combination of FLT3 and NPM1, LFS was similar in the four (FLT3+/NPM+, FLT3+/NPM-, FLT3-/NPM+, FLT3-/NPM-) groups, while a trend for longer OS was observed in FLT3-/NPM1+ patients compared to all other groups (5-yrs OS 60% vs 30%), even if difference didn't reach statistical significance. *Summary/conclusions.* Our data suggest that fludarabine was able to improve LFS and OS in FLT3-ITD+ patients, but did not completely abrogate the advantage of NPM1 mutation.

EARLY APOPTOTIC RESPONSE AND CLINICAL OUTCOME OF INDUCTION CHEMOTHERAPY IN PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA. PILOT TRIAL

A Bogdanovic,[1] M Cemerikic Martinovic,[2] D Colovic,[1] Z Bumbasirevic[3]

[1]*Hematology, Clin Ctr of Serbia and School of Medicine Belgrade, Serbia, Belgrade, Serbia*
[2]*Hematology, Clin Ctr of Serbia, Belgrade, Serbia*
[3]*Histology, School of Medicine, Belgrade, Serbia*

Background. Many studies revealed that apoptosis is one of the major mechanisms of action of cytotoxic drugs used in treatment of leukemia. In *in vitro* conditions, leukemic cells undergo apoptosis after exposure to cytotoxic drugs within several days in culture but less is known about those effects *in vivo*. *Objective.* In pilot trial we evaluated morphologically recognized apoptosis measured as apoptotic index (AI) during induction antileukemic treatment and its relationship with clinical features and initial treatment outcome (CR/NR). *Materials and Methods.* We analyzed bone marrow samples (particles) from a cohort of 35 patients suffering from *de novo* AML, aged 46 yrs (19-64 yrs), treated with similar antileukemic induction treatment (ADE/MAE 26 pts, and DA/MC schedule 8 pts). After obtaining informed consent, samples were taken at diagnosis and also at 3rd day (D3) from start of therapy (48h of exposure *in vivo*). Analysis was performed on morphological level by counting cells with morphologically recognized apoptosis on at least 1000 cells and expressed as AI (%). We evaluated bcl-2 positivity in leukemic cells by immunohistochemistry with use of commercial Bcl-2 antibody and imaging kits (LSAB2 and CSA, Dako Danmark) at treshold of 20% bcl-2+ cells. Statistical analysis included parametric and nonparametric tests. *Results.* According to morphology of blasts, 20 patients had myeloid leukemia (3 with M1 and 17 with M2). Monocytic morphology was present in 15 patients (12 had M4 and 3 had M5 type). No dysplastic features were found. Twenty three patients achieved CR (65%) and 12 were non responders. Initial mean AI was 3.4±2.2%. There was no difference in initial AI between patients according to leukemia type (myeloid/monocyte) or prognostic karyotype groups (ANOVA & Kruskal Wallis & Mann Whitney U tests p>0.05). AI was increased to 8.1±4.7% at D3 (t-test p<0.01). We have not found differences in rise of AI concerning leukemia type or cytogenetic groups. When we analyzed increase of AI and outcome of induction therapy we have found that patients achieved CR have significantly higher therapy induced AI at D3 than nonresponders (ΔAI 6.4±5% vs. 2.5±1.9%, t-test and Mann Whitney p<0.05). Bcl-2 nega-

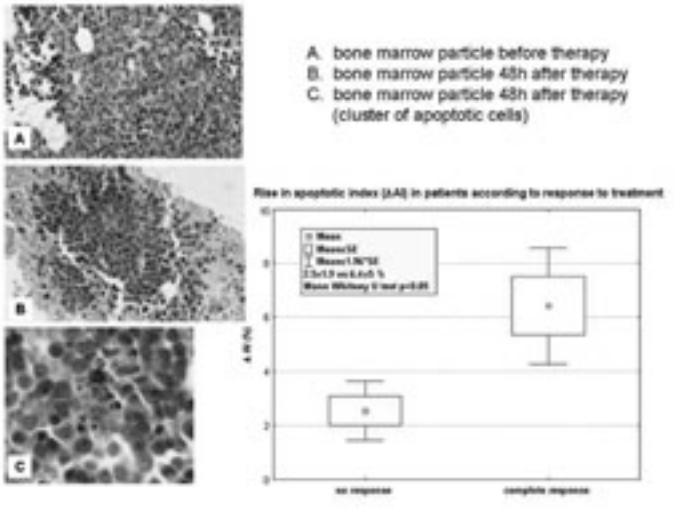

Figure 1. Apoptosis in bone marrow.

tive patients in CR had higher increase of ΔAI (6.1±1.9%) than patients with NR (1.8±1.6%). That difference was much lower in group of bcl-2 positive patients. *Conclusion.* Our results in a small cohort of patients revealed that we can also measure treatment induce apoptosis *in vivo*, during induction treatment of AML like in *in vitro* assays. That increase in apoptosis have impact on treatment outcome and possibly have prognostic significance like blast clearance, but further studies are needed.

SECONDARY HEMATOLOGICAL MALIGNANCIES AFTER TREATMENT OF NON-METASTATIC BREAST CANCER

C Arslan,[1] E Ozdemir,[2] E Dogan,[2] Y Ozisik,[2] K Atundag[2]

[1]*Hacettepe University Institute of Oncology, Ankara, Turkey*
[2]*Hacettepe University, Ankara, Turkey*

Background. Survival of early breast cancer patients improved due to modern chemotherapies in last two decades. However long term toxicities as secondary hematological malignancies due to improved survival have been a major concern. *Aim.* We aimed to determine the frequency of secondary hematological malignancies in non-metastatic breast cancer patients (BCP) who received adjuvant chemotherapy and radiotherapy. *Method.* Data of BCPs followed at Hacettepe University Insititute of Oncology, Department of Medical Oncology between years 2004 to 2010 were analyzed retrospectively. *Results.* There were 1319 non-metastatic BCPs out of 1475 followed between years 2004 to 2010. 1183 (89,7%) patients among non-metastatic BCPs received adjuvant radiotherapy and/or neoadjuvant/adjuvant chemotherapy. 1066 (80,8%) patients received adjuvant or neo-adjuvant cytotoxic chemotherapy. Adjuvant radiotherapy was applied to 960 of non-metastatic BCPs (72,8%). 228 (17,3%) patients received only adjuvant/neoadjuvant chemotherapy and 117 (8,9%) patients received only adjuvant radiotherapy. 11 (1%) out of 1066 adjuvant/neoadjuvant chemotherapy received BCPs were also treated with granulocyte colony stimulating factors (GCSF). The frequency of secondary hematological malignancies among adjuvant or neo-adjuvant chemotherapy received BCPs was 0,56% (6/1066) and 0,59% (7/1183) among radiotherapy and/or chemotherapy treated non-metastatic BCPs. There were five AML patients; three of them were AML - FAB M3 and two of them could not be subclassified. One patient had multiple myeloma and the other had diffuse large B cell lymphoma. However the latter did not receive cytotoxic chemotherapy for breast cancer. *Summary/conclusions.* Treatment-associated secondary hematological malignancies, especially myeloid leukemias is a growing problem due to high prevelance of breast cancer and dismal outcome of secondary leukemias. Further studies are neded to determine the risk for other hematological malignancies with contributing factors; radiotherapy and novel chemotherapy agents.

0610

COMPARATIVE STUDY OF ACUTE MYELOID LEUKEMIA WITH INV(3)/T(3;3) AND OTHER ACUTE MYELOID LEUKEMIAS ASSOCIATED WITH ABNORMALITIES OF 3Q: A GROUP OF ENTITIES WITH THE SAME CLINICAL BEHAVIOR?

JM Raya,[1] E Luño,[2] C Sanzo,[2] M Perez-Sirvent,[3] E Such,[3] J Navarro,[4] F Milla,[4] A Domingo,[5] E Alonso,[5] M Rozman,[6] M Diaz-Beya,[6] A Batlle,[7] S Gonzalez-de-Villambrosia,[7] T Vallespi,[8] E Tuset,[9] M Ortega,[8] A Bermejo,[10] M Fernandez-Guijarro,[11] J Bosch,[12] S Iraheta,[1] F Sole,[13] L Florensa[13]

[11]*Hospital Doce de Octubre, Madrid, Spain*
[12]*Hospital Insular, Las Palmas, Spain*
[13]*Hospital del Mar, Barcelona, Spain*

Background. Acquired abnormalities of the long arm of chromosome 3 have been reported in approximately 3-3.5% of patients with acute myeloid leukemia (AML). However, the revised 2008 WHO classification recognizes only AML with inv(3)(q21q26.2) or t(3;3)(q21;q26.2) as an independent clinicopathological entity with a poor outcome. Controversy exists concerning if all AML with any 3q abnormality could be reunited in the same group. *Aims.* Our purpose was to compare, from a biological and clinical perspective, a group of patients with AML inv(3) or t(3;3) with another group carrying different abnormalities of 3q at q21 or q26. *Methods.* We collected 55 patients [35 with AML inv(3)/t(3;3), 50 ± 20 years, range 14-84, men 54%, and 20 with AML associated with other 3q aberrations, 53 ± 19 years, range 2-79, women 55%]. The group of AML abn(3q) included four cases of t(2;3), three of t(1;3), three of del(3), two of t(3;10), two of der(3)t(1;3), and one of t(3;21), t(3;11), t(3;6), dup(3), del(3)t(3;12) and del(3)t(3;16). Among others, we recorded at diagnosis the existence of a previous history of MDS, chemotherapy or radiotherapy; blood cell counts, presence and degree of cellular dysplasia, serum lactate dehydrogenase, data from bone marrow aspirate and/or biopsy, immunophenotype of blasts, and other associated cytogenetic findings. The therapeutic approach (including hematopoietic stem cell transplantation, HSCT), response to treatment, overall survival (OS) and disease-free survival (DFS) were also recorded. In the statistical analysis, relations between variables were studied using the Fischer exact test (categorical) and the Mann Whitney U test (continuous). *Results*. There were no differences in sex, age, history of previous MDS or chemo-/radiotherapy, clinical presentation, WBC and platelet counts, haemoglobin level, serum LDH, degree of cellular dysplasia (significant in both groups) and bone marrow findings. The immunophenotype of blasts was similar (immature myeloid pattern, CD33+CD13+CD117+HLA-DR+, with frequent aberrant CD7 expression), but the frequency of CD34 positive cases was higher in the inv(3)/t(3;3) group (96% vs. 73%, p=0.04). Of note, the association with monosomy 7 was significantly more prevalent in the inv(3)/t(3;3) group (43% vs. 10%, p=0.01), while the presence of del(5q) or a complex caryotype were found in similar proportions (9% vs. 10%, and 26% vs. 30%, respectively). When intensive chemotherapy was used (80% and 78% of the cases), bone marrow remission after first cycle of induction was achieved only in 6% of patients with inv(3)/t(3;3) and 20% in the other group. Allogeneic HSCT was performed in 29% of patients with inv(3)/t(3;3) compared to none in the group of patients with other 3q aberration (p=0.05). Mortality rate and median OS and DFS were similar in both groups, extremely unfavorable. *Conclusions.* In our experience, clinical behaviour of AML with inv(3)/t(3;3) and other AML abn(3q) is similar. Although the association with monosomy 7 is significantly more frequent in the first group, this does not seem to influence outcome. Our results are in concordance with a recent refinement of cytogenetic classification in AML (Grinwade *et al.*, 2010), which includes both subset of AML patients together in the group of adverse prognosis.

OUTCOME OF THERAPY RELATED ACUTE MYELOID LEUKEMIA - A SINGLE CENTRE EXPERIENCE

N Suvajdzic,[1] Z Cvetkovic,[2] V Djordjevic,[3] N Kraguljac,[3] D Stanisavljavic,[4] M Mitrovic,[3] M Virijevic,[3] N Colovic,[1] D Antic,[3] I Djunic,[3] A Vidovic,[1] I Elezovic,[1] D Tomin[1]

[1]*Clinic of Hematology Clinical Center of Serbia, School of Medicine, Belgrade, Serbia*
[2]*Clinical Hospital Center Zemun, Belgrade, Serbia*
[3]*Clinic of Hematology Clinical Center of Serbia, Belgrade, Serbia*
[4]*Institute for Medical Statistics and Informatics, School of Medicine, Belgrade, Serbia*

Background. Therapy related acute myeloid leukemia (t-AML) is the most serious late complication of prior chemo (CT) and /or radiotherapy (RT) for malignant or nonmalignant diseases. This uncommon distinct entity is considered to have poor prognosis. *Aim.* To evaluate the prognostic parameters affecting outcome in t-AML managed in a single center. *Methods.* A total of 42 patients (pts) with t-AML (median age 56.07 years, range 23-84; 30 females) were diagnosed between 2000 - 2010. Prior malignancy had 37/42 (88.15%) pts - 9 hematological [CLL -2(4.8%), NHL- 4(9.5%), HL -2(4.8%), B-ALL 1(2.4%)] and 28 solid cancers, predominantly of breast - 14(33.3%) and cervix - 6(14.3%). Five (11.9%) pts. had no malignancies (2 multiple sclerosis, 3 connective tissue diseases). History of previous CT alone had 18/42 (42.9%), RT alone 11/42 (26.19%) and combined CT+RT 13/42 (30.1%) pts. G-CSF during therapy for prior disease had been administered in 3/42 (7.1%) pts. Therapy related myelodysplastic syndrome (t-MDS) preceded t-AML in16/42 (38.1%) pts. On t-AML diagnosis median ECOG performance status was 2.5 (ECOG≤1- 7/42; 16.7% pts.) and median HCTI-comorbidity index was 3.69 (HCTI-CI<3- 10/42;

23.8%). Cytogenetic risk groups were assessed according to refined MRC criteria. *Results.* For all 42 pts median WBC count was 27.23x109/L (range 1.1-177), platelet count 62.29x109/L (6-207), hemoglobin level 87.83g/L (47-133), peripheral blood blast percentage 30.7% (0-98), bone marrow blasts 66.7% (22-98), LDH 1216 U/L (257-6204). DIC was registered in 30/42 (71.4%) pts. Median latency period from prior CT/RT was 54.62 months (6-243); primary disease was active in 11/42(26.2%) pts. FAB distribution was as follows: M0-1(2.4%), M1-3(7.1%), M2- 15(35.7%), M3- 3(7.1%), M4- 6(14.3%), M5- 6(14.3%), M6- 1(2.4%). In 5 pts FAB could not be determined and 2 (4.8%) pts had T/My AML. Coexpression of B and T lymphoid markers was registered in 7/39 (17.9%) and 6/39 (15.4%) pts, respectively. Cytogenetic analysis was eligible in 33/42 (78.6%) pts: favourable karyotype 5/33 (15.2%), intermediate 14/33 (42.4%) and unfavorable 14/33 (42.4%). Normal karyotype was registered in 9/33 (21.4%) pts, while complex and monosomal karyotypes were registered in 8/33 (24.2%) and 9/33 (27.3%) pts, respectively. Abnormalities of chromosomes 5 and/or 7 were present in 10/33 (30.3%) pts, either alone or within complex/monosomal karyotypes. Total of 24 (57.1%) pts received standard induction CT (3+7 and variants). Haematologic complete remission (CR) was achieved in 10 (23.8%). Early death within two weeks occurred in 8 (19%) pts. For all 42 pts, the median overall survival (OS) was 5.94 months (range 0.5-34); in 10pts achieving CR median disease free survival (DFS) was 11.8 months (range 4-32 months). Among all parameters assessed only pretreatment karyotype, ECOG PS, HCT-CI and activity of primary disease had impact on outcome. ECOG PS, HCT-CI and active primary disease had impact on OS ($p<0.05$). Favorable karyotype proved a good prognostic parameter concerning outcome, CR rate, OS and DFS ($p<0.05$). *Conclusion.* Survival in t-AML is very poor. Among all evaluated patient-related and disease-related parameters only pretreatment karyotype proved significant concerning CR rate, OS and DFS, while ECOG PS, HCT-CI and active primary disease influenced only OS.

0612

CLOFARABINE IN THE TREATMENT OF ACUTE MYELOID LEUKEMIA - SINGLE CENTER EXPERIENCE

M Toskova, Z Racil, D Dvorakova, J Prochazkova, J Mayer

University Hospital Brno, Brno, Czech Republic

Background. Clofarabine (CLO) is a purine nucleoside antimetabolite. It demonstrated its efficacy and safety not only in acute lymfoblastic leukemia patients (pts.), but also in pts. with acute myeloid leukemia (AML). *Aims.* To evaluate efficacy and safety of CLO in salvage treatment of AML. *Methods.* A retrospective analysis of pts. with AML treated with clofarabine-based regiments. For refractory or hematological relapsed AML we used combination with antracycline (CLO 22.5 mg/m2 once daily intravenously for 5 days plus idarubicine 9 mg/m2 intravenously for 3 days, consolidation cycle with 25% dose reduction) and for pts. with molecular relapse CLO in monotherapy (CLO 40 mg/m2 intravenously for 5 days, consolidation cycle in the same dose). *Results.* In the study period 4/2009 - 9/2010 we have treated 21 pts. with CLO-based regiments (9 pts. with molecular relapse and 12 pts. with hematological relapse or refractory AML). The mean age was 49 years (range 18-67 years). 7 pts. had favorable, 10 pts. intermediate and 4 pts. adverse cytogenetic risk. In relapsed pts., observed time to molecular relapse was 5.3 months (n=9) and to hematological relapse 10.2 months (n=4). From 9 pts. with molecular relapse 6 pts. (67%) achieved complete molecular remission, 1 pts. (11%) partial molecular remission and 2 (22%) had molecular or hematological progression. From 12 pts. with refractory and relapsed AML 5 (42%) achieved complete remission (CR), 3 (25%) partial remission (PR), 1 (8%) stable disease (SD), 2 (16%) progression and 1 died before assessment. 6 pts. received 1-3 consolidation cycles and 10 pts. underwent allogeneic hematopoietic stem cell transplantation (allo HSCT) (6 pts. in CR, 4 pts. with active disease). We observed neutropenia and thrombocytopenia gr. III-IV (according CTCAE 4.0) in 100% of CLO treated pts. Infections were the most frequent complications associated with CLO therapy - 4 pts. (44%) treated for molecular relapse and 8 pts. (66%) with relapsed or refractory AML, 5 (42%) of them had severe infection (pneumonia). The frequency of infectious complication decreased after introduction of posaconazole prophylaxis (66% vs.33% respectively). Mortality in molecular relapse group and relapsed/refractory disease group was 22% and 67%, respectively. 6 months disease free survival (DFS) in molecular relapse group was 85% and overall survival (OS) 75% and in relapsed/refractory disease group 75% and 50% respectively. *Summary/Conclusions.* The use of clofarabine shown 78% response rate in pts. with molecular relapse AML and 67% in pts. with hematological relapse or refractory AML. The most serious complications are severe infections, which could be reduced using posaconazole prophylaxis.

0613

VALIDATION OF BONE MARROW ASPIRATES IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DAY 14 OF INDUCTION THERAPY

J Souto Filho, M Loureiro, M Nucci, R Portugal

Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background. Current treatment of non-M3 acute myeloid leukemia (AML) usually includes 7+3 chemotherapy followed by a bone marrow assessment between day 14 (D14) and 17 after treatment initiation. This evaluation may change decisions concerning therapy and have prognostic implication. *Aims.* The objectives of this study were to evaluate different modalities of D14 bone marrow aspirate (BMA) evaluation (quantitatively and qualitatively), determine the inter-observer agreement and compare the results with D14 bone marrow biopsy (BMB). We included 119 patients with AML who received 7+3 and had D14 bone marrow evaluation. The analysis was performed by two independent observers, blind to patient and remission status. The evaluation included confirmation of the diagnosis of AML and identification of residual leukemia in a quantitative (percentage of blasts) and qualitative (Likert scale) manner. The qualitative assessment of blasts was determined by stratification in 5 categories: definitely infiltrated, probably infiltrated, doubtful, probably free and definitely free. *Results.* The evaluation of the BMA (n=107) by both observers using a Likert scale yielded a significant agreement between observers (Kappa w = 0.737, 95% CI 0.642 to 0.832, $p<0.001$). The correlation of the quantitative evaluation was also significant ($rs=0.798$, $p<0.001$). ROC curves were obtained correlating the BMA quantification of blasts and Likert scale by both observers with bone marrow biopsy results (n=82). The areas under the curve (AUC) were 0.924 and 0.946 for observer 1 and 0.867 and 0.870 for observer 2 for assessments of the number of blasts and Likert scale, respectively. Comparing the ROC curves between the two methods of BMA evaluation (quantitative and qualitative) by the same observe we found the differences between AUC of 0.025 observer 1 ($p = 0.220$) and 0.002 for observer 2 ($p = 0.967$). The evaluation of different cutoff points for blasts percentages in BMA showed a better sensitivity and specificity at the rate below 6% and 7% blasts for observers 1 and 2, respectively. A similar analysis for the Likert scale showed the best cutoff point as the 4th item of the scale (probably infiltrated) for both observers. *Conclusion.* Evaluation of bone marrow at D14 using quantitative or qualitative scale had a significant agreement between observers. Both tests were predictive of bone marrow involvement comparing with biopsy. The evaluation using a qualitative scale is easier to perform.

THE COST-EFFECTIVENESS OF A NEW DIAGNOSTIC TEST THAT IDENTIFIES NEW PROGNOSTIC SUBTYPES IN ACUTE MYELOID LEUKEMIA

A Leunis,[1] W Redekop,[1] B Löwenberg,[2] C Uyl-de Groot[1]

[1]*Erasmus Universiteit, Rotterdam, Netherlands*
[2]*Erasmus MC, Rotterdam, Netherlands*

Background. Acute myeloid leukemia (AML) is a heterogeneous disease consisting of cytogenetic and molecular subtypes with a prognostic impact. Currently, patients are classified into risk groups mainly based on the presence of cytogenetic abnormalities. However, large differences in survival outcome still exist within the intermediate risk group. Therefore, many studies now focus on identifying new prognostic subtypes within the intermediate risk group. Based on this research, a new diagnostic test, the AMLprofiler, has been developed that identifies some of these new prognostic subtypes. *Aim.* The aim of this study is to evaluate the cost-effectiveness of the new diagnostic test for patients with AML aged 18-60 years. *Methods.* An individual patient simulation decision-analytic model has been developed, because the cost-effectiveness cannot be evaluated alongside a clinical trial due to the small incidence of the new subtypes. The structure of the model and the identification of relevant parameters were based on the literature and interviews with clinical experts. All input parameters were estimated from clinical trial data from patients aged 18-60 years. The model was validated by comparing the model-based survival results with the results from the clinical trials and the literature. The model was used to estimate survival outcome and costs of two alter-

natives: current care and care if the AMLprofiler is used at time of diagnosis. Resource use was derived from all patients diagnosed in 2008 and 2009 in two hospitals. The resource use was combined with Dutch tariffs to calculate the costs for the Netherlands. *Results.* The AMLprofiler identifies patients who could be treated with chemotherapy instead of a (allogeneic) stem cell transplantation (SCT). These patients would not have to be exposed to the high risks of the transplantation. Other patients were identified who would need the most intensive treatment to have some chance to be cured. These patients coull be given other types of allogeneic SCT (from a matched unrelated donor or cord blood transplant) instead of autologous SCT or chemotherapy. Combining this information in the decision-analytic model showed that the use of the AMLprofiler could lead to higher 5-year overall survival and lower costs. *Conclusion.* The AMLprofiler has the potential to be a dominant choice over current tests as the use of the AMLprofiler could lead to higher overall survival and lower costs. The health outcome could be further improved if targeted treatments were to become available for the specific subtypes of AML.

LARGE PNH CLONES ARE UNCOMMON IN PATIENTS WITH INTRAABDOMINAL THROMBOSIS

J Ahluwalia, V Baloda, Y Chawla, N Varma

Dept. of Hematology, PGIMER, Sector 12, Chandigarh, India

Background. Paroxysmal Nocturnal Hemoglobinuria (PNH) usually presents with hemolysis or cytopenias. Thrombosis, often at unusual sites-intraabdominal, cerebral or dermal may develop during the course of the disease. However there is a paucity of data on how many cases of PNH present primarily as thrombosis. Current guidelines recommend screening for PNH in patients with the above mentioned sites of thrombosis .We screened patients with intraabdominal thrombosis to determine the frequency of the PNH clone by flow cytometry in this population *Aim.* To assess the presence of PNH clones in RBCs and granulocytes, by flow cytometry in patients with intrabdominal thrombosis. *Methods.* Patients with intra abdominal thrombosis -Budd Chiari Syndrome (BCS), Extra Hepatic Portal Vein obstruction (EHPVO), mesenteric, iliac or renal vasculature as confirmed by imaging studies and referred for thrombophilia workup to the department of Hematology, PGIMER, Chandigarh were included in the study. Patients with recent transfusions and blood samples more than 48 hours old were excluded from analysis. EDTA peripheral blood samples were analysed by flow cytometry using CD55, CD59 on both RBCs and granulocytes and additionally CD16 on granulocytes. 10,000 events were acquired and analysed on the FACS Calibur (BD Biosciences).Patients with > 5% deficient RBCs and granulocytes were labelled positive for PNH clone .Normal controls were included in each run. *Results.* In the 3 year period, 86 adult cases of intra abdominal thrombosis were tested. There were 50 (58%), 27 (32%), 3 cases of EHPVO, BCS and Superior mesenteric vein thrombosis respectively. Iliac vein thrombosis, isolated arterial and combined arterial and venous thrombosis was seen in a single case each. Recurrent thrombosis with involvement of the abdominal vessels at least once was seen in 3 cases. Patients with EHPVO had significant cytopenias as compared to those with BCS. Small populations of CD55 deficient RBCs were seen in 8 cases (9.3%). None of the cases showed significant CD 59 negativity on the RBCs. Whereas 3(3%) cases had granulocytes with CD 59 deficiency, CD 55 deficiency was seen in a single case. Results for CD 16 showed presence of a clone in at least 11 out of the 52 cases tested. This was not significant when compared with normals. *Summary/Conclusion.* Flow cytometry with CD55 and CD 59 yielded isolated small clones with a PNH phenotype in the RBCs or granulocuytes of 12 (13.9%) cases patients with intraabdominal thrombosis. No case had deficiencies on both red cells and granulocytes. CD 16 was not a useful marker for detecting PNH cells in this population. Large clones of PNH type cells, reported to occur in thrombosis in known patients of PNH on follow up, were conspicuously absent in the study population. PNH with a primary thrombotic presentation is therefore rare in cases with intraabdominal thrombosis. In a resource constraint setting, effectivity of screening all patients with intraabdominal thrombosis for PNH therefore needs reconsideration.

[3]*Molecular Medicine Branch, NIDDK, National Institutes of Health, Bethesda, United States of America*

Erythropoietin (EPO) is a cytokine that stimulates erythropoiesis and also induces its own receptor (EPOR) during differentiation of erythroid progenitor cells. However, as we showed previously, EPOR is expressed in cells beyond the erythroid lineage including endothelial cells. EPOR in endothelial cells is further increased at low oxygen tension. With EPO stimulation of endothelial cells during hypoxia, there was also a corresponding increase in nitric oxide (NO) production and endothelial NO synthase (eNOS) expression. We now present evidence for NO regula-

tion of endothelial EPOR expression. We use primary human umbilical vein endothelial cells (HUVECs) and the human bone marrow microvascular endothelial cell line (TrHBMEC) to study effect of NO donor diethylenetriamine NONOate (DETANO) on EPOR expression. HUVEC treated with 10-50 μM of DETANO at different oxygen tension for 24 hours showed statistically significant induction of EPOR gene expression at 5% and 2% of oxygen with 25 μM of DETANO and 50 μM of DETANO at 2% oxygen. Also TrHBMEC cultured at 21 and 2% oxygen for 3, 24, 48 hours with 50 μM DETANO demonstrated a time and oxygen dependent induction of EPOR mRNA expression after 24 hours particularly at low oxygen tension. In TrHBMEC and HUVEC EPOR protein was significantly induced by DETANO at 2% oxygen. We used EPOR promoter/luciferase reporter gene assay to examine if NO could regulate EPOR expression at transcriptional level. HeLa cells were transfected with different constructs containing the EPOR 5' UTR and extending upstream to about 2 kb and 200 bp from the transcription start site. DETANO treated HeLa cells, with the 2 kb promoter construct, increased luciferase activity at 2% oxygen about 50 %, and 70 % with the 200 bp construct. There was no induction of EPOR promoter activity after DETANO stimulation at 21% of oxygen, suggesting that NO regulated EPOR expression at the transcriptional level in promoter region only at low oxygen tension. Different signaling pathways in TrHBMEC were examined after DETANO stimulation and we found that DETANO activated MAPK kinase in TrHBMEC after 30 min both at 21% and more at 2% oxygen. The effect of EPO on MAPK activation was not statistically significant. However, both EPO and DETANO induction of EPOR were blocked with MAPK inhibitor PD98059, suggesting direct effect of DETANO on MAPK kinase activation. These data provide a new effect of NO on EPOR expression and regulation in endothelial cells under normal and low oxygen tensions.

Background/Aims. Inflammation in sepsis activates blood coagulation that may lead to thromboses of the vessels of the microcirculation and consequently organ failure. So estimation of haemostasis system state is extremely important. Conventional diagnostic methods are insensitive to procoagulant changes in sepsis. Our aim was to study changes in haemostasis system state for patients with sepsis and septic shock by a method of spatial clot growth created in our laboratory and to compare the sensitivity of this new method to conventional ones. *Methods.* 16 patients (age 21-60) with hematological malignancies and sepsis were enrolled in the study. All patients have been surveyed from 1st to 5th day and on 7th, 14th, 21st and 28th days from the infection beginning. The spatial clot growth is the original method of investigation of haemostasis. Its principle consists in registration of clot formation after local activation of coagulation by immobilized tissue factor by light scattering in non-stirred thin layer of platelet-free plasma containing inhibitor of contact activation. Contemporarily clotting time tests, thromboelastography, plasma D-dimer level assay were performed. *Results.* Spatial clot growth showed growing hypercoagulation in 6 patients. Plasma D-dimer levels rose after that in 5 of them. Contrariwise, plasma D-dimer levels did not raise and were statistically significant lower if spatial clot growth did not show hypercoagulation. Mean values were 457μg/l and 234 μg/l, respectively (P<0.05). Other tests did not show hypercoagulation during all time of the study. Other 10 patients had elevated plasma D-dimer level on 1st day. It gradually reduced or stayed the same. Spatial clot growth showed normalization of coagulation in survivors or growing hypocoagulation in non-survivors. Routine tests showed normal and hypocoagulation or only hypocoagulation respectively. *Conclusions.* Spatial clot growth is more sensitive to the procoagulant changes of haemostasis system state than routine tests and can predict prothrombotic tendencies in sepsis.

DIVERGENT ROLE IN THROMBOTIC AND INFLAMMATORY MECHANISMS REGULATED BY THE G455A POLYMORPHISM OF THE BETA CHAIN OF FIBRINOGEN IN PATIENTS WITH STABLE ANGINA

M Kozanitou, N Papageorgiou, N Tousoulis, A Vlachopoylou, E Kotridis, M Bounta, C Stefanadis, Z Pallantza

Hippocratio Hospital, Athens, Greece

Purpose. Patients with coronary artery disease (CAD) exhibit increased levels of thrombotic and inflammatory biomarkers including fibrinogen, interleukin 6 (IL-6) and sCD40L. However, it remains obscure, whether the genetic variability on fibrinogen beta chain modifies thrombosis and inflammation in those patients. In the present study we investigated the impact of the G455A genetic polymorphism on the aforementioned biomarkers. *Methods.* We genotyped 393 patients with documented CAD and 236 controls. The G455A polymorphism was determined by polymerase chain reaction (PCR) and the specific HaeIII restriction enzyme. Serum levels of fibrinogen were measured by the von Clauss method. Moreover, IL-6 and sCD40L levels were assessed by enzyme-linked immunosorbent assay (ELISA). *Results.* Genotype distribution was GG: 54.6%, GA: 36.8%, AA: 8.6% for controls and GG: 50.1%, GA: 42.0%, AA: 7.9% for CAD. Interleukin 6 levels (pg/ml) were enhanced in patients with CAD compared to controls (4.40±3.13 vs 3.41±2.76, p<0.01). However, the G455A polymorphism failed to affect IL-6 levels between GG+GA vs AA both in CAD and controls (p=NS). Similarly, sCD40L levels (ng/ml) were significantly higher in CAD compared to controls (2.07±1.47 vs 1.82±1.68, p<0.001). Although no difference was observed in sCD40L across the study genotypes both in controls and in CAD (p=NS), the G455A polymorphism defined sCD40L levels (GG+GA vs AA) in the total population (1.91±1.41 vs 2.77±2.23, p<0.05). Finally, fibrinogen levels (mg/dl) were significantly higher in CAD compared to controls (436.0±126.8 vs 373.2±91.7, p<0.001). Importantly, the present polymorphism affected significantly fibrinogen levels (GG+GA vs AA) not only in controls (366.6±85.8 vs439.1±122.3, p<0.05), but also in CAD (426.0±122.7 vs 521.8±113.1, p<0.001). *Conclusions.* The G455A genetic polymorphism has a striking effect on fibrinogen levels both in controls and in patients with coronary artery disease. In addition, it affects partly sCD40L in the total population. Our findings suggest that the G455A polymorphism affects the thrombotic process and consequently promotes atherosclerosis, especially via its significant impact on fibrinogen.

IDENTIFICATION OF MOLECULAR BASIS OF ANTITHROMBIN DEFICIENCY: CLINICAL FEATURES OF 30 INVESTIGATED PROBANDS AND REPORT OF 12 NOVEL MUTATIONS

V De Stefano, S Marietti, E Rossi, T Za, A Ciminello, S Betti, P Chiusolo, G Leone

Institute of Hematology, Catholic University, Rome, Italy

Background. More than 200 mutations of antithrombin (AT) gene cause type I (quantitative) or type II (qualitative) deficiency. Type II is subclassified according to dysfunction of the reactive site (RS) or heparin binding site (HBS) or pleiotropic effects. Type II HBS is associated with a low thrombotic risk. *Aims.* To investigate the gene mutations causing AT deficiency. *Patients and Methods.* DNA of 23 patients with AT deficiency and venous thromboembolism (VTE) was sequenced according to Picard *et al.* (Thromb Haemost 2005;93:57). Seven asymptomatic women with AT deficiency identified by screening before pregnancy or oral contraceptive intake were also analyzed. *Results.* Twenty-one different mutations were identified in patients with VTE. Three novel (E34X, W307X, Y260_P352del -two cases) and five known (C-4X, A94V, R129X -two cases, R132X, R425QfsX8) mutations were found in ten heterozygous patients with type I deficiency. In two of them heterozygous factor V Leiden (+R129X) and prothrombin G20210A (+C-4X) were present. Four novel (E205K, E265K, D342G, E377D) and one known (M251I) mutations were found in five heterozygous patients with type II RS deficiency, in one of them associated with heterozygous factor V Leiden (+E377D); three known mutations (L270P, A404T, L409P -two cases) were found in four heterozygous patients with pleiotropic (quantitative-qualitative) AT deficiency. Two known mutations (P41L, R47C) were found in two heterozygous patients with type II HBS deficiency, in both cases with additional abnormalities (LAC and anti-beta-2-glicoprotein I in the former case, homozygous factor V Leiden in the latter). One novel heterozygous mutation (E180K) was found in one patient with type II HBS deficiency who had first VTE at 77 years of age. Finally, one patient with type I deficiency was double heterozygous for two novel mutations, L210PfsX43

and G2R; the father heterozygous for L210PfsX43 had type I deficiency, whereas heterozygous G2R mutation had null effect in the mother. Among the asymptomatic women, three with type I deficiency had two novel (S250IfsX16 and V303CfsX13) and one known (C-4X) heterozygous mutations. Four with type II HBS deficiency had three known heterozygous mutations (R47H, R47C, L99F -two cases), in one of them associated with heterozygous prothrombin G20210A (+L99F). In four pregnant women (one type I and three type II HBS) antithrombotic prohylaxis was tailored according to the phenotype. *Conclusions.* The molecular bases of AT deficiency are heterogeneous; their identification can provide data to understand AT structure-function and to give advice for antithrombotic prophylaxis tailored according to different AT deficiency subtypes.

THE RELEASE OF PLATELET FACTOR 4 (PF4) IS IMPAIRED IN PATIENTS WITH ET, ESPECIALLY THOSE PRESENTING BLEEDING COMPLICATIONS

B Sokolowska,[1] M Kowalska,[2] K Bykowska,[3] A Nowaczynska,[1] A Walter-Croneck,[1] S Chocholska,[1] E Mendek-Czajkowska,[3] T Gromek,[1] K Wejksza,[4] M Kandefer-Szerszen,[4] J Windyga,[3] K Warzocha,[3] A Dmoszynska[1]

[1]*Medical University, Lublin, Poland*
[2]*The Children's Hospital of Philadelphia, Philadelphia, United States of America*
[3]*Institute of Hematology and Blood Transfusion, Warszawa, Poland*
[4]*Virology and Immunology, University of Marie Curie- Sklodowska, Lublin, Poland*

Background. Essential thrombocythemia (ET) is characterised by bleeding tendency, thrombotic complications and qualitative platelet defects. PF4 is synthesized in megakaryocytes and stored in platelet α-granules. After platelet activation PF4 is released in high concentration in the vicinity of vessel wall injury. That is why PF4 is the most important marker of platelet activation. According to the literature, clot formation and stability are optimal at phisiological levels of PF4. Both increased and decreased PF4 levels in platelets disrupt normal clot development. Our previous results indicated that platelets of ET patients release less PF4 during *in vitro* clot formation, but the examined group of patients was too small. *Aim.* In this study we assessed serum PF4 level and plasma activity of main coagulation factors in a group of 106 ET patients and looked for correlation between these parameters and bleeding or thrombotic complications. *Methods.* We have examined 106 patients with ET (80 females and 28 males, mean age 54 (23-82). The control group (CG) consisted of 20 healthy persons: 6 males and 14 females (mean age 41 (31-54)). We evaluated serum level of PF4, cholesterol and triglycerides and plasma activity of factors: I, VIII, XII, AT, protein C and S. We assessed also von Willebrand factor antigen and activity and urokinase plasma level. *Results.* In 21 patients (19.8%) from ET group 37 thrombotic complications occurred an in 22 (20,75%) patients bleeding episodes were noticed. Concentration of PF4 was higher in ET patients serum as compared to the CG (median 86.25;P25-75%,66.69-98.18 versus 70.00;49.00-90.50IU/ml, p<0.05). To eliminate the influence of elevated PLT amount on PF4 concentration a ratio of PF4 per million platelets was calculated. The ratio PF4/ 1mln PLT was significantly lower in ET group as compared to CG (median 108.94,P25-75%,82.40-125.06 versus 251.71,180.52-387.36, p <0.001). Additionally, PF4/ 1mln PLT ratio was statistically significantly lower in patients presenting bleeding complications compared to patients with thrombotic complications (median 95.42,P25-75%:74.05-120.66, versus 121.29,P25-75%,93.39-154.88, p<0.05). When evaluating plasma activity of main coagulation factors we found an interesting tendency. Von Willebrand factor activity (vWF:RCo) was reduced below normal limit in 25% of ET patients with bleeding episodes, in 10,5 % of ET patients with thrombotic complications and in 21,8% of ET patients without any complications. Because of this, the median von Willebrand factor activity in patients with bleeding episodes was lower than in patients with thrombotic ones (median 66.50%, P25-75%, 48.90-90.70 versus 87.40%, 67.00-134.00, p<0.05). The urokinase serum level was higher in ET patients compared to CG (median 0.581, P25-75%, 0.456-0.823 versus 0.439; 0.354-0.558 ng/ml, p<0.05) but we didn't notice any difference between patients with bleeding and thrombotic complications. *Conclusions.* Platelets of ET patients presenting bleeding complications release significantly less PF4 during *in vitro* clot formation than platelets of ET patients with thrombotic complications, which may indicate impaired platelet function and impaired clot formation *in vivo*. Bleeding tendency observed in ET patients may be a result of the coexistence of impaired platelet function and some other causes of diathesis, such as low von Willebrand factor activity.

0622

SENSITIVE APTT FOR LUPUS ANTICOAGULANT (LA) DETECTION. IS IT USEFUL AS A FIRST STEP IN A BASED-TEST ALGORITHM IN CLINICALLY SUSPECTED ANTIPHOSPHOLIPID SYNDROME (APS) DIAGNOSIS?

N Fernandez-Mosteirin, C Salvador-Osuna, M Torres, M Abio, A Iborra, C Sierra, L Saez, L Costilla, C Gallegos, I Parra, M Andrade, I Cuadrado, A Montes, J Lucia, D Rubio-Felix

Hospital Universitario Miguel Servet, Zaragoza, Spain

Background. According to the guidelines for LA detection updated in 2009 by the ISTH (V. Pengo *et al.*, JTH 2009; 7: 1737-40), testing for LA should be limited to patients with a significant probability of having APS, or unexplained prolonged aPTT. Single test is not sensitive to detect LA, being necessary to perfom two different tests: Diluted Russell Viper Venom Time (dRVVT) as first choice, followed by a sensitive aPTT (low phospholipid and silica as activator). Neverthless in some centers aPTT is the first choice for LA detection. *Aim.* To define a laboratory based algorithm depending on the test performed for the first step evaluation in LA detection in patients with APS. *Patients and Methods.* Along a period of two months, 220 patients underwent evaluation for suspected hypercoagulability status. In cases with clinical criteria of APS according to the Sapporo International Consensus Statement, the clinical files (demographic, clinical and inherited and acquired thrombophilic risk factors) of patients, were reviewed. Sensitive aPTT and dRVVT were performed using an ACL TOP-3G automatized coagulometer (Instrumentation Laboratory). *Results.* 220 patients were evaluated for hyperocoagulable status (including LA). Positive result for LA was detected in 43 patients (19.5%) male (M) 18 (41.8%) and female (F) 25 (58.1%) with a median age of 50 years (range: 5-82). Prolonged sensitive aPTT was detected in 19 of these 43 patients (44.2%), M 9 (47.4%) and F 10 (52.6%) with a median age of 52 years (range: 5-79). Clinical events were deep vein thrombosis/pulmonary embolism 14 (32.5%); cerebrovascular disease 9 (20.9%); arterial ischaemia 5 (11.6%); venous and arterial thrombosis 2 (4.6%); obstetric complications 1 (2.3%); connective tissue disease 8 patients (18.6%) and 4 (9.3%) prolonged aPTT. 17 patients were diagnosed of APS on the basis of clinical and biological data. 7 (41.2%) of these APS patients were negative for prolonged sensitive aPTT (aPTT ≤ 38.0 sec), 5 M and 2 F, median age of 52 years (range: 46-71), 4 patients presented venous thrombosis and 3 patients arterial thrombosis. No prolonged sensitive aPTT was detected in absence of LA positive detection. *Coclusions.* 1) According to the latest updated recommendations, dVRRT must be considered as the first choice as first step in LA detection due to the possibility of misdiagnosis when sensitive aPTT is performed as first choice. 2) Combination of both tests seems to be the better choice in performing a test-based algorithm for LA detection. 3) Guidelines for LA detection and their updating in facets of test performance including preanalytical, analytical, and postanalytical issues are necessary to improve knowledge and experience.

0623

ASSOCIATION BETWEEN INTERLEUKIN-6 AND CORONARY ARTERY DISEASE SEVERITY AMONG NON-ELDERY PATIENTS

M El-Ali, T Theodoridis, S Koulouris, K Triantafyllou, M Karantza, A Manolis, V Christopoulou- Cokkinou

Eyangelismos General Hosptial, Athens, Greece

Background. Systemic inflammation and carotid atherosclerosis markers have been used to detect patients at high risk of cardiovascular disease. We investigated the association of hs-CRP and a cytokine panel (IL-6, IL-1b, IL-8, IL-10 and TNF-a) to coronary artery disease (CAD) extent, accounting for the effect of subclinical carotid atherosclerosis. *Methods.* Eighty-three patients (92.8 % males, 54.5±7 year-old) had their first coronary angiogram after an acute coronary syndrome (81.9%) or for recently diagnosed or suspected stable CAD (18.1%). Coronary arteries with stenosis ≥50% (CS), Gensini score (GS) and Hamsten score (HS) were used as indices of CAD severity. Carotid B-mode ultrasound was performed bilaterally to measure maximal carotid intima-media thickness (CIMT) and maximal carotid plaque thickness (CPT). Serum levels of lipid parameters, hs-CRP and a cytokine panel (IL-6, IL 1b, IL-8, IL-10 and TNF-a) were also measured. Spearman rank correlations, logistic regression models and ROC curves were used for statistical analysis. *Results.* Hs-CRP significantly correlated with IL-6 (0.422, p<0.001), but not with any other cytokine. IL-6 correlated strongly with all CAD severity scores (CS: r=0.362, p=0.001, GS: r=0.380, p < 0.001, and HS: r=0.370, p=0.001), but not with CIMT or CPT. In contrast, hs-CRP did not correlate with any of the above coronary or carotid ather-

osclerosis indices. Patients in the highest IL-6 concentration tertile had increased CAD scores and more often multi-vessel CAD (85.2% of cases) compared to patients in the middle (51.9%, p=0.018) or the lowest tertile (44.8%, p=0.002). Patients in the highest versus lowest IL-6 concentration tertile were more likely to have multi-vessel CAD, after adjustment for risk factors, age, gender and CIMT (adjusted OR: 2.464, 95% CI: 1.16-5.233, p=0.019) or CPT (adjusted OR: 2.523, p=0.015). At ROC curve analysis IL-6 was a significant albeit modest predictor of multi-vessel CAD (AUC=0.693, 95% CI: 0.577-0.809, p=0.003). Circulating IL-6 levels >4.8 pg/ml predicted multi-vessel disease with 64% sensitivity and 67% specificity. *Conclusions.* Among non-elderly patients with initially diagnosed or suspected CAD, circulating IL-6 levels were associated with CAD severity, suggesting an important link between IL-6 and coronary atherosclerosis.

0624

FIBRINOGEN MODIFICATION BY SHEAR STRESS ACTIVATED PLATELETS

J Suttnar, K Pimková, J Štikarová, J Dyr

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background. Laminar shear stress in bulk circulation activates platelets to different levels and may initiate arterial thrombosis at sites of pathological blood flow. The exposition of platelet surface receptors is changed, and storage proteins and low molecular species either stored or formed de novo are released. The low molecular substance malondialdehyde (MDA) is formed as a consequence of lipid peroxidation and/or of prostaglandin's metabolism in platelets. MDA is reactive toward amino groups of proteins and nucleic acids, it has been inferred to have mutagenic and cytotoxic roles, possibly to be a participant in the onset of atherosclerosis. In a previous work we studied the influence of oxidative modification of fibrinogen on platelet dynamic adhesion and found significantly lower platelet adhesion on fibrinogen modified with MDA. *Aims.* The aims of the present study were to determine wheather MDA is formed in shear stressed platelets suspended in fibrinogen and if it modifies the fibrinogen molecules. *Methods.* Blood was drawn from healthy volunteers, who had not ingested any drug for at least two weeks, in accordance with the Ethical Committee regulations of our Institute. Washed blood platelets were isolated by differential centrifugation of blood and resuspended in Tyrode buffer at pH 7.4 in the presence of human fibrinogen (final concentration 1 mg/ml). High shear was applied with a cone and plate analyzer, the Impact-R (DiaMed) in acordance with manufacturer's manual. Samples (washed platelets - fibrinogen) were placed onto a polystyrene plate onto which a Teflon cone was perfectly fitted. After incubation (10 s) shear was applied (shear rate 1800 s^{-1}) for 1, 5, 15, 30 minutes. The protein carbonyls formed in platelet suspension were estimated using dinitrophenylhydrazine, the released serotonin and formed MDA derivatized with thiobarbituric acid were estimated using chromatographic methods. Dinitrophenylhydrazine derivatized proteins (DNPH-proteins) were analysed using SDS-PAGE and immunoblotting. Adhered platelets stained with May-Grunwald were analyzed by an image analyzing system. The platelet adhesion was recorded by an examination of the percentage of the total area covered with platelets, expressed as a surface coverage (SC, %). *Results.*We found the release of serotonine, time-dependend icreasing formation of MDA and DNPH-proteins and increasing platelet adhesion throughout the experiment. Both serotonine release and MDA formation reflected the platelet activation due to shear stress. The most pronounced bands of DNPH-proteins on SDS-PAGE immunoblots were the fibrinogen alpha, beta and gamma chains. *Summary/conclusions.* Fibrinogen is the protein most vulnerable to oxidative stress products and indeed the fibrinogen molecules were preferable modified with MDA. We found that MDA formed in platelets activated by shear stress and modified platelet proteins and fibrinogen in buffer. According to our previous results malondialdehyde modification of fibrinogen decreases platelet adhesion, therefore the MDA production by platelets activated by shear stress may possibly protect platelets from further activation.

SMOKING AND ADAMTS-13 LEVELS IN HEALTHY MALES

A Al-Awadhi,[1] M Jadaon,[2] F Al-Sayegh,[3] S Al-Sharrah[2]

[1]*Faculty of Allied Health, Kuwait University, Sulaibekhat, Kuwait*
[2]*Faculty of Allied Health Sciences, Kuwait University, Jabriya, Kuwait*
[3]*Department of Medicine, Faculty of Medicine, Kuwait University, Jabriya, Kuwait*

Background. The procoagulant protein von Willebrand factor (vWF), which has prothrombotic activity, was reported to be elevated in smokers leading to increase incidence of thrombosis. vWF is down-regulated by ADAMTS-13 protease (members of a disintegrin and metalloprotease with thrombospondins 1 repeats). No reports on the effects of smoking on ADAMTS-13 are currently present, particularly in Arab ethnicity. *Aim.* To determine the effects of smoking on ADAMTS-13 antigen and activity levels in healthy Arab smokers in Kuwait. This will clarify the role of ADAMTS-13 in hemostasis and thrombosis, and adds on to the mechanism of thrombosis in smokers. *Methods.* 200 Arab males were recruited. After obtaining consent, venous blood samples from 80 smoker and 80 nonsmoker healthy subjects were collected after asking subjects to fast and refrain from smoking for 8 hours (smokers here were termed "smokers at rest"). Similar sampling was done for 40 smokers, who were asked to smoke one cigarette immediately before taking blood (termed "acute smokers"). For all blood samples, plasma was separated and used to measure ADAMTS-13 antigen and activity levels, as well as vWF collagen binding activity levels using commercial ELISA kits. *Results.* No difference in ADAMTS-13 antigen level was found between smokers at rest and nonsmokers, but ADAMTS-13 and vWF activities were significantly lower in smokers ($p<0.018$). Compared to smokers at rest, acute smokers had significantly higher levels of vWF activity and ADAMTS-13 antigen and activity levels ($p<0.01$). *Conclusions.* The increase in vWF activity in smokers is an acute mechanism that occurs in respond to endothelial injury caused by cigarette consumption. High vWF activity is accompanied by an increase in ADAMTS-13 activity as a natural physiological mechanism to degrade the elevated vWF molecules. If not followed by a subsequent smoke, the activities of both proteins subside. The repeated increase in vWF and constant degradation by ADAMTS-13 result in lower overall levels of both proteins in smokers (at rest) compared to nonsmokers who do not experience a similar (repeated) injury to the endothelium.

ASSESSING THE IMPACT OF THE G58A POLYMORPHISM ON FIBRINOGEN A-CHAIN GENE IN PATIENTS WITH STABLE ANGINA: EFFECTS ON SPECIFIC MARKERS OF COAGULATION

M Kozanitou, A Vlachopoylou, N Papageorgiou, N Tousoulis, G Katsadiotis, E Papagrigoriou, C Stefanadis, Z Pallantza

Hippocratio Hospital, Athens, Greece

Purpose. Evidence suggests that the G58A polymorphism on fibrinogen a-chain gene is associated with increased fibrinogen levels in healthy individuals. However, it is still unclear, whether this polymorphism is associated with coagulation/thrombosis in patients with coronary artery disease (CAD). In the present study we examined the impact of this polymorphism on fibrinogen levels, D-dimers levels and plasminogen levels. *Methods.* The study population consisted of 395 subjects, 246 of which angiographically documented for CAD. The G58A polymorphism was detected by polymerase chain reaction (PCR) and appropriate restriction enzymes. Fibrinogen levels were measured by immunonephelometry, while plasminogen and D-dimers levels were measured by standard coagulometry techniques. *Results.* The genotype distribution was GG: 37.8%, GA: 39.4% and AA: 22.8% for patients with CAD, while GG: 33.5%, GA: 44.3% and AA: 22.2% for controls. Patients with CAD had significantly higher fibrinogen levels (mg/dl) than controls (434.7±132.7 vs 384.7±103.7, p=0.0002). However, in patients with CAD fibrinogen levels were not significant higher for 58AA homozygotes vs 58G carriers (453.6±131.4 vs 441.1±140.6, p=NS), while similar difference occurred in controls (AA: 385.2±129.4 vs GG+GA: 392.6±103.0, p=NS). Moreover, D-dimers levels (mg/L) were significantly higher in CAD patients than controls (409.7±188.2 vs 332.8±199.4, $p<0.0001$). In addition, there was a significant difference for 58G carriers vs 58AA homozygotes for CAD patients (506.4±418.8 vs 662.2±627.1, $p<0.05$), but not for controls (AA: 415.6±289.6 vs GG+GA: 355.9±276.5, p=NS). Finally, CAD patients and controls had no significant difference in plasminogen levels (u/ml) (119.8±79.1 vs 113.9±22.9, p=NS). Patients with CAD had no difference in plasminogen for 58AA homozygotes vs 58G carriers (110.2±20.6 vs

112.2±17.2, p=NS), while no significant difference was observed for controls (AA: 112.3±16.7 vs GG+GA: 114.3±23.5, p=NS). *Conclusions.* Our findings indicate that the G58A polymorphism on fibrinogen a-chain gene affects D-dimers levels in patients with coronary artery disease. These findings provide a possible mechanism by which this polymorphism may affect thrombotic process/coagulation independently of fibrinogen levels and may have important clinical implications.

ALTERED COAGULATION PROCESS IN PATIENTS WITH HYPERTENSION: THE ROLE OF THE G455A POLYMORPHISM

M Kozanitou, A Vlachopoylou, N Papageorgiou, N Tousoulis, E Andronopoulou, S Kontos, C Stefanadis, Z Pallantza

Hippocratio Hospital, Athens, Greece

Purpose. Genetic polymorphism G455A on fibrinogen b-chain gene has been associated with the risk of coronary artery disease. However, it is unknown whether it affects the prothrombotic profile of patients with hypertension (HT). In the present study we examined the impact of this polymorphism on fibrinogen, D-dimers, factor V (fV) and factor X (fX) levels in the aforementioned population. *Methods.* The study population consisted of 266 HT and 165 non HT. The G455A polymorphism was determined by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique, while circulating levels of fibrinogen were measured by the von Clauss method. D-dimers levels, fV and fX levels were measured by standard coagulometry techniques. *Results.* The genotype distribution in non HT and HT was GG: 50.9%, GA: 41.8%, AA: 9.7% and GG: 51.5%, GA: 37.6%, AA: 10.9% respectively. There was no significant difference in fibrinogen levels (μg/dl) between 455AA homozygotes and 455G allele carriers in non HT patients (448.3±34.6 vs 395.4±9.9, p=NS). Importantly, 455AA genotype presented with much more elevated levels of fibrinogen compared to the GG+GA in HT patients (535.4±25.3 vs 414.2±8.0, p<0.001). Moreover, HT 455AA homozygotes had significantly increased D-dimers levels (μg/l) compared to 455G allele carriers (640.3±83.6 vs 485.5±27.2, p<0.05). No difference was observed for non HT regarding D-dimers between the 455AA genotype and GG+GA (477.6±74. vs 450.8±40.7, p=NS). Interestingly, 455AA genotype presented with higher fV(%) and fX(%) levels compared to GG+GA in HT patients (133.6±5.8 vs 117.8±3.3, p<0.05, for fV) and (101.9±4.6 vs 92.2±2.4, p<0.05, for fX). However, no difference was observed in fV and fX levels between 455AA and GG+GA in non HT (105.8±11.6 vs 118.7±4.4, p=NS for fV) and (95.8±8.0 vs 119.4±29.1, p=NS for fX). *Conclusions.* The genetic polymorphism G455A on fibrinogen b-chain gene has a remarkable impact on prothrombotic profile of patients with hypertension, given its effect on fibrinogen, D-dimers, factor V and factor X levels. These findings provide evidence that this polymorphism affects significantly the mechanisms of the coagulation process in hypertensives.

ALTERED ENDOTHELIUM-DEPENDENT RELAXATION INDUCED BY ERYTHROCYTE MEMBRANE FROM SUBJECTS WITH DIFFERENT HAEMOGLOBIN GENOTYPES IN ISOLATED RABBIT CAROTID ARTERIES

I Ajayi

University of Benin, Benin City, Nigeria

Background. The literature contains conflicting reports concerning changes in vascular reactivity following interaction between erythrocytes and vascular endothelial cells. *Aim.* The goal of this study was to characterize the effect of constituents of erythrocytes from subjects with different Hb genotypes on acetylcholine-induced endothelium-dependent vasorelaxation. *Methods.* Isometric contractions of ring preparations (5mm long) of rabbit carotid artery (n=6) suspended in 20ml organ baths and bubbled with 95% O2, 5% CO2 were studied pharmacologically using standard *in vitro* techniques under an initial load of 1g, at 37oC and pH 7.4. Concentration-dependent contractile responses induced by phenylephrine (PE) as well as relaxation responses induced by acetylcholine (Ach) were examined and their respective EC70 and IC70 values obtained. Acetylcholine (IC70M)-induced relaxations of pre-contractions induced by EC70 M phenylephrine were examined in control rings as well as in rings exposed for 30 minutes to (a) intact washed erythrocytes (b) erythrocyte ghosts and (c) haemoglobin - all obtained from subjects of different haemoglobin genotypes (AA, AS and SS). Arterial rings were exposed to 50μl of each of the erythrocyte constituents at an adjusted haematocrit of 0.6. *Results.* Ach-induced relaxation was significantly (p<0.05) enhanced by AA erythrocytes (46.2±3.25 and 69.5±5.4% for control and test, respectively). In contrast, AS and SS erythrocytes as well as exposure to Hb did not significantly alter Ach relaxation whereas AS and SS ghosts significantly (p<0.01) attenuated Ach relaxation. Compared with AA, erythrocytes but not Hb from AS and SS subjects elicited significantly greater inhibition of Ach relaxation; futhermore, inhibition of Ach relaxation by erythrocyte ghosts was significantly greater with AS than SS. *Conclusions.* Our results show that a membrane-bound factor may account for the genotype-dependent attenuated Ach-induced relaxation following interaction between erythrocytes and vascular endothelial cells.

A SINGLE NUCLEOTIDE POLYMORPHISM ON FIBRINOGEN BETA CHAIN GENE MODIFIES ATHEROGENESIS INDEPENDENTLY OF FIBRINOGEN LEVELS

M Kozanitou, N Papageorgiou, A Vlachopoylou, N Tousoulis, A Bramos, A Tsatsi, C Stefanadis, Z Pallantza

Hippocratio Hospital, Athens, Greece

Purpose. Evidence suggests that impaired coagulation process contributes to atherogenesis and its clinical manifestations. In addition, the role of the genetic variability on fibrinogen beta chain gene on fibrinogen levels is widely speculated. In the present study we sought to examine whether a single nucleotide polymorphism could affect the coagulation cascade beyond its effect on fibrinogen. *Methods.* The study population consisted of 318 patients with documented coronary artery disease (CAD) and 221 controls. The G455A polymorphism was estimated by polymerase chain reaction (PCR) and the specific HaeIII restriction enzyme. Serum levels of D-dimers, factor (f) V, factor (f) X were measured by standard coagulometry techniques. *Results.* The genotype distribution was GG: 49.3%, GA: 41.2%, AA: 9.5% for CAD and GG: 55.2%, GA: 35.7%, AA: 9.1% for controls. Through the study (overall) population the G455A polymorphism affected significantly D-dimers levels (μg/l) between the G allele carriers and the AA homozygotes (median: 2.55[2.37-2.71] vs 2.68[2.38-2.83], p<0.05), as well as fV (%) (114.6±24.7 vs 126.8±26.6). No effect was observed on fX levels (p=NS). Moreover, there was no significant difference in the studied parameters across the genotypes in the control group (p=NS for all). Controversially to the control group, the G455A polymorphism defined D-dimers and fX and fV levels in CAD patients. More specifically, the AA homozygosity was associated with significant increased levels of D-dimers (median: 2.75[2.50-2.90] vs 2.60[2.40-2.70]), fV (135.0±20.5 vs 119.5±24.8) and fX (102.4±19.6 vs 90.1±22.8) compared to the G allele carriers (p<0.05 for all). *Conclusions.* A single nucleotide polymorphism on beta chain fibrinogen gene, regulates D-dimers, factor V and factor X levels in patients with advanced atherosclerosis. Our findings indicate that the G455A polymorphism may affect the coagulation, a responsible underlying mechanism for atherogenesis and this is beyond its effect on fibrinogen.

ADMISSION MEAN PLATELET VOLUME PREDICTS LEFT VENTRICULAR SYSTOLIC DYSFUNCTION IN PATIENTS WITH ACUTE ST-ELEVATION MYOCARDIAL INFARCTION TREATED WITH PRIMARY ANGIOPLASTY

M Vrsalovic,[1] M Marusic Vrsalovic,[2] B Getaldic[1]

[1]*University Hospital Sestre Milosrdnice, Zagreb, Croatia*
[2]*University Hospital Dubrava, Zagreb, Croatia*

Background. Left ventricular systolic dysfunction (LVSD) after acute myocardial infarction (AMI) worsens short- and long-term prognosis. Admission mean platelet volume (MPV), an indicator of platelet reactivity, is an independent predictor of impaired angiographic reperfusion and of both short- and long-term mortality after AMI. *Aim.* The aim of the study was to investigate the role of admission MPV on LVSD post AMI. *Methods.* The study included 360 patients (pts) with first acute ST-elevation myocardial infarction (STEMI), admitted to the University hospital from January 2003 to December 2007. In all the pts angioplasty of the culprit lesion was performed (only pts with < 12 h after the onset of symptoms were included and pts with malignant or inflammatory disease and cardiogenic shock were excluded from the study). Whole group characteristics: 70% man, mean age 63 years, diabetes in 27%, hypertension in 64%, current smoking in 35%, hyperlipidemia in 34%, infarct related artery: left anterior descending artery in 43%, left circumflex artery in 14%, right coronary artery in 43%, Killip class >1 in 23%, multivessel disease in 54%, TIMI flow: >1 pre PCI in 22%, >1 post PCI in 96%, time to treatment 4.8±3.6 h. MPV, platelet count (PLT) and C-reactive protein (CRP) were obtained at the time of admission

and samples were processed within 1 h of venepuncture. LVSD (defined as left ventricular ejection fraction <0.50) was assessed using transthoracic echocardiography (Simpson's method) within 6 days post AMI. *Results.* 126 pts (35%) had LVSD. Pts with LVSD were older, more frequently had anterior myocardial infarction, multivessel disease, heart failure on admission and longer time to reperfusion. Peak creatine kinase and admission troponin were significantly higher in pts with LVSD while CRP, admission creatinine, baseline and final TIMI flow, gender and cardiovascular risk factors were comparable in both groups. MPV was higher in pts with LVSD (8.82 vs. 8.46 fL, p<0.001), and increased with the degree of admission heart failure (8.46, 8.77, 9.32 fL for Killip class I-III respectively, p<0.001) while PLT did not differ between groups. MPV negatively correlated with PLT (r=-0.33, p<0.001) and positively with peak creatine kinase (r=0.16, p=0.03). ROC curve analysis showed that values of MPV>8.6 fL had 71.4% sensitivity and 57.3% specificity for predicting LVSD. After multivariable adjustment the independent predictors of LVSD were: MPV (OR 1.533, 95% CI 1.079-2.179), age (OR 1.095, 95% CI 1.029-1.165), anterior myocardial infarction (OR 6.094, 95% CI 1.808-20.538), multivessel disease (OR 3.538, 95% CI 1.105-11.333) and peak creatine kinase (OR 1.0006, 95% CI 1.0003-1.0009). *Conclusion.* Admission MPV is independent predictor of LVSD in pts with STEMI treated with primary angioplasty.

ANALYSIS OF BLOOD COAGULATION PROCESS WITHIN MURAL THROMBI GENERATED UNDER WHOLE BLOOD FLOW CONDITIONS

M Sugimoto, H Matsui, T Mizuno, M Doi, M Hamada, Y Matsunari, H Fukushima, K Nishio, A Yoshioka, M Shima

Nara Medical University, Kashihara, Nara, Japan

Background. Mural thrombus formation at sites of damaged vessel walls is fundamentals for both physiologic haemostasis and pathological intravascular thrombosis. Blood coagulation process playing a role in stabilizing thrombi has been studied so far basically in classic experimental approaches, such as APTT assays, that evaluate fibrin clot formation in a plasma solution devoid of blood cell components including platelets. However, such classic coagulation assays cannot necessarily reflect the *in vivo* mural thrombus formation, in which platelet adhesion/aggregation and blood coagulation can upregulate each other under whole blood flow conditions. *Aims.* We therefore established the *in vitro* assay system that can precisely evaluate the blood coagulation process during mural thrombus formation under whole blood flow conditions. *Methods.* Using an *in vitro* perfusion chamber system, blood coagulation during mural thrombogenesis under whole blood flow was visually evaluated by confocal laser scanning microscopy (CLMS) as the extent of intra-thrombus fibrin network formation, which was calculated as the ratio of fibrin relative to fibrinogen within mural thrombi generated on a collagen- or von Willebrand factor-coated surface in an immune-fluorescent method. The blood coagulation process within thrombi under flow was also evaluated in detail by the time-course changes of P-selectin expression, tissue factor (TF) accumulation, or thrombin binding on platelets. *Results.* Analysis by CLMS during perfusion of whole blood anticoagulated to various extent revealed that the size and shape of thrombi was dependent on the amount of intra-thrombus fibrin deposition under high shear rate conditions. The generation of platelet procoagulant activities was confirmed to occur with the sequence of (1) P-selectin expression, (2) TF accumulation, (3) thrombin binding, and eventually (4) fibrin deposition within platelet thrombi. *Summary/Conclusions.* Our system enables real-time observation of fibrin network formation in mural platelet thrombi, as well as analysis of the functional link between blood coagulation and mural thrombogenesis under whole blood flow conditions. With this approach, we visually evaluated successfully mural thrombogenicity of hemophilia patients with or without addition of activated coagulation factor VII, as well as the antithrombotic effects of 3-hydroxyl-3-methylglutaryl coenzyme A reductase inhibitors ("statins") under whole blood flow, an experimental situation most relevant for the *in vivo* haemostasis and thrombosis.

0632

HEMOSTATIC MARKERS EVALUATION IN A TRIAL OF THROMBOPROPHYLAXIS FOR NEWLY DIAGNOSED MYELOMA PATIENTS TREATED WITH LENALIDOMIDE AND DEXAMETHASONE

M Marchetti,[1] F Cavallo,[2] L Russo,[1] A Leuzzi,[1] A Vignoli,[1] A Palumbo,[2] A Falanga[1]

[1]*Ospedali Riuniti di Bergamo, Bergamo, Italy*
[2]*University of Torino, A.O.U. S. Giovanni Battista, Torino, Italy*

Background. Multiple myeloma (MM) patients receiving lenalidomide and dexamethasone combined therapy have an increased risk of thrombosis. Low-molecular weight heparin (LMWH) and low-dose aspirin (ASA) are used as thromboprophylaxis in these patients. In a prospective, multicenter phase III trial (RV-MM-PI-209) of newly diagnosed MM patients treated with lenalidomide and low-dose dexamethasone during induction therapy, the safety and the efficacy of low-molecular weight heparin (LMWH) or low-dose aspirin (ASA) as anticoagulant prophylaxis was assessed. *Aims.* In a group of MM patients enrolled in the RV-MM-PI-209 trial, selected markers of hemostatic system activation were measured in order to evaluate: 1. the biomarkers' predictive value for thrombosis, and 2. the modulation of the biomarkers by thromboprophylaxis during lenalidomide administration. *Methods.* Induction treatment consisted of four 28-day cycles of lenalidomide (25 mg d 1-21) and low-dose dexamethasone (40 mg d 1,8,15,22). All eligible patients were randomly assigned to receive LMWH (Enoxaparin 40 mg/d, N=166) or ASA (100 mg/d, N=176) for the duration of the induction therapy. Plasma samples from 36 patients were available for analyses at baseline (T0) before starting treatments (22 LMWH/14 ASA). In addition, plasma samples from 15 study subjects (10 LMWH/5 ASA) were obtained at the end of induction therapy (T1). On all plasma samples we measured prothrombin fragment F1+2 and Tissue Factor (TF), as markers of coagulation activation, and thrombomodulin (TM) as marker of endothelial cell activation. Forty healthy subjects acted as the control group. *Results.* At baseline, the levels of F1+2 (138±10.7 vs 100±13 nmol/L; p=ns), TF (115±20 vs 69±10 ng/ml; p=0.03) and TM (34±5.7 vs 11±0.9 ng/ml; p<0.001) were increased in the 36 MM patients compared to healthy controls. To evaluate the effect of lenalidomide/dexamethasone therapy, in association with LMWH or ASA, data from patients having samples available at both T0 and T1 were compared. The results showed that a reduction occurred from T0 to T1 for F1+2 (124±13 vs 109±16 nmol/L; p=ns), TF (164±21 vs 64±6.9 ng/ml; p=0.02), and TM (32±4.3 vs 25±2.8 ng/ml; p=ns) plasma levels. In addition, the plasma levels of both F1+2 and TF at the end of the induction therapy were similar to that of control subjects. Differently, at the same time point, the levels of the endothelial activation marker TM, were still significantly higher compared to controls. The decrease of F1+2 observed at T1, the marker of thrombin generation, was statistically significant for the subgroup of patients under LMWH (p=0.01), but not in those on ASA. *Conclusions.* Our data confirm the occurrence of blood coagulation and endothelium activation in MM patients. After induction therapy, the levels of the two blood coagulation makers tended to normalize towards controls' values. Differently, TM was still significantly higher, suggesting an insult of the antitumor therapy on endothelium. The analysis of data according to the type of thromboprophylaxis, showed that F1+2 significantly decreased in those patients receiving LMWH, but not in those receiving ASA. No thrombotic events occurred in the analyzed subgroup of patients to allow evaluation the predictive value for thrombosis of these markers.

Cellular immunotherapy and vaccination

POTENTIAL ROLE OF GLUTAMINE METABOLISM IN IMUNOMODULATION OF T-LYMPHOCYTES BY MESENCHYMAL STROMAL CELLS

F Araujo, G Ferreira, A Araujo, C Izumi, L Greene, D Covas, M Zago, R Panepucci

University of São Paulo, Ribeirão Preto, Brazil

Background. Mesenchymal stromal cells (MSCs) exert an immune regulatory function and suppress T-cell proliferation, but the mechanisms underlying this property are not completely known. Glutamine, the most abundant free amino acid of the human body, is metabolized by the enzyme glutaminase generating glutamate. However, in situations of glutamine deficiency, the enzyme glutamine synthetase produces glutamine from glutamate. Glutamine regulates cell proliferation by activating protein kinase A and mTOR signaling. Interestingly, inhibition of the mTOR pathway leads to an increased generation of regulatory T-cell. *Aims.* In this work, we evaluated the potential role of MSCs in the modulation of glutamine levels, as an immunomodulatory mechanism acting upon T lymphocytes. *Methods*. Peripheral blood CD3+ T-cell from 3 individuals were activated by anti-CD3/CD28 beads and cultured or not with MSC. Following a 5 day period, CD4+ T-cells and CD8+ T-cells were purified and profiled by whole genome microarrays and selected genes validated by RT-PCR. T-lymphocytes from 3 independent individuals were similarly activated and cultured. In addition, we cultivated MSCs alone or in presence of activated T-cell supernatant. Following a 5 day period, glutamine and glutamate levels were analyzed in culture medium by hplc. In another experiment T-lymphocytes were co-cultivated, as described, and T-cell proliferation was analyzed upon addition of glutamine at different concentrations (0.5, 0.7 and 1.0mM). *Results*. As expected, proliferation of lymphocytes co-cultured with MSCs was significantly inhibited (cfse). Using the Ingenuity Pathway Analysis, our microarray data revealed that mTOR pathway was down regulated in lymphocytes immunomodulated by MSC. Concordantly, these immunomodulated lymphocytes expressed higher levels of genes associated with regulatory T-cells, such as IL10, FOXP3, CTLA-4 and GITR (validated by RT-PCR). Levels of glutamine were lower in the culture media of T-cells cultivated with MSCs (as compared to those cultured alone), while the levels of glutamate were higher. In line, the expression of glutamine synthetase was increased in immunomodulated lymphocytes. Interestingly, while high levels of glutamine were found in the media of MSCs or activated lymphocytes cultured alone; when the culture media from MSCs cultured alone was substituted by that of activated lymphocytes cultured alone (in the 3rd day of culture), glutamine levels at the last 5th culture day were strikingly reduced, indicating that the inflammatory stimuli provided by the media of activated T-cells lead MSCs to consume the glutamine present in the media. This mechanism can be responsible by the low levels of glutamine found in the co-culture of MSCs and lymphocytes. Finally, while the addition of glutamine to cocultures partially restored the proliferation of immunomodulated T-lymphocytes in a dose dependent manner, lymphocytes cultured alone showed no change in cell proliferation by addition of glutamine. We are currently addressing the potencial role of MSCs glutaminase, in the consumption of glutamine, by using a glutaminase inhibitor. *Conclusions*. Our results point to a new immunoregulatory mechanism, by witch MSCs would restrict lymphocyte proliferation, trough the consumption and deprivation of glutamine from the surroundings. Finally, reduced glutamine levels would implicate reduced mTOR signaling, contributing to an increase in the generation of regulatory T-cell.

0634

DELICATE BALANCE BETWEEN THE ABSOLUTE NUMBERS OF ANTIGEN-PRESENTING CELLS AND ANTIGEN-SPECIFIC T CELLS DETERMINES THE LIKELIHOOD OF SUCCESSFUL *IN-VITRO* PRIMING OF IMMUNE RESPONSES

TS Lam, M van de Meent, C Hoogstraten, A Raven, J Pots, F Falkenburg, I Jedema

Leiden University Medical Center, Leiden, Netherlands

Background. In-vitro generation of primary T cell responses from a naive repertoire against selected antigens (Ag) is essential for the development of adoptive immunotherapeutic strategies. Although feasible, the limited robustness of the procedure hampers broad scale clinical application so far. *Aims.* In this study, we investigated in detail the role of the type of the antigen-presenting stimulator cells and antigen dosing in priming, survival, and expansion of antigen-specific precursor T cells (Tprec). *Methods.* We developed an *in vitro* model that allows kinetic functional monitoring of activation and proliferation of antigen-specific T cells using fluorescent dye (PKH or CFSE) labeling, CD137 counterstaining and quantitative flow cytometry. T cell clones (or purified naive T cell populations in a selected number of experiments) were stimulated with antigen-presenting cells (APC) derived from various sources, including monocytes, monocyte-derived dendritic cells (DCs), EBV-LCL and primary leukemic APC at CTL/stimulator (CTL/S) ratios ranging from 10/1 to 1/625 in the presence of variable numbers of innocent bystander T cells, mimicking different frequencies of antigen-specific Tprec within a total responder (R) cell population. *Results.* Using professional APC like monocyte-derived DCs as stimulator cells, optimal T cell activation was observed at CTL/S ratios critically ranging between 1/1 and 1/10. This phenomenon occurred irrespective of the presence of different numbers of innocent bystander T cells, illustrating that optimal T cell activation is determined by the specific Tprec/S ratio rather than the total cellular R/S ratio. Exposure of individual CTL to higher numbers of stimulators resulted in overstimulation and activation-induced cell death (AICD) of the specific T cells. Within the naive repertoire, specific Tprec frequencies for a single antigen are estimated to be as low as 1 in 1,000.000 to 1 in 10,000. Taken the above data into account, application of the widely chosen R/S ratio of 10/1 for priming of specific Tprec with a Tprec frequency of 1 in 10,000 would correspond to an effective Tprec/S ratio of 1/1000, which may often result in the induction of AICD of the specific Tprec. Our data show that a maximum of 10 APCs per Tprec results in optimal stimulation, but this may seem to be in conflict with the likelihood of specific Tprec to encounter an APC among the bulk of bystander cells. Simultaneous triggering of multiple Tprec by targeting multiple antigens may therefore lower the likelihood of induction of AICD in the specific Tprec. This was confirmed by the generation of primary immune responses against (completely) HLA-mismatched APC. Using stimulator cells with an inferior APC phenotype (e.g. monocytes or primary leukemic cells), similar dose-response relationships were observed, but the range of optimal Tprec/S ratios was broader and was shifted towards a higher APC amounts per Tprec. Increasing the antigen dose on the APC surface shifted the Tprec/S ratio towards lower amounts of stimulators per Tprec. *Conclusions.* In conclusion, our data showed that a delicate balance between the absolute numbers of antigen-specific Tprec and antigen-presenting stimulator cells determines the likelihood of successful priming and survival of antigen-specific Tprec.

INTERLEUKIN-15 SKEWS HUMAN MONOCYTE DIFFERENTIATION INTO CD56+ DENDRITIC CELLS WITH CYTOLYTIC ACTIVITY AGAINST MYELOID LEUKEMIC CELLS

S Anguille,[1] K Couderé,[2] E Lion,[2] Y Willemen,[1] WP Lee,[2] K Lenders,[2] N Cools,[2] E Smits,[2] V van Tendeloo,[1] Z Berneman[1]

[1]*Antwerp University Hospital, Edegem, Belgium*
[2]*University of Antwerp, Vaccine & Infectious Disease Institute (LEH), Antwerp, Belgium*

Background. Recent research has underscored the potential clinical utility of dendritic cells (DCs) for antileukemia immunotherapy. Nonetheless, current DC-based immunotherapy strategies leave considerable room for improvement, particularly when it comes to the generation of DCs with maximal immunostimulatory potency. We and others have recently reported on a novel, improved protocol for DC generation using interleukin (IL)-15 (IL-15 DCs). *Aims.* A subpopulation of these IL-15 DCs was incidentally found to express the natural killer (NK) cell-related molecule CD56. The aim of the present study was to determine whether IL-15 DCs also possess NK cell-like effector functions that would allow them to exert direct cytolytic activity against myeloid leukemic cells. *Methods.* Human peripheral blood monocytes were allowed to differentiate into immature DCs for 24-36hr in the presence of granulocyte macrophage colony-stimulating factor and IL-15. CD56+ and CD56- IL-15 DC fractions were separated by positive immunomagnetic selection, and further matured for 18hr in the pres-

ence of the Toll-like receptor 7/8-agonist resiquimod. DC-mediated cytotoxicity towards the myeloid leukemic cell line K562 was measured by flow cytometry after overnight co-culture at different effector:target (E:T) cell ratios. Cytotoxicity blocking assays were performed using concanamycin A, an inhibitor of perforin/granzyme B-induced apoptosis, and neutralizing antibodies against tumor necrosis factor-related apoptosis-inducing ligand (TRAIL). *Results.* Flow cytometric immunophenotyping confirmed the expression of CD56 on a subpopulation of IL-15 DCs (34.3±2.1%). Contamination of NK cells was excluded on the basis of phenotypic analysis. Interestingly, CD56+ IL-15 DCs induced apoptotic cell death in up to 22.6±1.0% of K562 cells at an E:T ratio of 50:1. Compared to their CD56- counterparts, CD56+ IL-15 DCs displayed significantly stronger tumoricidal activity towards K562 cells at E:T ratios 50:1 (P=0.0002) and 25:1 (P=0.0063). The perforin inhibitor concanamycin A partially abrogated the cytotoxic effect of CD56+ IL-15 DCs (-51.8±11.7%). A further significant decrease in cytotoxicity was obtained by treatment with anti-human TRAIL antibodies (-22.5±2.8%). *Summary/Conclusions.* Here, we describe the unique ability of IL-15 to promote rapid differentiation of monocytes into CD56+ DCs endowed with cytotoxic activity against the myeloid leukemic cell line K562. The perforin/granzyme B-pathway, and to a lesser extent TRAIL-induced apoptosis, were implicated in IL-15 DC-mediated cytotoxicity. The observation that IL-15 DCs exert a direct antileukemic action provides strong support for their use in cellular immunotherapy of myeloid leukemia.

EX-VIVO ALLOGENEIC STIMULATION SIGNIFICANTLY IMPROVES EXPANSION OF CYTOKINE-INDUCED KILLER CELLS WITHOUT INCREASING THEIR ALLOREACTIVITY ACROSS HLA-BARRIERS

M Todorovic,[1] M Mesiano,[1] L Gammaitoni,[1] V Leuci,[1] L Giraudo Diego,[1] C Cammarata,[1] F Carnevale-Schianca,[1] S Gallo,[1] F Fagioli,[2] A Cignetti,[3] M Aglietta,[1] D Sangiolo[1]

[1]*Institute for Cancer Research and Treatment, Candiolo, Italy*
[2]*Ospedale Infantile Regina Margherita, Turin, Italy*
[3]*Ospedale Mauriziano, Turin, Italy*

Background. Cytokine-induced killer (CIK) cells are a heterogeneous subset of *ex-vivo* expanded T lymphocytes with a mixed T-NK phenotype and endowed with a HLA-unrestricted antitumor activity. CIK cells can be used in the autologous setting of cancer patients or as alternative to standard donor lymphocyte infusion following allogeneic hematopoietic cell transplant (HCT). CIK cells present a reduced risk to induce graft versus host disease (GVHD) in HLA identical siblings but retain a certain degree of alloreactivity when challenged across major HLA-barriers. Even if CIK cells can be efficiently *ex-vivo* expanded, their expansion rate has been reported to be greatly variable, ranging from only few to more than 1000 folds. This variability may be a potential limitation for their effective clinical applications in patients with poor expansion rates. *Aims.* We evaluated whether alloreactivity of CIK cells might be exploited as a new method to favorably increase their *ex-vivo* expansion preserving the antitumor ability and safety profile. Our hypothesis is that a timed allogeneic stimulation might provide CIK cells with a proliferation boost and potentially decrease the overall alloreactivity versus hypothetical third party recipients. *Methods.* Starting from healthy donors (n=7), we compared in parallel the standard expansion protocol of CIK cells, based on IFN-γ, Ab anti-CD3 and IL2, with a new one including the addition of irradiated allogeneic PBMC (ratio 1:1) as stimulators on day +7 and +14. After 4 weeks we compared expansion rates, antitumor activity and residual alloreactivity across major HLA-barriers (assessed by MLR versus third party HLA-mismatched PBMC, different from those used as stimulators during the experimental expansion). *Results.* Allo-stimulated CIKs (AS-CIK) presented significantly higher expansion rates (median 131 fold, range 24-720) compared to standard controls (median 32 fold, range 9-121, p <0.03). The expansion of the CD3+CD56+ fraction, main responsible for the antitumor activity, was significantly higher (2243 fold, range 443-4319) within AS-CIKs compared to controls (403 fold, range 67-1722, p< 0.03) (Fig. 1). AS-CIKs retained effective tumor killing ability (64%, 57%, 52% and 43% of specific killing, assessed versus osteosarcoma cell lines, at 40:1, 20:1, 10:1 and 5:1 effector/target ratio respectively) that resulted comparable with controls. The alloreactivity of AS-CIK cells against third party HLA-mismatched PBMC was reduced, without reaching statistical significance, compared to controls; the median percentage of alloreactive-proliferating cells within AS-CIKs was 29% (range 27,7-31,8) compared to 45,5% (range 30,2-54) of controls. The membrane expression of CD8+, CD4+ and NKG2D molecules was comparable between AS-CIKs and standard counterparts (p>0.05). Interestingly, AS-CIKs and standard controls presented a similar lifespan with a comparable telomere length (median 8.5 vs 8.7 Kb). *Conclusions.* Our data suggest that *ex-vivo* alloreactivity of CIK cells may be exploited to obtain significantly higher expansion rates without affecting the resulting antitumor ability, safety profile, phenotype or lifespan. If validated into clinical settings, these findings may improve the efficacy of adoptive immunotherapy with CIK cells; the reduced alloreactivity versus third party might have important implications into HCT settings to generate CIK cells with a further reduced risk of GVHD across major HLA-barriers.

THE INVOLVEMENT OF NCRS IN THE PRIMING STAGE OF NK CELL ACTIVATION BY TUMORS

M Tsirogianni, J North, S Jide-Banwo, M Lowdell

Royal Free Campus, University College London, London, United Kingdom

Background. CTV-1 tumor cells can specifically prime resting NK cells without triggering NK cell lysis. CTV-1 primed NK cells (pNK) have been used in a phase I trial for treatment of patients with AML. The pNK cells are able to lyse NK-resistant primary AML and tumor cell lines, even in the presence of inhibitory ligands (1). The CD69 surface molecule is upregulated on resting human NK cells by CTV-1 stimulation and can be used as a marker of successful priming. *Aim.* To assess the involvement of lectin-type and Ig-SF like NCRs in the NK cell priming process. *Methods.* CD56+ NK cells were purified from PBMCs of 6 normal donors by direct immunomagnetic separation. pNK cells were generated by coincubation with CTV-1 cells (ratio 1:2) for 16-20h. Matched pairs of NK/pNK cells (CD56+/CD3-) were immunophenotyped for CD69 (to assess NK activation), C-type lectin receptors (NKG2D, NKp80) and for Ig-SF like NCRs (NKp30, NKp44, NKp46). The proportion of cells expressing the specific Ag and its relative density of expression (median channel fluorescence-MedCF) were compared. To investigate the involvement of C-type lectins and Ig-SF like NCRs in the CTV-1 mediated NK priming, purified CD56+ NK cells from normal donors were preincubated for 30 minutes with cocktails of NK-receptor blocking antibodies before co-culture with CTV-1 cells. Four groups were tested: pNK1 - NK cells without added mAbs, pNK2 - NK cells pre-coated with anti-NKG2D, anti-NKp80 mAbs, pNK3 - NK cells pre-coated with anti-NKp30, anti-NKp44, anti-NKp46 mAbs and pNK4 - NK cells pre-coated with all Abs. After 24hours and 48 hours incubation period the CD69 percentage and MedCF expression of matched pairs of groups were compared as a measure of NK priming. *Results.* Within 24 hours co-incubation with CTV-1 CD69 was significantly up regulated in proportion (p=0.0061, 95%CI of mean of dif 17.17-61.75) and MedCF expression (p=0.013, 95%CI of mean of dif 6.68-32.44) compared with matched, non-stimulated NK cells. NKp80, NKp30 and NKp44 were unaffected by tumor priming while NKG2D and NKp46 were significantly downregulated. The blocking of C-type

lectins receptors significantly suppressed the proportion of pNK cells and the intensity of CD69 upregulation on pNK cells after coincubation with CTV-1 cells after 24 hours and 48 hours. In contrast, blocking of Ig-SF like receptors had no effect even when combined with the blockade of C-type lectins (Fig). CD69 is a known triggering ligand for human NK cells and we hypothesise that its presence and degree of expression is a marker of the pNK readiness to lyse tumor target cells. *Conclusion.* C-type lectin are the predominant NCRs involved in the process of NK cell priming by tumor cells while the Ig-SF like receptors have little or no role in the priming process.

LARGE SCALE GMP-GRADE PRODUCTION OF IL-2 VERSUS IL-15-ACTIVATED ALLOGENETIC NK CELLS AGAINST ACUTE MYELOID LEUKEMIA: PRE CLINICAL RESULTS OF THE NK-ACT TRIAL

D Rea, N Dulphy, V Hubert, E Melgire, JM Miclea, E Raffoux, N Boissel, J Larghero, A Toubert, G Socie, H Dombret

Hopital Saint-Louis, APHP, Paris, France

Background. Allogeneic natural killer (NK) cells have the potential to provide anti-leukaemic effects without inducing graft versus host disease. Several lines of evidence suggest that allogeneic NK cell-based immunotherapy in a non transplantation setting may be a promising approach against acute myeloid leukaemia (AML). *Aims.* In the NK-ACT trial, we aimed at (1) developing a good manufacturing practice (GMP)-compliant procedure for large scale production of allogeneic activated NK cells for immunotherapy of AML, (2) comparing NK activation driven by interleukin (IL)-2 and IL-15. *Methods.* Three healthy volunteers were enrolled after written informed consent. All reagents were manufactured under GMP conditions. Mononuclear cells (MNC) were collected on day -1 using a Cobe Spectra cell separator and stored overnight at 4-8°C. Platelets were removed on day 0 and MNC were incubated with CD3 and CD19 reagents (Miltenyi Biotec). T- andcells were depleted from MNC on the CliniMACS system, (separation program DEPLETION 3.1). depleted MNC were split into 3 equal fractions, placed in VueLife FEP bags (AFC) in serum-free SCGM CellGro® medium (CellGenix) at $2x10^6$/ml and incubated overnight at 37°C under 5% CO_2 in medium alone, IL-2 (Proleukin, 1000UI/ml) or IL-15 (10ng/ml, CellGenix). On day 1, cells were harvested, washed 3 times in 0.9% NaCl and resuspended with 5% human albumin and 0.9% NaCl prior to analysis. The final product enriched in activated NK cells was evaluated for total nucleated cells (TNC), NK, T-cells, B-cells and monocytes content, viability and stability, microbiological testing, NK cell receptor repertoire expression and cytolytic activity against AML cell lines. *Results.* Leukapheresis products contained $12.05x10^9$-$14.34x10^9$ TNC with 58.1%-65.8% CD3+ T-cells, 8.8%-11.7% CD20+ B-cells, 14.1%-20.8% CD14+ monocytes and 5.2-8.1% CD3-CD56+ NK cells. Cell selection consistently resulted in a >3-log T- and B-cell depletion efficiency, yielding a final T- andcell content of 12.2-28.2x105 and 3.3-12.7x105, respectively. TNC and NK recovery were respectively 19.2%-26.5% and 81.2-82.9%. depleted MNC contained 24.2 to 26.2% NK cells, other cells were mainly monocytes. After overnight culture, no T-cell expansion occurred. TNC recovery from IL-2 and IL-15-activated products were comparable and ranged from 48% to 63.3%. NK cell recovery did not significantly differ between IL-2 and IL-15-activated products and ranged between 58.6 and 100%. IL-2 and IL-15-activated cell products contained between 27.5% and 47.2% NK cells. Viability was reproducibly over 80%. When compared to medium alone, both IL-2 and IL-15 proved efficient in activating NK cells, as attested by the upregulation of CD69 and a remarkable increase in NK cytotoxicity against K562 and the following AML targets: HL-60, KG-1, OCI/AML3, THP-1 (1.9 to 3.5-fold increase in CD107a+ NK cells). Microbiological cultures were negative. Final cell products proved stable upon storage for up to 6h at 4-8°C. *Conclusion.* We successfully generated large numbers of T/B cell depleted GMP-grade allogeneic NK cells suitable for immunotherapy of AML patients. Both IL-2 and IL-15 proved efficient in triggering NK activation. NK-ACT provides a solid basis to further assess the clinical efficacy of such activated NK cells in adults with high-risk AML in a non transplantation setting.

The imidazoquinoline derivate imiquimod induces inflammatory responses and protection against transplanted tumors when applied to the skin in combination with a cognate peptide epitope (transcutaneous immunization, TCI). Investigating the influence of UV irradiation on the induction of a peptide-specific CTL-response we found that combining TCI with low dose UV-B boosted the CTL-response and induced potent memory formation. For UV-irradiation the induction of regulatory as well as NK-T cells and the release of suppressive cytokines like IL-10 and IL-4 has been described. As we were interested in the mechanisms behind supporting and inhibiting factors we depleted FoxP3+ regulatory T cells and found that specific CTL-responses were greatly enhanced. In *in vivo* studies it has been published that naturally occurring as well as induced Treg produce IL-10 to control immune responses. Here we can show that in our immunization protocol Treg mediated immune suppression is only partly dependent on the release of Treg-derived IL-10 which itself inhibits immune response formation as could be shown in experiments with IL-10-/- mice or application of an anti-IL-10-receptor-Ab. As the manipulation of NKT cells seems to play a substantial role in UV-induced suppression we immunized in a NK-T cell free system and induced increased immune responses showing suppressive capacities for this cell type. Understanding the structure behind UV-enhanced TCI could lead to further improvements and advanced vaccination protocols against tumors and persistent virus infection. arandalopez@uni-mainz.de

MOLECULAR MECHANISMS INVOLVED IN T-CELL SUPRESSION AND REGULATORY T CELL GENERATION BY MESENCHYMAL STROMAL CELLS

F Araujo, A Araujo, D Covas, M Zago, R Panepucci

University of São Paulo, Ribeirão Preto, Brazil

Introduction. In recent years, Mesenchymal Stem Cells (MSCs) have aroused the attention from scientific community for their capacity of suppress the T-cell proliferation and regulatory T-cells (Tregs) generation. These immunological properties of MSC attracted the interest of basic and clinical investigators, in light of its potential therapeutical use in different immunological diseases. Nevertheless, successful translation into clinical practice requires further dissection of the ways by witch MSCs modulate the signaling pathways activated on T-lymphocytes. *Aims.* Explore the molecular mechanisms underlying the induction of T-cell suppression and Tregs generation by MSCs. *Methods.*

Peripheral blood T-lymphocytes from 3 individuals were activated by anti-CD3/CD28 beads and cultured either in the absence or in the presence of MSC. Following a 5 day period, CD4+ lymphocytes were purified and profiled by whole genome microarrays. Real-time PCR was used for evaluations. MSCs inhibited the proliferation of activated T-lymphocytes, as compared to cells cultured alone. The proliferative suppression was clearly paralleled by a general transcriptional repression of components related to TCR signaling and to cell cycle progression. For instance, transcript levels of major components mediating TCR signaling, such as, CD3, LCK, Vav, ZAP70, LAT and GRB2 and controlling cell cycle progression trough the G1 phase, such as Cyclins D1 and E, and corresponding CDK4 and CDK2 kinases, were all repressed in lymphocytes cocultured with MSCs. Interestingly, the control of TCR signaling is not only involved in the suppression of T-cell proliferation but also in the induction of Treg, as continued TCR stimulation leads to a loss in Foxp3 inducibility. Moreover, the antagonism of the continued TCR stimulation over Foxp3 expression would be mediated by the PI3K/AKT and mTOR signaling pathways, as inhibition of these pathways in activated T-cells induces transcriptional changes driving the generation of Tregs phenotype. Strikingly, our results show that these pathways are clearly transcriptionally repressed on activated T-cells cocultured with MSCs; with the down-modulation of transcripts that include central components of these pathways, namely, the catalytic subunit of PI3K, PDPK1, AKT1 and 2, FKBP1A, among others. Moreover, we have evidences that upon co-culture with MSCs, canonical NF-kB pathway signaling on activated T-cell is inhibited and substituted by noncanonical signaling, and that this correlates with the acquisition of Treg-related genes. The general transcriptional repression of components of TCR, PI3K/AKT and mTOR signaling pathways in activated T-lymphocytes cocultured with MSCs, indicates that a molecular mechanism with a broader action would be implicated in the suppression of the proliferation and the concomitant induction of Tregs. In line with this, our results provides evidences that MSCs can modulate the expression of crucial components of the epigenetic machinery in activated T-cells leading to the general repression observed by us. *Conclusion.* Our results shown that several pathways related to T-cell activation, proliferation and involved with the induction of a regulatory phenotype, are modulated in lymphocytes, upon coculture with MSCs. These findings are useful to understand the molecular mechanisms involved in T-cell immunomodulaton by MSCs and help further studies to ensure the success on the clinical use of these cells.

Background. Although cellular immunotherapy based on antigen-specific cytotoxic T lymphocytes (CTLs) against tumors including leukemia and severe infections is a promising strategy, one of the pivotal issues is a hardship in constant supply of high quality antigen presenting cells for generating CTLs against tumor or pathogen-associated antigens. We established a leukemic plasmacytoid dendritic cell (pDC) line (PMDC05) with potent antigen presenting capacity from leukemia cells of a HLA-A*0201/*2402 patient with pDC acute leukemia. PMDC05 possessed a considerable antigen presenting ability to naïve T cells, which was enhanced by culturing with IL-3 or influenza virus and especially by LPS. *Aims.* In order to establish PMDC05-based tumor immunotherapy, we investigated whether PMDC05 could be efficiently used for generating CTLs specific for antigens of leukemia cells or pathogens. In addition, in order to elevate the efficiency of PMDC05-based anti-tumor immunotherapy, we evaluated the effectiveness of newly synthesized inhibiting agent for indoleamine-2,3-dioxygenase (new IDO inhibitor) for potentiating antigen presenting ability of PMDC05. *Methods.* PMDC05 cells, which was stimulated with 0.1 μg/mL LPS and loaded with 10 μg/mL WT1 peptides (HLA-A*2402-restricted, modified-type 9-mer peptide; CYTWNQMNL) or CMV pp65 peptides (HLA-A*2402-restricted, 9-mer peptide; QYDPVAALF) for 24 hours, were irradiated (60 Gy) and co-cultured with allogeneic $CD8^+$ T cells which were purified from peripheral blood mononuclear cells (PB-MNCs) of HLA-A*2402^+ healthy donor (PMDC05:$CD8^+$ Tcells = 1:10). 50 U/mL IL-2 was added to the co-culture at day 2, and IL-2 as well as 10 ng/mL IL-7 were added every 3 days thereafter. Induction of WT1 or CMV-specific CTLs was evaluated by flow cytometry analysis using HLA-A*2402 WT1 tetramer or CMV tetramer every week. In addition, PMDC05 cells were treated with new IDO inhibitor during the stimulation with LPS and IFN-γ and used as stimulator cells in mixed leukocyte culture (MLC) using PB-MNCs as responder cells. MLC was performed in both CFSE-based proliferation and ^{3}H-thymidine incorporation methods. *Results.* PMDC05 began to induce WT1 $tetramer^+CD8^+$ T cells at week 4 and the percentage of WT1 $tetramer^+$ T cells in $CD8^+$ T cells rose to more than 75% at week 7. Likewise, CMV $tetramer^+CD8^+$ T cells were amplified in $CD8^+$ T cells co-cultured with CMV peptide-pulsed PMDC05. By treateing PMDC05 cells with new IDO inhibitor, antigen presenting ability was increased in both CFSE-based proliferation and ^{3}H-thymidine incorporation methods. *Conclusions.* These data suggested that PMDC05 could be efficiently used for generating CTLs specific for tumor or pathogen-associated antigens and newly synthesized IDO inhibitor could be applicable for enhancing the antigen presenting ability of PMDC05. These findings revealed that PMDC05 cells in combination with new IDO inhibitor could be a promising strategy in cellular immunotherapy for tumors and severe infections.

[4]*Department of Paediatric Haematology; Justus-Liebig University, Giessen, Germany*
[5]*Department of Paediatric Haematology; Julius Maximilians University, Wuerzburg, Germany*

Treatment options for B cell malignancies in pediatric patients refractory to standard therapy are limited. Thus novel treatment approaches are urgently required. Bispecific antibodies, especially in combination with allogeneic stem cell transplantation (SCT) and donor lymphocyte infusion (DLI) represent a highly attractive therapeutic concept to direct immunity towards tumor cells. Seven children (three with relapsed diffuse large B-cell lymphoma (DLBCL), one with mature Burkitt lymphoma, two with mature B-cell acute leukemia and one with pre-B cell acute lymphoblastic leukemia) were treated in individual settings with escalating doses of FBTA05. All patients were extensively pretreated and presented refractory to standard treatment (radiation, chemotherapy) including rituximab. Five children received HLA-identical allogeneic SCT before FBTA05 treatment. In two patients FBTA05 application was followed by DLI. In one child with DLBCL FBTA05 and DLI were combined with lenalidomide in a second treatment cycle. For safety reasons dose escalation always started with 10 μg followed by 20 μg and 50 μg every third day. Thereafter weekly applications (100-300μg) were performed. Due to tumor progression before start of therapy daily application of FBTA05 were performed in three patients up to maximum doses of 200, 500 and 1000μg, respectively. Six of the seven children displayed a clinical response: five stable diseases and one complete response (CR). Remarkably, in this patient a CR even in the bone marrow was achieved without SCT and DLI. Overall survival is in the range of 85 up to 551 days (updated at time of presentation). Three out of the seven children died due to relapse or tumor progression. FBTA05 infusions were well tolerated by all children. Adverse events were restricted to fever and chills and could be managed by supportive treatment. Also the combination of lenalidomide and FBTA05 was well tolerated with nausea and increase of pre-existent leucocytopenia during the first cycle (10 and 15 mg daily), while a dose of 5 mg daily in the following cycles was well tolerated. In only one patient, human anti-mouse antibodies were detectable. Importantly, this patient could be safely treated with

two additional applications of FBTA05. The cytokine profile was characterized by transient increase of IL-6, IL-8 and IL-10. Plasma concentrations of FBTA05 strictly correlated with the corresponding dosing schedules with up to 0.19 µg/mL after daily escalating applications of FBTA05 up to 1,000 µg accompanied by the rapid clearance within few days. Graft versus host disease (grade III-IV) developed in two patients (in one case after DLI), but could be controlled by further immunosuppressive therapies. Based on these encouraging results, FBTA05 shall be further tested in children in a clinical study. Currently, a phase I/II study in combination with DLI in adult patients with low and high grade B-cell lymphoma after allo-SCT (STP-LYM-01-V01) is performed.

A NOVEL SINGLE CHAIN P53TCR PREVENTS GVHD IN A HUMANIZED MOUSE MODEL OF ADOPTIVE T CELL TRANSFER

H Echchannaoui,[1] E Antunes,[1] C Lotz,[2] T Thomas,[1] RH Voss,[1] M Theobald[1]

[1]*University Medical Center, Mainz, Germany*
[2]*Actelion Pharmaceuticals Ltd, Allschwil, Switzerland*

Background. Adoptive cell therapy with T cells retrovirally transduced with tumor-associated antigen (TAA) specific TCRs is a promising approach for immunotherapy in patients with hematological malignancies. The TAA p53 is over-expressed in approximately 50% of human tumors. One barrier to the development of T cell-based immunotherapies is the absence of high-affinity tumor specific TCRs in the patient due to self tolerance. We have reported that HLA-A*0201 (A2.1) transgenic mice can be used to circumvent self-tolerance to universal human TAA and to generate efficient tumor-reactive CTL. We used A2.1 transgenic mice, in which the mouse CD8 molecule cannot efficiently interact with A2.1 to generate a high-affinity, CD8-independent p53(264-272) specific TCR. Retroviral expression of CD8-independent p53-specific TCR into T cells, allowed CD8+ T lymphocytes to acquire a broad tumor-specific CTL activity but also redirected CD4+ T cells into potent tumor-reactive, p53-specific T helper cells. However, a particular safety concern with TCR gene transfer, is the formation of mixed TCR heterodimers between the introduced TCR α and β chains with the endogenous TCR chains, resulting in the potential generation of autoreactive T cells. *Aim.* Our aim is to optimize p53TCR construct to prevent mixed dimers formation. *Methods.* To reduce the formation of TCR mixed dimers an additional inter-chain disulfide bond (Cys.) between the TCR α and β chain constant domains was introduced. We further improved the expression level of p53 TCR transgene using codon-optimization (Opt.) of the TCR sequence in retroviral vector containing the self-cleaving 2A virus-derived peptide element. To prevent the formation of mixed TCR dimers, we engineered a novel p53(264-272)-specific Opt.Cys single chain (sc) TCR construct. The safety of engineered Opt.Cys p53TCR constructs was assessed in a humanized mouse model of adoptive T cell transfer. *Results.* Mouse T cells transduced with p53(264-272)A2.1-Opt.Cys TCR showed higher expression levels of the introduced TCR as compared to p53(264-272)-specific WT TCR. Importantly, p53(264-272)A2.1-Opt.Cys and sc TCR transduced CTL recognized and killed a wide variety of malignant A2.1 tumor cells with altered p53 expression, but not p53-deficient A2.1 cells more efficiently as compared to CTL transduced with the WT p53(264-272)-specific TCR. However, when p53(264-272)A2.1-Opt.Cys TCR transduced mouse T cells are adoptively transferred into p53-deficient partially humanized (A2Kb) mice, under conditioning-induced lymphopenia, expansion of infused T cells following high dose IL-2 administration is associated with the development of lethal autoimmunity similarly to mice receiving p53(264-272)-specific WT TCR transduced T cells due to the formation of self-reactive TCRs. In contrast, mice receiving T cells transduced with p53(264-272)A2.1-Opt.Cys scTCR did not develop any sign of GvHD. *Conclusions.* Our data demonstrate that p53(264-272) TCR gene transfer-induced off-target autoimmunity observed in preclinical mouse model could be prevented by the use of p53(264-272) engineered scTCR, suggesting that sc p53TCR may represent a new and safe approach for TCR-based gene therapy of p53-associated hematological malignancies.

[2]*Garden State Cancer Center, Center for Molecular Medicine and Immunology, Morris Plains, New Jersey, United States of America*

Background. IFNα2 has been used in therapy of a variety of hematopoietic neoplasias, including myeloma (MM), NHL, hairy cell leukemia (HCL), and CML. However, its therapeutic potential is limited by its short circulating half-life and systemic toxicity. Fusion of IFNα2 to a monoclonal antibody (MAb-IFNα) improves solubility and stability, and markedly increases circulating half-life. In addition to allowing less frequent and lower doses due to extended pharmacokinetics, targeting of IFNα2 to tumor sites using a tumor-directed mAb can reduce systemic concentrations and increase local concentration and tumor retention of IFNα2, thereby improving the therapeutic index. Increased tumor concentrations of IFNα2 can augment its direct anti-proliferative, apoptotic and anti-angiogenic activity, as well as prime an antitumor immune response. *Aims.* We evaluated the therapeutic potential of HLA-DR-targeting MAb-IFNα and identified specific hematological diseases that might be of benefit. *Methods.* We previously used the DNL method to generate stably-tethered immunocytokines (Rossi *et al.*, Blood 2009;114:3864-71; Rossi *et al.*, Cancer Res 2010;70:7600-9), which include 20-2b-2b (CD20-targeted mAb-IFNα comprising tetrameric IFNα2b and veltuzumab) and 20-C2-2b (bispecific CD20/HLA-DR-targeting dimeric IFNα2b). Here we describe the potent *in vitro* and *in vivo* anti-tumor activities of a third immunocytokine, C2-2b-2b, comprising tetrameric IFNα2b and the anti-HLA-DR mAb, hL243, against myeloma, lymphoma and leukemia cell lines. *Results.* C2-2b-2b bound HLA-DR+ cells with similar avidity to hL243 and exhibited high IFNα specific activity. *In vitro*, C2-2b-2b inhibited a panel of 20 hematopoietic cancer cell lines including NHL (Burkitt, mantle cell & follicular), leukemia (HCL, AML, ALL & CLL), and MM. In most cases, C2-2b-2b was more effective than CD20-targeted mAb-IFNα or a mixture comprising hL243 and IFNα. The responsiveness of the cell lines correlated with HLA-DR expression/density and sensitivity to IFNα and hL243. *In vivo*, a single 1 microgram dose of C2-2b-2b significantly ($P<0.0001$) improved survival in advanced Daudi (NHL) and CAG (MM) xenograft models, and single doses of ≥10 micrograms resulted in 70-100% long-term survivors (cures). In the advanced Daudi model, the group treated with a single 1 microgram dose of C2-2b-2b exhibited a median survival time (MST) of >130 days, compared to the saline control group MST of 42 days. C2-2b-2b was significantly ($P<0.0001$) more effective than molar equivalent treatments of hL243 + rIFNα2b (MST=52.5 days) or non-targeting mAb-IFNα (MST=45.5 days). Additionally, C2-2b-2b was superior to peginterferonalfa-2a used at four- and 20-fold greater concentrations (MST=71 and 91 days, respectively; $P<0.001$). C2-2b-2b depleted Daudi (91% depletion) and CAG (98%) cells from whole blood (*ex vivo*) more effectively than hL243 IgG or non-targeting mAb-IFNα. C2-2b-2b was less toxic to normal B cells (62%), monocytes (58%) and T cells (0%) compared to Daudi or CAG. C2-2b-2b depleted dendritic cells, with myeloid DCs (90%) being more sensitive than plasmacytoid DCs (48%). *Conclusions.* The DNL method provides a modular approach for producing defined multimeric immunocytokines, resulting in superior *in vivo* potency compared to the original cytokines due to improved pharmacokinetics, targeting and reduced systemic toxicity. These results suggest that C2-2b-2b might be useful in the treatment of various HLA-DR+ hematological malignancies.

0645

A SINGLE INJECTION OF AAV-8 VECTOR EXPRESSING IL-24 EFFICIENTLY SUPPRESSES TUMOR GROWTH MEDIATED BY MULTIPLE ANTI-TUMOR MECHANISMS IN MLL/AF4 POSITIVE ALL MODEL MICE

H Tamai, K Miyake, H Yamaguchi, K Inokuchi, T Simada, K Dan

Nippon Medical School, Tokyo, Japan

Mixed-lineage leukemia (MLL)/AF4 positive acute lymphoblastic leukemia (ALL) is a very common leukemia in infant and is associated with high relapse rate and poor prognosis even after allogenic bone marrow transplantation (allo-BMT). The resistance to graft-versus-leukemia (GVL) effect may be responsible for the poor effect of allo-BMT on MLL/AF4 positive ALL. Interleukin 24 (IL24) selectively induces apoptosis in cancer cells without harming normal cells. It also exerts immunomodulatory and anti-angiogenic effects, as well as potent antitumor bystander effects, making it an ideal candidate for use in a new anti-cancer gene therapy. Here, we examined the feasibility of adeno-associated virus type 8 (AAV8) vector-mediated muscle directed systemic gene therapy of MLL/AF4 positive ALL using IL24. *In vitro* study using TUNEL assay showed that IL24 induced apoptosis against MLL/AF4 positive cell lines (SEM and RS4;11) with dose dependency of IL24 concentration. Western blotting analysis showed that down-regulation of expression of HOXA9 by IL24 treatment and synergic up-regulation of p53-Caspase8 apoptosis pathway in IL24 and TNFα treated MLL/AF4 positive cell lines were detected. Moreover, the activities of p53-Caspase8 apoptosis pathway of MLL/AF4 positive cell lines were significantly lower than those in MLL/AF4 negative cell lines (H9, MOLT4, and Raji) under single TNFα stimulation. To assess the *in vivo* effects of muscle targeted AAV8-mediated systemic delivery of IL-24, we established a MLL/AF4 positive ALL murine model in which the SEM cells expressing luciferase gene was inoculated into the caudal vein of SCID mice. Using this MLL/AF4 positive ALL murine model, we can detect the tumor growth and metastases by a real-time *in vivo* imaging analyze system (IVIS). After single injection of AAV8-IL24 (1.5x1011 vg/body) into the right quadriceps muscle of the model mice, tumor cell growth was monitored by IVIS. Suppression of tumor growth was observed in AAV8-IL24 injected mice compared to control GFP expressing AAV injected mice (4.9±1.7x105 vs. 11.7±2.0x105 photon/sec; p=0.01). Survival effect was also detected in AAV8-IL24 mice (median 49M vs. 63M, P=0.022). Finally, we confirmed the *in vivo* effects of AAV8-IL24 by treatment of MLL/AF4 transgenic (Tg) mice model. A single intramuscular injection of AAV8-IL24 significantly inhibited appearance of lymphoma or leukemia with suppression of angiogenesis in MLL/AF4 transgenic (Tg) mice. These results clearly demonstrate that AAV8-IL24 was effective for MLL/AF4 leukemia through down-regulation of HOXA9, anti-angiogenesis and up-sensitivity to TNFα, which is a key factor of graft versus leukemia effect, followed by up-regulation of p53-Caspase8 apoptosis pathway. Thus, gene therapy using AAV8-IL24 combined with allo-BMT may be the promising strategy of MLL/AF4 positive ALL.

TGF-B1 MODULATES LPS-INDUCED CYTOKINE/CHEMOKINE PRODUCTION AND INHIBITS NF-κB, ERK AND P38 ACTIVATION IN DENDRITIC CELLS<

MF Lin, H Mou, H Huang, Z Cai

First Affiliated Hospital of Zhejiang University, Hangzhou, China

Background. There is growing evidence that dendritic cells (DC) can be not only immunogenic but also tolerogenic, both intrathymically and in the periphery. Previously, we have found that, compared with immature DC (iDC), TGF-β1 treated DC (TGFβ-DC) are resistant to maturation stimulus-lipopolysaccharide(LPS) and might have correlation with the downregulation of Toll-like receptor(TLR)-4 expression. Moreover, we also have demonstrated that recipient-derived TGFβ-DC induce major histocompatibility complex (MHC)-specific tolerance in a murine bone marrow transplantation (BMT) model. However, the molecular mechanisms underlying the phenotypical and functional changes in TGFβ-DC upon LPS stimulation have not been clearly elucidated. *Aims.* To analyze whether TGF-β1 affected the production of cytokines/chemokines and proteins in the TLR4 signal transduction pathway following LPS stimulation. *Methods.* C57BL/6J murine bone marrow cells were cultured with different cytokines combination to generate iDC (GM-CSF only) and TGFβ-DC (GM-CSF+TGF-β1). Afterwards, they were stimulated by lipopolysaccharide (LPS) for 2 days to induce nuclear translocation of nuclear factor(NF)-κB and maturation of DC. The concentrations of murine IL-12p70, IFN-γ, IL-18 and IL-10 in culture supernatants were assayed by ELISA. The mRNA levels of CCL2, CCL3, CCL5, CXCL10 were detected by reverse-transcriptase polymerase chain reaction (RT-PCR). We used electrophoretic mobility shift assay (EMSA) to determine the NF-κB activity in DC. ERK1/2 and p38 mitogen activated protein kinases (MAPKs) protein expression were checked by Western blot analysis. *Results.* In the resting state, both two types of DC produced low levels of cytokines. LPS stimulation induced cytokine production, but with a distinctly different pattern for each subset. The production of IL-12p70 in TGFβ-DC was significantly less than that of iDC (115.4±15.2 pg/ml vs 517.0±29.7 pg/ml, P<0.01), but the production of Th2 cytokine-IL-10 was significantly higher (132.1±17.5 pg/ml vs 75.1±16.6 pg/ml, P<0.05). We also found that levels of Th1-inclined chemokines mRNA, CCL2, CCL3 and CXCL10 increased earlier and remained relatively higher in iDC than in TGFβ-DC after LPS stimulation. In contrast, CCL5 mRNA was expressed at comparable levels between the two subsets of DC. The results suggested that NF-κB DNA binding activity was significantly increased in iDC in response to LPS, but the addition of TGF-β1 to DC decreased NF-κB binding. Furthermore, TGF-β1 was effective in suppressing LPS-induced activation of ERK1/2 and p38 kinase, the level of phosphorylation of ERK1/2 and p38 kinase were lower than iDC. *Conclusions.* Our findings reveal that TGF-β1 modulates the secretion of inflammatory cytokines/chemokines in DC. These effects may result from interfering with the activities of key elements of TLR4 pathway, such as NF-κB, ERK1/2 and p38 MAPKs. This study strengthens the notion that TGFβ-DC are a unique type of tolerogenic DC exhibiting some distinct characteristics.

Chronic lymphocytic leukemia - Biology 2

Background. The difference in clinicobiological behavior of chronic lymphocytic leukemia (CLL) can be related to genetic aberrations present either at diagnosis or acquired during disease course. This clonal evolution has been studied by means of conventional cytogenetic analysis (CCA) and fluorescence *in situ* hybridization (FISH). However, SNP-arrays enable to investigate clonal evolution at a higher resolution. *Aims.* This study aimed to characterize clonal evolution using different approaches and to identify a possible association with disease progression, i.e. therapy initiation. *Methods.* Patient selection met following inclusion criteria: (i) diagnosis of CLL, (iia) at least two available stored samples, (iib) second sample (S2) obtained at least one year after the first (S1), and (iii) patient untreated at both times of sampling. Sequential samples were investigated by CCA, FISH and Affymetrix cytogenetics whole-genome 2.7M arrays on peripheral blood or bone marrow samples. Clinical and biological data were available for all patients. *Results.* Fifty-three patients fulfilled the selection criteria. The median interval between sampling was 41 months (range 13-102 months). Male/female ratio and median age at diagnosis were 32/21 and 58.4 years (range 30.1-82.8 years), respectively. Patients presented with more advanced Binet stages at S2 vs. S1 (A/B/C in 34/12/7 vs. 47/5/1 patients, respectively). In addition, lymphocytosis was higher and lymphadenopathy, splenomegaly, thrombocytopenia, anemia and hypogammaglobulinemia were more frequent at S2. IGVH was unmutated in 15 and mutated in 32 patients. Treatment was initiated in 33 patients after a median duration of 51 months (range 19-173 months) after diagnosis and 1 month (range 0-54 months) after S2. Karyotyping revealed clonal evolution in 17/53 cases: acquired aberrations included unbalanced translocations (n=7), del(13)(q14) (n=4), del(11)(q22q23) (n=4), del(17)(p13) (n=2), del(6)(q) (n=2) and balanced translocations (n=2) and various other aberrations (n=5). In contrast, FISH using the CLL-"4 probe panel"revealed clonal evolution in only 11 cases. All cases with evolution by FISH, showed del(13)(q14) either as a new or additional subclone. The del(13)(q14) was accompanied by a new del(11)(q22q23) and del(17)(p13), in one case each. Whereas array analysis detected more gains at S1 vs. S2 (9009 vs. 7220 segments, respectively including copy number variations), losses were predominantly found at S2 (n=1293 vs. 2907 segments at S1 and S2, respectively). Recurrent losses were located in the regions 13q14.3, 11q22-23 and 17p13 (n=11/18, 3/7, 0/2 patients at S1/S2, respectively). Losses of 8p23-11.23, 15q11.2, 22q11.23, 9p21.1, 9p23-21.3 and 14q21.3-22.1 (n=9/5, 5/3, 1/3, 2/1, 2/2 and 2/1 patients at S1/S2, respectively) were also recurrent. In addition, the size of the losses was larger at S2 vs. S1 and in the cohort of patients with impending need vs. without need for therapy; i.e. the mean number of segments lost in patients without vs. with need for therapy at S1/S2 was 18/31 vs. 54/66 in general, 3/12 vs. 11/19 for 13q14.3, and 0/3 vs. 0/13 for 11q22-23, respectively. *Conclusion.* The present study confirms the occurrence of clonal evolution, especially losses in CLL. Further analysis is ongoing, in order to elucidate the clinical significance of clonal evolution in CLL.

ROLE OF THE GLYCOSYLATION STATUS OF THE SURFACE IGM IN DISEASE PROGRESSION OF CLL

V Coelho, S Krysov, G Packham, F Stevenson

University of Southampton, Southampton, United Kingdom

The B-cell receptor (BCR) has a critical influence on the fate of both normal B-cells and of the majority of B-cell malignancies. This key molecule determines the fate of antigen-specific B cells, by integration of multiple signals from antigen and from the microenvironment. Our most recent data show that in CLL, the surface IgM (sIgM) exists in two different glycoforms which are expressed in variable proportions, presumably depending on the engagement with antigen *in vivo*. The two sIgM glycoforms exhibit different N-glycosylation patterns in the µ-constant region. One glycoform is a mannosylated form which is a characteristic of the immature ER-located Igs, and the other is the complex form which is normally expressed on normal B-cells. However, treatment of normal B cells with anti-IgM *in vitro*, converted the complex form of its sIgM to a high-mannose form. Also, the expression of the mannosylated form on CLL cells, could be reverted to the mature form following incubation *in vitro*. This novel observation that antigen engagement alters the glycosylation status of the sIgM, suggests that mannosylation of the µ-chain might be an index of antigen engagement. We also show that both glycoforms are able to signal following surface IgM engagement *in vitro* leading to enhanced tyrosine phosphorylation. The localization of candidate lectin-bearing cells, specially those surrounding the Ki67+ cells within the proliferation centers (PCs) of SLL/CLL lymph nodes, was investigated by immunohistochemistry. Preliminary analysis showed the presence of (CD68+) macrophages, known to express high levels of the mannose receptor (MR), within the PCs. This study gives a new insight into the CLL disease and also reveals a new potential therapeutic target.

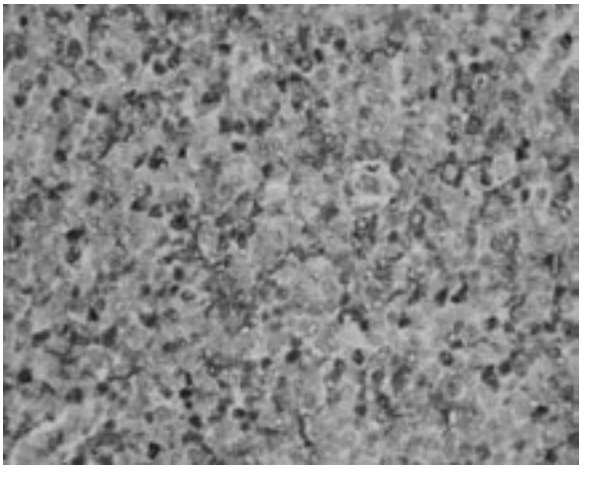

Figure 1. SLL lymph node double stained for CD38 and Ki67.

[3]*Dept. Medicine and Experimental Oncology, University of Turin, Torino, Italy*

Background. Serological proteome analysis has been demonstrated to be a useful method to detect tumor antigens (Ag) eliciting antibody responses in human malignancies. Ag identified in tumor patients can provide information regarding intracellular molecules engaged in the transformation process and may be useful for the development of immune-based therapeutic strategies. *Aims.* aim of this study is to identify potential biomarkers predicting disease aggressiveness and specific targets for immune-based approach in CLL. *Methods.* Twenty-one untreated CLL pa-

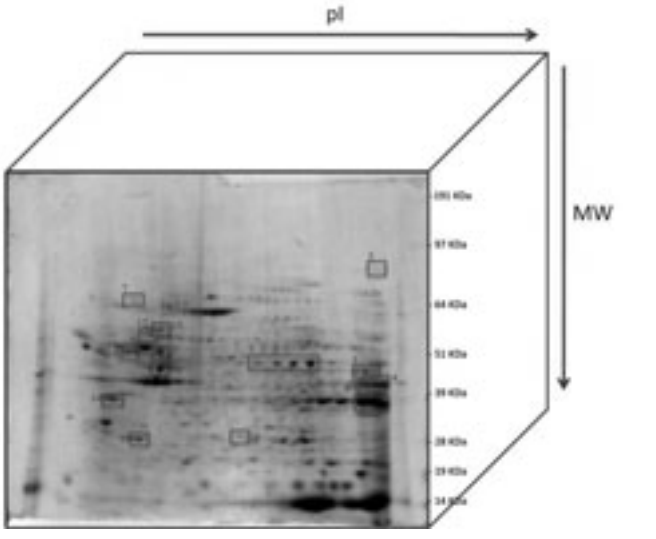

Figure 1.

tients were included in the study. Proteins extracted from leukemic cells were separated by 2-D electrophoresis (2-DE) and transferred onto membranes by electroblotting to obtain 21 2-DE proteomic maps. Each map was probed with the corresponding autologous serum by Western Blot (WB). To verify the CLL-specificity of antibodies recognition, 7 out of 21 maps obtained from CLL patients were also probed with sera collected from 7 healthy donors (HD). For identification, Ag spots in WB were aligned with proteins in 2-DE maps. The protein spots corresponding to the assigned Ag were excised from the gel, trypsin digested and analyzed by peptide mass fingerprint by MALDITOF Mass Spectroscopy (MS) with the software MASCOT. T cells isolated from the peripheral blood (PB) of 3 CLL patients with anti-ENOA antibodies were stimulated with autologous unpulsed and ENOA-pulsed dendritic cells (DC), and evaluated for their ability to secrete IFNγ through an ELISPOT assay. *Results.* Sixteen out of 21 CLL sera (76%) showed immunoreactivity against at least one Ag and produced an overall number of 45 Ag spots. By contrast, sera from HD were significantly less reactive ($p<.03$) and produced an overall number of 3 Ag spots. Eleven out of 16 (69%) reactive CLL sera recognized from 2 to 6 different Ag. All the Ag spots were characterized and consisted of 16 different proteins (Fig.1). Sera from 48% CLL patients exhibited reactivity against a protein which was identified by MS as α-Enolase (ENOA). ENOA recognition was CLL specific since none of the sera from HD showed reactivity against this protein. The IGHV mutational status was available in 20 CLL patients and 12 patients were mutated (M), while 8 patients were unmutated (UM). ENOA was recognized from sera of 7 out of 12 M patients (58%), but only from sera of 2 out of 8 UM patients (25%). The ability of ENOA to induce Ag-specific T cell responses was assessed in 3 patients. T cells isolated from the PB of CLL patients with antibody-based ENOA reactivity were stimulated with autologous ENOA-pulsed DC. The results showed that CLL-derived ENOA-pulsed DC stimulated autologous T cells to secrete IFNγ. This response was ENOA-specific because it was not induced by unpulsed DC or DC pulsed with an irrelevant protein, and also CLL-specific because IFNγ release was not induced when T cells from a HD were stimulated with autologous ENOA-pulsed DC. *Summary/Conclusions.* Our results indicate that ENOA is capable of eliciting CLL-specific humoral and cellular immune responses. Therefore, ENOA can be considered a promising biomarker and a potential target for immune-based approaches in CLL.

BCR STIMULATION INDUCES A DIFFERENTIAL MICRORNA (MIR) PROFILING BETWEEN B LYMPHOCYTES DERIVED FROM CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS AND HEALTY DONORS

S Tavolaro,[1] S Chiaretti,[2] N Peragine,[2] S Bonina,[2] F Brugnoletti,[2] S Santangelo,[2] M Marinelli,[2] I Del Giudice,[2] F Mauro,[2] A Guarini,[2] R Foà[2]

[1]*Division of Hematology, Rome, Italy*
[2]*Dept of Cellular Biotechnologies and Hematology, "Sapienza", University of Rome, Rome, Italy*

Background. MicroRNAs (miRs) are small non-coding RNAs that modulate the expression of genes at the post-transcriptional level, playing a pivotal role in many physiological and pathological processes. In lymphocyte ontogenesis, an involvement of miR-181a and miR-150 in B- and T-cell development has been documented. Moreover, in chronic lymphocytic leukemia (CLL) several miRs are associated with disease pathogenesis and/or outcome. *Aims.* In order to investigate a potential role of miRs in BCR stimulation, we evaluated the expression of these small RNAs following IgM and IgD cross-linking in CLL cells, as well as in healthy B lymphocytes. *Methods.* Peripheral blood mononuclear cells isolated from 9 untreated CLL samples and 2 healthy donors were enriched in CD19+ B cells and subsequently stimulated with a F(ab')2 anti-human IgM or with a F(ab')2 anti-human IgD, at a final concentration of 10 μg/ml. Following 24 and 48 hours of incubation, total RNA was extracted from unstimulated (US) and stimulated (S) samples for miR profiling analysis, performed using the GeneChip miRNA Affymetrix arrays. An unsupervised clustering was applied to evaluate samples responsiveness to BCR ligation. To identify differentially expressed miRs between US and S cases, a t-test retaining only probesets with a p-value <0.05 and a fold change >1.5 was used. *Results.* An unsupervised approach highlighted that, after both IgM and IgD stimulation, healthy donors clustered apart from CLL cases, suggesting a differential miRs expression pattern in healthy and leukemic B lymphocytes in response to BCR engagement. Based on these findings, we performed a t-test to compare US and S cells: in agreement with the unsupervised analysis, this approach showed a homogeneous signature associated to stimulation in B cells isolated from healthy donors and allowed to identify specific sets of miRs differentially expressed following IgM and IgD ligation, respectively. In CLL, we observed the modulation of several miRs both at 24 and 48 hours of IgM cross-linking, while miR expression changes occurred exclusively at 48 hours after IgD stimulation, suggesting a delayed activation in this context. Remarkably, miRs selected in CLL S cases were different from those identified in healthy donors, confirming a distinct miR regulation in BCR signaling of these samples. *Conclusions.* Our study reveals a differential miR expression pattern following IgM and IgD ligation between CLL and healthy B lymphocytes, suggesting that distinct mechanisms regulate BCR signal transduction at the physiological and pathological level. Further investigations to combine miR and gene expression profiles obtained from the same samples are currently underway with the aim of identifying putative miR targets.

CLONAL EVOLUTION IN CHRONIC LYMPHOCYTIC LEUKEMIA: ANALYSIS OF CLINICOBIOLOGIC CORRELATIONS IN 105 PATIENTS

F Cavazzini, L Rizzotto, O Sofritti, G Daghia, F Cibien, S Martinelli, M Ciccone, MA Bardi, E Tammiso, E Volta, E Pezzolo, E Pregnolato, D De Pasquale, E Saccenti, M Dabusti, A Cuneo, GM Rigolin, L Scarfò

Section of Hematology, Ferrara, Italy

Background. Clonal evolution (CE) involving chromosomes 17p, 11q, 6q, and 12 was reported in 15-42% of Chronic Lymphocytic Leukemia (CLL) cases using conventional karyotyping or fluorescence *in situ* hybridization (FISH). The incidence of this phenomenon depends on the length of follow-up and on the number of probes used for interphase FISH analysis. Attention was recently devoted to 14q32 translocation involving the immunoglobulin heavy chain gene (IGH). This aberration was found in 6-19% of CLL patients at diagnosis and was associated with therapy-demanding disease and inferior outcome. The incidence of this aberration at CE is presently unknown. *Aims.* To analyze the incidence, characteristics and clinicobiological significance of CE including 14q32 translocations in CLL. *Methods.* 105 patients seen at our institution between 1995 and 2004 were analyzed sequentially by FISH with the following probes: 13q14/D13S25, 11q22/ATM, 17p13/TP53, #12-centromere and 14q32/IGH break-a-part probe. FISH analysis was performed at diagnosis or before 1st line treatment. FISH was repeated at 4-6 year intervals in patients receiving ≤1 line of treatment. In relapsed patients who started 2nd line treatment, FISH was performed sequentially before administration of the 2nd line and before each subsequent line of therapy. These 105 patients fulfilled the following criteria: diagnosis of CLL based on morphology and immunophenotyping; successful FISH analysis at diagnosis and during follow-up (cases with t(11;14)(q13;q32)/BCL1-IGH were excluded); clinical records available for review. *Results.* The median follow-up of the entire series was 73 months (range 12-180 months). CE was observed in 15/105 patients after 24-170 months (median 64). Recurring aberrations at clonal evolution were 14q32/IGH translocation in 7 patients;

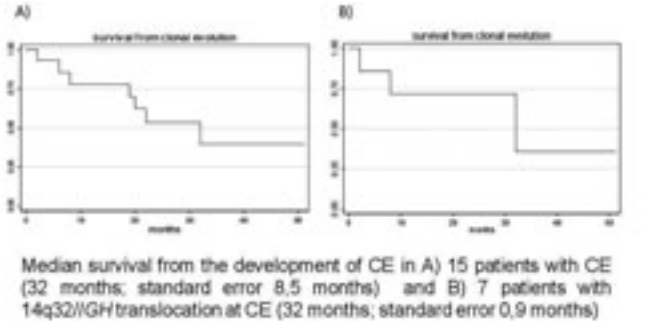

Figure 1. Survival from the development of CE.

17p- in 4 patients, 11q- in 2 patients, biallelic 13q- in 4 cases, hemizygous 13q- in 1 case, and 14q32 deletion in 1 patient. A 17p deletion was associated with 14q32/IGH rearrangement in 3/7 patients, one of whom also developed a biallelic 13q14 deletion. CE was detected in 15/58 pre-treated patients; to the contrary none of 47 untreated patients developed CE ($p<0.0001$). The 14q32/IGH rearrangement was detected after 1-4 lines of treatment (median 3 lines). In 3/7 cases with 14q32/IGH translocation BCL2 was the identified partner. In two cases the appearance of 14q32/IGH translocation was first detected in the bone marrow (BM) or in the lymph node (LN) and 13-58 months later in the peripheral blood (PB). ZAP70+ and high risk cytogenetics predicted for the occurrence of CE with borderline statistical significance ($p=0.055$ and 0.07, respectively). A shorter time to first treatment (TTT) and shorter time to chemorefractoriness (TTCR) was noted in 15 patients with CE ($p=0.033$ and 0.0046, respectively). Survival after the development of CE was 32 months (standard error 8,5). *Conclusions.* (i) 14q32/IGH translocation may represent one of the most frequent aberrations acquired during the natural history of CLL; (ii) The 14q32/IGH translocation may be detected earlier in BM or LN samples; (iii) CE including 14q32/IGH translocation occur in pre-treated patients with short TTT and TTCR; (iv) survival after CE is relatively short.

[2]*NIHR Biomedical Research Centre - Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom*

Background and Aims. B-cell chronic lymphocytic leukaemia (CLL) is the most common leukaemia in the Western World. It is characterised by a chronic relapsing course and the development of chemotherapy resistance. There is mounting evidence that the immunoglobulin heavy chain (IgH) locus plays a central role in antigenic drive and that this may be important for disease maintenance and progression. Previous studies using next generation amplicon sequencing (NGAS) of the IgH locus have identified small sub-clones in patients with hypermutated IgH. In this study, we focussed on unmutated poor prognosis CLL and used NGAS to study clonal evolution of the IgH locus in sequential samples of the same patients. *Methods.* We amplified the clone-specific VDJ rearrangement in the immunoglobulin heavy chain using published Biomed consensus primers on sequential samples taken at diagnosis, after first treatment and at subsequent relapse on 4 CLL patients with an unmutated IgH. These products were sequenced on a 454-FLX (Roche Diagnostics). Resulting sequences were grouped using a Perl script to identify recurring reads. Reads of greater than 100 copies were analysed using Jalview and IGMT. Reads present less then 100 times were excluded from the analysis. *Results.* An average of 30000 reads were obtained for each sample. Within each sample we detected a dominant clone representing approximately 60% of all reads included in the analysis. In addition to this clone, multiple productive rearrangements were also identified when aligned to the germline using IGMT. These were present in a minority of reads. All subclones were clonally related to each other and the frequency of both dominant and additional subclones remained constant over time in the different samples despite treatment. Interestingly, one patient with an unmutated V1-69 dominant clone was found to have a hypermutated V1-69 subclone present at all three time-points. *Conclusions.* Together the data suggests that, in unmutated CLL, the leukaemic population consists of a mixture of clonally related dominant and minor IgH clones. The composition and proportion of these IgH clones remains remarkably stable over time. Further analyses of sequential samples are on-going.

GENOMIC AND FUNCTIONAL ANALYSES OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS FOLLOWING IGD STIMULATION

S Tavolaro,[1] N Peragine,[2] S Chiaretti,[2] MR Ricciardi,[1] M Messina,[1] S Santangelo,[2] M Marinelli,[2] V Di Maio,[1] I Del Giudice,[2] F Mauro,[2] R Foà,[2] A Guarini[2]

[1]*Division of Hematology, Rome, Italy*
[2]*Dept of Cellular Biotechnologies and Hematology, "Sapienza", University of Rome, Rome, Italy*

Background. Proliferation of chronic lymphocytic leukemia (CLL) cells may be influenced by antigenic stimulation and accessory signals from the microenvironment. Indeed, these factors induce different effects in distinct subgroups of patients, thus sustaining clinical heterogeneity of the disease. *Aims.* To investigate CLL responsiveness to B-cell receptor (BCR) stimulation, we evaluated the gene expression profile upon IgD cross-linking in different classes of patients, subdivided on the basis of their IGHV mutational status and clinical outcome. Microarray results were validated at the functional level using several *in vitro* assays. *Methods.* After 24 and 48 hours of incubation with a F(ab')2 anti-human IgD (10 µg/ml), unstimulated (US) and stimulated (S) CD19+ B cells isolated from untreated CLL patients underwent microarray analysis using the HGU133 Plus 2.0 Affymetrix arrays. Unsupervised clustering, t-test and Analysis of Variance (ANOVA) were performed. In addition, at 24 and 48 hours from the stimulus, antigenic expression was investigated by immunophenotypic analysis, cell cycle distribution changes were evaluated using the Acridine Orange (AO) technique, cell proliferation was measured by 3H-TdR uptake and, finally, apoptosis was analyzed by the Annexin-V and/or AO technique. *Results.* Unsupervised gene expression analysis showed that all CLL cells were responsive to stimulation, regardless of the clinico-biological features. T-test performed between US and S samples confirmed these findings and allowed to identify 290 differentially expressed genes - mostly involved in BCR signaling, cell adhesion, antigen processing and presentation, and MAPK cascade - after 24 hours of stimulation. At variance, at 48 hours, we selected 188 transcripts involved in regulation of transcription, chromatin organization, apoptosis and cell differentiation, suggesting that in CLL cells gene expression activation following IgD cross-linking occurs at later time points of stimulation. Furthermore, to assess the effects of IgD ligation in specific CLL subgroups, we used two different supervised approaches: t-test and ANOVA. Both analyses showed that the IGHV configuration and the status of the disease of the cases evaluated did not affect the responsiveness of cells to BCR engagement via sIgD. To validate the microarray results, we compared the antigen mean fluorescent intensity (MIF) ratio of US vs S cases of a set of selected transcripts encoding for B-lineage antigens involved in cell activation. This approach confirmed the downmodulation of CD79a, CD79b, CD27 and CD62L in all samples upon IgD ligation. Next, at 24 and 48 hours from the stimulus, cell cycle analysis and proliferation assay documented that IgD cross-linking induced a decrease of proliferative activity in CLL cells, irrespective of their clinico-biological characteristics; accordingly, at the same time points apoptosis increased significantly in S samples. *Conclusions.* Gene expression profile highlights that the majority of CLL are responsive to IgD stimulation, irrespective of the clinico-biological characteristics of the samples analyzed. In agreement with microarray results, *in vitro* experiments have shown a reduction of cell proliferation and a concomitant increase in the apoptotic rate of S cases, providing new insights into the mechanisms that regulate BCR engagement via sIgD in CLL.

CORTACTIN EXPRESSION IS TIGHTLY CONNECTED TO B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA AGGRESSIVENESS

L Trentin,[1] C Gattazzo,[2] V Martini,[1] F Frezzato,[1] V Trimarco,[1] E Ave,[1] S Carraro,[1] A Cabrelle,[2] A Bradaschia,[1] S Garbisa,[1] G Semenzato,[1] L Trentin[1]

[1]*University of Padova, Padova, Italy*
[2]*Venetian Institute of Molecular Medicine, Padova, Italy*

Background. B-cell Chronic Lymphocytic Leukemia (B-CLL) is a disorder characterized by the accumulation of clonal CD5+ B lympho-

cytes due to uncontrolled growth and resistance to apoptosis. Several protein kinase pathways have been claimed to be involved in the regulation of apoptosis and cell survival of the neoplastic clone. We previously demonstrated that Src kinase Lyn displays anomalous properties in leukemic cells when compared to normal B lymphocytes. *Aims.* The protein cortactin is an ubiquitous actin-binding protein; it was originally identified as a substrate for Src kinases and overexpressed in several human tumors. Moreover its over-expression was correlated to cancer metastasis and poor prognosis of patients. Here we investigated the expression of cortactin in neoplastic B cells and its involvement in B-CLL pathogenesis and aggressiveness. *Methods.* Blood samples were collected from 106 patients that satisfied standard morphologic and immunophenotypic criteria for CLL B cells and from 15 healthy controls. Informed consent was obtained from all patients according to the Declaration of Helsinki. Untouched peripheral blood B cells were isolated from blood samples by negative selection using the RosetteSep for B cells isolation kit (StemCell Technologies; Vancouver, CND). The purity of B cells was at least 95% (CD19+), as assessed by flow cytometry. The expression level of cortactin was evaluated by real-time PCR, using GAPDH gene as calibrator, and by Western blotting analysis, using monoclonal Anti bodies against cortactin and β-actin as internal calibrator. Activity of matrix metalloproteinase 9 (MMP-9) in conditioned medium was evaluated by Zymography assay after 24h of culture with and without CXCL12/SDF1a chemokine; expression level of MMP-9 was also evaluated by real-time PCR. Migratory activity of B cells was induced by CXCL12/SDF1a chemokine and evaluated by chemotaxis test in a Boyden chamber. *Results.* We found that cortactin is overexpressed in B-CLL lymphocytes (1.10±0.12 SE) with respect to normal B cells (0.19±0.06 SE, Student's t-test $p<0.05$); when we investigated the correlation between level of cortactin and presence of somatic hypermutations (SHM) in the immunoglobulin heavy-chain variable region (IgVH) of B-CLL cells we found that unmutated patients expressed an higher levels of cortactin (SHM-: 1.46±0.27 SE) with respect to mutated ones (SHM+: 0.90±0.11 SE, *$p<0.05$, Student's t test) .We also evaluated the ability of neoplastic B cells to migrate after incubation with CXCL12/SDF1a chemokine and we observed that the overexpression of cortactin was associated with an increased B-CLL migration index ($r = 0.9$). Finally, the release of MMP-9 in cultured medium by neoplastic cells correlated with cortactin expression levels: in zymografy assay, patients without MMP-9 expression presented low cortactin level (0.46±0.20), while patients characterized by abundant expression of MMP-9 showed high cortactin level (2.43±0.04; $p<0.05$). *Conclusions.* The results that cortactin is overexpressed in neoplastic B cells and that this overexpression correlated with migration index after CXCL12 stimulus and MMP-9 release in cultured medium, suggest a role of cortactin in the aggressiveness of B-CLL neoplastic cells and support the cortactin as biomarker for diagnosis and prognosis of B-CLL.

NON-CANONICAL WNT SIGNALLING AND VIMENTIN IN CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL)

H Wheadon,[1] M Corrigan,[2] E Dobbin,[1] W Freeburn,[3] F Quinn,[2] A Catherwood[2]

[1]*University of Glasgow, Glasgow, United Kingdom*
[2]*Belfast City Hospital, Belfast, United Kingdom*
[3]*University West of Scotland, Glasgow, United Kingdom*

Background. CLL is the most common adult leukaemia in the western world, with over 3000 new diagnosis per year in the UK. CLL represents a clonal population of B-lymphocytes characterized by low proliferation rates and defective apoptotic pathways. Although CLL is an extremely heterogeneous disorder there is a cohort of patients who require urgent treatment and usually have a rapidly fatal disease. This cohort have an aggressive disease and often exhibit poor prognostic markers (high CD38, Binet B/C, poor risk cytogenetics (T12, 11q-, 17p), IGHV UM, ZAP70+), require immediate treatment and many die of CLL within three years despite therapy, leading to over 1000 deaths per annum in the UK. Deregulation of Wnt signalling has been reported to occur in CLL, which may contribute to the pathogenesis of the disease through up regulation of vimentin. Vimentin is an intermediate filament, important for cell migration, signalling and determining the rigidity of lymphocytes. *Aim.* To determine whether vimentin expression is higher in poor prognostic CLL patients and the role Wnt signalling plays in regulating vimentin. *Methods.* Expression of vimentin, Wnts and Wnt signalling in B-CLL cell lines and CLL patient samples was assessed using RQ-PCR, Western blotting and flow cytometry. Staining for vimentin was also performed in lymph node biopsies. Association of vimentin with Raf, pERK, 14-3-3 and PKC was assessed by immunoprecipitation and fluorescent microscopy. *Results.* We have screened 35 patients and confirmed a correlation between high vimentin levels and patients with poor prognostic markers (High CD38, Binet stage B/C, Poor risk cytogenetics and IGHV UM). Lymph node biopsies also revealed higher expression for vimentin in poor prognostic patients (n=13). In addition we have developed a flow cytometry based assay to measure vimentin and initial results indicate an excellent correlation with other poor prognostic markers. Stimulation of CLL cells with Wnt5a and Wnt4 indicate that non-canonical Wnt signalling increases vimentin levels. Immunoprecipitation and fluorescent staining indicate that vimentin co-localises with 14-3-3/Raf-1, ERK and PKC beta following stimulation. *Summary/Conclusion.* High vimentin expression is associated with progressive disease and a shortened time from diagnosis to initial treatment. Vimentin levels are controlled by non-canonical Wnt signalling and once expressed it forms dimers then tetramers, and eventually spindles. In addition, the inability of vimentin to disassemble has been linked to defective mitosis leading to chromosomal abnormalities, a phenomenon observed in these patients. Vimentin plays an important role in relaying intracellular signals, with phosphorylation and Ca2+ levels facilitating its interaction with signalling molecules such as PKC beta, 14-3-3/Raf-1 complex and pERK, pathways previously reported to be deregulated in CLL.

PERIPHERAL BLOOD MINIMAL RESIDUAL DISEASE AND RESPONSE ARE INDEPENDENT PROGNOSIS FACTORS OF SURVIVAL IN CHRONIC LYMPHOCYTIC LEUKEMIA, WHEN USED IN ROUTINE PRACTICE AND REGARDLESS OF TREATMENT LINE

T Aurran-Schleinitz, C Bosian, B Esterni, D Coso, J Schiano, V Ivanov, A Stoppa, D Blaise, L Xerri, R Bouabdallah, C Arnoulet

Institut Paoli-Calmettes, Marseille, France

Background. Eradication of minimal residual disease (MRD) has been shown to correlate with better outcome in chronic lymphocytic leukemia (CLL) in clinical trials. However the impact of peripheral blood (PB) MRD evaluation in routine practice is not established. *Aims.* To evaluate the impact of PB MRD detection on progression free survival (PFS) and overall survival (OS) in a large cohort of CLL patients and to determine its independent value when analyzed against the type of treatment, the line of treatment, the response status, the time of evaluation. *Methods.* 130 CLL patients were treated in a single institution. 76 patients (58.5%) received immunochemotherapy [fludarabine/rituximab (FR) +/- cyclophosphamide (FCR)], 23 (17.7%) fludarabine/cyclophosphamide, 14 (10.8%) fludarabine monotherapy and 11 (8.5%) alemtuzumab. Median follow-up was 33 months (0.5 - 115 months). MRD was determined in PB by 5 colors flow cytometry with limit of detection of 2x10-4, after 1st, 2nd, and 3rd or more line of therapy in 63%, 26.2% and 10.8% patients respectively. *Results.* 56.9% patients achieved a clinical complete response (CR), 14.6% patients a CR with incomplete marrow recovery (CRi), 26.9% patients a partial response (PR). MRD was negative (MRD-) in 56.2% patients. MRD negativity was achieved in 68.9% CR, 57.8% CRi and 31.4% PR patients. MRD negativity was correlated to significant improvement in both PFS and OS ($p<.001$) with 5 years PFS of 42.1% and 17.2% in MRD- and MRD+ population respectively. Nor the percentage of residual CD19+ B cells neither the delay of MRD assessment after the end of treatment (< or ≥ 60 days) influenced this result ($p>0.05$). Within the MRD- population, univariate analysis demonstrated prognosis correlation to line of therapy, type of treatment and response: 5yPFS was 51.3% versus 24.3% after 1st versus 2nd or more line of treatment ($p=.0324$); 61.1% versus 23.6% in "FCR"versus "other than FCR"treatment groups ($p=.0211$) and 62.7% versus 18.9% for CR versus not-CR patients ($p=.025$). The impact of MRD status on PFS was studied against line of therapy and response to treatment by multivariate analysis. Both MRD status and response, but not treatment line, were shown to be independent prognosis factors for PFS and OS. At the end of treatment, four categories of patients were defined: MRD-/CR, MRD+/CR, MRD-/not-CR and MRD+/not-CR categories with median PFS not reached, 42.2 months, 40.5 months and 14.8 months respectively. Interestingly, median PFS was not significantly different in MRD+/CR and MRD-/not-CR categories ($p=0.71$). We could then identify three prognosis groups of patients: favorable (MRD-/CR), intermediate (MRD-/not-CR or MRD+/CR) and unfavor-

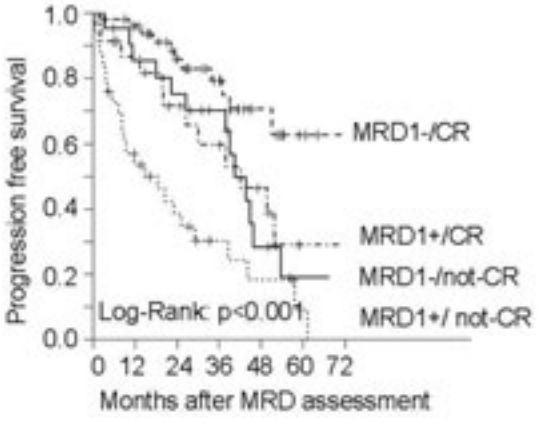

Figure 1.

able (MRD+/not-CR) (p<0.001). *Conclusions.* Although studied in a heterogeneous cohort with a limit of detection of 2x10-4, PB MRD status and clinical response were both found to significantly correlate to survival regardless of the line of treatment. Circulating residual B cells number and precise timing of the assessment did not seem to influence these results. PB MRD is clinically relevant in routine practice in CLL.

Background. Chronic lymphocytic leukemia (CLL) is a common and heterogeneous disease. An accurate prediction of outcome is highly relevant for the development of personalized treatment strategies in CLL. Microarray technology was shown to be a useful tool for the development of prognostic gene expression scores. However, limited availability and high costs have so far prevented its widespread use. *Aim.* We set out to develop and validate a simple but powerful gene expression score that predicts overall survival (OS) in CLL patients and can easily be assayed in a routine diagnostics setting. *Methods.* 151 CLL microarray data sets (44 Affymetrix HG-U133 A&B and 107 Affymetrix HG-U133 Plus 2.0 chips) were correlated with OS using Cox regression and supervised principal component analysis to derive a prognostic score. This score was validated in an independent group of 149 CLL patients by quantitative real time PCR (qRT-PCR). An additional predictive value of the score was assessed using prediction error curves. *Results.* A prognostic score was developed based on the expression levels of eight genes (PS.8). PS.8 was predictive for OS and time to treatment (TTT) in univariate Cox regression in a heterogeneous validation data set (OS: p<0.001; TTT: p<0.001). The prognostic value of PS.8 could be demonstrated in patients without previous treatment, at first diagnosis, Binet A patients and subgroups defined by the traditional molecular markers. Multivariable Cox regression models were fitted to OS and TTT using PS.8, *IGVH*-status, 17p13 deletion, 11q22-23 deletion, age (< 65 years vs. ≥ 65 years) and sex as covariates. PS.8 had a highly significant association with both endpoints. For OS, 17p13 deletion, age and PS.8 were the only significant covariates. In the multivariate model for TTT PS.8 is dominating all other covariates and is the only covariate significantly associated with TTT. Prediction error curves showed that PS.8 achieved superior prognostic accuracy compared to models based on fluorescence *in situ* hybridization analysis and *IGVH*-status. *Conclusion.* We developed a prognostic score for OS using the largest gene expression profiling data set available for CLL patients with long-term follow-up. This score (PS.8) is based on the expression levels of eight genes and was validated on a different technical platform (qRT-PCR) in an independent group of 149 patients. PS.8 showed additional prognostic value for OS and TTT and improves the prognostic accuracy of previously used molecular markers. Specifically, PS.8 was able to add information in several subgroups defined by the established molecular markers and in Binet A patients. In addition, this eight gene score can be determined fast and cost effectively and is suitable for routine diagnostics. Prospective confirmatory trials are now required to assess the relevance of PS.8 to guide individualized treatment choices to improve the clinical outcome of CLL patients.

LEVELS OF TRANSCRIPT EXPRESSION OF P66SHC ADAPTER, A NOVEL REGULATOR OF B-CELL SURVIVAL, PREDICTS OUTCOME AND CHEMOREFRACTORINESS IN CLL

F Forconi,[1] E Sozzi,[2] N Capitani,[3] E Cencini,[2] A Fabbri,[2] A Pietrini,[2] R Crupi,[2] A Sicuranza,[2] C Ulivieri,[3] C Baldari,[3] F Lauria[2]

[1]*Hematology,University of Siena, Siena, Italy*
[2]*Hematology, University of Siena, Siena, Italy*
[3]*Department of Evolutionary Biology, University of Siena, Siena, Italy*

Background. p66shc is a novel regulator B-cell survival that induces apoptosis by uncoupling B-cell receptor signaling. p66Shc expression is impaired in chronic lymphocytic leukemia (CLL), and levels in unmutated (U)-CLL are lower than in mutated (M)-CLL (Capitani *et al.*, 2010). *Aims.* Aims of this study were to investigate the prognostic significance of p66shc in relation to time to first treatment (TTFT), overall survival (OS) and refractoriness to Fludarabine-based combinations and/or Alkilators. *Methods.* p66shc transcript levels were measured by Real-time PCR (Capitani *et al.* 2010) in a series of 143 patients with CLL defined according to the IWCLL-2008 criteria. cDNA from purified B-cells pooled from 11 healthy donors was used as a standard and given the arbitrary value of 1. The best cut-off to distinguish low vs high p66shc levels was determined by ROC analysis and the Youden's index (death as state variable). p66shc levels were investigated for any association with i) clinical and biological prognostic parameters at diagnosis ii) TTFT (of patients diagnosed in stage 0) and OS (of all patients) and iii) refractoriness and time to refractoriness to Fludarabine and/or Alkilators. *Results.* Rai stage was 0 in 94/143 (65,7%), I-II in 37/143 (25,9%), III-IV in 12/143 (8,4%) patients Sixty-five/143 (54,6%) CLL used U-IGHV, 60/143 (43%) scored CD38+ve (cut-off>30%). 81/137 (59,1%) scored ZAP70+ve (cut-off>20%), 103/143 (73,6%) had del13q or normal FISH, 18/143 (12%) had 12 trisomy, 13/143 (9,5%) del11q, 8/143 (5,5%) del17p. TP53 disrupture by mutations and/or deletion was found in 12/143 (8,5%). Interquartile Median p66shc level was 0,335 (range 0,202-0,600). Based on the best cut-off (0,375), 63/143 (44,1%) patients had high p66shc (p66hi) and 80/143 (55,9%) low p66shc (p66lo) levels. A significant association was found between p66lo status and U-IGHV (18/63, 28,6% p66hi vs 47/80, 58,8% p66low, p<.001), CD38+ve (17/60, 28,3% p66hi vs 43/79, 54,4% p66low, p=.002), ZAP70+ve (29/60, 48,3% p66hi vs 52/77, 67,5% p66low, p=.02), overall lack of del13q only or normal FISH (53/61, 86,9% p66hi vs 50/79, 63,3% p66lo, p=.002), trisomy 12 (3/61, 4,9% p66hi vs 15/79, 17,3% p66low, p=.01), del17p (0/61, 0% p66hi vs 8/79, 10,1% p66low, p=.01) or overall TP53 disrupture (1/61, 1,6% p66hi vs 11/78, 14,1% p66low, p=.009). p66lo status also associated with shorter TTFT of stage 0 CLL (median 245 in p66hi vs 65 months in p66low, p<.001). By multivariate Cox-analysis (covariates: CD38+ve, ZAP70+ve and U-IGHV), p66lo (95%-CI 1,1-2,9, HR=1,7, p=.04) scored as independent prognostic factors for TTFT. p66lo status also associated with shorter OS (median OS not reached in p66hi vs 112 months in p66low, p<.001). By multivariate Cox analysis (covariates: U-IGHV and del17p), p66lo (95%-CI 1,1-7,9, HR=2,9, p=.03) scored as independent prognostic factors for OS. Remarkably, p66lo associated with shorter time-to-fludarabine-refractoriness (median not reached in p66hi vs 125 months in p66low, p=.02) and time-to-alkilator-refractoriness (median 245 in p66hi vs 60 months in p66low, p=.008). Interestingly, 10/16 (62,5%) fludarabine-resistant and 19/32 (59,3%) alkilator-resistant patients scored p66lo in the absence of TP53 disrupture. *Conclusions.* These data suggest that p66shc play an important (independent) role in defininig outcome and chemorefractoriness risk in CLL patients.

0659

THE IMPACT OF SPECIFIC MUTATIONS IN TP53 GENE ON THE RESULTS OF ALEMTUZUMAB THERAPY IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

M Doubek,[1] J Malcikova,[1] Y Brychtova,[1] A Panovska,[1] P Kozmon,[1] P Dobes,[1] G Vankova,[1] J Smardova,[1] P Kuglik,[1] M Mraz,[1] B Tichy,[1] L Sebejova,[1] J Mayer,[1] M Trbusek,[1] S Pospisilova[2]

[1]*University Hospital, Brno, Czech Republic*
[2]*Central European Institute of Technology, Brno, Czech Republic*

Background. A poor prognosis in chronic lymphocytic leukemia (CLL) is associated particularly with the presence of del(17p) and/or p53 mutation. The recommended therapeutic approach for patients with TP53 loss or mutation involves primarily a use of monoclonal antibody alemtuzumab. It remains unclear whether the type of TP53 mutation influences the results of alemtuzumab therapy. *Aim.* The aim of the study was to evaluate the efficacy of alemtuzumab therapy in CLL patients with p53 defects *Patients and Methods.* We analyzed the data of CLL patients with p53 defects, which were identified at our institution by the p53 yeast functional assay coupled to sequencing together with complementary I-FISH analysis detecting del(17p), and were treated by alemtuzumab. The response rate, progression-free survival (PFS) and overall survival (OS) after alemtuzumab administration were evaluated. Patients were divided according to the presence of p53 mutation in vs. outside DNA-binding motifs (DBM), structurally well defined part of the p53 DNA-binding domain. *Results.* Forty-nine CLL patients (23 females, 26 males) were included in the analysis, receiving in total 58 courses of alemtuzumab. The average age at diagnosis was 59 years (range 26-67). The average number of therapies prior to alemtuzumab was 2 (0-6). 41 patients were treated with a fludarabine based regimen prior to alemtuzumab. The Rai stage of patients at the start of alemtuzumab therapy was as follows: Rai I 14%; Rai II 1%, Rai III 40%; Rai IV 45%. All patients had unmutated IgVH locus. The frequency of chromosomal aberrations (Döhner's hierarchical model) was as follows: del(17p) n=40 (69%); del(11q) n=3 (5%); trisomy 12 n=2 (3%); del(13q) n=5 (9%); and normal karyotype n=8 (14%). The average cummulative dose of alemtuzumab was 702mg per course (29-1280). The median OS assessed from the time of the first alemtuzumab administration was significantly reduced in patients harboring missense mutation located in the p53 DBM (n=27) in comparison with those having missense mutations outside DBM or non-missense mutations (n=31) (471 days vs. 1056 days; p=0.03) (Figure).

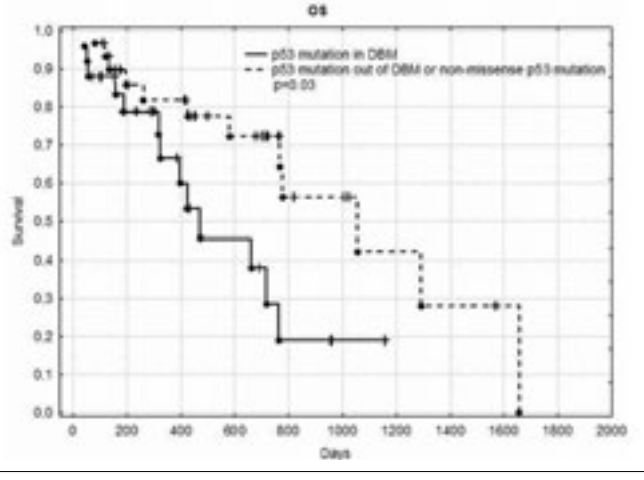

Figure 1.

On the other hand, we did not find any difference in PFS between these patients' groups, after the administration of alemtuzumab (221 days vs. 222 days; p=ns). The overall response rate (ORR) was similar for both groups (63% vs. 58%). The patients' groups did not differ significantly in the other parameters (chromosomal aberrations; alemtuzumab cumulative dose). *Conclusion.* The TP53 mutations located in DBM do not seem to have an effect on ORR or PFS after the therapy of CLL patients with alemtuzumab compared to remaining p53 mutations. However, the survival is obviously substantially reduced in patients with DBM mutation. It may be a consequence of (a) a more severe progression and/or (b) a worse response to the subsequent therapy.

MONOCYTE COUNT AT DIAGNOSIS IS AN INDEPENDENT PREDICTOR OF TIME TO FIRST TREATMENT IN CHRONIC LYMPHOCYTIC LEUKAEMIA

R Mazumdar,[1] P Evans,[2] J Bailey,[1] D Allsup[1]

[1]*Hull and East Yorkshire NHS Trust, Hull, United Kingdom*
[2]*Haematological Malignancy Diagnostic Service, St James's University Hospital, Leeds, United Kingdom*

Background. The survival of chronic lymphocytic leukaemia (CLL) cells in-vivo is critically dependent upon interactions between the malignant cells and non-malignant stromal cells and is mediated by pro-survival chemokines and cytokines. Cultured monocytes are capable of sustaining the survival of CLL-cells *in-vitro* and monocyte-derived soluble CD14 promotes the survival of CLL cells and has prognostic value. We hypothesised that an elevated monocyte count in the peripheral blood at diagnosis would be an adverse prognostic factor in CLL. *Aims.* To determine the prognostic value of the monocyte count in patients with newly diagnosed CLL in terms of time to first treatment (TTFT) and overall survival (OS). *Methods.* We conducted a retrospective cohort study. All newly diagnosed CLL cases identified between January 2000 and December 2010, were examined. We stratified patients based on a monocyte count ≤ or > 0.8 x10^9/L which represents our laboratory upper limit of normal and Kaplan Meier analysis was used to assess TTFT and OS for the entire cohort. Data were also analysed to exclude the confounding effects of known prognostic markers including Binet stage, CD38, IgVH mutational status and ZAP-70. *Results.* We identified 234 patients (M:F;150:84). The median age was 66 years (range 35 -91). Binet stage at presentation was as follows: stage A 191 (82%), stage B 23 (10%) and stage C 20 (8%). Mean duration of follow up was 54 months. The median monocyte count at presentation was 0.61 x10^9/L (range 0.0 - 5.6 x10^9/L). 74 (32%) patients presented with a monocyte count > 0.8 x10^9/L of whom 45% commenced treatment within the study period versus 33% amongst those with a monocyte count ≤ 0.8 x10^9/L. Patients with a monocyte count >0.8 x10^9/L had a significantly shortened TTFT (41 vs 99 months; p=0.002, Figure 1). The prognostic importance of monocyte count was associated with Binet stage, but was independent of CD38, IgVH and ZAP-70. An elevated monocyte count was associated with a trend towards reduced OS, but this did not achieve significance (95 vs 109 months, p=0.094). *Conclusions.* Monocytosis at presentation in CLL is an independent adverse prognostic factor and is associated with a significantly shortened time to first treatment. This is a routinely and inexpensively measured parameter that warrants further investigation in prospective studies.

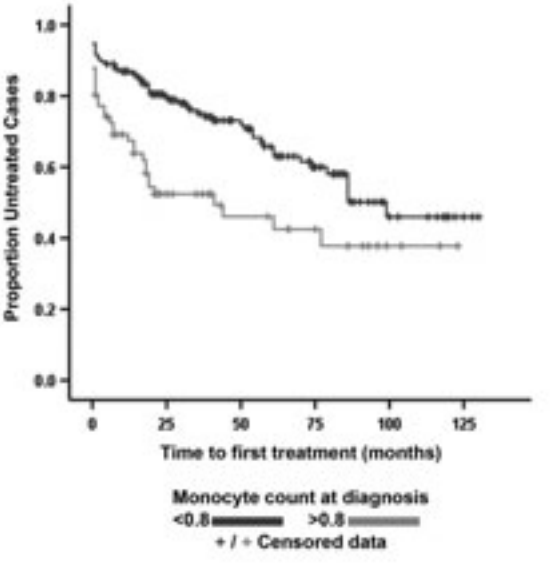

Figure 1. Kaplan Meier curve. p=0.002.

BCL2L12, A NOVEL MEMBER OF THE BCL2 FAMILY, IS DRAMATICALLY ELEVATED IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS AND CONSTITUTES AN UNFAVORABLE BIOMARKER IN CLL, PREDICTING POOR OVERALL SURVIVAL

C Kontos,[1] S Papageorgiou,[2] V Pappa,[2] H Thomadaki,[1] F Kontsioti,[2] J Dervenoulas,[2] E Papageorgiou,[2] D Vasilatou,[2] C Economopoulou,[2] A Scorilas[1]

[1]*University of Athens, Athens, Greece*

Background. BCL2L12 is a recently identified gene belonging to the *BCL2* family, members of which are implicated in hematological malignancies, including chronic lymphocytic leukemia (CLL). The clinical course of individual CLL patients is extremely heterogeneous, with survival ranging from months to decades. Notably, an important subset of patients presenting with low grade CLL will develop a more aggressive and life-threatening disease. Since these patients might potentially benefit from early treatment, it is critical to reliably predict patients' prognosis at diagnosis, especially those in an early disease stage, thus allowing personalized, risk-adapted therapy. Hence, there is high need for biomarkers accurately identifying those patients in early stages that will progress from those who will remain indolent. *Aims.* The purpose of this study was to analyze the mRNA expression of the novel apoptosis-related *BCL2L12* gene in patients with CLL, and to examine its prognostic and predictive value, and potential clinical application as a novel molecular biomarker for CLL. *Methods.* Total RNA was isolated from peripheral blood of 65 CLL patients and 23 healthy donors. An ultra-sensitive quantitative real-time PCR (qRT-PCR) methodology for *BCL2L12* and *BCL2* mRNA quantification was developed using SYBR® Green chemistry. After preparing cDNA by reverse transcription, relative quantification analysis was performed using the comparative CT ($2^{-\Delta\Delta CT}$) method. Moreover, analysis of *IGHV* mutational status, CD38 expression, and detection of apoptosis by double staining with annexin V-FITC and propidium iodide were performed. *Results. BCL2L12* mRNA expression was significantly higher in CLL patients than in healthy donors ($p<0.001$). Moreover, ROC analysis demonstrated that *BCL2L12* expression had significant discriminatory value, distinguishing very efficiently CLL patients from non-leukemic population (AUC=0.833, $p<0.001$). *BCL2L12* expression was also shown to predict the presence of CLL, as demonstrated by both univariate and multivariate logistic regression analyses ($p=0.001$ and $p=0.003$, respectively). Finally, high *BCL2L12* mRNA levels were associated with advanced clinical stage ($p=0.028$) and shorter overall survival ($p=0.043$) of CLL patients. *Conclusions. BCL2L12* mRNA is overexpressed in the majority of CLL patients and constitutes a powerful predictor of the presence of the disease. In addition, high *BCL2L12* mRNA expression is associated with advanced stage of the disease and predicts poor overall survival in CLL patients.

T REGULATORY CELLS (TREG) IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) TREATED WITH HIGH DOSE METHYLPREDNISLONE (HDMP) AND RITUXIMAB (RTX)

R Pileckyte,[1] R Matuzeviciene,[2] A Janiulioniene,[2] M Jurgutis,[3] T Zvirblis,[2] L Griskevicius[2]

[1]*Vilnius University Hospital Santariskiu Clinic, Vilnius, Lithuania*
[2]*Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania*
[3]*Klaipeda Seamen's hospital, Klaipeda, Lithuania*

Background. Regulatory T cells were found to be lower in healthy population than in CLL patients. Treg were particularly increased in untreated CLL patients with advanced stage and higher Treg frequencies predicted shorter time to the first treatment. It has not been evaluated if Treg values predict survival in treated patients. Aim of the study was to evaluate T reg dynamics during treatment and their impact on survival. *Methods.* Two-center, single arm, open-label, prospective study was conducted to evaluate the efficacy of dose-dense HDMP in combination with Rtx in pretreated CLL patients with clinically or biologically high-risk disease. T regulatory cells, defined as CD4+CD25+CD127-FoxP3+ cells, were calculated as percentage of total CD4+ T lymphocytes and were assessed by 4-colour flow cytometry in peripheral blood at screening, after three treatment cycles and two months after the last treatment cycle. All patients provided informed consent. *Results.* 29 patients with CLL were enrolled. Median age was 59 years (range 45-76), 22 (76%) patients had Rai III-IV stage, 17 (59%) had bulky (> 5 cm) lymphadenopathy. 25 (86%) patients had unmutated IgVH, 13 (45%) had 17p del and/or p53 mutation, 11 (38%) had 11q del, and one (3%) patient had trisomy 12, 10 (34%) were fludarabine refractory. Overall response rate (ORR) in 26 evaluable patients was 62%, all patients achieved partial response (PR). The median (range) Treg frequency at screening was 3.7% (0.06%-10.46%) and then decreased to 1.1% (0.25%-7.03%) after three treatment cycles and to 2.475% (0.21%-3.66%) at the end of therapy ($p<0.001$ and $p=0.006$ compared to Treg at screening, respectively). Treg frequency at screening did not correlate with response to treatment ($p = 0.661$) or with other prognostic factors such as bulky lymphadenopathy ($p = 0.829$), fludarabine refractoriness ($p = 0.109$), adverse cytogenetics ($p = 0.676$). The median follow-up for all patients was 22 months (range: 1-37). The median progression free survival (PFS) was 12 months (95% CI: 8-16) and the median overall survival (OS) was 31 months (95% CI: 20-42). More prominent Treg decrease between screening and 3 treatment cycles and between screening and the end of therapy predicted better PFS ($p = 0.036$ and $p=0.041$, respectively) by linear regression method. In univariate analysis, patients with higher Treg frequency reduction between screening and three treatment cycles had a trend towards better OS ($p=0.084$) In multivariate analysis, only response to treatment ($p=0.01$) had a significant impact on PFS and fludarabine refractoriness ($p=0.022$) and response to treatment ($p=0.01$) predicted OS. *Conclusion.* HDMP and Rtx combination effectively reduces T regulatory cells in pretreated high risk CLL patients. However, Treg reduction during treatment was not an independent predictive factor for either PFS or OS. Further evaluation of T lymphocyte subsets and their impact on survival is being performed. (ClinicalTrials.gov identifier: NCT005 58181; supported by EEA and Norway grant No. 2004-LT0040-IP-1EEE.).

[3]*Haematology Department, Laikon General Hospital, University of Athens, Athens, Greece*
[4]*Haematology Department, University Hospital, University of Crete, Heraklion, Greece*

Background. Chronic lymphocytic leukemia (CLL) and spenic marginal zone lymphoma (SZML) are both B-lymphoproliferative disorders that have possible common pathogenetic mechanisms. CLL follows a variable course with survival ranging from months to decade, while a small fraction of SZML patients display more aggressive behavior. TCL1 oncogene, a target of chromosomal translocations and inversions at 14q31.2 and zeta-associated protein (ZAP 70), a member of the Syk family of tyrosine kinases, are associated with adverse outcome in CLL patients, while the expression and role of these genes in SMZL are not fully clarified. *Aim.* To evaluate TCL1 and ZAP70 expression in CLL and SMZL patients and correlate them with clinical and laboratory characteristics. *Methods.* 55 patients diagnosed with SLL and SMZL were included in the present study, based on the availability of tissue specimens. Their baseline clinical and laboratory features were recorded. All patients underwent bone marrow (BM) aspiration and biopsy at diagnosis. Analysis of the IgVH somatic mutations as well as FISH for 11q- and 17p- were performed at diagnosis in CLL patients. TCL1 and ZAP70 were studied in paraffin embedded tissue using Envision kit. Analysis was performed in bone marrow sections in all CLL patients and among 22 SMZL patients while in 2 SMZL on spleen sections. *Results.* 55 patients (31 CLL and 24 SMZL) patients were included. Among 31 CLL patients with a median age of 58.5 years (42-71), 19 were male, 23 were staged A and 8 B (Binet). IgVH mutation analysis performed in 20 patients, 13 of them were unmutated. FISH analysis for 17p- and 11q- was made in 20 and 16 patients respectively. One patient had 17p- deletion and 2 presented 11q-. All patients underwent immunohistochemical analysis of ZAP 70 and 20 of them were ZAP 70 (+), while 18 underwent TCL1 analysis and 9 of them were TCL1 (+). The clinical-laboratory characteristics of TCL1 (+) patients were as follows: 6/9 were male, median absolute lymphocyte count (ALC) was 79.78×10^9/l ($5\text{-}152 \times 10^9$/lt) with rapid duplication time in 2 patients, Binet stage was A in 8/9, 7 had intermediate or diffuse pattern

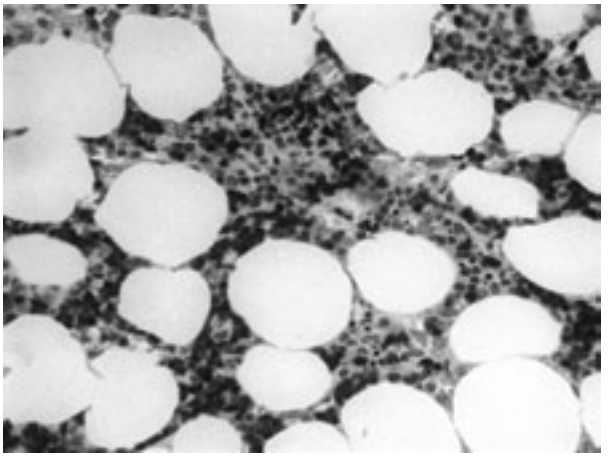

Figure 1. TCL 1 expression in CLL.

of bone marrow infiltration. 3 were unmutated, no patient presented 17p-,1 had 11q- and 7/9 had ZAP70 (+). The only correlation of borderline significance was between ZAP (+) and TCL (+). Among 24 SMZL patients with median age 61 years (45-78), 10 were male,10 had elevated LDH and 3 patients were classified as high/intermediate IPI. ZAP 70 and TCL1 were evaluated in 21 patients. 20/21 were negative and only one was found positive to both antigens. *Conclusions.* Immunohistochemical detection of TCL1 and ZAP 70 is feasible in CLL. TCL1 (+) and ZAP70(+) correlation is statistically significant in CLL patients. TCL1 positivity may be associated with other unfavorable CLL markers such as BM infiltration pattern and ALC. Expression of TCL1 and ZAP70 is rare in SMZL patients.

LIPOPROTEIN LIPASE AS A PROGNOSTIC MARKER AND IGVH MUTATION SURROGATE IN CHRONIC LYMPHOCYTIC LEUKEMIA

Z Matrai,[1] H Andrikovics,[2] A Bors,[2] A Tordai,[2] A Kozma,[1] E Ádám,[1] E Karászi,[1] T Masszi[1]

[1]*St László Hospital, Budapest, Hungary*
[2]*Molecular Diagnostics Laboratory, National Blood Transfusion Service, Budapest, Hungary*

Background. Chronic lymphocytic leukemia (CLL) is a highly heterogeneous condition clinically and biologically. In the era of rapidly improving treatment options, there is an increasing demand to predict outcome early in the course of the disease, a task not fulfilled by clinical stage. Among the numerous markers introduced recently, lipoprotein lipase (LPL) has been reported to be informative as a prognostic marker, related closely to IgVH mutation status in CLL. *Aims.* Our objective was to test LPL in the clinical practice as a predictor of outcome and correlate its expression with other prognosticators. *Methods.* Using peripheral blood samples of 73 unselected CLL patients, lipoprotein lipase mRNA levels were determined by quantitative PCR. LPL/ ABL expression levels were normalized to healthy controls. A cutoff of 1.77 was established by ROC analysis in order to distinguish between positive and negative clones. IgVH mutation status was analysed by a multiplex PCR method and BIOMED-2 standardized primers. Greater than 4% sequence divergence from the germline was considered mutated. For CD38 evaluation a 7% cutoff was applied. *Results.* LPL positive patients showed significantly shorter survival than negative ones (median survival 175 months vs not reached, $p<0.0001$). A close relationship was found between LPL expression and IgVH mutation status with 22 of 24 (92%) LPL positive cases being unmutated and 23/32 (72%) LPL negative cases mutated. When CD38 was employed as an IgVH surrogate, the sensitivity and specificity were 75% and 65%, respectively. A linear relationship was detected between LPL and CD38 ($p<0.003$). Interestingly, within the good prognostic group having 13q-, LPL positivity identified a subgroup with shorter survival (median survival 136 months vs not reached, $p<0.009$). *Conclusions.* as measured by PCR from unselected peripheral blood, LPL determination proved to be a powerful predictor of outcome refining prognosis in the good-risk category of CLL. As an IgVH mutation surrogate, LPL outperformed CD38 in this series. These findings justify further study and eventually, the routine application of LPL in the diagnostics of CLL.

HUMAN AND MOUSE DOCK10 SPLICING ISOFORMS WITH ALTERNATIVE FIRST CODING EXON USAGE ARE DIFFERENTIALLY EXPRESSED IN T AND B LYMPHOCYTES

A Parrado, M Alcaraz-García, N Ruiz-Lafuente, S Sebastián-Ruiz, C González-García, M Majado

Hospital Universitario Virgen de la Arrixaca, Murcia, Spain

Background. Dedicator of cytokinesis (DOCK) proteins are a family of guanosine nucleotide exchange factors (GEF) for Rho GTPases, constituted by 11 mammalian members. Diverse Rho GTPases play crucial roles in lymphocyte development, activation, differentiation and migration. We have previously reported the cloning of a full length human DOCK10 cDNA [Yelo *et al*, Mol Immunol 2008; 45: 3411-8], whose expression is distinctively induced by IL-4 in normal peripheral blood B lymphocytes and chronic lymphocytic leukemia (CLL) B cells. Here, we analyzed DOCK10 mRNA diversity produced as a result of alternative splicing. *Aims.* To define the DOCK10 protein-coding transcripts in the human and the mouse and to gain insights into regulation of their expression. *Methods.* Full-length cDNA clones of DOCK10 were obtained from total RNA of both normal human peripheral blood mononuclear cells (PBMC) (10 clones from 10 individuals, total 100 clones) and mouse spleen (10 clones), by high fidelity RT-PCR. B and T lymphocytes from normal individuals and CLL B cells were isolated using negative selection and cultured in the presence of 10 ng/ml of IL4 (BD Pharmingen). Expression of the DOCK10 isoforms was measured by quantitative PCR (Q-PCR) and western blotting. Panels of human and mouse tissues were analyzed for mRNA expression. Protein and mRNA expression were also studied in a panel of human lymphoid, myeloid and epithelial cell lines. *Results.* Alternative first coding exon usage led to two main protein-coding transcripts, which we named DOCK10.1 and DOCK10.2. Full-length cDNA clones of both isoforms were obtained from both normal human PBMC and mouse spleen, for the first time for human DOCK10.1, mouse DOCK10.1, and mouse DOCK10.2. Human and mouse DOCK10.1 clones corresponded to the protein coding assemblies provided by NCBI as Reference Sequences (RefSeq) for DOCK10. Our analysis especially focused on human cDNA clones, of which 63% were alternatively spliced forms involving diverse exons and introns (17% in frame, 46% frame shifts). The most frequent variations were shortened versions of exons 5, 12, 18, 35, 43, and 45. Deletions of entire exons were also found, e.g., exons 8, 28, 31, and 40. The consensus rules for intron-exon boundaries were fulfilled in all the subvariants. DOCK10.1 expression was enriched in normal T cells, and DOCK10.2 expression was enriched in normal and CLL B cells. Some lymphoid cell lines express one isoform preferentially over the other. Both isoforms were up-regulated in response to interleukin-4 (IL-4) in B cells, both normal and CLL, but not in T cells. *Summary/Conclusions.* Two DOCK10 isoforms, named DOCK10.1 and DOCK10.2, arise from the use of alternative first exons. Whether the frequent shortened and truncated isoforms play specific functional roles or are just transcriptional noise remains to be elucidated. The two isoforms are expressed in human and mouse tissues, mainly in lymphocytes and lymphocyte-rich organs. DOCK10.1 is enriched in T cells and DOCK10.2 in B cells. IL4-treatment up-regulates both isoforms in B cells, but not in T cells. Our data suggest that cell-specific mechanisms regulate expression of the alternative first exon variants of DOCK10 in vertebrates. antonio.parrado@carm.es

Background. Chronic myeloid leukemia (CML) is a clonal expansion of hematopoietic progenitor cells, resulting in myeloid hyperplasia, leukocytosis, neutrophilia, basophilia and splenomegaly. Imatinib Mesylate (IM) used in the treatment of CML, interacts with membrane efflux transporters such as MDR1. Polymorphisms in this gene have been associated with changes in its functionality and may be involved in the response to IM treatment. *Aims.* The aim of this study is to investigate the relationship of MDR1 gene polymorphisms (C1236T (rs1128503), C3435T (rs1045642) and G2677T/A (rs2032582)) with response markers to treatment with IM in patients with CML. *Methods.* 118 patients in chronic phase of CML, both genders with age range 18 to 80 were studied. All patients were initially treated with a standard dose of IM (400 mg/day) and divided in two groups according to response. The first group ("responder") comprised 70 patients who had a complete cytogenetic response within 18 months of treatment. The second group ("non responder") comprised 48 patients who did not have a complete cytogenetic response with the initial dose (400 mg/day) of IM or who relapsed during treatment and were submitted to higher doses of 600 or 800 mg/day. Criteria of failed response to treatment were established by European Leukemia Net. Patients with cytogenetic patterns other than the Philadelphia chromosome and patients with mutations in the BCR-ABL1 gene were excluded from this study. Major molecular response (MMR) was defined as a reduction of BCR-ABL1 transcripts levels to ≤ 0.1% in the peripheral blood standardized on the International scale. MDR1 gene polymorphisms were determined on all patients using RFLP PCR. *Results.* The frequencies of MDR1 variant alleles were 41.1% (1236T), 37.3% (3435T), 32.2% (2677T) and 2.1% (2677A), respectively for C1236T, C3435T, G2677T/A polymorphisms. No subject had the MDR1 2677AA genotype. The genotypes frequencies for C1236T, C3435T and G2677T/A polymorphisms were similar in the two groups (responder and non responder; p>0.05). In the responder group, the frequency of 1236CT/2677GT/3435CT haplotype was higher in patients with MMR (51.7%) than in patients without MMR (8.3%, p= 0.010). Furthermore, carriers of 1236CT/2677GT/3435CT haplotype had a 11.8 fold greater odds ratio (95%CI: 1.43-97.3, p=0.022) of achieving molecular response compared with all who had others haplotypes in logistic regression. *Conclusions.* The 1236CT/2677GT/3435CT haplotype in the MDR1 gene is positively associated with major molecular response to treatment with IM.

This study was supported financially by Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP 2009/54184-0).

CONNECTING DIAGNOSTIC RISK SCORES TO INDIVIDUAL PATIENT RESPONSE UNDER NILOTINIB THERAPY

D Dingli,[1] T Lenaerts,[2] F Castagnetti,[3] A Traulsen,[4] J Pacheco,[5] G Rosti[3]

[1]*Mayo Clinic, Rochester, United States of America*
[2]*Université Libre de Bruxelles, Brussels, Belgium*
[3]*University of Bologna, Bologna, Italy*
[4]*Max Planck Institute, Plon, Germany*
[5]*University of Lisbon, Lisbon, Portugal*

Introduction. At diagnosis early chronic phase CML (ECP-CML) patients are typically categorized in low, intermediate or high-risk groups using the Sokal or Hasford scoring systems, that provide an indication of the patient survival probability if treated with chemotherapy or interferon respectively. Given that tyrosine-kinase inhibitors have become the first-line treatment method for these patients, one can wonder how individual patient response to drugs like imatinib or nilotinib relates to the standard scoring systems at diagnosis. *Methods.* Combining a computational model of hematopoiesis and CML with individual serial Q-RT-PCR data for disease burden (BCR-ABL) under nilotinib therapy of 73 patients, we estimated for every patient independently the self-renewal probability of CML cells (eCML), the fraction of CML cells responding to therapy (z NILO) and the impact of TKI on the self-renewal probability of CML cells (eNILO) under therapy. These estimates were obtained from the data on response to treatment, and independent of the calculation of the prognostic categories. As such they allow to one to correlate scores with the values of these three model parameters. *Results.* The results show that two model features, i.e. self-renewal probabilities for CML cells (eCML) and treated CML cells (eNILO), provide the best partitioning of the response data. The first feature differentiates between two clusters: One cluster (A) with eCML>0.7 and another (B) with eCML<0.7, that partition patients into two clusters. Within each group, the second feature differentiates between patients responding optimally or suboptimally to therapy, making it possible to introduce again two types of subclusters. Examining the relationship between the cluster a patient belongs to based on response dynamics and its Sokal or Hasford score shows only a slight correlation: Most low-risk patients are in cluster A, whereas most high-risk are in cluster B. However patients from all prognostic categories can be found in most clusters and those in the best group are not necessarily patients in the low-risk Sokal group. *Conclusions.* Through our computational model of hematopoiesis and CML we can classify patients' response to therapy based on two important features: the fitness of the CML cell before therapy and the fitness-change induced by treatment. Together these features allow one to categorize a patient response to TKI treatment and correlate it with prognostic scores calculated at diagnosis. Our results show that the correlation appears to be weak, requiring on the one hand that new prognostic tools based on TKI therapy should be designed and on the other hand that one might take early therapy-response markers into account to improve patient treatment in the long run.

THE GENE EXPRESSION EVALUATION OF THE SEPT5 IN PATIENTS WITH CML, AT THE DIAGNOSIS, HEALTHY BLOOD DONORS AND CELL LINES OF HUMAN AND MURINE

C Mascarenhas,[1] A Cunha,[2] S Gambero,[1] A Brugnerotto,[1] R Gontijo,[3] K Pagnano,[1] F Costa,[1] C De Souza[1]

[1]*University of Campinas, Campinas, Brazil*
[2]*Federal University of São Carlos, São Carlos, Brazil*
[3]*Catholic University of Brasilia, Brasilia, Brazil*

Background. SEPT5 is a member of nucleotide binding proteins, called septins that were firstly described in yeast as cell division cycle regulatory proteins. This gene was reported in patients with acute myeloid

leukemia translocated with MLL gene and with high expression in myeloid leukemia cell line and in adult human brain and heart in association with alpha granules of human blood platelets. In a recent study using SSH libraries, we compared the gene expression pattern between granulocytes of health control and CML patients, and we identified this gene expressed only in CML patients. Although several studies in literature, there is not a clear relationship between the expression of this gene and the development of CML, making it an interesting target for functional studies with regard to their function in differentiation, proliferation and apoptosis of granulocytic cells and myeloid progenitors. *Aims.* Functional analysis of SEPT5 gene expression in the granulocytic lineage of CML patients and the relationship between this gene and the development and progression of CML. *Methods and Patients.* The evaluation was made in peripheral blood granulocytes and mononuclear cells of CML patients and healthy blood donors, and in the cell lines K562, BaF3/BCR-ABLp210 and BaF3T315I using real time PCR. *Results.* To validate the result found in the SSH library, the gene expression of SEPT5 was evaluated by real time PCR using the same samples used in the library construction. These results confirmed our previous results showing that the SEPT5 expression is increased in the granulocytes of CML patients. The same results was observed when we studied the expression comparing individually 11 patients at diagnosis and 05 health controls, suggesting that this protein could be increased in all human cells that have the translocation BCR-ABL. However, using cell lines of murine BaF3/BCR-ABLp210 and BaF3T315I, the expression of this gene was absent, suggesting that this gene had a very low expression in the translocated cells of this model and that could be involved in the human CML. *Conclusion.* Despite major advances in the treatment of CML, the treatments available are not capable of inactivating all the signaling pathways activated by BCR / ABL. Our results demonstrate that SEPT5 could be involved in the development of CML and the importance of the study of possible pathways that could culminate in its high expression or the triggering of other unknown pathways involved in the development of CML by this gene. This work was supported by FAPESP.

GENE EXPRESSION MARKERS OF RESPONSE IN CHRONIC MYELOID LEUKAEMIA: DYSREGULATION OF THE AURORA KINASES AND MGMT

G Gareth, L Soriano, S Hill, B Bak, J Sorouri-Khorashad, M Alikian, AC Lim, H De Lavallade, A Reid, D Marin, J Apperley, L Foroni

Imperial College London, London, United Kingdom

Background. The t(9;22)(q34;q11) translocation, resulting in the BCR-ABL1 fusion gene and subsequent constitutively activated tyrosine kinase oncoprotein is both the hallmark and initiator of Chronic Myeloid Leukaemia (CML). Although initially indolent and generally responsive to first line tyrosine kinase inhibitor therapy (Imatinib), heterogeneity of response is observed in a proportion of patients, leading to primary and secondary resistance, suggesting that other genomic lesions play a role in determining outcome. Aurora Kinase A and B (AURKA, AURKB) have roles in regulating cell division and their dysregulation is frequently observed in solid-tumours and is associated with chromosomal instability. The MGMT gene encodes a DNA repair protein and its expression is known to be epigenetically silenced by promoter hypermethylation in glioblastomas, leading to poor treatment response. *Aims.* To ascertain whether the differential expression of AURKA, AURKB and MGMT correlated to treatment response, and additionally to investigate whether promoter CpG methylation played a role in MGMT down-regulation. *Methods.* Gene expression of AURKA, AURKB and MGMT (normalised against GUSB) were determined using RT-qPCR on 22 normal peripheral blood (PB) samples, 21 diagnostic CML samples (in chronic phase) and 42 CML remission (MMR) samples. qPCR results were expressed as delta-CT relative expression ratios (RER), calibrated against the BV173 cell line, and assayed for significance using the Kruskall-Wallis test. Diagnostic gene expression levels were stratified into low & high (maximal chi-square) and correlated against Imatinib treatment efficacy (400mg/day; time to complete cytogenetic response (CCyR); Kaplan-Meier). MGMT promoter hypermethylation at 5 CpG sites in the 5' UTR was investigated using pyrosequencing on bisulfite-treated DNA from paired samples from 3 CML patients. *Results.* Compared with normal and remission samples, gene expression of AURKA and AURKB were significantly up-regulated (median RER: 0.14, 0.13, 0.28; $p<0.001$ and 0.04, 0.06, 0.34; $p<0.01$, respectively) and MGMT was down-regulated (0.42, 0.36, 0.15; $p<0.01$). Patients with low relative MGMT expression (RER ≤0.20) were shown to have a significantly increased time to CCyR compared to those with high expression (>0.20) (median 10mnth and 6mnth, respectively; $p=0.046$). For AURKA there was a trend for those with higher expression (>0.17) to achieve CCyR later (6mnth and 10mnth; $p=0.076$); for AURKB there was no difference. Pyrosequencing showed no evidence of MGMT promoter hypermethylation at the investigated CpG sites (<3% methylation, comparable to the negative control). *Summary/Conclusions.* Although both AURKA and AURKB were significantly over-expressed in diagnostic CML samples, only AURKA was associated with a slower treatment response at a level that approached significance. Down regulation of MGMT lead to a significantly slower response to Imatinib, but there was no evidence that epigenetic silencing by promoter CpG hypermethylation was functionally involved; although caution must be taken when drawing conclusions from such a relatively small sample number. In summary, both AURKA and MGMT gene expression levels were found to be candidates as prognostic indicators for treatment response in CML, possibly reflecting the dysregulation of their roles in maintaining genomic stability. Down-regulation of MGMT may occur through mechanisms other than promoter hypermethylation.

0670

A RAT MODEL TO PREDICT ALTERATIONS IN BONE GROWTH AND METABOLISM IN CHILDREN WITH CML ON IMATINIB

J Tauer, L Hofbauer, S König, M Suttorp

University Hospital Carl Gustav Carus, Dresden, Germany

Background. Chronic myeloid leukaemia (CML) is a rare malignancy in paediatric patients (pts) and constitutes only approximately 2% of all childhood leukaemias. The diagnostic hallmark of CML is the Philadelphia chromosome (Ph+; t(9;22)(q34;q11)) resulting in the BCR-ABL fusion protein a constitutively active, oncogenic tyrosine kinase. Since 2001 the tyrosine kinase inhibitor (TK-I) imatinib mesylate (IMA; Glivec®, Novartis, Basle, Switzerland) has been established as front line therapy for adult pts with CML and has been fully licensed for treatment of CML in children since the year 2003. However, also related tyrosine kinases necessary for bone "remodelling" like PDGF-R, and c-FMS are blocked by IMA. First reports in adult pts described disturbances in bone and mineral metabolism (hypophosphatemia; inhibition of osteoclasts) as so far unexpected side effects after prolonged periods of treatment of CML. Up to know, in children the efficacy of IMA has been evaluated only in prospective trials with small pts numbers pointing to growth retardation in paediatric pts while on imatinib treatment. *Aim.* In an ongoing study we investigated the influence of IMA on the growing skeleton in juvenile rodents. *Methods.* Starting at an age of 4 weeks (w) [development milestones: weaning 3w; puberty 7w; adolescence 9w] juvenile male Wistar rats were chronically exposed to IMA via the drinking water. Over a ten week period, groups A and B were exposed daily to IMA at 500 mg/l (A) and 1000 mg/l (B), respectively, while group C received 1000 mg/l intermittently (3 days 'on' treatment, 4 days 'off'). Animals were sacrificed after 2w, 4w and 10w of IMA exposure to analyze the following parameters: bone length, bone mass density, bone metabolic parameters: amino-terminal propeptide of type I procollagen (PINP), C-terminal cross linking telopeptide of type 1 collagen (CTX-I), osteocalcin (OC) and tartrate resistant acid phosphatase (TRAP). In addition serum levels of IMA, testosterone and growth hormone (GH) were monitored. *Results.* IMA was well tolerated at all concentrations. Weight gain of rats was delayed in groups B and C while no change in animals overall growth, development and behaviour was observed. However, rats exhibited significantly reduced longitudinal bone length with reduced trabecular but normal cortical bone density. Femoral length in group C paralleled reduced length in group A, while length in group B was mostly impaired. Biochemical markers for bone resorption revealed no significant differences for CTX-I but decreased levels of TRAP of group A and B during exposition time and a "push up effect"in group C which declined to control range after puberty. Markers for bone resorption indicated reduced levels for OC and reduced levels of PINP prepubertal of group B and C increasing to levels of control group during puberty. Furthermore, testosterone levels were reduced permanently while GH measurement exhibited increased levels at the 4thw of IMA exposure. *Conclusion.* Here we could demonstrate alterations of bone metabolic parameters in the juvenile still growing bone confirming published data in children. Side effects of TK-I treatment observed in children can be predicted and mimicked in juvenile rodent models.

DIFFERENTIAL ROLE OF THE JAK2-STAT5 SIGNALING MODULE IN BCR-ABL-DEPENDENT TRANSFORMATION

W Warsch,[1] O Hantschl,[2] E Eckelhart,[3] G Superti-Furga,[4] V Sexl[5]

[1]*Institute of Pharmacology, Vienna, Austria*
[2]*CeMM-Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria*
[3]*Center for Pharmacology and Physiology, Medical University of Vienna, Vienna, Australia*
[4]*CeMM, Vienna, Austria*
[5]*Department of Biomedical Science, Veterinary University Vienna, Vienna, Austria*

Background. Activation of the transcription factor STAT5 is a critical event for the initiation and maintenance of Chronic Myeloid Leukemia (CML) that is causally linked to the expression of the tyrosine kinase Bcr-Abl. *AIM.* A possibility to inhibit STAT5 activation in CML could be the use tyrosine kinase inhibitors (TKIs) targeting the JAK2 kinase that was shown to be the upstream activator of STAT5 in different physiological and pathological setting. *Methods/Results.* Using conditional JAK2 mouse knock-out models, we show that JAK2 is dispensable for myeloid and lymphoid Bcr-Abl-driven leukemia and initial myeloid transformation, whereas JAK2 is required for initial lymphoid transformation. These observations speak for an uncoupling of STAT5 activation from JAK2 at different stages of transformation depending on the oncoprotein. We further show that JAK2 TKIs induce apoptosis in JAK2-deficient cells irrespective of the presence of JAK2. This is likely caused by the direct 'off-target' inhibition of Bcr-Abl. Using a combination of siRNA and pharmacological interference excluded a requirement for tyrosine kinases other than Bcr-Abl for STAT5 activation and indicating a direct phosphorylation of STAT5 by Bcr-Abl. This finding was further supported by enzymatic studies that indicated STAT5 phosphorylation with similar efficiency than the known Bcr-Abl substrate CrkL. *Summary.* Our results excluded a dominant role of JAK2 in Bcr-Abl dependent transformation and withdraw the rationale of a clinical use of JAK2 TKIs in CML.

0672

HIGH-RESOLUTION MELTING CURVE ANALYSIS FOR SCREENING FOR MUTATIONS IN THE BCR-ABL KINASE DOMAIN OF CML PATIENTS

K Wienand, C Viljoen, S Sreenivasan, V Louw

University of the Free State, Bloemfontein, South Africa

Background. Chronic myeloid leukaemia (CML) is characterized by the BCR-ABL fusion oncogene. The oncogene encodes for a tyrosine kinase that can effectively be inhibited by tyrosine kinase inhibitors (TKIs). Nevertheless, some patients acquire resistance to treatment as a result of mutations in the BCR-ABL kinase domain. Mutations impair the binding of TKIs to the kinase domain. Thus the detection of mutations in the kinase domain is important to explain sub-optimal responses or the loss of response as a result of resistance to TKIs. Mutations in the BCR-ABL kinase domain are usually detected through sequencing. Recently, high-resolution melting curve analysis (HRM) has been suggested as a method to screen the BCR-ABL kinase domain for single base mutations prior to sequencing. There have also been a few reports on the possible impact of indels in the kinase domain and gene amplification on patient prognosis. However it is not known whether HRM can be used to identify indels or duplications associated with the kinase domain. *Aim.* The aim of this study was to determine whether HRM analysis can be used to screen the BCR-ABL kinase domain for mutations including indels and duplications prior to sequencing. *Methods.* Informed consent was obtained from 33 CML patients on TKI treatment. Of these, 13 patients were suspected of having mutations due to sub-optimal response or a loss of response with TKIs. Sequencing of the kinase domain was performed according to Branford and Hughes (2006). HRM analysis was performed using the Melt-Doctor HRM Reagent Kit and primers from Poláková *et al.* (2008) on the ABI 7500 Fast. *Results.* Thirteen samples were found to contain mutations in the BCR-ABL kinase domain, including three samples with single base changes, one with a previously described 35 base pair insertion and nine with duplications of which seven contained indels not previously described. There was an overlap in Tm range for samples with mutations compared to samples without mutations, irrespective of the mutation type and so difference plots were used to identify samples with mutations. Samples with duplications were identified as different variants in the difference plot, from those with only single base mutations. Compared to this, samples with either one or two single base mutations were found in the same variant group in the difference plot. *Conclusions.* HRM analysis was successfully used to screen for mutations in the BCR-ABL kinase domain. Samples with mutations were not readily identifiable from shifts in Tm but were indicated as variants in the difference plot. An insertion in the BCR-ABL kinase domain as well as duplications of the kinase domain, were also detected by HRM analysis. Based on this study, HRM analysis can be used to screen the kinase domain for mutations including single base changes, indels and duplications, prior to sequencing.

0673

IDENTIFICATION OF SARI (SUPPRESSOR OF AP-1, REGULATED BY IFN) DOWN-REGULATED BY BCR-ABL IN K562 CELLS: A NOVEL TARGET FOR TREATMENT OF CML

Q Huang, S Huang, XQ Li, Y Yang

Union Hospital, Wuhan, China

Backgrounds. SARI (Suppressor of AP-1, Regulated by IFN) is a novel basic leucine zipper containing type I IFN-inducible early response gene that exerts cancer-selective growth inhibitory effects. The constitutive SARI expression was detected in multiple lineage-specific normal cells, whereas its expression was not detected in their tumorigenic counterparts. However, little is known so far about SARI expression in patients with CML (chronic myelogenous leukemia), the regulation of SARI expression in CML cells. *Aims.* To investigate whether Bcr-Abl would play a role in down-regulation of SARI expression in CML-derived cell line K562. *Methods.* Forty-six Chinese patients with CML and forty healthy Chinese volunteers were recruited and informed consent at Union hospital of Wuhan in this study. SARI expression in the peripheral blood mononuclear cell of CML patients and healthy Chinese volunteers was assayed by using Real-time quantitative PCR. *In vitro*, in respective experiment, K562 cells were incubated with the Bcr-Abl inhibitor STI571 (Imatinib, Gleevec) (0.5, 1.5, 2.5μM) at 37°C and 5% CO2 for 6, 12, 24hours followed by detection of SARI expression using Real-time quantitative PCR. Further, the correlative downstream pathways were identified by using signal pathway inhibitors. K562 cells were incubated with PI3-kinase inhibitor LY294002 (20μM), MEK inhibitor PD98, 059 (50μM), JAK inhibitor Ag490 (50μM) at 37°C and 5% CO2 for 24 hours in respective experiment, then SARI expression were detected by Real-time PCR. All experiments were repeated three times. Statistical analysis was performed using SPSS 17.0. *Result.* Compared with healthy volunteers, expression of SARI mRNA in PMBCs of CML patients presented a lower level ($p<0.001$). *In vitro*, after exposure of K562 cells to STI571, the SARI expression was higher than those in control K562 cells (without STI571 treatment). SARI expression was enhanced in K562 cells as early as 6hours after treated with STI571 (1.5μM) and SARI expression was up-regulated in a time-dependent manner. In addition, after treated with JAK inhibitor Ag490, PI3K inhibitor LY294002 and MEK inhibitor PD98, 059 respectively, SARI mRNA expression was up-regulated by Ag490 ($p<0.05$)and PD98, 059 ($p<0.001$), but not by LY294002 compared with control K562 cells (without any treatment). *Conclusion.* The suppression of SARI expression is implicated in CML pathogenesis. Bcr-Abl mediates the down-regulation of SARI mRNA expression in K562 cells. Moreover, Bcl-Abl down-stream signal pathways, including JAK signal pathway and MEK signal pathway are involved in the down-regulation of SARI mRNA expression in K562 cells. These findings suggest that SARI is a potential gene target in CML therapy.

0674

THE ROLE OF CELL DIVISION CYCLE 6 OVEREXPRESSION IN CHRONIC MYELOID LEUKEMIA CELLS

JH Zhang, YL He, J Liu, JX Yao, JH Xiao, W Liu, J Ding, S Huang

Union Hospital of Tongji Medical College, HUST, Wuhan, China

Background. The cell division cycle 6 (Cdc6), a protein in eukaryotic cells, is an essential regulator of DNA replication and plays important roles in the activation and maintenance of the checkpoint mechanisms in the cell cycle that coordinate S phase and mitosis. Recent documents indicated the deregulation of CDC6 expression in human cells posed a serious risk of carcinogenesis. Down-regulation of CDC6 was observed in prostate cancer. Up-regulation of Cdc6 was found in cervical cancer, lung cancer and brain cancer. Chronic myeloid leukemia (CML) is a form of leukemia characterized by the

increased and unregulated growth of predominantly myeloid cells in the bone marrow and the accumulation of these cells in the blood. And the cause of CML was confirmed the central importance of BCR-ABL. But up to date, the relationship of Cdc 6 and CML is still obscure. *Aims.* Our Aim is to investigate the expression of Cdc6 and its role in CML cells. *Methods.* The expression of Cdc6 in normal bone marrow mononuclear cells, CML primary cells and K562 cells (CML cell line) was detected by real time quantitative RT-PCR and Immunofluorescence assay. The effects of Cdc6 gene silencing by siRNA on cell proliferation and apoptosis in K562 cells were evaluated by CCK-8 assay and Flow Cytometry. The effects of specific inhibitors Imatinib, LY294002, PD98059 and AG490, which separately target BCR/ABL, PI3K, MAPKK and JAK, on the expression of Cdc6 in K562 cells were determined by real time quantitative RT-PCR and Western Blot. *Results.* Cdc6 expression was significantly up-regulated in CML primary cells and K562 cells, compared to normal bone marrow mononuclear cells. Cdc6 gene silencing by siRNA effectively inhibited DNA replication and induced apoptosis in K562 cells. Imatinib, a BCR/ABL inhibitor, induced down-regulation of Cdc6 expression in K562 cells. LY294002 and AG490, but not PD98059, decreased the expression of Cdc6 in K562. *Conclusions.* These data indicated Cdc6 overexpression contributed to the high proliferative activity and the low apoptosis, and regulated by BCR-ABL signal transduction through downstream PI3K/Akt and JAK/STAT pathways in CML cells. It was also suggested that Cdc6 protein may be an attractive target for the development of effective anti-cancer strategies in adult chronic myeloid leukemia patients.

0675

EXPRESSION OF TRANSKETOLASE-LIKE GENE 1 (TKTL1) CHANGES DURING ACCELERATION OF CHRONIC MYELOID LEUKEMIA

M Philipp,[1] J Schwaab,[1] B Hanfstein,[1] L Kalmanti,[1] U Munjal,[1] WK Hofmann,[1] WK Hofmann,[1] A Hochhaus,[2] MC Mueller,[1] P Erben[1]

[1]*UMM, Mannheim, Germany*
[2]*Universitätsklinikum Jena, Jena, Germany*

Background. Development of resistance or progression to blastic phase in chronic myeloid leukemia (CML) occurs in a significant proportion of patients under tyrosine kinase inhibitor (TKI) therapy. Overexpression of transketolase-like gene 1 (TKTL-1) on mRNA and protein level has been linked to tumour progression, metastasis and poor patient outcome in many solid tumours. A TKTL1 knockout in tumour cells results in reduced activity of the pentose phosphate pathway (PPP), lower lactate production and G0/G1 arrest. Therefore TKTL1 is regarded as a potential target for drug therapy. Until today little is known about TKTL1expression in CML. *Aims.* We sought to evaluate TKTL1 gene expression in different CML phases. *Patients and Methods.* 108 peripheral blood samples of 79 CML patients (pts) (median age 56 years, range from 17 to 84) were investigated. 49 samples were collected from pts in chronic phase (CP), 22 from pts in major molecular response (MMR), 22 from accelerated phase (AP) pts. and 15 in blast crisis (BC) pts. A control group consisted of 21 healthy individuals. TKTL1 mRNA expression levels were determined by quantitative reverse transcription PCR (qRT-PCR) using LightCycler® technology and normalized against beta-glucuronidase (GUS) expressio n. TKTL1 expression has also been determined in granulocytes isolated by Ficoll gradient centrifugation from blood and in immature CD34+ and CD34-/CD33+ cells isolated from bone marrow by MACS beads technology. *Results.* A significantly lower TKTL1 expression was found in the CP group compared to the group of healthy donors (TKTL1/GUS ratio 2.5% vs 8.7%, p<0.01, Table). Intermediate expression levels were observed in AP (1.1%). Lowest expression levels were observed in the BC group (0.9%). No significant difference could be found in the MMR group compared to healthy individuals (6.4% vs 8.7%, p=0.25). In addition, this evaluation revealed no significant difference of TKTL1 expression at baseline in CP patients with subsequent favourable outcome (MMR within one year) and those with subsequent progression (AP or BC) during therapy. Further experiments showed significantly higher TKTL1 expression in mature granulocytes in comparison to immature CD34+ and CD34-/CD33+ cells. *Conclusions.* TKTL1 expression levels appear to decline in the course of CML with lowest levels during BC. This might be due to the suppression of matured cells by the clone of immature blasts with a lower expression of TKTL1. However, in this study TKTL1 expression levels at diagnosis failed to give a predictive information about disease progression.

Table 1.

Summary of TKTL1 expression levels and P values

	TKTL1/GUS ratio (%) Median (range)	P value (Mann-Whitney test)		
Healthy volunteers	8.7% (2.8-35.2%)	<0.01		
CP	2.5% (0.1-40.6%)		<0.01	0.25
AP	1.1% (0.02-23.4%)	0.26		
BC	0.9% (0.05-5.3%)			
Patients in MMR	6.4% (0.83-49.1%)			
CP patients with favourable outcome (MMR)	2.7% (0.2-18.4%)	0.78		
CP patients with subsequent acceleration	2.3 (0.1-40.6%)			

0676

IMATINIB DISCONTINUATION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA WHO HAVE RECEIVED FRONT-LINE IMATINIB THERAPY AND ACHIEVED COMPLETE MOLECULAR RESPONSE

JA Kim,[1] JY Kwak,[2] HY Yhim,[2] S Shin,[1] NR Lee,[2] EK Song,[2] CY Yim[2]

[1]*Catholic University of Korea College of Medicine, Suwon, South-Korea*
[2]*Chonbuk National University Medical School, Jeonju, South-Korea*

Background. Imatinib (IM) is an effective treatment in patients with chronic myeloid leukemia (CML). Complete molecular response (CMR) was only attained in 10-20% of chronic phase (CP) CML patients at 24 months, and the proportion was substantially increased by continuing IM therapy. Mahon and colleague showed that 41% of patients who achieved and maintained CMR for 2 years on IM therapy remained CMR after IM discontinuation. However, they included patients with front-line treatment of interferon, who didn't represent current patient population. Thus, the aims of this study were to investigate feasibility of IM discontinuation in patients with CML, who have treated with front-line IM therapy and achieved CMR, and also to evaluate the prognostic factors associated with loss of CMR in terms of time to loss of CMR (TTLC). *Methods.* We consecutively enrolled CP CML patients, who had their IM therapy discontinued after achieving CMR during at least one year on IM therapy at 2 Korean institutions from June 2009 to September 2010. CMR was defined by undetectable levels of BCR-ABL transcript by RQ-PCR with at least 10,000 ABL transcripts per volume cDNA. After discontinuation, BCR-ABL/ABL ratio was monitored by RQ-PCR monthly during the first 6 months and every 2-3 months thereafter, and relapse was defined by detectable levels of BCR-ABL transcript in two successive assays. *Results.* Fourteen patients were included. The median age was 60 (range, 29-78) years, and 10 patients were women. All patients were CP and received IM as an initial treatment. Sokal score at diagnosis was low in 1 patient, intermediate in 6, and high in 7. IM was started at a dose of 400mg/day. The median interval from IM initiation to CMR was 19.2 (range, 7.0-71.9) months. After achieving CMR, IM therapy was continued for a median of 32.3 (range, 12.1-72.4) months. And, the median duration of IM therapy was 56.4 (26.2-82.0) months. After IM discontinuation, molecular relapse occurred in 9 patients at 1.1 to 6.9 months. With a median follow-up of 13.4 (2.5-20.4) months, TTLC at 1-year was 31.4% (95% CI, 18.5-44.3). In the univariate analysis of factors affecting molecular relapse, high-risk of Sokal score (p=0.004) and more than 24 months of interval between IM initiation and CMR (p=0.008) were associated with frequent molecular relapse. Duration of IM after CMR was not significantly related with molecular relapse, but there was a trend of lower molecular relapse in patients with at least 32 months. IM was resumed in all patients with molecular relapse. 6 of 9 patients showed decrease in their BCR-ABL transcript levels and 3 achieved a CMR after IM rechallenge. *Conclusion.* IM discontinuation in patients with CML who have received IM as initial treatment and achieved a CMR might be feasible, as one-third of patients remain CMR at 1-year. Baseline Sokal score and achieving a CMR within 24 months after IM initiation are associated with lower rate of molecular relapse after IM discontinuation. Thus, treatment strategies that may increase the rates of CMR in early should be investigated, and further studies are warranted.

Background. Mutations within the BCR-ABL domain are the most frequent mechanism of imatinib (IM) resistance. The second generation inhibitors (SGI) are indicated for imatinib intolerance or resistance and the initials trials showed similar response rates in IM resistant patients after IM failure, independent of mutation status, except T315I. *Aims.* The aim of this work was to report the frequency of BCR-ABL mutations in chronic myeloid leukemia (CML) patients with imatinib resistance in a Latin American population and to evaluate the clinical impact of SGI treatment in this group of patients. *Methods.* A total of 187 resistant patients with BCR-ABL mutations were analyzed. After imatinib resistance, 120 received SGI (87 dasatinib, 28 nilotinib and 5 bosutinib). Mutations were detected by direct sequencing from bone marrow or peripheral blood samples, collected during imatinib (129), dasatinib (29), nilotinib (21) or other treatments (8). The median follow-up from mutation detection was 12 months. Overall survival (OS) was calculated from date of mutation detection until last follow-up or death, whereas the progression-free survival (PFS) from date of mutation detection until progression to accelerated phase or blast crisis, last follow-up or death. For the statistical analysis was used log-rang test using SPSS 14.0 software. *Results.* the median age of patients at diagnosis was 42 years. 73% were in CP, 19% in AP and 8% in BC. According to Sokal score, patients were stratified in low risk (27%), intermediate (37%) and high (36%); 32% had used Interferon. The median time from diagnosis until Imatinib treatment was 28 months (1-310) and from Imatinib start until mutation detection was 38 months (1-100). Mutations region: P-loop (57 / 30.5%), nucleotide contact site (47 / 25.1%), catalytic domain (46 / 24.6%), A-loop (8 / 4.3%) and others (29 / 15.5%). The most frequent mutations detected were: T315I (29/15.5%), F359V (24/12.8%), M244V (17/9.1%), G250E (16/8.6%), E255K (11/5.9%), M351T (9/4.8%), Y253H (7/3.7%). Twelve patients presented more than one mutation. During Dasatinib treatment mutation T315I was detected in 8/29 patients, F317L in 6/29 and E255K in 6/29. During Nilotinib treatment 7/21 patients presented mutation F359V and 4/21 T315I. Overall survival in the total group was 44% (95% CI: 30-58%) with a median time of 12 (1-91) months. There was no difference in survival comparing P-loop mutations and others (P= NS). In the group where mutations were detected during imatinib treatment, OS and PFS were superior in patients that received a SGI in comparison with other treatments after resistance (57% versus 43% and 40% vs 18%, P=0.001 and P=0.004, respectively). Twenty-four/55 died from disease progression; 5 from infections; 3 from graft versus host disease; 1 hemorrhage; 1 cardiac failure; 1 second neoplasia and 20 were not reported. *Conclusions.* the frequency of T315I, M244V, E255K were similar to previous reports. F359V was the second most frequent mutation detected in our population. Treatment with SGI clearly had a positive impact on patients' survival after imatinib failure.

0678

HIGHER ADHERENCE RELATED TO COMPLETE MOLECULAR RESPONSE (CMR) IN CHRONIC MYELOID LEUKEMIA PATIENTS USING IMATINIB MESILATE

MH Almeida, K Pagnano, E Miranda, C Souza

University of Campinas, Campinas, Brazil

Background. Tyrosine Kinase Inhibitors are currently the treatment of choice for Chronic Myeloid Leukemia (CML). Treatment adherence is an important factor to obtain good therapeutical results. The WHO definition of adherence is: "the extent to which a person's behavior - taking medication, following a diet, and/or executing lifestyle changes, corresponds with agreed recommendations from a health care provider". *Aims.* to evaluate the adherence to Imatinib Mesilate (IM) in patients with CML and to identify factors can affect adherence to treatment. *Methods.* a prospective and observational analysis was performed, between March 2009 and December 2010, with 86 patients taking IM, in first line of treatment at Hematology and Hemotherapy Center, University of Campinas, Brazil. Adherence ratios were monitored for almost one year (308 to 433 days). The adherence was calculated using the mean medication possession ratio (MPR), calculated as total days' dose of IM divided by the number of the days in the observation time. Quantitative PCR were measured in peripheral blood pre and post analysis time and each 12 weeks during the interval. Statistical analysis began with descriptive analysis and we applied Spearman's correlation and t-Test or ANOVA, what it was adequate, considering significant p-value 0.05 (SPSS 14.0 software). *Results.* a total of 86 patients were evaluated. The median age was 49 (20-82) years. The majority of patients were male (59%) and the median of IM treatment time was 39 months (6-106). Considering all patients, the mean and median of adherence were 89% and 96% respectively and 24% of patients were completely adherents with 100% of MPR. Adherence decreased with longer term therapy (p= 0.02) and longer duration of disease (p= 0.002). The adherence was superior in patients enrolled in clinical trials (p=0.007). CMR rates were superior in patients more adherent (p=0.01 - ANOVA and p= 0.02 - Bonferroni). On the other hand, adherence was inferior in patients using higher dose (600/800mg) of IM (p=0.01). There was not significant difference in adherence regarding sex, age, socioeconomic status, marital status, Sokal and instruction level. *Conclusion.* higher adherence in CML patients using IM is related with superior CMR, IM lower doses and clinical trial participating. However, the poor compliance was associated with longer term therapy and longer duration of disease.

0679

LONG-TERM ESTIMATE OF QUALITY-ADJUSTED LIFE EXPECTANCY FOR NILOTINIB AND IMATINIB AS FIRST-LINE TREATMENT FOR NEWLY DIAGNOSED PATIENTS WITH PH+ CHRONIC MYELOID LEUKEMIA IN THE CHRONIC PHASE (CML-CP)

M Botteman,[1] J Stephens,[1] S Snedecor,[1] J Ji,[1] M Hussein,[2] J Coombs,[3] M Abuelkhair,[4] H Alizadeh[5]

[1]*Pharmerit International, Bethesda, United States of America*

[4]*Pharma/Medicine and Medical Products Regulation Section, Health Authority, Abu Dhabi, United Arab Emirates*
[5]*Tawam Hospital Consultant Hematologist-Oncologist, Al Ain, United Arab Emirates*

Background. In the ENESTnd study, the 12-month rates of major molecular (MMR) and complete cytogenetic (CCyR) responses were significantly higher in newly diagnosed Ph+ CML-CP patients initiating nilotinib (300 mg BID) than imatinib (400 mg QD) (MMR: 44% v. 22%, respectively; CCyR: 80% v. 65%, respectively; all P<0.001). Nilotinib patients had a significant reduction in progression to accelerated phase or blast crisis v. imatinib patients (P = 0.01). *Aims.* Model the long-term quality-adjusted life expectancy (LE) of newly-diagnosed Ph+ CML-CP patients initiating first-line therapy with nilotinib or imatinib in the United Arab Emirates (UAE). *Methods.* A state-transition Markov model was developed. A central model feature was the rate at which patients discontinue initial therapy, which was (1) based on direct observations from ENESTnd (for the first 12 months of the model) and, (2) dependent on patients' 12-month ENESTnd treatment responses and modeled from the long-term IRIS outcomes. After initial treatment discontinuation, patients were modeled to receive an additional tyrosine kinase inhibitor (TKI), and prognosis was modeled using published lit-

erature. Uncertainty was assessed using intervals comprising 95% of 1,000 model replications generated via Monte-Carlo simulations (95% credible intervals [CI]). *Results.* Initiating TKI therapy with nilotinib resulted in an estimated mean (95% CI) LE of 28.03 (26.73-29.34) years and quality-adjusted LE of 25.14 (23.42-26.73) years. The corresponding estimates for imatinib first-line therapy were 24.43 (22.70-25.97) years and 21.56 (19.87-23.33) years, respectively. The differences in mean (95% CI) LE and quality-adjusted LE between nilotinib and imatinib were 3.68(2.04-5.35) years and 3.58 (2.03-5.14) years, respectively. *Conclusions.* First-line nilotinib was more efficacious than imatinib in the ENESTnd trial at 12 months. As trial data collection is ongoing, modeling can be used to estimate the long-term value of these treatments. The present model suggests that nilotinib is likely to substantially increase quality-adjusted LE v. imatinib.

IMPROVEMENT OF IMATINIB-RELATED CHRONIC LOW-GRADE NONHEMATOLOGIC ADVERSE EVENTS (AES) IN PHILADELPHIA-POSITIVE (PH+) CHRONIC MYELOID LEUKEMIA-CHRONIC PHASE (CML-CP) PATIENTS SWITCHED TO NILOTINIB

J Mauro,[1] C Miller,[2] S Ailawadhi,[3] L Busque,[4] J Lipton,[5] L Akard,[6] J Pinilla-Ibarz,[7] S Ericson,[8] J Shah,[8] J Cortes[9]

[8]*Novartis Pharmaceuticals Corporation, East Hanover, United States of America*
[9]*MD Anderson Cancer Center, Houston, United States of America*

Background. Many CML patients treated with imatinib experience low-grade AEs that require chronic treatment and may impact quality of life (QOL). Nilotinib is approved for adults with Ph+ CML-CP or accelerated phase who are intolerant or resistant to imatinib and for patients with newly diagnosed Ph+ CML-CP. Cross-intolerance between imatinib and nilotinib is rare (4% in the nilotinib registration study). *Aim.* Assess the potential improvement of chronic low-grade nonhematologic AEs in patients with Ph+ CML-CP when switched from imatinib to nilotinib therapy. *Methods.* This is an on-going, multicenter, open-label study. To be eligible, patients with Ph+ CML-CP must have received imatinib 400 mg daily for ≥3 months before screening, experienced an imatinib-related Grade 1 or 2 nonhematologic AE persisting >2 months or recurring more than 3 times and persisting despite best supportive care. At enrollment, patients are switched to nilotinib 300 mg twice daily. The primary endpoint is change in imatinib-related nonhematologic AEs using the Common Terminology Criteria for Adverse Events (CTCAE) version 4.0 after 3 months (end of cycle [EOC] 3) of nilotinib. Secondary endpoints include response to nilotinib and patient-reported outcomes as measured by QOL questionnaire and the MD Anderson Symptom Inventory (MDASI)-CML. The study was conducted in accordance with Declaration of Helsinki; patients provided written informed consent. This preliminary analysis was performed on 23 patients enrolled as of the data cut-off date of November 30, 2010. *Results.* The median duration of nilotinib was 3.6 months. There were 105 baseline imatinib-related nonhematologic AEs (72 Grade 1; 33 Grade 2), persisting for a median 24.8 months. Fifteen patients completed EOC 3 by cut-off. Of the 75 imatinib-related AEs reported among these patients, 45 AEs were improved (30, 7, and 3 AEs resolved by months 1, 2, 3, respectively; 5 AEs decreased from Grade 2 to 1), 27 were unchanged, and 3 increased in severity. At study entry, 20 patients had achieved major molecular response (MMR, 3-log reduction of Bcr-Abl); 3 additional patients achieved MMR by cut-off. Eleven patients completed QOL questionnaires; 82% reported QOL improvements at EOC 3 compared to baseline. Mean reduction from baseline in MDASI-CML severity score and interference score were 1.47 & 1.86 (EOC 1) and 1.45 & 1.33 (EOC 3), respectively, indicating improvement in symptoms. Nilotinib dose was reduced in 7 patients for nilotinib-related nonhematologic AEs. Fourteen Grade 3 AEs were reported in 6 patients; 10 (increased bilirubin and lipase, dehydration, hypokalemia, hypophosphatemia, worsening of arthralgia, joint pain) were suspected to be nilotinib-related. No patient had a Grade 4 AE. Most AEs were managed by brief dose interruption. Two patients discontinued nilotinib (1 hyperglycemia, 1 upper abdominal pain/oral pain/headache). The maximum QTcF change from baseline was 37 msec; QTcF prolongation >500 msec did not occur. *Conclusions.* Switching to nilotinib improved nonhematologic imatinib-related, low-grade AEs in >50% of CML-CP patients in this analysis. Overall improvement in symptoms was observed and 82% of patients experienced improved QOL, including 5 of 6 patients with Grade 3 AEs. Longer-term evaluation and enrollment continue.

0681

PATIENT REPORTED OUTCOME RESULTS FROM A PHASE III RANDOMIZED TRIAL COMPARING NILOTINIB AND IMATINIB IN PATIENTS WITH NEWLY DIAGNOSED CML-CP

J Beaumont,[1] C Nowinski,[1] J Coombs,[2] T Szczudlo,[2] R Blakesley,[2] N Gallagher,[2] J Burns,[1] D Cella[1]

[1]*Northwestern University Feinberg School of Medicine, Chicago, United States of America*
[2]*Novartis, Florham Park, NJ, United States of America*

Background. Nilotinib has been shown to be a more potent inhibitor of BCR-ABL than imatinib. A randomized Phase III study was conducted comparing these two therapies in adult patients with newly diagnosed Philadelphia Chromosome positive (Ph+) chronic myelogenous leukemia (CML) in chronic phase (CP). Major molecular response by 24 months was significantly improved with nilotinib 300mg BID (71%) and nilotinib 400 mg BID (67%) compared to imatinib 400 mg QD (44%); $p < 0.0001$ for both comparisons. Adverse event (AE) profiles differed among the treatment arms, and patients treated with nilotinib 300mg BID had the lowest rate of discontinuation due to AE. *Aims.* To evaluate the patient-reported outcomes, including health-related quality of life (HRQL) and functioning, within the phase III trial. *Methods.* A total of 846 patients were randomized to receive nilotinib 300mg BID (n=282), nilotinib 400mg BID (n=281), or imatinib 400mg QD (n=283). HRQL was assessed in this open-label study using the Functional Assessment of Cancer Therapy-Leukemia (FACT-Leu) and the Short Form 36 Health Survey (SF-36). The FACT-Leu consists of four general subscales measuring physical, social/family, emotional, and functional well-being and a 17-item leukemia-specific subscale. The FACT-Leu Total score is the sum of all five subscales. The SF-36 assesses eight domains (physical functioning, role-physical, bodily pain, general health, vitality, social functioning, role-emotional, and mental health) that can be combined to create a mental component score (MCS) and a physical component score (PCS). Both questionnaires were administered at baseline, and at 3, 12, and 24 months. *Results.* Questionnaire completion rates at baseline were 86-92%, and 64-70% at 24 months. High baseline scores reflected that these newly diagnosed patients (median age 47) were in relatively good health and their CML was mostly asymptomatic. FACT-Leu subscale and Total scores were similar across treatment arms at baseline and at follow-up assessments, with differences between treatment arms less than 2 points. At 24 months compared to baseline, FACT-Leu subscale scores were maintained or improved for 87% of patients receiving nilotinib 300mg BID, with 13% experiencing worsening. At each time point

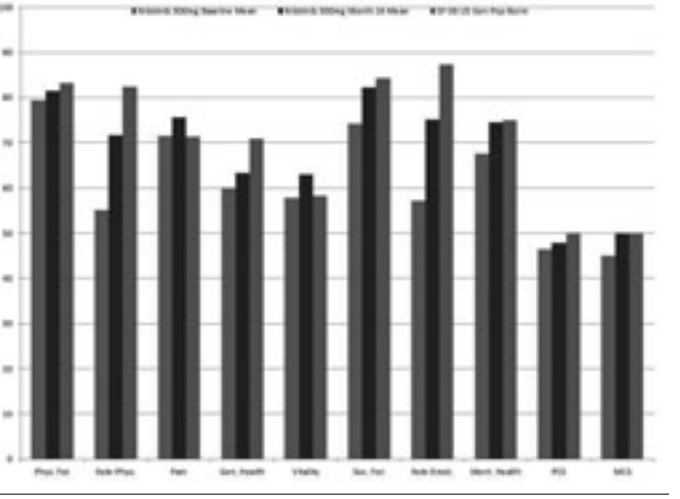

Figure 1. SF-36 scores compared to the US general population.

across treatment arms, differences among the PCS and MCS scores of the SF-36 were less than 1.5 points. Compared to the SF-36 norms for 45 -55 year old individuals in the US, mean nilotinib 300mg BID scores were similar to population means for most of the domains at 24 months (Figure). *Summary/conclusions.* Nilotinib 300mg BID demonstrated superior efficacy including significantly lower rates of progression to AP/BC, lower rates of discontinuation due to AE compared to imatinib, and maintains health-related quality of life and functioning in patients with newly diagnosed CML-CP, at a level nearly comparable to general population normative values. These findings provide a patient perspective and underscore the significant advances in the treatment of Ph+ CML, where patients can achieve deep clinical responses and maintain a near-normal life.

Background. The treatment of chronic myeloid leukemia (CML) has changed dramatically over the last decade with the advent of targeted therapies but there is lack of data concerning the long term impact on quality of life and symptoms from the patients' perspective. *Aims.* The aim of this study was to investigate the predictive value of socio-demographic and clinical treatment related data of self-reported symptom severity in CML patients undergoing Imatinib (IM) over the long run. *Methods.* A large multicenter case-control survivorship study including 26 centers was set up to investigate the main research objective and included 422 CML patients who started IM, as first line therapy, in the early chronic phase of the disease. Patients were receiving IM treatment (regardless of dose) for at least three years and were in complete cytogenetic response (CCyR) at the time of study entry. Patient reported symptoms were measured with a previously devised nine items checklist for CML patients undergoing IM treatment. This checklist had a one-week time recall period and all items were rated on a four point likert-type scale (i.e. "not at all", "a little", "quite a bit"or "very much"); these measurement characteristics were selected to be consistent with other symptom scales/items included in other psychometric robust measures, widely used in similar long-term studies. The selection of the core symptom domains was based on an extensive literature review, published data on side effects of IM as well as from patients input. Items investigated the following issues: abdominal discomfort, diarrhea, edema, fatigue, headache, muscle cramps, musculoskeletal pain, nausea and skin problems. An overall symptoms index was derived by averaging all symptoms standardized scores. A regression analysis was performed for symptoms index as response variable and a number of potential key covariates were investigated including: gender, age, toxicity, performance status, living arrangements, education, time to achieve a first CCyR, haemoglobin, comorbidity and IM current dose. *Results.* Fatigue was the most prevalent symptom with 82% of patients reporting it with any level of concern. Nausea and abdominal problems were the less frequently reported symptoms. A univariate analysis identified the following variables predicting symptom severity: gender (P<0.001), age (P=0.002), living arrangements (P=0.007), comorbidity at diagnosis (P<0.001), assuming other drugs not related to the diagnosis of CML (P=0.008) and having had a previous diagnosis of cancer (P=0.036). The final model retained the following variables predicting a lower reported symptom severity: being male (P<0.001), living with a spouse or partner (P=0.027) and not reporting comorbidity at the time of diagnosis (P=0.002). The total variance explained with this model was, however, small being 13% thus suggesting that other unexplored factors might have an important role in determining patient-reported symptom severity. *Conclusions.* This is the first evidence based data investigating possible clinical determinants of patient-reported symptoms in CML patients suggesting that gender, comorbidity and living arrangements are of importance. Further possible determinants need to be investigated in future analyses.

A NEW SYMPTOM MEASURE IN CHRONIC MYELOID LEUKEMIA

L Williams

The University of Texas MD Anderson Cancer Center, Houston, Texas, United States of America

Background. Symptom burden is the combined impact of symptoms from disease and treatment on daily functioning. While the severity of symptoms experienced by patients with Philadelphia chromosome positive chronic myeloid leukemia (CML) receiving kinase inhibitor (KI) therapy may be less than with more intense forms of cancer therapy, these symptom are experienced for years rather than days or months. This may lead to overall equal or greater symptom burden and resultant functional impairment for these patients. A major barrier to effective symptom management in CML is inadequate assessment. In addition, patient-reported outcomes (PROs) can be endpoints in clinical trials to establish treatment benefits. *Aims.* We aimed to develop a short, easily-understood, valid, and reliable PRO measure of CML symptoms for research and practice. *Methods.* After providing institutional review board-approved informed consent, 127 patients with CML completed the 13 symptom severity and 6 interference items of the core MD Anderson Symptom Inventory (MDASI) plus 7 CML-specific symptom items (Table 1), generated from patient and expert input, measured on a 0-10 scale (0 = none, 10 = worst imaginable). 85 patients completed the same items 2 weeks later. Patients also answered a single quality-of-life (QOL) question. Demographic and disease information was collected on all patients. Multivariate analysis examined relationships among items. Psychometric procedures determined reliability and validity of the MDASI-CML. *Results.* Mean subject age was 50.4 years (standard deviation [sd] = 13.7). 54% of the subjects were female, 76% were white, 62% were employed, 99% had an ECOG performance status < 2, and 98% were in chronic phase. 94% were receiving KI therapy (of total receiving KI therapy, 48% were receiving imatinib, 28% were receiving dasatinib, 16% were receiving nilotinib, and 9% were receiving an investigational KI). Mean overall quality of life rating was 8.2 (best = 10, sd = 1.9). Selected symptom severity and interference scores are in Table 1. All items were retained as clinically significant and non-redundant. The reliability index (Cronbach α) and test-retest reliability of the 20 symptom items were 0.94 and 0.93 respectively and of the 6 interference items were 0.94 and 0.91 respectively. The MDASI-CML discriminated between patients who were employed versus those medically disabled and with good versus poor QOL. Symptom severity explained 87% of the variance in interference, with the core symptoms explaining 83% and the CML-specific symptoms explaining 76%. Patients receiving imatinib reported significantly (p = 0.048) more severe CML-specific symptoms (mean = 1.83, sd = 1.60) than patients receiving dasatinib or nilotinib (means = 1.27 and 1.03 respectively, sd = 0.99 and 1.30 respectively). *Summary/Conclusions.* We have validated an analytic tool, the MDASI-CML, for quantifying CML symptoms. The MDASI-CML is being used to assess side effects in treatment trials and to monitor symptoms in clinical care. Additional research on the longitudinal symptom burden, including differences based on type of KI therapy, is needed.

Chronic myeloid leukemia - Clinical 2

LOSS OF MAJOR MOLECULAR RESPONSE (MMR) IS MORE ACCURATE THAN LOSS OF COMPLETE MOLECULAR RESPONSE (CMR) FOR RESTARTING IMATINIB AFTER IMATINIB DISCONTINUATION IN CP-CML PATIENTS WITH LONG LASTING CMR

P Rousselot,[1] P Cony-Makhoul,[2] D Réa,[3] L Legros,[4] M Tulliez,[5] L Roy,[6] A Charbonnier,[7] F Guilhot,[8] FX Mahon[9]

Background. We have reported the results of imatinib discontinuation in 100 CML (Chronic Myelogenous Leukemia) patients in complete molecular response (CMR) for more than 2 years under imatinib therapy (STIM study). The molecular relapse was defined by two consecutive positive values of the BCR-ABL/ABL ratio. Using this criterion, 59% of the patients had to restart imatinib therapy and achieved a second CMR (Mahon *et al.* Lancet Oncology 2010). However, we identified patients experiencing occasional positive values without a confirmed molecular relapse. We then asked whether the loss of major molecular response (MMR) could be a more accurate criterion for restarting imatinib in an independent cohort of patients. *Patients and Methods.* Patients were retrospectively analysed. CP-CML patients were eligible if they were in CMR (CMR 4.5 log) under imatinib therapy for more than 2 years. Those patients were not enrolled in the STIM study because the study was not initiated or closed or because they experienced one positive value of the BCR-ABL/ABL ratio during the 2 years follow-up. The criterion for restarting imatinib was the loss of MMR. We were then able to calculate molecular relapse free survival using different end-points such as loss of CMR (only one BCR-ABL positivity), loss of CMR using the STIM definition and loss of MMR. *Results.* 25 CP-CML patients were included in the analysis. Median follow-up is 54.8 months (33-102.7). Sex ratio (M/F) was 53% with a median age of 55.7 years (32.7-76.7). Sokal score distribution was 39.1%, 34.7% and 26% for low, intermediate and high values respectively. 14 out of 25 patients received interferon therapy prior to imatinib. Median duration of imatinib therapy and median duration of CMR prior to discontinuation was 58.7 months (30.1-117.6) and 33.2 months (13.6-72.8). One patient had a CMR duration less than 24 months. 11 out of 25 patients (44%) had a least one BCR-ABL positive value after the achievement of CMR. 9 patients (36%) restarted imatinib including 7 patients after the loss of MMR and two patients after the loss of CMR (these two patients were censored at the time of treatment initiation for the loss of MMR analysis). We next compared different end-points in order to evaluate the best criterion for restarting imatinib after discontinuation. Median relapse free survival was 4.8 months, 13.7 months and not reached using loss of CMR, loss of CMR according to the STIM study and loss of MMR criteria (p=0.035). At 48 months, 32%, 40,9% and 78.7% of the patients were relapse free using the same criteria respectively. Of note, among the 18 patients experiencing a persistent MMR after imatinib discontinuation, 7 (38.9%) lost their CMR according the STIM criteria and did not restart imatinib. *Conclusions.* Using the loss of MMR, 78.7% of the patients are relapse free (and treatment free) at 48 months following imatinib discontinuation. We were able to identify patients with long lasting MMR despite a loss of CMR suggesting that a proportion of these patients were able to control their tumour burden without the need of imatinib therapy.

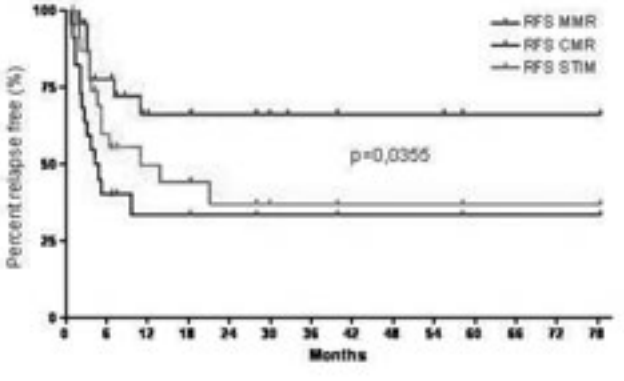

Figure 1. Kaplan Meier analysis of relapse free survival usi.

0685

OPERATIONAL CURE OF CHRONIC MYELOID LEUKEMIA AFTER TREATMENT WITH INTERFERON-ALPHA: A RETROSPECTIVE LONG-TERM STUDY FROM NORTHERN MORAVIA REGION

E Faber, A Kuba, J Zapletalova, M Divoka, P Rohon, M Holzerova, M Jarosova, K Indrak

University Palacky in Olomouc, Olomouc, Czech Republic

Background. Tyrosine kinase inhibitors (TKIs) are today the drugs of choice in the treatment of patients with chronic myeloid leukemia (CML). However, their potential to cure the disease is limited as survival of CML stem cells is probably not dependent on Bcr-Abl kinase activity. Interferon-alpha (INF), on the other hand, may have significant impact on CML stem cells due to wide range effect on cytokines, cell cycle and immune system. *Aims.* To analyze long-term results of CML patients treated exclusively with INF (as single-agent therapy or in combination with hydroxyurea or cytarabine) and impact of achievement of complete cytogenetic response (CCyR) and BCR-ABL negativity in nested reverse-transcriptase polymerase chain reaction (RT-PCR) on overall survival (OS) of patients. *Methods.* Retrospective analyses of all consecutively patients with CML in chronic phase treated with INF in the region between 1989 and 2006. INF dosage was adjusted according tolerability in order to maintain leukopenia 2-4x109/l between 3MU three times weekly and 10 MU daily. BCR-ABL negativity was assessed by standard nested RT-PCR. INF treatment was stopped in actual patient after one year of gradual dose reduction only after two years duration of BCR-ABL negativity. OS was calculated according method of Kaplan and Meier, log-rank test, Mann-Whitney test and Cox regression analysis were used for statistic evaluation. Patients were censored for OS evaluation at the time of allogeneic stem cell transplantation or initiation of treatment with TKIs. *Results.* Treatment results of 118 patients with CML in first chronic phase (67 males and 51 females at median age 50 years; range 18-71) were analyzed. Median follow-up of all patients was 82.6 months (range 12.4-212.6). 61 patients were treated with INF for more than 12 months. Their mean OS calculated from the first dose of INF was 137 (95% CI 117.6-156.4) months. 18 (29.5%) of them reached CCyR in median time of 16.7 months (95% CI 3.7-47.3). Nine of these patients (14.8% of patients treated more than one year; 7.6% of the whole cohort) achieved BCR-ABL negativity in nested RT-PCR and 6 of them remain in operational cure without any treatment for 3-9 years; while two continue with INF therapy and one died due to unrelated cause. Percentage of peripheral blasts, splenomegaly, anemia (Hgb ≤110g/l) and Sokal score had significant impact on OS in univariate statistic assessment but only Sokal score remained significant in multivariate analysis. *Conclusions.* Despite numerous adverse effects and treatment failures a significant group of CML patients can gain long-term profit from INF. Unlike the patients with the sole CCyR of whom majority lost CCyR despite continuing INF therapy and later required treatment with TKIs, patients who achieved BCR-ABL negativity in nested RT-PCR had excellent long-term outcome and high probability of operational cure.

Acknowledgement. Study was supported by the grants MSM 6198959223 and MSM 6198959205 of the Ministry of Education Youth and Sports of the Czech Republic.

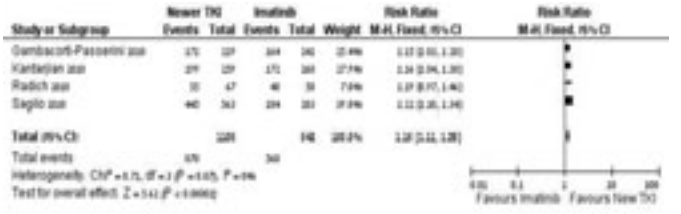
THE NEW TYROSINE KINASE INHIBITORS FOR FIRST-LINE TREATMENT IN PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA - SYSTEMATIC REVIEW AND META-ANALYSIS

R Gurion,[1] A Gafter-Gvili,[1] L Vidal,[1] A Leader,[2] R Ram,[1] A Sacham-Abulafia,[1] I Ben Bassat,[1] O Shpilberg,[1] P Raanani[1]

[1]*Rabin Medical Center, Petach Tikva, Israel*
[2]*Meir Medical Center, Kfar Saba, Israel*

Background. Imatinib is considered first line treatment in chronic phase (CP) chronic myelogenous leukemia (CML) patients. Despite the excellent results obtained from the IRIS trial, 30% to 35% of patients discon-

Table 1. Complete cytogenetic response at 12 months.



tinue imatinib for various reasons. One way to overcome this is to use second generation tyrosine kinase inhibitors (TKIs). These newer agents show a high rate of response in patients with imatinib failure or intolerance. Several trials evaluated response rate and long-term outcomes with second and third generation TKIs compared to imatinib for first-line treatment in patients with CP-CML. *Aims.* We aimed to evaluate the efficacy and safety of the newer TKIs (second and third generation) vs. imatinib for first line treatment of patients with chronic phase CML. *Methods.* Systematic review and meta-analysis of randomized controlled trials comparing treatment with the newer TKIs to imatinib as first line treatment in patients with CP-CML. The Cochrane Library, MEDLINE, conference proceedings and references were searched until February 2011. Two reviewers appraised the quality of trials and extracted data. Outcomes assessed were: complete cytogenetic response (CCyR), major molecular response (MMR), progression to accelerated phase (AP) / blastic crisis (BC), all-cause mortality and toxicity, all at 12 months. Relative risks (RR) were estimated and pooled. *Results.* Our search yielded four trials including 2120 patients, two of them published as abstracts. These trials examined the effect of nilotinib, dasatinib and bosutinib vs. imatinib. Data from the four trials, including 1950 patients were available for analysis of CCyR at 12 months. Treatment with the newer TKIs significantly improved CCyR in all patients (RR 1.18, 95% CI 1.11-1.25, 4 trials) without any differences when the analysis was conducted according to intention to treat or per protocol. Also, treatment with the newer TKI improved CCyR in patients at high risk, (RR 1.33 95% CI 1.11-1.60, 2 trials, 333 patients). There was a significant advantage in favor of the newer TKIs in terms of MMR at 12 months (RR 1.82, 95% CI 1.26-2.64, 4 trials, 2014 patients). Importantly, progression rate to AP/BC was significantly lower with the newer TKIs compared to imatinib (RR 0.32, 95% CI 0.17-0.59, 4 trials). However there was no difference in all-cause mortality (RR 1.17, 95% CI 0.56-2.46, 3 trials) and in the number of adverse events requiring discontinuation of treatment (RR 1.57, 95% CI 0.84-2.93, 4 trials). *Conclusions.* The newer TKIs are superior to imatinib in terms of CCyR, MMR and progression to AP/BC with no further toxicity. A survival advantage could not be shown, probably due to a short follow-up period and the excellent prognosis of CML patients treated with imatinib. Thus, the newer TKIs may be considered as an optional first line treatment in CP-CML patients.

Background. Imatinib mesylate (IM) has shown remarkable efficacy for the treatment of Chronic Myeloid Leukemia (CML) patients (pts) in the chronic phase of the disease. However, a growing number of pts either fail IM or develop intolerance to the drug. *Aims.* To identify biological parameters predictive of IM response (at diagnosis or during the first months of therapy) in order to recognize pts with a more aggressive disease that should receive alternative treatments. *Methods.* We examined the outcomes of the first 192 CML pts accrued to the observational SCREEN (Sicily and Calabria CML REgional ENterprise) multicenter non-sponsored study, recruiting newly-diagnosed CML pts receiving IM 400 mg daily. Median follow-up was 37 months (range 12-72). Complete hematological (CHR), cytogenetic (CCyR) and major molecular responses (MMR) were rated according to the European Leukemia Net 2006 guidelines. Peripheral blood samples were used for BCR-ABL determination by quantitative real-time polymerase chain reaction according to the International standardized Scale (IS) using either GUS (at diagnosis) or ABL (at every other time-point) as reference genes. Pts were stratified according to clinical and molecular responses or BCR-ABL transcript levels at diagnosis and analyzed for their outcome on an intention to treat basis. *Results.* At 12 months, cumulative incidences of CHRs, CCyRs and MMRs were 100%, 80% and 46.5%. At 24 months, incidences of CCyR and MMR increased to 92.7% and 72%, respectively. According to the ELN criteria, 106 pts (55.3%) achieved an optimal response; 45 pts (23.4%) had a suboptimal response; 35 pts (18.2 %) failed IM because of either primary (22 pts) or secondary (13 pts) resistance. Only 6 pts (3.1%) were intolerant to IM. Kaplan-Meyer estimates for overall, progression-free, event-free (EFS) and failure-free survival (FFS) at 60 months were 98.6%, 96.1%, 80.5% and 69.5%. When we clustered all subjects in optimal responders (ORs) and suboptimal/resistant (S/R) pts and correlated response to therapy with various molecular characteristics we found that high BCR-ABL^{IS} transcripts at diagnosis (using GUS as a reference gene) predicted response to IM (p=1.076e-9). Moreover, high BCR-ABL^{IS} transcripts at diagnosis significantly correlated with a lower probability of obtaining a CCyR (p=0.000861) and lower rates of EFS (p=0.0001864) and FFS (p=0.00005935). As WBC counts were not significantly different between ORs and S/R pts (p=0.2065), increased amounts of BCR-ABL transcripts were probably representative of the aggressiveness of the leukemic clone. We also observed that pts displaying >10% BCR-ABL^{IS} after 3 months of IM or >1% BCR-ABL^{IS} after 6 months of therapy had a significantly lower probability of achieving a CCyR (p=0.00000000388 and p=2.631e-16, respectively). *Conclusions.* Approximately 40% of newly-diagnosed CML pts will either fail IM or obtain a suboptimal response. High levels of BCR-ABL^{IS} transcripts at diagnosis allow the rapid identification of CML pts that are unlikely to benefit from IM. Furthermore, failing to achieve BCR-ABL^{IS} transcript levels <10% after 3 months or <1% after 6 months of IM significantly reduces the probability of subsequently obtaining a CCyR.

0688

HIGH IMATINIB PLASMA LEVEL IS CRITICALLY IMPORTANT FOR COMPLETE CYTOGENETIC RESPONSE MAINTENANCE IN CML PATIENTS

Background. The treatment of patients with chronic phase (CP) Ph-positive chronic myeloid leukemia (CML) with imatinib has resulted in high rates of cytogenetic and molecular responses. However some patients lose achieved complete cytogenetic response (CCyR). Recent data have shown that the achievement of CCyR to imatinib therapy is related with more than 1000 ng/ml Imatinib plasma level (IPL). *The Aim* of our study was to elucidate the role of IPL in maintenance of CCyR

Table 1.

Imatinib plasma level (C_{trough}) in CP CML patients with CCyR and loss of CCyR

Imatinib Dose	Patients	n	Age Median [min-max]	Male/ Female	Imatinib Treatment Duration (months)	C_{trough} of Imatinib (ng/ml)		
						Median [min-max]	Mean	P value
400 mg QD	Loss of CCyR	24	52,8 [22-77]	14/10	38,6 [12,1 – 66,9]	645 [259-1702]	651±66	<0,0001
	CCyR	183	54,2 [18-75]	106/77	24,3 [12,7 -90,3]	1232 [375-2003]	1162±30	
600 mg QD	Loss of CCyR	27	53,7 [32-72]	12/15	36,5 [12,5 -93,6]	791 [178-2631]	878±91	<0,0001
	CCyR	82	53,4 [19-76]	40/42	33 [12,6 – 119,7]	1688 [328-2789]	1709±61	

by comparison IPL in CML patients with stable CCyR and with loss of CCyR. *Methods.* IPL were detected in 316 CP CML patients with Imatinib treatment duration more than 12 months. The age of patients was 18-78. Male/female ratio was 172/144. Imatinib doses were 400 mg QD (n=207) and 600 mg QD (n=109). Blood samples were collected in 21-27h after the last Imatinib dose intake. All patients gave informed consent before blood sampling. Imatinib concentrations (C trough) were determined by a validated LC/MS/MS method. *Results*. The obtained results were analyzed in 4 groups CP-CML patients: CML patients in imatinib treatment with 400 mg QD with CCyR and loss of CCyR, with 600 mg QD with CCyR and loss of CCyR (Tab.1). The mean of IPL in CML patients treated with Imatinib 400 mg QD with CCyR was 1162±30 ng/ml vs 651±66 ng/ml in patients with loss of CCyR (p<0,0001). The mean of IPL in CML patients treated with Imatinib 600 mg QD with CCyR was 1709±61ng/ml vs 878±91 ng/ml with loss of CCyR (p<0,0001). *Conclusions.* The IPL in CML patients achieved stable CCyR significantly higher than in patients with loss of CCyR. High level of IPL is important for maintenance of CCyR. Probably the achievement of CCyR in cases with low level of imatinib concentration in plasma is associated with low stability of achieved CCyR.

COST EFFECTIVENESS OF NILOTINIB VS. IMATINIB AS FIRST-LINE TREATMENT FOR NEWLY DIAGNOSED PATIENTS WITH PH+ CHRONIC MYELOID LEUKEMIA IN THE CHRONIC PHASE (CML CP): SWEDISH PERSPECTIVE

M Botteman,[1] J Stephens,[1] S Snedecor,[1] D Patel,[1] J Ji,[1] K Carpiuc,[1] J Coombs,[2] A Ovanfors[3]

[1]*Pharmerit International, Bethesda, United States of America*
[2]*Novartis Pharmaceuticals Corporation, Florham Park, United States of America*
[3]*Novartis, Sverige, Sweden*

Background. The ENESTnd study showed that, vs. imatinib (400 mg QD), nilotinib (300 mg BID) results in superior major molecular and complete cytogenetic responses and time to disease progression as first line (FL) therapy in newly-diagnosed patients with Ph+ CML-CP. *Aims.* To assess, from a Swedish societal perspective, the direct and indirect costs and quality adjusted life years (QALYs) of FL imatinib vs. nilotinib in newly-diagnosed Ph+ CML-CP. *Methods.* A literature-based Markov model was developed to estimate the lifetime QALYs and costs of Ph+ CML-CP patients initiating therapy with nilotinib or imatinib. A central model feature is the discontinuation rate from FL therapy, which was based on ENESTnd for the first 12 months and, thereafter, on the rate observed in the IRIS study, stratified by initial 12-month FL responses. Patients discontinuing FL therapy were modeled to receive one additional tyrosine kinase inhibitor (TKI). Prognosis after FL discontinuation was modeled using published studies. Clinical outcomes and drug exposure were obtained from the ENESTnd study. Non-TKI-drug costs and productivity loss were assumed to increase as disease progressed. Quality of life varied by disease stage and response. *Results.* Compared to FL imatinib (Table), FL nilotinib results in increases in net discounted FL drug therapy costs, decreases in other direct medical costs and productivity loss, and gains in discounted survival and QALYs. The discounted incremental cost/LY and cost/QALY are estimated at 16 028 € and $18 163 €, respectively. In probabilistic sensitivity analysis, 95% of model replications cost ≤44 500 €/QALY gained. *Conclusions.* FL nilotinib is cost-effective in Swedish patients with Ph+ CML-CP who are initiating TKI therapy.

Table 1.

	Imatinib	Nilotinib	Difference
*FL Drug Costs**	477 660 €	581 751 €	104 091 €
*Other Direct Medical Costs**	180 320 €	152 603 €	-27 718 €
*Productivity**	513 327 €	564 436 €	51 109 €
*Net Cost Difference**			25 265 €
*Life Expectancy (years)**	17,30	18,82	1,52
*QALY**	14,39	15,78	1,39
*Cost / LYG**			16 668 €
*Cost / QALY**			18 163 €

THE EUROPEAN POPULATION-BASED CML-REGISTRY - OBJECTIVES AND FIRST RESULTS

J Hasford,[1] J Guilhot,[2] C Piccolo,[3] B Simonsson,[4] M Baccarani[5]

[1]*Ludwig-Maximilians-Universitaet, Munich, Germany*
[2]*University Hospital Poitiers, Poitiers, France*
[3]*Novartis Pharma S.p.A, Origgio, Italy*
[4]*University Hospital Uppsala, Uppsala, Sweden*
[5]*S. Orsola-Malpighi University Hospital, Bologna, Italy*

Background. Comparatively little is known about the epidemiology and the presenting features of chronic myeloid leukemia outside of clinical studies. *Aims.* Thus, a European CML registry was established with the aim to assess epidemiology, management and outcome of CML, with particular reference to the incidence, the stage of disease at time of diagnosis and the initial clinical management. *Methods.* All European countries were invited to collaborate. Regions had to be defined to allow for the estimation of incidence, and all newly diagnosed patients had to be recorded and reported. A follow-up of these patients is planned. The registry is strictly non-interventional and national laws and regulations are fulfilled. In late 2009 the registry was started. *Results.* Up to now 25 study groups from 24 European countries have registered 846 CML patients (evaluable: 833 pts.). At time of diagnosis 93.6% were in chronic, 4.1% in accelerated and 2.3% in blastic phase. The EuroScore risk group distribution was: 32.9% low, 50.2% intermediate and 16.9% high risk. Chromosomal abnormalities in Ph^+ cells were seen in 7.9%. The majority of the patients showed a WHO-score of 0 (52.3%) or 1 (36.8%). There are considerable differences between the European countries, e.g. the proportion of high risk patients is considerably higher in the eastern and northern countries of Europe and the UK. Data about the clinical management are not yet available. *Summary.* It is considered a major achievement that 25 study groups of 24 different European states are collaborating to establish a European population-based CML-Registry. The data indicate that patients recruited for clinical trials may not be fully representative of all CML patients.

0691

ANALYSIS OF BCR-ABL TYROSINE KINASE DOMAIN ABNORMALITIES IN IMATINIB-TREATED CHRONIC PHASE-CHRONIC MYELOID LEUKEMIA PATIENTS BASED ON 2009 EUROPEAN LEUKEMIA NET RECOMMENDATIONS

DH Kim,[1] SH Kim,[1] HG Goh,[1] SH Choi,[1] JH Bang,[1] J Lee,[1] SM Oh,[1] WJ Song,[1] EJ Jang,[2] DW Kim[2]

[1]*The Catholic University of Korea, Seoul, South-Korea*
[2]*Seoul St. Mary's Hospital, Seoul, South-Korea*

Background. Abnormalities in BCR-ABL kianse domain (KD), such as point mutation, 35 base pair insertion (35INS), and deletion of exon 7 (Del ex7) have been found in chronic myeloid leukemia (CML) patients. Among such abnormalities, point mutations have been known as the clinically most relevant mechanism of imatinib resistance with 40~80% of detection frequency in imatinib resistant patients. 2009 European Leukemia Net (ELN) guideline recommends mutation screening of patients with suboptimal response and treatment failure during imatinib therapy. However, there has not been much information about BCR-ABL KD abnormality status in suboptimal responder. In addition, 35 INS and Del ex7 have not provided their clinical relevance yet al-

Table 1. Table 1. Abnormalities in BCR-ABL kinase domain.

	Months after IM Tx	Optimal N=228	Suboptimal N=52	Failure N=22
Point mutation	3 mons.	0 of 20 (0%)	0 of 1 (0%)	0 of 1 (0%)
	6 months	6 of 97 (6%)	1 of 8 (13%)	1 of 2 (50%)
	12 months	4 of 91 (4%)	1 of 8 (13%)	2 of 12 (17%)
	18 months	1 of 20 (5%)	3 of 35 (9%)	3 of 7 (43%)
	Total	11 of 228 (5%)	5 of 52 (10%)	6 of 22 (27%)
35INS or Del ex7	3 months	3 of 20 (15%)	0 of 1 (0%)	0 of 1 (0%)
	6 months	11 of 97 (11%)	0 of 8 (0%)	0 of 2 (0%)
	12 months	12 of 91 (13%)	0 of 8 (0%)	0 of 12 (0%)
	18 months	2 of 20 (10%)	9 of 35 (26%)	1 of 7 (14%)
	Total	28 of 228 (12%)	9 of 52 (17%)	1 of 22 (5%)

though they have been found frequently in CML patients including suboptimal responders. *Aims.* We analyzed abnormalities in BCR-ABL KD from CP-CML patients with suboptimal response or treatment failure to imatinib, and investigated their mutation status and clinical relevance of the abnormalities. *Methods.* This study included 151 CP-CML patients registered in Seoul St. Mary's hospital since 2002. Serial samples of patients at 3, 6, 12, and 18 months were collected from the Korea leukemia bank in the form of cryopreserved cells or isolated RNAs depending on availability of each sample. Abnormalities in BCR-ABL KD were analyzed using direct sequencing. The 2009 ELN guideline was employed for definition of patient's response including optimal response, suboptimal response and treatment failure at each time point. *Results.* We analyzed total 302 serial samples (228 optimal, 52 suboptimal and 22 failures samples) from 151patients at different time points including 3, 6, 12 and 18 months after initiation of imatinib treatment. KD abnormalities were found with difference in each response group. Point mutations were found in 5% of optimal responders, 10% of suboptimal responders and 27% of treatment failures with higher frequency at 6 months in all 3 response groups. Other abnormalities in BCR-ABL KD, including 35INS and Del ex7, were detected in 12% of optimal responders, 17% of suboptimal responders and 5% of treatment failures with higher frequency at 18 months in suboptimal responders and failure group. Interestingly, patients with other abnormalities in BCR-ABL KD showed significantly ($p<0.024$) higher ratio of turning out suboptimal response; Among 18 optimal patients with 35INS or Del ex7 by 12 months, 72% (n=13) turned out suboptimal responders at 18 months while 38% (n=15) became suboptimal responders among 39 optimal responders without any abnormalities in BCR-ABL KD by 12 months. *Conclusions.* Patients with suboptimal response or treatment failure showed tendency of much higher chance of BCR-ABL KD point mutation in comparison with optimal responders, suggesting that mutation screening is important for patients with suboptimal response as well as treatment failure on the basis of 2009 ELN guideline. Especially, optimal responders harboring 35INS or Del ex7 turned out suboptimal response at 18 months than optimal responders without those abnormalities. However, solid clinical relevance of 35 INS and Del ex7 requires long-term follow up with large cohort.

0692

PLEURAL EFFUSION IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CML-CP) WHO RECEIVED FIRST-LINE DASATINIB IN THE DASISION TRIAL: PATIENT CHARACTERISTICS, MANAGEMENT, AND OUTCOMES

K Porkka,[1] M Baccarani,[2] J Cortes,[3] A Hochhaus,[4] H Kantarjian,[3] N Shah,[5] B Bradley-Garelik,[6] C Zhu,[6] P Laneuville[7]

[1]*Helsinki University Central Hospital, Helsinki, Finland*
[2]*University of Bologna, Bologna, Italy*
[3]*University of Texas MD Anderson Cancer Center, Houston, Texas, United States of America*
[4]*Universitätsklinikum Jena, Jena, Germany*
[5]*University of California, San Francisco, California, United States of America*
[6]*Bristol-Myers Squibb, Wallingford, Connecticut, United States of America*
[7]*Royal Victoria Hospital, Montreal, Quebec, Canada*

Background. In the randomized phase 3 DASISION trial of dasatinib vs imatinib in newly diagnosed CML-CP, dasatinib continued to show superior efficacy (higher, faster, and deeper response rates) and acceptable safety/tolerability at 18 months of follow-up (Shah *et al.* Blood 2010; 116: abs 206). Whereas fluid retention was more frequent among imatinib-treated patients, pleural effusion was observed only in dasatinib-treated patients. *Aims.* To perform retrospective and exploratory analyses of patients with drug-related pleural effusion in DASISION, including assessing if pleural effusion impacted efficacy and describing how pleural effusions were managed. *Methods.* In DASISION, after informed consent, patients were randomized 1:1 to receive dasatinib 100 mg once daily (QD; n=259) or imatinib 400 mg QD (n=260). The primary endpoint was confirmed complete cytogenetic response (cCCyR) rate (defined as complete cytogenetic response [CCyR] on two consecutive assessments) by 12 months. Patients with baseline pleural effusion were excluded. Chest x-rays were performed at baseline and at 6 months, or more frequently if indicated clinically. Pleural effusions were graded according to CTCAE v3.0 criteria: grade 1, asymptomatic; grade 2, symptomatic, ≤2 therapeutic thoracenteses; grade 3, symptomatic requiring supplemental oxygen, >2 therapeutic thoracenteses; grade 4, life-threatening, hemodynamic instability. *Results.* After 18 months' median treatment duration, pleural effusion had occurred in 31/258 dasatinib-treated patients (12%; 3% grade 1, 9% grade 2, <1% grade 3). Median age was higher in patients with pleural effusion (n=31; 59 years; range 28-82) compared with those with no pleural effusion (n=227; 44 years; range 18-84). In patients with vs without pleural effusion, median dasatinib dose by last follow-up was 93 vs 100 mg/d and Hasford risk score was low in 23% vs 35%, intermediate in 68% vs 45% and high in 10% vs 20%, respectively. In patients experiencing pleural effusion, median time to effusion was 33 weeks, with 87% of effusions occurring more than 8 weeks after start of treatment. Pleural effusions were managed by dose modification (therapy was interrupted in 24 patients and reduced in 13 patients) and/or medical intervention (13 patients received diuretics, 11 received corticosteroids, eight received both diuretics and corticosteroids, and three had therapeutic thoracentesis). Four patients (1.5%) discontinued therapy due to pleural effusion. Within available follow-up, most effusions (84%) have not recurred. Based on consensus from an expert panel, a pleural effusion management algorithm will be presented. Pleural effusion did not seem to impact efficacy: 94% and 65% of patients who had a pleural effusion achieved a CCyR and major molecular response (MMR), compared with 84% and 56% of patients without pleural effusion, respectively. In patients with or without pleural effusion, peripheral lymphocytosis (defined as absolute blood lymphocyte count > 3.6 x 109/L occurring on ≥2 occasions after >4 weeks of dasatinib treatment) occurred in 42% vs 19%. *Conclusions.* After 18 months of treatment in patients with CML-CP receiving first-line dasatinib, pleural effusion was predominantly mild to moderate in severity, managed by dose modification and/or medical intervention, more commonly associated with lymphocytosis, and did not seem to affect the achievement of CCyR and MMR.

[15]*Hematology, University of Bari, Bari, Italy*

Background. The TKIs Nilotinib and Dasatinib offer additional therapeutic options for patients with CML who are resistant or intolerant to Imatinib. Preliminary results suggest that some patients may respond

to a second TKI used as third line therapy, but little is known about the long term benefit of such an approach. *Aim* of this collaborative Italian study was to verify the response and the clinical outcome in patients with CML treated with a third TKI after sequential failure of the previous ones. *Methods.* We evaluated 82 patients with CML, resistant/intolerant to Imatinib and treated with Dasatinib or Nilotinib, then switched to a third- line TKI after treatment failure; 34 patients were treated with dasatinib after imatinib/nilotinib failure and 48 with nilotinib after imatinib/dasatinib failure. *Results.* A total of 82 patients were treated with sequential TKIs; 62 (75.6%) patients had received interferon-a before starting Imatinib. At the start of nilotinib as second line, 30/34 (88.2%) patients were in CP, 2 in AP, and 2 in BP. 9 patients had developed mutations before starting treatment. In the resistant patients 5 new mutations were identified. At the start of dasatinib as second line, 41/48 (85.4%) patients were in CP, 6 in AP, 1 in BP. 10 patients (20.8%) had developed mutations before starting treatment. In the resistant patients 8 new mutations were identified. At the start of the third TKI, 68/82 (82.9%) patients were in CP, 9 in AP, and 5 in BP. Of these, 9 patients on dasatinib and 8 on nilotinib had mutations before starting treatment. The best response to the third line treatment with TKI was 13 (15.8%) MMR, 14 (17.1%) CCyR, 11 PcyR (13.4%), 6 (7.3%) mCyR, 25 (30.5%) CHR and 13 (15.8%) No Response (NR). In the dasatinib group, 14 (41.2%) patients discontinued treatment because of toxicity versus 24 (50%) patients in the nilotinib group. Two new mutations (F317L, E255V) emerged with dasatinib and two new mutations (Y253H, G250E) emerged with nilotinib as third line therapy. After a median follow up of 14 months, 58 patients are continuing therapy;70 patients (85.3%) are still alive for a median overall survival of 46 months (57 CP, 7 AP, 6 NA). Discussion About one third (28.4%) of patients derived benefit from the use of three sequential TKIs; patients with better response to third TKI were the same patients with a better response to the Imatinib and 2TKIs therapy. In this subset of patients, 6 developed mutations that were sensitive to the sequential treatment. The lack of a durable cytogenetic remission could be explained by the emergence of new kinase domain mutations and a change of therapy resulted in an adequate response. *Conclusions.* Although allogeneic SCT is the treatment of choice in all patients failing 2 TKI, alternative strategies are required for ineligible patients. The use of a third TKI after failure of two previous TKIs induces response in some patients. Longer follow up of a larger series of patients is needed to determine the long term impact of the response.

0694

GENETIC MECHANISMS OF TYROSINE KINASE INHIBITOR RESISTANCE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

N Meggyesi,[1] A Kozma,[2] G Halm,[2] S Nahajevszky,[2] A Batai,[2] S Fekete,[2] A Barta,[2] G Ujj,[3] S Lueff,[2] A Sipos,[2] E Adam,[2] A Bors,[1] P Remenyi,[2] T Masszi,[2] A Tordai,[1] H Andrikovics[1]

[1]*Hungarian Blood Transfusion Service, Budapest, Hungary*
[2]*St. István-St. László Hospital, Budapest, Hungary*
[3]*Géza Heténvi Hospital, Szolnok, Hungary*

Background. Additional chromosome abnormalities (ACA), mutations of the BCR-ABL tyrosine kinase domain (TKD) and BCR-ABL splice variants may cause resistance for first- and second-generation tyrosine kinase inhibitors (TKI) in chronic myeloid leukemia (CML) and Philadelphia positive acute lymphoid leukemia (Ph+ ALL). *Aims*. The aim of the study was to investigate three potential resistance mechanisms during first- and second-generation tyrosine TKI treatment in CML and in Ph+ ALL. *Methods.* Karyotyping and BCR-ABL TKD mutation screening were performed in 71 imatinib resistant CML and 6 Ph+ ALL patients. Exon 7 deletion (Δexon7) was screened by sequencing in all patients at the time of TKI failure and by fragment analysis in selected samples of CML patients and healthy controls. 56 out of 77 patients received second generation TKI. *Results.* ACA were present in 30/65 (46%) imatinib resistant patients. In 27/77 (35%) imatinib resistant patients, 15 different BCR-ABL TKD mutations were detected. Mutations were found in 25% (12/47) of chronic-phase, 33% (5/15) of accelerated-phase, 71% (5/7) of blast crisis CML and 100% of ALL patients. In second generation TKI resistance, the spectra of mutations has changed and fewer types of mutations were detected. In nilotinib-resistant patients, Y253H, T315I, F359V/I; in dasatinib-resistant patients, L248M, E279K and T315I mutations were detected. T315I was found more frequently on dasatinib than on imatinib therapy (p=0.005). The presence of ACA predicted shorter survival during first and second generation TKI therapy, while TKD mutations only influenced survival during second generation TKI therapy. The detection rate of Δexon7 was highly dependent on the sensitivity of detection method (23% by sequencing and 70% by fragment analysis) and on the expression levels of ABL or BCR-ABL. Δexon7 was detected more often in samples at diagnosis and resistance compared to samples collected at times of imatinib sensitivity. In addition, Δexon7 was detected on ABL not involved in BCR-ABL translocation in 100% of control and 70% of CML samples. *Summary*. Our report represents a systematic analysis of the clinical outcome and dynamics of BCR-ABL TKD mutations and ACA during sequential TKI therapies. Our results suggest that the frequency and type of TKD mutation depends on disease phase and TKI applied. For patients with imatinib resistance, mutation and ACA screening may play a role in identifying patients with poorer prognosis. Screening for BCR-ABL TKD mutations is recommended in TKI resistance before changing TKI, because the presence of different mutations may influence the selection of TKI and the therapeutic response. ABL Δexon7 is likely to be unrelated to TKI-resistance since it was abundantly detected in imatinib naive CML patients on BCR-ABL and the alternative splicing is independent from BCR-ABL translocation. In case of sequencing, we recommend using a primer annealing in ABL exon 7, because Δexon7 may lead to a sudden deterioration of sequence quality.

0695

EFFICACY OF NILOTINIB VERSUS HIGH-DOSE IMATINIB IN EARLY CP CHRONIC MYELOID LEUKEMIA PATIENTS WHO HAVE SUBOPTIMAL MOLECULAR RESPONSES TO STANDARD-DOSE IMATINIB (RE-NICE MULTICENCENTER STUDY)

HG Goh,[1] SY Choi,[2] D Kim,[2] SH Kim,[2] J Lee,[2] EJ Jang,[2] JH Bang,[2] SM Oh,[2] WJ Song,[2] R Woodman,[2] T Szczudlo,[2] HJ Kim,[2] S Jootar,[2] HJ Kim,[2] SK Sohn,[2] JS Park,[2] SH Kim,[2] DY Zang,[2] SJ Oh,[2] DW Kim[2]

[2]*Seoul, South-Korea*

Background. Achievement of major molecular response (MMR) is a significant prognostic factor in CML as it has been shown to be associated with longer duration of complete cytogenetic response (CCyR) and long-term progression-free survival. In IRIS study, patients who achieved both CCyR and MMR showed higher progression-free survival rates, compared to those who had CCyR without MMR and those who did not achieve CCyR. Compared to standard dose of imatinib, higher doses of imatinib are expected to yield higher CCyR and MMR rates, and second-generation tyrosine kinase inhibitor, nilotinib also produces high CCyR and MMR rates in patients with CP CML who are resistant to imatinib. *Aims.* In this study, the efficacy of nilotinib and high-dose imatinib was investigated in suboptimal molecular response patients who received first line imatinib therapy at a daily dose of 400 mg. *Methods.* Early CP CML patients who have achieved CCyR but no MMR after at least 18 months and up to 24 months (≥ 18 to ≤ 24 months) on first line imatinib therapy at a daily dose of 400 mg were enrolled in this clinical trial, and informed consents were obtained prior to participation. In nilotinib arm, patients received oral dose of 400 mg BID (800 mg/day), and patients received 800 mg/day administrated as 400 mg BID in imatinib dose-escalation arm. To assess the drug efficacy, cytogenetics and RQ-PCR analysis were performed at regular intervals, and baseline mutational analysis was conducted for every patient with subsequent mutational analyses performed in patients demonstrating either lack of response or disease progression. Primary endpoint is to evaluate the cumulative MMR rates by 12 months, and secondary endpoints are to evaluate the cumulative CMR rates and time to and duration of MMR and CMR during further 24 month follow-up. Progression-free survival and safety profiles will also be assessed as secondary endpoints. *Results.* A total of 21 patients were randomized into nilotinib arm (n = 10) or imatinib arm (n = 11). With a median follow-up of 6 months (range, 1 - 24 months), all patients have maintained CCyR without progression to advanced disease, and progressive decrease in BCR-ABL transcript levels was observed in all patients. Cumulative MMR rates by 12 months were significantly higher in nilotinib arm compared to imatinib dose-escalation arm (68.90% vs. 22.10%, P = 0.0274), and patients treated with nilotinib also showed faster molecular response rates, with 5 patients achieving MMR within 3 months of nilotinib therapy. (Figure 1) Although toxicity was observed more frequently in imatinib dose-escalation arm, no patient required dose reduction or discontinuation of therapy due to toxicities in both randomized groups. *Conclusions.* These preliminary results demonstrate that BCR-ABL transcript levels in suboptimal molecular responders progressively decrease in both

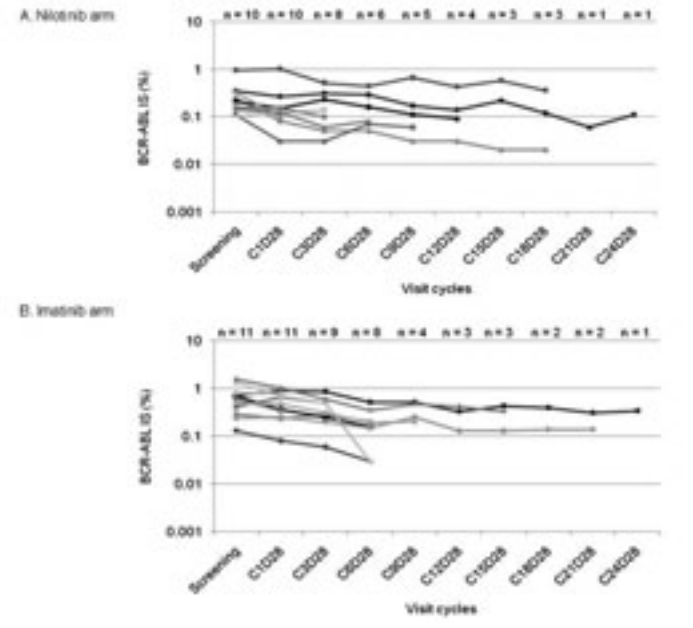

Figure 1. Molecular follow-up in 21 patients.

nilotinib and imatinib arms at a daily dose of 800 mg with higher and faster molecular responses in nilotinib arm. Through further clinical investigation on a large patient population and longer period of observation, the efficacy of early intervention of suboptimal molecular response using nilotinib or dose escalation of imatinib will be assessed.

0696

OUTCOMES OF CHRONIC MYELOID LEUKEMIA PATIENTS WITH SUBOPTIMAL RESPONSE TO IMATINIB

V García-Gutiérrez, P Herrera, M Jimenez-Rolando, M Tenorio, M Calbacho, D Velasco, JM Alonso, L Ramos, P Ramos, MD Rey, J López-Jiménez

Hospital Universitario Ramón y Cajal, Madrid, Spain

Background. Most of the patients with chronic myeloid leukemia (CML) treated with imatinib response favourably. Nevertheless, some patients fail to achieve optimal responses or loose the response. Monitoring endpoints correlate with long-term outcomes, and guidelines have been established to judge response using cytogenetic, polymeresa chain reaction (PCR), and mutation testing. The European Leukemia Net (ELN) guidelines classified patients according to dynamic responses in time. Patients with suboptimal response criteria are a heterogeneous group of patients with different outcomes where the best therapeutic options have not been established. *Aims.* Analyze the evolution of CML patients with suboptimal response critera (ELN), and identify patients with different outcomes. *Patients and Methods.* We studied 80 CML patients in chronic phase treated with imatinib with a median follow up of 66 months. The follow up was done following the ELN recommendations. We have classified the patients in two groups according to the moment when suboptimal response was identified. Group 1: Lack of cytogenetic response at 3 months, less than partial cytogenetic response at 6 months or partial cytogenetic response at 12 months; group 2: included patients with complete cytogenetic response who had not achieved mayor molecular response. *Results.* Responses to treatment in our patients were: failure 16%, suboptimal response 37% and optimal response 47%. We have identified 30 patients with suboptimal criteria at any time during treatment. Of the 30 patients with suboptimal response, 8 (27%) corresponded to group 1 and 22 (73%) to group 2. The evolution of these patients until last follow up or treatment change was: failure 62% vs 9% (p=,007), and achievement of late mayor molecular response 37% vs 54% (p>,005) for group 1 and 2 respectively. We have found no correlation among failure and classical prognostic factors (Sokal-Index, mutations at the TK domain or imatinib plasma levels). *Conclusions.* Suboptimal response criteria fail to identify patients with similar outcomes. In our experience, patients with early suboptimal response (group 1) seem to behave as failure, while a high percentage of patients with late suboptimal response (group2) achieve an optimal response later on.

[14]*Hospital Universitario de la Princesa, Madrid, Spain*

Background. The RELMC Registry is a continuous, 17-hospitals-based cancer registry whose aim is to describe the treatments received by patients with CML in Spain, their outcomes, and the variables that influence treatment choices. *Patients and Methods.* 491 CML patients in chronic phase (CP). Two subgroups according to treatments received: 275 were newly diagnosed and 216 received IM as second line. *Results.* They are depicted in figure 1. Late CP group: 216 patients (M 126/F 90) with a median age of 51 y and Sokal I L*H (47%/43%/10%) and Hasford Index* H (56%/40%/4%). 25 patients received BMT and 145 interferon before IM. 15 patients with transformation before IM. Median follow up from diagnosis and IM treatment were 9,2 and 6,4 years respectively. Patients were treated with different schemes of treatment, always including Imatinib as first TKI (see Table). Major molecular response: MMR was lower in patients who changed to 2nd generation TKI's; Pearson's: 19,4(a)p=0,001. Sokal and Hasford index didn't have influence in MMR. 40 patients achieved MMR before 18 months (median: 11,8 months), 116 after 18 (median: 52) and 40 didn't achieve MMR, with a follow up of 57 months. Transformations and Transformation free survival (TFS) 49 patients (22%) progressed to AP or BC (39) or died of non-CML related causes (10). Sokal and Hasford index influenced TFS (p=0,001), but not treatment schemes (p=0,2). Patients with MMR before 18 months had less transformations or deaths 2/40 (5%), than patients after 18 months 13/116(11%) and patients without MMR 20/40 (50%); Pearson's 38,3;p<0,0001. This variable also influenced TFS. Newly diagnosed group: 275 patients (male 164 female 111) with a median age of 52 y and Sokal L*H (36%/50%/14%) and Hasford Index* H (46%/49%/5%). Median follow up from diagnosis and IM

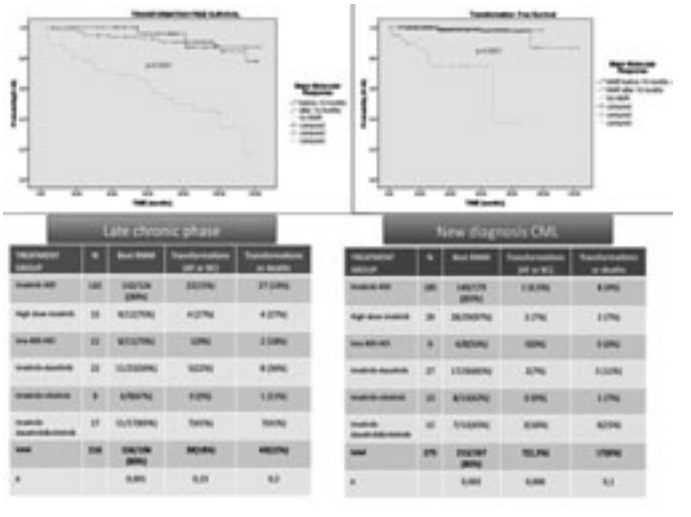

Figure 1.

treatment were 3,8 and 3,7 years respectively. Patients were treated with different schemes of treatment, always including Imatinib as first TKI (see Table). Major molecular response: MMR was lower in patients who changed to 2nd generation TKI's; Pearson's= 20;p=0,001. Hasford Index influenced the rate of MMR (Pearson's: 6,4 p=0,04. 103 patients achieved MMR before 18 months (median: 13 months), 111 after 18 months (median: 40 months) and 56 didn't achieve MMR (follow up: 12,7 months). Transformations and Transformation free survival (TFS) 17 patients (6%) progressed to AP or CB (7) or died of non-CML related causes (10). Sokal and Hasford index influenced TFS (p<0,001), but not treatment groups (p=0,2). Patients with MMR before 18 months had less transformations or deaths 1/102 (1%), than patients after 18 months 3/111 (3%) and patients without MMR 10/56 (18%); Pearson's: 23, p<0,0001. This variable also influenced TFS. *Conclusions.* Imatinib-based regimes produced a high molecular response rate (≈ 80%), especially in patients with high IM dose upfront. Rescue therapy with 2ndG TKI obtained a MMR in the range of 55%. Sokal and Hasford high-risk patients showed worse outcome regardless of treatment chosen. Patients with a MMR were highly protected from transformation to AP or BC regardless of the 18 month cut-off.

SECOND ATTEMPT OF IMATINIB DISCONTINUATION IN CP-CML PATIENTS WITH A SUSTAINED SECOND COMPLETE MOLECULAR REMISSION

L Legros,[1] P Rousselot,[2] M Tulliez,[3] F Huguet,[4] F Nicolini,[5] FX Mahon[6]

[1]*Hopital Archet, CHU de Nice, Nice cedex, France*
[2]*Centre Hospitalier de Versailles - Hôpital André Mignot, Le Chesnay, France*
[3]*Hôpital Henri-Mondor, Creteil, France*
[4]*Hôpital Purpan, Toulouse, France*
[5]*Hôpital Edouard Herriot, Lyon, France*
[6]*Groupe Hospitalier Pellegrin, Bordeaux, France*

Background. Imatinib is able to induce sustained responses including complete molecular responses (CMR) in patients with chronic phase chronic myeloid leukemia (CP-CML). Recent results from the STop IMatinib trial suggest that imatinib may be safely discontinued in patients with long-lasting CMR (Mahon *et al.* Lancet Oncol. 2010). Actually, 60 % of patients had a recurrence of the disease i.e a molecular relapse which was defined as positivity of BCR-ABL transcripts in quantitative RT-PCR (sensitivity 4.5log), confirmed by a second analysis point, indicating an increase at two successive assessments. All patients who relapsed responded to reintroduction of imatinib. So, we explored the possibility of a second attempt of imatinib discontinuation for the patients who achieved again a prolonged CMR. *Patients and Methods.* The recommendation was to stop again the treatment using the same criteria, i.e, in patients with a second CMR during at least 1 year after imatinib reintroduction. 15 patients were included in this pilot study. The kinetic of BCR-ABL quantification was identical between the first and the second discontinuation of imatinib. At diagnosis, the Sokal risk group was low, intermediate, high or unknown in respectively 15, 2, 2, and 1 patient. All patients were treated with imatinib 400 mg per day. The median time on imatinib prior to the 1st discontinuation was 49 months (range: 32-105) and the median duration of 1st CMR was 31 months (range: 27-61). The 1st molecular relapse occurred with a median of 2.6 months (range: 0.9-8.4) and a second CMR (CMR2) after imatinib re-challenge was obtained after a median of 5.3 months (0-18.9). *Results.* The median duration of CMR2 was 19 months (range: 3-28). In 10 out of 15 patients (66%) a molecular relapse was observed 2 months in median after imatinib discontinuation (1-14). Among them, 8 were re-treated with a tyrosine kinase inhibitor (imatinib, n=9; dasatinib n=1). 2 patients with a non confirmed molecular relapse remained free of treatment with a follow up of 12 and 15 months respectively. In 5 patients a prolonged CMR2 after the second episode of imatinib discontinuation was observed with a median follow-up of 24 months (6-49). *Conclusions.* It is possible to safely attempt to discontinue imatinib for a second time after a sustained CMR2. However, 66% of our patients experienced a second molecular relapse and restarted TKI therapy. At the other hand, 34% of the patients remained free of treatment with either a non confirmed molecular relapse (13%) or a sustained second CMR (20%). A larger number of patients and with a longer follow up will be presented.

[6]*Clinical Oncological Dispensary 1 of Healthcare Department of Krasnodar Territor, Krasnodar, Russian Federation*

Background. Tyrosine kinase inhibitors (TKI) therapy has improved a survival rate and a life quality for the majority of patients with chronic myeloid leukemia (CML). Therefore pregnancy management in CML patients is one of the important issues. We should be informed about the outcomes and therapy risks on TKI therapy by analyzing the existing data. *Aim and Methods.* We provide an information about pregnancy outcomes in CML patients on TKI therapy (imatinib, nilotinib, dasatinib) collected into the Russian CML Registry and pregnancy cases observed in Hematology Research Center, Moscow. *Results.* The outcomes for 32 pregnancy cases in CML patients on imatinib therapy and about 4 pregnancies on TKI2 (in females and in partners of males) are shown in Table 1. There were 13 pregnancy cases in partners of CML males on imatinib. All of them were in chronic phase (CP), imatinib dose was from 400 to 600 mg daily, no treatment interruption at conception. There were 19 pregnancy cases on imatinib treatment in 17 females. 15 females were in CP CML, 2 in accelerated phase (AP) at diagnosis. Two of them had subsequent pregnancies: the 1st pregnancy ended with medical abortion at the beginning of imatinib treatment and at the 2nd one was planned during complete molecular response (CMR) and resulted in healthy infants delivery in both cases. Imatinib dose was from 400 to 600 mg daily. One female had a treatment interruption at conception. The general approach was to stop imatinib after pregnancy diagnostics. The females in CMR were monitored by Real-time polymerase chain reaction (PCR) for minimal residual disease (MRD) and did not require any therapy. The supportive treatment was used in case of cytogenetic or hematologic relapse (interferon alpha, hydroxyurea, one woman refused from therapy). One woman received imatinib during the whole pregnancy period. After delivery the women restarted imatinib immediately, 2 women continued the treatment interruption for 1 and 3 months correspondently for safe breast-feeding. We also report about 4 pregnancy cases in CML CP patients on TKI2 therapy who were switched to TKI2 due to hematologic relapse on imatinib. 1 pregnancy in the male's partner on nilotinib ended with premature delivery (the child had severe hyperbilirubinemia). 1 pregnancy (ongoing, 22nd week) in female was diagnosed on imatinib+hydroxyurea therapy, then the patient was switched to nilotinib since 10th week of therapy. 2 pregnancies occurred on dasatinib

Table 1. Pregnancy outcomes in CML patients on TKI.

Pregnancy outcome	Therapy				
	Imatinib		Nilotinib		Dasatinib
	Partners of males	Females	Partners of males	Females	Females
Delivery at term, healthy infants	12	9			1
Premature delivery		1 (death)	1 (hyperbilirubinemia)		
Ongoing pregnancy	1	3		1	
Spontaneous abortion		1			
Medical abortion		5			1
Total number of cases	13	19	1	1	2

therapy. For the 1st one a medical abortion was planned. The 2nd one was prolonged: dasatinib was stopped since 6th week and the patient continued on hydroxyurea since the 2nd trimester, a healthy infant was born at term. *Conclusions.* In most cases of pregnancy in CML males partners on imatinib the outcomes were favorable. For CML females on imatinib the disease status at conception was very significant. The lowest risks of safe pregnancy management was observed for patients in CMR. The data about pregnancy outcomes on TKI2 therapy are limited, the current recommendation should be to avoid pregnancy. A careful study of all cases is needed to develop further recommendations.

0700

DASATINIB EFFICACY AND TOLERANCE IN THE TREATMENT OF CHRONIC MYELOID LEUKEMIA (CML) PATIENTS RESISTANT/INTOLERANT TO IMATINIB IN THE CONTEXT OF REAL CLINICAL PRACTICE MANAGEMENT

D Zackova,[1] H Klamova,[2] J Muzik,[3] E Cmunt,[4] B Dobesova,[1] J Rysava,[2] Z Racil,[1] K Machova Polakova,[2] D Dvorakova,[1] T Jurcek,[1] F Razga,[1] J Moravcova,[2] M Doubek,[1] A Oltova,[1] J Brezinova,[2] P Cetkovsky,[2] M Trneny,[2] L Dusek,[3] J Mayer[1]

[1]*University Hospital and Masaryk University Brno, Brno, Czech Republic*
[2]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic*
[3]*Institute of Biostatistics and Analyses, Masaryk Univ., Brno, Czech Republic*
[4]*General University Hospital, Prague, Czech Republic*

Background. Most of the data about dasatinib treatment of CML patients resistant or intolerant to imatinib come from clinical trials. The data from real clinical practice are still scarce. *Aims.* To evaluate efficacy and tolerance of dasatinib as the second line therapy for CML patients resistant/intolerant to imatinib managed in the context of every day clinical practice. *Methods.* We analyzed data about CML patients from the defined region stored in a detailed database INFINITY. Minority of the patients (N=18) were included in the clinical trials (CA180-034, CA180-035). We assessed rates and cumulative incidences of complete hematologic responses (CHR), major (MCgR) and complete cytogenetic responses (CCgR), major molecular responses (MMolR), and a comprehensive set of survivals: overall (OS), transformation-free (TFS), progression-free (PFS), where progression was defined as in the START-R,-A,-B,-L trials (Kantarjian, Blood, 2007; Cortes, Blood, 2007; Guilhot, Blood, 2007), failure-free (FFS), where also loss of CCgR, failure to the second line therapy as provisionally defined by ELN (Baccarani, J Clin Oncol, 2009), and dasatinib discontinuation for toxicity were included, total failure-free (TFFS), where also stop of the treatment for any reason was added; and alternative treatment-free survival (ATFS), reflecting the real proportion of patients remaining on dasatinib despite an event. Among others we evaluated dasatinib toxicity according to CTCAEv.3. *Results*. A total of 98 patients (median age at diagnosis 53.5 years, 19-75; at dasatinib start 57 years, 19-79; 43 males and 55 females) underwent the analysis; 68% were in CP and 32% in AP or BC at the start of dasatinib treatment. Ninety (91.8%) patients were pretreated with imatinib in a median of 24 months (range: 0.2-75). Dasatinib was administered after a median of 39 months (range: 1-175) from the time of CML diagnosis and the median follow-up on dasatinib was 12.9 months (0.2 - 50.8). Reasons for the second line dasatinib therapy were: resistance (77%), intolerance (14%), and others (9%). Estimated cumulative incidences of CHR, MCgR, CCgR and MMolR at 24 months were 92.1%, 76.2%, 66.7% and 58.5% for patients in CP, and 51.6%, 30.8%, 17.4% and 9.7% for patients in AP/BC, respectively. The best response rates for CP and AP/BC patients were as follows: 95.5% and 51.6% of CHR, 52.2% and 12.9% of CCgR, 59.7% and 19.4% of MMolR. Estimated OS, TFS, PFS, FFS, TFFS, and ATFS at 24 months were 90.6%, 92.9%, 90.4%, 66.8%, 63.7% and 66.9% for CP patients and 37.2%, 46.8%, 34.2%, 15.1%, 14.6% and 25.1% for AP/BC patients, respectively. Non-hematological and hematological toxicities of all grades occurred in 63.3% and 85.7% of patients, with 26.4% and 48.4% of cases with grade 3/4 toxicity, respectively. In total, 44 patients permanently discontinued dasatinib therapy for various reasons. Twenty one patients died during the follow-up. *Conclusions*. Dasatinib in second line setting was confirmed as a safe and effective therapy as well as with patients treated generally outside clinical trials at well-managed specialized centers. As for advanced phases of the disease, the results are still not satisfactory.

Background. After 6-8 years' follow-up, 45-56% of patients with chronic-phase chronic myeloid leukemia (CP-CML) discontinue first-line imatinib (Hochhaus *et al.* Blood 2009), primarily due to inadequate response and/or intolerance. Interventional studies suggest that earlier and deeper responses to dasatinib correlate with better outcomes. Also, in resistant patients, time from first detection of imatinib failure to initiation of second-line BCR-ABL inhibitor therapy is a significant predictor of response (Milojkovic *et al.* Haematologica 2010). However, very limited data have been gathered, to date, from real-life observation. *Aims.* FORTE, a large, real-life, observational, European study, aimed to estimate the relationship between time elapsed from first detection of imatinib failure until initiation of dasatinib and best response to dasatinib, adjusted for other potentially explanatory factors. *Methods.* Adult patients with CP-CML who had failed imatinib and were treated with dasatinib for ≥2 months were enrolled at 124 sites across 12 European countries. Disease history, response to imatinib, criteria defining imatinib failure and response to dasatinib were collected from patient charts retrospectively and prospectively for up to 6 months. A predefined selection of covariates (gender; age at dasatinib initiation; time from diagnosis to dasatinib initiation; best response to imatinib and last imatinib dose) were entered/removed in a Proportional Odds model to identify factors potentially influencing dasatinib best response over the entire observation period. *Results.* Of 457 eligible patients, 176 (38.5%) were imatinib intolerant and 352 (77%) imatinib resistant, including 71 patients who were both imatinib resistant and intolerant. Approximately half the patients (51.6%) were male. Median age at dasatinib initiation was 57.2 years; median times from diagnosis to imatinib and dasatinib initiation were 2.2 and 45.1 months, respectively, and Sokal and Hasford scores were intermediate/high in 219/306 (71.6%) and 188/268 (70.1%) patients, respectively. Overall, 51.6% of patients evaluated had achieved complete cytogenetic response (CCyR) or major molecular response (MMR) on prior imatinib. Median time from imatinib failure to dasatinib initiation was 8.8 months and 67.6 % of patients received a starting dasatinib dose of 100 mg/day. During the entire observation period, 336/454 patients (74%) achieved CCyR or MMR on dasatinib. An analysis of 443 patients showed a statistically significant effect of time, in months, from imatinib failure to dasatinib initiation on the achievement of a better response to dasatinib ($p<0.023$), with an estimated odds ratio [95% CI] of 0.987 [0.976-0.998] after adjusting for the effect of time from diagnosis to dasatinib initiation and best imatinib response. The odds ratio suggests that with a 6-month delay in starting dasatinib, there would be a 7.5% decrease in the odds of achieving a better dasatinib response (including CCyR/MMR). The corresponding decrease in the odds with a 12-month delay is 14.4%. *Conclusions.* Delaying time to dasatinib initiation has a negative impact on response to dasatinib in CP-CML patients with previous imatinib failure. Results from this observational study are consistent with data from interventional trials in resistant patients and underscore the importance of earlier intervention in patients with CP-CML who have failed imatinib.

Clinical bleeding disorders

QUALITY OF LIFE IN CHILDREN WITH HEMOPHILIA A UNDERGOING PROPHYLAXIS OR EPISODIC THERAPY:RESULTS FROM THE ESPRIT STUDY

S Riva,[1] A Gringeri,[1] F Fusco,[1] PM Mannucci,[1] B Lundin,[2] L Mantovani,[3] S Von Mackensen[4]

[1]*University Hospital of Milan, Milan, Italy*
[2]*University of Lund, Lund, Sweden*
[3]*Fondazione Charta, Milan, Italy*
[4]*University of Hamburg, Hamburg, Germany*

Introduction. Bleeding events lead to joint impairments, arthropathy and chronic pain. Prophylaxis was shown to be the most effective method to prevent bleeding events. The ESPRIT study has investigated whether Health-Related Quality of Life (HR-QoL) was improved in patients treated in prophylaxis compared to those on episodic treatment. To compare HR-QoL in children on prophylaxis VS episodic treatment. *Methods.* ESPRIT study was a multicenter, randomized, comparative, open, trial aimed to evaluate the efficacy of prophylaxis. Forty-five severe hemophilia A patients aged 1-7 years, with no clinical and radiologic signs of joint damage were enrolled and randomized to prophylaxis or to episodic treatment and followed-up for 10 years. Self-reported and proxy-reported HR-QoL was assessed by Haemo-QoL questionnaires at the end of the study. *Results.* The Haemo-QoL score for both treatment groups was 29.9 (SD=9.3), similar to that given by parents (mean 28.90; SD=11.2). Patients and parents reported mainly problems in the dimension friends (mean 56.3; SD=22.2), perceived support (mean 52.92; SD=30.2) and dealing (mean 51.15; SD=33.1). A significant difference was found between episodic treatment and prophylaxis for the dimension family ($p<0.029$), which was more impaired in the episodic treatment group (mean 44.0; SD=22.6) than in prophylaxis group (mean 11.27;SD=8.7). In fact, children on episodic treatment felt often/always more overprotected by their mother (80%) and their father (80%) than those was on prophylaxis (11% by their mother; 20% by their father). Eventualy 20% of patient on episodic treatments perceived that their parents had often or always to limit their time at work or leisure, 10% felt their parents had to limit their work or leisure sometimes, compared to none of the patients on prophylaxis. *Discussion.* HR-QoL was found to be significantly worse in children on episodic treatment in the dimension family compared to those on prophylaxis. Indeed children complained that parents had to limit their work/leisure time to take care of them: probably prophylaxis gives parents definite reassurance, so that they do not have the need to look after them obsessively.

0703

PROPHYLAXIS TREATMENT IN YOUNG SEVERE HEMOPHILIA A PATIENTS: EFFICACY, FVIII CONSUMPTION, TROUGH FVIII LEVELS AND THERAPY COMPLIANCE

F Biondo, C Santoro, E Baldacci, A Leporace, R Foà, MG Mazzucconi

Hematology, Rome, Italy

Background. Long-term prophylaxis is the gold standard treatment for severe hemophilia A patients (pts); it is effective in the prevention of hemophilic arthropathy in children and in young pts. The standard prophylaxis regimen consists of the administration of FVIII ~30 IU kg-1, every other day or three times a week, with the aim of maintaining a level of FVIII >1%. Venous access, especially in children, can be a barrier to prophylaxis; thus, different regimens which involve a lower number of venipunctures are under evaluation. *Aims.* To evaluate different prophylaxis regimens in young severe hemophilia A pts, and to compare efficacy, FVIII consumption, trough FVIII levels and patient/family's compliance. *Methods.* Twenty severe hemophilia A pts (≤18 years) started prophylaxis because of either increasing hemorrhages or presence of a target joint. Three prophylaxis regimens were planned: FVIII, 50 IU kg-1 once a week in 2 pts, 50 IU kg-1 twice a week in 12, 30 IU kg-1 thrice a week in 6. The median age of pts at the start of prophylaxis was 6.9 years (1.1-13.5). *Results.* All pts were treated with rFVIII. Actual rFVIII doses were: once a week, 50 IU kg-1; twice a week, mean dose 46.5 IU kg-1; thrice a week, mean dose 37 IU kg-1. The median annual number of hemarthroses/other bleedings pre-prophylaxis was 4 (1-12) and 5 (1-20), respectively. During the last 12 months of prophylaxis, we recorded: hemarthroses, median 0 (0-2), other bleedings, median 1 (0-2). Mean/median values of trough FVIII levels were 1.1% and 0.7% (0.22%-8%), respectively. Values of trough FVIII >1% were recorded in 5 pts (4 under twice, 1 under thrice a week regimen). No significant differences in concentrate consumption were recorded between twice and thrice a week schedules. There was no difference in the orthopedic score before (median 0; 0-2) and during prophylaxis (median 0.5; 0-2). Median follow-up was 12.7 years (2.6-17.3). During prophylaxis, no inhibitor development was recorded; moreover, 4 low-responding inhibitors (titer <5 BU mL-1) which were present before the start of prophylaxis start disappeared. *Conclusions.* Twice a week prophylaxis can be an alternative regimen to the standard one in young severe hemophilia A pts. Indeed, we found no significant differences both in trough FVIII levels and efficacy between twice/week and thrice/week regimens. Moreover, reduction of venipunctures, especially in small children, improves the compliance of pts and their families.

0704

SONOGRAPHY FOR THE ASSESSMENT OF HAEMOPHILIC ARTHROPATHY OF ANKLES AND KNEES - A NEW TOOL IN HAEMOPHILIA CARE

M Muca Perja, D Mago, F Fusco, S Riva, A Gringeri

University Hospital of Milan, Milan, Italy

Introduction. Imaging such as plain film radiography imaging has always been considered an important tool for the evaluation of complications and for therapeutic follow-up of haemophilic arthropathy. Recently, magnetic resonance imaging has been used for its capability of identifying early joint damages. Unfortunately it is expensive, requires time and sedation in small children, limiting its routine and repeated use. Sonography has been increasingly used for evaluation of joint status for its greater feasibility and better sensitivity for synovial changes. *Aims.* To evaluate the clinical utility of sonography in hemophilic patients *Methods.* In order to evaluate the clinical utility of sonography in hemophilic patients, the authors we have retrospectively analyzed medical records of subjects who underwent sonography of at knees and ankles at annual check-up from January 1, 2009 to June 30, 2010. The findings were compared to orthopedic evaluation. *Result.* Overall 325 joints (115 ankles, 210 knees) in 131 patients with haemophilia (aged 6-79 years, median 32 years) were examined: sonography showed abnormalities in 49% of ankles and in 34% of knees. Synovial hypertrophy and cartilage alterations were the most frequently features (96% of abnormal ankles and 86% of abnormal knees, respectively). Prevalence of abnormalities increased with age and defect severity. Only joints of patients on early prophylaxis showed a lower prevalence of changes of patients on delayed prophylaxis or on demand treatment (2/22, 9% vs. 126/303, 42%). Comparison of sonographic and orthopedic findings showed the latter had a lower sensitivity, especially in the evaluation of ankles (18%). *Discussion.* In this series of cases, sonography was able to identify soft tissues changes of ankles and knees unidentified by the clinical evaluation. For its properties of low running costs and practicability represents a very good tool for a better assessment and monitoring. Therefore, its use should be intensified in the routinary management care of patients with haemophilia

0705

REDUCED BONE MINERAL DENSITY IN PATIENTS WITH HEMOPHILIA A AND B IN NORTHERN GREECE

P Anagnostis,[1] S Vakalopoulou,[2] M Charizopoulou,[3] E Kazantzidou,[4] T Chrysopoulou,[4] E Moka,[2] A Agapidou,[2] V Garipidou[2]

[1]*Aristotle University of Thessaloniki, Thessaloniki, Greece*
[2]*Division of Hematology, 2nd Propedeutic Department of Internal Medicine, Thessaloniki, Greece*
[3]*Aristotle University, Thessaloniki, Greece*
[4]*Radiology Department, Hippokration Hospital, Thessaloniki, Greece*

Background. Hemophilia A and B has been associated with increased prevalence of osteopenia or osteoporosis (67-86%) in a few studies. *Aims.* The aim of this study is to estimate (i) the prevalence of bone disease in hemophilics followed-up in the hemophilia centre of Northern Greece and (ii) its association with hemophilic arthropathy, physical activity as well as with the presence of hepatitis C virus (HCV) and human immunodeficiency virus (HIV) infections. *Methods.* 104 male patients and 44 age-matched controls were screened. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry

(DXA) in lumbar spine (LS), femoral neck (FN) and total hip (TH). Severity of arthropathy was estimated with Pettersson scores and Arnold-Hilgartner classification system. For patients >50 years of age, T-score values between -1 and -2.5 standard deviations (SD) were defined as "osteopenia", while values below -2.5 SD were defined as "osteoporosis". For patients <50 years, Z-score of <-2 SD was defined as "below the expected range for age", according to the criteria for the definition of osteoporosis in males by the World Health Organization. *Results.* Ninety-nine patients aged 45.4±15.2 years (85 with hemophilia A, 14 with hemophilia B) were included. Five patients with diseases related to secondary osteoporosis were excluded. Eighteen patients (18%) were suffering from severe hemophilia, 21 (21%) from moderate and 60 (60%) from mild disease. HCV infection was diagnosed in 38 (38%) and HIV in 7 (7%) patients. Low BMD was diagnosed in 26 of 99 patients (26%) being significantly higher than its incidence in controls (20%) (P=0.0001). Seven patients manifested decreased BMD only in LS, 8 only in TH and 11 in both LS and TH. With respect to the severity of haemophilia, decreased BMD was observed in 5 (28%) of those with severe, in 9 (43%) of those with moderate and in 12 (20%) of those with mild disease. With respect to virus infections, 11 (29%) of the HCV and 3 (43%) of the HIV patients manifested decreased BMD. Low BMD was significantly associated with the severity of hemophilia (P=0.0001), the presence of HCV (P=0.026) or HIV (P=0.0001) and the degree of physical activity (P=0.0001), in unadjusted analysis. An inverse association between the degree of arthropathy assessed by Pettersson or Arnold-Hilgartner score was evident only for the knees (P=0.032 and P=0.019, respectively). In multiple regression analysis, after adjusting for age, BMI, HCV, HIV, number of affected joints and risk factors for developing osteoporosis, such as smoking, alcohol, previous fracture, family history of osteoporosis or hip fracture, only the degree of physical activity and the severity of arthropathy in ankles assessed by Pettersson score were associated with low BMD. *Conclusions.* Our study showed a high incidence of decreased BMD in patients with hemophilia, lower than usually reported. The degree of physical activity and the severity or arthropathy are independent risk factors associated with low BMD.

0706

OSTEOPOROSIS IN EGYPTIAN PATIENTS WITH HEMOPHILIC ARTHROPATHY AND ITS CORRELATION WITH SERUM COPPER, MAGNESIUM AND ZINC LEVELS

M Ayoub, E Ghaniema, S Fathi, I Amin

Ain Shams University, Cairo, Egypt

Background. Hemophilia is a coagulation disorder characterized by acute hemorrhages into the musculoskeletal system leading eventually to arthropathy and disability. Patients with severe hemophilia are at risk for developing reduced bone density in childhood and adolescence for number of reasons as arthropathy and joint deformities result in prolonged immobilization, reduced physical activity and predispose them for osteoporosis. This can lead to an increasing tendency of bone fragility and fractures in patients after trivial trauma. Osteoporosis is a multifactorial disease with particular considerations to calcium, magnesium and other trace elements as copper and zinc. *Objective.* To find out the presence of osteoporosis in patients with hemophilic arthropathy and its relation to serum levels of trace minerals as zinc, copper and Magnesium. *Methodology.* Twenty male patients with hemophilia A and twenty healthy age and sex matched controls were enrolled in the study. Evaluation was carried out clinically, functionally and radiologically. The lower limb joint score of ankles and knees was done according to world Federation of Hemophilia. Juvenile arthritis functional assessment report scale was used. Plain x ray on both knees with bone densitometry (DEXA) were done at femoral neck and lumbar spine (L1 - L4) for all patients and controls. Laboratory investigations included Hb, complete liver and kidney function tests, serological screening for Hbs Ag and HCV. Serum Calcium, phosphorus and alkaline phosphatase to rule out metabolic bone disorders. Determination of magnesium, copper and zinc levels in serum were done by using the flawless atomic absorption spectrometry. *Results.* Severity of osteoporosis assessed by DEXA revealed highly significant lower T and Z scores of lumbar spine and neck of femur in hemophlic arthropathy patients versus controls ($p < 0.001$). T score of neck of femur correlated negatively with total joint score ($r = - 0.46$, $p = 0.03$), functional assessment score ($r = - 0,45$, $p = 0.04$) and total xray score ($r = - 0.46$, $p = 0.03$). There was no significant difference in either T or Z score of lumbar spine and neck of femur between patients with or without hepatitis C virus ($p > 0.05$). In hemophilic arthropathy patients, a highly significant decrease was found in serum levels of Mg, Cu and Zn compared to controls ($p < 0.001$) while there was no statistically significant difference as regards serum calcium levels ($p > 0.05$). Also, serum levels of Cu and Zn correlated positively with Z score of neck of femur ($r = 0.61$, $p = 0.004$ and $r = 0.83$, $p = 0.001$ respectively). On the other hand, there was no significant correlation between serum levels of either calcium or magnesium and the severity of osteoposis as measured by T and Z scores ($p > 0.05$). *Conclusion.* Osteoposis represents a frequent concomitant observation in patients with hemophilia which can complicate management of these patients. Screening of young haemophiliacs for reduced bone density is recommended with measuring the serum levels of trace elements as Zn, Cu and Mg for better assessment of the disease.

0707

A REVIEW OF PCC PROPHYLAXIS IN SEVERE FACTOR X DEFICIENCY IN THE REPUBLIC OF IRELAND

M Kavanagh,[1] I Kelly,[1] E McLaughlin,[1] A O Sullivan,[2] I Regan,[1] M Byrne,[2] D Cawley,[1] J O Donnell,[2] B Nolan[1]

[1]*Our Lady's Children's Hospital, Dublin, Ireland*
[2]*National Centre for Hereditary Coagulation Disorders, St. James Hospital, Dublin 8, Ireland*

Severe Factor X (FX) deficiency is a rare autosomal recessive bleeding disorder. Patients with FX:C level of <0.01-0.03 iu/ml have a severe bleeding phenotype with haemarthrosis occurring in 69% of patients and intracranial haemorrhage accounting for 15% of all bleeding events. Prophylactic FX replacement is challenging because there is no purified FX concentrate available. Fresh frozen plasma, solvent detergent plasma and prothrombin complex concentrate (PCC) contain FX but there are concerns regarding possible thrombogenicity. Seven patients aged 7-303 months old with severe FX deficiency are treated with PCC prophylaxis. Six are born to consanguineous parents. One patient was diagnosed by cord blood FX level while five presented with bleeding episodes; 2/5 with gastrointestinal bleeding at day 1 and day 3 of life, 1/5 presented with umbilical stump bleeding at day 4 of life and 2/5 with intracranial haemorrhage at day 1 of life. The seventh patient is from a non-consanguineous relationship and presented with epistaxis at day 3 of life. All seven patients commenced prophylactic FX replacement therapy with PCC in the first week of life. Dosing regimens range from 25 - 60 IU per kilogram once to twice weekly. 5/7 patients have had central venous access devices to facilitate the administration of PCC. Two patients have had line related thrombosis. 1/7 has Spastic Diplegia secondary to the intracranial bleed at day 1 of life and 2/7 have required extra PCC to treat bleeding episodes secondary to traumatic events. There have been no spontaneous life or function threatening bleeding episodes while on prophylaxis. We conclude that prophylaxis with PCC reduces the number and severity of bleeding episodes a population with severe FX deficiency.

0708

MANAGEMENT OF MENARCHE AND JUVENILE MENORRHAGIA IN GIRLS WITH VON WILLEBRAND DISEASE AND CONGENITAL SEVERE FACTOR VII DEFICIENCY

A Batorova,[1] D Jankovicova,[1] Z Niznanska,[2] T Prigancova[1]

[1]*National Hemophilia Centre, Bratislava, Slovakia*
[2]*Dept. of Gynecology and Obstetrics, University Hospital, Bratislava, Slovakia*

Background. Women with hereditary bleeding disorders are compromised in their lives with many situations increasing demands on hemostasis. Menarche may be the first occasion for the manifestation of the mild bleeding disorder, however, in girls with severe coagulopathy it may lead even to a life-threatening bleeding. Menorrhagia is a well-known complication of childbearing age in patients with von Willebrand disease (vWD), however, in other bleeding disorders this problem is often underestimated. *Aim.* We report on the management of menarche and juvenile menorrhagia in patients with severe congenital bleeding disorders. *Methods*. Girls with bleeding dosorders and menorrhagia are managed by hematologist and pediatric gynecologist in the comprehensive hemophilia care centres. Pictorial blood assessement chart is used for assessing the intensity of menstrual bleeding. *Results.* Eight girls with severe congenital bleeding disorders (age 11-13 years) were referred to our haemophilia centre with heavy menstrual bleeding despite factor replacement therapy started in regional hospitals: four girls suffered from severe FVII deficiency (FVII<

1%), three had type 3 von Willebrand disease (vWD) and one severe vWD type 2A. Abnormal bleeding occured in 6 and 2 patients at menarche and during the second menstrual cycle, respectively. The median duration of the first abnormal menstruation was 12 days (7-30 days). In four patients severe bleeding resulted in severe posthemorrhagic anemia (Hbg 5,7-9,0 g/dL), requiring prolonged hospitalization and administration of 2-30 RBC transfusions. Mean treatment duration of the first menorrhagia with Haemate P and Factor VII concentrate or r-FVIIa was 15 days (range 2-25) and 8.5 days (range 2-22), respectively. Subsequent abnormal menstrual cycles despite the use of prophylactic replacement led to the start of hormonal treatment with gestagens in all the girls after a median of the first 3 (2-6) cycles. Prophylaxis with factor concentrates and antifibrinolytics during menstruation were used for additional 4-8 cycles, then the stabilization of menses with hormons was achieved. Later on monophasic combined oral contraceptives were used with no further need for replacement therapy. The median of PBAC score is 68; range 56-108 (normal <80), hemoglobin 12.3; range 10.6-13.2 g/dL (normal limit 12.0-13.5g/dL) and serum ferritin 25, range 10-40 µg/L (normal limit 15-150µg/L), respectively. *Conclusion.* The course of the first menses is similar in patients with severe forms of vWD and FVII deficieny. Despite availability of high effective factor concentrates the juvenile menorrhagia still represent a high risk situation in these girls. The preventive approach and close cooperation of hematologist with patient family and pediatrician-gynecologist are of paramout importance for proper managent of this situation. The control of menstrual bleeding can be succesfuly achieved with hormonal therapy and factor replacement can be avoided.

0709

IMMUNE TOLERANCE WITH PLASMA DERIVED FVIII/VWD CONCENTRATE IN BOYS WITH SEVERE HAEMOPHILIA A AND RESISTANT INHIBITORS

M Mathias, K Khair, R Liesner

Great Ormond Street Hospital, London, United Kingdom

Background. High titre alloreactive FVIII antibodies remain the most challenging complication of severe haemophilia A in countries with access to FVIII concentrate. There is some evidence that using plasma derived FVIII containing von Willebrand factor (pdFVIII/VWF) to induce immune tolerance (IT) increases the likelihood of success. Most data available includes patients exposed to a variety of different pdFVIII/VWF concentrates. *Aims.* We present 5 boys (aged 7-15 years) with high titre inhibitors who have failed at least one attempt at IT with recombinant FVIII (rFVIII) and were then switched to pdFVIII/VWF with a single concentrate (Fanhdi, Grifols). *Methods.* We carried out a retrospective case note review on our cohort as part of a national data collection exercise which is ongoing. The parents and where appropriate the patients gave informed consent. Data collected included, IT regimen, ethnicity, FVIII mutation, Bethesda titres, number of bleeds pre and post switching to Fanhdi and concurrent use of any immune suppression. *Results.* Three of the boys are Black African and 2 are Caucasian. They all had historical inhibitor titres of >10BU but at the time of switching to Fanhdi 3 of them had inhibitor titres of <5BU. Two boys had had 25-46 months of high dose rFVIII IT prior to switching, 2 boys had failed a previous IT attempt at another centre and were on bypassing agents and the fifth boy had had a relapsed inhibitor. Four boys were given 100iu/kg bd or 200iu/kg od of FVIII and 1 had 80iu/kg 3 times a week. Four of the boys received a total of 6 courses of rituximab (375mg/m2 x 4) and 3 of the boys had mycophenolate mofatil (10mg/kg bd) for 5-12 months (both off-label uses). The mean inhibitor titre pre Fanhdi IT was 18.2BU and the mean most recent inhibitor titre was 2.4BU. The mean follow-up is 39 months. Four of the boys continue on daily or alternate daily treatment with Fanhdi with measurable FVIII levels at 24 or 48 hours and a gradually decreasing FVIII dose in 3 boys, but only 2 have a inhibitor level of <0.5BU currently (achieved at 31 and 32 months after switching). One boy has stopped IT and is now on daily or alternate daily prophylaxis with an activated prothrombin complex concentrate. None of the patients had any complications from immune suppression. *Summary.* In this small cohort attempting IT with a single PDFVIII/VWF concentrate we found that all the subjects had a reduction in their inhibitor titre after switching from rFVIII IT and that they had few bleeding problems and were able to attend school and partake in most normal activities. The most rapid reductions in inhibitor titre were observed in the 2 boys who started IT with Fanhdi at the same time as having a course of rituximab.

0710

SAFETY AND EFFICACY OF RALTEGRAVIR IN PATIENTS WITH HAEMOPHILIA AND ANTI-HIV MULTIDRUG RESISTANCE

L Mangiafico,[1] A Gringeri,[2] M Muca-Perja[2]

[1]*University Hospital of Milan, Milan, Italy*
[2]*University Hospital of Milan, Milan, Italy*

Background. The treatment of patients with HIV infection and congenital bleeding disorders poses specific questions on its safety and efficacy because of presence of long duration of HIV infection, antiretroviral drug multi-resistance due to previous sequential mono-/dual-therapy before the advent of highly active antiretroviral therapy (HAART), and concomitant HCV-/HBV- related chronic liver disease. Raltegravir (Isentress, Merck, NJ, USA), the first approved inhibitor of HIV integrase, is a recently approved drug licensed initially for patients with multidrug resistance. *Aim.* We retrospectively assessed safety and efficacy of raltegravir in patients with hemophilia A or B, HIV infection, multidrug resistance, on treatment with raltegravir for at least three months. *Methods.* For safety evaluation, we checked for clinical adverse events, clinical course, blood tests, CD4 lymphocyte subsets, plasma viral load and overall consumption of coagulation factors, in order to recognize a higher bleeding tendency and/or resistance to replacement therapy. Effectiveness criteria were disease progression, viral load decrease <5,000 HIV-RNA copies/ml, increased or stable CD4 lymphocyte count above 200 cells/µl. *Results.* Six patients, all with HCV coinfection (3 also with HBV infection) had been treated with raltegravir for overall 111 months (median 20 months, min-max: 5-29 months). One patient had suffered from an AIDS-defining disease (Pneumocystis jiroveci pneumonia), 2 patients had CD4 count <200 cells/µl. The median viral load was 8,785.5 copies/ml (min-max <40-37,807 copies/ml). No new opportunistic infections or AIDS-related cancers occurred. All patients showed suppression of viral replication (<40 copies/ml). The CD4 cell count showed a median increase of 137.5 cells/ml (min-max: 27-458/µl). No adverse events occurred. There was no evidence of increased bleeding frequency, modification of bleeding sites, lack of response to replacement therapy. *Conclusions.* HAART-containing raltegravir appeared to be effective and well tolerated in patients with haemophilia with multidrug resistance and it might represent an useful option in these patients

0711

VENOUS THROMBOEMBOLIC COMPLICATIONS IN PATIENTS WITH SEVERE COAGULOPATHY UNDERGOING MAJOR SURGERY

G Saccullo,[1] A Malato,[1] A Tagliaferri,[2] P Redossi,[3] L Lo Coco,[1] P Solimeno,[4] G Tagariello,[5] S Siragusa[1]

[1]*Policlinico P. Giaccone, Palermo, Italy*
[2]*Ospedale di Parma, Parma, Italy*
[3]*Ospedale di Castelfranco Veneto, Castelfranco Veneto, Italy*
[4]*Centro M.G. Gatti-Randi, Milano, Italy*
[5]*Ospedale di Castelfranco, Castelfranco, Italy*

The risk management for venous thromboembolism (VTE) is still unsatisfactory in patients with severe coagulopathy undergoing major surgery that requires peri-operative replacement of lacking coagulation factor. In fact, information about the incidence of proven VTE is lacking in this setting. Some patients receive pharmacological antithrombotic prophylaxis but the efficacy and safety of such approach is doubtful; moreover, when applied, the dosage and duration of anticoagulant prophylaxis is controversial. The first step to evaluate whether patients with severe coagulopathy may need antithrombotic prophylaxis is to evaluate the incidence of post-operative VTE. For this purpose, we conducted, among four centres in Italy (Palermo, Milano, Castelfranco Veneto and Parma), a prospective investigation to objectively evaluate the occurrence of proximal deep vein thrombosis (DVT) and or pulmonary embolism (PE) in consecutive patients with severe coagulopathy planned for major surgery. During the period 2003-2007, 47 patients with congenital coagulopathy who underwent major surgery were evaluated in the post-operative period for symptomatic DVT or PE and asymtpomatic DVT, detected by compression ultrasonography (C-US) of the lower limbs. C-US was performed 10 _ 3 days after surgery (short-term follow-up); the clinical surveillance was conducted for the entire period of 3 months after surgery (long-term follow-up). None of the patients received pharmacological antithrombotic prophylaxis pre or post-operatively; mechanical prophylaxis (with compression graduated stocking) was applied in most of them

Table 1. Events.

Intervention	C-CUS basal	C-CUS post	DVT
Major surgery (n=43)	42/43	41/43	none
Minor surgery (n=4)	4/4	4/4	none
Invasive procedures (n=2)	2/2	2/2	none
Total (n=49)	48/49	47/49	0

(41/47, 87.2%) in the post-operative period. During the shortterm followup (10 _ 3 days) or during the long term clinical surveillance (3 months) no symptomatic or C-US detected thromboembolic events were registered (0/47, 0% 95 CI-0.7-0.7). In conclusion, in patients with severe coagulopathy undergoing major surgery requiring replacement therapy, the incidence of proven DVT in the immediate or delayed followup is low, < 1%; in these patients, mechanical antithrombotic prophylaxis seems to be an effective and safe approach.

0712

COMPARISON OF ATTITUDES OF EUROPEAN HAEMOPHILIA CLINICIANS TOWARDS SPORTS ACTIVITIES IN PATIENTS WITH HAEMOPHILIA

S von Mackensen,[1] K Khair[2]

[1]*Institute of Medical Psychology, Hamburg, Germany*
[2]*Great Ormond Street Hospital Hospital for Children NHS Trust, London, United Kingdom*

Background. Until the '70s sport activities were not recommended for patients with haemophilia (PWH) due to risks of muscle and joint bleeds. Although sport activities are considered beneficial for physical health, motoric coordination and psychological equilibrium, there are still several obstacles towards sport activities such as worries of the family and limited knowledge of potential benefits. Therefore three surveys into the assessment of attitudes of haemophilia specialists towards sports activities in PWHs were conducted in Italy, Germany and the UK. *Methods.* All haemophilia centres/treaters in Italy (n=49), Germany (n=70) and he UK (n=73) received a questionnaire via email/mail containing the following information: physician's sociodemographic characteristics, information about the haemophilia centre (number of patients, experience in the field, and cooperation with other disciplines) attitudes towards sports for haemophilic children (recommendation of sports, frequency, sport competition and specific circumstances) and own sports activities. *Results.* The questionnaire was compiled by 47 centres in Italy (96%), 35 centres in Germany (50%) and 26 centres in the UK (36%). Most of the British haemophilia centres collaborated with a physiotherapist (83%), followed by German (75%) and Italian centres (62%). In Germany one third collaborated with a sports physician, but only one fifth in Italy, while in the UK only one centre did so. In general physicians recommended sports activities for PWH twice a week. Different recommendations were found among countries: a 100% consensus on recommended and not recommend sport activities was achieved only for few sport categories such as swimming, gymnastics and rugby. *Conclusions.* Attitudes of haemophilia specialists towards sports activities are quite important, since physicians are influential on the decisions of parents. Physicians should support parents to let their children develop normally.

0713

EFFICACY AND SAFETY OF ANTITHROMBOTIC PROPHYLACTIC THERAPY WITH LOW-MOLECULAR WEIGHT HEPARIN (LMWH) AFTER ORTHOPEDIC SURGERY IN HEMOPHILIA PATIENTS

F Biondo,[1] E Baldacci,[1] F La Cava,[2] A Leporace,[1] L Poggini,[1] C Santoro,[1] F Falez,[2] A Antonaci,[3] R Foà,[1] MG Mazzucconi[1]

[1]*Hematology, Rome, Italy*
[2]*U.O.C. Ortopedia e Traumatologia, Ospedale S. Spirito in Sassia, Rome, Italy*
[3]*Medical Corner, Ospedale S. Giovanni Addolorata, Rome, Italy*

Background. Deep venous thrombosis (DVT) is a common post-operative complication in normal subjects undergoing orthopedic surgery of lower limbs. Therefore, thromboprophylaxis with LMWH or other antithrombotic agents is strongly recommended. On the contrary, LMWH thromboprophylaxis after orthopedic surgery is still controversial in hemophilia patients (pts). *Aims.* To evaluate the efficacy and safety of post-operative anti-thrombotic therapy with LMWH in severe or moderate hemophilia A and B pts, treated with factor concentrates, undergoing orthopedic surgery of lower limbs. *Methods.* Twelve pts [severe/moderate hemophilia A: 9/1; severe/moderate hemophilia B: 1/1; median age 36 years (30-60)], underwent orthopedic surgery because of a significant hemophilic arthropathy. The following surgical interventions were performed: 3 knee replacements, 3 ankle replacements, 3 knee synovectomies, 2 ankle synovectomies, 1 femur fracture reduction. Recombinant FVIII or FIX were administered as bolus infusions at the following dosages: 1) joint replacement: 1 hour before surgery (t0): 100 IU Kg-1; from the 12th to 60th hour (t12hàt60h) after surgery: 50 IU Kg-1 every 12 hrs; from the 3rd to 7th post-operative day: 40 IU Kg-1, 2 bolus day-1; 2) synovectomy: t0: 80 IU Kg-1; t12hàt60h: 40 IU Kg-1, 1 bolus every 12 hrs; from the 3rd to 7th post-operative day: 25 IU Kg-1, 2 bolus day-1; 3) femur fracture reduction: t0: 100 IU Kg-1; from the 12th hour to the 7th post-operative day: 50 IU Kg-1, 1 bolus every 12 hrs, followed by tapering. All patients received post-operatively prophylactic antithrombotic therapy with enoxaparin at a dosage of 50 IU kg-1 day-1; the first administration of LMWH was performed at the 12th hour after surgery and was continued until complete mobilization of the pts (5-7 post-operative days); in case of femur fracture reduction, enoxaparin was given until plaster cast removal, 4 weeks after surgery. *Results.* Twelve severe/moderate hemophilia A/B patients underwent orthopedic surgery. They were prophylactically treated either with factor concentrates or with LMWH, and no bleeding or thrombotic complications were recorded. *Conclusions.* Adequate pre- and post-operative replacement therapy, enables the use of LMWH given at lower doses than the standard ones. Hence, thromboprophylaxis with low doses of LMWH is effective and safe in hemophilia pts.

0714

MANAGEMENT OF DENTAL EXTRACTIONS IN EGYPTIAN CHILDREN WITH BLEEDING DISORDERS OPTIMIZING THE USE OF TRANEXAMIC ACID: A SINGLE CENTER STUDY

M Abdelwahab

Cairo University Pediatric Hospital, Cairo, Egypt

Background. Most of the reports in the literature deal with management of dental extractions usually of adults and rarely of children with haemophilia A and B of variable severity whilst few studies discussed patients with von Willebrand Disease (VWD), rare coagulation disorders and platelet disorders.Replacement therapy remains the mainstay of management inspite of its hazards. The use of tranexamic acid, systemically and locally, as a single not adjunctive therapy to reduce the incidence of postoperative bleeding in these disorders is a subject of debate and large studies are not available till now evaluating its use as opposed to replacement and local measures with none conducted in Egypt. *Aim.* To optimize the use of tranexamic acid pre and post dental extraction in Egyptian children with bleeding disorders and so minimizing the use of replacement therapy. *Methods.* One hundred patients with bleeding disorders who required dental extractions were recruited from the paediatric haematology and dental outpatient clinics, Cairo University Paediatric Hospital over a 3-year period after a consent was obtained. This included 50 children with platelet disorders [45with Idiopathic thrombocytopenic purpura (ITP), 3 children with Bernard Soulier and 2 with Glanzmann's thrombasthenia]. In patients with ITP, intervention was done with platelet count ≥ 30,000. The study also included 50 children with inherited coagulation disorders [37 children with haemophilia A, 3 children with haemophilia B, 4 with type 1 vWD and one with type 3vWD, one with FX deficiency and 4 with FV deficiency]. The management protocol was individualised according to the severity of the bleeding disorder and dental history. Patients were divided into two groups according to the treatment regimen, group 1(n=83) including patients with mild and some with moderate bleeding tendency receiving only tranexamic acid systemically and then tranexamic acid mouth wash (TAMW) 5% post-extraction and group 2 (n=20)including few with moderate and all severe bleeding disorders receiving replacement therapy to increase the deficient factor to 20 % and then TAMW 5% post-extraction. Follow up was done on day one, three and seven post-extraction Results 103 extractions were done in children with a mean age of 11.2 years. Post-extraction complications were reported in 11/103 (10.7%) [6 children with haemophilia A, 1

child with vWD, 3 patients with ITP and 1 patient with thrombasthenia) but none required hospitalization or extra replacement. The patient group on tranexamic acid showed less frequent bleeding complications as compared to those receiving replacement but the latter had a more severe bleeding tendency. Though the protocol was to use TAMW for a week yet bleeding usually stopped after 2 days and all children found the mouthwash easy to use, palatable and very effective. *Conclusion*. The protocol proposed in this study is feasible allowing haemophiliac children to be treated on an outpatient basis with containment of cost and relatively low number of haemorrhagic complications especially for mild and some moderate bleeding disorders. Further multicenter controlled studies are recommended on a larger scale exclusively on children to standardize guidelines for this unique group of patients.

SUCCESSFUL PREGNANCY AND DELIVERY IN PATIENT WITH CONGENITAL COMBINED DEFICIENCY OF FACTORS V AND VIII ASSOCIATED WITH LUPUS ANTICOAGULANT

I Elezovic,[1] D Antic,[1] P Miljic,[2] F Peyvandi,[3] D Plecas[4]

[1]*Clinic of Haematology Clinical Centre of Serbia, Belgrade, Serbia*
[2]*Medical Faculty University of Belgrade, Belgrade, Serbia*
[3]*Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, University of Milan, Milan, Italy*
[4]*Ginecology and Obstetric Clinic Clinical Center of Serbia, Belgrade, Serbia*

Combined deficiency of coagulation factors V (FV) and VIII (FVIII), known as F5F8D, is an autosomal recessive bleeding disorder characterized by the concomitant reduction in both factors and bleeding symptoms. F5F8D is extremely rare (1:1.000.000) and developed due to mutations in genes lecitin mannose-binding 1 (LMAN1) and multiple coagulation factor deficiency 2 (MCFD2) which encoded proteins involved in the FV and FVIII intracellular transport. Mutation of LMAN1 gene accounts 70% of F5F8D families, whereas mutations in MCFD2 account 30%. In MCFD2 mutations, FV and FVIII are significantly lower than in LMAN1 mutations. F5F8D is characterized by mild bleeding, as the observed FV and FVIII levels are sufficient to prevent major spontaneous bleeding. However, bleeding commonly follow surgery, dental extraction and trauma. Treatment of bleeding requires substitution with FV (FFP) and FVIII (desmopressin or FVIII concentrates). Recently, recombinant activated factor VII (rFVIIa) has been used for the treatment of bleeding in F5F8D. The aim of our study is to present clinical, molecular features and treatment of F5F8D associated with strong lupus anticoagulant (LA) during pregnancy and delivery. A 28-year-old pregnant woman had history of abnormal bleeding after tooth extraction. The family bleeding history was unremarkable for abnormal bleeding. Results of prothombin time (33%) and APTT (123 s) were prolonged. Laboratory assays showed decrease of FV:C 5%, FV:Ag 2%, FVIII:C 4%, FIX:C 28%, FXI:C 41%, and FXII:C 30%. Strong LA (1.8-2.1), anticardiolipin (IgM 35.5) but no beta 2 glikoprotein I antibodies were detected. Molecular diagnosis indentified homozygous mutation c.149+5 G/A in MCDF2 gene. Her mother (FV:C 105%, FV:Ag 100%, FVIII:C 109%) and father (FV:C 75%, FV:Ag 97%, FVIII:C 50%) were heterozygous for the same mutation. A diagnosis of F5F8D with LA were established 5 years before. During the pregnancy levels of FV:C and FVIII:C were low but she did not have a bleeding, and LA was elevated but results of D-dimer were normal. Patient underwent delivery after administration of FFP (10 ml/kg) and FVIII concentrates (30 U/kg) with increment of FV:C to 14%, FVIII:C to 17% and LA 1.55. However, when FV, FVIII and LA were measured in platelet reach plasma (PRP) before and after platelets lysis, by frozen and heating, level of FV:C increased from 36% to 74% and FVIII:C from 46% to 66%. We supposed that phospholipids released from platelets neutralised LA (from 1.39 to 0.68) and factors increased on real levels. Patient was successfuly delivered (female, 2750 g, Apgar score 9) without bleeding complications and thrombotic events. She has been substituted on same maner two days after delivery and then doses were reduced for 50% next 7 days. Prothrombin time was prolonged at newborn, and after the treatment with vitamin K it has been normalised. To our knowledge this is the first patient with F5F8D associated with LA who was successfuly delivered without bleeding and thrombotic complications. LA is a risk factor of thrombosis and it was main reasons why she has been substitute with FV and FVIII on lower levels and rFVIIa was not used.

GASTROINTESTINAL HAEMORRHAGE IN PATIENTS WITH BLEEDING DISORDER

A Hopkins, J Blundell, S Johns, D Creagh

Royal Cornwall Hospital, Truro, United Kingdom

Introduction. In recent years improvements in the treatment for individuals with bleeding disorders in the United Kingdom (UK) means the life span of haemophiliacs and people with severe Von Willebrands disease is similar to that of the UK general population. The emergence of a population of healthy adults with inherited bleeding disorders presents a new challenge for their care. They develop medical and surgical diseases not previously seen in this group. In the UK practice is based on guidance from the UK Haemophilia Doctors Organisation and the World Federation of Haemophilia. Registered hospital centres delivery care; however there is ongoing debate regarding the appropriate clinical setting for the treatment of this patient group. The RCH Haemophilia Centre delivers care to 180 registered patients and based on national guidelines has a policy covering attendances in such patients. *Aims.* To review the presentation, management, investigation and outcome of patients with bleeding disorders that have presented to the RCH with significant gastrointestinal (GI) bleeding between January 2007 and January 2011. *Methods.* Patient's details were obtained from the Haemophilia Centre records. Relevant clinical details were extracted from hospital notes. Details of factor concentrate used were retrieved from the laboratory records. *Results.* There were seven events of GI haemorrhage in six patients with bleeding disorders; 3 moderate haemophiliacs, 1 mild haemophiliac, 1 severe Von Willebrands disease and 1 2A Von Willebrands disease. Duration of symptoms ranged from 24hours to ten days. Three presented with dark blood loss and four with fresh blood loss. Four patients presented out of hours directly to the admissions unit and 2 contacted the haemophilia nurse in working hours. In 6 cases there was documented discussion with on call Haematologist before factor concentrate was administered however in 3 patients there was a delay in administration of factor concentrate. Four patients required blood transfusion. All patients had Factor concentrate; two had continuous infusions and five had bolus therapy. Investigations and management for the GI haemorrhage was in accordance with the RCH guidelines in all but 1. This patient had a barium meal rather than endoscopy. This may have been in part due to a possible risk of vCJD infection and the need to quarantine an endoscope. The diagnoses were varied; 1 haemorrhoids, 2 diverticular disease, 2 colonic polyps, 1 a small bowel bleed and 1had no diagnosis. All patients were discharged when symptoms settled. *Conclusions.* Patients with bleeding disorders do present to other specialities with bleeding unrelated to their original diagnosis. These are often emergencies and there is therefore a need for local management. They should be managed according to established protocols for these conditions along with specialist haematology input. It is essential to clearly communicate the practicalities of factor 8 issue, prescribing and administration to ward staff. Some patients presented late with significant bleeding. This may be because they have not needed recent treatment for their bleeding disorders and/or did not think their bleeding disorder was relevant. Continued patient education is important.

DIRECT COSTS OF CHILDREN WITH HAEMOPHILIA A UNDERGOING PROPHYLAXIS OR EPISODIC TREATMENT: RESULTS FROM THE ESPRIT STUDY.

F Fusco,[1] A Gringeri,[1] S Riva,[1] LG Mantovani,[2] S von Mackensen,[3] PM Mannucci[1]

[1]*University Hospital of Milan, Italy, Milan, Italy*
[2]*Charta Fondation, Milan, Italy*
[3]*University of Hamburg, Hamburg, Germany*

Introduction. Bleeding events lead to progressive arthropathy and invalidity. Prophylaxis was shown to be the most effective method to prevent bleeding events and slow down joint destruction. The ESPRIT study has assessed the direct costs of prophylaxis and episodic treatment in children with hemophilia A from the third party payer perspective. *Methods.* ESPRIT study was a multicenter, randomized, comparative, open, trial aimed to evaluate the efficacy of prophylaxis. Forty-five severe hemophilia A patients aged 1-7 years, with no clinical and radiologic signs of joint damage were enrolled and randomized to prophylaxis or to episodic treatment and followed-up for 10 years. Cost analysis was based on the annual FVIII concentrate use. The third party payer perspective was adopted (Italian National Health System). After having quantified the resources absorbed,

costs were expressed in Euro as at 2010. *Results.* Monthly FVIII usage per patient was 8'852 IU (patients on prophylaxis) vs. 3'981 (patients on episodic treatment). Assuming an average price per IU of recombinant FVIII concentrates of 0.75€, yearly cost for prophylaxis was 79'668€ vs. 35'829€ for patients on episodic treatment. The Incremental Cost-Efficacy Ratio (ICER) for bleeding event avoided in patients on prophylaxis was 7'537€ (10'048.6 IU x 0.75€). We calculated the ICER for maintaining all joints pristine over the whole treatment period (mean study time: 82 months): it was 201'601.12€ (28'800.16€ a year). *Discussion.* The cost of prophylaxis was more than the double compared to episodic treatment. ICER per bleed avoided showed the need for a high investment of resource (7'537€). On the other hand, the additional cost for maintaining pristine joints in a child with hemophilia was lower than 30,000 € a year.

0718

BLEEDING PROPHYLAXIS WITH AN ANTI-INHIBITOR COAGULANT COMPLEX (AICC) IN PATIENTS WITH HEMOPHILIA A AND INHIBITORS CAN IMPROVE QUALITY OF LIFE: RESULTS OF THE PRO-FEIBA STUDY

F Fusco,[1] A Gringeri,[1] LG Mantovani,[2] PA Cortesi,[3] LG Mantovani[2]

[1]*University Hospital of Milan, Italy, Milan, Italy*
[2]*Charta Fondation, Milan, Italy*
[3]*University of Milano-Bicocca, Monza, Italy*

Background. Patients with hemophilia A and inhibitors are at high risk for severe bleeding and progression of joint disease with consequent deterioration of their health-related quality of life (HRQoL). Prophylaxis with bypassing agents has been suggested as a potential therapeutic option in these patients. *Method.* A prospective, randomized, crossover study (Pro-FEIBA Study) was designed to evaluate safety and efficacy of an anti-inhibitor coagulant complex (AICC) for bleeding prophylaxis in hemophilia A patients >2 years with high-responding inhibitors. The study compared 6 months of AICC prophylactically dosed at 85 U/kg ±15% on 3 nonconsecutive days per week with 6 months of on-demand therapy (target dose: 85 U/kg ±15%). The 2 study periods were separated by a 3-month washout, during which time patients used on-demand therapy. Quality of life in patients >14 years was assessed at the beginning and end of each study period with 2 generic instruments: the Short-Form 36 (SF-36) and the Euro-QoL 5-Dimensions (EQ-5D). *Results.* Twenty-five patients with median age of 30.2 years (range: 16.1-67.9 years) completed at least one QoL questionnaire. Sixteen patients completed both the SF-36 and the EQ-5D at the beginning and end of each study period, 1 patient completed only the SF-36, and 1 patient completed only the EQ-5D. A comparison of the 2 study periods showed a trend towards HRQoL improvement favoring prophylactic therapy. The results reached statistical significance (for conventional levels) for the SF-36 physical component summary score. Specifically, the mean difference in the summary scores before and after episodic treatment was -1.7 (SD 7.9) versus +4.4 (SD 8.4) before and after prophylaxis (p=0.025). *Conclusion.* AICC prophylaxis significantly improved HRQoL as compared with episodic treatment. Larger cohorts and longer follow-up are necessary to confirm these data.

[12]*Azienda Ospedaliera Universitaria Careggi, Florence, Italy*

Background. Although immune tolerance induction (ITI) is generally accepted as first choice treatment to eradicate inhibitors (Inh) in hemophilia A patients (pts), little is known about determinants of outcomes and cost consequences. *Aim and Methods.* The Immune Tolerance and Economics Retrospective (ITER) study is an observational, retrospective, multicentre, multinational study aiming to estimate cost of treatment in hemophilia A pts, undergoing ITI after 1995 with any type of FVIII. Data on hemostatic treatment given in the following time periods were collected: up to 12 months before the diagnosis of Inh, between Inh diagnosis and ITI start, during ITI, and 12 months after the end of ITI. Costs of treatment were calculated in the perspective of the third party payer and expressed as mean €/patient-month. *Results.* 71 valid pts, with median age at ITI start=3.8 (0.4-41) years, were enrolled. Before ITI the median Inh peak titre was 18.5 (0.80-704) BU. ITI was applied for a median of 1.22 (0.1-14.0) years and was successful in 84.5% pts. Before Inh diagnosis, pts cost 670€/patient-month for on-demand or prophylaxis treatment. Cost was 3,188€/patient-month between the Inh diagnosis and ITI start (92.1% for bypassing agents), and 60,078€ during ITI (76.8% for ITI, 19.4% for extra FVIII treatment, 3.8% for extra treatment with bypassing agents). The mean cost after ITI was 13,211€/patient-month. No significant relationship was found between cost during and after ITI and the success rate. Discussion: ITI applied on pts with the characteristics of those involved in the ITER study is successful in 84% of them at a mean cost of 60,000€/patient-month during ITI, plus 13,000€/patient-month through 1 year later. Further research is encouraged to value long term benefits and costs attributable to ITI versus non-ITI, in order to identify the most efficient treatment option for the pts' and for the health care system.

0720

THE IMPACT OF TRANSITION FROM ADOLESCENCE TO ADULTHOOD ON THE HEALTH-RELATED QUALITY OF LIFE OF HAEMOPHILIA PATIENTS (THE HYQOL-EUROPE STUDY)

S von Mackensen,[1] R Klamroth,[2] A Gringeri[3]

[1]*Institute of Medical Psychology, Hamburg, Germany*
[2]*Haemophilia and Haemostaseology Centre, Vivantes Clinics Friedrichshain, Berlin, Germany*
[3]*Department of Medicine and Medical Specialities, Fondazione IRCCS Cà Granda, Osp, Milan, Italy*

Introduction. Despite considerable evidence demonstrating chronic pain, disability and reduced health status in haemophilia patients, little is known about the impact of transitional life events in terms of educational, vocational and relational changes on the disease and its treatment, and patients' health-related quality of life (HRQoL). For adolescents and young adults with haemophilia independence, self-management of treatment and integration in job life are main concerns. The HyQoL-Europe Study aims to evaluate the impact of transitional events on HRQoL. Additionally, key transitional life events like partnership, living and professional situation will be identified. *Methods.* In this prospective, longitudinal, multicenter, non-interventional study ca. 100 patients aged 14-35 years with moderate or severe haemophilia A using Helixate from 7 countries are enrolled. The study is divided into two phases: a recruitment phase of up to 18 months, followed by a data-collection phase of 36 months for each individual patient. The following variables are assessed: socio-demographic characteristics, HRQoL (generic: SF-36, EQ-5D; disease-specific: Haemo-QoL, Haem-A-QoL), sports and physical functioning (HEP-Test-Q, short EPIC Norfolk index), living situation, sexuality, spirituality/religious beliefs, treatment adherence and transitional life events. Clinical data on bleeding history, treatment, orthopaedic status, etc. are collected by physicians. All evaluations will be carried out at baseline and yearly over 3 years. *Results.* In Europe 3 regions were identified capturing different socio-economic, cultural and transitional situations (Regions: I: Germany, Austria, Switzerland, II: France, Belgium, III: Italy, Spain). 44 patients are enrolled up to now in Italy (n=12), Austria (n=10), Germany (n=9), France (n=8), Belgium (n=1), Switzerland (n=3), Spain (n=1). Mean age of patients is 24.2 years (SD=6.2), 68% are living with their parents and 63% are working. 81.8% of the patients are severely affected, 25% receive on-demand treatment, 75% prophylaxis (twice/week). In average they report 6 days off at school/work (range 0-30) due to haemophilia in the past 12 months. Discussion: The HyQoL-Europe Study together with a similar project in Canada is the first study investigating the crucial period of transition in the life of young haemophilia patients. Recognition of specific transitional life events and their impact on HRQoL in adolescents and young adults may allow treaters to provide and/or tailor better quality of medical care, improve support of patients' self management and facilitate a more efficient allocation of resources.

Clinical hemoglobinopathies 2

0721

ASSOCIATION BETWEEN HAEMOLYSIS AND MICROALBUMINURIA IN ADULTS WITH SICKLE CELL ANAEMIA

E Drasar,[1] T Day,[1] T Fulford,[2] C Sharpe,[1] SL Thein[1]

[1]King's College and King's College Hospital, London, United Kingdom
[2]MRC International Nutrition Group, London School of Hygiene & Tropical Medicine, London, United Kingdom

Background. Sickle cell nephropathy (SCN) is highly prevalent and potentially life-threatening in sickle cell anaemia (SCA). End stage renal failure is present in around 11% of SCA patients, increasing with age. While significant associations have been found between microalbuminuria and markers of haemolysis in the paediatric population, similar studies in adults have not consistently replicated these findings. *Aims.* To investigate the prevalence of microalbuminuria amongst adults with SCA, and to examine their association with haemolysis. *Method.* This is a retrospective study based on adult patients (> 16 years of age) attending King's College Hospital over a four year period (1st of January 2006 to 31st of December 2010). Steady-state data linked to clinic visits were collected, including haemoglobin (Hb), reticulocyte, bilirubin and lactate dehydrogenase (LDH) levels, serum cystatin C, estimated glomerular filtration rate [eGFR] calculated using modified diet in renal disease [MDRD] and Hoek formulae [using cystatin C]) and urine albumin/creatinine ratio [ACR]. Bilirubin levels were adjusted for the UGTA1 genotype. Data was also collected on sex, age at clinic visit and alpha-thalassaemia status. Patients were excluded from the study group if they were regularly transfused, or had other causes of albuminuria or chronic renal failure. Analysis was limited to patients with Hb SS and Hb Sβ0 who had at least one ACR value. All laboratory test results were treated as continuous variables and were log transformed if appropriate. Random effects regression was used to allow for multiple observations from each individual. Variables were analysed using both simple correlation and controlling for co-variates (sex, age, genotype- including alpha thalassaemia trait, hydroxyurea use and white blood cell count). *Results.* The study group consisted of 207 patients (59% female), mean age 31 years (SD+/- 11, range 16-60). Microalbuminuria (ACR ≥4.5mg/mmol) was present in 97 (47%) of the group. Using simple correlation, ACR correlated significantly with LDH (p<0.0001 95% CI 0.002-0.003), bilirubin (p<0.0001 95%CI 0.500-1.09), reticulocyte count (p=0.024 95%CI 0.00 -0.001), and negatively with Hb (p=0.001 95%CI -0.229 to 0.062). Alpha-globin genotypes were available in 39% patients. Presence of alpha-thalassaemia correlated negatively with ACR (p>0.008 95%CI-0.824"'0.124). After controlling for co-variates the correlation with reticulocytes became non-significant, however all other correlations remained significant; LDH p<0.0001 (95%CI 0.002-0.003), bilirubin p<0.0001 (95%CI 0.431-1.05) and Hb p=0.0006 (95%CI -0.246 to -0.061). eGFR (both MDRD and Hoek methods) correlated positively with reticulocyte count using simple analysis (p<0.0001 95%CI 0.027-0.065 and p<0.018 95%CI 0.003-0.028, respectively) and when controlling for co-variates (p<0.0001 95%CI 0.044-0.084 and p<0.0001 95%CI 0.012-0.040, respectively). Bilirubuin and LDH levels correlate positively with eGFR (p<0.001). *Summary.* Microalbuminuria is a common complication of SCD and correlates strongly with all markers of haemolysis, the first time that this has been shown in an adult population with SCD. Correlation of bilirubin and LDH with eGFR suggests an association of haemolysis with hyperfiltration. Alpha-thalassaemia, known to reduce haemolysis in SCA, has a protective effect against microalbuminuria adding further support to the theory that sickle cell nephropathy is linked to the haemolytic sub-phenotype of SCD.

0722

EFFECT OF (6R)-5,6,7,8-TETRAHYDRO-L-BIOPTERIN ON REAL TIME NITRIC OXIDE AND REACTIVE OXYGEN SPECIES GENERATION IN NEUTROPHILS OF SICKLE CELL DISEASE PATIENTS WITH AND WITHOUT HYDROXYUREA THERAPY

R Saini, K Fertrin, N Conran, F Costa

Center of Hematology and Hemotherapy (Hemocentro), UNICAMP, Campinas, Brazil

Background. Sickle cell disease (SCD) is associated with decreased bioavailability of nitric oxide (NO) via the reactive oxygen species (ROS)-mediated consumption of this vasoactive molecule. Decreased bioavailability of NO is mainly due to reduced availability of substrate (L-arginine) and cofactor (6R)-5,6,7,8-tetrahydro-L-biopterin (BH4) of enzyme NO synthase (NOS). The NO donor property of hydroxyurea (HU) effectively participates in treatment of SCD. Administration of hydroxyurea and L-arginine increases NO to greater level than either hydroxyurea or L-arginine treatment alone. Augmenting BH4 levels also has greater efficacy for NO production than L-arginine supplementation alone. However, the effect of BH4 on NO/ROS generation in presence of hydroxyurea remains unexplored. *Aims.* We therefore investigated modulation of real time NO/ROS generation by BH4 in neutrophils of steady state SCD patients and SCD patients on hydroxyurea therapy (SCD-HU), as compared to controls. *Methods.* Neutrophils from controls, SCD and SCD-HU patients were included in study with informed consent. Real time NO/ROS generation was monitored utilizing specific probes (4,5-diaminofluorescein-2-diacetate (DAF-2DA;10 μM) for NO; 2,7-dichlorofluorescein (H2DCF-DA;10 μM) for hydrogen peroxide (H2O2) and dihydroethidium (DHE;10 μM) for superoxide anion (O2-), respectively, using confocal microscopy. To examine effect of BH4 (10 μM), cells were preincubated with BH4 before adding probes and alterations in fluorescence was quantitated by flow cytometry as mean fluorescence intensity (MFI). Preincubations with NOS inhibitor, Nω-nitro-L-arginine-methyl-ester (L-NAME;1mM), ROS scavenger, superoxide dismutase (SOD;100U/ml) were also done and their effect on NO/ROS generation was assessed. *Results.* Flow cytometric studies revealed that NO production was significantly lower in SCD neutrophils as compared to controls (1.54±0.42; 5.31±0.59 MFI, respectively, n=6, p<0.005) but hydroxyurea treatment augmented NO production (3.97±0.17 MFI, n=6, p<0.005) in SCD-HU neutrophils. ROS generation was higher in the neutrophils of SCD patients as compared to neutrophils of SCD-HU patients [84.75±6.71; 62.32±5.85 (H2O2) and 30.17±2.12; 12.53±0.26 (O2-) MFI, respectively, p<0.005]. On pretreatment with BH4, there was significant increase in NO production (6.26 ±0.18; 5.31±0.59 MFI, respectively, p<0.005) and decreased generation of ROS [36.82±3.54; 40.46±6.11 (H2O2) and 13.66±0.45; 16.09±0.82 (O2-) MFI, respectively, p<0.005] in control neutrophils. NO production increased (1.69±0.08; 1.54±0.42 MFI, respectively, p<0.005) with decreased ROS generation [50.85±4.12; 84.75±6.71 (H2O2) and 15.80±0.61; 30.17±2.12 (O2-) MFI, respectively, p<0.005] in presence of exogenous BH4 in neutrophils of SCD patients. Interestingly, exogenous BH4 did not significantly increased NO levels in SCD-HU patients (3.97±0.17; 4.02±0.32 MFI, respectively) but instead increased ROS generation [79.15±6.21; 62.32±5.85 (H2O2) and 14.58±0.75; 12.53±0.26 (O2-) MFI, respectively, p<0.005], possibly suggesting autooxidation of BH4 in these cells. Results were corroborated by confocal microscopy where real time NO/ROS generation was monitored. Addition of NOS inhibitor L-NAME and ROS scavenger, SOD abolished fluorescence of DAF-2DA and DHE respectively, confirming the specificity of the probes. *Conclusions.* Hydroxyurea treatment inceases NO production in SCD patients and might further deplete arginine stores in SCD-HU patients. Exogenous BH4, instead of augmenting NO further, increases ROS generation and possibily suggests BH4 autooxidation in presence of increased superoxide radicals in neutophils of SCD-HU patients. dr.rashmisaini@gmail.com

Table 1. NO/ROS generation in neutrophils of SCD patients.

		Control MFI (n= 6)	SCD PATIENT MFI (n= 6)	SCD-HU PATIENT MFI (n=6)
DAF-2DA Fluorescence (NO)	Basal	5.31 ± 0.59	1.54 ± 0.42	3.97 ± 0.17
	BH4	6.26 ± 0.18	1.69 ± 0.08	4.02 ± 0.32
H2DCF Fluorescence (H2O2)	Basal	40.46 ± 6.11	84.75 ± 6.71	62.32 ± 5.85
	BH4	36.82 ± 3.54	50.85 ± 4.12	79.15 ± 6.21
DHE Fluorescence (02-)	Basal	16.09 ± 0.82	30.17 ± 2.12	12.53 ± 0.26
	BH4	13.66 ± 0.45	15.80 ± 0.61	14.58 ± 0.75

The objective of this study was to determine the efficiency of the neonatal screening (NS) program for Sickle Cell Disease (SCD) which was implemented in 1994 in few maternities and extended in 2003 to all maternities in Brussels. It is a systematic screening performed on liquid cord blood. Affected children are referred to a specialized center. We reviewed 146 medical records of patients with SCD born in Belgium and prospectively followed from the time of their diagnosis in three Brussels' Academic Centers and focused on the subgroup of patients older than 3 years of age at December 31, 2007. They were divided into two groups: the NS and the no NS groups. The incidence of major events (first septicemia, first stroke, first severe anemia, number of hospitalization days from 0 to 3 years, and death) was compared. 55 patients (median age 6.7 year, range: 3-16) were in the NS group and 49 (median age 11.2 year, range: 4-27) were in the no NS group. The median age at diagnosis for the no NS cohort was 1 year (range: 1-6). The follow-up of the NS and no NS cohorts accounted for 301.5 and 473.8 patient-years, respectively. Most of the patients were homozygous for Hb S. Incidence of a first episode of septicemia was similar in both groups (9.1% versus 12.3%). The median age at the time of sepsis was 26 months and 13 months in the NS and no NS groups, respectively. All the patients from the NS group were on penicillin prophylaxis versus 50 % in the no NS group. The main pathogen remained Streptococcus pneumoniae and there were no resistant strain despite regular prophylaxis. Incidence of stroke was 1.8% (1/55) in the NS cohort compared to 8.2% (4/49) in the no NS cohort. There was no difference in the incidence of the first severe anemia or the number of hospitalization days for both groups. Two deaths occurred in the NS cohort in the very early childhood (septicemia in one and acute severe anemia for the other). These deaths were attributable to no compliance to antibio-prophylaxis and poor follow-up. Furthermore these deaths occurred in the very early period after NS has been initiated. No death occurred in the NS group since 12 years probably due to better parents' education and comprehensive care. One death was observed in the no NS group (sudden rupture of cerebral aneurysm). In conclusion, NS program is feasible, safe and appropriate to detect SCD. Although the relative small size of our study and the bias due to unreported early deaths by infection or severe anemia in the no NS group before the diagnosis of SCD has been done, our results are very encouraging: NS delays the age of the first severe infection and might reduce the incidence of early neurological complications. It also underlines the better outcome with improvement of parental education and comprehensive care. These data emphasize the need to continue NS for SCD in Brussels and to extend it to all Belgian maternities.

CO-INHERITED A-THALASSEMIA BLUNTS THE CLINICAL RESPONSE TO HYDROXYCARBAMIDE IN SICKLE CELL DISEASE

N Vasavda,[1] C Woodley,[2] M Allman,[3] E Drašar,[4] M Awogbade,[3] J Howard,[2] SL Thein[4]

[1]*King's College London, London, United Kingdom*
[2]*Guy's & St Thomas' Hospital, London, United Kingdom*
[3]*King's College Hospital, London, United Kingdom*
[4]*King's College London & King's College Hospital, London, United Kingdom*

Background. Hydroxycarbamide (HC), a key therapy in the treatment of sickle cell disease (SCD) reduces transfusion requirement and the frequency of acute pain episodes, mainly through fetal hemoglobin (HbF) induction. Although HbF levels are markedly increased in many sickle patients receiving HC therapy, up to 40% of sickle patients do not respond clinically. Various genetic variants have been implicated, including co-existing α-thalassemia (data from our previous retrospective study). As α-thalassemia is present in approximately 30% of SCD patients, any effects on HC response would have clinical implications. In a separate study we showed that plasma cell-free DNA (cfDNA), a marker of tissue damage, is elevated during sickle acute pain and reduced with HC therapy. *Aims.* We performed a larger, prospective study to further investigate the effects of co-inherited α-thalassemia on HC response. We wished to expand on our preliminary findings by collecting data on acute hospital admission and combining this with a comparison of cfDNA levels between patients with SCD alone (SCD) or with co-existing α-thalassemia (α-SCD). *Methods.* Participants: 62 participants were recruited from the specialist hematology clinics at King's College (n=45) and St Thomas' (n=17) hospitals, London. 18 patients had α-thalassemia. All participants gave informed, written consent. 33 patients were already receiving HC therapy, 22 never had HC therapy, 4 commenced HC during the study and 3 were excluded due to intermittent HC therapy or frequent transfusions. Clinical Data: For patients treated with HC, clinical data (hematological indices, hospital admissions, HC dosing) was collected retrospectively for the year prior to starting HC therapy and prospectively throughout the study from 6 months after commencement of HC therapy. "Non HC"patient data was collected prospectively. Blood samples: Blood samples were collected prospectively for cfDNA measurement. Samples were processed using published methods and cfDNA was measured using real-time PCR. *Results.* We compared data for the SCD and α-SCD groups, on and off HC therapy. The α-SCD group showed: significantly higher cfDNA levels, both for patients on HC (p=0.04) and off HC (p=0.04); significantly smaller increases in MCV (p=0.02) and MCH (p=0.01) in response to HC therapy; smaller reduction in the number of days spent in hospital due to SCD pain (p=0.02). *Conclusion.* Clinical response to HC (as measured using MCV, MCH and days spent in hospital due to sickle pain) was significantly attenuated in the SCD patients with co-existing α-thalassemia. We also showed that cfDNA levels (a known marker of trauma and organ damage) were higher in the α-SCD group, both on or off HC therapy. This may be related to reduced hemolysis in α-SCD patients. Co-inherited α-thalassemia, present in a third of all SCD patients, should be taken into consideration both in the clinical and laboratory setting when interpreting HC response.

CLINICAL MANIFESTATION OF SICKLE CELL DISEASE IN THE HBS/HBA CHILD: CAN CRITERIA TO IDENTIFY 'NON HEALTHY' CARRIERS BE ESTABLISHED?

R Colombatti,[1] E De Bon,[2] A Bertomoro,[2] M Fantinato,[1] MT Sartori,[2] L Sainati[1]

[1]*Pediatric Hematology Oncology Unit, Azienda Ospedaliera-University of Padova, Padova, Italy*
[2]*Coagulation Group and 2nd Chair of Internal Medicine, Department of Cardiologic, Padova, Italy*

Background. Sickle-cell trait (SCT) affects more than 300 million people worldwide (100.000 in Italy) and has been considered as a benign carrier state. Recently, evidence of severe clinical manifestations (renal medullary cancer, exercise related deaths, exertional rhabdomyolysis, venous thromboembolic events) associated with the carrier state has emerged, mainly in the adult population. Moreover, it has been reported that adults with SCT can develop conditions that are typical of sickle disease (SCD), such as acute chest syndrome (ACS) and vaso-occlusive pain crises (VOC). Less information is available for SCT children, even if an increase in invasive pneumococcal disease and single case observations of VOC have been reported. *Aims.* To evaluate if clinical features of SCD can develop in SCT children; to determine social, clinical or laboratory predictive factors for precocious development of such complications in SCT children in order to identify a subgroup of SCT carriers that might benefit from close clinical observation or therapeutic options. *Methods.* All SCT children at the Sickle Cell Clinic of the Pediatric Hematology Oncology Unit receive a full blood test and clinical examination once a year. We performed a retrospective analysis of the charts of SCT children evaluated at our Center from January 2000 to December 2010 to identify admissions or reports of clinical events related to SCD. Social, clinical and laboratory variables were evaluated to identify possible predictors of a more severe phenotype of the SCT child. Informed consent was obtained. *Results.* 50/163 patients were HbA/HbS, therefore SCT. 23 M and 27 F. 86% were African, 10% European and 4% South-American. Mean age at diagnosis was 37 months. 7/50 children had been admitted at least once for some cause; 4 of them (4/50, 8%) were admitted for SCD related complications: ACS (1), VOC (2) and haemolytic crisis (1) (Table 1). Moreover, patient n3 (see Table 1) displays frequent VOC that require minor opioid treatment at home. At steady state, children admitted for SCD related complications (Group 1) had higher mean

Table 1.

Diagnosis and treatment for children with SCT admitted due to SCD related complications

	Age	Clinical Manifestation	Treatment
Patient 1	2 years	VOC crisis with Hemolysis	i.v. pain killers, i.v. hydration Top-up Transfusion
Patient 2	6 years	ACS- Necrotizing Pneumonia Pneumococcal Sepsis	O2, Salbutamol, i.v. Antibiotics, Red Cell Exchange Transfusion
Patient 3	6 years	Recurrent VOC requiring hospitalization	i.v. pain killers-morphine, i.v. hydration
Patient 4	2 years	Hemolytic crisis with fever	i.v. hydration, i.v. Antibiotics

WBC (9827/m3 vs 7019; p=0.002), Hb (12 g/dl vs 11; p=0.014), MCV (77 fL vs 70; p=0.002) compared to children never admitted for SCD related complications (Group 2), while percentage of HbS and HbF were similar in the two groups (32.9% vs 32.3%, p=0.73 and 2% vs 5%, p=0.38, respectively). Interestingly, Group 1 children also showed higher FVIII activity (183.6% vs 124.7%, p=0.001) and VWF antigen (171.8% vs 113%, p=0.001), with normal inflammatory markers in both groups. *Conclusions.* A subgroup of SCT children displays clinical manifestations of SCD, even at young age. Several laboratory values seem to be higher in symptomatic SCT children. The expression of a hypercoagulable pattern could represent a risk factor for disease severity in children with SCT. Some coagulation tests might be a non invasive and useful tool to identify a subset of carriers with an increased risk of SCD related complications. These children could deserve a clinical approach similar to that recommended for SCD patients. Prospective and larger studies are needed to confirm our findings. rcolombatti@gmail.com

NEWBORN COHORT WITH SICKLE CELL ANEMIA: ASTHMA INCREASES THE RISK FOR ACUTE CHEST SYNDROME BUT NOT THE RISK FOR THOSE OCCURRING FOLLOWING VASO-OCCLUSIVE CRISES

F Bernaudin, A Kamdem, C Arnaud, N Médejel, F Madhi, C Tassel

Intercommunal Creteil Hospital, Creteil, France

Background. Acute chest syndrome (ACS) is a frequent cause of morbidity and a leading cause of death among individuals with sickle-cell-anemia (SCA). ACS is characterized by new pulmonary infiltrates on the chest X-ray with varying degrees of respiratory signs and fever. ACS can have infectious (pneumococcus, mycoplasma…) or noninfectious (vascular thrombosis, fat embolism) causes. Asthma is associated with a risk of frequent ACS. *Aims.* to evaluate if asthma also increases the risk of ACS occurring following vaso-occlusive crises (VOC/ACS). *Methods.* SS/Sb0 patients of the Creteil Newborn Cohort, seen before 3 months of age and followed at the SCA-Center in Créteil (CHIC) from 1986 to 2010, were included in this study (n=286). Alpha/beta genotypes and G6PD activity were determined. Blood parameters were recorded at steady state during the second year of life. VOC requiring hospitalizations, ACS and ACS occurring following VOC (VOC/ACS) were recorded. The latter was ascribed to patients who were not febrile and had a normal chest X-ray at admission for VOC and who subsequently developed ACS with presence of a new pulmonary infiltrate on the chest X-ray. The yearly rates of VOC, ACS and VOC/ACS were calculated for the period before any intensification (transfusion program, hydroxyurea or stem-cell transplantation). *Results.* Out of the 286 SCA-patients (140M, 146F), 29 (10.1%) had a physician-assessed diagnosis of asthma. Alpha-Thal was present in 102/232 (44%) patients; beta-haplotypes, available in 207 patients, were Car/Car in 91 (44%), Ben/Ben in 45 (22%), Sen/Sen in 15 (7%), and others in 56 (27%). G6PD-deficiency was present in 32/249 (12.8%). At baseline, mean (SD) blood parameters were: Hb: 8g/dL (1.2); Ht: 24% (3.9); MCV: 79.1 fL (8.9); HbF: 14.8% (8.4); LDH: 947 UI/L (380) and reticulocytes: 294 (121); WBC: 14.1 (5.1), neutrophils 5.8 (3.2) x 109/L. Median follow-up was 8.2 yr (range 0.2-22), providing an overall of 2638 patient-years during which 1661 VOC, 455 ACS including 158 VOC/ACS, were observed. Intensification (n=165/286) consisted of hydroxyurea (n=87), transfusion program (n=129), geno-identical stem-cell transplantation (n=47), with several patients receiving more than one intensive therapy. During the1765 patients-years before any intensification, the mean rates (events/year of follow-up without intensive therapy) of VOC, ACS and VOC/ACS were 0.87, 0.35 and 0.15, respectively. The KM-estimated cumulative risk of at least 2 ACS episodes by age 8 was 36.2% (95%CI: 32.4-40%) in patients without asthma but 62.3% (95%CI: 52.5-72.1%) in those with asthma (Log-Rank p<0.001). In contrast, the risk of VOC/ACS was not significantly different in patients with or without asthma [39.9% (95%CI: 29.7-50.1%) vs 35.1% (95%CI: 31.4-38.8%)] and (Log-Rank p=0.1). Cox-regression analysis showed that gender, G6PD deficiency, beta-haplotypes and alpha-thal were not risk factors for ACS and VOC/ACS whereas asthma significantly increased the risk of ACS occurrence (HR: 3.6, 95% CI:2.1-6.2,p<0.001) but not that of VOC/ACS (HR: 1.6, 95% CI:0.9-3,p=0.11). *Conclusion.* Results from this newborn cohort confirm that a diagnosis of asthma increases the risk of ACS but show that it does not associate with VOC/ACS, suggesting that only ACS due to infections are implicated.

SERUM FERRITIN AND TOTAL UNITS TRANSFUSED FOR ASSESSING IRON OVERLOAD IN SICKLE CELL DISEASE

E Drasar,[1] N Vasavda,[2] N Igbineweka,[2] M Allman,[3] M Awogbade,[3] SL Thein[1]

[1]*King's College and King's College Hospital, London, United Kingdom*
[2]*King's College, London, United Kingdom*
[3]*King's College Hospital, London, United Kingdom*

Background. Blood transfusion therapy in sickle cell disease (SCD) is increasing and with this comes the morbidity and mortality associated with the consequent iron overload. Whilst patients on regular blood transfusions have their iron indices monitored regularly, patients receiving "as required" blood transfusions can accrue a substantial iron load unnoticed. Serum ferritin (SF) is widely available but can be unreliable in SCD due to the inflammatory nature of the condition. R2 magnetic resonance imaging (R2MRI) is a recognised non-invasive method of estimating LIC but has limited availability. A simple method of assessing iron load in patients having regular and intermittent transfusions is required. *Aims.* To assess the prevalence of iron overload in patients with SCD with a view to highlighting those for further investigation or chelation. *Method.* This is a retrospective review of patients in our sickle cell database (King's College Hospital [KCH], London) over a 20 year period from 1st January 1990 to 31st January 2011. Adult patients (≥16 years of age) were identified who had steady-state SF levels and accurate transfusion history. Patients of all genotypes and chelation histories were included. LIC was assessed non-invasively by R2MRI (Ferriscan®) in 52 patients and cardiac T2* was performed concurrently in 18 cases. Clinical characteristics obtained were age, frequency of transfusion (regular vs as-required), total top-up units transfused (TUT) and LIC. *Results.* 317/660 patients had received at least one unit of blood. 52/317 patients (mean age 35 years, range 20-62) had SF ≥1000 ng/ml, mean 2550ng/ml (range 1003-16000). R2MRI data was available in 31/52 patients; 30 (97%) of which had LIC ≥2mg/g dry-weight [gDW] (NR 0.7-1.8), mean 21 mg/gDW (range 2.1 - >43). 27/30 (87%) of the patients with increased LIC had received ≥20 TUT (mean 152, range 26-342), transfusions were planned in 13 and "as required" in 14. The mean LIC in this group of 27 patients was 23.4mg/gDW (range 4.4->43), 22 patients had LIC≥7mg/gDW (mean 27.2, range 7.2->43). Transfusions were planned in 18/52 (35%) patients, their mean SF was 3985ng/ml (range 1244-9093) and mean TUT, 181 (range 22-342). 13/18 patients had R2MRI data and all 13 had increased LIC (mean 20.1, range 4.7->43 mg/gDW). Transfusions were sporadic in 34/52 (65%) patients; their mean SF was 2826 ng/ml (range 1003-16000) and mean TUT, 76 (range 12-335). 18/34 patients had R2MRI data of which 17 had LIC ≥2 mg/gDW (mean 21.6, range 2.1 - >43) and 11 had LIC ≥7mg/gdw (mean 31.5 range 8.5->43), none of whom were chelated. Only 6 patients with SF ≥1000ng/ml had received <20 TUT, these were all sporadically transfused; 3 had LIC data (2.1, 2.1 and 2.3mg/gDW, respectively). All cardiac T2*MRIs were within normal limits (mean 34 ms, range 27-43.1). *Summary.* Sporadically transfused patients can become heavily iron overloaded with mean SF and LIC on par with those on transfusion programmes; a combination of ≥20 TUT with SF≥1000ng/ml is suggested as a useful screening test. This audit highlights the need for addressing iron chelation therapy in both sporadically and regularly transfused SCD patients.

0728

REVISITING RISK FACTORS FOR SILENT CEREBRAL INFARCTION IN A COHORT OF LEBANESE PATIENTS WITH SICKLE CELL DISEASE

A Inati, M El Hawari, S Alameddine

Rafik Hariri University Hospital, Beirut, Lebanon

Background. Studies from the US and Europe continue to confirm a high rate of silent cerebral infarction (SCI) in children and adults with sickle cell disease (SCD), and highlight several potential risk factors. Data from Middle Eastern countries is scarce. *Aims.* to prospectively evaluate the prevalence and risk factors for SCI in Lebanese patients with SCD. *Methods.* This was a prospective study on a sample of SCD patients attending two comprehensive SCD centers in Lebanon. Patients with history of overt stroke were excluded. All patients underwent brain magnetic resonance imaging (MRI) as part of their annual surveillance. Complete blood counts, hemoglobin electrophoresis, steady-state serum ferritin, bilirubin, and lactate dehydrogenase levels were determined. Patient charts were reviewed for demographics, transfusion and spleen status. Written informed consent was provided by all patients. *Results.* A total of 123 patients (87 SS and 36 SThal) were included in the analysis. The mean age was 14.6 ± 10.3 years (range, 2-51 years), with 73 (59.3%) patients being males. Twenty (16.3%) patients had evidence of silent cerebral infarction (SCI) on brain MRI. Patients with SThal had a lower yet statistically similar frequency of SCI as patients SS (11.1 vs. 19.3%, P=0.274). Patients with SCI were significantly older than patients without SCI (mean age 20.2 ± 10.2 vs. 13.5 ± 10.0 years, P=0.007), but had a similar proportion of males (65% vs. 58.3%, P=0.574). A statistically similar proportion of patients were splenectomized (SCI: 10% vs. no SCI: 26.3%, P=0.118) or had persistent splenomegaly (SCI: 40% vs. no SCI: 43.4%, P=0.777) in both groups. Patients with SCI had significantly lower mean HbF% (11.9 ± 8.3% vs. 17.3 ± 11.8%, P=0.019) and higher mean HbS% (79.9 ± 13.3% vs. 69.3 ± 17.4%, P=0.012) than patients without SCI; but had similar mean total hemoglobin levels (9 ± 1.1 mg/dl vs. 9 ± 1.2 mg/dl, P=0.956). There were no statistically significant differences in mean white blood cell counts, reticulocyte count, total or direct bilirubin, or lactate dehydrogenase levels between the two groups. The median number of total life time transfusions and the median steady-state serum ferritin levels were comparable in both groups (SCI: 17 units vs. no SCI: 10 units, P=0.0311) and (SCI: 258.5 ng/ml vs. no SCI: 245.5 ng/ml, P=0.531). On multivariate logistic regression, a 1-% increase in HbS% was associated with a 1.06 increased odds of having a SCI (95% CI 1.01-1.11) and a 1-year increase is age was associated with a 1.06 increased odds of having a SI (95% CI: 1.01-1.10). *Conclusions.* Silent cerebral infarction in patients with SCD is associated with advancing age and increasing HbS%, but not with anemia, hemolysis, transfusion status or iron overload. SThal patients can have SCI as frequent as patients with SS.

0729

MATERNAL AND FETAL COMPLICATIONS IN SICKLE CELL DISEASE: OUTCOMES FROM A 10 YEAR STUDY AT MOUNT SINAI HOSPITAL IN TORONTO, CANADA

R Ward,[1] E Warner,[1] M Sermer[2]

[1]*University Health Network/University of Toronto, Toronto, Canada*
[2]*Mount Sinai Hospital/University of Toronto, Toronto, Canada*

Background. Sickle cell disease is an inherited recessive hemoglobinopathy affecting nearly 1 in 600 African Americans. The disease is caused either by homozygous substitution of valine for glutamic acid (HbSS), or less commonly compound heterozygous with lysine (HbSC), in the number 6 position of the β globin polypeptide chain causing haemoglobin polymerization and subsequently sickling of the red blood cells in deoxygenated states. This leads to hemolysis-related nitric oxide depletion, anemia and painful vaso-occlusive crises with resultant chronic ischemia-reperfusion injury. While pregnancy was discouraged in the past, recent improvements in patient management, transfusion medicine and neonatal care have led to pregnancy and delivery becoming increasingly safe. As one of the largest hemoglobinopathy centres in North America, we have undertaken the first known study in Canada to examine these outcomes in our population. *Aims.* To identify maternal and fetal complications in pregnant women with Sickle Cell Disease, with reference to the Ontario population. *Methods.* A retrospective study of consecutive deliveries of sickle cell patients (SS, SC, HbS/BetaThal) at Mount Sinai hospital from September 2000 through December 2010 was conducted. Maternal demographics, pregnancy complications including transfusions, mode of delivery, apgar scores and fetal complications were recorded. Patients were identified from the Special Pregnancy Database and the Delivery Databases of Mt. Sinai Hospital. Electronic patient records from the Toronto General Hospital, and paper charts from Mt.Sinai Hospital were reviewed. *Results.* A total of 83 pregnant patients: 71 (86%) HbSS, 10 (12%) HbSC and 2 (2%) HbS/BetaThal was reviewed. All had singleton live birth deliveries with no neonatal mortality. Median maternal age was 27 years (range 17-38) with a median gestational age of 38 weeks (range 26-42). Twenty two women (27%) delivered before the 37th week and 32 women (39%) delivered by Caesarean Section. Pregnancy complications: preterm premature rupture of membranes 4 (5%), pregnancy induced hypertension 5 (6%), gestational diabetes 5 (6%), hospitalizations for pain crisis 22 in 15 patients (18%) (range 1-4), transfusions 15 (18% of pregnancies) acute chest syndrome 2 (2%), pneumonia 3 (4%), urinary tract infection 4 (3 upper and 1 lower; 5%).The mean birth weight was 2838±734 g. Eighteen neonates (22%) had a birth weight< 2.5 kg. Mean apgar scores at 1 and 5 minutes were 7.9±1.9 and 8.8±0.8 respectively. Fetal complications were few: IUGR 3(3.6%), oligohydramnios 2(2%), meconium stained amniotic fluid 23%. There were no fetal malformations. *Summary/Conclusions.* The C-section rate was higher than the 2006/2007 Ontario rate for the general population of 28%, but similar to other sickle cell studies reported in the literature with reported rates of 29-36%. Preterm labour and neonates with a low birth weight(<2.5 kg) are similar to the 25% and 21%, respectively found in the Cooperative Study of Sickle Cell disease but larger than the 2005/ 2006 Ontario rates of 8.6% and 7% respectively. Other pregnancy and fetal complication rates compare favourably to previous reports. Pregnancy in women with Sickle Cell Disease can be managed effectively by an experienced multidisciplinary team including hematologists and high risk pregnancy obstetricians.

0730

CARDIAC, RENAL, AND THROMBOEMBOLIC COMPLICATIONS OF SICKLE CELL TRAIT AND DISEASE

M Bucknor,[1] A Coates,[2] J Goo,[3] M Coppolino[3]

[1]*University of California, San Francisco, San Francisco, United States of America*
[2]*Division of Research, Kaiser Permanente, Oakland, CA, United States of America*
[3]*Kaiser Permanente Medical Center, San Francisco, CA, United States of America*

Background. Many complications of Sickle Cell Trait (SCT) and Sickle Cell Disease (SCD) have been well established, but other potential comorbidities remain controversial. Few large cohort studies have addressed these questions. *Aims.* To examine the frequency of select cardiac, renal, and thromboembolic complications which may be associated with SCT (hemoglobin AS) or SCD (hemoglobin SS) by examining a large cohort of African-American patients with SCT, SCD, and normal hemoglobin, in the Kaiser Permanente Northern California patient databases. *Methods.* Institutional review board approval was obtained according to institutional standards. A retrospective cohort study was conducted of African Americans in the Kaiser Northern California patient databases. Inclusion criteria were all African Americans at least age 18 on December 31, 1996 who were known to have normal hemoglobin, SCT, or SCD. Cohorts were defined through a combination of laboratory data and charted ICD-9 codes. The following outcomes were investigated: renal disease (acute, chronic), coronary artery disease, congestive heart failure, ischemic stroke, and thromboembolism. Outcomes were defined using both chronic conditions registries and charted ICD-9 codes. Preliminary analysis compared 2794 patients with SCT to 282 patients with SCD and 11,609 patients with normal hemoglobin. Relative risks were calculated and adjusted for sex, age-group, hyperlipidemia, obesity, and months of membership during 1997 through 2008. *Results.* The following adjusted relative risks compared to patients with normal hemoglobin were calculated. The relative risk of chronic kidney disease in SCT patients was 1.14 (95% confidence interval [CI] 1.04-1.25) and the relative risk of pulmonary embolism was 1.31 (95% CI 1.03-1.67). There were no other significant differences in the outcomes for SCT patients compared to the AA cohort. The relative risk of acute kidney injury (2.24, 95% CI 1.75-2.86), chronic kidney disease (1.38, 95% CI 1.12-1.69), congestive heart failure (1.46, 95% CI 1.03-1.65), and pulmonary embolism (3.50, 95% CI 2.31-5.31) were significantly higher in patients with SCD compared to controls with normal hemoglobin. Other venous thrombosis/embolic events were not significantly increased in the SCD group. *Summary/Conclusions.* We report a slightly elevated risk of chronic kidney disease and an elevated risk of pulmonary embolism in SCT patients relative to those with normal hemoglobin, however we did not demon-

strate any relative increase in any of the interrogated cardiac outcomes. Patients with SCD demonstrated an increased risk of acute and chronic kidney disease, CHF, and pulmonary embolism.

0731

ELEVATED TRICUSPID REGURGITANT JET VELOCITY IN LEBANESE PATIENTS WITH SICKLE CELL DISEASE IS ASSOCIATED WITH MORE SEVERE DISEASE, FAMILIALY CLUSTERED AND NOT RESPONSIVE TO HYDROXYUREA

M Abboud,[1] R Khoury,[2] D Karam,[2] S Muwakkit,[2] R Saab,[2] P Nietert,[3] M Arabi,[4] F Bitar[4]

[1]*American University of Beirut, Medical Center, Beirut, Lebanon*
[2]*Children's Cancer Center of Lebanon,American University of Beirut, Medical Center, Beirut, Lebanon*
[3]*Department od Medicine, Medical University of South Carolina, Charleston, United States of America*
[4]*Department of Pediatrics, American University of Beirut, Medical Center, Beirut, Lebanon*

Background. Elevated tricuspid regurgitant jet velocity (TRV), a measure of pulmonary hypertension, is associated with increased morbidity and mortality in adult patients with sickle cell disease (SCD). Its significance in a younger population is unclear. *Aim.* The objective of our study was to find an association between elevated TRV and parameters of disease severity, hemolysis and hydroxyurea (HU). *Methods.* We conducted a review of all patients with SCD referred to our comprehensive care center. We assessed disease severity by the frequency of vaso-occlusive crises, acute chest syndrome, findings on transcranial doppler screening (TCD), in addition to the presence of retinopathy, stroke, splenic sequestration, proteinuria, and avascular necrosis. Elevated TRV was defined as ≥2.5m/s. *Results.* We studied 220 patients with SCD at our institution, 92 (41.8%) patients had a TRV ≥2.5 m/s. Four patients underwent cardiac catheterization, and all of them were found to have an elevated pulmonary artery pressure. The median age was 15 years (range: 3 to 43 years) with a M:F ratio of 1.04. Of the 92 patients, 78 (84.7%) had HbSS, 10 (10.8%) HbSβ+, 3 (3.2%) Sβ0, and one has HbSD. Patients with an elevated TRV were significantly more likely to have at least 3 vaso-occlusive crises per year (42.4%) and recurrent episodes of acute chest syndrome (45.6%) as compared to patients with a TRV<2.5m/s. Seventeen patients (18.5%) had avascular necrosis of at least one joint, four patients (4.3%) had proteinuria, three (3.3%) had retinopathy, and 2 patients (2.1%) had a stroke. Nineteen patients with elevated TRV underwent transcranial Doppler (TCD) screening and all were within normal limits. Fifty-seven patients (62%) had been on hydroxyurea upon presentation with a mean dose of 18.5mg/kg/day. Currently, sixty-four (69.6%) patients are on HU with a mean dose of 21.5 mg /kg/day. Increasing the HU dose by a mean of 3mg/kg/day, did not have any effect on lowering the TRV, but was associated with a decrease in LDH by a mean of 82 IU/L, and a modest mean decrease in total bilirubin (0.3mg/dL), WBC count (2285/cu.mm) and reticulocyte count (1.5%). Hemoglobin and MCV increased by a mean of 0.5g/dL and 8fL respectively. Similar results were seen when using 2.6m/s as a cutpoint. In addition to that, we found that 17 families had 2 or more members with elevated TRV, and patients with a positive family history of high TRV had a higher index of severity for the disease. *Conclusions.* The prevalence of elevated TRV ≥ 2.5 m/s was 42% in our population of patients with SCD. While increasing the hydroxyurea doses did result in a decrease in the hemolysis parameters, it did not seem to lower the TRV. Patients with elevated TRV had severe disease as compared to those with normal TRVs. Familial clustering of elevated TRVs was seen in our highly consanguineous population, which might point to an underlying genetic predisposition for developing pulmonary hypertension.

0732

RENAL IRON LOAD IN SICKLE CELL DISEASE CORRELATES WITH HAEMOLYSIS BUT NOT WITH HEPATIC IRON

N Vasavda,[1] L Gutierrez,[2] M House,[2] E Drašar,[3] T St Pierre,[2] SL Thein[3]

[1]*King's College London, London, United Kingdom*
[2]*University of Western Australia, Crawley, Australia*
[3]*King's College London & King's College Hospital, London, United Kingdom*

Background. Sickle cell disease (SCD) is characterised by chronic hemolysis and frequent vaso-occlusive episodes eventually leading to end organ damage. Renal impairment affects 11% of patients with sickle cell anaemia, increasing further with age. Both the vaso-occlusive and hemolytic aspects of SCD have been implicated in renal failure, as assessed by glomerular filtration rate (GFR) and microalbuminurea. Additionally, the increasing use of blood transfusion therapy SCD has resulted in a sub-population with secondary iron overload. Studies have shown that, for similar liver iron concentration (LIC), the prevalence of organ damage differs between patients with β-thalassemia and SCD. *Aims.* To investigate the significance and etiology of renal iron accumulation in SCD patients. *Methods.* 41 patients from the specialist hematology clinic at King's College Hospital, London had already had an assessment of hepatic iron loading by spin density projection assisted R2-MRI (FerriScan®) as part of their clinical care programme and/or as part of another study approved by the NHS Research Ethics Committee (REC 05/Q0703/21). Due to the retrospective nature of the study, a waiver was obtained from the REC and informed consent was not required of patients for this study. Renal R2 (R-R2) values were derived from monoexponential fits to kidney image data obtained during LIC assessment in order to assess kidney iron concentration. Clinical data were collected retrospectively for the 2 year period prior to the MRI scan. Thresholds for renal hyperfiltration and microalbuminurea were MDRD eGFR ≥140 ml/min/1.73m^2 and albumin:creatinine ratio ≥4.5 mg/mmol, respectively. *Results.* R-R2 values showed no correlation with LIC. Highly significant correlations were seen between R-R2 and bilirubin ($r=0.62$, $p<0.0001$) and with lactate dehydrogenase levels ($r=0.61$, $p<0.0001$). α-globin genotypes were available in 37 patients; those with co-inherited α-thalassaemia had a lower mean R2 (22.86 ± 1.727 N=12) than those without (28.22 ± 1.924 N=25), but this did not reach significance (p=0.086). R-R2 was significantly higher (p=0.014) in patients with renal hyperfiltration (mean 30.48 ± 2.655) than those without (23.11 ± 1.468). A weak but significant negative correlation was observed between renal R2 and age ($r=-0.35$, $p=0.027$). We note that the renal hyperfiltration group were also significantly younger (p=0.003) than those with normal filtration rates (29.8 ± 2.9 vs. 42.3 ± 2.5 years). However, microalbuminurea showed no relationship with R-R2. *Conclusion.* We showed that renal R2, a surrogate for renal iron load, is not related to liver iron concentration, but correlates strongly with markers of hemolysis. Though not significant, mean renal R2 was noticeably lower in the α-thalassemia group, in keeping with studies showing that reduced hemolysis and delayed onset of renal impairment in SCD patients with α-thalassemia. The relationship between R-R2, hyperfiltration and age could be related to the increased total renal blood flow and increased GFR at a young age falling as nephropathy progresses with age. While hemolysis is a major determinant of renal vasculopathy and impaired renal function, the small sample size do not seem to show any correlation between microalbuminuria and renal R2.

0733

BONE DISEASE IN YOUNG EGYPTIAN PATIENTS WITH BETA-THALASSEMIA MAJOR AND INTERMEDIA: CORRELATION WITH BIOCHEMICAL, HORMONAL AND GENETIC PROFILES

A Tantawy,[1] H Elsedfy,[2] A AAdly,[2] E El Gohary,[2] A Mortaga[2]

[1]*Faculty of Medicine, Ain Shams University, Cairo, Egypt*
[2]*Faculty of Medicine, Ain Shams University, Cairo, Egypt*

Background. Bone disease is an important cause of morbidity in beta-thalassaemia major (TM) and thalassemia intermedia(TI) patients. Thalassemia osteopathy results from a variety of genetic and acquired factors. Objectives: to study the magnitude of bone disease in TM and TI patients and to assess the influence of biochemical, hormonal and genetic factors. *Methods.* In a cross sectional study ,95 patients (55 TM ,40 TI), aged 13-30 years (mean 17± 3.8 years) were evaluated for BMD by Dual x-ray absorptiometry for lumbar spine and femoral neck. Anthropometric measures and Tanner stage were assessed. The effects of sex, transfusion/chelation program as well as disease duration were evaluated. Laboratory evaluation included: CBC, serum calcium, phosphorus, serum ferritin level, bone alkaline phosphatase, parathyroid hormone and 25-OH-vitamin D. PCR - RFLP technique was used to analyze VDR gene FokI polymorphism. *Results.* Weight/Height SDS, Height/Age SDS, sitting height SDS were comparable in TM and TI; BMI SDS was lower in TM compared to TI (P=0.02). Hormonal replacement therapy was given to 65% of studied patients. Six TM patients (5%) reported pathological fracture, 61.7% gave history of bone pain (66% TM and 40% TI). BMD was reduced in 90 % of thalassemics: 60% had osteoporosis and 30% had osteopenia. In TM patients spine Z-score (-3.3 ± 1.4) was lower than femoral Z-score (-0.68 ± 1.3, p= 0.000). The spine Z score was lower

in TM compared to TI patients (P=0.039). Negative correlation was found between the age and femur Z-score [P= 0.000], femur T-score [P= 0.000] and spine Z-score [P= 0.03]. Sex was not correlated to BMD. Positive correlation was present between pretransfusion Hb and spine Z score (P<0.05); transfusion frequency and both spine Z score (p<0.000) and Femur T-score (P<0.04). Negative correlation was present between serum ferritin and femur T-score [P= 0.019], femur Z-score [P= 0.03], spine T-score [P= 0.03]. BMI SDS had positive correlation with femur T-score [P= 0.04], spine T-score [P= 0.03] and spine Z-score [P= 0.04]. Positive correlation was found between spine Z score and Height /Age SDS [P= 0.004], sitting Ht SDS [P= 0.03]. 75% had low serum calcium, none was symptomatic. 72.5% had low PTH level and 9% had hypoparathyroidism. None had low 25-OH-vitamin D. Bone alkaline phosphatase was elevated in 95% of patients. BMD was not correlated to serum calcium or PTH levels. Spine Z-score was negatively correlated with bone alkaline phosphatase [P<0.001]. The genotypic frequency of VDR FokI gene was: FF 52.5%, Ff 22.5%, ff 17.5%. BMD femur Z score was highest in FF genotype (p = .041). *Conclusion.* Thalassemia osteopathy is multifatorial but in our community inadequate transfusion and the resulting bone marrow expansion as well as poor chelation resulting in iron toxicity to the osteoblasts are important factors, possibly modified by the VDR gene polymorphism.

0734

RENAL DYSFUNCTION IN CHILDREN AND YOUNG ADULTS WITH B-THALASSEMIA MAJOR

M Economou, A Teli, A Kondou, N Printza, F Papachristou, M Athanassiou-Metaxa

Hippokration General Hospital, Thessaloniki, Greece

Backround. Patients suffering from β-thalassemia major have now improved life expectancy due to regular transfusions and chelation therapy, however, chronic complications still develop - some only recently identified. Both tubular and glomerular dysfunction has been reported, although in a relatively limited number of reports. Renal involvement has been attributed to iron overload, chronic anemia, transfusion rate and chelation therapy, mainly to the newer chelator deferasirox. The exact mechanism of renal injury still remains unclear to a large extent. *Aims.* Evaluation of renal involvement in children and young adults with β-thalassemia major and correlation of findings with iron overload and chelation therapy. *Methods.* Thirty three patients on regular transfusion and chelation therapy, aged 4-20 years (mean age 12±4.7 years), participated in the study. Mean pre-transfusional haemoglobin level was 9.4±0.37 g/dl. For analysis purposes, patients were divided into 2 groups based on chelation therapy: group A consisting of 18 patients receiving deferasirox and group B of 15 patients receiving other chelation (3/15 patients receiving deferioxamine, 2/15 patients deferiprone and 10/15 patients combined deferioxamine and deferiprone therapy). The two groups did not differ with regards to age, sex and haemoglobin, but group A presented with lower ferritin values compared to group B (mean 1003±505ng/dl and 1744±592ng/dl, respectively, p=0.001). None of the patients presented additional risk factors for renal involvement. In addition to conventional renal biochemistries, acid-base balance, glomerular filtration based on the Schwartz formula, fractional excretion of sodium (FENa), tubular phosphorus re-absorption and urine calcium and protein were measured. *Results.* All participating patients had normal blood markers of renal function and electrolyte values, as well as normal acid-base balance parameters. Mean glomerular filtration rate was 125±19.9ml/min/1.73m2, mean tubular phosphorus re-absorption 93±1.9% and mean FENa 0.54±0.2%. 75.7% of patients (25/33) presented with increased urine calcium, with a mean value of 6.4±3mg/kgr/24h. 45% of patients (15/33) had an increased urine protein level, with a mean of 146±102 mg/24h. Protein and calcium urine levels did not differ statistically between the two chelation groups (p=0.85 and p=0.77, respectively). With regards to iron overload, there was a negative correlation between ferritin value and urine protein (r=0.454, p=0.09). Finally, a positive correlation was found between protein and calcium urine levels (r=0.304, p=0.085). *Conclusions.* Study results confirm the presence of renal involvement in thalassemia patients, developing at an early age. In addition, the study demonstrates a high risk of proteinuria in patients with lower ferritin values, possibly due to chelation nephrotoxicity developing at lower iron burdens. Although the study does not demonstrate correlation between tubular or glomerular dysfunction with any of the iron chelation methods, further studies are needed in order to arrive at safer conclusions.

0735

EVALUATION OF RENAL INVOLVEMENT IN CHILDREN AND ADOLESCENTS WITH SICKLE/BETA THALASSEMIA OF GREEK ORIGIN

M Economou,[1] E Papadopoulou,[2] A Teli,[2] N Printza,[2] V Tzimouli,[2] E Farmaki,[2] N Gompakis,[2] F Papachristou,[2] M Athanassiou-Metaxa[2]

[1]*Aristotle University of Thessaloniki, Thessaloniki, Greece*
[2]*Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece*

Background. Sickle cell nephropathy encompasses a large spectrum of abnormalities. However, few studies have assessed parameters of renal involvement in patients of young age with sickle cell disease (SCD), while relative literature in sickle/beta-thalassemia (S/b-thal) patients is even more limited. *Aim.* The aim of the present study was to evaluate the renal function in children and adolescents with sickle/beta-thalassemia of greek origin. *Patients and Methods.* For the purpose of the study 17 S/b-thal patients, aged 3.5 to 18 years (mean 10.97 ± 4.87 years) were evaluated. Mean haemoglobin (Hb) level was 9 ± 0.7 g/dl. None of the patients was recently hospitalized, was on hydroxyurea or a chronic transfusion program, nor presented additional risk factors for renal disease. In addition to conventional renal biochemistries, estimated glomerular filtration rate, serum cystatin C (Cys C), fractional excretion of sodium (FENa), tubular phosphorus re-absorption and urine calcium, protein, microalbumin and β2 microglobulin (β2 MG) were measured. Moreover, renal ultrasound was performed. *Results.* Mean eGFR was 142.2 ± 22.5 ml/min/1.73m2, with approximately half of the patients (8/17) presenting with an eGFR of > 150 ml/min/1.73m2. Mean urine specific gravity was 1011.3 ± 3.9. No patient presented with microscopic hematuria or with hypercalciuria. Biochemical urine analysis revealed normal sodium excretion and phosphate re-absorption. In all patients serum Cys C and urine β2 MG levels were within normal range. However, 29.4% of patients (5/17) demonstrated impaired glomerular function with proteinuria or microalbuminuria (11.8% and 17.6%, respectively). Regression analysis revealed no correlation between age, annual number of vaso-occlusive crisis, Hb, HbF, eGFR, LDH, Cys C or β2 MG levels with the presence of proteinuria or microalbuminuria. Renal ultrasound was normal in all cases. *Conclusions.* Our study revealed a considerably high rate of proteinuria and microalbuminuria in the young S/b-thal group studied. To the best of our knowledge, this is the first study to specifically assess renal involvement in young patients with sickle/beta-thalassemia and of the same ethnic origin. Of interest is the finding of proteinuria and microalbuminuria in patients during their first decade of life. Given that glomerular damage seems to develop early and irrespective of pain rate in S/b-thal patients, it is recommended that regular testing of relative markers is performed in this patient group.

0736

PERCUTANEOUS ENDOSCOPIC GASTROSTOMY FEEDS IMPROVE WEIGHT AND BODY MASS INDEX IN CHILDREN WITH SICKLE CELL DISEASE AND FALTERING GROWTH

Y Leigh, A Nolan, J Cryer, D Lethaby, M Doukrou, B Kaya, A Simmons, H Newell, J Khair, S Phelps, P Telfer

Barts and the London Hospital NHS Trust, London, United Kingdom

Background. Children with Sickle Cell Disease (SCD) frequently experience malnutrition, faltering growth and delayed puberty. Growth failure in children with SCD is linked to increased nutritional requirements, endocrine dysfunction, metabolic derangement and deficiencies in specific nutrients. It is postulated that haemolysis and increased erythropoietic activity lead to increased protein and nutrient turnover and utilisation. Faltering growth is unusual in children with SCD below 2 years old, becomes more apparent by 8-9 years of age, and is seen most frequently in the pubertal years. Nutritional supplementation, hydroxyurea and long term blood transfusions have been shown to improve growth in children with SCD. *Aims.* This study aims assess the impact of instigating Percutaneous Endoscopic Gastrostomy (PEG) feeds on growth parameters in children with SCD and faltering growth. *Methods.* Children attending the Paediatric Haematology clinic at the Royal London Hospital aged 5-16 with SCD and faltering growth (Body Mass Index (BMI) <9th centile, and/or weight static for 6 months), in whom dietary fortification and nutritional supplementation had failed, had a PEG inserted. An overnight feed regime of 500-1000 mls Fresubin Energy was then instigated over 8-10 hours. Weight and height data was collected at 3 monthly intervals pre- and post- PEG insertion. Weight, height and BMI Z-scores were calculated and change

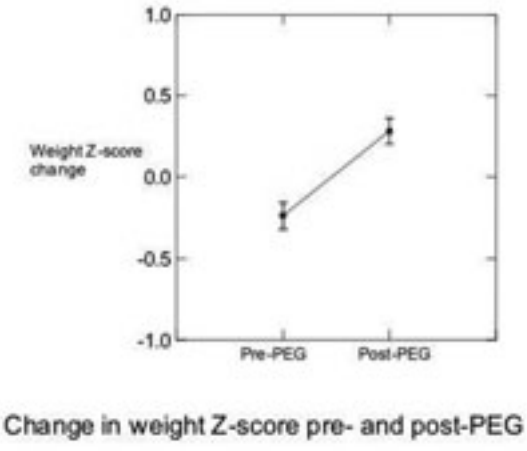

Figure 1.

in Z-scores analysed using SYSTAT 10.2. *Results.* Gastrostomies were inserted in 12 children between November 2008 and February 2011 (9 boys and 3 girls). The median age at PEG insertion was 14 years (range 11-15 years). There was one death prior to completion of the study unrelated to the PEG. Change in weight, height and BMI Z-scores were calculated and compared pre- and post-PEG insertion. Using the ANOVA Estimate Model there was a statistically significant difference in weight Z-score change (P=0.001, see fig. 1) and BMI Z-score change (P=0.01) after commencing PEG feeds. There was a non-significant positive change in height Z-score (P=0.329). *Summary/Conclusion.* Faltering growth and maturational delay are common in children with SCD. This study provides evidence that PEG feeding improves weight and BMI Z-scores in children with SCD and faltering growth. Although height Z-scores did not change significantly this may reflect the lag in linear growth versus weight gain, or the small sample size. Pubertal delay was frequently seen and the majority of subjects demonstrated improved pubertal development. Patient and carer surveys demonstrated high a level of patient and carer satisfaction with PEG feeding. We plan to commence a randomized controlled trial of PEG feeding versus standard nutritional supplementation in children with SCD and faltering growth

0737

LONG-TERM EFFICACY AND SAFETY OF DEFERASIROX IRON CHELATION IN 104 PEDIATRIC PATIENTS WITH TRANSFUSION-DEPENDENT ANEMIAS IN TWO UK INSTITUTIONS

R Gregg,[1] M Marsella,[2] M Howard-Jones,[1] S Lawson,[1] H Newell,[2] N Fofana-Kaje,[2] P Telfer,[2] P Darbyshire[1]

[1]*Birmingham Children's Hospital, Birmingham, United Kingdom*
[2]*Barts and the London NHS Trust, London, United Kingdom*

Background. Children with transfusion-dependent anemias require lifelong iron chelation. Deferasirox, a once-daily oral iron chelator, provides an attractive alternative to subcutaneous chelation. Published sub-analyses demonstrate that, compared with adult patients, children achieve slower dose escalations and have differing pharmacokinetics. This may impact efficacy. These concerns, coupled with the requirement for lifelong usage in pediatric patients, provide compelling reasons to monitor the long-term safety and efficacy of deferasirox in children. *Aims.* To examine the efficacy and safety of deferasirox in 104 pediatric patients with transfusion-dependent anemias in two UK institutions. *Methods.* Data on 104 patients pediatric patients (<16 years) with transfusion-dependent β-thalassemia and sickle cell disease were retrospectively collected in two UK institutions. Data were collected from initiation of deferasirox therapy (up to 54 months). Efficacy was monitored via serum ferritin (SF) and MRI T2*/R2 data. Iron burden was calculated from annual transfusional requirement. Dosage, toxicity and safety were assessed by examination of contemporaneously recorded patient records and measurement of laboratory parameters, including serum creatinine and liver enzyme levels. *Results.* The median age of patients was 9y 1m (range 26m -16y). Disease characteristics were: Sickle cell disease (n=45) and thalassemia (n=59). Annual blood transfusion was 188 ml/kg for β-thalassemia and 121 ml/kg for sickle cell disease. Median duration of evaluation for sickle cell patients was 18 months (range 3-54m). Thalassemic patients were followed for a median duration of 24 months (range 12-39m). The mean starting dose of deferasirox for thalassemic patients was 15mg/kg, with a mean dose of 27mg/kg at final follow-up. In sickle cell disease the mean doses were 19mg/kg and 21 mg/kg respectively. Mean (SD) SF at baseline for thalassemic patients was 2009 ng/ml (770 ng/ml), 2773 ng/ml (967 ng/ml) for sickle cell disease. Mean SF was significantly reduced over time (p=0.003). The change in SF over time was inversely correlated with the dosage of deferasirox for the thalassemia cohort (Fig. 1).

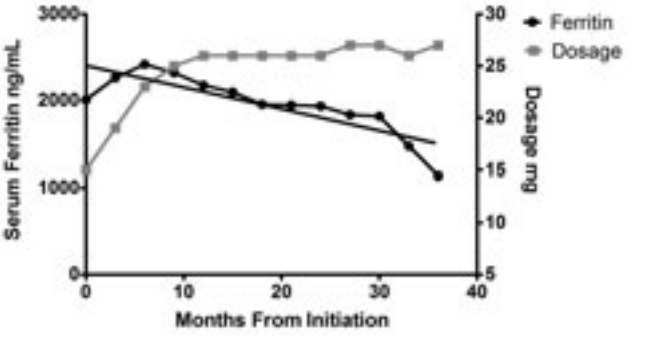

Figure 1.

This association was not apparent in sickle cell disease. Sequential T2* MRI Data was available for 36 patients over at least 2 consecutive years. A reduction in the mean cardiac T2* time of 6.04ms (95% CI -9.907 to -2.175) was seen (p=0.007). Liver T2* showed no significant change. The most commonly recorded adverse events were transient gastrointestinal symptoms. 23 patients (22%) experienced abdominal pain, nausea, vomiting and diarrhoea. These symptoms rarely required dose adjustment (n=4) or discontinuation (n=3). Skin rash occurred in 6 patients with 1 discontinuation. Increases in serum creatinine were observed in 19% of patients receiving deferasirox. Sustained increases of greater than 33% outside of the age appropriate normal range occurred in 7 patients. 4 of 7 responded to dose reduction with 3 patients being discontinued. Discontinuations for other reasons included one patient with an increased alanine aminotransferase and two with unsatisfactory efficacy. *Summary/Conclusions.* Our data confirm deferasirox effectively reduces the SF and cardiac iron burden and highlights the importance of dose titration. Deferasirox was generally well tolerated in pediatric patients with a safety profile consistent with data from previous clinical trials.

Genomics

0738

ROLE OF ETO2 IN THE EPIGENETIC REGULATION OF ERYTHROID GENES

T Fujiwara, A Wael, H Harigae

Tohoku University Graduate School of Medicine, Sendai, Japan

Background. Developmental control mechanisms often utilize multimeric complexes containing transcription factors, coregulators, and additional non-DNA binding components. It is challenging to ascertain how such components contribute to complex function at endogenous loci. We recently analyzed the function of components of a complex containing master regulators of hematopoiesis (GATA-1 and Scl/TAL1) and the non-DNA binding components ETO2, the LIM domain protein LMO2, and the chromatin looping factor LDB1. We revealed that ETO2 and LMO2 regulate distinct target gene ensembles in erythroid cells. Furthermore, it was found that ETO2 commonly represses GATA-1 function via suppressing histone H3 acetylation, and also regulates methylation of histone H3 at lysine 27 (H3-trimeK27) at select loci, which suggested that ETO2 might be an important determinant of the erythroblast epigenome (Fujiwara *et al.* PNAS. 2010). *Aims.* We investigated the role of ETO2 in the epigenetic regulation of erythroid genes. *Methods.* CBFA2T3 mRNA (which encodes ETO2 protein) was cloned into pcDNA3.1 (Clontech) and Flexi HaloTag vector (Promega), and ETO2 was transiently overexpressed in K562 cells using Amaxa nucleofection technology® (Amaxa Inc.). Quantitative ChIP analysis was performed using anti-acetylated H3K9 (abcam), anti-trimethyl H3 (Lys 9 and 27) (Millipore) and anti-Myc (Santa Cruz). To induce erythroid differentiation of K562 cells, hemin was treated at a concentration of 30 uM for 24h. For transcription profiling, human whole expression array was used (Agilent). Gene Ontology analysis was based on DAVID software (http://david.abcc.ncifcrf.gov/home.jsp). *Results.* Overexpression of ETO2 in hemin-treated K562 cells resulted in decreased ratio of benzidine-staining positive cells, suggesting ETO2 retards the erythroid differentiation of K562 cells. Next, we conducted microarray analysis to characterize ETO2 target gene ensemble in K562 cells. The analysis demonstrated that 598 genes were downregulated in the ETO2-overexpressed cells (>2 fold). To test what percentages of ETO2-repressed genes could be direct target genes of GATA-1 or GATA-2 in K562 cells, we merged the microarray results with ChIP-seq profile (n= 5,749 and n=21,167 for GATA-1 and GATA-2 ChIP-seq peaks, respectively) (Fujiwara *et al.* Mol Cell. 2009), and demonstrated 23.1% and 40.5% of ETO2-repressed genes contained significant GATA-1 and GATA-2 peaks in their loci, respectively. Gene Ontology analysis among ETO2-repressed genes revealed significant enrichment of genes related to "oxygen transport/ hemoglobin complex" (p=0.00128). Overexpression of ETO2 in K562 cells resulted in the significant decrease in the expression of globin genes such as HBG, HBB, HBE1, HBA, HBM and HBZ by quantitative RT-PCR. Quantitative ChIP analysis revealed ETO2 occupancy at globin HS2. Furthermore, the overexpression significantly increased H3-trimeK27 and reduced acetylated H3K9 at γ-globin promoter. Co-immunoprecipitation analysis revealed the interaction between ETO2 and EZH2, a member of polycomb repressor complex responsible for H3-trimeK27-mediated transcriptional repression. We are currently analyzing the mechanism of ETO2-dependent transcriptional repression and how ETO2-dependent histone marks are established in erythroid cells. *Conclusion.* In conjunction with the evidence that ETO2 binds histone deacetylases and associates with GATA-Scl/TAL1 complex that binds epigenetic modifiers, ETO2 appears to have important roles in establishing the erythroblast epigenome. We consider this is important from the perspective of elucidating mechanisms of hematopoiesis and leukemogenesis.

0739

INTEGRATION OF GLOBAL SNP-BASED MAPPING AND EXPRESSION ARRAYS WITH MICRORNA PATTERNS REVEALS DEREGULATION OF MIR-370 AND PERMITS THE IDENTIFICATION OF ITS TARGET GENE NF1 IN ACUTE MYELOID LEUKEMIA

L García Orti, I Cristóbal, C Cirauqui, E Guruceaga, N Marcotegui, M Gonzalez-Huarriz, A Orta, C Vicente, MM Alonso, MD Odero

CIMA, Pamplona, Spain

Deregulated microRNA (miRNA) expression has been largely reported to play a crucial role in tumorigenesis. Recent studies have shown different mechanisms leading to miRNA deregulation in cancer: mutations, chromosomal translocations, epigenetic alterations, and defective miRNA biogenesis; however, alterations affecting miRNAs by DNA copy number variations (CNV) remain poorly studied. Our aim was to identify if CNVs affect the expression levels of miRNAs in acute myeloid leukemia (AML), modulating the expression levels of their target genes. We analyzed 16 myeloid cell lines by an integrative approach including high resolution SNPs arrays, mRNA expression arrays, and quantification of 250 miRNAs by real-time PCR. We found correlation between the expression levels of 19 miRNAs and CNVs affecting the genomic regions in which these miRNAs are located: 16 miRNAs were upregulated and located in two genomic regions of amplification (11q24 and 14q32), and 3 miRNAs were downregulated and located in regions with genomic deletions (13q14 and 9p21). These results prompted us to analyze the expression levels of their predicted target genes. After performing a whole genome expression analysis in the cell lines, we obtained a set of candidate genes whose altered expression (B>0) may result from deregulation of 9 out of these 19 miRNAs. The differential expression of these selected 9 miRNAs and their predicted targets were validated by QRT-PCR. Three miRNAs had NF1 as a potential target gene; therefore, we analyzed whether miR-370, miR-379, or miR-494, all located on 14q32.31, could regulate NF1. The AML cell line HL-60, with low expression of the miRNAs was chosen as a cellular model for miRNA overexpression experiments. Analysis by QRT-PCR confirmed overexpression of these microRNAs after transfection with the corresponding pre-miRNAs. Western blot analysis showed that NF1 levels decreased after miR-370 overexpression. No changes in NF1 levels were observed after ectopic expression of miR-379 and miR-494. Furthermore, transfection with pRL-NF1(3'UTR) in cells ectopically expressing miR-370 showed decreased luciferase reporter activity, indicating that miR-370 binds to 3'UTR of NF1 regulating its expression. These results highlight that presence of copy number alterations affecting miRNAs represent an alternative mechanism to deregulate the expression of genes with importance in myeloid leukemia development. Further studies are in progress to identify other genes with importance in AML and deregulated by CNVs affecting miRNA expression. e-mail address: laura_garcia_orti@hotmail.com

ANTIBODY ARRAY-BASED PROTEOMIC PROFILING OF CHILDHOOD ACUTE LEUKEMIA

T Kalina,[1] V Kanderová,[1] J Stuchl ,[1] K Fišer,[1] D Cerná,[1] A Holm,[2] W Wu,[2] O Hrušák,[1] F Lund-Johansen[2]

[1]*Charles Univ., 2nd Faculty of Medicine, Praha 5, Czech Republic*
[2]*University of Oslo, Oslo, Norway*

Background. Mapping of signaling pathways and searching for new prognostic molecular markers is a promising approach to design specific treatment of leukemia while minimizing the adverse effects. Large-scale proteomic profiling is expected to yield more direct answers to functional and pharmacological questions than does transcriptional profiling on mRNA level. Performing large-scale proteomic profiling on primary leukemia samples and understanding the effect and functional consequences of targeted anti-cancer agents requires high-throughput technologies as well as novel analytical strategies. Here, we employ bead-based antibody arrays, which can follow changes in protein expression levels that may associate with clinical presentation and therapy efficacy of acute leukemias. *Methods.* Cellular proteins are separated by a differential detergent treatment to cytoplasmic, membrane and nuclear proteins, labeled with biotin and subjected to size-exclusion chromatography to obtain 24 fractions. Fractions are incubated with a mixture of 1700 color-coded beads each carrying antibodies against single protein target. Mixture of all beads binding their specific proteins is analyzed by flow cytometer that resolves beads' color-code and records the amount of captured protein.[1] This novel concept has several advantages: 1) High level of multiplexing by color-coded beads (1700 bead types) 2) Additional information based on protein size profiles (e.g. protein-protein interactions) 3) Flexibility in array composition (custom selected e.g. phospho-specific antibodies) 4) Semi-automated analysis (gating, quality control, normalizations) Algorithms for semi-automated analysis are implemented in R-project environment. It allows for color-code interpretation, captured protein signal read-out and downstream batch analysis including protein size recognition and clustering of results. Array performance was tested on ten representative B-cell precursor (BCP-ALL), T-cell acute lymphoblastic leukemia (T-ALL) and acute myeloid leukemia (AML) cell lines. Next, 30 bone marrow specimens of childhood leukemia at diagnosis were analyzed.

Results. Antibody arrays can accurately determine lineage assignment of leukemia cells (BCP-ALL, T-ALL, AML) in cell lines as well as in patient samples. In parallel to surface proteins, intracellular proteins are quantified (transcription factor Ikaros, E2F, Pax-5; cell cycle machinery CDKN1A, CDKN2D; phosphorylated signaling molecules BLNK, CBL, FYN, IRS1). In total, over 300 protein entities were found. The array allowed us to obtain dose dependent and reproducible results. *Conclusions.* High-throughput quantitative analysis of cellular proteome opens new possibilities for understanding cellular signaling and biology of acute leukemias.

Mantle cell lymphoma (MCL), an aggressive B-cell NHL is characterized by a poor long-term prognosis with a median survival of 3-5 years. Obinutuzumab (GA101), a Fc-engineered type II CD20 humanized IgG1 antibody has been shown to result in higher direct cell death induction, increased ADCC and a significant higher cytotoxicity when compared to type I anti-CD20 antibody Rituximab. We conducted our study to investigate possible differences in downstream signal pathways of the antibodies. Using sensitive MCL cell lines Rec-1 and Granta-519 we evaluated the effect of GA101, rituximab and the combination of both antibodies on cell viability and proliferation. Granta 519 and Rec-1 were treated at a cell density of 5x105 cells/ml with GA101 or rituximab at a dose of 10 µg/ml. Samples of 3x106 cells were harvested and processed for 2D-PAGE analysis after a 4h exposure. Distinct protein spots with altered expression after antibody treatment from untreated controls were identified and analyzed by mass spectrometry. Affymetrix micro-array of MCL cell lines (Granta-519, HBL-2, Jeko-1, Rec-1, Z-138) was performed after 4h exposure of either GA101, rituximab or combination of both antibodies. Ingenuity Pathway Analysis of the identified genes was performed to elucidate downstream pathways. Mono-treatment with GA101 achieved 70% cell reduction in Granta-519 and 40% in Rec-1. In contrast, rituximab led to 25% and 5% cell reduction in Granta-519 and Rec-1. Combination treatment of both antibodies led to a cytotoxicity comparable to rituximab mono-exposure. Analysis of 2D-PAGE protein maps revealed 40 and 39 distinct differently expressed protein spots after GA101 and rituximab treatment. Analysis revealed that 23 of these protein spots were commonly altered after both antibodies (CCDC158, MACF1, RAB39, RAD23B). 17 (ENO1, MKI67, NPM1, HSPA5) and 16 proteins were uniquely altered after GA101 and rituximab treatment only (e.g. DST, G3BP2, LMO7, PSMD13). Micro-array-analysis showed 2-3 (Granta 519) to 14-78 (HBL) modulated genes after antibody exposure in all five MCL cell lines. Distinct sets of candidate genes after rituximab (BCL2A1, CHL1, LILRA4, LPL, LY9, RHEBL1, SOX11, WNT3) and GA101 (EGR2, EGR3, NFATC1, SPRY2, ZBTB24) were affected in multiple cell lines. Proteome and transcriptome-based analysis depicted different sets of candidate molecules, which were mapped to common cellular functions including e.g. "cell death", "cellular growth and proliferation" and "cell cycle". Interestingly, combination of GA101 and rituximab resulted in a rituximab-like expression pattern, both on RNA and protein level. Proteome and transcriptome-based experiments showed antibody-specific downstream expression patterns of GA101 and rituximab. These results might represent the molecular basis of the superior effect of GA101 in comparison to rituximab. Combination treatment with both antibodies revealed a rituximab-like expression pattern that confirmed our previous experiments on cell viability and proliferation. Proteomic screening identified a group of proteins relating cellular stress response mechanisms and cellular energy metabolism to the treatment of the therapeutic antibody GA101. These results indicate a possibly involved autophagy mechanism after GA101-treatment and a stress response mechanism effecting regulation of cellular metabolism. These results will provide a further step into identifying molecular-based rationales for new combined therapeutic approaches to treat MCL.

Background. MDS is a clonal bone marrow disorder characterized by cytopenia due to ineffective hematopoiesis and a high risk of evolution to AML. MDS is mainly a disease of the elderly and is rare in pediatric patients. The WHO classifies MDS in several subgroups in the first place based on morphologic assessment of bone marrow cells. Even if similar morphological diagnosis is used to identify MDS it is understood that pediatric MDS is quite different from adult MDS. Since some years genomic aberrations in MDS are reported and aid in improving molecular-risk classification. Mutations in the *TET2* gene are described in MDS and MPN with percentages varying from 12-22% and in AML *TET2* mutations found in 23% of patients have prognostic impact and are significantly association with older age. In fact, several studies have reported that *TET2* mutations were not identified in pediatric MDS specimens. NGS (NextGenerationSequencing) 454 amplicon sequencing offers a fast, reliable and highly sensitive method of screening for sequence variants and is currently investigated for reproducibility across laboratories. *Aims.* To set up a platform for NGS sequencing for 454 amplicon sequencing of pediatric leukemia and MDS/JMML specimens and to verify in the first place the occurrence of *TET2* mutations in pediatric MDS/JMML. *Methods.* In the context of the Interlaboratory Robustness of Next-Generation Sequencing study (IRON) nine pediatric patients, 6 with diagnosis of JMML and 3 with MDS were sequenced for 27 amplicons covering all coding exons of *TET2*. Primers pairs included a 10-base molecular identifier barcode sequence (MID) to recognize each specific patient. We used Genome Sequencer Junior instruments (Roche Applied Science). All data was generated using the GS Junior Sequencer Instruments Software and sequence alignment and variant detection was performed using the GS Amplicon Variant Analyzer (AVA) software version 2.5 (Roche Applied Science). Sequencing analysis by Sanger sequencing was used to confirm mutation detection in 454 ultra deep screening. *Results.* We generated amplicon ultra deep sequencing of 27 amplicons of *TET2* gene for 9 MDS/JMML patients with a median coverage per amplicon of 650-fold. In total we identified 68 variants in *TET2* gene occurring in more than 1% of bidirectional reads. Of these variants, 6 were known SNPs in MDS and JMML patients with a coverage of > 40% (40-100%) of reads per patient (rs61744960, rs12498609, rs17253672, rs2454206 and rs 34402524). In one MDS patient, a 16 years old boy we found a novel missense mutation C/T in exon 11 of *TET2* at aminoacid T1980I (ENST 00000380013) (RMA = 43.91% of reads). The mutation was confirmed by Sanger sequencing. *Summary/Conclusions.* Ultra-deep amplicon sequencing offers a fast and reliable approach for mutation detection and can be basically implemented in mutation screening of candidate genes in leukemia diagnostics laboratories. We have counter currently detected a novel *TET2* mutation in an adolescent boy with MDS seemingly indicating that *TET2* mutations are rare in pediatric MDS/JMML but may be found in the upper age group of pediatric patients.

[2]*Virgen de las Nieves University Hospital, Granada, Spain*

Invasive Pulmonary Aspergillosis (IPA) is the most common cause of infection-related deaths in patients with haematological cancers. Despite

the availability of new antifungal drugs, the incidence of IPA is rising as a result of a wider use of broad-spectrum antibiotics, novel immunomodulatory therapies and an increasing proportion of susceptible patients such as solid organ transplantation recipients or critical care patients. Dendritic Cell-Specific Intercellular adhesion molecule-3-Grabbing Nonintegrin (DC-SIGN), Dectin-1 and Dectin-2 are transmembrane C-type lectins that are involved in the recognition of fungal pathogens. The recognition of Aspergillus conidia by dendritic cells or macrophages as well as the chemotactic activity mediated by CCL2/CCR2 ligand-receptor axis, are critical steps in the defence response against Aspergillus. It has been suggested that both processes might be, at least in part, genetically determined. Thus, the aim of this study was to assess whether the presence of single nucleotide polymorphisms (SNPs) within DC-SIGN, Dectin-1, Dectin-2, CCL2 and CCR2 genes influence on the risk of Invasive Pulmonary Aspergillosis. A tag SNP approach resulted in a selection of twenty-seven tagging polymorphisms that were genotyped in 217 high-risk patients with haematological malignancies. Out of 217 haematological patients, seventy patients were diagnosed with proven or probable IPA (following the EORT/MSG criteria, update 2008) and the remaining 147 patients were classified as not infected. Our results revealed that patients bearing the DC-SIGN_rs4804800_G, DC-SIGN_rs11465384_T and DC-SIGN_rs7248637_A alleles had an increased risk of IPA infection (per-allele OR=2.73 95%CI 1.53-4.87; PTrend=0.0004; OR=2.73 95%CI 1.39-5.40; PTrend=0.0035 and OR=2.08 95%CI 1.16-3.72; PTrend=0.013, respectively). In addition, carriers of the DC-SIGN_rs7252229_C showed a slightly increased risk of IPA infection (per-allele OR=1.68 95%CI 0.94-3.00; PTrend=0.078). Likewise, patients harbouring the DC-SIGN_rs4804800_G or DC-SIGN_rs7252229_C alleles showed an increased frequency of galactomannan positivity that those carrying the A or G allele, respectively (p=0.06 and p=0.08). These results strong suggest that DC-SIGN polymorphisms might modulate the risk of IPA infection and might be useful as biomarkers for patient stratification and to develop personalized treatment strategies. Nonetheless, these results need to be confirmed in larger cohorts of haematological patients.

LEUKEMIA GENE ATLAS - A PUBLIC PLATFORM TO SUPPORT RESEARCH AND ANALYSIS OF MOLECULAR DATA OF LEUKEMIAS

K Hebestreit, S Gröttrup, HU Klein, C Ruckert, C Bartenhagen, M Dugas

University of Münster, Münster, Germany

Background. The number of published studies regarding leukemias has been increasing enormously over the last few years. A vast amount of molecular data is collected, analyzed and published every year. Nevertheless, meta-analyses and comparisons of published studies are performed rarely. For researchers it is time consuming to get an overview of the range of published data and results. To obtain an insight into published data or to re-analyze data, e.g. to compare it with ones own data and results, is demanding for researchers who may lack the statistical background to analyze high-dimensional data. Conventional repositories, such as GEO, ArrayExpress and Oncomine, do not feature leukemia specific biological and medical annotations and do thus not cope with this particular kind of research. *Aims.* The Leukemia Gene Atlas was designed to support research and analysis of molecular data of leukemias and hence to fill this gap. *Methods.* The central part of the Leukemia Gene Atlas is a database storing the molecular data of published studies with the corresponding laboratory and clinical data, as well as results, e.g. gene signatures. Currently, the data spans from gene expression to methylation to next-generation sequencing data. The samples associated with the molecular data were classified and annotated leukemia specifically according to their biological and clinical characteristics. The database is publicly available via a website which supports the search and selection of studies and samples with comprehensive search functions. The website also provides a wide range of visualization and analysis tools to process the stored data. An exceptional implement is the search in published result tables which supports, for example, the search for studies and groups of samples whose gene expression patterns significantly differ for certain genes of interest. The website also offers the down- and upload of data. *Results.* Currently, the database stores 290 result tables and the data of 5,000 samples from nine studies and four data types (gene expression, methylation, genotypes and NGS). We intend to integrate many further data sets and thus to increase its versatility and usability. *Conclusion.* The Leukemia Gene Atlas supports the interpretation of newly measured data and is now online: www.leukemia-gene-atlas.org

IDENTIFICATION OF CHARACTERISTIC IGF2BP EXPRESSION PATTERNS IN B-LINEAGE NEOPLASMS

M Stoskus, E Gineikiene, V Valceckiene, B Valatkaite, R Pileckyte, L Griskevicius

Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania

Insulin-like growth factor 2 mRNA-binding proteins IGF2BP1, IGF2BP2, and IGF2BP3 have been shown to have diagnostic and prognostic utility in a number of epithelial and soft tissue tumors but the expression of these molecules in different types of leukemia is largely unknown. By using an RT-qPCR approach we have systemically analyzed the expression of the three *IGF2BP* coding genes in normal hematopoietic tissues and diverse hematopoietic malignancies. We show that low *IGF2BP1* and *IGF2BP3*, and high *IGF2BP2* expression are characteristic to donor bone marrow (BM) and peripheral blood (PB). Myeloid malignancies - acute myeloid leukemia (AML) and chronic myeloproliferative neoplasms (MPN) - essentially retain the "normal" *IGF2BP* expression profile. In contrast, lymphoid lineage neoplasms - acute lymphoblastic leukemia (ALL), chronic lymphocytic leukemia (CLL), and multiple myeloma (MM) - are associated with characteristic perturbations of *IGF2BP* expression pattern (Figure 1a). Namely, all lymphoid malignancies tend to underexpress *IGF2BP2* when compared to the normal corresponding tissue and myeloid lineage malignancies though it was statistically highly significant only in the case of CLL and MM ($p<0.001$) as revealed by 1-way ANOVA. In addition, CLL also shows a remarkable variation in *IGF2BP3* expression levels while MM appears to be virtually negative for this transcript (Figure 1a). The most prominent perturbations were identified in ALL where *IGF2BP1* and *IGF2BP3* varied over five and four orders of magnitude, respectively. As ALL is comprised of biologically and clinically different disease entities *IGF2BP* profiles were further reanalyzed with respect to this (Figure 1b). We have identified significant associations of overexpressed *IGF2BP1* with *ETV6/RUNX1*-positive ($p<0.001$), underexpressed *IGF2BP2* with *E2A/PBX1*-positive ($p<0.01$), and overexpressed *IGF2BP3* with *MLL/AF4*-positive ($p<0.001$) leukemias. In contrast to T-ALLs, B-ALLs negative for recurrent fusion genes underexpress *IGF2BP2* ($p<0.01$) and overexpress *IGF2BP3* ($p<0.001$) when compared to donor BM. Altogether, our results show that deregulation of normal *IGF2BP* expression pattern is associated with malignant B-lymphopoiesis. The potential utility of *IGF2BP* profiling in B-lymphoid neoplasms will emerge as the functions of *IGF2BP*s are further delineated.

This study was supported by the European Economic Area and Norwegian Financial Mechanism Grant No. 2004-LT0040-IP-1EEE.

C-CBL MEDIATES CYTOSKELETAL SIGNALS THROUGH RAC AND REGULATES INTERACTION OF IMMATURE HEMATOPOIETIC CELLS WITH THE BONE MARROW MICROENVIRONMENT

E Uehara,[1] T Suzuki,[1] M Sasazaki,[1] H Okabe,[1] M Ueda,[1] T Nagai,[1] T Ohmori,[1] Y Sakata,[1] M Sanada,[2] S Ogawa,[2] K Ozawa[1]

[1]*Jichi Medical University, Shimotsuke, Japan*
[2]*University of Tokyo, Tokyo, Japan*

c-Cbl is a ubiquitin E3 ligase and functions as a negative regulator for signals induced by various activated tyrosine kinases, by promoting ubiquitination and proteasomal degradation of these kinases. Recently, mutations of the c-cbl gene have been reported in hematopoietic malignancies, and regulation of hematopoietic stem/progenitor cells (HSPCs) by c-Cbl is attracting attention. c-Cbl has a C-terminal end with putative tyrosine residues that can interact with several signal transduction molecules, e.g. p85 subunit of PI3-kinase and adaptor molecule Crk, and several reports have denoted that this interaction may be important for cytoskeletal regulation. Since it is known that cytoskeletal dysregulation and impaired interaction of hematopoietic cells with the bone marrow microenvironment might be associated with malignant transformation, we investigated cytoskeletal regulatory mechanisms mediated by c-Cbl in immature hematopoietic cells. To examine the migratory capacity of the HSPCs, we performed migration chamber assay for SDF-1 was performed. We found that c-Cbl deficient HSPCs showed significantly decreased migration to SDF-1; the migration capacity of the Cbl deficient cells was one eighth compared with the wild-type (Wt) counterparts. Then, to evaluate *in vivo* homing ability to the bone marrow microenvironment, transplantation assays were performed. We transplanted 2.5 x 10e6 of HSPCs from c-Cbl deficient or Wt Ly5.2 mice into lethally irradiated Wt Ly5.1 mice. Three hours after transplantation, chimerism of the transplanted Ly5.2 cells in the bone marrow was examined, and we found that the proportion of transplanted cells was smaller in c-Cbl deficient cells, showing that homing capacity of c-Cbl deficient HSPCs was impaired. In c-Cbl deficient HPSCs, activity of Rac, a member of small G-protein GTPases, was significantly decreased. To confirm the role of Rac in the c-Cbl-mediated cytoskeletal signaling pathways, we transduced lentiviral vectors expressing Rac1 G12V, a constitutively active form of Rac1, into the Wt or c-Cbl-deficient HSPCs. G12V-trancduced c-Cbl-deficient HSPCs regained migration capacity to SDF-1 and bone marrow homing ability, suggesting that Rac1 is a key mediator for the cytoskeletal regulation by c-Cbl. Reduced Rac activity, impaired migration and homing abilities of c-Cbl-deficient HSPCs were rescued by re-expression of the full-length c-Cbl. But transduction of the c-Cbl Y700F/Y774F mutant could not restore these defects. Interestingly, transduction of the Y731F mutant, which abrogates the putative biding site for PI-3K, could recover these cytoskeletal functions, indicating that either Y700 or Y774, not Y731 is essential for the cytoskeletal regulation in HSPCs. In summary, we found that c-Cbl-deficient HSPCs showed impaired migration activities to chemoattractants and altered homing ability to the bone marrow microenvironment, with decreased activation of Rac. This cytoskeletal regulation is mediated by Y700 or Y774 residues of c-Cbl. Since phosphorylation of Y774 and Y700 creates binding sites for Crk, signaling cascades via c-Cbl/Crk/Rac might have a role in the engraftment of HSPCs. Our data propose a novel biological function of c-Cbl on the regulation of HSPC-microenvironment interaction.

CANONICAL WNT SIGNALLING MODULATES THE BEHAVIOUR OF STEM CELLS TRANSFORMED BY THE ACTIVE TYROSINE KINASE FUSION PROTEIN TEL/PDGFR BETA

E Dobbin,[1] A Tarafdar,[1] R Freeburn,[2] H Wheadon[1]

[1]*Paul O'Gorman Leukaemia Research Centre, Glasgow, United Kingdom*
[2]*University of the West of Scotland, Glasgow, United Kingdom*

Background. Leukaemia is initiated by the transformation of a haemopoietic stem cell (HSC). Aberrant activation of the Wnt pathway has been linked to leukaemia through various mechanisms; autocrine up-regulation of Wnt morphogens, epigenetic silencing of negative regulatory molecules and activation of down-stream signalling molecules. Although evidence supports a role for the canonical Wnt pathway in normal HSC self-renewal and haemopoiesis, how vital intrinsic and extrinsic Wnt signals are in sustaining leukaemic stem cells (LSC) and the leukaemic phenotype is still unclear. *Aims.* To determine the importance of intrinsic and extrinsic Wnt signalling in self-renewal and differentiation decisions using a LSC model. *Methods.* To address this we utilised a previously established and characterized tetracycline regulated embryonic stem (ES) cell model to express the oncogene Tel/PDGFRbeta. Activation of the pathway was achieved via pharmacological GSK3beta inhibitors, Wnt3a stimulation or by over-expressing a dominant positive form of beta-catenin. Self renewal was assessed by alkaline phosphatase staining and TaqMan Stem Cell Pluripotency Array. Haemopoietic commitment was assessed by flow cytometry and haemopoietic colony assays. *Results.* Expression of Tel/PDGFRbeta down-regulated the Wnt/GSK3beta/beta-catenin pathway and reduced ES cell self-renewal. Activation of the Wnt pathway substantially suppressed Tel/PDGFRbeta mediated differentiation, with Wnt 3a stimulation, over-expression of beta-catenin and the GSK3beta inhibitor BIO all having this capacity. Analysis via the pluripotency array identified the gene signature involved in Tel/PDGFRbeta mediated early differentiation. As expected key self-renewal genes were down-regulated and key differentiation genes up-regulated by Tel/PDGFRbeta. Several of which are implicated in other malignancies the most interesting being; Flt1 an active tyrosine kinase involved in angiogenesis, HBZ and Cdx2 which are also linked to leukaemic transformation. Activation of the canonical Wnt pathway either through expression of active beta-catenin or BIO treatment enhanced expression of self renewal/pluripotency genes down-regulated by Tel/PDGFRbeta (Nanog, Rex1, GDF3, sFRP2 & c-Kit), whilst suppressing expression of differentiation genes (Dnmt3b, Flt1, Podx1, Cd9, GCM1 & GFAP) and haemopoietic genes (GATA family, Mafb, Egr1 & 2, Nab2). These findings indicate Wnt signalling reduces the transcriptional flux induced by this oncoprotein, leading to suppressed differentiation and enhanced self-renewal of Tel/PDGFRbeta expressing stem cells. During haemopoietic differentiation Tel/PDGFRbeta biased ES cells to form myelomonocytic colonies. Flow cytometry analysis indicates that the oncogene drives haemopoiesis, by up-regulating the HSC specific markers; Sca1 and c-Kit and multipotent progenitor marker Flt3, resulting in more CD45+ haemopoietic cells present by day 8 of differentiation and more myelomonocytic colonies by day 15. Over expression of active beta-catenin was able to suppress Tel/PDGFRbeta ability to up regulate c-Kit and Flt3, and myelomonocytic differentiation. *Summary/conclusions.* Overall our data indicates that ES cells are a valuable tool for modelling leukaemia, especially to delineate the complex interactions occurring within the BM microenvironment. We clearly demonstrate that activation of the canonical Wnt pathway modulates the behaviour of LSC in our model, leading to enhanced self-renewal and suppressed differentiation. This has important implications as it demonstrates that the Wnt morphogens potentially play a greater role in sustaining LSC within the BM niche than previously perceived.

NOTCH REGULATES THE EXPRESSION OF HOXB4 AND GATA3 IN HEMATOPOIETIC STEM CELLS

J Schiavinato, L Oliveira, G Araujo, D Orellana, P Palma, T Covas, A Zago, R Panepucci

Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil

Background. The study of transcription factors (TF) and signaling pathways controlling processes involved in the biology of hematopoietic stem cells (HSCs), has conceptual and practical importance in the fields of stem cell expansion and differentiation for therapy purposes. In a previous study, we showed that the transcript levels of the NF-kB subunits RELB and NFKB2, NOTCH1, HOXB4 and GATA3 were at higher levels in the more primitive CD133+ enriched HSC subpopulation, as compared to total CD34+ HSC. Moreover, transcript levels of NOTCH1 were highly correlated to those of HOXB4 and GATA3, and of RELB and NFKB2. Additional promoter analyses, revealed the existence of binding sites (BS) for CSL (the DNA-binding partner of the active Notch intra cellular domain) in the promoters of all these transcripts; and also of NF-kB BS (except in NOTCH1 promoter). These results indicated the potential existence of a regulatory relationship among TF with important roles during T cell lymphopoiesis. *Aims*. To investigate, the potential regulation of GATA3 and HOXB4 by the Notch pathway, and its potential modulation by TNF-α, an activating-stimulus of the NF-κB pathway with known positive effects in T cell differentiation. *Methods*. Human CD34+ HSC were immunomagneti-

cally purified from umbilical cord blood (obtained after informed consent) and co-cultured for different periods (ranging from 12 to 132hs) with cells expressing the ligand Delta like 1 (OP9-DL1) agonist of Notch signaling, or not (OP9-GFP). Additional experiments were carried in the presence or absence of TNF-alpha (0.25ng/ml) and the Notch inhibitor DAPT (10μM), using HSC pre-treated (or not) with the protein synthesis inhibitor cycloheximidine (CHX) (10μg/ml). Real-time PCR was used to quantify transcriptional levels of the NOTCH targets, HES1 and HEY1, as well as GATA3 and HOXB4. GAPDH was used for normalization and relative expression was calculated using HSC co-cultured with OP9-GFP as reference samples. A nonparametric paired t-test was used to statistically access significance, using Prism 5 software. *Results*. As observed for HES1 and HEY1, the Notch pathway regulated the expression of GATA3 in the absence of de novo protein synthesis, inducing its expression after only 12h of coculture. The expression of HOXB4 was also induced by Notch signaling (peaking at 36h), probably indirectly, since, when protein synthesis was inhibited, its expression was observed even in the absence of Notch signaling (DAPT). Finally, Notch-induced expression of HEY1, GATA3 and HOXB4 were positively modulated by TNF-α at a physiologically relevant concentration (two orders of magnitude lower than commonly used in the literature). *Summary*. Our results demonstrate for the first time the transcriptional regulation of the HOXB4 and GATA3 by the Notch pathway in HSCs. This mechanism is very relevant in the context of early colonization of the thymic microenvironment, since, it establishes a direct link between the role of Notch in T cell commitment, with the role of HOXB4 in self-renewal and proliferation of early progenitors. Further dissection of these mechanisms may contribute for the development of new protocols for HSCs transplantation and in the study of leukemogenesis. Author email: josililian@gmail.com.

ACTIVATION OF DORMANT HEMATOPOIETIC STEM CELLS *IN VIVO* BY THE ENDOTOXIN LPS

M Essers,[1] R Lutz,[2] S Thamm,[3] A Kuck,[3] S Wurzer,[3] A Trumpp[1]

[1]*HI-STEM, DKFZ, Heidelberg, Germany*
[2]*HI-STEM, Heidelberg, Germany*
[3]*DKFZ, Heidelberg, Germany*

Maintenance of the blood system is dependent on dormant hematopoietic stem cells (HSCs). In order to both maintain a supply of mature blood cells and not exhaust HSCs throughout the lifespan of the organism, most adult HSCs remain quiescent and only a limited number are cycling at any given time. The balance between self-renewal and differentiation of HSCs is controlled by external factors such as cytokines, as well as interactions of HSCs with its niche environment. We have recently shown that the cytokine IFNa very efficiently activates dormant HSCs *in vivo*. Within hours after treatment of mice with IFNa HSCs exit G_0 and enter the active cell cycle. In general, IFNa is produced in response to viral infections by cells of the immune system, and plays an important role in the host defense against viral infections. We now questioned whether endogenous IFNa is also produced in response to other forms of bone marrow stress and whether this affects the proliferation rate of HSCs. To monitor IFNa production in the bone marrow *in vivo*, we have generated MxCre; ROSA-R25-EYFP mice and found that treatment with both the chemotherapeutic agent 5-FU as well as the endotoxin LPS leads to the production of IFNa in HSCs. In addition, LPS treatment *in vivo* induced a strong increase in proliferation of HSCs. To our surprise, mice lacking the IFNa receptor still respond to LPS, indicating that the induced proliferation of HSCs upon LPS treatment is independent of signaling via the IFNAR. In general, LPS will bind the TLR4-CD14 receptor complex on cells, leading to the cellular response to LPS. When mice lacking TLR4 are treated with LPS, HSCs are no longer activated in response to LPS, indicating that also the effect of LPS on HSCs is dependent on TLR4 signaling. Interestingly, LPS induced activation correlated with increased expression of Sca-1 on HSCs, similar to the increased Sca-1 expression upon IFNa treatment. As for IFNa, the up-regulation of Sca-1 is required for LPS induced proliferation, since Sca-1-/- mice do not respond to LPS stimulation. In summary, these data suggest that LPS induced bone marrow stress leads to the production of IFNa in the bone marrow and increased proliferation of the HSCs. Thus, in addition to viral infection also other forms of bone marrow stress, like LPS, result in activation of dormant HSCs in the bone marrow. Furthermore, both IFNa and LPS induced activation of HSCs are dependent on the up-regulation of Sca-1, suggesting a more general role for Sca-1 in the activation of stem cells.

[3]*MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom*

Background. The insulin-like growth factor (IGF) signalling pathway is important for proliferation and differentiation of haematopoietic stem cells (HSC) in mice. Activating mutations and/or aberrant IGF signalling are implicated in human cancers, including childhood leukaemia and myeloma. The 2 principal ligands, IGF1 and IGF2, both signal through the same transmembrane receptor, IGF1R while IGF2R negatively regulates IGF signalling by binding and internalising IGF2. Previous studies in mice suggest that IGF2 regulates fetal haematopoiesis and blocking IGF2/IGF1R signalling in human ES cells reduces their survival and clonogenicity. However, whether IGF1 and 2 are produced by fetal liver (FL) and bone marrow (BM) haematopoietic niches and their role in human fetal haematopoiesis are not known. *Aims and Methods.* To investigate this we assessed: i. IGF1/2 production by human FL and fetal BM MSC and fetal hepatocytes (cBAL111) ii. FL HSC and progenitor numbers and IGFR expression and response compared to adult BM HSC/progenitors (MPP, LMPP, CMP, MEP, GMP and B-cell progenitors- BCP). *Results.* IGF2, as assessed by qRT-PCR, confirmed by Western blotting, was similarly highly expressed by FL, fetal BM and adult BM MSC (n=4 each) and human fetal hepatocytes. IGF1 was expressed by adult BM MSC but barely detectable in fetal MSC and hepatocytes. Flow cytometric analysis in conjunction with clonogenic and lymphoid differentiation assays showed that FL compared to adult BM CD34+ cells contained a 2-fold lower frequency of HSC and BCP but 2-4-fold higher frequency of MPP, LMPP, CMP, MEP and GMP. Consistent with a physiological role for IGF2 in fetal haematopoiesis we found distinctly different patterns of IGF1R/IGF2R on fetal and adult BM CD34+ cells. In FL >95% of HSC and progenitors highly expressed IGF1R. IGF1R and IGF2R were highly co-expressed on HSC while fewer MPP, LMPP, CMP, MEP, GMP and BCP co-expressed IGF2R with IGF1R and at considerably lower levels than HSC. In contrast to FL, fewer adult BM CD34+ cells expressed IGF1R and IGF2R and at much lower levels (MFI ~7-fold-3-fold less).The selective production of IGF2 by FL niche and differential expression pattern of IGF2R on FL CD34+ sub-populations is consistent with a modulatory role for IGF2-IGF2R interaction on these cells. Co-expression of high IGF2R levels with IGF1R on FL HSC may restrict HSC expansion hence the lower frequency of FL HSC while lower IGF2R in MPP and other progenitors would facilitate their expansion which may explain high MPP/HSC ratios in FL. In clonogenic assays IGF2, but not IGF1, increased clonogenicity of FL CD34+ cells. IGF2 caused marked stimulation of BFU-e and megakaryocyte (MK) colonies and some CFU-GEMM and EPO-independent BFU-e. IGF1 caused modest stimulation of EPO-independent BFU-e at the expense of CFU-GM, although did not stimulate MK or CFU-GEMM suggesting differential downstream effects of IGF1R signalling in response to IGF2 compared to IGF1 in FL CD34+ cells. *Conclusion.* Together these data suggest a unique role for IGF2, rather than IGF1, in regulating normal fetal haematopoiesis in humans which may provide insight into the role of aberrant IGF signalling in childhood leukaemia, particularly in Down syndrome.

THE INFLUENCE OF MYCN GENE ON THE TRANSCRIPTIONAL REGULATION OF HEMATOPOIESIS

LJ Shen,[1] FY Chen,[1] M Zhong,[1] Y Zhang,[1] Y Kuang,[2] H Zhong,[1] JH Zhong[1]

[1]*Renji Hospital affiliated to School of Medicine,Shanghai Jiaotong University, Shanghai, China*
[2]*Shanghai Research Center for Biomodel Organisms, Shanghai, China*

Background. The MYCN oncogene is a well-established poor prognostic marker in hematopoietic malignancies (eg. AML), however the role of MYCN expression and the mechanisms by which it acts to promote an aggressive phenotype remain largely unknown. *Aims*. Induced murine MYCN gene overexpression in embryonic zebrafish

through heat-shock promoter, to establish stable germline transgenic zebrafish in order to study the influence of MYCN gene on the transcriptional regulation of hematopoiesis. *Methods*. Murine source MYCN cDNA was fused into the VEGF-tagged pSGH2 vector and was injected into zebrafish embryos at the one- or two-cell stage of development. These embryos were heat shocked in a 38°C incubator for 1 hour once between 14 to 19.5 hours post-fertilization(pf). MYCN-EGFP transgenic founder lines were identified on the basis of GFP expression at about 60 days pf. These founders were identified by fin clipping and genotyping, using PCR primers F:ATCACTGT-GCGTCCCAAGA, R:TTAGCAAGTCCGAGCGTGT. Then we established the stable germline transgenic zebrafish lines, to show its influence on hematopoietic regulatory factors through RT-PCR and the peripheral blood smear. *Results*. Eighteen of 256 (7.0%) mosaic F0 zebrafish embryos injected with the constructed vector were identified the germline transgenic zebrafish, including 8 male,10 female. We extracted blood cells at 60 dpf from wild-type and the F1, F2 generation of transgenic fish. Using cytology, we determined that the blood cells from wild-type fish are predominantly erythrocytes, with myeloid cells only occasionally observed. By contrast, the blood cells from the transgenic fish contain abundant blast-like cells, which are larger than the erythrocytes and have high nuclear to cytoplasmic ratios. We extracted RNA from embryos of 1 dpf, 3 dpf, 7 dpf, and adult fish of 2 months pf, using RT-PCR, we found that MYCN expression remarkablly results in scl (stem cells transcription factor, which is requirement in primitive hematopoiesis), mpo (myeloperoxidase; granulocyte specific gene) and gata1 (which is a master regulator in erythrocyte development) downregulation. Reversely, it upregulates c-mybwhich is predominantly expressed in immature hematopoietic cells, and its expression decreases as these cells differentiate. Correspondingly, MYCN expression downregulates NDRG1(N-Myc downstream regulated gene 1, which is defined as differentiation related gene 1). Therefore, the blood phenotype induced by MYCN expression results in an accumulation of immature hematopoietic blast cells, significantly inhibiting erythropoiesis, and the differentiation of myelopoiesis. *Summary.* Zebrafish offers the advantages of high-throughput scale in the study of gene function *in vivo*. We report here the generation of a highly tractable model of MYCN expression, showing that induced expression of MYCN in zebrafish embryos results in rapid manifestation of a robust phenotype that exhibits cytological and transcriptional hallmarks of human hematopoietic malignancies (eg. AML), suggesting that MYCN signaling pathways are likely to be conserved between human and zebrafish. Most importantly, using this model enabled us to track the molecular changes that take place well before morphological phenotypes can be detected, and to determine the roles of candidate MYCN target genes. We demonstrate that MYCN regulates scl and several lineage-specific transcription factors, reprogramming hematopoietic cell fate *in vivo*.

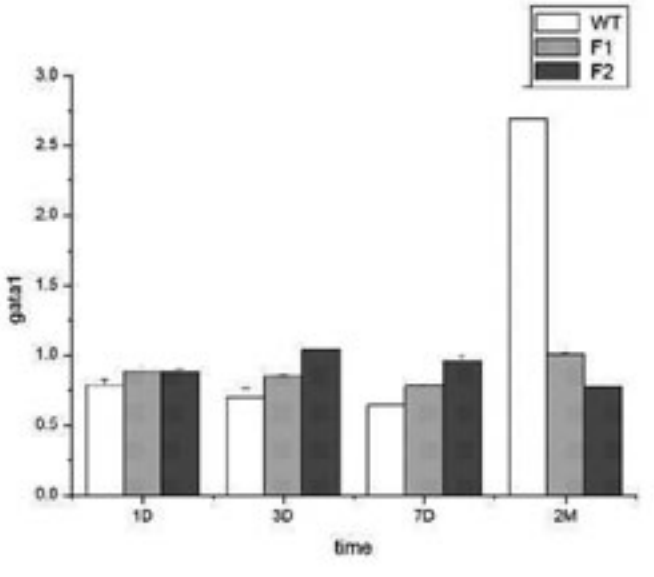

Figure 1. Comparation of gata1 expression between wild type.

THE GENERATION OF MONKEY AND PIG INDUCED PLURIPOTENT STEM CELLS OF EASY HANDLING FOR HEMATOLOGICAL RESEARCHES

Y Hanazono, S Fujishiro, S Masuda, T Abe, Y Mizukami, R Ishino, Y Furukawa

Jichi Medical University, Tochigi, Japan

Background. We have been studying hematopoietic reconstitution with stem cells *in vivo* in large animals such as monkeys and sheep. In this subject, induced pluripotent stem (iPS) cells have become very important as donor cells; however, human iPS as well as ES cells are not easy to handle. For instance, human iPS/ES cells grow slowly, their plating and subcloning efficiencies are very low, and transfection is quite difficult, as compared to mouse iPS/ES cells. iPS cells have also been generated from large animals including monkeys and pigs. These animal iPS cells have similar shortcomings to those of human iPS cells, and it hinders us to reproduce mouse results in large animal models. Recently, human iPS cells of easy handling with mouse-type characters have been generated by culturing the cells in the medium supplemented with LIF, signal transduction inhibitors (MEKi and GSKi), and an agonist for the protein kinase A pathway (forskolin) (Jaenisch *et al.* PNAS 2010;107:9222-9227). *Aims.* The aim of our study is to overcome the shortcomings (difficulties in handling) of human and large animal iPS cells previously generated, and to facilitate their use for hematological researches. In the present study, we have tried to generate monkey and pig iPS cells of easy handling (with characters similar to those of mouse iPS/ES cells). *Methods.* We prepared embryonic fibroblasts (PEFs) from cynomolgus monkeys and Clawn miniature pigs, and introduced Yamanaka's four genes (human Oct3/4, Sox2, Klf4, and c-Myc) with retroviral vectors into the cells. The cells were cultivated in the presence of forskolin. *Results.* After 14-20 days of the cultivation, emergent colonies were plucked and expanded for further analyses. Our newly generated monkey and pig iPS cells express pluripotency markers. They can be differentiated into three germ layer cells *in vivo* (<*ie.* teratomas in immunodeficient mice) and *in vitro*. Our monkey iPS cells resembled mouse iPS cells at first, but they became human iPS-like cells after several passages. On the other hand, our pig iPS cells have retained the mouse-type characters after extended passages unlike previously reported pig iPS cells. They show round-colony formation, rapid growth, LIF-dependency, capability of single-cell cultivation without a ROCK inhibitor, high viability after freeze-and-thaw, and easy transfectibility, like mouse iPS/ES cells. In addition, mouse iPS/ES cells do not express Xist (<*ie.* XaXa) or MHC class I, and that is also the case with our pig iPS cells. *Summary/Conclusions.* We have generated Clawn miniature pig iPS cells, which are easy to handle and similar to mouse iPS/ES cells in all the aspects tested. Their abilities to contribute to offspring chimeras remain to be investigated. In the Clawn miniature pigs, inbred animals are available and thus congenic transplant of our pig iPS cells is feasible. Currently, we are transplanting our pig iPS cells in the congenic setting.

HETEROGENIETY OF HUMAN BONE MARROW DERIVED MESENCHYMAL STROMAL CELLS

E Bigildeev, O Zhironkina, N Sats, I Shipounova, N Drize

National Hematological Scientific Centre, Moscow, Russian Federation

Background. In attempt to classify mesenchymal stem and progenitor cells basing on their proliferative potential (PP) the occurrence of hierarchy *in vitro* was revealed. Bone marrow (BM) mesenchymal cells were found to contain mesenchymal cells with high PP (HPP), with low PP (LPP), mesenchymal cluster-forming cells (MCFC), and mature mesenchymal cells (MMC). *Aims.* The aim of this study was to investigate the PP and clonal composition of BM derived multipotent mesenchymal stromal cells (MMSCs) during passages in culture. *Methods.* MMSCs from 6 donors (4 males and 2 females) 15-43 years-old were analyzed. $3x10^6$ BM nucleated cells were plated in 25 cm^2 flask in aMEM with 10% of fetal calf serum. The cells were passaged at the density 10^5 cells per flask after they reached confluent monolayer. MMSCs were infected with self-inactivating 4th-generation lentiviral vector bearing enhanced green fluorescent protein. At each passage the proportion of marked by lentivector (green) and viable cells was measured and MMSCs were cloned 1 cell per well in 96-well plate in standard medium supplemented with 5 ng/ml of basic fibroblast growth factor. Clones were transferred to 24-well plate, then to 6-well plate and finally to 25 cm^2 flask. The ability of MMSC clones to adipose and

osteogeneic differentiation was assessed at this stage. Clones were considered to have HPP if they reached confluent monolayer in 25 cm^2 flask, LPP if they grew to confluence in 6-well plate, were named MCFC if reached confluence in 24-well plate and MMC if they didn't manage to cover the bottom of 24-well plate. MMSC clones with HPP from 1 donor were analyzed by means of ligation-mediated polymerase chain reaction (LM-PCR). *Results.* It was shown that the proportion of MMSC clones with HPP was 3.7 ± 0.6% at 1st passage, reached maximum of 5.0 ± 1.4% at 3d passage and then declined. Clones with HPP were not detected at 7th passage. The proportion of MMSC clones with LPP reached maximum of 6 ± 2% by 2nd -3d passage and then also declined. Such clones were not detected at 7th passage as well. The maximum proportion of MCFC clones was 23 ± 12% at 3d passage and then declined to 7% at 7th passage. The majority of MMSC clones possessed very low PP (MMC) and their mean proportion through passages was 82 ± 4%. The vector integration sites were determined in 10 out of 14 MMSC clones with HPP obtained from one donor. Each analyzed clone contained unique integration sites. It means that every analyzed clone was a progeny of distinct parental MMSC. Clonal composition of MMSC was unique in each passage. The dominant clones were not revealed. Thus not a single true mesenchymal stem cell with the ability to self-renew was detected by LM-PCR among studied clones. *Conclusions.* MMSCs represent a heterogeneous population of cells with different but limited PP. The probability of the presence of genuine mesenchymal stem cells in the population of MMSCs seems to be very low.

PERSISTENT MICROCHIMERISM IN BONE MARROW: INFLUENCE OF MESENCHYMAL STEM CELLS

O Horky, J Mayer, M Krejci, M Borsky, D Kratochvilova, D Dvorakova

University Hospital Brno, Brno, Czech Republic

Background. Microchimerism in bone marrow (BM) can be detected even years after allogeneic hematopoietic stem cell transplantation (Allo-HSCT), in spite of complete donor chimerism (CDC) attainment in peripheral blood (PB). *Aims.* The aim of our study was to explore the source of the persisting autologous feature in BM with particular interest in mesenchymal stem cells (MSC), which are known to remain of recipient origin after Allo-HSCT. *Methods.* BM cells obtained from patients with CDC detected in PB (n=14; 8 after reduced intensity conditioning, 6 after myeloablative conditioning; the median day post Allo-HSCT= 1499) were cultured in cytokine-free medium, and MSC were expanded. After three or four passages, the origin of acquired cells was determined. All analyses were performed by real-time PCR exploiting insertion/deletion polymorphism with the detection limit of almost 0.01%. Authenticity of MSC was affirmed morphologically and by flow cytometry analysis (positivity for CD105, CD73, CD44, and CD90 and negativity for the hematopoietic markers - CD14, CD19, CD34, and CD45). *Results.* The proportion of autologous cells observed in the whole BM was below 0.1% in all samples (see table). On the other hand, analysis of cultivated MSC revealed their autologous origin, as only a minimum of donor cells was detected (below 0.1% in mean). The amount of donor cells decreased with the number of performed passages. Interestingly, the host origin of the MSC was also identified in two samples with no autologous cells detected in whole BM. *Summary/Conclusions***.** Our results confirm and extend previous observations of the autologous origin of MSC. For the first time, we clearly emphasize connection between MSC and persisting microchimerism in BM. The impact of MSC must be taken into account, especially when danger of incipient relapse relating to microchimerism analysis in BM is considered. Furthermore, undetected autologous cells in BM do not signify even partial donor origin of MSC. e-mail: ohorky@fnbrno.cz

[4]*Baskent University, Adana Teaching and Medical Research Center, Adana, Turkey*

Background. Mesenchymal stem cells (MSC) have high proliferation and differentiation capacity into other cell lineages. MSC could be used in regenerative medicine because of these potentials. Distraction osteogenesis is the most prevalent therapy in bone defects. There are many restricted situations in bone defects therapy such as collapsing of callus, loss of lengthening and the long time of consolidation. *Aims.* The aim of this study is to examine therapeutic potentials of mesenchymal stem cells in bone defects. *Methods.* In this study, 21 New Zealand rabbit were used. These rabbits were separated into control, stem cell and osteoblast differentiated stem cells. Serum physiologic was applied to the first group of rabbit, adipose-derived mesenchymal stem cells were injected to callus site of the second group after distraction process to and osteoblasts differentiated from mesenchymal stem cells were injected to callus site of the third group of rabbits. Before injection, we characterized stem cells by flow cytometry and the cells were tagged with "green flourescent protein" (GFP). After four and eight weeks, the rabbits were sacrificed and evaluated radiologically, biomechanically and histopathologically. *Results.* Radiological analyses revealed that callus density and ossification rate increased in Group III as compared to Group I and Group II. In biomechanical tests, the highest rates were observed in Group III comparing to the others. As a result of histopathological studies, it was also observed that the quality of newly formed bone and the cells active in bone formation were significantly higher in Group III as compared to Group I and II rabbits. *Summary/Conclusions.* Taken together all these results revealed that osteoblasts differentiated from mesenchymal stem cells shortens the the consolidation period of distraction osteogenesis. Stem cells can be used effectively for the treatment of bone defects.

MYOFIBROBLASTS ORIGINATING FROM MYELOGENOUS LEUKEMIA CASES FORM BLASTOMA IN SEVERE COMBINED IMMUNODEFICIENCY MICE

R Shirasaki, H Tashiro, T Yamamoto, Y Oka, A Akiyama, K Kawasugi, N Shirafuji

Japan/Teikyo University School of Medicine, Tokyo, Japan

Background and Aims. We recently reported that acute myelogenous leukemia (AML) blasts as well as chronic myelogenous leukemia (CML) cells convert to stromal myofibroblasts to create an environment for the proliferation of leukemic cells *in vitro* and *in vivo*. To ascertain the biological characteristics of the bone marrow-derived myofi-

broblasts, myelogenous leukemia-derived stromal myofibroblasts were transplanted to NOD/SCID mice *in vivo*. *Materials and Methods.* The institutional ethical committee approved our study, and after obtaining informed consent bone marrow cells were collected from AML and CML patients as well as from informed normal individuals. Mononuclear cells were separated with gravity sedimentation method, and adherent cells were isolated by the two hours-culture, and further cultured for a long term. During the culture, cells were splitted with trypsin/EDTA once a week. After two months the myofibroblasts were prepared,which characterized with flow cytometry to deter mine the expression of the specific proteins on their cell-surface. The prepared myofibroblasts (1 x 107 cells) were injected intravenously to two gray-irradiated NOD/SCID mice, and mice were bred in a pathogen free room with antibiotics-containing water. Anti-asialo GM1 antibody was injected every 11th day subcutaneously for the suppression of NK cells. *Results and Discussion.* Between at day 40 and 60 after transplantation mice were dead. Autopsy findings revealed tumor formation at the liver. The transplanted myofibroblasts expressed expressed STRO-1, and smooth muscle actin but not lineage-spcific molecules including CD56; however, blastoma-forming cells expressed CD56 strongly but not other lineage-specific cell-surface markers. CD31, CD73, CD140a, and CD326(EpCAM) were also negative. These myofibroblast-derived blastomas expressed vascular endothelial growth factor (VEGF)-A and its receptor type 1, and 2, and showed growth-promotion when cells were cultured with VEGF-A. These observation indicate that myeloid leukemia-derived myofibroblasts form blastoma in an autocrine-fashion of VEGF-A, and also that the CD56-positive specific fraction of myofibroblasts is selectively engrafted to form blastoma.CD56 positive myofibroblast sarcoma of the liver is very rare disease that called Nested stromal epithelial tumor of the liver. Here we can reproduce this tumor in NOD/SCID mouse system, and we think CD56 positive fraction of myofibroblasts are its origin. Further study will reveal its precise biological characteristics.

ACCELERATED TELOMERE SHORTENING IS AN EARLY AND PERMANENT SIGNATURE IN CULTURED HUMAN MESENCHYMAL STEM CELLS EXPOSED TO CHEMOTHERAPY

S Buttiglieri,[1] M Ruella,[2] A Risso,[1] T Spatola,[1] L Silengo,[1] V Avvedimento,[3] C Tarella[4]

[1]*Molecular Biotechnology Center (MBC), Torino, Italy*
[2]*University of Torino, Torino, Italy*
[3]*University Federico II, Torino, Italy*
[4]*AO Ordine Mauriziano - Umberto I, Torino, Italy*

Background. Induction of cell senescence has been shown to be produced by various agents, including chemotherapeutic drugs. However, the mechanisms involved in the ageing pathway, in particular the distress on telomere produced by chemotherapy are still undefined, above all in human stem cells. *Aims.* In order to address these issues, human Mesenchymal Stem Cells (MSC) were assessed as target cells to investigate the initiation of the ageing process by chemotherapy. *Methods.* MSC were obtained from bone marrow (BM) cells from normal adults and grown in the presence of platelet lysates. Cultured MSC were identified for immunophenotype, and for growth and differentiation properties. MSC were exposed to sub-lethal doses of drugs able to induce double-stranded DNA breaks, i.e. doxorubicin (Doxo, 10 nM) and etoposide (Eto, 500 ng/ml). Telomere length (TL) was assessed by both flow-fish and southern blotting. *Results.* An initial TL shortening was detectable in MSC already at 5 days after exposure to Doxo and Eto, with a progressively marked reduction compared to untreated cells documented at 7, 14, 21 and 28 days in culture. Following a single drug exposure, MSC were unable to regain the lost telomere sequences, for up to 28 days in culture. ATM phosphorilation was documented early after Doxo and Eto exposure, while no telomerase activation was observed. Chemotherapy- Induced TL shortening was associated with reduced clonogenic activity *in vitro* and accelerated adipose differentiation. An analogous behavior in the differentiation pattern was observed in naturally aged MSC. *Conclusions.* the results indicate that: i. cultured MSC represent a useful cellular model to investigate novel drugs that may favor or, conversely, might prevent TL loss on human stem cells; ii. TL shortening is early detectable in cultured MSC following exposure to chemotherapy; iii. it remains as a permanent signature of previous chemotherapy-mediated DNA damage and predicts impaired proliferative and differentiation potential.

0758

CD146 AS A MARKER FOR CHARACTERISATION OF MSC POPULATIONS

I Dmitrieva, R Minullina, A Bilibina, V Tarasova, V Anisimov, Y Zaritskey

Almazov Federal Heart, Blood and Endocrinology Centre, St-Petersburg, Russian Federation

It is often assumed that expression of a certain broad set of markers defines various types of cell cultures as MSCs, but in reality, most of these markers are expressed by cultures of fibroblastic cells from any tissue. In addition, most of these markers are highly modulated in culture, which makes it difficult to characterize stromal cell cultures. In human BM, CD146 marks adventitial reticular cells a classically known stromal cell type residing in a subendothelial position over the abluminal surface of BM sinusoids. In other tissues, CD146 is expressed by pericytes, the cell that are considered as the MSCs found in different tissues. This study was designed to find out if CD146 could be used as a surrogate marker for characterization of MSC populations. *Patients and Methods.* 30 donors without bone marrow disorders were involved in this study. MSC cultures from BM (BM-MSC) were evaluated in successive passages (P)for immunophenotype (FACS analysis), frequency of colony-forming units (CFU-F) in MSC population, frequency of adipo- and osteo-progenitors (CFU-Ad, CFU-Ost) in the same population and for dynamic of changes in these properties with successive passage. CFU, CFU-Ad and CFU-Ost were studied by limiting dilution assay followed by induction of adipo- or osteo- differentiation: cell suspension was serially diluted two folds across the 8 columns of 96-well plates, resulting in columns containing from 50 to 0,39 cells per well. After 10 days of culture the number of positive and negative wells was determined for each cell concentration and CFU frequency was calculated. Then plates were induced to undergo adipogenesis and osteogenesis and CFU-Ad was determined by Oil Red staining and CFU-Ost by Alizarin Red staining after 14 and 21 days respectively. All calculations were performed as for CFU-F; β-galactosidase activity was used as biomarker for assessing replicative senescence; growth rate was estimated using on-line calculator www.doubling-time.com. *Results.* in present study we have found that, as expected, MSC at all passages were positive for stromal cell markers CD105/90/73 and negative for hematopoietic markers CD34/19/14/45. The level of expression of stromal markers remain stable at all passages. However, while the population of CD146+ cells was abundant in MSC at early passages, this population declined with successive passage (40+ 8% at P1 vs 14+ 6% at P5). This decline in CD146+ population correlated with decline in frequency of CFU-F (30,6%+4,9% at P1 vs 8,0%+1,5% at P4), CFU-Ost (17%+4,9% at P1 vs 5% + 2% at P4) and CFU-Ad (10% + 2% at P1 vs 3% + 1% at P4), in MSC sample. Additionally, while CD146+ population decreased in MSC sample, population doubling time increased dramatically and β-galactosidase activity increased. *Conclusion.* the population of CD146 positive MSCs declined with subsequent passages and correlated with the decrease of the ability to differentiate to Ost and Ad and increase of population senescence. The level of CD146 expression could be used to predict some of the properties of BM-MSC sample.

0759

NUCLEATED RED BLOOD CELLS, RETICULOCYTES AND IMMATURE RETICULOCYTE FRACTION IN TERM AND PRETERM INFANTS IN UMBILICAL CORD BLOOD

K Palla,[1] F Kalfadopoulou,[2] E Apazidou[1]

[1]*Chania General Hospital, Chania, Greece*
[2]*Lab Diagnostics, Athens, Greece*

Background. Nucleated red cell (NRBC) count varies widely at birth. Increased number of NRBCs seems to be related to fetal hypoxia. Furthermore the development of automatic flow cytometry techniques have led to improvement in the accuracy and precision of reticulocytes (RET). The immature reticulocyte fraction (IRF), which is the sum of the reticulocyte populations of high and medium immaturity, rather than just the reticulocyte count may reflect the intensity of erythropoietic stimulation. *Aim.* This study was aimed to establish normal range of reference values for percentage and absolute nucleated red cells (NRBC), absolute reticulocyte (RET) count and immature reticulocyte fraction(IRF) by using automated hematology analyzer, in term healthy newborns in umbilical cord blood (UCB), to compare these results with those corresponding to preterm fetuses and to define the state of erythropoiesis by using IRF versus RET count. *Methods.* UCB samples

from 329 (290 full term and 39 preterm) healthy newborns with gestational age between38-41 and 29-37 weeks respectively, delivered either vaginally or by cesarean section, were prospectively studied. Among preterm infants 4/39 were twins. Gestational age was determined from the last menstrual period and early ultrasonography. Blood samples were collected from the umbilical vein in tubes with EDTA K3, immediately after delivery and were analyzed within 3 hours. The hematological variables were determined in automated counter Sysmex XE2100 (Japan). Reference values were performed according to non-parametric percentile method (CLSI C28-A3). *Results.* Higher NRBC count was recorded in preterm newborn infants regardless from the type of delivery. Modest correlation was obtained between IRF and the RET count, but significantly different from zero. The data verified that the number of circulating RET corresponds to a greater fraction of young reticulocytes. Reference values in UCB in relation to gestational age for term infants (n=290) and preterm infants (n=39), respectively: NRBC% 0,00-20,508 (n=290) and 0,600-50,400 (n=39), NRBC 103 /uL 0,00-2,826 (n=287) and 0,080-5,550 (n=39), RET 106 u/L 0,093-0,244 (n=288) and 0,095-0,283 (n=37) and IRF% 18,0223-47,288 (n=288) and 20,70-44,00 (n=37). *Conclusion.* It is important to define reference values for the interpretation of blood count in the neonatal period. Our data showed decreased NRBC count with advancing gestation. We underline the possible value of high NRBCs in UCB suggesting an intrauterine hypoxic event several hours before birth. The IRF seems to have an independent role as an early and sensitive marker of erythropoietic activity and is becoming helpful in routine laboratory practice.

Hodgkin lymphoma - Biology & clinical

0760

CTLA4 POLYMORPHISMS AND MICROENVIRONMENT IN PEDIATRIC CLASSICAL HODGKIN LYMPHOMA. CLUES FOR THE UNDERSTANDING OF THE SUPPRESSOR PHENOTYPE

R Hassan, M Barros, V Scholl, A Costa, I Zalcberg

Instituto Nacional de Cancer, Rio de Janeiro, Brazil

Background. Classical Hodgkin lymphoma (cHL) is characterized by a low percentage of Hodgkin and Reed-Sternberg cells amidst a high number of infiltrating inflammatory cells, mostly CD4+ lymphocytes with a suppressor profile. The cytotoxic T-lymphocyte antigen-4 (CTLA4) is an immunoreceptor that inhibits T-cell proliferation and activation. Its polymorphisms appear to differentially influence its inhibitory activity. Particularly, the CTLA4 +49GG and CT60GG genotypes, and the CT60G/+49G haplotype were associated with a low inhibitory potential and with the susceptibility to autoimmune diseases. The inverse model was proposed for cancer, where genetic variants with high inhibitory potential (CT60A/+49A) would negatively influence anti-tumor immune surveillance. Thus, a better clinical response would be expected in the presence of genetic variants with increased anti-tumor capacity (low inhibitory potential). *Aims.* To investigate if CTLA4 polymorphisms influence the tumor microenvironment composition, clinical characteristics and outcome in cHL. *Methods.* 100 children (3 to 18y, median 15) diagnosed with cHL were included. DNA was extracted from peripheral blood or tumor diagnostic samples. Two CTLA4 polymorphisms (+49A/G and CT60A/G) were evaluated by TaqMan allele discrimination assays (ABI7000). CD4, T-bet (Th1), c-maf (Th2), CD8, Granzyme-B, Tia-1, FoxP3, CD20 and Ki67 expression were evaluated by immunohistochemistry in tissue microarray (TMA) slides. EBV was detected by EBER-ISH. *Results.* The presence of the CTLA4+49A allele was associated with high numbers of T lymphocytes (>451 /mm2, percentile 25) (p= 0.033). Genetic variants with high inhibitory potential (CT60A allele and +49A/CT60A haplotypes) were associated with high numbers of CD4+ lymphocytes (p= 0.023), which was secondary to an increase of Th2 lymphocytes(C-maf+), as compared to Th1 (T-bet+) lymphocytes (p= 0.046). CT60 low inhibitory potential variants (CT60G allele and GG genotype) were related with higher numbers of CD8+ (p= 0.014) and FoxP3+ lymphocytes (p= 0.007). These results suggested that while CTLA polymorphisms may influence the activation status and proliferation of Treg cells, the CD8+ lymphocytes sub-population appears to be a target for the inhibitory effect imparted by another cell population(s) expressing high CTLA4 levels. A better event-free survival (EFS) was associated with the CTLA4+49AA genotype (p= 0.045, Log-rank test), while a worst EFS was observed in cases with CTLA4 haplotype 49G/CT60G (p= 0.015). Differences in EFS were more marked in the EBV+ group, suggesting that FoxP3+ lymphocytes might be engaged in the immune response against EBV antigens. In the Cox regression adjusted by EBV status, haplotype 49G/CT60G maintained its independent prognostic impact (p= 0.043; HR CI95% 0.08-0.95). *Conclusions.* This is the first study to investigate CTLA4 polymorphisms in cHL and shows a potential effect of CTLA4 variants on cHL microenvironment, and outcome. In the pediatric cHL, high inhibitory potential CTLA4 variants were not associated with worse anti-tumor responses, but to favorable microenvironmental characteristics and better therapeutic responses. This reinforces the existence of a distinct anti-tumor model of immune response in hematopoietic malignancies as compared to solid cancers and highlight, through a genetic approach, the suppressor nature of the immune response against classical Hodgkin lymphoma.

Background. Hodgkin/Reed-Sternberg (HRS) cells represent the malignant fraction of infiltrated lymph nodes in Hodgkin lymphoma (HL). Although HRS cells display multiple chromosomal aberrations, few are

recurrent and the targeted genes unknown. *Aims.* Cell line L-1236 was used as a model to specify recurrent chromosomal breakpoints in HL. *Methods.* Fluorescence *in situ* hybridization (FISH), genomic copy number analysis by Agilent 4x180K-arrays, quantitativ real-time PCR (RQ-PCR), Western blot, Immuno-cytochemistry, RNAi-mediated knockdown, expression profiling by Affymetrix U133A arrays. *Results.* Here, we analyzed the karyotype of HL cell line L-1236 by multicolor FISH and identified multiple abnormalities, including t(4;8)(q27;q24). We focused on this alteration because both breakpoint regions (4q2 and 8q24) are recurrently involved in HL. Mapping these breakpoints was performed by FISH using tilepath BAC clones together with high density genomic arrays, while expression analysis of candidate target genes was tested by RQ-PCR and Western blot. The data revealed activation of phosophodiesterase PDE5A at 4q27 and activation of homeobox gene ZHX2 at 8q24. This breakpoint is located in the far upstream region of ZHX2, thereby removing potential binding sites for transcription factors XBP1 and MSX1. Expression analysis of ZHX2 and of promoter-constructs demonstrated ZHX2 activation by XBP1, and repression by MSX1 in combination with corepressor histone H1C. L-1236 cells showed silencing of XBP1 and elevated coexpression of MSX1 and H1C, associated with chromosomal alterations of the histone gene cluster at 6p22. Conspicuous expression of XBP1 in SUP-HD1 HL cells coincided with downstream deletions and enhanced ZHX2 levels, together confirming the activating role of XBP1 while highlighting an alternative mode of aberrant ZHX2 expression. To identify ZHX2 target genes we performed expression profiling of L-1236 cells following ZHX2 knockdown by siRNA treatment. Our data revealed suppression of STAT1 and several interferon-beta-targets, suggesting aberrant activation of STAT1-signaling by ZHX2. ZHX2-mediated STAT1-overexpression was confirmed in L-1236 cells by RQ-PCR and Western blot. Additionally, elevated expression of STAT1 protein was detected in all analyzed HL cell lines in contrast to control B-cell lines, highlighting a general feature of HL. Interestingly, treatment of L-1236 with PDE5A-inhibitor Sildenafil inhibited STAT1-phosphorylation and -signaling, indicating synergistic activity of the t(4;8)-target genes PDE5A and ZHX2. *Conclusion.* Taken together, we have identified a novel aberration in HL, t(4;8)(q27;q24), activating PDE5A and ZHX2. Both genes promote STAT1-signaling, which is generally elevated in HL cells and may contribute to the malignant phenotype. Furthermore, our data suggest that phosphodiesterase-inhibitors may represent a promising therapeutic avenue in HL.

A LOW PERIPHERAL BLOOD CD4/CD8 T CELLS RATIO PREDICTS POOR PROGNOSIS IN CLASSICAL HODGKIN'S LYMPHOMA

F Gaudio, C De Risi, T Perrone, A Mestice, A Giordano, A Spina, F Laddaga, D D'alessandro, G Specchia

Hematology - University of Bari, Bari, Italy

Background. Classical Hodgkin's lymphoma (cHL) is characterized by the presence of neoplastic cells in a rich background of T and B cells, macrophages, and other inflammatory cells. The contribution of these non tumoral cells to the pathogenesis of HL is still poorly understood; T cells constitute a significant component of the reactive infiltrate in cHL with an elevated T helper/T suppressor (CD4/CD8) ratio. T helper cells (Th) are central to the development of an immune response, activating antigen-specific effector cells and recruiting cells of the innate immune system. Until recently, the CD4/CD8 ratio was considered to be an index of immunosuppression in cancer patients. *Aim.* to evaluate the prognostic significance of a low peripheral blood (PB) CD4/CD8 cells ratio at diagnosis in cHL patients (pts). *Methods.* Flowcytometer immunophenotyping of PB samples was performed at diagnosis in 92 immunocompetent pts with cHL treated at our institution between January 2007 and December 2008 with first line ABVD chemotherapy. Median age at diagnosis was 34 years (range 15-82), 42 pts (45.6%) were male, 52 pts (56.5%) presented advanced stage disease (IIB-IV), 36 (39%) bulky disease, 40 (43.5%) had B symptoms, 24 (26%) spleen involvement, 25 (27.17%) extranodal disease. The histology was nodular sclerosis in 79 (85.9%), mixed cellularity in 13 (14.1%). *Results.* A PB CD4/CD8 T cells ratio <1.5 (Low CD4/CD8 ratio) was recorded in 40 pts (43,5%). The clinical features present with a higher rate in the low CD4/CD8 T cells ratio group were: nodular sclerosis histology (96% vs 77% p=0.07), high-stage disease (70.4% vs 45.72%; p<0.05), B symptoms (51.8% vs 37%; p<0.05), bulky disease (51.8% vs 28.57% p<0.05), spleen involvement (40.7% vs 14.3% p<0.05). In the low CD4/CD8 T cells ratio group a lower rate of complete remission was observed (77.7% vs 91.4% p<0.05) and a higher rate of disease progression

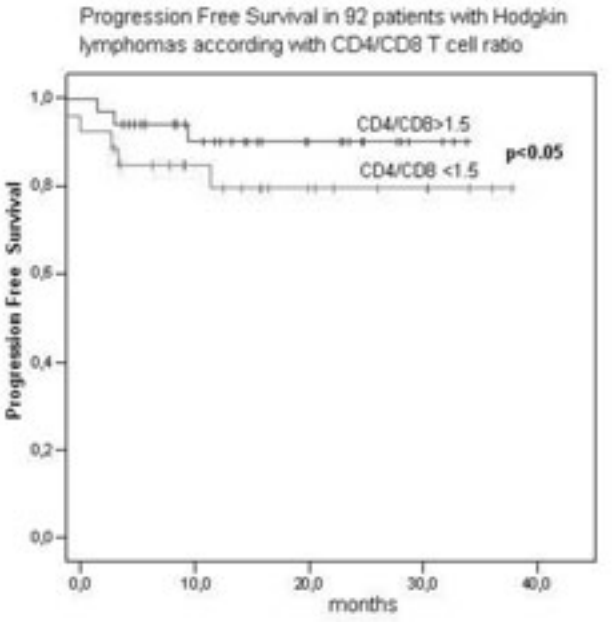

Figure 1.

(14.8% vs 2.85%; p<0.05). At a median follow-up of 24 months, 15 (16.3%) pts developed progressive/relapsed disease; 70% of these patients had a CD4/CD8 t cells ratio <1.5. The incidence of positive PET after two courses of chemotherapy was higher in pts with a low CD4/CD8 t cells ratio (40.7% vs. 17.14%; p<0.05). The 24 months progression free survival (PFS) rate was 76.2% in low CD4/CD8 t cells ratio pts and 92.2% in patients with a CD4/CD8 t cells ratio >1.5 (P<0.05). No significant differences were observed for sex, absolute lymphocyte count, VES, LDH and extranodal disease between the low and high CD4/CD8 ratio groups. *Conclusion.* A low PB CD4/CD8 t cells ratio at diagnosis seems to be associated with unfavorable clinical features and a worse prognosis. Further investigations including analysis of t reg, cytokine, chemokine, are needed to confirm these results.

[4]*Present position: Athens Medical center, Athens, Greece*

Background. Serum CRP levels are elevated in the majority of patients with HL at diagnosis, reflecting tumor burden and aggressive biologic behavior. Despite being an easily and frequently measured marker, data on its potential prognostic significance are extremely limited. *Aim.* To analyze the correlation between baseline CRP levels and clinical-laboratory findings and outcome of patients with HL treated with anthracycline-based chemotherapy with or without radiotherapy (RT). *Patients and Methods.* Baseline CRP levels were recorded in 496 patients with HL, who were treated with anthracycline-based chemotherapy with or without radiotherapy (RT) in 2 Centers. Baseline CRP levels were correlated with other baseline clinical-laboratory features (Spearman correlation coefficient or Mann-Whitney test), Failure Free Survival (FFS) and Overall Survival (OS) (Kaplan-Meier curves, log-rank comparison). Multivariate FFS analysis was based on Cox's proportional hazards model. CRP levels ≥5 mg/L were considered elevated. *Results.* The median value of CRP levels in the 496 evaluable patients was 21.10 mg/L; 27% and

73% had normal and elevated CRP levels respectively. Baseline CRP levels correlated with virtually all other parameters reflecting tumor burden or disease aggressiveness: There were strong correlations with advanced stages and B-symptoms (p<0.001) as well as specific extranodal sites (bone marrow, lung, liver). Baseline CRP presented a very strong correlation with ESR (Spearman's rho 0.74, p<0.001), strong correlations with haemoglobin (inverse), platelet counts and albumin (inverse) (S-rho 0.40-0.60, p<0.001) and looser correlations with white blood cell counts, serum LDH, and absolute lymphocyte counts (inverse) (S-rho <0.35, p<0.001). A trend towards a dose-response effect with FFS was observed: 5-year FFS for patients with CRP levels <5, 5-21.09, 21.1-69.99 and ≥70 mg/L (roughly the CRP quartiles) was 81%, 78%, 68% and 66% (p=0.02). The difference was more pronounced for patients with normal versus elevated CRP levels (81% versus 71%, p=0.006). Differences in OS were not significant (p>0.10). The prognostic impact of CRP on FFS was borderline in early stage patients (IA,IIA: 5-year FFS 83% versus 75% for normal versus elevated levels, p=0.09), but no difference was detected in advanced disease (68% versus 66%, p=0.48). CRP was an independent adverse prognostic factor for FFS, when adjusted for stage (III/IV versus I/II), B-symptoms and IPS factors (except of lymphocytopenia). However, baseline CRP was not analyzed along with ESR in the same model, because of their very strong correlation, raising issues of collinearity. *Conclusions.* CRP levels are elevated in ~70% of HL patients at diagnosis and correlated with FFS independently from other established prognostic factors included in the IPS. The very strong correlation between baseline CRP and ESR probably suggests that only one of them should be included in a given prognostic model. Even larger patient series should be analyzed in order to draw definite conclusions, but the final selection might be relied on specific biologic and technical advantages of either marker.

0764

BCL2 IMMUNOHISTOCHEMICAL EXPRESSION IN CLASSICAL HODGKIN'S LYMPHOMA AT DIAGNOSIS AS AN INDEPENDENT BIOLOGICAL PROGNOSTIC MARKER

L Bento de Miguel,[1] G Rodriguez Macías,[2] P Balsalobre,[2] J Gayoso,[2] I Gonzalez-Gascón y Marín,[2] C Muñoz-Martínez,[2] P Font,[2] C Encinas,[2] S Osorio,[2] M Kwon,[2] D Serrano,[2] A Escudero,[2] J Menárguez,[2] JL Díez-Martín[2]

[1]*H. Gregorio Marañón, Madrid, Spain*
[2]*H. G.U. Gregorio Marañón, Madrid, Spain*

Background. Most patients with classical Hodgkin's Lymphoma (CHL) are cured with primary treatment. However, a significant proportion of them do not achieve a complete response (CR) or relapse after completion of initial therapy and need to be rescued with a second line of chemotherapy (2LC) and/or autologous or allogeneic stem cell transplantation (auto-SCT and allo-SCT, respectively). The identification of clinical and biological characteristics of these patients at diagnosis is still a challenge and most prognostic systems fail to identify a proportion of patients with worse prognosis. In this context, different groups are currently analyzing several biological markers as determinants of clinical outcome. It has been reported that Bcl2 immunohistochemical overexpression in Hodgkin's Reed Sternberg cells (HRSC) might confer a worse prognosis. Objetive: To analyze clinical outcomes following 1st line chemotherapy according to Bcl2 expression at diagnosis. *Patients and Methods.* 72 CHL patients, older than 16 years old, receiving at least 1 line of treatment, were retrospectively studied for Bcl2 expression in diagnostic samples. For this purpose, tissue sections were immunostained and semiquantitatively assessed for this marker. Cumulative incidence (CI) of 2LC was defined as primary outcome. 2LC was considered when a different treatment regimen was set up due to lack of response, relapse or failing to achieve CR following 1st line. 2LC-free survival and overall survival (OS) were also analyzed. *Results.* Main patient and clinical features are shown in Table 1. At a median follow up of 32m [30m (2-140) for Bcl2 negative patients and 35m (4-221) for Bcl2 positive patients] CI of 2LC was 17% and 54.4% for the negative and positive cohorts, respectively (p=0.04). Median 2LC-free survival was 39.5m and 30m for the negative and positive cohorts, respectively (p=0.1).Within the cohort of Bcl2 positive patients, 20/35 (57%) underwent SCT (13 auto-SCT, 4 allo-SCT and 3 allo-SCT for the treatment of post-auto-SCT relapse) while 9/37 (24%) of Bcl2 negative patients received an auto-SCT (p=0.02). OS 4 years after diagnosis was 85% negative and 75% for positive patients (p=NS). *Conclusions.* According to these preliminary results, Bcl2 expression in HRSC at diagnosis may constitute an independent biological prognostic marker in CHL patients, seemingly associated with worse outcome and need of 2LC. A longer follow up is needed in order to confirm that aggressive treatment strategies such as SCT may overcome the negative impact in survival of Bcl2 expression in this population.

Table 1.

Main patient and clinical features.		
CLASSICAL HODGKIN´S LYMPHOMAS:	Bcl2 EXPRESSION:	
	POSITIVE:	NEGATIVE:
N (72):	35	37
SEX (M/F):	20/15	21/16
MEDIAN AGE (R):	30 (17-74)	39 (18-78)
HISTOLOGY:		
Nodular sclerosis	28 (78%)	17 (46%)
Mixed cellularity	6 (19%)	12 (32%)
Lymphocyte predominant	1 (3%)	7 (19%)
Lymphocyte depleted	0 (0%)	1 (3%)
Ann Arbor stage at diagnosis:		
I-II	14 (40%)	20 (54%)
III-IV	21 (60%)	17 (46%)
Patients with unfavorable EORTC prognostic factors (stages I-II CHL): n (%)	8 (57%)	10 (50%)
Patients with IPS >2 (stages III-IV CHL): n (%)	6 (28%)	5 (29%)

[2]*Division of Hematology, Ferrarotto Hospital, Catania, Italy*
[3]*Division of Hematology, A.O. Garibaldi, Catania, Italy*
[4]*Division of Radiology, A.O. Cannizzaro, Catania, Italy*

Background. Lymphoid suppression plays a key role in determining the tumor growth and progression in Hodgkin's' Lymphoma (HL) and this inflammatory dysregulation seems to be linked with the interim-PET assessment. CD62L reduction on the surface of lymphocytes represents a marker of immune-suppression. *Aim.* In the present work, we evaluated the CD62L expression on lymphocytes surfaces in HL patients at diagnosis and related these findings with the interim-PET outcome. *Methods.* 27 HL patients, 18 at stage I-II and 9 at stage III-IV, treated with ABVD as first line, were enrolled and PET assessment was performed at diagnosis and after two cycles (interim-PET). PET images were interpreted visually according to Dann *et al.*, 2010. 2 out of 18 patients (11.1 %) at early stage and 3 out of 9 (33%) at stage III-IV had a positive interim-PET. CD62L has been evaluated from peripheral blood at diagnosis on CD4 and CD8 T-lymphocytes and expressed as intensity mean fluorescence (IFM). T-test has been performed in order to assess if there is a statistical difference in CD62L levels between different groups. Pearson correlation has been used to define the relationship between CD62L expression and other clinical-laboratoristic parameters. Receiver-operating-characteristic (ROC) curves has been used in order to determine cut-off levels. Informed consensus has been signed. *Results.* We observed reduced levels of CD62L expression on CD8+ lymphocytes surface between HL patients at diagnosis and healthy controls matched for gender and age (57.2 vs 42.48) (p=0.007), but not on CD4+ lymphocytes (average 62.4 vs 61.7) (p=0.88). No statistical differences have been found in CD62L expression on CD4+ and CD8+ lymphocytes at early stage versus advanced stage (p=0.06 for CD62L on CD4+ and p=0.8 for CD62L on CD8+). Interestingly, CD62L expression levels on CD8+ cells was not related with interim-PET assessment in any stage, whereas CD62L reduction on CD4+ lymphocytes related with the interim-PET assessment only in patients at early stage, being in patients with interim-PET negative higher than in patients with interim-PET positive (average 68.69 vs 54) (p=0.03). Additionally, CD62L expression on both CD8+ and CD4+ lymphocytes did not relate with prognostic and inflammatory factors. *Conclusion.* On the whole, our findings suggest that HL patients have a reduced expression of CD62L on CD8 compared to healthy controls and patients at early stages who have also a reduction of CD62L on CD4+ lymphocytes have a poorer prognosis.

0766

HODGKIN LYMPHOMA (HL) IN PATIENTS =60 YEARS OLD: CLINICAL AND LABORATORY FEATURES, OUTCOME AFTER ANTHRACYCLINE-BASED TREATMENT AND COMPARISON WITH YOUNGER PATIENTS: A SINGLE CENTRE EXPERIENCE

T Vassilakopoulos,[1] G Pangalis,[1] G Boutsikas,[1] S Kokoris,[1] Z Galani,[1] M Siakantaris,[1] E Dimitriadou,[1] M Dimopoulou,[1] G Georgiou,[1] M Dimou,[1] C Kalpadaki,[1] F Kontopidou,[1] MC Kyrtsonis,[1] V Pappis,[1] O Tsopra,[1] P Tsirkinidis,[1] K Koutsoukos,[1] E Zografos,[1] E Variamis,[1] A Viniou,[1] P Panayiotidis,[1] J Meletis,[1] M Angelopoulou[2]

[1]*Laikon General Hospital, Athens, Greece*
[2]*National and Kapodistrian University of Athens, Laikon General Hospital, Athens, Greece*

Background. Published data regarding the effect of advanced age on the outcome of patients with HL are contradictory. Reported differences in prognosis between older and younger patients may have been due to differences in treatment intensity, inadequate staging, inferior efficacy of salvage therapy and presence of comorbid conditions. *Aims.* To compare the clinical and laboratory features and the outcome of patients with HL ≥60 years treated with anthracycline-based chemotherapy (CT) or combined modality therapy with the subgroup of younger patients. *Methods.* Patients ≥60 years old, who were diagnosed with HL and treated with anthracycline-based CT±RT in our Department, were evaluated and compared with younger patients for their demographic, laboratory features and outcome. Older patients were further subdivided in 3 age groups: 60-66, 67-74, ≥75 years old, which were also compared. *Results.* Among 1004 patients with HL treated with anthracycline-based CT±RT, 113 (11%) were ≥60 years old. When compared with younger patients, they had a higher incidence of advanced disease (55% vs 45%, p=0.03). Several potential adverse prognostic features were significantly more prevalent in older patients, including B-symptoms (p=0.01), bone marrow (p=0.005) and liver (p=0.001) involvement, low serum albumin (p=0.003) and elevated β2-microglobulin levels (p<0.001). IPS was clearly higher in older patients (p<0.001). In contrast, lung involvement (p=0.004) and significant leukocytosis (p=0.057) were more prevalent in the younger age group. This probably reflected the much higher incidence of nodular sclerosis in younger patients (70% vs 41%) with corresponding lower incidence of mixed cellularity (19% vs 44%) (p<0.001). The 10-year failure free survival (FFS) was not significantly different in older patients compared to young ones (76% vs 76%, p=0.76). However, older patients had a higher incidence of deaths during treatment (0.2% vs 4.4%, p<0.001), inferior 10-year overall survival (86% vs 46%, p<0.0001), HL-specific survival (91% vs 73%, p<0.0001) and 5-year survival after failure (62% vs 14%, p<0.0001). Among the 113 patients aged ≥60 years, 47, 45 and 21 were 60-66, 67-74 and ≥75 years old respectively. These subgroups had similar baseline characteristics with the exception of worsening anaemia and more β2-microglobulin elevations with increasing age. However, deaths during treatment were 0%, 6.7% and 9.5% respectively (p=0.14), while the 5-year survival after failure was 27%, 0% and 0% respectively (p=0.0008). No significant differences were observed for FFS, while OS and HL-specific survival were marginally inferior in more advanced age groups. *Summary/Conclusions.* Despite differences in baseline clinical and laboratory features, patients with HL ≥60 years old have similar failure rates with younger ones when treated with anthracycline-based CT±RT. However, the higher incidence of deaths during treatment and the poor results of salvage therapy resulted to inferior overall and HL-specific survival rates. Within the ≥60 years group, the latter problems were pronounced in more advanced age subgroups.

0767

HODGKIN'S DISEASE AND HIV INFECTION (HD-HIV): PROGNOSTIC FACTORS IN 596 PATIENTS (PTS) WITHIN THE EUROPEAN GROUP FOR THE STUDY OF HIV AND TUMOURS (GECAT)

M Spina,[1] M Spina,[1] J Ribera,[2] J Gabarre,[3] C Wyen,[4] S Montoto,[5] U Jaeger,[6] R Talamini,[1] A Re,[7] U Tirelli[1]

[7]*Spedali Civili, Brescia, Italy*

Background. Hodgkin's disease (HD) is the most common non-AIDS defining tumour diagnosed in HIV setting. The introduction of highly active antiretroviral therapy (HAART) has opened a new prospective in the treatment of pts with HD-HIV since the better control of the underlying HIV infection allows the use of more aggressive chemotherapy regimens, including high dose chemotherapy. However, up to now prognostic factors on overall survival (OS) or time to treatment failure (TTF) have not yet been identified. *Methods.* in order to identify prognostic factors, we analyzed data on 596 pts with HD-HIV diagnosed and treated in 90 different Institution from 6 European countries from October 1983 to March 2010. All factors were analyzed for OS and TTF. *Results.* 86% of pts were male and the median CD4 cell count was 224/dl (range 3-1274); 52% of pts had mixed cellularity subtype, stages III-IV were diagnosed in 72% of cases and 55% of pts had extranodal involvement (bone marrow 35%, spleen 21%, liver 14%). *Conclusion.* We identified a new "European Score" for HD-HIV able to predict different outcomes in these patients. This score should be considered for future prospective studies.

0768

VEBEP REGIMEN IN PATIENTS (PTS) WITH HD AND HIV INFECTION (HD-HIV): FINAL RESULTS OF A PHASE II STUDY OF THE ITALIAN COOPERATIVE GROUP ON AIDS AND TUMORS (GICAT)

M Spina,[1] M Spina,[1] A Antinori,[2] M Bibas,[2] A Re,[3] S Mancuso,[4] A Levis,[5] R Talamini,[1] U Tirelli[1]

[1]*National Cancer Institute, Aviano (PN), Italy*

[3]*Spedali Civili, Brescia, Italy*
[4]*University of Palermo, Palermo, Italy*
[5]*Ospedale Civile, Alessandria, Italy*

Background. The outcome of pts with HD-HIV is still poor, because the duration of complete remission (CR) is generally short. To improve the prognosis of HD-HIV, a feasibility study with the VEBEP regimen and HAART was started in previously untreated HD-HIV pts. *Methods.* CT included epirubicin 30 mg/m2/day (days 1-3), cyclophosphamide 1000 mg/m2 (day 1), vinorelbine 25 mg/m2 (day 1), bleomycin 10 mg/m2 (day 3) and prednisone 100 mg/m2/day (days 1-3). HAART was given concomitantly to CT. *Results.* From September 2001 to December 2008, 73 pts have been enrolled. The median age was 41 yrs. The median CD4+ cell count was 248/mm3 and 51% of pts had a detectable HIV viral load. Stage III-IV was present in 50/71 (70%) pts. Histologic subtypes were: MC 70%, NS 20%, LD 4%, LP 2%, unknown 4%. Four toxic deaths (5%) were observed (septic shock, PCP, hepatic failure and pneumonia during neutropenia). An absolute neutrophil count <500 was noted in 60% of pts. Grade 3-4 anaemia was observed in 38% of pts and severe thrombocytopenia in 22% of pts. Twenty-two per cent of pts had febrile neutropenia with 19 documented infections in 16 pts (4 varicella, 4 bacterial pneumonia, 3 bacterial sepsis, 2 PCP, 1 cerebral toxoplasmosis, 1 oesophageal candidiasis, 1 HBV reactivation, 1 HCV reactivation, 1 prostatitis, 1 salmonellosis). CR was obtained in 49/73 pts (67%) and PR in 8/73 pts (11%). With a median follow up of 40 months (range 2-106), only 5 of CR pts have relapsed. The 3-yr OS and TTF at 24 months were 66% and 63%, respectively. An IPS greater than 2 (HR 2.87, 95%CI 1.08-7.63, p=0.03) and a ECOG-PS greater than 1 (HR 2.79, 95%CI 1.21-6.44, p=0.02) were significantly associated with a higher risk of death. *Conclusions.* Our data demonstrate that VEBEP regimen in combination with HAART is feasible and active in pts with HD-HIV. As observed in HD of the general population, the IPS is able to stratify patients with different outcome.

This study was supported by ISS grants.

Background. Hodgkin's lymphoma is a malignant diseases with the highest rate of cure particularly if diagnosed in early stage. Neverthe-

less a small proportion of patients with localized stage do not respond to therapy and progressed. *Aims.* To explore the predictive value on therapy outcome of an early evaluation of treatment response by 18F-fluorodeoxyglucose positron emission tomography (FDG-PET) scan performed after two corses of ABVD in pts with localized Hodgkin's disease. *Methods.* From 2002, 263 localized stage Hodgkin's lymphoma pts were consecutively admitted to 13 Italian hematological centers on behalf of Fondazione Italiana Linfomi (FIL). Pts with stage I-IIA according to Ann Arbor stage, independent of presence of bulky disease were evaluated. Bulky disease pts were the object of our analysis. FDG-PET was mandatory at baseline, after two cycles and at the end of therapy. Mediastinal blood pool activity is recommended as the reference background activity to define PET positivity according to International Harmonization Project (IHP). We evaluated the progression free survival of pts starting from the time of diagnosis to relapse or progression of disease or last follow-up. No treatment variation based only on PET-2 results was allowed. *Results.* 78 pts presented bulky disease, the median age was 32 years (13-66). All pts but three were treated with combined modality. The FDG-PET performed after two cycles (PET2) was positive in 18/78 pts (23%): 8 (44%) progressed or relapsed and 10 manteined CR. By contrast 53/60 (88%) pts with a negative PET2 remained in CR. Thus the positive predictive value of a PET2 in bulky disease was very low (44%) and the negative predictive value was 88%. The sensitivity and specificity of PET2 were 53% and 84%, respectively. Radiotherapy was performed in 17 PET2 positive pts, 10 did not fail (59%), one pt with PET2 positivity did not perform radiotherapy and progressed. A FDG-PET was performed at the end of therapeutical program (PET6), all pts (10) with positive PET6 and 5/68 with negative PET6 progressed. In univariate analysis negative FDG-PET performed after two cycles (p .002) and in particular negative PET6 (0.000) were statistically correlated with a better progression free survival. With a median follow-up of 37 months (range 4-103) 73 pts are alive and 63 (81%) are free from progression. The 2-yr PFS probability for PET2 negative and for PET2 positive patients were 92% and 40% respectively (p: .002). *Conclusions.* With the IHP interpretation criteria we observed a large number of false positive PET2 in mediastinal bulky early stage Hodgkin disease. For this reason new PET evaluation methods in this subset of pts are mandatory. Moreover in bulky disease pts radiotherapy could permit to overcome the poor prognostic significance. This multicentric study confirms that a negative FDG-PET scan performed after two courses of conventional standard dose therapy in localized bulky disease pts was able to predict a favourable outcome.

Background. In Hodgkin Lymphoma (HL) the interim PET (after 2 cycles of ABVD chemotherapy) is the most important prognostic factor and it is probably linked to the persistence of the reactive microenvironment that promotes tumor cells survival. CD68+ tumor associated macrophages (TAM) are increased in cases with poor prognosis, thus to be proposed as additional prognostic marker at diagnosis of HL. Their progenitors circulating in peripheral blood are well known in solid tumors as Myeloid Derived Suppressor Cells (MDSC) for their ability to suppress T-cell immune responses. In mice, MDSC are broadly defined as being GR1+CD11b+ cells capable of suppressing antigen-specific or nonspecific T cell activation, but there is no accord on the correspondent phenotype in humans. *Material and Methods.* We evaluated by flow cytometry circulating levels of immature im-MDSC (CD11b+, CD13+, CD14-, CD34+, CD45+) in peripheral blood of 37 HL patients at diagnosis and after 2 cycles of chemotherapy. We correlated MDSC to clinical findings included interim-PET response and treatment outcome, and T-cell subpopulations, including Treg (CD4+CD25+FoxP3+). *Results.* We found that at diagnosis HL patients have higher levels of im-MDSC, when compared to healthy controls (HC) matched for sex and age (p=0.0001) and these cells return to normal values within the first 2 cycles of chemotherapy in five evaluated responders. Absolute number of im-MDSC was positively correlated to Treg absolute count (r = 0,95, p 0,014), in accord to the biologic observation that MDSC are able to expand Treg compartment, but not with other T cell subpopulations. Conversely, no correlation was found with markers of inflammation (ferritin, ESR, C-RP, fibrinogen) tumor burden (stage, IPS, presence of bulky disease) and SUV-PET at diagnosis. Ten patients out of 37 (27%) had increased im-MDSC count at diagnosis (>4.5 cells/μL), with documented positive interim-PET or progression/relapse of disease for 6 of them. Three out of four patients with a positive interim-PET had increased im-MDSC count at diagnosis. The ROC-curve to predict the outcome of interim-PET based on im-MDSC cell count at diagnosis had area=0.96, p=0.0003. PFS in patients with im-MDSC>4.5 cells/μL were comparable to those interim-PET positive (p=0.57) and significantly worse than im-MDSC<4.5 cells/μL (p=0.002). *Summary/Conclusion* im-MDSC are increased in peripheral blood of HL patients at diagnosis and correlate with interim PET assessment (look at the image in attachment). They could represent an earlier and more easily accessible prognostic factor than interim-PET and an attractive therapeutic target to improve HL immunotherapy.

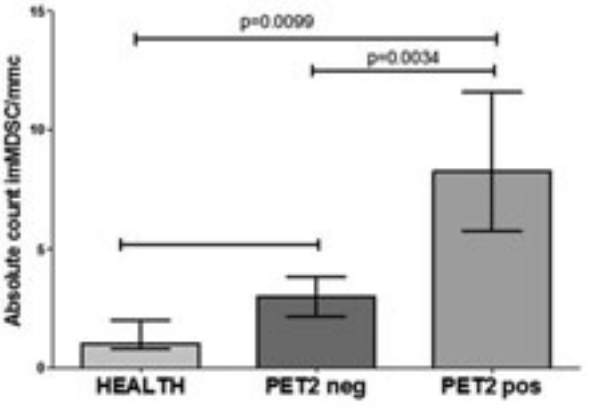

Figure 1. Absolute count of imMDSC in HC and HD.

Background. Hodgkin's Lymphoma (HL) is a highly curable malignancy that mostly affects young adults; however despite satisfactory results, about 20% of patients still die of relapsed/refractory disease and late toxic effects rate, often due to overtreatment, continue to rise with time. Consequently, the optimal treatment should be designed based on prognostic models, but currently all of them predict the outcome with imperfect accuracy. Since "early FDG-PET"and more recently tissue macrophages infiltration in diagnostic specimens emerged as powerful prognostic predictors, we hypothesized that macrophagic infiltration could be the shadow of the inflammatory microenvironment, that FDG-PET identifies in HL and that persists at early assessment in patients who will fail the treatment. *Aims.* the primary endpoint of this study was to verify the prognostic role both of "early-FDG PET" and of macrophagic infiltration, while the secondary endpoint was to test if "early-FDG PET" positivity could correlate with high macrophagic infiltration in diagnostic specimens. *Methods.* A homogeneous cohort of fifty-two patients (M/F: 28/24; median age 33 yrs) diagnosed and treated at Siena and Florence hematology departments between February 2007 and July 2010 was extracted from local databases and retrospectively analyzed. All patients had completed staging with whole body CT scan, FDG-PET and bone marrow biopsy. One patient had stage I, 20 pts. Stage II, 24 stage III and 7 stage IV. Treatment plan

consisted of 4-6 courses of ABVD and, if indicated, involved field radiation therapy. Patients repeated CT scan and FDG-PET after two cycles and after the completion of therapy. Macrophages infiltration in paraffin embedded diagnostic specimen was determined by immunohistochemistry and classified in 3 groups based on the percentage of CD68+ cells, as previously reported by Christian Steidl and coworkers. *Results.* After two cycles of ABVD, FDG-PET was negative in 41/52 patients (79%) and positive in 11 cases (21%). Overall, 40 out of 52 (77%) patients achieved a CR and 12 presented relapsed/refractory disease; interestingly among this patients "early FDG-PET2" was positive in 9/12 cases (75%). CD68 expression in diagnostic specimens was low, intermediate or high respectively in 8(15%), 25(48%) and 19 (37%) cases; moreover among patients with relapsed /refractory disease was low in 2 cases, intermediate in 8 cases and high in 2 cases. Finally, no statistical correlation was found between "early FDG-PET"and CD68 expression by Pearson's chi-square test. *Conclusions.* Our data do not seem to confirm the hypothesis of a possible correlation between "early FDG-PET"and macrophages infiltration in diagnostic specimen, while "early FDG-PET"maintains a high prognostic value.

Background. Persistent PET positivity following 2 cycles ABVD (PET-2) is a strong unfavorable prognostic factor in advanced HL. Progression Free Survival is approximately 95% vs 15% for patients with negative vs positive PET-2 respectively. The evaluation of PET-2 is based on well defined, though arbitrary, criteria, which require prospective validation. Whether PET-2-based early treatment modification can improve prognosis is unknown. However, it is known that the continuation of ABVD after a positive PET-2 is associated with an unacceptably high risk of treatment failure. *Aims.* (1) To analyze patients with advanced stage HL who were evaluated by PET-2 after ABVD x2 in relation to the final response; (2) To analyze the impact of PET-2 on subsequent treatment plan; (3) To make an attempt to validate current criteria for PET-2 positivity. *Patients and Methods.* We present a retrospective study of 26 patients with advanced stage HL (25/26 younger than 60 years). Advanced stage was defined as stage IIB with mediastinal bulk and/or E-disease, stage III or IV according to the German Hodgkin Study Group(GHSG) definition. PET-2 was evaluated using the established 5-grade scale (see below). *Results.* Median age of the patients was 28 years (19-72), 69% were men, 77% had nodular sclerosis, 3, 10 and 13 had stage II, III and IV respectively, and 70% had B-symptoms. The median value of IPS was 2.5 (0-5). 81% of the patients (21/26) had a negative PET-2: It was completely negative in 10 patients; 8 patients had residual uptake <liver; 3 patients developed new sites with an alternative explanation available and regression of the initial sites of disease (to uptake <liver). PET-2-Negative Patients: A final PET examination was available in 15 patients (too early for 6 patients): 14/15 were PET-neg, but 1/15 developed frankly progressive disease at the end of treatment. At a median follow up of 13 months, only 1/14 PET-neg patients had relapsed. Overall 2/21 patients have failed so far: 1/10 with completely negative PET-2 and 1 out of 8 patients, who had mild (<liver) residual FDG uptake. PET-2-Negative Patients: Among 5 PET-2 positive patients, only one was switched to BEACOPP-escalated x6 (continuous CR for 16 months) and 4 continued n ABVD (2 converted to PET-neg and remain in CR and 2 progressed at 4 and 7 months). If all of the 26 above patients had been treated with BEACOPP-escalated x6-8, they would have had received 156-208 chemo cycles. In fact, only 1 patient received 6 cycles of BEACOPP-escalated; at most 30 cycles would have been administered, if all PET-2 positive patients had been switched to BEACOPP-escalated. *Conclusions.* According to our preliminary data, current criteria for PET-2 evaluation appear to be valid. During this initial phase of incorporation of PET-2 in treatment strategy, a negative result appeared to be reassuring. However, treating physicians tended to be reluctant to make early modifications in the treatment plan, in case of positive PET-2. A more homogeneous strategy according to predefined interim PET positivity criteria might prevent overtreatment and, hopefully result to improved outcome in advanced HL.

[3]*University of Palermo, Palermo, Italy*
[4]*Spedali Civili, Brescia, Italy*
[5]*Niguarda Hospital, Milan, Italy*

Background. The introduction of HAART has significantly improved the outcome of pts with HD-HIV. However there are no data on the long term follow-up of HD-HIV pts treated with conventional chemotherapy (CT) regimens. In 2002, we reported the results of a prospective phase II study with the intensive 12-week CT with adjuvant radiotherapy (Stanford V) and concomitant HAART in 59 pts (Spina *et al.* Blood 2002;100:1984-1988). *Methods.* To analyze the long term outcome of patients included in the Stanford V and HAART protocol. *Results.* The median follow-up is 67months (range 3-156 months The 5-yr overall survival (OS), freedom from progression (FFP), disease free survival and event free survival are 54%, 52%, 60% and 37%, respectively. The 5-year OS is significantly different in pts with an international prognostic score (IPS) >2 in comparison to that of pts with an IPS <3 (84% vs 36%, p= 0.0005). Similarly, the percentages of FFP at 5 years in these groups are 72% and 45% (p= 0.03). *Conclusions.* Our data confirm the long term efficacy of Stanford V regimen in combination with HAART in HD-HIV. However, Stanford V is significantly less effective in pts with IPS>2 and therefore new strategies be tested in this setting.

Supported by AIRC and ISS grants.

[5]*Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*
[6]*Barnet and Chase Farm Hospitals NHS Trust, London, United Kingdom*
[7]*Royal Free Hampstead NHS Trust, London, United Kingdom*

Background. There is approximately a 10-fold increase in the incidence of Hodgkin lymphoma (HL) in patients with Human Immunodeficiency Virus (HIV) and patients often present with advanced disease. A number of studies have demonstrated a good outcome after ABVD (doxorubicin, bleomycin, vinblastine and dacarbazine) chemotherapy combined with highly active antiretroviral therapy (HAART) in patients with HIV-HL. There is still much debate whether more aggressive regimens such as escalated BEACOPP are more appropriate in patients with advanced disease. The prognostic significance of interim PET in HIV negative patients with HL is now well established. However, there is no published data regarding interim PET scanning in pa-

tients with HL in the HIV setting. *Aims.* Our objective was to evaluate the role of interim FDG-PET imaging during ABVD chemotherapy in determining response assessment for patients receiving first-line treatment for advanced HIV-HL and to assess the outcome in such patients. *Patients and Methods.* 21 patients with HIV-HL from five UK centres treated with ABVD and concomitant HAART were included. Interim PET after two or three cycles of ABVD (PET-2 or PET-3) was carried out in all patients. At the time of therapy, the median age was 42 (range 32-60; 18 M: 3 F). *Results.* Median CD4 count at diagnosis of HL was 187 cells/μl (range 33-995 cells/μl) and majority of patients (76%) had an undetectable plasma HIV viral load (VL). All patients presented with either advanced stage disease (n = 18) or stage 2a disease with adverse prognostic factors (n = 3). Just under half (48%) presented with stage IV disease. All cases were of classical HL and histologic subtypes included: mixed cellularity 8 (38%), nodular sclerosing 7 (33%), unknown 6 (29%). Median Hasenclever IPS was 3 (range 1-6). Of 21 evaluated patients, 20 achieved complete remission (CR) after first-line therapy. Interim PET was negative in 86% (18/21) of patients. Treatment failure was seen in 1 of the 3 interim PET positive patients and none of the 18 interim PET negative patients. The 2-yr progression free survival for patients with a positive interim PET was 67% and for negative interim PET was 100% (p = 0.012). After a median follow up of 20 months (range 5-43), all patients are in continued complete remission (1 after second line chemotherapy for relapse) with no deaths. *Conclusions.* Our findings suggest a negative interim PET maybe highly predictive of successful treatment outcome in Hodgkin's lymphoma even in the setting of HIV disease.

0775

RISK-ADAPTED TREATMENT WITH BEACOPP AND ABVD IN UNFAVORABLE HODGKIN'S LYMPHOMA: A SINGLE CENTER EXERIENCE

A Symeonidis, P Lampropoulou, D Pavlopoulou, V Lazaris, A Kouraklis, V Labropoulou, M Liga, E Tzouvara, E Fragopanagou, A Spyridonidis, M Tiniakou, M Karakantza, N Zoumbos

University of Patras Medical School, Patras, Greece

Aims. To describe the results of treatment of 66 patients with Hodgkin's lymphoma (HL) and advanced disease stage or unfavorable prognosis, by using both, BEACOPP and ABVD regimens, in a patient-based, risk-adapted, tailored treatment approach. *Patients and Methods.* Patients were 40 males and 26 females, with a median age of 31 years (range 16-70 years). Sixty-three had classical HL (nodular sclerosis 35, mixed cellularity 22, lymphocyte-rich 5, lymphocyte-depleted 1), two had composite lymphoma and 1 lymphocyte-predominant HL. Disease stage was IIA with multiple (>3) sites of involvement in 12 (18.2%, IIBE: 3), IIB in 11 (16.7%), IIIA in 8 (12.1%), IIIB in 15 (22.7%, IIIBS: 3), IVA in 5 (7.6%) and IVB in 14 (21.2%, IVBE: 5). At presentation 26 patients had B symptoms (39.4%), 17 had bulky mediastinal disease (25.8%), 13 (19.7%) pulmonary- and 8 (12.1%) liver involvement, 40 (60.6%) exhibited anemia (Hb<12 g/dl), 17 (25.8%) leucocytosis >16 x 109/l, 23 (34.8%) thrombocytosis >400 x 109/l, 10 (15.2%) lymphocytopenia (<0.7 x 109/l), 33 (50%) had elevated serum LDH, 13 (19.7%) elevated CRP, 12 (18.2%) elevated beta2-microglobulin and 12 (18.2%) reduced serum albumin (<4 g/dl). The IPS was 0-1 in 20, 2-3 in 36 and >3 in 10. First-line treatment consisted of BEACOPP alone in 46 patients (69.7%), whereas 8 patients (12.1%) were shifted to ABVD, after the achievement of CR, following 2-4 cycles of BEACOPP. ABVD alone was initially administered in 13 patients with stage II (20%), but 7 of them, who did not achieve complete remission (CR) after 4 cycles, they were shifted to BEACOPP. The remaining 6 patients were treated with BEACOPP at their first relapse. *Results.* Overall, 55 patients achieved CR (84.6%), 47 of the 52 evaluable patients, who received BEACOPP as first-line treatment (90.4%, group A) and 8 of the 13, who initially were treated with ABVD (61.5%, group B). Seven additional patients, 5 from group A and 2 from group B achieved partial response (overall response rate 95.4%), whereas 3 patients did not respond. Seven of the 10 patients with refractory or residual disease and additional 5, who later relapsed, received second/third-line treatment followed by high-dose therapy (BEAM) plus autologous stem-cell transplantation (ASCT). Three patients, who achieved CR with BEACOPP, before ASCT remained in continuous CR, additional 3 achieved CR only following ASCT, one is in third CR after relapse, following ASCT, one is alive with active disease and 4 have died. After a median of 62.5 months (range 0.5-154 months) 57 patients are alive, 54 of them disease-free, two have active disease and one is still under treatment. Nine patients have died, 5 of them from infectious complications during chemotherapy-induced aplasia, 3 from disease related complications and 1 from fulminant secondary AML while in remission from the HL. *Conclusions.* Results from this group with advanced or unfavorable HL demonstrated that risk-adapted treatment by using both, ABVD and BEACOPP regimens is feasible and is accompanied by high CR rates, even when CR is not achieved after the initial 3-4 cycles of chemotherapy.

THE PROGNOSTIC SIGNIFICANCE OF SPECIFIC ORGAN INVOLVEMENT AND THE NUMBER OF INVOLVED EXTRANODAL SITES IN ADVANCED STAGE HODGKIN'S LYMPHOMA

L Jakovic,[1] B Mihaljevic,[1] A Bogdanovic,[1] B Andjelic,[1] M Perunicic Jovanovic,[2] V Bumbasirevic[3]

[1]*Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia*
[2]*Department for Histopathology, Clinical Center of Serbia, Belgrade, Serbia*
[3]*Institute of Histology and Embryology, School of Medicine University of Belgrade, Belgrade, Serbia*

Background. Extranodal dissemination has independent prognostic value within advanced stage Hodgkin lymphoma (HL). It remains controversial whether a specific organ involvement and the number of involved extranodal (EN) sites are prognostically unfavorable. *Aims.* To analyze the prognostic value of specific organ involvement and number of involved EN sites in advanced stage classical HL patients (pts). *Methods.* In a cohort of 100 advanced stage classical HL pts treated with ABVD (1997-2005) we analyzed the prognostic relevance of bone marrow, lungs and liver involvement, as well as two or more involved EN localizations. The median follow up was 7 years. Their significance was tested according to response rate an overall survival (OS). *Results.* The distribution of EN dissemination was: 28 pts with bone marrow infiltration, the lungs involved in 14 pts, the liver involved in 12 pts and other sites involved in 4 pts. Two or more EN localizations involved were found in 14 pts. Complete remission rate was significantly lower in pts with liver involvement (50% vs 83%, p=0.017). A shorter OS was associated with bone marrow (p=0.003), lungs (p=0.022) and liver (p=0.001) involvement. Furthermore, two or more EN sites had adverse effect on OS (p=0.000). Lung involvement and EN two or more localizations had adverse effect on event free survival (EFS) (p=0.000; p=0.001), respectively. Cox's multivariate model revealed EN two or more localizations as a significant independent prognostic factor for OS (p=0.000) and lungs involvement for EFS (p=0.000). *Summary/Conclusions.* Advanced stage classical HL pts with EN two or more localization and lungs involvement are at higher risk of treatment failure and might be eligible for more effective treatment approach.

0777

OUTCOME AND PROGNOSTIC FACTORS IN HODGKIN LYMPHOMA (HL) PATIENTS WHO RELAPSE AFTER HIGH DOSE THERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION (HDT/ASCT)

M Angelopoulou,[1] S Masouridis,[1] G Pangalis,[1] O Tsopra,[1] M Moschogiannis,[2] V Pappi,[1] P Tsirkinidis,[3] Z Galani,[1] K Petevi,[1] M Dimou,[1] K Koutsoukos,[1] G Georgiou,[1] S Sachanas,[2] P Panayiotidis,[1] I Meletis,[1] T Vassilakopoulos[1]

[1]*National and Kapodestrian University of Athens, Athens, Greece*
[2]*Athens Medical Center, Athens, Greece*
[3]*401 General Army Hospital, Athens, Greece*

Background. Patients with HL who relapse after HDT/ASCT are considered incurable. *Aims*. To evaluate the outcome and prognostic factors of 45 HL patients, who relapsed after HDT/ASCT. *Methods*. Out of 95 consecutive patients with primary refractory/relapsed HL undergoing HDT/ASCT at a single unit from March 1996 to January 2010, 45 patients who relapsed after HDT/ASCT were recorded. Thirty-one out of 45 (69%) were males, their median age at ASCT was 28 years (19-54), 18 (40%) underwent HDT/ASCT at first relapse, 5 (10%) for multiple relapses and 23 (50%) for primary refractory disease. Prior to HDT/ASCT, 14 (31%) were in complete remission (CR), 18 (40%) in partial remission (PR) and and 13 (29%) were chemoresistant. *Results*. Median time between ASCT and the following relapse was 6.3 months (1-54). At relapse after ASCT median hemoglobin was 11.8 g/dL (7.6-14.4), 32%, 18%, 24% και 26% had clinical stage I, II, III και IV respectively and 27% had B symptoms. The median number of involved sites was 3 (1-12), 16% had bulky and 41% extranodal disease. The most common involved extranodal sites were lungs, bones and soft tissue.

Patients received the following therapies: 47% radiotherapy (RT), 25% chemotherapy containing gemcitabine/vinorelbine +/- liposomal doxorubicin, and 22% MOPP-like chemotherapy. Furthermore, 5 patients underwent a second ASCT and 2 patients allogenic stem cell transplantation. At a median follow up of 36 months, 3-year freedom from second failure (FF2F) and 3-year overall survival (OS) after relapse was 23% και 64%, respectively. Thirteen out of 45 patients died of HL, 4 due to secondary myelodysplatic syndrome/acute non lymphoblastic leukemia, 15 are alive with active HL and 13 are alive in CR. Prognostic factor analysis for FF2F disclosed that a short (<12months) interval between ASCT and relapse (p<0.002), chemoresistance prior to ASCT (p<0.002), anemia (p<0.004) and B symptoms at relapse post ASCT (p<0.02) were of unfavourable prognostic significance. Chemoresistance prior to ASCT (p<0.005), anemia (p<0.03) and B symptoms at relapse (p<0.0001) were unfavorable prognostic parameters for OS, as well. In addition, age ≥45 (p<0.03) proved as a poor prognostic factor for OS. Despite the limited number of patients, multivariate analysis revealed that chemoresistance prior to ASCT and B symptoms at relapse post ASCT were independent prognostic factors for FF2F and OS. *Conclusions*. Patients with HLwho relapse after ASCT have a poor prognosis. However, the natural history of the disease remains long, with 2/3 of the patients remaining alive at 3 years after relapse. Chemoresistance prior to ASCT, B symptoms and anemia at relapse post ASCT, as well as, relapse in <12 months after ASCT, are unfavorable prognostic parameters.

0778

BEACOPP-14 VS. BEACOPP-ESC IN PATIENTS WITH HODGKIN'S DISEASE FROM POOR-PROGNOSIS GROUP: INTERIM ANALISYS OF PROSPECTIVE RANDOMIZED MULTICENTER STUDY

I Kriachok,[1] I Titorenko,[1] K Filonenko,[1] O Novosad,[1] T Kadnikova,[1] A Martynchik,[1] V Oliynik,[2] V Stratiyenko,[3] V Kovtun[2]

[1]*National Cancer Institute, Kyiv, Ukraine*
[2]*Obloncodispanser, Zaporizhzhya, Ukraine*
[3]*Oblasna Klinichna Likarnya, Kherson, Ukraine*

Aim. To compare the efficacy and toxicity of the treatment with B EACOPP-14 and B EACOPP-esc regimens in patients with Hodgkin's disease (HD) from high risk group in prospective randomized study. *Methods*. since September 2008 103 patients in 6 Ukrainian centers from 18 to 65 years old (median 29 years), 48 male and 55 female with stage B with ≥1 unfavorable factors and stage III-IV were randomized to receive the treatment with B EACOPP-14 (48 pts, 301 cycles, 6.27 cycles per patient) and B EACOPP-esc (55 pts, 315 cycles, 5.95 cycles per patient). The treatment efficacy in both groups was evaluated after 4, 6 and 8 cycles by heson criteria (1999, 2007). Toxicity rate was evaluated with NCI-CTC. After completion of chemotherapy patients with initial sites >5 cm, residual lymph nodes >2 cm and PET-positive sites received radiotherapy (30-36 Gy). Additionally the similar group of patients, who received the therapy with ABVD, was selected for the historical control from National Cancer-register. *Results*. Maximal observation period in both groups is 29 months. Overall response rate (ORR) after the completion of the treatment was 97.9% in the group of BEACOPP-14 and 98.1% in the group of BEACOPP-esc; p>0.05 (Table). In the group of historical control ORR was 80.39%; that is significantly lower than in both studied groups; p<0.05. The therapy in 4 patients in the group of BEACOPP-14 and 6 patients in the group of BEACOPP-esc was changed to ABVD according to the toxicity. The most frequent toxicity type in both groups was hematological toxicity of different grades (72.8% in the group of BEACOPP-14 and 67.6 in the group of BEACOPP-esc, p>0.05). The special feature of BEACOPP-14 treatment was significantly higher rate of anemia: 25% compare to 12.5% in the group of BEACOPP-esc. In 7.5% the BEACOPP-14 cycles were not completed due to neutropenia of 4th grade. 1 patient in the group of BEACOPP-esc died because of infectious complication. Nonhematological toxicity was observed in 45.6% cycles of BEACOPP-14 and in 51.5% cycles of BEACOPP-esc. The most frequent nonhematological complications were nausea and vomiting (Table). *Conclusion*. The therapy efficacy in both groups of BEACOPP-14 and B EACOPP-esc was higher than in the group of historical control (treatment with ABVD). Both comparative regimens show almost equal treatment efficacy and toxicity rates in patients with HD of the poor prognosis group. However, the results are preliminary and should be confirmed in larger number of patients and with a longer follow-up.

Table 1. Efficacy and toxicity rate.

Data	BEACOPP-14, %	BEACOPP-esc, %	Significance
Early relapse	0 patient	2 patient	
Progression during the therapy	1 patient	1 patient	
ORR, 6 cycles	97.9	98.1	
ORR, 8 cycles	97.9	98.1	
CRR, 6 cycles	86.6	81.25	p>0.05
CRR, 8 cycles	97.9	98.1	
Neutropenia	35.5	37.3	
Febrile neutropenia	8.3	6.6	
Nausea and vomiting	33.3	45.6	
Mucositis	12.0	6.9	
Anemia	25	12.5	p<0.05

GNRH-ANALOGOUS IN YOUNG PATIENTS AFFECTED BY HODGKIN DISEASE (HD) TREATED WITH ABVD

M Giannoccaro,[1] C Minoia,[1] A Rana,[1] A Iacobazzi,[1] A Lapietra,[1] A Raimondi,[1] A Kardhashi,[2] V Trojano,[2] A Guarini[1]

[1]*Istituto Tumori Giovanni Paolo Ii, Dept. Oncologia Medica, U.O. Ematologia, Bari, Bari, Italy*
[2]*Istituto Tumori Giovanni Paolo Ii, U.O. Ginecologia, Bari, Bari, Italy*

Background. The mechanism by which chemotherapy causes long-term gonadotoxic effect is not completely understood. Few data are available on features predicting infertility risk and gonadic dysfunction. Despite there aren't standardized methods evaluating fertility in this subset of patients, resumption of the menstrual cycle is considered as expression of the ovarian reserve. This resumption represents a desirable goal in long-term survivals of treated Hodgkin's Lymphoma, in order to protect from unfavorable effects of premature amenorrhea. There are currently no approved procedures certainly effective in trying to preserve fertility (ovarian suppression by treatment with estro-progestinic or gonadotropin-releasing hormone agonist analogue, ovum or ovarian tissue cryopreservation). The gonadic function in patients with HD seems to be adversely affected by therapies containing alkylating agents or procarbazine, by employed doses (BEACOPP and BEACOPP esc.), by advanced stage disease and by age. Conversely there is no evidence on the gonadotoxic potential of ABVD protocol. Matter under discussion is the induction of ovarian suppression by administration of GnRH analogue (GnRH-a) in order to reduce the risk of ovarian failure associated with chemotherapy. *Aims.* Aim of this study was to evaluate the gonadotoxic potential (High/Intermediate/Low/No risk) of ABVD protocol and to examine the ovarian reserve after chemotherapy in a group of patients with HD treated according to protocol ABVD alone or in combination with GnRH-a, defining as primary end-point recovery and regularity of menstrual cycles. *Methods.* We studied 31 patients aged between 16 and 35 years (mean age 23.5 years), affected by HD (70% nodular sclerosing; 30% mixed cellularity; 93% stage I-II, 15% of which with bulky disease; 7% stage III-IV) homogeneously treated with 4-6 cycles ABVD and not receiving pelvic radiotherapy. At diagnosis no patients had disorders of the menstrual cycle. Twenty-two patients received prophylaxis with GnRH-a (triptorelin / DecapeptylTM). Amenorrhea, irregularity and regularity of menstrual cycles were evaluated as end-points events in both groups (GnRH-a +/-): analysis was performed using Fisher exact test and evaluation of the relative risk (RR). Gonadotoxic potential of ABVD protocol was compared to homogeneous historical group of HD (17 pts) receiving protocol MOPP/ABVD (GnRH-a +/-) and efficacy of prophylaxis with GnRH-a evaluated on historical group too. *Results.* In our group of patients the incidence of amenorrhea after ABVD protocol was 1/31. The analysis for the event amenorrhea between the groups GnRH-a +/- showed no significant differences; the analysis conducted for the events irregularity and regularity of menstrual cycles showed differences within the limits of statistical significance between groups GnRH-a +/- (p = 0.07). Significant was the assessment of the relative risk: for amenorrhea RR 3.75 (CI 2.1-6.8), irregular cycles RR 6.3 (CI 1.1-8.9) and regular cycles RR 0.32 (0.1-0.9). ABVD group vs historical group had lower risk for amenorrhea (p=0.01) and GnRH-a decreased gonadotoxic effect (amenorrhea) of high-risk chemotherapy (MOPP/ABVD/GnRH-a vs MOPP/ABVD p= 0.04). *Con-*

clusion. These data suggest low-intermediate gonadotoxic potential of ABVD protocol and indicate a protective effect (RR>1) of inhibition of the hypothalamic-pituitary axis by the administration of GnRH-a on the risk of amenorrhea and irregular menstrual cycles after treatment with ABVD protocol.

SALVAGE THERAPY FOR RELAPSING OR RESISTANT HODGKIN LYMPHOMA: RETROSPECTIVE ANALYSIS OF RESULTS UTILIZING THREE DIFFERENT DEBULKING REGIMENS INCLUDING DHAP, IGEV OR IGEV FOLLOWED BY ESCALATED BEACOPP

M Gotti,[1] C Rusconi,[2] V Fiaccadori,[1] V Zilioli,[2] C Gabutti,[2] M Mazzucchelli,[2] M Bonfichi,[1] E Alessandrino,[1] E Morra,[2] E Brusamolino[1]

[1]*Fondazione IRCCS Policlinico S.Matteo, Pavia, Italy*
[2]*Divisione di Ematologia, A.O. Niguarda Cà Granda, Milano, Italy*

Background. Peripheral blood autologous stem cell transplant (PBASCT) is the standard therapy for patients with relapsed or refractory Hodgkin lymphoma. The aim of second-line chemotherapy regimens utilized in this subset of patients before transplant is to mobilize peripheral blood stem cells and reduce tumor burden, but no consensus has yet been reached on which scheme is the best one. *Aims.* To retrospectively evaluate our experience with different debulking regimens including DHAP, IGEV and IGEV followed by escalated BEACOPP. *Patients and Methods.* We reviewed 90 patients treated from April 1998 to December 2009 for resistant or relapsed Hodgkin lymphoma. Second-line chemotherapy changed over-time from DHAP x 2 cycles (group A) to IGEV x 1 followed by escalated BEACOPP x 2 (group B) and IGEV x 4 cycles (group C). Patient features are illustrated in the Table.

Table 1.

Features	DHAP (A)	IGEV + BEACOPP (B)	IGEV (C)
Total	28	23	39
Median age (yrs)	31 (16-67)	24 (16-61)	31 (15-61)
Early relapse (< 12 mos)	5	4	12
Late relapse (> 12 mos)	4	6	13
Resistant	19 (68%)	13 (57%)	14 (36%)

Overall, first-line CT was ABVD in 83 and MOPP alternated to ABVD in 7 patients. Involved-field RT had been given in 32 patients. PBSC mobilization was carried-out after the first cycle of DHAP or the first cycle of IGEV, both in group B and C. Survival was calculated with the actuarial method. *Results.*The overall response rate (ORR) of group A was 57% (CR in 8 of 28 pts: 29%), of group B 82% (CR in 15 of 23 pts: 65%) and of group C 77% (CR in 11 of 39 pts: 28%). No patient failed to mobilize PBSC; the median number of harvested CD34+ cells after DHAP (group A) was 11.8 x 106/Kg (range: 2.6-48), and after IGEV (groups B and C) 12.3 x 106/Kg (range: 3.7-50.8). Overall, 81 patients underwent PBSCT (25 in group A, 21 in group B, 35 in group C); 34 of them (42%) were given additional chemotherapy before BEAM conditioning: 14 (50%) in group A, 4 (17%) in group B, 16 (41%) in group C. The 2-yr PFS was 35%, 56% and 34% in groups A, B and C; in the same groups, the 5-yr overall survival was 81%, 78% and 63%, respectively. *Conclusions.* The retrospective nature of this survey does not allow firm conclusions on the best second-line therapy in Hodgkin lymphoma. Altogether, the three different approaches allowed an overall response rate of 72%, with a 2-yr PFS of 42%, and no difference in the 5-yr overall survival between the three groups of therapy was observed. In our experience, both IGEV and DHAP showed a good mobilizing capacity, while the inclusion of escalated BEACOPP produced a better CR rate compared to DHAP and IGEV and a higher 2-yr PFS rate.

PATIENTS WITH REFRACTORY AND RELAPSED HODGKIN'S LYMHOMA COULD BENEFIT FROM AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION

M Cioch,[1] M Legiec,[1] D Jawniak,[1] M Wach,[1] W Legiec,[1] J Manko,[1] A Walter-Croneck,[1] A Dmoszynska,[1] E Staroslawska[2]

[1]*Medical University in Lublin, Lublin, Poland*
[2]*Regional Oncology Center in Lublin, Lublin, Poland*

Background. The autologous haematopoietic stem cell transplantation (AHSCT) in the last two decades has became the optimal therapeutic method in patients (pts) with refractory or relapsed Hodgkin's lymphoma (HL). *Aims.* The aims of our study was the estimation if refractory and relapsed Patients with Hodgkin's lymhoma could benefit from autologous haematopoietic stem cell transplantation. *Methods.* We report the results of a retrospective analysis of 78 patients (pts) with HL (37 female and 41 male; mean age 29 years) treated with AHSCT after failure of conventional chemotherapy between November 1997 and September 2010. Among them there were 77.4% of pts with nodular sclerosis, 19.4% with mixed cellularity and 3,2% with lymphocytic depletion. HL stage at diagnosis by Ann Arbor criteria was IV in 53.0% of pts, III in 22.7% and II in 24.3%. The median lines of chemotherapy was 3.5 and the standard scheme of first line chemotherapy was ABVD. 47.7% of pts were transplanted due to refractory (non-responders pts, NR) and 52.3% due to relapsed lymphoma (29.2% of relapse after complete remission and 23.6% of relapse after partial remission; CRR and PRR respectively). The standard regimen of first-line mobilization was ETO (1.6 g/m^2). The Ara-C regimen (2.4 g/m^2) was applied in remobilization and in first-line of mobilization in heavily pretreated pts (radiotherapy or more than 3 line of chemotherapy). Pts with refractory, active disease were collected after ESHAP regimen. The dose of G-CSF was 5-10 mcg/kg. The conditioning regimen was BEAM in all pts. The median of CD34+ transplanted cells was 3.5x10^6/kg. All patients engrafted. There was no case of death during mobilization and transplantation procedure. *Results.* Patients were evaluated on day 100 after AHSCT. There were 72.3% of pts with CR, 14.3% with PR and 12.5% with disease progression (DP). The median overall survival (OS) of all pts was 42.5 months, those with CRR was 47.2 months, those with PRR was 52.6 months, and those with NR was 34.5 months. There was no significant difference between those three groups (p=0.19). The median overall survival (OS) of pts with CR in 100 days after AHSCT was 46.0 months, those with PR was 47.1 months, and those with DP was 25.1 months. The difference between tree groups was significant (p=0.001). *Conclusions.* In conclusion, AHSCT is safe and have a high efficacy in pts with refractory and relapsed HL, who achieve remission in 100 days after transplantation.

Immune thrombocytopenia and other platelet disorders

[11]*Gaucher Clinic, Shaare Zedek Medical Center, Hebrew University, Jerusalem, Israel*

Background. Thrombocytopenia in type 1 Gaucher disease (GD1) may result in surgical, obstetrical and spontaneous bleeding. Thrombocytopenia generally responds rapidly to imiglucerase enzyme replacement therapy but, in rare cases, the platelet response seems to be delayed and thrombocytopenia persists. *Aims.* To identify patient characteristics associated with (and potentially predictive of) persisting thrombocytopenia despite therapy. *Methods.* Patient characteristics associated with persisting thrombocytopenia were investigated by retrospective analysis of data from the International Gaucher Group (ICGG) Registry. A total of 1,016 GD1 patients with an intact spleen, for whom date of diagnosis, therapy initiation, and platelet counts were known and who received continuous imiglucerase therapy for 4-5 years, were classified into four groups by last platelet count: >120 x 10^9/l (n = 772); >100 to <120 x 10^9/l (n = 94); >80 to <100 x 10^9/l (n = 80); and <80 x 10^9/l (n = 70; 20 with <60 x 10^9/ l). Patients were characterized by initial and cumulative average imiglucerase dose, BMI, platelet count, anemia, hepatomegaly, splenomegaly, and skeletal assessments at baseline and after 4-5 years of therapy. Possible associations with persisting thrombocytopenia were tested using a multivariate proportional odds regression analysis, which adjusted for age at diagnosis and therapy initiation, genotype, gender, year of diagnosis, and year of therapy initiation. A statistical analysis of the relationship between spleen volume and platelet count was performed across all patients with reported spleen volumes (n = 660; 2,299 observations) using scatter plots with a smoothing curve calculated through the loess method. Because methods used to determine spleen volume are not always captured by the ICGG Gaucher Registry and may be based on estimates from ultrasound or palpation, a scatter plot was also performed using data from 50 patients (538 observations) attending the AMC, the Netherlands, irrespective of treatment status and for whom spleen volume had been determined accurately by CT or MRI. *Results.* Correlations were found between persisting thrombocytopenia and baseline platelet count (<80 x 10^9/l), splenomegaly, and anemia (all p<0.0001). After 4-5 years, correlations were found with splenomegaly (p<0.0001), anemia (p<0.0001), WBC (p = 0.049), hepatomegaly (p = 0.004) and bone pain (p = 0.035). Analysis of the relationship between spleen volume and platelet count across patients in the ICGG Gaucher Registry suggested an exponential relationship between the two parameters. Analysis of spleen volume versus platelet counts in patients attending the AMC, demonstrated a similar curve indicating that platelets increase only when spleen volume has decreased substantially. *Summary/conclusions.* The strong association between splenomegaly, anemia and thrombocytopenia at the initiation of therapy and persisting thrombocytopenia after 4-5 years of treatment in a minority of patients suggests that extensive spleen involvement before therapy initiation may be predictive of persistent thrombocytopenia. The exponential relationship between platelet number and spleen volume suggests that the initial platelet response may be slow in cases of extensive splenomegaly.

0783

PREOPERATIVE USE OF ROMIPLOSTIM IN THROMBOCYTOPENIC PATIENTS WITH CHRONIC HEPATITIS C AND LIVER CIRRHOSIS

M Moussa, N Mowafy

Ain Shams University, Cairo, Egypt

Background. Romiplostim is a thrombopoietin mimetic "peptibody" comprising a human immunoglobulin IgG1 Fc domain covalently linked at each of its two C-terminals to two 14-amino-acid peptides that bind to and stimulate the thrombopoietin receptor. Continuous treatment with Romiplostim increases platelet counts in patients with immune thrombocytopenia for up to 5 years, with few adverse effects. Hepatitis C virus (HCV) represents the second most common blood-borne illness in the world, affecting up to 2% of the world's population. Egypt reports the highest prevalence of HCV worldwide, ranging from 6% to more than 40% with an average of 13.8%. Thrombocytopenia, usually from Hypersplenism (and possibly from altered thrombopoietin metabolism or antiplatelet antibodies), is common in patients with cirrhosis. *Aim.* To detect the efficacy of Romiplostim use in thrombocytopenic patients with chronic hepatitis C and liver cirrhosis preoperatively. *Methods.* Our study was performed on 12 patients in the Electricity Hospital, Cairo, Egypt, having chronic liver disease with liver cirrhosis and they were classified as Child-Pugh score C with thrombocytopenia. All the patients started Romiplostim injections at a dose of 2 mcg/kg once weekly for four weeks. CBC, liver and kidney function tests, bone marrow aspirate and biopsy were done to all patients at start of the study and at day 90. CBC was done for all patients every 3 days till day 90. *Results.* The mean baseline platelet count was 31x10^3 /microL (range 21x10^3 - 42x10^3). Eleven of the 12 studied patients showed a highly significant (p value 0.000) increase in the platelet count with a maximum peak of 220x103/microL, occurring between days 15 - 33 in most patients. These patients proceeded to their planned surgery which included cataract, hernia and fracture fixation. No postoperative bleeding complications were recorded. There was no change in the reticulin grade in bone marrow of any of the patients. There were no significant change in liver function but there was a significant increase in the bilirubin level. One patient did not respond by platelet count increase during the time schedule of the study and hence did not undergo surgical intervention. *Conclusion.* Romiplostim can be used under close follow up in chronic hepatitis C patients with liver cirrhosis and severe thrombocytopenia preoperatively in a dose of 2 mcg/kg once weekly for four weeks. Additional studies are necessary to define the optimal dose and schedule of romiplostim.

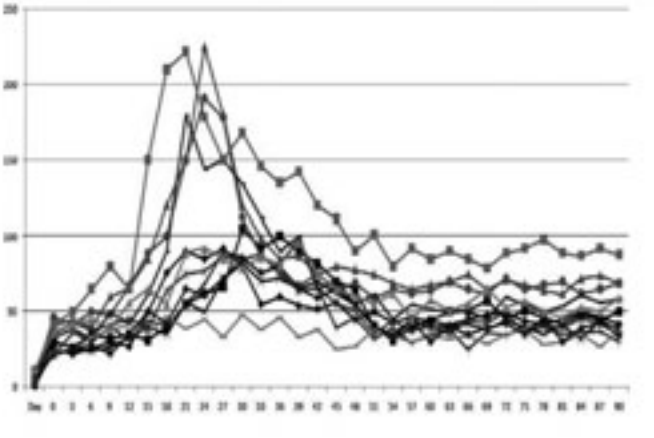

Figure 1. Platelet count in patients.

PRESENCE OF ADAMTS13 AUTOANTIBODIES IN OBESE SUBJECTS AS A POSSIBLE LINK BETWEEN OBESITY AND THROMBOTIC THROMBOCYTOPENIC PURPURA

AM Lombardi,[1] R Fabris,[2] V Zanato,[2] P Scarparo,[3] G Berti De Marinis,[3] R Vettor,[2] F Fabris[3]

[1]*University of Padova, Padova, Italy*
[2]*Dep of medical and surgical sciences-Third chair of internal medicine, Padova, Italy*
[3]*Dep of medical and surgical sciences - Internal medicine, Padova, Italy*

Background. Thrombotic thrombocytopenic purpura (TTP) is a rare but often fatal disorder, whose mechanisms are yet to be fully understood. It is characterized by widespread thrombosis in the arterioles and capillaries of multiple organs and is mainly associated with severe deficiency of ADAMTS13, a disintegrin and metalloprotease with thrombospondin (TSP)-1 repeats. This enzyme cleaves high molecular weight von Willebrand Factor1 (ULVWF) multimers freshly released from activated endothelial cells to smaller and less active forms. Recently it has been reported that morbid obesity represents a risk factor for TTP, but the possible mechanisms underlying the phenomenon are still unknown. In obesity a low grade chronic inflammation state exists, with increased levels of adipokines, among them thrombospondin-1 (TSP-1). *Aims.* We aimed to investigate possible mechanisms linking obesity and risk of developing TTP. We also tried to understand the role of TSP-1 as a possible causative factor of TTP in obesity, given its structural homology with ADAMTS13 and its high expression by adipose tissue. *Methods.* 80 obese and 39 lean subjects were characterized by anthropometric, metabolic and inflammatory parameters and compared to 32 patients with TTP in clinical remission. ADAMTS13 antigen levels and activity, ADAMTS13 autoantibodies, TSP-1 and various cytokines' levels were measured. *Results.* 21.3% of obese patients had a positive titre of non-inhibitory ADAMTS13 autoantibodies, while all lean subjects were negative. TSP-1 levels were significantly higher in obese and patients with TTP than in lean subjects. TSP-1 levels in obese patients were inversely correlated with ADAMTS13 activity. Moreover anti-ADAMTS13 antibodies cross-reacted with TSP-1 in obese subjects and patients with TTP in clinical remission. *Conclusions.* The presence of non-inhibitory anti-ADAMTS13 autoantibodies in some obese subjects may be induced by increased TSP-1 levels. Autoantibodies are probably directed against TSP-1 and cross-react with ADAMTS13 thrombospondin-domains. Over time somatic hypermutations could generate inhibitory activity, leading to an acute episode of TTP.

0785

MARKED VARIABILITY IN PLATELET RESPONSE TO ASPIRIN IN HEALTHY INDIVIDUALS: A CROSSOVER STUDY OF PLATELET FUNCTION TESTS

S Fairley,[1] MF McMullin,[2] F Kee,[3] P McKeown[4]

[1]*Belfast Hospitals Trust, Belfast, United Kingdom*
[2]*Queen's University Belfast / Haematology Dpt, Belfast City Hospital, Belfast, United Kingdom*
[3]*UKCRN Centre of Excellence for Public Health NI, Belfast, United Kingdom*
[4]*Queen's University Belfast / Belfast Hospitals Trust, Belfast, United Kingdom*

Background. The Antiplatelet Trialists' Collaboration reported a 25% reduction in death, MI, CVA in high-risk patients treated with aspirin. 'Aspirin resistance' describes recurrent events in aspirin-treated patients with reported rates between 0.4 and 83% depending on the assay used. This study assessed aspirin response in healthy individuals and the performance of various assays. *Aims.* This study assessed the prevalence of aspirin resistance in a cohort of healthy individuals. In addition, the performance of various platelet function tests was examined. A genetic substudy was also performed. *Methods.* A repeated measures, crossover trial was performed in healthy aspirin-naive subjects aged 18-60 years. Written informed consent was obtained. Ethical approval was granted by the Office for Research Ethics Committee NI (ORECNI). The study was funded by Royal Hospitals Trust, Belfast and Northern Ireland Chest Heart and Stroke Association (NICHSA). Subjects were randomised to aspirin dose (75mg or 300mg) and sequence (ABBA, BAAB, ABAB, BABA, A=Aspirin, B=Placebo). The study consisted of 4 3-week treatment periods. Testing (Optical Platelet Aggregation, PFA-100, VerifyNow, serum TXB2 and urinary 11-dTXB2) was performed at baseline and at the end of each treatment period. Standard definitions of aspirin resistance were used. OPA (AA 0.5) was deemed the 'gold standard' (max aggregation ″20%). Compliance was deemed satisfactory at interview. Statistical analysis was performed using Windows SPSS17. *Results.* The overall rate of suboptimal aspirin response was assay-dependant and varied greatly from 2.4% (OPA AA) to 63.5% (OPA ADP). Only 3 subjects were 'aspirin resistant' (via OPA AA) on all occasions. Overall sensitivities ranged from 27.5% (OPA ADP) to 87.5% (serum TXB2). Overall specificities ranged from 85.4% (VerifyNow) to 95% (serum TXB2). In addition, selection of alternative 'cut-off' values chosen for the PFA-100, OPA ADP and serum TXB2 produced marked variation in the calculated prevalence, sensitivities and specificities of these assays. No association was found between aspirin resistance and genetic polymorphisms. *Summary/Conclusions.* Response to aspirin shows significant inter- and intra-individual, inter-assay and temporal variability. The overall prevalence of aspirin resistance ranged from 2.4 to 63.5% depending on assay selection. Testing on multiple occasions using several assays is necessary to reliably predict aspirin response. Selection of alternative 'cut-off' values alters assay performance and caution should be used before categorising patients as 'aspirin resistant'.

0786

ENHANCED P2Y12 INHIBITION IN PATIENTS WITH PREVIOUSLY LOW CLOPIDOGREL RESPONSE AFTER DOUBLING THE DOSE

H Makhloufi,[1] H Seidel,[2] S Buchbinder,[2] C Dücker,[2] E Kirchhoff,[2] T Hoffmann,[2] R Scharf[2]

[1]*University Hospital Düsseldorf, Düsseldorf, Germany*
[2]*Department of Hemostasis and Transfusion Medicine, University Hospital, Düsseldorf, Germany*

Aim. Residual platelet reactivity evaluated by platelet function tests is associated with adverse cardiovascular events in patients at risk on antiplatelet therapy. We compared the *in vitro* efficacy of antiplatelet treatment in patients with double and standard dose of clopidogrel assessing vasodilator phosphoprotein (VASP) P2Y12 specific assay and light transmission aggregometry (LTA). *Methods.* We retrospectively evaluated a cohort of 431 patients by calculating the platelet reactivity index (PRI) based on the VASP assay and by ADP-induced platelet aggregation (ADP max, using 5 µM ADP). Among the patients, 390 were under dual antiplatelet therapy with acetylsalicylic acid and standard dose clopidogrel. A total of 129 patients (33.1 %) showed a PRI >79, indicating a low response to clopidogrel. *Results.* Overall PRI and APD max were 60 ± 41 % and 52 ± 36 %, respectively. There was no significant difference in PRI and ADP max between standard and double dose clopidogrel (student t-test p>0.5). Patients with low clopidogrel response under standard dose revealed PRI and ADP max of 83 ±14% and 61 ± 24%, respectively. In patients with previously poor clopidogrel response, treatment with double dose clopidogrel resulted in significantly lower PRI 60 ± 33% (n=41, student t-test p <0.00001), whereas ADP max showed only a trend to significance (see figure) (ADP max 54 ± 33%, p=0.06). *Conclusions.* In accordance with previous data, we observed no significant difference in an overall cohort of patients between standard and double dose clopidogrel. However, for patients with low clopidogrel response, doubling the dose enhanced the P2Y12 inhibition assessed by VASP and LTA.

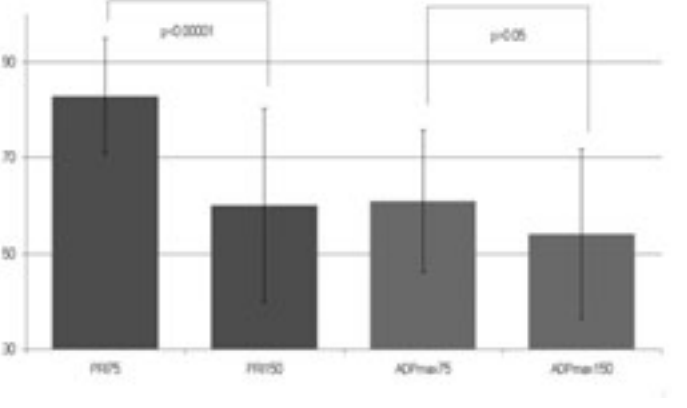

Figure 1. Reduction in platelet reactivity with double dose.

0787

THE USE OF IMMUNOPLATELET COUNTING FOR ESTABLISHING AN ACCURATE PLATELET COUNT DURING PREGNANCY

F Moita, S Robinson

Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background. The determination of platelet count in pregnancy using automated counters can lead to erroneous results as it excludes the large platelets that are commonly present in both immune and gestational thrombocytopenia. The immunoplatelet count has been validated as an international reference method for determining an accurate platelet count. *Aim.* The aim of this study was to determine if there is a significant difference between automated platelet count and immunoplatelet count in thrombocytopenia in pregnancy and whether this difference would impact upon treatment decisions. *Methods.* A retrospective analysis of patients referred to an Obstetric Haematology Clinic in the past two years with platelet counts less than 100 x 10^9/L during pregnancy or with a history of immune thrombocytopenia (ITP) was conducted. The diagnosis of ITP was established if platelet counts were less than 60 x 10^9/L or if there was a previous diagnosis of primary or secondary ITP. Gestational thrombocytopenia was considered if platelet counts were above 60 x 10^9/L and resolved postpartum. Automated platelet counts were performed on Beckman Coulter analyzers LH750. Immunoplatelet count was performed by flow cytometry using the platelet specific antibodies CD41 and CD61. The thresholds considered for treatment and for epidural anesthesia delivery were based on International consensus report and local guidelines. *Results.* A total of 42 women were referred to our clinic for thrombocytopenia during pregnancy. Immunoplatelet counts were performed in 27 women (total of 68 samples analyzed) at different stages of pregnancy and compared to automated platelet counts. A diagnosis of ITP was established in 14 women and of gestational thrombocytopenia in 13 women. When comparing the platelet count using automated analyzers and immunological methods the immunoplatelet count was greater than the automated platelet count in 97% of samples (n=66/68). Using Wilcoxon matched pairs, signed rank test the difference between automated and immunoplatelet counts was significant for both ITP and gestational thrombocytopenia ($p<0.001$). According to the Mann-Whitney U-test this difference was greater in the ITP subgroup ($p=0.007$). The median increase in platelet count in this subgroup was 68% compared to 38% in the gestational thrombocytopenia subgroup. If we apply the International Consensus Recommendations, using the automated platelet count, 1 woman in the first 33 weeks of pregnancy and 5 women in the late stages of pregnancy would have required treatment. Using the immunoplatelet count all patients had platelet counts above the treatment thresholds. The immunoplatelet count was determined in 8 women at delivery. According to the automated platelet count 5 had a platelet count less than 70 x 10^9/L and may not have been considered suitable for epidural anesthesia. Of these 5 women 4 had an immunoplatelet count greater than 70 x 10^9/L. *Conclusion.* During pregnancy platelet count determination using automated instruments underestimates the platelet count. This may lead to unnecessary treatment as well as preventing the delivery of epidural anesthesia. We suggest further studies to establish the use of immunoplatelet count to guide treatment decisions and interventional procedures in women with thrombocytopenia in pregnancy.

RITUXIMAB WITH OR WITHOUT CORTICOSTEROIDS IS AN EFFECTIVE TREATMENT FOR PATIENTS WITH AUTOIMMUNE HEMATOLOGICAL DISORDERS

A Symeonidis,[1] M Kavasi,[1] P Lampropoulou,[1] N Giannakoulas,[2] AL De Lastic,[1] S Michalopoulou,[1] E Tzouvara,[1] A Kouraklis,[1] M Tiniakou,[1] M Karakantza[1]

[2]*University of Thessaly, Medical School, Larissa, Greece*

Backround. During the last few years rituximab has been proved effective in the elimination o autoreactive B-lymphocytes and has demonstrated efficacy in many types of autoimmune disorders. However, the most appropriate schedule of rituximab administration in these conditions has not yet been defined. *Patients and Methods.* We have treated with rituximab 41 patients (18 males, 23 females, median age 45 years, range 16-84 years) with various non-malignant hematologic disorders of autoimmune basis, refractory or relapsed to at least a first-line treatment. Rituximab was administered at a dose of 375 mg/m^2 (24 patients) or 200 mg/m^2 (11 patients) or with an initial dose of 375 mg/m^2, then tailored to 200 mg/m^2 (6 patients) on weeks 1, 2, 3, 4, 6, 8, 10, 14, 18, 22, 36, 48 and 60. Patients were diagnosed with autoimmune hemolytic anemia (AIHA, N=9), idiopathic thrombocytopenic purpura (ITP, N=17), thrombotic thrombocytopenic purpura (TTP, N=8), antiphospholipid syndrome (APS, N=2), Evans' syndrome (N=1) and an acquired inhibitor of factor VIII (AIFVIII, N=1). Six patients in total had been previously splenectomized for hypersplenism (3) or refractory disease (3), and three AIHA patients were multitransfused beta-thalassemics. One patient was HBsAg(+), two had anti-HCV(+) and additional 2 with ITP out of 5 tested, were H.Pylorii positive. Previous treatment consisted of corticosteroids (n=41), intravenous immunoglobulin (IV-Ig, N=29), plasma ad/or plasma exchange (N=9), cyclophosphamide (N=7), danazol (N=6), cyclosporine-A (N=6), azathioprine (N=2), vinblastine (N=2) and romiplostim (N=1). Twenty patients (48.8%) were refractory to previous treatment, 19 (46.3%) had relapsed and 2 (4.9%) were intolerant to corticosteroids. All evaluable patients (39) received at least 4 cycles of therapy (median 10, range 4-28). *Results.* Overall, 27 patients achieved a complete response (CR, 65.8%), 5 a partial response (PR, 12.2%) and 7 (17%) did not respond. Response rates were similar among the different nosologic subgroups (CR: AIHA 50%, ITP 64.7%, TTP 75%, other 100%, PR: AIHA 25%, ITP 11.8%, TTP 12.5%). Response rates were similar among patients administered higher or smaller dose of rituximab, as well as among patients younger and older than 50 years old. Median duration of response was 22.4 months for the whole group, and it was 24.5 months for patients with AIHA, 13.6 months for those with ITP, 24.8 months for those with TTP and 24.8 months for patients with other diseases. Overall, 10 of the 32 responded patients (31.3%) relapsed, following treatment discontinuation, and 7 of them were retreated with rituximab alone (2) or in association with pulses of high dose dexamethasone (5). Six of these patients responded again to rituximab +/- steroids and achieved a second CR (4) or a PR (2). After a median follow-up of 30 months (range 1.1-110 months) 39 patients are alive, 31 of them in CR, 6 in PR and 2 have active uncontrolled disease. Two patients have died due to disease-related complications. *Conclusions.* Rituximab alone or in combination with corticosteroids is an effective second-line treatment for patients with autoimmune hematological disorders at a smaller dose than that administered to patients with lymphoproliferative disorders.

ASSOCIATION OF PLATELET INDICES WITH THYROID-STIMULATING HORMONE AND THYROID HORMONES IN EUTHYROIDIC HEALTHY SUBJECTS

M Dalamaga,[1] K Daskalopoulou,[2] M Pantelaki,[1] M Triantafilli,[3] G Sotiropoulos,[3] K Karmaniolas,[3] A Lekka[3]

[1]*Attkon General University Hospital, Athens, Greece*
[2]*Elpis General Hospital, Athens, Greece*
[3]*NIMTS General Hospital, Athens, Greece*

Background. Platelet parameters and especially mean platelet volume, an important determinant of platelet function and morphology, constitutes a novel emerging risk factor for atherosclerosis and its complications such as coronary heart disease. Mean platelet volume (MPV), platelet distribution width (PDW), platelet count and their correlations with thyroid-stimulating hormone (TSH), thyroxine (T4) and triiodothyronine (T3) have not been studied in depth. *Aim.* The aim of this study was to explore the correlation of platelet indices with TSH and thyroid hormones in euthyroidic healthy subjects. *Methods.* We have evaluated 82 euthyroidic healthy subjects (63 women and 19 men) with a mean age: 58 years (range: 22-78 years). None of the subjects had infectious and neoplastic conditions, diabetes mellitus, hypertension and dyslipidemia. To assess thrombopoiesis, we have determined platelet indices using Sysmex 9000 analyser. TSH, free-T3 and free-T4 were determined using electro-chemiluminescence immunoassay intended for use on Elecsys 2010 analyzer (Roche Diagnostics, Indianapolis, USA). Statistical analysis of data was performed with SPSS® version 17 for Windows software. Pearson or Spearman correlation coefficients (r) were used for normally or not normally distributed variables respectively. *Results.* From the statistical analysis of the data, the following results emerged: 1) There was a significant negative correlation between TSH and MPV in euthyroidic subjects (Spearman $r=-0.747$, $p<0.001$), 2) There was a significant negative correlation between TSH and PDW (Spearman $r=-0.818$, $p<0.001$), and 3) No statistically significant associations emerged between free-T3, free-T4 and platelet parameters ($p>0.05$). In a multiple linear regression model, con-

trolling for age, gender, body mass index and thyroid hormones, serum TSH is a statistically significant predictor of MPV and PDW levels ($p<0.05$) in euthyroidic healthy subjects. *Conclusion.* Our results indicate that TSH levels play an important predictive role in platelet markers which reflect platelet morphology and function. These results may also suggest that individuals with lower TSH levels tend to present increased platelet activation which could contribute to an increased risk of atherothrombotic complications in the future.

[3]*Elpis General Hospital, Athens, Greece*

Background. Subclinical hyperthyroidism (SCH) is often encountered in the general population. Patients may be asymptomatic or may present non-specific symptoms. It has been suggested that SCH could be a risk factor for cardiovascular disease. On the other hand, platelet parameters and especially mean platelet volume, an important determinant of platelet function and morphology, constitutes a novel emerging risk factor for atherosclerosis and its complications such as coronary heart disease. Increased mean platelet volume (MPV) reflects active and large platelets that could release more thromboxane than smaller ones. MPV, platelet distribution width (PDW), platelet count (PLT) have not been studied in depth in subclinical hyperthyroidism. *Aim.* The aim of the present study is to compare the platelet count as well as the platelet parameters MPV and PDW in subclinical hyperthyroidism and in euthyroidic healthy subjects and to investigate whether SCH may have a predictive significance in the determination of platelet size. *Methods.* In a cross-sectional study between 2007 and 2010, we have evaluated thirty five patients with subclinical hyperthyroidism prior to any therapeutic intervention (26 women and 9 men) with a mean age: 32.5 ± 8.1 years (range: 18-48 years) and an equal number of euthyroidic healthy subjects (26 women and 9 men) with a mean age: 32.4 ± 7.1 years (range: 20-46 years). Healthy subjects were matched on gender, age (±5 years) and year/month of diagnosis (±1 month). None of the subjects (patients and controls) presented any infectious and neoplastic conditions, diabetes mellitus, hypertension and dyslipidemia. To assess thrombopoiesis, we have determined platelet indices using Sysmex 9000 analyser. Thyroid-stimulating hormone, triiodothyronine (T3), free-T3, thyroxine (T4) and free-T4 were determined using an electrochemiluminescence immunoassay intended for use on Elecsys 2010 analyzer (Roche Diagnostics, Indianapolis, USA). Statistical analysis of data was performed with SPSS® version 17 for Windows software. *Results.* Cases presented significantly higher MPV (mean ± SD: 12.27 fL ± 0.46) and PDW (mean ± SD: 15.8 % ± 1) than controls (mean MPV ± SD: 10.65 fL ± 0.78, $p<0.001$ and mean PDW ± SD: 13.5 % ± 1.34, $p<0.001$). On the contrary, patients with subclinical hyperthyroidism had similar number of platelets per mm3 than healthy euthyroidic subjects (mean PLT in patients: 253 x 103/mm3 ± 34 versus mean PLT in controls 264 x 103/mm3 ± 38, $p=0.18$). In a linear regression model, adjusting for age, gender, body mass index and smoking status, the presence of subclinical hyperthyroidism was the most significant predictor of MPV and PDW levels ($p<0.001$). *Conclusion.* These results suggest that subjects with subclinical hyperthyroidism tend to present increased platelet size and activation. Elevated platelet activation could contribute to an increased risk of atherothrombotic complications observed in SCH. Finally, these findings suggest that platelet morphologic changes observed in subclinical hyperthyroidism, such as higher MPV and PDW could be attributed to metabolic parameters.

0791

HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN ADULT SERBIAN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA

N Suvajdzic Vukovic,[1] R Zivkovic,[2] T Pekmezovic,[3] A Vidovic,[1] I Djunic,[1] I Elezovic,[1] D Tomin,[1] D Marisavljevic,[2] O Markovic[2]

[1]*Clinic of Hematology, Belgrade, Serbia*
[2]*Clinical Hospital Bezanijska Kosa, Belgrade, Serbia*
[3]*School of Medicine, Belgrade, Serbia*

Background. Multiple available treatments in ITP are aimed at minimizing the risk of bleeding and increasing the patients' platelets. However, these treatments beside bleeding may impact on patients' HRQoL. *Aim.* To evaluate the effect of ITP and its treatment on the patients' HRQoL. *Methods.* Short form SF-36 health Survey was used to measure HRQoL; it was analyzed referring to the most important demographic and clinical characteristics in multivariate regression analysis. Hamilton tests were used for the assessment of anxiety and depression. The patients fulfilled a questionnaire developed from the literature review; it consisted of clinical information including demographics, the course of the disease, previous and current treatments and complications. Non-parametric measures of correlation were performed using the Spearman's rank correlation coefficient. Differences between subgroups were analyzed by $\chi 2$ test and ANOVA test. Predictive value of variables investigated was assessed by multiple linear regression analysis. *Results.* 111 adults with ITP (mean age 47.6 years; female 74%; median disease duration 4 years; median platelet count $14x10^9$/L) were assessed. Throughout their disease 84% patients experienced bleeding and 81.1% patients received some therapy: 95.6% corticosteroids, 24.4% intravenous immunoglobulins (IVIg), 22.2% danazol, 13.3% micophenolate mofetile, 7.8% azathioprine, 6,7% vincristine, 4,4% ciklosporine, 3,3% cyclophosphamide, 1,1% dapsone. A total of 48/111 (43.2%) patients reported a history of transfusions for the treatment of ITP. At the time of the survey the median platelet count was $76x10^9$/L, range 3-$500x10^9$/L; bleeding was present in 18 (16.2%) patients; 44 (39.6%) patients received some therapy: 81.8% corticosteroids, splenectomy 29,7%, 13.6% danazol, 20.5% micophenolate mofetil and 4.5% azathioprine. Herbs/supplements were used by 47 patients (42.3%). Treatment side effects were reported by 85 (96%) patients on corticosteroids and 5 (23.7%) patients on IVIg. At the time of the survey 66.7% reported commorbidities, mainly attributed to the ITP treatment. Regarding the effects of the disease on the patients' life style 90% reported absence from work/school. Patients were bothered the most with reduced work ability (26.1%), fear (25.2%), fatigue (19.8%), bleeding (19.8%), infections (7.2%) and corticosteroid side effects (21.4%). Some degree of fear was reported by 57% of all patients; 20.7% of patients were anxious and 72.1% had some degree of depression. The patients' HRQoL was decreased in the domains of general health (GH), mental health (MH), physical functioning (PF) and vitality (V), as well as in composite score of physical functioning (PCS) and mental composite score (MCS). Disease duration, platelet count, corticotherapy, IVIg administration and side effects of IvIG/ corticotherapy did not impact on HRQoL. On the contrary, treatment with azathioprine and micophenolate mofetile affected GH as a negative predictor, while splenectomy and herbs/supplements improved GH perception. Bleeding significantly decreased HRQoL in 5/8 of SF-36 domains ($p<0.05$). Fear of bleeding increased patients' depression and anxiety and they both significantly decreased all HRQoL domains ($p<0.01$). Age, education, employment and marital status impaired HRQoL, too ($p<0.01$). *Conclusions.* This study shows that the impact of ITP on patients' HRQoL in Serbia is substantial. The most important negative predictors of impaired HRQoL are lower education level, comorbidities and bleeding.

0792

HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN CHRONIC IMMUNE THROMBOCYTOPENIA (ITP) PATIENTS: RESULTS FROM A LONG-TERM STUDY OF ROMIPLOSTIM

S Mathias,[1] J George,[2] L Aledort,[3] R Deuson,[4] A Giagoundis,[5] C Kessler,[1] K Nie,[4] R Rodeghiero[6]

[1]*Health Outcomes Solutions, Winter Park, United States of America*

[4]*Amgen, Thousand Oaks, United States of America*
[5]*St. Johannes Hospital, Duisburg, Germany*
[6]*Department di Cell Therapy and Hematology, Vicenza, Italy*

Background. HRQOL is an important outcome for understanding the morbidity of ITP and the effects of treatment. *Aims.* To assess HRQOL in patients treated with romiplostim for 48 weeks. *Methods.* Romiplostim is a novel thrombopoiesis-stimulating peptibody that increases platelet production by stimulating the thrombopoietin receptor. This is an analysis of HRQOL during the first 48-weeks of an open-label extension study of romiplostim treatment in adult chronic ITP patients who had participated in earlier studies. Each patient completed the ITP-Patient Assessment Questionnaire (PAQ) at baseline, and at weeks 4, 12, 24, 36, and 48 in this extension study and also as part of the earlier study. The ITP-PAQ contains 44 items and 10 scales, with scores ranging

Table 1.

ITP-PAQ Scale Scores* by Assessment and Change Scores from Baseline

ITP-PAQ Scale	Baseline Score (n=253)	Scale Score Week 48 (n=208)	Change Score All patients (n=208)	Change Score Splenectomized patients (n=71)	Change Score Patients with no Exposure to Romiplostim within 24 weeks prior to Study (n=73)
Symptoms	74.1 ± 19.1	79.3 ± 17.3	4.2 ± 13.2*	6.8 ± 14.5*	7.7 ± 13.8*

n is the number of patients who completed both the baseline and the week 48 ITP-PAQ.
* Data represent mean ± SD.
* 95% confidence interval did not overlap with zero.
**Sample sizes varied slightly by scale, but were greatly reduced for Work and Reproductive Health since Work included only those who worked for pay, and Reproductive Health included women only.

from 0-100. Previous research on the ITP-PAQ found that 8-12 points reflects clinically meaningful changes for most scales. Scores at each assessment, and change scores from baseline to week 48 for all patients and for subgroups (splenectomized patients and those with no prior exposure to romiplostim) were calculated. 95% confidence intervals were used to determine whether change scores significantly differed from zero, representing statistical significance. *Results.* Results demonstrate a significant improvement with romiplostim treatment in all scale scores, with the greatest improvement for all patients in Bother (6.4 point-change), Activity (5.2 point-change), and Overall Quality of Life (QOL) (8.3 point-change). Change from baseline for the two subgroups for all scales other than Work was higher than change from baseline for all patients (e.g., 6.8 and 7.7 for the two subgroups for Symptoms vs 4.2 for the all patient cohort). The greatest improvement for splenectomized patients was in Bother (12.2 point-change), Activity (11.1 point-change) and Overall QOL (12.0 point-change). Similarly, change scores for patients who had previously received placebo were also highest in these three scales, Bother (9.2 point-change), Activity (7.9 point-change) and Overall QOL (11.8 point-change), with the addition of Reproductive Health (8.6-point change). It is likely that some of these subgroup differences were confounded by the fact that patients that received romiplostim as part of the earlier study (prior romiplostim patients) entered this current study with higher ITP-PAQ scores, therefore resulting in less room for improvement. Some change scores within the subgroups (e.g., Bother, Overall QOL) were also clinically meaningful since they exceeded the 8-point threshold. *Summary/Conclusions.* Adult patients with chronic ITP who received romiplostim for 48 weeks had significant improvement in all aspects of HRQOL. Change scores for both the subgroups (splenectomized patients and patients who were not exposed to romiplostim within 24 weeks) were higher than the change scores for all patients and also reflected significant improvements. Additional research is needed to more fully compare baseline ITP-PAQ scores and change scores during the course of the study.

0793

BONE MASS AND BIOCHEMICAL MARKERS OF BONE TURNOVER IN CHILDREN AND ADOLESCENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: RELATION TO CORTICOSTEROID THERAPY AND VITAMIN D RECEPTOR GENE POLYMORPHISMS

A Tantawy,[1] E A.El Bostany,[2] R M.Matter,[1] E A.El Ghoroury[2]

[1]*Faculty of Medicine, Ain Shams University, Cairo, Egypt*
[2]*National Research Centre, Cairo, Egypt*

Background. Chronic immune thrombocytopenia (ITP) develops in less than 15% of childhood acute ITP. Management is usually conservative, however in compromised patients optional drug therapy includes standard oral steroids, pulsed high dose steroid therapy, IVIG, antiD, and immunosuppressive therapy or thrombopoietin receptor agonists in refractory patients. *Objetives.* As steroids play an important role in the management of ITP whether acute or chronic, this work aimed to study the bone mass in children and adolescents with chronic ITP in relation to biochemical markers of bone turnover, cumulative steroid therapy,and the possible modulating effect of vitamin D receptor (VDR)gene polymorphisms. *Methods.* 36 children and adolescents (mean age 10.67±4.72yrs) with chronic ITP were recruited from the Hematology Clinic, Children's Hospital, Ain Shams University, and the Hematology Clinic of the National Research Centre in Egypt ,and compared to 43 healthy age and sex matched controls (mean age 9.32±2.99 years). The files of the patients were revised and the total cumulative dose of steroids was calculated.After informed consent, patients and controls were subjected to clinical assessment, CBC, bone markers (serum osteocalcin and propeptide I precollagen (CPIP) and urinary deoxypyridinoline excretion). Polymerase chain reaction-restriction fragment length polymorphism (PCR - RFLP) technique was used to analyze VDR gene distribution (Bsm1 and FokI) in patients and control groups. Bone mass was assessed by dual energy X-ray absorptiometry (DEXA) at lumbar and hip regions to measure the bone mineral density (BMD).*Results.* The duration of ITP ranged from 2-10 years(mean 4.4 ± 3.9 years). Compared to controls, ITP patients had higher BMI (P=0.02) and lower height for age SDS (P=0.001). Patients had lower levels of osteocalcin (P<0.001) and CPIP(P<0.001) and higher urinary DPD excretion (P<0.001) when compared to controls. BMD was significantly lower in chronic ITP compared to controls for both spine and hip z-score.BMD was not significantly correlated to serum osteocalcin and CPIP, however urinary deoxypyridinoline excretion was inversely correlated to BMD (P=0.015 and P=0.006 for spine and hip z score,respectively). BMD in ITP was inversely correlated to age (P<0.05), BMI (P<0.01), and cumulative steroid dose (P<0.01),but not to the disease duration. The correlation between cumulative steroid dose and BMD was highly significant in patients receiving frequent oral steroids on daily or alternate days protocols(P=0.014 for spine and P=0.001 for hip z score), while the correlation was non significant in patients receiving monthly pulsed intravenous steroid therapy(P=0.74 for spine and P=0.505 for hip z score). There was no relation between BMD and Bsm1 polymorphism, however FokI polymorphism was significantly related to BMD (P=0.038 for spine, P=0.024 for hip z score). *Conclusion.* High cumulative doses of corticosteroids increase bone resorption in young chronic ITP patients. FokI gene polymorphism could be an accentuating factor in steroid induced bone resorption .Monthly pulse high dose steroids has less effect on bone mass than daily or alternate day oral steroid therapy Protocols of therapy of ITP should restrict chronic steroid use in growing children and favour alternative less harmful therapies.

0794

SINGLE NUCLEOTIDE POLYMORPHISMS OF THE INFLAMATORY CYTOKINE GENES IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA

M Pavkovic,[1] R Angelkovic,[1] S Trpkovska-Terzieva,[1] A Dimovski,[2] M Spiroski,[3] O Karanfilski,[1] L Cevreska,[1] A Stojanovic[1]

[1]*Department of Hematology, Skopje, Macedonia*
[2]*Faculty od Pharmacy, Skopje, Macedonia*
[3]*Institute for Immunobiology and Human Genetics, Skopje, Macedonia*

Background. Immune thrombocytopenic purpura (ITP) is an autoimmune disease characterized by thrombocytopenia due to platelet autoantibodies, causing an accelerated clearance of opsonized platelets by phagocytes. The etiology of ITP remains unclear, but both genetic and environmental factors are thought to play role in the development of the disease. *Aim.* The aim of our study was to investigate a possible association of some single nucleotide polymorphisms (SNP) in genes for interleukin beta IL-1β (-511 C/T), tumor necrosis factor beta TNF-β (+252 G/A) and tumor necrosis factor alpha TNF-α (-308 G/A) with ITP. *Methods.* We have analyzed 125 unrelated adult patients with ITP (35 men and 90 women) with median age of 47 (range 14-83) and 120 healthy matched controls. The median follow up of the patients was 44 months (12-384). Refractory ITP was defined as platelet count lower than $50x10^9$/L despite treatment with standard dose of corticosteroids and splenectomy. All 125 patients were initially treated with corticosteroids, 38 of which were splenectomized. Forty two (34%) patients were refractory to corticosteroids and splenectomy and were defined as having refractory ITP. Genotyping was performed by using polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) methods. The distribution of genotypes and allele frequencies were compared between patients and controls using a chi-squared test or Fisher's exact test. *Results.* Our results demonstrated significantly different distribution of the TNF-β (+252 G/A) genotypes in patients with ITP (n=125; G/G=3, A/G=38, A/A=84) comparing with controls (n=120; G/G=16, A/G=35, A/A=69), p=0.005. Allele frequencies for TNF β (+252 G/A) were also significantly different in patients with ITP (A allele 82.4%, G allele 17.6 %) comparing with controls (A allele 72.1%, G allele 27.9 %), p=0.009 with Yates correction. We didn't found significant differences in the genotype distribution or al-

lele frequencies for two other genes. Allele frequencies for TNF-α (-308 G/A) were 8.4% for A allele and 91.6% for G allele in patients and 11.3% for A allele and 88.7% for G allele in controls, p=0.363 with Yates correction. For IL-β (-511 C/T) allele frequencies were 69.2% for C allele and 30.8% for T allele in patients and 70.4% for C allele and 29.6% for T allele in controls, p= 0.845 with Yates correction. We found significantly different genotype distribution of TNF-α (-308 G/A) between patients with nonrefractory ITP (n=83; G/G=75, A/G=8, A/A=0) and refractory ITP (n=42; G/G=30, A/G=11, A/A=1), p=0.016. Allele frequencies for TNF-α (-308 G/A) were also significantly different in patients with refractory and nonrefractory ITP (A allele 15.5% versus 4.8%), p=0.009 with Yates correction. There was no significant difference in genotype distribution and allele frequencies for TNF-β (+252 G/A) and IL-β (-511 C/T) between these two groups of patients. *Conclusion.* The obtained data indicate that the A allele of TNF-β (+252) is more frequent in patients than in controls and that this polymorphism may play role in disease susceptibility. The A allele of TNF-α was significantly more frequent in patients with refractory ITP, indicating that this gene polymorphisms may contribute to therapy resistance and refractory form of ITP.

0795

INCIDENCE OF ANTIPHOSPHOLIPID ANTIBODIES AND THEIR SIGNIFICANCE IN THE PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA

N Suvajdzic-Vukovic,[1] J Jovanovic,[2] I Djunic,[3] A Vidovic,[1] A Novkovic,[4] D Tomin[1]

[4]*Clinic Hospital Center, Zemun, Belgrade, Serbia*

Background. The presence of antiphospholipid antibodies (APA) in immune thrombocytopenic purpura (ITP) has been reported, but their pathogenetic role and clinical importance is not clear. *Aims.* In this investigation we estimated the incidence of APA's presence and their influence on development of antiphospholipide syndrome (APS) and systemic autoimmune diseases (SAID) in patients with ITP. *Methods.* This study involved 59 adults patients with ITP. They were pretreatment evaluated for platelet count (<50x10/L vs ≥50x109/L), presence of APA: lupus anticoalgulant (LA) and anticardiolipin immunoglobulin G/M (IgG/M) antibodies (ACA) and antinuclear antibody (ANA). According age, sex, platelet count and APA positivity, the incidence and risk factors for development of APS (thrombosis or fetal loses) and SAID were estimated. The follow-up period was 96 months. Risk factors were identified using the univariate and multivariate analysis. *Results.* The median age of patient was 32 years, range 18-79 years, 69.3% were female and 30.7% were male. At presentation od disease, the paletelet count <50x109/L had 70% of patients and 30% had ≥50x109/L. The presence of APA detected in 48% of patients: ACA and LA in 10.7%, ACA alone in 12% nad LA alone in 25.2% of patients. At presentation of disesase, the incidence of APS was significantly higher in patient with APA positivity and platelets <50x109/L (p<0.05). During the follow-up period, the incidence of development APS was significantly higher in group of patients with LA positivity (p<0.001) and ACA IgG class positivity (p=0.001). The incidence of development SAID was significantly higher in female patients (p=0.004), age over 32 years (p=0.027) and in patient with LA positivity (p=0.039) and ANA positivity (p=0.005). The univariate analysis identified male sex (p=0.010) and both ACA and LA positivity (p=0.007) as a significant risk factors for development APS in patients with ITP. Multivariate analysis proved that most significant risk factor for development of APS was both ACA and LA positivity: p=0.007, relative risk (RR) = 0.063 (95% CI 0.008-0.471). The univariate analysis also identified age over 32 years (p=0.022) and LA positivity (p=0.037) as the significant factors for development of SAID in patients with ITP, while multivariate analysis indicated the LA positivity as the most sifnificant risk factor for development of SAID in patients with ITP: p=0.021, RR=0.047 (95% CI 0.004-0.628). *Conclusions.* The inverse correlation between APS and platelet count, in presens of APA positivity, was found. The most significant risk factor for development of APS in patients with ITP was positivity of ACA and LA mutual, while most significant risk factor for development of SAID was LA positivity. It may be concluded that estimation of APA at presentation of ITP is important for identification of risk group of patients for development APS and SAID.

0796

PROLONGED RESPONSE TO ELTROMBOPAG IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA

G Cheng,[1] H Frederiksen,[2] K Bakshi,[3] C Bailey,[3] A Brainsky[3]

[1]*Prince of Wales Hospital, Shatin, China*
[2]*Odense University Hospital, Odense, Denmark*
[3]*GlaxoSmithKline, Collegeville, United States of America*

Background. Although difficult to quantify, spontaneous remission of chronic immune thrombocytopenia (ITP) has been estimated at 0.1% per year.[1] American Society of Hematology guidelines refer to 12 case series with observation over 61 years, demonstrating a spontaneous remission rate of approximately 5% of patients after failing to respond to glucocorticoids, splenectomy, and subsequent therapy.[2] Instances of prolonged response have been reported with different therapies; it is not always possible to distinguish a prolonged response from a remission. Treatments for ITP have traditionally addressed the platelet destruction component of the disease; the advent of thrombopoietin receptor agonists has addressed the impaired production of platelets. Eltrombopag is an oral, nonpeptide thrombopoietin receptor agonist that is approved for the treatment of chronic ITP. In 6-week and 6-month placebo-controlled trials in patients with chronic ITP, eltrombopag increased platelet counts, reduced bleeding, and reduced the need for concomitant ITP therapy. Long-term treatment with eltrombopag is being evaluated in EXTEND, an ongoing open-label extension study in chronic ITP patients who completed a previous eltrombopag study. *Aim.* To evaluate prolonged platelet responses to eltrombopag in the EXTEND study. *Methods.* Patients in EXTEND had received eltrombopag or placebo in one of the following studies: two 6-week phase 2 and phase 3 studies (TRA100773A/B), a 6-month phase 3 study (RAISE), or a phase 3 study of intermittent treatment (REPEAT). Dosing in EXTEND is individualized according to platelet counts with a goal of maintaining platelets ≥50,000/μL and <200,000/μL while minimizing the use of concomitant ITP medications. Patients remain in the study until withdrawal or commercial availability of eltrombopag. An ad-hoc analysis was conducted to evaluate the proportion of patients in EXTEND who experienced a prolonged response, defined as a platelet count ≥50,000/μL that was sustained for ≥12 weeks after the last dose of eltrombopag, without any rescue therapies. *Results.* Among 299 patients enrolled in EXTEND between June 2006 and February 2010, a prolonged response was obtained in 14 patients (5%), which is equivalent to 1.4% per year of observation in EXTEND. The median age of these patients was 55 years (range, 20-71 years), and 11 (79%) were female. Five patients had been splenectomized prior to enrollment in EXTEND, and all patients had received at least 1 pharmacologic agent (range, 1-7 prior therapies) before study entry. A median of 26 months (range, 9-128 months) had elapsed since the diagnosis of ITP, and patients had been treated with eltrombopag for a median of 160 days while in EXTEND (range, 14-1107 days). *Conclusion.* Treatment with eltrombopag in the EXTEND study was associated with a prolonged response in 5% of patients over 4 years, which is higher than the expected proportion of spontaneous remission. However, it is not possible to assume that the patients with a prolonged response also experienced remission of chronic ITP, because subsequent follow-up is not available for most of these patients.

[2]*Hemato-Oncology Department, "Sf Maria" Children's Hospital, Iasi, Romania*

Background. The management of chronic idiopathic thrombocytopenic purpura (ITP) and the decision to perform the splenectomy in children with chronic ITP remain two controversial issues. *Aims.* The aim of this retrospective study was to analyze our centre experience with splenectomy in children with chronic idiopatic thrombocy-

topenic purpura. *Methods.* We retrospectively examined the records of 25 children who underwent splenectomy for chronic ITP between 1999 and 2009.We studied the time between diagnosis and splenectomy, long term hematological response, morbidity, mortality and predictors of response to splenectomy. Platelet response are categorized as complete response (CR≥150.000/µl), partial response (PR ≥50.000/µl, but < 150.000/µl) or nonresponse (NR <50.000/µl). *Results.* The median age at moment of the splenectomy was 10.6 (3,5-18,2) years.All patients were treated only with glucocorticoids as first line of therapy (because of the high costs of intravenous immunoglobulin). Five patients had a corticoresistant ITP with recurrent hemorrhagic events and 20 children had a corticodependent ITP.The median time between diagnosis and the moment of the splenectomy was12(4-48)months.Presplenectomy vaccination was administered in all patients. After splenectomy was not used antibiotic profilaxy. The perioperative mortality was zero and the overall morbidity was 2,5%The median postsplenectomy follow-up time was 41(4-96)months.The overall immediate response rate was 92% (22 patients had CR and 1 patient had PR).Two children had NR.An improvement in quality of life was observed in 96% of children. During follow-up 2 children relapsed (at 8 and 12 months respectively after splenectomy) and required intermittently corticotherapy. No correlation existed between CR to splenectomy and age, platelet count at diagnosis and last platelet count before splenectomy. All 5 patients with corticoresistant ITP had CR to splenectomy. One of the two children who had NR at splenectomy obtained a stable PR with Rituximab 100 mg/m2/weekly iv x 4 weeks. *Conclusions.* This study shows that splenectomy is effective, provide long-term control of disease and is associated with low morbidity, important improvement in quality of life and a good cost efficiency. In our centre the splenectomy represents an important option for the treatment of chronic ITP in children.

0798

THROMBOPOIETIN RECEPTOR AGONISTS (TPOA) DO NOT CAUSE ACTIVATION OF THE COAGULATION-FIBRINOLYTIC SYSTEM IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP)

W Ghanima,[1] S Barsam,[1] PM Sandset,[2] J Bussel[1]

[1]*Weill Cornell Medical College, New York, United States of America*
[2]*Oslo University Hospital, Oslo, Norway*

Background. TpoA stimulates thrombopoietin receptors, increasing platelet counts (PC) in 70-80% of ITP patients. Venous thromboembolism (VTE) was reported in up to 4% of TpoA trials, triggering speculation regarding TpoA activation of the coagulation process, particularly in the absence of evidence for platelet activation. *Aims.* This study used D-dimer (DD) as a marker of coagulation and fibrinolysis to determine the effect of TpoA on this system. *Methods.* We retrospectively evaluated DD in ITP patients on TpoA, performed during routine visits. Two DD assays were used: DD-Dade (cut-off 1.2 mg/L) and DD-HS (cut-off 230 ng/mL). DD-HS was used in 11/108 analyses and these values were not included in estimating median DD. Normal range of fibrinogen (F) was 180-400 mg/dL and CRP <1 mg/dL. *Results.* Median age of 46 patients was 55 years; 40% males. No patient developed VTE during TpoA treatment, in this study. Median time from pre-treatment DD measurement to TpoA initiation was 3 weeks. Median (IQR) pre-treatment DD (n=40) was 1.3 mg/L (0.7-2.2); PC (n=40) 25 x10^9/L (17-53); F (n=12) 315 (199-345) mg/dL; CRP (n=6) 0.47 mg/dL (0.2-3.7). Median duration from TpoA initiation to first available DD on treatment was 12 weeks. Median (IQR) DD on treatment (n=38) was 1mg/L (0.5-2); PC (n=38) 57 x10^9/L (31-165); F (n=7) 319 mg/dl (203-367); CRP (n=8) 0.4mg/dL (0.1-0.7). No significant difference was found between pre- and on-treatment DD values (n=32, p=0.1) although DD tended to decrease with the duration of TpoA treatment (Figure). DD for both assays were positive in 24/40 (60%) pre-treatment and 17/32 (53%), 6/29 (35%) and 5/19 (26%) at 4, 8 and 12 months during continuing treatment, respectively. A comparison of the various ITP therapies for those patients with positive (n=24) vs negative (n=16) DD pre-TpoA initiation was: 42% vs 25% IVIG; 38% vs 19% steroid; 13% (but 8% were also on IVIG) vs 6% rituximab; 0 vs 19% Rigel; and 17% vs 44% no treatment (p>0.05). There was no correlation between paired PC and DD values pre-treatment, 4, 8 or 12 months during treatment. *Conclusion.* This study does not support the evidence for increased VTE in ITP patients treated with TpoA being related to a general activation of the coagulation system. Treatment of ITP with TpoA did not activate the coagulation-fibrinolytic pathway as evidenced by no increase in DD following initiation of TpoA. In fact, DD tended to decrease while patients were receiving ongoing Tpo-A treatment. There is a suggestion, although not a significant difference, that the pre-treatment DD may be related to the therapy, or lack of, received at that time. Further studies are needed to determine the pathoaetiology of the infrequent TpoA-associated-VTE.

XENOTROPIC MURINE LEUKAEMIA-RELATED VIRUS (XMRV) AND IMMUNE THROMBOCYTOPENIA (ITP)

S Barsam

WeillWeill- Cornell Medical College of Cornell, New York, United States of America

Background. Fatigue in ITP results in decreased health-related quality of life (HRQoL); its pathogenesis is unknown. Emerging evidence suggests that T regulatory cells, natural killer cells, innate immune dysfunction and cytokine imbalance, in addition to organic causes such as hypothyroidism or iron deficiency, may lead to fatigue in ITP. Xenotropic murine leukaemia-related virus (XMRV), a human gammaretrovirus, has been associated with chronic activation of the innate immune system and natural killer cell dysfunction in chronic fatigue syndrome (CFS). XMRV is present in 2-4% of the general population. *Aims.* The aims of this study were to assess the level of fatigue expressed and to determine any associations between fatigue and XMRV in patients with ITP compared to healthy controls. *Methods.* Blood samples were collected prospectively with consent at routine clinic visits from ITP patients and from healthy controls, older than 15y, for complete blood count and blinded XMRV detection via: serological techniques to detect XMRV/MRV Env antibody protein; RT-PCR detecting viral RNA; and isolation in culture. Fatigue was tested concurrently for every subject, using the standardized Multidimentsional Fatigue Inventory (MFI) questionnaire: a high score reflects severe fatigue. *Results.* 36 patients with ITP, mean age 50y (range 19-84y),50% female. Eight of 20 (40%) patients with ITP were positive for XMRV compared to 3/13 (23%) controls (p=0.419). Mean MFI score for every scale was worse for ITP patients than controls (Table). There was no difference in fatigue on any scale between ITP patients XMRV positive and negative. Three patients were on immune suppression, of whom

Table 1. MFI scores, mean (+/- SE).

	General fatigue	Physical fatigue	Reduced activity	Reduced motivation	Mental fatigue
All patients, n=22	11.10(+/-0.82)	9.62(+/-0.89)	8.52(+/-0.79)	9.38(+/-0.79)	7.67(+/-0.65)
All controls, n=13	7.69(+/-0.81)	6.31(+/-0.71)	7.00(+/-0.93)	5.77(+/- 0.48)	6.00(+/-0.75)
p	0.014	0.009	0.166	0.002	0.059
Patients +ve XMRV, n=8	12.29(+/-1.49)	9.50(+/-1.77)	8.75(+/-1.28)	10.10(+/-1.26)	7.70(+/-0.99)
Patients -ve XMRV, n=12	10.92(+/-1.10)	9.69(+/-1.00)	9.15(+/-1.11)	9.15(+/-0.93)	8.23(+/-0.90)
p	ns	ns	ns	ns	ns
Control +ve XMRV, n=3	8.00(+/-1.00)	7.00(+/-1.00)	7.00(+/-2.08)	5.67(+/-0.33)	4.00(+/-0.00)
Control -ve, n=10	7.58(+/-0.87)	6.33(+/-0.77)	7.08(+/-1.00)	5.75(+/-0.52)	6.17(+/-0.79)
p	ns	ns	ns	ns	ns

2 (67%) were positive for XMRV, compared to: 3/10 (30%) with a splenectomy; 6/12 (50%) on thrombopoietin receptor agonists (TPO-A); 1/3 (33%) on IVIG; none of 2 on GMA161 (an anti-FCγRIII antibody); and none of 3 on no treatment. Among those patients testing positive for XMRV, the mean platelet count was not significantly lower. The platelet count, median 207 x109/L (range 8-1160), was associated with fatigue for Reduced motivation (p=0.022) and showed trends for General fatigue (p=0.081) and Physical fatigue (p=0.105). Increasing disease duration, median 17 years (range 3.25-32), tended to have worse scores for Mental fatigue (p=0.128). *Summary/Conclusions.* ITP patients in this study population expressed higher levels of fatigue than controls across all MFI scales, with an association between lower platelet counts and worse scores for 3/5 scales, illustrating again the importance of fatigue as a manifestation of ITP. This study demonstrates a 40% incidence of XMRV in patients with ITP and 23% in healthy controls. There was no difference in fatigue expression between patients who were XMRV positive and negative, thus XMRV may not be involved in the pathogenesis of fatigue in ITP. Given the small numbers and preliminary nature of the results there may be a potential association between immune suppression and XMRV infectivity. Studying more patients may clarify clinical associations of XMRV in ITP. Table: MFI scores, mean (+/- SE) (higher scores = worse fatigue), p values representing differences between: patients and controls; and positive and negative XMRV results, for each MFI scale.

[9]*Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Italy*

Background. The mortality of Invasive Aspergillosis (IA) still affects from 27% to 55% of high risk hematologic patients. The reasons of such a poor outcome also rely on several drawbacks limiting the diagnostic accuracy of non cultural based diagnostic methods (NCBDM) and hampering the opportunities for an early intervention. Studies in mice model of IA and in healthy subjects have shown that Aspergillus-specific T-cells producing interferon-gamma (IFN-gamma-T1) are protective, while Aspergillus-specific T-cells producing interleukin-10 (IL-10-T2) are non-protective to IA. *Aims.* We have investigated whether the identification of Aspergillus-specific IFN-gamma-T1 and/or IL-10-T2 through an *ex-vivo* enzyme linked immunospot (ELISPOT) assay may be effective in the diagnosis of IA in high risk patients. Furthermore, in the proven IA patients, we have functionally and phenotipically characterized such T cells through the cytokine secretion assay (CSA). *Methods.* 180 patients (168 hematologic and 12 solid organ transplant patients) have been enrolled. They were classified, according the revised EORTC/MSG criteria, as follows: 18 proven, 35 probable, 17 possible IA cases and 110 controls. The control patients were divided in two groups: group 1 included 86 (78.2%) patients with hystological and/or cultural verified infectious/inflammatory/neoplastic diseases, but other than IA; group 2 included 24 (21.8%) patients without clinical and/or microbiological features of IA. ELISPOT has been performed, as described [Potenza *et al.* Leukemia 2007; 21: 578-81], by using as antigens Aspergillus either conidia or recombinant antigens, namely CRF1p, GEL1p, PEP1p, SOD1p, α1-3 glucan, β1-3 glucan and galactomannan (GM). *Results.* The patient and sample positivity rates were 94.4%/89.5% in proven, 45.7%/35.3% in probable, 35.3%/50% in possible IA cases and 1.8%/4.5% in the controls, respectively. The sensitivity and specificity of ELISPOT for the diagnosis of IA resulted 94.4% (95% CI, 73%-99%) and 98.2% (95% CI, 93%-99%), respectively. The PPV of the test was 89.5% (95% CI, 67%-99%), the NPV was 99.1% (95% CI, 94%-100%) and the efficiency was 97.6% (95% CI, 92.3%-99.4%). The positive likelihood ratio (LR) resulted 51.89, the negative LR was 0.06 (Table 1A,B). In proven IA patients, CSA demonstrated that Aspergillus-specific IL-10-T2 were predominantly central memory (CM) CD4+ T cells (median frequency 0.37%/0.22%), while Aspergillus-specific IFN-gamma-T1 were either CD4+ or CD8+ cells of either effector memory (EM) or CM phenotype (median frequencies 0.24%/0.20%). Also lower frequencies of Aspergillus-specific either CD4+ or CD8+ T cells producing IL-4 (0.11%/0.19%) of EM phenotype, and EM CD8+ cells producing IL-17 (0.18%), were detected. Moreover, although CRF1p, GEL1p, α1-3 glucan and SOD1p resulted the antigens eliciting the highest number of Aspergillus-specific IFN-gamma-T1, only GEL1p and α1-3 glucan were those most constantly targeted by protective immune responses along the entire course of the IA. *Conclusions.* Our findings demonstrate the potential of ELISPOT in the diagnosis of IA, suggesting that it may complement the other NCBDM, enabling a more consistent diagnosis of IA. Furthermore, this study describes for the first time the Aspergillus-specific immune responses in patients with proven IA, identifying

Table 1.

A,B. Diagnostic Accuracy of the ELISpot assay for the diagnosis of Invasive Aspergillosis (IA).

A. Rate of positivity of the assay per-patient and per-sample. B. Sensitivity, Specificity, Positive Predictive Value, Negative Predictive Value and Efficacy of the assay matching proven IA with control cases.

SURVEY ON ANTIFUNGAL COMBINATION THERAPY FOR TREATMENT OF PROVEN OR PROBABLE INVASIVE FUNGAL DISEASES IN ITALIAN HEMATOLOGICAL CENTERS. THE SEIFEM-COMBO STUDY (NCT 00906633)

A Candoni,[1] M Caira,[2] S Simone,[3] A Busca,[3] M Giacchino,[3] R Fanci,[3] G Specchia,[3] A Nosari,[3] A Bonini,[3] C Cattaneo,[3] L Melillo,[3] P Musto,[3] M Offidani,[3] J Peccatori,[3] N Vianelli,[3] A Venditti,[3] L Pagano[2]

[1]*University of Udine, Udine, Italy*
[2]*Department of Hematology, Università Cattolica Sacro Cuore, Rome, Italy*
[3]*SEIFEM group (Sorveglianza Epidemiologica IFI in Emopatie Maligne), Italy*

Background. This prospective observational Clinical Trial (NCT 00906633) evaluated the feasibility, efficacy and toxicity of Antifungal Combination Therapy (Combo) as treatment of proven or probable Invasive Fungal Diseases (IFDs) in Hematological patients (pts). *Materials and Methods.* Between Jan 2005 and Dec 2009, 84 cases of Combo were reported from 20 Hematological Centers in Italy. Median age of pts was 34 yrs (range 1-73) and 37% had less than 18 yrs. Acute Leukemia was the most common underlying hematologic disease (68/84; 81%). The status of hematologic disease was: onset 21/84 (25%), remission 18/84 (21%), refractory/relapse 45/84 (54%). The main site of fungal infection was lung with or without other sites. The etiological agents were: Aspergillus sp 68 cases (81%), Candida sp 6 cases (8%), Zygomycetes 4 cases (5%), Fusarium sp 4 cases (5%) and other (2 cases). *Results.* The most used Combo were: Caspofungin + Voriconazole 35/84 (42%), Caspofungin + Liposomal Amphotericin B (L-AmB) 20/84 (24%), and L-AmB+Voriconazole 15/84 (18%). The median duration of Combo was 19 days (range 3-180). The Overall Response Rate (ORR) was 73% (61/84 responders) without significant differences between the Combo regimens. The most important factor that significantly influenced the response rate (in univariate and multivariate analysis) was Polymorphonuclear (PMN) recovery during Combo ($P < 0,0001$). Only one patient discontinued therapy (voriconazole related neurotoxicity) and 22% experienced mild and reversible adverse events (hypokalemia, ALT/AST increase, creatinine increase) without differences between pediatric and adult pts. The IFD attributable mortality rate was only 17%. *Conclusion.* This is the first multicenter, prospective, observational study exploring feasibility, efficacy and toxicity of Antifungal Combination Therapy (Combo) as treatment of proven or probable Invasive Fungal Diseases (IFDs) in Hematological patients (pts). The results of this study indicate that: 1) Combo was well tolerated in both children and adults hematologic pts. 2) The Overall Response Rate was 73% and the mortality IFDs related was only 17%. 3) The most used Combo regimens were Caspofungin+Voriconazole (ORR 80%) and Caspofungin+L-AmB (ORR 70%). 4) In univariate and multivariate analysis PMN recovery during Combo predicts a better outcome.

ADOPTIVE IMMUNOTHERAPY TO PREVENT AND TREAT HHV-6 REACTIVATION POST ALLOGENIC STEM CELL TRANSPLANT

U Gerdemann,[1] L Keukens,[2] A De Pagter,[2] H Heslop,[1] C Rooney,[1] A Leen[1]

[1]*Baylor College of Medicine, Houston, United States of America*
[2]*Department of Pediatric Immunology and Hematology,Wilhelmina Children's Hospital, Utrecht, Netherlands*

Background. Viral infections cause morbidity and mortality in allogeneic hematopoietic stem cell transplant (HSCT) recipients. Antiviral drugs are costly, often have severe adverse effects, and are frequently ineffective. As an alternative treatment option our group has shown that adoptive transfer of *in vitro* generated trivirus-specific cytotoxic T lymphocytes (CTL) targeting EBV, CMV and Adv antigens is effective and protective *in vivo*. Reactivation of Human Herpes Virus type 6B (HHV6B) also plays a critical role in the outcome of patients after HSCT. HHV6B is detected in >50% of HSCT recipients and associated with severe clinical symptoms including encephalitis, acute GvHD, bone marrow suppression and increased overall mortality. However, to date, production of CTLs directed against this virus has been hindered by lack of information regarding immunogenic/protective T-cell target antigens. *Aims.* The goals of this study were to identify immunodominant HHV6B T-cell antigens which can be used for T-cell studies and as targets for T-cell therapy. *Methods.* We assessed the cellular immune response directed against 5 HHV6 antigens (U71, U90, U11, U14 and U54), whose counterparts in the significantly homologous CMV or HHV7 viruses were found to be immunogenic. For T-cell stimulation we isolated PBMCs from HHV6 sero+ve, CMV serove healthy donors (thus eliminating the possibility of cross-reactive T-cell recognition) pulsed them with peptide libraries spanning each antigen (pepmix) or infected them with the HHV6B wild type virus strain Z29 and then expanded them *in vitro* for 10 days. *Results.* Pepmix-stimulated lines were polyclonal as confirmed by V-beta repertoire analysis with a predominant antigen response in the CD4+ T-cell compartment (mean CD4+: 62+/-6%, n=15). Using IFNg ELIspot we identified a hierarchy of immunodominance, with all donors responding to U90 (median 216; range 53-812 SFC/1x105 cells), U14 (164; 43-666), U11 (143; 25-209) and U54 (138; 44-247) whereas only 8/15 donors responded to U71 (50; 25-80). Furthermore we mapped several MHC class I-restricted T cell epitopes using individual peptides derived from each of the antigens. T cells cultured with HHV6B Z29 wild-type virus-infected PBMCs as a stimulus showed comparable phenotype and frequencies of antigen specific T-cells, confirming that our chosen antigens are relevant targets. The CTLs were polyfunctional, producing multiple cytokines (IFN-γ, TNF-α, IL-2) and effector molecules (Granzyme B) upon stimulation with cognate antigen. They demonstrated cytolytic activity against pepmix-pulsed and HHV6B Z29 wild-type virus-infected autologous monocytes in a standard 4hr Cr51 release assay. Finally, we were able to detect U11, U14, U54 and U90 specific T-cells in peripheral blood of patients who controlled their HHV6 reactivation post-HSCT, proving the *in vivo* relevance of T cells specific for these antigens. *Summary.* In summary we were able to identify a hierarchy of immunodominance against 5 HHV6 antigens in both healthy donors and patients after HSCT. Generated HHV6 CTLs were functional in cytokine production and cytolytic activity. Pepmixes can now be used to further delineate the tempo of endogenous T-cell recovery in patients after allogenic HSCT and to generate effective and protective HHV6B-specific CTL for adoptive transfer.

IMMUNOGENICITY OF A NOVEL INFLUENZA A (H1N1) VACCINE IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES

J Mariotti,[1] F Spina,[1] C Carniti,[1] A Guglielmi,[2] D Lucini,[1] A Vendramin,[1] F Pregliasco,[2] P Corradini[1]

[1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*
[2]*Dipartimento di Sanità Pubblica, Microbiologia, Virologia Università di Milano, Milan, Italy*

Background. Immunocompromised patients are particularly at risk for developing fatal complications after infection with influenza A (H1N1). A novel vaccine against the virus strain A/California/07/2009 (H1N1) was proved to be protective in healthy volunteers, while its efficacy in immunocompromised patients, in particular those with cancer, is unknown. *Aims.* The aim of this study was to determine the safety and efficacy of the 2009 H1N1 vaccine in patients with hematologic malignancies. *Methods.* We prospectively evaluated the humoral and cellular immune responses after one injection of monovalent adjuvated influenza A/California/2009(H1N1)-like strain surface antigen vaccine in 47 adults with hematologic malignancies and 77 adult controls. Antibody titers were measured by hemagglutination-inhibition assay and virus-specific T-cell responses by flow-cytometry on days 0, 28, 50 and 90 after injection. *Results.* Of the 47 patients, 15 had lymphoma, 21 multiple myeloma, 9 myeloproliferative disease; 15 patients were in follow-up, 17 were receiving treatment, 13 were recipients of allogeneic hematopietic stem cell transplant (HSCT). By day 28, immunologic response was lower in the patient cohort relative to controls by all parameters ($p< 0.05$). At subsequent time points, seroprotection (antibody titers ≥ 1:40) rates and geometric mean titers (GMT) increased in the patient group and were not significantly different from healthy volunteers. In marked contrast, seroconversion rates (≥ 4 fold increase in antibody titer) were lower in the patient group also at later time points ($p<0.05$). Subgroups analyses were performed to evaluate the influence on vaccine efficacy of follow-up, treatment, previous HSCT. Patients in follow-up had immunologic responses similar to controls at all time points. Conversely, patients receiving treatment had lower seroprotection rate on day 28 and lower seroconversion rates on day 28 and day 50 relative to controls. Of note, within the treated group, patients receiving immunomodulatory drugs (IMIDs) displayed a trend for improved seroprotection (day 90, 100% vs 60%, p=0.06) and increased GMT (day 28, 246 vs 87, p=0.3) compared to other treatments. Patients vaccinated after HSCT had the lowest seroconversion and seroprotection rates on day 28 and day 50 ($p< 0.01$ relative to controls), with a slight increase on day 90. Accordingly, GMT was lower than in controls on day 28 ($p< 0.001$) and subsequently it slightly increased. We also assed the cellular response to H1N1 vaccine by enumeration of fold increase of virus specific CD4+ and CD8+ cells on day 21, day 50 and day 90 relative to day 0. In the control group, specific CD4+ (6.0 ± 2.4, day 50, $p<0.05$) and CD8+ cells (21.7 ± 12.0, day 50, p=0.08) significantly increased on day 21 and day 50 relative to day 0. A similar trend was observed in the patient cohort for specific CD4+ (28.0 ± 11.0, day 50, $p< 0.01$) and specific CD8+ cells (16.5 ± 5.9, day 50, $p< 0.05$). *Summary/Conclusions.* Patients in follow-up or receiving IMIDS were protected by H1N1 vaccination. In contrast, patients receiving other types of treatment and those treated with HSCT responded poorly. These results may contribute to improve the vaccination strategy especially for poor responders.

PROPHYLAXIS OF INVASIVE FUNGAL DISEASES WITH POSACONAZOLE IN ACUTE MYELOID LEUKEMIA. A REAL LIFE EXPERIENCE

A Candoni,[1] E Simeone,[2] M Caira,[3] M Mazzucco,[2] R Fanin,[2] L Pagano[3]

[1]*University of Udine, Udine, Italy*
[2]*Department of Hematology and SCT, University of Udine, Udine, Italy*
[3]*Department of Hematology, Università Cattolica Sacro Cuore, Rome, Italy*

Background. Acute Myeloid Leukemia (AML) patients are at high risk of Invasive Fungal Diseases (IFDs). We report our real-life experience with POS prophylaxis in AML. We also compare the performance of POS prophylaxis with an historical, well matched, control group of AML pts who received prophylaxis with Fluconazole (FLUCO) or Itraconazole (ITRA). *Patients and Results.* Fifty-five unselected and consecutive AML pts received POS prophylaxis (600 mg daily) between Jan 2009 and Oct 2010. Median age of this population was 47 yrs (range 18-69). All cases were given chemotherapy with anthracyclines and cytarabine. The POS was started when neutrophil (PMN) count was less than 1000 mL and was stopped at PMN recovery. The median duration of severe neutropenia (PMN lower than 500 mL) was 15 days (range 7-41); 10/55(18%) of cases had an oral mucositis grade II-III CTC (common toxicity criteria) and 73%(40/55) of these pts received a proton pump inhibitor. An active diagnostic work up was made in all cases with Galactomannan assay, standard chest X-ray and thoracic CT scan in case of fever (FUO) lasting over 48 hours. The median duration of POS prophylaxis was 15 days (range 7 to 41). Only 4/55(7%) of pts required parenteral empiric or pre-emptive antimycotic therapy and only 2/55(4%) experienced a proven IFDs (Fusarium solanii fungemia and Aspergillus sp pneumonia). Mortality IFDs related was 0%. POS was well tolerated and only 9%(5/55) of pts experienced mild drug related side effects. No cases of POS discontinuation, due to the side effects or intolerance, were reported. When we compare the 55 pts who received POS with an historical control group of 55 AML pts who received FLUCO (45/55) or ITRA (10/55)prophylaxis, between Jan 2008 and Jun 2009, no significant differences were observed for underling disease status, age, IFDs risk factors, days of severe neutropenia and days of prophylaxis.Instead, there were significant differences in breakthrough IFDs (4% in POS group vs 16% in control group; P=0,02), and in days of parenteral antymicotic therapyn (37 vs 163). *Conclusions.* This real-life experience confirms that POS prophylaxis is feasible, safe, well tolerated and effective (prevention of IFDs) in unselected AML patients. Only 7% of these high risk pts required parenteral antimycotic therapy and only 4% experienced breakthrough IFDs. We also confirm that POS is more effective than FLUCO or ITRA as antifungal prophylaxis in AML pts.

0805

ELEVATED COMBINED SERUM FREE LIGHT CHAIN (CFLC) LEVELS ARE SIGNIFICANTLY ASSOCIATED WITH INCREASED MORTALITY

S Basu,[1] A Seetharam,[1] J Faint,[2] T Lovatt,[1] A Macwhannell,[1] A Jacob,[1] S Handa,[1] G Mead,[2] S Harding,[2] A Bradwell[3]

[1]*Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom*
[2]*The Binding Site, Birmingham, United Kingdom*
[3]*Division of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom*

Background. Though abnormal serum free light chain (FLC) ratios are diagnostically important in almost all plasma cell disorders an absolute rise of polyclonal FLC levels are often discarded as inconsequential. Here we report a striking association between increased combined FLC (summated FLCκ and FLCλ; cFLC) concentrations and mortality. *Aims.* To evaluate and correlate the prognostic impact of elevated cFLC levels and other biomarkers in a haemological referral cohort. *Methods.* 753 serum samples were sent for various haematological investigations. Serum cFLC, albumin, C-reactive protein (Crp), erythrocyte sedimentation rate (ESR), estimated glomerular filtration rate (eGFR determined by the MDRD equation) and total IgG, IgA and IgM immunoglobulins were measured by standard techniques. Patients with abnormal serum protein electrophoresis, and / or abnormal FLC ratio with confirmed positive IFE were removed. The remaining 528 patients with absolute rise of polyclonal FLC levels were followed for up to 4.5 years. Statistical analysis was performed using SPSS (version 19). *Results.* Over the 4.5 years of follow-up there were 99 deaths (18.8% mortality). A Kaplan-Meier survival curve revealed that a large proportion of the deaths were within the first 100 days (29 deaths; 29% of all deaths). As a consequence, Cox regression analysis was performed separately to deter-

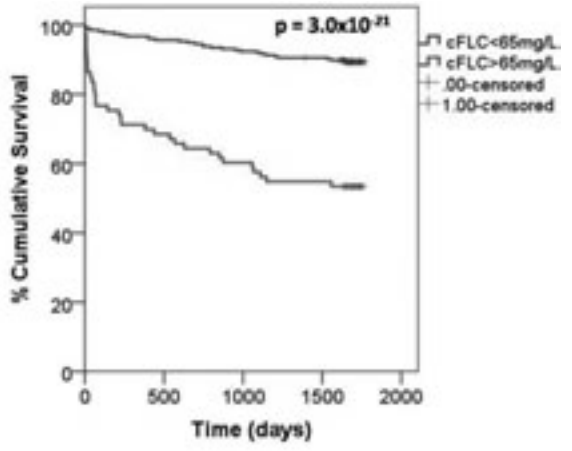

Figure 1.

mine risk factors for all deaths and deaths within 100 days. The relative risk of death increased proportionally with increasing combined FLC (cFLC) concentrations. Patients with cFLC concentration >50mg/L had a significantly increased risk of death compared to patients with cFLC concentration <50mg/L (75%ile overall survival (OS) <50mg/L not reached, >50mg/L 851 days, $p = 8.7x10^{-12}$). Receiver Operator Characteristic Curves (ROC) analysis indicated that cFLC concentrations >65mg/L was the optimum cut off associated with mortality in this population (75%ile OS <65mg/L not reached, >65mg/L 298 days, $p = 3.0x10^{-21}$. Figure 1). Univariate analysis identified albumin <33g/L, Crp >10mg/L, ESR >12, eGFR <30mL/min/1.73m^2, age >75 and cFLC >65mg/L as being significant predictors of mortality for the whole population and for mortality within 100 days. Gender was associated with mortality within 100 days only. Using multivariate analysis only cFLC concentrations >65mg/L, albumin concentrations <33g/L and eGFR <30mL/min/1.73m^2 were independently associated with mortality within 100 days and for the entire duration of follow up. Age >75 years old was independently associated with mortality over the duration of follow up but not for mortality within 100 days. A simple risk stratification model based on albumin <33g/L and cFLC >65mg/L identified 86% mortality within 100 days and 62% over the duration of follow up, compared to 50% and 24% using albumin <33g/L and 73% and 50% using cFLC >65mg/L independently. *Conclusion.* Polyclonally raised cFLC measurements predict significantly high mortality both within 100 days and beyond. cFLC levels can used in a simple risk stratification model to identify 'high risk' patients with increased mortality even in those *without* B cell disorders.

0806

EMPIRIC ANTIBIOTIC STRATEGIES IN FEBRILE HAEMATOLOGICAL PATIENTS IMPACT ON EPIDEMIOLOGY AND LETHALITY OF BLOODSTREAM INFECTIONS

C Cattaneo, F Antoniazzi, L Baushi, E Borlenghi, M D'Adda, C Carbone, E Morello, C Pagani, AM Pelizzari, A Re, G Rossi

Haematology, Spedali Civili, Brescia, Italy

Background. Adequate empiric antibiotic therapy in febrile neutropenic patients is mandatory for a favourable outcome of infectious complications. Epidemiological surveillance of infections occurring at a Haematology Unit is essential to drive an effective antibiotic strategy. *Aims.* To determine epidemiology, prognostic factors and emerging antibiotic resistance of bloodstream infections (BSI) according to empiric antibiotic strategy adopted. *Methods.* All BSI consecutively occurred at our Institution during a 78 month period (June 2004-December 2010) were evaluated and correlated with type and state of underlying disease, neutropenia, associated pneumonia, previous antibiotic therapy, including prophylaxis with fluoroquinolones, resistance to antibiotics and outcome. Empiric antibiotic therapy was different during time according to epidemiological data collected. *Results.* During the entire period of observation, 502 BSI were recorded. Fungi were responsible in 8 (1.6%) cases; Gram-positive (G+) bacteria in 167 (33.3%), Gram-negative (G-) bacteria in 293 (58.4%). In 35 (7%) cases a polymicrobial (PM) BSI was observed. Globally, no significant differences in the distribution of fungal, G+, G- and PM BSI were recorded over time. Empiric antibiotic strategies adopted were ceftriaxone+amikacin from June '04 to March '06 (21 months: period A), piperacillin/tazobactam+amikacin from April '06 to June '09 (38 months: period B) and ceftazidime+amikacin from July '09 to December '10 (19 months: period C). BSI/month ratio was 5.7, 6.8 and 6.3 during period A, B and C respectively. P. aeruginosa BSI were more frequent during B and C in comparison with A (21% and 19% vs 9% respectively, p=0.005 and 0.04); multiresistant Pseudomonas (MR Pseud) were absent in A and accounted for 12% and 9% in B and C respectively. Vancomycin-resistant enterococci (VRE) accounted for 25% and 22% of all enterococcal BSI in A and B, respectively, whereas they were absent in C. Frequency of extended-spectrum β-lactamases (ESBL+) enterobacteriaceae was lower during B (10%) in comparison with A+C (21%) (p=0.037). Overall mortality was 9.6%; it was significantly higher during B in comparison with A+C (12.3% vs 6.2%, p=0.021). P. aeruginosa BSI lethality was absent during A; during B it was higher than during C (31.5% vs 17.4%), although not significantly. MR Pseud BSI lethality was significantly higher during B in comparison with C (46.9% vs 9.1%, p=0.033). Among other MR pathogens, 3/7 patients with a VRE BSI and 1/33 patients with ESBL+ BSI died. Univariate analysis showed that uncontrolled haematological disease (p<0.0001), P. aeruginosa BSI (p<0.0001) and associated pneumonia (p=0.0014) were statistically significant risk factors for death. Piperacillin/tazobactam+amikacin as empiric antibiotic approach was also associated to increased risk of death at our Haematology Unit (p=0.021). *Summary/Conclusions.* The empirical approach with ceftazidime+amikacin showed higher efficacy in terms of reduced MR Pseud BSI lethality; for this reason at present it is the association still adopted at our Haematology Unit. When piperacillin/tazobactam+amikacin was chosen as empirical antibiotic therapy the frequency of ESBL+ enterobacteriaceae was reduced; however, the impact of ESBL+ BSI on mortality seems to be limited. Further epidemiological surveillance is warranted in order to monitor emerging resistant strains (particularly ESBL+) and related mortality.

0807

RISKS OF POST-SPLENECTOMY SEPSIS: ARE PATIENTS AWARE? A SURVEY

M Khandelwal, E Ewart, P Moore

Scunthorpe General Hospital, Scunthorpe, United Kingdom

Introduction. Splenectomy is associated with a lifelong increase in the risk of sepsis. The aim of this survey was to assess the level of knowledge of patients who have undergone splenectomy in Northern Lincolnshire and Goole NHS Trust. *Methods.* Adults undergoing splenectomy between 1993 - 2009 in our trust were invited to participate in the survey. Standardised postal questionnaires were completed by them. *Results.* 245 splenectomies were carried out in that duration. 85 responses were obtained from 145 patients who were alive as per our records in Jan. 2010. Most of them (94%) were aware of increased risks of certain infections. Majority of them (69.6%) didn't think they (or their family) received any counselling before/after the operation. 54% had standby antibiotics readily available to them. 48% of them carried an asplenia card/identifying bracelet or necklace to alert others of their splenectomy. Majority of them were not aware of travel precautions (62.4%) and increased risk of Malaria (73%). *Conclusion.* Although most patients displayed a good knowledge of infection risks of post-splenectomy sepsis, deficiencies were identified. We propose the development of a splenectomy protocol and patient briefing to improve patient education to reduce the risks of post-splenectomy sepsis. We also propose the development of a national database for Asplenic/Hyposplenic patients.

0808

FIRST LINE TREATMENT OF PROBABLE AND PROVEN INVASIVE ASPERGILLOSIS WITH CASPOFUNGIN IN ONCOHEMOPATIC PATIENTS. A SINGLE CENTRE EXPERIENCE

A Bonini

Azienda Ospedaliera ASMN, Reggio Emilia, Italy

Background. Infections are the main complication for oncohemopatic patients (pts) with severe neutropenia. Caspofungin (Caspo) inhibits the growth of the fungal cell wall. *Aims.* to evaluate the tolerability and efficacy of Caspo. *Methods.* Between 2004 and 2009 we have treated 70 consecutive adult neutropenic pts with probable or proven invasive aspergillosis with Caspo as first line therapy. In case of persistent fever (3 days) despite broad spectrum antibiotic therapy, a high-resolution CT-scan of the lungs and galactomannan test were performed. According to the revised EORTC criteria and Cornely *et al.* (CID 2007) we defined as probable the infections with clinical criteria and a highly suggestive CT-

scan. The pts were 39 males and 31 females; the mean age was 56 yrs (range 18-77 yrs). The diagnoses were: leukemia 54 (77%), myeloma 2 (3%), lymphoma 14 (20%); the disease's phases were: new onset 30 (43%), remission 18 (26%), relapse 22 (31%). Thirteen pts received an allogeneic and 5 an autologous transplant; the other pts received an induction or consolidation or rescue chemotherapy course. *Results.* Infections were proven in 15 cases (21%: 12 aspergillus spp, 2 aspergillus fumigatus, 1 G. capitatum) and probable in 55 cases (79%). The first site of infection was the lung in 69 pts (99%) and paranasal sinuses in 1 patient (1%). CT scan was positive (halo sign or air-crescent sign) in all the pts with a lung localization, while the chest X-ray was positive in 40% of them. BAL was performed in 36 pts. Galactomannan on BAL and serum was positive in 32/36 (89%) and 30/70 cases (43%) respectively. Caspo was administered at the dose of 70 mg i.v. on day 1 followed by 50 mg i.v. in 1 hour daily. The mean time of treatment was 17 days (range 13-25 days). Caspo was well tolerated and not discontinued for adverse events. No premedication was necessary. The global (partial and complete) response, defined as clinical and radiological, was 60/70 (86%); 10 pts died for fungal infection. The responses were similar for probable and proven infections. No breakthrough fungal infections were found. All surviving patients, upon discharge from the hospital, received oral treatment with Voriconazole or Posaconazole. Among the 60 responsive patients, 30 (50%) died later: 26 for hematologic disease and 4 for sepsis. In 3 cases there was the recurrence of the fungal infection. *Conclusions.* For all the cured pts, there was a concomitant recovery of neutrophils so also in our experience this appears to be crucial for the resolution of the infection. In conclusion the resolution rate of the infections is very high (86%); Caspo seems safe, it does not preclude any other treatment, it is well tolerated and the cost is lower than other antifungal treatments.

0809

THE EFFECTIVENESS OF MEGA-DOSE METHYLPREDNISOLONE AND FRESH FROSEN PLASMA TREATMENTS IN PATIENTS WITH CRIMEAN-CONGO HAEMORRHAGIC FEVER ASSOCIATED WITH REACTIVE HAEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

E Erduran, A Bahadir, Y Gedik, A Palanci

Karadeniz Technical University, Trabzon, Turkey

Background. Crimean Congo Hemorrhagic Fever (CCHF) is characterized by a macrophage activating syndrome, which starts during the period when viremia decreases. A cytokine storm initiates and triggers the development of haemophagocytic lymphohistiocytosis (HLH). Cytokines mediating vascular dysfunction causes disseminated intravascular coagulation (DIC). The causes of hemorrhage are DIC, thrombocytopenia and endothelial damage. DIC may develop due to direct damage of endothelial cells by the virus, liver disfunction and cytokine storm (increase in interleukin (IL)-1, IL-6, IL-12, IL-18, tumor necrosis factor (TNF)-α and intereferon (IFN)-γ). *Aims.* The effectiveness of mega-dose methylprednisolone (MDMP) (5-30 mg/kg/d) and fresh frozen plasma (FFP) (15 ml/kg 1-3 doses in a day) was investigated in patients with CCHF associated with reactive haemophagocytic lymphohistiocytosis (HLH). *Methods.* Seven patients with CCHF in association with reactive HLH were included in the study and treated with MDMP and FFP. 2 patients were treated with intravenous immunoglobulin (1 g/kg/d for 2 days) in addition to the MDMP and FFP treatments because the patients had resistant thrombocytopenia. *Results.* All patients were succesfully treated with MDMP and FFP. Fever decreased under 37'C in 1,6 ± 0,9 days, WBC increased above 4.500/ul in 4,0 ± 2,1 days, platelets increased above 150.000/ul in 8,6 ± 5,3 days and D-dimer decreased under 1 mcg/dl in 5,9 ± 3,8 days. *Conclusions.* We suggest that CCHF associated with reactive HLH should be treated with MDMP and FFP to supress the macrophage activation and cytokine storm, and to complement the deficient coagulation factors due to disseminated intravascular coagulation, respectively.

0810

CHARACTERISTICS AND RISK FACTORS FOR ABSCESSES IN A CONSECUTIVE COHORT OF PATIENTS WITH ACUTE MYELOID LEUKEMIA PATIENTS: A TERTIARY CARE CENTER EXPERIENCE

Y Hsieh,[1] CJ Liu,[2] CY Liu,[2] LT Hsiao,[2] JH Liu,[2] JP Gau,[2] TJ Chiu,[2] CH Tzeng,[2] HC Hsu,[2] PM Chen,[2] YB Yu[2]

[1]*Shuan-Ho Hospital, Xinbei City, Taiwan*
[2]*Veterans General Hospital Taipei, Taipei, Taiwan*

Background. Abscesses may occur as an infectious manifestation in acute myeloid leukemia (AML) patients. Early reports primarily focused on anorectal infection in leukemic patients only. Recently, articles of leukemic patients developing abscess mostly focused on brain abscesses or fungal infections and were case reports only. There were no systemic analyses done before regarding the pathogens prevalence, risk of abscess, survival, or treatment consensus in leukemic patients diagnosed of abscesses. *Aims.* We focused on the prevalence of abscess in patients with AML and the clinical characteristics, risk factors, and prognosis of AML patients developing abscess. *Methods.* 354 newly diagnosed patients were retrospectively analyzed. Eligible patients were sub-grouped as abscess group (n = 34) and non-abscess group (n = 320). We determined the factors potentially associated with abscess incidence. *Results.* The prevalence of all kinds of abscesses in AML patients is 9.6% with predominant sites at perianal and hepatosplenic abscesses. Bacteria were the major pathogen of abscesses. The two independent risk factors predicting abscess development in AML patients are secondary AML and receiving intensive induction (P = 0.001, HR = 3.739; P = 0.002, HR = 3.773, respectively). We categorized patients according to the numbers of two independent risk factors they possessed (0, 1, and 2 risk factors). Figure 1 showed the cumulative incidence of abscess within 36 months after AML diagnosis according to the risk stratification system (1.7% vs. 12.4% vs. 22.2%, 0 factors vs. 1 factors vs. 2 factors, P = 0.001). Patients developed abscesses in non-remission status of AML are associated with higher post-abscess 100 days mortality (92.3% vs. 42.0%, P = 0.004). *Conclusion.* Abscesses are not uncommon in AML patients. Patients who have secondary AML and receiving intensive induction chemotherapy warrant special attention since they are prone to have abscess. Leukemic free status at abscess diagnosis predicts a better survival in AML patients with abscess.

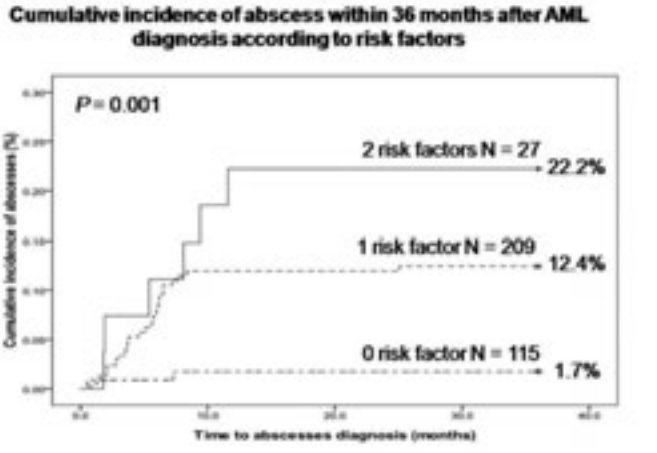

Figure 1. Cumulative incidence of abscess within 36 months.

0811

MORPHOMETRIC NEUTROPHIL DATA FOR EARLY DIAGNOSIS OF SEPSIS IN PATIENTS WITH HAEMATOLOGICAL MALIGNANCIES

G Lobreglio, S Scolozzi, A Accogli, S Minniti, D Turco, V Pavone

A.O. Card G Panico, Tricase, Italy

Background. Early diagnosis of serious blood stream infections is essential to improve treatment and survival of patients with haematological diseases. C-reactive protein (CRP) in combination with neutrophil counts and the manual band counts in blood smears are often used for predicting systemic clinical infections (sepsis). However CRP rises several hours after the onset of infection, so it can be falsely negative; on the other side, the manual myeloid immaturity differential count is a time consuming procedure, requiring well-trained skills of the laboratory technicians. Neutrophils are early activated by mediators of inflammation in systemic infections and rapidly change their volume and granularity. *Aim.* To investigate the clinical usefulness of additional morphometric data from automated hematology analyser of reactive neutrophils for predicting systemic clinical infections (sepsis) in patients with haematological malignancies. *Methods.* Morphometric research population data (Volume, V; conductivity, C; Scatter; S) were obtained by VCS technique of the Beckman Coulter DxH 800 hematology analyser during automated differential counts of peripheral blood of 134 consecutive adult haematologycal patients with positive blood culture and nucleic acid amplification tests for Gram (+) and

Gram (-) bacteria and in 65 patients from the Haematology Unit but without systemic infections. 64 patients investigated were affected by lymphoprolipherative disorders, 40 by myeloproliferative disease, 23 by multiple myeloma, 50 by myelodysplastic syndrome and 22 had undergone stem cell transplantation. *Results.* Statistically significant increase of mean neutrophil volume (MNV) was observed in peripheral blood of septic patients when compared to patients without infections (MNV: 161 ± 15.1 vs 144 ± 8.6, $p < 0.001$) whereas CRP and absolute neutrophil counts did not discriminate between these two groups. With a cut-off of 153 for MNV were achieved a sensitivity and a specificity of 74.3 % and 85 %, respectively. *Conclusions.* MNV is easily and rapidly obtained by routine analysis of peripheral blood on new haematology analyser; it seems to be a promising useful marker for early onset systemic infections.

0812

SAFETY AND EFFICACY OF AN EDUCATIONAL PROGRAM IN REDUCING COMPLICATIONS OF PERIPHERALLY INSERTED CENTRAL CATHETERS (PICCS) IN HAEMATOLOGICAL PATIENTS

A Malato,[1] A Luppino,[2] R Pipitone,[2] MG Donà,[2] D Turri,[2] R Felice,[2] S Magrin,[2] F Fabbiano[2]

[1]*Policlinico Universitario di Palermo,Istituto di Ematologia, Palermo, Italy*
[2]*U.O.di Ematologia ed UTMO, Ospedali Riuniti Villa Sofia-Cervello, Italy*

Purpose. Patients with haematological disorders frequently require the insertion of medium or long-term central venous catheters (CVCs) for stem-cell transplantation, the administration of chemotherapy, or transfusion of blood products. Although peripherally inserted central catheters (PICCs) have been in use for many years, little data exist on their use in patients receiving intensive chemotherapy. *Methods.* Evidence-based interventions were implemented in our department in December 2010, and include: 1) An high level nurse education program for correct practices and prevention of catheter-associated complications. was developed for PICC nursing team; 2) The use of ultrasound guide for the insertion of the tip of PICCs, thanks to a special operator training; 3) Bedside placement and confirmed PICC tip placement by chest radiography after removal of the guidewire and before the securing of the catheter; 4) Maintenance of maximum sterile barrier precautions during PICC insertion and aftercare; 5) chlorhexidine preparation, replace 10% povidone iodine for skin antisepsis; 6) adoption of PICC patient nurse archive, including the information of weekly PICC line review at our department for each patient. *Results.* Ninety-five PICCs were in place for a total of 7,295 PICC days (range, 1-331 days; mean, 76,7 days).Sixty-six PICCs were inserted during severe thrombocytopenia (platelets < 50 x 10(9)/L), and 70 during severe neutropenia (neutrophils < 0.5 x 10(9)/L). The majority of the patients were affected by leukaemia, and PICCs were inserted to ensure adequate access throughout chemotherapy. There were 2 thrombotic complications PICC-related (0,27 per 1,000 CVC days), and only one CRBSI (0,13 per 1,000 CVC days) during neutropenia. Other mechanical complications occurred in 11 catheters, and were accidental dislodgement (4), catheter break (3), catheter inadequate (4). *Conclusions.* Our results indicate that a training and competence assessment program is effective in reducing the main complications PICCs-related in haematological setting.

Table 1.

Complications requiring early removal of peripherally inserted central catheter (PICC).

Complications	n.	per 1000 CVC days (total days 7.295)
Mean duration of PICC	Range 1-331 days	76.79 days
Infective complications:		
Definite CRBSI	1	0.13
Non infective complications		
Thrombosis	2	0.27
Occlusion	5	0.68
Accidental dislodgment	4	0.54
Catheter breakage	3	0.41
Catheter inadequate	4	0.54

[2]*Intensive Unit, Hospital of Udine, Udine, Italy*

Introduction. Catheter stabilization devices are becoming standard of care for peripheral venous and arterial lines but scarce data are available about sutureless attachment devices of Central Venous Catheters (CVC). *Objective.* The aim of this prospective observational study was to evaluate the effectiveness of securing CVC in hematologic patients with sutureless StatLock adhesive attachment devices instead of traditional securement techniques like sutures and/or tape. *Methods and Results.* From January 2010 to December 2010, a total of 211 short-term CVC and 5162 catheter days were studied. All CVC were bilumen and secured with a sutureless StatLock attachment devices (Figure 1). No patient was given prophylactic antibiotics or anticoagulation drugs for infection or thrombosis. All patients received close dressing on the CVC insertion site every 3 days. The insertion sites of CVC were: internal jugular vein 156/211 (74%) and subclavian vein 55/211 (26%). The median CVC life span was 24 days (range 1-106 days). We evaluated the success rate of correct implantation of CVC, the dislodgement rate, the incidence of exit site infections and CVC infections related. The success rate of CVC implantation was 98 % (208/211). The incidence of catheter related infections were 3,5/1000 catheter days, that was very low according to the literature data on this topic. The exit site infections were only 14/211 (7%). Premature dislodgement rate of CVC and extravasion rate were 1,4 % (3/211) and 2% (4/211), respectively. *Conclusions.* The sutureless stabilization technique is safe and effective with a low complication rate. These securement devices can replace the traditional suture fixation of CVC in hematologic patients and appear to improve care in this setting by reducing infectious and noninfectious complications.

VORICONAZOLE PLASMA LEVELS AND GENETICS POLYMORPHISM OF CYP2C19 IN HEMATOONCOLOGICAL PATIENTS

J Winterova,[1] Z Racil,[2] L Malaskova,[3] M Lengerova,[2] K Hrncirova,[2] M Toskova,[2] J Mayer[2]

[1]*University Hospital Brno and Masaryk University, Brno, Czech Republic*
[2]*Department of Internal Medicine - Hematology and Oncology, Masaryk University an, Brno, Czech Republic*
[3]*Department of Clinical Biochemistry, Masaryk University and University Hospital, Brno, Czech Republic*

Background. Voriconazole (VORI) is a broad spectrum antifungal which exhibits a wide spectrum of its plasma concentrations. Among others, differences in drug metabolism due to polymorphic gene expression of CYP2C19, is discussed as an possible reason for this variability of VORI plasma concentrations. *Aims.* To evaluate the genotype of

Table 1.

	wild type	heterozygous mutations
number of patients	90	33
number of samples	333	136
median of VORI plasma concentration µg/ml	1.04	1.73
mean VORI plasma concentration µg/ml	1.34	1.44
VORI plasma concentration <1µg/ml	47.7% (n=159)	30% (n=41)
Vori plasma concentration 1-4µg/ml	49.6% (n=165)	65.5% (n=89)

CYP2C19 in hematooncological patients treated with VORI in our institution and its correlation with VORI plasma concentrations obtained during the VORI treatment. *Methods.* Trough VORI plasma concentration were measured using a high performance liquid chromatography assay. A retrospective analysis of laboratory results from patients treated with VORI between August 2005 and January 2010 was preformed. The genotype status of CYP2C19 was determined retrospectively using a polymerase chain reaction. *Results.* From 122 patients included in the study 90 patients have got wild type in both alleles of CYP2C19. 32 patients have got heterozygous mutations. There was no patient with homozygous mutations in our study. In our patient group VORI was administered in 40.7% as prophylaxis, in 13.5% as an empirical antifungal treatment and in 45.8% as a preemptive treatment or treatment of provenof invasive fungal infection. VORI was administered mainly orally; only in 2% of 481 analyzed samples intravenously. The median plasma concentration (after standard daily dose 400 mg orally) was in the wilde type group 1.04 µg/ml and 1.73 µg/ml in the group with heterozygous CYP2C19 mutations. The VORI plasma concentration was < 1.0 µg/ml, below the level associated with a better response to treatment of invasive aspergilosis, in 47.7% in wild type group and in 30% in heterozygous group. There was a significant difference between medians of VORI plasma concentration in group with wild type and group with heterozygous mutations - 1.04 and 1.73 (p=0.014, median test). The results are in Table 1. *Conclusion.* The knowledge of genotype status of CYP2C19 could be an useful guide during the antifungal treatment. Together with VORI plasma concentrations monitoring help us to achieve the plasma and tissue concentrations and improve the outcome of invasive fungal infection in hematooncological patients.

CLONAL PATTERNS OF X-CHROMOSOME INACTIVATION IN FEMALE PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA USING REVERSE TRANSCRIPTION POLYMERASE CHAIN REACTION METHOD

M Semeli, V Vaziourakis, I Mavroudi, M Velegraki, K Pyrovolaki, M Spanoudakis, K Pavlaki, G Goulielmos, H Papadaki

University of Crete School of Medicine, Heraklion, Greece

Background. Chronic idiopathic neutropenia (CIN) is a disorder of granulopoiesis characterized by increased apoptosis of the granulocytic progenitor cells and presence of activated, oligoclonal T-lymphocytes with myelosuppressive properties in the bone marrow. The underlying T-cell activating stimulus remains obscure. The possibility of the clonal origin of CIN, that might induce the immune system activation, has never been investigated so far. *Aims.* To probe the hypothesis of the clonal origin of CIN by looking for clonal patterns of X-chromosome inactivation in peripheral blood (PB) cell subsets of female CIN patients. *Methods.* We have studied the expression of the polymorphism at nucleotide (nt) 1311 of glucose-6-phosphate dehydrogenase (G6PD) and at nt 438 of iduronate-2-sulfatase (IDS) using a reverse transcription polymerase chain reaction (RT-PCR), in 77 females fulfilling the diagnostic criteria for CIN and 18 female healthy controls. Lymphocytes were purified from PB samples by density gradient centrifugation whereas granulocytes were isolated from the red cell pellet by Dextran precipitation. DNA extracted from total PB cells was screened for heterozygocity at nt 1311 of G6PD and/or at nt 438 of IDS. RNA was extracted from the isolated cell subpopulations of individuals showing heterozygocity of at least one of the two genes and assessed further by means of RT-PCR. Samples showing the expression of >95% of one allele in granulocytes and/or lymphocytes were classified as a "clonal pattern". *Results.* Overall, 19 CIN patients and 6 healthy individual heterozygous for G6PD and/or IDS were further studied. Of these subjects, 10 CIN patients and 3 healthy individuals were heterozygous for the nt 1311of G6PD whereas 12 CIN patients and 4 healthy individuals were heterozygous for the nt 438 of IDS. Clonality analysis using the G6PD polymorphism showed that 6 of 10 CIN patients (60%) displayed a clonal pattern in both granulocytes and lymphocytes. Two patients (20%) showed a clonal pattern in granulocytes but a polyclonal pattern in lymphocytes. Two patients (20%) showed expression of both alleles in granulocytes and lymphocytes compatible with polyclonality. Clonality analysis using the IDS polymorphism showed that 7 of 12 CIN patients (58.3%) displayed a clonal pattern in both granulocytes and lymphocytes. One patient (8.3%) showed a clonal pattern in granulocytes but a polyclonal pattern in lymphocytes. Four patients (33.3%) showed a polyclonal pattern in granulocytes and lymphocytes. Analysis of samples that were informative for both polymorphisms showed that the results were concordant in every case. None of the controls showed a clonal pattern in G6PD and/or IDS expression in either granulocytes or lymphocytes. Combining the G6PD and IDS results, clonal patterns were observed in granulocytes of 13/19 CIN patients (68.4%) and 0/6 normal individuals (p<0.01). *Summary/Conclusions.* Clonal patterns of granulocytes occasionally in association with clonal patterns of lymphocytes are identified in a significant proportion of CIN patients. These data suggest the possible involvement of a pruripotent or myeloid committed clonal stem cell in the pathogenesis of CIN, indicating for first time the possible clonal origin of this disease.

PREGNANCY OUTCOME IN GENETIC SUBTYPES OF CONGENITAL NEUTROPENIA

C Zeidler, B Brand, S Wehnert, K Welte

Medical School Hannover, Hannover, Germany

Severe congenital neutropenia (CN) comprises a heterogeneous group of disorders with a common hematological and clinical phenotype characterized by a maturation arrest of myelopoiesis at the level of the promyelocyte/myelocyte stage with peripheral blood absolute neutrophil counts (ANC) below 0.5 - 109/l and early onset of bacterial infections. Current data on the molecular causes suggest that CN is a multigene disorder. CN follows an autosomal dominant or autosomal recessive pattern of inheritance. To date more than 10 gene mutations have been described which are involved in disorders associated with CN. Genetic analyses in autosomal dominant and sporadic cases of CN indicate that the majority of these cases are attributable to mutations in the elastase 2 (ELANE) gene encoding neutrophil elastase. However, mutations in the ELANE gene do not discriminate between patients with CN and patients with cyclic neutropenia (CyN), another rare congenital disorder with a cycling haematopoiesis of 21 days. In addition, a number of less frequent other mutations has been identified in recessive CN, which are mainly associated with multi-organ involvement such as p14, SBDS, G6PT, G6PC3, TAZ or WAS. Since 1987, recombinant human Granulocyte-Colony stimulating factor (G-CSF) has been available for treatment of CN. More than 90 percent of patients respond well to G-CSF with a sustained increase of absolute neutrophil counts and a prolonged life expectancy. Since our first patients reach adulthood the desire for parenthood is coming up. In this study we assessed the outcome of 22 pregnancies in 12 mothers and 13 pregnancies from 7 fathers with different genetic subtypes of congenital neutropenias or unknown gene mutation as shown in the table below.

Table 1.

	Genotype	Mother/Father (n)	Life births	Miscarriages		
				Newborn with CN	Newborn without CN	Unknown
ELANE	CN	Mother	3	4	1	1
		Father	4	4	1	1
SDS		Mother	1	1		
		Father	0			
ELANE	CyN	Mother	2	3		
		Father	2	3	2	
	CN	Mother	4	3	3	1
	UNKNOWN	Father	1	1	1	
	CyN	Mother	2	2	1	1
	UNKNOWN	Father				
		Total Mothers 12				
		Total Fathers 7				
Total pregnancy outcomes			16	9	7	3

Conclusion. Out of the 32 life births 16 newborns presented with congenital neutropenia documenting the inheritance of the genetic defect from the affected parents, 9 were healthy and in 7 the outcome was not reported. In 3 mothers a miscarriage was documented. No other neonatal abnormalities were reported in our cohort, independent of any cytokine treatment during pregnancy. 32 of the 35 pregnancies resulted in a life birth. However, the proportion of newborns with congenital neutropenia reflects the inheritance of the genetic defects from their affected parents and reveals the need for genetic counseling.

Background. Infections are important causes of morbidity/mortality in children with severe congenital (SCN), autoimmune (AN) and idiopathic (IN) neutropenia. Few data on the incidence and type of infections are available in the literature *Aims.* to describe incidence and type of infections in a large population of neutropenic patients. *Patients and Methods.* Patients affected with SCN, AN and IN followed from 2000 to 2009 in 8/20 centres of the Italian Neutropenia Registry entered the study. As infections data contained in the INR were not enough detailed for the aims of our study and in order to uniform infection diagnostic criteria,a dedicated CRF was sent to each centre for retrospective data collection.The occurrence of infections was calculated during a period "at risk"defined as person-days at risk (pdr). The infection rate (IR) was calculated by dividing the number of events by the pdr and expressed as episodes/1000 pdr (95% CI). *Results.* Seventy three patients (28 females and 45 males) of whom 12 (16%) with SCN, 38 (52%) with AN and 23 (32%) with IN were analyzed. At least one infectious episode was observed in 100% of SCN and in 30% of both AN and IN. Overall 2/73 patients died (2,7%). They were both SCN subjects of whom one deceased of haploidentical HSCT related complication after of done for loss of response to G-CSF and the other of sepsis after the parents decided to stop G-CSF. From birth to the last follow up, a total of 108 infections occurred in 31/73 subjects (42%): 69 episodes in 12/12 patients with SCN, 25 infections were concentrated in 12/38 patients with AI and 14 episodes in 7/23 IN. Skin/subcutaneous infections (49%) and pneumonia (18%) were the most frequent localizations. Othomastoiditis, tonsillar phlegmons, osteomyelitis (10%) and deep abdominal infections (5%) occurred almost exclusively in SCN. Microbiological characterization was possible in 26/108 episodes and showed a slight prevalence of Gram-negatives (13/26) over Gram-positives (9/26) without differences according to the type of neutropenia. Fungal infections was diagnosed in two different SCN subjects.G-CSF was used in all SCN patients, in 26% of AN and 4% of IN. In the whole population and in each group, the IR in the time-span from birth to the emergence of neutropenia was significantly higher vs IR calculated from the emergence of neutropenia to the last follow up (p<00,1). *Summary/Conclusion*. Among neutropenic children the highest infectious burden was observed in SCN, but was not negligible in AN and IN. Skin was the main involved site. Gram-negatives were the slightly prevalent microorganisms while fungi occurred only in SCN. The significant decrease of IR after diagnosis of neutropenia vs previous period can probably be attributed to the increased awareness of the patients/family, to early antibiotic intervention and to the G-CSF therapy.

0818

DETECTION OF ANTI-NEUTROPHIL ANTIBODIES IN CHILDREN WITH CHRONIC NEUTROPENIA

A Kattamis, K Stokidis, S Boiu, T Petropoulou

National and Kapodistrian University of Athens, Athens, Greece

Background. The widespread use of automatic blood counters has led to the diagnosis of neutropenia in an increased number of children. Chronic neutropenia in children may be caused by autoimmune mechanisms, mainly related to circulating antineutrophil antibodies. Primary autoimmune neutropenia of infancy and childhood is characterized by moderate to severe neutropenia, exhibits a self-limited course and is usually not associated with serious infections. The treatment of this condition is mainly supportive. *Aims.* To investigate the role of the detection of antineutrophil antibodies in the differential diagnosis process of children with chronic neutropenia. *Methods.* Blood samples from children with neutropenia of at least 3 months; duration were tested for anti-neutrophil antibodies in specialized laboratories by using Granulocyte Immunofluorescence Test (GIFT), Granulocyte Agglutination Test (GAT) and selectively Monoclonal Antibody Immobilization of Granulocyte Antigens Assay (MAIGA). Clinical data on the occurrence of bacterial infections and treatment were collected. *Results.* We evaluated 100 patients who presented with chronic moderate-severe neutropenia defined as an absolute neutrophil count below 1,000/μl for at least 3 months. The mean age at diagnosis was 28 months (median, 15 months; range, 3 months-13 years). The male-to-female ratio was 1:1.2. Neutrophil-specific antibodies were detected in 75 patients (75%) (75% with GIFT, 34% with both GIFT and GAT). To identify the specificity of the detected anti-neutrophil antibodies MAIGA was performed in 21 patients. Most of these patients had antibodies against Fcγ receptor IIIb (20 out of 21, 95%). Positive antibodies were demonstrated in 2 out of 4 patients, who were retested after an initial negative result. Further evaluation in 3 of 24 seronegative patients established the diagnosis of congenital neutropenia (Barth syndrome, Kostmann syndrome, severe congenital neutropenia syndrome, respectively). The clinical course of seropositive patients was, in general, benign. Supportive treatment was required for patients with frequent or serious infections and included antibiotic prophylaxis (15 patients), regular infusion of IVIG (2 patients), and short term G-CSF administration (2 patients). *Conclusion.* Anti-neutrophil antibodies are frequently detected in children with chronic neutropenia. The different methods used have limited and often complementary sensitivity; their results need to be correlated with the clinical course of the patient. Detection of anti-neutrophil antibodies is of significant value in establishing the diagnosis of autoimmune neutropenia and may limit the breadth of necessary workup. Autoimmune neutropenia in childhood has a benign, yet prolonged, course.

CHRONIC NEUTROPENIA: CAUSES, CLINICAL-LABORATORY CHARACTERISTICS AND FOLLOW UP OF 229 PATIENTS

P Yiakoumis,[1] C Kalpadakis,[2] S Sachanas,[1] H Kyritsi,[3] E Papageorgiou,[3] M Moschogiannis,[1] T Vassilakopoulos,[3] M Angelopoulou,[3] G Pangalis[1]

[1]*Athens Medical Center, Athens, Greece*
[2]*Haematology Department, University of Crete, Heraklion, Greece*
[3]*Haematology Department, Laikon General Hospital, University of Athens, Athens, Greece*

Background. Chronic neutropenia, usually discovered in routine examination, constitutes a rather common medical condition. Patients often undergo strenuous and repeated tests for this condition which troubles them as well as their physicians. *Aim.* The study of clinical and laboratory characteristics as well as the frequent causes of chronic neutropenia, and the verification of an algorithm for the investigation and follow up of this condition. *Methods.* Patients who attended the Outpatient Hematology Clinics of the University of Athens and Athens Medical Center presenting neutropenia ($1.8x10^9$/l) of >6 months duration were evaluated. Complete blood counts (CBC) and blood smear examination (BSE) as well as laboratory investigation, including BUN, liver function tests and LDH were performed. Patients also underwent the following examinations: Serum thyroid tests and autoantibodies, ferritin, B_{12}, folic acid, antibodies against EBV, CMV, toxoplasma, HBV, HCV, HIV, a direct Coombs test and ultrasonography of liver/spleen. Previous CBC's revealing duration of neutropenia were reviewed. A blood immunophenotype with CD3, CD4, CD8, CD16, CD19, CD20, CD38, CD56, CD57 monoclonal antibodies was performed in all pa-

Table 1. Special causes of chronic neutropenia.

Causes of neutropenia	#	%
Thyroid disorders (Hashimoto's thyroiditis / Other)	61 (30 / 31)	27
T-LGL (Clonal TCR)	56 (27)	24
Autoimmune disorders SLE / Sjogren syndrome / Rheumatoid arthritis/ Sarcoidosis / Polymyalgia rheumatica	10 (3/3/2/1/1)	4
Drug intake	10	4
MDS	8	3
B12 insufficiency	5	2
Viral infections (HBV / EBV / HCV)	5 (3/1/1)	2
No specific cause-(common idiopathic neutropenia / autoimmune neutropenia)	74	32

tients. If T-large granular lymphocytosis was found, T-cell receptor rearrangement (TCR) was examined. Patients with clonal TCR expansion or suggestion of myelodysplastic disorder in BSE underwent a bone marrow examination (BME). Follow up was performed with clinical examination, CBC and BSE every 6 months in patients with neutrophils<1.5x10^9/l and every 12 months in the rest, unless a specific disorder was found. *Results.* During 2004-2010, 229 patients with chronic neutropenia were examined. Male to female ratio was 1:4 and median age at diagnosis 55(15-83) years. Median duration of neutropenia was 4(1-20) years. Median WBC at presentation was 3,68x 10^9/lt(1.62-6.1 x 10^9/l) and median neutrophil count was 1,66x 10^9/l(0,16-1.8 x 10^9/l). Infectious complications were observed in 75 patients (33%). Frequent complications included recurrent urinary infections (37 pts), apthous stomatitis (30), recurrent febrile upper respiratory infections (9) and chronic sinusitis (8), which were usually successfully treated with the appropriate antibiotic therapy. Median neutrophil count of patients with common infections was not statistically different from those without recurrent infections. 45 patients underwent a BME -17 with clonal T-LGL in 13 of whom a scarse lymphocytic infiltration was found and among the rest 28 pts, 8 were diagnosed with myelodysplastic syndrome and 8 with reactive/myelodysplastic-like findings. Neutropenia was attributed or related to special causes as shown in Table 1. In 74 patients no related cause was found and they were classified to the chronic idiopathic neutropenia (CIN) group. Median follow up was 26 (6-75) months. During follow up, GCSF was not administered to our patients except to those with diagnosis of myelodysplastic syndrome. No life-threatening infection was recorded. *Conclusions.* Chronic neutropenia constitutes a common problem of the general population and is frequently attributed to thyroid disorders, T-LGL, autoimmune diseases, drug intake and CIN. Serious complications are very rare and infections, when observed, are recurrent but mild and easily treated. Follow up should include a CBC and BSE. Longitudinal follow up is, however, required to confirm the favorable prognosis of chronic neutropenia.

0820

SEVERE NEONATAL ALLOIMMUNE NEUTROPENIA IN A NEWBORN DELIVERED BY A CD16 DEFICIENT GYPSY WOMAN

M Mariani,[1] A Cattaneo,[1] G Bottelli,[1] L Pugni,[2] F Mosca,[2] F Colombo,[1] S Mazzucchelli,[1] P Rebulla,[1] L Porretti[1]

[1]*Flow Cytometry Center, Milan, Italy*
[2]*NICU, Department of Maternal and Pediatric Sciences, Milan, Italy*

Background. Neonatal Alloimmune Neutropenia (NAN) is an uncommon disease of the newborn due to maternal IgG alloantibodies against fetal human neutrophil antigens (HNA) or leukocyte antigens (HLA) inherited from the father but absent in the pregnant mother. The involved antibodies can readily cross the placental barrier, causing neutropenia in the newborn that can range from mild (1000-1500/µl) to severe (<500/µl). The incidence of NAN has been estimated to 1:1000/6000 live births, mainly due to HNA-1a or1b and HNA-2a antigens. *Aim.* We describe a severe case of NAN due to FcγRIIIb (CD16) alloantibodies occurred in a Roma (Gypsy) family. *Patients and Methods.* A female child was born from second, uncomplicated pregnancy to a healthy 16-year mother, at the 40th week of gestation. Mother had a normal neutrophil count and the first child was healthy. Severe neutropenia (190/µl) and ocular infections, with otherwise normal laboratory findings, was detected on the first day of the newborn's life and persisted for 3 weeks. Direct (D) and indirect (I) granulocyte immunofluorescence tests (GIFT) were performed on newborn's and mother's blood samples. Flow cytometry cross-match of mother serum against father granulocytes was also performed. Family HNA-1, -3, -4 and -5 genotypes were evaluated using BAGene HNA-Type extra 3 kit (BAG Health Care). Anti-CD177 monoclonal antibody was used to determine HNA-2a phenotype. *Results.* A strong positive reaction was observed in the newborn's D-GIFT. As reported in the table, family genotyping indicates that the HNA-1b antigen could be involved in this NAN case. Mother and newborn sera showed a strong reaction against father's neutrophils and against 16 typed HNA blood donor neutrophils (including 6 HNA-1b subjects). Only one donor showing FcγRIIIb deficiency did not react with mother's and newborn's sera, indicating that the alloantibody specificity was not related to HNA-1b but to whole FcγRIIIb. Interestingly, both mother and father resulted HNA-3a negative. *Conclusions.* Alloantibodies against FcγRIIIb were the cause of this case of severe NAN developed in a CD16 null Gypsy mother. The described family had the HNA-3b phenotype that is quite rare in the Caucasian population. It would be interesting to determine the HNA frequencies in Gypsies.

HUMAN NEUTROPHIL ANTIGEN-3 (HNA-3) EXPRESSION IN BRAZILIANS

L Lopes,[1] W Baleotti,[2] R Suzuki,[2] A Fabron,[2] A Chiba,[1] J Vieira-Filho,[1] B Castro,[1] A Kuniyoshi,[1] J Bordin[1]

[1]*Universidade Federal de São Paulo, Marília, Brazil*
[2]*Faculdade de Medicina de Marília, Marília, Brazil*

Background. Recently, it was characterized that the HNA-3 arises from a nucleotide polymorphism in the choline transporter-like protein-2(SLC44A2), as a result of a single nucleotide polymorphism rs2288904. The HNA-3a and HNA-3b variants are encoded by a guanine and adenine at nucleotide position 461, respectively, resulting in either an arginine or a glutamine residue at amino acid position 154. The role of the HNA-3 is still unknown, but it is a target antigen in febrile transfusion reactions, immune neutropenias and transfusion-related acute lung injury (TRALI). *Aims.* To develop a technique of genotyping for HNA-3, and determine the prevalence of HNA-3a and HNA-3b in the Brazilian population. *Methods.* We obtained DNA of 500 healthy blood donors, 120 Amerindians, 39 Japanese individuals, and 124 patients with sickle cell anemia (SCA). All individuals were genotyped for rs2288904 by PCR-RFLP assay. The amplified product was digested with enzyme Taqα1, specific to nucleotide guanine (HNA-3a). Genomic DNA of 9 blood donors (3 HNA-3a/a, 3 HNA-3a and 3 HNA-3 was sequenced to confirm the results of the PCR-RLFP. *Results.* The genotyping results showed that 66.2% of blood donors were homozygous for antigen HNA-3a, 30.2% were heterozygous (HNA-3a/b), while 3.6% were homozygous for antigen HNA-3b. All Amerindians typed homozygous for the antigen HNA-3a. Among Japanese subjects 43.6% were homozygous for HNA-3a, 43.6% were heterozygous, and 12.8% were homozygous for HNA-3b. Among African Brazilian individuals 72.6% were homozygous for HNA-3a, 25.8% heterozygous, while 1.6% were homozygous for HNA-3b. Overall, the frequency of the allele HNA-3a in the population of Brazilian blood donors was 0.80 and the allele HNA-3b was 0.20. The frequency of the HNA-3 was significantly different between blood donors and Japaneses (HNA-3a - 66.2% vs 43.6%, p=0.0045; HNA-3b -

Table 1.

Frequency of HNA-3 genotypes in Brazilians

Group	HNA-3a/a (%)	HNA-3a/b (%)	HNA-3b/b (%)
Blood Donors	66.2	30.2	3.6
Amerindians	100.0	0.0	0.0
Japaneses	43.6	43.6	12.8
SCA	72.6	25.8	1.6

3.6% vs 12.8%, p=0.0061); Amerindians and: blood donors (HNA-3a - 100% vs 66.2%, p<0.0001; HNA-3a- 0.0% vs 30.2%, p<0.0001; HNA-3b - 0.0% vs 3.6%, p=0.0057), Japaneses (HNA-3a - 100% vs 43.6%, p<0.0000; HNA-3- 0.0% vs 43.6%, p<0.0001; HNA-3b - 0.0% vs 12.8%, p<0.0001), African Brazilians (HNA-3a - 100% vs 72.6%, p<0.0001; HNA-3a- 0.0% vs 25,8%, p<0.0001); and Japaneses and African Brazilians (HNA-3a - 43.6% vs 72.6%, p=0.0009; HNA-3- 43.6% vs 25.8%, p=0.0346; HNA-3b - 12.8% vs 1.6%, p=0.0026). *Conclusions.* This study describes for the first time the frequencies of the antigens HNA-3 in Brazilians. The prevalence of HNA-3 antigens in Brazilian blood donors is similar to those described in Europeans (63.1% of HNA-3a/a, 32.1% HNA-3a and 4.8% of HNA-3 Greinacher et. al., 2009) and North Americans (59.8% of HNA-3a/a, 35.5% of HNA-3a and 4.7% of HNA-3 Curtis et. al., 2010). However, we found that all Amerindians were HNA-3a/a, while African Brazilians showed a slightly lower frequency of HNA-3b and Japaneses had a significant higher prevalence of HNA-3 The PCR-RFLP assay well validated by DNA sequencing, suggesting that this technique could be useful in transfusion practice to elucidate cases of HNA-3 incompatibility and reduce reactions involving anti-HNA-3.

THE OXIDATIVE BURST OF NEUTROPHILS IS INFLUENCED BY COMBINED HORMONAL CONTRACEPTIVES IN A COMPLEMENT-DEPENDENT AND -INDEPENDENT MANNER

R Bertozi, B Stocco, A Azzolini, YM Lucisano-Valim, MR Torqueti, CM Marzocchi-Machado

Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Universidade de São Paulo, Ribeirão Preto, Brazil

Background. Neutrophils are crucial in host defense against invading microorganisms through reactive oxygen species (ROS) production that is also known as oxidative burst (OB). ROS are products of normal cellular metabolism and are generated by a tightly regulated enzyme complex, NADPH oxidase. Beneficial effects of ROS involve physiological roles in defence against infectious agents and maintenance of cellular redox homeostasis. However, inherited/acquired dysfunctions involving the OB response may result in oxidative stress and/or contribute to impaired neutrophil functions and inflammatory processes. The use of estrogen as hormonal contraceptives or hormonal replacement therapy is associated with the thromboembolic and chronic inflammatory diseases. In particular, the complement receptors (CR) are important mediators of the OB of neutrophils and are also involved in the inflammation. Of recent interest are the known antioxidant and pro oxidant properties of estrogens and their effects on neutrophil functions, as well as the influence of the sex hormones upon susceptibility to infections. *Aim.* To evaluate the effect of the estrogen and progestagen, as combined hormonal contraceptive (CHC), upon the OB of neutrophils mediated or not by CR. *Methods.* This study was approved by local Research Ethics Committee (protocol #114). All volunteers agreed to provide blood samples and gave written informed consent to participate in this study. Healthy women (n=54; 18-35 years-old), CHC users or not > 6 months, were assigned to one of three groups: control (CHC non-users, n=19); group 1 (30mg ethinylestradiol (E)/3mg drospirenone (D); n=17); group 2 (20mg E/3mg D; n=10); group 3 (30mg E/0.15mg levonorgestrel; n=8). The OB of neutrophils was measured by a luminol-dependent chemiluminescence (CL) assay. Isolated neutrophils were stimulated with Zymosan (Zy), opsonised or not with complement from normal human serum (NHS), hormonal contraceptive serum (HCS) or NHS inactivated by heat (NHI) as control. Cells in the absence of stimulus were also used as negative control. Area under the curve of CL profile was calculated. *Results.* The following differences were observed among the groups: an increased OB in neutrophils from women of the group 1 when stimulated with Zy/NHS and Zy/HCS compared to control group (Zy/NHS) (p<0.05, t-test); and the OB of neutrophils of group 3 was significantly higher than that observed for the control group when stimulated with Zy not opsonised (p<0.05, t-test). No differences were observed among the different CHC. *Summary.* These results suggest that different CHC influence the OB of the neutrophil in a complement-dependent (Zy/NHS and Zy/HCS) or -independent (Zy) manner. These observations may have significant consequences to inflammatory and homeostatic processes involving neutrophils, complement and hormonal regulation and these findings need to be investigated further in future. clenimar@usp.br

A STUDY OF NEUTROPENIA IN INFANTS AND CHILDREN ADMITTED IN A UNIVERSITY CHILDREN HOSPITAL IN CAIRO,EGYPT

A Tantawy, T Sallam, D Ibrahim, M Sallam, A I.Goda

Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background. Neutropenia is defined as absolute neutrophil counts (ANC) <1,000/mm3 in infants and <1,500/mm3 in children. Neutropenia may be congenital or acquired with infection being the most common cause followed by autoimmune neutropenia (AIN) whether primary or secondary. *Aim* of this work was to study the prevalence, severity, and etiological causes of neutropenia in infants and children admitted to a University Children hospital in Cairo, Egypt. *Methods.* 200 patients with neutropenia were recruited from the inpatients in The Children's Hospital Ain Shams University form April 1st 2010 to July 30th 2010, after having parental consent. Patients with a known hematological or immunological disease were excluded from the study. The patient's age ranged from 2 months-15 years (mean 24.4 ± 28 months), with male:female ratio of 1.1:1. Patients were classified according to ANC into mild, moderate and severe groups. Moderate and severe neutropenic children were followed for three months period. Follow up ANC was done till recovery or an underlying cause is uncovered. Viral serology was done for moderate/severe neutropenia patients including cytomegalovirus (CMV), Epstein-Barr virus (EBV),hepatitis B virus (HBV), hepatitis C virus (HCV),and HIV. Anti-Neutrophil Cytoplasmic Antibody (ANCA) tested by enzyme immunoassay and bone marrow aspirate were done for prolonged moderate / severe neutropenia (persisting for 3 weeks or more). *Results.* Out of 200 patients,neutopenia was mild in 90 (45%) moderate in 56 (28%) and severe in 54 (27%). The clinical diagnosis at admission was bronchopneumonia (38%), PUO (17%), bronchiolitis (13%), urinary tract infection (9%), acute gastroenteritis (8%), hepatitis (6.5%), septicemia (5%), others (3.5%). All patients with mild neutropenia recovered within one week of follow up. Among the 110 patients with moderate/severe neutropenia, 80(73%) recovered in <3 weeks,while 30 patients (27%) had prolonged neutropenia. Predictors of prolonged neutropenia were patient's age <18 months (P<0.01), ANC < 500/mm3 (P<0.05), hemoglobin <10 gm/dl (P<0.05) and positive CMV serology (P<0.05). Sex was equivocal.None of the patients with moderate/severe neutropenia had serological evidence of HCV, HBV, or HIV, while CMV serology was positive in 38 patients (34.5%) and EBV serology was positive in 8 patients (7.3%, all had severe neutropenia). ANCA was positive in 9 patients (aged 5-15 months), representing 30% of patients with prolonged neutropenia and 42.8% of prolonged severe neutropenia patients,all had hypercellular bone marrow with normal sequence of maturation. *Conclusion.* Neutropenia is a frequent finding in Egyptian infants and children, usually mild and transient,and mainly associated with infection. Cytomegalovirus and Epstein-Barr virus are important infections associated with prolonged moderate/severe neutropenia. Immune neutropenia is a common cause of moderate/severe neutropenia in the first two years of life. Close clinical and laboratory observation and adequate supportive care of the neutropenic child is of crucial importance.

FCG RECEPTOR IIA AND FCG RECEPTOR IIIB POLYMORPHISMS: FREQUENCIES OF THE ALLELIC VARIANTS AND THEIR COMBINATIONS IN BRAZILIAN SYSTEMIC ERYTHEMATOSUS LUPUS PATIENTS

I Vigato,1 J Toller-Kawahisa,[1] J Pancoto,[2] J Del Lama,[1] E Donadi,[2] P Louzada-Júnior,[2] A Azzolini,[1] YM Lucisano-Valim,[1] CM Marzocchi-Machado[1]

[1]*Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Universidade de São Paulo, Ribeirão Preto, Brazil*

[2]*Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo, Ribeirão Preto, Brazil*

Background. Recent data have provided evidence that genetic polymorphism of the receptors for Fc of IgG (FcgR) is associated with im-

mune abnormalities and risk to development of systemic lupus erythematosus (SLE). FcgRIIa and FcgRIIIb display functionally relevant genetic polymorphisms (H/R-131 and HNA-1a/1b, respectively), which allelic variants can influence the biological responses and the susceptibility to and course of infectious diseases. In particular, the presence of the FcgRIIa-R131 allotype results in lower affinity binding to IgG2, a subclass of IgG specific for encapsulated bacteria. In addition, the homozygosis for FcgRIIa-R131 and FcgRIIIb-HNA-1b combination has been associated with impaired phagocytosis and the FcgR polymorphisms have been also implied in the susceptibility to and prognosis of infectious and autoimmune diseases. *Aim.* To assess the frequencies of the alleles for the FcgRIIa and FcgRIIIb polymorphisms and their combinations in Brazilian SLE patients compared to healthy subjects. *Methods.* Committee approval was obtained for the taking of blood samples and all studied patients agreed to provide them. All patients were diagnosed at Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto-USP and fulfilled the American College of Rheumatology classification criteria for SLE (n=47). Ninety one healthy volunteers were included in this study as the control group. Genomic DNA was isolated from EDTA-anticoagulated blood using the salting out method. Determination of FcgRIIa and FcgRIIIb genotypes were performed using polymerase chain reaction (PCR)-based allotyping methods with allele-specific primers and the PCR products were analyzed by electrophoresis (2% agarose gel with gel red dye). *Results.* With respect to FcgRIIa, the heterozygosis FcgRIIa-HR-131 was the genotype most frequent in both SLE (53.2%) and healthy (45%) groups, being higher in SLE group. However, the frequency of the homozygosis H-131 was reduced in SLE (12.8%) compared to healthy (23%) groups. For FcgRIIIb, the heterozygosis HNA-1a, 1b was the most frequent genotype in SLE (44.4%) and healthy (45%) groups with an equal frequency in both groups. In SLE the homozygosis for HNA-1a was more frequent than that observed in controls, 26.7% and 16.5%, respectively; while the homozygosis for HNA-1b was more frequent in healthy (38.5%) group compared to SLE patients (28.9%). It was found the following frequencies for the alleles studied in SLE and healthy groups, respectively: H-131, 0.39 and 0.45; R-131, 0.61 and 0.55; HNA-1a, 0.49 and 0.39 and HNA-1b, 0.51 and 0.61. The most frequent genotypic combination observed in SLE patients was HR-131/HNA-1a, 1b (24.2%) and HR-131/HNA-1b and R-131/HNA-1b in healthy group (17.4%). *Summary.* This study has implications and can contribute for the understanding of neutrophil abnormalities in SLE and identifying genetic markers that would predict patients who are at high risk for infections. clenimar@usp.br

MYELODYSPLASTIC SYNDROME WITH DEL(5Q) CAN BE DISCRIMINATED FROM OTHER CYTOGENETIC SUBTYPES OF MYELODYSPLASTIC SYNDROME BY IMMUNOHISTOCHEMICAL DETECTION OF P53 OVEREXPRESSION IN BONE MARROW TREPHINES

N Trim,[1] T Murphy,[2] A Warren,[3] W Erber[2]

[1]*Addenbrooke's Hospital, Cambridge, United Kingdom*
[2]*Department of Haematology, Addenbrooke's Hospital, CB2 0QQ, Cambridge, United Kingdom*
[3]*The Department of Haematology, University of Cambridge, Hills Road, CB2 0XY, Cambridge, United Kingdom*

Background. Haploinsufficiency for the RPS14 gene that encodes ribosomal protein RPS14 has been implicated in the pathogenesis of the 5q-syndrome, a subtype of myelodysplastic syndrome (MDS). Genetic studies indicate that a p53-dependent mechanism underlies the macrocytic anaemia and bone marrow dysplasia in a murine model of the 5q-syndrome. Consistent with this hypothesis, nuclear p53 staining accumulates in the bone marrow of patients with 5q- syndrome. *Aims.* We set out to test the hypothesis that bone marrow trephine (BMT) biopsy specimens from patients with del(5q) associated MDS may show higher levels of p53 staining than BMT biopsies from patients with other cytogenetic subtypes of MDS. *Methods.* We collected 30 BMTs obtained at diagnosis from patients with *de novo* MDS (26), MDS/MPN (2), or treatment-related MDS (2) whose bone marrow at the time of biopsy had been analysed by *fluorescence in situ hybridisation (FISH)* for the most common MDS associated cytogenetic abnormalities (trisomy 8, monosomy 7, del(5q) and del(20q)). The immunohistochemical detection of p53 (antibody clone DO-7, Novocastra) in BMT sections was performed on a BondMax automated immunostainer using an immunoperoxidase method, diaminobenzidine (DAB) substrate and haematoxylin counter-stain. Fourteen lymphoma staging BMTs that were negative for marrow involvement were used as normal controls. Light microscopy was used to visually assess the p53 expression levels in 200 cells in each of 5 representative fields of view (x400 magnification), totalling 1000 cells per BMT. Cellular p53 expression was graded 0-3 based on stain intensity (0 = negative, 1 = positive, punctate/light staining, 2 = positive, uniform, medium staining, 3 = positive, uniform, dark staining). The percentage of cells in each grade category was multiplied by its grade (0-3) and the value of all grades accumulated to give an aggregate score for each BMT section (0=lowest possible score and 300=highest) (adapted from the neutrophil alkaline phosphatase scoring system - Rutenberg *et al.*, 1965). Aggregate scores were plotted against the MDS cytogenetic abnormality. *Results.* Aggregate scores for p53 expression levels were shown to be higher in MDS cases with del(5q) either as the sole abnormality or with additional cytogenetic abnormalities (ranges = 75-190.2 and 88.4-204.6 respectively), compared to MDS cases without del(5q) and normal controls (range = 18.3-75.6). *Conclusion.* Our results suggest that a high p53 expression score (>76.0) can discriminate del(5q) MDS from other cytogenetic subtypes, and supports the hypothesis that haploinsufficiency of *RPS14* and possibly additional genes within the del(5q) region causes overexpression of p53. Longitudinal studies and current investigations into which cells are responsible for this p53 overexpression may help determine the diagnostic and prognostic significance of these findings.

EPIDEMIOLOGY AND LONG-TERM FOLLOW-UP OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES FROM A TERTIARY CENTER. DATA FROM 1990 TO 2010

C Calderón, J Falantes, D Alonso, A Martín Noya, R Parody, I Espigado, JA Pérez-Simón

Hospital Universitario Virgen del Rocío, Seville, Spain

Background. Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal disorders characterized by impaired bone marrow (BM) function, peripheral cytopenia/s and eventually progression to acute myeloid leukemia (AML). Incidence of MDS varies among registries, significantly increasing with age, estimated 22-45/105/year over age of 70. We report preliminary analysis of MDS patients (pts) at Hospital Virgen del Rocío (Seville, Spain) in a two-decade time period. *Patients*

Table 1.

Age (mean; range)	71 (17-93)
Sex	Male: 257 (57,4%) Female: 191 (42,5%)
Type of MDS	Lower-risk MDS: 335 (74,6%) Higher-risk MDS: 100 (22,3%) Lost: 14 (3,1%)
FAB/OMS	RA/RARS: 198 (44%) RCMD: 67 (14,9%) RAEB-1: 49 (10,9%) RAEB-2: 66 (14,7%) RAEB-t: 25 (5,5%) CMML: 41 (9,1%) Lost: 3 (0,6%)
Hemoglobin (g/L)	91 (35-154)

Baseline characteristics

Table 2.

	OS (months)	P
BM blasts	<4%: 44m (33-54) 4-9%: 19m (10-27) 10-20%: 6m (3-8)	0,001
Hemoglobin (g/L)	<100: 13m (8-17) >100: 55m (43-66)	0,001
Platelet (x10⁹/L)	>150: 46m (32-59) 50-150: 23m (11-34) <50: 7m (3-10)	0,001
Transfusion dependency (at diagnosis or 6m after)	No: 50m (41-58) Yes: 13m (9-16)	0,001

Overall survival

and Methods. Four hundred and forty nine MDS pts have been analyzed for demographics, stage and evolution during follow-up. Characteristics are presented in table 1. Most pts (335/449; 74,6%) were lower-risk MDS (<10% BM blasts), being refractory anemia and refractory cytopenia with multilineage dysplasia the more frequent subtypes. Karyotype was available in 150 pts, mainly those diagnosed from 2005. *Results.* Incidence rate of MDS pts increased over time: 1990-95: 66 (14,7%), 1996-2000: 59 (13%), 2000-2005: 138 (30,7%), 2005 to present: 172 (38,3%). Overall, 346 pts are dead (77,1%). For lower-risk MDS, 24 and 48-month survival were 56,9% and 42,8%, compared to 22% and 10,5% for higher-risk MDS (p<0,001). Variables associated to overall survival (OS) were (all p>0,001): percentage of BM blasts (<10% vs >10%), hemoglobin (>100 g/L vs <100 g/L), platelet (>150x109/L, 50-150x109/L, <50x109/L) and transfusion dependency. Transfusion-dependent anemia was documented in 63,5% of pts at diagnosis. Supportive care including blood transfusion was the most common approach followed by observation until progression. Evolution to AML could be evaluated in 254 pts. 96/254 (37,7%) progressed to AML. Age at diagnosis (>75y) and BM blasts (>10%) were variables related to AML evolution. Causes of death were identified in 219 pts from medical charts and electronic records. Comorbidity was the main cause of death. Progression to AML (20,9%) and second neoplasia (9%) were identified as other major causes of death. *Conclusions.* Epidemiology of MDS remains unknown as many pts are underdiagnosed as observed by year of diagnosis. This analysis reflects preliminary approach to a large cohort of MDS pts from a tertiary center, with similar results to other registries. Depth of cytopenias seems to affect outcome together with classic prognostic factors. Detailed study for subgroups of pts and effect of intensive/disease modifying treatment is ongoing.

0827

PSYCHOMETRIC TESTING AND VALIDATION OF THE QOL-E QUESTIONNAIRE - A DISEASE-SPECIFIC QUALITY OF LIFE QUESTIONNAIRE FOR PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS) IN GERMANY

S von Mackensen,[1] U Germing,[2] K Goetze,[3] A Giagounidis,[4] E Oliva[5]

[1]*Institute of Medical Psychology, Hamburg, Germany*
[2]*Clinic of Haematology, Oncology and Clinical Immunology, Heinrich-Heine Universi, Düsseldorf, Germany*
[3]*III. Medical and Policlinic, Klinikum Rechts der Isar of the Technical Universit, München, Germany*
[4]*4 Medical Clinic 2, St. Johannes Hospital, Duisburg, Germany*
[5]*Haematology Department, Bianchi-Melacrino-Morelli Hospital, Reggio-Calabria, Italy*

Introduction. Patients with myelodysplastic syndromes (MDS) have a variably low survival while mainly depending on supportive care. Anemia and transfusion-dependence have been associated with poor quality of life (QoL). Patient- reported outcomes are a valuable measure of efficacy of therapeutic approaches aimed at alleviating symptoms due to cytopenias. Specific tools for the assessment of QoL are necessary and must undergo appropriate linguistic validation. QOL-E v. 2 is a self-administered questionnaire developed for the evaluation of QoL in patients with MDS (Oliva *et al.*, 2002, 2008). It explores four general dimensions (physical, functional, social, sexual), a nearly-specific (fatigue) and a specific disease-related dimension of QOL. Scores are standardized on a scale from 0 to 100, where higher scores reflect better QOL. It has been validated in Italian, Bulgarian and USA English. In the present study, the German translation is being assessed in an epidemiological survey in 100 consecutive MDS patients in 3 German centers. *Aims.* To linguistically validate the QOL-E, to evaluate the psychometric characteristics and stability of the QOL-E tool in Germany, and to identify disease-related disturbances and their associations with disease-specific factors in German MDS patients. *Methods.* The validated QoL-E was translated into German according to EORTC guidelines (2 independent forward translations, 1 reconciliation, 1 backward translation). The quality of the translation was tested in a pilot-test in 10 German MDS patients regarding its comprehensibility and the possibility to make suggestions for reformulation of unclear items. MDS patients > 18 years of age with primary or secondary MDS with at least one form of cytopenia according to IPSS criteria, willing and able to complete the questionnaire, were included. QoL-E v2 was completed by patients before the clinical visit and a retest was performed after 1 month. Psychometric characteristics in terms of reliability (Cronbach's alpha) and validity were performed. *Results.* The mean age of patients enrolled in the pilot-test was 68.6 years (SD=13.1) with a mean Hemoglobin (Hb) level of 9.7 g/dl (SD=1.8). Seven patients had low or Int-1 risk IPSS and very low or low risk WPSS scores. Patients found the German translation comprehensible, but had a problem with the meaning of the examples given for the item "performing heavy activities"('running', 'jumping') which were reformulated. For patients who were already retired the question whether "their health is an impediment for them to keep a paid job"was difficult to answer. Psychometric characteristics of the QoL-E were acceptable to good for all domains of the QoL-E (α=.56-.88), but for the physical dimension, which is probably due to the small number of patients from the pilot-test. Highest impairments in patients' QoL were found in the dimensions 'social' (mean 44.6 ± SD 33.7) and 'functional' (mean 55.6 ± SD 35.6). *Conclusion.* QOL-E v. 2 is the only specific instrument available for the evaluation of QoL in MDS. Its linguistic validation may identify QoL-E as a new tool for the evaluation of QoL in the German MDS population.

0828

LONG-TERM OUTCOME OF ISOLATED THROMBOCYTOPENIA ACCOMPANIED BY HYPOCELLULAR MARROW

DY Jo, GW Yun, YJ Yang, IC Song, SW Baek, KS Lee, HJ Lee, HJ Yun, KC Kwon, S Kim

Chungnam National University Hostpital, Daejeon, South-Korea

Background. Most of the patients with isolated thrombocytopenia do not undergo bone marrow (BM) examination and a presumptive diagnosis of immune thrombocytopenia is made when the history, physical examination, complete blood counts, and examination of the peripheral blood smears do not suggest other etiologies. Hypocellularity of BM, which is not associated with significant dyshematopoiesis, is often found in patients with isolated thrombocytopenia, but its clinical implications have not been studied. *Aims*. To define the clinical features and natural history of isolated thrombocytopenia accompanied by hypocelluar marrow without apparent etiologies in adults. *Methods.* We prospectively evaluated adult patients with isolated thrombocytopenia accompanied by hypocellular marrow (cellularity < 30% in patients aged less than 60 years; < 20% in patients aged 60 years or more) in the absence of significant dyshematopoiesis, cytogenetic abnormalities, or megakaryocytic hyperplasia. Patients with autoimmune disorders and infections were excluded. *Results.* Between January of 2002 and December of 2006, a total of 224 patients with isolated thrombocytopenia were studied, including by BM examination. Among them, 20 patients (17 males and three females) were consistent with isolated thrombocytopenia accompanied by hypocellular marrow. The median age of the patients was 29 years (range: 18-70 years). At the initial presentation, the platelet counts ranged from 12,000 to 99,000/μL (median 63,000/μL) and were >50,000/μL in 16 patients (80%). BM cellularity ranged from 5 to 25% (median 15%) and was ≤10% in six patients (30%), 11-20% in 13 patients (65%), and 21-25% in 1 patient (5%). A weak positive correlation was present between the BM cellularity and platelet counts ($R2 = 0.2044$, $P = 0.045$). During the median 48-month follow-up (range: 12-90 months), three of the 20 patients recovered platelet counts to normal levels (>150,000/μL) after 12, 56, and 66 months, respectively. Three patients developed pancytopenia after 11, 70, and 90 months, re-

spectively. Two patients were consistent with moderate aplastic anemia, and one was confirmed as refractory cytopenia with multilineage dysplasia. In the remainder of the patients, the platelet counts remained unchanged. *Conclusions*. Isolated thrombocytopenia accompanied by hypocellular marrow encompasses a group of heterogeneous conditions, and its subgroups represent the early manifestations of aplastic anemia, myelodysplastic syndrome, or temporary BM depression of unknown etiology. Regular follow-up is therefore mandatory in patients with this condition and a large-scale observational study is warranted.

0829

CYTOGENETIC FEATURES AND PROGNOSIS IN 496 ARGENTINEAN PATIENTS WITH PRIMARY MYELODYSPLASTIC SYNDROMES

C Belli,[1] W Correa,[2] R Bengió,[1] M Giunta,[3] S Benasayag,[4] R Campestri,[5] D Penchasky,[6] M Agra,[7] L Crisp,[8] D Fantl,[6] M Prates,[6] I Larripa[1]

[7]*Servicio de Hematología, Hospital General de Agudos "Tornú", Buenos Aires, Argentina*
[8]*Servicio de Hematología, Hospital Nacional Posadas, Buenos Aires, Argentina*

Background. Myelodysplastic Syndromes (MDS) include a group of heterogeneous hematological disorders with variable risk of evolution to Acute Myeloid Leukemia (AML) and short survival. Around 40-50% of patients show abnormal karyotype at diagnosis. Recently, some isolated deletions have been related with a favorable outcome in MDS (i.e. 9q-, 11q-, 12p-) and Breems *et al.*, 2008, proposed that monosomal karyotypes (MK) are an indicator of poor prognosis in AML. *Aims.* To characterize the cytogenetic profile, to test its prognostic value and to evaluate cytogenetic groups of risk in the Argentinean MDS population. *Methods.* This is a multicenter retrospective study of 496 primary Argentinean patients with primary MDS evaluated from 1984 to 2010 (including 239 patients from the Pilot Study and from the MDS Registry sponsored by the Argentinean Society of Hematology). Refractory cytopenia was defined according to Valent *et al.*, 2007 and patients were classified following FAB and WHO criteria. The median age was 69 (17-93) years with a male/female ratio of 1.3. During the follow-up (mean: 26 months), 111 (22.4%) evolve to AML and 222 (44.7%) died. *Results.* Gender, percentage of bone marrow blast, hemoglobin level, platelets count, number of cytopenias, LDH level and red blood cell transfusion requirements, FAB and WHO classification, IPSS and WPSS prognostic systems were significant predictive variables for prognosis (Kaplan-Meier and Long-Rank test, p<.001). Patients with normal karyotype (n=289, 58%, median survival: 51 months) had better outcome than those with cytogenetic alterations (n=207, 42%, 26 months, p<.001). Among abnormal karyotypes, 137 (66%) showed deletions and/or monosomies, 124 (59%) involved, at least, one chromosome #5, #7, #8 and/or #20. The most common cytogenetic aberrations were: -5/5q- (22% among cases with abnormal karyotype), -7/7q- (15%), +8 (21%), 20q- (9%) and -Y (8%). Karyotypes were divided according to IPSS (p<.001) into Good (n=334, 67%, median survival: 48 months), Intermediate (n=102, 21%, 32 months) and Poor (n=124, 12%, 15 months). In order to find the prognostic value of certain cytogenetic findings, karyotypes were divided as follows: normal, low risk alterations (n=45, 9%, median survival: 43 months), karyotypes with isolated deletions (n=20, 4%, 50 months), trisomy 8 (n=25, 5%, 25 months), other intermediate findings (n=54, 11%, 28 months), chromosome 7 alterations (n=19, 4%, 15 months), MK (n=30, 6%, 16 months) and other complex karyotypes (n=15, 3%, 18 months). No significant differences were observed among MK and other Poor cytogenetic findings (median survival: 15 months, p=.592). Patients with isolated deletions showed a similar behavior than Good cytogenetic findings (p=.437) and a borderline better outcome than the rest of the Intermediate ones (p=.07). An intermediate prognosis was observed when karyotypes included a deletion + other alteration (n=13, 3%, 31 months, p=.523). *Conclusions.* Cytogenetic findings had a clear impact in our population. Results in the present series, the largest in Latin America, suggest that MK are indicators of poor prognosis whilst the presence of an isolated deletion (not including 7q-) would be a good cytogenetic finding. However, the wide spectrum of low frequency aberrations stresses the importance of large study groups.

[6]*Second Department of Pediatrics, University of Athens, Greece, Athens, Greece*

Background. Diamond Blackfan Anemia (DBA) is a rare inherited disease characterized by congenital defective erythropoiesis. Patients present early in life with severe normochromic, macrocytic anemia, while about 50% of the patients have also congenital anomalies. Heterozygous mutations in 9 ribosomal proteins genes have been identified in ~50% of patients. More than 30% of these mutations are located in the RPS19 and RPL5 genes. *Aim.* To evaluate the clinical and hematologic phenotype, as well as, the incidence of mutations in the RPS19 and RPL5 genes in Greek patients with DBA. *Methods.* A questionnaire for patient with DBA, requesting data on clinical and hematological phenotype was sent to all the pediatric hematology, hematology and transfusion units in Greece. Informed consent was obtained. Genomic DNA was extracted from peripheral blood lymphocytes from the identified patients with DBA. Molecular analysis with PCR, ECMA (Enzymatic Cleavage Mismatch Analysis) and direct sequencing was performed allowing detection and characterization of disease-causing mutations. PCR primers were specifically designed to amplify the whole coding region and the flanking intron/exon junctions of RPS19 and RPL5 genes. *Results.* 17 Greek patients (7 females and 10 males, mean age: 11.4±11 years) with DBA phenotype were included in this study. Congenital anomalies in different organs, including craniofacial, upper extremities, hands, eyes, heart and kidneys were present in 71.4% of the patients. Regarding the clinical course of the patients, 4 are treated with steroids and 8 are on regular transfusions. One patient, who had been on regular transfusions, was transplanted at the age of 8 years from an HLA-matched unrelated donor. Four patients are lost to follow up. One patient developed thyroid cancer at the age of 46 years. 6 patients (35.2%) were indentified to carry mutations to either the RPS19 gene (3 patients,) or the RPL5 gene (3 patients). 2 of the 3 mutations detected in the RPL5 gene, c.C390G (p.Y130X) and c.197_198insA (p.Y66X) are novel. *Conclusions.* This is the first report on the clinical and genetic evaluation of DBA patients in Greece. We have observed similar frequencies of mutations in the RPS19 and the RPL5 genes but higher frequency of physical malformations to the ones reported from other countries. Higher rates of transfusion dependency may be related to referral bias. The occurrence of thyroid carcinoma in an adult patient with DBA is worth-noticing.

0831

MOLECULAR ANALYSIS OF SBDS GENE IN GREEK PATIENTS EVALUATED FOR SHWACHMAN-DIAMOND SYNDROME

P Delaporta,[1] C Sofocleous,[2] S Doudounakis,[3] G Tapaki,[4] M Economou,[5] S Kostaridou,[4] A Kattamis[1]

[4]*'Penteli' Children's Hospital, Athens, Greece, Athens, Greece*
[5]*First Department of Pediatrics, University of Thessaloniki, Greece, Thessaloniki, Greece*

Background. Shwachman-Diamond Syndrome (SDS) is a rare autosomal recessive disorder resulting from loss-of-function mutations in the highly conserved Shwachman-Bodian Diamond Syndrome (SBDS) gene. As a multisystem disease SDS is characterized by bone marrow dysfunction, exocrine pancreatic insufficiency, metaphyseal chon-

drodysplasia, short stature and increased risk of neoplasms. SBDS gene, located in chromosome 7q11, is the only gene presently known to be associated with SDS. Roughly 75% of patients with SDS carry mutations resulting from a gene conversion event with the adjacent pseudogene, SBDSP. In a limited number (<10%) of patients who present with clinical indications of SDS no mutations in SBDS are detected. *Aim.* To evaluate the clinical and hematologic phenotype, as well as, the incidence of mutations in the SBDS gene in Greek patients with SDS. *Patients and Methods.* 7 patients, including 2 sisters, (5 females and 2 males, mean age: 12.4±5.9 years), meeting the diagnostic criteria for SDS were screened for SBDS mutations. Genomic DNA was extracted from peripheral blood lymphocytes and molecular analysis with PCR, ECMA (Enzymatic Cleavage Mismatch Analysis), RFLPs and direct sequencing was performed allowing detection and characterization of disease causing mutations. PCR primers were specifically designed to amplify the whole coding region (five exons) and the flanking intron/exon junctions of SBDS gene but not the SBDSP pseudogene. RFLPs used the Bsu36I and AciI enzymes for the detection of the two most common c.183-184 TA>CT and 258+2T>C mutations respectively. Data on clinical and hematological phenotype were collected for each patient after informed consent was obtained. *Results.* Evaluated patients had a significant heterogeneous clinical presentation. 4 patients presented with neutropenia, and 2 with thrombocytopenia. 1 patient had trilinear cytopenia, evident at birth, with 32% of her marrow progenitors carrying an iso (7q) chromosomal abnormality. This patient was successfully transplanted from a matched sibling donor. One patient have had a stable clonal abnormality (46,X,del(X)(q24[ARROWRIGHT]qter)) in around 35% of her myeloid progenitors. 80% of patients showed congenital abnormalities mainly affecting the bones and the heart. Only one patient is receiving therapy with granulocyte colony-stimulating factor, due to chronic neutropenia. Pancreatic insufficiency was mild to severe, with only 2 patients requiring pancreatic enzymes replacement. Growth hormone was used in 2 patients. 4 patients were compound heterozygotes for the common 183-184 TA>CT and 258+2T>C mutations. One of those was a mosaic which explained her very mild phenotype, while another was heterozygous for the 183-184 TA>CT and homozygous for the 258+2T>C mutation. One patient was compound heterozygote for 258+2T>C and c.460-1G>A novel mutation. Finally, one patient was found to carry only the normal c.635 T>C (p. I212T) variant. *Conclusions.* Mutations in SBDS were detected in approximately 85.7% of patients, with 258+2T>C and 183-184TA>CT were the most frequent mutations, consistent with previous reports. Extreme phenotypic heterogeneity was present and varied from severe to normal. No significant association was observed between the different SBDS mutations and phenotypic severity.

0832

GEOGRAPHICAL DIFFERENCES IN IRON OVERLOAD AND IRON CHELATION PRACTICES IN ANAEMIA PATIENTS: PRELIMINARY RESULTS FROM THE TRANSFUSIONAL HEMOSIDEROSIS REGISTRY STUDY (TORS)

I Ilhan,[1] M Pehlivan,[2] J Ma,[3] E Volodicheva,[4] JW Lee,[5] N Siritanaratku,[6] BS Ko,[7] F Grifi,[8] A El-Ali,[9] B Tannir,[9] O Ocak Arikan,[9] B Han[10]

[10]*Peking Union Medical College Hospital, Beijing, China*

Background. Data describing iron chelation and transfusion practices as well as diagnoses of iron overload in patients with anaemia across geographical regions are limited. Baseline data from the large EPIC trial (with the oral iron chelator deferasirox) however, suggest that these practices differ between the European, Middle Eastern/African and Asia-Pacific regions (Viprakasit *et al. Blood* 2010;116(21):abst 4272). A prospective epidemiological study may provide further insights into clinical practices for these conditions. Here, we report preliminary data from the multinational TORS on iron overload and iron chelation practices. *Aims.* To examine differences in baseline characteristics among anaemia patients requiring chronic transfusion therapy, to assess the extent of iron overload and to gain insight into patterns of care surrounding the use of iron chelation therapy in different geographical regions. *Methods.* TORS is a prospective, multinational, non-interventional study to collect information from patients >2 years of age requiring chronic transfusion therapy with newly diagnosed anaemias (<12 months from diagnosis), including Low and Intermediate-1 myelodysplastic syndromes (MDS), aplastic anaemia (AA), Diamond-Blackfan anaemia (DBA) and other transfusion-dependent anaemias. Patients were recruited from Turkey, Russia and South Africa as well as from countries within the Asia-Pacific and Middle East regions. Patients with secondary or therapy-related MDS; Intermediate-2 or High-risk MDS; or acute leukaemia were excluded. At the time of patient inclusion (baseline), patient demographics and details of iron overload and iron chelation therapy use were assessed. Transfusional haemosiderosis (iron overload) was defined as ≥1 serum ferritin measurement >1000 ng/mL after onset of transfusion therapy; or a liver iron concentration (LIC) >2 mg Fe/g dry weight; or if serum ferritin or LIC measurements were not available, evidence of ≥20 red blood cell transfusions. *Results.* Of 539 patients recruited into the registry, the majority of patients had a diagnosis of MDS (58.8%, n=317), followed by AA (31.9%, n=172), DBA (1.1%, n=6) and other anaemias (5.9%, n=32). The highest numbers of patients were recruited from Turkey (23.7%, n=128), China (18.0%, n=97) and Thailand (15.4%, n=83; Figure 1). The mean age (±SD) of the patients was 51.2 ± 23.7 years (range 2-92); 49.0% (n=264) were male and 50.3% (n=271) were of Asian origin. At study entry, the percentage of patients receiving transfusions ranged from 47.0-100.0%. The numbers of patients assessed with iron overload ranged from 4.1% (4/97) in China to 38.5% (5/13) in South Africa. The numbers of patients receiving iron chelation therapy ranged from 2.4% (2/83) in Thailand to 26.6% (34/128) in Turkey (recordings of iron overload and iron chelation therapy do not have to apply to the same patients). *Summary/Conclusions.* The data suggest that iron overload and iron chelation practices vary between countries in these newly diagnosed patients with transfusion-dependent anaemias. These analyses are limited by the small numbers of patients in some countries and by a potential bias towards recruitment of patients with specific anaemias. These preliminary data nonetheless provide a better understanding of disease-management practices of newly diagnosed patients with anaemia across different geographical regions.

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal hematopoietic stem cell disease which can lead to life-threatening complications including intravascular hemolysis, thrombotic events (TE), and kidney disease. Improvements in the understanding and utilization of high sensitivity diagnostic tests and availability of targeted terminal complement blockade treatment have led to improved awareness and prognosis of PNH. There has been little systematic research focused on pediatric patients diagnosed with PNH due to small patient numbers. *Aims.* To describe the clinical characteristics of patients diagnosed with PNH as children and to compare these characteristics to patients diagnosed as adults in a large, international, observational disease registry. *Methods.* Data from 153 clinical sites in 19 countries on 5 continents (as of 31/Jan/2011) were analyzed to evaluate clinical presentation of PNH in patients first diagnosed at age <18 years (pediatric patients N=79) and at age ≥18 years (adult patients N=666). Baseline demographics, laboratory values (including flow cytometry), PNH-related medical history (including TE and kidney disease), and physician-reported PNH symptoms were compared for pediatric and adult patients. Patients (or guardians) gave informed consent prior to enrollment. Analyses were also stratified by percent GPI-deficient granulocytes (clone size) at registry enrollment (<50%, >50%). *Results.* Of the 79 patients diagnosed as children, 25 (32%) were still <18 years old at study enrollment. Approximately half of pediatric and adult patients were female. Years from disease start to enrollment was significantly higher for pediatrics than adults (mean ± SD: 10.7 ± 11.6 vs. 7.8 ± 8.4, respectively, p=.006). Overall, patients diagnosed with PNH as children were similar to those diagnosed as adults. There was no difference between pediatric and adult patients for underlying bone marrow disorders (39% vs. 43%), clone size (mean 63% vs. 64%), LDH fold above normal upper limit (mean 3.4 vs. 3.0), history of TE (10% vs. 18.2%, p=.07), history of renal impairment (10% vs. 13%) or use of transfusions prior to registry enrollment (33% vs. 41%). Physician reported hemoglobinuria and abdominal pain were comparable between pediatric and adult patients (54.5% vs. 56.3% and 44.3% vs. 36.9%, respectively). Pediatric patients had higher total red blood cell counts (mean 3.5 vs. 3.1 x1012/L, p<0.001) and less fatigue (52% vs. 72% p<0.001) than adults. Among patients with clone size ≥50%, pediatric patients were less likely to have a history of TE (7% vs. 22%, p=.02) and less likely to have fatigue (61% vs. 78%, p<0.01) but more likely to have headaches (54% vs. 36%, p=.02) than adults. Pediatric patients were more likely than adults to receive a bone marrow transplant during registry follow-up (5.1% vs. 1.5%, p=.03). *Summary/Conclusions.* PNH patients diagnosed in a pediatric setting present with similar clinical characteristic to adults such as LDH levels, hemoglobniuria, abdominal pain, underlying bone marrow disorders, TE and history of renal impairment. Among patients with clone size ≥50%, pediatric patients had less history of TE than adults, although TE is still an issue for pediatric patients. New clinical sites and geographic regions are encouraged to participate in the Registry (pnhregistry@iconplc.com).

Aims. An efficiency of different oral iron chelators was studied in a group of 113 MDS patients with < 10% of bone marrow blasts. *Patients and Methods.* Sixty-five patients were treated with oral iron chelator deferasirox (Exjade®). Median initial serum ferritin level was 2677,5 µg/l (range 780-9923 µg/l), the daily dose of the drug ranged from 10 to 40 mg/kg. Median duration of chelation treatment was 13,7 months (range 4-36 months). The results were compared to previously studied efficiency of deferiprone (Ferriprox®) in 48 patients with the same subgroup of MDS. *Results.* Chelation was effective (maintained or decreased iron stores) in 83% of patients (in 85% of 25 patients with serum ferritin ≤ 2000 µg/l and in 80% of 40 patients with serum ferritin > 2000 µg/l. Incidence of adverse effects was 56,9% and led to discontinuation of deferasirox treatment in 6% of patients. GIT symptoms represented the most frequent adverse effect (33,8% patients) that limited an effective escalation of the daily dose of the drug. An increase in serum creatinine level was observed in 20% of patients, after decease in daily dose or transient discontinuation of the drug serum creatinine level stabilized in all patients. Skin rash was present in 4,6 % as well as oedema and weight increase. When compared to our previous study with deferiprone, deferasirox effectivity was similar to that of deferiprone in patients with serum ferritin ≤ 2000 µg/l (85% v.s. 76% responding patients with deferiprone) but significantly higher in those with serum ferritin > 2000 µg/l (80% responders v.s. only 46% treated with deferiprone). Incidence of adverse effects was similar (56,9% v.s. 62,5% after deferiprone), and GIT symptoms were the most frequent events after treatment with both the drugs. However, symptoms of deferasirox toxicity were mild and mostly transient and no myelosuppresive effect related to the drug administration was observed in contrast to deferiprone where drug related granulocytopenia occurred in 17% of patients and the treatment had to be discontinued in 29% of patients. *Conclusions.* Deferasirox administered in a daily dose of 15-40 mg (depending on initial serum ferritin level) represents an effective and safe treatment for iron overloaded patients with early phase of MDS without excess of blasts.

0835

MYELODYSPLASTIC SYNDROMES (MDS): DOES THE HEPATITIS C VIRUS (HCV) INFECTION PLAY A ROLE?

A Fragasso, C Mannarella, A Ciancio, O Scarciolla

ASM-Hospital, Matera, Italy

HCV infection plays a well-documented role in the aetiology of malignant lymphomas. HCV-infected persons are more likely to have low neutrophil and platelet count; some researches support the hypothesis that HCV infection can itself cause cytopenias, but the mechanism is still unclear. Only a few studies have investigated the relationship between HCV and MDS, and the reports are contradictory. This research is aimed at evaluating the prevalence and clinical features of HCV infection in a population of MDS patients with a monocentric, retrospective analysis. One hundred twenty four patients, 84 males and 40 females, have been studied, mean age 76 years old (range 54-93), mean follow up 31 months (range 3-158); all underwent a complete blood cell count, routine serum chemistry, peripheral blood and bone marrow examination, and were tested for HCV-antibodies, HIV-antibodies and serum hepatitis B virus (HBV) HbSAg antigen. Cytogenetic analysis has been performed in 98 patients. Clinical outcomes were evaluated using Kaplan-Meier analyses. According to the WHO classification, 31 cases were classified as refractory anemia (RA), 28 as refractory cytopenia with multilineage dysplasia (RCMD), 11 as refractory anemia with ringed sideroblasts (RARS), 16 as refractory anemia with excess blasts (RAEB-1), 16 as RAEB-2, 3 as MDS unclassified (MDS_U), and 19 as chronic myelomonocytic leukaemia (CMML). All patients were nega-

tive for HIV infection; only 2 patients were HbSAg positive (1 in the AR group and 1 in the RAEB-2 group, respectively). Nineteen patients (15%) out of 124 were HCV positive; 12 out of 19 HCV positive patients were diagnosed with chronic hepatitis and 5 with mixed cryoglobulinemia. None of them was on antiviral treatment. Noteworthy, the HCV prevalence was significantly different among the WHO subtypes, as follows: RA=0,3% (1 out of 31), RARS=0% (0 out of 11), RCMD= 21% (6 out of 28), RAEB-1=43% (7 out of 16), RAEB-2=0% (0 out of 16), CMML=26% (5 out of 19), MDS_U= 0% (0 out of 3). The median overall survival (OS) was 49 months (mo) for RA patients, 71 mo for RARS, 25 mo for RCMD, 21 mo for RAEB-1, 9 mo for RAEB-2, 36 mo for CMML patients, respectively. In the WHO subgroups with the higher HCV prevalence no significant difference between HCV positive and HCV negative patients has been found either for OS (RCMD: p=0.82; RAEB-1: p=0.41; CMML: p=0.36) or leukemia free survival (LFS) (RCMD: p=0.93; RAEB-1: p=0.19; CMML: p=0.76). *Conclusions.* 1) in this experience the HCV prevalence rate in MDS patients (15%) was slightly higher than the values reported in the general population of comparable age in this geographic area (7-8%); 2) the HCV positive MDS patients are clustered in the WHO subgroups RAEB-1, CMML, and RCMD; 3) in these WHO subgroups the HCV infection has no prognostic significance; 4) the HCV positive cytopenic patients require a careful evaluation for possible MDS.

0836

PROLONGED HEMATOLOGIC AND MOLECULAR RESPONSE AFTER A LIMITED NUMBER OF AZACITIDINE CYCLES IN LOW-RISK MYELODYSPLASTIC SYNDROMES

C Finelli,[1] C Clissa,[1] M Follo,[2] D Russo,[3] C Filì,[3] A Curti,[1] S Paolini,[1] C Bosi,[4] S Mongiorgi,[2] L Manzoli,[2] C Papayannidis,[1] S Parisi,[1] G Martinelli,[1] L Cocco,[2] M Baccarani[1]

[3]*University of Brescia, Brescia, Italy*
[4]*Hospital of Piacenza, Piacenza, Italy*

Background. Azacitidine (AZA), at a dosing schedule of 75 mg/m2/d subcutaneously for 7 days every 4 weeks, induces high hematologic response rates (60-80%) in patients with Myelodysplastic Syndromes (MDS), and prolongs overall survival in high-risk MDS patients *(Silverman, 2002; Fenaux, 2009)*. However limited data are available concerning the efficacy and safety of AZA in low- risk MDS. Moreover, although continuation of AZA treatment is generally recommended in all responder patients, the optimal duration of therapy has not been clearly defined, especially for low-risk patients. Recently, a community-based study mainly involving low-risk MDS *(Lyons, 2009)*, showed that the lower dose AZA 5 regimen (75 mg/m2/d subcutaneously for 5 days), which avoid week-end dosing, can induce therapeutic responses consistent with the currently approved schedule. *Aims.* These data prompted us to investigate the therapeutic effect of the AZA 5 regimen, administered as induction treatment for a total of 8 courses, in low-risk MDS patients with symptomatic anemia refractory to erythropoietin (EPO). *Methods.* From September 2008 to February 2010, 34 patients with low-risk MDS (IPSS score low or intermediate-1) were enrolled into the study. Age at diagnosis ranged between 56 and 84 years. Moreover, as our group *(Follo, 2009)* previously demonstrated that the inositide signalling pathways, in particular phosphoinositide-phospholipase C (PI-PLC) beta1, may represent a target for AZA, we quantified the degree of PI-PLCbeta1 methylation and gene expression before and during AZA administration. *Results.* According to the 2006 International Working Group criteria *(Cheson, 2006)*, overall response rate (ORR) was 61% (14/23 evaluable patients), including Complete Remission (CR) (22%), and Hematologic Improvement (HI) (39%). Unexpectedly, in 3/14 responder patients we observed a long duration of response, still ongoing, after discontinuation of AZA. Patient 1, a 77 yr male, (WHO diagnosis: Refractory Anemia; IPSS risk: low; karyotype: normal) started AZA on September 2008. He showed a 1st response (HI, erythroid response), with a significant reduction of transfusions, after 3rd course of AZA, and became completely transfusion-independent from August 2009, 3 months after the completion of the 8th course (duration of response: 18 months). Patient 2, a 61 yr female, (WHO diagnosis: Refractory Anemia with Excess of Blasts-1; IPSS risk: intermediate-1; karyotype: normal) started AZA on October 2008, became transfusion-independent after 5th course, and achieved CR after 8th course (duration of response: 24 months). Patient 3, a 70 yr female, (WHO diagnosis: Refractory Cytopenia with Multilineage Dysplasia; IPSS risk: intermediate-1; karyotype: normal) started AZA on February 2009, and achieved HI (erythroid response) after 2nd course (duration of response: 22 months). All the patients showed an increase in PI-PLCbeta1 expression, in association with the hematologic response, and still maintain the molecular response. *Summary/Conclusions.* Our clinical and biological results support the feasibility and effectiveness of AZA treatment in low-risk MDS, especially in the case of EPO refractoriness. After achievement of hematologic response, discontinuation of AZA might be attempted, especially in low-risk MDS, where the risk of leukemic evolution is lower. However, the effectiveness of AZA resumption, in case of relapse, is still unknown.

0837

LENALIDOMIDE IN LOW AND INT-1 RISK MDS: CLINICAL RESULTS OF THE QOL-ESC REVMDS TRIAL

Background. Lenalidomide induces remissions in MDS patients with del5q. Patient reported outcomes associated with erythroid responses have not yet been reported. *Aims.* We present results of a prospective single-arm trial in 44 low and Int-1 IPSS risk MDS patients with del5q treated with lenalidomide to evaluate safety, efficacy, and changes in QoL. *Methods.* Inclusion criteria required an Hb level < 10 g/dL. All patients received lenalidomide at an initial 10 mg daily dose. Dose reduction was prescribed according to adverse events. Responses were evaluated according to Cheson's criteria (2006). QoL (QOL-E v2 questionnaire) was measured at baseline and weeks 8, 12, 24 and 52. Bone marrow assessment was performed every 3 months. *Results.* Thirty patients were transfusion-dependent. IPSS risk was 0 in 30, 0.5 in 13 cases and 1.0 in 1 case. Eleven cases had an additional cytogenetic abnormality. At 12 weeks, Hb increased from 8.6 ± 0.8 to 11 ± 2.1 ($p<0.0001$) in 40 evaluable patients of which 30 (75%) obtained an erythroid response. There were 11 cytogenetic remissions. Physical QoL scores increased from 40 ± 25 to 55 ± 29 (p=0.007) Drug discontinuation followed by dose reduction was required in all but 4 patients. One patient refused to continue study drug because of progressive anemia. There were 2 progressions observed during the trial. Complete data at 52 weeks will follow. *Conclusions.* Though the starting dose was relatively low, initial hematological toxicity did limit lenalidomide dosing so that most patients required an early reduction. Preliminary results confirm that lenalidomide induces erythroid responses and transfusion independence with cytogenetic remissions and significant improvements in QoL.

0838

INCIDENCE OF APLASTIC ANEMIA AND ITS ASSOCIATION WITH VARIOUS HLA ANTIGENS

M Taj, T Sultan Shamsi

National Institute of Blood Disease Center and Bone marrow Transplantation, Karachi, Pakistan

Background and Objectives. Aplastic anemia arises from failure of marrow to produce insufficient quantities of haematopoietic cells, which causes peripheral pancytopenia with fatty or empty bone marrow. The

most severely affected patients have neutrophil counts of less than 200 cubic per millimeters, platelet count of less than 20,000 and reticulocyte counts of less than 60,000 per cubic millimeters along with marrow cellularity of less than 25%. Immunologic events that precede the destruction are less clear. Involvement of the lymphocytes of CD34 or helper cells has been inferred from the over expression of the class II histocompatibility antigen HLA DR2 in white patients with Aplastic anemia and in various studies association of HLA antigens has been established to the response to different modes of treatment. For this purpose we conducted a retrospective study to know the exact epidemiology of Aplastic anemia in our setup as well as its association with various HLA antigens. *Aims and Methods.* Total 315 patients with the confirmed diagnosis of Aplastic anemia were registered in our center from April 1998 till April 2006 and their detailed asseement was performed. After the initial counseling of the illness and symptomatic treatment; these patients were offered the ultimate treatment considering Allogenic BMT as first line treatment option.HLA typing was performed of only those patients who were fulfilling the criteria of bone marrow transplantation. Later on results of HLA antigens were analyzed. *Results.*Total 318 patients were enrolled out of which 237 were males and 71 females. 131patients belonged to pediatric age group (under 15) and 171 above that. The mean age of presentation was 20.79, while the median was 17.21% of the patients under went BMT, 22% patients were given cyclosporin and 5% received ATG with or without cyclosporin. In HLA typing results, there was strong association with HLA B5 (52). *Conclusion.* Aplastic anemia has about 3-4 fold higher incidence in Asian population. Although these results reflect the number of cases from only one tertiary care center, but still the magnitude of disaese can be roughly estimated. Further studies are needed to establish the other causal factors like occupational history and drugs history of last 6-8 months period of time, so that further details regarding this neglected illness could be explored.

0839

EXPERIENCES OF DECITABINE IN ELDERLY PATIENTS WITH MYELODYSPLASTIC SYNDROME

SK Park,[1] SH Kim,[1] HJ Kim,[1] JH Won,[1] DS Hong,[1] HS Park,[1] S Lee,[2] JY Kwak,[3] JA Kim[4]

[1]*Soonchunhyang University Hospital, Bucheon, South-Korea*
[2]*Catholic Hematopoietic Stem Cell Transplantation Center, The Catholic University, Seoul, South-Korea*
[3]*Chonbuk National University Hospital, Jeonju, South-Korea*
[4]*St Vincent Hospital, The Catholic University of Korea, Suwon, South-Korea*

Background. Patients with myelodysplastic syndromes (MDS) are challenging to treat, given the advanced median age and comorbidities of the population. Decitabine, a hypomethylating agent that allows for the re-expression of tumor suppressor genes, represents a treatment option for MDS patients. In phase 2 and 3 studies, decitabine has been associated with durable responses in MDS patients and delayed time to acute myeloid leukemia (AML) transformation or death compared with supportive care. Decitabine has been shown to be well tolerated with a toxicity profile expected for this class of agent. However, the treatment of older patients ≥70 years seemed to be associated with increased toxicity in the first two courses. The delayed cycles of subsequent treatment might be caused by prolonged myelosuppression owing to the continuing presence of underlying disease and the adverse effect of decitabine. And febrile neutropenia occurred frequently (around one third) in patients who received decitabine. *Aims.* We need to confirm the efficacy and safety of decitabine in patients 70 years old and over with myelodysplastic syndrome. *Methods.* We analyzed clinical data of 26 MDS patients ≥70 years who were treated with decitabine. Patients received decitabine 20mg/m2 intravenously daily for 5 days. Decitabine was given for a median of 4 courses (range, 2-11 courses) and median follow-up duration was 13 months. *Results.* Overall response was 57.7% (15 of 26 patients) including bone marrow CR with hematologic improvement in 4 patients. Median time to response was after two cycles in patients achieved any response and four of responding patients showed an effect as late as cycle 6. There were no significant differences in clinical outcomes of patients 70 years old and over to compare to those of patients under 70 years old, except the median time to erythroid response. In elderly patients erythroid response was faster (two cycles). Febrile neutropenia was observed in 15 patients (57.6%) and the majority of infectious complications were happened for first two cycles. Treatment related mortality was 15.4% (4 of 12 patients) at 3 months and was attributed to prolonged myelosuppression and disease progression. *Conclusions.* In elderly patients with MDS, we confirmed that the efficacy of decitabine was comparable with that in younger patients and decitabine was generally well tolerated. However, the treatment of older patients ≥70 years seemed to be associated with increased risk of infectious complications in the first two courses. Therefore, we need the effective strategy to prevent infection at the earlier cycles of decitabine treatment, especially in elder patients with severe neutropenia.

0840

EFFICACY AND TOLERABILITY OF 5-DAY AZACYTIDINE DOSE INTENSIFIED REGIMEN IN HIGHER RISK MDS

F Pierdomenico, A Parreira, A Almeida

IPO Lisboa, Lisboa, Portugal

Background. Azacytidine is a hypomethylating agent indicated for treatment of higher risk Myelodysplastic Syndromes (MDS). A recently published phase III trial demonstrated improved overall survival (OS) of MDS patients treated with azacytidine compared to those receiving conventional care regimens, thus establishing this treatment option as first line therapy in those patients for whom bone marrow transplantation is not an option. *Aims.* Evaluate the efficacy of azacytidine regimen in terms of transfusion independence (TI), overall response (OR), time to AML transformation and tolerability in patients with higher risk MDS and AML with 20-30% blasts. *Methods.* Higher risk (International Prognostic Scoring System - IPSS INT-2 and high risk) MDS patients were treated with azacytidine for at least 4 cycles in our institution. OR, including complete response (CR) and partial response (PR) and TI, defined according to the 2000 International Working Group Criteria (IWG), were assessed by blood and bone marrow examination. Treatment cycles were repeated until toxicity or disease progression. *Results.* A total of 48 patients were treated with azacytidine between June 2006 and September 2010; of these, only 26 were treated for at least 4 cycles. Mean age was 65 years old (range 85-36) and male sex was predominant (M:F of 1.3.) Eleven patients had refractory anaemia with excess blasts (RAEB), six had secondary AML, five had chronic myelomonocytic leukaemia (CMML), two had refractory cytopenias with ringed sideroblasts and two had acute erythroblastic leukemia. Most patients were high risk according to IPSS scoring (78%). Azacytidine was used as first line therapy in 35% and as second line in half. An average of 8 cycles (4-22) per patient were administered. The transfusion independence rate was of 50%, with average response duration of 6.5 months. Overall response rate was 31% (7 CR and 1 PR). During the follow-up period, fourteen patients died. Five patients showed disease progression to AML: four of them had never shown any response to azacytidine, while the other one had obtain transfusion independency. Overall survival (OS) from diagnosis was of 26 months, while OS from beginning of treatment was 22 months. There was limited toxicity, mainly grades I and II gastrointestinal and skin toxicity. Eleven patients (42%) had Grade III haematological toxicity and four (15%) suffered Grade IV haematological toxicity. *Conclusion.* The efficacy of azacytidine in achieving TI and prolonging survival in MDS is well recognized. In this study, azacytidine improved quality of life and overall survival regardless of the quality of response. Treatment was well tolerated, with limited toxicity. Our results, though coming from a small group of patients, were comparable to those reported in the literature.

Introduction and Aims. Paroxysmal nocturnal hemoglobinuria (PNH) is a debilitating and life-threatening hematopoietic stem cell disorder

characterized by chronic uncontrolled complement activation. PNH evolves from the clonal expansion of hematopoietic stem cells with complete or marked loss of the terminal complement inhibitors CD55 and CD59, consequently rendering red blood cells susceptible to systemic lysis. This chronic hemolysis underlies the severe morbidities and mortality associated with the disease: life-threatening thromboembolism (TE), chronic kidney disease (CKD), pulmonary hypertension, end organ damage, fatigue, abdominal pain, dysphagia and dyspnea. While many patients with PNH have anemia, low hemoglobin levels and transfusion requirements may not adequately reflect the burden of disease due to hemolysis since these parameters are influenced by other factors unrelated to hemolysis or complement activation including bone marrow dysfunction, patient specific factors and physician clinical assessment. There is a paucity of reported data in Japanese PNH patients who are not transfused that sufficiently captures their burden of disease. Here, we report the efficacy response of two patients recently treated with eculizumab in the AEGIS study who received no blood transfusions in the 2 years prior to study participation. *Methods.* Eculizumab was administered to 29 Japanese PNH patients (14 men and 15 women; median patient age, 47 years; range 26-70 years) at 9 institutions in Japan for 12 weeks in the AEGIS study. This report summarizes the evaluation of two patients with history of no blood transfusions that enrolled and were treated in the AEGIS study. *Results.* At baseline, the two patients who had received no blood transfusions prior to study participation were hemolytic (LDH approximately 7 and 11 fold above normal), demonstrated significant organ damage with evidence of thrombosis (1 patient with DVT) and renal disease (CKD stage 2 and 1), and suffered disabling quality of life as measured by FACIT-fatigue and EORTC-QLQ C-30 scores. In both patients, eculizumab treatment resulted in substantial 78%-88% reductions in LDH, significant improvements in fatigue as measured by FACIT-fatigue (changes of 5 and 23 points; >3-point improvement is clinically meaningful), improvement in dyspnea in one patient (change of 33 points from baseline; ≥10 point improvement is clinically meaningful), and elimination of CKD with no subsequent thrombotic events in both patients. The LDH reduction in these non-transfused patients compares favorably to the 87% reduction in LDH observed in the entire AEGIS patient population. *Conclusion.* These data demonstrate that despite a history of no transfusions, at baseline these non-transfused PNH patients had significant clinical evidence of disease burden including chronic hemolysis, history of thrombosis, renal disease, and impaired quality of life. These findings underscore the central role of uncontrolled complement activation and the resultant sequelae associated with hemolysis, rather than anemia or transfusion requirements, in guiding the treatment of patients with PNH. Further, inhibition of terminal complement activation with eculizumab in patients with PNH improves hemolysis, fatigue, dyspnea and other significant morbidities of disease whether or not they had received transfusions prior to participation in the AEGIS trial.

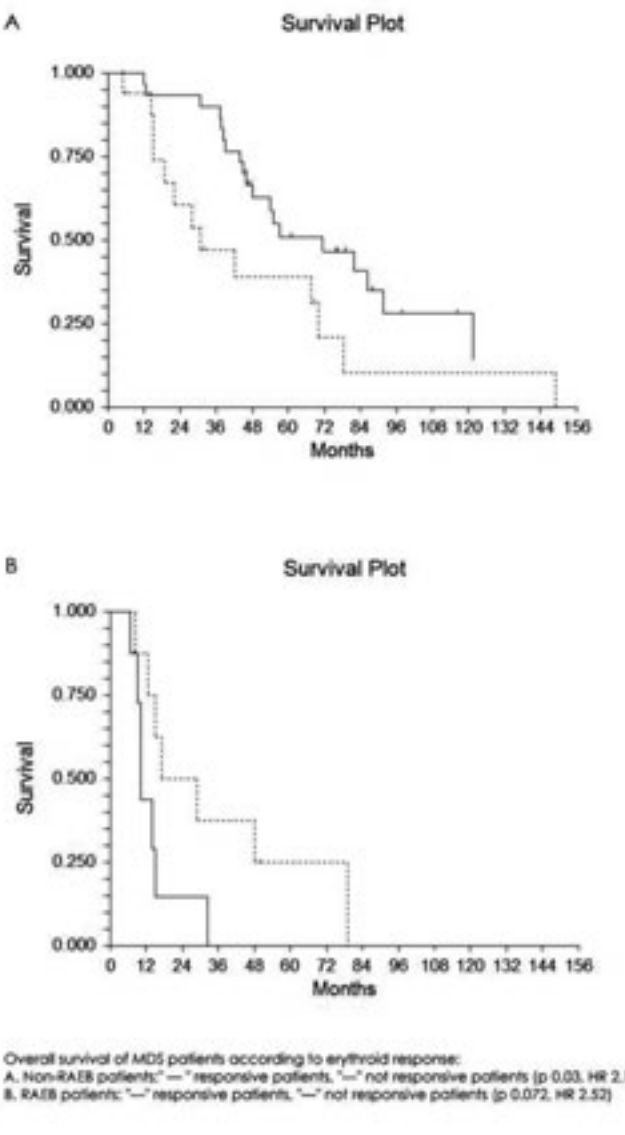
0842

LONG TERM SURVIVAL AND TREATMENT RESPONSE IN LOW-INTERMEDIATE RISK MYELODISPLASTIC SYNDROME PATIENTS TREATED WITH RECOMBINANT ERYTHROPOIETIN PLUS 13-CIS-RETINOIC ACID AND DIHYDROXYLATED VITAMIN D3

E Crisà

Università delgi Studi di Torino, Torino, Italy

Background. In our previous paper (Ferrero *et al.*, BJH 2009) we reported the treatment of 63 MDS patients (median age 75, 16 RAEB1, 47 non RAEB) with a combination of human recombinant erythropoietin (EPO) (alfa or beta epoetin, 30-80000 U/ week, median 65000U/week),13-cis-retinoic acid (20 mg day) and dihydroxylated vitamin D3 (1 ug day). Eleven of the 16 RAEB1 patients also received intermittent, low dose of 6-thioguanine. In spite of adverse prognostic factors for response to erythropoietin (all patients with Hb <9.5 g/dl, 70% transfusion dependent, 51% IPSS intermediate 1 or 2) 64% of non RAEB and 50% of RAEB1 displayed an erythroid response according to Cheson *et al.* (Blood 2006). At previous evaluation (41 months of follow-up) an overall survival (OS) advantage was evident for non RAEB patients with erythroid response. *Aims.* Now we updated the casistic after 3 years from the previous evaluation. *Methods and Results.* Overall survival and response duration were estimated using Kaplan Meyer method. Median follow up for alive patients is now 65 months (5 months - 13 years). Median duration of erythroid response is now increased to 22 (2-95+) months for non RAEB and 6 (2.5-34.5+) months for RAEB1, 21% of responses in non RAEB patients have lasted more than 3 years. Thirty two of 46 non RAEB and 14 of 16 RAEB1 patients died, with a median survival respectively of 55 and 15 months. Acute myeloid leukemia evolution occurred to 11 patients (5 RAEB1 and 6 non RAEB patients). In non RAEB patients survival was significantly affected by IPSS score (median OS 45 months for intermediate1 plus intermediate2 patients vs 149 months for low risk patients, p= 0.05, HR 2.47) and transfusion dependance (p 0.006, HR 2.93) as expected. These parameters did not significantly modify RAEB patients OS, possibly due to the low patient number. Although the erythroid response did not correlate with known risk factors such as IPSS score, caryotype and transfusion requirement, it confirmed its positive prognostic role for survival in non RAEB patients (p 0.03, HR 2.14): median survival 71.5 months (range 12-156+) for responders, 30.6 months (range 5-149) for non responders. A trend towards a better survival for responder was also observed among RAEB1 patients (median survival 17 months for responders, 10 months for non responders), however, due to the low numbers of patients in this group, the difference was not statistically significant, even if border line (p 0.072, HR 2.52). *Conclusions.* In conclusion our long term follow-up confirmed the positive role of our combined treatment for response duration and survival in a group of non RAEB patients, most of them with unfavorable prognostic features, compared to literature data on EPO alone treatments.



Overall survival of MDS patients according to erythroid response:
A. Non-RAEB patients: "—" responsive patients, "—" not responsive patients (p 0.03, HR 2.14)
B. RAEB patients: "—" responsive patients, "—" not responsive patients (p 0.072, HR 2.52)

ERYTHROPOIETIN PLUS DANAZOLE, PREDNISONE, B12 AND FOLATE IN REFRACTORY CYTOPENIA WITH MULTILINEAGE DYSPLASIA. MONOCENTRIC PROSPECTIVE STUDY

G Giordano,[1] P Mondello,[2] R Tambaro,[1] M De Maria,[1] F D'Amico,[1] G Sticca,[1] C Di Falco[1]

[1]*Center "John Paul II", Catholic University, Campobasso, Italy*
[2]*University Hospital "G. Martino", Messina, Italy*

Background. RCMD is a well defined entity in MDS. The overall median survival is about 30 months. The appropriate treatment of RCMD is still unclear. *Aims.* To verify if immunosuppressive treatment with danazole and prednisone plus erythropoietins and vitamins is safe and feasible in RCMD treatment. *Methods.* This is a monocentric, prospective, randomized study, regarding the period from July 2008 to December 2010. 30 patients with RCMD were randomized to receive erythropoietin alpha 40000 UI sc/weekly or erythropoietin beta 40000 UI sc/weekly, B12 400 mg/day and folate 5 mg/day (15 patients - group A) or erythropoietin alpha or beta plus B12 and folate at the same dose and danazole 400 mg/day for 1 year and prednisone 50 mg/day for 1 month, then gradually suspended in the following month (15 patients - group B). Median follow-up was 15 months (R 5-29 months). In the group A median age was 67 years (R58-73). M/F was 9/6. 2 patients presented a karyotype with +8, and 1 with +9. In the group B median age was 65 years (R55-70). M/F was 8/7. No patient had an abnormal karyotype. In the group A all patients received erythropoietin beta. In the group B 8 patient received erythropoietin alpha and 7 beta. In group A at diagnosis median Hb level was 9 g/dl (R7-10), PLT 90000 (R70000-98000), ANC 750 (R250-1000). In group B at diagnosis median Hb level was 8 g/dl (R7-9), PLT 45000 (R30000-70000), ANC 450 (R250-900). Every 6 months all patients received a liver ecography and blood liver test, to prevent danazole-related hepatocarcynoma, and only male patients received a transrectal prostatic ecography and PSA dosage, to prevent danazol related prostate carcinoma. *Results.* In group A all patients after therapy achieved a better Hb level with a median increase of Hb of 1.5 g/dl after a median of 2.5 month (R1-5). No improvement was observed in neutrophil and platelets count. In group B all patients achieved a normal Hb (>10 g/dl), PLT (>100000/mcl)and absolute neutrophil count (ANC > 1000/mcl) after a median of 1 month of treatment (R1-3 month). The 8 patients of group B treated with erythropoietin alpha achieved a normal level of Hb (>10 g/dl) with a median of 1 month sooner than the 7 patients of group B and all patients of group A treated with erythropoietin beta (median: 1 month in group with epo alpha, 2 monthin group with epo beta). At December 2010 no patients died for all cause. Patients in group A have a need of platelet transfusion of a median of 1 unit every 2 months and have a median number of hospitalization per year of 6 versus 1 for patients in group B. No patient developed an hepatocarcynoma or a prostate carcinoma during follow-up period. *Summary/Conclusion.* In RCMD treatment with erythropoietin, danazol an prednisone with B12 and folate support seems to be safe feasible and effective. In consideration of the small number of patients treated, these results need confirmation in a larger cohort of patients.

[7]*Department Hematology, University Hospital, Helsinki, Finland*
[8]*University Sacred Hearth, Rome, Italy*

Background. Availability of new technologies has expanded the possibilities for education of microscopic morphology on internet. Among others virtual microscopy has enabled evaluation of whole microscopic smears from peripheral blood or marrow aspirate up to a significant magnification. *Aims.* To assess the quality of virtual microscopy internet project used for pregraduate education of medical students. Access to the project is currently restricted only to students and members of project team at www.e-hematologie.cz. *Methods.* Seven experts from the Czech Republic, Finland, Germany and Italy have evaluated the pictures of single normal and pathologic cells and full scope scans of marrow or blood microscopic smears obtained by CellaVision DM 96 (Sysmex) and dotSlide system (Olympus). *Results.* 94 cathegories of normal and pathologic cells on 1-5 pictures depicting single or few cells including special stainings and 58 virtual scans of normal peripheral blood, normal marrow aspirates and marrow aspirates in various hematologic conditions were evaluated. Technical quality of pictures including sharpness and magnification of cells, including lack of the possibility to further magnify the pictures was the most frequent finding (comments raised by 3 to 5 experts on proerythroblasts, promyelocytes, unmature eosinophiles and basophiles; by 4 experts on quality of special staining). Experts agreed on the need to exchange the provided picture or scan for a new one because of poor selection in these cases of: mastocytes (6 of 7 experts); prolymphocytes (4/7); monoblasts, promonocytes, megakaryoblasts, micromegakaryocytes (3/7). A better selection of scaned smears was suggested by 3 experts in cases of APL, AML with inv16, MDS and acute monoblastic leukemia. Scans more than one case of HCL and chronic prolymphocytic leukemia should be provided. *Conclusions.* A very good level of agreement between the authors of the project and external auditors was achieved. Modern tools enabling virtual microscopy have been confirmed as excellent or very good for education of morphology (agreement among all experts). Careful selection of the smears and appropriate use of technologies may avoid scans and pictures of inadequate quality. Implementation of unified morphology classification and links to other national and European projects are mandatory to further improve the quality of the project. The use of these ICT tools is nowadays essential for a consensus morphological diagnosis, that is mandatory in those hematological malignacies where the identification and enumeration of abnormal cells still remain mandatory for the diagnosis.

Acknowledgement. Project was supported by the grant CZ.1.07/2.2.00/07.0294 of ESF and state budget of the Czech Republic through the Operating program Education for Competitiveness provided by the Czech Ministry of Education Youth and Sports of the Czech Republic.

LONG-TERM OUTCOMES AFTER IMMUNOSUPPRESSIVE TREATMENT FOR MODERATE APLASTIC ANEMIA

A Kulagin,[1] I Golubovskaya,[1] I Kruchkova,[2] S Bondarenko,[1] N Stancheva,[1] I Lisukov,[1] B Afanasyev[1]

[1]*R.M. Gorbacheva Memorial Institute of Children Hematology and Transplantation, St. Petersburg, Russian Federation*
[2]*Institute of Clinical Immunology SB RAMS, Novosibirsk, Russian Federation*

Background. The clinical course and current management of acquired moderate aplastic anemia (MAA) are variable and few data concerning long-term results of immunosuppressive therapy (IST) are available. *Aims.* To evaluate of IST efficacy and long-term outcomes in patients with MAA. *Methods.* We analyzed the long-term outcome of 59 patients with MAA (28 M and 31 F, age 6-65 years, median 25) treated with ATG and CsA (n=41, including repeated courses in 14 patients) or with CsA alone (n=18) in two centers between April 1994 and February 2011. MAA was defined as hypocellular bone marrow and at least bi-lineage cytopenia lasting more than 4 weeks without meeting the criteria for severe AA. This study includes both retrospective and prospective phases (before and after 2005 respectively). The hematological response was evaluated according to the strict response criteria (Camitta B., 2000). Adult patients or parents of children under 18 years of age signed informed consent. *Results.* A total of 46 patients (78 %) responded to IST but only 10 patients (17 %) achieved complete response. Eleven patients (24 %) relapsed and 9 responded again after retreatment with ATG or/and CsA. Late events included MDS/AML (n=5), rectal cancer (n=1) and hemolytic PNH (n=2). There were 1 early and 5 late deaths. With a median follow-up of 38 months (range 1-201), the probability of 5-, 10- and 15-year overall survival were 93.3 ± 3.7 %, 82.7 ± 7.8 % and 66.2 ± 16.1 % respectively. Due to high incidence of relapse and late events the failure-free survival was much lower: 52.2 ± 8.2 % and 32.3 ± 8.6 % at 5 and 10 year respectively with no apparent plateau in the curve. *Conclusions.* These data demonstrate that despite encouraging short-term results the long-term prognosis of MAA after IST is rather poor and unpredictable. Longer follow-up in a larger cohort and further studies into biologic heterogeneity are warranted to determine optimal treatment strategy in MAA. Careful monitoring of hematologic response would be required in order to clarify the role and timing of allogeneic bone marrow transplantation.

Myeloma and other monoclonal gammopathies - Biology 2

[2]*Institute of Molecular Medicine, Trinity College Dublin,, Dublin, Ireland*
[3]*Haemato-Oncology Laboratory, Belfast HSC Trust, Belfast, Northern Ireland*
[4]*Haematology Department Desio Hospital, Desio, Italy*

Background. Multiple myeloma (MM) is a clonal malignancy of plasma cells characterized by several genetic and epigenetic aberrations. IGFBP-3 gene is a member of the insulin-like growth factor binding protein (IGFBP) family and it can regulate cell growth and death by its ability to bind insulin-like growth factors (IGFs) as well as its IGF-independent effects involving binding to other molecules. Its role in carcinogenesis in other tumors is still debated. Previous studies demonstrated that in patients with MM the levels of IGFBP-3 protein in serum are decreased. We have recently shown that the gene expression of IGFBP3 in myeloma cell lines were decreased. *Aim.* we analyzed the gene expression of IGFBP3 samples from patients with monoclonal gammopathies at diagnosis and we evaluated the correlation between IGFBP3 gene expression levels and overall survival of patients in order to determine the clinical relevance of this gene. *Methods.* 128 samples of patients at the moment of diagnosis (14 MGUS and 114 with MM) were retrospectively evaluated. The diagnosis was based on standard criteria. IGFBP3 mRNA expression was measured in each samples by real-time PCR using TaqMan Gene Expression Assays and the 7900HT Real-Time PCR System (Applied Biosystems Foster City, CA). *Results.* 128 patients; male 76; female 52; median age 68 years (range 40-89). ISS stage: stage I 41%; stage II 33%; stage III 26%. In 73/128 (57%) patients we found lower levels of IGFBP3 expression compared to the calibrator sample, the remaining 55/128 (43%) patients showed increased level of gene. We analyzed the correlation between overall survival and IGFBP3 levels and we surprisingly observed that patients with lower levels of the gene had a significantly better overall survival (p 0.0215). *Conclusion.* These results suggest IGFBP3 down-regulation as a good prognostic factor. Further analysis of correlation of IGFBP3 gene expression with clinical and biological characteristics in these MM patients is ongoing. More studies are needed to better understand the role of IGFBP-3 in myeloma pathogenesis.

[3]*Department of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic*

Background. Neural stem cell marker nestin is considered to be a characteristic marker of multipotent proliferative precursors with primitive and undifferentiated phenotype found in some embryonic and fetal tissues. Nestin expression has been also detected in many solid tumors and is proposed to be a suitable diagnostic and prognostic indicator of malignancy and a putative marker of cancer stem cells in solid tumors. Unexpectedly, our previous results confirmed nestin levels in mature $CD138^{+}38^{+}$ plasma cells (PC) of multiple myeloma (MM) patients by flow cytometry; significant differences were found between nestin levels in MM and individuals without any hematological malignancy. One third of MM patients had more than 50% of nestin-positive PC. Nestin seems to be a specific marker only for $CD138^{+}$PC. Expression of stem/progenitor cell marker nestin might be a novel prognostic factor for MM. *Aims.* The aim of this pilot study was to analyze nestin expression in $CD138^{+}$PC of MM and evaluate relationship between nestin expression and cytogenetic aberrations in $CD138^{+}$PC of MM. *Methods.* A total number of 22 MM patients (12M/10F; median age 58 years) were included in this study. Nestin expression was evaluated as $2^{-\Delta\Delta Ct}$ of nestin gene by quantitative real-time PCR in 22 MM patients. As a calibrator was used commercial total bone marrow RNA from healthy donors. $CD138^{+}$PC of MM patients were analyzed for del(13q14), del(17p53), IgH rearrangement (IgH), 1q21 gain and hyperdiploidy/non-hyperdiploidy (HY/non-HY) by interphase FISH. HY was assessed as trisomy of chromosome 5, 9 and 15. Differences of nestin expression between cytogenetic-aberration positive and negative patients were analyzed by non-parametric Mann-Whitney U test. *Results.* The whole group of MM patients had the median $2^{-\Delta\Delta Ct}$ 2.62 (range; 0.49-39.41). Statistical significant differences were found between IgH-positive: median $2^{-\Delta\Delta Ct}$ 5.42 (range; 0.49-39.41) and IgH-negative patients: median $2^{-\Delta\Delta Ct}$ 0.72 (range; 0,46-6,62), p=0.025; HY-patients: median $2^{-\Delta\Delta Ct}$ 0.72 (range; 0.46-24.44), and non-HY-patients: median $2^{-\Delta\Delta Ct}$ 7.00 (range; 0,62-39,41), p=0.024; trisomy 15-positive: median $2^{-\Delta\Delta Ct}$ 0.59 (range; 0,46-4,24) and trisomy 15-negative patients: median $2^{-\Delta\Delta Ct}$ 8.43 (range; 0,99-39,41), p<0.001. *Summary.* Our results confirmed that nestin expression is associated with IgH rearrangement and hyperdiploidy. High nestin expression was related to IgH rearrangement and to non-HY patients. We suppose that nestin might be associated with unfavorable prognosis, since IgH rearrangements and non-HY are unfavorable prognostic factors. However, further studies are required to assess nestin role in multiple myeloma pathogenesis. Supported with research program MSM of Czech republic Nr. LC06027, P304/10/1395 and MSM 0021622434.

Background. Naturally occurring regulatory cells play an active role in maintaining immune system homeostasis. In various hematological malignancies and solid tumors it was proved that T regulatory cells (Tregs) were increased and functionally active in abrogating immune responses. Few studies documented the expansion of Tregs in the relapsed multiple myeloma (MM) patients after lenalidomide and dexamethasone treatment. *Aims.* To screen the frequency of regulatory (CD4 and CD8 Tregs) and suppressor (Ts) cells between pre- and post-induction cycle by lenalidomide plus dexamethasone combination in newly diagnosed MM patients. *Methods.* Thirteen newly diagnosed

Table 1.

Comparison of regulatory and suppressor cells between pre- and post-induction by lenalidomide and dexamethasone

Pre-induction	Post-induction cycles		P value
CD4 Tregs in median% (range%)			
2.90(0.97-5.42)	1st	4.03 (1.99-7.71)	0.38
	2nd	5.91 (2.57-10.81)	**0.001**
	3rd	6.14 (1.42-7.60)	**0.001**
	4th	6.73 (1.81-8.88)	**0.045**
CD8 Tregs in median% (range%)			
0.32(0.01-1.21)	1st	0.53 (0.16-0.96)	**0.02**
	2nd	0.44 (0.26-1.33)	0.75

	4th	49.24 (30.47-62.97)	0.72

MM patients were included in this study. Median age of the patient cohort was 60 years (range: 50-64). Based on international staging system (ISS) patients were represented as: ISS1-4/13 (31%), ISS2-7/13 (54%), and ISS3-2/13 (15%). All patients were induced by lenalidomide plus dexamethasone combination for 4 cycles at 28 days interval [lenalidomide (25mg/1-21 days) and dexamethasone (40 mg on days 1,8,15, 22)]. One million of erythrocytes lysed peripheral blood (PB) cells were labeled with following fluorochrome combinations: FoxP3-FITC/ CD28-PE/ CD4-PerCpCy5.5/ CD8-APC/ CD25-PE-Cy7 and analyzed by multiparameter flow cytometry. We compared the PB frequency of CD4 Tregs, CD8 Tregs and Ts cells between pre-induction and post-induction cycles in all 13 patients. Ten age-matched healthy volunteers (HVs) PB samples were also analyzed for comparison. *Results.* CD4 Tregs were strictly identified as CD4+CD25hi+FoxP3+ and CD8 Tregs were characterized as CD8+FoxP3+. Ts cells were identified by absence of co-stimulatory molecule (CD8+CD28-). We observed similar frequency of CD4 Tregs in between MM patients and HVs [median (range) = 2.9% (0.97%-5.42%) vs. 3.0% (1.96%-3.59%); P=0.78]. Whereas, for CD8 Tregs MM patients had significantly elevated level compared to HVs [CD8 Tregs median (range)= 0.32% (0.01%-1.21%) vs. 0.15% (0.04%-0.22%); P= 0.009]. Similarly to CD8 Tregs, Ts cells were also prominently increased in MM patients compared to HVs [median (range)= 54.38% (19.68%-71.25%) vs. 30.36% (12.77%-60.97%); P=0.031]. Post-induction cycle observations showed significant increase in CD4 Tregs compared to pre-induction (Table 1). For CD8 Tregs and Ts cells an increasing trend was observed in post-induction cycles compared to pre-induction, but statistical significance was observed in first post-induction cycle for CD8 Tregs (Table 1). *Conclusions.* In summary, regulatory cells were increased after induction with lenalidomide and dexamethasone combination in newly diagnosed MM patients. This observation should be taken into consideration to efficiently improve the immuno-stimulatory effects for MM patients.

ROLE OF THE PLATELET DERIVED GROWTH FACTOR-AB IN TUMOR GROWTH AND ANGIOGENESIS IN RELATION WITH OTHER ANGIOGENIC CYTOKINES IN MULTIPLE MYELOMA

G Tsirakis,[1] K Sfiridaki,[2] C Pappa,[2] M Kaparou,[1] M Stratinaki,[2] A Xekalou,[1] F Psarakis,[2] E Stathopoulos,[1] M Alexandrakis[1]

Background. Angiogenesis is a complex process indispensable to growth, invasion and metastasis in various malignant tumors, including multiple myeloma (MM). Various angiogenic cytokines have been implicated in the angiogenic process. Among them, platelet derived growth factor-AB (PDGF-AB), has been reported to be potent stimulator of angiogenesis not only in solid tumors but also in haematological malignancies, including MM. *Aims.* The aim of the study was to investigate the relationship between PDGF-AB, microvascular density (MVD) and various angiogenic cytokines, such as basic-fibroblast growth factor (b-FGF), angiogenin (ANG) and interleukine-6 (IL-6), in patients with newly diagnosed MM. *Methods.* Serum concentrations of the above cytokines were determined in 47 MM patients before treatment, in 22 in plateau phase, as well as in 20 healthy individuals. Serum PDGF-AB, b-FGF, ANG and IL-6 measurements were performed by ELISA with a commercially available kit. We also performed bone marrow biopsies prior and after treatment, in plateau phase. MVD was determined by staining bone marrow vessels with anti-CD31. *Results.* Mean serum values of PDGF-AB and b-FGF were significantly higher in the group of MM patients in comparison to control group ($p<0.001$ and $p<0.001$ respectively). The means ±SD values of PDGF-AB and b-FGF were significantly higher with increasing stage of MM disease ($p<0.001$ and $p<0.001$ respectively). Significant positive correlations were observed between serum PDGF-AB, ANG and IL-6 levels with MVD ($r=0.361$ $p<0.01$, $r=0.0376$ $p<0.001$ and 0.345 $p<0.01$ respectively). Furthermore we found significant positive correlations between PDGF-AB and b-FGF, IL-6, ANG and B2M ($r=0.324$ $p<0.02$, $r=0.491$ $p<0.0001$, $r=0.437$ $p<0.002$ and $r=0.365$ $p<0.01$ respectively). We also found that patients with high MVD had statistically significant higher serum levels of PDGF-AB ($p=0.017$), when as cutoff point of MVD was used the median value 7.7. Furthermore significant difference was found between serum levels of PDGF-AB in pre and post-treatment patients ($p<0.001$). Serum ANG concentrations in the entire group of MM patients ranged from 246.40-1615.4 pg/ml with a mean ± SD of 669.6±332.5 pg/ml. These values were significantly higher than those found in the control group ($p<0.001$), which ranged from 105.78-354.63 pg/ml. Mean values for ANG in the group of MM patients were significantly higher with increasing stage of disease ($p<0.001$). Mean values of MVD were significantly higher in MM patients than in controls ($p<0.0001$). Among the stages in the entire group of MM patients MVD was significantly higher only in stage III in comparison to stage I ($p<0.01$). There was a difference in survival times between patients with high vs. low PDGF-AB levels (51 vs. 66 months) and high vs. low ANG levels (57 vs. 67 months), but the difference could not reach statistical significance in either case. In contrast, only in MVD groups survival time was significantly higher in MVD median group (76 vs. 51 months, $p<0.02$). *Conclusions.* Our results showed that there is a strong positive correlation between PDGF-AB and studied angiogenic cytokines, as well as with MVD, which indicates a role of PDGF-AB in the complex network of cytokines in inducing bone marrow neovascularization in patients with MM.

LENALIDOMIDE TREATMENT POST AUTOLOGOUS TRANSPLANTATION FOR MULTIPLE MYELOMA DECREASES TERMINALLY DIFFERENCIATED CD4 AND CD8 T CELLS AND INCREASES NUMBER OF TREG

E Clave,[1] C Douay,[1] C Bompoint,[2] H Moins-Teisserenc,[1] M Carmagnat,[1] N Gorin,[2] D Charron,[1] A Toubert,[1] L Garderet[2]

[1]*University Paris Diderot, INSERM U940, Paris, France*
[2]*Hematology department, Hopital St-Antoine, Paris, France*

Background. Treatment with Lenalidomide, a structural analogue of Thalidomide, plus dexamethasone (Dex) increases time to progression in relapse or refractory multiple myeloma. However, due to its pleiotropic effect, it's not known if its efficacy is due only to a direct tumor toxicity or benefit also of its immunomodulatory effects. *Aims.* We wanted to assess *in vivo* the changes induced by Lenalidomide treatment on T-cell reconstitution in a cohort of multiple myeloma patients. *Patients.* Thirty-four myeloma patients were treated with the induction combination bortezomib plus Dex, followed by high dose melphalan (140-200 mg/m2) and an autologous transplantation with peripheral blood stem cells. Between 3 to 6 months post autograft, patients were randomized in 2 groups: 12 received 25 mg/day of Lenalidomide for 2 months, 3 weeks per month plus 40 mg of Dex, once a week, then 10 mg/day of Lenalidomide only until relapse. 22, a placebo only. *Methods.* T lymphocyte subpopulation percentage and absolute counts were assessed by multicolor flow cytometry from diagnosis until 18 month after autograft. *Results.* After Lenalidomide plus Dex treatment, we observed a significant decrease in percentage and absolute counts of CD4+ or CD8+, CD45RA+CCR7- effector T cell subpopulations. Surprisingly, CD4+CD25high or CD4+CD25+CD127-/low Treg increased significantly more in treated patients. No correlation was found with documented infections, relapse or survival. *Conclusions.* These data suggest that, *in vivo*, in Human, Lenalidomide plus Dex efficacy on Myeloma tumor is not T cell mediated but this treatment could have a

negative impact on T cell immunosurveillance. Additional studies are required to better assess the respective effects of Lenalidomide and Dex on immune function.

METAPHASE INDUCTION IN MULTIPLE MYELOMA: A NEW CYTOGENETIC APPROACH FOR G-BANDING ANALYSIS

F Oliveira, L Oliveira de Oliveira, L Figueiredo-Pontes, E Magalhães Rego, R Falcão

Faculty of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

Background. The usefulness of conventional cytogenetic analysis for the classification and prognostication in acute and chronic leukemia has been demonstrated. In multiple myeloma cytogenetic abnormalities also play an important role as prognostic factor. However, classical cytogenetic fail to detect these abnormalities because the low mitotic index of plasma cells *in vitro*. The analysis of a set of subjects for the most commonly known aberrations is usually done by FISH on interphase cell. *Aims.* The goals of this investigation were the use of the oligonucleotide DSP30 in combination with IL-2, IL-6 and IL-10, as a B-cell mitogen for cytogenetic investigation in MM and the comparison between the karyotype analyses obtained (G-banding) with FISH profile from unstimulated cells. *Methods.* For metaphase induction, bone marrow mononuclear cells of 55 patients with MM were cultured in RPMI 1640 medium with 20% fetal calf serum in the presence of the immunostimulatory CpG-oligonucleotide DSP30 and IL-2/IL-6/IL-10 for 72h. Additionally, two extra set of cell culture was performed for each patient without any stimulant agent (G-banding analysis, when possible and FISH). The FISH panel included probes for the detection of translocations involving IGH gene (14q32), gains associated to 11q23-q25 and 1q21 and deletion of 13q14. The cut off levels for IGH translocations was (>3.2%), gains of 11q23-q25 and 1q21 (2.4% and 2.7%, respectively) and deletion 13q14 (2.8%). All cut off values were established according to the FISH patterns observed in a group of 12 age and sex-matched normal control peripheral blood samples studied with the same probes. *Results.* In the cells treated with stimulus, the cytogenetic analysis was possible in 42 patients (76.5%). On the other hand, in the group without any stimulus, the cytogenetic profile was successful in 20 patients (36.4%), being 8 (40%) with normal karyotype and 12 with chromosomal abnormalities (60%). The group that received stimulus, normal karyotype was found in 16 patients (38%) and metaphases with abnormal karyotype were seen in 26 subjects (62%). Among the cytogenetic profile obtained in both groups were observed aneuploidies involving the chromosomes +3, +5, +9, -13, -14, +15, +16, -18, +19, +20, -22 and structural abnormalities such as add(1)(p21), inv(3)(q21q26), del(13)(q14), add(14)(q32) and t(14;16)(q32;q23). FISH analysis performed in those patients whose bone marrow cells were not stimulated displayed the same chromosomal abnormalities as identified in the group with stimulus. *Conclusion.* These results indicate that the addition of the immunostimulatory oligonucleotide DSP30 in combination with IL-2, IL-6 and IL-10 showed to be effective to induce cell cycle progression of MM cells *in vitro.*

THE ASSESSMENT OF PROLIFERATING CELL NUCLEAR ANTIGEN (PCNA) AND ITS RELATIONSHIP WITH PROINFLAMMATORY CYTOKINES AND PARAMETERS OF DISEASE ACTIVITY IN MULTIPLE MYELOMA PATIENTS

G Tsirakis,[1] C Pappa,[2] M Kaparou,[1] V Katsomitrou,[1] A Hatzivassili,[2] A Alegakis,[1] A Xekalou,[1] E Stathopoulos,[1] M Alexandrakis[1]

[1]*University Hospital of Crete, Heraklion, Greece*
[2]*Venizeleion Hospital, Heraklion, Greece*

Background. Multiple myeloma (MM) is a malignant disease of plasma cells that localize to the bone marrow (BM). Clonal plasma cells and BM stromal cells produce several proinflammatory cytokines that are involved in the pathogenesis of the disease. *Aims.* The aims of the study were to investigate circulating levels of proinflammatory cytokines such as Interleukine-1β (IL-1β), Interleukine-6 (IL-6), Interleukine-8 (IL-8), Macrophage Inflammatory Protein-1α (MIP-1α) as well as LDH and B2 microglobulin, in MM patients before treatment, and to discuss its significance in tumor progression. Additionally we analyzed the correlation of measured mediators with the proliferative activity assessed by proliferating cell nuclear antigen (PCNA) immunohistochemistry staining. *Methods.* 44 newly diagnosed MM patients and 20 healthy controls were studied. Patients were staged with Durie-Salmon system. Serum samples were collected at the diagnosis. We also performed BM biopsies prior to treatment. We determined serum levels of IL-6, IL-1β, IL-8 and MIP-1α using enzyme-linked immunosorbent assay (ELISA), as well as PCNA expression in the BM. *Results.* The mean concentrations of the measured cytokines IL-6, IL-1β, IL-8 and MIP-1α in the entire group of patients were 6.2±5.9 pg/ml, 2.8±1.3 pg/ml, 39.3±15.6 pg/ml and 51.7±34.9 pg/ml, respectively. All the above measured parameters were significantly different among the three stages of disease, with higher values with advancing disease stage ($p<0.001$ in all cases). Furthermore in the entire group of patients with MM serum levels of IL-6, IL-1β, IL-8 and MIP-1α were significantly higher in patients in comparison to controls ($p<0.001$, $p<0.001$, $p<0.002$, $p<0.001$ respectively). A positive statistical correlation was found between IL-6 and IL-1β ($r=0.462$ $p<0.002$), IL-6 and IL-8 ($r=0.358$ $p<0.01$), IL-6 and MIP-1α ($r=0.380$ $p<0.001$). Similarly IL-8 and MIP-1α were positively correlated with factors of disease activity such as B2M ($r=0.502$ $p<0.001$, $r=0.413$ $p<0.005$ respectively) and LDH ($r=0.415$ $p<0.006$, $r=0.475$ $p<0.001$ respectively). PCNA immunostaining was identified in the nuclei of the cells in all the cases of the disease. Concerning the three stages of the disease, the proliferation index as assessed by PCNA immunostaining was evaluated in stage I with mean value 6.6±5.2% (range 1-18%), in stage II 24.0±12.4% (range 5-50%) and in stage III 41.4±29.0% (range 10-98%). In the entire group of MM PCNA expression was higher with advancing disease stage ($p<0.001$). Furthermore PCNA expression correlated significantly with parameters of disease activity such as B2M and LDH ($r=0.406$ $p<0.006$, $r=0.581$ $p<0.0001$ respectively). Similarly the number of myelomatous cells positive for the PCNA protein correlated with the measured cytokines IL-6, IL-1β, IL-8 and MIP-1α ($r=0.520$ $p<0.0001$, $r=0.545$ $p<0.0001$, $r=0.320$ $p<0.03$ and $r=0.358$ $p<0.01$, respectively). *Conclusions.* Our results showed that the proliferative activity, as assessed with PCNA, was increased in parallel with disease stage. The positive correlation between PCNA and other measured mediators, such as IL-6, IL-1β, IL-8 and MIP-1α, supports the involvement of these factors in the biology of myeloma cell growth and can be used as markers of disease activity and as possible therapeutic targets.

0853

NEPHELOMETRIC MEASUREMENTS OF FLC κ AND FLC λ FOR MONITORING LIGHT CHAIN MULTIPLE MYELOMA PATIENTS

H Avet Losieau,[1] L Mirbahai,[2] P Young,[2] C Mathiot,[3] M Attal,[4] P Moreau,[4] JL Harousseau,[1] A Bradwell,[5] S Harding[2]

[1]*Clinical Hematology Department, University Hospital, Nantes, France*
[2]*The Binding Site, Birmingham, United Kingdom*
[3]*Department of Hematology, Institut Curie, Paris, France*
[4]*Centre Hospitalier Universitaire, Toulouse, France*
[5]*Division of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom*

Introduction. Serum free light chain (sFLC) measurements are important in multiple myeloma (MM), have replaced urine electrophoresis in diagnostic algorithms and are required to characterise a complete response. However, with the exception of oligosecretory disease, their use is not recommended in current guidelines for routine monitoring. *Aim.* To investigate the use of sFLC measurements for monitoring light chain MM (LCMM) patients. *Methods.* sFLC κ and sFLC λ levels were measured nephelometrically on serial samples from 25 LCMM patients (14 FLCκ and 11 FLCλ); specifically at presentation, after cycles 2 and 4 of therapy and post autologous stem cell transplantation (ASCT). The results were compared with historic urine protein electrophoresis (UPE) plus urine and serum immunofixation electrophoresis (uIFE and sIFE); to identify residual disease sIFE was performed on all patients after 2 cycles of therapy. *Results.* At presentation all patients had a detectable band on uIFE and measurable disease using UPE (>200mg/L). 22/25 patients had a detectable monoclonal band by sIFE, with 1/25 patients having a monoclonal band quantifiable by SPE (11.5g/L). In the FLCκ subgroup of patients, all 14/14 patients had increased FLCκ levels in the serum. The median FLCκ was 3740 mg/L (range, 689-13100 mg/L). Additionally, all 14 FLCκ patients had abnormally increased FLC κ/λ ratios, with a median value of 532 (range, 42- 2400). In the FLCλ subgroup, all 11/ 11 patients had both increased FLCλ levels and abnormally decreased FLC κ/λ ratios in the serum, with the median value of 3000 mg/L (range, 875-22000 mg/L) and a median ratio of 0.001 (0.0001-0.02). Table 1 shows the patient responses as-

Table 1.

	UPE/ UFE		FLC	
	VGPR	CR	VGPR	CR
Cycle 2	25% (5/20)	35% (7/20)	45% (9/20)	10% (2/20)
Cycle 4	14% (3/21)	57% (12/21)	57% (12/21)	14% (3/21)
ASCT	18% (4/22)	59% (13/22)	50% (11/22)	36% (8/22)

sessed using UPE/UFE or sFLC measurements alone; there were no patients with positive UFE results and normal FLC ratios. After 2 cycles of therapy a normal FLC ratio (18/20) correlated well to sIFE (17/20) results in the identification of residual disease (Pearson's r=0.7; p<0.001). The median involved FLC (iFLC) level in these patients was 152 mg/L (range, 52- 202 mg/L). UFE (13/20) under-estimated the number of patients with residual disease and correlated less well to sIFE (Pearson's r=0.5; p=0.03). Post ASCT, uIFE and sIFE indicated CR in 13 patients, however, sFLC measurements detected residual disease in 5/13 patients (median iFLC level of 25 mg/L (range, 15- 25.35 mg/L)). *Discussion.* sFLC measurements correlated well to sIFE measurements in the detection of residual disease. There were no instances when residual disease was detectable by UPE or UFE but not detectable by FLC measurements. In conclusion, FLC measurements could replace UPE and UFE to effectively monitor LCMM patients.

MONITORING SERUM LEVELS ELR+ CXC CHEMOKINES AND RELATIONSHIP BETWEEN MICROVESSEL DENSITY AND ANGIOGENIC GROWTH FACTORS IN MULTIPLE MYELOMA

C Pappa,[1] G Tsirakis,[2] A Boula,[1] P Kanelou,[2] M Kaparou,[2] A Xekalou,[2] E Stathopoulos,[2] D Kyriakou,[3] M Alexandrakis[2]

[1]*Venizelion Hospital, Heraklion, Greece*
[2]*University Hospital of Heraklion, Heraklion, Greece*
[3]*University Hospital of Larisa, Larissa, Greece*

Background. The ELR+ CXC chemokines are important mediators of tumorigenesis, related to their angiogenic properties. Angiogenesis appears to be a prominent feature in the progression of multiple myeloma (MM). CXC chemokines have four highly conserved cysteine amino acid residues, with the first two cysteine molecules separated by a single amino acid. The angiogenic potential of this group is determined by the presence of three amino acid residues (Glu-Leu-Arg: the ELR motif) preceding the first cysteine amino acid, in the NH2 terminus. *Aims.* The purpose of this study was to determine serum concentrations of angiogenesis-related chemokines ELR+ motif, such as interleukine-8 (IL-8), epithelial neutrophil activating protein-78 (ENA-78) and growth-related gene alpha (GRO-α), as well the bone marrow microvascular density (MVD) in patients with MM at diagnosis and after treatment, in plateau phase. We also evaluated the relationship among them with other known growth factors involved in angiogenesis, such as vascular endothelial growth factor (VEGF), hepatocyte growth factor (HGF) and tumor necrosis factor-a (TNF-α). *Methods.* Serum levels of the above chemokines were determined in 63 newly diagnosed MM patients, in 28 in plateau phase and in 20 healthy controls. Serum measurements of IL-8, ENA-78, GRO-α, VEGF, HGF and TNF-α were performed with a commercially available kit for ELISA. Bone marrow biopsies were performed before and after treatment, in plateau phase, in order to determine MVD by staining vessels with anti-CD31. *Results.* Serum concentrations of IL-8, ENA-78, GRO-α and TNF-α were significantly higher in the group of MM patients (44.5±25.3pg/ml, 765±572.1pg/ml, 186±129.1pg/ml and 4.2±2.8pg/ml respectively) in comparison to control group (27.3±6.3pg/ml, 335.1±268.6pg/ml, 112.5±76.1pg/ml and 1.3±0.8pg/ml) (p<0.0004, p<0.002, p<0.01 and p<0.0001 respectively). We also found that untreated patients had higher levels of IL-8, ENA-78, GRO-α than post treatment patients, but statistical significant difference was found only for IL-8 (48.36±30.93pg/ml vs. 35.05±19.77pg/ml, p<0.001). Furthermore IL-8, GRO-α, TNF-α, HGF and VEGF were significantly higher with increasing disease stage (p<0.001 in all cases). ENA-78 serum levels were higher in stage III than in stage I and II, but without statistical significance. Additionally we correlated each proinflammatory cytokine with well known angiogenic factors such as HGF, VEGF and TNF-α. A positive correlation was found between serum HGF and IL-8 and GRO-α (r=0.316 p<0.01, r=0.297 p<0.01 respectively). Similarly serum VEGF correlated with ENA-78 and GRO-α (r=0.421 p<0.001, r=0.361 p<0.004 respectively) while a trend to correlate was found between TNF-α and IL-8 (r=0.242 p<0.056). In the pretreatment group of patients a positive correlation between bone marrow MVD and serum levels of GRO-α was found (r=0.304 p<0.01) while MVD did not correlate with IL-8 and ENA-78. There was a difference in survival times between patients with higher than median versus low IL-8, ENA-78 and GRO-α levels, but the differences could not reach statistical significance in either case. *Conclusions.* These findings support the hypothesis that ELR+ motif CXC chemokines, such as IL-8, ENA-78 and GRO-α correlate with angiogenic growth factors and may play a role in the progression of MM. Further studies are needed to determine their prognostic and predictive significance.

LIGHT-CHAIN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE IN GERMANY

L Eisele, J Dürig, A Hüttmann, U Dührsen, S Mohamad, M Bröcker-Preuss, B Bokhof, R Erbel, KH Jöckel, S Moebus

University Hospital Essen, Essen, Germany

Background. Light-chain monoclonal gammopathy of undetermined significance (LCMGUS) is thought to be the precursor condition leading to light-chain myeloma. *Aim.* To determine 5-year incidence, prevalence and mortality rate of LCMGUS we utilized the biobank of the ongoing population-based, prospective Heinz Nixdorf Recall study. *Methods.* The Heinz Nixdorf Recall study comprises 4814 men and women aged 45 - 75 from 3 large adjacent cities in Germany. Subjects were randomly selected from statutory lists of residence and gave informed consent. Free light-chain (FLC) κ and λ measurements were performed on a Dade Behring BNII automated nephelometer (Siemens, Germany) utilizing a commercially available kit (FREELITE, The Binding Site Ltd, Birmingham, UK). To identify monoclonal proteins, a sensitive approach using standard serum protein electrophoresis combined with screening immunfixation was used (Hydragel 12IF, Sebia). We screened serum samples from both the baseline examination which took place from 2000 until 2003 and the 5-year follow-up. LCMGUS was defined as abnormal FLC ratio (<0.26 or >1.65), increase in the FLC that caused the abnormal ratio and no detectable intact immunoglobulin. Age-standardized prevalence was obtained by direct standardization to the U.S. 2000 population. 5-year cumulative incidence was estimated from samples with available FLC measurements at baseline and follow-up. Standardized mortality ratio (SMR) was calculated comparing LCMGUS cases against the whole Heinz Nixdorf Recall cohort as reference using 10-year age-intervals. *Results.* 4702 and 4059 baseline and follow-up samples were analyzed, respectively. 3986 samples had FLC measurements at both time points. 34 LCMGUS cases were identified among the baseline samples (prevalence 0.7%, 95%-CI 0.5 - 1.0; age-standardized prevalence 0.8%, 95%-CI 0.5 - 1.1). Median age of LCMGUS cases was 66.5 years (range 47 - 74), 29 (65%) were male. As observable for MGUS, the LCMGUS prevalence increased with age and was higher in males. Of these cases 4 (12%) died before follow-up examination. While 13 (38%) cases were still classified as LCMGUS at follow-up, 14 (41%) previously identified LCMGUS cases showed a subsequent normal FLC ratio. All but one of the latter cases involved FLC κ with ratios < 2. Using a reference range adapted to renal function did remove 2 of these cases. Between baseline and 5-year follow-up 9 new cases developed yielding a 5-year cumulative incidence of 0.2% (95%-CI 0.1 - 0.4). The SMR was 1.88 (95%-CI 0.62 - 5.66). In one LCMGUS case a monoclonal protein was identified at follow-up leading to the diagnosis of MGUS. None of the LCMGUS cases progressed to myeloma during a median observation time of 7.2 years. *Conclusion.* We present for the first time incidence, prevalence and mortality rate estimates of the recently defined clinical entity LCMGUS. Using the published FLC ratio reference range of 0.26 - 1.65 in our cohort resulted in a considerable number of potential false-positives, suggesting that a more stringent reference range should be used to define LCMGUS. Additionally, our findings suggest that an abnormal FLC ratio can also precede conventional MGUS. As follow-up continues updated data will be presented at the conference.

0856

IMMUNE-RELATED CONDITIONS INCREASE THE RISK OF MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE: RESULTS FROM A POPULATION-BASED STUDY

E Lindqvist,[1] L Goldin,[2] O Landgren,[3] C Blimark,[4] U Mellqvist,[4] I Turesson,[5] A Wahlin,[6] M Björkholm,[7] S Kristinsson[7]

[7]*Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden*

Background. The etiology of multiple myeloma (MM) and monoclonal gammopathy of undetermined significance (MGUS) is largely unknown. There is evidence for genetic factors in the etiology of MM and MGUS. Several study groups have shown that immune dysregulation plays a major role in lymphomagenesis. Much less is known regarding immune-related conditions and risk of plasma cell disorders, and results from previous smaller studies have been inconsistent. *Aims.* The aim of the study was to determine whether a previous personal history of immune-related conditions (autoimmune diseases, infections and inflammatory conditions) is associated with an increased risk of MM and/or MGUS. *Methods.* Using national Swedish registries we identified 19,112 patients with MM, 5,403 patients with MGUS, and 96,617 matched control subjects. The patients were diagnosed from 1965 through 2004. We calculated odds ratios (ORs) and 95% confidence intervals (CIs) for each immune-related condition (from the centralized Inpatient register) and for categories of conditions using logistic regression. To avoid detection bias, immune-related conditions occurring less than one year prior to diagnosis of MM/MGUS were excluded. *Results.* A personal history of all autoimmune diseases combined was associated with a significantly increased risk of MGUS (OR = 2.1, 95% CI = 1.9-2.4) but not of MM. Several specific autoimmune diseases elevated the risk of MGUS, however polymyalgia rheumatica (OR = 1.9, 95% CI = 1.4-2.6 for MM, OR = 2.9, 95% CI 2.1-4.1 for MGUS), giant cell arteritis (OR = 7.8, 95% CI = 3.3-18.2 for MM, OR = 11.3, 95% CI = 4.8-26.7 for MGUS), and autoimmune hemolytic anemia were associated with an increased risk of both MM and MGUS. A personal history of all infections combined was associated with a significantly increased risk of MM (OR = 1.2, 95% CI = 1.1-1.3) and of MGUS (OR = 1.6, 95% CI = 1.5-1.7). A personal history of pneumonia, septicemia, sinusitis, meningitis, myocarditis, and other conditions, was found to significantly elevate the risk of MM and/or MGUS. A personal history of all inflammatory conditions combined was associated with a significantly increased risk of MGUS (OR = 1.4, 95% CI = 1.2-1.5) but not of MM. A personal history of nephrotic syndrome, chronic osteoarthritis, diverticulitis, and other conditions, was found to significantly elevate the risk of MM and/or MGUS. The increased risk of MM and MGUS that was associated with these diseases remained statistically significant for the majority of these conditions at more than five years of latency. *Summary/Conclusions.* In this large population-based case-control study including almost 20,000 MM patients, more than 5,000 MGUS patients, and their close to 100,000 matched control subjects, we found that a personal history of several specific immune-related conditions was associated with an increased risk of MGUS and to a lesser degree MM. Our findings suggest that immune-related conditions or the treatment of them are of importance in the etiology of MGUS and possibly MM.

EXPRESSION OF CCL3 BY NEOPLASTIC CELLS IN PATIENTS WITH WALDENSTRÖM'S MACROGLOBULINEMIA: AN IMMUNOHISTOCHEMICAL STUDY IN BONE MARROW BIOPSIES OF 67 PATIENTS

E Terpos,[1] A Tasidou,[2] E Eleftherakis-Papaiakovou,[1] D Christoulas,[1] M Gavriatopoulou,[1] M Gkotzamanidou,[1] M Roussou,[1] E Kastritis,[1] T Papadaki,[2] MA Dimopoulos[1]

[1]*University of Athens School of Medicine, Athens, Greece*
[2]*"Evangelismos" General Hospital, Athens, Greece*

Background. C-C motif ligand 3 (CCL3) chemokine, previously known as macrophage inflammatory protein-1 alpha is a member of the C-C chemokine family and has chemotactic function against monocytes/macrophages, T-lymphocytes, mast cells, dendritic cells, eosinophils and natural killer cells. Waldenström's macroglobulinemia (WM) is a distinct B-cell lymphoproliferative disorder characterized by lymphoplasmacytic bone marrow infiltration along with an IgM monoclonal gammopathy. Our group has previously shown that CCL3 is elevated in the serum of WM patients and correlates with adverse disease features. However, there is no information for the source of the production of CCL3 in WM. *Aims.* The aim of this study was to evaluate the expression of CCL3 by WM cells in bone marrow biopsies of WM patients to test the hypothesis of production of CCL3 by WM cells. *Methods.* We evaluated bone marrow biopsies from 67 patients with WM (39M/28F; median age: 72 years, range: 39-85 years) who were diagnosed, treated and followed-up in a single center (Department of Clinical Therapeutics, University of Athens, Greece) between 1999 and 2009. Forty-six patients had newly diagnosed WM (4 with asymptomatic disease), while 21 patients had active disease after treatment. Bone marrow biopsy sections were immunochemically tested for the expression of CCL3 (using an anti-CCL3 monoclonal antibody by Santa Cruz Biotechnology, Santa Cruz, CA, USA), CD20, CD79alpha, CD138, MUM-1, as well as for mu, alpha, gamma heavy and kappa and lambda light immunoglobulin chains. The immunoreactivity of CCL3 was examined on the basis of positive lymphoplasmacytic and/or plasma cells with a cut-off value of >20% positive cells to be defined as positive expression. *Results.* In all WM cases, either at diagnosis or at relapse, the whole number of the neoplastic cells, including CD20(+)/CD138(-)/MUM-1(-) small B-lymphocytes, plasmacytoid lymphocytes and rare immunoblasts as well as CD20(-)/CD138(+)/MUM-1(+) plasma cells revealed strong cytoplasmic positivity for CCL3. Due to such strong positivity for CCL3, no definite correlations between CCL3 expression by the neoplastic cells and disease features were able to be established. Regarding the putative role of CCL3 overproduction in WM, only hypotheses can be made. In chronic lymphocytic leukemia (CLL), an abnormally high number of infiltrating CD68+ monocyte/macrophages has been described in the CLL-involved areas of trephine biopsies from CCL3/CCL4-producing CLL cells. Thus, we performed a CD68 (PGM-1) staining in the trephine biopsies of our symptomatic WM patients and found a high number of CD68+ cells in the infiltrating areas. These cells may contribute to the WM cell survival in a similar way observed in CLL. CCL3 is also a chemoattracting factor for mast cells and it is well established that the mast cells support lymphoplasmacytic cell growth in WM. In all our cases, there was a high number of mast cells in the infiltrating areas, supporting a possible role of CCL3 in this accumulation. *Summary/Conclusions.* CCL3 is overexpressed by WM cells. This result supports a possible role of CCL3 in WM biology through interactions of the malignant clone with the marrow microenvironment and reveals CCL3 as a potential target for developing novel drugs against WM.

ALTERED FIBRIN CLOT PROPERTIES IN NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) PATIENTS AND AFTER TREATMENT WITH THALIDOMIDE

L Usnarska-Zubkiewicz,[1] M Podolak-Dawidziak,[2] J Debski,[2] K Kuliczkowski,[2] A Undas[3]

[1]*Wroclaw Medical University, Wroclaw, Poland*
[2]*Dept. of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Medical U, Wroclaw, Poland*
[3]*Institute of Cardiology, Jagiellonian University School of Medicine, Krakow, Poland*

Background. The risk of venous thromboembolism (VTE), including deep vein thrombosis and pulmonary embolism, is high in newly diagnosed patients with multiple myeloma (MM). The use of thalidomide containing regimens seems to be associated with further increase of thrombotic complications. *Objective.* To investigate fibrin clot properties in MM patients prior and after induction remission with thalidomide. *Patients and Methods.* We studied 38 consecutive MM patients, 19 men and 19 women, aged 49 to 81 years (mean 63.5 years), with no history of VTE. There were 18 cases of IgG MM, 10 of IgA MM and 10 with light chain disease (LCD). Staging according to Durie and Salmon disclosed 5 subjects with IIA stage, 2 with IIB, 17 with IIIA, and 14 with IIIB. Fifteen patients completed treatment according to CTD, 2-6 cycles, mean 3.7 (cyclophosphamide 500 mg/m2/d i.v., day 1, thalidomide 100 mg/d, dexamethasone 10 mg/d on days 1-4 and 9-12). All MM patients received aspirin 75 mg/d. The control group comprised of 38 healthy subjects matched for age and gender. Plasma fibrin clot permeability, turbidity and fibrinolysis were assessed at baseline and after treatment with thalidomide. *Results.* Fibrinogen plasma concentration was higher in MM patients compared with controls (4.03 ±

1.48 vs 2.62 ± 0.43 g/L, P<.0001). The highest fibrinogen was found in LCD subgroup. Fibrin clots in MM patients compared with those obtained from controls had lower clot permeability (5.19 ± 1.28 v 8.89 ± 0.77 10-9cm2, respectively, P< .0001), prolonged clot lysis time (12.5 ± 2.2 v 8.06 ± 0.94 min, P<.00001), and lower baseline maximum clot absorbancy at 405 nm (0.56 ± 0.1 v 0.79 ± 0.06, respectively, P<.0001). Baseline maximum velocity of D-dimer release from plasma clots subjected to tissue plasminogen activator was lower in the MM group than in controls (0.066 ± 0.006 v 0.077 ± 0.006 mg/L/min, P<.00001), while the initial maximum D-dimer level was higher in MM patients (4.76 ± 0.62 v 3.48 ±0.27, mg/L, P<.00001). MM patients with renal insufficiency (n= 16) had significantly lower clot permeability than the remainder (n=22;P<.0013). Comparison of fibrin clot obtained from patients after treatment with thalidomide with that prior the treatment did not show changes in fibrinogen concentrations (3.9 ±1.2 v 4.03 ±1.48 g/L, P<.2), in clot permeability (5.49 ±1.3 v 5.19 ± 1.28 10-9 cm2, P <.4),or in clot lysis time (12,3 ± 1,78 v 12,5 ± 2,2 min, P<.7) but maximum clot absorbancy (0.72 ± 0.1 v 0.56 ± 0.1, P <.003) and the rate of D-dimer release from clots (0.073 ± 0.008 v 0.066 ± 0.006 mg/L/min, P<.0069) was higher. Out of 38 MM patients treated with thalidomide 6 subjects developed venous or arterial thrombosis and they had lower clot permeability compared to the remaining individuals (P<.05); other fibrin clot variables were similar in both subgroups. *Conclusion.* Substantial prothrombotic alterations of fibrin clot properties, including markedly impaired fibrinolysis occur in patients with MM and thalidomide-containing regimens further modify clot phenotype, which seems to contribute in thrombotic complications.

Background. The depth of response has been associated with longer Progression Free Survival (PFS) in Multiple Myeloma (MM).Serum free light chains (sFLC) and ratio (sFLCR), are used for the evaluation of sCR. They constituted the background for developing specific antibodies that bind the junction of the heavy and light chains on individual immunoglobulin isotypes (Hevylite®), making possible to quantify the IgGκ, IgGλ, IgAκ, IgAλ and their ratios IgGκ/IgGλ, IgGλ/IgGκ, IgAκ,/IgAλ and IgAλ/IgAκ (HLCRs) separately. *Aim.* To investigate the importance of sFLCR and HLCRs normalisation at plateau on PFS. *Patients and Methods.* 51 intact immunoglobulin MM patients were studied from diagnosis to last follow up. All patients were symptomatic. Their sera samples (n=312) were analyzed for sFLC by immunoassay (Freelite®) and for IgGκ, IgGλ IgAκ, IgAλ with Hevylite® antibody, nephelometrically. Serum FLCR and HLCRs values above the 95%-ile of normal individuals were considered as abnormal. File data were reviewed. *Results.* Median lines of therapy were 2 (range 1-11). Median follow up was 28 months (4-135). Retreatment was initiated in all patients according to standard criteria. HLCR was abnormal in all patients at diagnosis. As expected the quality of response correlated to PFS and patients in sCR, CR and nCR had a longer PFS than the others. Both sFLCR and HLCRs normalization were strong parameter of increased PFS after treatment at any line (p=0,029 and p=0,016 respectively). *Conclusion.* Both sFLCR and HLCRs normalization reflect prolonged responses.

0860

HLA-DRB1*13 AND *15 ARE ASSOCIATED WITH RESPONSE TO THALIDOMIDE IN PATIENTS WITH MULTIPLE MYELOMA

S Toprak,[1] M Bakanay Ozturk,[2] E Cakmak,[2] D Ozu,[2] K Dalva,[2] M Beksac[2]

[1]*Baskent University, Ankara, Turkey*
[2]*Ankara University, Ankara, Turkey*

Background. Thalidomide (T) has been approved for treatment of myeloma. There is no generally accepted predictor for response. *Aims.*

Table 1.

	T responders	T non-responders	p
N=46	16 (35%)	30 (65%)	
Age (median,range)	50 (35-73)	50 (31-64)	0.38
Sex (M/F)	8/8	23/7	0.1
Paraprotein IgG Non-IgG	 11 5	 22 8	0.74
Prognosis ISS-I ISS-II or III	 6 10	 15 11	0.34
Number of previous CT cycles (median, range)	6 (0-9)	6 (1-13)	0.31
Number of previous CT lines (median, range)	1 (0-3)	2 (1-3)	0.02
Previous ASCT Present Absent	 9 7	 25 5	0.07
Del13q Positive Negative	 7 0	 8 6	0.06
p53 Positive Negative	 1 1	 7 2	0.42

Table 2.

	T Responders	T non-responders	p
HLA-DRB1*15 Positive Negative	 5 11	 4 26	0.24
HLA-DRB1*13 Positive Negative	 8 7	 4 25	0.01
HLA-DRB1*11 Positive Negative	 2 13	 16 13	0.01

The aim of this study was to analyze the impact of HLA antigens on response to T. *Methods.* Patients (n=46) who received T either as monotherapy (n=36) or combination therapy with dexamethasone (n=10) were retrospectively analyzed. Patient characteristics were: median age 50 (31-73), male/female 31/15, IgG/IgA/IgM/light chain 33/6/1/6 and ISS-I/II/III 21/10/11. Numbers of patients given T for induction/consolidation/relapse were 2/18/26. Patients were given T at doses 50-400 mg for a median duration of 10 (2-72) months. Thalidomide was stopped whenever disease progression or side effects grade≥3 occurred. Response to T was classified as responders ≥ partial remission (PR) or non-responders (disease progression on T). *Results.* 16 patients had response, 18 patients had disease progression and 12 patients had stable disease on T. Parameters which may have contributed to response to T were compared between responders and non-responders (Table 1-2). There were no statistically significant difference between the responders and non-responders in terms of age, sex, paraprotein, prognostic subgroup or the number of previous chemotherapy cycles. The only significant differences were the number of previous chemotherapy lines and the HLA frequencies. *Summary/Conclusions.* In a recent study (Beksac *et al.* 2008), it was demonstrated that HLA-DRB1*15, HLA-DRB1*13 and HLA-DRB1*11 were observed 7.2%, 18.2% and 21.1% in MM population, respectively. In this study, the percentage of response to T in HLA-DRB1*15 positive and HLA-DRB1*13 positive patients were 55.5% and 66.6%, respectively. There were 4 patients who were HLA-DRB1*15/*13 and all of them responded to T. On the other hand, HLA-DRB1*11 was associated with refractoriness to T (11% response, p=0.01). Host related factors such as HLA may have impact on response to T similar to that observed in aplastic anemia-immunosupression-HLA-DRB1*15.

0861

CORRELATION OF SERUM FREE LIGHT CHAIN QUANTIFICATION WITH SERUM AND URINE IMMUNOFIXATION IN MONOCLONAL GAMMOPATHIES

M Kraj, B Kruk, R Poglod, A Szczepinski

Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Objectives. Standard methods for detection and monitoring of monoclonal proteins include electrophoresis and immunofixation (IFE) of

serum and urine samples. Recently, automated quantitative immunoassay for serum immunoglobulin free light chains (FLCs) has become available for clinical use. The aim of this study was to assess the efficacy of serum FLC assay in detection and monitoring of monoclonal proteins in different variants of monoclonal gammopathy. *Material and Methods.* Diagnostic value of serum FLC κ/λ ratios was compared with serum and urine protein electrophoresis and IFE in 106 multiple myeloma, 4 solitary plasmacytoma patients and 8 patients with monoclonal gammopathy of undetermined significance (MGUS). FLCs were measured using Siemens BNII nephelometer with the FreeliteTM Kit (Binding Site). *Results.* Of 37 light chain (LC) myeloma patients, 21 were positive for κ LC and 16 for λ LC. All of these patients had monoclonal LC detected by IFE in urine and 31 also detected in serum. Although 27 patients had M spike in urine, only 9 had M spike in serum. All patients in κ subgroup had an increased κ FLCs in serum and increased FLC ratio. In λ group all patients had both increased λ FLCs and decreased FLC ratio in serum. In 5 of 8 patients with nonsecretory myeloma and negative serum and urine IFE, the FLCs were increased. In all 38 myeloma patients with intact immunoglobulin (G 26, A 8, M 1, D 2, E 1) assessed at diagnosis or in disease progression, the FLC ratio was abnormal; in 3 patients in CR after bortezomib therapy the FLC ratio was normal and in 2 of 3 patients with PR the FLC ratio was abnormal. In 13 of 29 patients treated with autologous stem cell transplant the normal FLC ratio documented stringent complete response. Discrepancy between IFE and FLC results was found in 5 patients. Abnormal FLC ratio in 3 patients was ahead of the disease progression that was revealed in IFE and histology. In contrast, in one case, the appearance of M-protein in IFE and increased plasma cell rate in bone marrow was observed earlier in relation to FLC level which remained normal. In all 4 patients with solitary extramedullary plasmacytoma the FLC ratio was normal. Three of 8 MGUS patients with follow-up from 10 to 26 years had abnormal the FLC ratio. Multiple myeloma progression developed in one patient with normal FLC ratio. *Conclusions.* Serum FLC assay allows improved detection rates of light chain multiple myeloma and nonsecretory multiple myeloma. This test enables also monitoring of these diseases, and allows more precise definition of remission status.

0862

EVALUATION OF IGG, IGA AND IGM MONOCLONAL AND BICLONAL GAMMOPATHIES BY NEPHELOMETRIC MEASUREMENT OF INDIVIDUAL IMMUNOGLOBULIN κ/λ RATIOS - HEVYLITE ASSAY VERSUS IMMUNOFIXATION

M Kraj, B Kruk, R Poglod, K Warzocha

Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background. Availability of antibodies which bind to conformational epitopes spanning the junctional regions between bound κ or λ light chains and their respective heavy chain partners has allowed the specific measurement of serum IgGκ, IgGλ, IgAκ, IgAλ IgMκ and IgMλ concentrations. In turn, this has enabled the calculation of IgGκ/IgGλ, IgAκ/IgAλ and IgMκ /IgMλ ratios (heavy/light chain or HLC ratios) for individual patients (Bradwell *et al.* Clin Chem 2009; 55: 1646, Avet-Loiseau *et al.* Blood 2009;114:722). *Aim.* In this study, the diagnostic value of HLC ratios was compared with the serum protein immunofixation (IFE) results. *Methods.* Fresh and archived, frozen sera from 51 patients with monoclonal and biclonal gammopathy including 34 with multiple myeloma and 11 with Waldenstrom's macroglobulinemia were assayed. Serum protein electrophoresis and IFE were performed using HYDRASYS 2 apparatus (Sebia, France) and antisera from the same company. Igκ/λ pairs concentrations were measured on a Siemens BNTMII nephelometer, using reagents from the Binding Site, UK. *Results.* IFE and HLC ratio results were concordant for 44 of the 51 IFE - monoclonal protein positive samples. IFE detected 2 "minor"IgGκ bands (1 oligoclonal after autologous stem cell transplantation, 1 reactive) and one IgAλ with polyclonal background that were not detected by HLC assay. In 5 cases with biclonal IgGκ + IgGλ gammopathy revealed in IFE, HLC ratios were normal and in 4 cases with biclonal IgG + IgA gammopathy, including 3- IgGκ + IgAκ cases and one IgGκ + IgAλ, HLC ratios were concordant with IFE. In one patient with Waldenstrom's macroglobulinemia and 3 homogenous IgG+IgA+ IgM in serum IFE analysis, HLC assay correctly revealed only IgMκ/IgMλ abnormal ratios while IgGκ/IgGλ and IgAκ/IgAλ ratios were normal. *Conclusion.* HLC and IFE are complementary methods. IFE is more sensitive than HLC assay but the latter provides numerical results.

0863

NORMAL RANGES AND REFERENCE INTERVALS OF SERUM FREE LIGHT CHAINS VALUES ARE HIGHER IN ELDERLY PEOPLE: STUDY IN A SPANISH URBAN POPULATION

JM Hernandez,[1] H Muñoz,[1] MJ Jimenez Cobaleda,[1] JA Queizan,[1] M Latorre,[1] B De la Hoz,[2] B Perez Sanchez-Moneo,[3] L Gonzalvez[4]

[1]*Hospital General de Segovia, Segovia, Spain*
[2]*Centro de Salud Segovia-1, Segovia, Spain*
[3]*Centro de Salud Segovia-2, Segovia, Spain*
[4]*Centro de Salud Segovia-3, Segovia, Spain*

Background. The value of determination of serum free light chains is growing in certain monoclonal gammopathies: Although some work has been focused on the reference values in the normal population, it is important that these studies are conducted in different countries, distinguishing some features of population as age or renal function. *Aims.* To determine normal ranges and reference values of serum concentrations of free kappa and lambda chain in a spanish urban population. *Material and Methods.* We analyzed 613 serum samples of participants in a spanish urban population study for screening of monoclonal gammopathies. The method of recruitment of participants in the study was through family doctors or by personal letter. Inclusion criteria: 1) to have completed 50 years on October 1 2008; 2) to live in Segovia capital. The determination of serum free light chains (serum free Kappa (sFK), serum free Lambda (sFL) and ratio Kappa/Lambda (RK/L)) was carried out by turbidimetry. We studied the possible presence of serum monoclonal component (MC) by capillary electrophoresis and serum immunofixation. Furthermore, serum immunofixation was performed in doubtful cases. Renal function of participants was estimated by glomerular filtration rate using Modification of Diet in Renal Disease (MDRD) formula. Statistical *Methods.* Descriptive statistics of central tendency and distribution. We evaluated the normality of the series with the test of asymmetry, kurtosis and Kolmogorov-Smirnov. To assess the reference ranges was performed logarithmic transformation of the values in order to achieve Gaussian distribution; concentrations were calculated limiting 95% of the determinations. Nonparametric test (Mann-Whitney U) for the comparison of independent samples. *Results.* 19 MC were detected among 613 participants, so the analysis was conducted on 594 people who had no serum MC. Descriptive statistics of the three parameter was: sFK (mean±SD: 10.44±5.83; median(range): 9.09(2.9/70); sFL (16.9±9.07; 14.8(6.11/127.36); RK/L (0.66±0.35; 0.61(0.08/6.31). Table 1 specifies the concentrations of these parameters by gender, age (cutoff point 70 years) and renal function (MDRD cutoff point 60 ml/h). There were no significant differences between the values by gender. By contrast, concentrations of sFK ($p < 0.001$), sFL ($p < 0.001$) and RK/L ($p < 0.001$) were significantly higher in patients older than 70 years. Also, concentrations of sFK ($p<0.01$) and sFL ($p<0.05$) were significantly higher in patientes with renal function worsened, although RK/L was not significantly different by MDRD. The elderly people (> 70 years) had significant worsening renal function ($p<0.01$). The test proved the non-Gaussian distribution of the series. For this reason, we applied the statistic methods described above for determining reference intervals that were: sFK: 3.97-22.19 mg/L; sFL: 6.89-34.12 mg/L; RK/L: 0.28-1.31. *Conclusion.* The reference values and intervals obtained in our population are similar to

Table 1.

	Sex	n	Median (Range)	Age	n	Median (Range)	MDRD	n	Median (Range)
Free Kappa chain (mg/L)	Men	232	9.11 (2.9-70)	<70	369	8.43 (2.9-70)	≤60	269	9.79 (3.56-36.8)
	Wom	360	9.1 (3.36-61.6)	≥70	223	10 (3.6-61.6)	>60	300	8.6 (2.9-70)

MYELOMA CELL CONTAMINATION OF PERIPHERAL BLOOD STEM CELL HARVESTS ESTIMATED BY MULTIPARAMETRIC FLOW CYTOMETRY: POTENTIAL CORRELATION WITH COMPLETE REMISSION RATE AND DURATION

N Stoyanov, P Ganeva, I Tonev, G Balatzenko, L Garcheva, G Arnaudov, G Michailov, M Guenova

National Specialised Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria

Background. High-dose therapy and autologous stem cell transplantation (ASCT) remains an integral component of the myeloma treatment algorithm for patients considered eligible for the procedure. Recent studies suggest that the presence of malignant plasma cells in the peripheral blood stem cell harvest (PBSCH) may correlate with the clinical outcome after high dose chemotherapy followed by ASCT. *Objectives.* To estimate the presence and the proportion of plasma cells (PC) in PBSCHs in correlation with clinical data. *Methods.* PBSCHs from 30 myeloma patients (21 men and 9 women, n = 30) who underwent ASCT were studied by 6-color flow cytometry (FCM) using the following combination of fluorochrome-conjugated antibodies, CD38/CD56/CD45/CD117/CD138/CD19. Response to therapy was assessed at the time of mobilization, at day +100 and at the end of the study after 14 months median period of follow up. The 2006 International Myeloma Working Group criteria were applied as follows: complete response (CR) (n= 8), very good partial response (VGPR) (n=8), and partial response (PR) (n=14). Mobilization regimens included G-CSF (n=30), Cyclophosphamide (n=3), Plerixafor (n=2). The Chi-square and Fisher exact tests were used to compare differences between nominal variables and the Mann-Whitney U test for continuous variables. *Results.* Plasma cells bearing CD138+CD38+CD45+CD19+CD117-CD56- immunophenotype were identified in 29/30 cases. The mean PC percentage by FCM was 0,029% (0-0,27%). Plasma cell contamination in PBSCHs showed positive correlation with (1) the degree of bone marrow infiltration by morphology (Pearson correlation 0,62; p=0,000) and (2) monoclonal immunoglobulin levels (Pearson correlation 0,4; p=0,043) at mobilization. Importantly, patients who achieved CR at day 100 had ten-fold lower PC in the PBSCH than those with VGPR or PR (mean 0,005% vs. 0,046% Mann Whitney U, p = 0,02). Moreover, at latest follow-up, patients in CR showed significantly lower levels of contamination compared to the VGPR/PR group (mean 0,0046% vs. 0,03%, p=0,006). *Conclusion.* Patients with low or undetectable contaminating plasma cell levels (by FCM) in the stem cell harvest have a significantly higher probability to achieve and remain in CR following high-dose chemotherapy and ASCT.

[4]*Hôpital Saint Louis, Paris, France*
[5]*CHU de Bordeaux, Bordeaux, France*
[6]*Institut Bergonié, Bordeaux, France*

Background. Bortezomib (BTZ) represents an important progress in the treatment of multiple myeloma (MM). BTZ combined with other agents is becoming a standard of care particularly in elderly patients not eligible for autologous stem cell transplantation. To date, no evaluation of BTZ in a real-life setting has been conducted in France. *Aims.* To describe and compare patterns and effectiveness of BTZ use in two age groups: ≤75 years (youngers) vs >75 years (olders). *Methods.* VESUVE is a national cohort conducted in 60 French centres that included patients initiating BTZ from May 2004 to April 2006 using nominative hospital pharmacy dispensations. Patients treated for MM were followed for 2 years. Data regarding treatment modalities, response and survival outcomes (overall survival, OS and progression-free survival, PFS) were collected through medical files. BTZ cycles were categorized as standard or not according to market authorisation (dose, injection and cycle rhythm). Response was assessed by an independent committee according to adapted International Myeloma Working Group criteria. *Results.* Among the 793 patients included, 82.3% were aged ≤75 years and 17.7% >75 years. Concomitant use of other agents was more frequent in youngers (73.5% vs 65.0%; p=0.04) especially regarding conventional chemotherapy (16.7% vs 1.1%; p<0.01). Mean ±SD number of BTZ cycles did not differ between groups (5.0±3.5 vs 4.6±3.0; p=0.15) but mean BTZ cumulative dose per cycle was 7.9±1.6 mg in youngers vs 7.1±1.9 mg in olders (p<0.01). The proportion of patients with at least one non-standard cycle was 68.0% in youngers vs 77.9% in olders (p=0.02). BTZ was withdrawn for safety reasons in 20.1% in youngers vs 26.4% in olders (p=0.10). Among the 588 evaluable patients for response, the overall best response rate was 57.1% in youngers vs 64.1% in olders (p=0.19). The 2-year OS rate was 44.2% (95%CI 40.2-48.0; median 20.4 months) in youngers vs 36.3% (28.2-44.4; 14.1 months) in olders (p=0.02). The 2-year PFS rate was 11.6% (9.3-14.3; 7.3 months) in youngers vs 13.8% (8.6-20.3; 6.5 months) in olders (p=0.69). *Conclusions.* Despite differences regarding use, these results show that BTZ leads to very similar survival outcomes in patients over 75 years of age as compared to younger patients.

CONSOLIDATION/MAINTENANCE THERAPY AFTER INTENSIVE INDUCTION IMPROVES QUALITY OF RESPONSE AND OUTCOME IN PATIENTS WITH RELAPSED-REFRACTORY MULTIPLE MYELOMA (R-RMM)

M Offidani,[1] L Corvatta,[2] C Polloni,[1] S Gentili,[1] A Mele,[2] R Rizzi,[3] M Catarini,[2] P Caraffa,[1] A Samori,[2] N Blasi,[2] M Ferranti,[2] L Malerba,[2] M Brunori,[2] L Pietro[1]

[1]*Clinica di Ematologia Azienda Ospedaliero-Universitaria, Ospedali Riuniti Ancona, Ancona, Italy*
[2]*Marche Myeloma Network (GEMaMM), Fabriano, Italy*
[3]*Sezione di Ematologia, Dipartimento di Patologia ed Ematologia, Università Bari, Bari, Italy*

Background. There are some evidences that consolidation/maintenance therapy improves quality of response and remission duration in newly diagnosed MM. However, the impact of these strategies in relapsed/refractory MM (r-rMM) are still unknown. *Aims.* We assess the impact of consolidation-maintenance (C-M) therapy on quality of response and outcome, performing a post-hoc analysis of a prospective phase II study exploring an intensive combination as induction followed by consolidation and maintenance therapies in r-rMM. *Methods.* Patients

received 6 28-day cycles of oral thalidomide 100 mg/day continuously, oral dexamethasone 20 mg on day 1-2, 4-5, 8-9, 11-12, pLD 30 mg/m2 iv on day 4 and Velcade 1.3 mg/ m2 iv on day 1, 4, 8, 11 (ThaDD-V). As consolidation patients underwent to 6 28-day cycles of rotating Velcade 1.3 mg/ m2 iv on day 1, 4, 8, 11 plus dexamethasone 20 mg on day 1-2, 4-5, 8-9 (3 courses) and thalidomide 100 mg/day continuously plus dexamethasone 20 mg on day 1-4 (3 courses). Maintenance therapy included thalidomide 100 mg/day until relapse or intolerable toxicity. Due to an excess of peripheral neuropathy, protocol was amended as follow: Velcade 1.3 mg/m2 on day 1, 4, 11 and thalidomide 50 mg/day in all therapeutic phases. Response, time to progression (TTP), progression free survival (PFS) and overall survival (OS) were assessed according to International Myeloma Working Group (IMWG). To assess the role of C-M therapy we compared TTP and OS of patients who were able to continue planned therapy with those of patients not receiving C-M because of toxicity by a 6-months landmark analysis. *Results.* Median age of 46 patients was 63.5 years (range 31-85 years) and the median number of prior regimens was 1 (range 1-4). Fifty-two percent had undergone autologous stem cell transplantation, 59% thalidomide, 17.5% bortezomib and 35% were refractory to the last regimen. After induction 13% of patients achieved sCR, 21.5% CR, 32.5% VGPR and 8.5% PR. Additional 4 patients had SD while 7 progressed. Out of 46 patients undergone induction, 26 (56.5%) received consolidation therapy since 10 patients progressed or died during induction, and 10 developed severe toxicities requiring therapy interruption. Five (25%) among the 20 patients without a prior sCR further improved response. Therefore, the best response after induction and consolidation was 17.5% sCR, 19.5% CR, 34.5% VGPR and 4.5% PR. The 20 patients receiving thalidomide maintenance therapy had no improvement in response. Globally, median TTP and PFS were 18.5 and 17.5 months, respectively while median survival was 40 months. Patients achieving sCR had a significantly better 3-year TTP if compared with those obtaining CR (86% vs 46%; p= 0.035) or VGPR-PR (86% vs 11%; p= 0.003). Patients who completed the protocol had a significantly longer TTP (NR vs 7 months, p= 0.001) and OS (NR vs 28 months; p= 0.038) compared with those who did not. *Conclusions.* This retrospective analysis suggests that, in r-rMM, the possibility of receiving intensive and continuous therapy containing bortezomib and thalidomide allowed to improve quality of response that translates into a significantly better outcome.

Background. The international, non-interventional electronic bortezomib observational study (eVOBS) is ongoing to prospectively evaluate the efficacy and clinical outcomes associated with bortezomib-based therapies for primarily relapsed/refractory multiple myeloma (MM) in the 'real-world' clinical practice setting. *Aims.* With study enrollment now complete, we report patient demographics, baseline disease characteristics, and efficacy data for the entire eVOBS study population. *Methods.* Adult patients scheduled to begin bortezomib-based therapy for the treatment of predominantly relapsed/refractory MM were eligible for enrollment into the study. Patients were enrolled at clinical practices in Belgium, Brazil, Canada, France, Greece, Russia, Spain, Sweden and Turkey, and provided written informed consent. Treatment history was retrospectively documented for 1 year prior to initiation of bortezomib-based therapy. Prospective observational data were collected for up to 3 years after initiation of bortezomib-based therapy to document efficacy data. All administered bortezomib doses and concomitant treatments were permitted, except for investigational therapies. MM disease stage was assessed at the time of initiation of bortezomib-based therapy using Durie-Salmon (DS) or International Staging System (ISS) criteria. Responses were investigator-assessed and based on European Group for Blood and Marrow Transplantation (EBMT), Southwest Oncology Group (SWOG), or M-protein criteria. Response data were censored at the start of subsequent therapy, and for deaths. *Results.* 1560 patients were enrolled between October 2006 and December 2010. Sociodemographics, chronic co-morbidities, and patient characteristics were recorded at baseline (Table). The majority of patients (97%) included in this study received bortezomib-based therapy for relapsed/refractory MM; 3% of patients received bortezomib as their first-line therapy for MM. The most common prior MM treatments documented within 1 year of starting bortezomib-based therapy were melphalan-prednisone combinations (20%), thalidomide-dexamethasone (9%), vincristine-doxorubicin-dexamethasone ± cyclophosphamide (9%) and thalidomide monotherapy (6%); 5% of patients had received an autograft and 41% had no MM treatment in the previous year. The majority of patients received bortezomib in combination with other agents including dexamethasone (44%), prednisone (9%, mostly with melphalan), thalidomide (4%, mostly with dexamethasone), and lenalidomide (2%); 30% of patients received bortezomib monotherapy. Most (84%) patients received bortezomib at an initial dose of 1.3 mg/m2. At the data cut-off of 08 January 2011, and after a median follow-up of 15.3 months, 26.9%, 16.7%, 32.5%, and 8.4% of patients achieved a best response of complete response (CR), near-CR (nCR), partial response (PR), and minimal response (MR), respectively. In responding patients, the median time to CR, nCR, PR, and MR was 3.9, 3.2, 1.9, and 1.6 months, respectively. *Conclusions.* The eVOBS database contains valuable information about the efficacy of bortezomib-based therapies for relapsed/refractory MM in 'real-world' clinical practice. These results provide a useful comparator for data collected in the highly controlled clinical trial setting. Patients continue to be followed for long-term outcomes.

Table 1.

Characteristic	No. of patients (N=1560)
Median age, years (range)	62 (27–95)
Male / female, %	50 / 50
Time since first MM treatment, years (range)	2.1 (0–21)
Stage III MM by DS or ISS, %	49
No. of co-morbidities at baseline, 0 / 1 / 2 / ≥3, %	27 / 26 / 20 / 27
No. of prior lines of therapy, 0 / 1 / 2 / ≥3, %	3 / 56 / 22 / 19

Background. 25 mg once-daily Lenalidomide on days 1-21 of a 28 day cycle in combination with 40 mg dexamethasone has demon-

strated significant improvements in time to progression (TTP) and overall survival (OS) in patients with relapsed/refractory multiple myeloma who have received ≥ 1 prior therapy. A pooled analysis (Dimopoulos *et al.* Leukemia. 2009;23: 2147-2152) of two large multicenter phase III trials (MM-009 and MM-010) assessed long-term outcomes (median follow-up 48 months in surviving patients) of 25 mg once-daily lenalidomide plus 40 mg dexamethasone vs. placebo plus 40 mg dexamethasone. This analysis demonstrated significant response and survival benefit with the lenalidomide plus dexamethasone combination (overall response rate (ORR) of 60.6% in patients receiving lenalidomide plus dexamethasone compared with 21.9% in patients receiving dexamethasone plus placebo). Median OS for the combination was 38.0 months with the combination and 31.6 months with dexamethasone plus placebo. *Aims.* To evaluate treatment response (CR, VGPR, PR, MR, SD and PD), OS, and safety with lenalidomide 25 mg given once-daily or every-other-day for 21 days of a 28 day cycle in patients with relapsed (53%)/refractory (47%) multiple myeloma. *Methods.* In this clinical practice chart review, 169 evaluable patients, 58% male, median age 64.3 years, received 25 mg once-daily (n=140) or every-other-day (n=29) oral lenalidomide-based regimens [57% with glucocorticoids (87% dexamethasone,160 or 320 mg per cycle); 43% with glucocorticoids plus conventional cytostatic agents]. Patients treated with lenalidomide monotherapy were excluded from this analysis. Patients in both groups received a median of 3 previous lines of therapy, 89% and 86% with ≥2 therapies, in the once-daily and every-other-day lenalidomide groups, respectively. *Results.* VGPR was 7.9% and 0%, PR was 30.3% and 10.0%, and MR was 6.7 and 20.0% with lenalidomide 25 mg once-daily and every-other-day, respectively. Despite a short median time to follow-up of 8.4 months (range 0.3 - 26.2), ORR (≥PR) was 38.2% versus 10%. Based on the definition of response (60 days after end of treatment), 89 and 10 patients were evaluated. Median OS from the start of therapy was 16.7 and 10.3 months in the lenalidomide 25 mg once-daily and every-other-day groups (evaluated in 140 and 29 patients, respectively). Lenalidomide once daily did not result in significantly higher incidence of hematologic adverse events. Grade 3/4 adverse events included neuropathy (5.6%, 3.4%), thrombosis (8.6%, 3.4 %), infection (14.9%, 3.6%), thrombocytopenia (12.4%, 3.4%), neutropenia (34.1%, 27.6%), and anemia (14.8%, 6.9%) in the once-daily and every-other-day lenalidomide groups. There was no significant difference between the two treatment groups in grades 1-5 thrombocytopenia or neutropenia. One patient treated with 25 mg once-daily lenalidomide experienced grade 5 thrombosis and one patient experienced grade 5 infection. *Conclusions.* Lenalidomide is active and generally well-tolerated in relapsed/refractory myeloma. These results support the approved 25 mg once-daily dosing of lenalidomide on days 1-21 of a 28 day cycle in patients with relapsed/refractory multiple myeloma and indicate that every-other-day dosing compromises response with no significant difference in tolerability.

0869

THE DOSE OF INFUSED NKT CELLS IN THE AUTOGRAFT DIRECTLY CORRELATES WITH LYMPHOCYTE RECOVERY AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN MULTIPLE MYELOMA (MM)

SM Yim, SE Lee, SA Yahng, BS Cho, YJ Kim, NK Chung, DC Jeong, CK Min

Hematology, Dept. of Internal Medicine, Seoul St. Mary's Hospital, Seoul, South-Korea

Early lymphocyte recovery after ASCT in MM is an important predictor of survival. The dose of infused lymphocytes in the autograft directly correlates with early lymphocyte recovery (*Porrata LF et al. Leukemia 2004;18:1085, Hiwase DK et al. Biol Blood Marrow Transplant 2008;14:116*). However, limitations of previous studies are the lack of lymphocyte subset analyses. Thirty-two patients with MM who underwent ASCT were examined to investigate the correlation between infused cell populations and lymphocyte subsets at engraftment. The cell populations of infused autograft and lymphocyte subsets of peripheral blood at engraftment were examined by flow cytometry. Immunophenotyping was performed for the T cell panel (CD3/CD4/CD8), B cells (CD19), and natural killer (NK) cells (CD56/16). By Spearman correlation coefficients, we identified a correlation between absolute lymphocyte count (ALC) at engraftment and each lymphocyte subset at engraftment (Table 1). The cell dose of infused NKT cells ($CD3^+CD56^+CD16^+$) was significantly associated with $CD3^+$ ($r_s = 0.435$, $P = 0.013$), $CD4^+$ ($r_s = 0.455$, $P = 0.009$), $CD8^+$ ($r_s = 0.399$, $P = 0.024$), $CD19^+$ ($r_s = 0.392$, $P = 0.027$), and ALC ($r_s = 0.395$, $P = 0.025$) at engraftment. On the contrary, the dose of infused $CD34^+$ cells was not associated with changes of any lymphocyte subsets. In addition, the recovery of $CD4^+$ cells was significantly associated with the dose of infused $CD3^+$ and $CD8^+$ but not $CD4^+$ cells. Our data suggest that a certain number of NKT cells as well as the number of $CD34^+$ cells should be aimed for successful ASCT in MM. Table1. Spearman correlation coefficient between infused cell population and lymphocyte subset at engraftment** P: <0.01* P: <0.05

Background. Primary systemic AL amyloidosis is a clonal plasma cell disorder in which the N-terminal fragments of monoclonal light chains form fibrils that accumulate in various tissues ultimately leading to organ dysfunction and death. Renal injury is a very frequent feature in AL amyloidosis patients. Serum cystatin-C and free light chain (s-FLC) κ and λ levels were investigated to evaluate clinical severity degree of renal impairment in AL amyloidosis, also in terms of prognosis. Cystatin-C is a non-glycosilated protein with low molecular weight (13kDa) produced at a constant rate in all nucleated cells. It is freely filtered, reabsorbed for 99% in proximal tubule and not secreted so it has higher sensitivity than creatinine determination for detecting initial GFR reduction. This peculiarity may be useful for evaluation of kidney and heart dysfunction for patients with systemic diseases. *Aims and Methods.* We evaluated serum cystatin-C and s-FLC levels in 7 patients (median age 63.1 yrs) with recent diagnosis of systemic AL λ amyloidosis admitted to our Unit. Ten age-matched healthy control subjects were selected. According to age and disease risk stratification six out 7 patients were treated with upfront oral MelDex association (Melphalan 9 mg/sm, Dexamethasone 20mg day 1-4 q28). One subject started first line therapy with BorDex association (Bortezomib 1.3 mg/sm, Dexamethasone 20 mg day 1,4,8,11 q21). Three samples of peripheral blood were performed (treatment day 1, day 8 and at con-

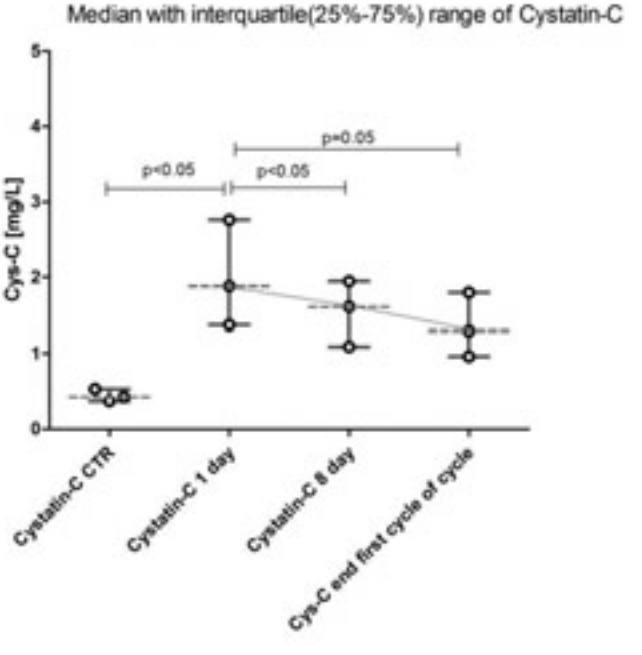

Figure 1.

clusion of the first cycle of therapy). The blood was separated into plasma at the time of blood draw and frozen to -80°C. In the evaluation of results Mann-Whitney U test, paired t test, Kruskal-Wallis one-way analysis of variance (Dunn's Method versus Control Group), Spearman rank correlation and Linear Regression were performed. P values ≤ 0.05 were considered statistically significant. *Results.* In all patients s-FLC κ/λ ratio was increased at the end of first cycle of therapy (p = 0.002). Both s-FLC λ and cystatin-C levels were significantly decreased during treatment (p < 0.05 and p = 0.05). A positive correlation between s-FLC λ and cystatin-C values was observed at all times (r2 = 0.99, p < 0.001 at day 1; r2 = 0.89, p = 0.006 at day 8 and r2 = 0.99, p <0.001 at the end of first cycle). Both treatments have been effective in terms of disease response and renal function improvement. Among 4 patients with persistent high serum levels of cystatin-C at the end of cycle, 3 had poor outcome (2 deaths with heart and renal failure respectively, 1 alive with end stage renal disease in haemodialysis). *Conclusions.* On the basis of these results we could consider cystatin-C a useful biomarker for renal function assessment with prognostic value according to treatment in patients with systemic AL amyloidosis.

0871

HIGH RESPONSE RATE IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS TREATED WITH A COMBINATION OF CYCLOPHOSPHAMIDE, LIPOSOMAL DOXORUBICIN, DEXAMETHASONE AND BORTEZOMIB

C Giannakoulas, D Palassopoulou, J Befani, T Zisaki, A Bouronikou, G Vassilopoulos, T Matsouka

University Hospital of Larisa, Larisa, Greece

Background. Autologous stem cell transplantation (ASCT) and the use of new agents have significantly improved the outcome of multiple myeloma patients. The achievement of complete response after induction treatment is prerequisite for long term overall survival. Although ASCT is still considered standard of care, its necessity in first CR may be challenged in the era of the new agents. *Aims.* The aim of our study was to evaluate the efficacy and toxicity of an intensive treatment protocol in newly diagnosed patients with multiple myeloma. *Methods.* 26 patients (21 male, 5 female) of median age 60 years (45-75) were treated after informed consent with a combination of cyclophosphamide 750mg/m2 d1, liposomal doxorubicin 40mg/m2 d1, dexamethasone 40mg d 1-4 and bortesomib 1,3mg/m2 d1,4,8,11 every 28 days. All patients also received zoledronic acid 4 mg every 28 days and erythropoietin to maintain haemoglobin > 10.5 gr/dl. The median follow up was 17 months (3-40). The ISS stage was: low in 6, intermediate in 7 and high in 13 patients. The monoclonal globin type was IgG in 12 patients, IgA in 9, IgD in one, IgE in one and free light chain in 3. Renal impairment (Cr≥2) was present in 5 patients and hypercalcemia in 7 patients. Radiotherapy was applied in 7 patients. *Results.* All patients (n=26) who received at least two cycles of therapy were evaluated. The median number of cycles was 6 (range 2-8). 23/26 (88.5%) had responded. Thirteen patients (50%) had complete response (6 nCR, 7 CR IF-), 7 (27%) patients had very good partial response (VGPR), 3 (11.5%) had partial response (PR) while 3 (11.5%) patients didn't respond or had progressive disease. Three patients in CR had a sufficient collection of CD34+ cells but only one finally underwent ASCT. The toxicity of the treatment was acceptable. Haematological toxicity: neutropenia grade II 3/26, grade III 5/26, grade IV 1/26, thrombocytopenia grade II 7/26, grade III 2/26. In terms of non-haematological toxicity, one patient had deep vein thrombosis and more than half of the patients experienced gastrointestinal disturbances. Two patients were hospitalized with neutropenic fever. Maintenance treatment with thalidomide 50mg/d or lenalidomide 10-15 mg/d 1-21/mo after the achievement of CR or VGPR was introduced to 10 patients for at least 6 months. The progression free survival for the patients who achieved CR or VGPR was 14,5 months. The probability of relapse is 35% at 36 months. Four patients died, one in CR and three in relapse due to infections. The probability of survival at 36 months is 68 %. None of the analyzed factors in mono- and polyparametric analysis were significant for probability of relapse and survival. *Conclusions.* The above protocol was efficient in terms of response rate. It was safe with acceptable and manageable toxicity. Addition of bortezomib in 1st line treatment significantly improves the response rate. Larger number of patients and longer follow up is needed to define if our approach may lead to improved progression free and overall survival, without the necessity of ASCT in first CR.

Background. Several studies have examined the prevalence of Monoclonal Gammopathy of Undetermined Significance (MGUS) and its characteristics. However, few studies have focused on IgM Monoclonal Gammopathies (MG), especially IgM MGUS, entities with different pathophysiological significance and follow-up, opposite to non-IgM MGUS. *Aims.* To analyze the incidence, clinical and biological characteristic of the IgM MG detected in a urban population study. *Material and Methods.* Prospective cohort study in the urban population over the age of 50 years old in Segovia (Spain). The serum monoclonal component was detected by electrophoresis and confirmed by immunofixation. The selection of the participants was done through Health Centers or personal letter. *Results.* At the first 26 months, it has been contacted by 16161 people of whom 6681 agreed to take part in the above mentioned study. 147 MG was detected, which 24 were IgM and 2 biclonals (IgM + IgG) (17.7 % of the MG series, 0.36% of the population). It was 21 males and 5 females, with a median age of 71 years (54-85 years). Distribution for light chain show a clear predominance of the light chain κ (20) opposite to light chain λ (8). 5 of these cases could not be studied because lack of consent or other social/sanitary circumstances, 1 case was a transitory Gammopathy and in 3 cases the Gammopathy was secondary to other diseases. Of 17 remaining patients, 13 (76 %) was catalogued of Monoclonal Gammopathy of Undetermined Significance (MGUS) and 4 (24 %) of asymptomatic Waldenström's Macroglobulinemia (aWM). No case of symptomatic Waldenström's Macroglobulinemia. The patients with MGUS were 10 males and 3 women, with a median age of 76 years (56-85). The median of the component monoclonal by electrophoresis was 0.6 g/l (0.22-1.74). Median hemoglobin, serum creatinin and albumin levels were: 14.3 g/dl (11.6-15.4), 1.1 mg/dl (1-1.2) and 4.35 g/dl (4-4.9). From diagnoses, a patient has evolved to aWM. The patients with aWM were all males, with a median age of 71 years (56-80). The median of the component monoclonal was of 1.16 g/l (0.57-1.5). Median hemoglobin, serum creatinin and albumin levels were: 14.1 g/dl (11.9-15), 1 mg/dl (0.8-1.3) and 4.4 g/dl (4.3-4.7). *Conclusions.* In our population study, the proportion of IgM MG is similar to reported in other studies, although the incidence appears somewhat lower. These information will be updated in the meeting.

PERCUTANEOUS VERTEBROPLASTY IN MULTIPLE MYELOMA: A SINGLE CENTRE EXPERIENCE.

B Gamberi,[1] G De Berti,[2] L Masini,[1] M Maggi,[2] L Tognazzi,[1] F Merli[1]

[1]*Asmn, Haematology Unit, Reggio Emilia, Italy*
[2]*Asmn, Radiology Unit, Reggio Emilia, Italy*

Background. Multiple myeloma (MM) is frequently associated with osteolytic lesions with bone pain and pathological fractures: vertebral compression fractures are present in 60% of patients at diagnosis. Percutaneous vertebroplasty (PVP) is a minimally invasive, radiologically guided procedure, in which bone cement is injected into destructed vertebrae. It has been shown to provide rapid pain relief and improved rehabilitation in acute fractures when bed rest, analgesic, bisphosphonates and radiotherapy fail (80% of cases). This study was conducted to test the efficacy and safety of PVP. *Methods.* A prospective analysis was performed on a total of 59 levels in 26 patients with vertebral pain refractory to conventional medical therapy for at least two months. Vertebral fractures were recognized when local pain coexisted with acute compression fracture findings by magnetic resonance imaging (MRI). Twenty-four out of 26 patients were on therapy with zoledronic acid an 12 of them received radiotherapy. All the procedures were performed by two experienced neu-

roradiologist, after obtaining informed consent. Under fluoroscopic guidance, the vertebral body was reached via a transpedicular route, while a posterolateral approach was usually considered when the pedicle was too small or sagitally oriented (thoracic spine). We use 13 G needles in the vast majority of cases, but in some instances we have adopted 11 G or, for passing through small pedicles, 15 G needles. Polymethilmethacrylate is usually inserted by means of a screw injection device or, in some situations, manually, utilizing small (1,5 cc) syringes. The visual analog scale (VAS) and the Eastern Cooperative Oncology Group (ECOG) scale were used to estimate patients' perception of pain and functional status, respectively, at -1, + 1, + 30, + 90, + 180, and every years after PVP. *Results.* Fifty-nine procedures were performed in 26 patients. Regarding the type of vertebral deformity, we found 2 cases of complete body crush, 14 wedge shaped failures, 17 dips both endplates, 16 dips in only one endplate, 10 cases of MRI altered signal in the absence of deformity or body height loss. Involved levels ranged from T4 and L5; L1 and L4 were the most frequently affected, with 8 procedures each. All patients but one were discharged from hospital the day after the surgical treatment. Patients were able to reduce their analgesic requirements by 55%. The mean VAS pain score decreased from 7,1 to 2,6. Patients presented a median pre-procedural ECOG scale of 3; after VTP, it improved to 1.7. Despite leakage of PMMA was detected in 38% of cases (21 out of 55), only two patients developed a transient and responsive to medical therapy neuralgia. Besides these two cases, we didn't observe any adverse event, except for one case of moderate fever. *Conclusions.* Our experience suggests that PVP is safe and effective and results in pain control and improvement of quality of life in MM patients. Furthermore it is associated with low toxicity and costs. Therefore, due to efficacy and safety, early treatment with PVP should be considered in the management of MM.

Background. The combination of bortezomib with adriamycin & dexamethasone (PAD) is a highly effective induction agent with response rates of up to 95% (Oakervee, *et al.*, BJH 2005; 129:755-62). We have previously shown the superior efficacy of PAD chemotherapy over VAD/VAD-like regimens by comparing response to PAD given following relapse to the response previously obtained with VAD/VAD-like regimen in the same patients. *Aims.* To demonstrate the efficacy of bortezomib, adriamycin and dexamethasone combination therapy in patients with refractory myeloma. *Methods.* This was a phase 2 study with 3 cohorts, of 23 patients. Cohort 3 was for patients refractory to VAD and who proceeded directly to PAD chemotherapy. *Results.* 23 patients (6 females, 17 males, median age 62 years) achieved <PR to a median of 4 (range 2-6) courses of VAD or VAD-like therapy (C-VAD n=2, VAD n=15, Z-DEX n=6). Following PAD therapy 4 patients achieved ≥VGPR (CR n=2) based on their PAD protein level at the time of starting PAD therapy. A PR was recorded in 12 patients. When compared to the responses achieved by VAD therapy, the exact McNemar significance probability was p=0.0005. The fall in median paraprotein levels post-VAD was 23.6% and after PAD was 56.5% (using pre-PAD protein level for comparison) (p=0.0002 using the Wilcoxon signed rank test). *Conclusion.* Using a novel trial design, requiring only small numbers of patients we have shown that PAD is superior to VAD using two independent statistical methods.

Background. Systemic hypogammaglobulinemia (SH) is a very common finding in Waldenström's Macroglobulinemia (WM). Low levels of IgG have been associated with disease progression.[1] Specific polyclonal antibodies, that recognise epitopes spanning the junction of the heavy and light chains of the individual immunoglobulin isotypes have been recently developed (Hevylite®). Decreased concentrations of polyclonal isotypes of the same Ig class (ISC) have been associated with shorter progression free survival in multiple myeloma.[2] *Aim.* The purpose of the study was to evaluate the effect of SH and ISC on time to first treatment (TTT) and overall survival (OVS) in a series of WM patients. *Methods.* Retrospective sera from 70 WM patients (35 male /35 female) at diagnosis were included in the study. Median age was 66yrs (range 44-91). Analysis of IgG and IgA was performed using standard antibobies, while IgMκ and IgMλ with Hevylite® antibody, nephelometrically. SH was defined as IgG<700 mg/dl, IgA<70mg/dl or both, ISC as IgMλ<10mg/dl in IgMκ patients or IgMκ<10mg/dl in IgMλ ones. *Results.* 48 out of 70 patients were or became symptomatic during follow up. Median follow up was 37 months. At diagnosis median IgG was 896 mg/dl (206-4750), median IgA 89 mg/dl (22-638), median IgMκ 2000mg/dl (7-17300) and median IgMλ 28mg/dl (1-13000). SH was present in 34/70 patients, ISC in 18/70 and both in 9/70. Sixteen patients died from disease. Neither SH nor ISC or both correlated with TTT (p=0,358, p=0,874 and p=0,718 respectively) or OVS (p=0,159, p=0,817 and p=0,854 respectively). *Conclusions.* In our experience SH and ISC are not adverse factors for TTT and OVS.

younger patients with multiple myeloma (MM). Although new drugs such as lenalidomide or bortezomib have been shown the promising results as induction treatment, many different type of induction treatment regimens still have been used. We evaluate the efficacy and safety of the short course of high dose dexamethasone and the response adopted PAD (Bortezomib, Adriamycin, Dexamethasone) or VAD (Vincristine, Adriamycin, Dexamethasone) induction chemotherapy in the newly diagnosed younger patients with MM. *Methods.* 83 newly diagnosed patients with MM from 20 institutions received 2nd cycles of high dose dexamethasone followed by PAD or VAD chemotherapy according to the response to the initial high dose dexamethasone. The primary endpoint was complete response (CR) + near CR rate after ASCT. Among 83 patents enrolled this study from November 2009, 19 patients (23%) have been dropped out. This trial will be continued until total 210 patients will be enrolled. The trial is registered on National Cancer Institute website, number NCT01255514. *Results.* Eighty three patients (41 male, 42 female) were enrolled (median age; 56). 17 (21%) light chain disease were included. 26 (31%) patients were D-S stage II and 51 (62%) were stage III. According to the ISS, 15 (18%) patients had stage I, 41 (49%) had stage II and 27 (33%) had stage III. 24 (29%) patients had abnormal cytogenetics. There were 32% del13, 7% del17, 18% t(4;14), 13% t(14;16) and 27% t(11;14) in FISH analysis. Among the 64 evaluable patients, CR + PR rate was 44% (28/64) after 2nd cycles of high dose dexamethasone therapy. 28 patients (44%) received subsequent VAD chemotherapy and 33 patients (52%) received PAD chemotherapy. Among the 42 patients finished VAD or PAD chemotherapy, CR + PR rate was 81% (34/42). 29 patients were finished ASCT until now. 11% (7/64) treatment related deaths were observed. The cause of death was disease progression (n=3) and infections (n=4). *Conclusion.* The short course of high dose dexamethasone and the response adopted PAD or VAD induction chemotherapy followed by ASCT showed acceptable response rates and acceptable toxicities. We will report update results of this trial.

0877

EFFICACY AND SAFETY OF BORTEZOMIB IN PREVIOUSLY TREATED PATIENTS WITH MULTIPLE MYELOMA IN ROUTINE CLINICAL PRACTICE: SLOVAK EXPERIENCE

Z Stefanikova, K Masarova, K Richterova, M Mistrik

University Hospital of Bratislava, Bratislava, Slovakia

Background. Bortezomib is the first proteasome inhibitor approved for the treatment of patients with relapsed/refractory multiple myeloma (R/R MM). Since April 2005 bortezomib is reimbursed for the treatment of patients with multiple myeloma (MM) in relapse settings in Slovakia. *Aims.* This large, retrospective, non-interventional, single-center analysis was conducted to evaluate bortezomib efficacy and safety in patients with R/R MM in routine clinical practice. *Methods.* 169 patients with MM who received bortezomib treatment after at least one prior therapy and have demonstrated disease progression at the biggest Slovakian myeloma center were evaluated in this study. The starting dose was 1,3 mg/m2 twice or once weekly, lenght

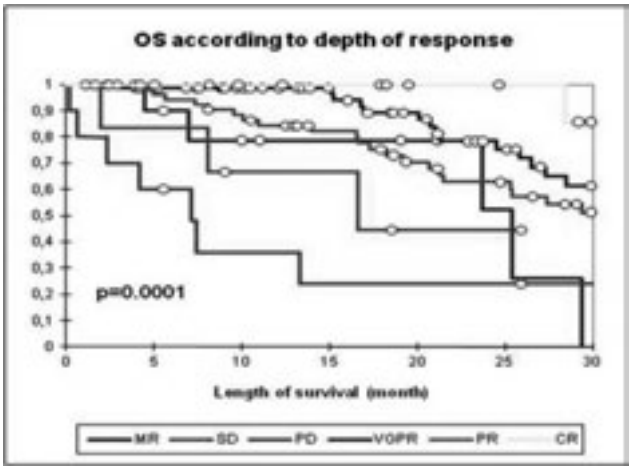

Figure 1.

of cycle 21 or 35 days, maximum 8 cycles. Bortezomib was administered as monotherapy, 2-drug (VD, bortezomib + dexamethasone) or 3-drug (BDD, bortezomib + dexamethasone + doxorubicine, VMP, bortezomib + melphalan + prednisone, VCD, bortezomib + cyclophosphamide + dexamethasone) combination. *Results.* Demographic and baseline characteristics: median age: years (range) 67 (35 - 84); male sex: n (%) 68 (40); ISS I: n (%) 18 (11); ISS II: 112 (66); ISS III: 39 (23); one prior therapy: n (%) 104 (62); two prior therapies: 48 (28); three and more prior therapies: 17 (10). Treatment exposure: median treatment cycles (range): 6 (1 - 8); bortezomib monotherapy: n (%) 19 (11); 2- drug combination: 38 (23); 3 - drug combination: 112 (66). Overall response of R/R MM patients to bortezomib: ORR (CR + VGPR + PR): n (%) 143 (85); CR: 15 (9); VGPR: 71 (42); PR: 57 (34); MR: 10 (6); SD: 6 (4); PD: 10 (6). Safety: all grades of peripheral neuropathy (PN): n (%) 79 (47); Gr 3: PN 9 (5); no Gr 4; all grades of thrombocytopenia: n (%) 20 (12); Gr 3: 3 (2); no Gr 4; GIT toxicity Gr 1,2: n (%) 20 (12), other adverse events Gr 3,4: n (%) 4 (2), for combination of all adverse events: no AE: n (%) 67 (40), Gr 1,2: 86 (51), Gr 3: 16 (9) Outcomes median (95% CI): TTP: 23,1 (19,8-25,6) months; OS: 34,7 (27,4-inf) months. Depth of response was in significant association with long-term outcome (p<0.0001), graph 1. There were no statistically significant differences in TTP and OS between monotherapy, 2 - drug and 3 - drug combinations, Long-rank test: p=0,49 (TTP) resp. p=0,80 (OS). *Conclusions.* R/R MM patients treated with bortezomib had high overall response rates and survival outcomes comparable with previously published results from phase 3 clinical studies. The safety profile was predictable, manageable and similar to experience in clinical trials. Bortezomib is the headstone of efficacy concerning combination MM treatment in routine clinical practice.

KYPHOPLASTY AS FIRST LINE TREATMENT FOR VERTEBRAL LESIONS DUE TO MULTIPLE MYELOMA: A SINGLE CENTER EXPERIENCE

S Sachanas,[1] G Pangalis,[1] X Yiakoumis,[1] M Moschogiannis,[1] P Stavros[2]

[1]*Athens Medical Center, Athens, Greece*

[2]*Orthopaedics/Spine Department, Athens Medical Center, Athens, Greece*

Background. The complications of spinal bone disease in multiple myeloma (MM) include local pain and vertebral compression fractures (VCF). The treatment of MM vertebral lesions traditionally involves radiotherapy (RT) combined or not with bed rest, bracing and analgesics with or without chemotherapy. Recently new minimally invasive interventional methods such as Vertebroplasty and Balloon Kyphoplasty (BKP) are applying to treat the bone lesions. BKP as compared to Vertebroplasty is a more efficient method for restoration of lost vertebral height with lower incidence of cement leakage. *Aim.* To determine the safety and the efficacy of the BKP in patients with vertebral fractures secondary to MM. To verify the role of BPK as treatment of choice for vertebral bone lesions instead of the traditional treatment with local radiotherapy. *Methods.* Patients with MM and vertebral fractures or osteolytic lesions were treated with BKP the last 2 ½ years in our Department. Through minimal incisions, two special inflatable balloons were transpedicularly or extrapedicularly inserted and inflated in each treated VB. After appropriate inflation of the balloons a certain degree

Table 1. Comparison of BKP with RT.

	BKP	RT
Pain control	90%	80-85%
Biomechanical stability	+++	-
Fracture reposition	+++	-
Onset of the analgesic effect	Immediate	After 10-15 d
Osteonecrosis	-	++
Refracture (same vertebra)	-	+
Neurological complications	±	+

of reposition of the VCF was obtained. Consequently a proper amount of PMMA (polymethylmethacrylat) cement was injected in every VB. Deformity correction was evaluated using standard calculation formula based on the fractured vertical height pre and post operatively. Pain degree was estimated before and after the procedure using the VAS score. *Results.* 17 patients (4 male, 13 female, median age 67, range 45-79) with a total of 43 vertebral fractures or significant osteolytic lesions were treated. All 17 pts tolerated the procedure well. Postoperatively, all pts were admitted to the one-day clinic and all of them were discharged ambulatory the following morning. The deformity correction was 90% for the 23% of the VCF, 60-89% for the 61% and 30-59% for the rest of the reducable fractures. Six months later the correction was stable. For a median follow up time of 18 months (range 4-30) there were no early or late complications related to the technique as cement extravasation, ARDS, relapse of the MM in the same VB or even refracture. All patients experienced immediate and stable pain relief (median VAS pro-post: 6-1) and improvement in the quality of life. No patient was in need of additional local radiation therapy in the reconstructed vertebrae. The comparison of BKP in our patients vs RT (historical data) are presented on table 1. *Conclusions.* Balloon Kyphoplasty is an effective and safe minimal invasive surgical procedure. The correction of the kyphosis by BKP results in significant biomechanical advantage. Rapid and significant relief of pain is achievable with BKP. BKP could substitute local radiotherapy as treatment of choice for vertebral lesions. Absence of local relapse may reflect a possible control of the disease by mechanical or functional intervention.

0879

NEUROLOGICAL FINDINGS IN A SERIES OF PATIENTS WITH MONOCLONAL PARAPROTEINEMIA WITH OR WITHOUT ADMINISTRATION OF NEUROTOXIC DRUGS

C Zaroulis,[1] S Sachanas,[2] X Yiakoumis,[2] M Moschogiannis,[2] C Chairopoulos,[1] MC Kyrtsonis,[3] G Pangalis[2]

[1]*417 Military Hospital, Athens, Greece*
[2]*Haematology Department, Athens Medical Center, Athens, Greece*
[3]*Haematology Department, Laikon General Hospital, University of Athens, Athens, Greece*

Background. A number of studies have demonstrated an association between monoclonal paraproteinemia and peripheral neuropathy (PN). Besides, many chemotherapeutic agents that mostly used in hematologic malignancies, especially in multiple myeloma, such as vincristine, thalidomide, and more recently bortezomib, induce peripheral neuropathy of variable severity. *Aim.* To evaluate the neurological status of patients with monoclonal paraproteinemia at diagnosis as well as after neurotoxic drug administration. *Methods.* Neurological examination was performed in 65 patients. 57 patients with relapsed/refractory multiple myeloma(MM) and 8 patients with Waldenstrom macroglobulinemia (WM). 23 MM patients were evaluated before bortezomib administration(6 patients were treatment naïve, 9 had received a prior line of chemotherapy with VAD regimen and 8 had received at least 2 prior lines of chemotherapy including thalidomide) and 34 were evaluated at different time points during bortezomib therapy while all MW pts were evaluated at the time of diagnosis. The neurological status was obtained from a questionnaire, examination by the neurologist and neurophysiologic examination at one concrete laboratory center. The method used to grade the neuropathy was the Total Neuropathy Score (TNSr). Electroneurophysiological study(ENG) included sensory nerve conduction of sural nerve and motor nerve conduction of the common peroneal nerve assessment. Motor and sensory nerve conduction studies were performed by standardized equipment and techniques. *Results.* Before Bortezomib administration, 4 out of 6 treatment naive MM patients had laboratory findings consistent with sensory neuropathy without any clinical symptoms.11 out of 17 patients who had received prior chemotherapy presented peripheral neuropathy (4 had received thalidomide and 7 the VAD regimen). Of note was the fact that 3/4 patients with prior thalidomide exposure presented sensorymotor PN. 10 out of 15 (66%) had laboratory findings of demyelination and 4/15 (27%) of axonal damage. 30 MM patients (79%) evaluated after Bortezomib initiation (median time to evaluation 3 months) presented treatment related neuropathy characterized mainly by numbness, paraesthesias, burnings and pain mainly in the lower extremities. In details 7/30 (23,3%) experienced sensory neuropathy, 1/30 (3,3%) motor neuropathy and 22/30 (73,3%) sensory motor neuropathy. 5/30 (16,6%) presented demyelinating neuropathy while 22/30 (73,3%) axonal and 3 (10%) demyelinating with secondary axonal degeneration. 3 out of 8 patients with WM(37,5%) presented peripheral neuropathy characterized by sensory symptoms, gait disorders, reduced or absent tendon reflexes, loss of vibration and pin sensibility with predominance to the lower extremities. ENG evaluation revealed findings that were consistent with a sensory motor neuropathy of demyelinating type. *Conclusions.* ENG study in MM patients is consistent with axonal degeneration neuropathy while in WM patients with primarily demyelinating sensory motor neuropathy. Bortezomib induced peripheral neuropathy is a sensory motor neuropathy of axonal type with predominance to the lower extremities, including mainly serious sensory symptoms. Preexisting peripheral neuropathy in MM patients before Bortezomib administration is common and should be taken into account. -Baseline neurological evaluation in patients with monoclonal paraproteinemia is important allowing early detection of peripheral neuropathy.

LENALIDOMIDE PLUS MELPHALAN AND PREDNISONE FOLLOWED BY LENALIDOMIDE MAINTENANCE PROVIDES FAVOURABLE EFFICACY AND HEALTH-RELATED QUALITY-OF-LIFE IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS =65 YEARS

MA Dimopoulos,[1] M Delforge,[2] R Hájek,[3] M Kropff,[4] MT Petrucci,[5] P Lewis,[6] A Nixon,[7] J Zhang,[8] J Mei,[8] A Palumbo[9]

Background. Lenalidomide maintenance following induction with melphalan, prednisone, and lenalidomide has been shown to provide sustained disease control by prolonging progression-free survival and decreasing relative risk of progression in patients with newly diagnosed multiple myeloma (NDMM) [Palumbo, 2010]. Alongside efficacy enhancements in cancer treatment, health-related quality-of-life (HRQoL) is an increasingly important determinant for choice of therapy [Osoba, 1999]. Recent findings on novel treatment of NDMM have shown efficacy of melphalan, prednisone, and bortezomib (VMP) treatment to be associated with an intermittent deterioration in patients' HRQoL [Dhawan, 2009]. *Aims.* HRQoL data were assessed from an ongoing prospective, randomized phase 3 trial designed to evaluate the efficacy and safety of continuous lenalidomide treatment (MPR-R: melphalan, prednisone, and lenalidomide induction for 9 cycles followed by lenalidomide maintenance until disease progression) vs a fixed 9 cycle duration of melphalan and prednisone (MP) or melphalan, prednisone, and lenalidomide (MPR) in transplant ineligible patients ≥65 years old with NDMM. *Methods.* Data up to Cycle 16 with the cut-off date of 11MAY2010 were analysed. Patient-reported HRQoL data from

Table 1.

Observed Minimal Important Differences (MIDs) from Baseline[a]

HRQoL Domain (scale: points from 0 -100)	Minimal Important Difference (MID)[b]	Assessment Time Points with Patients On Average Achieving MID, Cycle		
		MPR-R	MPR	MP
Global Quality-of-Life	+7	Cycles 7,10,13,16	Cycles 7,10,13	Cycle 16
Physical Functioning	+9	Cycles 10,13,16	Cycle 13	None observed
Fatigue	-10	Cycle 16	Cycle 13	None observed
Pain	-12	Cycles 4,7,10,13,16	Cycles 4,7,10,13	Cycles 4,13,16
Disease Symptoms	-10	Cycle 16	None observed	None observed
Side Effects of Treatment	-6	None observed	None observed	None observed

[a]Data from patients who discontinued from the study were carried forward to the next planned time assessment time point.
[b]MID, Minimal Important Difference; threshold for clinically meaningful score changes from baseline are based on domain-specific standard error measurements (SEM). Positive values denote improvements for Global Quality-of-Life and Physical Functioning. Negative values denote improvements for Pain, Fatigue, Disease Symptoms and Side Effects of Treatment.

EORTC QLQ-C30 and QLQ-MY20 were collected at baseline, at the beginning of every 3rd cycle, and at study discontinuation. Five HRQoL measurement time points subsequent to baseline were assessed. Six out of 19 HRQoL domains were preselected based on clinical relevance: Global Quality-of-Life, Physical Functioning, Fatigue and Pain from QLQ-C30 and Disease Symptoms and Side Effects of Treatment from QLQ-MY20. Clinically meaningful HRQoL improvements from baseline were assessed for individual treatment arms and classified as exceeding minimal important differences (MIDs). MIDs were determined through domain-specific standard error measurement (SEM) whereby positive values denote improvements in Global Quality-of-Life and Physical Functioning while negative values reflect improvements in Pain, Fatigue, Disease Symptoms and Side Effects of Treatment. Within group statistical significance tests ($p \leq 0.05$) were also conducted. HRQoL observations at discontinuation were carried forward to the next planned measurement time point; data with separate HRQoL measurements at discontinuation were also evaluated. *Results.* Data from all 459 randomized patients were evaluated. Clinically meaningful improvements from baseline were more frequently observed in patients receiving MPR-R than those receiving MP. HRQoL improvements were observed as early as Cycle 4. At Cycle 16, MID was achieved in 5 out of 6 domains (Global Quality-of-Life, Physical Functioning, Fatigue, Pain, and Disease Symptoms) in patients receiving MPR-R while only 2 out of 6 domains (Global Quality-of-Life and Pain) achieved MID in the MP arm. MID improvements were not reported in the MPR arm at Cycle 16 (Table). When compared to baseline, all 48 lenalidomide-related observations (6 induction-related measurements at cycles 4, 7 and 10 for MPR and MPR-R patients plus 2 additional measurements at cycles 13 and 16 for MPR-R patients during lenalidomide maintenance) at a minimum showed preservation of HRQoL across the six domains. *Conclusions.* Lenalidomide is generally well tolerated and when taken continuously, it prolongs progression-free survival in patients with NDMM. MPR-R elicited frequent and often sustained clinically meaningful improvements in patient reported HRQoL from baseline, thus showing a favourable balance between efficacy and HRQoL.

HEALTH RELATED QUALITY OF LIFE INSTRUMENTS FOR USE IN PEOPLE WITH MULTIPLE MYELOMA: A SYSTEMATIC LITERATURE REVIEW

T Osborne,[1] C Ramsenthaler,[1] R Siegert,[1] P Edmonds,[2] S Schey,[2] I Higginson[1]

[1]*King's College London, London, United Kingdom*
[2]*King's College Hospital, London, United Kingdom*

Background. Recent treatment advances in multiple myeloma have improved survival, although a cure remains elusive. Alongside improved survival emerges a need to better understand health related quality of life (HRQOL) across all disease stages and into survivorship. Yet few trials measure HRQOL in myeloma, and there is no consensus regarding the best instruments to use. We conducted two parallel systematic reviews to help address these issues. *Aims.* Review 1: To identify multidimensional HRQOL instruments for use in people with multiple myeloma, and describe their measurement properties. Review 2: To determine the domains of quality of life important to people with multiple myeloma. *Methods.* We conducted systematic literatures reviews searching MEDLINE, PsycINFO, EMBASE, CINAHL, BNI and AMED databases. Search terms were Myeloma OR Haematological Cancer OR Bone Marrow Transplant OR Palliative Care AND Quality of Life OR Patient Reported Outcomes OR Psychometrics OR Test Validity (and synonyms). We ran database searches on 28/9/10 with no limits by date or language, and supplemented these with manual searching of key journals and reference / citation searching of all included articles and relevant review articles. Review 1: Inclusion criteria were 1) any study developing, validating or using a multidimensional HRQOL instrument AND reported some appraisal of that instrument; 2) any study with myeloma specified in the published sample, including mixed haematological, cancer or palliative samples; and 3) studies with all participants over 18 years old at diagnosis. We extracted any psychometric or other appraisal of the HRQOL instruments, including predictive or prognostic properties. Review 2: Inclusion criteria were 1) any study identifying the domains of quality of life important to people with myeloma using methods such as (but not limited to) surveys, focus groups or interviews; 2) studies with samples entirely of myeloma patients; and 3) studies with all participants over 18 years old at diagnosis. *Results.* The database searches indentified 10,650 references. Review 1: 26 studies met the inclusion criteria, containing 10 different HRQOL instruments. Some instruments appeared only once, with the most frequent and extensively validated being the European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30. We report the measurement properties of all included instruments. Review 2: 3 additional studies met the inclusion criteria for Review 2. This highlights the relative lack of published research exploring the issues important to quality of life in this group. *Discussion*. Myeloma patients can often fall within mixed samples used to validate treatment specific instruments (e.g. for use in bone marrow transplant), or 'area' specific instruments (e.g. for use in cancer or palliative groups). Disease specific instruments may not be appropriate in settings such as palliative care, where validation of existing palliative instruments in myeloma patients may be more appropriate. *Summary/Conclusion.* There is a need for more research exploring the domains of HRQOL important to people with myeloma. The lack of such research has implications for the validity of existing HRQOL instruments in this group.

Background. Patient satisfaction is an indicator of quality of care and its assessment provides feed-back to clinicians and to services. Thus it may stimulate improvement initiatives. It is also considered as an outcome measure which allows to assess the superiority of one treatment, program of care, health care organisation or system over another. *Aims.* Deepening the knowledge on multiple myeloma patients' perception of their disease and on the quality of the treatments received. *Method.* A questionnaire, built on the results of a previous study (Pelagalli e al. 2010), contained 44 items, assessing: relationship with physicians; level of satisfaction with current treatments; quality of life; sources of information on the disease; experience of and reaction to the disease; relationship with other patients and family; life styles. The questionnaire was anonymous and self-reported by the patient (Oct-Nov 2010). The

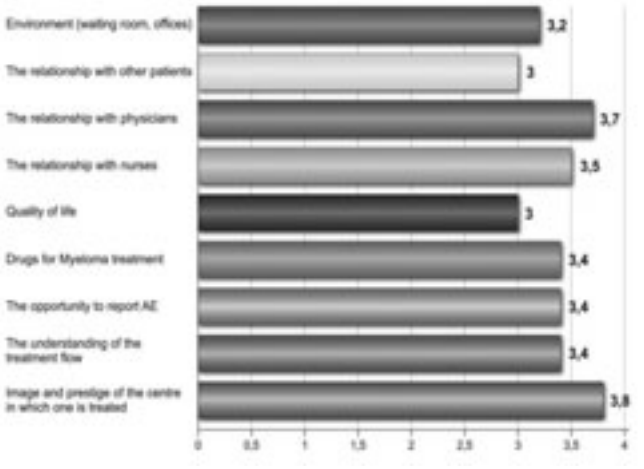

Figure 1.

sample consisted of 482 patients, aged 18"'65 years, treated in 11 Italian Centres, 49% men and 51% women, diagnosed with myeloma between 1982 and 2010. *Results.* Here, we highlight the results on satisfaction for the different components of the 'patient care' process. The questionnaire included a question on the level of satisfaction on 9 elements of the 'patient care' process (environment, relationship with other patients, with physicians, and with nurses, quality of life, drugs, possibility of reporting adverse events, understanding of the treatment flow, image and prestige of the Centre in which the patient is treated). For each item the patient could answer on a 4 point scale (from 1 "not at all satisfied"to 4 "completely satisfied"). The mean score for each item is shown in figure 1. Results highlight an excellent opinion of the Centre in which the patient is treated (mean score 3,8) and satisfaction relies on the relationship with the physician (mean score 3,7). By contrast, satisfaction is lower in the perception of the quality of life (mean score 3) and in the relationship with other patients (mean score 3). Though differences in disease phase among the various treatment groups existed, the survey reported a mean satisfaction score of 3,4 for "drugs for myeloma treatment"and suggested a higher level of satisfaction for oral drugs (thalidomide 3,3; lenalidomide 3,6) rather than intravenous drugs (bortezomib 3,1; chemotherapy 3,2). Comparing "oral"therapies (thal. e len.) vs "intravenous" therapies (bort. e chem.) mean scores, the t-test shows a higher appreciation for oral drugs (p=.0011). *Conclusions.* Patient satisfaction appears to be mainly determined by the quality of the relationship with the physician and with the Centre. Differences on perceived satisfaction between oral and intravenous treatments were also shown. Further studies are needed to confirm these preliminary results.

COST-EFFECTIVENESS OF ZOLEDRONIC ACID VERSUS CLODRONIC ACID AND PAMIDRONIC ACID IN PATIENTS WITH MULTIPLE MYELOMA FROM A CANADIAN HEALTHCARE SYSTEM PERSPECTIVE

T Delea,[1] K El Ougari,[2] J Rotter,[1] S Kaura[3]

[1]*Policy Analysis Inc. (PAI), Brookline, MA, United States of America*
[2]*Novartis Pharmaceuticals Inc., Dorval, Quebec, Canada*
[3]*Novartis Pharmaceuticals Corporation, Florham Park, NJ, United States of America*

Background. The Medical Research Council (MRC) Myeloma IX study demonstrated that the intravenous (IV) bisphosphonate, zoledronic acid (ZOL) 4 mg q 3-4 wk improves overall survival (OS) and progression-free survival (PFS) and reduces the incidence of skeletal related events (SREs) compared with the oral bisphosphonate, clodronic acid (CLO) 1,600 mg/d PO, in patients with newly-diagnosed multiple myeloma (MM) in addition to chemotherapy (CT). Previous analyses have demonstrated the cost-effectiveness of ZOL vs. CLO in this setting. However, in many countries, pamidronic acid (PAM) is the usual alternative to ZOL. *Aims.* To evaluate the cost-effectiveness of ZOL vs. CLO and ZOL vs. PAM in patients with newly-diagnosed MM. *Methods.* An economic model was used to project PFS, OS, the incidence of SREs and adverse events (ARF, ONF, thromboembolism, and infection) as well as expected lifetime healthcare costs for patients with newly-diagnosed MM who are alternatively assumed to received ZOL 4 mg q 3-4 wk, CLO 1,600 mg/d PO, or PAM 90 mg IV q 4 wk x 9 cycles, in addition to CT. Cost-effectiveness was expressed in terms of incremental cost per quality-adjusted life-years (QALYs) gained with ZOL vs. CLO and ZOL vs. PAM. Estimates of OS, PFS, SREs, and incidence of AEs for ZOL and CLO were based on data from the MRC Myeloma IX trial. Hazard ratios (HRs) for SREs and AEs for PAM vs. ZOL were from the Phase III trial of ZOL vs. PAM. HRs for PFS and OS for PAM vs. CLO were from an adjusted indirect comparison of controlled trials of PAM and CLO vs. no bisphosphonate therapy. AEs with PAM were assumed the same as with ZOL. Costs (2009/10 Canadian dollars) and utility values were from published sources. Costs and QALYs were discounted at 5% annually. *Results.* Expected lifetime costs of bisphosphonate therapy (including administration and monitoring costs) were estimated to increase by $13,026 with ZOL vs. CLO ($15,530 vs. $2,504) and by $13,436 with ZOL vs. PAM. Expected costs of SREs were projected to be reduced by $720 with ZOL vs. CLO ($4,152 vs. $4,872) and by $324 with ZOL vs. PAM. Expected total lifetime costs were estimated to increase by $12,923 with ZOL vs. CLO ($32,088 vs. $19,165) and by $2,397 with ZOL vs. PAM. Life expectancy (undiscounted) was increased by 0.83 years with ZOL vs. CLO (6.43 vs. 5.60) and by 0.65 with ZOL vs. PAM. On a discounted basis, QALYs gained were 0.37 with ZOL vs. CLO (3.57 vs. 3.20) and 0.28 with ZOL vs. PAM. Cost per QALY gained was $34,848 with ZOL vs. CLO and $44,272 with ZOL vs. PAM. Results were sensitive to methods used to estimate PFS and OS and the estimated HR for OS with PAM vs. CLO. *Conclusions.* In patients with newly-diagnosed MM, the cost-effectiveness of ZOL vs. CLO and ZOL vs. PAM is substantially below the generally-accepted threshold of $100,000 per QALY gained in Canada. Given this threshold, ZOL should be the preferred bisphosphonate treatment for patients with newly-diagnosed MM in Canada.

0884

IMPROVED PROGRESSION-FREE AND OVERALL SURVIVAL WITH THALIDOMIDE MAINTENANCE THERAPY AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA: A META-ANALYIS OF FIVE RANDOMIZED TRIALS

C Hahn-Ast, M von Lilienfeld-Toal, P van Heteren, S Mückter, P Brossart, A Glasmacher

Universitätsklinikum Bonn, Bonn, Germany

Background. In two randomized studies, lenalidomide maintenance therapy after autologous stem cell transplantation (autoSCT) improved progression-free survival (PFS) but not yet overall survival (OS) in patients with multiple myeloma (MM). For thalidomide, more data are available and meta-analyses have been performed but the effect of maintenance therapy after autoSCT on OS remains unclear (Hicks *et al.* Cancer Treat Rev 2008, Hahn-Ast *et al.* EHA 2010). Recently, new studies or updates of previous data were published. *Aims.* We performed a new meta-analysis to evaluate the influence of thalidomide maintenance on OS in patients with MM after autoSCT. In addition, we also analysed PFS and toxicity. *Methods.* PubMed, the Cochrane Library and conference proceedings from ASH, ASCO, IMW, and EHA were searched using the headings "myeloma"and "thalidomide", lastly in February 2011. Studies were included if they were randomized controlled trials (RCTs) of patients with MM receiving thalidomide maintenance treatment as monotherapy or combination therapy. Data were pooled using the random effects model. Measures of treatment effect were hazard ratios (HR) for survival data and relative risk (RR) for toxicity. When not available from the articles, HRs were estimated using the methods of Parmar *et al.* (Statist Med 1998). *Results.* Five RCTs of thalidomide maintenance therapy after autoSCT reporting survival data were identified (4 published as full papers, one in abstract form). The trials included 2069 patients and compared thalidomide as monotherapy (one trial) or combination therapy (corticosteroids two trials, corticosteroids + interferon one trial, and pamidronate one trial) with interferon (one trial), interferon + dexamethasone (one trial), prednisolone (one trial) or no maintenance (two trials). Dose of thalidomide ranged between 50 and 400 mg/d, but 400mg/d were rarely tolerated.

All trials included only patients with newly diagnosed MM. In two trials thalidomide was also part of the induction regimen. PFS was significantly improved with maintenance thalidomide (HR 0.64, 95%CI 0.55-0.75, p<0.001). The effect was similar in trials with or without prior thalidomide-containing induction treatment. Interestingly, OS was also improved with maintenance thalidomide (HR 0.73, 95%CI 0.60-0.89, p=0.002). In the subgroup of trials with prior thalidomide induction, the effect also reached significance (HR 0.83, 95%CI 0.69-0.99, p=0.04). No significant heterogeneity among all RCTs existed between PFS or OS HRs (I^2=51%, p=0.09 and I^2=34%, p=0.20 respectively). Toxicity was not significantly different between thalidomide and comparators except for grade 3/4 neuropathy (reported in two trials), which was worse with thalidomide (RR 6.97, 95%CI 1.44-33.78, p=0.02). The rate of thromboembolic events (TE) grade 3/4 was reported in four trials. No significant difference was detected, although there was a trend to more thromboembolic events in the thalidomide arm (RR 2.01, 95%CI 0.96-4.23, p=0.07). *Conclusion.* In our meta-analysis we found an improved PFS and for the first time also an improved OS for thalidomide maintenance therapy after autoSCT in patients with MM. This effect was accompanied by a higher rate of grade 3/4 neuropathy whereas the rate of TE was not significantly increased.

IG'KAPPA/ IG'LAMBDA MEASUREMENTS IMPROVE DISEASE MONITORING AND IDENTIFY MINIMAL RESIDUAL DISEASE IN PATIENTS WITH MULTIPLE MYELOMA

H Ludwig,[1] J Faint,[2] D Milosavljevic,[3] N Zojer,[1] A Bradwell,[2] S Harding[2]

[1]*Wilhelminenspital, Vienna, Austria*
[2]*Binding Site Group Ltd, Birmingham, United Kingdom*
[3]*Institute of Laboratory Medicine, Wilhelminenspital, Vienna, Austria*

Background. Currently monoclonal protein measurements are not used to prognosticate multiple myeloma (MM) patients; but they are important tools to assess responses to therapy. Traditional electrophoresis techniques (serum protein electrophoresis (SPE), capillary zone electrophoreses (CZE) and immunofication (IFE) are commonly used but the results generated can be inaccurate depending of the co-migration of the monoclonal protein with other serum proteins. Polyclonal antibodies recognising junctional epitopes between immunoglobulin light chains and their heavy chain partners (heavy/light chain [HLC]) have been developed. *Aim.* To assess the utility of HLC measurements to identify, prognosticate and monitor MM patients. *Methods.* HLC pairs (IgA κ and IgA λ; IgG κ and IgG λ) were retrospectively assessed in serial sera samples from 103 (33 IgGκ / 18 IgGλ and 31 IgAκ / 21 IgAλ) MM patients and results compared to historic markers of disease. *Results.* Patient characteristics were: median age 67 (range 32-94), 37 stage 1, 42 stage 2, 26 stage 3, median follow up was 27 months (0-158) with a median overall survival of 46 months (range 27-66). At presentation HLC ratios (HLCr) were abnormal in all 103 patients. In 36/103 patients (4 IgG and 32 IgA) MM patients with M-protein was not accurately quantifiable by CZE or SPE. Multivariate Cox regression analysis identified β2-M (p=0.01), LDH (p=0.0004) and HLCr (p=0.049) as independent prognostic markers. A risk stratification model based on β2M>3.5mg/L and abnormal HLCr (<0.025 or >40) identified patients with 0, 1, or 2 risk factors and was associated with OS (median survival 131.2 v 53.6 v 29.2 months respectively; p=0.01). Throughout monitoring there was good correlation between percentage change in SPE and percentage change in involved HLC (Pearsons' correlation: IgA= 0.98 [p=0.00001]; IgG=0.9 [p=0.00001]). Following treatment, 13/103 patients (4 IgG /9 IgA) achieved complete response (CR). HLCr remained abnormal in 4/13 patients who achieved CR. In 2/13 patients relapse of the disease was identified by HLCr before IFE (range 71-112 days), suggesting HLCr correctly identified residual disease that is undetectable by IFE. Interestingly, different responses were seen between FLC and HLC measurements in 3/103 patients: 1/3 patients relapsed with a FLC producing clone that was not identified using either IFE or HLC; in 2/3 patients FLC levels and ratios normalised at maximum response. In both cases the patients relapse was characterised by a clone producing only intact immunoglobulin. *Conclusion.* HLCr can detect hard to quantify IgA and IgG and low levels of both IgA and IgG paraproteins, indicate persistent disease in IF negative patients, depict relapse earlier than IFE, and can provide prognostic information.

0886

THE COMBINATION OF THE PROTEASOME INHIBITOR BORTEZOMIB WITH DOXORUBICIN AND DEXAMETHASONE (PAD REGIMEN) IS EFFECTIVE IN REVERSING RENAL IMPAIRMENT IN NEWLY-DIAGNOSED HIGH-RISK MULTIPLE MYELOMA

K Liapis,[1] F Panitsas,[1] S Delimpasi,[1] I Baltathakis,[1] E Terpos,[2] E Kastritis,[2] A Christoforidou,[3] A Pouli,[4] K Tsatalas,[3] MA Dimopoulos,[2] N Harhalakis[1]

[4]*Department of Hematology, Aghios Savvas Hospital, Athens, Greece*

Renal impairment (RI) due to light-chain induced nephropathy is a common presenting feature of multiple myeloma (MM), and is associated with increased morbidity and inferior survival. Reversion of RI is therefore essential for the management of MM. Among novel agents, bortezomib has shown promising efficacy in this context due to its an-

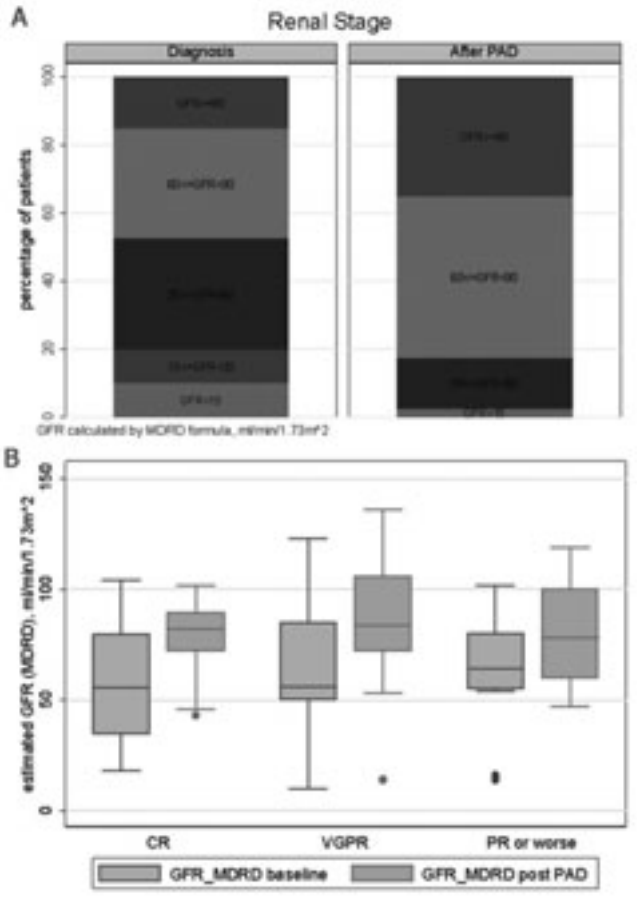

Figure 1. A. Renal stage change. B. GFR vs myeloma response.

timyeloma and anti-inflammatory effects. We examined the impact of treatment on renal function in a group of patients with high-risk MM, who received upfront therapy with a bortezomib-based regimen in a prospective phase II study. The study group consisted of 40 patients, aged 41-70 (median, 59) years, with newly diagnosed MM with high-risk features (ISS stage II/III by serum albumin and beta2-microglobulin, and/or detection of 13q deletion by karyotype or FISH). The treatment protocol included 4 cycles of the PAD regimen, i.e. the combination of bortezomib (1.3 mg/m^2 on days 1, 4, 8, and 11), doxorubicin (9 mg/m^2 on days 1-4), and dexamethasone (40 mg on days 1-4 and 8-11), administered every 21 days. Tumor response was assessed at the end of induction with PAD by the International Myeloma Working Group (IMWG) uniform response criteria (2006). Renal function was assessed at diagnosis and at the end of treatment with PAD by the estimated glomerular filtration rate (eGFR) using the Modification of Diet in Renal Disease (MDRD) study equation. Stage of RI was classified from 1 to 5 for eGFR values of ≥90, 60-89, 30-59, 15-29, and <15 ml/min/1.73 m^2, respectively. For the subgroup of patients with eGFR <50 at diagnosis, renal response to antimyeloma therapy was defined as complete (CRrenal), partial (PRrenal), or minor (MRrenal) according to the IMWG criteria (2010). All patients completed the 4 cycles of PAD, with the exception of one who died of pneumonia during the 2nd cycle. The overall myeloma response rate was 95%. Complete or very good partial remission (CR+VGPR) was achieved in 27/39 (69.2%), and partial remission (PR) in 10/39 (25.5%). At diagnosis, RI was mild (eGFR, 60-89) in 13/40, moderate (eGFR, 30-59) in 13/40, severe (eGFR, 15-29) in 4/40, and end-stage (eGFR <15) in 4/40 patients. ISS stage III, lambda light chain isotype, and high serum concentration of the involved free light chain were independent risk factors for higher stage of RI (p=0.018, 0.012, and 0.028, respectively). After the 4 cycles of PAD, a significant increase in eGFR was observed in comparison with baseline eGFR (median, 83 vs. 59 ml/min/1.73 m^2, respectively; p<10^{-5}), and an improvement in the stage of RI was documented in 25/39 (64%) patients. Improvement in renal function was seen irrespective of the type of myeloma response (CR vs. VGPR vs. PR or worse, p=0.79). Among the 11 patients with pre-treatment eGFR <50, CRrenal was achieved in 4 (36%), PRrenal in 2 (18%), and MRrenal in 2 (18%). In conclusion, induction with bortezomib in combination to doxorubicin and dexamethasone resulted in overall improvement in renal function in patients with high-risk MM. Moreover, meaningful renal responses were achieved in more than half of patients with moderate to severe RI.

TRENDS AND OUTCOMES OF MODERN STAGING OF SOLITARY PLASMACYTOMA OF BONE

R Warsame, M Gertz, M Lacy, R Kyle, F Buadi, D Dingli, P Greipp, S Hayman, S Kumar, J Lust, K Short, S Rajkumar, S Russell, T Witzig, J Mikhael, S Zeldenrust, A Dispenzieri

Mayo Clinic, Rochester, United States of America

Background. Solitary plasmacytoma of bone (SPB) is a rare localized plasma cell dyscrasia (PCD) with no evidence of systemic disease. The majority of patients with SPB progress to multiple myeloma with a median disease free survival of five to ten years. *Aims.* Our hypothesis proposed that the low rate of cure of SPB is in part due to inadequate clinical staging, i.e. occult bone or bone marrow involvement. *Method.* A retrospective analysis of 127 Mayo Clinic patients with a diagnosis of SPB seen between 2000 and 2010 was performed. The trends in imaging techniques (magnetic resonance imaging, computed tomography, and nuclear medicine imaging), immunohistochemisty and flow cytometry were evaluated. Inclusion criteria were 1) patients with biopsy proven plasmacytoma; 2) patients with no evidence of systemic disease on skeletal survey; and 3) patients with fewer than 10% plasma cells on bone marrow biopsy. Patients with any form of systemic disease defined as anemia, hypercalcemia or renal injury related to plasma cell dyscrasias were excluded. Overall survival was calculated using the Kaplan-Meier method. *Results.* There was significant increase in the use of CT-PET (p=0.002) and flow cytometry (p=0.005) for initial staging of SPB in the latter half of the decade. Overall survival (follow up months vs. proportion surviving) was significantly improved in the latter five years, p=0.05. *Conclusion.* These data suggest that more optimistic estimates of overall survival may be appropriate for patients with SPB in the modern era when more advanced staging and selective application of the term SPB is employed.

CIRCULATING PLASMA CELLS (CPCS) PREDICT THE OUTCOME OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RR MM)

V Peceliunas, A Janiulioniene, R Matuzeviciene, T Zvirblis, L Griskevicius

Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania

Background. Pretreatment detection of peripheral blood malignant CPCs by immuophenotyping has been shown to be of negative prognostic value in MM and related disorders. The number of CPCs tends to decrease in response to treatment. We hypothesized that assessment of CPC kinetics in response to one therapy cycle may be of prognostic significance and could be helpful in the early detection of MM refractoriness to treatment. *Aims.* The aims of our study were to assess the prognostic significance of pretreatment values of normal and aberrant CPC subsets as well as the prognostic significance of CPC kinetics in response to the first treatment cycle in RR

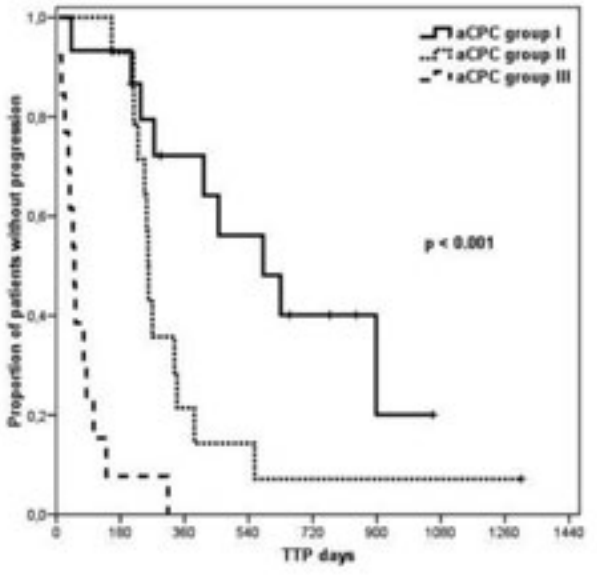

Figure 1.

MM. *Methods.* Patients were prospectively included if they had RR MM according to EBMT criteria after at least one prior line of therapy and were scheduled to receive either a Bortezomib containing regimen or VAD (vincristin, doxorubicin and dexamethasone). All patients provided informed consent. We used six-color flow cytometry to identify immunophenotypically normal (nCPC) and aberrant plasma cell (aCPC) subsets in peripheral blood (PB). Assays were performed with two tubes stained with antibody combinations: CD56/CD138/CD45/CD19/CD38/CD20 and cLambda/cKappa/CD138/CD19/CD38/CD56. Plasma cells were identified as normal (nCPCs) if they were CD138+/CD38+/CD19+/CD56-/normal kappa/lambda ratio/CD45 variable or aberrant (aCPCs) if they displayed CD138+/CD38+/CD19-/CD56+/-/abnormal kappa/lambda ratio/CD45 variable. We measured aCPC and nCPC subsets immediately before and then after one therapy cycle in RR MM patients. *Results.* 42 patients with refractory or relapsed (RR) MM were enrolled. 39 patients were treated with bortezomib containing regimen, three patients received VAD. After the median observation time of 21 month (1-49), patients with detectable pretreatment aCPCs had shorter time to progression (TTP) compared to patients with undetectable aCPCs (median 218 vs. 456 days, respectively (p=0.008)). Median TTP of 51 day and median overall survival (OS) of 308 days was shortest in patients whose aCPCs did not decrease after one therapy cycle compared to patients with decreasing (median TTP 258 days and OS 856 days) or undetectable (median TTP 581 days and OS 1006 days) aCPCs ($p < 0.001$ and $p = 0.007$ for TTP and OS, respectively). aCPC2/aCPC1 ratio of 0.8 could predict early progression with the sensitivity of 100% and the specificity of 93.8% in patients with detectable aCPC. *Conclusions.* Detection of aCPCs in PB before treatment may identify patients with more aggressive disease. Nonreduction of aCPCs in RR MM patients after the first cycle of therapy may be useful to identify resistant patients early who may be candidates for immediate switch to alternative therapy. Figure 1 Time to tumor progression in three aCPC kinetic groups: group I - patients with no detectable aCPCs in both pre and postchemotherapy samples, group II - patients with a decrease in aCPCs postchemotherapy as compared to aCPCs before chemotherapy, group III - patients with no change or increase in aCPCs postchemotherapy as compared to aCPCs before chemotherapy.

0889

PROGNOSIS OF MULTIPLE MYELOMA (MM) PATIENTS AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN THE LAST DECADE. COMPARISON OF TWO COHORTS WITH DIFFERENT INDUCTION TREATMENT APPROACHES

A Oriol,[1] JM Ribera,[1] M Batlle,[1] I Llombart,[1] C Motllar[1] Y Gonzalez,[2] S Vives,[1] C Ferrà,[1] B Xicoy,[1] JM Sancho[1]

[1]*ICO-Hosp Germans Trias i Pujol, Badalona, Spain*
[2]*ICO-Hosp Josep Trueta, Girona, Spain*

Background. The incorporation of bortezomib and IMIDs to MM treatment has improved substantially improved pre-SCT overall and complete remission (CR) rates in candidates to SCT. However, post-SCT results have not dramatically improved and disease-free survival (DFS) is only marginally superior. In available randomized trials, overall survival (OS) appears to be the same regardless of the first line pre-SCT induction treatment administered. *Aims.* Compare the outcome in terms of survival of two cohorts of patients with newly diagnosed MM and treated with different induction strategies. *Patients and Methods.* Data of two cohorts of patients with a newly diagnosed MM, treated in a single centre and submitted to ASCT in first response were collected. The first cohort (C1: 1999-2005) received dexamethasone, alkylanting agents and anthracyclin-based induction before ASCT and bortezomib and/or IMIDs at relapse. The second cohort (C2: 2005-2009) received IMIDs and/or bortezomib first line and was submitted to ASCT in first response and were treated at relapse with the same or alternative drugs. All patients had at least one year follow-up after ASCT. Post-ASCT CR rates, time to progression (TTP), event-free survival (EFS), time to next treatment (TNT) and OS were determined for both cohorts to compare their outcomes. *Results.* Out of 141 potential ASCT candidates diagnosed during both periods, 88 received an ASCT after induction (N=49 in C1 and N=39 in C2). Their median age was 58 years (range 32-68). Both cohorts were comparable in terms of gender, age, type of myeloma and stage. Median time from diagnosis to ASCT was 34 weeks (range 14-80 weeks) without significant differences between cohorts. Post-SCT CR rates were 35% for C1 and 61% for C2 (p=0.025). During the first year post-ASCT 6 patients died due to toxicity or infection (12%), 3 relapsed (6%) and 1 died of unrelated causes among 49 patients at risk in C1, during the same period, 1 patient died due to progression (2%) among 39 patients at risk in C2. During the second year post-ASCT 1 patient died due to toxicity or infection (2%) and 3 relapsed (8%) among 38 patients at risk in C1, while during the same period, no events were recorded among 36 patients at risk in C2. During the first year after SCT, both the probability of death of any cause (p=0.012) and the probability of infectious or toxic death (p=0.025) were significantly higher for C1. Differences in outcome, after a median follow-up of 6 years for C1 and 3 years for C2, are reflected in the following table. The projected post-ASCT for C2 at 4 years was 83% (95%CI 68-98%). *Conclusion.* In our experience, patients with MM who received chemotherapy as first line induction presented an increased risk of death due to infections or toxicity during the first year post-ASCT compared with those receiving bortezomib or thalidomide first line. Post-ASCT CR rate and survival of patients were superior for the cohort of patients treated with bortezomib or thalidomide as pre-ASCT induction.

Table 1.

	Cohort 1		Cohort 2		
	Median (years)	95% CI	Median (years)	95% CI	p-value
TTP	2	1.5-2.7	3.4	1.8-5	0.243
EFS	1.8	1.1-2.4	3.4	1.8-5.1	0.049
TNT	1.9	1.3-2.4	3.6	2.3-4.9	0.034
OS	4.1	1.1-7	NA*	NA*	0.02
			*projected post-ASCT for C2 at 4 years was 83% (95%CI 68-98%).

Background. Carfilzomib, a novel, highly selective epoxyketone proteasome inhibitor, has demonstrated single-agent activity in patients

Table 1.

Linear Regression of PK Parameters as a Function of Creatinine Clearance

Parameter	n	Slope (95% CI)	p-Value for Slope
Carfilzomib clearance (L/h)	19	-0.607 (-2.129, 0.914)	0.4114
C_{max} (ng/mL)	27	0.225 (-0.242, 0.692)	0.3299
AUC_{last} (hr·ng/mL)	27	0.008 (-0.031, 0.048)	0.6635
AUC_{inf}	19	0.012 (-0.030, 0.054)	0.5496

C_{max}, peak plasma concentration; AUC_{last}, exposure based on first and last plasma measurements; AUC_{inf}, exposure extrapolated to infinity

with relapsed and/or refractory multiple myeloma (MM) with an acceptable safety and tolerability profile. Renal insufficiency, a common and often progressive complication of MM, is known to impact the pharmacokinetic (PK) behavior of multiple drugs, potentially affecting tolerability and toxicity and necessitating dosing modification. *Aims.* This study examined the impact of renal dysfunction on the PK parameters, safety, and activity of carfilzomib in patients with relapsed and/or refractory MM. *Methods.* Patients with relapsed, refractory, and/or progressing MM, treated with ≥2 prior regimens, were eligible to participate in this phase 2 open-label, multicenter study. Creatinine clearance (CrCl) was used to categorize normal (CrCl >80 mL/min), mild (CrCl 50-80 mL/min), moderate (30-49 mL/min), and severe (<30 mL/min) renal dysfunction, including patients receiving hemodialysis. Carfilzomib was administered by slow intravenous push (≤10 min) on days 1, 2, 8, 9, 15, and 16 of a 28-day cycle (15 mg/m^2 in cycle 1, 20 mg/m^2 in cycle 2, and 27 mg/m^2 in subsequent cycles, based on safety and tolerability). Patients achieving stable disease or better (IMWG criteria) after 2 cycles could continue to receive carfilzomib for a total of ≤12 cycles. Dexamethasone 40 mg/wk could be added to the regimen after cycle 3. The primary endpoint was the influence of renal function on carfilzomib. PK parameters of peak and total carfilzomib exposure were compared between patients with varying degrees of renal dysfunction. Adverse events (AEs) and serious AEs were monitored and graded by NCI CTCAE v3.0 standards. In the event of a reversible AE, carfilzomib dose could be reduced to the previous level. Best overall response (≥PR), response duration (DOR), and time to progression by IMWG criteria were also assessed. *Results.* At baseline, 12 patients had normal renal function, 30 had renal insufficiency of varying degrees (12 mild, 10 moderate, and 8 severe), and 8 were on chronic hemodialysis. As of November 2010, patients received a median of 21.5 doses of carfilzomib (4-72); with mean doses per administration consistent across groups (14.3-25.3 mg/m^2). Renal function did not appear to affect carfilzomib clearance, peak exposure, or total exposure, even with age/weight included as covariates (Table). There were no significant differences in PK parameters between cohorts. The frequency and grade of AEs did not differ among groups. The most common AEs (≥10%, grade 3/4) were anemia, thrombocytopenia, lymphopenia, fatigue, pneumonia, and pain. Serious AEs occurred in 33 patients. Notably, in these heavily pretreated patients, ORR was 21.3%. Six patients were treated with carfilzomib for more than a year by continuing on extension protocol PX-171-010. Two patients on chronic hemodialysis improved their renal function, no longer needing dialysis treatment. *Conclusions.* Renal impairment had no observed effect on the PK and safety profiles of carfilzomib and should not necessitate a change in carfilzomib dose or treatment schedule. AEs in this population were manageable and comparable to those seen in other studies with carfilzomib in MM.

Background. Multiple myeloma is a malignant plasma cell disorder. It is the second most frequent haematological malignancy and characterized by malignant plasma infiltration of the bone marrow and is associated with an increased level of monoclonal protein in the blood and/or urine. The treatment of multiple myeloma (MM) has undergone significant developments in recent years. The development of new agents with potent anti-tumor activity has considerably improved the survival of MM patients. Bortezomib has been investigated as part of a number of different induction regimens. A randomized phase III study by the French Myeloma Study Group (Intergroupe Francophone du Myélome [IFM]) examined the combination of bortezomib plus dexamethasone and found this to be significantly superior to the comparator arm, which consisted of VAD, with respect to response rates postinduction and post-transplant, as well as the 2-year PFS rate. A number of bortezomib induction regimens are now available. The results of the IFM trial indicate that the combination of bortezomib and dexamethasone is an appropriate regimen that is superior to the traditional VAD regimen. *Aim.* Evaluation of the effect and safety of combination of bortezomib, doxorubicin and dexamethasone (PAD) in the treatment of relapsed/ refractory myeloma patients in the retrospective analysis. *Patients and Methods.* 101 patients were treated for median of four 28-day PAD cycles (1-8). Bortezomib was given at 1.3 mg/m2 (days 1, 4, 8,11), doxorubicin at 9 mg/m2 (days 1-4) and dexamethasone 20 mg po (days 1-4, 8-11). *Results.* 101 patients were evaluable for efficacy and safety, 63.2% had refractory disease and 36.8% were relapsed. The median age was 60 years (41-78), 45.5% were male, 54.5% female. Median time from diagnosis was 12 months (1-139) and median number of prior therapy lines was 1 (1-4): 90.9% had undergone thalidomide-base regimen, 9.1% conventional chemotherapy and 23.9% were autografted. Overall response rate of 77.4% was observed, 32.8% of patients achieved a complete response (CR), 19.8% a very good partial response(VGPR), 24.8% a partial response (PR). Stable disease (SD) was observed in 15.8%. After PAD 42.9% of patients were autografted. The median progression free survival (PFS) was 19.3 months. The probability of 2-years overall survival (OS) was 68.7% and the median of OS was not reached. The most common grade 3-4 toxic effects were neutropenia 14%, thrombocytopenia 15%, anemia 4.3%, infections 5.4%, peripheral neuropathy 4.3% and gastrointestinal disturbances 2.1%. One toxic death (1.1%) due to sepsis was noted. *Conclusion.* The combination of bortezomib, doxorubicin and dexamethasone (PAD) is well tolerated and induced clinically significant responses and prolonged remission duration in patients with relapsed and refractory MM .

0892

OVERALL SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION: RELATION WITH KINETICS OF NEUTROPHIL AND PLATELET RECOVERY

C Fernández de Larrea, L Rosiñol, N Tovar, MT Cibeira, F Fernández-Avilés, C Martínez, P Marín, M Rovira, A Urbano, J Bladé

Hospital Clínic, Barcelona, Spain

Background. Autologous stem cell transplantation (ASCT) is the gold standard as first-line treatment in young patients with multiple myeloma (MM). Prognostic factors have been usually related to patient characteristic and disease stage. Few investigations on the impact of

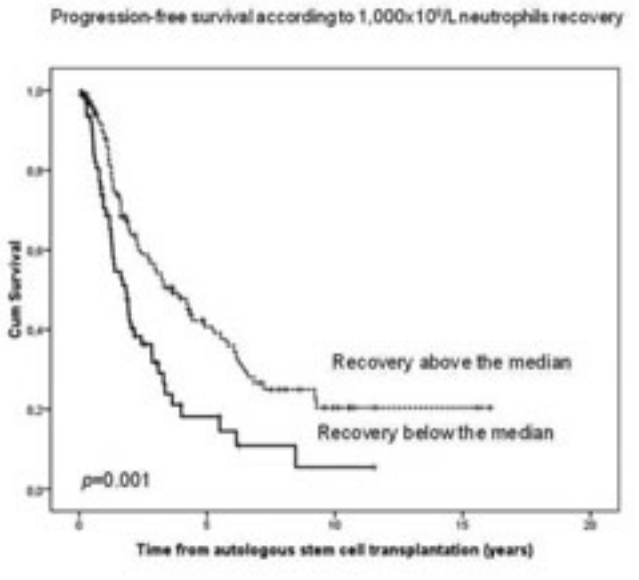

Figure 1.

platelet and neutrophil recovery after ASCT have been addressed. The *aim* of this study was to investigate the prognostic influence of the kinetics of peripheral blood recovery on progression-free survival (PFS) and overall survival (OS) after ASCT. *Patients and Methods.* One hundred and ninety one patients (109M/82F; median age 55 years) underwent melphalan-based ASCT in our institution from 1994 to 2010. The median follow-up after ASCT was 4 years (range 4 months to 17 years). Peripheral blood recovery was assessed as the day when the neutrophils reached 500 (N500) and 1000x109/L (N1000) and platelet count 20,000 (P20) and 50,000x109/L (P50) after CD34+ infusion. Patients were classified in two groups according their recovery above or below the median. *Results.* N1000 (Figure), P20 and P50 predicted for a longer OS ($p<0.05$). No significant association with the number of infused CD34 cells was observed. PFS was also correlated with N1000 (Figure) ($p=0.001$) and there was a trend for N500 ($p=0.053$), with no impact of P20 and P50. In Cox multivariate regression analysis, including age, international staging system and immunoglobulin isotype, N1000 remained at significant level for PFS ($p=0.02$), and there was a trend for OS ($p=0.09$). Finally, a stratification model showed 3 prognostic stages according to the achievement of complete remission and early N1000 after ASCT ($p<0.001$). *Conclusion.* Early neutrophil recovery was associated with significantly longer PFS and OS, while platelet recovery was only associated with OS.

0893

REAL LIFE HIGH DOSE TREATED PATIENTS BENEFITS FROM NOVEL AGENTS

H Nahi,[1] J Liwing,[2] K Uttervall,[1] J Andreasson,[3] P Näsman,[4] A Gruber,[1] J Aschan[2]

[1]*Karolinska, Stockholm, Sweden*
[2]*Janssen AB, Sollentuna, Sweden*
[3]*Södersjukhuset, Stockholm, Sweden*
[4]*Center for Safety Reserach, KTH, Stockholm, Sweden*

Background. Treatment results in clinical practice and in real life can be different from each other. Therefore, evaluating real life outcomes of high dose treated (HDT) Multiple Myeloma (MM) patients in order to understand what is effective treatment in clinical practice is very important. *Aim.* Evaluate real life responses, time to progression (TTP), time to next therapy (TTNT) and overall survival (OS) and prognostic power of patient variables in real life HDT MM patients. *Methods.* All HDT patients, n=214, with MM between Jan 2000 and Jul 2010 at Karolinska Huddinge and between Jan 2005 and Jul 2010 at Karolinska Solna were included. Near complete response (nCR) was defined as an immeasurable M-protein by standard electrophoresis. Very good partial response (VGPR), partial response (PR), no response (NR) and TTP were defined according to IMW criteria. Standard statistical methods were used. *Results.* The median age was 58 years with 66% male. Baseline creatinine was 89 µmol/L, albumin 34 g/L, hemoglobin 110 g/L and β2-microglobulin 2.9 mg/l. The median number of treatment lines was 2. 53% of the patients were given at least 2 treatment lines and only 36% 3 or more. The most common 1st line treatment was VAD + HDT (43%). The response distribution nCR/VGPR/PR/NR was 51/23/15/11 in 1st line, 28/17/22/33 in 2nd line. nCR in the 1st line implied a 48% probability to receive a ≥VGPR and 35% probability to receive an nCR in 2nd line. NR in the 1st line implied a 25% probability to receive a NR in the 2nd line. Logistic regression analysis shows that the patients receiving novel agents (Bortezomib, Lenalidomide, Thalidomide) in 1st line had a higher probability of achieving nCR. Baseline creatinine values seem to be of importance for the response and most likely Hb and albumin as well. The median TTP/TTNT was 538/639 days in the 1st line 210/257 in 2nd line and 186/212 in 3rd line. There was a significant trend of increasing TTP/TTNT in 1st line depending on the increased depth of the response with TTP/TTNT for nCR of 706/879 days, VGPR 511/533 days, PR 393/536 days and NR 58/63. Median OS was 6.3 years 95% CI [5.3;8.5] with 74% censored. Patients receiving an nCR in 1st line had a median OS of 6.9 years. There is a correlation between TTP in the 1st line and increased OS. *Summary.* HDT patients receiving 2nd and 3rd line treatment were declining rapidly. To get a good response in 1st line increases the likelihood of having a good response in 2nd line. Receiving an nCR in 1st line seems to be very important. Receiving a VGPR or PR seems to give similar results, less good than nCR but better the NR. Variables of importance are creatinine, albumin and hemoglobin. The use of novel agents improves response in 1st line.

0894

VORINOSTAT PLUS BORTEZOMIB COMBINATION THERAPY IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: VANTAGE STUDY PROGRAM UPDATE

MA Dimopoulos,[1] D Siegel,[2] S Jagannath,[3] R Hajek,[4] S Yoon,[5] S Lonial,[6] JP Laubach,[7] T Graef,[8] J Houp,[8] L Lupinacci,[8] K Anderson[7]

[6]*Winship Cancer Institute, Emory University School of Medicine, Atlanta, United States of America*
[7]*Dana-Farber Cancer Institute, Boston, United States of America*
[8]*Merck Research Laboratories, Upper Gwynedd, United States of America*

Background. Vorinostat is an oral multi-histone deacetylase inhibitor approved for treatment of patients with cutaneous T-cell lymphoma who have progressive, persistent, or recurrent disease following 2 prior systemic therapies. Vorinostat regulates genes and proteins involved in tumor growth and survival. The synergistic effects of vorinostat and bortezomib have been shown in preclinical studies and confirmed in phase I trials in patients with relapsed/refractory multiple myeloma (MM), producing objective response rates (ORRs) of up to 42% and overall clinical benefit of up to 90%. *Aims.* To provide an enrollment update and demographic data for patients with relapsed/refractory MM participating in the Vantage clinical trial program. *Methods.* Vantage 088 is a global, phase III, randomized, double-blind study investigating bortezomib plus vorinostat or placebo in patients with relapsed MM and progressive disease after 1-3 prior regimens. The primary objective is determination of progression-free survival; secondary objectives include assessment of safety, overall survival, time to progression, and ORR. Vantage 095 is a phase IIB open-label study of vorinostat plus bortezomib in bortezomib-refractory patients with relapsed/refractory MM who had received ≥2 prior antimyeloma regimens and were relapsed, refractory to, intolerant of, or ineligible for other MM therapies, including immunomodulatory drugs. The primary objective is to determine the ORR. In both studies, patients receive 21-day cycles of bortezomib (1.3 mg/m^2 IV; days 1, 4, 8, and 11) plus oral vorinostat 400 mg/day (or matching placebo in Vantage 088) on days 1-14. Efficacy is assessed by European Bone and Marrow Transplantation Group criteria. Adverse events, including clinical and laboratory events are assessed and recorded using the National Cancer Institute Common Terminology Criteria for Adverse Events (version 3.0). All patients in both studies gave written informed consent prior to enrollment. *Results.* Both trials have been fully enrolled (Vantage 088 in January 2011; Vantage 095 in October 2010). As of February 10, 2011, 185 of 637 patients in Vantage 088 and 15 of 143 patients in Vantage 095 were still on active study therapy. Vantage

088: The median patient age is 62 years (range, 29-86 y), 59% of patients are male, and 56% are white. Patients had received a median of 2 prior regimens (range, 1-3), 23% had previously received bortezomib, and 35% had received a prior autologous transplant. Vantage 095: The median age of the patient population is 63 years (range, 37-81 y), 61% of patients are male, and 71% are white. Patients had received a median of 4 prior regimens (range, 2-17), all had received prior bortezomib, and 74% had received a prior autologous transplant. Both trials have passed protocol-specified futility analyses by the independent data monitoring committee. *Conclusions.* Two ongoing global, multicenter, investigational trials of vorinostat plus bortezomib in patients with relapsed/refractory MM have completed enrollment, with final results expected in 3Q2011.

0895

A PHASE I STUDY OF BHQ880, A NOVEL OSTEOBLAST ACTIVATING, ANTI-DKK1 HUMAN MAB, IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA PATIENTS TREATED WITH ZOLEDRONIC ACID AND ANTI-MYELOMA THERAPY

S Padmanabhan,[1] J Beck,[2] A Stewart,[3] J Shah,[4] K Kelly,[1] K Anderson,[5] S Bilic,[6] LM Chiang,[6] S Chica,[6] R Isaacs,[6] M Li,[6] P Savage,[6] M Song,[6] N Munshi[5]

Background. DKK1, a negative regulator of the Wnt signalling pathway, is overexpressed in multiple myeloma (MM) patients with osteolytic lesions. BHQ880 is a novel human mAb that neutralises DKK1, resulting in activation of the Wnt signalling pathway, leading to upregulation of osteoblasts and increased bone mass. Although both osteoclast activation and osteoblast inhibition contribute to lytic bone disease in MM, approved treatment options, such as bisphosphonates, are focused on inhibiting osteoclast function. Therefore, dual therapy with zoledronic acid (Zol) to decrease bone resorption and BHQ880 to increase new bone formation may provide an effective treatment strategy for MM bone disease. *Aims.* Determine the maximum-tolerated dose and characterize dose-limiting toxicity of escalating BHQ880 doses in combination with MM therapy and Zol. Evaluate bone-related effects of this treatment. *Methods.* Patients with relapsed/refractory MM with prior skeletal-related event/s were treated with IV BHQ880 q28 days. Patients also received Zol 4 mg and approved MM therapy (excluding bortezomib). Bone markers and serum DKK1 levels, along with BMD via DXA, were measured. Full PK profiles were obtained for the first and second cycles, after which predose samples were collected to assess accumulation. *Results.* Twenty eight patients (18:M;10:F), with a median age of 60 years (range: 38-79 years), PS 0 (n=12), 1 (n=13), or 2 (n=3) were enrolled at dose levels (mg/kg) 3 (n=5), 10 (n=10), 20 (n=7), or 40 (n=6). Sixteen patients received >6 cycles, 12 received >12 cycles, 9 patients ongoing (maximum 21 cycles). No BHQ880-related SAEs have been reported. No MTD was defined. One grade 3 neutropenia was observed in a patient with a history of pancytopenia receiving filgrastim; other toxicities, hypertension, bone pain, muscle spasm, chills, dysgeusia, alopecia, insomnia, cough, congestion and hirsutism were all grade 1. BMD data available from 21 patients showed a >6% increase from baseline in seven (33%) patients. Positive changes in BMD were noted across all dose cohorts, with positive slopes exceeding those with static or negative change. Bone marker changes with serial sampling at least until the end of cycle 2 were analysed in 24/28 patients; 10/24 patients showed a decrease in uNTx of >50%, and 3/24 patients showed a pattern suggestive of sustained increase in PINP and osteocalcin. Baseline free DKK1 levels from 28 patients ranged from ≤0.3 to 13.7 ng/mL. PK is available from 28 patients. Despite nonlinear pharmacokinetics, due to target mediated drug disposition, dose proportional increases in partial $AUC_{0\text{-}672\ h}$ and C_{max} were observed with doses of ≥10 mg/kg, suggesting saturation of DKK1. After second infusion, mean $t_{½}$ from doses 3, 10, 20 and 40 mg/kg ranged between 10.3-16.9 days. *Conclusions.* At doses up to 40 mg/kg, IV BHQ880 q28 days appears to be well tolerated in combination with Zol and chosen MM therapy. Recommended Phase II dose of 10 mg/kg is supported with current data predicting maximal saturation and suppression of DKK1. BMD changes > 6% from baseline in 33% of patients and changes in bone markers in this patient population suggest a potential anabolic effect.

0896

AN OPEN-LABEL, PHASE 1/2 TRIAL OF BENDAMUSTINE PLUS BORTEZOMIB IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA

R Berenson,[1] O Yellin,[2] A Bessudo,[3] R Boccia,[4] S Noga,[5] D Gravenor,[6] D Patel-Donnelly,[7] R Siegel,[8] T Kewalramani,[9] E Gorak,[10] R Swift,[1] D Bensen-Kennedy[11]

Background. Although significant improvements in the understanding and treatment of multiple myeloma (MM) have been realized over the last decade, MM remains an incurable disease, and novel, effective treatment combinations are needed for patients with relapsed or refractory disease. Bendamustine, approved in Europe for the treatment of MM, is an akylating agent with a multifaceted mechanism of action. Bortezomib is a proteasome inhibitor approved for the treatment of MM that has demonstrated efficacy in combination with alkylators (e.g., melphalan and cyclophosphamide). *Aims.* To assess the efficacy and safety of bendamustine plus bortezomib in patients with relapsed or refractory MM. *Methods.* This open-label, phase 1/2 study enrolled patients ≥18 years, with measurable, relapsed or refractory MM; patients were required to provide informed consent. Escalating doses of bendamustine IV at 50, 70, or 90 mg/m^2 (days 1 and 4) plus bortezomib at a fixed dose of 1.0 mg/m^2 (days 1, 4, 8, and 11) were administered for up to eight 28-day cycles. Dose-limiting toxicity (DLT) was assessed after cycle 1. A standard 3+3 approach was used to determine the maximum tolerated dose (MTD). The MTD cohort was expanded until a total enrollment of 40 patients was reached. Study endpoints included response, duration of response (DOR), time to progression (TTP), and safety. *Results.* Thirty-eight patients (median age, 67; range, 43-89) received study drug and were included in the analysis. Patients received a median of 3.5 (range, 1-21) prior therapies, including bortezomib in 71% and alkylators in 68%. A median of 3 treatment cycles (range, 1-9) were administered; study treatment remains ongoing in 14 patients (median cycles to date: 4 [range, 1-7]). No DLT was observed in phase 1 and the MTD was not reached; thus, the maximum dose (90 mg/m^2) of bendamustine plus bortezomib 1.0 mg/m^2 was studied in phase 2. Grade 3/4 adverse events that occurred in ≥10% of patients were neutropenia (13 patients [34%]), thrombocytopenia (7 [21%]), and anemia (4 [11%]). Grade 3/4 infection was reported in 3 patients (8%) and grade 3 renal failure in 2 patients (5%). No grade 3/4 peripheral neuropathy (PN) was observed; grade 1/2 PN was reported in 10 patients (26%), but 8 of these had grade 1/2 PN at baseline. Among 36 evaluable patients, the objective response rate (ORR) was 47%, including 1 very good partial response, 6 partial responses, and 10 minimal responses. An additional 17 patients had stable disease for a clinical benefit rate of 94%. In patients who received bendamustine at the 90 mg/m^2 dose (n = 27), the ORR was 52%. In patients previously treated with bortezomib (n = 27) or alkylators (n = 26), the ORR was 37% and 40%, respectively. Median DOR and TTP have not been reached. *Conclusions.* The combination of bendamustine 90 mg/m^2 on days 1 and 4 plus bortezomib 1.0 mg/m^2 on days 1, 4, 8, and 11 is well tolerated and demonstrates promising efficacy in heavily pretreated patients with MM.

A SYSTEMATIC REVIEW ON THE USE OF BORTEZOMIB IN MULTIPLE MYELOMA PATIENTS WITH RENAL IMPAIRMENT: WHAT IS THE PUBLISHED EVIDENCE?

E Piro, R Levato, R Cantaffa, M Kropp, D Magro, S Molica

Dipartimento di Oncoematologia Azienda Ospedaliera Pugliese Ciaccio Catanzaro, Catanzaro, Italy

Background and Aims. A systematic and comprehensive search of the literature was performed using MEDLINE databases from 1978 to 1st December 2010 and hand search of references. We used the following Medical Subject Headings (MESH) to identify potential studies: 'myeloma renal failure' (hits1225) and 'bortezomib' (hits 2554). An additional search performed by combining the MESH terms 'myeloma renal failure' and 'bortezomib' yielded 50 citations. Five additional case-control studies judged relevant for the purpose of study were also included. *Methods.* In total, 6 case reports, 9 cases series, and 9 case control studies were identified that reported on myeloma, renal failure and bortezomib. Only case series and case control studies were considered.We formulated some key questions dealing with reversal of renal impairment (RI), doses and association of bortezomib therapy as well as toxicity. *Results.* Overall 877 patients were considered suitable for this analysis.Median age was 65 years (range 40-88) and M/F ratio 1.02 while most patients hadrelapsed/refractory MM (597 out of 877 or 68%) and 79% were in Durie& Salmon stage III. Heterogeneous were methods used for assessing the extent of RI. Serum creatinine concentration has been used in 6 studies and CrCl in 12. Another relevant issue concerns the heterogeneity of threshold selected to define RI. A CrCl value of 30 ml/min was used in 3 studies, between 50 and 60 ml/min in 3 additional reports, while CrCl cutoff was increased to 80 ml/min in a single study.Even definition of reversal of RI shows differences across studies. In 7 reports reversal of RI meets criteria of a reduction of creatinine levels. A more accurate method to define the degree of reversal of RI based on Ludwig criteria has been used in 4 recently published studies. Overall response rate after treatment with bortezomib was relatively high and did not reflect the pre-treatment renal status.Time to reversal of RI assessed in 10 reports appears to be relatively short (median 1.4 months; range from 0,5 and 3,7 months) and led to the dialysis independence 8 out of 32 (25%) previously dialyzed patients. Almost all patients were treated according standard schedule at dose of 1.3 mg/m 2 on days 1, 4, 8, and 11. re¬peated every 21 days. Adverse events and side effects were described in all 18 studies considered. Remarkably toxicity was generally found comparable in 5 studies including MM patients with and without renal failure. *Conclusion.* Despite the paucity of data, this article represents the first systematic review of the entire body of available clinical evidence dealing with the use of bortezomib in MM patients with RI.

PX-171-007: A PHASE 1B STUDY EVALUATING THE SAFETY AND EFFICACY OF A 30-MINUTE IV INFUSION OF CARFILZOMIB IN PATIENTS WITH RELAPSED AND/OR REFRACTORY (R/R) MULTIPLE MYELOMA (MM)

P Papadopoulos,[1] P Lee,[2] S Singhal,[3] J Holahan,[1] A Tolcher,[1] A Patnaik,[1] D Vesole,[4] S Rosen,[5] P Rosen,[6] E Bilotti,[4] T Woo,[7] S Lee,[7] A Hannah,[7] D Siegel[8]

[8]*John Theuer Cancer Center, Hackensack, NJ, United States of America*

Background. Carfilzomib is a novel, highly selective, epoxyketone proteasome inhibitor. In MM patients, single-agent IV carfilzomib shows significant activity at doses up to 27 mg/m^2 when given over a period of 2-10 min. In rats, 48 mg/m^2 was the LD50 when carfilzomib was administered as an IV bolus, however the same dose was nonlethal with minimal toxicity when given as a 30-min infusion. *Aims.* We conducted a dose-escalating trial of carfilzomib given as a 30-min IV infusion to patients with R/R MM. The intent of this study was to define the MTD and safety profile of carfilzomib delivered by this route. *Methods.* Carfilzomib was given as a 30-min IV infusion on days (D) 1, 2, 8, 9, 15, and 16 of a 28-day cycle (C). C1 D1-2 doses are 20 mg/m^2, with subsequent escalation to 36, 45, 56, or 70 mg/m^2. Dexamethasone (4 mg for ≤45 mg/m^2, 8 mg for >45 mg/m^2) was given prior to infusion. Responses were determined according to International Myeloma Working Group Uniform Response Criteria. Pharmacokinetic and pharmacodynamic analyses were performed on samples obtained at C1D1 and C2D1. *Results.* A total of 20 patients are enrolled (4 at 36 mg/m^2; 3 at 45 mg/m^2; 11 at 56 mg/m^2; 2 at 70 mg/m^2). The median number of prior treatment regimens for all patients is 4 (range 1-9). The current median duration of treatment is 4 cycles (range 1-13+). Dose-limiting toxicities (DLTs) were seen in both patients treated at 70 mg/m^2 (Grade 3 reversible renal failure after the first dose; Grade 3 fatigue with fevers after 4 doses). 11 patients enrolled at 56 mg/m2, with 1 DLT (Grade 3 hypoxia/fever). Responses for the 17 evaluable patients are shown in the table below. Three patients treated at 20/56 mg/m^2 were not evaluable for efficacy (patients were withdrawn due to: DLT after 3 doses; Grade 4 neutropenia after 2 doses; and Grade 4 thrombocytopenia after 3 doses). The C_{max} obtained with the 30-minute IV infusion of carfilzomib is ~4-fold lower than that achieved with the 10-minute IV push. Proteasome inhibition of >90% was observed at doses ≥36 mg/m^2. Increased immunoproteasome inhibition was seen with the 56 mg/m^2 dose compared with the 20 mg/m^2 dose. The most common adverse events (AEs), irrespective of relationship to carfilzomib, were nausea (42%), fatigue (37%), chills (26%), pyrexia (26%), and vomiting (21%). *Conclusions.* Carfilzomib administered as 30-minute IV infusion is highly active and well tolerated at 20/56 mg/m^2 (the recommended dose for R/R MM via 30-minute infusion). Enrollment will continue at 20/56 mg/m^2 for a total of 25 patients. Similar to animal studies, improved safety outcomes in MM patients can be achieved with near complete proteasome inhibition when carfilzomib is administered as a 30-minute IV infusion.

Table 1.

Best response	20/36 mg/m^2 (n=4)	20/45 mg/m^2 (n=3)	20/56 mg/m^2 (n=8)	20/70 mg/m^2 (n=2)

[4]*1st Dpt of Propedeutic Internal Medicine,Laikon Hospital, Athens Medical School, Athens, Greece*

Background. Serum free light chains (sFLC) and ratio (sFLCR), are used for the evaluation of sCR in intact immunoglobulin (Ig) MM. Their use is not established for follow up and treatment initiation in intact Ig Multiple Myeloma (MM). *Aim.* To investigate the importance of sFLC and sFLCR elevation for the detection of clinical relapse, in the absence of any other clinical and laboratory finding. *Patients and Methods.* 51 intact immunoglobulin MM patients were studied from diagnosis to last follow up. Their sera samples (n=312) were analyzed for sFLC quantification using Freelite® immunoassay. *Results.* Median lines of therapy were 2 (range 1-11). Median follow up was 28 months (4-135). Retreatment was initiated in all patients according to standard criteria. In 8/51 patients during remission (2 in plateau,1 in MR, 1 in PR, 3 in nCR and 1 in sCR) only sFLC and sFLCR increased gradually (light chain clonal escape) and shortly after they relapsed, (2 acute renal failure,1 acute renal failure and rise of paraprotein, 2 plasmatocytomas, 1 liver plasmacytoma and rise of paraprotein, 1 rise of paraprotein and 1 plasmacytic leukemia).Median time from onset of light chain clonal

escape to clinical relapse was 6 months (2-11months). *Conclusion.* Light chain clonal escape was observed during disease course in 15% of patients with intact Ig MM; shortly after they relapsed. Measurement of sFLC during follow up is useful for early detection of relapse in a subset of patients.

Background. Many patients with multiple myeloma (MM) do not respond to currently available bortezomib-based therapeutic strategies and novel combinations are urgently needed. Panobinostat is an oral pan-deacetylase inhibitor (pan-DACi) with demonstrated synergistic anti-myeloma activity in combination with bortezomib through dual inhibition of the aggresome and proteasome pathways. In the dose escalation phase of a phase Ib study (B2207) of panobinostat + bortezomib, responses of ≥ minor response (MR) of 76% (36/47) were observed. Of note, a ≥ MR rate of 66% (10/15) was observed among bortezomib-refractory patients. Based on these data, a multicenter, U.S.-based, single-arm phase II trial was initiated to further evaluate panobinostat + bortezomib + dexamethasone in patients with relapsed and bortezomib-refractory MM. In B2207, panobinostat was originally dosed in all 3 weeks of the treatment cycle. In the PANORAMA 2 study, the dosing schedule of panobinostat is modified to 2 weeks out of 3; matching the dosing schedule for bortezomib. *Aims.* The aim of this study was to determine if panobinostat could sensitize patients with relapsed and bortezomib-refractory MM to a bortezomib-based therapeutic regimen. *Methods.* Adult patients with relapsed and bortezomib-refractory MM (≥ 2 prior lines of therapy including an immunomodulatory drug and who had progressed on/within 60 days of last bortezomib-based therapy) are eligible. Treatment is comprised of two phases. Phase 1 consists of 8 three-week cycles of panobinostat (20 mg days 1, 3, 5, 8, 10, 12, ie, thrice weekly (TIW) 2 wks on 1 wk off) + bortezomib (intravenous 1.3 mg/m^2 days 1, 4, 8, 11) + dexamethasone (20 mg on day of and day after each bortezomib day). Patients demonstrating clinical benefit can proceed to treatment phase 2 which consists of 4 six-week cycles of panobinostat (20 mg TIW 2 weeks on 1 week off, and repeat) + bortezomib (intravenous 1.3 mg/m^2 day 1, 8, 22, 29) + dexamethasone (20 mg on day of and day after each bortezomib day). A Simon two-stage design will be used to test for the primary endpoint of overall response rate (≥ partial response) with ≥ 4 responses required to proceed to Stage 2. Secondary endpoints include MR rate, time to and duration of response, progression-free survival, time to progression, overall survival, and safety, including assessment of peripheral neuropathy. *Results.* As of Jan 24, 2011, 24 patients were enrolled and responses have been seen in bortezomib-refractory patients, with manageable toxicity reported to date. Further assessment for response is ongoing and additional evaluation for toxicity is in process. *Summary/Conclusions.* Enrollment to Stage 1 has been completed and interim analysis is underway, with Stage 2 anticipated to start soon. Updated demographic information along with preliminary safety and efficacy data will be presented at the meeting.

0901

BORTEZOMIB PLUS DEXAMETHASONE (VD) FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) PRODUCES MOLECULAR REMISSIONS (MOLR) IN 23% OF PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM)

R Silvennoinen,[1] V Kairisto,[2] M Itälä-Remes,[2] TT Pelliniemi,[2] P Anttila,[3] A Sikiö,[4] M Säily,[5] K Penttilä,[6] T Kuittinen,[6] J Opas,[7] T Honkanen,[8] T Lundan,[2] V Juvonen,[2] K Remes[2]

[3]*Helsinki University Hospital, Helsinki, Finland*
[4]*Central Finland Central Hospital, Jyväskylä, Finland*
[5]*Oulu University Hospital, Oulu, Finland*
[6]*Kuopio University Hospital, Kuopio, Finland*
[7]*Seinäjoki Central Hospital, Seinäjoki, Finland*
[8]*Päijät-Häme Central Hospital, Lahti, Finland*

Background. The depth of complete remission (CR) may be critical for the long-term outcome of patients with MM. Thus, MolR is proposed as the new goal of treatment. *Aim.* The aim of this Finnish study was to explore the response rates after VD induction followed by ASCT, including minimal residual disease (MRD) assessment in patients with at least near-CR response. *Methods.* Until Dec 2010, 35 symptomatic MM patients with a median age of 61 (53-65) years with informed consent have been included. Study protocol consists of induction with four cycles of VD followed by ASCT with melphalan 200mg/m^2. Patients were evaluated first time for response after two cycles of induction treatment. Those who had not attained at least partial remission (PR) were taken out of protocol treatment. In case of progressive disease patients were also out of protocol. MRD was assessed by allele specific quantitative polymerase chain reaction (PCR) using pretreatment sample with proportion of myeloma cells determined by flow cytometry as the reference. *Results.* After VD induction nine patients (26%) were in nCR/CR; two of them were PCR negative (sensitivity 0.003%-0.01%) and four PCR positive (range 0.002%-0.2%). Three patients had inadequate samples. Sixteen patients (46%) were in very good partial remission (VGPR) or in PR, and seven (20%) patients had response less than PR. Three patients are not yet evaluable. Two more patients were PCR-negative (sensitivity <0.001%) after mobilisation. Eighteen patients have underwent ASCT. Three months after ASCT, 12 patients (34%) are in nCR/CR, four in VGPR/PR, 10 patients not yet evaluable and nine patients out of study. Five patients are out of study, because their response was less than PR after two induction cycles, two patients had progressive disease, and two had severe adverse event (thromboembolic events with treatment delay). Of the 12 patients in nCR/CR, six are PCR-negative (sensitivity 0.001%-0.007%) and six PCR-positive (range 0.003%-0.09%). Two more patients have achieved PCR-negativity six months after ASCT. In all patients, except one, PCR-negativity is confirmed with two consecutive samples. *Conclusion.* Even with the relatively short median follow-up time PCR-negativity has already been achieved in 23% of the patients. Longer follow-up is needed to study if molecular remission is associated with beneficial long-term outcome.

0902

CHROMOSOMAL ABNORMALITIES AMP(1Q21) AND DEL(13Q14) PREDICT SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA TREATED WITH CTD REGIMEN

M Morawska, M Hus, N Grzasko, D Jawniak, A Dmoszynska

Medical University of Lublin, Lublin, Poland

Background. Chromosomal abnormalities are frequently found in multiple myeloma(MM) and play a major role in patient outcome and management of the disease. The most important chromosomal aberrations associated with worse outcome are del (17p13), t(4,14), t(14,16) and t(14,20). Others that may be associated with adverse prognosis include del(13q14), del(8p21), amp(1q21) and hypodiploidy. In the era of novel agents such as thalidomide, lenalidomide, and bortezomib, risk stratification by chromosomal abnormalities may enable rational therapeutic approach in patients with MM. *Aims.* The study aimed to investigate the influence of amp(1q21) and del(13q14) on survival of MM patients treated with CTD (thalidomide, cyclophosphamide and dexamethasone) regimen. *Methods.* We analyzed the prognostic value of del(13q14) and amp(1q21) by fluorescence *in situ* hybridization (FISH) and hyper- (H-MM) or hypodiploidia (NH-MM) by conventional cyto-

genetic methods in a series of 71 patients with newly diagnosed MM treated with CTD between 2007 and 2010. *Results.* We found del(13q14) in 35 patients, amp(1q21) in 37 patients and combination of del(13q14) and amp(1q21) in 25 patients. Response rate assessed according to EBMT criteria, was 90% for NH-MM patients without additional aberrations (≥VGPR in 60%), 63% for H-MM patients without additional aberrations (≥VGPR in 45%) and 50% for patients with combination of del(13q14) and amp(1q21). The median overall survival (OS) for H-MM patients reached 31 months and was significantly longer than in NH-MM group (17 months, p<0.001). The combination of del(13q14) and amp(1q21) was adverse cytogenetic signature resulting in shortened OS in both groups (13 for H-MM and 6 months for NH-MM, p<0.01). *Summary/Conclusions.* The results of the study suggest that combination of del(13q14) and amp(1q21) is adverse prognostic factor that affects OS by patients H-MM and NH-MM. Improved therapeutic strategies including bortezomib and lenalidomid are required for these patients.

0903

HOSPITAL COSTS DURING TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA IN THE ERA OF TARGETED THERAPIES: REAL-WORLD ESTIMATES FROM THE NETHERLANDS

G Gaultney,[1] M Franken,[1] S Tan,[1] H Blommestein,[1] P Huijgens,[2] W Redekop,[1] P Sonneveld,[3] C Uyl-de Groot[1]

[1]*Institute for Medical Technology Assessment, Erasmus University, Rotterdam, Netherlands*
[2]*Department of Haematology, VU University Medical Center, Amsterdam, Netherlands*
[3]*Department of Haematology, Erasmus University Medical Center, Rotterdam, Netherlands*

Background. Targeted therapies for multiple myeloma (MM), such as thalidomide and bortezomib, promise gains in health but come at increased acquisition costs. Newer targeted therapies for treatment of MM are expected in the near future, and assessment of cost-effectiveness may be required for decision-making regarding their use. In the Netherlands, treatment with targeted therapies has until recently been confined to relapsed/refractory disease (RRMM). We conducted a cost study to estimate the total costs and drivers of increased costs during treatment for RRMM in the era of targeted therapies in the Netherlands. *Aims.* To describe the costs of treatment for RRMM and determine whether there are differences between the treatment costs of thalidomide and bortezomib. *Methods.* Patients in this cohort represented a subset of 139 patients treated in the HOVON50 study, which compared VAD (vincristine adriamycin dexamethasone) with TAD (thalidomide adriamycin dexamethasone) in first-line treatment of MM. In this subset, 65% (n=90) progressed from the VAD treatment arm compared to 35% (n=49) from the TAD treatment arm, of which 23% (n=21) and 17% (n=8) received autologous stem cell transplantation during first-line therapy, respectively. Detailed clinical data were retrospectively collected for each patient up until last known follow-up between January 2001 and May 2009. Total costs for individual patients were determined by the identification of hospital resource use and unit costs of all cost components. Monthly resource use and costs attributable to each cost component were described across all treatment lines and separately by treatment line. Results were also calculated for thalidomide- and bortezomib-based treatment regimens. *Results.* The combination of treatment regimens and sequence of administration throughout treatment of RRMM varied greatly. Total mean follow-up of the patient group equaled 24 months (range: 0.6-70.1) with 49% of patients still in follow-up at the time of data collection. In total, 87 patients were treated with thalidomide and 72 with bortezomib, with some patients receiving either therapy more than once as well as concurrently in combination during treatment of RRMM. Mean total monthly costs for treatment of MM patients in the Netherlands were approximately €4,109 and the minimum-maximum range was large (€142-€31,740). Mean total monthly costs did not differ significantly between patients still in follow-up and those with complete follow-up. The structure of the total costs incurred during treatment differed between bortezomib and thalidomide treatment lines. Total mean monthly acquisition costs for bortezomib were higher compared to thalidomide (€2,574 vs €603; unit prices were €955/3.5 mg vial of bortezomib and €0.24/mg of thalidomide). Moreover, monthly costs associated with adverse events and drug administration were higher during bortezomib-based treatment regimens compared to thalidomide-based treatment regimens. *Summary/Conclusions.* The costs of treatment during RRMM are substantial and vary depending on the order in which therapies are given. Cost-effectiveness analyses of targeted therapies for MM should take into account the impact of increased therapy-related costs on the total treatment costs. Furthermore, the costs of potentially avoidable adverse events associated with specific treatment regimens should be considered when determining the most cost-effective treatment sequence for RRMM.

0904

PROGNOSTIC FACTORS IN ELDERLY MYELOMA PATIENTS RECEIVING BORTEZOMIB, MELPHALAN, PREDNISONE AND THALIDOMIDE FOLLOWED BY BORTEZOMIB AND THALIDOMIDE (VMPT-VT) AS FIRST LINE TREATMENT

A Palumbo,[1] S Bringhen,[1] D Rossi,[2] R Ria,[2] V Magarotto,[1] M Offidani,[2] F Patriarca,[2] C Nozzoli,[2] A Levi,[2] T Guglielmelli,[2] G Benevolo,[2] V Callea,[2] L Baldini,[2] F Morabito,[2] M Grasso,[2] R Marasca,[2] S Amadori,[2] A Falcone,[2] D Gottardi,[2] V Montefusco,[2] C Musolino,[2] N Di Renzo,[2] P Omedè,[1] P Musto,[2] MT Petrucci,[2] F Di Raimondo,[2] G Gaidano,[2] M Boccadoro[1]

Background. bortezomib-melphalan-prednisone (VMP) is now considered the new standard of care for newly-diagnosed myeloma (MM) patients ≥65 years. Bortezomib-melphalan-prednisone-thalidomide (VMPT) showed to be effective in relapsed/refractory setting. *Aims.* this phase III trial compared VMPT followed by maintenance with bortezomib-thalidomide (VMPT-VT) with standard VMP in newly-diagnosed elderly MM patients. The primary end point was progression-free survival (PFS). *Methods.* 511 patients were randomized to receive 9 6-week cycles of VMPT-VT (N= 254; induction: bortezomib 1.3 mg/m^2 days 1,4,8,11,22,25,29,32, cycles 1-4 and days 1,8,22,29 on cycle 5-9; melphalan 9 mg/m^2 days 1-4, prednisone 60 mg/m^2 days 1-4, thalidomide 50 mg continuously; maintenance: bortezomib 1.3 mg/m^2 every 14 days and thalidomide 50 mg/day) or VMP alone (N=257). In March 2007, the protocol was amended with weekly infusion of bortezomib in both arms. *Results.* patients characteristics were well balanced (median age: 71 years). Response rates were higher in VMP-VT with 42% of complete remission (CR) vs 24% in VMP (p< 0.0001). After a median follow-up of 32 months, the 3-year PFS was 51% in VMPT-VT and 32% in VMP (p< 0.0001). The 3-year time to next therapy (TNT) was 70% in VMPT-VT and 51% in VMP (p< 0.0001). The 3-year overall survival was 85% vs 80% (p=0.35), respectively. The achievement of CR was a strong predictive factor of longer PFS in both groups (P < 0.0001): in VMPT-VT arm, 3-year PFS was 66% in CR patients and 47% in PR patients; in VMP arm, it was 70% and 30%, respectively. In patients ≥75 years old and in those with high risk disease (presence of cytogenetic abnormalities [t(4;14) or t(14;16) or del17p] and ISS 3) VMPT do not add any significant PFS advantage to VMP (p=0.5). Grade 3-4 neutropenia (38% vs. 28%, p=0.02), cardiological events (10% vs. 5%, p=0.04) and thromboembolic events (5% vs. 2%,p=0.08) were more frequent among patients receiving VMPT-VT. Moreover, weekly infusion of bortezomib reduced the incidence of peripheral neuropathy (PN) to less than 10%. 149 VMPT-VT patients were assessable for maintenance treatment. After a median duration of maintenance of 14.4 months, the PR rate was 90%, including 45% CR. The 1-year landmark analysis of PFS, showed a 2-year PFS of 63% in the VMPT-VT group and 40% in the VMP group, with a risk reduction of disease progression of 52% (p<0.0003). This advantage was less evident in patients ≥75 years (P=0.87) and in those with high-risk of disease progression (p=0.77). Maintenance with VT had favorable safety profile: 3% of patients experienced grade 3-4 hematological toxicity, 5% grade 3-4 PN and 7% discontinued due to adverse events. *Summary.* VMPT-VT showed a higher CR rate, prolonged PFS and TNT compared to VMP; achievement of CR was a strong predictive factor of longer PFS; higher dose-intensity seemed to be less effective in patients ≥75 years and in those with high risk disease; maintenance with VT further improved PFS with a good safety profile; bortezomib weekly-infusion significantly reduced PN incidence. A longer follow up is needed to assess overall survival.

Background. Bortezomib-dexamethasone-doxorubicin (PAD) induction, followed by reduce-intensity autologous transplantation proved to be safe and effective in elderly newly diagnosed multiple myeloma (MM) patients. Lenalidomide is less neurotoxic than thalidomide and represents an optimal agent to include in maintenance strategies. *Aims.* These observations provided the rationale for investigating a sequential approach including bortezomib as induction and lenalidomide as consolidation-maintenance in elderly MM patients undergoing reduced intensity ASCT. In this analysis, efficacy and safety end-points of post transplant lenalidomide consolidation and maintenance were updated. *Methods.* A hundred and two newly diagnosed patients, aged 65-75 years or younger not eligible for high-dose chemotherapy, were enrolled. Patients received PAD induction, tandem melphalan 100 mg/m2 and stem-cell support followed by consolidation with four 28-day cycles of lenalidomide-prednisone (LP), and subsequent lenalidomide maintenance (L) until relapse or until tolerated. *Results.* LP-L consolidation-maintenance therapy improved post transplant responses: VGPR rate raises from 82% to 92%, complete response (CR) rate from 38% to 71%: 1 patient improved from stable disease (SD) to partial response (PR), 1 from SD to very good partial response (VGPR), 1 from PR to VGPR, 2 from PR to CR, 16 from VGPR to CR. After a median follow-up of 3 years, the 3-year progression-free survival (PFS) for all patients was 66%, the 3-year time-to-progression was 73% and the 3-year overall survival was 85%. By exploratory analysis stratified by group, PFS was not significantly different between patients older or younger than 70 years. The 3-year PFS rate was 74% in patients with International Staging System stage I disease, 71% in patients with stage II, and 30% in patients with stage III disease. Patients who achieved CR had 3-year PFS of 81%, patients who achieved VGPR had a 3-year PFS of 56% and patients who achieved PR had a 3-year PFS of 31%. Patients with high-risk cytogenetic profiles, including del17, t(4;14), or t(14;16) and patient with standard cytogenetic profiles had no significantly different 3-years PFS (61% vs 68%). In patients with standard-risk cytogenetic abnormalities who achieved CR 3-year PFS was 100%. Consolidation-maintenance treatment was well tolerated, grade 3-4 adverse events included neutropenia (31%), thrombocytopenia (15%), pneumonia (8%), cutaneous rash (7%); no treatment-related deaths were reported. *Conclusions.* This sequential approach improved depth and rate of response, was well tolerated, and can be considered a safe and effective treatment strategy for elderly MM patients eligible for reduced-intensity ASCT.

Background. Safety and efficacy of pomalidomide at 0.5 and 2 mg/d with or without prednisone was reported in myeloproliferative neoplasm (MPN)-associated myelofibrosis and cytopenia (J Clin Oncol 2009; 27:4563-4569, Leukemia 2011;25:301-304). We studied (ClinicalTrials.gov No. NCT00669578) efficacy of pomalidomide 2 mg/d alone or, when no response after three months, combined with prednisone (starting dose of 30 mg/d). *Aims.* To evaluate clinical efficacy of pomalidomide alone and combined with prednisone in patients with MPN-associated myelofibrosis and cytopenia. *Methods.* Patients with primary myelofibrosis (PMF) or post-polycythemia vera/essential thrombocythemia (post-PV/ET MF) myelofibrosis were included. The main eligibility criteria were red blood cell (RBC)-transfusion-dependence or hemoglobin <10 g/dL, and/or thrombocytopenia <50/nl and/or neutropenia <1.0/nl; patients >50 years were eligible. The main exclusion criteria were history of thrombosis or pulmonary-embolism. The primary endpoint was response assessed by the International Working Group for Myeloproliferative Neoplasms Research and Treatment criteria extended by the criterion transfusion-independence (Leuk Res. 2011;35:8-11). Concurrent hydroxyurea for proliferative disease and acetylsalicylic acid 100 mg/d in patients with platelets between 50/nl and 1000/nl were included. The statistical design of the study was based on the Simon optimal two-stage design. Here we report on the first stage of the study. *Results.* Pomalidomide 2 mg/d was given to 38 patients (median age 71 years), 25 were male. Twenty-seven had PMF, 3 had post-ET and 8 post-PV MF. Disease stage at study-entry according to the Dynamic International Prognostic Scoring System was high-risk in 13 (34%), intermediate-2 risk in 22 (58%) and intermediate-1 risk in 3 (8%). Karyotype was available in 30 patients with high-risk cytogenetics in 6 (20%). JAK2 V617F mutation was present in 21 (55%) and MPL W515L mutation in 7 (18%) of 38 patients, two patients had both mutations. Twenty-six (68%) were RBC-transfusion- and 7 (18%) platelet-transfusion-dependent, 18 of 38 patients had platelets < 100/nl. Eleven stopped treatment within 3 months and additional 5 within 6 months. Prednisone was added after month 3 in 19 of 27 eligible patients. Non hematological serious adverse reactions potentially related to pomalidomide were thromboembolism (n=2), pulmonary infection (n=2), rash (n=2), worsening of general condition (n=2), hypertension (n=1) and cardiac failure (n=2). Six patients (16%) experienced transformation into blast phase disease (n=3, high-risk; n=3 intermediate-2 risk). Pomalidomide dose-reduction (n=10, 1mg/d; n=2, 0.5mg/d) was performed for fatigue (n=3), thrombo- or neutropenia (n=8) and rash (n=1). There was an anemia response in 5 patients (4 receiving concomitant prednisone) and all became RBC-transfusion independent, platelet response was evident in 6 patients (2 receiving concomitant prednisone). Responses occurred in 3 patients within 3 months in 3 within 6 months and in 5 beyond month 6 of treatment. 5 of 11 responders had pomalidomide dose reduction due to toxicity, notably before response occurred. No correlation was evi-

dent between responses and JAK2 or MPL mutational status or cytogenetics. *Conclusions.* Pomalidomide with or without prednisone may be effective in the treatment of cytopenia in patients with MPN-associated myelofibrosis. Most responses were seen during combined therapy with pomalidomide and prednisone beyond month 3 of treatment.

0907

LONG-TERM SAFETY AND EFFICACY ANALYSIS OF THE TWO PHASE 1 STUDIES OF SB1518, A NOVEL ORAL JAK2 INHIBITOR, IN PATIENTS WITH ADVANCED MYELOID MALIGNANCIES

J Seymour,[1] B Scott,[2] A Roberts,[3] B To,[4] O Odenike,[5] Z Estrov,[6] J Cortes,[6] D Thomas,[6] J Zhu,[7] A Dorr,[7] H Kantarjian,[6] H Deeg,[2] S Verstovsek[6]

[6]*University of Texas MD Anderson Cancer Center, Houston, United States of America*
[7]*S*BIO Pte Ltd, Singapore, Singapore*

Background. SB1518 is a potent inhibitor of both wild-type JAK2 and JAK2V617F, implicated in the pathogenesis of myeloproliferative neoplasms. In mid-2008, we initiated two Phase 1 studies of SB1518: one in patients with advanced myeloid malignancies, and the other exclusively in patients with myelofibrosis (MF). We previously reported the study data that supported 400 mg/d as the recommended Phase 2 dose (RD). These trials are ongoing, as some patients continue to receive SB1518. *Aims.* To report the overall safety and efficacy results for the combined study populations as of January 2011. *Methods.* Qualifying patients with MF had palpable splenomegaly ≥5 cm. Patients were sequentially assigned to doses from 100-600 mg/d and were dosed continuously. Intrapatient dose escalation was allowed up to the RD once the MTD was established. *Results.* Sixty-three patients were consented and enrolled; 39 (62%) were men, and median age was 65.5 years. Fifty-six had MF, and 7 had AML. Fifty (79%) were JAK2V617F mutation-positive (46 MF, 4 AML). At baseline, hemoglobin ranged from 5.6 to 16.3 g/dL (median, 9.4). Platelet count ranged from 5 to 954 x 103/μL (median, 122 x 103/μL); with 16 patients having baseline counts <50 x 103/μL, 12, 50-100 x 103/μL, and 35; <150 x 103/μL. Median time on study is 13.3 months (1-29+). As of January 2011, 21 MF patients remain on study. The most common treatment-related AEs were gastrointestinal, which were generally low grade and manageable. GI AE's > Gr 2 included 5 patients with Gr 3 diarrhea (7.9%) and 1 patient each (1.6%) with Grade 3 nausea, Grade 3 abdominal pain, and Grade 4 vomiting. Grade 4 hematologic AE's considered possibly related to treatment were rare and comprised anemia (n=2, 100 & 200 mg), and thrombocytopenia (n=1, 300 mg). These events occurred after 5.7-18.5 months on study. Two patients were discontinued for these AE's and one continues on study at 200 mg dose. Fifteen patients had dose reductions, most within the first 6 months; of these, 11 (73%) started treatment at ≥500 mg/d. No patients discontinued study medication because of a dose-limiting toxicity. No long-term toxicities were identified. Forty-one MF patients had palpable baseline splenomegaly ≥5 cm and were evaluable for spleen response; 18 (44%) of these 41 experienced clinical improvement (CI) (IWG criteria). Three patients had CI in platelet count (IWG criteria), and one patient had CI in hemoglobin (IWG criteria). Twenty-one patients achieved stable disease (IWG criteria). Overall, 39 (70%) of the 56 MF patients experienced CI or stable disease. Among all enrolled patients, duration of progression-free survival (PFS) ranged from 1 to 875 days (median, 563 days), with an estimated 67% rate of PFS at 12 months (Kaplan-Meier). *Conclusions.* SB1518 shows promising efficacy in MF patients with splenomegaly. Once-daily dosing is well tolerated to 29 months, with manageable GI toxicity as the main AE. SB1518 does not appear to cause myelosuppression; patients with significantly impaired hematopoiesis can receive full-dose daily SB1518 without exacerbating hematocytopenias.

0908

BLEEDING IN ESSENTIAL THROMBOCYTHEMIA: ANALYSIS OF INCIDENCE AND RISK FACTORS IN A COHORT OF 565 PATIENTS

F Palandri,[1] N Polverelli,[1] L Catani,[2] D Sollazzo,[2] E Ottaviani,[2] S Parisi,[2] M Baccarani,[2] N Vianelli[2]

[1]*Department of Hematology and Clinical Oncology "L. and A. Seràgnoli", Bologna, Italy*
[2]*Department of Hematology and Clinical Oncology "L. e A. Seràgnoli", Bologna, Italy*

Background. Hemorrhages are potentially severe complications of essential thrombocythemia (ET). Extreme thrombocytosis and previous bleedings are currently considered the main risk factors for bleeding; however, only few data are available. *Objectives.* We retrospectively analyzed the hemorrhagic events of 565 consecutive ET patients followed for a median time of 7.8 years, with the aim to evaluate: (1) the incidence and the type of the bleeding complications; (2) the correlation between these events and clinical/laboratory data and (3) the therapeutic implications of the study findings. *Results.* Sixty patients (10.5%) had one or more hemorrhages, for a total of 77 hemorrhagic events. Twenty-four major bleeding (grade 3-4 according to WHO criteria) occurred in 23 patients (4%) at ET diagnosis (4) or during follow-up (20). The remaining 53 hemorrhages were minor (cutaneous or mucosal). Overall, 85.6% of the patients received a cytoreductive treatment during the observation time, achieving at least a partial response in 78% of the cases. Antiplatelet drug was administered to 521 patients (92%), with no differences between patients with or without hemorrhages. The incidence rates of total and severe bleeding were 13.4 and 4.8 events per 1000 person-years, respectively. The risk of hemorrhage was higher at diagnosis (0.5%) and progressively decreased during the follow-up. Patients with hemorrhages presented more frequently splenomegaly and displayed lower hemoglobin concentration and higher leukocyte and platelet count (Student's t-test and $\chi 2$ test). By univariate (log-rank) analysis, splenomegaly baseline ($p<0.0001$), a history positive for hemorrhages ($p=0.005$), a platelet count higher than the median value ($p=0.003$) and higher than 1000x109/L ($p<0.0001$) and a leukocyte count>11x109/L ($p<0.0001$) significantly correlated with subsequent bleedings. JAK2V617F mutational status (qualitative analysis) was not found to correlate with bleeding: however, only 2 patients were homozygous. Analogously, antiplatelet treatment, which was administered to the great majority of the patients, did not appear as a risk factor. By multivariate (Cox) analysis, splenomegaly (HR 2.9, 95% CI 1.5-5.4, $p=0.002$), platelet count>1000x109/L (HR 2.3, 95% CI 1.3-3.9 $p=0.003$) and leukocyte count>11x109/L (HR 1.9, 95% CI 1.1-3.2, $p=0.023$) retained their prognostic significance. Considering these 3 parameters, patients were stratified in 3 subgroups, characterised by an increasing risk for hemorrhage: low (no risk factors, 339 patients), intermediate (1 risk factor, 160 patients) and high (2 or 3 risk factors, 66 patients). The cumulative risk for haemorrhage at 10 years was 8.2% in the low-risk, 14.4% in the intermediate risk ($p=0.22$) and 45.8% in the high risk group ($p<0.001$). When severe hemorrhages were considered separately, only splenomegaly retained its prognostic significance on bleedings. In one case, bleeding was the ultimate cause of death. *Conclusions.* During the course of ET, bleeding represents a relatively rare event, whose incidence decreases over the time. Marked thrombocytosis, leucocytosis and spleen enlargement, particularly when concomitant, identify a cohort of patients at higher hemorrhagic risk. In these cases, the use of antiplatelet treatment should be balanced between the risk of bleeding and the thrombotic risk, which may itself be increased by the same features.

Background. Pegylated interferon alpha-2a (Peg INF2a) has been demonstrated to be active therapy for high risk essential thrombocythemia (ET) and polycythemia Vera (PV), as well as treatment for early myelofibrosis (MF). We retrospectively analyzed the outcomes of Peg INF2a therapy in MPN patients treated outside the constraints of a clinical trial in the USA and EU. *Methods.* Clinical records of MPN patients treated at the participating centers, receiving Peg INF2a outside of the context of a clinical trial, were analyzed for response (ET and PV by ELN criteria; MF by EUNMET and IWG-MRT criteria), toxicity, and duration of response. *Results. Patients:* 90 patients were identified [46 PV (51%), 30 ET (33%), 14 MF (16%)] with a median age (57) and gender distribution (56% Females) typical for the disorders. The patients were a median of 96 months (2.0-324 months) after the diagnosis of the MPN and 65% harbored the JAK2-V617F mutation. 80% of patients had received at least one prior cytoreductive therapy for their disease [58 hydroxyurea, 28 anagrelide, 21 prior interferon (non pegylated)]. There were 18 patients with vascular events (15 thrombotic, 3 hemorrhagic) prior to initiating Peg INF2a, with no vascular events occurring while on therapy. *Therapy.* Median starting dose of Peg INF2a was 90 µg/week (range: 45-180) with peak doses ranging from 45 to 270 µg. A total of 75 patients (83%) remain on Peg IFN2a with median duration of treatment of 17 months (range: 2.0-58). *Toxicity.* Overall the Peg INF2a was well tolerated. Hematological toxicity was Gr 3 or lower. There were 6 cases with anemia (7%), 9 with thrombocytopenia (10%) and 9 had leukopenia (10%). Most common non-hematologic toxicities were Fatigue Gr 1-3 in 17(19%), Gr 1 LFT elevation in 6 (7%) and Gr 2-3 mood disorder in 3 (3%) patients. Only 11 (12%) discontinued therapy secondary to toxicity. *Response.* ET-PV: By ELN criteria, 20 PV patients achieved CR (43%), 21 achieved PR (46%) and NR in 5 (11%). In ET, the responses were CR in 15 (50%), PR in 10 (30%) and NR in 5 (15%). MF: the responses by IWG criteria were 1 CR (7%), 2 PR (14%), 4 CI (28%) and 7 SD (50%). By EUNMET, there were 2 CR (14%), 5 Major responses (36%), 4 moderate responses (29%), 1 minor response (7%) and 2 no response (14%). *Conclusions.* Peg INF2a used at doses consistent with published clinical trials is active and well tolerated when administered in an active clinical setting outside of the support of a clinical trial. Given the majority of patients had previously failed cytoreductive therapy these results further substantiate prior observation of Peg INFa in MPNs. Upcoming randomized clinical trials through the Myeloproliferative Disorders Research Consortium will help further define the role of Peg INFa as first line therapy in high risk MPNs.

SEQUENTIAL EVALUATION OF CHROMOSOMAL ABERRATIONS USING HIGH-RESOLUTION SNP MICROARRAYS IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASM EXPERIENCING DISEASE PROGRESSION

E Rumi,[1] A Harutyunyan,[2] C Elena,[1] D Pietra,[1] T Klampfl,[2] T Berg,[2] C Pascutto,[1] F Passamonti,[3] R Kralovics,[2] M Cazzola[1]

[1]*Division of Hematology Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy*
[2]*Center for Molecular Medicine, Vienna, Austria*
[3]*Division of Hematology, Azienda Ospedaliera-Universitaria Fondazione Macchi, Varese, Italy*

Background. Myeloproliferative neoplasms (MPN) include polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). Both PV and ET may evolve into myelofibrosis, and all conditions are also characterized by an increased risk of progression to acute myeloid leukemia (AML). The genetic mechanisms underlying these transformations are poorly defined at present. *Aims.* The aim of the present study was to establish whether disease progression is associated with development of chromosomal aberrations in MPN, and whether the acquisition of these abnormalities has an impact on overall survival. *Methods.* This study included 24 MPN patients who progressed to secondary myelofibrosis (MF) or AML and could be followed with collection of at least two sequential DNA samples in different phases of disease. In detail, 14 patients progressed from chronic-phase MPN to AML, five patients from PV to post-PV MF, and five from ET to post-ET MF. All patients provided their written informed consent before DNA collection. The Genome-Wide Human SNP 6.0 Array was used to detect chromosomal aberrations, including copy number variation (CNV) and copy-neutral loss of heterozigosity (LOH). Paired samples collected before and after disease progression were compared by means of the Wilcoxon test for paired data. *Results.* Considering the whole cohort, disease progression from chronic-phase MPN to secondary MF or AML was associated with a significant increase in the number of chromosomal aberrations (P=0.0023) without any significant change in JAK2 (V617F) mutant allele burden (P=0.189). This increase remained statistically significant even after distinguishing patients with evolution from chronic-phase MPN to AML (P 0.016) and those with evolution from PV/ET to secondary MF (P=0.043). As abnormalities involving chromosome 5, 7 and 17p have been previously shown to be associated with worse survival in de novo AML, we evaluated whether the acquisition of these specific aberrations during follow-up had an impact on survival. By applying a Cox regression analysis, the acquisition of one or more of the above aberrations was associated with reduced survival from the time of the initial diagnosis of MPN (Hazard ratio 18, 95% CI 1.9-164, P=0.011). Fisher exact test showed that the acquisition of aberrations of chromosome 5, 7 and 17p was closely associated with leukemic transformation (P=0.013). *Conclusions.* MPN patients who progress to secondary MF or AML show a significant increase in the number of chromosomal aberrations such as CNV and LOH. The acquisition of aberrations involving chromosome 5, 7 and 17p is closely associated with leukemic transformation.

MANAGEMENT OF ELDERLY PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA: AN OBSERVATIONAL STUDY OF 471 PATIENTS OF 80 YEARS AND OLDER INCLUDED IN THE EXELS EUROPEAN STUDY

JJ Kiladjian,[1] C Besses,[2] M Griesshammer,[3] L Gugliotta,[4] C Harrison,[5] G Birgegard[6]

[1]*APHP, Hopital Saint-Louis, Paris, France*
[2]*Hospital del Mar, Barcelona, Spain*
[3]*Johannes Wesling Klinikum Minden, Minden, Germany*
[4]*Hospital S. Orsola-Malpighi, Bologna, Italy*
[5]*St Thomas' Hospital, London, United Kingdom*
[6]*Uppsala University, Uppsala, Sweden*

Background. Essential thrombocythemia (ET) is usually diagnosed in patients aged around 60 years and its incidence increases with age. According to international guidelines, an age above 60 years is a risk factor for thrombosis and therefore, all patients aged >60 years receive cytoreductive therapy. However, there are no pharmaco-epidemiological data available in elderly ET patients. We identified patients aged ≥80 years in the cohort of ET patients included in the European observational EXELS (Evaluation of Xagrid Efficacy and Long-term Safety) study. *Aims and Methods.* To present data from elderly ET patients enrolled in this observational study. Clinical and biological data are collected every 6 months. Analyses were performed in Feb 2011 (based on data cut in Sept 2010). *Results.* Among the 3604 patients included from 13 European countries, 471 patients were ≥80 years at study enrollment. Across countries, the proportion of included patients aged ≥80 years ranged from 10 to 19%. There was no difference between patients ≥80 years (elderly) and <80 years regarding gender (66% and 60% females, respectively), history of vascular events (41% vs. 36%), proportion of treatment-naive patients (16% vs 20%), and antiaggregation therapy (both 69%). Anagrelide was the current cytoreductive treatment at enrollment in 40% of patients <60 years, 14% of patients 60-79 years, and 9% of patients ≥80 years. Evolution of blood cell counts over time showed similar efficacy with comparable decreases in platelet counts in all patients, irrespective of age. Hematological tolerance to cytoreductive therapy was also comparable between elderly and younger patients. Switch from anagrelide to another cytoreductive

therapy was recorded in 10% of patients <80 years, and in 26% of those ≥80 years. The proportion of patients switching from hydroxyurea (HU) to another drug was similar in both age groups (10% and 12%, respectively). Median time to switch from anagrelide was 239 days in elderly patients, and 266 days in younger patients. Reasons for switch from anagrelide in patients ≥80 years was intolerance in 7/18 cases (vs 30/97 in patients <60 years), and no elderly patient changed because of inefficacy (vs 18/97 for <60 years). Reasons for switch from HU in patients ≥80 years was intolerance in 17/57 (vs 30/105 in patients <60) and inefficacy in 10/57 (vs 26/105 in patients <60). The number of patients with predefined events recorded (including vascular events and transformation to leukemia) was numerically higher in patients ≥80 years (19% of patients had one event vs. 7% in patients <60, and 12% in patients 60-79 years), but numbers are too low to allow subgroup analyses. *Conclusion.* This cohort of 471 elderly patients (age ≥80 years) with ET enrolled in a prospective observational study shows that elderly patients' characteristics do not differ substantially from those of younger patients at presentation. These elderly patients received similar management across EU countries, and the use of anagrelide decreased along with increasing patient age. Anagrelide tolerability and efficacy appeared comparable in elderly and younger patients, and no new safety concerns arose in this patient population.

Background. Symptom burden is a major component of MF. *Aims.* The MFSAF (Mesa *et al. Leuk Res*. 2009) was developed to measure MF-associated symptoms. The modified MFSAF v2.0 diary (a refined version of the instrument) was implemented to evaluate effects of the JAK1 and JAK2 inhibitor ruxolitinib (INCB018424) on MF symptoms over a 24-week period compared with placebo in a randomized trial. *Methods. Ruxolitinib Trial:* 309 patients with ≥ intermediate-2 risk MF provided informed consent and were randomized to start placebo or ruxolitinib at doses of 15 or 20 mg BID depending on baseline platelet count, with dose modifications allowed for efficacy and safety. *Symptomatic Change Assessments:* The modified MFSAF v2.0 diary is a daily e-diary comprising 7 items, each scored on an 11-point scale from 0 (absent) to 10 (worst imaginable) in the 24 hours prior to assessment. The instrument measures patient-reported symptoms and impacts: abdominal discomfort (AD), abdominal fullness/early satiety (ES), bone/muscle pain (BMP), pain under the left side of ribs (P), night sweats (NS), itching (I), and MF-related inactivity (first 6 items are pooled to create the total symptom score [TSS]). Patients completed the modified MFSAF v2.0 diary daily for 1 week prior to starting therapy (baseline, BL) and for 24 weeks on therapy. A Patient Global Impression of Change (PGIC) scale was used for patient self-evaluation of treatment benefit. PGIC was measured monthly from BL through week 24 using a 7-point scale (1-very much improved to 7-very much worse). Change from BL for individual symptom scores and the TSS were anchored to PGIC responses at week 24. *Statistics:* The proportion of patients achieving ≥50% improvement (ie, treatment responders) in individual symptom scores and TSS were compared (ruxolitinib vs placebo) using chi-square tests. *Results.* 148 patients receiving ruxolitinib and 152 receiving placebo completed diary entries. No significant difference existed in individual BL mean symptom scores between the two groups. Mean change for TSS from BL to week 24 for ruxolitinib was -8.6 (18.0 to 9.4) vs 3.2 (16.5 to 19.7) for placebo (p<0.0001). The responder rate for TSS was 45.9% vs 5.3% for patients treated with ruxolitinib vs placebo, respectively (p<0.0001). Using a moving 7-day average of TSS, the median time to response was 4.4 weeks for patients receiving ruxolitinib but could not be estimated for placebo because of insufficient responders over the 24-week period. At week 24, treatment responders for individual symptoms for ruxolitinib vs placebo were: AD, 48.3% vs 9.4%; ES, 48.3% vs 10.9%; BMP, 39.6% vs 9.1%; P, 52.9% vs 14.8%; NS, 49.6% vs 11.2%; I, 58.5% vs 11.5%; and inactivity, 33.1% vs 10.9% (all p<0.0001). 91.2% of ruxolitinib patients who were TSS responders had PGIC scores of "much"or "very much improved,"while 73.6% of placebo nonresponders had PGIC scores of "unchanged"or "worsened". *Conclusions.* Serial administration of the modified MFSAF v2.0 diary demonstrated that treatment with ruxolitinib provided rapid, significant, and sustained improvements in MF symptoms vs placebo over the 24-week treatment period.

Backgroud. Hydroxyurea (HU) is the drug of choice for the treatment of patients with high risk myeloproliferative neoplasms (MPN). Its more frequent side effects are represented by gastrointestinal toxicity, cutaneous and mucosal toxicity, pulmonary toxicity and fever. A number of anecdotal cases have been reported in the literature, but epidemiological information on large series of patients are not yet available. *Aims.* To collect information on the rate and characteristics of HU-related side effects, we examined data from a retrospective survey of ten hematological centers in Italy. To ensure consistency of data, we only included clinically relevant HU-related manifestations such cutaneous and mucosal lesions, fever and pneumonitis. *Methods.* This study was performed within the GIMEMA (Gruppo Italiano Malattie Ematologiche Maligne dell'Adulto) MPN Working Party, under the auspices of AGIMM (AIRC-Gruppo Italiano Malattie Mileoproliferative). Centers were asked to identify, in their own data base, all subjects with a diagnosis of MPN who had received hydroxyurea and developed one of the side effects considered above. Diagnosis of PV, ET or PMF was made according to either the WHO2008 or PVSG/WHO2001 criteria, while diagnosis of post-PV or post-ET MF was made according to the IWG-MRT plus the histological WHO criteria. Furthermore, for comparison populations, each participating centre provided information on the total number of referring patients with matched diagnosis who had been in treatment with HU and had not developed side effects in the same period of time. *Results.* The whole study population was comprised of 3,411 MPN patients, of whom 963 were PV, 1912 ET, 357 PMF, 93 PPV and 86 PET. A total of 184 patients (5%) who developed HU-related side effects were identified: 16 of them developed fever, 167 muco-cutaneous lesions and 1 pneumonitis. Pulmonary toxicity attributed to HU was diagnosed in a 68-year-old male with JAK2V617F negative PMF who was being treated since ten years with 1 g/ daily. High degree (>39.°C) fever developed in 16 patients: 4 PV, 11 ET and 1 MF. Eight males and 8 females, median age 64 yrs (range 50-79 yrs), 86% were JAK2V617F mutated. Fever was reported after a median period of 31

Table 1.

	Mucosal lesions	Cutaneous ulcers	Other cutaneous lesions

M/F	4/24	46/72	13/8
Age (yrs) median	60 (19-76)	66 (23-85)	63 (38-81)
Disease	PV= 11 ET= 17 MF = 0	PV= 35 ET= 61 MF = 22	PV= 11 ET= 8 MF = 2
% JAK2V617F pos	83%	72%	65%
Previous therapy	Interferon =1 Anagrelide = 2	Pipobroman = 7 Interferon= 2 Busulfan= 3 Others = 3	No
Site	Oral =27 Genital =1	Footankle = 15 Malleolus = 58 Leg = 38 Other = 7	Keratosis=7 Dyschromias 4 Dermatitis=4 Basalioma =3
HU median daily dose (gr)	1 (0.5-5)	1 (0.25-2)	1 (0.15-1)
HU total dose for patient (gr)	1157 (41-6948)	1947 (12-9483)	1356 (54-4368)
Median time HU treatment (months)	41 (1-231)	78 (2-262)	60 (5-221)

days (range, 1-109) of treatment at median dosage of 0.5 g daily (range, 0.15-1 g), for a total HU median dose of 15 g (range, 0.5-52.5 g) for patient. Muco-cutaneous lesions were referred by 167 patients; 28 patients developed mucosal lesions, 118 patients presented cutaneous ulcers, while other cutaneous lesions including keratosis, dyschromia, basalioma and dermatitis developed in 21 patients, as detailed in the table. Two patients reported both mucosal and cutaneous lesions. *Conclusions.* With the intrinsic limitations of the retrospective design, this study provides, for the first time, an estimate of the rate of HU-related side effects (5%) overall strenghtening the good tolerability of the drug.

Background. We previously validated the MPN-SAF, a unique instrument for assessment of MPN symptoms based on patient reported outcomes, among 402 MPN patients including independent translations in English (USA), Italian and Swedish (Blood 2010). *Aims.* We sought to further validate MPN-SAF using prospective translations in French, Spanish, German, and Dutch and a new comparison cohort for English (UK). *Methods.* The MPN-SAF was translated using previously reported methodology involving four collaborating translators. MPN patients completed a symptom packet during a physician visit consisting of the MPN-SAF, EORTC-QLQC30, and survey-related feedback. Concurrently, physicians provided assessment of patient symptom burden and pertinent demographic and disease information. *Results.* Patients: 1,031 MPN-SAF surveys were administered (English (UK) (N=57), Dutch (N=236), French (N=482), German (N=59), and Spanish (N=197, including Argentina (n=22), Uruguay (n=8), Puerto Rico (n=10), and Spain (n=157)) in 433 ET (42%), 393 PV (38%), and 197 MF patients (19%) (8 missing). Participants were of typical age (mean 61.0, range 20 - 94 years) and gender (54% female) of disease. Prior hemorrhage (5%) and thrombosis (24%) were frequent, as were hematological abnormalities of anemia, thrombocytopenia, or leukopenia (21%). Validation of New Translations of the MPN-SAF: Patients were symptomatic (>50% prevalence) in the majority of MPN-SAF items (Table 1). MF in general had the highest severity and prevalence of symptoms, followed by PV and then ET. Fatigue was the most prevalent item (89%), with moderate or severe rating present in 60% of patients. Similarly, 75% of patients had reduced QOL and this reduction was moderate-to-severe in 34%. Patients rated the MPN-SAF as "easy to understand"(1.7/10) and having "addressed most symptoms"(2.0/10). Comparison to EORTC-QLQC30: Strong correlations existed between individual symptoms represented on both the MPN-SAF and the EORTC-QLQC30 including fatigue, inactivity, insomnia, and bone pain (r=0.51 to 0.82, all p<0.001). Additionally EORTC-QLQC30 subscales were highly correlated with corresponding items of fatigue, inactivity, concentration, and sad mood (r=-0.50 to -0.73, all p<0.001). Comparison to Physician Perceptions: Physician's blinded opinions of patients' symptoms displayed strong correlations for fatigue and weight loss (r>0.5, p<0.001 for both), with moderate correlations for fevers, night sweats, bone pain, and pruritus (r=0.34 to 0.48, p<0.001). Comparison Across Languages: After adjusting for age and MPN type, there were no significant differences across languages for specific MPN-SAF items of abdominal pain, abdominal discomfort, headache, numbness, insomnia, fever and weight loss. There were no significant differences between UK and USA cohorts for any MPN-SAF item. Comparison with prior MPN-SAF: After adjusting for age and MPN type, there were no significant differences between current data and prior English (USA), Swedish, and Italian cohorts, except for early satiety, inactivity, headache, and QOL (p<0.05). *Conclusions.* The MPN-SAF is a valid PRO assessment of symptom burden for MPN patients worldwide. Strong correlations were seen between the translations and co-validation measures. Minor language-specific variations in MPN-SAF severity exist which likely represent cultural influences, language nuances, or variations in patient cohorts. Further use of the MPN-SAF in clinical trials is recommended as a tailored assessment of MPN symptom burden internationally.

Table 1.

Symptomatic burden of MPNs as assessed by the MPN-SAF in a prospective international survey of 1,031 MPN patients (results are reported as mean [prevalence]). All items measured on a 0 (Absent) to 10 (worst imaginable) scale.

	English (UK) (N=57)	Dutch (N=236)	French (N=482)	German (N=59)	Spanish (N=197)	Total (N=1,031)

Background. Myeloproliferative neoplasms (MPNs) are a subset of hematological malignancies with significant symptomatic burden and a rapidly evolving treatment options. We have previously reported on the disease burden and impact on Quality of Life (QoL) among afflicted patients, but no prospective trials existed among a sizable European cohort. *Aims.* We prospectively sought to gauge the cultural relevance of a measure of symptom burden amongst a large cohort of MPN patients in France. *Methods.* Patient completed a symptom assessment packet including a French translation of the Myeloproliferative Neoplasm Symptom Assessment Form (MPN-SAF: French) and the French EORTC-QLQ-C30. Physicians concurrently completed a form detailing patient demographics, perception of the pt's symptomatic burden, and MPN diagnosis, treatment and clinical course. *Results.* Patients: 482 patients (ET (N=227; 48%), PV (N=175; 37%) and MF (N=75; 16%)) were prospectively enrolled from university and private hospitals in France. Patients were of a median age (62; range 22-91 years) and gender (56% females) typical of the disease with a median of 7 years (range:1-35) from their diagnosis. Patients frequently had a history of either thrombotic events (27%) and/or hemorrhagic events (4%). Anemia (13%), polycythemia (5%), leukopenia (5%), thrombocytopenia (8%), and thrombocytosis (9%) were common. Symptomatic Burden: The MPN-SAF: French indicated that insomnia, fatigue, problems with sexuality, numbness, and inactivity were most severe among French patients (see Table 1). Symptoms with highest prevalence included insomnia, numbness, early satiety, inactivity and sad mood. Similar to our prior studies, symptomatic burden was most severe and prevalent in MF, except for headache which was least severe in MF. Interestingly, pruritus was not most burdensome in PV patients. Validation Analysis: EORTC-QLQ-C30: Consistent with our experience findings, Pearson correlations between MPN-SAF: French individual symptom scores and the French EORTC-QLQ C30 showed excellent correlations with co-validation questions (>0.5 Pearson correlation). EORTC assessment of fatigue correlated significantly with overall BFI, worst BFI, inactivity and insomnia score ($p<0.001$). Additionally, excellent correlations were demonstrated between EORTC-QLQ-C30 subscales and corresponding MPN-SAF measurements, particularly for items of BFI, inactivity, concentration, and sad mood ($p<0.001$). Physicians and Patient's perceptions: Correlations between physician's blinded perceptions of disease burden and patient-reported symptom severity in six categories of disease symptoms (night sweats, fevers, fatigue, weight loss, bone pain, and pruritus) were excellent for all items ($p<0.001$). Patients indicated that they felt that the survey was comprehensive of their disease symptoms (mean score 2.2/10) and easy to understand (mean score 1.7/10). *Conclusions.* The MPN-SAF: French is an easily administered, clear 27-item inventory of patient-reported outcomes that is specific to MPNs and validated by 1) comparison to compiled international data on MPN-SAF scores and 2) the correlation with the EORTC-French. Utilization of the instrument in French MPN clinical trials will serve as a valuable and specific clinical marker of disease symptom severity among this population.

Table 1.

Symptomatic burden of MPNs as assessed by the MPN-SAF in 482 French patients based on disease type (results are reported as mean (% prevalence). All items measured on a 0 (Absent) to 10 (worst imaginable) scale.

	ET (N=227)	PV (N=175)	MF (N=75)	French (N=482)
Insomnia	2.8 (69%)	2.8 (66%)	3.0 (69%)	2.8 (68%)
Fatigue (BFI Score)	2.5 (33%*)	2.7 (41%*)	3.8 (61%*)	2.7 (53%*)
Sexuality Problems	2.3 (55%)	2.6 (56%)	3.6 (75%)	2.6 (58%)

Background. Mastocytosis is a rare disease characterized by an abnormal proliferation and accumulation of mast cells (MC) in several organs and tissues such as skin, bone marrow, liver, gastrointestinal tract and lymphnodes. It is a clonal disease associated to a somatic mutation of the proto-oncogene c-kit (KIT). Clinical signs and symptoms of mastocytosis mainly depend on the liberation of chemical mediators produced by the mast cells. While the diagnosis of systemic mastocytosis requires the presence of multifocal dense mast cell infiltrates in one or

multiple extra-cutaneous organs (mostly bone marrow, due to the origin of MCs), mastocytosis encompasses a wide range of clinical entities, extremely heterogeneous for clinical course and prognosis. Due to its heterogeneity, mastocytosis is a multidisciplinary pathology involving different specialists. *Aims.* The Italian Mastocytosis Registry was constituted in 2009 with the aim of collecting data about patients diagnosed with mastocytosis at a national level. *Methods.* Anagraphical, anamnestic, clinical, hystopathological, biological, treatment and follow-up data of patients are being routinely collected after written informed consent in 17 Italian centers. An on-line database (www.registroitalianomastocitosi.it) has been set up for this purpose. *Results.* At present, data on 293 patients have been collected. One-hundred-forty-two (48.5%) are females; 151 (51.5%) are males. Ninety-five (32.4%) were diagnosed when younger than 18 years old. One-hundred-thirty patients (44.4%) have been diagnosed with systemic mastocytosis and 73 (56%) of them progressed from a cutaneous disease. Two-hundred-thirty-six patients (80.55%) have cutaneous symptoms. Among the 98 adult patients who were assessed at the time of diagnosis, 88 (89.8%) were symptomatic. One-hundred-and-one (34.5%) patients reported allergies. Of 207 reported lines of therapy, 28% were symptomatic, 43% anti-HH1, 17% anti-HH2, 24% corticosteroids, 16% phototherapy, 4% alpha-interpheron and 13% chemotherapy (total exceeds 100% because therapy combination is allowed). As to histological findings, 134 (46%) patients have data on bone marrow biopsy: 98 (73%) had a positive finding, with a median cellularity of 25% (range 3%-90%). Among 208 patients tested for tryptase, 152 (73%) were positive (median 41.3 µg/L, range 11-746). Among the 128 patients who have been evaluated for both bone marrow biopsy and tryptase, there is a positive association between the two parameters. When considering both variables as dichotomous (positive vs. negative), the two tailed Fisher exact test shows a highly significant association (p=0.00003). When analyzing the 81 patients for which the percentage of bone marrow substitution was reported, there was a significantly positive correlation with the level of tryptase (Spearman rank correlation 0.59; p<0.000001). *Conclusions.* This is the first spontaneous observational study on mastocytosis in Italy. The on-line database is a useful tool for data collection at a national level. The Registry is an opportunity to carry out epidemiological studies aimed at estimating prevalence, incidence and geographical distribution of the disease. It will also provide a standardization of the histopathology criteria to improve the understanding of this disease, also in comparison to other diseases. It will finally allow specialists to investigate possible prognostic factors and provide a starting point for the research into ad hoc therapies.

[5]*Hematology Unit La Sapienza, Roma, Italy*

Background. In essential thrombocythemia (ET), the validated risk factors for thrombosis at onset and during the follow-up are represented by age over 60 y, and history of thrombosis. The thrombocytosis, constitutive abnormality in ET, is associated with both thrombotic and hemorrhagic complications. JAK2 mutation and leukocytosis have been reported as associated with high rate of thrombosis. *Aims.* To evaluate in a large cohort of ET patients the potential thrombotic risk factors as JAK2 mutation, leukocytosis, and other clinical and biological parameters. *Methods.* A cohort of ET patients (PVSG or WHO criteria) of the Registro Italiano Trombocitemia (RIT), with information also on the bone marrow biopsy at diagnosis, were considered for this retrospective analysis. *Results.* A total of 977 patients, 387 males and 590 females, presented at diagnosis: median age 55 y, median PLT count 783 x 10^9/L, median WBC count 8.8 x 10^9/L, median Hb 14.1 g/dL, history of thrombosis in 189 cases (19.3%), history of hemorrhage in 49 cases (5.0%). The patients at high risk (age over 60 y and/or history of thrombosis) were 511 (52 %). During the follow up (4088 pt-y), thrombotic events were reported in 35 patients (3.6%). The thrombotic events at onset of disease were significantly related to: age over 60 (p 0.001), male gender (p <0.05), lower grade of thrombocytosis (PLT < 783 x 10^9/L, p 0.001), higher grade of leukocytosis (WBC > 8.8 x 10^9/L, p 0.01), and JAK2 V617F mutation (p 0.06). No relationship was found with bone marrow fibrosis grade. The 977 patients were subdivided in four groups: lower thrombocytosis and higher leukocytosis (group 1: 202 pts); lower thrombocytosis and lower leukocytosis (group 2: 270 pts); higher thrombocytosis and higher leukocytosis (group 3: 272 pts); higher thrombocytosis and lower leukocytosis (group 4: 197 pts). In those patients, the rate of thrombosis at onset was: 26.7% in the group 1(both risk factors); 24.1% in the group 2 (PLT risk factor); 20.2% in the group 3 (WBC risk factor); 7.6% in the group 4 (no risk factors). The rate of thrombosis in patients with one or two of these risk factors was significantly (p 0.001) higher than in patients with no risk factors. The thrombotic events during the follow up are still object of analysis. *Conclusions.* In this cohort of ET patients the rate of thrombosis at onset of disease has been confirmed to be related to age over 60 y. Moreover, a significant relationship has been found with male gender, JAK2 mutation, WBC count over the median value (8.8 x 10^9/L), and PLT count below the median value (783 x 10^9/L).

0918

INFLUENCE OF 46/1 JAK2 HAPLOTYPE IN THE NATURAL EVOLUTION OF JAK2V617F ALLELE BURDEN IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

A Angona, A Alvarez-Larrán, L Martínez-Avilés, R Longarón, B Bellosillo, C Besses

Hospital del Mar, Barcelona, Spain

Background. The 46/1 JAK2 haplotype predisposes to the development of JAKV617F-associated myeloproliferative neoplasms (MPN) but its clinical relevance after diagnosis is unknown. Objetive. To assess the influence of 46/1 JAK2 haplotype on the natural evolution of JAK2V617F allele burden in patients diagnosed with JAKV617F-associated MPN. *Methods.* JAK2V617F allele burden was prospectively measured in 62 patients with newly diagnosed JAKV617F-associated MPN, corresponding to polycythemia vera (PV) and essential thrombocythemia (ET) in 26 and 36 cases, respectively. Molecular monitoring was performed at diagnosis and every 6-12 months while patients remained free of cytoreductive therapy. SNPs rs12340895 and rs12343867 were used to determine 46/1 JAK2 haplotype status. JAK2V617F allele burden at diagnosis and during follow-up was compared according to 46/1 JAK2 haplotype status (negative, heterozygous, homozygous). The study was approved by the local Ethics Committee and informed consent was obtained according to the Declaration of Helsinki. *Results.* Twenty cases (ET 13, PV 7) were negative for the 46/1 JAK2 haplotype whereas 42 patients carried the 46/1 JAK2 haplotype in heterozygosis (n=29: ET 16, PV 13) or homozygosis (n=13: ET 7, PV 6). Mean JAK2V617F allele burden at diagnosis was 27%, 34% and 41% in patients negative, heterozygous and homozygous for the 46/1 JAK2 haplotype, respectively (p=0.06). Median molecular follow-up was 50 months (range: 12-92) with mean JAK2V617F allele burden at last follow-up being 30%, 38% and 55% in patients negative, heterozygous and homozygous for the 46/1 JAK2 haplotype, respectively (p=0.01). JAK2V617F allele burden remained stable during follow-up in 44 patients whereas 18 patients showed a JAK2V617F increase higher than 10%. The mean increase in JAK2V617F allele burden from diagnosis to last sample was 4.5%, 6% and 15% in patients negative, heterozygous and homozygous for the 46/1 JAK2 haplotype, respectively (p=0.02). There was no significant difference in the mean percentage increase of JAK2V617F allele burden according to age, gender and type of MPN diagnosis. *Conclusion.* The natural evolution of JAK2V617F-associated MPN in patients carrying the 46/1 JAK2 haplotype in homozygosis is associated with a progressive increase in the JAK2V617F allele burden.

THE IMPACT OF CLINICO-HEMATOLOGICAL FEATURES AND MOLECULAR BIOMARKERS ON OUTCOME OF PATIENTS WITH PRIMARY MYELOFIBROSIS

MC Kuo,[1] TL Lin,[1] TH Lin,[2] YH Hung,[1] PN Wang,[1] P Dunn,[1] JH Wu,[1] TC Tang,[1] H Chang,[1] LY Shih[3]

[1]*Chang Gung Memorial Hospital, Taipei, Taiwan*
[2]*Chang Gung University, Taoyuan, Taiwan*
[3]*Chang Gung Memorial Hospital and Chang Gung University, Taipei, Taiwan*

Background. Primary myelofibrosis (PMF) is the rarest subtype of the Philadelphia-negative myeloproliferative neoplasms (MPN). Several

biomarkers, including Endogenous Erythroid Colony (EEC), PRV-1 mRNA expression, X-chromosome inactivation patterns (XCIPs) in females, JAK2^{V617F} and *MPL* gene mutations have been described as useful tools to characterize MPN. The implication of these biomarkers and their correlations to the clinico-hematological features and outcome remained to be determined in patients with PMF. *Aims.* We aimed to determine (1) the frequencies of the biomarkers, and (2) the correlations among the biomarkers, clinico-hematological data and outcome of PMF patients. *Methods.* Granulocytes were isolated from 115 patients with PMF diagnosed by WHO criteria. Allele-specific PCR assay was used to detect JAK2^{V617F}, PCR followed by direct sequencing for *MPL* mutation. EEC assay was performed in a serum-free culture system. PRV-1 mRNA expression in granulocytes was measured by RQ-PCR TaqMan assay, and HUMARA-PCR assay for XCIPs was performed in female patients. *Results.* Of the 115 patients, the median age was 63.8 years, 59 were males. The median level of Hb was 9.6 g/dL, WBC was 11.6 x 10^9/L and PLT count was 365 x 10^9/L. JAK2^{V617F} was detected in 58 of 115 (50.4%) with homozygous pattern in 9; *MPL* mutations in 3 of 93 (3.2%). EEC formation was present in 42 of 85 (49.4%), and PRV-1 overexpression in 32 of 59 (54.2%). Clonal XCIPs was detected in 19 of 22 female examined (86.4%). JAK2^{V617F} mutation was strongly associated with the presence of EEC formation and PRV-1 overexpression ($p<0.0001$). EEC formation was highly associated with PRV-1 overexpression ($p=0.0007$) and lower grade bone marrow fibrosis ($p=0.0245$). Both JAK2^{V617F} and EEC formation were associated with WBC >25.0 x 10^9/L and less circulating blast cells (<1%). PRV-1 overexpression was associated with a high WBC count only. Median overall survival (OS) was 70.2±11.3 months. Fourteen patients (12.2%) developed acute leukemia transformation. Adverse prognostic factors of OS were older age (> 65), Hb <10 g/dL, PLT count < 100 x 10^9/L and absence of EEC formation in a univariate analysis; older age and lower Hb level in the multivariate analysis. Patients who had EEC formation and less circulating blast cells (<1%) at diagnosis had a longer time to leukemia transformation. JAK2^{V617F} mutation and PRV-1 overexpression did not influence OS or time to leukemia transformation. Splenic radiation and ≥1% of circulating blast cells at diagnosis increased the risk of acute leukemia transformation, but other clinico-hematological data, the marrow fibrosis grade or the status of biomarkers did not. *Conclusions.* Our data showed that JAK2^{V617F} was highly associated with EEC growth and PRV-1 overexpression. Factors that adversely affected OS included older age, lower Hb, lower PLT count and absence of EEC formation. Splenic radiation and higher circulating blast cells increased the risk of acute leukemia transformation.

This study was supported by grants DOH100-TD-C-111-006, BMRPG380031 and CMRPG330303.

NEUROLOGICAL SYMPTOMS IN ESSENTIAL THROMBOCYTHEMIA (ET): INCIDENCE, ROLE OF BRAIN IMAGING, INFLUENCE OF JAK2V617F MUTATION, AND OUTCOME

JJ Kiladjian,[1] E Kouroupi,[1] S Billot,[2] J Le Guilloux,[2] B Cassinat,[1] C Jardin,[3] P Fenaux,[2] A Carpentier[2]

[1]*APHP, Hopital Saint-Louis, Paris, France*
[2]*APHP, Hopital Avicenne, Bobigny, France*
[3]*Centre Cardiologique du Nord, Saint-Denis, France*

Background. ET is characterized by thrombotic and ischemic complications in various vascular territories, including the brain. Such neurological complications include transient ischemic attacks (TIA), strokes or cerebral venous thromboses (CVT). In addition, patients may present with a broad range of transient neurological symptoms such as blurred vision, headache, tinnitus, dizziness. Those subjective symptoms are usually considered to be due to cerebral ischemia and highly sensitive to low-dose aspirin (ASA). They were frequently reported in retrospective series (in 20 to 55% of pts), but their incidence in newly diagnosed patients was not clearly assessed prospectively. *Patients and Methods.* From January 08 to June 09, all consecutive newly diagnosed ET patients (WHO criteria) from our center presenting with neurological symptoms were systematically referred to a neurologist for evaluation. Specific explorations included brain MRI with perfusion sequences, cardiac and supra-aortic echography in case of thrombotic symptoms. *Results.* 37 patients were newly diagnosed with ET during the study period. 11/37 (30%) pts complained of possibly ET-related neurological symptoms (several symptoms could be present in the same pt): TIA in 3, CVT in 1, cephalalgia in 5, dizziness / tinnitus in 5, visual disturbances in 2, loss of consciousness in 1 patient, respectively. In the majority of patients (8/11, 72%), those symptoms were subjective, chronic cephalalgia being the most frequent (5/8, 62%), and were always either transient (from few seconds to few minutes) or fluctuating. Neurological examination found no objective abnormality in any patient. Brain MRI (performed in 9/11 pts) failed to detect any objective substratum for these symptoms, even with perfusion sequences (performed in 7/9 pts). Clinical and hematological characteristics (including sex, age, cardiovascular risk factors, platelet counts, WBC, hemoglobin) were not statistically different between the 11 patients with, and the 26 patients without neurological symptoms. JAK2V617F mutation was found in 9/11 (82%) patients with neurological symptoms vs. 14/26 (54%) patients without symptoms. Response to ASA was heterogeneous (1/11 pts already on anticoagulant excluded): complete resolution of neurologic symptoms was observed in 3/10 (30%), improvement with persisting transient episodes in 2/10 (20%), and resistance to ASA in 2/10 (20%) of patients, respectively. In the 2 last patients, complete resolution of symptoms was only observed after initiation of cytoreductive therapy with hydroxyurea. *Conclusion.* In this prospective study of 37 consecutive, unselected newly diagnosed ET patients with specialized neurological evaluation, we found that: 1) incidence of neurological symptoms was 30%, mainly composed of subjective symptoms; 2) brain MRI was always normal in patients with subjective symptoms, suggesting that MRI is not useful in the baseline evaluation of ET patients with atypical neurological symptoms after careful exclusion of focal neurological deficits; 3) JAK2V617F mutation could be a risk factor for developing neurological symptoms in ET, if confirmed in a larger cohort; 4) in contrast to previous reports, low-dose aspirin successfully resolved neurological symptoms in only 30% of cases, the addition of cytoreductive therapy being necessary in some patients.

0921

PRELIMINARY DATA ON CLINICAL ASPIRIN RESISTANCE IN A LARGE COHORT OF PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

E Duner,[1] F Tezza,[2] M Treleani,[2] F Fabris,[2] M Randi[2]

[1]*University of Padua, Padua, Italy*
[2]*Dept. of Medical and Surgical Sciences, Padua, Italy*

Background. Thrombotic complications are major cause of morbidity and mortality in patients with myeloproliferative neoplasm (MPN). Low-dose aspirin significantly reduce the risk of thrombotic complications in polycythemia vera (PV) patients, and is commonly used also in essential thrombocythaemia (ET). In general population, however, some patients taking aspirin (ASA) have thrombotic event in spite of treatment: this is defined as "clinical resistance to ASA". The aim of our study was to retrospectively evaluate clinical ASA resistance in patients with MPN. *Patients and Methods.* The study comprehends 290 MPN patients diagnosed between 1970 and 2009 in accordance with the criteria in use at the time of the first observation and treated in agreement with the current treatment guide-lines. All major thrombotic events occurred during follow up were recorded. Among the 290 patients enrolled, 231 (group A; 79.6%) used ASA (100mg/day) and 59 (group B; 20.4%) did not. The main features of our patients are summarized in table 1. *Results.* 16 patients (4 males, 12 females; 8 ET and 8 PV) of group A (6.9%) had a thrombotic event after a median ASA therapy of 6.04 years: 8 arterial thromboses (3.4% of ASA-treated patients) (4 coronary disease, 1 stroke, 2 TIA and 1 intestinal infarct) and 8 venous thromboses (5 deep and 3 splanchnic vein thrombosis). 62.5% of patients had thrombosis after more than 5 years of treatment. All but 13 patients were JAK2V617F. 10 females (6 ET and 4 PV, all carrying JAK2V617F mutation) of group B (16.9%), had a thrombotic event after a median disease duration of 4.19 years: 3 arterial (1 coronary disease, 1 stroke and 1 TIA) e 7 venous (3 deep, 3 splanchnic vein e 1 cerebral sinus thrombosis). The overall occurrence of thrombotic complications was significantly less ($p = 0.03$) in group A than in group B. *Discussion.* The concept of therapeutic resistance emerged in general population with the clinical obser-

Table 1.

	TOTAL	GROUP A	GROUP B
Total	290	231	59
M/F	120/170	93/138	27/32
ET/PV/MF	154/132/4	127/101/3	27/31/1
Mean age at diagnosis (y)	53 ± 17	55 ± 16	51 ± 18
Median follow-up (y)	9.01	8.76	7.91
JAK2 V617F/WT	193/77	152/63	41/14

vation that aspirin-takers are not invariably protected from acute cardiovascular events. Moreover, loss of therapeutic advantage has been found in individuals on long-term treatment. Our study shows that also in MPN patients ASA-resistance occurs, mainly in long-time treated patients. While it is not surprising that vein thrombosis are not prevented by aspirin, the occurrence of arterial thrombosis in 3.4% of MPN treated with ASA suggest that clinical ASA-resistance is not absent in this particular set of patients. No relation with JAK2 mutational status was observed. Our results need to be confirmed by specific laboratory tests.

0922

HAEMATOLOGICAL ABNORMALITIES ARE COMMON IN NEONATES WITH DOWN SYNDROME AND MAY REVEAL CLINICALLY 'SILENT' LEUKAEMIA

G Hall,[1] A Norton,[2] H Richmond,[2] K Alford,[2] G Cowan,[3] A Roy,[3] G Vallance,[2] P Vyas,[2] I Roberts[3]

[1]*John Radcliffe Hospital, University of Oxford, Oxford, United Kingdom*
[2]*MRC Molecular Haematology Unit, Weatherall Inst of Molecular Medicine, Oxford, United Kingdom*
[3]*Centre for Haematology, Hammersmith Campus, Imperial College London, London, United Kingdom*

Background. Neonates with Down syndrome (DS) are uniquely predisposed to Transient Abnormal Myelopoiesis (TAM), a leukaemic disorder characterised by acquired mutations in the GATA1 gene, which transforms to a clonally-linked myeloid leukaemia (ML-DS) in 20-30% of patients. Children with ML-DS often have no history of TAM, suggesting TAM can be 'silent' since full blood counts (FBC) and blood smears are not routinely performed despite reports of frequent haematological abnormalities in DS neonates. *Aim and Methods.* The prospective Oxford Down Syndrome Cohort Study (ODSCS) systematically determined haematological indices and blood cell morphology in the first week of life in neonates with DS (n=170) compared to normal neonates (n=123). Mutational analysis of GATA1 was performed on leucocyte DNA by PCR. *Results.* Compared to gestation-matched controls, neonates with DS had higher Hb concentrations (20.1+0.2 v 16.6+0.2 g/dL; p<0.0001), increased erythroblastosis (23.5+5 v 3.2+0.5/ 100 leucocytes; p=0.0001) and macrocytosis (MCV 107.6 v 101.5fl; p<0.0001). Neonates with DS had lower platelet counts (165+7 v 252+5x109/L; p<0.001), 98.0% had abnormal platelet morphology and almost half (71/170, 41.8%) were thrombocytopenic (platelets <150 x 109/L). Leucocytes (p=0.0012), neutrophils (p=0.0005), monocytes (p<0.0001) and basophils (p<0.0001) were higher in DS neonates and dysplasic features, rare in controls, were seen in all DS neonates. Fourteen neonates (7.5%) had a final diagnosis of TAM confirmed by the presence of exon 2/3 GATA1 mutations. Neonates with TAM had lower Hb concentrations (17.7+0.8 v 20.1+0.2 g/dL; p=0.0012) and higher MCV (113.3+2 fl; p=0.0088) than DS neonates without TAM and a significantly higher mean platelet count (229.8+88.3 x 109/L; p=0.0042) with a very wide range (36-1208 x 109/L). Total leucocyte counts (38.3+5.4 v 15.2+0.6; p<0.0001) and neutrophils (16.2+2.2 v 9.7+0.5; p=0.0003) were higher in neonates with TAM compared to DS neonates without TAM but there was considerable overlap in values. Blast cells were present on blood smears from all neonates with TAM (33.3+4.5%, range 15-77%) and 98.1% of DS neonates without TAM (4.5+0.3%, range 0.2-18%) although only 7 neonates without TAM (4.4%) had >10% blasts and none of these neonates had GATA1 mutations. Automated blast cell counts were unreliable in nearly all cases. TAM was clinically 'silent' in 2/14 cases (14.3%) and there was no difference between the haematological features of these 2 neonates compared to the other 12 neonates with TAM. *Conclusions.* All neonates with DS have haematological abnormalities usually affecting red cell, platelet and myeloid cell lineages. The most serious complication, TAM, may be clinically silent. These data suggest that FBC and blood smears should be part of the assessment of all newborn babies with DS in the first week of life and screening for GATA1 gene mutations performed where blasts exceed 10%.

RISK OF EVOLUTION TO MYELOFIBROSIS AND ACUTE LEUKEMIA IN PATIENTS WITH ET OR PV.WITHOUT CLINICAL HEMATOLOGICAL RESPONSE. ACCORDING EUROPEAN LEUKEMIA NET CRITERIA

C Burgaleta, M Guillen, E Magro, M Callejas, J Garcia Suarez, N Curto, JJ Gil Fernandez

Hospital U. Principe de Asturias, Madrid, Spain

Background. Chronic myeloproliferative diseases, Polycythemia vera (PV) and Esential Thrombocytemia (ET) have the risk of evolution to Myelofibrosis (MF) and Acute Leukemia.(AL). European Leukemia Net (ELN) party have defined new criteria to asses clinical, histological and molecular response in order to evaluate prognosis and new therapeutic agents. *Aims.* We performed a retrospective analysis of evolution of PV and ET patients in order to analyzed incidence of transformation to MF or LA in relation to ELN clinical response criteria. *Material and Methods.* Date base with clinical and laboratory data from 147 patients diagnosed of ET or PV and followed in a teaching hospital of Madrid during the last 20 years were analyzed. *Results.* 108 patients present ET at diagnosis and 38 PV. Mean age at diagnosis was 61 and 67 years respectively. Incidence of ET was more often on females (57%F%/42%M) and PV was slightly more often on males (46%W/54%M). A total of 6% develop MF or LA under evolution. ET develop MF in 6 patients (5%) and acute leukaemia (AL) in 2 patient (2,8%). 3 patients with PV develop AL (5,1%). Evolution appear at diferent time intervals: AL appear in patients between 6 and 17 years from diagnosis. MF was developed between 3 and 20 years (mean 14 years). Other 12 patients (8%) died from additional complications (2 solid neoplasia, 2 sepsis, 5 ETE 1 Hemorrhagic, 2 unknown). All were patients of high risk and none of those patients showed Complete Clinical Response according to ELN during follow up. 21 present mayor complications (thrombotic or hemorrhagic) at diagnosis /or under evolution. Three of 6 patients with MF are still alive but present clinical resistance to HU before transformation. *Conclusion.* Resistance to treatment appears as a bad prognosis indicator in patients with ET and PV. Treatment oriented to achieve complete clinical response according to ELN seen to be mandatory in these patient population.

PROSPECTIVE VALIDATION OF THE DUTCH MYELOPROLIFERATIVE NEOPLASM SYMPTOM ASSESSMENT FORM (MPN-SAF: DUTCH) IN 236 MPN PATIENTS

S Slot,[1] S Zweegman,[1] P te Boekhorst,[2] S Commandeur,[3] H Schouten,[4] A Tefferi,[5] A Dueck,[5] R Mesa[5]

[1]*VU University Medical Center, Amsterdam, Netherlands*
[2]*Erasmus MC, Rotterdam, Netherlands*
[3]*LUMC, Leiden, Netherlands*
[4]*MUMC, Maastricht, Netherlands*
[5]*Mayo Clinic, Rochester, MN, United States of America*

Background. Myeloproliferative Neoplasma (MPN) give rise to specific symptoms generally not assessed by validated Quality-of-Life (QoL) Questionnaires. In view of the reported high impact of these specific symptoms on QoL and social participation, detailed information on the effect of new developed therapies is of importance. The MPN-Symptom Assessment Form (MPN-SAF) is a concise instrument of patient reported outcomes designed to assess the unique spectrum of symptoms present in patients with MPN. *Aims.* We sought to validate this instrument and to assess symptoms in a representative Dutch population of patients with myelofibrosis (MF), essential thrombocythemia (ET) and polycythemia vera (PV). *Methods.* The MPN-SAF was translated in Dutch by one of the authors fluent in both languages, confirmed by one member of the Dutch patient MPN Foundation and sent to all members of the Dutch MPN Foundation. The Dutch EORTC-QLQ-C30 was co-administered for validation purposes. In addition, data were compared to a cohort of 102 USA MPN patients completing the MPN-SAF English. *Results.* The questionnaires were sent to 874 patients. The response rate was 39%. A total of 236 patients were included in the analysis (ET [n=72; 30.5%)], PV [n=119; 50,4%] and MF [n=45; 19,1%]), as 104 questionnaires (34%) had not been completely filled out. The distribution of the type of MPN (19.6%, 22.5% and 57.8% respectively, p<0.001) and median age (mean 58.7 ± 11.5 versus 65.2 ± 12.5, p<0.001) were significantly different as compared to the USA cohort. The time between diagnosis and response was 7 years (median, range: 0-39). The majority of patients had received non-aspirin medical therapy 62% (n=147) and 56% (n=131) was on therapy at the time of completing the questionnaire. The frequency of thrombotic events was 19% (66% reported no events, 15% unknown) and that of hemorrhagic events was 8,5% (89% reported no events, 2,5% unknown). The MPN-SAF measured 19 items in the enrolled patients on a 0 to 10 scale (Table 1). *Validation analysis.* Consistent with our experience with the MPN-SAF English Pearson correlations between MPN-SAF Dutch individual symptom scores and the Dutch EORTC-QLQ C30 showed excellent correlations with co-validation questions concerning fatigue, pain, insomnia, early satiety, and sad mood (all p<0.001). *Comparison with MPN-SAF English.* Comparison with the USA cohort (when adjusting for age and MPN subtype) showed no sta-

Table 1.

	ET (n=72)	PV (n=119)	MF (n=45)	Total (n=236)
Fatigue (BFI score)	4,2 (3,7-4,8)	4,5 (4,1-4,9)	4,1 (3,3-4,8)	4,3 (4,0-4,6)
Early satiety	2,5 (1,9-3,2)	3,2 (2,7-3,7)	4,1 (3,2-5,0)	3,2 (2,8-3,6)
Abdominal pain	1,6 (1,0-2,1)	1,8 (1,4-2,3)	2,3 (1,4-3,1)	1,8 (1,5-2,2)
Abdominal discomfort	1,7 (1,1-2,2)	2,2 (1,7-2,6)	2,5 (1,6-3,4)	2,1 (1,7-2,4)
Inactivity	2,9 (2,2-3,5)	3,2 (2,6-3,7)	3,4 (2,5-4,2)	3,1 (2,7-3,5)
Headache	2,5 (1,9-3,1)	2,2 (1,8-2,7)	1,7 (0,9-2,4)	2,2 (1,9-2,5)
Concentration	4,4 (3,7-5,0)	4,4 (3,8-5,0)	2,8 (1,9-3,6)	4,1 (3,7-4,5)
Dizziness	3,0 (2,4-3,7)	3,3 (2,7-3,8)	2,4 (1,7-3,2)	3,0 (2,7-3,5)
Numbness	2,3 (1,7-2,9)	2,9 (2,3-3,4)	2,8 (1,9-3,7)	2,7 (2,3-3,0)
Insomnia	3,2 (2,5-3,9)	3,8 (3,1-4,4)	2,9 (2,0-3,8)	3,4 (3,0-3,8)
Sad mood	2,5 (1,9-3,0)	2,9 (2,4-3,5)	2,3 (1,6-3,1)	2,7 (2,3-3,0)
Sexuality problems	3,3 (2,6-4,1)	4,6 (4,0-5,3)	4,3 (3,2-5,5)	4,2 (3,7-4,6)
Cough	1,7 (1,1-2,2)	2,1 (1,6-2,6)	2,3 (1,4-3,2)	2,0 (1,7-2,3)
Night sweats	2,7 (2,0-3,4)	2,7 (2,2-3,3)	3,4 (2,4-4,3)	2,9 (2,5-3,2)
Itching	2,0 (1,4-2,7)	3,7 (3,2-4,3)	2,5 (1,5-3,5)	3,0 (2,6-3,4)
Bone pain	1,6 (1,0-2,2)	2,2 (1,7-2,7)	2,6 (1,6-3,6)	2,1 (1,7-2,4)
Fever	0,2 (0,1-0,4)	0,5 (0,3-0,8)	0,7 (0,1-1,3)	0,5 (0,3-0,6)
Weight loss	1,0 (0,5-1,5)	1,1 (0,7-1,5)	1,5 (0,7-2,3)	1,2 (0,9-1,5)
Quality of life	3,6 (3,0-4,1)	4,4 (3,9-4,9)	3,5 (2,8-4,3)	4,0 (3,6-4,3)

tistically significances between cohorts in all but 3 items, in which the severity was higher in the Dutch cohort (dizziness [p=0.04], effect on sexuality [p=0.005], and night sweats [p=0.03]). *Conclusions.* The MPN-SAF Dutch is a 19 item inventory of patient reported outcomes that is specific to MPNs. Additionally, the instrument is validated by 1) comparison to the Dutch EORTC-QLQ C30 2) the correlation with the MPN-SAF English. Utilization of the MPN-SAF Dutch will provide information on the effect of new treatment modalities on MPN-related symptoms. It will allow for useful comparison to patients in other countries and can be used in future international clinical trials. 34% of patients did not totally complete the questionnaire, however more detailed instructions will probably improve the use in general practice.

LONG-TERM USE OF ANAGRELIDE IN CHILDREN AND ADOLESCENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE DISEASES

F Giona,[1] G Palumbo,[1] ML Moleti,[1] AM Testi,[1] M Nanni,[1] D Marzella,[1] E Grimaldi,[1] A Amendola,[2] R Foà[1]

[1]*"Sapienza" University, Rome, Italy*
[2]*Ospedale San Carlo, Potenza, Italy*

Background. The efficacy and safety of anagrelide (ANA) have been demonstrated in adults with essential thrombocytemia (ET). The number of children treated with ANA is very low and data on the long-term use of this drug are sporadic. *Aim.* This single-center study was aimed at evaluating the efficacy of ANA in children and adolescents with Philadelphia-negative myeloproliferative diseases (Ph- MPD), previously untreated or resistant/intolerant to other cytoreductive drugs. *Methods.* Patients (pts) aged <20 years (yrs) at the time of a Ph- MPD diagnosis carried out according to the PVSG criteria and, from 2002 onwards, to the WHO criteria were treated with ANA at a dosage ranging between 0.5-1.5 mg/day. An informed consent was obtained in all cases. All pts were also investigated for biological markers (JAK2 mutations, PRV-1 expression, thrombopoietin and its receptor (c-MPL) mutations, clonality on female pts). *Results.* From April 1997 to January 2007, 12 pts with ET (11 pts) or familial thrombocytosis (FT = 1 pt) (8 female, 4 male; median age at diagnosis: 10 yrs [range:5-19]; median age at the ANA treatment: $15^{6/12}$ yrs [range: 5-31]) were treated with ANA alone (5 pts) or in combination with hydroxyurea (HU) when the platelet (plt) count was >1000 x 10^9/L and symptoms were present (7 pts). Ten pts had previously received HU + pipobroman (2 pts) + interferon-α (1 pt) for a median time of $5^{4/12}$ yrs; 2 pts were untreated. The median time from initial diagnosis was $5^{4/12}$ yrs (range: 1 month - 11 yrs); the median plt count prior to treatment was 1062 x 10^9/L (range 322-3338 x 10^9/L). A complete response (plt <450 x 10^9/L for >1 month) was recorded in 6/12 pts (50%) after a median time of 6 weeks (range 3-24 weeks) and a partial response (plt 450 - 600 x 10^9/L for >1 month) was observed in 3 pts after 12 months, so that 9/12 (75%) pts achieved a response at a median time of 2 months after starting treatment. Interestingly, the dose of ANA was tapered and finally stopped in 2 complete responders after 32 and 72 months, respectively, of therapy and they show a normal plt count after 26 and 10 months, respectively, without no further treatment. Six of the 9 responders are still being treated after a median of $7^{6/12}$ yrs. Ten pts experienced early isolated or combined side effects, as headache (n=7), abdominal pain (n=3), vomiting (n=1), diarrhea (n=1), that disappeared over time in all but 3 pts. In these cases, persistent headache resulted in discontinuation of ANA after 5 weeks, 11 and 28 months, respectively, of treatment. Over the long term, mild self-limiting anemia has been recorded in 2 females. None of the pts developed leukemia or myelofibrosis or thrombotic complications during the long-term treatment with ANA. *Conclusions.* In our experience, ANA proved effective in controlling the plt number in thrombocytemic pts. A decrease of side effects was observed during long-term treatment with ANA; although 25 % of the total cohort stopped ANA.

Non-Hodgkin lymphoma - Clinical 2

A PHASE II TRIAL ADDRESSING THE ROLE OF HELICOBACTER PYLORI-ERADICATING ANTIBIOTIC THERAPY AS EXCLUSIVE TREATMENT FOR STAGE I-II1 DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) OF THE STOMACH (HGL-1 TRIAL)

S Govi,[1] C Patti,[2] M Raderer,[3] F Ilariucci,[4] S Luminari,[5] A Guidetti,[6] A Mulè,[2] M Ponzoni,[1] E Viale,[1] S Dell'Oro,[1] P Arcidiacono,[1] A Ferreri[1]

[4]*AO Santa Maria Nuova, Reggio Emilia, Italy*
[5]*Dept.Onco-Hematology, Policlinico di Modena, Modena, Italy*
[6]*Oncologia Medica 3, Ist. Nazionale Tumori, Milan, Italy*

Background. Helicobacter pylori (Hp) infection is associated with both marginal zone lymphoma of Mucosa-Associated Lymphoid Tissue (MALT)-type and DLBCL of the stomach. Hp-eradicating therapy is the standard treatment for limited-stage Hp-associated MALT lymphoma of the stomach, whereas the role of this strategy in gastric Hp-associated DLBCL is controversial, with successful reports in a few, small monoinstitutional retrospective studies. On this background, we conducted a multicentre phase II trial addressing the role of Hp-eradicating therapy as exclusive treatment in gastric DLBCL. *Aims.* To assess feasibility, activity and efficacy of Hp-eradicating therapy as exclusive treatment for limited-stage DLBCL of the stomach. *Methods.* Inclusion criteria were histopathologic diagnosis of DLBCL, with or without concomitant MALT-type areas; Hp-infection assessed by breath test or on multiple gastric biopsies; stage I-II1 of disease; hemoglobin >9 g/dl; perigastric lymph nodes diameter <1.5 cm; normal LDH serum level. Registered patients received clarithromycin 500 mg bid, tinidazole 500 mg bid and omeprazole 20 mg bid, for 7 days as exclusive treatment. Objective response and bacterial eradication were assessed by gastric endoscopy-ultrasonography, biopsies and breath test after one and two months from antibiotics. Responsive patients were referred to observation; patients with stable (SD) or progressive (PD) disease received conventional treatment. *Results.* From 2003 to 2008, 15 patients (median age 70; range 40-87; 10 males) were registered. Five patients presented concomitants MALT areas, while 10 patients had de novo DLBCL. Five patients had stage IE, 10 patients had stage II1 disease. Five patients presented anemia; two patients had concomitant HCV infection. Eradicating therapy was completed in all patients without relevant toxicity. Eradication was documented at one month in 14 patients and achieved after second-line antibiotic-therapy in the remainder patient. According to the WHO criteria, lymphoma regression was complete in 7 (47%) patients, partial in 3 (ORR= 67%), with one SD and 4 PD. Objective response was not associated with stage or concomitant MALT areas. At a median follow-up of 37 months, six of the 7 CRs are relapse-free, the remainder experienced relapse at 10 months, with a median DFS of 31+ months. Two of the three patients in PR achieve CR after rituximab. Patients with SD/PD after antibiotics achieved CR with salvage R-CHOP ± radiotherapy; none of them experienced relapse after 6-93 months. No patient died of lymphoma; two patients died of cardiac failure and gallbladder cancer, respectively; the remaining 13 patients are alive (12 patients are disease-free), with a 5-yr OS of 92%. *Conclusions.* This is the first prospective trial addressing the role of Hp-eradicating therapy as exclusive treatment in patients with gastric DLBCL diagnosed in Western countries. Patients with stage I-II1 DLBCL can be safely managed with this strategy. Half of treated patients will achieve long-term remission without chemotherapy, a critical issue considering that two-thirds of patients are >65 years old. Unresponsive patients can be safely salvaged with conventional treatment. Analysis of correlation between treatment efficacy and biological features of these lymphomas are advisable in order to select the best candidates for this ultraconservative approach.

TEMSIROLIMUS FOR RELAPSED PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA: EFFICACY AND PHARMAKOKINETIC STUDY

P Kiewe,[1] T Grobosch,[2] E Thiel,[1] A Korfel[1]

[1]*Charité Campus Benjamin Franklin, Berlin, Germany*
[2]*BBGes - Clinical Toxicology and Pharmacology, Berlin, Germany*

Background. Salvage treatment is poorly defined in primary CNS lymphoma (PCNSL). Temsirolimus is a selective inhibitor of cell proliferation promoting intracellular protein mTOR with proven activity in lymphatic malignancies. *Aims.* We designed a phase II study (NCT00942747) to evaluate activity and toxicity of a temisrolimus (TEM) monotherapy in relapsed PCNSL and to study its penetration into cerebrospinal fluid (CSF). *Methods.* Included were immunocompetent patients with histologically confirmed PCNSL relapsing or progressive after HDMTX-based chemotherapy, age ≥18 years, and ECOG ≤ 2. Primary endpoint was overall response rate, secondary endpoints were toxicity, time to progression and CSF penetration of TEM and its metabolite sirolimus (SIR). For CSF studies blood and CSF samples were simultaneously collected 30-60min after first, second and fourth infusion, and concentrations of TEM and SIR were measured by HPLC with mass spectrometry detection. *Results.* Twelve patients (median age 64 years, median ECOG PS 2) were included. Six patients each received 25mg TEM or 75mg weekly with a median of 7 (range, 2-14) infusions. Median number of previous therapy regimens was 3 including whole brain irradiation in 3 patients and high-dose chemotherapy followed by autologous stem cell transplantation in 2. Best responses were CR in two and PR in 4 patients. 6 patients did not respond or progressed. Of all objective responses, 5 (including all patients with CR) were observed in the 75mg cohort. Responding patients have a PFS of 0.7+, 1+, 2+, 2,7, 3+ and 3.1 months each (3 patients still on treatment). CTC ≥grade III toxicity was leukopenia and thrombocytopenia in 3 patients each, fatigue and pneumonia in 2 patients each and anemia in one patient,. Five patients required dose reduction, four of them in the 75mg cohort. Fourteen blood/CSF pairs were collected in 9 patients (25mg cohort: 10 pairs in 5 patients; 75mg cohort 4 pairs in 4 patients). Mean maximum blood concentration was 292ng/ml for TEM and 37.2ng/ml for SIR in the 25mg cohort; 484 ng/ml (TEM) and 91,1 (SIR) in the 75mg cohort. No drug was detected in CSF (lower detection level 1ng/ml) in either cohort. *Conclusions.* Temsirolimus at a dose of 75mg weekly showed promising activity with tolerable toxicity in the treatment of relapsed/refractory PCNSL. Neither TEM nor SIR could be detected in the CSF.

0928

HOW TO PREDICT THE OUTCOME IN MATURE T- AND NK-CELL LYMPHOMA BY CURRENTLY-USED PROGNOSTIC MODELS?

HN Lin, CY Liu, P Jih-Tung, FP Chang, CF Yang, YB Yu, LT Hsiao, TJ Chiou, JH Liu, JP Gau, CH Tzeng, PM Chen, YC Hong

Taipei Veterans General Hospital, Taipei, Taiwan

Background. The prognosis of mature T- and natural killer (NK) -cell lymphoma (PTCL and NKTCL) is poor. Therefore, to select an appropriate prognostic model in treatment of mature T- and natural killer (NK) -cell lymphoma (PTCL and NKTCL) is crucial. *Aims.* This study investigated the usefulness of Ann Arbor staging classification 'International Prognostic Index(IPI)' Prognostic Index for T-cell lymphoma (PIT) and International peripheral T-cell lymphoma Project score(IPTCLP). *Methods.* Between 2000 and 2009, 176 patients (122 males) with PTCL and NKTCL were diagnosed and treated from a single institute in Taiwan. The correlation between complete response(CR) rate '3-year overall survival(OS)' early mortality rate and 4 prognostic models was analyzed. Thirty-one patients received hematopoietic stem cell transplantation (HSCT) and were analyzed separately. *Results.* Three-year OS rate was 34.7%, and ALCL harbored better outcome than others. IPI score had the lowest AIC value and was the best score in predicting OS. Ann Arbor stage classification can predict CR rate more precisely.

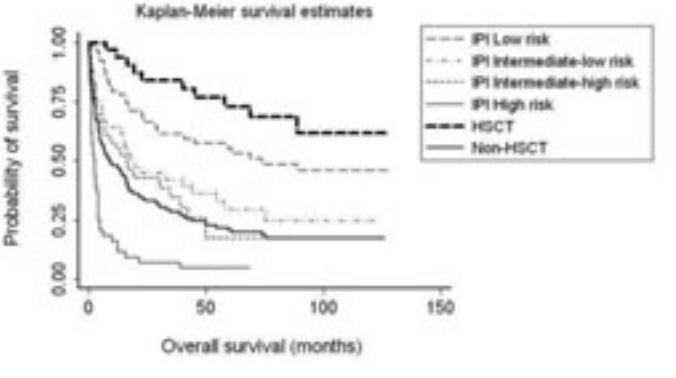

Figure 1. OS by Kaplan Meier method of HSCT group and IPI.

OS were significantly better in patients who received HSCT, even in patients with unfavorable features compared with chemotherapy alone. *Summary/Conclusion.* All prognostic models were useful to evaluate the outcome of patients with PTCL and NKTCL but IPI score did best in predicting OS.

This study also supported the role of HSCT in patients with high-risk or refractory PTCL or NKTCL.

0929

CLINICAL AND BIOLOGICAL DIFFERENCES BETWEEN PATIENTS WITH CHILDHOOD T-CELL LYMPHOBLASTIC LYMPHOMA (T-LBL) WITH AND WITHOUT MEDIASTINAL TUMORS

S Semochkin,[1] S Kulikova,[1] D Litvinov,[2] E Inyushkina,[3] N Myakova,[1] K Kondratchik,[4] L Baidun,[2] D Konovalov,[1] A Peregudov,[3] L Schelechova,[2] E Samochatova[1]

[1]*Federal Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation*
[2]*Russian Children's Clinical Hospital, Moscow, Russian Federation*
[3]*Regional Oncology Dispensary, Balashikha, Russian Federation*
[4]*Morozov Children Clinical Hospital ¢1, Moscow, Russian Federation*

Background. T-cell lymphoblastic lymphoma (T-LBL) is immature T-cell malignancies with similar morphological features and optimal treatment strategies with T-cell acute lymphoblastic leukemia (T-ALL). In adults, T-LBL is a rare form of non-Hodgkin lymphoma (NHL) with an incidence of < 1.7%. The incidence is the highest in children and adolescents, where T-LBL constitutes about 25-30% of all NHL [Swerdlow SH, *et al.*, 2008]. Results of treatment with intensive ALL-like regimens are fine and significant adverse prognostic factors could not be identified due to the small number of patients (pts) with this rare disease. Aim of this study was to investigate the effect of individual clinical and biological features on the disease outcome. *Methods.* From May 1991 to October 2008, 58 pts (m-40, f-18) with de novo LBL were treated with NHL-BFM 90 or 95 protocols for non-B-NHL (ALL-type) and 6 (10%) - NHL-BFM 90 (NHL-type). In an analysis of prognostic factors in 43 pts with T-LBL treated with ALL-type therapy were included. *Results.* Median age at time of presentation was 11.0 (range 1.5-21.6) years. 45 (90%) patients have a T-cell immunophenotype. 53 (91%) had advanced (III, IV) stage. The presenting sites of T-LBL included mediastinal mass - 35 (78%) and bone marrow (BM) involvement - 13 (29%). The complete response (CR) rate was 94 and 83% for non-B-NHL and B-NHL treatment respectively. 5-years event free survival (5y-EFS) was 0.80 ± 0.06 (median of observation 4.1 years) and 0.67 ± 0.19 (5.1 years) respectively (p>0.05). 5-years overall survival (5y-OS) was 0.85 ± 0.05 and 0.80 ± 0.06 respectively (p>0.05). The clinical features and outcome the T-LBL pts treated with ALL-type therapy was demonstrated in table 1. In a situation without mediastinal tumors the prognosis of T-LBL was unfavorable compared to without it (5y-EFS 0.56 ± 0.17 vs. 0.90 ± 0.05, p=0.036). Cases without mediastinal tumors were represented by early (pro-T/pre-T) immunological subtypes (100% vs. 36%, p=0.041) while those with mediastinal tumors by late (cortical/medullar T) subtypes. Sex, age, increased LDH, slow or fast therapy response, involvement of the central nervous system (CNS) or BM did not affect on the prognosis (p>0.05). *Conclusions.* Our data demonstrate that situation without the mediastinal tumors are a factor adverse prognosis for childhood T-LBL treated by ALL-BFM-type therapy. Based on the characteristics of a normal T-cell lymphopoiesis suggests the existence of significant biological differences between the variants of T-LBL with and without mediastinal tumors.

Table 1.

Clinical features and outcome in childhood T-LBL

Characteristic	Mediastinal tumor		P-value
	No (n=10)	Yes (n=33)	
Median age (range), years	13.5 (1.5-16.8)	10.5 (2.0-21.6)	0.41

0930

IMPACT OF RITUXIMAB MAINTENANCE TYPE AND FCGRIIA AND FCGRIIIA GENOMIC PROFILE IN PATIENTS WITH PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA

A Antonio, C Fernández, B Sánchez-González, M García, E Gimeno, A Angona, S Saumell, F García, S Serrano, C Besses, B Bellosillo

Hospital del Mar, Barcelona, Spain

Background. The PRIMA study has demonstrated that maintenance with Rituximab (R) during two years significantly improve progression free survival in patients with previously untreated follicular lymphoma (FL) responding to immunochemotherapy. Polymorphisms in the IgG Fc receptor FcγRIIIa and FcγRIIa genes have been associated with response in several lymphoma types. The aim was to retrospectively analyse our experience with R maintenance (RM) in pts with previously untreated follicular lymphoma (FL) responding to rituximab or immunochemotherapy and, also to analyse the impact of polymorphisms regarding progression free survival, incidence of hypogammaglobulinemia and Ig levels. *Patients and Methods.* patients with FL in CR or PR after first-line R o R-Chemo received RM: type 1) R 375 mg/m2/week x 4 consecutive weeks every 6 months during 2 years or type 2) R 375 mg/m2 every 3 or 2 months during 2 years. FcγRIIa and FcγRIIIa genotypes were determined following a PCR-restriction fragment length polymorphism method. *Results.* Thirty-nine consecutive pts were included. Clinical characteristics at diagnosis: median age 66 years (range, 27-85); 17 (44%) male; Ann Arbor III-IV: 33 (85%); B-symptoms: 5 (11%); FLIPI ≥3: 48%. Treatment previous maintenance: 6 (15%) chemo without R, 3 (8%) R and 30 (77%) R-chemo. Twenty-two (56%) received antracyclin-containing chemo. Status previous starting RM: CR in 80% and PR in 20%. Type of RM: RM1 in 16 (41%) and RM2 23 (59%). The distribution of polymorphisms was: FcγRIIa HH 15 (22%), HR 2 (5%) and RR 22 (56%), and FcγRIIIa VV 11 (28%), VF 21 (54%) and FF 7 (18%). At a median follow-up since first R maintenance infusion of 40 months (3-106), 9 pts (23%) have relapsed and 4 (10%) have died. Overall and progression free survival at 4 years were 95% and 79%, respectively. Antracyclin-containing chemotherapy was significantly associated with a different probability of progression (HR 5.2; 95% CI 1.1-25.1, p=0.022), but not the following variables: status prior to maintenance, type of maintenance and FcγRIIa or FcγRIIIa genotype. Hipogammaglobulinemia was present in 41% and 49 % of pts before and after R maintenance, respectively. Levels of IgM diminished at the end of maintenance in pts with FcγRIIa HR-RR (p=0.019) and in those with FcγRIIIa VF-FF (p=0.017). IgG and IgA levels did not significantly change during maintenance. *Conclusions.* R maintenance for two years in patients with previously untreated follicular lymphoma (FL) responding to immunochemotherapy is a very active therapeutic strategy, but those pts receiving antracyclin-containing treatment had lower probability of progression. The two schedules of R maintenance were effective and all pts benefited independently of FcγRIIa and FcγRIIIa genomic profile. Levels of IgM were significantly influenced according to FcγRIIa and FcγRIIIa genotypes.

0931

AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) AS A CONSOLIDATION OFFERS A DURABLE SURVIVAL BENEFIT IN PATIENTS WITH PERIPHERAL T-CELL LYMPHOMAS (PTCL)

G Helbig, K Machura, M Makowska, T Kandzia, M Kubeczko, T Oleksy, M Liszka, S Kyrcz-Krzemien

Silesian Medical University, Katowice, Poland

Background. Peripheral T-cell lymphomas comprise a heterogeneous group of malignancies which are characterized by an aggressive disease course and a poor clinical outcome after conventional chemotherapy with 20-25% of patients being alived after 5 years from treatment initiation. ASCT for relapsed and refractory patients with PTCL seems to be an effective salvage regimen with event-free survival exceeding 35%, however the risk of disease progression or relapse remains high. *Material and Methods.* In a single centre retrospective study, we analyzed the results of ASCT in 29 patients with advanced stage PTCL. Patients were proceeded to transplant after achieving first or subsequent complete remission (CR) or partial response (PR) after conventional chemotherapy. *Results*. Twenty nine patients (15 male and 14 female) at a median age at diagnosis of 45 years (range 20-66 years) were analyzed. The study cohort included 16 patients with ALK-negative or unknown anaplastic large T-cell lymphoma (ALCL) and 13 with peripheral T-cell lymphomas unspecified (PTCL-U). There were no significant difference in

demographic and clinical features between both cohorts except of tendency for higher platelet count in ALCL subgroup (p=0,06). The majority of patients in both subsets had advanced disease at diagnosis (III and IV clinical stages; 73%) and B symptoms (76%). International prognostic index (IPI) ≥2 was demonstrated in 10 PTCL-U and 6 ALCL patients. Induction chemotherapy consisted of a median of six CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone) cycles (range 1-10). The median number of all given cycles before ASCT for PTCL-U and ALCL was 8 (range 3-20) and 7 (3-18), respectively. There was no difference in median time from diagnosis to ASCT between subgroups. The disease status at diagnosis was as follows: eight CR and 5 PR for PTCL-U and 8 CR and 8 PR for ALCL. Conditioning regimen before ASCT consisted of CBV (cyclophosphamide, BCNU, etoposide) for 15 and BEAM (BCNU, cytarabine, etoposide, melphalan) for 4 patients. The engraftment was observed in all transplanted patients, there were no significant difference in hospitalization time and number of infections between compared subgroups. Among 29 transplanted patients, 7 (24%) died due to disease progression. Twenty two patients remain in CR. The median follow-up time was 4 years. The 4-year probability of the overall survival for whole group was 57% (58% for PTCL-U and 48% for ALCL). The probability of disease-free survival (DFS) after 4 years was 55% for whole cohort (56% for PTCL-U and 44% for ALCL). In an univariate analysis older age, the higher number of prior lines of chemotherapy and disease status at transplant were found to be associated with the lower probability of survival, but only age >45 years was found to influence the outcome independently in multivariate analysis. *Conclusions.* We have confirmed that ASCT as consolidation therapy for PTCL is a safe and efficient procedure for PTCL patients who are chemosensitive after induction chemotherapy. OS and DFS were comparable between PTCL-U and ALCL and older age at transplant was associated with inferior clinical outcome.

0932

ANAPLASTIC LARGE CELL LYMPHOMA ALK POSITIVE AND ALK NEGATIVE: CHARACTERISTICS AND OUTCOME OF 98 CONSECUTIVE PATIENTS FROM A SINGLE INSTITUTION OVER 25 YEARS

K Domanska-Czyz, B Ostrowska, G Rymkiewicz, J Romejko-Jarosinska, L Poplawska, E Paszkiewicz-Kozik, W Michalski, J Walewski

The Maria Sklodowska-Curie Memorial Institute and Centre of Oncology, Warsaw, Poland

Background. Anaplastic large-cell lymphoma (ALCL) is a T-cell lymphoma characterized by expression of CD 30, often associated with t(2;5) (p23;q35) involving anaplastic lymphoma kinase (ALK). ALK positive and ALK negative systemic ALCL are defined as distinct entities in the WHO 2008 classification. The first-line of treatment in adults patients is evaluated in clinical trials, especially in ALK negative cases. *Purpose.* Retrospective evaluation of outcome in 98 patients with ALCL ALK+ and ALK- according to clinical features and treatment regimen. *Patients and Methods.* Between 1985 and 2004 majority of patients received CHOP or CHOP-like chemotherapy (Group 1, n=75). Since 2004 most of patients were treated with intensive protocol of the German Multicentre ALL Study Group B-ALL/NHL 2002 (Group 2, n=23). ALK protein expression was tested in 82 pts. Kaplan-Meier method was used to estimate overall survival time and progression free survival time. Cox proportional hazards model was used in multivariate analysis of clinical variables. *Results.* Median age (range) was 40 (15-83), 59% were male, 45% were in clinical stage (CS) IV, 61% had B symptoms, 46% had bulky disease, 50% had LDH > N, and 56% had IPI score >1. Group 1 and Group 2 were significantly different in age: 42 vs 33 (p=0.003), ALK positivity: 41% vs 82% (p=0.001), HGB>12 g/dl: 59% vs 26% (p=0.008), and CS IV: 39% vs 65% (p=0.032), respectively. Median overall (OS) and progression free survival (PFS) was 63,5 months, 95% C.I.=[0.0,130,9] and 31,2 months, 95% C.I.=[0,00,72,40]. Five years OS and PFS was 50%, 95% C.I. = [40%, 61%] and 45%, 95% C.I. = [34%, 56%].On multivariate analysis, CS IV (p=0.001), B symptoms (p=0.001), bulky disease (p=0.001) and LDH>N (p=0.005) were independent adverse factors for OS. CS IV (p= 0.002), B symptoms (p=0.024), PS>1 (p=0.053) and group 2 (p=0.011) were significant factors for PFS. IPI score > 1 was significant adverse factor for OS (p=0.000) and PFS (p=0.000). Risk of progression was three-fold Iess in Group 2 than in Group 1. *Conclusions.* CS IV, B symptoms, bulky disease and high IPI were independent adverse factors for OS and PFS. Outcome of patients in Group 2, in majority treated with intensive chemotherapy, appears encouraging with emerging plateau on PFS, although there were marked differences in clinical characteristics between the groups.

ASSOCIATION BETWEEN THE IMMUNOHISTOHEMICAL GCB/NON GCB CLASSIFICATION AND THE OUTCOME OF THE PATIENT WITH DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH RITUXIMAB-CHOP REGIMEN: SINGLE CENTRE EXPERIENCE

S Trajkova,[1] I Panovska-Stavridis,[1] A Stojanovik,[1] G Petrusevska,[2] D Dukovski,[1] L Cevreska[1]

[1]*University Clinik of Haematology, Skopje, Macedonia*
[2]*Institute of Pathology, Skopje, Macedonia*

Immunohistohemical analyses classify diffuse large B cell lymphoma according to the origin of the tumor cells into two subcategories, as germinal center B-cell Like (GCB) and non-GCB DLBL. Many studies indicated that prognosis of GCB DLBL is better that of non-GCB DLBL after receiving CHOP regimen as initial therapy. However, recently the results from one large prospective study indicated that immunoblastic morphology and not immunohistohemical features predict the outcome of the DLBL. In order to investigate the prediction value of the immunohistohemical GCB/non GCB classification of DLBL of the outcome of our DLBL patient treated with the Rituximab (R)-CHOP regimen we conducted a retrospective study. Our study enrolled 132 DLBL patients diagnosed and treated at the University Clinic of Hematology in the period between February 2002 and December 2007. They were all treated with R-CHOP regimen and the median follow-up of the patient was 36 months. We analyzed the biopsy samples immunohistochemically for markers of germinal center (Bcl6), post-germinal center (MUM1) and apoptosis (Bcl-2).The patients were categorized as GCB subtype (68;51,6%) or non-GCB subtype (64; 48,4%). The median overall survival time (OS) were 65,25 months in GCB group and 61,1 months in non-GCB group, and median duration of the remmision (DoR) were 60,85 and 57,75months respectively for the both groups. The groups were statistically comparable regarding the both parameters. They were also comparable regarding the age, gender distributions and all others already established prognostic parameters as performance status, advanced IPI, albumin level except for the low IPI 0-2 which was statistically associated with the non-GCB group (p=.024). Our results did not show any statistical survival advantage and better outcome for the patient classified as GCB DLBL when treated with R-CHOP and indicate that immunohistohemical markers do not really reflect the molecular diversity of the tumor. They also support the studies that suggests that Rituximab eliminates or modulates the significance of some already established prognostic markers for DLBL and indicate that previously recognized markers should be re-evaluated in the context of the modern therapy and that new prognostic indicators for DLBL has to be identified.

[8]*Amgen Europe GmbH, Zug, Switzerland*
[9]*Hospital del Mar, Barcelona, Spain*

Background. EORTC guidelines (2010) recommend granulocyte-colony stimulating factor (G-CSF) primary prophylaxis (PP) for patients receiving chemotherapy at overall risk of febrile neutropenia (FN) ≥20%. CHOP ± rituximab (R) is frequently used in patients with high-risk follicular lymphoma both at presentation and relapse. R-CHOP-21 regimen in combination with older age and other individual risk factors can lead to high FN risk, where G-CSF PP is recommended. *Aims.* Describe current clinical practice in FN risk-assessment and G-CSF use in follicular lymphoma patients receiving R-CHOP-21 chemotherapy. *Methods.* IMPACT NHL is a multicentre, international observational study conducted in Europe and Australia. Eligible patients were age ≥18 years and planned to receive ≥3 cycles of CHOP±R. Patients provided written informed consent where required. This analysis reports data from follicular lymphoma patients who received R-CHOP-21. The pri-

mary outcome measure was the proportion of patients with an investigator-assessed individual-patient risk of FN ≥20% per guidelines who received PP G-CSF (pegfilgrastim or daily G-CSF initiated within days 1-7 of cycle 1). *Results.* Of 1829 NHL patients enrolled between 2005 and 2008, 345 had follicular lymphoma. Of these, the great majority (n=310, 90%) received R-CHOP-21 and are the focus of this analysis. The mean age was 58 (SD 12) years, almost half (43%) had poor FLIPI score, 76% had stage III-IV disease, 47% had a history of comorbidities, and 85% were previously untreated. FN risk was assessed by investigators as ≥20% in 57% (n=177) of patients, but only 37% of these (n=66) received PP G-CSF and 16% (n=28) experienced FN. Of 132 patients with <20% FN risk, 9% (n=12) received PP and 8% (n=11) experienced FN. In total, 39 patients (13%) experienced 48 separate FN events. FN was most commonly managed by hospitalization 33/48 events), followed by home care (7/48 events), and outpatient visits and no action taken (both 3/48 events). Furthermore, unplanned hospitalizations occurred in 53 (17%) patients; the most common reasons were neutropenia/FN (25/73 hospitalizations, 34%) and non-haematologic adverse events (24/73 hospitalizations, 33%); the median length of stay was 4 nights (interquartile range 3 - 8). The planned dose of chemotherapy matched the standard dose for each agent in R-CHOP (excluding vincristine and prednisone) in the large majority of patients. Most patients achieved a clinical response at the end of treatment, irrespective of G-CSF use (62% complete response, 30% partial response). Pegfilgrastim PP was received by 17% of patients (n=52). Among patients receiving daily G-CSF PP (n=26, 8%), the mean (±SD) number of doses per cycle was 4.9 (1.3). Patients who received PP G-CSF were older (mean 63 vs 56 years), more likely to have a history of comorbidities (56% vs 44%) and a poor FLIPI score (53% vs 40%) than those who did not. *Summary/Conclusions.* Follicular lymphoma patients treated with R-CHOP-21 may be at risk of FN and related complications. Older patients with a high-risk profile were more likely to receive PP G-CSF; however, inconsistency was observed between investigator FN risk-assessment and G-CSF administration, with only 37% of high-risk patients administered G-CSF PP per guideline recommendations.

DOSE SELECTION FOR PHASE III STUDIES OF THE MONOCLONAL ANTI-CD20 ANTIBODY OBINUTUZUMAB (GA101) - A RATIONAL APPROACH

A Morschhauser,[1] A Salles,[2] A Cartron,[3] A Crump,[4] J Birkett,[5] A Carlile,[5] H Sehn[6]

[1]*Centre Hospitalier Regional, Lille, France*
[2]*CHU Lyon-Sud, Lyon, France*
[3]*Centre Hospitalier Universitaire, Montpellier, France*
[4]*Princess Margaret Hospital, Toronto, Canada*
[5]*Roche, Welwyn, United Kingdom*
[6]*British Columbia Cancer Agency, Vancouver, Canada*

Background. Obinutuzumab (GA101) is the first type II, glycoengineered, humanized monoclonal anti-CD20 antibody to enter clinical trials. *Phase I results.* Two phase I studies, BO20999 and BO21003 (Salles, ASH 2008, 2009; Sehn, ASH 2009), in patients with CD20+ NHL showed that GA101 at doses of 50-2000mg was well tolerated, with no dose limiting toxicities and promising efficacy. Pharmacokinetic (PK) data from both studies indicated increasing plasma levels of GA101 following doses ranging from 400/800mg to 1200/2000mg, consistent with modeling and simulation target saturation levels. In contrast to the pre-clinical models, no clear dose-response relationship could be established, possibly due to patient variability including various tumor sizes, histologies and number of prior therapies. However, GA101 PK data, similarly to published rituximab data, indicated that patients with higher disease burden may have faster clearance of GA101 and consequently these patients may require higher doses to achieve target saturation. *Phase II results.* To determine the phase III dose, NHL patients in the phase II part of study BO20999, (indolent [n=40] and aggressive (n=40 [25 DLBCL/15 MCL]), were randomised to receive GA101 at either a dose of 400mg for all infusions or 1600mg on Days 1 and 8 and 800mg for subsequent infusions. Results showed that GA101 was well tolerated at both dose levels and favored the 1600/800mg dose level, in indolent NHL patients with an end of treatment response (EOR) of 55% (including 50% EOR in refractory patients), compared to the 400mg dose group (EOR 17%), (Salles EHA, ASH 2010). Higher GA101 plasma concentrations were observed in the 1600/800mg group compared to the 400mg group with both mean Cmax and Cmin values rapidly reaching steady state after cycle 2 at the 1600/800mg dose level. Steady state PK at cycle 2 was observed for the 1600/800mg dose only, in indolent and aggressive NHL patients (Mean Cmax and Cmin values at steady state were 500- 600ug/mL for indolent and 300- 400ug/mL for aggressive patients), with target saturation incomplete at the 400mg dose level. Thus, early target concentrations could be best achieved using a 1600mg loading dose on d1 and d8. Modeling and simulation indicated that the same might be achieved with a more practical schedule of 1000mg used throughout a treatment course and one additional dose given at d15 of the first cycle. Moreover, comparison of the PK data obtained from study BO20999 with that from study BO21003 (where GA101 was administered weekly over 4 doses), indicates that higher GA101 plasma concentrations are achieved earlier with the more intensive regimen, indicative of target saturation. *Summary.* Based upon all available clinical data, a dose of 1000mg (flat dose) was selected for phase III studies in lymphoma, with GA101 to be administered on days 1, 8 and 15 of the first cycle to rapidly achieve and maintain adequate exposure levels. *Conclusions.* GA101 monotherapy shows promising efficacy in heavily pretreated NHL patients, including refractory patients. The phase III dose of 1000mg is currently being investigated in combination with various chemotherapeutic agents in first line, relapsed and refractory NHL.

TOLERANCE OF R-CVP FOR FOLLICULAR LYMPHOMA IN AN UNSELECTED POPULATION AND IMPACT OF DOSE REDUCTION ON OUTCOME

T Todd,[1] M Karanth,[2] D Jackson,[3] S Alford,[4] J Danielson,[5] M Ewings,[4] N Shah[1]

[1]*The Royal Devon and Exeter Hospital, Exeter, United Kingdom*
[2]*West Suffolk Hospital, Bury St Edmunds, United Kingdom*
[3]*Lismore Base Hospital, Lismore, Australia*
[4]*Musgrove Park Hospital, Taunton, United Kingdom*
[5]*North Devon District Hospital, Barnstaple, United Kingdom*

Background. 6-8 cycles of R-CVP is widely regarded as standard initial therapy for advanced follicular lymphoma (FCL) with studies demonstrating high response rates and durable remissions. However, there is very little published data on tolerance in unselected patients or the impact of dose reduction on outcome. *Aims.* To establish the proportion of unselected patients in routine practice able to receive full dose R-CVP for advanced FCL and the impact of dose reduction on response rate and duration. *Methods.* All patients with stage 3 or 4 FCL (excluding grade 3b) commencing therapy between 1st Sept 2005 and 31st March 2010 were identified at four centres with similar patient populations and supportive care protocols. Patients with prior chemo- or radiotherapy for a haematological disorder or HIV were excluded. Indications for treatment were bulky disease, B symptoms, symptomatic splenic or nodal enlargement or cytopenia due to marrow involvement. Progression free survival (PFS) was calculated from date of first chemotherapy. Receiving fewer than 6 cycles was considered multiple drug dose reduction unless treatment was abandoned for progressive disease (1 patient). *Results.* 88 patients were identified. Two died during treatment, one was lost to follow up, these patients were excluded from analysis. Of the remainder, 46 (52%) completed 6 cycles of full dose R-CVP (Rituximab 375mg/m2, Cyclophosphamide 750mg/m2, Vincristine 1.4mg/m2, (maximum 2mg), and prednisolone 100mg for 5 days) and 39 had some dose and/ or cycle number reduction. 2 patients received maintenance rituximab and were excluded from progression free survival analysis. Cyclophosphamide dose was reduced in 21 (median 80% of full 6 cycle dose), vincristine in 28 (median 50% full dose), rituximab in 15 (median 83% full dose),10 patients had ≤5 cycles (median 4). 18 patients had 6 cycles with reduction in only a single agent per cycle (2 rituximab, 6 cyclophosphamide and 10 vincristine), the other 21 had fewer than 6 cycles and/or reductions in dose of multiple agents. The commonest reasons for dose reduction were age (55%), neuropathy (20%) and poor tolerance (9%).There was no difference in FLIPI (median 2), ECOG performance status (median 1) or median age (64 vs 65years) between those receiving full dose or not or between those receiving reductions in single agents or in multiple drugs. Median follow up was 27 months. PFS, complete and partial response rates were determined for full dose (695 days, 37% and 63%), any dose reduction (705 days, 36%, 61%), single agent (760 days, 28%, 67%) and multiple agent (705 days, 42%, 52%) dose reduction. There were no statistically significant differences between these groups (figure 1 shows full dose vs any dose reduction). *Summary/Conclusions.* Outside clinical trials, a substantial proportion (45%) of patients with stage 3 or 4 FCL are deemed unable to receive R-CVP at full dose. However, moderate reduction in the doses of its components has no significant impact

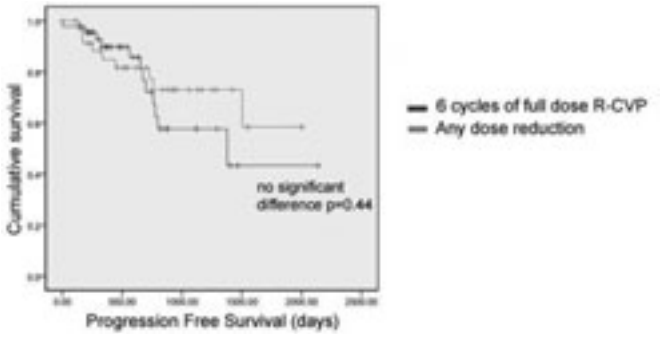

Figure 1. Kaplan Meier PFS curves full dose vs reduced.

on response rates or duration, suggesting that current standard doses may be higher than necessary to achieve useful and durable responses, especially in older or frailer patients.

0937

PET-SCAN FOR RESPONSE ASSESSEMENT AFTER RITUXIMAB-CHOP (R-CHOP) IN PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA (PMLBCL): PROGNOSTIC SIGNIFICANCE AND IMPLICATIONS FOR SUBSEQUENT RADIOTHERAPY (RT)

T Vassilakopoulos,[1] G Pangalis,[2] S Masouridi,[3] V Prassopoulos,[4] A Katsigiannis,[5] E Terpos,[6] C Kalpadakis,[7] P Rondogianni,[8] Z Galani,[3] S Papageorgiou,[9] C Poziopoulos,[10] S Chatziioannou,[11] D Boutsis,[12] N Constantinou,[13] E Vrakidou,[14] S Sachanas,[3] G Georgiou,[3] S Kokoris,[3] M Siakantaris,[3] M Dimou,[3] X Yiakoumis,[15] N Viniou,[3] D Christoulas,[6] MC Kyrtsonis,[3] I Datseris,[8] H Papadaki,[7] MA Dimopoulos,[6] P Panayiotidis,[3] P Roussou,[16] M Angelopoulou,[3] I Meletis[3]

Background. R-CHOP is superior to CHOP and is probably the current standard of care for the treatment of PMLBCL. Given the rarity of the disease and the <20% failure rate after R-CHOP, the identification of prognostic factors is difficult. PET-scan is a potent method to detect the presence of active disease in diffuse large B- cell lymphomas after R-CHOP, as well as in Hodgkin lymphoma. PET-scan has not been evaluated separately in PMLBCL, where there is also a question regarding consolidation RT. In fact, the use of PET-Scan in PMLBCL is based on the projection of data derived from Hodgkin and aggressive B-cell lymphomas. *Aims.* The evaluation of PET findings in patients with PMLBCL who have responded to R-CHOP, the assessment of their prognostic significance and their impact on the decision for subsequent RT. *Patients and Methods.* Among 52 consecutive patients with PMLBCL, who were treated in 10 Greek Centers, 40 underwent PET-scan after having responded to R-CHOP (CR, CRu, PR). The remaining 12 patients were not included in the study for the following reasons: documented progressive disease (n=7), PET done after RT (n=3), no PET availability (n=2). The endpoint was Progression Free Survival (PFS), measured from the time of PET examination. *Results.* The median post-PET follow-up was 16 months (up to 60). Among 40 evaluable patients, 24 were PET-neg (60%) and 16 (40%) PET-pos. Among 24 PET-neg patients, 13 (54%) did not receive RT and 11 (46%) were irradiated at a median dose of 3480 cGy. Two (2/13) non irradiated patients relapsed (mediastinum and isolated CNS relapse respectively) vs. 0/11 irradiated patients. Among 16 PET-pos patients, 14 (88%) were irradiated at a median dose of 4000 cGy, one was not irradiated and one was forwarded to high dose therapy and autologous transplant: 3/16 patients relapsed (all irradiated). The 2-year PFS was not significantly different between PET-neg and PET-pos patients (91% vs. 76%, p=0.41). However, among PET-pos patients, SUVmax appeared to discriminate a minority of them with adverse outcome: The 2-year PFS was 100% vs. 44% (p=0.02) for patients with SUVmax<5 (0/10 relapsed) and SUVmax≥5 (3/6 relapsed) respectively. So far 6 PET-pos patients had persistent positive findings at repeated examination after RT, but only 2 of them indeed had active disease or relapsed later. *Conclusions/Discussion.* PET-scan remains positive in a substantial proportion of PMLBCL patients who achieve a radiographic response with R-CHOP. In the majority of them, however, 18-FDG uptake is relatively low. Persistence of a positive PET was not clearly associated with inferior outcome, when additional RT was administered, although higher SUVmax values might predict a higher risk of relapse. Among 13 non-irradiated, PET-neg patients, only 1 relapse would be preventable by RT. According to these data, patients with PMLBCL should not be forwarded to autologous transplant simply based on a positive post R-CHOP PET-scan, if radiographic response is adequate.

0938

EFFICACY AND TOXICITY OF A NEW SHORT-TERM HIGH INTENSIVE PROTOCOL BL-M-04 FOR ADULT PATIENTS WITH BURKITT LYMPHOMA

E Baryakh, S Kravchenko, E Zvonkov, T Obukhova, A Kremenetskaya, A Vorobiev, A Lukina, A Magomedova

Hematological Research Center, Moscow, Russian Federation

Background. Burkitt lymphoma (BL) is the most aggressive B-cell lymphoid neoplasm, whose growth fraction approximates 100%, with specific chromosomal abnormalities (t(8;14)(q24;q32), rarely - t(2;8)(p12;q32), t(8;22)(q24;q11)). Despite the rapid proliferative rate, BL is one of the most chemosensitive lymphoid neoplasm.Though it was clear, that high intensive short-term alternating multiagent chemotherapy regimens are most effective in patients with BL, adults have a less favorable outcome than pediatric patients with BL. *Aims.* to evaluate the efficacy and toxicity of the protocol BL-M-04 for adult patients with BL. *Methods.* 46 previously untreated patients with BL were eligible for our study (they had specific c-myc rearrangement. All the patients (32 males and 14 females, mean age 29 years (from 15 to 62 years)) participated in the study performed in the Russian Hematological Research Center between August 2003 and December 2010. The treatment was based on experimental high intensive protocol BL-M-04. BL staging criteria developed by S. B. Murphy were used to stage the patients. Stage I, II, III, IV were diagnosed in 3, 5, 16, 6 patients respectively. B-acute lymphoblastic leukemia (L3) was diagnosed in 16 (35%) patients. The main aim of the new treatment regimen was greater efficacy of therapy due to intensification and shorter treatment duration. The new treatment protocol is based on the modified NHL-BFM protocol for high risk patients with a reduced dose of methotrexate from 5000 mg/m2 to 1500 mg/m2. As BL, is a chemosensitive tumor that often regresses after 1-2 courses of chemotherapy, we decided to treat patients with BL in 4 courses of chemotherapy (2 induction and 2 consolidation) irrespective of the initial tumor mass. As BL is most sensitive to high dose methotrexate and cytarabine, we used these drugs in the induction phase to achieve to maximize the cytoreductive effect. Courses A and C were used to achieve remission. Doxorubicin was added to course A, and methotrexate to course C. Consolidation courses were similar to induction courses. Hence, we used A and C courses (without course B), intensified with course B drugs (doxorubicin and methotrexate), the interval between the courses being 21 days. *Results.* 41 patients (89%) achieved a complete remission (CR) after 1-2 courses (18 patients - after the 1st course, 23 - after the 2d). 39 are alive in the first CR during 50 months (median 5-86 months). Five patients died. The cause of death in four patietns were chemotherapy related complication, in one - disease progression. Two patients died due to early relapse. The 5-year disease-free survival (DFS) was 95% with an overall survival (OS) of 85%. BL-M-04 therapy resulted in higher CR rates and longer DFS in adult patients with BL and confirmed high efficacy of short-term intensive therapy. Treatment duration was 3 months. *Summary/Conclusions.* BL-M-04 is a highly effective protocol. The 5-year DFS was 95% with 5-year OS of 85%. The use of

this protocol can achieve rapid tumor regression with a short treatment duration due to chemotherapy intensification and acceptable toxicity.

0939

IMPROVED OVERALL SURVIVAL FOR VERY ELDERLY PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA AFTER THE INTRODUCTION OF IMMUNOCHEMOTHERAPY

PO Andersson,[1] M Stenson,[1] S Hasselblom,[1] M Sender,[1] U Hansson,[2] C Lewerin,[1] H Nilsson-Ehle[1]

[1]*Section of Hematology and Coagulation, Gothenburg, Sweden*
[2]*Dept. of Pathology, Gothenburg, Sweden*

Background. Diffuse large B-cell lymphoma (DLBCL) is the most common lymphoma subtype and, as in most other malignant diseases, the incidence is strongly related to increasing age. Population-based studies have reported that the median age for DLBCL patients is 70 to 72 years and as high as about 20 % of all patients are above the age of 80. The prognosis of DLBCL patients has improved considerably during the last decade, mainly due to the introduction of the monoclonal anti-CD20-antibody rituximab combined with the standard CHOP-regimen. However, very old DLBCL patients (above the age of 80 years) are seldom included in clinical trials and, so far, there is very little information available on the survival impact of immunochemotherapy in such patients. *Aim.* To evaluate if the introduction of immunochemotherapy (R-CHOP) have influenced survival for very elderly patients. *Methods.* We have retrospectively analysed all DLBCL patients over the age of 80, who were diagnosed in the Gothenburg region during two time-periods (1997-2000; 'pre-R' and 2006-2009; 'post-R'). Patients with previously known indolent lymphomas or with primary CNS lymphoma were excluded from the study. *Results.* There were 30 and 40 patients ≥ 80 years in each time period, corresponding to 20.5 % and 23 %, respectively, of the entire DLBCL population diagnosed during these two periods. Performance status ≥ 2 was 48 and 47 % in each period and no difference in aaIPI was found. Fifty-three % in the post-R period were treated with a curative intent compared to 37 % in the pre-R period ($p<0.05$). The estimated 3-year PFS was 42 % in the post-R period and 20 % in the pre-R period ($p=0.045$). Similarly, the estimated 3-year OS in the post-R group was 40 % and 19 % in the pre-R group ($P=0.01$). *Conclusions.* After the introduction of R-CHOP, both PFS and OS was improved for a population of very elderly DLBCL patients. Based on our data, high age by itself should not be a reason to exclude the patient from an effective treatment with immunochemotherapy.

CONCURRENT CHROMOSOMAL BCL2 AND MYC TRANSLOCATIONS IN LARGE B CELL LYMPHOMA

V Pitini,[1] C Arrigo,[1] C Micali,[1] E Quartarone,[2] P Sciarrone,[2] G Altavilla[1]

[1]*University, Messina, Italy*
[2]*Blood Center, Messina, Italy*

Background. Concurrent chromosomal BCL2 and MYC translocations involving the BCL2 and MYC protooncogenes in Large B Cell Lymphoma (NHL) (double-hit, DH) recently, have received increased attention (2008 WHO classification, 'B cell lymphoma unclassifiable with features intermediate between DLBCL and BL). Patients with DH lymphomas often present with poor prognostic parameters, including elevated LDH, bone marrow and CNS involvement, and a high IPI score. All studies on larger series of patients suggest a poor prognosis, also if treated with RCHOP or high-intensity treatment modalities. *Aims.* We conducted a retrospective study of DLBCL to evaluate the frequency of double-hit B translocations in DLBCL and to analyse pathologic and/or clinical features correlated with the presence of a double-hit translocations. *Methods.* DLBCL samples, diagnosed according to the WHO criteria of 2008 and derived from 93 patients treated with R-CHOP or HD, have been subjected FISH using commercial break-apart probes for BCL2 and MYC. Clinical data were collected from patient files. *Result.* Double-hit BCL2/MYC translocations were detected in 9 of 93 cases (10%); 7 DLBCL, 1 BCLU, 1 unclassified. All double-hit DLBCL were GCB immunophenotype and showed varying morphology. Ki-67 index ranged from 15-95%. Characteristic clinical parameters included a high IPI score, a high stage an extranodal presentation with CNS involvement(4/9). Furthermore DH was also associated with an inferior OS. *Conclusions.* Our results suggest that DH is more frequent than previously estimated but could not be identified only by morphology or proliferation rate.

0941

HISTORY OF MYELOID MALIGNANCIES IN RELATIVES OF PATIENTS WITH WALDENSTRÖM MACROGLOBULINEMIA AND IGM-MONOCLONAL GAMMOPATHIES

M Varettoni, L Arcaini, C Pascutto, E Orlandi, C Astori, A Corso, S Rattotti, S Mangiacavalli, M Lazzarino, M Cazzola

Division of Hematology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background. The etiology of Waldenström macroglobulinemia (WM) is unknown. A possible role for genetic factors has been suggested by reports of familial clustering of WM. Familial cases reported so far show two patterns of aggregation: multiple cases of WM only, or mixed B-cell disorders. *Aims.* The aim of this study was to evaluate the incidence and characteristics of hematologic disorders among family members of 212 unrelated patients with IgM-monoclonal gammopathies diagnosed and followed at our Institution from 1986 to 2010. *Methods.* An interview-based investigation of family history was performed to identify a history of hematologic diseases among relatives. Diagnosis of WM, IgM-monoclonal gammopathies of undetermined significance (MGUS), and IgM-related disorders (IgM-RD) was made according to the Consensus Panel Recommendations from the Second International Workshop on WM (Owen *et al.*, 2003) for patients diagnosed from 2003 onward. The same criteria were retrospectively applied to patients diagnosed before. *Results.* We analyzed 212 patients with IgM-monoclonal gammopathies, further classified as WM (=66 patients) or IgM-MGUS/IgM-RD (=146 patients). The median age was 63 years (range: 19-92), 125 were males and 87 females. A familial history of hematologic disorders in one or more relatives was reported by 31 patients (15%), totalling 40 affected relatives. Hematologic disorders were diagnosed in 28 first-degree and 12 second- or third-degree relatives. The median number of relatives affected per family was 1 (range: 1-3). Patients with familial IgM-monoclonal gammopathies were significantly younger as compared to those with sporadic disease (53 versus 64 years, $p<0.0001$). The proportion of familial cases was higher among patients with WM as compared to those with MGUS/IgM-RD (23% versus 11%, $p= 0.02$). Specific information regarding the type of hematologic disease in the family members was not available in one case. Among the remaining 39 cases, the diagnoses were as follows: WM (=4), MGUS (=9), non-Hodgkin's lymphoma (=8), chronic lymphocytic leukaemia (=3), Hodgkin's lymphoma (=1), hairy cell leukaemia (=1), multiple myeloma (=1), acute lymphoblastic leukaemia (=1), acute myeloid leukaemia (=7), chronic myeloid leukemia (=1), polycythemia vera (=2), essential thrombocythemia (=1). According to the previously reported patterns of aggregation, we observed multiple cases of WM only in 3 families (10%) and mixed B-cell disorders in 18 (60%). In the remaining 9 families (30%) we found clustering of IgM-monoclonal gammopathies with hematologic myeloid malignancies. *Conclusions.* In this study we found that 15% of patients with IgM-monoclonal gammopathies have a familial history of hematologic disorders. Familial cases are more common among WM patients than in other IgM-monoclonal gammopathies and are characterized by younger age at diagnosis. In addition to the two patterns of aggregation described so far, we identified a subset of IgM monoclonal gammopathy patients with a familial history of myeloid malignancies. This suggests a thorough investigation of family history in patients with IgM-monoclonal gammopathies, encompassing also myeloid malignancies. Further investigations might clarify whether familial clustering reflects a genetic predisposition rather than exposition of family members to the same environmental risk factors.

[3]*Pathology Department, University of Athens, Athens, Greece*
[4]*Pathology Department, Evangelismos Hospital, Athens, Greece*
[5]*Haematology Department, Hipokrateion Hospital, Athens, Greece*
[6]*Haematology Department, Laikon General Hospital, University of Athens, Athens, Greece*
[7]*Haematology Department, 401 Military Hospital, Athens, Greece*

Background. Recently we have described a new category of MZL, the PBMMZL, characterized by bone marrow infiltration and blood in-

Table 1. Pts characteristics with SMZL and PBMMZL.

Characteristics	PBMMZL (%)	SMZL (%)
Median age (range)	64 (38-77)	64 (48-78)
Male sex	43	48
B symptoms	0	4
Palpable splenomegaly Enlarged spleen by CT	0 0	100 100
BM infiltration	100	100
LDH elevated	9	40
HCV (+)	0	0
IPI Low+low intermediate	96	95
Anemia (Hb<12g/dl)	17	52
Thrombocytopenia (<100x109/l)	0	28
Lymphocytosis (>4x109/l)	70	55
M-component	30	25
Autoimmune phenomena	0	5
CD5/ CD23/ CD38/ CD11c/ CD25/ sIgκ	0/48/4/43/22/70	10/7217/61/33/68

volvement without any other disease localization. PBMMZL harbour many similarities with SMZL besides splenomegaly. *Aim.* To compare SMZL and PBMMZL on the basis of clinical and laboratory characteristics, morphology and immunophenotypic data. *Patients and Methods.* 23 SMZL and 21 PBMMZL patients were included in the present study. Clinical and laboratory features were recorded. Blood and bone marrow mononuclear cells were studied by flow cytometry for the mAbs CD5, CD23,CD10,CD25,CD38,CD11c on CD19+ cells, while bone marrow (BM) biopsies were evaluated using morphologic and immunohistochemical methods. *Results.* Clinical and laboratory features were very similar between the two groups (table 1), except that cytopenias and elevated LDH were more common in SMZL patients. Immunophenotypic features of blood and bone marrow mononuclear cells were also similar. The percentage of BM infiltration was 40 (15-85) and 25 for SMZL and PBMMZL respectively. The histological pattern of bone marrow infiltration was variable, with the nodular infiltrates being the most frequent and typical pattern in both groups (78% for the SMZL and 62% for PBMMZL). Intrasinusoidal infiltration was observed in both groups usually in association with other patterns of infiltrates (48% for SMZL and 38% for PBMMZL). Cytological aspects were very heterogeneous in both groups with several types usually associated in varying proportions: small lymphocytes, centrocyte-like cells, small cells with plasmacytoid differentiation, monocytoid cells and variable content of medium to large cells. Well-formed germinal centres were identified in 48% of SMZL cases in contrast to only 1 case with PBMMZL. In all the cases the immunophenotypic profile of BM neoplastic population (CD20+ strong, CD79a+, CD3-, CD5-, CD10-, cyclin-D1-, BCL-6-) was consistent with a marginal zone-derived neoplasm. PBMMZL patients presented a very indolent clinical course. Only 3 patients have required so far therapy while all SMZL patients were in need of therapy at diagnosis. No death was recorded in the PBMMZL group at a median follow up time of 36 months (12-105), while 5 SMZL patients have died (3 disease related) at a median follow up time of 72 months (16-181). *Conclusions.* PBMMZL presents many similarities with SMZL, although the former presents a more indolent clinical course and is not complicated by splenomegaly.

0943

NEW MODIFIED PROPHYLACTIC SCHEME AGAINST LIPOSOMAL CYTARABINE (DEPOCYTE®)-INDUCED ARACNOIDITIS IN ADULT LYMPHOMA PATIENTS

B Sanchez-Gonzalez,[1] A Llorente,[2] J Sancho,[3] C Panizo,[4] J Guinea,[5] A Cladera,[6] MC Mateos,[7] A Salar[1]

[1]*Hospital del Mar, Barcelona, Spain*
[2]*H. Joan XXIII, Tarragona, Spain*
[3]*Hospital Universitario Germans Trias i Pujol, Barcelona, Spain*
[4]*Clínica Universitaria de Navarra, Pamplona, Spain*
[5]*H. Txagorritxu, Vitoria, Spain*
[6]*H. Son Llatzer, Mallorca, Spain*
[7]*H. Virgen del Camino, Pamplona, Spain*

Background. Liposomal cytarabine (DepoCyte®) is a slow-release formulation of cytarabine designed for intrathecal administration, ensuring prolonged drug exposure. In all clinical studies, chemical arachnoiditis, a syndrome manifested primarily by nausea, vomiting, headache and fever, was a common adverse event. To reduce the incidence and severity of chemical arachnoiditis, all patients must be treated with dexamethasone 4 mg bid orally or intravenously on days 1 to 5 of each cycle beginning concurrently with administration of DepoCyte. *Aim.* We designed a new prophylactic scheme against Liposomal Cytarabine -induced aracnoiditis in patients with lymphoma to improve adherence to concomitant oral dexamethasone. *Patients and Methods.* Patients were consecutively recruited from 7 Spanish institutions. Thirty-three adult patients with lymphoma, median age of 57 years (27-79). Type of lymphoma: diffuse large B-cell lymphoma 24 pts, mantle cell lymphoma 3 pts, Burkitt 2 pts and other types 4 pts. Type of concomitant systemic chemotherapy: CHOP±R 13 pts, MegaCHOP±R 5 pts, HyperCVAD+R 3 pts, ESHAP±R 3 pts and other types 9 pts. Liposomal cytarabine (50 mg) was administered by lumbar puncture. Prophylactic scheme against Depocyte-induced aracnoiditis was: Dexamethasone 4 mg by lumbar puncture immediately after the injection of Depocyte and dexamethasone 4 mg bid orally on days 1 and 2. Toxicity was graded according to Common Terminology Criteria for Adverse Events, version 3.0. *Results.* Reasons for Liposomal Cytarabine administration were: therapeutic in 12 pts (36%) and prophylactic in 21 (64%). A total number of 78 injections of Depocyte were administered. The median number of doses per patient was 2 (range, 1-6). Liposomal cytarabine was generally well tolerated. Overall, 15 pts had some type of adverse event (all but one in prophylaxis and 9 of them with the first injection). No toxicity was observed in 56 administrations. In 22 administrations (28%) some type of toxicity was recorded for a total of 34 adverse events. Most of these events were transient and resolved spontaneously. Adverse events are listed in the Table. Only 2 events were considered clinically relevant: 1 patient with headache grade 3 with diplopia grade 2 and other patient with aracnoiditis grade 2. Interestingly, the patient who had aracnoiditis fully recovered and received 3 additional administrations of Depocyte with a dose reduction of 25 mg. He was given the same prophylactic scheme against Depocyte-induced aracnoiditis showing excellent tolerance and without any relevant symptoms. Regarding efficacy, all evaluated patients cleared cerebrospinal fluid and/or improved clinical symptoms. At last follow-up, nine patients have died, being the main causes of death: 5 systemic lymphoma progression, 1 systemic plus neurologic progression, 1 isolated neurologic progression, 1 concomitant solid tumour and 1 neutropenic sepsis. *Conclusion.* Administration of concomitant inthratecal dexamethasone and oral dexamethasone only for two days appears to be safe and well tolerated prophylactic scheme against Liposomal Cytarabine (Depocyte®)-induced aracnoiditis in adult patients with lymphoma. This strategy reduces the number of days with oral dexamethasone, while also might improve adherence allowing to administer the scheduled number of Depocyte injections.

Table 1.

	Total number	Grade 1	Grade 2	Grade 3
Headache	13	8	4	1
Nausea	6	4	2	
Vomiting	4	2	2	
Vertigo	4	1	3	
Diplopia	1		1	
Fever	1	1		
Paresthesia	3	2	1	
Hypotension	1		1	
Aracnoiditis	1		1

SPLENIC MARGINAL ZONE LYMPHOMA: CHARACTERISTICS AND TREATMENT

H Julhakyan, A Magomedova, S Kravchenko, T Moiseeva, S Karagulyan, T Savenko, R Samoylova, I Kaplanskaya, T Obukhova, E Gemjyan, A Vorobjev

Hematological Scientific Center of Russian Federation, Moscow, Russian Federation

Splenic marginal zone lymphoma (SMZL) characterized with primary spleen involvement and indolent course. SMZL is rare and found in less than 1% of all Non-Hodgkin`s lymphomas. *The aim* of our study was to

find stricter definition for SMZL and to determine the most effective treatment strategy. *Materials and Methods.* Eighty six patients (33 males (38%) and 53 females (62%)) between January 2001 and February 2011 were included in the study. The median age was 59.6 years (ranging from 16 to 86 years). Splenomegaly was noted in all cases. Visceral lymphadenopathy was detected in 44 (50%) patients and was shown as an increase of liver size and splenic hilar lymph nodes. In the laboratory data anemia was found in 31 patients (36%), thrombocytopenia - in 66 (76,7%), leukopenia - in 30 (35%), leukocytosis - in 39 (45,3%). Absolute lymphocytosis was detected in 2/3 of patients. High LDH was observed in 46 patients (53,5%). M-component detected in 35 patients (40,7%). Viral hepatitis markers were positive in 12 cases (14%). Aberrant expression of CD5 was detected in 4 (5.8%) patients. Expression of DBA44 were found in 45 patients. Ki-67 was below 10%. Forty six (53,6%) cases had various chromosomal abnormalities, including deletion of chromosome 7, trisomy 3, trisomy 12, trisomy 18 and in 3 cases t(14;19)(q12;q32) sequence was revealed. In order to determine the role of surgical treatment in patients with SMZL, we compared two groups of patients selected on the basis of the first-line therapy. The first group included 17 patients who completed chemotherapy in the first line, and the second group consisted of 47 patients in whom splenectomy was first-line treatment. *Results and Discussion.* All patients who received chemotherapy as a first line treatment demonstrated little clinical and hematologic effects, but some patients had even longer recurrent-free period than those in the second group. On average, progression of disease occurred during 6-8 months in all patients and manifested with spleen size increase and progression of cytopenia. One patient from the first group died due to infectious complications. Splenectomy was performed to all patients in this group with good clinical results obtained. In patients who underwent splenectomy as first-line therapy was obtained a good clinical response. In the second group 1 patient died from disease progression. Overall survival rate in both groups about 98% with 9 years follow-up. However, we obtained significant differences in the progression-free survival: in the first group (chemotherapy in first line) relapse rate during 9 years was about 90%, meanwhile the second group (splenectomy in the first line) it was 30% (p = 0,01). *Conclusion.* SMZL heterogeneous disease and characterized by different clinical manifestations, chromosomal abnormalities, secretion of M-component, often aberrant immunophenotype, but in all cases, splenomegaly played a leading role in the treatment strategy. Effectiveness of splenectomy was noted in the first-line therapy compared with chemotherapy. It was demonstrated with statistical significance that splenectomy as a first-line therapy in these patients was three times more clinically effective than chemotherapy with subsequent surgery.

0945

ADDITION OF RITUXIMAB TO REDUCED DOSE CHOP CHEMOTHERAPY IS FEASIBLE IN ELDERLY PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

HJ Shin, JS Chung, YJ Choi, M Song, Y Seol, GJ Cho

Pusan National University Hospital, Busan, South-Korea

Background. Recently, rituximab plus dose intensified CHOP chemotherapeutic regimens have been shown to be effective in elderly patients with diffuse large B cell lymphoma (DLBL). However, hematological toxicities and treatment related mortality were hard to be neglected in terms of relatively poor performance in elderly patients. Rituximab is effective immunotherapeutic drug in DLBL, if that, addition of rituximab to reduced dose CHOP chemotherapy may be appropriate for elderly patients with DLBL. *Aims.* To investigate outcomes and toxicity profiles of addition of rituximab to reduced dose CHOP chemotherapy in elderly patients with DLBL. *Methods.* Patients aged 60 years and over have been enrolled consecutively between January 2005 and December 2009. Reduced dose CHOP chemotherapy consisted cyclophosphamide (600 mg/m2 intravenously), doxorubicin (30 mg/m2 intravenously), and vincristine (1 mg intravenously) on day 1, and prednisone (40 mg orally) given on day 1 to 5. Patients were treated every 3 weeks for 6 to 8 cycles. Rituximab was administered at a dose of 375 mg/m2 on day 1 for each cycle. *Results.* Total 84 cases were analyzed in this study. Median age was 69 years old (range, 61-85 years old) and males were 44 (52.4%). 65 patients received at least 6 cycles of chemotherapy and 19 patients dropped out from these regimens early because of treatment-related death (4 patients), loss of follow up (4 patients), progression of disease (4 patients) and refusal of further treatment (7 patients). Mean cycles of modified R-CHOP chemotherapy was 5.96 (range, 1-8). Overall response rate was 89.3% (CR rate, 66.7%; PR rate, 22.6%). Estimated 5-year event-free survival rate was 61.5% ± 6.2% and overall survival rate was 78.3% ± 5.2%. Main hematological adverse events were 21.4% in grade 3/4 neutropenia and 3.6% in grade 3/4 anemia. Among non-hematological toxicities, grade 3/4 asthenia was reported 3.6% and other toxicities were tolerable. *Conclusions.* Addition of rituximab to reduced dose CHOP chemotherapy is an effective and tolerable treatment regimen in elderly patients with DLBL.

0946

ROUTINE METAPHASE CYTOGENETICS MAY AUGMENT THE PROGNOSTIC CAPABILITY OF THE MANTLE CELL LYMPHOMA INTERNATIONAL PROGNOSTIC INDEX (MIPI) FOR STAGE IV MANTLE CELL LYMPHOMA

H Than,[1] K Tay,[2] C Diong,[1] HT Mya,[1] LC Lim,[1] R Quek,[2] M Tao,[2] ST Lim,[2] SY Tan,[1] D Tan[1]

[1]*Singapore General Hospital, Singapore, Singapore*
[2]*National Cancer Centre, Singapore, Singapore*

Background. Mantle cell lymphoma (MCL) is a rare and distinct subtype of lymphoma with a highly variable clinical course. The majority of patients (pts) present in advance stage with bone marrow involvement (Stage IV). While the majority of cases are clinically aggressive, it is increasingly recognized that a subset of MCL characterized by a rather indolent course and typically presenting with stage IV disease, and associated with a longer survival exists. The upfront identification of such patients however, remains a challenge. Although the MIPI is a robust tool for predicting the prognosis, the lack of genetic factors in the model may be its limitation. *Aim.* We evaluated the survival outcomes of pts with biopsy proven MCL in a single institution and sought to examine the prognostic capability of the MIPI, as well as bone marrow cytogenetics for pts with MCL. *Methods*. Cases of MCL diagnosed from 2000 to 2010 were identified from our lymphoma database, yielding unique 37 pts. The baseline patient and disease characteristics, together with the treatment history were retrospectively evaluated with respect to overall survival (OS) outcomes. Outcomes were compared using log-rank analysis of Kaplan-Meier survival analyses, and MIPI was calculated in accordance with the initial publication. *Results*. Pt characteristics at diagnosis were: median age 62 (range 41-85), 81% male and 68% stage IV disease. Five pts had the blastoid variant of MCL, while 8 pts had leukemic presentation. MIPI scores at diagnosis were: low (24%) / intermediate (38%) / high (33%). Median follow-up is 2.5 years and the median OS is 6.4 years. Although the MIPI was discriminating of 3 separate risk-groups, with OS of 7.5 yrs, 6.8 yrs and 2.2 yrs (p=0.001) for low, intermediate and high MIPI respectively (Figure 1), the distinction between intermediate and low -risk MIPI was less apparent. Bone marrow cytogenetics data were able to further fine-tune the prognostication. Among pts with high-risk MIPI, 2 pts with del17p detected on metaphase cytogenetics had the worst OS (0.13 vs. 2.2 yrs, P=0.1). Among pts with intermediate/low risk MIPI, the presence of any cytogenetic abnormality predicted for a worse outcome (1.8 vs. 12.8 yrs, p=0.03). For pts with stage IV MCL, there was a trend for a higher Ki67 (>40%) among those with detectable abnormalities on metaphase cytogenetics. *Conclusion*. Based on the follow-up of 37 pts, we are able to validate the accuracy and ease of application of the MIPI for prognostication. However, the prognostic capability can be further augmented with the inclusion of simple bone marrow metaphase cytogenetic results. Presence of metaphase cytogenetic abnormalities may reflect a higher proliferation index which portends a more inferior prognosis. We propose that similar to multiple myeloma, MCLs can be further risk-stratified with routine cytogenetic analysis. The routine use of more sensitive interphase-FISH analysis with probes for TP53, ATM gene mutation and SOX 11 to further complement metaphase cytogenetics ought to be further explored.

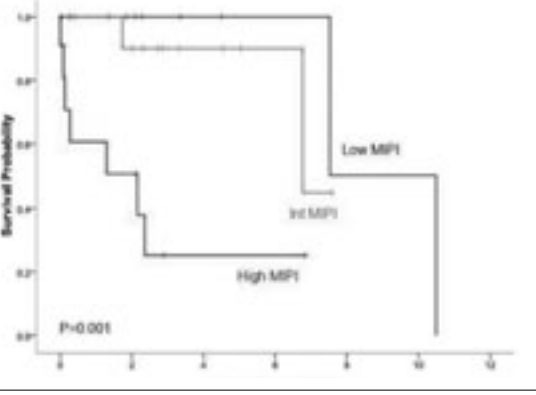

Figure 1. Overall survival by MIPI risk groups.

Non-Hodgkin lymphoma - Clinical 3

SWITCHING BCL6 POSITIVE TO NEGATIVITY IN RELAPSING DIFFUSE LARGE B-CELL LYMPHOMA

M Todorovic,[1] B Andjelic,[1] B Balint,[2] Z Radisavljevic,[3] B Mihaljevic[1]

[1]*Clinical Centre of Serbia, Belgrade, Serbia*
[2]*Institute for Medical Research, Belgrade, Serbia*
[3]*Brigham and Women's Hospital, Harvard Medical School, Boston, United States of America*

Background. Diffuse large B-cell lymphoma (DLBCL) is the most complex and heterogeneous lymphoma in adulthood presented as a biologically and clinically distinct subtypes including germinal centre B-cell-like (GCB) and activated B-cell-like (ABC). In DLBCL BCL-6 is associated with the germinal centre subtype and has a good response to modern chemotherapy. It is known that BCL-6 expression is a favorable prognostic factor in DLBCL. However, the effect of BCL-6 expression on relapse of the DLBCL was not studied. *Aim.* to show Bcl-6 gene expression changes and biological response in relapsed DLBCL and their patterns which include: LDH, b2M, CRP, Fe, ferritin, TIBC, hemoglobin, uric acid and International Prognostic Index (IPI). *Methods.* We investigated 43 (21F/20M) patients with relapsed DLBCL and role of immunohistochemically determined Bcl6 tested in 22 patients. All patients were treated with R-CHOP protocol. We also investigated biological parameters such as LDH, b2M, CRP, Fe, ferritin, TIBC, hemoglobin, uric acid level as well as IPI at the presentation of DLBCL and at the time of relapse. *Results.* Mean age of female patients was 53.1±12.7 vs. male 52.8±12.1 and overall age of patients was 53.0±12.3SD years with no significant difference. Investigated relapsed group of 41 patients with DLBCL had own control at the beginning of diseases. From 22 immunohistochemically (IHC) investigated patients for Bcl6 protein expression, 19/22 was positive and 3/22 was negative at the beginning. DLBCL was diagnosed in gastrointestinal tract (13), liver and spleen (7) lungs (5), CNS (4), ovarian (2), vertebral (1), and lymph nodes (9). Patients with Bcl6 negative relapses of DLBCL had very aggressive lymphoma, malignant in nature with the biological responses including significant higher levels of the LDH (1832.5±443.8 SD in relapsed vs. 457.3±88.3 SD U/L at presentation) ($p<0.0001$), b2M (8.4±0.8 vs. 2.5±0.8 mg/L) ($p<0.0001$), CRP (35.9±11.4 vs. 2.5±0.7 mg/L) ($p<0.0001$), uric acid (287.2±65.7 vs. 153.9±33.1 µmol/L) ($p<0.0001$), and significantly low ($p<0.01$) Fe (11.2±4.4 vs. 21.8±7.6 µmol/L) ($p<0.008$), TIBC (35.5±9.2 vs. 46.8±7.0 µmol/L) ($p<0.009$), hemoglobin (91.7±13.2 vs. 126.5±8.6 g/L) ($p<0.0001$), and significantly higher ferritin (2735.6± 628.2 vs. 88.5±20.2 µg/L) ($p<0.0007$) at the time of relapse DLBCL. At diagnosis all 19/22 patients were Bcl6 positive (IHC) and switched to Bcl6 negative at the time of relapse. IPI index as biological indicator was initially vs. relapse 2.01±0.8 vs. 4.4±0.6 respectively ($p<0.0001$). *Summary/Conclusion.* The Bcl-6 negative relapses of DLBCL was associated with very aggressive lymphoma and significant increase of the biochemical parameters such as LDH, B2M, CRP, uric acid, ferritin and significant decrease of serum Fe, TIBC, hemoglobin resulting in anemia of chronic disease. Expression of the single gene Bcl-6 strongly predicts poor outcome of relapsed DLBCL. In human genome it is very rare that single gene can predict outcome of diseases such as Bcl6, but also can predicts relapse as showed in this report. Switching positive into negative Bcl6 expression was strong indicator of DLBCL relapse.

0948

OUTCOME OF PATIENTS WITH DLBCL AFTER ADDITION OF RITUXIMAB TO CHOP: A POPULATION-BASED TIME PERIOD ANALYSIS IN MANITOBA

R Kumar,[1] K Guilbert,[1] B Joseph,[2] B Lozar,[2] M Geirnaert,[2] P Lambert,[2] V Bourrier,[2] M Rubinger,[1] S Navaratnam[1]

[1]*University of Manitoba / CancerCare Manitoba, Winnipeg, Canada*
[2]*CancerCare Manitoba, Winnipeg, Canada*

Background. Addition of Rituximab to CHOP chemotherapy (R-CHOP) as primary therapy for diffuse large B-cell lymphoma (DLBCL) is associated with improved survival. This benefit has been demonstrated in clinical trials where patients met strict selection criteria. Hence it is important to evaluate if similar outcomes continue in population based studies. *Aim.* To assess if R-CHOP administered to unselected patients with DLBCL living in a diverse geographic area leads to similar improvements as those reported in clinical trials. *Methods.* A population based retrospective study was undertaken of all patients diagnosed with DLBCL in the Province of Manitoba, identified by the Manitoba Cancer registry (MCR), and treated with CHOP or R-CHOP over a period of 36 months pre and post funding of Rituximab for this indication. Funding of Rituximab was approved for patients age 60-80 on 28 October 2002 and for all age groups on 22 June 2004. The provincial oncology drug program (PODP) database was used to identify patients who received the above treatment. Charts of all patients were reviewed to confirm the treatment received. *Inclusion criteria:* DLBCL patients who received at least one cycle of CHOP or R-CHOP as primary therapy and were Manitoba residents. *Exclusion criteria:* HIV +ve, primary CNS lymphoma, post-transplant lymphoproliferative disorders, transformed lymphomas, primary therapy with less intensive drugs. *Analysis.* The cohort was analyzed according to two characteristics: (1) A Time- Period Analysis, using the drug funding date as a cut-off point, in which all patients were included according to the time period, irrespective if they got Rituximab or not (an intention to treat analysis) (2) A Drug-Period Analysis, where in the Pre-Funding period, patients who received Rituximab were excluded and in the Post-Funding period, patients who did not get Rituximab were excluded. Overall Survival (OS) was calculated as time from the date of diagnosis to the date of death or the last day of follow-up (May 1, 2010). Multivariate analysis was performed using Cox proportional hazards model to assess the independent effect of treatment in the post rituximab period on OS, after controlling for age and sex. Data was analyzed using SAS version 9.1. *Results.* Patient characteristics: Time-Period Analysis- Total number 237 (male 118); Pre-rituximab 112 (median age 62 years, median follow up 55 months); Post-rituximab 125 (median age 65 years, median follow up 45 months). Drug-Period Analysis- Total number 196 (male 97); Pre-rituximab 94 (median age 62 years, median follow up 56 months); Post rituximab 102 (median age 64 years, median follow up 45 months). After controlling for age and gender, there was significant improvement in OS in the Post-rituximab era for both the Time-Period Analysis (hazard ratio, 0.53; 95% CI 0.31 to 0.92; $p = 0.02$) and the Drug-Period Analysis (hazard ratio, 0.52; 95% CI 0.28 to 0.98; $p = 0.04$). *Conclusion.* The study shows a significant improvement in OS of patients with DLBCL treated in multiple Community Cancer Centers and two Academic Centers in the Province of Manitoba, after the addition of Rituximab to CHOP as primary therapy.

[7]*Medical University of Vienna, Vienna, Austria*

Background. Primary prophylaxis with granulocyte-colony stimulating factor (G-CSF) is recommended by the ASCO and EORTC guidelines to support chemotherapy delivery in patients with a high (≥20%) risk of FN. R-CHOP regimens used to treat aggressive non-Hodgkin lymphoma (NHL) are associated with high FN risk, and G-CSF prophylaxis is particularly important in dose-dense R-CHOP-14 to support full chemotherapy dose intensity. Older age is a known additional risk factor for FN. IMPACT NHL was an observational study designed to evaluate current clinical practice with respect to FN risk assessment in NHL patients treated with R-CHOP. *Aims.* To evaluate the impact of age group on FN risk assessment, G-CSF use, FN incidence, and chemotherapy delivery in patients with DLBCL receiving R-CHOP regimens. *Methods.* The study was conducted in Europe and Australia. All patients gave informed consent where required. Physicians assessed each patient's FN risk based on the planned chemotherapy regimen and individual patient risk factors. The primary outcome measure was the proportion of patients who had investigator-assessed individual patient risk of FN ≥20% per guidelines who received primary prophylaxis G-CSF; other outcome measures included primary prophylaxis by GCSF type used, incidence of FN, and measures of chemotherapy delivery. For this analysis, outcomes were calculated for patients aged <65 vs

Table 1. Outcomes by chemotherapy regimen and age.

	R-CHOP-14		R-CHOP-21	
	< 65 years (n=241)	≥ 65 years (n=168)	< 65 years (n=343)	≥ 65 years (n=361)
Mean (SD) age, years	49 (12)	72 (5)	52 (11)	73 (5)
Physician-assessed rate of FN ≥ 20%, n (%)	189 (78%)	134 (80%)	179 (52%)	255 (71%)
Received GSCF prophylaxis, n/N (%)	162/189 (86%)	108/134 (81%)	69/179 (39%)	136/255 (53%)
G-CSF prophylaxis and experienced FN, n/N (%)	32/162 (20%)	27/108 (25%)	11/69 (16%)	28/136 (21%)
Primary prophylaxis				
Pegfilgrastim, n (%)	129 (54%)	97 (58%)	60 (17%)	114 (32%)
Any daily GCSF, n (%)	79 (33%)	40 (24%)	30 (9%)	48 (13%)
FN rate				
cycle 1, n (%)	12 (5%)	12 (7%)	26 (8%)	37 (10%)
any cycle, n (%)	42 (17%)	39 (23%)	48 (14%)	85 (24%)
Chemotherapy RDI ≥ 90%, n (%)	176 (73%)	88 (52%)	275 (80%)	244 (68%)
Dose delay > 3 days, n/N (%)	107/240 (45%)	102/165 (62%)	128/342 (37%)	172/351 (49%)
Dose reduction ≥10%, n (%)	15 (6%)	40 (24%)	49 (14%)	93 (26%)

≥65 years receiving R-CHOP-14 or R-CHOP-21 regimens. *Results.* Out of a total of 1829 patients who initiated chemotherapy between Jan 2005 and Aug 2008, 1113 (61%) had DLBCL and received R-CHOP, and were included in this analysis. Demographics and outcome measures are shown in the table. Despite guideline recommendations, not all patients with investigator-assessed FN risk ≥20% received G-CSF primary prophylaxis. Of those who received R-CHOP-14, a similar proportion of younger and older patients were assessed with ≥20% risk of FN, although 14% of the younger patients and 19% of the older patients did not receive G-CSF primary prophylaxis despite meeting the criterion. Of those who received R-CHOP-21, a greater proportion of older than younger patients were assessed with ≥20% risk of FN, and G-CSF primary prophylaxis was more likely to be administered to older patients. Younger patients receiving R-CHOP-21 were the least likely group to be assessed as high risk. For both 14- and 21-day R-CHOP regimens, older patients had higher rates of FN; and, as a result of more dose delays and reductions, fewer patients received the planned RDI relative to younger patients. Unplanned hospitalizations occurred frequently and were more common in patients aged ≥65 years, occurring in 26% of younger and 40% of older R-CHOP-14 patients and 22% of younger and 36% of older R-CHOP-21 patients; neutropenia or FN was the most common reason in all age and treatment groups. *Summary/Conclusions.* Inconsistency was observed between overall FN risk assessment and use of G-CSF primary prophylaxis leading to lack of adherence to EORTC guidelines in both younger and older NHL patients. Elderly patients experienced more frequent neutropenia-related complications and reduced RDI in both 2-weekly and 3-weekly R-CHOP, suggesting that G-CSF primary prophylaxis may be particularly important in this patient population.

[2]*German Cancer Research Center, Heidelberg, Germany*
[3]*Onkologische Schwerpunktpraxis, Mannheim, Germany*
[4]*University of Bonn, Bonn, Germany*

Background. Clinical and pharmacokinetic data suggest that the effect of rituximab could be improved by prolonged exposure to the drug. *Aims.* To test for this hypothesis we performed a prospective randomized trial of rituximab maintenance therapy in patients (pts) with CD20+ B-cell Non-Hodgkin-Lymphoma. *Methods.* After completion of standard treatment pts with CD20+ B-cell lymphoma were randomized to either observation or maintenance therapy with rituximab (375 mg/m2) administered every 3 months for 2 years. Both pts after first line therapy and pts after relapse treatment were included in the study. Primary endpoint of the study was event free survival (EFS), secondary endpoints were relapse rate (RR), relapse free survival (RFS) and overall survival (OS). EFS and OS were analysed using an asymptotic logrank test, RFS using a competing risk model and RR using Fisher's exact test. *Results.* After recruitment of 171 pts the planned final analysis was performed on an intention to treat basis. Complete data sets of 163 pts were evaluable. At study entry, 120 pts (74%) were in CR, 2 pts (2%) in unconfirmed CR and 41 pts (25%) in PR. Histological subtypes included diffuse large cell lymphoma (67 pts), follicular lymphoma (35 pts), mantle cell lymphoma (18 pts), primary mediastinal lymphoma (16 pts), marginal zone lymphoma (7 pts), Burkitt's lymphoma (5 pts), and other lymphomas (15 pts). After a median follow up of 28 months, EFS (HR 0.50, 95% CI 0.23-1.09, p=0.037,) and RFS (HR 2.52, 95% CI 1.11-5.70 p=0.03) were superior for the maintenance group. In regards to diagnostic subgroups, EFS was in particular prolonged in pts with mantle cell lymphoma (p=0.055, one sided logrank test) and to a lesser extent in pts with follicular lymphoma (p=0.16) and diffuse large cell B cell lymphoma (p=0.18). Relapse occurred more often in the observation group than in the treatment group, however this effect was not significant (relapse rate observation group/treatment group = 2.31, 95% CI 0.86-6.75, p=0.08). There was no difference in OS between the two groups (p=0.74). Maintenance therapy was generally well tolerated: in 5 pts a WHO Grade 3 toxicity event occurred, which were arrhythmia, neuropathy, leucopenia (n=1 each) and infections (n=2). In one pt two WHO Grade 3 toxicities were observed (pain and infection). *5. Conclusion.* Rituximab maintenance therapy is feasible, safe and well tolerated and improves EFS in patients with CD20+ B-cell lymphoma.

ORAL CYCLOPHOSPHAMIDE AND RITUXIMAB IN THE TREATMENT OF MARGINAL ZONE LYMPHOMA

E Orciuolo, F Ghio, G Buda, S Galimberti, M Pelosini, N Cecconi, G Cervetti, M Petrini

Azienda Ospedaliera-Universitaria Pisana, Pisa, Italy

Introduction. MZL accounts between 5% and 17% of all non-Hodgkin lymphomas. MZL are most often very indolent malignancies that usually present with limited stage disease, which may be controlled with local treatment, with 10 years survival approximately 75-80%. Standard treatment option for stage I-II disease has not been yet established because the paucity of prospective trials, the heterogeneity of treatment and short follow-up and the indolent nature of disease justify a conservative approach. Patients with systemic stage III-IV disease should be considered for a more aggressive treatment. However a standard chemotherapic approach for MZL is missing. *Aim.* We are reporting a retrospective study on the use of oral cyclophosphamide (CTX) and rituximab in the treatment of advanced stage MZL patients. Cyclophosphamide is a nitrogen mustard alkylating agent identified as a lymphocyte cytotoxic agent. It determinates DNA crosslinks between (interstrand crosslinkages) and within (intrastrand crosslinkages) DNA strands at guanine N-7 positions in irreversible manner, leading to cell death. Adding rituximab allows targeting CD20 MZL positive cell, obtaining a synergistic effect on lymphoma cells. Patients and *Results.* 38 patients with MZL were included in the study and received 100 mg/die orally CTX for 15 days a month and 375 mg/sqm rituximab on day 8 of CTX therapy, monthly, for a 6 months treatment program. 31 patients are retrospectively valuable. The global overall response rate was 90.3%, with 51.6% complete response (CR) and 38.7% partial response (PR). The remaining 9.7% patients obtained a stable disease or a disease progression at the end of treatment. The principal side effects were recorded with rituximab use, with 4 patients that presented infusional reactions despite paracetamole and antihistamine premedication. One patients experienced herpes zoster reactivation. Patients achieving a response (CR or PR) underwent to follow-up, with a median of 10 mounts (mean 15). PFS presented a median of 23 months, and no statically significant differences documented between patients achieving a CR or a PR, due to short follow-up. All patients underwent at diagnosis to bone marrow aspiration and further analysis for IgVH rearrangement by PCR, to monitor minimal residual disease after therapy. Of the 31 pretreatment evaluable patients, 20 were positive and 11 negative at PCR. After treatment 10 patients were positive, 13 negative and 8 not evaluable. All PCR negative patients remained negative at the end of therapy. With regard to PFS, in the PCR negative subgroup we recorded 16.7% disease relapse, while 57.1% in the positive subset, confirming a predictive role of molecular biology status at the end of treatment (see figure). *Conclusions.* in the absence of comparative trial, it is difficult to know if any particular regimen should be preferred for the treatment of MZL. Oral cyclophosphamide combined

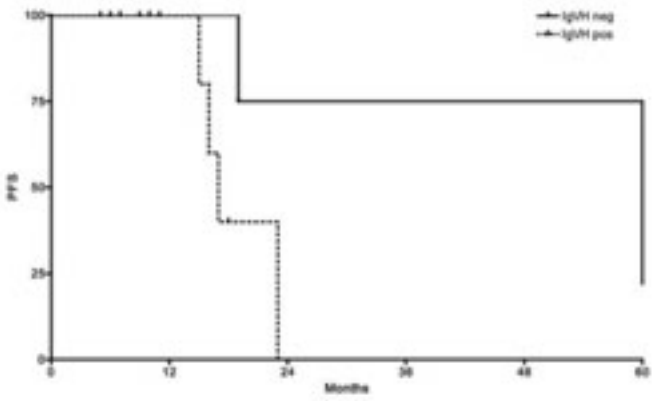

Figure 1. PFS according to minimal residual disease status.

with rituximab immunotherapy is effective, safe and reliable in the treatment of MZL. Minimal residual disease condition at the end of treatment may have a predictive role of disease relapse. Prospective randomized studies are necessary to validate our results and to define a standard approach in advanced stage MZL patients.

CLINICAL IMPACT OF EBV-ENCODED LMP1 IN EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE

N Kanemitsu, Y Isobe, A Masuda, K Sugimoto, N Komatsu

Juntendo University School of Medicine, Tokyo, Japan

Background. Extranodal NK/T-cell lymphoma, nasal type (ENKL) is a rare disease and more frequently develops in East Asia than in Western countries. Although more than 95% of the cases harbor Epstein-Barr virus (EBV) genome in the neoplastic cells, little is known regarding the roles of EBV-associated gene products in ENKL. *Aims.* To elucidate detailed expression profiles of EBV-associated gene products and their impact on clinical behavior in ENKL. *Methods.* ENKL cases referred to Juntendo University Hospital between August 1996 and June 2010 were retrospectively studied. All cases were diagnosed according to the latest World Health Organization classification. Expressions of EBV-associated gene products were evaluated by immunohistochemistry in formalin-fixed, paraffin-embedded tissue sections. This study was conducted with approval of the Institutional Review Board of Juntendo University, and informed consent was obtained in accordance with the Declaration of Helsinki. *Results.* Total 30 ENKL cases were analyzed. The cases consisted of 19 males and 11 females, and the median age at diagnosis was 62 years (range 27-85 years). All cases were positive for EBERs and lacked EBNA2 expression. ZEBRA was detected in four cases (13.3%). LMP1 and LMP2A were detected in 22 cases (73.3%) and 12 cases (40.0%) respectively. However, co-expression of LMP1 and LMP2A was observed in 10 cases (33.3%). LMP1-positive cases tended to have higher levels of phosphorylated Akt. The 2-year overall survival rates were 78.3% (95% CI, 59.3 to 97.3%) and 12.5% (95% CI, 0.0 to 35.4%) in LMP1-positive and -negative cases, respectively. Compared with LMP1-negative cases, LMP1-positive ones presented with limited disease (p=0.037, chi-square test) and showed better prognosis (p=0.001, log-rank test). *Summary/Conclusions.* Although the expression patterns of LMPs were heterogeneous, LMP1-positive cases showed more limited disease and had a survival advantage in ENKL.

0953

RELAPSE PATTERN AND PROGNOSTIC FACTORS OF PRIMARY CNS LYMPHOMA

JE Kim, DH Yoon, K Shin, JH Kim, YH Yoon, HS Chi, SW Lee, JR Huh, C Suh

Asan Medical Center, Seoul, South-Korea

Background. Primary central nervous system lymphoma (PCNSL) rarely relapses in extracranial sites, but there has not been a specialized guideline for follow-up evaluation. High-dose methotrexate based chemotherapy and high-dose chemotherapy(HDC) followed by autologous stem cell transplantation (ASCT) were shown as alternative strategies for PCNSL recently, but data on prognostic factors with these treatment scheme are limited. *Aims.* The aim of this study was to evaluate the pattern of relapse and investigate prognostic factors for PCNSL with single institution experience. *Methods.* Between November 1995 and August 2010, 67 patients with newly diagnosed PCNSL at the Asan Medical Center, Seoul, Korea were included. *Results.* The median age was 54.5 years (range, 26-77 years) and 55 (78.6%) patients had intracranial lesions only. Nine patients had leptomeningeal involvement, 2 had ocular lesions, and one had spinal cord lesion. Twenty-nine patients (43.3%) were treated with chemotherapy only, 13 (19.4%) with chemotherapy followed by whole brain radiotherapy (WBRT), while 20 (29.8%) were given HDC followed by ASCT. Two patients received palliative WBRT only and 3 received best supportive care. While all patients achieved CR (complete response, 76.2%) or PR (partial response, 23.8%) with ASCT, overall response rate (ORR) to chemotherapy and chemotherapy followed by WBRT were 64.5% and 84.6%, respectively. No systemic relapse was noted among 27 patients experiencing relapse; intracranial lesion only in 23 patients, 3 with leptomeningeal involvement and one with ocular relapse. Median overall survival (OS) and failure free survival (FFS) of all patients were 35.8 and 13.1 months, respectively. Age< 60 years (44.9 ±12.41 versus 27.0 ± 6.93 months, p=0.040) and Eastern Cooperative Oncology Group performance status (PS) < 2 (44.9 ± 12.41 versus 13.2 ± 13.81 months, p=0.002) were the only variables related to prolonged OS. Other variables in the International Extranodal Lymphoma Study Group prognostic scoring system and Memorial Sloan-Kettering Cancer Center prognostic model were not predictors of survival in this group. Patients received ASCT had longer OS (58.6 ± 21.48 versus 33.3 ± 8.65 months) but without statistical significance (p=0.083), while they had significantly better FFS (35.5 ± 19.83 versus 9.9 ± 2.96 months, p=0.013). *Conclusions.* Considering no systemic involvement of relapsed PCNSL in current study, regular evaluation with computed tomography or positron emission tomography to investigate extracranial sites might not be necessary in PCNSL patients. Age and PS still retain prognostic significance irrespective of treatment scheme, and ASCT could lead to improve response rate and FFS.

0954

TOXICITY ADAPTED HIGH-DOSE THERAPY IN MANTLE CELL LYMPHOMA PATIENTS, USING SCHEMES EPOCH, HMA AND GIDIOX, AUTOLOGOUS STEM CELL TRANSPLANTATION AND RITUXIMAB

V Vorobyev,[1] T Obukhova,[1] E Gretsov,[1] A Melikjan,[1] J Mangasarova,[1] A Sidorova,[1] D Mar'in,[1] I Galtseva,[1] E Gribanova,[1] V Zherebtsova,[2] S Kravchenko,[1] Y Lorie[1]

[1]*National Research Center for Hematology, Moscow, Russian Federation*
[2]*P.A. Herzen Moscow Oncological Research Institute, Moscow, Russian Federation*

Background. Mantle cell lymphoma (MCL) is aggressive B-cell neoplasm diagnosed predominantly among elderly men. (R)CHOP-like schemes are effective in remission induction, but progression free survival is short with median overall survival of 3-5 years. Upfront use of high-dose cytarabine (12 g/m^2), autoSCT and rituximab at all stages of therapy is the most effective treatment but possible only with younger patients. Decrease in AraC doses to 4 g/m^2 per cycle significantly reduce progression free survival. Prominent efficacy of gemcitabine-oxaliplatin combinations and irinitecan in relapsed and refractory MCL patients allowed including these drugs in first-line treatment in cases when the scheme R-HD-Met-AraC (Romanguera J. 2005) is impossible. *Aim.* toxicity and efficacy assessment of schemes R-EPOCH/R-GIDIOX and R-EPOCH/R-HMA in primary MCL patients eligible for autoSCT. *Methods.* Since May 2008 17 untreated MCL patients (average 55 years (29-63), 9 males and 7 females, MIPI: 35% high, 30 % intermediate, 35% low risk) were enrolled. After first R-EPOCH cycle (Wilson W. 2003) patients were stratified according to toxicity they had received either R-EPOCH/ R-HMA or R-EPOCH/R-GIDIOX (gemcitabine 800 mg/m^2 days 1 and 4, oxaliplatin 120 mg/m^2 day 2, irinotecan 100 mg/m^2 day 3, dexamethasone 10 mg/m^2 IV days 1-5, ifosfamide 1000 mg/m^2 days 1-5) for those who got higher hematological toxicity (grade 4 for more than 3 days). Depending on the terms of response, patients received 6-8 cycles of immunochemotherapy and autoSCT (BEAM) with *in vivo* purging by rituximab before harvest and reinfusion. Patients with residual tumor after autoSCT were consolidated with local radiotherapy. MRD was diagnosed and controlled by flow cytometry. Rituximab maintainance was performed every three months for 2 years. *Results.* 29 GIDIOX cycles were analyzed with evidence that GIDIOX is less intensive and toxic regimen than HMA, but in our selection hematologic toxicity in R-GIDIOX and R-HMA arms were similar due to less fit patients in R-GIDIOX arm, except thrombocytopenia, that was more prominent and lasting in R-HMA arm. Main non-hematological toxicity of GIDIOX was hepatic, with ele-

Figure 1. The scheme of treatment.

vated aminotransferases grades 1-2 and 3 in 48% and 3% of cycles respectively, without clinical signs. Complete responses were obtained for 16 out of 17 patients after a median of 6.5 cycles in both arms. The sources of stem cell were PB in 15 patients and BM in one case of harvest failure after GIDIOX. Median number of collected stem cells was $4.07x10^6$/kg. 8 patients achieved CR (MRD-) among 9 ones in HMA arm, 1 induction death after first HMA cycle (acute renal failure and septic shock), and one relapse in 8 months after autoSCT, with observation from 1 to 13 months. GIDIOX arm included 8 patients: OR 100%, 7 CR (including 1 patient who achieved CR after radiotherapy), one patient with partial remission continues to get treatment, observation from 1 to 23 months, without relapses. *Conclusion.* GIDIOX scheme is less toxic than HMA and equally effective in response induction and mobilizing, so it could be recommended for those in whom high-dose AraC and methotrexate can potentially cause severe adverse consequences.

0955

FEASIBILITY OF THE TNM-BASED STAGING SYSTEM OF OCULAR ADNEXAL EXTRANODAL MARGINAL ZONE LYMPHOMA OF MUCOSA-ASSOCIATED LYMPHOID TISSUE (MALT LYMPHOMA)

SG Cho,[1] SE Lee,[2] SA Yang,[2] J Paik,[1] WK Cho,[1] BO Choi,[1] SN Lee,[1] SE Jung,[1] KS Park,[1] CS Kang,[1] SW Yang,[2] JW Park[2]

[1]*The Catholic Univerisity of Korea, Seoul, South-Korea*
[2]*The Catholic University of Korea, Seoul, South-Korea*

Background. Malignant lymphomas of the ocular adnexa account for 1-2% of non-Hodgkin lymphomas and 8% of extranodal lymphomas. Although immunohistochemical and molecular analyses have resulted in ocular adnexal lymphoma (OAL) being diagnosed more frequently, previous studies do suggest that there has been a true and inexplicable rise in the incidence of these tumors in the last decades. Among OALs, the most common subtype by World Health Organization (WHO) classification is marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma). Several studies have shown that the relative incidence of ocular adnexal MALT lymphoma (OAML) varies among different populations. The proportion of OAML among primary OALs is higher in Korea (86-98%) than in Western countries (50-78%). Although the prognosis of patients with OAML is generally favorable, some situations such as higher clinical stage, nonconjunctival primary site, nodal involvement, and bilaterality at presentation have been associated with a worse prognosis. However, based on the Ann Arbor staging system, two-thirds of OAMLs have been recorded as stage IE tumors, because the Ann Arbor staging system does not distinguish among OAMLs based on anatomic location, extent of primary tumor infiltration, multicentricity, or bilaterality. *Aims.* The Ann Arbor staging system is not particularly useful in determining the prognosis for these patients. The American Joint Committee on Cancer (AJCC) proposed the tumor, node, metastasis (TNM)-based clinical staging system for primary OAL to overcome the weak points of the Ann Arbor staging system, but the clinical impact of TNM-based staging on primary OAML has not been determined. This study is novel and demonstrates the feasibility of the TNM-based staging system for OAML. *Methods.* We performed this study to evaluate the feasibility of the TNM staging system for ocular adnexal extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (OAML). The data form 66 total eyes from 54 patients with biopsy-confirmed OAML according to World Health Organization classification were retrospectively analyzed. *Results.* Using the TNM staging system, we reclassified all patients into two categories: (1) T1N0M0 stage group (n=26), for patients with lymphoma involving only the conjunctiva; and (2) above T1N0M0 or bT1N0M0 stage group (n=28), for patients with lymphoma extending to the orbit, eyelid, or adjacent structures, and/or bilateral OAML. After a 24-month median follow-up period for all patients, the T1N0M0 group revealed higher progression- free survival (PFS) than the above T1N0M0 or the bT1N0M0 group (P=0.041). In a separate analysis of only 50 patients categorized as Ann Arbor stage IE, the T1N0M0 group demonstrated higher PFS (100%) than the above T1N0M0 or the bT1N0M0 group (84.7%; P=0.067). *Conclusions.* Our data show that the poor prognostic group classified as Ann Arbor stage IE can be further distinguished by using the TNM staging system. Thus, further studies to develop treatment strategies for reducing relapse after treatment for OAML should use the TNM staging system.

0956

TREATMENT OF BURKITT LYMPHOMA IN ADULTS USING AN ADAPTED PEDIATRIC ALL PROTOCOL: A SINGLE CENTER EXPERIENCE

L Oosten, P Jansen, F Falkenburg, P von dem Borne

LUMC, Leiden, Netherlands

Background. Burkitt lymphoma is an aggressive B-cell malignancy that accounts for 1% to 2% of all adult lymphomas in Europe. Treatment consists of dose-intensive, multi-agent chemotherapy and is highly effective but associated with considerable toxicity and treatment-related mortality. Several therapeutic strategies are currently in use, but the optimum treatment has yet to be defined. *Aims.* We report the results of a series of adult patients treated for Burkitt lymphoma with a protocol adapted from the LMB regimens of the Société Française d'Oncologie Pédiatrique. *Methods.* Twenty-three patients, 18 male and 5 female, were diagnosed with Burkitt lymphoma or Burkitt leukemia between 1997 and 2009. Median age was 39 years (14 to 74 years). No patients were HIV-positive. Fifteen patients presented with stage III-IV disease, 8 of which had central nervous system involvement. According to the revised WHO 2008 criteria 5 cases would now be diagnosed as B-cell lymphoma unclassifiable, with features intermediate between diffuse large B-cell lymphoma and Burkitt lymphoma. All patients were treated with an adapted LMB protocol consisting of an initial cytoreductive phase (COP), followed by 2 induction cycles (COPADM), 2 consolidation cycles (CYVE), and 4 maintenance cycles. Fourteen patients also received rituximab. Median follow-up was 31 months. *Results.* The adapted LMB protocol was well tolerated by most patients. Frequent toxicities included myelosuppression, neutropenic fever, and grade I-II mucositis and vasculitis. Three patients experienced grade III mucositis, 1 patient grade III neuropathy, and 2 patients nephrotoxicity (1x grade II, 1x grade III). Tumor lysis syndrome occurred in 3 patients. Eighteen out of 23 patients achieved a complete response (CR). Four patients had refractory disease. One patient achieved a partial response and received an autologous stem cell transplantation (SCT). He relapsed several years later and died during salvage therapy. Three patients underwent myeloablative allogeneic SCT: 2 in 1st CR because of extensive disease and the presence of a sibling donor, 1 following relapse after initial CR. Two of these patients died from treatment-related complications. The remaining 16 patients are alive and in CR as of today, including 4 out of 5 patients with B-cell lymphoma unclassifiable. The 2-year event-free survival and overall survival rates were 73.9% and 78.3% respectively. 2-year overall survival rates were significantly better for patients < 40 years (91.7% versus 50.0%), patients with early disease (100% versus 60.0%), and patients with low or low-intermediate IPI scores (100% versus 50.0%). *Conclusions.* The adapted LMB protocol is an effective regimen in adult patients with Burkitt lymphoma, Burkitt leukemia, and B cell lymphoma unclassifiable with a Burkitt-like phenotype. Survival rates are similar to the outcomes in case series using other treatment regimens such as CODOX-M/IVAC. However, compared to these studies we report a relatively low incidence of grade III-IV mucositis and grade III-IV neuropathy. The role of allogeneic SCT for Burkitt lymphoma should remain limited to salvage therapy.

0957

MSCT FOLLOW UP IN PATIENTS WITH MALIGNANT LYMPHOMA: DOES SEMI-AUTOMATED VOLUMETRY IMPROVE THERAPY RESPONSE CLASSIFICATION COMPARED TO MANUAL MEASUREMENTS?

B Buerke, M Puesken, A Knauer, W Heindel, C Schuelke, J Wessling

University of Muenster, Muenster, Germany

Background. Standardized staging and response assessment are crucial in lymphoma clinical trials in order to afford assessment of treatment strategies and facilitate comparison among studies. *Aims.* Impact of semi-automated volumetry compared to unidimensional measurements on therapy response classification in CT follow-up of malignant lymphoma. *Methods.* MSCT scans of 65 patients with malignant lymphoma prior to therapy (baseline) and after 2 cycles of chemotherapy

(follow-up) were included. A total of 313 target lymph nodes (56 cervical, 131 thoracic and 126 abdominal) were evaluated by two radiologists independently. Long axis diameter (LAD), short axis diameter (SAD) and volume were determined manually and using semi-automated segmentation software. Relative interobserver difference (RID) and time for manual and semi-automated segmentation were evaluated. Therapy response was calculated for each parameter based on "IWC" lymphoma-guidelines and "RECIST"-adapted guidelines. Mean of metric and volumetric measurements served as the reference standard. Statistical analysis encompassed intraclass correlation coefficients (ICC), t- and McNemar-test. *Results.* Over all regions mean lymph node size in baseline/follow-up was 23.8±10.3 mm/17.0±9.2 mm for LAD and 7.2±13.5 ml/3.4±9.9 ml for volume. RID was consistently low in baseline and follow up with high ICC>0.96 for semi-automated measurements. Mean evaluation time for semi-automated segmentation without need for correction was shorter (16.6±11.7 sec) than for manual measurements (29.0±14.5 sec). In 65% of all lymph nodes correction was necessary and evaluation time increased to 39.5±25.9 sec. Regarding therapy response, semi-automated volumetry obtained significantly more accurate classifications than semi-automated and manual LAD and SAD (e.g. volume 87.8% vs. semi-automated LAD 83.8%, manual SAD 78.9%, all p<0.05). *Summary/Conclusions.* Semi-automated lymph node volumetry is more accurate for therapy response classification in patients with malignant lymphoma as compared to established LAD.

Background. Bendamustine (B) is a purine analog/alkylator hybrid with antitumor activity. B is currently licensed by EMEA for use in NHL, CLL and multiple myeloma. *Aim.* Our aim was to analyze retrospectively the efficacy and toxicity of B for NHL and CLL in Spain. *Patients and Methods.* From June 2009 to September 2010, a questionnaire form was sent to Spanish centers in which B had been used as Compassionate Use Program. Patients with relapsed or refractory NHL or CLL after at least 1 prior treatment regimen were eligible. Any B regimen was included. *Results.* 109 patients (pts) were included from 22 institutions. Histology: 42 pts CLL; 18 pts aggressive NHL; 49 pts indolent NHL. Median time from diagnosis to B treatment was 4.9 years (range 1-24). Median number of previous treatment regimens was 3 (range 1-11). 44 pts (40%) were refractory to prior treatment. The most frequent used regimen was rituximab plus B (RB) independently of the histology. 63% of the pts had adverse events grade 3 or 4 (mainly hematology toxicity). Overall response rate (ORR) was 66% (30% complete response (CR)). Response rate was higher in mantle cell lymphoma (86%). ORR observed in refractory pts was 45%, including fludarabine resistant pts. The median progression-free survival (PFS) was 12.7 months (95% CI%, 7.14 to 18.23). Among follicular NHL and CLL pts, median PFS time was 12.4 vs 8.9 months, respectively. The factors significantly affecting PFS were number of treatments prior to B, resistance to prior chemotherapy and type of response achieved to B therapy. *Conclusions.* 1. Bendamustine containing therapy achieved a high response rate in this heavily pretreated CLL and NHL pts with an acceptable toxicity profile. Responses were seen in indolent and aggressive histology, and also in patients with chemoresistant disease to previous regimen. 2. Histology and number of prior treatment were the most important factors affecting PFS.

0959

FDG-PET/CT STAGING IN FOLLICULAR LYMPHOMA AND IMPACT ON FLIPI SCORE

I El-Najjar, T Szyszko, J Matthews, N Avril, J Gribben, S Montoto

Queen Mary University of London, London, United Kingdom

Background. [F18]fluorodeoxyglucose positron emission tomography (FDG-PET) is currently recommended by the International Harmonisation project for staging of Hodgkin Lymphoma and Diffuse Large B-cell Lymphoma. However the role of FDG-PET in the staging of Follicular Lymphoma (FL) has not yet been clearly defined. Despite this FDG-PET and PET/CT are increasingly being used by multiple centres in the staging of FL. *Aims.* To investigate the impact of FDG-PET/CT on the staging of FL and to evaluate the potential changes in the FLIPI score. *Methods.* Between 2008 and 2010, 40 patients with grade 1-3 FL (either newly diagnosed or at relapse) underwent whole body FDG-PET/CT, a contrast enhanced CT (ceCT), a bone marrow aspirate and trephine (BMT). We compared the number of lymph node regions and the site of extranodal involvement assessed by FDG-PET with those as assessed by ceCT and BMT. *Results.* FDG-PET identified 160 involved lymph node regions compared to 137 by ceCT. In 7% of patients with a negative BMT, FDG-PET showed bone marrow involvement by demonstrating focally increased glucose metabolism. However, FDG-PET failed to identify bone marrow involvement in 17% of patients with a positive BMT. FDG-PET upstaged 12% of patients compared to ceCT while 15% were downstaged. The management of 2 patients was affected by a change in stage due to the identification of extranodal involvement on FDG-PET not detected on ceCT. The FLIPI score was altered in 20 % of patients by using FDG-PET/CT: the prognostic group according to the FLIPI changed from low to intermediate risk in 5% of the patients, and from intermediate to poor risk in 10%. *Conclusion.* FDG-PET/CT resulted in a change of stage in 27% of FL patients but this resulted in a change in the management in 2 patients only. As a result of identifying more involved lymph node regions, the FLIPI score was altered. The issue of whether FDG-PET or ceCT only is performed for staging needs to be taken into account when using the FLIPI to define and compare study populations.

Table 1. Percentage of patients in each risk group.

Risk group FLIPI	ceCT	FDG-PET/CT
Low (0 - 1)	42.5 %	30.0 %
Intermediate (2)	15.0 %	17.5 %
High (3 - 5)	42.5 %	52.5 %

POPULATION BASED ANALYSIS OF CHEMO-IMMUNOTHERAPY IN ADULT BURKITT LYMPHOMA AND LEUKAEMIA (BLL)

T Zvirblis,[1] I Vengalyte,[1] R Pileckyte,[1] D Pranys,[2] M Jurgutis,[3] L Griskevicius[1]

[1]*Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania*
[2]*Lithuanian University of Health Sciences, Kaunas, Lithuania*
[3]*Klaipeda Seamen's Hospital, Klaipeda, Lithuania*

Background. Adult sporadic BLL is a rear and highly aggressive malignancy. It is known to strongly express surface CD20 antigen. Recent data indicates that the outcome of adult BLL patients can be improved by the addition of anti-CD20 antibody rituximab to multi-agent chemotherapy. The population based outcome data of BLL is rarely presented and may

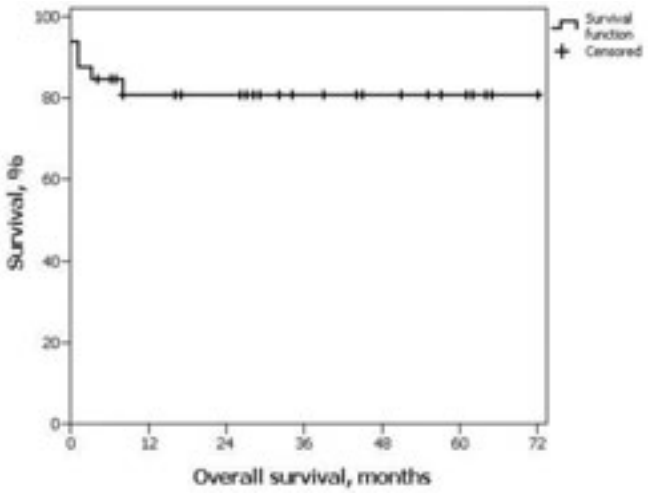

Figure 1. Overall survival of all patients.

help to avoid reporting bias. *Aim.* The outcome of patients 18 years of age and older diagnosed with BLL. *Methods.* Adult BLL cases diagnosed in Lithuania (average annual population 3.34 million) in 2004-2010 were retrospectively identified through Hematology Monitoring System of Lithuania and their medical records were reviewed. BLL was diagnosed according to the World Health Organization criteria. *Results.* 32 adults were diagnosed with BLL (26 lymphoma and 6 leukemia). The median age was 32 years (range 18-81). 24 (75%) patients were male, 3 (9%) were HIV positive. 20 (77%) of lymphoma patients had St. Jude stage III-IV disease. The main location of lymphoma was gastrointestinal tract 11 (42%). 2 (6%) patients had neuroleukaemia. Two (6%) patients were not treated: one refused therapy and one died before treatment and 30 (94%) patients received short, intensive high-dose methotrexate, fractionated alkylator based therapy. Rituximab 375 mg/m2 (off-label use) was administered 1 day before each chemotherapy cycle in 27 (90%) of the treated patients. Autologous stem cell transplantation was used to consolidate 2 (7%) partial remissions. The median follow-up was 28.5 months (range: 0 - 71). Among the treated patients, 24 (80%) and 2 (7%) achieved complete and partial remission, respectively and 3 (10%) patients had primary progressive disease. 6 (19%) patients died during the first 8 months of the diagnosis: 2 were not treated, 3 deaths were due to primary disease progression and one was due to traumatic subdural hematoma. 2 year overall and progression free survival were 81% (95% CI: 62% - 91%) in all patients (Figure 1). In patients who received treatment, 2 year overall and progression free survival were 86% (95% CI: 67% - 96%). *Conclusion.* Our population based analysis confirms favorable outcome of adult BLL receiving brief intensive chemotherapy combined with anti-CD20 immunotherapy. 10% of the patients have primary refractory disease.

Background. In lymphoblastic lymphoma (LL) the role of mediastinal radiotherapy (mRT) and stem cell transplantation (SCT) remains controversial. In a risk-oriented design, we adopted a flexible treatment in which (1) patients with persistent mediastinal abnormality, evaluated by postinduction CT scan, received mRT; and (2) those with persistence of MRD, evaluated by molecular analysis of BM, underwent stem cell transplantation (SCT). *Aims.* To evaluate the clinical outcome, prognostic factors and the pattern of recurrence adopting this innovative strategy. *Methods.* Between 2000 and 2008, 6 B-LL and 24 T-LL untreated pts, median age 27 years (range, 16-57), M/F 17/13, 21 with mediastinal and 12 with BM involvement (<20%) were enrolled in the NILG 09/00 protocol (Bassan, *et al.*, Blood, 2009). The treatment included an induction/early consolidation with Ida/V/P/Asp/Cy (blocks 1-3, 5, 6, 8), HD-MTX/Ara-C (4, 7), CNS phase and mRT (Gy 24-32) for pts with pathological postinduction CT scan. Postconsolidation therapy was MRD/risk oriented. MRD negativity (Mneg) was defined by low positive (<10-4) and negative determinations obtained before blocks 6 and 8, respectively. Mneg pts received maintenance, while Mpos underwent family-related/unrelated SCT (or 2-4 autologous stem-cell supported hypercycles [H/C: L-PAM/VP/6MP/; HD-MTX/Ara-C] followed by maintenance). Pts with undefined MRD were scheduled to receive maintenance if standard risk (SR -only the pts with CD10+ B-LL), and SCT if high risk (HR-all other pts). *Results.* Twenty-eight pts (93%) (T-LL, n=24; B-LL, n=6) achieved CR and 2 had refractory T-LL and died. Of 21 pts with mediastinal mass, 13 (62%) achieved a CR after chemotherapy alone, whereas 6 (28.5%) required additional mRT. Eleven pts were evaluated for MRD: 6 were Mneg and 5 Mpos. On the basis of MRD findings and clinical risk characteristics, 14 pts underwent SCT, 13 received maintenance chemotherapy, and one had local RT. Five pts relapsed. Among the 14 nonirradiated pts with T-LL, the mediastinal recurrence rate was only 7%. After a median follow-up of 3.9 years (range, 0.8-9.2+ years) 22 pts (73%) who responded were alive: 21 in 1st and one in 2nd CR. Postremission failure was due to recurrence (n=5, 18%) in the BM (B-LL, n=1; T-LL, n=3; 1 irradiated and 2 non-irradiated patients) or mediastinum (n=1, non-irradiated T-LL patient), and other malignancy (n=2, 7%; 1 sAML and 1 sDLBCL). The projected 5-year OS, DFS, and relapse rate were 72% (83% for B-LL and 69% for T-LL), 77% (83% for B-LL and 71% for T-LL), and 18%, respectively. The probability of OS and DFS was not significantly affected by any of examined prognostic factors, however the achievement of Mneg status was associated with a better outcome in comparison with Mpos cases (5-yrs DFS 80% vs. 60%, P=ns). *Conclusions.* This programme induced high remission and survival rates, with an acceptable toxicity profile. Avoidance of mRT and SCT in patients with an early response in the mediastinum and without molecular evidence of disseminated LL limits treatment-related toxicity and warrants high cure rates in a significant proportion of patients exposed to standard chemotherapy only.

0962

THERAPY WITH 90Y IBRITUMOMAB TIUXETAN IN RELAPSED/REFRACTORY NON-HODGKIN LYMPHOMA. ANALYSIS OF RECENT OUTCOMES

P Giraldo,[1] M Andrade,[1] A Rubio-Martinez,[1] J Grasa,[1] P Lievano,[1] T Baringo,[1] L Lopez-Gomez,[2] P Navarro,[1] E Arroyo,[1] E Arroyo,[1] L Cueva de La,[1] D Abos[1]

[1]*Miguel Servet University Hospital, Zaragoza, Spain*
[2]*Royo Villanova Hospital, Zaragoza, Spain*

Introduction. Add-on treatment of follicular non-Hodgkin's lymphoma (NHL) with 90Y Ibritumomab tiuxetan (Zevalin®) has become an efficient alternative. The aim of this study is to analyze our updated information of patients treated with 90YIbritumomab/tiuxetan in a prospective study according clinical practice setting and to analyze treatment outcome. *Subjets and Methods.* 87 relapsed/refractory lymphoma patients were included in a clinical protocol conducted by a multidisciplinary team and treated in the same centre. According the inclusion criteria: found relapsed/refractory CD20+ NHL patients with neutrophils ≥ 1,5 x 109/L, platelets ≥ 100 x 109/L, bone marrow lymphocytes CD20+ ≤ 25%. All patients received 0,3 or 0,4 mCi /kg IV (88%) of 90YIbritumomab/tiuxetan and response evaluation was performed 12 weeks after. Period of study: September 2005/September 2010. Endpoints: objective response rate (ORR), time to relapse (TTR) overall survival (OS) and safety. Other clinical prognostic factors were observed to assess their possible influence upon treatment value. *Results.* Until September 2010, 87 patients had received treatment with 90YIbritumomab/tiuxetan, and were considered to analysis; M/F 52.6%/47.4%; mean age 61.88 years (30-86); ECOG 0-1 96.2%; 68 follicular NHL (63.8%), 8 mantle cell NHL (13.8%), 9 BDLG NHL (15.5%) and 2 Hodgkin Lymphoma (6.9%). According FLIPI score distribution: (0-1) 70.2%, FLIPI (>1) 29.8%, ECOG 0-1 96.2%, Previous therapy schedules 1-2 (44.8%), >2 (55.2%). The median follow-up time: 30.23 months,

medianTTP: 34.4 months (95% CI: 29.7; 39.0). Mean OS 46.0 months (95% CI: 38.0; 53.9), median: NA for FNHL. Completed response (CR) was different according lymphoma subtype: 58 (CR) follicular NHL, 7 (CR) mantle cell NHL and 6 (CR) NHL BDLG. ORR: 76.8%. Complete response 73.4%, partial response 3.4% and relapsed 23.1%, 11.3% patients have died or withdraw. Median TTR was 42 months for follicular NHL vs 15 months for other NHL subtypes. Safety: thrombocytopenia being the most frequent (27.6%) haematological toxicity, median time to G3-4: fourth week, and neutropenia (22.4%), the median time to recover normal values was 4.2 and 2.6 weeks respectively. In 10.3% of patients red blood cell transfusion was required, and platelet transfusions in 27.6%. The most frequent non haematological toxicity was asthenia. One patient developed a severe mucositis. Two patients have concomitant associated tumours (colon and prostate) and two patients developed secondary malignancies (skin and lung tumours). *Comments*. In our experience 90Y Ibritumomab tiuxetan (Zevalin®) is a safety and effective therapy in relapsed NHL, especially in patients with follicular non-Hodgkin's lymphoma that can obtain higher complete response than other types of lymphoma and prolonged median survival time.

0963

EARLY STAGE FOLLICULAR LYMPHOMA: ROLE OF MOLECULAR MONITORING IN PATIENTS TREATED WITH LOCAL RADIOTHERAPY ± RITUXIMAB

A Pulsoni,[1] I Della Starza,[1] F De Angelis,[1] G Annechini,[1] GM D'Elia,[1] S Panfilio,[1] I Prosso,[1] M Cavalli,[1] L Grapulin,[2] R Foà[1]

[1]*Hematology Sapienza University Rome, Rome, Italy*
[2]*Dept. of Radiology and Radiotherapy, Sapienza University, Rome, Italy*

Background. Conventional treatment of stage I-II follicular lymphoma (FL) is local radiotherapy (RT), which allows eradication of the disease in about 50% of patients. *Aim.* To evaluate the role of anti-CD20 MoAb and of minimal residual disease (MRD) in this setting of patients. *Methods.* 41 consecutive patients with a confirmed diagnosis of stage I/II FL were investigated by PCR in order to identify the presence of Bcl-2 rearranged cells in the bone marrow (BM) and/or peripheral blood (PB). All patients were treated with involved field RT (36 Gy). Subsequently, MRD was evaluated every 6 months in patients positive at baseline. *Results.* PCR analysis revealed Bcl-2 rearranged cells in 24/41 patients (58.5%) at presentation. After irradiation of the sole site of the disease, Bcl-2 rearranged cells disappeared in 15 of the 24 (62.5%) patients positive at baseline; in 8 (19.5%) MRD was positive, while 1 patient refused the test. After a median follow up of 50 months, 5 patients (12.2%) had a clinical relapse. MRD evaluation demonstrated that: - 17/41 Bcl-2 negative patients at the basal evaluation were not subsequently retested; only 1/17 patients had a clinical relapse (the new biopsy documented a mantle cell lymphoma). - Of the 15 patients positive at baseline and who became negative after RT, 3 have had a molecular relapse during the follow-up, leading in one case to an overt clinical relapse. - Of the 8 patients persistently Bcl-2 positive after radiotherapy, 3 had a clinical relapse. Rituximab (375 mg/m2 x 4) was administered to 5 patients with a persistently positive Bcl-2 after RT: 3 of them became Bcl-2 negative. *Conclusions.* Viable Bcl-2+ cells can be demonstrated in the BM and/or PB of the majority of stage I-II FL patients (despite a negative BM biopsy). Irradiation of the sole nodal/extranodal disease sites allows disappearance of Bcl-2+ cells in the majority of previously positive patients (62.5%). Pre-treatment Bcl-2 BM and/or PB evaluation has a prognostic role: no clinical relapses were observed in Bcl-2 negative cases at baseline except for one patient, relapsed as mantle cell. MRD evaluation has a prognostic role: among 32 Bcl-2 negative patients after treatment, 2 relapses (6.2%) were observed (1 relapsed as mantle cell), while among 8 Bcl-2 positive patients after treatment 3 relapses (37.5%) were observed. Prognosis of early stage FL treated with local RT ± rituximab is excellent: only 5 patients have so far relapsed at a median follow up of 50 months.

0964

RITUXIMAB RETREATMENT IN PATIENTS WITH RELAPSED OR REFRACTORY B CELL NON-HODGKIN'S LYMPHOMA: PREDICTIVE FACTORS AND SAFETY

MH Hung, CY Liu, YB Yu, YC Huang, HT Liu, YC Hong, LT Hsiao, JH Liu, JP Gau, TJ Chiou, PM Chen, CH Tzeng

Taipei Veterans General Hospital, Taipei, Taiwan

Background. Use of rituximab, a monoclonal antibody targeting CD20, is a milestone for B-cell non-Hodgkin's lymphoma (NHL) treatment. In patients with relapsed B-cell NHL, retreatment of rituximab, with or without salvage chemotherapy, has been shown to exert promising safety and efficacy. However, a substantial proportion of patients would eventually fail by this approach. *Aims.* In this retrospective study, we aimed to explore factors predictive for response of rituximab retreatment and determine whether response could be translated into progression-free survival (PFS). A second objective is to re-exam the

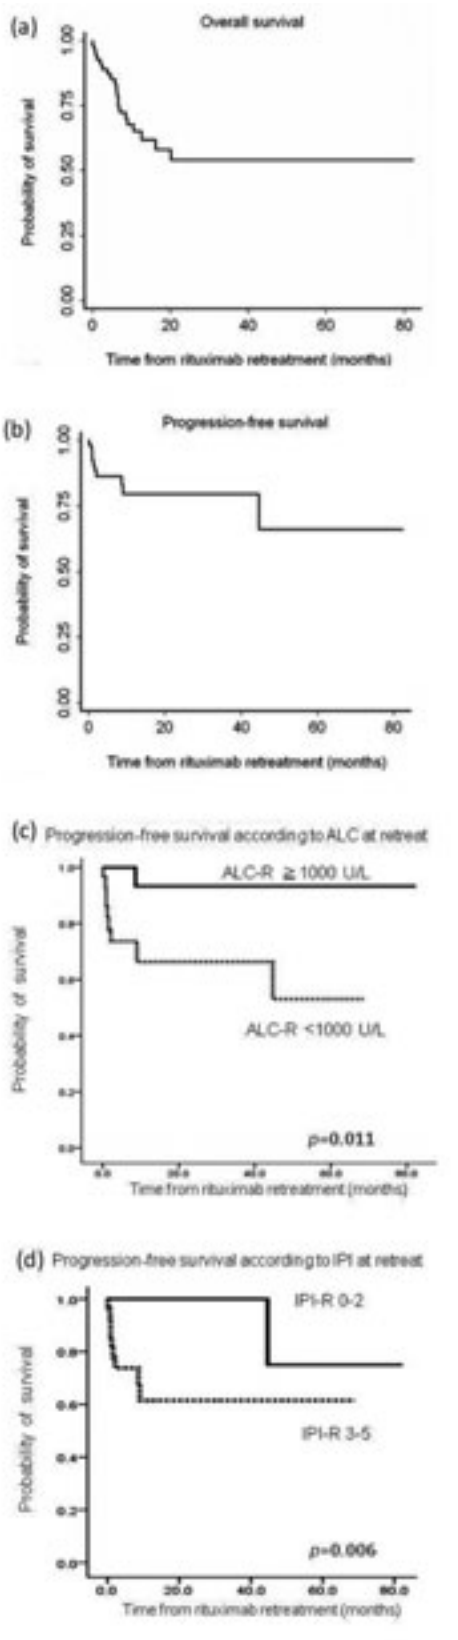

Figure 1. Response and factors of rituximab retreatment.

safety and efficacy of rituximab retreatment in a hyperendemic area of chronic hepatitis B virus infection. *Methods.* This is a single institute study that retrospectively analysis patients with relapsed or refractory B cell NHL, who had received retreatment of rituximab either alone or in combination with salvage chemotherapy. All patients had received first-line rituximab-containing treatment. Patient's characteristics at initial diagnosis and at relapse were collected. Response to treatment was evaluated by chart review and was defined as complete response (CR), partial response (PR), stable disease (SD), and progressive disease (PD). For those who reached complete response and partial response were defined as responder. *Results.* A total of 54 patients who received rituximab retreatment were identified. The overall response rate to first-line rituximab-containing treatment was 88.9% (CR 27.8%, PR 61.1%). Most patients (92.5%) received rituximab retreatment in combination with salvage chemotherapy. The overall response rate of rituximab retreatment was slightly lower than the first-line treatment (61.1%) but the CR rate was similar (27.8% vs 29.6%). Median PFS and median overall survival (OS) from rituximab retreatment were not reached, with a 5-year PFS rate of 81.5% and a 5-year OS rate of 63.0%. Factors associated with better response to rituximab retreatment were high absolute lymphocyte count at retreatment [(ALC-R), defined as absolute lymphocyte count ≥1000/UL, p=0.006) and low IPI at retreatment [(IPI-R), defined as IPI ≤2, p <0.001). Both of which were significant independent predictive factors in multivariate analysis. Incidence rate of febrile neutropenia was 38.8% but was not associated with response rate, PFS or OS. Moreover, a high incidence of herpes zoster reactivation (14.8%) and a low incidence of HBV reactivation (3.7%) were observed during rituximab retreatment. *Conclusion.* For patient with relapsed/refractory B cell NHL, retreatment with rituximab-containing regimen is a promising and generally tolerable salvaging approach. Patients with low ALC-R and high IPI-R might predict worse response to rituximab retreatment. Febrile neutropenia and herpes zoster reactivation are the most common adverse events during or after rituximab retreatment. Acute exacerbation of hepatitis B virus infection or other opportunistic infections were uncommon. Further prospective controlled trials are needed to warrant our findings.

0965

COST-EFFECTIVENESS OF FIRST-LINE RITUXIMAB MAINTENANCE TREATMENT FOR FOLLICULAR LYMPHOMA

E Soini,[1] J Martikainen,[1] V Vihervaara,[2] K Mustonen,[2] T Nousiainen[3]

[1]*ESiOR Oy, Kuopio, Finland*
[2]*Roche Oy, Espoo, Finland*
[3]*Department of Medicine Kuopio University Hospital, University of Eastern Finland, Kuopio, Finland*

Background. Rituximab (R) and chemotherapy induction treatment has been recommended for patients with follicular lymphoma (FL). Just recently, guidelines have started to recognize the first-line R-maintenance treatment (1LRMT). FL patients receiving no 1LRMT are likely to relapse earlier compared to the patients receiving 1LRMT. *Aims.* To project the lifetime health outcomes for the 1LRMT and observation, and to compare the lifetime cost-effectiveness of the 1LRMT and observation in patients presenting with FL in Finland. *Methods.* A probabilistic Markov state-transition model based on the PRIMA (Primary RItuximab and MAintenance) phase III trials' 38 months first-line results and EORTC20981 phase III 60 months' subsequent-line trial results and literature was developed in order to perform the analysis from the Finnish public health care payer perspective. The model was used to simulate patients' transitions between first-line progression-free (PF1), PF2, progression and death states using a second order Monte Carlo simulation (2000 simulations recorded), one month cycle, and half cycle correction. Parametric extrapolation for the PRIMA PF1 results was done. The best fitting survival model was Gompertz and the maximum of 4 year treatment benefit was assumed for R in PF1 state due to the immature PRIMA data. After PF1, eligible patients were assigned for second R-maintenance based on the PRIMA results and the recent ESMO guideline for FL. For PF2, the recently published Finnish modelling results based on the EORTC20981 5-year data (maximum 5 year treatment benefit assumed) were used. Age-dependent transition to death was set equal to the larger of EORTC20981 trial or Finnish background mortality. Case-mix adjusted Finnish treatment, safety, monitoring, management and test costs were included in 2010 real value, and the most affordable public drug costs (2/2011; drug wastage included) were used. EQ-5D-based utilities were used. Discounting with 3% per annum was used for costs and health outcomes. The impacts of various assumptions (e.g. discounting with 0%, and PF1 function forms as Weibull, Exponential, Log Logistic, Log Normal and Gamma) were assessed. *Results.* The difference in survival estimates was significant for 1LRMT in comparison to observation; 1LRMT was projected to result to expected 8.56 (95%CI 7.85-9.38) quality-adjusted life-years (QALY) and 11.25 (95%CI 10.40-12.25) life-years meanwhile observation resulted to 7.18 (95%CI 6.38-8.16) QALYs and 9.61 (8.57-10.98) life-years. The incremental cost-effectiveness ratio (ICER) for 1LRMT vs. observation was €10025 per QALY gained and €8431 per life-year gained. According to the cost-effectiveness acceptability frontier, 41.6%, 96.1% and 99.9% of patients with 1LRMT were cost effective (i.e. had lower ICER than the willingness to pay threshold) at the WTP levels of €10000, €15000 and €20000 per QALY gained, respectively (Figure). The expected value of perfect information was highest with the ICER value of €10025 per QALY gained (€1830 per patient; Figure). The relative results were robust according to the sensitivity analyses. *Conclusions.* 1LRMT was projected to result to significant gains in health outcomes. In addition and irrespective of the conservative assumptions, 1LRMT was a potentially cost-effective treatment option for the FL.

TEMPORAL AND GEOGRAPHIC VARIATIONS OF WALDENSTRÖM'S MACROGLOBULINEMIA INCIDENCE: A LARGE POPULATION-BASED STUDY

L Wang,[1] H Wang,[1] Y Chen,[1] F Li,[2] K Delasalle,[1] R Alexanian,[1] L Kwak,[1] L Rustveld,[3] X Du[4]

[1]*University of Texas MD Anderson Cancer Center, Houston, United States of America*
[2]*Qilu Hospital, Shandong University, Jinan, China*
[3]*Department of Family and Community Medicine, Baylor College of Medicine, Houston, United States of America*
[4]*School of Public Health, Division of Epidemiology, University of TX Health Cente, Houston, United States of America*

Background. Waldenström's macroglobulinemia (WM) is a non-Hodgkin lymphoma (NHL) subtype. Little is known about the incidence and trends for this disease in the United States.*Methods.* Twenty-year data from the Surveillance, Epidemiology, and End Results (SEER) program were used for this study. SEER*Stat was used for data analysis. *Results.* Of the 95 797 cases of NHL diagnosed between 1988 and 2007 in nine SEER registries, 1835 (1.9%) were new cases of WM. Median age at diagnosis of WM was 73 years. The overall annual age-adjusted incidence was 0.38 per 100 000 persons per year, which increased with age, ranging from 0.03 in patients <50 years to 2.85 in patients ≥80 years. The incidence of WM was higher in men (0.54) than in women (0.27) (P < .001) and was higher in whites (0.41) than in African Americans (0.18) or other races (0.21) (P < .05). The annual percent change (APC) for the whole population was 1.01% (P > .05). The APC was 1.21% for whites (P < .05) and 0.80% (P > .05) for non-White. Significant APC increases were seen in the 70-79 age group (1.24%; P < .05) and in three geographic registries (P < .001). *Conclusions.* Although the overall incidence of WM remained steady over time, significant increases in incidence were seen over the past 20 years in whites, in those aged 70 to 79 years, and in three geographic registry areas.

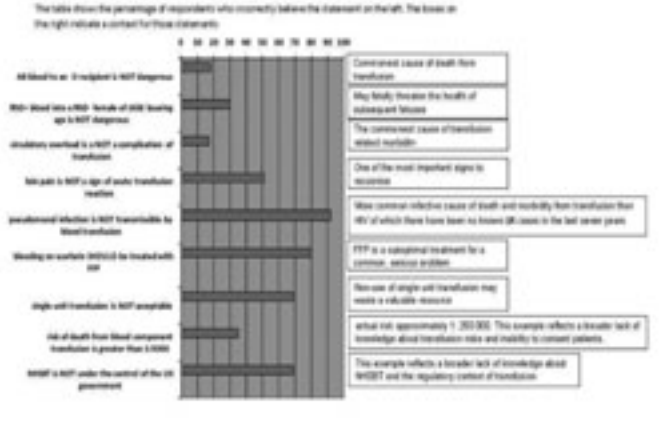
KNOWLEDGE DEFICITS IN BLOOD COMPONENT TRANSFUSION AMONG JUNIOR DOCTORS IN THE UNITED KINGDOM

T Todd,[1] M Besser,[2] E Gudgin,[2] A Godfrey,[2] D Veale,[1] N Grigoropoulos[2]

[1]*The Royal Devon and Exeter Hospital, Exeter, United Kingdom*
[2]*Addenbrooke's Hospital, Cambridge, United Kingdom*

Background. 2.9 million units of blood products are administered annually to approximately 400 000 patients in the UK, usually prescribed by junior doctors. Most adverse events reported are, at least partly, attributable to human error. However, blood transfusion occupies a very small part of the undergraduate curriculum and most postgraduate exams. No published data exists on the level of knowledge junior doctors have of blood product transfusion, its indications and risks. *Aims.* To determine knowledge among non-consultant grade doctors of the indications for, risks, compatibility, complications and broader context of blood component transfusion. *Methods.* A questionnaire distributed to non-consultant, non-haematology trainee, but otherwise unselected, hospital doctors at 6 hospitals, three with medical schools and three without, The questionnaire contained 14 multiple response questions covering 1. Respondent qualifications, grade and specialty 2. Indications for transfusion of platelets, FFP and Packed red cells 3. Nature and magnitude of risks associated with use of these products 4. The products themselves and issues of compatibility 5. Recognising complications of transfusion 6. National Health Service Blood and Transplant (NHSBT) and the regulatory context of blood transfusion. The responses were compared to pre-determined correct answers drawn from the annual UK Serious Hazards of Transfusion reports, official government statistics, UK transfusion guidelines, current legislation and information that could reasonably be expected to be taught to medical staff or be available in standard medical textbooks (especially ABO compatibilities). *Results.* 205 valid questionnaires were returned (approximately 40% response rate). No respondent correctly identified all the indications for transfusion of blood components. 6.5% would inappropriately use red cell transfusion to promote wound healing. 80% would use FFP to treat major haemorrhage due to warfarin, an inferior approach. 35% overestimated the risk of death from blood component transfusion by at least 50 times, 7% thought contracting HIV from blood component transfusion was as likely as dying in a car accident. 30% identified imaginary complications of transfusion, such as acute psychosis or transfusion associated acute liver disease (TaLiD), as real while 17% did not identify volume overload, the commonest cause of transfusion related morbidity, as real. 18% did not recognise the most frequently fatal ABO incompatibility of AB blood to an O recipient as dangerous while 30% did not identify RhD+ blood to an RhD- female recipient of child bearing age, which would risk haemolytic disease of the fetus or newborn in subsequent pregnancies, was dangerous. 69% believe the UK NHSBT is controlled directly from Europe. Figure 1 shows responses to some of the questions asked. *Conclusion.* Appropriate use, avoidance of waste, informed consent from patients and recognition of complications and risks are important aspects of blood transfusion yet it appears that the main prescribers of blood products in the UK have incomplete and sometimes poor understanding of these issues. These deficiencies need to be addressed urgently in undergraduate and postgraduate medical curricula and there should be greater oversight of junior doctor involvement in blood component use.

Table 1. Selected knowledge deficits amongst junior doctors.



0968

KINETICS OF CLOTTING FACTORS INACTIVATION DURING PASTEURIZATION AS APPLIED TO FLEBOGAMMA® AND FLEBOGAMMA® DIF MANUFACTURING PROCESSES

N Marzo

Instituto Grifols S.A., Parets del Vallès, Barcelona, Spain

Background. An increased rate of thromboembolic adverse events associated with the use of an IVIG from a specific manufacturer has been ascribed to increased residual FXIa, and possibly other impurities, in that product. Pasteurization is a process with demonstrated capacity to inactivate clotting enzymes during IVIG production (José *et al.* WebmedCentral Immunotherapy 2010;1(12):WMC001425. Available at: www.webmedcentral.com/wmcpdf/Article_WMC001425.pdf). *Aims.* In this work we describe the kinetics of Pasteurization-induced inactivation of procoagulant activity, in the conditions applied during the production Flebogamma® and Flebogamma® DIF, two pasteurized IVIGs from Grifols. *Methods.* Plasma fraction (Fr) II+III derived samples, containing artificially activated clotting factors, were spiked 1/5, 1/10, 1/20 (v/v) in samples taken from the IVIG manufacturing materials before acid pH treatment (4.5h, pH 4.0, 37°C) or before Pasteurization treatment (10h, 60°C) were applied to the mixtures. The following activation markers were studied: non-activated partial thromboplastin time (NaPTT) with platelet poor plasma (PPP, either neat or after dilution in the assay buffer) or with FXI deficient (FXIdef) plasma, PKA, "kallikrein-like" activities, thrombin generation (TGT) standard test or with FXIdef plasma, and FXI antigen (FXI:Ag, ELISA). The Pasteurization effect was also assessed at different time points (0, 0.5, 2, 3, 5 and 10 h) in 1/5 (v/v) spiked samples and in non-spiked controls as well as in equivalent samples spiked with 1 or 0.1 nM FXIa. *Results.* Samples of industrial materials before acid pH treatment or before Pasteurization spiked with artificially activated FrII+III derived samples showed positive results when assayed for coagulation markers in all tests performed (i.e., in the spike 1/5 samples values ranged 24-77 s for NaPTT-PPP neat, 43-155 s for NaPTT-PPP diluted, 53 - 114 IU/ml for PKA, 0.015-0.038 ∅ AU/min for "kallikrein-like", 89 s for standard TGT, 331-502 s for FXIdef plasma TGT). With the exception of PKA, which was significantly reduced to <2 IU/ml, levels of markers in all the spiked mixtures remained practically unchanged after acid pH treatment even at the lowest spike proportion (1/20), thus pointing out a very limited effect of this treatment on coagulation factor inactivation. In contrast, Pasteurization rendered the spiked mixtures negative for all assays even at the highest spike proportion (1/5). Moreover, after only 2 h of Pasteurization, activation markers were already negative for NaPTT -both tests-, TGT -both tests-, PKA and "kallikrein like"tests, while after 3 h Pasteurization thrombin generation showed a reduction of 80-90%, being undetectable after 5 hours. *Conclusion.* Even after only 2h of treatment, Pasteurization effectively inactivated relevant concentrations of procoagulant activities in artificially spiked FrII+III samples, higher than those found in the real Flebogamma® and Flebogamma® DIF production conditions. Acid pH treatment showed a very limited capacity to separate or inactivate these compounds.

0969

DOES FIBRINOGEN CONCENTRATE REDUCE BLOOD PRODUCTS USE IN MAJOR OBSTETRIC HAEMORRHAGE?

S Ahmed,[1] S Johnson,[1] S Mc Morrow,[2] J Fleming,[2] R Fanning,[2] C Flynn,[2] B Byrne[1]

[1]*RCSI/Coombe Women and Infants University Hospital, Dublin, Ireland*
[2]*CWIUH, Dublin, Ireland*

Background. In July 2009, the Irish Blood Transfusion Service (IBTS) replaced cryoprecipitate with fibrinogen concentrate with the aim of reducing the potential risk of pathogen transmission. Fibrinogen concentrate appears to have similar efficacy in treatment of major haemorrhage but there is limited data about its use in Major Obstetric Haemorrhage (MOH). *Aims.* The aim of this study was to assess the impact of this change on estimated blood loss (EBL) and blood product use in MOH. *Materials and Method.* Prospective detailed audit of MOH began at our institution in January 2009. Cases are defined by EBL of 2.5 litres, transfusion of 5 or more units of Red Cell Concentrate (RCC) or treatment of a coagulopathy. The EBL and the use of blood products were compared between those that sustained an MOH with associated hypofibrinogenemia before and after cryoprecipitate was replaced with fibrinogen concentrate. *Results.* 59 cases of MOH were identified in 2 years (3.3/1000 deliveries). 29 required treatment for hypofibrinogen-

emia; Cryoprecipitate (14) and Fibrinogen concentrate (15). The two groups were similar in age, parity, ethnicity and gestation at delivery. The main cause of bleeding was uterine atony followed by retained placental tissue. Medical and surgical management were similar among the two groups. Haemostasis was achieved in all cases. Minimum serum fibrinogen level recorded was 0.19g/l. The estimated blood loss was found to be higher in the cryoprecipitate group (mean+/-SD=5+/-4 versus 3.5+/-2.6). The use of red cells and octaplas were similarly higher in the cryoprecipitate group, however there was no difference in the use of platelets among the two groups. *Conclusion.* The replacement of cryoprecipitate with Fibrinogen concentrate in MOH was associated with a reduction in EBL and a reduction in use of RCC and Octaplas. These cases, however, were diverse and complex and fibrinogen replacement was only one factor in the overall management but replacement with a small volume bolus that can be administered rapidly without thawing may facilitate more rapid correction of coagulopathy and earlier haemostasis.

0970

EXPERIENCE IN THE MANAGEMENT OF LOOKBACKS IN A TERTIARY HOSPITAL TRANSFUSION SERVICE

I Gonzalez-Gascón y Marín,[1] A Perez-Corral,[1] J Anguita,[1] C Pascual,[1] A Richart,[2] A Rodriguez,[1] L Bento,[1] JL Diez-Martin[1]

[1]*Gregorio Marañon Hospital, Madrid, Spain*
[2]*Centro Regional de Transfusión, Madrid, Spain*

Background. Donor selection and the use of serological and nucleic acid testing in blood donations have greatly reduced the infectious window for several transfusion-transmitted pathogens; however, this window has not been totally eliminated. Lookback programs involve identification and notification of components collected from donors that are later found to be reactive in specific serological tests. This strategy is supposed to prevent progression of disease in a transfusion recipient who has unknowingly been infected, especially if the treatment provides a clear benefit to the patient (e.g. syphilis). Although mandatory under European law, the process is complex and laborious, and its real utility and cost-effectiveness remain doubtful. *Aims.* To analyze the impact of lookbacks on the transfusion service of a tertiary hospital. To report the effectiveness of the protocol and screening results. *Methods.* We reviewed lookbacks managed in 2009 and 2010 in the transfusion service of Hospital Gregorio Marañon (Madrid, Spain) which performs 36.645 transfusions annually. Lookbacks are reported from the regional transfusion centre to the transfusion service, which reviews all available records to identify the recipient. Once a recipient is identified, the hospital information system is searched to determine the recipient's last known status (living or dead). If the recipient is recorded as living we have 2 options: 1.Alert the patient's physician and request that the patient be notified and tested; 2. Notify the recipient directly. If the first strategy is not effective, we apply the second: Notify the recipient directly and if it is not possible, we send a letter to the recipient or to the patient's physician. The regional transfusion centre offers testing to all recipients. *Results.* The regional transfusion centre reported a total of 51 notifications distributed as shown in Table 1. A flow chart depicting the overall results of the lookbacks is presented in Figure1. We were able to ascertain test results for only 15 of 25 living recipients (60%) of which 13 were obtained by notifying the recipient directly (first or second strategy), and 2 by alerting the patient's physician. None of the recipients tested had a positive serology result. *Conclusion.* Our success ratio of 60% is reasonable and consistent with findings in the literature. Nevertheless, the low serological positivity (0%) and the effort involved calls into question the cost-effectiveness of this process. -In our experience, contacting the recipient directly was much more successful than alerting the patient's physician, although this could generate concern for the patient. These findings lead us to question whether it might be necessary to change our protocol in the future.

HAEMOVIGILANCE IN THE GLOBALISATION CONTEXT: THE ANDALUSIA EXPERIENCE. FOCUS ON TRALI

F López Jiménez,[1] R Ríos Tamayo,[1] A Rivera Ginés,[1] A García Ruiz,[1] S Oyonarte Gómez,[2] J Limón Mora,[3] M Jurado Chacón[1]

[1]*University Hospital "Virgen de las Nieves", Granada, Spain*
[2]*Regional Transfusion Centre, Granada, Spain*
[3]*Andalusian Regional Ministry of Health, Sevilla, Spain*

Background. Haemovigilance is a tool to improve the quality of the blood transfusion chain focusing on safety. Some common efforts have been made but the approach to haemovigilance is different in each country. *Aims.* Our purpose is to evaluate the development of our regional haemovigilance system, at an early stage, in the context of the national haemovigilance network, and to compare it with a well consolidated system as SHOT (Serious Hazards of Transfusion) in the UK (United Kingdom), with emphasis on TRALI. *Methods.* We performed a descriptive analysis of transfusion-related incidents reviewed between 2006-2009, in the Andalusian, Spanish, and English haemovigilance reports, considered as such adverse reactions (major and minor), transfusion errors and near miss events, regardless the degree of imputability. We focused on TRALI, because of its special importance as the current most common cause of transfusion-associated major morbidity and death. The data has been extracted from official sources, such as the Ministry of Health of Spain (http://www.msps.es/profesionales/saludPublica/medicina Transfusional / publicaciones/publicaciones.htm), the Regional Ministry of Health of Andalusia, and the SHOT report (http://www.shotuk.org/home/). *Results.* The main data from the haemovigilance systems through the study period are as follow: in Spain, the rate of reports has progressively risen from 1 per 1.562 transfusions to 1 per 909; in the UK, the increase was from 1 per 2.325 transfusions to 1 per 1.176. In Andalusia, from 1 per 1.000 transfusions to 1 per 602. In Granada, from 1 per 3.448 to 1 per 1.492. Reporting on TRALI has been greater in Spain (1 per 71.4289, on average) than in the UK (1 per 166.666), during the study period. There were no reported cases of TRALI in Andalusia until 2009 (1 per 90.909 transfusions). Granada reported no TRALI cases for the whole period. The results are shown in the table below. *Conclusions.*The transfusion activity

NBCI: Number of blood components issued
R/1.000:Reports/1.000 units

and the rate of reports during the 2006-2009 period have pointed to an increase in all haemovigilance systems analyzed, showing a growing awareness of the need to improve transfusion safety. Globally considered, the rate of reports in Spain and the UK are similar, highlighting a positive growth of the Spanish haemovigilance system. The number of reports on TRALI have grown in all systems, beeing higher in Spain which can be attributed to the different transfusion policies of both countries. Haemovigilance systems provide a mechanism for monitoring the transfusion activity that allow comparisons between countries and help to develop policies to make blood as safe as possible.

0972

ADVANCED RED BLOOD CELL INDICES AND IRON STATUS AS COMPLEMENTARY FACTORS IN THE MANAGEMENT OF REGULAR BLOOD DONORS

M Semmelrock,[1] R Raggam,[1] HJ Semmelrock,[1] F Prueller,[1] K Amrein,[1] G Lanzer,[1] E Rohde[2]

[1]*Medical University of Graz, Graz, Austria*
[2]*Paracelsus Medical University Salzburg, Salzburg, Austria*

Background/Aims. Frequent blood donations may lead to depletion of body iron stores resulting in development of anaemia. Currently, screening for iron deficiency (ID) is done by determination of haemoglobin concentration (Hb) prior to each donation. Hb measurement has limitations due to the late response in case of an iron deficient state. Several methods for early detection of iron deficiency are available but lack practicability. We therefore evaluated the association of iron status with advanced red blood cell (RBC) indices in regular whole blood donors. *Methods.* In a prospective study, the iron status including serum ferritin and soluble transferrin receptor (sTfR) was tested in 1308 healthy blood donors after written informed consent. The ferritin index is representing the most relevant marker for ID and was calculated as the ratio of sTfR to the logarithm of ferritin. Full RBC count including percentage of hypochromic mature erythrocytes (%HYPOm) and reticulocyte haemoglobin content (CHr) was determined on the automated haematology system Advia 2120i (Siemens Healthcare Diagnostics). Gender matched study populations were assessed for signs of ID and impaired haemoglobinisation. The areas under the receiver operating characteristic (ROC) curves were calculated using CHr and %HYPOm to assess their practicability in ID diagnosis. *Results.* Cut-off values to detect an ID were generated by evaluating the 97.5th percentile of the ferritin index obtained in controls (male (m): 0.960, female (f): 1.621 donors). Considering these cut-offs, the highest percentage of ID (54.5%) was obtained in male donors with the highest allowed donation frequency (6 times per year). Interestingly female donors displayed the highest rate of ID already after three donations per year (24.7%), and ID rate was not higher after further donations. Among these iron deficient donors reduced levels of CHr and increased rates of %HYPOm were observed. Using CHr as a marker for ID, areas under the ROC curves were 0.790 (m) and 0.907 (f). When %HYPOm was used, areas under the ROC curves were 0.808 (m) and 0.922 (f). *Conclusion.* A strong correlation between iron status and RBC indices was not found. However, measurement of RBC indices allows for an early estimation of impairment in red blood cell haemoglobinisation, especially while donors may show normal haemoglobin values in absence of clinical signs and symptoms for ID. Additional testing of CHr and %HYPOm is feasible for routine screening of regular whole blood donors to better prevent the development of ID based anaemia at a very early stage.

0973

NON-ABO RED BLOOD CELL ALLOANTIBODIES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

N Cantoni, M Stern, J Sigle, L Infanti, J Halter, J Passweg, A Gratwohl, A Buser

University Hospital Basel, Basel, Switzerland

Background. The appearance of alloimmune hemolytic anemia (AHA) due to anti-A and anti-B antibodies in patients undergoing a major or minor ABO-incompatible allogeneic HSCT is one of the most common and dangerous immunohematological complication. Less frequently, other red blood cell (RBC) antigen systems have been implicated in the development of AHA. Although the hemolytic complications following ABO-incompatible allogeneic HSCT have been investigated by several authors, the development of alloantibodies against RBC antigens other than ABO has been less well investigated. *Aims.* We were

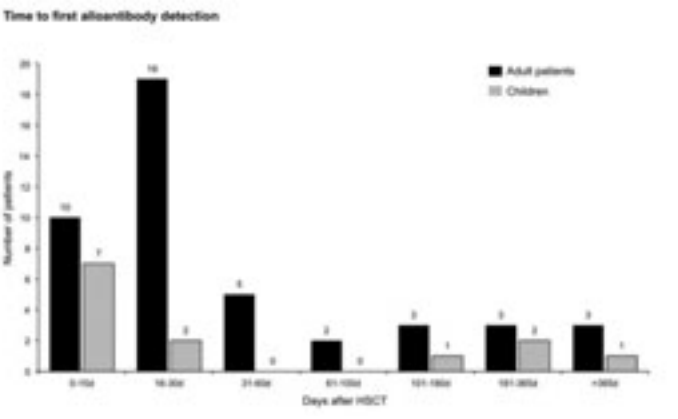

Figure 1. Time to first alloantibody detection.

therefore interested to examine in a single center study the presence of non-ABO RBC alloantibodies in patients treated with allogeneic HSCT between 1996 and 2009. *Methods.* This retrospective cohort study is based on standardized, prospectively collected clinical data from the stem cell transplant unit of the University Hospital Basel, Switzerland, and serological tests from the database of the Blood Bank Basel, Switzerland. Between January 1996 and September 2009, 514 adult patients and 73 children received 604 respectively 85 HSCT. *Results.* In the first two years after allogeneic HSCT the cumulative incidence for the development of non-ABO RBC alloantibodies was 7.27% (95% CI 7.25-7.29%) in adult patients respectively 14.15% (95% CI 13.87-14.43) in children. The most common detected alloantibodies were Anti-E and Anti-Lua. In all the patients in whom antibody specificity was identified, the antibody was directed against RBC antigens absent in donor or recipient's RBCs. However in 43 (74% of the patients with alloantibodies) respectively 11 (19%) patients the alloantibody was directed against an antigen present in the transfused RBC units respectively platelet (PLT) units. In the remaining 7% of the patients the causes of alloimmunization remain unclear. The mean time between transplant and antibody detection was 18 days (range 1-2239 days), and the most alloantibodies were detected in the first 30 days after allogeneic HSCT (s. Figure 1). In the univariate analysis, GvHD prophylaxis, conditioning regimen, and number of transfused RBC units were associated with a higher risk of development of alloantibodies. After stepwise introduction in the multivariate model, the number of RBC units remained the only variable that significantly influenced the formation of non-ABO RBC alloantibodies. In fourteen patients (24% of the patients with alloantibodies) there was evidence of hemolysis after antibody detection; two of these patients developed a documented severe immune hemolytic anemia in the early post transplant period and died. *Conclusions.* To the best of our knowledge this is the largest cohort study describing the development of non-ABO RBC antibodies after allogeneic HSCT. In our analyze, the cumulative incidence of alloantibodies formation was with 7% in adult patients and 14% in children higher in comparison with those reported by other authors. The only risk factor for developing non-ABO RBC antibodies was the amount of transfused RBC units. Virtually all the antibodies resulted following blood products (RBC and PLT) positive for the respective antigen; no antibodies emerged in an antigen-mismatched situation between donor and recipient. However, the most common alloantibodies detected, Anti-E and Anti-Lua, are potentially naturally occurring antibodies, not necessarily due to transfusion.

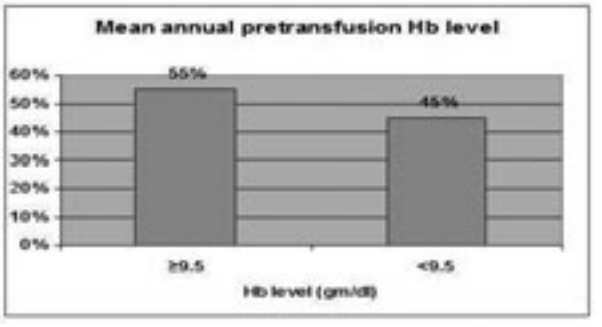
0974

AUDIT OF MEAN ANNUAL PRE-TRANSFUSION HB LEVEL OF PATIENTS WITH B THALASSEMIA MAJOR AT THALASSEMIA CENTRE

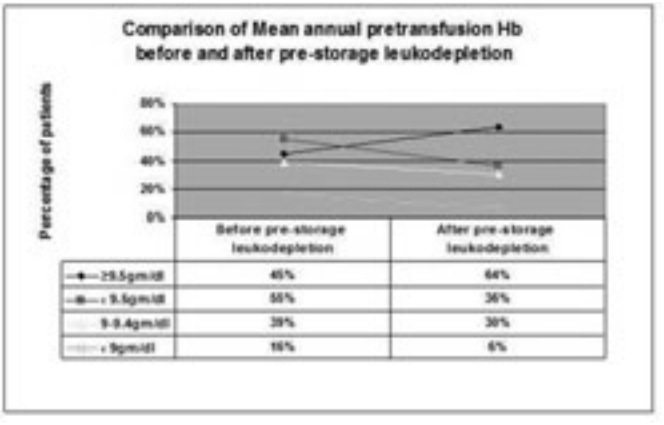
K Belhoul,[1] M Bakir,[2] M Eldin[1]

[1]*Dubai Health Authority, Dubai, United Arab Emirates*
[2]*Thalassemia Center, Dubai, United Arab Emirates*

Background. Thalassemia center transfusion guidelines assess the efficiency of the blood transfusion program implemented at the centre through maintaining the mean annual pre-transfusion Hb ≥9.5gm/dl. This is essential in the management of B Thalassemia major patients to improve wellbeing and overall outcome. In April 2009, pre-storage leukocyte depleted packed RBCs were introduced while bedside blood



Graphs 1.



Graphs 2.

filters were used previously. *Aims.* To evaluate the mean annual pre-transfusion Hb level of patients with B Thalassemia major transfused at the center and the impact of pre-storage leukocyte depleted blood on the mean annual pre-transfusion Hb. *Methods.* This was a retrospective audit where pre-transfusion Hb was obtained form Oct-2008 till end of Sep 2009 by reviewing patients' files. Random sample of 100 B Thalassemia major patients on regular blood transfusion every 3-4 weeks at thalassemia centre were selected. Patients with increased risk of further Hb drop other than the original disease were excluded. *Results.* 55% of patients had mean annual pre-transfusion Hb levels of ≥9.5gm/dl (graph 1). Analyzing the remaining 45%, 80% (36patients) of them had mean annual pre-transfusion Hb level between 9-9.4 gm/dl and 20% (9 patients) < 9gm/dl. Further analyses to correlate patients' age with the mean annual pre-transfusion Hb level revealed that 72% of adults had their mean annual pre transfusion Hb levels ≥9.5gm/dl compared to 30% of pediatrics counterpart. Studying the overall effect of pre-storage leukodepleted blood introduction revealed that the mean Hb level of all patients was significantly higher after introducing pre-storage leukodepletion (P<0.0001), (graph 2). *Conclusions.* The mean annual pre-transfusion Hb level of patients with B-Tthalassemia major at Thalassemia Centre still is not meeting the standard as only 55% had Hb level > 9.5 gm/dl, although the majority of patients maintained their Hb level > 9gm/dl. Surprisingly this failure to achieve the target was mainly observed in the pediatrics population. This could be attributed to children being under transfused to avoid blood wastage. Pediatric blood units that would allow the transfusion of the full calculated amount with minimal waste were not available so this audit has exposed the importance of provision of these bags to meet the guidelines. Positive impact of pre-storage leukodepletion on the mean annual pre-transfusion Hb was an interesting outcome that needs to be studied further.

0975

A NOVEL RHD VARIANT WITH RHD G339V

CW Park, EJ Oh, YG Kim, KJ Han, JY Yang

Seoul St. Mary's Hospital, Seoul, South-Korea

Background. Due to the strong immunogenicity of D antigen, about 80% of RhD-negative patients are at risk for anti-D alloimmunization when exposed to RhD-positive erythrocytes. Therefore, the accurate determination of the RhD type is of clinical significance. *Aims.* We experienced a novel RhD variant by RhD typing using the serologic and molecular methods. *Methods.* The patient was a 41-year old male on the waiting list for liver transplantation. The ABO and RhD blood typing with anti-D reagent (Millipore Ltd, UK) were performed. By using gel cards (Bioclone, Ortho-Clinical diagnostics, US), the Rh subgrouping was done. Direct anti-globulin test and antibody screening test (DiaMed AG, Switzerland) for unexpected blood group antibodies were also performed. Serologic test for partial D was accomplished with ID-Partial D Typing cards and Extended Partial D Typing cards (DiaMed AG). The RhD zygosity type by sequence-specific priming polymerase chain reaction (SSP-PCR, BAG Healthcare GmbH, Germany) and molecular determination of partial D type test (BAG Healthcare GmbH) were accomplished. In addition, direct DNA sequencing (Bristol institute, UK) of all 10 exons of RHD gene was done. *Results.* The blood was typed as A and considered D-negative by RhD typing. The erythrocytes revealed positive reaction to indirect antiglobulin test for the presence of weak D. In the Rh subgrouping, the phenotype was D/C/E/c/e (-/+/-/+/+). It showed negative reaction to direct Coomb's test and to antibody screening test for unexpected blood group antibodies. By using ID-Partial D Typing cards and Extended Partial D Typing cards, DFR type was suspected but didn't completely agree with that type. RHD positive/RHD negative (Dd) was determined by SSP-PCR. In molecular determination of partial D test, it revealed standard RHD. In direct DNA sequencing of RHD gene, a novel RHD allele was identified. It had a single nucleotide substitution of G to T at 1016 in exon 7, resulting in glycine-to-valine amino acid substitution at amino acid residue 339 (p.G339V). *Conclusions.* Thus, c.1016G>T(p.G339V) mutation found in this patient is identified as a novel partial D variant.

0976

HEPARIN INDUCED THROMBOCYTOPENIA: MEASURES TO IMPROVE PRE-TEST PROBABILITY SCORING, APPROPRIATE REQUESTING AND EFFICIENCY OF LABORATORY TESTING

S Bhartia, U Paulus, J Tomkins

SNBTS, Glasgow, United Kingdom

Background. Heparin Induced thrombocytopenia (HIT), an immune mediated thrombocytopenia paradoxically associated with thrombosis, is caused by development of IgG antibodies against platelet factor4 (PF4)-heparin complex. Combination of well defined pre-test probability scores and interpretation of laboratory HIT assays determines the overall probability of HIT. The BCSH HIT guideline recommends use of the 4T's score which relies on adequate clinical information. Our centre provides testing service for entire West of Scotland. We introduced a new HIT assay request form in order to obtain accurate clinical information, improve accuracy of 4Ts scores, assess appropriateness of requests, and provide guidance for requesting clinicians. *Aim.* To compare the quality of clinical information provided and appropriateness of requests for HIT assays since introduction of new request form. *Method and Results.* We split data from 1st October 2010- 21st Feb 2011 in 2 phases. As of 16th January 2011 we asked requesters to use the new forms which explicitly required information on indication, type and route of administration of heparin, platelet count kinetics and documented scoring for each of the 4T categories discouraging testing in low-probability cases. 84 samples (51 phase 1 and 33 phase 2) were analysed during that time period using the PF4 enhanced ELISA kit which identifies IgG, IgA and IgM antibodies. Overall 28 samples (33%) tested positive using an optical density (OD) cut-off value of 0.40. The median OD was 0.62(0.42-3.5). Indication for heparin was given in 65% of patients during phase 1, increasing to 76% in phase 2. 51% of requests had HIT scores provided in phase 1, increasing to 73% in phase 2. Likewise requests for low pre-test probability scores (0-3) reduced from 6 to 2. Interestingly requests with scores >3 increased from 37% (19/51) to 66% (22/33) in phase 2, with positive results unexpectedly dropping from 48% to 28% respectively. We were able to review clinical information provided and rescore ourselves 19 of 33 phase 2 requests: 63% (12/19) scores led to a change with 9 downgraded (4/9 from intermediate to low probability and all had correspondingly negative test results). 3 were upgraded (1/3 changed from intermediate to high probability). *Conclusion.* Our audit highlights that introduction of the new forms improved the quality of clinical information provided. However, the scoring was inaccurate in a significant number of phase 2 requests

with a tendency towards higher pre test probability, but drop in percentage of positive results which raises the possibility of scores being skewed towards higher probability. We aim to overcome this by screening all requests and communicating with requesting team. Given the high percentage of negative results we aim to introduce a sensitive rapid gel agglutination card technique as a screening method subsequently confirming positive results with an IgG specific ELISA including confirmation with heparin inhibition. Given the current workload we hypothesize that further improved communication we will reduce the number of inappropriate requests and introduction of rapid screening will significantly reduce staff time and cost. We aim to re-audit once the above are implemented.

COMPARISON OF *IN VITRO* EFFECTS OBTAINED BY COLLAGEN STIMULATION OF FRESH WHOLE BLOOD AND RECONSTITUTED WHOLE BLOOD

I Nepstad, H Reikvam, T Hervig

Haukeland University Hospital, Bergen, Norway

Background. The use of whole blood (WB) has nearly completely been replaced by blood component therapy in transfusion medicine. However, in situations where blood components are not available or affordable, i.e. military condition or major catastrophes, enlarged documentation of the quality of fresh WB is warranted. Also, there is an increasing debate regarding the storage lesion of blood component, e.g. reduced quality of both stored red blood cell (RBC) concentrates and platelets. Even regarding fresh frozen plasma, there is an issue because the thawing time may be critical in massive bleedings - and the concept of pre-thawed plasma has been introduced, although debated. *Aims.* Based on these considerations we performed a study to compare; (i) *in vitro* responses to collagen stimulation in fresh WB, with (ii) responses obtained by stimulation of reconstituted WB of different compositions. Furthermore, we investigated potential varying in responses between age of RBC and the platelets in the units. *Methods.* Nine groups of reconstituted WB with different compositions of platelets, RBCs, and plasma were compared (Table). Platelets stored for 1, 3, and 5 days were combined with RBC stored for 0-4 days, 12-16 days, and 26-35 days. Platelet concentrations for all samples were determined by the impedance method. Platelet aggregation was expressed as percentage of single platelet disappearance (SPD). Thrombelastography (TEG) was performed on fresh WB samples and reconstituted WB samples, and the effects of storage time on fresh WB were tested to preclude this as a source of error. *In vitro* thrombin generation was estimated by thrombin-antithrombin (TAT), quantified by standard enzyme-linked immunosorbent assay (ELISA). *Results.* A significant decrease (P<0.001) in SPD between unstimulated samples and samples stimulated with collagen was seen in all groups, with exception of E, F and I. SPD was found to be lowest in WB and the groups containing the oldest RBC- and platelet concentrates. Regarding the stimulated samples, significant differences were found between WB vs. group A and B, in addition to group A vs. E, F, and I, and group B vs. F and I. Results from TAT complexes showed that thrombin generation decreased according to storage time in stimulated reconstituted WB samples, corresponding to the results obtained from the SPD. TAT complexes were significantly lower in fresh WB as compared to group A and B after collagen stimulation. None of the groups show significant deviations from standard TEG parameters. *Conclusion.* The results show that storage time of both RBCs and platelets may influence the effects of blood component therapy. Results indicate that the use of WB over reconstituted WB will result in decreased SPD. Further studies to clarify the clinical relevance of these effects are warranted.

Table 1. The composition of the groups - with SPD.

	Platelets	Red Blood Cells	Plasma	% Single Platelet Disappearance: Addition of 5 µl collagen	Addition of 10 µl collagen	Addition of 20 µl collagen
Group A	1 day	0 - 4 days	Fresh	71.3	75.7	81.3
Group B	1 day	12 - 16 days	Fresh	54.2	68.8	75.6
Group C	1 day	26 - 35 days	Fresh	39.4	56.9	77.9
Group D	3 days	0 - 4 days	Fresh	48.0	52.5	61.5
Group E	3 days	12 - 16 days	Fresh	32.4	37.9	59.7
Group F	3 days	26 - 35 days	Fresh	29.4	35.1	56.4
Group G	5 days	0 - 4 days	Fresh	45.3	48.4	70.1
Group H	5 days	12 - 16 days	Fresh	52.8	63.0	69.6
Group I	5 days	26 - 35 days	Fresh	24.1	31.5	40.9

FREQUENT USE OF BLOOD TRANSFUSIONS IN CURRENT TREATMENT PRACTICE FOR CHEMOTHERAPY-INDUCED ANEMIA COUNTERACTS TREATMENT RECOMMENDATIONS AIMING FOR LESS TRANSFUSIONS

H Ludwig,[1] M Aapro,[2] Y Beguin,[3] C Bokemeyer,[4] J Glaspy,[5] M Hedenus,[6] T Littlewood,[7] A Österborg,[8] B Rzychon,[9] D Mitchell[9]

[1]*Wilhelminenspital, Vienna, Austria*
[2]*IMO Clinique de Genolier, Genolier, Austria*
[3]*University Hospital Liège, Liège, Belgium*
[4]*University of Hamburg, Hamburg, Germany*
[5]*UCLA School of Medicine, Los Angeles, United States of America*
[6]*Sundsvall Hospital, Sundsvall, Sweden*
[7]*John Radcliffe Hospital, Oxford, United Kingdom*
[8]*Karolinska Institutet and Karolinska Hospital, Stockholm, Sweden*
[9]*Vifor Pharma, Glattbrugg, Switzerland*

Background. Patients with cancer frequently experience chemotherapy-induced anaemia (CIA) and iron deficiency (ID). Clinical evidence suggests intravenous (I.V.) iron supplementation of erythropoiesis-stimulating agents (ESAs) as effective treatment for CIA. However, an analysis of patient records across Europe revealed that markers of ID are underused in CIA patients (e.g. transferrin saturation tested in only 12%) and only a minority receives I.V. iron whereas the majority of patients receive ESAs and blood transfusions as part of their treatment. *Aim.* This analysis aimed to quantify the role of blood transfusions and explore reasons for their regular use in current treatment practice. *Methods.* Eligible onco-hematologists were recruited at random and completed records on their last five patients treated for CIA in two waves: Wave one (France, Germany, Spain, Switzerland, UK; Jun-Oct 2009), Wave two (Austria, Italy, Netherlands, Sweden; Aug-Nov 2010). Overall results are presented as median between and [range] across countries and detailed results of wave two countries as % of all cases and [range] across countries. *Results.* 375 physicians recorded 1730 cases of CIA, 58% [38-77%] in patients with solid tumors of whom 52% [30-60%] had metastatic disease. At diagnosis of anemia, 14% [8-25%] of patients presented with severe anemia (Hb <8 g/dL) and 20% [8-41%] of ferritin-tested patients with absolute ID (ferritin <30 µg/L). 52% [11-93%] received a transfusion at some stage and 73% [15-100%] received an ESA. Iron was given to 22% [11-61%] and thereof only 19% [4-77%] received I.V. iron. Of all patients receiving transfusions, 60% [11-100%] received a combination with ESA and 27% [7-51%] with iron. Detailed questions regarding the use of blood transfusions by physicians participating in Wave two (131 physicians, 651 cases) show that blood transfusions were given as regular treatment in 76% [48-85%] of cases and except for Italy (44%) only rarely as emergency treatment (11-13%; 15% of all cases). In 45% [26-53%], blood transfusions were given at least once every three months and in 3% [0-7%] even weekly or more often. Over a 12-month period prior to the survey, transfused patients received 5 units [2-6 units] blood concentrates. Among the options in the questionnaire, 'easily available' (47% [15-68%]) and 'uncomplicated use' (34% [0-52%]) were most commonly selected as reasons for administration of blood transfusions. Further reasons were that anemia was not controlled by ESAs alone (29% [14-69%]) or by the given iron treatment (24% [0-39%]). In 82% [77-84%] of these iron-treated patients, oral iron was administered at high total doses of 16.6g [10.6-32.8g] given over 12 weeks [9-20 weeks]. *Conclusions.* More than half (52%) of the patients treated for CIA received blood transfusions while ESAs were given to 73% and iron (mostly oral) to only 22% of patients. Frequently, transfusions were given on a regular basis and not only as a rescue therapy reflecting the suboptimal results obtained with ESAs alone or in combination with oral iron. As I.V. iron supplementation of ESAs improves hematologic response, awareness of this option should be increased in order to minimize the use of red blood cell transfusions.

Background. Atypical hemolytic uremic syndrome (aHUS) is a rare, life-threatening disease, characterized by systemic thrombotic microangiopathy (TMA), which is caused by chronic uncontrolled terminal complement activation. Systemic TMA presents as endothelial damage, hemolytic anemia and platelet consumption and leads to progressive renal disease, multi-organ damage and, ultimately death. Importantly, many patients with aHUS receive chronic plasma exchange/infusion, but despite this, still continue to have persistent TMA and poor clinical outcomes, and up to 60% of patients develop end-stage renal disease or die within 1 year of diagnosis. *Aims.* In a phase II trial, we evaluated the efficacy and safety of eculizumab, a terminal complement inhibitor, in plasma exchange/infusion-resistant aHUS patients. *Methods.* This is a 26-week, controlled, open-label, single-arm trial. Patients were enrolled who were ≥12 years and had plasma exchange/infusion-resistant aHUS (persistent TMA despite ≥4 plasma exchange/infusion sessions 1 week before screening). The eculizumab intravenous dosing schedule was 900mg/week for 4 weeks, 1200mg at week 5, then 1200mg q2 weeks. All patients received a meningococcal vaccine. The primary endpoint was the change in platelet count (a measure of TMA) over 26 weeks. Secondary endpoints included TMA event-free status (≥12 weeks of stable platelet count, no plasma exchange/infusion and no new dialysis), TMA intervention rate (number of plasma and new dialysis events/patient/day), renal function, pharmacokinetics/pharmacodynamics (PK/PD), health-related quality of life ([HRQoL] measured by ED-5D) and safety. *Results.* A total of 17 patients were enrolled; 15 received eculizumab for the entire 26-week period. Median age was 28 years (range 17-68 years), 29% were males, 76% had an identified complement regulatory factor mutation, 41% had a kidney transplant, and 29% were on dialysis immediately prior to eculizumab. Following eculizumab treatment, platelet count increased from baseline to week 26 by a point estimate 73x109/L (95%CI: 40-105x109/L) (primary endpoint; p=0.0001). The increase in platelet count was seen as early as Day 7 and maintained throughout the study. Platelet count was normalized in 13/15 patients (87%) who had abnormal platelets at baseline. A total of 15 patients (88%; 95% CI 64%-100%) became TMA event-free and median TMA intervention rate decreased from 0.88 to 0 events/patient/day (p<0.0001). Ten patients (59%) had a sustained improvement in chronic kidney disease by ≥1 stage. Importantly, 4 of 5 patients became dialysis-free. For all endpoints, eculizumab was efficacious in patients regardless of the presence of identified complement regulatory factor mutations. PK/PD blood sampling confirmed that eculizumab provided complete and sustained inhibition of terminal complement activation and validated the selection of the dosage. The improvement in HRQoL using EQ-5D scores was highly statistically significant; mean change from baseline to week 26 was 0.33±0.09 (p<0.0001). The most frequently reported adverse events were headache, anemia and diarrhea (all mild-moderate in severity). *Conclusions.* In summary, the primary and secondary endpoints were achieved with high clinical and statistical significance. Eculizumab prevented TMA, restored renal function, removed the need for plasma exchange/infusion and improved HRQoL. Eculizumab was also well tolerated.

[11]*The Hospital for Sick Children, Toronto, ON, Canada*

Background. Atypical hemolytic uremic syndrome (aHUS) is a rare, life-threatening disease that can occur in adults and children of any age. In aHUS, chronic uncontrolled terminal complement activation causes systemic thrombotic microangiopathy (TMA). Systemic TMA, through haemolytic anemia and platelet consumption, leads to progressive kidney destruction as well as cerebral and cardiac damage. Many aHUS patients receive chronic plasma exchange/infusion, but despite this, patients still have uncontrolled terminal complement activation, which means the TMA remains so within 1 year of diagnosis most aHUS patients (up to 60%) present with end-stage renal disease or die. *Aims.* In a phase II trial, we evaluated the efficacy and safety of eculizumab, a terminal complement inhibitor, in aHUS patients receiving chronic plasma exchange/infusion. *Methods.* In this 26-week, controlled, open-label, single-arm trial, patients enrolled were ≥12 years and receiving plasma exchange/infusion for aHUS. After an 8-week observation period, during which the platelet count and plasma intervention frequency were stable, patients discontinued plasma exchange/infusion and started eculizumab dosed at 900mg/week for 4 weeks, 1200mg at week 5, then 1200mg q2 weeks). Patients also received a meningococcal vaccine. The primary endpoint was TMA event-free status defined as ≥12 consecutive wks of stable platelet count, no plasma exchange/infusion and no new dialysis. Secondary endpoints included TMA intervention rate (no. of plasma and new dialysis events/patient/day), renal function, pharmacokinetics and pharmacodynamics (PK/PD) and safety. *Results.* In this interim analysis, 20 patients received eculizumab; 15 had ≥12 weeks of follow-up. Median age was 28 years (range: 13-63 years), 70% had an identified complement protein mutation(s), 40% had a prior kidney transplant, 55% had eGFR levels <30 ml/min/1.73 m2, 10% were on dialysis, and 45% were receiving 2-3 plasma exchange/infusion sessions/week at baseline. The primary endpoint was highly statistically significant with 87% of patients (13/15; 95% CI 60%-98%) becoming TMA event-free following eculizumab treatment. Median TMA intervention rate decreased from 0.16 to 0 events/patient/day (p<0.0001, sign-rank test). eGFR stabilized or increased with eculizumab vs. chronic plasma exchange/infusion, which was given during the observation period (median 31 vs. 27 ml/min/1.73 m2). Eculizumab was similarly effective in patients with/without an identified complement regulatory factor mutation. PK/PD blood sampling confirmed that eculizumab provided sustained terminal complement blockade and validated the selection of the dosage. Eculizumab was well tolerated. The most frequently reported adverse events were diarrhea, headache, hypertension and nausea (mild-moderate in severity). *Conclusions.* In this interim analysis, treatment with eculizumab sustained suppression of TMA, led to permanent discontinuation of chronic plasma exchange/infusion, stabilized or improved renal function, and was well tolerated.

ECLIPSE: A FRENCH STUDY CONCERNING THE DIAGNOSIS OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH)

P Rodriguez-Otero,[1] A Petropoulou,[1] T Lamy,[2] M Michallet,[3] Z Amoura,[4] R Peffault de Latour,[1] G Socié[1]

[1]*Hopital Saint Louis, Paris, France*
[2]*Hopital Pontchaillou, Centre Hospitaliere Universitaire Rennes, Rennes, France*
[3]*Hôpital Edouard Herriot, Lyon, France*
[4]*Internal Medicine, Pitie Salpetriere Hospital, Paris, France*

Aim. PNH is a rare life-threatening disease with prevalence between 7.3 and 15.9 cases/million. Diagnosis is difficult and often delayed because of clinical polymorphisms. ECLIPSE is a French study aimed to evaluate the delay between the onset of PNH symptoms and diagnosis, to identify the clinical signs leading to diagnosis and to determine which medical specialists are seen first by PNH patients. *Patients and Methods.* 4920 physicians were asked to participate: 992 hematologists, 1638 internists, 1155 gastroenterologists, 697 nephrologists, 438 neurovascular physicians. Physicians were divided into 3 groups: (A) having diagnosed PNH at least once, (B) having suspected a PNH without having confirmed the diagnosis, (C) neither having suspected nor diagnosed PNH. *Results.* 528 physicians accepted to participate in the study (overall response rate: 10.7%). 507 answers were analyzed. Among the 507 physicians, 108 (21 %) belonged to group A, 213 (42 %) to group B, and 186 (37 %, CI95% [32.49 % - 41.05 %]) to group C. In group A, clinical signs and symptoms leading to diagnosis were: pancytopenia (44%), anemia (37%), haemolysis (23%), peripheral venous thrombosis (18%), hepatic vein thrombosis (14%) and hemoglobinuria (14%). Clinical situations raising the suspicion for diagnosis within group A physicians were: unexplained thrombosis (86%), hemoglobinuria (84%), aplastic anemia (83%), Coombs negative anemia (80%), cytopenias (71%). Physicians were also asked to describe the circumstances of their latest PNH diagnosis. The patient was referred to the physician by the Emergencies (23%), a haematologist (22%) or internist (21%). Most frequent functional symptoms were: fatigue (39%), anemia (24%), abdominal pain (20%) and thrombosis (14%). 7% of patients were asymptomatic. PNH diagnosis was confirmed in a mean time of 9.32±11.46 months after the onset of symptoms, and a maximum delay between first symptoms and diagnosis being 60 months. Biological signs raising the suspicion for a PNH were: anemia (80%), increased LDH (60%), increased biluribin (44%), thrombocytopenia (41%) and/or neutropenia (28%). Confirmation of PNH diagnosis was made by flow cytometry in 87% of the cases. Among the 213 physicians belonging to group B, 50% had suspected at least 5 times PNH without confirmation. Clinical and biological signs prompting group B physician to suspect PNH were: Coombs negative anemia (48%), pancytopenia (42%) and/or aplastic anemia (38.5%), myelodysplastic syndrome (18%), hemoglobinuria (15.5%), increased LDH associated with venous or arterial thrombosis (15%), abdominal pain (14%), dark urine (12%) or jaundice (11%). 186 physicians belonged to group C. 6.5% of physicians had never heard about PNH. *Conclusions.* PNH was mainly diagnosed by hematologists. Frequent symptoms leading to diagnosis were unexplained thrombosis, hemoglobinuria, Coombs negative anemia, aplastic anemia, cytopenias and myelodysplastic syndrome. Flow cytometry, the gold standard for PNH testing, was only used in 87% of cases. Diagnosis was usually delayed with a maximum of 5 years between onset of symptoms and diagnosis. Fatigue and abdominal pain were commonly reported and should therefore be more routinely assessed.

0982

HIGH PREVALENCE OF IRON DEFICIENCY ACROSS DIFFERENT TUMORS CORRELATES WITH ANEMIA, INCREASES DURING CANCER TREATMENT AND IS ASSOCIATED WITH POOR PERFORMANCE STATUS

H Ludwig,[1] E Müldür,[1] G Endler,[1] W Hübl,[1] P Moneuse,[2] B Klement[2]

[1]*Wilhelminenspital, Vienna, Austria*
[2]*Vifor Pharma, Glattbrugg, Switzerland*

Background. Iron deficiency (ID) with or without anemia affects physical function and quality of life. In patients with cancer or chronic inflammatory diseases, impaired iron utilization can limit effective erythropoiesis. Presently, only limited data on iron status and its relation to hemoglobin levels, clinical status and applied cancer treatment are available. *Aim.* This analysis aimed to assess the prevalence of ID and its relation to hemoglobin levels, performance status, cancer type, and disease and treatment status in a large cohort of unselected cancer patients with different cancer types. *Patients and Methods.* 1528 cancer patients that presented consecutively from October 2009 to January 2010 at our center were evaluated for ECOG performance status, cancer type, stage at initial cancer diagnosis, status of disease at evaluation (CR/no evidence, persistent, or progressive disease) and for time of last treatment. Further, iron parameters and hemoglobin levels were assessed. The following definitions were applied: anemia (hemoglobin, Hb ≤12 g/dL), ID (transferrin saturation, TSAT <20%), absolute ID (AID, serum ferritin <30 ng/mL or TSAT <10% if ferritin was not available) and functional ID (FID, ferritin ≥30 ng/mL or TSAT >10%). *Results.* 1053 patients presented with solid tumors and thereof 48.2% had metastatic disease. Anemia and ID were most prevalent in pancreatic cancer (≥50%; Table). Anemia was more prevalent in patients with stage IV (42.2%) compared to those with stage I/II or stage III disease (23.8%). The prevalence of FID increased with stage (29.1%, 35.3% and 45.6% in stage I/II, stage III and stage IV respectively) whereas AID was comparable across stages (6.7%, 10.0%, 7.7%, respectively). The prevalence of anemia and FID correlated with worse ECOG performance status (ECOG 0-1: 29.3% anemic, 36.1% FID; ECOG 2-4: 61.1% anemic, 52.8% FID). A concomitantly higher prevalence of anemia and FID was also observed in patients receiving anticancer treatment within 12 weeks prior to evaluation compared to patients without therapy (anemia 48.6 vs. 32.4%; FID 42.3 vs. 38.4%). Among patients who have received treatment more than 13 weeks prior to evaluation, anemia, FID and AID were less prevalent (17.1 %, 33.9%, 3.8%, respectively). Persistent and progressive disease at time of evaluation was associated with high rates of anemia and ID (47.1% and 56.8%, respectively). Notably, although 77.8% of patients in complete remission achieved normal Hb levels, 36.4% remained iron deficient. *Conclusion.* This analysis shows a high prevalence of iron deficiency, in particular functional iron deficiency, across different tumor types. The prevalence of ID correlates with the prevalence of anemia and progression of the disease. ID is also associated with worse performance status. In patients receiving anticancer treatment, the higher prevalence of anemia is paralleled by a higher prevalence of ID.

Table 1. Prevalence of ID across different tumor types.

	% ID	% AID	% FID	% Anemic
Pancreatic cancer	63,1	10,5	52,6	50,0
Colorectal cancer	51,9	11,5	40,4	35,0
Lung cancer	51,3	9,2	42,1	43,4
GI/Esophageal cancer	49,0	7,8	41,2	49,0
Genitourinary cancer	43,9	1,5	42,4	31,8
Breast cancer	39,6	6,0	33,6	27,5
Gynecological cancer	34,5	6,9	27,6	41,4
Testicular cancer	19,4	0,0	19,4	3,2
Other	41,8	4,1	34,7	23,5

ID iron deficient, AID absolute ID, FID functional ID, GI Gastrointestinal

[9]*Praxis für interdisziplinäre Onkologie und Hämatologie, Freiburg, Germany*

Background. Anemia and iron deficiency are frequent complications in cancer patients. Intravenous iron as a supplement to erythropoiesis-stimulating agents (ESAs) has been shown to improve hemoglobin (Hb) levels, reduce the number of blood transfusions and decrease the need for ESAs in anemic cancer patients. *Aim.* This observational study evaluated the effectiveness and tolerability of ferric carboxymaltose (FCM) in routine treatment of anemia in cancer patients. *Methods.* Adult cancer patients with anemia were enrolled from Dec 2008 - Jul 2010 at 68

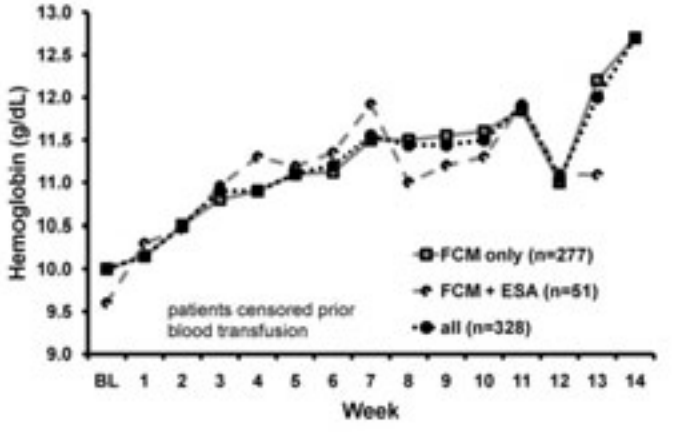

Figure 1. Median Hb over time.

German hematology/oncology practices and observed until Week 12 (+2) post inclusion or the termination visit. FCM was administered without restriction on dosing, concomitant use of ESAs or transfusions. Of 639 enrolled patients, 364 with available Hb measurements at baseline and at least one follow-up visit were analyzed for Hb increase (primary endpoint), 420 with available Hb measurements at baseline for secondary effectiveness parameters and 619 who received at least one FCM dose for safety. Effectiveness analyses included stratification by baseline Hb-, ferritin levels and subgroups who received FCM only or FCM and ESAs. Patients who received blood transfusions were censored prior to the transfusion. Data are shown as median values (25%, 75% quartiles) unless otherwise stated. *Results.* Most patients in the effectiveness population (female 54.8%, 67 years [58, 73]) presented with solid tumors (91.2% total; 25.2% breast, 19.8% colorectal, 8.8% stomach), of which 61.0% were metastasized. 74.3% received concomitant cytotoxic chemotherapy and 24.3% had received at least one anemia treatment during four weeks prior to study inclusion (13.1% transfusions, 8.3% ESAs, 4.0% i.v. or oral iron, 0.7% others). Median baseline Hb in the effectiveness population was 10.0g/dL (9.1, 10.6), 37.5% of tested patients had a ferritin ≤100ng/mL and 75.6% a transferrin saturation <20%. Median total iron dose per patient was 1000mg (600, 1500). Median increase in Hb levels was 1.4g/dL (0.2, 2.3) in the overall population, 1.4g/dL (0.2, 2.3) in patients who received FCM only, 1.6g/dL (0.7, 2.4) in patients who received FCM plus ESAs, and 1.4g/dL (0.3, 2.3) in patients censored for transfusions during the study. Hb levels improved steadily after the first FCM administration. From Week 5 onwards, mean Hb levels remained stable in the range of 11-13g/dL and were comparable between patients treated with FCM alone or concomitant ESAs as well as in patients with mild (baseline Hb 10-11g/dL) and moderate-to-severe (baseline Hb <10g/dL) anemia. Patients with baseline ferritin levels <100ng/mL achieved Hb levels >11g/dL earlier (Week 3-4) than those with baseline ferritin ≥100ng/mL (Week 7). FCM was well tolerated. Possibly or probably drug-related adverse events (AEs), mainly nausea and diarrhea, were reported for 2.3% (n=14) of patients. Three serious AEs (SAEs) comprised one fatal case after a possibly related respiratory insufficiency and two unlikely related events of tachycardia and dyspnea. *Conclusions.* FCM effectively improved and stabilized Hb levels of anemic cancer patients at 11-13g/dL in routine clinical practice, even without concomitant ESAs. Furthermore, the results of this observational study suggest that FCM can provide benefit to cancer patients independent of baseline Hb levels.

THE EFFECT OF HEMOGLOBIN LEVEL AT DARBEPOETIN ALFA INITIATION ON TRANSFUSION REDUCTION AND POTENTIAL COST-SAVING IMPACT IN THE TREATMENT OF CHEMOTHERAPY-INDUCED ANEMIA

M Deger,[1] L Kutikova,[1] W Eisterer,[2] S Salek[3]

[1]*Amgen (Europe) GmbH, Zug, Switzerland*
[2]*Innsbruck Medical University, Innsbruck, Austria*
[3]*Cardiff University, Cardiff, United Kingdom*

Background. Patients with cancer who receive chemotherapy may develop chemotherapy-induced anemia (CIA). Efficacy of erythropoiesis-stimulating agents (ESAs) in reducing the incidence of transfusions and increasing hemoglobin (Hb) levels has been demonstrated (Aapro, The Oncologist. 2008;13 (suppl 3):33-36). According to current guidelines in the US and Europe, ESA treatment should be initiated as the Hb level approaches either 10 g/dL (NCCN, USA) or between 9-11 g/dL (EORTC, Europe) in patients with anemia-related symptoms. *Aims.* The objective of this study was to understand the impact of Hb level at the start of darbepoetin alfa (DA) treatment on transfusion reduction and to identify the cost-saving impact of this reduction on CIA treatment costs. *Methods.* Two separate systematic literature reviews were performed. We conducted a systematic review of the clinical literature in PubMed, as well as ASCO, ASH, ESMO, ESMO/ECCO, and EHA conference abstract databases between 2006 and 2010. Search terms included "DA"and "CIA". DA is an ESA with dosing regimens up to every three weeks. A systematic review of economic studies on cost-of-transfusion was performed using a PubMed search from 2000-2010. Reference lists of retrieved studies from this review were scanned to identify additional articles. Mesh terms included "anemia/economics". *Results.* Eight studies were retrieved from the clinical literature review; six full-text articles and two conference abstracts. Six were based on clinical trials whereas two were based on observational studies. Despite the differences in baseline patient characteristics, length of the studies and analytical techniques, the need for transfusions decreased across all studies when DA initiation occurred at higher Hb levels. Twenty-one studies met the inclusion criteria for the economic literature review. These studies indicated that the cost of one unit of red blood cell (RBC) transfusion ranged from €240-414 in Europe, USD$107-529 in USA, £90-402 in UK, CAN$280-456 in Canada and AUS$143 in Australia. Few studies reported actual number of units transfused. When the number of transfusions was reported, more than one unit was usually transfused in the majority of patients. To estimate potential savings in CIA treatment associated with Hb level at the time of DA initiation, the difference in transfusion rates was multiplied by the midpoint of transfusion cost range in Europe (€327). An illustrative example using two of the eight identified clinical studies (latest studies) is presented in Table 1. Potential cost savings ranged from €589-3,548 for every 10 patients treated. We performed the same analysis using the remainder of identified studies and found the same trend of cost-savings (data not shown). *Conclusions.* The findings of the clinical systematic review suggest that transfusion incidence decreases with higher Hb levels at DA initiation. Cost of transfusions was found to vary from country to country and depended on cost items included (e.g. direct costs, indirect costs). Our findings suggest that the resulting cost-savings depends on the number of RBC units transfused and cost items included. Initiation of DA according to guidelines is important in terms of reducing the number of transfusions as well as the potential cost-saving impact on CIA treatment.

Table 1.

Impact of different Hb levels at DA initiation on transfusion rate and cost of CIA treatment

	Canon 2010			Eisterer 2011		
	Baseline Hb at DA initiation					
	<9 g/dL	9 to <10 g/dL	≥ 10 g/dL	<9 g/dL	9 to 10 g/dL	>10 g/dL
Transfusion rates (TR) (%)	62%	35%	19%	50%	19%	10%
Difference in % points of TR		27%	16%		31%	9%
Cost-saving for every 10 patients(€)(2 units)*		1,766	1,046		2,027	589
Cost-saving for every 10 patients(€) (3.5 units)**		3,090	1,831		3,548	1,030

Canon 2010 reports Kaplan- Meier % TR for W1-W13 (Week)

DONOR ALLELE (GT)16 IN THE PROMOTER/ENHANCER REGION POLYMORPHISM OF FOXP3 GENE IS ASSOCIATED WITH A HIGHER INCIDENCE OF RELAPSE AFTER MYELOABLATIVE HLA-IDENTICAL SCT

V Noriega,[1] C Martinez-Laperche,[2] N Sanchez-Hernandez,[2] M Kwon,[2] P Balsalobre,[2] D Serrano,[2] J Gayoso,[2] JL Diez-Martin,[2] I Buño[3]

[1]*H.G.U. Gregorio Marañón, Madrid, Spain*
[2]*H.G.U. Gregorio Marañon, Madrid, Spain*
[3]*H.G.U Gregorio Marañon, Madrid, Spain*

Introduction. The FOXP3 gene located on chromosome Xp11.23, encodes a protein that is a member of the forkhead/winged-helix family of transcriptional regulators. It is mainly expressed in CD4+CD25+ regulatory T cells, and is involved in the regulation of T-cell activation after Allogenic Stem Cell Transplantation. A microsatellite (GT)n polymorphism of the promoter/enhancer region of FOXP3 gene, located on the intron zero is associated with the degree of inmunological reactivity mediated by this protein. Some studies suggest a lower reactivity when (GT)16 alele is present. However, the influence of the polymorphism in donor and recipient cells on the immunological fenomena developed after Allo-SCT is unknown. *Objetive.* The main objective of this study was to analyze the role of FOXP3/Scurfin gene intron zero (GT)n polymorphism in the outcome of myeloablative HLA-identical Allo-SCT. *Patients and Methods.* Twenty-seven patients submitted to myeloablative HLA-identical Allo-SCT at our institution were included in the analysis with a median follow up of 424 days (23-4369 days) were included in the analysis. Genomic DNA was purified from peripheral blood using a QIAamp DNA extraction kit (Qiagen). Genotyping of intron zero (GT)n polymorphism in the FOXP3 gene was performed by fluorescent PCR revealed by capilar electroforesis as described by Bassuny *et al.* (Immunogenetics 55:149, 2003). *Results.* Distribution of (GT)n alleles in donors and recipients are summarized in Table 1. Since the FOXP3/Scurfin gene is located on the X chromosome, females can be homozygous or heterozygous while males are hemizygous. The presence of allele (GT)16 in the donor is associated with a higher relapse rate (50% vs 7.7 %; p=0.033), and a lower Time to Progression (TTP; 426 days vs not reached, p=0.03). Patients transplanted from donors with allele (GT)16 showed less gr.III-IV acute and extensive chronic graft versus host disease incidence (p=NS; Table 2). The higher incidence of relapse led to a worse event free survival (EFS) and overal survival (OS), although statistical significance was not achieved. *Conclusions.* The microsatellite (GT)n polymorphism in the promoter/enhancer region of the FOXP3 gene seems to influence outcome of myeloablative HLA-identical Allo-SCT. Indeed, the presence of allele (GT)16 in the donor is associated with a higher incidence of relapse and a lower TTP. In the case these observations are confirmed in a larger patient cohort, they may be useful for an individualized management of transplanted patients.

OPTIMAL CUTOFF VALUE OF THE HEMATOPOIETIC PROGENITOR CELL (HPC) COUNT FOR EFFICIENT AUTOLOGOUS STEM CELL HARVEST

JC Jo,[1] DH Yoon,[2] S Shin,[2] SS Jang,[3] CJ Park,[3] HS Chi,[3] JR Huh,[4] C Suh[2]

[1]*Asan Medical Center, Seoul, South-Korea*
[2]*Department of Oncology, Asan Medical Center, Seoul, South-Korea*
[3]*Deparment of Laboratory Medicine, Asan Medical Center, Seoul, South-Korea*
[4]*Department of Pathology, Asan Medical Center, Seoul, South-Korea*

Background. Even if enumeration of CD34+ cells in peripheral blood is a reliable index for timing efficient autologous stem cell collection (ASCC), flow cytometric techniques to measure CD34+ cells are complex and costly. We previously have shown that hematopoietic progenitor cell (HPC) count enumerated by SE-9000 automated hematology analyzer is a useful surrogate for the timing of ASCC. *Aims.* We aimed to fine-tune cutoff value of HPC in predicting successful ASCC. *Methods.* Between May 2002 and January 2011, 378 patients (median age, 50 years; Male:Female = 230:148) with hematologic malignancy including 152 patients with multiple myeloma, 196 with Non-Hodgkin's lymphoma, 23 with Hodgkin's lymphoma and 7 with POEMS syndrome, underwent ASCC in the Asan medical center. A receiver operating characteristic (ROC) curve was used to define a threshold value of collected CD34+ cell count on day 1 and HPC for optimal ASCC (total CD34+ cell ≥ 5.0 x 10^6/kg). The involvement of the various factors that may affect ASCC was analyzed by a multiple logistic regression analysis. *Results.* In a series of consecutive 378 patients, 1116 leukapheresis were performed. The median number of harvested CD34+ cells was 11.27 x 10^6/kg (range, 0.01-172.7) with the median number of collection of three (range, 1-8). The ROC curve revealed that the most reliable parameter for optimal CD34+ cell collection was a number of CD34+ cells collected on day 1 ≥2.0 x 10^6/kg (AUC 0.803, 95% confidence interval [CI] 0.759 - 0.848, p <0.001) and the best cutoff value of HPC was 20 x 10^6/L (HPC 20) for the collected CD34+ cell count on day 1 ≥2.0 x 10^6/kg (sensitivity of 70.0% and specificity of 77.7%). On the basis of HPC 20 (HPC ≥20 vs. HPC <20), optimal collection rates were 94.8% and 75%, respectively. Failure to achieve optimal CD34+ cell collection was significantly associated with prior exposure to alkylating agents (p <0.001, odds ratio [OR] 2.86 [95% CI, 1.64 - 4.92) and the number of prior chemotherapeutic regimens (<2 vs. ≥2, p <0.004, OR 2.30 (95% CI, 1.30 - 4.06) in the multiple logistic regression analysis. *Summary/Conclusions.* We defined cutoff value of HPC to be 20 x 10^6/L for optimal ASCC. Prior exposure to alkylating agents or heavy treatment was a significant cause for inefficient ASCC.

0987

EFFICACY AND TOXICITY OF THE FLAMSA/RIC REGIMEN IN 40 PATIENTS WITH HIGH-RISK AML: A SINGLE CENTRE EXPERIENCE

M Krejci, Y Brychtova, M Doubek, M Toskova, Z Racil, Z Koristek, M Navratil, M Tomiska, O Horky, V Sandecka, J Mayer

University Hospital Brno, Brno, Czech Republic

Background. Sequential use of chemotherapy and reduced-intensity conditioning (RIC) for allogeneic stem cell transplantation (SCT) in high-risk leukemia patients (pts) represents a promising approach (Schmid *et al.*, JCO 23, 2005: 5675-87). Here we present our experience with this therapy at cohort of 40 pts with acute myeloid leukemia (AML). *Methods.* High-risk was defined by progressive or refractory AML (n = 23), AML on the second or third remission (n = 8), or AML on the first remission with unfavorable cytogenetics (n = 9). Fludarabine (30 mg/m2), cytarabine (2 g/m2), and amsacrine (100 mg/m2) for 4 days (FLAMSA) were used for cytoreduction. After 3 days of rest, RIC consisting of 4 Gy TBI, anti-thymocyte globulin (ATG-Fresenius) 10-20 mg/kg/day for 3 days, and cyclophosphamide 40-60 mg/kg/day for 2 days followed. Prophylactic donor lymphocyte transfusions (pDLT) were given from day +120 in pts who were free of immunosupressive medication for at least 30 days without developing GVHD. We analyzed 40 pts with AML undergoing FLAMSA/RIC in our centre from March 2006 to March 2010. Disease status before SCT was: CR1, n=9; CR2, n=6; CR3, n=1; PR1, n=1; refractory/progressive disease, n=23. Median age of pts was 49 years (range 25-62). Types of donors and used grafts were as follows: HLA identical sibling, n=10; unrelated donor, n=30; PBSCs, n=37; BM, n=3. *Results.* The median time of neutrophil engraftment (above 0.5x10E9/L) was 16 days, 34 pts engrafted, 6 pts died in aplazia on days 1, 3, 7, 8, 10 and 19 after SCT. Incidence of acute GVHD was

evaluated in 33 pts: 58% (19/33) of pts had GVHD (grade I+II in 16 pts, grade III in 3 pts). Incidence of chronic GVHD was evaluated in 28 pts, 64% (18/28) of pts had GVHD (limited in 14 pts, extensive in 4 pts). Eight pts fulfilled the criteria for pDLT and received pDLT (median 2 doses). So far, 2 pts of 8 have got AML relapse and they died, 6 pts of 8 are alive in remission of AML. The cumulative incidence of non-relapse mortality (NRM) at 1 year and 2 years was 28% (11/40) and 30% (12/40). Causes of death were refractory GVHD (n=3), septic shock (n=4), multiorgan failure (n=3), brain hemorrhage (n=1) and posttransplant lymphoproliferative disease (1). The other most frequent toxicities were grade III/IV infections according to common toxicity criteria in 22 of 34 pts and gastrointestinal toxicity (grade III in 10 of 34 pts). Treatment response was evaluated in 34 pts: remission was achieved in 28 pts (82%), 6 pts (18%) had progression. With the median follow-up from SCT of 33.5 months (range 10-60), the 1- and 2-year progression-free survival (PFS) was 44.0% and 38.0%, and the overall survival (OS) was 46.0% and 41.0%, respectively. Twenty-four pts died (12 deaths from NRM, 12 deaths from relapse or progression), 16 pts are alive and disease free. *Conclusion.* FLAMSA/RIC regimen seems to be feasible and effective alternative for pts with high-risk AML with acceptable toxicity and high response rate (82%), 2-year OS after SCT is 41%.

0988

ALLOGENEIC STEM CELL TRANSPLANTATION FOR ADULTS WITH MYELODYSPLASTIC SYNDROMES: RELEVANCE OF PRE-TRANSPLANT DISEASE STATUS

C Fraira,[1] A Busca,[1] B Allione,[1] MT Corsetti,[2] M Pini,[2] E Audisio,[1] C Pecoraro,[1] A Castiglione,[3] G Ciccone,[3] M Falda,[1] U Vitolo[1]

[1]*SCDO Haematology 2, AOU San Giovanni Battista-Molinette, Turin, Italy*
[2]*SC Haematology AO SS Antonio e Biagio, Alessandria, Italy*
[3]*Unit of Epidemiology, CPO Piedmont, Turin, Italy*

Background. allogeneic hematopoietic stem cell transplantation (HSCT) is currently the only potential curative therapy for myelodysplastic syndromes (MDS). Approximately 40% of patients may be cured with HSCT, although advanced age, medical comorbidities and the lack of suitable donor limit this strategy to a selected minority of patients. Aim of the study was to investigate the outcome of adult patients with MDS who received an allogeneic HSCT in two Italian hematological centers. *Methods.* We retrospectively analyzed 77 adult MDS patients (median age 53, 30-70 years) receiving an allogeneic HSCT between January 1995 and September 2010 at two main Piedmont Hematological Institutions. Patients were classified according to standard FAB criteria: 8 (10%) had refractory anemia, 3 (4%) refractory anemia with ringed sideroblasts, 36 (47%) refractory anemia with excess of blasts, 8 (10%) refractory anemia with excess of blasts in transformation, 14 (19%) chronic myelomonocytic leukemia and 8 (10%) had MDS not otherwise specified. At the time of diagnosis, 3 patients (4%) had IPSS low-risk disease, 19 (25%) had intermedate-1, 25 (33%) intermediate-2 and 9 (12%) high risk disease; 49 out of 77 patients (64%) received active treatment before HSCT including hypomethylating agents and AML-like induction chemotherapy. At the time of HSCT, 22 patients (29%) were in complete remission, 12 (16%) were untreated, while 43 (56%) had relapsed/refractory disease. Peripheral blood stem cells was the graft source in 68 cases (88%), bone marrow in 8 (10%) and umbilical cord blood in 1 case (2%); 50 patients (65%) received grafts from an HLA-identical sibling, 24 (31%) from a matched unrelated donor and 3 (4%) from a partially matched related donor. Forty-three patients (56%) received myeloablative preparative regimens and 34 (44%) received reduced intensity conditioning. *Results.* primary neutrophil engraftment was achieved in 71 patients (92%) at a median of 16 days after transplantation (range 11-30 days) and platelet engraftment was achieved in 57 patients (74%) at a median of 14 days (range 7-51 days). The cumulative incidence of acute graft-versus-host disease (aGVHD) by day +100 and chronic GVHD by 1 year were 30% (19%-41%, 95% confidence interval [CI]) and 57% (45%-68%, 95% CI) respectively. The cumulative incidence of transplant-related mortality (TRM) at 100 days and 1 year were 13% (5%-21%, 95% CI) and 20% (11%-29%, 95% CI) respectively. The 2-year progression free survival (PFS) and overall survival (OS) were 41% (30%-52%, 95% CI) and 48% (36%-59%, 95% CI) respectively. On multivariate analysis, advanced disease stage at transplantation was the major independent variable associated with an inferior 2-year PFS (HR 4.48, 2.13-9.45 95% CI, p<0.001) and OS (HR 4.11, 1.94-8.70 95% CI). The use of a donor other than an HLA-identical sibling (HR 2.81, 1.04-7.63, 95% CI, p 0.04) was the independent variable associated with TRM. *Summary/Conclusions.* our data suggest that disease status at the time of transplant is the major predictor for improved PFS and OS, and treatments required to reach this goal may have value in leading to improved outcome. Additional studies are justified for clarify the role of HSCT in MDS.

DIAGNOSTIC STRATEGIES AND RISK FACTORS FOR CYTOMEGALOVIRUS INFECTION IN PATIENTS WITH LYMPHOMA UNDERGOING AUTOLOGOUS TRANSPLANTATION: A RETROSPECTIVE ANALYSIS FROM THE ROME TRANSPLANT NETWORK

F Marchesi,[1] F Giannotti,[2] M Petti,[3] G Avvisati,[4] F Pimpinelli,[5] P Paba,[6] M Dessanti,[3] R Cerretti,[2] M Tirindelli,[4] A Picardi,[2] M D'Andrea,[3] A Spadea,[3] F Ensoli,[5] C Perno,[6] A Mengarelli,[3] W Arcese[2]

[1]*Hematology, University Campus Bio-Medico, Rome, Italy*

[5]*Molecular Virology, San Gallicano Dermatological Institute, Rome, Italy*
[6]*Molecular Virology Laboratory, University Tor Vergata, Rome, Italy*

Background. Routine monitoring for Cytomegalovirus (CMV) infection are considered unnecessary in patients undergoing autologous hematopoietic stem cell transplantation (ASCT) because of the low likelihood of progression from infection to disease, with the exception of high-risk subgroups, including those receiving CD34-selected grafts and prior treatment with Fludarabine, Cladribine or Alemtuzumab. However, current data on CMV infection and disease following ASCT for malignant lymphoma are very limited. The starting point for this study was the quality accreditation process of the Rome Transplant Network (RTN) according to the JACIE standards, considering that two different CMV infection diagnostic strategies were set within the participating Institutions: a clinically driven diagnostic approach based on plasma quantitative Polymerase Chain Reaction (PCR) assay in patients with clinical signs suggesting a CMV infection and a CMV surveillance based on a routine monitoring of all patients by plasma quantitative PCR assay. *Aims.* The aim of the study was to compare two different CMV infection diagnostic strategies (i.e. clinically driven vs surveillance) in terms of CMV symptomatic infection and/or end-organ disease incidence, diagnostic timing, transplant-related mortality (TRM), CMV-related mortality (CMVRM), PCR testing cost and to provide insights on the risk factors for CMV symptomatic infection or end-organ disease and TRM. CMV symptomatic infection and end-organ disease were defined according to published recommendations. *Methods.* We perform a retrospective analysis on 144 adult patients (median age 47 years, range 17-71) with diagnosis of malignant lymphoma consecutively undergoing non-selected peripheral blood ASCT in 3 Hematology Institutions participating in the RTN. *Results.* Considering the two CMV infection diagnostic strategies, PCR testing cost was significantly higher in the surveillance arm (€199 vs 824, p=0.000), whereas no statistically significant difference was observed concerning CMV symptomatic infection or end-organ disease incidence (11.5 vs 10.5%, p=1), diagnostic timing (day 33 vs 26, p=0.294), TRM (7 vs 3.5%, p=0.422) and CMVRM (4.9 vs 0%, p=0.116). In multivariate analysis, the HBcIgG seropositivity [HBcIgG- HR 0.13 (95% CI: 0.03-0.6), p=0.004] and conditioning regimens containing 90Y-Ibritumomab Tiuxetan (Z-BEAM or Z-FEAM) [HR 28.5 (95% CI: 2.9-278.6), p=0.004] or non-Carmustine-based [HR 34.8 (95% CI: 5.2-231.9), p=0.000] proved to be independent significant variables for the risk of developing CMV symptomatic infection or end-organ disease. The number of Rituximab administrations as risk factor remains controversial, since the multivariate analysis (p=0.124) did not confirm the predictive value observed in univariate analysis (p=0.002). Overall, 1 out of 5 (20%) patients with CMV end-organ disease and 3 out of 11 (27%) with symptomatic infection died, demonstrating the clinical impact of CMV indirect effects such as secondary infections. In multivariate analysis, the occurrence of CMV symptomatic infection or end-organ disease was the only factor influencing the risk of TRM (6-fold risen, p=0.017). *Summary/Conclusions.* Routine monitoring for CMV infection following ASCT should be carried out not only in lymphoma patients grafted with CD34-selected cells or previously treated with Fludarabine, but also in lymphoma patients HBcAb+. From our study, 90Y-Ibritumomab Tiuxetan in conditioning and non-BCNU-based regimens should be considered as further risk factors for CMV symptomatic infection or organ disease.

INTRABONE CORD BLOOD TRANSPLANT: PRELIMINARY RESULTS FROM A PROSPECTIVE PHASE II STUDY

F Bonifazi,[1] G Bandini,[1] M Arpinati,[1] M Stanzani,[1] MR Motta,[1] S Rizzi,[1] E Dan,[1] G Tolomelli,[1] A Bontadini,[2] E Massari,[1] M Fusari,[3] M Baccarani[1]

[1]*Institute of Hematology and Medical Oncology "L. & A. Seràgnoli", Bologna, Italy*
[2]*Immunogenetics Laboratory, St. Orsola-Malpighi Hospital, Bologna, Italy*
[3]*Emergency Dept. St. Orsola-Malpighi Hospital, Bologna, Italy*

Background. Intrabone transplantation has been described as an efficient way to infuse cord blood. *Aims.* The study was a phase II prospective monocenter study approved by local ethical Committee and registered at http://clinicaltrials.gov/; primary endpoint was engraftment rate and 17 patients are planned. *Methods.* the All patients signed a written informed consent. End of recruitment is planned within may 2011.Conditioning regimen was myeloablative (Bu- Cy or unfractioned TBI-Cy); prophylaxis of GVHD was CsA, micophenolate 30 mg/kg/die and ATG-F 30 mg/kg, total dose. G-CSF was routinely given from Day +7 until recovery.CB processing was as described by Frassoni *et al.* Briefly, cord blood units were thawed, washed with the Rubinstein solution to remove DMSO and reduced the final volume up to 30 ml.Infusion was performed in operating room using a monitored anaesthesia care sedation with propofol and remifentanil.Median age was 36 years (29-54), median weight of recipient was 60 kg (51-93); diagnosis were AML (8) ALL (4) MM (1) CML (1). Phase at transplant was mainly advanced (for AML 6 with resistant/relapsed disease, 2 II CR; for ALL 1 II CR and 3 resistant disease; MM: 1 progressive disease and CB for CML). 3 patients had a previous allotransplant and 3 a autotransplant. All CB units were 4/6 except for one (5/6). *Results.* Median total cell infused was 1.91 x 10e7/kg and median CD34 pos cells 0.52 x 10e5/kg.Median time to 0.5 x 10e9/L ANC was 21 days and median time to 20x 10e9/L and 50 x10e9/L platelets were 46 and 60.5 days, respectively. At day +100 the evaluable patients had 121x 10e9/L plt (range 104-192). Three patients died before engraftment for CNS bleeding (+6) or for myocarditis (+16) and sepsis (+6)One patient didn't graft and a second unit, again via intrabone, was given, after 2 months and with a RIC regimen, with successful engraftment.All the evaluable patient achieve a complete response (CR), except for the MM pt, who obtain a nCR); two patients relapse at 4 and 7 months from transplant. GVHD occurrence was very low: no severe acute GVHD and only one case of extensive GVHD were recorded. *Summary/Conclusions.* Preliminary results of this study with advanced disease suggest that intrabone injection of CB resulted in short term good engraftment, expecially for platelets, low GVHD and good outcome. Longer follow up is needed to estimate the actual antileukemic effect.

0991

UNRELATED STEM CELL TRANSPLANTATION IN ADULTS WITH HIGH-RISK ACUTE LYMPHOBLASTIC LEUKEMIA: HLA-MATCHING DEGREE AND GRAFT SOURCE-BASED ANALYSES OF LONG-TERM OUTCOMES

S Lee,[1] NG Chung,[1] JY Kwak,[2] JA Kim,[1] SK Park,[3] BS Cho,[1] KS Eom,[1] YJ Kim,[1] HJ Kim,[1] CK Min,[1] DW Kim,[1] JW Lee,[1] WS Min,[1] CW Park[1]

[1]*Catholic BMT Center, The Catholic University of Korea, Seoul, South-Korea*
[2]*Chonbuk National University Medical School, Chonju, South-Korea*
[3]*Soonchunhyang University Medical School, Bucheon, South-Korea*

Background. Adults with high-risk acute lymphoblastic leukemia (HR-ALL) have a poor outcome with standard chemotherapy and usually undergo unrelated donor stem cell transplantation (URD-SCT) if a matched sibling donor is not available. However, long-term results of URD-SCT, especially based on HLA-matching degree and graft source, are scarce in adult HR-ALL patients. *Aims.* We report long-term outcomes in 106 consecutive adult HR-ALL patients who received URD-SCT using bone marrow (BM; n=67) or peripheral blood progenitor cells (PBPC; n=39) at our center between 2000 and 2008. *Methods.* Median age was 24 years (range, 15-54 years). All patients had one or more high-risk features, including adverse cytogenetics [t(9;22), t(4;11), t(8;14), complex, Ho-Tr], older age (≥35 years), high leukocyte counts, or delayed first complete remission (CR1). Eighty patients (75.5%) were transplanted in CR1; 9 (8.5%) in CR2; and 17 (16.0%) in advanced status. Using allele-level typing (for HLA-A, HLA-B, HLA-C, and HLA-DRB1 loci), graft sources were classified as (1) 8/8-matched BM (n=30), (2) 8/8-matched PBPC (n=17), (3) 7/8-matched BM (n=35), and (4) 7/8-matched PBPC (n=24). All patients received TBI (≥12 Gy)-based myeloablative conditioning or reduced-intensity conditioning (fludarabine plus melphalan) regimens. Graft-versus-host disease (GVHD) prophylaxis was uniformly attempted by administering tacrolimus plus methotrexate. Antithymocyte globulin (2.5 mg/kg) was administered to 59 patients who received 7/8 matched grafts. All patients and donors provided written informed consent, and the treatment protocol was approved by the institutional review board of The Catholic University of Korea. *Results.* Compared with 8/8-matched transplants (BM and PBPC) and 7/8-matched BM transplants, 7/8-matched PBPC transplants were older (P=0.050) and received a reduced-intensity conditioning regimen (P=0.015). Disease status at the time of transplantation was more advanced for 7/8-matched BM transplants (P=0.009). After a median follow-up of 53 months (range, 24-124 months) for surviving transplants, the 5-year cumulative incidence of relapse and non-relapse mortality were 31% and 25%, respectively, and the 5-year disease-free survival (DFS) rate was 52%. The risk of relapse was higher for 7/8-matched transplants (42%; 48% for PBPC and 37% for BM) than for 8/8-matched transplants (19%; 18% for PBPC and 20% for BM; P=0.019), while the risk of non-relapse mortality was similar between groups. As a result, DFS at 5 years was lower using 7/8-matched grafts (44%; 42% for PBPC and 46% for BM) than 8/8-matched grafts (62%; 59% for PBPC and 63% for BM; P=0.041). In each group of patients showing the same HLA-matching degree, overall transplantation outcomes were similar between PBPC transplants and BM transplants. Regardless of HLA-matching degree and graft sources, disease status at transplantation (CR1 versus beyond CR1) was an independent predictive factor affecting relapse (HR 3.21, 95% CI 1.46-7.07; P=0.004) and DFS (HR 2.75, 95% CI 1.41-5.36; P=0.003) in multivariate analysis. The presence of chronic GVHD was also associated with lower relapse (HR 5.03, 95% CI 2.01-12.61; P=0.001) and better DFS (HR 2.37, 95% CI 1.23-4.57; P=0.010). *Summary/Conclusions.* Our long-term data suggest that outcomes are similar for transplantation using PBPC or BM sources in the setting of 8/8-matched or 7/8-matched URD-SCT for adult HR-ALL.

Background and Objectives. Radiolabelled immunotherapy is a promising treatment in malignant lymphomas. We designed a Phase II clinical Trial with Yttrium-90 (Y-90)-ibritumomab tiuxetan as a part of a RIC regimen associated with melfalan and fludarabine (Clinical Trials Identifier: NCT00644371). The main objective was evaluate one year Progression free Survival (PFS), and secondary objectives: toxicity, engraftment, acute and chronic GVHD and one year non relapse mortality (NRM) and overall survival (OS). *Patients and Methods.* 20 patients from 10 Spanish centers with aggressive non-Hodgkin's lymphoma (NHL), including diffuse large B-cell, follicular grade 3, Burkitt and mantle-cell lymphomas, were eligible for the trial. Inclusion criteria were: to reach less than a partial response (PR) after two lines of chemotherapy, relapse after an autologous SCT (ASCT), positive PET before or after ASCT, or failure in mobilization of stem-cells for ASCT. Conditioning regimen consisted of rituximab 250 mg (day -21), Y-90 ibritumomab IV (2,08 mg, day -14) plus Fludarabine 30 mg/m^2 IV (days -3,-2) plus Melphalan 70mg/m^2 IV (days-3,-2) or only -2 plus tiotepa 10 mg/kg (day -8). All donors were family matched. We report here preliminary analysis of results. *Results.* Median age was 49 years (range 32-63). At the moment of transplant, 7 patients (39%) were in complete remission (CR), 7 (39%) in PR and 4 had refractory disease (RD). Five patients had a prior ASTC. Y-90 ibritumomab infusions were well tolerated, without immediate reported adverse reactions. All patients engrafted, and median of days to reach more than 500x10^9 granulocytes and more than 20x10^9 platelets were 15 (12-24) and 12 (2-19) respectively. Incidence of grade 3-4 acute GVHD was 31.2%. With a median follow-up of alive patients of 17 months (range 3 to 27 months), 11 patients (55%) are alive, 9 of them (82%) in CR. Global postransplant re-

lapse was 25% and at one year, PFS was 44%. At day +100, NRM was 15% and overall NRM was 25% (2 patients due to acute GVHD and 3 infectious complications). Median OS has not been reached. 2-year estimated OS was 54%. *Conclusions.* Our results show that yttrium-90-ibritumomab tiuxetan as a component of reduced intensity conditioning for allogeneic transplantation is feasible in patients with high-risk relapsed or refractory aggressive B-cell lymphoma. Longer follow up is needed in order to design future trials.

CLINICAL IMPACT OF GLUTATHIONE S-TRANSFERASE M1 POLYMORPHISM ON OUTCOME AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

A Tomaszewska,[1] K Guz,[1] M Przybylski,[2] J Smolarczyk-Wodzynska,[1] B Nasilowska-Adamska,[1] M Lakomy,[1] E Brojer,[1] B Marianska[1]

[2]*Medical University of Warsaw, Department of Medical Microbiology, Warsaw, Poland*

Background. Despite significant progress in allogeneic hematopoietic stem cell transplantation (allo-HSCT), this procedure is still associated with substantial morbidity and mortality. Various pretransplantation and transplantation-related clinical risk factors have been implicated, but so far there is no method to estimate the occurrence and severity of transplant-related complications. The most common complication after allo-HSCT which affects survival remains graft versus host disease (GvHD). Single nucleotide polymorphisms in genes coding cytokines and chemokines have been shown to influence GvHD and outcome after allo-HSCT. Besides pharmacogenomics is a new field investigated in the HSCT setting. This study aimed to determine association between polymorphism of glutathione S-transferase M1 (GSTM1) genotypes with the outcome of allo-HSCT performed between May 2001 and October 2010 in our center. *Materials and Methods.* The allelic variants of GSTM1 gene were determined in 83 patient/donor pairs by real-time polymerase chain reaction. Patients characteristics were: median age 36 (range 18-65), underlaying diseases-hematologic malignancies in 77 and aplastic anemia - in 6 cases. Donors were HLA-identical sibling-in 61 and unrelated-in 22 transplants, the median age-37 (range 14-65). The studied end points were GvHD, haemorrhagic cystitis, toxicity and venooclusive disease (VOD) of the liver and survival. The Spearman's rank correlation test was used in statistical analysis. *Results.* The allelic distribution of examined polymorhisms was similar to that reported in Caucasoid population. Acute-GvHD was recognized in 35/83 (42,2%) and chronic-in 43/83 (51,8%) of patients. Overall survival in analysed group was 60,2%. Our study revealed significant correlation between the occurrence and severity of aGvHD and the GSTM1-positive genotype compared with those with the GSTM1-null genotype (P=0.00786). Besides we found a significant correlation between the GSTM1-null genotype and increased overall survival obtained by the Kaplan-Meier method (P=0.016). We couldn't find any correlation between: 1) examined polymorphism and the rest of analysed end points, 2) donor genotype and HSCT complications (P=ns). *Conclusion.* Our data revealed that GSTM1 gene polymorphism is correlated with aGvHD, and overall survival after allo-HSCT. These findings confirmed some previously published data, but results remains variable between investigators, so should be studied prospectively and in the larger group of patients.

[4]*National and Kapodistrian University of Athens, Athens, Greece*
[5]*Department of Nuclear Medicine, Evangelismos Hospital, Athens, Greece*

Background. The prognostic significance of PET-scan in advanced stage HL patients treated with ABVD as first line treatment is well established. However, the prognostic impact of PET scan in the relapsed setting is not clearly defined, while chemosensitivity before HDT/ASCT - as assessed with conventional imaging - is one of the most important prognostic factors for outcome. *Aims.* To study the prognostic significance of PET scan before and after HDT/ASCT in patients with relapsed/primary refractory HL. *Methods.* Clinical staging with computed tomography (CT) and clinical examination, as well as PET-scan were performed after salvage chemotherapy just prior to ASCT and at 3 months post transplant and findings were correlated with failure free survival (FFS). PET scan was considered negative when no uptake was present, positive, when any lesion was FDG avid with SUV≥ 4 and minimal residual uptake positive (MRUp), when any lesion showed abnormal uptake with SUV<4. Chemosensitive patients were considered those who had achieved complete or partial remission, whereas chemoresistant those with stable or progressive disease by conventional clinical staging pre-ASCT. Failure-free Survival (FFS) was calculated from ASCT to relapse, progression, death from any cause or last follow-up. *Results.* Sixty-one patients were retrospectively studied. Eighty % were chemosensitive by CT criteria. PET scan was available in 52 patients before HDT/ASCT, 59 after HDT/ASCT and in 50 at both time points. Pre-ASCT PET scan was positive or MRUp in 23/42 chemosensitive patients, vs 10/10 chemorefractory. The analysis of the prognostic significance of pre-transplant PET scan revealed: three relapses were observed among 19 PET negative patients, vs 17 among 33 MRUp or positive ones, leading to a 2-year FFS of 77% vs 45%, respectively (p=0.02). Post ASCT PET scan had a strong prognostic impact on outcome: 2-year FFS was 87% for PET negative or MRUp patients vs 6% for positive ones, (p< 0.0001). The analysis of the 50 patients who had a PET scan available both pre- and post-transplant disclosed: a. One relapse was recorded for those who were PET scan either positive or MRUp pre-ASCT and became negative or MRUp after ASCT (1/16 patients), b. 15 patients relapsed among 16, who were PET scan positive or MRUp pre-transplant and remained or became positive post-transplant c. 2 relapses were recorded among 16 patients who were negative both pre- and post-ASCT. These differences were statistically significant (p<0.0001). *Conclusions*. PET scan positivity prior to ASCT does not preclude a favorable outcome in patients with primary refractory/relapsed HL, since approximately 50% remain disease free after ASCT. Patients who remain or become PET scan positive after ASCT have a dismal outcome in contrast to those who become PET negative.

0995

EXTRA- AND INTRA-CELLULAR IRON DISTRIBUTION IN PRE-TRANSPLANT BONE MARROW TREPHINE BIOPSIES AND OUTCOME AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

H Al-Ali, C Wickenhauser, M Hoeppner, R Krahl, N Jaekel, D Niederwieser, H Al-Ali

University of Leipzig, Leipzig, Germany

Limited data are available on the patterns of pre-transplant iron deposition in the bone marrow (BM) [interstitial and/or in macrophages] and their impact on outcome [survival, non-relapse-mortality (NRM), and graft-versus-host-disease (GvHD)] after allogeneic hematopoietic cell transplantation (HCT). Also, the correlation of BM iron stores (Fe-S) with inherited (HFE-genotype), treatment-related factors [pre-transplant units of packed red blood cells (URB) transfused] and serum ferritin (SF) is not clearly defined. Therefore BM-biopsies of 90 patients (AML, n=68, MDS, n=22), taken for diagnostic purpose at a median of 24 days pre-HCT, were analysed for iron deposition (Perls` reaction) and macrophage identification (CD68 immunostaining). Grading (G0-G5) for Fe-S, and (G0-G3) for interstitial iron (Fe-I) was used to express iron deposition. The percentage of iron storing macrophages in relation to all CD68+ macrophages (Fe-Mac) and of CD68+ macrophages in relation to all haematopoietic cells (Mac) was expressed as percent. Peripheral blood parameters were measured 7 days pre-HCT with a median C-reactive protein of < 5 mg/l [48 males/42 females, median age 57 years]. Donors were matched-related (MRD) in 17 (19%) and matched-unrelated (MUD) in 73 (81%). Preparative regimen was conventional conditioning with 12 Gray TBI/cyclophosphamide 120 mg/kg in 32 (35.6%) and reduced intensity conditioning with fludarabin 30mg/m2/day for 3 days and 2 Gray TBI in 58 (64.4%). Mutated HFE-genotype was found in 27 patients pre-HCT (heterozygosity (het) for H63D,n=15, het C282Y,n=7, het S65C,n=2, and homozygosity for H63D,n=3). Median SF was 2009 (range 36-16900 ng/ml) with 25% of patients having a SF >3000ng/ml. Median URB was 26 (0-115) units. Correlations between

Fe-S and both Fe-I and Fe-Mac (r=0.8, p<0.0001) and between Fe-I and Fe-Mac (r=0.8, p<0.0001) were strongly significant but augmented Fe-S was not associated with increasing Mac (p=0.4). Also, higher SF values were associated with higher grades for Fe-S (p=0.002), Fe-I (p=0.01), and Fe-Mac (p=0.004) but the correlation was poor (r=0.3). There was a significant correlation of SF level (r=0.6, p<0.0001) but not of Fe-S and URB transfusion. Additionally, Fe-S was not influenced by HFE-genotype. After a median follow-up of 24 months, acute and chronic graft-versus-host-disease (GvHD) occurred in 70% and 53% of patients respectively. Survival was 58% and NRM was 22%. Fe-S, Fe-I, and Fe-Mac did not correlate with GvHD, survival or NRM. However, elevated SF levels were highly predictive for inferior survival (p=0.002) and higher NRM (p=0.007) as in patients with SF >3000ng/ml, survival and NRM were 37% and 49% versus 78% and 9% respectively in patients with lower SF (p=0.001). In addition, SF levels >3000ng/ml were associated with acute GvHD (p=0.002) but not with chronic GvHD. In the face of transfusional iron overload, iron is deposited in the bone marrow equally both interstitially and in macrophages. Iron overload measured by an elevated SF is usually accompanied by augmented marrow iron stores but the correlation remains poor. The pre-transplant marrow iron status, unlike serum ferritin, could not predict outcome after HCT. Keeping the well-known limitations in mind, serum ferritin remains a cheap and non-invasive tool to measure iron overload.

0996

IRON OVERLOAD IN HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT). SINGLE-CENTER EXPERIENCE

G Rodriguez Garcia, R Rojas, J Casaño, MA Alvarez, C Martin, J Sanchez, V Martin, A Torres

Hospital Reina Sofia, Cordoba, Spain

Background. Serum ferritin is sensitive but not specific for iron overload and is a poor predictor of body iron burden. However, accumulating evidence has established the negative impact of elevated pretransplantation serum ferritin on transplant related toxicity and mortality (MRT), related in particular to graft-versus-host disease (GVHD), infection, nonrelapse mortality and survival, but this relationship is not clear. *Aims.* The aim of the present study was to study impact of elevated pretrasnsplantation serum ferritin level on transplant toxicity and mortality in our single-center serie. *Methods.* We retrospectively evaluated the prognostic effect of serum ferritin level on the post-transplantation outcome (overall survival, transplant related mortality, infection related mortality, and acute graft versus host disease) of 187 patients who underwent transplantation between 2006 and 2010 in our center. Serum ferritin was measured within the 3 months before transplantation. Patients were divided in 3 groups depending on the serum ferritin level (<500 ngr/mL; 500-1000 ngr/mL; >1000 ngr/mL). We also analyzed our serie with 2 of the most commons cut-off points described in literature (600 and 1000 ngr/mL). Kaplan-Meier and log rank test were used to analyze survival, and χ^2 or Mann-Whitney test to analyze association with infection and aGVHD. *Results.* The HSCT grafts were autologous in 114 patients, and allogeneic in 73 (43% non-myeloablative).

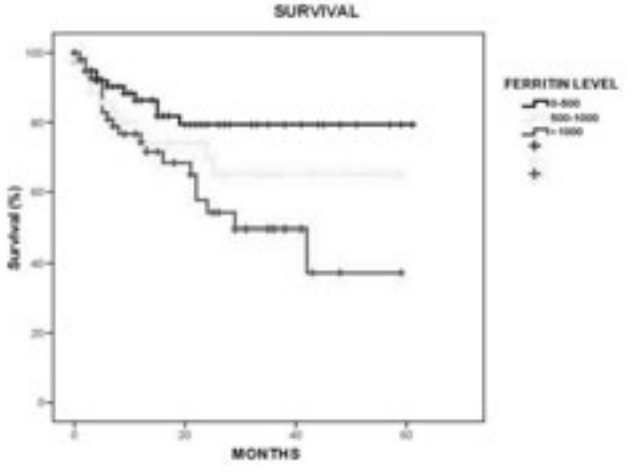

Figure 1.

Follow up was 17,24 months (0.-61). Survival in the entire group was 75,9% (142 patients). MRT was 5,3% and MRT-100 3,2%, mainly due to infection and acute GVHD. Mean (SD) pre-HSCT serum ferritin concentration was 951 (1125) ng/mL in the entire group, 704 (929) ng/mL in autologous recipients, and 1337(1291) ng/mL in allogeneic recipients. Ferritin level was <500 ngr/mL in 82 patients (43,9%), 500-1000 in 46 patients (24,6%), and >1000 in 59 patients (31,6%). High ferritin concentrations (500-1000 ngr/mL and >1000 ngr/mL) were significantly associated with overall survival (79,3%,65,1% and 37,2% respectively; log rank test p=0,044) (figure 1). Ferritin level >600 ng/mL was significantly associated with higher mortality secondary to infection (89% vs 72,4%;p=0,033). We didn't found association between serum ferritin level and MRT, MRT-100 or aGVHD (grade 0-2 vs 3-4). *Summary/Conclusions.* in our serie pre-transplantation serum ferritin level divides patients into 3 groups of risk with significantly different survival. Ferritin level was also associated with higher risk of mortality secondary to infection.This study suggest a predictive role of pre-transplantation ferritin levels in selecting a subset of patients at increased risk for HSC, and could be useful in making treatment decisions for individual patients.

0997

THE IMMUNE PHENOTYPIC PROFILE OF HEMATOPOIETIC STEM CELLS IN DIFFERENT MOBILIZATION REGIMENS AND GENE EXPRESSION PROFILES OF G-CSF MOBILIZED PERIPHERAL HEMATOPOIETIC STEM CELL PRODUCTS

A Donmez, M Tombuloglu, H Aydin, O Gulbahar, S Cagirgan, B Arik, N Gokmen, F Vural, E Gokmen

Ege University, Izmir, Turkey

Background. There is no detailed information about immune phenotypic profile of hematopoietic stem cells (HSC) in different mobilization regimens and gene expression profiles of G-CSF mobilized HSC products. The effects of these properties on the outcome of transplantation largely unknown. *Aims and Methods.* In this prospective study, surface immune phenotypic features (PE-CD11a, FITC-CD18, PE-CD31, APC-CD38, FITC-CD44, APC-CD62e, FITC-CD62L, FITC-CD90, PE-CD117, PE-CD135, PE-CD184) of HSCs which had been mobilized with three different regimens (group I: growth factor alone, group II: cyclophosphamide + growth factor, group III: ESHAP + growth factor) from a total of 44 patients (median age: 46 F/M: 18/28) have been investigated. CD34+ cell sorting was done by flow cytometry (BD FACSAria cell sorter). The relationship between HSC immune phenotype and the duration of the neutrophil and platelet engraftment has also been studied. Additionally, in 9 stem cell products (without cell sorting) which had been mobilized by using G-CSF alone, whole genom expression profiling was carried out. Moreover the effects of these gen profiles on graft versus host disease (GVHD) was evaluated. *Results.* The median duration of neutrophil engraftment after transplantation was 12 (9 - 21) days and platelet engraftment was 12 (7 100) days. The immune phenotypic features of group I, II and III mobilized HSCs were not significantly different. The surface antigens most commonly expressed by CD34 positive stem cells were CD31, CD44, CD90, CD117 and CD135. The CD31 (platelet endothelial cell adhesion molecule-1) positivity ratio of the HSCs were inversely correlated with the duration of the neutrophil (r= -0.32, p= 0.03) and platelet (r= -0.36, p = 0.02) engraftment. No relationship was found between engraftment duration and the expression status of CD184 (CXCR4). There was a relationship between the acute GVHD and the increased expression of genes that are associated with immunity, cell communication and metabolic processes. Another relationship was also found between the development of chronic GVHD and the expression levels of genes which are related to growth and metabolic processes. *Conclusions.* As a result we found that the surface immune phenotypic profiles of CD34+ peripheral HSCs harvested by different mobilization regimens were not different. To our knowledge, it has been demonstrated for the first time that CD31 expression of HSC could positively affect both neutrophil and platelet engraftment. Additionally, CD184 (CXCR4) expression ratio and even CD184 negativity of HSCs have found no effect on neutrophil or platelet engraftment. When these results are evaluated, additional surface antigens (such as CD31) might be more effective in the homing process. More studies investigating the effects of stem cell products whole genom expression on graft versus host disease are needed.

This study was supported by Ege University Research Foundation (2006-TIP-002).

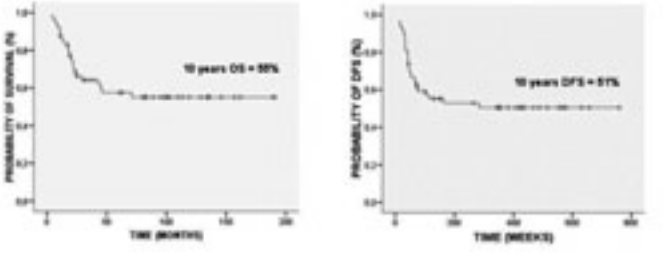
IS THERE STILL A ROLE FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA?

F Al Sabty,[1] E Demeckova,[1] M Hrubisko,[2] E Bojtarova,[1] S Kubalova,[1] B Stancokova,[1] M Mistrik[3]

[1]*University Hospital, Bratislava, Slovakia*
[2]*Slovak Medical University, Bratislava, Slovakia*
[3]*Comenius University, Bratislava, Slovakia*

Background. the role of autologous stem cell transplantation (ASCT) in the treatment of patients with acute myeloblastic leukemia (AML) remains unsettled. *Aims.* we report our results of ASCT in patients with AML during the last 15 years. *Methods.* between December 19, 1994 and May 10, 2010, a total of 63 patients with AML without HLA-matched donor in the department of Hematology and Transfusion Medicine, University Hospital, Bratislava, received an ASCT. The median patient age was 41 years (range 20-61 years). 35 (56%) males and 28 (44%) females. At the time of ASCT, 50 (79%) patients were in first complete remission (CR), 11(18%) patients were in second CR and 2(3%) patients were in relapse. The median time interval from CR to ASCT was 107 days (range 48 - 281). Five (8%) patients received bone marrow (BM), 53 (84%) patients received peripheral blood stem cells (PBSC) and 5 patients (8%) received BM plus PBSC. Patients were stratified into three risk groups; poor, intermediate and good-risk groups on the basis of cytogenetic and molecular analyses at diagnosis. *Results.* with a median follow-up of 92 months (7.6 years), the 10 year overall survival (OS) and disease free survival (DFS) of all patients is 55% and 51%, respectively (Figure 1.). Transplant-related mortality is 6%. The relapse rate is 38% and 9 years probability of relapse is 44%. Low white blood cell count (WBC) at diagnosis, favorable and intermediate cytogenetic-risk was independently associated with clinical outcome by univariate analysis. *Conclusion.* we conclude that ASCT is still an effective post-remission treatment in AML patients without HLA-matched donor; with the possibility of long-term survival or even cure in remarkable proportion of patients with AML, particularly in patients with favorable and intermediate cytogenetic risk.



The 10 years Kaplan-Meier estimated probabilities of overall survival (OS) and disease free survival (DFS) after ASCT for the whole group of patients

Figure 1.

DEVELOPMENT OF RISK SCORE TO PREDICT SIGNIFICANCE OF POSITIVE FUNGAL ISOLATES IN RECIPIENTS OF ALLOGENEIC AND AUTOLOGOUS STEM CELL TRANSPLANTATION

A Khoder,[1] K Tabassum Malik,[1] M Petrou,[2] C Thomas,[2] E Kanfer,[3] D Marin,[3] A Rahemtulla,[3] D MacDonald,[3] D Milojkovic,[3] J Apperley,[3] R Szydlo,[3] K Rezvani[3]

[1]*Imperial College, Lonodn, United Kingdom*
[2]*Microbiology Dept, Hammersmith Hospital, London, United Kingdom*
[3]*Hematology Dept, Hammersmith Hospital, London, United Kingdom*

Background. Invasive fungal infections are a major cause of mortality following stem cell transplantation (SCT). The significance of a positive microbiological isolate with yeasts and molds in this population remains uncertain. *Aims.* to address the clinical significance of isolation of yeasts and mold species from any site in SCT recipients. *Methods.* we retrospectively reviewed all microbiological data, including cultures and direct microscopic examination for yeasts and mold species in 760 autologous SCT (auto-SCT) and 455 allogeneic SCT (allo-SCT) recipients at our institution between 1997 and 2006. Specific fungal species, predisposing factors and survival rates at 100 days after a positive fungal isolate were analysed. *Results.* a total of 494 positive fungal isolates were documented in 187 patients. Fungal isolates were reported in 100 (22%) allo-SCT and 87 (11.4%) auto-SCT recipients. Of these, 407 were yeasts and 87 filamentous fungi. Non-albicans Candida accounted for 57% of all yeasts and Aspergillus species for 74% of filamentous fungi. The 100-day overall survival after a positive fungal isolate was 56.2% for auto-SCT and 59.4% for allo-SCT recipients (p=0.72). In allo-SCT recipients with a positive fungal isolate, the following risk factors were associated with significantly lower 100-day survival on univariate analysis: Neutropenia (37% vs. 51%, p=0.024), immunsuppressive treatment (29% vs. 67%, p=0.033), fungemia (28.6% vs. 57.1%, p=0.035), creatinine >120 µmol/L (35.7% vs. 63%, p=0.013), isolation of non-albicans Candida and aspergillus species (aspergillus species 57.4% vs. non-albicans Candida 46.8% vs. C. Albicans and other yeasts 75%, p=0.021), *in vitro* resistance to >1 antifungal drug (none=63% vs. one=50% vs. two=33.3%, p=0.009), lymphopenia <1x109/L (41% vs. 56%, p=0.003), concurrent fever for >96 hours (32% vs. 66%, p=0.005), respiratory symptoms (20% vs. 78%, p=0.001) and presence of a central line (43% vs. 53%, p=0.004). In auto-SCT recipients with a positive fungal isolate, the only factors associated with lower 100-day survival were creatinine >120 µmol/L (p= 0.0004) and fungemia (P= 0.003). Previous history of positive fungal culture, multiple isolates, abnormal chest X-ray or CT scan were not found to be associated with lower survival. In multivariate analysis only three factors, namely lymphopenia, creatinine >120 µmol/L and respiratory symptoms at the time of isolation remained significant for day-100 survival. Based on these results, we developed a fungal isolate risk score for allo-SCT recipients where each variable was assigned two scores; the presence of respiratory symptoms (yes=2 or no=0), creatinine >120 µmol/L (yes=1 or no=0) and lymphopenia (yes=1 or no=0). Patients with a score of 0-1 (n=18) had a significantly improved 100-day survival (100%) compared to patients who had a risk score of 2-3 (53.7%; n=67). None of the patients with a score of 4 (n=8) survived at 100 days. We propose that based on this risk score, patients with a positive fungal isolate and a score of 0-1 do not require treatment whereas patients with a score of 2-4 are at increased risk of mortality and should be considered for anti-fungal therapy. A prospective study to validate the fungal isolate score is underway.

OUTCOMES OF REDUCED-INTENSITY STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA WITH T(8;21)- IN COMPARISON WITH CONVENTIONAL STEM CELL TRANSPLANTATION

E Ki-Seong,[1] K Hee-Je,[2] C Byung-Sik,[2] L Seung-Eun,[2] Y Seung-Ah,[2] K Yoo-Jin,[2] L Seok,[2] M Chang-Ki,[2] K Dong-Wook,[2] L Jong-Wook,[2] P Chong-Won,[2] M Woo-Sung[2]

[1]*Yeouido St Mary's Hospital, the Catholic University of Korea, Seoul, South-Korea*
[2]*BMT Center, Seoul St Mary's Hospital, the Catholic University of Korea, Seoul, South-Korea*

Background. Patients with t(8;21) generally have a favorable prognosis with a higher rate of first complete remission (CR1) and higher rate of cure with high-dose cytarabine (HDARA-C), precluding these patients as candidates for stem cell transplantation (SCT). However, some studies raised questions regarding improved survival with autologous SCT (ASCT) in these patients. Moreover, there has been some concern that the rate of relapse after HDARA-C is higher than previously reported and although approximately 50% of CBF-AML patients achieve long-term survival, disease relapse is still a major cause of treatment failure. Of CBF-AML, t(8;21) patients are reported to be related to worse outcome than those with inv(16). Therefore, patients with t(8;21) might benefit from more intensive treatment such as SCT. To date, few studies have analyzed the outcome of reduced intensity conditioning (RIC)-SCT for this population specifically. *Aims.* From this point of view, we performed a study to evaluate the efficacy and safety of RIC-SCT for AML with t(8;21) and compared the results with those of the historical cohort who treated with conventional SCT (ASCT or myeloablative-SCT) in our institution. *Methods.* We transplanted 19 adult patients with AML who had t(8;21) after RIC since Mar 2007. RIC regimen consisted of fludarabine, busulfan and low dose total body irradiation. Their clinical features were compared with historical patients who were transplanted with autografting or myeloablative conditioning (MC) in our institution from 2001. *Results.* Probability of overall survival (OS) and disease free survival (DFS) was 77.5 ± 9.9% and 78.2 ± 9.7%, respectively, with a median follow-up of 34 months (range: 13.5+ to 45.2+ months) for surviving patients. 2-year cumulative inci-

dence of relapse (CIR) and nonrelapse mortality (NRM) was 11.9 ± 7.9%, respectively. By univariate analysis, age seems to be a dominant factor affecting DFS and OS in RIC-SCT and ASCT group ($P = 0.025$ and 0.029, respectively, for RIC-SCT group, and $P = 0.036$ and 0.013, respectively, for ASCT group). In ASCT group, presence of -Y was associated with inferior DFS ($P = 0.049$), whereas this difference disappeared when the patients were transplanted with RIC or MC. For patients with autografging, CIR was significantly lower in patients without -Y than with -Y ($P = 0.012$), while there was no difference in NRM between the two subgroups. *Summary/Conclusions.* RIC-SCT is effective treatment modality for AML with t(8;21), judging from little differenes in CIR and survival in comparison with those of MC-SCT, but greater effort should be put to reduce NRM further. Because ASCT was associated with extremely low NRM and demonstrated comparable efficacy to those of allo-SCT, this modality might be a preferable treatment option for this disease except for the subgroup of patients with -Y. In our study, patients with -Y demonstrated inferior survival only in the setting of ASCT, and these differences disappeared in allo-SCT groups, justifying that allo-SCT should be considered in this subgroup of patients. Finally, MC-SCT is not recommended in patients with t(8;21) in CR1 because it has no advantages in terms of relapse and NRM.

1001

TWO DAYS OF ATG IN THE CONDITIONING REGIMEN IS ASSOCIATED WITH A REDUCED INCIDENCE OF BOTH ACUTE AND CHRONIC GVHD WITHOUT INCREASING RELAPSE IN RIC TRANSPLANT FOR HEMATOLOGICAL DISEASES

R Crocchiolo, S Furst, B Esterni, L Castagna, J El-Cheikh, C Faucher, R Devillier, C Oudin, A Granata, D Blaise

Institut Paoli-Calmettes, Marseille, France

Background. the best combination of Fludarabine-Busulphan-ATG (FBA) in reduced-intensity conditioning for allogeneic hematopoietic stem cell transplantation (RIC-AlloSCT) is unknown, busulphan dose being crucial for disease control but limited by a dose-dependent toxicity and ATG playing a pivotal role in the prevention of both acute and chronic GvHD but with a potential higher relapse rate associated with higher doses. *Aims.* here we compared two FBA regimens among adult patients transplanted at our Institution for a hematological malignancy. We aimed identifying the impact of ATG dose on GvHD and other transplant outcomes. *Methods.* ATG was administered at a total dose of 2.5 mg/kg (1-day ATG) or, more recently, 5 mg/kg (2-day ATG). The effect of ATG dose on transplant outcomes was analyzed, both in univariate and multivariate analysis. *Results.* 124 patients and 105 patients were included in the 1-day and 2-day groups, respectively. The two cohorts significantly differed for: follow-up duration, year of transplantation, patient's age, patient/donor gender matching, busulfan formulation and donor type. No significant difference in OS, NRM, relapse/progression between the two ATG groups was observed, both in univariate and multivariate analysis. On the other hand, incidence of acute and chronic GvHD differed among the two groups, with a significant reduction of acute and chronic GvHD in the 2-day ATG patients, both in univariate and multivariate analysis. Multivariate hazard ratio (95% CI) of grade 2-4 acute GvHD was 0.27 (0.12 - 0.59) and for grade 3-4 acute GvHD was 0.26 (0.10 - 0.69); p=0.001 and p=0.007 respectively. The same protective effect played by ATG 5 mg/kg was also found on chronic GvHD, both overall and extensive form. Multivariate hazard ratio (95% CI) of extensive chronic GvHD was 0.23 (0.12-0.46) in the 2-day ATG vs. 1-day ATG group, with a p<0.0001. It is worth noting that the increased ATG dose was not associated with a higher risk of relapse or progression. *Conclusions.* in this monocenter series it seems that a higher dose of ATG significantly reduces the incidence and severity of acute and chronic GvHD, without increasing disease relapse. Taken together, present results show that a FBA-based regimen including two days of ATG appears to confer better outcomes in terms of GvHD and disease control and might represent an optimal dosage. Prospectively assessment is of interest.

1002

STUDY OF THE EFFECT OF TEMPERATURE IN PRE-FREEZING OVERNIGHT STORAGE IN 268 AUTOLOGOUS LEUKAPHERESIS PRODUCTS

M Lopez,[1] M Majado,[2] M Blanquer,[2] A Sanchez-Salinas,[2] E Salido,[2] C Funes,[2] C Gonzalez-Garcia,[2] P Menchon,[2] V Sanchez-Ibañez,[2] V Cabañas-Perianes,[2] C Garcia-Insausti,[2] JM Moraleda[2]

[1]*Hospital Universitario Virgen de la Arrixaca, Murcia, Spain*
[2]*S de Hematologia, Murcia, Spain*

Background. In autologous peripheral blood progenitor cells (PBPCs) overnight storage of leukapheresis (LAPH) products is necessary when immediate processing is not possible. Properties of PBPCs, could be altered by storage before cryopreservation. *Aims.* The aim of this study is to evaluate the effect of overnight (ON) storage, at 4°C (group A) and 20°C (group B), comparing the results with those of immediate freezing (IF) as well as to analyze the influence of the storage temperature. The viability, percentage of CD34+ cells, CFU-GM and bacterial contamination were analyzed. *Methods*. The LAPH performed, for PBPCs autologous transplantation, in our hospital in the last ten years were reviewed. Only those patients in which both, IF and ON storage, were done are studied in this report. PBPCs were cryopreserved with DMSO at final concentration of 10% plus autologous plasma or blood bank ABO isogroup plasma. CD34-positive cells were counted following the International Society for Haematotherapy and Graft Engineering protocol. CFU-GM assay was performed in agar-gel feeder-layer or enriched semisolid culture media, Methylcellulose Medium. The same culture method was always used to compare pre-freezing and post-thawing samples of the same cryo-preserved cell batch. Cell viability was determined by 0.2% Trypan blue dye exclusion test. Bacterial cultures were done immediately after mixing PBPCs with DMSO and in the post-thawing sample. The results pre-freezing and post-thawing were compared, as well as recovery in both storage temperatures. T-test was used to compare CD34+ cells, CFU-GM and viability, pre-freezing and post-thawing, and the recovery with both temperatures. Chi-square-test was used for bacterial contamination comparison. *Results.* A total of 123 patients, with 268 PBPCs LAPH (92 in group A and 176 in group B), were included. The median, aged was 49 years (3-73). Diagnoses were: 40 MM, 23 breast cancer, 22 NHL, 12 HD and 26 others diagnoses. Mobilization was done with: chemotherapy+G-CSF (17%), cyclophosphamide (1.5/m2)+G-CSF (57%) or G-CSF (26%). Half of the LAPH were IF and half were ON stored: 46 LAPH at 4°C, and 88 at 20°C.In the group A there were 92 LAPH (46 IF and 46 ON), and in the group B there were 176 (88 IF and 88 ON). In group A no significant difference was found between the IF CD34+ recovery (127.7±67.4) compared with those ON stored at 4°C (112.1±43.2). There were not significant differences in group B between IF (121.5±91.7) and 20°C (118.7±123.6).When the recovery of CFU-GM in group A, IF and ON storage, were compared no difference was found; the same occurred in group B. However, the pre-freezing viability was significantly decreased in the ON samples in both groups, in comparison with IF, (86.7±56.2% vs 92.3±5.7% in group A) and (76.3±15.7% vs 86.0±11.7% in group B). No statistical difference was found when viability, CFU-GM and CD34+ cells recovery between both groups were compared. The bacterial contamination incidence was not different in both groups. *Conclusions.* These data suggest that the ON pre-freezing temperature does not affect seriously the PBPCs quality. However, viability decreases when freezing is not performed immediately.

Background. High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) is considered standard of care for a variety of hematologic malignancies including Multiple Myeloma (MM), Non-Hodgkin Lympoma (NHL) and Hodgkin Lymphoma (HL). A significant proportion of patients fail to mobilize and collect a minimum of $2x10^6$ CD34+ cells/kg and a number of factors have been reported to

impact hematopoietic stem cell (HSC) mobilization, including baseline platelet counts. Thrombocytopenia prior to mobilization with G-CSF±chemotherapy is a significant predictive factor for mobilization failure in patients with Hodgkin's and non-Hodgkin's lymphoma *(Hosing C, Am J Hematol. 2009). Aims.* The purpose of this retrospective analysis is to assess the efficacy of HSC mobilization with plerixafor plus G-CSF in patients with low platelet counts. *Methods.* Patients who had failed at least 1 previous HSC mobilization were remobilized with plerixafor plus G-CSF as part of the European compassionate use program (CUP). G-CSF (10µg/kg) was administered subcutaneously (SC) every morning for 4 days and plerixafor (0.24 mg/kg SC) was administered in the evening on Day 4. On Day 5, G-CSF was administered and apheresis was initiated. Plerixafor, G-CSF and apheresis were repeated daily until patients collected the minimum of $2x10^6$ CD34+ cells/kg. *Results.* Data on platelet counts prior to mobilization are available for 189 patients from our European CUP database. Of these, 86 patients presented platelet counts ≤150 $x10^9$/L, median 115, range 18-150; NHL=40, MM=32, HL=10, other=4; 55% male; median age 57 years, range 20-75; median number of prior therapy regimens 3, range 1-10, and 103 patients had normal platelet counts >$150x10^9$/L, median 225, range 151-442; NHL=45, MM=37, HL=21; 53% male; median age 54 years, range 24-72; median number of prior therapy regimens 2, range 1-8. Following a similar number of aphereses in both cohorts (median 2, range 1-4), the median CD34+ cell yield was significantly higher in the normal platelet group ($3.2x10^6$/kg, range 0.5-32.6) than in thrombocytopenic patients ($2.56x10^6$/kg, range 0.18-9.2; p<0.001). Also a significantly higher proportion of patients achieved the target cell dose of $2x10^6$ CD34+ cells/kg in the normal platelet group (86% versus 58%, p<0.001). Sixty-five per cent of patients with normal platelet counts and 45% in the thrombocytopenic group have undergone ASCT, with similar time to neutrophil and platelet engraftment in both groups. *Conclusions.* In keeping with previous reports in first line mobilization, our data suggest that thrombocytopenia prior to remobilization with plerixafor and G-CSF remains a significant predictive factor for mobilization failure compared with patients with normal platelet counts. Nevertheless, 58% of such thrombocytopenic patients, who have already failed prior mobilization attempts, can be successfully rescued with plerixafor and G-CSF to collect ≥$2x10^6$ CD34+ cells/kg. Overall, this strategy provides a remarkable success rate in the mobilization of these challenging patients and subsequently proceeding to transplantation, compared with published alternatives for thrombocytopenic patients.

VARIABLES AFFECTING HEMATOPOIETIC STEM CELL MOBILIZATION FOR HIGH DOSE CHEMOTHERAPY AND STEM CELL RESCUE IN CHILDREN

J Sevilla, M Guillén, A Castillo, C Hernandez, M Cormenzana, M Andion, M Gonzalez-Vicent, A Lassaletta, A Perez, L Madero, M Diaz

H. Infantil Universitario Niño Jesús, Madrid, Spain

Background. A SDF-1alpha/CXCR4 binding inhibitor has been recently approved for adult patients diagnosed with multiple myeloma or lymphoma to enhance mobilization of hematopoietic stem cells (HSC) to peripheral blood (PB). Experience in children, however, is extremely limited. We have conducted a retrospective study in order to analyze variables related to poor mobilization in children to identify those patients who will likely benefit on the use of this new drug. *Aims.* To analyze variables related to poor mobilization of peripheral blood progenitor cells in children. *Methods.* We analyzed data prospectively recorded, since January 2000, from 183 consecutive patients mobilized with filgrastim at different doses prior to HSC collection. CD34+ cells on PB before the first apheresis were evaluated to consider poor mobilizers. Patients with less or equal to 10 CD34+cells/mcl on PB were considered poor mobilizers independently if they underwent collection or not. In our experience most children reach the target CD34+ cell dose after several procedures, even those considered as poor mobilizers, but in this study we tried to identify those who will likely benefit of new mobilization agents. All procedures were performed in the Transfusion Service at Hospital Infantil Universitario Niño Jesús (Madrid). Patients' diagnosis were as follows: central nervous system tumours 51(28%), Ewing sarcoma 42 (23%), neuroblastoma 35 (19%), rabdomyosarcoma 5 (3%), Wilms tumour 3 (2%), Osteosarcoma 6 (3%), Non-Hodgkin lymphoma 20 (11%), Hodgkin disease 12 (6%) and others 9 (5%). Disease status was: first complete remission 107 (59.1%), partial remission 44 (24.3%), disease progression 13 (7.7%), and complete remission after first relapse 17 (9.4%). Median age was 7 years (1-18), and median weight 23 kg (5-111). Mobilization regimens included: G-CSF 12mcgr/kg/12h (64.09%), 10mcgr/kg/24h (3.31%), 12mcgr/kg/24h (24.31%), 10mcgr/kg/12h (7.18%), others (1.1%). Contingency table was applied for categorical variables on the univariate analysis. Correlations were determined using logistic regression. *Results.* Median CD34+cells on PB before the collection was 40 (1-495). Twenty-six patients had less or equal than 10 CD34+ cells/mcl before the collection (14%). Of those, only 7 patients did not undergo HSC collection. Several variables were studied, but only radiotherapy was related on univariate analysis to poor mobilization (p=0.01). Other variables showed clear tendency but did not reach statistical signification: type of mobilization (p=0.14); age (p=0.15); diagnosis (p= 0.08); disease status ((p=0.08). We define a risk score giving one point each to radiotherapy, chemotherapy more than 6 cycles of chemotherapy before the mobilization, and age older than 9 year old. Those patients with 2 or 3 points have higher risk of mobilization failure (p=0.01). When these variables were included in a multivariate analysis, only prior radiotherapy HR 0.08 (0.18-0.35) p = 0.0009; and mobilization with 12 mcg/kg/day HR 0.29 (0.09-0.95) p=0.04, were related to poor mobilization. *Conclusion.* Prior use of radiotherapy is the main variable related to poor mobilization in children. No single variable is helpful to anticipate the need for using new mobilization agents in children. Only those patients with several risk factors may be candidates to be considered as potentially at risk for poor mobilization.

Background. Patients with multiple myeloma (MM) who are refractory to bortezomib and lenalidomide (double refractory) have limited treatment options and less than a year of life expectancy. In prior phase 1 and 2 studies, pomalidomide was administered at 4mg, 21 days of each 28-days or at 2mg 28 days of each 28-days. Additional responses were achieved by patients escalated to 4mg and in combination to dexamethasone. *Aim.* We have designed a phase 2 multicenter, randomized, open-label study aimed to determine the efficacy and toxicity profile of 2 modalities of pomalidomide in double refractory patients. *Method.* The patients had symptomatic, progressive, measurable and double refractory MM. The primary objective was to determine response rate (PR and better) to pomalidomide and dexamethasone using IMWG response criteria. The response and FISH cytogenetic analysis were assessed centrally. Pomalidomide was given orally either 4 mg daily on days 1-21 of each 28-days (arm A) or continuously on days 1-28 of each 28-days (arm B). Dexamethasone was given orally at 40 mg weekly. All patients received prophylaxis against venous thromboembolism. *Results.* Eighty three patients (56 male and 27 female) were enrolled between August first and June first, 43 in arm A and 40 in arm B, respectively. The median age was 54 years (range, 36-78). The median time from diagnosis to enrolment was 55 months (range 11-227) in arm A and 76 (30-281) in arm B. All patients had loss of 17p and t(4;14) cytogenetic abnormalities studied on bone marrow plasma cells. As of August first, the median follow-up was 119 days. The median number of cycles administered was 4 in either arm. Overall, 40 and 36 patients were evaluable for response evaluation in arm A and B, respectively. In arm A, 12 (30%) patients had PR and better, including 3 VGPR, and 21 (52%) had stable disease. In arm B, 17 (47%) patients had PR and better, including 1 VGPR, and 15 (41%) had stable disease. The median duration of response was 77 and 89 days in arm A and B, respectively. Twenty three (57%) and 22 (61%) patients remained progression free, and 5 patients have died in either arm, respectively. Toxicity (at least possibly related to treatment) consisted primarily of myelosuppression in both arms. The occurrence of neuropathy was not observed nor worsening of pre-existing neuropathy. No thromboembolic events have occurred. *Conclusion.* Pomalidomide and dexamethasone is active and well tolerated in this heavily pre-treated population of lenalidomide and bortezomib-refractory MM patients. This study provides further evidence that pomalidomide has no-cross resistance with lenalidomide and suggests that it can provide benefit for patients who have relapsed after other novel therapies. Final results will be provided at EHA 2011.

1006

RESULTS OF AN INTERNATIONAL, RANDOMIZED PHASE II CLINICAL TRIAL OF BORTEZOMIB ± MAPATUMUMAB (TRAIL-R1 AGONIST MONOCLONAL ANTIBODY) FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA (MM)

Background. Development of new therapies for patients with relapsed/refractory MM remains an important clinical need. Monocolonal antibodies (mAb) have made an important impact in B-cell cancers especially when combined with chemotherapeutics. Unfortunately, currently there are no approved mAb for MM patients. Mapatumumab is a fully human mAb that targets and activates the TRAIL-R1 receptor. In preclinical MM models, enhanced efficacy of bortezomib was noted when combined with mapatumumab. *Aims.* Based on these preclinical observations, a randomized phase II clinical trial was designed to evaluate the clinical efficacy of mapatumumab when added to bortezomib. *Methods.* Informed consent was obtained from all patients participating in this study. Patients with relapsed or refractory MM, who had measurable M-protein in serum and/or urine and had failed up to 2 prior therapies, were eligible for participation in this study. Patients were excluded if they had received prior bortezomib. Response was evaluated using the Bladé criteria. Treatment: Patients were randomized to either Arm A (bortezomib 1.3 mg/m2 on days 1, 4, 8, 11 every 21 days) or Arm B10 (bortezomib + mapatumumab 10 mg/kg on day 1 every 21 days) or Arm B20 (bortezomib + mapatumumab 20 mg/kg on day 1 every 21 days). Patients received a maximum of 17 cycles (1 year) and treatment was discontinued at any time for progressive disease or unacceptable toxicity. Subjects with complete response (CR) were treated for an additional 2 cycles after documentation of CR (not to exceed 17) and then followed to progression. This trial is registered with clinicaltrials.gov, number NCT00315757. *Results.* A total of 104 subjects were randomly assigned to the treatment arms. The median age of patients was 61.7 and mean prior therapies 1.6. Toxicity: The most common toxicities observed were hematological and peripheral sensory neuropathy. In general, addition of mapatumumab did not alter or enhance the toxicity profile of bortezomib. Overall incidence of grade 3/4 toxicity in Arms A, B10 and B20 was 88.6% 69.7%, and 61.1%, respectively. Efficacy: The ORR was 51.4%, 30.3% and 52.8% and the median duration of response was 8.5, 9.3

Table 1.

	Arm A (n = 35)	Arm B10 (n = 33)	Arm B20 (n = 36)
CR	0	0	2
PR	18	10	17
CR + PR n(%)	18 (51.4)	10 (30.3) p = 0.09[a]	19 (52.8) p = 0.91[b]
Median PFS mo (95%CI)	9.7 (7.8, 10.0)	4.7 (2.5, 7.4) p = 0.29[a]	5.7 (5.2, 8.9) p = 0.21[b]
Median Duration of Response mo (range)	8.5 (6.9, 14.2)	9.3 (3.9, 16.1) p = 0.92[a]	7.6 (4.3, 8.6) p = 0.41[b]
[a]p value for comparison of Arm A with Arm B10 [b]p value for comparison of Arm A with Arm B20			

and 7.6 months, in arms A, B10 and B20, respectively (Table). *Summary/Conclusions.* Mapatumumab is a novel mAb that effectively engages TRAIL-R1. Encouraging preclinical observations led to a well designed randomized phase II clinical trial to determine safety and effectiveness of targeting TRAIL-R1 in MM. Our studies demonstrate that mapatumumab was well tolerated with no significant toxicity when added to bortezomib. However, in patients with rel/ref MM, mapatumumab failed to improve meaningful clinical endpoints. As TRAIL-R1 remains an important therapeutic target in cancer and mapatumumab is actively investigated in other malignant disorders, our data provide valuable insight into the tolerability and expected toxicity of two different doses of this novel drug. Detailed safety and efficacy analyses will be presented at the meeting.

Background. Elotuzumab is a humanized monoclonal IgG1 antibody targeting human CS1, a cell surface glycoprotein. CS1 is highly and uniformly expressed on multiple myeloma (MM) cells, with limited expression on natural killer (NK) cells and CD8+ cells and little to no expression in most other normal tissues. Preclinical data indicate that the mechanism of action is primarily through NK-mediated antibody-dependent cellular cytotoxicity. In a MM xenograft mouse model, the antitumor activity of elotuzumab was enhanced by the addition of lenalidomide, significantly reducing tumor volume compared with either agent alone. A phase 1 study of elotuzumab plus lenalidomide and low-dose dexamethasone demonstrated an 82% response rate but did not identify a maximum tolerated dose in patients with relapsed/refractory MM. Responses proved durable; median time to progression not reached at a median follow-up of 12.7 months. *Aims.* To assess the efficacy and safety of elotuzumab in combination with lenalidomide and low-dose dexamethasone and determine the optimal dose of elotuzumab (10 mg/kg vs 20 mg/kg). *Methods.* Patients with relapsed/refractory MM who had received 1-3 prior therapies (excluding lenalidomide) were randomized to elotuzumab 10 mg/kg or 20 mg/kg IV (days 1, 8, 15, and 22 every 28 days in the first 2 cycles and days 1 and 15 of subsequent cycles), lenalidomide 25 mg PO (days 1-21) and dexamethasone 40 mg PO weekly. Prophylaxis for potential elotuzumab infusion-related adverse events (AEs) consisted of methylprednisolone (50 mg IV), diphenhydramine (25-50 mg PO or IV) or equivalent, ranitidine (50 mg IV) or equivalent, and acetaminophen (650-1000 mg PO). Treatment continued until disease progression or unacceptable toxicity. All patients provided informed consent. Objective responses were assessed according to IMWG criteria. *Results.* Among 63 enrolled patients (median age 63 years; range, 39-82), 57% had ≥2 prior therapies, 54% had prior bortezomib, 59% had prior thalidomide, and 52% had a β2 microglobulin level ≥3.5mg/L. In total, 81% of patients had ≥ partial response (PR) including 37% ≥ very good PR. Overall response rates (ORR; defined as ≥PR) were 90% in the 10 mg/kg group (n=31) and 72% in the 20 mg/kg group (n=32). Results were similar irrespective of prior thalidomide, prior bortezomib, number of previous therapies, and β2 microglobulin. Median time to response was 30 days (range, 21-100). After a median follow-up of 4.9 months, median progression-free survival had not been reached; 9 (14%) patients have progressed. The most common grade 3/4 treatment-emergent AEs were neutropenia (14%), lymphopenia (14%), and thrombocytopenia (13%). The most common infusion-related AEs were grade 1/2 nausea (16%), dizziness (13%), headache (13%), and pyrexia (10%). One patient had a grade 3 infusion reaction AE (rash). No patient withdrew due to an infusion reaction. *Summary/Conclusions.* Elotuzumab plus lenalidomide/dexamethasone resulted in rapid and high ORR in patients with previously-treated MM. The most common grade 3/4 treatment-emergent AEs were cytopenias. With premedication the incidence and severity of infusion reactions were low. Further clinical study of this combination using 10 mg/kg elotuzumab is warranted; a phase 3 trial is planned in 2011 (NCT01239797). Updated results will be presented at the meeting.

1008

BORTEZOMIB(VELCADE®)-THALIDOMIDE-DEXAMETHASONE (VTD) IS SUPERIOR TO THALIDOMIDE-DEXAMETHASONE (TD) IN PATIENTS WITH MULTIPLE MYELOMA (MM) PROGRESSING OR RELAPSING AFTER AUTOLOGOUS TRANSPLANTATION

In 2006, the EBMT and the IFM initiated a prospective, randomized, parallel-group, open-label phase III, multicenter study, comparing VTD (arm A) with TD (arm B) for MM patients in first progression/relapse after at least one autologous transplantation. TTP was the primary end point. Treatment was: bortezomib 1.3 mg/m2 as an i.v bolus on days 1, 4, 8 and 11, followed by a 10-day rest period (days 12 to 21), for 8 cycles (6 months) and then on days 1, 8, 15 and 22, followed by a 20-day rest period (days 23 to 42), for 4 cycles (6 months). In both arms, thalidomide was administered at 200 mg/day for 1 year and dexamethasone at 40 mg/day orally for 4 days every 3 weeks for 1 year. Response was assessed by EBMT criteria. Adverse events were graded by the NCI-CTCAE, Version 3.0. *Results.* On 01/07/10, a first interim analysis based on 246 patients and 134 events was performed. The trial was then stopped because of superiority of VTD over TD. We report an updated analysis as of 02/12/10. 267 patients (135 in arm A, 132 in arm B) had been enrolled in the study and 157 events had been observed. The median age was 61 years (range 29-76) The stage according to the ISS was I in 56 %, II in 27 %, III in 17 %. The number of previous autologous transplants was one in 71 vs 69 patients and two or more in 64 vs 63 patients, in arms A and B respectively. The median follow-up was 27 months. The median TTP was 19.5 vs 13.8 months respectively in arms A and B, with a cumulative incidence of relapse/progression at 2 years of 56% vs 71% (p=0.0011). The median PFS was 18.6 vs 12.7 months with a cumulative incidence at 2 years of 37% vs 23% (A vs B, p=0.0011). The OS in the first two years was 72% vs 68% (p=0.18). The probability of achieving CR and CR+PR

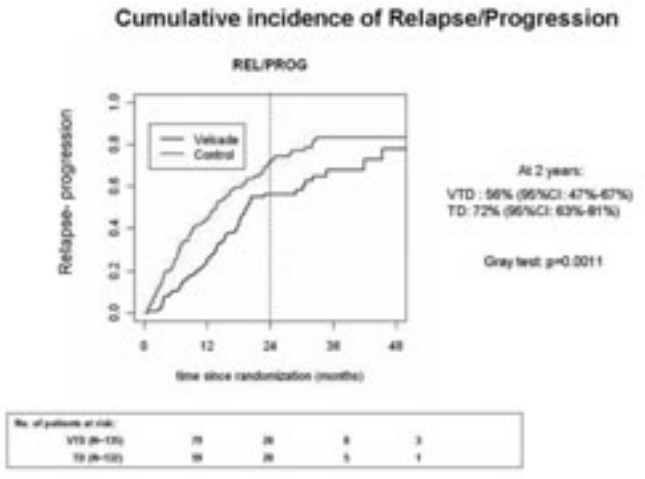

Figure 1.

during the first year was 32% vs 12% and 90% vs 69% with VTD and TD (p=0.0001, and p=0.0001). In the VTD and TD arms, the mean number of treatment cycles for the first 8 cycles were 6.25 vs 6.88 and for the 12 cycles, 7.56 vs 9.93 respectively. Treatment was discontinued due to toxicity in 48 patients (VTD= 36, TD=12). 33 patients died during the treatment period (VTD= 14, TD= 19).The incidence of thrombo-embolic events >= grade 3 was similar in the two arms (6.6% vs 5.2%, p=ns, VTD vs TD) while >= grade 3 thrombocytopenia was higher with VTD (16% vs 7%, p= 0.025). *Conclusion.* VTD resulted in significantly longer TTP and PFS in patients relapsing after ASCT with an acceptable toxicity. Protocol EU-DRACT number: 2005-001628-35.

Background. Multiple myeloma (MM) is an incurable malignancy characterized by multiple relapses, and eventually, refractory disease and death. In a pooled update of the phase 3 MM-009/010 trials comparing Len + Dex vs placebo plus dexamethasone (PBO + Dex), Dimopoulos *et al.* (2009) reported that overall survival (OS) was significantly longer in patients treated with Len + Dex vs PBO + Dex (median of 38.0 vs 31.6 months, respectively; P = 0.045). However, with longer survival a greater number of SPMs may be observed. Cancer registry data (2003-2007) indicate that the incidence of all invasive cancers increases from 0.8 per 100 person-years in persons aged 55-59 to 2.2 per 100 person-years among persons 85+, respectively (Surveillance, Epidemiology, and End Results [SEER] 2010; myelodysplastic syndromes [MDS] not included). Moreover, this incidence may be higher in patients with MM as result of immune deficiency and underlying genetic predisposition. *Aim.* This post hoc analysis of pooled MM-009/010 data was conducted to compare incidence rates (IRs) of SPMs between treatment arms and to compare these IRs with IRs of invasive cancers among similarly aged persons in the general population. *Methods.* Potential SPMs were identified by review of medDRA terms under the "Neoplasm" System Organ Class. SPM incidence rates per 100 person-years were evaluated during active, double-blind treatment. *Results.* The overall incidence of SPMs was low. There were 2 cases of MDS in the Len + Dex arm, and no cases of acute myeloid leukemia or B-cell malignancies in either arm. Non-melanoma skin cancers were noted in 14 Len + Dex patients and 2 PBO + Dex patients. Seven cases of solid tumors (5 with Len + Dex and 2 with PBO + Dex) occurred during double-blind treatment. IRs were similar between treatment arms. With an additional 1.5 average person-years during the extended follow-up phase, only one new SPM was identified in the Len + Dex arm, likely reflecting limitations in SPM ascertainment as only survival information was collected during this study phase. *Conclusions.* With a median follow-up of 48 months, a significant OS benefit for Len + Dex treatment in RRMM patients was observed. The number of SPMs was low and IRs during active treatment (when medical surveillance could be expected to be most equivalent) did not differ between treatment arms. Importantly, IRs in both arms were comparable to the expected background incidence of invasive cancer among older individuals. The low number and type of SPMs seen did not change the benefit-risk profile for lenalidomide in RRMM patients, especially given the survival advantage seen with this therapy. The role of lenalidomide in the RRMM setting is confirmed as an effective treatment option.

Table 1.

Variable	Len + Dex (n = 353)	PBO + Dex (n = 350)
Double-Blind Treatment		
Person-years	471.01	222.65
Cases of invasive malignancies*	5	2
IR per 100 person-years (95% CI)	1.06 (0.39-2.35)	0.90 (0.15-2.97)

*MDS and non-melanoma skin cancers not included

A NEW PROGNOSTIC SCORE (EUTOS SCORE) PREDICTING CYTOGENETIC RESPONSE AND PROGRESSION-FREE SURVIVAL IN 2060 PATIENTS WITH CHRONIC MYELOID LEUKEMIA ON IMATINIB TREATMENT

M Baccarani,[1] J Hasford,[2] V Hoffmann,[2] J Guihot,[3] S Saussele,[4] G Rosti,[1] F Guilhot,[3] K Porkka,[5] G Ossenkoppele,[6] D Lindoerfer,[2] B Simonsson,[7] M Pfirmann,[2] R Hehlmann[4]

[6]*VU Medical Center, Amsterdam, Netherlands*
[7]*Akademiska Sjukhset, Uppsala, Sweden*

Background. The outcome of chronic myeloid leukemia (CML) has been profoundly changed by tyrosine kinase inhibitors (TKI), but the prognosis of CML is still based on prognostic scores developed in the chemotherapy and interferon era. *Aims.* We analyzed for prognosis a multicentric multinational series of 2060 Ph+ BCR-ABL + CML patients who were treated front line with Imatinib or an Imatinib-based regime. *Methods.* First, we examined the relationships between the time of achieving a complete cytogenetic response (CCgR) during the first 18 months of therapy, the probability of achieving a CCgR later on, and the risk of progression to accelerated phase (AP) or blast phase (BP) after 18 months. *Results.* It was found that the most powerful predictor was the Cg status at 18 months, since only 31% of the pts who were not yet in CCgR at 18 mo, achieved a CCgR later on, and 23% of them progressed after 18 months. The whole series was then divided in a learning sample and a validation sample. The analysis of the learning sample, by logistic regression and chi-squared tests, identified spleen size (assessed by manual palpation and measured in cm below costal margin) and blood basophils percentage as the most significant prognostic variables. Using spleen size and basophils (7 x basophils + 4 x spleen size), a risk score could be assigned to all patients, and by the minimal p-value approach a "high risk"and a "low risk"group were identified (score more than 87 vs equal / less than 87). The score was validated in the validation sample. The positive predictive value of the new score was 34%, the sensitivity was 21%, and the specificity was 92%. Progression-free survival at 5 years was 90% (95% CI 88-92%) for high risk patients and 82% (95% CI 73-89%) for low risk patients. *Conclusions.* The power and the efficacy of TKIs are such that it is increasingly difficult to elaborate a prognostic system, but the new EUTOS score marks a significant improvement over prior, Sokal and Euro scores, and can be easily applied in clinical practice, until new biologic and molecular factors will be identified and shown to predict better the outcome and to select the treatment.

1011

EFFICACY AND SAFETY OF DASATINIB COMPARED WITH IMATINIB IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): MINIMUM 24-MONTH FOLLOW-UP FROM THE DASISION TRIAL

A Hochhaus,[1] N Shah,[2] J Cortes,[3] M Baccarani,[4] B Bradley-Garelik,[5] C Zhu,[5] H Kantarjian[3]

[1]*Universitätsklinikum Jena, Jena, Germany*
[2]*University of California, San Francisco, California, United States of America*
[3]*University of Texas MD Anderson Cancer Center, Houston, Texas, United States of America*
[4]*University of Bologna, Bologna, Italy*
[5]*Bristol-Myers Squibb, Wallingford, Connecticut, United States of America*

Background. In the phase 3 DASISION trial, first-line dasatinib showed higher and faster rates of complete cytogenetic response (CCyR) and major molecular response (MMR) compared with imatinib in patients with newly diagnosed CML-CP (Shah, Blood 2010; 116: abs 206). *Aims.* Assess 2-year efficacy and safety in the DASISION trial. *Methods.* After informed consent, patients were randomized 1:1 to dasatinib 100 mg once daily (QD) (n=259) or imatinib 400 mg QD (n=260). Primary endpoint was confirmed CCyR (cCCyR) rate (CCyR on two consecutive assessments) by 12 months. *Results.* Minimum 24-month follow-up will be presented. After 19.7 months' median follow-up (range 0.1-31.4), 81% and 80% of dasatinib-treated and imatinib-treated patients remained on therapy. 18-month cumulative response rates for dasatinib vs imatinib were: cCCyR 78% vs 70% (P=0.0366), CCyR 84% vs 78% (P=0.0932); and MMR 56% vs 37% (P<0.0001). MMR was more frequent with dasatinib in all Euro risk groups. BCR-ABL transcript levels ≤0.0032% (International Scale) occurred in 13% with dasatinib and 7% with imatinib (P=0.0119). Median time to CCyR or MMR calculated using competing risk analysis was shorter with dasatinib vs imatinib (CCyR: 3.2 vs 6.0 months; MMR: 15 months vs not yet reached). Transformation to accelerated/blast phase (AP/BP) occurred in six (2.3%) dasatinib-treated vs nine (3.5%) imatinib-treated patients; one additional patient transformed 183 days after discontinuing dasatinib; no patient achieving MMR transformed. Protocol-defined progression (death from any cause, transformation to AP/BP, increasing WBCs, loss of complete hematologic response or major cytogenetic response) occurred in 15 patients (5.8%) in each arm. For dasatinib vs imatinib, 18-month overall survival rates were 96% vs 98%, progression-free survival rates (no transformation to AP/BP or loss of response) were 95% vs 94%, failure-free survival rates (ELN 2006 criteria) were 93% vs 90%, and maximum clinical benefit rates (no progression, failure, or intolerance) were 87% vs 86%. Longer follow-up is needed and 5-year follow-up is planned. Drug-related nonhematologic adverse events (AEs; any grade) in ≥10% of patients (dasatinib vs imatinib) were fluid retention (23% vs 43%; including superficial edema: 10% vs 36%, pleural effusion: 12% vs 0%), diarrhea (18% vs 19%), nausea (9% vs 21%), vomiting (5% vs 10%), myalgia (22% vs 38%), fatigue (8% vs 11%), headache (12% vs 10%), and rash (11% vs 17%); grade 3/4 rates for these AEs were ≤1%. Only dasatinib-treated patients experienced pleural effusion (2% grade 1, 9% grade 2, <1% grade 3), which did not seem to impact efficacy. Grade 3/4 cytopenia rates with dasatinib vs imatinib were: anemia, 11% vs 7%; neutropenia, 22% vs 20%; and thrombocytopenia, 19% vs 10%. Most cytopenias (75%) occurred within 4 months of treatment. Grade 3/4 lab abnormality rates were ≤3% in both arms, except hypophosphatemia (dasatinib 5%, imatinib 24%). For dasatinib vs imatinib, 56% vs 39% had dose interruption, 25% vs 14% had dose reduction, and 6% vs 4% discontinued due to AEs. *Conclusions.* After 18 months, dasatinib continues to show significantly higher cCCyR and MMR rates over imatinib and remains generally well tolerated, supporting first-line dasatinib use in newly diagnosed CML-CP.

1012

TREATMENT OF CHRONIC PHASE (CP) CHRONIC MYELOID LEUKEMIA (CML) PATIENTS WHO HARBOR THE BCR-ABL T315I MUTATION WITH SUBCUTANEOUS OMACETAXINE RESULTS IN IMPROVED SURVIVAL COMPARED TO HISTORICAL DATA

N Nanda,[1] C Cortes,[2] J Lipton,[3] D Rea,[4] R Digumarti,[5] C Chuah,[6] AC Benichou,[1] A Craig,[1] M Michallet,[7] F Nicolini[7]

[5]*Nizam's Institute if Medical Sciences, Hyderabad, India*
[6]*Singapore General Hospital, Singapore, Singapore*
[7]*Hematology department, Hôpital Edouard Herriot, Lyon, France*

Background. Point mutations in the ABL kinase domain are emerging as the most frequent cause of drug resistance in CML with the specific T315I point mutation conferring the highest level of resistance to all approved TKIs. The T315I mutation is associated with disease progression and a poor prognosis. In the largest retrospective study of the natural history of T315I+ CML patients in CP, the median survival was only 22.4 months with a survival rate of 71% at one year from time of mutation detection (Nicolini *et al.*, 2009). New therapies, particularly ones that are independent of Bcr-Abl inhibitions are needed to provide a solution for this "Achilles Heel"in the TKI armamentarium and prolong survival in T315I patients. *Aim.* To evaluate the safety and efficacy of subcutaneously (SC) administered omacetaxine in imatinib-resistant T315I+ CML-CP patients. *Methods.* 62 adult CML-CP patients, who signed an informed consent, harboured the T315I mutation as confirmed by direct sequencing or DHPLC in a central laboratory, and demonstrated hematologic or cytogenetic resistance to imatinib therapy were enrolled in this study making it the largest prospective study in this patient population worldwide. Induction treatment con-

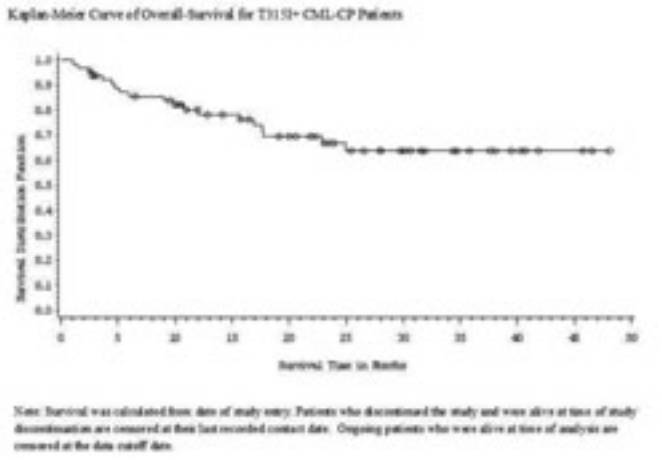

Figure 1. KM Curve of overall-survival.

sisted of 1.25 mg/m2 SC omacetaxine bid for 14-days every 28 days until hematologic improvement, followed by maintenance schedule of 1.25 mg/m2 SC omacetaxine bid for 7-days every 28 days and adjusted for tolerance. The primary efficacy endpoints were the achievement of complete hematologic response (CHR) and major cytogenetic response (MCyR) and a key secondary endpoint was median overall survival. *Results.* For the 62 CML-CP Patients enrolled the median age at entry was 59 yrs (26-83) with 69% male and a median disease duration of 51 months (13-234). All patients failed prior imatinib therapy, and 75% failed two or more prior TKIs (24% failed 3 or more TKIs). The median follow-up time was 19.1 months (1-48). CHR was achieved in 47 (76%) patients with a median duration of 8.9 months (1.5-43.6+) and MCyR was achieved in 24% patients (11 complete and 4 partial) with a median duration of 6.5 months (2.1-29+). At the latest follow-up the median overall survival time was not reached and the survival-rate at 24 months was 65.2% (Figure 1). Grade 3/4 related events occurred in 52/62 (84%) of patients. The most commonly reported events were thrombocytopenia (72%), anemia (44%) and neutropenia (36%). Non-hematologic toxicities were generally grade 1/2 with the most frequently reported; diarrhea (36%), pyrexia (27%), fatigue (25%), asthenia (25%), and nausea (24%). Treatment delays occurred in approximately 75% of the patients with median duration of 11 days (3-81). The primary causes of delay were; thrombocytopenia, neutropenia, pancytopenia and patient availability. Nine deaths occurred during the study. Three of these were considered to have a possible relationship to omacetaxine: sepsis, pancytopenia, and sudden death with unknown cause. *Summary.* Omacetaxine administration produces durable hematologic and cytogenetic responses with a safety profile primarily comprising of hematologic toxicities. The overall survival of T315I+ CML-CP patients treated with omacetaxine exceeds the survival reported in the literature.

1013

KIR2DS1 GENOTYPE IS ASSOCIATED WITH INCREASED SUSCEPTIBILITY TO CML AND POOR RESPONSE TO IMATINIB

H Gabriel,[1] D Marin,[1] S Ahmad,[1] L Foroni,[1] H De Lavallade,[1] R Clark,[2] S O'Brien,[3] R Sergeant,[1] C Hedgley,[3] D Milojkovic,[1] J Sorouri Khorashad,[1] M Bua,[1] A Alsuliman,[1] A Khoder,[1] K Stringaris,[1] N Cooper,[1] J Davis,[1] J Goldman,[1] J Apperley,[1] K Rezvani[1]

[1]*Imperial College NHS Healthcare Trust, London, United Kingdom*
[2]*University of Liverpool, Liverpool, United Kingdom*
[3]3 *Northern Institute for Cancer Research, Newcastle University, United Kingdom*

Background. Killer immunoglobulin-like receptors (KIR), expressed on the surface of natural killer (NK) cells, play an important role in determining NK function and cytotoxicity. NK cells are important in tumour-cell killing and the inherited KIR-repertoire has been shown to influence tumour susceptibility. *Aims.* As NK cells can kill chronic myeloid leukaemia (CML) cells including the leukaemia-initiating-cell (LIC), we investigated if KIR-genotype influenced susceptibility to CML development and response of CML patients to treatment with imatinib. *Methods and Results.* Comparison of 190 CML patients in 1st chronic-phase (CP) to 161 healthy-controls revealed over-representation of KIR2DS1 in patients, 59% (121/190) vs 47.3% (69/161); OR 1.607 (P=0.03). We then investigated if KIR2DS1 genotype in CML patients predicts for response to imatinib treatment. NK cells are expanded in CML patients on tyrosine kinase inhibitors (TKI). We evaluated the impact of KIR genotype on the outcome of 166 patients with CML-CP receiving first-line imatinib treatment. KIR2DS1 positive patients had significantly lower 2-year probabilities of CCyR (82.3% and 65.6%, p=0.03), PFS (98.4% vs 91.0%, p=0.01 respectively) and OS (100% vs 92.6% p=0.03 respectively) than KIR2DS1 negative patients. Multivariate analysis revealed KIR2DS1 genotype (RR=0.66, p=0.03) and Sokal-risk-score (low RR=1, intermediate RR=0.65, p=0.04 and high RR=0.59, p=0.034) to be the only independent predictors for CCyR. Furthermore, KIR2DS1 was the only independent predictor for both PFS (P=0.02) and OS (P=0.03). The association between KIR2DS1 and outcome was validated in 174 CML-CP patients treated in the multi-center SPIRIT-1 trial. KIR2DS1+ patients (n=66) had a lower probability of achieving CCyR and lower PFS and OS than KIR2DS1- patients (n=106) (76.9% vs 87.9%, p=0.004, 85.3% vs 98.1% p=0.01 and 94.4% vs 100%, p=0.02 respectively). Again on multivariate analysis KIR2DS1 remained the only independent predictor for all three outcomes. Because KIR2DL1 interaction with group 2 HLA-C molecules on target cells could theoretically inhibit an activating signal mediated by KIR2DS1, we hypothesized that any effect of KIR2DS1 would be greatest among individuals who are missing group 2 HLA-C ligand for KIR2DL1. We determined the various combinatorial frequencies of KIR2DS1 with group 2 HLA-C alleles in the discovery plus the validation patients (n = 340). The impact of KIR2DS1 on CCyR was more significant when the ligand for the corresponding inhibitory receptor, KIR2DL1 was absent; the 2-yr CCyR rate for KIR2DS1-/KIR2DL1+/C2+, KIR2DS1+/KIR2DL1+/C2+ and KIRDS1+/KIR2DL1+/C2- patients were 98.6%, 94.7%, and 64.1% respectively (P=0.00006). The mechanism by which KIR2DS1 increases susceptibility and affects outcome in patients with CML-CP on imatinib is unclear. KIR2DS1+ve NK-cells secrete TGF-beta following ligand interaction, which can inhibits Akt signalling, a suppressor of FOXO3a, in CML-LIC. This may represent an important mechanism for imatinib resistance. Alternatively, KIR2DS1 may be simply a surrogate marker for genes directly involved in CML pathogenesis. *Conclusion.* In conclusion, our data demonstrate that KIR2DS1 is over-represented in patients with CML and may predict response to imatinib and identify those patients at greater risk of treatment failure.

CESSATION OF DASATINIB OR NILOTINIB THERAPY IN CHRONIC-PHASE CHRONIC MYELOID LEUKAEMIA PATIENTS WITH SUSTAINED COMPLETE MOLECULAR RESPONSES

D Rea,[1] P Rousselot,[2] F Nicolini,[3] L Legros,[4] M Tulliez,[5] F Guilhot,[6] FX Mahon[7]

[1]*Hopital Saint-Louis, APHP, Paris, France*
[2]*CH de Versailles, Le Chesnay, France*
[3]*Hopital Edouard Herriot, Lyon, France*
[4]*GH l'Archet, Nice, France*
[5]*Hopital Henri Mondor, Creteil, France*
[6]*CHRU de Poitiers, La Miletrie, France*
[7]*Hopital Haut Leveque, Bordeaux, France*

Background. Despite the outstanding efficacy of tyrosine kinase inhibitors (TKI) in chronic myeloid leukaemia (CML), the curative potential of these drugs remains uncertain. Recent results from the STop IMatinib trial suggest that imatinib may be safely discontinued in pa-

tients with long-lasting complete molecular responses (CMR) (Mahon *et al.* Lancet Oncol. 2010). *Aims.* We asked whether second generation (2G)-TKI could ever be stopped in CML patients intolerant or resistant to imatinib who had achieved durable CMR. The primary objective was to evaluate the risk of loosing major molecular responses (MMR: BCR-ABL/ABL internationally standardized (IS) ratio ≤ 0.1%) and the key secondary objective to measure treatment-free survival. *Methods.* Patients aged at least 18 years with chronic phase (CP)-CML with prior imatinib treatment were proposed dasatinib or nilotinib discontinuation provided that (1) no prior progression to accelerated phase or blast crisis occurred (2) CMR was achieved and sustained on continuing therapy. CMR was defined by RQ-PCR, using a detection threshold of BCR-ABL of at least 4.5 Log (CMR4.5). After 2G-TKI discontinuation, BCR-ABL transcripts were quantified monthly during the first year and every 2 to 3 months thereafter. Dasatinib or nilotinib re-introduction was triggered by the loss of MMR which defined relapse. *Results.* As of February, 2011, 17 patients entered the study after informed consent. The results presented here focus on a subgroup of 12 patients with a minimum follow-up 6 months (median 12, range, 7-18). These were 7 females and 5 males, with a median age of 59 years (range, 34-81). The Sokal risk group was low in 8/12 (68%), intermediate in 1/12 (8%), high in 1/12 (8%) and unknown in 2/12 (16%). Imatinib was discontinued owing to intolerance (n=11) or resistance (n=1) and replaced by dasatinib (n=8) or nilotinib (n=4) after a median duration of therapy of 50 months (range, 3-92). At start of 2G-TKI, 1 patient had a complete hematologic response only, 2 had a partial cytogenetic response, 1 had a complete cytogenetic response but lacked MMR, 3 had a MMR without CMR and 5 had a CMR. The median time on 2G-TKI therapy prior to discontinuation was 33 months (range, 21-56). The median duration of sustained CMR was 29 months (range, 21-39). Subsequently, 30% (4/12) of patients lost MMR by 6 months. MMR was rapidly regained upon early 2G-TKI re-introduction. Treatment was also restarted in 1 patient without MMR loss but showing CMR loss on 2 consecutive assessments. Seven patients remained off therapy at the last follow-up after a median of 11 months (range, 7-18), with either a stable CMR or weakly detectable BCR-ABL transcripts on one or more occasions. Treatment-free survival rate by 6 months was estimated to 58.3 % (95%CI: 21.7-31.3). *Conclusion.* 2G-TKI may be safely discontinued in CML patients with stable CMR4.5. Importantly, a very low level of detectable residual disease after 2G-TKI withdrawal may be compatible with treatment-free survival. A longer follow-up is required to ascertain whether CML will recur. Our study provides a reasonable basis for subsequent prospective clinical trials. Updated results will be presented.

Acute myeloid leukemia - Clinical 2

RISK OF HEMATOLOGICAL MALIGNANCIES AMONG FIRST-DEGREE RELATIVES OF PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) AND MYELODYSPLASTIC SYNDROMES (MDS) - A POPULATION-BASED STUDY IN SWEDEN

M Björkholm,[1] S Kristinsson,[1] X Liang,[2] Å Derolf,[1] O Landgren,[2] L Goldin[2]

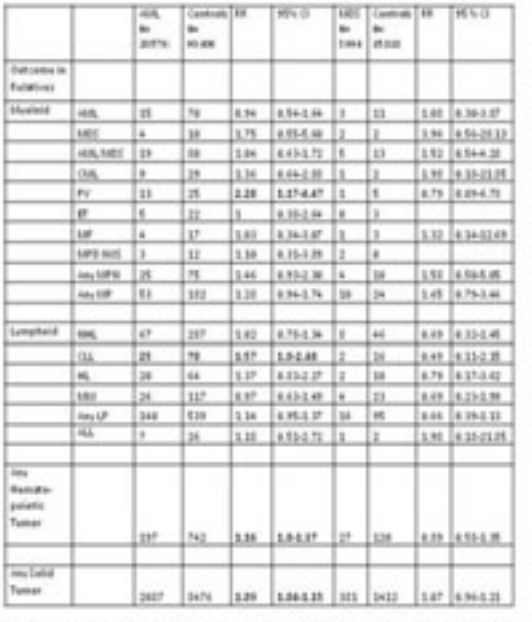
[1]*Karolinska University Hospital Solna and Karolinska Institutet, Stockholm, Sweden*

[2]*NIH, Washington, United States of America*

Background. Apart from rare pedigrees with multiple cases of AML there is limited data on the extent of familial aggregation in AML and MDS in the population. In a comprehensive population-based study, we estimated risk of AML, MDS, other hematological malignancies and solid tumors combined among first-degree relatives of AML and MDS patients compared to first-degree relatives of matched controls. *Design and Methods.* Swedish population-based registry data were used to evaluate outcomes in 20,579 first-degree relatives of 6,962 AML patients (diagnosed 1958-2004; median age 64 years) and 3,994 first-degree relatives of 1,388 MDS patients (diagnosed 1993-2004; median age 76 years) compared with 90,406 first-degree relatives of 37,384 and 15,818 first-degree relatives of 6,489 population-based matched controls for AML and MDS patients, respectively. Using a marginal survival model, we calculated relative risks (RR) and 95% confidence intervals (CI) as measures of familial aggregation. *Results.* AML and/or MDS did not aggregate significantly in relatives of patients of AML, MDS or in the combined group (Table). The risk of polycythemia vera (PV) was significantly higher in relatives of AML patients compared to controls but the increased risk of myeloproliferative neoplasms as a group did not reach statistical significance. Lymphoid malignancies showed some increased risk in relatives of AML patients (with a borderline significant increased risk of chronic lymphocytic leukaemia; CLL) but not in relatives of MDS patients. The global risks for any hematopoietic or solid tumor were significantly but modestly increased among relatives of AML patients. When analysing risks in relatives of younger patients (≤ 20 years at diagnosis) with AML a significantly increased risk (RR 7.53; CI 1.25-45.13) of AML/MDS and a 3.01-fold RR (CI 1.09-8.31) for all myeloid malignancies combined was ob-

Table 1.

Risk of Myeloid, Lymphoid, and Solid Malignancies in Relatives of AML and MDS cases



CML chronic myeloid leukaemia, PV polycythemia vera, ET essential thrombocythemia, MF myelofibrosis, MPD NOS unspecified myeloproliferative disorder, MPN myeloproliferative neoplasm (PV_ET_MF_MPD NOS), Myeloproliferative tumors (MP: AML, MDS, CML, MPN)

NHL Non-Hodgkin lymphoma, CLL chronic lymphocytic leukaemia, HL Hodgkin lymphoma, MM multiple myeloma, LP lymphoproliferative tumor (NHL, CLL, HL, MM), ALL acute lymphoblastic leukaemia

served. Among lymphoid malignancies, there was a significantly increased risk of multiple myeloma (RR 5.02; CI 1.25-20.11) but the numbers are small. All hematopoietic cancers combined were significantly increased (RR 1.85; CI 1.07-3.18) as well as all solid tumors combined (RR 1.27; CI 1.05-1.52). In general, despite the small sample size of younger patients, the relative risks were higher in this group than among all AML patients. *Conclusions.* The lack of familial aggregation of AML or MDS is striking and in sharp contrast to findings in patients with other myelo- and lymphoproliferative disorders. However, relatives of young patients do seem to be at increased risk of AML/MDS and other hematopoetic malignancies suggesting that they share a genetic susceptibility. Interestingly there is an increased risk of PV and small but significantly increased risks of any hematopoietic or solid cancer among relatives to AML patients. The results are important since many patients worry about a potentially increased risk of their family members to develop AML or MDS and many clinicians are of the opinion that there is a small but significant familial pathogenetic component. The increased risk of PV, any hematopoietic, any solid tumor and CLL among relatives of AML patients may point to the existence of broadly shared germ line susceptibility genes and/or environmental factors.

1016

INTEGRATIVE PROGNOSTIC RISK SCORE IN ACUTE MYELOID LEUKEMIA PATIENTS WITH NORMAL KARYOTYPE AGED 18-60 YEARS

A Ganser,[1] M Heuser,[1] M Morgan,[1] K Wagner,[1] K Görlich,[1] A Groβhennig,[1] I Hamwi,[1] F Thol,[1] E Surdziel,[1] W Fiedler,[2] M Lübbert,[3] L Kanz,[4] C Reuter,[1] G Heil,[5] R Delwel,[6] B Löwenberg,[6] P Valk,[6] J Krauter,[1] F Damm[1]

[1]*Hannover Medical School, Hannover, Germany*
[2]*University of Hamburg, Hamburg, Germany*
[3]*University of Freiburg, Freiburg, Germany*
[4]*University of Tübingen, Tübingen, Germany*
[5]*Lüdenscheid Hospital, Lüdenscheid, Germany*
[6]*Erasmus University Medical Center, Rotterdam, Netherlands*

Background. Prognostic risk factors have been described in AML including cytogenetics, WBC count, and response to induction chemotherapy and have been used extensively to stratify treatment. Patients with AML and normal karyotype (CN-AML) have usually been classified as intermediate risk. Many efforts have been made to identify genetic mutations (e.g. FLT3, NPM1, CEBPA, MLL, NRAS, IDH1/2, and WT1) that allow further sub-classification of CN-AML patients and possibly risk-directed therapeutic intervention. In addition to mutations, modulated expression of genes important for proliferation, survival, and differentiation have also been shown to be predictive for CN-AML patient outcome (e.g. MN1, BAALC, ERG, ID1, WT1). This molecular heterogeneity of CN-AML is not fully reflected in current classification systems. *Aims.* To integrate available clinical and molecular information for CN-AML patients into one risk score. *Patients and Methods.* 275 CN-AML patients from multicenter treatment trials AML SHG Hannover 0199 and 0295 were evaluated for mutations/polymorphisms in NPM1, FLT3, CEBPA, MLL, NRAS, IDH1/2 and WT1. Transcript levels were quantified for BAALC, ERG, EVI1, ID1, MN1, PRAME, and WT1. As an external control, 131 CN-AML patients from HOVON/SAKK protocols were analyzed for all molecular markers included in the integrative prognostic risk score (IPRS). *Results.* The IPRS was modelled in 181 CN-AML patients to represent patients with low, intermediate, and high risk of death. Complete remission rate (CR, P=.005), relapse-free survival (RFS, P<.001), and overall survival (OS, P<.001) were significantly different for the three risk groups. In two independent validation cohorts of 94 and 131 patients, the IPRS predicted different OS (P<.001) and RFS (P<.001). The value of allogeneic stem cell transplantation in first CR was evaluated in all 225 evaluable patients from the AML SHG trials. High-risk group patients with related donor had longer OS (P=.016) and RFS (P=.026) compared to patients without related donor. In contrast, intermediate-risk group patients with related donor had shorter OS (P=.003) and RFS (P=.05). Donor availability had no impact on the outcome of patients in the low-risk group. *Conclusion.* The IPRS may improve consolidation treatment stratification in CN-AML patients. This weighted prognostic risk score of clinical and molecular prognostic markers in younger CN-AML patients may become useful for outcome prediction of currently available consolidation treatment options. This score may be expanded when new markers are discovered, and it may be used to evaluate the efficacy of novel drug treatments in specific subsets of AML patients.

[6]*Universitätsklinikum Schleswig-Holstein, Kiel, Germany*
[7]*Universitätsklinikum Gieβen und Marburg, Marburg, Germany*
[8]*Städtisches Klinikum Karlsruhe, Karlsruhe, Germany*

Background. The *ASXL1* (*Additional Sex Comb-Like 1*) gene on chromosome 20q11.1 encodes a protein believed to be involved in chromatin modification and to act as a co-activator for the retinoic acid receptor. *ASXL1* mutations occur with high incidence in CMML (~40%) and less frequently in AML, CML, MDS and myeloproliferative neoplasia. They cluster in exon 12 and are mainly frameshift mutations creating a premature stop codon. A recent AML study reported on unfavorable impact of *ASXL1* mutations on induction success and overall survival (OS) (Chou *et al.*, Blood 2010;116:4086-94). *Aims.* To analyze the incidence, clinical, cytogenetic and molecular features of *ASXL1* mutations in younger (18-60 years) AML patients and to assess their prognostic relevance. *Methods.* Diagnostic samples from 799 patients who were intensively treated on AMLSG trials [AML HD98A (n=729), APL HD95 (n=70)] were analyzed for the presence of *ASXL1* mutations. Hot spots of *ASXL1* exon 12 were screened for mutations using GeneScan fragment analysis of PCR products followed by direct sequencing. Patients were also assessed for the presence of *NPM1*, *FLT3* (ITD, TKD), *CEBPA*, *IDH1/2*, *RUNX1* and *TET2* mutations by standard PCR-based methods. *Results. ASXL1* mutations were detected in 54 (6.8%) of 799 pts. All mutations were heterozygous. The most frequent mutation (38/54; 70%) was an insertion of guanine (c.1934dupG; p.G646WfsX12), which is concordant with the study by Chou *et al.*; all other frameshift mutations also created a premature stop codon. *ASXL1* mutations were found to be more frequent in older patients (P=.001), in males (P=.02), and in secondary AML (P<.001). Patients with *ASXL1* mutations showed lower values for WBC (P=.02), bone marrow blasts (P=.03) and LDH (P=.02). *ASXL1* mutations were not detected in AML with inv(16), and appeared to be less frequent in AML with t(15;17) or t(8;21). *ASXL1* mutations were more frequently associated with *RUNX1* (P<.001) and *IDH* (P=.002) mutations, but inversely correlated with *NPM1* mutations (P<.001). The median follow-up for survival was 6.5 years. Patients with an *ASXL1* mutation tended to have an inferior complete remission rate compared with patients exhibiting *ASXL1* wildtype (61% vs 72%; P=.09); the same was true for the subset of cytogenetically normal (CN) AML (56% vs 74%; P=.06). *ASXL1* mutations did not impact on relapse-free-survival in the entire AML cohort, and in CN-AML. However, in the entire cohort there was a trend towards a shorter OS in patients with an *ASXL1* mutation compared to those with *ASXL1* wildtype (P=.06; 5-year OS rates, 29% vs 41%). The adverse impact of *ASXL1* mutations on OS was more pronounced in CN-AML (P=.05; 5-year OS rates, 24% vs 41%). *Conclusions. ASXL1* mutations are detected in almost 7% of younger AML patients. They are associated with *RUNX1* and *IDH* mutations, and are less frequent in patients with *NPM1* mutation. The potential unfavorable prognostic impact of *ASXL1* mutations in AML still requires confirmation in further studies. Due to the involvement of the ASXL1 protein in epigenetic regulation and retinoic acid pathway *ASXL1* mutations should be evaluated in the context of epigenetic or ATRA-containing therapeutic approaches in AML.

1018

PRE-TREATMENT ASSESSMENT IN ELDERLY AML PATIENTS: ACCURACY OF PROGNOSTIC PREDICTIONS BY THE TREATING HEMATOLOGIST IN 343 PATIENTS FROM THE AML 60PLUS TRIAL

C Röllig,[1] M Bornhäuser,[1] M Kramer,[1] M Hänel,[2] R Herbst,[2] U Kaiser,[3] R Stuhlmann,[4] H Bodenstein,[5] KH Pflüger,[6] T Wagner,[7] M Wolf,[8] B Mohr,[1] C Thiede,[1] M Schaich,[1] U Platzbecker,[1] H Wandt,[9] G Ehninger,[1] U Schuler[1]

[8]*Klinikum Kassel, Kassel, Germany*
[9]*Klinikum Nord, Nürnberg, Germany*

Background. Most patients diagnosed with acute myeloid leukemia (AML) are older than 60 years. Response rates and long-term survival in this large group of AML patients are worse than in younger patients. In order to facilitate the process of decision making between intensive curative and palliative treatment options, a clinical and/or geriatric assessment is of particular importance in this patient group. Several scores focusing on laboratory organ function, vital signs or comorbidities have been proposed. Obstacles to a widely accepted standard clinical use are issues such as prospective validity, generalizability, and questions on which assessment system to use or which scores to combine. We prospectively evaluated the value of an simple prognostic judgment which relied on the clinical experience of the treating physician and is very easy to obtain. *Aims.* To prospectively assess the prognostic value of a clinical judgment score obtained at initial AML diagnosis by the treating hematologist in a large cohort of elderly patients treated in the AML60plus trial. *Methods.* All patients included in the AML60plus trial were categorized into three prognostic groups by the treating hematologist. Prognostic assessment was performed at initial diagnosis before the start of treatment. On the basis of comorbidities and the general clinical impression, the treating physician had to make a judgment regarding the probability of disease cure and survival in relation to the age-specific standard patient. The corresponding categories were "standard"(0), "reduced probability of cure"(-1), and "increased probability of cure"(+1). All patients received intensive induction and consolidation treatment according to the 60plus trial protocol. The potential influence of the clinical assessment scores on overall survival (OS) was assessed in univariate and multivariate analyses. *Results.* Pre-treatment assessments were available for 343 patients. Percentages of patients assigned to the clinical prognostic groups -1, 0, and +1 were 18%, 69%, and 13%, respectively. Survival analyses showed significant differences between the three prognostic groups with a median OS of 5.6 months, 10.7 months, and 14.8 months, respectively. In order to adjust for the influence of established biologic prognostic factors, we performed a multivariate Cox regression model for OS including the variables age, cytogenetic risk, WBC, LDH, NPM, FLT3-ITD, de-novo versus secondary AML, and ECOG status. Even after adjustment for these variables, the clinical judgment "increased probability of cure"remained of significant influence on OS, translating into a hazard ratio of 0.47 for death of any cause compared to the average prognosis. *Summary/Conclusions.* These are the first published prospective data demonstrating the additional prognostic value of clinical judgment in AML. The fact that the clinical prognostic score kept its significant influence on OS even after accounting for established biologic factors emphasizes the importance of clinical assessment and its ability to grasp integrated clinical prognostic information beyond clearly defined biologic parameters. Based on these results, physicians should be encouraged to include their clinical judgment in the shared decision making process for intensive curative versus palliative treatment options in elderly AML patients.

Background. FLT3-ITD mutations in AML are associated with poor survival and high relapse rates after standard chemotherapy. Quizartinib (AC220) is a potent, narrow-spectrum, oral FLT3 tyrosine kinase inhibitor that showed preliminary activity in FLT3-ITD+ patients (pts) during Phase I testing. *Aims.* This is an ongoing, Phase II study to determine the efficacy of quizartinib monotherapy in pts with relapsed/refractory FLT3-ITD+ AML. *Methods.* A planned interim analysis was performed for the first 62 pts: 25 pts in Cohort 1 (≥60 yrs and relapsed/refractory to 1st-line chemotherapy) and 37 pts in Cohort 2 (≥18 yrs and relapsed/refractory to 2nd-line chemotherapy or HSCT). All pts gave informed consent. *Results.* 62 pts (29 female, 33 male) with a median age of 59 yrs (21-86) received quizartinib. The most common drug-related AEs were nausea, QTc prolongation, vomiting, fatigue, dysgeusia, anorexia, febrile neutropenia, diarrhea, and dyspepsia. Drug-related SAEs in >15% of pts were febrile neutropenia and asymptomatic Grade 3 QTc prolongation. QTc prolongation occurred in 21 pts (Grade 3 in 12 pts). The incidence of QTc prolongation was decreased by reducing AC220 starting dose from 200 to 135 mg/day (males) and 90 mg/day (females). 4 pts discontinued due to AEs other than AML or progressive disease (febrile neutropenia, hyperbilirubinemia, bacterial sepsis, and dehydration; all considered not drug-related except Grade 4 hyperbilirubinemia). 14 pts (23%) experienced fatal AEs; none were considered drug-related. 53/62 (85%) pts were evaluable for efficacy (FLT3-ITD+ by central laboratory, received at least 1 cycle of quizartinib, and no major efficacy-related protocol deviations). The composite CR (CRc=CR+CRp+CRi) rate was 43% (23/53: 1 CRp, 22 CRi) and PR rate was 28% (15/53). Cohort 1 had a CRc rate of 36% (8/22), and Cohort 2 had a CRc rate of 48% (15/31). Starting dose did not affect response. Of the pts refractory to any prior therapy, 56% (15/27) had CRc and 22% (6/27) had PR in response to quizartinib treatment. Median duration of CRc has not yet been reached in Cohort 1 and was 10.6 wks in Cohort 2. Overall, 9% (2/22) of pts in Cohort 1 and 39% (12/31) of pts in Cohort 2 were bridged to HSCT and censored for duration of response at that time. Median overall survival was 20.0 wks in Cohort 1 and 24.4 wks in Cohort 2. *Conclusions.* These preliminary data suggest that quizartinib achieves clinically meaningful reductions in marrow blasts in a substantial proportion of pts with both refractory and relapsed FLT3-ITD+ AML, and many of these pts were successfully bridged to HSCT. These encouraging efficacy results and an acceptable safety profile in this high risk population support continued clinical evaluation.

Background. Dysregulated JAK-STAT signaling is a key feature of myelofibrosis (MF), a myeloproliferative neoplasm associated with splenomegaly, constitutional symptoms and shortened survival. Overall median survival is 2.25-4 years for high- and intermediate risk-2 patients, respectively as defined by IWG-MRT criteria (Cervantes *et al.*, Blood 2009). Approximately half of MF patients carry a gain-of-function mutation in the Janus kinase (JAK) 2 gene (JAK2V617F); dysregulation of the JAK pathway occurs regardless of JAK2V617F status and contributes to disease pathophysiology. There are currently no effective drug therapies for MF. Ruxolitinib is a selective JAK1 and JAK2 inhibitor with clinical activity in MF. *Aims.* COMFORT-II, a randomized (2:1), open-label, phase 3 study measured the efficacy, safety, and tolerability of ruxolitinib given twice daily compared to best available therapy (BAT), which could include no therapy or other agents, in adult patients with high- or intermediate risk-2 primary MF, post polycythemia vera MF or post essential thrombocythemia MF, with palpable splenomegaly. The primary efficacy endpoint is the proportion of subjects achieving ≥ 35% reduction in spleen volume from baseline to week 48 as determined by magnetic resonance imaging (MRI) or computed tomography (CT) and analyzed using the Cochran-Mantel-Haenszel test stratified by baseline risk category. For the 219 subjects enrolled, the power of two-sided CMH test with alpha level of 0.05 would be 93.7% assuming that the ratio of subjects with baseline prognostic category of intermediate- vs. high-risk was 1:1, response rate for intermediate-risk for active and control treatment groups was 40% and 15%, respectively, and for high-risk 30% and 5%, respectively. The key secondary endpoint is the proportion of subjects achieving a ≥ 35% reduction of spleen volume (by MRI or CT) from baseline to week 24, while other secondary endpoints include duration of maintenance of reduction in spleen volume, time to achieve a first ≥ 35% reduction, progression-free survival, leukemia-free survival, overall survival and change in bone marrow histomorphology. Patients were enrolled at 56 sites in Europe and the UK from July 2009 until January 2010. Primary analysis will occur in March 2011. *Results.* A total of 219 patients were randomized; 146 to ruxolitinib and 73 to BAT. Results for the primary and secondary endpoints will be reported. A summary of the most common adverse events in the ruxolitinib vs BAT arms will be reported as will the rate of treatment discontinuation. *Summary/Conclusions.* The results of COMFORT-II will provide important information that may result in a new standard of care for a large number of patients with myelofibrosis. A companion study, COMFORT-I, has met its primary and symptom assessment secondary endpoints. COMFORT-I enrolled 309 patients with similar eligibility criteria from the US, Canada, and Australia, and compared ruxolitinib to placebo with a primary endpoint of response defined as the percentage of patients achieving 35% or greater reduction in spleen volume at 24 weeks. It will be important to compare the results of these 2 studies that differ in their comparator arm and the timing of response assessment.

Background. Inactivating mutations of EZH2 (chr7q36) have been described in patients with myeloproliferative neoplasms (MPN), mainly primary myelofibrosis (PMF), myelodysplastic-MDS/MPN neoplasms (Ernst *et al.*, Nat Gen 2010) and MDS (Nikoloski *et al.*, Nat Gen 2010). EZH2 encodes a histone H3 Lys27 methyltransferase that is the catalytic unit of the polycomb repressor complex-2. EZH2 functions as a transcriptional repressor involved in gene silencing, and may behave as tumor suppressor or oncogene depending on the cellular context. *Aims*. To define the epidemiology and clinical correlates of EZH2 mutations in a large population of MF patients. *Methods*. The study population included 518 patients with MF: 370 PMF, 84 post-polycythemia vera myelofibrosis (PPV-MF), 64 post-essential thrombocythemia myelofibrosis (PET-MF). Sixty-two percent of the patients were JAK2V617F-positive, 4% were MPLW515L/K mutated. High-resolution melting (HRM) analysis was used to screen DNA in whole genome amplified samples from granulocytes. Products showing abnormal melt patterns were directly sequenced from genomic DNA. Whenever possible, sequencing of buccal swab samples was performed concurrently to rule out rare SNPs. Mutational status was correlated with baseline hematological and clinical characteristics. *Results.* Overall, 23 different EZH2 mutations were detected in 30 patients (6%); 23 patients had PMF (6% of all PMF) and 7 had PPV/PET-MF (5%). Nine mutations were located in SET domain, 5 in CXC domain, 6 and 4 in the D1 and D2 domain, respectively. Most exonic mutations were heterozygous missense changes caused by single nucleotide substitution, while 3 (10%) were homozygous; one patient presented two mutations. Four intronic mutations were identified, all in putative splicing sites. Forty-three percent of EZH2 mutated patients were JAK2 V617F-positive, none was MPL mutated; median V617F allele burden was 47±30% in EZH2/JAK2V617Fpos vs 53±25% in EZH2 wild-type/JAK2V617Fpos. No mutation in IDH1/2 was found in EZH2 mutated patients, while 50% of them harbored ASXL1 mutation. There were more EZH2 mutated patients in IWG-MRT high-risk category (19.6%) than low-risk (5.4%) (P=0.03). EZH2-mutated patients had significantly higher leukocyte (P=.02) or >1% blast cell count (P=.003) at diagnosis. There was no correlation of EZH2 mutation with age, gender, other hematologic characteristics at diagnosis including splenomegaly, constitutional symptoms and rate of leukemic transformation; the latter occurred in 81 patients, 28.6% and 17.8% of the EZH2-mutated or wild-type, respectively. After a median follow-up of 38 months, 128 patients (25.9%) died. Survival was influenced by IWG-MRT risk categories, age, leukocytosis, hemoglobin, platelet and blast count, constitutional symptoms, leukemia transformation, low JAK2V617F allele burden and EZH2 mutation. The overall median survival (OS) was significantly reduced in EZH2 mutated patients (25 mo, range 0-183) compared to wild-type (39 mo, 0-340; P=.001). In multivariate analysis OS was predicted by IWG-MRT high-risk category (P<.0001), a <25% JAK2V617F allele burden (P=0.04), and EZH2 mutated status (P=0.002). *Conclusions.* EZH2 mutations occur in 6% of patients with primary and secondary forms of myelofibrosis and are associated with shorter survival independent of other known risk factors including IWG-MRT score. (PG, FB, JS, NCPC, AMV equally contributed) (Supported by AIRC, Milano to AGIMM; Leukaemia and Lymphoma Research to N.C.P.C.)

Background. The $JAK2^{V617F}$ mutant enzyme has been linked to the pathogenesis of myeloproliferative neoplasms. SB1518 is a potent inhibitor of JAK2 and its $JAK2^{V617F}$ mutant. In previously reported Phase 1 studies, patients with myelofibrosis (MF) who received SB1518 achieved steady-state plasma levels above the IC50 for JAK2 at all doses (100-600 mg/d). Target inhibition, measured by phosphorylation of the STAT3, STAT5, and JAK proteins in PBMCs and whole blood, was also shown at all doses. 400 mg/d was chosen as the recommended dose (RD) for Phase 2 study. *Aim.* To assess the spleen response rate, defined as a ≥35% reduction in MRI-measured spleen volume between baseline and Week 24. *Methods.* Qualifying patients had primary, post-ET, or post-PV MF, palpable splenomegaly ≥5 cm below the left costal margin, and were not suitable for standard therapy. Based on minimal myelosuppression in the Phase 1 trial, no minimal hematology values were required for study inclusion. Each patient received daily oral SB1518 in ongoing 28 day cycles. Disease symptoms were evaluated using the MF-SAF. *Results.* Patients: In this ongoing trial, thirty-four MF patients (median age 58.5; range, 44-84 years) were consented and enrolled, of which 25 (74%) were men. Median baseline platelet count was 120,000/μL (range, 15,000-859,000/μL). Fifteen patients (44%) had platelet counts <100,000/μL, including seven <50,000/μL. Twenty-eight patients (82%) were $JAK2^{V617F}$ mutation-positive. Median time on study is 6.0+ months (range, 0.5 to 11.1 months). Safety: Seven patients (21%) discontinued SB1518 due to AEs. Seven patients required dose reduction, all within the first 6 months. The most common treatment-related AEs were gastrointestinal, which were generally low grade and easily managed. GI AE's >Grade 2 included only Grade 3 diarrhea in 2 patients (6%). Efficacy: SB1518 produced meaningful reductions in splenomegaly. Thirty patients (88%) showed reductions in palpable splenomegaly; 15 (44%) showed decreases of ≥50% and seven (21%) showed a reduction of 100%. At Week 24, 23 patients (68%) showed spleen reduction (3% to 50% by MRI volumetric assessment). Nine patients (26%) had reduction in splenomegaly by ≥35% reduction. Splenic reduction of 50% by PE correlated with a 25% reduction in spleen volume by MRI. Twelve patients (35%) had reduction in splenomegaly by >25%. Spleen response rates were as high among patients with low baseline platelet counts as those with normal baseline counts. Responses were durable; response duration among those achieving an IWG MRT response ranged from 1 to 164+ days (median, not reached). Two patients met IWG-MRT criteria for clinical improvement in hemoglobin and 1 for platelet count. At the 6 month visit, a significant reduction (>2 point improvement) was observed for MF associated symptoms, including abdominal pain, cough, and night sweats. *Conclusions.* SB1518 shows promising efficacy in alleviating MF-associated splenomegaly and constitutional symptoms at a dose that induces minimal myelosuppression. Once-daily dosing is well tolerated, with manageable GI toxicity as the main side effect. Given the lack of myelosuppression with SB1518, this JAK2 inhibitor is of particular importance for MF patients with impaired hematopoiesis.

1023

A PHASE II STUDY OF VORINOSTAT (MK-0683) IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

C Andersen,[1] E Ejerblad,[2] S Zweegman,[3] T Klausen,[4] MF McMullin,[5] HC Hasselbalch,[6] On Behalf of The COSMYD-Group[7]

[5]*Department of Haematology, Belfast City hospital and Queens's University Belfast, Belfast, Northern Ireland*
[6]*Department of Haematology, Roskilde Hospital, Roskilde, Denmark, Nederland*

Background. Conventional agents used in the management of polycythemia vera (PV) and essential thrombocythemia (ET) include hydroxyurea and in younger patients alpha-interferon or anagrelide as useful alternatives. Since all of these agents have side effects besides potential leukemogenic potential for hydroxyurea several clinical trials have been conducted to find alternative and better drug formulations. Histone deacetylase inhibition (HDACi) has been shown to impair the autonomous proliferation of haematopoietic cells of PV and ET patients carrying the JAK2 V617F mutation. *Aims*. The present study evaluates the efficacy and safety of vorinostat in the treatment of PV and ET in a non-randomized, open-label ongoing phase II study. *Methods*. Fifty-nine pts. (17 ET, 39 PV) from whom informed consent was obtained from Denmark, Sweden, Holland and the UK were included and given 400 mg of vorinostat daily for 6 months. *Results*. We report preliminary data for 59 pts, 70 % PV (m:f=53%/47%), 30 % ET (m:f=38%/62%) with a median follow-up from start of vorinostat of 8 weeks (range=0-36, IQR=4,28). Median age at inclusion was 64 years (29-82) (PV=65 (29-82), ET = 62 (50-77)). Period between diagnosis and inclusion was 2.8 years (0-27,4) (PV= 3,1 (0-27,4), ET=2,2 (0,01-22,6)). Treatment prior to vorinostat included hydroxyurea (53%) (PV=43%, ET=75%), interferon -alpha (8%) (PV=11%, ET=0%), anagrelide (12%) (PV=6%, ET=27%) and busulfan (4%) (PV=3%, ET=8%). Of the 14 patients (8 PV, 6 ET) evaluable for clinicohaematological response after visit 11 (completion of protocol), 4 achieved complete response (CR), 6 achieved partial response (PR) and 4 achieved no response (NR) identifying a response-rate of over 70%. Adverse effects (AE's) reported at visit 11 were all grade 1 and included constipation (1 pt), weight loss (1 pt.), fatigue (1 pt.), hyperglycemia (1 pt.) and mucositis (1 pt.) The most common AE's during the treatment period were gastrointestinal (anorexia, nausea, vomiting, diarrhea) typically grade 1/2, manageable and improving within months. Seventy-eight percent experienced hair loss, 1 pt. grade 3. Fourteen percent experienced renal toxicity (grade 1/2) and 7% liver toxicity of unknown grade. Other grade 3/4 non-hematologic toxicities were anorexia (14%), nausea (7%), diarrhea (7%), fatigue (7%), dry mouth (7%). Fifty-seven percent required at least one dose reduction. An additional 11 pts. dropped out before visit 11 due to AE's (no: 4), serious AE's (no: 4) and unknown (no: 3). Serious AE's included 1 pt. with a deep vein thrombosis, 2 pts. with thrombocytopenia (1 grade 3, 1 unknown) and 1 pt. due to renal toxicity. Of the 11 pts. 2 achieved CR, 2 achieved PR, 6 achieved NR as best response before dropping out of protocol. Further up-dating will be at EHA. *Conclusion and perspectives*. Vorinostat is effective in PV and ET patients. Clinical responses are achieved in a high proportion of patients adhering to therapy. After months of treatment vorinostat is generally well-tolerated with minimal AE's and hematologic toxicity. An early drop-out rate of 44% draws attention to side effects which in future trials may be diminished by dose reduction or combination therapy (eg. hydroxyurea, interferon-alpha or JAK2-inhibitors).

ASXL1 MUTATIONS IN PATIENTS WITH MYELOFIBROSIS. EPIDEMIOLOGY AND CLINICAL CORRELATIONS

F Biamonte,[1] P Guglielmelli,[1] T Fanelli,[1] A Pancrazzi,[1] L Villani,[2] A Bosi,[1] G Barosi,[2] A Vannucchi[1]

[1]*University of Florence, Florence, Italy*
[2]*Laboratorio Epidemiologia Clinica, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy*

Background. Additional sex comb-like 1 (ASXL1) gene (chr 20q11.1) belongs to the Enhancer of Trithorax and Polycomb gene family. It functions as dual transcriptional activator/suppressor including repression of retinoic acid receptor-mediated transcription. Mutations in ASXL1 were recently demonstrated in a spectrum of chronic- and blast-phase myeloproliferative neoplasms (MPN). *Aims.* The current study seeks to determine ASXL1 mutational frequency and clinical correlates in a large series of patients with myelofibrosis (MF). *Methods.* We investigated ASXL1 mutational status of 230 patients with MF including 166 PMF, 36 PPV and 28 PET. Somatic mutations of ASXL1 were identified by sequencing exon 12 of whole-genome amplified DNA isolated from granulocytes; all mutations were validated by re-sequencing genomic DNA from the archival sample. Mutational status was correlated with clinical and biological features. *Results.* At the time of writing, results were fully available for 117 of 230 patients; details of the whole series will be presented at the meeting. A total of 21 different mutations were identified in 36 patients (31%); 24 out of 64 with PMF (38%) and 12 out of 53 (23%) with PPV/PET-MF. All mutations were heterozygous deletions, missense or nonsense mutations presumed to truncate the plant homeodomain finger domain. Sixty-four percent of ASXL1 mutated patients were JAK2 V617F-positive and one patient was MPLW515L mutated. The frequency of ASXL1 mutations was similar in JAK2V617Fpos (30%) and JAK2V617Fneg (32%) cases. Median V617F allele burden was 48.6±26.7% in ASXL1/JAK2V617Fpos vs 57.9±24.4% in ASXL1wild-type/JAK2V617Fpos patients. Screening of EZH2 and IDH1/2 mutations in the same cohort showed that ASXL1, EZH2 and IDH1/2 are not mutually exclusive events. In fact, mutations of EZH2 and ASXL1 were simultaneously present in 6 cases. IDH1/2 mutations were found in 3 cases, two of whom showed concomitant ASXL1 mutation. ASXL1/IDH1-2 mutations were detected at chronic phase in both patients who later developed acute leukemia. Seven patients showed ASXL1 mutation as the sole molecular abnormality. There was no significant difference between mutated and unmutated patients as concerned age, sex distribution, clinical characteristics, leukemia transformation and overall survival. However, ASXL1 mutations were found to be preferentially associated with an abnormal karyotype; the latter occurred in 10 of 17 mutated patients (59%) compared to 7 of 29 unmutated patients (24%) (P=0.02). *Conclusions.* Preliminary data in 117 patients with MF analyzed for ASXL1 mutations discovered a high mutational rate in both primary and post-PV/post-ET MF. ASXL1 mutations did not associate with an unique phenotype nor deserved a detrimental effect on survival. However, the high frequency (32%) detected in JAK2V617F-negative subjects suggests that ASXL1 genotyping may be of help in the routine diagnostic path in MF patients. (A project of AGIMM supported by AIRC, Italy)

Myelodysplastic syndromes - Biology

Background. Myelodysplastic syndromes (MDS) are heterogeneous groups of myeloid neoplasms characterized by multi-lineage cytopenias of varying degrees and transition to acute myeloid leukemia (AML). At present, no curative therapeutics for MDS has been established except for allogeneic hematopoietic stem-cell transplantation, which is not applicable to the majority of the MDS patients due to their higher ages. Thus, to improve the outcome of MDS, it is essential to develop novel therapeutic agents with both high efficacy and low toxicity, and to this goal, the discovery of the key molecules for MDS pathogenesis is of particular importance. To date, a number of gene mutations have been identified and implicated in the pathogenesis of MDS, including NRAS, TP53, RUNX1, c-CBL, TET2, ASXL1, and more recently, IDH1, IDH2 and EZH2. However, in view of therapeutic targets, our current knowledge of disease causing mutations in MDS is still incomplete. Recently, high-throughput sequencing technologies have been shown to be effective for the identification of disease-related gene and been successfully used to determine the genetic basis of some neoplastic disorders, such as AML and diffuse large B-cell lymphoma. More recently, the resequencing technology targeted for all protein-coding subsequences (i.e., whole exome analysis) has enabled cost-effective comprehensive mutation analysis of coding sequences. *Aims.* In this study, to obtain a complete registry of genetic lesions in MDS and to identify novel therapeutic targets, we performed whole exome analysis for novel mutations using high-throughput sequencing technologies, combined with large-scale screening of mutations in candidate genes using barcode-labeled DNA for a panel of ~180 MDS samples. *Methods.* Whole exome analysis was performed for 20 MDS samples, where entire exon sequences were enriched by using SureSelect Human All Exon kit (Agilent Technologies) and were subjected to resequencing analysis using Genome Analizer IIx (Illumina). *Results.* More than 60% of mapped reads contained exon sequences. > 80% of exons were sequenced at the depth of >20 with average fold-coverage of >50 times. Given that the constitutive genomic DNA was difficult to obtain in MDS patients, paired CD3-positive T cells were used as a normal control. By comparing sequences in tumors and paired T cells, nearly 200 somatic mutations and 10 insertions-deletions were detected in the whole exome analysis. Novel gene targets were also explored by resequencing barcord-labeled DNAs from 180 MDS specimens, which targeted 80 candidate genes for MDS. A number of mutations were identified, including those in IDH2, ASXL1, TET2, EZH2 and novel target genes such as PHF6, which has been reported to be mutated in T-ALL previously, and other genes which have not been reported to mutated in human cancers. Nearly 3 mutations per sample were detected and multistep model of oncogenesis in MDS were revealed. *Summary/Conclusions.* Our results suggested that target-capture resequencing technology is a powerful method to identify new gene mutations that are implicated in the pathogenesis of MDS.

1026

THE CLONAL ADVANTAGE OF DEL(5Q) MDS STEM CELLS IS MEDIATED BY INCREASED ADHESION TO THE MICROENVIRONMENT

C Scharenberg,[1] V Giai,[1] M Jädersten,[1] G Karlsson,[2] M Jansson,[1] AM Forsblom,[1] S Karlsson,[2] E Hellström-Lindberg[1]

[1]*Karolinska Institute, Stockholm, Sweden*
[2]*Lund Stem Cell Center, Lund, Sweden*

Background. The myelodysplastic syndromes (MDS) constitute a heterogenous group of clonal disorders of hematopoietic stem cells (HSC) leading to ineffective hematopoiesis in one or more lineages in the bone marrow. The most frequent cytogenetic entity is the 5q-syndrome, characterized by loss of the 5q31-33 region. Lenalidomide has emerged as a very effective therapy for this subgroup of patients. Its mechanism of action, however, has hitherto remained elusive. Interestingly, the more primitive hematopoietic compartment seems to possess a clonal advantage where del(5q) HSC are able to outcompete non-5q HSC. We have previously demonstrated that lenalidomide is able to abrogate this clonal advantage and found that lenalidomide restored expression of the matricellular protein SPARC, a gene located within the commonly deleted region on chromosome 5q. We hypothesized that the decreased expression of SPARC in del(5q) HSC leads to increased adhesion of HSC to their respective niche cells, translating to increased rates of proliferation, partly explaining the competitive advantage against non-del(5q) HSC. *Aims.* We conducted a study to analyze the effect of lenalidomide on the HSC/progenitor compartment in del(5q) MDS in order to test whether an hematopoietic stem cell (HSC)-intrinsic decrease of SPARC explains the why and how a clone of cells inherently defective at spawning functioning cellular descendants is not selected against, but rather exhibits a clonal advantage. *Methods.* We analyzed cell cycle distribution, frequency of apoptosis, and expression of adhesion markers on normal and del(5q) HSPC by multi-parameter flow cytometry. We analyzed the adhesion of normal and del(5q) HSPC to defined matrix components of the microenvironment such as fibronectin and VCAM-1. We overexpressed SPARC by lentiviral transduction in HSPC and analyzed the effect on engraftment in NSG-mice. *Results.* Multiparameter flow cytometry revealed a slight increase in proliferation of del(5q) versus normal HSC. Patients treated with lenalidomide exhibited complex changes in their expression of adhesion markers. In functional adhesion studies we observed that HSPC from del(5q) patients exhibited stronger adhesion than normal bone marrow cells to fibronectin and VCAM-1. Recombinant SPARC protein abrogated adhesion to VCAM-1 specifically in a subset of patients, while having no significant effect on normal HSPC. Overexpression of SPARC led to severely reduced engraftment in NSG-mice. *Summary/Conclusion.* These studies suggest that decreased expression of SPARC leads to increased adhesion of del(5q) HSC/progenitor cells to defined components of the microenvironment and may explain why del(5q) HSC are able to outcompete the remaining healthy HSC. Our studies implicate that lenalidomide is able to abrogate this clonal advantage partly via its increase in SPARC expression with a consecutive decrease in adhesion.

1027

GENE MUTATIONS OF THE TELOMERASE COMPLEX IN PATIENTS PRESENTING WITH REFRACTORY CYTOPENIA OF CHILDHOOD (RCC) - DO WE NEED TO KNOW?

A Karow,[1] B Strahm,[1] C Flotho,[1] M Wlodarski,[1] M Schneider,[1] G Goehring,[2] K Lange,[2] B Schlegelberger,[2] I Baumann,[3] S Schwarz-Furlan,[3] C Niemeyer,[1] On behalf of EWOG-MDS[1]

[1]*University Hospital Freiburg, Freiburg, Germany*
[2]*Hanover Medical School, Hanover, Germany*
[3]*Institute of Pathology, Böblingen, Germany*

Refractory Cytopenia of Childhood (RCC), the most common form of myelodysplastic syndrome (MDS) in childhood, frequently presents with a hypocellular bone marrow. Thus, inherited bone marrow failure (IBMF) disorders are an important differential diagnosis. In particular, dyskeratosis congenita (DC), one of the most common types of IBMF, has to be taken into account. Because RCC and DC cannot be distinguished by hemato-morphological features, accurate clinical examination is mandatory. However, subtle clinical characteristics associated with DC may be overlooked or absent. Recently, our group reported on two patients with mutations in the gene of the human telomerase RNA component (TERC) who had been diagnosed with RCC in the absence of obvious clinical signs of DC. We hypothesized that a number of children presenting with hypocellular RCC may in fact suffer from DC identifiable by mutational analysis of the genes of the telomerase complex - namely, DKC1, TINF2, NOLA2, NOLA3, TERC and TERT. We therefore performed mutational screening for these 6 genes in 100 consecutive German patients enrolled in the prospective study EWOG-MDS-98 with primary hypocellular RCC without chromosomal aberrations or myelofibrosis. The two patients with known TERC mutations were included in this series. Including the 2 patients with TERC mutation previously published, we uncovered six patients with mutations in the 6 genes studied. One boy carried a mutation in DKC1, two patients had a TINF2 mutation and another patient harboured a mutation in TERT. No further TERC mutations were identified. All mutations detected were heterozygous, and, with the exception of one child with a TINF2 mutation, all aberrations proved to be of germline origin. Five of the six patients carried known mutations, while the patient with TERT mutation exhibited a novel alteration. None of these patients had clinical signs of DC at time of diagnosis of RCC. The boy with DKC1 mutation had stable low blood counts over several years and died of pulmonary fibrosis. Both children with TINF2 mutation underwent HSCT; the child with the somatic mutation in hematopoietic cells remains in stable condition, while the other patient died from severe skin and pulmonary GvHD. One of the two children with TERC mutation died of CMV reactivation after HSCT, while the other child with TERC mutation and the patient with TERT alteration showed decreasing blood counts in the absence of HSCT. In summary, 6% of phenotypically normal children with RCC were shown to carry germline or somatic mutations in one of 6 genes of the telomerase complex. At least one of the identified individuals had an unusually complicated course after HSCT. In view of the excellent outcome of HSCT in children with RCC, we suggest that it is important to identify patients with telomerase complex mutations. We currently perform telomere length analyses on granulocytes from the 100 patients to determine whether there is a significant difference in telomere length between RCC cases with or without telomerase complex mutations. Telomere length may provide a diagnostic tool for rapidly identifying RCC patients with mutations in one of these genes.

ABCB7 PLAYS AN ESSENTIAL ROLE IN THE PATHOGENESIS OF ACQUIRED REFRACTORY ANEMIA WITH RING SIDEROBLASTS

A Liu, M Nikpour, C Scharenberg, K Högstrand, S Conte, M Jansson, A Forsblom, A Grandien, E Hellström-Lindberg

Karolinska Institutet, Stockholm, Sweden

Background. Refractory anaemia with ring sideroblasts (RARS) is characterized by anaemia, erythroid apoptosis, and mitochondrial ferritin (FTMT) accumulation. To dissect the molecular mechanisms underlying the RARS phenotype, we recently described the gene expression profiles of erythroblasts generated from normal (NBM) and RARS marrow $CD34^+$ cells. The expression of ABCB7, an mitochondrial iron transporter, was severely down-regulated in RARS progenitors, and further decreased in cells undergoing erythroid differentiation. Importantly, ABCB7 expression was inversely correlated with the percentage of marrow ring sideroblasts. *Aim.* To test the hypothesis that ABCB7 has en essential role in the molecular pathogenesis of RARS. *Methods and Results.* During erythroid differentiation of K562 cells induced by hemin treatment, up-regulation of ABCB7 by lentiviral transduction, facilitated the expression of γ-globin and glycophorin A, indicating that ABCB7 potentiated erythroid differentiation. To study whether up-regulation of ABCB7 could rescue the erythropoiesis of RARS progenitors, bone marrow $CD34^+$ cells from RARS patients were transduced with lentiviral vector expressing ABCB7-YFP or mock vector. Colony forming cell assay was initiated from day 3 cultures and evaluated day 14 after transduction. ABCB7 over-expression, verified by qRT-PCR and YFP expressing colonies, significantly increased erythroid colony growth in 4/4 patients (Fig 1). In addition, up-regulation of ABCB7 reduced the expression of FTMT. Down-regulation of ABCB7 in K562 cells by lentiviral shRE1 vector, induced striking up-regulation of ALAS2 and accumulation of FTMT. Moreover, erythroid differentiation assessed by γ-globin expression was reduced during hemin-induced differentiation. Subsequently, normal bone marrow $CD34^+$ cells were transduced with the shRE1 vector and cell survival and colony forming capacity were assessed. The number of erythroid colonies was dramatically decreased, and erythroid cell survival was reduced when erythropoietin was added to induce terminal erythroid maturation. Interestingly, FTMT expression considerably increased in the ABCB7 down-regulated cells (Fig 2). *Summary.* Our results show that reduced

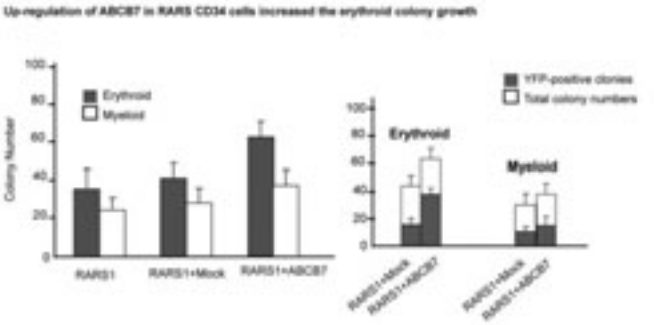

Figure 1.

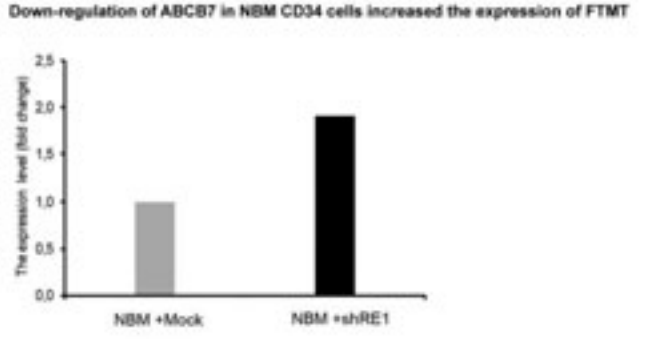

Figure 2.

ABCB7 expression plays a key role in mediating the erythroid failure, aberrant ALAS2 and FTMT expression and mitochondrial iron accumulation in acquired RARS. Moreover, up-regulation of ABCB7 restores RARS erythropoiesis and reverts ALAS2 and FTMT expression towards the normal range. In the absence of ABCB7 mutations or hypermethylation, upstream events are currently being investigated.

EXOME SEQUENCING IDENTIFIES THE MPL GENE AS A CAUSE OF FAMILIAL APLASTIC ANAEMIA

A Walne,[1] A Dokal,[1] V Plagnol,[2] R Beswick,[1] M Kirwan,[1] T Vulliamy,[1] I Dokal[1]

[1]*Queen Mary University of London, London, United Kingdom*
[2]*University College London Genetics Institute, London, United Kingdom*

Background. The primary cause of many paediatric diseases remains elusive; however in some cases they may represent recessive single gene disorders. The problem is therefore how to identify a gene defect in a particular individual. To this end, exome sequencing has become the method of choice. One problem with this methodology is that the discriminatory power often lies in comparing unrelated individuals with the same disease to identify a common causative variant. This depends on the disease being genetically homogenous, but this will not always be the case. An example is aplastic anaemia (AA) which can be "labelled" as idiopathic, acquired or constitutional. Although mutations have been described in some genes, these only account for a small proportion of cases of AA. *Aims.* From our collection of uncharacterised AA patients we selected a consanguineous family with severe AA in two siblings. In order to characterize this family one of the affected sibs had the entire exome sequenced. The disease causing gene identified in this family would then be screened in other uncharacterized AA patients. *Methods.* Genomic DNA from an affected individual was hybridised to a NImblegen exome library before being sequenced on a GAIIx genome analyzer. Sequencing data were processed and by comparing to the reference human genome sequence and the 1000 genomes project, unique homozygous changes were identified. Biologically relevant changes were confirmed by Sanger sequencing. After confirming segregation in the rest of the family, the *MPL* gene was screened for mutations in 33 index cases with AA (<13 years) using denaturing HPLC. Any abnormal traces were confirmed by direct sequencing. *Results.* A homozygous mutation c.1248 G>A, p.Trp416Stop in the thrombopoietin receptor gene, *MPL*, was identified by exome sequencing and was shown to segregate with the disease (patient 1). This is a novel mutation occurring in a gene that has been previously associated with congenital amegakaryocytic thrombocytopenia (CAMT) - a rare autosomal recessive bone marrow failure syndrome characterised by early onset of isolated hypomegakaryocytic thrombocytopenia that often evolves to affect all three marrow lineages. We then identified two further novel mutations in two different patients from our screen of 33 index cases with AA (patients 2 and 3, Table 1). Interestingly, in patient 3 with the Pro394Ser mutation, the mutant T allele is present at a reduced level compared with what would be expected for a normal heterozygote (26% rather than 50%). This suggests the possibility of a mosaic for this mutation which has not been previously described in *MPL*. *Summary.* A novel homozygous nonsense mutation was identified in *MPL* by exome sequencing in a patient with familial severe aplastic anaemia. Screening of 33 uncharacterized AA patients revealed two additional novel mutations, one of which was recurrent and appeared to present as a mosaic. This study demonstrates that in a subgroup of patients with AA the disease is due to biallelic mutations in the *MPL* gene.

Table 1. Coding changes identified in MPL in AA.

Patient	Sex	Age at sampling (diagnosis)	Coding change	Protein change	Exon	Status	Family segregation
1	F	3 years (3 years)	c.1248 G>A	Trp416Stop	8	homozygous	yes
2	M	6 years (18 mo)	c.1180 C>T	Pro394Ser	8	homozygous	yes
3	F	7 years (7 years)	c.1180 C>T	Pro394Ser	8	heterozygous	n/a
3	F	7 years (7 years)	c.314 T>A	Phe105Tyr	3	heterozygous	n/a

n/a = family samples unavailable, mo = months

COMBINING CELLULAR BARCODING AND MULTIPLEX DEEP SEQUENCING FOR HIGH-RESOLUTION QUANTITATIVE CLONAL ANALYSIS IN THE HEMATOPOIETIC SYSTEM

E Verovskaya, M Broekhuis, M Ritsema, O Kalmykowa, E Zwart, B Dykstra, G de Haan, L Bystrykh

University Medical Centre Groningen, Groningen, Netherlands

Background. Accurate assessment of clonality is important in a variety of hematopoietic stem cell research areas, including cell expansion, aging, gene therapy, cancer progression and treatment. However, detailed studies of stem cell clonality are hindered by the absence of methods with sufficient sensitivity and resolution to measure clonal contributions of both major and minor clones. Recently, we have designed and validated a novel cellular barcoding technique for clonal analysis of complex cell populations *in vitro* and *in vivo* (Gerrits *et al.*, 2010). We have demonstrated that cellular barcoding combined with Sanger sequencing-based detection technique allows direct and unbiased assessment of clonality. *Aim.* Now, we coupled the barcoding approach with a high-throughput sequencing detection system and tested if such set-up will allow detailed quantitative analysis in heterogeneous populations of hematopoietic cells. *Methods and Results.* First, we developed a multiplexing protocol which allows simultaneous analysis of up to 200 DNA samples containing barcoded cell populations in a single Solexa sequencing run. We applied this protocol to analyze clonal dynamics in cultures of primary mouse bone marrow cells transduced with barcoded vectors. A high number of sequence reads (4000 to 2000000 reads per sample) allowed detailed and quantitative assessment of clonal fluctuations of over 100 barcodes in these cultures over time. Next, we transplanted barcoded murine bone marrow cells into irradiated recipients in a limiting dilution setting and followed the changes in barcodes presented in various blood lineages at different time points post-transplantation. This allowed us to trace behavior of both individual stem cells in monoclonally-repopulated animals and analyze minor and major clones in polyclonal mice. *Summary/Conclusions.* These data confirm that cellular barcoding in combination with high-throughput sequencing is an effective tool for the study of cell population dynamics. This approach permits a quantitative, high-resolution assessment of clonality and offers an unprecedented sensitivity in the ability to analyze heterogeneous cell populations. In the future, we anticipate that this method can be used for detailed monitoring of clonal changes in gene therapy protocols.

FORCED EXPRESSION OF THE HISTONE H3K36 DEMETHYLASE FBXL10/KDM2B MAINTAINS THE SELF-RENEWAL CAPACITY OF MOUSE HEMATOPOIETIC STEM CELLS

K Takaaki,[1] V Miguel,[2] I Atsushi[1]

[1]*Department of Cellular and Molecular Medicine, Chiba University, Chiba, Japan*

[2]*Cell Proliferation and Development, Centro de Investigaciones Biologicas, CSIC, Madrid, Spain*

Post-translational covalent modifications of histone N-terminal tails are central to the epigenetic regulation of transcription, replication, and repair. Histone methylation marks contribute to transcriptional activation or repression depending upon the types and sites of modified residues and the degree of methylation. The methylation status of histones changes dramatically depending on cellular context and defines cell type-specific gene expression profiles. Histone demethylases have recently been implicated in this process. However, their roles in the regulation of hematopoietic stem cells (HSCs) remain poorly understood. To explore the relevance of histone demethylases in HSCs, we profiled the expression of 26 histone demethylase genes in mouse hematopoietic cells and found that *F-box and leucine-rich repeat protein 10* (*Fbxl10*, also known as *Kdm2b* or *Jhdm1b*) is highly expressed in $CD34^-c\text{-}Kit^+Sca\text{-}1^+$Lineage marker$^-$ ($CD34^-$KSL) HSCs and $CD34^+$KSL multipotent progenitors, but is markedly down-regulated during differentiation in bone marrow. *Fbxl10* belongs to the jumonji C domain-containing histone demethylases and is a demethylase specific to histone H3 mono/di-methylated at lysine 36 (H3K36me1/me2). Fbxl10 promotes the proliferation and functions as a physiological inhibitor of senescence in mouse embryonic fibroblasts through repression of *p15Ink4b* and *p16Ink4a*. Based on these data, we hypothesized that *Fbxl10* plays a role in the maintenance of HSCs and investigated the role of Fbxl10 in HSCs by conducting a gain-of-function analysis. $CD34^-$KSL HSCs were transduced with an empty control or an *Fbxl10* retrovirus and cultured in the presence of SCF and TPO. At day 14 of culture, although *Fbxl10*-transduced $CD34^-$KSL HSCs gave no apparent growth advantage to cells, the percentage of KSL cells was 2-fold higher in the *Fbxl10* culture than in the control culture. The total number of colony-forming cells (CFCs) derived from *Fbxl10*-transduced $CD34^-$KSL HSCs was slightly increased in the 3.5-day culture compared to the control, but increased up to 2-fold in the 10-day culture. Morphological evaluation of the colonies revealed that the control and *Fbxl10* cultures retained comparable numbers of colony-forming unit-neutrophil/macrophage/Erythroblast/Megakaryocyte (CFU-nmEM) with the potential for differentiation into multiple myeloid lineages at day 3.5 of culture while after 10-day culture, the *Fbxl10* culture retained more CFU-nmEM than the control culture. These data demonstrated that forced expression of *Fbxl10* in $CD34^-$KSL HSCs expands CFCs with multi-lineage differentiation potential during *ex vivo* culture. Forced expression of *Fbxl10* significantly repressed the expression of *p15Ink4b*, *p16Ink4a*, *p18Ink4c*, and *p57Kip2* in KSL cells expressing *Fbxl10*. Chromatin immunoprecipitation assays confirmed the direct binding of flag-tagged Fbxl10 to the *p15Ink4b*, *p19Arf*, *p16Ink4a*, and *p18Ink4c* promoters and a significant decrease in H3K36me2 levels and a moderate increase in H2Aub levels at these promoters and gene bodies on forced expression of *Fbxl10* in $Lineage^-c\text{-}Kit^+$ cells. Competitive repopulation assays demonstrated that *Fbxl10*-transduced $CD34^-$KSL HSCs prevents exhaustion of the long-term repopulating potential of HSCs following serial transplantation. We conclude that the histone H3K36 demethylase, *Fbxl10*, is a novel epigenetic regulator in HSCs, which plays an important role in maintenance of self-renewal capacity and multipotency of HSCs.

1032

ESSENTIAL ROLE OF TIP49 IN HEMATOPOIETIC STEM CELLS

O Bereshchenko,[1] E Mancini,[2] L Luciani,[2] C Riccardi,[1] C Nerlov[3]

[1]*University of Perugia, Perugia, Italy*

[2]*EMBL, Mouse Biology Unit, Monterotondo, Italy*

[3]*The University of Edinburgh, College of Medicine and Veterinary Medicine, UK, Edinbourgh, United Kingdom*

Background. Tip48 and Tip49 are members of a conserved protein family with homology to bacterial ATP-dependent DNA helicase RuvB. In eukaryotes, Tip48 and Tip49 perform essential functions as components of several multi-protein complexes, involved in regulation of transcription, DNA repair and telomere maintenance. In mammalian cells Tip48/49 regulate the function of several key regulators of cell proliferation, such as Myc, E2F, β-catenin, p53 and likely C/EBPα. Their function in mouse development and hematopoiesis has not been yet investigated. *Aims.* The aim of this study is to evaluate the importance of Tip49 protein *in vivo* by conditionally deleting tip49 gene in mice. The role of Tip49 is addressed during mouse development as well as in adult hematopoietic tissues, specifically in hematopoietic stem cells (HSCs). *Methods.* A conditional allele of Tip49 gene in mice has been generated using a standard Cre-LoxP approach. The floxed gene was then bred into homozygocity (tip49 fl/fl). In order to generate tip49-null allele, mice carrying the conditional alleles were bred to a general Cre deleter line. To specifically delete Tip49 in adult mice, tip49 fl/fl mice were crossed to Mx1-Cre interferon-inducible line to efficiently delete tip49 in bone marrow, spleen and liver. *Results.* General deletion of Tip49 results in early embryonic lethality at periimplantation stage, while inducible deletion of tip49 in hematopoietic system also results in rapid lethality associated with anemia and pancytopenia. Bone marrows of tip49-deficient mice manifested a rapid drop in total cell number, associated with a decrease in progenitor cells proliferation and disappearance of HSCs. The effects of tip49 gene deletion were hematopoietic cell autonomous, as Tip49 deletion in chimeric bone marrows led to an early apoptotic cell death exclusively in mutant long-term HSCs (Lin-Sca-1+c-kit+CD150+) and not in the wild type competitor HSCs. *Summary.* These data demonstrate the essential role of transcriptional regulator Tip49 in adult hematopoietic stem cells, and suggests that modulation of its activity may represent a way to impinge on HSC functions.

1033

PLEIOTROPHIN IS A SECRETED NICHE FACTOR WHICH REGULATES ENGRAFTMENT OF HEMATOPOIETIC STEM CELLS

R Oostendorp, R Istvanffy, M Kröger, S Graf, U Keller, C Peschel

Klinikum rechts der Isar der TUM, Munchen, Germany

Hematopoietc stem cells (HSC) are maintained at a quiescent state during steady-state hematopoiesis. HSC are charachterised by their ability to respond quickly to hematopoietic stress *in vivo*, as well as in culture, by increasing proliferation and inducing early lineage commitment. It is likely that secreted niche factors are involved in this transition from quiescence towards activation. We here show that knockdown of the secreted factor pleiotrophin (Ptn-KD) in stromal cells increases proliferation as well as production of hematopoietic progenitors and HSC activity in co-cultures with lineage-negative (Lin-) hematopoietic cells. Moreover, engraftment of cells co-cultured with Ptn-KD stromal cells is associated with increased numbers of Cd34- Lin- Sca+ Kit+ (LSK) cells and dominant myeloid regeneration. Despite clear effects of Ptn deficiency in co-cultures, steady-state hematopoiesis is not altered in Ptn knockout (Ptn-/-) mice. This suggests that Ptn May be involved in limiting HSC activation, but is probably not involved in quiescence. Indeed, engraftment of wild-type HSC in lethally irradiated Ptn-/- mice mirrors the cultures on Ptn-KD stromal cells in that engraftment is increased in serial transplantations with progressive myeloid skewing and accumulation of CD34- LSK donor cells. On a molecular level, steady state Ptn-/- LSK cells express decreased levels of cyclin D1, but an increased expression of the myeloid master- regulator C/EBPalpha. In contrast, the observed increase in hematopoietic regeneration in co-cultures on PtnKD stromal cells is associated with UPregulation of cyclin D1 (Ccnd1), whereas again C/EBPalpha was also increased. Thus, the difference between steady-state quiescence and activation of engraftment appears to lie in strict regulation of cyclin D1 through Ptn during early HSC activation. Interestingly, neither in steady state Ptn-/- cells, nor in wild-type LSK cells co-cultured on Ptn-KD stroma, did the regulation of cyclin D1 through Ptn depend on changes in transcript or protein levels of b-catenin. This finding indicates that regulation of HSC activation and engraftment through Ptn is independent of canonical Wnt signaling. In conclusion, our results point to different regulatory mechanisms in normal hemostasis and in hematopoietic regeneration. Moreover, our results support the hypothesis that Ptn secreted by the microenvironment is an important regulator of cyclin D1-dependent hematopoietic regeneration.

ENERGY METABOLISM OF GLUCOSE AND ATP AFFECTS THE GROWTH AND DIFFERENTIATION OF HEMATOPOIETIC STEM/PROGENTOR CELLS

K Matsui, E Ezoe, S Shibata, O Otsuka, O Oritani, K Kanakura

Osaka University Graduate School of Medicine, Suita, Japan

Background and Aims. Recently, it has been reported that undifferentiated state of hematopoietic stem cells is regulated by their environmental factors, such as oxygen concentration. Furthermore, we have clarified that a NAD dependent histone deacetylase, Sirt1, is involved in the fate of hematopoietic stem cell as energy sensor. In this study, we examine the effects of energy metabolism on the proliferation and differentiation of hematopoietic stem/progenitor cells. *Methods and Results.* To clarify the relation of energy metabolism and cell cycle of hematopoietic stem/progenitor cells, murine bone marrow derived lineage(-), Sca-1(+), c-Kit(high) (KSL) cells were double stained with Pyronin Y and Hoechst, and were divided into cells in G0, G1, and S/G2/M periods. The intracellular ATP concentrations rose as the cell cycles shift from G0, G1 to S/G2/M (0.25, 0.45, 0.60pg/cell, respectively). We also visualized intracellular NADH with 460nm excitation. Though NADH could be detected at a low level in cells in G0, potent fluorescence was observed in cells in S/G2/M. From these data, it was supposed that energy metabolism such as ATP or NADH production may be activated when a hematopoietic stem cell enters into cell cycle. Next, we cultured KSL cells in the medium containing 0, 50, 100, 150 or 200 mg/dL of glucose, supplemented with TPO, SCF, Flt-3L. Cell proliferations were promoted glucose-dose dependently. On the other hand, the residual KSL population was the highest in cells cultured with 50 mg/dL of glucose and the lowest in cells cultured with 200mg/dL. Next, we performed paired daughter cell colony assays. Murine bone marrow KSL cells were clonally sorted into 96 well plates and cultured with medium containing 50 or 200 mg/dL of glucose. When a sorted cell divided into two daughter cell pair, which were then separated by micromanipulation and transferred into methylcellulose medium containing 200mg/dL of glucose. We evaluated the period from sorting to the first division of each cell, and the colonies from each daughter cell pair were evaluated 8 days after manipulation. The periods of division were shorter in KSL cells cultured with 200mg/dL of glucose. If a stem cell is divided symmetrically into two stem cells, which means selfrenewal, the daughter cell pair will form mix/mix colony pair. Forty-four percent of daughter cell pairs from KSL cells cultured with 50mg/dL of glucose formed mix/mix colony pairs, in contrast to 22% in KSL cells cultured with 200mg/dL. These data demonstrated that low glucose concentration leads cell cycle suppression and promotes selfrenewal of hematopoietic stem/progenitor cells. We also performed the same paired daughter cell assays using KSL cells cultured with nicotinamide(NA), the inhibitor of Sirt1. NA-supplement cancelled completely the cell cycle suppression and partially mix/mix colony pair formation in KSL cells cultured in low dose glucose, suggesting that Sirt1 may be involved in the cell cycle suppression and the promotion of selfrenewal of hematopoietic stem/progenitor cells in low dose glucose environment. *Conclusions.* In hematopoietic stem/progenitor cells, the environmental glucose concentration and the intracellular energy metabolism are involved in the maintenance of stemness and the regulation of proliferation.

IDENTIFICATION OF A NOVEL MODE OF KINASE INHIBITOR RESISTANCE: AN F604S EXCHANGE IN FIP1L1-PDGFRA MODULATES FIP1L1-PDGFRA PROTEIN STABILITY IN A SHP-2 AND SRC-DEPENDENT MANNER

P Gorantla, N von Bubnoff, S Schneider, H Leischner, C Peschel, G Duyster

Technical University of Munich, Munich, Germany

FIP1L1-PDGFR alpha is a constitutively activated protein kinase which is associated with chronic eosinophilic leukemia (CEL). Imatinib is clinically active in FIP1L1-PDGFRA positive disease. However, clinical resistance to imatinib has been observed in FIP1L1-PDGFRA positive leukemia and was shown to occur due to secondary mutations in the PDGFR alpha kinase domain. Using a screening strategy to identify imatinib resistant mutations, we generated imatinib resistant single cell clones expressing FIP1L1-PDGFRA. Analysis of the PDGFRA kinase domain in these cell clones revealed a spectrum of resistance mutations including the clinically reported exchange T674I. Interestingly, one of the most abundant mutations was a Phe to Ser exchange at position 604 (F604S), which occurred alone or in combination with other exchanges. Surprisingly, FIP1L1-PDGFRA/F604S (F604S FP) did not increase the biochemical or cellular IC50 value to imatinib when compared to wild-type FIP1L1PDGFR(wt). However, F604S FP transformed Ba/F3, NIH3T3 and mouse bone marrow more efficiently compared to wt. Immunoprecipitation and immunoblotting indicated greatly increased amounts of F604S FP protein compared to wt in the cells. Pulse chase analysis revealed that F604S FP is strongly stabilized compared to wt. SRC coimmunoprecipitated with FIP1L1-PDGFRA but not with F604S FP. Co-expression of SRC in 293T cells augmented degradation of wt-FIP1L1-PDGFRA, but not F604S FP, indicating that SRC is a negative regulator of FIP1L1-PDGFRA protein stability. Accordingly, both the SRC inhibitor PD166326 and SRC siRNA mimicked the F604S phenotype and resulted in stabilization of the wt protein. Importantly, phosphatase inhibitor treatment of F604S FP led to destabilization and SRC recruitment indicating that phosphatases might be responsible for the enhanced stability of F604S FP. In fact, coimmunuprecipitaion experiments identified the phosphatase SHP2 as a specific binding partner of F604S and mapping experiments revealed that the phosphatase domain of SHP-2 directly interacted with F604S FP but not with wt- FIP1L1-PDGFRA. Together, these results suggest that stabilization of F604S FP is due to dephosphorylation by SHP-2 leading to lower activation of the SRC and Cbl mediated ubiquitination machinery. Therefore this work identified a novel class of resistance mutations in FIP1L1-PDGFRA, that do not act by impeding drug binding to the target, but increase target protein stability and abundance by interfering with SRC- mediated degradation.

TARGETING THE CDC2-C/EBPA PATHWAY INDUCES DIFFERENTIATION OF HUMAN ACUTE MYELOID LEUKEMIAS WITH FLT3ITD ACTIVATING MUTATIONS

M Alberich Jorda,[1] H Radomska,[1] B Will,[1] D Gonzalez,[1] R Delwel,[2] D Tenen[3]

[1]*Beth Israel Deaconess Medical center, Boston, United States of America*
[2]*ErammusMC, Rotterdam, Netherlands*
[3]*Harvard Medical School and CSI, National University Singapore, Singapore, Singapore*

Activating mutations in FLT3 (fms-like tyrosine kinase 3) receptor, such as FLT3ITD, are among the most prevalent mutations in acute myeloid leukemias. The oncogenic role of FLT3 mutants has been attributed to the abnormal activation of several downstream signaling pathways, such as STAT3, STAT5, AKT, or ERK1/2. We have previously demonstrated that ERK1/2 kinase can phosphorylate C/EBPA on serine 21, and consequently inactivate its function. C/EBPA is a transcription factor playing a critical role in granulocytic differentiation and often inactivated in various subtypes of leukemia by multiple mechanisms. Among FLT3ITD patients, only 39% demonstrated activation of MEK1, and thus the ERK1/2 pathway, yet we show here that C/EBPA can be still phosphorylated on serine 21. We identified cdc2 (also known as CDK1) as a novel FLT3ITD activated kinase and we determined that FLT3ITD mutant receptors superactivate cdc2 via upregulation of cyclins A and B. Furthermore, we demonstrate that cdc2 directly phosphorylates C/EBPA on serine 21 (*in vitro* and *in vivo*), which inhibits its differentiation-inducing function. Importantly, we found that pharmacological and genetic (knock-down) inhibition of cdc2 activity relieves the differentiation block in FLT3ITD cell lines. Next, we investigated the effect of cdc2 inhibitor, NU6102, in primary FLT3ITD leukemia patient samples collected at diagnosis. As expected, cdc2 inhibition led to a remarkable hypophosphorylation of C/EBPA and a dose-dependent decrease in immature myeloid surface marker expression, such as CD133 and CD38, as well as increase in CD15 expression. Moreover, the treatment of FLT3ITD carrying specimens with NU6102 for 7 days was accompanied by morphological changes suggesting granulocytic differentiation. Altogether, our data indicate that FLT3ITD mutants superactivate cdc2, which leads to phosphorylation of C/EBPA at serine 21 resulting in a differentiation block. Clinical trials with cdc2 inhibitors are currently under way for various malignancies. Our data strongly suggest that targeting the cdc2 pathway might be applied for the treatment of FLT3ITD mutant leukemias, especially of those resistant to FLT3 inhibitor therapies.

1037

COMPARATIVE GENOME-SCALE RNA INTERFERENCE SCREENS IDENTIFY THE MLL-FUSION ASSOCIATED GENE AF4 AS A REGULATOR OF CD133 TRANSCRIPTION

B Mak, J Moffat

University of Toronto, Toronto, Canada

Background. The AC133 epitope expressed on the pentaspan transmembrane glycoprotein CD133 was first discovered as a cell-surface marker of hematopoietic progenitor cells. Since then, it has been used as a marker for cancer stem cells from various tissue types, including blood. Although numerous studies have reported that DNA methylation of the CD133 promoter regulates its transcription regulation, the specific transcription factors involved remains poorly understood. *Aim.* To identify factors involved in regulating CD133 transcription. *Methods.* We performed a pooled short-hairpin RNA interference screen targeting >11,000 human genes in the CD133 endogenously expressing human epithelial colorectal adenocarcinoma Caco-2 cell line and in an engineered human embryonic kidney (HEK) 293 line exogenously expressing CD133. shRNA knockdowns that resulted in decreased cell-surface CD133 expression as determined by fluoresent-activated cell sorting were considered hits and their identities were deconvoluted using custom microarrays. To identify genes involved in endogenous CD133 transcription, we focused on shRNA hits specifically required for CD133 expression in Caco-2 cells, but not in the HEK 293/CD133 line. *Results.* We identified the transcription activator AF4 as a regulatory of CD133 transcription, as gene knockdown of AF4 results in a dramatic reduction in CD133 transcript levels. It has been well established that AF4 is associated as a MLL-fusion in acute lymphoblastic leukemia (ALL). Consistent with our findings, MLL-AF4 has been demonstrated to interact with the CD133 promoter in the ALL cell line SEM. Furthermore, MLL-AF4/AF4 was shown to be involved in a protein complex involved in transcription elongation. When we performed gene targeted knockdown of complex members, we observed a significant decrease in CD133 transcript, suggesting that MLL-AF4 and AF4 functions in this protein complex to regulate CD133 transcription elongation. *Summary.* Our study provides mechanistic insight into the transcriptional regulation of CD133 in MLL-AF4 expressing ALL cell lines and in non-leukemia cell lines.

DIFFERENTIAL STIMULATION OF CEBPA TARGET GENES DURING ATRA-INDUCED GRANULOCYTIC VERSUS CDDO-INDUCED GRANULOMONOCYTIC DIFFERENTIATION

S Koschmieder,[1] S Erichsen,[1] HU Klein,[1] C Elling,[1] F Sprenger,[1] L Kerstiens,[1] A Koppelle,[1] M Sporn,[2] M Dugas,[1] W Berdel,[1] C Mueller-Tidow[1]

[1]*University of Muenster, Muenster, Germany*
[2]*Dartmouth Medical School, Hanover, United States of America*

Background. Induction of differentiation may be a powerful means to treat human acute myeloid leukemia (AML). However, while all-trans retinoic acid (ATRA), which induces granulocytic differentiation, has been applied successfully in patients with acute promyelocytic leukemia, the clinical benefit in the other AML subgroups of patients has been much less promising. *Aims.* We have previously shown that 2-cyano-3,12-dioxooleana-1,9-dien-28-oic-acid (CDDO) induces granulomonocytic differentiation, and this was at least in part mediated by translational activation of the transcription factor CCAAT Enhancer Binding

Protein alpha (CEBPA) (Koschmieder *et al.*, Blood 2007). Here, we investigated similarities and differences between ATRA- and CDDO-induced effects. *Methods.* HL60, 32D, or 293T cells were used for analysis of RNA expression by RT-PCR, CEBPA transactivation potential using luciferase assays, and CEBPA target identification by chromatin immunoprecipitation (ChIP)-chip array techniques. *Results.* Both ATRA (1 μM) and CDDO (0.5 μM) induced Id1 and Id2 mRNA in HL60 cells, although Id1 induction was less pronounced with CDDO. Since Id1 and Id2 are CEBP target genes, we analyzed CEBPA binding to Id1 and Id2 target genes and found that CEBPA bound to Id1 and Id2 promoters as well as the Id1 enhancer. CEBPA stimulated luciferase activity of the Id1 enhancer but not the Id1 promoter. CEBPA, CEBPB, and CEBPD stimulated Id1 enhancer activity to different extents. Moreover, while ATRA and CDDO only weakly stimulated Id1 enhancer activity in parental 32D cells, concomitant transfection of CEBPA, CEBPB, or CEBPD additively increased this activity. ChIP-Chip array analysis of CEBPA binding in HL60 cells demonstrated remarkable similarities of known and novel CEBPA target genes induced by both ATRA and CDDO, including increased binding to Myd88, Vva1, IL3, Ly6e, Rgs2, Csf3, IL8 and decreased binding to Csf1 and EpoR. *Conclusions.* The differentiation inducers ATRA and CDDO stimulate similar pathways of granulocytic differentiation involving CEBPA and its target genes. In addition, our ChIP-chip array approach identified novel targets of CEBPA which may enhance our understanding of cell fate decisions during granulocytic versus monocytic differentiation.

Background. Low risk myelodysplastic syndromes (MDS) CD34+ cells exhibit high level of the death receptor Fas at their surface and abnormal Fas-dependent apoptosis. Fas expression decreases when the disease progresses to acute myeloid leukemia (AML). Based on recent evidence of higher DNA methylation level in high-risk MDS, we explore the epigenetic regulation of FAS gene during MDS evolution to AML. *Aims.* This study aims at investigating the regulation of Fas and FasL in MDS/AML cells. *Methods.* We quantify FAS gene expression by RT-qPCR in bone marrow mononuclear cells (BMMNC) from 136 patients (86 MDS, 30 AML) and in 20 controls, including 61 patients treated with azacitidine according to the FDA/EMEA schedule. Response is scored according to IWG2006 criteria for MDS and to Cheson for AML. DNA methylation on bisulfite DNA and ChIP assays for histone modifications (H3K9/14ac, H3K4me2, H3K9me2, H3K27me3) are performed in HL60 cell line, SW480 colon carcinoma cell line and in bone marrow-derived CD34+ MDS/AML cells before and during azacitidine treatment. *Results.* We observe a significant decrease in FAS mRNA in AML compared to MDS (P<0.001). Fas decrement significantly correlated with disease progression but its expression, at diagnosis, had no impact either on overall survival or leukemia-free survival. FAS promoter was hypomethylated with an open state of the chromatin while it is hypermethylated in the Fas-negative SW480 cell line. In BM CD34+ cells, the methylation of 3 CpG dinucleotides is significantly increased in 14 AML compared to 18 MDS. In 4 AML patients, DNA methylation decreases from 28% [range: 20 - 37] to 14% [range: 11 - 15] and active marks of the chromatin are enriched, mainly the H3K4me2 after 6 cycles of azacitidine. *In vivo* azacitidine removes chromatin repression at FAS promoter and increases Fas protein expression in correlation with clinical response (Chi-square test P= 0.002). Multivariate analysis showed that high Fas expression on CD45lo/CD34+ cells at diagnosis was predictive of failure of azacitidine treatment (Hazard ratio 3.6 [95%CI: 1.1 - 11.6], P=0.032), independently of IPSS, age and previous treatment. *Conclusions.* An epigenetic mechanism is responsible for the down-regulation of Fas in AML, which is corrected by azacitidine in responder patients. Our data show that FAS gene reactivation could predict the responsiveness to azacitidine and that its expression, at diagnosis, is a biomarker of the response to azacitidine.

Background. Patients with high-risk acute myeloid leukemia (AML) have few chances of cure without allogeneic stem cell transplantation (HSCT). HSCT can be used in first remission for pts with poor-risk cytogenetics, as rescue for pts refractory to chemotherapy, at first relapse or in second and subsequent remission. UCB is an established stem cell source for HSCT. *Methods.* We retrospectively analyzed 604 adult (>18y) with de novo AML who received UCBT as first transplant. *Results.* 229 patients were transplanted in first complete remission (CR1, 228 in second or third CR and 147 in advanced disease. Patients were transplanted from 2000-2010 in 131 EBMT centers. Median age was 41 years, 18% of the patients received a previous autologous transplant. Based on available cytogenetic and molecular markers at diagnosis (n=339) 56% were in intermediate risk and 31% in unfavorable risk group. Grafts were composed of 1 (sUCBT) (n=361) or 2 (dUCBT) (n=243) CB units, 39% of CB units were identical to recipient or had 1 HLA disparity (antigen level for HLA-A and B allelic level for DRB1) while 61% had 2-3 HLA disparities. At infusion median TNC cell dose was 3.1x10^7/kg (2.4x10^7/kg with sUCBT and 3.7x10^7/kg with dUCBT) and median CD34+, 1.2x10^5/kg (1x10^5/kg with sUCBT and 1.3x10^5/kg with dUCBT). Fifty-one percent of pts received a myeloablative conditioning regimen (MAC) and 49% a reduced intensity regimen (RIC). The most common regimens used were busulphan+fludarabine+thiotepa for MAC and cyclophosphamide+fludarabine+TBI2Gy for RIC. GVHD prophylaxis consisted of CSA±MMF in 58% of pts and CSA±steroids in 32%. Median follow-up was 18 months and it was 23 months for sUCBT and 15 months for dUCBT. Cumulative incidence (CI) of neutrophil recovery, acute GVHD (II-IV) and 1y TRM was 80±2%, 26±3% and 21±3%, respectively. CI of 2y relapse was 38±3% (27% CR1, 29% CR2 and CR3, 56% advanced, p=0.001). Relapse incidence was 31% for those patients transplanted with MAC (n=291) and 30% with RIC (n=282). The 2y probability of leukemia-free-survival (LFS) was 33±2% (45% CR1, 41% CR2, 16% advanced, p <0.001). In patients given a MAC, 2y LFS was 50% for CR1, 27% for CR2 or CR3 and 17% for more advanced phase of the disease whereas it was 35%, 44% and 18% for RIC respectively. Among patients transplanted in CR1 within intermediate risk group, 2 y LFS was 46±6% and it was 33±8% for those within unfavorable risk group, while for those transplanted in CR2 it was 38±6% and 30±9%, respectively. In multivariate analysis, disease status at transplant (remission vs advanced) was the main factor associated with improved LFS (HR 2.12, 95%CI 1.3-3.15, p<0.001). Causes of death were infections or other transplant-related events (n=195) or disease progression (n=149). *Conclusion.* In conclusion, this large series of patients shows that UCBT is an option treatment for adults with high risk AML after a myeloablative or reduced conditioning regimen without a suitable HLA matched donor.

1041

COMBINED MISSING SELF MODEL AND LIGAND-LIGAND MODEL CAN PREDICT HIGHER RELAPSE RATE AFTER HLA-MISMATCHED TRANSPLANTATION WITHOUT T CELLS DEPLETION *IN VITRO*

XJ Huang, XY Zhao, YJ Chang, LL Xu, MR Huo, LP Xu, DH Liu, KY Liu

Peking University People's Hospital, Beijing, China

Background. HLA-mismatched/haploidentical stem cell transplantation (SCT) is a feasible therapeutic option for advanced hemato-

logic malignancies patients who lack an HLA-matched related or unrelated donor. Conflicting results have been reported about the impact of alloreactivity of natural killer (NK) cells on the outcome of haploidentical SCT to leukemic patients. *Aims.* The goal of this study was to explore the predictive roles of missing self model in our HLA-mismatched/haploidentical transplantation without T-cell-depletion *in vitro*, and to develop a simple algorithm on the basis of recipients and donor HLA-C and HLA-Bw4 gene content that can be used today to identify HLA-mismatched donors who will provide the most protection against relapse in T cell-replete transplants. *Methods.* We studied the HLA genotype of 153 donor-recipient pairs, who underwent unmanipulated HLA-mismatched/ haploidentical transplantation without T cells depletion *in vitro*. To apply the missing ligand model, the first step was to divide our donor-recipient pairs into 2 groups according to the number of KIR ligand in donor and recipient, ie, 3 KIR ligands ("without missing self") versus fewer than 3 ("with missing self"). Meanwhile, to apply the KIR ligand-ligand model, donors who were classified as NK alloreactive against their recipients termed KIR ligand mismatched donors throughout, possessed HLA class I KIR ligand(s) which were missing in the recipients. *Results.* Among the 153 pairs of donor-recipients, 110 and 43 recipients received HLA-mismatched/haploidentical transplants from "with missing self"and "without missing self" donors, respectively. Using Ligand-ligand model, 119 and 34 recipients received haploidentical transplantation from "KIR ligand matched"and "KIR ligand mismatched"donors, respectively. In contrast to Perugia's KIR ligand-ligand mismatched model or Handgretinger's KIR missing self model between donor-recipient pairs, we found that the cumulative incidence of 7-year relapse rate were higher in patients received transplantation from "with missing self"or "with KIR ligand mismatched"donors compared with those from "without missing self"(p=0.00746) or "without KIR ligand mismatched"(p=0.01194) donors, respectively. When combined the above predictive model together, patients were subgrouped as receiving graft from "without missing self and without KIR ligand mismatch"(best, n=43), "with missing self and without KIR ligand mismatch"(better, n=76), and "with missing self and with KIR ligand mismatch"(neutral, n=34), respectively. We found the 7-year disease-free survival (DFS), overall survival (OS), and relapse rate were best predicted by the combination of missing self and KIR ligand mismatch between recipients and donors pairs (HR 1.517(1.081-2.128), p=0.016 for DFS; HR 1.518(1.077-2.142), P=0.017 for OS; HR 2.46(1.424-4.205), P=0.001 for relapse, figure1).

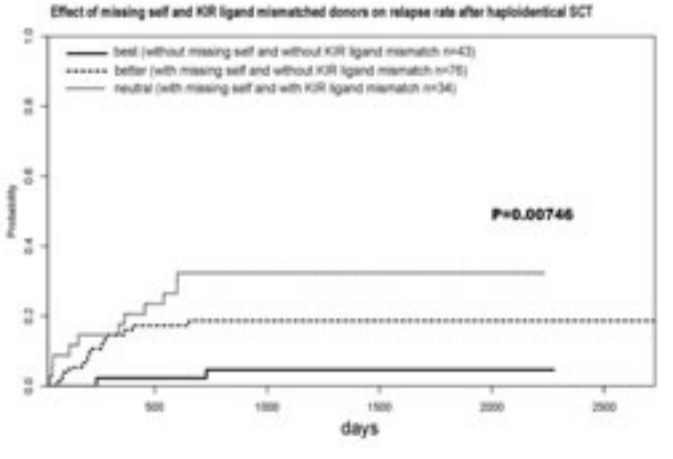

Figure 1. Seven years relapse rate after haploidentical SCT.

Conclusions. These data indicate that poor prognosis after transplantation is associated with the missing self and KIR ligand mismatch in recipients and T cell alloreaction may play a predominant role in this model. Meanwhile, we developed a simple algorithm on the basis of recipients and donor HLA-C and HLA-Bw4 gene content that can be used today to identify HLA-mismatched donors who will provide the most protection against relapse in T cell-replete transplants.

BIRTH ORDER IS NOT A MAJOR FACTOR INFLUENCING TRANSPLANT OUTCOME IN HLA-IDENTICAL SIBLING SCT - AN ANALYSIS ON BEHALF OF THE CIBMTR

C Dobbelstein,[1] M Haagenson,[2] KW Ahn,[3] S Spellman,[2] M Fernandez-Vina,[4] M Eder,[1] A Ganser,[1] S Lee[5]

[1]*Hannover Medical School, Hannover, Germany*
[2]*Center for International Blood and Marrow Transplant Research, Minneapolis, United States of America*
[3]*Medical College of Wisconsin, Milwaukee, United States of America*
[4]*M. D. Anderson Cancer Center, Houston, United States of America*
[5]*Fred Hutchinson Cancer Research Center, Seattle, United States of America*

Background. Recent single-center studies have found a birth order effect in HLA-identical sibling myeloablative stem cell transplantation (SCT): superior outcome (e. g. overall survival (OS), less relapse, lower relapse mortality) when the recipient is older than the donor. The proposed mechanism is microchimerism (MC) due to fetomaternal and transmaternal sibling cell trafficking as the donor is exposed to recipient antigens in utero. *Aim.* The aim of this study was to validate single-center data in a multicenter patient cohort. *Methods.* This is a retrospective analysis from the CIBMTR dataset. Patients with a diagnosis of a hematologic malignancy (AML, ALL, MDS, CML), at any age (adults and pediatric patients), receiving an allogeneic SCT from HLA-identical sibling donors (recipient and donor of different ages at the time of transplant, but no more than 15 years apart) since 1990 up to December 2007 were included. Outcome was analysed in terms of OS, relapse rate and relapse mortality, leukemia free survival (LFS), treatment related mortality (TRM), acute and chronic graft versus host disease (GvHD). *Results.* A total of 11877 patients (6089 where the recipient was older; 5788 where the donor was older) have been identified. The median age of the patient was 35 years (range 2-75y.) in the recipient older group compared to the donor older donor with 31 years (range < 1-72y.; p< 0,0001). In univariate analysis, recipient older pairs have a higher TRM which was confirmed in multivariate analysis. In multivariate analysis for survival, there was an interaction between age and birth order. A better survival was observed in recipient older pairs in the youngest recipient age group compared to a superior OS in donor older pairs when the recipient was 40-49 years. Further, there was no main effect on LFS, relapse rate, acute or chronic GVHD. Subset analysis limited to early stage myeloid diseases, peripheral blood T replete grafts, and myeloablative conditioning showed better survival in the donor older group (RR 0.78, 95% CI 0.64-0.96, p=0.02). *Conclusions.* The hypothesized positive effect of having the recipient older than the donor compared to pairs where the donor is older than the recipient was not observed in this study, except in the very youngest recipients.

1043

FASTER REGISTRATION ON INTERNATIONAL DONOR REGISTRIES AND SHORTER TIME TO ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION AFTER HAVING FOUND A DONOR CONFERS BETTER OUTCOME IN ACUTE LEUKEMIA PATIENTS

M Michallet,[1] M Sobh,[1] S Morisset,[1] X Thomas,[1] F Nicolini,[1] Y Chelghoum,[1] H Labussiere,[1] S Ducastelle,[1] F Barraco,[1] M Detrait,[1] G Cannas,[1] J Fattoum,[1] S Rey,[2] V Dubois[2]

[1]*Edouard Herriot Hospital, Lyon, France*
[2]*EFS, Lyon, France*

Background. A patient has 30% chance to find an HLA identical sibling donor (SD) and approximately 40% chance to find a suitable unrelated donor (UD), 40% of registered patients relapse or die before finding a donor. *Aims.* We evaluated the outcome in acute leukemia (AL) patients, whether they had an HLA identical SD, an UD or no donor (ND) after registration on France Greffe de Moelle (FGM) registry, either transplanted later or not. Secondary objectives were to evaluate the impact of intervals diagnosis-allo-HSCT, donor finding-allo-HSCT, registration-allo-HSCT, on OS and EFS. *Methods.* We analyzed 251 AL patients, 117 (47%) males and 134 females, median age at diagnosis 40 years [16-66], 177 (71%) AML and 75 ALL. Seventy six (30%) patients had an available SD and received allo-HSCT within a median time of 3.5 months (0.5-43) and 38 (15%) had SD but were not transplanted due to early relapse and/or death. For patients with no available SD, a registration on FGM registry was done, 137 patients were registered after a median interval of 2.3 months (0.4-135) from diagnosis, 33 (13%) patients did not find any donor and they received

Figure 1.

the standard of care; 104 (41%) patients found an UD or UCB unit after a median time of 1.6 months (0.3-26): 86 with UD of which only 60 have been transplanted within a median time of 2.3 months (0.4-14), 18 with UCB of which only 17 were transplanted. Among transplanted patients, 113 (74%) were in CR, 40 in <CR. Fifty (33%) received PBSC, 86 (57%) received BM and 17 (10%) UCB units. For conditioning, 56 (37%) were RIC and 96 standard. For HLA, there were 45 HLA 10/10, 14 HLA 9/10, 1 HLA 8/10 and for UCB 14 HLA 4/6 and 3 HLA 5/6. *Results.* After a median follow-up of 25 months (0.2- 234), the median OS was 78 months (51-133) for transplanted patients with SD (3years OS: 68%), it was 33 months (27-47) for transplanted patients with UD (3years OS:44%), 21 months (15-37) for not transplanted patients with available SD or UD (3years OS:34%) and it was 31 months (23-221) for patients with ND (3years OS:45%). Median EFS for the same groups was 38 months (23-133), 24 months (17-36), 15 months (11-24) and 23 months (14-48) respectively. In multivariate analysis, 3 significant factors affected OS: disease status (<CR) HR= 2.8 [1.5-5.3] p<0.001; long interval diagnosis-registration HR= 2 [1.2-3.6] p=0.001 and conditioning (standard) HR=0.27 [0.1-0.8] p=0.02. *Conclusion.* The interval diagnosis-registration appeared as major factor affecting survival in UD allo-HSCT settings.

Background. In 2003, Eurocord group has described outcomes after UCBT in 95 children with AML. *Aims.* Better define the role and to identify prognostic factors of UCBT in childhood with AML. *Methods.* Retrospective analyses of 390 children with AML who received single UCBT in EBMT centres. *Results.* Median age and median weight at UCBT was 6 years and 22 Kg. Transplantation were performed from 1994 to 2010: 37% during CR1, 42% in CR2 and 21% in more advanced disease. On the basis of cytogenetic and molecular characteristics, 253 children (65%) were stratified into 3 groups: 35% in the unfavourable, 22% in the intermediate and 8% in the favourable. The majority of grafts were HLA 5/6 (44%) or 4/6 (37%). Median number of infused total nucleated (TNC) and CD34+ cells were 4.95x107/kg and 1.9 x105/kg, respectively. The majority of patients (86%) received myeloablative conditioning regimen with TBI (25%) or busulphan (60%). ATG was used in 80% of cases. Median follow-up time was 24 months. Median time to achieve neutrophil and platelet recoveries was 24 and 42 days. Cumulative incidence (CI) of ANC recovery was 85%; in a multivariate model it was favourably associated with a higher TNC dose (> median, HR: 1.40, p=.008) and transplantation in CR1 (HR: 1.39, p=.015). At day 100, CI of grade II-IV acute GvHD was 34% (11% grade III, 5% grade IV). At 2y CI of NRM was 24%. Multivariate analysis showed that: TNC dose (HR: 0.58, p=.024) and disease status (CR1 vs others) at time of UCBT (HR: 0.55, p=.026) were associated with decreased NRM. There was a trend toward a decreased NRM in patients given a 6/6 or 5/6 HLA graft (p=.06). CI of relapse at 2 years was 17% in CR1, 26% in CR2 and 44% for more advanced disease. Estimated 2 y-LFS was 63% in CR1, 43% in CR2 and 22% in more advanced patients. LFS of 49 children transplanted in CR1 with unfavourable disease was 70±7 %, not statistically different from the overall CR1 group. For those transplanted in CR2, 2y-LFS was 71±9%, 33±9 % and 40±7% in the favorable, intermediate and unfavorable subgroup. Multivariate analysis in CR2 cohort identified 2 significant prognostic factors: favorable disease (HR:3,74, p=.005) and previous CR1 duration longer than 7 months (the threshold of the first quartile, HR:1,85, p=.03). *Conclusions.* We conclude that UCB is an attractive stem cell source in childhood AML when no HLA-identical donor is available. Cell dose remains an important factor for engraftment and NRM. Results are very encouraging for unfavorable diseases in CR1.

Progress in the treatment of non-Hodgkin Lymphomas

1045

DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) IN VERY ELDERLY PATIENTS (OLDER THAN 80 YEARS): PROMISING RESULTS IN THE ERA OF CHEMOIMMUNOTHERAPY DESPITE LOWER DOSE INTENSITY

T Vassilakopoulos,[1] P Papageorgiou,[2] M Angelopoulou,[3] K Petevi,[3] A Anastasopoulou,[3] A Stavroulaki,[4] P Konstantinidou,[5] J Kotsianidis,[6] MC Kyrtsonis,[3] M Siakantaris,[3] S Kokoris,[3] C Kalpadakis,[4] M Dimou,[3] G Georgiou,[3] M Moschogiannis,[7] X Yiakoumis,[7] V Pappis,[3] O Tsopra,[3] K Tsatalas,[6] H Papadaki,[4] J Dervenoulas,[2] P Panayiotidis,[3] J Meletis,[3] G Pangalis,[7] N Constantinou[5]

Background. The optimal treatment of very elderly patients with DLBCL has not been been well established. Many patients have received chemotherapy (CIT) without anthracyclines with rather poor results. The combination of Rituximab with CHOP has greatly improved the prognosis of DLBCL. The administration of Rituximab in very elderly patients might permit dose reductions in the chemotherapy regimen without significant loss in efficacy. *Aims.* To describe the clinical characteristics, the actually delivered doses of chemoimmunotherapy (CIT) drugs in routine clinical practice and the final outcome of very elderly patients with DLBCL in the era of CIT. *Patients and Methods.* Among 579 patients with DLBCL treated in 5 medical Centers in the era of CIT, 56 were older than 80 years (10%). We studied the clinical and laboratory characteristics of these patients (individual factors of IPI, gender, B-symptoms, anemia, lymphocytopenia, albumin), Progression Free Survival (PFS) and Overall Survival (OS) in comparison with 523 patients younger than 80 years, who were treated during the same period. In addition, we analyzed the relative dose intensity (RDI) of the 4 drugs (except of corticosteroids), which was actually delivered to the very elderly patients, using as reference the doses and time intervals of standard R-CHOP-21. *Results.* The median age of the very elderly patients was 82.5 years (80-91). The frequency of adverse prognostic factors (IPI, R-IPI, low serum albumin, severe lymphocytopenia) was significantly higher in very elderly patients, but the difference was mainly due to the favorable prognostic profile of the younger patient group (<60 years). In contrast, the characteristics of patients aged 61-79 and ≥80 years were similar. The 5-year PFS was 81%, 68% and 62% (p=0.0005) in the group of ≤60, 61-79 and ≥80 year-old patients respectively (p=0.12 for 61-79 vs. ≥80). The corresponding 5-year OS was 90%, 65% and 55% (p=0.0001, but p=0.048 for 61-79 vs. ≥80). In multivariate analysis of PFS, age ≥80 years had no independent prognostic significance when IPI and lyphocytopenia were taken into account. On the contrary, it was an independent prognostic factor for OS with a relative risk 2.9 (p<0.001) and 2.1 (p=0.01) compared to patients <80 years or 61-79 years respectively. Among patients ≥80 years-old, who received >1 cycle of anthracycline-based CIT, the median RDI and IQR were: Rituximab 85% (78-99), cyclophosphamide 76% (67-86), anthracycline 60% (50-69), vincristine 64% (50-76). Moreover, 6/56 patients did not receive anthracyclines and 2 received only 1 cycle. *Summary/Conclusions.* CIT provides prolonged survival in >50% of DLBCL patients ≥80 years-old. These results are very encouraging even though RDI for chemotherapeutic drugs was low in the everyday clinical practice. Age ≥80 years was not an independent prognostic factor for PFS but only for OS. These observations suggest that the majority of very elderly patients with DLBCL should not be treated with palliative approaches. Instead they should receive as complete R-CHOP-like CIT as possible with curative intent.

1046

TREATMENT OF SPLENIC MARGINAL ZONE LYMPHOMA WITH RITUXIMAB MONOTHERAPY VS SPLENECTOMY

C Kalpadakis,[1] G Pangalis,[2] T Vassilakopoulos,[3] S Sachanas,[2] F Kontopidou,[4] X Yiakoumis,[2] S Kokoris,[3] E Dimitriadou,[3] M Moschogiannis,[2] P Korkolopoulou,[5] MC Kyrtsonis,[3] P Tsirkinidis,[6] M Siakantaris,[3] H Papadaki,[1] M Angelopoulou[3]

[5]*Pathology Department, University of Athens, Athens, Greece*
[6]*Haematology Department, 401 Military Hospital, Athens, Greece*

Background. Treatment of splenic marginal zone lymphomas (SMZL) is not standardized. Splenectomy has traditionally been considered as the treatment of choice. Recent data indicate that rituximab is highly effective and that it could be considered as initial therapy for SMZL. *Aims.* To compare the efficacy of rituximab monotherapy versus splenectomy in SMZL patients. *Methods.* The studied population included 52 patients with SMZL who were diagnosed and prospectively treated in our Departments between September 2003 and July 2010 with rituximab monotherapy (induction phase at a dose of 375 mg/m^2 per week for 6 weeks and maintenance phase every 2 months for one year) and 26 patients who were diagnosed prior to rituximab period and who were faced by splenectomy only. Rituximab treated patients were evaluated for response 2 months after induction and 2 months after the end of maintenance phase. Demographic features, clinical and laboratory characteristics, type of response, response duration, overall survival, progression-free survival and cause of death were analyzed in all patients. *Results.* Patients characteristics were similar between the two treatment groups. The overall response rate (ORR) to rituximab after the end of induction phase was 92% (46% CR, 19% CRu, 13% PR, 13% CHR). The median time to hematologic and clinical response was 4 and 5 weeks respectively. 31/52 patients have already completed the maintenance phase, 29 of them (81%) sustained their initial response, while 5 improved their response and one progressed. 85% of splenectomized patients achieved clinical and haematological remission. The 5-year OS and PFS for rituximab treated and splenectomised patients was 97±3% and 75±9% (p value=0.01) respectively and 58±10% and 56±11% (p value=0.49) respectively (Table 1). Rituximab seems to confer a survival advantage over splenectomy, although so far no difference was noticed in the 5-year PFS time. One toxic death was recorded in the splenectomy arm. In the rituximab arm grade 2 neutropenia was noticed in one patient, grade 3 thrombocytopenia in another, while one patient could not complete therapy due to severe hypotension. *Conclusions.* Rituximab is a highly effective and well tolerated therapy and it can substitute splenectomy as the treatment of choice for SMZL.

Table 1. Rituximab vs splenectomy in SMZL pts.

Treatment	Pts (#)	ORR (%)	CR (%)	PR (%)	CHR (%)	5-year PFS (%)	5-year OS (%)
Rituximab	52	92	46	13	13	58	97
Splenectomy	26	85	0	0	85	56	75

ORR Overall Response Rate, CR: Complete Response, PR: Partial Response, CHR: Complete Haematological Response, PFS: Progression Free Survival, OS: Overall Survival

1047

INFLUENCE OF THE TYPE OF IMMUNOSUPPRESSIVE THERAPY IN THE DEVELOPMENT OF PTLD FOLLOWING ORTHOTOPIC LIVER TRANSPLANT: A SINGLE CENTER, LONG-TERM SURVEY ON 1,649 PATIENTS

C Tarella,[1] O Perotto,[1] C Ruella,[1] D Novero,[2] F Lupo,[2] A Ricchiuti,[2] R Passera,[2] M Salizzoni[1]

[1]*University of Torino, Torino, Italy*
[2]*AOU san Giovanni Battista - Molinette, Torino, Italy*

Background. Post-transplant lymphoproliferative disorder (PTLD) is a serious complication in solid organ transplant recipients. The incidence is quite variable, and the role of the immunosuppressive treatments on the risk of PTLD development remains to be elucidated. *Aims.* To evaluate the frequency and the risk factors of PTLD in a large series of Orthotopic Liver Transplant (OLT). *Patients and Methods.* Data have been collected on 1,803 OLT performed in 1,649 patients at the Liver Transplant Center in Torino, Italy, during the period 1990 - 2008. OLT was performed in patients aged up to 65 yr. old, with 60 pediatric patients (age at OLT < 12 ys) and two patients aged 65 to 68 yr. The most common indications for OLT were viral cirrhosis, biliary disease and alcoholic cirrhosis. Cyclosporine A (CsA) has been used as primary immunosuppression in most patients; in the last few years, tacrolimus has been increasingly employed as primary immunosuppressive drug; steroids are usually associated to Calcineurin-inhibitors. Overall, 1,189 (73.8%) patients received CsA in prevalence, 423 (26.2) had tacrolimus in prevalence. PTLD were diagnosed by histology and immunophenotipical analysis on biopsy specimens. Several parameters were evaluated for possible association with PTLD occurrence, including age, sex, liver disease and HCV state, presence of hepatocellular carcinoma, time elapsed from OLT to PTLD, CsA vs tacrolimus use, other drugs for graft rejection. The cumulative incidence of PTLD was determined using the Fine and Gray competing risk regression model. Treatment for PTLD included: i. reduction or discontinuation of the immunosuppression; ii. chemotherapy and/or radiotherapy (15 cases); Rituximab was delivered to 11 patients (combined with chemotherapy in 6). *Results.* At a median follow-up of 5.8 yrs. (range 0.1-17.5)., 1,298 (78.7%) patients are alive, with a 5-yr Overall Survival projection of 79.5 %. So far, 20 PTLD have been recorded, with a cumulative incidence of 0.94, 1.57 and 3.03% at 5, 10 and 15 yrs, respectively. Median time of PTLD occurrence was 32 mos. (range 2-155) since OLT. On competing risk multivariate analysis, the use of tacrolimus vs. CsA was the main factor associated with increased risk of PTLD (SDHR: 2.54, p=0.041). Despite the increased PTLD incidence, the overall risk of death was significantly lower with tacrolimus compared to CSA. An increased risk of PTLD was also observed in the 83 patients receiving OKT3, with a SDHR of 3.77, p=0.013. None of the other parameters had any significant impact on PTLD development. Treatment of PTLD resulted in good response in most patients and at a median follow up of 4.85 yrs., 17 out of 20 patients (85%) are alive. *Conclusions.* The overall incidence of PTLD in this large series of OLT is among the lowest reported so far in patients receiving solid organ transplant; the use of tacrolimus is shown as a significant risk factor for PTLD; nevertheless, the addition of tacrolimus significantly increased the life expectancy following OLT; the study confirms the improved outcome of PTLD and the availability of Rituximab is quite likely to have contributed to the prolonged survival observed.

THE USE OF INTERIM 18FDG-PET IS NOT JUSTIFIED IN DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) DURING FIRST LINE IMMUNO-CHEMOTHERAPY

MC Cox,[1] V Naso,[2] MP Bianchi,[2] E Cavalieri,[2] V Lanni,[3] S Pelliccia,[2] L Motisi,[2] F Scopinaro,[3] B Monarca,[2] MA Aloe Spiriti[2]

[2]*A.O. Sant'Andrea, Hematology, Rome, Italy*
[3]*A.O. Sant'Andrea, Nuclear Medicine, Rome, Italy*

Background. In diffuse-large-B-cell-lymphoma (DLBCL), the response to first line immuno-chemotherapy remains somewhat unpredictable. Interim 18FDG-PET (PET-int) analysis could fulfill this important goal, aiding early shift to intensified regimens. *Methods.* We prospectively evaluated the ability of PET-int carried out at mid-treatment of standard immuno-chemotherapy in predicting relapse in a series of 83 consecutive DLBCL. PET-int results were dichotomized as positive or negative using the recently validated five-point-scale scoring system. This

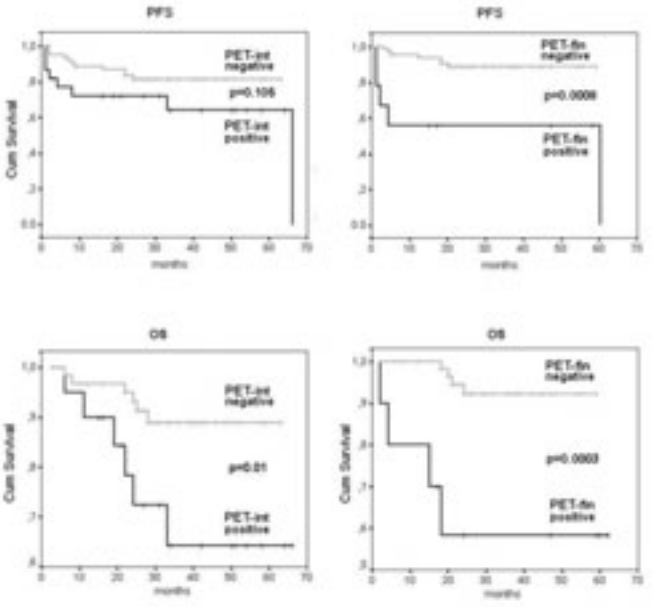

Figure 1. On the left: progression free survival (PFS) and.

exam was also compared with interim computerized tomography (CT-int) and final PET (PET-fin). End-points were: complete remission (CR); positive predictive value (PPV) of refractoriness and relapse; negative predictive value (NPV); overall survival (OS) and progression free survival (PFS). Observation time was fixed to 24 months unless a DLBCL-related event. *Results.* The PPV of PET-int was 63.6% and the NPV was 81.9%. Within PET-int positive patients who underwent targeted biopsy the incidence of faulty positive results due to inflammation was 57%. The achievement of CR was correlated with both PET-int and CT-int (p<.0001), but in multivariate analysis only CT-int was correlated with CR (p=.0002). CT-int and PET-fin were predictive of both OS and PFS, whereas PET-int was predictive only of OS (p=.018), but not of PFS (p=.105). In Cox-regression only PET-fin was predictive for both OS (p=.002) and PFS (p=.006). *Conclusions.* PET-int resulted unable to discriminate chemo sensitive patients who will later relapse. Therefore we think that the use of this expensive and radioactive tool is not justified as an interim analysis.

[4]*Busan Paik Hospital, Busan, South-Korea*
[5]*Dong-A MEdical Center, Busan, South-Korea*

Background. Aggressive Non Hodgkin's Lymphoma (NHL) has been staged according to the Ann-Arbor staging system, which originally designed for Hodgkin lymphoma (HL). Because of the heterogeneity and hematogenous spread pattern of dissemination in NHL in contrast to contiguous lymphatic spread with HL, Ann-Arbor staging system has a limited value in the context of assessment of accurate tumor burden in NHL. *Aims.* The objective of the present study is to investigate whether metabolic tumor volume (MTV) by PET can be a potential prognostic tool compared with Ann-Arbor stage in the patient with stage II and III nodal diffuse large B cell lymphoma (DLBCL). *Methods.* One hundred sixty patients with de novo nodal DLBCL whom underwent PET-CT at diagnosis were enrolled for the present study. All patients received 6 to 8 cycles of R-CHOP therapy by Coiffier *et al.* Median follow-up duration was 36 months. MTV was delineated on the PET images by a circle encompassing regions equal or greater than standard uptake volume (SUV) 2.5 in involved Lymph Node (LN) and each slice was determined by multiplying the area within the threshold margin by CT interval. The final MTV was calculated by adding all MTA of each slice using by fusion software (Syntegra, version 2.1E, Philips Co.). *Results.* The differences of several prognostic factors between stage II and III

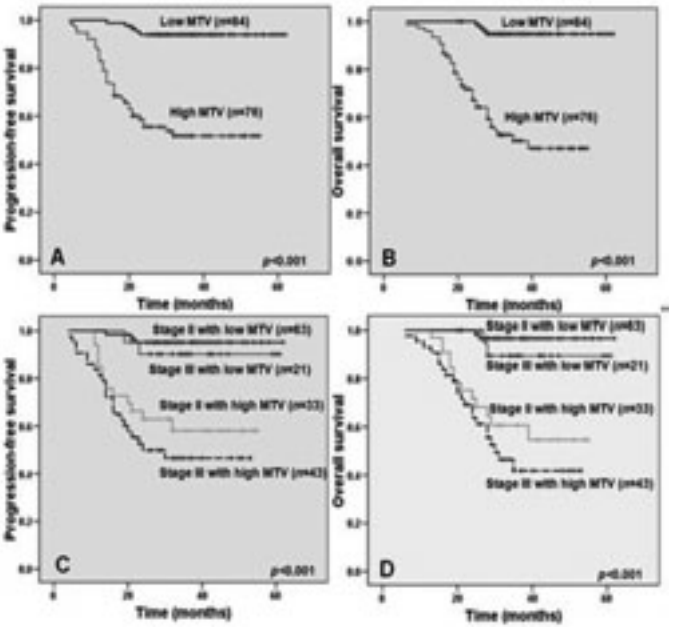

Figure 1. Comparisons of survival according to MTV and stage.

groups were not present. ROC curve analysis was used to calculate the accuracy of ideal cut-off value to distinguish between low MTV and high MTV group. Various cut-off values of MTV were used to obtain a reasonable balance of sensitivity and specificity. 169.3cm3 of various values acquired a sensitivity of 91.7% and specificity of 65.3%. The outcomes were compared among the four subgroups based on tumor burden and stage II or III. High MTV group regardless of stage had lower PFS and OS pattern compared to low MTV group (PFS & OS in stage II with low MTV, 95.2% & 96.8%; in stage III with low MTV, 90.5% & 90.5% versus in stage II with high MTV, 60.6% & 60.6%; in stage III with high MTV 48.8% & 48.8%; p<0.001, p<0.001) whereas prognostic impact of stage in same MTV group was absent. (in the low MTV group, difference of PFS and OS according to stage, p=0.431, p=0.261; in the high MTV, p=0.277, p=0.28, Figure 1). Multivariate analysis using Cox proportional hazard model was performed for high MTV and stage III. In the analysis high MTV was an independent factor predicting an unfavorable outcome (PFS, HR=9.243, 95% CI=3.543-24.115, p<0.001; OS, HR=11.660, 95% CI=4.062-33.465, p<0.001) whereas stage III had not significant value (PFS, HR=1.513, 95% CI=0.792-2.888, p=0.210; OS, HR=1.556, 95% CI=0.806-3.003, p=0.188). *Conclusion.* The present study suggests that total tumor burden of lymphoma is a more important prognostic parameter rather than Ann-Arbor stage in DLBCL. Our data reflect that Ann-Arbor staging system has limited worth in DLBCL due to heterogenous spread pattern of NHL. Therefore, simply classifying for prognosis according to diaphragm would be not wise at least for DLBCL in rituximab era.

Chronic lymphocytic leukemia - Genes and microenvironment

MISSENSE MUTATIONS LOCATED IN STRUCTURAL P53 DNA-BINDING MOTIFS ARE ASSOCIATED WITH EXTREMELY POOR SURVIVAL IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Trbusek,[1] J Smardova,[2] J Malcikova,[1] L Sebejova,[1] P Dobes,[2] V Vranova,[2] M Mraz,[1] H Skuhrova Francova,[2] M Doubek,[1] Y Brychtova,[2] S Pospisilova,[1] J Mayer[1]

[1]*University Hospital Brno and CEITEC, Brno, Czech Republic*
[2]*University Hospital Brno, Brno, Czech Republic*

Background. There is a distinct connection between TP53 defects and poor prognosis in chronic lymphocytic leukemia (CLL). It remains unclear whether patients harboring TP53 mutations represent a homogenous prognostic group. p53 missense mutations involved in a direct or indirect contact with the target DNA, have been shown to be associated with a particularly poor survival in, e.g., breast cancer or diffuse large B-cell lymphoma. *Aims.* To analyze an impact of specific p53 mutations on prognosis of CLL patients. *Methods.* We evaluated the survival of CLL patients with p53 defects identified at our institution by p53 yeast functional assay (FASAY) and complementary I-FISH analysis detecting del(17p) from 2003-2010. *Results.* A defect of the TP53 gene was identified in 100 of 550 patients. p53 mutations (n=96 patients) were strongly associated with the deletion of 17p and the unmutated IgVH locus (both P<0.001). The patients who had p53 mutation but also the mutated IgVH gene (range of homology 92.4%-97.9%) manifested substantially better survival than p53-mutated patients with the unmutated IgVH (homology ≥98%) (P=0.018). We therefore omitted the small subgroup (n=11) of p53-affected patients with mutated IgVH gene from the subsequent analysis, as their survival data would be misleading. In line with this, only the wt-p53 patients harboring the unmutated IgVH gene were used as a control group in all subsequent survival evaluations. Survival assessed from the time of abnormality detection (or investigation showing wt-p53) was significantly reduced in patients with both missense (P<0.001) and non-missense p53 mutations (P=0.004) in comparison with wt-p53 patients. In addition, patients harboring missense mutation located in p53 DNA-binding motifs (DBM), structurally well-defined parts of the DNA-binding domain, manifested a clearly shorter median survival (12 months) compared to patients having missense mutations outside DBM (41 months; P=0.002) or non-missense alterations (36 months; P=0.005). The difference in survival was very similar in the analysis limited to patients harboring mutation accompanied by del(17p) (n=50). A subset of p53 mutations was identified already at diagnosis. The p53 DBM mutations (n=12) once again resulted in a very short survival of only 17 months (P<0.001; hazard ratio to p53-wt patients 20.8; 95% CI 8.82-48.82); patients with the remaining p53 mutations (n=16) manifested 51 month median survival (P<0.001; hazard ratio to p53-wt patients 5.3; 95% CI 2.41-11.69); a median survival of wt-p53 patients was 110 months. The patients with p53 DBM mutation at diagnosis also manifested very short median time to first therapy (TTFT) (1 month); the remaining p53-affected patients had TTFT 6 months and p53-wt patients 19 months. *Summary/Conclusions.* The substantially worse survival and the short TTFT suggest a strong mutated-p53 gain-of-function (GOF) phenotype in CLL patients with DBM mutations. The impact of p53 DBM mutations on prognosis and response to therapy should be analyzed in investigative clinical trials. CLL patients with p53 DBM mutations should be primary candidates for allogeneic stem cell transplantation as their long-term survival is improbable. Background. Deletion at 13q14 (del13q) is detected by fluorescence in-situ hybridization (FISH) in about 50% of CLL. Although CLL patients with del13q as the sole cytogenetic abnormality (del13q-only) usually have a good prognosis, more aggressive clinical courses are reported for del13q-only CLL bearing high percentages of deleted nuclei. Moreover, del13q of different sizes have been described, the prognostic significance of which is still unknown. *Aims.* to investigate the prognostic significance of del13q by a FISH approach in 342 del13q-only cases and in 265 consecutive unselected CLL cases. *Methods.* FISH at diagnosis was performed using the following probes: LSI-D13S319 (detecting the *DLEU2/MIR15A/MIR16-1* region), LSI-RB1, LSI-ATM, LSI-p53, CEP12. *Results.* Maximally selected log-rank statistics identified the 70% of deleted nuclei as the most appropriate cut-off capable of separating del13q-only cases into two subgroups with different time-to-first-treatment (TTT, p=0.0022). Del13q-only CLL with ≥70% of deleted nuclei showed a shorter TTT than <70% del13q-only cases (median TTT 77 versus 120 months, p=0.0001). One hundred and thirty-five of 342 del13q-only cases (39.5%) had 13q deletions that included the *RB1* locus in at least 5% of nuclei (delRB1). Genomic profiles using Affymetrix GeneChip Human SNP6 arrays in 67 cases showed that larger deletions involving the *RB1* locus occurred in a proportion of del13q-only cases (34.3%) and were always monoallelic (median size 2,380 Kb versus 1,200 Kb for del13q without delRB1). We classified del13q-only cases combining both deletion load and size: i) del13q-only cases bearing del13q in <70% of nuclei without delRB1 (del13q<70%, n=144); ii) del13q-only cases bearing del13q in <70% of nuclei with delRB1 (del13q<70%+delRB1, n=95); iii) del13q-only cases bearing del13q in ≥70% of nuclei without delRB1 (del13q≥70%, n=64); iv) del13q-only cases bearing del13q in ≥70% of nuclei with delRB1 (del13q≥70%+delRB1, n=39). The median TTT of del13q<70% cases (not reached) was significantly longer than the median TTT of del13q<70%+delRB1 (92 months, p=0.012), del13q≥70% (68 months, p<0.0001) and del13q≥70%+delRB1 cases (82 months, p=0.0025). The presence of delRB1 in del13q<70% CLL was associated with a hazard ratio (HR) for progressive disease of 1.91 (95% CI 1.18-3.08; p=0.008), whereas no additional prognostic information was provided in del13q≥70% cases (HR=0.87, 95% CI 0.50-1.51; p=0.63). In multivariate analysis, the presence of delRB1 increased the risk of progressive disease of del13q<70% cases (HR=1.69, p=0.036), independently of Rai staging and *IGHV* status. In 265 consecutive unselected CLL, the presence of del13q in <70% of nuclei in the absence of delRB1 identified patients with particularly stable and benign clinical courses (n=48; median TTT not reached). Conversely, del13q<70%+delRB1 cases (n=24), or patients characterized by a del13q in ≥70% of cells (with or without delRB1, n=25) or a normal karyotype (n=75) had shorter median TTT intervals (range 105-129 months, p<0.01 in all comparisons). Finally, patients bearing trisomy 12 (n=48), 11q deletion or 17p deletion (n=45) experienced the worst clinical course (p<0.0001). *Conclusions.* FISH analysis of both deletion load and size allowed to reveal the prognostic heterogeneity of del13q-only cases. A novel prognostic flowchart involving sequential hybridization with the LSI-D13S319 and LSI-RB1 probes can be proposed.

FUNCTIONAL CD49D/CD38 MOLECULAR ASSOCIATION IS DETRIMENTAL FOR CLINICAL OUTCOME IN CHRONIC LYMPHOCYTIC LEUKEMIA

A Zucchetto,[1] T Vaisitti,[2] D Benedetti,[1] M Dal Bo,[1] R Bomben,[1] M Degan,[1] S Serra,[2] D Brusa,[2] MI Del Principe,[3] D Rossi,[4] G Pozzato,[5] G Del Poeta,[3] G Gaidano,[4] F Malavasi,[2] S Deaglio,[2] V Gattei[1]

[5]*Maggiore General Hospital, University of Trieste, Trieste, Italy*

Background. CD49d and CD38 are independent negative prognosticators, whose expressions are often correlated on chronic lymphocytic leukemia (CLL) cells. We recently reported a functional link between CD49d and CD38 as component of a pro-survival circuitry operating in CD49d+CD38+ CLL. This network includes in sequence the CD38/CD31 pair, the CCL3/CCL4 chemokines with the respective receptors, and the CD49d/VCAM-1 axis. *Aims.* The nature of this circuit was studied by investigating the physical association between CD49d/CD38 and their functions on CLL cell membranes; the validity of the hypothesized prognostic relevance of CD49d/CD38 co-expression was tested in a wide cohort of CLL patients. *Methods.* The organization of CD49d and CD38 on the membrane of primary CLL cells was investigated by confocal microscopy and biochemical assays. Mec-1, a CD49d+CD38- cell line derived from CLL cells was used in a comparative way with a clone where CD38 expression was induced by transfection (Mec-1/CD38+). These cells were analysed in terms of adhesion potential. Data on CD49d and CD38 expression along with time-to-first-treatment (TTT) were available for 564 patients. *Results.* Co-capping and immunoprecipitation experiments in CD49d+/CD38+ CLL cells demonstrated a clear membrane relationship between CD49d and CD38. Co-localization between the molecules was maintained when CLL cells adhered and spread onto VCAM-1 and fibronectin, the CD49d ligands. This finding is an indication that the CD49d/CD38 association is also functional. This issue was answered by designing adhesion assays on VCAM-1-coated plates using the Mec-1 model. Mec-1/CD38+ showed a marked increase in VCAM-1 adhesion compared to Mec-1 (adherent cells relative to control=5.4 vs. 2.3, and 5.4 vs. 1.9 at 15 and 30 min, respectively; p<0.05). Phase-contrast microscopy highlighted the existence of significant differences in the morphology of adherent cells; indeed, Mec-1/CD38+ cells were characterized by a more complex uropod pattern than Mec-1, suggestive of cytoskeleton re-organization. The last tested issue dealt with the influence of CD49d and CD38 co-presence on the network of apoptosis. To this aim, we checked whether adhesion to VCAM-1 might influence the apoptosis promoted by serum deprivation in Mec-1 and Mec-1/CD38+ cells. After 4-5 days of culture on VCAM-1-coated wells without serum, the mean values of Mec-1/CD38+ viable cells (62%±4.8, day 4, and 55%±3.2, day 5) were significantly higher than those observed in the Mec-1 sample (38%±4.2, day 4, and 36%±2.2, day 5; p<0.001 and p=0.003 respectively). To evaluate the clinical relevance of these observations, we compared the TTT in 564 CLL patients (303 CD49d-/CD38-, 125 CD49d+/CD38+, 95 CD49d-/CD38+, and 41 CD49d+/CD38-). Patients CD49d+/CD38+ were characterized by TTT significantly shorter as compared with patients expressing only CD38 (p=0.01) or CD49d (p= 0.001), the longest TTT being however observed in CD49d/CD38 double negative cases. *Conclusions.* The association between CD49d and CD38 on the CLL membrane is not only physical, but also functional. The validity of this conclusion is corroborated at a clinical level: the analysis of a simultaneous CD49d/CD38 expression produce a significant refinement of the prognostic potential provided by any of the two factors independently analysed.

INTERACTION BETWEEN ENDOTHELIUM AND CHRONIC LYMPHOCYTIC LEUKEMIA B-CELLS RESCUES FROM APOPTOSIS AND MODULATES GENE EXPRESSION PROFILE OF LEUKEMIC CELLS

R Maffei, S Fiorcari, S Martinelli, J Bulgarelli, G Debbia, M Fontana, L Faglioni, S Bigliardi, P Zucchini, F Narni, G Torelli, M Luppi, R Marasca

University of Modena and Reggio Emilia, Modena, Italy

Background. Despite an apparent long life *in vivo*, CLL cells die rapidly *in vitro*. This observation suggests that the apoptotic resistance is not intrinsic to leukemia B cells but extrinsic factors are necessary for CLL prolonged survival. *Aims.* we investigated the interactions between endothelial cells and CLL cells, highlighting molecular networks involved in this cellular crosstalk. *Methods.* we co-cultured CLL cells on HUVEC endothelial monolayer (HC) or in medium alone (CLL only). Then, we detected CLL viability by flow cytometry and we performed whole-genome high density microarrays. *Results.* we found that endothelial cells protected CLL from spontaneous apoptosis. After 48h, increased number of alive CLL cells was present in HC condition (59.7 ± 4.2%) compared to CLL alone (22.9 ± 5.1%) ($p<0.0001$). Moreover, we found that spontaneous *in vitro* apoptosis was higher in unmutated IGHV CLL (UM-CLL) compared to mutated ones (M-CLL). In HC condition, similar survival was detected between M-CLL and UM-CLL, implying a 2.2-fold increase in relative viability in M-CLL and a 6.1-fold increase in UM-CLL. Moreover, the endothelial cell layer decreased the *in vitro* sensitivity of CLL cells to Fludarabine-induced apoptotic cell death. The mean viability of CLL cells treated with 10 μM Fludarabine was 19.8% (±4.4%) after 48 hours and 3.8% (±1.3%) after 72 hours. In HC with Fludarabine addition, the mean viability of CLL cells was 37.8% (±9.1%) after 48 hours and 14.3% (±3.2%) after 72 hours. Then, we compared gene expression profiles (GEP) between CLL cultured in contact with EC layer and CLL at baseline to unravel the transcriptional modifications induced by EC cells. Overall 1944 genes were found to be modulated ($FC\geq2$, $p<0.05$). CLL cells in HC condition showed a 22.6-fold increase of CCL2, able to recruit tumor-activated monocytes ($p=0.0032$) and a 6.5-fold increase of PDGFC, chemoattractant for mesenchymal stromal cells ($p=0.0051$). Other soluble factors up-regulated by EC/CLL contact were VEGFC (FC=9.4, $p=0.0061$), ANGTL4 (FC=8.6, $p=0.015$), EDN1 (FC=9.2, $p=0.0061$), AMOTL2 (FC=4.3, $p=0.019$) and THBS1 (FC=45.1, $p=0.0004$) as well as the metalloproteases MMP2 (FC=8.3, $p=0.02$) and MMP4 (FC=3.0, $p=0.039$). The GEP data were confirmed by evaluating the secreted levels of soluble factors in conditioned medium collected after 48h-HC culture. In addition, CLL cells on endothelial layer maintained or increased the expression levels of anti-apoptotic factors Bcl-2, Bcl2A1, BIRC3/c-IAP2 and BIRC5/Survivin compared to CLL cells at baseline. Of interest, the Ang2 tyrosine kinase receptor Tie2 mRNA was found to be increased in CLL cells in co-culture (FC=10.7, $p=0.017$). We confirmed GEP data by flow cytometry finding a 2-fold and a 4.3-fold increase of percentage of Tie2+CLL cells at 48h and 72h in HC. *Conclusion.* our results demonstrate a role of endothelial cells in CLL survival advantage and Fludarabine-resistance. The intimate contacts with EC seem to determine a microenvironmental-driven angiogenic switch of CLL phenotype, improve the secretion of cytokines involved in regulation of microenvironmental elements such as stromal cells and macrophages and increase the expression of anti-apoptotic molecules.

Background. B-cell chronic lymphocytic leukaemia (B-CLL) is the most common leukaemia in the Western World. It is characterized by the accumulation of long-lived mature B cells. Autophagy is the process of cell component removal whereby cellular elements are encompassed in vesicles and transported to lysosomes for degradation. Autophagy has a role in both cell survival and apoptosis, and is involved in antigen presentation in mature B-cells. Deregulation of autophagy has been implicated in various cancers including leukaemia, although it has not been described yet in B-CLL. *Aims.* To determine if B-CLL patients have recurrent abnormalities in autophagic genes and if so, identify the affect of these abnormalities on the autophagy process. *Methods and Results.* We tested DNA samples from 212 patients with B-CLL using high-resolution SNP 1M-Duo arrays and analyzed the data using Nexus Biodiscovery software. The results were compared against the Database of Genomic Variants and data from the Wellcome Trust Case Control Consortium, as well as from germline samples in selected cases. Amongst the abnormalities noted were recurrent abnormalities involving important autophagy genes (ATG5, ATG6 and ATG7). Whole genome sequencing of two patients with B-CLL also detected mutations in a gene involved in the regulation of autophagy (NOD1). Next we investigated the autophagin flux in B-CLL using the Amnis Imagestream, which combines flow cytometry with cell imaging, allowing simultaneous assessment of morphological characteristics alongside fluorescence signals of large numbers of cells. This makes it an ideal instrument to calculate co-localisation of autophagosomal markers while identifying a subpopulation of cells by their surface markers. We analysed CD5+CD19+ B-CLL cells from eight patients (including one with an ATG5 deletion, 2 with TP53 abnormalities, one with a NOD1 mutation and 4 without genetic autophagic abnormalities) and CD19+ B-cells taken from age-matched controls. Cells were incubated under standard conditions for 2 hours either with or without lysosomal inhibitors prior to staining with antibodies for CD19, CD5, lysosome and LC3. We used the co-localization of LC3 and lysosome as a marker of autolysosomal formation and thereby autophagic flux. Autophagic flux was significantly higher in B-CLL samples when compared with normal B-cells, implying that B-CLL cells have a higher basal autophagy level than normal B-cells. Surprisingly, these increased levels were observed in the B-CLL samples both with and without abnormal autophagy genes. *Conclusion.* This is the first time that increased autophagy levels have been demonstrated in B-CLL. Investigations to determine whether this pathway might provide a mechanism of survival and perturbance of programmed cell death and therefore represent a new drug target in B-CLL are ongoing.

GENOMIC ALTERATIONS ASSOCIATED WITH BONE MARROW FAILURE AND PROGRESSION TO LEUKEMIA IN THE BONE MARROW OF DNA-REPAIR DEFICIENT MICE

J Haanstra,[1] P van Strien,[1] M Valkhof,[1] V Rockova,[1] M Sanders,[1] C Kockx,[1] W van IJcken,[1] M von Lindern,[2] I Touw[1]

[1]*ErasmusMC, Rotterdam, Netherlands*
[2]*Sanquin Research and Landsteiner Laboratory AMC/UvA, Amsterdam, Netherlands*

Background. Bone marrow (BM) failure may arise from (inherited) mutations or develop through sustained exposure to cytotoxic stresses. Secondary leukemia's arising from these BM failures are often refractory to current treatments. We focus on genotoxic-stress induced bone marrow failure, such as seen in Fanconi Anemia, Nijmegen breakage syndrome and therapy-related myelodysplastic syndrome/AML. These diseases have a high risk of progression to leukemia. We use a mouse model deficient for Ercc1, an enzyme involved in the repair of interstrand crosslinks (ICLs). In the absence of efficient repair, ICLs result in stalled replication forks and cause cell cycle arrest, mediated by activation of the cell-cycle gatekeepers p16/p19 and/or p53. We have previously shown that Ercc1-deficient mice have a strong reduction in hematopoietic stem- and early progenitor cells (LSK) throughout their lifespan of ~20 weeks. LSK levels are restored in mice deficient for both Ercc1 and p53. Ercc1-deficient mice do not develop leukemia during their lifespan, but when we transplanted Ercc1-deficient BM cells that were heterozygous for *Trp53* into lethally irradiated recipients more than 57% of the animals got leukemia and an additional 37% died prior to diagnosis. *Aims.* Our aim is to dissect the early and sequential molecular defects that occur in stem cells from BM failure to pre-leukemia and contribute to the development of overt leukemia. *Methods.* To monitor genetic changes in different maturation stages we determined gene expression changes in immature (LSK) and mature (BM) hematopoietic cells of 20-week old Ercc1-deficient and control mice. To determine genomic alterations associated with BM failure, we sequenced the exome of the BM 20-week old Ercc1-deficient animals and of Ercc1-deficient fetal liver cells, which contain normal LSK levels. *Results.* Ercc1-deficient BM cells show an up-regulation of the cell-cycle gatekeepers p16, p19 and the p53-targets *PUMA* and *NOXA*, which induce apoptosis. In contrast, none of these transcripts were up-regulated in purified LSK cells of Ercc1-deficient mice. Instead, LSK cells showed up-regulation of p21, which is involved in cell cycle arrest and plasminogen activator inhibitor -1 (*PAI-1*), which is a marker for senescence. In the sequences of two exomes of Ercc1-deficient BM we found 1170 and 780 exonic mutations, of which 360 were found in common. These mutations were acquired during the bone marrow failure, as they were not found at the fetal liver stage nor were they present in the mouse SNP database. We will next sequence the leukemia's arising from Ercc1-deficient BM that is heterozygous for *Trp53* to identify leukemia-associated genomic aberrations and compare them to genetic aberrations already present at the BM failure state. *Summary/Conclusions.* The gene expression response to ICL-damage in LSK cells is directed at survival by inducing cell cycle arrest/senescence without apoptosis, while in mature cells apoptotic genes are up-regulated. While BM failure is thought to prevent survival of cells with altered genomes, strikingly we found 360 common exonic mutations in two samples of Ercc1-deficient BM. Our mutational analysis is expected to elucidate critical players involved in early and late stages of leukemogenesis from DNA-damage induced BM failure.

ACE-536, A MODIFIED TYPE IIB ACTIVIN RECEPTOR PROMOTES ERYTHROID DIFFERENTIATION IN AN EPO INDEPENDENT MANNER AND PREVENTS ANEMIA IN MYELODYSPLASTIC SYNDROME

N Suragani, W Mulivor, M Cadena, M Mitchell, S Sako, M Davies, K Tomkinson, M Devine, J Ucran, A Grinberg, K Underwood, R Pearsall, R Kumar, J Seehra

Acceleron Pharma, Cambridge, United States of America

Myelodysplastic syndromes (MDS) are stem cell disorders characterized by impaired hematopoiesis and cytopenias. The majority of MDS patients present with anemia that is often refractory to treatment with erythropoietin (EPO). As an alternative approach to treating anemia in MDS patients, we have targeted the TGF β superfamily. This group of molecules has been implicated in erythropoiesis. We have developed a soluble receptor fusion protein consisting of a modified form of activin receptor IIB extracellular domain linked to a human Fc region (ACE-536) that generates a robust increase in RBC's in several animal models. The aim of this study is to investigate which erythrocyte precursors are affected by ACE-536 and to evaluate the efficacy of RAP-536 (murine analogue of ACE-536) in treating anemia in a murine model of MDS. Subcutaneous administration of ACE-536 (10mg/kg) to C57BL/6 mice resulted in a significant increase in hematocrit, hemoglobin and red blood cells as compared with the vehicle (VEH) group within 4 days. These effects were observed in the presence of an EPO neutralizing antibody suggesting that EPO is not directing the initial RBC response. BFU-E or CFU-E colony formation assays from bone marrow or spleen were also carried out at 48hrs following ACE-536 treatment and found that ACE-536 does not effect the erythroid progenitor population compared to VEH treatment. Differentiation profiling of bone marrow and splenic erythroblasts by FACS analysis following 72 hours after ACE-536 treatment revealed a decrease in basophilic erythroblasts and an increase in late stage poly-, ortho-chromatophilic and reticulocytes in bone marrow and spleen compared to VEH treated mice. The data demonstrate a novel mechanism of ACE-536 promoting maturation as contrasted to the noted effect of EPO which increases proliferation of BFU-E and CFU-E. To investigate the therapeutic potential of RAP-536 in a model of MDS, four month old NUP98-HOX13 transgenic mice (10/dose group) were treated with vehicle (VEH) or RAP-536 (10 mg/kg) twice per week. Wild-type littermates (10/dose group) were dosed with VEH or RAP-536 (10 mg/kg) and used as controls. Prior to the first dose (Day 0), the MDS mice had significantly decreased levels of RBC (-8.8%, P<0.05), hematocrit (-8.4%, P<0.05) compared to their wild-type control littermates. After 7 months of dosing, MDS mice treated with RAP-536 had increased RBC counts (+13.8%, P=0.09), hemoglobin (+19.8%, P<0.05) and hematocrit (+14.8%, P=0.05) in compared to VEH treated controls. These results demonstrate that ACE-536 may represent a novel therapy for severe anemia for patients with Myelodysplastic Syndrome.

Bone marrow failure syndromes of childhood comprise a heterogenous group of inherited and acquired hypocellular bone marrow conditions. Severe aplastic anaemia (SAA) and hypoplastic refractory cytopenia (RC), a subtype of childhood myelodysplastic syndrome (MDS) are the main and most difficult differential diagnoses. In the German childhood SAA 94 study the probability to develop clonal disease, particularly MDS and AML, was 23% after immunosuppressive therapy. To investigate whether the first morphological diagnosis has an impact on the outcome with respect to clonal disease, we established distinct morphological criteria to differentiate between SAA and RC. Only bone marrow trephines and smears with hematopoietic aplasia were diagnosed as SAA, whereas cases even with only small foci of MDS typical morphology. i.e. patchy erythropoiesis with defective maturation, in an otherwise adipocytic bone marrow where classified as RC. The participating centers of the European Working Group on Childhood myelodysplastic syndrome (EWOG-MDS) and German SAA 98 study established a central morphological review. Since introduction of the central review in 1998 the probability to develop clonal disease has continuously dropped to 3% (p<0.01). We performed a

double-blinded inter observer study of 100 different cases of SAA and RCC among 7 haematopathologists. Only in 4 out of 100 cases no agreement could be achieved whether to classify SAA or RC. The kappa-index was 0.79 indicating that the vast majority of SAA and RC cases can be reliably differentiated by morphological means only. Our results suggest that the main reason for development of MDS or AML after immunosuppressive therapy of SAA might be the initial morphological differentiation of SAA and RC in childhood and that a clear morphological differention reduces the secondary cases of MDS and AML after immunosuppressive therapy significantly.

Background. Panobinostat, a pan-deacetylase inhibitor (pan-DACi), has demonstrated anti-tumor activity in patients with myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML). Preclinical studies suggest the combination of a hypomethylating agent such as 5-azacitidine (5-aza) and a pan-DACi may, at least in part through gene reactivation and apoptosis induction, improve outcomes in patients with MDS and AML. *Aims.* This phase I, open-label, multicenter, dose-escalation study will assess the maximum tolerated dose (MTD) and safety of panobinostat in combination with 5-aza in patients with MDS, chronic myelomonocytic leukemia (CMML), and AML. *Methods.* Inclusion criteria of this ongoing study are: adult patients with IPSS intermediate-2 or high-risk MDS, CMML, or AML with multi-lineage dysplasia and 20-30% marrow blasts not eligible for hematopoietic stem-cell transplantation. Oral panobinostat (20 mg/day starting dose) is administered during a 28-day cycle on Days 3, 5, 8, 10, 12, and 15 in combination with a fixed dose of 5-aza (75 mg/m^2 sc) on Days 1-7 of each cycle. Safety and tolerability are described as type, duration, frequency, relatedness, and severity of adverse events (AEs) according to CTCAE, v3.0. The adaptive Bayesian logistic regression model is used to guide panobinostat dose escalation with overdose control at all dose levels. The minimum exposure criteria for determining MTD is 6 scheduled doses of panobinostat and 7 scheduled doses of 5-aza during cycle 1. *Results.* 18 patients, median age 69 years (range 34-80), have been enrolled to date including 13 with MDS, 3 with AML, and 2 with CMML. Patients were evaluated at 3 different panobinostat doses: 6 (20 mg), 5 (30 mg), and 7 (40 mg). The AEs analysis is based on currently available data of all 18 patients. AEs of all grades, regardless of study drug relationship, included nausea (12 [67%]), vomiting and diarrhea (11 each [61%]), fatigue (10 [56%]), decreased appetite (9 [50%]), and asthenia (6 [33%]). Grade 3/4 treatment-related AEs included thrombocytopenia (4 [22%]) and febrile neutropenia (3 [17%]). Serious AEs, regardless of study drug relationship, included febrile neutropenia and asthenia (4 each [22%]). One dose-limiting toxicity (DLT) was observed (grade 4 febrile neutropenia) in the 20 mg panobinostat cohort and two DLTs (grade 3 hyperbilirubinemia; grade 3 nausea and asthenia) in the 40 mg cohort. *Summary/Conclusions.* Current data show that the addition of panobinostat to 5-aza therapy is safe with no unexpected toxicities. To date, the most common AEs are gastrointestinal events and fatigue. The most common grade 3/4 treatment-related AEs include febrile neutropenia and thrombocytopenia, with one DLT observed in the 20 mg cohort and two in the 40 mg cohort. Based on the occurrence of two DLTs and one withdrawal of consent following grade 3 fatigue in the 40 mg cohort, the decision was made to enroll additional patients at a lower dose level to further assess safety and tolerability at 30 mg. In parallel, the ongoing patients at 40 mg are monitored for long term tolerability. Updated data, including preliminary efficacy data, will be presented at the meeting.

[3]*University of "La Sapienza", Rome, Italy*

Backgrounds. Myelodysplastic syndromes (MDS) are affecting mainly elderly patients, and age is considered per se a negative prognostic factor. Most patients have comorbidities that presumably impact negatively overall survival and quality of life, and may influence response to therapy. It was recently demonstrated that MDS patients aged > 75 yrs treated with azacitidine have a significantly longer overall survival respect to best supportive care treated patients. *Aims.* We wanted to analyze whether the presence of comorbidities could have an impact on survival, response and management of azacitidine treatment in MDS patients, in clinical practice. We also evaluated patient outcome, type of response according to IWG criteria 2006, as well as adverse events and cause of death. *Methods.* We analyzed 103 MDS patients (IPSS: 30% INT-1, 49% INT-2 and 21% High) treated with Azacitidine 75 mg/mq/day sc for 7 days every 28. Mean number of cycles was 9 (range:2-42). Mean age was 69 yrs (50-82); 30% of patients were >= 75 yrs and 39% of the latter >= 80 yrs; 71% of patients were male. Patients were evaluated by three different geriatric score: Charlson comorbidity index (CCI) (54 % of patients scored 0, 37% of patients 1 or 2, and 9% of patients >= 3), the Cumulative Illness Rating Scale (CIRS) (37% of patients scored 0, 37 % of patients 1 and 26% of patients >= 2) and the Adult Comorbidity Evaluation-27 (ACE-27) (41% of patients scored none, 29% of patients mild, 23 % of patients moderate and 7% severe). The OS of patients treated with azacitidine was compared with that of a diagnosis- and age- matched untreated control group of patients (n= 246) (Italian registry of MDS -AISSM) in whom comorbidities had been evaluated by CIRS score. *Results.* Median overall survival (OS) of our patient cohort was 22 months. Median OS in patients < 75yrs (25 months) and >= 75 yrs (15 months) was not significantly different (p value > 0.160). No correlation was present between comorbidity scores, age and hematological response. OS was strictly depending on scores. OS in patients with higher CCI, CIRS, and the ACE-27 was respectively 6.5 months, 10 months and 8 months vs OS in patients with lower CCI, CIRS and ACE-27 was respectively 20, 22 and 22 months. Overall response rate (HI, CR and PR) was 49%, stable disease was obtained in 37 % of MDS patients. IWG responses did not correlate with age, sex and comorbidity scores. Hematological or non hematological adverse events grade III and IV were presented by 34% and 36% of patients, respectively. Adverse events were uniformly distributed independently from age. *Conclusions.* MDS patients with comorbidities may be treated with success with azacitidine, without any substantial increase in AE and with improvement of OS respect to untreated patients. Nevertheless, comorbidities per se negatively influence OS. Evaluation of comorbidities with validated indexes is an useful and easily applicable tool to refine prognostic evaluation and should be include routinely in patient assessment.

DNMT3A MUTATIONS IN MYELOPROLIFERATIVE NEOPLASMS

F Stegelmann,[1] L Bullinger,[1] R Schlenk,[1] M Griesshammer,[2] P Paschka,[1] C Blersch,[1] S Kuhn,[1] S Schauer,[1] H Döhner,[1] K Döhner[1]

[1]*University Hospital of Ulm, Ulm, Germany*
[2]*Johannes Wesling Klinikum, Minden, Germany*

Background. An increasing number of gene mutations is being identified in the 'classic' myeloproliferative neoplasms (MPN) essential thrombocythemia (ET), polycythemia vera (PV), and primary myelofibrosis (PMF). For instance, use of array-based techniques led to the identification of mutations in candidate genes involved in epigenetic regulation such as *TET2*, *ASXL1*, and *EZH2*. Most recently, a whole-genome sequencing study in acute myeloid leukemia (AML) uncovered recurrent mutations in 22% of AML patients in another epigenetic regulator, the DNA methyltransferase 3A gene *DNMT3A* (Ley *et al.*, N Engl J Med 2010; 363: 2424-2433). *Aim.* To explore mutations of *DNMT3A* in a series of 115 well-characterized chronic- and blast-phase MPN cases: ET, n=30; PV, n=30; PMF, n=16; secondary MF (SMF), n=4; AML secondary to MPN (sAML), n=35. *Methods.* All coding exons of *DNMT3A* (2-23) were analyzed using direct DNA sequencing. Mutation data on *JAK2* V617F, *MPL* W515L, *CBL* (exon 8-9), *TET2* (exon 3-11), *ASXL1* (exon 12), *EZH2* (exon 2-20), and *IDH1/2* (exons 4) as well as 250K SNP-array profiling data were available in all cases. *Results.* In total, 12 heterozygous *DNMT3A* sequence variants were identified resulting in an overall frequency of 10% (12/115). *DNMT3A* alterations were most frequently detected in SMF (50%, 2/4) and sAML (17%, 6/35), followed by PV (7%, 2/30), PMF (6%, 1/16), and ET (3%, 1/30); they consisted of 8 nucleotide substitutions and 4 frameshift deletions (P264fs, W305fs, R488fs, and D768fs); 2 nucleotide substitutions resulted in direct stop codons (E523* and E477*), whereas 6 represented missense alterations; of these, the amino acid residue R882 was recurrently affected in 4 cases (R882H, n=3; R882C n=1). Somatic origin was confirmed in 5 cases including 2 known (E477* and R882H) and 3 novel (W305fs, R488fs, and E523*) *DNMT3A* mutations. Since presence of germline frameshift deletions is unlikely, tumor-specific origin remained uncertain in 2 missense alterations (N501S and W860R) due to lack of control DNA. Furthermore, none of the *DNMT3A* altered cases harbored *MPL*, *CBL*, *TET2* or *EZH2* mutations. In contrast, *DNMT3A* alterations occurred concurrently with *JAK2* (48%, 7/12), *IDH1/2* (33%, 4/12), and *ASXL1* (8%, 1/12) gene mutations. In SNP array analysis, no distinct patterns of concurrent genomic aberrations could be identified. In terms of clinical data, none of the ET/PV cases showed features of an aggressive clinical course, while outcome of sAML was poor. However, longer observation time and systematic collection of clinical data will be necessary to clarify whether mutated *DNMT3A* is of clinical relevance in chronic- and blast-phase MPN. *Conclusions.* Our data underscore the increasing complexity of MPN pathogenesis due to the growing number of genetic lesions being identified. Based on our data, one might speculate that *DNMT3A* mutations represent an important mechanism for advanced phase disease in a subset of MPN cases. Genotyping of single colonies and functional studies will be necessary to further elucidate the pathogenic interplay between *DNMT3A* and other mutations such as *JAK2*, *IDH1/2*, and *ASXL1* in terms of fibrotic and leukemic transformation.

1061

ROS1, THE ORTHOLOG OF DROSOPHILA SEVENLESS, REPRESENTS A NEW MOLECULAR DEFECT IN CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML)

D Cilloni,[1] S Carturan,[1] E Bracco,[1] M Pradotto,[1] F Arruga,[1] M Pautasso,[1] V Campia,[1] V Gaidano,[1] A Rotolo,[1] C Calabrese,[1] I Iacobucci,[2] G Martinelli,[2] F Frassoni,[3] G Saglio[1]

[1]*University of Turin, Turin, Italy*
[2]*University of Bologna, Bologna, Italy*
[3]*San Martino Hospital, Genova, Italy*

Background. Chronic myelomonocytic leukemia (CMML) is a clonal disorder sharing features of both myelodysplastic syndromes and chronic myeloproliferative neoplasms. Although rare aberrations are reported in CMML, the molecular defects underlying the disease are largely unknow. c-ROS codes for an orphan tyrosine kinase which is abnormally expressed and translocated in brain tumors. The involvement of ROS1 in MPN has never been described. Aims of the study were to evaluate the involvement of c-Ros in the pathogenesis of chronic myelomonocytic leukemia (CMML) and to establish the biological consequences of c-Ros activation. *Methods.* c-Ros expression was evaluated by RQ-PCR in 258 samples. 119 CMML patients were included (76 BM, 71 PB and 4 CD34+ purified samples), 25 samples from PMF (9 BM and 16 PB), 7 ET, 5 PV, 5 JMML, 7 AML and 9 MDS. As control, 23 BM, 14 PB and 7 CD34+ specimens from healthy donors and 5 from patients presenting reactive monocytosis were included. The protein amount and localization was analyzed by WB and immunofluorescence. To assess the causes of ROS1 overexpression, sequence analysis of ROS1 promoter and TK regions were performed. Since ROS1 ligand is still unknown, in order to establish the biological effects of c-ROS overexpression and activation, a chimeric receptor with the transmembrane and intracellular domains of ROS1 and the extracellular domain of EGFR was generated with the specific aim of activating ROS1 with EGF.The chimeric receptor was then transfected in NIH3T3 and HEK293T cells. Transfected and control cells were then stimulated with EGF and proliferation, cell adhesion and apoptosis evaluated.The activation of SOS/Grb/Akt/Erk pathways was investigated. *Results.* We found that ROS1 is quite undetectable in healthy subjects but it is overexpressed in 70% of CMML ($p<0,0001$) in both BM and PB cells with a median value of 2-DeltaDeltaCt of 13391±61895 (range 0-524288) in BM and 2031±4706 in PB. In CD34+ cells from healthy subjects c-ROS is undetectable while in CD34+ cells from CMML patients the mean value is 21136± 6273 (range 15287-29193). Sequence analysis revealed the absence of mutations of c-Ros promoter. SNPs analysis exclude the presence of duplications or deletions of the gene. The EGF induced activation of ROS1 significantly increased the proliferation rate, reduced cell adhesion and reduced apoptosis. In addition it was shown that the biological effects observed after ROS1 activation are mediated in both, cell lines and CMML cells, by SOS/Grb2/Akt/Erk activation. *Conclusion.* This study demonstrates that ROS1 is abnormally expressed in patients with CMML. The abnormal activation of ROS1 is responsible for loss of adhesion, increased proliferation and reduction of apoptosis. ROS1 is responsible for these effects in CMLL by activating Akt and Erk pathway. ROS1 is a TK which may represent a new target for molecular therapies leading us to test the *in vitro* effects of specific ROS1 inhibitors in CMML. daniela.cilloni@unito.it

Background. In a phase 2 trial of peg-IFNa-2a, we observed a substantial decrease of JAK2V617F allele burden in granulocytes from 29 patients treated with IFNa, including complete molecular remissions (CMR) in 7/29. Clinical significance of such decrease in JAKV617F allele burden remains unclear. In addition, some studies showed that several mutated clones might coexist in a single patient. We previously reported parallel evolution of JAK2V617F and TET2 mutation during IFNa therapy in a single patient with both mutations. In this patient, JAK2V617F was no longer detectable after IFNa, whereas TET2 mutation was unchanged. In contrast, opposite results (disappearance of TET2 mutation, no change in JAK2V617F allele burden) were recently reported in a single patient treated with IFNa in another clinical trial (Quintas-Cardama, ASH 2010). In order to confirm those findings, we studied the evolution of TET2 mutations during IFNa therapy in a series of 5 patients of our cohort carrying a TET2 mutation, including 4 with both JAK2 and TET2 mutations. *Methods.* We searched for JAK2 and TET2 mutations by genotyping from granulocytic DNA before and after IFNa therapy. Four patients presented both JAK2 and TET2 mutations (including 1 frameshift, and 3 different missense mutations), and one patient had only a TET2 missense mutation (patient #3, Table). Mean duration of IFNa therapy was 47.6 months (range: 41 - 60 months). JAK2V617F allele burden was measured with a quantitative allele specific assay, while mutant TET2 allele burden was estimated

Table 1.

Patients	JAK2V617F baseline	JAK2V617F After IFNa	JAK2V617F % evolution	TET2 mutation baseline	TET2 mutation after IFNa
1	20%	0	-100%	20%	unchanged
2	40%	0	-100%	50%	unchanged
3	Wild-type	NA	NA	50%	unchanged
4	20%	5%	-75%	45%	unchanged
5	100%	45%	-55%	60%	unchanged

from the sequencing analysis. *Results.* All the patients achieved clinical hematological response with IFNa therapy. Respective evolution of JAK2V617F and TET2 mutations are summarized in the Table. Median decrease in JAK2V617F allele burden was 100% (Q1 - Q3: 75% - 100%), and mean decrease was 86% (range: 55 - 100%). These long-term results show that IFNa therapy can induce sustained molecular responses regarding JAK2V617F mutation. In contrast, mutant TET2 allele burden estimated from sequencing analysis was unchanged after IFNa therapy in the 5 patients. *Conclusion.* In this series of PV patients with prolonged exposure to IFNa, we found that IFNa treatment was able to durably reduce the JAKV617F allele burden in PV, including long-term persisting complete molecular remissions. In contrast, TET2 mutated allele burden appeared unchanged after IFNa therapy, even after prolonged exposure to the drug (up to 60+ months). Our result suggest that, although inducing clear clinical responses, and marked decrease in JAK2 mutated clone, IFNa may not be able to eliminate cells bearing mutations in non-signaling molecules such as TET2.

1063

G6 ALLEVIATES JAK2-V617F MEDIATED MYELOPROLIFERATIVE NEOPLASIA BY PROVIDING SIGNIFICANT THERAPEUTIC EFFICACY TO THE BONE MARROW

P Sayeski,[1] S Park,[1] A Majumder,[1] M Gali,[2] M Reinhard,[1] H Wamsley,[1] J Zhao,[3] C Cogle,[1] K Bisht,[2] G Keseru,[4] A Kirabo[1]

[4]*Budapest University of Technology and Economics, Budapest, Hungary*

The discovery of the Jak2-V617F mutation in a large percentage of myeloproliferative neoplasm (MPN) patients has been a driving force behind the development of small molecule Jak2 inhibitors. Unfortunately, most drugs have been found to be merely palliative as they have little to no efficacy in the bone marrow and, therefore, cannot alter the natural history of the disease. We recently developed a small molecule Jak2 inhibitor called G6 and found that, in a xenograft model of Jak2-V617F mediated hyperplasia, it had noticeable efficacy in the peripheral blood, spleen, and bone marrow. Here, we hypothesized that it would have similar efficacy in a transgenic mouse model of Jak2-V617F mediated MPN. We implemented such a study and found that G6 provided therapeutic benefit to the peripheral blood in this model as determined by elimination of leukocytosis, thrombocytosis, and erythrocytosis. With respect to the spleen, G6 provided marked therapeutic efficacy as measured by normalization of spleen size and elimination of megakaryocytic hyperplasia. In the critically important bone marrow, G6 normalized the pathologically high levels of pJak2 and pSTAT5. It significantly reduced the megakaryocytic hyperplasia in the marrow and completely normalized the M:E ratio. Most importantly, G6 selectively reduced the mutant Jak2 burden by 67% on average with virtual elimination in one-third of all treated mice. This significant reduction in the Jak2 mutant burden correlated with the presence of G6 in the plasma. Lastly, clonogenic assays using marrow stem cells from the MPN mice revealed a time-dependent elimination of the clonogenic growth potential of these cells by G6. Collectively, these data indicate that G6 exhibits exceptional efficacy in the peripheral blood, spleen, and most importantly, in the bone marrow. As such, G6 appears to alter the natural history of Jak2-V617F mediated MPN.

1064

NF-E2 MEDIATES EXPRESSION OF THE CYTOKINE IL-8, AN INDEPENDENT PREDICTOR OF INFERIOR OUTCOME AND PRESENCE OF CIRCULATING BLASTS IN PMF PATIENTS

J Wehrle, D Pfeifer, H Pahl

University Hospital Freiburg, Freiburg, Germany

Background. The transcription factor nuclear factor erythroid-2 (NF-E2) is overexpressed in patients with myeloproliferative neoplasms (MPN) irrespective of the presence of the $JAK2^{V617F}$ mutation.[1,2] We have recently engineered a transgenic mouse model which recapitulates many features of MPN including thrombocytosis, leukocytosis, typical bone marrow features and transformation to acute leukemia[3,4] demonstrating a role for NF-E2 overexpression in the pathophysiology of MPN. Because the targets mediating NF-E2 effects are not well characterized, we conducted microarray analysis of $CD34^+$ cells lentivirally transduced to overexpress NF-E2 or to silence NF-E2 via shRNA, in order to identify novel NF-E2 target genes. *Aims.* To identify novel target genes of the transcription factor NF-E2. *Methods.* Peripheral blood $CD34^+$ cells from healthy donors were lentivirally transduced with a NF-E2 cDNA or with a shRNA directed against NF-E2. Cells were FACS sorted to obtain pure populations of transduced cells and assayed for gene expression using an Affymetrix Exon-Array (ST 1.0). IL-8 mRNA and protein expression were investigated by qRT-PCR of independently transduced $CD34^+$ cells, by intracellular FACS staining and by ELISA. The proximal 262 bp of the IL-8 promoter were used in a luciferase reporter gene assay. *Results.* Transduction of $CD34^+$ cells with the NF-E2 cDNA induced IL-8 mRNA expression 3-4 fold, while transduction of an shRNA against NF-E2 lowered IL-8 mRNA expression by 50% (n=4; p=0.008 by repeated measures ANOVA). Concurrently, IL-8 protein expression in the supernatant increased and decreased 1.7- and 2-fold, respectively. This effect was reproducible in the U937 cell line, where NF-E2 transduction also significantly increased IL-8 production, as measured both by ELISA and intracellular FACS staining (n=4 each; p=0.005 and p=0.02, respectively). Co-transfection of the proximal 262 bp of the IL-8 promoter with both NF-E2 and its obligate heterodimeric partner MafG, but not with either subunit alone, increased reporter gene activity 3-fold (n=3; p<0.001). NF-E2 binding to the IL-8 promoter *in vivo* was previously demonstrated by ChIP assay in K562 erythroleukemia cells[7]. *Summary/Conclusions.* We have identified IL-8 as a novel NF-E2 target gene. Serum levels of IL-8 are elevated in both PV and PMF patients.[5,6] Recently, increased IL-8 levels have been shown to be predictive of inferior survival in PMF patients in multivariate analysis.[6] Likewise, elevated IL-8 levels were associated with the presence of > 1% circulating blasts.[6] We therefore propose that one mechanism through which aberrant NF-E2 expression in MPN patients exerts its pathophysiological effect is by increasing IL-8 production.

Background. T-lineage acute lymphoblastic leukemia (T-ALL) is a malignancy of thymocytes. T-ALL represents about 15% of pediatric ALL cases but has an inferior outcome compared to B-ALL as approximately 30% of T-ALL cases relapse during therapy or within the first 2 years following treatment and eventually die. T-ALL is mostly characterized by genetic abnormalities that are crucial for T-cell pathogenesis. Various genetic rearrangements in T-ALL occur in a mutually exclusive pattern (such as *TLX1, TLX3, TAL1* and *LMO2* rearrangements) and these are identified in ~60% of pediatric T-ALL cases. For the remaining 40% the underlying oncogenic rearrangements remain unresolved. *Aims.* To identify novel oncogenic pathways in T-cell acute lymphoblastic leukemia (T-ALL) cases that lack a currently known (mutually exclusive) oncogenic rearrangement. *Methods.* We combined expression profiling of 117 pediatric patient samples and detailed molecular cytogenetic analyses including the Chromosome Conformation Capture on Chip (4C), arrayCGH, FISH and LM-PCR. *Results.* In a supervised cluster analysis based on the gene expression data, two T-ALL subtypes were identified that lacked rearrangements of known oncogenes, both comprising approximately 10% of the 117 pediatric T-ALL cases studied (n=12 in both groups). One subtype associated with cortical arrest, expression of cell cycle genes and ectopic *NKX2-1* or *NKX2-2* expression. In this subgroup 7 out of 12 cases carried *NKX2-1* or *NKX2-2* rearrangements involving T-cell receptor or *IgH@* loci, which have not been described in human cancer before. The second subtype associated with immature T-cell development and could also almost completely be predicted by an early thymic precursor signature (ETP-ALL) as previously published by Coustan-Smith *et al.* (2009). This entity highly expressed *LMO2, LYL1, HHEX* and the *MEF2C* transcription factor. In this subgroup we found several genetic rearrangements that all converge on the upregulation of *MEF2C*, a gene involved in muscle development. We also demonstrated by ChIP and knock-in and knock-out models, that MEF2C is a transcription factor that binds the promoters of LMO2 and *HHEX* and is responsible for part of the expression signature of this immature cluster. Knockdown of MEF2C also induced cellular differentiation in a cell line model. Furthermore, in cellular transformations assays using NIH-3T3 and BJ-EHT cells we could demonstrate transforming potential for MEF2C as well as NKX2-1 in combination with *RAS* or *MYC* oncogenes. *Summary/Conclusions.* We propose *NKX2-1, NKX2-2* and *MEF2C* as novel T-ALL oncogenes that are activated by various rearrangements.

Adult ALL is a heterogeneous disease at the genetic level. We have previously demonstrated a strong association between cytogenetics and outcome which is independent of other risk factors. The widespread use of fluorescence *in situ* hybridisation (FISH) and genomic technologies has revealed a plethora of genomic abnormalities in this disease: e.g. translocations involving the *IGH@* locus (*IGH@*-t); deregulation of the *CRLF2* gene (*CRLF2*-d) via *IGH@-CRLF2* or *P2RY8-CRLF2* (aka PAR1 deletion); and micro-deletions of *CDKN2A/B, IKZF1, PAX5, ETV6, RB1, BTG1* and *EBF1*. The aim of the study was to estimate the frequency of these abnormalities and assess their prognostic relevance among adults with Philadelphia-negative B-cell precursor ALL. The cohort comprised 454 adults (15-60 years old) treated on MRC UKALLXII and had a median follow-up time of 5.6 years. FISH, using a commercial IGH break-apart probe and validated home-grown probes, was used to detect *IGH@*-t (and partner genes), *IGH@-CRLF2* and *P2RY8-CRLF2*. Multiplex Ligation Probe Amplification (MLPA) using the SALSA P335-A1 kit was used to detect micro-deletions and *P2RY8-CRLF2*. A total of 49/439 (11%) patients had an *IGH@*-t: *IGH@-CRLF2* (n=12); *IGH@-ID4* (n=3); *IGH@-CEPBA/B/E* (n=6); unknown (n=28). Another eight patients harboured *P2RY8-CRLF2*, thus 20 (5%) patients had *CRLF2*-d. There was little overlap between *IGH@*-t, *CRLF2*-d and established chromosomal abnormalities (*MLL* translocations, t(1;19)(q23;p13), *ETV6-RUNX1*, high hyperdiploidy (HeH), low hypodiploidy/near-triploidy (HoTr), complex karyotype (CK) and iAMP21): *CRLF2*-d with HeH/iAMP21 (one each) and *IGH@*-t with *ETV6-RUNX1*/CK/iAMP21 (one each), HeH (n=2). Micro-deletions were highly prevalent with 203/304 (67%) cases harbouring at least one deletion. However, the frequency of each deletion varied by cytogenetic subgroup (see table). *IKZF1* deletions were present in 66% *CRLF2*-d cases but were rarer among t(4;11), t(1;19) and HeH cases. There was no correlation between age or sex and the presence of any of these new abnormalities. Patients with *IGH@-CRLF2* or *IKZF1* deletions had higher white cell count (WCC) (median 102x10e9/L v 10, 16 v 11) whereas patients with *ETV6* deletion had lower WCC (5 v 15). The 4-year EFS and OS for the 441 patients with follow-up data were 41% (95%CI 37-46) and 46% (41-50). Univariate Cox analysis showed that four abnormalities were associated with poor OS: *CRLF2*-d - hazard ratio 2.03 (95%CI 1.20-3.44), p=0.008; *IGH@*-t 1.65 (1.11-2.45), p=0.013; *EBF1* deletion 2.52 (1.11-5.71), p=0.027 and *IKZF1* deletion 1.54 (1.10-2.14), p=0.011. In contrast, the EFS and OS hazard ratios for patients with a *PAX5* deletion were 0.65 (0.42, 1.01), p=0.056 and 0.68 (0.43-1.06), p=0.09. Multivariate analysis adjusting for sex, age, WCC and cytogenetic risk group revealed that *CRLF2*-d, *IGH@*-t and *PAX5*

Table 1. Distribution of deletions by cytogenetic subgroup.

Deletion	Cases	Frequency							
		Overall	t(4;11)	HoTr	CK	*CRLF2*-d	*IGH@*-t	HeH	t(1;19)
Tested	304	304	34	16	12	12	20	32	10
CDKN2A/B	114	38%	18%	44%	50%	58%	45%	28%	40%
IKZF1	87	29%	15%	25%	33%	66%	30%	13%	10%
PAX5	56	18%	3%	6%	33%	42%	10%	9%	30%
ETV6 *	32	11%	3%	0%	8%	8%	15%	22%	0%
RB1	30	10%	0%	19%	17%	33%	10%	9%	0%
BTG1	26	9%	0%	0%	8%	50%	10%	3%	0%
EBF1	7	2%	0%	6%	17%	0	10%	0%	0%

* *ETV6-RUNX1*-positive (n=2), *ETV6-RUNX1*-negative (n=26), Unknown (n=4)

deletions were independent risk factors. The 4-year OS rates for these aberrations were: *CRLF2*-d 15% (3-37%); *IGH@*-t 29% (16-44%); *PAX5* deletions 58% (44-71%). In conclusion, micro-deletions of key B-cell differentiation and cell cycle control genes are highly prevalent in adult ALL but vary in frequency by genetic subgroup. There was evidence to suggest that deletions of B-cell differentiation genes were linked to outcome. *CRLF2*-d and *IGH@*-t represent distinct and prevalent subgroups of adult ALL which are associated with a poor outcome.

[5]*University of Münster, Münster, Germany*

Background. Cytogenetically normal acute myeloid leukemia (CN-AML) is biologically and clinically heterogeneous. During recent years genomic aberrations and deregulated gene expression signatures have been identified to provide important prognostic information. *Aims.* Our intention was to assess whether gene expression-based outcome prediction using novel biostatistical approaches applied to large data sets generated across four different laboratories could refine previous prognostic signatures in CN-AML. *Methods.* We generated gene expression profiles of 220 clinically well annotated CN-AML cases in a multicenter setting, comprising three different expert laboratories. For the analysis Affymetrix Human Genome U133plus2.0 Arrays and a standardized labeling protocol were used. Following data normalization and correction of batch artifacts, we applied L1-penalized Cox proportional hazards regression to develop a sparse prognostic model for overall survival. Our model was then validated by (i) leave-one-out cross-validation and (ii) by evaluating the prognostic accuracy in two independent CN-AML data sets (n=163 and n=79 cases) generated in a fourth laboratory. *Results.* We identified a 13-gene signature for overall survival that was successfully validated by means of cross-validation [P<0.001, Hazard Ratio (HR) 1.56, 95% Confidence Interval (CI) 1.21-2.00] as well as in both independent data sets (P<0.001, HR 1.85, 95%CI 1.40-2.46; and P=0.004, HR 1.85, 95%CI 1.22-2.81, respectively) using a Cox Proportional Hazards model. The gene signature retained its prognostic relevance in a multivariable model adjusting for age, FLT3-ITD and NPM1 alterations (P=0.007, P=0.004 and P=0.013). Genes contained in our outcome signature comprised candidates previously reported to be associated with molecular markers such as APP (amyloid beta precursor protein). Its expression pattern has been associated with NPM1 mutations and it was also found amplified in AML with complex karyotype. With regard to its potential biological impact APP can bind to acetyltransferase complexes to promote transcriptional activation and has been linked to gamma-secretase function and NOTCH signaling. Furthermore, we also confirmed candidates known to confer prognostic information such as LEF1 that might play a significant role in self-renewal. *Summary/Conclusions.* This is the first multicenter study to identify a refined prognostic gene signature followed in CN-AML. Our independent validation further proves the clinical potential of gene expression profiling in this AML subgroup.

RECURRENT NADH DEHYDROGENASE SUBUNIT 4 (ND4) MUTATIONS IN ACUTE MYELOID LEUKEMIA

F Damm,[1] T Bunke,[1] M Heuser,[1] F Thol,[1] K Wagner,[1] G Göhring,[1] B Schlegelberger,[1] G Heil,[2] C Reuter,[1] K Püllmann,[1] R Schlenk,[3] K Döhner,[3] H Döhner,[3] J Krauter,[1] A Ganser,[1] M Morgan[1]

[1]*Hannover Medical School, Hannover, Germany*
[2]*Klinikum Lüdenscheid, Lüdenscheid, Germany*
[3]*University of Ulm, Ulm, Germany*

Background. Recently, mutations in *NADH dehydrogenase subunit 4* (*ND4*), a mitochondrial encoded transmembrane component of the electron transport chain respiratory Complex I, have been described in acute myeloid leukemia (AML). *Aims.* In the present study, we investigated the prevalence and prognostic importance of *ND4* mutations in 452 AML patients. *Methods.* After obtaining informed consent according to the Declaration of Helsinki, DNA from diagnostic bone marrow or peripheral blood samples were analyzed from 452 adult patients (aged 17-60 years) with de novo (n=402) or secondary AML (n=50). All patients received intensive induction and consolidation therapy. *ND4* mutations were detected by direct sequencing and, when possible, the somatic or germline status was established by evaluating matched buccal swabs or healthy $CD3^{+}CD45^{bright}CD34^{-}$ T-cells sorted from diagnostic leukemia samples. *Results.* Homoplasmic and heteroplasmic *ND4* mutations (e.g. mutations affecting all or only a fraction of mitochondrial DNA copies) predicted to affect translation were detected in 34 of 452 patients (7.5 %). Thirty-one cases had single point mutations resulting in amino acid substitutions, two cases had two separate missense *ND4* point mutations, and another case had a one base pair deletion predicted to result in a truncated protein. *ND4* mutations were associated with younger age (P=.042) and *NRAS* mutations (P=.019), but were inversely associated with *NPM1* mutations (P=.039). Analysis of buccal swab samples available for three *ND4mutated* patients demonstrated that two heteroplasmic mutations were somatic and one homoplasmic mutation was germline. In six additional patients (five with heteroplasmic and one with homoplasmic *ND4* mutations), we sorted T-cells ($CD3^{+}CD45^{bright}CD34^{-}$) and leukemic blasts ($CD3^{-}CD45^{dim}$) from diagnostic leukemia samples. In the five heteroplasmic *ND4mutated* cases, we detected only wildtype *ND4* in the healthy T-cell population, while the *ND4* mutations were restricted to the leukemia blast population in all five cases, thus confirming the somatic nature of these mutations. In contrast, the homoplasmic *ND4* mutation was detected in both the healthy T-cell and the leukemia blast populations, demonstrating that this is a germline mutation. Additionally, analysis of *ND4* mutation status in complete remission samples revealed loss of the *ND4* mutation in 4/5 AML cases who had heteroplasmic *ND4* mutations at diagnosis, while the same was true for only 1/7 cases who presented with homoplasmic *ND4* mutations. Although univariate analysis demonstrated similar relapse-free (RFS; P=.676) and overall survival (OS; P=.948) for *ND4mutated* patients (n=34) compared to *ND4wildtype* patients (n=418), comparison of patients according to the heteroplasmy status of *ND4* mutations revealed longer RFS (P=.025) and OS (P=.012) for patients with heteroplasmic *ND4* mutations (n=12). *Conclusions.* These observations extend our knowledge of *ND4* mutations and further establish the link of mitochondrial mutations with leukemia. Our data suggests that hetero- and homoplasmic *ND4* mutations may elicit different effects in leukemia biology, such as contribution to leukemia maintenance or sensitization of leukemia cells to therapy.

1069

RUNX1-MUTATIONS ARE COMMON IN ADULT PRECURSOR T- CELL ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL)

V Grossmann, W Kern, S Harbich, S Schnittger, C Haferlach, T Haferlach, A Kohlmann

MLL Munich Leukemia Laboratory, Munich, Germany

Precursor T cell acute lymphoblastic leukemia (T-ALL) accounts for 20% of all lymphoblastic leukemia cases. The runt-related transcription factor 1, RUNX1, is crucial in the development of myeloid and lymphoid cell lineages. Mutations have been reported in approximately 30% of cases with MDS, CMML and AML and are associated unfavorable impact on outcome, at least in MDS and AML. We recently investigated 39 patients with chronic myeloid leukemia in blast crisis (BC-CML) with either myeloid or lymphoid features. In that study, 3/10 patients with a lymphoid BC-CML harbored RUNX1 mutations, indicating a potential role of these alterations in lymphatic malignancies. Recently, RUNX1 has also been demonstrated to be involved in lymphoid differentiation in particular in T cell differentiation. Expression of RUNX1 is found in naïve CD4-positive T cells and represses the expression of GATA3 and IL4, thereby influencing their further development into Th2 T helper cells. Here, we for the first time analyzed the RUNX1 mutation status in a cohort of 101 adult ALL patients (T-ALL, n=49; B-ALL, n=52). In addition, 5 cases with natural killer cell leukemia were analyzed. For molecular analyses, using the purified fraction of mononuclear cells after ficoll density centrifugation, a sensitive next-generation amplicon deep-sequencing assay was applied (454 Life Sciences, Branford, CT). A sequencing library was prepared interrogating the complete coding region of RUNX1, split

into 7 distinct amplicons (median length: 342 bp). NGS data were analyzed using GS Variant Analyzer Software 2.3 (454 Life Sciences) and Sequence Pilot version 3.4 (JSI Medical Systems, Kippenheim, Germany). In median, 821 reads per amplicon and patient (range 217-1687) were obtained, thus yielding a sufficient coverage for mutation detection with high sensitivity (<5%). Overall, 15 mutations were detected in 13 patients: 7 missense alterations, 1 nonsense mutation, 6 frameshift alterations, and 1 in-frame insertion. RUNX1 mutations were distributed across several exons, but like in myeloid malignancies predominantly clustered in the RUNT domain (aa 50-177; 11/15 mutations) and TAD domain (aa 291-371; 4/15 mutations). In the cohort of B-ALL (n=52 including 22 cases with BCR-ABL1 rearrangement), only 2 cases (3.8%) were RUNX1-mutated. Both of them harbored a BCR-ABL1 rearrangement. In contrast, in T-ALL 13 distinct mutations were observed in 11/49 cases (22.4%; p=0.007 vs. B-lineage). With respect to clinical associations, RUNX1 mutations in T-ALL were associated with a higher age (mean±SD 58±17 vs. 39±17 years; p=0.003; median age overall: 42 years) and with a lower white blood cell count (mean±SD 27±22 vs. 81±95 G/L; p=0.006), but not with platelet count, hemoglobin level, gender or karyotype. These findings may be a rationale for a pathogenetic role of RUNX1 mutations in T-cell precursor ALL as observed in the present series. In summary, our study revealed a high incidence of RUNX1 mutations in 22.4% of T-ALL patients. This data further support that RUNX1 plays an integral part in hematopoiesis in general and is not limited to myeloid differentiation. Considering the present results, RUNX1 mutation screening is warranted in future clinical studies and may enable an even more specific diagnosis of this disease.

PROGNOSTIC SIGNIFICANCE OF LEF1 EXPRESSION IN ADULT B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

A Kuehnl,[1] N Goekbuget,[2] M Kaiser,[1] C Schlee,[1] A Stroux,[1] T Burmeister,[1] L Mochmann,[1] D Hoelzer,[2] WK Hofmann,[3] E Thiel,[1] C Baldus[1]

[1]*Charite University Hospital Berlin, Berlin, Germany*
[2]*Johann Wolfgang Goethe-University, Frankfurt, Germany*
[3]*University Hospital Mannheim, Mannheim, Germany*

Background. The Wnt signaling pathway is linked to proliferation and survival of leukemia cells and has emerged as a potential target for antileukemic therapy. Lymphoid Enhancer Factor (LEF) 1, a key mediator of the Wnt pathway, was shown to directly promote leukemic transformation. Recently, microdeletions and mutations of the *LEF1* gene were identified in pediatric T-cell acute lymphoblastic leukemia (ALL). *Aims.* To further investigate the yet undefined role of *LEF1* in B-lineage ALL, we determined the prognostic impact of *LEF1* expression in adult B-precursor ALL patients. *Methods. LEF1* mRNA expression was determined by quantitative real time PCR in pretreatment bone marrow samples of 282 adults with newly diagnosed B-precursor ALL enrolled on the 06/99 (n=138) and 07/03 (n=144) GMALL multicenter trials. For statistical analyses, patients were grouped into quartiles according to *LEF1* expression levels [*LEF1* high (Q4; n=71); *LEF1* low (Q1-3; n=211)]. The median follow-up for living patients was 42.6 months. Patients who received allogeneic stem cell transplantation in first remission were censored at the time of transplantation for survival analyses. Multivariate analyses were performed according to the Cox proportional hazards model, including the following variables in the full model: white blood cell (WBC) count (10/nl increase), age (10-year increase), CD20 positivity, *BCR-ABL*, *MLL-AF4*, and immunophenotype. We focussed our analysis on standard risk (SR) patients as defined by GMALL (*BCR-ABL*- and *MLL-AF4*-negative patients with CR after first induction therapy and WBC ≤30/nl; n=91), as this patient group lacks molecular markers for further risk stratification. To evaluate the presence of *LEF1* mutations, we performed DNA sequencing of *LEF1* exons 2 and 3, as the observed hot spot regions in T-ALL, in 41 B-precursor ALL patients. *Results.* No significant differences regarding age, WBC, the immunophenotype, or GMALL risk groups were found between the two *LEF1* groups. High *LEF1* expression was associated with CD20 positivity (P=0.01) and inversely associated with the expression of myeloid markers (P=0.001). Patients with high *LEF1* expression had a significantly shorter relapse-free survival (RFS) compared to low *LEF1* expressers (5-year RFS: *LEF1* high: 29%, *LEF1* low: 51%; P=0.008). In mulitvariate analyses, *LEF1* was independently predictive for RFS [hazard ratio 1.9 (95% CI 1.1-3.3); P=0.02]; the other factors in the final model were WBC, age, and immunophenotype. Similarly in SR patients, high *LEF1* expression was associated with a significantly inferior RFS (5-year RFS: *LEF1* high: 39%, *LEF1* low: 61%; P=0.01). Upon Cox analysis, *LEF1* expression was the only factor with prognostic significance for RFS [hazard ratio 2.8 (95% CI 1.2-6.3); P=0.01] in SR patients. The mutational analyses revealed no *LEF1* mutations in exons 2 and 3, suggesting that in B-precursor ALL transcriptional activation of *LEF1* rather than inactivating mutations as in T-ALL might play a role. *Conclusions.* High *LEF1* expression identifies adult B-precursor ALL patients with significantly inferior RFS, supporting a pathogenetic role of Wnt signaling in ALL. Thus, determination of *LEF1* might improve pretreatment risk assessment in SR ALL patients. Moreover, patients with high *LEF1* expression may be considered for new molecular therapies, including agents targeting the Wnt pathway.

1071

DEXAMETHASONE VERSUS PREDNISOLONE FOR THE TREATMENT OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

C Zheng

Anhui Provincial Hospital, Anhui Medical University, Hefei, China

Background. Corticosteroids are essential and one of the mainstays in the treatment of acute lymphoblastic leukemia (ALL). The current randomized comparisons between dexamethasone (DXM) and prednisolone (PDN) in childhood ALL indicated a statistically significant

and clinically important decrease in rate of isolated central nervous system (CNS) relapses and an increase in event-free survival (EFS) with DXM. But the data were limited in adult ALL. *Aims.* We evaluate the role of DXM compared to PDN during induction or subsequent phases of therapy in adult ALL patients. *Methods.* From January 2000 to January 2010, ninety five standard risk (SR) and 132 high risk (HR) or very high risk (VHR) newly diagnosed adult ALL patients entered the randomized comparison of DXM at 6 mg/m2/d vs PDN at 60 mg/m2/d with ALL treatment protocol. HR ALL was defined as patients fulfilling at least one of the following criteria: age 35 years and older, WBC count greater than 30x109/L for B-lineage ALL or more than 100x109/L for T-lineage ALL at diagnosis, time to complete remission (CR) more than 4 weeks. Patients who had none of these risk factors were considered as SR, and patients with cytogenetics of t (9; 22) or BCR-ABL fusion gene positive were considered as VHR. *Results.* The median follow-up time was 3.5 years. There were no significant differences in terms of CR between the PDN and DXM arms, no matter in SR group (84% vs 87%, p =0.53) or in HR+VHR group (72% vs 75%, p =0.42). In patients with SR, the cumulative incidence of isolated CNS relapse was lower for DXM patients than for PDN patients, with 3-year cumulative estimates of 7.5% and 12.1%, respectively (p =0.015). The 3-year disease-free survival (DFS) and 3-year overall survival (OS) rates were 49% and 52% in SR patients who received DXM, which were significantly higher than 40% and 46% in SR patients who received PDN (p =0.005, 0.01). For patients with HR+VHR, the isolated CNS relapse rate was similar for patients assigned to DXM compared with that of patients assigned to PDN (3-year cumulative estimates: 11.6% vs 14.7%; p =0.15), and there were no differences in the 3-year DFS rates (32% vs 30%, p =0.59) and 3-year OS rates (35% vs 33%, p =0.36) based on steroids type (DXM vs PDN). During induction the incidence of grade 3- 4 infection was similar in the two arms (DXM 18.5% vs. PDN 15.3%, p =0.20), and during post-induction consolidation, it was higher in the DXM arm (15.5% vs 8.9%, p =0.02). Reversible hyperglycemia and myopathy were higher in the DXM arm than in the PDN arm (5.8% vs 4.8%, 4.2% vs 3.1%), but the differences were not statistically significant (p =0.5, 0.35). *Conclusions*. Our results indicates that DXM might have benefit in adult SR ALL patients, as it was proved in children, especially concerning the long-term survival and the CNS relapse. But for patients at HR of relapse, it is unlikely that only modification of steroids replacement would alter their dismal prognosis.

1072

LONG-TERM FOLLOW UP OF ADULT PATIENTS WITH NEWLY DIAGNOSED PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (PH+ALL) RECEIVING IMATINIB AND CHEMOTHERAPY AS FRONT-LINE TREATMENT WITHIN GMALL STUDIES

Background. Imatinib (IM) in combination with chemotherapy regimens followed by allogeneic SCT has become the standard treatment for younger patients with Ph+ ALL. Complete remission (CR) rates generally exceed 90%. The efficacy on the long-term outcome data obtained from a large group of prospectively evaluated patients is still unclear. *Aim.* The aim of this analysis was to analyze the efficacy of an early imatinib administration started simultaneously with induction chemotherapy according to the GMALL protocol 07/03 (A3). These results were compared with two consecutive patient cohorts of the GMALL study group, where IM was given alternating and/or concurrent, which has been previously reported by Wassmann *et al.* (Blood 2006;108:1469). *Methods.* A total of 335 patients with newly diagnosed Ph+ ALL who received IM given at a single daily oral dose of 600 mg within 3 successive treatment cohorts were compared. A1: IM was administered between induction (IND) and first consolidation (CONS1) and again after CONS1 (n=51); A2: IM was given during the second half of IND and then continued throughout CONS1 until SCT (n=105); A3: IM has been initiated together with start of induction chemotherapy and continued throughout CONS1 until SCT (n=179). Minimal residual disease (MRD) was serially assessed by quantitative RT-PCR, mutational analyses was performed by D-HPLC and direct sequencing. *Results.* The median age of all patients was 43 years (17-65 y), 57 (17%) patients were 55 years of age or older. CR rates in cohorts A2 and A3 were 89.4% and 85.7%, induction deaths occurred in 5.8% and 11.3% of patients, treatment failure was observed in 4.8% and 3% of pts., respectively. The molecular response rate based on PCR negativity for bcr-abl transcripts after CONS1 was superior in cohort A3 with 33% (26/79) as compared to 12.5% (5/40) and 4.2% (2/47) in cohorts A2 and A1, respectively (p=0.01). Overall treatment outcome improved with earlier initiation and more prolonged administration of IM in the three successive patient cohorts: Overall survival (OS) at 4 years was 31%, 40% and 50% in cohorts A1, A2 and A3, respectively. To date, 219 patients (66.4%) underwent SCT in CR1 (A1: n=39; A2: n=74; A3: n=106), with a median age of 39.5 years. The 3 year probability of DFS of pts. in cohort A3 who received myeloablative conditioning regimens combining TBI with cyclophosphamide or etoposide was 72. The incidence of relapse after SCT was lower among patients in cohort A3 (11.3%) than those in A2 (24.3%) or A1 (30.8%). For all pts. transplanted in CR1 irrespective of treatment cohort, median OS was 57% after 3 yrs. and 52% after 7 yrs. Patients who did not undergo SCT in CR1 had a dismal outcome, with a median OS of 9.4 months and 14% alive after 3 years. *Conclusion.* In conclusion, intensive chemotherapy and early administration of IM is feasible in patients with newly diagnosed Ph+ALL and is associated with superior treatment outcomes after SCT. SCT in CR1 remains the treatment of choice even in patients who achieve a good molecular response to initial therapy.

[4]*Hospital Germans Trias i Pujol - ICO Badalona, Badalona, Spain*

Background and aims. The addition of rituximab to specific chemotherapy for Burkitt's leukemia or lymphoma (BLL) has yielded promising results in phase II studies. However, most of these studies excluded patients infected by the human immunodeficiency virus (HIV). The results and toxicity of a phase II study including patients with BLL regardless of their HIV status are presented. *Methods.* This trial (Burkimab) derived from the B-ALL/NHL2002 (German Multicenter Adult Acute Lymphoblastic Leukemia Group, GMALL) consisted of a prephase with cyclophosphamide and prednisone, followed by cycles (A, B, C) including rituximab, iphosphamide, high-dose methotrexate and cytarabine. Patients in localized stages (I, II non-bulky) received 4 cycles (A1,B1,C1 and A2) and those with bulky stage II or in advanced stages (III, IV) or Burkitt's leukemia received 6 cycles (A1, B1, C1, A2, B2, C2), plus two additional doses of rituximab. Patients ≥55 yr. received only A and B cycles, with 50% reduction in doses of methotrexate and cytarabine. Informed consent was obtained from all patients. *Results.* 121 patients were included (2004-2010). Median age was 45 yr (range 15-83), 97 (80%) were in advanced stages (III-IV), with extranodal involvement ≥2 sites in 56 (46%) and Burkitt's leukemia in 24 (20%). LDH was elevated in 108 (91%), ECOG score was >2 in 54 (45%), and age-adjusted IPI was:

low 6 (5%), low-intermediate 17 (14%), intermediate-high 48 (41%) and high 47 (40%). The only difference between HIV- (n=80) and HIV+ (n=41) cohorts was age (48 vs. 42 yr, respectively, p=0.03). Seventy-three (HIV-) and 40 (HIV+) patients were evaluable for treatment results. Complete response (CR) was achieved in 63 (86%) vs. 33 (83%), 4 (5%) vs. 5 (13%) died during induction and 4 (5%) vs. 2 (5%) did not respond. The remaining 2 patients (HIV-) were removed early from the trial. After a median follow-up of 2 yr. (range 0.4-7), 4 relapses (5%) vs. 2 (5%) were observed (isolated BM: 2, isolated CNS: 2, combined BM+CNS: 1, extranodal: 1) and 3 (4%) vs. 5 (13%) patients died in remission during chemotherapy (p=0.12). The 4-yr. OS probabilities were 79% (95%CI, 69%-89%) vs. 67% (95%CI, 52%-82%)(p=0.11), the 4-yr. DFS probabilities were 90% (95%CI, 82%-98%) vs. 79% (95%CI, 65%-93%)(p=0.12), and the 4-yr. EFS probabilities were 76% (95%CI, 66%-86%) vs. 62% (95%CI, 47%-77%)(p=0.17). For patients aged <55yr. grade 3-4 hematological toxicity, mucositis and infections were significantly more frequent in HIV+ patients either as a whole or considering cycles A, B and C separately. For patients aged ≥55yr. only grade 3-4 neutropenia in A cycles was significantly more frequent in HIV+ patients. *Conclusions.* This phase II trial showed promising results of specific immunochemotherapy in adult patients with BLL. Although hematological, mucosal and infectious toxicity was higher in HIV+ cohort, the CR, DFS, OS and EFS were not significantly different according to HIV infection status.

GENOMIC VS. GENE EXPRESSION-BASED METHODS IN THE DETECTION OF IKAROS (IKZF1) ALTERATIONS AND EVALUATION OF THEIR PROGNOSTIC IMPACT IN CHILDHOOD ALL

J Volejnikova, E Mejstrikova, K Svojgr, J Stary, J Trka, E Fronkova

2nd Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic

Background. Recently, Ikaros (IKZF1) gene deletions have been described as adverse prognostic factors in childhood acute lymphoblastic leukemia (ALL). Nevertheless, there is still lack of data on IKZF1 impact concerning different treatment protocols, minimal residual disease (MRD) and the most suitable diagnostic method in BCR/ABL-negative ALL. *Aim.* To compare the DNA- vs. RNA-based approach assessing Ikaros status in a cohort of children with BCR/ABL-negative ALL treated by non-MRD based protocol ALL IC-BFM 2002. *Methods.* A) Gene expression of functional (Ik1, Ik2) vs. short (Ik4, Ik4A, Ik4del, Ik6, Ik6del, Ik8) IKZF1 isoforms was evaluated using Lab-on-a-chip (Agilent) electrophoresis and reported either as an absolute level or relative to the total signal. Thresholds for abnormal expression were set based on the analysis of peripheral blood of healthy donors, remission bone marrow (BM), and sorted B- and T-cell precursor subpopulations. B) MLPA (multiplex ligation-dependent probe amplification) was performed on BM DNA with probes for Ikaros exons 1 to 8. *Results.* Results of both gene expression and MLPA analysis were available for 182/244 children diagnosed between 2002 and 2007. MLPA revealed a deletion of at least one exon of IKZF1 in 12 (7%) patients. The proportion of non-DNA binding isoforms to the total IKZF1 expression was significantly increased (>80%) in 13 (7%) patients. The expression of a dominant-negative Ik6 isoform was significantly elevated (>50% of total) in 10 (6%) patients. Surprisingly, changes on DNA level were not always reflected in gene expression. Of 12 patients with gene deletion, only five had an increased short/long isoform ratio (4 pts due to Ik6 overexpression). The deletion on one allele did not cause a decrease in total IKZF1 gene expression level. Conversely, of 10 patients with Ik6 overexpression, six patients had no DNA alteration, suggesting a different mechanism of altered gene expression. Patients with IKZF1 gene deletion had significantly worse relapse-free survival (RFS) than other patients (5-year RFS 46±15% vs. 91±2%, p<0.0001). Patients with IKZF1 deletion had higher MRD in BM at day 33 (p=0.008). In gene expression analysis, Ik6 overexpression was the most important negative prognostic factor (5-year RFS 50±16% vs. 91±2%, p<0.0001), whereas elevated short/long isoform ratio (>80%) had only weaker impact (5-year RFS 69±13% vs. 90±2%, p=0.02). Gene expression of no other single IKZF1 isoform had impact on prognosis. Patients with Ik6 overexpression had higher MRD in BM at day 15 (p=0.009), day 33 (p=0.02) and at week 12 (p=0.01) and higher peripheral blood MRD at day 15 (p=0.05). *Conclusion.* Contrary to previous studies, we showed that deletions within IKZF1 locus do not necessarily correlate with altered Ikaros gene expression. Conversely, Ik6 overexpression was not accompanied by a deletion within IKZF1 locus in 60% of patients. Both DNA- and RNA-IKZF1 alterations had a strong negative prognostic impact in a cohort of children with BCR/ABL-negative ALL treated by a BFM-based protocol that did not use MRD in the risk group stratification. Ideally, both genomic and gene expression-based approach should be applied together for the evaluation of prognosis.

PLERIXAFOR IS A POTENTIAL THERAPY FOR MYELOKATHEXIS, WHIM SYNDROME

D Dale,[1] A Bolyard,[1] M Kelley,[1] E Westrup,[1] V Makaryan,[1] A Aprikyan,[1] B Wood,[1] F Hsu[2]

[1]*University of Washington, Seattle, United States of America*
[2]*Genzyme, Boston MA, United States of America*

Background. Myelokathexis or WHIM syndrome (warts, hypogammaglobulinemia, immunodeficiency and myelokathexis) is a rare autosomal dominant disorder attributable to mutations in the CXCR4 gene. The WBC is usually <1.0 x 109/L. with severe neutropenia and lymphocytopenia. Marrow examination shows abundant neutrophils with hypersegmented nuclei and remnants of neutrophils in marrow macrophages. The mutations in CXCR4 are activating and prevent the normal release of neutrophils from the marrow into the blood. Plerixafor is a small molecule inhibitor of the binding of CXCR4 to its ligand CXCL12. Subcutaneous administration of plerixafor causes a dose-dependent increase in circulating leukocytes. It increases circulating CD34+ cells and is currently used as an adjunct to granulocyte colony-stimulating factor (G-CSF) for mobilization of hematopoietic stem cells. *Aim.* Investigated the potential of plerixafor as therapy for myelokathexis/WHIM syndrome. *Methods.* We enrolled 6 patients (4 female, 2 male, ages 28 to 73 years) in this study, with informed consent and investigational review board approval of the University of Washington and Federal approval for investigation use of plerixafor. Five patients from three different families had the same mutation (R334ter); the other patient had a novel mutation (S324fs365ter). Single subcutaneous doses of plerixafor, increasing from 0.04 to 0.24 mg/kg, were administered at 2 to 4 day intervals. Complete blood counts were determined with an automated counter and leukocyte differential counts confirmed manually. CD34+ cells and lymphocyte subtypes were measured by FACS before and 6 hours after the 0.08 mg/kg dose. Plerixafor was discontinued if neutrophils were >2.0 x 109/L at 24 hours, after all doses were tested or if serious adverse events or illness occurred. Results were compared with five similarly studied normal subjects. *Results.* All 6 patients showed a prompt leukocytosis with maximum blood neutrophils and lymphocytes at 6 to 12 hours, declining toward baseline by 24 hours. Blood neutrophils peaked at 3.9 +/- 0.55 x 109/L (range 1.8 to 5.1 x 109/L) at 6 to 12 hours. Two of the 6 patients achieved > 2.0 x 109/L neutrophils at 24 hours. The lymphocyte responses were proportionally greater than the neutrophil responses. The greatest increase was in B cells (CD20+cells), a 60 fold increase at 0.08 mg/kg. CD34+ cells increased 6.8 fold at 0.08 mg/kg. Comparisons of patients and normal subjects showed larger proportional B and T cell responses in the patients. Hematocrit, hemoglobin and platelet counts were stable through the 10 day testing period, except for one patient with severe iron deficiency anemia who responded well to oral iron initiated during the study. None of the patients experienced any significant adverse effects. One patient discontinued the trial when she had a recurrence of pneumonia. All of the patients who had previously received G-CSF had neutrophil responses but no changes in lymphocyte counts. *Conclusions.* This trial shows that plerixafor can correct neutropenia and lymphocytopenia in patients with myelokathexis/WHIM syndrome and suggests that this agent may correct the underlying immunodeficiency. Plerixafor is a promising molecularly targeted therapy for this condition. Plans for a therapeutic trial are now underway.

1076

ACHIEVEMENT OF EFFICIENCY AND SAFETY BY THE USAGE OF A NOVEL SINGLE CHAIN TCR DESIGN IN HUMAN CYTOMEGALOVIRUS PP65 / P53 TUMOR ANTIGEN-BISPECIFIC T CELLS

D Stolle,[1] H Echchannaoui,[2] E Antunes,[2] B Hauptrock,[2] S Thomas,[2] S Klobuch,[2] P Guillaume,[3] W Herr,[2] P Romero,[4] M Theobald,[2] RH Voss[2]

[4]*Division of Clinical Onco-Immunology, Ludwig Institute for Cancer Research, Lausanne, Switzerland*

Allogeneic stem cell transplantation leads in immunosuppressed seropositive leukemia patients to reactivation of human cytomegalovirus (HCMV) and in this case to increased virus titer and mortality. Therefore, our aim is the generation of p53 tumor antigen- and HCMV-bispecific T cells for donor lymphocyte infusions (DLI). First, we isolated HCMV+ T cells from seropositive blood donors using pp65(NLVPMVATV(495-503)) peptide-specific stimulation. After one or two pp65 peptide-specific restimulations followed by CMV pp65-specific multimer cell-sorting in flow cytometry, we were able to enrich HCMV-specific T cells and assess their cytotoxic effector function using either pp65-loaded K562-A2 or recombinant HCMV-infected HLA-A*0201+ human fibroblasts as target cells. Different HCMV+ donors indicated high TCR affinities for the pp65 antigen by EC50-values ranging from 0.1 nM to 1.8 nM in peptide titration. Moreover, the HCMV+ T cells recognized HCMV-infected fibroblasts with superior efficiency. Next, we expanded the cells with irradiated and peptide loaded PBMCs and performed their retroviral transduction with a single chain (sc) as well as double chain (dc) p53(264-272) tumor antigen-specific TCR. In both cases the T cells acquired specific bifunctionality after stimulation with pp65- and p53- peptide loaded K562-A2 target cells in terms of cytotoxicity in chromium release assays as well as in terms of interferon-γ secretion in intracellular cytokine staining analysis. An alternative approach aims at the simultaneous retroviral transduction of HCMV- and p53 tumor antigen-specific TCRs in bulk human T cells which may be used in particular in case of HCMV-negative donor grafts. Analysis of tetramer staining elicited the expression of a substantial fraction of HCMV/p53 double TCR+ T cells which also proved bifunctionality towards their cognate antigen in CTL- and in intracellular IFNγ secretion-assays. However, the presence of endogenous TCRs which may mispair with the exogenous ones potentially leading to neoreactivity prompted us to assess whether residual mispairing takes place in our chosen scTCR approach and if yes to entirely prevent it by either protein design or shRNA technology. We performed mispairing analysis of the murine p53-specific scTCR with various human TCR alpha chains (TCRα) of different Vα subfamilies mimicking any endogenous TCRα chain. For this, we used the Jurkat-76 T cell line which lack endogenous TCRs and bulk human T cells. Flow cytometry analysis revealed residual mispairing of the murine p53-specific scTCR with any TCRα chain presumably by displacing the Variable alpha (Vα) domain of scTCR. Mispairing was less pronounced in human T cells most likely due to a more competitive situation between exogenous and human TCRα/β- chains. Preliminary results indicated less mispairing of the p53-specific scTCR encoded along with Cα as a transient bicistronic mRNA construct on a self-cleaving 2A peptide-based retroviral vector. In conclusion, we describe two approaches for the generation of HCMV- and p53 tumor antigen-bispecific human T cells. Importantly, our mispairing analyses emphasize the need to further optimize both TCR structures and the design of TCR transgene cassettes in retroviral vectors to safely apply them in adoptive immunotherapy.

1077

IMMUNE FUNCTION AGAINST MURINE CYTOMEGALOVIRUS IS SUPERIOR IN MICE TRANSPLANTED WITH PURE ALLOGENEIC HEMATOPOIETIC STEM CELLS AS COMPARED TO RECIPIENTS OF T-CELL REPLETE GRAFTS

M Mueller, S Shashidhar, N Kuepper, H Kohrt, J Brown, J Shizuru

Stanford University, Stanford, United States of America

Background. Infections due to impaired immune function are major causes of morbidity and mortality after allogeneic hematopoietic cell transplantation (HCT). Donor (do) T cells (TC) in the graft are thought to provide protective immunity, however, cause graft-versus-host disease (GVHD) and therefore require pharmacologic immunosuppression. *Aim.* To study how cell subsets contained in hematopoietic grafts influence functional immunity against murine cytomegalovirus (MCMV) post-transplant, using a minor-mismatched mouse model. *Methods.* Lethally irradiated BALB.B mice received grafts composed of purified hematopoietic stem cells (HSC; $cKit^+Sca1^+Thy1.1^{lo}Lin^-$) and TC populations from congenic C57BL/6 strains which were distinguished based upon CD45 alleles. At 2 or 8 weeks (w) post-transplant hosts were infected with MCMV. 2w post-infection immune function of: 1) transferred doTC from uninfected and pre-immunized donors, 2) HSC-derived doTC, and 3) residual host TC were assessed using MCMV-specific M45 tetramer staining for FACS analysis and ELISPOT. *Results.* Our key finding is that immune function against MCMV was superior in recipients of HSC alone compared with mice given allografts containing total TC (ToTC). In recipients of HSC alone residual host TCs provided the strongest responses early post-transplant, while at later times HSC-derived doTC also contributed to anti-viral reactivity. Adoptively transferred doTC from unimmunized or immunized donors did not yield higher anti-viral responses in allogeneic recipients,

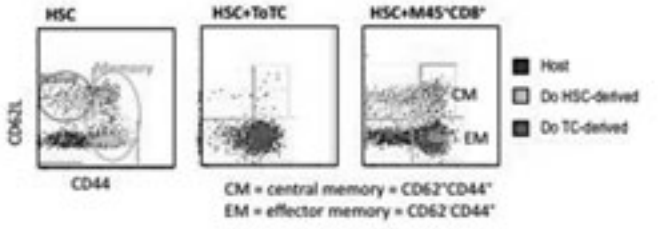

Figure 1. Naive/memory T cell reconstitution post-transplant.

although they reacted vigorously when infused into congenic mice. Likewise, immune function of allogeneic doTC was not restored when pharmacologic GVHD prophylaxis with cyclosporine A (CSA) was administered post-transplant. Separation of GVH-reactions and transfer of immunity was possible by strict selection of TC subpopulations that are enriched for or contain exclusively MCMV-specific TC, such as memory ($CD62L^{+/-}CD44^{+}$) or M45-tetramer^{+} CD8TC ($CD8_{M45}$). HSC+$CD8_{mem}$ or +CD_{8M45} resulted in better survival and significantly stronger anti-viral responses in MCMV target organs ($CD8_{mem}$: median 0.65%; $CD8_{M45}$: 8.7% M45^{+}/hepatic CD8TC) than HSC+ToTC (<0.05% M45^{+}/CD8TC). Furthermore, transplantation of HSC alone or grafts composed of HSC+CD8TC subsets allowed the regeneration of a nascent doHSC-derived TC pool with naïve and central memory TC, that could theoretically provide better protection against a broad range of future infections. In mice given HSC+ToTC >90% of TC were expanded doTC with an effector memory phenotype (Figure). *Conclusions.* 1) Recipients of HSC alone have stronger immune responses against MCMV compared to hosts given TC-replete grafts; 2) Residual host cells contribute substantially to protective immunity in recipients of HSC alone early pTX, but are eradicated by conventional TC-replete grafts; 3.) GVHD-prophylaxis with CSA did not improve immune function; 4.) HSC-derived TC arising in a healthy host are superior to those that develop and undergo selection in a GVHD-affected lymphoid system; and 5) Transfer of small numbers of highly selected cell subsets, such as tetramer-sorted MCMV-specific CD8 TC, is feasible, as these cells expand dramatically in a lymphopenic environment and provide functional protection against infections. Our results challenge the conventional assumption that doTC in a hematopoietic allograft are required for optimal regeneration of the immune system. Rather, our studies suggest that long-term lymphoid function will greatly benefit from rigorous TC-depletion of the graft, and avoidance of GVHD.

1078

DIMINISHED LEVELS OF HAX1 OR ELA2 PROTEIN, BUT NOT MUTATED ELA2 PROTEIN LED TO DEFECTIVE MYELOID DIFFERENTIATION: IN VITRO MODEL OF CONGENITAL NEUTROPENIA

O Klimenkova, A Gigina, I Kusnetsova, K Welte, J Skokowa

Hannover Medical School, Hannover, Germany

Severe congenital neutropenia (CN) is a heterogenous disorder of hematopoiesis characterized by a maturation arrest of granulopoiesis in bone marrow at the promyelocyte stage. CN is a multigene syndrome caused by e. g. inherited mutations in the elastase 2 (ELA2) gene or HAX1 gene. The pathomechanism of defective granulopoiesis in CN patients downstream of ELA2 or HAX1 mutations is not completely understood. It is also not clear, why the same ELA2 mutations lead to cyclic neutropenia (CyN) or CN. Mutations in the HAX1 gene led to absent HAX1 protein. Although it has been demonstrated that mutations in HAX1 could contribute to the apoptosis of myeloid cells due to defective mitochondrial membrane potential, definitive effects of HAX1 mutations leading to isolated ineffective granulopoiesis in CN are still not well understood.We aimed to analyse the effects of mutations in HAX1 or ELA2 genes on granulocytic differentiation *in vitro*. Intriguingly, in CD33^{+} granulocytic progenitor cells of CN patients harboring HAX1 mutations, G-CSF failed to upregulate mRNA levels of the HAX1 interaction partner, HCLS1, as compared to healthy individuals. We found that HCLS1 in a complex with HAX1 transduced the G-CSFR signal via LEF-1 to the nucleus.We transduced the promyelocyte leukemia cell line NB4 with shRNA constructs specific for HAX1 or HCLS1. We also transduced NB4 cells with WT ELA2 cDNA or cDNA encoding mutated ELA2 (C42S and ΔV145-152 mutations are CN-specific; S97L mutation is typical for both CN and CyN). We assessed myeloid differentiation of transduced cells by FACS analysis, RT-PCR and cell morphology.We found that inhibition of HAX1 or its interaction partner HCLS1 led to a significantly reduced differentiation of the NB4 promyelocytic cell line in response to ATRA (16,9 % of CD11b^{+} cells in HAX1 shRNA group, 20,1 % of CD11b^{+} cells in HAX1 shRNA group vs. 63,2 % of CD11b^{+} cells in ctrl shRNA group), which mirrors the situation in CN. However, mutated ELA2 did not affect myeloid differentiation and even lead to increased proliferative capacity of cells. Previously, we demonstrated that levels of ELA2 mRNA expression in myeloid progenitors as well as of plasma NE protein were markedly reduced in CN patients harboring mutations in either ELA2 or HAX1 genes, as compared to CyN patients and to healthy individuals due to a lack of LEF-1 expression (Skokowa *et al.* Blood 2009). Therefore, we analysed if inhibition of ELA2 by ELA2-specific shRNA had any effects on myeloid differentiation. As a result, we found significant inhibition of ATRA-induced differentiation of the promyelocyte leukemia cell line NB4 after inhibition of ELA2, as compared to ctrl shRNA transduced cells (25,3 % of CD11b^{+} cells in ELA2 shRNA group vs. 41,2 % of CD11b^{+} cells in ctrl shRNA group). In line with diminished myeloid differentiation, mRNA expression of LEF-1 transcription factor was downregulated after inhibition of HAX1, HCLS1 or LEF-1.Taken together, diminished levels of HAX1, HCLS1 or ELA2 proteins leads to disturbed granulocyte differentiation. However, introduction of mutated ELA2 protein into cells has no effects on myeloid differentiation.

1079

UPDATE ON THE RISK OF SECONDARY LEUKEMIA IN GENETIC SUBGROUPS (ELA2, HAX1, WASP, G6PC3, P14) OF CONGENITAL NEUTROPENIA IN EUROPE

C Zeidler,[1] P Vandenberghe,[2] I Schäfer,[1] L Hoy,[1] M Zimmermann,[1] M Germeshausen,[1] K Welte[1]

[1]*Medical School Hannover, Hannover, Germany*
[2]*UZ Leuven, Leuven, Belgium*

Congenital neutropenia (CN) is well known as one of the premalignant bone marrow failure syndromes with an overall incidence of secondary leukemia of more than 10 percent. With the identification of new causative gene mutations the number of genetic subgroups is still increasing. In this study we assessed the incidence and potential risk factors of leukemic transformation in CN patients with known gene mutations in ELANE, HAX1, G6PT, G6PC3, WAS, SBDS, TAZ1 and p14 or no identified mutation, respectively, by analyzing all available data from the European Branch of the Severe Chronic Neutropenia Registry (SCNIR). For comparison we also analyzed patients with cyclic neutropenia (CyN) with or without ELANE mutations. Results from genetic testing were available for 195 of 311 CN patients. Of the 195 CN patients 68 patients revealed ELANE mutations, 25 HAX1 mutations, 46 SBDS, 18 WAS, 21 G6PT, 8 G6PC3, 4 p14 and 5 TAZ1 mutations. In addition, in 35 patients neither ELANE nor HAX1 mutation was detectable. 81 patients were not tested to date, but further genetic evaluation is not yet completed. Results from genetic testing were also available in 29 of 67 patients with CyN of whom 23 revealed ELANE mutations and 6 were negative for ELANE mutations. Secondary malignancies occurred in 37 of the 311 CN patients and 1 of the 67 patients with CyN. The distribution by genetic subtypes is shown in the table below:

Table 1.

Gene Mutation	Patients (N)	MDS/Leukemia n / (%)
Total CN	311	37 (11.9)
- ELANE-CN	68	11 (16,2)
- HAX1-CN	25	5 (20,0)
- ELANE neg/HAX1neg	35	6 (17,1)
- SBDS	46	4 (8,7)
- WAS	18	2 (11,1)
- G6PT	21	0
- G6PC3	8	0
- TAZ1	5	0
- p14	4	0
- not testet	81	9 (11,1)
Total CyN	67	1 (0.2)
- ELANE-CyN	23	0
- ELANE neg-CyN	6	0
- not testet	38	1 (0,3)

All subgroups benefit from G-CSF treatment. However, patients requiring higher maintenance doses of G-CSF are at greater risk of leukemic transformation (Rosenberg, Zeidler *et al.*, 2010). *Conclusion.* The incidence of secondary leukemia reflects the heterogeneity of congenital neutropenia ranging between no leukemia and 20 percent in patients with an underlying HAX1 mutation. However, patient numbers within each genetic subgroup are still limited. Patients with severe congenital neutropenia who have mutations in ELANE, HAX1, SBDS or WAS as well as those with no recognized mutation are at risk of secondary leukemia. Progression to MDS or leukemia has so far not been reported in G6PT, G6PC3, TAZ1 or p14 CN cases in our Registry. Despite mutations in the ELANE gene patients with cyclic neutropenia exhibit no increased risk for malignant transformation. Mutational analysis is helpful to identify the genetic cause of severe congenital or cyclic neutropenia but with limited numbers in genetic subgroups still does not serve to identify patients at risk of leukemic transformation.

CD4+CD25+ REGULATORY T-CELL DEPLETION TO IMPROVE GRAFT-VERSUS-TUMOR EFFECT AFTER DONOR LYMPHOCYTES INFUSION: BIOLOGICAL PREDICTORS OF CLINICAL RESPONSE

S Maury,[1] C Alanio,[2] Y Hicheri,[1] F Lemoine,[2] L Cabanne,[1] K Debbache,[1] M Cheraï,[2] JL Beaumont,[1] N Azar,[2] N Dhedin,[3] A Sirvent,[4] A Buzyn,[5] MT Rubio,[6] S Vigouroux,[7] D Bories,[1] JP Vernant,[3] C Cordonnier,[1] J Cohen,[1] D Klatzmann,[2] M Rosenzwajg[2]

[5]*Necker, Paris, France*
[6]*Saint Antoine, Paris, France*
[7]*Haut L'eveque, Bordeaux, France*

Background. We very recently published the first clinical trial showing that regulatory T-cells (Treg) depletion can improve alloreactivity and likewise the GVT effect in humans in the setting of donor lymphocyte infusion (DLI) after HSCT (Maury *et al.* Sci Transl Med 2010). Here, we aim to analyze T cell contents of donors and recipients before and sequentially after DLI to identify relevant biomarkers of clinical response. *Methods.* CD25+ Treg-depleted DLI (d-DLI) were given in 17 adult patients with malignancy relapse after HSCT. All but one had previously failed to respond to at least one standard DLI, and none had experienced GVHD. Overall, GVHD induction through Treg depletion was obtained in 6 out of the 17 patients and associated with partial or complete remissions of hematological malignancies. With a median follow-up of 24 months after d-DLI, this group of patients (GVH+) had an improved survival (p=0.035) as compared to the 11 others without GVHD induced (GVH-). CD4+, CD8+, B and NK cell subsets were monitored using flow cytometry and FoxP3 expression assessed by RTq-PCR on (i) d-DLI and (ii) PBMC collected from recipients before and at 7 time-points during the first year after d-DLI. *Results.* The CD25 magnetic depletion led to a very high Treg-depletion rate in all d-DLI products (mean CD4+FoxP3+ cell-depletion rate of 98% in accordance with a FoxP3 expression decrease by 92% by RTq-PCR) with no significant difference between GVH+ and GVH- patients. We could also not evidence any correlation between Treg monitoring in recipients after d-DLI and GVHD onset. However, a longitudinal monitoring of lymphoid subpopulations using a hierarchic clusterization (Genesis software, Graz, Austria) revealed that a lowering relative number of naïve CD4+CD45RA+ cells among CD4+ T-cells over time correlated with GVHD induction. At day 15 after d-DLI, i.e. before the occurrence of any GVHD, a low level of naïve CD4+CD45RA+ +/- CD62L+ cells correlated with GVHD onset (p=0.04, Fig 1). This remained significant at day 30 for both phenotypes of naïve cells. *Conclusion.* The ability of Treg depletion to break immune tolerance in HSCT patients refractory to alloreactivity seems to be associated with the decrease of the naive CD4+ T-cell population in recipients. Such a polarization to a memory phenotype that we found associated with GVH/GVT effects might represent a new relevant parameter to improve and predict responses to Treg-based antitumor immunotherapies.

1081

RELAPSE AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOLLOWING REDUCED INTENSITY CONDITIONING FOR AML AND MDS: DIAGNOSTIC AND THERAPEUTIC IMPLICATIONS FOR GRAFT CELLS

H Al-Ali, C Nehring, N Jaekel, R Krahl, C Becker, L Braunert, S Leiblein, J Edelmann, G Franke, W Poenisch, T Lange, D Niederwieser

University of Leipzig, Leipzig, Germany

Relapse after allogeneic hematopoietic cell transplantation (HCT) following reduced-intensity-conditioning (RIC) in patients with AML and MDS remains a major hazard. Therefore, identifying predictive factors which allow successful prevention and management of relapse is still a major challenge. For this purpose, we analysed 256 consecutive patients (138 male/118 female); median age 62 years with AML, n=205 (80%) and MDS, n=51 (20%) who received HCT after 200 cGy TBI +

fludarabine 30 mg/m^2 for 3 days followed by mycophenolate mofetil and cyclosporine. Donors were matched unrelated (MUD) in 201 (78.5%) and matched related (MRD) in 55 (21.5%) patients. Disease-stage at HCT was complete remission (CR)1,n=156 (61%), CR2,n=42 (16.4%), beyond CR2,n=37 (14.4%) and untreated-MDS,n=21 (8.2%). Cytogenetics were intermediate and high risk in 169 (66%) and 74 (29%) patients respectively. An initial positive leukemic CD34-phenotype was present in 54.7% of patients. Donor-cell-chimerism (DCC) in flow-sorted CD34+-marrow cells at days 28, 56, 84, and at 3 months interval thereafter was monitored by PCR of polymorphic micro satellite regions. After a median follow-up of 42 months, engraftment was 94%. Survival, disease-free-survival, and non-relapse-mortality at 5-years were 40%, 35%, and 27% respectively. Relapse-incidence was 48%. Interestingly, disease-specific parameters such as diagnosis, disease- stage, high-risk cytogenetics, and initial leukemic CD34-phenotype had no impact on relapse. While the donor-associated factors graft-versus-host-disease (GvHD) and CD34-DCC day28 strongly correlated with later relapse (p<0.0005). Irrespective of the severity, patients with acute and/or chronic GvHD relapsed less frequently (13.6%) compared to 48% of patients without GvHD (p<0.0005). Irrespective of initial leukemic CD34-phenotype, CD34-DCC day28 <90% was highly predictive of hematological relapse (HR) with 82% versus 38% relapse-risk if >90% (p<0.0005). Only 4.5% of patients who never relapsed had a CD34-DCC day28 <90%. Management of patients with (HR) and those with decreasing CD34-DCC below 90% without HR consisted of immunomodulation [tapering of immunosuppression and/or donor lymphocyte infusion] in 82.5%. Initial leukemic CD34-phenotype changed in 37% of patients at relapse with only 31% of patients expressing a positive CD34-phenotype. Overall, 34% of patients with overt HR achieved CR and 47.5% of patients with declining CD34-DCC below 90% a sustained complete CD34-DCC. A negative leukemic CD34-phenotype at relapse (p=0.02), relapse beyond day 100 after HCT, therapy for a decreasing CD34-DCC rather than a HR (p=0.05), and inducing GvHD with immunomodulation particularly in relapses within 100 days post-HCT (p=0.005) correlated with a superior response and survival after relapse. CR in the 51% of patients where GvHD was induced was 63% compared to 30% in patients without GvHD (p=0.004) highlighting the graft-versus-leukemia activity. After RIC-HCT, donor- rather than disease-related factors predict relapse and its treatment outcome in AML and MDS. Irrespective of the initial leukemic CD34-phenotype, monitoring of CD34+-DCC is an excellent marker to identify patients at risk of relapse and guide early immunomodulation which effectively enhances the graft-versus-leukemia effect thereby preventing hematological relapses or successfully treating them. Nevertheless, further research is needed to optimize immunosuppressive regimens to maximize the graft-versus-leukemia effect without the injurious effects of graft-versus-host-disease particularly in the early post-HCT phase.

1082

IMPACT OF PROPHYLACTIC CD8-DEPLETED DONOR-LYMPHOCYTE INFUSIONS AFTER T-CELL DEPLETED ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

EM Wagner, D Wehler, K Kolbe, M Theobald, W Herr, R Meyer

University Medical Center of the Johannes Gutenberg-University, Mainz, Germany

The combination of reduced-intensity conditioning and *in vivo* T-cell depletion by alemtuzumab prior to hematopoietic stem cell transplantation (HSCT) has demonstrated efficient engraftment and reduced graft-versus-host disease (GVHD). However, this regimen is associated with slow lymphocyte recovery leading to a delayed anti-infectious and anti-malignant immunity. In a phase I study, we investigated the prophylactic use of CD8-depleted donor lymphocyte infusions (DLIs) to improve immune reconstitution. We have previously shown the feasibility of this approach and demonstrated that the CD8-depleted DLI reliably converted a decreasing T-cell chimerism (Meyer *et al.* Blood 2007 & BMT 2010). Here we provide clinical follow up data of 101 patients with different hematological malignancies with a median observation time of 1 year post HSCT (range, 1-80 months). The majority of patients either suffered from an acute leukemia / MDS (n=42), lymphoma (n=28), myeloma (n=17), or myeloproliferative neoplasms (n=12). The median age of the patients was 56 years (range, 20-71) and none of them qualified for a conventional conditioning regimen. 45 patients had undergone previous transplantations (autologous: n=43, allogeneic: n=2). The donors were matched siblings (n=15), matched unrelated (n=48), or unrelated donors with single HLA mismatches (n=38). The calcineurin-inhibitor used for GVHD-prophylaxis was intended to be tapered until day 50 post HSCT. In the absence of GVHD, CD8-depleted DLI were subsequently administered prophylactically in escalating doses starting with 1x106 CD4 T cells / kg bodyweight. Following this procedure, 39 patients received at least one dose of DLI. Among those patients who did not qualify for DLI, 46 patients had primary GVHD. In 16 patients DLI were not administered for other reasons (donor unavailable, infections, relapse). In 64% DLI induced acute GVHD, which was the major reason for withholding the next DLI-dose step. The rate of acute GVHD > grade 2 was 30%. 10% suffered from extensive chronic GVHD. The 1 and 3 year overall survival was 63% and 43%, respectively. Survival significantly differed between the DLI and the non DLI group after 3 years (63% vs. 27%, p=0.002). Since this trial was not randomized, we also compared the DLI group to only those patients who did not receive DLI for other reasons than primary GVHD and found similar results (62% vs. 28%, p=0.01). Although DLI was associated with a survival benefit, the relapse rate did not differ from that of the no-DLI cohort. When we analyzed the diseases separately, there was no significant effect of DLI on the relapse rate, but we found a trend towards a lower relapse rate among AML/MDS- and delayed relapses in myeloma-patients. As expected, the presence of GVHD at any time was associated with a reduced relapse rate (55.8% vs 30.8%, p=0.013). In summary, the prophylactic application of CD8-depleted DLI in the absence of GVHD was associated with a survival benefit. However, we were not able to relate this benefit to a decreased relapse rate. Our data strongly support a randomized trial, comparing prophylactic vs. preemptive / therapeutic DLI application in the context of T-cell depleted HSCT.

1083

SECONDARY MALIGNANCIES AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION IN THE ERA OF REDUCED-INTENSITY CONDITIONING; THE INCIDENCE IS NOT REDUCED

A Shimoni, N Shem-Tov, Y Volchek, R Yerushalmi, A Nagler

Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background. Allogeneic stem-cell transplantation (SCT) is a potentially curative therapy for a variety of hematological malignancies and non-malignant diseases. Secondary malignancies are a known complication in long-term survivors. The incidence and kinetics of secondary malignancies have been reported mostly after myeloablative conditioning (MAC). Reduced-intensity conditioning (RIC) has been introduced over the last decade to allow SCT in patients not eligible for standard SCT. RIC has been shown to reduce the incidence of transplant-related complications, however due to the relative limited long-term follow-up of RIC recipients, the incidence and risk-factors for secondary malignancies following RIC have not been well defined. *Aims.* To determine the relative risks and risk-factors for secondary malignancies following RIC compared with MAC. *Methods.* A single institution database of 902 allogeneic SCTs given over the last 12 years was retrospectively reviewed to identify patients with secondary malignancies. Conditioning regimens included standard MAC (n=252), fludarabine-based RIC (n=452) or fludarabine-based reduced-toxicity myeloablative conditioning (RTC, n=198). The incidence of secondary malignancies was calculated by cumulative incidence analysis with death due to other causes considered competing risk. The incidence was correlated with patient and transplant characteristics. Three patients with PTLD and 2 with secondary leukemia and relapse of the prior malignancy after SCT were not considered a having secondary malignancies in this analysis. *Results.* Twenty-two patients had secondary malignancies including squamous cell carcinoma of the skin (n=5), penis (n=1) vagina (n=1), tongue (n=1) and esophagus (n=2), colon cancer (n=3), breast cancer (n=2), metastatic cancer of unknown primary (n=1), pancreatic cancer (n=1), metastatic sarcoma (n=1), Kaposi sarcoma (n=1) and donor-derived MDS/AML (n=3). The median age at SCT was 55 years (29-70). Nineteen patients were given fludarabine-based RIC/RTC and none had total-body irradiation. The median time from SCT to diagnosis of secondary malignancy was 38 months (7 months-11 years). Eighteen patients had prior chronic GVHD and 10 were still on immunosuppressive therapy at the time of diagnosis of secondary malignancy. The cumulative incidence of secondary malignancy 10 years after SCT was 5.5% (95%CI, 3.3-9.1%). It was higher in older patients (>50 years) than in younger patients; 7.3% Vs 4.4% (p=0.004). It was also higher in patients with a history of chronic GVHD; 11.2% Vs 2.1% (p=0.05). Secondary malignancies were less common in patients with CML and nonmalignant diseases compared with patients with prior chemotherapy; 1.1% and 6.5% (p=0.07). Patients given MAC had

a cumulative incidence of 1.9%, compared with 7.8% for patients given fludarbine-based RIC or RTC (p=0.02). Multivariable analysis identified chronic GVHD and advanced age as adverse prognostic factors with hazard-ratios of 3.5 (p=0.03) and 2.9 (p=0.05), respectively. *Conclusions.* Secondary malignancies are rare but significant complication after allogeneic SCT. Chronic GVHD and advanced age at SCT predict for higher incidence. The incidence is not reduced in the RIC era, possibly due to the inclusion of older and more heavily pretreated patients to these protocols. The possible adverse effect of fludarabine in the conditioning regimen can not be ruled out. Larger studies with a larger number of events are needed to confirm these observations.

Background. Epstein-Barr virus-associated post-transplant lymphoproliferative disease (EBV+PTLD) remains an important clinical problem following allogeneic stem cell transplantation (alloSCT). *In vivo* T cell depletion with Alemtuzumab has been previously thought to confer only a small increase in PTLD risk and the characteristics and outcome of such patients have not received detailed study. Furthermore, although quantitative-PCR monitoring for EBV reactivation post-HSCT is now commonplace, it's diagnostic and predictive value remains unclear. *Aims.* To characterise the clinicopathological features of PTLD occurring after an Alemtuzumab-based alloSCT, correlate with EBV qPCR data and analyse factors predicting response and outcome. *Methods.* This retrospective multicentre study analysed 75 cases diagnosed with PTLD following Alemtuzumab-based alloSCT during 2001-2010. Six cases were excluded because of insufficient evidence of PTLD and 7 cases comprised EBV-associated encephalitis or haemophagocytic syndrome. 62 patients with EBV+PTLD were included in the analysis, equating to an incidence of 4% following Alemtuzumab-based alloSCT. Forty-six were biopsy-proven whilst 16 had probable PTLD based on viral load and robust clinical/radiological evidence of lymphadenopathy or visceral lesions. *Results.* The median age at onset was 50 years (16-62). 17 patients received myeloablative (MA) whilst 45 received reduced-intensity (RI) conditioning and 44 occurred following an unrelated donor alloSCT. The median time from HSCT to PTLD onset was 120 days. Substantial clinicopathological heterogeneity was observed but B symptoms were manifest in 80% and extra-nodal disease was frequent (60%). The median viral load at the onset of PTL D was 49,300 copies/ml (50-65,200,000 copies/ml). Notably, the viral load was ≤10,000 and ≤40,000 copies/ml in 23% and 45% of cases respectively. With a median follow-up of 20.4 months, mortality attributable to PTLD was 31% (19/62). Eleven cases were post-mortem diagnoses or died rapidly after initiation of therapy. Fifty-one patients were therefore evaluable for treatment-response: 3 underwent a reduction in immunosuppression only; 36 received rituximab monotherapy (median total dose 1500mg/m2); 6 received rituximab-chemotherapy and 6 received donor T lymphocytes. The overall response rate was 78% and although there were no documented relapses, all those with progressive disease died of PTLD at a median of 33 days (13-257 days) from diagnosis. A four-point prognostic score (age ≥60; stage III/IV disease; ≥2 extranodal sites and poor performance status [ECOG 2-4]) was tested in multivariate analyses. A score of 3-4 correlated both with inferior response to therapy (odds ratio 0.10 [CI 0.02-0.55], p=0.008) and overall survival (hazard ratio 2.89 [CI 1.39-6.02], p=0.005). Donor-type, conditioning intensity, Alemtuzumab dose, lymphocyte count and, importantly, viral load at PTLD onset, were not associated with response or survival. *Summary/Conclusions.* This is the largest reported series of EBV+PTLD after Alemtuzumab-based alloSCT and describes a clinically diverse disease that is often rapidly progressive. At onset of PTLD, EBV loads are frequently below accepted thresholds for pre-emptive therapy, challenging current paradigms for monitoring and intervention. Although a majority of patients responded to Rituximab, 22% experienced progressive disease following immunochemotherapy. A 4-point score identifies those predicted to have a poor outcome and for whom novel antibody therapies or adoptive cellular therapy could be targeted.

A NOVEL SPLICED FUSION OF MLL WITH CT45A2 IN A PEDIATRIC BIPHENOTYPIC ACUTE LEUKEMIA

N Cerveira,[1] C Meyer,[2] J Santos,[3] L Torres,[3] S Lisboa,[3] M Pinheiro,[3] S Bizarro,[3] C Correia,[3] L Norton,[4] R Marschalek,[2] L Teixeira[2]
[1]*Portuguese Oncology Institute, Porto, Portugal*
[2]*Institute of Pharmaceutical Biology, Diagnostic Centre of Acute Leukemia, Frankfurt am Main, Germany*
[3]*Department of Genetics of the Portuguese Oncology Institute, Porto, Portugal*
[4]*Department of Pediatrics, Portuguese Oncology Institute, Porto, Portugal*

Background. Abnormalities of 11q23 involving the MLL gene are found in approximately 10% of human leukemias. To date, nearly 100 different chromosome bands have been described in rearrangements involving 11q23 and 64 fusion genes have been cloned and characterized at the molecular level. In this work we present the identification of a novel MLL fusion partner in a pediatric patient with de novo biphenotypic acute leukemia. *Aims and Methods*. Cytogenetics, fluorescence in situ hybridization (FISH), molecular studies (RT-PCR and LDI-PCR), and bioinformatic sequence analysis were used to characterize the CT45A2 gene as novel MLL fusion partner in pediatric acute leukemia. *Results*. Fluorescence in situ hybridization of the patient G-banded metaphases demonstrated a cryptic insertion of 11q23 in Xq26.3 involving the MLL gene. Breakpoint fusion analysis revealed that a DNA fragment of 653 kb from 11q23, containing MLL exons 1-9 in addition to 16 other 11q23 genes, was inserted into the upstream region of the CT45A2 gene located at Xq26.3. In addition, a deletion at Xq26.3 encompassing the 3' region of the DDX26B gene (exons 9-16) and the entire CT45A1 gene was identified. RNA analysis revealed the presence of a novel MLL-CT45A2 fusion transcript in which the first 9 exons of the MLL gene were fused in-frame to exon 2 of the CT45A2 gene, resulting in a spliced MLL fusion transcript with an intact open reading frame. The resulting chimeric transcript predicts a fusion protein where the N-terminus of MLL is fused to the entire open reading frame of CT45A2. Finally, we demonstrate that all breakpoint regions are rich in long repetitive motifs, namely LINE/L1 and SINE/Alu sequences, but all breakpoints were exclusively identified outside these repetitive DNA sequences. *Summary /Conclusions*. We have identified CT45A2 as a novel spliced MLL fusion partner in a pediatric patient with de novo biphenotypic acute leukemia, as a result of a cryptic insertion of 11q23 in Xq26.3. Since CT45A2 is the first Cancer/Testis antigen family gene found fused with MLL in acute leukemia, future studies addressing its biologic relevance for leukemogenesis are warranted.

THE SINGLE NUCLEOTIDE POLYMORPHISM OF GENE XPA?XPC?XPD?XRCC1 AND IN ASSOCIATION WITH THE RISK OF ACUTE LYMPHOBLASTIC LEUKEMIA

J Ouyang,[1] F Tang,[2] Y Xu,[1] R Zhou,[1] M Zhou,[1] B Chen[1]
[1]*Nanjing Drum Tower Hospital, Nanjing, China*
[2]*The Affiliated Drum Tower Hospital, Nanjing Medical University, Nanjing, China*

Backgroud. Polymorphisms of DNA repair genes can alter protein structure and may impair DNA repair capacity. It is becoming clear that defects in repair pathways are connected to many different types of diseases, including leukemia and cancer.This study was performed to evaluate the effect of the polymorphisms of DNA repair genes on risk of adult acute lymphoblastic leukemia(ALL) in a Chinese population. Aims: To study the relationship between polymorphism of gene XPA、XPC、XPD XRCC1 and the susceptibility to ALL in a Chinese population. Methods: Genotypes were determined by the MALDI-TOF mass spectrometry method in 114 confirmed ALLcases and 169 controls whose age and sex matched to above cases. Results: Multivariate logistic regression analysis revealed that individuals carrying at least one 23G variant allele(AG+GG genotypes)had a significantly increased risk for ALL (adjusted OR=2.00; 95%CI=1.07～3.76)compared with the wild-type genotype(23AA), and evidence that positive interactions between the polymorphisms in XPC Ala499Val/XPA A23G and XPD 751/XPA A23G may occur. Furthermore, individuals with both putative risk genotypes had a significantly higher risk (adjusted OR=5.6; 95%CI=1.57～19.9), compared with those with both wild-genotypes. By contrast, no significant association was observed between the XPD Lys751Gln、XRCC1 Arg399Gln、Arg194Trp polymorphism and ALL risk.Conclusions: These results suggest that the XPA A23G and XPC Ala499Val polymorphisms may contribute to the risk of developing ALL.There are signigicant combinations between XPC Ala499Val and XPA A23G. Further studies are needed to elucidate potential functional relevance of the those variant allele.

ACUTE LEUKEMIA IN CHILDREN WITH DOWN SYNDROME

O Muratovska, K Martinova, S Glamocanin, S Koceva, Z Antevska, B Coneska
University Pediatric Clinic, Skopje, Macedonia

Background. Down syndrome (DS) is the most common and the best known chromosomal disorder in human.The frequency is about 1 case in 800 live births and it is proportional with maternal age.The extra copy of the proximal part of 21q22.3 appears to result in the typical physical phenotype, mental retardation, hand anomalies, and congenital heart defects. Children with DS are predisposed to developing leukaemia (1 case to 300 or 15-20 times more than other children) with a ratio of acute lymphoblastic leukaemia (ALL) to acute myeloid leukaemia (AML) typical for childhood acute leukaemia. During the first 3 years of life AML is dominant , particularly transient myeloproliferative disorder (TMD) and acute megakaryocytic leukemia. Nearly all children with DS and leukaemia have mutations in the hematopoietic transcription factor gene, GATA1. Children with DS -ALL are mostly of B-cell precursors origin and aberrant expression of cytokine receptor CRLF2, associated with mutated JAK2. *Aim*. To present our experience regarding to frequency, clinical features, treatment results and follow up of children with DS and leukaemia. *Methods*. During the period from January 2006 to January 2011, 112 children with DS was diagnosed in Macedonia. The frequency of DS is 1 to 1000 live births. Three children developed acute leukaemia. Two boys, 1 and 2 years old, have AML (M0 and M7),one 3 years old boy has cALL and TMD was diagnosed in two newborns. First symptoms in all patients with acute leukaemia were fatigue, petechial haemorrhagy, recurrent respiratory infection. Two newborns had connatal infection. Child with AML M7 is without cardiopathy. Child with AML M0 has VSD. The thirth with ALL has hypothyreosis, atrioventriculat septal defect and Morgagni hernia which bouth were corrected in the age of 3 months. One of newborns with TMD had Tetralogy of Fallot and the other VSD. Moderate splenomegaly was detected in all of the patients. Results. Laboratory data confirmed anemia (Hb range: 49-60g/l), WBC number from 4,7 to 74x10^9/l and severe thrombocytopenia (11 to 15x10^9/l). Bone marrow analyses confirmed M0, M7 and common ALL in three patients. Imunophenotype profiles are: patient with AML M0 had CD68 pozitive in 60% blast cells,CD79,CD20 and CD34 in 30%. Patient with AML M7 had expression of CD33, CD13, CD117, CD56, CD36 and parcial CD42b. Patient with cALL had BCR-ABL1 negative, MLL and TCF3 rearrangement negative, ETV6-RUNX1 positive. CD19,CD34, CD22, CD79A positive. Children with AML were treated according ML DS-BFM 2006 protocol and they are in complete remission 2 and 2,5 years after completed therapy. Child with ALL is in remission but still on chemotherapy. Newborn with complex cardiopathy died six month later during serious pulmonary infection but with normal blood and bone marrow features on 1 month age. The other is still alive without any sign of TMD. *Conclusions*. Children who develop AML have generally favourable prognosis. Outcome of DS-ALL has been considered worse than the outcome of ALL without DS. Majority DS-ALL may benefit from therapy blocking the CRLF2/JAK2 pathway and for DS-AML, mutations of GATA1 gene.

1088

IMMUNOGLOBULIN AND T-CELL RECEPTOR GENE REARRANGEMENT PATTERN IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA WITH MLL GENE REARRANGEMENTS

M Dawidowska,[1] M Kraszewska,[1] L Sedek,[2] M Kosmalska,[1] K Derwich,[3] R Tomaszewska,[2] M Witt,[1] T Szczepanski[2]
[1]*Institute of Human Genetics Polish Academy of Sciences, Poznan, Poland*
[2]*Department of Pediatric Hematology and Oncology, Silesian Academy of Medicine, Poland*
[3]*Department of Hematology, Oncology and Hematopoietic Stem Cell Transplantation, Poznan, Poland*

Background. Rearrangements of the mixed lineage leukemia (MLL) gene are the most common genetic aberrations found in infant acute lymphoblastic leukemia, occurring in approximately 75% of patients younger than 1 year. Although less frequently, the MLL gene is also rearranged in older children (≥1 year), particularly in CD10-negative ALL

cases. These three factors: MLL rearrangements, younger age and pro-B immunophenotype are inter-correlated and closely associated with poor prognosis. They have also been postulated to influence the immunoglobulin (Ig) and T-cell receptor (TCR) gene rearrangement pattern. *Aims*. We aimed at characterization of Ig/TCR gene rearrangement pattern in a group of 19 MLL-positive ALL patients: 12 infants (10 pro-B-ALL, 2 B-cell precursor ALL with myeloid co-expression) and 7 patients older than 1 year, aged 1.6-17.5; mean age: 7.8, median age 6.5 (6 pro-B-ALL and 1 common/pro-B-ALL). We also aimed at comparison of the Ig/TCR pattern identified in the study group with the pattern previously reported in a group of 58 B-cell precursor ALL (BCP-ALL) patients. *Methods*. Polymerase chain reaction with the use of standard BIOMED-1 and BIOMED-2 primers was used for detection of Ig/TCR gene rearrangements. Clonality of the rearrangements was assessed by heteroduplex analysis and confirmed by sequencing. *Results*. At least one clonal rearrangement was found in 68% of 19 MLL positive patients, in contrast to 97% in 58 BCP-ALL patients. The frequencies of rearrangements in the MLL positive group were as follows: 32% VH-(DH)-JH, 26% DH-JH, 53% total IGH, 11% Vκ-Kde, 21% Vδ2-Dδ3, 11% Vγ-Jγ, 5% Dβ-Jβ vs. 74%, 9%, 74%, 31%, 45%, 50%, 4%, respectively, in 58 BCP-ALL group (DH-JH and Dβ-Jβ rearrangements were studied in a subgroup of 23 BCP-ALL patients). In contrast to BCP-ALL group no Intron-Kde, Dδ2-Dδ3, Vδ2-Dδ3-Jα29 and Vβ-Dβ-Jβ rearrangements were found in the MLL positive patients. *Summary*. As compared to BCP-ALL group Ig/TCR gene rearrangements in MLL positive patients are characterized by more immature pattern (i.e. rearrangements are less frequent with predominance of IGH rearrangements, relatively frequent occurrence of DH-JH rearrangements and lower frequencies of IGK-Kde and cross lineage TCRD, TCRG, TCRB rearrangements; complete TCRB and TCRD/A rearrangements were not found in the study group). The study will be continued in a larger cohort of MLL positive patients. *Conclusions.* Immature Ig/TCR gene rearrangement pattern most probably reflects maturation arrest at early lymphoid developmental stages. It is postulated that early (in case of infant ALL- in utero) oncogenic transformation is determined by occurrence of the MLL gene rearrangements.

Background. Therapy success rate for T-ALL is lower than in precursor B-ALL, which reflects higher T-ALL aggressiveness and its heterogenous biology. In many cancer subtypes it is possible to distinguish heterogenous DNA hypermethylation patterns. Identification of patient-specific CpG island methylator phenotype (CIMP) might facilitate treatment stratification. *Aim*. We aimed at assessing CIMP patterns in T-ALL. *Patients and Methods*. Methylation status of 20 genes was assessed by MS- PCR in 63 children with de novo, T-ALL treated at the centres of Polish Paediatric Leukemia and Lymphoma Study Group (PPLLSG). Additionally, 11 healthy bone marrow donors younger than 17 years of age and thymic subsets from healthy children were tested as controls. *Results*. Two groups of patients were delineated: CIMP- and CIMP+. Additionally, computational clustering of patients was concordant with CIMP groups (p<0,0001). Analysis of correlation between CIMP and traditional clinical risk assessment factors, EGIL T-ALL classification or NOTCH1 and FBXW7 mutation status, showed no significant association. *Conclusion*. Methylation patterns differ between controls and T-ALL patients. It is possible to divide patients into two groups characterized by two main methylation patterns. Results of our study indicate existence of CIMP phenomenon in childhood T-ALL, although its biological and prognostic significance needs further studies.

CDKN1A-MEDIATED RESPONSIVENESS OF ACUTE LYMPHOBLASTIC LEUKEMIA TO AURORA KINASE INHIBITORS

YP Chen,[1] HJ Lin,[2] KC Chang,[1] JS Chen,[1] WC Su,[1] LY Hung,[2] TY Chen[1]

[1]*National Cheng Kung University Hospital, Tainan, Taiwan*
[2]*National Cheng Kung University, Tainan, Taiwan*

Background. The prognosis of acute lymphoblastic leukemia (ALL) is related to the cytogenetic status and age. Unfavorable cytogenetic abnormalities and old age in ALL will lead to dismal outcomes. Recent studies showed that Aurora kinases were therapeutic targets in cancer therapy, including acute myeloid leukemia, Philadelphia-positive leukemia and multiple myeloma. It is currently unclear whether the therapeutic activity of the compounds in leukemia is primarily due to selective Aurora kinase or multi-kinase inhibition. *Aim*. The aim of this research was to investigate the molecular mechanism regulating the differences in the responsiveness of ALL to Aurora kinase inhibitors. *Methods*. In this study, we used Aurora kinase inhibitor "VE-465". Nine ALL cell lines containing t(4;11) and non-t(4;11) ALL cell lines were used to evaluate the expressions of Aurora kinases by Western blot and RT-PCR and the treatment effect of Aurora kinase inhibitors by MTT assay. The effects of Aurora kinase inhibitors on the cell cycle were evaluated by flow cytometry. The expressions of CDKN1A (p21) in mRNA and protein levels were compared between the drug-sensitive and drug-resistant cell lines. *Results*. Cells treated with Aurora kinase inhibitors (VE-465) inhibited the phosphorylation of Aurora kinases effectively. Among nine ALL cell lines, RS4;11 was more sensitive to Aurora kinase inhibitors (IC50 <10 nM) and the treatment resulted in an increased G2/M and sub-G1 populations. RPMI-8402 and Raji were most resistant to Aurora kinase inhibitors (IC50 >1000 nM) and the treatment led to the polypoidy status. The different treatment efficacy was not related to the expression of Aurora kinases or their activators. The mRNA and protein expression levels of CDKN1A were up-regulated after treatment with Aurora kinase inhibitors in the drug-sensitive cell lines, but were still very low in the drug-resistance cell lines. Blockage of Aurora kinases activated CDKN1A in drug-sensitive cell lines, but not in drug-resistant cell lines. *Summary/Conclusion*. In this study, cell lines containing t(4;11) were more sensitive to Aurora kinase inhibitors. Expression of Aurora kinases and their activators did not correlate with the drug susceptibility in ALL cell lines. Activation of CDKN1A significantly increased the susceptibility to Aurora kinase inhibitors in ALL cell lines. Further investigation of the role of CDKN1A in the response to Aurora kinase inhibition is warranted in the future.

EFFECTS OF FORMIN-LIKE 1 (FMNL1) SILENCING IN A HUMAN LYMHOBLASTOID CELL LINE

P Favaro,[1] F Traina,[2] J Machado-Neto,[2] M Lopes,[2] F Costa,[2] S Olalla Saad[2]

[1]*Federal University of Sao Paulo, Diadema, Brazil*
[2]*Hemocentro-Unicamp, Instituto Nacional de Ciência e Tecnologia do Sangue, Campinas, Brazil*

Background. FMNL1 has a highly restricted expression in malignant lymphoid derived cells, including in cells from chronic lymphocytic leukemia and Non-Hodgkin lymphoma patients; and has been described

as a tumor associated antigen. The function and regulation of FMNL1 have not yet been well characterized; however its restricted expression suggests that FMNL1 represents an attractive target for novel immunotherapies in hematopoietic malignant disorders. Aims: Herein, we evaluated the role of FMNL1 in proliferation, colony formation and migration in the Namalwa cell line, a human B lymphoma cell line. Methods: Specific shRNA-expressing lentiviral vector targeting FMNL1 or LacZ genes (control) were used. Cell growth was measured using the MTT colorimetric reduction method. Colony formation was carried out in semisolid methyl cellulose medium and was detected after 8 days of culture by adding 1mg/mL of MTT reagent and scored by Image J quantification software. Both assays were carried out in lentiviral transduced cells, treated or not with different concentrations of rapamycin (10 or 100nM). Migration assays were performed in triplicate using 5-μm Transwells and the lower compartment was filled with 600 μL 0.5% BSA/RPMI containing 100ng/mL SDF-1. P value <0.05 was considered statistically significant. *Results*. The levels of FMNL1 mRNA and protein in FMNL1 knockdown cells were reduced by approximately 70%. Inhibition of FMNL1 resulted in a significant decrease of proliferation and clonogenicity by 40% and 32% respectively, when compared with control cells (P<0.001). Interesting, the combination of FMNL1 inhibition/rapamycin treatment showed higher reduction in both assays when compared with FMNL1 inhibited cells alone (P<0.01) or rapamycin treated cells (P<0.05). Moreover, FMNL1 silencing resulted in a significant decrease by 62% of cell migration when compared to control cells (P<0.01). *Conclusions.* Our findings indicate that FMNL1 participates in the regulation of proliferation, colony formation and migration of the Namalwa cell line, which suggests that FMNL1 represents an attractive therapeutic target. Interestingly, we observed a synergic effect on FMNL1 silencing and rapamycin inhibition in proliferation and clonogenicity, suggesting that they may act through different pathways. Based on this result, we hypothesized that combinatorial inhibition of these pathways would be effective for the treatment of lymphoid malignancies. AUTOMATED ANALYSIS OF CEREBROSPINAL FLUID (CSF)

A Lemes,[1] Y Ramos,[2] C Rodriguez,[2] C Sánchez,[2] M Gordillo,[2] K Quiroz,[2] S Fumero,[2] T Molero[2]

[1]*Hospital Universitario de Gran Canaria Dr Negrín, Las Palmas de Gran Canaria, Spain*

[2]*Las Palmas de GC, Spain*

Background. Reference method for CSF cells count is cytometric chamber nowadays. However this method is quite slow; inter-observator variability has been reported and some errors are commonly committed. So, automated and standarized methods are desirable to simplify and to reach reliable results in the analysis. On the other hand, early detection of CSF neoplastic cells is very important in order to establish a suitable treatment in cancer diseases. New hematologic autoanalizers with biologic fluids software incorporated can help us to detect neoplastic and non neoplastic cells. Sysmex XE-5000 TM (SXE) are capable to carry out a leukocyte and differential counts and also to detect high fluorescence cells (HFBF) which show neoplastic, mesotelial and activated monocyte/macrophagic cells excluding them from leukocyte counts. *Aim*. Our aim was to evaluate SXE blood cell counts in CSF samples and to make a quantitative and qualitative analysis. We also compared SXE CSF results with those obtained by cytospin microscopic observation and flow cytometric studies. *Methods*. 232 CSF samples from patients with hematologic diseases (acute leukemia and NHL n=216), non hematologic cancer diseases (n=4) and infectious, inflammatory diseases and others (n=12) were analysed. CSF samples were firstly acquired in SXE counter and then manually processed for cytospin, May-Gründwald-Giemsa stain and microscopic observation. Flow cytometric analysis (FC) with four colour monoclonal antibodies according to pathology was also carry out. When initial diagnosis was unknown we used HLA-DRFITC /CD19PE / CD3PERCP/ CD45APC panel. All events from 0.5-1 ml sample were acquired in a FACScalibur (BD) machine. Paint- a- gate analysis software was used. Samples were classified as follows: non cellular, neoplastic or activated. *Results*. Sensibility for leukocytes detection was higher in SXE than cytospin interpretation (88% versus 51% respectively). 42.9% of neoplastic infiltrated samples showed more than zero HFBF, but only 8% of non cellular and 10% of activated CSF samples. We found statistic differences in HFBF percentages between all groups (Kruskal Wallis p<0.001). When we applied U de Mann-Whitney test, we could find higher HFBF % in infiltrated samples compared to non cellular (p< 0.001) and to activated ones (p=0.015). Differences in HFBF% between activated and non cellular samples (p>0.801) were not found. Infiltrated samples by FC had a tendency to have higher HFBF values. However, within the three classified types it was more frequent to find values close to zero. *Conclusion*. SXE autoanalyser could be a rapid, reliable and straightforward method to detect and differentiate SCF cells. High HFBF values in neoplastic samples might suppose a valid screening tool when flow cytometry is not available.

1093

MIR-155 INHIBITION EFFECT ON CELL PROLIFERATION AND APOPTOSIS INDUCTION OF JURKAT (ACUTE T CELL LEUKEMIA) CELL LINE

S Alizadeh,[1] S Kaviani,[2] M Soleimani,[2] A Pourfatollah,[2] N Amirizadeh,[3] F Kouhkan[1]

[1]*Tehran University of Medical sciences, Tehran, Iran*

[2]*Tarbiat Modares University, Tehran, Iran*

[3]*Irania Blood Transfusion Organization, Tehran, Iran*

Backgrounds. MicroRNAs are small non-coding RNA molecules with approximately 22 nt in length and cause inhibition of translation or degradation of mRNA. Mir-155 is a molecule with different functions, such as role in proliferation and immunity. Overexpression of this miRNA has been found in a number of cancers. One of its best known functions is apoptosis that affectsa on caspase-3 activity. *Aims*. The main aim of this study was evaluation of LNA mir-155 inhibitor effect in apoptosis. *Methods*. In this study, Jurkat cells were used and for evaluation of sensitivity to varied concentrations (25, 50 and 75 nmol) of mir-155 inhibitor using MTT assay. Mir-155 expression level was analyzed using the quantitative real-time polymerase chain reaction (QRT-PCR). Caspase-3 activity was measured by caspase-3 colorimetric activity assay kit. Unpaired t test test were used for analysis of the MTT and apoptosis results. Probability of 5% was assumed as statistically significant. *Results*. According to our results, the use of mir-155 inhibitor increased activity of caspase-3 by 2 fold in 75 nmol concentration. In this research, we found that the proper increase of mir-155 inhibitor concentration can inhibit mir-155 and consequently increase caspase-3 activity and induce apoptosis in the Jurkat cells leading to cell death ultimately. *Conclusions*. Apoptosis stimulation by miRNAs is probably one of the best and low risk ways of cell death induction in malignancies. Due to role of mir-155 in several cancer cells, it may be used as a therapeutic tool in future.

1094

META-ANALYSIS REGARDING THE RELATION BETWEEN ACUTE LYMPHOBLASTIC LEUKEMIA TREATED IN CHILHOOD AND THE APPEARANCE OF THE METABOLIC SYNDROME

RG Mihaila,[1] R Dancu[2]

[1]*Lucian Blaga University of Sibiu, Sibiu, Romania*

[2]*Emergency County Clinical Hospital, Sibiu, Romania*

Background. Are there metabolic disorders that influence the apparition of ALL and finally the metabolic syndrome (MS) or the treatment of ALL favors MS? In the moment when ALL was diagnosed in children, a potentially atherogenic lipid profile was noted, that persists during the induction phase. The treatment of ALL can also be involved in the ulterior appearance of MS. Aims. Our objective is to study the arguments, existing in literature, that advocate for a connection between the MS and a pre-existing childhood ALL. Methods. The meta-analysis included all the 7 existent studies in MEDLINE, until January 2011, that refers to the relation between ALL and MS. The analyze studied: the period of time passed from the end of the ALL treatment, the type of treatment (chemotherapy and/or radiotherapy), the percentage of patients with MS, the percentage of the present criteria that defines MS and the relation with the growth hormone (GH). Results. The meta-analysis included 260 patients. The median period of time from the end of treatment was 13.04 years. The average proportion with patients having MS was 11.38%. There was only one study that compared the proportion of patients having both MS and ALL in antecedents (16.6%) with the one in general population of the same age and gender (17.5%); the proportion of MS was not significant different. In 2 of the studies the average percentage of obese subjects was 14.97% and the overweight subjects percentage was 42.10%. In a study 55.7% from the subjects had at least one of the criteria that define MS. In another study the criteria that define MS were present in the following proportions: hypertriglyceridemia - 17.63%, low levels of HDL - 10,08%, high fasting glucose - 6.01%, obesity - 24,71% and hypertension - 17,63%. Four studies noted that anterior cranial radiotherapy favors the decrease of the GH levels (more than

chemotherapy), decrease that correlate more frequently with an increase in total body fat, hypertriglyceridemia, hyper-LDL-cholesterolemia, hypo-HDL-cholesterolemia, a more frequent increase of fasting insulinemia, and a more frequent hypertension. In the study of a group of patients treated with both chemotherapy and radiotherapy, where the MS was present in a proportion of 33.33%, after 12 months of treatment with GH, the MS was present in only 5,56% of them, and after 24 months none of them had MS; they also noted an increase in left ventricular mass index and an improvement of cardiac systolic function. The cardiovascular toxicity of chemotherapy consists especially in left ventricular dysfunction induced by antracyclines and in endothelial dysfunction produced by the increase of homocysteine levels induced by methotrexate. Summary. The criteria that define MS are frequently present in the patients that were anterior treated for ALL. Anterior cranial radiotherapy favors a decrease in GH levels (more than chemotherapy), decrease that correlate more frequently with the presence of MS compounds. There is the necessity of studies that compare the metabolic dysfunctions present before ALL with those that appear after the treatment.

1095

ADOLESCENT AND YOUNG ADULT ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH PEDIATRIC PROTOCOL: A TUNISIAN MONOCENTRIC STUDY

M Medhaffar, I Frikha, N Ajmi, O Kassar, H Bellaj, S Hdiji, M Elloumi
Hedi Chaker Hosptal, Sfax, Tunisia

Background. Pediatric protocols give good results in childhood acute lymphoblastic leukaemia (ALL) comparing to adults treated with other protocol. *Aims*. We report in this study the results of pediatric protocol used for adolescent and young adult acute lymphoblastic leukemia *Method.* Between Januaty 2000 and December 2007, we retrospectively analyze the data of acute lymphoblastic leukaemia patients aged from 16 to 30 years treated according to the pediatric EORTC 58951 protocol. Patients were stratified in average and high risk groups according to white blood count at diagnosis, blasts phenotype, cytognenetics abnormalies and response to corticotherapy (cortico-sensitivity: blasts less than 1000/mm3 at day 8) and chemotherapy (complete remission: CR). Finally we analyzed the 5 years overall survival (OS), event free survival (EFS) and disease free survive (DFS). *Results*. Thirty three adolescent and young adult were treated according to the EPRTC 58951 pediatric protocol. Median age was 18 years (16 to 28) and sex ratio was 1.53. Median WBC was 53.000/mm3. B and T phenotype were observed in respectively 38 and 62% cases. Cortico-sensitivity was noted in 73% of patients. Three patient dead during induction and eight dead after, sepsis was the frequent cause of mortality (10 cases). Twinty nine patients achieved CR (96%). Four patients relapsed. Five years OS, EFS and DFS were respectively 48, 48 and 79%. *Conclusion*. This study showed that pediatric protocol can offer good results concerning CR and DFS to adolescent and young adult ALL. However OS an EFS, better than adult ALL treated during the same period by adult protocol (OS=18%, EFS=18% and DFS=24%) was not yet satisfactory because the high toxic mortality rate.

1096

ANTIOXIDANT STATUS IN EGYPTIAN CHILDREN WITH MALIGNANCIES

N Elbarbary, G Mokhtar, S Shaaban, N Elbarbary, H Ahmed, H Abdel Razek
Ain Shams University, Cairo, Egypt

Background. Combination of chemotherapy received by Children with malignancies make them prone to peroxidative injury. *Objectives*. The aim of this study was to evaluate antioxidant status in children suffering from different types of malignancies and to estimate the relation between antioxidants status and chemotherapy related side effects. *Patients and methods*. In a sample of 60 children having different childhood malignancies, antioxidant status was evaluated initially at diagnosis, after 3 and 6 months(6 ms) of therapy by measuring endogenous antioxidants (uric acid, albumin, bilirubin) , exogenous antioxidants (vitamin C , total antioxidant capacity [TAC]), and Malondialdehyde as oxidative marker. *Results*. Regarding exogenous antioxidants there was no statistical significant changes in albumin, bilirubin and uric acid, after 3or 6ms of therapy. Vitamin C and TAC showed significant reduction during follow up period when compared to baseline levels ($p < 0.001$ for all) while Malondialdehyde levels showed significant increase after 3 and 6 ms of chemotherapy when compared to baseline levels ($p<0.001$). Marked decrease level of endogenous antioxidants over 6 ms of chemotherapy treatment was associated with dose reduction and increase incidence of infection ($p=0.001$,$p=0.002$ respectively) but there was no significant changes in stoppage of chemotherapy and hospitalization throughout treatment when compared to baseline rate.No correlation between VIT C, TAC, and Malondialdehyde levels were found ($r=-0.17$ $P=0.37$,$r=0.09$ $p=0.63$,$r=0.00$ $p=0.99$). Levels of exogenous antioxidants and Malondialdehyde were not different among hematological or solid type of malignancies or in different age groups and both sexes .Patients with solid tumors showed significantly higher rate of chemotherapy stoppage after 6 ms compared to hematological tumors($p=0.03$). *Conclusion*. Children undergoing treatment for malignancy receive combination of chemotherapy which is associated with free radical production and increase oxidative stress in those children and related to complications of treatment.

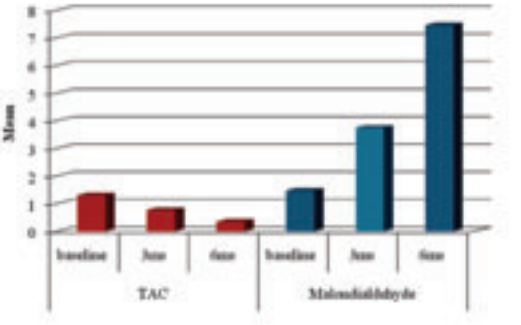

Figure 1. Mean values of TAC and MDA during treatment

1097

HOW TO TREAT ADOLESCENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

J Konja, L Rajic, E Bilic, R Femenic, M Anicic
University hospital Centre Zagreb, Medical faculty Zagreb, Zagreb, Croatia

Background. Adolescents with acute lymphoblastic leukemia (ALL) have languished in the shadow of successful therapeutic outcome in childhood ALL. While 80% of children aged 1-15 years are long-term survivors, less than 40% of adults are cured with current therapies. Adolescents and young adults who may be eligible for both adult and pediatric protocols have continued to have an intermediate outcome, which has remained inferior to that in children. *Aims*. This article has summarized the recent and updated retrospective comparative analysis of adolescents treated with pediatric and adult trials. *Methods*. Data on ALL adolescents aged 16-18 treated with pediatric trial ALL IC-BFM 2002 were compared with literature reports on the treatment of ALL adolescents according to adult protocols. *Results*. During the 2002-2006 period, 143 ALL patients aged 16-18 were treated with pediatric trial ALL IC-BFM 2002. The 3-year event free survival (EFS) was 71%. During the 1997-2002 period, 67 ALL patients aged 15-17 were treated with adult trial UKALLXII/E2993, and 61 ALL age-matched patients were treated with pediatric trial MRC ALL97, with 5-year EFS of 49% and 65%, respectivelly. A similar 6-year EFS has been reported for the American pediatric regimen (CCG) that was by 26% higher in comparison with their adult regimen (Cancer and Leukemia Group B,CALCB). *Conclusion*. Therapeutic outcome in adolescents with ALL treated according to pediatric protocols is better (16 - 26%) in comparison with adult regimen.

1098

LONG-TERM OUTCOME AND PROGNOSTIC IMPACT RISK FACTORS IN 117 ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED WITH CHEMOTHERAPY WITH OR WITHOUT STEM CELL TRANSPLANTATION

L Tukic, D Stamatovic, O Tarabar, M Elez, Z Tatomirovic, B Todoric Zivanovic, B Cikota, M Strnad, O Tasic, B Balint, A Ivic Zivanovic, M Malesevic
Military Medical Academy, Belgrade, Serbia

Background. Adult acute lymphoblastic leukemia (ALL) is often incur-

able despite intensive chemotherapy with or without hematopoietic stem cell transplantation (HSCT). Estimated overall long-term survival rate for adult ALL patients (pts) is about 20-50%. Aim. To present our results of treatment adult ALL and impact high risk factors on overall survival (OS). Patients and Methods. Since January 1989 till January 2011 we were treated 117 (male 83, female 43) pts with adult ALL, average age 30 years. Immunophenotype were determined in 85 (B-ALL 57, T-ALL 28) and cytogenetic/molecular analysis were succeeded in 55 pts. At the time of initial presentation: 29 pts had high white blood cell (WBC), 5 pts had CNS involvement and 19 pts had mediastinal mass. Pts treated with induction, consolidation and maintenance therapy under modified YU-ALL regimen for *high risk* (82), HyperCVAD (13), LALA 94 (8), CHOP, BFM, GMALL, EzOG UKCR, etc. (14). High risk pts was defined by the presence of at least one of following factors: age > 35 years, WBC > $30x10^9$/l (B-ALL) or $100x10^9$/l (T-ALL), CNS involvement, more than 4 weeks to achieve complete remission and finding Philadelphia chromosome (or bcr-abl+), t(4;11)+ or t(1;19)+. Medicament prevention (without radiotherapy) of CNS disease was applied to every pts under 50 years. Results. Complete remission (CR) was achieved in 104 pts (delayed CR in 18). Resistant to therapy were 5 (4.3%) pts, 6 (5%) pts have died (2 early deaths, 2 before evaluation of remission, and 2 in CR during the intensification due to infective complications). Maintenance therapy (MT) was applied for 24-36 months. HSCT was done in 44 pts: allo in 27 pts (CR1 in 15, CR2 in 8, and with partial response in 2 pts) and auto in 17 pts (CR1 11, CR2 5 and with molecular relapse 1 pts). Relapses have occurred in 67 pts (63%) with median time of 9 months. Frequency of relapses were higher in pts on MT (45/62 - 73%) comparing to HSTC pts (22/44 - 50%: auto HSCT 10/17 - 58% and allo HSCT 12/27 - 44%, respectively). The secondary allo HSCT was done in 5 pts (2 are still alive). Long-term survival without relapses had 19/106 (27.4%) pts; 10-years disease free survival (DSF) in MT pts was 13.65 +/- 5%, auto HSCT pts 16.4 +/- 11.5%, and allo HSCT pts 26.4 +/- 11%. Univariate analysis of impact high risk factors on overall survival showed significance in age (p=0.025) and CR achieved in 4 weeks (p=0.00028), marginal significance (p=0.070) in CNS involvement, while cytogenetics (p=0.90) and WBCs were without impact on outcome/overall survival in this cohort of pts. *Conclusion*. Results of our retrospective analysis are similar to the others and confirms that treatment of adult ALL is unsatisfactory. It is necessary to define precise prognostic factors, to stratify pts according to them and to use intensive chemotherapy with or without HSCT.

1099

PHILADELPHIA-POSITIVE ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: REAL LIFE OF TWO GEOGRAPHICAL REGIONS

Background. Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ ALL) in adult patients is associated with a particularly unfavorable prognosis, although some progress has been made with the use of tyrosine kinase inhibitors (TKIs). Aims: Assessment of outcomes of adult Ph+ ALL patients treated in hematological centers in two geographical regions in the Czech Republic with a population of about 4.1 million between 1997 and 2010. *Methods*. Thirty-eight consecutive patients with newly diagnosed Ph+ ALL were included in the analysis, 26 (68%) patients were treated with chemotherapy and a TKI (imatinib or dasatinib), 12 (32%) with chemotherapy alone, mostly in the pre-TKI era. Sixteen (42%) patients underwent stem cell transplantation (SCT); 12 matched unrelated donor SCT, one HLA identical sibling donor SCT and 2 autologous SCT. Data were evaluated for complete hematological remission (CR), complete molecular remission (CMR) and relapse rates and for risk factors affecting overall survival (OS). We were also interested in the effect of a TKI added to chemotherapy. Results: Out of the total number of 38 patients, 29 (76%) achieved a CR (median time to CR 38 days, range 6-134 days), 17 (57%) of 30 evaluable patients achieved a CMR (median time to CMR 76 days, range 32-358 days). Ten (34%) patients experienced a relapse (median time to relapse 7.4 months, range 1.1-37.5 months) with a very short post-relapse survival regardless of the salvage therapy used. Molecular relapse was in all but one cases followed by a hematological relapse (median time to molecular relapse 2.9 months, range 1.4-13.1). At the end of the follow-up period with a median of 8.7 months, 14 (37%) patients were still alive in CR (only one treated in the pre-TKI era) and 24 (63%) died, mainly of infection (9 patients, 38%), multiple organ failure (7 patients, 29%) or disease progression (6 patients, 25%). Median OS was 9.0 months; the highest survival benefit was observed in patients achieving a CR (p<0.001) or a CMR (p=0.002) and treated with allogeneic SCT (p<0.001). The addition of a TKI to chemotherapy was associated with a higher CMR rate (p=0.026), but not with a higher CR rate (p=0.29), lower relapse rate (p=0.26) nor a prolonged OS (p=0.13). Summary/conclusions: In adult patients with Ph+ ALL the best outcome is achieved with the combination of chemotherapy, TKI and allogeneic stem cell transplantation. However, more than half of the patients are not eligible to undergo such intensive treatment. Although the investigated geographical area was wide, incidence of Ph+ ALL is very low and multicentric or international cooperation is therefore very helpful.

1100

LOW DOSE AMPHOTERICIN LIPID COMPLEX FOR PRIMARY PROPHYLAXIS AGAINST INVASIVE FUNGAL INFECTIONS IN TEENAGE AND YOUNG ADULT PATIENTS UNDERGOING INDUCTION CHEMOTHERAPY FOR ACUTE LYMPHOBLASTIC LEUKAEMIA

J Tomlins, D Kaye, M Dennis, A Bloor

Christie Hospital, Manchester, United Kingdom

Patients with acute lymphoblastic leukaemia (ALL) are at high risk of developing invasive fungal infections (IFI) during induction treatment with significant mortality and morbidity. The reported incidence of IFI is up to 40% and with an associated reported mortality of 20-50%. In Teenage and Young Adult (TYA) patients, there is increasing use of paediatric protocols, however the increased intensity of these regimens potentially increases the risk of developing IFI. There is no consensus regarding the optimal antifungal strategy in this population. In addition the interaction between vincristine and azoles restricts the choice of drugs. We have previously reported the efficacy and tolerability of low dose amphotericin B lipid complex (Abelcet) as anti-fungal prophylaxis in adult patients undergoing ALL induction. We therefore applied this regimen to our TYA population receiving treatment according to the UKALL 2003 protocol. 20 consecutive patients (aged 16-24) with newly diagnosed disease treated at a single centre (March 2007 - Jan 2011) were included in this retrospective series. 3 were non-evaluable as they received induction treatment elsewhere. Chemotherapy consisted of induction (35 days) comprising weekly vincristine (x5) and daunorubicin (x4), daily dexamethasone and 2 doses of pegylated asparaginase (days 4 and 18) followed by standard BFM consolidation comprising weekly cytarabine (4 days per week for 16 doses), daily 6-mercaptopurine and 2 doses of cyclophosphamide (days 1 and 15). 2 patients received augmented BFM consolidation. Patients were hospitalised during induction during which time they received antifungal prophylaxis using Amphotericicin. 17 patients received Abelcet (100mg 3 x per week by intravenous infusion). Only one patient was intolerant of Abelcet and was treated with Ambisome (5mg/kg once weekly by intravenous infusion). Consolidation chemotherapy was predominantly administered in the clinic and upon completion of vincristine, antifungal prophylaxis was switched to daily itraconazole liquid (200mg bd) or capsules (200mg tds). Fungal infections were categorised into possible, probable or proven according to the EORTC/MSG criteria. Four patients developed a possible or proven IFI during the study period with a cumulative incidence of 32.5% (95% CI 16.4-64.2%). All infections occurred during the consolidation phase with one death due to infection. A further 3 patients received empiric antifungal therapy (1 during induction and 2 during consolidation) due to suspected fungal infection (predominantly unresponsive fever), although they did not meet the EORTC/MSG criteria for a possible IFI. Our data indicate that low dose Abelcet is an effective and well-tolerated strategy for primary antifungal prophylaxis in TYA patients undergoing induction chemotherapy for newly diagnosed ALL. However, patients remain at high risk of developing fungal infections through subsequent consolidation treatment during which itraconazole prophylaxis appears ineffective. The optimal antifungal strategy during this phase of treatment has yet to be established although is of importance given the significant risks associated with IFI. Our results suggest that continued low dose intermittent amphotericin B lipid complex may be effective although is inconvenient in the outpatient setting.

Background. Philadelphia chromosome positive (Ph+) acute lymphoblastic leukemia (Ph+ALL) includes at least one-quarter of all adults with ALL. The conventional chemotherapy programs that are effective in other precursor B-cell ALL cases are unable to cure these patients. The availability of imatinib mesylate and other tyrosine kinase inhibitors (TKIs) changed the treatment programs and the prognosis for these patients. In Romania Imatinib combined with chemotherapy was approved as standard therapy for Ph+ALL in 2006. *Aims*. We studied the outcome correlated with treatment programs for 21 patients with de novo Ph+ALL. Materials and methods: There were 11 male and 10 female, aged between 17 and 71 years (median = 48y) diagnosed 2007-2009. Imunophenotypic diagnosis was ALL preB for 9 patients, ALL - common for 10 and biphenotipic acute leukemia for 2 patients. All patients (even at 71 years old) received curative chemotherapy for induction and consolidation and imatinib, 600 mg daily (except 1 patient who received 400mg/d). *Results*. Complete remission achieved 76% patients at on average of 44.8 days from diagnosis (limits 24 - 66 days). Complete molecular response was documented for 42.8% patients, at a median of 385 days (limits 177 - 485 days). Imatinib was started after second induction or after first consolidation. For 57.14 % of patients chemotherapy during imatinib was low dose or reduced intensity. Due to SCT policy in our country for ALL, no patient was transplanted in first remission. PFS was 13.8 months (limits 3 - 37 months). Relapsed treatment was: intensive chemotherapy for 4 patients, 1 patient switch to dasatinib and other 3 patients received tandem therapy with dasatinib and nilotinib. Only one patient was transplanted in the second CR, and received Dasatinib after transplant. At the end of our study, 5 patients were living at 8, 14, 16, 20 and 37 months respectively, 4 of them with CR, one relapsed. Disease/relapse related mortality was 27.7%. Treatment related mortality was 44.4%. Overall survival was on average 12.25 months. *Conclusions*. The prognosis of adult patients with Ph+ ALL treated only with chemotherapy is poor, with a less than 10% probability of long-term survival. The use of imatinib as part of front-line treatment in combination with cytotoxic agents has greatly improved the rates of complete hematologic and molecular remission and overall outcome in adult patients with newly diagnosed Ph+ ALL. However the allogeneic SCT is the only treatment option with definite curative potential. Our data show that only aggressive chemotherapy combined with imatinib would really change the outcome of Ph+ALL new diagnosed patients.

EVALUATION OF THE CCG 1991 AND CCG 1961 PROTOCOLS OF THERAPY OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA IN TWO EGYPTIAN ONCOLOGY CENTERS: A PILOT STUDY

A Tantawy,[1] F El-Rashidy,[2] I Ragab,[3] O Ramadan,[3] M El-Gaafary[3]
[1]*Faculty of Medicine, Ain Shams University, Cairo, Egypt*
[2]*Faculty of Medicine ,Menoufeya University, Shebeen El Kom, Egypt*
[3]*Faculty of Medicine ,Ain Shams University, Cairo, Egypt*

Clinical trials in childhood ALL have yielded 5-year event-free survival (EFS) rates as high as 80%, yet we did not reach comparable results partly due the high mortality and morbidity rates associated with high dose methotrexate therapy .Since 2004, the Pediatric Oncology Centers in Ain Shams University and Menoufeya University shifted the protocol of therapy of standard risk ALL to the CCG 1991 , and the high risk ALL patients were shifted to the CCG 1961 protocol, being more cost effective and not including HDMTX like the previously used BFM 90 protocol.Aim of the work: This study aimed to evaluate the efficacy of the CCG protocols (CCG 1991and CCG 1961)in the treatment of childhood ALL in Ain Shams and Menoufeya University Pediatric Oncology Centers and the associated morbidity and mortality rates . Methods:A prospective study including 50 ALL patients less than 17 years old diagnosed in both University Centers in the period from April 1st 2004 to December 31st 2005 , recruited after having parental consent. Patients were classified into 3 risk groups, standard risk (SR), high risk standard arm (HR-SA) and high risk augmented arm (HR-AA) based on clinical and morphological data and response to therapy. Risk stratification used did not include cytogenetics or minimal residual disease. Protocol CCG 1991 (Arm OS with single delayed intensification) was used for standard risk patients. Protocol CCG 1961 (Arm A standard BFM arm of standard duration) was used for HR-SA patients , and CCG 1961 (augmented BFM arm using doxorubicin) was used to treat HR-AA acute lymphoblastic leukemia patients .Results: The mean age of the patients was 5.9 (+3.3) years, male to female ratio was 1.6:1. CNS leukemia was present in 6% of patients at diagnosis . 14 patients (26.9%) had T-ALL and 38 (73.1%) had preB-ALL. Initial total leucocytic count >50.000/cmm was present in 16 patients(30.8%). According to risk stratification : 25 patients were SR (48.1%), 16 HR-SA (30.8%), and 9 HR-AA (17.3%).The 5-year overall survival (OS) and 5-year EFS of the total number of patients was 83% and 67% respectively. The 5 year overall survival (OS) was 97% , 55%,88%, for SR , HR-SA, and HR-AA ,respectively. The 5-year EFS for the SR, HR-SA and HR-AA patients was 60%, 58% and 70% respectively. Grade 3-4 adverse events were reported in five patients. Relapse and death occurred in 3(12%) and 1(4%) in SR patients respectively, in 2(15.4%) and 4(30.8%) in HR-SA,and in 1(8.3%) and 1(8.3%) in HR-AA respectively ,(P=0.05). Conclusion: The outcome of SR and HR-SA protocols used was not satisfactory, accordingly intensification of protocols was done shifting SR ALL to CCG 1961 arm OD with double delayed intensification (DDI), and shifting HR-SA to CCG 1991 HR-SA ARM B (standard BFM with increased duration and DDI).Cytogenetics and Minimal residual disease assessment are mandatory for prediction of risky patients in SR ALL and in HR-SA groups for better risk stratification of therapy to achieve better childhood ALL survival.

1103

CHEMOTHERAPY RELATED ACUTE SIDE EFFECTS IN CHILDREN TREATED FOR ALL

M Sezgin Evim, F Demirtas, B Baytan, A Meral Günes
Uludag University, Bursa, Turkey

Background. The survival rate in childhood ALL has reached to 80% with the contemporary chemotherapy protocols and increased supportive care. However, chemotherapy related acute side effects may stil cause serious problems leading to morbidity and mortality during treatment. Although the reports about the late effects among the survivors are frequent, the data related to the acute adverse effects are scarce. *Aims*. This study evaluated the acute side effects of chemotherapy in children with ALL. *Method*. The acute toxicity according to the WHO criteria for each chemotherapy phase in 210 children treated as ALL between the years 1993 and 2009 were, retrospectively, evaluated from their hospital records. Children received either BFM-95 (76.5%) or BFM-2000 (%23.5) protocols. *Results*. The data of 187 children were evaluable. The mean age and male to female ratio were 62±51.7m and 1.7, respectively. The median follow-up period was 61.3±43.4m. Children were stratified into 3 risk groups as standart (19.8%), median (61.5%) and high (18.7%). General well being was similarly effected during the induction phase in all risk groups ($p>0.05$). However, poor condition was significantly more frequent in high risk group blocks ($p<0.001$). Bone marrow toxicity was more prominent during induction phase in each risk group, however, it was significantly depressed during high risk blocks ($p<0.05$). The frequency of nausea were found similar during all treatment phases. Vomiting, stomatitis, diarrhea were significantly occurred in high risk blocks along with elevated liver transaminases ($p<0.001$). MTX related skin changes (Grade 1/2) were observed in 3.2% (n:6) of the patients. Allergic drug reactions due to L-asparaginase including urticaria and/or anaphylaxis occured in 31% (n:58) of children. Seven out of 187 children (3.7%) developed tumor lysis syndrome with reversible acute renal insufficiency during induction phase. Grade 1 and 2 increase in serum creatinine level were significantly frequent in HRG blocks ($p<0.001$) and one of them required hemodialysis. Cardiac dysfunction and hypertension were determined in 6.9% (n:13) and 9.6% (n:18) of the children, respectively. Hyperglycemia related to steroid and/or L-asparaginase occurred in 13.9% (n:26) of the patients. CNS toxicity including, seizures, thrombosis, hemorrhage, infarct, PRES and encephalopathy was observed in 20 (10.6%) children. The number of febrile episodes per patient was 4.8. The primary site of infection could be determined in

%39.1(n:348) of these episodes. Causative microbiologic agent could be demonstrated in 23.3%. The frequency of grade 3 and 4 infections were significantly more in HRG (p<0.001). Overall and event free survival rates were found 86% and 82.9%, respectively. Twenty-six patients (%13.9) died of either infection (46.2%) or relapsed/refractory disease (53.8%). None of the childeren were lost due to drug related acute toxicity.

1104

9P21 DELETIONS IN ACUTE LYMPHOBLASTIC LEUKEMIA OF CHILDHOOD

M Sezgin Evim, B Baytan, A Meral Günes, T Yakut
Uludag University, Bursa, Turkey

Background: The putative tumor suppressor gene called CDKN2/INK4A/p16 was also mapped to chromosome band 9p21. The gene codes for cyclin-dependent kinase inhibitors (CDKI). These CDKIs can bind and inhibit the kinase function of the cyclin-dependent kinase 4 (CDK4) and CDK6, resulting in the blockade of the cell cycle between G1 and S, leading to a suppression of cellular proliferation. For this reason, these CDKIs may act as tumor suppressors. Therefore, their inactivation might contribute to development of cancer. Deletion of the 9p21 chromosomal region are frequent in childhood acute lymphoblastic leukemia (ALL) but, the prognostic significance is controversial. In childhood ALL, CDKN2/INK4A/p16 inactivation is found in more than 20% of B-lineage ALL and 50% of T-ALL. Methods: We studied 85 children (aged 12 months to 17 years) consecutively diagnosed as ALL. Of the 85 children, 64 had B-ALL, whereas 21 had T-lineage ALL. All patients were treated according to the protocols of the BFM-ALL 2000 between January 2008 and December 2010. CDKN2A inactivation by deletion was studied using Fluorescence In Situ Hybridization (FISH). Results: Bi-allelic and mono-allelic deletion were found in, respectively, 4 (4.7%) and 8 (10.5%) of 84 children. At the time of analysis, the median follow-up was 1.2 years (range 6 months-3 years). Summary. A pathogenetic role for p16 gene deletion in the development or progression of those ALL, suspected because of the potentially antiproliferative properties of p16, will have to be clearly shown.

Table 1. Clinical outcome according to 9p21 status

	Total population studied (n:85)	9p21 subgrup	
		Bi-allelic deletion (n:4)	Mono-allelic deletion (n:8)
Immunophenotype			
T-cell	21	4	3
B-cell	64	0	5
No event	80	1	7
No CR	1	0	0
Relaps	2	2	1
Death in CR	2	1	0
Survival status			
Alive	79	1	8
Death	5	3	0

GASTROINTESTINAL TOXICITY SECONDARY TO TREATMENT OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

R Berrueco,[1] S Rives,[2] A Catala,[1] M Camos,[1] T Toll,[1] M Torrebadell,[3] J Estella[1]
[1]*Hospital Sant Joan de Deu, Esplugues de Llobregat (Barcelona), Spain*
[2]*Sant Joan de Deu, Esplugues de Llobregat (Barcelona), Spain*
[3]*Hospital Sant joan de Deu, Esplugues de Llobregat (Barcelona), Spain*

Background. Acute lymphoblastic leukemia (ALL) is the most frequent cancer in childhood. Although intensive chemotherapy has improved survival in those patients, important side effects, including acute gastrointestinal (GI) toxicity are frequent. Although GI toxicity is frequently described in reported ALL series of patients, the different criteria used to define severe GI toxicity translates in very different incidence of such complications in the literature. *Aim*. To describe the incidence of severe acute GI toxicity in a series of ALL patients treated in a single centre during the last 11 years, and to report the short and long-term outcome of these complications. *Patients and methods*. Data from children diagnosed with ALL in Hospital Sant Joan de Déu from july 1999 to january 2011 were collected. Patients were treated according to two sequential trials of the Pediatric Hematology and Oncology Spanish Group (SEHOP), SHOP ALL-99 and SHOP ALL-2005 that include standard agents for ALL treatment. Severe (grade III-IV) GI complications were analyzed. *Results*. During this period 143 children were diagnosed with ALL at our institution. Sixteen of them (11.1%) presented enterocolitis-typhlitis and two (1.3%) appendicitis during the induction phase (n=14), consolidation (n=1) and intensification (n=1). The main clinical findings were abdominal pain (100%), defined as severe in 77% of cases, and mucositis (77%). Neutropenia was present in 83% of the patients (severe neutropenia in 55%), with a mean duration of 15 days. Blood cultures were positive in 4 children for S. aureus, P. aeruginosa, E. coli and S. epidermidis, respectively. Most patients (n=10) improved with medical treatment but 5 patients (3.4%) needed surgical treatment and one child died because of refractory sepsis (P. Aeruginosa). Twelve patients (8.3%) presented an elevation of pancreatic enzymes (amylase ranged from 114 to 1499 UI/L and lipase from 158 to 455 UI/L), related to L-asparraginase administration. Seven patients were asymptomatic and the rise in pancreatic enzyme was transient; however, five patients (3.4%) presented an acute pancreatitis with severe abdominal pain that needed analgesic treatment and delayed the scheduled chemotherapy administration. One patient died from fulminant pancreatitis and the other patients had a favorable outcome Three patients (2%) presented a grade III-IV increase in bilirrubin levels during induction phase. One of them developed a fulminant hepatitis and died, while the others improved after adjustment of the chemotherapy doses. Overall, the incidence of severe GI toxicity in our series was 16% and the mortality rate due to GI complications was 2%, similarly to other previously reported data. *Conclusions*. GI toxicity of standard chemotherapy regimens is frequent in ALL patients. Close monitorization of pancreatic enzymes is necessary during the L-asparraginase administration, but in most cases isolated rise in pancreatic enzyme levels in an otherwise asymptomatic patient will be transient and will not require treatment interruption. Although most GI complications were manageable with medical treatment, some patients eventually died due to GI toxicity.

1106

PEDIATRIC-LIKE INTENSIFIED THERAPY IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE CENTRE EXPERIENCE

S Parisi, S Paolini, I Iacobucci, C Papayannidis, A Curti, MC Abbenante, E Ottaviani, N Testoni, M Baccarani, G Martinelli
Institute of Hematology 'Seràgnoli', Bologna, Italy

Background. Acute lymphoblastic leukemia (ALL) shows different outcome in children and adults, with event-free-survival (EFS) rates of 70-80% and 30-40% at 5 years, respectively. Recently, results improved in young adults/adolescents aged 15-21, with de novo ALL, when treated with pediatric intensive regimens rather than with typical adult regimens. Clinical studies are ongoing in older patients, toxicity related-therapy seeming the limiting issue. *Aims*. We report a single centre experience on adult ALL patients treated with an intensive pediatric-inspired schedule, aiming to assess its tolerability and efficacy. *Methods*. From 11/07 to 02/11 we treated 22 ALL patients (M/F=16/6) according to modified AIEOP-LAL2000 regimen. Treatment consisted of 7 days steroid pre-treatment, and four drugs 78-days induction (phase IA and IB) after which high risk (HR) patients were treated with three polychemotherapy blocks, while intermediate (IR) and standard risk (SR) patients went on 8-weeks consolidation and subsequent intensification. A 2 cycle consolidation therapy with nelarabine was planned for T-ALL patients. Patients with HLA-matched donor underwent allo-SCT; 2-years maintenance therapy was given to the others. Median age was 32 years (17-47). *Results.* 20/22 patients completed the phase IA, 2 being out for grade IV toxicity (intestinal occlusion and sepsis). 15 (68%) obtained a complete remission (CR), 5 (23%) were refractory. Three of the resistant patients subsequently achieved CR: one after polychemotherapy blocks, two after phase IB. Median induction duration (IA+IB) was 95 days (82-136); delays were mostly accumulated during the interval between phase IA and IB and were due to logistic reasons and extra-hematologic toxicity. A higher absolute number of adverse events during phase IA than during IB was registered (infections and gastrointestinal), without a significant prolongation of phase IA. After induction, 3 of the 15 CR patients received consolidation therapy, then 2/3 underwent allo-SCT. 5 patients received blocks: 3/5 undewent allo-SCT, 2/5 dropped out after the first and the second block for reversible grade II-III renal toxicity. 3 patients were treated with nelarabine, then 1/3 underwent allo-SCT. 3/15 directly underwent allo-SCT, while 1 patient completed the whole

therapeutic program because no suitable donors for allo-SCT were found. Median CR duration was 12 months (3+-44+); 6 patients relapsed, 3/6 after allo-SCT. With a median follow up of 13 months (3-49), 14/22 (63,6%) patients are alive, 7 in CR (4 underwent allo-SCT). 8 patients died, 4 for relapsed/refractory disease, 4 in CR (3 after allo-SCT). On the basis of pediatric management, minimal residual disease assessments on days 33 and 78 of induction were scheduled. Important technical and logistic problems were found: MRD was possible only for 7 of the 15 CR patients, due to no probe individuation, no sample collection or degradated sample at diagnosis. *Conclusions*. A pediatric-inspired therapeutic regimen seemed to be feasible in adult ALL patients, even if significant delays due to logistic reasons and extra-hematological toxicity caused a lack in dose-intensity maintenance. The overall outcome seemed to be lower than the one reached in other studies conducted on larger population: a longer follow-up and a larger population are needed to draw definitive conclusions.

1107

IMATINIB ASSOCIATED BONE MARROW FAILURE IN A PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA PATIENT

S Iraheta Reyes, MJ Rodriguez Salazar, JM Raya Sanchez, B González González, B Soria, M Hernández García, L Hernandez Nieto

Hospital Universitario de Canarias, La Laguna, Spain

Background. Imatinib is a tyrosine kinase inhibitor (TKI) that have improved substantially the outcome of Philadelphia-positive (Ph-positive) acute lymphoblastic leukemia (ALL) patients. Before the advent of TKIs, Ph-positive ALL carried a dismal prognosis and was characterized by a poor response to most chemotherapy combinations, short remission durations, and poor survival rates. Imatinib combined with chemotherapy induced complete remissions in >90% of patients with newly diagnosed Ph-positive ALL. *Aims.* Description of an unusual clinical case of bone marrow aplasia after imatinib treatment. *Methods.* Literature search from clinical cases reporting bone marow aplasia/failure/severe pancytopenia related to TKI. *Results.* A 44 year old man was diagnosed of Ph-positive ALL on March 2009. He started treatment according to the PETHEMA Group LAL-Ph-08 protocol receiving imatinib 600 mg/d in combination with chemotherapy. Complete response (molecular included) was achieved on day +29 since treatment initiation. No HLA-identical siblings were available; therefore he was offered an autologous bone marrow transplantation (BMT) according to the clinical trial. Neutrophils and platelet engraftments were documented on day +17 and +33 respectively. He never reached normal peripheral blood cell count due to a mild thrombocytopenia. On day +92 he started maintenance therapy including imatinib 600mg/d, 6-mercaptopurine 40mg/m2/d and methotrexate 15 mg/m2/w until two years from complete remission. Five months from maintenance initiation the patient was admitted to hospital facilities and diagnosed from interstitial pneumonitis assumed to be caused by an unidentified viral agent. He was discharged 3 weeks later without ALL treatment due to bicitopenia (anemia and thrombopenia). One month later hemoperipheral counts showed no improve. Bone marrow aspirate was normal and karyotyping showed cytogenetic response. Seven weeks after treatment discontinuation, imatinib was started at the same dose with progressive aggravation of citopenias. There were no peripheral causes involved. Bone marrow biopsy performed three months later showed non-severe bone marrow aplasia with no morphological evidence of disease progression and the patient stayed on molecular remission. Imatinib treatment was discontinued and peripheral counts recovered close to normal values after several weeks. *Summary.* The literature describes few cases of pancytopenia associated to TKIs use, mostly related to chronic myeloid leukemia (CML) probably due to the larger number of patients presenting the disease. We have found only one publication describing bone marrow failure in this clinical scenary. As in CML, Ph-positive ALL patients seem to have no other treatment options to preserve molecular remission. Bone marrow failure related to TKIs utilization is a potentially serious adverse event. We are not able to predict the clinical outcome but is reasonable to think that TKIs interruption could lead to disease relapse. In our opinion, some issues remain unclear, as if temporary interruption of TKI will be enough, when to restart medication or which dose should we use. Other items to address should be the possibility of using a different TKI or what to do if marrow failure is observed after drug reintroduction. Therefore an effort to collect and analyze data from this population should be made in order to offer the best therapeutic options available.

1108

EXPRESSION OF PIM-2 AND NF-KB IS INCREASED IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) AND ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) AND CORRELATES WITH COMPLETE REMISSION RATE

K Kapelko-Slowik,[1] D Urbaniak-Kujda,[1] D Wolowiec,[1] J Dybko,[1] B Jazwiec1, M Slowik,[1] J Jakubaszko,[1] D Woszczyk,[2] K Kuliczkowski[1]

[1]*Wroclaw Medical University, Wroclaw, Poland*

[2]*District Hospital, Opole, Poland*

Background. PIM-2 is a proto-oncogene that encodes for serine/threonine kinase which interacts with various signalling molecules. PIM-2 is highly expressed in neoplastic tissues and in leukaemic and lymphoma cell lines which is consistent with a its role during oncogenic transformation. The nuclear factor kappa B (NF-κB) pathway appears to be deregulated in variety of tumors, with sustained activity of NF-κB leading to apoptotic resistance in tumor cells The aim. The aim of this study was to investigate whether the PIM-2 and NF-κB expression is altered in acute myeloid leukemia (AML) and acute lymphoblastic leukaemia (ALL). *Patients and methods*. One hundred fourty-three patients were included: 91 with AML and 52 with ALL (42 with B-ALL and 10 with T-ALL), aged 18-84 (median=41). Seventy-five patients reached complete remission (CR): 50 in AML and 25 in ALL. Bone marrow samples were collected at the time of diagnosis. Control samples were obtained from 24 healthy donors. We analysed PIM-2 and NF-κB expression by RQ-PCR analysis. *Results*. Expression of both PIM-2 and NF-κB in all leukaemic patients and in subgroups: AML and ALL was significantly higher than in controls. In AML group patients who reached CR expressed PIM-2 and NF-κB at significantly lower levels than patients with primary resistance to chemotherapy (with no CR, NCR). Moreover in AML, we have found the correlation between PIM-2, NF-κB expression and blasts in myelogram and PIM-2 and patients` age. Summary. Our data indicate that PIM-2 and NF-κB genes expression is increased in patients with AML and ALL and correlates with CR rate in AML patients.

DYNAMICS IN SOME PARAMETERS OF IRON STATUS MARKERS AND ANTIOXIDANT SYSTEM IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

S Gritsaev, D Shihbabaeva, L Rybakova, K Abdulkadyrov

Russian Institute of Hematology and Blood Transfusion, St. Petersburg, Russian Federation

Background. Iron overload is a negative marker in patients with myeloid neoplasms as it associated with non-leukemic events including VOD, GvHD and fungi infection. The mechanism of tissue damage by free iron includes formation of NTBI and LPI with following excess generation of ROS. Intensive chemotherapy is possible way of NTBI formation in patients with AML and risk factor of infection in collaboration with neutropenia. Aim. To find out the association between dynamics in some parameters of iron status and AO system in AML patients after intensive chemotherapy. Methods. The serum of 14 AML patients with median age 46 y (34-68) was prepared before and after chemotherapy, at day of WBC level >1x10^9/L and day of the following hospitalization. The chemotherapy regimens were 7+3 induction therapy (3 patients), courses with Ara-C dose ≥1 g/m^2 (8 patients) and Bu+Cph before AutoSCT (2 patients) and AlloSCT (1 patient). The levels of transferrin saturation, malone dialdehyde concentration, and activity of superoxide dismutase, catalase and ceruloplasmine were detected by standards assays. *Results*. After chemotherapy the range of TS levels was 92.8%-101.5% and the median value was significantly higher than before therapy: 96.8% vs 41.9%; p<.0001. At the time of hematopoiesis restoration the level of TS was lower than after chemotherapy: 89.5% vs 96.8%; p=.003. Activity of antioxidant enzymes was changed differently, and the variability of MDA levels during and after chemotherapy was without any significant change. After chemotherapy and during the period of aplasia the activity of catalasa was significantly lower than before therapy: 3.8 and 3.3 vs 5.7; p=0.028 and p=0.011. Activity of SOD was decreased only at the time when WBC was ≥1.0x10^9/L: 21.0 vs 41.0; p=0.018. At the same time the activity of CP was significantly higher than before chemotherapy: 1.1 vs 0.8 g/L; p=0.029.Three episodes if infection complications were registered after chemotherapy. One patient was diagnosed with herpes simplex skin involvement after restoration of hematopoiesis. Two cases of sepsis were diagnosed during aplasia with one lethal outcome. *Summary*. As the level of TS exceeded ≥80% is associated with NTBI formation (*Sahlstedt L. et al. Br.J.Haematol*

2001;113:836) we conclude that there is a phase of free iron overload in AML patients during the period of postCT cytopenia. The data support the idea that the changes of AOS are the compensate mechanism which have to deteriorate the complications of non-transferrin-bound iron after chemotherapy. The prospective clinical trial will be design to compare the clinical effectiveness of antioxidants after intensive chemotherapy.

1110

METABOLISM OF MEMBRANE PHOSPHOLIPIDS IN ACUTE LEUKEMIA AND DURING OF CHEMOTHERAPY

Y Hakobyan
Hematology Centre, Yerevan, Armenia

Background and aims. Membranes of blood lymphocytes were characterized with the significant phylogenetically stabilized phospholipids-phospholipids interrelations. It is well known that abnormalities of these interrelations play an important negative role in the development of pathogenic mechanisms, which condition inactivation of the membrane bound enzymatic systems, catalyzing the reactions transportation through membranes, as well as transduction of the external signals into the cell. The quantities and qualitative structure of phospholipids in the lymphocyte membranes, as well as lipids peroxidation processes and activity of phospholipase A2 have been studied in patients with acute leukemia and during of chemotherapy. *Materials and methods*. Experimental studies were carried out on 24 patients with first diagnosed acute leukemia. Biochemical analyses were done on first day and on tenth day: one group during traditional chemotherapy, second group during chemotherapy with additional antioxidant therapy. Fractionation of the individual phospholipids (PL) was realized by thin-layer chromatography with silica gel LC 5/40 m. After that the lipid phospholipids was defined. Lipids peroxidation activity has been determined by the reaction of malonic dialdehyde with tiobarbituric acid by the known method. Study of phosphlipasa A2 activity was accomplished by spectrophotometric assay modified. *Results and conclusions*. Our investigation showed to acute leukemia it is peculiar essential disturbance of the qualitative and quantitative contents of almost all representatives of lymphocytes membrane PL, mainly phosphatides. Under these conditions a pronounced increase of cytotoxic lysophosphatidylcholones (LPC) is accompanied by simultaneous pronounced of phosphatidylcholines (PC) concentration, which testifies about phospholipase A2 and lipid peroxidation processes activation. Hence, the acute leukemia is characterized by noticeable increase of the contents of diphosphatidylglycerides (DPG), while spingomyelins (SM), phosphatidylinosites (PI), phosphatidylethanolamine (PE) and phosphatidylserine (PS) decrease. While using chemotherapy alone in the treatment of acute leukemia is usually programmed for and followed by certain positive clinical outcomes, the combination of such treatment with additional antioxidant therapy results in more expressed biochemical changes. This method is bringing to normalization of phospholipase A2 and lipid peroxidation activity and balanced qualitative and quantitative structure of lymphocyte membrane PL. The changes of membrane PL can be qualitative characteristics of process activity. The same time level of balancing qualitative and quantitative structure of lymphocyte membrane PL is voluble index to appreciate treatment effectiveness.

TRIPTASE: A NEW ACUTE MYELOBLASTIC LEUKEMIA MARKER

S Fumero,[1] MT Gomez Casares,[1] CE López-Jorge,[1] J Lopez Brito,[1] L Guerra,[1] J Gao,[1] H Luzardo,[1] A Suarez[1], JD Gonzalez San Miguel,[2] K Quiroz,[1] Y Ramos,[1] A Losada,[1] T Molero[1]
[1]*Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain*
[2]*Hospital Insular, Las Palmas de Gran Canaria, Spain*

Background. Triptase is the main protein of human mast cell secretory granules. Recent studies have shown that serum triptase levels are high in 40% of patients with acute myeloblastic leukaemia (AML), especially in those with favourable karyotype, inv 16 and t(8;21), with or without association of KIT mutations. Aims. To study the incidence of high triptase levels in acute myeloblastic leukaemia. To analize the correlation between high triptase levels and other markers like CBF alterations and KIT mutations. To analize its relevance as minimal residual disease (MRD) biological marker. *Methods*. The study was performed prospectively and retrospectively on a total of 58 patients with acute myeloblastic leukaemia (except promyelocitic M3): 29 men and 19 women (27-87 years old). Serum triptase levels were quantified by FEIA. Acute myeloblastic leukaemia subtype, karyotype and molecular biology were examined at diagnosis of every patient included. Results: Out of 58 patients, 17 showed high triptase levels (29%): 1 M0, 1 M1, 4 M2 (1 M2 Eo), 6 M4 (5 M4 Eo), 2 M5 and 3 unknown subtype. Taking into account molecular alteration, high triptase levels were observed in 3 of 4 AML1-ETO positive patients (one of them with KIT mutation), 1 of 2 patients with inv16 and 2 of 9 patients with FLT3-ITD mutations. Higher triptase levels (>200) were observed associated with inv 16 and t(8;21). Out of these 17 patients with high triptase levels, we have evolution data of 12. We observed that out of these 12 patients, 6 reached normal triptase levels concurring with complete remission of the disease and in 2 patients, high triptase level kept despite achieving CR (these patients had the highest triptase levels among all the samples processed, 165 and > 200) and levels came back to a normal range afterwards. Out of these 12 patients, 4 showed refractory disease; 3 of them kept high triptase levels and in the one left (with slightly high levels at diagnosis), triptase came back early to a normal range, despite having active disease. From the patients who achieved CR, just one relapsed. She has a central nervous system relapse and bone marrow relapse later in time; showing an increase in triptase levels with the bone marrow relapse. *Conclusions*. 29% of AML patients showed high serum triptase levels, which is lower than the incidence published so far. The higher triptase levels (> 200 µg/L) were found in patients with AML1-ETO and inv 16, there seems to be an association with CBF rearrangement, as it has been described before. Triptase levels tend to decrease when CR is achieved, so it might be useful as a MRD biological marker, taking into account that this should be confirmed studying a greater number of patients.

1112

PLATELET AGGREGATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES -CORRELATIONS WITH THE FLUIDITY MEMBRANE CHANGES AND ROS LEVEL

I Popov,[1] A Vladareanu,[2] E Kovacs,[3] T Savopol,[3] M Iordache,[3] M Begu,[1] H Bumbea,[2] M Onisai,[2] A Nicolescu,[2] M Moisescu[3]
[1]*County Emergency Hospital, Pitesti, Romania*
[2]*Emergency University Hospital, Bucharest, Romania*
[3]*University of Medicine and Pharmacy Carol Davila Biophysics Department, Pitesti, Romania*

Background. Patients with myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) present severe alterations of platelet function. Platelets from these patients are dysplastic and have alterations in membrane and granular content. Aim The purpose of this study was to identify abnormalities in platelet function and a possible correlation with changes in platelet membrane fluidity and the reactive species level. Material and method We present a prospective study on 73 cases with MDS compared with 33 cases with AML admitted in University Emergency Hospital Bucharest. Three patients with AML were investigated in early stages and the phase of complete remission of the disease. Platelet function was investigated by platelet aggregation using as stimuli ADP, collagen, epinephrine and ristocetin. Membrane fluidity was assessed by fluorescence anisotropy measurements using TMA-DPH, the ROS level determination was performed using DCFDA method. Results. Platelet aggregation was altered in both groups of patients, more pronounced for AML patients. (AML vs. MDS: ADP 28.10 vs. 37.88, p=0.009; collagen 40.69 vs. 58.37, p=0.003; epinephrine vs. 16.48 24.16, p=0.14; ristocetin 43.73 vs. 50, p=0.37). No significant differences were obtained in the lag phase in the two groups of patients. The platelet aggregation response was ımproved in remission phase of AML for all reagents .The membrane anisotropy was ıncreased in AML patients compared with MDS patients(r = 0.1711 vs. 0. 1372, p = 0.002), this result correspond to low fluidity of membrane. There was not obtained a statistically significant correlation between the degree of membrane anisotropy and severity platelet function. Reactive species level is slightly higher in AML patients (0.0005280 vs. 0.0004051, p = 0.52). This level is significantly increased in advanced phase of disease.(LAM patıents 0.0006078 vs. 0.0001413, p= 0.003; MDS patıents 0.0005452 vs. 0.0001804, p=0.005). We could not establish a correlation of the fluidity changes depending on the level of ROS. *Conclusion*. AML patients have an advanced degree of alteration of platelet function and a low fluidity of platelet membranes compared to MDS patients. Achieving a clinical remission may improve platelet function, possibly due to a more appropriate expression of platelet receptors and / or improving cellular signaling, possibly correlated with low levels of reactive species.

1113

BENZENE - THE MOST IMPORTANT LEUKEMOGENIC FACTOR IN VOJVODINA

D Pejin,[1] S Popovic,[2] N Macvanin,[3] J Sudju,[3] G Bogdanovic,[4] D Jakimov,[4] J Mrdjanovic,[4] S Solajic[4]
[1]*Serbian Academy of Medical Sciences, Novi Sad, Serbia*
[2]*Clinic of Hematology, Faculty of Medicine, Novi Sad, Serbia*
[3]*The Institute for the Health Protection of Workers Novi Sad, Novi Sad, Serbia*
[4]*Oncology Institute of Vojvodina, Sremska Kamenica, Serbia*

Background. Benzene is the most toxic substance for hematopoesis. Hematotoxic effects are expressed as cytopenia, aplastic anemia, myelodysplasia, acute leukemia and other hemoblastoses, due to genotoxic effect or epigenetic modification. The most common consequence is acute myeloblastic leukemia (AML). There is no safe benzene concentration, no tolerance to benzene, and susceptibility is individual. Permissible concentration of benzene does not exist. Risk of AML is increased at cumulative exposure above 2 ppm-years and with intensity over 0.8 ppm. Inhalation is the most common exposure to benzene. During benzene metabolism, produced free oxygen radicals damage DNA, which could cause gene mutation or epigenetic modification with gene silencing. In Vojvodina, with petrochemical industry, agriculture with high pesticide usage and intensive road traffic, permanent increasing trend of AML was recorded during the last tree decades. On the basis of our clinical studies this can be explained by higher exposure to benzene. Of all adult patients with AML in Vojvodina 25% are from Novi Sad. *Aims*. The aim of this study was to analyze consequences of benzene exposure in residents of Novi Sad who are living near oil refinery. The second aim was to evaluate potential genotoxic damage in oil refinery workers occupationally exposed to benzene. *Methods*. Oxidative stress (OS) and DNA damage in the group of 60 residents environmentally exposed to benzene was investigated measuring 8-OhdG, which implies oxidation of DNA, in urine by gas chromatography-tandem mass spectrometry (GC-MS). Control group represented 60 residents from other parts of Novi Sad. Genotoxic biomarkers were investigated in peripheral blood lymphocytes in 313 refinery workers exposed to petroleum and its derivates using sensitive sister chromatid exchange test (SCE) and in minority of the workers by mononucleus test (MN). Control group represented persons without contact with benzene. *Results*. Examination of OS in environmentally exposed residents showed increased values of 8-OhdG. This result was significantly higher than in control group. Genotoxic biomarkers SCE and MN were significantly higher ($p<0.05$) in workers directly exposed to benzene in comparison to office workers. Cigarette smoking additionally increased SCE frequency. *Conclusions*. These results confirm our previous clinical studies which implicated that benzene is the most important leukemogenic factor. Low doses of benzene after inhalation can be enlarged by additional dermal contact or oral benzene intake with water. It is possible that low doses of benzene act in synergism with confounders (smoking, radiation, chemicals). Low doses of benzene and its metabolites could cause epigenetic modifications and immunodeficiency. On the basis of our research we would strongly support regulations for benzene concentration in Serbia and reduction of occupational full shift exposure in the range of 0.5-1 ppm, without high short exposures. Adequate individual protection, monitoring of biomarkers and hematologic examination are necessary. For ambiental air benzene concentration European limit is 5µg/m3. and benzene in gasoline is low (<1%). In agriculture biopesticides and biofertilizers are recommended. Persons with signs of oxygen stress, positive biomarkers for genotoxicity or epigenetic modification need chemoprevention by dietary polyphenols. Some AML patients with epigenetic modifications could be treated with hypomethylalting agents.

[13]*Hospital del Mar, Barcelona, Spain*

Background. The 2008 WHO classification recognizes acute myeloid leukemia (AML) with inv(3) (q21q26.2) or t(3;3) (q21;q26.2) as an independent clinicopathological entity, with an aggressive course and short survival. Its incidence is very low (1% of all AML) and immunophenotypic studies of this type of AML are limited. *Aims*. The purpose of the study was to analyze retrospectively the immunophenotypic features of leukemic blasts in patients with inv(3)(q21q26) or t(3;3)(q21;q26.2), through collecting a significant number of cases within the Spanish Group of Hematological Cytology (a working group into the Spanish Hematology and Hemotherapy Society). *Methods.* We collected a total of 35 cases [23 patients with AML inv(3) and 12 with AML t(3;3), mean age 50 years, range 14-84, males 54%], diagnosed between 1983 and 2010, in 13 national hospitals. During the time they were diagnosed, 2-, 3- or 4-color flow cytometric analysis was performed on peripheral blood or bone marrow aspirate specimens collected in EDTA. Although the panels of MoAb were not exactly similar in different centers, all included the most frequently used at diagnosis in acute leukemias. Cases were considered positive if 20% or more of the cells expressed the specific antigen. We compare our findings with those reported by Medeiros *et al*. in the most important series published to date (*Leuk Res, 2010*). *Results.* The following table compares the findings in our series with those published by Medeiros *et al*.

MoAb	Medeiros et al. (N = 15)	Spanish Group of Hematological Citology (N = 35)
CD34	13/15 (87%)	27/28 (96%)
CD33	15/15 (100%)	28/30 (93%)
CD13	15/15 (100%)	26/28 (93%)
CD117	9/13 (69%)	20/23 (87%)
CD38	3/14 (21%)	9/11 (82%)
HLA-Dr	11/14 (79%)	17/21 (81%)
CD7	7/15 (47%)	14/23 (61%)
CD123	NE	6/10 (60%)
CD11b	NE	9/18 (50%)
CD36	NE	5/11 (45%)
CD15	NE	8/19 (42%)
CD4	NE	7/18 (39%)
MPO	3/13 (23%)	7/19 (37%)
CD14	5/14 (36%)	7/20 (35%)
CD65	NE	3/9 (33%)
CD56	4/13 (31%)	4/20 (20%)
CD41/CD61	5%	3/19 (16%)
CD64	4/13 (31%)	1/7 (14%)
CD11c	7/14 (50%)	NE

Table 1. NE: not evaluated.

In our experience, more than 80% of the patients were positive for CD34, CD33, CD13, CD117, and HLA-Dr. Of note, contrary to Medeiros *et al*. and similarly to the revised 2008 WHO classification, we find a considerably high proportion of cases showing CD38 positive blasts. But also a relatively high rate of patients (>40%) were positive for CD123, CD11b, CD36 or CD15. The aberrant expression of CD4 is found in more than one third of cases. In our study, positive expression for CD3, CD8, CD10, CD20, TdT, or glycophorin (all antigens not analyzed in the other study) was never observed. *Conclusions.* Basically our results are consistent with those found by Medeiros *et al*., and blasts exhibit an immature myeloid phenotype with a frequent aberrant expression of CD7. However, an expanded panel can also find cases

positive for CD123, CD11b, CD36, CD15 and CD4. For the best of our knowledge, this is the largest series of patients with AML with inv(3)/t(3;3) that specifically studies the immunophenotypic characteristics of leukemic blasts.

1115

THE CHLOROQUINE DIPHOSPHATE CHANGES PROTEIN PNAS-2'S SUBCELLULAR LOCATION IN LEUKEMIC CELLS AND INDUCE THEM TO APOPTOSIS

HR Wang,[1] J Liu,[2] Z Zhong,[3] Z Zhong,[3] C Chen,[3] RR OuYang[3]
[1]*RenJi Hospital,School of Medicine, Shanghai Jiaotong University, Shanghai, China*
[2]*Department of Hematology, Ren-Ji Hospital and Shanghai Institute of Hematology, Shanghai, China*
[3]*Department of Hematology, Ren-Ji Hospital and Shanghai Institute of Hematology,, Shanghai, China*

Background. Previous studies in our laboratory had found PNAS-2 was an anti-apoptosis gene and might participated in leukemogenesis, this was confirm by scholars in Germany. When we studied Pnas-2-GFP fusion protein, we found Pnas-2's subcellular location in leukemic cells might be abnormal with instable membrane of multivesicular body. Some articles had reported chloroquine diphosphate (CQ) could stabilize membranal structures. *Aims*. We hypothesized that CQ might normalize Pnas-2's subcellular location in leukemic cells and by this way induce them to apoptosis. In this study, we explored whether CQ could induce leukemic cells to apoptosis or stabilize membrane of multivesicular body in leukemic cells. *Methods.* Both leukemic cell lines such as HL60, U937 and leukemic primary cells were studied. All samples were obtained with informed consent. *De novo* samples of 12 patients with acute leukemia (AL) were used in this study, including 1 M3, 6 M4, 5 M5 and 1 ALL patients. Seven samples of relapsed acute myeloid leukemia (1 M2, 4 M4 and 2 M5) and 4 CR patients (1 M3, 2 M4, 1 M5) were also assessed. Immunofluorescence method were applied to investigate Pnas-2's subcelluar location by using monoclonal antibody of PNAS-2 which was prepared by our laboratory. Annexin -V-APC/PI kit was used, after that, laser scanning confocal microscope and flow cytometery were applied to study apoptosis. U937 cells was study in each experiment and severed as a calibration to avoid experimental error. *Results*. We found just like we suspected previously, Pnas-2 protein was not only located in vesicles nearby the nucleus but also distributed throughout the cytosol in leukemic cells, instead of in vesicles which was nearby the nucleus in 293T cells and cells from healthy volunteers (*data not shown*).

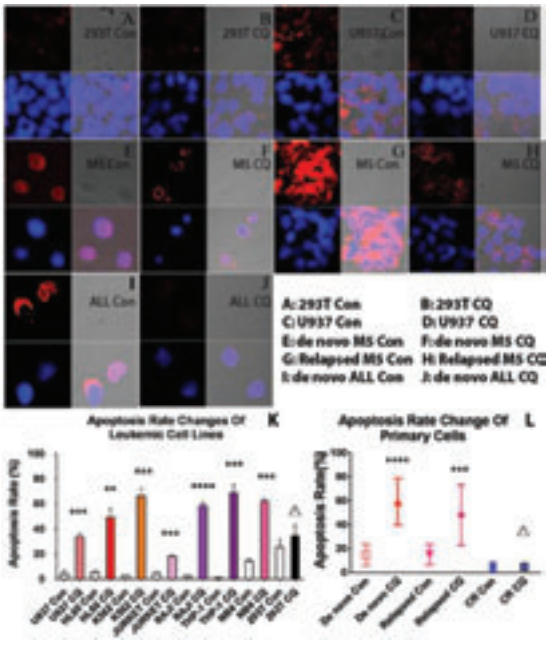

Figure 1. Pnas-2's subcellular location and apoptosis rate.

After the treatment CQ, Pnas-2 protein rehabilitated its subcellualar location: in vesicles nearby the nucleus.(Figure 1, A 293T Con, B 293T CQ, C U937 Con, D U937 CQ, E de novo M5 Con, F de novo M5 CQ, G Relapsed M5 Con, H Relapsed M5 CQ, I *de novo* ALL Con, J *de novo* ALL CQ) A remarkable increasing of apoptosis rate in leukemic cell lines and primary cells when treated by CQ was detected by both laser scanning confocal microscope and flow cytometery. But there was not statistic difference after the treatment CQ in cells from 293T and CR patients. (Figure). *Conclusions*. Pnas-2's subcellular location might be abnormal in leukemic cells. Pnas-2 protein was just in the multivesicular body nearby the nucleus in non-leukemic cells, but it was distributed throughout the cytosol in leukemic cells, this phenomenon might indicate the membranal structures of multivesicular body in the leukemic cells were instable. So we presumed that instability of membrane structures in leukemic cells might participate in leukemogenesis. CQ could induce leukemic cells to apoptosis when Pnas-2's subcellular location was recovered，as we mentioned, some experts had reported that CQ could stabilize membranal structures, so this phenomenon might indicate the mechanism of chloroquine diphosphate treatment for leukemia: stabilizing membrane of multivesicular body, then inducing leukemic cells to apoptosis.

1116

MEMBRANE MOLECULE PROFILE AND MUTATIONAL STATUS IN ACUTE MYELOID LEUKEMIA

H Reikvam,[1] K Petersen,[2] Ø Bruserud[3]
[1]*Institute of Medicine, University of Bergen, Bergen, Norway*
[2]*Department of Bioinformatics, University of Bergen, Bergen, Norway*
[3]*Institute of medicine, University of Bergen, Bergen, Norway*

Background. Flowcytometric characterization of membrane molecule expression is important for the characterization of the leukemic cells in patients with acute myeloid leukemia (AML). The membrane molecule profile is useful mainly as a diagnostic tool, e.g. to distinguish between myeloblasts and lymphoblasts and to detect lineage-associated differentiation markers, whereas mutational analyses (especially FLT3 and NPM1 mutations) are important in the prognostic evaluation of AML patients. *Aims*. We wanted to use a limited number of well-characterized differentiation markers to characterize the membrane molecule profile of primary human AML cells derived from an unselected cohort of AML patients, to use bioinformatic tolls to subclassify the patients based on this profile, and finally to investigate whether there was an association between these patient clusters and biological or clinical patient characteristics. *Methods*. The membrane molecule profile was investigated by flow cytometry for 162 consecutive AML patients. Unsupervised hierarchical clustering methods were used to identify distinct immunophenotypic clusters. *Results*. The markers CD11c, CD13, CD14, CD15, CD33, CD34, CD45 and HLA-DR were used in an unsupervised hierarchical cluster analyse (Persons correlation, with complete linkage), and six major different patient clusters (I-VI) were then identified based on the expression levels. The figure describes the major characteristics for each cluster. The left panel describe the immunophenotypic characteristics. Black symbols indicate that the patients in that cluster mainly stained positive for the respective membrane molecule. Likewise white squares represent mainly negative expression of the respective marker.

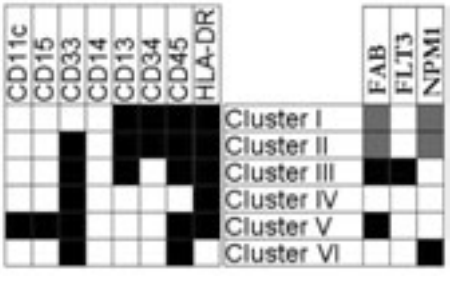

Figure 1. Characteristics of the immunophenotypic clusters.

The French-American-British (FAB) classification was used for a morphological evaluation of leukemic cell differentiation. Grey squares represent either (i) FAB subclasses M0/M1/M2, or (ii) FLT3/NPM1 wild type being present in at least 80% of the patients in the cluster. In contrast, black squares represent monocytic differentiation (FAB-M4/M5) or mutated FLT3/NPM1 alleles in at least 80% of patients in a specific cluster. White squares indicate no predominant morphology or mutational status in the respective cluster. The six clusters did not differ with regard

to age of the patients, hemoglobin levels or platelet count at diagnosis; in contrast to the morphology as well as frequency of genetic abnormalities which differed between the clusters. *Summary/Conclusions*. Our results suggest that there is an association between mutational status and morphological as well as molecular signs of differentiation in primary human AML cells. Our bioinformatical analysis suggests that the membrane molecule profile can be used to identify different subsets among patients with similar genetic abnormalities. Only future studies can clarify whether the patient clusters differ with regard to chemosensitivity and prognosis, and the potential role of specific mutation in for the phenotypic characteristics.

MONITORING OF MRD BY NPM1 MUTATIONS FROM MRNA AND GENOMIC DNA AND ITS COMPARISON WITH EXPRESSION OF WT1 GENE IN AML PATIENTS

R Petrbokova,[1] H Hájková,[1] J Polák,[1] O Fuchs,[1] C Šálek,[1]
D Dvoráková,[2] C Haškovec[1]
[1]*UHKT Praha, Prague 2, Czech Republic*
[2]*Fakultní Nemocnice Brno, Brno, Czech Republic*

Mutations of nucleophosmin 1 (NPM1) gene are the most frequent mutations in acute myeloid leukemia (AML) patients. In our Institute 20% AML patients have a mutation in NPM1 gene. Mutations in NPM1 gene were suggested as useful molecular markers for monitoring minimal residual disease (MRD) in AML patients. We compared monitoring of MRD by NPM1 mutations from both mRNA and genomic DNA with those of Wt-1 gene expression. The mutations of NPM1 gene and Wt-1 expression was estimated by a quantitative (RT)-PCR. MRD was estimated in 28 AML patients with mutation A of NPM1 gene and with a high Wt-1 expression at diagnosis. The results showed a very good correlation between NPM1 mutations and Wt-1 expression and a clinical course of the disease. Comparison of results of MRD monitoring by NPM1 mutations from mRNA and genomic DNA showed in 10 AML patients a utility of both approaches. The results obtained from genomic DNA seem to fit better clinical data. Molecular relapse estimated by NPM1 mutations and Wt-1 expression preceded hematological relapse by 36 (median) days. The advantage of the NPM1 gene as the marker of MRD is his negativity in control healthy persons and in AML patients in permanent remission. The presented results showed a utility of both NPM1 mutations and Wt-1 expression as molecular markers of MRD in AML patients.

The study was supported by IGA MZCR grant NS10632-3/2009 and IHBT00023736.

ACQUIRED COPY NUMBER ALTERATIONS AND COPY NEUTRAL LOH IN ADULT AMLS WITH NORMAL KARYOTYPE IDENTIFIED USING SINGLE-NUCLEOTIDE POLYMORPHISM MICROARRAY

SY Shin, EJ Seo, SS Jang, CJ Park, HS Chi, JH Lee, JH Lee, KH Lee
Asan Medical Center, University of Ulsan, College of Medicine, Seoul, South-Korea

Background. FLT3, ITD, and NPM1 are recently discovered biomarkers dissecting prognostic subgroups of AML with normal karyotype (AML-NK). Genome-wide single-nucleotide polymorphism (SNP) analys has devoted to reveal the previously unrecognized microdeletions and copy neutral LOH (CN-LOH). *Aims*. In the present study, we aimed to identify significant acquired CN-LOH and copy number alterations in AML-NK. *Methods*. Total 26 adult AML-NK cases were subjected. Exclusion criteria were any recurrent gene rearrangements of PML/RARA, BCR/ABL1,RUNX1/RUNX1T1, MLL, and CBFB/MYH11 or mutations in FLT3, ITD, and NPM1 genes. DNA was extracted from the bone marrow cells collected at the time of diagnosis. Parallel study was available with the bone marrow samples at complete remission state from 3 cases. Genome-wide SNP analysis was performed with HumanCytoSNP-12 bead chip (Illumina Inc.,USA). *Results*. Additional chromosomal copy changes were detected in 5 cases (19.2%); gains at 3p12.1-p14.1 (14.9Mb), 7q33-q36.3 (25.4Mb), 13q12-q34 (92.9Mb), and deletion at 11q13-q25 (61.1Mb), 13q14.11-q21.31 (21.2Mb). The parallel study with CR samples showed 9 germ line CN-LOH regions larger than 2Mb, all of which were smaller than 3.2 Mb. Overall 16 CN- LOH regions larger than germ line ones (>3.2 Mb) were observed in 14 cases, which were discriminated to two subgroups of different sizes. Eight CN-LOH regions observed in 7 cases were smaller than 6.0 Mb. While, the other 8 regions observed in 8 cases (30.8%) were distinctively large, including 3p12.2-q11.22 (17.3Mb), 4q22.1-q35.2 (102.2 Mb), 7q11.23-q36.3 (85.2Mb), 9p24.3-p13.3 (35.6Mb), 11p14.3-p11.12 (28.9 Mb), 11p15.5-p11.2 (45.7 Mb), 19q12-q13.43 (28.6 Mb and 31.3 Mb). CN-LOH in 19q12-q13.43 was recurrently observed in two different cases. *Summary/conclusions*. SNP microarray revealed additional copy number alterations at 19.2%, which were not detected in conventional karyotyping. We found significantly large CN-LOHs in 30.8% of AML-NK patients. Prognostic genes harbored in the large CN-LOHs, especially recurrent LOH region at 19q12-q13.43, need to be identified in further studies.

EXPRESSION OF APOPTOSIS-ASSOCIATED GENES IN ACUTE MYELOID LEUKEMIA (AML) - CORRELATION WITH PROGNOSIS AND DISEASE OUTCOME

N Tosic,[1] T Karan-Djurasevic,[1] M Stojiljkovic Petrovic,[1]
M Radmilovic,[1] T Kostic,[1] N Colovic,[2] M Colovic,[2] S Pavlovic[1]
[1]*IMGGE, Belgrade, Serbia*
[2]*Institute of Hematology, Clinical Center of Serbia, Belgrade, Serbia*

AML is a heterogeneous group of malignant disorders characterized by deregulation in differentiation, proliferation and apoptosis. Abnormalities in apoptotic pathways determine survival advantage and clonal domination of leukemic cells. The aim of this study was to determine expression pattern of the key genes involved in two distinctive apoptotic pathways. In extrinsic, receptor-mediated pathway, we analyzed the expression of Fas-receptor (Fas) and Fas-ligand (FasL) genes. In intrinsic pathway, mediated by Bcl2 gene family, we analyzed the expression of anti-apoptotic Bcl2 and pro-apoptotic Bax gene. We also examined the differential expression of membrane (mFas) and soluble (sFas) Fas transcripts, because up-regulation of sFas expression is implicated in pre-receptor blockage of Fas-induced apoptosis. Using RQ-PCR method we analyzed the m-RNA expression of Fas, FasL, Bcl2 and Bax gene in PBMCs collected from 39 AML patients and 6 healthy individuals. On the basis of cytogenetic findings patients were divided into 3 prognostic groups (Grimwade D, Blood 1998). Relative expression level for Fas and FasL gene was calculated using standard curve method, and for Bcl2 and Bax we used ddCt method. Abl gene was used as endogenous control and as a calibrator we used median expression from the healthy individuals. The mFas/sFas transcript ratio was determined on 2100-Bioanalyzer(Agilent). The expression of Fas (0.0-10.13, median 0.67) and FasL (0.00-17.00, median 0.045) among patients was very heterogeneous. In the case of FasL, the expression was significantly lower compared to the healthy individuals (0.41-1.32, median 1.00)(p=0.004). Using median expression level for Fas and FasL as a cut-off-value, the patients were divided into two groups with high or low expression. We didn't find any significant association between the expression levels of these genes and prognosis/outcome of the disease. Range of the obtained mFas/sFas ratio values among patients was very wide (0.39-17.33, median 2.28) and it wasn't significantly different from the values found in healthy individuals (1.34-2.19, median 1.82). The domination of sFas transcript (mFas/sFas<1,00) was found in 18.6% of AML cases, and it wasn't associated with an adverse outcome of the disease. The expression of Bcl2(0.14-1.29, median 0.48) and Bax(0.04-3.72, median 0.41) among patients was very heterogeneous, with no significant difference compared to the healthy controls. Using median expression level of Bcl2 and Bax as a cut-off-value, the patients were divided into two groups with high or low expression. High Bcl2 expression was associated with CD34+status (p=0.029), bad prognosis, and adverse outcome. Contrary to expectations, we found significant correlation between reduced expression of Bax and favorable prognosis (p=0.039). Based on the heterogeneous Fas and FasL gene expression pattern in AML patients, we concluded that the disruption of Fas-induced apoptosis is not essential for leukemogenic process. The domination of sFas transcript that was found in 18.6% of cases, further led to the conclusion that this mechanism of resistance to Fas-induced apoptosis is not dominant in AML. Our findings that patients with high Bcl2 expression level are in high risk of fatal outcome indicate that application of new therapeutics (antisense-Bcl2 oligonucleotides) could contribute to better survival of this group of patients.

THE EFFECT OF CURCUMIN ON TELOMERE LENGTH AND CASPASE ACTIVITY IN ACUTE MYELOID LEUKEMIC U937 CELL LINE

W Allers, E le Roux, M Meiring
University of the Free State, Bloemfontein, South Africa

Introduction. Apoptosis is a controlled cell death mechanism of eradicating irreversibly damaged or unwanted cells from the body. Activation of this process is achieved by the shortening of telomeres at chromosomal endpoints to a critical length. Apoptosis is then induced by either caspase-dependent or -independent pathways. Highly activated telomerase, a reverse transcriptase may prevent shortening of telomeres to the critical length needed to activate apoptosis. This may result in uncontrolled proliferation of cancerous cells and lead to disorders like acute myeloid leukaemia. Curcumin, commonly known as turmeric, has been reported to have anti-tumour and apoptotic potential. It may influence telomerase activity and cause apoptosis via a caspase dependent pathway. *Aim*. To determine the effect of Curcumin on telomere lengths and caspase 3 and -4 activity in U937 acute myeloid leukaemia cells. *Methods*. The U937 cell line was cultured and treated with different Curcumin concentrations for 24- and 48 hours respectively. The relative telomere lengths were determined using Flow FISH. This assay was performed to determine how Curcumin influences telomerase. ELISA's on caspase 3 - and caspase 4 activity, involved in the endoplasmic reticulum apoptotic pathway were performed. This was done to determine whether Curcumin influence the endoplasmic reticulum apoptotic pathway. *Results*. An increase in telomere lengths were observed with increasing Curcumin concentrations at 24 and 48 hour treatment periods. At a concentration of 10μM for the 24 hour treatment period, the telomeres were shortened. Caspase 3 - and caspase 4 activity mostly increased with increasing Curcumin concentrations. *Conclusions*. Curcumin might influence telomerase and cause telomere shortening, however an alternative way of telomere elongation have to be considered in that case. Curcumin does influence the endoplasmic reticulum pathway of apoptosis as illustrated by increasing caspase 3 - and caspase 4 activity and decreasing cell viability with increasing Curcumin concentrations.

EXPRESSION OF THE STEM CELL MARKERS CD133 AND CD90 ON BLASTS IN ACUTE MYELOID LEUKEMIA AND IN MYELODYSPLASTIC SYNDROMES IS ASSOCIATED WITH POOR PROGNOSIS

L Rigollet,[1] F Solly,[1] P Flandrin-Gresta,[1] N Nadal,[1] K Augeul-Meunier,[2] E Tavernier-Tardy,[2] D Guyotat,[2] L Campos-Guyotat[1]
[1]*CHU De St Etienne, Saint Etienne cedex 2, France*
[2]*Institut de Cancerologie de la Loire, Saint Etienne, France*

Background. CD133 and CD90 are surface markers expressed on various types of normal and cancer stem cells. Thus, we hypothesised that the expression of these two molecules could be of prognostic value in acute myeloid leukemia (AML) and in myelodysplastic syndrome (MDS), as describe in some other cancers. *Aims*. In this study, we analysed the expression of CD133 and CD90 on blasts in AML and MDS cases. The aim was to evaluate the stemness of the blasts and to correlate the expression of CD133 and CD90 to clinical outcome and to classical prognostic factors. *Methods*. The expression of CD133, CD90, CD34, CD38 and CD33 was evaluated by 8-colors flow cytometry on bone marrow samples collected at diagnosis for more than one hundred AML and MDS. On the blast population, we assessed the level of expression and the different co-expression profiles of these markers. Clinical and biological data were also collected. Results. Blasts expressed CD133 in approximately 40% of cases, generally at a high level. CD90 was detected in 10 to 40% of cases, depending on the cut-off chosen (3 to 20% of cells stained) with a level of expression fainter than CD133. Significant correlations exist between the stem cell markers assessed. As expected, CD133+ blasts are more immature than CD133-, and express CD34 higher. The expression of CD90 is correlated to that of CD34 too. Interestingly, in several cases, we could isolate two distinct subsets in blasts: CD34+ and CD34- displayed different patterns regarding the expression of CD133 and CD90. In most cases CD133 was present on CD34+ blasts while CD90+ was preferentially expressed on CD34-. Co-expression of CD133 and CD90 in the same subset is very rare. We assessed the correlation between the expression of CD133 or CD90 and usual prognostic factors, and clinical outcome. The expression of CD133, as that of CD90, was significantly different between patients with a favourable, intermediate or unfavourable karyotype. Expression of CD133 correlated also with the molecular prognostic profile. Moreover, CD133 and CD90 were associated with a higher risk of relapse. *Summary/conclusions*. CD133 and CD90 are expressed on normal haematopoietic stem cell (HSC) and other stem cells. They are markers of poor prognosis in several cancers but few studies analysed their expression in hematologic diseases. In this study we demonstrate that their expression correlates with prognosis factors as strong as cytogenetics. Interestingly, we observed different co-expression patterns for CD133, CD90 and CD34 within blasts. That heterogeneous population contains several subsets with different degree of stemness, as described in its normal counterpart. This could explain the relationship between CD133 and CD90 expression and clinical outcome. The prognostic value of the expression of CD133 and CD90 on blasts in AML and MDS must be confirmed and refined. Nevertheless, these encouraging results provide new insights into the leukemic stem cell characteristics. Moreover, as CD133 and CD90 correlate with robust prognostic factors, they may represent novel prognostic markers in AML and MDS, particularly for patients with intermediate risk karyotype.

INVESTIGATING THE IMPORTANCE OF MSI2 IN MLL-FUSION INDUCED ACUTE MYELOID LEUKEMIA

L Zhao, V Walf-Vorderwuelbecke, J de Boer, H Osaki, M Mangolini, O Williams
UCL Institute of Child Health, London, United Kingdom

Chromosome translocations that disrupt the mixed lineage leukaemia (MLL) gene are associated with a unique subset of Acute Myelogenous and Lymphoblastic Leukaemias. MLL translocations are most prevalent in infant leukaemia, where they comprise 80% of cases of acute lymphoblastic leukaemia and 60% of cases in acute myeloid leukaemia. Expression of MLL-fusion proteins is known to induce malignant transformation of normal haemopoetic progenitor cells. To identify transcriptional target genes required for the immortalisation, previous work in the lab involved generating constitutively and conditionally immortalised primary mouse haemopoietic progenitor cells. Global gene expression analysis, upon loss of MLL-fusion protein, identified a number of genes that are differentially expressed. One of these genes was Msi2, an RNA binding protein, which is found to be expressed in haemopoetic stem cells. MSI2 prevents cell differentiation by binding to the mRNA of the cell fate determinant protein, Numb, and repressing its translation. Recent reports identified MSI2 to be highly expressed in both Acute Myeloid Leukaemia and Chronic Myeloid Leukaemia. Using the conditionally MLL-ENL immortalised cell lines, the expression of Msi2 and Numb was analysed by qPCR. Loss of MLL-ENL fusion protein resulted in significant reduction in Msi2 expression and an increased level of Numb mRNA. shRNA mediated knockdown of Msi2, in the constitutively immortalised MLL-ENL cell lines, led to decreased cell proliferation in culture and reduced colony formation in methylcellulose. Interestingly Numb over-expression, in these immortalised cells, had no effect on proliferation but reduced their colony forming capability. In vivo studies, examining the importance of Msi2 and Numb in MLL-fusion induced leukaemia, are currently under investigation.

REGULATION OF THE MTG16 LEUKEMIA ASSOCIATED NUCLEAR CO-REPRESSOR GENE

A Ajore, K Kumar, S Dhanda, G Gullberg, O Olsson
Lund University, Lund, Sweden

The MTG16 gene, a member of the highly conserved ETO homologue family of corepressors also containing ETO and MTGR1, is implicated in hematopoietic development, in controlling erythropoiesis/megakaryopoiesis and is the 3´partner of t(16;21) generating the leukemic AML1-MTG16 fusion gene. We examined MTG16 gene promoter regulation to shed light on hematopoietic functions. A TATA- and CCAAT-less promoter containing a GC box close to start site was identified. Mutation of an evolutionary conserved GATA -301 consensus binding site repressed promoter function. Furthermore, results from in vitro antibody-enhanced electrophoretic mobility shift assay and in vivo chromatin immunoprecipitation indicated specific binding of GATA-1 to the GATA -301 site. The leukemia associated AML1-ETO fusion gene strongly suppressed all the ETO homologue promoters. In conclusion an evolutionary conserved GATA binding site is critical in transcriptional regulation of the MTG16 promoter. ETO has been shown previously also to be regulated by GATA-1. The third ETO homologue member, MTGR1 was found to be a *housekeeping* gene with a TATA-less promoter possibly regulated by the ubiquitous transcription factor SP1. Our results show ETO homologue promoters to be regulated differently consistent with hematopoietic cell type-specific expression and function.

1124

THE PRESENCE OF NPM1 MUTATIONS AS AN UNFAVORABLE FACTOR FOR OVERALL SURVIVAL AND FOR ACHIEVING COMPLETE REMISSION IN ACUTE MYELOID LEUKEMIA (AML)

N Tosic,[1] V Spasovski,[1] N Suvajdzic,[2]A Vidovic,[2] I Dunic,[2] D Tomin,[2] I Elezovic,[2] N Colovic,[2] M Colovic,[2] S Pavlovic[1]
[1]*IMGGE, Belgrade, Serbia*
[2]*Institute of Hematology, Clinical Center of Serbia, Belgrade, Serbia*

Background. Mutations in nucleophosmin (NPM1) gene are the most frequent abnormalities found in AML. Based on current findings, the presence of NPM1 mutations is associated with increased probability of complete remission (CR) and better overall survival (OS). *Aims*. To evaluate the incidence and the prognostic relevance of NPM1 mutations, their association with FLT3 mutations and other clinical characteristics. *Methods*. Bone marrow or peripheral blood samples from 92 adult de novo AML patients (median age 50 years, range 16-75; M/F: 53/39) were studied. NPM1 mutations were detected by PCR method and the products were directly sequenced (*Falini B, N Engl J Med 2005*). FLT3 mutations were detected as previously described (*Kiyoi H, Leukemia 1997; Yamamoto Y, Blood 2001*). *Results*. NPM1 mutations were detected in 17/92 patients (18.5%). Three types of mutation were detected; type A in 15/17 patients (88.2%) while the remaining two patients were carriers of type D and type K mutations, respectively. NPM1 mutations were closely associated with normal karyotype in 85.7% of cases, and with CD34- status (p=0.003). In 9/17 NPM1+ patients (53%), NPM1 mutations were associated with the presence of FLT3 gene mutations; in 6 (66.7%) patients with FLT3/ITD mutations, and in 3 (33.3%) patients with FLT3/D835 mutations. Complete remission was achieved in 7/17 NPM1+ patients. CR rate in NPM1+ patients was significantly lower than in NPM1-/ FLT3- patients (p=0.02). When double positive NPM1+/ FLT3+ patients (9 patients) and single positive FLT3+ patients were excluded from the calculation, CR rate was even lower (p=0.008) and CR was achieved in only 2/8 NPM1+ patients. No significant difference between NPM1+ and NPM1- patients was found concerning median duration of disease-free-survival (DFS) (10.5 vs. 12 months, p=0.38 Log-rank). Surprisingly, median OS among NPM1+ patients was significantly lower compared to NPM1- patients (4 vs. 10 months, p=0.015 Log-rank). *Conclusions*. The frequency of NPM1 mutations (18.5%) found in our study was slightly lower than in other previously published reports. The explanation for this may lie in the fact that 30% of our patients were younger than 40 years and only 13.5% were older than 60 years, while NPM1 mutations have been shown to be more frequent in older patients. Young age structure of our cohort may also be the reason for unexpected finding that NPM1 mutations had an unfavorable impact on the CR rate and OS. It was previously shown that NPM1 mutations had favorable prognostic impact in older patients, especially those age ≥ 70 years, while in some other studies carried out on cohorts with different age structure, NPM1 mutations were associated with a higher relapse rate and poorer DFS. Association of NPM1 mutations with FLT3/ITD mutations, which have dominant adverse prognostic effect (also found in our study), may explain this unfavorable impact of NPM1 mutations. Recent data show that even in the presence of prognostically favorable NPM1 mutations, some AML patients may have an adverse outcome, suggesting that some other secondary genetic lesions may cooperate with NMP1 mutations influencing prognosis.

CCAAT/ENHANCER BINDING PROTEIN ? EXPRESSION IN T(15;17) ACUTE PROMYELOCYTIC LEUKEMIA

N Kassem,[1] R Khalifa,[2] H El Zawam[2]
[1]*Kasr Al-Aini, School of Medicine , Cairo University, Egypt, Cairo, Egypt*
[2]*Kasr Al-Aini, School of Medicine; Cairo University, Cairo, Egypt*

Background. Given the role that CCAAT/enhancer binding protein α (C/EBP α) plays in myelopoiesis, we anticipated that their expression might be disrupted in myeloid neoplasms including acute promyelocytic leukemia (APL). *Purpose*. To estimate the expression of C/EBPα in patients with APL for evaluation of its role in the pathogenesis of the disease, and to assess response of these patients with variable expression levels of CEBPα to therapeutic regimen combining all-transretinoic acid (ATRA) with chemotherapy. *Patients and Methods*. Forty APL patients with t(15; 17), detected by FISH analysis, and 10 age and sex matched healthy controls were included in the study. Blood samples of patients and controls were analyzed for CEBPα expression by quantitative RT-real time PCR using TaqMan technology. *Results.* Thirty six (90%) patients out of the 40 showed low expression levels of CEBPα below the cutoff value with median of 0.51 (range:0.0007-0.96). Following therapy, full maturation of myeloid series was seen in 31 patients (77.5%). These patients had higher median level of CEBPα of 0.6 (range: 0.22-26.7) compared to other 9 patients (22.5%) who showed partial response to therapy (median level: 0.03; range: 0.0007-0.15; p<0.0001). *Conclusions*. Our findings are highly suggestive that C/EBPα may have a role in the pathogenesis and prognosis of APL.

1127

CORRELATION OF WT1 EXPRESSION WITH THE BURDEN OF TOTAL AND RESIDUAL LEUKEMIC BLASTS IN BONE MARROW SAMPLES OF ACUTE MYELOID LEUKEMIA PATIENTS

JM Alonso Dominguez,[1] M Tenorio,[2] S Grande,[2] J Rodriguez Gambarte,[1] E Roldan[2], R Ayala[3]
[1]*Hospital Ramon y Cajal, Madrid, Spain*
[2]*Hsopital Ramon y Cajal, Madrid, Spain*
[1]*Hospital 12 de Octubre, Madrid, Spain*

Background. WT1 gene encodes a transcription factor that is physiologically expressed in hematopoietic stem cells. It is related to cell development and survival. It is overexpressed in different haematological malignancies like acute myeloid leukemia. Hence, it can be used as minimal residual disease marker. *Aims*. Given that WT1 is expressed in developing not aberrant hematopoietic stem cells, we want to check if its level of expression is more accurately related to the total blast burden than to leukaemic blast burden in bone marrow samples of *de novo* acute myeloid leukaemia patients (non M3). *Patients and methods*. We have collected 18 minimal residual disease values measured at different time points in 11 different patients. Median age was 52 years (17-75). All of them had a basal diagnostic determination of WT1 expression and others following chemotherapic treatments. WT1 expression was determined by RT-qPCR. A retrotranscription reaction was performed and WT1 transcripts were measured using a relative quantification with GUS as a housekeeping gene. Four colours flow cytometry (FC) was used to quantify residual leukaemic blasts. Total blast burden was determined by bone marrow cytology. Flow cytometry (FC) and bone marrow cytology values were transformed into percentages referred to basal diagnostic ones to mimic the way WT1 measurements are expressed. Three samples were not evaluable by bone marrow cytology. Statistical analysis was carried out using Spearman test correlating 18 sample values of FC and RT-qPCR and 15 values of RT-qPCR and bone marrow cytology. *Results*. We have found a mild correlation (0.56, p< 0.01) between leukemic blasts count and WT1 expression and a stronger correlation (0.86, p< 0.0001) between WT1 expression and total blast count. Conclusions. The stronger correlation found between total (leukaemic and regeneration) blast count and WT1 expression levels confirms that it is related to normal hematopoietic stem cell development. It also suggests that this way of determining minimal residual disease in bone marrow samples of acute leukaemia patients after receiving chemotherapy or G-CSF is not reliable.

1128

ACUTE MYELOID LEUKEMIA IN UNSELECTED COHORT OF ELDERLY PATIENTS: RESULTS OF INDUCTION VERSUS NONCURATIVE TREATMENT

M Colovic,[1] D Tomin,[1] N Colovic,[1] M Radojkovic,[2] D Stanisavljevic,[2] N Kraguljac,[1] N Suvajdzic[1]
[1]*Clinic of Haematology, Clinical Center Serbia and Medical Faculty Belgrade, Belgrade, Serbia*
[2]*Medical Faculty, Belgrade, Serbia*

Introduction. The aim of our study was to analyze the results of treatment in elderly group of patients with AML diagnosed at the Institute of Hematology in Belgrade over a period of 6 years. We wanted to identify prognostic factors important for making decision how to treat elderly patients, with induction chemotherapy or with supportive or palliative therapy only. *Material and results*. A retrospective analysis of 210 consecutive patients aged ≥ 65 years (median age 69, range 65-88) with acute myeloid leukemia (AML) diagnosed at a single center over the period of 6 years from January 2001 to December 2006 was performed. All patients who were included in this study provided informed consent

according to Helsinki Declaration. There was 179 (85.2%) patients with de novo AML and 31 (14.7%) with secondary. The patients' morphological FAB type equivalents were M0 23 (11%), M1 36 (17.15%), M2 57 (27.1%), M3 8 (3.8%), M4 45 (21.4%), M5 31 (14.8%), M6 1 (0.5%), M7 1 (0.5%) and 8 (3.8%) unclassified. The patients with M3 FAB type were excluded from the further analyses. Cytogenetic analysis was performed in 172/202 (85%) patients,. Normal karyotype was found in 81/172 (47%), favorable in 13/172 (7.5%), complex karyotype in 32/172 (18.6%) and analysis was unsuccessful in 28 (16.2%) patients. The whole cohort of patients was divided in NIC group (no induction chemotherapy but palliative and supportive therapy) which consisted of 115 (56.9%) patients and 87 (43.1%) patients in IC group (patinets who received induction chemotherapy). Complete remission (CR) was achieved in 45/87 (51.7%) and in 5 patients in NIC group which were treated with low doses cytosine arabinoside. After median follow up of four years deaths occurred in 194 patients (96%). In univariate analysis, significant factors for longer OS were age, ECOG performance status (p=0.000, CI 95.0%, 1.358-2.049), serum LDH (p=0.000, CI 95.0%, 1.465-2.946), number of white blood cells, (p=0.011, CI 95.0%, 1.102-2.100), splenomegaly (p=0.015, CI 95.0%, 1.082-2.102), hepatomegaly (p=0.008, CI 95.0%, 1.125-2.171). In multivariate analysis significant factors for OS were induction chemotherapy, sLDH, ECOG performance status and achievement of CR. *Conclusions*. Elderly AML patients belong to different prognostic subgroups which can benefit from different therapeutic approaches. Treatment decision in elderly AML patients is complex and the results of intensive versus palliative treatment should be investigated in randomized prospective studies and this group of patients representing the vast majority of AML patients should not be neglected.

1129

PRIMARY RESISTENT ACUTE MYELOID LEUKEMIA

N Colovic,[1] D Tomin,[1] A Vidovic,[1] G Jankovic,[2] N Suvajdzic,[2] V Palibrk,[1] I Djunic,[1] V Djurasinovic,[1] M Virijevic,[1] N Kraguljac,[1] V Djordjevic[1]

[1]*Clinic of Hematology, Belgrade, Serbia*
[2]*Medical Faculty, Belgrade, Serbia*

Aim of the study. Standard combination (anthracyclines and ARA-C) as remission induction chemotherapy for de novo acute myeloid leukemia (AML) results in complete remission (CR) rates of 55-70%, the rest showing a partial response, absolute resistance or leukemic regrowth after two courses of remission-induction therapy. These rates had not improved for the last 20 years with. We analyzed prognostic factors in 53 patients with AML who failed to achieve CR after the first-line standard-dose remission-induction therapy. *Results*. Over a study period of five years, fifty three patients with AML (48 with de novo and 5 with a secondary) received two cycles of the MRC AML10 protocol as a first-line standard-dose remission-induction therapy [ARA-C, days 1-7 and daunorubicin, days 1-3]. The HDAC (5 pts), MiDAC (7 pts), and FLAG-IDA protocols (3 pts) were given as salvage. All patients who were included in this study provided informed consent according to Helsinki Declaration. None of the patients achieved CR. There were 27(49%) males and 26 (51%) females (median age, 55.7 years (range 28-76). None presented with the central nervous system involvement. Six (11.1%) patients had M0, 9 (16.9%) M1, 20 (37.7%) M2, 4 (7.5%) M4, 11 (20.8%) M5, and 3 (5.6%) the mixed phenotype AML (FAB Classification). Thirty one (57.4%) patients had the intermediate risk karyotype changes and 12 (22.6%) the unfavorable ones. The medians of WBC count were 53 (range 0.9 -350) $x10^9$/L, platelets 55 (range 1-204 $x10^9$/l) and the bone marrow blasts, 67%. Two (3.8%) patients scored 3, 11 (20.8%) scored 2, 12 (2 2.6%) scored 1 and 16 (30.2%) scored 0 by Sorror comorbidity score. Median overall survival (OS) was 5 months (range 1-14). There was a significant correlation between OS and ECOG PS . Patients with ECOG 0-2, suvived longer than patients with ECOG 3 and 4(p<0.001). Presence of hepatomegaly influenced OS (p<0.01) while splenomegaly was of no consequence (p>0.05). Patients with the WBC ≤ $25x10^9$/l had a longer OS (p<0.001). The platelet count had no impact on OS ((p>0.05). The serum level of LDH had no influence on OS. The OS significantly differed between patients with intermediate-risk and unfavorable cytogenetics (p<0.001) and between patients with and without trilineage dysplasia (p<0.01). The comorbidity score influenced OS, the patients with score 1 surviving significantly longer than those with score 2 (p<0.01). *Conclusions*. The subgroups of patients with AML show distinctive clinical characteristics suggesting a different biology of disease. A higher prevalence of comorbidity and a sharp diversity in biological features account for the poor response to therapy in this cohort of AML patients.

1130

AGE AND KARYOTYPE ARE THE MAIN PROGNOSTIC FACTORS IN PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA

S Gritsaev, I Martinkevitch, M Ivanova, L Martinenko, S Tiranova, K Abdulkadyrov

Russian Institute of Hematology and Blood Transfusion, St. Petersburg, Russian Federation

Background. The main method to determine the intensity of chemotherapy of patients with acute myeloid leukemia is the stratification according to prognostic factors. There are many markers of prognosis including clinical, morphological, cytogenetic and genetic lesions. It has been shown previously that the survival of older AML patients is worse than younger patients. Another principal marker is karyotype which aloud to stratify AML patients into three prognostic categories. *Aim.* To determine whether age and karyotype are associated with overall survival of patients with de novo AML. *Methods*. The retrospective analysis of history of 214 patients with de novo AML was performed. The patients were treated with different kinds of induction and postremission therapy including AlloSCT and AutoSCT during the period from 1990 till 2009. The median age of patients was 57 y. (16-84). The patients were separated into 3 age groups: 16-40, 41-60 and ≥61. As there was no difference in OS between first two groups they were united. Four cytogenetic groups were designed in every age categories. The cases without cytogenetics abnormalities were separated into independent group. The group with balanced karyotype includes t(8;21), t(15;17) and inv(16). Cases with ≥3 chromosomal aberrations were united into complex karyotype. All others cases were joined in group with unbalanced aberrations. *Results*. The difference in the median OS of patients aged ≤60 years and ≥61 years was statistically significant: 18.6 mo. vs 7 mo.; p<.001. The 5-y. OS in the aged groups was 31.5% vs 0%. The difference in the median of survival between patients' groups with balanced, normal, unbalanced and complex karyotype was statistically significant, too: 15 mo., 13 mo., 10 mo. and 6.0 mo, respectively; p<.001. The 5-y. OS in the groups with different karyotype was 40.5%, 26.7%, 12.4% and 3.6%. In multivariate analysis the age (≤ 60 y. vs ≥ 61 y.) and karyotype (4 groups) were independent prognostic factors: p<.001 and p=.004; respectively. When patients with different karyotype were grouped according to the age (≤60 y. and ≥61 y.) the difference in median survival was significant only in the younger patients. The median OS in younger patients with balanced, normal, unbalanced and complex karyotype was 16, 15, 12 and 8 mo, respectively; p=0.006. Estimated 5-y. OS of patients ≤ 60 y. with different karyotype was 44.4%, 34.6%, 15.2% and 1.4%, respectively *Summary*. The data aloud to use age (≤60 y. vs ≥61 y) and karyotype (in patients ≤60 y.) as prognostic factors for stratification AML patients at the time of diagnosis of the disease.

1131

RESPONSE TO 5-AZACITIDINE IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND SECUNDARY AML: RESULTS

D De Miguel

Hospital Universitario de Guadalajara, Guadalajara, Spain

Background. 5-azacitidine (AZA) significantly prolonged overall survival in higher-risk patients with myelodysplastic syndromes (MDS) in international phase III trial (AZA-001). However, data about efficacy of AZA in lower risk MDS are less consistent and only few studies have addressed this topic. *Material and Methods*. we evaluate the efficacy and safety in all MDS groups and secondary AML patients, non candidates to aggressive therapy. Results. In our institution, a total of 27 patients were treated with AZA since 2006. We evaluated 13 patients diagnosed according to WHO criteria as low/intermediate-1 International Prognostic Scoring System (IPSS) risk MDS, 10 patients as high/int-2 IPSS risk MDS and 4 secondary AML diagnosed patients. At baseline, median age was 73.2 years (range 46-86), male/female ratio 15/12. Median time from diagnosis was 29.4 months (range 1-192). 85% patients were transfusion-dependent, 89% had received a prior treatment (rhu-EPO+G-CSF 55%, only rhu-EPO 34%). High risk MDS and AML patients received AZA dose of 75mg/sqm/d subcutaneously during days 1-7, in a 28-day cycle; and low-risk received same schedule by 5 days. The median number of monthly cycles was 10.0 (range 1-39), and 70.3% completed at least 6 cycles. Grade 3-4 adverse events documented in these patients were neutropénica (11%), anaemia and thrombopenia (7.4%), injection site reaction (18.5%), 25.9% constipation, 11% diarrhea and 3.7% nauseas. Response duration ranged from 1 to 8 months. There were no significant differences in response rate according to age, previous treatment, transfusion requirements, basal EPO and Hb pre-AZA. 5 patients were trans-

formed to AML after median 10.4 cycles of AZA (2-13). *Conclusions*. 1.- 90% patients achieved a hematologic response. 2.- Time to response is early (3months), although some patients response later (5 cycles or more). 3.- Efficacy and safety of AZA treatment is a valid alternative in low/int-1 risk MDS patients, although more studies are necessary. 4.- In secondary AML patients, AZA is a excellent alternative therapy in patients with co-morbidity and poor performance status.

1132

ASSOCIATION OF CD34 CELL SURFACE ANTIGEN EXPRESSION WITH CYTOMORPHOLOGICAL CHARACTERISTICS OF ACUTE PROMYELOCYTIC LEUKEMIA BLASTS AND CLINICAL CHARACTERISTICS OF PATIENTS: ONE CENTER EXPERIENCE

A Ostojic, M Pazur, Z Siftar, M Kardum-Paro, B Jelic-Puskaric, N Gredelj-Simec, D Radic-Kristo, I Kardum-Skelin, R Vrhovac, B Jaksic
University Hospital Merkur, Zagreb, Croatia

Background. Acute promyelocytic leukemia (APL) is characterized by leukemic cells blocked at the promyelocytic stage of granulocytic differentiation (APL-blasts). Two main cytological subtypes are recognized: classical hypergranular promyelocytic leukemia (M3) and the microgranular promyelocytic leukemia variant (M3v). A 3-parameter classification system (nucleus, granularity and Auer rods) leads to the distinction of 12 categories of APL-blasts with 3 additional categories (with basophilic granules, Chediak granules and Pelger-like maturing cells). Low or negative CD34 expression in addition to absent HLA-DR used to be the paradigm of the APL immunophenotype. However, higher CD34 expression can occur in APL and appears to be associated with leukocytosis, hypogranular morphology and poorer clinical outcome. AIMS: to investigate association between cytomorphology and immunophenotypic expression of CD34 cell surface antigen of APL-blasts and their relationship with clinical and laboratory characteristics of patients with acute promyelocytic leukemia. *Patients and Methods.* Sixteen consecutive patients diagnosed with APL at Department of Hematology, University Hospital Merkur, between August 1998 and December 2010, were included in this study. Patients' clinical and laboratory features, cytomorphological characterstics of APL-blasts and their immunophenotype determined by flow cytometry were analyzed. Patients were grouped into 2 groups, CD34(-) and CD34(+), and were then compared according to clinical and laboratory characteristics. Expression in more than 20% blast cells was required to define antigen positivity. RESULTS: Mean age of patients at diagnosis was 43.9 years (range: 18-78, SD14.9), 69% of patients were male. All evaluable patients had high CD13 and CD33 expression, with low HLA/DR expression, except one who had higher HLA/DR expression (HLA/DR(-) blasts: 27.6%). There was no statistically relevant difference between patients grouped according to CD34 expression according to gender, age or WBC counts. Mean value of hypogranular/agranular APL-blasts in CD34(+) group was 34% (range: 9-60, SD 24.4), markedly higher than in the CD34(-) group, 11.5% (range 0-38, SD 13.7), with borderline statistical significance (Mann Whitney, p=0.055) (fig. 1). CD34(-) patients had significantly better overall survival than CD34(+) ones (p=0.02). *Conclusions*. Our results are consistent with the results of other published studies and point to the fact that higher CD34 expression and lower cytoplasmic granularity of APL-blasts are factors that seem to define a specific subgroup of patients with APL. Together with other diagnostic tools they could be of value in planning treatment of patients with acute promyelocytic leukemia.

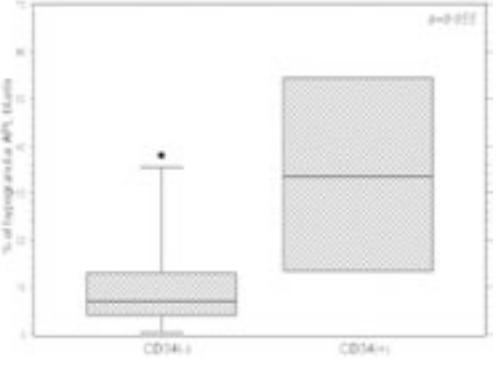

Figure 1. Hypogranular APL-blasts and CD34 expression.

1133

COMPLETE REMISSION AND EARLY DEATH AFTER INTENSIVE CHEMOTHERAPY IN PATIENTS AGED 60 YEARS AND OVER WITH ACUTE MYELOID LEUKEMIA: RESULTS OF A POPULATION-BASED APPLICATION OF A WEB-BASED SCORING SYSTEM

C Carey, T Menne, N Bown, G Jackson, G Jones
Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

Background. Acute myeloid leukaemia (AML) in patients aged ≥ 60 years at diagnosis is difficult to treat, with median survival typically < 12 months. Recently, the German AML Cooperative Group and the Study Alliance Leukaemia Investigators published a predictive scoring system using data from clinical trials of intensive induction chemotherapy (IIC) (*Krug et al., Lancet 2010; 376: 2000-8*). This scoring system can potentially predict the probability of complete remission (CR) and early death (ED) amongst patients considered fit for IIC. Used alongside clinical assessments, this could be a valuable tool when counselling patients regarding potential risks and benefits of treatment. *Aims*. To assess the utility of the published web-based scoring system when applied retrospectively to a population-based cohort of AML (excluding acute promyelocytic leukaemia [APL]) patients aged ≥ 60 years, diagnosed January 2007-December 2010. *Methods*. Records of our team's multidisciplinary meetings (MDM) were reviewed to identify the study cohort. The regional population studied was that of Northumberland, Newcastle upon Tyne, Cumbria and County Durham (population approximately 1.5 million). Diagnostic material was centrally reviewed. Well recognised prognostic information was collected including age, haemoglobin concentration, platelet count, serum lactate dehydrogenase concentration, *de novo*/secondary disease, plasma fibrinogen concentration and cytogenetic risk group (low, intermediate or high, as per Krug et al). Treatment intention, response, dates of relapse, death and cause of death were recorded. CR was defined as marrow blasts <5% with peripheral blood count recovery. ED was defined as death within 60 days of chemotherapy commencement. Risk scores were calculated at *www.AML-Score.org*. *Results*. 46 patients (median age 65, range 60-75years) were diagnosed with AML and deemed fit for IIC, during the study period. Cytogenetic information was available for 40 patients: 2 low risk, 29 intermediate risk and 9 poor risk. FLT3 and NPM1 mutation status was available for 41 patients. CR rate was 28/43 (65%) on intention to treat analysis; 4 patients were non-assessable due to early death, data missing (n=2). There were 9 early deaths (21%) with data missing for 1 patient. Median disease free and overall survivals were 9 and 10 months respectively. Median probabilities of ED predicted by the model for patients who experienced ED or not were 22.6%(range 15.3-37.5%) and 20.6%(range 10.4-50.1%) respectively. Median probabilities of CR predicted for patients who attained CR or not were 55.9%(range 20.7-80.3%) and 55.6%(range 25.2-73.7%) respectively. Of patients with scores predicting >50% probability of CR, 18/22 entered CR (82%), for those with predicted CR <50%, 10/15 (66%) entered CR. *Conclusion*s. In this population-based cohort the AML scoring system was not a useful predictor of individual's ED or attainment of CR. Patients in this cohort were younger than those of Krug et al where median age was 67 years (range 60-85); we may have a more conservative approach to the use of IIC than the German Group. This may explain the slightly higher CR rate in our study (65% vs 53%). It would be useful to reassess this model prospectively in a larger cohort.

1134

OUTCOME OF FIT AML OLDER PATIENTS IN A SINGLE CENTER: MAJOR ROLE OF CYTOGENETICS

J Nguyen,[1] T Vo,[1] B Bailly,[2] S Benghiat,[1] B Dessart,[2] P Lewalle,[1] B Cantinieaux,[3] N Meuleman,[1] D Bron[1]
[1]*Institut Jules Bordet, Brussels, Belgium*
[2]*Hôpital Erasme, Brussels, Belgium*
[3]*Hôpital St Pierre, Brussels, Belgium*

Background. Acute Myeloid Leukemia (AML) is most common in older patients and they are often thought to be unfit for chemotherapy. Patients with poor prognostic karyotype are even not recommended for treatment outside clinical protocols. In this context prognostic factors are important tools for clinical judgement, decision making and pt information. Objectives. We retrospectively reviewed whether this assessment is validated in our AML population older than 60 yo. Population and methods. 89 AML pts, 60 yo and older, PS < 2, were referred to our centre between 1997 and December 2009. Pts requiring treatment were

treated according to the EORTC (LAM 13 and LAM 17) protocols for pts above 60 yo. AMLs were classified according to the old FAB classification. Cytogenetic data were obtained by routine karyotype and additional FISH analysis since 1995. Complete remission was defined by morphology and flow cytometry on bone marrow smear. Karyotypes were stratified according to good and intermediate 1 versus intermediate 2 and poor prognosis (ELN recommendation). Statistical analyses using age and Karyotype were performed for the following outcomes: complete remission (CR), overall survival, median survival and disease-free survival. *Results*. 82 files were evaluable for cytogenetic data and outcome. Median age was 70 (60-86) yo. Because we are a referral tumour centre, all the pts had a PS <3 and no geriatric syndrome (falls, dementia, incontinence). The median follow up time was 40 (1-180) months. Overall survival for the whole population was 17% at 180 months with a median survival of 7 months. Median survivals of pts below 70 yo was significantly better ($p < 0.0001$) than pts above 70 yo (38 vs 7 months). Whatever the age, median survival was significantly better for pts in CR after the induction (48 vs 6 months) and presenting with a favourable Karyotype (35 vs 9 months). Taking into account the cytogenetic data and age, the median survival of AML pts below 70 yo with a favourable Karyotype was 64 months with 40% of CCR, very similar to the younger population Conclusions. In our series of selected fit elderly AML pts, we confirm that cytogenetic data have a major impact of OS and CCR in pts between 60 and 70 yo. For patients above 70 yo, median survival remains unsatisfactory and these pts should be offered new alternative treatment approaches after an extended geriatric assessment.

1135

CLOFARABINE IN THE TREATMENT OF POOR PROGNOSIS ACUTE MYELOID LEUKEMIA PATIENTS. A SINGLE INSTITUTION REVIEW

S Solórzano, A De la Fuente, M Estévez, R De Oña, R Iglesias, A Martinez, J Fernandez de Velasco, JF Tomás
MD Anderson IE, Madrid, Spain

Introduction. The incidence of Acute Myeloid Leukemia (AML) increases with age, and Cytarabine plus Antracycline based treatments usually unfit for older patients, therefore worsening their prognosis and increasing the relapse rate. Clofarabine is a purine nucleoside antimetabolite indicated in refractory pediatric Lymphoblastic Leukemia, but with demonstrated efficacy in AML patients in combination with Cytarabine, with tolerable side effects, becoming an option for those patients with relapse/refractory AML, as well as for those non candidates for aggressive approaches. *Aims*. To evaluate the effectiveness and toxicity profile of Clofarabine in AML elderly patients. *Methods*. This is a single-center retrospective review of patients with AML treated with Clofarabine based regimens in patients aged 60 and above. Main points were complete response as IWRv2003 criteria and toxicity as CTCAE v3.0 del NCI criteria. *Results*. In the period between January 2007 and December 2010, 6 AML patients above the age of 60 began treatment with Clofarabine (30 or 20 mg/m2/day x 5 days) plus AraC (500 mg/m2/12h x 8 doses). The mean age was 68.5 (63-77), and the ratio male/female 4/2. AML *de novo*: 2 patients. Salvage therapy: 4 patients. Five of the 6 patients (85%) presented poor prognosis cytogenetic alterations. *Effectiveness*. Two patients (33%) obtained complete remission, with a progression free survival of 7 and 4 months (mean 5.5), and an overall survival of 9 and 10 months (mean 9.5), respectively. No effective data of 30 mg/m2/day dose patients are collected, because they were exitus within the first cycle. *Toxicity*. Hematologic toxicity was observed in all patients, grade 4 Neutropenia, grade 4 trombocytopenia and anemia transfusion-dependent.

Age	Status	Cytogenetic	Previous lines	Clofarabine Dose (mg/m2)	Response	PFS (months)	Overall Survival
63	Refractory	Poor	1	30	Not evaluated	--	1
66	Relapse	Poor	1	20	CR	7	9
68	Relapse	Poor	1	30	Not evaluated	--	1
65	Relapse	Normal	4	20	Refractory	--	7
72	De novo	Poor	0	20	Refractory	--	10
77	De novo	Poor	0	20	CR	4	7
							Mean 5.8

The 2 patients treated with 30 mg/m2/day x 5 days were exitus because of septic shock during the induction cycle. There was no correlation between number of previous lines received and toxicity. No relevant extrahematologyc toxicity was reported in patients treated with 20 mg/m2/day x 5 days. *Conclusions*. Our experience confirms that Clofarabine at 20mg/m2/day (instead of the initially proposed 40 mg/m2 , or the 30 mg/m2 we have tried before) x 5 days plus AraC 500 mg/m2/12 x 8 doses, is effective, obtaining a complete remission rate of 33% in these poor prognosis settings, and well tolerated. These preliminary results encourage the testing of Clofarabine in AML patients, and reveal the need of post remission consolidation or maintenance to increase PFS and overall survival.

1136

HIGH-DOSE DAUNORUBICIN VERSUS STANDARD-DOSE IDARUBICIN REMISSION-INDUCTION THERAPY FOR NEWLY DIAGNOSED PATIENTS WITH ACUTE MYELOID LEUKEMIA

E Gurkan
Çukurova University, Adana, Turkey

Continuous infusion of cytarabine with an anthracycline has been the mainstay of therapy in acute myeloid leukemia (AML). Recent studies suggested that intensification of anthracycline dose might improve complete remission rates in AML patients. Results of high-dose daunorubicin induction studies demonstrated improvements not only in complete remission rates but also overall survival. In this retrospective study we investigated the efficacy of remission-induction therapy for adult patients with newly diagnosed AML either as high-dose daunorubicin (90 mg/m2 daily for 3 days) or idarubicin (12 mg/m2 daily for 3 days) in combination with 100 mg/m2 cytarabine by continuous infusion daily for 7 days. Patients achieving complete remission received intensive postremission therapy that consisted of 4 courses of high-dose cytarabine. Nine of the 20 patients had high-dose daunorubicin. Remaining 11 patients received standard-dose idarubicin as a part of induction therapy. The median age of all patients was 40.5 years (range, 19-67). Cytogenetic risk groups were similar in both groups. There were no significant difference in complete remission rate between two induction groups (P= 0.2). The median (? SEM) follow-up time was shorter in daunorubicin induction group (7 ? 1.1 months) compared to idarubicin induction group (13 ? 5.2 months) (P=0.04). Relapse rates were not different between two groups (P=0.4). The incidence and the intensity of adverse effects were comparable. Our data revealed that high-dose daunorubicin and standard-dose idarubicin therapies were equally effective as remission-induction treatment however longer follow-up with larger series is definitely needed.

1137

ADAPTIVE DESIGN OF VALOR, A PHASE 3 TRIAL OF VOSAROXIN OR PLACEBO IN COMBINATION WITH CYTARABINE FOR PATIENTS WITH FIRST RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

C Mehta,[1] G Michelson,[2] M Salganik,[1] J Feaster,[3] R Allen,[2] A Cahill,[4] J Fox,[2] S Ketchum,[2] F Ravandi,[5] H Erba,[6] G Schiller,[7] R Stuart,[8] N Vey,[9] E Feldman[10]

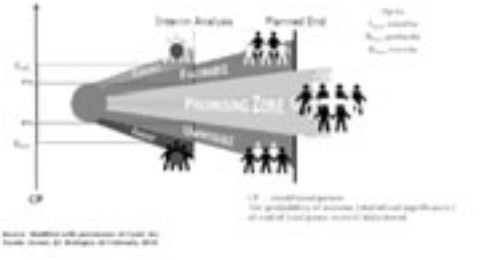
[9]*Institut Paoli-Calmettes, Marseille, France*
[10]*Cornell Medical Center, New York, NY, United States of America*

Background. Patients with relapsed or refractory AML have a short median overall survival (OS) of 3 to 6 months. Vosaroxin (formerly voreloxin), a first-in-class anticancer quinolone derivative, showed promising activity in combination with cytarabine in a single-arm phase 2 trial in this patient population (N=69). Median OS was 7.1 months, combined complete remission (CR) rate (CR+CRp+CRi) was 29%, CR rate was 25%, median leukemia-free survival is currently 14.5 months, and 30-day all-cause mortality was 3%. Aims: Given the uncertainty of basing study design on historical data, and the inherent challenges of extrapolating from a phase 2 dataset to a larger, multinational study, an adaptive design was incorporated into the VALOR phase 3 trial to mitigate the risk of negative outcome where statistical significance is not reached at the final analysis, yet where a truly clinically meaningful benefit could be detected if sample size adjustment were made at interim analysis. An adaptive study design allows staged commitment of patients and

resources compared with a conventional design that assumes a smaller difference in OS between treatment arms, requiring a larger initial commitment of patients. *Methods*. Adaptive Trial Design: VALOR is a phase 3, randomized, controlled, double-blind, multinational clinical study of the efficacy and safety of vosaroxin and cytarabine versus placebo and cytarabine in patients with first relapsed or refractory AML. Vosaroxin (90 mg/m2) or volume-equivalent of placebo is administered on days 1 and 4 by short, ≤ 10-minute IV infusion. Cytarabine (1 g/m2) is administered on days 1 through 5 by 2-hour IV infusion. The primary endpoint is OS; key secondary endpoints include CR rate and safety parameters. Base case assumed 40% improvement in median OS, from 5 months for the placebo plus cytarabine arm to 7 months for the vosaroxin plus cytarabine arm (hazard ratio, HR=0.71); 375 OS events are required to provide 90% power at a 2-sided alpha of 0.05 with one interim look allowed at 50% OS events. The interim result is partitioned into zones based on conditional power (Figure 1).

Figure 1. Adaptive Design – Possible Outcomes at Interim Analysis



The Data and Safety Monitoring Board (DSMB) can recommend stopping early for futility or efficacy, or if the interim result is in either the unfavorable or favorable zone, completing per base case. However, if the result falls in the promising zone, the DSMB can recommend a one time sample size adjustment, increasing the final number of events and sample size by 50% (from 450 to 675 evaluable patients) in order to detect a smaller but relevant treatment effect (HR >0.71) (Mehta, Pocock, Stat Med 2010). For example, if the HR is 0.77 rather than 0.71, the 50% increase in sample size boosts the conditional power within the promising zone from approximately 70% to slightly greater than 90%. *Results*. VALOR is enrolling patients as of December 2010. *Summary/Conclusions*. The key advantage of VALOR's adaptive design is that the 50% increase in patients is recommended only if the interim result demonstrates that the increase substantially reduces the risk of failing to detect a clinically meaningful OS benefit.

1138

EFFICACY OF PETHEMA LPA-99 PROTOCOL: A SINGLE CENTER EXPERIENCE

M Mitrovic N Suvajdzic,[1] A Bogdanovic,[1] A Novkovic,[2]
A Sretenovic,[1] N Kraguljac,[1] D Antic,[1] I Djunic,[1] A Vidovic,[1]

[1]*Clinics of Hematology CCS, Belgrade, Serbia*
[2]*Clinical Hospital Centre Zemun, Belgrade, Serbia*
[3]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Background. In acute promyelocytic leukemia (APL) a cure rate of 75-80% can be anticipated with a combination of all-trans retinoic acid (ATRA) and anthracyclines. *Aim*. To evaluate the efficacy of PETHEMA LPA-99 in adults with newly diagnosed APL, managed in the Clinic of Hematology. *Method*. From 2004 to 2010, 42 consecutive APL patients (pts) confirmed either by t(15;17) or PML/RARA were treated with PETHEMA LPA-99. The median follow-up was 32 months (range: 1-78). *Results/Patients characteristics*. Median time from the first symptoms to diagnosis was 23 days (range: 5-90). Pretreatment pts characteristic were as follows: median age 42 years (range: 21-69), 22/42 male; mean WBC 25.6 x10^9/L (range: 0.6-183); mean platelet count 34x10^9/L (range: 4-101); hypergranular form in 39/42 (93%) pts; PETHEMA risk stratification: high 17/42 (40%), intermediate 17/42 (40%), low 8/42 (20%); mean D-dimer 3606 µg/L (range: 996-11340). DIC was confirmed in 32/42 (86%) pts, mean score 6 (range: 3-7). Additional cytogenetics abnormalities were detected in 8/42 (19%) pts (trisomy 8 in 4/8). Therapy results: 33/42 (76%) pts achieved complete remission (CR). Induction death occured in 9/42 (21%) patients due to: differentiation syndrome (DS)- 4/42 (9.5%), central nervous system hemorrhage- 4/42 (9.5%) and infection- 1/42 (2.3%). Early died pts had higher WBC (55.9x10^9/L vs. 14.1x109/L, p=0.014), higher percentage of peripheral blood (PB) promyelocytes (15.0% vs. 9.59% vs., p=0.03) and higher DIC score (6.32 vs 5.85, p=0.014). All died patients were CD15 negative and with a DIC score of >5. DS occured in 11 pts (26%) with a median onset time of 4 days (range: 1-24) and a median WBC of 25.9x10^9/L (range: 1.4-87.7x10^9/L). DS was severe in 9 cases/ 4 fatal and moderate in 2. Pts with DS had significantly higher percentage of PB promyelocytes (48% vs. 28.68%, p=0.04). Microgranular subtype was predictive for DS (p=0.048). Three relapses occured after the third consolidation, during a maintenance and 6 months after the maintenance termination, respectively. Mean time to relapse was14 months (range: 2-31). The 26/42 (62%) pts are alive in first continuous CR. Three-year overall survival (OS) is 76% and disease free survival (DFS) 82%. Tolerance and toxicity according NCI: Leuko-thrombocytopenia grade 3-4 was registered in 30 pts in induction (mean duration 15 days), and in 28 (13 days), 26 (10 days), and 13 (8 days) pts during consolidation, respectively. Hepatotoxicity grade 2-4 (2 with MTHFR) developed in 10 pts; severe cardiotoxicity in 2 pts; genital ulcer one pts; headache grade 3-4 2 pts; pneumonia 7 pts (3/7 Aspergilosis); thrombosis in 6 pts. Patients with thrombosis were older (52 vs. 41 years; p=0.04). *Conclusions*. PETHEMA LPA-99 proved effective in our APL patients concerning CR rate, OS, DFS, toxicity and realpse rate. High rate of early death could be attrubuted to the numerous high-risk pts and increased rate of DIC. WBC >10x10^9/L, DIC score >5 and CD15 negativity were poor prognostic factors for early death. Reduction of the incidence of early deaths is mandatory and requires a timely diagnosis and better management of both DS and bleeding.

1139

CHEMOTHERAPY WITH LOW-DOSE MERCAPTOPURINE IN ELDERLY, UNFIT PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

A Colita,[1] A Lupu,[1] N Berbec,[1] G Barca,[2] O Ciocan,[1] A Ciobanu,[2]
M Closca,[2] C Saguna,[1] S Angelescu,[1] D Barbu,[2] A Arghir,[3]

[1]*UMF Carol Davila, Bucharest, Romania*
[2]*Coltea Hospital, Bucharest, Romania*
[3]*V. Babes Institute, Bucharest, Romania*
[4]*Fundeni Clinical Institute, Bucharest, Romania*

Background. Acute myeloid leukemia (AML) is a disease affecting especially elderly patients with a median age at onset of 68 years. AML in older adults seems to be a distinct entity due to specific characters: resistance of leukemic cells to standard chemotherapy; comorbidities; impaired bone marrow stem cell reserve; high percentage of poor prognosis cytogenetics. The current chemotherapy-based treatment has disappointing results: CR rate <45% (, high treatment related mortality, short median overall survival, high relapse rate is. Aim of the study: to evaluate the efficacy of low-dose 6 Mercaptopurine (6 MP) therapy and outcome in elderly, unfit patients with AML. *Patients and methods*. 18 elderly patients with AML followed between Sept. 2002 - December 2010; median age 76 years (range 66 - 84 years); sex ratio: M/F: 7/11. Diagnostic was established after bone marrow aspiration examination, and in 4 cases with confirmation of trephine bone biopsy. Ten patients had AML following myelodisplasia (MDS), 2 after Ph-negative chronic myeloproliferative diseases (1 postpolycythemic myelofibrosis, 1 unclassified myeloproliferation - both were positive for JAK2 (V167F) mutation) and 6 with *de novo* AML. Cytogenetics was available in 6 patients - 3 normal, 1 with (-Y), 1 with (20q-), 1 complex ((-6,del(9),der(17), t(6;17)). All patients had performance status ≥ 2 at diagnosis and at least 2 comorbidities. Chemotherapy consisted in 3+7 courses in 5 cases, 2+5 regimen in 2 cases and low - dose Ara-C regimens for 11 cases. Due to failure of conventional therapy or after severe infectious complications during induction the therapy was changed to low-dose 6MP oral palliation.The dose of 6MP was 100 - 150 mg/week. Treatment decision was made after consulting the patients and their families. Results: Five patients had complete remissions ranging from 12-66 month (3 AML secondary to MDS, 1 de novo AML, 1 postmyelofibrosis). Other 6 patients achieved partial responses with duration of 4 - 15 month. The patient with unclassified chronic myeloproliferation achieved partial remission with bone marrow blast count< 7% but had persistent thrombocytosis and leucocytosis (therapy with hydroxiurea and methotrexate had to be associated) and relapsed to overt AML after 15 months. The CR rate was 27,7% with a median duration of 24 month; partial response was obtained in 33,3% of cases. Overall response rate was 61 %. The 6 MP therapy was well tolerated; in 7 cases the treatment was temporary (5 -10 days) discontinued due to neutropenia (<1000/µl); 2 patients had severe thrombocytopenia, no infections were recorded dur-

ing the treatment period. All patients with cytogenetic abnormalities were poor responders. The patients who failed to obtain response had survivals of 1 - 5 months. In our opinion there might be a group of elderly patients with AML that would have a real benefit in terms of survival and quality of life using low-dose 6 mp therapy. This hypothesis has to be confirmed by further studies on larger patient population combined with cytogenetic and molecular analysis.

EVALUATION OF TREATMENT OF ACUTE PROMYELOCYTIC LEUKEMIA (APL) BY A PROTOCOL INCLUDING ALL-TRANS RETINOIC ACID (ATRA)

RM Hamladji, F Belhadri, H Moussaoui, A Talbi, F Harieche, N Ait Amer, F Tensaout, F Boukhemia, F Zerhouni
Pierre and Marie Curie Center, Algiers, Algeria

Introduction. The APL is a rare form of acute myeloid leukemia (AML) but potentially serious because of the risk of bleeding involving immediate threat to life. The introduction of all-trans retinoic acid (ATRA: Tretinoin), whose first results were published in 1997, has completely revolutionized the treatment and prognosis of this disease *Material and methods.* From January 2000 to December 2009, 50 patients (pts) with APL were diagnosed from a total of 308 AML (16%). The diagnosis was made on the morphological study of blood and bone marrow smears according to FAB classification criteria. Including ATRA treatment was applied in 37 pts. Among the remaining 13 pts, 8 died before any treatment of hemorrhagic syndrome and 5 had received only chemotherapy (CT). The median age of 37 pts was 30 years (12-66), 26 were female and 11 male (sex ratio: 0.3). At diagnosis, all pts but one, have an hemorrhagic syndrome, 22 pts/37 (56%) were febrile, no tumor syndrome was observed. On haematological, thrombocytopenia is consistent with a median of 21.10^9/L (2-63), 16 pts (43%) have leucocytosis with with blood count (WBC) more than 10.10^9/L part of the high-risk prognostic group (Sanz, Blood 2000). Symptomatic treatment involving transfusions of platelets to maintain a platelet count greater than 30.10^9/L and fresh frozen plasma is associated with specific treatment protocol follows: ATRA 45 mg/m2/day only if rate WBC ≤ 5.10^9/L. The 3+7 protocol is started at day 5 if WBC ≥ 6.10^9/L, at day 10 if WBC ≥ 10.10^9/L or after obtaining a complete remission (CR) and 2 courses of consolidation followed by maintenance therapy comprising ATRA. Among the 37 pts, eight received ATRA alone for induction and 29 of ATRA + CT; all pts received consolidation therapy and maintenance therapy. The median follow-up was 60 months (15-112). *Results*. CR was achieved in 30 pts/37 (81%), 6 pts (16%) died during induction within 5-19 days (23 septic shock, an acute respiratory distress, 1 hemorrhage cerebrospinal meningitis, 2 of unknown cause), 1 pt died in failure at 3 months. During follow-up among the 30 CR, 5 pts died (3 due to septic shock after a course of consolidation, after an allograft and 1 after early relapse at 5 months). In total, 25 pts/37 (67%) are in persistent CR. The actuarial overall survival (OS) and event-free (EFS) are 68% to 112 months (9 years). *Conclusions*. Our CR rate of 81% is lower than that reported in the literature where it is in good standing over 90%, wich can be improved by strengthening the symptomatic treatment by deletion of ARA-C in induction CT as it is shown that ATRA-anthracycline combination is sufficient and an easing of consolidation treatment in the forms of good and intermediate prognosis

CLINICAL AND BIOLOGICAL CHARACTERISTICS OF ADULT BIPHENOTYPIC ACUTE LEUKEMIA (BAL): A SERIE OF 49 ALGERIAN PATIENTS

A Talbi, F Harieche, H Moussaoui, F Belhadri, M Benakli, R Ahmed Nacer, F Zerhouni
Pierre and Marie Curie Center, Algiers, Algeria

Background. BAL is a rare disorder that can be difficult to diagnose. The first published reports mentioning the entity of BAL can be found in the 80's. By definition BAL displays features of both myeloid and lymphoid markers in one leukemia cell lineage, there are several classification criteria for BAL diagnoses, the most commonly used is the EGIL classification. *Design and Methods.* Between January 2002 and December 2010, 480 pts with acute leukemia (AL) were diagnosed in our unit. The diagnoses of AML and ALL were performed according to the FAB classification; BAL were performed according to the EGIL score. All the pts have morphology and cytochemical analysis on blood and bone marrow aspiration. Only 20 pts have a genetic profil. All of the pts have an immunophenotyping performed on fresh bone marrow or blood specimen. All pts with negative peroxydase, received ALL treatment (Daunorubidomycine, vincristin, asparaginase and prednisolone), and all pts with positive ones received AML treatment (Daunorubicine and cytarabine). *Results.* Of 480 pts with AL, 49 cases of BAL were diagnosed (10,2%), among them 37 pts (75,5%) were Lymphoid and Myeloid, 12 pts (26,6%) were T Lymphoid and Myeloid, no cases of B/T or trilineage differentiation. The median age of the series is 28 years old (15-81), the sex ratio is 1,6 (30/19), the median count of white cells is 32000/mm3 (1100-239000), the median rate of Hb is 8,1 g/dl (4,4-15,9), the median rate of platelet is 64000/mm3. The median prevalence of blast in the bone marrow is 94% (27-100), The extra medullary infiltration concerned 20% of the pts (10 pts). (Mediastinum: 19 pts (40%), lymph nodes: 19 pts (40%), spleen: 14 pts (28,5%), both:12 pts (24%). The incidence of CD34 antigen were 73,3%. Above 20 pts with genetic profil, 6 pts (30%) have t(9-22). Forty five pts (91,8%) received an ALL treatment, with a complete remission rate of 83%, only 2 pts (6,9%) received an AML treatment and 2 pts do not have any treatment. The median follow up is 6 years (1-96). Among the 47 pts who were treated, 26 pts are alive (55,3%) in complete remission. Two pts are alive in relapse, 19 pts (40,4%) dead. The relapse concerned 9 pts/47 (19,1%). The overall survival and the disease free survival are 41,1% and 38,1%. *Conclusions.* The prognosis of BAL seems less poor than other acute leukemia however the type of treatment of induction (ALL mainly in our series) may have a serious influence on the rate of the complete remission (good in this trial) and on the occurrence of the relapse. The rate of death in complete remission is too high, because of the remoteness of sanitary structures. The place of the allograft may be discussed in this indication.

TREATMENT OF ELDERLY, UNFIT PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) WITH VALPROIC ACID AND LOW-DOSE MERCAPTOPURINE

A Colita,[1] A Lupu,[1] G Barca,[2] N Berbec,[1] M Closca,[2] A Ciobanu,[2] O Ciocan,[1] C Saguna,[1] S Angelescu,[1] D Barbu,[2] A Arghir,[3] A Lungeanu,[3] A Ivanescu,[2] R Manolache[2]
[1]*UMF Carol Davila, Bucharest, Romania*
[2]*Coltea Hospital, Bucharest, Romania*
[3]*V. Babes Institute, Bucharest, Romania*

Background. Acute myeloid leukemia (AML) is a disease affecting especially elderly patients with a median age at onset of 68 years. Because of specific characters of AML in older adults (resistance of leukemic cells to standard chemotherapy; comorbidities; impaired bone marrow stem cell reserve; high percentage of poor prognosis cytogenetics) the current chemotherapy-based treatment has disappointing results: low CR rate, high treatment related mortality, short median overall survival, high relapse rate. These disappointing results are a major challenge in the therapy of this patients and call for more effective and less toxic treatment strategy. Valproic acid is a inhibitor of histone deacetylase activity and we already had cases treated with low dose mercaptopurine showing encouraging results in some cases of AML in elderly patients Aim of the study: to evaluate the efficacy of the association of valproic acid and low-dose 6 Mercaptopurine (6 MP) therapy and outcome in elderly, unfit patients with AML. *Patients and methods*. 8 elderly patients with AML followed between Jan. 2005 - December 2010; median age 76 years (range 65 - 85 years); sex ratio: M/F: 4/4. All patients had performance status ≥ 2 at diagnosis and at least 2 comorbidities. Diagnostic was established after bone marrow aspiration examination. Six patients had AML following myelodisplasia (MDS), 2 after Ph-negative chronic myeloproliferative diseases (1 postpolycythemic myelofibrosis, 1 unclassified myeloproliferation). All patients did not responde to initial chemotherapy (2+5 regimen in 2 cases and low - dose Ara-C regimens for 6 cases) and all patients had severe, life-threatening complications during chemotherapy (severe infections - 6 cases, hemorhage - 2 cases, severe anemia associated with heart failure or cardiac ischemia - 3 cases). After failure of conventional therapy the therapy was changed to low-dose 6MP oral treatment (100 - 150 mg/week) in association with valproic acid (Convulex 900 mg/day, orally). Treatment decision was made after consulting the patients and their families. Results: Two patients had complete remissions with duration of 6 and 36 month, respectively (both AML secondary to MDS, 1 with AML6 subtype and t(12;15)). The other 6 patients did not achieve hematologic responses, but 2 of them had stable disease with survival of 14 and 20 month despite the lack of remission. For the other 4 patients the survival varied between 3 - 7 month. In our opinion that some elderly with AML could respond to the association of valproic acid and mercaptopurine and even in the absence of remission there might be some benefit in terms of survival. This hypothesis has to be confirmed by further studies on larger patient population combined with cytogenetic and molecular analysis.

[3]*University of Medicine, Hematology, Iasi, Romania*
[4]*Emergency University Hospital Hematology, Bucharest, Romania*

Background. Clofarabine (2-chloro-20-fluoro-deoxy-9-b-D-arabinofuranosyladenosine) is a second-generation nucleoside analog, which was developed as a hybrid molecule to combine the most favorable pharmacokinetic properties of both fludarabine and cladribine. Aims: The encouraging clinical response rate in the heavily pretreated study group, tolerable toxicity profile, and associated pharmacokinetic and pharmacodynamic parameters led us to investigate clofarabine in relapsed or resistant acute myeloblastic leukemia (AML). Materials and methods: We had studied 9 patients with relapsed AML (7 patients) or resistant AML (2 patients) diagnosed in 2010. Three patients had relapsed secondary AML post SMD, other 5 had relapsed high risk AML. One patient had relapsed AML after allotransplant, matched related donor (twin brother). There were 3 female and 6 male, median age 53 years. Clofarabine based regimens was variable: 4 patients received Idarubicine 12 mg/sm 3 days combined with Clofarabine 32 mg/sm 5 days, 3 patients received monotherapy with clofarabine, 32 mg/sm/d 5 days, 1 patients received Clofarabine 32 mg/sm/d 5 days combined with low dose AraC (7 days) and 1 patient received Clofarabine 32 mg/sm/d 4 days combined with AraC 1g/sm/d 4 days. Results: Clofarabine, given at 32 mg/sm daily for 5 days per course combined with idarubicine had a significant antileukemic activity in heavily previously treated relapsed AML, with CR an average duration of 3 months. Nonhematological side effects were tolerable and mostly reversible. Hematological (thrombocytopenia and neutropenia) grade III-IV toxicity had 89% patients, with an average duration of 23 days. Summary: We found that patients younger than 40 years were much better tolerated treatment with clofarabine than older people. Also, treatment toxicity in patients with early relapse was shorter in duration than those with full relapse. These observations could lead to reconsider the indication of treatment with clofarabine in adult AML

[4]*Pathology, Clin Ctr of Serbia, Belgrade, Serbia*

Background. Current WHO classification of AML decribes the entity of AML with trilineage dysplasia. This type of leukemia is hard to diagnose since many patients lack enough morphological details due to expansion of leukemia. Thus, not many biological features were described in selected group of patients. *Aim.* The aim of our study was to analyze patients diagnosed with AML with dysplasia according to WHO (2000/2008) classification and to compare their features with similar patients from the same period within single academic institution. *Patients*. Between 1998-2003, we have identified 50 pts with de novo AMLtd among 270 leukemia cases diagnosed. Comparisson was made with 30 patients without dysplasia (AML) treated in the same period, with same chemotherapy based on MRC AML 10 trial. We analyzed hematological, morphological, cytogenetic and biological data such as proliferation and spontaneous and drug-induced apoptosis (in vivo apoptosis after 48h of therapy), bcl-2 positivity by immunohistochemistry. Also we analyzed response to treatment.
