Results. The incidence of this type of AML is roughly 18% of all AML. Patients with AMLtd are elder than others (50.3 vs 42.2). They had in general more myeloid leukemia (M2) than monocytic forms. The incidence of aleukemic type is much more common in AMLtd (54 vs 16%), meaning that WBC and blast counts are also lower. In morphology, when enough myeloid tissue besides leukemia was present, all morphological dysplastic changes in all lineages were found, with prominent dysplastic changes in eryhtroid and granulocytic series (megaloblastic E lineage, dysplastic nuclei; pseudopelgers, disturbed or hypogranulated G lineage). Karyotype revealed that AMLtd patients had typical cytogenetic lesions affecting chromosomes 5, 7, 8, multiple aberations (52%) but also normal karyotype, no prognostically favourable karyotype was found. Remisison rate was lower 42.5% vs 73%, with higher induction death 22.5% and longer aplasia (19 days). Median OS was shorter (9 vs 15 mths) with 11 vs 28% at OS5y. Patients with AMLtd had higher number of proliferative cells (Ki67+, 13.5 vs 6.5%), and this gropu also had higher incidence of patients with Ki67+>10% (43% vs 16%). There was no difference in spontaneous apoptosis rate 3.7 vs 3.5%, but hemotharapy induced apoptosis was higher in patients without dysplasia 5.8±5.2% vs 3.6±3% in AMLtd. Bcl-2 positivity (IHC) revealed that 65% with AMLtd were positive compared to 43% in AML group (p=0.07). *Conclusions*. Patients with AML with trilineage dysplasia had charateristic form of disease, with lot of poor prognosis features, and low response to treatment. In case that they are elegible, they probably will benefit from more intensive treatment approaches.

GENE MUTATION IN PAIRED INITIAL PRESENTATION AND RELAPSE SAMPLES FROM ACUTE MYELOID LEUKEMIA

S Wakita, H Yamaguchi, Y Mitamura, F Kosaka, K Inokuchi, K Dan

Division of Hematology, Department of Internal Medicine, Nippon Medical School, Tokyo, Japan

Background and Aims. Several gene mutations were found in acute myeloid leukemia (AML) and were expected to be used as prognostic factors and minimal residual disease (MRD) markers. We have studied Flt3, NPM1, CEBPA, IDH1/2 gene mutations in paired samples at initial presentation and relapse of AML to ascertain the biological meanings of these mutations and to evaluate whether they can be used as MRD marker. *Methods.* We analyzed paired samples at initial presentation and relapse from 30 adult patients with de novo AML who diagnosed at Nippon Medical School from 2000 to 2010. Bone marrow or peripheral blood samples containing 20% or more blast cells obtained were used for mutation analyses. Mutation analyses were performed for Flt3ITD by PCR amplification, Flt3TKD by PCR-RFLP, and NPM1, CEBPA, IDH1/2, mutations by direct sequence. To validate sequencing results, PCR products were inserted into the pCR2.1-TOPO vector using a TOPO TA cloning kit (Invitrogen, Carlsbad, CA). Recombinant plasmids isolated from 8 to 12 white colonies were sequenced. *Results*. Flt3ITD, Flt3TKD, NPM1, CEBPA, IDH1/2 mutations were detected in 9 (30.0%), 3 (10.0%), 10 (33.3%), 1 (3.3%), 2 (6.7%) samples at initial presentation samples, and 8 (27.6%), 0 (0%), 7 (23.3%), 1 (3.3%), 2 (6.7%) samples at relapse, respectively. Among 24 available samples for chromosomal analysis at relapse, 16 (66.6%) showed additional chromosomal aberrations, 6 (25.0%) changed to be complex chromosomal aberrations. Chromosomal instability at relapse was observed in many cases, but frequency of gene mutations at relapse was lower than those at initial presentation. About 40% of AML patients at relapse did not have these gene mutations detected at initial presentation. CEBPA mutation

was found in one paired sample. IDH1/2 mutations were detected in 2 paired samples of patients. Interestingly, 3 of 9 patients with Flt3ITD mutation at initial presentation had no Flt3 ITD mutation at relapse. Flt3/TKD mutations were found in 3 patients at initial presentation, but all of them were lost in these three cases at relapse. Among the 10 patients with NPM1 mutation at initial presentation, 3 had no detectable mutation at relapse. These results indicate that Flt3ITD, Flt3TKD, and NPM1 mutations should be used carefully for the detection of MRD. Furthermore, among the 6 patients with NPM1 mutation without Flt3ITD mutation that is known as favorable factor, Flt3ITD mutations were detected in 2 patients at relapse. There was a possibility that detection sensitivity for Flt3ITD is not sufficient by PCR amplification method. *Conclusions*. Our study showed that about 65% of the patients with Flt3ITD mutation had the same mutation at relapse, which means that these mutations may contribute to expand resistant clones. On the other hand, detection of Flt3ITD mutation only at relapse suggested that a minor clone harboring Flt3ITD mutation might be overlooked at diagnosis. We have developed a highly sensitive mutation detection method (15th. Congress of European Hematology Association, 2009, Barcelona, Spain) and studies to clarify these findings are ongoing.

GEMTUZUMAB-OZOGAMICIN AS POST-CONSOLIDATION THERAPY IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA: A PILOT STUDY

D Capelli,[1] M Chiarucci,[1] G Mancini,[1] A Poloni,[1] M Montanari,[1] M Offidani,[1] S Rupoli,[1] G Gini,[1] S Trappolini,[1] B Costantini,[1] I Scortechini,[1] A Olivieri,[2] P Leoni[1]

[1]*Ospedali Riuniti Ancona, Clinica di Ematologia, Torrette di Ancona, Italy*
[2]*Ospedale San Carlo, Divisione di Ematologia, Potenza, Potenza, Italy*

Background. The optimal post-remission treatment for elderly patients with acute myeloid leukemia (AML) is currently unknown. Autologous transplantation is not always feasible in this setting because unsuccessfull mobilization and comorbidities. The high relapse risk of the disease raise the issue of exploring alternative consolidation regimens. Aims. We evaluated safety and efficacy of low dose Gemtuzumab-Ozogamicin (GO) as post-remission late consolidation therapy in a cohort of 19 consecutive patients, failing mobilization, enrolled in a pilot prospective study. *Methods*. Between June 1999 and February 2010 we observed 152 elderly patients, aged more than 60 years and affected by AML. One hundred and two patients (67%) were considered fit for aggressive therapy and received intensive induction and consolidation therapy including HD Ara-C, Idarubicine and Amifostine. Thirty-nine patients (38%) were over 70 years, 38% had a secondary disease, 35% unfavourable, 45% intermediate and 4 % favourable prognosis Karyotype. Those achieving successful mobilization received autologous transplant while poor mobilizers received a second consolidation with three monthly courses of GO 3 mg/sm i.v. followed by three other courses of GO administered every 3 months. A third group received chemotherapy alone for patient decision. The three groups showed similar disease and patient characteristics. *Results*. Seventy-two patients achieved CR (69%) after induction: one patiente died in CR, 5 patients had a PS ≥2 and the remaining 66 were elegible for first consolidation. Fifty of these maintained the CR status and received a second consolidation: 19 with GO, 20 with Autologous Transplant, and 6 with chemotherapy alone for patient decision. Five patients with a family donor received Allogeneic Transplant and were not included in this analysis. GO was well tolerated: no major adverse events were seen. We overall observed 18 WHO grade III/IV adverse events were all transitory and included hematological toxicity (n = 17), hypertransaminasemia (n = 1). Eight patients (42%) relapsed after GO consolidation and received a GO reinduction: five eventually died after a median follow-up of 13 months while three are still alive with a median follow up of 10 months. Five out of 20 patients died of transplant related toxicity (25%) and 9 of the remaining 15 relapsed (60%) after autologous transplant. All nine patients died of progressive disease. Five of the 6 patients receiving chemotherapy (83%) relapsed and died. Five years Overall survival was 22% and Disease Free Survival 29.5% in the whole cohort of patients (median follow-up: 50 months). The landmark analysis showed a superior outcome in patients receiving GO with a 60% 5 yrs OS and DFS (median follow-up: 60 months) in comparison with patients receiving autologous transplant (28% 5 yrs OS and DFS with median follow-up 70 months) and chemotherapy (17% 5 yrs OS and DFS with a median follow-up of 77 months) (p= 0.009). *Conclusions*. Patients receiving GO had a better outcome in comparison with patients receiving autologous transplant and chemothearapy. High percentages of poor mobilizers and transplant related mortality seem to jeopardize autologous transplant feasibility and safety in elderly patients. GO showed to be an alternative and feasible choice in this setting.

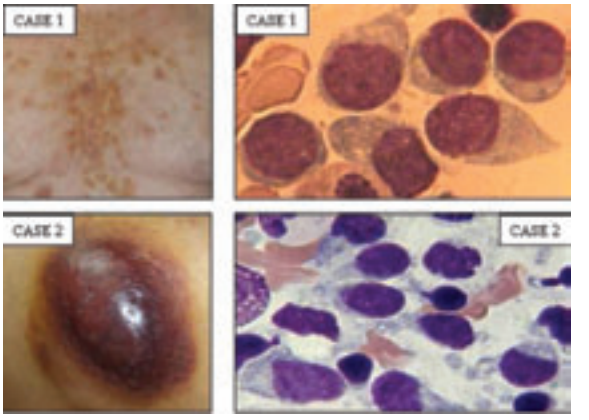
BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASIA (BPDCN): REPORT OF 2 CASES

I Gonzalez-Gascón y Marín, M Ballesteros, I Perez-Sanchez, M Infante, A Perez-Corral, A Escudero, M Kwon, C Martinez Laperche, L Bento, F Carretero, J Menarguez Palanca, JL Diez-Martin

Gregorio Marañon Hospital, Madrid, Spain

Background. BPDCN is a rare hematopoietic disease that typically involves the skin, lymph nodes, peripheral blood and bone marrow. Prognosis is dismal with a median overall survival of only 12-14 months despite aggressive chemotherapy. We report 2 cases of BPDCN associated with dysplasia. CASE 1: A 68-year-old man consulted for asymptomatic, infiltrated, disseminated skin lesions that had appeared during the previous 6 months, with progressive onset of anemia (hemoglobin 112 g/L) and leukopenia (2.8 x10^9/L). Platelet count and lactate dehydrogenase were normal. A skin biopsy revealed a dermal infiltration of monotonous medium-sized mononuclear cells with expression of CD4 and CD56 but not CD3 or CD20. Bone marrow aspirate was infiltrated by 48% medium-large sized blasts with a peculiar morphology. The nucleus was irregularly shaped and the chromatin was lacy with a blastic appearance. The cytoplasm was large, grey and agranular, with pseudopodium-shaped expansions and occasionally vacuoles. Myeloperoxidase was negative and esterase was not conclusive. Trilineage dysplasia was observed. Flow cytometry immunophenotyping confirmed the diagnosis of BPDCN (positivity for CD4, CD56, CD123, and HLA-DR; negativity for B, T and myelo-monocytic markers). Fluorescence in situ hybridization (FISH) revealed +12, del (13q14.3) and del (13q34). The karyotype was not available. FLAG-Ida (fludarabine, cytarabine, idarubicin and G-CSF) was administrated as induction therapy. Consolidation therapy with FLAG-Ida is ongoing and the patient is scheduled for allogeneic hematopoietic stem cell transplantation. He is currently in remission, with negative minimal residual disease documented by flow cytometry and FISH although with persistence of trilineage dysplasia and cytopenias. CASE 2: A 78-year-old man was monitored for a medical history of ischemic heart disease and refractory anemia that progressed to refractory anemia with excess blasts type 1 (RAEB-1). His clinical course over the previous 4 years has been stable. He presented with a purple asymptomatic cutaneuos lesion on his left shoulder and weakness. A blood count revealed neutrophils 0,4 x 10^9/L, platelets 16 x 10^9/L, and hemoglobin 76 g/L. Cytological examination of bone marrow showed 79% blast cells with the same morphology and cytochemistry as case 1, as well as myelodysplasia of the 3 cell lines.



Immunophenotyping revealed BPDCN (positivity for CD4, CD56, CD123, HLA-DR, negativity for B, T and myelo-monocytic markers). A cytogenetic study revealed a complex karyotype. Cutaneous biopsy showed massive dermal infiltration by BPDCN. In view of the patient´s age and comorbid conditions, supportive care was provided and he died 4 months later. *Conclusions*. The clinical presentation of both patients was very similar, with cutaneous involvement and cytopenia. Morphologic and cytochemical features were characteristic and similar. Immunophenotyping was diagnostic. Both patients had chromosomal changes. Survival is usually poor without treatment. This justifies aggressive protocols with bone marrow allotransplantation.

ACUTE LEUKEMIA: HOW WELL DO HISTOLOGY AND FLOW CYTOMETRY CORRELATE AT DIAGNOSIS?

E Byrne,[1] R Morilla,[2] R Ahmad,[1] D Horncastle,[1] E Matutes,[2] K Naresh[1]
[1]*Imperial College NHS Healthcare Trust, London, UK*
[2]*Section of Haemato-Oncology, Institute of Cancer Research., London, UK*

Background. Acute leukemia is a common haematological malignancy, which comprises acute myeloid leukaemias (AML), acute lymphoblastic leuaemias (ALL) and acute leukaemias of ambiguous lineage. Diagnosis is by bone marrow trephine biopsy (BMTB), flow cytometry (FC), bone marrow aspirate, peripheral blood investigations and cytogenetics. Review of the available literature showed correlation rates between FC and histology of 88% when sampling lymph nodes in non-Hodgkin lymphomas (*El Sayed et al. 2008*) and 87% in marginal zone lymphoma when sampling bone marrow (Boveri et al. 2009). No literature could be found on this parameter in acute leukaemias. Aim: To compare BMTB with FC in patients with suspected acute leukaemia at diagnosis. Methods: Diagnostic BMTB and FC reports, from May 2004 to December 2010, from patients suspected to have an acute leukaemia on either multicolour FC or BMTB were reviewed. Results were included if the FC and BMTB samples were sent within two weeks of each other. FC panels included antibodies to CD10, CD117, CD13, CD34, CD33, myeloperoxidase, HLA-DR, CD45, TdT, CD79a, CD19, cCD22, CD2, cytCD3, CD7, CD14 and CD15. Immunohistochemical panels on BMTB included CD34, CD117, myeloperoxidase, HLA-DR, TdT, CD68, CD68R, CD33, glycophorin C, CD61/CD42b, CD20, CD79a, PAX5 and CD3. *Results*. A total of 46 cases were studied. In 44 cases (96%) both FC and BMTB reported an acute leukaemia. In the remaining 2 cases - 1 was reported as AML on FC and as myelofibrosis with dysplastic megakaryocytes on BMTB, the other was reported as suspicious of AML on BMTB and as lymphocytosis on initial FC, though the subsequent FC in this patient did diagnose AML. Of the 44 cases where both investigations reported acute leukemia: Both FC and BMTB reported precursor B-cell ALL in 5 cases and T- cell ALL in 1 case. In 35 cases, both FC and BMTB reported AML. Of these 4 were reported as acute promyelocytic leukemia; 2 by both FC and BMTB, 1 by FC only and 1 by BMTB only. A further 8 were reported as having monocytic differentiation; 5 by both FC and BMTB, 2 by FC only and 1 by BMTB only. In 1 case, the BMTB suggested erythroblastic differentiation which was not confirmed by FC, this sample was reported as being haemodilute. In 1 case, the BMTB suggested megakaryoblastic differentiation which was not confirmed on FC.In 2, FC reported poorly differentiated acute leukemia, and in 1 of these cases BMTB reported acute leukaemia - not otherwise specified (NOS), in the other case BMTB reported pro B-cell ALL. In 1, FC reported mixed phenotype acute leukemia and the BMTB reported AML-NOS. *Conclusions*. BMTB and FC correlated in 96% of cases of acute leukemia (44/46). A concordance of 95% was seen in the diagnosis of the subtypes of acute leukemia (42/44). Within AML, where lineage/subtype-specific subtype differentiation was attempted, BMTB and FC correlated in 50% of cases (7/14). This study emphasizes that FC and BMTB are complementary in the diagnosis of acute leukemia and shows an excellent correlation rate between the two investigations.

TREATMENT OF ACUTE MYELOID LEUKEMIA IN THE ELDERLY - A SINGLE CENTER EXPERIENCE

J Carda,[1] M Pereira,[2] P Sousa,[1] P Olim,[1] E Cortesćo,[1] S Almeida,[1] A Crisóstomo,[1] C Moucho,[1] L Jorge,[1] A Paiva,[3] A Teixeira[1]
[1]*Hospitais da Universidade de Coimbra, Coimbra, Portugal*
[2]*Serviço de Hematologia - Hospitais da Universidade de Coimbra, Coimbra, Portugal*
[3]*Centro de Histocompatibilidade do Centro, Coimbra, Portugal*

Background. Treatment of the elderly with Acute Myeloid Leukemia (AML) is a challenge, considering the pre-existing comorbidities that could limit the therapeutic spectrum in a patient suffering from a biologically aggressive disease. While overall survival in patients with AML decreases with age, most studies performed in elderly patients show Complete Remission (CR) rates between 40 and 60%, but only if they are treated aggressively, potentially limiting their quality of life and prolonging the duration of hospitalization. *Aims.* This study aims to characterize an elderly population with a diagnosis of AML (considering age subgroups, cytogenetic risk groups, type of intended treatment and use of consolidation) and to analyze the impact of different treatment approaches on their overall survival (OS). *Methods*. Retrospective analysis of clinical and laboratory data from 131 patients aged over 59 years, with the diagnosis of AML (excluding acute promyelocytic leukemia, according the 2008 World Health Organization classification), treated in our institution between 1st January 2005 and 31st December 2010. Statistical analysis performed using the 19.0 version of SPSS. *Results*. Both genders were equally represented (M:F=1). The median age at diagnosis was 70 years and 70% of patients were over 65. The majority of cases (55%) were secondary to a pre-existing hematological disease (myelodysplastic or myeloproliferative syndromes) or to chemotherapy for other malignancy. According to the French-British-American classification, there was a predominance of AML with monoblastic features (40%), followed by the M1 subtype (26%), M2 (22%) and M0 (12%). We obtained conventional karyotype cytogenetic results in 60% of our patients, of whom 6% were of low risk, 71% of intermediate risk and 23% of high risk. OS was 35% at 12 months and 10% at 36 months with a statistically significant difference in survival between the 60-65 and over 65 age groups at 12 months (50% vs 20%; p<0.05), and an equally significant difference between the palliative and aggressive treatment groups at 12 months (10% vs 45%; p<0.05). We opted for an aggressive treatment strategy in 75% of our patients, pre-selected according to age, performance-status and comorbidities, attaining a CR rate of 53%. The use of consolidation therapy after CR in this age group didn't improve overall survival (60 vs 58% at 12 months, p=N.S.) or progression-free survival (25% vs 24% at 12 months, p=N.S.). *Conclusions*. Although the decision to treat is based on the patient's co-morbidities and performance status, we conclude that the outcome of aggressively treated patients is better, with prolonged overall survival and no significant increase in treatment-related complications. On the other hand, the use of consolidation didn't improve OS or PFS, in our series. While treatment decisions should be individualized to each patient, according to risk factors, performance status and co-morbidities, the recommendation to, whenever possible, enroll the patient in a clinical trial still prevails.

1150

MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA WITH INV(3)(Q21Q26.2) OR T(3;3)(Q21;Q26.2) ABNORMALITY. SINGLE CENTER EXPERIENCE

C Calderón, J Falantes, R Bernal, R Morales, D Jiménez, J González, I Espigado, JA Pérez-Simón
Hospital Universitario Virgen del Rocío, Seville, Spain

Background. Recent World Health Classification (WHO) has incorporated acute myeloid leukemia (AML) with inv(3)(q21q26.2) or t(3;3)(q21;q26.2) as a new entity in the category of AML with recurrent genetic abnormalities, that accounts for 1%-2% of AML. This type of AML can arise de novo or from pre-existing MDS. Prognosis of patients with MDS/AML with 3q abnormality (3q abn) is very poor with low complete remission (CR) rate and short long-term overall survival (OS) with standard chemotherapy. P*atients and methods*. We report baseline characteristics and outcome of 6 cases of patients with MDS or AML with 3q abn from our center. Demographics, blood counts, bone marrow features and evolution are shown in Table 1. *Results*. Four out of 6 pts were aged <65y. All of them received standard intensive chemotherapy (IC). No complete remission was achieved followed by progression in all 4 cases. One pt underwent allogeneic stem cell transplant with subsequent early relapse. Other 2 pts (#5 and #6) have been recently diagnosed. Treatment received were non-intensive chemotherapy (NIC): one of them low-dose AraC and 5 azacitidine the other, carrying additional chromosomal abnormality (monosomy 7 in the context of monosomal karyotype). The only treatment offering stable disease with OS over 1 year was 5 azacitidine (16 months after diagnosis). No serious adverse events with this approach occurred and treatment is ongoing. Our results compare with data recently reported in this group of very-poor prognosis MDS/AML pts in which treatment options are still unclear.

	Sex	Age	Hb	ANC	Platelet	BM blast	Dysplasia	Treatment	Status
Patient #1	M	57	84	0.53	1653	49.25	E	IC	Death
Patient #2	W	34	76	2.4	367	22	E/WC/P	IC, AlloSCT	Death
Patient #3	M	48	89	0	25	75.5	No	IC, AlloSCT	Death
Patient #4	W	45	76	0	12	40	W/B	IC	Alive
Patient #5	W	68	76	0.4	36	29	E/WC/P	IC, 5-aza (17 courses)	Alive
Patient #6	W	78	81	0	45	59	E/WC	NIC (LD-AraC)	Alive

Table 1. Baseline characteristics of pts. Treatment and outcome. M: Male. F: Female. Hb: Hemoglobin (g/L). ANC: Absolute neutrophil count (x10 9/L). Platelets (x10 9/L). E: Erythroid. WC: White-cell. P: Platelet.

*Conclusion*s. It is well known poor prognosis and decreased survival in patients with AML and genetic abnormalities on chromosome 3. Most are refractory to intensive chemotherapy and generally not well tolerated when dealing with elderly patients with frequent comorbidities. However, certain drugs as hypomethylating agents (5 azacitidine) have incorporated to treatment strategies after approval for low-blast count (20-30%) AML with promising results even in older AML pts when compared to conventional care regimens. Achievement of CR was not needed to extend survival in this pts. Whether this could be effective in this subset of pts with 3q abn must be addressed in larger prospective studies.

1151

WT-1 EXPRESSION LEVEL FOR MINIMAL RESIDUAL DISEASE MONITORING IN ACUTE MYELOID LEUKEMIA

D Jardan, R Talmaci, C Jardan, D Coriu, C Arion, A Colita
University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Monitoring of minimal residual disease in AML is an important part of patient management which potentially can increase overall survival by early detection of relapse. Many targets has been proposed for MRD monitoring in AML, but all have known limitations as being useful only for a small subset of AML cases. WT-1 was shown to be overexpressed in most AML patients and is a useful target for MRD. *Materials and methods:* we used a previously described method which standardized the use of RQ-PCR for WT-1 expression monitoring. A total 140 patient samples along with normal controls were analyzed. Samples were taken from 40 patients at presentation and different time point during follow-up. *Results*. Most of patients presented elevated levels of WT-1 expression at presentation (above 50 WT-1/10^4 ABL) ranging from 1 to 1,5*10^4 WT-1/10^4 ABL. During and after the therapy levels of WT-1 transcripts steadily decreased reaching normal levels. In 5 patients raise in WT-1 transcript level was predictive of a relapse as confirmed by fusion gene expression monitoring (4 cases with PML-RARA and 1 with AML-ETO). *Conclusions*. Due to expression of WT-1 in normal hematological tissue sensitivity of this assay is somewhat reduced, but in comparison of other methods of MRD monitoring it permits monitoring of the majority of AML patients regardless of other genetic abnormalities.

AZACITIDINE FOR ACUTE MYELOID LEUKEMIA TREATMENT. ENCOURAGING RESULTS OF THREE SPANISH HOSPITALS

A de la Fuente,[1] M Estévez,[1] E Prieto,[2] V García-Gutiérrez,[1] AM Martin Moreno,[4] D Velasco,[3] E Askari,[2] JL Lopez Lorenzo,[2] S Solorzano,[1] R Iglesias,[1] R De Oña,[1] JF Tomás[1]
[1]*MD Anderson IE, Madrid, Spain*
[2]*Hospital Fundacion Jimenez Diaz, Madrid, Spain*
[3]*Hospital Universitario Ramon y Cajal, Madrid, Spain*
[4]*Fundacion MD Anderson IE, Madrid, Spain*

Introduction. The potential and limitations of the standardized cytotoxic chemotherapy (AraC plus Antracycline) for Acute Myeloid Leukaemia (AML) have been assessed by different trials. In the search for novel treatment strategies, different trials have evaluated, with promising results, the role of Azacitidine (AZA), a DNA methyltransferase inhibitor, in the treatment of AML de novo or relapsed, before or after transplantation, or as maintenance after complete remission. *Aims.* To evaluate effectiveness and toxicity profile of Azacitidine in the treatment of AML patients. *Methods.* A retrospective study was carried out at 3 Spanish institutions including patients diagnosed with AML, defined as bone marrow blasts count >20%, receiving Azacitidine either as front line, salvage therapy or maintenance. Main points were progression free survival (PFS), overall survival (OS), complete response (CR) according to the IWG v2003 criteria; and toxicity, graded according to the CTCAE v3.0 of NCI criteria. *Results*. Data from 26 AML patients treated with AZA 75 mg/m^2/day x 7 days every 28 days, were analyzed. Baseline characteristics were: mean age 67.6 years old (38-80), median 68y. Ratio male/female 17/9. Clinical history of previous Myelodysplastic Syndrome (MDS) 54% (14 /26). *Effectiveness.* AZA as front-line therapy: 13 patients, mean age 72.6y (62-80). Previous MDS 8/13 (62%) and poor prognosis cytogenetic 3/13. Five patients achieved cytological complete response (CR). At the time of report, with a mean follow up of 12.1 months (5-43), 8 patients are alive, 4 of them remain in CR, and 5 patients have died because of leukemia progression (mean OS 10.6 months), all of those with previous MDS. AZA as salvage therapy: 8 patients, mean age 63.6y (38-77). Previous MDS in 4 patients, mean of previous lines received: 1.5 (1-2). 2 patients achieved CR, one of them was consolidated with allogeneic transplant and died because of leukemia progression. At the time of report 1 patient is alive in CR with a follow up of 12 months, and 7 have died (OS 3.5 months). Hyperleucocytosic (>20,000/uL) presentation was correlated with a poor response rate and shorter OS; at the time of report there has been 4 deaths out of 5 hyperleucocytosic patients. On the other side, pancytopenic patients presented high response rate, often associated to a significant increase in platelet count, which allowed most patients to become transfusion-independent. AZA as maintenance after CR: 5 patients, mean age 61.1y (48-71). Previous MDS 2 patients. The mean of cycles received was 9.8 (2-21). With a mean follow up of 22.6 months (5.7-33.3), 3 patients are alive in CR, and 2 died with an OS of 22.9 months. *Toxicity.* Hematologic toxicity was observed in all patients, neutropenia grade IV in 23 patients, febrile neutropenia in 12 patients and thrombocytopenia grade IV in 18 patients. All deaths were related to leukemic progression. No relevant extrahematologyc toxicity was reported. *Conclusions*. This study shows Aza is effective in AML and safe with no serious adverse event reported.

[5]*Hospital Ciudad de Jaén, Jaén, Spain*
[6]*Hospital Virgen de las Nieves, Granada, Spain*
[7]*Hospital San Juan de la Cruz, Ubeda, Spain*

Background. 5-Azacytidine (AZA) prolongs survival in higher-risk MDS patients including those with 20-29% marrow blasts, currently diagnosed as Acute myeloid leukemia (AML). However, no large AML series, especially with BM blasts >30%, treated with AZA have been reported. *Patients and Methods*. We have retrospectively analyzed results in patients having received at least 1 cycle of AZA in 7 centers for refractory/relapsed AML or not eligible for intensive chemotherapy (CT). 63 patients were included between Feb/07 to Feb/11; M/F: 42/21; median age 69 years (range 31-84). Median WBC was 2,2x10^9/L (0,1-17,5). Median BM Blasts: 29% (20-94). 30 cases had >30% BM blasts. Karyotype (MRC classification), was adverse in 18 patients (including 5 Complex karyotype; 5 del5q; 6 -7/del7q, and 2 patients with 3q26), Intermediate in 37 (Normal karyotype 31, NPM1mut/FLT3wt in 4 and FLT3-ITD in 3 patients) favorable in 2 cases (1 t(8;21) and 1 t(16;16) and failed in 6 patients. Eighteen patients were treated for refractory/relapse AML after intensive CT or SCT (Auto-SCT=4; Allo-SCT=3); 22 had prior MDS y 23 as first line therapy. AZA doses were 75-100 mg/m^2/day x 7 days (5+2). First evaluation was made after 4-5 cycles according to the International Working Group criteria (AML-IWG-2006). *Results.* With a median follow-up of 9,5 months, patients had received a median of 5 AZA cycles (1-24). In first evaluation made after 4-5 cycles, an overall response rate (ORR) was observed in 17 evaluated patients (30%) including 9 CR (16%) and 8 PR (14%). Additionally, 16 (28,6%) patients achieved hematologic improvement (HI, according to MDS-IWG 2006 criteria). No pretreatment characteristics as age, prior MDS, karyotype, % BM blasts were statistically correlated with response. Eight responder patients progressed within a median time of 8 months. The 12 mo Overall Survival (OS) was 40,9%, and 24 mo OS 15% and median OS of 11 months. In our series, pre-treatment characteristics as higher WBC (p=0,042), adverse vs intermediate cytogenetics (26% vs 54%, p<0,001) and >30% BM blasts (27% vs 50%, p=0,095) showed negative prognostic significance for 12 mo-OS. However, prior MDS (55% vs 31% 12 mo-OS, p=0,13) and disease status (AZA as first line or advanced disease: 42% vs 35%, p=0,5) did not influence OS. Achievement of ORR was associated with improved OS (12 mo-OS 57% vs 33%, p=0,0013). In patients with no AML-IWG response, HI also predicted better survival (p=0,03). *Conclusions*. Patients diagnosed with relapsed AML and those not eligible for intensive CI have limited treatment options. AZA can be a well-tolerated and effective alternative option in this group of patients. In our experience, these patients can achieve OOR of 30% with a 12 mo OS of 40.9%. Higher WBC counts, adverse karyotype and >30% BM blasts were associated with poorer OS but did not preclude response to AZA. Moreover, achievement of ORR or even HI is significantly associated with improved overall survival.

PEDIATRIC AML IN LEBANON: BIOLOGIC FEATURES AND OUTCOME

A Farah,[1] G Horkos,[1] D Bustros,[1] Z Farhat,[2]
[1]*St George University Hospital, Beirut, Lebanon*
[2]*Rizk Hospital University Medical Center, Beirut, Lebanon*

Background. AML is a disease with marked heterogeneity in clinical and biologic features, response to therapy and survival. Despite major achievements in the treatment of AML, long term survival remains poor. About half of pediatric AML patients relapse and die internationally. There is no published data on pediatric AML in Lebanon. Aims: We aimed to identify clinical, cytogenetic, molecular findings and outcome data in the Lebanese population in comparison to international and regional data and to identify specific needs in order to improve outcome. Methods: We underwent a retrospective chart review of children with AML diagnosed at 3 institutions in Lebanon in the past ten years. We filled and analyzed data collection sheets for each patient including demographic information, clinical, laboratory, molecular, therapeutic and outcome data. *Results*. We identified 24 patients with AML, 12 girls and 12 boys. Two had Fanconi anemia, one had Down syndrome, one had myelodysplastic syndrome with monosomy 7, and one had secondary AML after treatment for Burkitt lymphoma. Mean age was 8.6 years (range 1 to 24 years). Mean WBC at diagnosis was 86,500 (Range 2,100-376,000). Two were diagnosed as M0, 4 as M1, 2 as M2, 6 as M3, 5 as M4, 0 as M5, 2 as M6, and 1 as M7. Karyotype was normal in 37.5 % of patients. 25% had t(15;17), 4.1% had t(8;9), 4.1% had t(7;11), 8.3% had t(8;21), 8.3% had inv 16, 4.1% had t(9;11) and 4.1% had complex abnormalities. FLT-3 was positive in 3 patients and was associated with high WBC at presentation and a poor outcome. NPM1 was tested in one patient and was negative. Death in induction was observed only in 3 patients with APML, hyperleucocytosis and bleeding and one child with M6 AML and Fanconi (16.6%). BMT was indicated in 17pts and was performed in 8 pts in Europe or the United States: 1 had a cord blood transplant, 2 had a haploidentical BMT, 5 had matched related sibling BMT. Survival after transplant was 37.5%. Median survival for patients who died from disease progression was 25.8 months. Overall disease-free survival was 30.4% *Summary/Conclusions.* This is the first report looking at pediatric AML in Lebanon. Overall survival in this cohort was 30.4% . Areas of improvement would be initial support of patients with APML and hyperleucocytosis as high mortality was observed in these patients, and availability of BMT in a timely fashion for high risk patients. FLT3 positive patients did poorly with or without transplant. Further data collection to include the entire country is in process.

ANTICANCER ACTIVITY OF 2-AMINOPHENOXAZINE-3-ONE (PHX-3) AGAINST HTLV-1-POSITIVE LEUKEMIA CELLS

A Tomoda,[1] N Miyano-Kurosaki[2] K Kurosaki[3]
[1]*Tokyo Medical University, Tokyo, Japan*
[2]*Chiba Institute of Technology, Narashino, Japan*
[3]*Toho Medical Univeristy, Tokyo, Japan*

Background. It is very difficult to treat patients with adult T cell leukemia (ATL), a malignant tumor of human CD4+ T cells infected with a human retrovirus, T lymphotropic virus type l (HTLV-1). Moreover, ATL is recognized to precede by oligoclonal expansion of HTLV-1-infected T cells, where the virus expands via cell-to cell transmission. Therefore, the agents, which cause apoptosis of this malignancy and prevent the cell-to-cell transmission of the virus, are urgently required. *Aims*. Present research aimed at studying the cytotoxic and proapoptotic effects of 2-aminophenoxazine-3-one (Phx-3) on HTLV-1-positive leukemia cells, as well as its preventing effect against the cell-to-cell expansion of the virus. *Materials and Methods*. HTLV-1-positive leukemia cells, MT-1 cells, HUT-102 cells and MT-2 cells and HTLV-1-negative rat sarcoma cell line, XC cells were treated with different concentrations of Phx-3, which was prepared by the reaction of o-aminophenol with bovine hemoglobin solution, and were incubated in a humidified incubator containing 5% CO2 and 95% air at 37°C. The syncytium formation assay for detecting the cell-to-cell transmission of HTLV-1, consisted of a coculture of HTLV-1-bearing MT-2 cells and indicator XC cells. *Results*. Phx-3 (10 μg/ml) suppressed the viability, arrested cell cycles at sub G0/Gl phase, and induced apoptosis of MT-1, HUT-102 and MT-2 cells, but did not suppress the viability of XC cells and phytohemagglutinin-activated human peripheral blood mononuclear cells. In addition, Phx-3 extensively inhibited the syncytium formation between HTLV-1-positive cells (MT-2 cells) and HTLV-1-negative cells (XC cells), indicating that the transmission of HTLV-1 from HTLV-1-positive cells to HTLV-1 negative cells was prevented by Phx-3. *Conclusions*. Phx-3 may be useful as a therapeutic agent for the treatment of patients with ATL.

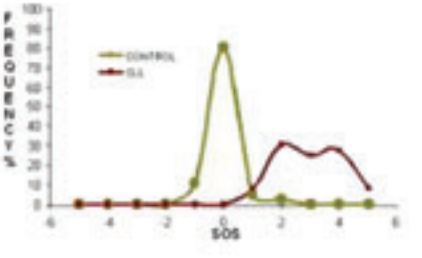
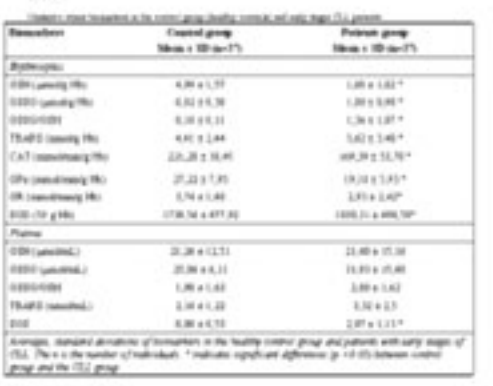
OXIDATIVE STRESS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA EARLY STAGE. ASSESSMENT AND CORRELATION WITH PROGNOSTIC FACTORS

X Ortín,[1] M Giralt,[2] M Romeu,[2] M Llort,[2] V Sanchez-Martos,[2]
M Rodríguez-Luaces,[3] L Font[3]
[1]*Hospital de Tortosa Verge de la Cinta, Tortosa, Spain*
[2]*Farmacology Department. Medicine University, Reus, Spain*
[3]*Hematology Department. Verge de la Cinta Hospital, Tortosa, Spain*

Background. An important area of research of CLL is the identification of markers that are useful for predicting the likelihood of disease progression. Measurement of oxidative stress (OS) makes reference to the imbalance in favour of prooxidating state in front of antioxidative state. Aims. In a population diagnosed of early stage CLL and in a matched group control, we describe the values corresponding to different OS biomarkers. Its weight was set in a model of overall score (SOS) to assess the degree of OS in patients in early stages of CLL. Finally, we assessed whether there were differences in markers of OS in relation to different recognized prognostic factors. *Methods*. Informed consent was obtained. In a group of 37 patients, the values of different recognized prognostic factors were collected. In patients and in a matched group control, we determined the following markers of OS: superoxide dismutase, catalase, glutathione peroxidase, glutathione reductase, reduced and oxidized glutathione, thiobarbituric acid reactive substances and global antioxidant capacity through the ORAC method. Then, we propose an SOS based on the analysis of these biomarkers. SOS was related with the presence of poor prognosis factors, in an attempt to introduce SOS as a prognostic marker of CLL early stage. Results. The SOS of patients did not follow a normal distribution. The score moved significantly towards more positive values, indicating OS (Figure 1). Higher oxidative state was evidenced through each patient's biomarkers compared to control group (Table 1).

Figure 1
Frequency distribution of the SOS in the control groups and the patients group





We found correlations between biomarkers of OS and analyzed prognostic markers. We created the variable 'number of prognostic factors'

(NFPP) that groups patients without poor prognostic factors, patients with 1-2 factors and patients with 3-4 prognostic factors. Most of the biomarkers of and the SOS have values indicative of greater OS in the group of 3-4 prognostic factors. The frequency distribution suggests a tendency to classify patients into patients without poor prognostic factors for CLL that have low SOS, a second group with maximum NFPP (3 or 4 poor prognosis factors) and SOS (five points), and intermediate group regarding NFPP (1 or 2 poor prognostic factors) as the SOS (2 to 4 points). *Summary/Conclusions*. Patients with early stage CLL have greater oxidative distress in all biomarkers analyzed. There is a positive relationship between biomarkers of oxidative distress and most CLL prognostic factors. The presence of poor prognostic factors confers greater OS. The information from the SOS is more accurate than that obtained with each of the biomarkers studied individually and it represents more accurately the state of prooxidant-antioxidant balance of the individual. The SOS is a possible clinical parameter to consider when evaluating the oxidative distress routinely and individually.

[4]*Exposure, Epidemiology and Risk Program, Harvard School of Public Health, Boston, USA*

Background. Chronic lymphocytic leukemia (CLL) is a genetically heterogeneous disease with a variable outcome. The identification of factors that could predict the clinical course of early-stage CLL represents a crucial objective in this malignancy. Although previous studies indicated that telomere length may be a useful independent prognostic factor in the risk stratification of CLL patients, limited information has been reported in asymptomatic early stage patients (Binet stage A). *Aims*. The present study was aimed at investigating the association of telomere length with the major biological and cytogenetic markers known to predict clinical outcome in CLL. The global DNA methylation levels of Alu and LINE sequences, was also investigated. Correlation with disease progression, measured as the time elapsed from diagnosis to first treatment, was evaluated. *Methods*. We measured relative telomere length (RTL) by real-time PCR in a panel of highly purified (>90%) peripheral mononuclear CD19+ cells from 7 healthy donors and 77 untreated CLL patients. All cases were characterized by FISH for the most frequent chromosomal aberrations, namely trisomy 12 and 17p13.1, 11q22.3 and 13q14.3 deletions (*Fabris et al. GCC, 2008*). Molecular markers including mutation status of the heavy chain variable regions of immunoglobulin genes (IGVH), the expression of the 70-kd zeta-chain T-cell receptor-associated protein kinase (ZAP-70) and CD38 cell surface antigen protocols were previously reported (*Cutrona et al. Haematologica, 2008*). A quantitative bisulfite-PCR Pyrosequencing method was used to evaluate methylation of Alu and LINE-1. *Results*. We found a significantly lower RTL values in CLLs (median RTL=0.4 IQR 0.3-0.6) as compared with controls (median RTL=1.0 IQR 0.9-1.3) ($P < 0.001$). A progressive and significant RTL decrease in low (13q- and normal karyotype), intermediate (+12) and high (11q- and 17p-) cytogenetic risk categories (P for trend =0.008) was observed. Patients with IGVH mutated genes had longer telomeres than patients with unmutated genes ($P<0.001$). No significant association between telomere length and either CD38 or ZAP-70 expression was found. Telomere shortening was significantly correlated with hypomethylation of Alu (P=0.048) and LINE-1 (P=0.001), indicating a contribution to chromosome instability. Finally, follow-up analysis, available for 63 patients, showed a significantly higher risk of starting treatment for patients with shorter telomeres (P=0.037). *Conclusions*. Our results extended previous evidence that telomere length could be used as marker for the identification of CLLs with a different prognostic risk.

Background. Chronic Lymphocytic Leukemia (CLL) is a clinically heterogeneous disease characterized by recurrent chromosomal aberrations of prognostic significance. Although Fluorescence in situ Hybridization (FISH) is the most common technique used to detect these abnormalities, it still remains a quite expensive time-consuming method. *Aims*. We aimed to evaluate the potential of the novel Multiplex Ligation-dependent Probe Amplification (MLPA) technique, to detect genomic alterations in CLL. *Methods*. Highly purified (>90%) peripheral mononuclear CD19+ cell populations from 100 untreated CLLs in early stage disease (Binet stage A) were included in this study. All samples were investigated by fluorescence in situ hybridization (FISH) for the presence of trisomy 12 and 17p13.1, 11q22.3 and 13q14.3 deletions. For MPLA analysis, DNA was amplified by means of 2 commercially available probes sets allowing the simultaneous screening of 56 genomic sequences. *Results*. Overall, a high degree of concordance (95%) between MPLA and FISH results was found provided that abnormal clone was present in more than 30% of leukemic cell population. The use of multiple MPLA probes allowed the fine the mapping of the 13q14 deletion and the identification of intragenic or small alterations undetected by FISH. Moreover, additional alterations in 2p24 (MYCN) (3pts), 8q24 (C-MYC) (1pt), 9p21 (CDKN2A-2B) (1pt), 1q21 (LMNA) (1pt), and 6q25-26 (1pt) regions not covered by a standard FISH assay were detected and all confirmed by FISH. *Conclusions*. Our data extend previous limited evidence that MLPA may represent a useful technique to characterize well-known lesions as well as to investigate additional genomic changes in CLL.

1160

THE POTENTIAL ROLE INKT CELLS IN THE DEVELOPMENT AND PROGRESSION OF CHRONIC LYMPHOCYTIC LEUKEMIA

J Hus, A Bojarska-Junak, A Dmoszynska, E Wasik-Szczepanek, M Gorska, J Rolinski

Medical University of Lublin, Lublin, Poland

Backgroud and Aims. Chronic lymphocytic leukemia (CLL) is characterized by multiple and complex immune disorders. It was recently demonstrated that in addition to conventional T and NK cells, an important role in tumor immunity, plays a third type - natural killer T (NKT) cells. Invariant NKT (iNKT) cells are CD1d-restircted T cells which express invariant T-cell receptor (TCR) incorporating Vα24 chain paired with Vβ11 chain and NK cell markers. Human Vα24+ NKT cells play crucial roles in various immune responses including autoimmune and antitumor responses. Little is known however about the role of iNKT in patients with CLL. The aim of the study was to evaluate iNKT cells numbers in peripheral blood of CLL patients and their correlations with the other populations of immune cells and prognostic factors. Methods: We investigated iNKT cells numbers in peripheral blood of 60 untreated patients with CLL and 20 healthy individuals matched for age. iNKT cells were labeled with anti-Vα24 and anti-CD3 antibodies and analyzed using flow cytometry. *Results*. Analysis of Vα24 surface expression on CD3+ T cells revealed significantly lower median percentage of iNKT cells in peripheral blood of CLL patients (0.57%) than in healthy donors (0.80%; p=0.04) and significantly lower in patients in 3-4 stages according to Rai (0.08%) compared to the stage 0 (0.39%; p=0.04). There were also correlations between iNKT cells and populations of CD4+ (R=0,362; p=0,026) and CD8+ cells T (R=0,324; p=0,047), and inverse correlations between the percentage of iNKT cells and the percentage of CD19+CD5+ leukemic B cells (R=-0,372; p=0,021) and percentage of CD4+CD25high T regulatory cells (R=-0.506; p=0.03). Analysis of the relationship between iNKT cells and selected prognostic parameters showed inverse correlations between the percentage of iNKT cells and peripheral blood WBC (R=-0.378; p=0.03)

and lymphocyte count (R=471; p=0.04), β2-microglobulin serum level (R=-0.479; p=0.04) and the percentage of leukemic cells with the expression of ZAP-70 (R=-0.436; p=0.0.008) and CD38 (R=-0.374; p=0.004). The median treatment free survival (TFS) was significantly longer in patients with iNKT cell percentages higher than the median in the whole group (0,57%) as compared to patients with the lower percentages. *Conclusions*. Patients with CLL have lower percentages of Vα24 cells in peripheral blood as compared to age-matched healthy control. Moreover iNKT percentages decrease along with disease progression, correlate with CD4+ and CD8+ T cells and NK cells, and adversely correlate with Tregs as well as will negative prognostic factors. These results suggest an important role of iNKT cells in the development and progression of CLL, as well as their potential prognostic significance. Further studies involving larger groups of patients, and an assessment of iNKT cell function in patients with CLL are ongoing.

1161

TH17 CELL FREQUENCIES IN PERIPHERAL BLOOD OF PATIENTS WITH CLL ADVERSELY CORRELATE WITH T REGULATORY CELLS AND POOR PROGNOSTIC FACTORS

J Hus, A Bojarska-Junak, A Dmoszynska, E Wasik-Szczepanek, M Gorska, M Kusz, J Rolinski
Medical University of Lublin, Lublin, Poland

Backgroud and Aims. Th17 cells have been defined as a subset of CD4+ lymphocytes, characterized by their production of IL-17 and expression of the transcription factor ROR? T. They have been implicated in inflammation and autoimmune diseases but still little is known about their prevalence and function in human cancer. In contrast to T regulatory cells, there are data showing both beneficial and harmful implication of Th17 cells in tumor development. In patients with chronic lymphocytic leukemia (CLL), many abnormalities in T cells populations have been described, but the data on TH17 cells are very limited. The aim of the study was to evaluate Th17 cells in peripheral blood (PB) of CLL patients and their correlations with the other populations of immune cells, such as: T regulatory cells, NK cells, iNKT cells and prognostic factors. Methods: Frequencies of Th17 cells among CD3+CD4+ T cells, were measured in 56 patients with CLL, and 20 healthy individuals matched for age. Peripheral blood CD4+ T cells were analyzed for intracellular expression of IL-17A, FoxP3, IL-2, IL-4, IL-10, IFNγ and TNF using flow cytometry. Th17 cells were defined as CD3+CD4+/CD17A+, T regulatory cells (Tregs) as CD4+CD25+FoxP3+; NK cells as CD3-/CD56+CD16+ and iNKT cells were counted as CD3+ Vα24+ cells. *Results*. Analysis of intracellular expression of IL-17A in CD4+ T cells revealed significantly higher median percentage of Th17 cells in peripheral blood of CLL patients (18.4%) than in healthy donors (3.28%; p=0.003) and significantly lower in patients in 2-4 stages according to Rai (4.48%) as compared to the stage 0 (36.16%; p=0.04). There were significant correlations between the percentages of Th17 cells and iNKT cells (R=0.556; p=0.04), and inverse correlation between the percentage of Th17 cells and T regulatory cells (R=-0.280; p=0.04), CD3+CD4+/IL-4+ (R=0.545; p=0.04) and CD3+CD4+/TNF+ T cells (R=0.592; p=0.01). The percentage of Th17 inversely correlated with β2-microglobulin serum level (R=-0.293; p=0.04) and the percentage of leukemic cells with the expression of ZAP-70 (R=-0.244; p=0.04) and CD38 (R=-0.333; p=0.01). In patients requiring therapy during observation period, median percentage of Th17 cells was significantly lower comparing to untreated ones (5.74% vs 10.97%, p=0.02). *Conclusions*. Percentage of Th17 cells in peripheral blood of patients with CLL was significantly higher than in age-matched healthy control, it decreased along with disease progression, correlated with iNKT cells, and adversely correlated with Tregs, CD4+ T cells expressing IL-4 and TNF as well as with negative prognostic factors. These preliminary results suggest that Th17 cells might be involved CLL pathogenesis, and higher percentage in patients with early stage CLL, may suggest that they take an important part in the control the leukemic cells growth in early, stable phase of CLL. Further studies are required to confirm these observations.

1162

IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH STEREOTYPED IGH4-39/IGHD6-13/IGHJ5 REARRANGEMENT PROGRESSION MIGHT BE CONSIDERED AS RICHTER'S TRANSFORMATION INDEPENDENTLY OF HISTOLOGIC CONFIRMATION

E Orlandi, P Bernasconi, S Zibellini, M Boni, I Giardini, R Zappatore
Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background. Among factors predictive for CLL transformation to diffuse large B-cell lymphoma (Richter's syndrome, RS), there is the usage of the IGHV4-39 gene with a stereotyped HCDR3 belonging to subset 8 (according to *Murray et al, 2008*). *Aims*. This study describes 3 CLL cases carrying IGHV4-39 with stereotyped HCDR3-subset 8 in whom transformation presented with a sudden and impressive increase in peripheral B-cell count. *Methods*. Diagnosis of CLL was based on clonal B-lymphocytosis > 5.00x10^9/L (phenotype score >3); ZAP70 and CD38 expression was assessed by flow cytometry; FISH analysis was performed using commercialy available probes (LSI13, LSID13S319, CEP12, LSIp53, LSIATM, and BCL3 split signal probe [Dako]); cytogenetic analysis was performed after CpG-oligonucleotide DSP30 and IL2 stimulation. IGHV mutational status was evaluated according to IMGT. Results: Among 408 unselected CLL patients, 15 (3.7%) carried the IGHV4-39 gene and among them 3 showed the IGH4-39/IGHD6-13/IGHJ5 rearrangement. In these pts a stereotyped HCDR3-subset 8 was detected. No other pts displayed this specific stereotyped HCDR3. At diagnosis, these 3 pts (all Binet stage A) showed similar biologic characteristics: IGHV unmutated status, ZAP70 and CD38 positivity, surface IgG (λ light chain in 1 and k in 2), and isolated trisomy 12. Two pts carried BCL3 translocation, occurring as a consequence of t(14;19)(q32.3;q13.2). First-line treatment was administered at 20, 23 and 8 mos from diagnosis: pt 1 and 2 (age >70 yrs and comorbidities) received mono-chemotherapy and achieved a partial response, while pt 3 (a 63-year-old female) received a fludarabine-cyclophosphamide combination and achieved a complete response with low-level minimal residual disease. Transformation (at 65, 43, and 45 mos from diagnosis) was characterised by a sudden increase in lymphocyte count to > 150.00x10^9/L after a period of stable disease. Morphologic evaluation revealed the predominance of large, lymphoma-like cells; enlargement of retroperitoneal lymph-nodes was detected in pt 2, but a biopsy could not be performed because of poor performance status. Splenomegaly was absent. LDH value was extremely high in all cases (from 6,300mU/ml to 42,900mU/ml). Bone marrow was extensively infiltrated by large B-cells. Cytogenetic re-evaluation detected del17p in pt 1, no clonal evolution in pt 2 and a highly complex karyotype (defined as ≥3 abnormalities) in pt 3. CD23 expression was reduced in pt 2 and 3, while CD5 and CD20 expression was maintained. In all cases, analysis of IGHV-D-J rearrangement confirmed that B-cells were clonally related to the CLL phase. Pt 1 died 2 mos after transformation while on treatment with Alemtuzumab; pt 2 is still receiving treatment; pt 3 experienced an incredibly poor clinical course and died of respiratory failure caused by multiple pulmonary infiltrates in a few days after admission. *Conclusions*. (i) In our experience, HCD3-subset 8 stereotypy was associated with an aggressive outcome characterised by a predominant involvement of peripheral blood and bone marrow. Independently of a pathologically-proven shift to lymphoma, progression in pts with this peculiar HCD3 stereotypy might be considered as a transformation to Richter's syndrome. (ii) In CLL the t(14;19) may cooperate with the stereotyped IGHV4-39/IGHD6-13/IGHJ5 rearrangement in causing aggressive evolution.

1163

EVALUATION OF TP53 MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA USING RESEQUENCING MICROARRAY PLATFORMS

J Jana,[1] J Malcikova,[1] J Smardova,[2] L Wu,[3] S Truong,[3] B Tichy,[1] V Navrkalova,[1] P Dobes,[2] K Plevova,[1] L Sebejova,[1] S Pavlova,[1], B Dvorakova,[1] N Patten,[3] A Nakao,[3] J Mayer,[1] M Trbusek, S Pospisilova[1]
[1]*University Hospital Brno, CEITEC, Masaryk University Brno, Brno, Czech Republic*
[2]*University Hospital Brno, Brno, Czech Republic*
[3]*Roche Molecular Systems, Inc., Pleasanton, USA*

Background. TP53 abnormalities in CLL are currently considered to be a very important prognostic and predictive factor. In addition to the 17p deletion (10-15% patients), which is typically assessed, but also TP53 mutations have been confirmed to have negative impact on disease progression and response to chemotherapy. However, the most comprehensive method for mutational analysis is being discussed here. *Aims*. The aim of this project was to compare mutation detection by two microarray resequencing assays - Roche AmpliChip p53 Test (Roche Molecular Systems) and CLL custom resequencing Microarray (Affymetrix), with the functional analysis of separated alleles in yeast (FASAY) coupled to sequencing of colonies with mutated TP53. *Methods*. CLL patients harboring TP53 mutations detected by FASAY (53 mutations/46 samples) or gDNA sequencing (3 mutations/3 samples) were selected together with 12 samples previously assessed as wt-TP53 by FASAY. In all cases, the 17p

deletion was examined by I-FISH. All samples were analysed using two research assays based on an Affymetrix Microarray platform- (i) AmpliChip p53 Test (Roche) - a resequencing microarray designed for detection of single base substitutions and single base deletions in the coding and splice site regions of exons 2 - 11. (ii) CLL custom resequencing microarray (Affymetrix) containing probes for TP53 exons 2-11 and splice sites and for 9 other cancer-related genes; in particular, probes for 1nt substitutions in the whole coding region and a probe for a common 2-nt deletion in TP53 (del 2N 209) were included. For discordant cases, the particular exon was analyzed by Sanger sequencing. *Results*. In all 12 samples previously assessed as wt-TP53 by FASAY, no mutation was found by either microarray assay. Across all three methods, 64 mutations were detected in 49 samples - 49 (76,6%) substitutions (i.e. 41 (63,1%) missense, 5 (7,7%) splice-site, 3 (4,6%) nonsense mutations), and 15 (23,4%) ins/del mutations (including 3 one nucleotide deletions). However, only 35 (54%) mutations out of 64 were recognized by all methodologies - 32 substitutions and only 3 ins/>1bp del mutations. Both microarray assays reached the same number of recognized mutations. Irrespective of the FASAY results, each microarray detected 47 mutations out of 64 (73,4%), 41 of which overlapped. Vice versa, 10 additional mutations identified by microarrays were not detected by FASAY (2 missense, 2 nonsense, 4 splice-site mutations, two 2-nt deletions), 4 of which were not possible to be detected by gDNA sequencing. *Summary/Conclusions*. Microarray resequencing methods are less time-consuming than classical sequencing. AmpliChip p53 Test is more user-friendly, while the CLL custom resequencing microarray enables parallel mutational analysis of multiple genes. All tested platforms may fail to detect mutations present in low percentage of cells (approx. 15-25%). Ins/>1bp del mutations and one nucleotide deletions may not be detected by all methods, suggesting that no single methodology currently used for TP53 mutational screening is able to detect all present mutations. Therefore, further studies should be done in order to design the most suitable approach for detection of the majority of TP53 mutations in CLL patients.

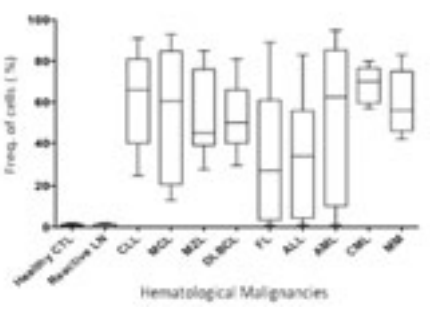
Background. ROR1 is a member of the receptor tyrosine kinase (RTK) family and related to muscle specific kinase (MUSK) and Trk neutrophin receptors. It is considered a potent survival kinase. ROR1 is of importance during embryogenesis and organogenesis and is not expressed on normal adult lymphoid and non-lymphoid tissues. Our published data showed an ectopic expression of ROR1 in all chronic lymphocytic leukemia (CLL) cases. A recent publication has described expression of ROR1 in hematologic malignancies of lymphoid origin. In the present study we have investigated the surface protein expression of ROR1 molecule in a series of patients with lymphoid and myeloid malignancies. *Aims*. To study the expression pattern of ROR1 in hematological malignancies of lymphoid and myeloid origins using a ROR1 monoclonal antibody recognizing the extracellular domain of ROR1.



Methods. 137 cases belonging to different hematological malignancies including 35 cases of CLL, 8 cases of mantle cell lymphomas (MCL), 7 cases of marginal zone lymphoma (MZL), 11 cases of diffuse large B-cell lymphoma (DLBCL), 30 cases of follicular lymphoma (FL), 16 cases of acute lymphoblatic leukemia (B-ALL), 12 cases of acute myelogenous leukemia (AML), 9 cases of chronic myelogenous leukemia (CML) and 9 cases of multiple myeloma (MM) were analysed by flow cytometry. Ten aged-matched healthy donors PBMC and 10 reactive lymph nodes were used as controls. *Results*. Our results showed a statistically significant variation in the expression of ROR1 in various hematological malignancies as compared to controls (no expression of ROR1 in PBMC of healthy donors or *reactive* lymph nodes). In flow cytometry, 35/35 of CLL cases were positive for ROR1 surface expression range of 25-91%, 8/8 MCL (13-93%), 7/7 MZL (28-76%), 11/11 DLBCL (30-81%), 20/30 FL (12-89%), 12/16 ALL (11-83%), 9/12 AML (32-95%), 9/9 CML (57-80%) and 9/9 MM (42-83%). *Conclusions*. ROR1 is widely expressed at the protein level in most types of lymphoid and myeloid malignancies but not on normal blood cells. These results suggest that ROR1 may be a candidate molecule for targeted therapy in various types of hematological malignancies

REARRANGEMENT OF λ IMMUNOGLOBULIN LIGHT CHAIN IN CLL IS COUPLED WITH MIRNA-650 EXPRESSION

M Mraz,[1] K Plevova,[2] D Dolezalova,[3] K Stano Kozubik,[2] V Mayerova,[2] K Cerna,[2] S Pavlova,[2] M Doubek,[2] Y Brychtova,[2] M Trbusek,[2] A Hampl,[3] J Mayer,[2] S Pospisilova[2]

Background. MicroRNAs constitute 3-5% of predicted genes in human genomes, and are located in the introns (~60%) or exons (~10%) of protein-coding genes, or outside of known genes (~30%). Although their important role in the regulation of protein-coding mRNAs was described, very little is known about the actual regulation of their expression. Interestingly, the locus for immunoglobulin λ light chain (IgL) in humans includes an annotated miR gene miR-650 (encoded by 4 members of V2 subgenes for IgL) (*Das, 2009*). This could be of particular importance because it is known that the biology of CLL is driven by processes that depend on immunoglobulin structure and microRNA expression (*Calin, 2005; Mraz, 2009*). Moreover, microRNAs are physiologically involved in regulation of IgG production and V(D)J recombination (*Vigorito, 2007; Koralov, 2008*). *Aims*. The aim of this study was to characterize the expression and function of miR-650 in CLL. *Methods*. We have defined the immunoglobulin λ light chain rearrangement in a cohort of 40 CLL patients using BIOMED-2 protocol and the expression of surface immunoglobulins was verified by flow cytometry. The qRT-PCR (TaqMan, ABI) was used to study the expression of miR-650 in this cohort. To assess the function of miR-650 cell lines (MEC-1, NALM-6) and CLL cells were electroporated with a RNA mimicing miR-650 (Dharmacon). This was followed by microarray expression profiling and western blot analysis 24/48 hours post transfection. *Results*. The analysis of IgL rearrangement by PCR showed that 51% patients (21/40) had a productive rearrangement in immunoglobulin λ light chain. Interestingly, the Real-Time PCR for miR-650 reported ~10 fold higher expression of miR-650 in CLL cells utilizing specifically V2-8, V2-5, V2-14, V2-23 subgenes for IgL (n=10) compared to samples utilizing different V lambda family (n=11) or expressing kappa Ig (n=19). These IgL subgenes of V2 family include homologues for miR-650. The coupled expression of miR-650 with IgL is remarkable because miR-650 was first identified in colorectal cells and it was believed to be regulated independently of immunoglobulin gene. Interestingly, the higher expression of miR-650 in our cohort was associated with statistically significant longer OS (161 vs. 173 months) and TFS (28 vs. 60 months). To elucidate the role of miR-650 in CLL we have transfected miR-650 into B-cells and assessed protein expressions of targets previously identified in solid tumors ING4 (Inhibitor of Growth 4) and CDK1 (cyclin dependent kinase 1) (Zhang, 2010; Chien, 2010) and also putative targets (EBF3, Bcl2, MDM2, MDMX, cyclin D1, pRb, Dicer). We were not able to demonstrate the regulation of any of these targets by miR-650 in B-cells. The microarray analysis of transfected cells revealed that the electroporation with miR-650 led to a down-regulation of dozens of potential target mRNAs, and the validation of the putative targets is currently in progress. *Conclusions*.

We have shown that the expression of miR-650 is coupled with the regulation and usage of variable subgenes for lambda immunoglobulin light chain and this has potential relevance for B cell biology.

Background. Monoclonal B-cell lymphocytosis (MBL) is a disease entity characterized by lower than 5000/μL circulating clonal B-cells in absence of other features of lymphoproliferative disorders. Regulatory T-cells (Tregs) constitute a small subset of cells involved in antitumour immunity and are generally increased in patients with chronic lymphocytic leukemia (CLL), for the diagnosis of which more than 5000/μL clonal B-cells in peripheral blood are required. *Aims*. To evaluate the number of circulating Tregs in patients diagnosed with *clinical* MBL and CLL and to compare it to clinical-biological features of the diseases. Methods. Tregs number have been detected, by means of multicolor flow cytometry (CD45/CD4/CD25/CD127), in the peripheral blood of 56 patients with *clinical* MBL (30 M/26 F; mean age 66.5 ± 9.7 years; range 44 - 86 years), 74 patients with previously untreated CLL (36 M/38 F; mean age 68.7 ± 12.5; range 35 - 90 years) and 40 healthy subjects (20 M/F 20; mean age 55.8 ± 14.3 years; range 30 - 81 years). *Results*. MBL patients showed a lower absolute number of Tregs (37.6/μL ± 38; range 4-154/μL), compared to CLL patients (70.7/μL ± 112; range 10-820/μL; p=0.0004), but higher than controls (27.3/μL ± 10.9; range 5-49/μL) without statistical significance. Noteworthy, there was not a higher number of CD4+/μL cells within the CLL subset compared to MBL (p=0.16). No significant correlation was found between Tregs number and CD38+B-cell/μL or ZAP-70. Moreover, the absolute cell number of Tregs directly correlated both with more advanced Rai/Binet clinical stages (p=0.02) and peripheral blood B-cell lymphocytosis (p<0.0001). Of note, the absolute number of Tregs was found lower within MBL patients than within CLL patients staged as 0/A Rai/Binet (p=0.02). *Conclusions*. This study showed that Treg cells are abnormally increased in *clinical MBL* patients compared to normal subjects, despite at a lower degree than in CLL patients. A significant direct relationship was also found with the tumor burden expressed by B-lymphocytosis. In light of these data, MBL seems to be a preliminar phase preceding the onset of CLL and the progressive increase of Tregs number might contribute to the evolution of MBL to overt CLL.

Background. The transplantation of CLL into immunodeficient mice represents an attractive model for the studies of disease biology and drug resistance. Recently, Bertilaccio et al. (2010) developed a xenograft model by engrafting the CLL cell line MEC-1 into Rag2(-/-)gamma(c)(-/-) mice. These mice lack a functional receptor for interleukins and do not have functional T, B and NK cells, in contrast to NOD/SCID mice that retain NK cells. Several animal models utilizing NOD/SCID mice were also tested for engraftment of primary CLL (Shimoni,1997; Durig,2007). Unfortunately, the efficiency of the CLL engraftment in mouse models is not yet optimal. *Aims*. The aim of the study was to establish a CLL xenotransplant model using NOD/SCID IL2Rgamma(-/-) mouse (NSG). We hypothesized that the absence of functional T, B, and NK cells might enable sufficient engraftment of CLL cells. *Methods*. We used 31 non-irradiated NSG mice at age two months. The first group of mice was injected i.p. (n=5) and s.c. (n=5) with 5x10e6 MEC1 cells and sacrificed after 4 weeks. In the second group (n=14) mice were injected i.p. with Histopaque-separated 25x10e6 CLL cells. Cells from 3 patients were transplanted each in two mice and animals were sacrificed after 4 weeks. Cells from other 4 CLL samples were injected each in two mice and analyzed 4 and 6 weeks after the transplantation to assess the evolution in number of engrafted cells. Seven control mice were injected with PBS only. Samples of PB, spleen, liver, and bone marrow were analyzed by flow-cytometry and immunohistology for expression of human CD45/CD3/CD5/CD19/CD20/CD23. *Results*. The s.c. and i.p. injection of MEC1 cell line led to successful engraftment in all animals. The transplantation of MEC1 led to a significant weight loss, hepatomegaly, and massive splenomegaly in all subjects. Severe anemia, thrombocytopenia, and leukocytosis with the presence of immature human B-cells in the peripheral blood occurred in the transplanted animals. Immunohistological analysis revealed a massive focal infiltration of liver, spleen, and bone marrow by immature polymorphic human cells (CD19+, CD20+). Moreover, rapidly growing subcutaneous tumors occurred after s.c. injection of MEC1. In mice transplanted with CLL samples (n=7) flow-cytometry confirmed the engraftment with human CLL cells in all subjects after 4 weeks. The highest relative engraftment of CLL B-cells was observed in the spleen with an exception of 1 CLL sample where B-cells were present only in peripheral blood. The immunohistological analysis revealed a mild infiltration by CD20 positive cells in the spleen, liver, and bone marrow for 2 samples and massive infiltration by CD20+CD23- (B-cells) and CD3+5+ (T-cells) cells in spleen for 4 CLL samples. The detected B and T cells had high proliferative activity (80% of cells Ki67+). This corresponds with the observation of increased number of human cells for 3/4 of sequentially tested samples (in one case only T-cell counts increased). *Conclusions*. The use of NOD/SCID IL2Rgamma(-/-) mouse strain led to 100% engraftment efficiency for MEC1 and CLL cells making it a promising tool for CLL xenotransplant studies.

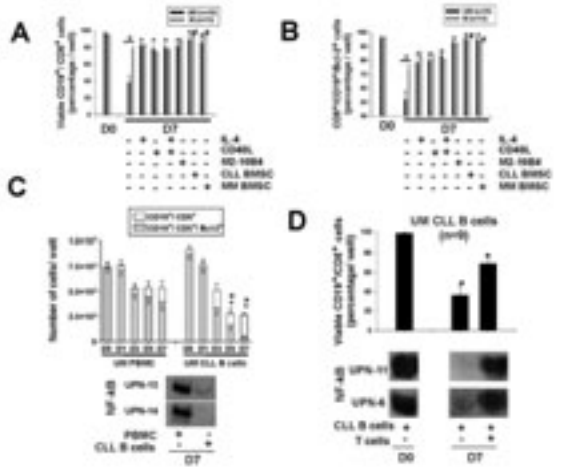
Background. Chronic lymphocytic leukemia (CLL) is a clinically heterogeneous disease. Patients with unmutated (UM) tumor immunoglobulin heavy chain variable regions (IGHV) have a worse prognosis than patients with mutated (M) IGHV. The tumor microenvironment [cytokines (i.e. IL-4 and CD40L) bone marrow stromal cells (BMSC) and nurse-like cells (NLCs)] are important survival factors for CLL B cells. *Aims*. Aim of this study is to assess whether and to what extent UM and M CLL cells differently depend on the local microenvironment for their survival. *Method.* M and UM CLL cells negatively selected by magnetic beads isolation were cultured in the presence or in the absence of IL-4, CD40L, murine stromal cells (M2-10B4), NLCs, CLL-derived BMSC and autologous, negatively selected T lymphocytes. Apoptosis an necrosis were evaluated by annexin V and propidium iodide (PI) staining. The intracellular expression of Bcl2 and the activity of NF-kB were evaluated by flowcytometry and by EMSA, respectively. Quantitative analysis of RelA and RelB NF-kB subunits was performed with the TransAM Flexi NF-kB Family assay kit (Active Motif, USA). CK and chemokines (CC) were measured using a multiplex suspension array system (Bio-Rad Laboratories S.r.l.) in culture supernatants. *Results*. Leukemic cells purified from the peripheral blood (PB) of UM patients (UM CLL B cells) showed a significantly higher apoptotic rate in 7-day cultures as compared to M CLL B cells. In both M and UM CLL B cells, high basal levels of Bcl-2 expression and NF-kB activity were detected. On day 7, Bcl-

2 and both RelA and RelB NF-kB subunits were significantly lower in UM than in M CLL B cells. CD40L, IL-4 and stromal cells significantly improved UM CLL B cells viability with a Bcl-2 dependent (Figure 1A-B), but NF-kB independent, mechanism. Interestingly, cell viability, Bcl-2 expression and NF-kB activity were preserved when cells were cultured as UM unfractionated PB mononuclear cells (UM PBMC) as compared to purified UM CLL B cells (Fig. 1C).



This observation suggested the presence of a pro-survival element in the PB of these patients. NLCs were not responsible of this prosurvival effect since, unexpectedly, NLC were defectively generated from the PBMC of UM patients, whereas they were abundantly generated by the PBMC of M patients. In spite of the lack of generation of NLC, leukemic cells viability was very similar in the non adherent fraction of M and UM PBMC. Conversely, autologous T cells played an essential role in supporting UM CLL B cells survival. Indeed,a significant NF-kB-mediated prosurvival effect was observed when purified UM CLL B cells were cultured in the presence of autologous purified T cells (Figure 1D). This prosurvival effect of circulating T cells was exerted both in cell-to-cell contact and in trans-well condition and was associated to increased secretions of TNF-α, PDGF-BB and IL-8. *Conclusions*. Despite their more aggressive features, UM CLL B cells are more susceptible to spontaneous apoptosis and their viability strictly depend from the presence of environmental prosurvival signals. This vulnerability of UM CLL B cells might be exploited as a selective target of therapeutic interventions.

1169

GENE EXPRESSION PROFILE OF AURKA AND AURKB IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): CORRELATION WITH CLASSICAL CYTOGENETIC (GTG) AND HEMATOLOGICAL PARAMETERS

F Oliveira,[1] A Lucena de Araújo,[1] L Figueiredo-Pontes,[1] E Paton,[2] F Saldanha-Araújo,[1] E Magalhaes Rego,[1] R Falcao[1]

[1]*Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil*

[2]*Hematology and Stem Cell Transplantation Unit - Pio XII Foundation, Barretos, Brazil*

Background. Aurora kinases are mitotic kinases especially important in the regulation of G2/M phase of the cell cycle and various mitotic events, including centrosomal duplication, mitotic spindle assembly, chromosome segregation and cytokinesis. The three major aurora kinases (AURKA, AURKB and AURKC) have been previously described and they are related to different stages of mitosis. Furthermore, aurora kinase overexpression leads to genetic instability and trigger the development of tumors. However, the majority of studies involving AURKA/B are addressed to cancer immunotherapy and no study has comprehensively examined the role of these genes in leukemogenesis. AIMS In the present investigation, we have evaluated AURKA and AURKB gene expression in peripheral blood (PB) cells of CLL patients, by real time quantitative PCR and correlate the findings with hematological parameters established for CLL and classical cytogenetics METHODS Sixty two CLL patients (23 female and 39 male) and 10 age-matched hematologically healthy donors were selected for our study. The majority of the patients were classified as Binet A (63%). The comparative analysis of AURK/B expression of leukemic and normal samples was calculated as a relative quantification to the GAPDH gene. Moreover, AURKA/B gene expression from leukemic samples was calculated as relative quantification to normal CD19+ cells from healthy donors and expressed as 2-ΔΔCt. The metaphase induction in CLL was performed by using the immunostimulatory method that employs the combination of DSP30 and IL-2. Chromosome preparations were obtained by using standard procedures and the subsequent cytogenetic analysis and interpretation were made according to the ISCN (2009). All cytogenetic and gene expression data (AURKA/B) were validated by FISH analysis with a specific set of probes. RESULTS According to median value of AURKA/B expression, patients were divided into two groups (≥ 3.4, considered as AURKA+ and > 2.3, considered as AURKB+) and their clinical and biological characteristics were correlated. Higher AURKA/B expression were observed in CLL samples compared with PB normal samples (AURKA [mean value of ΔCt ± SD]: 0.093±0.003 vs 0.071±0.001, p=0.02; AURKB: 0.166±0.01 vs 0.09±0.002, p=0.02). Moreover, AURKA/B+ patients presented a significantly high leukocyte count compared with AURKA/B- patients (AURKA [WBC countx103 ± SD]: 37.8±5.5 vs 68.8±5.8, p=0.0003; AURKB: 40±5.5 vs 66.6±6.2, p=0.0023, respectively). However, no significant differences were found regarding to Binet classification, gender or platelets count. In addition, Pearson correlation showed that there is a significant association between high expression of AURKA/B and complex karyotype (relative risk: 2.4 [95%CI: 1.46-3.93], p < 0.001). Among the classical cytogenetic profile obtained, normal karyotype was found in 15 patients (24%) and metaphases with abnormal karyotype were seen in 47 subjects (76%). CONCLUSION In this investigation we demonstrated a significant correlation among high expression levels of AURKA/B genes in CLL with chromosomal abnormalities and other hematological parameters. Overexpression of aurora kinase genes have been extensively studied in solid tumors. In CLL this observation may be associated to the genesis of chromosomal abnormalities and possible be used to predict the course of genomic instability in CLL patients.

PERSISTENT POLYCLONAL BINUCLEATED B-CELL LYMPHOCYTOSIS (PPBL): IDENTIFICATION OF A SPECIFIC CYTOGENETIC PROFILE AND A LONG TERM FOLLOW UP OF 151 PATIENTS

E Cornet,[1] H Mossafa,[2] K Courel,[2] JF Lesesve,[3] G Sébahoun,[4] X Troussard[1]

[1]*CHU Caen, Caen, France*

[2]*Laboratoire Cerba. Département Génétique., Cergy Pontoise, France*

[3]*CHU Nancy-Brabois. Service d'hématologie biologique Vandoeuvre-lès-Nancy, France*

[4]*CHU Nord Marseille - Service d'Hématologie, Marseille, France*

Background. PPBL is a rare disease characterized by a chronic, stable, persistent and polyclonal B-cell lymphocytosis, the presence of binucleated lymphocytes in the peripheral blood and a polyclonal increase in serum immunoglobulin-M. *Aims*. We report here the cytogenetic characteristics and the long-term follow-up of 151 patients with PPBL. Moreover, a pangenomic study of 10 patients using the most resolutive cytogenetic method based on SNP array was performed in order to study more extensively cytogenetic abnormalities in PPBL. *Methods*. PPBL was diagnosed in 151 patients. Conventional cytogenetic analysis (CCA, n=139), fluorescent in situ hybridization (FISH, n=129) and SNP array were performed at diagnosis and during the course of PPBL. We used Affymetrix® Cytogenetics Whole-Genome 2.7M Arrays® in 10 typical PPBL patients. The DNA was extracted from peripheral CD19+ B-cells and CD19- cells purified using Miltenyi® technology (AutoMACS Pro Separator®). *Results*. PPBL was diagnosed in 26 male and 125 female patients, with a median age of 40 years (18.9-66.2). At diagnosis, supernumerary isochromosome 3q (+i(3)(q10)) was detected in 82/139 patients (59%) using CCA and FISH. PCC was detected as a sole abnormality in 7/139 patients (5%). No abnormality was identified in 50/139 patients (36%). Chromosomic instability was observed in 77/139 patients (55%) at diagnosis and persisted during PPBL follow-up. SNP arrays were performed in 10 patients (3 male, 7 female). CD19+ B-cells were separated by immunomagnetic cell sorting. We performed DNA arrays on CD19+ and CD19- cells in 7 patients, CD19+ cells in 2 patients and CD19- cells in 1 patient. Recurrent gene copy number (GCN) gains were detected on the long arm of chromosome 3 (3q) and identified only in CD19+ cells. The size of GCN gains was variable between patients, from thirty kilobases to the whole 3q. GCN gains did not involve all the CD19+ B-cells (mosaicism phenomenon). Non recurrent GCN aberrations involving the whole genome confirmed the presence of genetic

instability in all patients. Out of the genes amplified on 3q of CD19+ cells, we identified with a high frequency (7/9 patients) partial or complete amplification of one particular gene. After a median follow-up of 34 months (1-347), six cases of IgM MGUS were observed. Three patients developped solid cancers (2 pulmonary cancers and 1 cervical carinoma). Three patients developped diffuse large B-cell lymphoma (DLBCL), two patients a splenic marginal zone lymphoma (SMZL). *Conclusions*. Isochromosome 3q has been implicated in the progression of cervical carcinomas. In addition to MGUS cases, we report here 5 cases of lymphomas developped during the course of PPBL. The clinical follow-up with genetic instability and the presence of recurrent cytogenetic abnormalities on 3q led us to consider PPBL as a premalignant state and require a carefully long-term follow-up of PPBL patients.

MUTATIONAL STATUS AND GENE REPERTOIRE OF IGHV-D-J REARRANGEMENTS IN SERBIAN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

T Karan-Djurasevic,[1] V Palibrk,[2] N Tosic,[1] T Kostic,[1] V Spasovski,[1] M Stojiljkovic Petrovic,[1] M Colovic,[2] N Colovic,[2] D Antic,[2] B Mihaljevic,[2] S Pavlovic[1]

[1]*IMGGE, Belgrade, Serbia*

[2]*Institute of Hematology, Clinical Center of Serbia, Belgrade, Serbia*

Background. The mutational status of immunoglobulin heavy variable region (IGHV) genes is the most stable molecular prognostic marker in chronic lymphocytic leukemia (CLL). It defines two CLL subtypes, mutated (M-CLL) and unmutated (U-CLL), with significantly different clinical course. M-CLL cases usually present a non-progressive disease and have considerably longer survival than unmutated cases, who tend to have a progressive disease. Biased IGHV gene usage in CLL vs. normal B lymphocytes as well as in mutated vs. unmutated CLL cells, and the expression of almost identical, "stereotyped"heavy complementarity-determining region 3 (VH CDR3) sequences among some patients implies the role of specific antigens in the pathogenesis of the disease. Furthermore, there are population differences in mutational status and IGHV gene usage which may reflect different genetic background and/or effect of environmental factors. *Aims*. The aim of this study was to analyze the mutational status and IGHV gene repertoire in Serbian CLL patients. It included 85 CLL patients, 57.4 % with progressive and 42.6 % with non-progressive disease. *Methods*. IGHV-IGHD-IGHJ rearrangements were amplified by multiplex RT-PCR using 5' primers specific for leader sequences of IGHV gene subgroups, in conjunction with 3´ primers complementary to IGHJ genes. Clonal RT-PCR products were sequenced and analyzed using the ImMunoGeneTics database. *Results*. Overall 88 alleles have been analyzed, since 3 patients (3.5%) expressed biallelic rearrangements, both of the same mutational status (mutated). We found that 56.8% of rearrangements carried mutated IGHV genes, whereas 43.2% carried unmutated IGHV genes. Among M-CLL patients, 44.7% presented a progressive disease, in contrast to 73.3 % among U-CLL patients. Comparison of PFS means revealed a significantly longer PFS in mutated cases ($p<0.01$). The most frequent IGHV subgroup was IGHV3 (55.7%) followed by IGHV1 (27.3%), IGHV4 (12.5%), IGHV5 (2.3%), IGHV2 (1.1%) and IGHV6 (1.1%). No IGHV7 subgroup members were identified. IGHV3 subgroup genes were found predominantly in mutated rearrangements (69.4% vs. 30.6%), in contrast to IGHV1 subgroup genes which were predominantly unmutated (70.8% vs. 29.2%). A total of 29 IGHV genes were identified, 7 of them accounting for 56.9% of all rearrangements. The most frequent were IGHV3-23 (14.8%), IGHV1-69 (10.2%), IGHV3-33 (8%), IGHV1-2 (6.8%), IGHV1-18 (5.7%), IGHV3-30 (5.7%) and IGHV3-48 (5.7%). GHD genes showed the following distribution: IGHD3 - 38.4%, IGHD2 - 22.1%, IGHD6 - 12.8%, IGHD1 - 10.5%, IGHD4 - 8.1%, IGHD5 - 7% and IGHD7 - 1.2%. The most frequent IGHJ gene was IGHJ4 (48.9%), followed by IGHJ6 (28.4%), IGHJ3 (11.4%) and IGHJ5 (11.4%). No IGHJ1 and IGHJ2 genes were identified. IGHJ4 was used preferentially in mutated (72.1%) and IGHJ6 in unmutated rearrangements (80%). There was a significantly lower median VH CDR3 length in mutated (15 a.a.) vs. unmutated (21 a.a.) cases ($p=<0.001$). *Conclusions*. Our study showed strong correlation between IGHV gene mutational status and clinical course of CLL. Progressive disease was observed predominantly in patients expressing unmutated rearrangements, while non-progressive disease predominated among M-CLL patients ($p=0.026$). Frequencies of IGHV subgroups and their mutational status resembled those observed in other Mediterranean countries, with exception of IGHV4 subgroup genes which were underrepresented in our cohort.

1172

THE INTERPLAY BETWEEN PKC α AND PKC β II IN CLL

M Vukovic,[1] R Nakagawa,[2] E Cosimo,[1] A McCaig,[1] A Michie[1]

[1]*Paul O'Gorman Leukaemia Research Centre, Glasgow, UK*

[2]*Laboratory for Lymphocyte Differentiation, RIKEN Research Centre, Yokohama, Japan*

Background. PKCα and PKCβII belong to a classical subfamily of serine/threonine protein kinases that are involved in regulation of proliferation, differentiation, cell migration and apoptosis in normal cells. These two enzymes are structurally similar and are activated by phospholipids, diacylglycerol (DAG) and Ca2+ binding. In a number of cancers including breast, prostate, brain and gastric cancer, PKCα has been implicated as a tumour promoter. However, in other cancers such as colon, thyroid, pituitary and pancreatic cancer, it serves a tumour suppressive role. Thus it is important to delineate the particular function of PKCα in specific cancers in order to better direct therapies. PKCβII plays an important role in regulating signals generated by the BCR, and has been shown to be overexpressed in CLL compared to normal mature B cells, correlating with a worse overall prognosis. In the current study, we explore the relationship between these two isoforms in CLL. *Aims*. Although the expression profile of PKCβII has been associated with a more aggressive CLL phenotype, its function in the generation and propagation of CLL remains largely unclear. Here we characterise the role of PKCα and PKCβII in CLL by investigating the signalling mechanisms associated with their expression. *Methods.* Murine CLL-like cells were generated from stem/progenitor cells of wild type ICR mice by retroviral introduction of kinase inactive PKCα construct, and subsequently maintained in an *in vitro* B-cell supportive system or injected into RAG-/- mice for *in vivo* studies. For translational significance, human CLL cells were isolated from peripheral blood of diagnosed patients and subsequently co-cultured in a microenvironment mimicking that of circulating and proliferative compartments. *Results*. Our studies indicate that PKCα acts as a tumour suppressor in CLL, and its subversion leads to an upregulation and sustained overexpression of the PKCβII isoform. Importantly in human CLL, we show a decrease in PKCα transcript and protein levels in more than half of CLL cases studied, complimented by an increase in PKCβII transcript and protein levels. In addition, the increase in PKCβII expression positively correlates to increases in tumour-associated ERK and mTor signalling. Finally we identify cyclin D1 to be overexpressed in our mouse model of CLL and in human CLL, which, alongside the implicated signalling pathways leads to cells that have a survival and proliferation advantage over normal B cells. *Summary*. Although structurally similar, PKCα and PKCβII serve very different and significant roles in CLL. The downregulation of tumour suppressor PKCα results in an upregulation of PKCβII coupled with increased oncogenic signals, contributing to the malignant phenotype of CLL.

CD38 RS6449182 POLYMORPHISM IS ASSOCIATED WITH OVERALL SURVIVAL IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

N Bilous,[1] I Abramenko,[1] A Chumak,[1] Z Martina,[1] I Dyagil,[1] I Kryachouk,[2] I Filonenko[3]

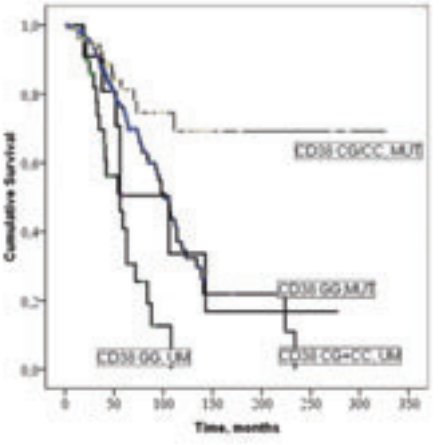
[1]*Research Center for Radiation Medicine, Kyiv, Ukraine*

[2]*National Cancer Institute, Kiev, Ukraine*

[3]*Regional Hospital, Poltava, Ukraine*

Background. CD38 antigen is well-established independent marker of poor prognosis in B-CLL. CD38 molecule is thought to be also one of the key pathogenetic elements in the disease development, which is involved in delivering of growth and survival signals in leukemic cells. The single nucleotide polymorphism 184C>G in the regulatory region of CD38 gene (CD38 rs6449182 SNP) has recently shown to affect CD38 expression. The association of variant G allele with some poor prognosis markers, advanced clinical stage and elevated risk of Richter transformation was demonstrated, the association between CD38 polymorphism and CLL risk has been questioned. *Aims*. Aim of our study was to evaluate if CD38 rs6449182 polymorphism influence the risk of CLL development and whether it provide prognostic information on the clinical outcome of the disease. *Methods*. PCR-RFLP analysis was used for CD38 rs6449182 genotyping: genomic DNA was amplified in PCR using primers designed by *Aydin et al*., 2008, with following enzymatic digestion of PCR products. The digested products were resolved on 3% agarose gel and analyzed. Results: SNP was studied in a total of 304 CLL patients and in the group of 217 control individuals. The median follow-up from diagnosis in CLL patients was 4.1 years (range 0.1-27

years). The majority of patients were at Binet A or B stage at diagnosis (45% and 40% correspondently), 70% cases were IgVH unmutated. We found that the frequency of the variant homozygous CD38 rs6449182 GG genotype was significantly higher in CLL group in comparison with control (14.8% vs 6.9%, P=0.012).



The distribution of heterozygous CD38 rs6449182 CG genotype did not differ significantly between groups. The variant G allele frequency was found in CLL group and controls as 0.30 and 0.26 (P=0.03). The highest CD38 rs6449182 homozygous GG genotype frequency was observed in group of 29 patients who developed Richter syndrome (RS) during follow-up period (34.5%). It differed significantly when compared both with the CLL cohort without RS (12.7%), and with treated CLL patients without RS during follow-up at least 2 years (11.8%), P<0.05. The distribution of heterozygous CG genotypes in these groups was comparable. The overall survival (OS) of patients with GG genotype was significantly shorter in comparison with those with at least one wild C-allele: for the entire CLL cohort (median 56 vs 111 month, P=0.0001), for Binet A/B stage patients (median 59 vs 123 month, P=0.0001), for CLL group with unmutated IgVH status (median 56 vs 101, P=0.0001), and for patiens with mutated IgVH genes (median 106 vs did not reach , P=0.019) (Figure1). We failed to found some significant correlation between the CD38 rs6449182 genotypes and other relevant prognostic factors such as Binet stage, IGHV mutation status, or CD38 expression. *Conclusions*. Our results suggest that CD38 rs6449182 SNP may be a factor predisposing to CLL. The variant homozygous CD38 rs6449182 GG genotype identify poor risk CLL group concerning OS and RS transformation.

1174

IMPAIRED ANTIGEN PRESENTATION AND POTENT PHAGOCYTIC ACTIVITY IDENTIFYING TUMOR-TOLERANT HUMAN MONOCYTES: DEMONSTRATION IN ISOLATED CELLS FROM CHRONIC LYMPHOCYTIC LEUKEMIA

R Cordoba,[1] E Lopez-Collazo[2]
[1]*Hospital Infanta Sofia, San Sebastian de los Reyes, Spain*
[2]*Hospital Universitario La Paz, Madrid, Spain*

Background. Monocyte exposure to tumor induces a transient state in which these cells are refractory to further exposition to cancer. This phenomenon, termed "tumor tolerance", is characterized by a decreased production of proinflammatory cytokines in response to tumors. *Aims*. Identify tumor tolerance phenomena in monocytes from Chronic Lymphocytic Leukemia patients and their relationship with prognostics markers. Methods: Samples of peripheral blood from CLL patients were procesed for monocyte isolation and phagocytic activity was measured. Tumor lymphocytes were cocultured with control monocytes and induced tolerance status was measured. Results: We have established a human model of tumor tolerance and have observed a marked downregulation of MHCII molecules as well as the MHCII master regulator, CIITA. These cells combine an impaired capability for antigen presentation with potent phagocytic activity. We also show that circulating monocytes, isolated from patients who suffer from mature B-cells neoplasm, share all the determinants that characterize cells locked in a tumor tolerant state. In addition, lymphocytes from these patients and supernatants from their culture induced a tumor tolerance state in controls monocytes. *Conclusions*. Monocytes from CLL patients are locked in a tumor tolerant state with a lower capability of antigen presentation and therefore an impaired immune response.

ANALYSIS OF POTENTIALLY BICLONAL CLL PATIENTS WITH TWO OR THREE PRODUCTIVE IGH REARRANGEMENTS

K Plevova, H Skuhrova Francova, B Tichy, L Jurackova, K Brazdilova, K Burckova, O Stehlikova, Y Brychtova, M Doubek, J Mayer, S Pospisilova
University Hospital Brno, CEITEC, Masaryk University, Brno, Czech Republic

Background. Majority of chronic lymphocytic leukemia (CLL) patients develop a monoclonal disease and thus can be characterized by single immunoglobulin heavy chain gene (IGH) rearrangement. Interestingly, double productive IGH rearrangements can be sporadically detected with an incidence about 2-4% and can indicate simultaneous biclonal/biphenotypic disease. Malignant subclone diversification due to BCR receptor editing or monoclonality with a lack of IGH allelic exclusion has been previously described as other possible reasons of this phenomenon. Here we present the detailed analysis of patients expressing two/three functional IGH rearrangements who were examined for IGHV mutational status. Aims: We performed a detailed characterization of selected CLL cases with double/triple productive rearrangements and followed their clonal evolution during course of the disease. *Methods*. B-lymphocytes were separated from peripheral blood using Ficoll-Paque PLUS (GE Healthcare) and RosetteSep Kits (StemCell). IGHV status was assessed according to the ERIC recommendations and Ig light chain (IGL) utilization was examined using cDNA as an input material. At DNA level, clonal IGH and IGL rearrangements were confirmed by BIOMED-2 protocol and also unproductive rearrangements were analyzed. Immunophenotypization was performed on separated CD19+ cells using panels of monoclonal antibodies including those against CD19/IgLambda/IgKappa, CD19/CD20/CD23, CD19/CD43/FMC7. Other prognostic markers, such as chromosomal alterations and TP53 mutational status, were available in all cases. *Results*. Double/triple productive IGH rearrangements were in total detected in 35 patients comprising 3,36 % of our cohort. Ig light chains (IGL) utilization was assessed and according to the number of double productive IGL rearrangements, 18 patients were considered as biclonal CLL. Interestingly, in nine patients, alterations in the proportion of IGH rearrangements were observed during the disease course. In three patients, selection of other clone was accompanied by unfavorable de novo TP53 mutation detection. Out of these 35 patients expressing multiple in-frame IGH rearrangements, 12 of them (34%) were further analyzed in three subsequent samples per patient in average. At DNA level, all productive rearrangements were confirmed; out-frame IGL rearrangements were found in nine cases (75%). Immunophenotypization revealed two separated populations in five cases (42%) differing mainly in Kappa and Lambda IGL that corresponded with PCR results and were considered as true biclonal cases. In one patient, biclonality was presumed while two in-frame IGL Lambda were present. Based on bioinformatics analysis, BCR editing was excluded in all 12 patients because no pair of IGH rearrangements shared D-J junction. *Summary/conclusions*. Biclonal CLL is a very infrequent phenomenon representing approximately 50% of cases with double productive IGH rearrangements. We performed particular characterization of 12 potentially biclonal patients. Six of them were biclonal at least in one time-point during their course of CLL according to immunophenotype and/or PCR. In several cases, proportion of particular populations changed in time. BCR editing was excluded in all these patients. We conclude that subsequent monitoring of CLL patients and repeated IGH rearrangement assessment is necessary for understanding of malignant disease evolution. Further analysis of these patients is in progress.

GENOMIC ABNORMALITIES DETECTED BY MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION (MLPA) MAY PRECEDE THE CLINICAL ONSET OF CHRONIC LYMPHOCYTIC LEUKEMIA BY SEVERAL YEARS

M Frezzato, N Guercini, M Bernardi, A Montaldi, I Giaretta, F Rodeghiero
S. Bortolo Hospital, Vicenza, Italy

Background. Chronic lymphocytic leukaemia (CLL), the most common leukaemia in adults in Western countries (Linch, 1992), is a biologically heterogeneous disease with a variable clinical course and many aspects of the pathogenesis are awaiting final clarification. B lymphocyte monoclonal rearrangements may last for longer than 7 years before the disease becomes clinically detectable (Frezzato 2005, Landgren 2009) but the triggering events leading to the disease progression are largely unknown. No data are available on the time of the first onset of the cytogenetic abnormalities detected by Fluorescence In Situ Hybridization (FISH) in more than 50% of cases at diagnosis (Dohner, 2000). *Aims.* To identify genetic abnormalities in healthy subjects, enrolled in a prospective population based investigation, who subsequently developed CLL. *Methods.* Six patients with a diagnosis of CLL, according to standard morphologic and immunophenotypic criteria (Cheson 1996) have been identified in a cohort of 14396 healthy subjects who had been enrolled during years 1993 - 1996 in an ongoing prospective clinical survey also providing DNA samples preservation. FISH analysis has been performed in all these cases as part of the diagnostic work-up for CLL. We performed Multiplex Ligation-dependent Probe Amplification (MLPA) analysis (an emerging new tool apt to detect some genomic abnormalities with high sensitivity and specificity) (Buijs, 2006; Al Zaabi, 2010) in all these subjects as well, after an informed consent was obtained. If a chromosomal abnormality was detected (by FISH and/or MLPA) we performed MLPA on DNA preserved samples collected at the enrolment in the clinical survey, 54 to 89 months before diagnosis. Interphase FISH with SEC63 (6q21), C-MYC (8q24), ATM (11q22), GLI (12q13), DLEU1 (13q14 and p53 (17p13) probes was performed on peripheral blood samples according to the ISCN criteria (Brothman, 2009). DNA was analysed with MLPA P040 test kit (MRC Holland), including set probes for 11q23 (ATM), 12p12.3-12p13, 12q14-12q24.3, 13q14.2 (RB1), 13q14.3 (KCNRG-ATP7B), 17p13.1 (p53) chromosomal regions, according to the manufacturer's protocol. *Results*. FISH analysis at diagnosis showed a del:13q14 in 3 subjects (nuclear positive interphases: 90% in 2 cases; 10% in 1 case). MLPA result was consistent with FISH only in the two patients with 90% deletion. In one of them MLPA revealed the same deletion to be present 54 months before diagnosis (see Table for details). *Conclusions*. We firstly report a CLL-associated genetic deletion detected a long time before the clinical diagnosis. The deletion includes the DLEU1 locus, proposed as the most likely candidate CLL-associated tumour suppressor gene (*Wolf, 2001; Ouillette, 2008*). We have been able to evaluate only a few cases but our report could prompt future investigations on the role of different genetic abnormalities and their meaning in the pathogenesis of CLL

CHARACTERIZATION OF CLL CASES BY I-FISH, IGHV STATUS AND CD38 EXPRESSION: A SINGLE CENTER STUDY

A Gabbas, G Piras, M Monne, A Uras, A Palmas, M Murineddu, A Piras, G Pira, S Muredu, M Cucca, A Gabbas
San Francesco Hospital, Nuoro, Italy

Background. Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with a variable clinical course. *Aims*. Here we report the characterization of a cohort of 90 CLL patients from central Sardinia using an integrated diagnostic laboratory work-flow including immunophenothyping, cytogenetics and IGHV mutation status. *Methods*. Ninety CLL patients (M 54, F 36, age 41-90) were diagnosed between 2007-2010 by standard criteria . FISH analysis on interphase nuclei with probes for the detection of trisomy 12, 11q22.3 (ATM), 13q14 (D13S25 and D13S319) and 17p13 (TP53) was perfomed in peripheral blood cells. In a subgroup of 30 CLLs, peripheral blood was cultured in the presence of the immunostimulatory CpG-oligonucleotide DSP30/Interleukin-2 (IL2) and RNA was analyzed for IGHV mutation status following the Biomed-2 protocol. Sequence data were analyzed using the International Immunogenetics database (IMGT, http://imgt.cines.fr). The IGHV status was assigned as mutated with a cut-off of 2%. Expression of CD38 was analyzed on FACScan flow cytometry using direct conjugate antibodies (anti-CD38-FITC/anti-CD19-PE) and positivity was assigned with a cut-off of 20%. *Results*. All patients included in the study could be successfully analyzed by interphase FISH. Trisomy 12 was detected by FISH in 15,5% (14/90) patients, 13q14 deletion in 40/90 (44%), TP53 deletion in 12% (11/90), while the 11q deletion was observed in 7 patients (7,7%). Correlation between CD38 expression and FISH aberrations showed del13q14 in 40% of the CD38-negative CLLs while TP53 was present in the 74% of the CD38-positive subgroup. The status of somatic mutations in the IGHV gene was available in 45 cases. Twentysix (58%) displayed an unmutated IGHV status, while the remaining 19 cases (42%) had a mutated IGHV gene. The IGHV gene family usage within the mutated subset was VH4>VH3>VH2> VH1>VH7, whereas IGHV3 was the most frequently used in the unmutated group, being expressed in 13 patients. IGHV1-69 genes were present in 3 CLL patients overall (2 unmutated). Correlation between cytogenetic categories and mutation status showed that the poor prognosis marker TP53 deletion was present in 3/26 (11,5%) of unmutated CLLs and in 2/19 (10%) of mutated cases. CD38 expression was detected in the 43% and 28% of the mutated and unmutated cases respectively, and showed a tendency to correlate with cytogenetic abnormalities. According to age, TP53 and 13q14 deletions (21% and 60%, respectively) were more frequently detected in CLL cases diagnosed before age 55 when compared to older patients. When clustering analysis was performed, only 8 out of 45 sequences were assigned to a specific subset according to Murray et al, while 13 sequences, all unmutated, clustered based on the pattern they shared following the TEIRESIAS algorithm. This cluster included stereotype rearrengements in the IGHV3-21, IGHV3-11 and IGHV1-69 with the longest HCDR3 sequences. *Summary*. We found that cytogenetic adverse prognostic markers were more frequently detected among younger CLL patients and the ratio of unmutated/mutated patients is higher than in other population. We have a low incidence of IGHV3-21 and IGHV1-69 in Sardinian CLLs suggesting that the frequency of specific IGHV CLL may be related to geographic, ethnic, or environmental background.

1178

GENE EXPRESSION PROFILE IN PATIENTS WITH CLL TREATED WITH CLADRIBINE AND CYCLOPHOSPHAMIDE REGIMEN

I Franiak-Pietryga,[1] A Salagacka,[1] H Maciejewski,[2] J Blonski,[1] A Kotkowska,[1] M Mirowski,[1] T Robak,[1] A Korycka-Wolowiec[1]
[1]*Medical University of Lodz, Lodz, Poland*
[2]*Wroclaw University of Technology, Wroclaw, Poland*

Background. An accumulation of CD5/CD19/CD23 positive cells in bone marrow and peripheral blood due to their resistance to apoptosis is a key event in chronic lymphocytic leukemia (CLL). Therefore, apoptotic gene expression could be essential to understanding the background of the disease. The microarray technique is one of the most innovative and powerful tools, providing a wealth of information on gene expression which can be helpful in identification of diagnostic and prognostic factors and than can lead to a selection of the most appropriate therapy. Cladribine and cyclophosphamide (CC) is a safe and very effective drug combination used in the first line therapy for CLL patients. *Aims.* The aim of this study was to investigate the gene expression profile in CLL cells with regard to factors involved in the apoptosis cascade in patients treated with CC protocol. *Methods*. The study involved 8 CLL patients who were previously untreated. All the patients were diagnosed and followed at the Department of Hematology, Medical University of Lodz, Poland, according to the IWCLL 2008 criteria. The study received the approval of The Ethical Committee of Medical University of Lodz (Dnr. RNN/196/07/KE). Informed consent was obtained from all the patients. Fresh blood samples were collected from all the enrolled patients before and after 2 weeks of the first cycle of CC treatment

(cladribine 0.12mg/kg - days 1-3, cyclophosphamide 600mg/m2 - days 1-3; q 4 wks × 6 courses). Mononuclear cells (MNCs) were separated according to the standard protocol and used for further studies. The gene expression profiling was measured by means of microarray method (TaqMan Low Density Array, Human Apoptosis Panel). This microarray method was based on real-time PCR technique. Ninety six transcripts were placed on the array, 3 of which were endogenous controls. Measurements were conducted in duplicates. The relative expression of each gene was quantified by the comparative cycle treshold (Ct) method (ΔΔCt), using 18S as an endogenous control. Fold change (RQ) for each gene was evaluated. RQ is the differential expression after treatment to gene expression before treatment. For significant fold change the value of 2 or greater than 2 was chosen. *Results.* Data analysis highlighted 8 out of 93 examined apoptotic genes whose expression was significantly important. 5 genes (BIRC 1, BIRC5, BIRC8, CARD6, HRK) form a cluster by means of average linkage method. The most significant differences in gene expression before, against and after treatment are demonstrated by antiapoptotic genes such as: BIRC1, BIRC5, BIRC8 whose expression decreased. However, the expression of 5 proapoptotic genes such as: PUMA, CARD6, HRK, APAF1 and TNFRSF10B (TRAIL-R2) significantly increased. *Conclusions*. Our results show that the treatment with CC regimen leads to overexpression of genes involved in the intrinsic pathway of apoptosis. Nevertheless, further studies into the clinical usefulness of this observation for the development of new therapeutical strategies are vital.

Background. The B-CLl, is the most common type of leukaemia in the West countries. Several immunophenotypic, genetic and molecular markers allow their inclusion in different prognostic groups, recently serum free light chain (FLC) quantitation have shown abnormalities in 39-54% of CLL patients and this marker is associated with shorter time to treatment (TTT) and inferior overall survival (OS). *Objectives*. To determine FLC abnormalities in a prospective cohort of CLL patients (EPIGEN project) and explore the effects of both monoclonal and polyclonal FLC elevations in the outcome of CLL patients. *Material and Methods*. A prospective, descriptive, and analytical and cross section of incidental cases of B-CLL in Aragon, Navarra, Basque Country and Cantabria during the period: 1/09/2007- 31/08/2008. The study involved 13 hospitals that have collected the clinical characteristics at diagnosis and biological samples for DNA, RNA and serum extraction stored in the Biobank. The study has the approval of the Committee on clinical trials and investigation of Aragon (CEICA) and patients have signed IC. We designed a database for the study where the variables are collected: demographic, staging (Rai / Binet), lymphocyte count, immunophenotyping (IP) (CD38, Zap70), genetic testing (CG) and molecular (Ig VH genes mutation), esearch serum samples using the Freelite FLC assay (The Binding Site, Ltd., Birmingham, UK). Elevated FLC was defined as either kappa or lambda above the reference range (k>19.4 mg/L, l>26.3 mg/L). Monoclonal FLC elevation was defined as elevated FLC with an abnormal FLC ratio. Polyclonal FLC elevation was defined as elevated FLC with a normal FLC ratio (0.26-1.65). Follow-up to progression, development of primary tumors and response to treatment were analyzed. RESULTS: We collected data from a total of 96 new patients. The analysis includes 61 cases: men (H) 31 (50.8%) females (M) 31 (50.8%). Average age: 70.8 years (41-91) Males: 63.3 years and Females: 71.6 years. 52.4% were older than 70 years. Staging at diagnosis (Binet and Rai): A0 68.8%, 13.1% AI, AII 3.2%, 1.6% BI, BII 8.1%, BIII 3.2%, 3.2% CIV. 13.1% starts with splenomegaly. 29.5% had no lymph node involvement or extranodal affectation. CG: del13q (18.0%), trisomy 12 (18.0%), del11p (6.5%), del17p (1.6%), normal (45.9%). IP: CD38 positive (22.9%), Zap70 positive (16.3%). Ig VH mutated (21.3%). Abnormalities in FLC were present in 48% of the CLL patients. In 35.0% elevated kappa or lambda was observed, 20.0% had a monoclonal FLC and 15.0% had a polyclonal FLC elevation. Monoclonal FLC elevation was associated with high risk features of CD38+, CD49D+, ZAP70+, IGHV unmutated and having high risk FISH (del 17p13; del 11q22). *Conclusions*. The more common genetic aberrations were: del13q and trisomy 12. Normal kariotype apparently is related to early stages, absence of spleen enlargement and B symptoms, typical morphology and predominance of IgVH gene mutation and CD38 and Zap70 negatives. The analysis of FLC at diagnosis could be a predictive biomarker in CLL.

MATURATION OF THE MIR15A/MIR-16-1 FAMILY IS IMPAIRED IN CHRONIC LYMPHOCYTIC LEUKEMIA

D Mertens,[1] D Allegra,[2] T Zenz,[1] H Döhner,[1] S Stilgenbauer[1]

[1]*University of Ulm, Ulm, Germany*
[2]*DKFZ, Heidelberg, Germany*

A role as tumor suppressor has been proposed for the miR15a/miR-16-1 family of miRNA genes localized in a critical region in 13q14 that is deleted in more than 50% of CLL patients. These two miRNA genes regulate cell cycle progression and apoptosis in cell lines and in vivo, and knockout of the syntenic region in mice results in the development of a CLL-like phenotype. We measured by qRT-PCR mir15a and miR-16 in CLL samples (n=38) and normal B-cells (n=14) and observed reduced levels in CLL independent of the 13q deletion status. We then assessed the levels of the primary precursors of the mature miRNAs (pri-miRNAs 15a, 16-1 and 16-2). No difference could be identified between patients with a deletion of 13q and patients with a retention of both copies of 13q14. However, CLL cells had increased levels of pri-miRNAs when compared to CD19-sorted normal B-cells. Moreover, in CLL cells levels of miR-16 and miR15a were inversely correlated to their pri-miRNA transcripts, while a miRNA used as a control (miR-155) had a positive correlation with its primary transcript as expected. In addition, also the levels of precursor miRNA molecules of the 13q14 miRNA genes were low in CLL patients. This strongly suggested a defect of miRNA maturation at the Drosha processing step that produces the pre-miRNA from the pri-miRNA molecule. Therefore, we grouped patients according to the observed levels of pri-miRNA and pre-miRNA: CLL patients with a ratio of these two processing intermediates (pri-/pre) above the average levels observed in non-malignant CD19-B-cells were included in the *high ratio*group (58% of our cohort CLL patients), while the rest was grouped in the *normal ratio* group (42%). Patients with high pri-/pre ratio had significantly lower mature miRNA levels compared to patients with normal ratio. In contrast, the respective ratio of the precursor molecules of miR-155 that were used as control did not differ in the two groups. These findings suggest that there is a processing defect that reduces maturation of the miR15a/miR-16 in a subset of CLL patients. In order to test the actual processing activity in CLL cells, we used a luciferase based in-vivo Drosha processing assay and could show a significant reduction of pri-16-1 processing in patients belonging to the "high pri-/pre ratio"group. These findings underline the role of miR15a/miR-16 in the pathomechanism of CLL and show a complementary route of inactivation that supplements genomic loss of the critical region in 13q14 and its transcriptional downregulation in CLL.

1181

MEASUREMENT OF SERUM FREE LIGHT CHAIN (SFLC) IS A SIMPLE, COST EFFECTIVE AND POWERFUL TEST TO EVALUATE ADVERSE FORM OF CLL AT DIAGNOSIS AND TO FOLLOW THE RESPONSE TO TREATMENT

S Durrieu, J Dubois, P Correia, F Demarthe, G Etienne, H Eghbali
Institut Bergonie, Bordeaux, France

Background. Previously published data have emphasized the utility of SFLC assessment in newly diagnosed CLL and have concluded that abnormal SFLC ratio was related to adverse prognostic factors and a shorter time to first treatment. *Aims.* The aims of our study were to confirm the utility of SFLC at CLL diagnosis in a prospective study, to compare with known prognostic factors, and to evaluate the interest of the

test in treated patients' follow-up. *Methods.* We investigated SFLC level and ratio in 63 patients newly diagnosed with CLL in our centre between August 2007 and December 2010. Blood lymphocytes immunophenotype systematically included CD for RMH scoring and surface light chain expression analysis. Prognostic factors such as Binet stage, lymphocyte doubling time, CD38 and ZAP-70 expression, FISH analysis for P53, ATM, or RB deletion and chromosome 12 number, serum thymidine kinase and serum soluble CD23 were systematically evaluated. Serum B2-microglobulin and immunoglobulin (G, M and A) levels were also measured. In the same period of time, SFLC were assessed before and after chemotherapy in 52 treated patients, allowing 121 control measurements (one to seven per patient), and were compared to clinical and haematological response and minimal residual disease (MRD) measured by 5-colour flow cytometry, according to international recommendations. *Results.* Thirty patients (48%) had an abnormal SFLC level and/or ratio at diagnosis. The ratio kappa/lambda was increased in 19/21 cases (90%). No relation was found between the level of SFLC and white blood cell and/or blood B lymphocytes number, neither with the level of light chain expression on B lymphocytes as determined by immunophenotype. The type of free light chain was constantly the same than the one expressed at the B lymphocyte surface. Abnormal SFCL was associated with adverse prognostic factors such as advanced Binet stage at diagnosis (B and C, $p < 0.001$), short lymphocyte doubling time (LDT) ($P<0.0001$), ZAP-70 positivity ($p < 0.05$), adverse cytogenetics (P53 deletion, ATM deletion or trisomy 12, $p <0.01$). No relation was found with the presence of a serum monoclonal immunoglobulin peak, which was detected in 3 patients only. However a decrease in normal immunoglobulin serum level was evidenced in 22 of the 30 patients with abnormal SFLC (73%), with a significant correlation ($p = 0.001$). Analysis of treatment-free survival (TFS) duration between diagnosis and first line treatment showed a relation to SFLC. Multivariate analysis confirmed that short LDT, ZAP-70 expression, and P53 or ATM deletion were independent risk factors in Binet stage A CLL, and that abnormal SFLC was a high independent risk factor. Abnormal SFLC CLL had shorter TFS (HR = 27, 95% CI = 4.15-175.5), confirming that the disease was more aggressive in this group. When analysed during patients' follow-up after treatment, abnormal SFLC were associated with a positive MRD ($p< 0.0001$), with a specificity of 86% and a positive predictive value of 96%. *Conclusions.* SFLC assessment is a simple, immediate and cost-effective test to appreciate the aggressiveness of CLL at diagnosis and to follow the response to treatment.

1182

CLONAL EVOLUTION IN CLL PATIENTS. ACQUISITION OF NEW CYTOGENETIC ABERRATIONS IS RELATED TO THE EXPRESSION OF CD38 AT DIAGNOSIS.

A González Serna,[1] M Osma,[2] F Ortuño,[2] H Cano,[3] V Vicente[2]
[1]*University Hospital Los Arcos del Mar Menor., Murcia, Spain*
[2]*Servicio of Hematology and Medical Oncology. Regional Center of Blood Donation., Murcia, Spain*
[3]*University Hospital Los Arcos del Mar menor., Murcia, Spain*

Introduction. The acquisition of new genetic alterations in the development of CLL is a known phenomenon, but published studies show conflicting results. For some authors, this phenomenon is not related to the expression of CD38 while others find a relationship either with unmutated cases or the expression of ZAP-70. *Patients and Methods.* In a series of 200 patients diagnosed with CLL, we included those who had been studied by FISH both at diagnosis and later on during their clinical course. We analyzed clinical and biological prognostic factors (age, stage, B2M, ZAP70, CD38, del13q, +12, and del17p del11q) in the diagnosis and follow-up. We also studied variables such as the number of treatment lines, vital status, lymphocyte doubling time, newly acquired cytogenetic abnormalities and secondary neoplasms. *Results.* We evaluated 60 patients with a mean age of 64 years (range 35-79). In the group that did not show clonal evolution (29/60), 21 had neither cytogenetic abnormalities at diagnosis nor at follow-up, and the remaining 8 showed the same abnormalities throughout their evolution [del13q (4 / 29), del11q (1 / 29), +12 (2 / 29), t (2; 5) (1 / 29)]. 31 patients showed a clonal evolution. In patients with normal FISH at the time of diagnosis, the most frequent acquired abnormality was isolated del13q (11/31), followed by +12 (1 / 31), del17p (1 / 31) and t (11, 14) (1 / 31). With regard to changes involving del11q, 4 patients with normal FISH acquired both del11q and del13q, 1 patient with del11q acquired del13q. Del17p acquisition was associated with gaining of either trisomy 12 or del13q in two patients with a normal initial study; del17p was observed in two patients one with previous trisomy 12 and another with del13q; finally two patients with del13q plus del11q acquired deletion of 17p. Two patients with initial trisomy 12, one of whom had an associated del11q, acquired del13q. When performing univariate analysis, variables related to the diagnosis of clonal evolution were: advanced clinical stage, splenomegaly, B2-M> 3 mg /dl and expression of CD38. Also significant was the number of treatment lines. ZAP-70 was not significant. In addition, the group of clonal evolution showed a trend to the appearance of second malignancies ($p = 0.05$). In multivariate analysis only CD38 expression at diagnosis was significantly associated with decreased survival. Finally, when examined separately, the subgroup of patients with high risk cytogenetics at diagnosis, were more likely to acquire new cytogenetic abnormalities and show a trend to be treated earlier ($p = 0.09$). *Conclusions.* In our series, clonal evolution is associated with the expression of CD38 at diagnosis. In addition it is related with a greater number of treatment lines and lower survival. Ultimately these results reflect a more aggressive disease that might require a specific therapeutic approach.

1183

RITUXIMAB-BASED CHEMOTHERAPY FOR AUTOIMMUNE CYTOPENIA OF CHRONIC LYMPHOCYTIC LEUKEMIA

S Bougherira, F Grifi
Hospital University, Annaba, Algeria

Background. Chronic lymphocytic leukemia (CLL) is characterized by an acquired immune defect that can cause autoimmune complications, including anemia (AIHA) and thrombocytopenia (ITP). AIHA occurs in 10% of advanced stage CLL patients; ITP occurs in 2 - 3% in early stage disease and may be a presenting manifestation. And there are limited effective treatment options for steroid refractory autoimmune cytopenias. Rituximab, an active agent against B cell malignancies, has also been noted to be active in certain autoimmune hematologic disorders. The purpose of this study was to evaluate the safety and efficacy of Rituximab-based chemotherapy in this complication of CLL. *Patients and Methods*. This prospective study examines the outcome in CLL patients with autoimmune phenomena (AIHA, Evans' syndrome). Five patients were treated at our institution. Two patients who had been previously treated with alkylating agents (CHOP/CVP), one of them had received Fludarabine, two patients were newly diagnosed and had not receive any treatment. Treatment regimen (RCD): Rituximab was given at a dose of 375? m2 intravenously (i.v.) on day 1 (D-1). Dexamethasone 40 mg i.v. D-1. Cyclophosphamide at a dose of 1000 mg (total dose) i.v D-1. The treatment was repeated every 2 weeks of a total of six cycles. *Results*. Median age was 65 years (range 44 -74) and there were five male patients. All of them had Binet stage C disease, and ECOG Performans status was 1. Response in autoimmune cytopenias was evaluated by frequent blood counts and Coombs test. 4 of five patients achieved a remission of their cytopenia. One of them is still received the treatment. Median pretreatment hemoglobin was 6.7 g/dl and post-treatment hemoglobin was 12.3 g/dl. The mean pretreatment platelet was 147 G/L and post treatment was 213 G/L. Three patients converted to Coombs negative after RCD. Median duration of response was 14 months. The patients were evaluative for toxicity: grade ¾ toxicity neutropenia was noted in one patient and needed supportive care by haemopoitic growth factors. One patient died of progressive disease (CLL) 06 months after the response to RCD therapy. *Conclusions*. Autoimmune phenomena, largely related to blood cells, are based in the immune dysregulation of CLL. Our results indicate that a rituximab-based combination regimen (RCD) is highly effective in treating this complication of CLL, and show a safety profile.

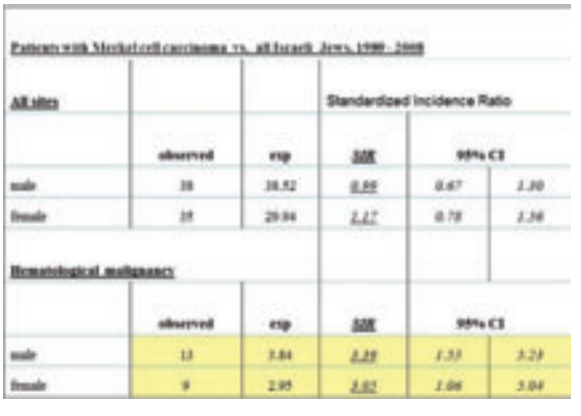
1184

ASSOCIATION OF HEMATOLOGICAL NEOPLASIAS AND MERKEL CELL CARCINOMA

T Tadmor,[1] I Liphshitz,[2] A Aviv,[3] M Barchana,[2] A Polliack[4]
[1]*Bnai Zion Medical Center, Haifa, Israel*
[2]*National Cancer Registry, Ministry of Health, Jerusalem, Israel*
[3]*Hematology-Oncology Unit, Emek Medical Center, Afula, Israel*
[4]*Hadassah University Hospital and Hebrew University Medical School, Jerusalem, Israel*

Background. Merkel cell carcinoma (MCC) is a rare and aggressive neuro-epithelial skin tumor which has been reported to occur in association with other primary neoplasms, including haematological malignancies. Immune suppression and dysregulation are well established risk factors for the development of MCC and may provide the explanation for the reported association of this tumor with neoplasms of the immune sys-

tem, predominantly lymphoid malignancies. *Aims*. The purpose of this study was to analyze data from the Israel Cancer Registry (ICR) relating to the epidemiological characteristics and the incidence of second cancers in patients with MCC, with special emphasis on haematologic malignancies and especially chronic lymphocytic leukaemia (CLL) /small lymphocytic lymphoma (SLL) *Methods*. Examination of the ICR records revealed 305 cases of MCC diagnosed in Israel during the period 1982 and 2009. Data were collected on age, gender and ethnic origin, dates of diagnosis of MCC and other tumors, as well as causes and dates of death when applicable. The incidence of second neoplasms in MCC was compared to those recorded in 4446 age-ethnic and period matched controls diagnosed with primary neoplasms in the Jewish population.Age specific standardized incidence ratio(SIR) was calculated with a 95% confidential interval (CI). *Results*. Incidence of MCC increased during the time periods reported. 97 % of MCC cases occurred in Jewish Israelis, while the remaining 3 % included Arabs and non- Arabs non- Jews. Median age at diagnosis in the Jewish patients was 73.3 years and 56 years in the Arab population respectively .One hundred and four patients (34%) had a second neoplasm, 73 evident before, and 31 after the diagnosis of MCC. The SIR for non- haematologic malignancies did not show a higher proportion of second tumors among MCC patients.Thirty of the 104 second cancers (28.8%) were haematological malignancies and of these 23 were detected before and 7 after the diagnosis of MCC. The SIR for second haematologic malignancy was 3.39 for males (95 % CI: range; 1.55-5.23) and 3.05 for females (95 % CI: range; 1.06-5.04).The most frequent haematologic neoplasias recorded were SLL/CLL (46.6%) and lymphoma (30%).There were also two cases of myeloproliferative diseases and single patients with multiple myeloma, hairy cell leukaemia, myelodysplastic syndrome (CMML) and mycosis fungoides. *Conclusions*. There is a high incidence of second haematologic neoplasms in Israeli Jews with MCC and these are mostly CLL and lymphomas. These results are in accordance with some reports from other countries showing a high prevalence of MCC especially in patients with CLL and lymphoma. This rare but significant association should be taken into consideration when evaluating patients with B-cell lymphoproliferative disorders and a co-existent skin tumor.



Patients with Merkel cell carcinoma vs. all Israeli Jews, 1989 - 2008

CLINICAL EXPERIENCEOF BENDAMUSTINE-RITUXIMAB TREATMENT FOR RELAPSED INDOLENT NHL AND CLL

D De Miguel, N Golbano, I L San Roman, M Diaz, J Arbeteta, D Morales, S Herrero, B Pinedo

Hospital Universitario de Guadalajara, Guadalajara, Spain

Background. Promising results have been reported in studies evaluating the combination of Bendamustine and Rituximab (B-R) in patients with relapsed/refractory indolent or mantle cell lymphomas. *Patients and methods*: we have analysed the role of the combination B-R in 8 patients since January 2009. They received Rituximab 375mg/m2 (day 1) plus Bendamustine 90-100 mg/m2 (days 1+2) every 28 days for a maximum of 6 cycles. The median patient age was 69.9 years (56-86 range). Most patients were in advanced stages (III-IV). Histologies were distributed: MALT NHL 10 %, grade 2 follicular NHL 10%; mantle cell NHL 30%, CLL/lymphocytic lymphoma 50%. Patients were heavily treated with a median of 3 prior regimens, including anthracycline containing chemotherapy (n= 4) and purine analog chemotherapy (n= 7). All patients had received previously rituximab. *Results*. Of the 10 patients, 2 are going in the treatment and they have not yet evaluated, 1 patient died at 3 cycles to infection, and 1 patient was lost follow-up. A median number of 4.5 cycles was given (2-6 range). At the time of analysis 2011 February, the median observation time was 10 months (2-22). Overall response 100% rate for patients treated with B-R. CR rate was 42.9% and 57.1% PR. Two patients in PR progressed at 9 and 10 months after they completed therapy. 1 patient in PR progressed, after 3 cycles. Hematologic toxicities were observed for neutropenia grade 3+4. Patients were admission in hospital in 22% cycles of bendamustine (Table 1). The B-R regimen was good tolerated by the patients, as evidenced by a lower rate of alopecia, number of infectious complications and estomatitis. We observed drug-associated erythematous skin reaction (rash) in one patient. There is not association between prior purine analog chemotherapy. *Conclusions*: the combination of Bendamustine +Rituximab have a excelent tolerability profile, and CR rate in heavily treated patients with relapsed/refractory indolent or mantle cell lymphomas. Further follow-up will determine whether the high RC/RCu rate corresponds to prolonged PFS. Additional updates on response will be available at the time of presentation.

MONOCLONAL ANTI-CD52 ANTIBODY TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS THAT ARE REFRACTORY TO FLUDARABINE-CONTAINING CHEMOTHERAPY REGIMENS

P Zagoskina,[1] E Zotina,[2] I Grishina,[2] V Demyanova[2]

[1]*Kirov scientific research institute of hematology and blood transfusion of FMBA, Kirov, Russian Federation*

[2]*Kirov Scientific Research Institute of Hematology and Blood Transfusion of FMBA, Kirov, Russian Federation*

Anti-CD52 monoclonal antibody (alemtuzumab) is a new treatment option in chronic lymphocytic leukemia (CLL). *Aims*. To study the efficiency and toxicity of alemtuzumab in a monoregimen in recurrence and refractory CLL. *Materials and methods*. Twelve CLL patients (11 male and 1 female) were included in the study. The age of the patients ranged from 36 to 66 years (median: 54). Nine patients were in stage B, and 3 in stage C according to the Binet classification. The ECOG performance status was ≤2 balls. The median time from diagnosis until alemtuzumab treatment was 16 months (range, 1-28). Nine patients received FC, FCM, and RFC treatment, 3 of them were refractory to the FC program, and 1 to FCM. Five CLL patients were in relapse, 3 of these after FC (6 courses), one after FCM (4 courses), and one after RFC (6 courses). The remaining three patients were treatment-naïve. In all tested patients ZAP-70 protein expression before treatment was revealed by using flow cytometry on more than 20% lymphocytes and expression membrane antigen CD38 on more than 30% lymphocytes. The average β2-microglobuline level in blood serum was 5.92±0.8 mg/l (3.91-8.7 mg/l). Cytomegalovirus (CMV) screening was done by serology and the PCR-method before alemtuzumab therapy. CMV monitoring was undertaken every 2 weeks and if a fever of unknown origin occurred. Alemtuzumab therapy was performed in a monoregimen by subcutaneous injection with dose escalation (3 mg, 10 mg, 30 mg) by 30 mg 3 times a week. The treatment duration was 14 weeks in 1 patient, 12 weeks in 9 patients, and 8 weeks in 2 patients. *Results*. As a first line therapy alemtuzumab induced complete remission in 2 patients after 6 and 8 weeks of treatment, which progressed to molecular remission; one patient developed partial remission. Among the patients resistant to earlier treatment and with relapse, overall response was achieved in 8 (89%) patients, complete remission developed in 5 (56%) patients, and partial remission in 3 (33%). One (11%) patient had no remission on therapy.

It is necessary to note that in 3 (60%) patients with complete clinical and morphological remission, molecular remission developed too. The results of the study have shown that a response on alemtuzumab therapy depends on the duration of this therapy and the spread of the tumor process. *Conclusions*. Monoclonal anti-CD52 antibodies are high effective among CLL patients that are refractory to fludarabine-containing chemotherapy regimens, and with the relapses of the disease, but toxicity was considerable.

1187

THE INTERNATIONAL ON-LINE REGISTRY OF RARE, CUTANEOUS AND CNS LYMPHOMAS OF CHILDHOOD

Z Krenova,[1] J Feit,[1] M Moulis,[1] L Kren,[1] R Kodet,[2] J Sterba[1]
[1]*University Hospital Brno, Brno, Czech Republic*
[2]*University Hospital Motol, Prague, Czech Republic*

Background. Certain types of lymphomas (follicular lymphoma, small cell lymphoma, marginal zone lymphoma, mantle zone lymphoma etc.) are rare in childhood. Also, CNS lymphomas and skin lymphomas are also relatively rare in childhood. Because of this rare occurrence the knowledge of clinico-pathologic correlations and prognostic factors is low worldwide. *Aims*. The project objective is to study clinico-pathologic correlations and analyse prognostic factors in rare lymphomas, CNS lymphomas and skin lymphomas in children (i. e. in the fragile population), further standadisation of therapy protocols, which will mean a benefits in the health care in Oncology and Pediatrics. Owing to the fact of rarity/low incidence of such lymphomas even in specialised centres there is a necessity of not only interinstitutional, but also international cooperation. *Methods*. Starting international database/registry in Brno (under auspices of I-BFM) is being designed as a virtual site which will collect all diagnostic and clinical information by means of filling the on-line accessible (but secured by codes) forms, placed on the web site of the database/registry. A part of the database/registry will be freely accessible www atlas of microscopic/histologic images (on-line virtual microscope). Data will be acquired inter-institutionally and internationally by means of filling of secured web forms (initial data will be put along with sending a case by cooperating institution, follow-up data will be added prospectively. Number of cases will depend on amount of these rare diagnoses in cooperating institutions. After collection of statistically significant amount of cases from one type of lymphoma, data will be analysed. Clinico-pathologic correlations and therapy responses will be analysed by standardised statistic methods. Prognostic markers will be analysed mostly by means of detection of expression of those potential markers by immunohistochemical antibodies which will work on lent formalin fixed paraffin embedded tissue material (paraffin tissue blocks), then after semiquantitative evaluation of presence/absence of expression will be statistically analysed with aim to find possible prognostic correlations. Information about cases will be supported by web atlas. The atlas will contain free online accessible high resolution diagnostic images of histology of every case with short English description (high resolution virtual misroscope) which can help to histopathologists in making the right diagnoses. *Results*. After collecting significant amount of cases from cooperating institutions there will be statistic analysis of clinico-pathologic correlations and analysis of prognostic factors. Standardisation of therapy protocols will be performed. *Summary/conclusions*. The project will enable a study of prognostic factors, clinico-pathological correlations and standardisation of therapy protocols in rare lymphomas of childhood, in CNS lymphomas of childhood and in skin lymphomas of childhood (i. e. in fragile population) by means of interinstitutional/international database/registry shared on secured web site (*www.rarelymphomas.eu*).

1188

EFFICACY, TOLLERABILITY, COST-SAVING OF FRONTLINE ORAL FLUDARABINE AND CYCLOPHOSPHAMIDE COMBINATION THERAPY FOR CHRONIC B-CELL LYMPHATIC LEUKAEMIA AND LOW GRADE NON HODGKIN LYMPHOMA ELDERLY PATIENTS

M Bergamaschi, A Ghiso, M Miglino, M Clavio, F Ballerini, L Canepa, A Cagnetta, M Gobbi, I Pierri
University of Genoa, Genova, Italy

Backgroun. The treatment decision of elderly patients has to be made individually considering, not only the stage and risk factors of the disease, but also patients' physical condition and social environment. Fludarabine was the first purine analogue with an oral formulation available for clinical use. The oral formulation offers equivalent efficacy and an improved tolerability profile compared to the IV formulation. IV fludarabine requires several administrations that will expose patients to the risk of IV injection complications and the cost of trip to the hospital. *Aims*. We would like to show that frontline oral fludarabine and cyclophosphamide combination therapy, for B-cell lymphatic leukaemia and low grade non Hodgkin lymphoma aged patients, is well tolerated, efficacy and cost-saving. *Methods*. Between April 2005 and December 2010, 10 elderly untreated patients (mean age 75, range 68-86) with treatment requiring B-cell lymphatic leukaemia (according to ESMO guidelines working group) and 10 elderly indolent stage ≥3 lymphoma non Hodgkin untreated patients (mean age 74, range 59-80) received therapy with low dose of oral fludarabine (25mg/mq/die) and cyclophosphamide (150mg/mq/die) (FC) both from days 1 to3 in once a day administration. Study design consisted of 6 cycles repeated at 4 weeks intervals in outpatient regimen. Patients received antibiotic prophylaxis with trimethoprim/sulphamethoxazole (160/800 mg twice a day, 3 times a week) and allopurinole (300 mg once a day from days 0 to 4). Performance status was WHO ? 2 in all patients. Comorbidities, which included diabetes, hypertension and chronic heart disease, were present in 12 patients. The mean of administered cycles was 4 with range 2-6. No patients reduced dose and number of cycle because of haematologic and extra-haematologic toxicities. Specifically only 2 patients experienced grade III neutropenia, treated with GCSF. *Results*. Definition of response was reviewed according to the updated IWCLL-NCI 2008 international general practice criteria.17 of 20 (8 RC and 9 RP) obtained a response with an overall response 85%. All responder patients are alive and maintained response after mean follow-up of 20 months (range 2-44). We used Genzyme sponsored Excel program to compare direct hospital cost of oral to IV FC (both 3 days regimen). IV treatment required 18 day hospital accesses with total cost of €7.527, oral regimen required 6 ambulatory accesses with total cost of €1.642 (costs including: pharmacy, nurses and physicians resources). In this analysis we didn't consider social and psychological cost: transports, relatives' lost of working hours, disease consciousness, trauma of repeated venipunctures. *Conclusions*. These results suggest that this regimen could be effective and well tolerated for elderly patients unfit for more aggressive treatments. Moreover this therapy compared to chlorambucil, the most used agent in these patients, is more effective and better tolerated. In fact although some patients relapsed or progress, most of them do not experience severe toxic side effects or required hospitalisations, obtaining satisfactory quality of life and survival. In addition ambulatory regimen is preferred by our patients, who are treated in an environment friendly, with fewer complications and minor use of hospital resources.

1189

TREATMENT OF B-CLL AND T CELL NON-HODGKIN LYMPHOMAS PATIENTS WITH ALEMTUZUMAB; THE EXPERIENCE OF A SINGLE ROMANIAN CENTER

I Ursuleac, O Georgescu, M Vasilica, E Niculescu-Mizil, R Stoia, S Badelita, D Coriu, A Moicean, A Tatic, D Colita, R Niculescu
Fundeni Clinical Institute, Bucharest, Romania

Background. Treatment with Alemtuzumab has been useful not only to consolidate remission in patients with B-CLL treated with Fludarabine or/and Rituximab as frontline,but also as salvage therapy for patients refractory or resistant, especially those with del 17p. In T cell lymphomas Alemtuzumab is combined with intensive chemotherapy inducing a rate of response around 70% (*Gallaminic&al- Blood, 2007*), but complications due to serious infections are frequent. *Objectives*: to evaluate a lot of patients diagnosed with B-CLL and Tcell lymphoma type treated with Alemtuzumab between May 2006- May 2010 in Fundeni Clinic Of Hematology(indications for treatment, adverse reactions, complications and treatment response). *Material and Methods*: a single center retrospective clinical and epidemiological study of 44 patients diagnosed with B-CLL(37 patients) and T cell lymphomas(7 patients- 1 angioimmunoblastic, 1 anaplastic , 5 PTCL- NO). *Results.* Alemtuzumab was administered subcutaneously, in standard dose, as first line therapy(2 patients), as consolidation for previously treated responsive patients(9 patients) or for refractory/ progressive disease(33 patients).15 patients were checked for del 17p (3 patients del17p+). CMV reactivation was confirmed in 8 patients(2 deaths with encephalitis). 19 patients died; main causes of death were: progressive disease (10 patients), sepsis(6 patients) and hemorrhagic events (5 patients). *Conclusions*. Alemtuzumab is efficient and well-tolerated for treating early stages of B-CLL and for consolidation therapy; heavily pretreated patients gets a lower and transient rate of response and high rate of morbidities and deaths. In

Tcell lymphomas the efficacy was lower in our study than in the literature studies, mainly because Alemtuzumab was used as salvage therapy, in multiple treated patients.

1190

INCIDENCE OF ADVERSE EFFECTS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA TREATED WITH FC VERSUS FCR

G Mihaescu, L Stoian, S Dan, C Gug
Oncomed, Timisoara, Romania

Background. CLL is the most common form of adult leukemia, accounting for 25%. CLL is a slowly unfolding from year to decades. Treatment of FC was and still is widely used in the treatment of first line in patients with CLL, with good results. However, introduction of Rituximab treatment in CLL patients has resulted in better outcomes and especially lower adverse reactions. *Material and Methods*. Between January 2008 - January 2011 we evaluated 62 patients with CLL in different stages of disease, of which 46 have followed treatment of FC and rituximab was introduced at 14, Of these, 24 were stage A, 6 stage B and 32 stage C, 32 were men, 30 women. All six cycles were performed either FC or FCR. *Results*. Blood complications occurred in 35 patients, 26 with FC (56.5%), 9 FCR (64.2%). Of these, neutropenia appeared in 20 patients treated with FC (43.5%) and 6 with FCR (42.8%), anemia in 15 patients treated with FC (32.6%) and 4 with FCR (28.6%), thrombocytopenia in 11 patients with FC (23.91%) and 3 with FCR (21.4%). Infectious complications occurred in 10 patients treated with FC (21.7%) and 2 with FCR (14.3%), most viral infections (herpes, EBV). Gastrointestinal side effects such as nausea and vomiting occurred in 2 patients, one from each group, given preventive treatment used antiemetic therapy. Anorexia and stomatitis occurred in the first group in 3 patients (6.52%) and 1 patient in the FCR treated group (7.14%). Asthenia and fatigue, due in part to anemia were reported in 40% of patients with FC and 45% of those with FCR treatment. Alopecia with marked psychological impact was seen in 13 patients (28.26%) of the first group and six in the second (42.8%). *Conclusions*. The data reported in our study are comparable with the literature, not statistically significant differences between the two groups.

1191

CLINICO-BIOLOGICAL FEATURES FEMALES AND MALES WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

E Wasik Szczepanek,[1] A Bojarska-Junak,[2] D Koczkodaj,[3] I Hus,[1]
A Dmoszynska[1] M Wach[1] D Szczepanek[1] K Sloma-Madej[1]
[1]*Hematooncology, Lublin, Poland*
[2]*Dept. of Clinical Immunology, Medical University of Lublin,, Lublin, Poland*
[3]*Dept. of Human Genetics, Medical University of Lublin,, Lublin, Poland*

B-cell chronic lymphocytic leukemia (B-CLL), the most common leukemia in the Western world is characterized by quite variable clinical course, which have been correlated with some clinical and biological markers. Among proposed prognostic factors the significance of gender is unclear, although in published trials females survive longer. A group of 286 unselected patients with B-cell chronic lymphocytic leukemia were studied for clinical and biological features. Sample analysis included CD38 and ZAP-70 stainings, fluorescence in situ hybridization (FISH) for chromosomes 11, 12, 13 and 17, level of bFGF, VEGF and TNF. There were168 men and 118 woman. The sex ratio was 1.4:1. The median age at presentation was similar, for men was 64.0 (range 34.0-83.0) and woman 64.5 (range 36.0-86.0) p=0.8207. Patients were staged at diagnosis according to the Rai classification. The distribution of patients with Rai stage eg. low-risk (stage 0), intermediate-risk (stage 1 and 2) or high-risk (stage 3 and 4) was: 28.8%, 50.8% 20.4% for female and 22.6%, 54.2%, 23.2% for males respectively. There was significant lower median rate of hemoglobin and higher rate of thrombocytes and percentage of CD3+ cells in females than males with B-CLL (12.63±1.96 vs 13.17±2.44, p=0.0045; 193.44±68.33 vs 170.36±70.05, p=0.0007; 16.02±13.41 vs 13.15±12.13, p=0.0369). Overall, the median survival of females was 56.91 months compare to 50.49 months for males (p=0.1076). Treatment-free survival was better for females than males (median time to treatment 17.55 months versus 9.27 months, p=0.0208). All group of studied patients received different kind of chemotherapy as front line treatment (chlorambucil alone, chlorambucil and prednisone, fludarabine containing regiments, COP and CHOP regiments); 63.6% females and 75.4% males had required treatment. There were significance differences in how females and males were treated (p=0.0255): 31.3% females and 28.4% males received chlorambucil alone or chlorambucil and prednisone, 8.6% females and 16.6% males were treated with COP or CHOP, and 23,7% females and 30.4% males received fludarabine containing regiments. 48.6% females and 46.0% males achieved complete response after front line treatment; in 22.2% females and16.8% males partial response and in 12.5% females and 15.1% males progression disease was observed. There was no a significant correlation between percentage of CD38 and ZAP-70 cells, percentage cells with genetic abnormalities, level of bFGF, VEGF, TNF and gender of patients with B-CLL.

1192

PROGNOSIS OF RELAPSED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AFTER COMBINED FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB (FCR) TREATMENT

A Panovska,[1] Y Brychtova,[1] G Vankova,[2] B Tichy,[1] S Pospisilova,[3]
J Mayer,[3] M Doubek[3]
[1]*University Hospital and Masaryk University Brno, Brno, Czech Republic*
[2]*University Hospital and Masaryk University, Brno, Czech Republic*
[3]*Central European Institute of Technology, Masaryk University, Brno, Czech Republic*

Backround. FCR regimen, as the first-line therapy in CLL patients, results in high response rates, improved progression free survival (PFS) and overall survival (OS). However, more than 30% of patients relapse or have disease progression in 3-4 years after. An appropriate therapy for these patients still has not been determined. *Aims*. The aim of our study was to analyze further course of the disease in relapsed CLL patients (pts) after FCR treatment. *Methods*. 39 CLL patients relapsed after FCR, followed in our center from January 1995 to January 2011, were included in this retrospective analysis. We identified 2 main subgroups - relapsed patients after FCR regimen given as the first-line therapy (23pts, Group A) and patients who had been given FCR as the second-line (or more) therapy (16pts, Group B). *Results*. Groups' characteristics were as follows: Group A, a median age at the start of FCR was 62 years (49-74; median FCR cycles: 3). Rai stage before therapy: Rai I n=4 (17%), Rai II n=6 (26%), Rai III n=5 (22%), and Rai IV n=8 (35%). Regarding new prognostic factors, unmutated IgVH gene was detected in 91%, mutated in 9% of patients. A certain evolution in cytogenetic aberrations was observed in pts pre- and post FCR treatment: normal karyotype (4 vs. 6pts), del(13q) (5 vs. 3pts), del(11q) (7 vs. 5pts), trisomy 12 (2 vs. 2pts.) and del(17p) (1 vs. 3pts). In terms of response to therapy, 14pts (61%) achieved complete remission (CR), 7 (30%) partial remission (PR) and 2pts (9%) had progressive disease (PD). The same analysis was performed in the Group B. A median age was 64.5 years (38-78; median FCR cycles: 3). Median number of previous treatments was 1 (range 1-5), 7pts were treated with fludarabine. Rai stage before the start of FCR: Rai I n=2 (3%), Rai II n=4 (25%), Rai III n=5 (31%), and Rai IV n=5 (31%). Unmutated IgVH gene was detected in 88%, mutated in 12% of patients. Cytogenetic abnormalities: normal karyotype (7 vs. 5pts), deletion of 13q (5 vs. 4), deletion of 11q (2 vs. 2), trisomy of 12 (2 vs. 0) and deletion of 17p (0 vs. 2). Nine patients (56%) achieved CR, 3pts (19%) PR, 1pt (6%) had stable disease and 3pts (19%) PD. Median PFS1 (after FCR treatment) was similar in both groups: 11 (A) vs. 12 months (B), p=0.59, PFS2 (after a subsequent therapy, irrespective of the type) was 10.4 (A) vs. 3 months (B), p0.03. Median OS calculated from the time of diagnosis was 85.8 (A) vs. 100.9 months (B), p0.38 (Figure). *Conclusions*. Compared with other treatment options, FCR is superior in CLL patients regardless being administered as a first-line therapy or a treatment of relapsed CLL, however increased number of poor prognosis cytogenetic aberrations is observed after FCR regimen in relapsed patients. Prognosis of CLL patients relapsed after FCR appears to be very poor irrespective of the type of subsequent therapy.

RITUXIMAB THERAPY IN PATIENTS WITH EXTRA NODAL MANIFESTATIONS OF CHRONIC LYMPHOCYTIC LEUKAEMIA

R Ramakrishna, K Sarathy
IPCCC, Sydney, Australia

Chronic lymphocytic leukaemia (CLL) is a common adult leukaemia, occurring in patients over 50 years of age with median age at diagnosis of around 65 years. While it remains an incurable disease, its indolent nature results in a varied prognosis with a median survival of greater than 10 years reported in early stage disease. Treatment is typically initiated when patients become symptomatic including alkylating agents (chlorambucil or cyclophosphamide) but combination chemotherapy with vincristine, prednislone or fludarabine may be required in some patients. Rituximab, a chimeric anti-CD20 monoclonal antibody, has shown significant activity in a variety of B-cell lymphoproliferative disorders. The CD20 antigen is also found on B-cells in CLL and rituximab therapy has shown clinical benefit in these patients. Extra nodal infiltration by small lymphocytes in patients with CLL is an uncommon manifestation. There is limited data on specific therapeutic strategies for treating these patients. The following case reports highlight the usefulness of rituximab in CLL patients with extranodal infiltration, with minimal additional use of chemotherapy. We present seven patients with various extranodal manifestations including 3 patients with cutaneous lesions with one of them showing amyloid deposits; 2 patients with renal involvement including minimal change glomerulonephritis(GN) and mesangial GN; 2 patients with pulmonary nodal infiltration. All these patients received a short course of chlorambucil therapy followed by rituximab therapy with significant improvement. The therapy consisted of weekly infusions at 375 mg/m2 followed by monthly infusions for 4 months. Some of the patients have required maintenance rituximab therapy. Follow up period range: 2-8 years (median 4 years). 5 patients are alive and well and 2 patients died of unrelated causes. The surviving patients have not required any additional therapy to treat CLL or extranodal manifestations. Hence, rituximab can be used as a single agent therapy in these patients.

1194

CLONAL DIVERSITY IN CONCOMMITANT MULTIPE MYELOMA AND CHRONIC LYMPHOCYTIC LEUKEMIA CASES DEMONSTATED BY IMMUNOPHENOTYPIC, FISH AND WHOLE GENOME SNP ANALYSIS

J Lazarchick, N Phahitis, B Davis, L Zhang, D. Wolff
Medical University of South Carolina, Charleston, USA

The occurrence of multiple myeloma (MM) and chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) in the same patient is rare. We present three such cases and document clonal diversity by flow cytometry, FISH and molecular analyses. Informed consent was obtained for all studies. Case 1 is a 54 year old female diagnosed originally with CLL who presented with bone pain. On FISH analysis two distinct cell types were noted - small cells having +12 and plasma cells (PCs) showing 3-4 copies of FGFR, D12Z1, CCND1, ATM, TP53 and MYB. Marrow showed κ restricted plasma cells with aberrant CD117 and CD19, CD5, CD23 + λ restricted B-cells. Whole genome SNP analysis (Infinium System) confirmed dual clonal disease. Case 2 is a 68 year old male diagnosed with CLL 2 years previously. Marrow exam showed panmyelosis with increased PCs showing λ restriction. Lymph node showed lambda restricted CD19, CD5, CD23 + B-cells. CLL FISH probes were negative. IEF showed three M components - IgM λ, IgG kappa and IgG lambda. Case 3 is a 27 year old female diagnosed with MM. Flow cytometric analysis performed on marrow showed kappa restricted PCs with aberrant CD117expression. FISH analysis two morphologically distinct cell types: cells with smaller nuclei had an extra copy of 1q and loss of 13q14; cells with larger nuclei appeared tetraploid with 4 copies of 1p and 6 copies of FGFR3, CCND1, TP53 and BCR and 5-6 copies of IGH. Genome SNP analysis is pending. The results in all cases support distinct clonal evolution of these two B-cell neoplasms.

1195

PILOT STUDY OF THE COMBINATION OF RITUXIMAB, IFOSFAMIDE AND FLUDARABINE (R-IFLU) IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

M Sciumè,[1] G Gritti,[2] G Reda,[1] V Ferla,[1] F Binda,[2] A Cortelezzi[2]
[1]*Fondazione IRCCS Cà Granda-Ospedale Maggiore Policlinico, Milan, Italy*
[2]*Università degli Studi di Milano, Milan, Italy*

Background. Fludarabine given with cyclophosphamide and rituximab is considered the cornerstone of chronic lymphocytic leukemia (CLL) treatment. While several purine-analogs have been evaluated in combinatory trial, no other member of the oxazaphosphorines family has been investigated in this setting. Ifosfamide has shown significant activity in non-Hodgkin lymphomas, but has been not yet evaluated in CLL. *Aims*. We conducted a pilot phase II study of ifosfamide given in combination with fludarabine and rituximab (R-IFLU) in relapsed/refractory CLL patients. *Methods*. Thirteen patients with relapsed/refractory CLL were enrolled. Therapy consisted of ifosfamide (750 mg/m2) and fludarabine (25 mg/m2) for three consecutive days (D1-3), and rituximab (375 mg/m2) on D3. Treatment was administered every 21 days up to 6 cycles. Response was assessed using the NCI-WG 1996 criteria. Maintenance with monthly rituximab (375 mg/m2) infusions was administered in responders for a total of 4 months. *Results*. Median patient age was 63 years (range 51-71). The median WBC count was 61,800/mmc (3,160-122,000), and 9 patients were in advanced Binet stage (5 B and 4 C). Six (46%) patients presented with bulky lymph nodes (>5 cm). Five patients (38%) showed an unfavorable cytogenetic profile, including 4 patients with del(11q) and 1 patient carrying del(17p). The median number of previous lines of therapy was 2 (1-4); all the patients were previously exposed to chlorambucil (69% being refractory) and 29% to fludarabine (54% being refractory). A median of 4 cycles of therapy was administered (2-6); the overall response rate (ORR) was 69%, including 23% of CRs. After a median follow-up of 4 years all the patients progressed, with a median progression free survival of 20.5 months (95% CI 8.1-40.1). Median overall survival was 47.6 months (95% CI 33.8-86.6). Hematologic toxicities were frequent: grade 3-4 neutropenia, thrombocytopenia and anemia were reported in 69%, 15% and 8% of the patients, respectively. Infusion related toxicities occurred in 3 patients and were mild in all the cases. Infections occurred in 8 patients (62%) during therapy, a grade 3-4 event was reported in one patient. *Conclusions*. This pilot study shows that combination of ifosfamide, fludarabine and rituximab is feasible and effective in relapsed/refractory CLL. Further studies are needed to evaluate the potential role of ifosfamide as alternative oxazaphosphorine drug in those patient only partially responding to cyclophosphamide-containing regimen.

1196

CORRELATION OF BCL2 GENE EXPRESSION AND BCL2/BAX RATIO WITH CLINICAL AND IMMUNOPHENOTYPIC CHARACTERISTICS OF B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

V Palibrk,[1] T Karan,[2] N Tošic,[2] N Kraguljac,[3] S Pavlovic,[2] M Colovic[4]

[4]*Medical Faculty, Belgrade, Serbia*

Background. B-cell chronic lymphocytic leukemia (B-CLL) is a lymphoproliferative disorder characterized by accumulation of clonal B-lymphocytes, mainly due to aberrant apoptosis. The Bcl2 gene regulates apoptosis and is known to be overexpressed in B-CLL. The activity of this protein is opposed by Bax, a homologous protein that accelerates the rate of cell death. B-lymphocyte Bcl-2 and Bax protein levels were found to be significantly altered in B-CLL. The mutational status of immunoglobulin heavy chain variable region (IGHV) divides B-CLL into two prognostic groups, depending on the presence or absence of somatic hypermutation, where unmutated IGHV genes are associated with considerably worse prognosis than mutated IGHV. *Aims*. We analyzed clinical characteristics, immunophenotypic profile, IGHV mutational status, Bcl2 and Bax gene expression in 53 patients with B-CLL. We evaluated the immunophenotypic caracteristics in correlation with Bcl2 gene expression and Bcl2/Bax gene expression ratio in patients with mutated and unmutated IGHV. *Methods*. Bone marrow (BM) and/or peripheral blood (PB) derived cell flow cytometric analyses were performed for following antigens (Ag): CD19, CD20, CD22, CD23, CD25, CD10, SmIg, kappa, lambda, CD79b, CD38, FMC7, CD3, CD2, and CD5. Cut-off for Ag expression was accepted positive > 20%. Pathohistology and immunohistochemical testing were performed on BM (bone marrow) biopsy samples. We used following monoclonal antibodies: CD5, CD20, CD23, CD10 and CD79b. Multiple RT-PCR and sequencing analysis were used to determine IGHV mutational status. RQ-PCR was used to determine Bcl2 and Bax gene expression. The correlation between clinical parameters, surface antigen expression Bcl2 and Bcl2/Bax ratio was estimated by Pearson correlation coefficient. All patients signed informed consent according to Declaration of Helsinki.

Results. High expression level of CD23 surface antigen correlates with shorter PFS (p=0.04), higher level of bone marrow infiltration (p=0.035), shorter lymphocyte doubling time (p=0.004) and advanced Rai clinical stadium (p=0.014). The expression of CD38 surface antigen correlates with shorter PFS (p=0.008). High level of Bcl2 gene expression and Bcl2/Bax ratio correlates with shorter lymphocyte doubling time and shorter PFS, but only in the group of patients with mutated IGHV (p=0.01; p=0.004). High level of Bcl2 expression correlates with the following immunophenotypic profile: low expression level of FMC7 (p=0.02) and high expression level of CD23 (p=0.032) in all patients. High Bcl2 expression correlates with lower FMC7 expression level in the group of patients with unmutated IGHV (p=0.003). High Bcl2 expression correlates with higher expression level of CD23 in the group of patients with mutated IGHV (p=0.042). There is no correlation of immunophenotypic profile with Bax expression, nor with Bcl2/Bax ratio in this study. *Conclusions*. Our analyze showed that B-CLL with higher CD23 surface antigen expression have more aggressive course with shorter progression free survival. Higher Bcl2 gene expression and Bcl2/Bax ratio correlate with the shorter progression free survival in B-CLL patients with mutated IGHV. We suggest that B-CLL with high level of Bcl2 gene expression is characterized by distinct immunophenotypic profile with increased CD23 and reduced FMC7 surface antigen expression.

Background. Chronic lymphocytic leukemia(CLL), the most frequent chronic lymphoproliferative disorder, mainly in elderly people seems to have real incidence higher than in reports. The diagnosis based especially on flowcytometry, and molecular and genetics changes should define the prognosis subgroups of CLL. *Aims*. The present study done by the Romanian Group of Initiative in Diagnosis of CLL proposes to introduce flowcytometry in current screening of patients with lymphocytosis suspected for CLL in Romania. At the same time, to assess the real incidence of CLL in Romania based on the same panel and protocol concerning the recommended ESMO guidelines. *Methods*. We have analyzed 214 patients suspected with CLL in last year in few centers in Romania. Clinical assessement was done as the guidelines recommended in all patients. The samples for immunophenotyping were collected from peripheral blood and sent from the centers to the central laboratory. The diagnosis was made by flowcytometry on a BD FACS Flow Calibur, with classical association of markers CD19,CD20,CD5, CD23,CD79b. In these patients we have analyzed other surface markers, like CD43,CD38, and intracellular markers ZAP-70. P53 mutation was done by FISH in a central laboratory, too. Statistical analysis with SPSS software was used to find correlations between clinical, immunophenotypical and genetic parameters, and therapy, too. *Results*. The patients with CLL were stratified by Rai clinical stage as follows: 17.39% stage 0, 16.30% stage I, 39.13% stage II, 10.87% stage III, and 16.30% stage IV. Positive diagnosis for CLL was found in 146 patients, represented 68% from the suspected cases. Negative cases represent other lymphoproliferative disorders and reactive lymphocytosis. 11 cases(5%) were diagnosed as monoclonal B-cell lymphocytosis. A presumptive incidence was calculated from the regions which were involved in subjects' recruitment. We found an incidence of 4.0559 : 100,000 people related to 3,476,357 people, higher than the incidence reported in US(3.35-3.69). p53 mutation was found positive in 8% of cases, in a higher percentage than usual(5-7%). Related to the diagnosis panel, we found a significant correlation between CD5 and CD79b(r:0.62), and between intensity of CD79b and CD38(r:0.60), which could be explained by an atypical immunophenotype associated with progression risk. A correlation between CD38 and ZAP-70 expression was found and with lower expression of CD23(r:0.666), which correspond to an atypical immunophenotype with progression risk. *Conclusions*. This is the first study which uses the same protocols in diagnosis of CLL cases from multiple centers, and different regions. The positive ratio of diagnosis is considered very well, and could be a useful way to identify earlier phase new CLL cases in Romania. The incidence of CLL seems to be higher than in other regions of world, and with a higher number of high risk (p53 positive) cases. It could be a high risk of this region related to the nuclear incidents from 80's involved in this pattern or not? We consider that this preliminary data are very useful to assess the real incidence and ethiologic factors of CLL occurrence in Romania.

Funding: thanks to Roche-Hofman Romania and Genzyme Romania for their support.

RITUXIMAB IN COMBINATION WITH HIGH DOSE METHYLPREDNIZOLONE FOR THE TREATMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AND P53 DELETION

P Konstantinidou,[1] S Georgiadou,[1] M Varthaliti,[1] T Dimou,[1] N Spiridis,[1] A Fotarelli,[2] P Michailidis,[1] E Verrou,[1] K Zervas[1]
[1]*Theagenion Cancer Hospital, Thessaloniki, Greece*
[2]*Theagenion Cancer Hospita, Thessaloniki, Greece*

Chronic lymphocytic leukemia (CLL) patients with del (17p) or del p53 do not respond to conventional treatment and have shorter survival. Studies have demonstrated that high dose methylprednisolone (HDMP) either alone or in combination with Rituximab is effective in such patients *Purpose*. We evaluated the efficacy and complications of the combination of high dose methylprednisolone(HDMP) with the anti-CD20 monoclonal antibody, rituximab (R-HDMP) in heavily pre-treated CLL patients with del p53. *Patients and Methods*. We retrospectively studied 9 patients with CLL, (4 men and 5 women), who had del p53. The median age was 72 years (range 59-82 years). Two patients had Rai stage I, one patient Rai stage III and the remainder 6 patients were Rai stage IV. Four patients had bulky disease. All 9 patients had previously received other chemotherapy regimens (2-7 prior therapies). HDMP was given intravenously at a dose of 1 gm daily for 5 days in combination with rituximab 375mg/m2 on day 1 of a 28 day cycle for 2-6 cycles. They also received trimethoprim-sufamethoxazole, valacyclovir and fluconazole as prophylaxis during therapy and for two months after its completion *Results*. Eight out of nine patients developed side effects (hyperglycemia: 3 patients, edema of low extremities: 3 patients, increase of infections: 4 patients, osteoporotic fracture:1 patient and myocarditis: 1 patient). Four out of 9 patients (44.45%) achieved partial response (PR), 2/9 patients (22.23%) had steady disease (SD), and 3/9 patients (33.33%) had progressive disease (PD). With a median follow up of 5 months all patients with PR had progression of the disease and one of them died, while all patients with SD and PD died. *Conclusions*. Although the number of patients is small, the results indicate that the combination of high dose methylprednisolone(HDMP) with rituximab (HDMP-R) is an active regimen in a poor prognostic patient group like heavily pretreated CLL patients with del p53. Further evaluation in controlled trials is needed.

1199

LYMPHOCYTE CELL POPULATION DATA PROVIDED BY UNICEL DXH 800 IMPROVE IDENTIFICATION AND CLASSIFICATION OF LYMPHOPROLIFERATIVE DISORDERS

F Gervasi,[1] L Carnevale,[1] S Vlah,[1] C Giambanco,[1] A Ferraro,[1] G Cardinale,[1] N Di Gaetano,[2] G Pagnucco[1]
[1]*Hematology Division Civic Hospital, Palermo, Italy*
[2]*Instrumentation Laboratory, Milan, Italy*

Background. Lymphoproliferative disorders (LD) and B cell chronic lymphocytic leukemia (B-CLL), are heterogeneous disease whose diagnosis is based on automated WBC count, microscopy and immunophenotyping . Our previous experience with VCS technology of Beckman Coulter showed important correlation between VCS Cell Population Data (CPD) and other data coming from microscopy, flow-cytometry, cytogenetics and molecular biology.2. Aims: Since all these test are still part of the routine in clinical practice for B-CLL and LD diagnosis and classification, we decided to further explore UniCel DxH800 CPD could provide the same useful information to laboratory and clinical hematology.3. Methods: 16 patients samples (7 of them, untreated CLL) and 50 healthy donors were analyzed in this study with UniCel DxH800 that

performs leukocytes differential with the Flow Cytometric Digital Morphology (FCDM) technology, based on the measurements of Volume (V), Conductivity (C) and 5-angle Scatter light laser (UMALS, MALS, LMALS, LALS, AL2) on cells in their native state. Mean (M) and standard deviation (SD) of FCDM measurements are collected in 56 CPD. Diagnosis of CLL and LD are based the WHO classification criteria.4. Results. Reference interval for lymphocyte CPD were calculated and compared with pathological samples' ones. We confirmed our previous data showing the statistically difference ($p<0.05$) of mean volume LY (MV-LY) in CLL samples versus normal samples (83 a.u. vs 89 a.u.); SD-V-LY was 18.8 in CLL and 14 in normals. We discovered that axial-light-loss (M-AL2-LY) is also lower (41 vs 68). These CPD were able to describe the morphological findings of both clonal lymphocyte populations with low homogeneous volume and CLL with heterogeneous features. Even in some leukemic lymphomas we found correlation between MV-LY (95), AL2-LY (74) and morphological abnormalities of lymphoma cells. As an example we found a 3-years old ALL sample with lymphocytosis and without leukocytosis in which the value of SD-LY-AL2 (14) vs normal (10), induced us to follow-up in the diagnosis. Scatter light CPDs seem to be also useful in differentiating abnormal cells and therefore they need to be investigated.5. Conclusion. In this study we presented some considerations on the useful information to laboratory and clinical hematology provided by UniCel DxH800 CPD. Different patterns of scatterplot with different CPD values can be the basis for the validating process both in large laboratories and in clinical hematology lab. The first ones need screening tools while the second ones need classification tools useful also in the follow-up of the patients' therapy and prognosis. These preliminary observations are now under investigation in a multicentric evaluation.

BORTEZOMIB ENHANCES THE SENSITIVITY OF IMATINIB TO K562/G01 CELLS

L Ma, Y Zhou, W Wang
Second Hospital of Medical University, Shanxi, Taiyuan, China

Objectives. To explore the effect of proteasome inhibitor Bortezomib (BOR) on the sensitivity of imatinib to K562/G01 cell (imatinib-resistant chronic myeloid leukemia cell line) and the mechanism. Methods MTT assay was used to observe the effect of growth inhibitory of cells. flow cytometry was uesed to detect cell cycle; Real time-PCR was performed to detect expression of COX-2 and MDR-1 mRNA. Results Combined with 10、20nmol/L BOR could significantly enhance the sensitivity of drug, the reverse fold respectively was 1.83 and 2.72 . G2 / M phase cell cycle arrest could be seen by flow cytometry with BOR. K562/G01 cell over-expression of COX-2 and MDR-1, BOR could down-regulate COX-2 and MDR-1 expression. Conclusion BOR can enhance the sensitivity of imatinib to K562/G01 cell,the mechanism may be related to cell cycle G2 / M phase arrest and down-regulating the expression of COX-2 and MDR-1.

STUDY OF THE ASSOCIATION OF CYP2D6*4 POLYMORPHISM WITH THE RISK OF CHRONIC MYELOID LEUKEMIA

N El Husseiny,[1] S Hussein,[2] A Abd El Aal,[2] R Afify[2]
[1]*Cairo University, Cairo, Egypt*
[2]*Clinical Pathology Unit, Cairo, Egypt*

Background. PCYP2D6 is a member of cytochrome P450 enzymes family which are involved in the detoxifcation of a wide range of xenobiotics and drugs. Several genetic polymorphisms had been shown to affect its activity which may results in increased susceptibility to malignant disorders. Aim of the Study: This study aimed to determine whether any association exists between genetic polymorphism in CYP2D6*4 and risk of chronic myeloid leukemia (CML). Subjects and Methods: Our study groups consisted of 50 CML patients and 40 unrelated healthy volunteers as a control group. *Results*. The frequencies of EM genotype (wild type) were 64% and 95% in CML and control groups, respectively. The frequencies of polymorphic IM genotype (heterozygous variant) were found to be 28% in CML patients and 5% in controls. The PM genotype (homozygous variant) was 8% in CML and not observed in control group. There was a statistical signifcant correlation between the CYP2D6*4 gene polymorphism and chronic myeloid leukemia patients with the frequencies of IM and PM CYP2D6*4 were higher in CML cases compared to controls (28% versus 5%, 8% versus 0%, $p=0.004$), on contrary, the frequency of EM was higher in controls cases compared to CML patients (95% versus 64%). As an estimate for the relative risk, the odds ratio for CYP2D6*4 polymorphism was 10.688 with a 95% confdence interval of 86.597-1.319. Conclusion: These data indicate a higher risk for CML in individuals carrying the IM and PM CYP2D6*4 and reflect the major role of environmental factors in CML pathogenesis. The present study establish signifcant association of CYP2D6*4 polymorphism with CML.

1202

EXPRESSION OF PHOSPHORYLATED STAT5 IN CHRONIC MYELOID LEUKEMIA: RELATION TO DISEASE STAGESA

Background. Chronic myeloid leukemia (CML) is characterized by the presence of the Ph chromosome (BCR/ABL chimeric gene) in hematopoietic stem cells. Clinically, it is manifested in three distinct phases: chronic, accelerated, and blastic. Signal transducer and activator of transcription (STAT) proteins are known to be regulated by cytokine receptors and are critical for driving transcription necessary for growth, survival, and differentiation of hematopoietic cells. BCR-ABL expression results in constitutive activation of STAT5 and essentially bypasses cytokine or growth factor-dependent activation of STAT5. Aims: The aim of our work was to investigate the state of STAT5 phosphorylation in relation to CML disease stages as a possible indicator of BCR/ABL tyrosine kinase activity. Methods: The study was conducted on 39 CML patients including 17 male and 22 female with an age range of 19-79, a mean of 39.88±15 and a median of 41.5 years. Patients were diagnosed as CML and stages defined according to the WHO classification of myeloid neoplasms. Twenty two patients were in chronic phase (group I) and 17 were in accelerated phase or blastic crisis (group II). Patients were divided into 3 risk groups according to Hasford score: Low risk group: score 780, Intermediate risk group: score 781-1480 and High risk group: score > 1480. After informed consent, analysis of phosphorylated STAT5 (pSTAT5) was done using Flow Cytometry. Results were expressed as percentage positivity and florescent ration in CD34 positive and CD34 negative cells. pSTAT5 expression was studied in relation to various hematological and clinical parameters. Results: pSTAT5 was expressed in all cases tested. The level was statistically significantly higher in advanced phases than in the chronic phase ($p=0.006$). CD34 positive cells% was 1.74 ± 1.61% and 21.3 ± 20.4% in group I and II respectively ($p=<0.001$). All CD34 positive cells were pSTAT5 positive. CD34 negative cells were pSTAT5 negative (<10%) in 8/22 (36.4%) and 5/17 (29.4%) patients in group I and group II respectively. pSTAT5% expression was significantly higher in group II as compared to group I (56.4 ± 27.6% vs. 33.9 ± 21% respectively; $p=.006$); however the florescent ratio was comparable in both groups. CD34-ve/pSTAT5+ve % was higher in Group II than in Group I but the difference did not achieve statistical significance. pSTAT5% expression showed significant positive correlation with both peripheral blood and bone marrow blast percentage ($r= 0.39$ and 0.37; $p= 0.017$ and 0.02 respectively). The distribution of the 3 Hasford risk groups among the two patients groups revealed 8/21 (38.1%) low risk, 8/21 (38.1%) intermediate risk and 5/21 (23.8%) high risk in Group I as compared to 4/16 (25%), 8/16 (50%) and 4/16 (25%) in group II; the difference is statistically insignificant. No correlation was encountered between pSTAT5 expression on one side and age, Hasford score or duration of chronic phase on the other side. Summary/Conclusions: The level of expression of pSTAT5 is higher in advanced phases of CML reflecting a higher tyrosine kinase activity of the BCR/ABL chimeric protein. It may serve as an indicator of the BCR/ABL expression level.

Aversa (CE), Italy; [5]Department of Haemathology, Hospital A. Cardarelli, Naples, Italy

Background. Chronic myeloid leukemia (CML) is a hematopoietic stem cell disorder caused by the oncogenic activity of the Bcr-Abl protein, a deregulated tyrosine kinase. The iperactivity of tyrosine kinase (TK) of this fusion protein activates multiple signal transduction pathways, which leads to malignant transformation. Our previous results demonstrated that peripheral blood mononuclear cells derived from CML patients displayed decreased intracellular calcium [Ca2+]i fluxes both after InsP3 and ATP administration (*Ciarcia et al. J.Cell.Physiol.,2010*). On the other hand several transcription factors are activated in response to physiopathological increases and intracellular calcium levels. It is widely known that BCR-ABL can inhibit apoptosis also by activating at cytoplasmic level the PI3K/AKT pathway and furthermore, the important anti-apoptotic pathway passing through the transcription factor NF-kB/Rel, appears activated in CML patients. *Aims*. In present study we evaluated the levels of transcription factors NF-kB and AP-1 as well as the intracellular calcium measurement in peripheral blood leukocyte of control or CML patients before and after treatment for three months with imatinib 400 mg in order to determine whether treatment with imatinib was able to change these parameters. Methods. NF-kB, AP-1 and intracellular calcium levels were measured on lymphocytes isolated from blood of n. 8 healthy volunteers and n. 8 CML patients in first of diagnosis and after three months treatment with imatinib. Intracellular Ca2+ concentrations were measured by using the radiometric fluorescent indicator dye FURA-2/AM, the membrane-permeant form of FURA-2/AM as previously described and opportunely modified by Pagnini U et.al (Anticancer research, 2000). To detect and quantify NF-kB and AP-1 activation in our samples, we used ELISA-based Trans-Am transcription factor kits (Active Motif, Carlsbad USA). Results. Our results showed that InsP3 induced an increase in maximum levels of [Ca2+]i by depletion of the intracellular calcium stores with a significant higher effect in CML untreated than treated patients for three months with imatinib increasing from 121,9±8.1 to 373,5±29.7nM in CML untreated and from 120.3±7.4 to 252.2±18.7nM (-53.1 %) in treated patients. ATP increased intracellular Calcium concentration by Ca2+ influx with a significant higher effect in CML untreated from 115.2 ± 6.4 to 251.8±22.3 nM than treated patients from 121.4 ± 7.6 to 197.3 ± 14.2nM (-52.9 %). The results of NF-kB and AP-1 in CML samples, demonstrated that respect to the constitutive expression of NF-kB and AP-1 in primary CML lymphomonocytes, Imatinib treatment was able to significantly reduce NF-kB (-92.7%) and AP-1 (-84.6%) activation. Conclusions. Our results suggest that the inhibitory activity of imatinib on both intracellular calcium levels and NF and AP-1 activation could be used as a prognostic factors to address the follow-up in patients with CML treated with imatinib.

COMBINATION OF RESVERATROL AND NILOTINIB INHIBITS CELL PROLIFERATION AND INDUCE APOPTOSIS SYNERGISTICALLY IN CHRONIC MYELOID LEUKEMIA CELLS

Y Baran, Z CakirIzmi
Institute of Technology, Izmir, Turkey

Background. Resveratrol (3,5,4'-trihydroxy-trans-stilbene) is a naturally occurring phytoalexin, which presents especially in red grapes. It is a potential anticancer agent which inhibits tumor initiation and progression. This inhibitory effect of resveratrol causes cell death in various cancer cells. Nilotinib is a recently developed and an effective tyrosine kinase inhibitor used for the treatment of chronic myeloid leukemia. Nilotinib was methodically and rationally designed to create a better topological fit in the ABL kinase domain of BCR-ABL resulting in enhanced BCR-ABL inhibition. It is an aminopyrimidine derivative of imatinib, structurally changed to eliminate two energetically unfavorable hydrogen bonds with the replacement of the N-methylpiperazine ring of imatinib by a trifluoromethyl-substituted phenyl group. Nilotinib does not inhibit only BCR-ABL kinase activity, but also inhibits c-KIT and platelet derived growth factor . It only binds the inactive conformation of ABL. Aims. The natural product resveratrol has anti-cancer effects on cancer cells. Furthermore, it was demonstrated that resveratrol do not have side-effects on cells. This makes resveratrol powerful therapeutic agent in cancer. In this study, we aimed to determine the possible synergistic antiproliferative and apoptotic effects of nilotinib and resveratrol in K562 chronic myeloid leukemia cells. Methods. Human K562 cells were grown in RPMI1640 medium containing 10% FBS and 1% penicillin-streptomycin. Cytotoxicity analyses of resveratrol, nilotinib and combination of both were conducted by XTT cell proliferation assay. Then, possible synergistic apoptotic effects of both agents were carried out via measuring loss of mitochondrial membrane potential and changes in caspase-3 enzyme activity. Results. IC50 values (the drug concentration which inhibits cell proliferation by 50% as compared to untreated control group) of nilotinib and resveratrol, were found as 42 nM and 85 µM, respectively. There were 10 and 15% decreases in cell proliferation in response to 0.1 and 1 nM nilotinib, respectively, while the same concentrations of nilotinib in combination with of 85 µM of resveratrol resulted in 43 and 55% decreases in cell proliferation, respectively. 0,5 and 5 nM nilotinib or 85 µM resveratrol increased caspase-3 enzyme activity 14 and 25% or 44% respectively. But, combination of the same doses of nilotinib in combination with 85 µM resveratrol increased caspase-3 enzyme activity to 280 and 404%, respectively. Furthermore, in K562 cells exposed to combination of 0,5 and 5 nM nilotinib or 85 µM resveratrol, there were 1,26 and 1,29 or 96,60-fold loss of mitochondrial membrane potential comparing to untreated controls while combination of resveratrol with the same doses of nilotinib resulted in 106,95 and 154,47-fold increases in loss of mitochondrial membrane potential, respectively. *Summary/Conclusions*. The results of this study demonstrated that resveratrol may increase therapeutic efficiency and activity of nilotinib in chronic myeloid leukemia cells.

HIGH RESOLUTION MELTING CURVE ANALYSIS FOR THE DETECTION OF SNPS IN CYP3A4 OF SESOTHO CML PATIENTS BEING TREATED WITH IMATINIB

G Thompson, C Viljoen
University of the Free State, Bloemfontein, South Africa

Background. Tyrosine kinase inhibitors (TKIs) have become the treatment of choice for chronic myeloid leukemia (CML). However, up to 5% of patients may experience intolerance to TKIs as a result of adverse drug reactions (ADRs). TKIs are primarily metabolized by Cytochrome P450 enzyme CYP3A4. Although it appears that the metabolism of TKIs, specifically imatinib, is not affected by the inhibition of CYP3A4, the role of this enzyme in ADRs to TKIs is uncertain. Allelic variants based on single nucleotide polymorphisms (SNPs) in CYP3A4 have been found to be associated with altered catalytic activity in exons 5, 7, 10, 11 and 12 that may potentially contribute to inter-individual differences in drug metabolism. Since SNP profiles differ between populations, it is important to screen all 13 exons of CYP3A4. Unfortunately, sequencing all the exons of CYP3A4 is time consuming, laborious and expensive. However, high resolution melting curve (HRM) analysis has successfully been used to screen for SNPs in different genes reducing the need for unnecessary sequencing. *Aims*. To determine whether HRM analysis can be used to screen for SNPs in CYP3A4 of Sesotho CML patients. *Methods*. Blood samples were obtained from 38 Sesotho CML patients being treated with imatinib after obtaining informed consent. DNA was extracted from samples after Trizol stabilization. HRM primers were designed for exons 5, 7, 10, 11 and 12 using the online primer design program Primer3Plus. HRM analysis was performed using MeltDoctor HRM reagent on the ABI 7500 Fast. Samples were sequenced using the BigDye Terminator v3.1 cycle sequencing kit. *Results*. Of the 38 patients screened by HRM analysis, only 3 were found not to have any SNPs. The range in Tm for variant samples overlapped with that of the reference sample making it difficult to distinguish between them based on the use of the Tm. In comparison, the use of difference plots identified a total of 3 variants in exon 5, 20 in exon 7, 25 in exon 10, 2 in exon 11 and 13 in exon 12 with SNPs. Of the 27 SNPs identified, 21 have not been previously described. *Conclusions*. HRM analysis was successfully used to detect the presence of single and multiple SNPs in exons 5, 7, 10, 11 and 12 of CYP3A4 prior to sequencing. A total of 21 SNPs, not previously described, were identified in Sesotho patients. The use of HRM analysis in this study allowed the exclusion of 112 exon sequencing reactions which is a major cost saving factor in SNP screening. The effect of these SNPs on CYP3A4 gene expression now needs to be tested.

CYTOGENETIC CHANGES IN PHILADELPHIA CHROMOSOME NEGATIVE CELLS OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA DURING IMATINIB TREATMENT

A Lukyanova,[1] O Zotova,[1] M Valchuk,[1] K Kotlyarchuk,[1]
B Pienkowska-Grela[2]
[1]State Institution „Institute of Blood Pathology and Transfusion Medicine

UAMS„, Lviv, Ukraine;
[2]Maria Sklodowska-Curie Memorial Cancer Centre and Institute, Warsaw, Poland

Background. Since treatment of chronic myeloid leukemia (CML) with imatinib mesylate (IM) has been improved there is an increasing number of reports on chromosomal aberrations in Philadelphia chromosome negative cells (Ph-) in patients with CML. Here we describe 5 cases of the emergence of clonal evolution in Ph- cells in patients treated with IM. Methods. The group of 76 CML patients treated with imatinib and achieving cytogenetic response were examined for the presence of chromosomal abnormalities in Ph negative cells. The methods of conventional cytogenetics (GTG) and fluorescence in situ hybridization (FISH) were used. *Results*. Cytogenetic abnormalities in Ph negative cells were observed in 5 patients in whom the first diagnosis of CML showed a sole t(9;22) (6,6% of investigated group). Such a clonal evolution of Ph- cells was observed between 12 and 36 months after starting of IM treatment (median: 27 months), after obtaining a cytogenetic response. Trisomy 8 was found in 4 cases (80%), and del(7)(q22) was present in 1 case (20%). The appearance of aberrations in the Ph- clone occurred during complete cytogenetic response (CCyR) in one patient. In the remaining 4 cases, progression in Ph- clone was revealed during a partial cytogenetic response (PCyR) in 3 patients or minor cytogenetic response (MCyR) in 1 patient with del(7). Ph- cells with aberration on time of first detection accounted from 10% to 52% of examined bone marrow. During follow-up trisomy 8 was present in 3-30% of bone marrow cells; the patient with del(7q) was not re-examined yet. None of the patients showed hematological progression after appearance of trisomy 8 in Ph- cells. One CCyR patient who developed trisomy 8 at 24 months of IM treatment, remained in complete remission with +8 clone within the next 12 months. The next patient developed +8 at the same time losing CCyR (PCyR in 38 month of treatment) and then maintained both PCyR and +8 clone up to 51 months follow-up. One patient continued in PCyR from 12 up to 56 months of therapy, when CCyR without +8 was established. The last patient maintained PCyR up to 29 months of observation with the continuous presence of +8 cells. The patients with trisomy 8 were examined retrospectively by FISH for the presence of trisomy 8 before treatment and no +8 cells have been identified. *Conclusions*. Our observations indicate that aberrations in Ph- cells appear *de novo* during of imatinib treatment in patients with cytogenetic response. The most common abnormality in this group is trisomy 8. Regardless of the variable course of the disease, the emergence of trisomy 8 is not a serious threat of imatinib failure. During time of observation no clear clinical consequences could be identified. However, the presence of other aberrations such as del(7q) may be an early symptom of acute hyperplasia.

THE HMOX1 GTN POLYMORPHISM IS ASSOCIATED WITH CHRONIC MYELOID LEUKEMIA

M Ayala,[1] E Córdova,[2] M Morales,[2] X Aquino,[1] E Crespo,[3] J Vela,[1] L Orozco[2]
[1]Hospital de Especialidades del CMN „La Raza„, IMSS, México, Mexico;
[2]Instituto Nacional de Medicina Genómica (INMEGEN), México, Mexico;
[3]Instituto Nacional de Ciencias Médicas y de la Nutrición Salvador Zubirán, México, Mexico

Background. Chronic myeloid leukemia (CML) is a complex disease with strong inter-individual susceptibility. Human genetic variation is based on the presence of polymorphisms along the DNA sequence. Polymorphisms located at the promoter or the coding region of the gene could change the level of the encoded protein or the protein activity, respectively. To avoid the damage caused by oxidative stress or diverse environmental hazards such as, xenobiotics, the cell has developed several anti-oxidant and detoxificant mechanisms. Genetic alterations in components of these protection mechanisms have been associated with cancer susceptibility. *Aims*.The aim of this study was to determine the association among CML susceptibility and polymorphism located in a battery of anti-oxidant and detoxificant. Methods.-We collected blood sample from 250 individuals with CML and 250 healthy subjects. Cases and controls were matched by age, gender and ethnicity. Single nucleotide polymorphism (SNPs) at the genes GSTP (A1404G) and NQO1 (T609C), were genotype by TaqMan assays, meanwhile short tandem repeat at HMOX1 promoter region (GTn) was determined by Gene Scan analysis. Significant differences in allelic and genotype frequency distribution and odd ratios (OR) was determined by Chi-squared and Fisher's exact test. After genotyping, all polymorphisms tested were in Hardy-Weinberg equilibrium in both, case and control population. *Results*. We found no significant differences in allelic and genotypic distribution of GSTP and NQO1 SNPs between CML and healthy individuals. However, short allele (S) from HMOX1 (GTn) polymorphisms showed a higher frequency in CML individuals compared to healthy subjects (0.18 vs 0.13). Likewise, the SS genotype were associated with CML susceptibility (OR=1.497 CI[1.23-4.78], p=0.008). *Conclusions*. Our data suggested that the short allele from HMOX1 could be a susceptibility factor against CML.

1208

KINETIC PROFILE OF BCR-ABL PROTEIN IN AN IMATINIB-EXPOSED CML CELL LINE

H Wai, X Yang, K Lam, C Bush-Donovan
BD Biosciences, San Jose, USA

Introduction. Imatinib (STI571; Gleevec) is a specific inhibitor that targets the tyrosin kinase activity of the BCR-ABL fusion protein in CML cells (t9;22). The biological response to imatinib exposure is not well understood. Using a surrogate K562 (t9;22) CML model, we examined the imatinib effect on the BCR-ABL fusion protein, Bcr-Abl fusion mRNA, cell viability, and cell differentiation. *Methods*. The K562 cells were continuously exposed to 5 µM of imatinib; imatinib was replenished at 24, 48, and 72 hours. Cells were harvested at 24, 48, and 72 hours and underwent protein, mRNA, viability, and differentiation analysis. BCR-ABL fusion protein in the cell lysate was quantitatively measured at each time-point using the BD® Cytometric Bead Array Research Use Only BCR-ABL Protein* (BD Biosciences, San Jose, CA, USA). Bcr-Abl mRNA transcripts were measured using Q-PCR assay (Ipsogen Corp, Stamford, CT). Cell viability was determined by trypan blue staining and apoptosis was determined by flow cytometry through Annexin V/7-AAD double staining. Erythroid differentiation was scored by benzidine staining and Glycophorin A as hemoglobin synthesis and erythroid lineage markers by flow cytometry, respectively. *Results*. Exposure to imatinib for 24, 48, or 72 hours reduced the BCR-ABL protein concentration by 50%, 70%, and 90%, respectively (Figure 1). At the same series of time points, the Bcr-Abl mRNA transcript level was reduced by 20%, 70%, and 90%, respectively. The fusion protein showed significantly faster reduction than fusion mRNA at 24 hours. The trypan blue and Annexin V/7-AAD stainings showed that the continuous drug exposure induced cell apoptosis in a time-dependent manner.

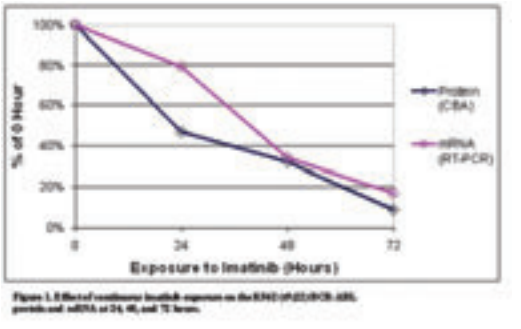

Figure 1. Effect of continuous imatinib exposure on the K562.

Appearance of benzidine-positive cells and increased Glycophorin A expression were observed after 48 hours of imatinib exposure indicating erythroid lineage differentiation. *Conclusions*. Using the K562 (t9;22) in vivo CML model, the present work suggests that the BCR-ABL fusion protein has a quicker response to imatinib than fusion mRNA at 24 hours. Both morphologic and phenotypic analyses indicate that imatinib exposure reduces cell viability, possibly through apoptosis, and induces erythroid lineage differentiation with hemoglobin and Glycophorin A expression. With the availability of the BCR-ABL Protein Kit, researchers can conduct more systematic studies on the BCR-ABL protein and its drug interaction.

1209

CHARACTERISTICS OF NILOTINIB AND IMATINIB RESISTANT CHRONIC MYELOID LEUKEMIA CELLS

S Okabe, T Tauchi, K Ohyashiki
Tokyo Medical University, Tokyo, Japan

Background. Imatinib has improved the treatment of BCR-ABL posi-

tive leukemia such as chronic myeloid leukemia (CML) and Philadelphia chromosome (Ph) positive acute lymphoblastic leukemia (ALL), however, imatinib resistance is often reported in patients with advanced-stage disease by the mutations in kinase domain (KD) of BCR-ABL. Nilotinib is also a potent and selective inhibitor of BCR-ABL tyrosine kinase. In the phase 3 Evaluating Nilotinib Efficacy and Safety in Clinical Trials-Newly Diagnosed Patients (ENESTnd) clinical trial, nilotinib was demonstrated superior efficacy to imatinib with higher and faster molecular responses against CML patients. *Aims*. Nilotinib is the very high rates of responses were achieved during the first 12 months on treatment, however, there are fully not known about nilotinib resistance. *Methods*. We established the imatinib (K562 IM-R) and nilotinib (K562 AMN-R) resistant cell line and examined the mechanism of drug resistance by cell proliferation assay, microarray assay and immunoblot assay. *Results*. We first evaluated the gene expression profiles and intracellular signaling of CML cell line K562 exposed to imatinib or nilotinib. When their gene expression profiles were compared, there was an increase of 934 genes in imatinib and 1234 genes in nilotinib and 854 genes overlapped. In contrast, there was a decrease of 582 genes in imatinib and 816 genes in nilotinib and 515 genes overlapped. In apoptosis related gene, Myb and Myc gene was decreased in nilotinib treatment. We next examined the drug sensitivity of imatinib and nilotinib resistant cell line. Cell proliferation of K562 IM-R and K562 AMN-R did not decrease after imatinib (10 μM) or nilotinib (2 μM) treatment compared with parental cell line, K562. Imatinib resistance occurs through a variety of mechanisms, including BCR-ABL kinase domain mutation, and amplification or overexpression of BCR-ABL. The BCR-ABL expression was not enhanced in these cell lines compared with K562 by FISH and immunoblot analysis. The BCR-ABL kinase domain mutation was not found in K562 IM-R and K562 AMN-R cells by direct sequence analysis. We next examined the intracellular signaling by using these cell lines. One of the Src family kinase, Lyn was activated in resistant cells. The protein expression of Lyn was also enhanced. Ponatinib (AP24534), an oral multiple tyrosine kinase inhibitor, is a potent pan-BCR-ABL inhibitor with activity against imatinib resistant cells. We next examined the efficacy of ponatinib against imatinib and nilotinib resistant cell lines. We found the cell proliferation was decreased after ponatinib treatment. We also found the phosphorylation of BCR-ABL, Lyn and Crk-L was reduced and Poly (ADP-ribose) polymerase (PARP) was activated after ponatinib treatment. *Summary*. These results suggest that the expression and protein activation signatures identified in this study provide insight into the mechanism of resistance to nilotinib and imatinib and we demonstrate ponatinib has anti-leukemia effect by reducing ABL and Lyn kinase activity.

1210

COMPARISSON BETWEEN TWO QUANTITATIVE REAL TIME PCR FOR BCR-ABL DETECTION IN CML: EAC METHOD AND GENEXPERT

C López-Jorge,[1] MT Gomez Casares,[1] A Jiménez-Velasco,[2] M García-Bello,[1] S De la Iglesia,[1] T Ramirez,[1] M Alcala,[2] J Lopez Brito,[1] G Sanchez Sanchez,[3] A Heiniger,[2] T Molero[1]
[1]*Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain*
[2]*Hospital Carlos Haya, Málaga, Spain*
[3]*C.A.E Vecindario, Las Palmas, Spain*

Background. Recently, some efforts have been made in Europe in order to standardize BCR-ABL quantification as well as to certify laboratories which are able to express the results in an international scale applying a conversion factor (CF). However, light variations in the techniques which are used can cause CF modifications. The GeneXpert is an automated closed system for the quantification process, performing a nested-PCR using ABL as control gene. AIMS: To determine whether BCR-ABL results obtained by GeneXpert are comparable with the ones given by the standard method with the CF. *Material and Methods.* BCR-ABL was determined by both methods in 58 samples from bone marrow and/or peripheral blood of patients with CML (25 in Carlos Haya Hospital; 33 in Dr. Negrin Hospital). For the analysis with the standard method, LightCycler platform was used according to Europe Against Cancer (EAC) conditions. Both laboratories showed the results in an international scale, applying each one its CF. GeneXpert analysis was performed according to manufacturer instructions. With both methods, the quantification is automated by every equipment software and the final result is expressed as BCR-ABL/ABL x 100. The obtained results were statistically analyzed by Passing Bablok method in order to establish the relation between these techniques and by Bland andAltman to estimate the concordance. RESULTS: GeneXpert results are slightly higher (0,14761 logs greater) than the ones obtained by the standard method, being significant the difference of the means between the logarithm of the standard one corrected with CF and the logarithm of the GeneXpert ($p<0,004$). The concordance indicates that both techniques are significantly correlated, being the correlation coefficient of 0,9507 (Pearson correlation factor of 0,9571). Besides, it doesn't exist a significant deviation of linearity ($P>0,10$) between both measurements. Finally, according to the standard technique and after applying the CF, 28 samples were in MMR (≤0,1%). Out of them, 22 matched up with the results given by the GeneXpert. The other 6 showed levels of >0,1%, but very close (range 0,11-0,23%). Just 2 samples in MMR by GeneXpert didn't show the same result with the standard method once CF was applied (0,11% and 0,12%). *Conclusions*. 1) The concordance level between both measurements is quite good. 2) The result obtained with the standard method can be predicted by GeneXpert, although slightly overestimated. 3) None of the measurements showed a relevant difference between standard variable scores and GeneXpert, so that we can consider GeneXpert as an alternative and useful method to determine molecular response.

1211

ASSOCIATION OF SINGLE NUCLEOTIDE POLYMORPHISMS OF TRANSPORT PROTEINS SLC22A1, ABCB1 AND ABCG2 WITH RESPONSE TO IMATINIB AND IMATINIB PLASMA LEVEL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

F Vrbacky, P Belohlavkova, J Voglova, J Malakova, J Nekvindova, M Pecka, J Maly
University Hospital and Faculty of Medicine, Charles University, Hradec Králové, Czech Republic

Background, Many cases of imatinib resistance leading to suboptimal response or failure of imatinib mesylate therapy can be explained by tyrosine kinase mutations but many cases are resistant without any mutation found. It can be caused by overexpression of BCR/ABL gene or polymorphic alleles of genes involved in transport and metabolism of imatinib. Several studies regarding role of relevant polymorphisms have been done. However, their results are often heterogeneous and role of many polymorphisms remain unclear. *Aims*. To study single nuclear polymorphisms (SNPs) of one influx (SLC22A1) and two efflux transporters (ABCB1 and ABCG2) and their association with response to imatinib and imatinib plasma level in our cohort of chronic myeloid leukemia (CML) patients. *Methods*. We retrospectively analyzed response to imatinib according to European LeukemiaNet recommendations of 58 patients in chronic phase of CML treated with imatinib (400 mg /day). Patients with treatment failure due to mutations in kinase domain of ABL were not included. SNPs were detected using allelic discrimination with labeled probes. Imatinib plasma level was detected by liquid chromatography from samples taken 24 hours (+/- 2 hours) after the last imatinib dose. Statistical analysis of response was done using chi-square test. Imatinib plasma level was evaluated using ANOVA. *Results*. No significant association of different response (optimal vs suboptimal or failure) of individuals carrying homozygotic allele T or C of ABCB1 C3435T (TT vs CT or CC, $p=0.437$; CC vs CT or TT, $p=0.460$) or heterozygotic genotype (CT vs CC or TT, $p=0.923$) was revealed. Response to imatinib therapy is not associated with ABCG2 C421A ($p=0.299$) and SLC22A1 G480C ($p = 0.496$) too. No association of imatinob plasma level was observed ($n = 51$; ABCB1 C3435T, $p = 0.890$; ABCG2 C421A, $p = 0.978$; SLC22A1 G480C, $p = 0.923$). *Conclusions*. Our study did not confirm any association of analysed SNPs with different response of CML patients to imatinib as observed in some other studies. Imatinib plasma level was not significantly influenced too. More pharmacogenetic studies will be needed to validate association of genetic polymorphisms of analyzed and other transport or metabolic genes with different clinical outcome.

INCREASED LEVELS OF MYELOID-DERIVED SUPPRESSOR CELLS AND PROGRAMMED DEATH RECEPTOR LIGAND IN CHRONIC MYELOID LEUKEMIA PATIENTS

H Christiansson,[1] S Söderlund,[2] M Bengtsson,[1] B Simonsson,[2] U Olsson-Strömberg,[2] A Loskog[1]
[1]*Uppsala University, Uppsala, Sweden*
[2]*Uppsala University and Uppsala University Hospital, Uppsala, Sweden*

Background. The role of the immune system in cancer biology and therapy is currently in focus. Thyrosine kinase inhibitor (TKI) therapy intended to act directly on the tumor cells in chronic myeloid leukemia

(CML) has shown interesting effects also on the patients immune cells and the immune status of these patients is therefore of interest. Anti-tumor immune reactions in cancer patients may be hampered by immune escape mechanisms, including recruitment of suppressor cells like myeloid-derived suppressor cells (MDSC) or expression of immune inhibitory molecules such as programmed death receptor ligand 1 (PDL1) on tumor cells and programmed death receptor 1 (PD1) on T cells. Immune escape mechanisms in CML have so far not been extensively studied. *Aims*. The aim of the study was to investigate immune escape mechanisms in CML patients. *Methods*. Cryopreserved leukapheresis samples (n=18) from high (n=11) and low (n=7) sokal score risk group CML patients and buffy coats from healthy controls (HC, n=21) were investigated for the presence of MDSCs (CD11b+CD14-CD33+) and the immune inhibitory cell surface markers PD1 and PDL1 by flow cytometry. The level of the MDSC-associated molecule Arginase-1 in cells from CML patients (n=5) and controls (n=5) was assessed by real time PCR. T cell proliferation upon tumor cell encounter was determined by flow cytometry. *Results*. The level of MDSCs in leukapheresis samples from CML patients was significantly higher compared to the levels in healthy controls (medians 2,6% in CML and 0,8% in HC). When CML patients were divided into sokal high and low risk groups the high risk group had higher MDSC level (median 3,6%) compared to the low risk group (median 0,8%). The level of MDSC in sokal low risk group did not significantly differ from the level in HCs. Arginase-1 is a molecule linked to the immune inhibitory effects of MDSCs. The expression level of Arginase-1 was higher in CML patients compared to HCs as assessed by real time PCR. Further, the expression of PDL1 on CD11b+ myeloid cells was higher on cells from CML patients compared to controls. There was no difference in PDL1 expression levels between sokal low risk and sokal high risk groups. PDL1 is known to inhibit T cells by binding to PD1 on the T cell surface. In our study the expression level of PD1 on CML T cells was higher compared to the expression of PD1 on healthy T cells. However, blocking PDL1 could not increase proliferation of healthy T cells mixed with CML cells. *Conclusions.* CML exert multiple immune escape mechanisms including high levels of MDSCs, Arginase-1, PDL1 and PD1 expression. Interestingly, some mechanisms investigated seem to correlate with sokal score demonstrating the relevance of immune biomarkers in CML. Treatment with TKIs lowers tumor burden and affect immune cells. It remains to investigate if TKIs could affect immune escape mechanisms in CML leading to long lasting anti-tumor control.

1213

THE BCR-ABL TRANSCRIPT LEVELS IN CML PATIENTS AT PRESENTATION HAVE NO PROGNOSTIC SIGNIFICANCE FOR THE MOLECULAR RESPONSE TO IMATINIB

R Talmaci,[1] D Coriu,[1] D Jardan,[1] A Vulpe,[2] C Jardan,[1] M Dragomir[3]
[1]*University of Medicine and Pharmacy "Carol Davila" Bucharest, Romania*
[2]*University of Bucharest, Bucharest, Romania*
[3]*Fundeni Clinical Institute, Bucharest, Romania*

Background. The chronic myeloid leukemia (CML) outlook has radically changed since treatment with Imatinib mesylate. Responce prediction has proven useful and might guide therapeutic decisions in the era of targeted therapy. As the majority of CML patients treated with Imatinib achieve a complete cytogenetic remission (CCyR), there is a need for a molecular analysis that measures the level of BCR-ABL transcripts in order to detect minimal residual disease. *Aims*. We have studied the significance of BCR-ABL transcript levels at presentation for the response to treatment with Imatinib. The BCR-ABL levels were measured during 18 months of treatment with Imatinib. *Methods*. We have monitored BCR-ABL transcript levels by RQ-PCR in 57 CML patients with CML-CP starting at presentation. The BCR-ABL transcript level at baseline was considered in order to evaluate a correlation with MMR achievement. Transcript quantification by RQ-PCR was measured every 3 months from baseline. As a national refference laboratory for CML molecular monitoring, a conversion factor (CF=0,7838) was used for International Scale alignment. *Results*. 55% of the patients that achieved CCyR at 6 months have a baseline transcript level range between 4-78%. 13% of patients achieved major molecular response (MMR) at 6 months, having baseline transcript levels between 21-61%. The remaining 32% of patients achieved MMR at 12 months and transcript level at baseline was between 4-75%. The type o transcripts was about 60% b3a2 and 40% b2a2 in these three groups. *Conclusions*. Achieving an early MMR seems to show no correlation with BCR-ABL transcript levels at diagnosis. The level of BCR-ABL transcripts at presentation should not be a prognostic factor for the response to Imatinib treatment. This study is in progress, in order to extend the group of patients.

1214

SLC22A1 POLYMORPHISMS ARE NOT ASSOCIATED WITH CYTOGENETIC AND MOLECULAR RESPONSE TO IMATINIB MESYLATE IN CHRONIC MYELOGENOUS LEUKEMIA PATIENTS

M Guerra-Shinohara,[1] C Bueno,[1] L Lima,[1] D Vivona,[1] R Hirata,[1] M Hirata,[1] A Luchessi,[1] C Chiattone,[1] M Zanichelli[3]
[1]*Faculdade de Ciencias Farmaceuticas da Universidade de Sao Paulo, Sao Paulo, Brazil*

[3]*Departamento de Hematologia do Hospital Brigadeiro, Sao Paulo, Brazil*

Background. The roles of drug efflux and drug influx proteins have been investigated in the development of resistance to imatinib mesylate (IM). The activity of IM has recently been linked with the organic cation transporter 1 (OCT1), an influx transporter, which is codified by SLC22A1 gene. However, few studies have shown the effects of SLCA22A1 polymorphisms in cytogenetic and molecular response to IM in chronic myeloid leukemia (CML) patients. *Aims*. To investigate the relationship between SLC22A1 polymorphisms and response to IM in patients with chronic myeloid leukemia (CML). *Methods*. One hundred and eighteen patients in the chronic phase of CML, both genders with an age range of 18 to 80 were studied. All patients were initially treated with a standard dose of IM (400 mg/day) and divided into two groups according to their response. The first group (*responder*) comprised 70 patients who had a complete cytogenetic response within 18 months of treatment. The second group (*non responder*) comprised 48 patients who did not have a complete cytogenetic response with the initial dose (400 mg/day) of IM or who relapsed during treatment and were submitted to higher doses of 600 or 800 mg/day. Criteria of failed response to treatment were established by European Leukemia Net. Patients with cytogenetic patterns other than the Philadelphia chromosome and/or with mutations in the BCR-ABL1 gene were excluded from this study. Major molecular response (MMR) was defined as a reduction of BCR-ABL1 transcript levels to ≤ 0.1% in the peripheral blood standardized on the International scale. The SLC22A1 (848C>T (rs4646277), 859C>G (rs4646278), 1222A>G (rs628031) and 480C>G (rs683369)) polymorphisms were detected by Real Time PCR. *Results*. Minor allele frequencies for SLC22A1 polymorphisms were similar between responders (859G: 8.7%; 1222G: 74.6% and 480G: 12.3%) and non responders (859G: 6.2%; 1222G: 67.7% and 480G: 12.5%; P>0.05). The 848C>T variant was not detected in this sample. The frequencies of SLC22A1 (859C>G, 1222A>G and 480C>G) haplotypes in both groups were also similar (P>0.05). Association between SLC22A1 genotypes or haplotypes and MMR was not found in CML patients independently of type of IM response. *Conclusions*. SLC22A1 859C>G, 1222A>G and 480C>G polymorphisms do not influence the cytogenetic and molecular response to IM in CML patients.

VARIANT PHILADELPHIA TRANSLOCATIONS - CYTOGENETIC EVOLUTION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

C Gug, R Mihaescu, H Ionita, L Cheveresan, V Dumitrascu
University of Medicine and Pharmacy Victor Babes, Timisoara, Romania

Background. The Philadelphia chromosome (Ph1) is the hallmark of chronic myeloid leukemia (CML). Whereas the majority of Ph-positive CML patients show the standard Ph translocation involving chromosomes 9 and 22, t(9;22)(q34;q11), the minority of cases presents a variant type of Ph translocation. Available data indicate that variant rearrangements do not confer any specific phenotypic or prognostic impact as compared to CML with a standard Ph chromosome. *Methods*. The study was conducted between January 2002 and January 2011. The cytogenetic studies were made on hematopoietic bone marrow using culture for 24-48 hours on a culture medium dedicated for hematopoietic cells, followed by standard cytogenetic exam, GTG banding and karyotyping. The hematologic and cytogenetic evaluations of patients were monitored during the treatment. *Results*. Out of 87 patients with chronic myeloid leukemia cytogenetic analyzed, 8 patients had Philadelphia (Ph) negative, 71 patients had Ph positive, of which 5 patients carried a variant Ph translocation. Four patients had complex translocations involving 9q34, 22q11, and a third chromosome: t(9;10;22)(q34;q24;q11), t(6;9;22)(p21.3;q34;q11), t(7;9;22)(p22;q34;q11) and (9;11;22)(q34;p11;q11). One patient had a complex variant Philadelphia (Ph) translocations, t(8;19;22), with no obvious involvement of chromosome

9. Two patients, had after treatment the unusual secondary changes t(1;4)(q32.1;q13.2) and t(14;20)(q24.2;13.1), which were transient. *Conclusions*. The present findings strongly suggest that variant Ph translocations of CML occur as primary cytogenetic changes similar to the classical Ph1 translocations. Some complex chromosomal rearrangements are associated with rather poor prognosis and respond poorly to antileukemic treatment.

1216

THE EFFECT OF IMATINIB TREATMENT OF CHRONIC MYELOID LEUKEMIA (CML) ACCODING TO CLINICAL AND EPIDEMIOLOGICAL DATA OF REGIONAL MONITORING

A Volkova,[1] O Kovalishena,[1] N Borovkov,[1] S Samoilova,[2] N Samarina,[3] V Muraviev,[4] A Gostuzhova,[2] V Shurigina[2]
[1]*Nizhniy Novgorod State Medical Academy, Nizhniy Novgorod, Russian Federation*

[3]*Dzerzhinsk Emergency aid Hospital, Dzerzhinsk, Russian Federation*
[4]*City Clinical Hospital N12, Nizhniy Novgorod, Russian Federation*

Background. Since 2005-2007 Imatimib (IM) has been the current standard of real-life out-patient therapy of patients with CML in the Russian Federation and is financed by the federal program. *Aims*. To evaluate the clinical effectiveness of IM in unselected population in the real-life out-patient therapy and epidemiological rates of CML on the basis of the regional monitoring from 2000 to 2010. *Methods*. We analyzed the data of the regional register of CML-patients. Clinical effectiveness criteria: 1) frequency of no 'failure' after 18 month according to the ELN, 2009, 2) cumulative frequency of complete cytogenetic response (CCgR) at the moment of the last research after ≥ 12 months of IM treatment. The analysis of IM effectiveness has been carried out in the three groups of patients: 1st - the early chronic phase (ECP) - ≤6 months from the establishment of CML till the beginning of IM treatment, 2nd - the late chronic phase (LCP)-> 6 months from the establishment of CML till the beginning of IM treatment (7 to 127, median 23) and 3d - the progression phase (PrP) which combined the patients with the accelerated phase and the blast crisis. Epidemiological rates: incidence, prevalence, mortality were calculated by the standard methods of the variation statistics to the number of the acquisitive population (adults >14 years) with an assessment of average multiyear rates, multiyear dynamics and trends. Statistical validity was determined by the method Chi-square. *Results*. Since 2000 CML, Ph-positive was established in 248 patients, the age (13-82 years, a median 52, including 2 children cases), sex (M-112, F-135), 161 CML patient have received IM treatment: 76 in ECP, 75 in LCP and 10 PrP. The frequency of no 'failure' after 18 months and the cumulative frequency of CCgR at the moment of the last research after ≥12 mouths of IM treatment are presented in the table 1. Nobody in PrP has not reached CCgR. The IM treatment has been stopped in 42 (25.5 %) to 161 patients. The average multiyear incidence rate was 0,77±0,080/0000: max 1,040/0000 in 2004, min- 0,640/0000 in 2008, without trend (T=-0,04%). The quantity of deaths of CML patients was 197. The average multiyear mortality rate was 0,6±0,120/0000: max 1,1 0/0000 (in 2000), min 0,170/0000 (in 2010), - with a marked trend to decreasing for 10 years of mortality (T =-6,6%). The average multiyear prevalence rate was 3,6 + 0,420/0000: max 4,90/0000 in 2010, min 2,70/0000 in 2002, - with a marked trend to growth of CML prevalence for 10 years (T=+7,8%), especially for the last 5 years. *Conclusions*. IM in real-life out-patient therapy of CML patients has shown high clinical effectiveness without changes of average multiyear incidence rate with decreasing average multiyear mortality rate and increasing average multiyear prevalence rate.

	ECP (n=76)		LCP (n=75)		p
	n	%	n	%	
IM treatment ≥18 months	37	48.7	68	90.6	
No "failure" after 18 months	24	64.9	32	47.1	0.05

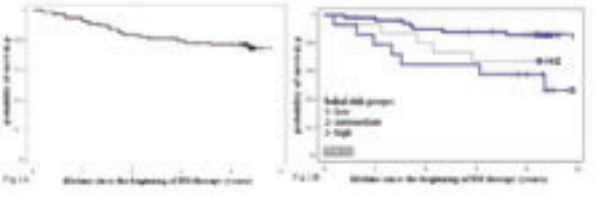
LONG-TERM RESULTS OF IMATINIB THERAPY AND SURVIVAL IN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA RESISTANT OR INTOLERANT TO INTERFERON- ALPHA THERAPY

O Lazareva, A Turkina, G Gusarova, O Vinogradova, E Chelysheva, E Zakharova, I Tischenko, S Kulikov, N Khoroshko
Hematology Research Center, Moscow, Russian Federation

Background. In Russian Federation a selective BCR/ABL tyrosine kinase inhibitor (TKI) imatinib (IM) was introduced for the first time in 2000y for chronic phase (CP) CML patients(pts) after interferon α (IFN-α) failure. The 2nd and more potent generation of TKI (TKI-2) became available since 2005-2007y. At present time we summarize the long-term therapy results. *Objectives*. To evaluate the efficacy of 1st and 2nd generation TKI therapy: frequency and stability of complete cytogenetic response (CCyR), frequency of major molecular response(MMR) and complete molecular response (CMR), incidence of second tumors and overall survival (OS). *Patients and treatmen*t. The analysis included 79pts. Criteria for inclusion into an open non-randomized study were: CP CML; diagnosis confirmation by standard cytogenetic study; IFN-α therapy discontinuation and initiation of IM therapy from Jul.2000 till Sep.2001. Median (Me) age 39 (15- 64) years, males:females =41:38. Distribution by Sokal groups: low-50 (63%) pts, intermediate + high - 15(19%) pts plus 14(18%) pts. Me duration of CML before IM therapy was 35.1 (3-157) months: less than 1 year in 12pts (15%), from 1 to 5 years in 50pts (63,5%) and more than 5 years in 17pts (21,5%). Me period of IFN-α pretreatment was 26 (0,5-156) months. Me duration of IM therapy (Jul2010) was 80 (2,4- 118) months. The initial dose of IM was 400mg/day. Me duration of TKI-2 therapy was 31 (2-51) months. 4 (5%) pts received more than two TKIs-2. Me duration of CML (from diagnosis to analysis- July 2010) was 120.5 (13-259) months. Statistical analysis was performed using the package v.SAS9.1.3. *Results*. 59 of 79pts (75%) alive on Jul2010 received TKI therapy: IM 34 (43%)pts /TKI-2 24 (30%)pts/ 1(1,3%)pt treated by hydroxyurea (resistant to all available TKI). For the entire observation period CCyR was obtained in 64%(51pts). The cumulative incidence of CCyR was 54% (43pts) with a Me to CCyR 9 months (5-53). Acquired cytogenetic resistance was observed in 16 of 43 (37%)pts (or 20% of the total group). CCyR was again achieved on IM for 27(34%) pts (still on IM) and for 8(10%) pts on TKI-2 therapy for the first time. 34(43%) pts with CCyR continue IM therapy (27 of them have stable CCyR). MMR in pts with CCyR on IM therapy was observed for 21 (26,7%) of 79 pts, CMR was achieved in 11 (14%) pts.



Discontinued IM therapy 45(57%)pts and 29 (35%)pts were switched to TKI-2 treatment. 20(25%) pts died. Death causes were: progression to advanced CML phases (16pts), brain hemorrhage (2pts), generalized infection (1pt), hepatocellular carcinoma (1pt). Importantly, during the 9-year IM therapy period there were only 2 (2,5%±1,8%) cases of secondary malignances (1 pt alive with CMR). Estimated 9-yr OS of all pts on TKIs is 75% (Figure 1A), progression-free survival is 78,5%. OS (108 months) by Sokal risk groups is 86% /67%/50% for low, intermediate and high risk group accordingly (p=0,0094)(Figure 1B). *Conclusions*. The results showed high survival rates and efficacy of IM and TKI-2 therapy in a special long-time observed group of patients in CP CML with IFN-α failures, with rare second tumors detection.

1218

CYTOKINE SYNTHESES BY T-CELL SUBSETS OF CML PATIENTS PRIOR TO AND DURING IMATINIB THERAPY: RELATION BETWEEN THE LEVEL OF RESPONSE TO THERAPY (OPTIMAL VERSUS NO OPTIMA) AND ENDOGENOUS T-CELL FUNCTION

I Hassan,[1] N Negelkerke,[1] S Bendect,[1] J Kristensen,[2] H Alizadeh[3]
[1]*Faculty of Medicine & Health Sciences, United Arab Em, Al Ain, United Arab Emirates*
[2]*Oncology Dept Tawam Hospital, Al Ain, United Arab Emirates*
[3]*Dept of oncology Tawam Hospital, Al Ain, United Arab Emirates*

Background. The majority of imatinib (IM) treated chronic phase chronic myeloid leukemia patients achieved complete haematological and cytogenetic remission but relatively few of them achieve complete molecular remission. Although T-cells cytokines role in the long term

control of CML is well established, previous studies showed contradicting results regarding imatinib effect on the endogenous T-cell function by IM. The variability in the patients population included in these studies may contributed to this where in some of them cells were obtained from patients in CcyR or patients with resistant/intolerance to previous therapy with IFN-alpha. *Aims*. the purpose of this study was to determine the relation between the endogenous T-cell function prior to therapy and the degree of response to IM therapy in CP CML. In addition, modulation of the endogenous T-cell function during IM therapy was studied. *Methods*. Using flow cytometry, we studied Th1 and Th2 cytokine synthesis by PMA activated CD4 and CD8 T cell subsets of 22 patients with newly diagnosed CML in chronic phase prior to and during IM therapy compared to that of 5 patients with IM resistance and 10 healthy donors. Patients were grouped into optimal or no optimal response according to the disease status at last follow, disease progression or treatment failure. All patients and healthy donors signed and informed consent. *Results*. In 11 patients with optimal response, pre treatment cytokine studies showed lower Th1, but higher percentage of e Th2 and TNF-α producing CD4 and CD8 T cells compared to that of healthy donors. Significant higher levels of Th2 and TNF-α producing CD4 and CD8 T cells were found compared to those from patient with no optimal response and those known to have IM resistance. Lower level of Th2 and TNF-α producing T cells were found in the last 2 named groups of patients compared to that of healthy donors. Cytokine response with shift from Th2 profile to Th1 profile was detected early during IM therapy (6 weeks) in patients with optimal response coinciding with the CHR in addition to decline of TNF-α producing CD4 and CD8 T cells. This immunological response of T cell subset during IM therapy preceded both the cytogenic and molecular response which was maintained throughout the follow up period. In patients with no optimal response initially increase in the percentage of IFN-γ and TNF-α synthesizing CD4 and CD8 T cells at 6 weeks of therapy to levels exceeding that of healthy donors and those with optimal response followed by a rapid decline in the cytokine levels at later follow ups. *Conclusions*. CP CML patient with optimal response has Th2 cytokine and suppressed Th1 cytokine profile at diagnosis with restoration to normal levels during therapy. On the other hand patients with no optimal response and those known to have IM resistance showed suppression of Th1, Th2 cytokines and TNF-α. The role of pre treatment indigenous IL-4 and TNF-α in determining the response to IM therapy needs further investigation.

1219

IMPACT OF SWITCHING THERAPY FROM IMATINIB MESYLATE TO GENERIC COPY OF IMATINIB ON HEMATOLOGIC RESPONSE IN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA: SINGLE CENTER STUDY

F Alwan, A Alshami, A Hatim, A Ali
The National Center of Hematology, Baghdad, Iraq

Background. Imatinib mesylate is a tyrosine kinase inhibitor of BCR-ABL; it has revolutionized the treatment of chronic myeloid leukemia (CML). Imatinib is widely accepted as the standard of care for the first-line treatment of CML due to its high hematologic, cytogenetic, and molecular response rates and favorable long-term safety profile which has been documented in many studies. A copy version of imatinib, has become commercially available .The lower price has prompted some health-care authorities in Middle East to substitute the copy for the branded imatinib. *Aims*. The aim of this study was to evaluate hematologic responses of chronic phase CML patients who switched from imatinib mesylate to generic copy of imatinib. *Methods*. A prospective study conducted at the national center of hematology in Baghdad from January 2010 to November 2010.It included 126 patients with chronic phase CML who were switched from imatinib mesylate to a generic copy. At time of switching, all patients were in complete hematologic response and received generic copy of imatinib for at least 9 months. Informed consent was obtained. Physical examination, Complete blood count, and peripheral blood smear were performed in order to assess hematologic response. Evaluation of patients done at 3 month, and 6 months interval. *Results*. Eighty-four (66.6%)of the patients showed sustained durable hematologic response after switching that had no significant relationship with a patient's age or sex (P>0.05). while 42(33.3%)of patients lost their response to imatinib after switching to generic copy . Twenty-two out of 42 patients (52.3%) lost hematologic response after 3 months(4 patients had blast crisis, 18 accelerated phase).after 6 months ,twenty patient (47.6%) out of 42 had substantial hematological change(anemia, leucopenia ,and thrombocytopenia) in whom FISH study showed that they had cytogenetic relapse. *Conclusions*. The use of generic copy of imatinib instead of imatinib resulted in inferior outcome of a previously stable response. Loss of hematologic response in CML can lead to grave consequences of accelerated phase or blast crisis phase of the disease.

1220

THE RESPONSE TO TYROSINE KINASE INHIBITORS IS PREDICTABLE BY *IN VITRO* ANALYSIS OF BCR- ABL PHOSPHORYLATION

M Shibata
Osaka University Graduate School of Medicine, Suita, Japan

Background and Aims. Although tyrosine kinase inhibitors (TKIs) targeting Bcr-Abl have dramatically improved the treatment of CML, a substantial proportion of the patients treated with imatinib have been reported to exhibit either primary or secondary resistance or intolerance. To overcome the resistance and intolerance to imatinib, second- and third-generation TKIs, such as nilotinib, dasatinib, bosutinib and INNO-406 have developed. In parallel with the availability of new therapeutic compounds, we need more information to select the best TKI. In this study, to establish a system with which we can predict the response of each patient to TKIs, we investigated the phosphorylation of Crkl, a major target of Bcr-Abl, after in vitro incubation with or without TKIs in peripheral blood (PB) samples from patients either newly diagnosed or resistant to imatinib. *Methods and Results*. Ten mL of PB samples were obtained from thirty-one patients with CML in the chlonic phase (CP) with informed consent at the beginning or before the initiation of imatinib, nilotinib or dasatinib. Half of each sample was used for examination of the Bcr-Abl sequence, and the other half was used for immunoblot analysis. From the preliminary experiments to establish the experimental procedures, incubation time was optimized to 5 hours. The concentrations of imatinib, nilotinib and dasatinib were fixed from pharmacokinetics to 5μM, 5μM, and 0.1μM, respectively. To quantify the in vitro responsiveness to TKIs, we measured the density of each blot using a densitometric method, and then defined "Residual Index (RI)"for each TKI by the numerical expression. Newly diagnosed patients (n=15) were separated into two groups in accordance with the most recent outcome, the imatinib-sensitive (n=13), who achieved an optimal response after the sample collection, and the imatinib-resistant (n=2), who did not. The median RI of the patients in the sensitive group was 4.2% and that in the resistant group was 43.2% (p<0.05). Among 8 patients imatinib resistant had undergone nilotinib-therapy, the median RIs of 4 achieved optimal responses and those of 4 failed were 3.5% and 31.2%(p<0.05), respectively. Also in the dasatinib treated patients, RIs of three achieved response were almost 0%, and that of one failed was 92%. Imatinib-responsiveness could predict with 100% of sensitivity and 77% of specificity when the RIs were separated at 10%. On the other hand, although the sample size was small, the immunoblot analysis was able to predict the clinical responsiveness to nilotinib or dasatinib with 100% sensitivity and specificity. We also examined the relation of RIs with Bcr-Abl point mutaions. Although, among 4 patients with mutations, RIs in 3 cases agreed with the reported IC50s of the mutations, the RIs in one patient were contradictory to the reported responsiveness to nilotinib or dasatinib but consistent with his clinical outcome. Conclusions. The immunoblot system described here has the capacity to detect TKI-resistant subclones, including CML cells with Bcr-Abl mutations, and when used together with the cellular IC50 values and Bcr-Abl sequence, this immunoblot system should help improve the treatment of patients with CML.

1221

SKIN REACTIONS DUE TO IMATINIB TREATMENT IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML)

S Novakovic,[1] M Nikolic,[2] A Djordjevic,[1] R Lekovic,[1] A Bogdanovic[3]
[1]*Hematology, Clin Ctr of Serbia, Belgrade, Serbia*
[2]*Dermatovenerology, Clin Ctr of Serbia, Belgrade, Serbia*
[3]*Hematology, Clin Ctr of Serbia, School Medicine of University, Belgrade, Serbia*

Background. Imatinib (IM) is current standard treatment for newly diagnosed patients (pts) with CML. Treatment with IM is generally well tolerated, and the risk for severe adverse events is low. Cutaneous reactions to imatinib are common and occur in 9.5% to 69% but in general are mild. Edema, periorbital edema, maculopapullar and erythematous eruptions are the most common side events. Imatinib can also induce severe skin eruptions (generalized rash, purpuric vasculitis, mycosis fun-

goides like reaction). Rare changes are hyperpigmentation, psoriasis and pithyriasiform eruptions. *Aims*. The aim of our study was to analyze cutaneous changes during IM treatment in large cohort of our CML pts. *Methods*. Between 2002 and 2010, 110 pts with CML were treated with IM in our institution. IM therapy was commenced in a dose of 400 and in some cases escalated to 800 mg/d.

Results. In our group, 76 patients (69%), 40 males and 36 females, mean age 39 years (28-78 yrs) had some skin changes. All pts were in chronic phase CML, 30 pts had low risk, 27 pts intermediate and 19 pts high risk Sokal score. Periorbital edema was the most common, occurring in 70 pts (64%); almost all had typical, mild form, pronounced in the morning. But 5 pts had also severe edema (CTC Gr. 2), without cessation of imatinib therapy. Edema developed in our group from two weeks to 20 months of IM treatment (median 12 months) and was treated by various means, e.g. low-salt diet, oral diuretics and in some cases topical 1% hydrocortisone. Six patients (5.4%) had other different cutaneous reactions. Two patients had acute maculopapullar rash (CTC Gr. 2) with pruritus, needed topical steroids bid during two weeks. One patient had worsening of vitiligo with extension in areas and pronounced edge hyperpigmentation, and second one worsening of psoriasis but responded to more frequent psoriatic treatment. Two previously healthy patients had a severe, recidivant psoriasis-like reaction with subcutaneous edema and pruritus from 3rd week of IM treatment proven by skin biopsy (CTC Gr. 2), responding to pause in IM treatment and to topical/systemic steroids. Unfortunately, in one patient due to recidivant skin changes IM treatment was discontinued for good. We have not found any correlation of any changes with Sokal score or some other pretreatment variable. *Conclusions*. Imatinib has many mild adverse events but the incidence and management of cutaneous side effects has been rarely reported. Most cutaneous eruptions caused by IM do not need discontinuation of treatment and are usually self limited. Administration of oral or topical corticosteroids can ameliorate some of imatinib induced cutaneous changes without need for treatment cessation.

1222

ECONOMIC BURDEN OF PROGRESSION IN PATIENTS WITH PHILADELPHIA CHROMOSOME-POSITIVE CHRONIC MYELOID LEUKEMIA (PH+ CML) IN CHRONIC PHASE

J Stephens,[1] K Carpiuc,[1] V Bollu,[2] J Coombs[2]
[1]*Pharmerit International, Bethesda, USA*
[2]*Novartis Pharmaceuticals Corporation, Florham Park, USA*

Background. The ENESTndstudy showed that after 12 month of therapy, newly-diagnosed chronic phase (CP) Ph+ CML patients (pts) receiving nilotinib (300 mg BID) had a significant superior major molecular and complete cytogenetic response and improvement in the time to progression to accelerated phase (AP) or blast crisis (BC), compared with those receiving imatinib (400 mg QD) (P=0.01). *Aims*. To estimate the economic burden associated with early progression to AP in the US. Methods: A literature-based Markov model was developed to estimate the 5-year economic burden associated with early progression to AP despite first-line therapy. The model follows longitudinally cohorts of hypothetical pts who have progressed to AP after failure of first-line therapy in CP. Pts in the AP phase were assumed to initially receive therapy with a second generation TKI. These pts could discontinue this second generation TKI therapy due to intolerance or progression to BC. Patients who were off TKI (in the AP or BC) phase were assumed to receive primarily supportive care and/or transplant. The rate of transplantation in the latter patients was approximately 5% per year.

Resource	Avg Cost/Pt
TKI drug costs (including AE management)	$191,805
Inpatient care	$91,743
Transplants	$11,710
Physician and Nurse Visits	$9,964
Tests	$5,749
Palliative care	$3,323
Direct Costs	**$314,294**
Indirect Costs	**$176,179**
Total	**$490,473**

Prognosis was modeled using published data. Non-TKI-drug costs and productivity loss were assumed to increase as disease progressed. Quality of life varied by disease stage and treatment response. Resource use and costs were obtained from published estimates. Productivity was estimated using the human capital approach and considered the opportunity cost of CML-AP (i.e., productivity of progressed pts minus productivity of non-CML age/gender-matched individuals). Results: Pts who have progressed to AP experience high direct medical ($314,294) and indirect costs ($176,179) (TABLE) and poor prognosis (5-year overall survival=24%, average survival 3.74 years of which 2.66 years in AP and 1.09 years in BC, average quality adjusted life years = 2.11). 87% of costs were assumed to occur in AP and 13% in BC. Overall, the total direct and indirect costs of progression were $490,473/pt. *Conclusions*. In addition to poor survival prognosis, CML disease progression is associated with a heavy economic burden. Preventing progression is therefore an important therapy goal in CML- CP.

[4]*Polyclinique Bordeaux Nord Aquitaine, Bordeaux, France*
[5]*CH R.Boulin, Libourne, France*

Background. Frontline therapy with imatinib (IM) have dramatically improved the survival of chronic phase chronic myeloid leukaemia (CML-CP) patients. While treatment with IM is effective, most of the patients have detectable residual disease documented by real-time quantitative polymerase chain reaction (RQ-PCR) and will have to continue IM at least indefinitely. Only a minority of them will achieve a complete molecular response (CMR). As sustained CMR can lead to cessation of IM without relapse in some cases, so it is the major goal of treatment and become the molecular endpoint in future trials with tyrosine kinase inhibitors. *Patients and methods.* We analyzed the data of previously untreated CML-CP patients who received IM as initial therapy in our department in order to identify the incidence and median time to CMR and characteristics of the patients who achieved a CMR under IM therapy. CMR was defined as CMR as undetectable BCR-ABL transcripts with sensitivity of at least 4.5 logs and undetectable BCR-ABL transcript on two consecutive assessments at least two months apart. Loss of CMR was defined as detectable BCR-ABL transcripts on two consecutive assessments. *Results*. Between September 2000 and December 2009, 161 ECP-LMC patients were initially treated with IM 400 mg (n=134-83%) or 600 mg daily (n=25-16%) or 800 mg (n=2-1%). The median age at diagnosis was 56.7 years [18.5-88.9] and 63% were male. The Sokal risk score was low in 28%, intermediate 42% high in 21%, unknown in 9%. Clonal evolution was documented in 12 patients (7%) at the time of

diagnosis. The median follow-up on imatinib therapy is 44.8 months [2.53-122.24]. One hundred and thirty patients (80.7%) achieved a CCR with a median time to CCR of 6.38 months, 116 (72.5%) a major molecular response (MMR) with a median time to MMR of 15.32 months. Fifty patients (31%) had stopped imatinib du to failure (n=22, 13%), intolerance (n=12, 7%), suboptimal response according to the molecular criteria (n=8, 5%) and participation to the French study STIM (n=9, 6%). The median time to imatinib cessation du to lack of efficacy was 27.09 months [2.53-110.93]. Fourty-six patients (28%) achieved a CMR. Median time to CMR was 35.3 months. The characteristics of those patients are detailled above (table). The median duration of CMR was 15.65 months [0.00-81.31]. *Conclusions*. Preliminary results suggest that patients who achieved a CMR had a faster MMR than the other . The identification of factors correlated with CMR in CML-CP treated with imatinib as frontline therapy is ongoing.

Table. Characteristics of the 46 patients who achieved a CMR as defined previously.

DASATINIB EVEN AT LOWER DOSES IS AN EFFECTIVE FOR CHRONIC MYELOID LEUKAEMIA TREATMENT IN PATIENTS RESISTANT OR INTOLERANT TO IMATINIB

H Klamova, M Stastna Markova, K Zemanova, J Brezinova, K Michalova, P Cetkovsky, M Trneny, K Machova Polakova
Institute of Hematology and Blood Transfusion, Praha 2, Czech Republic

Background. Dasatinib a multitargeted tyrosine kinase inhibitor (TKI) is effective for the treatment of chronic myeloid leukaemia (CML) patients resistant or intolerant to imatinib. The recommended daily dose is 100 mg/day for patients in the chronic phase (CP) and 140 mg/day in the accelerated or blastic phases (AP, BP). However it is not always possible to keep the dose. The major reason is CTCAEv.3 grade 3/4 adverse events as well as persisting symptoms of prior treatment toxicity. *Aims*. To evaluate the efficacy of reduced dose of dasatinib on CML patients resistant or intolerant to imatinib managed in the context of every day clinical practice. *Methods*. We evaluated the outcome of 24/49 patients (48%) treated with reduced doses of dasatinib after the switch due to resistance and intolerance to imatinib. Group A: Daily dose of dasatinib was reduced in 14/24 patients due to haematological or nonhaematological adverse events (AEs) grade 3/4 on standard dose. Group B: patients with persisting symptoms of AEs prior imatinib toxicity (10/24). Two regimens were used: dasatinib 50 mg/day or alternative doses of dasatinib 50 mg and 100 mg/day. The median duration of reduced dosing treatment was 6 months (3-24) in group A, with total dasatinib duration 40 months (10-60), and 10 months (2-18) from total 28 months (14-39) in group B. Patients were followed by routine haematological and cytogenetic assessment and molecular monitoring. Resistant patients (n=15) were screened for baseline BCR-ABL mutations, in 6 patients mutations were identified. *Results*. Group A: After dasatinib dose reduction there was no worsening in response quality (i.e. cytogenetic and molecular) in 9/11 patients and quality of life improved with AE remission. The 10/11 (90%) patients survived for median 40 months (10-60), 9/11 (82%) without progression. In 5 patients 5 types of baseline mutations in BCR-ABL kinase domain were identified. Three of these completely disappeared during the treatment, in one patient the mutated clone declined from 100% to 23%. In one patient the mutated clone remained 100%. In two patients (with existing F311I and Y253H mutation) the further progression to AP was solved with nilotinib followed in one with allotransplantation, while the second one died from progression. One patient interrupted dasatinib treatment for pregnancy period (10 months). After dasatinib readministration she re-achieved CCgR and MMoIR. Group B: CCgR was achieved in 8/10 patients (80%) and MMoIR in 5 of them after 4-12 months. In other 3 pts even CMoIR was accomplished. In 2 pts CCgR has not been achieved yet, one of them had baseline E459K mutation, which disappeared after 9 months. No other mutation occurance was detected. All patients are alive with satisfactory quality of life with no progression. *Conclusions*. Our findings from clinical practice show the efficacy of reduced doses of dasatinib inducing or maintaining response in CML patients resistant or intolerant to imatinib. Further experience are warranted to confirm our findings.

THERAPEUTIC RESULTS WITH IMATINIB IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA ACCORDING TO THE EUROPEAN LEUKEMIANET CRITERIA

A Rosca,[1] A Colita,[2] D Coriu,[2] R Talmaci,[2] A Ilea[3]
1MedLife Policlinic of Fast Diagnosis Brasov, Brasov, Romania
2Fundeni Clinical Institute, Bucharest, Romania
3Ritus Biotec, Brasov, Romania

Background. Imatinib has changed the evolution of CML from a disease with an average survival of 3-5 years to a disease with a survival of 86% at 7 years. The implementation of the ELN criteria allows us to check the optimal response and to change the therapy in case of suboptimal response or therapeutic failure. The aims of this study are to evaluate the quality of the hematological, cytogenetic and molecular response, the overall survival and event free survival for 2 lots of patients treated with imatinib as a first and second line of therapy. *Methods*. This is an observational study, retrospective (01.01.2001-12.31.2006) and prospective (01.01.2007-01.07.2010). 170 patients with CML in chronic phase have been treated and monitored in 2 departments of haematology from Romania (Fundeni Clinical Institute and Emergency Clinical County Hospital Brasov). The collected data have been analyzed using the SPSS programs (Kaplan Mier method/log rank test Mandel Cox). *Results*. 56 patients (33%) treated with imatinib as a first line (median age of 41,5 years) and 114 patients (67%) treated with imatinib as a second line of therapy (median age of 50,4 years) have been included in this study. After 3 months of therapy, CHR was 91,07% in the first line lot and 84,2% in the second line lot. After 6 months, the rate of CHR was similar in both lots: 98,2% fot the first line and 95,8% for the second line, without significant diferences (p=0,508). The probability to lose the CHR until the 48th month is significantly higher for patients in the second line group comparing to the patients in the first line group (p=0,045). After 12 months, CCR was observed at 48,2% of first line patients and only at 17,5% of second line patients. The rate of MCR is 82,1% for the first line of therapy group and 68,7% for the second line of therapy group. CCR achived after 12 months was sustained at 48 months by 65% second line of therapy patients comparing to 96,3% first line therapy patients.(p=0,000019) After 18 months, 33,9% of first line therapy patients achived MMR, this type of response being sustained by 100% of the patients at 48 months. Event free survival after 48 months is superior in the first line group (80,3%) comparing to 52,6% in the second line lot (p=0,0152). The overal survival at 48 months is similar in both lots: 94,6% in the first line and 88,6% for the second line (p=0,46). *Conclusions*. Imatinib 400 mg/day induces high rates of CHR, MCR and MMR, these responses being sustained at 48 months by patients in the first line of therapy. The overal survival at 48 months is significantly improved in both of the lines of therapy lots.

STUDY OF EFFECTIVENESS RECOMBINANT HUMAN ERYTHROPOIETIN IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH ANEMIA INDUCED IMATINIB THERAPY

N Romanenko, K Abdulkadyrov, S Gritsaev, S Bessmeltsev
Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background. Imatinib is a tyrosine kinases inhibitor (TKI) that revolutionaryly changed prognosis and survival in patients with chronic myeloid leukemia (CML). It allowed to achieve not only cytogenetic but so molecular response. TKI may cause hematological toxicity according to anemia, leukocytopenia and thrombocytopenia. *Aims*. To investigate the effectiveness of Recombinant Human Erythropoietin (rHuEPO) in CML patients who developed anemia as toxic effect of Imatinib on erythropoiesis. Methods. 90 patients with CML received Imatinib in

dosage 400-800 mg daily during 6-48 months. The patients were in chronic (n=82), accelerated (n=6) phases and blast crisis (n=2). The median age of patients was 62.4 years. 36 patients revealed anemia. The level of Hb in 18 patients was less than 10,0 g/dl and they werw administrated rHuEPO. If Hb concentration was <8,0 g/dl, the patients were performed red blood transfusions before rHuEPO treatment. rHuEPO was injected subcutaneously on 10.000IU 3 times a week (30.000IU a week). The target Hb level was 12,0 g/dl. *Results*. The anemia was revealed in 36 patients (40%) for the period of observation since 6 to 48 months. I degree (by WHO classification) was at 29 patients (32.2%), II degree - 5 (5.6%), III degree - 1 (1.1%) and IV degree - 1 patient (1.1%). 18 patients had level Hb less 10.0 g/dl and they needed correction of Hb concentration. CML patients with anemia were in chronic phase (complete cytogenetic response was in 11 patients and partial cytogenetic response - 4), acceleration phase (n=2) and blast crisis (n=1). Mean baseline Hb concentration was 9.24±1.08 g/dl (5.9-10.0 g/dl), RBC count was 2.89±0.47x1012/l (1.78-3.60 x1012/l) and Ht was 29.9±4.4% (19.9-38.0%). Two patients with III and IV degree of anemia (Hb 5.9 and 7.4 g/dl, respectively) before rHuEPO-therapy received red blood transfusions to correct the main symptoms of anemia and Hb concentration. Besides both patients was stopped treatment with Imatinib within two weeks. The period of rHuEPO-therapy was from 4 to 20 weeks (mean 9.7±4.6 weeks and median follow-up of 9 weeks). During the study period in whole group, the Hb concentration, RBC count and Ht increased from baseline to 12.41±2.08 g/dl (p<0.02), 3.80±0.64x1012/l (p<0.01) and 37.4±7.0% (p<0.02) before rHuEPO-therapy, respectively. An Hb increase >2 g/dl or achieving the target Hb level 12,0 g/dl was observed in 13 patients (72.2%), while a non-response was observed in 5 patients (27.8%). 5 patients (27.8%) needed the dose reduce (from 30.000IU to 20.000IU a week) because of too high response (Hb concentration increased <2,0 g/dl during 4 weeks). 12 positive response patients were observed above 18 months and needed in repeated administration of rHuEPO-therapy (3-4 times) because of anemia relapsed (Hb decreasing <10,0-11,0 g/dl). However we could to continue administration of Imatinib without break off. *Summary*. rHuEPO is effective at increasing Hb and prevention of stop therapy in patients developed anemia as toxic effect of TKI.

1227

THE GROWTH OF A PH-NEGATIVE, MONOSOMY 7 CLONE ARISEN UNDER SECOND-GENERATION TYROSINE-KINASE INHIBITOR THERAPY IS UNEXPECTEDLY SLOW DOWN BY BCR-ABL IN A CHRONIC MYELOID LEUKEMIA (CML) PATIENT

E Orlandi, P Bernasconi, M Boni, B Rocca, I Giardini, I Dambruoso
Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background. The appearance of clonal abnormalities in the Ph-negative metaphases during second-generation tyrosine-kinase inhibitors (2nd-TKI) therapy has been recognized in CML pts, but the frequency and clinical implications of this event have not been assessed. *Aims and Methods*. The present study describes the unusually indolent course of a -7, BCR-ABL negative acute myeloid leukemia developed in a Ph+ CML during treatment with a 2nd-TKI. *Results.* In June 2006, a 58-year-old man affected with CML switched from imatinb to dasatinib because of a less than partial cytogenetic response after 18 mos. Under dasatinib, he achieved a partial response and a near-major molecular response (BCR-ABL mRNA transcript: 0.5%-0.9% according to International Scale, IS). After 48 mos, he developed grade II cytopenia and monocytosis (2.66x10^9/L), with 10% myeloid blasts (CD34+ CD117+, CD33+, Cd13+, DR+) in peripheral blood. At this time, bone marrow biopsy documented 40%-50% of CD34+, CD117+, KP1/CD68+, PGM/CD68R+, MPO-, CD56- blasts. Bone marrow aspiration was consistent with acute leukemia, as 50% of atypical promonocytes and blasts were detected. On immunophenotyping 2 blast cell populations were observed: 26% CD34+, CD117-, CD33+, DR+ blasts and 40% CD34+, CD117+, CD33+, CD14+, DR+, Cd11c+ blasts. On RT-QPCR, BCR-ABL mRNA transcript was 0.5% (IS). Conventional karyotype was 46,XY, t(9;22)(q34;q11)[9]/45,XY, -7[11], and FISH on peripheral blood revealed monosomy 7 in 240/300 (80%) of the interphase nuclei (LSI D7S486 (7q31) SO/CEP7 SG probes, Abbott Mol.) and BCR-ABL rearrangement (LSI BCR/ABL ES dual color translocation probe, Abbott Mol.) in 8% of the interphase nuclei. MLL and c-MYC rearrangements were absent and RT-PCR excluded FLT3-ITD mutations. Interphase FISH revealed that the abnormal clone was undetectable at CML diagnosis, but was present in 6% of interphase nuclei at the time of switching to dasatinib and progressively increased over time in 48 mos. Dasatinib was discontinued and no other treatment was initiated. At this time, cytopenia improved to normal values, peripheral and bone marrow blast percentage slightly decreased, and the patient was in good clinical condition. At the latest evaluation (6 mos after documentation of overt leukemia), BCR-ABL transcript load was 3,4% (IS) and marrow karyotype was 46,XY, t(9;22)(q34;q11)[8]/45, XY, -7[11]/46,XY, del(7)(q31;q35)[1]. Interphase FISH showed that monosomy 7 was present in 199/300 (66%) nuclei and BCR-ABL rearrangement in 18% nuclei. *Conclusions*. Literature data suggest that monosomy 7 is an ominous sign when detected in Ph- cells under TKI therapy. Our case shows an unexpected discordance between the unfavorable cytogenetic and morphologic data and the indolent clinical course. Despite the unequivocal morphologic and immunophenotypic findings, the -7, Ph-negative leukemic clone expanded very slowly over 4 years under the selective pressure of the second TKI. This case is noteworthy, as it represents a therapeutic dilemma: the patient refuses both allotransplant from an unrelated donor and conventional chemotherapy, as without any treatment he feels well, with normal Hb level, and neutrophil and platelet counts. On the other hand, therapy with another TKI has no sense and new drugs effective in leukemic progression of Ph-negative myeloproliferative neoplasms have limited efficacy in Ph-positive CML.

1228

BCR/ABL MUTATION ANALYSIS IN CML - SIGNIFICANCE AND CONTROVERSIAL ISSUES

K Kotlyarchuk,[1] L Lukavetskyy,[1] O Tsyapka,[1] Y Karol,[1]
A Lukjanova,[1] V Shimansky,[2] Z Maslyak[1]
[1]*SI Institute of Blood Pathology and Transfusion Medicine, UAMS, Lviv, Ukraine*
[2]*Volyn Regional Clinical Hospital, Lutsk, Ukraine*

Despite high efficiency of modern treatment of CML, the issue of disease resistance remains important. Among its main contributors are BCR/ABL gene mutations; however, their significance for occurrence of resistant clone is a subject of debate. This study comprises results of mutation analysis in a small group of patients with different stages of CML, including newly diagnosed. Aim of the study was to analyze efficacy of treatment with tyrosine kinase inhibitors (TKI) depending on presence and type of BCR/ABL mutations; to investigate significance of the method for understanding CML resistance; its importance for treatment selection. Methods. BCR/ABL mutation status was investigated in 19 patients with different stages of CML. In 16 of them it was tested due to disease progression or resistance; 3 patients were investigated at the initial diagnosis. BCR/ABL kinase domain mutations were investigated by method of direct sequencing. Results. The group of newly diagnosed patients included 2 chronic phase subjects and one in blast phase (BP). None of them was found positive for mutations. The second group included 15 patients tested for mutations at treatment change to nioltinib, the only 2nd line TKI registered in Ukraine. One patient was investigated due to decision to switch from interferon to imatinib. BCR/ABL mutations were detected in 6 of these patients (37,5%). In one case M351T mutation was detected. Treatment with nilotinib was started and appeared ineffective, despite reportedly high sensitivity of this mutation to the drug. In 3 months the patient developed BP and died. In two cases E255V and E255K mutations were revealed. Treatment was changed to nilotinib and both patients achieved complete hematological remission (CHR) with no cytogenetic response (CyR) detected. Two more patients had F359V mutation. The only therapeutic option for these subjects at that time was nilotinib. Their treatment results were surprisingly different: one patient achieved major cytogenetic response already at 6 months, complete CyR at 12 months; major molecular response and no BCR/ABL mutation at 18 months. The second patient with this mutation at 6 months achieved no response at all. The last patient of this subgroup with Y253H mutation was also resistant to nilotinib. In the second subgroup of 10 pretreated patients with no BCR/ABL mutations three responded to their treatment including one achieving complete molecular response. One patient lost CHR after 18 months of nilotinib. Another subject continued in CHR, yet no CyR was found at 6 months. The remaining patients in this group maintain their CHR; follow-up assessments of CyR were not yet performed. Conlusions: the data presented emphasizes controversy in the influence of BCR/ABL mutations on the efficacy of CML therapy taking into consideration different results of nilotinib treatment in 2 patients with F359V mutation; unsatisfactory treatment results of patient with M351T, considered as sensitive to TKIs; lack of treatment response in some of the patients without BCR/ABL mutations. Undoubtedly, T315I mutation is an indication for allogeneic stem cell transplantation; however significance of other kinase domain mutations for CML treatment selection needs further clarification.

1229

MEAN DAILY DOSE, MEASURED FROM 2~6 MONTHS OF IMATINIB THERAPY AS AN APPROPRIATE PREDICTOR FOR CYTOGENETIC AND MOLECULAR RESPONSE IN MONTH 6

J Lee, HB Seo, SM Oh, HG Goh, SY Choi, JH Bang, D Kim, S Kim, WJ Song, EJ Jang, DS Lim, D Kim
The Catholic University of Korea, Seoul, South-Korea

Background. Imatinib, tyrosine kinase inhibitor for BCR-ABL of CML has shown favorable results in clinic. Aims. This study was designed to observe the relationship among the response rate of imatinib (CyR; cytogenetic response, MR; molecular response), imatinib mean daily dose of month 1 treated, mean daily dose from month 2~6, imatinib plasma trough blood level of day 29 and day 168 (month 6) and Sokal score. Methods. In this study, 21 patients who receive imatinib 400mg QD as initial treatment after diagnosed as CP-CML were involved and cytogenetic and molecular assay are performed at baseline and every 3 month. Within 22-26 h after the previous dose of imatinib, blood sample were collected for measurement of imatinib plasma trough blood levels at day 29 and month 6. Results. When we compared the group achieving the complete CyR (CCyR) (n=14/21) and group not achieving CCyR (n=7/21), it has significant difference (p=0.002) in their mean daily dose from month 2~6 (means; 389.64? 25.1 and 362.86? 46.5, respectively). However, there is no significance in mean daily dose from month 1, imatinib plasma trough blood level of month 1 and 6 and Sokal score between these two groups. Group achieving 2-log reduction in MR in month 6 (n=14/21) has significant difference (p=0.000) in their mean daily dose from month 2~6 (395.42? 14.7 and 351.28? 45.7, respectively) compared with group not achieving 2-log reduction (n=7/21). Regarding CCyR, there is no significance in mean daily dose from month 1, imatinib plasma trough blood level of month 1 and 6 and Sokal score between these two groups. To observe the correlation with mean daily dose from month 1 and month 2~6, CyR and MR of month 6 and Sokal score, imatinib plasma trough level of month 1 and 6 respectively were grouped into 4 quartile. On the analysis based on quartile, imatinib plasma trough level of month 6 showed correlation with that of month 1 (p=0.024) and imatinib plasma trough level of month 1 had weak correlated with MR of month 6 (p=0.052). *Conclusions*. From statistical analysis, mean daily dose from month 2~6 showed correlation with CCyR and MR achieving 2-log reduction from baseline in month 6. This study on the process may show more relationship of the response rate of imatinib, imatinib mean daily dose of month 1 treated, mean daily dose from month 2~6, imatinib plasma trough blood level of day 29 and month 6 and Sokal score in the further follow-up.

1230

THE IMPACT OF THERAPY INTENSIFICATION AND OUTCOME OF 6 CML PATIENTS WITH THE SAME TYPE OF BCR-ABL MUTATION M244V

K Machova Polakova, A Brouckova, S Nadvornikova, V Polivkova, K Zemanova, M Trneny, H Klamova
Institute of Hematology and Blood Transfusion, Praha, Czech Republic

Mutation in the kinase domain of BCR-ABL is not always the direct cause of imatinib resistance in CML patients. Also degree of mutation resistance to imatinib is very variable in different patients. The aim of this study was to evaluate the outcome and resistance overcoming by therapy intensification of 6 CML patients who on imatinib developed the same type of mutation M244V. In our clinical practice, three patients were treated with imatinib in the first line (group A) and other 3 were pretreated with hydroxyurea or hydroxyurea followed by interpheron-alpha for 32-67 months (group B). The transcript levels of wild type BCR-ABL and BCR-ABLM244V were quantified using standardized real-time qPCR (IS) and using Mutation Surveyor (Softgenetics) after direct sequencing (Polakova KM et al. Exp.Hem.2010;38:20), respectively. The group A responded to the first line imatinib optimally with CCgR 3-12 months from 400 mg initiation. One patient achieved MMR in the 3rd month however BCR-ABL transcript level has remained unchanged for 18 months at 0.01% with following rise over 2.5 logs. BCR-ABLM244V transcript (100%) was detected at the time of MMR lost. Daily dose of imatinib was increased to 800 mg three months after the rise of total BCR-ABL and mutation detection. This resulted in no further increase of total BCR-ABL and in BCR-ABLM244V lost, but novel mutation F359V appeared. Patient was switched to dasatinib 10 months after BCR-ABL increase and achieved CMR after 4 months. In other two patients, the BCR-ABLM244V was detected 10 and 8 months from imatinib start. However patients remained in CCgR for next 10 and 19 months, respectively. Patient who remained in CCgR for 10 months was switched to nilotinib 3 months after CCgR lost and responded with CMR after 6 months. The BCR-ABLM244V ratio fluctuated between 27-80% in the patient who remained in CCgR for 19 months after first mutation detection. Probably the presence of both clones with mutated and unmutated BCR-ABL resulted in partial sensitivity to imatinib and thus in longer CCgR duration. Patient was switched to dasatinib after CCgR lost with intermittent dose reductions. However, wild type BCR-ABL increased 5x and BCR-ABLM244V decreased 2x six months after dasatinib start. Patients from group B failed to achieve CCgR on imatinib and BCR-ABLM244V was detected 2, 12 and 70 months on imatinib; i.e. 37, 48 and 137 months from diagnosis. Imatinib dose was escalated in 2 patients, but their total BCR-ABLM244V transcript level did not decrease below 10%. Two patients were switched to dasatinib and one to nilotinib. In one patient mutation disappeared and MMR was achieved 6 months from nilotinib start (60 months from diagnosis). Other two patients on dasatinib showed slight decrease of BCR-ABL and BCR-ABLM244V 4 months from dasatinib initiation (103 and 142 months from diagnosis). In conclusion, our data outlined that type of BCR-ABL mutation itself is not predictive for sensitivity to therapy change alone. The stage of disease, treatment duration and other individual parameters influence disease outcome and response to therapy intensification.

REAL-LIFE EXPERIENCE OF CML TREATMENT IN SAINT-PETERSBURG

K Abdulkadyrov,[1] A Abdulkadyrova,[1] V Shuvaev,[1] V Udaleva,[1] E Usacheva,[1] I Zotova,[1] D Shikhbabaeva,[1] I Martynkevich,[1] N Tsybakova,[1] M Moskalenko,[1] V Aksenova,[1] L Martynenko,[1] M Ivanova,[1] E Petrova,[1] M Ivanova,[2] E Machulaitene,[2] E Poznyak,[2] E Karyagina,[3] N Ilina,[3] N Lazorko,[4] E Lomaia,[4] A Zaritskey[4]

[3]*City Hospital N15, Saint-Petersburg, Russian Federation*
[4]*Centre for Heart, Blood & Endocrinology, Saint-Petersburg, Russian Federation*

Background. Chronic myeloid leukemia (CML) is one of the first diseases, in which target therapy with high affinity to cornerstone of pathogenesis had become centerpiece of treatment. Implementation of tyrosine kinase inhibitors (TKI) made revolutionary improvements on CML course. At present, CML-associated mortality is less than other causes rate of death in CML patients. Wide use of imatinib was started in Russia in 2005. ELN CML (2006) recommendations gave rise to comprehensive treatment strategy. *Aims*. To assess the outcomes of CML patients' treatment in routine practice in population of Saint-Petersburg during 2005-2010 period. *Methods*. Patients charts, laboratory reports, population registry. *Results*. 182 CML patients living in Saint-Petersburg with diagnosis established in 2005-2010 were included into analysis. This group consisted of 88 males and 94 females. Median age was 57 years (17-86 years). Annual rate of newly diagnosed patients was 22-40 (median 30 patients per year). CML was diagnosed in chronic phase in 158 patients (86.8%), in acceleration phase in 22 (12.1%) patients and 2 (1.1%) patients were diagnosed in blastic phase. 118 patients received cytoreduction with hydroxyurea (median treatment time 1,9 months). 171 of 182 patients received imatinib as first-line treatment. Average time from diagnosis to start therapy with imatinib was 2.7 months. The remaining patients were treated with nilotinib (1), chemotherapy (6), hydroxyurea (4). Complete hematologic response (CHR) in three months was obtained in 151/171 patients (88.3%). The highest rate of CHR - 95.8% was observed in 6 months of treatment. In accordance with ELN criteria partial cytogenetic response (PCgR) after 6 months imatinib therapy was 67.8% (116 cases). 96 patients (56.1%) had complete cytogenetic response (CCgR) after one year of therapy with median time achievement of 11.8 months. The highest CCgR rate of 73.0% was registered in 36 months of therapy. Follow-up duration was 36.1 months in average (1-71 months). There were 21 deaths, overall survival was 88.5%. On time of analysis 151 patients were alive and regularly observed. 138 patients are still in chronic phase, 12 patients transformed into acceleration and 1 patient - in blastic phase. 110 patients are still continuing imatinib, 27 patients switched to second generation TKI (14-nilotinib, 11-dasatinib, 2-bosutinib), some patients were treated with hydroxyurea (9 patients), interferon (4 patients), 1 patient refused to

treatment. CHR was preserved in 129 (84.5%) patients. Cytogenetic monitoring was performed in 148 patients. At present: 90 patients (60.8%) had CCgR, 17 (11.5%) PCgR, 2 (1.4%) minor cytogenetic response, 10 (6.8%) minimal cytogenetic response and 29 (22.3%) had no cytogenetic response. Molecular response was assessed in 106 cases: 40 (37.7%) patients are in complete molecular response, 20 (18.9%) - major molecular response, 46 (43.4%) patients had no molecular response. *Conclusions*. Effectiveness of TKI in routine practice is similar to results obtained in most of clinical trials. Strict cytogenetic and molecular monitoring of minimal residual disease is of great value to accurate response assessment and timely switch to second generation of TKI.

1232

FREQUENCY OF BCR-ABL TYROSINE KINASE DOMAIN MUTATIONS IN CHRONIC PHASE-CHRONIC MYELOID LEUKEMIA PATIENTS WITH IMATINIB RESISTANCE ACCORDING TO DAILY MEAN DOSE OF IMATINIB

SH Kim,[1] DH Kim,[1] HG Goh,[1] SY Choi,[1] JH Bang,[1] J Lee,[1] SM Oh,[1] WJ Song,[1] EJ Jang,[2] DW Kim[2]

[1]*The Catholic University of Korea, Seoul, South-Korea*

[2]*Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea*

Background. BCR-ABL kinase domain (KD) point mutation causes resistance to tyrosine kinase inhibitors (TKI) in CML patients through impaired binding of TKI to the target site. Such point mutations have been known as the clinically most relevant mechanism of TKI resistance. During TKI treatment, daily mean dose can be changed by several reasons including dose escalation, dose reduction, and temporary dose interruption. Among them, dose interruption by adverse events or patient's request is relatively common. However, there has not been much information about correlation between daily mean dose and frequency of BCR-ABL KD point mutations in imatinib resistant CML patients. *Aims*. We investigated effect of daily mean dose of imatinib on frequency of specific BCR-ABL KD mutations with imatinib resistant patients harboring BCR-ABL KD mutations. *Methods*. This study included 37 CP-CML patients registered in Seoul St. Mary's hospital since 2003. All of the patients started imatinib within 6 months of diagnosis without prior treatment for leukemia except for hydroxyurea, and were imatinib resistant with harboring any type of BCR-ABL KD mutations. Mutations in BCR-ABL KD were analyzed using direct sequencing when patients showed sign of imatinib resistance. Imatinib resistance was defined by one of the following criteria: lack of complete hematologic response (CHR) after 3 months of imatinib treatment, lack of cytogenetic response (CyR) after 6 months of imatinib treatment, lack of major cytogenetic response (MCyR) after 12 months of imatinib treatment, loss of hematologic response (HR) or CyR at any time during treatment, or disease progression from CP to AP occurring during treatment. Daily mean dose was defined as an average of drug amount taken actually from the imatinib start day up to a specific time point with the consideration of every medication of imatinib, dose modification and interruption. *Results*. We analyzed total 37 new CP-CML patients who showed BCR-ABL KD mutations after direct sequencing due to imatinib resistance. 8 patients started imatinib of 600 mg/day and 26 patients started 400 mg/day and 3 patients started 300 mg/day.

Table 1. Daily mean dose and mutation frequency.

	Group1 n=9	Group2 n=10	Group3 n=8	Group4 n=10	Overall n=37
Daily mean dose, Median(range) mg/day	293 (107-313)	380 (315-393)	400 (394-400)	441 (401-600)	393 (107-600)
Age, Median(range) yr	33 (20-62)	33 (20-61)	33 (18-60)	36 (19-71)	33 (18-71)
P-loop, n(%)	2(22.2)	2(20.0)	0(0)	4(40.0)	8(21.6)
T315I, n(%)	2(22.2)	4(40.0)	1(12.5)	2(20.0)	9(24.3)
Duration up to mutation detection, Median(range) mos					
P-loop	14.0 (11.2-16.8)	5.3 (4.1-6.4)	—	8.0 (3.2-11.6)	8.7 (3.2-16.8)
Any type	11.2 (4.2-80.6)	9.5 (2.1-57.3)	23.2 (4.1-37.8)	10.1 (2.9-44.1)	12.5 (2.1-80.6)

Daily mean dose up to the detection of the first mutation in each patient was calculated and patients were divided into 4 groups according to their daily mean dose; group1 with median 293 mg/day (107~313), group 2 with 380 mg/day (315~393), group 3 with 400 mg/day (394~400) and group 4 with 441 mg/day (401~600). Median age and Sokal risk score were not significantly different among four groups. We focused on P-loop mutations and T315I mutation. Frequency of them was not significantly different among four groups although frequency of P-loop mutation was higher in group 4. *Conclusions*. Lower daily mean dose was mainly caused by temporary interruption of imatinib treatment by adverse events while higher daily mean dose was caused by dose escalation due to non-optimal response. Daily mean dose did not make significant influence on selection of specific types of mutations in this study. However, investigation with large cohort can provide more solid correlation between daily mean dose and frequency of specific type of BCR-ABL KD mutation.

1233

QUANTIFICATION OF T315I MUTATION IN IMATINIB RESISTANT CHRONIC MYELOID LEUKEMIA

A Jiménez-Velasco,[1] M Barrios,[1] M Alcalá-Peña,[1] A Contento,[1] C Ruiz-Nuño,[1] L Entrena,[2] M Galán,[3] S Del Castillo,[2] A Heiniger[1]

[1]*Carlos Haya Hospital, Málaga, Spain*

[2]*Virgen de la Victoria Hospital, Málaga, Spain*

[3]*Antequera Hospital, Antequera, Spain*

Introduction. T315I mutation is located in the kinase domain of the ABL1 gene and represents one of the main mechanisms of resistance in Chronic Myeloid Leukemia (CML) patients, since none of the available tyrosine kinase inhibitors (ITKs), imatinib (IM), dasatinib or nilotinib, is active against it. T315I mutation has been found in 2 to 20% of CML resistant patients, depending on the phase of the disease, the method used to determine the mutation and the pattern of resistance (primary or secondary). The aim of this work was the study of T315I mutation in patients with chronic phase CML who become resistant to first-line therapy with IM. A quantitative analysis of the mutation at different times since the diagnosis has been performed. *Patients and methods*. Eighty-three chronic phase CML patients treated with IM as first-line therapy were included in the study. The European LeukemiaNet criteria (Baccarani et al, 2006) were used to define treatment failure. T315I mutation was retrospectively analyzed by allele-specific real-time PCR in those patients who accomplished resistance criteria. Quantification was expressed as a normalized ratio between the mutated and the wild type ABL1 copies. The sensitivity of the assay to detect the mutation was established at 0.1%.

Table 1. Quantification of T315I mutation before allogeneic transplantation.

Ratio T315I-ABL1 / ABL1 wild type						
	Diagnosis	3 months	6 months	12 months	15 months	18 months
Patient 1	<0.1%	<0.1%	3%	28%	59%	70%
Patient 2	<0.1%	<0.1%	<0.1%	0.12%	1%	9%

Results. Fourteen out of 83 CML patients (17%) showed cytogenetic resistance to first-line IM treatment, and T315I mutation could be detected in two of them (14%). Patient 1 failed to reach cytogenetic response after 6 months of treatment, and was also resistant to dasatinib and nilotinib. He received a reduced intensity allogeneic transplantation, with autologous recovery and maintainance of the T315I mutation at three months of follow-up post-transplant. Patient 2 lost cytogenetic response after 12 months of treatment with IM. He received a myeloablative syngeneic transplantation and remained in complete molecular response eight months after transplantation. T315I levels at diagnosis, and after 3, 6, 9, 12 and 15 months of treatment with ITKs are shown in table 1. *Conclusions*. In our series, the incidence of T315I mutation in chronic phase CML patients with cytogenetic resistance to IM was similar to that reported in previous publications. The quantification of mutated copies along the patient follow-up would have allowed an early detection of T315I mutation (still at low levels at the beginning), and would have shown how the resistant clone became selected and progressively raised during the TKIs treatment.

THE TREATMENT OF CHRONIC MYELOID LEUKEMIA BY IMATINIB MESYLATE GENERIC: ABOUT 26 CASES

H Eddou, S Astati, E Mahtat, H El Maaroufi, M Bouaouad, S Jennane, N Alami Drideb, K Doghmi, M Mikdame
Military Hospital Mohammed V, Rabat, Morocco

Background. Chronic myeloid leukemia (CML) is a chronic myeloproliferative disorder. It's characterized by the presence of chromosomal translocation (9.22), which is transcripted at chimeric protein tyrosine kinase. Its prognosis has been transformed since the advent of Imatinib Mesylate (GLEEVEC®) a specific tyrosine kinase inhibitor (TKI) Some generics (copies) of this molecule are used in many countries, including Morocco, but no study of their effectiveness has been conducted. *Aims*. The study of the efficacy of treatment with imatinib mesylate. Methods. It is a retrospective study conducted between April 2005 and May 2010. Within the Department of clinical haematology of Military Hospital in Rabat (Morocco), this study included all the cases of CML treated by imatinib mesylate generic. Results. Twenty six patients were examined. Their median age was 43,3years (16 to 75 years). The sex-ratio H/F was the 0,85. The average time of diagnosis was 3 months (0 to 12 years). The clinical presentation was characterized by splenomegaly in 22 patients (85%). The hepatomegaly was found in 2 patients (8%). In 3 cases (12%), the discovery was coincidental. The leukocytosis was over than 105/mm3 in 16 patients (70%), the hemoglobin was less than 11 g / dL in 9 patients (35%) and thrombocytosis was detected in 8 patients (31%). The diagnosis was confirmed by conventional cytogenesis in 24cas (92%) and the molecular biology is performed in 2 cases. Additional abnormalities were found in 2 patients. 21 patients were in chronic phase, 4 in accelerated phase and only 1 in blastic phase. The Sokal score was low in 6 cases and intermediate in 16 patients. All patients received treatment with a generic (copy) of Imatinib Mesylate, produced in India (400mg per day for those in chronic phase and 600 mg per day for those in accelerated phase or transformation). The treatment was stopped in two patients because of intolerance in one and pregnancy in the other. The complete hematologic response at 3 months was 96% (23/24). The major cytogenetic response at 18 months was 77% (17/22) and the major molecular response was achieved in 2 cases. Two patients progressed to blastic phase and 2 others required the use of treatment with TKI of the second generation after the detection of mutations in the tyrosine kinase domain. *Conclusions*. Despite the small number of patients and limited resources in our serie, our results in terms of hematologic and cytogenetic responses were close to the international series.

1235

CD 68 EXPRESSION IN PATIENTS WITH HODGKIN LYMPHOMA: DOES IT REALLY HAVE A PROGNOSTIC SIGNIFICANCE?

A Stamatoullas Bastard, A Charbonnier, N Piton, M Cornic, JM Picquenot, H Tilly
Centre Henri Becquerel, Rouen, France

Background. Even if classical Hodgkin Lymphoma (cHL) is a curable neoplasia, 20 % of patients die from progressive disease. The international Prognostic Score (IPS) and most reported biomarkers are not sufficient to predict individual patient's evolution. Tumor-associated macrophages have been associated with an unfavourable outcome. In this study, we compare the CD68 status of patients with refractory or relapsed cHL and patients who achieved a durable complete remission (CR). *Methods*. Immunohistochemical analysis of CD68 expression was performed on initial lymph node biopsies from 28 patients with refractory or relapsed HL and 27 in persisting CR1 recruited in a single institution between 1995 and 2009. CD 68 positive cells were counted in representative areas containing Reed Steinberg Cells (RSC), without fibrosis and necrosis. Three groups were defined based on published data and correlation with clinical groups were realised. *Results.* In refractory (18) and relapsed (1O) cHL, median age was 42.5 years (range: 15-70), 19 patients had advanced disease (stage III-IV). IPS was 0-2 in 10 patients, 3-4 in 13 patients, >5 in 3 patients and in 2 patients IPS was not available. Patients received conventional chemotherapy (23 ABVD, 1 MOPP, 4 MOPP/ABV). FDG-PET was performed in 8 patients; two were negative after two courses of chemotherapy. Ten patients died, 5 from toxic death, and 5 from progressive disease. Eighteen patients are alive (13 in CR and 5 with progressive disease). CD68 expression was <5% in 2 patients, 5-25% in 10 patients and > 25% in 16 patients. Among the 27 patients who achieved and maintained a first CR, median age was 39.5 years (range: 17-61). Seventeen patients had advance stage (III-IV). Sixteen patients had IPS score 0-2, 9 patients had IPS 3-4, and 2 patients had IPS >5. All patients but one were treated with ABVD +/- radiotherapy. The remaining patient was treated wit BEACOPP. FDG-PET was available in 7 patients and 5 were negative after two courses of chemotherapy. All patients are alive and in CR. CD68 expression was <5% in 3 patients, 5-25% in 8 patients and >25% in 16 patients. No significant statistical correlation could be found between CD68 positivity and age, stage, IPS, treatment response, event free survival and overall survival. Because of the small number of FDG-PET evaluation, correlation was not performed. *Discussion*. In this small retrospective cohort, we could not demonstrate any prognostic impact of macrophages infiltration. We could not correlate with early FDG-PET because of the small number of patients. Prospective evaluation of the CD68 positivity impact has to be proposed in clinical trials.

1236

HODGKIN'S LYMPHOMA ASSOCIATED WITH NEPHROTIC SYNDROME

G Gaman, A Gaman
University of Medicine and Pharmacy Craiova, Craiova, Romania

Background. Minimal change glomerulopathy has commonly been associated with Hodgkin's disease. Method and results. We report three cases of nephrotic syndrome accompanied by renal insufficiency (RI) and Hodgkin's disease. The first patient is a 26-year old man, who was diagnosed with moderate RI and nephrotic syndrome. Renal biopsy disclosed minimal change nephropathy. He was treated initially with steroids and a partial remission of the nephrotic syndrome has been achieved after 3 months of treatment. The second patient , a 62-year old man, was diagnosed with nephrotic syndrome. The renal biopsy disclosed glomerulonephrytis with minimal messangial proliferation. He was treated with cyclophosphamide and steroids without complete remission. Nephrotic syndrome was followed by acute renale insufficiency. The third patient , a 47-year old man, was diagnosed with nephrotic syndrome. Renal biopsy disclosed minimal change nephropathy without renal insufficiency. Six , nine and five months respectively after the beginning of renal disease, nodular sclerosis Hodgkin's lymphomas were diagnosed to all the three patients. After chemotherapy (6 ABVD cycles) at all patients, a complete remission of nephrotic syndrome as well as a normalisation of renal function was achieved. *Conclusions*. An extensive evaluation for a lymphoproliferative disease could be advisable in adult patients developing minimal change nephropathy with steroid resistant syndrome.

1237

THE SERUM LEVEL OF TARC AND IL6 IN CLASSIC HODGKIN LYMPHOMA

Z Molnar, B Deak, B Kapuvari, J Kovacs, A Rosta, T Schneider, E Szaleczky, F Varga, E Varady, B Vincze
National Institute of Oncology, Budapest, Hungary

Background. The citocines and chemokines have become important in the diagnosis and prognostic evaluation of malignant diseases. "Thymus and activation-regulated chemokine"(TARC) is an 8 kDa volume polypeptid. It is expressed in large quantities by Hodgkin and Sternberg-Reed (HSR) cells and the secretion of Interleukin-6 is also observed in HSR cells. Our aim was to investigate the serum level of TARC and IL-6 in classic Hodgkin lymphoma (cHL). Methods. IL-6 and TARC level was measured by ELISA. The results were evaluated by MedCalc statistical programme. *Results*. The serum level of TARC was defined in 108 (49 active, 59 remission), the IL-6 concentration in 64 cases (20 active and 44 remission). The median value of TARC concentration in the active goup (n=49) was 2069 pg/ml [95 % confidence interval (CI):1892,67-2561,57 pg/ml]. In remission (n=59) the median value was 418 pg/ml (95% CI: 363,03-491,50). The Mann-Whitney test proved significant ($p < 0,0001$) difference between the two groups of patients. The median serum level of IL-6 was 8,48 pg/mL (95% CI: 6,43-15,23 pg/mL) in the active group (n=20), but in remission it was 2,20 pg/mL (95% CI: 2,05-3,07 pg/mL). The difference was again significant ($p<0,0001$). *Conclusions*. IL-6 and TARC level showed significant connection with the disease state (active or remission). Further investigations are needed to assign their prognostic value and their capacity to forcast relapse.

1238

BLEOMYCIN INDUCED LUNG TOXICITY IN PATIENTS WITH HODGKIN'S DISEASE TREATED WITH BLEOMYCIN CONTAINING REGIMENS (QATARI PROSPECTIVE)

M Yassin,[1] R Kamzoul,[1] H El-Ayyoubi,[2] R Singh,[1] M Al-Badri[1]
[1]*Hamad Medical Corporation, Doha, Qatar*
[2]*HMC-Al Amal Hospital, Doha, Qatar*

Background. Bleomycin pulmonary toxicity (BPT) has been known since the early clinical trials of bleomycin in the last century. Postulated risk factors include cumulative bleomycin dose, reduced glomerular filtration rate (GFR), and raised creatinine, older age, supplemental oxygen exposure. Cigarettes smoking, preexisting lung disease, radiotherapy the mount of hydration patient received. And among those with toxicity the supplemental oxygen, corticosteroids use and intervention with bronchoscopy may play a role in outcome. *Aims*. To evaluate the postulated risk factors for Bleomycin Induced Lung Toxicity in patients with Hodgkin's disease treated with Bleomycin Containing regimens in Qatar. Patients and Methods. From our retrospectively collected data of 72 patients diagnosed with Hodgkin's disease treated at Al-Amal Cancer Centre (Qatar) with bleomycin-containing regimens (ABVD, BEACOPP, STANFORD V) for Hodgkin's Lymphoma between January 2002 and December 2008, with median follow up of 30 months to identify those with BPT. Results. Eleven out of seventy two patients with Hodgkin's disease (15%) had BPT, range from mild dyspnea to respiratory failure and even death. And radiologicaly, X-ray/CT ranges from normal to overt fibrosis. There were two deaths out of the treated patients directly attributed to BPT. The median time from the start of bleomycin administration to documented lung toxicity is 5 months (range 3 - 8 months). the following risk factors were evaluated among patients with BPT the patients age were (16-61 year) with median age of 43 year, gender (eight males and three females), none of the patients with BPT is a smoker, weight upon starting bleomycin in patients with toxicity (62-107kg) with a median of 73 kg. Subtypes of HD (6 patients with nodular sclerosis and 5 with mixed cellularity), stage of the disease (6 patients with stage II, 3 patients stage III, and two patients with stage IV), chemotherapy protocols (ten out of eleven patients with BPT received ABVD while the eleventh patient received Stanford V), the cumulative dose of bleomycin ranged from (68-262 international units) with median of 136 IU. Calculation of Creatinine Clearance revealed that none of our patients had grade 2 or more chronic kidney disease. Radiological evaluation of the chest before starting bleomycin containing regimens by CT scan revealed that none of them had pre-existing parenchymal lung disease or fibrosis. *Conclusions*. In our evaluation for BPT we found toxicity occurring more in males, younger age group and those with nodular sclerosis and mixed cellularity subtypes. It seems that direct toxicity could happen regardless of the dose, and certain races maybe more susceptible to Bleomycin Pulmonary Toxicity, keeping in mind the small number of patients, we feel that further studies are needed to confirm the above mentioned findings.

1239

AUTOLOGOUS TRANSPLANTATION IN REFRACTORY OR RELAPSED HODGKIN'S DISEASE

J Rodríguez, E Martín, A Palma, MV Moreno, JA Quesada, K Gómez, A Garcia-Sola, S Ramírez, A Amian, JC Diéguez, A Fernández-Jurado
Hospital Juan Ramón Jiménez Huelva, Spain

Background. Relapsed or refractory Hodgkin's disease is still a challenging problem for hematologists. The standard management of these patients should include the use of salvage chemotherapy followed by autologous stem cell transplant in patients who are chemotherapy sensitive. *Aims*.- We present our experience in 14 patients with relapsed or refractory Hodgkin's disease who received platinum based protocols as salvage chemotherapy followed by an autologous transplantation as a consolidation therapy. *Methods*. Fourteen patients (5 males, 9 females), mean age 19.3 years (17-48) are presented. Histologic subtypes included 1 case of lymphocyte predominance subtype, 11 nodular sclerosis and 2 mixed cellularity. Five cases were relapsed and 9 resistant to previous therapies (1 patient radiotherapy; three patients ABVD+radiotherapy; ten patients ABVD). *Results*. Mobilization scheme was salvage chemotherapy (platinum based protocols) plus G-CSF in 13 patients while the other received only G-CSF. The mean number of these cycles was 2.8 (2-4; median 3). Responses to these cycles and situation of the disease previous to transplant was 5 (35.7%) complete responses (CR), 7 (50%) partial responses (PR) and 2 (14.3%) no response (NR). In all cases the source of progenitors was peripheral blood. Mean number of aphereses performed was 1.35 (1-2; median 1) and no significative problems were registered during the procedures. In all patients enough number of progenitors could be collected. No other mobilization agents (plerixafor) should be used. All patients were invariably conditioned with BEAM protocol. Mean CD34+ cells infused was 6x106/Kg (3-18; median 6). After transplantation 12 (85,8%) patients achieved CR, 1 (7,1%) PR and 1 (7,1%) NR. Both patients with no response to salvage therapy achieved CR after transplantation but one of them early relapsed (4 months). Only 1 additional patient (8.3%) relapsed at 9 months after transplantation. Mean overall survival was 25.3 months (4-55+; median 19.5). *Conclusions*. In our experience, autologous transplantation is a useful and safe procedure in patients with relapsed or resistant Hodgkin's disease. Salvage therapy with platinum-based protocols plus G-CSF allowed the collection of enough progenitors in all patients with a low number of aphereses. Overall complete response rates after transplantation is high (including one case not responding to prior salvage therapy) and the number of relapses low. Mean overall survival in our series is, up to now, slightly higher than two years.

1240

RECOVERY OF SPERMATOGENESIS (SP) AFTER BEACOPP14 (B-14) PROTOCOL IN HODGKIN'S LYMPHOMA (HL) YOUNG MALES

A Vinokurov,[1] S Varfolomeeva,[1] D Tarusin,[1] T Moiseeva[2]
[1]*Federal State Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation*
[2]*Hematological Research Center of Russian Academy of Medical Sciences, Moscow, Russian Federation*

Background. The B-14 protocol is one of the latest cure strategies in advanced stages of HL. There is no medical information on B-14 and gonadal toxicity in young males. *Aims*. To evaluate the frequency of sperm disorders and infertility, to measure sex hormone concentrations (LH, FSH, Ts) as well as the number of patients who succeeded in achieving fatherhood with and without assisted reproductive technologies .Patients and Methods: from 2008 to 2011, 25 men of mean age 23yrs (18-29) with IIB-IV sts of classical HL were examined after cessation of treatment with 6-8 of B-14 and IFI irradiation in some pts with bulky mediastinum. All patients had the established fact of paternity (spouse pregnancy) and/or had cryopreservation of sperm prior to treatment. Time from the end of chemotherapy to the beginning of the survey averaged 16 mos (2-42). *Results*. Recovery of Sp was established in 60% pts (15 of 25) with mean time of recovery 16 mos (2-42). Azoospermia was observed in 40% pts (10 of 25) with mean 17 mos (4-42) of observation. Levels of sex hormones were evaluated in 24 of 25 pts, changes were noted in 71% pts (17 of 24). In Sp recovery group the following trends were observed: Ts decrease and LH, FSH increase - 1pt, FSH increase-1, Ts and LH decrease - 1, Ts decrease -3, LH decrease-1, no changes -7 pts. In azoospermic group: Ts decrease- 1pt, FSH increase-6, Ts decrease and FSH increase - 2, LH increase - 1 pt. All patients with recovered Sp have some deviations of Sp: oligozoospermia (O)/astenozoospermia (A)/nekrozoospermia (N)/ theratozoospermia(T): with A-1 pt, T-1t, AT-1, AN-1, OAT-2, ANT-3, OANT-2. 3 healthy children were born to 3 pts without assisted reproductive technologies. *Conclusions*. 6-8 courses of B-14 causes azoospermia in 40% of cured young male pts. This fact makes semen cryopreservation before HL therapy a necessary procedure to all reproductive males. Changes in levels of sex hormones (LH, FSH, Ts) are not always associated with azoospermia. Increased FSH levels are most often associated with azoospermia. Low Ts level is not linked with functional impairments. Spontaneous recovery of Sp is always associated with its deterioration. The probability of spontaneous recovery of Sp, improvement of sperm parameters after recovery, as well as necessity of Ts replacement therapy require further study.

1241

TREATMENT OF COMPLICATED AND COMPOUNDS FORMS OF HODGKIN´S DISEASE

JR García Fernández, F López Berenguel, JJ Perez Guerrero
Hospital de Baza (Servicio Andaluz de Salud), Baza, Spain

Background. Treatment of Hodgkin´s disease (HD) is well established in "standard"cases; front-line therapy with ABVD or ABVD-like regimens +/- radiotherapy are the cornerstone treatments of disease. The problem appears when HD is associated with another disease: another tumour, infection, autoimmune disease,… or when the illness itself relapse after several lines of therapy including bone marrow transplantation. In this cases and "wide"and "creative"management of the disease is compulso-

ry. AIMS: we try to describe and explain the management of special forms of HD in which we have to make a decision of treat 2 serious diseases simultaneously with a curative approach, or the specific treatment of HD in an out of protocol approach. *Methods.* We describe 5 cases of Hodgkin lymphoma of different subtypes: mixed cellularity (2) and nodular sclerosing(3), stage IA to IVB with complicated onset or evolution, in four of this HD was associated with others diseases, the other was a third relapse, after autologous bone marrow transplantation (BMT), without compatible donor. *Results.* In all cases the initial treatment (alone or combinated) was standard dosage ABVD without reduction or discontinuation, in 4 cases was associated simultaneously or sequentially with another/s treatment/s depending on concomitant disease: Case 1 was associated with VIH infection: treatment with antiretroviral therapy was simultaneous, consolidation with gemcitabine-vinorelbine was added because of a PET-TAC positivity after 3º cycle. Case 2: advanced stage prostate cancer, diagnosed simultaneously and treated with a regimen active for both of them: ABVD (contains an antracycline)+radiotherapy. Case 3: a combined lymphoma treated sequentially with maintenance therapy. Case 4: haemolytic autoimmune anaemia glucocorticoids-resistant treated with rituximab a dosage of 100 mg/week x 4 doses. Case 5 was a relapse of HD after BMT without compatible donor treated with a *sandwich* regimen: Gemcitabine-vinorelbine(x6) + local radiotherapy + Gemcitabine-cisplatin(x2). (table 1).

Hodgkin lymphoma	Diagnostic (2)	Gender/ age	Initial treatment	Adjuvant therapy	Results
1 -Mixed cellularity IIIA	VIH infection	Male/28	ABVD(x6)	Gemcitabine-vinorelbine (x3) + antiretroviral therapy	CR 24 months
2 -Mixed cellularity IVB	Prostate adenocarcinoma	Male/57	ABVD(X8)	RT+ bicalutamide	CR 23 months
3 -Nodular sclerosing IIIA	Follicular lymphoma	Male/69	ABVD(X6)	Maintenance clorambucyl x 6 months	CR 14 Months
4 -Nodular sclerosing IIA	Relapse after BMT	Female/ 32	ABVD(X6)	Gemcitabine-vinorelbine (x6) +RT+Cis-Pt	CR 60 Months
5 -Nodular sclerosing IA	AIHA/ PTI	Male/56	ABVD(X6) RT	Steroids Rituximab (x4)	CR 40 Months

Summary. The ABVD and ABVD like regimens are the basis of treatment of HD even in compounds and complicated forms, It´s a well-known regimen with a well-known toxicity profile, so it is possible associate another treatment without serious side-effects. As in all complicated/compounds diseases in these cases it is essential to innovate and adjust the treatment to the characteristic of the patient and illness, because actually there are not validated guides adapted to each possible case.

1242

HODGKIN LYMPHOMA - PROGNOSIS AND EVOLUTION

O Ciocan, A Ciobanu, I Triantafyllidis, C Draghici, A Colita, N Berbec, S Angelescu, M Tevet, G Barca, A Lupu
Coltea Hospital, Bucharest, Romania

Background. Hodgkin's lymphoma is a malignancy of lymphocytes and their progenitors and young people age 15-35years are usually affected. *Aims*. In this study we aim to discover prognostic factors to identify high-risk group of patients and treatment response rate. We performed a retrospective study of 85 patients diagnosed with Hodgkin's lymphoma in our Clinic of Hematology. Evaluation criteria of patients were: age, sex, number of lymph nodes affected areas, determining mediastinal, extranodal determinations, clinical stage of disease, histological type of disease, this splenomegaly, anemia, lymphopenia, serum iron, LDH, ALKP, response to treatment . RESULTS: The study group was found predominance of females. Mediastinal mass were met in 28 patients. Most cases were in stage at diagnosis II / III. Primary extranodal Hodgkin lymphoma affecting lung in one case, a case with pericardial tumor and spinal disease in one case was found.13 cases had onset splenomegaly. In terms of histological type in our study group was found predominance nodular sclerosis subtype. In the study group there were two cases of composite lymphoma (Hodgkin's lymphoma and non Hodgkin's lymphoma). Most patients showed B symptoms. In terms of biological evidence found biological inflammatory syndrome in most patients, low sideremia was present in one fourth of patients, anemia in half the patients in the study, increased LDH in 58 of the cases. CONCLUSIONS: All patients in the study group followed ABVD combination chemotherapy such as first-line treatment with obtaining complete remission in 27 of patients. Remission period was from 1 to 7 years. Relapsed appeared in some cases ~ 4 months after ABVD courses. Salvage chemotherapy was offered to patients who relapse or with refractory disease.In evolution three cases had pulmonary evolving, determining pericardial three cases, one case of chest wall tumor, and one case jugular vein thrombosis. Eight patients in the study group did autotranspant of which seven patients were favorable evolution and a bad case of post-transplant evolution, disease progression and patient exitus.Two allotransplant performed, one with good evolution.Advanced disease stage, extranodal disease, B symptoms, anemia, more affected lymph node areas are poor prognostic factors.

1243

FERRITIN EVALUATION AT DIAGNOSIS CAN IMPROVE THE CHEMOSENSITIVITY AND RESPONSE ASSESSMENT OF EARLY STAGE HODGKIN LYMPHOMA PATIENTS

C Vetro,[1] A Romano,[2] D Donnarumma,[2] A La Fauci,[2] V Innao,[2] P Fiumara,[2] A Chiarenza,[2] G Palumbo,[2] M Ippolito,[3] F Di Raimondo[2]
[1]*Division of Hematology, Ferrarotto Hospital, Catania, Catania, Italy*
[2]*Division of Hematology, Ferrarotto Hospital, Catania, Italy*
[3]*Division of Radiology, A.O. Cannizzaro, Catania, Italy*

Background Inflammation dominates both the clinical and histological pictures of Hodgkin Lymphoma (HL). The interim-PET findings seem to reflect the chemo-sensitivity more than the real tumor eradication, related to the ability of chemotherapy to reduce the inflammatory microenvironment. *Aims*. In the present study, we evaluated the role of Ferritin in predicting the interim-PET results and the outcome. Methods Forty-four patients with early stage HL with unfavorable prognosis were treated with ABVD as first line and PET assessment was performed at diagnosis, after two cycles (interim-PET), and at the end of treatment. PET images were interpreted visually according to Dann *et al*., 2010 and 5 of them (11.36%) had a positive interim-PET. Response assessment was valuable for forty patients; three out of five patients with positive interim-PET (60%) progressed or relapsed although their early shift to BEACOPP regimen. Three more patients relapsed although their interim-ET was negative. The median follow-up was 17.1 months with a range between 0.4 and 65 months. Informed consensus has been signed according to Good Clinical Practice and Helsinki declaration. Results Ferritin levels showed a wide variation with a median of 142 ng/mL and a range between 11.3 and 1530 ng/mL. We found a significant correlation between ferritin levels at diagnosis and interim-PET positivity, having patients with an interim-PET assessment levels of ferritin greater than patients with a negative interim-PET (p=0.05). Additionally, we found that patients with high ferritin levels at diagnosis tend to have a reduced PFS compared to subjects with normal or moderately increased ferritin (p=0.06), independently from IPS score (respectively, 17.48 months vs not achieved median). *Summary/Conclusion*. Taken together, our observations suggest how the evaluation of ferritin at diagnosis can add prognostic information in early stage HL patients helping in suspecting the interim-PET assessment and the response to treatment.

1244

THE RESULTS OF GPOH-HD 95 PROTOCOL IN CHILDREN AND ADOLESCENTS WITH HODGKIN'S DISEASE: SINGLE INSTITUTION RESULTS

S Anak, AA Ozguven, A Unüvar, Z Karakas, L Agaoglu, G Oztürk, O Devecioglu
Istanbul University, Faculty of Medicine, Istanbul, Turkey

Background: Hodgkin's disease (HD) is a curable malignancy in over 90% of patients in childhood using chemotherapy and radiotherapy. But long term side effects of combination therapies are serious and may impair the patients' quality of life. In our institution, children with newly diagnosed HD have been treated with GPOH-HD 95 chemo-radiotherapy regimens in order to to decrease therapy related side effects since 2000. In this study, the treatment results of the patients who had been treated with GPOH- HD 95 protocol were presented. Patients and methods: During the period 2000-2010, 38 children and adolescents with HD were reffered to our institution. Patients were excluded from the study if they were diagnosed in another center or their admission was for relapsed HD. So we retrospectively analyzed the epidemiological characteristics, clinical and laboratory datas and primary endpoints of the 28 previously untreated patients. Results: 21 males (75%) and 8

females (25%) (male/female ratio : 3; age : 3-15 years, median age : 9) were treated with GPOH-95 protocol. The lymph node regions involved at the diagnosis were 20 cervical (71%), 5 mediastinal (18%), 2 supraclavicular (7%), 1 inguinal (4%). Erythrocyte sedimentation rate (ESR) was high in 84% of the patients at diagnosis and in three patients admitted with the diagnosis of relapsed HD. Staging was as follows: stage I : 2 (7%); II : 15 (54%); III : 9 (32%); and IV : 2 (25%). Histopathology was nodular sclerosis in 15 patients (53%); 10 had mixed cellularity (MC; 36%) and 2 lymphocyte depleted (7%) and one patient (4%) lymphocyte-rich classic Hodgkin disease. Constitutional symptoms : 16 patients were asymptomatic (A; 43%) and 12 had constitutional complaints (B; 57%). Eleven patients (39%) were allocated into risk group 1, 7 (25%) risk group 2, and 10 (36%) risk group 3. Twenty seven patients (%96) received radiotherapy (20-25 Gy). Three (10%) patients relapsed over a period of 10 years (median follow up 40 months) and the autologous bone marrow transplantation was performed in one of them but two early - relapsed patients died. The EFS and OS rates at 5 years were 88.4% and 87,4%, respectively. Conclusion: The high number of early stage patients at diagnosis compared to our previous studies, was hopeful for the awareness of the society for malignancies. In contrast to our previous studies, nodular sclerosis was the predominant histologic subtype, while mixed cellularity was the most frequent histologic subtype beforehand. The investigation of this switching between the histologic subtypes may clarify the physiopathology of HD. Also, the importance of erythrocyte sedimentation rate persists in primary diagnosis and relapsed patients. It seems that, GPOH-HD 95 protocol is efficient, easy to use and has low toxicity. But the rates of OS and EFS are lower than the results of the DAL/GPOH-HD 95 These results may be due to low number of patients, high rates of patients with B symptoms and the lower socioeconomic level of the society.

1245

FEASIBILITY OF TANDEM AUTO/REDUCED-INTENSITY T-REPLETED HAPLOIDENTICAL BONE MARROW ALLOGRAFT FOR RELAPSED/REFRACTORY HODGKIN'S LYMPHOMA

E Todisco, B Sarina, S Bramanti, A Ibatici, A Santoro, L Castagna
Humanitas Cancer Center, Rozzano, Italy

Background. Tandem auto/reduced-intensity allograft (auto-SCT/RIC-allo) is a feasible approach in poor prognosis Hodgkin lymphoma patients (HL). However, a minority of patients have an available matched related or unrelated donor. For those patients, haploidentical donor could be an viable alternative donor. Recently, post-transplantation cyclophosphamide (Cy) is effective to prevent graft versus host disease (GVHD) and graft rejection, using T-replete bone marrow. *Aims*. To investigate feasibility of tandem auto-SCT followed by RIC-haplo with high-dose post-transplantation Cy in poor prognosis HL patients. *Patients and Methods*. From January 2009, 6 HL patients were treated with auto-SCT followed by RIC-haplo, with high-dose post-transplantation Cy. Patients not in FDG-PET complete remission (CR) after 2 chemotherapy lines were included. No patients were relapsed after previous HDC. High dose chemotherapy (HDC) consisted of Melphalan 200 mg/m2 in 5 patients, and BEAM in 1 patient. RIC-haplo conditioning consisted of fludarabine (30 mg/m2 x 5 days), Cy (14.5 mg/kg/day x 2 days, and TBI (2 Gy). Unmanipulated bone marrow cells were infused (target MNC dose 4x 108/kg of recipient). GVHD prophylaxis consisted of Cy 50 mg/mKg/day for 2 days (d +3 and 4), and tacrolimus and MMF (starting from d +5). Results. At time of auto-SCT, four patients had progressive disease (PD), one stable disease and one partial response (PR). After auto-SCT, 3 patients achieved CR and 3 patients PR. Median time between transplant procedures was 2.5 months (range 1-3). Sorror score was 0 before transplantation. Median number of MNC, CD34+ and CD3+ cells in the graft were 4 x 10^8/kg, 3.1 x 10^6/kg and 40 x 10^6/kg respectively. Median time to myeloid and platelet engraftment was 22 (17-32) and 32 (22-43) days, respectively. Median hospitalization time was 33 days (range 23-48). Between day 30 and 45 days after RIC-haplo, all patients achieved a full, donor chimera chimera. No graft failure occurred. After tandem procedure 6/6 patients obtained CR. After a median observation time of 400 days (97-916), 5/6 patients are alive in CR and 1 died in PD. Two patients developed skin acute GVHD (one grade I and one grade II). No chronic GVHD was observed. Infectious complications were depicted in Table. *Conclusions*. Our results suggest that tandem auto-SCT/RIC-haplo with high-dose post-transplantation Cy is feasible and well tolerated, with no enhanced toxicity. However, these preliminary data should be confirmed in more patients.

IT IS NECESSARY A SURVEILLANCE IMAGING IN HODGKIN LYMPHOMA PATIENTS IN EARLY REMISSION?

P Giraldo,[1] M Andrade,[1] C Gallegos,[1] A Rubio-Martinez,[1] N Padrón,[1] P Mayayo,[1] J Grasa,[1] M García-Miralles,[2] J Banzo[3]
[1]*Miguel Servet University Hospital, Zaragoza, Spain*
[2]*GammaScan, Zaragoza, Spain*
[3]*Nueva Clínica Quirón, Zaragoza, Spain*

Background. The majority of patients with Hodgkin lymphoma (HL) achieve disease remission after primary therapy. Early response evaluated by positron emission tomography/computed tomography (PET/CT) alter two chemotherapy cycles has demonstrated a predictive value in several studies. Nevertheless, there are not consensus exists about perform postremission surveillance imaging. *Methods.* Retrospectively, we have analyzed 40 adult patients with classic HL treated in our center between January 2005-December 2010. Patients were treated with ABVD schedulle for stages I, II, IIIA and BEACOPP14 ifor stages IIIB and IV. In all cases a PET/CT was performed after two cycles and after therapy was completed. Events were defined as recurrent HL or secondary malignancies. Primary outcome was positive predictive value (PPV) of surveillance PET/CT alter two chemotherapy cycles and secondary outcomes were costs and radiation exposures of surveillance scans. *Results.* Seven (17.5%) recurrent HL cases were detected during a median follow-up of 30 months. In 33 patients early PET/CT performed alter two cycles demonstrated non hypermetabolic disease activity. All cases with early negative PET/CT showed absence of metabolic activity when another PET/CT was performed after completed therapy were. Factors that were found to significantly improve the PPV of scans in detecting recurrent HL included PET/CT concordance involvement of a prior disease site, or the occurrence of systemic symptoms. There were too few events to determine whether event detection by PET/CT or the presence of symptoms at the time of event detection affected overall outcomes. The analysis of cost to detect a single event is high and radiation exposure to detect a single event should be considered. *Conclusions*. For patients with HL in first disease remission, surveillance PET/CT appears to be expensive, with limited clinical impact.

1247

THE SIGNIFICANCE OF EBV VIREMIA IN KOREAN PATIENTS WITH HODGKIN LYMPHOMA

EM Lee,[1] JE Kim,[2] DH Yoon,[2] S Kim,[2] SW Lee,[2] HS Chi,[2] JR Huh,[2] C Suh[2]
[1]*Kosin University Gaspel Hospital, Busan, South-Korea*
[2]*Asan Medical Center, Seoul, South-Korea*

Background. Epstein-Barr virus (EBV) is known to be frequently associated with Hodgkin's lymphoma (HL). However the significance of EBV infection reguarding the clinical outcomes of HL patients has been unclear. Furthermore, due to relative paucity of the disease in Asian countries, the role of EBV-DNA infection in pathogenesis and prognosis of HL has not been explored yet. Several recently studies have reported the presence of EBV-DNA in blood of patients with EBV-positive HL. Aims: The aim of this study is to investigate the frequency of detection of EBV-DNA in blood of Korean HL patients and the clinical characteristics of patients with EBV viremia. *Methods*. Between October 2007 and

May 2010, a total of 34 patients with newly diagnosed HL were tested for EBV-DNA titer in blood before treatment, using real-time quantitative PCR. *Results*. Among them, 6 (17.6%) patients had a detectable EBV-DNA. *In situ* hybridization (ISH) for EBV-encoded RNA (EBER) in tumor tissues was performed in 5 of the 6 patients and all of them were positive. EBV-ISH could not be perfomed in one patient as tissue was not available. Patients with EBV viremia seemed to be older (median 62 years, range 47-68 years), compared with those without EBV viremia (median 31 years, range 14-77 years). In patients with EBV viremia, the proportions of advanced stage (Ann Arbo stage III-IV, 83.3% vs. 46.4%), extranodal involvement (66.7% vs. 39.3%), and international prognostic score (IPS) more than 3 (83.3%, vs. 18.5%) seem to be higher than in patient without EBV viremia. Monitoring of viral load was performed in 4 patients. After treatment, EBV-DNA was undetectable in two patients with initially low titers (6250 and 1075 copies/mL), and other 2 patients with relatively higher titers at baseline showed decrease in titers(12250 to 3500, and 14500 to 8000 copies/mL). These 4 patients achieved complete response while the one lost to follow-up and the other one is still under the treatment. *Summary/Conclusions*. Although these observations were based on very small number of patients, our data suggest that the detection of EBV-DNA in blood may be associated with risk factors indicative of a poor prognosis such as older age, advanced stage and higher IPS. Furthermore, serial monitoring of EBV-DNA titer may help to predict response to treatment in Korean HL patients.

1248

RELEVANT FACTORS FOR OUTCOME AND PROGNOSIS IN HODGKIN LYMPHOMA: A SINGLE CENTER EXPERIENCE

S Arghirescu,[1] C Jinca,[1] A Isac,[2] O Ciocarlie,[1] A Balan,[2] A Oprisoni,[1] I Ionita,[1] M Serban[1]

[1]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania*
[2]*Louis Turcanu Emergency Children Hospital - IIIrd Pediatric Clinic, Timisoara, Romania*

Background. Although Hodgkin lymphoma (HL) is associated with high curability rates reaching 90 % in children and young adults, unfortunately in a reduced number of patients the outcome is unfavorable. *Aims*. Therefore we aim to study the factors influencing outcome and prognosis in HL. *Methods*. In a retrospective unicentric study we included 35 patients with ages between 3 and 25 years diagnosed with HL during a 5 years period in the IIIrd Clinic of Pediatrics Timisoara. At onset of disease we analyzed the influence of the following factors: patient age, presence of *B symptoms*, level of hemoglobin (Hb) and serum lactic acid dehydrogenase (LDH) level, clinical stage and histological type. We also evaluate the state of disease and 5 years survivals by Kaplan-Meyer curves after classical chemo/radiotherapy and/or autologous hematopoietic stem cell transplantation (HSCT). Results: In 66 % of cases the patients' age was between 6 and 18 years. 60 % had "B symptoms"at onset and 74 % were diagnosed in late stages (III and IV). The serum level of LDH was elevated in 23 % of cases and the level of Hb was over 10 g% in 57% of patients. Histological 54 % were diagnosed with HL with nodular sclerosis. In all patients was administered chemotherapy, 85 % received additional radiotherapy and 40 % had also undergone an autologous HSCT. After initial treatment, 74 % were in complete remission, 23 % in partial remission, 3 % had stable disease. 51% relapsed after initial therapy. Survival curves revealed a predictive overall survival (pOS) at 5 years of 100% in mixed cellularity and lymphocyte depleted histological types compared with 83 % in nodular sclerosis and 67% in lymphocyte predominance types. Taking into account the clinical stage of disease pOS at 5 years was 93% in CS III, 89 % in CS II and 73% in CS IV. Serum LDH level had not influenced the pOS. In the group with age at onset under 6 years the pOS was 100%, in children between 18-25 years pOS was 97%, and in age group over 18 years the pOS was only 81 %. Predictive event free survival (pEFS) at 5 years was significantly influenced by Hb level: 71 % in the group with Hb>10 g% comparative with 50 % in the patients with Hb<10 g%. Conlusions: In our study, favorable predictive factors for outcome and prognosis were: age under 6 years, Hb level over 10 g % and histological types with lymphocyte depletion and mixed cellularity. Serum LDH levels did not influenced the chemo/radiotherapy response. Initial response to chemo and/or radiotherapy is defining for prognosis. HD in advances clinical stage at onset, refractory or relapsed HD has favorable outcome if treatment protocol includes autologous HSCT.

1249

AUTO-IMMUNE CYTOPENIAS IN NON RELAPSING HODGKIN'S DISEASES

P Cougoul, T Comont, K Delavigne, D Adoue, S Ollier, O Beyne-Rauzy

Purpan Universitary Hospital, Toulouse, France

Background. Association between auto-immune cytopenias and Hodgin's disease (HD) is described (1, 2). AIC could occur before or after the diagnosis of lymphoma or during relapse of the disease. Few data are available in patients with AIC and no symptoms of relapse. We report 3 cases of AIC occurring a long period after Hodgkin's disease treatment in patients still in remission. Cases report: Case 1: immune thrombopenic purpura in 37 years old man ITP occurred 9 years after HD diagnosis, stage IIAa (cervical lymph nodes). Treatment of HD was chemotherapy (3ABVD) and radiotherapy. No relapse was found to explain ITP (18FDG-PET/CT scan, bone marrow biopsy). ITP was treated with corticosteroid and intravenous immunoglobulin (IGIV) but sustained response was not observed. Romiplostim was efficient at maximal dose. Case 2: 77 years old woman was treated in 2009 for stage IVBb HD's with COOP/ABV. In January 2010 she developed auto-immune haemolytic anaemia and severe bleeding due to ITP (platelets 2.10^9/L, haemoglobin 88g/L). No relapse was found to explain ITP (18FDG-PET/CT scan, bone marrow biopsy). Initial corticosteroid therapy and IVIg was successful but relapse was observed. Treatment with Rituximab was efficient in 3 weeks. Case 3: A 16 years old man with history of HD staging IV Ab by lung and liver diagnosed 2 years ago (December 2004), and treated with chemotherapy type OPPA/COPP associated with radiotherapy with complete response, was affected by ITP. Clinical and biological findings were cutanous purpura, thrombocytopenia at 50.10^9/L, and a peripheral origin on bone marrow aspiration. secondarly appeared auto immune haemolytic anemia with warm antibodies with a minimum value of haemoglobin level at 58 g/L. Treatment by corticosteroids was unsuccessful and RITUXIMAB was introduced with an increased of the 2 lineages obtained in few days. *Conclusions*. autoimmune cytopenias could affect patients with a history of Hodgin's disease in the absence of relapse. In all cases cytopenias were resistant to the first level of treatment. Severe symptoms allow us to use major therapy of ITP or AIC as Rituximab or Nplate to avoid life-threatening complcations.

UNDIAGNOSED SARCOIDOSIS MANIFESTING AS PERSISTENT FDG-PET POSITIVITY AFTER TREATMENT OF LYMPHOMA

A Burke,[1] A Dyszkiewicz-Korpanthy,[1] L Wilson,[2] C Johnston,[3] J McHugh,[1] H Enright[1]

[1]*AMNCH, Dublin, Ireland*
[2]*Blackrock Clinic, Dublin, Ireland*
[3]*St James' Hospital, Dublin, Ireland*

Background. Positron emission tomography (PET) with [18F]fluorodeoxyglucose (FDG) scanning has become an increasingly important tool in decision-making in patients with high-grade non-Hodgkin's lymphoma (NHL) and Hodgkin's disease (HL). Sensitivity and specificity of FDG-PET for detection of residual disease after completion of first-line therapy is reported as 84% and 90% for HL and 72% and 100% for high grade NHL, respectively. *Aims*. We report two patients with persistent positivity on FDG-PET scanning after treatment for lymphoma that suggested persistent active lymphoma but was subsequently diagnosed as sarcoidosis. *Methods*. Retrospective chart review to collate clinical details, laboratory results and radiology reports. Results. Patient 1 is a 23 year old female diagnosed with biopsy-proven nodular sclerosing Hodgkin's disease, stage III. The initial biopsy material (cervical lymph node) did not show any evidence of granulomatous inflammation. She did not have a PET scan at diagnosis. She received 6 cycles of doxorubicin/bleomycin/vincristine/dexamethasone (ABVD) combination chemotherapy. However, she had persistent mediastinal PET positivity at interval imaging and given that a positive early interim FDG-PET is highly predictive of progression in patients with advanced-stage HL (Hutchings et al, Blood 2006), her treatment was escalated to ifos-

famide/etoposide/vincristine (IEV) combination chemotherapy. She proceeded to stem cell mobilisation and collection. Several attempts at that time to biopsy the areas of persistent PET positivity failed because of morbid obesity. She remained otherwise very well and a watch and wait approach was adopted. However, progressive widespread PET positive lymphadenopathy developed and biopsies were again attempted 2 years later. Pathology confirmed extensive non-caseating granulomatous inflammation. There was no evidence of residual Hodgkin's lymphoma. Serum angiotensin converting enzyme level was normal at 21 IU/L (normal range 8-52 IU/L). Patient 2 is a 72 year old female diagnosed with extensive diffuse large B-cell lymphoma (DLBCL), with bulky para-nasal sinus involvement. She received 8 cycles of rituximab/cyclophosphamide/doxorubicin/vincristine/prdnisolone (R-CHOP) combination chemotherapy with CNS prophylaxis with inthrathecal methotrexate. An FDG-PET scan at the end of treatment showed persistent FDG avid mediastinal lymphadenopathy. Endobronchial ultrasound guided biopsy of these lymph nodes was performed and samples from the two nodes biopsied showed non-caseating granulomata. There was no evidence of residual high-grade lymphoma. Serum angiotensin converting enzyme level was just above the normal limit at 55 IU/L (normal range 8-52 IU/L). *Conclusions.* FDG-PET scanning is fast becoming a cornerstone in the management of certain lymphomas. However, use of this imaging modality for detecting residual disease during and after treatment may be confounded by other reasons for positivity including sarcoidosis. Biopsy confirmation of suspected residual disease may be important before proceeding to high-dose salvage chemotherapy.

1251

IS COMBINATION OF FOUR CYCLES OF EBEACOPP AND FOUR CYCLES OF BBEACOPP APPROPRIATE TREATMENT OPTION FOR PATIENTS WITH ADVANCED STAGE HODGKIN´S LYMPHOMA?

P Stepankova, D Belada, A Sykorova, J Maly
University Hospital Hradec Kralove, IInd Dept. of Internal Medicine, Hradec Králové, Czech Republic

Introduction. HD-12 trial of the GHSG de-escalated therapy of advanced stage of Hodgkin lymphoma (HL) by comparing 8 cycles of escalated BEACOPP with 4 cycles of escalated BEACOPP and 4 cycles of baseline BEACOPP. We evaluate efficacy and toxicity of this schema used in our institusion since 2001. *Patients and methods.* A total 78 patients with newly diagnosed HL - advanced stage were treated with this approach between December 2001 and December 2010. 62 of them (median age 31 years, range 18-61 years) with minimal follow-up of 12 months from the end of therapy were finally evaluated. Initial stage II/III/IV disease was found in 12/32/18 patients, respectively. We analyzed this group of patients for early toxicity, outcome in interim restaging and treatment outcome. Results: A total of 59 (95%) patients achieved complete remission. One patient progressed on treatment, one had stable disease. One patient died during treatment. Radiotherapy was given to 10 patients with residual PET positivity. Three patients experienced disease relapse 13/22/22 months after the beginning of the therapy. Relapse or progression occured in only 5 patients (8%). With the median of follow-up (FU) 59.5 months FFTF for all patiens is 92 %, OS is 93 %. Toxicity: Preplaned 8 cycles of the therapy completed 54 patients (87%). 5 patients didn´t complete treatment due to adverse events (AE), 2 due to noncompliance. Major toxicities were hematologic. The grade 3-4 anemia has occured in 26 patiens (42 %), grade 3-4 neutropenia in 55 (89 %) and grade 3-4 thrombocytopenia in 23 (37 %) patients. G-CSF support in baseline BEACOPP was needed in 41 (66 %) patients, 9 patients were hospitalized due to febrile neutropenia. Other examined early averse events were aseptic necrosis of the had of femur, venous thrombosis, soft tissue absces, chronic osteomyelitis, peripheral neuropathy, pneumonitis and osteoporosis. During the FU period 1 patient had secondary malignancy, 1 patient myelodysplasia following salvage high-dose chemotherapy with stem cell rescue. *Conclusions.* These data showed that combination of escalated and baseline BEACOPP chemotherapy seems to be effective treatment with acceptable acute toxicity, very promising effectivity. Longer follow-up is needed for evaluating of late toxicity of this regimens.

1252

PATIENTS WITH MYELODYSPLASTIC SYNDROMES SHOW REDUCED FREQUENCIES OF CD4+CD8+ DOUBLE POSITIVE T-CELLS

C Fozza, S Contini, A Galleu, P Virdis, S Bonfigli, M Longinotti
University of Sassari, Sassari, Italy

Background. Even though the expression of CD4 and CD8 on thymocytes is considered mutually exclusive, CD4+CD8+ double positive T-cells (DP) represent a small subset of T-lymphocytes which have been described in the peripheral blood of normal individuals as well as in some pathological conditions. In particular an age dependent accumulation of monoclonal DP has been shown in elderly healthy subjects. From the functional point of view DP are able to act as differentiated effector memory cells with specific antiviral functions. However, considering the concomitant expression of granzyme B, Foxp3, interleukin 17 as well as of both Th1-type and Th2-type cytokines, it is very likely they are able to mediate different functions, not only in the peripheral blood but also in other sites. *Aim and methods*. Although a DP cell population has been described in the lymph nodes of patients with nodular lymphocyte predominant Hodgkin's Lymphoma, the relative representation of this cell subset has never been analyzed in patients with myeloid malignancies. As myelodysplastic syndromes (MDS) are a group of clonal disorders characterized by a marked immune dysregulation specifically involving the T-cell compartment, we evaluated the frequency of DP in the peripheral blood of 41 patients with MDS and 40 age-matched normal controls by using flow cytometry. Results: We showed that MDS patients when compared with normal controls had reduced frequencies of DP (0,99% ± 0,72% vs 1,38% ± 0,80% calculated on total lymphocytes; p<0,05). We then looked at the possible impact on DP frequencies of several patient- and disease-related factors but, after stratifying patients by WHO adapted Prognostic Scoring System (WPSS), cytogenetics, hemoglobin levels, neutrophil and platelet counts, transfusion dependence and coexistence of autoimmune phenomena, we could not detect any statistically significant difference. However by comparing DP frequencies in patients belonging to different WHO subclasses, we demonstrated a further reduced frequency of DP in patients with refractory cytopenia and multilineage dysplasia (CRDM) than in patients belonging to the other WHO subclasses (0,98% ± 0,43% vs 1,00% ± 0,68%; p<0,005). *Conclusions*. Our data further suggest that an abnormal activation of the T-cell compartment may be deeply involved in the pathophysiology of MDS, especially in subtypes such as RCMD which are more likely characterized by the functional inhibition of hematopoietic precursors mediated by autoaggressive T-lymphocytes described in these disorders. The very recent evidence that Myb is a fundamental promoter of DP survival, along with the demonstration that this gene is typically down-regulated in MDS patients due to the abnormal expression of specific micro-RNA, could well explain the reduced frequency of DP we observed in our patients.

1253

THE *EX VIVO* CLONAGENIC POTENTIAL OF SELECTED CD34+ CELLS FROM PATIENTS WITH MDS APPEARS PRESERVED

G Davison,[1] N Novitzky,[2] R Abdulla[2]
[1]*Cape Peninsula University of Cape Town, Cape Town, South Africa*
[2]*University of Cape Town, Cape Town, South Africa*

Background. The myelodysplastic syndromes are a heterogeneous group of haematological malignancies characterized by cytopaenias and ineffective haemopoiesis. A role for the immune system in the pathogenesis has been suggested and research has implied that T-lymphocytes inhibit colony growth of early progenitors leading to variable degrees of cytopaenia. However, previous investigations have shown that the cells undergoing apoptosis are the mature CD34- progenitors and that when separated from stromal and bone marrow accessory cells the colony growth of the CD34+ cells is similar to normal. Aim: Our aim was to develop a unique dual layer culture system which would serve to examine the effects of activated and non-activated immune cells on selected bone marrow clonogenic progenitors from MDS patients, which were devoid of stromal and bone marrow accessory cells. Methodology: 17 patients with myelodysplasia were studied. All patients and normal individuals were required to sign a consent form according to University of Cape Town guidelines. The autologous peripheral blood mononuclear cells were separated and activated using phorbol 12-myristate13 acetate (PMA) and thereafter analysed, for expression of the activation antigen CD69 employing standard flow cytometry. The effect of these autologous immune cells populations on clonogenic marrow cell growth was then studied by culturing selected CD34+ cells with both PMA activated and non-activated autologous lymphocytes using a double layer culture technique. In this system the CD34+ cells were isolated from the accessory cells in the bone marrow and incubated in dose response with lymphocytes immobilized in an agar underlayer. Thus, physical contact with the activated immune cells was prevented. Clones containing more than 40 cells were scored and compared to age matched control samples. Results: In MDS patients the median percent of CD3+

T-cells expressing CD69 was reduced in comparison to age matched controls (p=0.025). The effects of the immune cells on clonagenic cell growth was heterogeneous, however when the results were compared with control cells there was no difference in the colony stimulating capacity of autologous PMA stimulated or unstimulated lymphocytes from MDS patients. In addition the number of CFU-GM increased similar to control values, as increasing numbers of lymphocytes and monocytes were added (p=0.02). MDS CD34+ cells cultured with PMA activated immune cell populations had higher numbers of colonies than those cultured with non activated cells (p=0.05) Conclusions: Our investigations suggest that soluble factors secreted by lymphocytes and monocytes, when not in direct contact with CD34+ progenitors, have the ability to stimulate colony growth of autologous CD34+ cells. In addition, in contrast to previous reports, these experiments also show that when the CD34+ progenitors are separated from the bone marrow environment and the local accessory cells, their proliferative capacity is preserved. Therefore the role of accessory cells such as stromal and antigen presenting cells in the pathogenesis and the maintenance of an abnormal environment in MDS require further investigation.

1254

MATURE MONOCYTE DERIVED DENDRITIC CELLS HAVE ABNORMAL ANTIGEN EXPRESSION BUT APPEAR TO STIMULATE AUTOLOGOUS CD8+ T-CELLS IN MDS PATIENTS

G Davison,[1] N Novitzky,[2] R Abdulla[2]
[1]*Cape Peninsula University of Cape Town, Cape Town, South Africa*
[2]*University of Cape Town, Cape Town, South Africa*

Background: An activated immune environment has been described in MDS and it is hypothesized that T-cells are reacting to antigens present on the surface of the malignant cells leading to inhibition of colony growth and apoptosis. However it has been demonstrated that selected CD34+ cells in the presence of cytokines and the absence of accessory cells in the bone marrow have colony growth similar to normal. It has therefore also been suggested that T-cells are not solely responsible for the characteristic cell death observed in the bone marrow and that other cells such antigen presenting cells could also play a role. Dendritic cells have been shown to be clonal and abnormal in MDS and therefore their defective interaction with T-cells could be important and requires investigation. Aims: The aim of this study was to examine the ability of antigen presenting cells to mature, express co-stimulatory molecules and activate both allogeneic and autologous CD4+ and CD8+ T-cells. Methodology: 5 patients with MDS were studied. All patients and normal individuals were required to read and sign a consent form according to University of Cape Town ethical guidelines. Monocyte derived dendritic cells (MoDC) were generated by culturing peripheral blood monocytes with GM-CSF and IL-4 for 5 days. The immature MoDC were then activated using LPS and TNFα and thereafter analysed for the expression of co-stimulatory and activation antigens (CD80, CD86, CD83, HLA-DR, CD11c, CD1a) using standard 4 colour flow cytometry. The activated antigen presenting cells were then cultured with both autologous (from the same patient) and allogeneic (donor) T-cells. After 72 hours of culture, CD4+ and CD8+ T-cells were examined for expression of the activation antigen CD69 using standard flow cytometry. The results were compared to 9 normal controls which were cultured in the same manner. Results: After activation with LPS and TNFα the percentage and mean fluorescent intensity of expression of HLA-DR (p=0.04), CD11c (p=0.03), CD80 (p=0.05) and CD86 (p=0.03) was reduced in 4 out of the 5 patients with MDS when compared to the normal MoDC. CD1a and CD83 expression was however similar to normal. The mature MoDC had a reduced ability to stimulate allogeneic donor T-cells but the activation and CD69 expression of autologous CD3+ and CD8+ T-cells was increased when compared to normal controls. Conclusion: This study confirms that antigen presenting cells in myelodysplasia do not mature normally, have reduced expression of co-stimulatory molecules and are unable to effectively stimulate allogeneic T-cells. However, the results also imply that their capacity to activate autologous T-cells is enhanced indicating that that they are able to present antigen. These findings suggest that both T-cells and dendritic cells could be utilised to develop anti-tumour immune based therapies in myelodysplastic patients.

AGE-ASSOCIATED ALTERATION OF GAMMA/DELTA T CELL REPERTOIRE AND DIFFERENT PROFILES OF ACTIVATION-INDUCED DEATH OF V-DELTA1 AND V-DELTA2 T CELLS

Y Michishita, M Hirokawa, YM Guo, Y Abe, J Liu, K Ubukawa, N Fujishima, M Fujishima, T Yoshioka, Y Kameoka, H Saito, H Tagawa, N Takahashi, K Sawada
Akita University Graduate School of Medicine, Akita, Japan

Background. Although γδ T cells have been suggested to be involved in certain autoimmune disorders, the role of γδ T cells in bone marrow failure syndrome remains largely unknown. Since age and race have been reported to influence the γδ T cell repertoire, appropriate reference data matched for age and race are absolutely required for clinical studies. *Aims*. The principal aim of this study was to establish reference data on γδ T cell repertoires in a healthy Japanese population and to identify the mechanisms shaping the γδ T cell repertoire. *Methods*. We examined the γδ T cell repertoire in 120 healthy volunteer donors by flow cytometry. Flow cytometry-based analysis of peripheral blood T cell subsets was performed using a whole blood lysis technique in order to avoid the potential loss of certain T cell subsets. Lymphocyte counts were calculated from the white blood cell count and the percentage of lymphocytes determined by flow cytometry. The monoclonal antibodies (mAbs) used in this study were as follows: anti-CD3 (SK7); anti-TCR-α/β-1 (WT31); anti-TCR-γ/δ-1 (11F2); anti-Vδ1 (TS8.2); anti-Vδ2 (Immu389); anti-NKp46 (9E2/NKp46); anti-CD56 (MEM188); anti-CD95 (Fas/APO-1) (DX2); control mouse IgG1-PE (679,1Mc7); mouse IgG1-FITC (DAK-GO1) and mouse IgG1-PerCy5.5 (X40). Activation-induced apoptosis and expansion of the γδ T cells in vitro were also analyzed. Expression of Intracellular Bcl-2 family proteins was examined by staining the permeabilized cells with anti-Bcl-2 and anti-Bim mAbs. This study was approved by the institutional review board at Akita University. Results: The average numbers of T lymphocytes in blood from all donors examined (n=120) were as follows: 1,084 ± 369 (SD) αβ T cells, 68 ± 44 γδ T cells, 16 ±12 Vδ1 T cells and 43 ± 36 Vδ2 T cells (/μl). The absolute numbers of γδ T cells were reduced in association with aging (R=-0.378 , p<0.001). The decrease of γδ T cells was a result of age-related reduction of Vδ2 T cells (R=-0.419, p<0.001) but not of Vδ1 T cells (R=-0.098, p=0.299) . As a result, the Vδ2/Vδ1 ratio showed an age-dependent decrease. Gender also affects the γδ T cell repertoire, and the numbers of Vδ2 T cells were significantly higher in male donors than female donors (p=0.007). The numbers of αβ T cells, Vδ1 T cells and NK cells were significantly higher in CMV-seropositive donors than CMV-seronegative donors. The Vδ2 T cells but not Vδ1 T cells showed a rapid reduction in cell numbers against mitogen stimulation, and exogenous addition of IL-2 did not rescue the Vδ2 T cells to die. Annexin-V binding was increased at 6 hours of PHA stimulation in all T cell subsets, and the Vδ2 T cells showed the strongest Annexin-V binding. Bcl-2 protein expression was down-regulated in mitogen-stimulated Vδ2 T cells but not in Vδ1 T cells. Summary/conclusions: These results indicate that age and gender have great impact on the γδ T cell repertoire in Japanese donors as well as European and American donors. Age-related decrease of Vδ2 T cells might be explained by their susceptibility to activation-induced cell death.

[4]*University Medical School, Bari, Italy*

Cytogenetic analysis of the bone marrow is indicated in MDS not only for diagnostic purposes, but also to assess individual prognosis according to the IPSS scoring guidelines and to plan tailored therapy. Conventional cytogenetic (CC) analysis is performed in clinical practice to detect chromosomal abnormalities. It has been reported that fluorescence in situ hybridization (FISH) is a more sensitive approach, however this analysis is limited to detection of the more frequent abnormalities on chromosomes 5, 7, 8, 11, and 20, and conflicting data are reported in literature. A new method has recently been described for the meas-

urement of the gene/chromosome copy number using genomic DNA: Multiplex Ligation-dependent Probe Amplification (MLPA). The purpose of this study was to compare the results of the MLPA assay with the CC data obtained in a series of 38 MDS patients (M: 28, F:10, median age 70 years, range 44-87). In accordance with the WHO classification, 10 cases were classified as RA, 10 as RCMD, 4 as RAEB-1, 8 as RAEB-2, 1 as MDS_U, and 5 as CMML. The MLPA assay contains 61 specific target sequences for chromosome regions commonly involved in MDS: 5q (9 probes), 5p (1 probe), 7q (8 probes), 7p (2 probes), 8q (8 probes), 8p (2 probes), 11q (8 probes), 12p (6 probes), 17q (2 probes), 17p (4 probes), 20q (5 probes), 20p (1 probe) and 21q (5 probes). The MLPA was performed on all samples according to the manufacturer's recommendations (MRC-Holland).

Table I

38	No anomalies	46, XY

The CC study was performed following standard protocols and at least 20 metaphases were analyzed. Our study showed a good correlation between the MLPA and CC results (Table 1), since most of the alterations being detected by both techniques. Discrepancies were found in 7 samples (18.5%). MLPA analysis did not detect the presence of a chromosomal (chr.) translocation (sample n°4); a chr. deletion and a chr. translocation (sample n°11); a chr. deletion (sample n°15); several chr. translocations and deletions (sample n°20); a chr. gain (sample n°27). In fact, the MLPA assay is not able to detect chr. translocations but only chr. loss or gain; it can only analyse the chr. regions commonly involved in MDS (5,7,8,11,12,17,20,21); it can reveal chr. abnormalities providing the percentage of cells carrying the alterations is about 30-35% and it do not show mosaicism. On the other hand, CC analysis did not show a small deletion in 2 samples: a deletion of the MLL gene in 11q23 (sample n°23) and deletion of 7q22 (sample n°37). With CC we also observed a karyotype failure (no metaphases) in 4 samples, while the MLPA assay showed three chr. deletions (sample n°14), but no anomalies in the other 3 samples (25, 29, 32). MLPA proved rapid, cost effective, relatively easy to perform, had high throughput and enabled simultaneous analysis of many samples by automated data processing. MLPA and CC resulted complementary techniques, MLPA being particularly useful in MDS cases with karyotype failure and for identifying small rearrangements.

1257

SETTING-UP OF THE FCM OGATA PROTOCOL FOR DIAGNOSIS OF MDS: EXAMPLE OF A FRENCH EXPERIENCE

E Guerin,[1] P Cecco,[1] JL Faucher,[1] MJ Couraud,[1] MP Gourin,[2] C Ouk-Martin,[3] A Le Guyader,[4] F Trimoreau,[1] D Bordessoule,[2] J Feuillard[1]

[1]*Laboratoire d'Hématologie UMR CNRS 6101, Limoges, France*
[2]*Service d'Hématologie clinique, Limoges, France*
[3]*Cytometry Imagery Mathematics Platform, université, Limoges, France*
[4]*CTCV et Angiologie, Limoges, France*

Background. Initial evaluation of patients with suspected MDS requires among other a careful assessment of their peripheral blood smear and blood counts, as well as morphology of bone marrow cells and specific diagnostic marker. Diagnosis of low-grade MDS without conventional markers (excess of blasts, cytogenetic abnormalities, Ring sideroblasts...) is more difficult to assess. It is necessary to take into account the clinical history and to rule out others conditions which are associated with dysplastic myeloid cells (viral infection, heavy metal, deficiency of vitamin, drug, ethanol...). In these cases, flow cytometry (FCM) is recognized by the WHO classification as a useful diagnosis tool. Aims. Our aim was to adapt the simple three color FCM protocol developed by Ogata and applied on a Japanese and an Italian cohort (*Ogata and al. Haematologica 2009; 94(8), 1066-10*). The protocol is based on CD34, CD45, CD10 labeling. We have added labeling of the CD19 marker to sensitize the detection of B-cells precursors. *Methods*. Fifty one bone marrow samples, including 17 proven MDS, 13 control patients (2 normal subjects and 11 patients with non-clonal cytopenia), 21 patients with suspicion of MDS but without enough evidences to firmly assess the diagnosis, were included. All the samples were treated within 16 hours. The nucleated cells were stained with four antibodies CD45-FITC, CD10-PE, CD19-PC5, CD34-PC7. At least 100000 cell events were acquired. We used the reference range (RR) published by Ogata. We thus analyzed four parameters: (1) the percentage of CD34+ myeloblast in all nucleated cells (RR<2.4%): (2) the percentage of CD34+CD19+ cells in all CD34+ cells (RR>5%); (3) the lymphoblast/myeloblast ratio (RR=4-7.8); (4) the granulocyte/lymphocyte SSC peak chanel ratio (RR>6). One point was given for each abnormal parameter. *Results.* One patient of the control group had a score of two. In that case, diagnosis of drug toxicity was obvious. Among proven MDS, 11/17 (65%) of patients had a score of 2 or more (specificity=93%, sensitivity= 65%). 23% of patients with suspicion of MDS had a score of two or more. Interestingly, the two most frequently abnormal parameters, were the SSC ratio and the percentage of CD34+CD19+ cells. *Summary/Conclusions.* The Ogata FCM protocol is a simple FCM method that was easily adapted to four colors by including the CD19 marker. In an attempt to improve the diagnostic power of the Ogata's score, we will work out our own reference range. Furthermore, all the cases in the group of suspicious MDS will need to be reevaluated. However, it is already very striking that, using the same reference range of Ogata *et al*., we reached the same sensitivity and specificity that the one published.

1258

FAS AND FAS LIGANT (FASL) EXPRESSION IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

M Figueiredo,[1] R Pavani,[1] S Gualandro,[2] M Satake,[3] E Kimura,[1] M Yamamoto[1]

[1]*Universidade Federal de Sao Paulo (UNIFESP), São Paulo, Brazil*
[2]*Disciplina de Hematologia, Universidade de Sao Paulo, São Paulo, Brazil*
[3]*Hospital do Servidor Publico Estadual, São Paulo, Brazil*

Background. The Fas/Fas ligant (FasL) system dysfunction has been associated with hematological and non hematological diseases. In PNH, evidences suggest that this system could select and maintain the proliferation of the mutational clone by promoting normal cells apoptosis. *Aims:* The aim of this study was to analyze the expression of Fas and FasL in neuthophils and monocytes from PNH patients. We tried also to detect a possible relation between these expressions and clinical subtypes of this disease. *Methods*. We studied 16 patients followed at Universidade de Sao Paulo (USP), Universidade Federal de Sao Paulo (UNIFESP), and Hospital do Servidor Publico Estadual (HSPE). The patients were clinically classified as classic PNH (PNH/CL: 9 patients) and PNH in the setting of another bone marrow failure syndrome (PNH/BF: 7 patients). The expression of Fas and FasL in neutrophils and monocytes were analyzed by flow citometry (FACScalibur, Cell Quest software - BDB). In PNH, the neutrophils were divided according to the CD59 expression (59+/Nt or 59-/Nt), and in monocytes according to the CD14 expression (14+/Mo or 14-/Mo). The Fas and FasL expression in neutrophils and monocytes were also analyzed in 10 normal individuals as control group (59/CG and 14/CG, respectively). *Results.* No statistical difference was found in Fas expression among the neutrophils 59+/Nt, 59-/Nt and 59/CG. The same result was observed among monocytes 14+/Mo, 14-/Mo and 14/CG. FasL expression in 59-/Nt was significantly lower than in 59+/Nt (p=0.008), but there were no statistical difference between

14+/Mo and 14-/Mo. When we analyzed the data according with clinical subtypes, PNH/BF patients had lower Fas expression on both 59-/Nt (p=0.041) and 14-/Mo (p=0.014) than PNH/CL. In addition, when we analyzed PNH/BF group, we observed that 59-/Nt expressed less FasL than 59+/Nt (p=0.031). CONCLUSIONS: Previous studies had been show higher expression of Fas in CD59+/stem cells than CD59-/stem cells in PNH. In this study, PNH/BF patients had less Fas expression on 59-/Nt and on 14-/Mo than PNH/CL patients. This data suggest that 59+/Nt and 14+/Mo cells could be more susceptible to apoptosis, which is in agreement with the PNH clone survival advantage hypothesis. FasL expression was higher on 59+/Nt than on 59-/Mo, especially in the PNH/BF group. We could speculate, with this data, that FasL in excess could act in bone marrow, initiating the stem cells apoptosis process, what explain the characteristics bone marrow alterations found in PNH. Although the importance of FasL in apoptosis, this is the first study to analyze its expression on PNH.

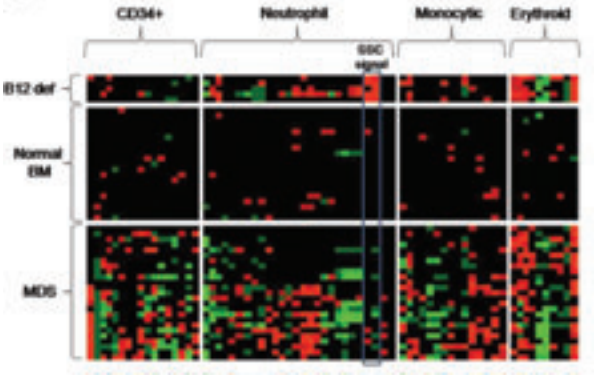
MARROW CELLS OF VITAMIN B12 DEFICIENCY CASES SHOW A PHENOTYPIC PROFILE SIGNIFICANTLY DIFFERENT FROM MYELODYSPLASTIC SYNDROME

F Mannelli, S Bencini, A Sanna, I Cutini, G Gianfaldoni, V Carrai, G Rotunno, V Santini, A Bosi

UF Ematologia, Università degli Studi di Firenze, AOU Careggi, Firenze, Italy

Background. The diagnosis of myelodysplastic syndromes (MDS) relies on documentation of morphologic dysplasia in bone marrow (BM) cells. Many reports have proposed flow cytometry (FC) as an useful integrating technique in this subset. Nonetheless some non-malignant disorders, such as vitamin-B12 deficiency (B12 def), mimic MDS causing macrocytic anemia and megaloblastic-like abnormalities. *Aims*. We compared the immunophenotypic characteristics of B12 def patients' BM cells to normal BM and MDS samples. Our aim was to verify if FC was able to differentiate between the diseases and to identify any phenotypic feature useful to suspect a deficiency-related pathogenesis. Methods. 2x106 BM cells were stained with quadruple combinations of a wide panel of monoclonal antibodies; 50,000 events of global BM cellularity were acquired; if required, a second step was performed to collect 1x103 CD34+ cells at least. Data acquisition was performed using FACSCalibur flow cytometer and CellQuestPro software (Becton Dickinson). For data analysis, Infinicyt (Cytognos) software was used. Our approach was adapted from what described by Matarraz et al (Leukemia 2008). Some major BM compartments were identified on the basis of forward (FSC) and sideward (SSC) light-scatter and reactivity for CD45/CD34. Sixty-nine phenotypic parameters were expressed as percentage of positive cells within a compartment and/or mean fluorescence intensity (MFI;arbitrary relative linear units, scaled from 0 to 104). Phenotypic aberrancies were quantified considering deviations from normal profile, defined by mean value ± two standard deviations. The phenotypic data were also displayed through a color code (Figure 1): black corresponded to normal expression; red and green to higher and lower than the mean, respectively; color intensity was proportional to deviation degree.



Results. BM of 5 patients with proven B12 def were analyzed, and 25 newly-diagnosed MDS patients; according to WHO, they were classified as: RA, 7 patients; RARS, 1; RCMD, 5; RAEB-1, 8; RAEB-2, 4. CD34+ cells of B12 def showed no significant phenotypic difference from controls. Conversely, neutrophil compartment had several deviations from normal pattern. As highlighted in Figure 1, SSC resulted significantly higher for B12 def (median value 291 vs 226,p=0.011); this finding appeared more evident restricting the analysis on stage-IV mature granulocytes (395 vs 250,p=0.0002), likely expressing the phenotypic counterpart of hypersegmented neutrophils. Moreover, in MDS subset, stage-IV granulocytes showed a significant reduction of SSC in a substantial fraction (24%) of patients, as expression of hypogranularity and pseudo-Pelger abnormality. Monocytic lineage showed an increased FSC for B12 def (560) compared to controls (462,p=0.0006) without any other relevant difference. Erythroid subset was featured by several alterations, primarily regarding an increase on global cellularity (30.3% vs 9.9%,p=0.0002). The cells revealed higher FSC (283 vs 226,p=0.0002) and SSC (30 vs 20,p=0.0084), while the antigenic profile showed a weaker CD36 (1125 vs 1704,p=0.04) and CD71 (1077 vs 3207,p=0.0245) expression. As depicted in Figure 1, the phenotypic aberrancies of B12 def within the erythroid compartment resembled what found in MDS. *Summary/conclusions*. Through a multiparameter and systematical approach, we highlighted some aberrancies shared by patients with B12 def and defined a useful profile to distinguish it from clonal disorders.

1260

THE SIGNIFICANT ASSOCIATION BETWEEN PRIMARY MYELODYSPLASTIC SYNDROME AND SINGLE NUCLEOTIDE POLYMORPHISMS

M Belickova,[1] A Jonasova,[2] D Mikulenkova,[1] Z Krejcik,[1] R Neuwirtova,[2] J Cermak[1]

[1]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic*
[2]*General Faculty Hospital, Prague, Czech Republic*

Background. Myelodysplatic syndrome (MDS) represents a heterogeneous group of clonal disorders with ineffective hematopoiesis and its etiology has not been fully explained. Additionally, MDS may be induced by some chemotherapeutic toxins or mutagenic environment factors but the association with certain genes has yet not been detected. *Aims.* To expand the understanding of MDS etiology we sought to identify genes and polymorphisms associated with MDS using multiplex genotyping. *Methods.* We used the Illumina Cancer SNP Panel containing 1421 single nucleotide polymorphisms (SNPs) derived from 408 genes thought to be involved in cancer. We conducted a case-control study of 189 patients with primary MDS and 262 controls in Czech population. Firstly, the quality control for all SNPs and samples was implement and then, Chi2 p-value, odds ratio (OR) and upper and lower limits of 95% confidence interval of OR were calculated. When applying Bonferroni correction for multiple testing, the p-value is supposed to show significant association of SNP with the phenotype. *Results*. Ten SNPs showed significant case-control differences at the level of p< 0,0001. Findings included an increased risk associated with variants in the anion exchange gene SLC4A2 (p-value=0,0000000001;OR=2,64;95% Cl=1,97-3,55), two ATP-binding cassette transporters genes ABCB1 and ABCC2 (p-value=0,0000005;OR=3,38;95% Cl=2,08-5,48 and p-value=0,00001;OR=2,11;95% Cl=1,05-2,95), the DNA ligase I LIG1 (p-value=0,0000008;OR=2,10;95% Cl=1,57-2,82) the aurora kinase A STK6 (p-value=0,000003;OR=2,51;95% Cl=1,70-3,71), the progesterone receptor PGR (p-value=0,000008;OR=2,14;95% Cl=1,54-2,99), DNA mismatch repair protein MSH3 (p-value=0,00008;OR=6,71;95% Cl=2,49-18,08) and the DNA repair gene RAD52 (p-value=0,00006; OR=1,88;95% Cl=2,38-2,55) and decreased risk associated with the ROS1 gene (p-value=0,000002;OR=0,44;95% Cl=0,31-0,61). These findings are biologically plausible since association of SNPs in SLC4A2, ABCC2, STK6, LIG1, GPX3 and RAD52 genes with some kind of cancer were described. *Conclusions.* We observed a significant association between MDS and the common genetic variants described above. This evaluation of genetic polymorphisms identifies SNPs which may be involved in the pathogenesis and biology of this disease. Specific genes associated with risk may have particular relevance for gene function and/or carcinogenesis.

MYELODYSPLASTIC SYNDROME. EGYPTIAN EXPERIENCE

N El Husseiny, S Mohamed, M Mattar

Cairo University, Cairo, Egypt

Background: Myelodysplastic syndromes (MDS) incidence is unclear because of historical lack of population-based registration and possibly because of under diagnosis. Purpose: To present some retrospective data

on the epidemiology of myelodysplastic syndrome (MDS) in Egypt, as reflected by a single center based Registry which is the largest tertiary referral center in Egypt. Patients and Methods: Patients diagnosed with MDS and referred to Clinical Haematology unit of Internal Medicine Department Cairo University, Egypt between 2007-2010 were identified. Complete demographic and clinical data, laboratory results, treatment modalities were collected and analyzed. Results: 69 patients with MDS were identified. 39 (57%) females, 30(43%) male. Mean age was 55 years. 9 (13%) patients were positive for HCV. Mean ferretin level was 844 ng/ml and mean blood transfusion units were 12 units. 26 (38%) patients were RCMD, 15 (22%) patients with RA-EB, 10(14%) patients with hypoblastic MDS and 18 (26%) patients with RA and RARS. 12(17%) patients were less than 40 years, 4 (5%) of them had RA-EB. There were a strong correlation between ferretin and ALT (r=0.415 P:0.002), ferretin and blood units (r=0.26 P:0.046) and negative correlation between ferretin and age (r=-0.27 p:0.03). 48 (70%) patients were from rural areas. Summary and Conclusion: We consider this number of diagnosed MDS is a large one and reflects the increased awareness of the disease and improved methods of diagnosis. The young age of diagnosis and appearance of RAEB in young patients may reflect the impact of environmental pollution especially water and soil (70% were from rural areas) on the development of genetic mutation. Iron overload is a permanent feature of MDS. The higher prevalence of HCV is part of the problem of increasing hepatitis among Egyptians and could be related to blood transfusion during course of treatment though the strict measures in blood banks . The correlation between ALT with ferretin reflected the impact of under treatment of those patients with iron chelation therapy on progression of liver disease especially in presence of HCV.

1262

INTRAVENOUS IRON SUPPORT VS ORAL LIPOSOMIAL IRON SUPPORT IN PATIENTS WITH REFRACTORY ANEMIA TREATED WITH EPOα. MONOCENTRIC PROSPECTIC STUDY

G Giordano,[1] P Mondello,[2] F D'Amico,[1] M De Maria,[1] G Sticca,[1] C Di Falco[1]

[1]*Center John Paul II, Catholic University, Campobasso, Italy*
[2]*University Hospital G. Martino, Messina, Italy*

Background. Intravenous iron support simultaneous to erythropoietin administration improve response to erythropoietin in myelodysplastic patients. In fact intestinal absorption of common commercial oral iron compounds is considerably impaired. Moreover, in MDS patients, absorbed iron is frequently stored in tissues and is'nt bioavailable. Oral liposomal iron, bypassing normal intestinal mechanism of absorption, shows an increased haematic absorption, better than usual commercial oral iron compounds. *Aims*. Aim of this study is to verify if in MDS patient support with oral liposomal iron is not inferior to iv iron support. Methods. Between july 2008 and december 2010, 24 patients affected by refractory anemia were studied. Median follow-up was 12 months (R10-24). Patients were randomized 1:1 to receive in group A sodium ferrigluconate 62.5 mg iv in NS 100 ml in 1 h/day in the day when patient received α erythropoietin 40000 IU sc/week + calcium levofolinate 7.5 mg/day orally + Vitamin B12: 400 mg/day orally. In group B patient received lipofer 14 mg 2 tablets orally/day + α erythropoietin 40000 IU sc/week + calcium levofolinate 7.5 mg/day orally + Vitamin B12: 400 mg/day orally. In group A median age was 70 years (R65-75), M/F: 4/8. In group B median age was 66 years (R60-70), M/F: 6/6. Caryotype was normal in group A and B patients. Median level of haemoglobin was 9 g/dl in group A (R8.5-11) and 8.8 g/dl (R8.5-11.5) in group B. *Results*. Group A patients increased Hb level of 1 g/dl after a median time of 4 weeks (R4-7) and after a median time of 5 weeks (R4-8) in group B. Most frequent side effects in group A were erythema in site of injection in 4 patients (33%), hypotension in 1 patient (8%). Most frequent side effects in group B were grade 2-3 diarrhoea in 4 patients (33%). During median follow-up time patients of A and B group gaigned near 3 g/dl of Hb. *Summary/Conclusions*. Oral liposomial iron supporting erythropoietinic therapy seems to be safe, feasible and substantially not inferior to intravenous iron support in patients affected by refractory anemia.

1263

ASSOCIATION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND PAROXYSMAL NOCTURNAL HEMOGLOBINURIA WITH A SMALL CLONE: A CASE REPORT

P Moncharmont,[1] F Barraco,[2] J Bernaud,[1] A Raffin,[1] M Michallet,[2] D Rigal[1]

[1]*EFS Rhone Alpes Site de Lyon Gerland, Lyon, France*
[2]*Department of Clinical Haematology Hôpital E Herriot 5 place d'Arsonval, Lyon, France*

Background. Paroxysmal nocturnal haemoglobinuria (PNH) is a haematologic disorder characterized by a clonal expansion of haematopoietic stem cells bearing a deficiency of the glycophophatidylinositol (GPI)-linked proteins due to an acquired mutation. Usually PNH clones are detected in patients with aplastic anaemia although non systematically ; they are rarely observed in monoclonal gammopathies of undetermined significance (MGUS). Here is reported the case of a 77-year old woman with both a MGUS and a small PNH clone which remained steady during several years Case report : A monoclonal IgG lambda gammopathy with a PNH clone was diagnosed in 2001. In 2008, no plasmacytosis was observed on the bone marrow smear and there were no clinical or radiological symptoms of myeloma. Methods : Three markers on red blood cells (RBC) were studied by flow cytometry (CD55, CD58 and CD59) also two markers on granulocytes (GN) (CD55 et CD59) and one on monocytes (MN) (CD14). The direct antiglobulin test (DAT) was performed on RBC by gel filtration. Results: In April 2008, CD55-, CD58- and CD59- RBC were at 2.9%, 2.1% and 0.6% respectively. On GN, CD55- and CD59- cells were at 0.9% and 1.8% and on MN, CD14- cells at 5.4%. The haemoglobin (Hb) level was at 94g/L, the haptoglobin and total bilirubin levels were normal at 0.9 g/L and 9.0 micromole/L respectively. The DAT was negative. In July 2009, the size of the PNH clone was still low (CD55-, CD58- and CD59- RBC were at 1.8%, 0.6% and 0.6%; CD55- and CD59- GN at 1.7% and 2.8%; CD14- MN at 3.5%). The Hb level was at 107g/L, the lactate dehydrogenase (LDH) level at 330 IU/L, total bilirubin level at 6 micromol/L, the DAT was negative but the haptoglobin level decreased to 0.2 g/L (normal higher than 0.7g/L). In April 2010, the same pattern was observed on PNH cells : CD55-, CD58- and CD59- RBC were at 0.7%, 0.6% and 0.6%; CD55- and CD59- GN at 1.2% and 2.0%; CD14- MN indicated doubtful results. No sign of haemolysis was noted, only a low level of haptoglobin (0.2 g/L). Nevertheless, in June and December 2010, CD14- MN began to increase to 6.4 and 10.1% without change for the other blood cells. *Summary/conclusions*. This case combines an unusual association of two blood disorders. When first observed the size of the PNH clone was low and remained such for several years without sign of haemolysis but with a low level of haptoglobin. No sign of myeloma has been observed during the clinical course.

1264

LOW RISK MDS: 5-AZACITIDINE, WHAT´S ELSE?... LENALIDOMIDE!

D De Miguel, N Golbano, I L San Roman, D Morales, M Diaz, J Arbeteta, D Subira, S Herrero, B Pinedo

Hospital Universitario de Guadalajara, Guadalajara, Spain

Alternative treatments are poor and limited effect, in low risk MDS patients. However, everybody have some younger patients, that they could receive 5-azacitidine or lenalidomide when it failed. Patients: We reported 4 patients have been treated with 5-azacitidine, they researched a good erithroid response, but they lost it. In this moment, we offer them to initiate therapy with lenalidomide. Case 1: Male 50 years-old was diagnosed of SRA (low IPSS, normal cytogenetic) 3 years ago. He had a transitory respond to EPO. 6 months later, he received 5-aza with a good respond 4 months later. This was mantened to nine cycles. Later, he has initiated Lenalidomide (initial dosage was 10 mg/d, actually he intakes 5mg/48h), he has managered the independent transfusional. Initial Hb was 4.8 g/dL, and now Hb is 10 g/dL, after 6 months of treatment. . At 5 months, he has lost the respond (Hb 5.2g/dL). He has completed 14 cycles. Case 2: Female 81 years-old was diagnosed of SRA (int-1 IPSS, normal cytogenetic) 2 years ago, she had a transitory respond to EPO. 18 months later, she began 5-aza therapy, with good respond 2 months later. She did keep up to 14th cycle. Later, she has initiated Lenalidomide at dosage 10 mg/d, actually she intakes 5mg/48h), she has managered the independent transfusional. Initial Hb was 6.0 g/dL, and now Hb is 11 g/dL, after 10 months of treatment. At present, she has Hb 9.8 g/dL after 12 months of therapy. Case 3: Male 78 years-old diagnosed of SRA (low IPSS, normal cytogenetic) 1 year ago. He had a transitory respond to EPO. 2 months later, he began 5-aza therapy, with good respond 3 months later. He did keep up to 15th cycle. Later, he has initiated Lenalidomide at dosage 10 mg/d, he has managered the independent transfusional. Initial Hb was 6.0 g/dL, and now Hb is 9 g/dL, after 8 months of treatment. Case 4: Female 63 years-old was diagnosed of SRA (low IPSS, normal cytogenetic) 20 years ago. She began 5-aza therapy, with good respond 3 months later, and this was maintained 24 months later. Later, she has initiated Lenalidomide at dosage 10 mg/d. At present, she hasn´t respond yet, after 5 months of therapy. Results. the three patients reached the independent transfusion, but we were

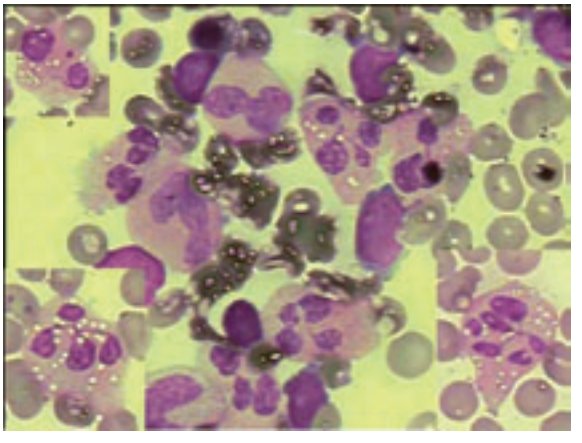
obligated to tapering dosage and we must wait 6-10 months to research the respond. We reported hematologic toxicity: G3-4 neutropenia and thrombocytopenia. We used G-CSF treatment by 48-72h. Conclusions. 1) In low risk MDS patients, non 5q-, lenalidomide is an alternative therapeutic, when 5-aza has failed; 2) Lenalidomide used dosage, is lower than recommended, by hematological toxicity; 3) The response, if it happens, is later than we hope (between 6-10 months).

1265

A CASE REPORT OF WHIM SYNDROME (MIELOKATHEXIS) IN BRAZIL - CLINICAL FEATURES AND BONE MARROW MORPHOLOGY

F Naoum
Academia de Ciência e Tecnologia, São José do Rio Preto, Brazil

Background. WHIM syndrome is a very rare congenital disorder with approximately 40 cases described until now. This syndrome is characterized by severe chronic neutropenia, retention and apoptosis of mature neutrophils in the bone marrow (myelokathexis), hypogammaglobulinemia and recurrent bacterial infections. *Aim*. To report a case of WHIM syndrome in a brazilian patient.



Methods. Clinical and key laboratory data were recorded during the follow up of the patient before and after treatment. *Results*. A 2-year old girl was evaluated at our hematology clinic with a past history of recurrent infections (3 episodes of pneumonia and 5 episodes of urinary tract infection) and persistent low neutrophil counts, ranging from 64 to 650/μL since she was 10 months old. There were no abnormalities on physical examination. Investigational tests showed hypogammaglobulinemia (gamma globulin=0,29g/dL) on protein electrophoresis and the examination of the bone marrow aspirate revealed a hypercellular bone marrow with granulocytic hyperplasia, characterized by an increased number of mature neutrophils with hypersegmented nuclei and cytoplasmic vacuolization. Neutrophils showed nuclear lobes often separated by long strands of chromatin (Figure 1). These typical bone marrow morphologic findings of myelokathexis in association with the clinical picture were consistent with the diagnosis of WHIM syndrome. Treatment with G-CSF (5mg/Kg per day subcutaneously) was initiated after diagnosis confirmation, leading to an increase in neutrophil count to 550/μL after 12 days of therapy and to 1300/μL after 24 days. No side effects or new episodes of bacterial infection were observed after therapy initiation. *Summary/Conclusions*. (i). Careful morphological examination of bone marrow aspirate is determinant for diagnosis of myelokathexis, especially in clinical settings where genetic and molecular characterization is unavailable. (ii). Response to G-CSF is in accordance with previous reports.

1266

CLINICAL AND BIOLOGICAL CHARACTERISTICS, EVOLUTION AND IMPLEMENTATION OF THE NEW PROGNOSTIC SCORE IN A SERIE OF PATIENTS WITH CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML)

S Piernas, E Rámila, L Muñoz, G Perea, G Navarro, M Gómez, J Soler, I Roig
Hospital Parc Tauli, Sabadell, Spain

Background. CMML is a heterogeneous clonal hematologic neoplasm with both myeloproliferative and myelodysplastic features. The International Prognostic Scoring System (IPSS) is of limited usefulness. Recently a new prognostic model (*Kantarjian et al, Cancer 2008*) has been proposed that predicts better survival in these patients. Aims and Methods. Retrospective analysis of clinical and biological characteristics, evolution and application of a new prognostic model for patients with CMML diagnosed in a community hospital between January 2003 to May 2010. Results. Thirty nine patients were identified. They were 28 (72%) male and 11 (18%) women; median age was 75 years (range 55-93). In 18% the performance status measured by ECOG scale was higher than 2. Average and extreme analytical values at diagnosis were as follows: Hb 112 g/L (44-175), WBC 35.1x10^9/L (3.5-82), monocytes 3.6x10^9/L (1-17.9), platelets 151x10^9/L (17 - 750). At the time of diagnosis, thirteen patients (33%) had leukocytosis >13x10^9/L, 8 (20%) had peripheral blasts (range 2-11), 19 (49%) had mielemia and 5 (13%) had splenomegaly. Thirty five (90%) of the 39 patients had CMML type 1 and 4 (10%) had CMML type 2. Eight (20%) patients had cytogenetic abnormalities (+8 (n=2), 11q (n=1), -4 (n=2), -7 (n=2), -5q (n=1)). Seven patients (18%) had previously required blood transfusions. The distribution of patients according to the IPSS was 25 (64%) low risk, 10 (26%) intermediate-1 risk, 4 (10%) intermediate-2 risk and no patient had high-risk IPSS. The distribution according to the score proposed by Kantarjian et al was: 22 patients (56%) low risk, 4 (10%) intermediate-1 risk, 6 (15%) intermediate-2 risk and 7 (18%) high risk. Four patients (10%) of the 39 patients progressed to acute leukemia. Of these, 3 had cytogenetic abnormalities and all showed intermediate-1 IPSS while 3 had a score intermediate-2 or high risk under the new score. With a mean of 23 months (0-84), 19 patients (49%) survived, 17 (43%) have died and over 3 their status is unknown. In 60% the cause of death was secondary to CMML. The medians and ranges of survival (months) of patients stratified by IPSS were as follows: 16 (0-75) in the low risk group, 22 (0-52) in the intermediate-1, 5 (2-6) in the intermediate-2. Applying the new score they were: 22 (0-75) in the low risk, 21 (12-30) in intermediate-1, 16 (0-24) in the intermediate-2 and 5 (2 - 24) in high-risk. Conclusions: The CMML affects elderly patients. Their clinical and biological features are heterogeneous. A minority presents cytogenetic abnormalities. While the small number of patients in this serie, the new prognostic score seems to be better than the IPSS stratifying patients into different risk groups.

1267

TRANSFUSIONS IN HOME CARE PATIENTS WITH MYELODYSPLASTIC SYNDROMES

P Niscola,[1] A Tendas,[1] M Trawinska,[1] M Giovannini,[1] L Cupelli,[1] M Palombi,[1] G Brunetti,[2] A Perrotti,[1] C Cartoni,[2] F Efficace,[3] P De Fabritiis,[1] F Mandelli[4]
[1]*S. Eugenio Hospital, Hematology, Rome, Italy*
[2]*Division of Hematology, Policlinico Umberto I, University La Sapienza, Rome, Italy;*
[3]*Health Outcomes Research Unit, GIMEMA Data Center, Rome, Italy;*
[4]*Italian Association Against Leukemias, Lymphomas, and Myeloma, Rome, Italy*

Background. The majority of patients diagnosed with myelodysplastic syndromes (MDS) are individuals of older age often afflicted by several comorbid conditions for which they are generally unsuitable for disease-modifyng treatments. The treatment of anemia is an essential part of the global management of most MDS patients. In erythropoietin-failed patients or in those unsuitable for this option, red blood cell (RBC) transfusions remain the only available measure. For this category of frail patients and for their families, home care (HC) represent a valuable option allowing to preserve the patient's quality of life and to avoid useless hospital admissions. *Aims*. To evaluate the management of RBC transfusions at home during the last two years. Methods. There were 68 MDS (27 male) with a median age of 86 (69 - 98) years. Patients were followed at home for a mean of 8.8 (1 - 24) months. Therapy with erythropoietin stimulating agents was used in 41 pts (60%). *Results*. Overall, 55 (81%) patients required transfusions, for a total of 927 RBC units; RBC units / transfused pt were a median of 10 (1-68). RBC units monthly requirement in transfused pts were a median of 1.5 (0.05-5.7). A lower baseline Hb concentration and the time for the primary diagnosis of MDS strongly correlated with the number of transfused RBC units. All transfusions were safely administered at home without any untoward effect. *Conclusions*. QoL is a particularly important issue for older MDS patients. With this regard, management of chronic patients requiring multiple and repeated admissions to receive RBC transfusions may be a concern for the affected individual and for its family. Our experience demonstrated that the administration of RBC transfusion at home is a feasible, reliable and effective in our older MDS patient, avoiding social

and economic costs due to an inappropriate removal from his domestic environment. In conclusion, in our experience domiciliary management of RBC transfusions represented an important added value to home care program, allowing the best humanization of this procedure for our patients.

1268

EVALUATION OF CIRCULATING COLONY-FORMING PROGENITOR CELLS AND TREATMENT RESPONSES IN PATIENTS WITH APLASTIC ANEMIA: A SINGLE CENTER EXPERIENCE

W Fuereder, A Paulitsch-Buckingham, W Sperr, W Rabitsch, E Jaeger, P Valent

Medical University Vienna, Vienna, Austria

Aplastic anemia (AA) is a life-threatening hematopoietic disorder characterized by bone marrow failure with *empty* marrow and peripheral pancytopenia. Standard treatments include hematopoietic stem cell transplantation (SCT) and immunotherapy (IST) with antithymocyte globulin (ATG) and cyclosporin-A (CSA). However, not all patients can be cured with SCT or ATG/CSA. Only a few, more or less robust, prognostic factors predicting long term relapse-free survival in AA are available. We have retrospectively analyzed a cohort of fifty patients with AA (27 males and 23 females) treated in our department between 1987 and 2007. The median age was 37 years (range 14-70 years). Fourty two patients received ATG/CSA, and 7 were transplanted upfront using a matched sibling donor. One patient was treated with CSA and growth factors only. In the group of transplanted patients, one patient died from multi-organ failure and 6 are alive and are in continuous complete remission (CR). Of the 43 patients receiving ATG/CSA or CSA, 28 patients (65%) achieved a CR including the one patient who was only treated with CSA, 7 (16%) entered a partial remission (PR), and 8 patients (19%) did not respond to treatment. Eight patients (19%) relapsed after IST. To evaluate possible prognostic factors predicting responses to IST, patient age, karyotype, existence of PNH clones, pre-treatment blood counts, progenitor cell counts, and outcome were evaluated. In this analysis, we found that in IST-treated patients with AA, the numbers of colony-forming progenitor cells increased but remained below the normal range of healthy controls in all patients. We also found that the numbers of granulocyte-macrophage colony-forming progenitor cells (CFU-GM) increased during successful therapy and were higher in those who underwent SCT than in patients who received IST ($p<0.05$). However, we were unable to detect a prognostic risk factor that would predict long term responses or relapse-free survival in these patients, which may be because of the low number of patients examined. In summary our data show that an increase in the numbers of circulating colony-forming progenitor cells is associated with regeneration of bone marrow function in AA patients successfully treated with SCT or IST, although normal CFU levels are not reached. Prospective studies with more patients are required to define prognostic factors predicting relapse-free survival in these patients.

1269

CYTOLOGICAL FINDINGS OF PAGET'S DISEASE DIAGNOSED BY BONE MARROW ASPIRATION

S Mavropoulou, Z Tatsiou, G Xanthopoulidis, D Papadopoulou, T Leptidou, A Goutzouvelidis

General Hospital Xanthi, Xanthi, Greece

Paget's disease is estimated to occur in 1-3% of individuals older than 45-55 years and in up to 10% in persons older than 80 years. Because early diagnosis and treatment is important, a range of specific imaging and laboratory studies are essential. Clinical diagnosis often is difficult and a bone biopsy may be needed, especially to exclude a metastatic bone disease. Only one case of Paget's bone disease initially diagnosed by bone marrow aspiration has been reported in english literature. We report the case of a 53-year-old man who presented with vertigo and hypertension of two days duration. On x-ray and CT-scan of the skull osteoblastic bone lesions were noted and a bone scintiscan followed which revealed a multifocal osteoblastic activity with lesions on the skull, vertebrae, pelvis and long bones of the lower leg. A bone marrow aspiration was performed and in the aspirate smears were identified multiple osteoblasts mainly in small aggregates and few osteoclasts, findings which were consistent with Paget's disease. The core biopsy showed an abnormal bony architecture with osteolysis accompanied by osteoblastic bone formation with an increase in the number and activity of the osteoblasts and replacement of the normal marrow with fibrous tissue, findings which confirmed the diagnosis of Paget's disease. In conclusion, we describe the second case of Paget's disease diagnosed by bone marrow aspiration which proves to be a relatively simple, cost-effective, and accurate method in the diagnosis of a clinically suspected disease, confirm the radiological impression and may exclude the presence of a malignant process.

1270

5-AZACITIDINE IN PATIENTS WITH MYELODYSPLASIA AND ACUTE MYELOID LEUKEMIA: A SINGLE CENTRE EXPERIENCE

I Capodanno, P Avanzini, F Merli

Arcispedale Santa Maria Nuova, Reggio Emilia, Italy

Background. Hypometilating agents have recently been shown to prolong overall survival and improve quality of life in patients either with INT-2 and high IPSS risk myelodysplasia (MDS) or with low bone marrow blast count acute myeloid leukemia (AML). Aims. The aim of our retrospective analysis was to evaluate the efficacy and the feasibility of 5-azacitidine therapy in a cohort of patients for whom no alternative therapy is available. Methods. Since September 2008 we have been treating with 5-azacitidine 33 patients affected by acute myeloid leukemia (18 patients), MDS (13 patients) or chronic myelomonocytic leukemia (2 patients). The median age of patients at treatment starting time was 70 years (range: 51-82). Azacitidine was administered subcutaneously (75 $mg/m^2/d$) for 7 days of every 28-day cycle until loss of response or disease progression. Patients received a median number of 6.5 cycles of therapy (range 1-24). According to International Working Group MDS and LMA criteria, in the overall study population we evaluated overall improvement (CR + PR + HI), the best response obtained and adverse events. In the subgroup of patients who received at least 6 cycles of therapy (13 patients) we also evaluated overall survival (OS) and progression free survival (PFS). *Results*. In the AML cohort, after a median number of 4.6 cycles (range 1-17), we observed a complete response in 5% of patients, a hematological improvement (HI) in 22% of patients, a stable disease (SD) in 39% of patients and a lack of response in 33% of patients. In the MDS cohort, after a median number of 8.5 cycles (range 2-24), we observed a complete response (CR) (including a complete cytogenetic response) in 31% of patients, a partial response (PR) in 7,5% of patients, a hematological improvement in 46.5% of patients and a stable disease in 15% of patients. The overall improvement (CR + PR + HI) was 28% in AML cohort and 84.5% in MDS cohort. In the CMML cohort, after a median number of 10.5 cycles (range 9-12), we observed a partial response in 50% of patients and a hematological improvement in 50% of patients. In the subgroup of patients who received at least six cycles of therapy, the overall survival was 14 months and the progression free survival was 11.5 months. In the overall study population, only two patients (6%) discontinued treatment as a result of adverse events. *Conclusions*. The limited number of cases and the short period of follow-up don't allow us to evaluate overall survival and progression free survival in the whole study population. In the subgroup of patients who received at least six cycles of therapy, we observed that 5-azacitidine plays an important role in treatment of MDS and low bone marrow blast counts AML, particularly with prolonged OS and good safety profile. Further trials should assess the number of cycles required for treatment, the role of hypometilating agents in low-risk MDS and in patients with AML and a bone marrow blasts counts > 30%

1271

THE IMPORTANCE OF COMPLEX BLOOD COUNT ASSESSMENT FOR DIAGNOSTICS AND PROGNOSIS IN MDS PATIENTS

J Vondráková,[1] J Zapletalová,[2] J Indráková,[1] K Indrák[1]

[1]*University Hospital, Olomouc, Czech Republic*

[2]*Institute of Medical Biophysic, Medical Faculty, Palacky University, Olomouc, Olomouc, Czech Republic*

Background. The myelodysplastic syndrome (MDS) manifests as mono-, bi- or pancytopenia in peripheral blood and therefore the full blood count (CBC) play a key role in its diagnostics and diferential diagnostics. The careful evaluation of all parametres of blood count can contribute to fast estimation of MDS prognosis. Aims: The goal of retrospective analysis of 100 MDS patients examined within the period from 2000 - 2008 was evaluation of initial parametres of blood count for the risk of leukemia development and overall survival (OS). Methods: Clinical and laboratory data at diagnosis were analysed to assess the prognosis and the risk of leukemia development, were observed the course of disease and overall survival. The cohort consited of 100 patients (pts), 51 males

and 49 females (ratio 1:1), the age was 28 - 90 year (median 65 years). Results:According FAB clasification was OS (mean and median) for RA 68,7 months (median unobtained), for RARS 39,2 and 52,7 months, for RAEB 22,9 and 13,6 months (p=0,0003). The mean time to AML development was 77,6 months for RA, 50,5 months for RARS and for RAEB 17,4 (median 10,3), p<0,0001. 41% pts transformed to AML. According WHO 2001 classification to AML transformed: 1 pt from 8 RARS, 1 pt from 8 5q- syndrome, 5 pts from 30 RCMD, 3 pts from 8 RCMD-RS, 13 pts from 20 RAEB-I, 18 pts from 23 RAEB-II. 58 pts died - the reason was: AML - 25 pts (43%), infection - 6 pts (10%), 1pt brain haemorrhage, 1 pt myocardial infarction, reason unknown was in 25 pts (43%). Initial parameters of blood count were: Hb 44 - 149 g/l (Me 93), leucocytes 1 - 30.10^9/l (Me 3,5), neutrophiles 0,1 - 17.10^9/l (Me 1,7), lymfocytes 0 - 5.10^9/l (Me 1,3), MCV 77 - 125 fl (Me 96), trombocytes 3 - 702.10^9/l (Me 113), plt mass (MPVx trombocytes) 0 - 6,8 ml/l (Me 1,6), peripheral blasts 0 - 12 % (Me 0). Statistically significant unfavourable prognostic factors for OS showed trombopenia, neutropenia, presence of blast cells in peripheral blood, peripheral blast cells ≥ 5% and low platelet mass. The favourable factors were macrocytosis and lymfopenia. The level of hemoglobin (Hb), MPV and RDW were not shown as statistically significant for the prognosis. The risk factors of leukemia development were trombopenia, low or normal platelet mass, normal or low MCV, presence of blast cells in peripheral blood, neutropenia, lymphocytosis. The another parametres of CBC (Hb, RDW, MPV) were not statistically significant for leukemia development in our group. Summary/conclusion: This analysis confirms the importance of CBC not only as a basic diagnostic laboratory test but also as a prognostic indicator for MDS patients.

1272

DURABLE ERYTHROID AND CYTOGENETIC RESPONSE AFTER SHORT-TERM LENALIDOMIDE TREATMENT IN TWO PATIENTS WITH MYELODYSPLASIA AND DEL(5Q)

I Capodanno, P Avanzini, F Franchi, F Merli
Arcispedale Santa Maria Nuova, Reggio Emilia, Italy

Background . Lenalidomide is a immunomodulatory drug that has an impressive effect on myelodysplasia with deletion of the long arm of chromosome 5, leading to transfusion-independence, a complete erythroid and cytogenetic response in over 65% of cases. Aims. In this report we describe unexpected erythroid and cytogenetic responses in two del(5q) MDS patients treated with lenalidomide for less than 12 weeks. Little is known about these types of responses. Methods. Since November 2008 we have been treating two patients with myelodysplasia (MDS) and a deletion of the long arm of chromosome 5 [del(5q)] with lenalidomide. The monthly transfusion requirement before starting treatment was 6 packed RBC units. Lenalidomide was started at a full dose (10 mg/day for 21 days every 4 weeks). Results. Patient 1 received a diagnosis of *5q- syndrome*. She stopped therapy after only 10 days due to severe agitation and panic attacks: however, one month later we observed a progressive reduction of transfusion need. Two months later, the patient was transfusion-free and the response had been ongoing for 6 months; she obtained a very good partial cytogenetic response. After 6 months the anaemia worsened again; we started lenalidomide 10 mg/day, but after 15 days the therapy was stopped due to the same side effects. Forty days later, we observed transfusion-independence for another 6 months, and a very good partial cytogenetic response. When patient's condition worsened again, she was treated with lenalidomide 10 mg on alternative days with a better tolerance. After the first cycle of therapy she presented the same side effects. Again the karyotype analysis showed a very good partial cytogenetic response. In Patient 2 the morphologic analysis was compatible with RAEB-1 and the cytogenetic analysis showed a [del(16)(q22)] together with del (5q). Lenalidomide was stopped after 15 days due to renal impairment, cardiopulmonary and cardiac failure; she was then given only palliative therapy, but four weeks after she achieved a complete erythroid response and remained transfusion-free for one year. In January 2010 the patient worsened and started Lenalidomide again (10 mg/day for 21 days every 4 weeks) with good tolerance, a complete hematologic response and a very good partial cytogenetic response. In these two patients, after a very short treatment with lenalidomide we observed a complete erythroid response and a very good partial cytogenetic response. The median time to achieve the response was 6 weeks. Transfusion-independence was durable (24 and 38 weeks respectively). One patient experienced grade III hematologic toxicity during the first cycle of therapy; despite this, we did not observe severe infectious nor hemorrhagic complications. Conclusion. We observed unexpected effects of lenalidomide in myelodysplastic patients with del(5q) and a low-int1 IPSS risk who were treated for a very short period; additionally, this response was observed again at least twice when treatment was begun again: although these patients obviously represent only selected cases, the good erythroid and cytogenetic responses suggest that some patients with MDS and del(5q) may benefit from lenalidomide treatment even if this must be discontinued.

1273

INTERSTITIAL LUNG DISEASE: UNCOMMON BUT POTENTIALLY SEVERE EFFECT OF HYPOMETHYLATING AGENTS

P Cougoul, G Prevot, K Delavigne, T Comont, D Adoue, O Beyne-Rauzy
Purpan Universitary Hospital, Toulouse, France

Background. Hypomethylating agents represent gold standard therapy in high risk myelodysplastic syndromes (MDS) not eligible for intensive chemotherapy or stem cell transplantation. Since drug approval, Azacitidine in USA and Europe, and Decitabine in USA, 3 cases of interstitial lung disease were published, two after treatment with Azacitidine (1, 2) and one after Decitabine therapy (3). Purpose: we report three new cases of interstitial lung disease (ILD) involving patients treated with hypomethylating agents for high risk myelodysplastic syndromes (MDS). Cases: Case 1 70 yrs old man, progressive dyspnea occurred after 12 cycles of treatment, chest X ray and tomodensitometry showed interstitial lung disease, diagnosis was confirmed by bronchioloalveolar liquid analysis. Treatment was discontinued. Lung function recovered within few months. Case 2 76 yrs old woman, fever and interstitial lung disease occurred after 6 cycles of treatment infectious causes were excluded. After drug discontinuation and corticosteroid therapy lung status improvement was observed. Case 3 76 yrs old man, after one cycle of treatment while anemia was corrected, he developed dyspnea due to ILD. Drug discontinuation was performed and lung function was recovered. *Conclusions*. Between 2007 and 2010 three cases of ILD associated with hypomethylating agents were published. Clinical presentation includes cough, dyspnea, and less commonly fever. Risk factors of lung interstitial disease associated with hypomethylating agents remain unknown as well as the possibility to use the other member of this therapeutic class after such reaction. Lung function evolution is often favorable after drug discontinuation. Corticosteroid therapy could be usefull. In our center approximately 150 patients received this treatment during the same period so estimated prevalence of this effect is 2%. Larger exposure to drug reveals new uncommon adverse events. In one patient Decitabine was used without lung fibrosis relapse.

[5]*Internal Medicine Department, Kayseri, Turkey*

Therapy-related myeloid neoplasms (t-MN) account for approximately 10% to 20% of all cases of AML, MDS, and MDS/MPN. Topoisomerase-II inhibitors significantly associated with an increased risk of AML/MDS. Anthracycline-containing chemotherapy is currently the gold standard in breast cancer patients. In our study, we evaluated peripheral blood smear samples and hemogram values in breast cancer patients, receiving adjuvant anthracycline regimen that are in remission. Material and method. The patients, receiving anthracycline based adju-

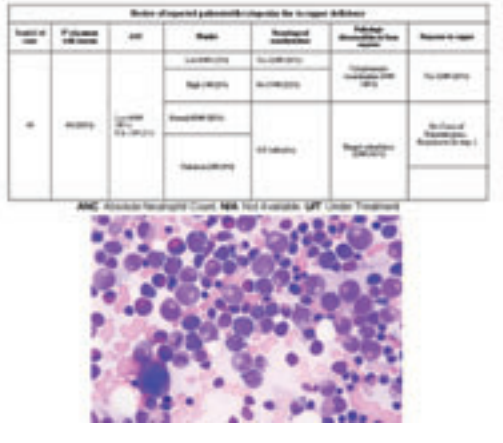
vant chemotherapy treatment were evaluated. A total of 78 patients from Kayseri Research and Training Hospital and Mersin State Hospital were enrolled in the study. Their adjuvant treatments had been completed at least 18 months before. No patient had either chronic or infectious diseases. Patients with abnormal ferritin, vitamin B12 or folate levels were excluded from the study. Results. Two patients complained of anemia (2,2%) (Hb<11mg/dl); leucopenia was observed in seven patients (7,7%) (Leukocyte<4000/mm3); thrombocytopenia was observed in four patients (4,4%) (PLT< 150.000/mm3). It was established that ovalomacrocytes were 14%, macrocytes 37%, acanthocytes 1%, stomatocytes 12%, teardrops 12% , nucleated erythrocytes 1%, basophilic stippling 14% and Howell-Jolly bodies 1%. There were 38% hypo-granulation, 26% Pelger-Huet abnormality, 20% hypersegmentation, 8% immature granulocytes and 6% blasts. We have established 50% of giant platelets and 19% of platelets hypogranulation. Discussion. According to the peripheral blood smear assessments of our study, we suggest that breast cancer patients should be evaluated for MDS at the early stage, starting from Month 18, even if the automated blood counts are normal.

1275

PATIENT WITH COPPER DEFICIENCY MIMICKING MYELODYSPLASTIC SYNDROME (MDS)

JM Bosch Benitez, M Marrero, V Peri, M Tapia, F Fdez, M Caballero, S Guedes, M Losada, J Glez-Sanmiguel, J Ruano, S Soler, R Fdez, J Diaz Cremades
Hospital Insular, Las Palmas, Spain

Myelodysplastic syndromes (MDS)are a group of heterogenous clonal stem cell disorders characherized by variable degree of cytopenias, cytogenetic abnormalities and evolution to acute myeloid leukemia. I n the low risk categories of MDS without cytogenetic abnormalities diagnosis relies on morphology and exclusion of other possible causes of cytopenias such as Vit B12 or folate deficiency. Copper deficiency is ussualy not taken in account in the study of a possible MDS. , several cases of bone marrow failure due to its deficiency have been reported. We present a case of Copper deficiency mimicking MDS. Case report and methods A 65 years old male with anemia (Hb=59gr/L VCM=94) and severe neutropenia (WBC=1.1X10^9/L, neutrophils=320/mm^3) and normal platelet levels was seen at our institution. The patient had progressive gait disturbance. A neurological exam was consistent with subacute combined degeneration as seen in Vit. B12 deficiency. Serum levels of B12, folate and ferritin were in the normal range. A bone marow exam disclosed dysplastic features in granulocyte and erythroid lines with a prominent vacuolization of progenitors of both lines(Picture 1) and 16% ring sideroblasts. A standard cytogenetic analysis did not show any clonal abnormality and FiSH was also negative for del 5q, monosomy 7; trisomy 8 and del 20q. A presumptive diagnosis of MDS refractory cytopenia with multilineage dysplasia of the WHO classification was established. The patient was treated with growth factors with anemia improvement but neutropenia persisted. Due to the vacuolization of marrow progenitors and the presence of ring sideroblasts Copper, Zinc and lead levels were determined.



On two separate samples copper was very low <9 μg/dl (80-155) and Zinc was increased 239μ g/dl (60-150).The patient has just started oral copper sulfate therapy 3mg 3 times daily *Discussion*. To our knowledge 49 patients have been described to date, including ours, and most of them had also neuropathy, vacuolated marrow progenitors and many of them ring sideroblasts (Table 1). Copper has a role in iron absortion, transfer from the reticuloendothelial cells and cytochrome oxidase activity in mitochondria, all possible mechanism for the anemia associated with its deficiency.. Copper deficiency is ussualy seen in malnourished patients, parenteral nutrition and after gastrectomy. In some cases, like ours, no cause could be found. Our patient , like others, had hyperzyncemia without known exposure, a fact believed by some authors to be an epiphenomenon. Zinc induces metallothionin production in enterocytes for which copper has a great affinity displacing Zinc. Copper is therefore acumulated in gastrointestinal tract and being eliminated with cell shedding. All the patients described normalized blood counts with copper therapy or Zinc withdrawall but neurological symptoms did not improve. Our patient has just begun treatment to evaluate response but the clinical, morphology and serum levels of Copper and Zinc are concordant with other cases described. Some of the patients described in the literature were detected before a bone marrow trasplant. We and others suggest that Copper deficiency should be routinely ruled out before establishing a diagnosis of MDS in the low risk categories specially if they have vacuolated marrow progenitors, ring sideroblasts or neuropathy to avoid potentially harmful therapies.

1276

NEUTROPENIA IN MYELODYSPLASTIC SYNDROMES BASED ON THE DATA OF A SINGLE CENTER ROMANIAN REGISTRY

O Georgescu, A Tatic, I Ursuleac, D Vasilache, V Moraru, R Gologan
Fundeni Clinical Institute, Bucharest, Romania

Background. The myelodysplastic syndromes (MDS) are a group of clonal disorders with an annual incidence of 4 cases/100000 in the general population. Neutropenia is a common cytopenia in MDS. *Aims.* The purpose of this study is to evaluate the incidence of neutropenia in MDS and the overall survival of these patients in our department. Methods: this retrospective, epidemiological study incudes 560 patients diagnosed and treated in our department during 1982-2010. Among them 184 cases with neutropenia were found. The registration form was kindly provided by the MDS Foundation (USA) and the diagnosis of MDS was based on well-accepted FAB minimal diagnosis criteria. Neutropenia was dfined as a neutrophils count < 1500/dL and was divided into three subgroups of severity (mild 1500-1100/dL, moderate 1000-500/dL, severe <500/dL). The parameters age, sex, rural/urban location, temporal trend and distribution by FAB subtypes were analyzed comparatively in neutropenic and nonneutropenic MDS cases. We also analyzed the complications appeared and the evolution of the disease. Results: the lot includes 184 patients (89 females and 95 males) with an average age of 63 years. The distribution by rural/urban location was grater for urban (114 patients) than for rural location (70 patients). According to FAB criteria, the distribution of neutropenia in MDS patients was: 12.50% RA, 8.69% RARS, 37.50% RAEB, 13.04% RAEB-T, 3.81% CMML and 24.45% U-MDS. Regarding the severity of neutropenia we found 32.06% patients with neutrophils between 1500-1100/dL, 36.41% cases between 1000-500/dL and 31.52% under 500/dL. Severe infectious events were found in 31.60% patients; the site of infection was commonly pulmonary (42 cases), cutaneous (5 cases) and digestive tract (11 cases). 11 patients required intensive unit care transfers due to acute respiratory distress syndrome, and 10 died. Overall mortality rate was 15%. *Conclusions*. Neutropenia in MDS is a challenging finding because, when severe, it is an important cause of death by life-threatening infections. The interest in MDS-related neutropenia increases when we are thinking to the economic aspects of its management.

1277

SAFETY AND EFFICACY OF COMBINATION THERAPY WITH DEFERASIROX AND DEFEROXAMINE FOR MANAGEMENT OF IRON OVERLOAD IN MULTITRANSFUSED HEPATOPATIC PATIENT WITH MYELODYSPLASTIC SYNDROME: A CASE REPORT

C Cerchione,[1] G Cerciello,[2] R Della Pepa,[2] R Ciancia,[1] M Matarazzo,[1] F Alfinito,[2] F Pane[2]
[1]*Federico II, Napoli, Italy*
[2]*Dipartimento di Biochimica e Biotecnologie Mediche - Federico II, Napoli, Italy*

Myelodysplastic Syndromes (MDS) are a heterogeneous group of haematopoietic stem cell disorders characterized by cytopenia and hyperplastic bone marrow: in this context red blood cell transfusions represent a life-saving treatment for patients with chronic anaemia. Iron overload is the consequence of a long term transfusion therapy thus it

is necessary to prevent this complication by applying a correct iron chelation therapy. Deferasirox is a well tolerated oral iron chelator drug that produces relevant benefits but, because of its potential hepatotoxicity, it is not recommended for patient with preexisting hepatic diseases. Here we report the case of a 62-year-old man affected by HCV positive cirrhosis and MDS (Refractory Anaemia, IPSS 0.5). Recombinant Erythropoietin therapy was ineffective and a RBC transfusion program was started (2 blood package pro month). At a ferritin serum concentration near 700 ng/mL iron chelation therapy with deferoxamine was proposed in consideration of patient hepatic disease: compliance to subcutaneous injection was very bad, transfusion need increased exponentially until to 2 blood package pro week and serum ferritin concentration reached, in 12 months, the level of 6198 ng/mL. Since high levels of ferritin correlate with a very dangerous condition for hepatic cells, therapy with deferasirox was started but at reduced dosage (10 mg/kg/die). Before treatment start an accurate study of hepatic, renal and cardiac functions was performed. After three months serum ferritin concentration was not modified as well as other biochemical parameters, then deferasirox dosage was gradually increased reaching 30 mg/kg/die after two months and no liver damage was observed. After five months of iron chelation therapy with deferasirox at full dosage serum ferritin concentration remained very high (5098 ng/mL). Then, considering all risks related to transfusion dependent secondary hemochromatosis, with patient informed consent, a combined iron chelation therapy with deferasirox (30 mg/kg/die) and deferoxamine (2 g/day for 5 days/week) was established and after 3 months serum ferritin concentration lowered to 3000 ng/mL. At the present time, the patient receives 2 RBC package pro week and, after two years of combined iron chelation therapy, serum ferritin concentration is at a stable level nearby under 3000 ng/mL. No serious adverse event has been observed. In conclusion we suggest that combined therapy with deferasirox and deferoxamine could be considered a safe and useful therapeutic choice in the management of critical transfusion dependent iron overload in old MDS patients with hepatic disease.

1278

MYELODYSPLASTIC SYNDROMES AND CHRONIC MYELOMONOCYTIC LEUKEMIA (ABOUT 23 CASES)

S Jennane,[1] EM Mahtat,[1] M Bouaouad,[1] A Raïssi,[2] K Doghmi,[1] M Mikdame[1]

[1]*Hôpital Militaire d'Instruction Mohammed V, Rabat, Morocco*
[2]*Hôpital Militaire d'Istruction Mohammed V, Rabat, Morocco*

Background. Myelodysplastic syndromes (MDS) are a set of oligoclonal disorders of hematopoietic stem cells characterized by ineffective hematopoiesis that manifest clinically as anemia, neutropenia, and/or thrombocytopenia of variable severity. Since 2001, the WHO classification considers chronic myelomonocytic leukemia (CMML) as an intermediate entity between Myelodysplastic and Myelproliferative syndromes. Aims. The aim of this study is to report the experience of the clinical hematology department, of the Military Hospital Mohammed V, in MDS and CMML. Patients and methods. This is a retrospective study including all patients who consulted for MDS or CMML since the creation of clinical hematology department in 2006 until December 2010. The patients with MDS were classified according to 2008 WHO classification. Prognostic scores used are the IPSS and WPSS (CMML excluded). Response criteria adopted are those of: modified IWG Criteria response in myelodysplasia (2006). Results. Twenty-three patients are included; the median age at diagnosis is 63 years (32 to 98 years). The sex ratio [H / F] is 1.55. The distribution of the twenty patients with MDS according to WHO classification 2008 is as follows: 1 refractory anemia (RA), 3 refractory anemia with ringed sideroblasts (RARS), 8 refractory cytopenia with multilineage dysplasia (RCMD), 1 RCMD and ring sideroblasts, 4 refractory anemia with excess blasts type 1 (RAEB1) and 3 RAEB2. In addition to two patients with CMML1 and one patient with a CMML2. Seventeen patients of twenty three had a karyotype (74%), which is normal in 88% and intermediate risk in 12% cases. Concerning the IPSS score: 29.4% are classified as low risk, 41.2% as intermediate 1 risk and 29.4% as intermediate 2 risk. 14 patients are included in the WPSS score: 50% are low risk, 14% intermediate risk and 35.7% high risk. 6 patients benefits from 3 to 12 cures of Azacitidine with achieving a complete remission in 2 cases, partial remission in 2 cases and no response in 2 cases. 8 patients received erythropoietin (EPO) alone (5 cases) or associated with G-CSF (2 cases). With achieving transfusion independence in 62.5% and reduced transfusion requirements in 37.5% of cases. The therapeutic abstention was indicated in 8 patients, 50% had never been transfused and 50% are under transfusion support. The transformation to AML occurred in 3 patients (at 18 months, 4 months and 2 months). During the study period 5 patients died: 2 by transformation, 2 by sepsis and one patient by hemorrhagic shock. Conclusions. The management of MDS has been shaken in recent years by the emergence of new therapies. The availability of Azacitidine in Morocco is recent and its use still limited because of its high cost and low coverage of health insurance in the country. This study is one of the first to have evaluated Azacitidine in Morocco.

1279

MYELODYSPLASTIC SYNDROMES WITH DEL(5Q) AND JAK2 V617F MUTATION: A CASE OF HEMATOLOGIC RESPONSE TO LENALIDOMIDE THERAPY

R Della Pepa, C Cerchione, G Cerciello, B Izzo, G Muccioli Casadei, F Alfinito, F Pane

Università degli Studi di Napoli Federico II, Napoli, Italy

Deletion of long arm of chromosome 5 (del5q) is one of the most common cytogenetic abnormalities in Myelodysplastic Syndromes (MDS). The JAK-2 V617F somatic mutation is the molecular marker most frequently detected in the BCR/ABL negative myeloproliferative neoplasms (MPN). Here we describe simultaneous occurrence of JAK-2 V617F mutation and del(5q) in a case of MDS successfully treated with Lenalidomide. A 62-year-old woman had been treated with hydroxyurea for 5 years because of a diagnosis of Essential Thrombocytemia (ET) before admission to our hospital for normocytic anemia (Hb 9,5 g/dL) thrombocytosis (PLT 853x10V/L) and mild leucopenia (WBC 2,9x10^9/L). Bone marrow aspirate showed increased number of megakaryocytes with dysplastic features, dyserythropoiesis and dysgranulopoiesis, no ringed sideroblast was observed. Cytogenetic analysis performed by Fluorescence in Situ Hybridation (FISH) revealed an isolated interstitial deletion of the long arm of the chromosome 5. Polymerase Chain Reaction (PCR) was positive for JAK-2 V617F mutation. Treatment with Lenalidomide (10mg/day on days 1 through 21 of repeated 28 days cycles) was started after red blood cell transfusions. After seven cycles a complete recovery of hemoglobin and platelet concentration was obtained (Hb 13 g/dL, PLT 180x10^9/L), while worsened leucopenia needed supplementation with growth factor. Several authors have already reported the presence of del(5q) in MPN as well as MDS with JAK 2 V617F somatic mutation, furthermore some cases of ET with concurrent presence of del(5q) and JAK 2 mutation have been referred and finally Ingram and coll. have described six cases of MDS arboring del(5q) and JAK2 alteration. There is not yet an univocal evaluation of the prognostic significance concerning the association of JAK 2 mutation and del(5q) in MDS or in MPN, in future probably new entities will be identified with the more extensive application of molecular investigation. Here we underline the very good response of this patient to Lenalidomide therapy with normalization of thrombocytosis, previous resistant to the Hydroxyurea administration, and recovery of hemoglobin concentration with no further need of transfusion therapy.

1280

EXTRA-MEDULLARY LOCALIZATION IN HIGH RISK MYELODYSPLASTIC SYNDROMES: A NEW MODALITY OF RELAPSE AFTER THERAPY IN ELDERLY

T Comont, J Moeglin, N Gaudre, P Cougoul, V Demas, K Delavigne, S Ollier, O Beyne-Rauzy

Purpan Universitary Hospital, Toulouse, France

Background: extra-medullary localization in myelodysplastic syndromes (MDS) is a rare complication (1) but represents a pattern of relapse following allogenic bone marrow transplantation in about 20% of acute myeloid leukemia (AML) (2). Features of relapse following hypomethylating agent therapy in high risk MDS involved usually bone marrow leading to AML transformation. Purpose: we report 3 cases of extra-medullary localization following hypomethylating agent treatment in high risk MDS. Cases: Case 1 after 15 cycles of Decitabine, a 73 years old man developed mental impairment including confusion, somnolence and desorientation; Weight loss and disability with falls increased in few days. While blood analysis showed no features of relapse, cerebral fluid analysis revealed massive presence of blasts cells. Case 2 after 14 cycles of Azacitidine, a 72 years old man developed pulmonary symptoms (cough). Biopsy of a tumoral lung lesion was confirmed MDS relapse. Case 3 after 13 cycles of Azacitidine, a 80 years old woman developed diplopia due to ocular muscle impairment. MRI showed tissular lesion of the right caverous sinus. Bone marrow aspira-

tion showed no relapse of RAEB. Massive blasts infiltrate was detected in cerebral fluid analysis. *Conclusions*: extra-medullary localization in high risk MDS is a new modality of relapse following therapy. Diagnosis could be difficult, poor outcome is the rule. Role of hypomethylating agent in this issue should be studied.

IRON CHELATION IN MYELODYSPLASTIC SYNDROMES: A DUAL CENTER EXPERIENCE

S Bacchu,[1] V Sampath,[1] P Dewan,[2] C Conway,[2] S Birdsall,[2] J Kell[2]
[1]*Bristol Childrens Hospital, Bristol, United Kingdom*
[2]*Univeristy Hospital of Wales, Cardiff, United Kingdom*

Background. Iron overload is common in patients with myelodysplastic syndromes (MDS) who are treated with red blood cell (RBC) transfusions. Transfusion dependency is associated with leukemic progression and shorter survival. Guidelines recommend iron chelation therapy for management of iron overload, but little is known about chelation patterns in daily clinical practice. *Aims*. The objective of this dual centre study was to evaluate iron status and management in MDS patients, especially the utilisation of iron chelation therapy and chelation patterns Method. A total of 77 patient records between January 2006 and December 2009 were analysed for this retrospective, cross-sectional, observational study. *Results*. Median age at diagnosis was 75 years. There were no statistically significant differences between chelated and nonchelated patients in terms of International Prognostic Scoring System score(IPSS score). Fifty-three patients had an IPSS score of low/intermediate-1 and hence eligible for assessment of iron chelation. Eighteen patients had received more than 25 RBC units in the past 12 months and therefore were eligible for iron chelation therapy. Medium serum ferritin was 1930μg/L. Eleven patients (61%) did not receive any iron chelation therapy. Their median ferritin was 1930μg/L. Reasons for not receiving iron chelation therapy were refusal (2), malignancy (1), parkinsonism (1), stroke (1) and age (98yrs) (1). No reasons were documented in five patients. Seven patients (39%) received iron chelation therapy with either deferoxamine (1), deferiprone followed by deferasirox (3) and deferiprone (3). Their median ferritin was 2534μg/LNone of the patients on deferiprone had a therapeutic response. *Summary/Conclusions*. Iron chelation therapy may be underutilized in transfusion-dependent MDS patients. This can be reduced by using a combination of clinical judgment, a serum ferritin level >1,000 μg/L and/or two or more RBC transfusions per month for the past year. The key reasons for not initiating iron chelation therapy were related to poor patient prognosis, patient age, and comorbidities. Deferiprone was not an effective iron chelation agent in this study and warrants further study to demonstrate its effectiveness.

1282

THROMBOTIC EVENTS IN DEL(5Q)ASSOCIATED MYELODYSPLASTIC SYNDROMES.

T Comont, K Delavigne, T Challan-Belval, S Ollier, D Adoue,
V Demas, P Cougoul, O Beyne-Rauzy
Purpan Universitary Hospital, Toulouse, France

Background. Thrombocytosis is the hallmark of the *5q-syndrome* but subsequent risk of thrombotic events remains unclear. JAK2 V617 mutation clones and del(5q) in myelodysplastic syndromes could be associated (1). Recent publications suggest that JAK2 and del(5q) arise in discordant clones (2). Whether if thrombotic events could be linked to JAK2 occurrence moreover than del(5q) is an unresolved question. Patients and methods: thrombotic events assessment in a cohort of myelodysplastic syndromes (more than 800 patients) localization, risk factors evaluation (including thrombophilic factors, JAK2), ongoing treatments. Correlations between platelet level, cytogenetic features, treatments of the disease (EPO, lenalidomide) were evaluated. *Results*. 6 thrombotic events occurred in del(5q) associated MDS 2 deep venous thrombosis (DVT), one deep venous thrombosis with pulmonary embolism, 2 intra-abdominal thrombosis and one transient ischemic stroke. Mean age was 70 years (59-85). In 50% of patients thrombosis occurred before the diagnosis of MDS. Risk factors of thrombosis (except thrombocytosis) were JAK2 mutation in 2 cases (1 DVT and 1 intra-abdominal thrombosis), post-surgery period in 1 case and lenalidomide treatment initiation in 2 cases. In the two reminding patients no risk factor was found. During the same period 1 case of DVT and 1 ischemic stroke occurred in non del(5q) MDS. *Conclusions*. Spontaneous risk of thrombosis in del(5q) seems to be higher than in overall MDS population. Some additional risk factors have to be evaluated as JAK2 mutation especially if intra-abdominal thrombosis was observed. Thrombotic risk prevention could be discussed in the field of del(5q) treatment.

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) IN THE CANARY ISLANDS: DESCRIPTION OF NINE CASES

JM Bosch Benitez,[1] V Peri,[1] F Fdez,[1] JM Calvo-Villas,[2] T Molero,[2]
H Luzardo,[2] A Lemes,[2] J Garcia-Talavera,[2] N Hernanz,[2] M Herrera,[2]
M Marrero,[2] M Rios,[2] S De la Iglesia[3]
[1]*Hospital Insular, Las Palmas, Spain*
[2]*Club de Citologia y Citometria, Canary Islands, Spain*
[3]*Hospital Dr. Negrin, Las Palmas, Spain*

PNH is a very rare clonal stem cell disorder due to an acquired mutation of PIG-A gene which causes deficiency of glycosy lphospahatidyli nositol and several proteins linked to it,. Some of these proteins play a central role in protecting cells from the lityc activity of complement, therefore rendering blood cells highly sensitive to complement.. PNH is a chronic disease with predisposition for thrombosis and variable degrees of bone marrow failure. We present the data of 9 patients diagnosed and treated in our community Material and methods . Median age at diagnosis was 48y (33-70), Male/female ratio was 2. Blood counts median were Hb =91gr/L, Plateletes=135x10E9/l and WBC=4.1X10E9/L. Median LDH=1855UI/L (n<247) ,bilirrubin 1,7 mg/dl (N<1.4) and creatinine 1.15mg/dl (N<1.4). All patients, except one with aplastic anemia , had classical PNH. 7 of 9 had moderate to severe quality of life impairment that interfered with laboral and social life due to chronic invalidating fatigue or abdominal pain. 4 cases had one thrombotic episode in different territories: one right leg deep vein thrombosis, one portal vein, one suprahepatic veins and one CNS vein stroke. All patients are since then on oral anticoagulation. 4 cases had chronic renal damage and 2 others experienced acute renal failure during a crisis. Diagnostic was performed by flow citometry analyzing CD16, and CD55 expression in granulocytes and CD55 and CD59 in red cells. 8 of 9 cases had a granulocyte size clone over 50%. Bone marrow cellularity was increased except in the case with aplastic marrow. No cytogenetic abnormalities were detected in any case. All patients received folic acid suplementation and iron if deficiency was detected. 5 cases were transfusion dependent regularly and 2 were ocasionally transfused during an acute attack. Due to the cost of Eculizumab health authorities in our community encouraged the design of a therapeutic guide by hematologists for PNH patients. In summary according to our guide, therapy with eculizumab was indicated in adult patients if they were transfusion dependent or poor quality of life and had a size clone type III>10% with overt hemolysis (LDH>1.5 over normal range) and preserved marrow function (platelets>30.000) . Chronic renal damage (not justified by other causes) or thrombotic episode were by themselves indication for therapy. 7 patients started eculizumab after meningococceal vaccination last year . No adverse reaction was seen during infusion. 3 of the patients became transfusion independent and the rest had a dramatic reduction in transfusion requirements. One patient with chronic renal failure normalized serum creatinine (2.3mg/dl to 1.3) In one patient with breaktrough haemolysis the dose was increased to 1200mg every 2 weeks with good response. No Coombs positive extravascular haemolysis has been observed so far. All patients wether transfusion dependent or not experienced a marked improvement in quality of life Conclusions The prevalence of PNH in our community is 0.43 by 100.000 inhabitants. Clinical data does not differ essentially from other series. Although folow up in patients with eculizumab in our community is too short tolerance end response seems to be excellent. Due to the cost of eculizumab clinical guidelines could help in decision making

DEMOGRAPHIC AND SURVIVAL DATA OF INCIDENT CASES OF MDS/CMML IN MANITOBA DURING 2006-2007: DIFFICULTIES IN RETROSPECTIVE PROGNOSTICATION

R Kumar,[1] J Tompkins,[1] A Ponnampalam,[1] H Khair,[2] G Noonan,[2] C Musuka[3]

[1]*University of Manitoba / CancerCare Manitoba, Winnipeg, Canada*
[2]*CancerCare Manitoba, Winnipeg, Canada*
[3]*Diagnostic Services of Manitoba / University of Manitoba, Winnipeg, Canada*

Background. With the availability of newer, but more expensive therapies for MDS, demographics and prognostic scoring are increasingly important to allocate resources for health planning. We have earlier reported on the Incidence of MDS/CMML in Manitoba during the years 2006-2007 (*Kumar et al Blood 2009; 114: Abstract#245*). This cohort provided us with an opportunity to study prognostic characteristics of this cohort. *Aims*. To study the demographic and prognostic characteristics of MDS patients in Manitoba for health care planning. Methods: After obtaining ethics sanction, the clinical records of all incident cases of MDS/CMML diagnosed during a two year period (2006 and 2007) were retrospectively studied to categorize the subtype according to the WHO classification and determine the prognostic features. The Manitoba Cancer Registry was used to study survival data. Kaplan-Meier (KM) curves were used for estimates of median overall survival. Log rank test was used to compare KM estimates between groups. All analyses were conducted using SAS version 9.1.Last date of follow up was Apr 30, 2010. Results: The newly diagnosed cases of MDS/CMML in the study period of two years consisted of 43 males and 37 females with a median age of 73 yr (range 45-90). Nine patients were <60 yr (11%). The following subtype categories and number of patients were identified: RA- 9; RARS-11; RCMD-22; RCMD-RS- 2; RAEB1- 5; RAEB2- 7; MDS del(5q) -1; MDS-U- 12; MDS/CMML - 7 and MDS/MPD- 4. Bone marrow cytogenetics were available in only 17 patients and could be classified in the following categories: Good risk -10, Intermediate -2, Poor -5. IPSS Score was determined in 17 Pts - Low risk: 5, Int-1: 3; Int-2: 7; High risk: 2. Blood counts at initial diagnosis were available in 75 patients with the following median values: Hb 91g/L (range 55 -140); Platelets $124x10^9$/L (range 5 - 1108); ANC $3.3x10^9$/L (range 0.12 - 31) with ANC < $0.5x10^9$/L in 11%. There was little data on ferritin values and the WPSS scoring was not possible in 65 Pts (81%). The median OS was 14.4 months (95% CI 9.96-25.22). Median OS for females was 12.04 months and 18.40 months for males (difference not significant p= 0.45). *Conclusions*. This retrospective analysis showed a poor OS in the cohort. It could not accurately determine the prognostic group of most patients due to inadequate investigations or records. For population based prognostic scoring, there is a need to create MDS Registries and collect data prospectively.

PNH CLONAL EXPANSION FOLLOWING BONE MARROW TRANSPLANT: CASE REPORT

E Benavides Lopez

Unidad de Cancerologia Hosp Universitario Hernando Moncaleano, Neiva, Colombia

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a chronic and life-threatening hematopoietic stem cell disorder characterized by deficiency of the GPI-anchored complement inhibitory proteins CD55 and CD59 on blood cells. The resulting uncontrolled complement activation is responsible for chronic hemolysis and can lead to serious clinical morbidities including thromboembolism (TE) and chronic kidney disease (CKD), which have been shown to increase risk for mortality. Patients experience debilitating quality of life (QoL) issues, including fatigue, shortness of breath, erectile dysfunction, and abdominal pain; a number of these symptoms have been shown to increase TE risk, thereby increasing risk of mortality. The complement inhibitor, eculizumab, has been shown to reduce the incidence of TE and CKD, and improve survival in PNH patients by inhibiting chronic hemolysis. While bone marrow transplantation (BMT) remains the only potentially curative option for PNH, the risk for substantial morbidities and mortality still exist. In patients with PNH, up to 45% of patients receiving BMT die or develop graft-versus-host disease. *Aims*. Presented here is a case report of a PNH patient whose PNH clone reappeared and expanded following un-related BMT. Case Report: A 39 year-old male patient first presented with PNH symptoms in 2001, with hemolytic anemia, thrombocytopenia, and elevated LDH. He was transfusion dependent beginning in September 2004, at which time he experienced a deep vein thrombosis and was treated with warfarin and prednisolone. PNH diagnosis was made in March 2005, following flow cytometry analysis showing loss of CD55/CD59 expression on granulocytes, monocytes, and lymphocytes (Table 1). In June 2005 he presented with fatigue, *coke-colored* urine, decreased hemoglobin, and a positive Ham's test. With no related donor, 3 compatible umbilical cord blood units were located in New York. He received treatment with fludarabine, melphalan, and thymoglobulin with prophylactic tacrolimus and serolimus. He underwent BMT in September 2007. Post- BMT, he required almost 5 months hospitalization for severe anemia requiring RBC transfusions, infections with urinary focus, and furunculosis. In March 2008, secondary bone marrow failure was detected; he experienced a severe hemolytic crisis with anemia requiring multiple RBC transfusions, leukopenia, indirect hyperbilirubinemia, and high corpuscular volume. The patient described strong abdominal pain, back pain, severe headaches, fatigue at rest, and hematuria. Flow cytometry in July 2008 showed loss of CD55/CD59, indicating reappearance of PNH (Table 1). Due to severe symptomatology, he was placed on eculizumab therapy in July 2009, and experienced sustained hematologic response. He continues therapy with eculizumab, cyclosporine, folic acid, and ferrous fumarate without complications. *Conclusions*. This is a unique case detailing the reappearance and expansion of PNH clones following BMT. Although BMT is considered a potentially curative option in PNH, it is associated with a high risk of mortality and morbidities, and may not be curative in all patients. In light of the improved survival of PNH patients on eculizumab from clinical trials and single-center studies, this case highlights the potential benefits of eculizumab and reinforces the complexity of considering potentially dangerous treatment options such as BMT in PNH patients.

Table 1. Flow Cytometry Before and After BMT

	March 2005	July 2008
% Cells Deficient for CD55		
Granulocytes	22.3%	94.0%
Monocytes	0.56%	NA
Lymphocytes	10.0%	NA
Platelets	NA	90.0%
% Cells Deficient for CD59		
Granulocytes	14.26%	99.0%
Monocytes	2.76%	NA
Lymphocytes	19.96%	NA
Platelets	NA	95.0%

APLASTIC ANEMIA IN CHILDHOOD: 8-YEARS EXPERIENCE AT A SINGLE INSTITUTION

Z Pana,[1] A Tragiannidis,[2] E Hatzipantelis,[2] T Papageorgiou,[2] V Tsotoulidou,[2] I Peristeri,[3] V Kitra,[3] E Goussetis,[3] S Graphakos,[3] F Athanassiadou[2]

[1]*AHEPA General Hospital, Thessaloniki, Greece*
[2]*Pediatric Hematology Oncology Unit, 2nd Pediatric Department, AHEPA Hospital, Thessaloniki, Greece*
[3]*Stem Cell Transplant Unit, Aghia Sophia Children's Hospital, Athens, Greece*

Background. Aplastic anemia (AA) is a rare acquired or inherited syndrome of bone marrow failure and early stem cell deficiency characterized by peripheral pancytopenia, bone marrow hypoplasia, and mild macrocytosis due to stress erythropoiesis. Chemical exposure, medicines, viral infections and immunodeficiencies are the aetiological factors responsible. Immunosuppressive therapy (IST) and allogeneic bone marrow transplantation (BMT) have improved the outcome of AA in childhood, though the best treatment options remain to be established. Aims: Diagnostic evaluation, treatment, short and long term follow up and outcome of children with AA who were hospitalized at a single Pediatric Hematology Oncology Unit. *Materials and Methods*. Retrospective analysis of children with the diagnosis of moderate or severe AA in the last 8 years (aetiological factors, treatment response, and overall survival rates). Results: Seven children were diagnosed with AA with mean age 9.2 years (± 1.6), of which five (71%) were girls. The main initial symptoms were pallor (75%), bleeding with ecchymoses (69%) and mucosal bleeding (46%). At diagnosis, the mean values of WBC, Hb and PLT were $2x10^9$/L, 7.2 g/dL and $21x10^9$/L respectively. Exposure to known etiologic agents was found in 4 children (57%) (recent parvo

B19 infection in 3 children, recent HCV infection in 1 child). One child suffered from inherited AA (Fanconi anemia). Of all the children, two received only supportive treatment (28.6%), while the remaining five (71.4%) received combination therapy with cyclosporin A, anti-thymocyte globulin (ATG) and G-CSF. The response rate to treatment was 28.5%. Mean follow up was 3.8 years. Four out of seven children (57%) underwent finally bone marrow transplantation (75% response). The overall survival rate was 57.1%. *Conclusions*. The course of the disease to recovery is variable one but is similar to that reported in the international literature. The role of etiologic factors and the best treatment options in childhood AA is not fully disambiguating and needs further investigation.

DYSKERATOSIS CONGENITA A POTENTIAL CAUSE OF BONE MARROW FAILURE

P Cougoul, G Prevot, N Chassaigne, K Delavigne, T Comont, S Ollier, D Adoue, O Beyne-Rauzy
Purpan Universitary Hospital, Toulouse, France

Background. Dyskeratosis congenita (DC) is a genetic syndrome including usually abnormal cutaneous pigmentation, nail dystrophy and mucosal leukoplasia. In addition, an increased risk of neoplasia, myeloid hemopathy, organ fibrosis (lung, liver) and dysimmunity is described. Patient survival is strongly impaired by bone marrow failure. Pleomorphic presentation of the disease leads to frequent misdiagnosis. We report the case of a 53 years old man with bone marrow hypoplasia and severe lung fibrosis. The diagnosis of DC was performed and a new TERT (Telomerase reverse transcriptase) mutation was described. Familial history of cirrhosis (brother) and association between bone marrow failure and lung fibrosis were significant parameters to assess the diagnosis. Conclusion: New modality of transmission of DC were recently described. Recessive X-linked (DKC1 mutation) and recessive autosomal form (TERC mutation) were first described. More recently, mutations with regard to telomerase complex's proteins (TERT, NOP10, NHP2) and its steady proteins were reported. These new mutations allow us to explain different clinical pathways and transmission's forms of the disease.

CYCLOSPORINE A MONOTHERAPY IN CHILDREN WITH SEVERE APLASTIC ANEMIA :SINGLE CENTER EGYPTIAN EXPERIENCE

G Mokhtar, A Tantawy, D Ibrahim, M Sallam, O Fetouh
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background. Immune suppression (IS) therapy has provided an opportunity of cure or improvement in the aplastic anemia patients who are not feasible candidates for bone marrow transplantation. Although the combination of cyclosporine A (CSA) and antithymocyte globulin (ATG) is superior to either agent alone, CSA monotherapy is an easily available, safe and cheap (IST) option. These advantages are particularly valuable in developing countries where ATG is frequently not available. *Methods.* In the Hematology Department at Children's Hospital Ain Shams University, 35 patients (24 males and 11 females), with a median age of 8.5 years with severe aplastic anemia (SAA) were prospectively identified and managed with CSA monotherapy at a dose of 6-10 mg/kg/day (divided every 12 hrs) during the period between January 2006 and January 2011. Seven patients(20%) expressed PNH-like clones at diagnosis, 3 patients (8.5%) had non-A, non-B, non-C hepatitis 3-6 weeks before presentation, one patient gave history suggestive of drug toxicity, 5 patients had a preceeding upper respiratory tract infection, and in the remaining patients, no possible cause was identified (idiopathic). *Results.*30 eligible patients giving parental consent were treated with cyclosporine for at least 6 months . After 6 months of therapy, 4 patients (13.3%) achieved complete remission (CR) , 9 patients (30%) achieved partial remission (PR) .After one year of therapy 10 patients(33.3%) achieved CR and 11 (36.7%) remained in PR. Two patients (1.5%) lost follow up and 2 patients (1.5%) died of serious septic and bleeding events before the fourth month. Discontinuation of CSA before the sixth month occurred in one patient for serious neurotoxicity, otherwise, other side effects were modest and easily monitored. Short term steroid therapy was used in frequently transfused alloimmunized children. Hospital admission was more frequent during the first 3 months of IST and was mainly for febrile neutropenia and serious infection .Younger age, shorter interval between diagnosis and treatment, lower monthly requirement of platelets transfusion, higher hemoglobin levels before IST therapy, and, higher bone marrow cellularity were positively associated with response. *Conclusions.* In developing countries where facilities are modest and most patients cannot afford adequate treatment of SAA, CSA monotherapy can provide an available easily monitored immunosuppressive tool for patients with SAA.

1289

IRON CHELATION THERAPY WITH DEFERASIROX IN TRANSFUSION DEPENDENT MYELODYSPLASTIC SYNDROME PATIENTS

M Vasilica, A Tatic, A Bardas
Fundeni Clinical Institute, Bucharest, Romania

Background. The majority of low-intermediate risk patients (pts) with MDS require red blood transfusions, which can result in iron overload and its clinical sequelae. The recent development of a safe and efficient once daily oral iron chelator (Deferasirox, Exjade) made possible regular chelation therapy in transfusion dependent MDS patients. *Methods*. Fifty-nine transfusion dependent IPSS low-intermediate1 risk MDS patients were studied. Baseline characteristics were the following: median age was 67 years (range 25 - 84); 28 were IPSS low risk and 31 Intermediate1; duration of transfusion dependency before treatment was 24 months (12-36) corresponding to 58 (22-72) packed red blood cells transfusions received. Baseline serum ferritin was 2000 ng/ml (1471-3500). Mean duration of transfusions 3.5 years (1-5) MDS therapy include hydroxiuree, anagrelide and growth factors. Patients started treatment with the standard 20 mg/kg Deferasirox dose but dose adjustments on clinical indications were done. *Results*. Over 12 months the mean dose of Deferasirox was 20mg/kg/day, and the mean transfusion rate was 3.4 units/months. The reduction in feritin level was achieved after 3 months of treatment. Hematological improvement by IWG2000 criteria was achieved in 7 pts (11.8%); erythroid response in 5; platelet in 1 and neutrophil in 1. *Conclusions*. In these MDS iron overloaded pts, Deferasirox was generally well tolerated. Serum feritin behavior confirms Deferasirox efficacy. The serum feritin reduction was more evident in the more heavily overloaded population indicating successful iron depletion in this group of patients as clinically requested.

1289a

CAN BLOOD FILM ANALYSIS OF HEALTHY INDIVIDUALS BE USEFUL IN DETECTING EARLY SIGNS OF MYELODYSPLASTIC SYNDROME; A POPULATION BASED STUDY OF 922 FILMS IN THE IRISH POPULATION

T Hyland,[1] M Khan,[1] T McNamee,[2] J Harrington,[2] T Fitzgerald,[3] IJ Perry,[2] MR Cahill[1]
[1]*Cork University Hospital, Cork, Ireland*
[2]*Dept. of Epidemiology, Public Health & HRB Centre for Health & Diet Research, Cork, Ireland*
[3]*Dept. of Epidemiology & Public Health, Cork, Ireland*

Background. Our subjects (aged 45-75+) took part in the SLAN national survey of lifestyle, attitudes and nutrition enrolling 10,364 participants nationwide. Data on the relevant variables were available on 1,191 participants. *Aims.* We aimed to analyse blood films for reproducible evidence of myelodysplasia and haematinic deficiency in a population based cohort of 922 blood films taken from 1,191 subjects participating in a sub-study of the Irish national SLAN survey. *Methods.* We analysed 922 blood films for 19 agreed features of myelodysplasia, B12 deficiency and iron deficiency. We assessed for morphological changes including blasts, red cell stippling, monocytosis, anisopoikilocytosis, hypogranular neutrophils, atypical lymphocytosis and EDTA change. All 922 films were analysed by one observer (Ob 1) and two further observers (Ob 2 & 3) analysed a subset of 52 randomly selected films. 48 films with significant morphological findings were sent to an external morphology expert for validation. *Results.* Most films showed some degree of EDTA change as expected in EDTA blood collected from centres around the country and analysed centrally in Dublin. Evaluation of interobserver variation on 48 abnormal films demonstrated agreement on features such as hypogranular neutrophils and atypical lymphocytes was fair

(Kappa statistic 0.25-0.23) while on Pelger abnormality and anisopoikilocytosis moderate agreement was reached (Kappa 0.45-0.46). *Conclusions*. Evaluation of blood films in a cohort study is difficult as transport times to the laboratory adversely affect film quality. Interobserver concordance on early blood film features is poor - limiting the value of film analysis for early myelodysplastic features. Film analysis for features of haematinic deficiency - the differential for myelodyslastic syndrome was also unsatisfactory.

Table I. This table demonstrates the degree of interobserver concordance for each morphological feature identified.

Morphological Feature	Observer 1 % identified	Observer 2 % identified	Cohen's kappa measure	Agreement strength	P Value
Anisocytosis	0.3	1.7	0.663	Good	0.000
Macrocytosis	20.9	20.9	0.621	Good	0.000
Microcytosis	16.6	14.8	0.407	Moderate	0.01
Anisopoikilocytosis	22.9	29.2	0.457	Moderate	0.01
Fragments	0	6.3	*	poor	*
Hypersegmented Neutrophils	0	0	*	*	*
Hypersegmented Neutrophils	6.3	8.3	0.342	Moderate	0.234
Microcytosis	4.2	2.1	0.464	Moderate	0.063
Duplicate Hemocytes	2.1	0	*	poor	*
Thrombocytopenia	0	0	*	*	*
Thrombocytosis	16.7	23	0.502	Moderate	0.000
Hypogranular Neutrophils	6.3	8.3	0.231	Fair	0.052
Atypical Lymphocytes	12.5	14.6	0.252	Fair	0.111
Hemoglobin	8.3	2.1	0.379	Fair	0.013

*Indicates that a Kappa measure was not given as agreement was considered no better than chance thus no P value was given.

1290

LOW PERCENTAGE OF PERIPHERAL BLOOD DENDRITIC CELLS IN PATIENTS WITH MULTIPLE MYELOMA CORRELATES NEGATIVELY WITH INTERLEUKIN-6 AND BETA-2-MICROGLOBULIN LEVELS

I Micheva, H Varbanov, L Gercheva
University Hospital, Varna, Varna, Bulgaria

Several studies demonstrate the presence of quantitative and functional abnormalities in the dendritic cell subsets in patients with multiple myeloma (MM). The inhibitory effect of IL-6, TGF-β, IL-10 and beta-2-microglobulin is highly suspected. The aim of the study was to evaluate the myeloid and plasmacytoid dendritic cells (MDC and PDC) in newly diagnosed patients with MM in correlation with various biologic markers. Thirty patients with newly diagnosed MM were included in the study. All the laboratory parameters were obtained at time of diagnosis. Thee color flowcytometry with ILT3/lin/CD11c was used for the detection of the two peripheral blood DC subsets. The plasma levels of IL6 were detected by ELISA (standard curve range: 2-200pg/ml). The median age of patients was 61,5r (36-89). The mean M-protein concentration was 46,5±16,2 g/l. IgG kappa was detected in 15 patients, IgG lambda-in 4, IgA kappa-in 7, IgA lambda-in 3. The mean level of beta-2-microglobulin was 7,0±5,7mg/l (1,82 - 22,49 mg/l); β-2-microglobulin was used to determine the stage according to the ISS. The mean level of IL6 was 27, 73±21,47pg/ml 4,6-72,5 pg/ml). The percentage of MDC and PDC were significantly lower in the patients with MM in comparison to healthy subjects (0.08%±0.09% vs 0.21%±0.02% and 0.04%±0.03% vs 0.16%±0.01%, respectively). A statistically significant difference was found between the percentage of MDC and PDC in the different stages. There was a negative correlation between MDC and PDC and the levels of β-2-microglobulin (p=0.02 and p=0.02), as well as between MDC and the IL6 levels (p=0.04). No correlation was found between MDC, PDC, levels of M-protein and the type of paraprotein. Our results demonstrate the relationship between peripheral blood DC, IL6 and β-2-microglobulin and confirm the published data for the inhibitory effect of the two factors on DC differentiation and maturation *in vitro*. The monitoring of β-2-MG and IL6 may have clinical implication as a predictor of the immune system status as well as for the yield of harvested DCs for vaccination.

1291

ASSOCIATION STUDIES OF FUNCTIONAL ICOS GENE POLYMORPHISMS WITH MULTIPLE MYELOMA IN THE POLISH POPULATION

I Frydecka,[1] L Karabon,[1] A Jedynak,[2] D Woszczyk,[3] D Wolowiec,[1] M Kielbinski,[2] S Potoczek,[1] K Kuliczkowski[1]
[1]*Medical University Wroclaw, Wroclaw, Poland*
[2]*Institute of Immunology & Experimental Therapy, Wroclaw, Poland*
[3]*State Hospital, Opole, Poland*

Background. Inducible costimulatory molecule (ICOS) which is expressed on the T-cell surface after activation enhances all the basic T-cell responses to a foreign antigen, namely proliferation, secretion of lymphokines, the up-regulation of molecules that mediate cell-cell interaction, and effective help for antibody secretion by B cells. *Aims*. The study was undertaken to evaluate the association between three ICOS polymorphisms (which were recently described as functional ones) and susceptibility to multiple myeloma (MM) in a Polish population. Methods: A case-control study of 454 individuals including 201 MM patients was conducted on polymorphisms in the ICOS gene. Genotyping of the polymorphisms ICOSISV1+173T>C, ICOSc.1624C>T, and ICOSc.602A>C and ICOSc.1564 T>C was done using allelic discrimination methods with the TaqMan SNP Genotyping Assay. Results: We noted that frequencies of alleles ISV1+173T>C [T], ICOSc.602A>C [A], and ICOSc.1564T>C [T] were higher in MM patients than in healthy controls, but differences did not reach statistical significance (0.91 vs. 0.88, p=0.17; 0.82 vs. 0.79, p=0.19 and 0.83 vs 0.79, p=0.2, respectively). The distribution of alleles and genotypes for ICOSc.1624C>T polymorphism was similar in both groups. *Conclusions*. The result of present study do not strictly confirm the association of investigated polymorphisms with susceptibility to MM due to small size of studied group, but warrant further investigation through replication studies.

1292

PROTEIN Z CONCENTRATION IN MULTIPLE MYELOMA PATIENTS

L Bolkun, J Piszcz, K Mazgajska-Barczyk, E Cichocka, J Oleksiuk, A Szumowska, J Kloczko
Medical University Bialystok, Bialystok, Poland

Background. The potential role of alterations of protein Z levels in the pathogenesis of thrombotic diseases has been investigated in several studies and has revealed conflicting results. A relationship between venous thrombosis and PZ plasma levels has been excluded in four case-control studies. In addition, the studies indicated that only very low levels of PZ, arbitrarily considered as lower than 5.0 percentile of controls have been associated with a moderate thrombotic risk. AIM: The aim of our study was to estimate the concentration of protein Z in patients with multiple myeloma (MM) and to assess a correlation between PZ levels and the thrombotic disturbances. Additionally we evaluated the influence of chemotherapy on the PZ concentration. *Materials and Methods.* Sixty five patients hospitalized at University Hospital in Bialystok, Poland, with a new diagnosed multiple myeloma were studied. The median age of patients was 53 (range: 40-66 years). Patients were not under the oral anticoagulant before treatment and had normal liver function. None of the patients had any thromboembolic complications at time of diagnosis. All patients were divided into three groups based on international staging system (ISS), twenty six patients at 1st stage, eighteen patients at 2nd stage and twenty one at 3rd stage. For all studied patients the induction regimens were thalidomide, dexamethason and cyclophosphamide (CTD), every 28 days (according to Polish Myeloma Study Group). The evaluation was done after the third and sixth cycle of chemotherapy with the same methods as at the diagnosis. Response was assessed according to the European, International, and Autologous Bone Marrow Transplant Registries (EBMT/IBMTR/ABMTR) criteria. The control group consisted of fifty healthy individuals, age- and sex-matched. Quantitative determination of protein Z in the plasma was done using commercial test (Asserachrom Protein Z Elisa Kits, Diagnostica Stago). The PZ assay methods were compared using T-student test for dependent and independent samples. The statistical significance of the measured differences was determined using an alpha index of 0.05. *Results*. The mean PZ concentration of MM patients (n=65) and healthy individuals (n=50) were with no statistical significant differences (1.50±0.77 μg/mL vs 1.58±0.42 μg/mL, p=0.6). According to ISS, we found significant differences of mean PZ concentration between the stage one of the disease (1.71±0.77 μg/mL) and other stages: 2nd (1.44±0.69 μg/mL) and 3rd (1.00±0.56 μg/mL), p=0.34 and p=0.007, respectively. The study revealed decreased concentration of PZ during

the treatment with statistical significant difference at month 3rd (1.18±0.46 μg/mL) and 6th (1.17±0.52 μg/mL), respectively p=0.04 and p=0.05. Venous thrombosis (DVT) occurred at the time of treatment in eight (12.3%) of MM patients. The study revealed tendency of a modulating effect of protein Z on the DVT in the entire group of patients, as well in the group with PZ concentration below 5th percentile, but not with the statistical significant correlation, p=0.13 and p=0.08, respectively. *Conclusions*. This reduction to the level below 5th percentile during IMIDS containing therapy may be an additional puzzle in explanation of the increased rate of thrombosis in MM patient treated with thalidomide.

1293

A NEW INDICATION FOR AN OLD DRUG; THERAPEUTIC POTENTIAL OF PROPRANOLOL ON HUMAN MULTIPLE MYELOMA CELLS

Y Baran,[1] I Kozanoglu,[2] K Melis,[1] O Hakan,[2] S Faik[1]
[1]*Izmir Institute of Technology, Izmir, Turkey*
[2]*Baskent University, Adana Teaching and Medical Research Center, Adana, Turkey*

Background. Propranolol, a nonselective -adrenergic receptor blocker, has been used for the treatment of the patients with hypertension for more than 50 years. Propranolol is also used in the treatment of angina pektoris, anxiety, tachycardia, arrhythmia, tremor, migraine, panic attack, and thyrotoxicosis. There are several in vitro and in vivo evidences that β-adrenergic receptor antagonists inhibit proliferation and angiogenesis, decrease tumor metastasis, and also increase apoptosis in breast, stomach, skin, and colon cancers. Multiple myeloma is the second most common hematological malignancy. Despite of the high dose chemotherapy and other treatment approaches, there is no efficient curative approach yet. *Aims*. In this study, we aimed to investigate the cytotoxic and apoptotic effects of propranolol, the nonselective β-adrenergic receptor blocker, on U266 human multiple myeloma cells. Methods. Time-dependent proliferation of U266 cells exposed to increasing concentrations of propranolol was determined by MTT cell proliferation assay. Apoptotic effects of propranolol on human U266 multiple myeloma cells were examined by analyzing the changes in caspase-3 enzyme activity, mitochondrial membrane potential, and also the localization of phosphatidylserine in the plasma membrane. For this purpose, caspase-3 colorimetric assay kit, JC-1 mitochondrial membrane potential detection kit and Annexin V-FITC apoptosis detection kit were used, respectively. *Results*. IC50 values (drug concentrations that inhibit the proliferation of cells by 50%) of propranolol in U266 cells were calculated as 141-, 100-, and 75 μM after 24, 48, and 72 hour propranolol exposure, respectively. Incubation of U266 cells with 50-, and 100 μM propranolol for 48 or 72 hours resulted in 10 and 18% or 46 and 50% increases in caspase-3 enzyme activity, respectively. The same concentrations of propranolol resulted in 8 and 35% increases in loss of mitochondrial membrane potential after 48 hours, and 73 and 77% increases in loss of mitochondrial membrane potential after 72 hours, respectively, as compared to untreated control group. To confirm these data we detected apoptotic cells by examining the localization of phosphatidylserine. The results revealed that propranolol induced apoptosis significantly in a time- and dose-dependent fashion in multiple myeloma cells. *Summary/Conclusions*. These results revealed that propranolol has antiproliferative and apoptotic effects on U266 human multiple myeloma cells. Being supported by *in vivo* analyses, propranolol can be a good and economical way to treat multiple myeloma patients.

1294

APOPTOTIC EFFECTS OF SUNITINIB ON MULTIPLE MYELOMA CELLS

Y Baran, E Gencer, G Gucluler
Izmir Institute of Technology, Izmir, Turkey

Background. Multiple myeloma is the second most comultiple myelomaon hematological malignancy characterized by abnormal increases in the number of plasma cells. The direct interaction of the multiple myeloma cells with the other cells within the microenvironment has a vital importance for the progression of the disease since these interactions triggers the release of some cytokines and growth factors, critical for signaling pathways for multiple myeloma cells and for the cells in the microenvironment. Different therapeutic agents and treatment protocols were used for the treatment of multiple myeloma and some of them could increase survival time and quality life of the patients. But, despite these succesful responses, multiple myeloma still remains to be an uncurable disease. Sunitinib is a multi-targeted receptor tyrosine kinase inhibitor that repress the activity of many receptors involved in important signaling pathways that regulate cell growth, proliferation and apoptosis. Aims. In this study, we aimed to desipher the cytotoxic and apoptotic effects of sunitinib on multiple myeloma cells and determine the roles of caspase-3 and mitochondrial membrane potential in sunitinib-induced apoptosis. Methods. Antiproliferative effect of sunitinib on U266 multiple myeloma cells was determined by XTT cell proliferation assay. Apoptotic effects of sunitinib on U266 cells were evaluated by the examination of changes in caspase-3 enzyme activity, mitochondrial membrane potential and Annexin V assays. These analyses were conducted by using caspase-3 colorimetric enzyme activity assay, JC-1 mitochondrial membrane potential detection kit and Annexin V-FITC kit, respectively. *Results*. IC50 value of sunitinib, the drug concentration which inhibits cell proliferation by 50% as compared to untreated control group, was calculated from cell proliferation plots and found to be 4 μM. There were 7, 17 and 20% increases in loss of mitochondrial membrane potential in response to 1, 5 and 10 μM sunitinib, respectively, compared to untreated control. The same soncentrations of sunitinib increased caspase-3 enzyme activity by 10, 30 and 160%, respectively comparing to control group. In order to confirm these results, apoptotic deaths were detected by AnnexinV and results revealed that 1, 5, 10 μM concentrations of sunitinib induced apoptosis in 9, 55 and 98% of U266 cell population, respectively. *Summary/Conclusions*. The results of this study showed that sunitinib can be an alternative treatment approach for multiple myeloma. These studies should be confirmed further by in vivo analyses.

1295

DETERMINATION OF CYTOTOXIC EFFECTS OF GOSSYPOL ON MULTIPLE MYELOMA CELLS

Y Baran, Z Cakir
Izmir Institute of Technology, Izmir, Turkey

Background. In multiple myeloma, plasma cells reproduce in an uncontrolled manner due to a number of molecular changes such as chromosomal translocations, point mutations and oncogene activation. Then, these plasma cells produce excess amount of a single type of immunoglobulin. Multiple myeloma is diagnosed with the detection of more than 30% plasma cells in bone marrow. Furthermore, the cancerous cells accumulate in the bones and bone marrow. In the treatment of multiple myeloma, different agents have been administered as standard for many years. Although some novel agents increased the quality of life and survival times of patients, cure is still not possible and serious side effects of the agents is still a big issue. Therefore, investigations to find out novel agents are very important. Gossypol is a natural phenol derived from the cotton plant. Gossypol can induce apoptosis through downregulating Bcl-2 and upregulating Bax. It also inhibits protein kinase D. Gossypol has antimalarial, antiviral activities in addition to its anticancer potential. *Aims*. In this study, we aimed to identify the cytotoxic and apoptotic effects of gossypol on multiple myeloma cells. Methods. Multiple Myeloma cells lines, ARH77, were cultured in RPMI1640 medium containing 10% FBS and 1% penicillin-streptomycin. The cytotoxic effects of gossypol on ARH77 cells were conducted via XTT cell proliferation assay. Then, apoptotic effects of gossypol on ARH-77 cells were tested by loss of mitochondrial membrane potential, increases in caspase-3 enzyme activity, and location of phosphotidylserine by using caspase-3 colorimetric enzyme activity assay, JC-1 mitochondrial membrane potential detection kit and Annexin V-FITC kit, respectively. *Results*. The XTT data showed that there were dose-dependent decreases in proliferation of ARH-77 cells. There were 29, 45 and 61% decreases in cell proliferation in response to 10, 20 and 50 μM gossypol, respectively, compared to untreated control group. Apoptotic analyses showed that there were 12 and 290% increases in loss of mitochondrial membrane potential in ARH-77 cells exposed to 5 μM and 20 μM gossypol for 72 hours, respectively, compared to control group cells while 5 and 20 μM gossypol increased caspase-3 enzyme activity in ARH-77 cells, respectively, comparing to control group cells. Phosphotidylserine location analyses by Anexin V staining also confirmed dose-dependent increases in apoptosis in ARH-77 multiple myeloma cells. *Summary/Conclusions*. All together these findings demonstrated cytotoxic and apoptotic effects of gossypol on human ARH-77 multiple myeloma cells. Gossypol induced apoptotsis through deformation in mitochondrial membrane potential and increases in caspase-3 enzyme activity.

1296

EFFECTS OF BRUCINE ON METABOLISM OF OSTEOBLAST AND OSTEOCLAST IN MULTIPLE MYELOMA

YP Ma
Shanxi Medical University, Taiyuan, China

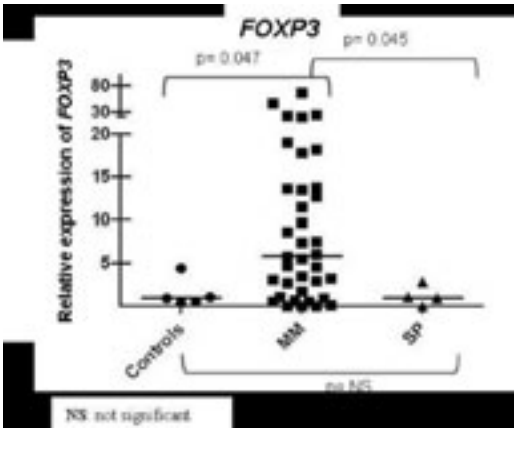
This study was aimed to explore the influence of brucine on the early differentiation of osteoblast and the metabolic pathway of osteoclast in multiple myeloma(MM) and to eompare the effects between brucine and bontezomib on MM.MTT method was used to determine IC50 of brucine and bontezomib on the MM cell line U266.The supernatant of cultured U266 cell line was added to the culture system for incluing the differentiation of osteoblast cell line MC3T3-E1. Aftter aseptic assay,RT-PCR was used to determine the in RNA levels of alkaline phosphatase (ALP), osteocalcine (OC), osteoprotegerin (OPG) and osteoprotegrin ligand (RANKL). As a result, the median inhibitory concentration (IC50)of bortezomib on U266 cell line for 48h was 22.4 nmol/L,and that of strychnine was 0.16 nmol/L. The mRNA levels of ALP,OC and OPG in osteoblast co-intervened by brucine combined with the supernatant of MM cells ($p<0.05$). The degree of increasing or reducing was larger than the level of control group intervened only by bortezomid($P<0.05$)).The above-mentioned results indicated that the therapeutia effects of brucine on MM might be carried out through the regulation of osteoclast by osteoblast ,and the experiment confirmend that the theoapentic efteds of brucine on MM was superior to that of bortezonid.

1297

EVALUATION OF T REGULATORY AND TH17 CELLS RELATED-GENES EXPRESSION IN BONE MARROW ASPIRATES OF SOLITARY PLASMOCITOMAS AND MULTIPLE MYELOMA PATIENTS

W Braga,[1] AC Carvalho,[1] F Corbi,[1] A Vettore,[1] D Atanackovic,[2] G Colleoni[1]
[1]*Federal University of Sao Paulo - UNIFESP, Sao Paulo, Brazil*
[2]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Introduction. Underlying biological mechanisms of multiple myeloma (MM) involve a series of genetic alterations and changes in the bone marrow microenvironment, favoring the growth of the tumor and the failure of the immune system in controlling it. T regulatory (Treg) cells play an important role in the maintenance of self-tolerance and modulation of overall immune responses against infections and tumor cells. Th17 cells have a critical function in eliminate extracellular pathogens and tumor cells. The balance between Treg and Th17 cells may be essential for maintaining homeostasis of anti-tumor immunity. In this scenario, the aim of this study was to characterize the expression of Treg- and Th17-related genes in bone marrow (BM) aspirates of MM and solitary plasmacytomas (SP) to evaluate their potential as therapeutic targets in this disease. Material and Methods: Expression of Foxp3 and ROR-γt genes, respectively associated with Treg and Th17 subpopulations, were determined by quantitative real-time PCR (RQ-PCR) in BM aspirates of 37 newly diagnosed MM patients, 04 newly diagnosed SP and 05 healthy controls (allogeneic transplant donors). Genes were considered overexpressed when RQ-PCR results showed values at least 2 times higher in cases than in normal samples.



Results. Foxp3 was overexpressed in 72% of MM cases. A 5.89-fold increase in Foxp3 expression was observed in MM patients compared to controls ($p=0.0476$, Mann-Whitney test). On the other hand, MM patients and controls showed equal levels of ROR-γt expression and the difference between groups was not significant. Also, SP BM aspirates showed Foxp3 and ROR-γt levels similar to controls. *Conclusions*: Overexpression of Foxp3 in MM cases suggests an accumulation of immunosuppressive Tregs in the tumor environment and/or an immediate involvement of this gene in the development and progression of myeloma. Therapeutic approaches that specifically target Foxp3-expressing Tregs may provide more focused treatment strategies for MM.

1298

POINT MUTATIONS IN KINASE AND PSEUDOKINASE DOMAINS OF JAK1 GENE DO NOT SEEM TO BE RESPONSIBLE FOR ACTIVATION OF JAK/STAT PATHWAY IN MULTIPLE MYELOMA

F Corbi,[1] G Colleoni,[1] A Vettore,[1] S Han,[1] L Knoops,[2] JC Renauld[2]
[1]*Federal University of Sao Paulo, Sao Paulo, Brazil*
[2]*Ludwig Institute for Cancer Research, Brussels Branch, Brussels, Belgium*

Background: JAK/STAT pathway, which can be persistently activated in multiple myeloma (MM) patients due to constant stimulation by IL-6, was recently explored by Burger et al (2009) as potential therapeutic target in this still incurable disease: Janus Kinase (JAK) inhibitor INCB20 presented antiproliferative and apoptotic effects on human myeloma cells *in vitro* and *in vivo*. *Aim*s. To search for point mutations in JAK1 gene kinase and pseudokinase domains in an attempt to define any critical and recurrent alteration that could be used as therapeutic target for MM. *Patients and Methods*. We obtained RNA from purified CD138-positive cells from MM bone marrow samples using microbeads conjugated to monoclonal anti-human CD138 (sydecan-1) by the MACS methodology - Magnetic Cell Sorting of Human Cells (Miltenyi Biotec, Bergisch Gladbach, Germany) from 21 newly diagnosed patients MM, four healthy controls (one peripheral blood and three reactive tonsils) and four MM cell lines (U266 , Sko-007, SKMM-2, RPMI). After amplification of of JAK1 pseudokinase (exons 12-18) and kinase (exons 19-24) domains in cDNA samples, we performed automatic sequencing of fragments using forward and reverse primers. Results: 15 of the 21 (71%) MM cases showed at least one polymorphism, all synonymous SNPs, being: 12/15 in codon 733 (CCA>CCG), 6/15 in codon 683 (AGC>AGT), 4/15 in codons 1032 (AAG>AAA) and 659 (CGC>CGT), and 3/15 in codon 699 (GCC>GCG). All the four cell lines also presented only synonymous SNP: 4/4 in codon 683 (AGC>AGT) and ¼ in codon 733 (CCA>CCG). Among the four controls, one showed synonymous SNP in codon 733 (CCA>CCG), one in codon 683 (AGC>AGT) and one in codon 1032 (AAG>AAA). *Conclusions*. Mutations in kinase and pseudokinase domains of JAK1 gene do not seem to be important for activation of JAK/STAT pathway in multiple myeloma and other underlying mechanisms, besides IL-6 stimulation, must be investigated.

1299

THE INFLUENCE OF CYTOKINE INTERLEUKIN-16 IN MULTIPLE MYELOMA

J Templin, Y Hildebrandt, T Luetkens, C Keller, S Meyer, K Bartels, C Bokemeyer, N Kröger, D Atanackovic
University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Multiple myeloma is a malignancy characterized by the expansion of a plasma cell clone that localizes to the human bone marrow. Myeloma cells and bone marrow stroma cells both produce soluble factors promoting the survival and progression of multiple myeloma. Interleukin-(IL)-16 is involved in regulating migration and proliferation of normal leukocytes, however, it has been unclear whether IL-16 also plays a role in the pathophysiology of human cancers. We found IL-16 to be strongly overexpressed in the bone marrow of myeloma patients. Myeloma cell lines as well as primary tumor cells from myeloma patients constitutively expressed IL-16 and its receptors CD4 and/or CD9 and spontaneously secreted soluble IL-16. Silencing of IL-16 had an anti-proliferative effect on the tumor cells which could be reversed by the addition of the C-terminal fragment of soluble IL-16. Most importantly, the application of a monoclonal antibody directed against IL-16 had a strong growth-inhibiting influence on myeloma cells. These findings indicate that cytokine IL-16 is an important growth-promoting factor in multiple myeloma and a candidate for novel diagnostic, prognostic and therapeutic applications for this incurable human malignancy.

EFFECT OF 13Q DELETION ON IL-6 PRODUCTION IN PATIENTS WITH MULTIPLE MYELOMA

N Kassem,[1] H Azim,[2] R Khalifa,[2] T Mohamed[2]
[1]*Kasr Al-Aini, School of Medicine , Cairo University, Egypt, Cairo, Egypt*
[2]*Kasr Al-Aini, School of Medicine; Cairo University, Cairo, Egypt*

Background. Numerous studies have shown a correlation between 13q deletion and poor prognosis in multiple myeloma (MM), but the mechanisms are not fully understood. Earlier studies suggest that this lesion involves large segments or the entire long arm involving the retinoblastoma (Rb) gene. In myeloma, Rb gene is believed to downregulate interleukin -6 (IL-6) which plays a central role in the pathogenesis of MM. Therefore, it has been hypothesized that loss of Rb gene might be associated with very high expression of IL-6 and subsequent bad prognosis. *Materials and Methods*. Forty MM patients and 20 matched controls were included in this study. Interphase fluorescence *in situ* hybridization (FISH) analysis was performed using LSI 13q14-specific probe. Serum levels of IL-6 were determined by ELISA. All patients received conventional chemotherapy. Refractory patients received other therapeutic regimen of Thalidomide or Bortezomib. *Results*. Significant increase ($p<0.001$) of IL-6 production was recorded in patients with 13qdeletion compared to patients with normal chromosome 13q status .These patients were also refractory to conventional chemotherapy but showed striking response to Thalidomide or Bortezomib. *Conclusions*. This study suggests that 13q deletions are associated with increased production of IL-6 in MM and this could be a possible cause of the associated bad prognosis. In addition, the results also show the potential to improve responses in patients with refractory MM with the introduction of novel therapies.

1301

EVALUATION OF APOPTOTIC MARKERS IN MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

C Geraldes,[1] AC Gonçalves,[2] V Alves,[2] A Teixeira,[1] I Sousa,[1]
M Santos Rosa,[2] J Nacimento Costa,[1] AB Sarmento Ribeiro[2]
[1]*Hospitais da Universidade de Coimbra, Coimbra, Portugal*
[2]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal*

Multiple myeloma (MM) is characterized by aberrant cellular responses to signals governing proliferation and apoptosis. Its' first pathogenic step is a pre-malignant monoclonal gammopathy of undetermined significance (MGUS). With progression from MGUS to MM, complex genetic and/or epigenetic events occur in the malignant plasma cells (PCs) and in the bone marrow microenvironment that contribute to cell signalling pathways deregulation. The knowledge of these mechanisms may provide new markers for disease progression and new molecular targets for therapy. Apoptotic cell death may be triggered by several mechanisms involving death receptors and/or by mitochondria (extrinsic and intrinsic pathways). The intrinsic pathway centers on mitochondria as initiator of cell death. Multiple signals converge on mitochondria causing these organelles to release cytochrome c (cyt c) and other apoptogenic proteins into cytosol. The B-cell lymphoma-2 (Bcl-2) family proteins are the most prominent of the intrinsic pathway. In this family some of them have pro-apoptotic properties, as Bax, Bad and Bid, while Bcl-2 and Bcl-Xl have an anti-apoptotic function. In contrast, the extrinsic apoptotic pathway relies on tumour necrosis factor (TNF) family death receptors for triggering apoptosis. TRAIL is a ligand that triggers and activates 4 receptors of TNF family, TRAIL-R1 and -R2, also known as death receptors, DR4 and DR5, and antagonistic or modulator receptors, TRAIL-R3 and-R4, also known as decoy receptors, DcR1 and DcR2. Many mechanisms may contribute to the complex effects of TRAIL, namely the differential expression of TRAIL-Rs or functional defects, like those related to cytoplasmatic inhibitors of apoptosis such as inhibitory apoptotic proteins as survivin. However, apoptosis deregulation during MGUS to MM progression is not yet clarified. AIMS: The aim of this study is to contribute to clarify the molecular mechanisms involved in MGUS and its evolution to MM, namely the involvement of apoptotic pathways.METHODS: For this purpose, we evaluated bone marrow PCs from 13 patients (6 MGUS and 7 MM). PCs were identified by flow cytometry by CD138 expression and malignant PCs were analyzed by gating the CD138+/CD19- population. In malignant PCs we evaluated the expression of apoptotic proteins Bax, p53, Fas/FasL, TNF/TNF-R1, TRAIL/TRAIL-R1-2, caspase 3 and the anti-apoptotic proteins TRAIL-R3-4, survivin and Bcl-2. Some of the proteins involved in survival, namely the transcription factor, NF-kB were also performed. RESULTS: The preliminary results from our study show that MM patients have highest levels of malignant PCs compared to MGUS patients (95% vs 67%, $p<0,05$). On the other hand, MM PCs show a statistically significant increase in p53, caspase 3, survivin and NF-kB ($p<0,05$) and a statistically significant decrease in BAX/BCL-2 ratio ($p<0,05$). These results may be related to the survival and apoptosis resistance of MM PCs. CONCLUSIONS: Our preliminary data suggest that in the progression from MGUS to MM a deregulation in apoptosis and survival pathways occur. The clarification of these mechanisms may contribute to the identification of new prognostic molecular markers and selection of patients for molecular targeted therapies.

1302

SEROTONIN STORED IN PLATELETS OF PATIENTS AFFECTED OF MULTIPLE MYELOMA REFLECTS THE ANGIOGENESIS SWITCH NEEDED TO SUBSTAIN BONE LESION

A Romano,[1] A Chiechi,[1] A Branca,[2] C Vetro,[2] N Parrinello,[2]
G Palumbo,[2] F Di Raimondo,[2] L Liotta,[1] V Espina[1]
[1]*George Mason University, Manassas, USA*
[2]*Department of Clinical and Molecular Bio-Medicine, Section of Hematology, Oncolo, Catania, Italy*

Background. Physiological interactions between the serotoninergic and skeletal systems have been implicated by clinical observations. Hypoxic conditions modify plasma levels of serotonin, serotonin transporter activity, and expression of 5-HT1B and 5-HT2B receptors. Under low oxygen tension, cells increase the transcription of specific genes via stabilization of the transcription factor hypoxia-inducible factor (HIF)-1. In lung, the 5-HT2B receptor via phosphatidylinositol-3 kinase/Akt activates nuclear factor-kappaB, which is involved in the regulation of HIF-1 expression. Immunoglobulins have been shown to induce platelet release when participating in immune reactions as antigen-antibody complexes. While MM patients with evidence of osteolytic lesions have been shown to have elevated concentrations of serum tryptophan and serotonin the consequences of this elevation have not been previously studied in the bone itself. Methods We retrospectively measured bone remodeling signal pathway perturbations in 15 bone marrow core biopsies from patients diagnosed with MM, at different clinical stages, and correlated this with the presence of osteolytic bone disease. We measured circulating serotonin levels by ELISA in a pilot set of MM patients (n=20), in both serum and platelets isolated from peripheral blood to confirm observations obtained by RPMA. Finally, we collected platelets from 19 peripheral blood of subjects affected of monoclonal gammopathy (5 MGUS, 14 MM at different clinical stages and treatment with or without biphoshonates). Samples were lysed, protein extracted, printed and stained on Reverse-phase protein microarrays (RPMAs). In this last independent test, RPMAs were used to quantitatively map 45 cell signaling pathway endpoints, including oxygen sensors and transmembrane receptors proteins, in order to provide quantitative information regarding post-translational modifications (e.g. phosphorylation, cleavage, acetylation) and/or total cell signaling kinase levels, more sensitive and accurate of ELISA kits actually available in commerce. Results Bone marrow core biopsies exhibited significant elevation of Serotonin, RANK, MMP-11, TNFα, TNF-R1, and Ezrin Tyr353 by RPMA in patients with osteolytic lesions compared to patients without evidence of bone disease. Cytokines IL-1β, IL-6, and IL-10 were also significantly elevated in the bone marrow cores of patients with bone disease. Free circulating serotonin in MM sera was elevated compared to healthy controls. In particular, in the platelets we found a positive correlation between the content of serotonin and HIF-1-α ($r=0.74$, $p=0.0005$). Both analytes decreased after treatment for at least 3 months to Zoledronic Acid 4 mg i.v. (respectively $p=0.0014$ and $p=0.0317$), suggesting as a drug effective to control bone disease is able also to modulate the content of platelets grains. Anti-angiogenic molecule like PEDF was not related to serotonin levels and it was not modulated by Zoledronic Acid. However patients with MGUS or MM did not exhibit a differential activation status of platelets, with no appreciable differences in expression of CD9 and CD63. Conclusions. Taken together, our data confirm the role of peripheral 5-HT system in mediatingmediated signaling cascades related to the pathogenesis of MM-induced bone disease. This insight could provide strategies for reducing osteolysis with agents that regulate serotonin, either alone or in combination with other molecular targeted inhibitors.

[3]*Virginia Cancer Specialists, Fairfax, VA, USA*

Background Interaction of Multiple Myeloma (MM) cells with bone marrow microenvironment cells has a pathogenetic role in the disease and may confer tumor cell resistance to conventional therapies. A great need exists to understand the differential effect of treatment on myeloma as well as non-myeloma cells. We designed an ex vivo study to rapidly screen treatment combinations to predict treatment efficacy. Methods A panel of signal pathway inhibitor treatments was applied to fresh bone marrow aspirate samples from patients undergoing standard of care hematological work up for multiple myeloma. Bone marrow aspirates were immediately subdivided and treated ex vivo with a panel of molecular targeted inhibitors, including combinations thereof that target a wide range of cellular pathways (autophagy, proteosome, angiogenesis, protein degradation, proliferation/survival, insulin response, and translation). Up to 48 different treatment conditions can be studied from 5mL aspirate. After overnight incubation the samples were placed in a preservative that suppresses fluctuations in kinase pathway proteins. CD138+ plasma cells were separated from CD138 negative cells via immunomagnetic sorting. Reverse phase protein microarrays were used to quantify 60 cell signaling proteins in both cell populations. *Results* At baseline, patients with active myeloma (untreated before or relapsed) exhibited an increased pro-survival signaling (TNFR1, Akt Ser473, Akt Thr308, B-Raf Ser445) and ligands (IL6, IL10, TNFα) in both $CD138^+$ and bone marrow microenvironment cells. Only 1 case exhibited the activation of NfKBp65Ser536 in CD138+ plasma cells. Only in plasma cells, a subset of patients exhibited higher levels of Beclin1 and LC3B, suggesting a potential role of autophagy in MM aggressive phenotype. Untreated before and relapsed patients did not show a unique hyperactivated pathway, except in a patient treated with lenalidomide, relapsed after 6 months and subsequently bortezomib resistant. In this specific case, almost endpoints evaluated were pretty higher than the other subjects included in the study, except for autophagy markers and c-kit signaling. When we evaluated the response of this patient to the treatment ex-vivo with Lenalidomide 1uM and Bortezomib 100nM, alone or in combination, we were able to predict his refractariety, since the lack of protein profiling after treatment. Plasma cells isolated from patients previously exposed to Bortezomib did not differ from Lenalidomide-exposed ones. However, in vitro these drugs triggered pathways different. After 12 hours of exposure to lenalidomide we confirmed the Caspase8 upregulation, yet reported in literature, associated to increased levels of Bcl-2Ser70 and reduced Caspase3 Asp175 and Caspase9 Asp330. Conversely, Bortezomib was not able to induce Caspase8 and Bcl-2 Ser70. Conclusion Taken together, our data confirm the value of the RPMA assay to investigate improperly activated pathways converging on apoptosis triggering. The proposed assay conducted at beginning of the treatment is a valid mean to individualize therapy and improve combination strategies.

1304

THALIDOMIDE EFFECT ON ANGIOGENESIS AND IN CD57+ LYMPHOCYTE POPULATION OF MULTIPLE MYELOMA PATIENTS

V Hungria, E Crusoe, A Quero, ML Botelho, I Schliemann, AL Peres, M Sampaio, R Paes, C Chiattone

Santa Casa de Sao Paulo, Sao Paulo, Brazil

Background. The thalidomide (thal) action has not been fully elucidate. This drug has been consolidated as a promising therapeutic option for multiple myeloma (MM) because of its antiangiogenic and immunomodulatory effect. The microvessel density (MVD) and the amount of bone marrow (BM) CD 57+ lymphocyte population from (MM) patients are correlated with disease activity. Aims- To evaluate the bone marrow angiogenesis and CD57+ lymphocytes amount before and after 3 months on thal treatment. *Materials and methods*. We collected BM biopsies from 20 MM patients treated with Thal up front. The Thal dose was 200 daily. Samples were collected at diagnosis and after 3 months on thal treatment. The angiogenesis was accessed by CD 34 staining and was estimated by microvessel-density (MVD) and cytotoxic lymphocytes / NK cells counting by CD 57+. Microscopy was performed by two independent blinded pathologists to the treatment time. Photographs of three areas of high vessel concentration were selected for CD 34 counting with 400X magnification. Analysis of cytotoxic lymphocytes / NK was performed by direct counting on three areas of high concentration for the CD57 marker. We also correlated the response rate to the MVD and lymphocytes number. Wilcoxon's matched pairs test was used. Results - The median age was 64 (40-82y). The isotype identified was: IgG = 14, IgA=2, and light chain=4. DS stage: IIA=2, IIIA/B=15/3 and ISS 1/2/3=4/9/7. The schemes used were: TD=14, CTD=4, CTD +TD=1 and MPT=1. The response rate observed was: VGPR=8, PR=7, MR=2, progression in 1 case and 2 were not analyzed. The reduction in MVD after 3 months with thal was significant (p=0.04). There was no significant difference in the amount of CD 57 + pre and post treatment. The response rate was not correlate with angiogeneses reduction or with the amount of CD57+ lymphocytes. *Conclusions*. Evaluation after 3 months on thalidomide treatment showed a significant angiogenesis reduction. The number of patients may have been insufficient to evaluate the CD57+ lymphocytes population. Probably, the variations of lymphocytes occur in later treatment phases.

1305

INVESTIGATION QUALITY OF LIFE IN MULTIPLE MYELOMA PATIENTS WITH ANEMIA RECEIVED RECOMBINANT HUMAN ERYTHROPOIETIN

N Romanenko, K Abdulkadyrov

Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background. Anemia in patients with Multiple Myeloma (MM) is a frequent symptom and can influence the efficacy of antitumor chemotherapy, survival rate and overall quality of life (QoL). Red blood cell (RBC) transfusions are routinely used to treat anemia, while Recombinant Human Erythropoietin (rHuEPO) treatment has been shown to significantly increase hemoglobin (Hb) concentration, reduce the number of RBC transfusions and improve QoL in patients with chemotherapy induced anemia. *Aims*. This study was performed to find out the effectiveness Recombinant Human Erythropoietin in multiple myeloma patients with anemia and improving QoL. Methods. There was done prospective study to investigate the effectiveness of rHuEPO (epoetin beta) on Hb concentration, RBC count and QoL in multiple myeloma patients with anemia (n=44). The median age of patients was 67 years (range 26-80). If Hb concentration was <8.0 g/dl, the patients were performed red blood transfusions before rHuEPO treatment. Recombinant human erythropoietin beta was injected subcutaneously on 30.000 IU 1 times a week. Before start of rHuEPO treatment all patients have been received two or more cycles of chemotherapy. The target Hb level was 12 g/dl. The positive response was estimated as increasing Hb concentrating on 2.0 g/dl and so achieving target Hb level (12 g/dl). QoL was assessed by FACT-An questionnaire. Results. Mean baseline Hb concentration was 9.02±1.19 g/dl and RBC count was 2.78±0.43x1012/l. 10 patients had Hb concentration less 8.0 g/dl (5.6-7.9 g/dl) therefore they were transfused 2-5 units of red blood until Hb increased up to 8.0-9.0 g/l. The period of rHuEPO-therapy was from 4 to 16 weeks (mean 9.1±3.6 weeks and median follow-up of 9 weeks). During the study period in whole group, the Hb concentration and RBC count increased from baseline to 11.46±2.08 g/dl ($p<0.01$) and 3.56±0.79x1012/l ($p<0.01$), respectively. An Hb increase >2.0 g/dl was observed in 30 patients (68.2%), while a non-response was observed in 14 ones (31.8%). The patients with positive response significantly increased Hb from 9.01±1.26 to 12.41±1.11 g/dl ($p<0.001$) and RBC count increased from 2.78±0.41x1012/l to 3.78±0.51x1012/l ($p<0.001$). In this group the initial dose of rHuEPO were reduced to 20.00 IU at 5 patients (16.7%) because of fast increasing their Hb (more than 2.0 g/dl during 4 weeks) to prevent arterial hypertension. In group non response patients there were not significant difference of Hb concentration and RBC count (from 9.05±1.06 to 9.20±1.91 g/dl ($p>0.2$) and increased from 2.79±0.47x1012/l to 2.88±0.88x1012/l ($p>0.2$), respectively). Besides out of ten patients four ones (40%) had been continued to receive red blood transfusions. FACT-An demonstrated that rHuEPO-therapy in group patients with positive response reduced such symptoms as: feeling fatigue, weakness all over, having trouble starting things because of tiredness, depression, drowsiness, giddiness, headaches, pain in thorax and dyspnea. Conclusions. The study has shown that rHuEPO is effective at increasing Hb concentration, count of RBC and improving QoL in anemic patients with Multiple Myeloma.

1306

THE KAPPA/LAMBDA RATIO IN GROUP OF BENCE JONES MYELOMA PATIENTS

V Radovic, M Zlatkovic
Institute of Research and Development STADA Hemofarm A.D., Belgrade, Serbia

The quantitation of the monoclonal immunoglobulins (Ig) and its fragments are used for the monitoring of Bence Jones myeloma (BJM) course and effect of therapy introduced. Bence Jones protein in urine (Ig free-light-chains (FLC)) is characteristic of light-chain multiple myeloma (LCMM). Relatively new laboratory tests in serum for the quantitation of kappa (κ) and lambda (λ) FLC and the calculation of the FLC ratio represents additional parameters of malignant plasmocityc production. The aim of FLC examination was to evaluate significance of FLC and kappa/lambda ratio (k/λ ratio) as a prognostic factor for progression, remission and survival in BJM patients. The concentrations of Ig and FLC were measured by immunonephelometric method on a "SIEMENS" DADE BN II analyser. The concentrations of Ig and FLC were measured by immunonephelometric method on a "SIEMENS" DADE BN II analyser. In this examination 37 BJM patients were investigate during the period of last 7 years. Reference interval for k/l ratio is (0.26-1.65). According to the ISS Model of stratification risk of disease progression, values < 0,03 ili > 32 represents high relative risk (RR), < 0,26 ili > 1,65 represents low-intermediate RR and < 0,125 ili > 8 represents high-intermediate RR of disease progression. Results showed that in BJM group 19/37 (51.4%) patients had high RR; 7/37 (18.9%) had low-intermediate RR, while 8/37 (21.6%) patients had high-intermediate RR. Also, 3/37 (8.1%) patients had normal k/l ratio, low RR and good prognosis. Nine patients was died during the period of 24 - 36 months. About 28% patiens which have lowered FLC values more than 50% under therapy, achieved the disease remission in group with BJ myeloma patients. Abnormal FLC ratio in group of BJM patients, could be an independent risk factor of progression and a worse disease prognosis. Serum assays could replace Bence Jones protein urine tests for patients with LCMM.

1307

ESTABLISHMENT OF A REFERENCE RANGE FOR FREE LIGHT CHAINS IN ELDERLY POPULATION

HK Park[1] YJ Kim[1] HI Cho[1] KR Lee[1] CH Lee[2] HJ Kim[2]
[1]*Seoul Clinical Laboratories, Seoul, South-Korea*
[2]*Konkuk University College of Medicine, Chungju, South-Korea*

Background. The quantitative assay of free light chains (FLCs) is a recently introduced commercial test reported to be sensitive and specific for detecting FLC diseases such as primary systemic amyloidosis (AL), light chain deposition disease (LCDD), nonsecretory multiple myeloma (NSMM), and light chain multiple myeloma. Aims. We evaluated the reference range of this test in the elderly population. Methods. We measured the concentration of κ and λ FLCs in the plasma samples of 884 elderly subjects aged over 65 years. Among the 884 subjects, those who had abnormal features (monoclonal peak in immunofixation, hypo or hypergammaglobulinemia, acute phase pattern C-reactive protein (CRP) of >1.0 mg/dL, and renal dysfunction Modification of Diet in Renal Disease (MDRD) glomerular filtration rate (GFR) of <60 mL/min/1.73 m2) were excluded. Levels of FLC were determined using the FLC assay (Freelite; The Binding Site, Birmingham, United Kingdom) performed on a Siemens Dade Behring BN II Nephelometer (Deerfield, IL). The assay consists of 2 separate measurements: one to detect free κ (normal range, 3.3-19.4 mg/L) and the other to detect free λ (normal range, 5.7-26.3 mg/L) light chains. The assay reports the FLC k/λ ratio (normal range, 0.26-1.65), and an abnormal FLC result was defined as an abnormal FLC k/λ ratio. Results Of the 409 subjects included in our study, 206 (50.4%) were male and 203 (49.6%) were female. Their median age was 75 years (range, 65-96). The 95% reference ranges for k FLC, λ FLC, and k/λ FLC ratio were 10.0-49.4 mg/L, 13.7-59.5 mg/L, and 0.54-1.32, respectively. *Conclusions*. Reference ranges were extended in elderly subjects compared with those established previously. This study suggests that the reference range of FLCs need to be established in the elderly population.

1308

EXPERIENCE WITH THE COMBINATION OF BORTEZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE IN NEWLY AND RELAPSED MULTIPLE MYELOMA AND PLASMA CELL LEUKEMIA PATIENTS

D De Miguel, N Golbano, I L San Roman, M Diaz, D Morales, J Arbeteta, S Herrero, B Pinedo
Hospital Universitario de Guadalajara, Guadalajara, Spain

Background. Novel sequential combination therapy for induction may improve the quality of response and therefore prolong survival in newly diagnosed multiple myeloma (MM) patients. This concept should be allocated in refractory / relapse multiple myeloma patients. Material and Methods: We present our experience with the combination of Bortezomib (1.3 mg/m2 D1, D4, D8, D11), Cyclophosphamide (600 mg/m2 D1, D8) and Dexamethasone (40 mg D1, D4, D8, and D11) for 21-days cycles in newly and relapsed multiple myeloma and plasma cell leukemia patients. From February 2009 until February 2011, we treated 18 patients (12 in first line). On the front line in less than 70 years old as induction therapy prior to stem-cell transplantation, have treated 8 patients (1 plasma cell leukemia included) and over 70 years, two patients with plasma cell leukemia. 7 relapsed patients had received at least one line of prior chemotherapy (1-4), and 2 patients had been transplanted previously. The number of cycles (BCD) administered ranged between 1-8 (mean 4.3). 5 patients received only one cycle, 4 died of disease progression (1 plasma cell leukemia) and in newly diagnosed patients stopped treatment for pneumonia (Candida plus H1N1 virus) and he admitted in intensive care unit because he did need mechanic ventilation support. *Results*. 11 patients are evaluable for response; Overall response rate was 100%, including 9.1% CR, and 98.9% partial response. 6 patients treated in first line had undergone stem-cell transplantation. Table 1. Toxicities were predictable and manageable; the most-commonly reported grade 3/4 toxicity was neuropathy (37.5%).The limiting toxicity was peripheral neuropathy, present in 3 patients, necessitating dose reduction of Bortezomib in one step in 2 patients, and in other patient was reduced two steps. 4 patients (50%) developed neutropenia grade 3-4, and required to use G-CSF. Infectious complications that required hospital admission in 4 patients (1 ZHV spread, 1 bacteriemia Staf., 2 pneumonias).

Table 1. MM patients: BCD treatment.

Conclusions. 1) The BCD combination gets quality and fast respond. 2) hematological toxicity, is easily manageable, and the incidence of infection complications is higher in refractory/relapsed patients and with associated comorbidity. 3) In refractory/relapse patients, respond rate is obtained as first-line patients. Patients retreated with bortezomid had good results, with an increased of neuropathy.

1309

PROGNOSTIC VALUE OF ELEVATED BNP AND NT-PROBNP LEVELS IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA AND CONCOMITANT CHRONIC HEART FAILURE

E Yurova,[1] S Semochkin,[2] A Roitman,[3] O Kisliak[1]
[1]*Russian State Medical Universitate, Moscow, Russian Federation*
[2]*Federal Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation*
[3]*Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation*

Background. Multiple myeloma (MM) is an incurable plasma cell disorder that comprises 10% of hematologic tumors. Incidence increases greatly with age: the median age at diagnosis is 70 years, with 65% of patients older than 65 years. The geriatric patients often have concomitant heart disease and in addition they are forced to receive cardiotoxic chemotherapy for MM. These circumstances as a whole certainly worsen the prognosis of life. *Aims*. To estimate the prognostic importance of

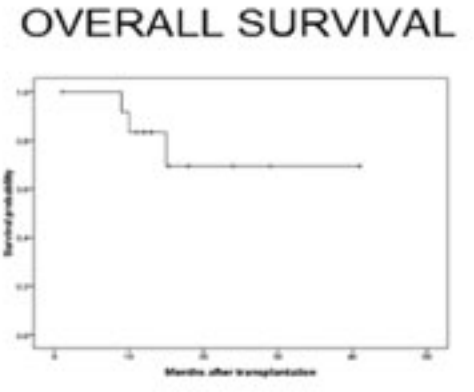
BNP and NT-proBNP markers in patients with MM and accompanying chronic heart failure (CHF). Material and methods: 45 patients are included in the analysis (m-15, f-30) with relapses or refractory MM for which were satisfied following conditions: (1) ECOG ≤ 2; (2) Anemia with Hb < 8.0 g/dL; (3) proved CHF; (4) basic therapy for CHF (inhibitor APF ± diuretic) was spent not less than within last 2 weeks and (5) the chemotherapy concerning MM was assumed. The patients with heart failure with New York Heart Association (NYHA) IV and/or the constant form of atrial fibrillation and/or heart diseases and/or a heavy arterial pathology didn't include in this study. CHF was diagnosed on basis of standard criteria and the present of the left ventricular enlargement or systolic functional impairment by echocardiography, according to the European Society of Cardiology guidelines. The levels of NT-proBNP and a BNP-fragment in blood serum have been defined at the moment of enroll in study by ELISA. The mathematical definition of threshold values of concentration of markers was spent by means of construction of ROC-curves and Kaplan-Mayer analysis. Results: The median of age of patients at the moment of enroll in study has made 66 (42-83 range) years. 3 (7%) patients had IIA stage on Salmon-Durie and 22 (49%) - IIIA and 20 (44%) - IIIB. 17 (38%) patients had no clinical signs of CHF. 16 (35%) patients have CHF with NYHA I and 9 (20%) - II and 3 (7%) - III. 28 (62%) patients have received salvage regimens of chemotherapy with bortezomib and 15 (33%) - with alkylating agents and 2 (5%) - high doses of dexamethasone. The objective response was documented for 26 (58%) patients including complete response (CR) or very good partial response (VGPR) - 7 (16%). 33 (73%) patients have alive at a median of follow up 11 months. The analysis of NT-proBNP levels has revealed correlation between the degree heart failure and a disease outcome ($p < 0.05$). Threshold concerning a failure of disease value of concentration NT-proBNP (sensitivity - 82%, specificity - 62%) has identified as 0.93 ng/ml. For a BNP-fragment of authentic distinctions in the conditions of the limited sample has not received. *Conclusions*. The elevated serum NT-proBNP levels > 0.93 ng/ml is identified as the poor prognostic factor for patients this MM and accompanying CHF.

1310

LENALIDOMIDE PLUS DONOR LYMPHOCYTES INFUSION (DLI) AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION (ALLO-SCT) WITH REDUCED-INTENSITY CONDITIONING IN PATIENTS WITH HIGH RISK MULTIPLE MYELOMA

J Elcheikh, R Crocchiolo, P Ladaique, S Furst, L Castagna, C Faucher, A Granata, C Oudin, C Lemarie, B Calmels, AM Stoppa, JM Schiano de Colella, S Duran, R Bouabdallah, C Chabannon, D Blaise
Institut Paoli Calmettes Marseille, Marseille, France

Relapse remains the main problem after allogeneic stem cell transplantation (Allo-SCT) in high risk Multiple Myeloma (MM) patients. The aim of our prospective study is to evaluate the anti-myeloma effect of lenalidomide followed of donor lymphocyte infusion (DLI) as adoptive immunotherapy after transplantation. *Patients and methods*. Twelve patients with refractory and high risk myeloma were analysed. Median age at transplantation was 56 years (46-64); 6 patients (50%) received lenalidomide before Allo-SCT. All patients received a RIC including Fludarabine 30 mg/m² 5 days, ATG 2,5 mg/kg for 2 days and Busilvex 3.2 mg/kg/day (3 days in 6 patients and 2 days in 6 patients). All but one received peripheral blood stem cells (PBSC). Donor was HLA id in 6 patients and matched unrelated in 6 patients. Patients were treated by lenalidomide if myeloma was progressive or residual disease was observed starting from day +100 and if no GVHD signs were evident. Dose was between 10 and 25 mg/day. DLI were administered after at least 2 cycles of lenalidomide. *Results*. The median time between Allo-SCT and lenalidomide was 10 months (3-38). The median initial dose of lenalidomide was 15 mg (10-25). The patients received a median of 6 cycles (1-10). 9 patients (60%) received an escalating dose of DLI; $1x10^7$/kg of CD3+ cells for the first DLI and 1 x 108/Kg of CD3+cells for the second DLI. One patient with GVHD and two patients with progressive disease after lenalidomide did not receive DLI. The toxicity related to lenalidomide was haematological grade II in 4 patients (33%) and grade I in 3 patients (25%); 7 patients (58%) had moderate asthenia. one patient developed a reversible renal insufficiency after 10 cycles of lenalidomide, none of our patients developed thrombo-embolism under treatment. At the last follow up, 9 patients are alive and all of them are under ongoing treatment. Four patients achieved complete remission (CR) and five patients partial remission at last evaluation. The 1 and 2 years probability of the progression-free survival (PFS) was 75% and 50% and overall survival (OS) was 83% and 69% respectively. The median OS was not reached and the median PFS was 23 months. Conclusions: These data show that lenalidomide has an acceptable toxicity profile is well tolerated after Allo-SCT. Combination with DLI should be further evaluated in a larger cohort of patients.



1311

THALIDOMIDE-INDUCED SENSORY NEUROPATY IN PATIENTS WITH MULTIPLE MYELOMA

M Bilinska,[1] L Usnarska-Zubkiewicz,[2] M Szymczyk,[3] L Noga,[4] S Potoczek,[2] K Kuliczkowski,[2] R Podemski[3]
[1]*Wroclaw Medical University, Wroclaw, Poland*
[2]*Dept.of Hematol,Blood Neoplasms and Bone Marrow Transplant., Medical University, Wroclaw, Poland*
[3]*Department of Neurology, Medical University, Wroclaw, Poland*
[4]*Department of Patophysiology, Medical University, Wroclaw, Poland*

Background. Chemotherapy-induced sensory neuropathies differ in clinical picture. There is predominance of paresthesiae in some of them while in others pain or deep sensation failure dominates. *Aim.* Clinical and electrophysiological assessment of peripheral sensory nerves in patients with multiple myeloma (m.m.) treated with thalidomide. Special attention was directed to function of subtypes of sensory fibres which convey different modalities of sensation. *Material and methods*. Twenty seven m.m. patients and 30 controls were examined. Neurological examination together with allocation to different groups acc. to sNCI-CTC scale were performed. Standard sensory conduction velocity was measured in ulnar and sural nerves. Quantitative Sensory Testing (QST) was used to determine thermal detection thresholds. *Results*. All patients informed about subjective positive sensory symptoms and sensory deficit of symmetrical, distal pattern was found. Electroneurography revealed axonal and demyelinating abnormalities with dominance of axonal injury. Warm and heat-pain detection thresholds were elevated, while threshold for skin cooling was decreased both in palm and foot in m.m. patients in comparison with controls. There were no differences in the thresholds for cold-pain detection between examined groups. *Conclusions*. Thalidomide-induced sensory neuropathy can appear shortly after the introduction of treatment. Patients with longer duration of treatment or with higher cumulative dose present higher degree of neuropathy acc. to the sCNI-CTC scale. Sensory deficit in thalidomide' neuropathy is associated with dysfunction in A delta and C caliber primary afferent fibres.

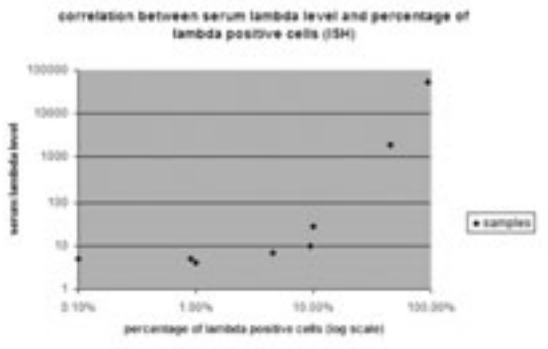
1312

CORRELATION OF SERUM LIGHT CHAIN LEVELS AND ISH LIGHT CHAINS STAINING IN TREPHINE BIOPSIES IN MULTIPLE MYELOMA PATIENTS: SOUTH AUSTRALIAN EXPERIENCE

KC Cheung, D Yeung, C Lee, M Roberts, LB To
IMVS, Adelaide, Australia

Background. The detection and quantification of monoclonal plasma cells in bone marrow biopsy is essential in the diagnosis of plasma cell neoplasms and in assessment of treatment response. Controversies exist relating to a standard for conventional immunohistochemistry staining (IHC) in the detection of Ig light chains, as interpretation is operator dependent and limited by heavy background staining. In situ hybridization (ISH) is an established technique in the detection of Ig light chain

mRNA, utilizing specific probes to demonstrate monoclonality in myeloma and B cell lymphomas.



Aims. This single centre retrospective review assesses the efficacy of this technique (ISH) by correlating with serum light chain levels. *Methods*. A random cohort of 20% of bone marrow biopsies performed between November 2009 and January 2011 for multiple myeloma was included in this review. The kappa and lambda positive cells in the marrows were quantified as a ratio of the percentage of kappa/lambda positive cells to the percentage of CD138 positive *cells.Results and conclusions*. The mean age of our patients was 65 years (range 38-85yrs) and 48% were female. The majority of patients had IgG kappa subtype (50%). A statistically significant correlation was demonstrated between serum lambda level and lambda positive cells in the trephine biopsy ($R=0.9069$, $p<0.0001$). There was no significant correlation between serum paraprotein level and kappa or lambda positive cells in trephine biopsy. Furthermore, six patients (15% - total 38 patients) were noted to have significant disease by CD138 and kappa/lambda staining despite having low plasma cell count (less than 10% by smear morphology and immunophenotyping). In conclusion, our study highlighted the greater sensitivity of ISH staining in comparison to conventional morphological criteria, with statistically significant correlation with serum free light chain levels and is therefore a useful tool in the diagnosis and follow up of myeloma patients. Further studies are needed to better clarify its role.

1313

MULTIPLE MYELOMA & OBESITY: A META-ANALYSIS

R Ríos Tamayo,[1] JJ Jiménez Moleón,[2] J Sainz Pérez,[3] F López Jiménez,[1] A Rivera Ginés,[1] MJ Sánchez Pérez,[4] M Jurado Chacón[1]

[1]*University Hospital „Virgen de las Nieves„, Granada, Spain*
[2]*Department of Medicine Preventive and Public Health. University of Granada, Granada, Spain*
[3]*Genyo-Pfizer-University of Granada-Andalusian Government Centre for Genomics, Granada, Spain*
[4]*Granada Cancer Registry. Andalusian School of Public Health, Granada, Spain*

Background. Excess body weight, expressed as increased body mass index (BMI, weight/height2), is associated with the risk of some common adult cancers. The prevalence of overweight, defined as a BMI of 25-29.9 kg/m2, and obesity, BMI ≥30 kg/m2, has been rapidly increasing during recent decades. The results of the first meta-analysis by Larsson et al. indicate that excess body weight may be a risk factor for multiple myeloma (MM), but controversy remain in more recent studies. *Aims*. To highlight the current evidence on the association between MM and obesity. *Methods*. We systematically searched Medline and Embase (from their commencements to February 2011) for studies on the association between obesity (as defined by WHO) and MM incidence or mortality as outcome, published in English as full reports, indicating relative risks (RR) with 95% confidence intervals on the association of MM with BMI. From each study, we collected information about publication data, study design, characteristic of the study population, sample size, exposure assessment, and potential bias. Summary RR estimates were calculated using a random-effects model. Statistical heterogeneity was assessed with the Cochrane Q test. The magnitude of the heterogeneity was evaluated with the I2 statistic. All statistical analysis were performed with Stata 11.0. Results. 4 case-control (with a total of 1,166 cases and 8,247 controls) and 19 cohort studies (with a total of 15,231 cases) were included in the meta-analysis. The risk of MM was statistically significantly higher among obese individuals compared with those who had normal weight: in cohort studies, overall RR 1.17 (1.08-1.26), men RR 1.17 (1.01-1.33) and women 1.20 (1.10-1.30); in case-control studies, overall RR 1.48 (1.28-1.69), men RR 1.47 (1.17-1.76) and women 1.50 (1.21-1.79). *Conclusions*. The results provide further evidence on the role of obesity as a potential risk factor for MM. From a public health perspective, in view of the global expansion of obesity prevalence, it is warranted to measure the impact of obesity on MM incidence.

1314

SKEWED RATIOS OF HEAVY CHAINS IGM-KAPPA /IGM-LAMBDA CHARACTERIZE REMISSION DEPTH BETTER AS IMMUNOFIXATION: APPRAISAL OF A NEW IMMUNOASSAY IN IGM PARAPROTEIN POSITIVE LYMPHOPROLIFERATIVE DISEASE

W Willenbacher,[1] W Prokop,[2] E Willenbacher[1]

[1]*Innsbruck University Hospital, Innsbruck, Austria*
[2]*Interdisciplinary Competence Center for haematological Diagnostics (IHK), Innsbruck, Austria*

Hevylite™, a novel immunoassay panel is designed for analysis of immunoglobulin heavy chain/light chain pairs. These assays can identify, separately, the different light chain types of each immunoglobulin class i.e. IgGκ IgGλ, IgAκ IgAλ, IgMκ, IgMλ. The molecules are then measured in pairs e.g. IgGκ/IgGλ to produce ratios of monoclonal immunoglobulin/background polyclonal immunoglobulin concentrations. Hevylite ratios (HLR) may serve as a parameter for plasma cell dyscrasia induced immunoparesis and serve as a new marker for validating remission depth and relapse probabilities. The lastly introduced IgMκ/IgMλ pair of assays was tested in patients supposed to be in remission or responding to specific treatments during routine surveillance visits for IgM parapotein secreting diseases [MALT NHL, IgM MGUS, Waldenstroems macroglobulinaemia (MW), IgM Myeloma (IgM MM) and AL-Amyloidosis] in comparison to serum measurements of total immunoglobulins, free light chain ratios (FLR) and immunofixation. Results were correlated to the patients further clinical course in the framework of informed consent to the local clinical registry. *Results*. 20 pts. with IgM MGUS (6 pts.), MW (6 pts.), IgM MM (3 pts.), MALT NHL (2 pts.), Amyloidosis (1 pt.) and previously suspected insecure IgM paraproteins (2 pts.) were analyzed. In comparison to standard electrophoresis (EP), immunofixation (IFT) and freelight ratios (FLR), HLR proved to be more sensitive detecting residual disease in 9 cases compared to EP (3), IFT (5) and FLR (3). 2 of the pts. exposing positivity in HLR only, later showed rapid clinical deterioration. *Conclusions*. As this case series illustrates HLR may serve as a sensitive new diagnostic tool for rational treatment allocation, especially with respect to maintenance and consolidation strategies. An update comprising data on IgA and IgG excreting diseases, mainly focused on myeloma, will be presented, as well as the outline of a cooperative European project to further validate this putative biomarker will be introduced. In the future HLR should be validated against techniques using sCR, flow-CR and molCR. Furthermore the effect of proven immunoparesis on complication rates respective to infections should be evaluated.

	No.	POSITIVE IN EP	POSITIVE IN IFT	POSITIVE IN HLR	POSITIVE IN FLR
IgM MGUS	6	1	1	2	0
MALT NHL	2	0	0	1	0
WM	6	0	2	4	1
Exclusion	2	0	0	0	0
Amyloidosis	1	0	0	0	0

IMMUNOGLOBULIN OLIGOCLONAL BANDS AND ISOTYPE SWITCHING AFTER BONE MARROW TRANSPLANTATION IN PATIENTS WITH ù MYELOMA

YT Chan, WI Kwong, R Ip, C Chim
Queen Mary Hospital, Hong Kong, China

Background: Appearance of new monoclonal or oligoclonal immunoglobulin bands was reported to be common in myeloma patients after receiving bone marrow transplantation (BMT). *Aims*: We aimed to study this phenomenon in a cohort of Chinese patients who had received autologous or allogeneic BMT as part of the treatment of myeloma. Methods: The clinical records and laboratory results of 41 patients over a 6-year period (2005-2010) were reviewed retrospectively. *Results:* The distribution of the original monoclonal immunoglobulin isotypes was IgA/L (n=7), IgA/K (n=3), IgG/L (n=3), IgG/K (n=13), IgD/L (n=4), Free L (n=5), Free K (n=5), hyposecretory (n=1). After receiving BMT, 23 patients (56%) develop new monoclonal or oligoclonal immunoglobulin bands detected by serum/urine protein electrophoresis and immunofixation. Of the remaining 18 patients, 4 were followed up for only 4 months or less and new immunoglobulin bands might develop subsequently. The isotypes of the new bands found were IgG/L (n=4), IgG/K (n=12), IgM/L (n=1), Free L (n=2), oligoclonal with no light chain restriction (n=4). Of those who were followed up for at least 23 months (n=20), 8 survived and 3 succumbed if new immunoglobulin bands were found. Although not statistically significant (p>0.05 by the Fisher Exact Probability Test) this survival rate was better than those who did not have new immunoglobulin bands (3 survived, 6 died). Of those who were followed up for less than 23 months (n=21), the survival rates were similar whether new immunoglobulin bands developed or not developed (10 survived 2 died and 9 survived 0 died respectively). *Conclusions:* This study demonstrates new monoclonal or oligoclonal immunoglobulin bands frequently develop after patients with myeloma receive BMT. Although not significant statistically the long term survival of patients who have new immunoglobulin bands appears more favourable than those who do not have new immunoglobulin bands. A larger cohort is needed to confirm these findings.

1316

PREVIOUSLY NOT DESCRIBED ASSOCIATION OF SKIN CRYOGLOBULINEMIA TO A SYSTEMIC CAPILLARY LEAK SYNDROME (SCLS) WITH MULTIPLE MYELOMA

T Gonzalez-Lopez,[1] G Hermida,[1] M Rodriguez Salazar,[1] J San Miguel,[2] P Greipp[3]
[1]*Hospital General Yague, Burgos, Spain*
[2]*University of Salamanca, Salamanca, Spain*
[3]*Mayo Clinic, Rochester, USA*

We submit the case of a 37 years-old woman diagnosed at the age of 29 of "Systemic Capillary Leak Syndrome"(SCLS),(Clarkson Syndrome). In April 2002 the patient had suffered an episode of hypovolemic shock, hemoconcentration, rhabdomyolysis, massive edema and acute renal failure. In May 2002 a IgG lambda monoclonal peak appeared in serum with 3% of bone marrow plasma cells (MGUS). With the diagnosis of SCLS the patient started prophylaxis with theophylline and terbutaline. Despite these drugs, the patient suffered two new episodes (2nd: October 2002; 3rd: May 2003;). A 4th attack in December 2004 was treated with a low dose of prednisone. A fifth episode in April 2005. The bone marrow study showed 0, 5% of polyclonal plasma cells. Peripheral blood flow cytometry showed CD25 coexpression in 50% of the CD4+ cells. She started treatment with Dexamethasone: 40mg per day, during 4 days every two weeks, for 3 months. She followed maintenance in July 2005 (Dexamethasone 40mg per day, four days each month) finishing in November 2007. In December 2007 a sixth episode occurred: Dexamethasone was discontinued and Verapamil was started. Two new episodes happened in December 2008 (7th) and in April 2009 (8th). In October 2010 the patient associated a symptomatic cryoglobulinemia (skin) to a multiple myeloma diagnosis (serum monoclonal component IgG Lambda of 3.01 g/dl. 11% of plasma cells with abnormal cytogenetics: t (4; 14) and del RB, a left iliac lytic lesion with negative spine MR and PET scan). The following diseases were ruled out: deficiency of C1 esterase inhibitor, autoimmune diseases, muscle disease and toxic exposure. After expert clinical advice the patient began CBD treatment (Cyclophosphamide i.v. 300 mg/m^2 days 1,8,15 and 22 ; Bortezomib 1.9 mg days 1,4,8 and 11; Dexamethasone 40 mg days 1,4,8 and 11) in December 16, 2010. After the first cycle, a 9th episode occurred in January 2011 that was managed (as all before) in the intensive care unit. Afterwards she has received two more cycles without no more episodes of the disease. Discussion. SCLS is a serious illness. The most important thing is an accurate diagnosis. The three criteria to be fulfilled are hypotension (usually with edema), an increase in hematocrit, and a decrease in albumin, accompanied often (75%) by a monoclonal gammopathy. The disease is sometimes confused with Acquired C1 esterase inhibitor deficiency. C1 esterase inhibitor levels both functional and antigenic and C3 and C4 levels should be normal but complement levels may be low. The treatment is prophylactic and consists of a methylxanthine combined with terbutaline. 80% of SCLS patients have MGUS. The risk of progression to myeloma is 1%/yr with an incidence similar in SCLS and in MGUS. In our case SCLS was associated with an MGUS which progressed to symptomatic MM during the disease evolution. Our case is unique because the association of SCLS with MM and cryoglobulinemia was not previously described. Our plan is to perform an autologous stem cell transplantation (ASCT) after chemotherapy that has never been done before to a SCLS patient.

HOW LARGE A DIFFERENCE BETWEEN SERIAL MEASUREMENTS OF FREE LIGHT CHAINS IS NEEDED TO INDICATE A RESPONSE OR PROGRESSION IN PLASMA CELL DISORDERS?

C Hansen,[1] L Nielsen,[2] N Abildgaard[1]
[1]*Odense University Hospital, Odense, Denmark*
[2]*Hospital of South West Denmark, Esbjerg, Denmark*

Background: since the commercially available immunoassay Serum FreeLite® Free Kappa & Free Lambda assay (the Binding Site Ltd, UK), for the measurement of free light chains (FLC) in serum was introduced, the use has been increasing along with the growing documentation for the utility of the assay. However, we lack information on the standards of analytical precision and to define the difference between serial results required for significance. *Aims*: to determine the biological variation of FLC when using the assay, thereby being able to set the desirable performance standards for the imprecision of the assay. Furthermore, we assessed the current imprecision of the analysis in use, measured on the Dade Behring BNII®, to determine whether it can meet the desirable standards. We also assessed the critical difference for two results to be significantly different ($p \leq 0.05$). Methods: FLC were measured in serum of 7 healthy persons (mean age 41 (21-60) years, 2 males and 5 females), 6 patients with multiple myeloma (mean age 63.2 (44-73) years, 3 males and 3 females) and 5 patients with monoclonal gammopathy of unknown significance (mean age 66.2 (62-70) years, 1 male and 4 females). From each patient we collected 8 serum samples, 5 of these taken every morning (between 8 and 9 am) for 5 days (day-to-day variation), and 3 samples during day one (between 12-13 pm, 16-17 pm and 20-21 pm) (24 hour variation). The serum samples were collected in PET serum tubes with gel. Samples were centrifuged, pipetted and stored at -20°C. All 8 samples from each patient were analysed in the same run, on the same instrument and by the same experienced technician. FLC were also measured in 17 serum samples with κ values from 15-11.000 mg/L and 15 serum samples with λ values from 14-516 mg/L to determine the imprecision. The critical difference is then calculated using the following formula: 2.77 (CVa2 + CVw2)½. *Results*. The intra-individual variation, CVw for κ and λ was found to be 6.8% and 7.4%. The inter-individual variation, CVb for κ and λ is 21.6% and 29.8%. The imprecision of the FLC assay, the coefficient of variation for the analysis, CVa, is 8.3% for κ and 5.1% for λ. The critical difference between two serial results to be significantly different is then calculated to be 29.7% for κ and 24.9% for λ. *Summary/conclusions*. We found a minimal and identical intra-individual biological variation for both healthy individuals and patients with monoclonal plasma cell disorders. The current FLC assay cannot meet the desirable laboratory performance standards, or analytical goals, for the imprecision of analytical methods derived from data on biological variation. The FLC analysis is showing great individuality, and the best reference for patients is their own former results. We calculated the critical difference between two serial results to be 29.7% and 24.9% for κ and λ, respectively, to be assessable as evidence of progression or response in plasma cell disorders.

1318

TRANSFORMATION OF MGUS INTO LIGHT CHAIN DEPOSITION DISEASE WITH A FAVORABLE RESPONSE TO BORTEZOMIB TREATMENT

S Vlastimil, J Minarik, T Pika, P Lochman, J Bacovsky, T Tichy
University Hospital Olomouc, Olomouc, Czech Republic

Background. Recent literature has described only rarely the transformation of MGUS into light chain deposition disease with successful treatment using bortezomib. *Methods and results.* Case description: A 24-year old male has been followed for 10 years for MGUS IgG lambda. During the examination for weight loss (15 kg) and dyspnea we found considerable anemia (Hb 86 g/L), increased levels of creatinine (143umol/L), serum M-protein 11,6 g/L, increase of λ serum free light chains (FLC) to 542.2 mg/l (κ/λ index 0.043), supression of normal immunoglobulin IgM (0.22 g/L), NT pro BNP 2813, slight focal increase of monoclonal plasma cells with expression of FLC -lambda, microscopic hematuria (294.0), proteinuria 2.1 g/24h (B-J-λ). Ultrasonography revealed kidney enlargement with hyperechogenity of the parenchyme, histology of the kidneys demonstrated linear FLC lambda deposits in the basal membrane of the tubules forming the diagnosis of LCDD type lambda. Spiral HR-CT and FDG-PET/CT displayed GGO of lower lung lobes and multiple lung parenchymal consolidations with left-sided pleural effusion. After 4 cycles of bortezomib and dexamethasone we could observe substantial improvement of overall condition, disappearance of dyspnea with pulmonary finding regression, normalization of blood count (Hb 132), decrease of M-protein (2,6g/L), FLC λ (25.8, kappa/lambda index 0.445), proteinuria (0.31 g/24h), creatinine (114 umol/l), decrease of beta2-microglobulin (2.8-1.6 mg/l). *Conclusions*. We conclude that MGUS patients need a permanent follow-up that might enable to record the transformation into another monoclonal gammopathy, in this case a LCDD with successful bortezomib and dexamethasone treatment as an induction for autologous stem cell transplantation.

PARTIAL 'LIGHT-CHAIN ESCAPE' PHENOMENON & CYTOGENETIC CHANGES - TWO CASE STUDIES

T Pika,[1] J Balcarkova,[2] P Mickova,[2] P Lochman,[3] J Minarik,[4]
J Bacovsky,[4] M Jarosova,[2] V Scudla[4]
[1]*Faculty Hospital, Olomouc, Czech Republic*
[2]*Department of Haematooncology, Faculty Hospital, Olomouc, Czech Republic*
[3]*Department of Clinical Biochemistry and Imunogenetics, Faculty Hospital, Olomouc, Czech Republic*
[4]*3rd Department of Internal Medicine, Faculty Hospital, Olomouc, Czech Republic*

Background. The 'light-chain escape' (LCE) phenomenon refers to the condition when, in the relapse/progression stage of multiple myeloma (MM), the secretion of monoclonal light chain becomes dominant to the detriment of the decreasing or only slightly increasing level of monoclonal immunoglobulin (MIG). This phenomenon is often observed in patients with the IgA isotype, after the completed chemotherapy involving the administration of latest biological agents. *Aims*. The communication aims at presenting 2 cases of detailed observation of LCE connected with cytogenetic change in the tumor clone. *Results*. Case 1: A 58-year-old patient with MM IgA-κ IIIA, ISS II (MIG 50 g/l, κ 129 mg/l), (46,XY[23]; FISH: 3 copies of IgH, 1, 7; 5 copies of 1q21; polysomy of 9,17), who achieved very good partial remission (MIG 1,47, kappa 20) after induction treatment with CTD and the subsequent autologous transplantation of stem cells (HD-T/ASCT). The following early progression was characterized by partial LCE (MIG 4,8, kappa 1763) and changed cytogenetics (46XY[17]/76-88[8]; FISH: 2 copies of IgH, t(8;14); 3 copies of 1; 6-7 copies of 1q21; polysomy 7, 9, 11, 17). The progression was associated with extramedullar proliferation and resistance to chemotherapy involving the administration of bortezomib as well as lenalidomid. Case 2: A 65-year-old patient with MM IgA-λ, IIA, ISS II (MIG 42, lambda 373), (46XX[9]; FISH: del RB1, t(4;14)) achieved stringent complete remission (sCR) after induction treatment with CTD and the subsequent HD-T/ASCT. After 15 months, focal relapse with extramedullar proliferation was proven in the pelvis area, while sCR was achieved after local radiotherapy and chemotherapy with VCD again. After next 4 months, systemic relapse of the disease was proven in the form of partial LCE (MIG 3,5, lambda 884) associated with karyotype evolution (43-45,XX,-2,-4,-15,+1-3 mar[cp9]; FISH: del RB1, t(4;14), del TP53. The relapse was connected with resistance to further chemotherapy, including the administration of lenalidomid. *Summary*. The above mentioned observation confirms that the presence of LCE and the unfavorable karyotype evolution in the disease progression/relapse tend to be related to the subsequent adverse course of the disease and resistance to therapy. Determining the serum levels of free light chains and repeated cytogenetic examinations allow to recognize early relapse/progression, particularly in case of LCE, and to identify patients with adverse prognosis requiring an early intensive chemotherapy.

THE IMPACT OF VELCADE TREATMENT ON SURVIVAL OF RELAPSED MYELOMA PATIENTS – A SINGLE INSTITUTION EXPERIENCE

TD Tan, MC Wu
Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan

Background. According to SUMMIT trial, Velcade salvage for repeated relapsed myeloma patients showed the overall response to have 28%. A randomized phase III multicenter, APEX trial, compared velcade to high dose dexamethasone in 669 patients with relapsed/refractory myeloma patients revealed superior median overall survival (29.8 vs 23.7 months) for velcade. Methods Between August 2005 and October 2010, nineteen relapsed myeloma patients underwent salvage velcade treatment at our institute and we compared the earlier 40 myeloma patients not received velcade. The endpoint is the overall survival in these patients with or without the use of velcade. Results. The median ages of velcade group and no-velcade group are 60.2 vs 61.7 (range 41~79 vs 39~80), respectively. The stage III disease percentages are 63.2% vs 55.0%. The median prior lines of treatment before velcade are 1.84. The median overall survivals of velcade group and no-velcade group are 60 vs 25 months (5-year survivals are 50.2% vs 15.5%). Conclusions -In our historical comparison between velcade and no-velcade groups of patients, velcade surely could prolong the overall survival of relapsed myeloma patients.

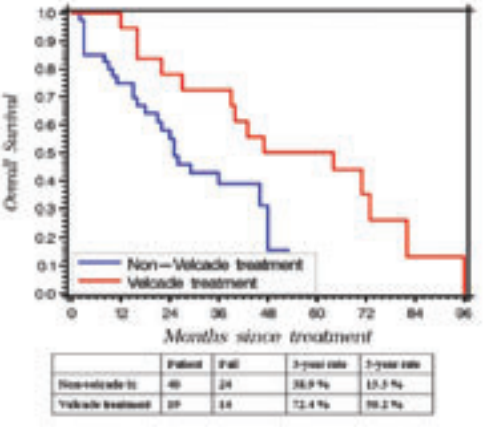

Figure 1. Overall survival of patients with/without velcade.

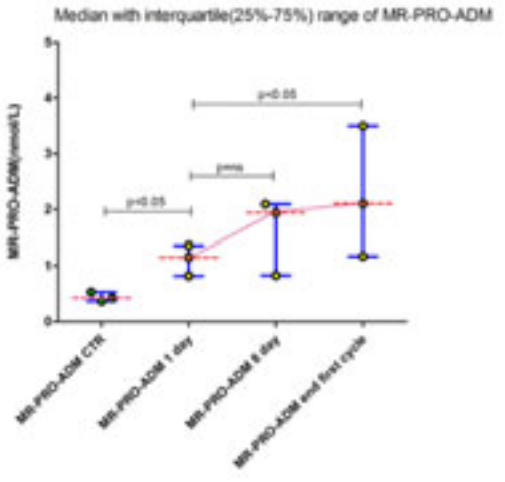
[5]*U.O.C.Diagnostica di Laboratorio - A.O.Sant'Andrea, Rome, Italy*

Background. Light-chain AL amyloidosis is the most common form of systemic amyloidosis and is associated with an underlying plasma cell dyscrasia. Circulation dysfunction is very frequent in AL amyloidosis patients. Serum midregional fragment of pro-adrenomedullin peptide (MR-proADM) and free light chain (s-FLC) κ and λ levels were investigated in order to evaluate circulation impairment in systemic AL amy-

loidosis. MR-proADM has been described as an useful marker for heart, respiratory and circulating dysfunction assessment and its role as a prognostic factor we evaluated in patients with systemic diseases. Aims and Methods. MR-proADM and s-FLC levels were detected in 7 patients (median age 63.1 yrs) with systemic AL λ amyloidosis at exordium observed to our Unit. Ten age-matched healthy control individuals were selected. According to age and disease risk stratification six patients were treated with upfront oral MelDex association (Melphalan 9 mg/sm, Dexamethasone 20mg day 1-4 q28); one subject started first line therapy with BorDex association (Bortezomib 1.3 mg/sm, Dexamethasone 20 mg day 1,4,8,11 q21). Three samples of peripheral blood were performed (treatment day 1, day 8 and at conclusion of the first cycle of therapy). The blood was separated into plasma at the time of blood draw and frozen to -80°C. In the evaluation of results Mann-Whitney U test, paired t test, Kruskal-Wallis one-way analysis of variance (Dunn's Method versus Control Group), Spearman rank correlation and Linear Regression were performed. P values ≤ 0.05 were considered statistically significant. *Results*. s-FLC λ values were significantly decreased during treatment ($p<0.05$). s-FLC κ/λ ratio and MR-proADM level were both increased at the end of first course of therapy ($p=0.002$ and $p<0.05$ respectively). On day 1 a positive correlation between s-FLC λ and MR-proADM level was observed ($r2=0.82$, $p=0.03$). *Conclusions*. The reduction of s-FLC levels observed in patients with systemic AL amyloidosis is indicative of hematological response to treatment. On the other hand, the progressive increase of MR-proADM serum level could represent a warning for possible vascular damage even if haematological response has been achieved. Therefore MR-proADM could be considered an additional useful biomarker in the evaluation of systemic AL amyloidosis



1322

PERCUTANEOUS VERTEBROPLASTY IN PATIENTS WITH SPINAL MYELOMA LESIONS

A Angona, E Abella, J Serra, A Solano, J Ares, M Ciria, S Saumell, E Gimeno, J Tena, A Alvarez-Larrán, C Pedro, C Jimenez, B Sanchez, A Salar, C Besses
Hospital del Mar, Barcelona, Spain

Background. About 80-90% of patients with multiple myeloma will develop skeletal-related complications, including diffuse osteopenia, focal lytic lesions, pathological fractures and bone pain. The therapeutic intervention for spinal myeloma lesions (SML) is based on analgesic medications, biphosphonates, radiation therapy, and in some cases, percutaneous vertebroplasty (PV) and balloon kyphoplasty. PV consists in the injection of polymethylmethacrylate into the damaged vertebral body via a percutaneous approach under image guidance. While in patients with non myelomatous osteoporotic vertebral fractures, 2 randomized trials have shown no beneficial effect of PV compared with placebo or a simulated procedure without cement, no specific data in controlled trials are available for myeloma patients. *Aims*. To evaluate the efficacy and safety of PV in patients with SML. *Methods*. Patients with SML not responsive to medical treatment were eligible. A computed tomography and/or magnetic resonance were performed, previously to the procedure. The presence of pathological fractures was evaluated by a rheumatologist and/or radiologist specialist and performed by an interventionist radiologist with local anesthesia and light sedation. In some cases, more than one vertebra was treated in the same procedure. Pain response was evaluated by a qualitative scale at 24 hours, 1 and 6 months after PV. *Results*. Nineteen PV were performed in 15 patients (12 females and 3 males). Thirty-eight vertebras were treated (maximum 4 vertebras in the same procedure), being the most frequent localization L3. Medium age was 74.8 years (range, 39 to 88 years). The evaluation of pain at 24 hours, 1 and 6 months after PV, showed improvement in 79%, 47% and 37% of cases, respectively. Notably, most patients reported pain in other skeletal localization caused by disease progression, but unrelated to treated vertebra. The incidence of cement leakage was 47%. Four out of 15 patients developed severe complications: 1 psoas hematoma without hemoglobin decrease in the first 24 hours after PV with good outcome, 1 death by respiratory failure of unknown etiology 11 days after PV and 2 pulmonary embolism (the first one died in the first 24 hours after the third PV because of a cement pulmonary embolism; the second one was hospitalized one week after PV and treated successfully with heparin). *Conclusions*. PV is an easy technique for SML not responsive to medical treatment that results in immediate pain relief in 79% of patients. Severe clinical complications secondary to cement leakage can be observed in 26% (4 out of 15) of patients, with some being life-threatening. These results suggest that PV can be useful in acute SML treatment to improve pain related but further studies with more patients and more follow-up should be undertaken to confirm the efficacy and the incidence of adverse effects.

1323

INTERNATIONAL STAGING SYSTEM PREDICTS PROGNOSIS OF CHINESE PATIENTS WITH MULTIPLE MYELOMA ACROSS DIFFERENT CALENDAR PERIODS WITH APPLICATION OF NOVEL AGENTS

LT Hsiao, SH Yang, HW Teng, YC Hong, CY Liu, YB Yu, JP Gau, JH Liu, PM Chen, TJ Chiou, CH Tzeng
Taipei Veterans General Hospital, Taipei, Taiwan

Background and Aims. The International Staging System (ISS) has been proposed since 2005 but the applicability of Chinese patients with multiple myeloma (MM) is not known, especially for those who had received treatments with novel agents. Methods. MM Patients who were newly diagnosed in Taipei Veterans General Hospital were enrolled between 1996 and 2007. Data of clinical features, laboratory tests and outcome at last follow up were collected. *Results*. Total 389 MM patients were enrolled, with median age of 71 years. Seventy-one percents of patients were male and more than 70% were older than 65 years. At diagnosis, patients had disease at Durie-Salmon (DS) stage III and ISS stage III were 72.7% and 56.2%, respectively; and those with serum creatinine Cr ☒2.0 mg/dL at diagnosis was noted in 34%. Comparing with those diagnosed in the first calendar period 1996-2001, patients of the second calendar period 2002-2007 were older and more have had received novel agents, especially for thalidomide.

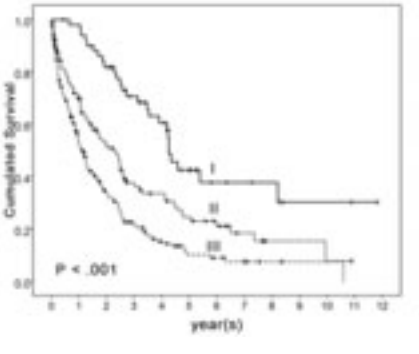


Figure 1. Survival curve of 351 MM patients by ISS.

The median overall survival was 20.5 months, with a significant increase in the second calendar period (15.3 and 28.2 months, respectively; P=0.002). In the Cox proportion model using those factors at diagnosis (except for DS and ISS themselves, and calendar period, those factors including elevated serum β2 microglobulin at diagnosis (>3.5), old age (> 65 years), and impaired renal function were independently associated with a poor survival. For the whole period, the ISS is better than DS in predicting the prognosis. The prognosis of MM patients in stage I and II of the second calendar period is significantly better than those of first period; however, the difference is not significant for stage III.

Conclusions. The findings of our study is the first to show the applicability of ISS in Chinese patients with MM, especially for those who have had received thalidomide.

1324

EFFECTIVENESS AND SAFETY OF LENALIDOMIDE IN PATIENTS DIAGNOSED OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA WITH EXTRAMEDULLARY DISEASE

Background. Secondary extramedullary plasmacytoma (EP) is an aggressive form of plasma cell disorders characterized by tumour masses of malignant plasma cells outside of the bone marrow in patients diagnosed of multiple myeloma (MM). Different therapeutical approaches have been reported with poor outcomes. Our study reports the role of lenalidomide for EP in daily clinical practice. We analyzed the clinical data of 18 Spanish patients (pts) with refractory or relapsed multiple myeloma with EP treated with lenalidomide outside of clinical trials in 12 GEM/PETHEMA centers between October 2007 and July 2010. The treatment consisted on lenalidomide ranging from 10 to 25 mg, given on days 1-21 of a 28-days cycles, combined with dexamethasone. The response rate was evaluated according to the international criteria and the response of EP by measuring size changes by physical examination and/or radiological imaging. The median observation time was 12 months (3 - 24). Safety data were evaluated according to the National Cancer Institute Common Toxicity Criteria for Adverse Events v.3. *Results*. Eighteen unselected patients (eight females, median age 68 years) were analyzed. A median of 3 previous lines of therapy (1 - 6) were given, including autologous stem cell transplantation (4/18), and novel agents such as bortezomib (18/18) and thalidomide (3/18). Median number of lenalidomide cycles administered was 7 (3 - 21) with a maximum response after a median of 3 cycles (2 - 10). The overall response rate (ORR) ORR of MM was 61.1%, (complete response (CR)CR 16.6%, very good partial response (VGPR)VGPR 22.2%). EP disappeared in 8/18; EP size decreased in 3/18. The progression free survival (PFS) and overall survival (OS) PFS and OS were 9.8 and 14.6 months, respectively. To date, 3/11 responding patients relapsed, and 10/11 patients are alive. Lenalidomide toxicity was predominantly hematologic (8/18) and; the incidence of venous thrombotic events was low (1/18). *Conclusions*. Our results suggest lenalidomide could be an effective and manageable drug for patients with advanced myeloma with EP. A randomised trial is needed to assess the role of lenalidomide compared with other treatment options for secondary EP.

1325

SURVIVAL ACCORDING TO END-ORGAN DAMAGE PATTERNS IN SYMPTOMATIC MULTIPLE MYELOMA

DY Kim,[1] DH Yoon,[2] S Kim,[2] CJ Park,[3] WK Min,[3] C Suh[2]

[1]*Department of Internal Medicine, Asan Medical Center, Seoul, South-Korea*
[2]*Department of Oncology, Asan medical center, Seoul, South-Korea*
[3]*Department of Laboratory Medicine, Asan medical center, Seoul, South-Korea*

Aims. This retrospective analysis was performed to evaluate the differences of survival according to end-organ damage (CRAB) patterns in symptomatic multiple myeloma patients. *Methods*. Between September 1995 and December 2009, 400 consecutive patients of symptomatic multiple myeloma were treated in the Asan Medical Center, Seoul, Korea. We retrospectively analyzed the results of these patients. The Cox proportional hazards model was used to assess prognostic significance of end-organ damage (CRAB) patterns adjusted for age, sex, performance status, autologous stem cell transplantation (ASCT), international staging system (ISS) stage and the use of novel agents. *Results*. The median overall survival was 30.0 months (95% CI 24.4-35.6) with a median follow-up period of 23.6 months (range, 0.2 - 184.8). The median age was 61 years (range 20-85). Male patients consisted of 55% (222/400). Calcium level increase (C, serum calcium >11.5 mg/dL) was present in 10% (40/389), renal insufficiency (R, serum creatinine > 2mg/dL) in 24.5% (98/390), anemia (A, hemoglobin 2 g/dL below the lower limit of normal or hemoglobin <10 g/dL) in 66% (264/392), and bone lesions (B, lytic lesions or osteoporosis with compression fractures) in 82% (328/395). ASCT was performed in 37.8% of patients (151/400) and 36.5% received novel agents at some time during treatment. In univariate analysis, ROTI patterns of R (C-R+A-B-), A (C-R-A+B-), RA (C-R+A+B-), RB (C-R+A-B+), AB (C-R-A+B+) and RAB (C-R+A+B) were associated with shorter overall survival (OS) (p<0.01). In multivariate analysis, only R, RA and RB patterns were prognostic for OS with marginal statistical significance (p=0.073, 0.082 and 0.090, respectively). However, R and RA patterns were significantly associated with poor prognosis in those who did not undergo ASCT (Hazard ratio 1.507, p=0.038; HR 1.694, p=0.016, respectively, Table 1).

Table1. Cox proportional hazards model for CRAB patterns in patients who did not undergo ASCT

Variable	Hazard Ratio	95% CI	P value
C	1.123	0.658-1.917	0.671
R	1.507	1.024-2.218	0.038
A	1.391	0.960-2.016	0.081
B	1.164	0.728-1.860	0.526
RA	1.694	1.101-2.606	0.016
RB	1.410	0.947-2.098	0.090
RAB	1.461	0.935-2.281	0.096

*Adjusted for age, sex, performance status, stage by international staging system and the use of novel agents at some time during treatment
*Other patterns are not shown here.

Conclusions. Patterns of end-organ damage may be prognostic in symptomatic multiple myeloma patients. Renal insufficiency in particular seemed to correlate with poor prognosis and it was more evident in those who did not undergo ASCT. In contrast to renal insufficiency, hypercalcemia or bone lesions were not related to OS.

1326

EMERGENCE OF OLIGOCLONAL BANDING IN PATIENTS WITH MULTIPLE MYELOMA AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

M Guimaraes,[1] F Trigo,[2] R Bergantim,[2] T Guimaraes,[3] JE Guimaraes[2]

[1]*Immunology Department, Faculty of Medicine UP, Porto, Portugal*
[2]*Hematology Department, Hospital Sao Joao EPE and Faculty of Medicine UP, Porto, Portugal*
[3]*Pathology Department, Hospital Sao Joao EPE and Faculty of Medicine UP, Porto, Portugal*

Background. The emergence of oligoclonal banding in immunofixation of patients with Multiple Myeloma (MM) after autologous stem cell transplantation (ASCT) is a well-recognized feature of humoral response. This oligoclonal pattern appears to reflect an indirect sign of immune reconstitution and a robust humoral response with an uncertain clinical meaning. *Aims*. To address the clinical meaning of the oligoclonal banding presence in MM patients after ASCT. Prevalence of oligoclonal humoral response (OHR), progression-free survival (PFS) and time to relapse (TTR) were considered as outcomes. Methods: MM patients who underwent ASCT in our Hospital, from 2000 to 2009, were retrospectively analyzed. PFS and TTR were assessed using the International Myeloma Working Group criteria. An oligoclonal humoral response was defined by a serum immunofixation (IFE) different either in heavy and/or light chain component from the original monoclonal protein resulting in multiple banding providing an typical oligoclonal serum IFE pattern. Serum analysis for immunoglobulins and other biochemical markers was performed. Results were expressed as median (range). Results: Sixty five patients (31 female, median age 56yr, median follow-up 12 months) were studied. The 3-year survival was 58.5% (95% CI, 51.9-65.1%) and 36 patients had relapsed. Thirty-five (53.8%) developed an oligoclonal humoral response after ASCT, 3 episodes of OHR was observed in 2 patients and 2 episodes of OHR in 7. Oligoclonal

humoral response was observed for 7 (1 - 37) months and in some cases it had persisted beyond relapse (5 patients). This response occurred with a 4 months increase in patient's survival. Interestingly, relapse occurred simultaneously with oligoclonal banding disappearance in 4 patients. Conclusion: Our results are consistent with the hypothesis that disappearance of oligoclonal pattern is a hallmark of an early relapse and may be used as a surrogate marker of response in patients with MM after ASCT.

AN AUDIT OF REVLIMID (LENALIDOMIDE) USAGE, MONITORING AND TOXICITY IN MYELOMA IN A SINGLE UK HEMATOLOGY CENTRE

K Lewis,[1] A Dillon,[2] J Byrne,[2] N Russell,[2] C Williams[2]
[1]*Nottingham University Hospitals NHS Trus, Nottingham, UK*
[2]*Centre for Clinical Haematology, Nottingham, UK*

Background. Myeloma has a median overall survival of 3-5 years from diagnosis. New drug therapies, such as Revlimid are now available with results from clinical trials (MM-009/MM-010) indicating a significant improvement in PFS and OS compared to conventional therapy. Following NICE guidance in June 2009, Revlimid has been used in relapsed myeloma patients after two or more lines of previous therapy. Regional East Midland (EM) Guidelines have also been written. Data on effectiveness and toxicity of Revlimid is limited outside of clinical trials and this study looks at usage at Nottingham University Hospitals (NUH) NHS trust, a large UK Haematology centre, which has treated the highest number of relapsed myeloma patients with Revlimid in the UK to date. Aims. To audit the use, response rates and toxicity of Revlimid in NUH against NICE guidance and EM guidelines. Methods. All patients initiated on Revlimid prior to September 2010 at NUH were audited using criteria defined by NICE(TA171) and EM guidelines. Case notes and online records were used to obtain information. Audit criteria included the indication for initiation of therapy, monitoring of response and continuation of therapy, frequency and management of grade III and IV haematological and non haematological toxicities (as per NIH CTC), initial dosing and modification, management of disease progression and all cause mortality. *Results*. The records of 78 patients, 37 female and 41 male, were audited. No females were of child-bearing potential. Median age of patients starting Revlimid was 70.5 years (range 42-87). All patients received Revlimid within its licensed indication. 76/78(97%) received it within NICE criteria. Median number of previous therapies was 3 (range 1-10) with 44/78 (56.4%) patients having had previous ASCT. Median number of cycles of Revlimid received was 7 (range 1-20). 47/78 (60.3%) patients received at least 6 cycles of treatment with 19/78 (24.3%) still on treatment after 12 cycles. 31/78 (39.7%) stopped prior to 6 cycles; 11 due to progressive disease and 14 due to toxicity. Dose was modified in 39/78 (50%) patients; 16 reduced due to declining renal function and 19 reduced due to haematological toxicity. Maximal response was achieved at a median of 3 cycles (range 1-10) and was CR in 8/78(10.3%), VGPR in 6/78 (7.7%) ,PR in 36/78 (46.2%) and SD in 19 (24.4%). 32/78 (42.3%) suffered grade III or IV haematological toxicity; 25 anaemia, 18 thrombocytopenia and 14 neutropenia. 31/78 (39.7%) suffered non haematological toxicity; including 6 with venous thromboembolism and 6 with worsening neuropathy. 47/78(60.3%) had a hospital admission during Revlimid therapy, most commonly with infection (23/47). 28/78 (36%) patients died: 19(67.9%) due to progressive disease and 7(25%) to Revlimid related toxicity including neutropenic sepsis and acute kidney injury. Summary/Conclusions. This single centre audit supports existing evidence that Revlimid is an effective treatment for relapsed myeloma, having maximal effect early in the treatment course. Its toxicity profile should not be underestimated, and its use requires careful monitoring and review.

1328

LENALIDOMIDE IN COMBINATION WITH LIPOSOMAL DOXORUBICIN AND LOW DOSE DEXAMETHASONE (RDD) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS

A Mele, B Rossini, S Sibilla, R De Francesco, C Del Casale, M Fina, D Carlino, G Greco, M Morciano, P Ferrara, A Ostuni, V Pavone
Card. „G. Panico„ Hospital, Tricase, Italy

Background. Despite advances in multiple myeloma (MM) therapy, the optimal treatment for relapsed/refractory MM patients has not been determined. Lenalidomide is approved, as single agent or in combination with dexamethazone, for treatment of myeloma relapsed patients. Previous trials have highlighted the activity of Liposomal Doxorubicin in this setting of patients. *Aims*. The aim of the study is to evaluate the efficacy and the safety of Lenalidomide in combination with Liposomal Doxorubicin and low dose dexamethasone (RDd) in relapsed/refractory multiple myeloma patients. *Methods*. Between June 2008 and November 2010, 17 relapsed/refractory myeloma patients were enrolled. Fifteen patients (9 male and 6 female; median age 72 years with range 62-83) are evaluable for response and toxicity. During treatment induction phase, patients received oral Lenalidomide 25 mg/die, on days 1 through 21, intravenous liposomal doxorubicin 30mg/mq on day 1 of the cycle, and dexamethazone 20 mg/die, on days 1, 8, 15, 22 of a 28 days cycle for 6 cycles. Subcutaneous low-molecular weight heparin has been used for thromboprophylaxis. Transfusion support, neutrophil and erythropoietic growth factors were allowed. The patients in complete and partial response (IMWG criteria) after induction phase, received 3 other cycles of RDd as consolidation. All responsive patients received low maintenance dose of Lenalidomide 10 mg/die on days 1 through 21 every 35 days until progression or unacceptable toxicity. If not reached partial response at least, the patients got out of study. Results: At the enrollment, 10 patients (67%) previously received two line therapies and 6 of these (40%) had been relapsed after autologous Stem Cell Transplantation. Six patients (40%) completed the induction and consolidation phase and are still in maintenance treatment; 5 patients (33%) completed only induction phase. Four patients are ongoing and not evaluable for response. At the end of the induction phase 8/11 patients were in VGPR (IMWG criteria), 1 in stable disease and 2 not response. All patients who finished 9 cycles are currently in VGPR (6 patients). With a median follow up of 15 months (6-18 months), 9 patients obtained VGPR, 1 SD, 2 died (1 for progression and 1 for transplant related mortality) and 3 patients are not evaluable. About toxicity, the most common adverse events were: neutropenia II/III grade in 9 patients (60%), anaemia and thrombocytopenia II/IV grade in 4 patients (26%). Thirteen patients (87%) needed G-CSF, 4 patients (26%) needed blood and platelet transfusion. Extra-hematological toxicity was: neuropathy I/II grade in 6 patients (40%), 2 case of FUO (fever of undetermined origin). One patient had deep venous thrombosis treated with therapeutic dose of subcutaneous low-molecular weight heparin. *Conclusions*. This preliminary experience suggests that Lenalidomide in combination with Liposomal Doxorubicin, and low dose of dexamethasone (RDd) seems to be efficacy and safety in relapsed/refractory myeloma patients.

1329

SEQUENTIAL THERAPY WITH VALD, BORTEZOMIB AND CYCLOPHOSPHAMIDE AND HIGH DOSE MELPHALAN AS INDUCTION THERAPY FOR MULTIPLE MYELOMA, FOLLOWED BY MAINTENANCE THERAPY WITH BORTEZOMIB AND INTERFERON

L Franceschini, M Postorino, L Pupo, S Vaccarini, M Rizzo, D Renzi, L Gianni, R Cannarsa, D Venditti, G Guiducci, F Gianotti, M Mirabile, L Cudillo, S Soave, P Caldarella, M Quaresima, D Hatzigiakoumis, M Cantonetti
Policlinico Tor Vergata, Rome, Italyì

Background. High-dose Melphalan and autologous stem cell transplantation (ASCT) is the standard therapy for Multiple Myeloma (MM) patients younger than 65 years even allogeneic Hemopoietic Stem Cells (HSC) donor is available. In multivariate analysis the Complete Remission (CR) before high-dose therapy is a significant independent variable for Overall Survival (OS) and Time To Progression (TTP). The advantages of a maintenance therapy and association with new drugs in a multi-step therapy is still under investigation. *Aims*. We tested the efficacy and toxicity of sequential therapy with Vincristine, Pegylated Liposomal Doxorubicin and Dexamethasone (VALD) followed by Bortezomib and Cyclophosphamide to obtain a CR before high dose of Melphalan and ASCT. The role of association Bortezomib and α-2-Interferon (α-2-IFN) as maintenance therapy was also investigated. Methods From September 2006 to June 2010 we treated 19 consecutive pts (6 M, 13 F) with new diagnosed symptomatic MM. Median age was 53 years (34-64). Thirteen pts had measurable M-protein: 8 presented IgG type and 5 IgA type. Two pts had non secretory and 4 micromolecular disease. International Staging System (ISS) score was 1 in 15 pts, 2 in 3 pts and 3 in 1 pt. All pts presented bone marrow plasmocytosis > 30% and 8/19 pts an extensive bone disease. Patients received every 21 days VALD regimen (V 2 mg, AL 40 mg/m2 at day 1 and Dexamethasone 40 mg day 1-4) for 3 cycles and 3 courses of Bortezomib (1.3 mg /m2 on days 1,4,8,11) followed by Cyclophosphamide 4g/m2 and G-CSF for HCS harvesting. On average 45 days later pts underwent to ASCT after infusion of Melphalan 200 mg/ m2 as conditioning regimen. The maintenance therapy with Bortezomib (1.3 mg/m2 every 21 days) was asso-

ciated to α-2-IFN (1,5 megaU/twice a week) for two years. α-2-IFN alone was administered at the same dosage until disease progression. Results All patients achieved Partial Remission (PR) after VALD scheme, 6/19 pts and 8/19 pts obtained a CR and a Very Good Partial Remission (VGPR) respectively after Bortezomib therapy with Overall Response Rate 73.7%. Three pts with a PR and 1 pt in early relapse after Bortezomib were excluded from the study. After Cyclophosphamide fourteen patients mobilized HCS and they harvested the CD34+ preset target (10x106/kg). Toxicity consisted in: 15 % WHO grade I-II neutropenia and 20% WHO grade I-II peripheral neuropathy. Two pts died for pneumonia, the first one after 2nd VALD cycle and the second one during autologous transplantation (pts showed ISS score 2 and 3, respectively). All 13 pts submitted to ASCT obtained a CR and 11 of them started maintenance therapy. After 33 months (range 7-46) of median follow-up 7/11 pts (63.6%) are in continuous CR. Conclusion The sequential therapy with VALD, Bortezomib and Cyclophosphamide, followed by high dose of Melphalan and maintenance therapy with Bortezomib-α-2-IFN is effective and low toxic as up-front therapy in MM and could be experienced in a larger number of patients.

1330

SIMILAR TOXICITY AND LOWER EFFICACY OF ALTERNATING WITH RESPECT TO CONTINUOS LOW-DOSE THALIDOMIDE FOR RELAPSED OR REFRACTORY MULTIPLE MYELOMA PATIENTS

S Mangiacavalli,[1] A Corso,[1] T Caravita,[2] G Albani,[3] F Cocito,[1] L Pochintesta,[1] A Pompa,[1] C Pascutto,[1] P Zappasodi,[1] S Bringhen,[4] A Palumbo,[4] M Cazzola[1]

[1]*IRCCS Fondazione Policlinico San Matteo, University of Pavia, Pavia, Italy*
[2]*Hematology Division, Ospedale S. Eugenio, Roma, Italy*
[3]*Neurology Division, Ospedale Civile, Verbania, Italy*
[4]*Azienda Ospedaliero Universitaria (A.O.U.) S. Giovanni Battista, Torino, Italy*

Background. Thalidomide is still a valid therapy for relapsed/refractory multiple myeloma (MM) patients. Prolonged exposure represents a risk factor for peripheral neuropathy (PN) occurrence. Aims. This study explores the feasibility of an alternating with respect to the standard continuous low-dose thalidomide scheme. Methods. Twenty-three MM pts relapsed refractory after at least one previous line of therapy were consecutively enrolled in a randomized multicenter two-arm trial. The study was performed according to the Declaration of Helsinki and approved by the ethics committee of each participating institution. Patients with baseline grade ? 2 NCI PN were not eligible. Pts received Thalidomide 100 mg on days 1-28 of each 28 day cycle in arm A (continuous treatment) and Thalidomide 100 mg on days 1-21 of each 28-day cycle in Arm B (alternating treatment). Oral Dexamethasone (20 mg on days 1-4; 14-18 of each cycle) was added to both treatment arms for the first six cycles then stopped if registering at least a partial response (PR). Thalidomide was given in both arms until progression or significant toxicity occurred. Additional neurologic assessment was performed with clinical neuropathy scores and nerve conduction studies at baseline, every three months for the first 2 years and then every six months until neurotoxicity resolution or end of follow-up for any cause. Results. Ten patients were randomized in arm A, thirteen in arm B. Patients in both arms had similar baseline characteristics. Twenty pts (86%) were in relapse after one previous chemotherapy. One patient had baseline grade 1 PN. The median follow up was 42 months (range 3-49 months). Twenty-two out of 23 pts were evaluable for response (there was one early-death for myocardial infarction). ORR was 77% (CR+VGPR 18%, PR 59%). Median time to best response: 5,7 months. OS from therapy starting was 44 months with 10 pts alive (43%). Sixteen pts progressed (73%), median PFS was 24.8 months. Arm A correlated to better responses and outcome. All patients in arm A were responsive (100%) with respect to 58% in arm B (p=0,03). In arm A there were 1 CR (10%), 2 VGPR (20%), 7 PR (70%), in arm B there were 1 CR (8%), 6 PR (50%), 5 NR (42%). Median PFS was 42 months in Arm A vs 7 months in B (p=0,02). Median OS was not jet reached in arm A compared to 24 months in Arm B. Seventeen pts (74%) developed PN: grade 3 PN was registered in 2 pts (12%), grade 2 PN in 7 pts (39%), grade 1 PN in 8 pts (49%). Median time to PN occurrence was 7,5 months. PN after thalidomide discontinuation was unchanged in 14 pts (82%) and slightly improved in 3 pts (18%). Incidence of PN (90% in arm A vs 62% in arm B, p=0,15) and time to PN occurrence (7,7 in arm A vs 5,6 months in arm B, p=0.3) were not statistically different in the two arms. Conclusions. Continuous low-dose thalidomide seems to give better results with a similar neurological toxicity to the alternating schedule.

1331

FIVE YEAR EXPERIENCE OF BORTEZOMIB FOR RELAPSED MYELOMA IN A REGIONAL CANCER NETWORK - THE ADDITION OF CYCLOPHOSPHAMIDE TO BORTEZOMIB IMPROVES RESPONSE RATE BUT NOT TIME TO NEXT TREATMENT

A Miles,[1] C Rudin,[1] G Balikai,[2] H Hunter,[2] D Turner,[3] J Blundell,[4] E Parkins[4]

[1]*Royal Devon and Exeter Hospital, Exeter, UK*
[2]*Derriford Hospital, Plymouth, UK*
[3]*Torbay Hospital, Torquay, UK*
[4]*Royal Cornwall Hospital, Truro, UK*

Background. The novel agent bortezomib has become a standard of care for relapsed myeloma within the UK. This followed National Institute of Clinical Excellence (NICE) guidance in 2007. However it is not certain whether bortezomib's effect is enhanced when given in combination with cyclophosphamide. *Aims*. We aimed to retrospectively determine the effect of bortezomib at relapse when given within a regional cancer network. At clinician's discretion, a cohort of patients also received cyclophosphamide in combination with bortezomib-steroid. In addition to determining response rate and time to next treatment, we also sought to establish the frequency of drug related side effects which limited treatment delivery. Methods. We audited the outcome of 118 myeloma patients identified chronologically who received treatment with bortezomib at first or subsequent relapse in the Peninsula Cancer Network, UK, between April 2005 and July 2010. Hospital records, chemotherapy prescriptions, and pathology systems were retrospectively analysed to provide audit data. Results. Median age at diagnosis was 61.6 (range 41.2-88.4), paraprotein class IgG (51%), IgA (30%), IgD (1%), light chain disease (18%). The median time from diagnosis to first receiving chemotherapy was 0.4 months (range 0-110.4). 39% of patients (n=46) received a melphalan autograft after initial chemotherapy. The median time from diagnosis to receiving bortezomib was 31.3 months (range 1.5-143.2). 68% received bortezomib at first relapse, 17% at second relapse, and 15% at third or subsequent relapse. 65.3% (n=77) received bortezomib alone or in combination with prednisolone or dexamethasone. 34.7% (n=41) received cyclophosphamide in addition to bortezomib-steroid at clinician discretion. Both groups received a median of 4 bortezomib containing treatment cycles (range 1-8). The overall response rate (ORR=CR+PR) was 56.1% (n=24) in patients who received cyclophosphamide-bortezomib-steroid compared to 39% (n=29) in the non-cyclophosphamide cohort (p=0.03) - CR 12.2%, PR 43.9% versus CR 10.4% and PR 31.2% in the cyclophosphamide vs no cyclophosphamide group respectively. Fewer patients receiving bortezomib with cyclophosphamide (2.4% versus 11.7%) ceased treatment because of loss of initial treatment response, although this did not reach statistical significance (p=0.16). There was no statistically significant difference in the median time to next treatment: 11.1 months for the bortezomib-steroid group, compared to 9.9 months for those receiving additional cyclophosphamide (p=0.502, Mantel-Cox test). 33.9% of all patients stopped treatment prematurely due to side-effects, mainly peripheral neuropathy (18.6% of all patients), indicating the difficulty in tolerating the regime, even if a response is occurring. The rates of treatment limiting neuropathy were similar in those receiving cyclophosphamide (17.1%) compared to bortezomib alone (20.8%). Six patients (5%) died whilst receiving treatment. *Summary/Conclusions*. In this retrospective audit, although the addition of cyclophosphamide to bortezomib produced a higher ORR, it did not result in an increase in the time to next treatment. Arguably the strategy of choosing myeloma treatments by best ORR also needs to consider the duration of the response. This study also demonstrates that more than one-third of patients needed to stop bortezomib therapy prematurely due to side effects, mainly neuropathy - highlighting the difficulties of bortezomib delivery in a *real world* clinical setting.

1332

COMBINATION OF BORTEZOMIB, MELPHALAN AND PREDNISONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

R García-Sánchez,[1] L Entrena,[1] S Duran,[2] A Hernandez,[3] M Casanova,[4] A Sanchez-Crespo,[5] M Anguita,[2] A Pascual,[6] A Bailen,[7] MC Galan,[8] G Ramirez,[1] M Almagro,[3] MP Queipo de Llano[1]

[5]Hospital Torrecardenas, Almeria, Spain
[6]Hospital de Ubeda, Ubeda, Spain
[7]Hospital Carlos Haya, Málaga, Spain
[8]Hospital de Antequera, Antequera, Spain

Background. Because of the incurable nature of multiple myeloma (MM), patients will inevitably experience relapse after initial therapy and require further treatment. The latest studies show that bortezomib plus melphalan-prednisone (VMP) is an effective therapy as first-line treatment in patients with MM ineligible for stem cell transplantation. Aim: To assess the efficacy and safety of VMP regimen in patients with MM previously treated with ≥ 1 lines of treatment. Patients and methods: 32 patients with relapsed/refractory MM received nine 6-week cycles of VMP: bortezomib (1.3mg/m^2 days 1,4,8,11,22, 25, 29, 32, cycles 1-4; and days 1, 8, 22, 29, cycles 5-9) plus melphalan (9mg/m2) and prednisone (60 mg/m^2) days 1 to 4, cycles 1-9. Response rates were measured using IMWG criteria and toxicities were assessed by CTCAE, v3.0. Results: Median age was 70 years (range 42-83) and included 15 male (47%). Disease characteristics at the time of diagnosis were: ISS I 39%, II 26%, III 35%, ECOG ≥ 3 in 17% and 21% of patients presented impaired renal function. Median number of prior lines therapies were 2 (range1-6).Previous schedules received were: conventional poliquimiotherapy 45%, alquilant agents 45%, bortezomib 48%, IMIDs-containing regimens 33% and ASCT 12%. With a median follow-up of 6 months (1-35) response rates could be evaluated in 20 patients (63%) after a median of 3.5 cycles (1-9) received. Overall response rate was 70% (20% CR, 5% nCR, 15% VGPR and 30% PR). OS was 87.5%. Most frequent grade ≥3 AEs included: anemia 16%, neutropenia 16%, thrombocytopenia 16%, peripheral neuropathy 16% and gastrointestinal symptoms 9%. 59% of patients required dose reduction of bortezomib, 18% and 9% of melphalan and prednisone, respectively. Ten patients (31%) discontinued treatment, 4 because adverse events. Summary: Our results confirms the tolerability and good responses possible with VMP schedule in previously treated MM patients and could be considered as alternative therapy in relapsed/refractory MM patients.

1333

THE EFFICACY AND SAFETY OF BORTEZOMIB,MELPLALAN PLUS PREDNISONA IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS NO ELIGIBLE FOR TRANSPLANTATION

R García-Sánchez,[1] L Entrena,[1] A Hernandez,[2] A Sanchez-Crespo,[3] M Casanova,[4] A Pascual,[5] M Anguita,[6] MC Galan,[7] A Bailen,[8] S Duran,[6] M Almagro,[2] G Ramirez,[1] MP Queipo de Llano[1]
[1]Hospital Virgen de la Victoria, Málaga, Spain
[2]Hospital Virgen de las Nieves, Granada, Spain

[5]Hospital de Ubeda, Ubeda, Spain
[6]Hospital de Jaen, Jaen, Spain
[7]Hospital de Antequera, Antequera, Spain
[8]Hospital Carlos Haya, Málaga, Spain

Background. Bortezomib plus melphalan and prednisone (VMP) is significantly better than melphalan plus prednisone alone for elderly patients with untreated multiple myeloma (MM).Our study reports the efficacy and safety of VMP schedule as first-line treatment in MM patients not eligible for high-dose therapy, in daily clinical practice. *Patients and Methods*. Between July 2007 and November 2010,we analyzed 62 patients treated with nine 6-week cycles of VMP: bortezomib (1.3 mg/m2 days 1, 4, 8, 11, 22, 25, 29 and 32, cycles 1-4 and days 1, 8, 22 and 29, cycles 5-9), with melphalan (9mg/m2) and prednisone (60mg/m2) days 1-4, cycles 1-9. Response was evaluated using the EBMT criteria. Toxicity was graded according to the NCI CTCAE v3.0. Results: Median age was 71 years (range 59-90) with 25 males (40%). After a median follow-up of 9.5 months (1-24), response was assessed in 48 patients (77%). Median cycles received was 4.25 (range 1-9). Overall response rate was 83 % (31% CR, 52% PR) with 2% MR, 8% SD and 6% progression. The incidence of grade 3-4 adverse events was: neutropenia 12%, anemia 7%, thrombocytopenia 7% and 10% gastrointestinal symptoms. Peripheral neuropathy was reported in 45% of patients, 13% grade 3-4. Seven (11%) patients had VZV infection. 39% required dose adjustment of bortezomib, 24% of melphalan and 7% of prednisone. Treatment was discontinued in 22 patients (36%), due to toxicity in 14. Overall survival was 87%. Conclusions: VMP is an effective and well tolerated treatment option for patients with newly diagnosed MM who are not candidates for intensive therapy. Our results are similar to those described in previous studies and requiring a longer follow-up for confirmation.

1334

ATYPICAL CASE OF POEMS SYNDORME WITH A GOOD RESPONSE TO LENALIDOMIDE - DEXAMETHAZONE

P Zikos, A Tsakiridou, O Drakoulogona, P Goudas, S Moulara, A Diamantopoulos
„Agios Andreas„ General Hospital of Patras, Patras, Greece

Poems syndrome is a rare disease characterized by peripheral neuropathy, skin lesions, organomegaly, endocrinopathy and monoclonal gammopathy. No effective treatment is available. We describe here a case of an atypical presentation of POEMS syndrome with response to lenalidomide. A 29 years old man was referred to our department due to anemia. Clinical examination revealed pale skin and maxilar lymph nodes in both maxilas, splenomegaly and ascites. Laboratory exams revealed an anemia, hypochromic microcytic, increase ESR, low iron levels and low TIBC levels with normal levels of ferritin and hypothyroidism. Lymph node biopsy revealed Castlleman's disease. The patient was treated with erythropoietin and methylprednizolone. Two months later peripheral neuropathy of left upper arm was occurred. The patient was admitted to the university hospital for evaluation. Detailed evaluation revealed, monoclonal gammopathy, and skin rash, while splenomegaly persisted despite the treatment with steroids. The patient was initially treated with 6 cycles of rituximab without any improvement. The patient was subsequent treated with Lenalidomide (25 mgr/2nd day) and Dexamathazone 40 mgr every week. A significant response was occurred after 2 months of treatment. Correction of anemia with normalization of red cell parameters, disappearance of monoclonal gammopathy, resolve of skin rash and decrease of splenomegaly was occurred . The patient continue the treatment and after 6 months of treatment is in a very good clinical situation. Conclusions : Poems syndrome is a rare disease with no specific treatment. Increased levels of VEGF and neoangiogenesis has been proposed as the pathogenetic mechanism. Different kinds of treatments (steroids, melphalan, monoclonal antibodies (rituximab)) have been used without success. Lenalidomide plus dexamethazone may be an potential treatment acting against VEGF, as we can propose, according to the results observed to our patient.

1335

THE OPG/RANKL SYSTEM IN MYELOMA BONE DISEASE

C Gurban, I Ionita, H Ionita, S Gotia, L Gotia
UMF Victor Babes, Timisoara, Romania

Aims. The aim of this study was to asses the implications of serum levels of OPG (osteoprotegerin) and sRANKL (soluble receptor activator of nuclear factor-κappa B ligand) in the process of bone remodeling in myeloma bone disease. Methods. The study was performed one group of patients with myeloma bone disease (n=9) compared with a control group (n=8, healthy patients). The serum levels of the bone markers were quantified by using ELISA (enzyme-linked immunosorbent assay) method. Results: In group with myeloma bone disease the serum levels of OPG were 32.55±2.65pg/ml ($p<0.001$), those of sRANKL were 47.53±4.25pg/ml ($p<0.001$), and OPG/sRANKL ratio were 0.684±0.061 ($p<0.002$), in comparing the control group: OPG were 42.15±3.19pg/ml, those sRANKL were 35.18±2.35pg/ml, and OPG/sRANKL ratio has the average of 1.198±0.134. Conclusions: The serum levels of OPG in myeloma bone disease decreased, secondary to the stimulation of osteoblastic apoptosis. These high levels of sRANKL certify the activation of osteoclasts with secondary increased bone resorption in myeloma bone disease. In this study we demonstrated a significant reduction of OPG/sRANKL ratio in group with myeloma bone disease, favoring osteolisis appearance, in comparison with the control group.

1336

BORTEZOMIB, ADRIAMYCIN AND DEXAMETHASONE IS SUPERIOR TO VAD-TYPE CHEMOTHERAPY: THE USE OF A NOVEL STATISTICAL METHODOLOGY IN THE PAD IRELAND TRIAL

C Morris,[1] P Kettle,[2] M Drake,[2] M Quinn,[2] T McGuigan,[2] G Cook,[3] K Yong,[4] M Leahy,[5] M O'Dwyer,[6] M Murray,[6] H Enright,[7] M McCloy,[8] P O'Gorman,[8] T O'Shea,[9] R Verghis,[10] R Popat,[11] H Oakervee,[11] J Cavenagh[11]

[11]*St Bartholomew's Hospital, London, United Kingdom*

Background. Bortezomib with adriamycin and dexamethasone (PAD) is a highly effective induction combination with response rates of up to 95% (Oakervee et al, BJH 2005; 129:755-62). In this study patients who had received VAD/VAD-like regimen acted as their own controls and were given further treatment using the PAD regimen and compared using appropriate statistical methods. *Aims*. To test the efficacy of bortezomib, adriamycin and dexamethasone combination therapy utilising a novel statistical analysis incorporating the patients own initial response to VAD as an internal control. *Methods*. This was a Phase 2 study with 3 cohorts of 23 patients. Cohort 1 was patients treated with VAD and auto transplanted, cohort 2 similar patients but not transplanted and cohort 3 was patients refractory to VAD who proceeded directly to PAD without any intervening chemotherapy. The paraprotein level at the start of each type of treatment (VAD or PAD) was used for estimation of response. *Results*. Using EBMT criteria with addition of VGPR, 7 patients in cohort 1 achieved CR after PAD compared to one patient achieving CR after VAD. Using the exact McNemar significant probability comparison of all responses gave p=0.0078 and using the Wilcoxon Signed Rank Test to compare reductions in paraprotein (or Bence-Jones protein) p=0.093 was achieved. A combined analysis of group 1 and 2 together gave similar results. In cohort 3 similar comparisons gave an exact McNemar significance of p=0.0005 and the Wilcoxon Signed Rank test p=0.002 in favour of the PAD therapy. Data on overall survival and toxicities will be presented. *Conclusions*. PAD was demonstrated to be significantly superior to VAD particularly in the refractory group. This type of study is an alternative to large phase 3 studies.

1337

RELATION BETWEEN SERUM FREE LIGHT CHAIN RATIO (FLC) AND SERUM MONOCLONAL PROTEIN CONCENTRATION IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

J Espinoza, L González García, J Espinosa Padrón, Y Perez Almeida, I Flores Fernández, M Abreu Gonzalez, A Kesper, M Moreno Moreno, M Barrios Suvelza, M Garcés Santos
Hospital „Nuestra Señora de los Reyes„, Valverde, Spain

Background. Serum FLC ratio has been identified as an independent risk factor for progression of monoclonal gammopathy of undetermined significance (MGUS) as reported in one retrospective study published by Rajkumar (Rajkumar et al., Blood 2005), where serum free light chains (FLC) ratio was abnormal in 33% of MGUS. *Aims*. To describe the frequency of abnormal serum free light chains measurement in a Canarian cohort of patients with MGUS and to correlate the results with the classic biological characteristics. *Methods*. Data from 22 patients with MGUS were analysed. FLC were measured during follow up consultation between January 2001 and December 2010. Demographic and laboratory data were compared using chi square tests for nominal variables and Kruskal-Wallis test for ordinal variables Results: Patients were 10 men and 12 women. Median age was 66 years (27 - 91). Isotype was: IgG in 16 patients (72%), IgA in 3 (14%), IgM in 2 (9%) and Light Chain in 1 (5%). Median level of monoclonal protein was 986 mg/dL (190-4850). Free-kappa light chain values ranged from 102 mg/dL to 847 mg/dL (median, 342 mg/dL), and free-lambda light chain ranged from 16 mg/dL to 563 mg/dL (168 mg/dL). Ten patients (45%) had elevated levels of k or l FLC. The median FLC ratio was 5.703 (r: 0.24-54.2). An abnormal FLC ratio was detected in 13 (57%) patients. The monoclonal protein was of the same isotype as the FLC in all patients. Patients with an abnormal ratio had higher monoclonal component concentration (median, 1306 mg/dL) than patients with normal FLC ratio (481 mg/dL) (p=0.011). There were no differences in the two groups about sex, age, hemogram, creatininemia, calcemia. According to the three factors risk models defined by Rajkumar (FLC ratio, size and type of monoclonal protein), 6 patients (27%) were classified in low risk group, 9 patients (41%) in low intermediate risk group, and 7 (32%) in high intermediate risk group. No patient was identified as belonging to high risk group. *Conclusions*. Our data report in this cohort that approximately a half of patients with MGUS have a normal serum FLC ratio and that approximately 70% of patients could be classified as low or low intermediate risk, with patients with an abnormal k/l ratio are associated with higher monoclonal component concentration Further prospective studies are necessary to confirm the predictive value of serum FLC ratio

1338

RETROSPECTIVE STUDY OF MONOCLONAL GAMMOPATHIES DETECTED IN THE CLINICAL LABORATORY IN A CANARIAN ISLAND: 9-YEAR SERIES

J Espinoza, L González García, J Espinosa Padrón, Y Perez Almeida, I Flores Fernández, M Abreu Gonzalez, A Kesper, M Moreno Moreno, M Barrios Suvelza, M Garcés Santos
Hospital „Nuestra Señora de los Reyes„, Valverde, Spain

Introduction: We studied the incidence, classification and isotype distribution of monoclonal gammopathies detected between 2001 and 2010 in the clinical laboratory of Hospital "Nuestra Señora de los Reyes", El Hierro Island, Canarias, with a population of approximately 9500 inhabitants. Aims: This retrospective analysis is to analyse the incidence of monoclonal gammopathies in our clinical population. Methods: Database results on routinely ordered serum protein electrophoresis (SPE), between 01/01 and 12/10, were analysed, looking for identification of pathological results. Age-specific prevalence rates for El Hierro island data were calculated by dividing the number of participants with MGUS in each age stratum by the number of participants in that stratum The age-adjusted incidences were standardized with respect to the WHO World Standard Population Distribution, based on the world average population between 2000 and 2025. The clinical diagnosis was recorded from the patient case history. Results: We examined the results of 2449 SPE registered during this period. M-protein with either SPE or IFE as well as sFLC results were detected in a total of 29/609 >18 years-old patients; all of them had been diagnosed within this period, representing a 2,76% prevalence in our population. The mean age-adjusted incidence of monoclonal gammopathy was 7,56 per 100,000 inhabitants/year, ranging from 2,31/100,000 in 2001 to 9,25/100,000 in 2009. The median patient age at diagnosis was 68 years (range 27-91 years), with males accounting for 41% of all cases of monoclonal gammopathy. A 76% of the patients were clinically defined as presenting monoclonal gammopathy of undetermined significance, and 24% presented multiple myeloma. The most frequent M-protein isotype was IgG (668%), followed by IgA (17%) and BJ protein (10%). Conclusion: Many of our community hospital patients are over 50 years of age and present with non-specific symptoms potentially related to disorders associated with an abnormal EEF requiring laboratory evaluation and in which the clinical haematological analysis should play an important role in the diagnosis of MGUS.

1339

COEXISTANCE OF MULTIPLE MYELOMA (MM) AND MYELOPROLIFERATIVE, LYMPHOPROLIFERATIVE OR AUTOIMMUNE DISORDERS; A SINGLE CENTER EXPERIENCE

A Bitsani, A Efthymiou, MC Kyrtsonis, E Pessach, V Bartzis, E Koulieris, T Tzenou, M Dimou, P Panayiotidis
Laiko Hospital, Drosia-Athens, Greece

Background. The simultaneous occurrence of multiple myeloma (MM) and myeloproliferative (MPD), lymphoproliferative (LPD) or autoimmune disorders (AD) is extremely rare. *Aims*. To report the characteristics of patients presenting coexisting MM and MPD, LPD or AA and to discuss the possible biologic mechanisms involved. Methods: Medical files from 297 MM patients diagnosed and followed in our section from 1999 to present were reviewed. *Results*. 15 patients that presented another MPD, LPD or AD together with multiple myeloma, were identified. Among them, 9 were females and 6 were males. Their median age was 55 years (range 25-70). 5 of the studied females had presented the other disease (one chronic myeloid leukaemia [CML], one chronic lymphocytic leukaemia [CLL], one Hodgkin lymphoma [HL], one follicular lymphoma [FL], one essential thrombocytosis [ET], one systemic lupus erythematosus [SLE]) prior to MM; their MM was asymptomatic, of IgG type and preceded by a documented IgG-MGUS in 5 of them; the 6th patient had light chain (LC) MM accidentally diagnosed with the onset of acute renal failure. The remaining 3 females (all symptomatic and of IgG type) presented the second disease (two idiopathic thrombocytopenic purpura [ITP], one Erythroleukemia) after MM; the patient with

Erythroleukemia was in CR and had previously received VAD and lenalidomide. 4 out of 5 males patients had symptomatic MM. In one ET and gastric MALT lymphoma preceded IgA-MM and in another myelofibrosis also preceded IgA-MM. In the other patients both disorders presented concomitantly (one vasculitis and IgA-MM, one polycythemia Vera [PV], one autoimmune haemolytic anaemia [AAA] and LC MM, one acquired FX and VIII deficiency and IgA-MM). *Discussion/Conclusions.* The frequency of concomitant MM and MPD, LPD or AD was equally distributed (5% for each subgroup). In the majority of females patients a documented MGUS coexisted with an MPD or LPD and preceded MM onset. In MM patients presenting AAA, ITP or acquired FX and VIII deficiency, the paraprotein may have act as autoantibody. In the other patients with a preceding or simultaneous MPD or LPD, a molecular abnormality could have been the triggering factor for the appearance of the second in turn disease.

1340

THE RELEVANCE OF THE INTERNATIONAL STAGING SYSTEM IN MULTIPLE MYELOMA IN THE ERA OF NEW TREATMENT MODALITIES

J Bila, J Bodrozic, M Smiljanic, B Andjelic, D Antic, M Todorovic, A Vidovic, M Gotic, I Elezovic, D Tomin, B Mihaljevic
Clinic of Hematology, Belgrade, Serbia

Background. The International Staging System (ISS) was established and validated, providing consistent risk distinction of multiple myeloma (MM) patients (pts). The aim of study was to analyze the relevance of ISS scor in the first relapse of MM patients treated with thalidomide or bortezomib based regimens. Patients and methods. The study included 53 MM pts (27 male/ 26 female, mean age 56 yrs, range 38-81) in the first relapse of myeloma. IgG myeloma was diagnosed in 38pts, IgA in 7pts, IgD in 1pts, light chains in 6pts and non-secretory in 1pts. According to the clinical stage (CS, Durie-Salmon), patients were distributed as follows: II 14pts; III 39pts. Regarding ISS score, the group included: ISS1 12pts; ISS2 14pts; ISS3 27pts. Renal impairment was present in 6pts. Thalidomide based regimens (Thal-Dex 13pts; CTD 7pts; TCED 5pts) were applied in the group of 25pts (mean no.6 cycles, range 2-8cycles), while 28 pts were treated with bortezomib based therapy (Vel-Dex 26pts; CVD 1pts; MPV 1pts, mean no.6 cycles, range 2-8 cycles). Results: In the group of pts treated with thalidomide based regimens, positive treatment response (CR+VGPR+PR+MR, EBMT criteria) was achieved in 18/25pts. According to the ISS score, there was no significant difference (Fisher test, p=0,378) in the treatment response between high-risk pts (ISS3: 13/25 pts) and myeloma pts of low- and intermediate risk (ISS1+ISS2: 12/25pts). High-risk pts had significantly shorter duration of progression-free interval (mean: ISS3 3,38m vs. ISS1+ISS2 26,8m, Mann-Whitney test p=0,021). Median overall survival for this group of pts was 81m (range 14-100m). In terms of the overall survival, no difference (Log-rank test p=0,175) was found between pts with ISS3 (median 62m, range 18-120m) and pts with ISS1 and ISS2 (median 48m, range 14-114m) treated with thalidomide based regimens. In the group of pts treated with bortezomib based therapy, treatment response (CR+VGPR+PR+MR, EBMT criteria) was achieved in 25/28pts. Still, there was no difference (Fisher test, p=0,5) in the treatment response between pts with ISS3 (13/28pts) and pts of low- and intermediate risk (ISS1+ISS2: 12/28pts). No difference was found in duration of the progression-free interval (mean: ISS3 15,17m vs. ISS1+ISS2 15,38m, Mann-Whitney test p=0,641). Median overall survival for pts treated with bortezomib based therapy was 72m (range 18-120m). Patients with ISS1 and ISS2 had significantly longer overall survival (Log-rank test, p=0,019) comparing to pts with ISS3 (ISS1+ISS2: median 84m, range 42-120m vs. ISS3: median 60m, range 18-96m). Conclusion: The ISS score, as a surrogate marker of MM activity, is of relevance for the relapsed myeloma patients in terms of "tailored-treatment"approach in the era of new treatment modalities. According to the ISS score, the notified influence of thalidomide- and bortezomib-based treatment on duration of progression-free interval and overall survival of relapsed myeloma patients indicates these agents as promising constituents of induction and maintenance therapy.

1341

BONE DENSITY CORRELATES WITH MICRO-CT TRABECULAR VOLUME CHANGES IN ROUTINE DIAGNOSTIC BONE MARROW SAMPLES IN MULTIPLE MYELOMA (MM) PATIENTS AFTER BORTEZOMIB EXPOSURE

M Zangari
University of Utah School of Medicine, Salt Lake City, USA

Bone disease is present at diagnosis in almost all patients with MM and decreased bone mineral density is also frequently observed. Available clinical data indicates that bortezomib has a positive impact on bone health through a bone anabolic effect. We prospectively analyzed sequential bone densities from 11 patients with MM (2 smoldering and 9 relapsed cases), treated with single agent bortezomib without use of biphisphonates. Dexascan was obtained at baseline and after treatment with a median time of bortezomib exposure of 6 months ranging from 2 to 12 months. We compared T-score changes at lumbar spine and at femoral neck with micro-ct analysis of bone marrow biopsies obtained at the time points of the radiological studies. With a median age of 63 years, 9 males and 2 females were enrolled. At baseline mean Lumbar Spine and femoral neck T-scores were -1, 08 and -1, 9 respectively. After bortezomib exposure the mean Lumbar Spine T-score was -0, 9 and the Femoral Neck T-score was -1, 5 with mean positive changes in lumbar T-score of 0.3 and at femoral neck of 0.57.Five patient's slides from routine diagnostic core biopsy samples were digitally scanned with the Aperio XT system (Vista CA USA). The entire hematopoietic area and bony trabeculae were identified using the genie pattern recognition algorithm and each compartment was quantified .The calculated trabecular area was then divided by total surface area to obtain trabecular volume (TV). The change in mean lumbar spine bone density (0.38), and the change in mean femoral neck bone density (1.1) were statistically significant (p=0.03, p=0.04 respectively) .At the same time the change in mean trabecular volume (23.8) was also found statistically significant (p=0.02 paired t-test). This pilot study has confirmed that patients treated with single agent bortezomib experience a significant increment in bone mineral density at lumbar spine and at femoral neck even after two months of therapy and for the first time we were able to report parallel statistical changes in TV by micro-ct analysis of routine diagnostic bone marrow biopsies.

1342

ALLELIC BURDEN OF JAK2 V617F MUTATION AND CLINICAL OUTCOMES IN MYELOPROLIFERATIVE NEOPLASMS

S Syed Rahim Shah,[1] N Mohamed Yusof,[2] R Harun,[2] Z Md Isa,[3] CL Wong[3]
[1]*Hospital Sultan Haji Ahmad Shah, Temerloh, Pahang, Malaysia*
[2]*UKM Medical Molecular Biology Institute, Kuala Lumpur, Malaysia*
[3]*Pusat Perubatan Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia*

Background. Myeloproliferative neoplasms (MPNs) are clonal haematopoietic stem cell neoplasms characterized by increased proliferation of the erythroid, megakaryocytic, and myeloid lineages. The discovery of JAK2 V617F mutation in 2005 had significantly advanced our understanding of the BCR-ABL negative MPNs. JAK2 V617F mutation is a point mutation in the pseudokinase domain of the Janus kinase 2 gene resulting in the substitution of valine for phenylalanine. To date, it is still unclear how a single mutation can give rise to the different clinical phenotypes seen in MPNs. It has been postulated that additional genetic factors such as the degree of allelic burden may be contributing to the difference in the clinical phenotypes. Aims. The main aim of this study was to investigate the relationship between the allelic burden of JAK2 V617F mutation and clinical outcomes in patients with polycythaemia vera (PV), essential thrombocythaemia (ET) and primary myelofibrosis (PMF). The clinical outcomes of these patients were studied according to common haematological parameters and clinical characteristics. Methods. A retrospective study was performed on patients who were diagnosed with PV, ET and PMF. Demographic data and peripheral blood samples were collected for molecular analysis of the JAK2 V617F gene mutation. In addition, full blood count, erythropoietin and ferritin levels were measured. RNA was extracted from the peripheral blood samples and amplified using reverse transcription-polymerase chain reaction (RT-PCR) and direct DNA sequencing techniques. Clinical outcomes of the patients were critically evaluated. Results. 48 patients were recruited into the study: 27 PV, 19 ET and 2 PMF. Although RNA was successfully extracted from all blood samples, only 46 out of 48 gene sequencing chromatograms were eventually analysed as the remaining 2 patients with PV had very high background interference rendering them uninterpretable. JAK2 V617F mutation was found in 31 out of 46 patients (67.4%). Out of the 25 patients with PV, 22 patients (88%) were found to have the mutation, 14 (63.6%) were homozygous and 8 (36.4%) were heterozygous. Out of the 19 patients with ET, 7 patients (36.8%) were found to have the mutation, all of whom were heterozygous. Both patients with PMF had the mutation, 1 homozygous and 1 heterozygous. At diagnosis, homozygous PV patients were noted to have significantly higher leucocyte counts ($p<0.05$) and lower platelet

counts (p<0.05) as compared to their heterozygous and wild-type counterparts. On the other hand, heterozygous ET patients had significantly elevated (p<0.05) haematocrit levels as compared to their wild-type counterparts. JAK2 V617F positive patients had more incidence of splenomegaly and thrombosis although this was not directly related to the degree of allelic burden. However, homozygous patients with PV demonstrated a higher incidence of constitutional symptoms and required more treatment. Conclusions. Although the incidence of JAK2 V617F mutation in MPNs is similar to previous studies, there is a higher incidence of homozygosity in patients with PV in Malaysia which is associated with significantly higher leucocyte counts and lower platelet counts, higher incidence of constitutional symptoms and more requirement for treatment. Further research is required to elucidate this further.

1343

JAK2 MUTATIONAL SCREENING: HIGH RESOLUTION MELTING CURVE ANALYSIS OR SEQUENCING?

Q Goodyear, A de Kock, C Viljoen
University of the Free State, Bloemfontein, South Africa

Background. The V617F mutation in the JAK2 gene is found in 95% of the patients with Polycythemia Vera (PV) and about half the patients with Myelofibrosis (MF) and Essential Thrombocythemia (ET). Commonly used methods for the detection of the mutation includes allele specific PCR, ARMS and sequencing. More recently however, high resolution melting curve analysis is being used as a screening tool as it is *Aims*.The aim of the study was to use high resolution melting curve analysis to screen exon 14 of the JAK2 gene in a cohort of patients with myeloproliferative neoplasms using copy DNA as template. The presence of the mutation in both the myeloid and lymphoid lineage was also investigated. Methods: A cohort of 15 patients diagnosed with several MPN's according to WHO 2008 criteria was selected. Blood was collected and the two cell lineages were separated using density gradient centrifugation and magnetic bead selection. RNA was extracted from each cell type, converted to cDNA and used as template for high resolution melting curve analysis and sequencing. Results: The V617F mutation was identified in ten of the fifteen patients and the mutation was found in both cell types for each patient. Sequencing identified the mutation to be negative in five patients, heterozygous in nine of the patients and homozygous in one PV patient. The melting curve data did not correlate with these findings. *Conclusions*. In the study the V617F mutation was the only identified mutation in exon 14. The mutation was found in 83.3% of the PV patients, 60% of the ET patients and 40% of MF patients when sequencing was performed which correlates well with the current prevalence data of the mutation in literature. High resolution melting curves analysis was unsuccessful to determine the V617F mutation accurately.

1344

THE MONITORING OF AUTOIMMUNE PROCESS IN PATIENTS WITH ACUTE AND CHRONIC MYELOID LEUKEMIA

N Tretyak, A Gordienko, T Perekhrestenko, Y Shorop, A Gordienko
Institute of Hematology and Transfusiology of NAMS of Ukraine, Kyiv, Ukraine

The inadequate reaction of the immune system on autoantigens develops due to the breakdown of the mechanisms supporting immunologic tolerance, and can be observed in blood diseases. It has been established that in patients with acute myeloid leukemia, before treatment, that the maintenance of T-regulative CD 4+CD25+ -lymphocyties in peripheral blood has lowered an average of 3.5 times in comparison with control group (p<0.05), whereas levels of autoantibodies in double-stranded deoxyribonucleic acid (DNA) of class M (anti-dsDNA-IgM) and class G (anti-dsDNA-IgG) in blood serum has raised an average of 2.3 and 2.2 times in comparison with control parameters (p<0.05). Between the number of T-regulative lymphocyties and levels of anti-dsDNA-IgM and anti-dsDNA-IgG a strong return correlation interrelation has been found. K.Spirman's coefficient of rank correlation (r) was equal to -0.92 and -0.81 accordingly. In patients with chronic myeloid leukemia in acceleration phase before beginning treatment the number of T-regulative lymphocyties in the peripheral blood has lowered by 6.1 times (p<0,01), and levels of anti-dsDNA-IgM and anti-dsDNA-IgG in serum have raised an average of 3.5 times (p<0.05) and 5.3 times (p<0.01) compared to control parameters. These patients also revealed a strong return correlation between the quantity of T-regulative lymphocyties and levels of anti-dsDNA-IgM (r= -0.83) as well as anti-dsDNA-IgG (r=-0.92). Therefore, one of the probable factors promoting the breakdown of immunologic tolerance at acute myeloid leukemia and chronic myeloid leukemia, can be the significant reduction of the subpopulation of T-regulative lymphocyties.

1345

EFFECTOR AND IMMUNOREGULATORY CELL IN POLYCYTHEMIA VERA

T Costello, M Sanchez, T Le Treut, D Olive, J Imbert
Université de la Méditerranée, Marseille, France

Background. Polycythemia vera (PV) is a myeloproliferative disorder of slow development, which may allow the development of an immune response. It is characterized in most cases (95%) by the presence of a mutation in the JAK2 gene, which constitutive activation leads to the proliferation of myeloid cells, especially red blood cells. Aims. We have focused our work on natural killer (NK) cells in since, on the one hand, NK cells have antitumor and antiviral properties, while, on the other hand, abnormalities of these cells, including a decrease in cytotoxic activity, have been described in the majority of haemopathies. Thus, we hypothesized that, in PV, NK cells share phenotypic or functional abnormalities that allow immune escape of the malignant clone. Methods after free and informed consent 16 patients before any cytotoxic treatment (15 of them sharing the the mutated JAK2 gene) and 25 healthy controls (matched for age and sex ratio) were studied for NK phenotype and function, together with analysis of the variois immune cell subpopulations. Results. While an equivalebt number of lymphocytes were numbered in control subjects and in patients with polycythemia vera, we observed in the latter an increased number of NK cells. Nonetheless, these NK cells displayed poor cytolytic activity, despite normal perforin and granzyme expression. Phenotypic analysis revelaed an increased expression od inhibitory receptors. Conclusions. We now have to explain the impaired cytolytic activities of NK cells by two main research axix; first, we will analyse the transcriptomic profile of normal versus polycythemia vera patients NK cells. Then, we will focus our attention on the transcriptional regulation of inhibitory and activating receptors in normal versus polycythemia vera patients NK.

1346

VITAMIN D 24-HYDROXYLAZE (CYP24A1) GENE IS UPREGULATED IN JAK2V617F POSITIVE ET AND PMF

T Stoos-Veic, I Crncec, A Livun, V Pejsa, O Jaksic, R Ajdukovic, V Haris, M Marusic-Vrsalovic, R Kusec
University hospital Dubrava, Zagreb, Croatia

Background: Vitamin D is myeloid cell-differentiating and proliferation controlling molecule. One of the metabolizing enzyme for vitamin D synthesis and degradation is the mitochondrial enzyme D-24-hydroxylaze (CYP24A1) that maps to 20q13.2, below the telomeric end of common deleted region in MPN. Aim: We studied the expression of CYP24A1 in a cohort of MPN patients and associated this to their JAK2 V617F mutation status and hematological data. Methods: Fifty newly diagnosed, untreated patients with MPN (12 PV, 26 ET and 12 PMF) were taken into the study after obtaining informed consent. RNA was isolated from unfractionated bone marrow MNCs and after RT tested for expression of CYP24A1 (AB Hs00989014 Taqman Assay) in AB7300 Real-time PCR analyzer.

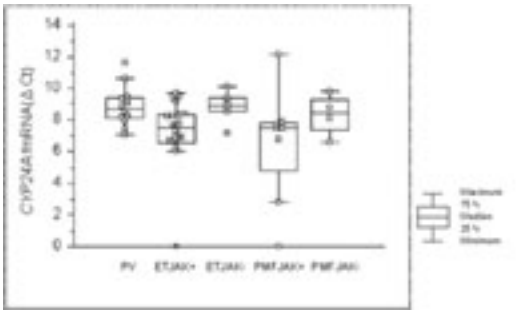

Figure 1. Post-hoc analysis of CYP24A1 expression

Data of relative expression of CYP24A1 were correlated to JAK2 mutation status and their core hematological parameters. Results: For the entire MPN group CYP 24A1 was not differently expressed concerning

the presence of JAK2V617F mutation: median ΔCT =7,823 for JAK2+ vs. 8,77 for JAK2- (p=0,10). However, when ET-JAK2+(67%ET) and PMF-JAK2+(66%PMF) were compared to their JAK2-mutation negative counterparts the expression was significantly higher in JAK2+ cases (7,48 vs 8,92; and 7,44 vs 8,42 respectively p< 0,05 (Figure 1). There was no correlation of CYP24A1 expression with patients' age, blood counts or ALP score. Conclusion: CYP24A1 gene for metabolizing the 1,25(OH)2D3, active form of vitamin D is upregulated in JAK2 mutated ET and PMF. Due to the important biological role of vitamin D in myeloid cell diferentiation and proliferation, this observation deserves further studies.

1347

JAK2 V617F MUTATION AND JAK2 46/1 HAPLOTYPE ANALYSIS IN A GROUP OF PATIENTS WITH ISCHEMIC STROKE. A PRELIMINARY REPORT

A Trifa,[1] R Popp,[1] A Catana,[1] M Porojan,[1] M Farcas,[1] A Cucuianu,[2] I Pop[1]

[1]*Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania*
[2]*Ion Chiricuta Cancer Institute, Cluj-Napoca, Romania*

Background. The JAK2 V617F mutation, the most common marker of the myeloproliferative neoplasms (MPN), has been reported to occur also in some patients with thrombotic events, including ischemic stroke, without any sign of an overt MPN. The JAK2 46/1 haplotype is a predisposing factor for the JAK2 V617F-positive MPN. *Aims*. To evaluate the frequency of the JAK2 V617F mutation in a group of patients with ischemic stroke, and the possible contribution of the JAK2 46/1 haplotype to the occurrence of the ischemic stroke. Methods. Ninety-five patients with ischemic stroke, without any overt MPN, and 150 individuals without ischemic stroke or MPN, were included in the study. The JAK2 V617F mutation was assessed in all the patients by a semiquantitative tetra-primer PCR assay. The rs10974944 (C/G) SNP, in which the G allele tags the JAK2 46/1 haplotype, was analyzed in all the patients and controls by a PCR-RFLP assay. *Results*. Only one patient (1%) was found to harbour the JAK2 V617F mutation; his mutant allele burden was less than 5%. The GG/CG genotypes of the JAK2 rs10974944 SNP had a similar distribution both in patients and controls (41% versus 45.3%, p-value >0.05). *Summary/conclusions*. Our results indicate that the JAK2 V617F is a rather rare finding in patients with ischemic stroke, without overt MPN. Also, the V617F-predisposing JAK2 46/1 haplotype, does not seem to have a significant contribution to the occurrence of the ischemic stroke.

1348

COMPARISSON OF TWO REAL TIME PCR METHODS FOR JAK2-V617F ALLELIC CHARGE DETERMINATION

MT Gomez Casares,[1] G Santana,[1] C López-Jorge,[1] G Sanchez,[2] M García-Bello,[1] T Ramirez,[1] J Lopez Brito,[1] A Lemes,[1] S De la Iglesia,[1] M Perera,[1] T Molero[1]

[1]*Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain*
[2]*C.A.E Vecindario, Las Palmas, Spain*

Background. In 2005, JAK2V617F mutation was detected in the vast majority of patients with PV and in nearly 50% of patients diagnosed of ET and PMF. Nowadays, several efforts have been made in order to standardize JAK2 allelic charge quantification, which has been considered to be useful in monitoring bone marrow transplanted patients or treated with alpha interferon or new JAK2 inhibitors. *Aims*. To compare two determination methods for allelic charge of JAK2-V617F. MATERIAL AND METHODS: 47 DNA samples of patients with a JAK2V617F positive myeloproliferative disorder were studied by two quantitative methods: 1) The standard one (Ipsogen Kit) was performed according to manufacturer instructions. It uses specific primers for the mutated allele and for JAK2 wild-type, normalizing the number of copies with plasmid calibration curves for the mutated and wild-type alleles. 2) The second one is also based on the use of specific primers for the mutated allele and for the total JAK2. We used as calibration curves DNA dilutions from HEL cellular line in K562 for the mutated allele and DNA dilutions from a healthy donor for the total JAK2. In both cases LightCycler platform was employed for the PCR and the ratio of mutated JAK2/total JAK2 was calculated as well. Results were analyzed by statistical methods. RESULTS: 1) Statistical analysis by concurrent test shows a correlation coefficient of 0,9421 (95% CI of 0,9033-0,9656). 2) Using Passing Bablok method, the linearity test, which is used to determine how data are adjusted to a line, shows lack of significant linearity deviation (p>0,10). However, the line that correlates both procedures is above the line of equality, which might indicate that our method slightly underestimates the quantity given by standard method, being the bias greater in medium and high values, what is confirmed by Bland & Altman analysis. 3) Using T-test to compare the means of both methods, we determined that the mean of our method is lower in an average of -3,61 (95% CI -5,5557 to -1,6486) with a p=0,0006. This was confirmed by U-Mann Whitney test (p<0,0001). *Conclusions*. 1) The coefficient of concurrent between both methods is quite high. 2) There exists a bias of 3,6 units lower in our method, being greater in higher values, which indicates that the bias is not constant, but proportional to those values. 3) Both methods are useful for MRD study, as it is within the lowest values where the concordance is higher.

1349

CLINICAL AND BIOLOGICAL CHARACTERISTICS ACCORDING TO THE BURDEN OF JAK2V617F MUTATED ALLELE IN BCR-ABL NEGATIVE MPNS

L Zamora,[1] B Xicoy,[1] M Cabezón,[1] L San Miguel,[1] S Marcé,[1] M Morgades,[1] J Ribera,[1] E Plensa,[2] C Soriano,[1] A Domingo,[3] D Dominguez,[1] I Portal,[4] I Granada,[1] M Hernandez,[5] A Cisneros,[1] L Rodriguez,[6] J Grau,[1] N López,[7] J Ribera,[1] E Feliu,[1] F Millá[1]

Background. The association of JAK2V617F mutation with BCR-ABL negative myeloproliferative neoplasms (MPNs) has been one of the most seminal medical discoveries in recent years. Although it is a controversial issue, some groups have shown that the amount of V617F allele correlates with a more pronounced myeloproliferative phenotype favoring a higher hemoglobin level and leukocyte count, higher risk of pruritus, splenomegaly and thrombosis and more probability of transformation either to myelofibrosis or to acute myeloid leukemia. *Aims*. The aim of this study was to analyze the prognostic relevance of JAK2V617F mutational status and the allele burden of mutated cases in serial newly diagnosed patients with MPNs who had not received previous treatment. Methods A total of 128 consecutive patients were included (median age 65; 59 males) with BCR-ABL negative classic MPNs (90 ET, 20 PV, 18 PMF) fulfilling the 2008 World Health Organization criteria. This study was conducted in accordance with the Declaration of Helsinki. Genomic DNA was extracted from peripheral blood samples using the QIAamp DNA mini kit (Qiagen). All samples were coded and assayed blindly in duplicate for the JAK2V617F mutation. To detect the presence or absence of JAK2V617F mutation an Allele-Specific PCR using TaqMan allelic discrimination was used. This assay is based on the simultaneous use of 2 specific TaqMan probes and the measurement of the respective fluorescence of the 2 alleles (FAM for V617F and VIC for wild-type) to differentiate the amplification of each allele. The JAK2 MutaQuant assay (Ipsogen, Luminy Biotech) was used to detect the JAK2V617F quantity in genomic DNA by real-time detection of fluorescent signals using double-dye hyrolysis oligonucleotide probes with calibration standards at 4 different concentrations, according to the manufacturer's protocol. Laboratory parameters (red blood cell indexes, leukocyte and platelet counts) and clinical data (constitutional symptoms, complications and progression) were collected. ResultsA total of 81 (63%) patients were JAK2V617F positive (57.8% ET, 95% PV and 55.5% PMF). The median value of V617F allele burden was 23.93% (range, 1.26%-95.02%). Neither a JAK2V617F mutated status nor the quantity of burden of mutated allele was correlated with the presence of constitutional symptoms or complications (thrombosis, hemorrhage, transformation or others). Patients harboring a JAK2V617F mutation had significantly higher hemoglobin level (mean (SD) 144 (36)g/L vs. 129 (17)g/L, p<0.001), leukocyte count (mean (SD) 11.4 (7.9)x10^9/L vs. 9.9 (9)x10^9/L, p=0.021) and lower platelet count (mean 650 (373)x10^9/L vs. 780 (463)x10^9/L, p=0.018). By considering the quantity of the JAK2V617F allele burden, a statistically significant correlation with leukocytosis (p=0.027, Rho Spearman positive coefficient of 0.252) was observed. Conversely, wild-type patients had a higher probability of progression (15%), than those harboring the mutation (4%), p=0.032. Summary In newly diagnosed MPNs the presence of JAK2V617F showed statistically significant association with a more pronounced myeloproliferative phenotype favoring higher hemoglobin lev-

el and leukocyte count. Nevertheless the platelet count was lower in mutated cases. When considering the quantity of the JAK2V617F allele burden, statistically significance was only confirmed for leukocytosis. The risk of progression was significantly higher in wild-type patients.

SOMATIC MPL MUTATIONS ARE NOT FOUND IN A LARGE COHORT OF PEDIATRIC PATIENTS WITH SPORADIC ESSENTIAL THROMBOCYTHEMIA

E Bonamigo
University of Padua, Padua, Italy

More than 50% of adult but only about 25% of pediatric patients with Essential Thrombocythemia (ET) carry JAK2V617F mutation. Furthermore, 1 to 9% of adult ET patients carry mutations in the thrombopoietin receptor, (MPL) gene, leading to ligand-independent activation. The known somatic mutations of this gene are MPLW515L, MPLW515K, MPLW515A while germinal MPLS505N mutation was discovered in familial thrombocytosis. ET rarely occurs in pediatric patients and few is known about MPL mutations in sporadic pediatric ET. To study the prevalence of MPL mutations in children with sporadic ET. This study includes 53 ET pediatric patients (29 females and 24 males, age range 0.6-18 years) who have been diagnosed with ET according to WHO criteria. In all cases platelet count continuously exceeding $600x10^9$/l in the absence of known cause of reactive/secondary thrombocytosis. Five patients (9,4%) resulted JAK2V617F-positive and were excluded from further analysis. We investigated the remaining 48 patients for MPL mutations with direct sequencing of granulocytes DNA. As controls, we searched MPL mutations in 46 ET JAK2V617F-negative adult patients with ET.We found only one germinal mutation (MPLS505N) in a girl coming from Rome area; her thrombocytotic mother and her grandfather, who had normal platelet count, carry the same mutation. This family seems to belong to the same cluster described by other authors (*Teofili et al, Haematologica 2009*). We didn't identify any MPL somatic mutation in pediatric population but MPLW515L in 4 (9%) adult patients. Our data confirm that pediatric thrombocytoses are heterogeneous diseases. In this rare set of patients there is a very low probability of carrying JAK2 mutation; MPL mutations are even rarer. The biological basis in pediatric ET seems different than in adults.

[4]*Department of Hematology L, Herlev Hospital, University of Copenhagen, Herlev, Denmark*
[5]*Department of Hematology L, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark*

Introduction. Olfactomedin 4 (OLFM4) is a member of the olfactomedin-related glycoprotein family, which is specifically expressed in neutrophils and gastrointestinal tract. The findings of highly expressed OLFM4 in immature neutrophils in the bone marrow and markedly downregulated in neutrophils in peripheral blood might suggest OLFM4 to be involved in trafficking of neutrophils from bone marrow into peripheral blood. Being involved in cell cycle regulation, cell adhesion and inflammation we focused upon OLFM4 as a candidate gene to be involved in these processes in PMF and related neoplasms. *Patients and Methods.* Gene expression microarray studies have been performed on whole blood from control subjects (n = 21) and patients with ET (n =19), PV (n = 41), and PMF (n = 9). Gene expression profiles were generated using Affymetrix HG-U133 2.0 Plus microarrays recognizing 54,675 probe sets (38,500 genes). Total RNA was purified from whole-blood and amplified to biotin-labeled aRNA and hybridized to microarray chips. Results: 20.439, 25.307, 17.417, and 25.421 probe sets were identified to be differentially expressed between controls and patients with ET, PV, PMF, and CPMNs as a whole, respectively (false discovery rate (FDR) adjusted p values < 0.05). Amongst the 50 most up-regulated genes in ET, PV and PMF, the OLFM4 gene and several other genes encoding constituents of neutrophil granules (MMP8, DEFA4, ELA2, CRISP3, CTSG, AZU1, MPO, BPI, PRTN3, LTF) were significantly and uniquely deregulated in PMF patients, not being found among the Top-50 in ET and PV. Among these genes, the MMP8 gene displayed by far the highest upregulation (fold change (FC) 22.5 and FDR adjusted p value $6.9x10^{-7}$) followed by DEFA4 (FC 12 and FDR adjusted p value $9.4x10^{-7}$), ELA2 (FC 12 and FDR adjusted p value $9.5x10^{-7}$) and OLFM4 (FC 11 and FDR adjusted p value $8.4x10^{-5}$). Except for MPO, CRISP3 and BPI all the above genes showed no significant changes in either ET or PV as compared to controls. *Discussion and Conclusion.* Using transcriptional profiling of whole blood, we have for the first time identified a highly significant and unique upregulation of the OLFM4 gene in patients with PMF. This gene may be involved in abnormal trafficking of immature myeloid cells into the circulation with egress of CD34 + cells from the bone marrow to extramedullary sites in spleen and liver. In support of this contention was the concomitant highly upregulated MMP8 and ELA2 genes, encoding enzymes which are considered to account for altered adhesion of myeloid progenitors to bone marrow niches in myelofibrosis. The highly upregulated OLFM4 may also contribute to clonal expansion both by enhancing myeloproliferation and myeloaccumulation consequent to decreased apoptosis. In conclusion, we have shown that OLFM4 together with other constituents of neutrophil granules are highly expressed in patients with PMF but not in ET and PV patients.

1352

MOLECULAR MARKERS IN MYELOPROLIFERATIVE NEOPLASMS THE NEED OF A STUDY ALGORITHM

T Magalhaes Maia, M Coucelo, C Bento, L Ribeiro
Centro Hospitalar de Coimbra, Coimbra, Portugal

Introduction. The molecular markers (JAK2 and MPL mutations) have been proven to have an enormous value not only for the understanding of the MPN's etiology and pathogeny but also for diagnosis. According to recent data, the JAK2 mutations are identified in 90-95% of the Polycythemia Vera (PV) and in 50-55% of Essential Thrombocythemia (ET) and Primary Myelofibrosis (pMF). Objectives. Identification of JAK2 and MPL mutations in a group of 271 patients suspected of MPN. Material and Methods.Observational, retrospective and descriptive study in a group of patients suspected of MPN, studied in the Hematology Laboratory of Centro Hospitalar de Coimbra between the 1st January 2008 and 31st December 2010. JAK2 V617F mutations were studied by ASO PCR and JAK2 exon12 and MPL (exon 10) mutations were studied by SSCP and sequencing. All data collected were statistically worked using SPSS® v 17.0. Results. During the period analyzed, we studied 271 samples from patients suspected of MPN (175 from our out-patient clinic - Group 1, and 96 sent from other hospitals - Group 2). Group 1: Median age 64 years, M:F ratio 81:94; 77/175 (44%) studied for polyglobuly, 98/175 (56%) for thrombocytosis; polyglobuly group: - 67,2% JAK2V617F positive; 2,6% with exon12 mutations - Median full blood count (FBC) values: - (JAK2 positive) Hemoglobin(Hb) 18,5g/dL, hematocrit (Ht) 56,3%, leukocyte (Leuk) 11,2 103/L and platelets 532 103/L;- (JAK2 negative) Hb 17,2g/dL, Ht 51,4%, leuk 6,4 103/L and platelets 211 103/L. Thrombocytosis group - 54% JAK2 V617F positive; 2,8% with MPL (exon 10) mutations. Group 2. In this group, as we only received blood samples (BS) for the JAK2 V617F screening, we could only analyze the information that was sent along with the samples. Median age 66y, M:F ratio 60:36; 46 (47,92%) studied for polyglobuly, 50 (52,08%) for thrombocytosis; Polyglobuly group - 26,09% JAK2 V617F positive; - Median FBC values: Hb 17,2g/dL, Ht 52,4%, leuk 7,07 103/L and platelets 228 103/L. Thrombocytosis group - 44% JAK2 V617F positive Conclusions. In group 1 - patients observed in our department - we diagnosed: 54 PVs, (51 JAK2 V617F positive, 2 exon12 positive and 1 PV JAK2 negative), corresponding to 98,15% JAK2 positive PVs; 72 ET (61,11% JAK2 V617F positive and 2,78% MPL exon 10 positive); 10 pMF (70,0% JAK2 V617F positive). Among all the MPN diagnosed we were able to identify a molecular marker in 75,71% of the patients. In Group 2, BS sent to our lab, curiously the median FBC values were similar to the JAK2 negative polyglobulies from group 1. Even though we lacked clinical information in group 2, when we compared the percentage of JAK2 V617F positivity in both thrombocytosis groups (1 and 2), the results were similar (54,08% Vs 44%). When comparing the polyglobuly groups, we found a very different positivity of JAK2 V617F: 67,23% group1 Vs 26,09% group 2. This last data emphasizes the importance of a study algorithm for polyglobulies which are, undoubtedly, a diagnostic challenge.

STUDY OF EFFICACY RECOMBINANT HUMAN ERYTHROPOIETIN IN PRIMARY MYELOFIBROSIS PATIENTS WITH ANEMIA

N Romanenko, K Abdulkadyrov
Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Sant-Petersburg, Russian Federation

Background. Primary Myelofibrosis (PMF) is Phyladelphia-negative myeloproliferative neoplasm with different clinical presentation including anemia, splenomegaly, leukocytosis or leukopenia, thrombocytosis or thrombocytopenia and constitutional symptoms. Anemia is frequent symptom and may get worse prognosis and survival of PMF patients. To correct anemia are used red blood cell (RBC) transfusions. However long period RBC transfusions may cause iron overload and reduce survival. Aims. To study the efficacy of Recombinant Human Erythropoietin (EPO) in PMF patients with anemia: reducing RBC transfusion-dependency, increasing hemoglobin (Hb) concentration and anemic symptoms. *Methods.* This study includes 26 PMF patients diagnosed between 1998-2009. Diagnosis of PMF was based on WHO criteria for Primary Myelofibrosis. The median age of patients was 70 years (range 50-84). All patients had anemia with initial Hb concentration 5.3-9.9 g/dL. RBC transfusion-dependency was defined as the persistence of RBC transfusion administrated to correct anemia with Hb concentration <8,0 g/dL. EPO-therapy was administrated to correct anemia for patients with Hb concentration <10,0 g/dL. EPO was injected subcutaneously on 10.000IU 3 times a week (30.000IU a week). The effectiveness of EPO was estimated on Hb concentration, red blood cells count and hematocrit (Ht) concentration. The target Hb level was 12,0 g/dl and planned duration of treatment with EPO within 24 weeks. Positive response was considered as 1) transfusion-independency in patients before needed RBC transfusions or 2) increase Hb level <2,0 g/dL. All patients received constantly antitumor therapy (Hydroxyurea, Interferon alpha, small doses Ara-C). The patients with iron, vitamin B12 deficiency and so severe hemolysis (bilirubin >30 µmol/L) were excluded in this investigational study. *Results.* Mean baseline Hb concentration was 8.09±1.49 g/dL (5.3-9.9 g/dL), RBC count - 2.55±0.59x10^{12}/L (1.35-3.31x10^{12}/L) and Ht - 24.4±5.9% (15.2-36.8%). 13 patients (Hb <8.0 g/dL) were depended on RBC transfusions and they needed of 2-9 unite of RBC every 1-3 months. Others (n=13) were transfusion-independent patients (Hb was 8.0-9.9 g/dL). The period of EPO-therapy was from 6 to 24 weeks (mean 11.1±6.2 weeks). During the study period out of 13 patients 7 ones kept on transfusion-dependency and their Hb level was depended on RBC transfusions. In whole group of PMF patients with anemia (n=26) positive response was observed in 12 patients (46.2%) and their Hb concentration, RBC count and Ht significantly ($p<0.05$) increased from baseline to 11.54±1.56 g/dL (10.3-14.6 g/dL), 3.38±0.77x10^{12}/L (2.59-7.70x10^{12}/L) and 35.3±4.8% (30-43%), respectively. Besides most patients with positive response reduced such symptoms as feeling fatigue, weakness all over, having trouble starting things because of tiredness, depression, drowsiness, giddiness, headaches, pain in thorax. However 11 positive response patients needed in administration of EPO-therapy in 2-4 months because of anemia relapsed (Hb concentration decreased <10,0 g/dL) but such way of persistent treatment could prevent RBC transfusions. We observe no one case of thrombosis during the period >6 months. The count of platelets before and after EPO-treatment was not significant difference ($p>0.1$): 372.5±248.7x10^{9}/L and 355.0±285.4x10^{9}/L, respectively. *Summary.* EPO-therapy is effective treatment of reducing RBC transfusion-dependency, increase Hb concentration and decrease anemic symptoms in PMF patients.

1354

ABNORMAL PRODUCTION OF INTERLEUKIN (IL)-6 IN ESSENTIAL THROMBOCYTHEMIA

R Cacciola, E Di Francesco, C Ferlito, F Pezzella, E Seria, E Cacciola
Hematology, University of Catania, Catania, Italy

The essential thrombocythemia (ET) is a myeloid neoplasm characterized by platelet-endothelial activation and a inflammatory component responsible for myeloproliferation. Therefore, we evaluated platelets, platelet factor 4 (PF4) and tissue factor pathway inhibitor (TFPI), tissue factor (TF) and von Willebrand factor (vWF), as indicators of platelet-endothelial activation, inteleukin-6 (IL-6) as inflammatory marker and white blood cell count (WBC) and lactate dehydrogenase (LDH), as myeloproliferative indexes. We recruited 25 patients with ET (10 males and 15 females, mean age 58 years) who fulfilled WHO criteria. Their mean duration of disease was 8 years (range, 5-21 years). All patients were on aspirin. PF4, TFPI, TF, IL-6 and vWF were measured by ELISA and immunoturbidimetric assay, respectively. Platelets and WBC were measured by automated analyser. LDH was determined by enzymatic method. All patients had thrombocytosis (961±235x10^{9}/L), high PF4 (153±62 IU/ml vs 6±2 IU/ml) ($p<.0001$), TFPI (142±66 ng/ml vs 91±11 ng/ml(($p<.0001$), TF (214±266 pg/ml vs 5±3 pg/ml) ($p<.0001$), low vWF (25±9.6% vs 81±18%) ($p<.0001$), high IL-6 (68±53 pg/ml vs 8.3±2.6 pg/ml) ($p<.0001$), leukocytosis (9.2±18x10^{9}/L vs 5.5±11x10^{9}/L) ($p<.0001$) and elevated LDH (461±190 UI/L vs 154±20 UI/L) ($p<.0001$). No correlation there was between IL-6 and platelets and PF4, and TFPI, and TF, and vWF. A positive correlation was found between IL-6 and WBC and LDH ($p=0.037$ and $p=0.001$, respectively). These data suggest that IL-6 may be a clonal marker promoting myeloproliferation.

1355

INCREASED PLATELET AND LEUKOCYTE ACTIVATION AS CONTRIBUTING MECHANISMS FOR THROMBOSIS IN ESSENTIAL THROMBOCYTHEMIA AND CORRELATION WITH JAK2 MUTATION STATUS

E Tothova, A Kafkova, B Benova, M Sarissky, M Hlebaskova
UPJS and University Hospital L.Pasteur, Kosice, Slovakia

Background and Aims:Leukocytes contribute to the pathogenesis of thrombosis in Essential thrombocythemia (ET) through recently discovered mechanisms of activation and interaction with platelets and endothelial cells. The aim of the present study was to ascertain the role of platelet and leukocyte activation in the thrombosis of ET. Methods: The activation status of platelets and leukocytes was assessed by flow cytometry studies in 74 patients with ET (34 with previous and 40 without history of thrombosis) and in a group of age-and sex-matched healthy individuals. The assessment included platelet P-selectin expression (measured both at baseline and after stimulation with ADP trombin, arachnoidic acid- (AA),and collagen, platelet-neutrophil and platelet-monocyte complexes, determination of CD11b in the platelet-neutrophils and monocytes. Results: As compared with controls, ET patiens had significantly higher values of baseline P-selectin expression,as well as higher platelet-neutrophil, platelet- Mo complexes and neutrophil CD11b expression. Platelet P-selectin, monocyte CD11b was significantly higher in ET patients with a history of thrombosis than in patiens without thrombosis. Patients with the JAK2V517Fmutation or thrombosis showed higher baseline and AA-induced platelet P- selectin expression than did those without thrombosis Conclusions.These results would support a role for platelet and monocyte activation in the thrombosis of ET, in these patiens, the presence of the JAK2V617F mutation is associated with higher platelet activation.

1356

NOVEL MULTIPLEX BEAD-BASED ASSAY WITH LNA-MODIFIED PROBES FOR DETECTION OF MPL EXON 10 MUTATIONS

V Shivarov[1], M Ivanova[2], E Hadjiev[2], E Naumova[2]
[1]*National Hematology Hospital, Sofia, Bulgaria*
[2]*Alexandrovska University Hospital, Medial University, Sofia, Bulgaria*

Background: MPL exon 10 mutations were the second class of mutations shown to be associated with the pathogenesis of Philadelphia chromosome - negative myeloproliferative neoplasms (MPNs). Various molecular approaches have been applied, yet universally accepted method is still lacking. Aims: We aimed at development and validation of a novel bead-based liquid assay for multiplexed detection of the following MPL mutations: W515L/K/A/R. *Results:* We developed a novel multiplex bead-based liquid assay for detection of the most frequent MPL exon 10 mutations using Locked nucleic acids (LNA)-modified oligonucleotide probes. Testing on both artificial plasmid constructs and on clinical samples revealed that the method was comparable in terms of specificity to direct sequencing and had a much higher sensitivity of 1% mutant alleles. *Conclusions:* This method could be successfully implemented in the diagnostic work-up for MPNs. Furthermore, the system allows further multiplexing for single-tube identification of different mutations associated with MPNs.

Funding: This work was support by Grant ID_09_157 (Contract 5/16.12.2009) of the National Science Fund, Bulgaria. V.S. is a 2010 EHA-ASH Translational Research Training fellow.

STUDY REGARDING THE ASSOCIATION BETWEEN MULTIPLE PRIMARY CANCERS THAT INCLUDES A MYELOPROLIFERATIVE DISORDER AND THE METABOLIC SYNDROME

RG Mihaila,[1] I Lisan,[2] R Dancu,[2] L Bera,[1] A Catana,[2] O Flucus,[2] C Grandore,[2] L Popa[2]
[1]*Lucian Blaga University of Sibiu, Sibiu, Romania*
[2]*Emergency County Clinical Hospital, Sibiu, Romania*

Background. It is known that cancer patients have a 20% higher risk of new primary cancer compared with the general population. Genetic instability, family predisposition, chemotherapy, radiation, environmental factors, smoking, alcohol consumption, infections, etc predispose to the appearance of a 2nd cancer. *Aims*. We aimed to study the prevalence of the metabolic syndrome and its components in patients with multiple primary cancers that include a myeloproliferative disorder comparing with those with only myeloproliferative disorders. Methods: Of the 668 patients with hematological malignancies who were registered in the Department of Hematology of the Emergency County Hospital Sibiu during January 2006 - January 2011 we selected the 239 with myeloproliferative Disorders, and among them were selected all 20 multiple primary cancers (group A), which were compared with a group of 37 consecutive patients with myeloproliferative disorders which were in our evidence in January 2011 (group B). We made a comparative analysis of the components of metabolic syndrome and hypercholesterolemia in the two groups. The results were statistically analyzed. Results: The average age in group A patients was 59.26+/-14.25 years, and those in group B - 60.11+/-16.18 years. Distribution by gender: group A - 14 men and 6 women, group B - 14 men and 23 women. The average time to onset of the 2nd cancer was 2.85+/-2.96 years. Among patients with myeloproliferative disorders 8.37% had multiple primary cancers: 6 - acute myeloid leukemia, 4 - lung cancer, 4 - nonHodgkin malignant lymphoma, 2 - skin carcinoma, 2 - breast cancer and one - multiple myeloma, colon cancer, essential thrombocythemia, primary myelofibrosis, fibrosarcoma or mediastinal tumor. Four patients had triple neoplasia. Patients in group A had more frequently obesity (50% vs. 16.22%) (p=0.007), diabetes (35% vs. 10.81%) (p=0.027) and hypertriglyceridemia (35% vs. 21.62%) (p>0.05). Those in group B were more often hypertensive (51.35% vs. 30%) (p>0.05). 25% of patients in group A and only 8.11% in group B had metabolic syndrome. The average of the metabolic syndrome components was higher in patients in group A compared with those of B (1.28+/-1.24 to 1.0+/-1.0) (p=0.027). Conclusions: A significant proportion of patients with myeloproliferative disorders has one or two primary cancers. They often have metabolic syndrome. Patients with multiple primary cancers that include a myeloproliferative disorder have obesity, diabetes mellitus, and more components of metabolic syndrome in a higher proportion, compared to the patients with only a myeloproliferative disorder. Studies are needed to investigate the mechanisms that explain the relationship between metabolic syndrome and multiple primary malignancies.

ESSENTIAL THROMBOCYTHEMIA AND FAILURE OF FIRST LINE TREATMENT: WHAT IS THE OPTIMUM METHOD FOR INITIATING ANAGRELIDE? THE FOX (FRANCE OBSERVATOIRE XAGRID) STUDY

J Rey,[1] JF Viallard,[2] K Keddad,[3] JJ Kiladjian[4]
[1]*Paoli-Calmettes, Marseille, France*
[2]*Hôpital Haut Lévêque, Bordeaux, France*
[3]*Medical Department, Shire France SP, Boulogne-Billancourt, France*
[4]*Hôpital Saint-Louis et Université Paris 7, Paris, France*

Background. Essential thrombocythemia (ET) is an acquired myeloproliferative syndrome that has little effect on the survival of patients, but may be complicated by severe thrombo hemorrhagic events. The therapeutic strategy is guided by assessing the risk of complications in each individual patient. In Europe, patients receive hydroxyurea (HU) as the first-line therapy. However, HU is ineffective or poorly tolerated in some patients and, in these cases, anagrelide is the recommended second-line treatment. Currently, there are no published recommendations or guidelines for switching a patient to anagrelide treatment, and methods for initiating anagrelide treatment vary according to the usual practice of individual prescribers. For example, immediate cessation of HU treatment or a gradual reduction of the dose, with or without a parallel escalation of the anagrelide dose, can be used. Aims. The objective of the current FOX (France Observatoire Xagrid) study is to appraise clinical practice in France when switching patients from HU to anagrelide treatment. The aims of the study are to determine whether the switching strategy may influence the tolerability and the efficacy of anagrelide in the second-line setting, or the care of the patients. The FOX study also offers the opportunity to identify the most efficient initiation protocol for anagrelide. Patients and Methods. FOX is a multicenter, prospective, observational study assessing adult patients with ET who switch to anagrelide following failure of, or intolerance to, HU. Patients will be assessed prospectively over a 6-month period following the introduction of anagrelide treatment. During the assessment period, all relevant data available from the patients' medical records will be compiled. No clinical examinations or procedures will be required during the study. The target recruitment is 180 patients from 60 participating centers, with the aim of obtaining 160 evaluable cases. Each investigator will enroll each consecutive patient fulfilling the inclusion criteria. Results. The study analysis will compare the number of patients maintaining treatment with anagrelide after 6 months, including details of the initiation schedules, using a Fisher exact-test. The study is ongoing and final results are expected in June 2012. The study is sponsored by Shire Pharmaceutical Development Ltd. *Summary/conclusions*. ET is a chronic condition with limited treatment options that requires long-term therapeutic management. Where there is intolerance or lack of efficacy with the first line treatment, HU, anagrelide is indicated as second-line therapy. The method of initiating treatment switch to anagrelide is not universally agreed but may have an impact on its efficacy and tolerability. This issue is currently being assessed in the FOX study in order to determine the optimal procedure for initiating treatment with anagrelide.

Background. The BCR/ABL (Ph)-negative myeloproliferative neoplasms (Ph-negative MPN) embody polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). These are pluripotent hematopoietic stem cell disorders and which have several clinical, laboratory and histological features in common. The discovery of JAK2-V617F and JAK2 exon 12 mutations and, more recently, mutations in MPL, TET2, CBL, and IKZF1 alleles has advanced the molecular taxonomy and our understanding of pathobiology of the Ph-negative MPN. The incidence of leukemic conversion of the Ph-negative MPN has an incidence of 2-30%. Little is known about the factors and mechanisms that lead to and bring on acute leukemic transformation in the Ph-negative MPN. *Aims*. A prospective single-centre study of immunophenotypic and cytogenetic characteristics as well as the clinical course and therapy outcomes in consecutive patients with acute leukemia supervening on the Ph-negative MPN. *Patients and Methods*. Twenty patients (pts) were studied (med. age, 61, range 34-73 years). Thirteen pts had PMF, four ET, and three PV. The type of acute leukemia was confirmed using flow cytometric methods and Immunohistochemistry. Cytogenetic analyses were performed in all patients at diagnosis of a primary disease and at the time of acute transformation of MPN. Results: The median duration of a chronic phase of MPN was 45.4 months (range 10.5-300). One pt developed acute myeloblastic leukemia (AML) M-1 (by FAB Group Classification), fifteen pts AML M-2, two pts AML M-4, and one pt AML M-7. One pt acquired the BCR/ABL-negative B-cell acute lymphoblastic leukemia. The karyotype evolution was evidenced in 7/20 pts. A 48,XY,+8,+16 was observed in two pts, del(20) in two pts, and i(17)(q10); der(20) and multiple kariotypic abnormalities in one patient each. Five out of eight JAK2-V617F-positive pts lost the signal of this mutation in the leukemic phase. Ten pts received intensive induction chemotherapy. Another ten were treated by palliative chemotherapy or support only. Two pts are presently alive and in complete remission (CR) for 59 and 50 months each. Two pts survived 47 and 42 months in CR and died in relapse. One patient in partial remission survived an average of 16.5 months. Four pts with stable leukemia lived 6, 16.5, 19, and 48.5 months. The remaining patients died within nine months of acutization. The pts on intensive chemotherapy lived distinctly (p=0.0470) longer and mostly had a preceding PMF (p=0.0479). *Conclusions*. Acute leukemia complicating the Ph-negative MPN merits further studies on larger cohorts of pts. This is warranted by the present study showing that long survival could be attained by a considerable proportion of younger (<60) patients without comorbidities.

HIGHLY SENSITIVE QPCR INCREASES THE RATE OF DETECTION OF JAK2-V617F IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

K Cuthill, E Nickless, K Tobal, M Qureshi, B Wilkins, C Harrison, D Grimwade
GSTFT, London, UK

Background. Approximately 95% of patients with polycythaemia vera (PV) and 50% of patients with essential thrombocythaemia (ET) or primary myelofibrosis (PMF) harbour the JAK2-V617F mutation with smaller numbers exhibiting either MPL or JAK2 Exon 12 mutations. The presence of JAK2-V617F has become a major diagnostic criterion for these disorders, emphasising the need for accurate testing. Recent data from external quality assessment schemes involving large numbers of European laboratories suggest marked variation in performance of assays measuring JAK2-V617F allele load, yielding highly divergent results. Targeted therapy using JAK2 inhibitors within clinical trials, and other modalities such as transplantation, may require accurate molecular monitoring. Interestingly, patients testing negative for JAK2-V617F may respond to targeted therapy and are not distinguishable from those with mutant JAK2. This is consistent with the finding of activated JAK signalling, but could also suggest that they may harbour the mutation at a lower level than presently detectable. *Aims*. To reassess a cohort of patients with myeloproliferative neoplasms (MPN), negative for JAK2-V617F by standard allele-specific PCR (AS-PCR), using highly sensitive real-time quantitative PCR (qPCR). *Methods*. We identified patients from our hospital laboratory records who had tested negative for JAK2-V617F mutation by AS-PCR between 01.08.2005 and 01.08.2010. AS-PCR was performed using a common reverse primer and two forward primers. The first forward primer was specific for the mutant allele, with an intentional mismatch at the third nucleotide from the 3' end, giving a 203-bp product. The second primer amplified mutant and wild type alleles to give a 364-bp product, acting as an internal control. During the study period, 824 samples had been tested for JAK2-V617F mutation, of which 569 tests were reported as negative. Of patients testing negative, 84 met the WHO criteria for ET, 23 were diagnosed as PMF, 6 as PV, 4 as myeloproliferative/myelodysplastic overlap (MPN/MDS) and 11 as MPN, unclassifiable (MPN-U). Peripheral blood samples were analysed using a qPCR assay which has been shown in QC rounds conducted within the European LeukemiaNet to detect a 0.1% level of JAK2-V617F. V617F was quantified relative to wild-type JAK2, and to albumin, used as an independent control gene. *Results*. 47 samples were tested; 32 ET, 12 MF, 1 PV, 1 MPN/MDS and 1 with MPN-U. In 46 cases, the albumin gene was amplified with a mean cycle threshold (CT) of 22 cycles (range=20-25) but no V617F was detected. One patient, with PMF, had 5.2% JAK2-V617F relative to wild-type JAK 2 and albumin. This patient has since undergone a reduced intensity conditioning allogeneic stem cell transplant. At reassessment four months post transplant, with full donor chimaerism, the V617F level had fallen to 0.2%. *Summary/conclusions*. In this small cohort of 47 patients, previously diagnosed as having JAK2 negative MPN, one was found to have a significant V617F mutant burden relative to wild type. There was a significant reduction in mutant load at reassessment four months post transplant. This finding supports qPCR as a highly sensitive method to detect JAK2-V617F and its potential role in monitoring residual disease during treatment.

MYELOPROLIFERATIVE NEOPLASMS, STEM CELL MOBILIZATION AND AUTOLOGOUS TRANSPLANTATION

J Rey,[1] V Ivanov,[1] S Wickenhauser,[2] B Richard,[2] P Ladaique,[1]
JM Schiano de Collela,[1] D Coso,[1] R Bouabdallah[1]
[1]*Paoli-Calmettes, Marseille, France*
[2]*University Hospital Caremeau, Nimes, France*

Background. Myeloproliferative neoplasms (MPN) are chronic disorders that evolved for many years but they can be complicated by thrombotic complications or haematological transformations as myelofibrosis or acute leukaemia. Actual management of MPN diminishes thrombotic complications but no treatment can cure the disease. The discovery of JAK2 mutation has led to the development of JAK2 tyrosine kinase inhibitors which may affect positively the disease and benefit many patients. Allografting is reserved for patients with haematological evolution as myelofibrosis. Autologous transplant is not a standard procedure in myeloproliferative disorders, apart for few cases reported in the palliative treatment of myelofibrosis. Recently increased incidence of lymphoid haematological malignancies has been reported in patients with MPN. Stem cell collection and autografting should be used in this setting in patients with both haematological malignancies. Aims - We report two cases of successful stem cell mobilization and autologous transplantation for plasma cell malignancies with concomitant myeloproliferative neoplasms, the first with multiple plasmacytoma and essential thrombocythemia and the second with multiple myeloma and primitive polycythemia. Methods - In our two cases, the myeloproliferative neoplasm was diagnosed several years before plasma cell malignancies (eleven and ten years respectively). Both patients were treated with hydroxyurea for ten and nine years before stem cell collection. Symptomatic plasma cell malignancies was then diagnosed in both patients and treated with bortezomib dexamethasone cycles. Stem-cell mobilization was realized after granulocyte colony-stimulating factor and allowing 7 x 106 and 5 x 106 CD34+ cells/kg, respectively. Conditioning chemotherapy before autografting was melphalan 200 mg/m2. No complications were noted during all these procedures. Platelet and granulocyte recovery after autografting are respectively 19 and 16 days for the first patient and 14 and 12 days for the second. Results - Our two cases show the feasibility of stem cell mobilization and autologous transplantation for haematological malignancy with concomitant myeloproliferative neoplasms. Although disease evolution of myeloproliferative neoplasms has reached the first decade for our two patients, stem cell mobilization seems to be possible. Moreover, cytoreductive treatment as hydroxyurea and possible fibroses seem do not influences stem cell mobilization. However, autografting does not seem to influence the course of MPN as the platelet count returned above normal range six months after autografting for our first patient. Conclusions - Stem cell mobilization and autologous transplantation are feasible for patients with haematological malignancy and concomitant myeloproliferative neoplasms, even after decades of history. It was an important point because an increased risk of lymphoid neoplasms has been described for patients with MPN compared with general population.

MYELOPROLIFERATIVE DISEASES AS A CAUSE OF THROMBOSIS

E Simonovic,[1] L Macukanovic-Golubovic,[2] M Stojkovic,[1] V Colic[1]
[1]*General Hospital, Leskovac, Serbia*
[2]*Clinic of Haematology, Nis, Serbia*

Myeloproliferative diseases (MPD) belong to the group of clonic malignant diseases of parent cell hematopoiesis, characterized by abnormal increase of one or several blood lines with normal or nearly normal maturing of those cells, both in bone marrow and in extramedullary hemotopoietic organs. According to the data from literature, thrombotic complications occur in about one third of patients with PV. The main cause of morbidity and mortality in ET are bleeding and thromboses. About 40% of patients showed a tendency to thromboses, and 60% to bleeding. Thrombotic complications are, as a rule, arterial thromboses, although venous thromboses appear as well, particularly in the deep veins of lower extremities. The most common sites of arterial thrombosis are cerebrovascular, peripheral, vascular and coronary circulation. Thromboses are common in splenic, hepatic, portal and mesenteric blood vessels. The aim of the paper is to show the extent to which the thrombotic complications occur in patients with certain forms of chronic myeloproliferative diseases. The investigation included 219 subjects of both sexes, between 17 and 83 years of age with the diagnosis of MPD. The patients were divided into five groups: A. Chronic myeloid leukemia (CML)-group; B. Polycythaemia vera (PV)-group; C. Idiopathic myelofibrosis (IMF)- group; D. Essential thrombocythaemia (ET)-group; E. Myeloproliferative disease that cannot be classified (MPS)-group. The methods of clinical examinations, endoscopies, exosonographies and computer-assisted tomographies have been used. In our research, presence of thrombotic complications was recorded in almost 20% of all subjects with MPD. In the group with CML about 5%, in the group with PV about 30%, and in the group with IMF about 7,6%, in the group with ET about 63%, and in the group with MPS about 42% of patients had one or more thrombotic complications. The highest percentage of thrombotic complications is within the group of subjects with ET, that is statistically more significant compared to PV (PV ($p<0,05$), IMF and CML ($p<0,001$). We proved that prevalence of thrombosis is in a statistical dependence on the type of MPD. Mechanism of thrombophilic state in patients with MPD is not entirely clear. Uncorrected polycythemia with elevated values of hematocrit and increased blood viscosity, increases the tendency to thrombosizing. Impaired platelet function within MPD could also be significant for the development of thrombotic and hemorrhagic complications as well.Some authors have described the disturbances in the fibrinolytic system and the function of natural coagulation inhibitors (AT III and protein C),

which further contribute to the tendency of thrombosizing in patients with MPD. One of the explanations for increased risk of thrombosis in patients with ET is that the total amount of thrombin generated on the surface of platelets in those patients, has been significantly higher than with the control group or in patients with reactive thrombocytosis. Thrombotic complications often accompany chronic myeloproliferative diseases. They are usually present in patients with ET and also in patients with PV and MPS, and much less frequently in patients with CML and IMF, which is in accordance with data from literature.

ACTUAL MANAGEMENT OF PH NEGATIVE MYELOPROLIFERATIVE MALIGNANCIES - THE EXPERIENCE OF AN EST EUROPEAN CLINIC

M Tevet, C Saguna, A Lupu, A Colita, O Ciocan, A Ciobanu, C Dragan, N Berbec

Coltea Hospital, Bucuresti, Romania

Background. The description of the JAK2V617F mutation in classical Philadelphia (Ph)-negative MPN provide us a rational target for novel innovative treatment strategies but currently, clinical studies testing various JAK2-inhibitors in PV, ET as well as in primary and secondary myelofibrosis (MF) are under way. Interestingly, first data indicate that despite marked clinical activity in terms of spleen size reduction and improvement of constitutional symptoms, these inhibitors might not sufficiently reduce disease burden. So we tried to compare eficacy of well established treatment strategies, such as inhibition of thrombocyte aggregation by low dose aspirin, cytotoxics (e.g. hydroxyurea, anagrelidum), immuno- and stroma-modifying therapy with interferon, tyrosine kinase inhibitors and, in selected cases, allogeneic stem cell transplantation and to make a correlation between the response at these therapeutical alternatives and the mutational status. Methods and results: We investigated a lot of 430 patients diagnosed in our clinic between 2004 and 2010; the study population was female in procent of 58%, ages ranged from 22 to 72 years (median age 52). We tried to establish the indications on our study group for cytoreductive therapy in which the key targets were to reduce thrombohemorrhagic complications, relieve disease-related symptoms and minimize the risk of transformation to secondary myeloid malignancy such as myelodysplasia, leukemia, and secondary myelofibrosis. We correlate the rate of disease progression with the mutational status and investigated the role of interferon treatement in JAK2 V617F positive cases. We tried to establish if there is a significant molecular response in these subset of patients. In our study 87% of patients treated wih IFN had a hematologic response, and from these 71% were complete responses (CRs). Conclusions: We reported that in our study group the patients with myeloproliferatives disorders treated with rIFN-2b had lower JAK2V617F allele burdens compared with a control group that included patients treated with phlebotomy, hydroxyurea, or anagrelide, or who remained untreated. May IFN induce high levels of clinical and hematologic remission and in some patients, a molecular CR?

PREVALENCE OF THE JAK2 V617F MUTATION IN CROATIAN PATIENTS WITH CLASSIC PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

D Duletic-Nacinovic,[1] A Dekanic,[2] I Hadzisejdic,[2] I Kusen,[1] B Grahovac,[2] D Grohovac,[1] T Valkovic,[1] I Host,[1] D Petranovic,[1] B Marijic,[1] N Jonjic[2]

[1]*Clinical Hospital Center, Rijeka, Croatia*

[2]*School of Medicine University of Rijeka, Rijeka, Croatia*

Background. The classic Ph-negative myeloproliferative neoplasms (MPNs) are clonal disorders of multipotent haematopoietic progenitors. The Janus-associated Kinase-2 mutation JAK2 V617F in such neoplasms has been described as a frequent genetic event in majority of these patients. Aims: To investigate the status of the JAK2-V617F mutation in patients with classic Ph-negative MPNs treated in Clinical Hospital Center Rijeka and to compare it with hemoglobin and hematocrit level, white blood cells and platelet count, splenomegaly, leukocyte alkaline phosphatase score and clinical features. Methods: DNA was isolated from peripheral blood granulocytes in 115 patients: 41 with polycythemia vera (PV), 43 with essential thrombocythemia (ET), 9 with primary myelofibrosis (PMF), 10 with myeloproliferative neoplasm-unclassifiable (MPN-u), 4 with secondary erithrocytosis and 5 patients with secondary thrombocytosis. The JAK2-V617 mutation was determined using allele specific PCR. Results: The JAK2-V617F mutation was found in 71/106 (66.98%) patients with MPNs or in 36/41 with PV (87.80%), 25/43 with ET (58.14%), 5/9 with PMF (55.56%) and 5/13 MPNs-unclassified (38.46%) disorders. The JAK2-V617 mutation was absent in patients with secondary erythrocytosis and seconrary thrombocytosis. There were significant differences in hemoglobin and hematocrit level, leukocyte alkaline phosphatase score and white blood cells at diagnosis in JAK2-V617F non mutated versus mutated patients with MPNs. Vascular events were present in 23/106 (21.7%) patients with MPNs or more specifically in 13/41 (31.7%) with PV, 8/43 (18.6%) with ET, 1/9 (11.1%) with PMF and 1/13 (7.7%) with MPN-u. The majority of those patients with one or more vascular events were JAK2-V617F positive. When analyzed within each entity than it could be emphasized that one or more vascular events, or recurrent thrombosis was detected in 13/41 (31.7%), 7/41 (17.1%) cases, respectively with PV, or in 10/13 with JAK2-V617F positive status. In patients with ET, compare to PV, vascular events (8/43) were less present (18.6%). Though, as noticed for PV, most of those patients (6/8) were associated with JAK2-V617F mutation. In patients with PMF only 1 vascular event was confirmed (patient was JAK2V617F negative), as well as in patients with MPN-u (patient was JAK2 positive). *Conclusions*. The JAK2-V617F mutation was frequently detected in our patients with MPNs in accordance with literature data, and therefore should be incorporated in the diagnostic evaluation of patients with suspected MPNs. Further analysis should focus on contribution of the JAK2-V617F mutation in the clinical phenotype of patients with distinct subgroups of MPNs.

1365

SPLACHNIC VEIN THROMBOSIS AND MYELOPROLIFERATIVE SYNDROMES. THE ROLE OF JAK2V617F MUTATION

T Kanellopoulou, A Alexopoulou, F Kontopidou, J Koskinas, D Pectasides

General Hospital of Athens „Hippokration„, Athens, Greece

Background. Myeloproliferative diseases(MPDs) are shown to have an increased risk of thrombotic complications such as splachnic vein thrombosis(SVT).Mutations on JAK2 pathway are thought to play key role on such thrombotic complications. *Aims*. The focus of the current work is to evaluate the risk of SVT in MPDs patients and its colleration with the mutation JAK2V617F. *Methods.* Patients with non-cirrhotic, non-cancer related SVT and with clinical or laborating findings suggesting MPD were assessed for the presence of JAK2V617F mutation. We suspected that normal or light increased platelet count might mask MPDs (portal hypertension-hypersplenism, occult bleeding).Assessment for hematological pro-coagulant conditions included factor V Leiden, antithrombin III, protein C, protein S, homocysteine, MTHFR mutation, prothrombin gene mutation PT20210A, anticardiolipin antibodies and lupus anticoagulant. Paroxysmal nocturnal hemoglobinuria was screened using standard flow cytometry techniques. Patients with known history of pylephlebitis were excluded. SVT was confirmed with computerized tomography and abdominal doppler ultrasound. SVT was characterized as chronic if there was evidence of intra-abdominal venous collaterals, carvenous transformation of the portal vein, or signs of portal hypertension. 4.Results:In the study 14 patients were included. The median age at the time of diagnosis was 50.71 years (range, 21-78) and 57% were male. All patients had chronic SVT, 64% had PVT and the rest were diagnosed with BCs. Every patient underwent bone marrow biopsy: polycythemia vera(PV) 4 patients, essential thrombocytosis(ET) 7 patients, primary myelofibrosis(PMF) 3 patients. JAK2V617F was analyzed in 12/14 patients and was positive in 100%. Inherited thrombophilia was not found. Acquired thrombophilia was mentioned in two patients. A woman with Budd-Chiari syndrome(BCs) who was provided oral contraceptive pills, and a man with portal vein thrombosis(PVT) postsplenectomy. Patients with BCs had mean age 43.2 years(range, 35-56) and 60% were female. Three were diagnosed with PV, 1 ET and 1 PMF. One patient died after 17 years and one was scheluded for liver transplantation after 6 years. The other three patients had no signs of ascites or portal hypertension in a six-year follow up. Patients with PVT had mean age 54.8 years(range, 21-78) and 67% were male. Six were diagnosed with ET, 2 PMF and 1 PV. On admission 5 patients had esophageal/gastric varices whereas 89% patients had splenomegaly. Five patients had also evidence of superior mesenteric vein thrombosis. Nobody died. All of the patients have signs of portal hypertension. Mean time of follow up is 1.8 years(range, 0.2-6). All patients were managed with routine anticoagulation therapy from diagnosis. Three patients had indications for decompressive procedures such as TIPS, all in the group of BCs. 5.Summary/Conclusions:SVT is frequent presenting complication of undiagnosed MPDs.In patients with SVT, portal hypertension is a virtually constant feature. The resulting hypersplenism and hemodilution decrease the accuracy of blood cell counts for MPD diagnosis. The

atypical peripheral blood picture in the setting of SVT has led to a variety of denominations such as *latent* MPDs. In our study, all patients with MPD and SVT were positive for the mutation JAK2V617F.The presence of this mutation may predict a more aggressive phenotype with an increased risk of thrombosis.

1366

ESSENTIAL THROMBOCYTHEMIA: CORRELATION BETWEEN JAK2 ALLELE BURDEN AND CLINICAL OUTCOME

F Valeri, B Nicolino, E Beggiato, A Borchiellini, L Riera, P Schinco
San Giovanni Battista Hospital, Turin, Italy

Essential thrombocythemia (ET) is a myeloproliferative disorder characterized by persistently elevated platelet count (>450x10^9/l, 2008 WHO classification) with normal red cell mass. Thrombosis, acute myeloid leukemia or myelofibrosis are its main complications. Janus kinase 2 mutation (JAK2V617F) appears involved in the molecular etiology of disease development. Its identification markedly simplified the approach to clinical diagnosis and provided molecular targets for the development of biologically targeted drugs. Recent studies reported an association between JAK2V617F and thrombosis in patients with myeloproliferative disorders, but it remains unknown whether inherited thrombophilia has an impact as an additive risk factor in mutated subjects. Therapeutic strategies are hydroxyurea (HU), anagrelide and alpha-interferon (IFN), aimed to reduce platelet count and ASA to control the thrombotic risk. We studied 52 patients with TE aiming to 1. evaluate variation in JAK2 (V617F) mutant allele burden during different treatments (HU, anagrelide, interferon or none); 2. evaluate relationship between allele burden and thrombotic risk; 3. evaluate role of additional thrombophilic risk factors in these patients. We analyzed JAK2 allele burden with MutaScreen kit at the beginning of treatement and after 21 months follow up, and split patients in 6 groups according to % of allele burden: 2-5%, 5-12.5% (heterozygotes), 12.5-31%, 31-50%, 50-78%, 78-100% (homozygotes). Furthermore we searched for thrombophilic risk factors (ATIII, omocysteinemia, factor V Leiden and prothrombin gene mutations, protein C and protein S levels, lupus anticoagulant, antiphospholipid antibodies). Statistical analysis was performed by the Student T test and l(2) test. RR for thrombosis was calculated with a 2 × 2 table (confidence interval of 95%). 24 patients were treated with HU and their allelic burden on average increased of 10.2%. 4 patients were treated with anagrelide with an allelic burden median increase of 4.6%. 2 patients were treated with IFN: in 1 case we found a decrease in allele burden from 50-78% to 12.5-31%, median decrease was 27.1%. 22 patients were not treated and their median increase in allelic burden was 21.3%. We observed 13 thrombotic events: 6 arterial events and 7 venous events. 5/52 patients (9.6%) were homozygous for the mutation and 47/52 (90.4%) heterozygous. Incidence of thrombotic complications was higher in the homozygote group: 2/5 (40%) compared to 11/47 (23.4%) in heterozygotes, with a RR of 1.7. Thrombophilia was recorded in 21/52; of these, 8 patients (8/21, 38%) developed thrombosis. Patients with allele burden > 12.5% and concomitant thrombophilic risk factors showed a higher incidence of thrombotic events (RR =7) compared to patients with allele burden < 12.5% and no additional risk factors. In our study IFN showed to reduce allele burden, according to literature. Subjects treated with HU demonstrated a statistically significant increase in allele burden (p=0.018) during follow up. Data analysis shows an association between allele burden > 12.5% and thrombotic risk, and this association becomes stronger in presence of further thrombotic risk factors. Evaluation of patients' thrombotic risk factors may influence the treatement choice in TE subjects.

1367

CYCLICAL THROMBOCYTOSIS AND ACQUIRED VWD ARE RELATIVELY COMMMON IN PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

E Verner,[1] C Forsyth,[2] A Grigg[3]
[1]*The Royal Melbourne Hospital, Parkville, Australia*
[2]*Wyong Hospital, Kanwal, Australia*
[3]*Austin Health, Melbourne, Australia*

Background. Cyclical thrombocytosis, acquired von Willebrand disease (vWD), aggressive non-melanoma skin cancers (NMSC) and hydroxyurea-related fever have been reported in Philadelphia-negative myeloproliferative neoplasms (MPNs) but to our knowledge their incidence and clinical consequences has not been clearly defined in a large cohort of patients. *Aims*. To conduct a retrospective analysis of less commonly reported disease and treatment related complications in patients with Philadelphia-negative MPNs. Methods. A retrospective audit was conducted on patients under the care of two haematologists, one at a metropolitan tertiary referral centre and the other at a regional community based practice. *Results*. 188 patients were included in the audit, of which 115 (61%) were female and 73 (39%) were male. The MPN subclassification breakdown was: 104 ET (55%), 62 (33%) PV, 18 (10%) PMF, and 4 (2%) MPN-U. 136 (72%) were JAK2+. The mean age at diagnosis was 61 years (0.4-93 years) with a mean length of follow-up of 7.7 years (0.5-44 years). 90% of patients were treated with hydroxyurea (HU) at some stage during this follow-up, with a mean dose of 707mg/day and an average length of exposure of 4.2 years. 54 patients were treated with non-HU cytoreduction including interferon, anagrelide, busulphan and radioactive phosphorous. 29 patients (15%) had platelet counts that varied by over 100x10^9/L over a 6 week period while on a stable dose of cytoreductive therapy. Platelet cycling occurred in all MPN subgroups (hitherto the literature has documented this in PV only); there was no difference in incidence according to gender or JAK2 positivity. 25 patients (86%) were taking HU at a mean dose of 920mg/day. The mean maximum difference between the lowest and highest platelet count over the 6 weeks was 350 x10^9/L (100 - 1346 x10^9/L). 60 patients (32%) had non-melanoma skin cancers, 29 (48%) of whom had multiple skin cancers. Those with skin cancers had a longer exposure to HU than the overall population (5.7yrs vs 4.2 years). Those with multiple NMSC were predominantly male (66%) and were older (mean age 79years). Acquired vWD occurred in 17 patients (9%), was mostly type 2 and was not associated with any haemorrhagic complications. HU 'allergy' was seen in 12 patients (7% of those taking HU) and predominantly presented as fevers (9 patients) that recurred in all those re-challenged with HU. Of those taking HU, 8 patients (5%) had leg ulcers and 6 patients (4%) experienced mouth ulcers. 77 patients (41%) had a thrombotic event with the majority of these (67%) occurring prior to or at diagnosis. Conclusions. Cyclical thrombocytosis is not infrequent in all Philadelphia-negative MPNs and appears associated with a higher HU dose. Other features that are intrinsic to the disease (such as acquired vWD) or occur as a consequence of therapy (skin cancers and HU-fever) are also not uncommon.

1368

FIRST CASE OF KIT SER715DEL AND JAK2 VAL617VAL MUTATION IN SYSTEMIC MASTOCYTOSIS WITH ASSOCIATED ESSENTIAL THROMBOCYTHEMIA

N Pugliese, A Peluso, F Grimaldi, C Quintarelli, B De Angelis, A Gravetti, G Ciancia, B Izzo, V Martinelli, F Pane
Federico II University of Naples, Naples, Italy

In March 2009 a 22-years-old woman presented to our Institution with persistent high platelet count (>650x10^9/L) and no other peripheral blood alterations. At physical examination splenomegaly was present; headache, erythromelalgia and diarrhea were referred. Blood chemistry was normal and reactive thrombocytosis was excluded. The morphological examination of the bone marrow (BM) aspirate revealed an increase of enlarged megakaryocytes (MK) with emperipolesis phenomena. BM smears showed also spindle shaped mast cells (MC) with oval and eccentric nuclei and focal granule accumulation. Eosinophil forms were increased. Biopsy specimens were hypercellular and showed a marked proliferation of giant MK, preferentially grouped into clusters; in addition to this myeloproliferative pattern, nodules of ovoid or spindle shaped MC were present, surrounded by areas of localized dense network of reticulin fibers. MC identity was confirmed by toluidine-blue and immunohistochemical staining for anti-CD117 (KIT) and CD2. Cytogenetic analysis revealed a normal karyotype. A specific immunophenotypic analysis of MC was not performed at this time. The allele-specific-PCR demonstrated the presence of the JAK2V617F mutation. DNA sequencing did not confirm the G>T substitution on the base 1849 codifying for the Val617Phe mutation, but we detected a G>T substitution on the nucleotide 1851 codifying for a silent Val617Val mutation. FIP1L1-PDGFRA and BCR-ABL transcripts search was negative. DNA sequencing of KIT gene, did not show D816V mutation, but detected a three nucleotides deletion (ACG; bases: 2143-2144-2145), on the exon 15 that bring to a serine 715 deletion. Systemic Mastocytosis (SM) clinical staging showed not skin involvement, normal bone density and a spleen volume of 500 mL by ultrasound; serum tryptase was 17,6 ng/mL. We concluded for SM with Associated clonal Hematological Non-Mast cell lineage Disease (SM-AHNMD), id est Essential Thrombocyhemia. Because of symptoms we began treatment with IFN-α-2a at 3 MU five times a week. The therapy was well tolerated, all

symptoms disappeared and the platelet count was lowered to less than 350 x10^9/L. After four months of therapy, IFN-α dose was tapered to three times a week. The BM aspirate was repeated after eleven months, showed the absence of MC and a MK reduction, while the BM biopsy demonstrated persistence of MC nodules. The specific immunocytofluorimetric assay was negative. The molecular analyses confirmed the Ser715 del on KIT gene but the JAK2V617V silent mutation was undetectable. The tryptase serum level was 20,9 ng/mL. The spleen volume was 290 mL and resulted reduced compared to the baseline. This is the first case of a SM-AHNMD harboring a silent mutation on JAK2 and Ser 715 del on KIT. This KIT deletion has been previously described in GIST and if it is an activating mutation or a gene polymorphism is still matter of debates. The significance of this mutation for myeloproliferative disease is unknown. However this mutation leads to deletion of a polar amino acid placed near Tyr719 which is necessary for KIT PI3K binding and downstreaming; this mutation could induce abnormalities in KIT local folding and signaling and contribute to pathogenesis of both MC and MK disease.

1369

HYDROXYUREA PLUS ANAGRELIDE COMBINED THERAPY IS MORE SUITABLE THAN SEQUENCE SCHEDULE OF THE TWO DRUGS

N Pugliese, A Gravetti, C Quintarelli, E Madonna, B Izzo, G Muccioli Casadei, C Cerchione, V Martinelli, F Pane
Federico II University of Naples, Naples, Italy

Background. Hydroxyurea (HU) and anagrelide are widely used treatment of Essential Thrombocythemia (ET). Given their different mechanisms of action, they can be used as combined therapy at reduced doses. This association could represent a second-line treatment in patients considered resistant or intolerant to HU, or a therapeutic option to reduce both HU and anagrelide related side-effects. The combined use of these two drugs gives a more balanced control of the hematological parameters, improving the platelet lowering action and better controlling WBC count, known to be correlated with thrombotic risk. We avoid larger doses of either drug because anagrelide is ineffective in lowering WBC count, and higher doses of HU have an unwanted Hb lowering action. Aims. We describe a combined sequence HU plus anagrelide therapy to improve patients' adherence to therapy and quality of life. Patients and methods. Five ET patients received a combined sequence therapy of HU and anagrelide. They were a spontaneously formed cohort of patients treated with others medicaments for comorbidities. They casually requested that the daily numbers of pills be reduced. We used a sequence therapy based on the following schedule: HU at a dose of 1 g daily for 10 days, followed by anagrelide at a dose of 1 mg daily for 10 days for three months. ET diagnosis was based on the 2008 WHO criteria. Patients' mean age was 48.6 years: 3 females and 2 males. Three were JAK2V617F positive. Results. All patients received HU as first line treatment and none achieved complete hematological response (CHR); this resistance was dealt with administering a schedule of HU and anagrelide combined, at a daily dose respectively of 1 g and 1 mg, for a total amount of 4 daily pills. All patients achieved CHR. Mean platelet counts compared to the one while on monotherapy, were 673,3 vs 379,4x10^9/L (p=0,0004). (fig.1.1vs2). Given the patients' need to take other pills we began to schedule a sequence therapy. The side effects reported decreased, but in all patients platelet count increased. Platelet count means were 379,4 vs 626x10^9/L (p=0,0003) respectively on combined and sequence therapy (fig.1.2vs3). Due to the lack of CHR, we interrupted the alternative sequence schedule and returned to the previous combined and continued therapy. Patients achieved CHR after only one month. The mean platelet counts compared with the sequence therapy were 626 vs 374,5x10^9/L (p=0,0002) (fig.1. 3vs4). Conclusions. Our data confirm that HU and anagrelide have a synergic or at least additional effect on platelet count reduction. Indeed, all patients, who took the two drugs simultaneously, achieved rapid CHR, which had never been reached with the previous monotherapy treatment. The sequence therapy, instead, was not as effectively as the combination therapy. Furthermore, patients' mean platelet counts were similar to those during monotherapy (673,3 vs 626x10^9/L; p=0,47), demonstrating the loss of CHR (fig.1.1vs3). Despite the availability of some management recommendation and guidelines on ET treatment, therapy based on the association of HU and anagrelide has not yet been codified.

CHROMOSOMAL TRANSLOCATION T(15;17)(Q22;Q25) WITH PML-RARA POSITIVITY IN PATIENT WITH PRIMARY MYELOFIBROSIS (PMF)

S Novakovic,[1] V Djordjevic,[1] J Jovanovic,[1] S Pavlovic,[2] V Spasovski,[2] M Perunicic Jovanovic,[1] D Lekovic,[1] A Bogdanovic[3]
[1]*Hematology, Clin Ctr of Serbia, Belgrade, Serbia*
[2]*Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia*
[3]*Heatology, Clin Ctr of Serbia, School Medicine of University of Belgrade, Belgrade, Serbia*

Background. Primary myelofibrosis (PMF) is a clonal stem cell disorders characterized by splenomegaly, fibrotic bone marrow, extramedullar hematopoiesis and leukoerythroblastic blood smear with dacryocytes. Approximately, one third of patients with PMF have cytogenetic abnormalities at diagnosis. They are respected as favorable (isolated abnormalities like 13q-, 20q- or +8) but also unfavorable (all other ones). Aims: We are presenting a male patient with PMF and with unusual cytogenetic abnormality, translocation t(15:17)(q22;q25) and JAK-2 V617F mutation. Patient and methods: A 58-year old man was diagnosed with a six months history of abdominal fullness, weakness, weight loss and pain in left upper abdomen. In August 2009, he was referred for further diagnostic work-up to Clinics of Hematology CCS, Belgrade. The diagnosis of PMF was confirmed by bone marrow biopsy and further clonality assays were performed by karyotyping and molecular biology. PCR was applied for detection of JAK-2 V617F mutation and BCR-ABL transcripts. Afterwards, RNA was extracted from the bone marrow sample and RT-PCR has been performed according to BIOMED-1 protocol in order to analyze PML/RARα fusion transcript. Results: Physical examination revealed splenomegaly, +10cm below LCM, or 22 cm on CT scan. Patient had normal hemoglobin, 142 g/L, slight leukocytosis 18,9x10^9/L with mild shift to the left and normal platelet count, 279x10^9/L. Standard blood chemistry tests were within normal range. Core bone marrow biopsy corresponded to PMF (clusters of hyperlobulated megakaryocytes and grade 3 fibrosis). Cytogenetics from bone marrow revealed balanced translocation t(15:17)(q22;q25) in 15 metaphases and 3 metaphases with addition on chromosome 18, add(18)(p11). According to International Prognostic Scoring System patient was low risk. PCR detected bcr1

fusion transcript of PML/RARα. This result was subsequently confirmed by direct sequencing of PML/RARα gene. JAK-2 V617F mutation was also positive. BCR-ABL rearrangement was absent. Patient commenced hidroxyurea 1g/d and after 16 months he reduced spleen to 16 cm (CT) and normalized blood counts, without any signs of acute leukemia during follow-up. Conclusions: The occurrence of PML-RARα and JAK-2 V617F mutation simultaneously in the same patient is exceptionally rare event. Even that our patient had unfavorable cytogenetic profile with JAK-2 mutation indicating adverse predictors for survival, he had a good response with hidroxyurea treatment, and no evolution into promyelocytic leukemia.

1371

SYSTEMIC MASTOCYTOSIS WITHOUT CKIT D816V MUTATION TREATED WITH DASATINIB; A CASE REPORT

M Lasa, MA Goñi, JM Arguiñano, MA Ardaiz, Y Burguete, I Ezpeleta, MC Mateos, MJ Paloma, M Perez, M Redondo, MV Aznar, T Zudaire, F Oyarzabal, G Tiberio

Complejo Hospitalario de Navarra. B, Pamplona, Spain

Background: Systemic mastocytosis (SM), often termed systemic mast cell disease (SMCD), is an hematologic clonal disorder characterized by abnormal growth and accummulation of Mast Cell (MC) in one or more organs. It is now considered a myeloproliferative neoplasm (MPN) in the 2008 revision of the WHO classification of myeloid neoplasms. The clinical symptoms and signs of SM are due to the accumulation of clonally derived mast cells in different organs, including bone marrow, skin, gastrointestinal tract, liver and spleen. In more than 80% of the patients, the cKIT mutation D816V is detectable. Those cases without the cKIT D816V mutation respond to Imatinib not to Dasatinib. We report a case of a SM without the cKIT D816V mutation, that achieved a good response to dasatinib after failing previous imatinib therapy. 2. Case report: A 77 year old man was admitted to our hospital because of astenia, hyporexia and fever during the three previous months. Blood analysis showed anemia, leucocytosis with monocytosis, thrombocytopenia, elevated GGT, alkaline phosphatase and hyperferritinemia. Abdominal ultrasound and thoraco-abdominal CT-scan showed homogeneus hepatomegaly, mild splenomegalia and retroperitoneal lymphadenopaties. Bone marrow biopsy revealed the presence of an excess of mast cells expressing CD2, CD25 and CD117 in flow cytometry testing. Tests for bcr-abl, JAK-2 and cKIT D816V mutations were negative and karyotype was normal. The hepatic biopsy reveled infiltration by MC. With diagnosis of SM, we started treatment with hydroxycarbamide 1gr/day and imatinib 400mg/day. One month later, our patient complained of intense asthenia, dyspnea and malaise. Abdominal ultrasound revealed moderate ascites and bilateral pleural efussion; This was considered a disease progression. We stopped imatinib and started prednisone 1mg/kg/day. Despite this treatment the disease progressed and caused weekly need of platelet and packed red cell transfusion. Finally we added dasatinib 70mg/day to prednisone. Four months later, astenia and dyspnea have improved considerably, as have ascites and patient's status. No new trasfusion have had to be made since the start of dasatinib therapy. As a side effect of the treatment the patient presented left pleural efussion that prompted dasatinib stop and hospital admission. Dasatinib was reintroduced after pleural evacuation and has maintained to date without significant side effects. *Conclusions*. Dasatinib shows promise in the treatment of systemic mastocytosis negative for D816V mutation in cKIT.

1372

BUSULFAN: STILL A USEFUL THERAPY FOR ESSENTIAL THROMBOCYTHAEMIA (ET) AND POLYCYTHEMIA VERA (PV)

S Jenkins, B Bailiff, N Jackson

University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK

Background. The chronic myeloproliferative disorders ET and PV are relatively common disorders with higher prevalence in the elderly. These disorders can lead to major morbidity and mortality through both disease progression/transformation and vascular events. A number of agents are available for cytoreduction in these disorders. Busulfan, a non-specific alkylating agent, has been in therapeutic use for over 50 years. Although other agents are often preferred (in part due to concern over leukemogenesis), Busulfan usually means less clinic attendance which makes it particularly useful in the elderly. Aims: To analyse the effectiveness of Busulfan in terms of blood count control and the incidence of thrombotic complications. To assess the incidence of side effects, such as leukaemic transformation and lung fibrosis.Methods: We retrospectively analysed the clinical records of 53 patients who received oral Busulfan for a diagnosis of ET (32) or PV(21) during the period Jan 2006 - Jan 2011. We assessed for vascular events, leukaemic transformation, platelet count / Hct at 0 months, 6 months and 12 months from commencing Busulfan. We recorded the indication for utilising Busulfan as opposed to other cytoreductive agents. Results: 53 patients were analysed (mean age at commencing Busulfan 81 years, range 44-94). Mean cumulative Busulfan dose was 270.5mg (range 18mg - 1106mg), given as intermittent short courses. A total of 2,435 patient-months of Busulfan therapy (mean 45.9 months per patient) were analysed. There was only 1 leukaemic transformation (possibly related to prior therapy). There were no cases of lung fibrosis. There was 1 definite arterial event (TIA) and 1 possible venous event (femoral DVT), thus there was only 1 clear (+ 1 possible) treatment failure in a cumulative 202 patient years of treatment. PV patients had a mean Hct at commencement of Busulfan of 0.492 l/l. At 6 months post commencement of Busulfan, mean Hct was 0.448 l/l, and at 12 months mean Hct was 0.454 l/l. For ET patients mean platelet count at commencement of Busulfan was $871x10^9$/l. At 6 months post commencement of Busulfan, mean platelet count was $478x10^9$/l, and at 12 months mean platelet count was $407x10^9$/l.Of the 33 patients who received Busulfan as a first line cytoreductive agent, logistical ease was recorded as the reason in 32 patients. 20 patients received Busulfan as a second line cytoreductive agent; 5 patients switched to Busulfan due to mouth/skin ulcers with Hydroxycarbamide; 8 patients were switched to Busulfan for greater logistical ease. Summary/Conclusions: Oral Busulfan for both ET and PV is both safe (with a low rate of leukaemagenesis and pulmonary fibrosis) and effective (with a low rate of vascular events), with reasonable control of platelet count or Haematocrit. Busulfan also offers the advantage of being logistically easier to deliver without risk of skin/mouth ulceration.

1373

THE RISK PROFILE FOR THROMBOTIC EVENTS IN EARLY PREFIBROTIC PMF - LEUKOCYTOSIS IS A RISK FACTOR FOR ARTERIAL THROMBOSIS IN EARLY PREFIBROTIC PMF BUT NOT IN ET

V Buxhofer-Ausch,[1] B Gisslinger,[1] L Muellauer,[1] S Frantal,[2] HM Kvasnicka,[3] J Thiele,[3] H Gisslinger[1]

[1]*Medical University of Vienna, Vienna, Austria*

[2]*University of Vienna, Vienna, Austria*

[3]*University of Cologne, Cologne, Germany*

Background. There is strong evidence indicating that the clear-cut separation of prefibrotic primary myelofibrosis (pPMF) from essential thrombocythemia (ET) by consequent application of the WHO 2008 criteria is reflected in different, well defined clinical pictures and divergent prognoses. All published data on vascular events in ET and primary myelofibrosis (PMF) so far were exclusively based on the outdated criteria of the Polycythemia Vera Study Group. Consequently risk profiles for vascular events within the sub-entities of Bcr-Abl negative myeloproliferative neoplasm ask for re-assessment. We aimed to evaluate whether patients with pPMF have a distinct risk profile for vascular events.Methods: Risk and risk profiles for vascular complications were determined in 87 patients from our database with a valid diagnosis of pPMF according to the WHO 2008 criteria and compared to a cohort of 127 patients diagnosed with WHO-defined ET. Results: Leukocytosis and a JAK2V617F mutated genotype emerged as significant risk factors for arterial thrombosis after diagnosis in pPMF, whereas in WHO-diagnosed ET generic vascular risk factors such as arterial hypertension and diabetes mellitus enhanced the risk for arterial thrombosis. Conclusions: Our results challenge the current knowledge of established and suspected risk factors for thrombosis and certainly need to be confirmed in larger studies. If validated, the finding of a different relevance of certain risk factors within the increasing variety of sub-entities will certainly change the current treatment strategies and help to better allocate patients to the appropriate treatment.

1374

FIRST RESULTS FROM THE GREEK ESSENTIAL THROMBOCYTOSIS REGISTRY

D Sotiropoulos, T Marinakis, M Tsirigotis, M Iskas, V Papadopoulos, E Papadakis, E Spanoudakis, I Kotsianidis, A Pouli, A Vassou, A Pigaditou, A Balta, M Dimou, M Kotsopoulou, C Matsouka,

M Protopappa, E Vlachaki, I Koratzis, I Dervenoulas,
N Anagnostopoulos, P Panayotidis, A Anagnostopoulos
Study group for Myeloproliferative Neoplasms - Greek Society of Hematology, Athens, Greece

In this study we present the first results from the registry of Greek patients with essential thrombocytosis, which has been developed by the study group for myeloproliferative neoplasms of the Greek Society of Hematology. There are 352 patients included in the study. 42% of them are male. Median age at diagnosis was 60 years. An elevated platelet count was a routine test finding in 80.5% of them. Thromboembolic and hemorrhagic events before the onset of treatment were observed in 9.1% and 2.9% respectively. In 21.7% there was a history of cardiovascular disease. Coronary disease was reported in 14.6%. JAK-2 V617F mutation was detected in 55.1% of the 352 patients. In 71% of them no fibrosis in trephine biopsy was detected, whereas fibrosis grade I and II was found in 19% and 9% respectively. 18.8% of them had splenomegaly at diagnosis. Watchful waiting strategy for more than 6 months was initially adopted in 155 patients (44%). First-line therapies were hydroxyurea, anagrelide and interferon in 76.7%, 13.4% and 7% patients respectively. Hudroxyurea was the treatment best tolerated and exhibited the best response rates in comparison to anagrelide and interferon (93.2.% vs 73.9% and 80.6% respectively).Thrombosis or hemorrhage during therapy was observed in 4.5% and 2.1% respectively. Secondary malignancies developed in 6.3% of the patients, 2.7% of them being hematologic. Comparing the presence of JAK-2 mutations with age we observed that patients bearing the JAK-2 mutation tend to be older (64 vs 56 years old, p=0.0002) and to have higher hemoglobin values (14.08 vs 13.32, p=0.0001). White blood cell count and platelet count does not seem to correlate to JAK-2 mutation. No correlation was also observed between JAK-2 mutation presence and fibrosis or splenomegaly. The probability for thrombosis was higher in patients with elevated haemoglobin levels but the difference was not statistically sighnificant.

1375

VERY LOW DOSE LENALIDOMIDE CAN RESULT IN PROLONGED TRANSFUSION INDEPENDENCE IN PATIENTS WITH MYELOFIBROIS

A Dyszkiewicz-Korpanty, WA Hassan, H Enright
Adelaide and Meath University Hospital, Dublin, Ireland

Background: Myelofibrosis is frequently associated with red blood cell transfusion dependence resulting in significantly reduced quality of life and complications including iron overload. Lenalidomide has been shown to be effective in some patients with myelofibrosis, but can result in neutropaenia and/or thrombocytopaenia. Aims: To analyse the effects of very low dose lenalidomide on transfusion requirements in patients with myelofibrosis. Methods: We describe 5 patients (aged 55-70 years old) with an established diagnosis of myelofibrosis - five with idiopathic myelofibrosis and one with myelofibrosis secondary to Polycythemia Vera - who were treated with very low dose Lenalidomide. The starting dose was 5mg daily or on alternate days, increasing to a maximum dose of 10mg daily. Three patients also received Erythropoietin. *Results*. Two patients were highly transfusion dependent prior to treatment, requiring two units of red cells every 1-2 weeks. Following two months of lenalidomide treatment their transfusion requirements significantly decreased (1-2 units every 2-3 weeks). One patient (treated with lenalidomide 5mg on alternate days) became transfusion independent 4 months after treatment was commenced. It was possible to discontinue his erythropoietin therapy (haemoglobin 12.9g/dl) and and he is now being treated for transfusion-related iron overload with therapeutic venesection. A third patient treated with both lenalidomide and erythropoietin became transfusion independent a month after lenalidomide was commenced, and continues to maintain a haemoglobin at the level of 10.5-13.9g/dl. Two patients treated with very low dose lenalidomide were anaemic but did not require any red cell transfusion prior to therapy. Both had a significant haematologic response, with an increase in haemoglobin of > 2g/dl after 2 months of treatment. No patients required therapy discontinuation or interruption due to neutropenia or thrombocytopenia. *Conclusions*. Very low doses of lenalidomide (5mg on alternate days) can produce dramatic clinical responses in some patients with myelofibrosis, and sustained transfusion independence can be achieved. Late responses (>4 months after commencing therapy) may occur. Starting lenalidomide at very low doses in patients with myelofibrosis may be an important strategy to avoid therapy interruptions due to cytopenia.

1376

INCIDENCE AND RISK FACTORS OF SPLANCNIC VENOUS THROMBOSIS (SVT) IN CHRONIC MYELOPROLYPHERATIVE NEOPLASMS (CMNS)

B Martino, K Alati, F Nobile
Azienda ospedaliera Bianchi Melacrinò Morelli, Italy, Italy

Several data in literature underline the clinical and pathogenetic role of JAK2 V617F mutation in CMNs. Its role in additional thrombotic risk in these patients is still under discussion. The same mutation has been identified as occult marker in several SVT patients; in particular, 45% of patients with Budd-Chiari syndrome (BCS) and 34% of portal vein thrombosis patients (PVT) have associated CMNs. The main BCS patients without CMNs present an additional congenital or acquired thrombosis risk factor. The aim of our study is to evaluate SVT incidence in CMNs patient followed up in our Istitution and the presence in the same population of other prothrombotic risk factors. Out of the 405 CMNs Ph1 negative patients retrospectively evaluated (jun 2000-jun 2010), 9 (7 females and 2 males) (2,2%) presented SVT. 6 of them had essential thromobocitemia(ET) 2 idiopatic myelofibrosis(IM) and 1 polycitemia vera(PV).Among ET incidence were 3% and 5/6 were femals They have been treated with antiagregant and anticoulant therapy . 6 have been treated with idrossiurea. All of them are JAK2 V617F positive. 7 patients had SVT before CMNs diagnosis, 2 of them had splenectomy. The other 2 CMNs patients have had a SVT diagnosis during routine CMNs follow up. 75% of SVT/CMNs patients had one prothromobtic risk factor, at least (factor V Leiden, Protein C deficience, hyperhomocystinemia) and 50% had 2 or more associated defects. The remaining CMNs patients (396) had a less significant prevalence of prothrombotic risk factors and developed other venous thrombosis: wbc, platelets values and JAK2 V617F mutation correlate with the thrombotic event The 7 patients had SVT before CMNs diagnosis no other major thrombotic event has been occurred during follow-up. Conclusion: Even SVT has a low incidence in CMNs patients, we discuss on the potential benefit of searching for other prothrombotic risk factors in the whole population in order to properly treat with anticoulant therapy.

1377

MORPHOMETRIC ANGIOGENESIS PARAMETERS FOR INDOLENT AND AGGRESSIVE NON-HODGKIN'S LYMPHOMA

E Kopic,[1] E Cickušic,[1] A Kopic,[1] A Arnautovic-Custovic,[1]
A Halilbašic,[1], L Tinjic,[2] S Hasic,[1] V Simendic[1]
[1]*University Clinical Centre Tuzla, Tuzla, Bosnia-Herzegovina*
[2]*Pharmaceutica Company Roche d.o.o.-Roche Ltd., Sarajevo, Bosnia-Herzegovina*

There is much evidence about importance of angiogenesis in development and progression of solid tumors. The role of angiogenesis, as an indicator of higher malignant potential in non-Hodgkin's lymphoma, is not clear at the moment. Morphometric characteristics of microvessels in lymph node sections in previously untreated patients with small lymphocytic lymphoma/chronic lymphocytic leukemia (SLL/CLL) and diffuse large B-cell lymphoma (DLBCL) were studied and relationship between angiogenesis and NHL histological malignancy grade was also evaluated. Lymph node biopsies samples of 30 newly diagnosed patients with SLL/CLL (n= 30) and DLBCL (n = 30) were studied. All samples were fixed in 10% buffered formalin solution and embedded in paraffin. Microvessels were visualized by immunohistochemical staining for anti F-8 antibody. In the area showing the most intense vascularization (i.e. the "hot spot"), microvessel density (MVD), total vascular area (TVA), as well as the size related parameters were estimated, by using image analysis program"analysSIS". *Results*. Number and size-related microvessels angiogenic morphometric parameters were statistically higher in group with DLBCL compared with SLL/CLL: MVD ($p=0.002$), TVA ($p<0.0001$), area ($p<0.0001$), perimeter ($p<0.0001$), minor axis length ($p<0.0001$) and major axis length ($p<0.0001$). It is to be noted that positive correlation existed between TVA and MVD in DLBCL and SLL/CLL. *Conclusions*. The present study supports the view that angiogenesis correlate with histological grade of NHL.

1378

NUCLEAR FACTOR-KB ACTIVATION IN PRIMARY LYMPHOMA OF BONE

F Heyning,[1] L Koens[2] A Szepesi[3] A Matolcsy[3] P Hogendoorn[2]
P Jansen[2]
[1]*Medisch centrum haaglanden, Amsterdam, Netherlands*
[2]*Leiden University Medical Center, Leiden, Netherlands*
[3]*Semmelweis University, Budapest, Hungary*

Background. Primary lymphoma of bone (PLB) is a rare type of extranodal diffuse large B-cell lymphoma (DLBCL) with a relatively indolent clinical behaviour and a favourable outcome. Previous reports have demonstrated a subdivision of PLB in germinal center (GC) and non-GC phenotype by immunohistochemistry. Recent scientific interest has focused on elucidating the role of nuclear factor (NF)- κB pathway in lymphomagenesis and its possible value as a therapeutic target. In nodal B-cell non Hodgkin lymphomas, constitutive activation of NF-κB appears to be especially involved in tumour cell survival in the non-GC type of DLBCL, although it is not exclusively restricted to this subtype. *Aims*. We here investigate NF-κB activation in PLB with GC and non-GC phenotype. *Material and methods*. In order to assess involvement of NF-κB activation in PLB, immunohistochemical staining procedures for NF-κB family members p50, p52 and p65 were performed on paraffin-embedded tumour tissues of 50 cases of PLB. Results: Nine cases (16% of our cohort) showed nuclear positivity for p50, and one case showed nuclear co-expression of p52. Positivity for p50 was not restricted to either GC- or non-CG phenotype of the tumour (20% and 25%, respectively), or related to an inferior prognosis or treatment resistance. P65 did not show significant nuclear staining. *Summary and conclusions*. The immunohistochemical nuclear staining for p50 in 16% of the cases suggests constitutive activation of NF-κB via the classical pathway in a minority of PLB patients. In contrast to other extranodal types of DLBCL, there was a lack of nuclear co-localization of p65 staining, which may suggest different pathway activation. The alternative pathway of NF-κB activation does not appear to be involved, as only one case showed significant nuclear staining for p52. Finally, nuclear expression of p50 was not preferentially detected in non-GC type or GC-type PLB, or related to an inferior prognosis.

1379

DIAGNOSIS OF NON HODGKIN'S LYMPHOMAS (NHL) BY FLOW CYTOMETRY (FC) ON LYMPH NODE CELL SUSPENSIONS AT BLIDA , ALGERIA

S Oukid, S Taoussi, M Abad
EHS ELCC, Blida, Algeria

Background. The diagnosis of malignant lymphoma is primarily based on histological examination. The FC is a powerful tool for cell analysis that helps a closer definition of cell proliferation. *Aims*. The aim of our study is to compare the FC analysis of cell suspensions obtained by grinding lymph node biopsy or fine-needle aspiration with histologic diagnosis. *Methods*. The diagnosis of NHL is confirmed by histological study on lymph node biopsy. The biopsy was divided into two fragments: one for pathological studies, the other is crushed and put into a culture medium to obtain a cell suspension; If the biopsy is deferred, a fine-needle aspirate of lymph node is performed. Once the cell suspension obtained, cells are washed with phosphate-buffered saline to remove cytophilic antibodies and then treated by FC ; FC immunophenotyping was performed with antibodies targeting T, B and NK lymphoid populations (CD3, CD2, CD4, CD8, CD5, CD7, CD1a, αβTCR, γδTCR, kappa and lambda light chains, CD19, CD20, CD22, CD10, CD43, CD79a, CD79b, CD23, CD25, CD11c, IgM, CD56, CD34 ; the acquisition was made using four-color multiparameter flow cytometry. Detection of immunoglobulin ligtht- chain-restriction was used for diagnosis of B NHL.Detection of multiple abnormalities in the sames cells and restriction of TCRs were used for diagnosis of T NHL. Results. Cell suspensions from 67 patients were included in this study: they involve 19 women and 48 men with an average age = 41 years (15 -76). A fine-needle aspirate of lymph node is performed in 42 patients (68.7%) with a mean of 13752 cells / µl (800-71 500) and lymph node crush in 21 patients (31.3%), with a mean of 11055 cells/µl (900-64560) ;in 04 cases, number of celles was insufficient (<100 cells / µl) for analysis. Thus out of 63 analyzed cell suspensions, FC showed no monoclonality of B or T in 10 cases for which histology revealed : Hodgkin lymphoma : 02 cases carcinoma: 01case, Tuberculosis : 01 case and a non specific lymphadenitis: 06 cases; in this group, concordance between FC and Histology was 80%. In 10 cases the histology was not available, the CMF showed the monoclonal proliferation of B cells in 7 cases and of T cells in 3 cases. In 43 cases, when biopsy was available, the FC has concluded for: B-cell NHL in 33 cases (76%) and T cell NHL in 10 cases (24%). In the group where the monoclonality was confirmed by FC, when histology was available (43 cases), the correlation between FC and histology was 90.8% ; discordance was related to 4 cases (9.2%) with advantage for FC in 2 cases and histology in 2 cases. Summary. Because the WHO classification of NHL incorporate immunophenotypic criteria, FC helps to better characterize these entities. In our study, FC has been contributory to the diagnosis of NHL, specifying monoclonality and has shown the absence of monoclonality in benign lymphoid hyperplasia, undifferentiated carcinomas and Hodgkin's disease. The CMF is a reliable and quick method for the evaluation of NHL.

1380

HIGH KI 67 INDEX IS A POOR PROGNOSTIC FACTORS FOR DLBCL TREATED WITH CHOP WITH OR WITHOUT RITUXIMAB

A Giordano, F Gaudio, T Perrone, P Curci, C De Risi, A Spina, F Laddaga, V Liso, G Specchia
Hematology - University of Bari, Bari, Italy

Background : Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous disease and patients exhibit a wide range of outcomes. The addition of Rituximab to CHOP chemotherapy (R-CHOP) has led to a marked improvement in survival and has altered the significance of previously recognized prognostic markers. Aim: we performed a retrospective analysis of 111 patients with de novo DLBCL to assess the impact of clinical variables and biologic features on Response Rate (RR), Overall Survival (OS) and Progression Free Survival (PFS). Methods: 58 patients were treated with R-CHOP (post-Rituximab era) and 53 with CHOP (pre Rituximab era). For each case the following clinical data were recorded: patient's age, sex; performance status, B-symptoms; serum lactate dehydrogenase (LDH); serum β2microglobulin (β2µg); bone marrow involvement; bulky disease; extranodal disease; clinical stage and International Prognostic Index (IPI). A maximal tumor burden > 10 cm was defined as bulky disease. Immunohistochemical analyses were performed: Bcl2 expression was scored positive when at least 50% of tumor cells expressed the protein; proliferative index assessed by ki-67 immunostaining was scored using a cutoff of >80%. Results: the variables predictive of RR in CHOP group were B symptoms (P=0.047), age > 60 years (P=0.045), clinical stage (P<0.032), bone marrow involvement (P<0.045), bulky disease (P<0.007), IPI risk group (P<0.001) and bcl2 expression (P<0.002); in the R-CHOP group they were bulky disease (P<0.002); bone marrow involvement (P<0.049), IPI risk group (P<0.011), and Ki67 expression >=80% (P<0.049). At multivariate analysis, in patients treated with CHOP the independent prognostic factors associated with PFS were age, bulky disease, IPI risk group and bcl2 expression; associated with OS were Performance Status, clinical stage, IPI risk group and bone marrow involvement. By contrast, among patients treated with R-CHOP, the variables proving to be independent prognostic factors were bulky disease on PFS, and Ki67 expression >=80% on OS and PFS. Conclusions: Our data show that a high proliferative index could represent possible predictive factor of poor prognosis, which would help to identify a high risk subgroup of newly diagnosed DLBCL. Further large-scale and prospective studies will be required to confirm these results.

1381

GSTP1 POLYMORPHISM AS A PREDICTOR OF CLINICAL OUTCOME OF THE THERAPY OF NON-HODGKIN'S LYMPHOMA IN ELDERLY PATIENTS

I Kriachok, N Khranovska, N Svergun, I Titorenko, K Filonenko, O Novosad
National Cancer Institute, Kyiv, Ukraine

Background. The worldwide incidence rate of non-Hodgkin lymphoma (NHL) increases on 2-3 % annually. Therapy of NHL was improved over the last two decades, but prognosis for a half of patients still remains poor. Glutathione S-transferase P1 (GSTP1) is a member of the GST enzyme superfamily involved in the metabolism and detoxification of chemotherapeutic agents. The proteins encoded by the different alleles of the gene show different abilities to metabolize carcinogens and anticancer agents. Therefore, genetic polymorphism of GSTP1 could be essential in the determination of the susceptibility to the toxic effects of chemicals, and might also be involved in the tumor response to anticancer drugs and influence clinical outcome of patients. Aim. The aim of this study was to evaluate the predictive value of the GSTP1 Ile105Val polymorphism on clinical outcome after the therapy of elderly patients with NHL. *Materials and methods*. The case group was comprised of 60 patients with B-cell NHL (small cell: 35, large cell: 25; median age: 70 years, range: 60-85; males: 33, females: 27, stages I-II: 17, stages III-IV: 43) and 158 blood donors (median age: 38 years, range: 17-59; males: 69, females: 89). The NHL type was diagnosed according to the World Health Organization (WHO) classification. Patients were categorized by the Ann Arbor staging system and the International Prognostic Index. Chemotherapy regimens CHOP or CNOP were administered for all

patients enrolled in the study and radiotherapy by indications. The response to the therapy was scored according to International Working Group criteria (1999, 2007). Genomic DNA from peripheral blood of all individuals was analyzed for identification of GSTP1 genotypes using TaqMan Polymerase Chain Reaction (PCR) allelic discrimination assays. Results. The genotypes of the GSTP1 gene in both control and patient groups did not differ significantly from those predicted by the Hardy-Weinberg distribution. Observed Val allele frequency was 0.32, similar to previous reports on allele frequencies for healthy Caucasians. The frequency of GSTP1 homozygous wild genotype was higher in patients with advanced stages (III-IV) than in patients with localized stages (I-II) (60,5 % versus 29,4 %, P = 0.02). Overall response rate after the first line therapy was better in patients with increasing number of Val alleles 68.25% comparative to 27.1% in patients with homozygous wild genotype (P=0.02). We observed a correlation between GSTP1 homozygous wild genotype and unfavorable prognosis for patients with advanced NHL: among patients with relapse 82 % were of Ile/Ile genotype. Moreover we did not noticed early relapses in patients with Val/Val and Ile/Val genotypes, while patients with Ile1/Ile have shown early relapses in 26,1 % of cases (P = 0.05). We carry on investigations with larger cohorts of patients for further assuring of our preliminary results. *Conclusions*. The results suggest that the Ile105Val polymorphism of the GSTP1 gene may predict clinical outcome of the therapy of elderly NHL patients. Hence the investigations of GSTP1 polymorphism are very promising, since it might provide a possible application of this genetic marker as an independent prognostic factor of NHL.

[5]*Stefan Nicolau Virusology Institute, Bucharest, Romania*

Background: Splenic marginal zone lymphoma (SMZL) is a rare, indolent subtype of lymphoma which accounts for less than 2% of all non-Hodgkin's lymphomas. It is the most frequent small B-cell lymphoma associated with splenomegaly and probably the most frequent splenic lymphoma. An important issue is the role of hepatitis C virus (HCV) infection in SMZL. Approximately 10%-15% of SMZL do occur in the setting of chronic hepatitis C. This association underlines the importance of antigenic stimulation in the proliferation of the tumor cells in HCV-associated. SMZL express surface IgM and IgD and are usually CD19+, CD20+, CD22+, CD79a+, FMC7+, CD10-, CD123-, and CD103-; DBA44, CD11c, CD23 and CD5 can be positive in a subset of cases. Cyclin D1/BCL-1 is not expressed, whereas the BCL-2 protein is intensely expressed. *Aims*: to study the immunophenotype of malignant lymphocytes in splenic marginal lymphoma with and without hepatitis viruses and highlight the differences that could guide the process of monitoring and treating these patients. *Methods:* we analyzed 14 patients diagnosed with splenic marginal zone lymphoma in the Hematology Department of Emergency University Hospital Bucharest; 5/14 patients with chronic infection with HCV or HBV - vSMZL and 9/14 patients without chronic infection with HCV or HBV - SMZL. We performed immunophenotypical analysis of peripheral blood and bone marrow aspirate on BD FACS Calibur flowcytometer, using the following panel of monoclonal antibodies (CD19, CD20, CD22, CD79a, CD79b, FMC7, CD5, CD10, CD23, CD103, CD11c, CD24, CD38, CD43, CD81, IgM , IgD, BCL-2) . Histological findings were combined with clinical, immunophenotypic, and laboratory data. Results: Patients' age ranged from 45 to 73 years (median, 65 years) with a male-to-female ratio of 1:1.4. 14/14 patients had splenomegaly, 14/14 patients had bone marrow involvement. Regarding the laboratory features, we observed differences between the 2 groups concerning: anemia, which was present in 4/9 patients with SLVL versus 4/5 patients with vSMZL; thrombocytopenia - present in 2/9 patients (SMZL) versus 2/5 patients (vSMZL), and higher LDH level, respectively 4/9 patients (SMZL) versus 3/5 patients (vSMZL). The immunophenotype was classical in most cases, but 1patient/14 was CD5+. We found important differences in the expression of the following markers: Md (median fluorescence intensity) 10 for SMZL versus 37 for vSLVL, CD38: Md 15 versus 43, CD43: Md 13 versus 35. The free light chain κ/λ ratio was: KAPPA+ (Md 7/1 vs. 15/1), LAMBDA+ (2/1 vs. 2,5/1). *Conclusions:* Splenic marginal zone lymphoma is often associated with chronic hepatitis viral infection. These patients must be considered as a special group with special clinical, laboratory findings and special treatment. The expression of CD 23, CD38, and CD43 (higher in vSMZL group than in SMZLgroup) in splenic marginal lymphoma might be related to viral antigenic stimulation and not to an aberrant phenotype. After antiviral therapy, the intensity of activation B-cell markers and light chain ratio could be used as a surrogate marker of the control of the HCV-related lymphoproliferation.

1383

IMPACT OF THE REACTIVE MICROENVIRONMENT ON THE BONE MARROW INVOLVEMENT OF FOLLICULAR LYMPHOMA

H Rajnai,[1] C Bödör,[1] Z Balogh,[1] E Gagyi,[1] J Csomor,[1] T Krenács,[1] E Tóth,[2] A Matolcsy[1]

[1]*Semmelweis University, Budapest, Hungary*

[2]*National Institute of Oncology, Budapest, Hungary*

Background. Follicular lymphoma (FL) is an indolent B-cell non-Hodgkin's lymphoma (NHL) which comprises about 20% of all NHLs in Europe and North America. Gene expression and immunohistochemical studies suggested that immune microenvironment of FL plays an important role in clinical behavior and progression of the disease: expression of genes which are enriched in T-cells and macrophages was associated with a favorable outcome, whereas genes which derived from macrophages and FDCs were associated with inferior outcome. In 40-70% of FL cases the bone marrow (BM) is also involved at diagnosis which has been considered as a poor prognostic factor. Although lymph node (LN) and BM compartments of FL are related to the same neoplastic clone, several morphologic, phenotypic and genotypic differences have been reported between the tumor cells within these two compartments. The cytological grade of the tumor is usually lower in the BM than in the LN; FL cells of the BM frequently lose the expression of BCL-6 and CD10 and the mutation pattern of IgH variable region genes of FL cells shows many differences between BM and LN. Aims: To investigate the role of the microenvironment in the bone marrow involvement of FL, we performed immunophenotypical analysis of the reactive cell populations in the lymph nodes and corresponding bone marrows of 35 patients with FL. The microenvironment patterns of the BM infiltrates were compared to the corresponding features of the LN in cases with BM manifestation; and the LN microenvironment was compared in FL cases with and without BM involvement. *Methods*. Automated image-segmentation-based localization and quantitation was performed in whole digital slides of immunostained tissue microarrays of formalin-fixed paraffin-embedded tissue biopsies. Results: We found significantly more CD8+ cytotoxic T-lymphocytes, FOXP3+ regulatory T-lymphocytes, and CD68+ macrophages and less PD1+ follicular B-helper T-lymphocytes in the BM than in the matching LN samples. Furthermore, we observed significantly less infiltrating CD8+ T-cells and CD68+ macrophages in cases involving the bone marrow compared to those localized only to the lymph nodes. *Conclusions*. Our study showed that the lower grade and proliferation of the BM could be explained by the different composition of the microenvironment in the BM. On the other hand, different tumor cell growth in the LN and BM may generate different microenvironment. Our study also suggested that cytotoxic T-lymphocytes and macrophages play a relevant role in the prevention of tumor cell propagation and migration and their elevated number in LNs prevents BM infiltration of neoplastic cells in FL.

1384

THYROID LYMPHOMA CONSISTENTLY DIAGNOSED BY FLOW CYTOMETRY OF FINE NEEDLE ASPIRATION BIOPSY SAMPLE

G Rymkiewicz, K Blachnio, B Maksymiuk, M Feliksbrot-Bratosiewicz, Z Bystydzienski, D Kolataj, R Woroniecka, JA Walewski

The Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland

Diagnosis of primary thyroid lymphoma (PTL) is most commonly based on histopathological (HP) and immunohistochemical (IH) examination of surgical specimen from thyroidectomy and occasionally on flow cytometry (FCM) of cell suspensions. The routine method (HP/IH)

is able to capture a tissue structure but is based on invasive biopsy, is time consuming and sensitive to the quality of the slides. In addition, a range of antibodies used in IH are limited. Furthermore, post-surgical complications may postpone initiation of the curative systemic treatment, and a permanent hormonal substitution is a rule. FCM of a cellular suspension obtained by the fine needle aspiration biopsy (FNAB) of thyroid gland is a safe, rapid, and cost-effective procedure. A broad range of antibodies may be used to determine a simultaneous expression of numerous antigens as well as clonality. Disadvantage of FCM may be possible loss of diagnostic cells and missing tissue structure. The thyroid polyclonal lymphoid infiltrate in Hashimoto thyroiditis (HT) represents the substrate from which PTL may arise. Assess the usefulness of FNAB/FCM in the diagnosis of PTL. We identified 11 cases of PTL in a database of 3000 lymphoma patients (pts) diagnosed by FNAB/FCM between 2000 and 2010. PTL cases were retrospectively reviewed by comparing conventional cytological smears and FCM. Clinical presentation included estimation of performance status (PS), lymph nodes status, LDH level a previous history of HT. Lymphoma monoclonal cells and polyclonal lymphoid reactive infiltrate cells associated with HT were evaluated by antibodies to the range of antigens: CD45, CD10, CD11c, CD19, CD20, CD22, CD23, CD25, CD38, CD43, CD44, CD52, CD16&CD56, CD56, CD79β CD138, FMC7, HLA-DR, bcl-2, CD62L, CD71, surface light/heavy chains of immunoglobulin and pan-T. Lymphoma subtype was defined according to WHO 2008 classification. Patients characteristics: females - 11 pts with a previous history of HT in 3/11 pts, median age - 74 yr (range 52-89), PS 0 - 10/11 pts, LDH > normal levels - 5/9 pts, cervical lymphadenopathy - 4/11 pts. Diagnosis: percentage of PTL cells in examined by FCM suspension was - 52% (range 7-95%). The final diagnosis comprised: DLBCL-NOS (GCB) - 5/11 pts, DLBCL-NOS (non-GCB) - 3/11 pts and MALT, FL, PTCL-NOS -one case each. Immunophenotype of all B-cell PTL (10 pts): $CD45^+$ (10/10 pts), $CD19^+$ (10/10 pts), CD20+ (10/10 pts), $CD22^+$ (10/10 pts), $CD23^+$ (1/10 pts), $HLADR^+$ (9/10 pts), $CD10^+$ (6/10 pts), $CD43^+$ (4/9 pts), $CD44^+$ (6/7 pts), $CD38^+$ (6/9 pts), $CD11c^+$ (7/ 9 pts), $CD25^+$ (1/9 pts), $FMC7^+$ (8/9 pts), $CD5^+$ (0/10 pts), $CD79\beta^+$ (0/4 pts), κ+/ λ- (5/10 pts), λ+/κ- (2/10 pts), κ-/λ- (3/10 pts), IgG+ (3/9 pts), IgG^+ /IgA^+ (1/9 pts), IgM^+ (1/9 pts), Ig- (4/9 pts), $bcl\text{-}2^+$ (3/8 pts), $CD71^{+++}$ {100% of positive cells} (7/10pts); HT: accompanying PTL was observed in 6/11 pts (based on infiltration estimated by FNAB/FCM): percentage of normal polyclonal B (κ+ and λ+) cells in suspension - 6,5% (range 0-27%) in 6/11 pts, percentage of normal T cells in suspension - 38% (range 5-64%) in 11/11 pts. Combined use of FNAB/FCM is a reliable and minimally invasive method for defining subtype of PTL.

1385

MOLECULAR DIFFERENTIAL DIAGNOSIS DISTINGUISHES BETWEEN PRIMARY MEDIASTINAL B CELL LYMPHOMA AND OTHER TYPES OF DIFFUSE LARGE B CELL LYMPHOMA

J Mangasarova, A Misuyrin, A Magomedova
Hematological Research Center, Moscow, Russian Federation

Background. Primary mediastinal B cell lymphoma (PMBL) has been recognized as a subtype of diffuse large B cell lymphoma (DLBCL) based on its distinctive clinical and morphological features but differs from other types of DLBCL due to its peculiar immunophenotype and gene expression profile. It was shown [A. Rosenwald et al., 2003] that PMBL is characterized by increase expression level of JAK2, MAL, PDL1, PDL2 and TRAF genes. Aims. To see if quantitative expression analysis of JAK2, MAL, PDL1, PDL2 and TRAF genes may distinguish PMBL cases from other variants of DLBCL with primary involved chest lymph nodes. Patients and methods. In this study there have been investigated biopsy samples of enlarged lymph nodes from 25 pts with DLBCL with primary involvement of mediastinal lymph nodes, biopsy samples of affected lymph nodes from 12 pts with DLBCL without involvement of mediastinal lymph nodes and lymphocytes from 6 normal donors. To evaluate expression level of JAK2, MAL, PDL1, PDL2 and TRAF genes we have exploited RQ PCR with TaqMan hydrolyzing probes. Results. Normal median value of JAK2, MAL, PDL1, PDL2 and TRAF gene expression have been established according the data obtained in the set of normal donors. The gene was considered to be overexpressed if its value was more than normal median value + 3SD. It turned out that in the 12 pts with DLBCL without involvement of mediastinal lymph nodes there was no overexpression of MAL, PDL1 and PDL2 genes. In this group of pts there was only 1 out of 12 (8%) with the overexpression of JAK2 and 2 out of 18 (16%) with the overexpression of TRAF. In the case of 25 pts DLBCL with primary involvement of mediastinal lymph nodes JAK2 gene was overexpressed in the 14/25 cases (56%), MAL - in the 6/25 (24%), PDL1 - in the 2/25 (8%), PDL2 - in the 5/25 (20%) and TRAF - in the 2/12 (16%). Therefore, in this group of DLBCL pts with primary involvement of mediastinal lymph nodes 14/25 (56%) have shown significant overexpression of at least 3 genes analyzed whereas in the other 11/25 (44%) pts with primary affected mediastinal lymph nodes all these genes levels never exceeded the threshold. Tacking into account these data as well as the data of immunophenotypic analysis the diagnosis of PMBL was confirmed for 14/25 pts. Summary/conclusions. Our data suggest that the quantitative molecular analysis of JAK2, MAL, PDL1, PDL2 and TRAF gene expression enables to distinguish PMBL from other types of DLBCL with primary involvement of mediastinal lymph nodes.

1386

DOES KI-67 PREDICT TIME TO FIRST TREATMENT IN MANTLE CELL LYMPHOMA?

A McCurdy, S Nolan, T Arnason, R Juskevicius, A Shawwa, D Macdonald
Dalhousie University, Halifax, Canada

Background: Treatment strategy for mantle cell lymphoma (MCL) is highly variable between centers and is debated worldwide. Some centres offer early aggressive treatment with chemotherapy +/- stem cell transplant at diagnosis. Others use a "watch and wait"approach whereby treatment is delayed until the patient becomes symptomatic. Our centre affords a unique opportunity to study MCL, as we have an institutional commitment to a "watch and wait"strategy. A biomarker predictive of early time to first treatment would be useful to make clinical decisions in treatment initiation and monitoring. Ki67 is an established predictor of shortened overall survival in MCL; however, its role in predicting treatment time has not been studied. Aims: The primary goal of our study is to determine if Ki67 can predict time to first treatment in MCL. Methods: All patients at our institution >17 years old diagnosed with pathologically confirmed Ann Arbor Stage III or IV MCL from January 1, 1999 to September 28, 2009 were enrolled. A tissue microarray was assembled using archived formalin fixed paraffin embedded tissue from all cases. Immunohistochemical stains, including Ki67, CD 20, and Cyclin D1 were applied to sections of the microarray. Cases were classified as high Ki67 when >20% of tumor cells showed nuclear staining for Ki67. Immunohistochemistry was performed and reviewed to confirm the original diagnosis. Time to treatment was determined by chart review. Results: 51 patients with MCL were identified from pathologic case records; of these, 26 patients with a confirmed diagnosis of MCL had adequate archived tissue for analysis and sufficient clinical records with long term follow up. The median age at diagnosis was 63 years (range 41-87 years). The median time to treatment was 27 days in the patients with high Ki67 index tumors (N=11) and 27 days in patients with low Ki67 index (N=15). Kaplan-Meier analysis showed overlap of the time to treatment curves for the two groups. The log-rank test showed no difference in time to treatment between the two groups (p=0.22). Proportion of patients treated within 90 days of diagnosis was 91% versus 67% in the high versus low Ki67 groups (p=0.197). Summary/Conclusions: While high Ki67 has been shown to correlate with decreased overall survival in MCL, it was not predictive of time to first treatment in our cohort of 26 patients uniformly treated according to a policy of watch and wait until onset of symptoms. The available data is underpowered to detect such a difference. This study reflects other published data, which indicate that the majority of MCL patients are not suitable for a strategy of deferred initial treatment.

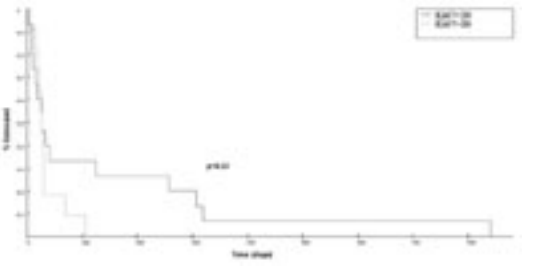

Figure 1. Time to Treatment

PLASMOBLASTIC LYMPHOMAS WITH SKIN INVOLVEMENT

T Micsik,[1] S Fekete,[1] N Eros,[2] J Csomor[1], A Matolcsy[1]
[1]*Semmelweis University Budapest, Budapest, Hungary*
[2]*Dermatology and Venereal Clinic of Semmelweis University, Budapest, Hungary*

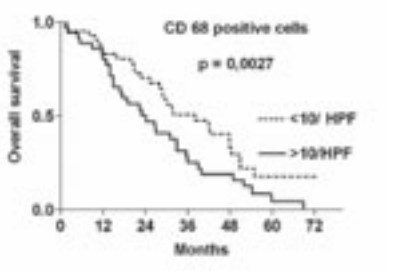
Background. Plasmablastic lymphoma (PBL) is a rare subtype of non-Hodgkin's lymphomas with a rather poor prognosis. The first cases were characterized as oral leasions of HIV+ patients, and later on more extra-oral cases were also found but up to now very few cases with skin involvement/origin of HIV- patients were reported. PBL usually has a strong association with immunsuppression (81% of cases are HIV+) and EBV-infection. PBL consists of typically CD20-, LCA-, CD138+, VS38c+ and lambda or kappa monoclonal immunoblast like large cells with excentrically located vesicular nuclei with one or sometimes more prominent nucleoli and with a high proliferation rate. There is a strong overlap between plasmablastic myloma multiplex and plasmablastic lymphoma and the differential diagnosis might be very difficult. Markers which can help the differentialdiagnosis are p53, Mum1, Pax5, EBER ISH. *Aims*. Here we report and review seven cases (one female and six males) of plasmablastic tumors of HIV-negative patients with skin involvement. *Methods*. Avarege age was 65 years at the diagnosis of the disease. Three of the cases had a medical history of myeloma multiplex which later progressed to an agressive plasmablastic tumor. Another two patients had immunsupressive therapy because of renal transplantation. We performed a thorough immunohistochemical analysis with 15 markers (CD20, CD79a, Kappa, Lambda, CD38, CD45, CD138, Vs38c, Ki67, CD10, CD30, MUM, MUM1, Pax5, EMA) and additionally EBV-detection with in situ hybridization methods to set up a reliable algorythm for the differentialdiagnosis of this rare lymphoma. Results: The best markers for PBL were CD138, Vs38c, IgG, Ki67, EMA, Pax5 and MUM. The most important differentialdiagnostic problem was to separate PBL from plasmablastic myeloma multiplex, which distinction can be made upon the exact medical history, clinical correlations and bone marrow investigation/staging supported by a coexpression of several immunohistochemical markers, but in doubtful cases only the EBV-detection could help us. *Conclusions*. Althought skin involvement of the very agressive plasmablatic lymphoma is an exceptionally rare occuring phenomen it can occur not only in HIV+ patients but also without HIV-infection and therefore can cause very serious differentialdiagnostic problems. Morphologic and (immuno)phenotypic characterization might be insufficient for distinguishing plasmablastic myeloma multiplex and plasmablastic lymphoma. In these cases exact clinical data/correlations and EBV detection can help the most effectively.

1388

TUMOR INFILTRATING CD 68 POSITIVE MACROPHAGES PREDICT SURVIVAL IN MANTLE CELL LYMPHOMA

C Schrader,[1] F Sirin,[2] P Meusers,[3] G Brittinger,[3] J Claasen,[2]
W Klapper[4]
[1]*Division of Stem Cell Transplantation and Immunotherapy, Kiel, Germany*
[2]*I. Department of Internal Medicine, University Hospital of Kiel, Kiel, Germany*
[3]*Division of Hematology, University of Essen, Essen, Germany*
[4]*Department of Pathology, University of Kiel, Kiel, Germany*

Background. Mantle cell lymphoma (MCL) is a malignant lymphoma associated with a relatively aggressive clinical course and a median overall survival time of 3-4 years. Only limited data about tumor associated macrophages and their influence on survival in MCL exists. *Methods*. We analyzed the amount of CD68 macrophages in relation to the clinical outcome in patients with MCL. Lymph node biopsies of 77 untreated patients (17 women and 60 men) enrolled in two multicenter trials (1975-1985) with a median age of 66 years (range 41-86 years) were included in this study. Biopsy specimens were investigated immunohistochemically with monoclonal antibodies against CD68 (Ki-M1P). 10 High power fields (HPF) were evaluated by random. Results: Patients with low account (less than 10/HPF) of CD 68 positive macrophages had a median overall survival time of 38.2 months, compared to 24.2 months for patients with high (more 10/HPF) CD 68 positive macrophages. The Kaplan-Meier analysis showed a significant difference in the overall survival time (p=0.0027). *Conclusion*s. Patients with mantle cell lymphoma and a low number of CD 68 positive macrophages have a better prognosis and can predict outcome.

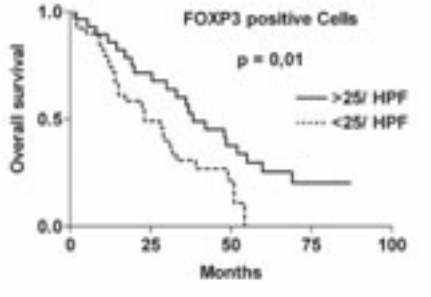


1389

ACCOUNT OF CD 8 AND FOXP 3 POSITIVE T CELLS PREDICT SURVIVAL IN MANTLE CELL LYMPHOMA

C Schrader,[1] Ö Akaltun,[2] P Meusers,[3] G Brittinger,[3] J Claasen,[2]
W Klapper[4]
[1]*Division of Stem Cell Transplantation and Immunotherapy, Kiel, Germany*
[2]*I. Department of Internal Medicine, University Hospital of Kiel, Kiel, Germany*
[3]*Division of Hematology, University of Essen, Essen, Germany*
[4]*Department of Pathology, University of Kiel, Kiel, Germany*

Background. The role of tumor infiltrating T-Cells in malignant B-Cell lymphomas is discussed controversial. There are only limited data on CD 8 and FOXP3 positive cells in mantle cell lymphoma. *Methods*: 81 biopsy specimens of patients (64 men and 17 women) with mantle cell lymphoma and a median age of 64 years (range: 41 to 86 years) were included in this study. The slides were stained immunohistochemically with CD3, CD8 and FOXP3. Positive T-cells of 10 High power fields (HPF) were counted and the average value was calculated.



Results. The CD 8 staining showed a range of 0 to 138 positive cells per HPF with a mean value of 19.4/HPF. A high account of CD 8 positive cells was associated with a significantly longer overall survival time (42 months) compared to MCL with a low account of CD 8 positive cells (28,8 months, p = 0.029). FOXP3 staining had a range of 0 to 104/HPF with a mean value of 28. Patients with MCL and a high number (>25/HPF) of FOXP3 positive cells had a median survival time of 38,2 months compared with the group with low account (<20/HPF) of FOXP3 positive cells (23 months). Kaplan Meier analysis revealed a significant difference (P=0.015) in overall survival time. *Conclusions*. High number of CD 8 and FOXP 3 T-Cells predicts a superior clinical outcome in patients with mantle cell lymphoma.

1390

APOPTOSIS REGULATING PROTEINS AND THE LEVEL OF APOPTOSIS CAN PREDICT SURVIVAL IN MANTLE CELL LYMPHOMA

C Schrader,[1] P Riis,[2] D Janssen,[3] P Meusers,[4] G Brittinger,[4]

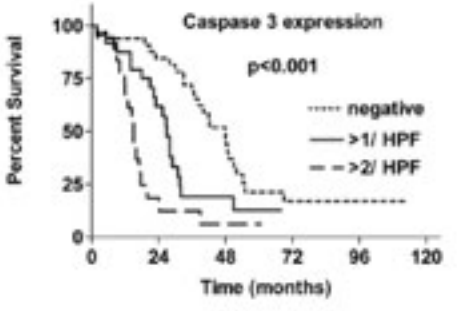
Background. The deregulation of apoptosis is has been implicated in cancer, autoimmunity and degenerative disorders. At the molecular level an external extrinsic death receptor pathway and the internal intrin-

sic (mitochondrial) pathway have been described. Only limited data exist on the expression of proteins involved in apoptotic pathways in mantle cell lymphoma are limited. *Methods*. We investigated the expression of p53, the indicator of DNA damage, and of proteins involved in the regulation of the internal intrinsic mitochondrial pathway (BCL2, Bax) and of effector proteins of apoptosis (caspase 8, caspase 3) in 93 cases of MCL mantle cell lymphoma and correlated the expression with the clinical outcome. *Results*. Similar to previous studies, we found that p53 expression was associated with a shorter overall survival. In contrast to diffuse large B-cell lymphomas, cases expressing the anti-apoptotic protein BCL2 had a favourable outcome. Interestingly, high levels of apoptosis in the tumor before treatment, as indicated by expression of active caspase 3, is are a strong indicator of poor clinical outcome ($p<0.001$). *Conclusions*. These data indicate, that the level of apoptosis itself is a strong prognostic marker in mantle cell lymphomas.



1391

DIET AND NON-HODGKIN'S LYMPHOMA RISK

Z Mozaheb, A Aledavood
Mashhad University of Medical Science, Mashhad, Iran

Background. The role of dietary factors in the epidemiology of Non-Hodgkin's lymphoma (NHL) remains largely undefined. Dietary habits may play a role in the etiology of NHL by influencing on immune system. Design and methods. We analyzed dietary patterns and the risk of NHL in the case control study, which includes 170 NHL cases (mean age 52 years) and 190 controls (mean ages 46 years). All subjects completed a validated food-frequency questionnaire. Dietary pattern investigated in nine groups and separately. Crosstab tables were used to estimate the odds ratios (OR) and the corresponding 95% confidence intervals (CI) and Ptrend. Results. Consumption of highest versus lowest quartile of proteins (OR, 8.088 Ptrend=0.000), fats (OR, 6.17 Ptrend=0.000) and sweets (OR, 8.806 Ptrend=0.000) were associated with a significantly increased NHL risk. Inverse association was found for fresh fruits (OR, 0.117Ptrend=0.000) and vegetables (OR, 0.461 Ptrend =0.010). Conclusions. An association between dietary intake and risk of NHL is biologically plausible because of immunosuppressive effect of fat and animal proteins and antioxidant properties of vegetable and fruits. It is recommended to encourage the general population to increase dietary fiber and to limit fat, red meat and sweet consumption.

1392

CHEMOTHERAPY WITH ALTERNATING REGIMEN MICMA/IGEV IN ELDERLY PATIENTS WITH REFRACTORY DLBCL: A FIGHT AGAINST WINDMILLS?

G Giordano, R Tambaro, G Sticca, C Di Falco
Center „John Paul II„, Catholic University, Campobasso, Italy

Background. In Europe, more than 50% of the lymphomas arise in patients older than 65 years. Now R-CHOP regimen is the gold standard in treatment of aggressive lymphomas in this patient subset. Salvage stategies are needed for these patients who are not cured with first line therapy, since high dose chemotherapy frequently is not suitable. 2nd line therapy with DHAP produces scarce results. Aims. To evaluate safety, feasibility, efficacy of 2nd line treatment in patients older than 60 yo with combined chemotherapy with MICMA - IGEV. Methods. In two years we treated 20 patients with resistent diffuse large B cell lymphoma (DLBCL) with MICMA-IGEV alternating chemotherapy cycles (MICMA: methylprednisolone 500mg/mq gg1-5, mitoxantrone 10 mg/mq gg1, cytarabine 2 g/mq gg5, carboplatynum 100mg/mq gg1-4; IGEV: hyphosphamide 2 g/mq gg1-4; gemcytabine 800 mg/mq gg1 and 4). Chemotherapy cycles were administered every 21 days only if complete hematopoietic recovery was occurred. M/F was 12/8, median age was 72.5 years (R65-84). Results 15 patients (75%) received 4 chemotherapy cycles, 1 patient (5%) received 6 cycles, 4 patients (20%) received 2 cycles. Median cycles administered were 4 (R2-6). At 29 months all patients were dead. Median survival was 12 months. At 24 months survival was 17.6%. 6 patients (30%) showed comorbidities. All patients showed G3-G4 neutropenia, 6 (30%) G3-G4 thrombocytopenia, 2 (10%) G3 mucositis, 9 (45%) had fever. All patients received G-CSF support. Only 2 patients (10%) had G3 hepatotoxicity. 3 patients (15%) had kidney toxicity. No patients died for therapy-related toxicity. 5 patients required 25-33% chemotherapy dose reduction for organ toxicity. 8 patients (40%) delayed chemotherapy administration for G3-G4 neutropenia or thrombocytopenia. Summary/Conclusion. In literature patients of all age resistent/relapsed after 1st line chemotherapy and treated with 3 ESHAP or 2 DHAP cycles had a 5 years survival of 23%. Elderly patients with more of 60 years with relapsed/resistent DLBCL and treated with 2-4 cycles of DHAP showed a median survival of 9 months. Our patients treated with 4 MICMA/IGEV alternating cycles showed a median survival of 12 months (R1-29 months). 4 cycles of alternating MICMA/IGEV chemotherapy seems to be relatively safe, feasible and effective in patients with more of 65 yo, also with comordidities. These data need of confirmiation on a large coohort of patients.

1393

HELICOBATER PYLORI ERADICATION WITH SEQUENTIAL THERAPY IN GASTRIC B-CELL, LOW GRADE, MALT-LYMPHOMA PATIENTS: PRELIMINARY RESULTS

A Andriani,[1] A Zullo,[1] N Villivà,[1] C Hassan,[1] P Meddi,[2] A Tesi,[2]
S Felici,[1] R Lorenzetti,[1] ME Martini[3]
[1]*Nuovo Regina Margherita Hospital, Rome, Italy*
[2]*Azienda Ospedaliera S. Camillo-Forlanini, Rome, Italy*
[3]*Ospedale Santo Spirito, Rome, Italy*

Background. H. pylori eradication is recognized as first-line therapy in early stage, B-cell, low-grade, gastric MALT-lymphoma patients. However, cure rate following standard triple therapies for such an infection is decreasing worldwide. This study assessed the efficacy of a 10-day sequential for *H. pylori* eradication in these patients. *Methods*. All patients diagnosed with gastric lymphoma were considered. Patients underwent upper endoscopy with biopsies, echo-endoscopy of gastric mucosa, total-body CT, and bone marrow biopsy. Only those patients with *H. pylori*-associated, low-grade MALT-lymphoma in stage I-II1 were enrolled. Patients received a sequential therapy including omeprazole 20 mg plus amoxicillin 1 g for the firs 5 days followed by omeprazole 20 mg, clarithromycin 500 mg and tinidazole 500 mg for the remaining 5 days, all given twice daily. Both bacterial eradication and lymphoma remission was considered achieved when 2 consecutive histological examinations were negative. *Results*. Data of the first 10 patients (Male: 6; Mean age: 58? 10 years; Stage I: 10) currently enrolled were analyzed. Median follow-up was 12 months (range 8-22 months). H. pylori eradication was achieved in all 10 (100%) patients, whilst lymphoma remission occurred in 8 (80%) cases. One patient achieved lymphoma remission with radiotherapy following anti-CD20 monoclonal therapy failure, whilst the other patient is still in follow up (10 months following bacterial eradication). *Conclusions*. *H. pylori* eradication rate following standard triple therapy is decreasing. This is the first study showing a high efficacy of the 10-day sequential therapy for curing such an infection in MALT-lymphoma patients.

1394

STUDY OF THE PREVENTION OF HEART DISEASE USING BIOCHEMICAL MARKERS AND LIPOSOMAL ANTHRACYCLINE IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

G Gini,[1] M Catarini,[2] C Bocci,[1] M Offidani,[1] S Rupoli,[1] M Montanari,[1]
D Capelli,[1] A Scortechini,[1] A Poloni,[1] I Scortechini,[1]

[2]*Medicina Generale-Ospedale Civile Macerat, Macerata, Italy*
[3]*Divisione di Ematologia-Ospedale S. Carlo Potenza, Potenza, Italy*

Background. The toxicity of anthracyclines is a known limiting factor in the treatment of patients with lymphoma. The pre-existing heart disease limits its use, while in patients with known risk factors and in

patients with unknown riskscould induce the onset. In the period 2008-2010 were analyzed prospectively 40 patients with newly diagnosed non-Hodgkin lymphoma by a serial samples of pro-BNP and Troponin I, before each cycle of chemotherapy inclusive anthracycline, at day +1 by the execution, at the end of therapy and during the follow up at 3 and 12 months. Before therapy and at the end was assessed left ventricular ejection fraction by echocardiography. On the basis of risk factors have been identified two groups (see Table I). Patient's age or history of heart disease was classified as high risk and received the CHOP scheme with the replacement of doxorubicin with MYOCET (non-pegylated liposomal doxorubicin). While the second group performed the standard therapy with CHOP scheme. Both groups received a total of 6 cycles every 3 weeks. Results. 32 out of 40 patients achieved a complete remission, 7 patients a partial remission and only one has progressed. At 1 year, 31 patients are alive and well. The PRO-BNP increased during the cycles of therapy in 35 to 40 (see Table II) and troponin I is increased in 3 patients (all in the group treated with conventional CHOP). At 3 months and 1 year 2 out of 40 patients have pro-BNP increased while no one with increased troponin I. At 1 year after the treatment in the group treated with CHOP-MYOCETTM 7 patients showed an impairment (not life treathing) of cardiac disease, while in the group treated with conventional anthracyclines three patients developed a new severe heart disease. Conclusions. The PRO-BNP in our study did not show a prediction as it increases in almost all patients. Appeared the most promising Troponin I, although given the small sample size will require more study. The use of the anthracycline liposomal MYOCETTM confirmed its efficacy and tolerance without inducing new heart disease in a group of patients at high risk for heart disease and ancient age.

STUDY REGARDING THE ASSOCIATION BETWEEN MULTIPLE PRIMARY CANCERS THAT INCLUDES A MATURE B-CELL NEOPLASM AND THE METABOLIC SYNDROME

RG Mihaila,[1] R Dancu,[2] I Lisan,[2] L Bera,[1] A Catana,[2] O Flucus,[2] C Grandore,[2] L Popa[2]

[1]*Lucian Blaga University of Sibiu, Sibiu, Romania*

[2]*Emergency County Clinical Hospital, Sibiu, Romania*

Background. It is known that cancer patients have a 20% higher risk of new primary cancer compared with the general population. We have published studies showing that patients with non Hodgkin lymphoma have more frequently components of metabolic syndrome compared to subjects without cancer. Aim: We aimed to study the presence of metabolic syndrome components in patients with multiple primary cancers that include a mature B-cell neoplasm comparing with those with only a mature B-cell neoplasm. *Methods*. Of the 668 patients with hematological malignancies who were registered in the Department of Hematology of Hospital Emergency Sibiu, during January 2006 - January 2011, we had selected 424 people with mature B-cell neoplasms, and among them we had chosen all the 21 multiple primary cancers (group A), which we compared with a group of 62 consecutive patients with mature B-cell neoplasms which were in our evidence in January 2011 (group B). We made a comparative analysis of the components of metabolic syndrome and hypercholesterolemia in the two groups. The results were statistically analyzed. *Results*. The average age of patients in group A was 66.57+/-12.32 years, and those in group B - 65.87+/-9.98 years. The average time to onset of the 2nd cancer was 3.52+/-6.24 years. Among patients with mature B-cell neoplasms, 4.95% had multiple primary cancers: 6 - skin carcinoma, 2 - lung cancer, 2 - malignant melanoma and one - gastric cancer, colon, rectum, kidney, breast, ovarian, metastatic with unspecified starting point, acute myeloid leukemia, acute promyelocytic leukemia, myelodysplastic syndrome, chronic myeloid leukemia and polycythemia vera. One patient had triple neoplasia. Patients in group B were more frequently obese (71.43% vs. 57.14%) and had hypertriglyceridemia (40.32% vs. 38.10%), while those in group A had more frequently high blood pressure (57.16% vs. 41.94%) and diabetes mellitus (33.33% vs. 20.97%). The average of metabolic syndrome components was higher in group A patients compared with those of B (1.86+/-1.24 to 1.61+/-1.11). The presence of two cancers predisposes to accelerate catabolic processes, which may explain the reduction in obesity and hypertriglyceridemia. In this group, which is more exposed to stress and various therapies, including corticosteroids, are more frequent high blood pressure and diabetes mellitus, and hypercholesterolemia (41.94% vs. 33.33%). The differences were not statistically significant. Only ischemic cardiopathy is more common in group A patients (p=0.025). *Conclusions*. A significant proportion of patients with mature B-cell neoplasia still has one or two neoplasms. While patients who have only mature B-cell neoplasia frequently suffer from obesity and hypertriglyceridemia, others with multiple primary cancers, including mature B-cell neoplasms, have high blood pressure, diabetes and more components of metabolic syndrome more frequently compared to the first. Studies on large groups of patients are needed so that results can have statistical significance.

1396

SINGLE CENTER EXPERIENCE WITH THE INTENSIVE PROGRAM PTL11-08 IN PRIMARY TESTICULAR DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL)

A Lukina, E Zvonkov, T Perestoronina, A Kremenetskaya, S Kravchenko, A Gubkin, A Morozova, E Nesterova, A Vorobjev

Hematology Scientific Center, Moscow, Russian Federation

Background. Primary testicular lymphomas (PTL) are rare aggressive, mostly B-cell extra nodal lymphomas with DLBCL comprising more than 90% of cases. Frequent central nervous system involvement predominantly in relapsed patients and continuous pattern of relapses are associated with poorer prognosis. CHOP-rituximab treatment with scrotal irradiation and CNS prophylaxis is the standard of care however resulting in poor response. *Aims*. To evaluate the toxicity and efficacy of intensive multidrug regimen (PTL11-08) in untreated patients with primary testicular DLBCL. Patients and Methods: From Aug 2008 six patients with primary testicular DLBCL aged 52-63 with Ann-Arbor stages IIE (2 pts) and IVE (4 pts) were evaluated and treated with intensive program PTL11-08. All three orchidectomised patients showed disease progression in 2-3 months after surgical treatment. All lymphomas immunophenotype had the activated B-cell-like subtypes (CD10-, bcl6, MUM1+). The treatment plan consisted of 2 alternating cycles: 1 (iv. methotrexate 1000 mg/m2 on day 1, vincristine 2 mg on day 1, ifosfamide 800 mg/m2 on days 1-5, etoposide 50 mg/m2 on days 4-5, cytarabine 150 mg/m2 on days 4-5 b.i.d., idarubicin 20 mg/m2 on day 3, temozolomide 150 mg/m2 on days 1-5, dexamethasone 20 mg on days 1-5) and 2 (procarbazine (orally) 35mg/m2 on days 1-14, iv. fotemustine 100 mg/m2 on day 1, cisplatin 100mg/m2 on day 2, temozolomide 150 mg/m2 on days 1-5) for 4 cycles with CNS prophylaxis (intrathecal dexamethasone 4mg + methotrexate 15mg + cytarabine 30mg) and colony-stimulating factor until recovery. The rational for this drug combination was the ability to penetrate the blood-brain barrier and blood-testicular barrier possibly. *Results*. Severe hematological toxicity (III-IV) was associated/ with the cycles 1 in all patients. Cycles 2 were associated with non-hematologic toxicities grade 1/2. All 6 patients fulfilled the treatment plan with complete response and after a median follow-up of 14 month (4-24 months) are alive and relapse-free. *Conclusions*. The program PTL11-08 for treatment testicular DLBCL is toxic but safe and effective. Future research is needed to increase the number of patients and period of observation.

1397

T CELL/HISTIOCYTE RICH LARGE B-CELL LYMPHOMA (THRLBCL): CLINICAL CHARACTERISTICS, PROGNOSIS AND MANAGEMENT: A REPORT ON 17 PATIENTS

A Vidovic,[1] J Gligoric,[2] I Djunic,[2] D Tomin,[1] M Perunicic-Jovanovic,[2] V Djurasinovic,[2] M Virijevic,[2] B Mihaljevic[1]

[1]*Clinical for Hematology, Clinical Center of Srerbia, Shool of Medicine, Belgrade, Serbia*

[2]*Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia*

Background. T cell/histiocyte rich large B- cell lymphoma (THRLBCL) is a rare subtype of diffuse B cell non Hodgkin lymphomas. Because of a considerable similarity to nodular lymphocyte predominating Hodgkin's lymphoma (NLPHL) and classic Hodgkin's lymphoma (cHL), an accurate diagnosis is based on exhaustive immunohistochemical and molecular genetic analyses. *Aims*. To analyze the laboratory and histology in patients (pts) with THRLBCL with selected aspects of the course and survival in relation to different choices of therapy. Patients and *Methods*. Seventeen pts were studied (m/f =11/6, median age 41 years, range 28-72). Comprehensive immunocytochemistry and imaging methods were used to reach the diagnosis and stage of THRLBCL. The B symptoms were present in 94% of pts, peripheral lymphadenopathy in 82%, splenomegaly in 70%, and hepatomegaly in 82%. Mediastinal and abdominal lymphadenopathy were evidenced in 65% and 82% of pts, respectively. Most pts (65%) had a nodular type of disease. Primary extranodal disease was diagnosed in 23.5% of pts. Increased serum levels of LDH and β2-microglobulin were used as single proliferative measures of disease. Anemia, thrombocytopenia, and leukocytopenia were present in 58.8%, 53%, and 18% of pts, respectively. Most pts were in a IVB stage of disease with a high average IPI score. The R-CHOP protocol was applied in eleven pts. Six patients were treated with CHOP, COD, ESHAP, R-EPOCH, ProMACE CytaBOM and DHAP protocols each. Complete remission was achieved in 11.8% of pts and partial remission in 64.7%. In 23.5% of pts disease progressed despite the chemotherapy. In the collective median survival was 36 months. *Conclusions*. The THRLBCL is an aggressive lymphoma and the comparison of pts with this disease and those with diffuse large B cell lymphoma reveals no significant difference in survival.

1398

PROGNOSTIC FACTORS IN THE TREATMENT OF PRIMARY EXTRANODAL DIFFUSE LARGE B-CELL LYMPHOMA WITH RITUXIMAB BASED IMMUNOCHEMOTHERAPY

L Popovic,[1] D Jovanovic,[1] D Petrovic,[1] A Sundji,[2] N Petrovic,[2] T Roganovic,[1] B Kukic[1]

[1]*Oncology Institute of Vojvodina, Sremska Kamenica, Serbia*

[2]*Faculty of Medicine, Novi Sad, Serbia*

Background. Primary extranodal lymphoma (ENL) constitute 25-50% of all non-Hodgkin lymphomas. About half of extranodal lymphoma are diffuse large-B-cell lymphoma subtype. The most common extranodal DLBCL localizations are stomach, central nervous system (CNS) and testis. Aims: The aim of this study was to determine the clinical and laboratory differences between patients with nodal (NL) and ENL DLBCL at the time of diagnosis, and the effect of clinical and laboratory parameters on overall and progression free survival (OS, PFS) in patients with extranodal lymphomas. Material and methods: The study included 95 patients with CD20 positive diffuse large-B-cell lymphoma treated at the Oncology Institute of Vojvodina between 2003. and 2010. Thirty seven (39%) of these patients had primary extranodal, and 58 (61%) had nodal localization. 16 of 37 ENL patients were presented with primary gastric, 3 with breast, testis, skin and lung, 2 with ovarium, thyroid gland, bone, soft tissue and one patient with parotid gland, colon, maxillary sinus and epipharynx localization. Three patients were presented with two extranodal sites and one patient with CNS lymphoma was excluded due to different treatment strategy. All patients received combination of rituximab and CHOP or CHOP-like protocols, without CNS prophylaxis. The study was divided into two phases. In the first phase, we have observed differences in clinical and laboratory parameters between primary nodal and extranodal diffuse large B cell lymphoma. In the second phase, patients with ENL were selected and we compared their OS and PFS depending on different disease stages, presence of B symptoms, prognostic scores (IPI, R-IPI), age, sex, and laboratory parameters: the level of lactate dehydrogenase (LDH), the absolute lymphocyte count, hemoglobin and albumin level. *Results*. The overall response (ORR) to therapy in all patients was 86.3% (CR 72.6%, PR 13.7%), while 13.7% had disease progression. Three-year overall survival was 64,3 %. ENL are more often diagnosed in stages I/II (67% vs 26%, p = 0.0094) and more likely to have low risk IPI score (54% vs 22%, p = 0.044). Despite of the favorable prognostic parameters, we neither found any difference in the number of patients who achieved complete remission with ENL and NL (75.6% vs 70.7%, p = NS) nor the difference in three-year overall survival (62,3% vs 67,7% P=NS). ENL patients with IPI score ≤ 2 had better OS and PFS (p = 0.0167; p=0,026). Patients younger than 60 years had better OS but not PFS (p = 0.0239; p=0,26). Patients who achieved complete remission had much better three year overall survival (84% vs 14%, p <0.0001). We found no statistically significant differences in OS or PFS in patients with ENL depending on the stage of the disease, the occurrence of B symptoms, R-IPI score, gender and laboratory parameters. *Conclusions*. The outcome of primary extranodal lymphoma is affected by IPI score, age and response to therapy. The results of ENL treatment with rituximab based immunochemotherapy are no different from the results of NL treatment with the same protocol.

1399

CLINICAL FEATURES AND OUTCOMES OF NASAL NK/T-CELL LYMPHOMA

S Bougherira

Hospital University, Annaba, Algeria

Background.Nasal natural killer (NK)/T-cell lymphoma is a unique type of non-Hodgkin lymphoma (NHL) that is almost always strongly associated with Epstein-Barr virus (EBV). The disease predominantly localizes to the upper aerodigestive tract, most commonly in the nose. It shows a strong association with EBV. Unfortunately diagnosis of NK/T-cell lymphomas often proves difficult, the treatment is unsatisfactory and its prognosis is poor with 5 years overall survival of 30 45%. The aim of this study was to investigate the frequency and clinicopathologic features of nasopharyngeal extra nodal NK/T-cell lymphoma, and evaluate the outcome of this disease. Patients and methods: Between 2003 and 2009, 08 new cases of nasal NK/T-cell lymphoma were diagnosed in our institution. The diagnosis is essentially based on the clinical presentation of extra nodal ulcerative lesions in the upper aero-digestive tract and histopathology analysis of biopsies using immunohistochemistry. Results. The median age was 46 years (ranges 19-77); male/female ratio was 4/4. The clinical features are: pain, obstruction, foul smell, discharge, and bleeding. Primary nasal lesions were ulcerative and are locally invasive and necrotic. This aggressive lymphoma remains localized in the nasal primary site in most cases. Systemic dissemination (stage IV) occurs in one patient (skin, testis) The histological findings showed angiocentric, necrosis, and pleomorphic infiltration. The immunophenotypes were: CD3+, CD56+, and CD45+ in all patients. The Ann Arbor stage was IE, IIE in 7 cases, and IVE in one patient. The patients were classified as having low IPI scores, and only two of them had bulky disease. Treatment modalities were given as follows: chemotherapy alone for 5 pts, chemotherapy with involved radiation therapy for 2 with a median dosage of 40 Gy. The chemotherapy regimens included CHOP (Cyclophosphamide, Doxorubicin, Vincristin, and Prednisone) for 3 pts on first line, but they were relapsed and received an L-Asparaginase based salvage regimen (L-asparaginase, velbe, and dexamethasone). Five patients (62%) were responsive to the treatment: Three patients achieved complete response; two of them obtained partial remission. The overall response rate (CR+PR) was 62, 5%. The 5-year overall survival rate was 37%. Conclusion. The nasal, nasal-type T/NK-cell lymphoma is a rare and distinct clinico-pathological entity. The Results of this clinical study indicated that the L-asparaginase-based regimen significantly improved the response rate. But the overall outcome in nasal NK/T cell lymphoma is poor.

1400

DETECTION OF RELAPSE IN PATIENTS POST TREATMENT WITH DIFFUSE LARGE B CELL LYMPHOMA.- THE ROLE OF BLOOD TESTS

N Shah, S Rule

Derriford Hospital, PLymouth, UK

Introduction. Blood testing in routine outpatient follow up of patients who have had successful treatment for Diffuse Large B Cell Lymphoma (DLBCL) is not helpful to predict or confirm relapse. There has been no conclusive evidence suggesting that blood tests help with predicting or diagnosing relapse of DLBCL. Despite poor evidence it has become routine practise in clinics. Aims. This study was done to provide evidence on whether blood tests are useful in the outpatient follow up clinics. *Methods*. A Retrospective study was undertaken to investigate all

patients with a diagnosis of DLBCL, treated at The Haematology Department in Plymouth University Hospital, Derriford, from 2005 to 2009. We selected patients with DLBCL who completed their chemotherapy and were in good partial remission or complete remission. Information was obtained from medical notes, X-ray PACS system and hospital laboratory results system. We looked at the all the full blood counts and clinical outcomes in the outpatients clinics. *Results*. Total number of patients: - 62 patients. Median age of diagnosis = 67yrs. 38/62(61%) had lymphadenopathy on presentation, 5/62(8%) had thyroid involvement, 8/62(13%) had GI symptoms, 5/62(8%) had bone involvement and 6/62(9%) had other involvement which included skin and parotid node. 5/62(8%) of the patients in the study showed partial response after chemotherapy and 57/62(92%) showed complete remission or very good partial response after standard chemotherapy. Median follow up period was 25 months (range 3months -60months) Median number of OPD clinic per patient was 6(range 1-22 clinics) in the study period. Median number of OPD blood tests done per patient in the study period was 6 (range 1-22 blood tests). 76/400(19%) of the full blood count were abnormal. Of the abnormal blood tests- 74/76(97%) of the FBC showed chronic anaemia, 1/74(1%) showed thrombocytopenia and 1/74(1%) showed CLL. 8/62(13%) of the patients relapsed in the study period. None of the patient who relapsed had any change in their blood counts to indicate or aid to diagnose relapse. All patients who relapsed presented with symptoms: lymphadenopathy 6/8 (62%), 1/8(12%) had stridor and 1/8(12%) had CNS symptoms at relapse. Conclusions. This observational study shows that blood tests do not help in predicting or diagnosing relapse in patients following successful therapy. Majority of the abnormality seen on blood counts were due to other unrelated medical conditions. All relapses were diagnosed in patients presenting with a specific symptoms and/or signs. Following this study, it was noted that, patients found reassurance if their blood counts were normal, however once patients were educated on the blood tests being uninformative with regards to their follow up, their *safety blanket* association with blood tests was significantly reduced. Therefore, in an Out -Patient Department, rationalisation of blood tests can be done economically and without having an adverse outcome on patient care. In the current economical climate this could produce beneficial savings for the department without compromising patient care.

1401

IMPROVEMENT OF PRURITUS IN SEZARY SYNDROME: LITERATURE REVIEW AND CASE REPORT

G Giglio,[1] G Giglio,[2] G Antuzzi,[3] F Carrozza,[3] M Musacchio,[3] A Silvestri,[3] A Antrilli[4]

[1]*O.C. „A. Cardarelli„, Campobasso, Italy*

[2]*Hematology Unit - O.C. „A.Cardarelli„ - ASREM, Campobasso, Italy*

[3]*Oncology Unit, O.C. „A.Cardarelli„ - ASREM, Campobasso, Italy*

[4]*Dermatology Unit, „A.Cardarelli„, ASREM, Campobasso, Italy*

Introdution. Pruritus (itch) can be defined as an unpleasant cutaneous sensation associated with the immediate desire to scratch and is an important symptom of cutaneous T-cell lymphomas (CTCL); it's frequent and severe and its pathophysiology remains unclear. Treatment is very difficult, especially in Sézary syndrome. The Sézary syndrome is a leukemic, cutaneous, epidermotropic T-cell lymphoma and is more aggressive form of CTCL, characterized by the association of an exfoliative erythroderma with the presence of atypical mononuclear cells in the skin and the peripheral blood (Sezary cells). Pruritus, insomnia, and depression impair the quality of life of patients with sezary syndrome. Pruritus originates within the cutaneous skin's free nerve endings. Activation of specific areas in the central nervous system results in perception of itch, leading to a scratch response. By a direct axon reflex mechanism, sensory nerve endings release neuropeptides, which may aggravate the itch response by stimulating release of pruritic mediators (kinins, prostanoids, and cytokines) from mast cells, immune cells epithelial cells and endothelial cells. Substance P is a key mediator of pruritus. An increase in the expression of its receptor, neurokinin-1, has been reported on keratinocytes in pruritic skin diseases. Aprepitant is an oral neurokinin-1-receptor antagonist. It is commonly used as an antiemetic agent in chemotherapy-induced nausea and vomiting. However, its action suggests a potential reduction in substance P-induced pruritus, even though pruritus is considered a rare side effect of this drug. Case report: After learning from an article in the N. Engl. J. Med (october 1, 2009) we have treated a patient with Sezary syndrome with aprepitant, obtaining the total resolution of itch. Our patient. 75 years old, accused incoercible itch and erythroderma, lymphadenopathy and splenomegaly. He was treated at beginning with topical therapy, extracorporeal photochemotherapy and for progression, with bexarotene and after with chemotherapy. The patient achieved a complete remission of the disease; maintenance therapy with alemtuzumab was performed. The itch was present during the first 3 cycles of chemotherapy and only after to introduction of aprepitant there was attenuation and then a disappeared of pruritus. The patient reported diminished insomnia and better quality of sleep. Discussion: The options of treatments for pruritus in CTCL are topical agents, extracorporeal photochemotherapy (option that reduce both disease activity and pruritus) and systemic agents (gabapentin, mirtazapine, rosiglitazone and bexarotene). A dramatic improvement was noted by A.Duval and L.Dubertret of Saint Louis Hospital of Paris in three patients with Sézary syndrome suffering from severe and uncontrolled pruritus after treatment with aprepitant, which is an antagonist of natural killer (NK) 1 receptor for substance P. *Conclusions*. In patients with CTCL, pruritus is frequent and often severe. This symptom negatively affects quality of life of patients. First-line treatment recommendation should be topical steroids or phototherapy, sometimes in combination with disease-modifying treatment, such as interferon or retinoids. In case of insufficient response, anticonvulsivants or antidepressants can be used. A possible alternative is provided by NK1 antagonists, aprepitant. Our experience confirms the effectiveness of apepritant against pruritus associated with Sezary syndrome.

[5]*Department of Medicine, Service d'Hématologie, Institut Gustave Roussy, Villejuif, France*

[6]*Department of Bio-Pathology, Institut de Cancérologie Gustave Roussy, Villejuif, France*

Background. 18F-FDG PET has demonstrated its utility for assessing treatment efficacy in patients with diffuse large B-cell lymphoma (DLBCL). However, there is no consensus on the significance of 18F-FDG-avid mediastinal residual masses after initial chemotherapy. *Aims*. To surgically restage patients with DLBCL of the mediastinum who have PET-positive residual lesions after an intensified immunochemotherapy regimen, in an attempt to avoid complementary radiotherapy or second-line treatment for patients without evidence of viable lymphoma. Methods. We retrospectively studied patients with DLBCL of the mediastinum, treated between 02/2007 and 12/2010, and who underwent surgical restaging because of a persistent positive PET scan. 18F-FDG PET was assessed semi-quantitatively using maximum standardized uptake value (SUVmax). Patients were planned to receive 4 cycles of the R-ACVBP regimen (rituximab, doxorubicin, cyclophosphamide, vindesine, bleomycin and prednisone) given at two-week intervals, followed by a sequential consolidation comprising 2 cycles of high-dose methotrexate, 4 cycles of rituximab, etoposide and ifosfamide, and 2 cycles of cytarabine given subcutaneously. Restaging with CT scan and 18F-FDG PET occurred after the 4th course of R-ACVBP in 3 pts, the 1st course of methotrexate in 2 pts and the 2d course of methotrexate in 2 pts. Results Seven patients were identified. The median age was 27 years (range : 25-39). 5 pts had stage I/II, and 2 pts had stage IV disease (lung 1 pt, pleura and pericardium 1 pt). The age-adjusted IPI was 0 or 1 in 6 pts. Diagnosis was DLBCL in 6 pts and primary mediastinal (thymic) B-cell lymphoma in 1 pt. Four pts had 18F-FDG PET before treatment. The result of CT scan at restaging was partial response in 5 pts, and complete response unconfirmed in 2 pts. The SUVmax in the most intense tumor at restaging ranged from 3,1 to 6,3. For the 4 patients who had PET at baseline, the SUVmax in most intense tumor were comprised between 22 and 24, and the reduction in SUVmax between 62% and 87%. Surgical restaging was performed by median sternotomy (5 pts), mini-thoracotomy (1 pt) and cervicotomy (1 pt). Complete resection of the residual mediastinal masses was achieved in 5 pts. The histological findings were necrosis, fibrosis and/or inflammation in 6 pts. The 7th patient had mediastinal lymph nodes showing traces of silicosis. No patient had viable residual lymphoma cell. All the patients received a sequential con-

solidation chemotherapy as initially planned, without consolidative radiation therapy. At a median follow-up of 14 months (range : 4-40), all patients are alive without disease progression. One patient presented respiratory failure due to pleural effusion after surgery, and had to undergo non-invasive ventilation for 4 days. Summary/Conclusions. In patients with DLBCL of the mediastinum, surgical restaging of 18F-FDG-avid residual mediastinal masses after initial chemotherapy, although not routinely recommended, demonstrated in a small series that tumor necrosis remains metabolically active. Restaging PET should be interpreted with caution to make treatment decisions, and the results of large prospective trials evaluating PET-guided treatment in DLBCL are eagerly waited.

1403

BENDAMUSTINE AND RITUXIMAB IN RELAPSED OR REFRACTORY LOW-GRADE LYMPHOMAS

A Araceli, B Jose Guillermo, A Juan Jose
Hospital de Cruces, Barakaldo, Spain

Background: Bendamustine is a hybrid of a purine analoge and an alkylating agent, with activity against low-grade lymphomas in combination with rituximab (BR) and a good toxicity profile. Bendamustine has recently become available in clinical practice and experience is limited. Aims: Herein we present our experience on treating relapsed or refractory low- grade lymphomas and mantle cell lymphomas with the combination of bendamustine and rituximab (BR). Patients and methods: Retrospective and observational study of all consecutive patients with relapsed or refractory low-grade lymphoma or mantle cell lymphoma treated with BR since April 24, 2008 to January 31, 2011. Modified Cheson criteria (2007) were used to assess response. Adverse effects were classified using the WHO toxicity criteria. Bendamustine (90mg/m2 daily) was administered the first and second days of each cycle. Rituximab (375mg/m^2) was administered a week before the first cycle, the first day of every cycle and four weeks after the last one. Cycles were administered every four weeks to a maximum of six. Patients were evaluable for response if they have received at least two cycles of BR. Statistical methods: Descriptive statistics and Kaplan-Meier survival analysis. *Results*. Thirteen patients, 6 woman and 7 men, were included. Mean age was 67,3 years and median age 70 years, range 45 to 82. Diagnosis was follicular lymphoma (FL) in six patients, mantle cell lymphoma (MCL) in three, small cell lymphocytic lymphoma (SCLL) in three and MALT lymphoma of the oral mucosa (relapsed in skin and conjunctiva) in one. Mean time from diagnosis was 5,4 years (2,6-10,5). Mean previous therapies was three (1-5), and two patients (one FL and one MCL) had undergone an autologous bone marrow transplantation. Seven patients received six cycles of BR, four patients 4 cycles and one patient 3 cycles. One patient received only two cycles, and the treatment was early terminated because of hepatitis C reactivation. Complete response (CR) was achieved in ten patients (76%) and partial response in one (7,5%). Two patients (15%) showed no response. Two patients with CR have relapsed (a SCLL and a MCL) at 19 and 21 months respectively, while the remaining eight maintain a CR. The median time to treatment failure was 19 months and the median survival was 21 months, with a median observation of surviving patients of 13 months. Adverse events were grade 3 or grade 4 neutropenia in seven patients (53%) and grade 3 thrombocytopenia in two (15%). An episode of febrile neutropenia and another of coagulase negative staphylococcus bacteriemia associated with indwelling catheter were reported. There was a transient hepatitis C reactivation with remission after BR termination. Five patients reported nausea and vomiting and two asthenia, both in grade 1 or 2. *Conclusions*. Treatment with BR was effective in a high percentage of our patients with relapsed or refractory low-grade lymphoma. Of note, tolerability and safety were good in elderly patients and responses were durable. More experience is needed to confirm the good profile of the combination in the long term.

1404

FEASIBILITY OF HIGH-DOSE METHOTREXATE, TEMOZOLOMIDE AND INTRATHECAL LIPOSOMAL CYTARABINE (HD-MTX-TMZ-IT LC) FOR THE TREATMENT OF CENTRAL NERVOUS SYSTEM (CNS) LYMPHOMA

L Falchi, M Gunnellini, I Angeletti, L Ferranti, AM Liberati
Oncohematology, Terni, Italy

Background. CNS lymphoma is an aggressive tumor. Combined systemic chemotherapy-radiotherapy may be associated with acute/delayed neurotoxicity. HD-MTX-TMZ appears to be an effective and relatively safe regimen. Adding IT LC may further improve therapeutic efficacy. *Aims*. We report our preliminary experience with HD-MTX-TMZ plus IT LC used upfront or as salvage in 4 CNS lymphoma patients. Methods: Induction: MTX 3g/ms IV d 1, 10, 20, TMZ 100 mg/ms d 1-5; maintenance (≥SD pts): MTX 3g/ms d 1, TMZ 100 mg/ms d 1-5, every month, for up to 5 cycles as long as response was documented. Fifty mg IT LC was given concomitantly, at least 14 days apart and at least 7 days from HD-MTX, up to 6 doses. Results: Pt 1, 56 y, male, testicular diffuse large B cell lymphoma (DLBCL), stage IVA, cerebellar relapse after CR, Karnofsky performance status (KPS) 50%. Rituximab-TMZ and IT MTX were initiated but soon discontinued due to CMV pneumonia. After recovery, HD-MTX-TMZ was started with precautionary stem cell harvest. Six cycles and 4 concomitant IT LC injections were given with no G3-4 toxicities. He obtained CRu. Pt 2, 76 y, male, primary CNS peripheral T-cell lymphoma not otherwise specified, multicentric, KPS 60%. He was treated with steroids and TMZ, but progressed in three months. He receive the complete HD-MTX-TMZ program with 4 IT LC injections. He experienced G2 renal insufficiency, managed with adequate pre-treatment hydration and reversed after the end of therapy, and reversible G3 iatrogenic diabetes mellitus due to pre-induction dexamethasone. He obtained CRu. Seven months later he relapsed in involved sites, received two further cycles of TMZ and is now in SD. Pt 3, 68 y, female, PCNSL, DLBCL, left cerebellar hemisphere, KPS 50%. HD-MTX-TMZ and concomitant IT LC were initiated as first-line therapy. She experienced G3 atrial fibrillation, resolved with appropriate treatment and never reappeared afterwards. Maintenance was completed. However, after the 5th IT LC injection the patient presented with leg pain and difficulty walking, saddle hypoesthesia, urinary and fecal retention, suggesting conus-cauda equina syndrome. IT therapy was thus withdrawn. Neurologic symptoms subsequently improved with physiotherapy and pregabalin, and stool softeners. She obtained very good PR after induction. She currently complains of residual perineal heaviness and mild difficulty waking, and is able to perform controlled micturition and defecation. Pt 4, 71 y, female, DLBCL stage IIIE (i.e. subcutaneous facial localization), with multicentric bilateral subcortical relapse. Five HD-MTX-TMZ cycles and 6 IT LC injections have been administered so far with no neurotoxicity. CR was attained after induction and sustained thus far. *Conclusions*. HD-MTX-TMZ-IT LC therapy appeared feasible and effective, even in elderly pts. CR/CRu was attained in 3/4 pts, with a response duration of 19+, 7, 11+, and 6+ months in pts 1, 2, 3 and 4, respectively. IT LC is associated with a number of neurologic complications, including Conus-Cauda equina syndrome. However it appears to be in part related to the lumbar puncture procedure itself and not a LC-specific side effect. No delayed neurocognitive impairment has been observed so far.

1405

THERAPEUTIC COMPARISONS OF SURGICAL RESECTION PLUS R-CHOP AND R-CHOP ALONE FOR PRIMARY INTESTINAL DIFFUSE LARGE B CELL LYMPHOMA

YS Kim
Kosin University Gospel Hospital, Busan, South-Korea

Background. Gastrointestinal tract (GIT) is the most commonly involved extranodal site of all non-Hodgkin's lymphoma (NHL). GIT involvement is represented 10-15% of all NHL cases and 30-40% of all extranodal sites. In the Rituximab era, the addition of rituximab led to an impressive improvement of response rates and survival outcomes in patients diffuse large B-cell lymphoma (DLBCL), Aims: In this retrospective studies, the purpose is finding appropriate treatment strategy according to comparing the efficacy of treatment in patients with primary intestinal diffuse large B cell lymphoma (DLBL) undergoing surgery followed Rituximab-containing chemotherapy or Rituximab- containing chemotherapy alone. *Methods*. Forty four patients were newly diagnosed with DLBL and received chemotherapy between March 2004 and December 2009. Primary intestinal lymphoma which had predominant intestinal lesions was diagnosed by specialized hemato-oncologist. All patients were treated with rituximab combined cyclophosphamide, adriamycin, vincristine, and prednisolone (R-CHOP). Patients were divided into two groups. One included patients who were undertaken surgery plus R-CHOP (surgery/CT group). The other included patients who were undertaken R-CHOP alone (CT group). Results : The characteristics of the patients were as follows: the median age was 58.5 years (range 15-85 years) with a female-to-male ratio of 25:19. Patients characteristics had no significant difference between two groups. The estimated 3 years event free survival rates (EFS) and overall survival rates (OS) of surgery/CT and CT group were 79.3% and 40.8%, (p=0.311) and 84.0% and 43.3%, (p=0.301) respectively. In univariate analysis, EFS and OS

were estimated in Lugano stage I, II1, II2, IIE and IV (p=0.079 and p=0.018), Low, Low-intermediate, high-intermediate and high risk (p=0.068 and p=0.019), LDH < 450 IU/L and ≥ 450 IU/L (p=0.027 and 0.140), and surgery/CT and CT alone, (p=0.311 and p=0.301), respectively. In multivariate analysis, there was no independent predictive factors for survival. Conclusions. atients treated with surgery followed R-CHOP were seemed to have higher survival rate than R-CHOP alone although there was no significant differences for survival rate. There was no significant prognostic factors for survival, but Lugano stage, IPI risk, LDH, and treatment modality could be possible prognostic factors for event free survival.

POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDERS IN LIVER AND KIDNEY RECIPIENTS: A SINGLE INSTITUTION EXPERIENCE

A Ferrario, D Vincenti, F Rossi, N Orofino, B Olivero, M Goldaniga, L Cro, L Baldini

Fondazione IRCCS Ca' Granda, Osp. Maggiore Policlinico, Università degli Studi, Milano, Italy

Background. Post-transplant lymphoproliferative disorders (PTLD) represent a heterogenous group of disease ranging from reactive polyclonal hyperplasia to aggressive non-Hodgkin lymphomas (NHL) and in the majority of cases they are associated with Epstein-Barr virus (EBV). PTLD develop as a consequence of the severe impairment of T cell function and the related reduction of T cell control on EBV latently infected B cell due to immusoppressive therapy after solid organ (SOT) or hematopoietic stem cell transplantation (HSCT). *Aims*. We analyzed the clinical features, treatment and outcome of a series of adult patients who developed NHL after liver and kidney transplantation. *Methods.* We retrospectively studied the clinical data of 16 patients that developed NHL occurred at our institution between 1998 and 2010. *Results.* 16 patients (M/F ratio 2.2) with a median age of 42 years (range 20-59) developed NHL after liver, 3 cases, and kidney, 13 cases, respectively. Previous liver diseases were: hepatitis C virus cirrhosis in two cases and primary sclerosing cholangitis in one case; previous kidney diseases were: glomerulonephritis in 10 cases and congenital syndrome in three cases. Median time from transplantation to PTLD was 111.5 (range 3-360) months. Six patients experienced acute transplant rejection that required intensification of immunosuppressive therapy. Hematologic diagnosis included 12 monomorphic PTLD (10 diffuse large B lymphoma, 1 peripheral T cell lymphoma, 1 anaplastic large cell lymphoma), 2 classical Hodgkin lymphoma-type PTLD, 1 lymphoplasmacytic lymphoma and 1 extranodal marginal zone lymphoma. Histologic diagnosis was made on lymph node and on extranodal tissue in seven and nine cases, respectively. Available histologic analysis of tumor tissue demonstrated that EBV was positive in 62% of cases. CD20 expression was available in all but two patients and was positive in 71% of cases. At diagnosis seven patients were in stage IV, two in stage III, one in stage II and 6 in stage I; median IPI and Mayo prognostic score were 2 and 1, respectively. Ten patients presented with extranodal disease; central nervous system (CNS) involvement was not observed. Eleven patients received immuno-chemotherapy (including anthracyclines) with rituximab and two only chemotherapy; among them only four patients required reduction of doses because of liver/renal toxicity, and one patient experienced infective toxicity (WHO grade 1-2). One patient was treated with only radiotherapy and two patients were observed because of indolent disease. After a median follow up of 51 months (range 1-128) from the end of therapy, 13 patients are alive and in complete remission, two are lost to follow up and one patient died for progressive disease.CONCLUSIONS: Although the limited number of patients involved, and the peculiar subset of renal and liver allograft in which the risk of PTLD is low-intemediate, our study demonstrated that the majority of our patients developed aggressive NHL and an immuno-chemoterapic regimen is feasible, well tolerated and allow to obtain an elevated percentage of remission.

1407

CLINICO-EVOLUTIVE ASPECTS AT 73 PATIENTS DIAGNOSED WITH HAIRY CELL LEUKEMIA ADMITTED IN FUNDENI CLINIC OF HEMATOLOGY BETWEEN 2000-2008

I Ursuleac, C Dobrea, V Moraru, O Georgescu, A Colita, A Dumitrescu, M Vasilica

Fundeni Clinical Institute, Bucharest, Romania

Background. Hairy cell leukemia(HCL) is an indolent B cell lymphoproliferative disorder that affect middle aged males; the main symptoms at diagnosis are : fatigue, splenomegaly, pancytopenia, hemorrhagic syndrome, infections. The morphological marker of the disease in hairy cell, an activated memory B cell with characteristic immunophenotype (panB$^+$, CD5$^-$, CD23$^-$, CD25$^+$, CD11c$^+$, CD103$^+$, CD123$^+$). The new methods of diagnosis (flowcytometry, immunohistochemistry) allow the diferrential diagnosis between classical an variant form, and/or another lymphomas(eg. Splenic marginal zone lymphoma, with villous cells). The response to the treatment with interferon and/or purine analogues is very good, with long term remissions. *Aims*. To compare data obtained with data from other studies. *Material and method*: clinical and epidemiological retrospective study of 73 patients diagnosed in Fundeni clinic of Hematology between 2000-2008. *Results* : 62 patients were diagnosed with classical form, 11 with variant form of HCL; most of the patients were males, with a medium age of 57,1 years; the main features at diagnosis were: splenomegaly(>12 cm diameter at abdominal ultrasound)-55cases; infections(24 cases), cytopenias(mono, bi or pancytopenia) -all of the73 patients, hemorrhagic syndrome- 15 cases; 11 cases had autoimmune manifestations. The treatment methods were: alfa interferon- 44 cases, Cladribine- 12 cases, combined secvential therapy with alfa interferon and Cladribine- 8 cases, splenectomy - 8 cases, alkilants agents - 5 cases. The response to the treatment was evaluated at 57 patients: 19 partial responses, 34 complete responses, 4 without response. 7 patients died, 3 because of severe toxico-septic shock. The complications in evolution were: infections(21 cases), hemorrhagic syndrome (2 cases), cardiovascular disease(2 patients); 2 patients achieved a second malignancy. Conclusion : HCL is an indolent lymphoproliferative disease, with well established diagnostic features (clinical, morphological, immunological), good response to the treatment, long remissions, but high incidence of infections, that appear at diagnosis or whenever through the evolution.

1408

DICHOTOMOUS MODEL TO EVALUATE TREATMENT OUTCOMES IN NON-HODGKIN'S LYMPHOMA PATIENTS

A Novik, T Ionova, S Salek

European PRO Task Force, Cardiff, UK

Efficacy of treatment of malignant lymphomas is traditionally based on objective clinical data. At present patient-reported outcomes are of increasing importance to evaluate treatment outcomes in this patient population. Recently, the dichotomous model to evaluate treatment outcomes in patients with hematological malignancies was proposed by the experts of the EHA SWG "Quality of Life and Symptoms". We aimed to test this model on new population of Non-Hodgkin's lymphoma (NHL) patients receiving conventional chemotherapy (CT). 54 new NHL patients were enrolled in the study (stage IIB-IV, mean age 30.2 (SD 13.5), males/females - 55/59). The lymphoma histopathology was as follows: diffuse large B cell lymphoma - 24, peripheral T cell lymphoma - 11, anaplastic large cell lymphoma - 11, follicular lymphoma - 4, mantle cell lymphoma - 2, angioimmunoblastic Tcell lymphoma - 2. All the patients underwent conventional CT: CHOP or CHOP-like regimens. QoL was assessed using the generic questionnaire SF-36. All the patients filled in the questionnaire at baseline and at different time-points after the end of CT. QoL treatment response was assessed using Integral QoL Index and was classified as improvement, stabilization or worsening. At 3 months after CT the following distribution of patients according to clinical response rates was observed: complete remission - 62%, partial remission - 6%, stabilization - 13%, progression - 19%. QoL improvement was achieved in 44%, QoL stabilization - in 44%, and QoL worsening - in 12% of patients. In a number of cases discrepancies between clinical response and QoL response rates were registered. Noteworthy, there were patients with complete remission who experienced QoL worsening after the end of CT. Thus, information about clinical and QoL response rates allows to obtain comprehensive information about treatment outcomes in NHL patients receiving conventional CT. The dichotomous model sounds feasible to measure effect of treatment both from physician's and patient's perspective. The evaluation of both clinical and QoL response may provide comprehensive information about the benefits and risks of treatment of malignant lymphoma patients.

1409

SALVAGE CHEMOTHERAPY WITH NON-PEGYLATED LIPOSOMAL DOXORUBICIN (ADRIAMYCIN), FLUDARABINE, OXALIPLATIN AND CYTARABINE (AFOXA) IN POOR-RISK B CELL NON-HODGKIN'S LYMPHOMA

A Thiel,[1] R Sabauri,[1] F Kroschinsky,[2] J Birkmann,[3] U Kreibich,[4] R Herbst,[1] M Wilhelm,[3] G Ehninger,[2] M Haenel[1]
[1]*Clinic of Internal Medicine III, Klinikum Chemnitz, Chemnitz, Germany*
[2]*Medical Clinic I, University Hospital Dresden, Dresden, Germany*
[3]*Medical Clinic 5, Klinikum Nuernberg, Nuernberg, Germany*
[4]*Clinic of Internal Medicine II, Klinikum Zwickau, Zwickau, Germany*

The aim of the present phase I/II study was to evaluate the feasibility and toxicity of the combination of non-pegylated liposomal doxorubicin, fludarabine, oxaliplatin and cytarabine (AFOXA) in patients (pts.) with prognostically unfavourable recurrent and refractory B cell non-Hodgkin's-lymphoma (NHL). Between 02/2005 and 06/2010 a total of 29 pts. (16 male, 13 female) with diffuse large B cell lymphoma (n=15), mantle cell lymphoma (n=8) and follicular lymphoma (n=6) were treated according to the AFOXA protocol. Pts. (median age 61, range 42-70) with primary refractory disease (n=22), refractory relapse (n=1) and second (n=5) or third (n=1) relapse were enrolled. The intensive pretreatment contained a median of 6 (range 1-18) cycles of chemotherapy. 25/29 pts. were pretreated with the anti-CD20 monoclonal antibody Rituximab. The AFOXA regimen consisted of non-pegylated liposomal doxorubicin (25 mg/m^2, days 1 + 3), fludarabine (25 mg/m^2, days 1-4), oxaliplatin (escalating doses of 100 or 130 mg/m^2, day 5) and cytarabine (escalating doses of 1000 or 1250 or 1500 mg/m^2, day 5). In the phase I part of the study (n=12) the maximal tolerable dose (MTD) was determined for oxaliplatin and cytarabine according to World Health Organization Common Toxicity Criteria (CTC). The primary objective of the subsequent phase II part of the study, which uses the determined MTD, is efficacy. RESULTS: In the phase I part we established the MTD for oxaliplatin with 130 mg/m^2 and for cytarabine with 1000 mg/m^2. Out of 29 pts.; 20 pts. were treated with the established MTD. 7 pts. (35%) achieved complete remission (CR or CRu) and 1 patient (5%) partial remission, with an overall response (OR) rate of 40%. A successful peripheral blood stem cell harvest through mobilization with the AFOXA regimen was possible in 10 pts. (50%). CONCLUSIONS: AFOXA is a feasible salvage protocol for patients with poor-risk recurrent or refractory NHL. The observed toxicity (MTD) seems to be acceptable considering the unfavourable prognosis and intensive pretreatment. The efficacy will be evaluated in the ongoing phase II study.

1410

INTENSIVE THERAPY OF THE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA WITH PRIMARY INVOLVEMENT OF MEDIASTINAL LYMPH NODES AND PRIMARY MEDIASTINAL B-CELL LYMPHOMA EFFICACY AND TOXICITY

J Mangasarova, A Magomedova, S Kravchenko, E Zvonkov, V Vorobiev, D Maryin
Hematological Research Center, Moscow, Russian Federation

Background. Primary mediastinal B-cell lymphoma (PMBCL) and diffuse large B-cell lymphoma (DLBCL) with primary involvement of mediastinal lymph nodes have different origins and, therefore, different immunological, molecular and genetic characteristics and response to therapy. *Aims*. To evaluate the efficacy and toxicity of the modified program NHL-BFM-90 (mNHL-BFM-90) for adult patients with PMBCL and DLBCL diagnosis and primary involvement of mediastinal lymph nodes. Methods. There were 37 patients with large B-cell lymphoma with primary involvement of mediastinal lymph nodes. The illness was diagnosed in accordance with WHO classification criteria, the differential diagnostics of PMBCL and DLBCL was performed on basis of the data obtained via immunohistochemical study through and assessment of the gene expression level by PCR. The diagnosis of DLBCL with primary involvement of mediastinal lymph nodes was established for 17 patients (7 men, 10 women, mean age 31 years (from 18 to 60 years)), PMBCL 20 (9 men, 11 women, mean age 31 years (from 21 to 70 years)). All patients were treated according to mNHL-BFM-90 program in the Russian Hematological Research Centre between November 2004 and July 2010. DLBCL and PMBCL staging criteria developed by Ann Arbor were used to stage the patients. All patients were diagnosed with II stage. Bulky mediastinal disease was found in 16 (94%) patients with DLBCL and in 19 (95%) patients with PMBCL. Serum lactate dehydrogenase level was increased in 17 (100%) patients with DLBCL and in 19 (95%) patients with PMBCL. ECOG 1 was established in 1 patient (2,7%), 2 - in 7 (18,9%), 3 - in 23 (62,1%), 4 - in 6 (16,7%) patients. The NHL-BFM-90 protocol was modified by us (a dose of methotrexate was reduced to 1500mg/m2 (12 h) in course A and B, doxorubicine (50 mg/m^2) was included in the course A). 4-6 courses were performed, their quantity being determined depending on achieving the remission time. The patients with residual tumor in mediastinum underwent radiotherapy as consolidating treatment in total dose of 36 Gray. *Results*. 16 (94%) of the patients with DLBCL with primary involvement of mediastinal lymph nodes achieved a complete remission, and 13 (65%) of the patients with PMBCL. One of the patients DLBCL has died from chemotherapy complications. One patient with PMBCL turned out to be primary-resistant. Early relapse was ascertained in 1 patient with DLBCL and 3 with PMBCL. The 3-year disease-free survival (DFS) and overall survival (OS) were similar, 94% in patients with DLBCL and 84 % with PMBCL. Most infectious and hemorrhagic complications occurred during the first course (course A), which can be explained by the initial poor condition of the patients and a large tumor mass at the start of treatment. *Summary/conclusions*. The modified mNHL-BFM-90 is a highly effective protocol. The 3-year DFS and OS were similar, 94% in patients with DLBCL and 84 % with PMBCL.

1411

INTRATHECAL LIPOSOMAL CYTARABINE PROPHYLAXIS IN VERY AGGRESSIVE LYMPHOMA: A SPANISH MULTICENTER STUDY

A de la Fuente,[1] J Peñalver,[2] M Olave,[3] I De la Fuente,[4] C Panizo,[5] C Grande,[6] R Del Campo,[7] P Miralles,[8] B Navas,[9] JA Garcia Marco,[10] JF Tomás[1]

[10]*Hospital Universitario Puerta de Hierro, Madrid, Spain*

Introduction. Lymphomatous meningitis (LM) in very aggressive lymphoma is a common complication with poor prognosis that usually occurs early in the course of the disease . Liposomal Cytarabine (LC) is an extended release formulation which has demonstrated better efficacy compared to standard Cytarabine for the treatment of LM in one randomized clinical trial. Retrospective studies have shown that prophylaxis with IT LC in DLBCL patients is feasible and effective. Aims: To evaluate effectiveness and toxicity profile of IT Liposomal Cytarabine as prophylaxis of LM in very aggressive lymphoma. Methods:.Main endpoints were effectiveness (LM incidence) and toxicity (CTCAE of NCI 3.0) of the IT prophylaxis. A retrospective study was carried out in 10 Spanish hospitals including patients diagnosed with Burkitt and Lymphoblastic Lymphoma that received LC as IT prophylaxis for LM in the period between January 2007 and January 2011. *Results*. Data from 16 patients were analyzed. Baseline characteristics were: 7 Burkitt and 9 Lymphoblastic Lymphoma. Mean age: 45 ± 20 years (range 20-79). Male/Female 15/1. Ann Arbor stage IV 11 (69%). All patients received alkylating based regimens and in 13 patients (81%) treatment included high dose systemic AraC and Methotrexate. LC was administrated at a dose of 50 mg. The total number of administrations was 52 with a mean of 3.25±1.65 doses per patient (range 1-6). In order to minimize side effects, as described before, administration of sistemic AraC and LC were separated in time for at least 7 days. Effectiveness: With a median follow up of 22 months (range 8-35) we have not found any case of LM. Eleven patients completed IT prophylaxis treatment (two patients continues the IT schedule at the time of this report, two patients were exitus before finishing prophylaxis and one patient was lost to follow up). Toxicity: Prevention of chemical arachnoiditis with steroids was given to all patients. There were 4 cases of headache, 2 patients with grade 1 and 2 with grade 2, reversible in all cases. *Conclusions*. This retrospective study with 22 months of median follow up and no cases of LM in very aggressive lymphoma, shows that CNS prophylaxis with LC is effective and well tolerated without serious adverse events reported, with the precautions and prevention meausures mentioned above.

1412

SCREENING FOR PRIMARY IMMUNODEFICIENCY IN PEDIATRIC PATIENTS WITH LYMPHOID MALIGNANCIES

I Ragab,[1] A Tantawy,[1] S Reda,[1] L Shalaby,[2] H Afifi[1]
[1]*Ain Shams University, Cairo, Egypt;*
[2]*Egyptian National Cancer Institute, Cairo, Egypt*

Background. Primary Immunodeficiency diseases (PID), although rare in the general population are the best characterized and strongest known risk factors for lymphoid malignancies. Clinical immunodeficiency related score (IDR) is a recently introduced tool to identify possible patients with PID. Aim of the work is to evaluate the possibility of primary immunodeficiency in children with lymphoid malignancies by applying the clinical scoring system and studying the humoral and cellular immune status at diagnosis. *Patients and methods*. We studied sixty two pediatric patients diagnosed as non Hodgkin lymphoma (NHL)(n=26) , Hodgkin disease (HD)(n=16) and acute lymphoblastic leukemia(ALL)(n=20).They were 41 males and 21 females aged 0.15-18 years. They were recruited from Ain Shams University, Children `s Hospital and National Cancer Institute in Egypt. Evaluation included a thorough history of previous illness followed by calculation of an immunodeficiency related score (IDR).IDR score ≥6 was suspicious of PID and IDR score≥8 was highly suggestive of PID. Laboratory testing was performed in thirty two patients prior to start of chemotherapy, complete blood picture , immunoglobulin (Ig) A,M,G assay by nephelometry and quantification of peripheral T cell subsets by flowcytometry. Results: IDR score ≥ 6 was found in 2 ALL(10%), 7 NHL(27%) and 6(37.5%) HL patients(p=0.08), while IDR ≥8 was found in 4 NHL(15%),3 HL(18.8%) and none of ALL patients (p=0.58). IgG was higher in ALL 90% compared to HD 37.5% and NHL 33.3% (p=0.03) . IgM level was lower in HD 50% compared to NHL 12.5% and ALL 0%(p=0.04), while no significant difference in IgA Level (p=0.25). ALL had the highest peripheral T cell subset levels. CD 3 and CD8 levels were significantly low in HD (66.7%- 66.7%) compared to NHL (12.5%- 12.5%) and ALL (40%- 20%) (p=0.05) respectively while CD4 levels were comparable (p=0.23). IDR score ≥8 was associated with low IgM level (p=0.05) but not other Igs or T cell subsets levels. Three patients with IDR score more than 8 were diagnosed as ataxia telangiectasia after their malignancy diagnosis (one Burkitt lymphoma, two HL) and one patient had leucocyte adhesion defect diagnosed prior to development of NHL (Burkitt lymphoma). *Conclusions.* Immunedysregulation either raised Igs and peripheral T cell subsets due to chronic immunostimulation or decreased immune parameters as part of PID is associated with lymphoid malignancies. Creating a scoring system for screening of PID at diagnosis of lymphoid malignancy may be a useful tool for case detection and specific therapy.

1413

RISK OF RELAPSE IN 81 PATIENTS WITH PRIMARY NODAL, LOCALISED (I-II STAGE) DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) IN 1ST COMPLETE RESPONSE

S Mercadal,[1] F Climent,[2] E Domingo-Doménech,[1] N García,[1]
A Oliveira,[1] V Romagosa,[3] A Fernández de Sevilla,[1]
E González-Barca[1]
[1]*ICO L'Hospitalet, Barcelona, Spain*
[2]*Hospital Bellvitge, Barcelona, Spain*
[3]*H. Bellvitge, Barcelona, Spain*

Background. DLBCL is an aggressive and potentially curable lymphoma. It presents itself as a localized disease in 30% of all cases and as primary nodal in 50-60% of these. Is known that in advanced disease, one third of them eventually relapse, but few data exist regarding localised disease. *Aim*s. To analyse the risk and the characteristics of relapse of patients with primary nodal localised DLBCL in complete response (CR). *Methods*. Eighty one patient (43/38 M/F; median age, 59 years) in CR after chemotherapy, mainly consisting anthraciclinic containing regimen, were included in the study. Main clinicobiological characteristics at diagnosis and at relapse were analysed. Uni and multivariate studies were performed. *Results*. Seventeen patients (21%) eventually relapsed. Late relapse, more than 2 years after CR, were 6 patients, and early relapse, less than 2 years after diagnosis were documented in 11 patients. The most important variables predicting relapse at diagnosis were age and being it the only predictive variable in the multivariate analysis. No differences were found according to the treatment given and if they received regimens with or without rituximab. The second CR rate obtained in the late relapsing patients after salvage therapies was higher that in early relapsing (27% vs 50%). Median time from diagnosis to relapse was 1 year for patients for early relapsing and 4.5 years for late relapsing. Five-year overall survival (OS) was 18% for early relapsing patients and 83% for late relapsing patients (p=0.012). For DLBCL relapse, two-year OS was 50% versus 18% with autologous transplantation or not, respectively (p=0.079).

	DLBCL (N=81)	Relapse DLBCL (N=17)
Age (median, range)	59 (18-87) y	64 (38-84) y
Sex (M/F)	43/38	10/7
ECOG 0-1 (%)	81	82
I/II stage (%)	33/67	35/65
B symptoms (%)	14	23
Bulky disease (%)	38	29
LDH > 3.4 ukat/L (%)	59	70
beta2-microglobulin > 2.2 mg/L (%)	44	50
IPI low/low-intermediate risk (%)	91	88

Summary. Late relapse is a common event in localised DLBCL with these patients achieving more frequently a second CR and having better survival than early relapsed patients. The outcome in relapsed patients remains poor and aggressive treatments like autologous transplantation should be performed whenever possible.

1414

GASTROINTENSTINAL (GI) TRACT INVOLVEMENT IN ADVANCED-STAGE DIFFUSE LARGE B-CELL LYMPHOMAS (DLBCL)

W Spychalowicz, J Wojnar, M Krawczyk, A Spychalowicz
Silesian Medical University, Katowice, Poland

Background and aims. The differentiation between primary extranodal GI tract lymphoma and secondary GI tract involvement in generalized lymphoma is difficult in many clinical situations but has a significant meaning while choosing treatment methods and strategies. The aim of this report is an attempt to characterize patients with GI tract involvement in advanced-stage DLBCL and indicating clues for treatment optimization. *Materials and methods*. We performed a retrospective analysis of 62 patients with CS IIB-IVB DLBCL treated in Chemotherapy Clinic in 2003-2009 regarding involvement of GI tract structures by lymphomatous process. Such changes were observed in 9 patients. The group consisted of 5 women and 4 men aged 31-76 (median-58). CS has been evaluated as II B (but multifocal nodal involvement in abdomen and pelvis)-3 patients, III A -2 patients, IIIB-1 patient, and IVB -3 patients. After standard diagnostic procedures patients were qualified for ICHT according to R-CHOP scheme (6-8 cycles). The following factors were considered in the analysis: 1) localization and characteristics of GI tract involvement, 2) molecular DLBCL subtype: ABC or GBC, 3)clinical parameters: generalized symptoms, IPI, LDH and β-2-microglobuline, 4) efficacy of surgical treatment if previously performed, 5) treatment efficacy understood as response to chemotherapy (CR/PR/SD/PD) and its duration (PFS/OS). Results: 1) the infiltration of stomach was found in 4 subjects, large intestine-3 subjects, small intestine-1 subject, a bifocal infiltration of small and large intestine-1 subject. The infiltration extanded across the entire GI tract wall to local lymph nodes or adjacent lymphatic tissue in 6 patients, however in as many as 3 patients it did not cross GI tract serosa. 2) molecular subtype ABC has been diagnosed in 3 cases, GBC-5 cases, in 1 case the molecular subtype has not been tested. 3) the incidence of systemic symptoms-66% has been comparable to that in the overall DLBCL group-61%, similarly mean IPI (3,2 /3,1), LDH and β-2-microglobuline. The only parameters that differed significantly between the groups were the incidence of anemia-56% in the group with GI tract involvement vs 35%, and need of RBC transfusions- 33% vs 14%. 4) surgical treatment preceeded ICHT in 4 cases,. In 3 patients lymphomatous infiltration has been found at the site of section or close to it during control ensoscopy performed between surgery and ICHT. 5) CR after ICHT (mean 7,1 cycles) has been achieved in 5 cases (55% vs 69% in the overall DLBCL group), in 3 patients with PR a radioimmunotherapy with ibritumomabem has been used as consolidation resulting in 1 CR +1PR+1PD (death during further treatment). Death of 1 patient caused by PD occured during ICHT. A 2- years-long PFS has been achieved by 5/9(56%)while in the overall DLBCL group by 43/62 (69%). A 2-years-long OS for patients with GI tract involvement was 6/9(67%) vs 48/62 (78%) in the overall DLBCL group. *Conclusions*. In advanced-stage DLBCL GI tract involvement is a negative prognostic factor for good ICHT R-CHOP response as well as its duration. Consolidation with ibritumomab in patients with PR only slightly improves treatment outcome.

1415

RITUXIMAB-TREATMENT FOR RECURRENT ACQUIRED ANGIOEDEMA UNDERLYING LYMPHOPROLIPHERATIVE DISORDERS: TWO CASE REPORT

L Pupo, M Postorino, L Franceschini, S Gumenyuk, S Vaccarini, M Rizzo, L Gianni, D Renzi, M Guarino, M Quaresima, M Refrigeri, G Allori, R Morandini, A Persichetti, A Scardocci, R Perricone, M Cantonetti

Policlinico Tor Vergata, Rome, Italy

Background: Acquired Angioedema (AAE) due to the C1-inhibithor deficiency is often the spy of an underlying autoimmune disorder or a lymphoprolipherative disease (LPD). In these cases the acute symptoms can be resolved by the infusion of C1-inhibithor factor. Corticosteroids as immediate and etiological therapy in many cases is incapable of reducing the intensity and frequency of the AAE attacks. Aims: To obtain a faster and deeper control of AAE attacks and to avoid interferences of chemotherapy in their instable Complement's Cascade, two Non Hodgkin Lymphoma (NHL) patients, refractory to corticosteroid therapy, were treated with Rituximab at 375 mg/mq weekly. CaseA: a 50 years old man with a history of recurrent AAE received, two years later, the diagnosis of Diffuse Large B Cell Lymphoma (DLBCL) from the biopsy of laterocervical lymph node with a presentation at stage III of disease. The C1-Inhibitor level was 4,8 mg/dl and functional C1-INH percentage was 5% without demonstrable antibodies against C1-inhibitor (C1Q=91mg/L). At moment of DLBCL diagnosis the patient presented weekly severe attacks of AAE without any benefit from corticosteroid therapy (Methylprednisolone 2mg/Kg BW). Due to progressive symptoms, we administered Rituximab at 375 mg/mq weekly for 4 weeks. After the 3rd dose the AAE attacks disappeared and C1-Inhibitor level and functional C1-INH percentage were 33,8 mg/dl and 45% respectively . Subsequently the patient received chemotherapy according to CHOP like scheme (Cyclophosphamide, Liposomal Pegilated Doxorubicin, Vincristine Prednisone) every 21 days for 6 doses and obtained a Complete Remission (CR). After one year the patient died due to acute myocardial infarction in CR from NHL and AAE. Case B: a 75 years old man with a recurrent AAE and a monoclonal gammopathy (0,98 mg/dl of IgG4 monoclonal component) presented a 40% of bone marrow involvement as unique manifestation by follicular NHL. C1-Inhibitor level was 6,4 mg/dl and functional C1-INH was 18 %. No antibody against C1-inhibitor was present (C1Q 116 mg/L). The AAE attacks (2-3 monthly) were refractory to corticosteroid therapy. Rituximab was administered at standard dosage weekly for 4 weeks and every 3 months for 1 year as maintenance therapy. After the 3rd dose the patient obtained a remission from AAE with C1-Inhibitor level 30mg/dl and functional C1-INH 44% and. after 8th dose NHL marrow involvement disappeared. The patient is still in CR for AAE and NHL, after 1 year from the end of maintenance therapy. Conclusion: our experience demonstrates the efficacy of Rituximab in the treatment of AAE LPD-related in patients refractory to corticosteroid therapy even in absence of antibodies against C1 Inhibitor.

[4]*University of Siena, Dept of Dermatology, Siena, Italy*

[5]*Univerisity of Florence, Dept of Dermatology, Florence, Italy*

[6]*University of Florence, Dept of Hematology, Florence, Italy*

[7]*University of Florence, Dept of Dermatology, Florence, Italy*

Background. The most common types of primary cutaneous B-cell lymphomas (PCBCL) are follicle center cell lymphoma (FCL), marginal zone B-cell lymphoma (MZL) and diffuse large B-cell lymphoma of the leg (DLBCL-LT). They represent approximately one third of all cutaneous lymphomas. FCL and MZL generally have an indolent behavior and an excellent prognosis (>90% 5-year survival), different from DLBCL (<60% 5-year survival). According to the EORTC/ISCL recommendations, the first line treatment of FCL and MZL is most often radiotherapy (surgery in a minority of cases with a single skin lesion), while patients with multifocal skin involvement deserve a systemic antiblastic treatment (similar to those with relapsed/refractory disease). The option of first-line chemotherapy, viceversa, is the rule in DLBCL-LT. CHOP-like regimens are by far the most commonly used, although hard to propose in patients over 80, who are frequent in this subset. In this regard, the association of rituximab (R) and liposomal pegylated doxorubicin (PLD) appear very promising. Aims: Based on the favourable results reported with R and PLD in several recent trials, we decided to test efficacy and safety profile of this combination. Methods: From June 2005 to January 2010, 11 patients with PCBCL were treated with R plus PLD at the hematology divisions of Siena and Florence. Five of them were males and six females, with a median age of 56 years (range 39-81). Four patients had FCL, 4 MZL, and 3 LBCL-LT. Ten patients had a stage II-III disease, while a female patient had a stage I disease with facial localization, and refused surgery and radiation therapy due to the high risk of aesthetic damage. Seven of 11 patients had relapsed after previous radiation treatment (3), phototherapy (2) and chemotherapy (2). Treatment plan consisted of 2 monthly cycles of R 375mg/m2 and PLD 20 mg/m2 d 1;15, followed (in responders) by two cycles at same dosage given only at day 1. All patients received prophylactic acetaminophen, clorphenamine, low dose steroids and pyridoxine to prevent rituximab infusional side-effects and Palmar-Plantar Erythrodysesthesia (PPE), respectively. Results: Ten out of eleven patients had a response (8 complete, CR; 2 partial, PR), while a patient did not respond (progressive disease, PD). All patients except two are alive and in stable remission, with a median follow-up of 24 months. One patient died due to progressive disease, and one due to a second neoplasm. Hematological toxicity was negligible (1 case of grade 2 neutropenia), as well as extra-hematological toxicity (2 cases of grade 2 PPE). Mild rituximab infusional reactions were registered in 3 cases at first infusion. *Conclusions*. These preliminary data suggest that R-PLD is very effective and well tolerated in the treatment of all subset of PCBCL. Moreover, this therapeutic option may be offered front-line in case of peculiar localization, in which radiotherapy or surgery may cause permanent aesthetic damage.

1417

HYPOALBUMINEMIA AS THE MOST SIGNIFICANT PREDICTOR OF POOR OVERALL SURRVIVAL IN PATIENTS WITH MUCOSA-ASSOCIATED LYMPHOID TISSUE NON-HODGKIN LYMPHOMA

M Virijevic,[1] B Andjelic,[1] M Todorovic,[2] M Smiljanic,[1] A Novkovic,[3] I Djunic,[1] B Mihaljevic[2]

[1]*Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia*

[2]*Clinical for Hematology, Clinical Center of Srerbia, Shool of Medicine, Belgrade, Serbia*

[3]*Clinic Hospital Center, Zemun, Belgrade, Serbia*

Background. Mucosa-associated lymphoid tissue (MALT) non Hodgkin lymphoma (NHL) belongs to the group of B cell non-Hodgkin's lymphoma (NHL), a subgroup of indolent lymphoma. The latest scientific papers on MALT lymphoma are aimed at finding both the clinical and laboratory as well as the biological parameters which would initially, before starting the treatment, isolate the group of patients at a high risk of rapid disease progression. *Aims*. The aims of this research were to investigate prognostic clinical and laboratory factors significant for outcome of patients with MALT lymphoma, as well as to compared these factors between patients with gastrointestinal (GIT) and nongastrointestinal (non-GIT) sites of primary lymphoma. *Methods*. This study involved 87 patients with diagnosis of MALT lymphoma. The followed pretreatment laboratory parameters were recorded: hemoglobin, serum albumin level, serum lactate dehydrogenase level (LDH), beta2-microglobulin (β2-M), virologic (HBsAg, HCV, HIV) and bacteriological (*Helicobacter pylori*) status. Estimated clinical features were: stage of disease (CS) according Ann Arbor classification, performans status (PS) evaluated by Europian Cooperative Oncology group (ECOG) recomandation, tumor mass voluminosity, number od extranodal localizations, presense of B simptomatology, splenomagaly and/or enlarged lymph nodes. Diagnosis of MALT lymphoma was based on histopathology analysis of tissue samples body, obtained by endoscopy or surgery. The followed-up period was 10 years. Risk factors were identified using the univariate and multivariate analysis. Results: The median patients' age was 58,3 years, range 28-82 years. The most frequent location in 29 (33,3%) patients was the GIT. The most common localizations of non-GIT MALT lymphomas were: the orbit in 13 patients (14,9%), the salivary gland in 11(12,6%), lungs in 9 (10,3%) and tonsils in 8 (9,2%). The median progression-free survival (PFS) was 36 months and at 5 years the OS rate was 64%. Significant longer overall survival (OS) had patients with non-GIT localization than those with GIT localization of MALT lymphoma (p=0.001). The univariate analysis showed that significant

predictors for poor OS were: age >60 years (p<0.001), CS III and IV (p=0.026), presence of B simtomatology (p=0.006), ECOG PS ≥2 (p=0.005), Helicobacter pylory positivity (p=0.015) and decreased serum albumin level (p<0.001). The multivariate analysis indicated the decreased serum albumin level to be the most significant predictor of poor OS: p<0.001, relative risk (RR)=5.060 (95% CI 2.055-12.458). In the group of patients with GIT localization of MALT lymphoma, the most significant predictor of poor OS was serum LDH level: p=0,031 (RR)=3,452 (95%CI 1,121-10,630), while the most significant predictor of poor OS in the group with non-GIT localization of MALT lymphoma was the decreased serum albumin level: p=0,001, (RR)=28,195 (95% CI 3,590"'221,456). Conclusions: It is shown that MALT lymphomas with non GIT localization have longer OS in compare with GIT localization. The most significant predictor of poor OS was decreased serum albumin level. At patients with GIT localization of MALT lymphoma, the most significant predictor of poor OS was serum LDH level, while at patients with non-GIT localization the most significant predictor of poor OS was also decreased serum albumin level.

1418

NON-HODGKIN LYMPHOMA OF OCULAR ADNEXAL SITES SUBTYPED ACCORDING TO THE REAL CLASSIFICATION: A 17-YEAR EXPERIENCE FROM SINGLE INSTITUTION

J Herrada, M Richards, K Le, C Vazquez, M Landeros, A Gupta
Texas Tech University Health Sciences Center, EL Paso, Texas, USA

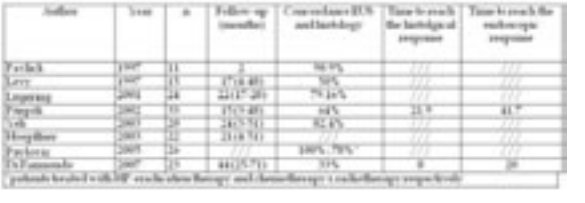
Background. The Revised European and American Lymphoma (REAL) classification (1994) provided a useful and practical tool to define lymphomas. *Aims*. To report our experience with this unusual malignancy diagnosed since the REAL classification was implemented.Methods: Retrospective review was performed on patients (pts) with ocular adnexal non-Hodgkin lymphoma sites between 1994 and 2011. Medical records, diagnostic imaging procedures, and pathology reports, including immunophenotypes, were reviewed. Histologic definition applied the REAL Classification. *Results*. 10 pts were identified. All but one were females. Median age at diagnosis was 69 years (54-84). Primary sites included conjunctiva (5), orbital soft tissue (3), eyelid (2). No lacrimal gland location was found. Ann Arbor stage at diagnosis was IE in most cases (7). One patient (pt) had stage IIE (conjunctival and maxillary sinus) and 2 pts had simultaneous bone marrow involvement (stage IV). 6 pts had marginal zone B-cell subtype, and the remaining 4 pts had small lymphocytic B-cell lymphoma. Radiation as single treatment modality was given to all 7 pts with stage IE, and all those achieved a complete remission (CR). CR was also achieved using chemotherapy with cyclophosphamide (C), vincristine (V), doxorubicin, prednisone (P), and rituximab followed by radiation in the pt with stage IIE. Of the 2 pts with stage IV, 1 achieved a CR with rituximab-based chemotherapy, and 1 never achieved a CR despite chemotherapy (chlorambucil, CVP). With a median follow-up of 23 months (9-70), the 9 pts that achieved an initial CR remain alive and disease-free. The only pt that did not achieved a CR lost follow-up at 18 months. *Conclusions*. Radiation alone appeared to be an effective treatment modality for stage IE. Achieving a CR seems to be a crucial factor for long term control of the disease.

1419

ROLE OF THE ENDOSCOPIC ULTRASONOGRAPHY IN THE MANAGEMENT OF GASTRIC LYMPHOMAS: METANALYSIS OF LITERATURE

C Vetro,[1] A Romano,[2] D Donnarumma,[2] A La Fauci,[2] P Fiumara,[2] A Chiarenza,[2] A Figuera,[2] G Palumbo,[2] G Bonanno,[3] F Di Raimondo[2]
[1]*Division of Hematology, Ferrarotto Hospital, Catania, Catania, Italy*
[2]*Division of Hematology, Ferrarotto Hospital, Catania, Italy*
[3]*Division of Gastroenterology, A.O. Vittorio Emanuele, Catania, Italy*

Background. After Sackmann et al, in 1997 introduced the concept that early stage PGL responds to eradication treatment, the last decade has viewed an escalating number of published materials, compared to previous decades, with a great quantity of prospective and retrospective studies. Aims. Due to the fact that the importance of EUS in initial assessment in gastric lymphoma is incontrovertible and that its role in follow-up is not clearly established (*Zucca & Dreyling, 2010*), the present work is focused in reviewing its role in diagnosis and follow-up. Methods A bibliographic research in MeSH database, using the key words [Stomach], [Lymphoma, Non-Hodgkin] and [Ultrasonography] has revealed a total amount of 117 papers published from 1971 to now. Manuscripts have been reviewed taking into account documents concerning staging and follow-up procedures. Results. STAGING: Despite first publications on the reliability of EUS in staging of PGL raised during the early '90's (*Caletti et al., 1993*) reported an accuracy of 80-92% and 77-90% for T and N stage respectively, these data were not confirmed by successive studies (*Fischbach et al., 2002*), reporting an accuracy of 59% and 71% for T an N stage, probably due to the fact that EUS is an operator-dependent technique (*Janssen, 2009*). Nevertheless, EUS has entered in the clinical practice of staging evaluation (*Pavlovic et al. 2005; Di Raimondo et al., 2007*) and has been indicated as the most appropriate technique in defining the loco-regional staging. FOLLOW-UP: Basically, there is a lack of studies concerning follow-up. Early reports with small series indicated a role of EUS both for staging and follow-up (*Pavlick et al., 1997; Lévy et al., 1997*). More recent reports, however, have shown that endosonographic remission is documented with a significant delay respect to histology (*Püspök et al., 2002*), even if at the same time another study confirmed that EUS is a dependable tool, finding a concordance between EUS and endoscopic biopsies of about 80% (*Lügering et al., 2001*), afterwards, two reports stated that EUS is reliable in determining the response evaluation and the detection of disease reappearance (*Yeh et al., 2003; Hoepffner et al., 2003*). Lately, the Serbian group, found a stringent correlation between EUS and histology in both patients treated with HP-eradicating therapy and/or chemotherapy ± radiotherapy. Afterwards, our group carried out a retrospective study in our patients observed in the last 10 years, in order to compare EUS with conventional endoscopy, not confirming the aforementioned studies, cause EUS was concordant with biopsies in a small portion of patients, about one third. In addition, the EUS findings returned to normal with a considerable delayed time in respect to gastroscopy with biopsy, even after a prolonged follow-up. (table 1) *Summary/Conclusion*. It is noteworthy that endoscopic ultrasound (EUS) assay is of great help in determining an appropriate staging of the disease, but its role in follow-up lack of evidences and is not recommended.



1420

PHASE I COMBINATION OF BORTEZOMIB AND EVEROLIMUS IN NHL: TOXICITY AND EARLY RESPONSE DATA

D Smith, E Hsi, B Bolwell, R Sobecks, R Dean, B Pohlman, J Sweetenham
Cleveland Clinic Foundation, Cleveland, USA

The mTOR/AKT and NFkB pro-survival pathways contribute to pathogenesis of various NHLs. Preclinical data suggests the AKT/mTOR pathway rescues cells from bortezomib's antitumor effect, and inhibitors of these pathways show synergy in vitro against myeloma and MCL. We devised a dual proteasome and mTOR inhibition strategy for phase I testing in NHL. This study combines bortezomib (B) with the oral mTOR inhibitor everolimus (E) in relapsed/refractory NHL to determine maximum tolerated dose (MTD), toxicity, and response rates. We present preliminary results. All pts with relapsed/refractory NHL are eligible. A standard dose escalation design was employed. Pts continue study treatment until disease progression, elective withdrawal, or excess toxicity with no maximum number of cycles. B is given D1,4,8,11 of a 21 day cycle and everolimus continuously by mouth. The dose levels are: 1)B 0.7 mg/m2 IV, E 5 mg PO QOD, 2) B 1 mg/m2 IV, E 5 mg PO QOD, 3) B 1 mg/m2 IV, E 5 mg PO QD, 4)B 1.3 mg/m2 IV, E 5 mg PO QD, and 5) B 1.3 mg/m2 IV, E 10 mg PO QD. 11 patients have been treated on study, with MCL (2 pts), Waldenstrom's macroglobulinemia (1 pt), transformed FL (1 pt), DLBCL (2 patients), FL (4 pts), and CLL/SLL (1 pt). The transformed FL pt was later deemed ineligible and received 1 dose of drug. The median number of study cycles given is 3 (range 1-41). Treatment-related grade 1-2 toxicities include thrombocytopenia in 6 pts (54%), anemia in 5 pts (45%), hyperglycemia in 4 pts (36%), and fatigue in 4 pts (36%). Grade 1-2 neuropathy, triglyceride elevation, nausea, diarrhea, AST elevation, or diarrhea occurred in 3 patients each (27%). Treatment-related grade 3-4 toxicities included 1 instance of lymphopenia, neutropenia, thrombocytopenia, hyperglycemia, fatigue, hypophosphatemia, hyperkalemia, and syncope. In addition, grade 3 systolic heart

failure occured in one patient after cycle 14, resolving on discontinuation of study drugs. The patient had no evidence of ischemic coronary disease on stress testing. Two other patients were removed from study at 2 and 4 cycles for adverse events possibly related to treatment, including grade 2 neuropathy and syncope/postural dizziness. Enrollment at the 3rd dose level proceeds; a DLT has been identified at that dose level. Responses are assessed using CT criteria every 3 cycles (9 weeks). 2 PR (both MCL pts), 3 stable disease (2 FL and one Waldenstrom's), 4 progressive disease (2 DLBCL, 1 FL, 1 CLL/SLL), and 2 not evaluable (off study for adverse events prior to first response assessment) were observed. The Waldenstrom's pt was treated for 41 cycles with radiographically stable disease and a decreasing paraprotein"thought ultimately progressed after 29 months, leading to discontinuation. The MTD of B+E has not yet been reached. Enrollment proceeds at the 3rd dose level. B+E appears active in MCL and Waldenstrom's but responses are not evident among other NHLs.

1421

CLINICAL AND MOLECULAR EVALUATION OF THE EFFICACY OF THE HIGH-DOSE POLYCHEMOTHERAPY IN ADULT PATIENTS WITH ANAPLASTIC LARGE-CELL ALK-POSITIVE LYMPHOMA

L Gorenkova, U Vinogradova, S Kravchenko, E Ilyushkina, E Zvonkov, A Misyurin

Hematology Research Centre, Moscow, Russian Federation

Background. Anaplastic large-cell ALK-positive lymphoma (ALCL) - a disease which is characterized by an onset in young age, an aggressive course with high frequency of extranodal involvement (skin, subcutaneous fat, bone, lungs) and poor prognosis. The diagnosis is based on the biopsy findings. Gistological study revealed a diffuse growth of large anaplastic cells, which express T-cell markers, CD30 and ALK. In 80% of cases the disease is characterized by the translocation t (2;5)(p23; q35) and in other cases - by the variant translocations. The overall 5-year survival in adult patients is 40-60% (depending on the stage of the disease) on CHOP and CHOP-like regimes. The using of high-dose chemotherapy protocol NHL BFM-90 in the treatment of ALCL in children leads to 80-100% 5-year disease-free survival (depending on the stage of disease). Relapse are more common in children with advanced stagies, in the presence of factors of poor prognosis and minimal residual disease. For adult patients currently no clear prognostic features. aims: to evaluate the efficacy of high-dose chemotherapy program NHL BFM-90 in patients older than 18 years and to determine the prognostic significance of the minimal residual disease in blood and/or bone marrow samples by RT-PCR. *Methods*. Patients older 18 years with diagnosed ALCL. Blood and bone marrow samples were examined for the quantity of NPM-ALK transcripts by RT-PCR before starting the treatment and after the end of protocol NHL BFM 90. Results: 20 adult patients with diagnosed ALCL were treated by protocol NHL BFM-90. The informed consent was obtained from all patients. All patients revealed generalized lymphadenopathy, 60% of the cases had extranodal sites, such as skin, subcutaneous tissues, bones and lungs. 80% of patients were diagnosed with stage III-IV disease. RT-PCR of NPM/ALK was employed to analyze the minimal residual disease to all patients. Patients with the unfavorable prognostic factors and the positive results of the minimal residual disease evaluation received autologous stem cell blood transplantation. We obtained a complete remission in 19 patients. One patient died of infectious complications during the first course of polychemotherapy. Two patients with stage IV and skin involvement relapsed during the first year after the end of the treatment. One of them died of the disease progression. One relapsed patient achieved the second long-term remission after allogeneic bone marrow transplantation. Thus, the overall 5-year survival rate is 90%. *Conclusions*. The using of child protocol NHL BFM-90 has shown the high efficacy in adult patients with ALCL compared with currently used chemotherapy regimes. The using of autologous stem cell transplantation may by rational in patients with poor clinical and molecular prognostic factors.

EVALUATION OF PROGNOSTIC VALUES OF CLINICAL AND HISTOPATHOLOGIC CHARACTERISTICS IN DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH RITUXIMAB-CHOP THERAPY

J Park,[1] J Hong,[1] SH Park,[1] HS Kim,[2] KH Kim,[1] JY Ahn,[1] M Jung,[1] SJ Sym,[1] EK Cho,[1] DB Shin,[1] JH Lee[1]

[1]*Gachon University of Medicine and Science, Graduate School of Medicine, Incheon, South-Korea*

[2]*Gachon University Gil Hospital, Incheon, South-Korea*

Background. After the introduction of rituximab, a monoclonal antibody to CD20, improved event-free survival (EFS) and overall survival (OS) among the elderly and younger patients with diffuse large B-cell lymphoma (DLBCL) has been reported. The mechanism of anti-tumor action of rituximab is fundamentally different from other known cytotoxic agents therefore, the prognosis associated with the clinical and histological characteristics of DLBCL need to be re-evaluated. Aims. To evaluate the relation of clinical and histopathologic characteristics to treatment outcomes in patients with DLBCL that were treated with rituximab-cyclophosphamide, adriamycin, vincristine, and prednisolone (R-CHOP) as first-line chemotherapy was investigated. Methods. Patients with newly diagnosed DLBCL treated with R-CHOP combination immunochemotherapy were retrospectively evaluated for their clinical characteristics, treatment efficacy and survivals. Immunohistochemistry (IHC) of CD10, bcl-6, MUM-1 was performed and according to the algorithm proposed by Hans, patients were subclassified into either germinal B-cell like (GCB) or non-GCB type. IHC for bcl-2 was also performed and the relation of patients' clinical and IHC characteristics to overall survivals were analyzed. Results. 87 patients (median age, 57 years) were analyzed for the association of clinical characteristics to OS. Age≥ 60 of the patients, elevated serum lactose dehydrogenase level, presence of 2 or more extranodal sites, and bone marrow involvement of DLBCL were powerful prognostic factors to OS in multivariate analysis. There was no significant difference of OS between the patients with GCB and those with non-GCB type. *Results* of bcl-2 also failed to demonstrate the relation to OS. Whereas no difference enough for OS was shown between high-intermediate risk group and high risk group classified by the standard International Prognostic Index (IPI) (P = 0.64), all 3 groups of revised IPI showed a clear-cut separation for EFS and OS. *Summary/Conclusions*. In this post hoc exploratory analysis, the revised IPI showed more clear-cut separation of patients according to their OS than the standard IPI, especially among patients that had more adverse clinical factors. Hans classification and the result of bcl-2 showed no predictive value for OS in patients with DLBCL treated with R-CHOP.

PROGNOSTIC FACTORS IN FOLLICULAR LYMPHOMA: A SINGLE INSTITUTION STUDY

C Saguna, M Tevet, N Berbec, O Ciocan, A Colita, R Manolache, G Barca, C Dragan, S Nada, I Ciobanu, I Triantafyllidis, A Lupu

Coltea Hospital, Bucharest, Romania

Background. For the prediction of overall survival (OS) in the field of follicular lymphomas, many prognostic models have proven useful. In our study we tried to evaluate these prognostic factors based on our experience. *Method.* We conducted a retrospective study on 71 newly diagnosed patients with follicular lymphoma, from a sum of 767 B ell lymphoproliferative disorders on a period of 7 years (2002-2008) in our clinic. We were focussed on clinical characteristics, symptom duration before diagnosis, pathologic findings, including grade, laboratory data, imaging studies at initial presentation and management. The male/female ratio was 1.09/1. Ages ranged from 32 to 84 years (median 57,80). By Ann Arbor classification the preponderence of our patients were diagnosed in stage IV (46.5%, 33 patients). B symptoms were present in 39,4%, 28 patients. Extraganglionary involvement was present in 57 patients from the study lot. Initial therapy was deferred in 39%. The remaining patients received stage-appropriate therapy. Survival was measured from time of diagnosis to death. Prognostic factors at initial diagnosis that were statistically significant in univariate log rank comparisons of Kaplan-Meier survival curves were used to build a multivariate proportional hazard regression model of OS. *Results*. OS differed with high (> 12 g/dl) versus low (< 12 g/dl) hemoglobin (p=.001) and in younger (< 60 years) versus older (> 60 years) patients (p=.05). Both hemoglobin and age were also significant in a multivariate proportional hazards analysis. Low hemoglobin and increased age were independent predictors of lower OS with hazard ratios of 6.6 (95% CI 2.2-20.1) and 3.7 (95% CI 1.2-11.7), respectively. Median survival for older patients who also had anemia was only 3.1 years. A test for interaction between age and hemoglobin was negative (p=.35). The estimated hazard ratio for an older individual with low hemoglobin was 24.7 (95% CI 4.0-153.3). *Conclusions*. The next aspects had prognostic significance: decrease in tumor mass with more than 50% after first treatment, type of response obtained, size and location of the adenopathies, serum of LDH level, platelet number, hemoglobin level at diagnosis, histological type of follicular lymphoma, value of the nuclear proliferation, Ki-67, performance status, IPI value, FLIPI.

CLINICAL CHARACTERISTICS, TREATMENT AND OUTCOME OF PRIMARY RECTAL LYMPHOMA: A SINGLE CENTER EXPERIENCE OF 16 PATIENTS

J Jeong, S Kim, JE Kim, DH Yoon, SW Lee, JR Huh, C Suh
Asan Medical Center, Seoul, South-Korea

Background. Rectum is a relatively uncommon site for lymphoma compared with other gastrointestinal sites and no consensus regarding management of primary rectal lymphoma (PRL) has been made due to its paucity. *Aims*. We aimed to investigate the clinical characteristics and treatment outcomes in PRL patients in a single center patient cohort. Methods. Between January 1993 and December 2010, 16 consecutive patients of PRL were identified and treated at the Asan Medical Center, Seoul, Korea. We retrospectively analyzed the results of these patients. *Results*. These 16 patients with PRL comprised 0.8% of all non-Hodgkin's lymphoma patients (n=1984). The median age at diagnosis was 41 years (range, 30-68 years) and 11 were male. The most common presentations were anal bleeding (n=7) and abdominal pain (n=4) while 3 patients were asymptomatic. Eleven patients had stage I/II disease by Ann-Arbor staging. B-cell lymphoma (n=14) made up of majority of the series and half of them were extranodal marginal zone lymphoma (n=7). The others included 4 diffuse large B-cell lymphomas and 3 mantle cell lymphomas. Ten patients were given systemic chemotherapy with (n=3) or without rituximab (n=7) and 4 of them received additional local therapy including radiotherapy (n=3) or surgical resection (n=1). The others were treated with radiotherapy (n=3) or endoscopic mucosal resection (n=3) as a first-line therapy sparing systemic chemotherapy. Twelve patients (75%) achieved a complete response (CR) after first-line treatment. Especially all of those with extranodal marginal zone lymphoma (n=7) achieved CR during or after initial treatment, while 5 of 9 patients with the other histologic subtypes succeeded to gain CR. During median follow-up of 27.0 months (range, 2.8 - 123.5 months), 3 patients died and 4 patients experienced progression resulting in 2-year progression-free survival rate of 78.1% and a 2-year overall survival rate of 78.6%, respectively. *Summary/Conclusions*. PRL is very rare and seems to be mostly B-cell type. Extranodal marginal zone lymphoma may be one of the most common types of PRL with favorable treatment outcome.

1425

HEPATITIS B REACTIVATION IN PATIENTS WITH NON HODGKIN LYMPHOMA CD20+ IN MAINTENANCE THERAPY WITH RITUXIMAB

I Ferrara,[1] A De Renzo,[1] S Luponio,[1] M Masarone,[2] M Persico,[2] R Cuccurullo,[1] F Pane[1]
[1]*Federico II University, Naples, Italy*
[2]*Second University of Naples, Naples, Italy*

Background. Anti CD20 antibody (Rituximab) based chemotherapy regimens increase the HBV reactivation risk although sporadic HBV reactivation cases are reported in patients on maintenance with Rituximab single therapy too. We evaluated how many HBV reactivation occurred among patients Hepatitis B core antigen positive (HBcAB +) and Hepatitis B surface antigen negative (HBsAg-) who received Rituximab single therapy during maintenance. *Aims*. The aim of this study is to assess the prevalence of HBV reactivation among patients HBcAb +/ HBsAg - during the maintenance therapy with Rituximab. Methods. In our Unit, 56 patients with non Hodgkin Lymphoma CD20+ received maintenance therapy with Rituximab (schedule: 375 mg/mq every 3 months for 2 years) from January 2007 to December 2010. 42% (25/56) of patients were treated with R-CHOP regimen; 57% of patients were treated with R-FN regimen. None of these patients received prophylactic therapy with lamivudine during induction or maintenance. All the patients were given blood tests for HBV (HbsAg; HbsAb; HbeAg; HbeAb; HbcAb) before starting maintenance therapy and liver function tests before each administration of Rituximab. *Results.* 28% of the patients (15/56) were HbcAb positive. 42% of the patients (25/56) completed the maintenance treatment and 28% of them are HbcAb positive (7/25): in none of these patients occurred the HBV reactivation (median follow up: 14 months). 55% of the patients (31/56) of the patients are still in therapy with Rituximab and 25% of them are HbcAb positive (8/31): even in these patients has occurred to date the HBV reactivation. *Conclusions.* In patients HBcAb +/ HBsAg - treated with Rituximab in single therapy is indicated the prophylaxis with lamivudine. In our observational study the HBV reactivation prevalence among patients HBcAb +/ HBsAg - not in prophylactic therapy with lamivudine during the maintenance therapy with Rituximab is 0%. More ambitious prospective studies are required to establish the clinical utility of prophylactic therapy with lamivudine during the maintenance therapy with Rituximab.

1426

HEPATITIS B REACTIVATION IN PATIENTS WITH NON HODGKIN LYMPHOMA CD20+ UNDERGOING CHEMOTHERAPY WITH AND WITHOUT RITUXIMAB

I Ferrara,[1] A De Renzo,[1] M Masarone,[2] M Persico,[2] R Cuccurullo,[1] S Luponio,[1] F Perna,[1] F Alfinito,[1] L Luciano,[1] M Picardi,[1] V Martinelli,[1] F Pane[1]
[1]*Federico II University, Naples, Italy*
[2]*Second University of Naples, Naples, Italy*

Background. Reactivation of HBV infection is a well-recognized complication in infected patients who undergo cytotoxic chemotherapy for cancer. The highest incidence of reactivation was reported in patients with non-Hodgkin's lymphoma (NHL) and hematopoietic stem cell transplantation. Several case reports demonstrated that severe hepatitis due to HBV reactivation after rituximab administration occurred both in hepatitis B surface antigen(HBsAg)-positive and HBsAg-negative patients. However, systematic evaluation of the relationship between HBV reactivation and rituximab is still limited. We conducted a study to investigate the relationship between rituximab-based therapy and HBV reactivation in 405 CD20-positive NHL patients at our institution. Methods. In our Unit, 405 CD20-positive NHL patients all newly diagnosed underwent measurement of HBsAg, anti-HBs,anti-HBc,HBeAg and anti-HBe. Patients were monitored by liver function tests during and after therapy as follows: on day 1and day 14 of each cycle, every month for a year. *Results*. 154/405 (38%) patients were HBcAb-positive. 107 had an aggressive lymphoma, 42 had an indolent lymphoma. HBV reactivation was observed in 2 patient (1,2%) who had received chemotherapy including steroid and rituximab and in 3 patients(1,9%) who had received chemotherapy including regimen with only fludarabine without rituximab Immediate administration of lamivudine therapy after elevation of HBV DNA level was conducted, and this resulted in reduction of it and improvement of liver function test. *Conclusions*. Rituximab plus steroid-containing regimens may increase the risk of HBV reactivation in HBsAg-negative and HBcAb-positive lymphoma patients but more attention should be paid on treatment with only fludarabine. More ambitious prospective studies are required to establish clinically useful or cost-effective follow-up methods for control of HBV reactivation in lymphoma patients with occult HBV infection.

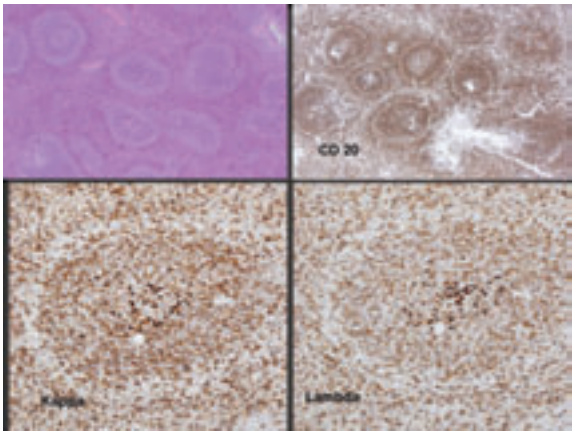
PERSISTENT B CELL POLYCLONAL LYMPHOCYTOSIS (PPBL) WITH MASSIVE SPLENOMEGALY MIMICKING MARGINAL ZONE LYMPHOMA

JM Bosch Benitez,[1] M Piris,[2] V Peri,[1] L Martin,[1] M Marrero,[1] M Mollejo,[2] J Diaz Cremades,[1] S Montes[2]
[1]*Hospital Insular, Las Palmas, Spain*
[2]*CNIO, Madrid, Spain*

Persistent polyclonal B-lymhocytosyi (PPBL) is a chronic expansion of polyclonal B lymphocytes seen predominantly in smoking women. Although considered as non- malignant it shares some features with malignant lymphomas like cytogenetic abnormalities and organomegaly. We present a case of PPBL with massive splenomegaly infiltrated by polyclonal lymphocytes resembling splenic marginal zone lymphoma. Case report and methods. A 46 years old smoking woman was seen at our institution in June 2006 for lymphocytosis. Blood counts were WBC=13.6X10E9/L (lymphocytes=10160/mm3) with some bilobated lymphocytes in blood film, Hb=104gr/L and platelets=143X10E9/L. Serum biochemistry revealed a Ferritin level of 11mg/dl (N>20) and LDH=240UI/l (<160). IgM levels were increased (1696mg/dl N=<230), the rest of immunoglobulins were in the normal range and no M spike was apparent in serum proteinogram , immunofixation was also negative. Immunophenotyping of lymphocytes by flow citometry revealed a B cell phenotype (CD19,CD22,CD20), positive for IgM, IgD , FMC7, CD27 ,and negative for CD5,CD10,CD23 with no light chain restriction. FISH analysis was negative for Chromosome3 and 8 abnormalities. IgH rearrangement by PCR was polyclonal. The patient was positive for HLADR7. A CT scan revealed an enlarged spleen and small paraaortic adenopathies. The patient developed progressive enlargement of the spleen measuring over 24cms with signs of portal hypertension and worsening of anemia and platelet level. Seplenectomy was performed in April 2009. The spleen weighted 3.9 Kg.. Histologically there was an extense lymphoid infiltration from the marginal zone of the white pulp affecting also the red pulp. By Flow cytometry the cells had the same phenotype as in peripheral blood. By paraffin IHC CD20, IgM, IgD, Bcl2, MNDA were positive and CD3, CD5, Cyclin D1, Bcl6, CD10, XBP1, CD23, CD43 negative without light chain restriction (Picture 1). Molec-

ular analysis showed polyclonal IgHV rearrengement. An isochromosome +i (3q) was detected by FISH. After splenectomy the patient blodd count return to normal range with no abnormal lymphocytes in the blood film. The presence of massive splenomegaly in patients diagnosed of PPBL has been recently recognized. To our knowledge only 6 cases including ours have been reported so far. All of them showed an histological pattern consistent with a marginal zone lymphoma but polyclonal in nature by immunophenotyping and molecular analysis. The biological mechanisms by which some patients with PPBL develop massive splenomegaly is unknown. Due to the rarity of this entity it shoud be kept in mind to avoid misdiagnosis



1428

NON-HODGKIN LYMPHOMAS IN CHILDREN WITH CHROMOSOME INSTABILITY SYNDROMES

O Kozlova,[1] L Kostyuchenko,[1] R Polishchuk,[1] I Cimbalyuk,[1] O Dorosh,[1] O Troyanovska,[1] L Skoropad,[1] O Stepanyuk,[1] O Kupchak,[1] V Loginsky[2]
[1]*Lviv Regional Council Public Institution, Lviv, Ukraine*
[2]*Institute of Blood Pathology and Transfusion Medicine, Lviv, Ukraine*

Background. Chromosomal instability syndromes (CIS) - a group of rare autosomal recessive diseases, which have common features of increased chromosome fragility phenomenon, immune deficiency, hypersensitivity to radiation and high predisposition to lymphoid tumour. CIS group include: ataxia-telangiectasia (AT), Nijmegen breakage syndrome (NBS), Bloom syndrome, Fanconi anemia and others. Methods. The diagnosis of NBS and AT is based on specific phenotype, results of clinical, laboratory and genetic investigations. The diagnosis of Non-Hodgkin lymphomas (NHL) is based of clinical, morphological and immunological researches of tumor substrate. Results. 85 children with NHL were treated in the department of hematology, Lviv Children's Hospital, during 1992-2009. 7 of them (8.2%) with CIS: 6 - with NBS (85,7%), 1 - with (14,3%). In 4 cases a diagnosis of CIS was established upon manifestation of oncological diseases in children, while in 3 children lymphoma developed during the follow up period. At the time of diagnosis of NHL median age of this children group was 9.3 years (4.3 years - 12.2 years). All patients with NBS and NHL were homozygoes for the 657del5 NBS1gene mutation. Children with NBS had typical craniofacial abnormalities (microcephaly, 'birdlike' face) and short stature. The skin malformations (spots of hypo- and hyperpigmentation) were diagnosed in 3 children. The other typical detected defects: sindactyly and clynodaktyly (2 patients), renal hypoplasia (1 patient). Clinical picture of AT was comprised of progressive cerebellar ataxia, oculocutaneous telangiectasias, spots of hypo- and hyperpigmentation. Lymphoblastic lymphoma was diagnosed for a 1 child, diffuse large B-cell lymphoma in 5 patients, lymphoma from large and small cells in 1 child. In most cases of the NHL the patients had nodal manifestation: a peripheral group of lymph nodes and spleen - in 7 (100%) patients, abdominal lymph nodes - in 3 (42,9%) children, lesion of mediastinum with the compression syndrome - in 5 (71,4%) patients. Atypical cells (L1/L2-type lymphoblasts according to FAB-classification) in the bone marrow revealed in one (14,3%) boy with lymphoblastic lymphoma. Involved extranodal sites included liver (6 (85,7%) patients), lung tissue and pleura (4 (57,1%) patients), kidney (one (14,3%) child), bones (one (14,3%) girl). Treatment was conducted according to BFM-group protocols (NHL-BFM-95/NHL-DGLLU-2000). Two patients died prior to beginning and two at the first stages of chemotherapy from complications of tumour process and severe concomitant infections, 1 patient - as a result of tumour progression. Specific therapy was effective in 2 (28,6%) children which currently have a long-lasting remission (11 and 7 years). Summary. The severity of clinical course of NHL in patient with CIS is caused by infectious complications related to the background of combined immunodeficiency, which requires a powerful antibacterial, antifungal protection and correction of immune status. Cytostatic treatment of NHL in children with CIS is possible and should be attempted. Intensity of therapy should be adjusted to individual risk factors and tolerance.

1429

DISSECTING FOLLICULAR DENDRITIC CELL SARCOMA INTO SUB-RISK GROUPS ACCORDING TO CLINICAL OUTCOME

G Park
Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea

Background. Follicular dendritic cell sarcoma(FDCS) is rare neoplasm and has been regarded as a low or intermediate-grade sarcoma. However, FDCSs show broad clinicopathological spectrum including some highly aggressive cases of short term survival. Currently, no well-established guideline is available for optimal treatment and predicting clinical outcome. *Aims*. To investigate clinicopathological factors predicting their clinical behavior and dissect them into sub-risk groups, and finally provide a base for optimal therapeutic planning, we analyzed 135 FDCSs with relevant clinicopathological parameters and clinical outcome. Methods: Among 34088 articles screened through Pubmed search (search terms; follicular dendritic cell tumor or follicular dendritic cell sarcoma or dendritic cell, 1986 to 2006), 71 articles which reported 135 FDCSs with available clinicopathological information were panned out. Repeatedly cited cases were carefully selected and adjusted to avoid the doubled data. Some missing pathological and clinical follow-up data were added by referring to original authors. 135 FDCSs were analyzed with relevant clinicopathological parameters including age, gender, location, tumor size, tumor margin, mitosis, nuclear atypism, hemorrhage, necrosis, Ebstein-Barr Virus (EBV) association, Castleman's disease association and treatement modality. For assessment of prognostic significance of each parameter, statistical analysis with Kaplan-Meier model and Cox-regression test were performed using SPSS, version 11.5. With combination of statistically validated parameters, we categorized FDCSs into three-tiered risk groups and analyzed their clinical outcome. Results: Mitotic Index (≥5/10 HPF)(P=0.0182) and intra-abdominal location (P=0.0003) were significantly correlated with the clinical courses including recurrence, metastasis and survival, whereas all other tested factors including tumor size, margin and nuclear atypism failed to achieve statistical significance. 66 FDCSs with well documented mitosis, tumor location and follow-up information were categorized into three groups; low risk(n=24, extra-abdominal location and mitosis <5/10HPF), intermediate risk(n=31, extra-abdominal location and mitosis ≥5/10HPF, or intra-abdominal location and mitosis <5/10HPF) and high risk(n=11, intra-abdominal location and mitosis ≥5/10HPF). Three groups showed distinct clinical outcome in event-free survival (P=0.0000) and overall survival (P=0.0001). The median event-free survival were 96 months, 24 months and 11 months (low, intermediate and high risk group, respectively). None of low risk group died of disease (100% survival by 10 years), whereas high risk group showed aggressive clinical outcome (57.1% of 2-year survival). The intermediate risk group showed borderline clinical course (81.2%, 62.5% and 25% of 2-year, 5-year and 10-year survival, respectively). *Conclusions*. Our results suggest that the FDCSs are very heterogenous in clinical outcome and could be subclassified into three-tiered risk group system which would be useful for predicting prognosis and optimal patient management.

1430

CAN WE CURE HTLV-I ASSOCIATED ADULT T CELL LEUKEMIA LYMPHOMA?

A Bazarbachi,[1] P Suarez,[2] O Hermine[2]
[1]*American University of Beirut Medical Center, Beirut, Lebanon*
[2]*CNRS UMR 8147 and Department of Hematology, Necker Hospital, Paris, France*

Background. Adult T cell leukemia (ATL) is one of the rare human cancers initiated by a transforming retrovirus, HTLV-I. After many years of

controversy, it is now accepted that the viral transactivator protein Tax plays a critical role in initiating the leukemic process, because Tax transgenics develop a disease with striking ATL features. However, its role in the maintenance of the lymphoproliferation remains still a matter of debate. Long-term prognosis of ATL patients remains extremely poor. In acute ATL, well conducted Japanese trials demonstrated that although combinations of chemotherapy improved response rate, they failed to achieve a significant impact on survival. Patients with chronic and smoldering ATL have a better prognosis but long-term survival is poor when these patients are managed with a watchful-waiting policy or with chemotherapy. *Aims and Methods*. We recently realized a worldwide meta-analysis. *Results*. We showing that the combination of zidovudine and interferon-alpha (IFN) is highly effective in the leukemic subtypes of ATL and should be considered as standard first line therapy in that setting. This combination has changed the natural history of the disease through achievement of significantly improved long-term survival in patients with smoldering and chronic ATL as well as patients with acute ATL and wild type p53. ATL lymphoma patients may benefit from initial induction therapy based on aggressive chemotherapy regimen in addition to or followed by antiretroviral therapy with AZT/IFN. In all patients, in order to prevent the occurrence of resistance and relapse, clinical trials assessing bone marrow transplantation additional targeted therapies such as arsenic/IFN combination or monoclonal antibodies, are mandatory after achieving CR. In that sense, we recently reported that the combination of arsenic trioxide, IFN, known to trigger Tax proteolysis in addition to zidovudine, yielded unprecedented response rates in chronic ATL patients, and may prevent relapses in ATL lymphoma responding patients after chemotherapy. To investigate the molecular mechanism of therapeutic action *in vivo*, we used Tax transgenic mice that develop a disease with striking ATL features. We demonstrate that the combination of arsenic trioxide and IFN cures Tax-driven murine ATLs through selective targeting of leukemia initiating cell (LIC) activity. Importantly, this effect requires proteasome function. *Conclusions*. Overall, our findings strongly suggest that in this model ATL LICs are addicted to the viral Tax oncoprotein and open the prospect of new strategies to cure ATL.

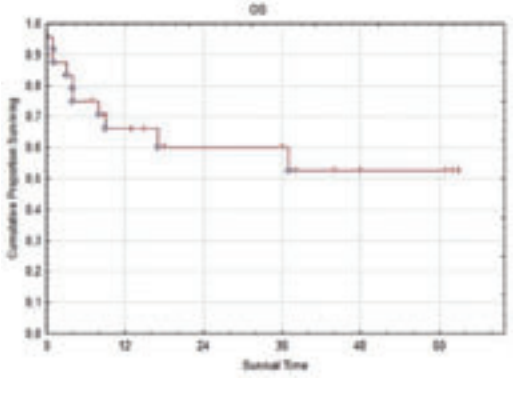
1431

DOSE ADJUSTED EPOCH - RITUXIMAB AS FIRST LINE TREATMENT FOR HIGH RISK, AGGRESSIVE B-NHL: A SINGLE CENTER EXPERIENCE

V Pejsa, Z Prka, R Ajdukovic, M Pirsic, M Lucijanic, P Senjug, R Kusec, O Jaksic

University hospital Dubrava, Zagreb, Croatia

Background. ose-adjusted EPOCH- rituximab (DA-EPOCH-R) is an infusional protocol (etoposide, vincristine, and doxorubicin for 96 hours with bolus doses of cyclophosphamide and oral prednisone) which is based on pharmacodynamical adjustment of drug dosage depending on laboratory values of absolute neutrophil count and platelets (*Wilson WH et al. Blood 2002;99:2685-2693*). Rationale for this regimen is that tumor cells are less resistant on prolonged exposition to low doses of chemotherapy than to short exposition to high doses. Aims. To assess clinical outcome in patients with aggressive B-NHL with poor prognostic factors (very aggressive histollogy, IPI ≥2 and/or high proliferation index; PI>80%, measured as percentage of Ki67+ cells) treated with DA-EPOCH-R in first line. Methods: From May 2005 to March 2011, 24 patients, median age 50.5 years (range 17-75) with poor prognosis, aggressive B-NHL, were included. Male/female ratio was 14/10.



Out of 24 patients 20 were DLBCL, 2 were Burkitt lymphomas and 2 were mantle cell lymphomas. Elevated LDH had 19 out of 24 patients (79%) and 18 out of 24 patients (75%) were in Ann Arbor stages 3 and 4. IPI ≥2 had 19 out of 24 patients (79%). DA-EPOCH-R was administred according to original schedule. Six of these patients proceeded to autologous hematopoietic stem cell transplantation (autoHSCT) as consolidation therapy due to very aggressive histology and biology of disease. In subgroup of 20 patients with DLBCL with median age of 55.5 years (range 17-75), 16 (80%) had elevated LDH, 16 (80%) were Ann Arbor 3 and 4 and 17 (85%) had IPI ≥2. *Results*: Overall response rate (ORR) was 75% (18/24), including 14 (58%) complete responses (CR) and 4 (17%) partial responses (PR). Overall survival (OS) was 52% at 5 years (median not reached) with median follow up of 14 months (range 0-63). Of patients who achieved complete remission, 12 are still in CR with progression free survival (PFS) 75% at 5 years. In subgroup of patients with DLBCL 15 out of 20 patients responded to therapy (ORR 75%), 11 patients achieved CR (55%). Overall survival in this subgroup was 50% with median follow up of 11 months (range 0-63). Summary/Conclusions: In this report we included only patients who had aggressive B-NHL with poor prognostic factors. Our results are in line with previous report (*Garcia-Suarez J et al. British Journal of Haematology 2007;136:276-285*) who also find this regimen effective as first line treatment in high risk DLBCL patients. In certain subgroups of patients it may be option to continue treatment with autoHSCT as consolidation therapy. Only 2 patients relapsed during follow up period. All 6 patients who were transplated are still in CR. When subgroup of patients with high risk DLBCL was analysed separately, the results were similar as for entire group. We conclude that DA-EPOCH-R is highly effective regimen as first line treatment in high risk group of aggressive B-NHL.

1432

OUTCOME OF CHRONIC LYMPHOPROLIFERATIVE DISORDERS ASSOCIATED WITH HEPATITIS VIRUSES INFECTIONS - SINGLE CENTER EXPERIENCE

[4]*Pathophysiology Department, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

Background. Chronic lymphoproliferative disorders (CLD) frequently associate hepatitis viruses infections. The role and timing of antiviral therapy remains to be defined - for HBV early therapy seems to prevent viral reactivation, for HCV the best strategy is not established. *Aims*. Analysis of hematological and virologic response after chemo/immunotherapy alone or combined with antiviral therapy in patients diagnosed with CLD associating hepatitis viruses B, C, D. Methods. Retrospective analysis performed in Hematology Department - Emergency University Hospital Bucharest, on patients diagnosed with CLD (lymph node/bone marrow biopsy) and positive serological tests for hepatitis viruses between December 2007-July 2010; all of them received chemo/immunotherapy +/- antivirals. The hematological response was assessed using CT scan and bone marrow biopsy, the virologic response by determining quantitative viremia using TaqManPCR method. *Results*. We selected a group of 52 patients with CLD and hepatitis virus infection receiving therapy. HCV had 26/52(50%), 23/52(44,23%) HBV and 3 patients double/triple infection. Different hystologic types were found and divided into indolent/aggressive type: see Table 1. Chemotherapy+/-Rituximab was given in 19/52(36,53%) patients, 32/52(61,53%) received also antiviral therapy and one patient Interferon alone. In the group of patients receiving Rituximab representing 17/52 (32,69%), 11/17(64,7%) associated HBV and 6/17(35,3%) HCV. All HBV patients with R-chemotherapy associated antivirals. Four HCV patients received R-chemotherapy and antivirals. Interferon was administered in 13/52(25%) HCV patients and one HBV. Ribavirine+Interferon received 2 patients. Lamivudine was administred in 17/52(32,69%) patients and Entecavir to one. Complete hematologic response was assessed according to the indolent/aggressive type of CLD and HCV vs HVB - see table 2. A possible explanation is that HCV was mostly found in indolent types of CLD, ressponding better to therapy. Twenty six patients achieved complete response, most of them receveing chemotherapy and antiviral, 10 chemotherapy alone and one only Interferon.

Hystologic type	Indolent	Aggressive
Diffuse large B-cell NHL	-	16/53(30,76%)
Small B-cell NHL (marginal, lymphocytic)	16/53(30,76%)	-
Chronic lymphocytic leukemia	2/53(3,66%)	-
T-cell NHL	-	4/53(7,69%)
Follicular NHL	3/53(5,76%)	-
Mantle NHL	-	1/53(1,92%)
Hodgkin's lymphoma	3/53(5,76%)	-
Waldenstrom macroglobulinemia	2/53(3,84%)	-
Total	51(98,08%)	2(1(40,38%)

Table 1. The chronic lymphoproliferative disorders - histologic types.

Hematologic response	Complete	Partial	Progressive disease
Indolent CLD	13/53(28,84%)	13/53(25,15%)	3/53(5,61%)
Aggressive CLD	13/53(21,15%)	3/53(5,76%)	7/53(13,46%)
Total	26/53(50%)	16/53(26,92%)	13/53(25,07%)
HCV infection	16/53(30,76%)	8/53(15,38%)	2/53(3,84%)
HBV infection	10/53(19,23%)	4/53(7,69%)	9/53(17,30%)
Total	26/53(50%)	12/53(23,07%)	11/53(21,15%)

Table 2. Complete hematologic response assessed according to the indolent/aggressive type of CLD and HCV vs HVB infection.

Complete hematologic response associated complete virologic response (negative viral load) in 13/26(50%) patients, partial response only 2 and progressive disease 3 cases of complete virologic response. In total, 18 patients obtained complete virologic response - 13/18 (72,22%) complete hematologic responses, 7/18(38,88%) with HBV and 6/18(33,33%) with HCV; one case of each virus had partial response and progressive disease 3(6,66%) patients with HBV and none with HCV. Most patients with CVR had chemotherapy+antivirals 10/18 (55,55%). Positive viremia was found in 34/52(65,38%) - 22 with combined therapy, 13 with chemoimmunotherapy. Viral reactivation was detected in 2 patients, both with HBV receiving R-chemotherapy+antiviral, one achieving complete hematologic response, and one with progressive disease. Cryoglobulins were found in 8/52(15,38%) patients, all associating HCV, 5 with indolent disease; equal number of complete/partial responses (4) were achieved, but only one complete virologic response. Conclusions. Best hematological responses (complete and partial) were obtained in indolent types of CLD associated to HCV infection treated with combination of chemo/immunotherapy and antiviral therapy. The complete virologic response was revealed in patients with combined therapy, but a significant number associating antivirals still have detectable viremia, revealing that virologic response doesn't parallel the hematological one. Still, adding antiviral therapy seems to be the best option as it prevented viral reactivation in most cases.

1433

INTRAPLEURAL INSTILLATION OF RITUXIMAB FOR THE TREATMENT OF MALIGNANT PLEURAL EFFUSIONS IN CD20+ NON-HODGKIN´S LYMPHOMA

S Voloshin,[1] V Shuvaev,[1] A Shmidt,[1] A Kuvshinov,[1] E Rusanova,[2] E Zueva,[2] K Abdulkadyrov[1]

[1]*Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation*

[2]*Saint-Petersburg Pavlov State Medical University, Saint-Petersburg, Russian Federation*

Background. Malignant pleural effusion is a common clinical problem in patients with neoplastic disease. Approximately 10% of malignant pleural effusions are caused by Non-Hodgkin´s lymphoma (NHL). Aim. Four patients with NHL presented with unilateral pleural effusion, flow cytometry revealed CD19 and CD20 positive malignant cells. Two patients with follicular (grade 2) histologycal type of NHL (FL) had lifetime of effusion above two months. Two patients with diffuse large cell B-cell histologycal type of NHL (DLBCL) had lifetime of effusion less one month. Methods and results. Systemic chemotherapy (FCR or R-CHOP) and repeated percutaneous drainage were unable to control the effusions. Rituximab was instilled in a dose-escalating manner (starting dose 100 mg, maximal dose 400 mg) via the chest tubes into pleural spaces. The effusions resolved in both patients with DLBCL in two-three weeks and the patients are free of symptoms: one - for six months and another - for two years to date. In two patients with FL in 60 days after the application of rituximab, pleural effusion is still present but reduced in size. Flow cytometry of pleural effusion performed after intrapleural instillation of rituximab showed CD19 positive cells with lack of CD20 epitope, which could be explained by either engagement or destruction of the CD20 epitope upon interaction with rituximab making the detection of the CD20 molecule impossible by routine flow cytometry. Complete remission was achieved in both DLBCL and FL patients. High-dose chemotherapy with stem cells support were used as consolidation in one patient with DLBCL. One patient with FL underwent pleurodesis (infusion of 5% suspension of talc in chest tube drainage) with complete disappearance of malignant effusion. Conclusions. Local therapy with intrapleural Rituximab may be a promising novel treatment option for management of malignant effusions in CD20+ NHL. Although our patients had no clinically significant adverse effects, further analysis of rituximab's activity and safety when applied intrapleurally are warranted. Long-lasting malignant effusion may cause negative impact on the local treatment efficacy.

1434

RITUXIMAB (RTX), METHOTREXATE (MTX) AND TEMOZOLOMIDE IS A SAFE OPTION FOR PATIENTS WITH PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA (PCNSL) AND POST TRANSPLANT LYMPHOPROLIFERATIVE DISEASE (PTLD)

A Feitosa Ribeiro, G Fleury Perini, R Helman, C Bley Nascimento, J Kutner, F Souza Santos, M Rodrigues, R Alves Assis, N Hamerschlak

Hospital Albert Einstein, Sao Paulo, Brazil

Background. Although considered a curable form of lymphoma, PCNSL prognosis is still dismal. The backbone of treatment, the use of drugs with high cerebrospinal fluid (CSF) penetration such as MTX and cytarabine, can be toxic in the majority of patients, especially in the elderly. The role of RTX is still not defined in these patients, and new drugs, like temozolomide are still under study. Aims: Describe the initial experience of a single institution in Brazil with a combined treatment with chemotherapy and immunotherapy in older or immunocompromised patients with PCNSL. Methods: From 2007 until now, all patients at our institution were treated following a regimen consisted of: RTX 375mg/m2 and MTX 1g/m2 on D1, D10 and D20, temozolomide 100mg/m2 D1-D5 and prednisone 120mg/m^2 every other day from D1 to D45. Intrathecal chemotherapy with MTX 15mg was delivered on D1, D5, D10 and D15. All patients received urine alkalinization and folinic acid rescue after MTX treatment until MTX levels were <0.01 mmol/L. Patients achieving at least PR received five cycles of maintenance therapy, consisting of RTX and MTX 1g/m2 D1 and temozolomide 100mg/m^2 D1-D5. *Results*. Five HIV-negative patients not suitable for standard protocols were treated in our institution with the described protocol. Two patients, 45 and 60 years old, were diagnosed as monomorphic PTLD, due to past history of liver transplant. The three other patients aged older than 70 years. The median age was 78 (range: 45-82). All patients achieved at least PR after first cycle (4 of them achieved CR) and proceeded to maintenance therapy. With a median follow up of 20 months (1,4 - 48,5) the overall survival was 53% (CI95% 5-100). No relapses were observed, and one patient is still on maintenance therapy. Only one of the patients (PTLD) died, due to infectious complications of chemotherapy and immunossupressive treatment. No neurotoxicity was observed in clinical exams. *Conclusions* Despite the small number of subjects and short follow up, our initial experience shows a regimen with temozolomide, RTX and MTX (1g/m2) without radiotherapy is a safe and feasible treatment for elderly patients with PCNSL and patients with CNS PTLD.

1435

BENDAMUSTINE IN THE TREATMENT OF RELAPSING AND REFRACTORY LYMPHOID MALIGNANCIES: A SINGLE CENTER EXPERIENCE

A Janssens, H Schoemans, T Devos, D Dierickx, M Delfogre, J Maertens, P Vandenberghe, G Verhoef

UZ Leuven, Leuven, Belgium

Background and Aims. Since 03-2009 we have had the opportunity to treat relapsing and refractory lymphoma patients with bendamustine. 29 patients with either follicular (3), mantle cell (2), marginal zone lymphoma (10), hairy cell leukemia (1), CLL (7), DLBCL (4) and Hodgkin's lymphoma (2) were treated with this bifunctional alkylating agent. Median age of the 27 NHL patients was 73y with a M/F of 11/16. These patients were extensively pretreated (median 3 (range 1-7)). The 2 female Hodgkin patients were younger (25 and 30y) with 5 to 6 pretreatment regimens. *Methods*. Bendamustine was administered every 4weeks for up to 6 cycles at a dose of 90 mg/m^2 days 1 and 2. For the CLL patients a dose of 70 mg/m^2 on days 1 and 2 was chosen. Rituximab was added on day 1 of each cycle in 14 patients. *Results*. 17 patients (59%) received the intended 6 cycles of bendamustine. Early withdrawals were due to adverse events (n=2), disease progression (n=4) or patient decision (n=3). Dose reductions and treatment delays occurred respectively

in 6/138 (4%) and 20/138 (15%) of cycles . Hematological and gastrointestinal toxicity were the most common adverse events. Grade 3-4 leucopenia , thrombocytopenia and anemia were seen respectively in 7/28, 7/28 and 5/28 patients in one or more cycles. Nausea and vomiting was manageable with the association of a 5-HT3 antagonist. 26 patients were evaluable for response. In 18/26 patients (70%) at least a partial response was observed. No response was seen in the patients with DLBCL. The not responding CLL patient appeared to have Richter transformation. Follow up is too short to look at progression free survival. 6/10 patients are still in remission 6 months after the end of treatment. *Conclusions*. Bendamustine demonstrates activity in this extensively pretreated population with lymphoid malignancies without safety concerns. Longer follow up will show how durable these responses are.

1436

INCIDENCE OF GASTRIC INVOLVEMENT IN NONGASTRIC MARGINAL ZONE LYMPHOMA

S Yoon, H Jung, S Kim, DH Yoon, JR Huh, C Suh
Asan Medical Center, Seoul, South-Korea

Background. There was an observation that a significant proportion of patients presenting with nongastric marginal zone lymphoma (MZL) had gastric involvement as well, thus arguing for esophagogastroduodenoscopy (EGD) as routine diagnostic workup of extranodal MZL. However, the incidence of gastric involvement in nongastric MZL has not been investigated in Asia, where the incidence of MZL is higher than that in Western countries. *Aims*. The present study was undertaken to assess the incidence of gastric involvement in nongastric MZL. Methods. Between April 1993 and December 2010, 153 consecutive patients with nongastric MZL were treated in the Asan Medical Center, Seoul, Korea. We retrospectively analyzed the results of these patients. Results. The median age at diagnosis was 51 years (range, 16 - 79 years), and male patients consisted of 42% (n=64). One hundred patients (86.3%) initially presented as localized disease (Ann Arbor stage I or II), 2 (1.3%), 15 (9.8%), 4 (2.6%) patients were stage IIIa, IVa, IVb, respectively. Most of the patients (n=136, 88.9%) had extranodal involvement of lymphoma at a single site. The most common primary sites were ocular adnexa or orbit (48.4%), intestine (11.1%), lung (9.8%) and nasal sinus (5.9%). Among those 153 patients, 47 (30.7%) had undergone EGD as part of their initial workup. None of these 47 patients was found to have gastric involvement of lymphoma. The most common endoscopic and pathologic finding of EGD was chronic superficial gastritis (n=16, 34%). *Summary*. None of the 47 patients who had undergone EGD had gastric involvement of EGD. Our findings do not support routine EGD in patients with extranodal MZL.

1437

A MONOCENTRIC EXPERIENCE OF CASTLEMAN'S DISEASE

R Porrini, B Veggia, G Antolino, A Ferrari, E Conte, E Montefusco, G La Verde, B Monarca
Ospedale Sant'Andrea, Roma, Italy

*Backgroun.*Castleman's Disease (CD), is a rare and poorly understood disease characterized by a pathologic growth of lymphoid tissue. This disease is composed of two different type: unicentric and multicentric disease. Actually the optimal therapy is unknown. We report our experience about patients with diagnosis of CD, seen at our Institution since 2004. Methods and Aims: From January 2004 to December 2010 we observed 6 patients affected by CD (2 males, 4 female, median age 65, range 49-82) Unicentric disease was defined as a solitary mass; multicentric disease compromised patients with multiple masses. We evaluated the involvement of human herpesvirus 8 (HHV-8) in all patients. Clinical, radiologic and laboratory data were analyzed to evaluate treatment response. Results: Among 6 patients, 2 presented unicentric disease, 4 multicentric. All patients underwent lymphonodal biopsy and were so classified: 1 in plasma cell type, 4 hyaline-vascular, 1 mixed; the 2 patients with multicentric disease presented hyaline-vascular histology. At evaluation of HHV-8 infection, 2/6 resulted positive at diagnosis; this patients presented a multicentric disease with systemic symptoms. The patient with plasma cell type (a female of 50 years old) developed CD from 6 years of diagnosis of POEMS syndrome; she was treated with high dose cyclophosfamide and was planned for autologous stem cell transplant. The 2 patients with HHV-8 infection were treated with polichemotherapy, resulting resistant. After chemotherapy they were treated with oral valgancyclovir, both obtaining a complete remission after 2 months of treatment and up to now they are in complete remission after 4 and 2 years respectively. The remaining 3 patients, the 2 monocentric disease underwent to lymphonodal excision and the last one 1 (multicentric CD) was submitted only to diagnostic lymphonodal biopsy. These 3 patients remaining symptoms free without any other treatment from 7,1 and 2 years respectively Conclusions: In our series, the asymptomatic patients (either unicentric or multicentric) did not need any treatment. The 2 symptomatic patients failing chemotherapy and benefited for antiviral treatment. A longer follow up and a larger series are needed to evaluate the better therapy for either symptomatic or asymptomatic disease.

1438

18FDG-PET/CT IN T-CELL LYMPHOMAS

Z Miltényi, F Magyari, E Páyer, Z Tóth, S Barna, I Garai, Á Illés
University of Debrecen, Debrecen, Hungary

Background. T-cell lymphomas has different clinical features, than B-cell lymphomas, thus we took it important to investigate the utility of PET/CT, especially interim PET/CT. Patients and methods: We examined between 01/01/2007-01/05/2010 T cell lymphoma patients at PET/CT Medical, Diagnostical Co in Budapest and Debrecen. Results: 20 T-cell lymphoma patients underwent PET/CT. FDG uptake was observed in every cases. The average SUVmax value was 13.52 (5.02-33.6) at staging. Patients achieving complete metabolic remission (CMR) - evaluated at interim PET/CT - had an average SUVmax value of 16.71 (5.2-33.6) at the time of staging, whereas the patients who did not achieve CMR, had an average SUVmax value of 6.41 (5.02-9) at staging, but this was not significant, p=0.062. A median follow-up was 13.54 (2-27) months. Overall survival was higher in patients, who were in CMR, than who were not (not significant). Overall survival was higher in patients who had higher SUVmax, than who had lower SUVmax (not significant). The median SUVmax was chosen as the cutoff value. Conclusions: Based on all of these findings at T-cell lymphomas, PET/CT has the authority particularly through staging. The role of interim examinations are still challenging, further studies are needed to evaluate its exact role.

1439

MONITORING OF MINIMAL RESIDUAL DISEASE IN MANTLE CELL LYMPHOMA

B Tichy,[1] D Salek,[2] A Mareckova,[1] J Supikova,[1] A Janikova,[2] S Pospisilova,[1] J Mayer[1]
[1]*University Hospital Brno, CEITEC, Masaryk University, Brno, Czech Republic*
[2]*Dept. of Internal Medicine - Hematology/Oncology, University Hospital Brno, Brno, Czech Republic*

Background. Mantle cell lymphoma (MCL) is characterized by a specific chromosomal translocation t(11;14)(q13;q32) resulting in cyclin D1 over-expression and cell-cycle dysregulation. It is historically considered to be incurable with conventional therapeutic approaches, with a median overall survival of only 4-5 years. The minimal residual disease (MRD) monitoring may help in prediction of clinical relapse and may allow an early treatment of the relapse. *Aims*. The study was made to investigate the clinical reliability and predictive value of MRD monitoring in MCL using polymerase chain reaction (PCR). Methods. A proportion of lymphoma cells in peripheral blood was monitored by quantitative PCR during the course of the disease in 15 patients after chemo- or immunochemotherapy. The t(11;14) breakpoint (n=14) or IGHV clone-specific sequence (n=1) were used as the molecular targets. Molecular remission (PCR negativity) was defined as two consecutive samples with no specific amplification, molecular relapse as two consecutive positive samples after period of PCR negativity or as an increase in number of PCR copies in two consecutive samples (in cases where PCR negativity after induction therapy was not achieved). When molecular relapse in peripheral blood was detected, the parallel bone marrow sample was also tested. Results. The molecular remission was achieved in 14 of 15 observed patients. The average duration of molecular remission in patients who relapsed (n=6) was 30 months (range 11-51). Of the six relapsing patients, 5 of them were previously PCR negative. Two patients have gone through 2 relapses. In total, 7 of 8 observed clinical relapses were preceeded by reappearance of PCR positivity or increase in number of t(11;14) breakpoint copies. The average period between a molecular relapse in peripheral blood and a clinical relapse was 3.3 months (range 1-6). At the time of relapse, the PCR positivity was detected in all cases both in peripheral blood and bone marrow. Summary. MRD level proved to be a strong predictor of clinical relapse in mantle cell lymphoma. This is documented by very good test statistics (positive predictive value 100%, negative predictive value 90%). The detection of

molecular relapse enables an early therapeutic intervention (for example with immunotherapy) resulting maybe in a prolongation of the period without a clinical relapse.

1440

RITUXIMAB PLUS BENDAMUSTINE (RB) REGIMEN IN ELDERLY PREVIOUSLY UNTREATED PATIENTS WITH INDOLENT, NON FOLLICULAR NON HODGKIN LYMPHOMA: PRELIMINARY DATA OF A SINGLE CENTRE STUDY

E Pennese, N Di Renzo
Vito Fazzi, Hospital, Lecce, Italy

Background: Bendamustine (B), a byfunctional chemotherapic agent, has shown considerable activity for solid and lymphoid malignancies. B has recently become available for clinical use, as a first-line treatment for chronic lymphocytic leukaemia (CLL) and as salvage therapy after Rituximab or Rituximab-based regimen, for early relapsed or refractory indolent B-cell lymphoma (NHL). Recent clinical trials have found B to be well tolerated and effective, both as first line treatment in CLL and as a treatment in relapsed or refractory indolent NHL. *Aims*: to assess the efficacy and toxicities of B in combination with Rituximab ® in elderly previously untreated patients (pts) with indolent, non follicular NHL. Methods: from October 2008 to May 2010, 20 pts (M/F=15/5) with previously untreated indolent, non follicular NHL were enrolled in the study. The median age was 74 yo (range: 64-85); seventeen pts (85%) were more than 70 yo and 11 (55%) had B-CLL/SLL, 8 (40%) LPL/WM an 1 (5%) SMZL. Eight pts (40%) present an ECOG PS > 1. ENS involvement was present in one (5%) and the BM involvement in all pts (100%). Fourteen (70%) pts had co-morbidity with more than 2 disease in 30% of cases. R-B regimen consisted of Rituximab 375 mg/mq iv on day 1 and Bendamustine 80 mg/mq iv on days 1, 2; all pts received six-eighth cycles delivered every 21-28 days; the response assessment was planned after 3 cycles and at the end of treatment. Median number of cycles delivered was 5 (range 3-8); 14 pts (70%) completed the planned treatment; dose reduction occurs in 4 pts (20%). Nine pts (45%) received G-CSF at the dose of 300 mcg/die as primary (10%) and secondary (25%) prophylaxis. ESA support was needed in 4 (22%). *Results:* complete response (CR) was achieved in 11 (55%) and partial response (PR) in 9 (45%) of pts with an ORR of 100%; no toxic death or relapses occurs. Ten out of 11 (91%) pts with B-CLL/SLL achieved CR, while all pts with LPL/WM obtained stable RP. The regimen was safe and well tolerated with dose reduction occurring only in 4 pts (20%). The mainly adverse events recorded was neutropenia occurring in (39%); severe neutropenia (WHO grade 3-4) was recorded only in 4 pts (20%). No extra-haematological toxicity was observed. With a median follow-up of 16 months (range: 4-23) OS, PFS and RFS were 94% and 100% respectively. *Conclusions*. RB is an effective regimen for elderly pts with previously untreated indolent non follicular NHL, mainly in CLL/SLL. RB is a safe regimen with major but tolerable toxicities consisting in myelosuppression. A longer follow-up is needed to define response duration and long-term safety.

1441

FDG PET CT SCAN ROLE ON DIAGNOSIS AND INITIAL STAGING OF LYMPHOPROLIFERATIVE DISEASES

P Yiakoumis,[1] M Moschogiannis,[1] T Vassilakopoulos,[2] S Sachanas,[1] M Angelopoulou,[2] V Prassopoulos,[3] P Rontoyianni,[14] C Kalpadakis,[5] G Pangalis[1]
[1]*Athens Medical Center, Athens, Greece*
[2]*Haematology Department, Laikon General Hospital, University of Athens, Athens, Greece*
[3]*Nuclear Medicine Department, Hygeia Hospital, Athens, Greece*
[4]*Nuclear Medicine Department, Evangelismos Hospital, Athens, Greece*
[5]*Haematology Department, University of Crete, Heraklion, Greece*

Background: FDG PET CT scan (PET) was recently introduced as a part of initial staging of many lymphoproliferative diseases. PET is currently used during initial and restaging to detect disease sites which are not recognized with other clinical and laboratory methods. However, the role of PET on diagnosis and staging of lymphomas remains to be seen. Aim: To study the findings of PET during initial diagnosis of lymphoma patients, to compare them with the findings of the conventional staging methods and to examine the possible role of PET on initial staging of lymphoma, in respect to its subtype. Methods: From 2003-2010, 131 patients with recent diagnosis of lymphoma, underwent PET as part of their initial screening. All patients underwent conventional clinical and laboratory initial staging with CT scan and bone marrow biopsy (BMB) and were staged according to standard systems. A comparison between conventional vs PET findings and staging, including special sites of disease, ie spleen and bone marrow (BM), in relation with the discrete subtype of lymphoma, was made. Results: 131 patients performed PET during initial diagnosis of lymphoma in Hematology Clinics of University of Athens and Athens Medical

Table 1. PET vs CT/ BMB findings in lymphoma pts.

	PET(+) findings /CT(-) % per disease(#)					CT(+) findings/PET(-) % per disease(#)			BMB (+)
	Lymph	*Spleen*	*Lung*	*BM*	*Other*	*Lymph*	*Spleen*	*Lung*	
HL (65 pts)	43 (28)	9 (6)	5 (3)	6 (4)	20 (13)	9 (4)	3 (2)	3 (2)	15 (10)
FL (21 pts)	38 (8)	0	0	5 (1)	14 (3)	9 (2)	0	0	29 (6)
DLBCL (18 pts)	39 (7)	0	6 (1)	0	33 (6)	6 (1)	0	0	0
SMZL (10 pts)	20 (2)	0	0	10 (1)	0	0	30 (3)	0	90 (9)
MZL (6 pts)	33 (2)	0	0	0	0	17 (1)	17 (1)	0	17 (1)
SLL (4 pts)	25 (1)	0	0	25 (1)	0	0	0		75 (3)
Other (7 pts)	14 (1)	0	0	14 (1)	14 (1)	14 (1)	43 (3)	0	57 (4)

The lymphoma subtype was Hodgkin (HL) in 65 pts, follicular in 21 pts, DLBCL in 18 pts (3 primary mediastinal), and other lymphoproliferative diseases in 27 [10 splenic marginal zone (SMZL), 6 other marginal zone (MZL), 4 small lymphocytic lymphoma (SLL), 3 multiple myeloma (MM), 2 T-NHL, 1 mantle cell lymphoma and 1 NK leukemia]. Differences between findings of CT and PET were noted in 89 patients (68%) and in 75 of them (57%) PET revealed more sites of disease compared with CT. In 17 patients (13%) CT revealed abnormal findings which did not present increased uptake on PET. In two of those patients, both with HL, lung nodules<1cm were found on CT, not revealed by PET. With PET findings included, patients' stage was increased in 13 (10%) and decreased in 1 (1%). From 33 patients (25%), who presented bone marrow infiltration by biopsy, only in 8 (6%) PET revealed increased bone marrow uptake consistent with disease infiltration. Among those 8 pts, 4 had HL, 1 SMZL, 1 FL grade 2, 1 SLL and 1 T-NHL. Further on, among 30 patients (23%) who presented spenomegaly at CT scan, 21 had increased uptake of PET in the spleen while only 9 (7%), (3 SMZL, 2 HL, 1 MZL, 1 NK leukemia, 1 SLL and 1 T-NHL) did not. Additionally, 6 pts (5%), all with HL, presented increased spleen uptake without splenomegaly on CT (Table 1). *Conclusions*. PET confirms practically all CT findings, as far as lymphadenopathy is concerned and ocassionally reveals additional involved sites. It also helps in defining splenic infiltration. It cannot frequently reveal bone marrow infiltration as compared to BMB. The histological subtype of disease should be taken under consideration for the interpretation of PET results. The clinical significance of PET contribution in staging of lymphomas should be further clarified, adding, in controversial cases, tissue biopsies.

1442

DIFFERENT RISK FACTORS FOR RELAPSED FOLLICULAR LYMPHOMA TREATED WITH CHEMOTHERAPY VERSUS IMMUNOCHEMOTHERAPY

B Andjelic, B Mihaljevic, D Antic, M Todorovic
Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. All widely accepted prognostic indices in follicular lymphoma (FL) were primarily designed for patients with newly diagnosed disease. Nowadays, the precise assessment of risk also in relapsed FL patients seems to be necessary, since lot of treatment strategies are available for these patients. Aims: The aim of this study was to compare the outcome of FL patients in first relapse treated with chemotherapy and immunochemotherapy and to identify high risk patients in both groups. The second aim was to evaluate the impact of adding rituximab to chemotherapy on overcoming the negative prognostic impact of previously identified risk factors in patients treated with chemotherapy. The third aim was to compare the outcome in both groups for identified risk factors in patients treated with immunochemotherapy. Methods: The retrospective analysis was performed on 60 patients with diagnosed

first relapse of FL grade I, II or IIIa, in the period February 2002-April 2009. In the first line, the patients were treated with R±CHOP or R±CVP. In the first relapse they were treated with fludarabine based regimens, 33 patients received immunochemotherapy (R-FC, R-FND) and 27 chemotherapy (FC, FND). The characteristics in first relapse examined as possible risk factors were age, higher histological grade in relapse, presence of B symptoms, presence of "bulky"tumor (>10 cm in diameter), ECOG performance status (ECOG PS), spleen enlargement, FLIPI score, hemoglobin level, LDH and ESR. Results: The median follow up after first relapse of FL was 26 months (range 4-97 months). The patients treated with immunochemotherapy had significantly longer time to second relapse (log rank 8.352, p<0.01) and overall survival after first relapse (log rank 8.234, p<0.01). Multivariate Cox regression analysis identified ECOG PS >1 and FLIPI high risk as the independent risk factors for patients treated with chemotherapy. Older age (>60 years) and presence of B symptoms in multivariate Cox regression analysis were identified as the independent risk factors for patients treated with immunochemotherapy. In the comparative analysis, significantly longer overall survival after relapse was revealed in patients with ECOG PS >1 (log rank 12.679, p<0.01), FLIPI score ≥3 (log rank 14.712, p<0.01) and B symptoms (log rank 4.676, p<0.05) if they were treated with immunochemotherapy. The improvement in survival after relapse by addition of rituximab was not recorded in elderly patients (log rank 0.001, p>0.05). Conclusions: The treatment with immunochemotherapy in first relapse of FL brought to clear benefit in survival. Older age and presence of B symptoms are risk factors for poor outcome in patients treated with immunochemotherapy. The addition of rituximab to chemotherapy overcame the negative prognostic impact of high FLIPI risk and poor ECOG PS in first relapse of FL. Studies with large series of patients treated with immunochemotherapy in relapsed FL are needed, in order to identify patients who maybe require more aggressive therapeutic approach.

1443

SUCCESSFUL TREATMENT WITH PREDNISONE ALONE FOR BING NEEL SYNDROME

L Masini, A Ferrari, L Facchini, B Gamberi, A Imovilli, I Capodanno, I Alvarez, F Ilariucci, P Avanzini, F Merli
Arcispedale Santa Maria Nuova, Reggio Emilia, Italy

Background.Waldenstrom's macroglobulinemia ((WM) is the result of clonal proliferation of lymphocytes that produce monoclonal immunoglobulin M. Many central nervous system (CNS) complications have been described, the majority associated with blood hyperviscosity syndrome. However, CNS infiltration by plasmacytoid lymphocytes (Bing -Neel syndrome) has only rarely been reported. We report two cases of diffuse Bing-Neel syndrome presentation effectively treated with low-intermediate dose prednisone. Case summary. Case 1. A 81-year old man diagnosed with Waldestrom's macroglobulinemia and progressive cognitive decline was admitted for seizure and coma in November 2003. Electroencephalogram showed mild diffuse cerebral dysfunction and moderate right frontotemporal slowing with epileptiform discharges. Cerebrospinal fluid (CSF) examination was unremarkable. Cryoglobulin testing was negative. Computed tomography of the head showed enhancing heterogenous periventricular hipodensities. Phenytoin was started with sudden neurological improvement. In the following months however the patient showed progressive cognitive deterioration with dizziness, confusion and lethargy associated with persistent monoclonal immunoglobulin In May 2004 low dose prednisone was started with complete and durable mental restoration. Case 2. A 61 year old man diagnosed with WM was admitted for septic fever, haemolytic anemia and mental deterioration in January 2010. He was started on steroid treatment with clinical and haematological improvement. In December 2010 due to the monoclonal immunoglobulin increase the patient received three weekly courses of Rituximab and was admitted with confusion and septic fever in December 2010. Despite of the septic state resolution the patient showed persistent cognitive decline with drowsiness. CSF examination revealed high protein concentration without cellular abnormalities. MRI of the brain showed left parietal white matter T2 hyperintensities. Intermediate dose steroid treatment (50 mg Prednisone) was started achieving remarkable clinical improvement. with persistent IgM concentration. Conclusions. Bing Neel syndrome is a rare and potentially treatable complication of WM. In patients presenting with rapidly progressive cerebral deterioration and monoclonal immunoglobulin M, Bing-Neel syndrome should be considered and effectively treated with corticosteroid therapy.

1444

PREVALENCE OF HAIRY CELL LEUKEMIA IN HUNGARY WITH SPECIAL EMPHASIS ON THE TREATMENT HABITS OF HUNGARIAN HEMATOLOGISTS

E Sari,[1] S Fekete,[2] T Masszi,[2] M Udvardy,[3] A Kiss,[3] J Iványi,[4] G Radványi,[5] Z Borbényi,[6] A Szoke,[6] M Dávid,[7] H Losonczy,[7] J Pammer,[7] L Szerafin,[8] M Egyed,[9] P Rajnics,[9] A Illés,[10] L Váróczy,[10] J Demeter[11]

Background. Hairy cell leukemia is a rare disease, it's incidence in Hungary is 2 patients per million inhabitants. According to the international guidelines, the treatment of choice drugs in HCL are cladribine and pentostatin. Overall survival of treated patients does not differ significantly from that of the general population. *Aims*. To establish the consequences of treatment choices on the quality of hairy cell leukemia care. Methods: We have sent questionnaries on treatment habits of Hungarian haematologists in HCL and on the main characteristics the HCL patients they care for. All Hungarian haematological departments and ambulances responded enabling us to evaluate retrospectively the data of 180 HCL patients. Results: Seventysix percent of the patients were male, 24% were female. Average age at diagnosis was 57 years (range 34-92). First line treatment modalities were the following: interferon-alpha (73% of cases), cladribin (14%), splenectomy (5%), watchful waiting (6%). Cladribine was given as second line treatment in 56% of cases, while further second line treatment options applied were alpha-interferon (32%), watchful waiting (31%), rituximab (7%), pentostatin (3%), splenectomy (1%). First line alpha-interferon was given for less than 3 monts in 19 percent of cases, for 3 to 12 months in 33% of patients, while duration of first line alpha-interferon treatment was more than 12 months in 48% of cases. Looking at second line treatment 43% of patients received alpha-interferon for 3 to 12 months, while the percentage of patients receiving alpha-interferon for more than 12 months was even higher, 57% of cases. At the time of our survey 77% of the patients had non-symptomatic stable disease, 6% had non symptomatic progressive disease, 6% had symptomatic progressive disease and 4% had symptomatic progressive disease, all three latter categories necessitating further treatment. Conclusions: Although cladribine treatment is cost-effective and one treatment cycle results in durable complete remission in 75-80% of cases, in Hungary long lasting interferon-alpha treatment is still wide-spread, because of the peculiar differencies of financing alpha-interferon and cladribine. Cladribine, even the sc. form receives financing only for inpatients, at the primary expense of the hospital. Looking at our findings, earlier and more widespread use of cladribine seems to be justified both from the medical and from the pharmoco-economic point of view.

Background. Introduction of the anti-CD20 antibody, Rituximab, in therapy of patients with diffuse large B-cell lymphoma (DLBCL) significantly improved survival and altered the predictive values of known prognostic factors in DLBCL. Assessment of tumor cell proliferation based on Ki-67 expression yielded conflicting prognostic predictions of patients with diffuse large B-cell lymphoma (DLBCL). *Aims.* The aim of this study was to evaluate the role and prognostic significance of the Ki-67 proliferation index (PI) in DLBCL patients treated with rituximab plus CHOP (R-CHOP). METHODS: Ki-67 was assayed immunohistochemically in tissue samples of 145 patients with newly-diagnosed DLBCL treated with R-CHOP between January 2007 and January 2011. *Results*. The complete response (CR) rates following R-CHOP administration were not significantly different, based on Ki-67 expression status (P=0.804). The 1-yr event-free survival (EFS) rates were: 82,2% in patients with a low index Ki-67 (Ki-67 < 80%, n = 107) compared with 73,7% in patients with a high index (Ki-67 ≥ 80%, n = 38). In patients with a low IPI (≤ 2), one-year survival was 87,4% and 69,8% in those with a higher index (IPI>2). In patients with diffuse large B-cell lymphoma Ki-67 PI of 80% was found to significantly discriminate patients with good or bad prognosis when combined with low IPI score (AUC = 0.649, P = 0.013). In multivariate analysis, Ki-67 expression combined with low IPI score (≤ 2) was a significant prognostic factor for EFS [hazard ratio (HR) = 1.760; 95% confidence interval (CI) 1.030-3.008; P = 0.039]. *Conclusions*. In diffuse large B-cell lymphoma, a cut-off value of 80% can distinguish patients with a good and bad prognosis when combined with another prognostic factor as low IPI score.

DIFFUSE LARGE B-CELL LYMPHOMA WITH HEPATITIS C VIRUS- INFECTION TREATED BY CHEMOTHERAPY WITH RITUXIMAB REGIMENS: PROGNOSIS AND TOXICITY

V Sergey1, I Storojakov1, A Kovrigina1, N Subortseva2, D Kosyura1, S Tumyn3, T Kondtatyeva3, A Ettinger1, A Kolomiytsev3, A Zeinalova3, A Chekan3, L Timofeeva2

1Russian State Medical Universitate, Moscow, Russian Federation

23Russian Academy for Postgraduate Medical Education Minisry of Health of Russia., Moscow, Russian Federation

3Cancer Research Center, Moscow, Russian Federation

Many epidemiologic studies have demonstrated an association between hepatitis C virus (HCV) infection and non-Hodgkin lymphoma, suggesting that HCV plays a role in the development of this malignancy. In a number of researches it is shown that level of various markers of a hepatitis C at patients from NHL can be taped at 30 % of patients. In our research we studied function of a liver at patients with NHL at carrying out immunochemistry with markers of a hepatitis C and without them. 41 patients (pts)with NHL have been included in research with markers HCV infection and 108 without it by which it has been spent immunochemistry. The age median patients who were HCV-positive was 47 years. 30 patients HCV-positive have III-IV stages of disease and 11 II stage. Normal level ALT and AST prior to the beginning of treatment was at 6 patients. The median serum level HCV RNA at the beginning of treatment was $2.3x10^5$/ml. The age median patients who were HCV- negative was 56 year, III-IY st was at 59 pts, I-II at 49 pts. Normal level ALT and AST was at 102 pts. All pts were treated by R-CHOP. Among 108 pts without markers HCV infection increased level ALT and AST only at 15 pts. The median was 2.3 norms. HCV RNA it was not defined at all this 15 pts. The treatment has not been stopped at any pts thanks to hepatic toxicity. CR has been reached 56 with DLBCL. Median follow up was 28 months. Serum level HCV RNA has increased at 23 of 41 pts. At all 23 pts before therapy had positive serum level HCV RNA . Level of HCV RNA was from $9x10^4$ to $8.8x10^7$/ml a median has made 6.7x106/ml. HCV-RNA levels significantly increased during immunochemotherapy 21 from 41 pts simultaneously with increased serum level HCV RNA increased level ALT and AST. Level ALT was from 4 to 50 norms, median- 11 norms. Level AST increased at 19 pts from 2 to 9 norms , median of 4.5 norms. The reason of stop treatment at 15 pts was hepatic toxicity. Complete remission (CR) in Pts with HCV infection has been reached 12 DLBCL. Median follow up CR was 12 months In conclusion, our study showed a high incidence of severe hepatic toxicity in patients who were HCV-positive. Hepatic function should be limied in patients who are HCV-positive and receive immunochemotherapy. High-risk patients having chronic active hepatitis receiving cytotoxic drugs, corticosteroids and rituximab should be closely monitored for serum transaminase, bilirubin and HCV RNA levels.

1447

TREATMENT OF SÉZARY SYNDROME WITH LOW DOSE SUBCUTANEOUS ALEMTUZUMAB RESULTS IN PROFOUND DISEASE RESPONSES BUT CAN LEAD TO SELECTIVE OUTGROWTH OF PREEXISTING CD52 NEGATIVE MALIGNANT CELL VARIANTS

C Halkes, I Jedema, E van Egmond, E Marijt, H Veelken, F Falkenburg, M Vermeer

Leiden University Medical Center, Leiden, Netherlands

Sézary syndrome is an aggressive cutaneous T cell lymphoma characterized by the presence of neoplastic T cells in peripheral blood, lymph nodes and skin leading to disabling squamous erythroderma with severe itching and systemic complaints. Treatment with intensive therapy is associated with increased infectious mortality, and many patients require long term high dose systemic corticosteroids for disease control. Low dose subcutaneous alemtuzumab (an anti CD52 monoclonal antibody, MoAb) has been used in small cohorts of SS patients and was associated with a high response rate and a good toxicity profile. After single agent treatment with alemtuzumab the occurrence of relapsing or resistant disease due to antigen loss or selection of antigen negative malignant cells has been shown in other malignant diseases like acute lymphoblastic leukemia or prolymphocytic leukemia, but has not been reported in Sézary syndrome so far. We treated 3 patients with Sézary syndrome with high peripheral blood counts of circulating Sézary cells (8*106/mL, 9*106/ mL and 6*106/ mL, respectively) and severe pruritus for which continuous treatment with systemic corticosteroids was needed, with repeated weekly doses of 10 mg alemtuzumab until numbers of circulating malignant cells were < 1*106/mL. This was reached after 5, 3 and 2 subcutaneous injections, respectively, with an impressive improvement of skin lesions and without side effects. In all patients systemic corticosteroids could be tapered. Recurrence of circulating Sézary cells and itching was observed again in all three patients after 3.5, 4 and 3 months, respectively, and all these patients responded to a second course of alemtuzumab (2, 1 and 1 injection, respectively). In one patient a CMV reactivation occurred after this second course, which was successfully treated with valganciclovir. 6 Weeks after the second course alemtuzumab, the first patient relapsed and retreatment with alemtuzumab did not have any effect on the number of circulating Sézary cells nor the skin. We investigated CD52 expression on circulating Sézary cells at the time of Alemtuzumab resistant relapse and before treatment with alemtuzumab. At the time of the alemtuzumab resistant relapse, 95% of circulating CD3+CD4+CD7- cells lacked CD52 expression. A CD52- population was already present before alemtuzumab treatment (0.02% of circulating CD3+CD4+CD7- cells). In patient 2, all circulating CD3+CD4+CD7- cells before alemtuzumab treatment were CD52+ and in patient 3, 0.04% of circulating CD3+CD4+CD7- cells were CD52- before treatment. At present, both patients show an ongoing response without appearance of CD52- Sézary cells (6 and 3.5 months after first alemtuzumab treatment, respectively). In conclusion, single agent treatment with low dose alemtuzumab for Sézary Syndrome effectively cleared circulating malignant cells and lead to an impressive improvement of skin lesions and systemic complaints. However, CD52 negative subclones may be present within the primary malignant cell population leading to resistance to alemtuzumab treatment due to selective outgrowth of the antigen negative variant/subclone.

1448

IMPACT OF RITUXIMAB MAINTENANCE IN RELAPSED FOLLICULAR LYMPHOMA

A Araceli, J Barreiro, JJ Alonso

Hospital de Cruces, Barakaldo, Spain

Background:The rituximab maintenance in follicular lymphoma (FL) relapsed after chemotherapy response has been effective in increasing the duration of response in clinical trials. However the results of a clinical trial may not always be reproducible in routine clinical practice. Aims: We present our experience with rituximab maintenance after response to chemotherapy in FL in the first relapse, since its approval in this indication, compared with similar patients treated without maintenance, before the authorization of rituximab in this setting. Material and methods. Retrospective study of our FL patients (1995-2010) in its first relapse with response at least partial to rescue chemotherapy, with rituximab maintenance since its approval in this indication (group A) or without maintenance before adopting the indication (group B). In both group we compared prognostic variables, time to treatment failure (TTF) for relapse, toxicity or dead, and overall survival (SV), as well as the

adverse effects (neutropenia and infectious episodes). Statistical methods: descriptive statistic, Student T, chi2 , survival by Kaplan- Meier method, long rank test and Cox proportional hazard regression method. Results. Forty patient with chemotherapy responsive rescue were included, 20 in the group A and 20 in the group B. 19 male and 21 females. Median age 63 years (30-80). FLIPI abbreviated : 0-1:14 (37%); II-IV: 24 (63%). Rescue treatments: chemotherapy with rituximab in group A and chemotherapy without rituximab (except 2 patients) in group B. Maintenance with rituximab consisted of an infusion of 375mg/m2 every three months for 2 years in 9 patients and 2 courses of 4 -times-weekly doses of rituximab, 3 and 9 months after completion of salvage therapy in 11 patients. 19 patients (47,5%) failed after salvage therapy and 14 (35%) died. 20% of patients had infectious episodes and another 30% grade 3 or 4 neutropenia. There was no significant difference in age or FLIPI between both groups. Five patients received maintenance rituximab in second or later relapse so they are excluded for the efficacy analysis. The probability of salvage therapy failure was lower in the rituximab maintenance group: TTF median has not been reached in group A (60% without failure at 4,75 years) and it was 3,9 years in group B (p: 0,06). In the multivariant analysis only the FLIPI was significant (p:0,016) and almost significant the rituximab maintenance. The median of SV was 6,6 years in group A and 4 years in group B (p: 0,11). In the multivariant analysis FLIPI was the only significant variable (p:0,02). We did not observe significant differences in neutropenia betwen both groups, but infections were more frequent in A group(p:0.03). Summary/Conclusions. Ours observations are consistent with the effectiveness described in clinical trials of rituximab as a consolidation of the chemotherapy response in first relapse of FL. The limited number of patients may justify the results did not reach statistical significance. The neutropenia has been similar in both group but the infectious episodes were more frequent in the rituximab group. A favorable FLIPI was associated with less likelihood of treatment failure and a longer SV.

1449

CENTRAL NERVOUS SYSTEM INVOLVEMENT IN PREVIOUSLY TREATED DIFFUSE LARGE B-CELL LYMPHOMA - A SINGLE CENTER EXPERIENCE

C Moreira, D Pereira, A Araújo, A Espírito-Santo, N Domingues, I Moreira, I Oliveira, A Martins, L Viterbo, M Marques, G Martins, JM Mariz

Instituto Português Oncologia Porto, Porto, Portugal

Background. The occurrence of central nervous system (CNS) involvement in patients with non-Hodgkin's lymphoma, including diffuse large-B-cell lymphoma (DLBCL), is an uncommon (1.6% to 5%), but almost always fatal event. Available studies report a latency time from initial diagnosis to CNS relapse varying from 5.4 to 8 months. Prognosis is very poor with a median time from CNS involvement to death of 2 to 4 months. IPI, LDH and number of extranodal sites seem to be the more relevant risk factors in predicting the risk of secondary CNS involvement. Aims. To evaluate the patients with DLBCL treated in our center who presented with CNS relapse. Methods. Between October 2007 and January 2011, we identified 9 patients, previously treated with R-CHOP (rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone) for DLBCL, presenting with CNS relapse. Data regarding diagnosis, staging, relapse clinical presentation and outcome was collected. Results. Of the nine patients, 55.6% were female with a median age of 66 years old (range: 33-80). At diagnosis, all patients were stage III or IV with IPI equal or superior to 3 and with elevated LDH (median=832; range: 220-1694; reference values: 67-190 U/L). Extranodal disease was present in 55.6% of patients; bone marrow was involved at diagnosis in 44.4%. Patients were treated in first-line with R-CHOP and 2 of them had intra-thecal prophylaxis with metothrexate. Six patients achieved complete remission (CR) at first-line (two of these had systemic relapse with achievement of a second CR) and two patients had resistant disease. Of the six patients in CR, five patients had an isolated CNS relapse. Both patients with resistant disease presented with CNS involvement while undergoing second-line therapy and one patient developed CNS disease before response to first-line therapy was evaluated. Median time from diagnosis to CNS relapse was 7.9 months (range: 4.3-68.4 months). Presenting symptoms of CNS involvement were paresis of lower limbs (n=5), visual impairment or diplopia (n=3), dysarthia (n=2), dysphagia (n=1) and palpebral ptosis (n=1). Work-up revealed parenchymal involvement (n=3), involvement of femoral (n=1) and optic (n=1) nerves; immunophenotyping of cerebrospinal fluid (CSF) at relapse was positive in seven out of eight patients tested: five expressed CD20 and two were CD20 negative. Two thirds of the patients had died at the time of our study. Median survival after CNS involvement was 3.8 months (range: 0.7-39.2 months). Medial overall survival of this group was 12.2 months (range: 5-72.4 months). Of the surviving patients only one is currently in CR after systemic and intra-thecal chemotherapy and autologous stem cell transplant. Conclusions. CNS relapse of DLBCL is an aggressive disease with a fatal outcome in most cases. Although all patients were advanced-stage, only two met criteria for intra-thecal prophylaxis and yet, it failed to prevent relapse. Recent literature questions the role of this form of prophylaxis after the introduction of Rituximab. It is necessary to find more accurate risk factors in predicting the risk for CNS secondary involvement and develop more effective forms to prevent it.

GENETIC VARIATION IN THE GENE FOR BETA7 INTEGRIN (ITGB7) AND CHRONIC GVHD AFTER ALLOGENEIC HSCT

M Petrek, Z Ambruzova, F Mrazek, E Faber, L Raida, K Indrak

Palacky University and Faculty Hospital, Olomouc, Czech Republic

Background: MAdCAM-1 / alpha4beta7 integrin signalling pathway has been implicated in the targeting of donor T cells to the mucosal tissues of the recipient after allogeneic haematopoietic stem cell transplantation (aHSCT). We have recently reported an association of MADCAM1 gene variants in recipient with chronic GVHD after HSCT (Ref.). Hereby, we extended our interest to the second partner in this signalling pathway - to the alpha4beta7 integrin. Aims: We wished to determine whether selected SNP variant of the gene encoding for beta7 integrin (ITGB7) is associated with development of acute or chronic GVHD and if it influences survival after aHSCT. Methods: Real-time PCR (TaqMan) was used to genotype ITGB7 SNP GenBank ID rs1554753 A/G in the Czech patients who underwent aHSCT (N=87) and their HLA identical related (N=70) or unrelated (N=17) donors. Results: A trend towards more frequent chronic GVHD was observed in recipients transplanted with a donor possessing at least one ITGB7 rs1554753*G allele than with AA homozygous donor (56.0% vs. 34.8%; p=0.08). Furthermore, the MADCAM1 rs2302217 AA homozygous recipients transplanted with a donor carrying ITGB7 rs1554753*G allele tended to develop chronic GVHD more frequently than patients with other combinations of MADCAM1 and ITGB7 genotypes (80.0% vs. 38.5%; p=0.07). Acute GVHD, overall survival and transplant-related mortality were not associated with the presence of ITGB7 variants in patients or donors. Conclusions: Our data indicate that ITGB7 gene polymorphisms in the donor may be associated with the risk of chronic GVHD, possibly in synergy with a particular recipient MADCAM1 genotype. Replication of our data in a larger cohort and/or assessment of the functional relevance of ITGB7 gene variants in aHSCT are required to confirm/extend these findings.

TH1 AND TH2 CYTOKINES REGULATE THE CONTRACTILITY OF THE MESENCHYMAL STEM CELL

R Muñoz,[1] G Ortiz-Ferrón,[2] JR García-Fernández,[3] E Leno-Durán,[2] A Prados,[2] E García-Olivares[2]

[1]*CSIC/ Instituto de parasitología y Biomedicina „López Neyra„, Armilla (Granada), Spain*

[2]*Instituto de Biopatología y Medicina Regenerativa,CIBM, Universidad de Granada, Armilla (Granada), Spain*

[3]*Hospital de Baza, Baza (Granada), Spain*

Mesenchymal stem cells (MSC) are nonhematopoietic cells of the bone marrow with capacity to support hematopoiesis, to proliferate and self-renewal. MSC are also considered a promising strategy for tissue repair, as they have been shown to differentiate into almost any cell type derived from all lineages. Besides this potential repair capacity, MSC mediate immunomodulatory effects in vivo and in vitro, and then they may have a therapeutic effect in inflammatory and immune diseases. Several authors have reported the expression of α-SM-actin by MSC. The polymerization of this protein in the cytoplasm is related to the cellular contractility. This capacity appears to be important for different MSC's functions, since changes in the cell shape may influence the cell-cell contacts. In this work, we study the effects of different cytokines on the polymerization of α-SM-actin and on the cellular contractility of MSC. Human bone marrow samples were obtained from bone marrow aspirates. Bone marrow mononuclear cells were isolated by density gradient centrifugation and cultured in Opti-MEM culture medium with

3% of Fetal Bovine Serum at 37 °C and 5% CO2. Bone marrow nonadherent cells were removed after 24 h, and culture medium was refreshed twice a week thereafter. Cells grew adherent and with a fibroblastic morphology. We observed by flow cytometry that almost all cells expressed CD10, CD29, CD73 and α-SM-actin, but lacked CD45. Other antigens such as CD54, CD106, CD21, and STRO-1 were also detected. We used the collagen gel assay to determine MSC contractility. IL-2, IFNgamma, TNF or LT αβ (all them Th1 cytokines) increased MSC contractility, whereas that IL-10 (a Th2 cytokine) or cytochalasin (an inhibitor of actin polymerization) decreased MSC contractility and induced cell relaxation. By confocal microscopy, we observed an increase in the number of α-SM-actin+ stress fibers in the MSC treated with IL-2, IFNγ, LTα1β2 or TNFα, whereas IL-10 decreased that number. Our results show that the MSC contractility is modulated by cytokines that regulate the incorporation of α-SM-actin into the stress fibers.

1452

ANALYSIS OF CMV SPECIFIC IMMUNITY RECONSTITUTION IN PATIENTS FOLLOWING ALLOGENIC STEM CELL TRANSPLANTATION BY TETRAMER TECHNOLOGY

V Tkacova, V Valkova, I Marinov, A Luxova, P Cetkovsky
Institute of Hematology and Blood Transfusion, Prague, Czech Republic

CMV specific memory CD8+ T lymphocytes (CMV CD8+ T ly.) play crucial role in the regulation of CMV infection. The tetramer technique is an important tool for detection and quantification of CMV specific T cell response. The aim of the present study was to investigate the role of donor CMV serological status on CMV CD8+ T ly. recovery following allogenic stem cell transplantation and the influence of graft versus host disease (GvHD) treatment and anti-thymocyte globulin (ATG) application in patients more than 100 days after transplantation. In cases with seropositive donors, CMV CD8+ T ly. reconstitution was observed approximately at day 20 following transplantation. In 5 (45%) patients with seropositive donor and without GvHD we found high values of CMV CD8+ T ly.: mean 26 b/µl (min. 16 b/µl, max 44 b/µl). 80% received ATG. In 6 (55%) patients without GvHD and CMV seronegative donors we found low numbers of CMV CD8+ T ly.: mean-1,6 b/µl (min. 0 b/µl, max 6 b/µl). 83% received ATG. 20 (65%) patients with both seropositive and seronegative donors were diagnosed and treated for GvHD. In 14 (70%) cases with low CMV CD8+ T ly. levels (mean 0, 9 b/µl, min. 0 b/µl, max 4 b/µl) 57% received ATG. In 6 (30%) cases with high CMV CD8+ T ly. levels (mean 11 b/µl, min. 7 b/µl, max 24 b/µl) 50% received ATG. CMV infection was not diagnosed in any of the above mentioned cases. Our results are in agreement with the hypothesis that donor serological status play crucial role in CMV specific immunity reconstitution. Our observations demonstrate significant negative influence of GvHD treatment on CMV specific immunity, while no effect of ATG application was proven.

1453

ASSESSMENT OF CHIMERISM AFTER ALLOGENEIC HEMATOPOIETIC TRANSPLANTATION USING SYBR GREEN-BASED REAL-TIME PCR ANALYSIS OF DNA POLYMORPHISM

E Hanusovska
Medirex, a.s., Bratislava, Slovakia

Background. Many haematology-oncology diseases are treated by allogeneic stem cell transplantation (allo-SCT). Assessment of the donor/recipient chimerism is a very important information in the first post-transplantation period.. In the past, cytogenetics and FISH method were available, however, their use was limited only for the sex mixed pairs. Although STR and VNTR detection is more universal, the detection limit is about 1 - 5%. The real-time PCR system with 12 NPs (nucleotide polymorphism) is donor/recipient sex independent and the sensitivity is below 1%. Aims. To measure and monitor chimerism after allo-SCT in sex mixed and sex identical pairs with using SYBR Green-based real-time PCR analysis and Gene Express software. Methods. Samples from patients and donors were provided by the Clinic of Haematology and Transfusiology in Bratislava, Slovakia (n = 69 pairs), before and after allogeneic transplantation by haematopoietic stem cells. DNA was isolated from PB after separation of WBC and stabilization in RNAlater solution. RQ-PCR was performed by the real-time PCR system using SYBR Green and 12 pairs of specific primers for two allelic variants (in the case of Y chromosome marker, only one). Primers for GAPDH were used as endogenous gene control. The amplification profile was identical as in TaqMan quantification protocol but with additional dissociation step .Results. In all cases the first step was aimed to find informative markers in DNA samples from donor and recipient before transplantation. We have screened 69 pairs donor/recipient and only in 1 case we didn't receive any informative DNA marker. After SCT only autologous DNA markers were quantified. An example of the quantification and monitoring of DNA informative markers is presented in the fig.1 Conclusions. We have established a simple method for the relative quantification of 12 autologous DNA polymorphic markers (11+Y chromosome) of recipient chimerism after allogenic haematopoietic transplantation. A relative amount of autologous DNA markers in peripheral blood can be estimated by relative quantification. Quotient RQ (in LOG10 or in %) have been obtained by the real-time PCR analysis using SYBR Green, which was based on measuring DNA informative markers. Denaturing melting point analysis of markers were also provided.

ACUTE GVHD IS A STRONG PREDICTOR OF FULL DONOR CD3+ T CELLS CHIMERISM (TCC) AFTER REDUCED INTENSITY CONDITIONING (RIC) FOR ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT)

J Elcheikh,[1] A Vazquez,[2] R Crocchiolo,[1] S Furst,[1] L Castagna,[1]
C Faucher,[1] C Oudin,[1] A Granata,[1] D Blaise[1]
[1]*Institut Paoli Calmettes Marseille, Marseille, France*
[2]*Institut paoli calmettes marseille, Marseille, France*

The monitoring of chimerism is a standard procedure to assess engraftment and achievement of full donor lymphoid chimerism after RIC. Post graft donor lymphocyte infusions are often determined on this study. However there is no consensus on when and how often to perform post-transplant chimerism. We retrospectively analysed our experience about the impact of acute GvHD in the prediction of allograft chimerism. All patients with hematologic malignancies excluding myelofibrosis, transplanted between 2001 and 2010 after Fludarabine-Busulfan-ATG RIC from a HLA identical donor and with T cells chimérisme (TCC) determination between day 30 and 120 were included. 115 patients fulfilled all criteria. Allo-SCT was performed from familial donor in 92 patients (80%) and from MUD in 23 patients (20%). The conditioning regimen consisted of fludarabine 90 to 180 mg / m², Busulfan 8 mg / kg orally or 6.4 mg / kg iv and ATG 2.5 or 5 mg /kg. TCC was serially assessed at 30, 60 and 90 days after allo-SCT. Recipient peripheral blood T lymphocytes were positively sorted by a mix of anti-CD4 and CD8 immunomagnetic beads (Dynal, Compiègne, France). T-cell purity was controlled by flow cytometry and was always > or =95%. Genomic DNA was amplified using fluorescent PCR primers for polymorphic variable number tandem repeats (VNTR) or short tandem repeats (STR). Mixed T-cell chimerism was defined as between 5 and 94% recipient cells, and full chimerism was defined as the presence of more than 95% donor cells. Full TCC was achieved in 94 patients (82%) at a median of 77 (30-120) days post transplant. Fifty eight patients (50.4%) developed acute GvHD. The cumulative incidence of Grade 2-4 GvHD in our population is 32% (95% CI 23-41). Overall the results showed that each of the 37 patients developing grade >= 2 AGVHD had a Full TCC prior day 120. On the other hand, all mixed chimerism were documented in patients not presenting Grade>=2 AGVHD (21 of the 78 patients (27%) without grade >= 2 AGVHD) (p=.002). No other parameter (ATG dose, Donor type...) achieved this level of individual

prognostic. These results, in a very homogenous population, raise the question concerning the utility of routine chimerism surveillance in patients presenting an acute GvHD following RIC Allo-SCT and that can imply a not negligible saving in terms of economic and human resources.

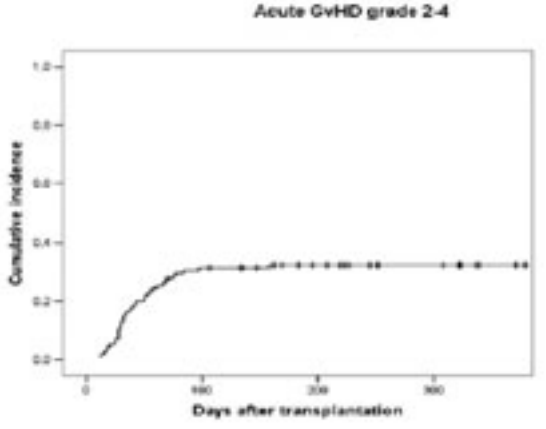

Figure 1: Cumulative incidence of acute GvHD. (Kaplan Meier).

[3]*Hematology/Oncology; Children's Hospital, Tuebingen, Germany*
[4]*Pediatric Cardiology; University Children's Hospital, Tuebingen, Germany*

Backgound. Transplant-related adverse events are a major cause of morbidity and mortality in pediatric patients after high-dose chemotherapy and hematopoietic stem cell transplantation (HSCT). T-cell depletion of the graft, post-transplant immune deficiency, extensive immunosuppression, and neutropenia are known risk factors for bacterial and viral infections. Most of the data about monocytes during infection are known from murine models. Less is known, however, about the role played by monocytes in defense against infections post HSCT. Monocytes consist of several subpopulations, which can be classified according to cell-size, granularity and different expression levels of CD16/CD14. Blood monocytes subpopulations have been defined in two major types CD14++/CD16- (M1), and CD14+/CD16++ (M3) and the intergradation between these subpopulations the CD14++/CD16+ (M2). We conducted a pilot study and analyzed the monocytes subpopulation during post transplant period and transplant related adverse events. Patient and Methods. The patient group consisted of 30 pediatric patients and young adults (7 autologous, 12 allogeneic and 11 allogeneic haploidentical transplanted) with hemato-oncological malignancies and immunodeficiency disorders. The median age was 9.5 years (range 0.5-38 years). The period of analysis was from the day before start of conditioning until 365 days after HSCT. Normal values of monocyte subpopulations were analyzed from a control group of healthy children and young adults (n=20). Surface marker expression (CD14, CD16, CD64, HLA-DR) of monocytes was determined by four-color flowcytometric analysis. *Results*. The median analysis period in the patient group was 228 days (range 43-379 days). Post transplant a significant ($p<0.001$) increase of monocytes was observed at time of "leukocyte -take", defined as the point in time after HSCT when leukocytes first reached levels above 1000/µl. We analyzed a subpopulation of monocytes, (M4), which has been up to this point difficult to distinguish from natural killer cells and shows a surface expression of CD14-/CD16++, looking at both the healthy population as well as pediatric patients and young adults after HSCT. The largest percentage of monocyte subpopulation in healthy subjects was M1 (85.3%) followed by M3 (7.5%), M4 (4.2%) and finally M2 (3.0%). In contrast with healthy populations, between day +30 and day +100 after HSCT the proportional share of M1 (74.5%) presented as too low, while M2 (7.9%), M3 (11.3%) and M4 (6.3%) were rather high. While M4 already showed a significant decrease ($p<0.05$) five days prior to bacterial infection, a significant increase in M4 ($p<0.01$) was observed at the moment of viral infection. During acute graft-versus-host disease (GvHD) grade III and IV a significant decrease was observed in M1 ($p<0.01$), but a significant increase in M4 ($p<0.05$) and M3 ($p<0.05$). *Summary*. Altered patterns of monocyte subpopulations were observed during immune reconstitution and during post transplant adverse events. The role of the individual monocyte subpopulations remains to be elucidated during these conditions.

LASER TRANSMYOCARDIAL REVASCULARIZATION (LTMR) WITH AUTOLOGOUS BONE MARROW CELLS (ABMC): ONE STEP METHOD FOR HARVESTING AND PROCESSING. EXPERIENCE IN 21 PATIENTS

A Alegre, B Aguado, C Cámara, M Fernández-Villalta, M Roig, N García-Fernández, S Martínez, N García-León
Hospital La Princesa, Madrid, Spain

Background: Recent studies suggest that Laser Transmyocardial Revascularization (LTMR) with Autologous Bone Marrow Cells (ABMC) could improve the results as cell therapy in diffuse coronary disease (DCD) respect to laser alone. We evaluated a point of care device which utilizes density gradient centrifugation to concentrate bone marrow mononuclear cells for transmyocardial laser injection. Patients and Methods: 21 patients with DCD and medically refractory class III/IV angina (mean age 66 years old), has been included in the study. At the time of surgery, 120 cc of autologous bone marrow were aspirated from the posterior iliac crest and anticoagulated with citrate. Using a density gradient centrifugal system (HARVEST®, Palex, USA), bone marrow harvested was separated into its components (Figure), which included 20 cc of concentrated mononuclear cells inclusive of the buffy coat which was immediately available for direct transmural myocardial laser channels injection. Cell counts and flow cytometry were used to determine the total number of mononuclear cells in addition to specific somatic stem cell populations such as CD34+ and CD133+ cells. Results: Time for bone marrow aspiration and concentration averaged 30 minutes. The complete processing was performed closed to the surgery room, in sterile ambient. There were no complications related to the bone marrow aspiration. Average cell counts pre and post concentration were significatively ($p<0.001$) increased (Table). No correlation between cell counts and patient demographics was detected. All patients received laser therapy with cell support without complications. 19 patients were evaluable for results. Conclusions and comments: These interim data shows that density gradient centrifugation with the HARVEST® device allows fast and efficient point of care concentration of ABMMC for cell-based therapies. Efficacy results regarding cardiovascular applications and clinical endpointswill be presented.

PROPHYLAXIS OF RELAPSE WITH MODIFIED DONOR LYMPHOCYTE INFUSION CAN SIGNIFICANTLY INCREASE SURVIVAL AFTER HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ADVANCED-STAGE ACUTE LEUKEMIA

Y Wang, DH Liu, LP Xu, KY Liu, H Chen, XH Zhang, YH Chen, W Han, FR Wang, ZJ Wang, CH Yan
Peking University People's Hospital, Beijing, China

Background Patients with advanced hematologic malignancies after allogeneic hematopoietic stem cell transplantation (HCT) have a poor prognosis because of a high rate of relapse and transplant-related mortality. Donor lymphocyte infusion (DLI) after allogeneic HCT exhibits definite anti-leukemia effects in this group of patients. Our primary data showed the feasibility of modified prophylactic DLI in HLA-mismatched HCT without in vitro T-cell depletion, but there have been no comparative clinical studies to confirm its efficacy. Aims The purpose of this non-randomized, single-center study was to comparatively analyze transplantation outcomes in a consecutive series of advanced-stage acute leukemia patients who either received prophylactic DLI or did not receive prophylactic DLI after HSCT from HLA-mismatched family donors during the same period at our institute. Methods The study was approved by the Institutional Review Board of the Peking University Institute of Hematology. All included patients were informed and signed an informed consent form. Consecutive patients with advanced-stage acute leukemia ((patients in CR3 or beyond, non-remission, n = 75) receiving HSCT from HLA-mismatched family donors during the same period (between January 2003 and September 2010) with (n=48) or without (n=27) prophylactic donor lymphocyte infusion (DLI) were enrolled. The conditioning therapy consisted of a modified BUCY2 plus ATG (thymoglobulin). Modified donor lymphocyte infusion (G-CSF-primed PBSCs instead of harvested non-primed donor lymphocytes and short-term immunosuppressive agents for prevention of GVHD after DLI) was planned from days 30-60 post transplantation before haematologic relapse was diagnosed Results Forty-eight patients received the prophylactic DLI at a median 48 (28-330) days after HSCT. The cumulative incidences of overall grades II-IV acute GVHD were 48% for patients receiving prophylactic DLI and 53% for patients not receiving prophylactic DLI , respectively (P = .55) with a relative risk (RR) of 0.51 (0.22-1.21) (P = .13). The cumulative incidences of overall chronic GVHD (including GVHD occurring before and after DLI) were 51% for patients receiving prophylactic DLI and 39% for patients not receiving prophylactic DLI , respectively (P = .42) with a relative risk (RR) of 1.99 (0.68-5.84) (P = .21). The 2-year cumulative incidence of relapse was significantly lower in patients receiving prophylactic DLI (34%) than in patients not receiving prophylactic DLI (55%) (P=0.018). The 2-year cumulative incidence of non-relapse mortality was comparable in patients receiving prophylactic DLI (38%) and patients not receiving prophylactic DLI (36%) (P = .95).

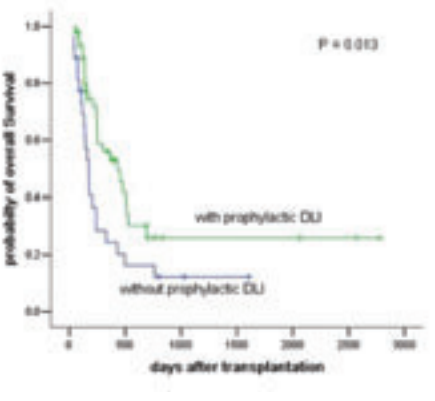

Figure 1. Overall Survival for patients receiving DLI or not.

The three-year probability of overall survival was higher in patients receiving prophylactic DLI (26%) than in patients not receiving prophylactic DLI (12%) (P = .013). *Summary/conclusions* the current study showed that a lower relapse rate, a similar NRM, and a higher survival probability was achieved with patients receiving prophylactic DLI than with patients not receiving prophylactic DLI. The results suggest that prophylaxis of relapse with modified donor lymphocyte infusion can significantly increase survival for advanced-stage acute leukemia patients even after HLA-mismatched T-cell-replete HCT.

GVHD PROPHYLAXIS WITH HIGH DOSE CYCLOPHOSPHAMIDE AFTER HLA-MATCHED OR HAPLOIDENTICAL ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

R Fedele, G Messina, T Moscato, M Martino, G Console, E Massara, I Callea, R Surace, P Scaramozzino, G Irrera, P Iacopino
Azienda Ospedaliera Bianchi Melacrino Morelli, Reggio Calabria, Italy

Background: recently, it was reported that after T-cell replete bone marrow transplant (BMT) from HLA-matched1 or haploidentical (haplo) related donor2, post-transplant cyclophosphamide (Cy), respectively given alone or with Tacrolimus (FK-506) plus Mycophenolate Mofetil (MMF) for GVHD prophylaxis, was associated with low incidence of graft rejection and acute and chronic GVHD (aGVHD, cGVHD) in patients (pts) with advanced myeloid malignancies (AMM). Methods: in our centre, 8 pts with AMM (1 CML in blast crisis, 1 CML in accelerated phase, 3 AML not in CR, 3 AML in CR2 relapsed after autologous BMT) underwent unmanipulated BMT from HLA-matched (2) and haplo (6) donors. GVHD prophylaxis was performed with Cy 50 mg/kg at days (d.) +3 and +4, alone or with FK-506 and MMF in HLA-matched and haplo BMT, respectively. In the haplo BMT, the conditioning regimen (Cond) was Cy 14.5 mg/kg at d. -6 and -5, fludarabine 30 mg/m2 from d. -6 to -3 and TBI 200 cGy at d. -1 in 4 pts; in a patient Cy was substituted with thiotepa 5 mg/kg at d. -6 and -5. In HLA-matched BMT, Cond was fludarabine 120 mg/m2 and busulphan i.v. 12.8 mg/kg in 4 days. Results: the median time to reach ANC>500/microl was 18 d. (r. 13-26) in 8/8 of pts, and platelets>30000/microl was 29 d. (r.19-40) in 7/8 of pts. After a follow-up of 8 months (m.) (r. 2-23), 5 pts are alive in CR (haplo and HLA-matched BMT in 4 and 1 case, respectively). Two pts (25%) developed steroid-responsive grade 2 cutaneous aGVHD at d. +18 and +39. After FK-506 and MMF withdrawing, 2 pts undergone haplo BMT had delayed grade 2 intestinal GVHD, responding to standard therapy. Interestingly, Foxp3 levels were significantly low in pts developing aGVHD. None of our pts showed cGVHD. Viral infections was documented and cured in 66% of pts. A patient (12.5%) died for transplant-related complications at 2 m. while 3/8 (37%) relapsed and 2/8 (25%) died after 4.3 and 8.5 m. Both these pts had refractory AML at the transplant and received BM from haplo donors. *Conclusions*: post-transplant Cy is a safe and effective prophylaxis of aGVHD and cGVHD in HLA-matched or haplo allogeneic BMT. To reduce relapse rate, especially after haplo BMT in pts with active disease, we are proposing clofarabine and busulfan i.v. as Cond in a multicenter study of GVHD prophylaxis with high-dose Cy after allogeneic BMT.

CLINICAL SIGNIFICANCE OF T-CELL LARGE GRANULAR LYMPHOCYTE EXPANSION POST ALLOGENEIC STEM CELL TRANSPLANTATION: A SINGLE CENTRE EXPERIENCE

M Martino, R Fedele, C Garreffa, A Dattola, S Dattola, A Pontari, E Massara, T Moscato, G Console, G Messina, G Irrera, P Iacopino
Azienda Ospedaliera Bianchi Melacrino Morelli, Reggio Calabria, Italy

Background: Polyclonal or oligoclonal T-cell Large Granular Lymphocyte (T-LGL) expansion is a rare disorder generally occurring in patients with autoimmune diseases, viral infections, malignancies, and solid organ or allogeneic hematopoietic stem cell transplantation (allo-HSCT). The clinical significance of finding T-LGL expansion post allo-HSCT is unclear. Aim of the study: to evaluate if there is an association between T-LGL expansion after allo-HSCT and stable chimerism, chronic graft-versus-host disease (GVHD), recurrence of primary disease, and overall survival. Methods: A retrospective study was done on 46 patients whose data were available undergone allo-HSCT with a median follow-up of 61.4 months (r. 17.8-212.5). LGL expansion has been supposed in case of 1) increasing number of peripheral blood lymphocyte counts>2000 cells/mm^3 for at least 3 months, and 2) the predominance of LGLs in the peripheral blood smears. Cases with LGL expansion were confirmed for immunophenotypic profiles (CD2, CD3, CD5, CD7, CD8 and CD57 positive) and T-cell receptor RT-PCR for T-cell monoclonality. Results: Out of 46 patients, 12 cases (26%) showed LGL expansion after allo-HSCT. The median onset of LGL expansion was 35.9 months (r.12.8-

100). In 10/12 patients (83.3%) it was associated with confirmed chronic GVHD, particularly with cutaneous or pulmonary scleroderma-like GVHD or Sjogren-like GVHD. In the remaining 2 cases LGL expansion was documented at a follow-up of 12.8 and 37.8 months when common but not diagnostic signs of chronic GVHD were present. These patients are in actual close follow-up to document an evolution of overt GVHD. Stable mixed hematopoietic chimerism assessed by quantitative real-time polymerase chain reaction was achieved in most patients (73.7% donor component with a range of 45-100%). None of 12 patients experienced disease relapse at a follow-up of 52.4 months (r.14.6-212.5). Conclusion: it seems that LGL expansion is strongly associated with chronic GVHD and with graft versus leukemia effect also in absence of full donor chimerism. We think that pts undergone allo-HSCT presenting LGL expansion need to be monitored carefully for systemic chronic GVHD. Further study in larger series of pts are needed to evaluate this complex mechanism.

SPLENECTOMY AND HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR THALASSEMIA PATIENTS

A Roveda,[1] M Villa,[2] P Sodani,[1] K Paciaroni,[1] C Gallucci,[1] C Alfieri,[1] G De Angelis,[1] J Gaziev,[1] A Isgro,[1] M Marziali,[1] F Torelli,[1] MD Simone,[1] F Rulli,[2] G Tucci,[2] G Lucarelli[1]
[1]*Mediterranean Institute of Hematology-tor Vergata General Hospital, Rome, Italy*
[2]*Department of General Surgery - tor Vergata General Hospital, Rome, Italy*

Background: beta thalassemia is a genetic disorder resulting in absent or reduced beta globin chain synthesis producing haemolytic anemia. Currently, the only cure for thalassemia is allogeneic bone marrow transplantation, which corrects the genetic defect in the hematopoietic system by the use of allogeneic stem cells, the origin of which must be immunologically acceptable. Patients with thalassemia can be categorized into 3 classes of risk for bone marrow transplantation (Pesaro classification), and the category of greatest risk is class 3. Aims: massive splenomegaly in patients with thalassemia is often a reflection of inadequate medical care and/or advanced disease and frequently is found in class 3 patients. It is also associated with increased blood transfusion requirement. Splenectomy is indicated if there is significant abdominal discomfort, splenic infarction, or symptomatic hypersplenism. Presence of splenomegaly prior to an SCT raises the theoretical concern of the removal of infused stem cells, which could potentially have an adverse impact on engraftment. Given this, splenectomy performed prior a SCT could modify engraftment kinetic, which in turn could have an impact on graft tolerance and development of GVHD. Methods: our experience runs on fifteen patients affected by thalassemia that underwent splenectomy in the Department of Surgery of the Tor Vergata University General Hospital of Rome from May 2005 to April 2010. All patients were prepared for surgery by preoperative blood transfusion to achieve more than 9.5 gr/dL of haemoglobin level and all received prior pharmacological immunization with vaccines for meningococcus, pneumococcus and haemophilus influenzae. Results: mean and median age were 11 yrs. (min 4 - max 26 yrs). Mean operative time for surgical procedure was 75 min (range 60 - 100 min). The average postoperative hospitalization time was 5.7 days (range 5-7). Minimum spleen weight was 495 gr and maximum 2397 gr. Only one patient at day +2 after surgery showed increased level of amylases and lipases, but he was given promptly i.v. sandostatine treatment and those above mentioned enzymes normalized in five days. Conclusions: in this retrospective analysis, we reported that splenectomy prior to an allogeneic SCT in patients with thalassemia is associated with faster engraftment, a reduced peri-transplant transfusion requirement, and with not a significantly increased risk of death from peri-transplant infections.

1461

HIGH-DOSE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA WITHOUT GROWTH FACTORS: EXPERIENCE FROM A DEVELOPING COUNTRY (ORAN, ALGERIA)

M Bekadja, S Osmani, M Brahimi, A Arabi, B Entasoltane, S Mahdad, F Attaf, B Benzineb, N Yafour, H Tadj
University Hospital, Oran, Algeria

Background: The need for growth factors after autologous stem cell transplant (ASCT) has been investigated recently. Data from developing countries are scanty. Aims: We analyzed and updated our experience"on 32 consecutive patients with multiple myeloma (MM) treated with ASCT without receiving growth factors after transplant. Patients and methods: Among the 32 patients 11 was females and 21 was males. The median age was 55 years (range, 37-64 years). Before transplant, patients received chemotherapy using VAD (vincristine, adriamycin and dexamethasone, n=10) or bortezomib-dexamethasone (n=22). The median number of CD34+ cells was 3,86x10 6/kg (range, 1,05 - 8,62). High-dose melphalan (200 mg/m2) was used for conditioning and followed after 24 hours by reinfusion of autologous non-frozen hematopoietic stem cells, which had been stored for 24 hours at 4°C. All patients received prophylactic ciprofloxacin,fluconazole and acyclovir. Results: All evaluable patients had a full hematopoietic reconstitution. Median time to achieve neutrophils ≥ 500/µl was 12 days [range 10-17] and median time to achieve an unsupported platelet count≥20 000/µl was 13 days [range, 11 - 28]. After ASCT , 87% of patients responded. Grade II-III mucositis was the major regimen related toxicity. The median follow-up was 07 months (range,1-20 months). Estimated overall survival and EFS at 20 months were 96.5%±0.05% (s.e.) and 93%±0.05% (s.e.), respectively. Conclusion: We conclude that it is feasible and reasonable to perform ASCT for MM without administering growth factors and the procedure is easy to perform without requiring costly growth factors.

1462

ENGRAFTMENT SYNDROME AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION: INCIDENCE AND ANALYSIS OF RISK FACTORS. A SINGLE CENTER EXPERIENCE

A Marco, P Fernandez
Hospital General Universitario de Alicante, Alicante, Spain

Background: Engraftment syndrome (ES) is an early complication following autologous stem cell transplantation (SCT). Nevertheless, there are no clearly established diagnostic guidelines. Aim: The aim of this study has been to analyze our experience as a single institution trying to identify risk factors predisposing to ES and a better characterization of the diagnostic criteria. Methods: We included patients that developed non-infectious fever within 5 days of engraftment (first day when neutrophils count>0.5x10^9/l). Moreover, we analyzed and compared diagnostic criteria of ES reported by Maiolino and Spitzer. *Clinical criteria for diagnosis of ES Spitzer criteria (3 major or 2 major+1 minor) within 96h of engraftment Major: non-infectious fever, skin rash, pulmonary edema, hypoxemia Minor: weight gain, hepatic or renal dysfunction and transient encephalopathy. Maiolino criteria Non-infectious fever plus: skin rash or pulmonary infiltrates or diarrhea commencing 24h before or at any time after the first appearance of neutrophils. Results: From January 2008 to December 2010, 10 patients (3 males, 7 females, median age of 50 years (range, 30-62) out of a total number of 50 patients who underwent an auto-SCT had clinical and biological data suggesting ES. Clinical diagnosis were: 7 multiple myeloma, 1 POEMS syndrome, 1 solid tumor and 1 Hodgkin´s lymphoma. At the end of neutropenic phase, five patients had only fever and skin rash, two developed fever and hypoxemia, 2 presented fever, rash and weight gain and 1 patient had fever, rash and diarrhea. All patients had negative cultures and no clinical documentation of infection was observed. The incidence varies according to Maiolino (20%) or Spitzer diagnostic criteria (10%). Peripheral blood was the source of stem cells in all cases. Four patients received G-CSF since day +7 after transplantation and median number of CD34+ cells/kg infused were 4.38x106/kg (range, 3.7-5.16). Median time to neutrophil recovery was 14 days (range, 9-18). All patients were treated with methylprednisolone (1 mg/kgr/12h) when ES was suspected and all had a rapid resolution of all symptoms and signs. They were discharged of hospital 7 days after ES diagnosis (range, 3-10). Summary: The differential diagnosis between ES and other complications at the end of neutropenic phase may be difficult. There is an increasing incidence of ES in the last years but it may vary according to the diagnostic criteria applied. Peripheral blood as stem cell source, higher numbers of CD34+ cells, use of G-CSF and the underlying disease (higher incidence in solid tumors, POEMS, amyloidosis and autoimmune disease) may favour its development. Corticosteroids is the treatment of choice and should be administrated early after the suggesting clinical and biological data appear.

[4]*National Key Laboratory of Medical Immunology & Institute of Immunology, Shanghai, China*

Graft-versus-host disease (GVHD) is a major complication after hematopoietic stem cell transplantation (HSCT) and remains to be a major cause of morbidity and mortality. The toll-like receptors4(TLR4) has been identified as a sole signal-transducing component in the LPS receptor complex with a conical shape(e.g. from Escherichia coli) and has been showed to be a key player in the innate immunity and immune tolerance. Activation of toll-like receptor4 (TLR4) by lipopolysaccharide (LPS) induces the NF-κB signaling pathway to release the critical proinflammatory cytokines and increases the recepient GVHD response. In order to clarify the role of TLR4 in the occurrence of acute GVHD after HSCT, we collected 208 samples from HSCT recipients and their HLA-identical donors to test the hypothesis that TLR4 polymorphism in the recipients or donors influence the risk of acute GVHD in allogeneic HSCT recipients. All patients received methotrexate and cyclosporine for GVHD prophylaxis and had either grade 0 or grades II to IV acute GVHD. The TLR4 Asp299Gly and TLR4 Thr399Ile polymorphisms of each sample were examined by using DNA sequencing and polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) methods, we used two restriction enzymes to randomly test samples, NcoI for the PCR-RFLP assay of the Asp299Gly allele and HinfI for the Thr339Ile allele. No homozygous or heterozygous variant alleles of the Asp299Gly or Thr339Ile polymorphisms were detected in any samples of our study. Our results demonstrated that the TLR4 Asp299Gly and Thr399Ile polymorphisms might be very rare in Chinese population. The results of this study cannot confirm the role of TLR4 mutation in the pathogenesis of GVHD in humans.We expect to reach a definite conclusion by a TLR4 knockout murine GVHD model in our ongoing project.

1464

IMPACT OF PRIOR AUTOLOGOUS MOBILIZATION STATUS ON ENGRAFTMENT AND OUTCOME AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR LYMPHOMA AND MYELOMA

R Crocchiolo, B Calmels, S Furst, C Lemarie, J El-Cheikh, L Castagna, R Bouabdallah, P Ladaique, D Coso, JM Schiano de Colella, A Stoppa, J Rey, V Ivanov, T Aurran-Schleinitz, C Faucher, C Chabannon, D Blaise
Institut Paoli-Calmettes, Marseille, France

Background: approximately 15% of patients who are candidates for autologous HSCT fail to collect an adequate amount of CD34+ cells (poor mobilizers). Reasons for poor mobilization include patient and treatment-related factors. Infra-clinical damages to the bone marrow (BM) micro-environment may play a role and affect the interactions of stem cells with stromal cells and the bone-blood barrier that contribute to efficient mobilization. If such a hypothesis stands true, then damages to the BM micro-environment should also affect the ability of donor stem cells to home and seed in the BM of recipients after allogeneic HSCT. *Aims*: we thus examined whether patients who underwent allogeneic HSCT at a single institution, using fludarabine-busulfan-ATG RIC conditioning after a failed attempt at autologous HSCT, were different in terms of hematopoietic recovery than patients who received a tandem autologous and allogeneic HSCT. Methods: inclusion criteria were age > 18 years, diagnosis of lymphoproliferative disease or multiple myeloma, prior mobilization (succesfully or not), HSCT from related or unrelated donor and RIC conditioning. Poor mobilization was defined as circulating CD34+ <20/µl on the first day of planned collection. PMN and PLT engraftment were determined for good and poor mobilizers, taking into account confounding factors such as age, type of donor and disease. Results: a total of 148 patients were included in this analysis, of which 125 were evaluable for CD34+ counts and engraftment (n=33 for poor-mobilizers and 92 for good mobilizers, see table 1). All but two patients engrafted. Overall, the median (range) day was 17 (0-47) for PMN >0.5 G/L, 8 (0-49) for PLT >20G/L and 12 (0-49) for PLT >50G/L. There was no significant difference in PMN or PLT engraftment between the two subsets. Nevertheless, NRM and overall mortality were higher in poor mobilizers (p=0.009 and p=0.01 respectively); relapse rate, acute and chronic GvHD were similar in both groups (p=0.81). Data were confirmed after adjustment for patient's age, type of donor and disease. *Conclusions*: our data suggest that lymphoma and myeloma patients with a history of poor mobilization defined as CD34+ <20/µl do not have different outcomes in terms of PMN and PLT engraftment. Despite the absence of difference in terms of early hematopoietic recovery after allogeneic HSCT, NRM and mortality were significantly higher in poor mobilizers. Identifying the exact reasons for such different outcomes will require further investigation.

THE USE OF 18F-FDG PET-TC IN THE ASSESSMENT OF RESPONSE AFTER ALLOGENEIC STEM CELL TRANSPLANT IN HEAVILY PRE-TREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A SINGLE CENTRE EXPERIENCE

B Vannata,[1] L Laurenti,[1] T Taralli,[2] V Rufini,[3] E Calcagni,[3] E Metafuni,[4] F Autore,[4] S Sica,[4] P Chiusolo,[4] A Giordano,[3] G Leone[4]

[2]*Institute of Nuclear Medicine University of Sacred Hearth of Rome, Rome, Italy*
[3]*Institute of Nuclear Medicine University of Sacred Hearth of Rome, Rome, Italy*
[4]*Haematology Institute University of Sacred Hearth of Rome, Rome, Italy*

Background. Chronic lymphocytic leukemia (CLL) is a heterogeneous lymphoproliferative disorder; the only potential curative option especially for high-risk patients is the allogeneic transplant. To our knowledge, no studies have been published on the role of 18F-FDG PET or PET-CT in evaluating response to allogeneic transplant in CLL. Aim: The aim of our study was to evaluate the role of 18F-FDG PET-CT in monitoring response to reduced-intensity conditioning (RIC) transplant and to compare the results with standard criteria according to International Workshop on Chronic Lymphocytic Leukemia (IWCLL). *Methods*. We retrospectively analyzed 9 consecutive high-risk CLL patients, affected by fludarabine-refractory (4 patients) or relapsed CLL (5 patients) who underwent RIC transplant from March 2004 to May 2009. PET-CT scanning was planned at about 8 months after transplant to assess response and at a mean 9 month period during follow-up. Overall, 42 PET-CT studies were performed. The mean long-term follow-up period was 39.7 ± 20.5 months. All studies were analysed qualitatively and scored as either negative or positive: any focal area of activity higher than vascular background, in any site incompatible with normal anatomy, was considered abnormal. *Results*. The first PET-CT performed after transplant showed abnormal FDG uptake in 5 patients: 4 patients classified as stable/refractory and 1 patient in partial remission(PR) at pre-transplant evaluation. No abnormal FDG uptake was observed in 4 patients who showed PR before transplant. Response assessment by IWCLL criteria performed at the same time of the first PET-CT (at about 8 months after transplant), showed persistent disease in 8 patients (5 PET positive and 3 PET negative) and complete response in 1 patient (PET negative). At the end of follow-up, all 4 patients with previously negative scans were still PET negative and are in complete remission by standard criteria. Similarly, all 5 patients with previously positive scans were still PET positive; of these, 1 died 27 months after RIC transplant for disease progression and

4 are alive with persistent disease. *Conclusions*. From our preliminary data in a small series of CLL patients, the first 18F-FDG PET-CT after transplant shows different metabolic findings that reflect the different pre-transplant status and seem to predict the patient outcome earlier than clinical evaluation by standard criteria. PET-CT performed during follow-up is useful to assess disease status and to early detect disease progression.

ETANERCEPT FOR STEROID-REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

SH Jeong, JS Park
Ajou University School of Medicine, Suwon, South-Korea

Treatment strategy for steroid-refractory acute GVHD after Allo-SCT needs to be standardized. We report our clinical experience of the effect of etanercept on steroid-refractory acute GVHD. A total of 18 patients who received allo-SCT and presented with steroid-refractory acute GVHD at Ajou University Hospital were retrospectively studied. Twenty-five milligrams of etanercept were given s.c. twice weekly for four weeks. Clinical responses were evaluated with regard to the severity of acute GVHD. The median age of patients was 43.5 years. By using paired t-test, etanercept showed down grading effect of acute GVHD ($p = .005$) but no patient experienced complete remission. Eighty percent of grade II, 14% of grade III, and 57% of grade IV patients showed a partial response. Skin and gut GVHD were well controlled with etanercept, whereas hepatic GVHD was not. Four patients died of fatal infection. There were no factors affecting the clinical outcome of etanercept. All the non-responders died and 56.6% of the responders survived ($p = 0.0008$). Etanercept can be effective in treating steroid-refractory acute GVHD after Allo-SCT, with tolerable side effects.

VON WILLEBRAND FACTOR (VWF) LEVEL IN THROMBOTIC MICROANGIOPATHY (TMA) IN CHILDREN UNDERGOING ALLOGENIC BONE MARROW TRANSPLANTATION: A SINGLE - CENTER EXPERIENCE

G De Simone, MR D'Amico, MR Lupone, G Maisto, R Parasole, M Ripaldi
Pausilipon Hospital, Naples, Italy

Introduction: Thrombotic microangiopathy is a well-documented complication that may occurr after hematopoietic stem cell transplantation (HSCT). The reported incidence of TMA after HSCT varies from 0,5% to 75%, is characterized by thrombocytopenia, microangiopathic hemolytic anemia, fever, neurologic and renal abnormalities resulting from formation of disseminated hyaline thrombi in the small vessels of the main organs due to generalized endothelial damage. VWF is a multimeric protein contained in endothelial cells, platelets and plasma that mediates platelet adhesion and aggregation at sites of vascular injury. Once released from the abnormally stimulated endothelial [by multiple factors: high-dose chemotherapy, immunosuppressants, graft-versus-host disease (GVHD), infection and irradiation] ultralarge multimers of VWF, present in the endothelium but not found in the plasma in physiological conditions, directly promote intravascular aggregation of the platelets and the consequent microvascolar thrombosis. Materials and methods: We report a retrospective analysis of patients (15 months to 17 years old) with hematologic disease who underwent allogenic HSCT between February 2007 and December 2009 at our insitution. We diagnosed transplantation-associated TMA in 5 of 36 transplanted patients. Table 1 shows the characteristics of patients who developed TMA after HSCT. The diagnosis was evaluated on the basis of clinical and laboratory criteria: microangiopathic hemolysis with negative Coombs test with unexplained drop in hemoglobin level and platelet count (Plt), increased number of reticulocytes (Ret), evidence of red cell fragmentation on the blood smear, increased value of indirect bilirubin (double of the normal value), increased serum lactic acid dehydrogenase (LDH) activity (more than 500UI/l), renal dysfunction (serum creatinine = Cre > 1,5 mg/dl), neurologic dysfunction. In addition, all patients were monitored for vWF levels (vWF Antigen kit-ELISA). Results The most relevant clinical and laboratory data concerning diagnosis, therapy and patient outcome with TMA after HSCT are listed in table 2. Five of 36 transplanted patients (13,8%) developed TMA for a median duration of 58 days (range 21-90). In 3 of 5 patients TMA occurred within 100 days after HSCT. All patients had increase in fragmented red cells, thrombocytopenia, significant elevation in LDH. Moreover we found elevated FvW levels until the early signs of thrombotic microangiopathy, even in a case was the first parameter to be altered with a modest decrease in platelets. Of these 5 patients, 3 responded to administration of DF, 1 responded to a combination of Df + PE and only one developed, during DF treatment, severe TTP and died from multiorgan failure. Conclusion TMA is a severe and relatively common complication after HSCT. The diagnosis in transplanted patients is difficult because its presentation overlaps with other post- HSCT complications. However is important to recognize it beforeTMA can have harmful effects. This retrospective analysis of transplanted patients in BMT Unit of Pediatric Center evaluate the impact of TMA and the relevance, even in our small series, of vWF levels as important parameter for the diagnosis and monitoring the evolution of the disease.

DOUBLE UNRELATED CORD BLOOD TRANSPLANTATION FOR ADULTS WITH HIGH-RISK ACUTE LYMPHOBLASTIC LEUKEMIA IN KOREA

S Lee,[1] NG Chung,[1] JY Kwak,[2] JA Kim,[1] SK Park,[3] BS Cho,[1] KS Eom,[1] YJ Kim,[1] HJ Kim,[1] CK Min,[1] DW Kim,[1] JW Lee,[1] WS Min,[1] CW Park[1]
[1]*Catholic BMT Center, The Catholic University of Korea, Seoul, South-Korea*
[2]*Chonbuk National University Medical School, Chonju, South-Korea*
[3]*Soonchunhyang University Medical School, Bucheon, South-Korea*

Background. Unrelated cord blood (CB) has been shown to be a valuable alternative source of hematopoietic stem cells for transplantation in patients who lack a suitable related or unrelated donor. Graft cell dose is an important determinant of hematopoietic recovery and overall outcome following CB transplantation (CBT), and the limited cell dose of single CB unit has been a major barrier to its more widespread use. Strategies to overcome this barrier include the use of two partially HLA-matched CB units (double CBT). Aims: We report the results of unrelated double CBT for 14 adults with high-risk acute lymphoblastic leukemia (ALL) between 2005 and 2010. Methods: The median patient age was 31 years (range, 16-52 years). All patients had one or more high-risk features, including 7 Philadelphia chromosome-positive ALL. Eleven patients (78.6%) were transplanted in CR1; 1 (7.1%) in CR2; and 2 (14.3%) in refractory/relapsed status. All patients received myeloablative preparation consisting of total body irradiation (12 Gy), fludarabine (150 mg/m2), and cytarabine (9 g/m2). Graft-versus-host disease (GVHD) prophylaxis consisted of tacrolimus and mycophenolate mofetil. CB unit was selected according to the number of total nucleated cells (TNC) per recipient's weight and HLA compatibility (HLA-A and -B by serotying and HLA-DRB1 high-resolution genotyping). No patients had a suitably matched related or unrelated donor available at the time of transplantation. All patients and donors provided written informed consent, and the treatment protocol was approved by the institutional review board of The Catholic University of Korea. Results: The median cell doses infused were 3.60x107 TNC/kg (range, 2.62-7.88), 1.80x105 CD34/kg (range, 0.65-5.85), and 8.04x107 CD3/kg (range, 6.24-13.49). All patients achieved a successful engraftment with full donor chimerism. Neutrophil recovery occurred at a median of 25 days (range, 17-109 days), and platelet recovery occurred at a median of 39 days (range, 20-185 days) after CBT. Acute GVHD was observed in 9 patients (64.3%; 7 grade II, 2 grade III). Four (36.4%) of the 11 evaluable patients had chronic GVHD (2 mild, 2 moderate). With a median follow-up duration of 13 months (range, 3-59 months) for surviving patients after CBT, 10 patients are alive with a leukemia-free status, while the other 4 patients have died

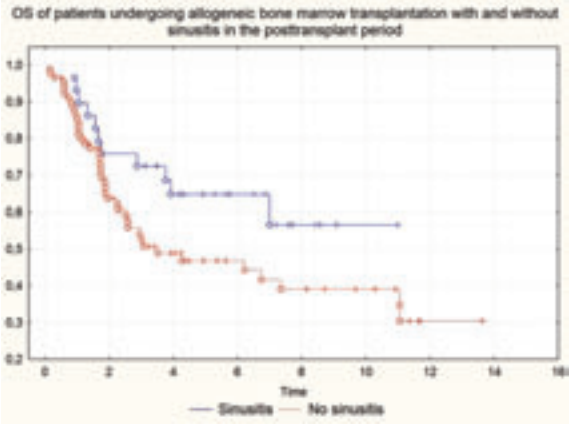
of relapse (n=3) or infection (n=1). The cumulative incidence of relapse and the probability of disease-free survival at 2 years were 23.8% and 76.2%, respectively. *Summary/Conclusions*. Our data suggest that adult high-risk ALL patients without suitable related or unrelated donors should be considered as candidates for double CBT and provide the rationale for a larger clinical study in Korea.

1469

SINUSITIS IN PATIENTS UNDERGOING ALLOGENEIC BONE MARROW TRANSPLANTATION

J Drozd-Sokolowska, J Sokolowski, K Niemczyk, W Jedrzejczak
Medical University of Warsaw, Warsaw, Poland

Background. Sinusitis is one of the most common infections in general population, but data on its incidence and impact on the overall survival in hematologic patients undergoing allogeneic bone marrow transplantation is scarce. *Aims.* Analysis of the frequency of sinusitis, its fatality and potential predisposing risk factors in allogeneic bone marrow transplant recipients. *Methods.* The records of 113 patients with different hematological diagnoses with the exception of chronic myelogenous leukemia who underwent altogether 128 allogeneic bone marrow transplantations, were retrospectively reviewed for the occurrence of sinusitis, its complications, survival and the transplant data. *Results*. Twenty nine patients (26,5%) developed sinusitis between day -1 and +2044 (269±376) post transplantation, with 43% of them within the initial 100 days. They were treated with antibiotics and only 2 patients required surgical intervention and one extensive surgery. The only factor which predisposed to sinusitis in the analyzed group was slower neutrophils recovery (19 vs 16.6 days; p=0.03).



The type of donor (related vs unrelated, matched vs mismatched), source of stem cells (peripheral blood vs bone marrow), number of transfused CD34+ cells/kg and CR status had no impact on the occurrence of sinusitis. Sinusitis did not deleteriously affect overall survival of transplanted patients (p=0,08). *Conclusions* Sinusitis is a frequent infection in recipients of allogeneic hematopoietic stem cells, occurring most frequently during the first 100 days post transplantation. It can successfully be managed with antibiotics in the majority of them and has no impact on the overall survival.

1470

THE OUTCOME OF HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION IN PRE AND POST MODERN THERAPEUTIC INTERVENTIONS

K Foley, S Al-Ismail, T Yin
Singleton Hospital, Swansea, UK

Background. We report the outcomes of high dose chemotherapy (HDT) and autologous stem cell transplantation (ASCT) in the first 100 cases treated in a single institute over 13 years. The two main groups of patients were those with Myeloma and Non-Hodgkin lymphoma. We assessed the outcomes of HDT and ASCT pre- and post-introduction of modern therapy in Myeloma and anti-CD20 in CD20 positive lymphomas. We also analysed the prognostic indicators at presentation in each disease group and compared our results to other centres. Aims This single-centre study is aimed at assessing the outcome of HDT and ASCT in our institute and analysing the results in relation to: - Prognostic indicators, previous treatments received and outcomes for Multiple Myeloma (MM), Diffuse Large B-cell Lymphoma (DLBCL) and Hodgkin Lymphoma (HD). - Outcome in patients with DLBCL following ASCT in relation to previous exposure to anti-CD20. - Outcome of ASCT in MM pre- and post-introduction of Thalidomide. - Compare the outcome of different disease groups in our institute to those already reported by others and identify which group of patients benefit the most from ASCT. Methods We analysed data on all patients treated with HDT and ASCT since the start of the service in 1997. The details of the patients, their disease and outcome at 100 days for the period including December 2009 have already been reported to the British Society of Blood and Marrow Transplantations (BSBMT). Results The median age of all patients that underwent ASCT was 53 (range 23-66). Overall survival (OS) at 1 year was 89.5% and progression-free survival (PFS) at 1 and 5 years were 83.7% and 57.4% respectively. Mortality rates at 3 months, 1 year and 5 years were 2.2%, 10.5% and 34.4% respectively. Two patients died within 100 days of transplant, both with NHL. Log-rank analysis demonstrated that those with HD had the best survival following ASCT compared to other groups (p-value 0.039). The main disease groups and the number of patients in each group analysed were: Myeloma (n=39), Hodgkin lymphoma (n=14) and Non-Hodgkin lymphoma (n=40). There was no significant difference in PFS or OS following ASCT for DLBCL between the 14 patients that received anti-CD20 as part of their initial therapy and the 11 patients that were anti-CD20 naïve. Treatment of Myeloma with Thalidomide did not have a significant effect on PFS or OS post ASCT. ISS and IPI scores at diagnosis were not significant in predicting outcome after ASCT in Myeloma and DLBCL (p-values 0.101, 0.081 respectively). Summary/Conclusions. The outcome of HDT and ASCT in HD was better than any other disease group, as was expected. Overall outcome for patients was better than the average outcome reported by BSBMT and EBMT. There was no difference in outcome following HDT and ASCT in patients treated after the introduction of anti-CD20 for CD20 positive lymphomas or the use of Thalidomide as first line treatment in Myeloma. However, the small numbers of patients in each disease group makes it difficult to draw firm conclusions.

1471

DOES CENTRAL VERSUS PERIPHERAL VENOUS ACCESS HAVE AN EFFECT ON THE CD34+ COLLECTION EFFICIENCY IN LARGE-VOLUME LEUKAPHERESIS?

A Verlinden, A Van De Velde, G Verpooten, K Janssen van Doorn
Antwerp University Hospital, Edegem, Belgium

Background. The yield of CD34+ cells obtained from an apheresis procedure can theoretically be predicted from the peripheral blood CD34+ cell concentration, the processed blood volume (PBV) and the efficiency of the collection (CE) (CE = total CD34+ cells collected/(peripheral blood CD34+ cells/µl x PBV in µl) (*Ford et al. Transfusion 1998*). Central venous lines (CVL) are frequently used to provide the high flow rates necessary for large-volume leukapheresis, when peripheral venous access (PVA) is determined to be inadequate after clinical investigation. *Aims*. The aim of this retrospective study was to evaluate the difference in CE between donors/patients undergoing apheresis by CVL or PVA. Methods: During 39 months, 71 donors/patients underwent 115 different apheresis procedures with a Cobe Spectra cell separator (Caridian-BCT). Haematological diagnoses included: healthy donor (n=29), multiple myeloma (n=18), lymphoma (n=24). The choice between CVL or PVA was made by both a medical and a nursing staff member, based on the adequacy of peripheral veins. 67 (58,3%) apheresis sessions were performed by CVL in contrast to 48 (41,7%) by PVA. All donors/patients were evaluated for age, sex, weight, BMI, diagnosis, collection time, PBV and pre-apheresis haematocrit (HCT), thrombocyte count (TRC) and white blood cell count (WBC). Determining factors for CE were assessed after correlation and linear regression analysis. *Results:* Donors/patients receiving a CVL were older (57,7 ± 1,4y versus 51,3 ± 2,1 y; p=0,01) and had a higher BMI (26,6 ± 0,7 versus 24,2 ± 0,5; p=0,01). Healthy donors received significantly less CVL (39,5%) compared to donors with myeloma (60%) or lymphoma (78,6%) (p=0,001). Collection times were shorter using CVL (225,5 ± 6,1min versus 252,8 ± 8,1min; p=0,008) and PBV were greater (20,1 ± 0,81L versus 15,2 ± 0,59L; p<0,001). Pre-apheresis laboratory results showed a lower HCT (33,8 ± 0,7% versus 37,9 ± 0,6%; p<0,001), lower TRC (145 ± 11 x 10^9/l versus 209 ± 12 x 10^9/l; p<0,001) and lower WBC (34,7 ± 2,8 x 10^9/l versus 46,1 ± 2,9 x 10^9/l; p=0,007) in donors/patients with CVL. CE was not significantly higher in donors with CVL (49,6 ± 2,5% versus 47,1±2,5%; p=0,5). HCT (r =-0,245; p=0,008), TRC (r=-0,267; p=0,004) and WBC (r=-0,376; p < 0,001) were all significantly inversely correlated with CE.

Stepwise multiple regression analysis showed WBC count to be the best predictor of CE (R^2=0,096). *Conclusions:* Donors with haematological disease, older age and higher BMI were more likely to need a CVL for CD34+ cell collection compared to healthy donors. Procedures using CVL were shorter in duration time and obtained a higher PBV. However, the use of CVL has no effect on CE. Low WBC seemed to be the best predictor of CE. This fact suggests, to take into account, the PBV in regard to the pre-apheresis WBC in order to avoid the necessity of multiple apheresis sessions.

1472

THE CLEARANCE OF INFUSED HEMATOPOIETIC STEM CELL FROM THE BLOOD CIRCULATION

A Donmez, F Ozsan, B Arik, N Ozkayin, S Cagirgan, S Mir, F Vural, M Tombuloglu
Ege University, Izmir, Turkey

Background. Homing is the essential step and is a rapid process in hematopoietic stem cell (HSC) transplantation. Aim and method: In the present study, using flow cytometry, we tried to determine the clearance time of the infused HSCs from the circulation following autologous HSC transplantation in 20 patients. *Results*. The median CD34+ cells were at the highest level at the first hour and reached below pre-infusion values at the first day after HSC infusion. By nonparametric analysis, positive correlation was found between CD34+ cell levels at the first hour and the post-thaw CD34+ cell dose (r= 0.57, p= 0.01). Inverse correlation was determined between CD34+ cell levels at the first hour and neutrophil engraftment (r= -0.54, p= 0.01). Compared with the patients having CD34+ cell count of ≥2/μL at the first hour after HSC infusion, the patients having CD34+ cell count of <2/μL had delayed neutrophil (20 vs. 12, p=0.008) and platelet (47 vs. 11, p=0.01) engraftment. *Conclusions*. Our results showed that infused HSCs were removed from the blood circulation within a day. In addition, CD34+ cell levels at the first hour might be an important indicator to predict the delay of neutrophil and platelet engraphment.

Funding: this project was supported by Ege University Grand (2005-TIP-030).

RISK FACTORS FOR MICROBIAL CONTAMINATION OF PERIPHERAL BLOOD STEM CELL PRODUCTS

A Donmez, S Aydemir, B Arik, A Tunger, F Cilli, M Orman, M Tombuloglu
Ege University, Izmir, Turkey

Background. In spite of the well known contamination rates and the microbial agents in stem cell products, the risk factors affecting microbial contamination have not been well described. Study Design and Methods: In a 12-year period, we retrospectively evaluated the culture results and risk factors after processing and thawing of a total of 510 peripheral blood stem cell (PBSC) products of 184 patients/donors. Results: Of 28 (5.7%) PBSC products in which microbiological contamination was detected after processing, growth was not detected in 13 (46.4%) products in the post-thawing period. Large volume leukapheresis (LVL) (odds ratio [OR]= 5.85, 95% confidence interval [95% CI] 1.52 - 22.49, p= 0.01) and the large number of the culture specimens that were sent (OR= 1.4, %95 CI 1.03 - 1.91, p= 0.03) were found to be risk factors for post-processing growth. The presence of post-processing microbial growth was found to be risk factor for post-thawing (OR= 20.22, %95 CI 6.67 - 125.15, p< 0.001) and post-transplant (OR= 3.25, %95 CI 1.24 - 8.50, p=0.01) microbial growth. Conclusion: Culture results should be monitored carefully in patients in whom post-processing growth risk increased when LVL was applied and when a large number of culture samples were sent. In transplantations performed with products having post-processing growth positivity, one must keep in mind the fact that growth of different pathogens may be seen at a high rate (30%) along with a markedly increased risk of culture positivity (OR=3.25).

1474

RISK FACTORS FOR ADVERSE EVENTS DURING COLLECTION OF PERIPHERAL BLOOD STEM CELL

A Donmez, B Arik, M Tombuloglu, S Cagirgan
Ege University, Izmir, Turkey

Background. Although collection of peripheral blood stem cells (PBSCs) by apheresis devices is a safe procedure, patients/donors-associated adverse events (AEs) and apheresis instrument related technical problems might be observed. Aim and Methods: We retrospectively reviewed of PBSCs collections following 528 mobilization cycles (413 patients and 75 related donors) over a 10-year period with the intent of identifying risk factors for AEs occurring in association with the procedures. *Results*. A total of 206 (13.1%) AEs occurred in association with the 1572 procedures. 191 (12.15%) of the AEs were classified as clinical AEs and 15 (0.95%) were classified as apheresis instrument-related AEs. The most common clinical AE was numbness of lips, tongue, or extremities (161 procedures, 10.2%) related to the infusion of acid citrate dextrose-A (ACD). Multivariate analysis revealed high amounts of ACD/weight (odds ratio [OR]= 1.11, 95% confidence interval [95% CI] 1.02 - 1.21, p= 0.009), high numbers of procedures (OR= 1.33, 95% CI 1.13 - 1.56, p< 0.001) and female gender (OR= 2.83, 95% CI 1.70 - 4.71, p< 0.001) as being significantly associated with clinical AEs. *Discussion*. Female gender was shown to be the most important risk factor for clinical AEs. Females who significantly increased risk of AEs would benefit from prophylactic calcium before and/or during PBSC collection.

1475

DOES SECOND ALLOGENEIC STEM CELL TRANSPLANTATION COULD BE TREATMENT OPTION FOR RELAPSES, GRAFT REJECTION OR ABSENCE OF ENGRAFTMENT AFTER FIRST ALLOGRAFT: SINGLE CENTER EXPERIENCE

D Stamatovic, L Tukic, M Elez, O Tarabar, B Balint, B Todoric Zivanovic, Z Tatomirovic, O Tasic, S Marjanovic, M Malesevic
Military Medical Academy, Belgrade, Serbia

Introduction. Allogeneic stem cell transplantation (SCT) is only potentially curative treatment option for different hematological malignancies. Despite efficacy, relapses are still possible and till now there is no standard approach neither for relapses, nor for other SCT failures. Current options for such cases are chemotherapy, donor lymphocyte infusion or second SCT. Aim: We are reporting outcome of second SCT in our center. *Patients and method*. From 1995 till 2010., 18 patients (pts) undergone second SCT for treatment of relapse (13 pts), graft rejection (2 pts) or absence of engraftment (3 pts) after first SCT. Median age in this cohort of pts was 22,5 (16-32) years, M/F ratio 11/7. Pts were suffering from various diseases: 2 AML, 9 ALL, 4 CML, 1 MDS, 2 AA. Median follow up is 30,5 (range 2-180) months. *Results*. Disease relapse had occured at a median of 18,7 months after first allo SCT (range 6-72). Graft rejection was observed after one year from first SCT in both cases with aplastic anaemia. Pts with acute and chronic leukemias had received *salvage* chemotherapy (Flag-IDA) and afterwards despite of marrow findings, underwent second allogeneic SCT with reduced intensity conditioning. Pts with aplastic anaemia were conditioned with Cyclophosphamide and ATG. All pts had received stem cells from same identical sibling donor. Peripheral blood was source of stem cells in 16 pts and bone marrow in 2 pts. Engraftment was observed in all pts with median neutrophil recovery after 16 (11-23) days. Prevention of graft versus host disease (GvHD) was modified according to specific situation (complete absence of prophylaxis in the cases of leukemia relapses or combination of Cyclosporin A with Metothrexate or MMF in the graft rejection or graft failure). Overall survival (OS) of all our pts is 37,5% with median follow up 60 (2-180) months. Conclusion: Our modest results have showed benefit of second SCT as treatment option for selected cohort of pts who have failed after first allografting. Further investigation on larger, homogenuos groups of pts is need.

1476

HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOIDE LEUKEMIA IN 77 PATIENTS UNDER 18 YEARS OLD

M Benakli, R Ahmed Nacer, A Talbi, M Baazizi, N Rahmoune, R Belhadj, F Mehdid, D Ait ouali, F Boumansour, R Hamladji
Pierre and Marie Curie Center, Algiers, Algeria

Background. The prognostic of acute myeloid leukemia (AML) in children has significantly improved over this last two decades, essentially with the help of the intensive chemotherapy. Several randomised trials have shown the superiority of HSCT in children with high risk AML in first complete remission (CR). This is a single centre retrospective study involving in 77 children receiving HSCT for HLA identical sibling donors for AML. *Material and methods*. From September 1998 to April 2010, 77 patients (pts) under 18 years old received an HSCT for AML, (62 pts were in 1st CR, 8 pts in 2nd CR and 4 pts were refractory). The cytologic types of AML (FAB: M1:16 pts, M2:27 pts, M3:3 pts, M4:15 pts, M5:4

pts, M6:1 pt, M7:1 pt, M0:2 pts, undetermined type: 8 pts). The conditioning regimens were: Santos (BU-EDX 50) for 63 pts, (BU-VP-EDX 60) for 13 pts and Tutshka (BU-EDX 60) for only 1 pt. GVHD prophylaxis associated Ciclosporin and Methotrexate. Median age is 11 years (4-17). Sex-ratio is 0,83. Median time from diagnosis to transplant is 7 months (3-45). Sixty eight pts received peripheral stem cells with a median rate of CD34 6,21x106/ kg (1,7-27), 8 pts received a bone marrow with a rate of mononuclear cells: 5,8x108/kg (2, 25-8,15), and one pt received a cord blood with a rate of nuclear cells 2,3x108/kg. Results: All the pts have a neutropenia; median duration of the aplasia is 15 days (8-25), overall median time to achieve neutrophils count > 500/mm3 is at day 14 (8-27). Forty two pts (54, 5%) needed blood transfusion, 72 pts (93,5%) required platelets transfusion. Three pts (3,8%) presented a complete resolutive hepatic veno-occlusive disease . Acute GVHD occurred in 26 pts (35,1%), in 19 pts (25, 6%) it was between grade II and IV. Chronic GVHD was observed in 27 pts (39,1%), extensive form in 22 pts (31, 8%). Only 5 pts (6,4%) have presented CMV infection at median time of the day 114 (53-237). Eighteen pts (23,3%) relapsed at a median time of 16 month s (2-36). TRM incidence is 16, 8%. At the 30 th of November 2010, median follow up was 70 months (7-145), 46 pts (59,7%) are still alive, 45 pts (58,4%) are in remission. Overall Survival and Event Free Survival at 12 years are respectively 56,3% and 55%. *Conclusions.* Most of the pts of this study are pts in a first complete remission, and all of them are with unknown cytogenetic profil, the results of the trial are interesting, the TRM and the relapse rate seems not higher than what we observed in other series. An algorithm for treatment depending on the disease risk and the transplant risk might appear in the future in order to decide how to planned HSCT: in first CR or a delayed HSCT.

1477

TREATMENT EFFICACY AND PROGNOSIS IN PATIENTS WITH EXTRAMEDULLARY RELAPSE OF ACUTE LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

O Slesarchuk, A Kulagin, E Semenova, S Bondarenko, I Lisukov, L Zubarovskaya, B Afanasyev

R.M. Gorbacheva Memorial Institute of Children Hematology and Transplantation, Saint-Petersburg, Russian Federation

Background. Leukemia relapse still remains a problem in patients after allogeneic hematopoietic stem cell transplantation (allo-HSCT). A lot of relapses occurred in extramedullary sites with or without bone marrow involvement. Extramedullary relapse (ER) seems to be less sensitive to chemotherapy and immunotherapy, and there is no standard treatment of pts with ER after allo-HSCT. *Aims.* To study frequency and clinical features of leukemia ER after allo-HSCT and to evaluate efficacy of different treatment options. *Methods*. We performed 10-year retrospective cohort single-center study of children and young adults who had leukemia ER after allo-HSCT. Results: Among 79 patients (pts) with acute leukemia who relapsed after allo-HSCT 8 pts (10%) had ER including 4 pts with ALL and 4 pts with AML. The mean age was 14.5 years (range, 1-21). At the moment of allo-HSCT 5 pts had complete remission (CR), 2 pts had relapse, and 1 pt had refractory disease. Allo-HSCT from matched unrelated and matched related donor was performed in 6 and 2 pts respectively. The conditioning regimen was myeloablative and reduced-intensity in 5 and 3 patients respectively. The median time between allo-HSCT and ER was 15 months (range, 3-26). Two pts had isolated ER with full donor chimerism in BM. In other cases ER with simultaneous bone marrow (BM) involvement (n=2), consecutive occurrence of ER and BM relapse (n=2) and BM relapse 3 and 10 months prior to ER (n=2) were diagnosed. The sites of ER were head and neck, salivary glands, breast, paravertebral tissue, bones, skin, kidneys, testes, ovaries, small pelvis. All pts received chemotherapy and immunoadoptive therapy with donor lymphocyte infusion (DLI, n=7) and NK-cells (n=2). Four pts underwent local therapy: 2 - surgery, 2 - radiotherapy. Complete remission (CR) after first ER was achieved in 6 pts, partial remission (PR) - in 2 pts. Duration of CR ranged from 1 to 10 months (median 4). Then 4 pts developed second ER in another sites, 1 pts had BM relapse, and 1 pts had ER in combination with BM involvement. At last follow-up 4 pts were alive including 2 pts in CR lasting 12 and 24 months. The longest CR is maintained with daily chemotherapy. Conclusions: This small study demonstrates that ERs compose about 10 % of post-transplant leukemia relapses. Current available treatment options with chemotherapy, immunotherapy and local control provide rather high rate of initial response but durable remissions are infrequent. Long-term maintain chemotherapy may be considered in this setting. Further prospective studies in a larger cohort would be required to develop optimal management of ER after allo-HSCT.

1478

THE USE OF ADJUSTED IDEAL BODY WEIGHT FOR OVERWEIGHT PATIENTS UNDERGOING HPC MOBILISATION FOR AUTOLOGOUS TRANSPLANTATION

C Hicks,[1] A Trickett,[2] Y Kwan,[3] S Ramanathan[1]

[1]*St George Hospital, Sydney, Australia*

[2]*The Agency for Clinical Information BMT Network NSW, Sydney, Australia*

[3]*Department of Haematology. Concord Hospital, Sydney, Australia*

Background. Generally, transplant protocols dictate the use of patients' actual body weight (ABW) to calculate the required minimum number of CD34+ cells to be harvested for later hematopoietic progenitor cell (HPC) transplantation. In recent years there has been a significant increase in obesity rates in developed nations. In Australia, the 55-64 age group had the highest combined rates of overweight and obesity. This age group is overall the most common age patients proceed to autologous transplant for haematological malignancies. More overweight patients requiring larger HPC collections to meet transplant target doses per kg body weight, equates to a higher demand on apheresis, transplant and HPC storage facilities. *Aims*. We have sought an improved measure of body weight (termed transplant weight) to reach HPC targets for overweight and obese patients undergoing mobilisation and subsequent autologous transplantation.Methods: In our centre for the last 10 years, for patients weighing 25% more than their ideal body weight (IBW) (defined as 'overweight'), their adjusted ideal body weight (AIBW) has been used as their transplant weight and is calculated as follows:IBW= for males; 50 + 0.91 x (height (cm) -152) and for females; 45 + 0.91 x (height (cm)-152).AIBW = IBW + 0.25 x (actual weight - ideal weight).AIBW is then used for determination of minimum blood volume to be processed for HPC harvest of 2 x 106 CD34/kg as follows:Litres processed = 6.5 x transplant weight/CD34 per microL peripheral blood1. AIBW is also used for determination of CD34 cell dosage given at transplant for overweight patients.Results: AIBW has been used at our institution for 65/153 (42%) of patients with haematological malignancies who have had autologous HPC harvests. For patients > 25% above IBW, median ABW was 90kg (range 62-175 kg) whereas median AIBW was 69kg (range 50-110 kg). Median volume of peripheral blood processed to achieve minimum 2 x 106 CD34/kg using AIBW was 13.2 L (range 5-33 L).For patients who then proceeded to transplant, 35/82 (43%) had AIBW used to determine CD34 dosage/kg. All patients engrafted with no significant difference between the groups. Median time to neutrophil and platelet engraftment for overweight patients collected and transplanted using AIBW was 13 (range 10-24) and 15 (10-40) days respectively. For normal weight patients collected and transplanted according to their ABW, median time to neutrophil engraftment and platelet engraftment was 12 (9-25) and 14 days (9-29) respectively.Summary and Conclusions: By using an AIBW for patients more than 25% above their ideal weight, we have reduced the volume of blood to be processed and hence apheresis time required to achieve the minimum number of CD34 cells per kg body weight. Further, this has reduced cryopreservation storage space needed and dose of DMSO given at transplant. There has been no adverse effect on engraftment times for these patients and we consider this a safe and more efficient strategy for body weight estimation for overweight patients undergoing autologous transplantation.1. INTRAVENOUS BUSULFAN-CYCLOPHOSPHAMIDE AS PREPARATIVE REGIMEN BEFORE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE LYMPHOCYTIC LEUKEMIA

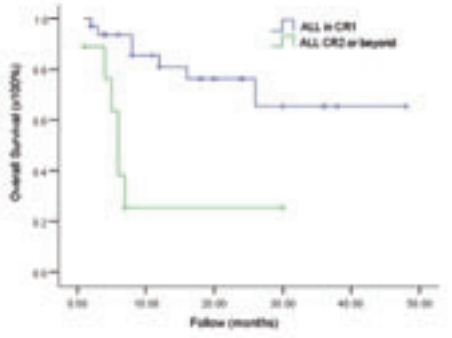
J Hu, T Tang, W Wang

Shanghai Institute of Hematology, Shanghai, China

Background. Intravenous bulsulfan-cyclophosphamide (IV BU/CY) may improve the outcome of allogeneic hematopooietic stem cell transplantation (allo-HSCT) by reducing the toxicity and TRM compare to the oral BU/CY regimen. There are still limited reports of IV BU/CY regimen in acute lymphocytic leukemia (ALL). *Aims*. This study was to evaluate the efficacy and toxicity of IV BU/CY in adult ALL patients undergo allo-HSCT from HLA-matched donors. *Methods*. We retrospectively analyzed 42 consecutive patients transplanted between Jan 2007 to Oct 2010. Thirty-three patients were in first complete remission (CR1), 2 in second remission (CR2) and 7 patients in more advanced stage with median age of 28 years (range, 17~55). The median follow-up was 15 months (range, 1~48).



Results. Overall, 13 patients died with 30-month OS at 56.0±10.6% (65.3±12.5% for CR1 vs. 25.4±15.5% for CR2 or beyond, p<0.001). Eleven patients relapsed 2 to 26 months after allo-HSCT with 30-month RR at 40.0±10.9% (32.0±12.7% for CR1 vs. 72.4±17.1% for CR2 or beyond, p=0.001). Overall, only 2 cases of clinical diagnosed VOD were documented (4.7%) and one died of severe VOD. Other conditioning associated toxicities were diffuse alveolar hemorrhage (DAH) in 1 and hemorrhagic cystitis in 8. A total of 4 patients died due to transplantation related mortality (TRM) with 30-month TRM at 9.7±4.6%. *Summary*. This study demonstrated that the IV BU/CY can be considered as a feasible regimen for adult ALL with low incidence of VOD and TRM.

PEGFILGRASTIM: SUCCESSFUL USE FOR PBSC MOBILIZATION IN ONE CENTER

E Oboukhova,[1] E Ogorodnikova,[2] A Davtian,[1] A Gordeeva,[1] E Gretsov[3]
[1]*Federal Medical Biophysical Center n.a. A.I. Burnazyan, Moscow, Russian Federation*
[2]*N.N. Blochin Cancer Research Center, Moscow, Russian Federation*
[3]*Hematological Research Center, Moscow, Russian Federation*

Background. The use of G-CSF is most widespread method of peripheral blood stem cells (PBSC) mobilization during past decade. This cytokine may be applied alone or in combination with chemotherapeutic agents. When pegfilgrastim became available, great interest appeared to replace multiple injections of conventional form of G-CSF by single injection of pegilated form. We took an attempt to estimate mobilizing activity of pegfilgrastim given as single dose of 18 mg following chemotherapy (CT). The aims of our research were: 1) to reveal the ability of this regimen to produce a suitable peak of CD-34+ cells in adults with cancer diseases; 2) to prove the possibility to collect after this mobilization the sufficient number of PBSC for subsequent autologous transplantation; 3) to assess side events of such mobilization approach. Methods. Seventeen consecutive cancer patients (pts) were treated from April 2010 to February 2011. They received pegfilgrastim as a single dose of 18 mg in combination with CT to mobilize autologous PBSC. There were 5 female and 12 male, age was 24 - 55 y.o (median 40). Diagnoses were lymphoma (7), multiple myeloma (3), poor-risk Hogkin lymphoma (4), ALL (2), thymoma (1). Nine pts received Cyclophosphomide (CY) 6 g per b.s.m. followed by 18 mg pegfilgrastim. Eight pts received other CT cycles followed by the same 18 mg pegfilgrastim. There were 6 heavy pretreated pts (2 in CY group, 4 in the other group). The target of harvest was to collect CD-34+ cells number sufficient for auto transplantation (not less, then 2 million per kilo b.w.). Duration of neutropenia, adverse events, time to neutrophil recovery, peak and harvest CD-34+ cells were recorded. *Results*. Fifteen of 17 pts (88%), including 5 heavy pretreated pts, had successful collection. It was collected leukocytes 32 - 100 milliard (median 70), CD-34+ cells consisted of 2,3 - 57 (median 10,6) million per kilo b.w. In all 15 pts we observed obvious peak of CD-34+ cells in PB. In pts, mobilized by CY the peak was registered on days 10 - 16 (median12), in those mobilized by other CT - on days 14 - 30 (median 19). Four of 15 pts were transplanted up today with fast and sustained engraftment. There were no considerable side events associated with mobilizing regimens. *Conclusions*. our experience demonstrates that combination CT with pegfilgrastim for PBSC mobilization is safe and effective. CY 6 g per b.s.m. followed by pegfilgrastim (single dose of 18 mg) shows high CD-34+ cell PB peaks, laid in restrict, well predictable time. Mobilized PBSC have high potency of hemopoietic reconstitution.

Background. Ovarian cancer is one of the most chemotherapy sensitive solid tumors. However, the role of dose intensity in the chemotherapy of advanced epithelial ovarian cancer has remained controversial. Accordingly, the current study attempted to analyze the outcome of high dose chemotherapy and autologous peripheral blood stem cell transplantation for ovarian cancer retrospectively. Methods. Clinical data were collected retrospectively from 6 transplant centers in Korea between January 1996 and July 2008. Results. Twenty three patients of total 6 centers were analyzed. The median age of the patients was 52 years (40-62 years). Nineteen patients (82.6%) were platinum sensitive and 4 patients were not. The conditioning regimens were reported to be ICE (ifosfamide, carboplatin, and etoposide) in 43.5 %, CTM (cyclophospamide, thiotepa, and melphalan) in 26.1 %, melphalan in 13%, other in 17.4 %. The median time to attain a neutrophil count greater than 500/mm3, following the transplantation, was 13 days (4~38), and to attain a platelet count greater than 20,000/mm3, was 13 days (4~38 days). There was primary graft failure of platelet in 3 patients. The median duration of progression free survival and overall survival were 6.3 months (95% CI, 0-19.3) and 19.7 months (95% CI, 10-29.4). The median overall survival was 25.9 months in the platinum sensitive patients and 17.4 months in the platinum resistant patients, however, there was no statistically significant difference in PFS between two groups. Poor prognostic factor for survival which retained statistical significance at multivariate level were platinum resistance (p=0.06, RR 3.99; 95% CI, 0.94-16.97) and clear cell type (p=0.015, RR 9.63; 95% CI, 1.56-59.45). *Conclusions*. Some subgroups (non clear cell types, platinum sensitive groups) of patients with ovarian cancer seem to have good outcomes after high dose chemotherapy with autologous stem cell transplantation, although several biases may have affected these observations.

1482

THE TREATMENT OF STEROID-RESISTENT GRAFT-VERSUS-HOST DISEASE WITH MULTIPOTENT MESENCHYMAL STROMAL CELLS

L Kuzmina, L Lubimova, N Petinati, I Shipounova, E Parovichnikova, E Gribanova, N Kalinin, N Drize, V Savchenko
National Research Center for hematology, Moscow, Russian Federation

Background. Acute and chronic graft-versus-host disease (GvHD) develops in more than 50% patients after hemopoietic stem cell transplantation (HSCT) and remains one of the main mortality causes. The first line of therapy is glucocorticoids, in combination with cyclosporine/tacrolimus. Different drugs are used as the second line (mycophenolate mofetil, ATG et al). But in many cases the therapy is not effective. Actually the search of new methods of GVHD treatment is very important. Now multipotent mesenchymal stromal cells (MMSC) are studied in the therapy of steroid-resistant GVHD. Aims. To research the efficacy of MMSC in the treatment of steroid-resistant GvHD. Methods. Between July 2007 and December 2010 8 patients after HSCT from HLA-identical sibling donors (7 patients), and from HLA-identical unrelated donor (1 patient) with steroid-resistant GvHD were treated with MMSC. Bone marrow derived MMSC from HLA-identical sibling donors (6 patients) and from haplo-identical family donors (2 patients) were cultured in alpha-MEM with 4% human platelet lysate. The intravenous infusion of MMSC was performed to 4 patients with acute steroid-resistant GvHD grades II-IV and to 4 patients with chronic extensive GvHD. The dose of MMSC was 0,8-1,6x106 per kg (median dose 1,1x106/kg cells). Five patients received MMSC once, two patients - twice, and 1 patient received MMSC 4 times. Most of the patients didn't have side effects during and after MMSC infusions. The effect was

estimated 30 days after MMSC infusion. The trial was approved by local ethic committee.Results. Among 4 patients with extensive chronic GvHD 2 patients didn't respond, and both of them died from infections. One patient had a clinical improvement (alive for 15 months after HCST), and one patient had a partial response on the therapy (alive 24 months after HCST). Four patients with acute steroid-resistant GvHD grade II-IV were treated with MMSC. One patient didn't respond (injection of MMSC +97 day after HCST) and died six months after HCST because of infections. One patient had clinical improvement (injection of MMSC +76 and +124 days) and one had complete response (injection of MMSC +82 day after HCST). They are alive 26 and 24 months without immunosuppressive therapy and GvHD respectively. The fourth patient received 1 infusion of MMSC for acute steroid-resistant GvHD grades II after HSCT (injection of MMSC +58 day) and complete response was achieved after this. Three months after HSCT the patient relapsed and was treated with donor lymphocyte infusion, remission was achieved with GvHD grade IV. The patient received 3 infusions of MMSC and had partial response. The patient alive 11 month after HSCT. The immunosuppressive therapy is continued. Conclusions. Good effect was observed in two cases among 4 patients with chronic extensive GvHD after MMSC infusion. In four among five cases with acute steroid-resistant GvHD injection of MMSC was effective. All of the patients who had response are alive, and patients who didn't have response died. The best results are fired in cases when MMSC were infused directly after the diagnosis of acute steroid-resistant GvHD.

1483

CARDIAC COMPLICATIONS AFTER BONE MARROW TRANSPLANTATION. A REPORT ON A SERIES OF 35 CASES IN THE DEPARTMENT OF BONE MARROW TRANSPLANTATION- TIMISOARA, ROMANIA

A Isac
Emergency Children Hospital L.Turcanu, Timisoara, Romania

Background. Cardiotoxicity is one of the non malignant complications after bone marrow transplantation and the principal clinical manifestations are: restrictive or dilated cardiomyopathy, arrhythmia, heart failure, pericarditis, hypertension, acute myocardial infarction. Aim : The purpose of this study was to estimate the frequency of the cardiac complications after BMT and of their impact on survival. Method: Cardiac complications related to bone marrow grafting were investigated in a group of 35 consecutive adults patients undergoing BMT (33 autologous, 2 allogeneic) in the transplant unit of Children's Hospital- 3rd Clinic of Pediatrics Timisoara, Romania between 2008 and 2010. We followed the next parameters: heart rate, blood pressure, ECG, echocardiography, Holter ECG, Holter for blood pressure, chest x-ray. From 35 cases - 5 patients have essential hypertension and 3 ischemic heart disease before transplant, without aggravation after transplant. *Results*. From 35 cases, 18 didn't have cardiac complications and 17 with cardiac complications; from 17 patients , 9 cases were Multiple Myeloma, 1AML, 4 Hodgkin's Disease, 1 MDS (AREB II), 2 Non-Hodgkin's Lymphoma. During the cells administration were no major cardiac complications. There were 2 cases of minimal pericarditis, 1 case of heart failure NYHA type II (EF<50%) , 5 arrythmias including 4 tahycardias and 1 ESV, 2 secondary hypertension, 7 diastolic dysfunction type I , 6 mitral regurgitation and 1 aortic regurgitation. After stem cell transplantation 9 cases developed dyslipidemia , considered one of the cardiovascular risk factor. The pregraft regimen was Melphalan, BEAM for autologous, Bu/Cy for allogeneic. Treatment before transplantation :VAD, Bortezomib+De - xamethasone for MM, R-ICE, R-CHOP, R-DHAP for NHL, ABVD, BEACOPP for HD, Cytosine-arabinoside + Anthracyclines for AML and MSD, mediastinal radiotherapy , were the factors basically responsible for the cardiac toxicity. Routine echocardiography confirmed the high incidence of subclinical cardiac abnormalities and their reversibility.The monitoring of the cardiac function is very important and the early treatment is essential; at these patients the cardiac treatment were with: beta-blocker=9 cases, ACE inhibitors=3 ,angiotensin-receptor blockers =2, statins=9, diuretics=1, nitrates=1, calcium chanel blockers=1, antiplatelet agents=1. *Conclusions*. Currently we consider that the cardiac toxicity is one of the most important limiting factors for bone marrow transplantation. We suggest, therefore, that the transplantation should be done as early as possible. In our cohort didn't appear major cardiovascular complications which required emergency cardiological intervention, only periodical follow-up. The major cardiotoxic events attributable to BMT are uncommon, comparable with another studies (in the literature occurring with a frequency of < 1-2 % after BMT) .

1484

ULTRASOUND DETECTION OF DELAYED FOCAL AND DIFFUSE LIVER DISEASES AFTER HEMATOPOIETIC STEM CELL TRANSPANTATION IN CHILDREN

P Gasperini, C Biagi, R Masetti, A Colecchia, D Festi, A Prete, A Pession
Sant'Orsola-Malpighi Bologna, Bologna, Italy

Background. During Hematopoietic Stem Cell Transplantation (HSCT) the liver is the target of many type of injures widely described in literature: toxicity related to the preparative regimen sinusoidal obstruction syndrome, hepatic acute graft-versus-host disease and acute hepatitis. In the setting of pediatric HSCT little is known about the role that HSCT may play in developing of late hepatic complications. At the state of art no guidelines exist regarding follow-up evaluation of liver status in pediatric patients after HSTC. AIMS. The aim of this study was to investigate the late effects of pediatric HSCT on the liver and to propose an adequate approach for monitoring liver status in post-transplanted children using abdominal ultrasound (US). *Methods.* Evaluation of liver status using abdominal US was performed before and after HSCT in 51 children (22 girls, 29 boys) with a mean age of 9.4 years (range 0.5 - 21). All the patients underwent HSCT (15 autologous, 36 allogeneic) at our Institution. The follow-up evaluation with abdominal US have been performed every six months. RESULTS. At a median follow-up of 28.3 months (range 2 - 91) out of 51 patients evaluated, 5 (9.8%) presented focal liver disease at abdominal US: 3 patients developed focal nodular hyperplasia (FNH) and 2 hepatic hemangioma. In 13 children instead we found the presence of diffuse liver disease (25.4%) with 10 cases of mild steatosis and 3 mild hepatomegaly. In 3 patients both steatosis and hepatomegaly have been observed. None of the patients had US hepatic disorders before HSCT. Characteristics of the patients who have developed hepatic disorders and of the HSCT procedure performed have been resumed in Table 1.

No patient experience symptoms and no peculiar laboratory findings have been observed. SonoVue-enhanced US has been performed in patients with suspected FNH and hemangioma in order to differentiate them from metastatic or malignant lesions. In 2 of the patients with FNH, magnetic resonance imaging together with hepatic biopsy have been required to confirm the diagnosis. None of these subsequent lesions presented malignant transformation. *Conclusions*. The findings of this study suggest that both focal and diffuse liver disease such as FNH, angioma, steatosis and hepatomegaly can occur in children as late hepatic complications of HSCT. Abdominal US seems to be a mandatory approach for children undergone HSCT and should be performed every 6 months. Future studies are needed to better investigate the late effects of HSCT on liver and understand how these complications are related both to the patients' characteristics and HSCT procedures.

1485

NON ABSORBABLE STEROIDS IN AUTOLOGOUS GRAFT-VERSUS-HOST DISEASE WITH GASTROINTESTINAL AND CUTANEOUS INVOLVEMENT AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION FOR NON HODGKIN`S LYMPHOMA. A CASE REPORT

J Monserrat, F Alberca, JM De la Peña, J Bermejo, A Bas, E Martínez, A Sánchez, M Majado, JM Moraleda
Hospital Virgen de la Arrixaca, Murcia, Spain

Background: Graft versus host disease (GVHD) is a potential life threatening complication tipically associated to allogeneic stem cell transplantation (AloSCT). Nonetheless, few reports in literature describe a GVHD-like syndrome occurring in patients undergoing to an autolo-

gous stem cell transplantation (AutoSCT). We discuss an autologous GVHD in a patient diagnosed with non hodgkin`s lymphoma who proceed to an AutoSCT with skin and gastrointestinal involvement. Case report: A 56 years old gentleman was diagnosed in may 2007 of diffuse large B cell lymphoma. At diagnosis, the stage was IV-B with a high IPI score. As induction chemotherapy he received 6 cycles of R-CHOP, achieving a complete remission (CR). Unfortunately, two years later he relapsed in a early stage (IIA) and was treated with 4 cycles of ESHAP achieving his second CR. Then he received an AutoSCT with BCNU 300 mgr/m^2, etoposide 800 mgr/m^2, cytarabine 1600 mgr/m2 and melphalan 140 mgr/m^2 (BEAM, total doses) as conditioning regimen. Graft composition was: total nucleated cells of 3.33x10^8/kgr compressing 6.38x10^6 Kg CD34+ cells. G-CSF was administered from d+5 to d+10. Neutrophil and platetelets engraftment occurred on d+9 and he was discharged on d+12. He received transfusions of 5 irradiated and filtered blood products (3 packed red cells and 2 platetelets units) without any adverse event during their infusion. Throughout the three months after the AutoSCT he was admitted twice (on d+20 for 16 days, and on d+92 for 10 days) because of recurring fever, diahorrea, hyporexia and weight loss of 11 kilograms, with persistent mycrobiological negativity of blood and stool samples for bacterial, viral, fungal and parasites examinations. We weren't able to identify any link between the drugs given to the patient as infection prophylaxis in the post-trasnplant period and his symptoms. However we stopped all of them with no clinical improvement. The symptoms showed a trend to spontaneusly ameliorate within the two admissions to finally outbreak again. Interestingly, a PET-TC done for residual disease monitoring on d+90 showed extensive bowel inflammation without sings of relapse. During his last admission a slight skin rash was found affecting mainly the back and the lower limbs. We performed skin and colonic byopsies and histological findings were consistent with GVHD in both of them. The patient was started on oral non absorbable steroid therapy with beclometasone 8 mgr four times in a day for two weaks, and then tapered off during two more weeks with rapid symptoms disappereance, including the skin rash. *Conclusions:* GVHD is a matter of concern in AloSCT. Few reports in the literature has described a GVHD-like syndrome in the AutoSCT setting. Some reports hypothesize a key role of certain immunosuppressant drugs given during the conditioning regimen as cyclosporine or alentuzumab. Our patient didn`t received any drug apart from the conditioning regimen itself and the standard infections prophylaxis. Interestingly the skin rash disappeared with the oral non absorbable steroids, suggesting a *trigger* role of the gastrointestinal tract in the whole picture of the GVHD as it has been highlighted in some animal models.

THYROID DYSFUNCTION AFTER HSCT - A SINGLE CENTRE EXPERIENCE

O Ciocarlie,[1] A Oprisoni,[1] B Zoica,[1] L Balint Gib,[2] A Balan,[2] C Popa,[1] C Jinca,[1] A Isac,[2] S Arghirescu,[1] G Doros,[1] M Serban[1]
[1]*V. Babes University of Medicine and Pharmacy Timisoara, Timisoara, Romania*
[2]*L. Turcanu Emergency Hospital for Children, Timisoara, Romania*

Background. Thyroid dysfunction after hematopoietic stem cell transplantation (HCST) is recognized as a late complication. It has been established that both imaging and serological investigation are required in order to monitor the thyroid function of patients after HSCT. Aims: to present the experience of a single center SCT Unit in long term endocrinological follow up focusing on thyroid complications. Material and method: this is a single centre retrospective study of 146 consecutive patients admitted in the HSCT Unit of Timisoara during 2005-2010. Forty-nine (33.56%) were children and 97 (66.44%) were adults. Gender distribution was 64 (44.83%) females and 82 (56.17%) males. The transplant was autologous in 118 (80.83%) patients and allogeneic in 28 (19.17%). The spectrum of diseases for which they received HSCT was: aplastic anemia 3 (2%), Hodgkin lymphoma 43 (29.4%), non-Hodgkin lymphoma 21 (14.4%), acute lymphoblastic leukemia 17 (11.7%), acute myeloblastic leukemia 12 (8.3%), chronic myeloblastic leukemia 1 (0.7%), multiple myeloma 28 (19.2%), neuroblastoma 3 (2%), primary neuro-ectodermal tumor 3 (2%), rabdomyosarcoma 5 (3.4%), Ewing's sarcoma 7 (4.8%) and nephroblastoma 3 (2%). The conditioning regimens were BEAM in 62 (42.5%), Melphalan in 29 (19.8%), Bu-Cy in 25 (17.2%), Bu-MEL in 12 (8.2%), regimens with carboplatin in 6 (4.1%), Bu-Cy-Eto 4 (2.7%) and other regimens in 8 (5.5%) patients. None of the patients received TBI. Cervical or upper-body irradiation was administered to 46 (31.5%) patients. All patients were tested before conditioning for TSH, FT3 and FT4. Patients with thyroid dysfunction prior to HSCT were excluded from this study. All patients were tested immediately after transplantation, then at 6 months intervals for TSH, FT3 and FT4 using the CMIA Abbott method. Thyroid ultrasonography was performed at 3 months intervals. Results: Thyroid dysfunction was observed in 31 patients (21.2%). The most frequent problem was represented by hypothyroidism in 19 (13%) patients. Overt hypothyroidism was discovered in 7 (4.8%) patients. All 7 had received BEAM conditioning and 6 of them were submitted to prior radiotherapy. Subclinical hypothyroidism was observed in 12 (8.2%) patients all of which had received melphalan conditioning. Only 4 had received radiotherapy. Euthyroid sick syndrome was seen in 5 (3.4%) patients and none of them had received prior radiotherapy. Seven patients (4.8%) developed hyperthyroidism in the first 0-6 months after transplantation. All 7 patients were conditioned with BEAM and 4 received prior radiotherapy. None of the patients who received conditioning with busulphan presented thyroid dysfunction. Radiation therapy has been recognized to have a key role in inducing thyroid damage. Out of the 46 patients who were submitted to radiotherapy, 14 (30.43%) developed thyroid dysfunction. *Conclusions*. The incidence of thyroid dysfunction in our center is lower than that reported in the literature, probably because most patients were monitored for less than 5 years and thyroid dysfunction is a long-term complication in HSCT patients. Long-term survivors of HSCT are at increased risk for thyroid abnormalities. This knowledge should promote efforts for regular screening to detect and treat thyroid illness early, especially in young adults transplanted during childhood or adolescence.

BIOSIMILAR G-CSF IN POST AUTOLOGOUS STEM CELL TRANSPLANTATION SETTING: PRELIMINARY RESULTS

S Sammassimo, G Andreola, S Bassi, P Paochi, A Gardellini, P Minga, L Orlando, M Negri, R Pastano, G Martinelli
European Institute of Oncology, Milan, Italy

Background. G-CSF is used in neutropenic phase post-high-dose chemotherapy to reduce infections and support engrafment. *Aims.* Nowadays biosimilar filgrastim products are available as Tevagrastim and data in the setting of autologous trasplantation for haematological malignancies are lacking. Methods. In our Institution from November 2010 and February 2011 15 patients underwent autologous peripheral stem cell transplantation for haematological malignancies (8 Non Hodgkin Lymphoma, 1 Hodgkin Lymphoma, 6 Multiple Myeloma). 13 patients received BEAM +/- Rituximab conditioning regimen and 2 pts high dose melphalan. The median age was 61 (range 17-76). A median dose of 4.2 (range 2.2-8.85) x 10^6 CD34(+)cells/kg was infused. On the fifth day after progenitor cells infusion, tevagrastim treatment was initiated in all patients at daily doses of 300 μg by subcutaneous injection. To assess tevagrastim efficacy, we evaluated duration of neutropenia as cut-off values neutrophil counts of 500 neutrophils/mm^3, time to platelets recovery > 20000/mm^3 and number of fever episodes during neutropenia. In addition, we select the last 15 patients with similar characteristics treated with originator G-CSF before starting with biosimilar use. *Results.* No adverse events were registered. Administration of tevagrastim resulted in neutropenia recovery in a median of 11 days (range 7-13) while platelets recovery was observed in a median of 12 days (range 7-22). Nine patients (60%) experienced febrile neutropenia resolved with endovenous broad spectrum antibiotics. No differences were reported in term of white blood cells and platelets recovery among patients receiving biosimilar G-CSF versus originator one. *Conclusions.* In our preliminary experience Tevagrastim resulted safe and effective in autologous stem cell transplantation with similar efficacy versus other registered growth factors. Considering that every patient received at least 10 days of growth factor support, the use of biosimilar G-CSF may lead to a cost reduction of about 200 €(approximately 50%).

1488

VIRAL INFECTIONS - STILL A CONSTANT RISK IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

C Jinca,[1] S Arghirescu,[1] A Balan,[2] V Ordodi,[3] M Baica,[2] D Mihailov,[1] E Gai,[3] L Balint-Gib,[2] A Isac,[2] I Ionita,[1] M Serban[1]
[1]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania*
[2]*Louis Turcanu Emergency Children Hospital - IIIrd Pediatric Clinic, Timisoara, Romania*
[3]*Emergency County Hospital, Timisoara, Romania*

Background. Viral infections remain an important cause of morbidity and mortality after hematopoietic stem cell transplantation (HSCT). *Aims.* To evaluate the frequency and type of viral infections after HSCT.

Methods: We performed a retrospective descriptive unicentric survey in Timisoara BMT Unit during 2001- 2010, on 166 consecutive transplants: autologous - 127 and allogeneic - 39 with patients mean age 28,04+/-16,81 years. Their pathological background consisted of leukemia-24,09%, malignant lymphoma-42,77%, aplastic anemia-1,8%, solid tumors-13,25% and others-18,07%. All of them had an identical supportive. A pretransplant serological screening for HIV, hepatitis, CMV, VZV, EBV and HHV was undertaken. Complex investigations were performed in febrile neutropenia, graft failure or in symptomatic patients. Results. We registered 49 episodes of documented viral infections, either of exogenous (34,69%) or endogenous (65,3%) origin. Their timing was early-7,5%, intermediate-40% and late phase 52,5%. Seven patients experienced more than one viral infection: one-CMV, polioma-BK and VZV, one- CMV and polioma-BK, one-HBV and polioma-BK and in 4 cases with HBV infection occurred also VZV reactivation. The reactivation or infection with herpesviruses families happened in 34 cases: CMV-5, VZV-28 and HHV6-1. Five patients presented CMV reactivation from which 80% before day+100. CMV appeared more often among the recipients of allogeneic grafts. None of the patients presented clinical signs but all cases were associated with elevated serum levels of hepatic enzymes and with moderate or severe neutropenia. All cases were treated with iv ganciclovir for a median of 3 months and experienced a negativation of CMV-PCR after a median of 2 weeks of therapy. All VZV reactivations/infections appeared after cessation of prophylaxis with acyclovir. 92,85% of patients were VZV-IgG seropositive before HSCT. The cutaneous presentation was: disseminated in 2 patients, extended in two dermatomes in 2 cases and limited to one dermatome in 24 patients. All cases responded to oral acyclovir treatment none of them requiring hospitalization. Post-herpetic neuralgia occurred in 25% of cases. HHV-6 was detected by PCR at day +16 in one patient who presented with severe altered functional liver tests. The evolution was fulminante to hepatic failure despite intensive antiviral treatment. We also identified adenovirus and polyoma-BK infections in 2 and respectively 4 cases. Viruses were detected by PCR in urine samples and the clinical expression was hematuria. A concerning aspect was constituted by hepatic viruses infections found in 9 cases: HBV-8 and HCV-1. In one case the HBV was a precore mutant type and in the rest of patients the HBV was wild type. None of the patients developed hepatic failure or died from HBV complications. *Conclusions*. In the structurally and functionally immunodepressed HSCT patients, viral infections continue to be a life threatening risk. There are evident limits of proven diagnosis in viral infections and a consequently high proportion of prophylactic and preemptive therapies. Early identification of infections, a specifically tailored therapy and an increased accessibility to diagnostic tools for viral diseases are only some conditions for improvement of life expectancy and increasing of cure rates.

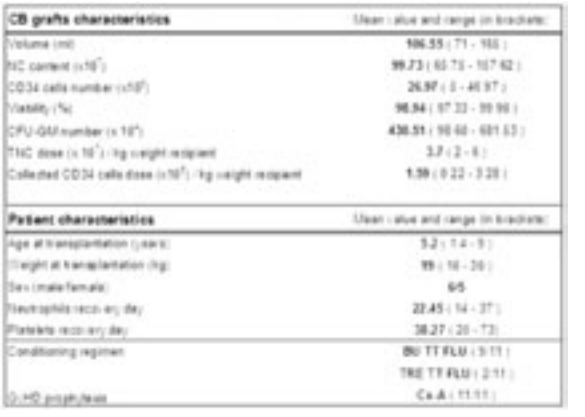
Nowadays, cord blood transplantation (CBT) represents an effective treatment for several malignant and non malignant haematological diseases. Substantial evidences have been accumulated indicating that HLA donor/recipient compatibility primarily influences the transplantation outcome. However, little is known about the extent to which minor histocompatibility antigens (mHAgs) mismatches are involved in engraftment. Compared to other stem cell sources, a CBT recipient may have a decreased probability of engraftment and a delay in neutrophil and platelet recovery. Platelet endothelial cell adhesion molecule-1 (PECAM-1, or CD31) and leukocyte endothelial adhesion molecule-1 (LECAM-1 or CD62L) are polymorphic proteins that can generate potentially immunogenic small peptides by intracellular cleavage. These molecules act as mHAgs and may activate alloreactive T lymphocytes in the transplantation setting. CD31 is expressed on several cell subsets including platelets and most leukocytes and is required for the transendothelial migration of leukocytes. CD62L acts as a 'homing receptor' for leukocytes to enter secondary lymphoid tissues, regulating leukocyte trafficking through the blood. Hence, the CD31 and CD62L mismatches should reasonably have a role in influencing neutrophil and platelet recovery times (RT). To test this hypothesis, 11 patients and their CB sibling donors were typed for the polymorphisms of CD31 (codons 125, 563 and 670) and CD62L (codons 206 and 213) genes by PCR-SSP technique using mHA Minitray kit (University Clinic Heidelberg Hospital).



CB grafts characteristics	Mean ± stv and range (in brackets)
Volume (ml)	186.55 (71 - 155)
NC content (x10⁷)	99.73 (65.75 - 167.62)
CD34 cells number (x10⁵)	26.97 (5 - 46.97)
Viability (%)	96.84 (97.33 - 99.99)
CFU-GM number (x 10⁴)	436.51 (98.60 - 681.53)
TNC dose (x 10⁷ / kg weight recipient	3.7 (2 - 6)
Collected CD34 cells dose (x10⁵) / kg weight recipient	1.39 (0.22 - 3.28)
Patient characteristics	**Mean ± stv and range (in brackets)**
Age at transplantation (years)	5.2 (1.4 - 9)
Weight at transplantation (kg)	19 (10 - 26)
Sex (male/female)	6/5
Neutrophils recovery day	22.45 (14 - 27)
Platelets recovery day	38.27 (20 - 73)
Conditioning regimen	BU TT FLU (5:11)
	TBI TT FLU (2:11)
GVHD prophylaxis	Cs A (11:11)

The CBs characteristics are shown in the table. The patients were homogeneous for age, weight, diagnosis (10 thalassemia and one sickle cell anemia), conditioning regimen and GvHD prophylaxis. Moreover, each donor/recipient pair was HLA-identical (HLA-A, B and DRB1). Regarding the GvHD direction, all couples were matched for CD31 and 10/11 couples for CD62L polymorphisms. Despite it is reported the association between CD31 and CD62L incompatibility and acute GvHD in HLA-identical transplantation, no patient included in our study developed GvHD, including the CD62L mismatched one. This may rely primarily on the naïveté of the CB immune system.In the rejection direction, we found that the mean values of platelet RT for the CD31 matched and mismatched couples were 41 and 31 days, respectively; whereas the mean values of neutrophil RT for the CD31 matched and mismatched couples were 24 and 19 days, respectively. On the contrary the mean values of neutrophil RT for the CD62L matched and mismatched couples were 21 and 37 days for codon 206, and 21 and 26 days for codon 213, respectively. Basing on our data, one can imagine that CD62L interactions with endothelial vascular cells may occur also in the recipient's bone marrow, thus providing a possible explanation for the delay in neutrophil recovery observed in the mismatched group. Anyway this hypothesis is not supported for CD31. Our data are preliminary and further studies are desirable, enrolling a larger number of patients, to understand the effective role of CD31 and CD62L polymorphisms in CBT setting. Especially since none of our patients experienced graft failure and overall the RT remained under the limits observed in the literature.

1490

EXTENSIVE FASCIITIS AS LATE MANIFESTATION OF GRAFT -VERSUS - HOST DISEASE, A PURPOSE OF A CASE

M Abio1, D Pecondon1, B Zubiri1, M Roca2, P Giraldo1

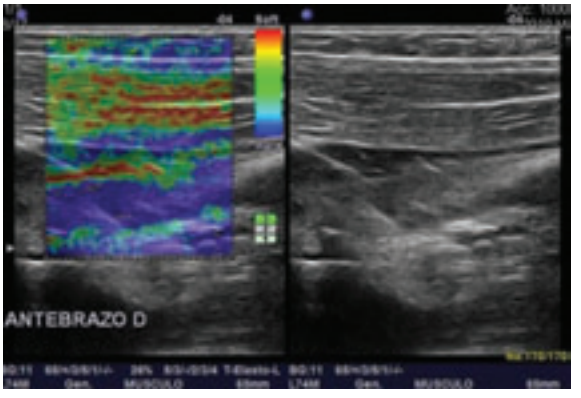
1Hospital Universitario Miguel Servet, Zaragoza, Spain

2Centro Diagnóstico Dra Roca, Zaragoza, Spain

INTRODUCTION: The cGVHD is a multisystem disease that occurs from the day +100 post transplant on and generates inflammatory phenomena that evolve in tissue fibrosis. Fasciitis as a manifestation of chronic graft versus host disease (cGVHD) is rare (incidence of approximately 0.55%).

PATIENT: Female 18 years old, diagnosed with T Acute Lymphoblastic Leucemia in June 2007. Cytoreduction is induced with hydroxiurea and leukocytapheresis (2 processes), and a high-risk LAL-PETHEMA-2003 scheme treatment is established, achieving complete remission (CR) after induction and remained in CR after consolidation. Maintenance: Methotrexate and mercaptopurine. An allogeneic familiar related transplantation with identical HLA and ABO peripheral blood hematopoietic progenitors was performed as much as a GVHD prophylaxis with cyclosporine (CSA) and short course methotrexate. In the

days: +43 post-transplant dyschromia skin rash arms (virus PCR negative) appeared; +66: loss of nails; +75: increases in liver enzymes and acne; +103: From day +100 on, the patient received CSA alternating with prednisone 30 mg. On day +240 CSA treatment was deleted and maintained with steroids, starting his reduction in day +330 and its total suppression at day +480 post-transplant. In the month +19: stiffness of small joints of the fingers, elbows and knees and orange peel in the lower extremities, moreover, waxy skin and underlying tissues attached to his forearms. It is suspected as possible scleroderma plates cGVHD compatible. Skin biopsy is performed with a normal and non inflammatory infiltrate result. Due to the fact that myositis or fasciitis was suspected it was performed: MRI demonstrating an inflammatory involvement of the fascia and septa interfascial, with extension to adjacent muscle fibers, discrete subcutaneous tissue involvement. Elastography: technique based on real time ultrasounds, with colour-coded images, evaluating elasticity of soft tissue stiffness, which discarded muscle involvement (Figure 1).



The results of nerve conduction, electromyography and muscle enzymes were normal. In this way extensive fasciitis as manifestations of cGVHD is diagnosed to the patient and she is on therapy with steroids and mycophenolate mofetil combined with PUVA. Nine months after a new MRI and elastographic exam showed an improvement of lesions mainly in upper arms. *Conclusions.* : The fasciitis is a rare complication in transplanted patients. The diagnosis can be obtained by biopsy, including skin, subcutaneous tissue, fascia and muscle, or alternatively with MRI data supported by other laboratory and / or symptoms. Elastography is a novel technique, useful to assess muscle damage in these cases. It is very important early treatment but we do not know any specific one. Support measures and infectious prophylaxis to prevent deterioration of the quality of life are also needed.

1491

CAN WE USE AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION AS AN INTENSIVE CONSOLIDATION THERAPY FOR ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA PATIENTS IN REMISSSION

S Genadieva -Stavrik, A Pivkova, Z Stojanoski, O Karanfilski, S Trajkova, L Cevreska, B Georgievski
University Hematology Clinic, Skopje, Macedonia

Background: Despite advances in our understanding of its pathogenesis, acute myeloblastic leukemia remains difficult to treat. During the past several decades, improvements in chemotherapeutic regimens and supportive care have resulted in significant but modest progress in treating AML. Conventional chemotherapy is highly effective in the treatment of acute myeloblastic leukemia (AML). About 50-80% of adult patients with de novo acute myeloblastic leukemia achieve complete remission (CR) with currently available chemotherapy regimens consisting of antracyclines and cytarabine. Although initial complete remission can be achieved in a high percentage of patients, relapse occurs in 70-80% of the patients. Two main approaches have been the attempt to eradicate the leukemic clonal cells population via chemotherapy with or without autologous stem cell rescue or to pursue a combined approach using an antileukemic therapy combined with an antileukemic immune response via allogeneic bone marrow transplantation. Autologous transplantation compares favorably against allogeneic bone marrow transplant in several ways. Autologous transplantation can be used as a consolidation therapy in the older population, and lack of a matched donor does not preclude the patients from this treatment. Aim: To evaluate autologous hematopoetic stem cell transplantation as an intensive consolidation therapy in adults with acute myeloblastic leukemia in remission. Methods: We report a retrospective analysis on 48 patients diagnosed with de novo AML, who did not have an available histocompatible donor, and who underwent autologous transplantation between years 2000-2009 at the University hematology Clinic, Skopje, Macedonia. All patients had ECOG score 1 or less. The patient's age ranged from 17 to 65 years with the median age 41 years. There were 26 males and 22 females. For stem cell mobilization patients received chemotherapy or chemotherapy plus G-CSF. The preparative chemotherapy regimen prior to autologous transplantation consisted of BuCy in 24 patient, BEAM in 22 and BuCyMel was used in the remaining 2 patients. We used bone marrow as primary source of stem cells in 18 patients, and peripheral blood stem cells in remaining 30 patients. Results:The five years overall survival was 52% and the 5 years disease progression free survival were 42%. We analyzed sever factors that can influence the overall survival and the disease free survival such as: age, disease status, stem cell source, chemotherapy regiments prior to transplantation, conditioning regiments, number of mobilized stem cells. Advanced age and bone marrow stem cell source seems to be more influent factors. We report that the clinical results of autologous hematopoietic stem cell transplantation are sufficiently encouraging to warrant future trials that include autologous transplantation as an option for appropriately selected patients with AML in CR1. We conclude that autologous hematopoietic stem cell transplantation is a reasonable and save intensive consolidation for patients with acute myeloblastic leukemia who do not have a suitable HLA -matched donor.

1492

OUTCOME OF ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR ACUTE MYELOGENOUS LEUKEMIA: A SINGLE CENTER RETROSPECTIVE ANALYSIS

I Sakellari, D Mallouri, C Apostolou, E Georgiadou, A Athanasiadou, P Kaloyannidis, I Batsis, C Smias, E Yannaki, C Lalayanni, A Papalexandri, N Stavroyanni, C Vadikoliou, D Sotiropoulos, R Saloum, A Fassas, A Anagnostopoulos
George Papanicolaou hospital, Thessaloniki, Greece

Background: The selection of patients (pts) upon the best stratification and the timing of transplantation are the key issues of clinical management in AML. Aim: We evaluated the outcome of all pts allografted consecutively for AML in our BMT-unit during 1991-2009. Methods: The data of 149 pts were analyzed. Donors were siblings (107), relatives (11), unrelated (25), double cord blood (CB) (1) , haploidentical (5). Sixty-three pts aged 35 (8-63) were transplanted in CR1 after myeloablative (MA) (56) and non- myeloablative (NMA) regimen (7). Peripheral blood (PB) was the main graft source (51). Karyotype was available in 40 pts (intermediate 32, poor risk 8). Eighty-six pts were allografted beyond CR1: 42 Prim.Ref, 15 CR2, 23 Rel1 and 6 advanced (CR3; Rel2+). The majority of pts received PB (72) and MA regimen (82). Karyotype was available in 71 (favourable 4, intermediate 53, poor 14). Results: For CR1 pts OS was 63%, NRM 23%, DFS 60% and RR 21% at 13 years, whereas for 46 pts transplanted after 1999 NRM was lower (17% at 9 years). DFS for CR1 pts with unrelated donor was 47% and 62% for siblings. The outcome post NMA was poor (DFS 21% vs 65% post MA). According to cytogenetics OS and DFS were 62% and 64% for the intermediate, 44% and 45% for poor risk respectively. For CR2 pts OS was 51% and DFS 46%, RR 43% and NRM 16%. For Prim.Ref. pts OS was 20%, DFS 17% (plateau at 2 years) and NRM 34% at 12 years. Poor risk karyotype pts (7) had dismal outcome (DFS, OS 0% vs 25% and 31% respectively for the intermediate risk group) (28). For pts in REL1 OS was 15%, NRM 56%, DFS 4% and RR 86%. For the 6 pts transplanted for advanced disease OS/DFS was 17% and RR, NRM rates high. The 5 pts undergone haploidentical hematopoietic cell transplantation (HCT) had OS and DFS 40% at 8 years. In multivariate analysis significant factors associated with better outcome were early phase disease (p=0.001), lower risk karyotype (p=0.001), presence of acute graft versus host disease (GVHD) and chronic GvHD (p=0.007, p=0.006). Factors associated with lower NRM were the time of transplantation (>2000, p<0.001), bone marrow graft (p=0.035) and absence of chronic GvHD (p=0.004). Conclusions: According to our experience, allogeneic-HCT for AML in early phase seems to have the potential to cure a significant proportion of pts with low NRM, even in the alternative setting, with improving results during the late time frame. In contrast, a small proportion of refractory pts may be rescued by HCT, specifically in the intermediate cytogenetic risk group.

1493

IMPROVED OUTCOME IN PATIENTS WITH ACUTE MYELOGENOUS LEUKEMIA POST HIGH DOSE CHEMOTHERAPY WITH THE COMBINATION OF BCNU, CYTARABINE, MELPHALAN AND AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION

I Sakellari, D Mallouri, C Apostolou, A Antoniou, I Batsis, P Kaloyannidis, C Kelaidi, A Sirigou, C Smias, G Papaioannou, D Sotiropoulos, G Dourvas, A Tsobanakou, A Fassas, A Anagnostopoulos

George Papanicolaou hospital, Thessaloniki, Greece

Background: Autologous hematopoietic cell transplantation for selected patients (pts) with acute myelogenous leukemia is a viable and reliable option of therapy, even in the era of alternative or reduced intensity transplants. The main advantage of the procedure is very low toxicity and treatment related mortality rate (TRM). Aim: We evaluated the outcome of pts autografted for AML in CR1 in our BMT-unit. Methods: In this retrospective study we analyzed the data of 51 pts, aged 37 (12-54) years with de novo AML (49) and secondary AML (2) auto-transplanted in CR1. The conditioning regimens used were: a)BEAM modified (marrow harvest on day -3, infusion of BCNU day -3, Etoposide and Cytarabine day -2, Melphalan day -1) and fresh marrow graft (20), b)BUCY-2 (10), c)BUCY-4 (6) and d)BCNU-AraC-Mel (BCNU 300 mg/m^2 day -3, Cytarabine 3 gr/m^2/12 hours day -2, Melphalan 140 mg/m^2 day -1) (15) with cryopreserved graft either marrow (14) or peripheral blood (PB) (17). The PB graft was mobilized post high dose Etoposide (1,6gr/m²) and has been used in the recent period 2000-2009. Results: For the whole cohort of 51 pts auto-transplanted form 1987-2009 the probability of DFS and OS was 28% and 33% respectively with a Δm follow-up 15 (9-20) years and TRM 6%. In terms of the time of transplant for the early period (1987-1999) the DFS rate was 27%, relapse rate 57% and TRM 10% at 21 years. On the contrary, the OS and DFS of pts who received the BAM regimen and mobilized PB as graft during the late period 2000-2009 was 53% and 83% respectively, while the TRM was 0% at 8 years. Interestingly, pts with intermediate risk group cytogenetic (17), mostly normal karyotype, succeeded rates of OS 82% and DFS 57% at 8 years. Summary/conclusions: The challenge of refinements of clinical management of patients with AML is to identify individual patients likely to benefit from specific therapeutic modalities, such as autologous hematopoietic cell transplantation, as an intensified consolidation treatment with zero morality rate. It can be employed to maintain the remission and cure the disease. Better supportive care has enhanced the ability of nearly each AML patient to deliver high dose chemotherapy plus autologous rescue with mobilized PB graft. Moreover, comparison of various used conditioning regimens demonstrated a DFS survival advantage of BAM (49%) over the others, ie modified BEAM (32%) or BUCY-2, BUCY-4 (31%) at 7, 21 and 18 years respectively.

1494

SUCCESFUL TRANSFUSION-FREE ALLOGENEIC STEM CELL TRANSPLANTATION IN A JEHOVA`S WITNESS PATIENT. A CASE REPORT

J Monserrat, A Sánchez, E Salido, M Blanquer, M Majado, V Cabañas, F Labbadia, A García, JM Moraleda

Hospital Virgen de la Arrixaca, Murcia, Spain

Background: Allogeneic stem cell transplantation (AloSCT) is a curative approach for patients with relapsed acute lymphoblastic leukemia (ALL). Less intensive modalities of the conditioning regimens have arisen to minimize the risks associated with the procedure. We discuss a patient with a relapsed ALL who proceded to a nonmyeloablative AloSCT from her HLA matched sibling without any transfusion support as a consequence of her denomination as Jehovah's Witnesses. Case report: A 35 years old lady was diagnosed with pre-B ALL in july 2007 without adverse cytogenetics. She refused any transfusion support during the chemotherapy treatment, which led to a lesser intensive induction chemotherapy mainly to minimize the risk of bleeding by thrombocytopenia albeit a higher risk of relapse. After induction chemotherapy with vincristine, daunorubicine and prednisone she achieved a complete remission (CR) and was started in maintenance therapy (MTT) for two years. On march 2010 she relapsed and was retreated with the same induction chemotherapy with a minimal residual disease (MRD) of 2% by flow cytometry in the bone marrow samples. Thereafter she received new MTT until august 2010 when she overt relapsed again. Rescue chemotherapy with vinblastine, cytarabine and VP-16 was administered achieving CR again with negative MRD. On October 2010 she underwent a nonmyeloablative AloSCT from a matched sibling. We adopted three strategies to prevent severe cytopenias during the AloSCT: firstly we administered a reduced intensity conditioning with total doses of 6.4 mgr/kg iv busulfan, 1000 mgr/m2 iv Cyclofosfamide and 90 mgr/m2 iv fludarabine. Secondly, we performed a larger than usual graft infusion of mobilized peripheral blood stem cell CD34+ cell from her donor (total dose of 7.75x106 /kgr) by three consecutives collection dates. The collected cells were infused "fresh"at the evening of the same collection day. Total CD3 infused cells were 54x106/kgr. Finally we used three different human recombinants growth factors to improve the engraftment: erythropoietin 10.000 UI three times a week from one month before the AloSCT, G-CSF 300 µgr daily from d+6 to d+13 and romiplostim 5 µgr/kgr 2 doses on d+5 and d+10. Neutrophil engraftment occurred on d+13. Platelet engraftment occurred on d+14. No significant bleeding occurred (platelet nadir of 31x103/ul on d+12). She was discharged on d+14 and has remained as an outpatient uptodate. No one single blood product has been infused to the patient since her diagnosis of ALL. Currently she`s alive in CR on d+125, with mixed chimerism and on treatment for grade II graft versus host disease. Conclusion: Transfusion-free stem cell trasnplantation has been described in isolated cases in the literature. New avalaible second generations thrombopoietic growth factors like romiplostin, allows a safer approach to this procedure. We conclude that transfusion-free AloSCT is feasible.

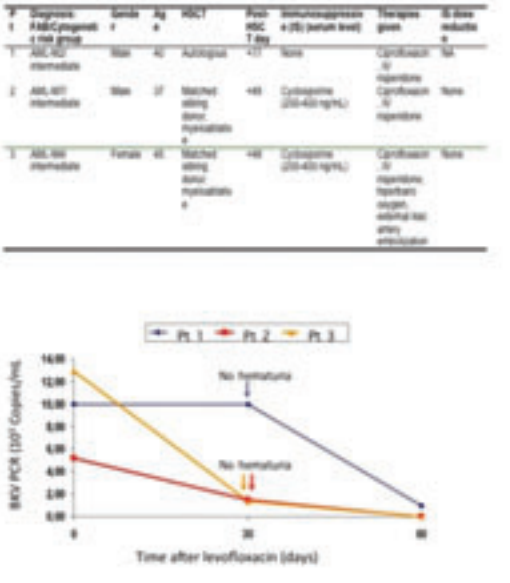
1495

LEVOFLOXACIN FOR BK VIRUS-ASSOCIATED HEMORRHAGIC CYSTITIS IN THE POST-HEMATOPOIETIC STEM CELL TRANSPLANTATION PERIOD

T Toptas, I Kaygusuz, T Kani, B Kantarcioglu, G Yilmaz, C Adiguzel, T Firatli-Tuglular, M Bayik

Marmara University Hospital, Istanbul, Turkey

Background: BK virus (BKV) is one of the most common causative agents of hemorrhagic cystitis (HC) in the early postengraftment period of hematopoietic stem cell transplantation (HSCT). Cidofovir may be a potentially effective treatment option with a 67% complete response rate. Unfortunately, it is not available in most European countries. High cost rate and possible renal side effects are the other important disadvantages of Cidofovir. In vitro activity of fluoroquinolones has long been known. But their in vivo effects are limited. There are no data about the efficacy of respiratory fluoroquinolones such as levofloxacin. Aim: We present here the clinical and molecular activity of levofloxacin in three patients with BKV-related HC experienced during postengraftment period following HSCT. *Methods:* Patients' chart records were reviewed retrospectively.



Results: Data about the three patients who experienced severe HC within the first 100 days of HSCT were reviewed (Table). All patients needed continuous intravesical irrigation because of gross hematuria and urinary obstruction caused by blood clots. Routine microscopic analyses and bacterial cultures revealed no specific pathogenic organism. Analyses for adenovirus, cytomegalovirus, mycoplasma, and ureaplas-

ma were all negative. Patients were receiving immunosuppressive agents in appropriate doses. None of the patients had any clinical sign of graft versus host disease. But BKV was detected in the urine of patients in varying degrees. All patients received ciprofloxacin at least two weeks and intravesical risperidone. Additionally, hyperbaric oxygen and subsequently external iliac artery embolization were performed in patient 3. But no improvement was observed. Patient 1 received levofloxacin, 500 mg/d, and his HC resolved completely in one week. The other two patients also received the same treatment and complete clinical response was achieved in both. Levofloxacin treatment was given for 8 weeks and urine BKV copies were monitored. BKV copies in urine decreased more than 90% in all (Figure). These patients are still disease- and GVHD-free and alive. Levofloxacin was given to another patient who had HC not related to BK within the 100 days of post-HSCT period. But no response was observed. *Conclusions*: Levofloxacin may be an effective treatment option in patients with refractory BKV-related HC experienced during post-HSCT period. Efficacy of levofloxacin may be associated with the inhibition of DNA topoisomerase IV and DNA gyrase. Some other factors specific to levofloxacin may have an effect on BKV.

1496

LARGE VOLUME LEUCAPHERESIS (LVL). FOR PERIPHERAL BLOOD PROGENITOR CELLS (PBPC) COLLECTION IN HEALTHY DONORS FOR ALLOGENEIC TRANSPLANTATION: EXPERIENCE OF A SINGLE CENTER

A Alegre, B Aguado, C Cámara, V Gómez, A Figuera, M Fernández-Villalta, M Roig, B Quereda, N Acedo, M Cuadrado, N García-León, S Martínez, N García-Fernández, I Vicuña
Hospital La Princesa, Madrid, Spain

Introduction: There are no defined guidelines to improve the efficiency of collections of peripheral blood cells in allogeneic transplant programmes. We present our experience using Large Volume Leucapheresis (defined as more than 3 times the total blood volume) for collection of PBPC in healthy donors, applied in our centre with the aim of simplification of procedure. *Methods and Donors:* 124 healthy donors (66 males and 58 females; median age 48, 19-73) were included in this study since November 2001 to December 2010. All donors received 12-14 g/kg/day s.c of rhG-CSF (filgrastrim®, Amgen, Thousand Oaks, CA, USA) in two doses during 4 days for mobilization. Our main objective was to yield at least 3x10e6/kg receptor weigth of CD 34+ cells. Leucapheresis was started on the fifth day after the administration of rhG-CSF. Large Volume Leucapheresis (LVL) was programmed and cells were collected through peripheral vein access in most cases, using a Cobe Spectra separator (COBE SPECTRA, Gambro BCT, Lakewood, CO, USA). Intraprocess controls were performed to finish the procedure according the objectives and results. *Results:* The median number of patient's blood volumes processed was 3 L (1-4). 113 donors (92%) required only one session to achieved the CD34+ cells objective. PBPC collection yield a median of 6.02x10e6/kg CD 34+ cells (2.85-13.57). No mobilization failure was observed. All products were transplanted with rapid and sustained engraftment in all cases. No serious adverse effects were observed and minor morbidity related to the PBPC collection was scarce and reversible. *Conclusions.* In our experience Large Volume Leucapheresis (LVL) allows an adequate PBPC collection for transplantation with the simplification of a single harvesting procedure valid for prompt hematological engraftment.

METHYLATION STATUS OF RUNX2, OSX, DLX5 AND BSP GENE P ROMOTERS IN OSTEOBLASTIC DIFFERENTIATION OF MESENCHYMAL STEM CELLS (MSCS)

Y Mortazavi[1], M Farshdousti Hagh[2], M Noruzinia[2], M Soleimani[2], S Kaviani[2], M Mahmodinia Maymand[3]
[1]*Zanjan Medical School, Zanjan, Iran*
[2]*Tarbiat Modares University, Tehran, Iran*
[3]*Sarem Cell Research Center (SCRC), Tehran, Iran*

Background. Epigenetic mechanisms, including DNA methylation, histone modifications, and non-coding RNA-mediated regulatory events, are essential to controlling the heritable cellular memory of gene expression during differentiation. DNA methylation is modulating gene expression by addition of a methyl moiety to the cytosine-5 position in CpG islands. Two specific osteoblast transcription factors and one non-specific transcription factor i.e. RUNX2, OSX and DLX5 are important in regulating osteoblast related genes as well as osteocalcin, BSP, OPN and collagen type Iα1. *Aims*. In this research we speculated whether epigenetic regulation of these genes plays any role in osteoblastic differentiation of mesenchymal stem cells. Therefore, we evaluated methylation status of RUNX2, OSX, DLX5 and BSP promoters in osteoblastic differentiation of MSCs. *Materials and Methods:* MSCs were isolated from human bone marrow (a written informed consent was obtained from all participants). Osteogenic differentiation was done under the influence of the synthetic glucocorticoid dexamethasone, beta glycerol phosphate, and ascorbate in the presence of 10% FCS. DNA and RNA extraction were carried out after the first, second and third weeks of culture and also from undifferentiated MSCs. After DNA extraction and bisulfate treatment, gene specific methylation analysis for RUNX2, OSX, DLX5 and BSP was carried out using methylation specific PCR (MSP). Moreover, qualitative RT-PCR was used to study the gene expression. Results: MSP analysis revealed that promoter methylation status didn't change in RUNX2, DLX5 and BSP promoters during osteoblastic differentiation of MSCs. In contrast, OSX promoter showed a dynamic change of methylation pattern while MSCs were gradually differentiated to osteoblasts. *Conclusions:* RUNX2, OSX, DLX5 and BSP promoter regions showed 3 different methylation patterns during MSCs differentiation. This study shed light on the osteoblastic differentiation of MSCs by showing dynamism in methylation change during this process.

HEMATOLOGIC ABNORMALITIES AND ETIOLOGICAL FACTORS OF OCCUPATIONAL TOXIC CYTOPENIAS, ABOUT 138 CASES

K Naourez[1], M Medhaffar[1], O Kassar[1], S Jammoussi[1], I Chabchoub[2], H Bellaj[1], S Hdiji[1], M Elloumi[1]
[1]*Hedi Chaker Hosptal, Sfax, Tunisia, Tunisia*

Background: innovations in the fields of industry and research and the proliferation of applications of chemistry explain the growth of the use of chemicals to which humans are exposed both in the workplace than in domestic. Exposure to these xenobiotics may be responsible for a blood-toxicity. *Aims:* We are interested in studying abnormal peripheral blood findings of toxic origin in the work environment and factors in the workplace. Methods: This is a retrospective study over a period of 5 years (January 2004-December 2008) on cases of cytopenia collected from patients with professional activity, followed by the hematology department of university hospital Hedi Chaker, Sfax, Tunisia and professional investigation which was conducted by the department of occupational medicine at the same hospital. *Results:* A total of 5611 patient records identified the number of patients with suspected toxic cytopenia is 138. The annual recruitment of hematology department of Sfax is 77 cases of presumed toxic origin cytopenia year. The prevalence is estimated at 7%. A male predominance is noted with a sex ratio of 1.76. The average age is 40 years. Nearly a third of the population belongs to the age of 25 to 34 years. A monocytopenia is found in 70% of cases with leukopenia 40% of cases, thrombocytopenia 27% and 3% of anemia cases. The bone marrow examination was performed in only 34 patients. This is normal marrow in 33 cases, poor in 6 cases and dysplastic in 4 cases Our patients perform in diverse industries, manufacturing is the leader with a rate of 49% followed by the services sector with a rate of 32% then 10% agriculture, building industry and public works 5% , 4% heavy industry. Three quarters of patients are workers. Professionals in agriculture are the most represented .Organic solvents, mainly benzene are the class of nuisance most reported in our series. *Conclusions:* In our series and in literature, the main industries using benzene are the chemical industries of plastic, mechanical petrochemicals. in the literature, very few data are available about the incidence of cytopenias toxic. Male predominance and young age of the patients are found both in our work in literature.

1499

SELF-RENEWAL ABILITY OF MARKED BY LENTIVIRAL VECTOR MESENCHYMAL STEM CELLS

O Zhironkina, N Sats, A Bigildeev, I Shipounova, N Drize
National Hematological Scientific Centre, Moscow, Russian Federation

Background. Stem cells have to be able to differentiate and self-renew. Mesenchymal stem cells (MSCs) form hematopoietic microenvironment in vitro in long-term bone marrow culture (LTBMC), while in vivo this ability could be analyzed by implantation of femur bone marrow plug or adherent cell layer (ACL) from LTBMC under renal capsule of syngeneic recipients. Stromal cells in such foci are derived from donor MSCs while hematopoietic cells have recipient's origin. The size of the foci formed is proportional to femur equivalent transplanted and can be used for semi-quantitative determination of MSC number. The golden stan-

dard for stem cells is their ability to self-renew which could be proved by retransplantation. After the retransplantation all differentiated stromal cells in the hematopoietic foci are lost and the microenvironment in newly formed foci develops from transplanted MSCs completely de novo. Aims. The aim of the study was to investigate the self-renewal ability of marked murine MSCs able to transfer hematopoietic microenvironment. Methods. ACLs of 2-week-old LTBMCs were infected with 100 mkl of concentrated (108 viral particles/ml) self-inactivating HIV LeGO vector encoding EGFP (all plasmids and Phoenix cells were provided by Prof. Boris Fehse) in 3 ml of aMEM with 10% FCS and 8 mkg/ml polybrene for 6 hours. In 2 weeks after the infection scrapped by rubber policemen ACLs were implanted under the renal capsule of syngeneic mice. Colony-forming units fibroblast (CFU-Fs) were analyzed by plating 20000 nucleated cells from the foci per well of 96-well plate in aMEM supplemented with 20% FCS and 5 ng/ml FGF2. In 6 weeks the number of marked CFU-Fs was measured in 4 foci formed and other foci were retransplanted under the renal capsule of secondary recipients. The procedures were repeated 4 times and the numbers of marked CFU-Fs were measured in 4 foci after each retransplantation. Results. The proportion of marked cells in ACLs before transplantation under the renal capsule was 5.3 ± 0.6 %. The size of the foci formed was stable throughout all retrasplantations, the marked CFU-Fs were revealed in all foci (table). All ossicles in the foci formed were EGFP positive.

Table. The size of the ectopic foci and the proportion of marked CFUs derived from the foci.

The transplantation number	The size of the foci formed, x10^6	The proportion of marked CFU-Fs, %
1	3.8 ± 0.6	3.8 ± 2.4
2	3.1 ± 0.7	5.6 ± 2.2
3	4.1 ± 0.9	6.3 ± 2.9
4	3.4 ± 0.7	8.1 ± 3.4

Conclusions. As CFU-Fs are the progeny of MSCs, the availability of genetically marked CFU-Fs in the foci points to the presence of marked MSCs. Obviously marked MSCs are able to transfer hematopoietic microenvironment at least 5 times and keep the ability to produce the considerable number of marked progeny, so their ability to self-renew is proved. Thus, all crucial MSCs features (prolonged lifespan, ability to self-renew and differentiate) are not affected by stable integration of the vector containing gene of interest meaning that these cells are preferable targets for gene therapy.

INCREASED LEVELS OF BONE MARROW ENDOTHELIAL CELLS, PROGENITOR AND MATURE, IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

E Stiakaki, G Martimianaki, C Perdikogianni, S Kyriakopoulou, M Kalmanti

University of Crete, Heraklion Crete, Greece

The role of endothelial progenitors (EPCs) and mature cells (ECs) in angiogenesis has attained the scientific interest of many recent studies. *Aim:* The immunophenotypic analysis of EC subpopulations in the bone marrow (BM) and the study of their potential role in the pathogenesis of various malignant and autoimmune diseases. Methods: Bone marrow cells from children with acute lymphoblastic leukemia at diagnosis (ALLd, n=8), at day 15 (ALL15d, n=5), and day 33 of treatment when remission is achieved (ALL33d, n=7), ALL under consolidation therapy (ALLct, n=10), ALL following the end of treatment (ALLet, n=10), solid tumors without BM involvement at diagnosis (ST, n=9), idiopathic thrombocytopenic purpura (ITP, n=4) and autoimmune diseases (AI, n=5) were studied. The putative antigenic phenotypes of EPCs and ECs were assessed using a 4-color flow cytometry procedure in both the CD45neg and CD45neg and dim cell subpopulation. *Results:* The highest levels of CD45negCD133+CD34+VEGFR-2+ EPCs were estimated in ALLd with statistically significant differences compared with ALLet (0.015±0.112 vs 0.0059±0.0025, p=0.016), and also with ITP (0.015±0.112 vs 0.00, p=0.034) and AI (0.015±0.112 vs 0.0013±0.0013, p=0.05). The levels of CD45negCD146+CD34+VEGFR-2+ are high following the end of treatment in the ALL group compared to the group of ST (p=0.036). CD45negCD31+CD34+VEGFR-2+ subpopulation is estimated to be equally high in ST, ALLd and ALL15d. Statistical analysis revealed significant differences between ALLd vs ALL33d (p=0.024), ALL15d vs ALL33d (p=0.003), ALL15d vs AI (p=0.046) and ALL33d vs ALLet (p=0.035). The highest levels of CD45negCD31+VEGFR-2+, CD45negCD34+VEGFR-2+ and CD45negCD133+VEGFR-2+, were determined in ALLd. The comparison of ALLd with ALL33d revealed statistically significant differences for all the three different immunophenotypic combinations (p=0.07, p=0.019, p=0.012 respectively) as well as with ALLet (p-0.016, p=0.009, p=0.007 respectively). ALLd compared with ALLct showed statistical differences for CD45negCD31+VEGFR-2+ (p=0.005) and for CD45negCD133+VEGFR-2+ (p=0.027). CD45neg CD146+VEGFR-2+ levels were significantly higher in ALLd vs ALL15d (p=0.048), ALLd vs ALL33d (p=0.004) and ALLd vs ALLct (p=0.032). The same tendency occurred for the comparison between ALLd and other childhood diseases of immunological origin studied (ITP, AI). In the CD45neg/dim cell subpopulation the CD133+CD34+VEGFR-2+ phenotype was significantly higher in ALLd vs ALL33d (p=0.006) and ALLd vs ST (p=0.038). In the above CD45neg/dim subpopulation the CD31+CD34+VEGFR-2+ cells were higher in ST and following the end of treatment in ALL(ALLet). *Conclusions.* The levels of both progenitor and more mature EC subpopulations seem to be highest in diagnosis of ALL among all the group of blood and autoimmune diseases studied. The more mature EC subpopulation tend to be higher following the end of treatment in ALL and solid tumors without BM involvement. The precise role of these findings warrant further investigation.

PHENOTYPICAL AND FUNCTIONAL CHARACTERIZATION OF MESENCHYMAL STEM CELLS DERIVED FROM PATIENTS AFFECTED BY SCHWACHMAN-DIAMOND SYNDROME

V André,[1] D Longoni,[2] M Cipolli,[3] A Biondi,[2] G D'Amico[1]

[1]*M. Tettamanti Research Center, Monza, Italy*

[2]*Pediatric Clinics, University of Milan-Bicocca, San Gerardo Hospital, Monza, Italy*

[3]*Cystic Fibrosis Center, Ospedale Civile Maggiore, Verona, Italy*

Background. Shwachman-Diamond Syndrome (SDS) is an inherited marrow failure disorder characterized by varying cytopenias, pancreatic dysfunction, and metaphyseal dysostosis. Neutropenia plays a crucial role in the occurrence of recurrent and severe infectious complications representing one of the major causes of death in SDS patients. Aims: the aim of our study is to better comprehend the marrow dysfunction occurring in SDS patients, by analyzing the functional properties of bone marrow (BM)-derived mesenchymal stem cells (MSCs). Methods: after informed consent, BM cells obtained from 20 SDS patients were plated in sterile tissue culture flasks. At the third passage of the culture, cells were tested for the expression of specific surface markers, their ability to differentiate into mesengenic lineages, their capability to abrogate T cell proliferation and their capacity to prevent neutrophil apoptosis. *Results*. MSCs derived from SDS patients (SDS-MSCs) displayed typical fibroblastoid morphology; they were consistently devoid of contaminating hematopoietic cells, being negative for CD34, CD45, HLA-DR, CD11b, CD19, and CD14, but expressed common MSC markers including CD90, CD73, CD105 and HLA-ABC. Similarly to MSCs obtained from healthy donors (HD-MSCs), these cells were able to differentiate into adipocytes and osteoblasts. In addition, SDS-MSCs drastically decreased the mitogen-induced lymphocyte proliferation, in a dose dependent manner. We also cultured neutrophils obtained from HD in presence or absence of MSCs at different time points. We demonstrated that SDS-MSCs were comparable to HD-MSCs in supporting the viability of neutrophils. Importantly, SDS-MSC were able to produce high amount of IL-6 (mean= 2658 pg/ml, range= 2086-3229 pg/ml), a crucial cytokine involved in the protection of neutrophils from apoptosis. Conclusions: we successfully isolated and characterized MSCs from SDS patients. These cells did not show any significant differences from HD-MSCs. Further studies are needed to better comprehend the functional and molecular features of SDS-MSCs, which are potentially involved in the hematological abnormalities typical of SDS patients.

1502

EXPRESSION CLONING OF A REPROGRAMMING ACTIVITY THAT INDUCES BONE MARROW ADHERENT MYOFIBROBLASTS TOWARD HEMATOPOIETIC STEM CELLS: INTERLEUKIN 1? PROMOTES THE EXPRESSION OF CD34 AND CYTOKINE RECEPTORS

H Tashiro, R Shirasaki, T Yamamoto, Y Oka, N Akiyama, K Kawasugi, N Shirafuji

Teikyo University School of Medicine, Tokyo, Japan

Background and Aims: We recently reported that acute myelogenous leukemia blasts and chronic myelogenous leukemia cells can convert to stromal myofibroblasts to create an environment for the proliferation of leukemic cells in vitro and also in vivo in the immunodeficiency murine bone marrow. In normal hematopoiesis, hematopoietic cells are also speculated to contribute to the formation of the hematopoietic stromal tissue. And we also hypothesized that bone marrow stromal myofibroblasts may convert to hematopoietic cells. To make clear this issue, bone marrow stromal myofibroblasts from informed healthy volunteers were cultured with phytohemagglutinin (PHA-P)-stimulated lymphocyte conditioned medium in vitro. After one week morphological changes were observed microscopically, in which bubbling from the spindle-shaped myofibroblast was demonstrated, and a few cells were detached from the dishes and were floating. To determine the mechanism of this biological finding, expression cloning was performed. *Materials and method*s. Blood was collected from the informed healthy volunteers, and lymphocyte-rich fraction was separated with gravity sedimentation method. PHA-P was added in the cultures, and after 48 hours lymphocytes were collected, with which cDNA library was constructed after ligation to the mammalian expression vector. Electroporation to Ecoli DH10β cells made 5x105 independent colonies, which were divided into sub-pools (1000 independent colonies/pool). Plasmids were prepared from each pool and transfected to COS7 cells with DEAE-Dextran method. After 3 days of culture supernatants were collected, and were cryopreserved until use. Bone marrow cells were aspirated from informed healthy individuals, and were separated to mononuclear cells. Adherent cells were prepared after 2-hour cultures in the coated dishes. Cells were further cultured long term with splitting using trypsin/EDTA once a week. After one month, bone marrow-derived STRO-1(+) and smooth muscle actin (+) myofibroblasts were prepared, which were used as a target for the expression cloning. The transfected COS7 supernatants were added in the myofibroblast-cultures (final 10%), and cells were further cultured for one week. RNA was extracted from the cultured cells, and cDNA was synthesized. Positive clones were selected with reverse transcription-polymerase chain reaction using human CD34 primers, and further selected to be a single clone. *Results and discussion:* Isolated single clone was revealed to be human interleukin 1β. When the purified interleukin 1β protein was added in the myofibroblast cultures, cell growth was increased, and up-regulation of the expression of several hematopoietic cytokine receptors including c-kit was observed. Now we determine the precise actions of human interleukin 1β on the reprogramming of bone marrow stroma-derived myofibroblasts toward hematopoietic stem cells.

1503

BONE MARROW MESENCHYMAL STROMAL CELLS PROMOTE PROLIFERATION OF LYMPHOMA CELLS AND GASTRIC CANCER CELLS VIA CELL-TYPE SPECIFIC MANNER

Y Lee
Catholic university of Korea, Seoul, South-Korea

Background: Bone-marrow derived mesenchymal stromal cell (bmMSC), one of major sources of MSC, has been known to participate for reconstituting microenvironment. Cancer cells, as like normal cells, have been known to need microenvironmental support for their survival and growth. Studies show that MSCs were recruited and integrated into tumors, however, what is the precise effect of MSC on tumor cells still remains unclear. Aims: To address this, investigators employed co-culture and mice co-transplantation assay with hematopoietic tissue-derived bmMSC and adipose tissue-derived MSC (ADSC), and hematologic and malignancies (lymphoma cells and gastric cancer cells). Methods: Lymphoma cells (Pfeiffer and Raji) and gastric cancer cells (SNU5FU and SNUADR) were cultured in RPMI 1640 with basic supplements. BmMSCs and ADSCs were cultured in DMEM with basic supplements. Transwell system (BD falcon, USA, 0.4um pore) was used for indirect contact co-culture. To assay apoptosis-protection effect of MSCs, 5-fluorouracil (5ug/ml) and doxorubicin (5ug/ml) were treated for lymphoma cells and gastric cancer cells, respectively. Viable cells were assayed by trypan blue method or flowcytometry with propidium iodide and Annexin V. Cancer cells (2x105) only or mixed with MSC (5x104) were transplanted into NOG/SCID mice (13-15 week-old) subcutaneously. Results: BmMSC increased the proliferation of Pfeiffer cells by direct contact (x3.5), but not by indirect contact compared with Pfeiffer alone at day 4. BmMSC also promoted the proliferation of SNU5FU cells by both direct (x1.9) and indirect (x1.6) contact at day 6. Whereas, Raji cells and SNUADR cells were minimally influenced. BmMSC-cocultured Pfeiffer showed increased cell viability (16.7%) compared with Pfeiffer alone (9.8%) under the doxorubicin treatment. For the SNU5FU cell under 5-fluorouracil treatment, two different bmMSCs didn't show chemoprotective effect, but ADSC-cocultured cells showed increased chemoresistance (84.1%) compared with SNU5FU alone (46.7%). In NOG/SCID mice cotransplantation assay, SNU5FU alone, SNU5FU-bmMSC and SNU5FU-ADSC cotransplanted mice showed 43%(3/7), 33%(1/3) and 75%(3/4) tumor formation, respectively. SNU5FU alone induced tumor and SNU5FU-bmMSC induced tumor showed compact tumor mass without desmoplasia, whereas SNU5FU-ADSC tumor showed marked stromal reaction, infiltrative growth and lung metastasis. Summary/Conclusions: BmMSC showed growth promoting effect on Pfeiffer and SNU5FU, but not on Raji. BmMSC showed chemoprotective effect on Pfeiffer cells, but not on SNU5FU cells. ADSC, but not bmMSC, showed in-vitro chemoprotection and in-vivo tumor promoting effect on SNU5FU. These findings suggest that the MSC type, the targeted tumor cell type and environmental condition should be considered for understanding the effect of MSC on tumor cells.

[9]*Pusan National University, Pusan, South-Korea*

Introduction. PNH is a debilitating and life-threatening hematopoietic stem cell disorder characterized by chronic hemolysis leading to significant morbidities, end organ damage and mortality in PNH patients. Historically, PNH was considered an anemic disease with management focused on improving hemoglobin (Hb) levels through transfusions. This has led to the perception by some that absence of transfusion requirements or mild anemia as a measure of mild or stable disease.Aims. To understand the impact of transfusions on the risk factors associated with poor patient outcome, we retrospectively analyzed medical charts of 123 PNH patients with no documentation of transfusions from national data registry in South Korea over the last 41 years. Results Patient ages ranged from 17 to 88 years (median 37 years), median PNH duration was 6.8 years (14 days to 27 years), and median PNH granulocyte clone size was 40% and median LDH at diagnosis was 4 fold above normal. Evaluating hemolytic symptoms associated with end organ damage, we found that approximately 12% of patients with no documentation of transfusions had late stage renal dysfunction (defined as history of renal failure or GFR <60 ml/min/1.73*m^2), a predictor of early mortality. Gastrointestinal pain, a symptom predictive of thrombosis and poor quality of life, was reported in 38% of non-transfused patients. Dyspnea, a symptom of pulmonary hypertension and predictive of thrombosis was reported in 28% of patients. Elevated hemolysis at diagnosis (as measured by LDH ≥1.5 above normal) is predictive of early mortality. We evaluated non-transfused patients with LDH ≥1.5 above normal at diagnosis (n=70) or LDH < 1.5 of normal (n=20) for patient death. There were 6 patient deaths reported (median 7.3 yrs disease duration) in the hemolytic non-transfused group compared to no reported deaths (median 4.6 yrs disease duration) in non-transfused patients with no elevated hemolysis at diagnosis. Conclusion: Our data demonstrates that patients who are not transfused suffer from significant disease burden. Elevated hemolysis leads to poor outcomes in PNH patients and should be the target for PNH management.

1505

TWO CASES OF LANGERHANS HISTOCYTOSIS X AND THEIR THERAPEUTIC APPROACH

P Koliou,[1] V Violaki,[2] A Kolovou,[2] F Markidou[2]
[1]*University Hospital of Ioannina, Ioannina, Greece*
[2]*Haematology Clinic Chania General Hospital 'Agios Georgios', Mournies Chania, Greece*

Background. Langerhans cell histiocytosis results from the abnormal accumulation of a class of dendritic cells normally found in the skin, which proliferate in many organ systems along with lymphocytes, macrophages and eosinophils. There is multisystem disease involvement described with lytic skull lesions, involvement of the skin and lymph nodes. Aims:To present the rare disease of Langerhans histiocytosis. Methods:Two clinical cases of the rare histiocytosis X cases are reported along with the therapeutic management. Results:A 24-year old woman presented with a 3-month history of headache localised to the right posterior parietal area. The patient reported concurrent migraines and vomiting. A brain MRI revealed a non-enhancing semicircular mass 1,3x0,9 cm of parietal bone with no pressure effects on the nearby structures, meninges and soft tissues. A whole body bone scan was free of disease. Biopsy of the osteolytic lesion revealed lesion similar to Langerhans histiocytosis with eosinophilic granulomatous origin based on positive immunochemistry for S-100/Langerin and CD1a (-/+). The histiocytes had medium size with nuclear grooves. The patient had normal lung function, and a negative for disease thorax CT. The abdomen CT was normal with no lymph nodes enlarged. Therapy included complete surgical excision and replacement of the area with bone transplant. She received prednisone 1mg/kg/day for 4 weeks and tapering over a 2-week period followed with a weekly infusion of vinblastine 6mg/m2 for 5 weeks. Then, the same dose of prednisone was administered (5 days/week) followed by vinblastine once every three weeks to complete a six month period. 6-mercaptopurine 30mg/m2 was not administered due to desire of future pregnancy. She was previously diagnosed with systemic lupus erythematosus under medication with hydroxychloroquinone 200 mg/day from June to September every year. The second patient a 45-year old female reported to our clinic after a painless palpable mass of the right submandibular area. An ultrasound at the area revealed a multilobular, compact mass 1,9X1,5 cm. The neck CT confirmed the mass as bilobular with central erosion. Later, it was totally excised and sent for biopsy. The biopsy was positive Langerhans cells (S-100+,Langerin+,KP1+,CD30+,CD20-,CD3). Near the atypic cells eosinophils were present with nuclear grooves. Last there was a great number of mast cells (mast-cell-tryptase+). The bone marrow biopsy was negative. An abdomen ultrasound showed increased spleen(10cm) and a liver mass. The thorax CT showed a few lymph nodes(<1 cm), an abdomen CT revealed a benign liver mass, negative for disease after biopsy. An abdomen MRI showed the liver mass sub-diaphragmatically 4,6X3,8cm with differential diagnosis problem arising between focal hyperplasia and adenoma. A bone-scan was negative for disease. Both patients had normal thyroid function tests and negative testing for thyroid autoimmune abnormalities. No treatment was followed after excision of primary site and she was put under follow-up. The 45 year-old woman had positive serum antithyroglobulin antibodies. Virology for Herpes Simplex Viruses-1,-2 were negative(IgM-). Conclusion:These two cases of Langerhans cell histiocytosis highlight the difficulty of disease diagnosis and its multifocal presentation. A different approach in the management of the disease is described according to patient profile.

HUMAN CHRONIC MYELOID LEUKEMIA HEMATOPOIETIC CELLS DO NOT TRANSDIFFERENTIATE INTO NEURAL LINEAGES

M Blanquer Blanquer,[1] X Férez,[1] P Iniesta,[1] N Marín,[2]
J García Estañ,[2] F Rodríguez Lozano,[1] C García de Insausti,[1]
J Gómez Espuch,[1] S Martínez,[3] M Moraleda[1]

[2]*Facultad de Medicina. Universidad de Murcia., Murcia, Spain*
[3]*Instituto de Neurociencias. Universidad Miguel Hernández, Elche, Spain*

Introduction. Adult hematopoietic stem cells (HSC) are able to survive in the CNS of animal models and to *transdifferentiate* into neural cells upon exposure to signals generated by CNS tissue injury (*Bonilla et al, 2002*). This fact has been difficult to prove when studying human HSC in animal models due to the lack of a good marker to follow the fate of the transplanted cells. Chronic myeloid leukemia (CML) is a stem cell disorder characterized by immune-scape and resistance to apoptosis due to an acquired chromosomal translocation, the t(9;22). This translocation generate a specific BCR-ABL chimeric gene that may be identified by Fluorescence in situ hybridization (FISH), and could facilitate tracking the fate of CML human cells in xenogeneic transplant experiments. *Methods:* We isolated CD34+ positive cells from two untreated chronic phase CML patients by Macs immunomagnetic selection. These cells were infused in the white matter of the parietal hemisphere of six adult Swiss mice, six neonates and six NOD.Cg-Prkdc scid Il2rgtm 1Wjl/SzJ immunosuppressed mice. Mice were sacrificed at 7, 15 and 30 days. LSI t(9;22) BCR/ABL Dual Fusion Dual Color Translocation Probe (Vysis) was used to perform the FISH. Neural differentiation was checked by colocalization of the FISH signal with antibetaIII-tubulin and antiGFAP by immunofluorescence. *Results:* The mice received 1 to 2x105 CD34 selected cells. No cells with the bcr-abl translocation could be observed at 7 day post-transplant in either the Swiss or the NOD.Cg-Prkdcscid Il2rgtm1Wjl/SzJ mice. In the 6 neonatal transplanted mice scarce bcr-abl positive cells could be observed at day seven, but not thereafter. We did not observe colocalization of the bcr-abl signal with betaIII-tubulin or antiGFAP. *Conclusions*: Human CML hematopoietic stem cells are not able to survive in the CNS of either normal mice or naturally or artificially immunosuppressed mice. CML cells are not a good candidate to study the HSC neural transdifferentiation potential.

FAS AND FAS LIGAND EXPRESSION IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA, BENIGN HEMATOLOGICAL DISEASES AND SOLID TUMORS

E Stiakaki, G Martimianaki, M Kaparou, C Perdikogianni, M Kalmanti
University of Crete, Heraklion Crete, Greece

Fas/FasL is a key pathway of cellular apoptosis. Fas receptor is expressed on membranes of both normal and neoplastic cells while, Fas ligand (FasL) mainly on activated T-lymphocytes. Fas-FasL abnormalities have been detected in malignancies and autoimmune diseases and implicated in resistance to treatment. The aim of the study was the determination of the levels of Fas, FasL and their coexpression in bone marrow cells of children with acute lymphoblastic leukaemia (ALL) at diagnosis, during the course of treatment and the comparison with relevant levels in other hematological and neoplastic diseases. Methods: Expression levels of Fas and FasL were determined with flow cytometry in children with ALL at diagnosis (ALLd, n=13), on day 15 of treatment (d15, n=6), on day33 (ALLd33, n=6), during consolidation (ALLhr, n=12) and at the end of therapy (ALLet, n=7) as well as in children with Langerhans Histiocytosis (LCH, n=4), cytopenias (Cytp, n=8) and solid tumors without bone marrow involvement at diagnosis (STd, n=5) and on therapy (STther, n=6). Results: The lowest levels of Fas expression were detected at diagnosis of ALL and were gradually statistical significantly increased until remission of day 33 (ALLd vs ALLd33: 8.02±1.94 vs 24.04±6.11, p=0.035). At consolidation Fas levels were found to be decreased compared to day33 (16.1±4.18) and were again increased at the end of therapy (ALLd vs ALLet: 8.02±1.94 vs 24.96±7.95, p=0.024). On the contrary, FasL levels were gradually decreased and finally increased to similar to diagnosis levels at the end of treatment (ALLd: 4.59±1.41, ALLet: 5.89±1.99). In solid tumors at diagnosis Fas levels were similar to the ones while on chemotherapy (STd vs STth:16.04±2.2 vs 15.19±6.4). The highest FasL levels were detected in the group of STd with the relevant levels on treatment being lower in comparison (STd vs STther: 10.91±3.32 vs 2.92±0.79, p=0.052). In LCH both Fas and FasL levels were found to be as low as at ALL diagnosis. In cytopenias no significant difference was observed between groups for either Fas (11.05±4.49) or FasL (3.01±0.62). As for Fas+FasL+ coexpression no difference was evident between ALLd, ALLet and STd or STther [ALLd (0.73±0.38), ALLet (0.64±0.17), STd (0.68±0.095), STther(0.66±0.38)]. The lowest coexpreesion levels were observed in the group of cytopenias with statistical significant difference compared to STd (0.68±0.095 vs 0.26±0.08, p=0.031). In conclusion, at diagnosis of ALL Fas levels were expressed in lowest levels that were found to be gradually increased at remission and at the end of treatment. This finding probably correlates with the apoptotic process of the leukemia clone and possibly with response to treatment.

THE ONCOGENE EVI1 ENHANCES TRANSCRIPTIONAL AND PROLIFERATIVE RESPONSES TO ATRA

R Wieser,[1] B Steinmetz,[1] I Arbesu,[1] H Hackl,[2] A Rommer,[1]
I Herbacek[1]
[1]*Medical University of Vienna, Vienna, Austria*
[2]*Medical University of Innsbruck, Innsbruck, Austria*

Background. EVI1 is an oncogene whose overexpression is associated with a poor prognosis in myeloid leukemias and certain solid tumors. Even though its protein product exhibits properties of a transcription factor, only few direct target genes have been identified. Several reports suggest that EVI1 may elicit its biological effects through modulation of the activity of other transcription factors. In this context we have recently shown that EVI1 affected all-trans retinoic acid (ATRA) dependent gene regulation in that it enhanced the ATRA induction of the RARbeta gene and counteracted its own upregulation by ATRA. Aims: In the present work we asked whether EVI1 would modulate the ATRA regulation of additional genes and whether it would also affect biological responses elicited by ATRA. *Methods*. Triplicate cultures of U937 cells with or without ectopic expression of EVI1 were incubated with ATRA or solvent for 24 h. RNA was extracted and subjected to microarray analyses (Affymetrix HG-U133 Plus 2.0). Candidate genes were confirmed by qRT-PCR. Cell cycle analysis was performed by FACS after propidium iodide staining. Results: Array analyses revealed that the transcriptional response to ATRA of 44 unique genes was modulated by EVI1 at least twofold and in a statistically significant manner. The ATRA induction of 34 and the ATRA repression of seven genes was enhanced by EVI1, while ATRA repression of three genes was counteracted by EVI1. Eight genes were selected for confirmation by qRT-PCR. The regulatory pattern observed in the array experiments was confirmed in all cases. To determine whether EVI1 would also enhance biological responses to ATRA, cell cycle analyses were performed. Upon treatment with ATRA a higher percentage of EVI1 overexpressing cells than of empty vector containing cells accumulated in the G0/G1 phase of the cell cycle, demonstrating that indeed EVI1 enhances biological responses elicited by ATRA. *Summary/Conclusions*. EVI1 enhances the transcriptional and growth inhibitory responses of ATRA in human myeloid cells. It will be interesting to investigate whether AML patients overexpressing EVI1 are responsive to differentiation therapy.

Background. Phosphatidylinositol phosphate kinases (PIPK) belong to a family of enzymes that generate various lipid messengers. The PIPK subfamilies are divided into type I (α, β and γ), type II (α, β and γ) and type III. In a recent study in our laboratory, the PIPKIIα gene was differentially expressed in reticulocytes from 2 siblings with hemoglobin (Hb) H disease. Expressions of both the PIPKIIα and β-globin genes were higher in the patient with the higher Hb H level, suggesting a possible relationship between PIPKIIα and the production of globins. However, the role of PIPK proteins in hematopoietic process has been rarely directly addressed. Aims: To evaluate the PIPKIIα expression in hematopoetic-devided cells lines and to investigate the effects of PIPKIIα silencing in K562 cells on alfa and gama globin expression and on proliferation, cell cycle, differentiation and apoptosis. Methods: K562, KG1, NB4, HL60 and P39 cell lines were used. Specific siRNA-expressing vector targeting the PIPKIIα gene or no specific sequence were electroporated in the K562 cell line. Cells expressing no specific sequence or parental cells were used such as control. Quantitative PCR (qPCR) and Western blot analysis were performed to determine the expression of PIPKIIα, alfa and gama globin. β-actin and GAPDH were used as control in qPCR and actin in Western blot. After 48 hours of culture, proliferation was analyzed by MTT assays, apoptosis by Anexin-V and propidium iodide (PI), cell cycle by incubation with PI and RNase A buffer and flow cytometry. After 15 days of silencing the differentiation was evaluated by glycophorin A and transferin fluorescence intensity and percentage of double positive cells. Imatinib was used as control in the arrest of proliferation and inductor of apoptosis in K562 cells. Results: qPCR and Wester blot showed that PIPKIIα was express in all the cell lines tested and was observed a slight increase of PIPKIIα expression in K562 cells when compared with other cells included in this study. The levels of PIPKIIα mRNA and PIPKIIα protein in knockdown cells were significantly reduced by 80% and 75%, respectively ($P<0.05$). MTT assays showed that the proliferation was slight reduced by 10% in PIPKIIα knockdown cells when compared with control cells ($P<0.05$). Cell cycle, apoptosis and differentiation analysis showed no difference in PIPKIIα knockdown when compared with control cells. Interestingly, PIPKIIα silencing resulted in a significant increase in alfa and gama globin expression compared to control cells, as observed by qPCR and Western blot ($P>0.05$). Conclusions: PIPKIIα is express in hematopoetic-derived cells and PIPKIIα silencing results in slight decrease in proliferation and an increase of alfa and gama expression. Our findings show that in K562 cells there may be, at least in vitro, a regulatory mechanism that acts on α and γ genes in response to the reduction in PIPKIIα gene expression.

MULTIVARIATE ANALYSIS REVEALS RELATIONSHIPS AMONG PROMOTERS OF HAEMATOLOGICAL INTEREST

G Mahon, M Dicato
Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg

Background. Human promoters tend to have a characteristic consensus sequence although variation about the consensus sequence has received little attention. We have used multivariate analysis to define groups of promoters with similar sequences, taking account of the correlations amongst them. Correlations have been addressed in the region of the transcription initiation site and upstream in the region of the TATA site. *Aims.* We have sought to analyse numerically coded sequences so as to group the promoters systematically and reveal the relationships amongst them. Methods: The DNA sequences of all 1975 promoters experimentally confirmed in humans were extracted from the Eukaryotic Promoter Database; each sequence was 60 bases long. A base was coded by two binary digits: GC vs. AT and purine vs. pyrimidine. A principal component analysis of the resulting 120 variables was carried out. Most of the eigenvalues showed a regular downward trend, consistent with random sampling. However, the first five eigenvalues were greater than expected from the trend. The corresponding eigenvectors were used to calculate principal components, dimensions across which the promoters were distributed and by which they were classified. Results: The consensus sequence was found to be ggggg gg(c/g)cg (c/g)g(c/g)(c/g)g gg(c/g)gg g(g/t)aaa ggggg ggggg gc(c/g)cg ggggg cgcca ttgcg g(c/g)cgg. The first principal component distinguished promoters which were particularly GC rich. The twenty promoters with the highest values for the first principal component contained 87% GC and only 13% AT, while the twenty with the lowest principal component were 32% GC and as much as 68% AT. The promoters with the largest positive value of the first component included APLP1_1 (amyloid β A4 precursor-like protein 1), BCL2_1 (B-cell leukemia/lymphoma 2 proto-oncogene) and TGFB1I1 (transforming growth factor β 1 induced transcript 1). In contrast, the promoters with the largest negative values included those of the genes for interferon α 4, 6, 7, 16 and 17, interleukin 2 and 4, and albumin. *Conclusions*. The first principal component sorts promoters according to sequence features, and separates promoters of different functional groups. Similarly, the second, third and further principal components could be used to distinguish further groups of promoters. This multivariate approach accounts in a systematic way for the variation of the promoter sequences about the consensus sequence and the correlations amongst them.

TYROSINE KINASE INHIBITORS MODULATE THE APOPTOMIRS: MIR-16, MIR-21, MIR-30E, MIR-145, MIR-142-3P, MIR-LET-7D, MIR-LET-7E AND MIR-15A EXPRESSION IN BCR-ABL-POSITIVE CELL

A Ferreira, L Moura, B Simões, W Silva Júnior, S Kashima, D Covas, AM Souza, F Castro
University of Sao Paulo, Ribeirao Preto, Brazil

Background. The oncogene bcr-abl codifies the BCR-ABL tyrosine-kinase which is responsible for cell malignant transformation and apoptosis resistance in Chronic Myeloid Leukemia (CML). CML patients are usually treated with imatinib mesylate (IM), a tyrosine kinase inhibitor (TKI). Unfortunately, resistance to TKI emerges, especially in CML patients in advanced. Thus, others molecules have been investigated as potential secondary targets for CML therapy. In this context, the present study investigates the microRNAs, which have target genes involved in apoptosis regulation in Bcr-Abl+ AIM: To quantify the microRNAs let-7d, let-7e, miR-15a, miR-16, miR-21, miR-26a, miR-30e, miR-142-3p and miR-145 in HL-60.Bcr-Abl treated with imatinib mesylate (IM), dasatinib (DAS) and nilotinib (NL). Methods. HL-60.Bcr-Abl+ was obtained by the HL-60 infection with the recombinant retrovirus (ψ2 + PA 317) containing the pSR MSV p185bcr-abl tkneo plasmid. The HL-60.Bcr-Abl

cells were cultured in complete RPMI medium with 10 mili molar of TKIs during four or eight hours. After this period, RNA from cell lines were extracted, RNA were reverse transcripted and real time PCR were performed to quantify miRNAs expression. The results of miRNAs expression were given as fold change (fc) between HL-60.Bcr-Abl+ treated with TKIs and untreated HL-60.Bcr-Abl. Results.M downregulates miR-16 (fc=0.73), miR-21(fc=0.53), miR-30e (fc=0.89) and miR-145 (fc=0.28) expression after four hours of treatment in HL-60.Bcr-Abl. In contrast, DAS upregulates miR-21 (fc=11.71) and miR-142-3p (fc= 7.12). The levels of miR-let-7d decreased (fc=0.01) while let-7e (fc=2.89), miR-15a (fc=3.97) and miR145 (fc=11.97) increased in HL-60.Bcr-Abl after eight hours of NL treatment. CONCLUSION: TKIs are capable of modulating the microRNAs miR-16, miR-21, miR-30e, miR-145, miR-142-3p, miR-let-7d, miR-let-7e and miR-15a, which are involved in apoptotic machinery regulation in BCR-ABL+ cells. Thus, it seems that miRNAs expression profile may contribute to TKI response and suggest the potential of miRNAs as a new marker of CML prognosis.

1513

RELATIONSHIP BETWEEN MCV/MCH AND SEVERITY OF βGLOBIN GENE MUTATIONS IN β-THALASSEMIA CARRIERS

M Ehsani, M Behfar, P Salamati, R Jamshidi, K Holakouie Naieni, P Derakhshandeh Peykar
Tehran University of Medical Sciences, Tehran, Iran

Thalassemia as a heterogeneous disease is one of the most common single gene disorder with a worldwide distribution. The aim of this study was finding a relationship between blood indexes and severity of beta globins gene mutations in beta-thalassemia carriers. In this cross-sectional study, we were determined 30 beta goblin gene mutations in 1206 unrelated beta thalassemia carriers. Furthermore their blood indexes, including CBC and electrophoresis were also prepared. Then, by using SPSS software and t-test, the relationship between genetic findings and the results of their blood parameters were analyzed. In this study, the relationship between the severity of beta goblin gene (β+/β○), in beta thalassemia carriers, and their average blood indexes, were evaluated. The results indicated that β+ thalassemia in comparison with β○ thalassemia had a lower mean MCV and MCH value. That means with less time and expense it could be possible to find a statistically significant relationship between a specific ranges of blood indexes and type of mutations in beta thalassemia carriers. The results confirmed a significant correlation with blood indexes and certain type of mutations in beta thalassemia carriers.

1514

HEMATOLOGIC DISORDERS CAUSING DIAGNOSTIC PROBLEMS IN DIABETES MELLITUS

E Nemes-Nagy,[1] AA Zahra,[1] K Róbert,[1]A Karola,[1] M Dobreanu,[1] D Reid2[2] T Higgins,[2] M-F. Gizella[3]
[1]*University of Medicine and Pharmacy, Tirgu Mures, Tirgu Mures, Romania*
[2]*Dynacare-Kasper Medical Laboratories, Edmonton, Romania*
[3]*UMPh, Tirgu Mures, Medical Biochemistry Department, Tirgu Mures, Romania*

Aims. Investigation of diagnostic problems caused by hemoglobinopathies in diabetes mellitus, comparision of different chromatographic methods to determine glycated hemoglobin (HbA1c) in certain types of diabetic patients, following blood samples after in vitro glycation. *Methods*. Glycated haemoglobin was determined by 5 chromatographic methods, including HPLC. The subjects were 2480 patients from Romania and 150 from Canada (including 27 persons with hemoglobinopathies). Statistical analysis of the experimental data was performed using the GraphPad InStat program. *Results*. The results of different chromatographic methods showed positive correlation (r>0,9, p<0,05), but elevated HbF was found in 1,8% of the patients from Romania, and HbF can be co-eluted with the HbA1c fraction in case of some chromatographic methods. Higher HbA1c values could be observed in type 1 diabetic patients compared to type 2 (p<0,001), and in subjects from rural areas compared to those from urban environment (p<0,05). Following in vitro glycation in blood samples from patients presenting HbS, Hb E, HbD, Hb Camden and Hb G Coushatta reveals new peaks on the chromatogram that could represent glycated fractions of these pathological hemoglobin variants. Conclusions: The presence of hemoglobinopathies could disturb the proper diagnosis and following of diabetic patients because of their interference with the HbA1c fraction. In some homozygotes HbA1c can be absent on the chromatogram, and another problem is caused by the glycated fractions of pathologic hemoglobin variants which can appear as unknown peaks on the chromatogram. Special attention is required in case of type 1 diabetic teenagers especially from rural areas, to prevent complications of the disease.

DERIVATIVE (6)T(1;6)(Q21;P21): A RECURRENT CYTOGENETIC ABNORMALITY IN TWO CASES OF PEDIATRIC THERAPY-RELATED MYELODYSPLASTIC SYNDROME

C Morerio, E Tavella, A Garaventa, C Cuoco, C Panarello, E Tassano
IRCCS Istituto G.Gaslini, Genova, Italy

Childhood myelodysplastic syndromes (MDSs) are a rare group of clonal hematopoietic stem cell disorders occurring de novo or secondary to cytotoxic chemotherapy and/or radiotherapy for a previous malignancy. Cytogenetic aberrations have been detected in about 50% of de novo MDS and in almost all therapy-related MDS (t-MDS) patients. The most common abnormalities are complete or partial loss of chromosome 7 and trisomy 8. Unbalanced rearrangements involving the long arm of chromosome 1 and leading to its trisomy, usually as t(1;7), are also recurrent. We report two cases of pediatric t-MDS with der(6)t(1;6)(q21;p21). This unbalanced translocation has been reported in the literature associated with adult chronic myeloproliferative disorders. The first patient developed refractory cytopenia 9 years after suspension of chemo- and radiotherapy for a medulloblastoma diagnosed at the age of 7 months. The second patient, a 6-year-old boy, is slowly developing MDS features after a diagnosis of neuroblastoma 4S at age 1 month and of anaplastic lymphoma 10 months later. Cytogenetic analysis of peripheral blood and bone marrow blasts of both patients revealed der(6)t(1;6)(q21;p21). FISH for the painting of chromosomes 1 and 6 confirmed the rearrangement. Further array-CGH analysis performed on the bone marrow of the second patient, using 5500 BAC clones, showed gain of material of chromosome 1 (q21.1[ARROWRIGHT]q44) and chromosome 6 (p22.1[ARROWRIGHT]p12.1) and loss of material of chromosome 6 (p25.3[ARROWRIGHT]p22.1). Array-CGH analysis is being carried out in the other patient to verify whether the imbalance is identical.

1516

CYTOGENETIC FINDINGS IN *DE NOVO* ACUTE MYELOID LEUKEMIA: A STUDY BASED ON 553 PATIENTS IN A SINGLE INSTITUTION OF GREECE

A Daraki, M Roumelioti, M Kalomiraki, M Karakosta, G Pantelias, C Sambani, K Manola
NCSR Demokritos, Athens, Greece

Background. Acute myeloid leukemia (AML) is a heterogeneous disease with regard to clinical features and acquired genetic alterations. Currently, cytogenetic aberrations detected at diagnosis constitute the most common basis for predicting clinical outcome. *Aims*. We performed a conventional cytogenetic study of 553 *de novo* AML patients in order to define the chromosomal abnormalities and their frequencies as well as the frequencies of AML subtypes according to FAB classification. *Methods*. Chromosome studies were performed on unstimulated bone marrow cells, derived from 553 AML patients, aged ≥16 years at the time of diagnosis, between 2006 and 2010. Patients were classified according to FAB classification. *Results*. Three hundred ten patients were male and 243 were female. The median age of patients was 55,1 years (range 16-88). FAB classification was available in 294 patients with M0 in 5.4%, M1 in 7.8%, M2 in 21.4%, M3 in 26.9%, M4 in 23.1%, M5 in 11.2%, M6 in 3.4% and M7 in 0.7%. Karyotypic analysis was successful in 529 patients (95.7%). Normal karyotypes were found in 208 patients (39.3%) and abnormal in 321 (60.7%). Among the abnormal karyotypes 32.7% were complex (≥3 chromosome aberrations) and 48.6% had only one aberration. Chromosome aberrations found in abnormal karyotypes were: +8 in 20.2%, t(15;17)(q22;q11-12) in 12.1%, -7 in 9.7%, -Y in 7.5%, del(7q) in 6.9%, -17 in 6.9%, inv(16)(p13q22) in 6.2%, del(5q) in 5.6%, -5, t(8;21)(q22;q22), translocations of 11q and -18 in 5% each, +21 in 4.1%, +22 in 3.7%, del(9q) in 3.1%, del(11q) in 3.1%, abnormalities in 12p in 3.1%, -X in 3.1%, t(9;22) in 2.8%, +11 in 2.8%, +13 in 2.8% and chromosome-markers in 14.3%. The most frequent sole abnormalities found in karyotypes with only one chromosome change were t(15;17)(q22;q11-12) in 18.6%, +8 in 15.4%, inv(16) in 6.4%, -7 in 3.8%, translocations of 11q in 3.8%, t(9;22) in 3.2%, -Y in 3.2%, del(7q) in 2.6%, t(8;21) in 2.6%, del(11q) in 2.6%, +21 in 1.9%, del(20q) in 1.3% and tetrasomy 8 in 1.3%. The most common abnormalities found in complex karyotypes were +8

in 23%, -7 in 21%, -17 in 19%, del(5q) in 18.1%, -5 in 15.2%, -18 in 15.2%, del(7q) in 13.3%, -16 in 10.5%, +22 in 10.5%, -13 in 9.5%, -15 in 9.5%, -21 in 9.5%, -Y in 8.6%, t(8;21) in 7.6%, -20 in 6.7%, +20 in 6.7%, +21 in 6.7%, del(11q) in 5.7%, inv(16) in 5.7%, +11 in 4.8%, t(15;17) in 3.8% and chromosome-markers in 45.7%. Summary/Conclusions: AML was slightly more common in men than women. Interestingly, the most common chromosome abnormality in total abnormal karyotypes and complex karyotypes was +8, with a median age of 59.4 years, while t(15;17) was the most common sole aberration. Marker chromosomes, del(5q) and monosomies are mainly restricted to complex karyotypes with the exception of monosomy 7. The main FAB subtypes showed a distribution different to that reported in the literature, with a higher incidence of M3 followed by M4 and M2.

1517

A CONVENTIONAL AND MOLECULAR CYTOGENETIC STUDY IN A LARGE SERIES OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M Karakosta, P Diamantopoulou, A Daraki, M Margariti, G Pantelias, C Sambani, K Manola

NCSR „Demokritos„, Athens, Greece

Background: In Chronic lymphocytic leukemia (CLL) karyotypic data have been scarce due to the low mitotic activity of B-CLL cells in vitro. Nowadays, the improvement of cultivation techniques and fluorescence in situ hybridization (FISH) studies give an opportunity to a much more heterogeneous pattern of genetic abnormalities to be revealed. The prognostic significance of these aberrations may be used for a novel, more accurate classification system for CLL patients. AIM: The aim of this study was to define the chromosomal abnormalities and their frequencies among Greek CLL patients, between 1998 and 2010, using conventional and molecular cytogenetic methods. Methods: Conventional cytogenetics were performed on unstimulated and stimulated initially with tetradecanoyl phorbol acetate (TPA) and more recently with the oligonucleotide DSP30 plus IL-2 bone marrow cells, derived from 505 patients, aged 16-88 years. Fluorescence in situ hybridization (FISH) studies were accomplished in 60 patients using the commercial CLL set probes LSI p53/LSI ATM και LSI D13S319/LSI 13q34/CEP12 Multi-Color Probe Sets. Results: Three hundred and thirty seven patients were male and 168 were female. The median age was 64.75 years. Karyotypic analysis was successful in 473 patients (93.7%). Normal karyotypes were found in 58% and abnormal in 42% of patients. Among the abnormal karyotypes 27.3% exhibited complex karyotypes and 51.5% carried only one aberration. The frequencies of chromosome aberrations in abnormal karyotypes were the following: +12 in 29.3%, -Y in 15.7%, abnormal (abn) 17 in 13.1%, abn14q in 10.6%, del(13q) in 9.6%, del(6q) in 6.6%, -X in 5.6 %, numerical abnormalities of chromosome 8 in 5.6 %, abn18 in 5.6%, del(11q) in 5%, translocations of chromosome 11 other than t(11;14) in 4.5%, del(7q), translocations of chromosome 18 and abn20 in 3.5% each, t(11;14) in 2%, and chromosome markers in 13.1%. The most common abnormalities found in karyotypes as sole aberrations were +12 in 27.7%, -Y in 16.8%, del(13q) in 5.9%, add(14q) in 4.9%, del(11q) in 4%, del(6q) and -X in 3.3%. In complex karyotypes, chromosome markers were found in 42.6%, abnX in 20.4%, -17 and del(6q) in 16.7% each. FISH analysis using the specific probes mentioned above was successful in all 60 patients while genetic aberrations were detected in 70% of them. The frequencies of these aberrations were: del(13)(q14.3) in 46.7%, del(13)(q34.3) in 3.3%, del(17)(p13.1) (p53) in 16.7%, trisomy 12 in 15% and del(11)(q22.3) (ATM) in 10% of patients. Summary/Conclusions: The sex ratio was 2M/1F. The combination of DSP-30 plus IL-2 was able to identify more clonal abnormalities than TPA. Trisomy 12 was the most common abnormality found in karyotypes (29.3%) followed by -Y (15.7%), while del(13)(q14) was the commonest aberration (46.7%) detected by FISH. Abnormalities of chromosome X, monosomy 17 and del(6q) were mainly found in complex karyotypes with high incidence. The different frequencies of chromosomal aberrations found in conventional and molecular cytogenetics, mainly due to the restricted number of probes that can be used in FISH and the disability of karyotype to identify submicroscopic rearrangements, depict the necessity of their parallel application for CLL investigation.

[3]*1st Medical Department, General Teaching Hospital, Prague, Czech Republic*

Background. Deletion of the long arm of chromosome 5 is a recurrent cytogenetic abnormality frequently found in myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML). Patients with isolated del(5q) have a more favorable prognosis than those with additional karyotypic defects. Several groups of investigators have defined common deleted regions (CDRs), predicted to contain tumor suppressor genes. The proximal CDR in 5q31.2 (970 kb) was localized both in MDS, AML and therapy-related MDS/AML, while the distal CDR in 5q32-q33.1 (1.5 Mb) is involved in the pathogenesis of 5q- syndrome. Aims. The aim of this study was to exactly determine the breakpoints and size of unusual deleted segments in three MDS/AML patients with 5q deletion and to evaluate the role of genes localized in this region for the initiation or progression of the disease. Methods: During the years 1993 - 2010 we found deletion 5q as a sole aberration in bone marrow of 126 patients with MDS/AML (sex ratio M/F was 28/98, median 68 years). FISH with locus probe Vysis LSI EGR1/D5S23, D5S721 Dual Color Probe (Abbott Molecular) and ON MDS 5q- (5q31, 5q33) / hTERT (5p15) TC (Kreatech Diagnostics) were done in all of them. To precisely determine the breakpoints, FISH with BAC clones (BlueGnome, 5q14.1-5q35.1 regions), multicolor banding (mBAND) for chromosome 5 (XCyte 5, MetaSystems) and array comparative genomic hybridization (aCGH, CytoChip Focus Haematology, BlueGnome) were performed. Results: In 119 patients (94.5%) deletion 5q was large involving both proximal and distal CDRs, in four patients (3.0%) deletion of only distal CDR was confirmed. However, in three patients (2.5%) loss of the material on the long arm of chromosome 5 was outside of both CDRs - results of FISH with LSI probes for 5q31/5q33 regions did not prove the deletion. In patient No.1, a 61-year-old female with diagnosis AML, deletion 5q14q21 was confirmed in a small clone (4 mitoses out of 30 examined). In patient No. 2, a 66-year-old female with MDS-MPS, deletion del(5)(q14q23.3) was found in all examined mitoses. The same range of the deletion, del(5)(q14q23.3) was determined in patient No. 3, a 73-year-old male with RCMD. The exact breakpoints of deletions were confirmed by combination of molecular cytogenetic techniques. Patient No. 2 died of acute heart failure 18 month after diagnosis, patients No. 1 and No. 3 live in complete remission. Conclusions: Out of 126 patients with myeloid malignancies and deletion 5q, we proved atypical extent of the deletion in three of them: proximal breakpoints were localized in 5q14 in all three patients, distal in 5q21 (patient No. 1) and 5q23.2, respectively (patients No. 2 and No. 3) with retained 5q31.2 and 5q32-q33.1 bands. To our knowledge, deletion of 5q14-5q23.2 as a sole aberration has not been described so far. Deleted region encompasses approximately 140 genes (*http://www.ncbi.nlm.nih.gov/mapview/*) and we assume that not only genes harbored in conventional CDRs but also genes localized in 5q14-5q23.2 region may contribute to malignant evolution of myeloid diseases.

INTERPHASE FISH ON PURIFIED PLASMA CELLS IS SUPERIOR TO FISH ON CULTURED BONE MARROW CELLS IN PATIENTS WITH MULTIPLE MYELOMA

M Stevens-Kroef, D Olde Weghuis, L Derksen, J Hooijer, A Simons, A Geurts van Kessel

Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background. Multiple myeloma is a heterogeneous disease with a highly variable clinical course. Genetic abnormalities such as t(4;14)(p16;q32), t(11;14)(q13;q32), t(14;16)(q32;q23), 17p loss, 13q loss, 1q gain, 1p loss and hyperdiploidy have been shown to provide prognostic information (Fonseca et al. Leukemia, 2009). In multiple myeloma karyotyping is hampered by the low proliferative index of plasma cells and, therefore, in only about 30% of the patients an abnormal karyotype is found. Interphase fluorescence in situ hybridization (FISH) can circumvent this problem, but its resolving power is hampered by the overall low percentage of plasma cells present in bone marrow samples. Aims. To evaluate the diagnostic potential of FISH on purified plasma cells as compared to FISH on cultured bone marrow cells. Methods. We have developed and optimized a protocol for the purification of CD138+ cells (plasma cells) from bone marrow samples for FISH applications. Interphase FISH results obtained from such purified plasma cells were compared to those obtained from cultured bone marrow cells using an extended probe panel according to the recommendations of the Dutch Working group on Hemato-oncologic Genome Diagnostics (WHGD). This panel allows the detection of IGH rearrangements, including t(4;14),

t(11;14) and t(14;16), 1p loss, 1q gain, 13q loss, 17p loss, and hyperdiploidy. Results. Our pilot study on 51 patient samples showed that clonal genetic abnormalities can be detected in 98% of the patients when purified plasma cells were used. In 34% of these patients the genetic abnormalities were not identified when FISH was applied on cultured bone marrow cultures. Furthermore, FISH on purified plasma cells resulted in the identification of higher percentages of genetic abnormal cells, thus allowing the detection of genetic sub-clones. Summary/Conclusions. We conclude that interphase FISH on purified plasma cells is superior to interphase FISH on cultured bone marrow cells for the detection of prognostic relevant genetic abnormalities in multiple myeloma.

[5]*CGB Laboratory, Ostrava, Czech Republic*

Background. Various aberrations of chromosome 5 are common cytogenetic findings in bone marrow cells of patients with MDS. The most frequent is interstitial deletion del(5q) occurring as sole chromosome abnormality or in combination with additional chromosomal changes. The size and breakpoints of deleted segment differs among patients, however the region 5q31 is commonly deleted in most of them. Two CDRs have been identified in 5q, indicating the presence of critical genes within these loci. Monosomy 5 is found by conventional cytogenetic methods in about 3-8% MDS cases only, usually in combination with other aberrations. *Aims*. The aim of this study was to perform detailed genome wide analysis in series of newly diagnosed patients with MDS and monosomy 5 detected by conventional cytogenetics, and to assess real frequency of true monosomy 5 in primary MDS. Methods: Fixed bone marrow cells of 46 MDS patients with suspected monosomy 5 found by G-banding (32 males, 14 females; median age 63 years) were retrospectively analyzed. To detect deletion 5q31 interphase FISH (I-FISH) with Vysis LSI EGR1/D5S23, D5S721 Dual Color probe (Abbott Molecular) was used. Complex aberrations were analyzed by mFISH/mBAND (MetaSystems). For identification of genomic imbalances BAC-based arrays (CytoChip Focus Hematology, BlueGnome) and/or SNP arrays (HumanCytoSNP-12 BeadChips, Illumina) were applied. Results: All 46 patients with suspected monosomy 5 presented a complex karyotype (≥3 chromosomal aberrations). Deletion of 5q31 was detected in 45 of them (97,8%) and loss of both regions (5p15 and 5q31) just in one by I-FISH. Whole genome molecular cytogenetic analyses confirmed that in all cases, parts of chromosome 5 material remains retained. No patient with true monosomy 5 was identified in this study. Common region conserved in all patients was established at 5p11.1-p14.2 [22.31Mb]. mFISH/mBAND revealed cryptic translocations and insertions of chromosome 5 material to several chromosomal partners (chromosomes 17, 3, 7 and 12 as the most frequent ones). Finding of complex karyotypes involving deleted chromosome 5 at diagnosis was connected with particularly poor overall survival (median 3 months). *Summary/Conclusions*. In all patients with suspected monosomy, the parts of the deleted chromosome 5 have been shown to be retained elsewhere in the karyotype. Therefore, we believe that the true monosomy 5, quoted in the literature, in bone marrow cells of MDS patients probably does not exist. We assume that 5q deletion is arising in myeloid precursor cells as the primary event and subsequently leads to chromosome instability and higher susceptibility to the rearrangements. This process is resulting in increased genomic damage and fast disease progression. In this study patients with deleted chromosome 5 involved into complex aberrations had an extremely poor prognosis.

PATIENT-SPECIFIC MICRORNA EXPRESSION PROFILES IN CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA AS A PLATFORM FOR MINIMAL RESIDUAL DISEASE DETECTION

V Shivarov, S Angelova
National Hematology Hospital, Sofia, Bulgaria

Background. MicroRNAs are a class of small noncoding RNAs playing a crucial role in the fine tuning of mRNA expression under physiological and pathological conditions. Recently, a number of reports demonstrated the applicability of genome-wide microRNA expression profiling in Acute myeloid leukemia (AML) for disease subclassification and prognostic stratification and suggested microRNAs as a novel clinically useful class of biomarkers. On the other hand, AML cases with normal cytoenetics (NC-AML) usually lack suitable molecular markers for minimal residual disease detection. It is, therefore, tempting to explore the utility of microRNA expression profiling for minimal residual disease detection. *Aims*. In this pilot study we aimed at examining the feasibility in clinical settings of identification of patient-specific profiles of overexpressed microRNAs in cases of NC-AML. Methods: We used a custom Flexmir v.2 (Luminex Corp., USA) bead-based liquid assay for single-tube detection of 50 selected microRNAs. A total of 36 newly diagnosed cases of NC-AML cases were included in the study and 1 commercially available normal bone marrow RNA sample was included as a normalization control. Mean expression value for each microRNA in each sample was background corrected, normalized to the normal control and log2 transformed. MicroRNAs were considered significantly overexpressed if the log2 value was ≥1.5. Results: Thirty (83.3%) cases had at least one significantly overexpressed microRNA. The number of overexpressed miRNAs varied between samples - 11 cases had 1-3 overexpressed microRNAs, 11 cases had 4-7 miRNAs and 8 cases had a profile with more than 8 overexpressed micoRNAs. The most frequently overexpressed microRNAs were as follows: miR-19a (in 21 cases), miR-181a (in 20 cases), miR-19b (in 18 cases) and miR-17 (in 17 cases) whereas a total of 15 miRNAs were not found to be overexpressed in either of the cases. *Conclusions*. We showed that it is possible to identify a patient-specifc profile of overexpressed microRNAs in more than 80% of the cases of NC-AML cases. Besides, some of the overexpressed miRNAs were present in most of the cases, which makes it possible to use custom assays for just a few microRNAs (bead-based liquid assay, qPCR) for screening of overexpressed microRNAs in clinical settings.

Acknowledgments. We are thankful to the staff of the Molecular Biology lab in our institution for collecting an storing some of the RNA samples.

THE BIOINFORMATIC ANALYSIS OF ALU-REPEAT IN 5'-AREA OF MDR1 GENE PROMOTER REGION

D Marinitch,[1] D Tsvirko,[1] N Volkovets,[1] T Shevchuk,[2]
O Dyachenko,[1] Y Buryanov[2]
[1]*Byelorussian Hematology Center, Minsk, Belarus, Republic of*
[2]*Branch of Institute of Bioorganic Chemistry, Pustchino, Russian Federation*

Alu repeats have obtained their name from the fact that most of them contain nucleotide AGCT, a cleavage site for the Alu I restriction endonuclease. A high concentration of Alu elements in the chromosome regions which contain a lot of genes allows duplication or elimination of genome fragments located between two Alu copies, as well as chromosome rearrangements. Alu repeats can affect the composition, organization and expression of the genome. Owing to their own promoter or enhancer activity, Alu repeats may enhance transcription of the adjacent locus. Transcriptional suppression is also possible, as Alu elements may expedite nucleosome assembly on the adjacent region. In addition, Alu repeats seem expedite methylation of neighboring loci, contributing to gene expression regulation. While methylation commonly suppresses transcription, cases are known when methylation of Alu repeats increases the transcriptional activity of the neighboring locus. Our aim was to investigate the interrupted ALU-repeat in 5'-area of multidrug-resistance gene (MDR1) promoter region. The investigation was performed on the DNA of lymphocyte cultures of healthy volunteers and on the DNA of leukemic cells of patients with acute lymphoblastic leukemia (ALL) and acute myeloid leukemia (AML). Totally 34 DNA samples (14 ALL, 10 AML and 10 of normal blood donors) obtained from mononu-

clear cells of peripheral blood or bone marrow were involved in the study. Almost all cases of the disease were untreated patients. Both peripheral blood and bone marrow samples were investigated. The methyl- sensitive (HpaII) and methyl-insensitive (MspI) restriction endonucleases were used for the digestion of the DNA-samples. The bisulfite sequencing method war applied in the study. The bioinformatic analysis we run had revealed the presence of interrupted ALU-repeat in 5'-area of MDR1 gene promoter region. This particular fragment does represent one of numerous subtypes of ALU-repeats and is enriched with CCWGG sites and deplete with CCGG sites being compared with "canonical"ALU sequence. Using bisulfite sequencing we revealed non-symmetrical cytosine methylation in the MDR1 gene promoter region. Comparative analysis of MDR1 promoter methylation using methylation-sensitive PCR showed distinctive differences of methylation pattern between myeloid and lymphoid kinds of acute leukemia with persistent reciprocal relationships. Namely, we observed demethylation of CG's and hypermethylation of CNG's for acute myeloid leukemia and the opposite relations for acute lymphoid leukemia: hypermethylation of CG's attended by CNG's demethylation. Overexpression of the MDR1 gene is well known marker of poor prognosis. But the genetic and epigenetic base of MDR1 'behavior' in various hematology malignancies still remains unknown. Our preliminary results suggest that epigenetic changes and thus functional activity of the MDR1 gene are not even in various hematological tumors and depends not only on cytotoxic influence, but also on the malignancy origin. This also highlights the interest to the enigma of epigenetic changes during the hematopoietic cells differentiation

POST-SCT CHIMERISM: THE MORE MARKERS THE BETTER?

R Clark, A Jack, L Holden, D Barnett, J Reilly
UK NEQAS LI, Sheffield, UK

Chimerism testing is a routine clinical decision measure of donor engraftment level in the recipient following allogeneic stem cell transplantation (SCT), with small percentage reductions used in the determination of therapy. Data from the last 5 samples issued (a total of 337 results) to 78 international laboratories participating in the UK NEQAS Post-SCT Chimerism External Quality Assessment programme were examined to determine if the number of Short Tandem Repeat (STR) markers used impacted upon the results returned. To allow data comparison the consensus median for each sample and the delta values from the relevant consensus median were calculated for each individual result. The larger the delta value, the further that data point was from the consensus median. Data was then grouped by the number of markers used in the percentage donor calculation, and this grouped data further separated by methodology (namely in-house or commercial kit); Kruskal-Wallis one way ANOVA was used to test for significance. Additionally, data grouped by methodology, irrespective of number of markers used in their calculation, was subjected to a Mann Whitney U Test. Analysis showed that number of markers used in percentage donor chimerism calculation had no significant impact on the calculated delta values (p=0.0873). Additionally, no significant difference was found when results were grouped according to number of markers used, with or without further method separation (p=0.116 and p=0.0924). However when the methodologies were compared, (irrespective of the number of markers used in the calculation), the in-house median delta was significantly higher than the commercial kits median delta (p=0.003). Statistical comparison of the number of markers used in the calculation by in-house compared to kit users is difficult as there is little overlap between the two sets of data (in-house users mode=2 markers compared to kit mode=8 markers). However, when comparing in-house users to kit users: on average they have smaller panels available (12 vs.14); analyse a smaller percentage of these available markers (74% vs. 98%); define a smaller percentage of these analysed markers to be informative (63% vs. 81%) and; use a smaller percentage of these informative markers in their final donor calculation (60% vs. 68%). In conclusion, our data has shown that statistically, results generated by in-house methodology have a larger delta value (further from the median) than those generated by a commercial kit. This difference may be due, in part, to the number of markers used in the calculation. However, this study has highlighted the urgent need for guidance and standardization in clinically significant post-SCT chimerism testing.

Deletions of the long arm of chromosome 6 (6q) are known to occur at relatively low frequency (3-6%) in B cell chronic lymphocytic leukaemia (B-CLL), and are more frequently observed at 6q21. Patients with B-CLL carrying a 6q21 deletion show clinicobiologic features, and their outcome should be allocated in an intermediate-risk category. Few data have been reported about other band at 6q with cytogenetic alterations in B-CLL. In the current study, we used Bacterial Artificial Chromosome (BAC) clones as probes for fluorescence in situ hybridization (FISH) to analyze the incidence and localization of 6q aberrations in 110 cases of B-CLL at diagnosis. In this study, we have four BAC clones mapping regions in bands 6q16 (RP11313A17), 6q23.3 (RP11323N12), 6q25.2 (RP11589G2), 6q27 (RP1137D8). The FISH study was performed on nuclei and metaphases after stimulation with a combination of CpG-oligonucleotide DSP30 and interleukin 2 (IL-2) as previously described. Of 110 samples studied with our set of BAC clones probes, 94% could be successfully analyzed by interphase-metaphase FISH. We identified 11 cases (10%) with 6q deletion, the percentage of cells containing 6q deletions ranged from 7% to 89%. Both trisomy for chromosome 12 and homozygous deletion of 13q14 as well as no anomaly were found in 4 cases deleted in 6q16 using FISH. Trisomy for chromosome 12 and loss of 17p were demonstrated in 1 patient with a 6q23.3 and a 6q25.2 deletion using FISH. We also observed a 6q25.2 deletion without other aberrations in 2 cases using FISH. In one patient was found deletion by our set of BAC clones probes in all investigated bands associated with 6q21deletion in FISH. One case showed deletion of 6q16 and 6q25.2 coupled with trisomy 12. In one sample 6q27 deletion was associated with homozygous deletion of 13q and loss of 17p13. The last case deleted in 6q25.2 and 6q27 showed no other anomalies in FISH. In our study, of 11 cases with 6q deletion, 6 have the data of chromosome banding analysis (CBA) available. In 4 cases the abnormalities observed in addition to the 6q deletion were a trisomy 12, a loss of 13q, 17p, 14q, a gain of 7p or presence of marker chromosome. In addition 2 cases with deletion 6q show a complex aberrant karyotype. Moreover six results showed borderline value which should be further investigated. Previous cytogenetic studies suggest that tumor suppressor genes that are involved in the pathogenesis of malignant lymphoid diseases have been localised in 6q site. Using our panel of BAC probes FISH procedure, we detected deletion in the region 6q16, 6q23.3, 6q25.2 and 6q27, and we identified 11 cases with a 6q deletion, but only one showed a deletion of at 6q21, which is recognized by the commercially available probe. We are correlating cytogenetic data obtained with clinical course to evaluate the prognostic value of 6q deletions. Our data revealed that the 6q deletion is characterized by increased genomic instability and suggested that these deletions represent a secondary event in tumorigenesis of CLL.

EVALUATION OF THE ASURAGEN® BCR/ABL1 QUANT TEST (CE IVD) FOR MONITORING THE BCR/ABL1 TO ABL1 RATIO BY RT-QPCR IN PH-POSITIVE CML PATIENTS EXPRESSING B2A2, B3A2, OR THE E1A2 FUSION TRANSCRIPT

D Colomer,[1] B Cabot,[2] S Cabezas,[1] B McLucas,[2] R Petraroli[2]
[1]*Hospital Clinic-IDIBAPS, Barcelona, Spain*
[2]*Life Technologies Corporation, Foster City, CA, USA*

Background. Real-time quantitative polymerase chain reaction (qPCR) of BCR-ABL hybrid transcripts is the standard method for monitoring the response to treatment in patients with chronic myeloid leukemia (CML) or Ph-positive-acute lymphoblastic leukemia (ALL). Recently, various methods based on RQ-PCR have been adopted to monitor residual dis-

ease in clinical studies. This has underlined an increased need for standardization and the adoption of CE-IVD regulated devices for BCR-ABL monitoring. The Asuragen® BCR/ABL1 Quant® Test is a quantitative in vitro diagnostic device to monitor the BCR/ABL1 to ABL1 ratio by RQ-PCR on whole blood or bone marrow of diagnosed Ph-positive CML patients expressing b2a2, b3a2, or e1a2 fusion transcripts. The kit includes a calibrator set to generate three calibration curves and an exogenous spike in control to assess process efficiency, both built with Armored RNA Quant® (ARQ) technology. Aims. The aim of this study is to evaluate the Asuragen® BCR/ABL1 Quant® for monitoring the BCR/ABL1 to ABL1 ratio by qPCR in Ph-positive CML patients express¬ing b2a2, b3a2, or e1a2 fusion transcripts by performing a comparative study on clinical samples with known percentages of tumour cells using the Asuragen® BCR/ABL1 Quant® Test, the Europe Against Cancer (EAC) method and the IPSOGEN FusionQuant® Kit. *Methods*. 45 clinical samples with known percentages of tumor cells were selected to show different methods' abilities to detect BCR-ABL transcripts at varying levels and to attest the reproducibility of the BCR/ABL1 Quant Test.Total RNA was extracted from the leukocytes using TRIZOL® Reagent and processed using the EAC method, the IPSOGEN FusionQuant® Kits and BCR/ABL1 Quant® Test. Results. Visual inspection of the data showed that all measurements closely followed the equality line. The results from the EAC protocol were converted to the International Scale (IS) for the p210 group and using the method comparison procedure of Bland and Altman, the bias between the BCR/ABL1 Quant® Test, IPSOGEN FusionQuant® Kits and the EAC method was determined. The BCR/ABL1 Quant® Test gives the comparable results to the EAC protocol and Ipsogen FusionQuant® kit. The best results observed in the p210 group indicate that the EAC protocol results were only calculated according to IS for the p210. *Conclusions*. Considering the increasing number of laboratories adopting methods for molecular monitoring in CML, concordance of results between different methodologies is essential to assure harmonization of results irrespective of the method used. In this study we demonstrated the concordance between the Asuragen® BCR/ABL1 Quant® Test, the Europe Against Cancer (EAC) program method, and the IPSOGEN FusionQuant® Kit. The multiplex format of the Asuragen® BCR/ABL1 Quant® Test enables the simultaneous detection and quantification of the three predominant BCR/ABL1 fusion transcripts and ABL1 endogenous control in a single reaction, providing the possibility to use less cDNA, less reagents and to invest less time in performing the analysis. The kit format eliminates much of the variability seen across different laboratories due to individual primer and probe preparation protocols. Using the standardized and high quality controlled Asuragen® BCR/ABL1 Quant® Test would help in saving time and providing more reproducibility in results.

DOES ADDITIONAL ABERRATIONS DETECTED BY METAPHASE CYTOGENETICS CHANGE THE FAVORABLE PROGNOSIS OF SOLE 13q14 DELETIONS DETECTED BY FISH ? - PRELIMINARY RESULTS

E Wawrzyniak,[1] A Kotkowska,[2] J Blonski,[1] T Robak,[1]
A Korycka-Wolowiec[1]
[1]*Medical University of Lodz, Lodz, Poland*
[2]*Copernicus Memorial Hospital, Lodz, Poland*

Background. Loss of genetic material from the long arm of chromosome 13 is the most frequent chromosomal aberration in CLL reported in over 50% of CLL cases and associated with a favorable prognosis when present as the sole genomic abnormality. However FISH analysis as a routine clinical test is usually performed only for the detection of 13q14, ATM and TP53 deletions, and trisomy 12. *Aims*. The aim of the study was to estimate the type and frequency of additional chromosomal aberrations detected by metaphase cytogenetics (MC) in CLL patients with sole del(13)(q14) and to answer the question if they are of clinical significance. Patients and methods. Twenty-four previously untreated CLL patients with sole del(13)(q14) were included into the study. Sole del(13)(q14) was defined as presence of del(13)(q14.3) and absence of: del(11)(q22.3), del(17)(p13.1) and trisomy 12. The patients were divided into two groups: with sole del(13)(q14) only (group A) and with additional aberrations detectd by MC (group B). Submicroscopic character of del(13)(q14) in 21 patients was confirmed by metaphase FISH. The diagnoses were based on the IWCLL criteria. The laboratory and clinical assessments included: age, absolute lymphocyte count (ALC), serum LDH activity, serum beta2microglobulin level, CD38 expression and Rai staging. Seventeen patients were treated with purine analogues and/or alkylating agents. The follow-up range as the time from the cytogenetic analysis to the last observation was from 20 to 42 months. Overall response rate (OR) for the patients was established. Chromosome banding analysis was performed after 72h culture with the CpG-oligonucleotide DSP30 according to standard protocol. FISH analysis was performed on peripheral blood smears using D13S319(13q14.3)/13q34/CEP12 and TP53(17p13.1)/ATM(11q22.3) probes. Mann-Whitney U test and Fisher's exact test were performed with $P<0.05$ as the threshold of statistical significance. Results. Group A consists of 11 patients (45.8%) and group B of 13 patients (54.2%). In group A karyotype was normal (n=9) or del(13)(q14) as the only aberration (n=2) was present. In group B additional aberrations were detected: in 5/13 (38.5%) cases karyotype was complex, only in 2/13 (15.4%) cases aberrations were balanced. The most recurrent regions involved in aberrations (especially translocations) included: 13q14 (n=3), 14q32 (n=2), 2p11-13 (n=2), 3p26 (n=2) and 6q13-26 (n=3, deletions). No significant differences between the two studied groups were observed with respect to age, ALC, LDH, beta2microglobulin and CD38, or to the stage of the disease: RAI stage 3 and 4 was established in 5/11 (45.5%) and in 7/13 (53.9%) patients in group A and B, respectively. OR was obtained in 5/7 (71.4%) patients of group A and in 7/10 (70.0%) patients of group B, and the difference was also not statistically significant. *Conclusions*. Patients with sole del(13)(q14) as determined by FISH do not represent a cytogenetically homogenous group. No differences were observed in laboratory and clinical data among patients with and without additional aberrations. However, the time of follow-up was too short to determine definitively if these additional aberrations have clinical significance, so further studies are continued.

Funding. The study was supported from government budget for science (Grant No 2553/B/PO1/2008/34)

DELINEATION OF REARRANGEMENT BETWEEN THE RUNX1 AND THE HOXA GENE CLUSTER; A POSSIBLE NOVEL MECHANISM FOR LEUKEMOGENESIS

Y Moon,[1] G Park,[2] K Humphries,[3] D Horsman[4]

[2]*Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea*
[3]*Terry Fox Laboratory, British Columbia Cancer Agency, Vancouver, Canada*
[4]*Department of Laboratory Medicine, BC Cancer Agency, Vancouver, Canada*

Background. Translocation involving the Runt-related transcription factor 1 (RUNX1) gene commonly occurs in hematologic malignancies. The HOX family consists of 39 HOX genes arranged in four clusters (A-D) that are located on chromosome 7, 17, 12 and 2, respectively. Studies have shown that some of the HOX gene family are expressed in human leukemia and play an important role in development of leukemia by fusion with NUP98. But the translocation between RUNX1 and HOX gene cluster has not been addressed so far. Currently we experienced acute myeloid leukemia with t(7;21) on G-banding implying the involvement of RUNX1 and HOXA genes. Aims: To address a possible role of RUNX1/HOXA gene fusion as a novel leukemogenic mechanism, we performed FISH analysis on human acute myeloid leukemia case and explored the breakpoint responsible for RUNX1/HOXA translocation. Methods: G-banding was performed on bone marrow cells of AML patient according to standard unstimulated 24-hour culture method. FISH using a commercial LSI AML1/ETO dual color, dual fusion probe (Vysis, Downers Grove, IL) was performed to assess and exclude the cryptic translocation of RUNX1 and RUNX1T1. And next, to explore the breakpoint on the short arm of chromosome 7 involved in the t(7;21), we referred to the human genome browser database and designed 5 paired-sets of dual color (SpectrumOrange and SpectrumGreen) break-apart probes with using relevant eight bacterial artificial chromosome (BAC) clones targeting the HOXA gene cluster. Results: G-banded karyotyping demonstrated 46,XX,t(7;21)(p15;q22)[5]. Metaphase fluorescence in situ hybridization (FISH) analysis using the AML1/ETO dual-color, dual-fusion probes showed three (one large and two small) green signals for AML1(RUNX1) implicating some aberration in one RUNX1 gene. The signals for the ETO(RUNX1T1) gene remained intact, which excluded the possibility that AML1/ETO gene fusion might involved in the leukemogenesis of this case. The results of FISH with 5 paired probe sets for the HOXA genes narrowed the candidate region for breakpoint. Metaphase FISH using RP11-163M21 labeled SpectrumOrange, HOXA1-7 spanning probe, and RP11-1148E13 labeled SpectrumGreen, HOX13 flanking probe on centromere side showed one fusion signal on normal chromosome 7, one red signal on der(21) and one green signal on der(7). These findings indicate that the region including HOXA1-7 is

translocated to der(21). Metaphase FISH using RP11-838G2 labeled SpecrumOrange, HOXA gene flanking probe on telomere side, and RP11-1025G19 labeled SpectrumGreen, HOXA7-13 spanning probe showed one fusion signal on normal chromosome 7, one small fusion signal on der(21) and small green signal on der(7). This finding indicates that the region including HOXA7-13 or part of HOXA7-13 is translocated onto der(21). Conclusions. These results clearly demonstrate that the translocation of RUNX1 and HOXA gene was involved in acute myeloid leukemia and suggest that juxtapositioning of the RUNX1 and HOXA genes would be a novel mechanism for leukemogenesis.

1528

EVALUATION OF A QUALITATIVE *IN VITRO* DIAGNOSTIC DEVICE FOR THE MULTIPLEX DETECTION OF SPECIFIC FUSION TRANSCRIPTS TO AID IN THE DIAGNOSIS OF LEUKEMIA

K Newell, J Mason, M Griffiths
West Midlands Regional Genetics Laboratory, Birmingham, UK

Background: Multiple recurring chromosomal translocations occur in leukaemia. Sensitive detection and accurate classification of the associated gene fusions is critical for the diagnosis and prognosis of many leukaemias. At the molecular level the breakpoints can vary over a wide region within the genes involved, and it is often necessary to determine the specific fusion sub-type for the purposes of ongoing monitoring with quantitative molecular techniques. Aims: To evaluate a new commercially available CE-marked IVD test kit in a clinical setting for the simultaneous detection of leukaemia fusion transcripts in a single multiplex assay. To determine diagnostic specificity and sensitivity of the test relative to standard cytogenetic and molecular methods. Methods: Archived total RNA samples from leukaemia patients at presentation were analysed using the commercial kit. The kit can detect 12 fusion transcripts (BCR-ABL1 e13a2, BCR-ABL1 e14a2, BCR-ABL1 e1a2, TCF3-PBX1, ETV6-RUNX1, MLL-AF4 e9e5, MLL-AF4 e10e4, PML-RARA bcr1, PML-RARA bcr3, CBFB-MYH11 type A, CBFB-MYH11 type D, RUNX1-RUNX1T1) and includes GAPDH as an endogenous control to assess sample quality. Following multiplex RT-PCR using 100 to 400 ng RNA per test, the identity of biotin-labelled PCR products was simultaneously determined by hybridization on a liquid bead array, containing target-specific probes, and flow cytometric detection. Qualitative calls (positive or negative for each target) relative to a fixed cut off signal (350 MFI) were generated and compared to known diagnostic status. Results: To date, 70 specimens have been evaluated, 58 positive and 12 negative. One sample failed (no signal) and one positive sample generated a low signal at 294 MFI, above the average background negative signal (51 MFI), but below the fixed cut off (350 MFI). These 2 samples are being further investigated. For the 69 samples with results, a total of 759 calls were generated for the individual fusion transcripts corresponding to an overall agreement with reference methods of 99.9% (758/759; 95% CI: 99.3 to 100%). Diagnostic sensitivity was 98.2% (56/57; 95% CI: 90.7 to 99.7%) and diagnostic specificity was 100% (702/702; 95% CI: 99.5 to 100%). Summary/Conclusions: The assay is quick, simple and reliable. It detected all twelve fusion transcript types in representative clinical specimens. Analytical sensitivity was not evaluated here (1% reported by the test manufacturer) but was appropriate for the analysis of samples at initial diagnosis. Further, the inclusion of an endogenous control enables determination of poor quality or low input samples. The kit also has the advantage of typing individual fusions, and assigned these correctly in 100% of cases. This could facilitate the downstream use of specific molecular assays such as RT-qPCR for follow-up analyses and minimal residual disease monitoring. Finally, multiplex detection in a single reaction can greatly improve laboratory efficiency, which would be further enhanced by the addition of more rare fusion subtypes such as BCR-ABL1 e13a3 and e13a4 or CBFB-MYH11 type E to the kit. Overall the CE-marked IVD test kit is an attractive novel molecular method that is compatible with the clinical laboratory workflow and complements standard cytogenetic methods.

Trisomy 3 was first reported as a sole abnormality in adult T cell lymphoma/leukaemia and subsequently in other subtypes of T-non Hodgkin lymphoma (NHL), particularly lymphoepithelioid and angioimmunoblastic. Later, it was identified as the most frequent abnormality in marginal zone B-cell lymphoma. In other B cell NHL it is relatively rare and is reported only sporadically in chronic lymphoproliferative disorders (CLPD). Although it is not a recognised recurrent abnormality associated with chronic lymphocytic leukemia (CLL), it is detected in 1.5%-2.8% of karyotypically abnormal cases and in around 3% of all cases by FISH. Given the importance of recognising new cytogenetic entities with differing clinical course and prognosis we set out to determine whether trisomy 3 is a rare recurrent abnormality associated with CLL or whether the presence of this abnormality in the karyotype should evoke a differential diagnosis. Twelve cases with a trisomy 3, complete or partial, for whom a diagnosis of CLL was retained by the referring institution, were retreived from the databases of two Belgian genetic centres. The sample type analysed was blood in four cases, bone marrow in two and blood and bone marrow in one. The clinical, biological and histological findings of these presumptive cases were reviewed. A diagnosis of typical CLL, or atypical-CLL, was retained for cases with either a Matutes-Catovsky score of ≥3 or histological confirmation of CLL on review. Five cases presented with Binet stage A and two with Binet stage B disease. On follow up, three had stable disease, two showed evolutive disease requiring treatment and two underwent Richter transformation. Morphological examination of all cases was consistent with CLL. Three cases displayed a typical immunophenotype with a score of 4 or 5, three had a score of 3 and one a score of 2, included after histological confirmation of typical CLL. One had a raised monoclonal IgMK and another cold agglutinins. Trisomy 3 was present as the sole abnormality in 3 cases, was associated with one other aberration in 2 cases (balanced translocation, trisomy 12), and occurred as part of a complex karyotype in 2 cases (>3 abnormalities). Interestingly, the two cases that underwent Richter transformation had a complex karyotype. To date, the clinical details associated with trisomy 3 have only been described in 5 cases of CLL (Wong 2002, Specchia 2002, Michaux 1998). For these cases a diagnosis of CLL was based on morphological criteria despite an atypical phenotype. Unlike those previously reported three of our cases had a typical CLL immunophenotype. This study brings the total number of reported cases of trisomy 3 associated CLL to twelve. Morphological criteria was consistent with CLL in all cases. Phenotype was frequently atypical, but not evocative of any other specific disease entity. Whether these atypical cases represent true CLL or a distinct subtype of CLPD with CLL like features remains to be determined. Indeed, as suggested by others, these cases may in the future correspond speculatively to a new disease entity warranting further investigation.

ANTICIPATION IN FAMILIAL HEMATOLOGICAL MALIGNANCIES

F Autore, S Giammarco, P Chiusolo, S Sica, L Laurenti, F Sorà, E Metafuni, B Vannata, MT Voso, F D'Alò, V De Stefano, G Leone
UCSC Policlinico Gemelli Ematologia, Roma, Italy

Background. The anticipation is the phenomenon in which a disease is diagnosed at an earlier age as it is passed on to the next generation. Whereas there are a lot of studies about it on solid neoplasms, there is not a good knowledge of it in the hematological field. *Aims*. Our purpose was to evaluate the anticipation in our experience. *Methods*. We observed thirty-four families with at least two members who presented a hematological malignancy diagnosed from 1950 to 2010. The male-to-female ratio was 42:33; they were affected by Non-Hodgkin's Lymphoma (25 pts), Chronic Lymphocytic Leukemia (11 pts), Hodgkin's Lymphoma (8 pts), Acute Myeloid Leukemia (8 pts), Chronic Myeloid Leukemia (4 pts), Myeloproliferative Neoplasms (4 pts), Multiple Myeloma (4 pts), Acute Lymphoid Leukemia (2 pts), Waldenstrom's Macroglobulinemia (1 pt) and Acute Leukemia non otherwise specified (8 pts). At this time 30 patients are dead. Two or three different generations are involved in twenty-two families including forty-nine patients. We have restricted our analysis to two generations because of the small number of cases in the previous ones. Then we studied fourteen families in which two or more

members are affected by hematologic malignancies (HMs) among the same generation. Anticipation is assessed with a logrank test for trend using GraphPad Prism software version 5.0. Results. The median age at diagnosis for patients of the first generation was 58 years (range 9-82 years) whereas the median age at diagnosis for patients of the second one was 30.5 years (range 3-61 years).

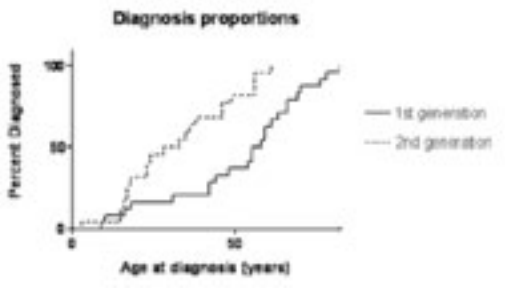

Figure 1. Age at diagnosis by generation.

We demonstrated the phenomenon of anticipation between the second and the first generation with an important and significant difference of 28.5 years (p=0.0003) (Image). The analysis on patients of the same generation showed that the median age at diagnosis for first-borns was 61 years (range 23-75 years) and for the second-borns was 53 years (range 17-68 years), with a difference of 8.0 years, which was not statistically significant (p=0.249). *Conclusions*. It is clearly recognized in the literature that there is a genetic basis for familial risk of HMs; however the causative mutation has not been identified. Future studies on these families should help to clarify genetic pathways underlying familial HMs.

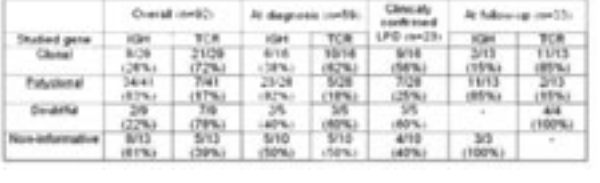
USEFULNESS OF IGH/TCR CLONALITY PCR STUDIES IN LYMPHOPROLIFERATIVE DISORDERS WITH DOUBTFUL CLONALITY BY FLOW CYTOMETRY

J Ribera,[1] L Zamora,[2] I Rodríguez,[2] J Juncà,[2] S Marcé,[2] M Cabezón,[2] D Dominguez,[2] C Soriano,[2] A Barberà,[2] L San Miguel,[2] I Granada,[2] N Ruiz-Xivillé,[2] M Xandri,[2] E Feliu,[2] J Ribera,[2] F Millá[2]

[1]*Fundació Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Spain*

[2]*Hospital Germans Trias i Pujol - ICO Badalona, Badalona, Spain*

Background. The kappa/lambda index in flow cytometry (FCM) is used to check clonality in B-cell diseases. A clonal result is considered when this index is >3 or <0.5. However, in borderline results it is difficult to assess the clonality. For T-cell clonality assessment the qualitative status of CD expression (crosslineage or asyncronous expression) and/or the quantitative status (absolute number of T cells or CD4/CD8 ratio) is used in FCM. *Aims.* To assess the clonality by PCR in patients with lymphoproliferative disorders with doubtful clonality by FCM. Samples DNA was extracted from 92 samples of peripheral blood, bone marrow, lymph node aspirates or biologic fluids from patients with suspicion of lymphoproliferative disorders in whom the clonality assessment by FCM was doubtful.



Three different regions of the IGH VDJ segment and two regions of the TCRg VDJ segment were amplified by PCR using a commercial kit (Invivoscribe Technologies, San Diego, USA) and analysed by Genescan. A study was considered polyclonal when a Gaussian distribution of transcripts was obtained and clonal when the area of the highest peak was three times bigger than the area of the third highest peak. A doubtful result was a peak 2-3 times higher than the polyclonal population without reaching the limit of clonality. A non-informative result was considered when no IGH or TCRg amplification was demonstrated but the specimen controls were correct. *Results*. Table 1 shows the frequency of informative and non-informative PCR results, as well as the correlation with clinical diagnosis for samples evaluated at diagnosis. *Summary*. PCR was informative in 76% of samples from patients with lymphoproliferative disorders with doubtful clonality by FCM, of whom 32% were clonal. Hematological neoplasm was confirmed in 56% of clonal disorders assessed by PCR at diagnosis.

MULTIPLEX LIGATION-DEPENDANT PROBE AMPLIFICATION (MLPA) A SENSITIVE TECHNIQUE FOR THE DETECTION OF TP53 DELETIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA?

H Robinson, J Forster, A Gardiner, A Parker, D Oscier

Royal Bournemouth Hospital, Bournemouth, K

Background. Detection of a deletion of TP53 on chromosome 17p13 influences choice of treatment in previously untreated or relapsed patients with CLL. Fluorescence in-situ hybridisation (FISH) is widely accepted as the *gold standard* for detection of TP53 loss however the technique is both costly and labour intensive. Multiplex Ligation-dependent Probe Amplification (MLPA), a molecular technique able to simultaneously detect copy number aberrations (CNA) of multiple loci in a single PCR reaction, has been reported as a non-subjective, accurate, cost- effective and high-throughput alternative technique for the detection of CNA in CLL. However, whilst published correlations between FISH and MLPA in CLL are promising, the number of reported cases with deletions of TP53 are too few to reliably asses the efficacy of this technique in the detection of this important gene deletion. Aims. The aim of this study was to investigate the specificity and sensitivity of MLPA for detecting known deletions of TP53 in CLL. Methods MLPA analysis was performed on peripheral blood mononuclear cell DNA using two commercial kits (P037 and P038, MRC Holland) designed to detect recurrent CNA in CLL. Each kit contains four different probes targeting TP53. The normal range for each individual MLPA probe was established from 36 normal control samples and the mean ±2SD was used to determine the cut off limits for gain or loss. Blinded analysis was performed with one or both kits on a total of 64 CLL samples previously screened by FISH with Vysis/Abott LSI TP53/CEP 17 probes. Of the 64 samples, 44 had TP53 deletion in 5-96% (median=76 %) of cells and 20 had no detectable TP53 deletion by FISH. Samples were categorised as TP53 deleted by MPLA when ≥2/4 of the TP53 probes in a single kit, or ≥3/8 TP53 probes across the two kits, were below their defined cut off limit. *Results*. The sensitivity of MPLA for correct identification of samples showing TP53 deletion by FISH was 90% (37/41, 95ci=79-97%), 76% (28/37, 95ci=61-87%) and 88% (29/33, 95ci=74-96%) for the P037 kit, the P038 kit and combined kits, respectively. The P037, P038 and combined kits all showed 100% specificity (20/20, 95ci=87-100%) for correct identification of samples without TP53 deletion by FISH. All four samples with TP53 deletion detectable by FISH but not by the P037 kit alone, or in combination with the P038 kit, had deletion in ≤ 14% of cells. Looking across the control sample data, the standard deviations for probes from the P038 kit were significantly higher than those from the P037 kit (p=0.01), leading to a wider normal range, possibly accounting for the lower sensitivity of the P038 kit. *Conclusions*. TP53 deletions in CLL samples can be reliably detected by MPLA using the combined data from the P037 and P038 MPLA kits provided deletion is present in approximately 20% or more of the tumour cells. This is close to the clinically relevant clone size as determined by FISH and as such MPLA shows potential for adoption in a routine setting subject to further validation.

Background. Leukemia is a heterogeneous genetic disease and a neoplasm involving many fusion oncogenes(1). These fusion oncogenes and their splice variants, resulted due to genetic abnormalities like translocations, deletions, are helpful in differential diagnosis and prognostic stratification as are directly involved in Leukemogenesis(2). As environmental factors coupled with natural genetic variations drive the genetic abnormalities and hence the fusion oncogenes, frequencies of fusion oncogenes and their splice variants can vary in different geographical regions and ethnic groups. Therefore, studying frequencies of different chromosomal abnormalities leading to fusion oncogenes in a given population and their clinical application can have a significant impact on management of Leukemia in terms of differential diagnosis, prognosis and treatment. Aims: The objective of this study was to find out the frequencies of various splice variants of different fusion oncogenes in Pakistani Leukemia patients (Group A), their comparison with western populations (Group B, taken from published literature) and to see how this data can be implicated in an oncology clinic to better diagnose, prognose and treat leukemia . *Methods*. Bone marrow samples were collected from 501 Leukemia patients. RNA was extracted by TriZol method(3). A very RT-PCR was used to study the different splice variants of the most common fusion oncogenes of prognostic and differential significance (3). Interphase-FISH was employed to confirm the results of RT-PCR wherever necessary(4). Results: No significant differences between Group A and Group B terms of frequencies of CBFB-MYH11 (inv 16 / t 16;16), AML1-ETO (t 8;21) in AML and PML-PARα (t 15;17) in APL/AML M3 while significant difference was found between two group in case of CML BCR-ABL splice variants b2a2 and b3a2 (Table 1, p=0.01). In ALL patients, significant differences were found between Pakistani and western populations with respect to frequencies of SIL-TAL1 (del 1),TEL-AML1 (t 12;21) oncogenes in adult ALL, BCR-ABL (t 22;9), E2A-PBX1 (t 1;19), TEL-AML1 (t 12;21), MLL-AF4 (t 4;11) in paediatric ALL (Table 1, Figure 1-3, p=0.01). This shows that cumulative frequencies of fusion oncogenes related with poor prognosis (BCR-ABL (t 22;9), SIL-TAL1 (del 1), E2A-PBX1 (t 1;19), MLL-AF4 (t 4;11) are higher in Pakistani pediatric ALL patients than western counterparts (74.2% vs 27%, p=0.01) while reverse is the case of TEL-AML (16.5% vs 25%, p=0.01) associated with good prognosis (Table 1). Conclusions and Discussion: Our data shows significant difference between Leukemia patients from Pakistan and western populations in terms of splice variants of different fusion oncogene frequencies, which is in accordance with other reports(5,6) which may be related to ethnicity. These results explain the molecular genetic basis of already-reported poor prognosis and survival of paediatric ALL and adult AML patients in Pakistan(7). Our studies have implications in clinical management of Leukemia at healthcare policy-making bodies and clinical centers.

Figure 1. Frequency of Leukemic oncogene splice variants.

RARE CYTOGENETIC FEATURES IN ACUTE PROMYELOCYTIC LEUKEMIA

S Salamanczuk,[1] S Merk,[1] D Marelli,[1] M Bernimoulin,[2] A Casini,[2] Y Chalandon[2]
[1]*Centre Medical Universitaire, Geneva, Switzerland*
[2]*Division of Hematology HUG, Geneva, Switzerland*

Acute promyelocytic leukemia (APL) is strongly associated with t(15;17)(q22;q12~q21) giving rise to the formation of two functional fusion genes, PML/RARA on the derivative chromosome 15 and RARA-PML on the derivative chromosome 17. A small group of patients with APL appears to have a submicroscopic insertion of the RARA gene into chromosome 15 or microscopically visible rearranged rearrengent of derivative 17.The prognostic significance of these genetic abnormalities is still under discussion. Among 13 newly diagnosed acute myeloid leukemia patients in 2010, 3 (23%) were classified as an acute promyelocytic leukemia with t(15;17) according to the WHO 2008 criterias. Typical t(15;17) was recognised by classical cytogenetic analysis in one case (case1, F/61y.o). Hematologic workup showed t-AML after previously treated breast cancer with PML-RARa fusion gene transcripts, FLT3 ITD and WT1 mutation. She was in minimal residual disease after 1th induction chemotherapy with cytarabin, idarubicin and ATRA. In the second patient (case2, M/27y.o), chromosome analysis showed a banding pattern compatible with an insertion (17;15) or "two way transloca-

tion" between derivative 17 and derivative 15. Interpretation was clarified by FISH using the PML/RARA Dual Fusion Translocation probe (Vysis) and whole chromosome paint (wcp) 15 and 17 probes, which demonstrated of two fusions and both paints on the abnormale chromosome 17 and no wcp 17 on either of two chromosomes 15. The findings of the microscopically visible der(17)t(15;17) (q24;q21) ins(17;15) (q21;q24) represents a new cytogenetic variants in APL. The patient was included in APL 2006 protocol and achieved a complete molecular remission after induction chemotherapy with cytarabin, idarubicin and ATRA. Cytogenetic analysis of the third patient (case 3, M/23 y.o) studied at diagnosis revealed der(15)(15;17)(q22;q21), ider(17)(q10)t(15;17) (q22;q21). Ider (17) originated from the duplication of the long arm of der(17) with an additional copy of RARA-PML, and resulted in a loss of the whole short arm of chromosome 17 (P53 on 17p13.3). The patient was also included in APL 2006 protocol and achieved a complete molecular remission after induction chemotherapy. Due to the rarity of the abnormalities described above, it is not known if there is any impact on the prognosis after induction chemotherapy based on ATRA, at least we found an excellent response to ATRA-based induction treatment and there is a need for longer follow up and more patients to evaluate better the impact of those additional abnormalities in APL.

1535

MUTATIONS IN IDH1/2 GENES IN ACUTE MYELOID LEUKEMIA WITH NORMAL KARYOTYPE: A SINGLE CENTRE STUDY OF 72 CASES

B Katrincsakova,[1] T Szotkowski,[1] J Muzik,[2] V Smutna,[1] M Divoka,[1] K Sicova,[1] M Holzerova,[1] J Hubacek,[1] M Jarosova,[1] K Indrak[1]
[1]*University Hospital Olomouc, Olomouc, Czech Republic*
[2]*Institute for Biostatistics and Analyses of Fac. of Medicine Masaryk University, Brno, Czech Republic*

Background. Normal karyotype acute myeloid leukemia (NK-AML) comprises a clinically and biologically heterogeneous group of AMLs accounting approximately for 45% of all cases. A number of molecular changes including mutations in FMS-like tyrosine kinase 3 (FLT3), nucleophosmin (NPM1) and CCAAT/enhancer binding protein alpha (CEBPA) genes provide either alone or in combination prognostic information particularly in NK-AML. Recently mutations in genes for the isocitrate dehydrogenase 1 and 2 (IDH1/2) have been reported recurrently in AML. The prognostic impact of these mutations still remains to be determined however their potential as candidate markers for monitoring minimal residual disease is of special interest in NK-AML. Aims: In this study we investigated the prevalence of IDH1/2 mutations in a cohort of NK-AMLs. We aimed to correlate IDH1/2 mutation status with clinical features, prognostic impact and additional recurrent mutations in AML occurring in FLT3, NPM1, CEBPA, Wilms tumor 1 (WT1) and Mixed-Lineage Leukemia (MLL) genes. Methods: A total of 72 patients diagnosed and treated in a period of 1997 - 2009 as de novo NK-AML (age 22 - 72) were assessed in this retrospective study. All patients were treated within a single centre trial. First-line treatment consisted of double induction and intensive consolidation therapy with high dose cytarabine, autologous or allogeneic stem cell transplantation. Diagnostic leukemic blasts were analyzed for mutations in IDH1/2, FLT3, NPM1, CEBPA, WT1 and MLL genes using fragment analysis and/or direct sequencing. An allele specific polymerase chain reaction assay with a sensitivity of ~1% was introduced to detect IDH1 R132H mutation in post-treatment samples. Results: Overall 28% (20/72) of patients were found to carry heterozygous IDH1/2 mutation with IDH1 mutations detected in 7 patients (10%, R132H only) and IDH2 mutations in 13 patients (18%; 12 cases with R140Q and 1 case with R172K). We revealed 9 patients (13%) with a synonomous (GGC/GGT) IDH1 single nucleotide polymorphism rs11554137. Additionally one patient presented with so far not identified T106M (ACG/ATG) IDH1 sequence variant. In our cohort IDH1 and IDH2 mutations were mutually exclusive. Both IDH gene mutations tended to coexist with NPM1 (11/20) and/or FLT3 (8/20) mutations. However in only 2 cases we found IDH2 R140Q mutation accompanied with concurrent mutation in CEBPA or MLL genes respectively. IDH1/2 mutation status did not correlate significantly with clinical characteristics of patients regarding age, sex, leukocyte count, bone marrow or peripheral blood blast counts. The differences were not statistically significant when comparing overall and disease-free survival between the IDH1/2 mutated and wild-type groups. *Summary/Conclusions*. Our data provide evidence about recurring IDH1/2 mutations that are mutually exclusive in our cohort of NK-AML and tend to overlap with prognostic mutations such as FLT3 and/or NPM1. Further evaluation of IDH1/2 mutations in post-treatment samples is in process and will determine the usefulness of these mutations in monitoring minimal residual disease in AML.

Funding. Supported by MSM 6198959205 and LF-2011-006.

TIROFIBAN VS ABCIXIMAB: IS TIROFIBAN UNDERDOSED?

W Janse van Rensburg,[1] J Roodt,[2] S Lamprecht,[1] M Meiring,[2] P Badenhorst[1]
[1]*University of the Free State, Bloemfontein, South Africa*
[2]*National Health Laboratory Service, Bloemfontein, South Africa*

Background. Tirofiban is a very promising anti-platelet drug, but has shown to lack the efficacy of abciximab in preventing ischaemic events, possibly due to underdosing. *Aims*. The aim of this study was to determine the efficacy and bleeding effect of escalating doses of tirofiban in comparison with abciximab in baboons. *Methods*. The femoral artery of baboons was shunted to the femoral vein. The artery was mechanically injured and external stenosis was applied. This resulted in thrombus formation measured by decreased blood flow. Thrombi were mechanically dislodged resulting in a pattern of cyclic flow reductions (CFRs). Escalating doses of tirofiban (n=5) and abciximab (n=4) were administered and the effect of this treatment on the CFRs was measured. Bleeding was assessed in an incision and a template bleeding model. Results: Tirofiban completely inhibited arterial thrombus formation after injection of 90 µg/kg (+ 1.35 µg/kg/min infusion). This dose is 9 times higher than the manufacturers recommended therapeutic dose (10 µg/kg bolus + 0.15 µg/kg/min infusion) for an adult human during angioplasty, and more than 3 times higher than the adjusted higher dose recommended (25 µg/kg bolus + 0.15 µg/kg/min infusion). However, in ex vivo platelet function tests, full platelet inhibition was observed at the therapeutic dose. Abciximab completely inhibited arterial thrombus formation after injection of 250 µg/kg (therapeutic dose for adults is a 250 µg/kg bolus + 0.125 µg/kg/min infusion). The maximum mean blood loss in the incision bleeding model was only a 3.4 fold increase from the saline phase in the tirofiban group at 27 times the therapeutic dose, compared with the 18.7 fold increase seen with abciximab at its effective dose (250 µg/kg). Conclusion: Tirofiban is a safe and effective antiplatelet drug in baboons, but is only effective at a dose 9 times higher than the recommended therapeutic dose for adult humans. It compares favourably to abciximab, but with less bleeding. We recommend that further in vivo testing should be done to determine the optimal therapeutic dose of tirofiban.

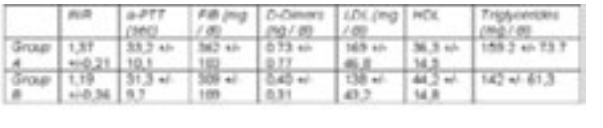
EFFECT OF THE ANTIPSYCHOTIC DRUGS ON BLOOD CLOTTING

S Patiakas,[1] K Rousos,[2] F Girtovitis,[3] C Charalampous[4]
[1]*General Hospital of Kastoria, Thessaloniki, Greece*
[2]*General Hospital of Veria-Health Center of Alexandria, Veria, Greece*
[3]*Universal General Hospital of Thessaloniki AXEPA, Thessaloniki, Greece*
[4]*Pathological Clinic of Psychiatric Hospital of Thessaloniki, Thessaloniki, Greece*

Background-Aim. A comparative study of cardiovascular risk factors such as lipid profile and blood clotting in psychiatric patients, as some antipsychotics (clozapine, olanzapine) are associated with sedation and weight gain, but causes increased growth adhesion and platelet aggregation. Material - Methods: We studied 46 patients on antipsychotic medication (31 men and 15 women) mean age 52.7 years (group A). In all we checked the coagulation system (prothrombin time, partial thromboplastin time, fibrinogen and D-dimer), as well as the lipid profile, and results were compared with those 50 people (32 men and 18 women) a random sample of the general healthy population similar age (mean 54.3 years) and was the control group (group B). *Results*. These are summarized in the table below. *Summary-Conclusions*. 1) It turns out therefore that although the prothrombin time and partial thromboplastin do not appear differentiated between the two groups, however, fibrinogen levels, particularly levels of d-dimer in psychiatric patients is particularly high in relation to general population, showing a statistically significant difference (p <0,05). 2) Also, regarding the lipid profile we recorded significant charges in the group of psychiatric patients compared with controls, the result of suppression of weight gain and worst-often neglected maintenance.



From the above, especially if one account and other predisposing factors (eg smoking in psychiatric patients who touches the vast majority

- 41 of 46 patients in our study) indicate that the cardiovascular risk in this category of patients is much higher than the general population, which should be not noticed our attention.

1538

LOW RESPONSIVENESS TO ASPIRIN AND CLOPIDOGREL IN PATIENTS FROM GRAN CANARIA (SPAIN) - INCIDENCE AND INFLUENCE FACTORS

J Ruano,[1] J Díaz-Cremades,[1] S Soler,[1] A Calatzis,[2]
V González-Campos,[3] S Guedes,[1] M Marrero,[1] M Tapia,[1]
F Fernández-Fuertes[1]

[2]*Department of Transfusion Medicine and Haemostaseology, University of Munich, Munich, Germany*
[3]*IZASA, SA. Coagulación - Grupo Laboratorio, Barcelona, Spain*

Background. Platelets are the key mediatiors in the pathophysiology of the atherothrombotic disease. Platelet function tests have been used to monitor patients response to antiplatelet therapy. Several studies suggest that low responsiveness to antiplatelet therapy, as measured in various function tests, correlates with high rates of incidences of ischemic events. One widely used method for platelet function analysis is multiple electrode aggregometry. So far most data with MEA have been established in the middle-european population. No data is so far available in west mediterranean population. *Methods*. 226 individuals were tested following informed consent and IRB approval. Hirudin blood was drawn (Dynabyte, Munich, Germany) and analyzed within 3 hours. 51 individuals were treated with aspirin (100 mg/d) alone, 27 with clopidogrel (75 mg/d) alone and 79 with a combination of aspirin and clopidogrel. In addition 69 blood donors were analyzed as a control group. MEA was measured as previously reported using the agonists ADP (ADPtest, 6.4 µM), arachidonic acid (ASPItest, 0.5 mM) and TRAP-6 (thrombin receptor activating peptide, TRAPtest, 32 µM). Results. Based on the results of the healthy volunteers a normal range was defined based on the 90% central interval, i.e. the range of values between the 5° and 95° percentile. These values are close but not identical to the normal ranges provided by the manufacturer of the Multiplate instrument. Differences may be due to differences between the groups used for the determination of the reference ranges (gender, age, genetic background, nutrition). Patients on aspirin or aspirin and clopidogrel showed a significantly reduced aggregation in ASPItest compared to the blood donors (Mann-Whitney U-test, $p < 0.05$). 11.7 % of patients treated by aspirin only had an aggregation of > 30 U, which is used by several authors as the cut-off for a full cyclooxygenase blockade. Only 1 patient (2%) of the aspirin-only group had an aggregation in the reference range for ASPItest. In the aspirin + clopidogrel group 6.4% of patients had an aggregation > 30 U. Patients treated with clopidogrel showed a significantly lower aggregation compared to the blood donors (Mann-Whitney U-test, $p<0.05$). However 37% of all clopidogrel-treated patients had an aggregation > 47U which was defined as a cut-off for increased risk for stent thrombosis and other ischemic events by Sibbing et al. Patients treated by clopidogrel alone had a low response rate of 44%, while patients treated by clopidogrel and aspirin in combination showed a low response to clopidogrel in 35% of the cases. Aspirin alone does not influence the TRAPtest, while clopidogrel has a weaker, but significant effect on the TRAPtest. *Conclusions*. Reference ranges have been established in Canary Island populations. Much less low response to aspirin than clopidogrel has been found. 8,6% of the aspirin-treated patients showed a low response to aspirin treatment. 37% of clopidogrel-treated patients had a low response to clopidogrel. No additive effect of aspirin on top of clopidogrel in respect to ADP induced aggregation. Higher ADP induced aggregation in aspirin-treated patients compared to blood donors.

ACTIVATION OF CASPASE-3 AND -9 AND DOWN-REGULATION OF SURVIVIN PROTEIN AS A MECHANISM OF APOPTOTIC DEATH IN K562 LEUKEMIA CELLS UPON EXPOSURE TO A DERIVATIVE FROM 4-ARYL-4H-CHROMENES FAMILY

M Mahdavi,[1] A Foroumadi,[2] M Zali,[3] J Davoodi[1]
[1]*Institute of Biochemistry and Biophysics (IBB), Tehran, Iran*
[2]*Department of Medicinal Chemistry, Faculty of Pharmacy & Pharmaceutical Sciences, Tehran, Iran*
[3]*The Research Center for Gastroenterology and Liver Diseases, Shahid Beheshti Uni, Tehran, Iran*

It has been recently reported the activity of 4-aryl-4H-chromenes family, to induce apoptosis in human cancer cells. Herein we report a derivative of 4-aryl-4H-chromene compound with higher apoptotic activity against Erythroleukemia K562. The cells were seeded in 24-well plates at 1×105 cells/well and treated with 50-80 nM of the 2-amino-4-(3-nitro phenyl)-3-cyano-7-(dimethylamino)-4Hchromene (3-NC). This compound was found to be highly active growth inhibitor with IC50 of 65±3.5 nM as determined by MTT assay. Proliferation of K562 cells was diminished by more than 70% and viability was decreased by about 50% upon 72 h of treatment with 50-80 nM concentration of the compound. Apoptosis as the mechanism of cell death was investigated morphologically by Hoechst 33258 staining, caspase-3 activation assay, as well as the formation of DNA ladder. K562 cells underwent apoptosis upon a single dose (at IC50 value) of the compound and also increased caspase-3 activity by more than 2-fold following 72 h treatment. Caspase-9 was also activated which could be detected 48 hours post-treatment. Furthermore, Western blot analysis revealed that the treatment with the compound down-regulated the expression of certain IAP protein including survivin. . Considering the negative effects of survivin on caspase activity, one can propose that the treatment of cells with 2-amino-4-(3-nitro phenyl)-3-cyano-7-(dimethylamino)-4Hchromene leads to degradation of survivin protein unleashing caspase activity and causing apoptotic cell death. Given the fact that survivin confer resistance to certain cancer cells and considering apoptotic cell death of cancer cells due to activation of caspases upon degradation of survivin, one can propose the down regulation of survivin as an effective approach for cancer therapy under conditions in which these proteins confer resistance to cancer therapy. These data further suggest that 2-amino-4-(3-nitro phenyl)-3-cyano-7-(dimethylamino)-4Hchromene may provide a novel therapeutic approach for the treatment of leukemia.

THE ROLES OF MACROMOLECULES IN IMATINIB RESISTANCE IN CHRONIC MYELOID LEUKEMIA

Y Baran,[1] A Camgoz,[1] C Ceylan[2]
[1]*Izmir Institute of Technology, Izmir, Turkey*
[2]*Izmir Institute of Technology, Department of Food Engineering, Izmir, Turkey*

Background. Imatinib is the first anticancer agent targeting BCR/ABL oncogene for the treatment of chronic myeloid leukemia. In the beginning of imatinib treatment very promising outcomes were observed in chronic myeloid leukemia patients. But resistance to imatinib is the main drawback for imatinib treatment. Fourier transform infrared spectroscopy (FTIR) is a sensitive, rapid and nondestructive method that can show changes in macromolecules. FTIR can be widely used in the analysis of various biological systems in any physical state requiring only minute amounts of samples. The method can be used to obtain valuable metabolic and structural information of the cellular components such as lipids, proteins, carbohydrates and nucleic acids in the level of functional groups in the progress of differentiation processes such as disease progression. Aims. In the present work we examined the changes in macromolecules in imatinib resistant K562 cells at the molecular level using Fourier transform infrared (FT-IR) spectroscopy. Methods. Human K562 CML cells were exposed to step-wise increasing concentrations of imatinib and 3 µM imatinib resistant K562 cells were generated and named as K562/IMA-3 cells. Antiproliferative effects of imatinib were determined by XTT cell proliferation assay. Changes in macromolecules in parental and resistant cells were studied by FT-IR spectroscopy. Results. K562/IMA-3 cells were shown to be more than 50-times more resistant to imatinib as compared to K562 cells. Imatinib resistance caused significant changes which mainly indicated that the membrane/lipid order increased, lipid peroxidation end products increased, the lipid-to-protein ratio increased and, the transcriptional status increased, structural and organizational changes in the nuclear morphology and changes in the proteome revealed by the FT-IR spectra. In addition, changes in the proteome and structural changes in both proteins and nucleus were observed in the K562/IMA-3 cells. Summary/Conclusions. The results indicate that raising imatinib resitance caused significant structural and organizational changes in the K562 cells. Similarly drug resistance related macromolecular changes in leukemia and other cancer types can be analyzed using FT-IR technique.

METHYLENETETRAHYDROFOLATE REDUCTASE (MTHFR) POLYMORPHISMS IN PATIENTS TREATED WITH INTERMEDIATE-HIGH DOSE OF METHOTREXATE (MTX)

R Porrini,[1] A Ferrari,[1] G Antolino,[1] B Veggia,[1] E Conte,[1]
S Tomassini,[1] E Montefusco,[1] MC Cox,[1] V Naso,[1] M SImmaco,[2]
B Monarca[1]
[1]*Ospedale Sant'Andrea, Roma, Italy*
[2]*Diagnostica Molecolare Avanzata, Roma, Italy*

Background. Association with MTHFR polymorphisms and toxicity or outcome of disease was investigated in haematological patients treated with methotrexate, with no univocal results. Methods and Aims:We retrospectively studied 22 patients (14 M / 8 F), mediane age 40 years , (range 27-63), affected by Non Hodgkin lymphoma (3 Mantle cells, 9 burkitt, 6 DLBC with 5 CNS localization, 1 anaplastic T cells, and 1 Acute Lymphoblastic Leukemia, submitted to different chemotherapeutic regimens, all containing intermediate high dose of MTX for a total of 61 courses. We divided patients in two groups:group A submitted to intermediate dose of MTX (1-2 gr/m2); group B with high dose of MTX (3-5gr/m2). We considered in particulary hepatic toxicity and incidence of mucositis, in association with delayed elimination of MTX. All patients were tested for MTHFR polymorphisms C677T and A1289C. *Results*. Group A: 9 patients, for a total of 25 courses. In 6/25 courses (24%), we have a delay in MTX elimination (>72h); hepatic toxicity of grade II-III were recorded in 7/25 (28%), mucositis in 16/25 (64%), 12 of grade I, 3 of grade II, 1 of grade III. Two patients showed a very high delay in MTX elimination (>120 hours), with mucositis of grade II without hepatic toxicity. Among 9 patients, 7 were mutated for C677T (5 heterozygosis, 2 homozygosis) and 2 were not mutated for both polymorphisms. The two patients with higher toxicity were not mutated. Group B: 14 patients, for a total of 36 courses. A delay of MTX elimination was seen in 20/36 (55%), hepatic toxicity in 18/36 (50%), 2 of grade III, 7 of grade II, 9 of grade I, mucositis in 21/36 (59%), 11 of grade I, 7 of grade II, 3 of grade III. In 9 out of 20 delayed MTX courses we recorded a very high delay (>120h) with hepatic toxicity in 6/9 and mucositis in 9/9 courses. Among these 14 patients, 3 showed C677T heterozygosis, 2 C677T homozygosis, 3 showed A1289C homozygosis and 6 showed both mutations in heterozygosis. In 12 out of 14 patients grade III-IV of haematological toxicity was seen: among these 12 patients, 8 were treated with an association with ARA-C, 3 were treated with polichemotherapy, while one patient received only MTX. Conclusions:We were not able to find any correlation between toxicity and MTHFR polymorphisms in this subset of patients.

1542

HLA ALLELES AND HAPLOTIPES: IMPLICATIONS FOR HEMATOPOIETIC STEM CELL DONOR SELECTION

B Manzanares,[1] R Gonzalez,[1] C Martin,[1] M Frías,[1] F Casaño,[1]
L Castro,[1] A Torres,[2] J Pena[1]
[1]*Hospital Reina Sofía, Córdoba, Spain*
[2]*Hospital Reina Sofia, Cordoba, Spain*

Background. Despite expansion of unrelated donor pools to a current state of more 10 million registered donors worldwide, matching each HLA allele between unrelated donors and recipients remains a problem for many patients because of HLA polymorphism. Consideration of other related donor available is appropriate for any patient who is in need of an allogeneic hematopoietic cell transplant but has no matching sibling or an unrelated donor or cord blood transplant. Analysis of common alleles and haplotipes may help to predict the chance of getting a suitable donor, and it also suggests strategies for improving success in the search. *Aims*. Our objective is to establish what HLA alleles and haplotypes are most common in our area. These results can be used to help to delineate search strategies for potential donors: related or unrelated *Subjects and methods*. The study includes 200 families residing in Andalusia, Spain. Informed consent was obtained in all cases. They were HLA-A*, B*, C* y DRB1* typed by high-resolution (Dynal RELITM SSO typing Kit, Dynal Biotech ASA, Oslo and Inno-Lipa HLA, Innogenetics N.V. Ghent, Belgium). Results. Only 35 HLA-A*, 55 HLA-B*, 23 HLA-C* and 39 HLA-DRB1 alleles were found. These alleles have been previously described in Caucasians as expected from the geographic origin of the studied families. The distribution of predominant alleles studied herein reveals great similarities with those in Spain, Western European and North American populations. In the analysis of haplotypes, their frequencies in the studied population were stimated by counting the number of any given haplotype among the total number of haplotypes. A high number were included within the most frequent haplotypes described in Spain. However, the results reveal that the ten most frequent haplotypes in our population were not the same as in other populations *Summary*. The data we present here on common alleles and haplotypes may help to predict the chance of getting a suitable related donor, and it also suggests strategies for improving success in the search

1543

PHARMACOGENETICS OF COUMARINS DOSING : PREVALENCE OF CYP2C9 AND VKORC1 POLYMORPHISMS IN THE LEBANESE POPULATION

I Djaffar Jureidini, N Chamseddine, S Keleshian, R Naoufal, L Zahed, N Hakime
St George Hospital University Medical Center, Beirut, Lebanon

Background : Polymorphisms in the genes encoding the cytochrome P450 2C9 enzyme (CYP2C9) and the Vitamin K Epoxide Reductase (VKORC1) are known to contribute to variability in sensitivity to coumarins. Patients with certain common genetic variants of CYP2C9 (*2 & *3) or a VKORC1 polymorphism (- 1639A Allele) require a lower dose of coumarin and are also at higher risk for over-anticoagulation and serious bleeding. In August 2007, the FDA label for warfarin was updated to highlight the benefit of genetic testing to predict warfarin response. Aims : Since the prevalence of these variants in the Lebanese population has not yet been reported, our aim was to determine the genotypes of CYP2C9 and VKORC1 in our population and to compare allele frequencies with previous findings from other ethnic groups. Methods : CYP2C9 (*1/*2/*3) and VKORC1 (*A/*G) allelic variants were assessed by Polymerase Chain Reaction-Restriction Length Polymorphism (PCR-RFLP) assays in a diversified sample of 161 unrelated healthy Lebanese volunteers. Results : The allele frequencies of CYP2C9 *2 and *3 were 0.112 and 0.096 respectively, whereas VKORC1 -1639A was 0.528. Carriers of the CYP2C9 *2 or *3 represented 34.2% of the subjects, while those of the VKORC1 -1639A represented 73.9%. Conclusion : Our data show no significant difference in the frequency of CYP2C9 allelic variants when compared to the Caucasian population, whereas the allelic frequency of VKORC1 - 1639A was very high. Over 50% of the Lebanese population seem to be carrying more than two independent "risk"alleles, and is therefore potentially at high risk of over-anticoagulation.

1544

LIPOPROTEIN PROFILE IN IRON DEFICIENCY ANEMIA

C Kanonidou,[1] M Pape,[2] S Arampatzi,[1] A Nikolaidou,[1]
M Karamouzis,[2] E Diza[1]
[1]*Hematology Laboratory, Department of Clinical Microbiology, AHEPA University Hos, Thessaloniki, Greece*
[2]*Laboratory of Biochemistry, AHEPA University Hospital, Thessaloniki, Greece*

Background. The relationship between iron metabolism and atherosclerosis is under investigation. Previous studies in subjects with iron deficiency anemia (IDA) have shown affected activity of antioxidant enzymes and higher concentrations of markers of oxidative stress. Aims: The aim of the study was to investigate the lipoprotein profile of IDA patients. *Methods*. A total of 20 patients (males/females: 7/13, mean age 41±15 years) with IDA were retrospectively examined. They were eligible for participation if they met the following criteria: Hb<12gr/dl, MCV<80fL, RDW-CV>15%, serum ferrum <37 μg/L, serum ferritin <15μg/L. 20 age and sex-matched healthy subjects were also included in the study as the control group. Patients with endocrine, hepatic, renal diseases and under hypolipidemic medication were excluded. Serum iron parameters (ferrum, ferritin) were determined by electrochemiluminescence immunoassay, lipid parameters [total cholesterol (TC), high density lipoprotein (HDL), triglycerides (TG)] with enzymatic colorimetric test (Elecsys Modular E170, ROCHE) and hematological indices [hemoglobin (Hb), hematocrit (Ht), mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC)] by cytometry method (XE-5000 SYSMEX, ROCHE). Student's t test and Pearson's correlation analysis were performed. Results: In patients with IDA, TG levels were found to be significantly elevated (101,30±53,07 vs 95,56±42,43 mg/dl, p<0,05) and HDL-C concentrations significantly lower (49,15±12,92 vs 56,62±8,19 mg/dl, p<0,05) when compared to controls. TG/HDL-C ratio, which is considered indicative of the predominance of small, dense LDL particles, was found higher in IDA subjects (2,17 vs 1,70, p<0,05). No significant

differences were observed in TC and LDL-C concentrations as well as in TC/HDL-C ratio between patients and controls. Ht and Hb values presented a significant inverse correlation with those of TG (r= -0,35, p=0,031 and r= -0,34, p=0,039 respectively) and a significant positive one with those of HDL-C (r=0,386, p=0,020 and r=0,420, p=0,011 respectively). *Summary/Conclusions*. The findings suggest that lipid profile disorders are observed when serum iron and ferritin levels are decreased. The effect of IDA and its degree on atherosclerosis should be further investigated.

1545

IN VITRO DETERMINATION OF APOPTOTIC EFFECT OF HEPARIN ON LYMPHOBLASTS BY USING FLOW CYTOMETRIC DNA ANALYSIS AND MEASUREMENTS OF CASPASE-9 ACTIVATION AND CYTOCHROME C LEVEL

E Erduran, O Deger, Y Tekelioglu, A Bahadir
Karadeniz Technical University, Trabzon, Turkey

Background: Heparin induces apoptosis on peripheral neutrophils, mononuclear cells of healthy subjects and on lymphoblasts of patients with acute lymphoblastic leukemia (ALL), in vitro. Aims: Caspase-9 activtity and cytochrome C level were studied to indicate the apoptotic effect of heparin on lymphoblasts by intrinsic pathway of apoptosis. Methods: Twenty bone marrow samples of the patients with ALL were included in the study. Cytochrome C level and caspase-9 activity were concomitantly determined with the percentage of apoptotic lymphoblasts when incubated in 0,10 and 20 U/ml heparin concentrations at 0,1 and 2 hours. Results: The percentages of apoptosis at first hour were higher than those at 0 and 2 hours in 10 and 20 U/ml heparin concentrations, separately ($p< 0.05$). The mean percentage of apoptosis in 20 U/ml heparin levels was significantly higher than those in 0 and 10 U/ml heparin levels at 1 and 2 hours ($p<0.05$). The highest apoptotic effect of heparin on lymphoblasts was determined at first hour in 20 U/ml heparin concentration. The mean caspase-9 activitity at first hour was significantly higher than those at 0 and 2 hours in 10 and 20 U/ml heparin levels, separately ($p<0.05$). The mean caspase-9 activity in 20 U/ml heparin concentration was significantly higher than those in 0 and 10 U/ml heparin concentrations at 1 and 2 hours ($p<0.05$). The highest caspase-9 activity was determined in 20 U/ml heparin levels at first hour. The mean Cytochrome C level at first hour was significantly higher than those at 0 and 2 hours in 10 and 20 U/ml heparin concentrations, separately ($p<0.05$). The highest cytochrome C level was determined in 20 U/ml heparin concentration at first hour. Conclusion: We claimed that heparin induces apoptosis on lymphoblasts by the activation of intrinsic pathway.

1546

META-ANALYSIS REGARDING SIMVASTATINUM TREATMENT IN MALIGNANT LYMPHOMA

RG Mihaila,[1] R Dancu[2]
[1]*Lucian Blaga University of Sibiu, Sibiu, Romania*
[2]*Emergency County Clinical Hospital, Sibiu, Romania*

Background: Simvastatinum (S) is a competitive inhibitor of 3-hydroxide-3-methylglutaryl CoA reductase, a cholesterol and some isopreonid products synthesis regulatory enzyme, like geranyl-geranyl pyrophosphate. Except the hypocholesterolemiant effect it also has anti-neoplastic pleiotropic properties. Aims: Our purpose was to study the existing literature arguments for the use of simvastatinum as an adjuvant therapy in malignant lymphoma. Methods: We analyzed the 10 existing studies in MEDLINE, in January 2011 regarding S therapy in lymphoma. Our study included: the types of lymphoma where it was use, therapeutic action, the results of the experimental studies and its experience in clinical study usage. Results: S was administrated in various lymphoma cells: a mouse model of Hodgkin's lymphoma (HL), Epstein-Barr virus (EBV)-driven lymphoma cells, Waldenstrom macroglobulinemia (WM) cells, adult T-cell leukemia cells (ATL), chronic lymphocytic leukemia (CLL) cells and in lymphoma patients. S induced caspase-related apoptosis via depletion of prenylation-substrates in several HL-cell lines. S induces apoptosis, G2/M cell cycle arrest, accumulation of p21(Waf1/Cip1), and effectively inhibits hyperproliferation of human Namalwa Burkitt lymphoma cells that display general apoptosis resistance and hyperproliferation. S inhibited cell growth, survival and IgM secretion on WM cells by inhibiting synthesis of geranylgeranyl pyrophosphate. S binds to the inserted domain of leukocyte function antigen 1 and inhibits its function, resulting in down-regulation of nuclear factor kappaB activity and induction of apoptosis of transformed B cells and EBV-transformed lymphoblastoid cell lines. S blocks the interaction of adhesion molecules that are important for cell-cell interactions including those between EBV-transformed B cells. S decreased Akt and extracellular signal-regulated kinase mitogen-activated protein kinase pathways. In ATL statins inhibited geranylgeranylation of small GTPases Rab5B and Rac1. In CLL cells S induced apoptosis concurrently with lowering of BCL-2/BAX ratio; its pro-apoptotic effect is tumor-specific, not affecting normal lymphocytes. Combinations of simvastatin + fludarabine and simvastatin + cladribine had a synergic effect in inducing apoptosis. In S lactone inhibited P-glycoprotein mediated rhodamine 123 transport in a murine monocytic leukaemia cell line that over-expresses the multi-drug resistance protein 1a/b. In vitro S induced apoptosis in a dose- and time-dependent way. In a mouse model for HL it effectively impaired tumor growth. It delayed development of EBV lymphomas and prolonged survival of animals. It induced inhibition of proliferation, had cytotoxic effect and produced apoptosis of WM cells. Furthermore, S enhanced the cytotoxicity induced by bortezomib, fludarabine and dexamethasone. Statins hinder the survival of ATL cells and induce apoptotic cell death. In combination with dexamethasone and doxorubicin, statins have a chemo-sensitizing effect and the patients with relapsed lymphoma can be treated with a dose-escalating regimen of simvastatin for 7 days followed by CHOP. High-dose simvastatin given immediately prior to chemotherapy was safe and tolerable up to a dose of 15 mg/kg/day. Summary: S inhibits geranylgeranylation - a critical process for the regulation of lymphoma tumor cell survival and proliferation. The pro-apoptotic effect of S is tumor-specific, not affecting normal lymphocytes. S has a chemo-sensitizing effect, useful in patients with relapsed lymphoma. By the P-glycoprotein inhibition it can reduce the multi-drug resistance.

1547

USING A NEW INTEGRATIVE APPROACH WITH SIXTEEN REFRACTORY CASES IN PEDIATRICS HEMATOLOGY/ ONCOLOGY AT KING ABDULAZIZ UNIVERSITY HOSPITAL IN SAUDIA

S Al Jaouni, E Elfiki, A Hussein
King Abdulaziz University Hospital, Jeddah, Saudi Arabia

Background. The goal of health care is to find the most effective and cost-effective approach to prevention, health promotion, and treatment of illness, considering the use of both conventional medicine and complementary and alternative medicine (CAM) therapies. Integrative oncology, the use of CAM in conjunction with standard medical treatment, seeks to improve the supportive care available to patients, while also determining through scientific clinical trials which adjuvant CAM therapies are medically sound, effective, and compatible with standard chemotherapy and radiation. Aims. To report the effectiveness and safety of a natural experimental agent used with conventional therapy in sixteen relapsed cases with different hematological malignancy who were refractory to conventional treatment. Methods. A phase I controlled clinical trial to use the Novel Experimental PM 701 combined with conventional chemotherapy in induction and maintenance phases in the treatment of refractory and relapsed cases in Pediatric Hematology/Oncology, in a period of 2005 to 2009, treated at King Abdulaziz University Hospital, Jeddah, Kingdom of Saudi Arabia. This natural agent has been fully studied with animal models and tissue cultures at the King Fahd Medical Research Center's laboratory at King Abdulaziz University and showed potent selective apoptosis of cancer cells, effective and safe in animal models. Results. All the sixteen cases showed complete remission through induction phase, by using the novel experimental PM 701 combined with conventional therapy. Fifteen cases alive ;with eleven patients off treatment. One patient with known case T-ALL died after a year refractory to the treatment; due to the shortage of supply of the experimental PM701 while in maintenance. Summary. We report in this phase I clinical trial a successful, effective, and safe management with the combination of conventional therapy with experimental medicine (PM 701) in the treatment of sixteen refractory and relapsed cases in Pediatric Hematology / Oncology. Complementary and alternative therapies need further control studies in the future to prove the efficacy and safety to be used on oncology patients.

APOPTOSIS INDUCTION MEDIATED BY HUMAN PARVOVIRUS B19 NON-STRUCTURAL PROTEIN (NS1) IN HUMAN ERYTHROLEUKEMIA CELL LINE THROUGH ACTIVATION OF P53 GENE

A Atashi,[1] S Kaviani,[1] M Soleimani,[1] M Norouzi nia,[1] Y Mortazavi,[2] E Arefian,[3] H Aghaee Bakhtiari,[4] A Golestaneh,[5] M Hafizi[3]

[5]*University of Tehran, Tehran, Iran*

Background. Many human leukemias do not express detectable levels of p53. It has been demonstrated that loss of p53 gene expression is likely to be an important step in leukemogenesis. This could be result from the loss of proper trans-acting factors or mutational/epigenetical silencing of cis-acting elements in regulatory regions of the gene. Apoptosis induction in leukemic cells by agents which trigger cancerous cells specifically is an active area in the field of treatment of leukemia. *Aims*. The objective of this in vitro study was to determine the application of NS1 protein of parvovirus B19 to induce p53 activity and apoptosis in K562 cell line as a p53-null erythroleukemia cell line. Methods. We have developed a lentiviral vector system to deliver the NS1 gene into K562 cells. Using qRT-PCR and protein analysis, we determined levels of p53 gene expression in transduced cells. Morphological studies as well as annexin-V and caspase-3 analyses were performed to assess apoptosis in NS1-transduced cells versus control. *Results*. Transduction of K562 cell line by lentiviral vector was resulted in 84% efficiency of NS1 gene delivery as measured by flowcytometry. Gene expression analysis in both RNA and protein levels showed strong activation of p53 gene in NS1-transduced cells versus mock virus-transduced cells. NS1 gene induced mean of 63% of K562 cells to undergo apoptosis within 4 days, which was five-fold increase over background level. Analysis of caspase involvement showed that NS1 gene could activate caspase-3 and induce apoptosis. *Conclusions*. NS1 protein of parvovirus B19 could be a good candidate in treatment of leukemia, due to high tropism of B19 virus to hematopoietic system and its ability to induce apoptosis through activation of p53 pathway in leukemic cells as demonstrated in the present study.

INFLUENCE OF NOVEL 5-AMINO-1,2-DIHYDROPYRROLE-3-ONE DERIVATIVE WITH ANTIPROLIFERATIVE ACTIVITY ON THE RAT BLOOD CELLS PARAMETERS AFTER TWO MONTH ADMINISTRATION IN THERAPEUTICAL DOSE

V Byelinska, V Rybalchenko, V Ostrovska, M Klipa, M Volovenko
Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Background. According to the preliminary studies the 5-amino-1,2-dihydropyrrole-3-one derivative (DD-1, 1-(4-(2-ethyl)morpholine)-4-(benzo[d]thiazol-2-il)-5-amino-1,2-dihydropyrrole-3-one)) suppresses proliferative activity of the tumor cells (HCT-15 Colon Cancer, UACC-62 Melanoma, A549/ATCC Non-Small Cell Lung Cancer, SR and K-562 leukemias et al.). DD-1 was designed as inhibitor of ATP-binding sites of protein kinases and synthesized by scientific production of Chemical-Biological Centre of Taras Shevchenko National University of Kyiv. The aim of the study was determination of DD-1 effects on blood cells parameters in healthy rats and under the action of 1,2-Dimethylhydrazine induction of colon tumors after two month administration. Methods. The outbred male rats was divided into four groups (10 rats in each group): I - control group (treated 0.1 ml of the sunflower oil containing 15% of DMSO per os daily and 0.1 ml of saline subcutaneous every week), II - group treated with 1,2-Dimethylhydrazine (20 mg/kg in saline subcutaneous every week, for induction of colon tumors, and 0.1 ml of the sunflower oil containing 15% of DMSO per os daily), III - group treated with DD-1 (2.3 mg/kg in 0.1 ml of the sunflower oil containing 15% of DMSO per os daily and 0.1 ml of saline subcutaneous every week), IV - group treated with DD-1 (2.3 mg/kg in 0.1 ml of the sunflower oil containing 15% of DMSO per os daily) and 1,2-Dimethylhydrazine (20 mg/kg subcutaneous every week) during two month. A DD-1 dose of 2.3 mg/kg corresponds to the 100% inhibition of tumor cells proliferation in vitro. Rat blood cells parameters were determined by routine method.Results. It is shown that DD-1 in the dose of 2.3 mg/kg does not effect erythroid parameters (erythrocytes count, hemoglobin, hematocrit, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC)) and leukocytes vs. control group after two month administration. 1,2-Dimethylhydrazine does not change none of blood cells parameters after two month administration. In IV-group treated with DD-1 and 1,2-Dimethylhydrazine MCH was decreased (18.05±0.31, $p<0.05$) and MCHC has a tendency to decrease (320.29±5.51, $p=0.07$) vs. control group (19.43±0.16, 335.69±3.66, respectively) after two month administration. The other parameters did not change. Conclusions. DD-1 does not affect the blood cells parameters in healthy rat in indicated dose and does not restrict application of this compound as a potential anti-tumour drug.

IAP INHIBITORS INDUCE APOPTOSIS IN CHILDHOOD ACUTE LEUKEMIA CELLS VIA NF-KAPPAB-ACTIVATION AND TNFALPHA-SECRETION IN A RIP1-DEPENDENT MANNER

M Schirmer,[1] S Löder,[1] S Fulda,[2] KM Debatin[1]
[1]*University Medical Center Ulm, Ulm, Germany*
[2]*Institute for Experimental Cancer Research in Pediatrics, Frankfurt, Germany*

Children with high risk acute lymphoblastic leukemia (ALL) or relapse of ALL do not respond well to current treatments and still have a poor prognosis. Because this failure is, in part, due to defects in apoptosis programs, new strategies are required that counter apoptosis resistance in order to improve the poor prognosis. Since *"Inhibitor of Apoptosis"*(IAP) proteins are expressed at high levels in acute leukemia and block apoptosis at a central point of the apoptotic machinery, they may present a suitable molecular target for therapeutic intervention. We already showed that neutralizing IAP proteins by small molecule IAP inhibitors is an effective approach to sensitize childhood acute leukemia cells for death receptor- or chemotherapy-induced apoptosis. Here, we report that in some acute leukemia cell lines small molecule IAP inhibitors alone, also at nanomolar concentrations, induce apoptosis. Cell lines which are sensitive for apoptosis induction by IAP inhibitors alone show rapid degradation of cIAPs, activation of NF-kappaB and secretion of TNFalpha, leading to an autocrine, apoptosis inducing TNFalpha-loop. Further analysis of signaling pathways reveals that IAP inhibition causes TNFalpha-dependent loss of mitochondrial membrane potential, caspase activation and apoptosis. In addition this signaling pathway is dependent on the availability of RIP1. RIP1-knockdown leukemia cells show significant reduction in IAP inhibitor induced loss of mitochondrial membrane potential, caspase activation and apoptosis. Also primary leukemia cells are in part sensitive for IAP inhibitor induced cell death. Since not all acute leukemia cell lines and primary leukemic cells are sensitive for IAP inhibitor induced apoptosis, it is very important to find markers, which indicate IAP inhibitor-sensitivity and provide a new successful treatment approach for acute leukemia.

SELECTIVE MICRO ERYTHROCYTES APHERESIS (SEMEA): A NEW THERAPEUTIC PROCEDURE FOR THE TREATMENT OF POLYCYTHEMIA VERA (PV)

M D'Onofrio,[1] L Paesano,[1] D Meomartini,[1] G Vaccaro,[1] E Madonna,[2] R Ciancia,[2] I Varinelli,[3] V Martinelli,[2] F Pane,[2] C Nocera[1]
[1]*PO San Giovanni Bosco ASL Na1 Centro, Naples, Italy*
[2]*DDBM Sezione di Ematologia, Università „Federico II„, Naples, Italy*
[3]*Haemonetics Italia, Milan, Italy*

Background. Polycythemia Vera is a myeloproliferative neoplasm characterized by increased red cell mass; in its course, this pathology often shows complications and death's causes associated with thromboembolic phenomena. In some periods of the disease, the typical framework of peripheral blood count is the presence of hypochromic microcytic polyglobulia with a highly mixed red cell population (with elevated RDW, but normal Hb and Hct). However high number of microcytes contributes to issues related to the overload of the microcirculation, while these cells, having low level of Hb, do not contribute to the

oxyphoretic capacity of the blood. Classically, the reduction in RBC mass is obtained with bloodletting by phlebotomy, in order also to induce hyposiderosis and iron-restricted erythropoiesis. Aims. In this study we report the preliminary data obtained with a new procedure of selective erythroapheresis, called SEMEA: SElective Micro Erythrocytes Apheresis, that we have designed in order to remove from the circulation mainly the microcytes. We have evaluated if this innovative and original procedure is able, compared to classis phlebotomy, to take away an increased red cell mass, and if it is also able, respect to non-selective erythroapheresis, to take a selected population of cells: the microcytes. *Methods*. During 2010, 10 male patients affected with PV, aged 64.5±7.94, were treated, after informed consent, by SEMEA, each underwent to a cycle of 6 apheresis in 30 days. Therapeutic procedures were performed with cellular separator Haemonetics MCS+, using the 971E kit for collection of PBSC, but opportunely modifying some parameters: a) AC ratio from 1:9 to 1:12; b) start collection set to 70%; c) detected RBCs set at 12%; d) removed volume of RBCs concentrates per cycle: 40 mL; e) no recycling; f) changing the original bowl with another one of 225-mL. *Results*. Observed data are expressed as mean±SD. Before our treatment: Hct = 48.98±4.4%, Hb = 14.3±1.51 g/dL, RBC = 6.83±0.2 x106/μL, MCV = 71.25±7.94 fL, RDW = 17.33±1.51%. Observed values on all collected units: RBC = 3.12±0.26, MCV = 69.75±6.65, RDW = 17.35±1.24. After SEMEA: Hct = 46.78±3.94, Hb = 13.9±1.71, RBC = 6.05±0.1, MCV = 72.5±6.85, RDW = 16.83±1.34. Conclusions. At the end of this first experimental course of treatment, we observed that: 1) the procedure was effective in reducing polyglobulia; 2) slight increase of MCV in vivo; 3) the MCV of collected RBCs was always 2-3 fL lower than basal MCV of the patient; 4) not significant change in Hb before and after SEMEA. Moreover the treatment has been well tolerated, in fact patients showed no adverse reactions despite the longer duration of the procedure compared to standard therapeutic erythroapheresis (50 vs 15 minutes). This original method, in addition to the reduction in RBCs count, has the advantage of affecting the real pathological cellular fraction of PV, as demonstrated by decreasing of RDW. On the basis of our results, we are encouraged to propose SEMEA to patients affected with PV showing a marked polyglobulia with hyposideremic anisopoikilocytosis after a series of bloodletting by phlebotomy.

DATA OF ADVIA 120® RBC MATRIX ARE USEFUL TO DISCRIMINATE B12/FOLATE DEFICIENCY, CHEMOINDUCED AND BETA THALASSEMIA MINOR ANAEMIA

G Giordano, A Tarasco, S Papini, M Piunno, C Antonelli, L Romano, B Zappacosta

Center John Paul II , Catholic University, Campobasso, Italy

Background. In automated peripheral blood cell analysis, ADVIA® technology (Siemens) provides a lot of information regarding also red blood cells (RBC). Among these information, those regarding red blood cells (RBC) contained in RBC matrix might be useful to define different aetiology of anaemia. Aims. Aim of this study is to define if information contained in RBC matrix is useful to define different aetiology of anaemia, before that data regarding iron balance, B12, folates, DAT and IAT and haemoglobin electrophoresis are available. Methods. We evaluated 148 patients with moderate/severe anaemia. M/F was 57/91. Median age was 65 years (R23-87). 14 patients presented B12 and folates documented anaemia (9%), 68 with chemoinduced anaemia (45%), 9 with beta thalassemia minor (6%) , 57 with sideropaenia (38%). Data were analyzed using RBC matrix of ADVIA 120® automated blood cell analyzer. In this matrix volume of RBC is plotted with haemoglobin concentration of RBC. In this matrix ther'are 9 box (RBC macro - cytic/hypocromic, macro/normo, macro/hyper, normo/hypo, normo/normo, normo/hyper, micro/hypo, micro/normo, micro/hyper). In each box ADVIA 120® provide absolute and percentual number of RBC with above mentioned charachteristics. Results. Among 14 patients with B12 and/or folate deficiency, 11 (78.6%) presented RBC simultaneously macrocytic/normochromic >2% and normocytic/hyperchromic>2%. In remaining 134 patients with anaemia without B12 and/or folate deficiency only 10 (7.5%) showed the same charachteristics, with a Chi Square Yates corrected of 46.962 ($p<0.0001$), with an Exact Fisher text with $p<0.0001$, with a sensibility of 78%, a specificity of 92% and a predictive negative value of 97.6%. Among 68 patients with chemorelated anaemia, 10 (14.7%) presented RBC normocytic/hyperchromic >2% . In remaining 80 patients only 3 showed the same charachteristics, with a Chi Square Yates corrected of 4.2 ($p<0.04$), with an Exact Fisher text with $p<0.038$, with a sensibility of 15%, a specificity of 96% and a predictive positive value of 77%. Among 9 patients with beta thalassemia minor, 8 (89%) presented RBC simultaneously microcytic/hypochromic >2% and microcytic/normochromic>2%. In remaining 139 patients no patient showed the same charachteristics, with a Chi Square Yates corrected of 113.8 ($p<0.0001$), with an Exact Fisher text with $p<0.0001$, with a sensibility of 89%, a specificity of 100% and a predictive positive value of 100% and a predictive negative value of 99%. Summary and Conclusions. ADVIA 120® RBC matrix is useful to define B12 and/or folate deficiency anaemia (RBC simultaneously macrocytic/normochromic >2% and normocytic/hyperchromic>2%), chemorelated anaemia (RBC normocytic/hyperchromic >2%), beta thalassemia minor (RBC simultaneously microcytic/hypochromic >2% and microcytic/normochromic>2%). These data need confirmation on a larger cohort of patients.

1553

JUVENILE HAEMOCHROMATOSIS

P Bignell,[1] A Schuh,[1] K Robson[2]

[1]*Molecular Haematology, Oxford, UK*

[2]*Weatherall Institute Molecular Medicine, University of Oxford,, Oxford, UK*

Juvenile haemochromatosis (JH) is the most severe form of inherited iron overload usually affecting either sex before the age of 30. Sadly the first manifestation of JH can be sudden cardiac failure. In Europeans the disease is associated with heart disease, diabetes, infertility and liver disease. In Asian patients JH associated heart disease is rare. The genetic picture with JH is not simple. JH is usually attributed to mutations in either hemojuvelin (HJV,HFE2) or hepcidin (HAMP). However JH can also be due to combinations of mutations in HFE and hepcidin or transferrin receptor 2 (TFR2) and HFE. JH rarely results from mutations in TFR2 alone. Hence in the majority of cases autosomal recessive inheritance of mutations in HJV, HAMP or TFR2 explain JH. Rarely combinations of mutations (digenic inheritance) are the explanation. Most commonly JH is due to mutations in the HJV gene. Mutations in HAMP gene are rarer and tend to be more severe. Nevertheless both conditions are rare. In Europeans the most common HJV mutation is G320V and in Asians G99R. The range of mutations is such that detailed genetic analysis is required for individual families. The age of onset may be determined by the ethnic background and the location of the mutation in HJV. Mutations in highly conserved residues result in severe disease. As part of the haemochromatosis screening service that has been set up in Oxford we have received requests to investigate the genetic basis of iron loading in a number of C282Y negative patients and their families. We have had 80 requests from referring departments to perform mutation screening in the genes encoding ferroportin, hemojuvelin, hepcidin and transferrin receptor 2. Apart from one case all had unexplained increased serum ferritin, some elevated transferrin saturation. Here we describe those requests relating to JH. In the first case the proband sadly died and it was a consequence of the postmorten that the diagnosis of JH was made. He was found to be negative for C282Y HFE mutations and the family were initially denied further screening. The proband was found to be homozygous for the common G320V HJV mutation. The second case was a family of Asian origin living in the UK where the proband was found to be homozygous for the common Asian mutation G99R. This family is not related to families living in the Midlands with the same mutation which had been described previously. The third case is a British male with congestive heart failure. He was referred to Oxford for further screening. He was found to be homozygous for the rare C80R HJV mutation that had previously only been described in a compound heterozygote living in France. From our findings we strongly recommend that any patient with unexplained raised serum iron parameters, found to be negative for HFE mutations is screened for mutations in HJV, HAMP, TFR2 and ferroportin.

1554

FERROPORTIN DISEASE, 4 NOVEL MUTATIONS

P Bignell,[1] A Schuh,[1] K Robson[2]

[1]*Molecular Haematology, Oxford, UK*

[2]*Weatherall Institute Molecular Medicine, University of Oxford, Oxford, UK*

The different genetic forms of HH share as their pathogenic mechanisms the deficiency or dysregulation of the hormone hepcidin or defects involving the hepcidin receptor, ferroportin. Ferroportin is the sole known cellular iron exporter in humans. Normally the cell surface concentration of ferroportin is regulated by its interaction with hepcidin. Hepcidin binding triggers the internalisation and degradation of the ferroportin-hepcidin complex, causing a decrease in cellular iron release into plasma. Mutations in the ferroportin SLC40A1 gene cause iron over-

load syndromes with AD inheritance. Ferroportin mutations result in spectrum of phenotypes, depending on the functional alteration of the protein. At one end of the spectrum, loss of function mutations, leads to increased macrophage iron and elevated serum ferritin, but normal transferrin saturation, and is known as "ferroportin disease". At the opposite end of the spectrum a distinct phenotype, similar to classical haemochromatosis, is associated with gain of function mutations. These mutations cause ferroportin resistance to the effects of hepcidin by preventing internalisation of the hepcidin-ferroportin complex From our cohort of patients that had been sent in for ferroportin gene screening 2 known and 4 novel mutations were identified. The novel mutations in exon 5, W158C, D157A and D157Y are all in highly conserved amino acid residues. Four different mutations have been found at codon 157. The mutation D157Y was found in an individual from north India. A molecular mechanism for mutations in this position can be explained by the D157G mutation in ferroportin leading to hepcidin-independent binding of JAK2 and ferroportin downregulation. Two previous ferroportin mutations had been found in India and Thailand and these were V162del and C326Y. They are rare mutations in this ethnic group. The mutation found in exon 8, H507R is a highly conserved amino acid residue which is predicted to be in the transmembrane domain (codons 492-514 in exon 8).

Table 1: Ferroportin mutations and their origin

Family	Protein	Exon	Nucleotide change	Amino Acid change	Origin
A	Ferroportin	3	c.239 G>A	G80E	Caucasian
B	Ferroportin	3	c.430 A>G	N144D	Caucasian
C	Ferroportin	5 (HOMOZ)	c.470 A>C	D157A	Caucasian
D	Ferroportin	5 (HOMOZ)	c.469 G>T	D157Y	Indian
E	Ferroportin	5 (HOMOZ)	c.474 G>T	W158C	Caucasian
F	Ferroportin	8 (HOMOZ)	c.1520 A>G	H507R	Caucasian

Table 2: Genotype and phenotype of families with type 4 haemochromatosis

Family	Sex	Age at diagnosis	TSat %	Ferritin µg/L	Serum iron µmol/L	TIBC mol/L	FPN mutation
A	F	43	H	HYPERFERRITINAEMIA	H	WD	G80E
B	M	30	H?	3782	38	38.3	N144D
C	M	60	H	>3000	H	WD	D157A
D	M	27	H	725	H	WD	D157Y
E	M	54	H	>2000	H	WD	W158C
F	M	66	H?	1350	RAISED	WD	H507R/CT

A published mutation p.Y501C has been found in the same transmembrane domain, this causes non-classical ferroportin disease. All individuals in the family were also heterozygous for C282Y mutation. Ferroportin disease is a clinically and genetically heterogeneous iron overload syndrome. Our results demonstrate the importance of screening patients found to lack HFE mutations for ferroportin mutations.

1555

TRANSFERRIN POLYMORPHISM AND ANEMIA IN HIV

J Philippé,[1] F Masaisa,[2] JB Gahutu,[2] J Mukiibi,[2] J Delanghe[1]
[1]*Ghent University, Gent, Belgium*
[2]*National University of Rwanda, Butare, Rwanda*

Background. Anemia is a common finding in developing countries, especially among women. Moreover, anemia is frequently observed in HIV, with prevalence up to 30% in patients with asymptomatic infection and in as many as 80% in those with AIDS. Importantly, anemia is associated with decreased quality of life and shortened survival. The main cause of deaths in HIV is opportunistic infection. Therefore we explored if anemia, and more especially if iron related parameters correlated with the risk to get opportunistic infections. More specifically we examined the impact of the genetic polymorphism of human transferrin (TF) since. it has been reported that the transferrin CD phenotype was associated with variations in certain measures of iron status. In Caucasians the common (CC) TF phenotype is almost found exclusively. Aims: To determine the prevalence and risk factors of anemia and the influence of HAART on anemia. To explore the relationship between transferrin polymorphism, anemia and the frequency of opportunistic infections. Methods: We conducted a cross-sectional study among 200 HIV positive and 50 HIV negative women in Butare University Teaching Hospital in Rwanda. Informed consent was obtained from all women. Complete physical examination was carried out and WHO HIV disease stage classification, hematological parameters, CD4 count, and iron related parameters were determined. TF phenotypes were determined using starch gel electrophoresis. *Results:* The prevalence of anemia was significantly higher among HIV positive women (29%) than in HIV negative women (8%), p<0.001. Risk factors for anemia (OR and 95% CI shown in brackets) were lower body mass index (OR:3.4[2.4-4.1]), Zidovudine use (OR:1.14[1.01-1.29]), lack of HAART (OR:1.44 [1.21-1.67]), oral candidiasis (OR:1.4[1.2-1.6]), pulmonary TB (OR:1.8[1.7-2.2]), cryptococcal meningitis (OR:1.6[1.21-1.8]), *Pneumocystis jiroveci* pneumonia (OR:1.41[1.20-1.65]) and CD4 lymphocyte count <200 cells/mL (OR:2.41[CI:2,01-3.067]). The mean hemoglobin of 10.9 ± 1.6 g/dL at HAART initiation significantly increased to 12.3±1.5g/dL in 8 months (p<0.001). For the transferring phenotype: The TF phenotype frequencies of TF CD, CB and CC were 14.5 %, 3 % and 82.5 %, respectively. The homozygous TF DD phenotype was not found. Subjects with TF CD phenotype had a significantly lower frequency of opportunistic infections than subjects with TF CC phenotype, 24% and 48% respectively (P=0.026). Subjects with TF CD phenotype had significantly lower values for serum beta2 microglobulin (P=0.0004) and transferrin (P=0.006) compared with TF CC subjects. There was a trend towards lower serum iron concentrations in subjects with TF CD (P=0.08). Overall hematological parameters, ferritin, transferrin saturation, CRP and CD4 count did not differ according to TF phenotype. Conclusions: The prevalence of anemia increases with HIV stage. HAART is associated with a significant improvement in hemoglobin levels. The outcome of HIV infection differs according to the various TF phenotypes. Iron status may play a role in this association. Subjects with TF CD phenotype have a major advantage in HIV infection since they have a lower frequency of opportunistic infections. They also have lower concentrations of serum beta2 microglobulin, associated with good prognosis in HIV infection.

1556

AGE-RELATED CHANGES OF PERIPHERAL BLOOD COUNTS IN MAN

R Mahlknecht,[1] S Kaiser[2]
[1]*Saarland University Medical Center, Homburg, Germany*
[2]*University of Heidelberg Medical Center, Heidelberg, Germany*

Anaemia is becoming a common concern in geriatric health. Even though its prevalence var-ies quite significantly among different groups depending on factors such as ethnicity, lifestyle or fitness, the appropriateness of current WHO definition of anaemia in the elderly may therefore be questioned. We have evaluated peripheral blood parameters from 1,724 individuals (908 women aged 18 to 101 years and 816 men aged 18 to 96 years), who were seen at the University of Heidelberg Medical Center in the absence of a known haematological history. Patients with a known malignant haematological or oncological disease, with chronic infec-tion or inflammation were excluded. Patients with disorders affecting the kidneys, thyroid or stomach as well as patients with a bleeding history, hemolysis or who had been previously diagnosed to have anaemia were excluded from this study. Average haemoglobin levels for men beyond the age of 70 and for women beyond the age of 80 were found to fulfil the WHO criteria for the diagnosis of anaemia. While in our cohort already ~ 20 % of men and women between 60-69 years of age were by definition anaemic, these numbers were steadily in-creasing to up to 63 % in females and to 76 % in males beyond the age of 90. Based on the results of our study and in accordance with the literature to this topic we suggest age-adjusted criteria for the diagnosis of anaemia in the elderly in conjunction with a geriatric assessment.

HEPCIDIN, A NEW HORMON OF IRON HEMOSTASIS

A Barbullushi, A Godo, E Refatllari, A Beqja, A Bulo
University hospital center „Mother Tereza„ Tirane, Albania, Tirane, Albania

Background. Anemia of chronic disease (ACD) results from 3 major processes: slightly shortened red cell survival, impaired reticuloendothelial system iron mobilization, and impaired erythropoiesis. Hepcidin is an acute-phase protein with specific iron regulatory properties, which, along with the anemia seen with increased hepcidin expression, have led many to consider it the major mediator of ACD. Hepcidin is a principal iron regulatory hormone and its expression is stimulated by cytokines. The aim of this study was to determine serum levels pro-hepcidinin in ACD anemia. Methods: The study included 115 patients, 72 males and

46 females. Anemia was defined as hemoglobin below 12 g/dl in females and 13 g/dl in males. We have 68(57.6%) anemic patients, 37(31.4%) have ACD, 17(14.4% IDA), 11(9.3%) ACD= IDA and 50(42.4%) no anemic patients. TNFα, interleukin IL6 and levels were determined by Immulite 1000. DRG ELISA kits were used for prohepcidine determinations. Independent Sample Test, Anova test, Chi-Square Tests was used for statistical analysis. Results: Serum prohepcidin, IL6, TNFα concentrations observed in ACD vs IDA is (329.42+263.22 vs102.63+38.63 p=0.000, 11.8+8.9 vs 4.4+5 p=0.000, 9.8+6.4 vs 8+5.3 p=0.012respectively). Serum prohepcidin concentration have a strong correlation with serum ferritin and IL6 concentration(r =.226, p=0.041 r =.309p=0.006 respectively) and IL6 have a strong correlation with serum ferritin and TNFα (r=.215 p=0.031, r=.507 p=0.000 respectively). Conclusions: We suggestion that hepcidin is a principal iron regulatory hormone in ACD and its expression is stimulated by IL6 cytokine.Serum prohepcidin concentration is the best marker to diagnose ACD.

HEMOGLOBIN EXTREMADURA [?64(E8)GLY>SER + ?133(H11)VAL>LEU]: A NEW MOLECULAR ANALYSIS AND CORRECTION OF A HAEMOGLOBIN PREVIOUSLY PUBLISHED

P Ropero,[1] G Martín-Núñez,[2] F González,[1] A Villegas,[1]
F De la Fuente-Gonzalo,[1] L Vinuesa,[1] J Martínez-Nieto,[1]
J Díaz-Mediavilla[1]
[1]*Hospital Clinico San Carlos, Madrid, Spain*
[2]*Hematology Service. Hospital Virgen del Puerto, Plasencia (Céceres), Spain*

Unstable hemoglobin (Hb) variants account for 9.5% of structural hemoglobinopathies. The majority of these unstable variants are the result of gene point mutations resulting in the substitution of a single amino acid by another. The presence of two mutations in the same allele is infrequent: of the 781 variants of the beta globin cluster described, only 32 are due to two point mutations (4.1% Hemoglobin (Hb) Extremadura is a structural variant that is included within the so-called unstable Hb. It was described in 1989 by Villegas et al., employing the most pioneering techniques available at that time, reverse phase HPLC to separate the abnormal chain (βX) digesting it with trypsin and analysis of the fragments with an automatic analyzer. The carrier was a 27-year-old who had a slight slight splenomegaly and hemolytic anemia (Hb 11.0 g / dL, PCV 31.5%, RBC 3.4 $x10^{12}$ / L; MVC 92fL, MCH 32.1 pg; MCHC 34.9 g/dL; Retis 5%), Heinz bodies (+). The Extremadura is electrophoretically silent Hb on cellulose acetate at alkaline pH, isoelectric focusing (IEF) and ion exchange HPLC, except on citrate agar at acid pH observed a diffuse band between Hb S and Hb C. By reverse phase HPLC eluting behind the chain βA (βA, βX and αA). Over these 20 years have maintained the values at diagnosis (Hb 10.5 g / dL, PCV 34.2%, RBC 3.2x10^{12}/L, MCV 106.4 fL, MCH 32.5 pg, MCHC 30, 6 g/dL; Retis 2.5%). She has had a daughter, who also presents mild splenomegaly and signs of minimal hemolysis (Hb 12.1 g/dL, PCV 38.0%, RBC 3.5 x10^{12}/L , MCV 109.7 fL, MCH 34.9 pg, MCHC 31.8 g / dL; Retis 2.2%), presence of Heinz bodies. At that time it made the study of globin chains by reverse phase HPLC, showing abnormal β chain compatible with the mother. It was decided to complete the study by sequencing the gene β globin, both mother and daughter, being a double mutation in the CD 64 of the 2nd exon GGC-->AGC (Gly-->Ser) and the CD 133 of the 3rd exon GTG-->CTG (Leu-->Val). The correct molecular characterization of these two point mutation Hb variants facilitates the understanding of how they influence changes in Hb stability, solubility and function (oxygen affinity), ultimately responsible for the clinical manifestations of the hemoglobinopathies, and permits the prediction of possible interactions with other Hb mutations, thus allowing more accurate genetic counseling) illustrating how infrequent these double mutations.

1559

HEMOGLOBIN SETIF IN NORTHERN GREECE. EPIDEMIOLOGICAL SURVEY

S Theodoridou, S Kotsiopoulou, O Karakasidou, V Aletra,
G Koleonidis, E Lefkou, F Klonizakis, M Alemayehou
Hippokration Hospital, Thessaloniki, Greece

Hemoglobin Setif (α 94 Asp-Tyr) was first described in 1972 in Algeria and since then several cases have been reported in families in Iran, Lebanon, Saudi Arabia and other Middle East states. The substitution in Hb Setif is in the α1β2 contact region of the molecule. This site of amino acid substitution in Hb Setif is an important contact point between α and β chains in the oxyconformation. Oxygen affinity is only slightly reduced nevertheless mild instability is produced. It has been reported that the most remarkable property of Hb Setif is its capacity to induce pseudo sickling of red cells in vitro. This does not have any clinical significance. Identification of Hb Setif is made by hemoglobin electrophoresis and ion exchange high pressure liquid chromatography (HPLC) as well as DNA studies. Hb Setif moves to the position of Hb S on starch gel and cellulose acetate at both alkaline and acidic pH. Hb Setif and Hb A separate on cation and anion exchange HPLC. The percentage of Hb Setif is 12-15% in heterozygotes, and it is reported that it could be as high as 30% in a compound heterozygotes with alpha and beta thalassemia mutations in the same person without any clinical consequences. The aim of this study was to investigate the incidence of Hb Setif in Northern Greece. A total of 78.254 subjects were screened for hemoglobinopathy in our prevention unit that covers the regions of Central and Western Macedonia in Northern Greece with a population of around 2.5 million. The carrier identification was carried out by a standard scheme, which included, CBC and red cell indices using the Coulter ONYX, a Cation Exchange HPLC variant system (Bio-Rad, Variant β-Thalassemia Short Program), to determine HbA, HbA2 and HbF levels.The different abnormal structural hemoglobins were investigated by electrophoretic techniques both at alkaline pH on cellulose acetate and at acid pH on citrate agar. Sickling test and tests for HbH inclusion bodies were also performed. Haemoglobin A2 was also quantified by column micro chromatography and serum ferritin levels were measured by micro Elisa technique. Only 6 individuals were found to be heterozygotes for Hb Setif and two cases were compound heterozygotes of Setif / beta thalassaemia. In heterozygotes the percentage of Hemoglobin Setif was from 16,2-17,4% and Hb A2 was within the normal limits. The combination with beta thalassemia was characterized by low hemoglobin Setif levels in the range as low as 2.2 to 2.7% unlike of the double heterozygosity. Both heterozygotes and compound heterozygotes did not manifest any clinical problem. Our data indicate that Hemoglobin Setif is rare in our country and clinically silent. Identification is important for genetic counseling of families since the coinheritance with beta thalassemia does not affect the hematological and clinical manifestations of the carriers. The fact that levels of hemoglobin Setif in compound heterozygotes with beta thalassemia genes are low as seen in our two cases is an interesting finding.

1560

STUDY OF THREE FAMILIES WITH HEMOGLOBIN AGRINIO IN SPANISH POPULATION: THREE HOMOZYGOTES CASES

P Ropero,[1] F De la Fuente-Gonzalo,[1] M Baiget,[2] I Badell,[2] L Vinuesa,[1]
J Martínez-Nieto,[1] F González,[1] A Villegas,[1] P Ricard,[3]
J Díaz-Mediavilla,[1]
[1]*Hospital Clinico San Carlos, Madrid, Spain*
[2]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*
[3]*Hospital Fundación de Alcorcón, Madrid, Spain*

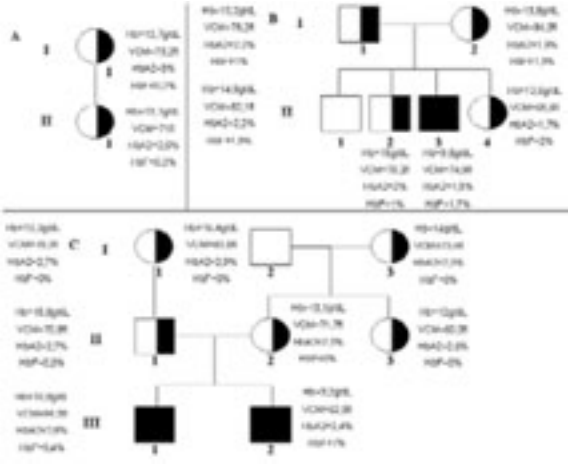
Background. Most α-thalassemia determinants are deletions involving one or both of the duplicated α-globin genes, however, non-deletional α-thalassemia mutations affecting RNA translation, RNA processing, or causing post-translational instability have been described. Hb Agrinio [CD29 (B10) Leu>Pro α2] is an hyperunstable structural variant of chain α wich phenotype is due to a postraduccional precipitation of the structurally anomalous chain in the erythroid precursors. This would explain the absence of abnormal globin chain in the electrophoretic and chromatographic studies. The first case of homozygous Hb Agrinio was described a Greek child at 12 months of age had a marked hypochromic microcytic anemia. *Aims*. We show three families with Hb Agrinio. In three of cases caused a intermedia thalassemia because they were homozygous. It is the first time described in spanish population. Methods. 16 samples of 3 different families were collected and studied to show microcytosis with normal HbA2 and HbF. Genomic DNA was extracted from peripheral blood leukocytes, employing a Bio-Robot EZ1. α gene deletions were ruled out by α-thalassemia StripAssay and the molecular characterization was studied by automated DNA sequencing with BigDye v1.1, specific for α2 gen. Results. We found 11 heterozygous cases, 3 homozygous cases and 2 cases with the triplication of α genes without Hb Agrinio. Moreover, the triplication appears in 2 subjects with Hb Agrinio. The individual genotipe of cases in study are:

Family a) I1: αAgα/αα; II1: αAgα/αα.

Family b) I1: αAgα/αα; I2: αAgα/αααα; II1: αα/αααα; II2: αAgα/αα; II3: αAgα/αAgα and inclusions body; II4: αAgα/αα.

Family c) I1: αAgα/αα; I2: αα/αααα; I3: αAgα/αα and G6PDH deficit; II1: αAgα/αα; II2: αAgα/αα; II3: αAgα/αααα; III1: αAgα/αAgα; III2: αAgα/αAgα and inclusions body.

Conclusions. Automatic sequencing is a great important method for the clinical diagnosis of non-deletional α-thalassemia syndromes. Homozygous cases show a severe hypochromic anemia, with a lower Hb and a decrease of VCM, which is supported by the literature on the subject. The VCM abnormally high for the case of homozygous Hb Agrinio could be explained by the fact that the individual has received a transfusion recently. In patients II.3 of family C and II.4 of family B, the VCM is too low considering that present Agrinio heterozygous Hb. However, this could be explained by iron deficiency anemia associated. Hb Agrinio heterozygous causes a thalassemia trait while in homozygotes behave as an intermedia thalassemia because they are affected both α2 genes, which have a higher rate of gene transcription compared to α1. This Hb is hyperunstable, why suffer instantaneous postradutional precipitation. Here, a residue highly conserved in evolution, essential to create the hydrophobic environment necessary for distal heme binding is affected, disrupting contacts with residues 55, 58, 59 and 101 of the α chain. The diagnosis of less common variants of this disease is essential to be applied to genetic counselling and prenatal diagnosis, reducing health and social costs associated with processing of these pathologies



1561

FIRST CASE OF HEREDITARY ATRANSFERRINEMIA IN SPAIN

R Joshi,[1] G Frigola,[1] M Moran,[1] C Diaz de Heredia,[2] M Sanchez[1]
[1]*IMPPC, Badalona, Spain*
[2]*Vall d'Hebrón University Hospital,, Barcelona, Spain*

Background. Hereditary atransferrinemia (OMIM 209300, Orpha number ORPHA1195) was first described in 1961 as a rare autosomal recessive metabolic disorder characterized by microcytic hypochromic anemia due to a functional deficiency of transferrin. Transferrin is the main plasma iron-binding protein encoded by the gene TF. In atransferrinemia, there is a reduction in delivery of iron to erythroid cells in the bone marrow, reduced haemoglobin synthesis, increased iron absorption, and severe iron overload of parenchymal organs. The disease has been reported in only 12 patients from 10 families world-wide. Just four of these families have been studied at the molecular level. *Aims*. Here, we report a new patient with this rare disorder, the first known case in Spain and the 13th patient to be reported in literature. We aim to characterise this family at the genetic and molecular level. *Methods and Patients.* The pre-treated transferrin levels of the proband were extremely low (12.5 mg/dL normal values: 202 - 336 mg/dL). The parents and other relatives had low transferrin levels (value range 124 - 184 mg/dL) as predicted for healthy carriers. Blood samples were taken from the patient and relatives and DNA was extracted. Lymphocytes were isolated using the Ficoll method and grown in cell culture. Cytokine treatment was added to induce transferrin expression and RNA was isolated. Primers were designed for genomic amplifications (PCR) and transcriptional analysis (RT-PCR and qPCR). PCR fragments were sequenced by the conventional Sanger method and mutational analysis was performed using Mutation Surveyor DNA Variant Analysis Software (SoftGenetics). *Results.* Genetic analysis of the transferrin gene in our case revealed common polymorphisms, silent mutations and three novel variations in intronic regions. In addition, the proband and her mother had a new missense mutation in heterozygous state; NM_001063.3:c.[1561C>A]+[=]; NP_001054.1:p.[Ala418Glu]+[=]. This mutation is located in a conserved region of the protein. Paternal genetic analysis did not reveal any mutation in the coding region. The patient is currently being treated satisfactorily with periodic infusions of purified apotransferrin. *Summary/Conclusions*. The detected Ala418Glu amino acid substitution predicts a structural change in the protein that probably affects transferrin function. As Atransferrinemia is an autosomal recessive disorder, we postulate the presence of a second mutated allele inherited from the father (healthy carrier). We are currently studying the TF promoter region and the implication of intronic variations in RNA missplicing.

Funding. This work was supported by 'Instituto de Salud Carlos III', Spanish Health Program (project number: PS09/00341 awarded to Dr Mayka Sanchez) and by the Spanish Ministry of Science and Innovation (RYC-2008-02352 research contract under the Ramon y Cajal program awarded to Dr Mayka Sanchez).

EVIDENCE OF PROGNOSTIC VALUE OF RETICULOCYTE COUNT AND RETICULOCYTE HEMOGLOBIN CONTENT IN SICKLE CELL DISEASE

K Chalvatzi, S Spiroglou, P Dimitriadis, A Dimitriadou, O Fotakeli, A Nikolaidou, E Diza
AHEPA Hospital, Thessaloniki, Greece

Background. Reticulocytes are generally accepted to be young red blood cells. Whenever red cell formation in the bone marrow is active, the proportion of reticulocytes in blood increases. To date, reticulocyte hemoglobin content (Ret-he) is the most widely studied of the reticulocyte indices. The hemoglobin content is considered to be constant throughout the lifetime of erythrocytes and circulating reticulocytes unless structural changes take place compromising the amount of cytoplasm or causing cellular fragmentation. During intramedullary development, reticulocytes actively synthesize hemoglobin. Furthermore, fetal haemoglobin (HbF) seems to be protective to sickle cell anemia patients and is also used for monitoring these patients. *Aims.* Evaluation of Reticulocyte count (RET) and Ret-he and their relation to HbF and HbS proteins in patients with homozygous sickle cell anemia Methods. Ninety four patients with homozygous sickle cell disease (40 males and 54 females) were retrospectively studied and the levels of RET, Ret-he, HbF and HbS were evaluated. The measurement of reticulocyte parameters were generated by the Sysmex XE 2100 whiles the levels of HbS and HbF determined by cation-exchange HPLC (High Performance Liquid Chromatography). Results. Mean levels of RET, Ret-he, HbF, HbS were 200100±112700 /UL, 24.87±5.8 pg, 14.52±9.65%, 71.07±11.61%, respectively. Reticulocyte count was negatively correlated with HbF ($r = -0.216$, $p < 0.05$) and positively correlated with HbS ($r = 0.217$, $p < 0.05$). Additionally, a positive correlation was found between HbF and Ret-He ($r = 0.342$, $p < 0.01$ and a negative correlation between HbF and HbS ($r = -0.440$, $p < 0.001$). *Conclusions.* The protective role of HbF was confirmed and the same conclusion was reached regarding Ret-he and Reticulocyte count. When the absolute amount of reticulocytes decreases, the improvement in bone marrow stress, due to tissue anoxia, is reflected. The fact that the reticulocytes decreased after the HbS increase would support the improved erythropoiesis hypothesis. The decrease of the Reticulocyte count and the increase of Ret-He could be used as indicative indices for the severity of sickle cell disease.

1563

MTHFR GENE POLYMORPHISMS ARE NOT ASSOCIATED WITH HEMATOLOGIC ALTERATIONS IN WOMEN WITH RECURRENT PREGNANCY LOSSES

M Guerra-Shinohara,[1] K Giusti[1], R Lazaro,[1] N Monteiro,[1] F Bertinato,[1] F Seino,[1] J Britto,[1] S Cavalcante,[1] M Carvalho,[2] A Amorim Filho,[2] M Zugaib[2]
[1]*Faculdade de Ciencias Farmaceuticas da Universidade de Sao Paulo, Sao Paulo, Brazil*
[2]*Departamento de Obstetrícia e Ginecologia, Faculdade de Medicina da USP, Sao Paulo, Brazil*

Background. Recurrent pregnancy loss (RPL) is defined as three or more consecutive spontaneous abortions prior to the 20th week from the last menstrual period. It is a multifactorial condition. Low concentration of serum folate was observed in carriers of MTHFR 677TT genotype and it could impair the hemoglobin concentration. The effects of haplotypes for MTHFR 677C>T and 1298A>C polymorphisms in the hematologic parameters are unknown. *Aims*. To investigate the relationship between MTHFR (677C>T and 1298A>C) polymorphisms and hematologic alterations in women with recurrent pregnancy losses (RPL). *Methods:* Two

hundred and forty two non-pregnant women with three consecutive losses prior to 20 weeks of pregnancy and 237 healthy fertile non-pregnant women (group 3) who had at least two children and no known pregnancy losses were studied. The primary RPL group was made up of women who had three or more consecutive losses without carrying a fetus to viability (group 1, N=109) and in the secondary RPL group, women were included who had three or more consecutive losses and with at least one viable pregnancy (group 2, N=133). The hemogram was obtained by using a hematologic cell counter Pentra 120 ABX. Cobalamin was determined by using a Immulite (DPC Medlab) kit. Serum folate was determined by a microbiological assay. The MTHFR (677C>T (rs1801133) and 1298A>C (rs1801131)) polymorphisms were detected respectively by RFLP PCR and Real Time PCR. *Results*. Variant allele frequencies for MTHFR 677C>T and 1298A>C polymorphisms were similar in three groups (P>0.05). The frequencies of haplotypes for MTHFR 677C>T and 1298A>C polymorphisms in three groups were also similar (P=0.555). The number of blood cells (erythrocytes, leucocytes and platelets) and hemoglobin concentrations were similar in three groups according to genotypes or haplotypes for MTHFR 677C>T and 1298A>C polymorphisms (P>0.05). No difference was observed in Cbl concentrations according to three groups of genotype women for two polymorphisms (P>0.05). Women from RPL groups took supplementation with folic acid when the blood was collected, thus serum folate concentrations were similar in group 1 and 2 according to genotypes for MTHFR 677C>T polymorphism and higher than serum levels found in the control group, however in the control group, carriers of 677TT genotype had lower serum folate when compared with CT and CC genotypes. No difference was found in the serum folate concentrations in three groups according to MTHFR 1298A>C polymorphisms. Conclusions: The MTHFR (677C>T and 1298A>C) polymorphisms are not associated with hematologic alterations in women with RPL.

Funding. This study was supported financially by Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP, Proc. 2007/57605-0).

1564

STRATEGY FOR MOLECULAR CHARACTERIZATION OF ALPHA THALASSAEMIA IN OMANI POPULATION

S Alkindi,[1] S AlZadjali,[1] A Pathare,[1] R Krishnamoorthy[2]
[1]*Sultan Qaboos University Hospital, Muscat, Oman*
[2]*INSERM, UMR_S763, Paris, France*

Background. Alpha-thalassaemia is known to be prevalent in the Sultanate of Oman. However, there are no studies that have reported molecular characterization of alpha thalassaemia from the Sultanate of Oman. Presence of Hb Barts in a neonate is pathognomonic of an underlying alpha thalassaemia. Materials and Methods. In a prospective study, cord blood samples from 7837 neonates, which showed abnormally high Hb Barts by a qualitative and quantitative high performance chromatography[HPLC](Biorad Laboratories, Hercules, CA, USA)were subjected to Genescan studies. [Figure] Samples with a single peak, suggestive of a deletion lesion were subjected to GAP PCR for alpha thalassaemia. Samples that showed two peaks, indicative of a non-deletional lesion were initially screened for common defects like alpha T-Saudi by Fast PCR. If negative these samples were then studied for rarer non-deletional defects by direct sequencing using ABI 3100 Genetic Analyzer®. (Applied Biosystems, Foster City, CA, USA). Results: Overall there were 4042 samples (51.58%) with normal HPLC (HbA + HbF). The remaining 3795 cases (48.42%) were associated the presence of Hb Barts, indicative of the presence of alpha-thalassaemia. Amongst these subjects, 229 cases additionally also had HbS, 28 cases had HbD, 30 cases had HbE, and 3 cases had HbC. Genescan studies revealed that 38.77% cases had non-deletional type[two peaks] but 61.23% subjects showed deletional (-alpha3.7) type of alpha-thalassaemia.[figure] . This was confirmed by GAP PCR for deletional cases whereas in non-deletional cases selective amplification and direct sequencing of both alpha2 and alpha1 genes was necessary. Conclusions?? : The incidence alpha-thalassaemia in this cohort of neonates was 48.42%. CBC and HPLC on a newborn sample can lead to the suspicion of an underlying alpha thalassaemia. A strategy to screen these samples with Genescan studies can be help to classify the underlying defect as either deletional or non-deletional type, so that further appropriate molecular characterization can be facilitated. Capillary electrophoresis of alpha-globin genes analyzed by the Genescan software is thus the ideal intermediary step to choose an appropriate molecular method to characterize the alpha-globin genotype.

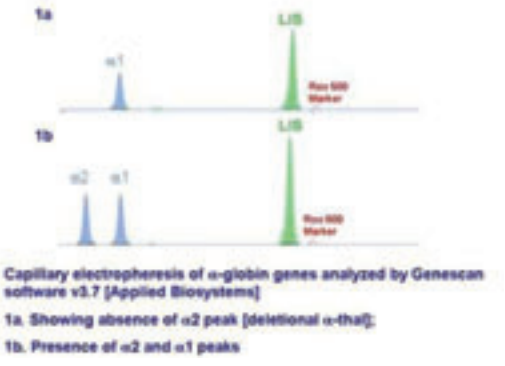

Figure 1. Alpha globin genes analysis by Genescan.

DEFERASIROX FOR THE TREATMENT OF TRANSFUSIONAL IRON OVERLOAD IN SICKLE CELL ANEMIA: A 2-YR PROSPECTIVE STUDY

R Cancado, M Olivato, P Bruniera, M Melo, C Chiattone
Santa Casa Medical School, Sao Paulo, Brazil

Background: Majority of patients with sickle cell disease (SCD) receive repeated blood transfusions by adulthood. Because the body has no physiological mechanism to actively excrete excess iron, chelation therapy is important for the management of iron overload (IOL) and its complications, including iron deposition into the liver, heart and endocrine organs, eventual death. Deferasirox (DFX) is a once-daily, oral iron chelator that is approved as first-line treatment of chronic transfusional IOL including SCD. Aims and Methods: Objectives of this prospective trial were to evaluate the IOL status, before and after two year-treatment with DFX, using liver iron concentration [LIC, mg/d dry weight] by magnetic resonance imaging (MRI), MRI cardiac (Cardiac T2*, ms), serum ferritin (SF, µg/L), and to evaluate the safety and tolerability of DFX. Results: A total of 31 patients with SCD and IOL received starting dose of 20mg/kg/day of DFX. Two patients discontinued treatment at 8 and 9 months, due to pregnancy and moving to other city, respectively. One patient died at 18 months due to pulmonary infection and hemorrhagic stroke. DFX was interrupted in 3 patients due to confirmed SF levels <500 µg/L at 18-month period of treatment and DFX was not reinstated in none of them during the final 6 months of study. Twenty-five patients completed 2-year treatment. Mean ± SD age 26.9 ± 12.5y; 84% female, 90% afrodescendent, 61.3% on regular blood transfusion; median (range) DFX dose over 24 months and DFX exposure were 20 mg/kg/day (15-25) and 90.5 weeks (35.6-98.0), respectively. Mean SF level (µg/L) did not significantly reduced at 12 months (p=0.052) but significantly dropped at 24 months compared to baseline [from 2344.6 to 1986.3 (p=0.040)]. Mean ± SD LIC significantly dropped at 12 months and at 24 months compared to baseline [from 13.0 ± 5.4 to 10.4 ± 6.3 (p=0.001) and to 9.3 ± 5.7 (p<0.001), respectively]. The proportion of patients with LIC levels (mg/g dw) ≤7.0, >7.0- ≤14.0 and >14.0 from baseline to 24 months by percentage of patients changed from 13.6% to 44.0%, 40.9% to 44.0% and 45.5% to 12.0%, respectively. In all patients, Cardiac T2* was normal (> 20 ms) at baseline, 12 and 24 months of treatment. There was no significant difference between left ventricular ejection fraction values at baseline and after 12 months but this parameter significantly increased at 24 months of treatment compared to baseline [from 62.2 ± 6.0 to 64.6 ± 6.2 (p=0.02)]. The most common drug-related AEs were mild, transient diarrhea (7 pts), headache (7), nausea (5), vomiting (3), skin rash (2), increases in ALT (2), serum creatinine increases that exceeded the ULN (2). No patient experienced progressive increases in serum creatinine or renal failure. Conclusions: Our data confirms that deferasirox is effective in reducing body iron burden in transfused patients with SCD, well tolerated in pediatric and adult patients and with a clinically manageable safety profile. The availability of deferasirox as a once-daily, oral iron chelator would potentially facilitate improved compliance, and thereby reduce morbidity and mortality from iron overload.

1566

COMPARISON OF CAPILLARY ELECTROPHORESIS TO HIGH -PRESSURE LIQUID CHROMATOGRAPHY IN THE EVALUATION OF HAEMOGLOBINOPATHIES

S Theodoridou1, T Vyzantiadis2, O Karakasidou1, V Aletra1, V Gastari1, M Alemayehou1
1Hippokration Hospital, Thessaloniki, Greece
2Aristotelion University, Thessaloniki, Greece

The precise detection of structural haemoglobins as well as the accurate precision of Hb A2 and Hb F are very important issues in clinical laboratories. The detection and diagnosis of several haemoglobinopathies is important for the genetic counseling of couples at risk. In this prospective study we compared the high-pressure liquid chromatography method (HPLC), (Variant, Biorad) that we routinely use for diagnosis, with the automated capillary zone electrophoresis (CE), (Sebia Minicap). 126 samples were examined by HPLC and CE. 62 samples were found to be normal, 25 were heterozygous for β-Thalassaemia, 26 samples of people with sickle cell trait or patients with sickle cell syndromes, 2 were carriers of δβ-Thalassaemia, and 11 were found to be carriers of abnormal haemoglobins as E, Lepore, H, E-Saskatoon, D, Hb Questembert. For the normal samples the mean value of Hb A2 with the HPLC method was statistically signigificantly higher in comparison to CE method, (2.934 ± O.44, and 2.7 ± 0.46 respectively) (p=0.00). For the samples from β-Thalassaemia carriers, the mean value of Hb A2 with the HPLC method was statistically signigificantly lower in comparison to CE method, (5.2 ± O.69, and 5.47 ± 0.74 respectively) (p=0.014). For the samples from people with sickle cell trait or patients with sickle cell syndromes, the mean value of Hb A2 with the HPLC method was statistically signigificantly higher in comparison to CE method, (4.4 ± O.97, and 3.63 ± 0.88, respectively) (p=0.00). Interestingly, CE method can measure the percentage of Hb H, fact that fails with HPLC method. Hb E co elutes with Hb A2 in HPLC method and Hb E-Saskatoon co elutes with Hb S. With CE method, Hb E is "identified"as Hb C and Hb E-Saskatoon as Hb O-Arab. As for Hb Lepore it is known that co elutes with Hb A2 in HPLC but in CE it is separated. The carrier of Hb Questembert was not identified neither in HPLC nor in CE. Both methods provide automated detection of variant haemoglobins. The use of HPLC has the advantage of a broad literature with the use also of classical electrophoresis at alkaline and acid gels. The use of CE in combination with the HPLC could become a useful tool in clinical laboratories.

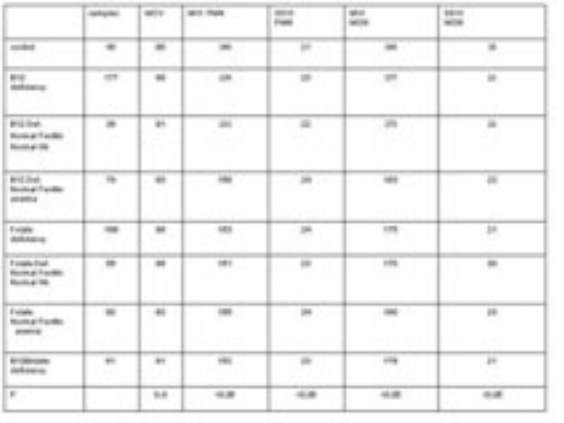
NEW PARAMETERS FOR THE DETECTION OF MEGALOBLASTIC ANAEMIA

E Papakonstantinou, E Yfantis, A Skourbouti, K Konstantinou, C Pegos, A Lavda, C Manti
Thriassion Hospital, Agia Paraskevi, Greece

The classical flow charts used widely for the diagnostic approach of anemia due to Vitamin B12 (B12) deficiency or anemia due folate deficiency includes the Mean cell Volume of the red blood cells (MCV) as one of the key tests for the suspicion of these diseases and the differential diagnosis of anemia. Only around half of the patients with B12 deficiency (B12) or folate deficiency have high MCV, in many of the situations because the coexistence of other causes of anemia. The Coulter LH 780 hematology analyzer (Beckman Coulter) has the ability to measure specific parameters of neutrophil and monocyte populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect morphologic changes in neutrophil and monocyte population. Using VCS parameters we investigated the correlation between megaloblastic neutrophils and monocytes in B12 and/or folate deficiencies. AIM The correlation of megaloblastic anaemia due to B12 and/or folate deficiencies with neutrophil and monocyte positional parameters. METHODS The study population included 427 patients. 177 had B12<145pg/mL and 189 patients had folate <2.33ng/mL There were 61 cases with both serum folate and B12 deficiency (46 of them had normal ferritin, 31 had anaemia). Anemia was defined according the WHO anemia criteria (Hb<12 g/dL in women and Hb<13 g/dL in men). We collected blood samples from 43 healthy control subjects. The VCS parameters and full blood count was obtained by the Coulter LH 780 hematology analyzer. B12, folate and ferritin values were obtained using paramagnetic particle chemiluminescent immunoassay (Access2). P value less than 0, 05 were considered significant.



The MVI and SDVI of neutrophils and monocytes may be used for the detection of megaloblastic neutrophils and monocytes. Megaloblastic neutrophils and megaloblastic monocytes may be seen in B12 and/or folate deficiency. Positional parameters have significant statistical role in the detection of those deficiencies in contradiction with the widely used MCV, because they are not affected by the presence at the same time of iron deficiency or other reasons of anemia. Although plausible, this hypothesis needs to be sustained clinically by a prospective study.

EVALUATION OF AN IMPROVED MICROCUVETTE FOR FAST AND EASY POINT OF CARE HEMOGLOBIN DETERMINATION

M Hirschfelder, C Dumschat, F Aβmann
EKF-diagnostic GmbH, Barleben, Germany

Background. Point of care testing for hemoglobin is often carried out using disposable microcuvettes based on the photometric determination of azidemethemoglobin [1]. The use of such microcuvettes enables a fast and accurate determination of hemoglobin outside the laboratory. One major problem arising from the use of microcuvettes is the formation of air bubbles during sample filling as it can cause incorrect hemoglobin readings. An improved microcuvette geometry comprising the integration of a slot which avoids this problem was developed by EKF-diagnostic GmbH (Hemo_Control microcuvette) [2]. Aims The aim of the study is the validation of the improved microcuvette on the Hemo_Control photometer in comparison to the classical reference method in hemoglobinometry and also to compare it to another widely-used microcuvette system (HemoCue B-Hemoglobin system). Methods. To evaluate the accuracy of the system, 112 venous blood samples (concentration range 30-256 g/L) were measured over 10 days with the Hemo_Control system, the Hemocue system and the reference method NCCLS [3]. 8 Hemo_Control devices, 10 lots of Hemo_Control microcuvettes, 4 HemoCue B devices and two lots of Hemocue cuvettes were used in the study to confirm calibration stability of the POCT system. Venous blood is the sample material of choice for comparison in order to avoid within sample variation. To evaluate the precision of the Hemo_Control system over 20 days, a control material was used because blood samples are not stable for that period of time. On each of 20 testing days, two separate runs with duplicate samples of three levels of hemoglobin concentration were measured. In the precision study 13 Hemo_Control devices, 19 Hemo_Control microcuvette lots and 4 operators were involved. The precision was calculated according to NCCLS EP5A [4]. Results. The results show an excellent correlation between the haemoglobin measurements from the Hemo_Control system and the NCCLS reference method for venous samples irrespective of the lot of microcuvettes. The correlation coefficient was 0.998 with an interception of 0.003 g/dL; the standard error was 0.26 g/dL. This lot to lot precision means that recalibration of the system is unnecessary. Furthermore the correlation coefficient to the results of Hemocue B devices was 0.997 with an interception of -0.46 g/dL. The standard error was 0.37 g/dL. The measured total precision of the Hemo_Control system was to 1.1 %. Assessing 100 venous blood samples, the within-run-imprecision gave a Cv of 0.63%. Summary/Conclusions The new microcuvettes show excellent accuracy and precision. The filling behaviour of the new microcuvette is considerably improved and the risk of air bubbles is substantially reduced. The measuring time is also shorter.

URINARY HEPCIDIN LEVEL AS AN EARLY PREDICTOR OF IRON DEFICIENCY IN CHILDREN

M Sanad, A Gharib

Zagazig University Hospital, Zagazig , Sharkia Governerate, Egypt

Background: The ideal screening test would be capable of identifying iron deficiency in the absence of anemia. This would allow for the treatment of iron deficiency in the pre-anemic stage, preventing iron deficiency anemia and it's associated mental, motor, and behavior effects. Such test is not widely used at this time. Aim of the work: To detect role of urinary hepcidin level in early prediction of iron deficiency in children. Methods: This case control study was performed on100 children in Hematology Unit of Pediatric Department, Zagazig University Hospital, Egypt. Parental informed consent was obtained from all participant cases be eligible for enrollment into the study. The medical ethics committee of the hospital approved the protocol. Children classified to 25cases of iron deficiency stage one (iron depletion), 25 cases stage two (iron-deficient erythropoiesis), 25 cases stage three (iron deficiency anemia) and 25 healthy children as a control group. Estimations of iron parameters were done (iron, ferritin, transferrin, free protoporphyrin, total iron binding capacity and transferrin saturation). Urinary hepcidin 25 level was detected by competitive ELISA. 96-well plates were coated with anti-human hepcidin antibody and biotinylated hepcidin-25 as tracer. Analysis of collected data was done by statistical software (SPSS for Windows, version 11; SPSS;Chicago, IL). All values were given as mean ± SD. One-way analysis of variance (ANOVA)was used to assess differences among means of the study groups. Multiple regression analysis was used to assess the influence of multiple variables on a single variable. Receiver operating characteristic (ROC) curve analysis was used to determine the discriminative properties of various cutoff levels of urinary hepcidin Levels. A value of < 0.05 was considered significant. Results: Our results revealed that urinary hepcidin-25 levels were significantly lower in all stages of iron deficiency than in control group, more significant reduction in its level was observed with the progress in degree of iron deficiency($p<0.01$). Urinary levels of hepcidin showed significant positive correlation with hemoglobin(Hb),mean corpuscular volume(MCV), hematocrit value, serum iron level, ferritin level and transferrin saturation(P value0.01).On the other hand urinary hepcidin levels showed significant negative correlation with serum transferrin and total iron binding capacity. Urinary hepcidin at cutoff point ≤0.94nmol/mmol Cr could Predict iron deficiency stage 1 with sensitivity 88% and specificity 88%. Cutoff point ≤0.42nmol/mmol Cr could predict iron deficiency stage 2 with sensitivity 96% ,specificity 92%, positive predictive value92.3% and negative predictive value 95.8%. Cutoff point ≤0.08nmol/ mmol Cr could Predict iron deficiency stage 3 with sensitivity 96%, specificity 100%, positive predictive value 100% and negative predictive value 96.2%. Conclusions: We can conclude that urinary hepcidin-25 level was a simple and non invasive test and could predict iron deficiency very early, before appearance of hematological affection.

STUDY ON THE RESULTS OF ERYTHROPOIETIN TREATMENT IN CANCER PATIENTS FROM SOUTHERN TRANSYLVANIA

RG Mihaila,[1] I Lisan,[2] R Dancu,[2] A Catana,[2] O Flucus,[2] C Grandore[2]

[1]*Lucian Blaga University of Sibiu, Sibiu, Romania*

[2]*Emergency County Clinical Hospital, Sibiu, Romania*

Background. Erythropoietin reduces transfusion needs, improves quality of life and increases the response to treatment of patients with cancer. Aim: We aimed to study the efficacy and safety of ß-epoetinum in cancer patients with different types of cancers. Methods: Of the 624 patients with oncological and onco-hematological diseases, hospitalized in Emergency Clinical Hospital Sibiu, treated with ß-epoetinum Sibiu in June 2009 - December 2010, all the 86 patients, who started therapy during this period were selected, in which we determined the serum hemoglobin initially and than at intervals of one month. ß-epoetinum dose was 30,000 IU/week, and if the serum hemoglobin did not increase after one month at least with 1 g/dl, the dose was doubled. In patients with an average hemoglobin decrease after one month of treatment, therapy with ß-epoetinum was stopped. The results were compared also depending the type of cancer and they were statistically analysed. Results: The average age of the 86 patients was 65.36+/-13.33 years. Distribution by gender: women - 53, men - 33. At the start of treatment, mean serum hemoglobin was 9.32+/-1.20 g/dl. It grew up to 10.92+/-1.26 g/dl ($p<0.00001$) after one month, 11.47+/-0.97 g/dl ($p<0.00001$) after 2 months, 12.22+/-1.20 g/dl ($p=0.011$) after 3 months. After the first month of treatment, mean hemoglobinemia increased 1.6 g/dl, after 2 months - with 2.15 g/dl, and after 3 months - by 2.9 g/dl. The average monthly increases were obtained in patients with chronic nonlymphoide hematological malignancies (1.93 g/dl, 2.66 g/dl, 3.97 g/dl), followed by those with chronic lymphoid hematological malignancies (1.86 g/dl, 1.66 g/dl, 2.79 g/dl). The smallest serum hemoglobin levels increases were observed in patients with solid neoplasms: after a month average increase of 1.17 g/dl, and 2 months - 2.09 g/dl. Most patients tolerated the treatment well. From the 624 patients treated with ß-epoetinum made in the 18 months, one patient developed splenic infarction and thrombosis of the inferior vena cava (with a favorable evolution on anticoagulant therapy), 1 - thrombophlebitis of a leg, 2 - alergodermia, 2 - high blood presure and 5 - dyspeptic symptoms possibly related to the treatment. There were no recorded deaths related to the ß-epoetinum therapy. Summary: ß-epoetinum therapy had an eficient control of the anemia in the majority of the oncological and hemato-oncological patients, reducing transfusion needs. The largest increases in serum hemoglobin were observed in patients with chronic nonlymphoide hematological malignancies, followed by chronic lymphoid hematological malignancies and those with solid malignancies. Side effects were rare and no deaths resulted.

1571

EVALUATION OF ANEMIA IN PATIENTS WITH CHRONIC KIDNEY DISEASE NOT SUBMITTED TO DIALYSIS TREATMENT

L Plotegher, H Grotto, G De Lima

Faculty of Medical Sciences. State University of Campinas, Campinas, Brazil

Background: Anemia is a common condition in patients with chronic kidney disease (CKD) due to insufficient erythropoietin (EPO) production. Iron deficiency and inflammation are often associated with and contribute to the impaired erythropoiesis in these patients. Aims: Evaluate the possible role of inflammation in the anemia and iron deficiency in various stages of renal failure. Methods: Adult patients with CKD and anemia neither undergoing dialysis nor using erythropoietin and iron supplementation. Haematological parameters (Sysmex XE2100), iron status and inflammatory activity were carried out in 77 patients with CKD (26 Stage II, 36 Stage III and 15 Stage IV of impaired glomerular filtration), 37 normal individuals (CG), and 22 normal subjects with iron deficiency anemia without renal disorder (IDA). Results: 33 patients had renal anemia (RA) without iron deficiency, and 44 had functional iron deficiency (FID) (serum ferritin <100 µg/dL and/or transferrin saturation (TS) <20%). Comparing patients with RA with and without iron deficiency, it was observed levels of protein C-reactive protein (CRP) higher in group with FID ($p <0.0001$, Mann-Whitney test) and higher levels of soluble transferrin receptor (sTfR) in group with FID ($p = 0.0144$). The degree of haemoglobinization of reticulocytes (Ret-He) was preserved in patients with CKD, similar to normal CG, both higher than IDA. A significant correlation (Spearman coefficient) between Ret-He and Mean Cellular volume (MCV) was observed in RA group ($p= 0.6132$, $p= 0.0001$), RA with FID ($r= 0.6167$, $p= < 0.0001$), CG ($r= 0.3892$, $p= 0.0172$) and IDA group ($r= 0.4337$, $p= 0.04356$). It was showed a progressive decreasing in hemoglobin level as renal dysfunction worsened. Although ferritin levels did not showed difference among the stages of DRC, levels of transferrin iron binding capacity (TIBC) and sTfR were increased and TS declined with increasing renal impairment. EPO levels were lower in the CKD than normal group and IDA. Inflammatory activity (CRP levels) were higher in the group with AR and FID ($p <0.0001$) than in RA and CG ($p <0.0001$). There was no correlation between haematological and iron parameters with CRP. Conclusions: According to the results we could conclude that the frequency of iron deficiency in those patients with CKD is quite high (57%), and that both anemia and iron deprivation are more evident in patients with more severe renal dysfunction. The role of inflammatory activity evaluated by CRP levels

in the physiopathology and progression of anemia was not observed, but other inflammatory markers such as interleukins and hepcidin may provide evidence about that association. Diagnosis of iron deficiency in patients with CKD is not always sufficiently investigated. Deprivation of iron in patients not undergoing dialysis should be diagnosed and, if possible, corrected. An increase in hemoglobin levels may improve the quality of life of these patients.

1572

EFFICACY OF COMBINED ORAL DEFERIPRONE AND SUBCUTANEOUS DESFERRIOXAMINE IN IRON-OVERLOADED CHILDREN WITH BETA-THALASSEMIA DISEASE: A TWO-YEAR EVALUATION

A Chuansumrit,[1] D Songdej,[2] N Sirachainan,[2] J Laothamatas,[3] P Wongwerawattanakoon,[4] W Sasanakul, P Kadegasem[2]
[1]*Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand*
[2]*Department of Pediatrics, Faculty of Medicine, Ramathibodi Hospital, Bangkok, Thailand*
[3]*Department of Radiology, Faculty of Medicine, Ramathibodi Hospital, Bangkok, Thailand*
[4]*Department of Nursing, Faculty of Medicine, Ramathibodi Hospital, Bangkok, Thailand*

Background. Iron overload is a serious complication found in transfusion-dependent patients with beta-thalassemia disease. Subcutaneous infusion of desferrioxamine (DFO) for five days per week creates the compliance and tolerability problem especially in pediatric patients. *Methods*. The daily dose of 50 mg/kg increasing up to 75 mg/kg of Thailand locally-manufactured deferiprone (DFP) plus twice weekly subcutaneous infusion of DFO 40 mg/kg to 58 transfusion-dependent children with beta-thalassemia disease. Their mean age was 11.0 years (SD, 3.7). Regular leukocyte-depleted packed red cell was given at a dose of 15 to 20 ml/kg every three to four weeks to maintain pre-transfusion hematocrit at 27%. *Results*. The patients had previously received regular transfusion for a mean duration of 9.1 years (SD, 3.4). All of them had been chelated by subcutaneous DFO for a median duration of 4.5 years (interquartile range 2.4-6.7) with an average dose of DFO at 27.7 mg/kg/d (interquartile range 22.3-31.8) for five days a week. The median serum ferritin level at the beginning of the study was 2909.4 ng/ml (interquartile range 2384.0-3708.8) while the mean transfusional iron load during the studied period was 0.31 mg/kg/d (SD, 0.07). None of the patients were hepatitis B carriers or had seropositive hepatitis C infection. All patients survived. The efficacy of combined therapy was evaluated in the 53 patients completed 24 month follow-up period. The median declination of serum ferritin was gradually increased: 169.6 ng/ml at 4 months, 404.4 ng/ml at 8 months, 663.7 ng/ml at 12 months, 746.7 ng/ml at 16 months, 772.3 ng/ml at 20 months and 1225.7 ng/ml at 24 months. Finally, the median serum ferritin level at 24 month was 1,438.7 ng/ml (interquartile range 1,004.6-3258.1).Eight out of 10 patients who had serum ferritin less than 1,000 ng/ml underwent cardiac MRI and LIC study. All patient had normal myocardial T2* with a median of 39.7 ms (interquartile range 33.3-43.4). However, the median hepatic T2* was 4.5 ms (interquartile range 3.0-6.8). Three patients were defined as no hepatic iron loading (<2mg/g) while five patients were defined as mild hepatic iron loading of 2-5 mg/g. Five patients dropped out from the study due to parental concern after adverse events including mild neutropenia (n=3), mild thrombocytopenia (n=1) and proteinuria (n=1). Another 11 episodes of adverse effects and abnormal laboratory results were found in eight patients during the studied period: GI discomfort (n=3), neutropenia (n=1), mild thrombocytopenia (n=2), elevated alanine aminotransferase (ALT) >250 u/L (n=3), serum creatinine >1 mg/dl (n=1) and arthropathy (n=1). Neutropenia and elevated ALT became normalized within one month of DFP interruption and DFP could be safely rechallenged in the following month. DFP was discontinued in patient with arthropathy although he was completely recovered after DFP interruption for one week. The rest of the events were mild, transient and spontaneous recovery without treatment discontinuation. No patient experienced agranulocytosis. *Conclusions*. The preliminary study of using locally-manufactured DFP combined with a two-day infusion of DFO showed an effective and tolerable means in chelating overloaded iron in transfusion-dependent children with beta-thalassemia disease.

1573

ACCURACY OF NONINVASIVE HEMOGLOBIN MEASUREMENT IN ANEMIC PATIENTS WITH KNOWN LOW HEMOGLOBIN LEVELS

Y Nakagawa,[1] K Suzuki,[1] N Katagiri,[2] H Fujii[3]
[1]*Japanese Red Cross Medical Center, Tokyo, Japan*
[2]*Masimo Japan Corporation, Tokyo, Japan*
[3]*Tokyo Women's Medical University, Tokyo, Japan*

Background. Hematology/Oncology patients with known anemia (low hemoglobin) are subject to routine invasive blood sampling in order to the monitoring of hemoglobin levels and the determination of red blood cell transfusion. Aims. The intention of this study is to determine whether noninvasive hemoglobin readings (SpHb) from patients with low hemoglobin are accurate compared to invasive hemoglobin measurements (tHb). Methods. Eligible in/outpatients at the Japan Red Cross Medical Center diagnosed with hematological or oncological diseases were enrolled following informed consent. Male and female patients, age ranging 41 to 85 years, had hemoglobin measurements performed by venous blood draws analyzed on a Sysmex XE-2100 hematology analyzer. Concurrently, noninvasive SpHb spot check measurements were obtained with a ReSposable finger sensor (R2-20 and R2-25, revision E) connected to a Radical-7 Pulse CO-Oximeter (SET software version 7.6.0.1.) (Masimo Corp., Irvine, CA USA). Both adult and pediatric size sensors were used. SpHb values were compared to tHb by calculating bias and precision and with a Bland-Altman plot. If the internally calculated signal confidence indicator on the Radical-7 was less than 50%, then a SpHb value was not displayed on the device. Low signal confidence occurs due to low perfusion in the finger, excessive motion, or other confounding factors. Data pairs that included low signal confidence readings were excluded from analysis. *Results*. Fifty patients (36 male/15 female) with an average age of 66 years were enrolled. A total of 50 analyzed data pairs included tHb ranging from 6.1-13.1 g/dL(from Sysmex device) and noninvasive hemoglobin SpHb ranging from 6.4-14.6 g/dL. Data were separated based on sensor type/finger size (R2-20 vs. R2-25). For patients with smaller fingers using sensor R2-20, the bias and standard deviation were -0.31 ± 0.66 g/dL. For patients using the adult size sensor (R2-25) the bias and standard deviation were 0.62 ± 1.02 g/dL. A subset of subjects (n=8) with very low hemoglobin (<8 g/dL) showed a bias of 0.34 ± 0.23 g/dL. Conclusions. Based on the results of these 50 patients, noninvasive SpHb with the Radical-7 showed good agreement with invasive tHb measurements from the laboratory reference device. Among patients with very low hemoglobin (<8 g/dL), SpHb showed even better agreement with the laboratory reference device with a bias and standard deviation of 0.34 ± 0.23 g/dL.The bias and standard deviation were consistent with a previous report of SpHb accuracy in volunteers undergoing hemodilution. Use of the Radical-7 with SpHb in this clinic allowed for instant, accurate and noninvasive hemoglobin monitoring in hematology/oncology patients, avoiding further blood loss in this already anemic population. This device is considered to be useful to determine the trigger point of red blood cell transfusion without venesection.

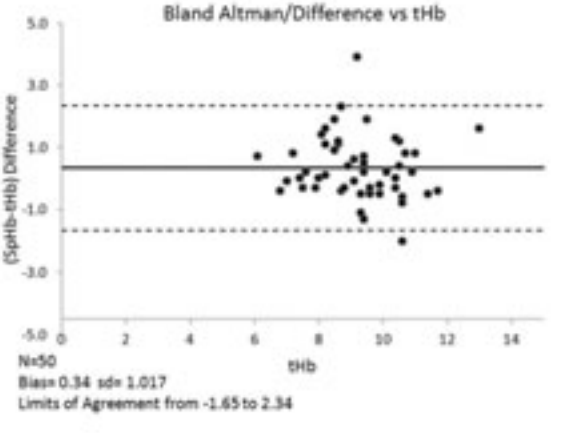

Figure 1. Bland Altman/Difference vs tHb.

IDIOPATHIC PULMONARY HEMOSIDEROSIS A RETROSPECTIVE STUDY FROM A PEDIATRIC HEMATOLOGY-ONCOLOGY CENTER

K Martinova,[1] S Stankovic,[2] O Muratovska,[1] S Glamocanin,[1]
Z Antevska-Trajkova,[1] B Coneska-Jovanova,[1] S Koceva,[1] O Karanfilski[2]

[1]*University Children's Hospital, Skopje, Macedonia*

[2]*University Clinic of Hematology, Skopje, Macedonia*

Background. Idiopathic pulmonary hemosiderosis (IPH) is a rare disease of unknown etiology, characterized by recurrent episodes of diffuse alveolar haemorrhage and sideropenic anemia which occurs most frequently in children. Sudden decrease in hemoglobin and hematocrit associated with the onset of active respiratory disease is strongly suggestive of IPH. Diagnosis of IPH should be considered when children have iron deficiency anemia and pulmonary signs and symptoms such as cough, hemoptysis and dyspnea. *Materials and methods*. We carried out a retrospective study using the medical charts of patients diagnosed with IPH, admitted at the Hematology-Oncology department- University Pediatric Clinic in Skopje which is the only institution that provides tertiary care and copes with this problem in our country. Results: Throughout a 45 years period (1965-2010) 43 patients (21 males and 22 females) were diagnosed with IPH, with an incidence of 0,38 per million yearly. Mean age at diagnosis was 6±3,64 years (range 0,25 to 15) with mean duration of follow up 77,86±100,65. The diagnosis was established through the evidence of recurrent pulmonary hemorrhages, associated with severe repetitive mycrocytic hypochromic anemia, and was confirmed by the detection of hemosiderin-laden macrophages in Perl reaction from gastric washings or bronchoalveolar lavage. Open lung biopsy was made just in one patient. Initial treatment consisted of prednisone in 40 patients (93%). Ten patients (23,2%) required long-term corticosteroid because of recurrent attacks; 19 patients (44,18%) required other immunosuppressants (Immuran or Leuceran) in addition to prednisone to control their hemoptysis. Ten patients died (9 of massive pulmonary hemorrhage and 1 from pneumonitis caused of Varicella) 1 to 12 years post diagnosis. Unfortunately, 23 patients were lost of evidence after mean follow up period of 50,04±49,08 months. Ten patients are alive: 2 with long term follow up of 35 and 27 years and being without treatment of 27 and 23 years respectively. Five year survival for IPH patients in our study was 78% (by Kaplan-Meier method). *Conclusions*. Pediatricians should raise suspicion for intrapulmonary bleeding in a patient who has recurrent dyspnea, hemoptysis and iron deficiency anemia. Our results show that long-term survival in IPH is possible with introducing early and long-term immunosuppressive therapy.

THE USE OF RECOMBINANT HUMAN ERYTHROPOIETIN IN ANEMIC PATIENTS WITH LUNG TUBERCULOSIS (PILOT STUDY)

G Demikhov1, V Inyakova1, N Dolzhenko2, F Morshchakova1

1Fed Research Center for Pediatric Hematology, Ryazan, Russian Federation
2Ryazan Regional Tuberculosis Hospital, Ryazan, Russian Federation

Tuberculosis (TB) is chronic infection which widespread in Russia and other countries. Hematological disorders are relation to chronic infections well known. But data about pathogenesis and treatment of anemia in TB patients are inadequate. To investigate a prevalence of anemia and erythropoiesis in TB infection patients we have observed 70 adults with lung TB. We determined Hb concentration, reticulocyte count, erythrocyte indexes (MCV, RDW), serum iron, total iron binding capacity and serum ferritin concentrations. Erythropoietin (EPO) values were measured immunoenzymometrically by using ELISA-EPO (IBL, Germany) kits. The adequacy of EPO level in relation to the degree of anemia was evaluated individually by computing the ratio between the logarithm of the observed value and the logarithm of the expected result O/E log (EPO) ratio according to the regression line constructed with the control group. Control group consisted of 27 iron deficiency anemia (IDA) patients. Total 8 patients of all detected anemic TB patients were treated with recombinant human erythropoietin (rHuEPO)(epoietin-alfa). Of 8 treated patients 6 were males and 2 patients were females. All patients received 300 IU/kg of rHu-EPO three times per week subcutaneously during 5-6 weeks. Anemia was detected in 40 (57,1%) of 70 adult patients. IDA was registered in 27,5% of anemic adults only. All other low Hb patients had anemia of inflammation. All anemic patients (both IDA and anemia of inflammation) showed inadequately low EPO production to degree of the anemia. As compared with controls, the mean O/E log (EPO) ratio was significantly lower in all anemic TB patients (0.63 vs. 1.0 in IDA controls). Six (75%) out of 8 patients showed a complete response to rHuEPO therapy, with Hb reaching normal levels within the first 4 weeks of the treatment. All 8 anemic TB patients, treated with rHu-EPO, showed complete reticulocyte reactions. We did not observe any adverse or side effects during the therapy with rHu-EPO. Thus anemia is widespread in adult lung TB patients. Main cause of low Hb in adult TB patients is anemia of inflammation. Inadequately low EPO production to degree of the anemia in TB patients is pathogenetic substantiation of erythropoiesis-stimulating agent's (ESA) therapy. Results of the pilot study demonstrated high effectiveness of rHuEPO therapy of anemic TB patients. We speculate that increased Hb level isn't the one benefit of rHuEPO therapy in these patients. Other advantage of the rHuEPO therapy seem is an improvement of quality of life them, so far as this effect is typical for all ESA. We hope that ESA therapy will be to improve outcomes and prognosis in anemic TB patients too.

1576

THROMBOPHILIC STATUS IN ASYMPTOMATIC GREEK CHILDREN AND YOUNG ADULTS PATIENTS WITH BETA THALASSEMIA INTERMEDIA

A Teli, M Economou, A Kondou, I Tsatra, N Gombakis, D Zafeiriou, E Kontopoulos, M Athanassiou-Metaxa

Hippokration General Hospital, Thessaloniki, Greece

Backround: Beta thalassemia is known to be characterized by a hypercoagulable state, with prothrombotic factors present and thrombotic events development in a number of patients. Aim: The aim of the present study was to evaluate the frequency of coagulation abnormalities in young asymptomatic patients with thalassemia intermedia. Methods: In this prospective study, 25 non transfused young patients were evaluated. The study group consisted of 12 (48%) boys and 13 (52%) girls, with an average age of 11.8±4.6 years (range 4.5 - 20 years), a mean hemoglobin value of 9.34±1.4g/dl, a mean hematocrit value of 29.01±4.4%, a median PLT value of 378000/ml (range 253000- 1179000) and a median serum ferritin value of 66 ng/ml (range 20-967). Of those examined, 6/24 (25%) had undergone splenectomy. Laboratory tests included prothrombin time (PT), activated partial thromboplastin time (aPTT), antithrombin III (ATIII), protein S (PS), protein C (PC), activated protein C resistance (APCR), fibrinogen, prothrombin fragment (F 1 + 2), thrombin-antithrombin complex (TAT), fibrinolysis products (D-dimmers), lupus anticoagulant (LA), anti-cardiolipin antibodies (ACA), beta 2 glucoprotein I antibodies (anti- β2 GPI- I) and genomic testing of MTHFR C677T, Factor V Leiden G1691A and Factor II G20210 mutations. Results: Normal findings resulted from prothrombin and partial thromboplastin time, fibrinogen and activated protein C resistance value testing. Anti-phospholipid antibodies were negative in all patients. With regards to natural coagulation inhibitors, low activity was found for ATIII, PC and PS in 4%, 56% and 48% of patients, with mean values of 92.3±11.2%, 69.6±14.8% and 66.3±14.1%, respectively. Increased d-dimers, as well as TAT and F1+2 values were found in 12%, 60% and 12% of patients, with median values of 182 (93-1462)ng/ml, 5.1(1-96)μgr/l and 135(71-1155)pmol/l, respectively. Heterozygosity and homozygosity for the MTHFR C677T mutation was found in 48% and 12% of patients, whereas heterozygosity for FV Leiden G1691A and G20210FII was found in 8% and 12.% of patients, respectively. Double heterozygosity for MTHFR/ FV Leiden and MTHFR/ G20210II mutations was found in 16% of patients. Conclusions: The original feature in the present study lies in the population characteristics of young asymptomatic patients with beta thalassemia intermedia of greek origin. The study results confirm the presence of haemostatic changes in patients with beta thalassemia intermedia, starting at an early age. Additionally, increased prevelence of thrombophilic mutations in the study group compared to Greek population is observed, adding to the risk of thrombotic event development.

1577

LEFT VENTRICULAR VOLUMES, MASS AND FUNCTION NORMALIZED TO THE BODY SURFACE AREA, AGE AND GENDER FROM CMR IN A LARGE COHORT OF WELL-TREATED THALASSEMIA MAJOR PATIENTS WITHOUT MYOCARDIAL IRON OVERLOAD

A Meloni,[1] G Aquaro,[1] P Festa,[1] F Gagliardotto,[2] A Zuccarelli,[3]

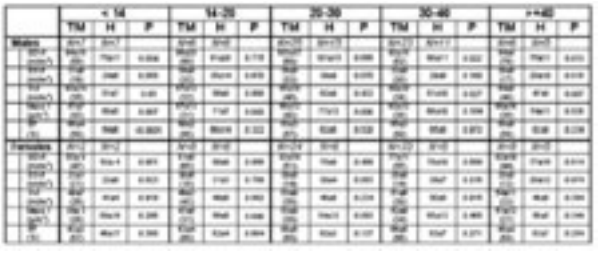
Background. Cardiovascular Magnetic Resonance (CMR) allows an accurate and reproducible quantification of left ventricular (LV) parameters. In Thalassemia major (TM) patients different *normal* LV values have been reported due to chronic anemia and eventually pre-existing iron burdens. Moreover, in this population it is unknown the influence of sex and age on LV parameters and no ranges of normal have been reported using MASS® software. *Aims*. The aim of this study was to establish the ranges for normal LV volumes, mass and ejection fraction normalized to the influence of body surface area (BSA), age and sex from CMR in a large cohort of well-treated TM patients without myocardial iron overload. Materials. Among the 923 TM patients who underwent CMR within the MIOT network for the assessment of cardiac iron overload, function and fibrosis, we selected 142 patients with no known risk factors or history of cardiac disease, normal electrocardiogram, no myocardial fibrosis and no myocardial iron overload (all the cardiac segments with a normal T2* value).



Moreover, we studied 71 healthy subjects matched for age and sex. LV function parameters were quantitatively evaluated in a standard way by SSFP cine images using MASS® software. LV end-diastolic volume, end-systolic volume, stroke volume, and mass were normalized to BSA (EDVI, ESVI, SVI, massI). Results. Table 1 shows the comparison of the CMR parameters with differentiation for sex and age in TM patients and healthy subjects and the cut-off of normality defined as mean - 2 standard deviation (SD). TM patients showed significantly lower BSA than the controls (P<0.0001). Significantly higher EDVI and SVI were found only for males < 14 years and > 30 years. Significantly higher LVEF were found only for males < 14 years. In TM patients all LV volumes indexes were significantly larger in males than in females (P<0.0001 in all cases). The EF was not different between the sexes. In males the ESVI and the EF were significant different among the age groups (P=0.006 and P=0.001, respectively). In females no significant differences were detected among the age groups. Conclusion. In a large cohort of well-treated TM patients significant differences in LV parameters compared to controls were limited to males < 14 years and > 30 years. Appropriate "normal"reference ranges normalized to BSA, sex and age should be used to avoid misdiagnosis of cardiomiopathy in TM patients.

Background. Cardiovascular Magnetic Resonance (CMR) has provided the opportunity to quantify right ventricular (RV) parameters with excellent reproducibility and accuracy. The role of the RV is gaining ground in thalassemia major (TM) patients and this population could experience different *normal* RV values due to chronic anemia and eventually pre-existing iron burdens. Aims. The aim of this study was to establish the ranges for normal RV volumes, mass and ejection fraction (EF) normalized to the influence of body surface area (BSA), age and sex from CMR in a large cohort of well-treated TM patients without myocardial iron overload. Materials. Among the 923 TM patients enrolled in the Myocardial Iron Overload (MIOT) network who underwent CMR for the assessment of cardiac iron overload, function and fibrosis, we selected 142 patients with no known risk factors or history of cardiac disease, normal electrocardiogram, no myocardial iron overload (all the cardiac segments with a normal T2* value) and no myocardial fibrosis.

All patients had been regularly transfused and chelated since early childhood. Moreover, we studied 71 healthy subjects matched for age and sex. RV function parameters were quantitatively evaluated in a standard way by SSFP cine images using MASS® software. RV end-diastolic volume (EDV), end-systolic volume (ESV) and stroke volume (SV) were normalized by body surface area (EDVI, ESVI, SVI). Results. Table 1 shows the comparison of the CMR parameters with differentiation for sex and age in TM patients and healthy subjects and the cut-off of normality defined as mean - 2 standard deviation (SD). TM patients showed significantly lower BSA than the controls (P<0.0001). TM males (except age group 14-20 yrs) showed significantly higher RV EF compared to controls. In TM patients all LV volumes indexes were significantly larger in males than in females (P<0.0001 in all age groups). The EF was not different between the sexes. In males as well as in females the RV volumes were no significant different among the age groups, while in males the EF was significant different (P=0.004). Conclusion. In a large cohort of well-treated TM patients males showed significantly higher RV EF compared to controls. Appropriate "normal"reference ranges normalized to BSA, sex and age should be used to avoid misdiagnosis of cardiomiopathy in the clinical arena in TM patients.

Background. Renal dysfunction, mainly caused by the is the iron overload consequent to regular transfusions, is frequently detected in adult

subjects with thalassemia .Multiecho T2* MRI is a well-established technique for iron overload assessment in heart and liver but there are very few reports concerning the kidneys in both healthy subjects and transfused patients. *Aims*. Our aims were to assess the feasibility and reproducibility of the MRI technique for measuring kidneys T2* values, to establish the lower limit of normal in a cohort of healthy subjects and to correlate the obtained values with age and gender. Methods. Twenty healthy subjects (13 men and 7 women, mean age 29.1 ± 7.2 years) underwent MRI exam. One transverse slice through the kidneys was obtained by a T2* gradient-echo multiecho sequence. T2* measurement was performed with a previously validated software program (HIPPOMIOT IFC-CNR®). For each kidney, T2* values were calculated in three different regions of interest. The ROI T2* values were averaged to obtain a representative value for both kidneys. The mean kidney T2* value was also calculated. The lower limit of normal for the T2* value was calculated on log-transformed data as mean minus 2 standard deviations. Results. Measurement of renal T2* values was feasible in all subjects. Average processing time was about 2 minutes. For the mean T2* value the coefficient of variability (CoV) and the intraclass coefficient correlation (ICC) were respectively 6% and 0.9 for the intra-operator reproducibility and respectively 12% and 0.8 for the inter-operator reproducibility. There was not a significant difference between left and right kidney T2* values (53.1 ± 8.1 ms vs 51.5 ± 9.0 ms; P = 0.183). The lower limit of normal for the mean kidney T2* value was 36 ms. The mean kidney T2* value did not show a significant difference between men and women (men 50.6 ± 8.9 ms vs women 55.6 ± 5.7 ms, P=0.153). There was no correlation between mean kidney T2* value and age (r=-0.049; P=0.838). Conclusions. In conclusion, renal T2* measurements appear to be feasible, reproducible, non-time-consuming and reliable. The renal T2* values in healthy subjects were independent of age and gender. This approach can be extended to thalassemia patients.

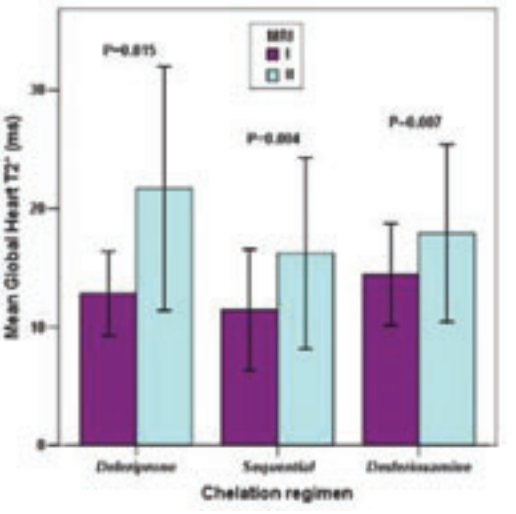
Background: Magnetic Resonance (MR) is the unique non invasive suitable technique to evaluate quantitatively the changes in cardiac and hepatic iron and in cardiac function in thalassemia major (TM) patients under different chelation regimens. Aims: Our aim was to prospectively assess the efficacy of the sequential deferiprone-deferrioxamine (DFP-DFO) versus deferiprone (DFP) and deferrioxamine (DFO) in monotherapy in a large cohort of TM patients by quantitative MR. Methods: Among the first 1135 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, 392 patients performed a MR follow up study at 18±3 months. We evaluated prospectively the 35 patients treated with DFP-DFO versus the 39 patients treated with DFP and the 74 patients treated with DFO between the 2 MR scans. Iron concentrations were measured by T2* multiecho technique. Biventricular function parameters were quantitatively evaluated by cine images. Results: Excellent/good levels of compliance were similar in the DFP-DFO (97.1%) versus DFP (94.9%) and DFO (95.9%) groups. No significant differences were found in the frequency of side effects in DFP-DFO (15.6%) versus DFP group (9.4%) .



The percentage of patients who maintained a normal global heart T2* value (≥20 ms) was comparable between DFP-DFO (96%) versus DFP (100%) and DFO (98.1%) groups. Among the patients with myocardial iron overload (MIO) at baseline (global heart T2*<20 ms), in all three groups there was a significant improvement in the global heart T2* value (DFO-DFP: 4.8±3.9ms P=0.004, DFP: +8.8±8.6 ms P=0.015 and DFO: 3.7±5.5 ms P=0.007; Figure 1) and a reduction in the number of pathological segments (DFO-DFP: -3.2±3.8 P=0.026, DFP: -6.0±5.6 ms P=0.031 and DFO: -2.9±3.7 ms P=0.001). In DFO-DFP and DFP groups there was a significant increment in the left ventricular ejection fraction (EF) (4.3±5.1% P=0.035 and 5.0±6.4% P=0.045, respectively) as well as in the right ventricular EF (6.7±6.6% P=0.017 and 6.8±3.7% P=0.001, respectively). The improvement in the global heart T2* and in biventricular function were not significantly different in DFO-DFP compared to the other groups. Among the patients with hepatic iron at baseline (T2*<9.2 ms), only in DFO group there was a significant improvement in the liver T2* value (2.0±3.5 ms P=0.010). Liver T2*changes were not significantly different in DFO-DFP versus the other groups. Conclusions: Prospectively we did not find significant differences on cardiac and hepatic iron or in cardiac function in TM patients treated with sequential DFP-DFO versus the TM patients treated with DFO or DFP in monotherapy.

Background. Using T2* Magnetic Resonance (MR) a randomized placebo controlled study from Sardinia demonstrated combination therapy with deferiprone and desferrioxamine (DFP+DFO) significantly more effective than DFO in improving myocardial iron. One non-randomized study from Sardinia and one observational study from Greece seem to confirm for DFP+DFO therapy the most rapid clearance of cardiac iron. No data are available in literature about prospective comparisons on cardiac iron and function and liver iron in TM patients treated with DFP+DFO versus DFP and DFO in monotherapy. *Aims*. The aim of our multi-centre study was to assess prospectively in a large clinical setting the efficacy of the DFP+DFO versus DFP and DFO in TM patients by quantitative MR. Methods: Among the 1135 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network we selected those with an MR follow up study at 18? 3 months who had been received one chelator alone between the 2 MR scans We evaluated prospectively the 51 patients treated with DFP+DFO versus the 39 patients treated with DFP and the 74 patients treated. Iron overload was measured by T2* multiecho technique. Biventricular function parameters were quantitatively evaluated by cine images. *Results*. The dosages were: combined therapy DFP 61.9±24.3 mg/kg per 6.1±1.4 days/week and DFO 40.7±6.0 per 3.5±1.1 days/week; DFP 73±13 mg/kg per 6.1±1.4 days/week; DFO 40.7±6.5 per 5.4±0.93 days/week. Excellent/good levels of compliance were comparable in the DFP+DFO (90.2%) versus DFP (94.9%) and DFO (95.9%) groups. The percentage of patients who maintained a normal global heart T2* value (≥20 ms) was comparable between DFP+DFO (96%) versus (100%) and DFO (98.1%) groups. Among the patients with myocardial iron overload (MIO) at baseline (global heart T2*<20 ms), in all three groups there was a significant improvement in the global heart T2* value (DFO+DFP:+4.5±6.1 ms P=0.001, DFP:+8.8±8.6 ms P=0.015 and DFO:3.7±5.5 ms P=0.007; Figure 1) and a reduction in the number of pathological segments (DFO+DFP:-2.4±3.8 P=0.004, DFP:-6.0±5.6 ms P=0.031 and DFO:-2.9±3.7 ms P=0.001). A significant improvement in the left systolic function was found only in DFP (+5.0±6.4% P=0.045) group. A significant improvement in the right systolic function was found in DFP+DFO (3.2±6.7% P=0.024) and DFP (6.8±3.7% P=0.001) groups. The changes in the global heart T2* as well as in biventricular function were not significantly different in DFO+DFP versus DFO or DFP groups. Among the patients with hepatic iron at baseline (T2*<9.2 ms), changes in liver T2* in DFO+DFP group (4.9±6.0 ms) were significantly higher versus the DFO group (2.0±3.5 ms) (P=0.012) and at the limit of the significance versus DFP group (1.3±3.3 ms). *Conclusions*. Prospectively in TM patients at the dosages used in the clinical practice combined DFP+DFO did not show superior reduction in myocardial iron or better improvement in biventricular function in comparison to DFO or DFP monotherapy, but it showed a greater reduction in liver iron versus DFO group.

Background. Detection and monitoring of tissue iron overload represent the key clinical factor in the management of patients with iron loading anemias. The Magnetic Resonance Imaging (MRI) multiecho T2* performed at 1.5T scanners is the most available noninvasive technique to assess hepatic and cardiac iron content. However, recently high field scanners, primarily 3T scanners, have been installed widely and are used in the clinical setting, bringing the need to assess the feasibility and reproducibility of T2* measurements at 3T. Feasibility of T2* measurements at 3T was documented by several studies, but the reproducibility of T2* measurements at 3T has never been investigated. A good reproducibility is vitally important for longitudinal follow-up of patients and also greatly reduces the sample size required for research. Aim: This study aimed to evaluate the reproducibility of T2* measurements at 3T. *Methods*. 38 transfusion-dependent patients (22 males, 36 ± 7 years) underwent MRI for T2* assessment at 3T. A single transverse slice through the liver was acquired using a T2* GRE multiecho sequence. The T2* value was determined over a large ROI of standard dimension, chosen in a homogeneous area. Three parallel short-axis views of the left ventricle were obtained using T2* GRE multislice multiecho sequence. The left ventricle was segmented into a 16-segments standardized model and the T2* value on each segment was calculated as well as the global value and the mid-ventricular septum T2* value. MRI image analysis was performed using a custom-written, previously validated software (HIPPO MIOT®, IFC-CNR). To assess the reproducibility of T2* values, data related to 20 patients were randomly selected from the entire data set. To evaluate the intra-observer variability, the 20 images were blindly reanalysed by the same observer who analysed the entire data set after two weeks. To evaluate the inter-observer variability, the selected images were presented in random order to an other operator, who didn't know the results obtained by the other one. The difference between two different analyses was evaluated by calculating the coefficient of variation (CoV) and the interclass correlation coefficient (ICC). The CoV was calculated as the ratio of the SD of the half mean square of the differences between the repeated values, to the general mean. The ICC was obtained from a two-way random effects model with measures of absolute agreement. An ICC ≥ 0.75 was considered excellent, between 0.40 and 0.75 good, and < 0.40 unsatisfactory. Results: The results of the intra- and inter-observer variability analysis performed in the selected images acquired at 3T are summarized in Table 1. An excellent ICC was always obtained (>0.929).

Table 1. Reproducibility data for T2* values at 3T.

	Intra-observer reproducibility		Inter-observer reproducibility	
	ICC	CoV (%)	ICC	CoV (%)
Liver	0.999	4.69	0.998	6.17
Global heart	0.998	2.53	0.995	3.82
Mid-ventricular septum	0.994	4.86	0.988	6.62
Segment basal anterior	0.967	12.51	0.931	15.69
Segment basal anteroseptal	0.994	7.04	0.986	9.27
Segment basal inferoseptal	0.989	6.47	0.977	8.52
Segment basal inferior	0.971	10.73	0.931	15.57
Segment basal inferolateral	0.958	11.79	0.899	16.92
Segment basal anterolateral	0.963	11.84	0.935	14.69
Segment medium anterior	0.977	9.70	0.973	10.07
Segment medium anteroseptal	0.988	6.96	0.980	8.27
Segment medium inferoseptal	0.986	7.10	0.991	5.33
Segment medium inferior	0.950	13.43	0.929	16.52
Segment medium inferolateral	0.964	10.84	0.961	11.07
Segment medium anterolateral	0.991	5.59	0.970	9.99
Segment apical anterior	0.976	10.25	0.965	12.33
Segment apical septal	0.996	4.05	0.970	11.11
Segment apical inferior	0.978	9.43	0.969	6.72
Segment apical lateral	0.994	4.77	0.983	8.14
All segments	0.979	8.94	0.965	11.39

Conclusions. The intra- and inter-operator reproducibility for T2* measurements at 3T were very good and comparable with these ones previously found for T2* measurements at 1.5T. As expected, the coefficient of variation for the global heart T2* was the smallest, due to a "compensation"of outliers that may lead to high variability in a single segment measurement.

1583

PREVALENCE SURVEY OF HAEMOGLOBINOPATHIES AND IRON DEFICIENCY AMONG NATIVES AND IMMIGRANTS PREGNANT WOMEN. ONE YEAR REFERRALS IN HAEMOGLOBINOPATHY PREVENTION IN NORTHERN GREECE

S Theodoridou,[1] F Klonizakis,[1] A Paraschou,[1] T Vyzantiadis,[2] O Karakasidou,[1] V Aletra,[1] E Lefkou,[1] G Koleonidis,[1] M Alemayehou[1]

[1]*Hippokration Hospital, Thessaloniki, Greece*

[2]*Aristotelion University, Thessaloniki, Greece*

Haemoglobinopathies constitute the most frequent monogenic disorders worldwide and Thalassaemias are the most frequent genetic disorders in Greece. The risk of giving birth to a thalassaemic child depends on the incidence of the thalassaemic gene in the population under study. The aim of the study was to determine the prevalence of haemoglobinopathies and iron deficiency in Greek pregnant women and in immigrant pregnant women and their haematological characteristics and epidemiological issues. The carrier identification was carried out by a standard scheme, which included, CBC and red cell indices using the Coulter ONYX, a Cation Exchange HPLC variant system (Bio-Rad, Variant β-Thalassemia Short Program), to determine HbA, HbA2 and HbF levels. The different abnormal structural haemoglobins were investigated by electrophoretic techniques both at alkaline pH on cellulose acetate and at acid pH on citrate agar. Sickling test and tests for HbH inclusion bodies were also performed. Haemoglobin A2 was also quantified by column micro chromatography and serum ferritin levels were measured by micro Elisa technique. 664 pregnant women were recruited in the study. 376 (56.6%) of them were native Greek women and 288 (43.4) were immigrants. 396 (59.6%) were at the first trimester of pregnancy, 226 (34.4%) were examined at the second trimester and 38 (6%)at the third trimester. 353 of the pregnant women that were tested in the first trimester had hemoglobin levels more than 11gr/d, 37 had hemoglobin levels from 9 to 10.9 gr/dl and 6 had hemoglobin levels less than 9 gr/dl. The hemoglobin levels of pregnant women during the second trimester was more than l0.5 gr/dl in 199 women, from 9 to 10.4 gr/dl in 22, and less than 9 gr/dl in 5 of them. The hemoglobin levels of pregnant women in the third trimester was more than 11gr/dl in 20 of them, from 9 to 10.9 gr/dl in 14 and less than 9 gr/dl in 4 of them. Iron deficiency with ferritin levels less than 12 ng/ml had 213 (32.1%) women, while 131 (19.7%) had 12-20 ng/ml, 272 (41%) of them had ferritin from 20 to 50 ng/ml and 48 (7.2%) had more than 80 ng/ml ferritin levels. Native pregnant women were found to have higher levels of ferritin in all trimesters and this was statistically significant p=0.000. We found that the number of the native pregnant women that are examined at the first trimester is statistically significant in comparison to immigrant pregnant women (263 to 133, p=0.000).The mean age of the native women was 28.7± 5.6 years in comparison to 26.68 ±5.3 years p=0.000. 575 (86,6%) of the pregnant women did not carry any haemoglobinopathies, 75 (11,4%) carried a beta thalassemic gene , 13 (1.85%) were found carriers of sickle cell gene, one carrier (0.15%) of hemoglobin D. Native pregnant women seem to ask for consultation earlier in pregnancy, are older in age and have higher incidence of thalassemic genes. The effective prevention and management of haemoglobinopathies in Greece will depend on the integrated community-based programs for education, carrier screening and genetic counseling.

Hereditary Spherocytosis (HS) ranges from asymptomatic to a life-threatening transfusion-dependent anemia. Splenectomy corrects the anemia, though the intrinsic erythrocyte membrane defect persists. Our aim was to study how the anemia, erythropoiesis and iron status were affected in HS patients after splenectomy, in accordance with the HS severity presented prior to splenectomy, to ascertain if patient's improvement could be related to the clinical severity experienced before spleen removal. In 60 HS patients (43 splenectomized and 22 unsplenectomized) and 35 controls, we performed a basic hematological study, osmotic fragility (OF) test and reticulocyte count; determined the plasma levels of bilirubin, erythropoietin (EPO), soluble transferrin receptor (sTfR), folic acid, vitamin B12, iron, ferritin, and transferrin; and calculated reticulocyte production index (RPI). Our data showed that splenectomy lead to correction of the anemia (normal values of erythrocytes, hemoglobin and hematocrit), however mean cell hemoglobin concentration (MCHC) sustained its high value and OF was higher in splenectomized than in unsplenectomized patients; red cell distribution width (RDW), bilirubin, EPO, sTfR, reticulocytes, RPI, folic acid, vitamin B12, iron, ferritin, transferrin, were reduced in relation to unsplenectomized, though significantly higher than controls. In splenectomized patients erythrocytes, hemoglobin concentration and hematocrit presented a trend to decrease with worsening of HS (as classified prior to splenectomy) and bilirubin and OF a trend to increase. In summary, splenectomy lead to a correction in the anemia and this improvement seems related to the severity of HS prior to splenectomy.

INTRAVENOUS IRON MONOTHERAPY FOR THE TREATMENT OF NON-IRON DEFICIENCY ANEMIA IN CANCER PATIENTS UNDERGOING CHEMOTHERAPY

A Al-Sadi, A Bani-Mustafa, R Eljaber, S Abbasi, H Abdulelah, H Abdel-Razeq

King Hussein Cancer Center, Amman, Jordan

Background. Anemia is a common complication of malignancy, occurring in over 50% of patients and may increase to more than 90% in patients with certain types of cancer and in those undergoing chemotherapy or radiation therapy. Anemia often enhances symptoms of fatigue, weakness, and dyspnea and thus, it may worsen Quality of life (QOL) and performance status in cancer patients. Blood transfusion is an effective way to treat anemia, but the effect is often temporary, and is linked to many serious adverse effects. Erythropoiesis-stimulating agents (ESA) produce significant increase in Hb level, decrease transfusion requirements, and improve QOL. However, 30-50% of patients do not respond. Additionally, many concerns were recently raised over the routine use of ESA to treat anemia in cancer patients; in several studies, ESAs were found to shorten overall survival or time to tumor progression. Aims: This trial will assess the efficacy and feasibility of IV iron therapy in cancer patients with non-iron deficiency anemia who are undergoing treatment with chemotherapy or radiation therapy without the use of ESAs. The study was approved by the Institutional Review Board (IRB) and informed consents were obtained. Methods: Adult patients with solid cancers and non-iron deficiency anemia (hemoglobin (Hb) level < 11 g/dL, ferritin level > 100 ng/ml, transferrin saturation > 20%, with normal folate and vitamin B12 levels) who are receiving anti-cancer treatment with chemotherapy and or radiation therapy were included in the study. Anemia related to hemolysis, bleeding, or bone marrow infiltrations were excluded. All patients received 200 mg of ferrous sucrose given in short intravenous (I.V) infusion weekly for a total of 12 weeks without the use of ESAs, blood transfusion, or other supplements. Hb level was measured at baseline, every 3 weeks, and at week 14. Adverse events related to IV iron were prospectively reported. Results: During the study period, 19 patients (14 females, 5 males) were included. The mean age (+ SD) was 58 (+ 10.2) years. All patients had cancer and were on active chemotherapy; 3 patients withdrew from the study at week 1, 4 and 6; convenience was the only reason in all. Three other patients were transfused while on iron therapy and considered as treatment failure. Thirteen patients had at least 8 weeks of IV iron therapy (10 had full 12

weeks and 3 had 8 weeks). The mean Hb level at baseline was 9.6 g/dL. Two weeks following the last dose of I.0V iron therapy, 9 (56.3%) patients had more than1.0 gm increase in their Hb while 3 (18.6%) others had <1.0 gm increment. The mean Hb level following completion of treatment was 11.8 g/dL; an overall mean increase by 1.9 (0.8, 5.3). No therapy-related toxicities were reported among all patients. *Conclusions.* IV iron treatment alone is safe and can reduce blood transfusion requirements and improve Hb levels in cancer patients undergoing anti-cancer therapy. This approach requires further randomized studies.

1586

THE RELATIONSHIP OF MEGALOBLASTIC ANEMIA AND THYROID FUNCTION DISORDERS BETWEEN GENDER AND MENAPAUSE

F Gok,[1] U Ergene,[2] D Özbalci,[2] B Ozyurt[3]
[1]*Celal Bayar University Medical Faculty Department of Internal Medicine, Manisa, Turkey*
[2]*Celal Bayar University Medical Faculty Department of Hematology, Manisa, Turkey*
[3]*Celal Bayar University Medical Faculty Department of Public Health, Manisa, Turkey*

Background. Megaloblastic anaemia (MA) preferentially affects cells with high metabolic turn-over such as hematopoietic precursors and gastrointestinal epithelium. Ageing is associated with thyroid function abnormalities and cobalamine deficiency that are mostly caused by autoimmune disorders leading to production abnormalities and gastric mucosa destruction respectively. *Aims*. In our study, we want to evaluate the relationship of MA and thyroid function disorders to sex and menopause. *Methods*. 157 patients (64 male, 93 female) who were deficient of either cobalamine and /or folic acid and had thyroid function abnormality were included in the study. Age, diet habits, smoking, medical history of all and menopause status of women patients were recorded. Hemogram, reticulocyte count, peripheral smear, cobalamine, folic acid, ferritin, serum iron, total iron binding capacity, homocystein, glucose, urea, creatinin, lipid profile, LDH, total biluribin, AST, ALT, ALKP, GGT, total protein, albumin, FT3, FT4, TSH, anti-thyroglobulin antibody, anti-microsomal antibody, PT and APTT of all patients were measured. FSH was sampled from women who had menopause. ECG and PA Chest X-Ray were evaluated in each patient. Patients who had been diagnosed as megaloblastic anaemia, thyroid function abnormalities, chronic renal failure, pregnant or lactation, coronary artery disease, diabetes mellitus, chronic liver disease were excluded from the study. Data were analysed by SPSS 13 for Windows. Pearson ki-square and Student's t test were used for statistical study. *Results*. 93 (59.2 %) cases were women and 64 (40.8 %) cases were men. 124 (79 %) cases had only MA and 33 (40, 3 %) cases had MA with thyroid dysfunction. MA only group, had more women than men and more premenopausal women then post-menopausal one but these were not statistically significant (p>0.05). 19 (20.5 %) of women had MA and thyroid dysfunction and 52.6 % of cases were in menopause and 47.4 % were not. MA were more common in women having menstrual cycle, but this has not reached statistical significance (p>0.05). The peak incidence of all cases was between 40-49 years old and mean age was 44.6 ± 15.4. In only MA group, 50 (40.3 %) of cases were under 40 years whereas 74 (59.7 %) of cases were over 40. MA was significantly higher in patients over 40 (p= 0.042). 33 cases were found in MA and thyroid dysfunction group; 7 (21.2 %) of them were under 40 years old and 26 (78.8 %) were over 40 and this was statistically significant (p=0.042). *Conclusions*. As a result; it was thought that regardless of sex and menopause status, all people after 45 years old should be examined for MA and thyroid dysfunction. It will be beneficial to make larger population studies in this field.

1587

FLOW CYTOMETRIC DETECTION OF PNH-LIKE CLONES ON PERIPHERAL BLOOD GRANULOCYTES IN PATIENTS WITH APLASTIC ANAEMIA IN PAEDIATRIC AGE GROUP

G Mokhtar, A Tantawy, D Ibrahim, M Sallam
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background: Aplastic anaemia (AA) and paroxysmal nocturnal hemoglobinuria (PNH) are both clonal bone marrow stem cell disorders with closely interlinked pathophysiology. Bone marrow failure has been regarded as one of the triad of clinical manifestations of PNH, and PNH in turn has been described to evolve in patients recovering from aplastic anemia. Several studies investigated the link between PNH and AA, but very few tested this link in pediatric age group. Subjects and Methods: In this study, the presence of CD55 and/or CD59 defective (PNH-like clone) peripheral blood granulocytes was evaluated in 30 newly diagnosed children with AA and in 20 healthy matched controls using flow cytometric immunophenotyping. Results: Minor population with deficiency of both CD55 and CD59 was detected in 8 cases (26.7%), while CD55 deficiency was detected in 4% of cases (13.3%) and CD59 deficiency in 5% of cases (16.7%). Conclusion: The results of this study highlight the strong association between AA and PNH. Expansion or regression of these PNH-like clones in response to therapy needs more evaluation in relation to disease outcome and response to immunosuppressive therapy.

CHANGES IN PLASMA LEVELS OF ADAMTS13 IN PAINFULL CRISIS AND ASYMPTOMATIC SICKLE CELL ANEMIA

A Tombak,[1] E Yengel,[2] N Tiftik[2]
[1]*Mersin University Medical Faculty, Mersin, Turkey*
[2]*Mersin University Medical Faculty Hematology Department, Mersin, Turkey*

Background. Sickle cell disease is a congenital disease with severe haemolytic anemia. This clinical statement is characterized with ischemic changes as a result of obstruction of vascular system by sickling erythrocytes. ADAMTS 13 (A Disintegrin and Metalloprotease with Thrombospondin type 1 repeats) is a metalloprotease that cleaves von Willebrand factor (vWF) multimers in plasma. Deficiency of ADAMTS 13 is the major pathogenic factor in thrombotic thrombocytopenic purpura (TTP). In some diseases in which thrombosis incidence is increased (ischemic stroke, ischemic heart disease, malignancies, collagen vascular disease etc.), ADAMTS 13 deficiency is reported. Aims:The aim of this study is to demonstrate if there is a relationship between ADAMTS 13 and painful crisis of SCA or not. Methods:Thirty sickle cell patients who admitted to emergency department for painful crisis and their controls after at least 1 month from the time of their painful crisis improved, and 30 healthy individuals were included to the study. The patients with acute coronary syndrome, renal disease, hepatic disease, malignancies, collagen vascular disease, active infections, acute inflamation (regardless of etiology), the patients using clopidogrel, ticlopidine, glycoprotein IIb/IIIa antagonist and pregnant women in which the levels of vWF and ADAMTS-13 can be affected were excluded from the study. The ADAMTS-13 and vWF antigen plasma levels were determined by ELISA method quantitatively. Results:The levels of vWF of the patient groups were found significantly higher than levels of the control groups (p=0.0001). There was no statistically difference when the ADAMTS-13 levels of both 2 groups were compared with the levels of the control group (p=0.295 and p=0.082). The ADAMTS-13 / vWF ratio was statistically significantly lower in both painful crisis and asymptomatic period when compared with the control group (p=0.0001). *Summary*. While there is no relationship detected between ADAMTS 13 and SCA, the high levels of vWF might be an indicator of vascular disease in patients with SCA.

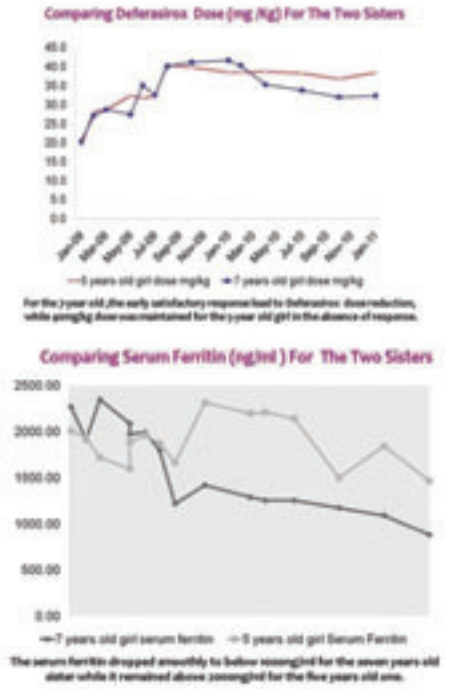
1589

ORAL IRON CHELATION CHALLENGES IN CHILDREN

K Belhoul,[1] M Bakir,[2] M Eldin,[2] A Kadhim,[2] M Eldin[1]
[1]*Dubai Health Authority, Dubai, United Arab Emirates*
[2]*Thalassemia Center, Dubai, United Arab Emirates*

Background. The availability of oral iron chelation therapy signifies a notable change in clinical practice that has relieved patients undergoing chronic blood transfusion from the burden of desferrioxamine infusions. Despite this, getting children on chronic blood transfusion to take iron chelation therapy regularly is still challenging for clinicians and parents. *Aims*. The aim of this case review is to present some of the challenges faced by doctors who deal with iron overload and oral chelation therapy in children. Making few suggestions and recommendation was another goal. Method. This was a case review analysis in which two sisters, five and seven years old , suffering from b-Thalassemia major and undergoing regular blood transfusion were monitored closely to follow their response to deferasirox, an oral iron chelator. This was in a form of file review as well as regular meeting with patients and parents. *Results*. These two sisters shared the same genetic background, diet, motivational tool (star chart), dose of deferasirox, and followed up at the same center to receive the same volume of blood per kg every three weeks. In spite of having all these similarities, they responded differently and the serum ferritin dropped smoothly to below 1000ng/ml for the seven years old sister while it remained above 2000ng/ml for the five

years old sister. For the younger girl (5-year old) it was reported by parents that it was difficult to get her to drink the full amount of the medicine.



We observed that low body weight for the girl made it hard to maintain the ideal deferasirox dose as any increment using the available tablet strength causes significant change in dose per kilogram. Producing lower tablet strength may help make dose adjustment easier in children. High deferasirox clearance in children between two to six years was reported in early clinical studies and could be contributing to the younger girl slow response. This has raised the question of the benefit of dividing deferasirox dose in children below five years to get a better control. *Summary*. Oral iron chelation therapy carries its own challenges in children on chronic blood transfusion. Children are resistant to drink the full amount of deferasirox and adjusting the dose utilizing the available tablets' strength has been challenging. Increased deferasirox clearance in children below five years may raise the question of the benefit of dividing deferasirox dose to get to a better control. The use of star chart as a motivational tool is old but still found to be effective in improving medication compliance among our chronically transfused young patients. Observing the individuality of each patient is warranted as each patient is unique and therapy need to be tailored to suit him.

1590

CLINICAL OUTCOME OF PATIENTS WITH MYELOPHTHISIC ANEMIA ARISING FROM ADVANCED GASTRIC CANCER

KH Kim, JY Kwon, J Yun, HJ Kim, SH Kim, HJ Kim, SC Lee, SB Bae, CK Kim, NS Lee, KT Lee, DS Hong, HS Park
Soonchunhyang University Hospital, Seoul, South-Korea

Background. Although it is not common to encounter patients with myelophthisic anemia arising from advanced gastric cancer, clinical features and optimal treatment are not yet to be elucidated. Prognosis for gastric cancer patients with bone marrow metastases is extremely poor. The current study was performed to evaluate clinical outcome of patients with myelophthisic anemia arising from advanced gastric cancer. Methods We retrospectively reviewed the medical records of 26 advanced gastric cancer patients with bone marrow metastases between September 1986 and February 2009 at Soonchunhyang University Hospital. Results The median age was 46 years (range 24-61 yeras). All patients had poorly differentiated adenocarcinoma, including 17 signet ring cell carcinomas. The majority of the patients showed thrombocytopenia, anemia, and elevation of lactate dehydrogenase. Sixteen patients (61.5%) were received palliative chemotherapy with a median of 4 cycles. (range, 1-13 cycles). Median survival durations after bone marrow metastases for entire patients were 37 days (95% CI, 12.5-61.5 days). The median survival times from bone marrow involvement were 11 days in the best supportive care group (range 9.5-12.5 days) and 121 days (range 94.7-147.3 days) in the palliative chemotherapy group (p <0.001). Patients died of tumor progression (11 patients, 45%), brain hemorrhage (6 patients, 25%), infection (5 patients, 21%), and DIC (1 patient, 4%). There were no chemotherapy related deaths. *Conclusions.* It is difficult to decide whether to proceed with aggressive treatment for gastric cancer patients with bone marrow metastases because of the hematologic findings, e.g. anemia, thrombocytopenia, and DIC. However, this study suggests that palliative chemotherapy should be actively considered in patients with myelophthisic anemia arising from advanced gastric cancer.

1591

PULMONARY HYPERTENSION IN SICKLE CELL DISEASE: STUDY OF 137 PATIENTS RANDOMLY SELECTED FROM A PUBLIC HEMATOLOGY HOSPITAL IN RIO DE JANEIRO, BRAZIL

C Lobo,[1] J Pinto,[2] B Morcerf,[3] P Chelles,[1] E Castro,[1] AM Mach,[1] R Abelha[1]
[1]*Instituto Estadual de Hematologia Arthur de Siqueira Cavalcanti - HEMORIO, Rio de Janeiro, Brazil*
[2]*Instituto Estadual de Hematologia - HEMORIO, UNIRIO, Rio de Janeiro, Brazil*
[3]*ECOR, Rio de Janeiro, Brazil*

Background. Sickle cell disease (SCD) is the most common monogenetic inherited hemoglobin disorders worldwide. Pulmonary Hypertension (PH) is one of the leading causes of morbidity and mortality and, in the other hand, hemolytic disorders are potentially among the most common causes of pulmonary hypertension. The pathogenesis of pulmonary hypertension in hemolytic disorders is multifactorial, including hemolysis, impaired nitric oxide bioavailability, chronic hypoxemia, chronic vosoclusives episodes, chronic liver disease, and asplenia. *Methods*. We randomly select 150 patients who have been assisted in the emergency room of Instituto Estadual de Hematologia Arthur de Siqueira Cavalcanti (HEMORIO), a public hematology hospital of State of Rio de Janeiro, Brazil, from 2009 June to 2010 August. Thirteen was excluded from the analysis, ten who did not show up to echocardiography, two who suffer at least one episode of acute chest syndrome (one of the exclude criterion) and one who die. Patients signed the informed consent to participate. *Results.* The majority was SS genotype (90%). The mean age was 30.9 ranging from 13 to 60 years old. The male/female ratio was 1.6, 62% of male and 38% of female. PH was diagnosed by echocardiogram. We consider PH when tricuspid regurgitant jet velocity (TRV) ≥ 2.5m/s which correspond to a pulmonary artery systolic pressure of approximately 30-39 mm Hg. 27% was classified as having mild PH (TRV between 2.5 and 2.9m/s), 5.1% as having moderate to severe PH (TRV > 3.0m/s). We could not classify 3 patients because they have not TRV despite they have others signs of PH. There was no significant difference between genders. A logistic regression was performed to estimate the effect of lactate dehydrogenase (LDH), the use of Hydroxyurea (HU) and the age on the prognosis of PH. Aging is related to increase in the incidence of PH (OR=1.05 CI95%=1.01 to1.09). Elevation of the plasma LDH is followed by a little increase of the incidence in PH and should not be a predictor in this sample. HU confers protection (OR = 0.33 IC95% = 0.12 to 0.81). In contrast to patients with traditional forms of pulmonary arterial hypertension, patients with hemolytic disorders have a mild-to-moderate degree of elevation in mean pulmonary pressures, with mild elevations in pulmonary vascular resistance. *Conclusions.* The hemodynamic etiology of pulmonary hypertension in these patients is multifactorial and includes pulmonary arterial hypertension, pulmonary venous hypertension, and pulmonary hypertension secondary to a hyper dynamic state. Currently, there are limited data on the effects of any specific treatment modality for pulmonary hypertension in patients with hemolytic disorders. This data suggest that HU could improve the outcome of SCD patients with PH.

1592

COMPARISON OF HBA2 QUANTITATION BY HPLC AND CE TO DETERMINE THE SEVERITY OF BETA GLOBIN GENE MUATATION IN THALASSAEMIA TRAIT

L Mikkelsen, D Felbab, S Bevan, C Whittington, B Kaya, P Telfer, F Cotter
Barts and the Royal London NHS Trust, London, UK

Background. Thalassaemia is a group of inherited disorders of haemoglobins characterised by a significant decrease in the rate of synthesis of one or more globin chains, which in beta thalassaemia will be the beta chain. In adults the haemoglobin A2 (HbA2) comprises 2-3.5% of total haemoglobin. In some patients the proportion of HbA2 is raised. This is diagnostic for beta thalassaemia trait, but can also be seen in some unstable haemoglobins. Mutations which cause decreased β-globin gene expression are classified as either β+ (reduced level of β-globin synthesis) or β0 (no β-globin synthesis). Aim In this study the HbA2 was quantified using two different methods, capillary zone electrophoresis (CE) and high-pressure liquid chromatography (HPLC). The results was correlated with the mutations found via β globin gene sequencing in order to establish whether or not quantitation of HbA2 by either method can be used to predict the β-globin mutation type (β+ or β0). Method The CE, HPLC and β globin gene sequencing were used to evaluate a total of 31 subjects with HbA2 > 3.5% (indicative of beta thalassemia trait). Results The HbA2 results produced by CE were statistically significantly lower than those obtained by HPLC when compared using a paired t-test (p= <0.001). Three of the thirty one patients were found not to have any common beta globin gene mutations, but were included as the HPLC showed an HbA2 percentage of 3.6, 3.7 and 3.9 respectively. Out of the 31 patients, 8 cases were diagnosed as having heterozygous β0 mutations including 4 patients with codons 41/42 (-TTCT) mutations, 2 patients with codons 8/9 (+G) mutations, 1 patient with a codon 15 (-T) mutation and 1 patient with a codon 39 (CAG-TAG) mutation. Twenty patients were found to be heterozygous for β+ mutations including 8 patients with IVS-1-5 (G-C) mutations, 6 patients with IVS-1-110 (G-A) mutations, 3 patients with -29 (A-G) mutations, 2 patients with -88 (C-T) mutations and 1 patient with an IVS-I-6 (T-C) mutation. When compared using the students t-test there was no difference between the HbA2 results obtained using HPLC for the β+ and β0 mutations cohorts (p=0.06). The same comparison performed using the HbA2 results obtained using CE showed a statistically significant difference between the β+ and β0 mutation cohorts (p=0.02). The predictive values of the measurement of HbA2 in establishing whether a patient has a β+ or β0 mutation calculated using Receiver operating characteristic (ROC) curves are 0.701 and 0.763 for HPLC and CE respectively. *Summary/Conclusion.* From the results of this study the CE is more sensitive in distinguishing between β+ and β0 mutations. Although this difference is relatively modest it is suggestive of a trend which may be more profound if the cohort was larger. The HbA2 level was significantly lower with the CE analyser. No attempt was made to compare the different β+ and β0 mutations as the sample size was insufficient.

1593

MOLECULAR CHARACTERIZATION OF BETA-THALASSEMIA AND HEMOGLOBIN VARIANTS IN THE CZECH AND SLOVAK POPULATIONS: AN UPDATE

M Divoka,[1] M Partschova,[2] R Mojzikova,[2] L Piterkova,[2]
M Horvathova,[2] J Cermak,[3] D Pospisilova,[1] K Indrak,[1] V Divoky[2]
1Faculty Hospital, Olomouc, Czech Republic
2Faculty of Medicine, Palacky University, Olomouc, Czech Republic
3Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background. β-thalassemia is considered to be a rare disorder in Middle Europe. Similarly to other non-malaria regions, the presence of β-thalassemia in Middle Europe reflects the historical as well as recent immigration and demographic changes that have influenced the genetic variability of the current populations living in this area. *Aims*. To assess the frequency and spectrum of mutations on the β-globin gene in Czech and Slovak patients with clinical symptoms of β-thalassemia or δβ-thalassemia. The results of the initial part of this research were published almost two decades ago (Indrak et al., Hum Genet 1992; 88: 399-404) and the aim of this work was to update this original report. Patients and Methods: Nearly 380 cases from seven hematological centers of Czech and Slovak Republics were analyzed. Blood samples were available for blood cell count measurements, hemoglobin (Hb) electrophoresis, chromatography and for genetic analyses. *Results*. Twenty-two β-thalassemia mutations were identified in more than 260 heterozygotes from 152 unrelated families of Czech or Slovak descent. Most of the mutations were of Mediterranean origin and accounted for 70% of patients. Newly discovered insertion of transposable element L1 into the β-globin gene represents a novel etiology of β-thalassemia due to a silencing effect of repressive chromatin associated with retrotransposon insertion (Piterkova et al, Heamatologica 2011; 96(s2): 417-8, (EHA meeting abstract)). The list of abnormal hemoglobins now contains 14 β-globin variants, involving the rare high oxygen affinity Hb Olomouc associated with familiar polycythemia and two unique Heinz body hemolytic anemia variants (unstable Hb Hradec Kralove and Hb Hana). *Conclusions.* In the Czech and Slovak populations, β-thalassemia appears to be an uncommon disorder, which, however, must be considered as the prevailing cause of congenital hypochromic microcytic anemia. All but four studied patients were heterozygous carriers, manifesting thalassemia minor, with rare exceptions of dominantly inherited β-thalassemia with phenotype that ranged from severe thalassemia minor to thalassemia intermedia. Three of the four homozygous or double-heterozygous β-thalassemia patients were recent immigrants from malaria countries. Genetic drift and migration in the past as well as recent immigration are responsible for introduction of the Mediterranean alleles, while several mutations, described in single families, originated locally.

GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY A SINGLE INSTITUTION EXPERIENCE

K Palla, E Perraki
Chania General Hospital, Chania, Greece

Background. Glucose-6-phosphate dehydrogenase deficiency(G-6PD) is an X-linked disorder affecting red cell metabolism. Its distribution varies significantly among different geographic regions .In Greece where this disease is endemic, an estimated 225.000 males and 92.000 females are affected. The main clinical manifestations are acute hemolytic anemia and jaundice triggered by infection or ingestion of fava beans or oxidative drugs. *Aims*. To present data indicating the frequency of G6PD deficiency in the population admitted to the hospital of Chania city (Crete island) where there is extensive consumption of fresh or dried fava beans and previously have been reported several cases of favism Methods: During 13 -year period (1997-2010), tests for the quantitative measurement of G-6PD activity by enzymatic colorimetric assay by a commercial kit (Trinity biotech, Menarini) were conducted on 1397 samples.Any individual with an activity below 4,6(U/g Hb) and 146 (U/1012 RBC) was considered G-6PD deficient. Results: Of the 1397 (1030 males, 367 females) screened , 267 (147 males, 120 females) were children. Among children 14/267 (5, 24%) were immigrants and 32/267 (11,98%)were found to have G-6PD deficiency. Complete enzyme deficiency was shown in 19/267(7,11%) males whereas 2/267 (0.74%) were immigrants. Moderate enzyme deficiency was identified in 13/267 (4, 86%)females. 4/267 (1, 49%) children were admitted to hospital with G6PD deficiency related acute hemolysis .The children with hemolysis were males, (2/5 were immigrants), younger than 5 years old and have consumed fava beans. Of the adults (220males, 910 females) 65/1130 (5,75%)were deficient in G6PD. Complete enzyme deficiency was shown in 40/1130 (3,53%) males and 6/1130(0.53%) were females . Moderate enzyme deficiency was identified in 19/1130 (1, 68%) females. The overall incidence of the deficiency in screened population (97/1397)was 6,94%. The rate among men was 59/1030 (5,73%) and among females, 38/367 (10,35%), with the male to female ratio 1:2. Conclusion: G6PD deficiency seems to affect more females than males. As neonatal screening for G6PD is long established in Greece ,clinical cases of favism are observed rarely. Acute hemolysis was found only in young children. We believe that the screening with a comprehensive education program should be performed for young children in order to prevent the occurrence of hemolysis.

1595

THE ROLE OF REGULATORY T CELLS AND FOXP3 EXPRESSION IN GREEK B-THALASSEMIA MAJOR PATIENTS

E Farmaki, M Economou, E Vlachaki, V Tzimouli, A Kondou, A Taparkou, A Teli, V Perifanis, M Athanassiou-Metaxa
Aristotle University of Thessaloniki,'Hippokration' General Hospital, Thessaloniki, Greece

Background: The suppressive/immunomodulatory function of CD4+CD25+FoxP3+ regulatory T (Treg) cells is crucial for the maintenance of immune homeostasis. Although a large number of studies have been performed on immune status of patients with β-thalassemia major, including T and B-lymphocyte subpopulations, little information is available regarding the role of Treg cells in this patient group. Aim: The aim of the present study was to determine B cells and T cells subpopulations,

including CD4+CD25bright+Foxp3+ Treg cells, and to correlate possible findings to iron chelation therapy. Methods: Fifty-two patients with beta-thalassemia major (30 males, 22 females) aged 6.5-46 years (mean age: 24.14 ± 10.439 years) participated in the study. Patients were regularly transfused and were on a regular chelation program. Data recorded included age, sex, chelation regimen, iron overload as measured by serum ferritin and heart and liver T2*MRI, cardiac function as measured by left ventricle ejection fraction (LVEF) and history of splenectomy. Iron chelation therapy consisted of deferasirox in 22 patients, deferiprone in 12, deferioxamine in 9 and combination of deferioxamine and deferiprone in 9 patients. Patients with HIV, HBV, HCV and CMV infections were excluded from the study. Twenty-seven healthy children and adults of the same age served as controls. All peripheral blood samples were analyzed on FC 500 Flow Cytometer (Beckman Counter). Four-color cytometric analysis was performed for the detection of CD19+ B cells, CD3+ T cells and T cells subpopulations CD3+CD4+, CD3+ CD8+, CD4+CD45RA+, CD4+CD45RO+, CD4+CD25+, CD4+ CD25bright+ FoxP3+ Treg using specific fluorochrome-conjugated monoclonal antibodies. The percentages of Treg were determined using the anti-CD4, anti-CD25, anti-CD127 (Beckman Coulter) surface and anti-FoxP3 (PCH101, e-Bioscience) intracellular monoclonal antibodies. Results: Percentages of CD19+ and CD4+CD45RO+ memory T cells were found to be significantly higher in patients compared to the control group (CD19+: 14.07±4.14 vs 11.62±2.26 and CD4+CD45RO+: 24.53±8.69 vs 16.38±4.01, p=0.0012 and p <0.0001, respectively). On the contrary, percentages of CD3+ and CD4+CD45RA naïve T cells were significantly lower in patient cohort compared to controls (CD3: 70.42±6.51 vs 74.57±6.28 and CD4+CD45RA: 17.64±6.24 vs 25.26±5.51, p =0.0099 and <0.0001, respectively). Finally, Treg cells were found to be significantly higher in patients compared to the control group (2.77 ±1.05 vs 1.75±0,57, p <0.0001). However, there were no correlation between Treg cells and any of the parameters studied (age, sex, iron chelation regimen, LVEF, serum ferritin, liver or heart MRI, history of splenectomy) (p>0.05). Conclusions: Elevated CD19 B cells as well as CD4+CD45RO memory T cells in thalassemia patients compared to controls might be indicative of chronic antigenic challenge, as a result of repeated blood transfusions. The increase of Treg percentage in patients could be attributed to their immune compensatory function. Further studies are needed in order to investigate the exact role of Treg in the immune system of thalassemia patients, as well as their potential in inducing transfusion tolerance.

1596

RETICULOCYTE HEMOGLOBIN AS AN INDICATOR OF IRON DEFICIENCY IN PATIENTS WITH CHRONIC KIDNEY DISEASE

C Kanonidou,[1] S Arampatzi,[1] M Pape,[2] A Nikolaidou,[1]
M Karamouzis,[2] E Diza[1]
[1]*Hematology Laboratory, Department of Clinical Microbiology, AHEPA University Hos, Thessaloniki, Greece*
[2]*Laboratory of Biochemistry, AHEPA University Hospital, Thessaloniki, Greece*

Background. The evaluation of iron status in patients with chronic kidney disease is crucial as it provides prerequisite information for deciding recombinant human erythropoietin treatment. As there are cases (e.g. inflammation) when the traditional biochemical markers for the estimation of iron deficiency seem to be inadequate, the introduction of more reliable tools remains a laboratory challenge. Reticulocyte hemoglobulin equivalent (RET-He) is a new parameter provided by modern automated hematologic analysers as a component of complete blood count. It provides an indirect measure of iron availablility for new red blood cell production and it is considered an indicator of iron-deficient erythropoiesis. *Aims*. To investigate the levels of RET-He in patients with chronic kidney disease, its correlation with other parameters of iron status and red blood cell indices and to examine whether it can be used as a useful marker in the assessment of iron status. Methods: A total of 31 patients (males/females:16/15) under hemodialysis referred to the outpatient dialysis unit of our hospital were studied. Iron deficiency was defined as having serum ferritin levels less than 100 ng/ml. For the determination of RET-He and red blood cell indices flow cell hematology XE-5000 Sysmex analyser (ROCHE) was used. Serum ferrum and ferritin concentrations were measured with Modular P800 analyser(ROCHE). Results: The mean RET-He value was 28,33±4,04 pg. Levels below the reference range were determined in 18/31 (58%) patients. RET-He was significantly and positively related to serum ferrum (r= 0,49, p=0,005), but not to serum ferritin. RET-He levels were positively correlated with mean corpuscular volume-MCV (r=0,55, p=0,001), mean corpuscular hemoglobin-MCH (r=0,68, p=0,000) and mean corpuscular hemoglobin concentration-MCHC (r= 0,49, p=0,005). The examined index was strongly and inversely related to red blood cell distribution width-RDW (r= -0,45, p= 0,01). No significant correlation with serum creatinine levels was observed (p>0,05). Summary/conclusions: RET-He levels in patients undergoing hemodialysis treatment were found to be lower than that of the normal population. RET-He was well correlated with conventional indices of iron deficiency. The potential utility of this simple, easily measurable and low-cost laboratory test as a reliable marker of iron status in chronic kidney disease patients should not be underestimated.

IMMUNOLOGICAL EVALUATION OF ?-THALASSEMIA MAJOR PATIENTS RECEIVING ORAL IRON CHELATOR DEFERASIROX

A Aleem, A Alsultan, F Algahtani, Z Shakoor, F Anjum, Z Iqbal, A Al-Momen
College of Medicine and King Khalid University Hospital, King Saud University, Riyadh, Saudi Arabia

Background. Several immunological abnormalities have been described in patients with beta thalassemia major. Deferasirox (DFX), an oral chelating agent used in the treatment of beta thalassemia major, has interesting properties including antiproliferative, apoptotic and antitumour effects. Aim: This study was performed to investigate whether DFX further contributes to the altered immune function in beta thalassemia major patients. *Patients and methods*. We prospectively studied the immune function in 17 consecutive beta thalassemia major patients between July and December 2009 at King Khalid University Hospital, Riyadh. All the patients were receiving regular blood transfusions from an early age and had previously received desferoxamine for iron chelation. The dose of DFX ranged from 20-30 mg/kg and the mean duration of DFX treatment was 24 months at the time of sample collection. Apart from the demographic and clinical data collection, serum immunoglobulins, IgG subclasses, serum levels of complement factors C3 and C4, and lymphocyte subsets were studied. Results: There were 5 males and 12 females with a median age of 26 years (range 15-32 years). Median serum ferritin level was 2528 μmol/l (range 974-13166) before starting DFX treatment and was 1875 μmol/l (range 563-6643) at the time of study. Serum ferritin decreased in 12 patients, increased in 3 and was stable in 2 patients. Fourteen patients were splenectomised. Serum IgG levels were increased in 7 patients, while IgA and IgM levels were increased in 4 and 2 patients respectively. Low C4 levels were found in 9 patients and low C3 in 2 patients. IgG subclasses were normal in most of the patients except IgG-1 levels, which were increased in 4 patients. Absolute total B and T lymphocytes were increased in 14 patients each as compared to the normal range. CD4+ and CD8+ cells were increased in 13 and 12 patients respectively. NK cells were also increased in 11 patients. CD4/CD8 ratio was increased in 8 patients, decreased in 2 patients and normal in 7 patients. Conclusions: The immunological changes observed appear to be non-specific and previously described in thalassemia major patients, and unlikely to be contributed by DFX. Larger studies including other aspects of immune system are needed to understand the effect of DFX on immune function of thalassemia major patients including comparison of immune status before and after starting DFX.

[2]*Servicio de Pediatría, Hospital Universitario de Canarias, Tenerife, Spain*
[3]*Servicio de Hematología, Hospital Universitario de Canarias, Tenerife, Spain*
[4]*Departamento de Hematologia, Centro Hospitalar de Coimbra, Coimbra, Portugal*
[5]*Unidad de Eritropatología, Hospital Clinic i Provincial, Barcelona, Spain*

Background. Pyruvate kinase (PK) deficiency is a congenital disease with heterogeneous severity, ranging from a mild asymptomatic to a severe transfusion-dependent haemolytic anaemia. Rare cases of hydrops fetalis and death in the neonatal period have been reported. Aims: To report the molecular background of a PK-deficient patient with hydrops fetalis associated with a severe haemolytic anaemia. Clinical history: A 6 year old boy, of Indian origin, with a transfusion dependent chronic haemolytic anaemia. He was born with a non-immune hydrops fetalis and severe

neonatal haemolytic anaemia requiring exchange transfusion: Hb=5 g/dL, reticulocytes=311 x 10^9/L and erytrobasts=250/100 leucocytes. His parents are non-consanguineous and have no history of anaemia. Father's red cells PK activity was 6.4 IU/gHb and mother's was 5.5 IU/gHb (n.r. 8.4-15.2). Methods: Haematological parameters and PK enzyme activity were measured by standard procedures. After informed consent, genomic DNA was extracted from EDTA peripheral blood samples and PKLR gene was studied by PCR-sequencing. Results: We identified a previously described PKLR gene missense mutation, c.1220A>G (p.Glu407Gly), in exon 9 at the homozygous state. Additionally, a second nucleotide substitution in the promoter region, -119G>A, not previously described, was also found at the homozygous state. Father and mother are heterozygous for both mutations. Conclusions: We describe a patient of Indian origin with a PK-deficient severe anaemia, homozygous for the missense mutation c.1220A>G (p.Glu407Gly) in cis with the nucleotide substitution -119G>A, a new promoter mutation. Mutation p.Glu407Gly was previously described in an Indian patient with severe haemolytic anaemia at birth, requiring exchange transfusion. The non-conservative substitution of the highly conserved Glu407 acidic residue for the tiny and small residue Gly occurs in the PK-R subunit A domain (Aα8a), near the active site of the enzyme, which is located between the B and A domains. Nevertheless, the second mutation identified in PKLR promoter region, -119G>A, modifies the CAC/Sp1 motif (-119gggtgg-113), and is expected to decrease the gene transcriptional activity. The additive effect of these two mutations may explain the severity of the phenotype.

INTRAVENOUS FERRIC CARBOXYMALTOSE IN THE TREATMENT OF IRON DEFICIENCY

D O'Donovan, L Wakeman, A Salamat, K Foley
ABM University Health Board, Swansea, United Kingdom

Background. Some patients with iron deficiency anaemia cannot tolerate any formulation of oral iron and require intravenous (IV) preparations. We have used iron sucrose since its introduction and we reported our experience previously. The need for repeated infusions placed major strain on nursing time, Day Unit capacity and caused significant patient inconvenience. Ferric carboxymaltose offers increased dosing intervals, though at a higher drug cost. Aims To establish the efficacy of the use of intravenous ferric carboxymaltose in the treatment of iron Deficiency anaemia. *Methods* Over the last two years; we have treated 51 patients with a fixed dose one gram IV ferric carboxymaltose (FCM) over 15 minutes infusion. Six patients (12%) with minimal response were excluded and including patients with beta thalassaemia, pernicious anaemia and anaemia of chronic disease. *Results.* Table.

IDA

No. patients	45 (36F;9M)
No. Treatment episodes	55
Mean pre treatment Hb (g/l)	9.9
Mean post treatment Hb (g/l)	11.2
Mean pre treatment serum ferritin ng/ml	29
Mean post treatment serum ferritin ng/ml	168.8
Mean pre treatment Tsf %	8.4
Mean post treatment Tsf %	16.9

Conclusions. Whilst ferric carboxymaltose carries higher prescribing costs compared with iron sucrose; it significantly reduces hospital visits, is very well tolerated and patients prefer the convenience that this drug offers. Advantages for the hospital include reduced nursing time, fewer hospital appointments and admissions, lower patient transport costs and quicker pharmacy processing, these benefits significantly offset higher drug costs. Treatments with ferric carboxymaltose were well tolerated and no adverse effects were reported and no treatment was discontinued. Conclusion: The safety and the short duration of administration of FCM may favour its delivery in the community, further improving ease of access and convenience for patients. Our study demonstrates that the use of ferric carboxymaltose should be targeted to the treatment of appropriate clinical conditions in order to achieve maximum patient benefit and acceptable costs.

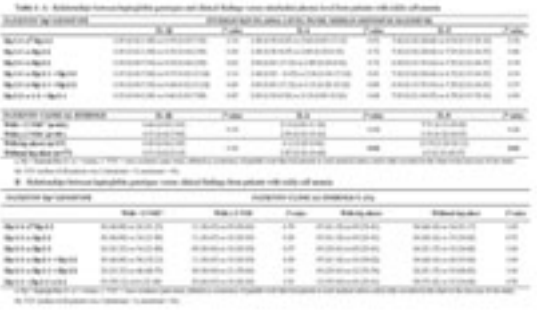
[3]*State University of Campinas - Unicamp, Campinas, Brazil*
[4]*Federal University of Pernambuco - UFPE, Recife, Brazil*

Background: Oxidative stress, particularly in the endothelium, exerts a strong influence on the genesis of sickle cell anemia (SCA) vaso-occlusion and, consequently, on patients' clinical evolution and survival. Recent investigations suggests that the profile of produced cytokines by immune response may influence the morbidity in patients with SCA. Haptoglobin (Hp) is a plasma glycoprotein whose primary function is to bind to free hemoglobin, preventing excretion of iron by the kidneys and protecting blood vessels from its oxidative effects. Three main genotypes (Hp1-1, Hp2-1, Hp2-2) correspond to distinct proteins with different properties. The protein Hp2-2 has the highest molecular weight and the lowest antioxidant capacity. Furthermore, Hp has immunomodulatory properties that seem to influence the pattern of inflammatory response and cytokine secretion. The Hp 1-1 genotype was associated with higher production of IL-6 and IL-10 than the Hp 2-2 genotype. Aims: Determine whether genotypes of Hp and plasma levels of IL-1β, IL-6 and IL-8 correlate with the clinical and laboratory aspects of adult patients with SCA, followed up at HEMOPE, in the state of Pernambuco, northeastern Brazil. Methods: Peripheral blood samples of 94 stable patients (median age: 27 years; 42 female; 52 male; all Afro- Descendants), without transfusion and without use of hydroxyurea, known to be carriers of SCA (HbSS) were analyzed. The genotype of Hp was determined, previously, by allele specific PCR and the plasma or serum levels of interleukins by ELISA. The patients' clinical characteristics were obtained from the records in medical chart. Adequate statistical analysis was performed using the GraphPad Prism Software-V.-5.00. Results: The Table 1 summarizes the partials results.



The patients' Hp genotype distribution was Hp 1-1 (28.7%), Hp 2-1 (41.5%) and Hp 2-2 (29.8%). Statistically, there is no significative differences in interleukins IL-1β, IL-6 and IL-8 plasma levels when compared with the distinct Hp genotypes patients groups. When we compared the frequencies of vase occlusive pain crisis (VOC) with the distinct Hp genotypes we did not find a statistically significant differences. Similarly, when we compared the Hp genotype and leg ulcers (LU) occurrences no statistically a difference was observed. However, when the dosages of interleukins were compared to patients with episode of LU, in past or in the moment of collected, we have found the IL-6 and IL-8 levels were significantly higher than in SCA patients who never has not been any event of LU ($P = 0.03$ and $P = 0.01$, respectively). Conclusions: In this preliminary analysis no significant differences between groups were observed in relationship to Hp genotypes, interleukins and VOC or LU. On the other hand, we have demonstrated that circulating levels of IL -6 and IL-8 were elevated in patients with SCA who developed LU. On the basis of our results, these findings suggest that the increased IL-6 and IL-8 levels may play a role in the development of the LU in our SCA patients. These findings in association with the genetic background of each patient can be associated with the clinical course of the disease.

1601

COMPARISON OF THE CORRECTION EFFICACY OF IRON DEFICIENCY ANEMIA WITH FERRIC CARBOXYMALTOSE AND IRON [III] HYDROXIDE-SUCROSE COMPLEX IN A PORTUGUESE HOSPITAL

J Martinez Marcos, A Marques, A Ramalhinho
Centro Hospitalar Cova da Beira, Covilha, Portugal

Background: Ferric carboxymaltose is a new formulation of intravenous iron that allows the administration of higher doses than traditional iron complexes, like iron [III] hydroxide-sucrose complex, which requires the administration of multiple doses in several treatment sessions. *Aims:* The aim of this work is to compare the efficacy of therapeutic with ferric carboxymaltose or iron [III] hydroxide-sucrose complex in the impact of iron and hemoglobin levels reposition in patients with iron deficiency anemia. *Methods:* The population studied consisted in 150 patients, 83 with digestive related anemia (gastric neoplasias, chronic inflammatory diseases and upper gastrointestinal bleeding) and 67 with gynecologic related anemia (obstetric complications, metroragies and hysterectomies). 72 patients were treated with iron [III] hydroxide-sucrose complex, with a weekly dose of 200 mg administered during 60 minutes and 78 patients were treated with a single dose of ferric carboxymaltose administered for 30 minutes. *Results*: The average age of patients was 52.24±17.74 years, 73.83% were females. The average dose of iron [III] hydroxide-sucrose complex was 1157.75±495.52 mg and of ferric carboxymaltose was 811.86±400.47 mg. The average values of laboratory results precedent and subsequent to iron reposition demonstrated that the administration of ferric carboxymaltose in a sigle dose has similar effects in the increase of serum hemoglobin, iron and ferritin to those achieved with several treatment sessions with iron [III] hydroxide-sucrose complex. However, the difference between the number of treatment sessions with one or other therapeutic formulation is significant (1.35±0.61 with ferric carboxymaltose and 3.87±1.68 with iron [III] hydroxide-sucrose complex, p<0.001). *Summary/conclusions:* The administration of ferric carboximaltose has demonstrated to produce similar effects to those obtained with iron [III] hydroxide-sucrose complex in increasing the levels of serum hemoglobin, iron and ferritin but the reduced administration time of the ferric carboxymaltose, associated to the high iron uptake accomplished with a single dose and absence of adverse reactions provides a major convenience both to patients and health practitioners.

1602

OBSTRUCTIVE SLEEP APNEA /HYPOPNEA SYNDROME IN CHILDREN AND ADOLESCENTS WITH SICKLE/BETA-THALASSEMIA

M Economou[1], E Papadopoulou[2], A Sakellaropoulou[3], A Teli[2], E Farmaki[2], J Goudanos[3], S Vakalopoulou[2], M Hatzistilianou[3], M Emporiadou[3], N Gompakis[2]
[1]*Aristotle University of Thessaloniki, Thessaloniki, Greece*
[2]*Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece*
[3]*Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece*

Background: The prevalence of obstructive sleep apnea/hypopnea syndrome (OSAHS) is reported to be high in patients with sickle cell disease (SCD) and has been associated to other manifestations of the disease, such as the occurrence of vaso-occlusive crises (VOC). It is also known that VOC are the result of complex mechanisms, involving increased cellular adhesion and chronic inflammation. *Aims:* The aim of the present study was to investigate the prevalence of OSAHS in children and adolescents with sickle/beta-thalassemia and to investigate possible correlations to clinical and laboratory parameters. *Methods:* For the purposes of the study 17 young patients with sickle/beta-thalassemia, aged 3.5 to 18 years (mean age 10.97±4.87 years), were evaluated. Mean haemoglobin (Hb) level was 9±0.7 g/dl. Age, sex and annual number of VOC were recorded. Overnight polysomnography was performed and severity of OSAHS was evaluated based on the Apnea Hypopnea Index (AHI). Tonsil's size was measured according to the Mallampati scale. With regards to laboratory parameters, von Willebrand Factor (vWF) antigen and ristocetin co-factor activity (vWF:RCo) were measured and surface expression of CD11a, CD11b, CD11c and CD18 were determined on patients' neutrophils by flow cytometry. *Results:* Of the 17 patients evaluated 16 (94.1%) presented with OSAHS. Mild OSAHS was recorded in 11/17 patients (64.7%), moderate in 2/17 (11.8%) and severe in 3/17 patients (17.6%). There was a negative correlation between the annual number of painful crises and the degree of OSAHS expressed as AHI, as well as with the basal oxygen during sleep and mean oxygen during desaturation, although these correlations did not reach statistical significance. A statistical significance was demonstrated between AHI and tonsils' size (r=0.585, p=0.028). vWF:RCo was significantly lower in patients with mild OSAHS (AHI<5) compared to patients with moderate or severe OSAHS (AHI>5) (98.68 ± 17.42 vs 128.92 ± 15.01, p= 0.006). VWF:RCo activity was inversely correlated to mean oxygen during desaturation (r=-0.485, p= -0.049) and to minimum value of oxygen during sleep (r= 0.499, p=0.069) and significantly correlated to AHI (r= 0.499, p=0.041). With regards to immunity parameters studied, a negative statistical trend between the expression of CD11a adhesion molecule and basal oxygen during sleep was found (r= -0.457, p=0.065). *Conclusions:* The study revealed a high rate of OSAHS in children and adolescents with sickle/beta-thalassemia compared to other reports on sickle cell disease patients, with adenotonsillar hypertrophy being one of the principal causes. Moreover, study findings suggest an association between hypoxemia and vWF levels as well as expression of CD11a adhesion molecule, OSAHS thus contributing to a given prothrombotic state.

1603

THE EVALUATION OF PULMONARY FUNCTIONS IN CHILDREN WITH SICKLE CELL DISEASE

C Kurt, I Sasmaz, B Antmen, K Ozgunen, S Kurdak, B Karagun, Y Kilinc
Cukurova University, Medical Faculty, Adana, Turkey

Background: The lung damage seen in sickle cell disease appears to be a complication of chronic haemolysis and repeated episodes of pulmonary vaso-occlusion. It is a source of acute morbidity, in the long term, a major determinant of survival. Approximately 4 % of sickle cell patients develop sickle chronic lung disease leading to end stage respiratory failure, characyterised by hypoxemia, restrictive lung disease and cor pulmonale. Such episodes start in childhood. *Aims*: In this study we evaluated pulmonary functions together with clinical parameters in children with sickle cell disease. *Materials and Methods:* 24 children with sickle cell anemia and 9 children as control group where include to the study. Complete blood count, hemoglobin electrophoresis and biochemical values were eveluated for both groups. The carbonmonoxide diffusion test performing for both groups. At the same day spirometric respiratory function evaluation and exercise test performed to all groups at department of sports physiology. Results:HbF, SGPT, ferritin, total bilirubine, direkt bilirubine and iron values were high at patient group (p<0.05). Hemoglobin and hematocrit values were low at patient group according to control group (p<0.05). Number of patient's who had one-three vasooclusive crisis were 14 (58.3%), who had 3 or more vasooclusive crisis were 7 (29.2%) and who had no vasooclusive crisis were 3 (12.5%). Acute chest syndrome was seen in 5 patients (20.9%). Impaired isole carbonmonoxide diffusion test was established at the 62.5% of the patient's. At patient group, spirometric FEV1 and MEF25 measurement were lower (p<0.05). At exercise test, oxyjen uptake/heart rate were lower for patient group (p<0.05). *Conclusions*: Our results confirm that lung disease in sickle cell disease begins in childhood. Pulmonary function tests differs significantly in children with sickle cell disease compared with healthy matched controls of similar age. Common abnormalities include restructive physiology and decreased diffusion capasity for carbon monoxide.

1604

MOLECULAR CHARACTERISTICS OF PATIENTS WITH SICKLE CELL ANEMIA AND STROKE IN A BRAZILIAN POPULATION

I Domingos[1], B Hatzhofer[2], C Ferreira[3], M Pinto[2], M Santos[3], D Albuquerque[3], K Mello[1], F Medeiros[1], K Fertrin[3], F Costa[3], A Araújo[4], M Bezerra[1]
[1]*Federal University of Pernambuco, Recife, Brazil*
[2]*Hematology and Hemotherapy Center of Pernambuco - Hemope, Recife, Brazil*
[3]*State University of Campinas - Unicamp, Campinas, Brazil*
[4]*Federal University of Pernambuco - UFPE, Recife, Brazil*

Background: Predicting the severity of sickle cell anemia (SCA) is important to provide better informed genetic counseling and better targeting of intensive therapies. Stroke is a catastrophic complication of sickle cell disease (SCD) and a leading cause of death in both children and adults. The risk for stroke can be inferred from abnormally high cerebral velocities assessed by transcranial Doppler (TCD) and can be reduced by chronic transfusion programs. Genetic factors that predispose to this complication are not well established. Classic modulators of SCD severity, such as βS cluster haplotype and α-thalassemia, have had controversial reports. A polymorphism in the promoter region of the TNFα gene

has previously been associated with stroke in children with SCD. *Aims*: We aimed to clarify which genetic risk factors are associated with stroke in SCA in a Northeastern Brazilian population followed at Hematology and Hemotherapy Center of Pernambuco, Recife, Brazil. *Methods:* We have determined the α-globin genotype, the βS haplotype, and the presence of eNOS promoter -786 T[ARROWRIGHT]C single nucleotide polymorphism (SNP), TNF promoter -308 G[ARROWRIGHT]A SNP, factor V (FV) Leiden G1691A, prothrombin (PRT) G20210A, methylenetetrahydrofolate reductase (MTHFR) C677T point mutations and G6PD202A- mutation of patients with proven SCA as confirmed by hemoglobin HPLC pattern. All molecular analyses were determined by PCR-RFLP, except for the α-globin genotypes, which were determined by gap-PCR. Statistical analyses used Fisher's exact test. *Results:* A total of 168 patients with SCA were included in our case-control study. Of these, 53 patients presented clinical signs and symptoms of stroke, defining the case group of this study. The control group consisted of 115 patients presenting normal TCD with absence of clinical signs and symptoms of stroke. The α-gene deletion (-α3.7Kb) showed significant difference (p=0.0008) between case and control groups [3 patients (5.7%) vs. 32 (27.8%), respectively], corroborating the previously reported protective effect of α-gene deletion in stroke. The CAR/CAR βS haplotype group had statistically higher frequence in the case group compared with the control group (p=0.0174). CAR/CAR individuals appear to be at higher risk for stroke than other patients. We found no difference in the other genetic markers frequencies comparing patients with and without stroke in our SCA population. *Conclusions:* From all genetic markers in our study, only α-globin genotype and βS haplotype showed reproducible influence as genetic modulators for stroke prevalence in our SCA population. This demonstrates that genetic heterogeneity among different populations may account for failure to prove reproducibility of previous gene association studies, and warrants further studies in worldwide collaboration to determine the actual relevance of findings involving genetic polymorphisms and their influence on the prevalence and predictability of clinical complications in SCA.

1605

THE NEW ORAL COMBINED CHELATION REGIMEN MAY IMPROVE SHORT STATURE AND PUBERTAL MATURATION IN JUVENILE β-THALASSEMIA MAJOR PATIENTS

K Farmaki, I Tzoumari, F Panitsas, C Pappa
General Hospital of Corinth, Corinth, Greece

Iron overload has a critical impact on multitransfused thalassemia major patients (TMp) inducing significant morbidities. Chelation with desferrioxamine (DFO), in addition to the burden of frequent infusions and local reactions, exhibits a toxic effect on bone formation, causing metaphysal dysplasia and platyspondylosis leading to a short stature. Orally active chelators deferiprone (DFP) and deferasirox (DFX) offer the promise of easier administration, better compliance without any toxic adverse effect in lower ferritin levels. Aims. The substitution of a chelation regimen in juveniles TMP with short stature, in order to attain a normal pubertal growth spurt in time. Additional objectives were to evaluate the efficacy on total body iron load and the safety of the oral combined chelation. *Patients and Methods.* 3 juveniles TMp, 1 male 2 females, mean age 11.3±2,3, were included in the study for a two years period. Hospital's Ethics Committee approval and appropriate written informed consent from guardians were obtained prior to participation. The protocol involved the combination of two oral chelators DFP: 100 mg/Kg/day and DFX: 20 mg/Kg/day. Primary endpoint measures were investigated by growth-charts for age percentiles and clinical staging of puberty according Tanner criteria. Regarding efficacy, yearly mean serum ferritin levels (CMIA), quantification of heart and liver iron by Signa-MRI-1.5-Tesla, multi-echo-T2*, liver iron concentration (LIC) mg/gr/dw by Ferriscan and LVEF, FS by cardiac-echo-Doppler, were analyzed. Safety was evaluated by close clinical and laboratory monitoring of adverse reactions according to updated SPC for each drug. Statistical analyses were performed using SPSS. *Results.* Although at baseline TMp had a decline of the height age percentile varying from <2% to <8%, after oral combined chelation they presented an overall increase in standing and sitting height and reached a normal height age percentile. In all 3/3 TMp mean body mass index increased from 15,8 to 19. Sexual development also progressed in the 2 elder from Tanner stage II to IV and in the younger one from stage I to III. LH and FSH, as peripheral hormone secretion increased. In both females menarche occurred at the age of 11 and 12 years old. Although at baseline they had mean ferritin <500 ng/mL, normal LIC and MRI T2*L, T2*H, after two years of oral combined chelation mean ferritin decreased to 173±52 ng/mL but LIC remained unchanged to 0,9 mgFe/g/dw probably because of a tended higher transfusional iron intake in adolescents. MRI T2*L increased from 32,6 to 34 msec, T2*H from 28,8 to 31,2 msec. Mean LVEF improved significantly from 61% to 66% and FS from 34 to 38%. Between MRI T2*H and FS a significant positive correlation (pearson) was found (p<0.05). No drug-related neutropenia or agranulocytosis or other toxicities known to be associated with the two chelators were observed. Pre and post-treatment creatinine remained unchanged in all TMp as well as eGFR calculated by Schwartz formula. *Conclusions.* These results indicate that oral combined chelation (DFP and DFX), seemed to be beneficial in juveniles TMp for attaining normal stature and sexual maturity. Additionally it improved cardiac function. It is also well tolerated, more acceptable for life-long chelation and influences significantly patients' quality of life.

1606

INVASIVE MOULD INFECTIONS (IMI) IN PATIENTS WITH ACUTE LEUKEMIA RECEIVING CHEMOTHERAPY

GC Wong, BH Tan
Singapore General Hospital, Singapore, Singapore

Background. Acute leukemia patients on chemotherapy receive itraconazole prophylaxis and are treated according to a febrile neutropenia guideline developed based on the hospital's flora and antibiotic resistance. *Aims.* To determine risk factors for and clinical features of invasive mould infections(IMI) in patients with acute leukemia receiving chemotherapy. *Methods.* Patients diagnosed with acute leukemia between 1st January 2004 and 31st March 2007 and treated with chemotherapy were included in the study, approved by the Institution Review Board. A retrospective review of their casenotes was made to establish patients' clinical profile, disease characteristics and IMI management. These cases were then matched to controls obtained from the Leukemia Registry. *Results.* Nineteen cases of invasive mould infections (IMI) were found in the period, giving an incidence of 11.2%, using only patients undergoing curative chemotherapy as denominator. The incidence in patients receiving the first cycle of chemotherapy was 8.9%; in patients receiving subsequent cycles of chemotherapy was 4%. Thirteen cases were proven by EORTC/MSG criteria, 8 of them by histology without positive cultures. There were 3 proven cases of fusariosis, and 1 each of aspergillosis and nodulisporiosis. Cases were more likely than controls to have had an absolute neutropenia for at least 14 days in the chemotherapy episode in which the IMI was diagnosed (p=0.045), to have been bacteremic prior to the diagnosis of IMI (p=0.045), and to have had fever not responding to a carbapenem (p=0,016). They also had a longer length of stay (51.8 vs 27.2 days, p=0.01). The use of anti-fungal prophylaxis was not less common in cases than controls. Common clinical features noted in cases included fever not responding to a carbapenem (84.7%), cough (42.1%), a rise in alkaline phosphatase(ALP) (36.9%), breathlessness (26.3%), and hemoptysis (21.1%). A pleural effusion was noted on CXR or CT chest in 52.8% of cases, and a characteristic CT thorax in 47.4% of cases. Sixty-eight percent of cases received amphotericin (conventional or lipid preparation) as part of a febrile neutropenia protocol, though only 15.8% received this agent when an IMI was considered. Clinical improvement was attributed to an increase in ANC in 26.3% of cases, and to the introduction of voriconazole in 10.5%. The next cycle of chemotherapy was delayed for 2-4 weeks in 15.8% of cases, and for more than 4 weeks in 31/6% of cases. Three patients (15.8%) died within three months of IMI diagnosis, 47.4% survived more than 1 year. *Conclusions.* Absolute neutropenia more than 14 days is a risk factor for IMI in patients with acute leukemias. Fever not responding to carbapenems, and a rise in ALP may be considered red flags for clinicians to consider the possibility of an IMI. The anti-fungal prophylaxis used during the period under study (itraconazole) did not reduce the likelihood of an IMI and a change should be considered.

1607

POLYMORPHISM IN TLR2 ARG753GLN AND SUSCEPTIBILITY TO FUNGAL INFECTIONS IN CHILDREN WITH LEUKEMIA

N Ozdemir[1], T Celkan[2], M Guven[3], B Batar[3], G Tuysuz[2], H Apak[2], I Yildiz[2]
[1]*Cerrahpasa Medical Faculty, Istanbul, Turkey*
[2]*Cerrahpasa Medical Faculty, Pediatric Hematology Oncology Department, Istanbul, Turkey*

3Cerrahpasa Medical Faculty, Medical Biology Department, Istanbul, Turkey

Background: Toll-like receptors (TLRs) are essential pattern-recognition receptors and have a role in activation of both innate and adaptive immune response. TLR2 recognizes various pathogen-associated molecular patterns of bacteria, virus and fungi. Intensive treatment protocols and stem cell transplantation improved survival rates in children with leukemia however invasive fungal infections (IFIs) represent a substantial cause of morbidity and mortality. Single nucleotide polymorphism Arg753Gln affect TLR2 responsiveness and may contribute to the course of infections. Aims: We aimed to investigate the association between TLR2 Arg753Gln polymorphism in children with leukemia and susceptibility to invasive fungal infections. Methods: TLR2 Arg753Gln was assessed in 96 children (1-18 years old) treated for acute lymphoblastic leukemia (ALL) and 103 age and sex matched controls. Toll-like receptor 2 genotyping was performed by hybridization probe assay specific for the TLR2 variant. Informed consent was obtained. Results: The mean age of the patients was 5,9 years old (±3,7 years), 52% were male. According to BFM-95 treatment protocol risk groups; 33,3% of the patients were in standart, 58,3% in medium and 8,3% in high risk group. During initial treatment (BFM-95) 8 (8,3%) IFIs were observed. According to the revised definitions of IFIs; 4 were proven, 2 probable and 2 possible. Leukemia relapsed in 15 patients, other 4 patients (26,6%) had IFI during relapsed ALL treatment protocol (BFM Rez-ALL). TLR2 753Gln mutant allele was found as heterozygous in 1 patient with ALL, this patient had no febrile neutropenia attack or IFI during leukemia treatment. TLR2 Arg753Gln polymorphism was not observed in controls. Conclusions: Limited data is available on the incidence of TLR2 mutation. This study is limited by the small number of positive patients with TLR2 mutation so no epidemiological conclusions can be drawn. However, interestingly the only patients who was heterozygous had no febrile neutropenia attack, IFI or any serious infection during the treatment. The known TLR2 polymorphism identified so far may not cause a crutial role in the pathogenesis of IFIs in children treated for ALL.

1608

FUNGAL COLONIZATION IN CHILDREN WITH CANCER: HOSPITAL ADMISSION AND SENSITIVITY PATTERNS; A SINGLE CENTER EXPERIENCE

I Ragab, G Mokhtar, S El Sayed
Ain Shams University, Cairo, Egypt

Background: Fungal infections represent a growing problem in children with cancer and fungal colonization is recognized as an important risk factor for these infections. Aim:The aim of the study was to detect the frequency of fungal colonization; fungal species characterization and antifungal sensitivity in pediatric oncology inpatients admitted at the Ain Shams University Pediatric Oncology and compare them to outpatients attending the clinic. A case-control study of fungal colonization in 50 children with cancer and receiving chemotherapy was performed; 22 patients admitted for febrile neutropenia compared to 28 outpatients as a control group. Each patient was evaluated for the occurrence of fungal colonization (defined as at least one positive surveillance culture). Samples were collected by swabbing both buccal mucosa, axillae in all patients, in addition to blood and stool studies during peak of fever, and perianal sample in the presence of inflammation or rash. All samples were cultured on Sabouraud's dextrose agar, thereafter, susceptibility of the identified isolates to antifungal drugs was determined. All isolates were of candida (C.) (100%) and aspergillus (A.) (90%) species. The most common colonizing species were *Aspergillus fumigatus* (90%), C. albicans (84%), Aspergillus flavus and C. glabrata (both 50%). A. flavus and C. tropicalis were significantly higher in inpatients than outpatients (68.2% vs 35.7% and 40.9% vs 7.1%, respectively P<0.05). The isolates were highly sensitive to amphotericin B (AMB) ranging from 50% to 100%. The sensitivity pattern to fluconazole (FCZ) was varying from 0% to 83.3% .C. albicans had higher sensitivity in outpatients to itraconazole (ITZ) (96.2%), and nystatin (88.5%) compared to inpatients (56.3%) and (37.5%) respectively (P<0.05). C. glabrata had higher sensitivity to AMB in inpatients (92.9%) compared to outpatients (27.3%) (P<0.05). Neutropenic patients had higher rate of colonization with C. glabrata (74.2%) and C. tropicalis (32.3%) versus non neutropenic patients (10.5%; P<0.0001) and (5.3%; P<0.05) respectively. Cancer patients are at increased risk for fungal colonization, therefore, they are more vulnerable to fungal infections. Neutropenia was the most important risk factor. Culture and sensitivity is important before starting of antifungal therapy due to the wide variability in drug sensitivity of each strain.

1609

INVASIVE FUNGAL INFECTIONS IN LYMPHOPROLIFERATIVE DISORDERS

M Riva[1], M Pioltelli[2], L Marbello[2], L Paris[2], A Tedeschi[2], F Ricci[2], E Vismara[2], V Speziale[2], C Rusconi[2], V Zilioli[2], C Gabutti[2], A Nosari[2], E Morra[2]
[1]*Ospedale Niguarda Cà Granda, Milan, Italy*
[2]*Niguarda Cà Granda Hospital, Milan, Italy*

Background. Few epidemiological data regarding invasive fungal infections (IFI) in chronic lymphoid malignancies are available in literature. Aims The aim of our study is to describe epidemiology, clinical manifestations and outcome of IFI in these patients. Methods We reviewed the records of patients (pts) affected by lymphoproliferative disorders, admitted to our department between 2003 and 2010 and treated for probable or proven IFI. Results and conclusions We registered 34 probable and proven IFI. In our population, the incidence of IFI was 2,7%; (moulds 2%, yeasts 0,4%, mixed infections 0,3%). Twenty-two patients were affected by lymphoma, 8 by chronic lymphocytic leukemia, 3 by Waldenström macroglobulinemia and 1 by hairy cell leukemia. The median age was 57 years (r: 17-71). Twenty-six patients (76%) had progressive or relapsed hematological disease, and 76% was treated with multiple lines of chemotherapy. According to the criteria of EORTC/MSG, risk factors were: deep and prolonged neutropenia (10 pts), immunosuppressive therapy after solid organ transplant (2), previous allogeneic HSCT (2), high dose steroid therapy (3), monoclonal antibodies such as rituximab (7) and alemtuzumab (2), nucleosidic analogue administration (2) or multiple of these risk factors (8) during the previous 90 days. Six patients developed a yeast infection; in 4 cases infection was documented by blood cultures (2 *C. albicans*, 1 *C. glabrata* and 1 *Blastoschyzomices capitatus*), in 1 by culture of a freshly placed biliary drainage (*C. glabrata*), and in the other by the microscopic observation of *Candida spp.* in the vitreum after vitrectomy. Twenty-five patients developed an invasive mould infection (IMI). Among 22 probable IMI, of which 19 had lung involvement, 2 a sinusal localization, and 1 a pulmonary infection disseminated to brain. Microbiological evidence of infection was more often provided by the positivity of the galactomannan antigen in the serum (8 pts), in the BAL fluid (1) or in both (3). Cultures resulted positive in 6 cases, 3 from the BAL fluid (2 *A. fumigatus*, 1 *Aspergillus spp*) , 1 from nasal swab (*A. fumigatus*) and 2 from the sputum (1 *A. fumigatus*, 1 *Fusarium*). In the remaining 4 patients both culture positivity from the BAL fluid (1 *A. flavus*, 1 *A. fumigatus*, 1 *Aspergillus spp*, and 1 positive for both *Scedosporium* and *Aspergillus*) and serological demonstration of the galactomannan antigen were present. We diagnosed also 3 proven IMI by the histologic evidence of Aspergillus (2) and Mucor (1) in the lung. Three mixed infections by both moulds and yeasts were observed. Twenty-one patients recovered. Thirteen died within 90 days from the beginning of the infection, all with uncontrolled hematological disease. Among these, 6 patients died due to a progressive hematological disease. In 6 patients, infection (2 by yeasts, 4 by moulds) was a concurrent cause of death. In 1 case IFI with mixed etiology (*Candida spp./Aspergillus spp.*) was the only cause of death as documented at autopsy. Fungal attributable mortality was 20% (7/34). The only significant risk factor for mortality at univariate and multivariate analysis was the persistence of neutropenia.

1610

HAS NOVEL INFLUENZA A/H1N1 2009 ASSOCIATED PNEUMONIA POTENTIAL TO BE MORE PATHOGENIC IN ADULT PATIENTS WITH HEMATOLOGICAL MALIGNANCIES? CASE REPORTS AND REVIEW OF THE LITERATURE

H Guillén, J García-Suárez, N Curto, M Callejas, Y Martín, JJ Gil-Fernández, M López-Rubio, E Magro, C Burgaleta
Hospital Príncipe de Asturias, Alcalá de Henares, Spain

Background and aims: During the recent winter, the northern hemisphere, especially Europe, experienced a second wave of novel influenza A/H1N1 2009 virus. A devastating complication of this viral infection is pneumonia. In hematological malignancies (HM), however, no studies have evaluated the novel A/H1N1 associated pneumonia outcome during this second wave. In addition, no comprehensive data have described whether outcome of novel A/H1N1 pneumonia during the initial wave is different from that observed after this second wave. To address these issues we analyzed all cases described in the English literature. HM from our department with novel A/H1N1 2009 virus pneumonia were also included in the analysis. Methods: MEDLINE was searched using the following key words: 2009 A/H1N1 influenza, HM

and HSCT. *Results*: The search identified 25 cases of A/H1N1 associated pneumonia (Table 1). All these reports were dated during the initial wave (April 2009-March 2010). Mean age was 43 years (range 15-72). The most common underlying HM was AML (32%) followed by NHL (20%). Sixteen (64 %) had previously undergone allo-HSCT. The median absolute lymphocyte and neutrophil counts were 625 cells/µl (20-3800) and 300 cells/µl (10-6020), respectively. All patients were treated with oseltamivir 150 mg daily for 5-10 days. The median time from illness onset until the start of oseltamivir was 3,5 days (1-22). Critically ill patients were also receiving combinations of antibiotics and anti-fungal treatment. Eight (32%) patients required mechanical ventilation. Mortality rate attributable to novel A/H1N1 pneumonia was 19%. On the other hand, during the second wave (December 2010- March 2011), no cases of novel A/H1N1 associated pneumonia have been reported in HM. Herein, we present the first two known cases (both died due to influenza). Patient 1, a 55-year-old woman presented with typical flu symptoms and bilateral pulmonary infiltrates. On admission showed leukocytes 5.6 x 10^9/l with 80% blasts. A diagnosis of AML FAB M2 was made. Novel A/H1N1 virus was detected by RT-PCR in both nasopharyngeal swab (NPS) and BAL; Oseltamivir 75mg/12h was started on day 3; however she died in ICU 10 days later due to respiratory failure despite broad spectrum antibiotics. Patient 2, a 52-year-old woman diagnosed with Multiple Myeloma in June-2010, achieved complete remission after a bortezomib-based combination. However, on February 2011, she experienced a meningeal relapse. While undergoing chemo- and radiotherapy she developed flu symptoms and alveolar infiltrate in right upper lobe. NPS specimen showed novel A/H1N1 virus by RT-PCR. Two days after the onset of symptoms oseltamivir 75mg/12h and antibiotics were started. For the next 6 days she developed worsening respiratory distress and died 5 days later. There was no correlation between severe lymphocytopenia and mortality risk.

Conclusions: During the second season of the novel A/H1N1 pandemic, it appears that HM with novel A/H1N1 associated pneumonia might present with a high mortality (100% vs 19% during the initial wave) despite early antiviral treatment. Additional studies are needed to confirm these data. Thus, prevention strategies (infection control and vaccination) for patients, family members and caregivers are clearly indicated.

1611

A FULMINANT COURSE OF INFLUENZA A (H1N1) VIRAL PNEUMONIA IN A PATIENT WITH MULTIPLE MYELOMA AFTER TREATMENT WITH BORTEZOMIB

R van Rijn, J van den Brand, T Kuiken, P Sonneveld
Erasmus Medical Center, Rotterdam, Netherlands

Background . In 2010, 63 deaths and 2193 hospital admissions were reported in the Netherlands due to the current pandemic of Influenza A (H1N1). Main victims were children aged 0-5 years old, pregnant women and immunocompromised patients. Interestingly, in a recent study of 92 hospitalized patients with flu-like symptoms, 6/13 H1N1 PCR-positive patients received treatment for multiple myeloma [Garland, BBMT 2010]. One of the main treatment strategies for multiple myeloma is proteasome inhibition by bortezomib. As a side effect, bortezomib induces apoptosis in human NK-cells, suppresses NKp46-mediated cytotoxicity and has significant cytotoxic effects on CD4+-T cells and dendritic cells. In children with influenza, NK-cells are known to transduce an important signal to activated CD8+-T cells through the NK-cell inhibitory receptor CD94/NKG2A, which limits lung injury. In a large clinical study, an increased risk of viral infections occurred in myeloma patients treated with bortezomib [Chanan-Kahn, JCO 2008]. In addition, unexplained severe lung injury was reported in 4/13 patients after bortezomib treatment [Miyakoshi, Blood 2006]. Aims. We report the case of a patient with multiple myeloma who died of severe lung injury following treatment with bortezomib and infection with H1N1. Results A 52-year-old man with multiple myeloma completed 3 monthly induction courses consisting of bortezomib (d1,4,8,11), doxorubicin (d1-4) and dexamethason (d1-2). His renal function had improved and serum IgG lambda had decreased from 25 to 11 g/L. Three weeks later he was admitted with fever, coarseness and dyspnea. He was treated with broadspectrum antibiotics. All cultures remained negative. Over the next week he developed diarrhea and respiratory insufficiency. The diagnosis of H1N1 was made and antiviral medication was started. Before bortezomib, peripheral blood levels of T-cells and NK-cells were normal (CD8+ 0.9x10^9/L, CD4+ 0.9x10^9/L and NK 0.09x10^9/L). Immunophenotyping at diagnosis of H1N1 showed slightly elevated CD8+-T-cells (1.0x10^9/L), but diminished CD4+-T-cells (0.37x10^9/L) and NK-cells (0.03x10^9/L). Broncho-alveolar lavage showed a particularly high copy number of viral RNA (CT value 21.9).

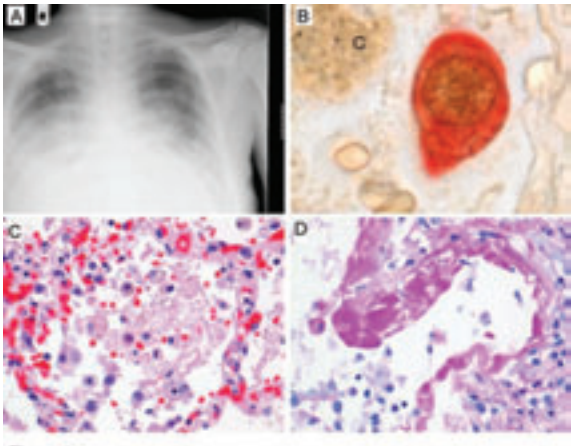

Figure 1.
Imaging, immunohistochemistry and histopathology of the patient infectd with H1N1 virus demonstrating infection of alveoli and related viral pneumonia. A. Thorax radiograph showing bilateral perihilar alveolar consolidation. B. Immunohistochemistry staining of intralesional alveolar epithelial cell with expression of viral antigen (brown nucleus) and keratin (red cytoplasm). C. Diffuse alveolar damage, H&E staining. D. Intraluminal hyaline membranes, PAS staining.

He was supported with mechanical ventilation, inotropic drugs and haemodialysis, but he finally died of lung injury, multi-organ failure and secondary sepsis. On autopsy, the lung parenchyma showed diffuse alveolar damage with hyaline membranes and edema. Immunostaining demonstrated influenza viral antigen in alveolar epithelial cells and alveolar macrophages in lesional lung tissue. H1N1v virus was detected throughout the respiratory tract as well as in brain and jejunum. Virus histochemistry demonstrated that H1N1v virus was also able to replicate in human alveolar epithelial cells. *Conclusions* . This fatal case of H1N1 demonstrates a rare finding: viral infection and replication of H1N1 in the alveolar epithelium. Furthermore, bortezomib treatment may lead to lung injury by uncontrolled CD8+-T-cell activity. Therefore, multiple myeloma patients may be at increased risk of a more fulminant course of H1N1 viral pneumonia.

1612

DISSEMINATTED CRYPTOCOCOSIS RESSEMBLING DISEASE PROGRESSION IN A PATIENT WITH A HLTV-1 ASSOCIATED ADULT-T-CELL LEUKEMIA-LYMPHOMA IN THE COURSE OF CHEMOTHERAPY ADMINISTRATION

N Curto, JJ Gil-Fernandez, H Guillén, Y Martin, J García-Suaréz, M Callejas, E Magro, M López-Rubio, T Pascual, C Burgaleta
Hospital Universitario Príncipe de Asturias, Alcala de Henares, Spain

Background. HTLV-1 retroviral infection is endemic in African coun-

tries, Japan and Caribbean region. Adult- T- Cell leukemia-lymphoma (ATLL) has been described in this population. ATLL is characterised by blood lymphoma signs, tumoral nodes and extranodal lesions, hypercalcemia and positive HTLV-1 serology. Cryptococcal infections have been described in immunocompromised hosts in associate to HIV, transplantation, lymphoma and LLC. Aims We report a case of an adult African patient with ATLL who developed a systemic opportunistic infection due to Cryptococcus neoformans in the course of chemotherapy administration, mimicking lymphomatous disease progression. *Case Report.* A 40 years-old healthy male, born in Ghana, was diagnosed of ATLL in July 2010, showing as main features: remarkable malaise with bone marrow and peripheral blood infiltration by typical flower- shaped lymphocytes, bilateral pulmonary nodules, hepatosplenomegaly, generalized adenophaties and high LDH. Systemic chemotherapy with Ifosfamide, Etoposide, Metilprednisolone, Doxorubicin, high dose Methotrexate and Dexametasone was started. Alpha Interferon and Zidovudine were added after positive HTLV 1 serology result. An initial favourable clinical response was achieved with improvement of peripheral blood infiltration, pulmonary disease and general condition. After five cycles of chemotherapy; thoracic CT Scan revealed a well- defined growing pulmonary mass (4,5x4,7 cm) located in upper right lobe. In the mean time, renal function deterioration and hypercalcaemia (14, 6 mg/dl), was developed. Under suspicion of unconfirmed lymphomatous disease progression, a fine needle aspiration was programmed, which disclosed typical encapsulated Cryptococcal yeasts with Indian ink technique. The patient developed cephalea and vomiting, with normal cerebral scan, however, cryptococcal yeasts were present in CSF and serum cryptococal antigen was 1/32. Combination treatment with liposomal Amphotericin B and Flucytosine was applied for the opportunist infection with a good evolution. *Conclusions*. Under the presence of hypocalcaemia and pulmonary nodules in patients with HTLV-1 infection, under chemotherapy and antiretroviral treatment are mandatory exclude opportunist infections.

1613

EARLY REACTIVATION OF HERPESVIRUSES IS ASSOCIATED WITH COMPLICATIONS OF HEMATOPOIETIC STEM CELL TRANSPLANTATION

A Chukhlovin, S Shiryaev, Y Eismont, O Pankratova, E Semenova, V Vavilov, L Zubarovskaya, B Afanasyev

R.M.Gorbacheva Memorial Institute of Children Hematology and Transplantation, Saint Petersburg, Russian Federation

Background. Cytostatic therapy preceding HSCT causes common infectious complications, including reactivation of viral and fungal pathogens. Aims. The aim of our study was to study possible associations between herpesvirus reactivation and common complications following HSCT. Patients and methods. A group of 143 patients at the age of 2 to 61 years old (a median of 18.5 years) with various oncohematological disorders underwent allogeneic HSCT. Ratio of marrow-to-peripheral stem cell transplants was 35:65; unrelated HSCT, 64% of cases; myeloablative conditioning was chosen in 58%. Common complications, i.e., acute GvHD, mucositis, cystitis, pneumonias, neurological disorders, severe general infections were registered post-HSCT. The study included a sub-group of 54 children and young patients up to 21 years old with ALL and AML who were subject to HSCT with myeloablative (n=31) or non-myeloablative conditioning regimens (n=23). DNA testing for cytomegalovirus (CMV), herpes simplex virus (HSV), Epstein-Barr virus (EBV), Candida albicans, and Toxoplasma gondii was performed in leukocytes by gene-specific PCR at a weekly basis, up to day +100. Results. In general group of the patients, the incidence of HSV, CMV and EBV after HSCT was, respectively, 51%, 57% и 45%. Meanwhile, frequency of viral reactivation proved to be age-dependent, i.e., HSV and CMV positivity rates were lower in younger children (1 to 4 years old), followed by increased viral reactivation rates at 10-20 years. Strong correlation was found between CMV and HSV, as well as CMV and EBV reactivation, thus suggesting mixed infectious states. We have not revealed any differences in viral reactivation among patients who underwent conditioning therapy of different intensity. However, a higher percentage of infectious complications was found among young HSV-positive patients vs HSV-negative cases (resp., 88% and 39%, p=0,057). In younger patients (<21 years), a correlation was found between HSV persistence and neurological symptoms (P=0.002). Skin mucositis severity and duration was connected with HSV and CMV reactivation (P=0.02, or 0.008). Risk of acute intestinal GvHD and hemorrhagic cystitis correlated with EBV reactivation (P=0.01). Polyomavirus DNA (BK, JC) was detected in urine sediments, and positive findings, generally, reflected clinical signs of cystitis. Conclusions. Post-HSCT reactivation of HSV in younger patients is significantly associated with higher incidence of early complications, including bacterial infections, skin mucositis and neurological complications.

1614

GRANULOCYTE TRANSFUSIONS AS ADJUNCTIVE TREATMENT OF INFECTIONS IN NEUTROPENIC PATIENTS

M Caira, N Piccirillo, M Mancinelli, P Chiusolo, L Fianchi, S Hohaus, M Maresca, R Putzulu, M Voso, G Leone, L Pagano

Catholic University, Rome, Italy

Background: The degree and duration of neutropenia have been recognized as crucial prognostic factors in hematological patients with invasive infections. Since the introduction of granulocyte colony stimulating factor (G-CSF), there has been a renewal of interest in granulocyte transfusions (GTX). However there is a large variability in the transfusion practice, and uncertainty about the beneficial effects of GTX as adjunctive measure to antimicrobial therapy. Aims: We designated a retrospective analysis to evaluate feasibility, efficacy and safety of GTX as adjunctive treatment for neutropenic fever unresponsive to antimicrobial therapy. *Methods:* We conducted a retrospective analysis about adult patients with hematological malignancies (HM) and fever during neutropenia (ANC<500x10^6/l and anticipated duration >7days) who received GTX after no clinical response to antimicrobial therapy. Volunteer donors received G-CSF 12h before the first of two consecutive collection procedures (5μg/kg). All of them had signed an informed consent for G-CSF administration and leukapheresis. Results: During a 7-year period (2004-10) 46 courses of GTX were administered to patients with HM and fever, after no clinical response to antimicrobial therapy. Patients were suffering from acute leukemia (30 myeloid and 5 lymphoid), lymphoma (9), multiple myeloma (2). Overall, 209 GTX were administered, with a median of 4 GTX per episode of infection (range 1-20). Infections causing fever were identified in 41 episodes: 17 bacterial sepsis, 23 invasive fungal diseases (IFDs) and 1 mixed bacterial/fungal sepsis. Remaining 5 cases were classified as fever of unknown origin (FUO). IFDs included 16 cases of pulmonary aspergillosis (proven/probable), 5 candidemia, 1 invasive zygomycosis, 1 invasive fusariosis and 1 infection due to Blastoschizomices capitatus. Donors' mean white blood cell (WBC) count at first leukapheresis was 27 x 10^9/l (range 13-45); at second procedure WBC count was lower (15 x 10^9/l, range 8-33), as expected. The mean yield was 25.6 x 10^9 PMN (range 3.5-75.8) at first procedure and 11.1 x 10^9 PMN at the second one (range 0.6-42.4). Mean transfused dose was 3.7 x 10^9/kg at first day (range 0.6-9.6) and 1.4 x 10^9/kg at second day (range 0.1-4.7). The combination of antimicrobial therapy with GTX led to a favourable clinical response in 33 of 46 valuable patients (72%); the acute infection-attributable mortality rate at 30th day after the last GTX was 29% for sepsis, 22% for IFD and 40% for FUO. *Conclusions:* at preliminary analysis GTX may be safe and efficacious in HM with severe infection to bridge the period of deep neutropenia, when antimicrobial therapy has failed. Controlled studies are needed to confirm this datum, and to define the proper role of this procedure and the optimal schedule for HM.

1615

PIPERACILLIN/TAZOBACTAM + AMIKACIN VS CEFEPIME + AMIKACIN AS EMPIRICAL ANTIBIOTIC THERAPY IN NEUTROPENIC PATIENTS. A SINGLE CENTRE RETROSPECTIVE ANALYSIS

A Bonini[1], A Tieghi[1], C Capatti[2], L Tognazzi[1], F Merli[1]

[1]*Hematology Azienda ospedaliera ASMN, Reggio Emilia, Italy*

[2]*Microbiology Azienda ospedaliera ASMN, Reggio Emilia, Italy*

Background: Hematologic patients (pts) are at high risk for infections because of the disease and the chemotherapy that could induce a prolonged and deep neutropenia. *Aims:* The aim is to evaluate the efficacy of two different empirical antibiotic regimens. *Methods:* Between 2001 and 2006, 316 consecutive pts were included. At the beginning of chemotherapy they were randomly assigned to receive piperacilline/tazobactam (162 pts, Group 1) versus cefepime (154 pts, Group 2) + amikacin. All received levofloxacin as prophylaxis. In case of fever after blood cultures levofloxacin was discontinued and each patient received the assigned regimen. The 2 groups were similar for gender, age and disease's phase. The diagnoses were for each group respectively: leukemia 74 and 63; lymphoma 27 and 37, myeloma 56 and 41; the remaining diseases (aplastic anemia, multiple sclerosis, solid tumors) were similar in the 2 groups. 140 pts received a SCT (108 autologous and 32 allogeneic); the transplants were homogeneously distributed in the 2 groups. A CVC was present in 113 pts (70%) of group 1 and in 110 pts (72%) of group 2. The days with PMNs <0.1 x 10^9/L were 10 (range 1-

40) for each group. Results: 92/162 (group 1) and 87/154 pts (group 2) had fever and received the assigned treatment. The mean days with fever was 8.4 for group 1 and 8 for group 2. The diagnoses of the febrile episodes were for group 1 and 2: FUO 28 vs 26, clinically documented 16 vs 16, microbiologically documented with bacteremia 47 vs 44, neoplastic 4 vs 5 and drug-related 5 vs 9. The gram positive bacilli were 32 and 28 for each group (85% of them were coagulase-negative staphylococci). The gram negative were 17 (9 pseudomonas, 5 escherichia, 1 stenotrophomonas maltophilia, 2 klebsiella) and 14 (7 pseudomonas, 5 escherichia, 2 enterobacter) for each group. The clinically documented infections were all pneumonia and were considered fungal infections so the pts received antifungal therapy. The duration of antibiotic therapy was respectively 9.8 and 10.3 days. In case of isolation of methycillin-resistant bacteria the pts received vancomycin. 13 and 11 pts needed a second antibiotic course in group 1 and group 2 respectively (they received carbapenems). Excluding the clinically documented episodes, antifungal therapy was administered in 12 of group 1 and in 5 phases of group 2 for suspected or documented breakthrough fungal infections. All the febrile episodes except 6 resolved: of the 6 deaths, 4 were in the first group and 2 in the second one. The infection-related mortality in the microbiologically documented infections cohort was 5 and 4 cases in group 1 and 2 respectively. Of them 2 pts in group 1 and 2 pts in group 2 dead for breakthrough fungal infection; the other pts dead for bacterial infections. *Conclusions:* the response in the 2 groups is similar in terms of days of fever, need for further antibiotic courses, need for antifungal therapy and resolution of fever even if further and larger studises are necessary to assess if one regimen is superior.

1616

A MILIARY TUBERCULOSIS CASE ACCOMPANIED BY HEMOPHAGOCYTOSIS AND PANCYTOPENIA

HS Semiz[1], U Ergene[2], H Aydede[3], N Özkütük[4], D Özbalci[2], N Nese[5], S Senol[6]

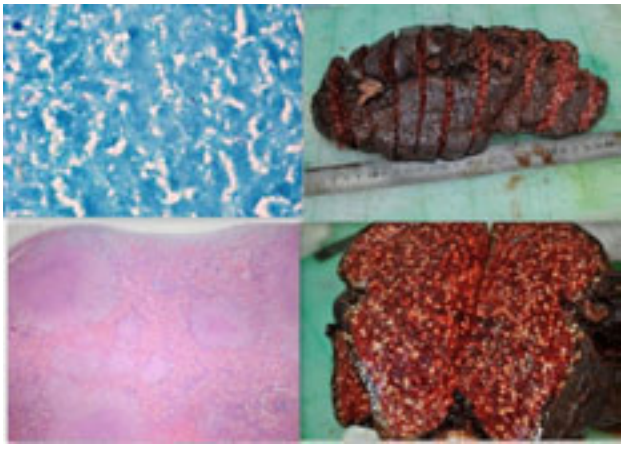
Background:Miliary tuberculosis occurs through uncontrollable spread of mycobacterium tuberculosis via lympho-hematogenous route. The symptoms of tuberculosis are quite variable; primary infection tends to be acute whereas late miliary tuberculosis is frequently subacute or chronic. The disease could go unnoticed because of the non-specific symptoms such that in USA, it was reported that % 20 of cases of miliary tuberculosis had a post-mortem diagnosis (2). Methods:A 25-year-old male patient sought medical help for fever, fatigue, weight loss and night sweats for three months; his fever was uncontrolled despite antibiotic and antifungal therapy. Hepatosplenomegaly and multiple cervical lymphadenopathies were detected in physical examination. His hemogram was Hg: 6.9g/dl, Hct: 20.6%, Plt: 125.000/μL, WBC: 4000/μL, Neu: 3600/μL, and in peripheral smear; there were marked anisopoicylocytosis, slight rouleaux formation, and 6 % of fragmented erythrocytes. In bone marrow aspiration; apparent dismyelopoiesis, hemophagocytosis and megaloblastic changes, an increase in eosinophilic series, in number of megakaryocytes, in blastic cells (4-5%) were seen, also atypical plasma cells (plasma cell proportion < 5%, few atypical mast cells were observed. Flowcytometry was nonspecific. Bone marrow biopsy was normocellular; a slight increase in precursor erythroid series, the cluster of megakaryocytes, and a relative decrease in granulocytes were observed. Bone marrow aspirates were also obtained for bacterial, micobacterial and parasite analysis. Protein electrophoresis was normal. The patient's temperature occasionally rose to 40°C during daytime and blood cultures which were taken during fever period were negative. Sputum ARB was negative. Salmonella, Brucella, Syphilis, Plasmodium, Leishmania, Toxoplasma, Echinococcus, CMV, EBV, HSV, HBV, HCV and HIV serologies were negative. Imaginig were obtained by CT and ultrasonography which showed hepatosplenomegaly (liver 207 mm and spleen 180 mm), multiple cervical and bilateral hiler lymphadenopathy. Excisional biopsy of lymp node was concordant with necrotizing lymphadenitis and medium-small vessel vasculitis. ANA was homogeneous granular pattern positive whereas other autoimmunity markers were negative. As LAP biopsy highlighted possible Wegener's Granulomatosis, paranasal sinus CT and cerebral MRI obtained but they were normal so as upper airway exam; then we performed renal biopsy and no signs of vasculitis were found. Bronchoscopy and brush biopsy were normal Transthoracic Echocardiogram was normal. In follow-up, pancytopenia developed; Hemoglobin: 5.8 g/dl, WBC: 1700/μL, Neutrophile: 1100/μL, PLT: 59000/μL. Besides, liver function tests followed a high and fluctuating course; AST: 110 U/L, ALT: 129 U/L. Results:We decided to perform splenectomy, liver wedge biopsy and peritoneal biopsy concurrently to the patient who had still fever to establish diagnosis. Tuberculosis bacilli were seen in the spleen microscopy(picture 1). The patient was diagnosed to have miliary tuberculosis and antituberculosis medications were started. In the liver and peritoneum biopsies, tuberculosis bacilli and granulomatous inflammation were seen. Later on, mycobacterium tuberculosis complex were also cultured in the bone marrow as well. Summary/Conclusion: Diagnosis of military tuberculosis is difficult because of nonspecific and unpredicted clinical course. It is unlikely that tuberculosis is accompanied by especially severe hemophagocytosis and pancytopenia. We have reported this case since it was difficult to diagnose and miliary tuberculosis was accompanied by severe hemophagocytosis and pancytopenia



1617

IMPORTANCE OF PRE-MEDICATION IN DECREASING THE INCIDENCE OF INFUSION-RELATED REACTION BEFORE USE OF AMPHOTERICIN B COLLOIDAL DISPERSION IN PATIENTS WITH ACUTE LEUKEMIA

I Djunic[1], N Suvajdzic-Vukovic[2], V Djurasinovic[1], A Vidovic[2], M Virijevic[1], A Novkovic[3], N Colovic[2], D Tomin[2]

[1]*Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia*
[2]*Clinical for Hematology, Clinical Center of Srerbia, Shool of Medicine, Belgrade, Serbia*
[3]*Clinic Hospital Center, Zemun, Belgrade, Serbia*

Background: Fungal infections cause significant morbidity and mortality in patients with acute leukemia (AL). Conventional amphotericin B deoxycholate (cAmB) has been successfully used for treatment of these infections. Nevertheless, the side effects and particularly nephrotoxicity of cAmB limits its use. Amphotericin B colloidal dispersion (ABCD) has decreased the rate of nephrotoxicity, but it seams that the frequency rate of infusion-related reaction (IRR) is still high in comparison to other forms of AmB, despite the pre-medication received before its use. The most commonly reported IRRs were chills, rigor, fever, nausea and vomiting. Aims: The aims of this single-center study were to determine the type and the incidence of IRR in patients with AL who were receiving ABCD according to the type of pre-medication used as well as ABCD's doses. Methods: In this study 32 patients with AL, receiving ABCD, were included. Indications for ABCD use were empirical in prolonged febrile neutropenia or therapeutical in documented fungal infection. Patients were divided into 2 groups according to the 2 types of pre-medication applied. Each group involved 16 patients. One group received type 1 pre-medication: methylprednisolone 300 mg + metamizol 2.5 mg intravenous (i.v.) 30 minutes before infusion of ABCD. The other group received type 2 pre-medication: methylprednisolone 40 mg i.v. + loratidine 10 mg per os (p.o.) + paracetamol 1000 mg p.o. 30 minutes before infusion of ABCD. Applied doses of ABCD were 2.5-5 mg/kg. Duration of IRR in days (started after first infusion of ABCD) were recorded. The median duration of ABCD's treatment was 9 days. The risk factors were identified using the univariate and multivariate

analysis. Results: The median age of a patient was 43 years, range 19-65 years. The average dose of applied ABCD was 3.25 mg/kg and the average duration of IRR was 2 days (range 1-8 days). Recorded IRR concerted the following symptoms: chills, rigor and fever. The other types of side effects and toxicity were not detected in patients involved in this study. IRR was recorded in 47% of patients. In the group who received pre-medication of type 1, IRR was recorded in 18.75%, while in the group who received pre-medication of type 2 IRR was recorded in 75% of patients. Thus, the patients, who received type 2 pre-medication, had IRR significantly more frequent compared with the patients who received type 1 pre-medication (p=0.004). The patients treated with the dose of ABCD >3 mg/kg had IRR significantly more frequent than those treated with the dose ≤3 mg/kg (p=0.033). The multivariate analysis indicated the type of pre-medication as the most significant risk factor for IRR: p=0.022, relative risk (RR)=0.231 (95% CI 0.066-0.810). The significant risk factors for prolonged duration of IRR were type 2 pre-medication (p=0.002) and the dose of ABCD >3mg/kg (p=0.005). The most significant risk factor for prolonged duration of IRR was the applied dose of ABCD >3mg/kg: p=0.003, RR=2.325 (95% CI 0.835-3.815). Conclusions: The pre-medication with high doses of methylprednisolone with metamizol significantly decreased the rate and duration of IRR in AML patients receiving ABCD.

1618

VOLUME, CONDUCTIVITY AND SCATTER PROPERTIES OF LEUKOCYTES (VCS TECHNOLOGY) IS A HIGHLY SENSITIVE AND SPECIFIC PREDICTOR OF BLOOD CULTURE PROVEN NEONATAL SEPSIS

L Simon[1], M Bhargava[2], U Sindhuri[2], S Saluja[2], A Saraf[2], S Dayanand[3]
[1]*Beckman Coulter Eurocenter, Nyon, Switzerland*
[2]*Sir Ganga Ram Hospital, New Delhi, India*
[3]*Beckman Coulter, Mumbai, India*

Background. Neonatal septicemia remains as the major cause of mortality in newborns. As per WHO estimates, more than 1/3rd of the estimated 4 million neonatal deaths around the world are caused by severe infections and a quarter, around 1 million, are due to neonatal sepsis/pneumonia alone. In India, in a community based study, septicemia and pneumonia accounted for 52% of neonatal deaths. In a hospital-based data have been reported 18.6% neonatal deaths to be due to sepsis and 37.6%. in extra-mural babies sepsis. The existing tests for sepsis screen include blood culture (gold standard), CBC, Immature neutrophils (smear), immature to total neutrophil (IT) ratio and C-reactive protein (CRP). *Aims.* We evaluated the new automated WBC morphology: data on individual cell volume (V), conductivity (C) and laser light scatter (S) (VCS technology, generating what is called Cell Population Data (@CPD), that are reported as numerical values (Mean and Standard Deviations (SD) for every type of leukocyte. Examples of these CPD data are: Mean Neutrophil Volume that has previously been reported as a good test for Sepsis and Bacterial infections. *Methods.* We have included 133 consecutive neonates (0-28 days of life) admitted to neonatal intensive care unit for suspected sepsis were enrolled in the study together with 36 gestation-matched controls. The blood samples were run on the Beckman Coulter® LH750 and LH755 hematology analyzers to provide CBC, WBC Diff, retics and CPD. Were also evaluated blood culture and CRP. Peripheral blood smears were made on all cases. In this study we analysed MNV, CRP and IT ratio as a single parameters and combinations of them to detect sepsis. Results. Searching for the best combination of parameters, we found that combining MNV and CRP, we obtain: sensitivity: 100.0%, specificity 85.7% cut-off>154.8, AUC: 0.968. and we found a discriminant function for sepsis (DFS=1.12 - 0.004* NE# - 0.065* HGB + 0.013*MNV - 0.019*MNS + 0.025SD -S-Ly) with 100% sensitivity,100% specificity, AUC=1 (Table 1) When we compare (proven sepsis + probable sepsis) and controls, DFS have shown 82.1% sensitivity and 100% specificity with AUC 0,889, at a cut-off >0.3242 (Table 2). Immature neutrophils (AUC 0.634) had a lower performance (P = 0.0044) than Mean Neutrophil Volume (CPD) (AUC: 0.922) even if they look for similar aspects of neutrophils, because is well known that Immature Neutrophils are bigger than segmented neutrophils (Woessner et al.). *Summary.* These findings demonstrate that the automated leukocyte morphology (CPD) and the combination of CPD and other parameters may dramatically improve the early detection of neonatal sepsis. Further studies could evaluate IL-6 to see if IL-6 could further enhance the predictive value. Also, prospective protocols on a larger number of cases and/or randomized co-operative studies could be designed to prove the clinical efficacy of the present findings so as to incorporate them in daily clinical practice.

A SURVEY ON CMV REACTIVATION IN 102 PATIENTS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: EFFECTIVENESS OF PREEMPTIVE THERAPY

R Greco, F Matteazzi, D Clerici, A Forcina, F Lorentino, MT Lupo Stanghellini, L Fumagalli, S Malato, F Giglio, S Girlanda, C Messina, S Claudiani, M Tassara, A Assanelli, E Guggiari, F Lunghi, M Carrabba, S Marktel, M Marcatti, M Bernardi, J Peccatori, C Corti, F Ciceri
San Raffaele Scientific Institute, Milan, Italy

Background: Cytomegalovirus (CMV) continues to cause major complications after allogeneic stem cell transplantation (allo-SCT). Materials and methods: In 2009 and 2010, 102 pts (median age 49; 68 males) received transplant for high risk haematological malignancies in our centre: 51 AML, 14 ALL, 2 biphenotypic AL, 6 MDS, 10 HD, 6 NHL, 3 CML, 3 MFI, 7 other diseases. Allo-SCT were performed in 96/102 from PBSC source; 10 from HLA identical sibling (Sib), 21 from unrelated volunteer (MUD), 65 from family haploidentical donor (Haplo) without ex-vivo T-cell depletion, 6 cord blood (CB). Pts were evaluated for CMV quantitative DNA PCR twice weekly within the first 3 months after allo-SCT. Donor/host serostatus was: -/- 8 (8 %), +/+ 52 (51%), -/+ 33 (32%), +/- 9 (9%). All pts received acyclovir as viral prophylaxis. Results: We observed CMV reactivation in 59/102 pts (58%), median time of onset 31.5 (3-91) days post Allo-SCT, median number of CMV PCR 1377 (93-346480) cp/mL. The donor/host (D/H) serostatus in these pts was +/+ 33 (56%), -/+ 23 (39%), +/- 3 (5%); 32 were Haplo, 5 CB, 15 MUD, 7 Sib allo-SCT. Preemptive therapy was administered in 39 pts; 13 pts received oral valganciclovir (VCGV) as first line preemptive therapy, 17 ganciclovir (GCV), 9 foscarnet (FCV). Median time of CMV infection was 28 days (5-407) days and we observed a median of 1 CMV further reactivation in the first year post transplant; these events were similar in all pts of this group. A total of 13 pts required drug cross-over; D/H serostatus was neg/pos in 9 pts, pos/pos in 4. Only 2 cases of CMV organ involvement were observed after MUD allo-SCT: in one the site of CMV disease was colon in the other lung. In these pts who experienced a CMV reactivation 37 are still alive, 22 were dead. No CMV reactivation was reported in 43/102 pts (42%). The donor/host (D/H) serostatus in these pts was -/- 8 (19%), +/+ 19 (44%), -/+ 10 (23%), +/- 6 (14%); 33 were Haplo, 1 CB, 6 MUD, 3 Sib allo-SCT. In these pts who not experienced a CMV reactivation 21 are still alive, 22 were dead. Conclusions: These data suggest the efficacy of CMV preventionin HCT recipients from all donor sources.

1620

INCIDENCE OF INFUSION-RELATED REACTIONS IN PREMEDICATED PATIENTS RECEIVING AMPHOCIL®: A SINGLE CENTER EXPERIENCE

S Nada, A Vidovic, I Djunic, V Djurasinovic, D Antic, M Mitrovic, B Andjelic, I Elezovic, D Tomin
Clinic of Hematology, Belgrade, Serbia

Background: Higher rate of infusion-related reactions (IRRs) occuring with Amhotericin B Cholesteryl Sulfate Complex for Injection (ABCD; Amphotec®/Amphocyl®) vs. other forms of amphotericin B are report-

ed. It has been recently shown that premedication prior to ABCD decreases the incidence of IRRs. Aim: To determine the IRRs incidence associated with Amphocyl® therapy in the context of the premedication. Patients and Methods: Patients beginning treatment with Amphocyl® were eligible. They were treated as follows: 1mg/kg first day and then 3-4mg/kg (maximum 6mg/kg); i.v infusion. At least two premedication drugs were recommended (ad libitum). The patients has received the same premedication combinations during the treatment. In the case of IRRs the infusions were stopped and Acetaminophen and/or Meperidine was administered. Corticosteroids were reserved for grade III of IRRs. Data on ABCD doses and premedications have been collected during the whole treatment period. Data collected included: demographics, co-infections, history of prior antifungals, routine laboratory values, type of fungal infection, premedication type, daily dose of ABCD and IRRs occurence/grade/type. Informations regarding the patients response to ABCD were collected. Mann-Whitney test was used to compare the rates of IRRs between various premedication regimens. Results: 39 adult patients (M:F-25/14; median age 40 yrs, range 18-65; median body weight 79 kg, range,48-108 were treated with Amphocyl® from March 2007-June 2008. The majority had acute leukemia 28/39; 22/39 received prior antifungals (convential amphotericin B 14, azoles 8). Two patients had definite, 6 probable and 17 possible fungal infections, respectively. Lungs were the most frequent infection site (21); 14 pts were treated with Amphocyl® empirically. There were 351 infusions in total, range 1-35; average daily dose was 3.46 mg/kg, range 1.7-5.80, average cumulative dose was 2613 mg, range 100-10.300; average therapy duration was 9 days, range 1-35. All the patients were premedicated- 19 received two, 20 three drugs. The premedications used were as follows: Acetaminophen, Loratadine, Meperidine, Dexamethasone, Methylprednisolone, Metamizol. The most frequent combinations of drugs in premedications were: Acetaminophen + Loratadine in 9 and Acetaminophen + Loratadine + one corticosteroid in 11 pts. 20/39 pts. experienced IRRs while IRRs were reported following 48 infusions (13.7%). The most frequent IRRs were: chills 40/48, fever 42/48 and rigors 16/48. All IRRs were low severity. The incidence if IRRs was highest in the first five days of therapy (d1: 17, d2: 13, d3: 7, d4: 4, d5: 2, d6: 1). Loratadine was associated with a statistically significant lower rate of IRRs vs. other types of premedication (p? 0.03). Reasons for Amphocil® discontinuation were as follows: recovery (17), death (10), identification of fungal organism (6), infusion intolerability (3) and infusion intolerability associated with recovery (3). No significant nephrotoxicity was registered. After 12 weeks of folow-up 27 pts were alive, all positively responding on Amphocyl®. *Conclusions*: We demonstrated lower rates of IRRs compared to historical rates which, is in agreement with the results of PRoACT. The incidence of IRRs decreased significantly from days 1-5 and desappeared after day 7. Premedication with Loratadaine was associated with significantly lower IRRs rate comparing with other type of drugs.

1621

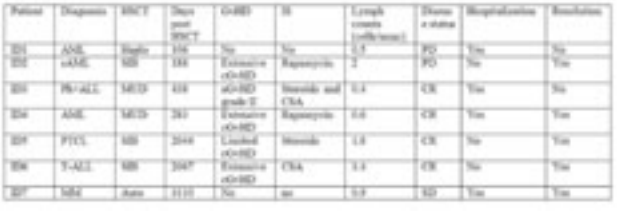
INFLUENZA A-H1N1 VIRUS INFECTION IN PATIENTS UNDERGOING HSCT

F Lorentino, R Greco, D Clerici, F Matteazzi, A Forcina, MT Lupo Stanghellini, L Fumagalli, C Messina, S Claudiani, S Girlanda, S Piemontese, M Tassara, A Assanelli, E Guggiari, F Lunghi, M Carrabba, S Marktel, M Marcatti, M Bernardi, J Peccatori, C Corti, F Ciceri

San Raffaele Scientific Institute, Milan, Italy

Background. Hematological patients (pts) under hematopoietic stem cell transplantations (HSCT) are at a high risk for severe viral infections. We analyzed the clinical impact of influenza A infection (H1N1) outbreak in our patients population. Material and Methods. From September 2009 to January 2011 we reported 7 cases of H1N1 infections in 7 HSCT recipients. Patients' characteristics are shown in table 1. Diagnosis of H1N1 was made by real-time PCR assay in nasopharyngeal samples. Results. Six pts were not vaccinated, one developed the first symptoms of influenza 19 days after the first dose of vaccine. The most frequent symptoms were: fever (100%), cough (86%), dyspnea (43%), rhinorrhea (28%), odynophagia (28%), headache (28%) and arthralgia (14%). All cases were confirmed by PCR in nasopharyngeal or bronchoalveolar lavage samples. Five pts had pneumonia; CT-scan showed multiple pulmonary nodules with ground glass appearance. Chest X-ray results were not diagnostic. All patients were treated with oseltamivir 75 mg bid for a median of 7 days (7-19), except for one who received oseltamivir 150 mg bid for the severity of the infection. Oseltamivir was started within 24 hours from the onset of symptoms. All pts received concomitant antimicrobial therapy for a median of 17 days (7-40). No major adverse events related to anti-influenza treatment were reported. We observed a decrease of platelet counts in four pts with pancytopenia at the time of infection, 3/4 pts required transfusion support. Resolution of symptoms was achieved in a median of 14 days (8-30) in 5/7 pts. Four pts needed hospitalization for a median of 15 days (10-18); 3/4 pts needed ventilatory support (C-PAP for ID1, C-PAP plus intubation for ID3, high-flow O2 therapy for ID4). All pts developed lymphopenia (<1000/mmc). Two pts died from respiratory failure: one was in progression disease, one other patient was in complete remission but profoundly immunosuppressed (high dose steroids plus Cyclosporin as GvHD therapy). Conclusions: H1N1 infections in HCST recipients can result in a severe and fatal syndrome. Since symptoms of a H1N1 infection are unspecific, early testing for H1N1 virus in hematological pts is mandatory. CT scan is the diagnostic investigation of choice to rule out pneumonia. Clinical courses of H1N1 infections in HCST recipients range individually. The early use of oseltamivir may help determinig the good outcome of the infection, but prognosis seems to be strongly related to the disease status and to the degree of immunosuppression. In our experience lymphopenia correlates with the outcome.

Table 1



1622

HUMAN HERPESVIRUS-6 (HHV-6) REACTIVATION IN HEMATOLOGICAL PATIENTS

R Greco, F Lorentino, D Clerici, A Forcina, F Matteazzi, MT Lupo Stanghellini, L Fumagalli, B Forno, S Malato, F Giglio, C Messina, S Claudiani, M Tassara, A Assanelli, E Guggiari, F Lunghi, M Carrabba, S Marktel, M Marcatti, M Bernardi, J Peccatori, C Corti, F Ciceri

San Raffaele Scientific Institute, Milan, Italy

Background: Human Herpesvirus-6 (HHV-6) can reactivate and sustain various clinical manifestations in immunocompromised patients (pts). Materials and methods: We retrospectively evaluated hematological pts who developed positivity to HHV-6, measured by quantitative PCR. Results: From January 2009 to January 2011 we observed HHV-6 positivity in 49 pts (median age 54; 30 males), 39 of them received allogeneic stem cell transplantation (allo-SCT), 2 autologous transplantation, 8 chemotherapy. At the time of reactivation all pts were receiving acyclovir as viral prophylaxis except 5 (3 pts off antiviral therapy, 2 on ganciclovir). A concomitant CMV positivity was detected in 11/49 pts, while a severe neutropenia in 23/49 pts. Allo-SCT was performed in 38/39 pts from PBSC source; 5 from HLA identical sibling, 3 from unrelated volunteer, 29 from haploidentical donor, 2 cord blood. Among allo-SCT pts 15 had GvHD (13/15 with grade III-IV aGvHD), and 32 were profoundly immunosuppressed with variable association of 2-4 drugs. Median time from allo-SCT to HHV-6 reactivation was 41 days (7-625). In 25 pts HHV-6 was detected in plasma, with a median number of 19937 cp/mL (34-4524600); 18/25 pts had fever (9 bacterial and 1 fungal infection), 8/25 skin rash, 4/25 worsening of liver function, 5/25 cytopenia. In 9 cases HHV-6 was present in bone marrow samples and 5 of them had concomitant HHV-6 plasma positivity; the median viral load was 25123 cp/mL (568-904000) and 3 pts developed cytopenia. In 11 pts HHV-6 was observed in bronchoalveolar lavage samples with a median of 502 cp/mL (57-50211); 9/11 pts had fever (5 bacterial and 1 fungal infection). In 16 pts (15 of them after allo-SCT, 9 with previous gut aGvHD) HHV-6 was also present in gastrointestinal biopsy (13 colorectal, 3 gastric) with a median of 5550 cp/mL (120-163800); in 4 cases HHV-6 was also found on plasma; 11/16 pts had diarrhoea. HHV-6 was found in cerebrospinal fluid in 3 pts (all within 30 days post allo-SCT); in 2/3 virus was also detected in peripheral blood; the median viral load was 19454 cp/mL (4508-39250); 3/3 pts experienced encephalitis showing confusion and anxiety, 1/3 seizure and 2/3 abnormal findings on brain MRI; all pts had fever and 1 skin rash. In all these cases HHV-6 was treated only when associated with potentially related clinical manifestations. Antiviral therapy was necessary in 23 pts (all received foscarnet

except 3) and 13 of them solved the event. Among pts who experienced HHV-6 reactivation, 26/49 pts (53%) died. Conclusions: HHV6 reactivation is associated with high morbidity and mortality in hematological pts undergoing intensive treatment. Particularly, in pts who underwent allo-SCT HHV6 reactivation is associated with a poor outcome. A regular DNA monitoring is prospectively performed and a pre-emptive treatment is implemented in the setting of allo-SCT.

1623

CHARACTERISTICS AND OUTCOMES OF ADULT HAEMATOLOGY PATIENTS ADMITTED TO THE INTENSIVE CARE UNIT (ICU)

C McCaughey,[1] B Blackwood,[2] M Brady,[2] MF McMullin[1]
[1]*Belfast City Hospital, Belfast, United Kingdom*
[2]*Queen's University Belfast. School of Nursing and Midwifery, Belfast, United Kingdom*

Background. The role of intensive care support for haematology patients has historically been contentious. *Aims.* To profile patient characteristics and assess outcomes of adult haematology patients admitted to ICU. Methods: Retrospective audit of medical notes, laboratory records and Intensive Care National Audit and Research Centre (ICNARC) data for all adult haematology patients admitted to Belfast City Hospital ICU in 2009. Results: Twenty one patients were admitted to ICU; mean age was 56-years (SD 12.5), 52% were male and 19 (82%) had a malignant diagnosis. The main indication for admission was neutropenic sepsis with associated organ impairment (n=18, 85%). ICU mortality was 43%. ICU survivors had lower acute physiology and chronic health evaluation (APACHE II) scores, and decreased requirements for invasive ventilation and inotropic support. Three and six-month mortality rates were 62% and 67% respectively. Of the post-six month survivors, one had relapsed, one had responding disease and five remained in remission. Two patients have subsequently undergone a reduced intensity conditioning transplant. Conclusion: A third of patients survived >6 months indicating that critically ill haematology patients may benefit from ICU admission, allowing progression to potentially curative therapies.

Table 1. Characteristics of ICU survivors and non survivors.

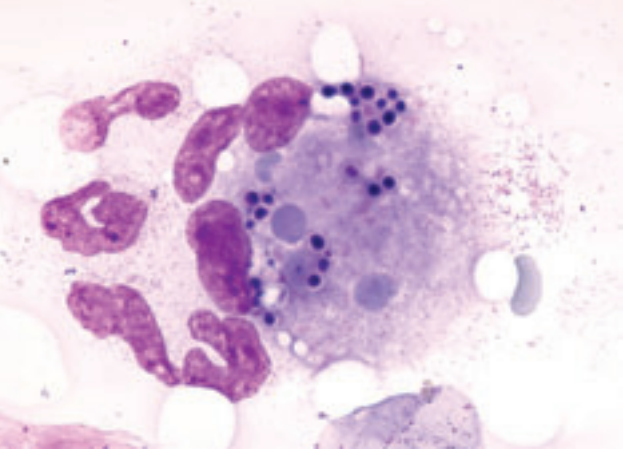
	ICU survivors (n = 12)	ICU non-survivors (n = 9)
APACHE II score, (mean, SD)	20 (5)	28 (6.6)
Invasive ventilation (n %)	6 (50%)	8 (90%)
Continuous renal replacement therapy	4 (33%)	3 (33%)
Inotropic support (n %)	3 (25%)	7 (78%)
Maximum no. of organs supported (mean, SD)	2.25 (1.1)	3 (0.7)
Days of ICU stay (median, IQR)	4.3 (2, 8)	4 (1, 7)

1624

BONE MARROW ASPIRATION DISCLOSES DISSEMINATED HISTOPLAMOSIS IN AN APPARENTLY IMMUNOCOMPETENT PATIENT

G Hurtado, D Etxeberría, L Iturre, ML Antelo, F Sala, JM Martínez-Peñuela, E Olavarría
Complejo Hospitalario de Navarra, Pamplona, Spain

Background. Histoplasma capsulatum is a dimorphic fungus endemic in the American continent, Africa and Asia. People acquire histoplasma through inhalation of spores from soils contaminated by bat or bird excrements. In Europe cases are usually imported and non frequent. Disseminated histoplasmosis normally affects patients with immunodeficiency. We report on a non-immunocompromised patient who developed a disseminated histoplasmosis due to a reactivation of a latent infection acquired during a previous travel to America more than 10 years earlier. Case report: A 39 year-old woman, with no prior medical history of interest, HIV negative, developed twelve days before admission, fever (39.6 °C), vomiting, diarrhoea and nocturnal cough. Blood tests showed thrombocytopaenia (platelets 59x10^9/L) and mild transaminase elevation as the only pathological findings. After admission, her condition worsened with the appearance of bilateral basal pulmonary infiltrates and persistent fever, irresponsive to treatment with Levofloxacin and Metronidazole. An abdominal ultrasound scan showed hepatosplenomegaly only. She was moved to the intensive care unit due to progressive respiratory failure that required intubation with mechanical ventilation and noradrenaline perfusion. A bronchoalveolar lavage was performed, with negative results for mycobacteria, fungi, viruses, legionella and other bacteria. Doxycycline and Meropenem were added to the treatment. All microbiological tests were repeatedly negative (blood cultures, coprocultures, parasites in stools, serological tests for HIV, brucella, Epstein Barr virus, cytomegalovirus, coxiella burnetti, s. pneumoniae, hepatitis, salmonella, chlamydia and mycoplasma, H1N1 virus, clostridium difficile toxin and Mantoux test). Some days later, the patient's clinical condition progressively improved, allowing the withdrawal of respiratory support, but the fever reappeared. The patient was transferred to an internal medicine ward, with progressive pancytopaenia (hemoglobin 7 gr/dl, leukocytes 3.7x10^9/L and platelets 37x10^9/L). A bone marrow aspirate showed an increased number of macrophages, with the presence of round PAS-positive pseudo-capsulated intracellular microorganisms, suggestive of infection by histoplasma capsulatum. A bone marrow biopsy showed the same microorganisms and a PCR for histoplasma capsulatum confirmed the diagnosis. Bone marrow cultures for bacteria, fungi and mycobacteria were negative. The patient was initially treated with Itraconazole, but due to sub-optimal response the treatment was changed to Amphotericin B (lipidic complex) for three weeks, followed by oral Itraconazole. At discharge, the patient was afebrile, asymptomatic, and the histoplasma capsulatum PCR in peripheral blood was negative. The only pathological finding in the blood count was an inflammatory anaemia that subsided after a month. Although the patient had not travelled recently to endemic areas, she had been in Costa Rica 12 years before this episode. Conclusions: this case highlights the utility of bone marrow aspiration/biopsy in the diagnosis of disseminated histoplasmosis. It emphasizes the importance of a detailed inspection of bone marrow aspirates, with special focus on macrophages if an infection is suspected.



1625

PREDICTION OF PROGNOSIS FOR CHILDREN CARED IN INTENSIVE CARE UNIT AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION.

NG Chung,[1] C Choi,[2] JW Lee,[1] DC Jeong,[2] C Cho,[1] PS Jang,[3] K Kim[1]
[1]*Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea*
[2]*Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, South-Korea*
[3]*Uijeonbu St. Mary's Hospital, The Catholic University of Korea, Uijeongbu-si, South-Korea*

Background. The pediatric index of mortality 2 (PIM-2) is a useful scoring system for prediction of prognosis in children with ICU support. The oncological pediatric risk of mortality score (O-PRISM) was also using for intensive cared children with hematopoietic stem cell transplantation (HSCT). Aims: Using both O-PRISM and PIM-2, we investigated risk factors, prognostic prediction tool, and survival for early detection of admission to intensive care unit (ICU). Methods: We reviewed retrospectively medical records of children cared in our institution ICU after HSCT between 2004 and 2010. There were excluded in patients died within 2 hours after moving to ICU. We used O-PRISM and PIM-2 for prediction of prognosis. We analyzed worst parameters in ICU by t-test, ANOVA, Cox-regression, multiple logistic regression, and receiver operating characteristics curve (ROC). Results: Fifty five out of 54 children were admitted to ICU on post-HSCT period. Non-malignant disease was 8 patients, and 16 children were transplanted with high risk disease

status. The source of stem cells were 14 matched sibling donor, 22 unrelated, 19 cord blood. The median duration in ICU was 9 days (0~110). The reasons of admission to ICU were 32 pulmonary, 14 neurologic, and 9 hemodynamic events. Twenty seven children did not take care of mechanical ventilation. Six patients (11.1%) were survived after intensive care. The factors with discharge with survival were mental status (P=0.04), although there were FiO2, prothrombin time, potassium, pupil reflex in univariate analysis. In multiple logistic regression, there were significant factors with PaCO2 (P=0.028), O-PRISM (P=0.039), and PIM-2 (P=0.004) for prognosis. For prediction of prognosis, O-PRISM (P=0.019) was superior to PIM-2 (P=0.435) in intensive cared children after HSCT. Conclusion: O-PRISM following HSCT is more predictable scoring system in children with ICU support, and Glasgow coma scale and PaCO2 were more reliable prognostic factors for ICU admission.

1626

CENTRAL VENOUS CATHETER INFECTIONS IN HEMATOLOGICAL PATIENTS: REPORT FROM A SINGLE INSTITUTION

F Bacchiarri,[1] M Tirindelli,[1] M Carassiti,[2] F Costa,[2] F Brescia,[2]
O Annibali,[1] E Cerchiara,[1] O Olimpieri,[1] G Avvisati[1]
[1]*Department of Hematology, University Campus Bio-Medico, Rome, Italy*
[2]*Department of Anesthesiology, University Campus Bio-Medico, Rome, Italy*

Central venous catheters (CVCs) are currently used in hematological settings for intravenous therapy, stem cell transplant (SCT), blood products and fluids infusions. However, catheter-related bloodstream infections (CRBSIs) are an important cause of morbidity and mortality. Aims: The study aimed at retrospectively analyzing infectious complications in hematological patients. Patients and methods: One hundred fifty-five CVCs (100 Port-a-Cath, 57 external CVC), inserted from March 2001 to June 2010, have been analyzed. Patients with external CVC received chemotherapy for acute leukemia or autologous SCT for myeloma or lymphoma. Patients with port-a-cath systems, affected by lymphoma or myeloma, underwent less intensive chemotherapy. Results: Out of 57 external CVCs, 6 experienced infections: 4 sepsis (P.aeruginosa), 1 skin tunnel infection (P.aeruginosa and S.epidermidis), 1 endocarditis (Streptococcus oralis). Three fatal cases occurred in leukemic patients treated with intensive chemotherapy. Infections did not affect catheter survival. Performance status did not influence catheter infections, neither fever nor infections at the time of procedure. Percutaneous technique was significantly associated to CRBSI (p=0.023). CVC infections were more frequently related to left side insertion and to percutaneous technique (p=0.023). CRBSI was not statistically related to the type of immunosoppressive therapy (p= 0.72). The underlying disease (p=0.03) and the type of therapy (p=0.029) were significantly associated with development of P.aeruginosa infections. Patients with a neutrophil counts < 500/? L for more than 10 days more frequently developed Pseudomonas infections (p=0.002). Out of 100 port-a-cath, sepsis occurred in 3 port-a-cath, 2 by S.epidermidis, and one by fungal infection. Overall, the infection rate per 1000cvc days was 0.71 in external CVCs, and 0.65 in ports. Cumulative survival was mainly influenced by infectious complications (Log Rank and Breslow p<0.0001). Although not statistically different, patients who developed a CR-BSI had lower neutrophil counts at the time of insertion. Less intensive chemotherapy in patients with port did not influence CRBSIs. Summary/conclusions: Some studies reported that CRBSIs are more frequent in patients with malnutrition and unfavorable performance status. However, the presence of infections and unfavorable performance status did not influence CRBSIs in our patients with external CVC and port-a-cath. There are conflicting data from the literature upon the importance of neutrophil counts at the time of insertion: according to some authors, neutropenia is a risk factor for CVC-related infections. Our study did not report a correlation between neutrophil counts and infection development neither in external CVCs or in ports. Diagnosis and therapy did not influence CRBSIs rate because of heterogeneity and/or low number of patients. In this retrospective study were confirmed the data reported by others that the side and type of venous access represent risk factors for CRBSIs. Materials and type of device may promote colonization and biofilm formation, with higher infection risk, but we were not able to find this association in 157 CVCs. The present study contributes to underline the complex management of hematological patients and their particular susceptibility to CVC infections.

1627

PREVALENCE OF HEPATITIS C AMONG MULTI-TRANSFUSED THALASSEMIA PATIENTS IN THE SULTANATE OF OMAN- SINGLE CENTRE STUDY

A AlNaamani,[1] I Al-Zakwani,[2] S Daar[2]
[1]*Sultan Qaboos University Hospital, Muscat, Oman*
[2]*Sultan Qaboos University, Muscat, Oman*

Background. Regular blood transfusion in thalassemia major is essential to maintain life. Risk of viral infections, especially hepatotropic viruses associated with blood transfusion, is a major concern. Screening of blood products for HIV, hepatitis B and C using the most sensitive methods have markedly decreased the risk of viral transmission. *Aims*. To evaluate the prevalence of hepatitis C in multi-transfused homozygous thalassemia patients in the Sultanate of Oman and to identify possible related risk factors. *Methods*. This is a retrospective chart review of all thalassemia major and intermedia patients (n=200) treated at the thalassemia Unit at Sultan Qaboos University Hospital in Oman. Relevant demographic and clinical characteristics were collected along with liver function tests, anti-HCV, and HCV RNA. Analyses were conducted using descriptive statistics. *Results*. Mean age of the patients was 23 ± 7 years ranging from 7 to 50 years. Eighty-one (41%) thalassemia patients were found to be HCV-Ab positive. HCV-Ab positive patients were significantly older compared to their HCV-Ab negative counterparts (28 versus 20 years; p<0.001). 11 patients (5.5%) have become sero-positive (PCR positive) after institution of donor screening. HCV-Ab positive patients were significantly more likely to be diabetic than HCV-Ab negative patients (26% versus 8%; p<0.001). HCV-RNA was performed in 62 patients out of the eighty-one patients positive for anti-HCV and found to be positive in 41% of the patients (33/62). Eighteen of the 33 patients (55%) had genotype 1, six (18%) had genotype 2 & 3 and five (15%) had genotype 4. Conclusions: High prevalence of hepatitis C among multi-transfused thalassemic patients in Oman is likely due to transfusion of blood before the implementation of hepatitis C screening. Blood screening initiated after 1991 in Oman has significantly reduced the risk of hepatitis C associated with blood transfusion. Nevertheless, despite this screening, a number of patients have become HCV PCR positive. Hepatitis C infection remains a major clinical complication in this group of patients.

TWO YEARS WITH PANDEMIC H1N1 2009 INFLUENZA A IN A TERTIARY HEMATOLOGY DEPARTMENT

M Kouba, P Soukup, M Hricinova, J Mertova, C Salek, V Valkova,
M Markova, M Kolar, J Cermak, A Vitek, P Cetkovsky
Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background. Pandemic influenza A H1N1 2009 has been the prevailing influenza strain in Czech republic from autumn 2009 till March 2011. Severly immunocompromised patients with hematological malignacies and after stem cell transplantation are at increased risk of severe and devastating complications of this infection. *Aims*. To evaluate the morbidity and mortality from H1N1 influenza A among immunocompromised patiens and the importance of aggressive approach in management in hematology department. *Methods*. We have retrospectivelly evaluated the cases of influenza H1N1 (PCR proven) among patients hospitalized in our 35 bed haematology and bone marrow transplantation department in Prague, Czech republic during two influenza seasons, 2009/2010 and 2010/2011. In total we identified 17 cases (13 patients with acute leukemia, 2 with non-hodgkin lymphoma, 1 with chronic myelocytic leukemia and one with thrombotic trombocytopenic purpura) 6 of the patients were after alogeneic haematopoietic stem cell transplantation. We changed the attitude to prophylaxis and management of the individual cases before 2010/2011 influenza season. In the 2010/2011 season we increased the percentage of vaccinated personnel, we instituted oseltamivir prophylaxis to all hospitalized patients (considering them close contacts) at the time of the first detection positivity of H1N1 in hospitalized patient. All immunocompromised H1N1 positive patients received combination treatment - oseltamivir 300 mg p.o. per day and zenamivir inhalation 20 mg per day. Results: There were 9 H1N1 positive hospitalized patients in 2009/2010 season, 6 of them had pulmonary involvement and 3 of them died (33%). There were 8 H1N1 positive cases in 2010/2011, 6 of them had pneumonia (not all cases of pneumonia in H1N1 positive patiens were confirmed by bronchoalveolar lavage) and none of them died. *Conclusions*. The consequences of H1N1 infection could be devastating among immunocompromised patients. Our experience strongly supports very aggressive surveilance, prophylaxis

and therapeutic approaches in hematology department. Immediate institution of aggressive treatment to early diagnosed cases in 2010/2011 season enabled recovery in all cases which contrasts with our early experiences from 2009/2010 season.

1629

CHARACTERISTICS AND RISK FACTORS FOR DEEP TISSUE ABSCESSES IN A CONSECUTIVE COHORT OF PATIENTS WITH ACUTE MYELOID LEUKEMIA: A NATIONAL POPULATION STUDY IN TAIWAN

Y Hsieh,[1] CJ Liu,[2] CJ Teng,[2] TJ Chen[2]
[1]*Shuan-Ho Hospital, Xinbei City, Taiwan*
[2]*Veterans General Hospital Taipei, Taipei, Taiwan*

Background. Abscess may occur as an infectious manifestation in acute myeloid leukaemia (AML) patients. However, deep tissue abscess is more complicated since bleeding tendency was a major obstacle for diagnostic approach or surgical drainage in leukaemic patients. *Aims*. We focused on the prevalence of deep tissue abscess in patients with AML and the clinical characteristics and risk factors of AML patients developing deep tissue abscess. *Methods*. 5066 newly diagnosed patients from Jan 1997 to Jun 2006 were retrospectively analyzed from the Taiwan National Health Insurance Research Database in Taiwan. Deep tissue abscess was defined as abscess occurred at gastrointestinal tract, genitourinary tract, liver, deep neck, eye, central nervous system, mediastinal or pulmonary, and oral cavity in all AML patients after the diagnosis of AML. Eligible patients were sub-grouped as abscess group (n=768) and non-abscess group (n=4298). We determined the factors potentially associated with deep tissue abscess incidence. *Results*. The prevalence of all kinds of deep tissue abscesses in AML patients is 15.2%. The most predominant site is gastrointestinal tract abscess (n = 290). The median time from AML diagnosis to deep tissue abscess is 131 days. 197 (25.6%) patients with deep tissue abscess have systemic infection within 30 days prior to the abscess diagnosis. Three independent risk factors were identified in predicting deep tissue abscess development in AML patients within 36 months after AML diagnosis. They are age less than 60 year-old (p<0.001, HR=1.871), male gender (p=0.004, HR ì=1.249), and secondary AML (p=0.01, HR=1.365). Risk stratification system was categorized according to the numbers of independent risk factors (0, 1, and more than 2 risk factors). The cumulative incidence of abscess within 36 months after AML diagnosis according to the risk stratification system was 0%, 9.4%, and 66.5% (0 factors vs. 1 factor vs. more than 2 factors, respectively, p < 0.001). *Conclusions*. Deep tissue abscess are not uncommon in AML patients. Patients who are man, older than 60 year-old and secondary AML warrant special attention since they are prone to have abscess after the diagnosis of AML.

1630

CIRRHOSIS ASSOCIATED WITH POOR OUTCOME IN ACUTE MYELOID LEUKAEMIA PATIENTS DEVELOPED LIVER ABSCESS: A NATIONAL POPULATION STUDY IN TAIWAN

Y Hsieh,[1] CJ Liu,[2] CJ Teng,[2] TJ Chen[2]
[1]*Shuan-Ho Hospital, Xinbei City, Taiwan*
[2]*Veterans General Hospital Taipei, Taipei, Taiwan*

Background. Liver abscess following prolonged neutropenic periods during disease course has emerged as a major infectious complication for patients with acute myeloid leukaemia (AML). Previous report has showed that bleeding tendency was a major obstacle for diagnostic approach and surgical drainage in leukaemic patients. *Aims*. We focused on whether the surgical drainage procedure can prolong survival and determined factors associated with survival in AML patients developing liver abscess. *Methods.* We retrospectively reviewed data drawn from the Taiwan National Health Insurance Research Database which cover the entire civil of Taiwan. Cases of liver abscess (ICD-9 code 572.0) were defined as an intrahepatic infection with abscess formation occurring in all patients after the diagnosis of AML between Jan 1997 to Jun 2006. Amoebic liver abscess is excluded. We computed the impact of surgical drainage on 30 days survival after the diagnosis of liver abscess. We further examined whether other comorbidities increased the relative risk of death of 30 days after the diagnosis of abscess among patients with AML. RESTULS: The prevalence of liver abscess in all AML patients is 2.6% (n=132, 132/5066). Only 8 patients (6.1%) received surgical drainage. The surgical drainage did not improve the 30 days survival after abscess diagnosis (p = 0.328). Liver cirrhosis (p = 0.032, HR = 3.661) and ischemic heart disease (p = 0.041, HR = 3.080) independently predict the 30 days post-abscess survival. Patients with either comorbidities has significantly lower survival 30 days after liver abscess diagnosis (p = 0.016). *Conclusions*. Surgical drainage cannot improve the 30 days post-abscess survival in AML patients. AML patients with liver cirrhosis or ischemic heart disease have increased relative risk of death 30 days after liver abscess diagnosis.

1631

COMPARATIVE EVALUATION OF CELL DIFFERENTIAL IN BODY FLUIDS USING AUTOMATED HEMATOLOGY ANALYZER AND VISUAL MICROSCOPY

P Dimitriadis, K Chalvatzi, A Dimitriadou, S Balodimos, M Raptaki, N Tsironas, A Nikolaidou, E Diza
AHEPA Hospital, Thessaloniki, Greece

Backround. The new generation automated hematology analyzer Sysmex XE-5000 provides rapid body fluid analysis, including the differentiation of polymorphonuclear and mononuclear cells. The technology used is based on fluorescence flow cytometry. The precision is ensured due to extended counting in contrast with the visual microscopy. It is important to determine whether the fluid is a transudate or an exudate because it can be helpful in diagnosing the disease or condition present. Aim. The aim of this study was to evaluate the accuracy of Sysmex-5000 in determination of the cell differential in common body fluids. Methods. Thirty Body fluid (BF) samples were prospectively evaluated: pleural fluid, ascitic fluid, continuous ambulatory peritoneal dialysis fluid, and synovial fluid. All fluids were collected in dipotassium ethylenediaminetetraacetic acid (K2EDTA) anticoagulated tubes. Differential counts were made by classical method, counting 200 cells under light microscopy on slides stained with May-Grünwald-Giemsa, and automatically with Sysmex-5000 without pre-treatment of the samples. Mesothelial, polymorphonuclear and mononuclear cells were differentiated. Results. Results for conventional cell categories compared excellently between Sysmex XE-5000 and visual microscopy. Strong correlation was observed between the manual and the automated method as for mesothelial, neutrophils and mononuclear cell differentiation (r=0.888, p<0.001, r=0,985, p<0.001, r=0,960, p<0.001, respectively). No extreme discrepancies, comparing the two methods, were noticed during measurement. Only in one sample the manual examination of 400 cells was needed in order to confirm the correspondence with the analyzer. Conclusion. In summary, our investigation revealed a excellent agreement between manual and automated differentiation of body fluid cells, indicating the reliability of the automated analyzer and therefore its utility in daily practice.

1632

FUNGAL INFECTION PROPHYLAXIS WITH POSACONAZOL IN ACUTE MYELOID LEUKEMIA

M Malo,[1] A De la Fuente,[2] M Olave,[1] S Valle,[1] R De Oña,[2] R Iglesias,[2] S Solórzano,[2] M Estévez,[2] JF Tomás[2]
[1]*Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain*
[2]*MD Anderson IE, Madrid, Spain*

Invasive Fungal Infection (IFI) is a poor prognosis complication in Acute Myeloid Leukemia (AML). Patients with hematological malignancies and prolonged neutropenia are at high risk of IFI. Posaconazol is a 2nd generation triazole indicated in IFI prophylaxis (IDSA NCCN and ECIL guides). Aims: To evaluate effectiveness of IFI prophylaxis with Posaconazol in profound neutropenia episodes in AML patients on intensive chemotherapy treatment. Methods: A retrospective study was carried out in two Spanish sites including AML patients treated with AraC based intensive chemotherapy receiving posaconazol as IFI prophylaxis. Effectiveness was defined as the occurrence of probable/proven IFI (EORTC criteria) and initiation of antifungal preventive therapy. Toxicity was evaluated with CTCAE v3.0 of NCI criteria. Results: In the period between January 2007 and December 2010, a total of 35 AML patients initiated IFI prophylaxis with oral Posaconazol 200 mg/8h. Mean age 57.3 years (26-76), male/female 19/16. Biweekly galactomannan antigenemia (AGA) was analyzed. All patients received support with G-CSF. There were 84 profound neutropenia episodes, with a mean duration of 19 days (10-38). The mean days of febrile neutropenia was 3 (0-7). Effectiveness: In 4 out of 84 episodes antifungal treatment with liposomal amphotericine was required: In 1 episode empiric therapy was initiated because of persistent fever with negative AGAs and no findings in HTCAT; in 2 episodes were initiated because of positive AGAs and pathologic HTCAT; and 1 episode had pathologic HTCAT without AGA. Toxicity: In 5 episodes Posaconazole prophylaxis was discontinued due to impossibility of oral administration: mucositis grade III-IV in

4 cases, and gastric hemorrhage in 1 case. No relevant renal or hepatic toxicity was reported. Conclusions: This retrospective study, with an incidence of probable/proven IFI of 2.3%, confirms Posaconazol as a high effective and well tolerated option for IFI prophylaxis, in patients with AML at high risk of fungal infection.

1633

GLYCOGEN PHOSPHORYLASE BB AS A POTENTIAL MARKER OF CARDIAC TOXICITY IN PATIENTS TREATED WITH ANTHRACYCLINES FOR ACUTE LEUKEMIA

J Horacek,[1] L Jebavy,[1] M Vasatova,[2] P Zak,[2] M Tichy,[2] J Maly[3]
[1]*FMHS, Hradec Králové, Czech Republic*
[2]*University Hospital, Hradec Králové, Czech Republic*
[3]*Charles University, Faculty of Medicine, Hradec Králové, Czech Republic*

Background. Chemotherapy-induced cardiotoxicity remains an unresolved problem strongly impacting the quality of life and the overall survival of cancer patients. Anthracyclines represent the greatest risk for development of cardiotoxicity. From cardiac biomarkers, cardiac troponins have been recommended for monitoring of cardiotoxicity in oncology. Glycogen phosphorylase BB (GPBB) is among proposed biomarkers of cardiac injury with very limited experience in this context. Aims: To assess plasma GPBB concentrations in acute leukemia patients treated with anthracycline-based chemotherapy to detect acute and chronic cardiotoxicity, and to compare plasma GPBB concentrations in acute leukemia patients with healthy blood donors. Methods: A total of 24 adult acute leukemia patients treated with 3 - 6 cycles of chemotherapy containing anthracyclines were studied. All patients had normal liver and renal functions during the study. Plasma concentrations of GPBB were measured at the diagnosis (before chemotherapy), after first chemotherapy with anthracyclines and circa 6 months after completion of treatment. The cut-off value for GPBB positivity was 10.00 µg/L as recommended by the manufacturer (Diagenics, Germany). Twenty-four healthy blood donors were used as a control group. Results: Before chemotherapy, mean plasma GPBB concentration was 5.25 ± 3.81 µg/L, increased above the cut-off in 1 patient (4.2 %). After first chemotherapy, mean GPBB was 6.61 ± 5.54 µg/L, positive in 7 (29.2 %) patients. Six moths after treatment, mean GPBB was 10.06 ± 11.41 µg/L, positive in 8 (33.3 %) patients. The difference between GPBB concentrations before chemotherapy and 6 months after treatment were statistical significant ($p < 0.01$). The patient with GPBB positivity before chemotherapy (18.55 µg/L) had higher GPBB positivity in the subsequent samples (20.53 and 32.16 µg/L). Mean GPBB concentration in 24 healthy blood donors was 2.14 ± 0.28 µg/L (range 1.81 - 3.05), negative in all subjects. The differences in plasma GPBB concentrations between healthy blood donors and patients treated for acute leukemia were statistical significant ($p < 0.01$ in all cases). Conclusions: Our results suggest that GPBB could become a potential biomarker for detection of acute and chronic cardiotoxicity associated with anthracycline chemotherapy. Plasma GPBB concentrations within 6 months after treatment were significantly higher in comparison with baseline values. The predictive value for development of treatment-related cardiomyopathy in the future is not known and will be evaluated during the follow-up, as well as correlation with established biomarkers of cardiac toxicity and echocardiography. A larger prospective and multicenter study will be needed to define the potential role of GPBB and other proposed biomarkers of cardiac injury in the assessment of chemotherapy-induced cardiotoxicity.

Funding. The work was supported by research projects MO 0FVZ0000503 and MZO 00179906.

Background. "Fungal infection database" (FIND) represents international database of invasive fungal infections in Czech and Slovak hematooncological departments. FIND - aspergillus covers all case of invasive aspergillosis (IA) in participating centers since 2001. Methods: The goal of our retrospective analysis was to evaluate incidence, early diagnostic procedures and effect of antifungal therapy in proven and probable IA that occurred in 9 institutions participating in FIND database between 2001-2009. We followed EORTC/MSG 2002 criteria in evaluation of IA diagnosis and therapy response. Results: 162 probable and 36 proven IA (91% isolated pulmonary IA, IPA) have been documented. Prolonged and profound neutropenia (63%) and long-term use of corticosteroids (31%) were identified as the major risk factors of IA. 161 cases (89%) had abnormality on pulmonary CT, however with non-specific infiltrates as the most frequent finding (49%). 74% pts. had consecutive positivity of serum-galactomannan (S-GM) (OD index > 0.5). 81% pts. with IPA and bronchoalveolar lavage (BAL) had positive GM in BAL fluid (OD index > 0.5). In pts. with IPA only 9% BAL fluids and 21% sputum samples had positive microscopic result for filamentous fungi and 16% BAL fluids and 61% sputum samples had positive culture for Aspergillus spp. Primary mold active antifungal prophylaxis was used in 23% pts. - 13% itraconazole, 4% voriconazole (VORI), 3% posaconazole and 3% others. Empiric antifungal therapy was used in 43% pts. with median of 5 days of administration before IA diagnosis (range: 2-44 days) - amphotericine B deoxycholate (C-AMB) was used in 31% of patients with empirical antifungal therapy, lipid-based AMB (LBA) in 24%, VORI in 18% and echinocandins (ECHINO) in 15%, respectively. The primary antifungal therapy of IA represents: in 38% of cases VORI, in 6% ECHINO, in 26% VORI+ECHINO, in 11% C-AMB and in 8% LBA. Overall RR to primary therapy of IA was 62% - VORI 62%, VORI+ECHINO 60%, C-AMB 32%, LBA 53%, ECHINO 20%. There was a statistically significant difference in overall RR to targeted therapy in pts. with neutophil count < 0,1 and > 1,0 $x10^9$/l at the end of therapy (21% vs. 71%). The overall mortality rate was 57%, with 42% attributable to IA. Conclusions: On the basis of our analysis we confirm typical risk factors for IA and critical role of S-GM and CT for early diagnosis and prompt start of antifungal therapy of IA. A reasonable treatment response was achieved using VORI, VORI+ECHINO or LBA in primary therapy of IA. We have confirmed neutropenia at the end of antifungal therapy as the major predictive factor for therapeutic response.

CLINICAL CHARACTERISTICS AND OUTCOME OF INFLUENZA A (H1N1) INFECTION IN HEMATOLOGICAL PATIENTS DURING TWO CONSECUTIVE WINTER-SEASONS

A López-Iglesias,[1] P Barba,[2] I Ruiz,[2] G Codina,[2] D Valcárcel,[2] P Abrisqueta,[2] O Salamero,[2] M Gironella,[2] E Sancho,[2] N Purroy,[2] C Barrenetxea,[2] F Bosch[2]
[1]*Hospital Vall d'Hebron, Barcelona, Spain*
[2]*University Hospital Vall d'Hebron, Barcelona, Spain*

Background. Influenza A (H1N1) (IA-H1N1) infection usually results in mild respiratory symptoms in immunocompetent patients, whereas in immunocompromised patients might lead to severe complications and even related-mortality. Clinical characteristics and outcome of IA-H1N1 infection in patients with hematological neoplasms are not well described and need further investigation. *Methods*. Data from patients and infectious episodes of IA-H1N1 in hematological patients from a single institution were prospectively collected from November 2009 to February 2011 (two winter seasons). All patients with clinical suspicion of respiratory viral infection underwent H1N1 real-time PCR analysis of nasopharyngeal aspirate or nasal swab. *Results*. A total of 25 patients were diagnosed with IA-H1N1 infection during the study period (11 in the 2009-10 season and 14 in the 2010-11 season). Median age was 66 years (range 17-89) Most frequent underlying diseases were non-Hodgkin lymphoma (n=9) and chronic lymphocytic leukemia (n=4). Five patients had received hematopoietic cell transplantation (2 allogenic). All patients but one (pneumonia) presented with upper respiratory tract infection. Main clinical symptoms were fever (n=24, 96%), cough (n=16,

64%) and rhinorrhea (n=8, 32%). All patients were treated with oseltamivir 150-75mg bid for a median of 5 days (range 5-20). A second RT-PCR determination of IA-H1N1 was performed in 9 patients with persistent clinical symptoms at the fifth day of treatment. Of them, four patients had persistent H1N1 positivity and were treated until negativization. Seventeen (68%) patients required hospitalization for a median of 5 days (range 1-40). Risk factors for hospitalization were low hemoglobin and platelet count, and low oxygen saturation measured by pulse oximetry at diagnosis. We did not observe IA-H1N1-related deaths. Five patients (20%) had received prior IA-H1N1 vaccine. No differences in the severity of the infection (oxygen saturation at diagnosis, duration of respiratory symptoms, or need for hospital admission) were observed between vaccinated and non-vaccinated patients. *Conclusions*. In patients with hematological diseases, clinical presentation and outcome of IA-H1N1 infection were similar to that described in immunocompetent patients. IA-H1N1 infection may occur in vaccinated patients and presents similar characteristics and outcome than in non-vaccinated patients.

NEW TECHNOLOGIES TO DEVELOP LONG-ACTING FILGRASTIM: GLYCO-PEGYLATION OF R-METHUG-CSF AND ALBUMIN-FUSION OF NATURAL G-CSF SERVE A ONCE-PER-CYCLE FIXED DOSE STRATEGY TO PREVENT FEBRILE NEUTROPENIA

W Mueller,[1] E Kohler,[2] N Avisar,[3] D Shen,[4] H Allgaier,[2] J Bock,[4] L Sands,[4] P Bias[5]
[1]*Teva Deutschland GmbH, Moerfelden-Walldorf, Germany*
[2]*BioGeneriX, Mannheim, Germany*
[3]*Teva Pharmaceuticals, Netanya, Israel*
[4]*Teva Biopharmaceuticals USA, Rockville, United States of America*
[5]*Ratiopharm, Ulm, Germany*

Background. Long-acting filgrastim offers the advantage of less dosing intervals when used for reduction of neutropenia and incidence of febrile neutropenia (FN) in patients treated with cytotoxic chemotherapy for malignancy. The target is a once-per-cycle fixed dose administration to prevent FN and being convenient for patients and their treating physicians. *Aims*. GlycoPEGylation and albumin-fusion were evaluated to serve as platform technologies to design a once-per-cycle fixed dose filgrastim.Methods Glyco-PEGylated r-metHuG-CSF (GPG) was designed by attaching a 20 kD PEG to glycan at natural O-glycosylation site. A completely recombinant albumin fusion protein was developed by fusing natural G-CSF to human serum albumin through recombinant DNA technology. Pharmacokinetic and pharmacodynamic non-clinical and clinical studies were performed for both products. Once-per-cycle fixed dose approach for the prevention of chemotherapy induced FN has been investigated in clinical studies with pharmacokinetic, pharmacodynamic, efficacy and safety endpoints. Results. Compared to unmodified natural G-CSF, both glyco-PEGylated r-metHuG-CSF (GPG) and albumin-fused hu-G-CSF (AFG) have a prolonged circulating half-life. GPG and AFG show the expected pharmacologic activity of G-CSF in vivo, i.e. they stimulate neutrophil recovery in a dose-dependent way measured by an increase of absolute neutrophile count due to the induction of neutrophile pre-cursors proliferation. Efficacy and safety data obtained in clinical studies showed the expected profiles for a long-acting filgrastim. Summary / Conclusions. The platform technologies of glyco-PEGylation and albumin-fusion can be used effectively to obtain long-acting filgrastims and many other proteins. Pharmacokinetic and pharmacodynamic characteristics of GPG and of AFG show that these long-acting filgrastims are suitable for a once-per-cycle fixed dose use to prevent FN in patients treated with cytotoxic chemotherapy for their malignant tumor disease. The results for pharmacokinetics and pharmacodynamics for both products as well as the current efficacy and safety endpoints are as to be expected for a long-acting filgrastim supporting an efficient and safe once-per-cycle fixed dose administration.

THE EMERGENCE OF MUCORMYCOSES IN PATIENTS WITH HEMATO-ONCOLOGIC DISEASES

R Bergantim, M Badior, F Trigo, JE Guimaraes
Hospital S. Joao, Porto, Portugal

Background: Mucormycoses in patients with hemato-oncologic diseases are increasing in past few years, representing the third leading cause of invasive fungal infection in this patients following Aspergillus and Candida species. This increase may correspond to changes related to antifungal prophylaxis, particularly with the azoles, and the widespread use of antifungal agents. Historically, Mucormycoses presents itself as a fatal fungal infection, reaching in some series 90% mortality. Aims and Methods: We proceeded to the retrospective analysis of Mucormycoses at our centre in the last six years. Diagnosis was defined as probable or definite according to the EORTC/MSG criteria. Results: Mucormycoses were diagnostic in 5 patients, median age 54 years (range, 18-64 years) with Acute Myeloid Leukemia (4/5) and bone marrow aplasia (1/5). The diagnosis was verified in neutropenia (median 20 days, range 3-57 days) during induction (2/5), consolidation (2/5) and salvage therapy (1/5) of current chemotherapy protocols. Regarding the mode of presentation, 2/5 of cases were with pulmonary involvement and 3/5 with rhinosinusal. Computed tomography was performed in all patients after prolonged febrile syndrome with symptoms suggestive of fungal infection and liposomal amphotericin B 5mg/kg/day was started empirically. Patients with rhinosinusal involvement underwent surgical debridement and those with lung involvement underwent thoracic surgery (right lower lobe and upper left lobectomy). One patient required a second surgery with lobectomy and partial hepatectomy for liver involvement and diaphragmatic extension of fungal process. The histological study of surgical specimens confirmed the diagnosis of suspected Mucormycoses in all patients. Mycological culture was negative in all cases. Liposomal amphotericin B was maintain for a median of 50 days (13-80 days), followed by a period of secondary prophylaxis also with Liposomal amphotericin B in tapered low dose scheme, for a median of 3 months (range, 1-6 months). No mortality was attributable to fungal complication, the only death verified was due progression of underlying disease. Remaining patients had resolution of Mucormycoses and 3/4 completed the chemotherapy protocol designed to reach complete remission of hemato-oncologic disease. Conclusions: Although we had a mortality rate lower than that reported in other series of patients, this experience shows the challenge that Mucormycoses represents in patients with hemato-oncological diseases. Clinical presentation is unspecific and diagnosis is difficult to establish. Early suspicion associated with high-dose antifungal therapy and aggressive surgical approach is the best option for treating these infections often fatal.

1638

DEVELOPMENT OF RESISTANT INTESTINAL BACTERIA IN HEMATOLOGICAL PATIENTS WITH PROLONGED NEUTROPENIA WHILE ON LEVOFLOXACIN PROPHYLAXIS

JM Alonso Dominguez, J Rodriguez Gambarte, J Lopez Jimenez, C Cuartero, A Sanchez
Hospital Ramon y Cajal, Madrid, Spain

Background: Levofloxacin prophylaxis (LP) is used to reduce the number of febrile episodes in neutropenic patients, although bacterial resistance is a matter of concern. We carried out a prospective study to know the impact of levofloxacin profilaxis (500 mg o.d) over the intestinal flora with special emphasis in extended spectrum? ? -lactamase Enterobacteriaceae (ESBL-E) and ampicillin-resistant Enterococcus faecium (ARE). Material and methods: 17 patients diagnosed of leukaemia, lymphoma or multiple myeloma who were receiving conventional chemotherapy or conditioning chemoradiotherapy before transplant, with an expected neutropenia time > 10 days, were enrolled in this study. Patients received levofloxacin until the development of fever, when a beta-lactamic was added empirically and levofloxacin withold. Faecal samples at admission, during LP and while on beta-lactamic therapy were seeded in ampicillin (10mg/L) m- Enterococcus agar for the screening of ampicillin resistant E.faecium (ARE) and in ciprofloxacin (0.1mg/L) and cefotaxime (1mg/L) MacConkey agars for ciprofloxacin resistant (CIP-R-E), extended spectrum B-lactamase (ESBL-E) and/or carbapenemase producing (CP-E) Enterobacteriaceae.

% of patients with Extended spectrum β-lactamase *Enterobacteriaceae* and Ampicillin-Resistant *Enterococcus faecium* isolates in the intestinal flora

	Admission	Under LP	After LP*	At any moment
Enterobacteriaceae:				
Rp resistant	12%	29%	59%	75%
ESBL producing strains	6%	0%	24%	41%
ARE	29%	65%	53%	70%

* Patients under treatment with β-lactamic as empiric neutropenic therapy

Colonies were screened for ESBLs and carbapenemases. Clonal relatedness was studied by PFGE. Blood and urine cultures, obtained while the patient was febrile, were studied according to standard methods. Results: 220 faecal samples in 28 different neutropenia episodes were studied.

Mean duration of levofloxacin treatment was 10 days per episode. Percentage of patients colonized in the different study periods is shown in Table 1. Clonal analysis led to: -ESBL-E: The detection of four strains of E. coli Fq-resistant in the blood cultures of two patients, one of them being an exact clone of the one isolated in that same patient's feces. No carbapenemase producing strain was detected. -ARE: ARE bacteremia was found in three patients (18%), all of them due to clone B (ST117) (the most prevalent and persistent clone, detected in 59% of the patients and 72% of the total of isolations). 75% of the isolations were resistant to Levofloxacin, 88% exposed high level resistance to streptomycin and all of them remained susceptible to vancomycin, teicoplanin, daptomycin and linezolid. Conclusions: In the neutropenic patient under LP, a high faecal colonization by Fq-resistant Enterobacteriaceae and ARE was found, whilst ESBL-E was less noticeable. The levofloxacin-selected clones may cause ulterior bacteriemia.

1639

NOSOCOMIAL INFECTIONS IN ADULT HEMATOLOGY/ONCOLOGY PATIENTS

S Arampatzi, E Protonotariou, G Kaiafa, Z Saouli, C Kanonidou, A Nicolaidou, A Papadopoulos, E Diza

Laboratory of Microbiology, University Hospital AHEPA, Aristotle University, Thessaloniki, Greece

Background: Hematology patients present an increased risk of nosocomial infections that vary in different populations and different institutions with considerable morbidity and mortality. Aims: The purpose of our study was to evaluate the frequency and patterns of nosocomial infections in 50 hematology patients and to determine the prevalence of causative organisms and their antimicrobial sensitivity. Methods: A retrospective analysis was made in the patients admitted between April 2010 and January 2011 to the Department of Haematology of the First Propedeutic Department of Internal Medicine of University Hospital AHEPA. The 50 patients showed 240 admissions and 4002 inpatient days. The Centers for Disease Control and Prevention criteria were used as a standard definition for nosocomial infections. *Results*. The overall rate of nosocomial infections in hematology patients was 9.7 and in neutropenic patients 22.9 per 1000 patient-days respectively. Nosocomial fever of unknown origin constituted 62.9% of cases. The frequent sites of nosocomial infections were respiratory system (42.7%), the blood stream (25.3%), the urinary system (22.2%) and others (9.8%). The incidence of nosocomial infections was significantly higher during neutropenic days (P<0.001). Gram-negative organisms represented 71,2 % of pathogens (Klebsiella 48.6%, Pseudomonas 35.7%, Acinetobacter 7,8%, E. coli 7,8%, and C. albicans 5.5%). Gram-positive organisms represented 28,8.% of pathogens (Staphylococci 81.5%, Streptococci 18,5%). Positive cultures were more frequent in winter (November to March). Susceptibility of isolated organisms was relatively low (ampicilline/sulbactam 49.9%, amikacin 35.9%, imipenem 34.4%). Methicillin-resistant S. aureus and extended spectrum beta lactamase represented 30% and 65% of isolated S. aureus and Gram-negative organisms respectively. Carbapenem-resistant strains of Klebsiella and Pseudomonas were isolated from the patients. KPC-2 carbapenemase-producing Klebsiella strains were isolated from the patients. *Conclusions*. Respiratory infection and fever of unknown origin are the most common nosocomial infections in adult hematology patients with a higher risk during neutropenic days. Isolated organisms are multi-drug resistant, predominantly Gram-negative pathogens with a high incidence of extended spectrum beta lactamase, methicillin-resistant S. aureus, and carbapenem resistant organisms.

1640

RISK ASSESSMENT FOR BLOOD TRANSFUSION REQUIREMENT OF AT LEAST 3 UNITS DURING THE APLASTIC PHASE FOLLOWING CHEMOTHERAPY

A Parvu, A Bojan, A Cucuianu, A Vasilache, L Urian, T Torok, M Zdrenghea, M Patiu, C Basarab, C Selicean, D Dima, A Zsoldos, L Petrov

Oncological Institute Cluj Napoca, Cluj-Napoca, Romania

Background. Faced with the ongoing reduction in the number of blood donors, the clinical hematologist must often ask patient families for help in finding suitable donors. Another benefit of the predictive models are improved communication with the blood bank, allowing the clinical hematologist to order the appropriate amount of blood units necessary for the whole duration of the aplasia. Our passed experience was creating a predictive model for blood transfusion requirement in a patient with acute leukemia in aplasia following chemotherapy using a linear model (multiple regression). The variables representing the best predictors of blood units number transfused to an acute leukemia patient in an aplastic phase following chemotherapy were: hemoglobin levels at chemotherapy start, disease stage at the beginning of chemotherapy regimen, hemorrhagic episodes during the next aplastic period and hemolytic transfusion reaction. *Aims*. Risk assessment for a blood transfusion requirement of at least 3 units of blood during the aplastic phase following chemotherapy administrered to acute leukemia patients Methods: Study type: analytical, cohort, retrospective. We studied 246 patients with acute leukemia admitted in the Hematology Clinic in Cluj-Napoca during 1995-2008 and treated according to international protocols (exclusion of palliative care therapy, deceased or transferred patients). 860 aplasia episodes secondary to chemotherapy were included in the study. All the patients signed the informed consent. The study has the agreement of Ethic Committee of Medicine University Cluj-Napoca, Romania. Statistical analysis was performed using a probabilistic model (logistic regression). Independent risk factors were identified using the probabilistic model of logistic regression using *amount of blood* as the dependent variable. The *amount of blood* is a dichotomous qualitative variable - large (the number of transfusions is equal to or greater than 3) or small (the number of transfusions is less than 3). Statistical analysis was performed using SPSS, Statistica and Excel. *Results*. 1Independent risk factors for performing at least 3 transfusions are: a.Hemorrhages during aplastic period (Minor hemorrhages: OR=6.60, 95% CI, 3.55-12.27, p=0.00<0.05Major hemorrhages: OR=91.01, 95% CI, 22.09-374.95, p<0.05) b. Haemolytic transfusion reaction (Haemolytic transfusion reaction: OR=7.92, 95% CI, 3.03-20.73, p<0.05) c.Disease stage at the beginning of chemotherapy (Disease stage- diagnosis: OR=7.62, 95% CI, 3.65-15.89, p<0.05; Disease stage- partial remission: OR=0.98, 95% CI, 0.65-1.49, p<0.05; Disease stage- complete remission: OR=0.50, 95% CI, 0.37-0.67, p<0.05; Disease stage- no response: OR=2.73, 95% CI, 1.57-4.73, p<0.05). 2.Probability of needing at least 3 transfusions: where e ≈ 2,71= Euler's number, x1, x2, ..., xn are independent variables and b1,..., bn are regression coefficients. The described model is appropriate for experimental data (according to Lemeshow-Hosmer test, p=0.76>0.05, rejecting the null hypothesis of the regression model being unfit to the studied data) and has about 83.5% correct prediction rate. Conclusions: Independent risk factors for performing at least 3 transfusions for acute leukemia patient in aplasia following chemotherapy are: hemorrhages during aplastic period, haemolytic transfusion reaction, disease stage at the beginning of chemotherapy.

1641

CLINICAL SIGNIFICANCE OF RED CELL ALLOIMMUNIZATION IN MULTITRANSFUSED PATIENTS

A Argyrou, E Papolia, M Matou

Agios Savvas Oncology Hospital, Athens, Greece

Background. Developing alloantibodies after being transfused with red blood cells is a major problem, especially for multitransfused patients, because it can cause episodes of alloimmune hemolytic anaemia. AIM: In this study we try to detect the alloantibodies developed after repeatitive red blood cell transfusions, and estimate the frequency of these antibodies among the multitransfused patients of our hospital, so as to avoid hemolytic episodes during next transfusions. *Methods.* Multitransfused patients of our hospital, suffering with solid tumors or haematological malignancies, are included in this study. What we routinely do with such patients in our department, is performing screening test (indirect antihuman globulin test) in order to detect unexpected alloantibodies, whenever these patients need to be transfused or whenever any reaction during or after the transfusion is reported to our department by the clinical doctors. Samples with positive screening tests are being tested (panel test) in order to identify the unexpected antibodies. Both screening and panel tests are being performed with an enzyme test by glass beads centrifugation method (microtyping system, Biovue Ortho Diagnostics). *Results.* A screening test was performed in 4739 samples of 4542 patients (49 patients were tested more than twice). 198 of these samples, referring to 91 patients (32 males and 59 females) were positive. Alloantibody identification revealed the following: 68 (74.7%) patients had a single, defined alloantibody. 9 (9.9%) patients had two or more defined alloantibodies. 14 (15.4%) patients had a combination of alloantibodies with undefined specificity. 12 (13.2%) patients had autoantibodies as well, as it was revealed by the positive direct antiglobulin test. The most frequent alloantibodies were: anti-Kell (28), anti-D (11), anti-E (9), anti-e (7), anti-C (6), anti-Jka (6), anti-Fya (5), anti-M (5), anti-P1 (5), anti-Lea (5), anti-Fyb (4),

anti-Leb (4), anti-Cw (4), anti-c (3), anti-Jkb (3). None of the patients above was reported to develop any kind of immediate or later hemolytic reaction, despite the repeatitive transfusions. *Conclusions*. The most frequent alloantibodies which are detected in the multitransfused patients of our hospital, are mainly versus the Kell and the Rhesus antigenic systems of the red blood cells, and less versus the Kidd, Duffy, MNS, P and Lewis antigenic systems. Continual and persistent searching and early detection and identification of these alloantibodies, and transfusion with red blood cell units which are negative for the analogue antigen, can offer in the prevention of severe reactions like the hemolytic episodes which worsen even more the bad general condition of the patients.

1642

THE USEFULNESS AND DEMERIT OF THE EXPECTED ELEVATION VALUE OF SERUM ALBUMIN BEFORE REPLACEMENT THERAPY

H Fujihara, C Yamada, H Watanabe, H Shibata, Y Funai, T Suzumura, M Kaneko, S Uchiyama, A Takeshita
Hamamatsu University School of Medicine, Hamamatsu, Japan

Background and Aims: Pharmaceutical albumin has been used excessively in Japan. In the 1980s, Japan consumed one third of the world supply. Although aiming to decrease dependence on albumin based treatments, Japan's consumption of pharmaceutical albumin was 57,541 kg in 1999, which was 1.6 and 6.2 times more than that of the U.S.A. and U.K., respectively. Since then, the target elevation value of serum albumin was adopted in the Japanese Guideline for Blood Transfusion to determine the necessary dosage of pharmaceutical albumin for patients. The dosage is calculated by the formula; the necessary dosage (g) = the expected elevation value (g/dl) x amounts of whole plasma (dl) / 0.4. It contributed considerably to decrease consumption to 36,816 kg in 2009. On the other hand, the measurement of serum albumin is recently shifting from bromcresol green (BCG) assay to bromcresol purple (BCP) assay because the latter has less contamination other than pure albumin. In this study, the clinical importance of the target value of serum albumin was reevaluated for the BCP assay. Methods and Results: We analyzed the serum albumin value by BCG and BCP analyses in 251 cases, and examined the correlation between them. Y (BCP) = 1.09X (BCG) - 0.52 served as the standard curve and total correlation of coefficient value (r) was 0.99. We changed the target elevation value in our institute according to the standard curve from 2.5 g/dl to 2.3 g/dl in chronic diseases. However, the consumption of pharmaceutical albumin increased 23 %. Extensive examination revealed the poorer correlation between them 6 months later. We analyzed a further 28 cases whose serum albumin levels were less than 3.0 g/dl with BCG assay. Y = 0.95 X - 0.29 served as the new standard curve and the correlation of coefficient value (r) was 0.87. After we modified the target elevation value to 2.0 g/dl for chronic disease, the consumption of pharmaceutical albumin returned to the previous level of 6 month ago. We also analyzed the purpose of pharmaceutical albumin treatment for each patient, and the background of each case. A hundred and nineteen bedside cases treated with albumin replacement therapy were investigated. We divided these cases into 3 groups according to serum albumin level (z); 2.5 g/dl ≤ z < 3.0 g/dl, 2.0 g/dl ≤ z < 2.5 g/dl, and z < 2.0 g/dl. The coefficient value (r) was significantly poorer in lower serum albumin levels, and the serum albumin value did not elevate more than expected after pharmaceutical albumin treatment in such cases ($p<0.05$). *Conclusions*. The indication of pharmaceutical albumin varies and is complex especially in cases whose serum albumin level is lower. Target elevation value of serum albumin might be continuously effective in reducing the consumption of albumin. However, we have to understand the difficulty in estimating the required clinical dosage of pharmaceutical albumin from laboratory data even if we adopted more advanced assay. Simultaneously, we need more information about efficacy on each background disease accompanying hypoalbuminemia.

1643

HOME CARE MANAGEMENT OF TRANSFUSIONS IN HEMATOLOGICAL PATIENTS

MM Trawinska,[1] P Niscola,[1] A Tendas,[1] M Giovannini,[1] L Cupelli,[1] M Palombi,[1] G Brunetti,[2] A Perrotti,[1] C Cartoni,[2] F Efficace,[3] P De Fabritiis,[1] F Mandelli[4]
[1]*S. Eugenio Hospital, Hematology, Rome, Italy*
[2]*Division of Hematology, Policlinico Umberto I, University „La Sapienza„, Rome, Italy*
[3]*Health Outcomes Research Unit, GIMEMA Data Center, R, Italy*
[4]*Italian Association Against Leukemias, Lymphomas, and Myeloma, Rome, Italy*

Background. Red blood cell (RBC) and platelets (PLT) transfusion is one of the most challenging tasks in the home care management of patients affected by hematological disease (HD). Indeed the treatment of anemia or thrombocytopenia are an essential part of the global management of most HD patients. In erythropoietin-failed patients or in those unsuitable for this option, RBC transfusions remain the only available measure and PLT transfusions, although less frequently required, are the unique effective treatment for symptomatic thrombocytopenia. *Aims*. To evaluate the management of RBC and PLT transfusions at home during the last two years (2009-2010). Methods. There were 266 pts (125 male) with a median age of 81 (20 - 98) years. Diagnosis was as follows : acute leukemia 51, multiple myeloma 34, lymphoma 35, myeloproliferative disease 30, myelodisplastic syndrome 68, solid tumor 23, other diagnosis 25. Patients were followed at home for a mean of 8,1 (1 - 24) months. Therapy with erythropoietin stimulating agents was used in 100 pts (38%). Results. Overall, 163 (61%) and 12 (5%) patients required RBC and PLT transfusions, respectively for a total of 2197 and 361 RBC and PLT units, respectively; RBC and PLT units in transfused pts were a median of 5 (1-60) and 13 (5-96), respectively. RBC and PLT units monthly requirement in transfused pts were a median of 0.83 (0.04-8.7) and 1,83 (0.4-13.8), respectively. AL and MDS diagnosis correlated with RBC units requirement; AL diagnosis correlated with PLT units requirement. All transfusions were safely administered at home without any untoward effect. Conclusions. QoL is a particularly important issue for hematological patients. With this regard, management of pts requiring multiple and repeated admissions to receive RBC or PLT transfusions may be a concern for the affected individual and for its family. Our experience demonstrated that the administration of RBC and PLT transfusion at home is a feasible, reliable and effective in our patient, avoiding social and economic costs due to an inappropriate removal from his domestic environment. In conclusion, in our experience domiciliary management of transfusions represented an important added value to home care program, allowing the best humanization of this procedure for our patients.

1644

EVALUATION OF NIGALE NGL XJC 2000'S PERFORMANCE IN P RODUCTIVE PLASMAPHERESIS AND QUALITY CONTROLS ON PLASMA (TYPE A) COLLECTED

M D'Onofrio,[1] L Paesano,[1] G Leonardi,[1] G Vaccaro,[1] G Lubrano,[1] T Sem,[2] S Misso,[3] C Nocera[1]
[1]*PO San Giovanni Bosco ASL Na1 Centro, Naples, Italy*
[2]*AVIS Campania, Naples, Italy*
[3]*PO San Giuseppe Moscati ASL Caserta, Aversa, Italy*

Background. The Nigale NGL XJC 2000, distributed by Hemotrans (Pomezia, Italy), is a new cellular separator exclusively dedicated to plasma production by apheresis. This instrument, characterized by a discontinuous blood flow with a single venous access, adopts the technology developed by Latham, namely the separation of blood components according to their density gradient by applying an appropriate centrifugal force. In the Nigale's kit, a blow moldeld bowl is included. It permits to obtain a plasma with a lower cellular contamination. AIMS. In our Transfusion Centre, we evaluated, in terms of effectiveness and efficiency, the qualitative and quantitative performances of this equipment. *Methods*. Between November and December 2010, one hundred plasmapheresis were performed with this new instrument, of course after informed consent, on 100 periodic blood donors with at least one previous experience in apheresis donation. In order to evaluate the operability and manageability of this cellular separator, the quality of its kits and the compliance of donors, we have recorded all adverse reactions to donation, any interruptions in the procedure due to malfunctions of instrument or abnormalities of the kit. *Results*. Only in 17 out of 100 plasmapheresis were recorded incidents. We have observed 15 mild adverse reactions due to citrate toxicity, resolved by changing the pump speed or with a little break, but completing the procedure; in one case the donation was interrupted by a fainting, an adverse reaction of moderate grade; while in the last case the apheresis failed due to a prolonged low-pressure in the collection, but without consequences for the donor. Serious reactions were not observed, thus no one procedure has been interrupted for malfunctions of instrument or for defects or disruptions of the kits. Mean factor VIII on collected plasma units was 90,35%. Mean fibrinogen was 332 mg/dL. All sterility controls resulted negative. Cellular contamination was not significant (mean erythrocytes=0,01 $x10^3$/microL; mean leukocytes = $0,1x10^3$/microL; mean thrombocytes = $11x10^3$/microL, with a minimum count of 2 and a maximum of 31). *Conclusions*. The availability of a new cell separator dedicated to plasmapheresis may allow a greater number of targeted donations. The Nigale

NGL XJC 2000, on the basis of our experience, is characterized by extreme simplicity in the mounting kit and by a simple and intuitive management software. The donation can be customized according to the parameters of the donor (sampling and re-infusion speed) and the amount of plasma to produce. The safety in the process is guaranteed thanks to the various sensors connected to alarms, moreover it is possible to re-infuse saline solution at will to achieve an optimal hemodynamic compensation. In this context we have also evaluated qualitative performance of this new instrument and our data (on factor VIII and fibrinogen dosage, microbial and cellular contamination) show that plasma collected by Nigale NGL XJC 2000 respect both Italian and European quality parameters. At the end the availability of another cell separator dedicated to plasmapheresis, also because offered at extremely attractive costs, may allow a greater number of targeted donations.

1645

TRANSFUSION-RELATED ACUTE LUNG INJURY IN HEMATOLOGIC PATIENTS

M Bourgeois, M Arefi, FJ Diaz Galvez, L Medina Marrero, A García de Coca, MJ Peñarrubia Ponce
Hospital Clinico Universitario Valladolid, Valladolid, Spain

Background : Transfusion-related acute lung injury (TRALI) is an underreported complication of transfusion therapy. It is the third most common cause of transfusion-associated death. TRALI is characterized by noncardiogenic pulmonary edema. The presence of HLA antibodies in the donor or recipient plasma supports the diagnosis of TRALI. There is no specific treatment other than supportive measures. *Case reports*: Case 1: A 46 year old male with Acute Myeloid Leukemia treated with "3x7"scheme with pancytopenia and without blasts in the bone marrow received platelets and two packed red cell units transfusion on the 21st day of treatment. 4 hours after the transfusion, he presented acute respiratory distress and was transferred to the ICU. All other causes of pulmonary edema were ruled out and TRALI was suspected. The patient died shortly afterwards. HLA antibodies in the donor resulted positive. Case 2: A 81 year old female with myelodisplastic syndrome and severe aortic stenosis was admitted because of cardiac failure. She required five packed red cell units over the following five days. On the sixth admission day, platelets were transfused because of severe thrombocytopenia. Two hours after transfusion, she had chills, fever, hypotension, dyspnea, bibasal crackles and tachycardia. She was transferred to the ICU, starting oxygen by mask, steroids, and diuretics. The patient recovered over the next 72 hours. Positive anti-HLA antibodies were present in the donor. *Comments.*: Endothelial cell damage and increased capillary permeability in TRALI are possibly caused by antibodies generated by the host against leukocyte antigens present in the blood products transfused, or by other substances that modify the biological response of the pulmonary bed neutrophils. The inflammatory reaction leads to pulmonary edema and respiratory failure. Antibodies against leukocyte antigens are positive in 60-90 % of patients with TRALI. There are wide variations in the reported incidence of TRALI. These discrepancies are probably explained by underdiagnosis, difference in diagnostic criteria and lack of standardized reporting. Joint efforts by international experts to standardize case definition may contribute to improve diagnosis. *Conclusion:* Our two cases illustrate TRALI as a relevant differential diagnosis in patients with sudden respiratory failure within six hours of transfusion. It is essential to notify immediately to the blood bank all potential TRALI cases, to ensure proper investigation of donor risk factors and to test for HLA antibodies.

HOME BLOOD TRANSFUSIONS: THREE YEARS OF EXPERIENCE IN MYELODYSPLASTIC SYNDROMES

P Boulanger,[1] T Comont,[2] K Delavigne,[2] P Cougoul,[2] MF Thiercelin-Legrand,[1] D Adoue,[2] O Beyne-Rauzy[2]
[1]*Santé Relai 31 Purpan, Toulouse, France*
[2]*Purpan Universitary Hospital, Toulouse, France*

Background. Transfusion-dependence is a common issue in myelodysplastic syndromes (MDS) including low risk MDS after EPO failure or supportive care in high risk MDS. *Purpose.* Red blood cells (RBC) transfusions are usually performed at hospital. Alternative solutions are available through the development of home blood transfusion services in collaboration with the general practitioner (1,2). We report our experience of home blood transfusions in MDS patients. *Patients and methods*. since 2009 our hospital developed home blood transfusion services. More than 220 red blood cell transfusions were made at home. We studied indications, safety, cost and feasibility of this modality of transfusion in comparison with standard procedure i.e. in hospitalization. Results: 116 transfusions were made in 25 patients. Mean age was 78.6 years (53-96). 16/25 patients (64%) suffered from myelodysplastic syndromes (MDS) or secondary acute myeloid leukemia (AML). Patients experienced no major adverse. In 10 cases transfusion was not possible due to nurse or general practitioner inaccessibility. No patient refused this modality of transfusion. Economic costs were evaluated: home transfusion appeared to be less expansive. Conclusion: home transfusion is safe and feasible. To receive treatment at home is a common patient's preference and increase quality of life particularly in chronic disease which affects elderly people. Home supportive care represent an alternative solution if both patient and gener practitioner are agree, that could improve hospital accessibility for more severe procedures.

ENDOCRINE DYSFUNCTIONS IN TRANSFUSION DEPENDENT THALASSEMIA PATIENTS

Z Karakas, N Ozcan, O Soyluk, B Kucukemre Aydin, F Bas, N Saka, L Agaoglu, S Anak, A Unuvar, G Ozturk, R Tanakol
Istanbul Medical Faculty, Istanbul, Turkey

Background. Patients affected by thalassemia major frequently have one or more endocrine dysfunctions. Despite use of intensive chelation therapy, it is difficult to prevent this condition, and this condition usually leads to a decrease in quality of life. *Methods*. Endocrinological evaluation of 36 thalassemia patients (22 female and 14 male) receiving deferasirox was done. The age range was 7.5-35 years; 29 patients; > 18 years, 6 patients; 10-18 years and 1 patient <10 years. Presence of growth failure, carbohydrate metabolism disturbance, hypoparathyroidism, thyroid dysfunction, hypogonadism and osteoporosis and the correlation of endocrine dysfunctions with age, sex, ferritin levels were investigated. *Results*. All patients had at least one endocrine disorder. Thirteen (36%) had growth failure, 15 (41%) had carbohydrate metabolism disturbance, 3(8.3%) had hypoparathyroidism, 2 (5.5%) had subclinical hypothyroidism, 2 (5.5%) had hypocortisolemia and 19 (52%) had hypogonadotropic hypogonadism. Thirteen of the 22 female patients (59%) had amenorrhea, 7 of the 14 male patients (%50) had low testosterone levels. Nineteen patients (52%) had osteoporosis. The frequency of growth retardation was not different between girls and boys, but carbohydrate metabolism disorders, hypogonadism and osteoporosis was found to be a little more frequent in girls. Ferritin levels were found to be directly correlated to growth retardation and hypogonadism, but there was no direct relationship between ferritin levels and osteoporosis and disorders of carbohydrate metabolism. In addition, these disorders are also found in those with ferritin levels below 500 ng/ml. Growth retardation, and carbohydrate metabolism disorder was found to have an earlier onset, seen starting from the age of 10. Hipogonadism and osteoporosis become more evident over the age of 18. *Conclusions*. Despite low levels of ferritin and intensive chelation therapy, many endocrine dysfunctions can occur in thalassemia major patients. It may be more effective to aim at lower levels of ferritin. Endocrine disorders arise from the age of ten. Close follow up for endocrine dysfunction and treatment will improve the quality of life in thalassemic patients.

1648

COMPARATIVE EVALUATION OF THERAPEUTIC EFFICACY OF PHOTOCHEMICALY TREATED AND GAMMA-IRRADIATED PLATELET CONCENTRATES TRANSFUSED TO PATIENTS AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION

M Ogorodnikova,[1] S Shamansky,[1] A Onufrievich,[1] E Ogorodnikova,[2] T Zabotina,[2] O Rukavitzin[1]
[1]*N.N. Burdenko Main Military Clinical Hospital, Moscow, Russian Federation*
[2]*N.N. Blochin Cancer Research Center, Moscow, Russian Federation*

Background. The maintaining of functional properties of blood components for transfusion is one of the important requirement for the processing methods. Gamma irradiation (GI) of apheresis platelet concentrates (A-PLT) is used for inactivation of allogenic T-lymphocytes to prevent

transfusion-associated graft versus host disease (TA-GvHD) in susceptible recipients. Photochemical treatment (PCT) of A-PLT with amotosalen and long-wavelength ultraviolet A (UVA) light has been developed to prevent transfusion complications, associated with pathogens and donors leukocytes. *Aims*. The aim is to compare GIed and PCTed A-PLT on the base of clinical markers of their functionality and viability. Methods: There were selected 30 A-PLT transfusions (15 transfusions of GIed and 15 - of PCTed A-PLT) to be characterized on the following criteria: 1h posttransfusion count increment (1h CI) and 1h corrected count increment (1h CCI), 24h posttransfusion count increment (24h CI) and 24h corrected count increment (24h CCI), hemostatic efficacy and acute transfusion reactions. A-PLT were collected in 35% plasma and 65% platelet additive solution. PCT of A-PLT was performed with 150 μM amotosalen and 3,6 J/cm2 UVA light. GI dose of A-PLT was 25 Gy. The platelet content per transfusion dose was 2,5 to 3,5 x 1011. Quality control of all physicochemically treated A-PLT samples was performed by flow cytometry on the base of activation (CD62P) and apoptosis (Annexin V binding) markers. All treated A-PLT were ABO compatible and were transfused to thrombocytopenic patients after autologous haematopoietic stem cell transplantation during the first 48 hours after collection. Results: After informed written consent was obtained, 12 patients were included in the study, each patient received 1 to 4 A-PLT transfusions. The mean pretransfusion platelet count was 19,25±5,2×10^9/L. The average 1h CI in the group received PCTed A-PLT was 25,7±7,49×10^9/L. There were no observed differences in patients groups with transfusions of PCTed and with GIed A-PLT: 1h CI in the group received GIed A-PLT was 23,85±5,22×10^9/L. The mean 1h CCI was similar in both groups: 19,4±7,2×10^3 for the group received PCTed A-PLT and 15,3±5,6×10^3 for the group received GIed A-PLT. The mean 24h CI was 12,4±5,6×10^9/L in PCT group, 24h CI for GI group was on the same level - 12,7±5,1×10^9/L. There were no differences in comparative assessment of average 24h CCI for PCT and GI groups: 24h CCI was 9,24±4,6 and 8,21±3,6×10^3 respectively. All transfusions had adequate hemostatic efficacy. No episode of posttransfusion reactions were observed in these groups. Summary/conclusions: The results of 1h CI and CCI, 24h CI and CCI were acceptable according to the European recommendations and to international guidelines. The physicochemically treatment of A-PLT was not lead to decreasing of therapeutic efficacy of A-PLT. PCTed and GIed A-PLT were demonstrated the identic clinical markers of their functionality and viability. The PCT of A-PLT prevent a broad spectrum of transfusions associated risks that is why this method is preferable for patients after autologous haematopoietic stem cell transplantation.

DIFFERENT METHODS FOR DETERMINATION OF LOW PLATELET COUNTS: THE REASON FOR POSSIBLE INAPPROPRIATE PLATELET TRANSFUSION

D Antic,[1] I Elezovic,[1] J Bjelanovic,[2] G Kartaljevic[2]
[1]*Clinical Center Serbia, Belgrade, Serbia*
[2]*Center of Clinical Chemistry, Clinical Center of Serbia, Belgrade, Serbia*

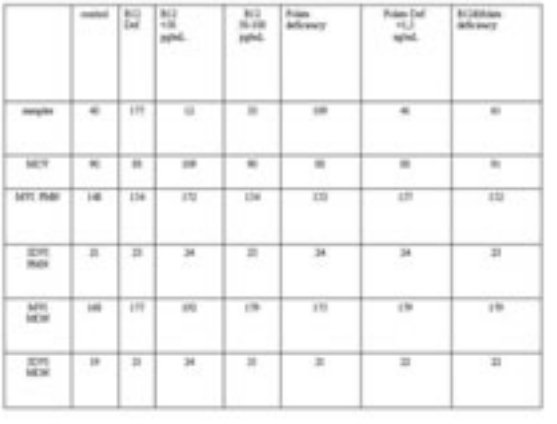
Background. It is known that the use of available hematology analyzers is based on two basic principles: electronic impedance (IMP) and optical light scatter analysis (OPT). Both methods may result in some inaccuracies in PLT measurement, which can be caused by interference from cells or materials of a similar size to the PLTs. Therefore, immunoplatelet method is proposed as a new reference method, using monoclonal antibody specific to a cluster of differentiation common to all platelets. *Aims*. We decided to evaluate low PLT counts by IMP and OPT methods and to compare them with the immuno plt CD61 measurement by flow- cytometry. We also examined the possibility of inappropriate PLT transfusion resulting from an inaccurate PLT count. *Methods*. We analyzed consecutive blood samples of patients with acute myeloid leukemia and OPT PLT counts of less than 50x10^9/L. Also, we compared the number of prophylactic PLT transfusion indications (threshold of 20 x 10^9/L) according to the PLT counts determined by the OPT and IMP methods with the number of prophylactic PLT transfusion indications according to CD61 method. In our study we used Cell-Dyn Sapphire (Abbott Diagnostics) hematological analyzer. This instrument measured the PLT count by three methods: OPT, IMP, and CD61 methods using monoclonal antibody directed against glycoprotein IIIa (CD61). *Results*. We collected 44 samples. The mean ± SD values of the PLT counts were 17x10^9/L, 16x10^9/L, and 21x10^9/L for the CD61, OPT, and IMP methods, respectively. The correlation of the OPT method when compared with the CD61method was very strong (r=0.872; p<0.001) and R2 was 0.761. The correlation of the IMP method when compared with the CD61 method was weaker (r = 0.686; p<0.001) and the R2 was 0.470. In the bias analysis, the IMP method (but not OPT) showed higher PLT counts when compared with the CD61 method (mean of difference 4.37x10^9/L; p=0,001 and 0.72x10^9/L, p>0,05, respectively). We saw overtransfusion in 29.5% of cases and undertransfusion in 2.3% of cases (p=0.002; McNemar's test) when we selected a threshold of 20x10^9/L with the IMP method. *Conclusions*. PLT counts determined by the IMP methods showed some disagreement when compared with the CD61 and OPT method. This disagreement caused both PLT undertransfusion and overtransfusion.

1650

POSITIONAL PARAMETERS FOR THE DETECTION OF VITAMIN B12 AND FOLATE DEFICIENCIES

E Papakonstantinou, E Yfantis, A Lakoumenta, K Konstantinou, C Pegos, P Georgoutsou, C Manti
Thriassion Hospital, Agia Paraskevi, Greece

Background. Classical flow charts used widely for the diagnostic approach of anemia due to Vitamin B12 (B12) deficiency or anemia due folate deficiency includes the Mean cell Volume of the red blood cells (MCV) as one of the key tests for the suspicion of these diseases and differential diagnosis of anemia. Only around half of the patients with B12 deficiency or folate deficiency have high MCV, in many of the situations because the coexistence of other causes of anemia. The Coulter LH 780 hematology analyzer (Beckman Coulter) has the ability to measure specific parameters of neutrophil and monocyte populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect morphologic changes in neutrophil and monocyte population. Using VCS parameters we investigated the correlation between megaloblastic neutrophils and monocytes in B12 and/or folate deficiencies.



Aims. Correlation of B12 and/or folate deficiencies with neutrophil and monocyte PP. METHODS Study population included 427 patients. 177 had B12<145pg/Ml, 189 patients had folate <2.33ng/mL There were 61 cases with both serum folate and B12 deficiency. Anemia was defined according the WHO anemia criteria (Hb<12 g/dL women, Hb<13 g/dL men). We collected blood samples from 43 healthy control subjects. VCS parameters and full blood count was obtained by the Coulter LH 780 hematology analyzer. B12, folate and ferritin values were obtained using paramagnetic particle chemiluminescent immunoassay . P value less than 0, 05 were considered significant. Anemia (mean Hb 11 g/dL) was found when B12 values were either less than <50pg/mL or between 50 to 100 pg/mL, while ferritin and folate mean values were normal at these groups. Statistically significant difference was observed for MCV only when we had B12 values lower than <50pg/mL(P<0.0001), all the other cases we studied P was equal to 0.4. PP correlation between controls and the other groups showed statistical significance (P<0.0001). SUMMARY/CONCLUSIONS. MVI and SDVI of neutrophils and monocytes may be used for the detection of megaloblastic neutrophils and monocytes. Megaloblastic neutrophils and megaloblastic monocytes may be seen in B12 and/or folate deficiency. Positional parameters have significant statistical role in the detection of those deficiencies in contradiction with the widely used MCV, because they are not affected by the presence at the same time of iron deficiency or other reasons of anemia. Although plausible, this hypothesis needs to be sustained clinically by a prospective study.

1651

THE STRUCTURAL PARAMETERS NEUT-X AND NEUT-Y IN MEGALOBLASTIC ANEMIA

A Agorasti, E Nikolakopoulou, D Konstantinidou
General Hospital of Xanthi, Xanthi, Greece

Background. NEUT-X and NEUT-Y are new structural parameters determined by the Sysmex XT-2000i analyzer (provided by service data). NEUT-X is the mean value of the side scatter diffraction of the neutrophil population and represents the structure of the neutrophils, while NEUT-Y is the mean value of the fluorescence measurement. Low values of NEUT-X and NEUT-Y reflect neutrophil dysplasia in myelodysplastic syndromes. *Aims*. The aim of this study is to evaluate these new parameters in patients with megaloblastic anemia (MA) due to vitamin B12 deficiency. *Methods*. Blood samples from 62 normal healthy subjects - controls (normal results of blood count and blood smear) and from 40 patients with MA (hemoglobin < 12.0 g/dl, serum vitamin B12 levels < 120 pg/ml, determined by Access, Beckman Coulter analyzer, and microscopical hypersegmentation of neutrophils) were performed with Sysmex XT-2000i analyzer. Statistical analysis: Student's t-test and Pearson correlation were applied. Values of $P < 0.05$ were considered to indicate statistical significance. Results: Patients with MA have statistically significant higher values of NEUT-X than normal controls, but there was no difference in NEUT-Y values (Table). In patients with MA, NEUT-X values correlate negatively, in a statistically significant degree, with vitamin B12 values (r=-0.577, P=0.001). *Conclusions*. The increased NEUT-X value (an index of the structure of neutrophils) observed in patients with MA, reflects the presence of hypersegmented neutrophils and could help with the diagnosis of megaloblastic anemia. The laboratory cytologist should consider above which threshold of NEUT-X value, a microscopical blood film review is routinely necessary.

Parameter	Normal controls, n = 62	Patients (MA), n = 40	*P* value
NEUT-X, mean ± SD	1384 ± 28	1412 ± 56	0.006
NEUT-Y, mean ± SD	390 ± 19	390 ± 27	0.860
Vitamin B12 (pg/ml)	325 ± 110	88 ± 29	0.000

1652

EXTENDED LEUKOCYTE DIFFERENTIAL OF LEUKOPENIC SAMPLES USING COMBINATION OF AUTOMATIC CELL ANALYZER AND 5-COLOR 6-ANTIBODIES FLOW CYTOMETRY

KJ Han, YJ Cho, JH Lim, YG Kim, YJ Park
Catholic University of Korea, Seoul, South-Korea

Background. The performance of the manual differential on leukopenic samples has very poor precision due to insufficient number of counted cells. Frequently, it is very difficult to classify cells and time consuming also. Recently, the HematoFlow method has been introduced as a combination of automatic cell analyzer and CytoDiff ® 5-colors 6-antibodies flow cytometry. Aims. We evaluated the usefulness of HematoFlow method in leukocyte differential of leukopenic samples. Methods. Leukopenic blood samples(249) showing WBC count of 500-2,000/uL were selected. The CBC samples were analyzed by flow cytometry using premixed reagent for leukocyte differential and no wash mode(CytoDiff, Beckman Coulter). HematoFlow results were selected or calculated using automatic blood cell analyzer(DxH800, Beckman Coulter) results and CytoDiff results. Manual differential counting was duplicated including a hematopathologist(reference count) and 50 to 100 cells were counted. Immature granulocytes(IG) of manual count was sum of metamylocytes, myelocytes and promyelocytes. IG was calculated by subtracting the DxH800 eosinophil count from sum of CytoDiff IG and eosinophil count. If basophil and nonB nonT blasts populations were not well separated, differential was performed using median fluorescence level of 3.5 using CD2+CRTH2. Statistical analysis was performed using Fisher's F test for analysis of precision and Pearson correlation test for correlation analysis. The study was approved by IRB. Results. The proportion of adjusting gates in CytoDiff was 19 out of 247 cases(7.7%) due to huge debris contamination(2 cases) and incomplete separation of basophils and blasts. The precision of HematoFlow was superior to manual differential in counting of 5 leukocyte subpopulations, IG and blasts(Table 1). Especially, the neutrophil count by duplicated manual count revealed 5.4±5.8% difference and by HematoFlow revealed only 1.24±2.70% difference. The blast was found in 46 samples and 17 samples showed blasts only in one manual count(37%), but all cases showed blasts in both HematoFlow counts. The manual blast count showed 1.7±6.6% difference and by HematoFlow only 0.65±1.99% difference. The eosinophil count of DxH800 showed best correlation to reference count. All data analysis is summarized in Table 1. Conclusion Leukocyte differential in leukopenic samples using HematoFlow is much more reproducible and accurate than manual differential. Especially, detection of leukemic blasts is much more reliable than manual differential. In conclusion, HematoFlow is very useful in differential counting of leukopenic samples.

Table 1. Results of HematoFlow differential to manual differential count

Cell population	Difference of repeated assay		Correlation to reference manual differential	
	Manual	CytoDiff		
Neutrophil	5.4±5.8	1.24±2.70 (*P*<0.001)	Manual1	0.9610(<0.0001)
			DxH800	0.9463(<0.0001)

OUTCOME AND RELAPSE RISKS OF THROMBOTIC THROMBOCYTOPENIC PURPURA: AN EGYPTIAN EXPERIENCE

N El Husseiny,[1] H Gobran,[2] H Fahmy,[1] N Tawfik,[1] H Mustafa,[1] S Amin,[1] M El Ekabby[1]
[1]*Cairo University, Cairo, Egypt*
[2]*Saskatoon Cancer Centre, Saskatoon, Canada*

Background: Thrombotic thrombocytopenic purpura [TTP] whether idiopathic or secondary is a rare but life threatening condition. Plasma exchange [Px] has decreased significantly the mortality from the disease but a substantial proportion of patients relapse. We describe the clinical spectrum and response to treatment and explore the risks for relapse in our cohort of patients. Patients and Methods: Patients treated for TTP at the Clinical Hematology Unit of the Department of Internal Medicine of Cairo University Egypt, between 2000 and 2008 were identified. Complete demographic and clinical data, laboratory results, treatment modalities and outcome data were collected and analyzed. The follow-up duration was 24 months. ADAMTS13 and its antibody were assayed for idiopathic patients admitted after June, 2007. Results: A total of 30 patients; 13 males (43%) and 17 females (57%) with a median age of 42 years were treated for 46 episodes of TTP. The median duration of disease onset-to-diagnosis for the first episode was 7 days. 23 patients (76.66%) were diagnosed as idiopathic primary and 7 patients (23.33%) were secondary TTP. Four patients died during the first 24 hours. Out of the 26 patients followed beyond 24 hours, 22 patients (84.6%) achieved remission with an average of 7.55 Px sessions, 13 of whom achieved a sustained remission (50%) whereas 4 patients (15.3%) were refractory. Nine patients relapsed thereafter (total 25 relapses) (mean 2.7 per patient) with an average of 9 Px sessions to achieve a subsequent remission. The 24 months overall survival was 80%. Initial low platelet count and high LDH were the only two statistically significant relapse predictors. Conculsions: The current results are conforming to the reported literature of the outcome of TTP. The very early mortality due to late referral highlights the need of education and awareness about the disease among primary health care providers.

MYH9-RELATED PLATELET DISORDERS: A CHALLENGE IN LABORATORY MEDICINE- CASE REPORT

G Kartaljevic,[1] J Bjelanovic,[1] N Suvajdzic,[1] G Paterakis,[2]
N Majkic-Singh[1]
[1]*Clinical Center of Serbia, Belgrade, Serbia*
[2]*Immunology Dept „G. Gennimatas„ Hosp, Athens, Greece*

Myosin heavy chain 9 (MYH9) - related platelet disorders belong to group of inherited thrombocytopenias. As a result of MYH9 gene mutation premature release of platelets from bone marrow is happening. Macrothrombocytopenia is present at birth and the only therapy that increases platelet count is transfusion of platelet concentrates. Considering the main characteristics of MYH9- syndrome, thrombocytopenia with very high MPV, laboratories should give precise platelet count, in order to avoid risk of inappropriate treatment. Impedance cell counters do not recognize giant platelets and, therefore, underrate both platelet count and platelet volume, so manual assessment is required. Mean of this work is to establish a modern approach of platelet counting, using immuno-determination of superficial antigen CD61, as the most accurate diagnostic tool. The patient, 25-year old male, with MYH9 syndrome, confirmed clinically by presence of macrothrombocytopenia and inclusion Döhle's bodies in granulocytes, was admitted to clinic for digestive surgery due to appendectomy. During routine laboratory investigation platelet counts, done by flow-cytometer Sapphire, Abbott Diagnostics, showed discrepancy in impedance and optical values (21 and 37 x 10^9/L, respectively). Because of very large MPV (15,1 fL) and the lack of experience in such atypical thrombocytopenias, presumption was that CD61 will give the most precise platelet count and this count was the highest (49x10^9/L), which was confirmed microscopically. Not underestimated the vigor of impedance principle, immuno-platelet counting, as a reference method, even in this rare clinical cases proves its strength for the best platelet enumeration.

1655

THROMBOTIC COMPLICATIONS IN PATIENTS WITH ADULT IMMUNE THROMBOCYTOPENIC PURPURA

N Colovic,[1] A Vidovic,[1] D Tomin,[1] P Miljic,[1] R Colovic[2]
[1]*Clinic of Hematology, Belgrade, Serbia*
[2]*Medical Faculty, Belgrade, Serbia*

Background. Immune thrombocytopenic purpura (ITP) is autoimmune disease characterized by platelet destruction and decreased platelet production. Occasionally in ITP a life-threatening hypercoagulable state develops after splenectomy. Also there are reports of thrombotic events after management of ITP with intravenous immunoglobulin (IVIg). We present two patients, the first with thrombotic complications after splenectomy as a result continuous platelet activation and normalization of platelet number and the second patient developed acute myocardial infarction 5days after finishing 5-day therapy with IVIg. Case 1. A 53-year-old woman was diagnosed with ITP in February 2007. She had not other thrombophilic risk factors. She was treated with corticosteroids with moderate response. In August 2008. she developed bronchopneumonia with formation of pulmonal abscess. After recovery from infection she was splenectomized in November 2008.g. After splenectomy the number of platelets normalized but on 21st day after splenectomy a portal vein thrombosis developed. The patient was reoperated and gangrenae of small intestine in 60 cm long was found, which was resected. The patient recovered from surgical procedure but again on 31st December 2008 she got left-sided hemiparesis and epi convulsion. Endocranial MRI revealed a thrombosis of superior sagital sinuses. She was on LMW heparin and afterwards on oral anticoagulant therapy. Now she is well with moderate thrombocytopenia. Case 2. A 49-year-old woman suffering from ITP for 13 years, without response to splenectomy were on several type of treatments and during the last year she was on cellcept(micophenolat mofetil). After viral infection her platelet count dropped to 1x10^9/l with diffuse haemorrhagic syndrome. She was admitted to hospital and she received IVIg 0.400 mg/kg/day for 5 consecutive days. She responded to the therapy with normalization of her platelet count but after 5 days she developed acute anterolateral myocardial infarction with creatin kinase 2260, troponin 27,8. She was treated conservatively with IV heparin and she completely recovered. During treatment with heparin the number of platelets dropped to 52x10^9/l and heparin was stopped. *Conclusions*. In first patient because platelet count did not increased significantly after splenectomy, factors other than platelet count are responsible for thrombotic events. We suggest that previous infection may have provoked life-threatening hypercoagulable state. We advise to be cautious after splenectomy for possible post-splenectomy thrombotic complications in the subset of ITP patients who may have persisting platelet activation. In second patient IVIg have promoted thrombosis by increasing blood viscosity, activating platelets, or causing vasospasm.

[3]*CHU Tivoli, La Louvière, Belgium*

Background: while smoking is a well-known cause of secondary polycythemia and neutrophilia, an association between smoking and an increased platelet count has not been reported. *Aims*: to identify and to characterize smokers developing, in addition to smoking-induced leukocytosis, an unexplained chronic thrombocytosis. *Methods*: a cohort of smoking patients with both a high leukocyte count and thrombocytosis observed during the last 18 years in Jolimont hospital (index cohort) was compared to similar patients from UCL St Luc Brussels(control cohort) observed during the last 16 years. Inclusion criteria included an unexplained thrombocytosis (no evidence of myeloproliferative neoplasm and of secondary thrombocytosis) confirmed at least 3 months apart, associated with tobacco-induced leukocytosis.

	Index cohort	Control cohort	p (test)
Patients with tobacco-induced leukocytosis (n)	168	68	
Patients with leukocytosis and unexplained chronic thrombocytosis (%)	13 (7.7%)	8 (11.7%)	.4 (Fisher)
Male/Female	4/9	4/4	.6 (Fisher)
Median age (range)	45 (31-71)	46 (23-57)	.8 (M-W)*
Median platelet count x 10^9/L (range)**	487 (404-680)	416 (358-562)	.04 (M-W)
Median leukocyte count x 10^9/L (range)	13 (11.4-17.3)	15 (10.9-18.3)	.3 (M-W)

*M-W: Mann-Whitney
** normal values were not identical in both cohorts (index cohort: <400, control cohort <350)

Results: in the index cohort, out of 168 smokers with chronic leukocytosis, 13 presented, in addition, a high platelet count while in the control cohort, out of 68 smokers with a high leukocyte count, 8 presented with thrombocytosis. There were no major differences between both cohorts (Table). In particular, the incidence of thrombocytosis in patients with tobacco-induced leukocytosis was similar (7.7 vs 11.7%, p=.4). The slightly lower platelet count in the control cohort may be related to lower normal values in the *control* laboratory. Overall, the thrombocytosis was modest, did not vary substantially during a protracted follow-up (median FU: 72 months), and was not associated with major arterial or cardiac events. *Conclusions*: although this study provides no direct evidence that thrombocytosis was induced by smoking, its unexpectedly high prevalence in persons with smoking-associated leukocytosis suggests a causal relationship with smoking, especially since similar incidence and characteristics were observed in 2 independent cohorts. Smoking-associated thrombocytosis should be considered in patients with otherwise unexplained long-standing, moderate, and stable thrombocytosis, associated with leukocytosis. The clinical course of this condition is benign. Such patients should not be submitted to aggressive or expensive investigations.

1657

CHRONIC ITP - CASE REPORTS OF THE TREATMENT BY TROMBOPOETIN ANALOGUES IN TWO CHILDREN

V Fiamoli, J Blatny, O Zapletal, S Kohlerova
Children´s University Hospital, Brno, Czech Republic

Background. Immune thrombocytopenic purpura (ITP) is a common acquired bleeding disorder in children characterized by skin and mucosal bleeding. There is an isolated thrombocytopenia caused by antithrombocytic antibodies. The standard treatment is corticosteroids and intravenous immunoglobulin. The alternative treatment can also be anti -

CD20 antibodies and other immune suppression regimens. The splenectomy should be considered if the above-mentioned treatment fails, although we always try to avoid splenectomy in very young children because of possible severe complications such as post-splenectomy sepsis. This was the reason for using thrombopoetin analogues in two girls under the age of eight years, presented on this poster Aims. To assess the efficacy of treatment with romiplostim in two children with chronic ITP Methods and Results In the first patient neither intravenous immunoglobulin nor corticosteroids in dose up to 2mg/kg lead to a sufficient and lasting response. The treatment with antiCD 20 antibodies induced remission for just 5 months. Then platelets decreased again after a viral infection. In the second patient, corticosteroids induced remission only for a few days and after intravenous immunoglobulin the remission was lasting only for 5 weeks. Moreover the patient had repeated severe allergic reaction to intravenous immunoglobulin. Both of our patients fulfilled the criteria of chronic ITP and we offered them and their families treatment with romiplostim with the dose scheme based on data published by Buchanan et al (ASH abstract 680, 2009). Since our patients have been commenced on romiplostim, the platelet count is stable between 100-200x10^9/l. Conclusion Although the prognosis in the patient with chronic ITP is uncertain and the treatment options may not guarantee permanent remission, the alternative treatment with thrombopoetin analogues induced long-term remission in our patients. This treatment also might help to postpone or avoid splenectomy in our two patients and thus improve their quality of life.

1658

CASE STUDY OF SEVERE THROMBOCYTOPENIA AND ASSOCIATION WITH THE COURSE AND FINAL OUTCOME OF THE DISEASEAT A RURAL HOSPITAL OF GREECE

S Patiakas,[1] K Rousos,[2] F Girtovitis[3]
[1]*General Hospital of Kastoria, Thessaloniki, Greece*
[2]*General Hospital of Veria-Health Center of Alexandria, Veria, Greece*
[3]*Universal General Hospital of Thessaloniki AXEPA, Thessaloniki, Greece*

Background-Aims. To study the severe thrombocytopenia (PLT <50.000) which is a frequent problem in hospitalized patients, a causal association with various diseases and demonstrate the important role it plays in the disease course and outcome. *Material-Methods*. We studied retrospectively 1250 records of patients. *Results*. There were 32 patients (19 men and 13 women) with a platelet count 4000-50000. Of these 23 (72%) experienced major bleeding disorders. The average age for men was 66 years for women 71. Causes identified: - In 12 cases of malignant disease with chemotherapy onward (37.5%) In 6 cases of malignant hematological diseases (18.8%) In 6 cases of hepatic cirrhosis (18.8%) In 4 cases of septicemia (12.5%) - In 3 cases of idiopathic thrombocytopenic purpura (9.4%) - In 1 case (3%) reptile bites Despite appropriate therapeutic treatment in 7 cases (22%) death occurred as a consequence of disseminated intravascular coagulation. Summary-Conclusions: 1)Most common cause of thrombocytopenia is a malignant disease after chemotherapy, followed by malignant hematological disease and followed by hepatic cirrhosis. 2)The profound thrombocytopenia is a serious prognostic sign and threatening situation for life itself, despite the appropriate measures. 3)Bleeding disorders occur at a low price in a large percentage of PLT. Attention, therefore, in these cases to the attention of all.

1659

RELAPSES AT THE PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA (ITP) TREATED AS FIRST-LINE THERAPY WITH HIGH DOSE DEXAMETHASONE VERSUS STANDARD STEROID THERAPY

A Gaman, G Gaman
University of Medicine and Pharmacy Craiova, Craiova, Romania

Background. Immune Thrombocytopenic Purpura (ITP) is an acquired disease characterized by an immunological peripheral platelet destruction , with a chronic evolution at adult patients. Glucocorticoids are first-choice therapy, but relapses appear in the third of cases. Aim of study: to evaluate if there is a significant difference of relapses at the patients with ITP treated with high dose dexamethasone (HD-DXM) versus standard steroid therapy. *Methods*: we studied 23 patients with ITP, median age 43 years, hospitalised in the Clinic of Hematology from Craiova (Romania), between 2007-2010. All patients were diagnosed with ITP, other causes of thrombocytopenia having been ruled out by bone marrow aspiration. All patients were treated with glucocorticoids : 11 patients with 1mg/kgc/day for 4 weeks, followed by a degression , and 12 treated with high dose of dexamethasone, 40 mg/day during 4 consecutive days, repeated every 21 days for six total courses. The response was evaluated considering complete response (CR) if platelet count was higher than 10 x 10^9/L, partial response (PR) if platelet count was higher than 5 x 10^9/L and failure if platelet count was lower than 5 x 10^9/L. At the end of glucocorticoids therapy, 15 patients had CR, 4 patients PR and 4 patients presented failure response, needed other therapies (vincristine, splenectomy). The median period of observation at responding patients was of 9,8 months. Seven patients of 19 responders relapsed: 4 of them initial treated with standard steroid therapy and 3 treated with HD-DXM needed other therapy (2 vincristine, 4 splenectomy, 1 eltrombopag) . Conclusion: our study didn't reveal major differences between relapses at the patients with ITP treated with HD-DXM versus standard steroid therapy.

HEREDITARY PLATELET FUNCTION DISORDERS INVESTIGATION; ONE YEAR REFERRALS IN THE HAEMOPHILIA CENTRE OF NORTHERN GREECE

S Theodoridou,[1] S Vakalopoulou,[2] D Kleta,[1] E Lefkou,[1] V Perifanis,[2] A Agapidou,[1] F Klonizakis,[1] A Nikolaki,[1] E Moka1, V Garypidou[2]
[1]*Hippokration Hospital, Thessaloniki, Greece*
[2]*Aristotelion University, Thessaloniki, Greece*

Hereditary platelet function disorders constitute a rare cause of symptomatic bleeding. These disorders are heterogeneous in clinical expression and also in laboratory evaluation. The accurate measurement of the platelet function and the identification of a congenital platelet disorder is complex, includes different assays and the repetition of testing. 55 patients (42 women/13 men) were referred for platelet function evaluation due to personal and/ or family bleeding tendency (51) and 4 to check the antiplatelet therapy. They all manifested symptoms of excessive mucocutaneous bleeding such as bruising or excessive bleeding following surgical or dental procedures. Patients with prolongation of PT, aPTTT and TT were excluded and they were investigated for coagulation factors deficiencies. All patients were tested for Von Willebrand's Disease. The platelet function investigation consisted of 1) the platelet count number and the 2) blood film report for white cell inclusions and platelet size, 3)the aggregation testing in platelet rich plasma with light transmission aggregometry (LTG)by the use of 5 agonists (arachidonic acid, ADP, adrenaline, collagen, ristocetin), and the 4)global test of haemostasis by PFA-100. The LTG was found normal in 34 patients (61,2%) and 21 patients (38,8%) had abnormal LTG. 14 patients among them (66,6%) were women as expected, since these disorders are more commonly diagnosed in women because of the menstrual cycle and the haemostatic challenge of childbirths. 13 were diagnosed as disorders of platelet secretion and signal transduction (8 women/5 men), 1 as thrombasthenia Glanzmann, 1 as aspirin like defect, 4 due to antiplatelet therapy, one had abnormal aggregation to collagen and one abnormal aggregation to all agonists. The use of PFA-100 in our patients showed that among 16 patients tested, 8 had normal values but 5 of them had abnormal aggregation tests and diagnosed as disorders of platelet secretion and signal transduction. Among the other 8 patients with abnormal prolonged PFA-100, 4 were found to have normal aggregation tests, 3 were diagnosed as disorders of platelet secretion and signal transduction and one was due to antiplatelet therapy. The abnormal platelet morphology was found in 4 out of the 13 patients diagnosed as disorders of platelet secretion and signal transduction. Platelet nucleotides release measurement was not feasible. The hemorrhagic history of the 13 patients who were diagnosed as disorders of platelet secretion and signal transduction was serious menhorhagia and bruises in the 8 women and the excessive bleeding following surgical and dental procedures in the 5 male patients. The aggregation tests give a lot of information about various platelet disorders as seen in our patients. Normal values of PFA-100 cannot exclude the diagnosis of a platelet function disorder as found in 5 of our patients, though the number of patients is limited. In literature and clinical practice there is a lack of consensus about the diagnostic tests concerning platelet function disorders. According to our findings, the aggregation tests seem to remain the gold standard in the evaluation of platelet disorders.

1661

EFFICACY AND SAFETY OF SIX DOSES OF RITUXIMAB (375MG/M^2) IN TREATMENT OF CHRONIC REFRACTORY IMMUNE THROMBOCYTOPENIA AN EXPERIENCE FROM QATAR

M Yassin,[1] H El-Ayyoubi,[2] H Muhammed,[1] R Kamzoul,[1] M Al-Badri,[1] H Al-Sabbah[1]
[1]*Hamad Medical Corporation, Doha, Qatar*
[2]*HMC-Al Amal Hospital, Doha, Qatar*

Background. ITP is an autoimmune disorder leading to premature platelet destruction and persistent thrombocytopenia. Treatment is generally not recommended until the platelet count is <30,000/μL, bleeding occurs, or there are other predisposing co morbid conditions.The goal of treatment is to raise the platelet count to a hemostatically safe level. Different doses of Rituximab were tried 1 Gram fixed dose day 1 and day 15 (Rheumatoid arthritis) like regimen , or 375mg/m2/ week for four weeks and 100mg/week for four weeks but nobody has tried 375mg /m2 /week for six weeks. *Aims*: to evaluate the efficacy and safety of 6 doses of Rituximab 375 mg/m^2, in treatment of patients with chronic refractory thrombocytopenia. *Patients and Methods*. From our retrospectively collected data of 14 patients diagnosed with chronic refractory thrombocytopenia between the January 2007 and January 2011 in AL-Amal hematology /oncology centre with mean follow up of 27 months all of them failed, steroid as first line therapy as well as IVIG, and 4 of them underwent splenctomy with no response, 8 were males and 6 were females with a mean age of 32 year, all of them had platlets count of less than 10.000 on presentation. Each of them received Rhituximab 375mg /m2 weekly for six doses and followed initial with weekly CBC for 3months and then every two months. Results: two patients did not achieve any response one is male and the other is female. Two patients achieved partial response platelets count more than 50.000 and less than 100.000 for more than six month and 12 achieved complete response defined as platelets count more than 100.000 for more than one year, with mean complete response of 28 months, none of them developed grade 2 or more infection as per WHO toxicity scale, and none of them developed progressive multifocal leucoencephalopathy. Conclusion: We concluded that six doses rituximab are safe effective and durable in patients with chronic refractory ITP keeping in mind the small number of patients further studies are needed to confirm these results.

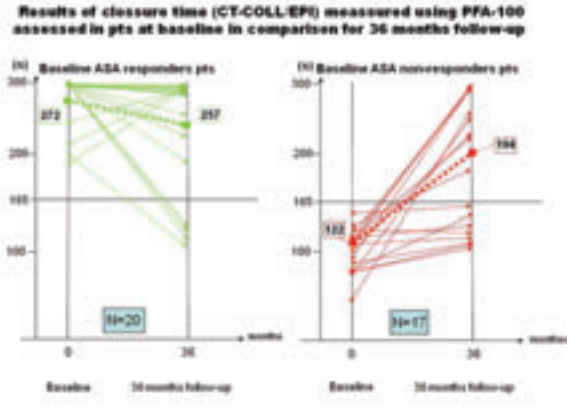
1662

TIME-RELATED CHANGES OF THE SENSITIVITY TO ANTI-PLATELET THERAPY IN PATIENTS WITH ACUTE CORONARY SYNDROME AFTER PERCUTANEOUS CORONRY INTERVENTION

M Jamrozek-Jedlinska, M Duszynska, I Jedlinski, M Slomczynski, K Zawilska

J. Strus Hospital, Poznan, Poland

Study population. 37 patients (pts), 26 male, one month after an episode of acute myocardial infarction treated by percutaneous coronary intervention (PCI) with stent placement. All pts were receiving dual antiplatelet therapy (ASA - 75 mg/pd and clopidogrel - initial 600 mg, next 75 mg/pd) for at least one month before entering into the study. During the second and third year of observantion all pts were on ASA 75-150 mg/pd. *Methods*: The platelet reactivity was assessed on a basic of closure time (CT) in platelet function analyz er PFA100 (Dade Behring). CT was measured on the 30 th day and 36 months after PCI. ASA resistance was defined as a normal collagen/epinephrine CT (<165 s) despite ASA treatment (compliance proved by a diminished intraplatelet mylonyldialdehyde [MDA] concentration).



Results. During 3 - years follow-up changes of ASA resistance status were observed in 14 pts - 10 from "responsive"to "resistant"and in 4 pts from "resistant"to "responsive"status. In 23 pts there were no changes of ASA resistance status. The results of CT in 30 th day and 36 months after PCI were presented on the figure. *Conclusions.*During 36 months follow-up the changes of ASA resistance status (assessed using PFA-100) were observed in 38% of pts treated with antiplatelet drugs after percutaneous coronary intervention (PCI) with stent placement.

PRELIMINARY DATA ON THROMBOPOIETIN RECEPTOR (CMPL) EXPRESSION IN DIFFERENT PLATELET DISORDERS

F Tezza,[1] S Vettore,[2] R Scandellari,[2] F Vianello,[2] F Fabris[2]

[1]*University of Padova, Padova, Italy*

[2]*Department of Medical and Surgical Sciences, Padova, Italy*

Background. Interaction between thrombopoietin (TPO) and cMPL appears to be critical in the platelet production, promoting CD34+ differentiation, megakaryocytes (MK) proliferation and maturation via cytoplasmatic down-stream signalling. Another consequence of TPO-cMPL interaction is the regulation of TPO level. It is know that TPO is high in thrombocytopenia secondary to MK hypoplasia but TPO levels are low in immune thrombocytopenia (ITP) as well as in inherited macrothrombocytopenia and variable in essential trombocythemia (ET). The aim of these study is to investigate cMPL expression in different cases of thrombocytopenia to better understand the therapeutic use of TPO mimetics. Patients and methods We enrolled 78 patients suffering from inherited and acquired platelet disorder: 20 ITP patients, 18 with an inherited macrothrombocytopenia(FAM) (MYH9 related disorder, Bernard Soulier classical, N41H or type2), 25 patients with a thrombocytopenia secondary to megacaryocyte hypoplasia(MK-Hyp) and 15 ET patients. We enrolled also 25 healthy subjects as control group. cMPL (82 kD, glycosylated) expression has been evaluated by Western-Blot on 2 x 107platelets lysates using1 mg/ml rabbit polyclonal anti-Human cMPL antibody. Anti CD41-clone SZ22 monoclonal antibody against platelet GpIIb complex was used as control on the same membranes, after stripping anti-cMPL antibody. Expression of both cMPL and anti CD41 was quantitated by densitometry analysis of Western Blot. The results are given as mean± SEM of cMPL/CD41 expression ratio for each group of patients. Serum thrombopoietin levels have been evaluated by an ELISA assay, using a trade kit (Quantikine, R & D System). Results ITP (0.17±0.04), FAM (0.19 ± 0.06) and Mk-Hyp (0.18±0.04) patients have higher cMPL expression than controls (0.04±0.01) and ET (0.0±0.01). There were no differences between controls and ET. TPO (pg/mL) in ITP (149±22) is higher (p=0.001) than controls (67±14); Mk-HYP have TPO levels (833±301) higher than controls (p=0.008) and ITP (p=0.029). All three form of thrombocytopenia have TPO level higher (p<0.05) than ET (respectively ITP 149±22, Mk-HYP 833±301, FAM 98±15 pg/mL vs ET 55±8 pg/mL). No correlation between TPO and cMPL has been demonstrated in our groups. *Conclusions*. Our preliminary data demonstrate that cMPL is overexpressed in thrombocytopenia in spite of the type. On the contrary TPO is increased above all in patients with Mk-Hyp. These findings justified the use of TPO mimetics in ITP and FAM.

1664

COMPLETE ITP REMISSION IN ADULTS FOLLOWING THE SPLENECTOMY IN LATVIA

I Vidmane-Ozola,[1] S Lejniece,[2] V Boka,[1] I Kalnins[3]

[1]*REUH clinic „Linezers„, Riga, Latvia*

[2]*REUC, State Hematology centre, Riga, Latvia*

[3]*Riga Stradinš University, Riga, Latvia*

Background. Immune thrombocytopenic purpura (ITP) manifests as decrease in platelet (PLT) count of various degrees, which can even cause fatal bleeding. Glucocorticoids (GC) and intravenous immunoglobulin (IgG) are used as the first line of treatment; splenectomy is "the second stage". *Aims*. Determine the rate of complete remission following the splenectomy patients with ITP. *Methods*. The 668 patients to 2.3 million people were cured with diagnosis ITP in the period from 2002 to 2010 at the Riga East University Hospital (REUH) clinic "Linezers"and State Hematology centre (SHC). The retrospective study included 13 patients which underwent surgery at the 8 years period. Demographic data, disease duration and previous therapy, full blood-count, spleen size, type of operation-laparoscopic (LS) or open (OS) splenectomy were analyzed. Indications for splenectomy were thrombocytopenia with bleeding signs and or lack of response to conservative treatment and low platelet count while on massive steroid. Processing of the data used nonparametric statistical methods. *Results*. The study includes 8 women and 5 men, the median age are 37 (IQR=18) years. The median duration of the disease prior to the surgery was 24 (IQR=80) months. Prior to the surgery 2 (15.4%) patients received only GC therapy, 5 patients (38.5%) received

GC and immune suppressive (IS) therapy, in 5 cases (38.5%) GC and IgG was applied. One patient, for whom the duration of the disease prior to the surgery was 7 months, had received GC, IS and IgG therapy (7.7%). All patients received pneumococcal vaccination prior the surgery. The median size of the spleen was 10.2 (IQR=2.1) cm detected by ultrasonography. In one US case and in one CT case accessory spleens were detected, which were removed during the surgery. 11 LS and 2 OS were done. The pre-operative median value of PLT 56 x10^9/L (IQR=93) had increased in a statistically significant way in accordance with Wilcoxon signed-rank test (z=2.76; p=0.006) compared to the median value of PLT 183 x10^9/L (IQR=220), which was detected during the last follow-up on median 36 (IQR=55) months after the surgery. Complete remission (PLT count >50x10^9/L, without additional therapy and bleeding signs) were observed in all patients at the median 36 (IQR=55) months observation period following the surgery. *Conclusions.* The splenectomy is safe and effective *second stage* procedure for patient with ITP in our study. Complete remission of ITP was observed in all cases.

1665

PLATELET GLYCOPROTEINS AND STICKY PLATELET SYNDROME

J Stasko, P Kubisz, L Bartosova, A Ocenasova, P Holly, D Kotulicova, J Ivankova

Jessenius Faculty of Medicine, Martin, Slovakia

Background/Aims. Sticky platelet syndrome (SPS) is a hereditary, autosomal dominant thrombophilia associated with an increased incidence of arterial and venous thrombosis. Light transmission aggregometry (LTA) is used to confirm a platelet hyperaggregation induced by very low concentration of platelet inducers - by adenosinediphosphate (ADP) and epinephrine (EPI). Etiology of SPS is unknown but some studies suggest that abnormalities of platelet surface glycoprotein (GP) receptors can lead to their hyperfunction. Aim of the study was to verify if there are some abnormalities in the expression of platelet membrane GP receptors in patients with SPS. *Materials and Methods*. Seventy-five patients with SPS were included into the study and examined by flow cytometry to assess the expression of platelet surface GP receptors: P-selectin (CD62P), CD63 and CD51. The control group included 30 healthy individuals. All patients and controls agreed with participation in the study and signed an informed consent. Results: The results of flow cytometric analysis of SPS patients have shown that there is a significantly higher expression of P-selectin (CD62P), CD63 and CD51 compared to healthy controls (P-selectin: p<0,001, CD63: p<0,05, CD51: p<0,05 respectively). These GP receptors are neoantigens expressed on the platelet surface only after platelet activation. *Summary/Conclusions*. On the basis of our measurements we can say that platelets in SPS patients are activated compared to the controls. We suggest that the increased expressions of CD62P, CD63 and CD51 may serve as predictors of thrombophilia in SPS patients.

IDIOPATHIC THROMBOCYTOPENIC PURPURA IN ADULTS IN THE LAST 10 YEARS: SINGLE CENTRE EXPERIENCE

M Pavkovic, S Trpkovska-Terzieva, A Latifi, T Sotirova, O Karanfilski, S Trajkova, L Cevreska, A Stojanovic

Department of Hematology, Skopje, Macedonia

Background. Adult idiopathic thrombocytopenic purpura (ITP) is a benign disease with low morbidity and mortality and frequent remissions that occur spontaneously or in response to first line treatment with steroids or splenectomy. *Aims*. The aim of this study is to analyze the clinical outcomes of 170 patients with ITP diagnosed and/or treated in our hospital in the period between 2000 and 2010. *Methods*. We retrospectively have analyzed the institution database for patients diagnosed and/or treated for ITP. All patients met the diagnostic criteria for ITP. *Results*. The median age at diagnosis was 47 years (range 14-83 years). Forty six (27%) were males and 73% were females. Forty three (25%) were asymptomatic, 65% had minor skin or mucosal bleeding and 10% had significant bleeding from gastrointestinal or genitourinary system. None of the patients had severe, life threatening bleeding symptoms. The median platelet count at diagnosis was 13x10^9/L (range: 0-98x10^9/L). Number of patients with severe thrombocytopenia (Plt <30x10^9/L) was 125/170 (73.5%), with moderate thrombocytopenia (Plt 30-50x10^9/L) was 14.1% and with mild (Plt 50-100x109/L) was 12.4%. Bleeding symptoms were more common in patients with severe thrombocytopenia 108/125 (86.4%) patients, comparing to 45.8% of patients with moderate and 38% with mild thrombocytopenia (p<0.001). Bone marrow examination was performed in 76% of patients. Anti-platelet antibodies were positive in 8/35 (23%) of patients. Direct antiglobuline test was positive in 7/135 (5.2%) patients and 2.9% patients had hemolytic anemia. Median follow up of all patients was 13 months. Ninety five patients had follow up longer than 12 months, with median 44 months (range 14-384). Corticosteroids were initial treatment for 95% patients, 38(22%) were splenectomized, 25(14.7%) were treated with intravenous gamma globulins, while 9 didn't received any specific treatment. Complete response to initial treatment (prednisone±splenectomy) was achieved in 55/161(34.2%), partial response in 55.9% and no response in 9.9% patients. The median platelet count at last control was 161x10^9/L (range: 2-704x10^9/L). At the last follow up, number of patients with severe thrombocytopenia was 12/170 (7.1%), with moderate was 12(7.1%), with mild 33(19.4%) and with platelet count >100x109/L was 66.4%. At the last control 46.5% patients were without therapy for ITP. In the group of patients with follow-up longer than 1 year; 28 (29%) patients had refractory ITP with median follow-up of 66 months. All patients with refractory ITP were treated with steroids, 11 were splenctomized, significantly more patients 12(43%) were treated with IVIG, p=0.005. Median age of 38 splenectomized patients was 28 years and it is significantly different from the other patients (p<0.001). There were no significant difference in other characteristic between splenctomized or refractory ITP and other patients at diagnosis. *Conclusions:* Results from our study are similar with previously reported in view of median age, sex distribution, hemorrhagic symptoms, response rate etc. Our results approved that most adults with ITP have a good outcome with low morbidity and mortality. But almost 30% of patients have refractory ITP, which represent significant medical problem due to a constant need of treatment.

MEAN PLATELET VOLUME DECREASED AFTER IMMUNOAPHERESIS OR CASCADE PLASMA FILTRATION THERAPY IN FAMILIAL HYPERCHOLESTEROLEMIA

M Blaha, M Lanska, I Fatorova, M Kostal, J Maly

Charles University, Medical Faculty, Hradec Králové, Czech Republic

Introduction: Platelet size, measured as mean platelet volume (MPV), is associated with platelet reactivity. If MPV would drop after LDL-lowering therapy, decreased MPV could be one of the simple markers of successful therapy (decreased atherosclerosis activity). Methods and patients: MPV was investigated in patients with severe familial hypercholesterolemia (FH) long-term treated (3-12 years) by LDL-apheresis (immunoapheresis) or cascade filtration. Plasma was obtained by centrifugation. Adsorbers Lipopak 400® were used for immunoapheresis and filters Evaflux 4A® were used for cascade filtration. 95 pair samples were measured (before and after the procedures) - 8 times during 4 years in 12 patients. Results: Mean MPV before the procedures was 10.891 fl (CI 10.25-11.53) and decreased after the procedures: 10.478 fl (CI 09.84-11.11) - this difference is significant (p = 0.036). MPV did not correlate with age, sex, platelet count, duration of therapy.Discussion: Our study gives a good evidence of MCV drop after the described therapy; we did not find any other data about MCV changes in FH with extracorporeal elimination therapy in the literature. MPV is easily available and is often disregarded, but sometimes may indicate the need for a careful assessment in patients with FH: The association of the MPV with the risk of coronary and cerebrovascular diseases and atherosclerosis activity was reported. *Conclusions*. MPV could be one of the markers of therapeutic efficacy in patients with FH treated by extracorporeal elimination. MCV examination is a simple, inexpensive and easily accessible method.

STUDY OF T-CELL IMMUNOGLOBULIN- AND MUCIN-DOMAIN-CONTAINING MOLECULE 3 POLYMORPHISMS IN PEDIATRIC EGYPTIAN PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA

E Radwan, E Youssef, N Sewilam, R Ismail, H Arnaout

Faculty of Medicine, Cairo, Egypt

Background. Idiopathic thrombocytopenic purpura (ITP) is an acquired autoimmune disease characterized by the production of autoantibodies that mediate platelet destruction. Dysfunctional T cell-mediated immunity plays an important role in the pathophysiology of ITP. In humans,

the T-cell immunoglobulin and mucin-domain (TIM) gene family, located on chromosome 5q33.2, consists of TIM-1, TIM-3, and TIM-4 genes, which encode cell-surface glycoproteins with similar structures. TIM-3 was reported as a central regulator of T-cell responses. Recently it was reported that TIM-3 mRNA expression in peripheral blood mononuclear cells was significantly lower in ITP patients than in healthy controls which indicated that TIM-3 may play an important role in the pathogenesis of ITP. One single study by Du et al (Human Immunology, 2009, 70:398-402) investigated the role of TIM-3 polymorphism in ITP in North China. Nonetheless, pharmacogenetic studies show marked ethnic variations. Also this study did not address the impact of the polymorphisms on severity and clinical course of the disease. *Aims*: (1) To study TIM-3 gene polymorphism as a risk factor for ITP in a cohort of Egyptian children. (2) To verify if any of the polymorphisms would have an impact on the severity or the clinical course of the disease. *Methods:* Under informed consent 100 patients (46 acute, 50 chronic and 4 persistent ITP cases) and 210 controls were tested for TIM-3 G1516T, T574G, and G4259T polymorphisms using PCR-RFLP. Allele frequencies were calculated for patients and controls. Patients were treated according to standard protocols. The impact of TIM-3 gene polymorphisms on severity and clinical outcome was studied. Results: No significant difference in the distribution of the wild, heterozygous and homozygous genotypes was encountered between cases and controls. Only TIM-3 T574G showed a near significant difference (p=0.058) where GG, TG and TT constituted 43.88%, 51.02% and 5.1% in cases as compared to 54.28%, 38.1% and 7.62% in the controls. T and G allele frequencies were 30.6% and 69.4% in cases as compared to 26.67% and 73.33% in the control. Neither was there significant association between any of the polymorphisms on one hand and the severity of disease or the clinical outcome on the other hand. However near significant association (p=0.08) was encountered between 4259TT and severity as represented by bleeding at presentation (61.3% vs. 38.7%). On the other hand 574GG showed near significant association with better quality of response (71.42% in responders vs. 42.1% in non-responders, p=0.07). Similarly, 4259TT showed near significant association with better quality of response (85.7% in responders vs. 57.8% in non-responders, p=0.09). *Conclusions:* This study confirms the previous report that TIM3 gene polymorphism might not play an important role as a genetic risk factor in the pathophysiology of ITP. Neither has it had a major impact on the severity or clinical course of the disease. Nevertheless studying a larger number of cases may further prove or disprove this notion.

1669

CHILDHOOD IMMUNE THROMBOCYTOPENIC PURPURA: A REGIONAL STUDY OF 140 CASES

O Kassar,[1] L Sfaihi,[2] Kh Aissa,[2] M Mdhaffar,[1] S Hdijji,[1] N Ajmi,[1] Th Kammoun[2]
[1]*Department of hematology, CHU Hedi Chaker Sfax, Tunisia*
[2]*Department of pediatry, CHU Hedi Chaker Sfax, Tunisia*

Introduction. Childhood immune thrombocytopenic purpura (ITP) is a rare disease. Physician management of childhood ITP is diverse. We report the clinical, therapeutic and outcome of childhood ITP in our hospital. *Patients and Methods*. We retrospectively analyzed cases of childhood ITP diagnosed in pediatrics and hematology departments of hospital Hedi Chaker Sfax, between January 1995 and December 2009. We analyzed the epidemiological, clinical, biological and evolution. Treatment response was defined as follows: complete response (CR), a plateled count ≥100000/mm^3 persisting for at least 2 months, partial response (PR): a platelet count between 50-100000/mm^3 and no response (NR): a platelet count <50000/mm^3. *Results:* During the study period, 140 cases of ITP were collected. The mean age at diagnosis was 6 years (3 months-15 years). The vast majority of children had mild bleeding symptoms: purpura and petechiae (100%), epistaxis (33%), gum bleeding (26%). Intracranial hemorrhage occurred in one child. Eighty four (60%) children were treated with corticosteroids alone and seventeen children (12%) with intravenous immunoglobulines (IVIG). One hundred forty two (90%) patients achieved good response (CR+PR) to corticosteroids. A chronic evolution was noted in 30 cases (21%). *Conclusions:* The data from our series revealed that clinical characteristics and outcome of childhood ITP are similar to those series reported in literature. Corticosteroids remain the first-choice treatment for childhood ITP resulting in a response in 90%.

1670

CHRONIC IMMUN THROMBOPENIC PURPURA: RETROSPECTIVE ANALYSIS OF 30 CHILDREN

O Kassar,[1] L Sfaihi,[2] R Krichen,[1] M Mdhafar,[1] Kh Aissa,[2] S Hdijji,[1] H Bellaaj,[1] N Ajmi[1]
[1]*Department of hematology, CHU Hedi Chaker Sfax, Tunisia*
[2]*Department of pediatry, CHU Hedi Chaker Sfax, Tunisia*

Childhood immune thrombocytopenic purpura (ITP) is an autoimmune acquired disorder. Approximately 20% to 25% of children manifest chronic ITP. We analyzed clinical characteristics and management of children with chronic ITP. *Patients and methods:* We retrospectively analyzed the clinical, therapeutic and evolution of children manifest chronic ITP diagnosed in pediatrics and hematology department of hospital Hedi Chaker Sfax, from January 1995 to December 2009. Treatment response was defined as follows: complete response (CR), a plateled count≥100000/mm^3 persisting for at least 2 months, partial response (PR): a platelet count between 50-100000/mm^3 and no response (NR): a platelet count <50000/mm^3. *Results:* During the period of study, 140 cases of PTI were collected in the department of haematology and paediatric. Twenty three children (21%) (22 girls and 8 boys) manifest chronic ITP at 6 months after the initial diagnosis of ITP. The mean age was 9 years. The distribution of cases according to age showed a maximum at 10-12 years. Twenty one children were treated in first line: with corticosteroid for 19 patients and intravenous immunoglobulin for 2 patients. Fourteen children, who were nonresponsive to first line treatment, 14 children were splenectomized and 2 children treated with immunosuppressive agents (vincristine, azathioprine). The follow up period after splenectomy ranged between 2 to 15 years. A complete remission (CR) was achieved in 78% cases without any relapse. There were no infections after splenectomy in any children.

PLATELETS ASSOCIATED ANTIBODIES PRE AND POST SPLENECTOMY IN HEPATITIS C PATIENTS WITH THROMBOCYTOPENIA

L Ibrahem, S Aref
Mansoura faculty of medcine-Egypt, Mansoura, Egypt

Background: The presence of platelet antibodies inducing thrombocytopenia in patients with HCV infection is a matter of great debate. *Subjects and methods*: The present study was conducted on 23 subjects categorized as follows: Group 1: included 23 cases diagnosed as chronic hepatitis C before splenectomy. Group 2: included the same 23 cases after splenectomy. For all subjects included in this study platelets counts was evaluated as well as platelets associated antibodies (IgM, IgG, IgA) Results All patients were thrombocytopenic before undergone splenectomy. Platelet counts (51.8±16.7). After splenectomy all patients were of normal platelet counts (174.2±35.8). The mean ±SD of platelets associated immunoglobulin were (64.2±9.6) for total Igs, (53.6±8.1)for IgG, (3.8±2.1) for IgM, (6.7±4.7)presplenectomy versus post-splenectomy for total Igs (13.4± 19.3), for IgG(5.4±1.8) , for IgM (1.9± 1.06), for IgA (2.1± 0.9) and the differences was statistically significant (P<0.001). The correlation studies between platelet count and PAIgs level in patients with chronic HCV infection pre-splenectomy revealed that there is significant correlation between platelets counts and total Ig (r -0.804, P= 0.000), (r -0.907 P= 0.000), (r - 0.467, P = 0.002),(r - 0.519, P 0.000). *Conclusions*: autoimmune mechanism plays an important role in the HCV associated thrombocytopenia and spleen is a major source of PAIgs.

1672

SERIOUS THROMBOCYTOPAENIA AS HEMATOLOGICAL MANIFESTATION OF NOONAN SYNDROME

P Nunes,[1] MJ Palaré,[2] S Aguilar,[2] A Ferrao,[2] A Medeira,[3] A Morais[2]
[1]*Unidade de Hematologia Pediátrica, Hospital Santa Maria, Lisbon, Portugal*
[2]*Unidade de Hematologia Pediátrica, Hospital Santa Maria, Lisbon, Portugal*
[3]*Serviço de Genética, Hospital Santa Maria, Lisbon, Portugal*

Bleeding anomalies have been reported in Noonan Syndrome although thrombocytopenia was not the most common, especially as first clinical manifestation. Abnormal platelet count or function could occur in this disorder. Boy, first child of nonconsanguineous parents, polyhydramnios diagnosed at 26 weeks of gestation. Birth weight was 2560 g (P5) and length was 45 cm (P<5), admitted for bleeding diathesis in the first day of life. On physical examination, petechial and purpuric rash, dysmorphic facies: low-set ears, high forehead, hypertelorism, and

bilateral cryptorchidism, syndactyly of four and five left foot fingers. There was no evidence of hepatosplenomegaly. Cardiologic investigations revealed an aortic valvar dysplasia with minimal insufficiency and atrial septal defect. An initial complete blood count showed a platelet count of 5.000 /ul. Evaluation of his neonatal thrombocytopenia included a platelet immune workup and a congenital infection workup; neither yielded positive results. Familial thrombocytopenia and the thrombocytopenia absent radius syndrome were ruled out. The patient was given several platelet transfusions and immune globulin over the first weeks of life because of repeated low platelet counts. The PT and PTT were within normal limits. Bone marrow aspiration was normal. Genetic analysis revealed the presence of a constitutive 218 C» G mutation in exon 3 of the PTPN11 gene that was associated with Noonan Syndrome. We present this case because Noonan Syndrome was rarely described as cause of serious inherited thrombocytopenia. This mutation was identified in several patients with juvenile myelomonocytic leukemia, hematological follow up is important in these patients.

1673

CARBAMAZEPINE-INDUCED IMMUNE THROMBOCYTOPENIA AND RELATED WITH TO PHENYTOIN

Y Altuner Torun,[1] H Gümüs[2]
[1]*State Educational and Research Hospital of the Government, Kayseri, Turkey*
[2]*Pediatric Neurology, Kayseri, Turkey*

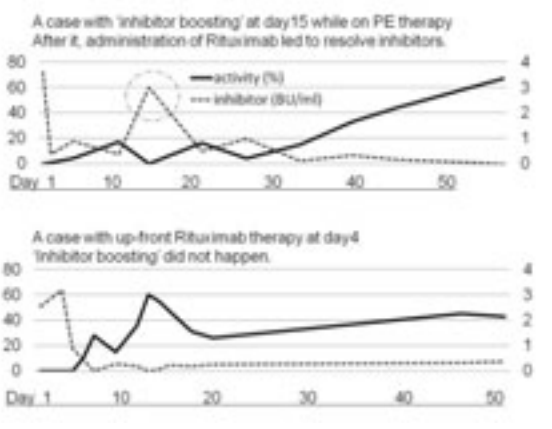
Background. Phenytoin and carbamazepine are rarely associated with serious hematological side effects. Carbamazepine (CBZ) is an effective anticonvulsant for children with partially and secondarily generalized seizures. It is considered safe and relatively less toxic than other anticonvulsant drugs. The hematological toxicity of CBZ is well known and thrombocytopenia is a rare manifestation of CBZ-induced myelotoxicity. Thrombocytopenia is a rare manifestation of hematological toxicity of CBZ, and results from myelosuppression which occurs within four weeks of initiating the treatment. Case report: A 10-year-old boy was admitted with generalized, non-itchy erythematous body rash. There was no associated fever, conjunctival hyperemia, oral ulcers or other systemic manifestations. Three months before the presentation, he had had a generalized seizure and was started on 5mg/kg/day of phenytoin in two divided doses. He developed severe urticarial lesions. Di-phenylhydantoin was discontinued and the patient was switched over to CBZ. There was no previous history of bleeding diathesis or drug allergy. Examination revealed extensive purpura and petechiae mainly over the limbs and a few scattered lesions over the trunk. There was ecchymoses, wet bleeds and epistaxis. The child had no pallor, bone-tenderness or lymphadenopathy. Abdominal examination revealed no hepatomegaly and splenomegaly. Investigations revealed hemoglobin 12g/dl, total leukocyte count 8800/mm3 with 60% neutrophils, 32% lymphocytes, 2% eosinophils and 4% monocytes. Platelet count was 3.000/mm3. Anti-nuclear antibody was negative. Bone-marrow aspiration showed decreased megakaryocytes with no abnormal cells. CBZ was discontinued and mega-dose steroid treatment was started. There was a rapid recovery with platelet count rising to 15.000/mm3 on the second day and further to 518.000/mm3 on the fifth day of starting prednisolon. The patient has remained seizure-free and thrombocytopenia has not recurred did not occur during a follow-up of one month. Results: Thrombocytopenia is a rare manifestation of hematological toxicity of CBZ, and results from myelosuppression which occurs within four weeks of initiating the treatment. In our patient, ten days after beginning CBZ treatment, thrombocytopenia developed. Thrombocytopenia usually resolves once CBZ is discontinued. We used mega-dose steroid treatment for serious thrombocytopenia and epistaxis. Bone marrow examination is usually required to differentiate it from primary bone marrow disorders. Summary / Conclusions: Hematological monitoring is recommended the patient who developed phenytoin toxicity since it does not identify the patients at risk of serious blood dyscrasias. Physicians prescribing CBZ should be aware of phenytoin toxicity; we advise another anticonvulsant therapy that developed side effects of phenytoin.

1674

BENEFICIAL EFFECT OF EARLY ADMINISTRATION OF RITUXIMAB TREATMENT FOR ACQUIRED THROMBOTIC THROMBOCYTOPENIC PURPURA

F Iioka, T Ishii, D Kanbe, D Shimomura, Y Maesako, F Nakamura, T Hayashi, Y Ohno
Tenri Hospital, Tenri city, Nara Prefecture, Japan

Background. Plasma exchange (PE) is first-line therapy for patients with acquired thrombotic thrombocytopenic purpura (TTP) because of the clearance of circulating ADAMTS13 inhibitors. However, there is a subset of patients who do not initially respond to PE treatment or subsequently deteriorate while on PE treatment around day 7-14. There are limited reports that describe detailed clinical and serial laboratory findings during this challenging process. The exact pathophysiology of this deterioration, we generally refer to as *inhibitor boosting*, remains still uncertain, furthermore, the appropriate management or prophylaxis is also unclear. Patients for refractoly TTP are at greater risk of complications and, therefore, early administration of Rituximab might be considerable option, which could reduce plasma requirement and avoid complications. Here we describe four patients with severe acquired TTP who were successfully treated with Rituximab. Aims: The purpose of presenting our cases is to highlight how early initiation of Rituximab could lead to a positive outcome, especially in a severely ill patient. We also present detailed laboratory analysis, including frequent ADAMTS13 measurements, during a phase of the 'inhibitor boosting'. Methods: We reviewed all the patients with acquired TTP treated with Rituximab at Tenri Hospital, 4 cases were identified from 2006 to 2010. Clinical and laboratory findings, including ADAMTS13 activity and inhibitors, were recorded and analyaed.



Results. All 4 patients (median age 67, range 40-78) showed severely decreased ADAMTS13 activity (<1.0%) with detectable inhibitor level (median 3.4 Bethesda U/ml, range 1.72-6.80). 3 patients presented during their first TTP episode while one patient had relapse of TTP after 10 months remission. We immediately treated all patients with PE at dianognosis with acquired TTP, however, in two cases of them, we subsequently administered Rituximab therapy because of deterioration while on PE treatment. At this time point (one patient at day 7, another at day 14), ADAMTS13 activity or inhibitor testing revealed considerable abnormal results. In another two high-risk cases, which were a recurennt case and a severe acute case of deep coma as the first episode, we administered up-front Rituximab thrapy after only a few PE treatments. After the addition of Rituximab (375mg/m2 each week for 4 week), all of the 4 patients achieved complete clinical and hematological remissions with rapid recovery of ADAMTS13 activity and resolution of detectable inhibitor. All patients required no additional plasma exchange after completion of rituximab and remained in sustained remissions with median follow-up of 30 months (range, 3-60 months). Disucussion: In refractory and recurrent cases, administration of Rituximab appears to be a reasonable therapeutic option. In our limited experiences, early up-front addition of Rituximab, before deterioration, may be also beneficial in avoiding exacerbation, decreasing the need for plasma exchange and sustaining long-terms remission. Prospective studies are needed to define the true efficacy and safety of up-front Rituximab therapy and timing of its initiation.

1675

RESPONSE TO THROMBOPOIETIN ANALOGUES (ROMIPLOSTIM) AS SECOND LINE TREATMENT IN SIX PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA REFRACTORY TO CORTICOSTEROIDS

Y Ramos, M Perera, A Suarez, H Luzardo, J Lopez, T Molero
Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Spain

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune disorder in which a high percentage of patients obtain complete remission after a first line therapy with corticosteroids. In other cases, recurrence or development of corticosteroid dependence forces us to choose a second line treatment. Although until now splenectomy appeared to be the first choice as a second line, the emergence of new therapeutic options (thrombopoietin analogues and rituximab), as well as patients refusal of surgery, have changed our clinical practice. Patients: We report 6 patients (2 males and 4 females) diagnosed with severe chronic ITP refractory to corticosteroid therapy, in whom we rejected splenectomy as second line for medical reasons. All of them initiated romiplostim as second line (one patient had previously received rituximab). Two patients started treatment with platelet counts (PC) > 100 x 10^9/L due to the effect of gamma globulin. The aim of treatment was to achieve a safe number of platelets, not to obtain complete remission. *Results:* All patients underwent dose escalation starting at 1 μg/kg/week. Rescue treatment with gamma globulin +/- prednisone was discontinued. Hemorrhagic symptoms disappeared in all cases except one, a female patient who did not respond despite escalation to the maximum dose of 10 μg/kg/week. Since her diagnosis was later changed to amegakaryocytic purpura (47, XX, +8), she was excluded from the response analysis. Four of the five remaining patients obtained a partial response (PC > 30 x10^9/L) within a week of treatment initiation (mean dose 1.5 μg/kg), and all of them achieved complete response (PC > 100 x10^9/L) after a mean of 31.4 days (mean dose 2.5 μg/kg)(table). All patients tolerated the treatment without clinically relevant side effects, except mild headache or bone pain, and were able to return to work, considerably improving their quality of life. Conclusions: Thrombopoietin analogues are a treatment option for patients with chronic ITP refractory to costicosteroid therapy, in whom other therapies such as splenectomy are contraindicated. In these patients, the administration of low doses of romiplostim, with the aim of restoring safe platelet counts, provides satisfactory responses from a clinical point of view, with safe platelet counts, decreased hemorrhagic symptoms and improved quality of life, with little or no adverse effects. Thus, thrombopoietin analogues are safe and effective as first choice for second line treatment of severe chronic ITP.

1676

EFFICACY AND SAFETY OF RITUXIMAB IN CHILDREN WITH CHRONIC IMMUNE THROMBOCYTOPENIA: A SINGLE INSTITUTION EXPERIENCE

A Tragiannidis,[1] Z Pana,[2] E Chatzipantelis,[2] E Farmaki,[1]
V Tsotoulidou,[1] T Papageorgiou,[1] M Hatzistilianou,[1]
F Athanassiadou[1]
[1]*Aristotle University of Thessaloniki, Thessaloniki, Greece*
[2]*2nd Pediatric Department, Thessaloniki, Greece*

Background. Recent recommendations concerning primary immune thrombocytopenia (ITP) in childhood defines ITP as an acquired immune mediated disorder characterized by isolated thrombocytopenia, defined as a peripheral blood platelet count less than 100x10^9/L, and the absence of any obvious initiating and/or underlying cause of the thrombocytopenia. Furthermore, a recently approved and promising treatment option in chronic ITP in childhood is reported and concerns rituximab. Rituximab is a chimeric monoclonal antibody against the protein CD20, which is primarily found on the surface of B cells, inducing B cells destruction and autoantibodies depletion. On the other hand, although previous results of rituximab in adults are promising, treatment doses, efficacy and safety in the pediatric setting remains to be established. Aims. Evaluation of the efficacy and safety of rituximab as salvage treatment in children diagnoseed with chronic ITP. Materials and Methods. A prospective unicenter study regarding the primary outcome data of rituximab therapy in children with the diagnosis of chronic refractory ITP was performed. The treatment response was evaluated after the every course of rituximab treatment. Duration of response was considered from the day of the initial infusion to the first time of relapse or to time of analysis. Complete response (CR) was defined as PLT count >100x10^9/l, partial response (PR) was as any PLT counts between 30 and 100x10^9/l and no response (NR) below 30x10^9/l. Relapse was also defined as a decrease of the platelet count to below 30x10^9/l after CR or PR. The patients received no other treatment in addition to rituximab. Results: Eight children out of 13 with chronic ITP (53.85%) received rituximab - 85.7% females- with mean age 9.5±1.6 years, mean PLT count 19x10^9/L and median time from initial diagnosis till rituximab treatment 1.28 years. Previous treatment included for 5 children (71.4%) combined treatment with corticosteroids and IVIG, for 1 child (14.2%) corticosteroids, IVIG and anti D globulin, and for 1 (14.2%) corticosteroids, IVIG, anti D globulin and splenectomy. Rituximab was administered intravenously at a dose of 375 mg/m2 weekly, for a total of four infusions in 4 patients (71.5%) and in a single dose in 2 children. CR was recorded in 5/7 children (71.4%) with median PLT 149x10^9/L and median follow up time 25.3 months. PR and NR was recorded in 1 child and 1 child respectively. Immunophenotype analysis revealed no circulating B CD 19+ (<1%) in six children and no significant B cell depletion (>4%) in one child (poor responder). Side effects were mild and transient and were recorded in only 1 of 7 patients (14.2%) with fever and cough which was successfully treated with antimicrobial agents. Conclusions: Rituximab therapy is beneficial for some children with severe chronic ITP who are refractory to standard agents. The toxicity profile of rituximab is acceptable in most patients. Further studies are needed to determine the optimal treatment schedule, the real rates of efficacy before and after splenectomy, the long-term side effects, and the drug's mechanism of action.

1677

SPLENECTOMY IN THE TREATMENT OF IDIOPATHIC THROMBOCYTOPENIC PURPURA

S Benlazar, H Hadjeb, K Tayebi, A El Mestari, N Siali, Z Zouaoui
Hematology unit, Sidi Bel Abbes, Algeria

Background. The objective of this study is to report the results of splenectomy in the treatment of idiopathic thrombocytopenic purpura (ITP) in adults. *Materials and methods*: This is a retrospective study between January 1994 and December 2009 in the hematology department of the University Hospital of Sidi Bel Abbes. All patients had ITP and received initial treatment with corticosteroids.In case of steroid resistance or dependence, splenectomy was performed. *Results*. Of the 60 selected ITP, 18 splenectomy were performed (30%) among 15 women and 3 men with a mean age of 33 years. Before splenectomy, the average number of platelets was 34,000 with hemorrhagic manifestations in three quarter of cases. Two weeks after surgery, there was a complete remission (CR) in 13 cases (72%), while partial response (PR) was noted in 3 cases (17%) and failure in 2 (11%). Of the 13 patients in CR, one relapsed after a period of 12 months. The 3 patients with PR have relapsed after a median time of 24 months. Finally 12 patients (66%) are still in CR with a minimum follow-up of 18 months. two factors of response to splenectomy are noted: the age of the patient below 50 years and the initial response to corticosteroids. *Conclusions*. Splenectomy is an important therapeutic modality of ITP with immediate effect, but especially in the long term of at least 60% responses.

1678

NOVEL PLATELET INDICES IN PATIENTS WITH HOMOZYGOUS OR HETEROZYGOUS SICKLE CELL ANEMIA COMPARED TO IRON DEFICIENCY ANEMIA

S Spiroglou, K Chalvatzi, A Nikolaidou, E Diza
AHEPA University Hospital, Thessaloniki, Greece

Background. Modern hematological analyzers have simplified registration of platelet indices, such as mean platelet volume (MPV), platelet distribution width (PDW), plateletcrit (PCT) and immature platelet fraction (IPF), which allows further study of these indices in disorders of hemopoiesis. Aims. The aim of this study was to compare the aforementioned platelet indices in patients with iron deficiency anemia and sickle cell anemia. Methods. We retrospectively studied patients with heterozygous sickle cell anemia (n=13, 7 female and 6 male), homozygous sickle cell anemia (n=92, 54 female and 38 male) and iron deficiency anemia (n=42, 26 female and 16 male). Hematological parameters were assessed by SYSMEX XE2100 hematological analyzer. SPSS Statistics for Windows, version 17.0 was used for statistical analysis. The significance level was defined as $p<0.05$. Results. The three patient groups were comparable as for age and sex. Mean PCT value was 0.2592± 0.118% for heterozygotes, 0.4147±0.1211% for homozygotes, and 0.2947±0.12174% for iron deficient patients. Mean PCT value differed

statistically significantly between homozygous and heterozygous sickle cell anemia patients (p<0.001), as well as between homozygous sickle cell anemia and iron deficiency anemia patients (p<0.001). Statistically significant positive correlations between IPF and MPV, as well as IPF and PDW were noted in homozygous sickle cell anemia patients (r=0.687, p<0.001, and r=0.651, p<0.001, respectively) and iron deficiency anemia patients (r=0.758, p<0.001, and r=0.763, p<0.001, respectively). *Conclusions*. Plateletcrit value was significantly higher in patients with homozygous sickle cell anemia, compared with heterozygous and patients with iron deficiency anemia, while no significant difference was observed between heterozygous and iron deficient patients. As for correlations among platelet indices, IPF was positively correlated with platelet indices MPV and PDW in homozygous patients with sickle cell anemia and in patients with iron deficiency anemia.

1679

A STUDY ON PLATELET INDICES IN PATIENTS WITH RHEUMATOID ARTHRITIS

C Kanonidou,[1] S Arampatzi,[1] A Nikolaidou,[1] V Tsavdaridou,[2] E Diza[1]
[1]*Hematology Laboratory, Department of Clinical Microbiology, AHEPA University Hos, Thessaloniki, Greece*
[2]*Laboratory of Immunology, Department of Clinical Microbiology, AHEPA University, Thessaloniki, Greece*

Background. Large platelets are more active and thus more thrombogenic than smaller ones, as they contain more dense granules, they produce greater amounts of vasoactive and prothrombotic factors and present an increased expression of adhesion molecules. Mean platelet volume (MPV) and platelet distribution width (PDW) are indicators of platelet function and activation and MPV has been reported to be influenced inversely by inflammation. Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disorder with various hematological manifestations. Altered platelet indices have been found in patients with RA and it remains intriguing to investigate the correlation of coagulation and inflammation in RA. Aims: The present study aims to examine the changes in platelet indices (platelet count, MPV and PDW) in patients with RA, and their interaction with biomarkers reflecting the inflammatory response [C-reactive protein (CRP), erythrocyte sedimentation rate (ESR)]. Methods: The study group consisted of 25 RA patients (males/females: 5/20, mean age: 47 years) at various disease phases and 30 age and sex-matched healthy controls. Platelet indices were measured with hematological analyser XE-5000 SYSMEX (ROCHE) with flow cytometry method within 1h of sampling in order to avoid the time-dependent swelling by EDTA. CRP was determined with the use of Immage 800 nephelometer (Beckman Coulter) and ESR with Ves-matic 20 (Diesse) analyser. Student parametric test (t test) and Pearson's correlation were used for the statistical analysis. P<0,05 was considered statistically significant. Results: The laboratory parameters are reported in Table 1. Platelet count, MPV and PDW have been found to be significantly higher (p<0,05) in RA. MPV values above the reference range were detected in the majority of patients tested (76%, 19/25). Platelet count was positively correlated with CRP and ESR in RA patients (p<0,05). The other platelet indices presented a positive but not statistically significant correlation with the examined inflammatory markers.

Table 1. Platelet parameters in RA patients and normal controls.

Laboratory parameters	RA patients (n=25)	Normal controls (n=30)	p-value
Platelet count (PLT. K/μL)	289.93±103.33	249.60±55.98	p<0.05
Mean platelet volume (MPV, fL)	11.15±1.09	9.79±0.44	p<0.05
Platelet distribution width (PDW, fL)	13.8±2.06	12.10±0.80	p<0.05

Summary/Conclusions: In RA patients alterations in platelet indices, indicative of platelet activation, were observed. Only thrombocyte count was correlated with the inflammatory markers tested. The association of platelet routine laboratory parameters with inflammation in patients with autoimmune inflammatory disorders and their clinical utility for the rapid assessment of the disease activity should be further investigated.

1680

SECONDARY POLYCYTHEMIA DURING THE COURSE OF IMMUNE THROMBOCYTOPENIC PURPURA (ITP) TREATMENT WITH ROMIPLOSTIM

T Comont, K Delavigne, P Cougoul, T Challan-Belval, S Ollier, D Adoue, O Beyne-Rauzy
Purpan Universitary Hospital, Toulouse, France

Background: Involvement of thrombopoietin (TPO) on erythropoiesis has been described in the literature (1). Then we can ask whether the polycythemia can occur as a side effect of TPO analogue, as Romiplostim. We report 2 cases of patients treated with Romiplostim and with increased hemoglobin level. Case 1: an asymptomatic thrombocytopenia (5.10^9 /L) found before a surgery lead to a diagnosis of ITP in June 2009, in a 40 years old man. Initial evolution was unfavorable with corticosteroids and intravenous immunoglobulin (IVIG) with the occurrence of relapses requiring repeated courses of IV Ig. Treatment with Danatrol and Rituximab were not efficient. Romiplostim was introduced in December 2009 with a good response obtained at a dosing of 3 mg/kg. In correlation with therapy initiation, appeared polycythemia with a hemoglobin level that reached 180 g / L in few days (13 g / L previously) without organic cause. Dose reduction was performed and provided a decrease on hemoglobin level. Case 2: a 74 years old man with the history of refractory ITP (including splenectomy) diagnosed in 1995, received in November 2009 a treatment with Romiplostim. Polycythemia appeared rapidly with a rise of hemoglobin level to 170g/L (versus 145 g/L before). A stable level of platelets was difficult to obtain requiring multiple variations of doses, which allows us to identify a positive relationship between the dose of Romiplostim and hemoglobin level. Conclusion: An increase in hemoglobin level was found in these 2 patients, and this soon after starting treatment with Romiplostim. This fact can suggest imputability of the drug in polycythemia, excluding other causes. Larger series will be necessary however to confirm this hypothesis.

PLASMA EXCHANGE IN THE TREATMENT OF THROMBOTIC THROMBOCYTOPENIC PURPURA - ONE CENTRE EXPERIENCE

M Lanska, M Blaha, V Maisnar, J Maly
University Hospital, Hradec Králové, Czech Republic

Background. Plasma exchange (PE) has changed significantly the prognosis of thrombotic thrombocytopenic purpura (TTP), so that remission occurs in more than 80% of patients, as is documented by the literature and our own 30-year experience. In spite of this several details remain to be cleared. *Aims.* We performed a retrospective analysis of therapy results of PE in TTP during the last 10 years when therapy at our workplace had been standardized. Methods: In the years 2000 - 2010 all patients sent for the therapy to our regional centre were evaluated. (The centre serves for a region of about 1.5 million inhabitants). All 40 adult patients (25 females, 15 men, mean age 43, range 20-79 years) had 66 episodes (initial treatment or relapses). PE was performed using Cobe Spectra separator (Caridian, Lakewood, Colorado, USA), software 7.0. Every day one plasma volume was replaced with fresh frozen plasma. ACD-A was used as anticoagulation fluid (Baxter, Munich, Germany). After the rise of thrombocytes above 150x10^9/L, PE was performed in gradually prolonged intervals. *Results:* In all 40 patients where TTP was confirmed (characteristic pentad of symptoms or at least unexplained thrombocytopenia + microangiopathic hemolytic anemia), PE was started within 4 hours. In initial therapy or in relapses 957 PE in total were performed (mean 14.5, range 3-59, median 9). Inherited TTP with

ADAMTS13 deficiency was confirmed in 3 patients, 12 cases were idiopathic, 7 patients had organ malignancies, 9 patients were after stem cell transplantation, myelodysplastic syndrome or myeloproliferative diseases had 3 patients, autoimmune diseases 3 patients, pregnancy 3 patients. Relapses occurred in 9 (22%) patients (mean number of relapses was 3.8, range 2 - 7, median 4). Within 30 days after initiation of PE 3 patients died. PE without effect was in all patients with malignancies and after stem cell transplantation and in 3 patients with idiopathic TTP. All patients received corticosteroids. Splenectomy was performed in 4 patients with relapse. 10.8% of side-effects were mostly allergic, none was clinically serious. Conclusions: Even with improved prognosis TTP remains a serious disease. All patients suspected of TTP should receive urgent PE which in our cohort was successful in 80 % of cases but never in organ malignancies ant after transplantation. PE is the key therapy in TTP - its early performance is a life-saving measure. PE is a safe method in hands of a skilled staff.

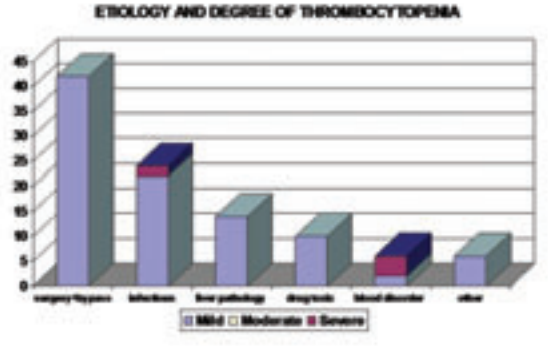
IMPLEMENTATION OF THE NEW HEP SCALE FOR THE EVALUATION OF HEPARIN-INDUCED THROMBOCYTOPENIA

M Abio, N Fernández Mosteirín, A Iborra, C Sierra, M Guillén, C Salvador Osuna, M Torres, JF Lucía, D Rubio
Hospital Universitario Miguel Servet, Zaragoza, Spain

Alterations of hemostasis and blood counts are common in patients admitted to ICU. Thrombocytopenia increases the morbidity and mortality being its aetiology very varied. *Objectives.*: 1) Analyze the incidence of thrombocytopenia in patients admitted to ICU: clinical, laboratory and therapeutic factors. 2) Reclassify the patients undergoing cardiac surgery according to different scales that assess the likelihood of heparin-induced thrombocytopenia (HIT). *Methods and patients*. A retrospective study by reviewing medical records of patients with thrombocytopenia (platelets <125x10^9/L) admitted to four ICUs of our hospital during a 40 days period, classified as mild (100-50x10^9/L), moderate (50-20x10^9/L) and severe (<20x10^9/L). Evaluation of patients undergoing cardiovascular surgery with cardiopulmonary bypass, classifying them according to the new scale presented as pre-test model for Cuker *et al.* and the 4 T's model (Journal of Thrombosis and Haemostasis 2010; 8: 2642-2650) RESULTS: 237 patients admitted during this period, 50 showed thrombocytopenia (21%) Cumulative incidence: 19.8% in 40 days, excluding those who previously had his income. Men 56%, Women 44%, mean age 70.7 (extremes 19-88). Depending on different UCI: Coronary 9 patients, mean age 67.5, cardiovascular 25 patients, mean age 70.0; Polyvalent 11 patients, mean age: 65.8; Traumatology 6 patients, the mean age: 75.6. Reason for admission: 32% valve replacement, infection 14%, ischemic heart disease 14%, respiratory 8% hepatectomy 8%, coronary artery bypass surgery 8%, ruptured aneurysm 4%, bleeding 4%, decreased consciousness 4%, other 6 %. Mild thrombocytopenia: 94%, moderate: 0%, severe: 6%. Nadir figure rating: 90x10^9/L. Average time duration of thrombocytopenia: 4.2 days, median: 2.5 days. Etiology: Image 1. Distribution due to drug: abciximab 8%, tirofiban 2%. Incidence bleeding: 30%, with major bleeding (10%) located in: mediastinal 2%, hematoma in back with 2% drop in hematocrit, HDA 2%, brain 2% pulmonary and 2%, the rest were minor bleeds. Thrombotic phenomenon not observed.



Transfusion: CH 54%, CP 22%. Incidence of coagulopathy: 30%. Regarding the administered treatment: plasma 12%, vit K 8% FVIIr and other measures 2%, Vitamin K and plasma 2%. The attributable mortality: 10 patients (20%). Of 78 patients undergoing cardiac surgery 25 showed thrombocytopenia (32%) and all of them had a low probability of HIT in both the 4 T's scale as in the HEP scale, presenting both a score of <= 3 and <= - 3, respectively. *Conclusions*: 1) Surgery bypass is the most common cause of thrombocytopenia, because of our center nature, followed by infectious causes. 2) In most cases, thrombocytopenia is mild and transient, short-lived, and have not needed treatment. 3) The classification of patients with the proposed scales.

1683

SERENOA REPENS AS A CAUSE OF DRUG-INDUCED THROMBOCYTOPENIA. APROPOS OF TWO CASES

M Fernández Rodríguez, A Bernardo Gutierrez, I Soto Ortega, JR Corte Buelga
Central Hospital of Asturias, Oviedo, Spain

Introduction. In the differential diagnosis of isolated thrombocytopenia should be considered drug induced. There are extensive listings of agents with causal relationship to the thrombocytopenia is likely although few are final. The diagnosis can only be done by the recovery of thrombocytopenia after discontinuation of the drug and confirmed his comeback to reintroduce it. Serenoa repens is a plant used for benign prostatic hyperplasia in herbal products and pharmaceutical specialties. CASE 1: 63 year old male visited the emergency department for hematuria, and spontaneous hematoma in the right hemithorax. He reported influenza vaccination for 15 days and a new treatment with an herbal product (Sabal extract) He had platelets/mm3 14000. Studies found no cause of thrombocytopenia. It began as emergency therapy steroids (1 mg / kg / day) and suspended Sabal extract. The patient's platelet count normalized in 7 days without subsequent relapse (follow-up two years). CASE 2: A 48-year-old, came to our Unit with cutaneous purpura mucosa detected platelets/mm3 3000. He complained of recent gastroenteritis and a contact with a young girl of his family suspected of having mononucleosis. He reported no chronic treatment. He started steroids (1 mg / kg / day), reaching normal levels of platelets in 15 days. Serology was found positive for C Hepatitis so he recieved treatment with interferon-ribavirin. Three years later the patient presented again with thrombocytopenia (5000 platelets / mm 3) and petechiae. Had no response to interferon-ribavirin but was stable in the liver. Receiving steroid treatment the platelet count normalized within a week. After insisting on the history the patient reported that days before the first episode had begun treatment with Neo-urgenin® (contains Serenoa repens) He discontinued the treatment on his own soon after starting steroids. Two weeks before the relapse he restarted the treatment because he had prostatic symptoms. *Discussion.*: The present cases suggest that thrombocytopenia in both patientes was induced by Serenoa repens. The drug was started a few days before the clinical detection of bleeding and thrombocytopenia. In both patients (and second in both events) thrombocytopenia disappeared quickly stop taking the drug. Although in the two patients steroids were empirically used that fact does not invalidate the diagnosis. The fact that in the second case to restart treatment with Serenoa repens caused a new episode of thrombocytopenia appears to confirm the involvement of this substance in the genesis of thrombocytopenia.

1684

ACQUIRED INHIBITOR OF FACTOR VIII ASSOCIATED WITH PROSTATE CANCER - A CASE REPORT

D Urbaniak-Kujda, K Kapelko-Slowik, M Podolak-Dawidziak, K Kuliczkowski
Woclaw Medical University, Wroclaw, Poland

Background. Acquired haemophilia (AH) is rare disease that occurs at a rate of approximately 1.0 per million each year, although it is likely that not all affected patients are reported. It is a severe bleeding diathesis that affects both males and females, caused by sudden appearing autoantibodies that interfere with coagulation factor VIII (FVIII) activity. In the approximately half of patients with inhibitors, no concomitant disease can be found, and in the conditions most commonly associated with factor VIII inhibitors include connective tissue disease, inflammatory bowel disease, some dermatologic disorders and malignancy (lymphoproliterative disorders and solid tumours, e.g. neoplasms of the colon, pancreas, kidney, prostate, testes, brain, and lung). Bleeding manifestations are often severe and may occur spontaneously or after minor trauma. In contrast to patients with congenital factor VIII deficiency those with acquired haemophilia principally experience soft tissue bleeding. Over-

all mortality associated with AH has been reported at between 8% to 42%. The aim. The aim of the presentation is a case of inquired haemophilia in the course of prostate cancer. Case report. A 71 -year-old man presented with sacrospinal, left forearm and brachial muscles non traumatic haematoma and spontaneous hematuria, but otherwise felt well. A coagulation screen was as follows: platelet count 140 G/L (range 150-400 G/l), prothrombin time was normal. Fibrinogen concentration was increased up 0.69 g/L (normal range 0.2-0.45 g/L). There was a prolongation of the activated partial thromboplastin time (aPTT) up to 82.1secs (normal range 26-40 secs), which did not correct following the in vitro addition of normal plasma. Acute disseminated intravascular coagulation (DIC) was excluded. The Factor VIII level was reduced to 0.6% (normal range 50% -150%). The Bethesda assay demonstrates an inhibitor 5.4 Bethesda Units (BU). He was screened for inflammatory and malignant disorder. Prostate specific antigen (PSA) rate was 400 ng/mL (normal range 0-4 ng/mL). Prostate cancer has been confirmed with multiple bone metastases. Treatment was aimed at stopping the acute bleeding, eliminating the inhibitor and curing the underlying disease. The patient was treated symptomatically with rFVIIa (Novo-Seven) 270µg/kg administrated every 3-5 days due to diathesis intensity. Efficacy was judged by decreasing bleeding episodes. Anticancer therapy was ordered by urologist (flutamide and triptoreline). For eradication of FVIII inhibitor after 10 days to that therapy cyclophosphamide 2mg/kg and prednisone 1mg/kg given every day orally was added. The acute bleeding stopped, but despite these therapy two weeks of immunosupressive therapy the FVIII level remained very low (0.1%) and the FVIII inhibitor level increased up to 14.7BU. Haematomas and acute mucosa bleeding reappeared. Bypass therapy with FEIBA 50U/kg administered every 12 h for 10 days had a small clinical effect, but after next three weeks bleeding symptoms diminished, and there was a notable increase in FVIII level up to 1.74% and significant decrease in FVIII inhibitor to 1.8 BU. Summary. In presented patient severe bleeding caused by factor VIII inhibitor associated with prostate cancer was controlled by a complex therapy.

1685

FACTOR XIII DEFICIENCY IN ADULTHOOD - INHERITED OR ACQUIRED?

S Dias, A Gonçalves, A Tavares, MJ Gomes
Hospital de Santa Maria, Lisboa, Portugal

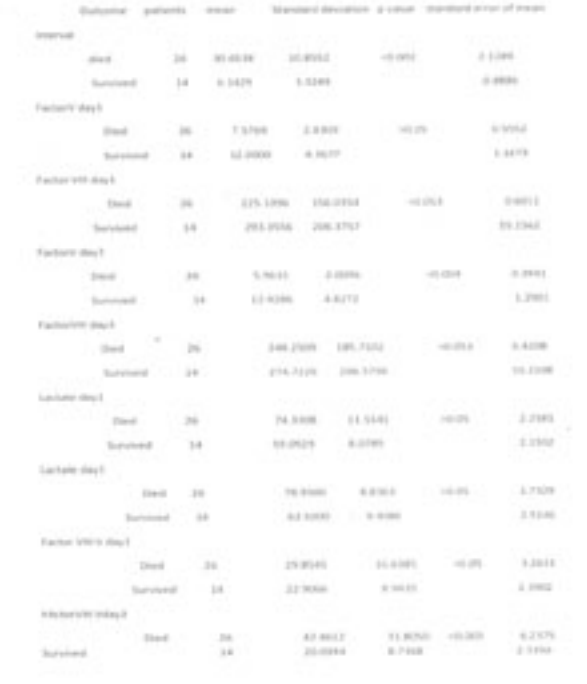
The inherited deficiency of factor XIII is very rare (1 case per 2 million population) and is transmitted as an autosomal recessive disease. The clinical manifestations depend on the amount of factor circulating, ranging from severe bleeding since birth to just slow healing of tissues. *Case report*. Male, 40 years old, without previous known diseases, suffered muscle rupture one month before admission, with consequent formation of gluteal hematoma, which kept gradually growing. In this first month he was observed in different hospitals and developed progressive disseminated intravascular coagulation (DIC). He also underwent needle aspiration of the hematoma with subsequent clinical deterioration. At admission in our hospital he was pale but hemodynamically stable, with a right gluteal hematoma extending to the dorsal region and knee. He had anemia (10,5 g/dL), thrombocytopenia (75 000x10^6/L), decreased haptoglobin (<8 mg/dL) and fibrinogen (94 mg/dL), D-dimer increased (12,66 ug/mL) and slightly prolonged PT and aPTT. We then proceeded to the determination of coagulation factors, including the rarest, which showed a deficiency of factor XIII (11%; normal range 75-150%). The patient received transfusion of concentrate of this factor, resulting in reduction of the hematoma, resolution of DIC, and increase of hemoglobin. We were told by the patient that he had slow healing of the skin and small late bleeding since childhood. He was also submitted to an appendectomy four years before, without major bleeding our other problems. In the outpatient clinic he remained without hemorrhage, with factor XIII between 50-70% without transfusion. *Conclusions*. The absence of both consanguinity in the family and prior major bleeding (including during surgery) suggested acquired deficiency. However, primary disease was excluded; also, the good response to the transfusion of the factor (suggesting inexistence of antibodies) and the presence of light but typical symptoms suggests inherited deficiency of factor XIII. In this case the deficiency was aggravated and only expressed in the context of DIC by trauma. The diagnosis of this entity allows the prevention of serious consequences, whether in the acute event or by performing prophylaxis. The transfusion of factor concentrate is effective and safe, without infectious complications.

1686

BLEEDING MAJOR SURVIVAL PREDICTOR IN PATIENTS OF VIRAL HEPATITIS INDUCED ACUTE LIVER FAILURE

L Gupta,[1] S Sharma,[2] A Mukhopadhyay[2]
[1]*Institute of Liver and Biliary Sciences, New Delhi, India*
[2]*All India Institute of Medical Sciences, New Delhi, India*

Background. In acute liver failure, variables favoring survival of patients is based on age, interval between onset of jaundice and encephalopathy, coagulation factor level, risk of bleeding but all these variables were concluded from the studies that were conducted in Western population where etiology most commonly is paracetamol poisoning and metabolic disorders like Wilson's disease; where as in Indian subcontinent set up major causative factor is viral hepatitis.



Thus we exploitedthe database collected by us in intensive care unit. 2.Aims-observational study to investigate major predictors of survival in viral hepatitis induced acute liver failure.Methods - observational study of 40 patients followed for 1 month to look for outcome- survival and death(7days) or less and measurement of metabolic parameters like lactate and arterial blood gases and assessment of bleeding risk by carrying out coagulation factor level V which is synthesized in liver and not affected by vitamin K and factor Viii which is not synthesised in liver. . Results-There were 12 patients who survived and had only 0-1 episode of mucosal bleeding. The analysis showed that patients who survived had factor V level on day 3 of diagnosis was in the range of 10%-25% and who died had factor V level below 10% ($p<0.004$)and had bleeding episodes of > 2 Conclusions-Factor V level on day 3 of diagnosis and episode of bleeding may help in predicting survival in patients of acute liver failure, thus help in triage for the need of orthotopic liver transplantation which is the only definite curative therapy in patients who have poor survival rates.

ASSESSING THE ORAL CONTRACEPTIVES EFFECTS ON THE COAGULATION AND FIBRINOLYSIS

B Stocco, R Bertozi, H Fumagalli, L Cataldi, S Franceschini, E Martinez, C Marzocchi, M Torqueti
Faculty of Pharmaceutical Sciences of Ribeirao Preto, Ribeirćo Preto, Brazil

More than 100 million women in the world make use of hormonal contraceptives and, from these, 93 million use the oral combined hormonal contraceptive. In spite of its desired effect on contraception, its metabolization occurs at liver, estimulating the synthesis of the plasmat-

ic proteins, among them, the ones that control the coagulation system and fibrinolysis. Initially, the estrogen present at the contraceptives was considered the sole responsible for the pro-thrombotic effects of hormonal contraception. However, with the continuous incidence of thrombosis induced by contraceptives containing low-concentrations of estrogen and different progestogens, it was possible observing that the hypercoagulant effect of the contraceptive was not only dose-dependent of estrogen, but also from the antiestrogenic activity of the progesterone used. Independent papers suggest that third and fourth generation progesterones have a smaller antiestrogenic activity in relation to the second generation one. In face of this, the purpose of this work was assessing the occurrence of hemostatic alterations on the Brazilian female population who is user of contraceptives from second and fourth generation. This study contemplated 70 participants from the Health Center School of Ribeirão Preto Medical School - USP and from the Faculty of Pharmaceutical Sciences of Ribeirão Preto - USP. These volunteers have given their consent, on written form, for participating on this study, and they were distributed into four groups: a control one (20 patients) and three oral combined contraceptive ones containing ethinylestradiol 20µg and 30µg combined with 3000 µg drospirenone (16 and 20 patients, respectively) and ethinylestradiol 30µg combined with 150µg Levonorgestrel (14 patients). From these were assessed the following parameters: TP, Factor VII, TTPA, Factor XII, Fibrinogen, Factor 1+2, Protein C, Protein S, Antithrombin, D-dimers and PAI - 1. The contraceptive containg ethinylestradiol 20µg and drospirenone has provoked favourable alterations to the hypercoagulability on the parameters TP, TTPA, Fibrinogen, Protein S and D-Dimers. For the formulation with ethinylestradiol 30µg and drospirenone we've found alterations on the parameters TP, Protein S and PAI - 1. And, for the formulation containing ethinylestradiol 30µg and levonorgestrel we've found alterations on TP and on the Protein C concentration. On this study, the alterations suggest that the fourth generation contraceptive (ethinylestradiol 20µg and drospirenone) is among the assessed formulations, the medicine with the larger number of alterations associated to the hypercoagulability, whereas, the second generation contraceptive (ethinylestradiol 30µg and levonorgestrel) continues being the safest option to avoid the development of thrombosis, since it has presented the least tendency to hypercoagulability, confirming the fact that the pro-thrombotic alterations generated by the contraceptives don't depend strictly from the estrogen dose, but are strongly related to the type of progestagen.

1688

TREATMENT WITH FIBRINOGEN CONCENTRATE IN A PATIENT WITH SEVERE POSTPARTUM HAEMORRAGHE

J Martinez Marcos, A Ramalhinho, J Ribeiro, R Oliveira, P Amantegui
Centro Hospitalar Cova da Beira, Covilha, Portugal

Background. Significant blood loss is a common complication of childbirth. Fibrinogen deficiency often results, and is exacerbated by large-volume transfusions of blood products or colloids/crystalloids (dilutional coagulopathy). Substitution with fibrinogen concentrate can correct hypofibrinogenaemia and reverse dilutional coagulopathy, but there are few reports of its use in obstetric hemorrhage. Here, we describe the use of fibrinogen concentrate, along with other haemostatic agents, in the successful management of a severe case of postpartum hemorrhage. *Aims*. to describe the use of fibrinogen concentrate in severe postpartum hemorrhage. Methods: In July 2010, a 32 years old woman, 39 weeks into her first pregnancy was admitted to the obstetrics department due to decreased foetal movements (day 1) and was decided to induce labour on day 2. During labour was determined to perform a ceasarean section because of suspected acute foetal suffering and worsening of foetal bradycardia. In the post surgical unit she presented severe haemorrhage. Ongoing postpartum hemorrhage led to hypovolaemic shock and decrease of haemoglobin (8 g/dL, compared with 12 g/dL pre-admission) and also to hypotension and tachycardia. The patient presented uterin atony without response to conservative treatment, carried out with perfusion of oxytocin and sulprostone, as well as uterine compression. Was submitted to a second surgery, with subtotal hysterectomy and bladder reparation, during which several transfusions were administered: nine units of erythrocyte concentrate, 8 mg of recombinant factor VII, 7 g of fibrinogen concentrate, six units of fresh frozen plasma, one platelet concentrate obtained by aphaeresis and 1000 IU of antithrombin III. During surgery the patient remained hypotense and with conservative diuresis, resulting in transfer to ICU. Sedation was administered and mechanical ventilation was implemented. During the hospitalization coagulation was not compromised in the puncture locals, but there was blood present in gastric drainage and microscopic haematuria was diagnosed. Patient was transfused with two units of erythrocyte concentrate due to anemia, although there were not evidences of haematic loss. Sedation and ventilation were withdrawn and extubation was performed without complications. Diuresis decreased, with some retention of nitrogen, resolved by fluid administration. Results: She was transferred to the obstetrics department (day 3) and was asymptomatic, received no further transfusions, and responded well to iron-saccharate treatment, haemoglobin level increased to 12.6 g/dL. On day 7, patient was discharged in good overall health. Haemodynamic stability was confirmed: blood pressure 100/60 mmHg, pulse rate 80 bpm. Haemostatic tests (prothrombin time, fibrinogen level, platelet count, haemoglobin level) were normal, as were renal function and respiration. In the follow-up, dysfibrinogenemia was accessed and came out negative, the analytical parameters were also normal. Both mother and baby remained healthy upon follow-up at 3, 6, 10 and 15 weeks. Results of laboratory haemostatic tests performed during the patient's hospital stay and follow-up are presented in the table. Summary/Conclusions: The successful outcome of this case can be attributed to effective haemostatic intervention, in particular, administration of fibrinogen concentrate was key to re-establishing haemostasis. Rapid, effective haemostatic therapy is vital for women with severe postpartum haemorrhage.

1689

EVALUATION OF THE ADMINISTRATION EFFICACY OF PROTHROMBIN COMPLEX: RETROSPECTION OF 4 YEARS OF USE IN A PORTUGUESE DISTRICT HOSPITAL

J Martinez Marcos, R Moras, V Brás, I Eusébio, P Amantegui, A Ramalhinho
Centro Hospitalar Cova da Beira, Covilhć, Portugal

Background. The human plasma-derived prothrombin complex concentrate containing coagulation factors II, VII, IX, X, Protein C and Protein S is indicated when rapid correction of haemostasis is necessary. It is used in patients with acute haemorrhage, mainly hypocoagulated patients, and in the correction of coagulation parameters in patients with hepatopathy, substituting fresh frozen plasma, as prothrombin complex improves haemostasis in a more rapidly way, without causing circulatory overload. Aims: The aim of this work is to analyse the use of prothrombin complex in several pathologies during four years in a Portuguese district hospital. Methods: We performed a retrospective study of the use of the therapeutic in 172 patients, from 2007 to October 2010, in relation to gender, age, diagnostic, number of vials used, number of administrations, efficiency of the therapeutic and thrombosis occurrence three months after administration. Results: Average age was 67,4 years (15-91 years). Patients were treated in order to correct alterations of coagulation parameters. The first group was constituted by 135 (78,5%) hypocoagulated patients or patients with hepatopathy. From these, 39 (22,7%) were waiting for pre programmed surgery or pre invasive procedures, 39 (22,7%) had digestive bleeding, 23 (13,4%) had brain haemorrhage, 19 (11,0%) had the need of emergent abdominal surgery and 15 (8,7%) had thoracic and abdominal bleeding. The second group comprised 37 (21,5%) patients with coagulopathy: 16 (9,3%) were patients submitted to intestinal neoplasia surgery, 10 (5,8%) had bleeding caused by multiple trauma, 7 (4,1%) had bleeding caused by severe infection, 3 (1,7%) had post surgery uncontrollable hemathuria and 1 (0,6%) had post caesarean bleeding. The average number of vials used per patient was 2,5, each vial corresponding to 500 IU, and the average number of administrations was 1,2 times. The treatment was efficient in 152 (88,3%) patients. The patients that did not respond to the therapeutic died as a result of uncontrollable bleeding, multiorganic failure or fatal brain haemorrhage. Thrombotic events were not found in any patient treated with prothrombin complex after three months of treatment. Summary/Conclusions: Our experience revealed that prothrombin complex has an important role in the correction of coagulation parameters and control of haemorrhagic conditions in a rapid and efficient way, and without occurrence of thrombotic events.

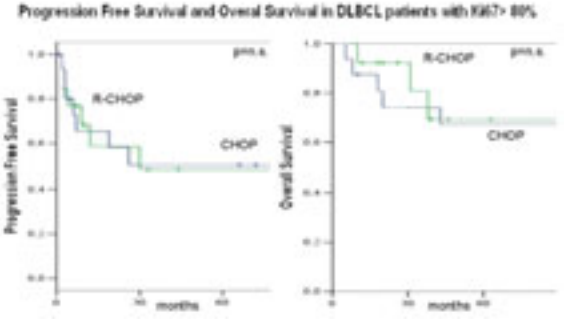
1690

EPIDEMIOLOGY OF BLEEDING DISORDERS IN ZAGAZIG UNIVERSITY CHILDREN HOSPITAL, EGYPT: RETROSPECTIVE ANALYSIS

M Beshir, M Hesham, N Abdel Samad, M Korkor
Zagazig University Hospital, Zagazig, Egypt

Background : Bleeding defects are of great interest in pediatrics since the prevalence of congenital forms and the early appearance of acquired ones. They have been identified with a heterogeneous group of clinical disease that differs from one another in etiology, pathogenesis, epidemi-

ology and incidence in population. Aims: to describe the epidemiological, laboratory, and clinical data of the various bleeding disorders observed in the Hematology Department of the Zagazig University Children Hospital, as based on retrospective analysis of clinical records between years 2006 and 2010. Patients and methods: The study included 279 children with bleeding disorders registered from 2006 to 2010 in Zagazig University Children Hospital. All cases with history of mucocutaneous bleeding or any other bleeding manifestations were subjected to full history and thorough clinical examination. Hematological profile (platelet count &function, bleeding time, PT, PTT and TT) and specific tests in congenital group (as coagulation factor assay and von willebrand factor assay) were done. Results: In this study bleeding disorders were significantly more common in males than females especially coagulation disorders. Platelets disorders were found in 71.3% of our patients while coagulation disorders in 28.7%. In this study hemophilia A was the commonest coagulation disorders (58.7%) followed by hemophilia B (20 %). Mild presentation represents the majority in 70% followed by moderate severity in 23.75 %. We reported 2 cases of mild hemophilia A in females (6.9%) in our study. The initial clinical presentation of coagulation disorders was not significantly affected by sex or severity. The commonest complication of coagulation disorders found was hemarthrosis. ITP was the commonest platelet disorders in our locality followed by aplastic anemia (45.9%, 22.6% respectively), 74.2% of patients with ITP were acute and 25.8% were chronic. The 5 years survival rate among patients with aplastic anemia was 69.3%, while the mortality rate was 31.7%. Conclusion: the most common bleeding disorders in our locality is ITP followed by aplastic anemia and hemophilia A. Attention must be given for early detection and accurate diagnosis of these disorders for appropriate management.



1691

THINK GLOBALLY, ACT LOCALLY - THE MEASURES OF LOCAL BLEEDING CONTROL IN PATIENTS WITH HEMOPHILIA AND INHIBITORS

N Rajic[1], S Popovic[1], A Savic[1], I Urosevic[1], G Marusic[1], M Popov[1], A Knezevic[1], B Bajkin[2], I Milosevic[1], I Savic[1]
[1]*Clinical Center of Vojvodina, Novi Sad, Serbia*
[2]*Dentistry faculty, Novi Sad, Serbia*

Background : By-passing agents made passible many invasive diagnostic or therapeutic procedures, in patients with hemophilia and high titer of inhibitors. But, these patients still have an increased risk of perioperative bleeding. In current literature, importance of the measures of local bleeding control are not enough emphasized. *Aims*: Analysis of our experiances in management of patients with hemophilia and inhibitors undergoing invasive diagnostic and therapeutic procedures. *Methods*: In our institution, since January 1st, 2008. until January 1st 2011, there were 7 invasive procedures in patients with hemophilia and high titer of inhibitors. Two of them were major surgeries (limb amputation due to compatment syndrome and phlegmona, nephrectomy due to renal tumor causing constant macrohematuria) and five minor interventions (3 surgical, mutiple tooth extractions, 1 diagnostic upper endoscopy and 1 upper endoscopy with hemoclipping and applicaton of fibrin glue for rare bleeding gastric Dieulafoy lesion). We used recombinant factor VIIa (Novoseven) or activated prothrombin complex (FEIBA). Former was used in dosis of 90-270 mikrogr/BM every 2 hours, with gradual prolongation of intervals between doses and later was applied in doses of 50 IU per kg/BM every 6, 8 or 12 hours. *Results*: Both by-passing agents showed excellent efficacy, but local measures of bleeding control (fibrin glue, hemocliping, compressive packing and suturae) were very important. Only after nephrectomy, not a single measure of local hemostasis was performed, due to large bleeding surface. As a result we had single significant bleeding. Bleeding was stopped when the renal lodge was filled with blood, and pressures were equalized. Later, that blood collection was transformed into the pseudotumor, still shrinking one year after intervention. All our patients had improved performance status after the invasive treatment. *Conclusions*: Both by-passing agents showed great efficacy, but mesures of local bleeding contol seems to be equaly important.

1692

INTRAMURAL HEMATOMA OF THE SMALL INTESTINE UNDER THE PROPHYLAXIS

H Atay, S Nural, E Kelkitli, N Yilmaz, Z Emer, R Kadi, N Güler
19 Mayis University, Samsun, Turkey

Intramural hematoma of the small intestine is a rare clinical condition. Spontaneous hematoma of the small intestine is seen in the warfarin overdose, and rarely in Hemophilia, ITP, vasculitis and malignancy. In this report, we will present a patient with Hemophilia developing small intestineal hematoma. A 25-year-old male patient who had been diagnosed since one year old as severe hemophilia was admitted to the emergency room with abdominal pain. He had a slight stomachache after meals for the last 2-3 days. A day before his admission, his abdominal pain got severed. After dinner on that day, he vomited. He was not suffering from fever, diarrhea or constipation. According to the laboratory results, The laboratory examination findings were as follows: white cell count: 10,500 (3,700-9,700), Hemoglobin: 15.9 (13.3-17,9) gr/dL, platelets: L, the level of Factor VIII: 1%, stool occult blood: positive,? 250,000 / abdominal X-ray and abdominal ultrasound were normal.Magnetic resonance imaging (MRI) of terminal ileum was also normal; there was a 1 cm diffuse symmetrical thickening of the wall in a segment of about 15 cm long (Figure 1). Intestinal hematoma was diagnosed. Factor VIII concentrate was started. Dose was calculated for to raise factor level to %40. After bolus dose of Factor, the level was checked as 55%. The patient's symptoms decreased within 2-3 days. A week later, MRI was taken again and in the ileum showed that the thickness of the wall regressed (Figure 2). Control stool occult blood was negative. The incidence of the intestinal hematoma in patients with hemophilia is not known. By the use of tomography, imaging the number of diagnosed cases has increased. Treatment is usually conservative. Surgery is not required. Bleeding can be stopped with a strong factor replacement. Hemophilia patients with developed intestinal hematoma have been reported in the literature. We have presented a case that developed intestinal hematoma under the prophylaxis. Unfortunately, the reason for health insurance system in Turkey, our prophylaxis doses are limited with 4500 Units in a week. This dose is not reaching to doses recommending, especially in adult patient. He was taking 1000 Units three times in a week. Nevertheless, the bleeding episodes in joints were controlled with this dose. He started to study in court as archive employees since last year. There was hard working such as carrying heavy files in his recent history, especially last week. This experience reminded us, prophylaxis doses should be reevaluated in hemophilia patients regularly and abdominal pain can be herald of the life threatening bleeding.

INTEGRATED POSTURAL ANALYSIS IN CHILDREN WITH HEMOPHILIA: A COMPARATIVE STUDY

E Boccalandro[1], A Gringeri[2]
[1]*Haemophilia and Thrombosis Centre ABB Bonomi, University Hospital of Milan, Milan, Italy*
[2]*University Hospital of Milan, Milan, Italy*

Background. integrated postural analysis represents a new approach to assess the presence of musculoskeletal alterations in children with

haemophilia. *Aim*: To applicate the postural analysis in haemophilic children. *Methods*: children with severe haemophilia were evaluate for postural analysis methods and compared to healthy children: 1. Test of postural tone (PT); 2. antero-posterior equilibrium test (APE); 3. latero-lateral equilibrium test (LLE); 4. podalic support test. RESULTS: forty children, aged 5 to 17 years (median 12) with haemophilia A or B (36 and 4 respectively), of whom 21 severe, 8 moderate e 11 mild were evaluated. They were compared to 40 healthy, age-matched, male children (median 10 years, range: 5-17). Children with haemophilia showed a higher prevalence of multiple disharmonies compared to controls at PT test (60% vs 22%, respectively, p<0.002), and more frequent abnormalities at LLE test (p<0.006). No difference where found at APE test, while more frequent podalic support abnormalities in children with haemophilia did not achieve a statistical significance level (p=0.08). *Conclusions.* : integrated postural analysis can represent an useful instrument in the management of musculoskeletal health of children with haemophilia.

1694

ACQUIRED LOSS OF THE LARGEST VON WILLEBRAND FACTOR MULTIMERS IN SEVERE TETRALOGY OF FALLOT: A CASE REPORT

S Barbar, A Casonato, E De Bon, E Pontara, A Bertomoro
2nd Chair of Internal Medicine, Padua, Italy

Background. Congenital heart defects can be associated with loss of high-molecular-weight von Willebrand factor (VWF) multimers, potentially leading to severe bleeding complications.Case report. We describe a 3-month-old patient diagnosed with tetralogy of Fallot (TF) with atresia of the pulmonary and major aortopulmonary collateral arteries, and right aortic arch, an aberrant right subclavian artery, intrauterine growth retardation, congenital glaucoma and vertebral dysraphism. Before the first surgical correction, the patient underwent ventricular angiography complicated by right femoral artery thrombosis followed by renal hematoma and ischemic stroke, occurring during anticoagulant therapy. Laboratory findings showed prolonged PFA-100 closure times, reduced VWF collagen binding (VWF:CB) to VWF antigen (VWF:Ag) ratio (VWF:CB ratio) (0.53 vs normal >0.75), and the absence of large VWF multimers. All other hemostatic parameters, except for protein C, were normal. The parents revealed no VWF multimer abnormalities, ruling out an inherited VWF defect. First-stage cardiac repair involved systemic-pulmonary shunting with a homograft common iliac artery. On postoperative day 3, the patient had massive bilateral hemothorax with cardiac arrest requiring cardiopulmonary resuscitation. The VWF:CB ratio decreased (0.49) and the large VWF multimers remained absent. There was no laboratory evidence of intravascular coagulation or sepsis. After this first repair procedure, FVIII was 84.21%, the VWF:CB ratio increased (0.73) and the VWF multimer pattern improved to some degree, but PFA-100 closure time was yet prolonged (>300 sec). The patient underwent a new ventricular angiography and subsequent second-stage cardiac repair involving ventricular septal defect patch closure and right ventricular to pulmonary arteries connection. Plasma-derived FVIII concentrates containing VWF (75 UI R:Cof/kg bid - Haemate, CSL Behring Marburg - adjusting dose according to FVIII levels) was administered in peri-operative period; no haemorrhagic complications was recorded during and after surgical treatment. Conclusions. CHD could cause acquired Von-Willebrand syndrome, leading to high haemorrhagic risk. Administration of plasma-derived FVIII concentrates containing VWF prevent hemorrhagic complications.

1695

ORTOPEDIC SURGERY IN PATIENT WITH ACQUIRED INHIBITOR TO FACTOR XII

D Antic, I Elezovic, P Miljic
Clinical Center Serbia, Belgrade, Serbia

Background: Acquired inhibitor to factor XII (FXII) is very rare and predominantly was describAim: The aim of this paper is to present a patient with inhibitor to F XII who should be underwent orthopedic surgery. Methods: A 68 year old woman presented with prolonged activated partial thromboplastin time (aPTT) during a presurgical screening for hip replacement. She had previous history of seronegative rheumatoid arthritis the last 20 years. She was treated with corticosteroids, sulphosalazine and methotrexate. Also, she had one delivery 43 years before, and did not receive any transfusion of blood products so far. Results: Her blood count and biohumoral status were without significant changes, prothrombin time (PT) was in normal range (91%) while aPTT was prolonged (57.5s) and failured to correct (44 s) with normal plasma in 1:1 mixing studies. Level of FXII level was 4% while levels of factors VIII, IX, XI were decreased 41%, 31%, and 31% respectively. Lupus anticoagulans (LA) was excluded with DRVVT test (LA1 44.3s, LA2 41.3 R=1.07). In mixing study with control plasma FXII insufficiently increased from 4% to 28% (control FXII 132%). Inhibitor to FXII detected with Bethesda like method shown level of 1.56 BU. This level of inhibitor correlates with ineffective increase of FXII with control plasma in mixing study. In next step clotting factors assayed at multiple dilutions. Factor XII appeared equally deficient no matter how much the patient plasma is diluted but other factors VIII, IX and XI increased over normal levels. This result strongly confirmed presence of FXII inhibitor. Also, we measured level of FXII in platelet reach plasma (PRP) before and after platelets lisys by freezen and heating. Levels were similar 4% and 6% respectively. All analysis indicated that patient have acquired deficience of FXII due to inhibitors against FXII. Conclusion: Patient received anticoagulant prophylactic therapy during surgery and postoperatively during 35 days with low molecular weight heparin (LMWH) in dosage range for anti-FXa between 0.2 to 0.5. Presence of inhibitor to FXII was not associated with bleeding complication during the surgery and with thromboembolic complications after surgery that was prevented with LMWH posteoperatively.

CHILDHOOD STROKE - LOOKING FOR A CAUSE!

P Nunes,[1] P Mendes,[2] MJ Balseiro,[2] A Machado,[2] J Freixo[2]
[1]*Unidade de Hematologia Pediátrica, Hospital Santa Maria, Lisbon, Lisbon, Portugal*
[2]*Hospital S. Bernardo, Setúbal, Portugal*

Childhood stroke is a rare condition that requires etiological investigation. Among its causes we find Rendu-Osler-Weber syndrome. This is manifested as epistaxis, mucocutaneous and gastrointestinal telangiectases, arteriovenous malformations in the pulmonary, cerebral or hepatic circulation, which may trigger thromboembolic events. We report the case of a of 6 years old female child, admitted by change in level of consciousness, chewing movements, fixed eye deviations, focal motor weakness followed by generalized tonic-clonic seizure. Physical examination showed central cyanosis with persistent hypoxemia that was fairly well tolerated. She had a personal history of recurrent spontaneous epistaxis as her father. Her brother also had pulmonary arterio-venous malformations. The MRI showed focal signal change in bilateral frontal and parietal hemispheres, suggesting hypoxia / ischemia in the barrier territory and postictal changes. She was admitted with stroke diagnosis. On laboratory evaluation, iron deficiency anemia, protein C activity, protein S activity, antithrombin III, activated protein C resistance, and homocysteine level were unremarkable. We didn't found any functional heart defect or abnormal vasculature in transthoracic echocardiography. Chest X-ray films revealed an abnormal shadow in right lower lobe. CT scanning and pulmonary angiography showed an arteriovenous malformation of the right lower lobe. Rendu-Osler-Weber syndrome diagnosis was made based on positivity at family and personal history, clinical examination, laboratory and instrumental findings. Despite being one of the rare etiologies of childhood stroke, it should be considered in the differential diagnosis.

1697

TRANSIENT ACQUIRED FACTOR VII DEFICIENCY AFTER LOBECTOMY PERFORMED FOR LUNG METASTATIC ADENOCARCINOMA: A CASE REPORT

J Devignes,[1] A Poinsar,[2] M Toussaint-Hacquard,[2] M Houot,[3]
G Grosdidier,[3] T Lecompte[2]
[1]*University Hospital of Nancy, Vandoeuvre-les-Nancy, France*
[2]*Laboratory of Hematology, Nancy University Hospital and INSERM U961, Vandoeuvre-les-Nancy, France*
[3]*General and Emergency Surgery Service, Nancy University Hospital, Nancy, France*

A transient isolated deficiency of factor VII (FVII) is uncommon but has been described in association with infection, malignancy or inhibitor. Proposed mechanisms include proteases of neutrophils and macrophages and consumption associated with endothelial injury in sepsis; release of tissue factor (TF) from tumor; fixation of FVII to the tumor; increased concentration of tissue factor plasmatic inhibitor (TFPI) produced by tumor and complex binding FT-FVIIa-TFPI; specific inhibitor (autoimmunity). We report a case the taking in charge of a patient with acquired FVII deficiency in the context of lobectomy for lung metastatic adenocarcinoma. The possible mechanism of FVII deficiency are discussed.

This reports a case of a patient with acquired FVII deficiency in the context of lobectomy for lung metastatic adenocarcinoma. Preoperative coagulation studies were normal and there was no personal or family history of a bleeding diathesis. Post-operative pulmonary infection with systemic sepsis occurred (procalcitonin: 3.72 ng/mL - N < 0.05 ng/mL, detection of Enterobacter aerogenes in bronchial aspiration). This sepsis was controlled by antibiotics including amoxicillin/clavulanic acid and levofloxacin. Two days after surgery, haemostasis tests showed prolonged prothrombin time corrected by mixing test. Further investigations brought out isolated FVII deficiency. Bethesda test to assess inhibitor activity was negative. Plasma levels of liver enzymes were normal and vitamin K administration did not normalize the prothrombin time. To prevent bleeding during chest drains removal, the patient received recombinant activated FVII (eptacog-alpha, 1mg, 13.8 µg/Kg). Calibrated Automated Thrombinography (Diagnostica Stago) assay showed a longer lag time than plasma control and injection of recombinant activated FVII shortened the lag time without changing endogenous thrombin potential. Systematic biological control revealed a spontaneous normalization of coagulation tests in five days. This case report displays a conjunction of several possible aetiologies of transient acquired FVII deficiency, namely sepsis, malignancy and FVII inhibitor. It should be noted the presence of lung metastatic adenocarcinoma did not lead to FVII deficiency before surgery. With the Bethesda test, we could exclude the appearance of a FVII inhibitor. Although it was rapidly controlled by antibiotics, sepsis could have lead to a secretion of granulocyte-associated proteases that cleave FVII and to an overconsumption of FVII consecutive to damaged vascular endothelium. Finally, the transient acquired FVII deficiency could be linked to an increased FVII clearance by circulating tissue factor or tissue factor pathway inhibitor released during tumor resection surgery.

1698

FACTOR XI DEFICIENCY EPIDEMIOLOGY IN IRAN

A Jafarpour,[1] A Jafarpour,[1] M Faranoush,[2] K Kourosh,[3] M Rahmani,[4] M Jazebi,[4] T Shashaani[4]

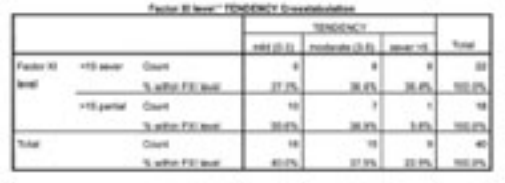
[1]*SUMS, Tehran, Iran*

[2]*Tehran university of Medical sciences, Tehran, Iran*

[3]*Elam university of medical sciences, Elam, Iran*

[4]*Comprehensive Hemophilia Clinic of Iran, Tehran, Iran*

Background. Factor XI deficiency categorized as a rare bleeding disorders with several clinical manifestation in patients. *Aims*. This review gives an overview of the epidemiology, clinical manifestations, and bleeding severity in Iranian factor XI deficiency patients. The correlation between FXI levels and the bleeding tendency is much less clear than in the hemophilias, and consequently the bleeding risk can be difficult to predict. *Methods*. In this study 42 patients with factor XI deficiency were interviewed and a bleeding history questionnaire completed at Comprehensive Hemophilia clinic of Iran. Blood was taken for coagulation assays. The questionnaires contain personal information, clinical manifestation, bleeding tendency, family history, and factor XI level. Ordinal logistic regression with logit link function was used to predict bleeding tendency using FXI levels.



Results. 52.4% and 47.6% of patients were male and female respectively. Mean (±SD) age of patients was 26.38 ±16.51 years. 40.5% (n=17) patients have mild bleeding tendency. 38.1%(n= 16) patients have moderate tendency and the other have (n=9) severe bleeding tendency. 22 (52.4) of our patients have severe factor xi deficiency and 42.9 % have partial factor xi deficiency. There was negative correlation between bleeding tendency and factor XI level (r=-.37,P=0.018). In the patients with factor XI level less than 15u/dl, 27.3% were in mild tendency category versus it was 55.6% in patients with factor XI more than 15. Ordinal logistic regression with logit link function show that factor XI was a predictor variable for bleeding tendency (P=. 021). *Summary*. In contrast of our previous study and other research we find out a predictor variable of factor XI for bleeding tendency in mild and moderate factor XI deficiency patients with this method of data analysis. We need to do this research in a larger group to establish the correlation of factor XI level and bleeding severity.

1699

PFA100 TEST AND FUNCTIONAL VON WILLEBRAND FACTOR UTILITY AS A SCREENING METHODS FOR TYPE-1 VON WILLEBRAND DISEASE DIAGNOSIS

F Carretero López, AM Rodriguez Huerta, A Roldán, M Infante, I Gonzalez Gascon y Marin, L Bento de Miguel, G Perez Rus, C Pascual, JL Diez Martin

Hospital General Universitario Gregorio Marañon, Madrid, Spain

Background. Type 1 Von Willebrand disease (VWD) is the most frequently diagnosed congenital coagulopathy. It follows an autosomal-dominant pattern of inheritance. In Type 1 VWD, Von Willebrand Factor levels are quantitatively decreased (10-50 U/dL) making these patients more proned to hemorrhage. Nevertheless, the misknowledge of the association between bleeding probability and Von Willebrand Factor levels shows heterogeneous plasmatic concentration of FVW among population. The cut-off point between normal and low Von Willebrand Factor levels is not well defined and this difficults Type 1 VWD diagnosis. PFA-100 test is a convenient tool for measuring 'In Vitro' platelet aggregation with Collagen/Epinephrine (COL/EPI) or Collagen/ADP (COL/ADP). AIMS. The objective is to evaluate PFA-100 test sensitivity at different Functional-VWF (F-VWF) plasmatic concentrations and its association with hemorrhagic symptoms. *Methods.* Family history of hemorrhagic diathesis, hemorrhagic symptoms and plasmatic levels of Von Willebrand Antigen and F-VWF were studied in 89 patients with clinical suspicion of Type 1 VWD. 43 patients were evaluated with PFA100 test (COL/EPI and COL/ADP), 40 were evaluated using bleeding time and in 6 patients no test was performed. According to the F-VWF plasmatic concentration 3 patient groups were established: Group A: F-VWF<25% (8), B: F-VWF 25-40% (26), C: F-VWF 40-50% (55). PFA100 Closure Time (CT) and bleeding time (Simplate IIR) was evaluated in each group (CT COL-EPI normal≤155", CT COL-ADP normal≤110", Simplate IIR normal <8.5 min). *Results.* PFA-100 test was pathologIcal in 75% of patients showing F-VWF plasmatic concentration <25% whereas Bleeding time was prolonged in 50% of patients with F-VWF<25%. With higher plasmatic concentrations of F-VWF (25-40% and 40-50%) PFA100 test loses sensitivity. 75% of patients in Group A (6/8), 42% in Group B (11/26) and 71% in Group C (39/16) presented hemorrhagic symptoms non related with F-VWF plasmatic concentrations. *Conclusions.* PFA100 test sensitivity changes depending on F-VWF plasmatic concentrations, what does not make PFA100 useful as a single screening method for Type 1 VWD.

FACTOR V LEIDEN IS THE MAIN ETIOLOGICAL FACTOR IN EGYPTIAN PATIENTS WITH BUDD-CHIARI SYNDROME

S Elsayed,[1] T Abdel Ghaffar,[1] M Sakr,[1] E Elsobky,[1] S Abdelhakam,[1] S Yousuf,[1] Y Egin,[2] N Akar[2]

[1]*Ain Shams University, Cairo, Egypt*

[2]*Pediatric Molecular Genetics Department of Ankara University, Ankara, Turkey*

Background. Budd-Chiari syndrome is a multifactorial disease where several prothrombotic disorders must concur for the development of thrombosis at this uncommon location. The prevalence and the interaction between genetic and acquired risk factors are variable in different parts of the world. Aims: To assess the prevalence and characteristics of inherited thrombophilia in Egyptian patients with Budd-Chiari syndrome. *Methods*. The study included 47 (20 children and 27 adults) patients with Budd-Chiari syndrome. Genotyping of factor V Leiden G1691A, Prothrombin G20210A and Methyltetrahydrofolate reductase C677T were performed by real time PCR using fluorescence melting curve detection analysis by means of the Light Cycler System. *Results*. Factor V Leiden was present in 28 patients (59.6%) which was signifi-

cantly higher compared to previous reports. It could be the sole factor causing Budd-Chiari syndrome in 19 patients and in 5 patients with inferior vena cava involvement. Myeloproliferative disease was present in only 10 (21.3%), antiphospholipid syndrome in 5 (10.6%) and Behcet disease in 3 patients (6.4%). Interestingly, 3 children with lipid storage disease had Budd-Chiari syndrome. *Conclusions*: Factor V Leiden could be considered as the main etiological factor for Budd-Chiari syndrome in Egyptian patients which could be attributed to the geographical distribution of this mutation in this area. Its sole presence could be considered as a strong thrombophilic factor and a leading cause of inferior vena cava thrombosis in these patients. Lipid storage disease should be included as a risk factor for this disease.

1701

STUDY OF URINARY 11-DEHYDRO-THROMBOXANE B2 AS A MARKER OF THROMBOEMBOLIC EVENTS IN BETA-THALASSEMIA PATIENTS

U El Safy[1], M Mourad[1], M Fathy[1], N Kamal[2]
[1]*Zagazig University, Zagazig, Egypt*
[2]*Cairo University, Cairo, Egypt*

Introduction: There is increasing evidence that chronic hemolytic anemia such as β thalassemia (βT) is characterized by a hypercoagulable state. In addition to increased thrombin and fibrin generation, increased tissue factor activity, and increased platelet activation, patients with hemolytic anemia manifest thrombotic complications, including venous thromboembolism and stroke. *Aims:* To evaluate the role of platelets activation by measuring the urinary level of 11-dehydro-thromboxane B2 as a marker of thromboembolic events in βT patients. *Subjects:* This study was carried out in at thalassemia outpatient clinic at Zagazig university hospitals. The study included a total number of 50 patients and 20 healthy controls, classified into: Group I: Included 20 healthy and haematologically normal subjects as a control group. Group II: Included 20 non-splenectomized β-thalassemia major (NSβTM) patients. Group III: Included 15 β-thalassemia intermedia (NSβTI) patients. Group IV: Included 15 splenectomized β-thalassemia major (SβTM) patients. *Methods:* All the patients and controls were subjected to the following: history taking and clinical examination, hemoglobin electrophoresis, prothrombin time (PT), Partial thromboplastin time (PTT), urine creatinine, D-dime, fibrinogen, brain MRI and Doppler ultrasound on the abdomen. The estimation of 11 dehydro-thromboxane B2 level was done by ELISA from DRG international company provided by clinilab and the results were reported as pg urinary 11dhydroTxB2 per ml urinary creatinine in order to normalize results for the concentration of the urine sample tested. *Results:* In this study Urinary 11 dehydroTXB2 pg/mg creatinine revealed very high significant increase in the all groups compared to that of the control group. In addition, there were significant difference between the patients group II and group III and IV ($P<0.05$), while there were no significant increase between group III & IV (βTI and SβTM), $P>0.05$.There was strong positive correlation in this study between 11 dehydroTXB2 and D-dimer level in groups II, III and IV. On the other hand there were strong negative correlation between 11 dehydroTXB2 and fibrinogen level in groups II, III and IV. In this results, no significant correlations were found between platelets counts and hypercoagulability markers (11 dehydroTXB2, D-dimer and fibrinogen) in all studied groups ($P>0.05$). A strong inverse correlation was found between HB F and both 11 dehydro TXB2 and D dimer in group II, III and IV. *Conclusion:* The elevated urinary 11-dehydro-TXB2 level can be used a marker of hypercoagulable state even in clinical asymptomatic thalassemic patients.

1702

RETROSPECTIVE ASSESSMENT OF RISK FACTORS FOR VTE IN ADOLESCENTS OF SOUTH MORAVIAN REGION, CZECH REPUBLIC WITHIN YEARS 2004-2010

O Zapletal,[1] J Blatnz,[1] V Fiamoli,[1] S Köhlerová,[2] J Vancara[2]
[1]*University Hospital Brno, Brno, Czech Republic*
[2]*Inst. of biostatistics and analyses, Masaryk University, Brno, Czech Republic*

Background. Venous thromboembolism (VTE) is multifactorial disease. There are many known risk factors (RF) for VTE, both acquired and inherited. VTE is relatively infrequent in children and adolescents compared to adults. *Aims*. To analyse RF of VTE in adolescents. *Methods*. We retrospectively analysed RF for VTE in consecutive adolescent patients treated in regional referral centre for their first VTE episode in years 2004-2010. The patients were 14 to 18 years old. Analysed parameters were as follows: age; sex; thrombus location; pulmonary embolism (PE) and respective RF- both inherited (antithrombin (AT) deficiency; protein C (PC) deficiency; protein S (PS) deficiency; FV Leiden mutation (FVL); prothrombin gene mutation (FII G202010A); high FVIII levels; protein C global test (PCG) positivity and family history positive for VTE) and acquired (obesity, smoking, lupus anticoagulant, surgery, knee arthroscopy, immobilisation, pregnancy, delivery, abortion, autoimmune disease and oestrogen-containing oral contraception (COC)). We excluded central venous line (CVL) related VTEs as well as other non-VTE thrombotic events from our cohort. *Results:* Seventy-two consecutive patients were analysed for their first VTE (46 female (63,9%) and 26 male (36,1%)). Median of their age was 16 years, ranging from 14 to 18. Thrombus location in this cohort of patients was as follows: DVT of lower extremities and pelvis 56 (77,8%), DVT of upper extremities 8 (11,1%), one (1,4%) thrombosis of hepatic veins, one (1,4%) thrombosis of internal jugular vein and 2 (2,8%) thrombosis of cerebral veins. In 4 (5,6%) patients with PE we were not able to identify the location of primary thrombosis. The total number of patients with PE was 8 (11,1%). One patient died due to PE. Prevalence of respective RF was: positive family history 11 (15,3 %), FVL 20 (27,8%), FII G20210A 4 (5,6%), deficiency of AT 3 (4,2%), PC 3 (4,4%), PS 6 (8,8%); isolated positivity of PCG 11 (15,7%), FVIII high 20(43,5%), vessel pathology 3 (4,2%), obesity 2 (2,8%), smoking 6 (8,3%), knee arthroscopy 7 (9,7%), LA positivity 5 (7,2%), other acquired RF 36 (50%), COC 30 (47,6% from all, 65,2% of girls). In median, our patients had 2 RF (range 0-6 RF/patient). Only one patient (1,4%) was free of any known RF. Twelve patients (16,7%) hade only inherited RF, 23 (31,9%) had only acquired RF and 36 (50%) of patients in our cohort had combination of both inherited and acquired risks. We estimated the overall incidence of DVT (non CVL related) in age group of 14 to 17 years old adolescents in our region to be minimally 16/100000/year (2004-10); in females minimally 21/100000/year and in males 10/100000/year. *Conclusions*. Incidence of VTE in our cohort is relatively high (compared to published data), higher then that in children and closer to that in adults. VTE form thus a real threat for Czech adolescents. Less then 20% VTE episodes in our cohort were idiopathic/unprovoked. Prevention of VTE is necessary in this age group, and should be based mainly on recommendations for adults. Further prospective studies are needed to confirm our findings on a national-wide basis.

1703

POSSIBLE INFLUENCE OF ACQUIRED AND INHERITED THROMBOFILIC DISORDERS IN CHILDREN AND ADOLESCENTS WITH EXTRAHEPATIC PORTAL VEIN THROMBOSIS

M Luciani,[1] A Pietrobattista,[2] J Abraldes,[3] M Candusso,[2] S Pancotti,[4] M Soldati,[4] L Monti,[5] G Torre,[2] V Nobili[2]
[1]*Research Institute, Children's Hospital Bambino Gesù, Vatican City, Vatican City*
[2]*Liver Unit, Research Institute, Bambino Gesù Children's Hospital, Vatican City, Vatican City*
[3]*Hepatic Hemodynamic Laboratory, Liver Unit University of Barcelona, Barcelona, Spain*
[4]*Laboratory Department, Bambino Gesù Children's Hospital, Vatican City, Vatican City*
[5]*Radiology Department, Bambino Gesù Children Hospital, Vatican City, Vatican City*

Aims. Aim of this study is to explore the prevalence of local and genetic thrombophilic disorders as risk factors for portal vein thrombosis (PVT) in our pediatric series. *Methods*: We conducted a case-control study enrolling 35 children with PVT and 26 age-matched controls. All were screened for thrombophilia, including genetic disorders, protein C, protein S and homocysteine deficiencies. All coagulation parameters were studied at least 3 mo after the diagnosis of portal vein obstruction. *Results.* In our study we showed that most pediatric patients with PVT have acquired prothrombotic risk factors, which are probably the most important factors leading to PVT. However, there is a clear association between the presence of inherited prothrombotic disorders and PVT, suggesting that these increase the risk of thrombosis in patients with local factors such as perinatal umbilical vein catheterization or sepsis. *Conclusions.* This series is the larger ever published so far. This study show that most patients with pediatric PVT have a history of a local prothrombotic factor, a figure much higher than that reported for adult portal vein thrombosis (around 30%). Patients with PVT should be screened for inherited prothrombotic disorders regardless of a history of an obvious local risk factor.

1704

SETTING A TARGET INTERNATIONAL NORMALIZED RATIO RANGE DOESN'T GUARANTEE GOOD ACHIEVEMENT OF THAT RANGE-A STUDY IN OMANI PATIENTS TAKING WARFARIN

CH Ho,[1] D Gravell[2]
[1]*College of Medicine, Sultan Qaboos University, Muscat, Oman*
[2]*Sultan Qaboos University Hospital, Muscat, Oman*

Background. Warfarin is a worldwide oral anticoagulant commonly used to prevent thrombosis, and international normalized ratio (INR) is used to monitor the dose of warfarin. INR is usually set either in the range of 2-3 or 2.5-3.5 dependent on the underlying disorders. Aims: To know the actual achievement of target INR in two groups of patients whose INR ranges were set either in 2-3 or 2.5-3.5. Methods: From September 2010 to January 2011, we consecutively enrolled 113 patients who were taking warfarin because of thrombosis, atrial fibrillation or mechanical heart valves (MHVs) and were regularly followed up in our specialist clinics. We reviewed their history, recorded the diagnosis, INR data and warfarin dosages. Two groups of patients were divided, Group A included patients with MHVs, the target INR range was set into 2.5-3.5; Group B included patients other than MHVs, and the target INR range was set into 2-3. We compared the percentage of time which was within the target INR ranges in these two groups. Results: Totally 113 patients, with 1976 results of INR were enrolled. The total follow-up period was 188.4 patient-years. Group A included 25 patients, their mean age was 43.4 ± 16.0 years, mean INR was 2.96±1.61, and mean warfarin dose was 4.69±2.03 mg. Group B included 88 patients with mean age 52.7±16.7 years which was significantly older than that in Group A (p=0.007). Their mean INR±SD was 2.67±2.16, which was significantly lower than that of Group A (p=0.001); their mean warfarin dose ±SD was 4.80±2.44 mg, which was not different from that of Group A (p=0.2155). 154 (32.8%) INRs were within the target range of 2.5-3.5 in Group A, whereas 533 (35.4%) INRs were within the target range of 2-3 in Group B. Interestingly, although the target INR in Group A was set in the range of 2.5 to 3.5, 187 (39.8%) INRs were found in the range of 2-3, which was more than those in the range of 2.5 to 3.5 (39.8% vs 32.8%) in the same group. Moreover, the percentage of INR range from 2-3 in Group A, which was originally set with INR range of 2.5-3.5, was more than the percentage found in Group B (39.8% vs 35.4%) whose INR range was initially set in 2-3. Thus, although the mean of INR in Group A was significantly higher than that in Group B, the percentage of INR ranging from 2-3 was higher in Group A than in Group B. i.e. the original setting of INR target with frequent monitoring could not result in a higher rate of that target. *Conclusions*. Simply setting the INR range and frequently monitoring INR by laboratory tests in a specialist clinic is not enough to achieve good INR targeting. Many other causes would influence the achievement of the target INR. As this might be a common phenomenon, attention to this problem with more studies to find out a way to solve this problem is urgently necessary.

1705

A COMPARATIVE EVALUATION OF SERUM FERRITIN LEVELS IN PATIENTS WITH DIABETES MELLITUS AND CHRONIC RENAL DISEASE WITH AND WITHOUT DEFECTS OF DIABETIC RETINOPATHY

C Kanonidou,[1] E Kanonidou,[2] R Papadopoulos,[3] A Michalopoulos,[3] L Papazisis[2]
[1]*AHEPA University Hospital, Thessaloniki, Greece*
[2]*Department of Ophthalmology, General Hospital of Veria, Veria, Greece*
[3]*Department of Nephrology, General Hospital of Veria, Veria, Greece*

Background. It has been hypothesized that the diabetes mellitus type 2 related microangiopathy may be associated with elevated absortion and storage of dietery iron represented by increased serum ferritin levels. Aims: To comparatively evaluate the levels of serum ferritin in diabetic patients with and without diabetic retinopathy lesions and concomitant renal disease. *Methods*: 53 patients (34 male and 19 female) with a mean age of 70.45 years (SD 8.21) participated in the study. All suffered from type 2 diabetes mellitus and had chronic renal disease. 31 had no lesions (group I) and 22 had lesions of diabetic retinopathy (group II) during fundus examination. The mean duration of diabetes was 9 years (SD 4.67). 21 healthy controls (11 male and 10 female) with a mean age of 71.28 years (SD 3.37) also participated in the study (group III). The serum ferritin levels were measured in the three groups and were comparatively evaluated. *Results*: Mean serum ferritin values in group I were 146.69 ng/ml, in group II 131.9 ng/ml and in the group III 48.59 ng/ml. There was a significant difference in the values of serum ferritin between the diabetic patients with and without diabetic retinopathy lesions and the healthy controls (p=0.010 and p=0.006 respectively), while no significant difference in the values between the two groups of diabetic patients was found (p=0.704). Moreover, there was no significant correlation between ferritin values and the values of HbA1c in both groups of diabetic patients (p=0.365 and p=0.941 respectively). *Summary/conclusions*: The results show that the levels of iron in diabetic patients may play a role in the occurrence of microangiopathy or its evolution.

1706

WARFARIN LOADING & DOSING AT A DISTRICT GENERAL HOSPITAL

M Nizamoglu, V Abbott
NHS, Crewe, UK

Background. Warfarin is a Vitamin K antagonist. It is a synthetic derivative of dicoumarol, a fermentation product of coumarin. In 1940 dicoumoral was isolated at University of Wisconsin. It was the first drug in its class, patented in 1941. Warfarin is a combination of Wisconsin Alumni Research Foundation (W.A.R.F.) and -arin indicating the link with coumarin. Warfarin was first registered for use as a rodenticide in the US in 1948. In 1954 Warfarin was first approved for medical use for humans as an anticoagulent. International Normalized Ratio (INR), is a system established by the W.H.O. and the International Committee on Thrombosis and Haemostasis for reporting the results of blood coagulation tests. Objectives. The goal of this audit was to look at the Warfarin loading and dosing regimes of patients at our institution between January 2009 and January 2010. We wished to compare our findings to the National standards, and provide evidence for the development of better standards of INR monitoring especially during the loading phase. Our standards included :- 1) All patients loaded on Warfarin should reach their target INR with in 5 days of starting, as in keeping with Fennerty et al. findings. 2) INR checked daily during loading process. 3) Warfarin loaded according to hospital protocol. Methods. A Retrospective audit measuring against the BCSH and local guidelines was performed. The inclusion criteria for this audit required patients to be loaded on Warfarin during their inpatient stay in the year 2009. Based on this criterion, a number of elements were extrapolated, including: - Age/gender ratio, reason for admission, reason for Warfarin loading, Anticoagulation prior to admission, INR on admission, INR at first loading dose of Warfarin, INR checked daily, number of days to target INR, loading dose, INR checked daily, whether patient was on Heparin during Warfarin loading, are referral letters to the anticoagulation clinic present, and if the referral letters to the anticoagulation clinic complete.

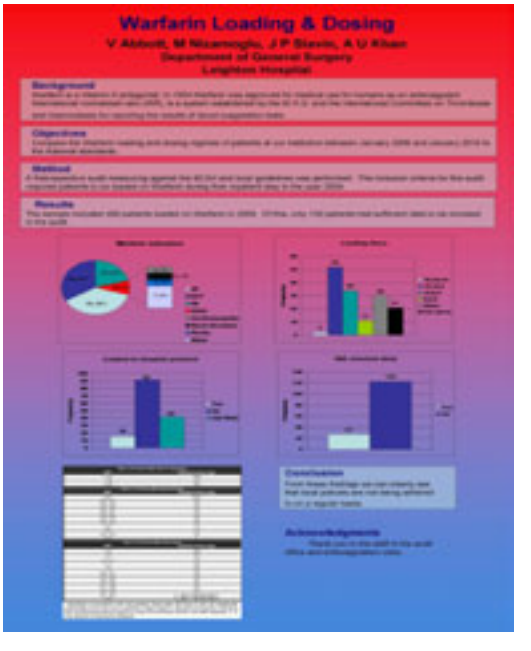

Figure 1. Warfarin loading and dosing poster.

Results. The sample included 400 patients loaded on Warfarin in 2009. Only 150 patients had sufficient data to be included in the audit. Of this

reduced sample, 41% reached their target INR with in 5 days. 18% of patients had an INR check on a daily basis. 11% of patients were loaded according to the hospital protocol that is based on the Fennerty et al study presented in the BMJ in 1984. *Conclusions*. Based on the findings of this audit, recommendations have been made including : (i) It is essential to implement loading protocols that all staff adhere to for general and vulnerable patient groups. (ii) INR should be checked daily, with all results and doses logged appropriately at the loading stage. (iii) Referral forms must be completed correctly; with dosing record should state clearly day 1 and (iv) Finger-prick INR to be introduced to enable daily easily implemented INR checks by nursing staff on a daily basis.

1707

PROLONGED CLINICAL OBSERVATION OF A GROUP OF PATIENTS WITH ASYMPTOMATIC ANTIPHOSPOLIPID ANTIBODIES

A Lehmann-Kopydlowska, K Zawilska
J.Strus Hospital, Poznan, Poland, Poznan, Poland

Antiphospholipid antibodies (APA) are well known risk factor for thromboembolic events and/or obstetric complications. They may be found incidentally in patients without thrombotic complications (asymptomatic APA), and they often lead to an incorrect suspicion of hemorrhagic diathesis, as well as to an unnecessary disqualification from surgical procedures or withdrawal from a proper antithrombotic prophylaxis during these procedures. The aim of the study was to register venous and/or thrombotic events in a group of patients with asymptomatic APA, diagnosed according to the international guidelines (Myakis et all. 2006). The study group consisted of 25 patients (18 women and 7 men) of the mean age of 46 years (20 - 75 years). Concomitantly 9 of them had other autoimmune disorders and 4 had neoplasms. Among risk factors for arterial thrombosis 5 patients had hypercholesterolemia, 5 - hypertension, 4 were smokers and 4 were obese (BMI >30 kg/m2). None of the patients had hereditary thrombophilia (antithrombin, protein C or protein S deficiency, factor V Leiden, prothrombin G20210A mutation, increased activity of factor VIII). Family history of venous thromboembolic disease has been noticed in 4 patients and of arterial thrombosis in 6 patients. The observation lasted for 3 to 127 months (mean 35 months). The number and percent of patients (n = 25) with abnormal results of different laboratory diagnostic assays for APA: Assessment aPTT- n(%) dRVVT-n(%) ACA-n(%) anti- β2-GPI-n(%) initial 24 (96) 23 (92) 11 (44) 10 (40) after 12 weeks 24 (96) 22 (88) 9 (36) 11 (44) aPTT - activated partial thromboplastin time; dRVVT- diluted Russell viper venom time, ACA - anticardiolipin antibodies, anti-β2-GPI - anti- β2-glycoprotein I antibodies; Abnormal results of more than one assay in any combination were found in 16 patients, lupus anticoagulant alone in 9 patients. Only 4 out of 25 patients have taken aspirin - 75mg daily, in the other 4 a prophylactic dose of low molecular weight heparin was administered temporarily because of surgery. During observation time no venous or arterial thrombotic events occurred in the study group. In two patients asymptomatic APA disappeared. Conclusion: independently of the type and quantity of asymptomatic antiphospholipid antibodies, there were no venous or arterial thromboembolic events in the group of patients observed for meanly 35 months.

1708

THE INFLUENCE OF ELECTIVE PERCUTANEOUS CORONARY INTERVENTION ON THE PLASMA MICROPARTICLES CONCENTRATION IN PATIENTS WITH CORONARY ARTERY DISEASE

J Wachowiak,[1] K Zawilska[2]
[1]*Regional Hospital in Poznan, Poznan, Poland*
[2]*J. Strus Hospital, Department of Haematology, Poznan, Poland*

Background. Mikroparticles (MP) are released into the circulation by cells including platelets, endothelial cells, leukocytes and erythrocytes. They play an important physiological roles (for exaple in coagulation) so are object of scientific interest. Aims. The aim of the study was to measure microparticles (MP) concentration in the plasma of patients (pts) with coronary artery disease (CAD) taking aspirin and clopidogrel, before as well as after elective percutaneous coronary intervention (PCI) with or without stent implantation. *Methods*. The study group consisted of 73 pts (44 men, 29 women) with CAD. During PCI stent implantation has been performed in 32 pts. MP concentration was measured using ZYMOPHEN MP-Activity test before, 24 h and 1 month after PCI. In the control group there were 26 healthy blood donors not taking antiplatelet drugs. Results. MP concentration (nM) in patients before and after PCI is listed in attached table. Result of the control group: 4,6 nM +/- 3,3; VC 72%.

	Patients with stent implantation					
	before stent implantation		24h after stent implantation		1 month after stent implantation	
	men	women	men	women	men	women
cMP[nM]	8,0	5,4	10,4	6,4	6,4	7,3
SD [nM]	4,1	4,2	4,2	3,5	3,2	5,6
VC [%]	51	78	40	54	50	77
	Patients without stent implantation					
	Before PCI		24h after PCI		1 month after PCI	
	men	women	men	women	men	women
cMP[nM]	6,1	5,7	7,7	9,4	7,6	7,9
SD [nM]	2,5	2,4	4,6	7,4	4,9	5,3
VC [%]	42	42	59	79	64	68

Conclusions. 1.Mean microparticles concentration in the plasma of patients with coronary disease taking aspirin and clopidogrel is higher than controls, but SD is high, therefore the difference is not statistically significant. 2.There is an increase of microparticles concentration 24h after percutaneous coronary intervention in women without stent implantation and in men 24h after stent placement.

1709

PREVALENCE, SPECTRUM AND CORRELATION OF LUPUS ANTICOAGULANT POSITIVITY WITH CLINICAL OUTCOME: EXPERIENCE FROM A SINGLE TERTIARY CENTRE IN OMAN

V Panjwani,[1] S Alkindi,[2] N Fawaz,[3] A Pathare[3]
[1]*Sultan Qaboos University Hospital, Muscat, Oman*
[2]*Department of Haematology, College of Medicine & Health Sciences, SQU, Muscat, Oman*
[3]*Department of Haematology, Sultan Qaboos University Hospital, Muscat, Oman*

Background. Lupus anticoagulants [LA] are immunoglobulins which prolong phospholipid-dependent coagulation tests. These inhibitors recognize anionic phospholipid epitopes and prevent or delay the generation phospholipid dependent activations complexes in vitro. However, in vivo, they are associated with endothelial injury that alters the fibrinolytic balance leading to vascular micro-infarcts which clinically manifest as thromboembolism, thrombocytopenia and recurrent pregnancy loss. *Aims*. To study the prevalence and spectrum of antiphospholipid antibody[LA] positivity diagnosed using the 2009 ISTH criteria and correlate it with one of the three clinical outcomes namely thrombosis, thrombocytopenia and recurrent pregnancy loss. 3. Methods: One hundred forty-seven consecutive patients (Males-47; Females-100) with mean age of 30.5 years [SD±17.1; Range 1-82 years] and an abnormal APTT that did not correct on mixing studies were retrospectively analyzed. Blood was collected for a complete blood count and serum and plasma samples were tested for IgG and IgM anticardiolipin[ACA] and anti-beta2-glycoprotein I(GPI) antibodies [by ELISA], along with a panel of Lupus coagulant test including a dilute APTT and a dRVVT followed by mixing and confirmation studies with normal plasma and hexagonal phospholipid reagent respectively. 4. *Results*: Out of 147 cases, 146 cases with a positive LA, 48 (32.9%) had SLE (primary-23,secondary-25); 26(17.8%) had thrombosis(DVT-12,Stroke-11, PE-1,MI-1,Portal vein thrombosis-1); 25(17.1%) had thrombocytopenia; 20(13.7%) had APLS (primary-8,secondary-12), and 13(8.9%) had pregnancy loss (Recurrent miscarraige-11, IUFD-2). Incidentally, one patient had an acquired factor V inhibitor with severe factor V deficiency (FV<1%). The overall prevalence of ACA and anti-beta2 GPI antibodies was 17.1% and 17.8%, whereas, in patients with SLE it was 2 fold higher at 31.3% and 29.2% , but in patients with APLS it was 4-fold higher at 70% each respectively[p<0.05; Chi Square test). Furthermore, there was a good correlation between the ACA and anti-beta 2 GPI antibodies (Pearson's correlation coefficient 'r'=0.55; p<0.05) 5. Conclusions: Antiphospholipid antibodies are heterogeneous, with LA positivity 5-fold more prevalent as compared to ACA or anti-beta 2 GPI antibodies. However, there was a good concordance between ACA and anti-beta 2 GPI antibodies positivity in the LA positive cohort. Furthermore both these antiphospholipid antibodies were equally prevalent in primary v/s secondary SLE and APLS patients.

1710

DETECTION OF MUTATIONS IN THE ATIII GENE IN PATIENTS WITH VTE AND ATIII DEFICIENCY

K Tsaousidou, Z Moschidis, I Anastasopoulou, A Karafoulidou, O Katsarou, P Kotsi
Laiko University Hospital, Athens, Greece

Antithrombin III (ATIII) is a 58kd protein synthesized in the liver that belongs to the family of serpins. It inhibits thrombin by binding to it and forming a complex in a stoichiometric 1/1 relationship. The rate of inhibition is greatly accelerated in the presence of heparin (>1000 fold). ATI-II also inhibits the action of factors IXa, Xa, XIa, and XIIa and the TF/VIIa complex. Its deficiency predisposes to recurrent VTE episodes. Normal levels range from 70-120%. It is inherited in an autosomal dominant manner, and has been identified only in the heterozygous state, suggesting that its total absence is incompatible with life. Homozygosity has been described in mutations that involve the heparin binding site. It is found with a frequency of 1% to 2% of VTE patients. The gene, located on chromosome 1q25.1, is 13.5 kb long, consists of 7 exons and encodes for a 432kb amino acid protein. Various mutations have been described, including missense, nonsense, splice-site mutations, frameshifts, insertions and deletions. The functional (ATIII: C, mean 46%, range 19-62%) and antigenic (ATIII:Ag, mean 58%, range 38-113%) levels of ATIII were measured in VTE patients (n=30) with ATI-II deficiency. We present preliminary results of the detection of ATIII mutations. DNA was isolated from whole blood and exons and intron-exon boundaries were amplified. Multiplex PCR was also performed, where the 7 exons of the ATIII gene are simultaneously amplified, along with an internal quality control. All products were analyzed using dHPLC. PCR products were denatured and then gradually frozen to form heterodimers (detection of point mutations, small deletions and insertions) that are separated by the WAVE system. In cases where the chromatograms showed presence of heterodimers, samples were further analyzed by sequencing. The multiplex PCR products (detection of large deletions in heterozygous form that cannot be otherwise detected due to the presence of one normal allele) were also separated by the WAVE system and compared to the chromatograms of healthy subjects. The presence of lower peaks in the patient samples suggested the deletion of exons. Up to date, 10 patients have been examined. 3 were found to have the Budapest III mutation in exon 2 of the gene, leading to substitution of a cytosine by thymine (CTC to TTC), resulting in the substitution of a leucine by a phenylalanine (L131F). This is thought to change the isoelectric point of the protein that perturbs the geometry of the positively charged surface at the heparin binding site resulting in a low affinity for heparin. A frameshift mutation was also identified in exon 2 of one of the patients, as well as point mutations that result in a non-synonymous change of the amino acid and in premature stop codons (exons 1,4,5 and 6 and in particular W189R, Q334X, D342G, R359X). To our knowledge, this is the first documentation of mutations in the ATI-II gene in Greece.

1711

PLASMA COBALAMIN, FOLATE, PYRIDOXINE AND HOMOCYSTEINE LEVELS AND THROMBOSIS IN CHRONIC MYELOPROLIFERATIVE NEOPLASMS AND HEMOLYTIC ANEMIAS

A Eskazan,[1] T Soysal,[1] S Ongoren,[1] M Ar,[2] Z Baslar,[1] I Mihmanli,[1] B Ferhanoglu,[1] Y Aydin[1]
[1]*Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey*
[2]*Istanbul Education and Research Hospital, Department of Hematology, Istanbul, Turkey*

Background. Hyperhomocysteinemia is a condition that may cause both arterial and venous thrombosis. In the etiology of hyperhomocysteinemia there are a lot of factors including folate, cobalamin and pyridoxine deficiencies. It has been shown that in chronic myeloproliferative neoplasms (MPNs) and chronic hemolytic anemias (CHA), the risk for thrombosis is higher than the normal population and plasma folate and cobalamin levels are significantly lower than the normal individuals. However there are small number of studies investigating the homocysteine (Hcy) levels in MPN and CHA patients. Aims: In this study, our aim was to investigate the thrombosis incidence, the effects of plasma total homocysteine (tHcy) levels on thrombosis formation and the correlations between folate, cobalamin, pyridoxine and homosisteine levels in MPNs and CHAs and to compare the results with the healthy control group. Methods:41 patients [MPN (n = 31) and CHA (n = 10)] and 40 age and sex matched healthy individuals representing the control group were included in the study. For all the objects plasma tHcy, folate, cobalamin and pyridoxine levels were measured, and bilateral lower extremity venous system B-Mode and colour Doppler compression ultrasound imagening was performed to investigate the deep venous thrombosis (DVT). All the patients and the objects in the control group were questioned for the past arterial or venous thrombosis and for the comorbities that may cause thrombosis. Also for each object smoking history was taken and recorded as package/year. The follow up durations were noted for each object as months. In addition we measured the D-dimer levels to exclude acute thrombosis and also investigated the thrombophilic disorders other than hyperhomocisteinemia in the objects with thrombosis. *Results*. 11 thrombotic events in 7 objects were detected among the patients whereas there were no thrombosis detected in the control group. Statistically significant and positive correlations were found between the follow up duration, comorbidity and thrombosis (r=0,455 and 0,248 respectively). There were no statistically significant correlations between the plasma tHcy and vitamin levels and thrombosis. In the MPN group, there were no statistically significant correlations between hematocrit, platelet counts and thrombosis. A statistically significant and negative correlation between plasma tHcy levels and folate (r=-0,312) also a statistically significant and positive correlation between tHcy and the amount of smoking (r=0,310) were detected. *Conclusions*. In conclusion, comorbidity may be an important factor in the etiology of the increased risk of thrombosis formation in MPN and CHA patients. Also we think that in these patients in order to keep the plasma tHcy levels low, folate replacement therapy and reducing smoking are the treatment modalities that may prevent thrombosis formation.

1712

THE EFFECT OF INFLAMMATORY CYTOKINES ON VON WILLEBRAND FACTOR SYNTHESIS

W Allers, M Meiring
University of the Free State, Bloemfontein, South Africa

Background: Upon vascular injury, during the early stage of systemic inflammation, endothelial cell stimulation lead to the secretion of a family of monocyte-derived peptides, which include the cytokines interleukin 6 (IL-6), IL-8 and tumour necrosis factor-α (TNF-α). Inflammatory cytokines stimulates the endothelial release of Ultra large Von Willebrand factor (ULVWF) multimers. Increasing VWF multimer levels may have inhibitory effects on the synthesis of the ULVWF cleaving enzyme, ADAMTS-13. This may ultimately lead to the deficiency of ADAMTS-13 during inflammation and the over expression of ULVWF multimers resulting in the initiation of thrombotic thrombocytopenic purpura (TTP). Furthermore, the role of the initiation of coagulation in TTP is not known.Aim: In this study, our aim was to examine the effects of inflammatory cytokines and coagulation factors such as tissue factor and thrombin on the release of ULVWF by cultured endothelial cells and the cleavage of these ULVWF by ADAMTS-13. This will allow us to evaluate potential links between inflammation and thrombosis and help us understand the mechanisms that lead to TTP in patients. Methods: Human umbilical vein endothelial cells (HUVEC) were treated with interleukin 6 (IL-6), IL-8 and tumour necrosis factor α (TNF-α) for 24 hours under static conditions. The cells were then assembled to form the bottom of the flow chamber and exposed to a shear stress of 2.5dyn/cm2 to expose VWF cleaving sites. The Von Willebrand factor secretion was then measured through an ELISA technique. Results: IL-8 and TNF-α stimulated the release of VWF after 24 hours of treatment while IL-6 did not induce the release of VWF due to the absence of the IL-6 receptor on HUVEC cells. *Conclusions*. These results suggest that inflammatory cytokines may stimulate VWF release. Further research will involve measuring ADAMTS-13 levels and activity after stimulation with the inflammatory cytokines as well as coagulation initiators, thrombin and tissue factor. The combined effect of specific cytokines with coagulation initiators will be tested to look at the possibility of enhanced secretion of VWF or inhibition of ADAMTS-13. The findings might describe a potential linkage between inflammation and thrombosis.

1713

ENDOTHELIAL MICROPARTICLES: A POSSIBLE ROLE IN INFLAMMATION AND THROMBOSIS

E le Roux, M Meiring
University of the Free State, Bloemfontein, South Africa

Background Microparticles are vesicles formed from activation of cells. These particles have an effect on a number of disorders including inflammation, diabetes mellitus, atherothrombosis, thrombocytopenia,

cardiovascular and other cellular disorders. Elevations of microparticles might be an indication of cellular dysfunction and may thus be usefull as a diagnostic marker. Microparticles can also be used as therapeutic targets in treatment of certain diseases, since these particles transports proteins and signals across cell membranes. Inflammatory cytokines and thrombotic stimuli are responsible for activation of cells and mediate microparticle formation. Von Willebrand factor is expressed on endothelial microparticle membranes upon activation of endothelial cells. This may indicate an important role for microparticles in primary clot formation in circulation. Aim The aim of the study was to determine the effect of inflammatory cytokines (Tumour necrosis factor α, Interleukin 8 and Interleukin 6) on human umbilical vein endothelial cell composition and its effect on thrombosis and von Willebrand factor in vitro. Methods Human umbilical vein endothelial cells were cultured in sterile conditions. Specific concentrations (0μM and 100μM) of inflammatory cytokines (tumour necrosis factor α, Interleukin 8 and Interleukin 6) were used to stimulate endothelial cells (HUVEC) in static conditions for 24 hours. Treated cells and untreated controls attached on the flask were circulated in round petri dishes for half an hour on a horizontal shaker to create a shear stress of 2.5dyn/cm2. Microparticles were isolated by a Ceveron microparticle filtration unit. Thrombin generation assays were performed and von Willebrand factor antigen levels were measured using only the isolated microparticles. Results Thrombin was generated and von Willebrand factor levels were increased with both inflammatory and thrombotic stimuli. Conclusions Human umbilical vein endothelial derived microparticles have been illustrated to increase the von Willebrand factor levels from untreated to treated cells. Endothelial microparticles also generated thrombin after inflammatory stimulation of cells. This suggests that microparticles might have an effect on thrombin generated in locations other than the static endothelial cell environment, where inflammation or thrombosis may occur. Continued studies on von Willebrand factor activity and the metalloprotease of von Willebrand factor, ADAMTS-13 will be conducted to determine the effect of endothelial microparticles on the breaking down of ultra large von Willebrand factor mulimers. This will give more insight on the effect of endothelial microparticles in inflammation and thrombosis

1714

ACQUIRED ACTIVATED PROTEIN C RESISTANCE IN PATIENTS WITH SARCOMA

N Soyer, B Kececi, Z Eroglu, S Kamer, C Ozcelik, S Cagirgan, M Tombuloglu, D Sabah, A Donmez
Ege University Medical School Hospital, Izmir, Turkey

Background: Although the relationship between cancer and thrombosis has been known for long years and the pathogenesis has partially been understood, the relationship between sarcoma and thrombosis has been reported recently and detailed information about its pathogenesis is lacking Aims: We studied the frequency of clinically detectable thrombosis and presence of acquired activated protein C resistance (aAPCR) in patients with newly diagnosed sarcoma. Methods: We detected the cases who developed aAPCR prospectively in 52 patients (in the period after the diagnosis and treatment) and 52 healthy controls. We also determined the Factor (F) V and FVIII levels. Results: While thrombosis was present in one patient (2.17%), we did not observe thrombosis in the control group after the cases with Factor V Leiden (FVL) mutations were excluded. Although the normalized activated protein C sensitivity ratio (nAPCSR) values which were minimum (median 87.25%) at the time of diagnosis increased following treatment (median 94.35%), it was found to be significantly lower compared to that of the control group (median 106%, $p<0.05$, $p<0.001$ and $p<0.001$, respectively). aAPCR was found as 13%, 0% and 4.2%, respectively, according to the groups. Post-treatment FV levels were found to be higher compared to the values at the time of diagnosis ($p<0.001$). An opposite relationship was found between the FV levels and the nAPCSR values of the patients in the post-treatment period ($r= -0.38$, $p<0.02$). *Conclusions*. We found out an increased frequency of venous thromboembolism (2.17%) in sarcoma patients. As an original finding, we also found out a decrease in the nAPCSR, persisting even after treatment. Thirdly, we found out that the significantly higher rate of aAPCR at the time of diagnosis (13% versus 4.2%), totally disappeared after treatment (0%).

Funding. Ege University Research Ethics Committee Decision Number: 06-6.1/9 . This study was conducted using kits that had been donated to the hematology laboratory by the Pharmaceutical Company Roche (Turkey).

CHANGES IN PLASMA HEMOSTATIC VARIABLES IN AMBULATORY CANCER PATIENTS ENROLLED IN A TRIAL OF THROMBOPROPHYLAXIS WITH LOW-MOLECULAR-WEIGHT HEPARIN (LMWH) NADROPARIN DURING CHEMOTHERAPY (PROTECHT)

A Vignoli,[1] M Marchetti,[1] M Mandalà,[1] L Russo,[1] M Kauling,[2] G Agnelli,[3] C Bianchini,[4] R Labianca,[1] A Falanga[1]
[1]*Ospedali Riuniti di Bergamo, Bergamo, Italy*
[2]*University of Maastricht, Maastricht, Netherlands*
[3]*University of Perugia, Perugia, Italy*
[4]*Italfarmaco, Milan, Italy*

Background. The results of the PROTECHT clinical trial (Agnelli et al., Lancet Oncology 2009) demonstrated the efficacy of thromboprophylaxis with the LMWH nadroparin in reducing the rate of thromboembolic events in ambulatory patients receiving chemotherapy for metastatic or locally advanced solid tumors. *Aims*. In this placebo-controlled randomized clinical trial, a study of plasma thrombotic markers [i.e. thrombin-antithrombin (TAT) complex, plasminogen activator inhibitor-1 (PAI-1) and von Willebrand factor (vWF)] was planned to evaluate: 1. the biomarkers' predictive value for thrombosis, and 2. the modulation of the biomarkers by thromboprophylaxis during chemotherapy. Methods Plasma samples from 141 patients were available for analyses at baseline (T0), i.e. before starting treatments (96 LMWH/45 placebo). Additional plasma samples from 31 study subjects (17 LMWH/14 placebo) were also obtained: before the 3rd chemotherapy cycle ± LMWH (T1), and at the end of treatments (T2). One hundred healthy subjects acted as a control group. *Results*. At T0, the levels of TAT, PAI-1 and vWF were significantly increased in patients compared to healthy controls ($p<0.05$). In the 31 patients analyzed over time, a significant reduction of TAT levels, from T0 to T1, occurred in subjects given LMWH, but not in those receiving placebo ($p<0.05$). After discontinuation of the study drug (T2), TAT levels returned to pre-treatment values. PAI-1 levels remained steadily elevated from T0 to T1 to T2 in both LMWH and placebo groups, while vWF levels were even significantly increased ($p<0.05$) over the chemotherapy period, with a similar profile in both study arms. Three out of the 141 patients experienced thrombosis during treatment. The small number of events did not allow to calculate the predictive value of plasma markers, but, interestingly, patients with thrombosis had significantly higher baseline levels of vWF than those without (247±5 vs 155±5%; $p<0.05$). *Summary/Conclusions*. The data show that LMWH nadroparin improved the patients' hypercoagulable state, as demonstrated by the reduction of plasma TAT levels, but did not influence the endothelial perturbance during chemotherapy, as measured by the levels of endothelial activation markers (i.e. PAI-1 and vWF). The alterations of endothelial markers may be possible candidates to identify ambulatory cancer patients at high thrombotic risk during chemotherapy.

1716

ALTERATION IN HUMAN ENDOTHELIUM CELL FUNCTION INDUCED BY HYPERGLYCEMIA AND HYPERLIPIDEMIA

I Meln
Almazov Federal Heart, Blood and Endocrinology Centre, Saint-Petersburg, Russian Federation

Excess vascular permeability due to secondary factors could promote more aggressive development of hematologic malignancies. We studied a development of endothelium dysfunction by hyperglycemia or hyperglycemia employing cultivating primary human endothelium cells (HUVEC) in different conditions. In order to study the effects of hyperglycemia we assessed cell response to normal glucose (5.6 mM) or high glucose (25.0 mM) content and used high sorbitol content (glucose 5.6 mM + sorbitol 19.4 mM) as osmolarity control. For hyperlipidemia, we used postprandial plasma collected from healthy volunteers 2.5 hrs following a fatty meal (300 g bread, 60 g butter); fasting plasma samples isolated from the same healthy volunteers served control. We than cultured HUVEC in a presence of 10% of plasma with high lipid content (HL) or fasting plasma with normal lipid level (NL) for 6 days. Lipid analysis revealed higher amount of triglycerides in postprandial plasma and similar level of high density and low density lipoproteins and cholesterol probably due to presence of excess amount of chilomicrons and remnant lipid-containing particles. Staining cells with lipid-soluble dye (Oil-red) reveal accumulation in cellular cytoplasm lipid-containing granules after two days of incubation. Growth rate analysis reveal that incubation with HL strongly suppresses cell proliferation and decreases percentage of viable cells, even more than high glucose level. We have observed that

when cultured in high glucose or high fat conditions for 2 days, HUVEC cells presented considerable signs of senescence, as detected with ? -galactosidase activity assay. We further found that a combined exposure to high lipid and high glucose has a substantial synergistic effect on induction of endothelial cells senescence. That could cause inability of the cells to sustain proper vascular homeostasis. Constant activation of pro-proliferative signaling pathways could result in decrease in cell viability by compensatory mechanisms, inhibiting excessive signal. We revealed that protein kinase Akt1 is strongly activated by HL in shot (30min) or long (6 days) incubation. Cells could be unable to proper react to growth factors stimulation and therefore decrease viability and become unable to sustain a barrier function. We also analyzed cellular contacts by staining for intercellular junctions (VE-cadherin and PECAM) and found that cells incubated in presence of high glucose and high lipid conditions in confluent monolayer were unable to sustain tight cell-cell contacts, possibly due to decreased level of particular proteins. In summary, we found that chronic exposure of endothelial cells to high glucose and high lipid conditions could alter cell viability and decreases barrier function.

1717

D-DIMERS: A SIMPLE, SENSITIVE MARKER OF PROCOAGULANT ACTIVITY

E Vagdatli, F Tsikopoulou, E Gounari, A Papoutsi, P Papapreponis, F Eleftheriou, O Serafimidou
Technological Educational Institution of Thessaloniki, Thessaloniki, Greece

Background. It is established that occurrence of thrombosis requires the coexistence of two or more, acquired or congenital, thrombophilic factors. Acquired thrombophilic factorscan be easily recognized. Congenital thrombophilic factors are difficult to be detected, because of bioethical and practical issues; a thorough investigation is very expensive, while only half of all congenital defects are known. *Aims*. The aim of the current study was to evaluate the measurement of D-Dimers as a simple and sensitive screening test, which could reveal early activation of coagulation, thus leading to investigation of congenital thrombophilic factors and/or adoption of preventive measures. *Subjects-Methods*. Our study group consisted of 32 individuals, with no personal history of thrombosis, who were tested for thrombophilia. We used ACL Advance coagulation analyzer in order to measure plasma antithrombin III (ATI-II), protein C (PC), protein S (PS), factor VIII (FVIII) and factor FXII (FXII) activities. We used the same analyzer in order to measure plasma total homocysteine and to investigate the existence of V-Leiden mutation (rdVAPC-resistance). Testing for prothrombin G20210A mutation was performed by use of an in house PCR protocol. Finally, ACL Advance coagulation analyzer was used for a latex-based determination of plasma fibrin D-Dimers. Demographic data and medical history of participants were collected through a structured questionnaire. Results: Study participants were divided into three groups, A,B or C, according to their positivity for the tested blood thrombophilic factors and into two groups, according to their positivity for plasma D-Dimers, as they are shown on the table below. All participants with positive D-Dimers had slightly increased levels (265-466 ng/ml, median: 290 ng/ml). According to the questionnaires, the three subjects with positive D-Dimers of group A had a family history of thrombosis at a relatively young age. Two of them also reported heavy consumption of cigarettes and coffee and the third had protein C activity at the lower normal level (77%). Two out of the three Group B subjects with positive D-Dimers had sickle/beta-thalassemia or sickle cell trait, respectively, while the third subject reported heavy cigarette and coffee consumption.

Groups	Thrombophilic factors	n	DDimers>255ng/ml (positive)	DDimers<255ng/ml (negative)
A	-	11	3	8
B	1	16	3	13
C	2	5	5	-

Conclusions: D-Dimers' test may be a simple and sensitive marker of early coagulation activity. The slightly elevated D-Dimers' levels in all subjects with positive D-Dimers, suggest that laboratories must use D-Dimers' tests with high sensitivity, not only to exclude a thromboembolic episode but also to indicate the presence of hypercoagulability.

1718

STUDY OF URINARY 11-DEHYDROTHROMBOXANE B2 AS A MARKER OF HYPERCOAGULABLE STATE IN CHILDHOOD HEMATOLOGICAL MALIGNANCIES

M Hesham,[1] M Beshir,[2] M Mourad,[1] A Abd Al Rahman[1]
[1]*Zagazig University, Zagazig, Egypt*
[2]*Zagazig University- Pediatric, Zagazig, Egypt*

Background. CXancer can confer a hypercoagulable state through an altered balance between the coagulation and fibrinolytic systems, which can be related to long term treatment. Association of prothrombotic markers with thrombosis in pediatric oncology patients is conflicting. Patients who exhibit elevated 11 dTXB2 levels; as a marker of hypercoagulablity; may be at increased risk for thrombembolic events. Aims : The aim of the work is to predict thromboembolic state in childhood hematological malignancies by estimation of 11-dehydrothromboxane B2 in urine. *Patients and methods*. This study was conducted on twenty-five patients with newly diagnosed hematological malignancies. They were followed up and treated in Oncology unit, Pediatric department, Zagazig University Hospitals. Patients were subjected to full history taking and thorough clinical examination with special attention to thromboembolic manifestations. Laboratory investigations were done before and after four months from starting chemotherapy: CBC, PT, PTT, urine creatinine, D-dimer and estimation of urinary 11 dehydro-thromboxane B2(TXB2) level. *Results*. Our data showed that there was no significant clinical presentations suggesting presence of thrombosis either before or after chemotherapy in both leukemic and lymphoma patients. There was a significant increase in D dimer and TXB2 / creatinine ratio levels in leukemic and lymphoma patients before the start of chemotherapy when compared to the controls. Also, there was a highly significant decrease in these levels after 4 months from starting chemotherapy in leukemic and lymphoma patients. Our data showed that there was significant correlation between TXB2 / Creatinin ratio values and D- dimer values, while, there was no statistical correlation between TXB2 / Creatinin ratio values neither with platelets count, PT and PTT values before and after 4 months from chemotherapy in both leukemic and lymphoma patients. *Conclusions*. children with hematological malignancy are at high risk of thrombosis; even if asymptomatic. So, those patients should be screened for additional prothrombotic risk factors and appropriate measures should be taken to prevent the development of thrombosis.

1719

IMPLEMENTATION VALIDATION OF THE REAL-TIME PCR FOR FACTOR V LEIDEN AND PROTHROMBIN G20210A MUTATION ON THE GENEXPERT DX SYSTEM

I Geerts, G Duson, J Frans, M Van den Driessche, J Moerman
Imeldaziekenhuis, Bonheiden, Belgium

Background Venous thromboembolism (VTE), including deep venous thrombosis and pulmonary embolism, has an estimated annual incidence of approximately 100 per 100.000 in the general population and is a major source of morbidity and mortality (White, 2003). Factor V Leiden and the prothrombin mutation are the most common inherited risk factors for VTE. After diagnosis of VTE, these trombophilic risk factors are commonly performed for etiological purpose and risk assessment of recurrent thrombosis. Aim To validate the Xpert HemosIL FII & FV kit (Instrumentational Laboratory, IL), a commercially available (CE-IVD and FDA approved) kit on the GeneXpert Dx System (Cepheid), for detection of factor V Leiden and prothrombin G20210A mutation. Methods All validation experiments were performed with 50 µl of EDTA whole blood. Molecular testing was performed on the GeneXpert Dx System according to the manufacturers instructions. This system combines extraction, real-time PCR, detection and result interpretation. The assay was checked for analytical sensitivity, specificity, precision and accuracy following international publications on molecular validation methods (e.g. ACMG, 2006). Twenty two patient samples were collected in Imelda Hospital over a 4-month period. To evaluate the clinical performance, these samples were tested with the HemosIL FII & FV kit as well as with the Light Cycler FRET system (Roche), performed in the University Hospitals Leuven. Results Sensitivity: The cycle

threshold (Ct) values for the prothrombin and factor V Leiden mutation ranged from 21.2 to 25.6 Ct and 21.8 to 28.1 Ct respectively. In this Ct-area errors related to limited or excess sample are rare. According to the manufacturer a volume of 50 µl of EDTA whole blood is sufficient to obtain a correct genotype. Specificity: Silent mutations (SNPs) in the probe binding area can occur. The manufacturer demonstrated that known rare factor V SNP's like A1696G, G1689A and A1692C can lead to an invalid result. However, valid results always revealed a correct genotype. Precision: Two samples (FII homozygous normal - FV homozygous normal patient sample and FII homozygous normal - FV heterozygous mutant control sample), were analyzed in triplicate on 3 different days. The standard deviation (SD) (Ct) was between 0.5 and 0.8 for both samples, meeting our validation criterion of SD < 1 (Ct). Accuracy: The 2010 INSTAND controls (whole blood), the NIBSC WHO reference panels and a 1 CE-IVD / FDA FII & FV control (IL) were used to check the accuracy of the HemosIL kit. A 100 percent agreement was found. Clinical performance: In 3 of the 22 patients APC resistance was detected and subsequently a heterozygous Factor V Leiden mutation was genetically confirmed. Nineteen patients were tested for the prothrombin mutation and only one heterozygous mutation was found. The other patients were homozygous normal for both factors. A 100 percent agreement with the Light Cycler FRET method was observed. Conclusion: The HemosIL FII & FV assay on GeneXpert Dx System met all our analytical and clinical validation criteria and was implemented in the daily routine.

1720

THROMBOPHILIA AND CRYPTOGENIC FOCAL EPILEPSY AMONG CHILDREN AND YOUNG ADULTS

M Luciani, P Zangari, V Pansini, F Prischich, D Funaro, M Soldati
Researche Institute, Children Hospital Bambino Gesu', Rome, Italy

Background. Epilepsy has frequently a multifactorial aetiology and recognize a single cause is often impossible. Advanced neurodiagnostic investigations resulted in decreased rate of epilepsy of unknown etiology. Magnetic Resonance Imaging (MRI) brain allowed to identify the cause of focal epilepsy and generalized epilepsy, respectively in 70 and 30% of cases. To determine the pathogenesis of idiopathic focal epilepsy in MRI negative cases in children and young adults, this study would investigate a possible role of prothrombotic risk factors. *Methods*. We studied 48 patients (32M, 16F), aged between 1 and 32 years (median age 11.5 years). All were affected by epilepsy in which it was possible to exclude any form of focal idiopathic epilepsy. The diagnostic procedure included a first phase includings history, physical and neuroradiological examinations, waking and/or sleeping EEG. In a second phase patients diagnosed with cryptogenic partial epilepsy were subjected to coagulation tests (plasma fibrinogen level, plasma D-dimer level, PT, PTT, antithrombin III) and thrombophilia screening (Factor VII, Factor VIII, Protein C anticoagulant, protein S anticoagulant, APC resistance, polymerase chain reaction-based analysis for the factor V Leiden, prothrombin gene G20210A mutations, total plasma homocysteine. Results: 15 patients (12M, 3F) showed increased levels of factor VIII (> 120%) (range 123-226, median 159), 10 patients (8M, 2F) had hyperhomocysteinemia (> 15 mmol / L) (range 15.9 - 47.3, median 24.5), 1 patient (F) had protein S level of <50% (37%). One patient presented a heterozygous Factor V Leiden mutation and another patient an heterozygous mutation of Factor II prothrombin. The study did not reveal more significant correlations for the other parameters. *Conclusions*. We observed a lower incidence of Factor V Leiden and an higher incidence of increased levels of factor VIII and homocysteine in our cohort compared to general population (11% and 5% respectively). In addition we reported an increased frequency of thrombophilic disorders in children and young adults studied. Further studies are necessary to confirm these data.

1721

VENOUS THROMBOSIS IN PEDIATRICS: THE ROLE OF METHYLENETETRAHYDROFOLATE REDUCTASE (MTHFR) MUTATION

M Luciani,[1] P Zangari,[1] V Pansini,[1] V Coletti,[1] M Soldati,[1]
S Pancotti,[2] A Minozzi,[1] V Nobili,[3] P Falappa[1]
[1]*Research Institute, Children Hospital Bambino Gesu', Rome, Italy*
[2]*Laboratory Department, Research Institute Children's Hospital Bambino Gesù, Vatican City, Vatican City*
[3]*Liver Unit, Research Institute Bambino Gesù Children's Hospital, Vatican City, Vatican City*

Background. Although the incidence of venous thrombosis is lower in children than in adults, it represents a significant source of morbidity and mortality in pediatric population. Both congenital and acquired factors contribute to the development of thrombosis. Hyperhomocysteinemia is a risk marker for venous thrombosis and it is consistently associated with methylenetetrahydrofolate reductase enzyme (MTHFR) gene mutation. Not always this association has been found and presence of MTHFR gene mutation with normal homocysteine level in vascular event suggests its role as independent risk factor. Our aim is to estimate the impact of MTHFR mutations alone as prothrombotic risk factor childhood. Methods: From 2002 through 2010 one hundred and twenty children aged between 1-192 months, affected by deep venous thrombosis were admitted into Bambino Gesù Children Hospital of Rome. They were submitted to thrombophilic screening and vascular imaging. Thrombophilic screening included the following tests: measurement of APC resistence, protein C, protein S, antithrombin III, polymerase chain reaction-based analysis for the factor V Leiden, C667T MTHFR and prothrombin gene G20210A mutations and assays for lupus anticoagulants, anti-cardiolipin/antiphospholipid antibodies and homocysteine. Results: The MTHFR polymorphism C677T was found in sixty patients (fifteen in homozygosis and forty-five in heterozygosis) with no other inherited thrombophilic risk factors.Eight heterozygous and eight homozygous patients presented increased plasmatic and urinary levels of homocysteine. Forty-four of these sixty (73%) patients presented normal homocysteinemia, thirthy-seven (84%) with MTHFR heterozygous genotype and seven (16%) with MTHFR homozygous genotype. Sixteen of sixty (27%) patients presented elevated levels of homocysteine, eight (13%) with MTHFR heterozygous genotype and eight (13%) with MTHFR homozygous genotype. Twenty-six were treated with low molecular weight heparin (enoxaparin 100 U/kg s.c. x 2 daily), then they all continued the treatment with oral anticoagulant for 6-12 months. Five patients were treated with antiaggregation therapy and all of them performed long term profilaxis with folic acid and B group vitamins. About remaining patients, since venous thrombosis was subsequent of thromboembolic event, three patients did not received treatments. *Conclusions*. Our data raise the question whether MTHFR gene polymorphism alone, with or without hyperhomocysteinemia, may somehow contribute to thrombophilia and suggest to perform anticoagulant prophylaxis in all patients with MTHFR mutation with previous thrombotic events in case of other thrombotic risk factors (pregnancy, oral contraceptives, sepsis and immobilization). Not always the MTHFR polymorphism leads hyperomocysteinemia. This may be due to the effect of homocysteine levels on thrombotic disease and to the variations of homocysteinemia that may depend on others conditions. The impact of the MTHFR mutation as independent thrombophilic marker on outcome and recurrence risk of venous thrombosis needs to be further investigated.

1722

HEMOSTATIC AND RHEOLOGIC CHANGES OF ACUTE MYOCARDIAL INFARCTIONS IN NIGERIANS

I Ajayi,[1] G Nweke[2]
[1]*University of Benin, Benin City, Nigeria*
[2]*University of Benin Teaching Hospital, Benin city, Nigeria*

Background. Myocardial infarction (MI) is defined as necrosis of a portion of cardiac muscle caused by obstruction in coronary artery through either artheriosclerosis, a thrombus or spasm. The causative factors has been well documented and its risk has been reduced to the barest minimum in advanced countries of the world while in developing countries such as Nigeria, the advent of MI as a major cardiovascular problem is moderately recent. Therefore, researches into the responses of of rheologic and fibrinolytic parameters are modestly new and ongoing. *Aims*. We therefore aimed to highlight basic information on haemorheologic and fibrinolytic parameters with a view to indicate their possible use as diagnostic and prognostic indices in MI. Methods: We investigated longitudinally, 10 acute myocardial infarction (AMI) patients together with 20 age and sex -matched apparently healthy subjects as controls. Blood samples were taken at the point of admission (Day 0), on the 4th and 7th day respectively after treatment has commenced. Rheologic and fibrinolytic indices such as complete blood count (CBC), erythrocye sedimentation rate (ESR), Plasma Fibrinogen concentration (PFC), D-dimer concentration (DDC), Euglobulin lysis time test (ELT) and Plasma viscosity (PV) as well as lipids were measured using standard laboratory methods. Results: We recorded a significantly reduced values of haematocrit and fibrinolytic activity coupled with significantly increased D-dimer levels, PFC, ESR and PV in AMI patients on admission compared with controls (P<0.05, respectively). However, PFC, DDC and PV became significantly lowered from the 4th day of admission while all the parame-

ters became significantly reduced from the 7th day of admission and treatment (P<0.05, respectively). On the other hand, lipids such as Cholesterol, Triglycerides, VLDL and HDL remained relatively unchanged from admission and throughout the duration of the study. *Conclusions*. We conclude therefore that hyperfibrinogenaemia coupled with hypofibrinolytic activity and high plasma viscosities could be likely associated risk factors of thrombosis in Nigerians with AMI and their reduction during treatment are positive indicators as factorials in its pathogenesis. The role of lipids in AMI pathogenesis in Nigerians seem to be unpronounced.

1723

D-DIMER ASSAY IN EGYPTIAN PATIENTS WITH GAUCHER DISEASE: CORRELATION WITH BONE AND LUNG INVOLVEMENT

E Sherif, A Tantawy, A Adly, E Abd El Rahman, H Kader
Ain Shams University, Cairo, Egypt

Background. Gaucher disease (GD) is the most frequent lysosomal storage disorder. Bone and lung involvement are two major causes of morbidity in this disease. D-dimer is a reliable indicator of active microvascular thrombosis, even in patients without overt hypercoagulation. Aim: This study aimed to assess D-dimer levels in GD correlating this marker to clinical characteristics and radiological parameters to investigate its role as a potential predictor for the occurrence and severity of skeletal and pulmonary manifestations. *Methods*. The study population consisted of 56 Egyptian patients with GD; 36 had type 1 (64.3%) and 20 had type 3 (35.7%). Thirty healthy individuals were enrolled as a controls. All patients were receiving regular ERT (the recombinant imiglucerase enzyme). Laboratory investigations were done including complete blood count, liver function and quantitative plasma D-dimer assay. Radiological; investigations X-rays long bones, abdominal ultrasound for assessment of liver and splenic volume, high resolution C.T chest (HRCT) as well as magnetic resonance imaging for pelvic spines and femur bones. *Results*. All Gaucher patients had shown remarkable improvement of growth and hematological parameters, as well as reduction of hepatic and splenic volumes after 6 months of the ERT. D-dimers in all Gaucher patients were significantly higher compared to controls with a mean of (2011±499 and 396±94 ng/ml respectively., p=0.001). D-dimers were significantly higher in type III compared to type I patients with a mean of (1063.5±414 and 830±275.2 ng/ml respectively., P=0.03). Pulmonary involvement and HRCT findings (ground glass appearance, interlobular thickening) were present in a higher percentage among type III compared to type I (71%, 37.5% respectively) (P=0.03). While bony involvement and MRI findings (bone marrow expansion, cortical thinning) were present in higher percentage of type I compared to type III patients (25%, 21% respectively) (p=0.62) .D-dimers were significantly higher in patients with ground glass appearance on HRCT chest (1163.61±457.1 ng/ml) compared to those with normal study (810.77±250 ng/ml; p=0.05). Platelets count were significantly higher in patients with ground glass appearance (218±95x10^9/L) compared to patients with normal study (117±49x10^9/L; p=0.03). *Conclusions*. D-dimer is significantly elevated in Gaucher patients particularly in type III. Higher D-dimers levels in Gaucher patients with clinical and radiological manifestations of bony and pulmonary involvement were found. Thus it's assay may be potentially predictive of bone and lung involvement in Gaucher disease and suggesting that the occurrence of these complications is induced initially as microthrombi.

1724

INFLAMMATORY BIOMARKERS IN ACUTE CORONARY SYNDROMES

H Christou, M Skoura, A Marinakos, L Sabadus, G Nikotian, M Pararas, C Theophanakis, E Paraskevopoulou, P Paraskevopoulou, S Patsilinakos
Konstantopoulio General Hospital, Athens, Greece

Background. Acute coronary syndromes occur in response to inflammation, plaque rupture and subsequent thrombosis. Inflammation is associated with the progress and stability of atherosclerotic vascular lesions and much interest has focused in some inflammatory parameters, such as white blood cell (WBC) count, interleukin-6 (IL-6) and matrix metalloproteinases (MMPs). Traditionally elevated WBC count considered as an indicator of systemic inflammation, but it has also been accepted as part of the healing response following acute myocardial infarction. IL-6 is an inflammatory cytokine which appears to play an important role in atherogenesis. Many studies have demonstrated that MMP-mediated degradation of extracellular matrix is critical for atherosclerotic plaque rupture, responsible for acute atherothrombotic syndromes. *Aims*. The present study was designed to investigate the association between these inflammatory biomarkers (WBC count, MMPs and IL-6), with acute coronary syndromes. Methods: We studied 45 patients (33 males - 12 females, mean age 64.4±12.9 years), either with ST-segment elevation (STEMI) or without ST-segment elevation (non-STEMI) myocardial infarction. From blood samples, which were taken from a peripheral vein, in the first post-infarction day, human pro-MMP-10 and IL-6 plasma levels were measured, using an enzyme immunoassay method. WBC count was also measured in the same samples. Results: WBC (and neutrophils), MMPs and IL-6 levels were found elevated to our study population. No statistically significant differences between STEMI and non-STEMI could be demonstrated. Results are summarized in the table. *Summary/Conclusions*. All inflammatory parameters were found elevated in patients with acute coronary syndromes, possibly because of the existing inflammatory process. Whether elevated WBC count, MMPs or IL-6, are only a marker of the inflammatory process or a direct risk factor for acute coronary events remains unclear.

Variable	All	STEMI	NSTEMI	p-value
Number of patients	45	20	25	-
WBC (x10^3/μL)	10.65±3.5	11.05±3.4	10.32±3.5	0.48
NEUT (x10^3/μL)	8±3.9	8.2±3.8	7.9±4.3	0.8
MMPs (pg/mL)	566.2±257.7	615.8±308.6	524.8±203.8	0.24
IL- 6 (pg/mL)	22.1±27.4	19.1±15.4	24.8±35.2	0.5

1725

DETECTION OF THROMBOPHILIC MUTATIONS IN WOMEN WITH ADVERSE PREGNANCY OUTCOMES

C Coriu,[1] G Mitroi,[2] C Ailenei,[2] M Carstoiu,[3] L Calin,[3] R Talmaci,[2] V Uscatescu[1]
[1]*Fundeni Clinical Institute, Bucharest, Romania*
[2]*University of Medicine and Pharmacy „Carol Davila„,, Bucharest, Romania*
[3]*Dept of Obstetrics and Gynecology, Emergency University Hospital, Bucharest, Romania*

Introduction. Inherited thrombophilia is associated with a high risk of pregnancy complications including early recurrent miscarriage, intrauterine fetal death, intrauterine growth restriction (IUGR) and preeclampsia. Factor V Leiden (FVL) G1691A, methylenetetrahydrofolate reductase (MTHFR) C677T/ A1298C, and factor II (FII) G20210A mutations are important causes of thrombophilia. The aim of this study is to evaluate the prevalence of these mutations in a group of obstetric patients. *Material and Methods*. The study enrolled 58 women with obstetric complications divided in: maternal complications - 3 patients with post C-section venous thromboembolism, and fetal complications - 31 women with 1-2 early miscarriages, 15 with >3 early miscarriages, 6 with IUGR, 2 with preeclampsia and 4 with intrauterine fetal loss. DNA was isolated from peripheral blood samples and then analyzed by Real-Time PCR and melting curve analysis (LightCycler 480 platform) for Factor V Leiden G1691A and FII G20210A mutation. The presence of C677T and A1298C mutations was investigated using Polymerase Chain Reaction - Restriction Fragment Length Polymorphism method based on Hinf I and Mbo II endonuclease digestion. *Results*. FV Leiden was detected in 17 women (29.3 %), 3 were homozygous and developed VTE. Five women (8.6%) had heterozygous prothrombin mutation and three of them presented intrauterine fetal death with severe IUGR. A high frequency of MTHFR mutations was obtained: 41 women (70.6%) with C677T mutation (9 homozygous, 32 heterozygous) and 28 women (48.2%) with A1298C mutation (6 homozygous, 22 heterozygous). Three patients had 3 simultaneous mutations, 29 had 2 mutations and one patient was found without any mutations. *Conclusions.* The investigated thrombophilic mutations were frequent among our patients. FV Leiden and prothrombin mutations generated the thrombotic events

with the highest morbidity. Thrombophilic molecular evaluation should be performed in selected women with adverse pregnancy outcomes. *Funding. This work was supported by the grant PN 42-099 from the Romanian Ministry of Research and Technology.*

1726

RENAL INFARCTION: CASE REPORTS IN PATIENTS WITH THROMBOEMBOLIC RISK FACTORS

L Costilla Barriga, C Gallegos LLerena, N Fernandez Mosteirín, I Parra Salinas, A Montes Limon, I Cuadrado, M Andrade Carmona, M Torres, JF Lucía, D Rubio
Miguel Servet University Hospital, Zaragoza, Spain

Background. The renal infarction is a rare, but serious and often misdiagnosed, condition. There is not a therapeutic consensus to treat this disease, because of the unfrequent episodes reported in different series. We can found different treatment choices: surgery, fibrinolysis and anticoagulation. *Aims*. Review of the cases of renal infarction diagnosed in our hospital: clinical diagnostic, therapeutic management and evolution. Case 1: 52-year-old male, with history of hypertension, active smoker, pulmonary emphysema, generalized atheromatous, chronic vascular ischemia, angor haemodynamic, cocaine use in treatment with methadone, derived from another hospital due to acute and refractary to analgesic pain in right hypochondrium, radiated to epigastric and neck associated with nausea and vomiting. Abdominal exam: painful to the palpation in flank and right iliac fossa, without signs of peritoneal irritation. Ultrasound: normal size and structure kidneys. Angio-CT: atheromatous stenosis of the principal branch of the right renal arterial. Reevaluation CT: right kidney with decrease of size and poor parenchymal opacification, suggesting chronic renal infarction. Treatment: conservative with oral anticoagulation developing good response. Angio-CT: resolution of the injury with arterial permeabilization. Case 2: 53-year-old male with history of hypertension, presented right hypochondrium pain, persistent and refractary to analgesic treatment. Abdominal exam: painful to the palpation in right flank, without signs of peritoneal irritation. Angio-CT: extensive renal infarction involving the middle third of the right kidney, with hypoperfusion in this area. Treatment: Fibrinolysis and non fractionated heparin. Hipercoagulability study reveled positive lupus anticoagulant suggesting an antiphospholipid syndrome. Genetic study showed heterozygote mutation of the MTHFR with high levels of homocistein. Case 3: 84-year-old male with history of hypertension, cardiac insuficiency, auricular fibrillation and chronic pulmonary disease, came to emergency from another hospital due to abdominal pain for 11 days, with nausea and vomiting, suggestive of cholecystitis. Ultrasound: biliar bladder with inflamatory signs, cortical cysts in right kidney. CT: severe aortoiliac atheromatous, hypoperfusion renal area, 35 % right and 15% left. Patient was in surgery because of perforated cholecystitis, then continued with anticoagulantion. Echocardiogram: Normal.

	Case 1	Case 2	Case 3	Case 4
Abdominal pain	+	+	+	+
Nauseas	+	+	+	-
Vomiting	+	-	+	-
Fever	-	-	+	-
Hematuria	-	-	+	-
Arterial Hypertension	+	+	+	+
Leucocyte count	18200	11600	13900	8600
Hemoglobin	9.5	13.3	12.2	15.2
Platelet count	588	176	233	234
Haemostasis	Act. Prot: 19% Tto: oral anticoagulation	Normal	Normal	Normal
Creatinine	1.4	1.3	1.3	0.99
LDH	-	484	355	335

Case 4: 56-year-old man with history of myorcardial infarction, prostate cancer and hypertension, presented abdominal pain and constipation for 15 days, associated to weight lost. Abdominal exam: reduced bowel sounds, painful to the palpation in rigth flank, without signs of peritoneal irritation. Angio-CT: stenosis of transverse colon because of tumor presence, splenic and bilateral renal infarction. At the same time it is detected positive for lupus anticoagulant. During hospitalization patient developed a small cerebral infarction, kidney failure, and worsening of previous clinic described. He was under surgery because of intestinal obstruction, subsequently worsening of kidney failure, multiorgan failure and death. *Comments*. Although acute renal infarction is a rare entity, it is necessary to suspect it in patients with abdominal pain and risk factors for thromboembolism. Early diagnosis is critical in order to diminish the morbimortality of this disease. Physicians must extend the ethiology study, because there are many entities that can cause this patology in patients without known risk factors like use of cocaine, sepsis, neoplasm and thrombophilia.

1727

EVALUATION OF THE EFFECT OF SUBCLINICAL HYPOTHYROIDISM ON BLOOD COAGULATION PARAMETERS

C Kanonidou,[1] D Lazaridou,[1] S Arampatzi,[1] A Nikolaidou,[1] M Pape,[2] M Karamouzis,[2] E Diza[1]
[1]*Hematology Laboratory, Department of Clinical Microbiology, AHEPA University Hos, Thessaloniki, Greece*
[2]*Laboratory of Biochemistry, AHEPA University Hospital, Thessaloniki, Greece*

Background. Subclinical hypothyroidism (SCH) is defined as a status of mildly elevated thyrotropin (TSH) levels associated with normal total or free T3 and T4 values. In general, it is an asymptomatic entity, usually diagnosed after routine screening or while exploring nonspecific clinical presentations, which has been associated with enhanced cardiovascular risk. There has been considerable controversy regarding the alterations of blood coagulation parameters in patients with SCH as both hypercoagulable and hypocoagulable states have been referred. *Aims*. To evaluate platelet activation and coagulation disorders in patients with SCH and the influence of TSH, peripheral thyroid hormones (FT3, FT4) and thyroid autoantibodies such as thyroid antithyroglobulin (anti-TG) and antithyroperoxidase (anti-TPO) on them. *Methods*. A total of 24 patients with SCH (males/females: 10/14) and 24 euthyroid control subjects matched for age and gender were enrolled to the study. Platelet indices [platelet count (PLT), mean platelet volume (MPV) and platelet distribution width (PDW)] were measured in whole blood samples by flow cytometry method with the use of XE-5000 Sysmex (ROCHE). Coagulation parameters [prothrombin time (PT), activated partial thromboplastin time (aPTT), international normalized ratio (INR), protein C and protein S] were measured in plasma samples using a fully automated analyser (ACL Top, ALAPIS). Serum TSH, FT3, FT4, anti-TG and anti-TPO levels were determined by electrochemiluminescence immunoassay with Elecsys Modular E170 analyser (ROCHE).

Table 1. Platelet and coagulation parameters in patients with subclinical hypothyroidism (SCH) and normal controls.

Laboratory parameter	Patients with SCH (n=24)	Normal controls (n=24)	p-value
PLT (K/μL)	277 ± 108.60	278 ± 57	0.960
MPV (fL)	10.80 ± 0.81	10.25 ± 0.42	0.009*
PDW (%)	12.95 ± 1.67	11.37 ± 2.49	0.016*
PT (sec)	12.04 ± 2.05	11.52 ± 0.89	0.406
INR	0.99 ±0.18	0.94 ±0.08	0.408
aPTT (sec)	29.61 ± 8.72	27.55 ± 2.46	0.405
Protein C (%)	96.25 ± 24.87	97.21 ± 21.29	0.916
Protein S (%)	90.25 ± 31.31	99.92 ± 22.08	0.366

Results: The results are presented in Table 1.The levels of MPV and PDW were significantly higher in the SCH group than in the euthyroidic one ($p<0,05$). No differences were observed in other coagulation parameters between SCH patients and control subjects. The above indices were not found to be correlated neither with the thyroid hormone concentrations nor with the measured autoantibodies levels. Summary/conclusions: Subclinical hypothyroidic patients present alterations in some blood coagulation parameters, which are indicative of platelet activation. The speculation that elevated MPV values may be involved in the increased risk of atherothrombotic complications in subclinical hypothyroidism should be further investigated.

1728

ANTICARDIOLIPID ANTIBODIES IN THE REAL WORLD: WHAT IS THE IMPACT OF A CONFIRMATORY TEST AT 12 WEEKS?

J Devignes,[1] D Wahl,[2] S Zuily,[2] T Lecompte[3]
[1]*University Hospital of Nancy, Vandoeuvre-les-Nancy, France*
[2]*Vascular Medecine Unit, Nancy University Hospital and INSERM U961, Vandoeuvre-les-Nancy, France*
[3]*Laboratory of Hematology, Nancy University Hospital and INSERM U961, Vandoeuvre-les-Nancy, France*

Background. Because of the possible transient nature of antiphospholipid antibodies, Sydney classification criteria for antiphospholipid syndrome recommend a confirmatory test, which was postponed at least 12 weeks apart from the first measurement. *Aims.* The aim is to evaluate the impact of this confirmatory test in patients referred to our hospital and having a first positive anticardiolipin antibody (aCL) ELISA. *Methods.* Home made aCL ELISA (IgG and IgM) was performed according to the requirements of the European Forum on antiphospholipid antibodies using cardiolipin for coating and with locally established cut-off values (>99th percentile 15UGPL -7UMPL). CV was 10%. *Results.* Among the patients prospectively included in our database (2005-2010), we identified 91 patients with a positive aCL ELISA either IgG (37) or IgM (41) or both (13). Median and range values were 60.9 (15-576) UGPL and 17 (7-288) UMPL for IgG and IgM respectively. Among them, 53 had a positive second result. Patients persistently positive had a higher level of antibodies at the first test: median and range were 63.8 (15-576) and 20.7 (15-26) UGPL respectively for persistent and non persistent aCL IgG and were 17.9 (7-288) and 8.3 (7 14) UMPL for persistent and non persistent aCL IgM (borderline statistical. *Conclusions.* At or beyond 12 weeks 58% were found to remain positive, but a subset of patients with further testing could become negative. Thus a second, confirmatory test, even when performed at 12 weeks rather than at 6 weeks as previously recommended, could be insufficient. The clinical relevance of the differing patterns of persistency remains to be elucidated.

1729

PROTHROMBIN MUTATION G20210A AND MUTATION MTHFR - RISK FACTOR FOR RECURRENT FETAL LOSS

L Ocroteala, M Stoenescu, N Fraticiu
Municipal Hospital Filantropia, Craiova, Romania

Background . In the recent years, thrombophilia as a risk factor for pregnancy complications and fetal loss gained much attention in the scientific community. However, data on this topic in the literature are conflicting. Prothrombin mutation G20210A and mutation MTHFR result in an increased susceptibility to develop venous thrombosis. The associated clinical manifestations can be heterogeneous as regards severity as well as type of event (VTE or obstetric complication). *Aims*. This study estimates the risk factor of the presence of inherited thrombophilia genetic defects in women with recurrent fetal loss. *Methods*. 95 women with a history of recurrent fetal loss were referred to our laboratory for thrombophilia genetic testing (prothrombin G20210A, MTHFR 677T) by PCR methodology during one year (2009). RESULTS. 88 (92.63%) women had a positive genetic testing: 24 (27.27%) had prothrombin G20210A mutation, 4 (4.54%) had homozygous for MTHFR, 29 (32.95%) had heterozygous and 31% (35.22%) had double heterozygosity. *Conclusions*. Considering the higher percentage of these genetic mutations in women with multiple fetal losses, there are many voices in the scientific community who suggest that maternal screening before pregnancy is a must, in spite of the high cost of this investigation.

1730

INHERITED THROMBOPHILIA IN WOMEN WITH RECURRENT PREGNANCY LOSS

S Al Farsi, S Al Zadjali, V Kumar, K Al Falahi, D Gravell, A Pathare, S Al Kindi
Sultan Qaboos University, Muscat, Oman

Background. Recurrent pregnancy loss (RPL) is a common clinical problem. Several groups have reported an association between inherited thrombophilia and RPL. *Aims*. The aim of this study was to investigate the prevalence of inherited thrombophilia in women between the ages of 18 and 45 referred to our clinic for evaluation of thrombophilia as the etiology of RPL. *Methods*. We retrospectively analyzed the records of women who had complete thrombophilia testing for RPL, defined as 2 or more otherwise unexplained pregnancy losses, between the period of January 2008 and December 2010. The following thrombophilic disorders were included: protein C deficiency (PC), protein S deficiency (PS), anti-thrombin deficiency (AT), activated protein C resistance (APCR), factor V G1691A (FVL), prothrombin G20210A (PTG) and Methyl tetrahydrofolate reductase C677T (MTHRF) done outside of pregnancy or the immediate post-partum period. Results: A total of 43 patients with complete data were identified. Median age was 33 years (range: 20-45). Median number of pregnancy losses was 3 (range: 2-8). 15 women (35%) were found to have a thrombophilic condition. PS deficiency was identified in 1 woman (2%), AT deficiency in 1 (2%) and APCR in 2 (4%), while no cases of PC deficiency were identified. In addition, 2 (4%) had FVL (same women identified as having APCR, both heterozygous), 1 (2%) had PTG and 11 (25%) had MTHFR (10 heterozygous and 1 homozygous). *Summary/conclusions*. Inherited thrombophilias are not uncommon in women with RPL. These results suggest that testing for thrombophilia may be warranted in women with RPL. A prospective study with a control group and more detailed thrombophilia testing, including confirmatory DNA analysis, to assess the true prevalence and significance of such defects in women with RPL is highly warranted.

1731

EVALUATION OF IMMATURE PLATELET FRACTION, MEAN PLATELET VOLUME AND ENDOTHELIAL DAMAGE IN PATIENTS WITH CORONARY ARTERY DISEASE

S Arampatzi, C Kanonidou, A Nicolaidou, D Lazaridou, E Diza
Laboratory of Microbiology, University Hospital AHEPA, Aristotle University, Thessaloniki, Greece

Background: The development of vaso-occlusion is believed to be multifactorial. The presence of activated platelets, subclinical inflammation and consequent activation of the vascular endothelium are important contributors that lead to coagulation activation. Large platelets are more active and more thrombogenic than smaller ones. Immature platelet fraction (IPF) is an index of reticulated platelets which are newly released platelets, larger and more reactive than mature ones. Increased mean platelet volume (MPV) and platelet distribution width (PDW) have been connected to morbidity and cardiovascular mortality in patients with coronary artery disease. Evidence of vascular endothelial damage, includes levels of plasma von Willebrand (vWf) factor. However, relationships between these factors in cardiovascular disease are unknown. Aims: The purpose of our study was the evaluation of the levels of IPF, MPV, PDW and vWf in patients with coronary artery disease . Methods: Our material consisted of 80 patients, (47 males and 33 females, aged 18-74 years old) suffering of coronary artery disease. A second group consisted of 40 normal controls (20 males and 20 females matched for age and ethnicity). Platelet count (PLT), IPF, MPV and PDW were measured by flow cytometry with the SYSMEX XE2100, when vWf was measured using the automated analyser ACL Top (ALAPIS). Exclusion criteria for entry into the study was the presence of co-existing thrombotic or hematological disease . Results: Mean values of PLT, IPF and MPV of patients presented statistically significant difference (all $p<0,05$) with that of the normal controls while mean value of PDW was not significantly different. Positive correlation was found between the values of IPF and MPV ($r= 0,638$, $p<0,01$). Von Willebrand factor was significantly higher in patients compared to the normal controls ($p<0,001$) and was also positively correlated with IPF ($r= 0,648$, $p<0,01$). Conclusions: Patients with coronary artery disease present abnormalities in their platelets. These patients present more numerous platelets, which are bigger and activated. In this disease activated platelets and activation of the vascular endothelium, may lead to coagulation activation.

1732

EVALUATION OF IMMATURE PLATELET FRACTION, MEAN PLATELET VOLUME AND HOMOCYSTEINE LEVELS IN PATIENTS WITH CARDIOVASCULAR DISEASE

S Arampatzi, C Kanonidou, A Nicolaidou, D Lazaridou, E Diza
Laboratory of Microbiology, University Hospital AHEPA, Aristotle University, Thessaloniki, Greece

Background. Immature platelet fraction (IPF) is an index of reticulated platelets which are newly released platelets, larger and more reactive than mature ones. Mean platelet volume (MPV) and platelet distribution width (PDW) are indicators of platelet function and activation. Increased mean platelet volume and platelet distribution width have been connected to morbidity and cardiovascular mortality. Increased mean platelet volume has also been recognized as a risk factor for myocardial infarction in patients with cardiovascular disease. Hyperhomocysteinaimia has

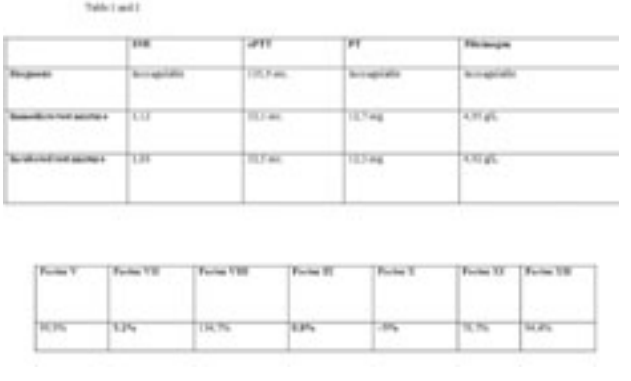
been identified as an independent risk factor of cardiovascular disease and thromboembolic incidents. *Aims*. The purpose of our study was the evaluation of IPF, MPV, PDW and levels of homocysteine (Hcy) in patients with cardiovascular disease. *Methods*. Our material consisted of 70 patients, (37 males and 33 females, aged 18-74 years old) suffering of coronary artery disease. A second group consisted of 40 healthy persons (20 males and 20 females matched for age and ethnicity). IPF, MPV and PDW were measured by flow cytometry with the SYSMEX XE2100 analyser. The levels of Hcy were determined with immunofluropolarimetry on the AxSYM-plus analyser. Exclusion criteria for entry into the study was the presence of co-existing thrombotic or hematological disease. *Results*. Patients with cardiovascular disease presented significantly higher IPF, MPV, PDW and Hcy values than normal controls (all p<0,05). A positive correlation was found between the values of IPF and Hcy (r=0,648, p<0,01) while no positive correlation was found between the value of Hcy and the value of MPV or PDW. *Conclusions*. IPF, MPV, PDW and Hcy are elevated in patients with cardiovascular disease. From our study is concluded that the combination of measurement of IPF, MPV, PDW and homocysteine is useful in patients suffering with cardiovascular disease as indices of risk of new cardiovascular incidents.

1733

HEMATURIA AND GINGIVAL BLEEDING IN A PREGNANT WOMAN

A Iborra, M Abio, C Sierra, N Fernandez-Mosteirin, A Rubio-Martinez, C Gallegos, L Costilla, I Parra, C Salvador-Osuna, M Torres, J Lucia, D Rubio-Felix
Hospital Universitario Miguel Servet, Zaragoza, Spain

Background. Antagonists of vitamin K (Vit K) are currently the most used rodenticides. Ingestion causes nausea, vomiting and bleeding within 36-48 hours. Serious intoxication is caused by repeated doses or by a single massive dose (>15 g). Diagnosis is based on clinical findings and the determination of the specific toxic is interesting from a forensic point of view. Bleeding risk may last for several weeks for compounds of long average life and Vit K treatment may be necessary for weeks or months until total recovery of coagulation parameters. Case report: 17 weeks pregnant woman without pathological history, was admitted for mild bleeding (hematuria and gingival bleeding) for 1 week. Laboratory findings presented global changes in coagulation parameters. Previous studies are normal. Amniocentesis had been performed 3 weeks before without complications. Analitical findings ares shown in Table 1. A moderate to severe acquired Vit K dependent clotting factors deficiency was confirmed: FII 3.3%, FV 99.9%, FVII 3.1%, FVIII 134.7%, FIX 8.8%, FX <5%, FXI 78.7%, FXII 94.4% . After the initial intravenous Vit K treatment bleeding improved and clotting parameters normalized. 24-48 hours oral Vit K was iniciated developing recurrence of coagulation disorders, suspecting the possible action of some long life substance. Differential diagnosis: bowel disease, malabsorptive, drugs ingestion, oral anticoagulants and/or rodenticides were discarded. The patient reported the use of rodenticide (brodifacoum) last year due to a rat invasion at her home, but denies current contact. Given the high suspicion of possible intoxication by *superwarfarin*, determination of levels in blood and urine samples were studied resulting positive in both samples. Hemostasis study was conducted in cohabitants to discard multiple intoxication resulting normal.



The patient was discharged from hospital with treatment of oral Vit K (initial dose 40 mg/day) lasting for 2 months and pregnancy came to term without complications. Conclusions: The 'superwarfarins' displays exert its toxic effect by inhibiting the reduction of Vit K, preventing its activation and resulting in a lengthening of TP, and in more serious cases lengthening of aPTT. Intoxication should be suspected when sustained and high doses of intravenous Vit K are needed to correct coagulation parameters, and this treatment may be sustained for one or two months. The most common cause is the accidental ingestion, especially in children, although the manifold intake in familiar surroundings must be discarded. Other causes are important due to legal involvement.

1734

IS PSYCHOLOGICAL ADJUSTMENT TO A DIAGNOSIS OF ACUTE LEUKEMIA INFLUENCED BY ACCEPTANCE OF DIAGNOSIS AND AMOUNT OF TIME ELAPSED TO ACCEPTANCE?

A Parvu
Oncological Institute Cluj Napoca, Cluj-Napoca, Romania

Background: Coping with cancer is a subject intensely analyzed by psycho-oncologists. It was proven that there are several factors that help patients to develop an effective coping: personality traits, efficient coping with other problems, internal and external psychological resources. *Aims:* We intend to analyze how acceptance of the diagnosis and the amount of time elapsed to acceptance influence coping with acute leukemia. *Methods:* From November 2007 to April 2009 we conducted 100 interviews with patients admitted at the Cluj Hematology Clinic, all with a diagnosis of acute leukemia, and treated with standard protocol chemotherapy. Patients were asked how long did it take to accept their diagnosis and to rate the degree of acceptance on a scale from 1 to 10 (1 = does not accept diagnosis, 10 = total acceptance). At the end of the interview (which focused on more aspects than those addressed by this study), the author (a psycho-social counselor and clinical hematologist) determined patients' coping strategy to leukemia as either efficient or inefficient. Data was analyzed with SPSS and Excel. Correlations between time/degree of acceptance of diagnosis and coping were made using Cramer contingency coefficients. Patients signed informed consent, and the study was approved by the Ethics Committee of Medicine and Pharmacy University Cluj-Napoca, Romania. *Results:* Patterns of efficient coping indentified in this group of patients were: fighting spirit, realistic approach toward disease, direct confrontation of disease, overcoming denial, and considering every possible disease outcome (favorable or unfavourable). In this group, 93% of the patients developed an efficient coping to acute leukemia Patterns of inefficient coping were: long-term denial of disease or prognosis, passive attitude, blaming others, anger, depression, and concealment of truth. The time period to accept the diagnosis ranged from immediate to four months. During the interviews patients were asked to describe and analyze the reason for their immediate or delayed acceptance of diagnosis. The reasons for the immediate acceptance were: presence of severe or neoplastic disease in patient's or his family's medical history, severe symptoms at initial meeting, hearing of suspicion of neoplastic disease from a different hospital, belief in a cure, hearing the diagnosis after a prolonged investigations. The degrees of acceptance varied from 4 to 10 on the scale described above, where about 2/3 of the patients ranked at ≥ 8. The time period to acceptance of diagnosis was not statistically relevant associated with efficient coping (F=3.73, p=0.508>0.05). A high degree of acceptance of the diagnosis was significantly associated with efficient coping (F=7.13, p=0.019<0.05). *Conclusions:* A high degree of acceptance of diagnosis influences the development of an efficient coping strategy. The time period to acceptance of diagnosis does not appear to influence coping. Patients with a low degree of diagnosis acceptance (4-6 on the 1-10 scale above) developed an inefficient coping and these patients would benefit from targeted and individualized psychological support.

1735

QUALITY OF LIFE IN NON-HODGKIN'S LYMPHOMA PATIENTS TREATED WITH 21 R-CHOP IN ASSOCIATION WITH PROFILACTIC GRANULOCYTE GROWTH FACTORS

L Stoian, G Mihaescu, M Dan, S Negru
Oncomed, Timisoara, Romania

During the last few years 21 R-CHOP has become the standard choice of treatment for patients with B cell non-Hodgkin`s lymphoma. It has been demonstrated that this combination is effective and safe. But we observed a relatively high frecquency of severe toxicity, infections, anemia and malnutrition in many patients, responsible for increased morbidity during treatment. The aim of this study was to evaluate whether the quality of life was improved after the use of profilactic granulocyte growth factors. QOL was assessed using the validated EORTC QOL-30 questionaire, which is a 30-item instrument developed specifically for

use in clinical cancer research. Methods: 80 patients were included between January 2008 and January 2011. 54 out of them were stage I-II and 26 stage III-IV, 42 were male and 38 female. Profilactic use of granulocyte growth factors began after the first cycle for 40 patients and in the other group of 40, after the first neutropenia. All patients completed the QOL-C30 questionaire at least 3 times: pre-treatment, after four cycles and post-treatment. In the second group, patients completed the questionaire after the first neutropenia and before every cycle until the end of treatment. Pre-treatment global health status and role functioning were almost identical. The first group followed the treatment at exact time and the neutropenia developed did not interfere with the course of treatment. They did not develop febrile neutropenia or grade III or IV neutropenia. Therefore, global health status and role functioning was not significantly decreased compared with the pre-treatment value. In contrast, in the second group, 32 patients developed neutropenia after approximately 3 cycles and global health status, physical and role functioning were significantly decreased and fatigue, dyspnoea and appetite loss significantly increased. After the introduction of granulocyte growth factors the incidence of neutropenia decreased and the patients continued with the treatment at regular times. The six parameters improved, especially the last 3 that were associated with respiratory infections that disappeared after the remission of neutropenia. After three months of post-treatment the patients generally scored equal.Conclusion: The use of profilactic granulocyte growth factors improves QOL in NHL patients treated with 21 R-CHOP and should be a standard in the course of the treatment because of the benefic effect over the patient`s state of well being during the treatment and also because of the costs that a febrile neutropenia involves.

1736

THE SOUTHERN TRANSYLVANIA PATIENTS OPINION ABOUT THE IMPORTANCE AND MANAGEMENT OF LIFE QUALITY OF PATIENTS WITH MALIGNANT HEMOPATHIES

RG Mihaila,[1] I Lisan,[2] A Tirmonia,[2] R Dancu[2]
[1]*Lucian Blaga University of Sibiu, Sibiu, Romania*
[2]*Emergency County Clinical Hospital, Sibiu, Romania*

Background. Clinicians are both interested in the therapeutic results and quality of life for patients. Therefore, regular questioning of patients on quality of care and quality of their life may contribute to increased efficiency of medical act. *Aims*. Our goal was to find out the opinion from the southern Transylvania patients about the importance and management of life quality of hematological patients. Methods: We had realized a transversal study on a group of 252 consecutive hospitalized patients who had agreed to answer at a questionnaire regarding their opinion about the importance and management of life quality of patients with malignant hemopathies. We have analyzed the rates of the answers, their significations and we have drawn useful conclusions for medical practice. *Results*. The medium age of the studied group was 55.42+/-15.02 years. The gender repartition: 59.52% women and 40.48% men. 61.9% of the interviewed patients considered that quality of life is more important than its duration. On a scale of 1 to 10, 64.29% of patients gave the importance of quality of life a 10. Despite the side effects, most patients (85.71%) would recommend chemotherapy/radiotherapy and only 14.24% a natural treatment. 99.21% agreed upon an adjuvant treatment during polychemotherapy sessions. 96.83% considered that anemia decreases quality of life. Despite the side effects of erythropoietin, 76.98% of respondents would recommend it for treating anemia. If they had to choose between erythropoietin and herbal treatments, however, 51.59% would indicate the last. If an iron deficiency is present in these patients, 63.49% would recommend medical treatment and only 36.51% - iron rich foods. 80.16% of questioned patients would indicate stem cells transplantation, if the patients had indication for this. If the patient did not respond to chemo/radiotherapy, to maintain a quality of life as little altered as possible, 53.97% would further indicate palliative chemo/radiotherapy, 21.43% - only the treatment of anemia and potential hemorrhage, 19.84% - only natural treatment and 4.76% - no treatment. 90.48% considered that patient's socioeconomic status can affect quality of life. 94.44% would be willing to donate blood and only 76.19% would be willing to donate bone marrow to increase the quality of life. Almost all (97.62%) felt that an adequate information made by the medical staff can enhance their quality of life. 92.86% found the questionnaire for assessing quality of life useful. Only 68.25% felt that mass media dissemination of information on patient's pathology may affect quality of life, and 29.07% of them felt that in a negative way. Summary : Most interviewed patients are concerned about quality of life, they support therapies with curative intent in parallel with the adjuvant ones, are willing to donate blood and bone marrow and wish to be adequately informed by the medical staff. Not everyone appreciates the proper risk/benefit ratio on erythropoietin therapy. Not all of them want that information on the pathology of the patient to be broadcast by the media. Most of the patients are aware of our present-day reality: socioeconomic status can affect quality of life for patients.

1737

RELIGIOUS COPING WITH MALIGNANT DISEASE

A Parvu, G Roman, R Gramma, S Moisa, R Chirita, S Dumitras, M Enache, C Chinole, B Ioan
Gr. T. Popa University of Medicine and Pharmacy Iasi, Cluj-Napoca, Romania

Background: Malignant patients develop a psychological adaptation (coping) process which relies on patients' internal or external psychological resources (family, hobby, personality, culture, friends). An important resource is faith and religion. Aims: Analyze the efficiency of religious coping of acute leukemia patients, and identify patterns of religious coping. Methods: We have performed 89 semi-structured interviews with acute leukemia patients who were admitted to the Cluj Hematology Clinic during 2009 and were treated with chemotherapy. Study admission criterion was patient's acknowledgement of religion as a psychological resource. Interviews were conducted by a psycho-social counselor who is also a clinical hematologist, and were analyzed by a bioethics committee (theologian, physicians, philosopher, law specialist).Patients signed informed consent, and the study was approved by the local Ethics Committee. The interviews were analyzed qualitatively using thematic analysis. This study is a part of POSDRU/89/1.5/S/61879 Project co-financed from European Social Fund through Human Resources Development Sectorial Operational Program 2007-2013. Results: Out of the 89 patients, 37% were Christian Orthodox, 5.6% Catholics, and 6.7% Protestants. These percentages are also reflected in the general population. All patients reached an efficient coping. 30% of them experienced inefficient coping periods such as frantically praying for a miracle, questioning God's love, hopelessness, blaming God for the disease, resignation (the disease was God's will), or interpreting cancer as a punishment. Patterns of efficient religious coping were: keeping the faith, and following Christ's example by combining suffering with trusting God. Some patients became more religious after the diagnosis, thus entering a process of spiritual awakening. They reinterpreted the disease as an opportunity for spiritual growth and study of religion. There was only one atheist patient, but his illness brought him to faith. The patients described bargaining with God as an efficient coping pattern. This is one of the phases in Elisabeth Kubler Ross' coping model. In *bargaining* the patient asks God to prolong his life or to allow him to take part in an important event in exchange for a Christian life. In our group, 38% of patients bargained for family-related matters (marrying, having children or grandchildren, seeing their children graduate), 7% bargained for profession-related matters, 2% committed to go on religious pilgrimages, and 17% did not reveal the subject of their bargaining. Some patients said that their religious coping was initiated by their priests (many priests advise patients to keep hoping and to maintain a positive atitude). However, other patients displayed a passive behaviour and accepted the disease as a fatality. Conclusion: It is important for the multidisciplinary team (oncologist, nurse, psychologist, theologian, social worker, family) that provide medical care to malignant patients to realize that religious coping is not always efficient, and to recognize the most common patterns of religious coping. It is recommended that when a member of the team identifies patients with inefficient religious coping, to refer those patients for specialized psychological or spiritual counseling.

1738

STUDY OF EFFECTIVENESS RECOMBINANT HUMAN ERYTHROPOIETIN AND QUALITY OF LIFE IN LYMPHOPROLIFERATIVE DISORDERS PATIENTS WITH ANEMIA

N Romanenko, I Slascheva, R Golovchenko, K Abdulkadyrov
Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Sant-Petersburg, Russian Federation

Background. Anemia in patients with lymphoproliferative disorders (LPD) is a frequent symptom and can influence the efficacy of antitumor chemotherapy, survival rate and overall quality of life (QoL). Red blood cell (RBC) transfusions are routinely used to treat anemia, while recombinant human erythropoietin (rHuEPO) treatment has been shown to significantly increase hemoglobin (Hb), reduce the number of RBC trans-

fusions and improve QoL in patients with chemotherapy induced anemia. Aims. To study the efficacy of rHuEPO and improving QoL in LPD patients with anemia. Methods. There were done this prospective study to investigate the effectiveness of rHuEPO in reducing RBC transfusion-dependency, increasing hemoglobin concentration and QoL in patients (n=83) with low-grade non-Hodgkin's lymphoma (n=18), chronic lymphocytic leukemia (n=21) and multiple myeloma (n=44). The median age of patients was 65.0 years (range 24-82). Recombinant human erythropoietin was injected subcutaneously on 450 IU/kg weekly. Before start of rHuEPO treatment all patients have being received two or more cycles of antitumor chemotherapy. The patients with Hb concentration <8.0 g/dl received RBC transfusions before rHuEPO treatment. The target Hb level was 12 g/dl and planned duration of rHuEPO treatment within 16 weeks. Positive response was estimated as increasing Hb concentrating <2.0 g/dl or achieving target Hb level (12 g/dl) during the period of rHuEPO therapy and so achieving RBC transfusion-independency. QoL was assessed using the FACT-An questionnaire. Results. Mean baseline Hb concentration was 8.73±1.53 g/dl (37-100 g/dl). Before rHuEPO-therapy 24 patients had received RBC transfusion (2-17 units) during last 3-6 months because of low Hb (3.7-8.0 g/dl). The period of rHuEPO-therapy was from 6 to 16 weeks (mean 9.0±3.4 weeks and median follow-up of 8.5 weeks). During the study period 7 patients (29.2%) followed RBC transfusions also after finishing of rHuEPO treatment and 17 ones of them (70.3%) showed RBC transfusion-independency. In whole group normal Hb concentration (<12.0 g/dl) showed 39 patients (47%). Whole we observed positive response in 53 patients (63.9%), Hb concentration increased from baseline to 12.4±1.19 g/dl (10.5-15.4 g/dl; p<0.01). However 4 patients who didn't receive transfusions before rHuEPO-therapy showed RBC transfusion-dependency because of their Hb fell down less 8.0 g/dl. The reason appearing of transfusion-dependency in these patients was progression of their diseases and so poor effectiveness antitumor therapy. FACT-An demonstrated that rHuEPO-therapy reduced symptoms such as: fatigue, force and physical efficiency, depression, drowsiness, giddiness, headaches, pain in thorax and dyspnea. On a scale from 0 to 4 points, the symptoms reduced from 1.79 to 1.28 in positive response patients indicating an improvement in QoL in the study patients (p<0.05; n=53). However we didn't observe any difference of the symptoms between before beginning and after finishing rHuEPO-therapy in non response patients (from 1.92 to 1.93; p>0.5; n=30); their Hb concentration wasn't changed significantly: from baseline to 9.03±1.99 g/dl (6.9-11.4 g/dl; p>0.1). Conclusions. The study has shown that rHuEPO is effective treatment of reducing RBC transfusion-dependency, increasing Hb and improving QoL in a group of anemic patients with lymphoproliferative disorders.

1739

THE EVALUATION OF EORTC QLQ-C30 AND ITS ASSOCIATION WITH ANXIETY AND DEPRESSION IN TURKISH MULTIPLE MYELOMA PATIENTS

B Karahan,[1] G Pamuk[2]
[1]*Trakya University Medical Faculty, Edirne, Turkey*
[2]*Trakya University Medical Faculty, Division of Hematology, Edirne, Turkey*

Background. Multiple myeloma (MM) patients have depression, anxiety and alterations in quality of life which could be explained by disease itself and by side effects of treatment modalities. AIMS: We evaluated quality of life, depression, anxiety, and their associations with parameters like patients' personal and demographic features and stage of disease. *Methods*. We included 50 (15 females, 35 males) MM patients (mean age, 61.8±9.1; median disease duration, 20.7 months) diagnosed according to IMWG criteria. Patients' age, sex, disease duration, disease type and stage, treatment modalities, and other medical data were recorded from hospital files. For staging purposes, ISS was used. The performance status of the patients were evaluated by means of the ECOG performance scale. Patients were administered EORTC QLQ-C30, EORTC QLQ-MY20, General Health Questionnaire (GHQ) and Hospital Anxiety and Depression Scale (HADS). In order to compare categoric variables, Chi-square test and to compare continuous variables, unpaired-t-test were used. Pearson correlation test was utilized for correlation analysis. Multiple linear regression analysis was used to determine independent factors which affected EORTC QLQ-C30. *Results*. The monoclonal protein was IgG in 22 (44%) of MM patients, IgA in 17 (34%), light chain kappa in 6 (12%) and light chain lambda in 4 (8%). Patients in early (stages I, II) and late (stage III) ISS stages were similar in functional scales, symptom scales, global QoL, subscales of EORTC QLQ-MY20, and HADS-A and HADS-D scores. When MM patients with good (ECOG 0, 1) and poor (ECOG 2 and higher) performance status were compared, it was observed that the functional and symptom scales of EORTC QLQ-C30, global QoL, subscales of EORTC QLQ-MY20, and HADS-A and HADS-D scores were significantly different (p values <0.05). Patients with HADS-D scores >7 were accepted to have depression. The functional and symptom scales of EORTC QLQ-C30, global QoL, subscales of EORTC QLQ-MY20, and HADS-A were significantly different between patients with HADS-D scores >7 and ≤7 (p values <0.001). The physical functioning (OR, 2.53; 95%CI, 1.7-5.8; p=0,001) and role functioning (OR, 4.09; 95%CI, 2.3- 45.5; p=0.03) scores of EORTC QLQ-C30 were independent factors which had positive effect on general quality of life. The treatment-related side effect score of EORTC QLQ-MY20 (OR, -3.2; 95%CI, -4.9 to -1.4; p=0.001) and the presence of depression as assessed by HADS-D (OR, -4.4; 95%CI, -2.6 to -0.4; p=0,007) were factors which had negative effect on general quality of life. *Conclusions*. The performance status as assessed by ECOG, presence of anxiety and depression were associated with quality of life and severity of symptoms in Turkish MM patients. The presence of depression in HADS-D was an independent prognostic parameter which had negative impact on general quality of life score. The factor which had the greatest negative influence on quality of life in MM was observed to be the treatment-related side effect score of EORTC QLQ-MY20.

ERYTHROPOIETIN USE IN PATIENTS WITH AML OR UNDERGOING ALLOGENEIC HSCT SIGNIFICANTLY IMPROVES QUALITY OF LIFE AND REDUCES RED BLOOD CELLS AND PLATELETS TRANSFUSIONS WITHOUT ANY SURVIVAL EFFECT

M Michallet, K Goldet, S Morisset, M Sobh, Y Chelghoum, X Thomas, H Labussiere, S Ducastelle, F Barraco, M Detrait, G Cannas, C Paillet, C Renzullo, C Pivot, P Badol-Van Straaten, A Denis, A Termoz, F Nicolini, I Jaisson-Hot
Edouard Herriot Hospital, Lyon, France

Background: Despite frequent anemia and multiple transfusions during allo-HSCT, recommendations and marketing authorization for EPO use are still missing.Aims: In this prospective study, as primary objective, we evaluated the effect of EPO on patient's quality of life (QOL). Secondary objective was hemoglobin (Hb) recovery. In addition, a paired matched analysis was conducted to compare platelets (Pt) and red blood cells (RBC) transfusion number. Material and methods: We included adult patients with Hb level ≤11g/dl induced after allo-HSCT for any hematological disease. EPO (NEORECORMON® 30000IU) was administered Sc. once/week during a maximum period of 6 months; Hb level was monitored every week. Injections were stopped once Hb level reached 12g/dl without any transfusion. If after 4 injections, no improvement was observed, doses were doubled, and if after 8 injections, no improvement was observed, patient was taken off-study for EPO inefficiency. The QOL was measured at baseline, at 1, 2, 3 and 6 months by the Functional Assessment of Cancer Therapy-Anemia (FACT-An). EPO responders patients were defined as having Hb level ≥12g/dl (EPO CR) or a ≥ 2g/dl increase [EPO partial response (EPO PR)] compared with baseline value without any transfusion requirement. The matching analysis took into account: diagnosis, conditioning, HSC source, number of previous transplants and GVHD. Results: Between April 2006 and December 2009, 61 patients were included, patient characteristics are summarized in Table1. The median number of EPO injections/patient was 8 (2 - 28). We have noticed a trend for improvement of QOL during the 6 months follow-up according to FACT-An anemia (p=0.07). There were 71% of EPO CR after a median time of 39 days (14 - 180). After the pair-matched analysis, 44 patients were matched with at least one case-control patient. When comparing RBC and Pt transfusions, there were 355 units and 555 units in the matched population versus 227 and 574 and in the EPO population p=0.004 and p=0.6 respectively. The multivariate analysis on EPO CR showed the positive impact of Pt levels at baseline, the negative impact of female recipient and major ABO incompatibility. We did not find any significant difference in terms of overall (OS) and event free survival (EFS) between EPO and control group. Conclusion: We showed a positive trend of EPO administration on QOL, an achievement of a normal Hb level and a significant spare of RBC transfusions. A cost-effectiveness study is ongoing and results will be communicated.

1741

COGNITION AND QUALITY OF LIFE IN ADULT *DE NOVO* ACUTE LEUKEMIA PATIENTS

S Verleden, K Audenaert, L Noens
UZ Ghent, Ghent, Belgium

Background. A significant percentage of cancer patients will develop cognitive impairment, during or after completion of aggressive treatment. Cognitive deficits are usually subtle and mild, but can occur in various cognitive domains. In AML/MDS patients, impaired cognitive functions have been described, even prior to initiation of chemotherapy. In addition, classical side-effects of aggressive chemotherapy in patients with acute leukemia can have a significant impact on quality of life and on emotional aspects of well-being. Aims: To measure baseline cognitive functions and short-term cognitive evolution, and to assess depression, emotional well-being, and quality of life in de novo acute leukemia patients before and after induction treatment. Methods: Longitudinal-prospective study of adult de novo acute leukemia patients, treated with chemotherapy. This study was approved by the local Ethical Committee and informed consent for each patient was obtained. Eligible patients were enrolled and investigated with a comprehensive cognitive test battery, within five days after admission (pre-induction) and after completion of induction (pre-consolidation). Cognitive functions assessed are attention, executive functions, motor dexterity, and also verbal memory. Depression, emotional aspects of well-being, and quality of life were assessed with self-report questionnaires. *Results*. Twenty adult patients were enrolled between 01/2009 and 06/2010. The median age was 43 years, 50% were male, 80% had AML (20% ALL), and median duration of education was 12 years. Baseline hematological values were assessed, with WBC count (10,4 10E3/uL), RBC count (3,1 10E6/uL) and HgB (9,8 g/dL). Adult patients had normal cognitive functions (range: 1 SD below normative mean) in different cognitive domains, and mainly in attention and executive functions (COWAT, and SCWT), except for mild cognitive deficits in verbal learning (AVLT A1-5), and also especially in motor dexterity (PPT). These functions were heterogeneous at baseline, ranging from severely impaired to good within a cognitive domain. In particular, at baseline low quality of life and role functioning, and a high level of fatigue were found. Global health status related with social functioning, and role functioning related with fatigue. At follow-up, attention, executive functions, motor dexterity, and verbal learning had all improved significantly ($p \leq 0.02$). Changes during chemotherapy treatment were found in depression ($p<0.005$), global health status ($p<0.001$), emotional functioning ($p<0.001$), and symptom scales fatigue ($p \leq 0.05$) and pain ($p<0.01$), and all five scales of well-being ($p<0.05$) (CES-D, EORTC QLQ-C30, and POMS). Global health status related with four of the five functional scales, except for cognitive functioning, and with symptom scale fatigue. Global health status related with depression and vigor. Conclusions: Adult de novo acute leukemia patients exhibit at baseline normal cognitive functions, except for verbal learning and motor dexterity. Cognitive deficits in attention, executive functions, and verbal learning were found similar to previous reported research. However, our data showed less impaired motor dexterity. Moreover, cognitive functions improved at follow-up. At baseline, adult de novo acute leukemia patients have low quality of life, high levels of depression and negative status of well-being. Changes over time, were observed across global health status, dimensions of quality of life, depression, and emotional aspects of well-being.

1742

PROSPECTIVE EVALUATION OF ORAL MUCOSITIS BY DAY-BY-DAY ASSESSMENT IN HEMATOLOGICAL PATIENTS UNDERGOING STEM CELL TRANSPLANTATION

A Tendas,[1] P Niscola,[1] L Cupelli,[1] D Dentamaro,[1] F Efficace,[2] P De Fabritiis,[1] W Arcese[3]
[1]*S. Eugenio Hospital, Hematology, Rome, Italy*
[2]*Health Outcomes Research Unit, GIMEMA Data Center, Rome, Italy*
[3]*Hematology, Policlinico Tor Vergata, Rome, Italy*

Background. Oral mucositis (OM) is a major issue in the setting of hematopoietic stem cell transplantation (HSCT), with serious effects on quality of life. Aim. A prospective observational study was conducted in our BMT Unit to assess the pattern and severity of OM and GIM in patients (pts)

Methods. Assessment of OM in patients (pts) undergoing autologous (auto) or allogeneic (allo) HSCT was conducted daily from conditioning regimen to day +20 or discharge. OM was assessed according to WHO scale. Results. 60 HSCT (10 alloHSCT, 50 autoHSCT) were performed from January 2008 to Agoust 2010 (high dose chemotherapy conditioning regimen), in adult patients with lymphoma (n=21), multiple myeloma (n=29), acute leukemia (n=8) or other diagnosis (n=2). All patients received high dose chemotherapy as conditioning regimen, according to the international guidelines for lymphoma or myeloma. OM prevention measures were: in allogeneic HSCT, mouth rinses alone (clorexidine based); in autologous HSCT, mouth rinses (clorexidine based) alone or associated with probiotics (Lattobacilus brevis CD2) in 43 and 7 pts, respectively. Oral criotherapy was associated in 42/50 pts undergoing intermediate-high dose melphalan-based conditioning regimen and autoHSCT. 57/60 HSCT were eligible for analysis. Data about OM are presented in table. Prevention of OM with oral criotherapy in autoHSCT (high dose melphalan conditioning in myeloma pts only) resulted on reduction of severe OM (grade 3-4). Data about OM prevention with probiotics are encouraging, although preliminary. *Conclusions*. Although preliminary, these data may be helpful to define the impact of OM on patients undergoing high-dose chemotherapy and evaluate preemptive and treatment approach of this complication, with the primary aim to improve patients quality of life.

1743

ACUTE AND CHRONIC STRENUOUS EXERCISES ALTER ANTIOXIDANT STATUS IN HEMOGLOBIN E TRAIT CARRIERS

A Palasuwan,[1] S Soogarun,[2] D Suksom,[3] I Margaritis,[4] A Rousseau[5]
[1]*Chulalongkorn University, Bangkok, Thailand*
[2]*Faculty of Allied Health Sciences, Chulalongkorn University, Bangkok, Thailand*

[3]*Faculty of Sport Sciences, Chulalongkorn University, Bangkok, Thailand*
[4]*French Agency for Food, Environmental and Occupational Health Safety (ANSES), Maisons-Alfort, France*
[5]*Faculty of Medicine, University of Nice Sophia-Antipolis, Nice, France*

The question of whether Hb E trait carriers are exposed to exercise intolerance at biochemical (antioxidant and oxidative damage) and physiological (physical fitness) levels is addressed. First, 10 Hb E trait(21.2±0.6 yrs) and 10-paired normal Hb (21.4±0.5 yrs) participants performed a maximal oxygen uptake test (VO2max) on a treadmill. Second, 16 Hb E trait (15.6±1.8 yrs) and 16-paired normal Hb E (15.6±1.9 yrs) athletes participated in a 10-week training camp. In Hb E trait, the activity of erythrocyte glutathione peroxidase (GPx) failed to recover after 45 minutes of rest (p=0.049). In both groups of athletes, the training camp allowed to improve anaerobic capacity and maximal muscular strength but depression score was increased and VO2max was decreased. Activities of plasma and erythrocyte GPx and erythrocyte superoxide dismutase were higher at the end of the training camp compared to before (p<0.001). Plasma GPx increase was higher in Hb E (p=0.002) compared to normal Hb athletes. We conclude that Hb E trait could explain inter-individual variability in blood antioxidant markers in response to exercise. Proper training programs (suitable training load and recover) should be of importance concerning Hb E carriers.

1744

FUNCTIONAL HEALTH STATUS ASSESSMENT IN HAEMOPHILIA PATIENTS WITH THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH (ICF, ICF-CY)

S Riva,[1] A Gringeri,[1] F Fusco,[1] M Bullinger,[2] S Von Mackensen[2]
[1]*University Hospital of Milan, Milan, Italy*
[2]*University of Hamburg, Hamburg, Germany*

Background. People with haemophilia experience a progressive deterioration of their functional health status. Its rRegular clinical assessment of functional health status provides insight into their process of disablement. As such, the development of a core-set of measurement tools is warranted. AIM: The aim of this the study was to gather data to identify clinically feasible items from existing haemophilia-specific instruments assessing the functional health status and Quality of Life (QoL) of haemophilia patients using the ICF for adults and children, (ICF-CY) frame. *Patients and methods*: Five haemophilia-specific instruments were linked to the ICF separately by 3 trained health professionals according to linking rules developed specifically for this purpose. The degree of agreement between health professionals was calculated by means of the kappa statistics. Bootstrapped confidence intervals were estimated. *Results*: Within the 5 selected instruments 365 concepts were identified, of which 283 concepts were linked to the ICF and ICF CY and mapped into 70 different categories. The estimated kappa coefficients ranged between 0.85 and 0.88. 19 Nineteen categories were included for body function (27%), 4 for body structure (6%), 35 for activities and participation (50%) and 12 for environmental factors (17%). High prevalence in health areas corresponding to ICF and ICF-CY categories for activities and participation were reported for mobility, work, school, sport and social activities. Environmental factors included in the instruments were health economic aspects such as treatment, assistive products for mobility and transportation, and restriction/facilitation in accessing health resources. *Discussion*: The results of This work may contribute to the formation of a preliminary core set of instruments to assess the functional health status of patients with haemophilia (children and adults) giving providing a new insights tool not only for clinical studies but also for epidemiological and health economics studies.

1745

QUALITY OF LIFE IN ACUTE LEUKEMIA PATIENTS

O Korobitsyna,[1] I Shmunk,[2] A Korobkin,[3] M Rusakov,[4] M Zacharova,[3] M Kiseleva,[3] Y Markova,[3] M Lubchenko,[3] O Kalev[1]
[1]*Chelyabinsk State Medical Academy, Chelyabinsk, Russian Federation*
[2]*Chelyabinsk Regional Haemotransfusion Station, Chelyabinsk, Russian Federation*
[3]*Chelyabinsk Regional Clinical Hospital, Chelyabinsk, Russian Federation*
[4]*Chelyabinsk State City Hospital #1, Chelyabinsk, Russian Federation*

Background. Quality of life is now considered an important outcome measuring in patients with malignancies. *Aims*. The aim of our study was to examine the relationship between self-reported quality of life and some clinical, socio-demographic and psychological factors in acute leukemia patients. *Methods*. 63 patients of 15-69 years of age (Median 42 years) with newly diagnosed Acute Myeloid (n=42) or Acute Lymphoid Leukemia (n=21) admitted to a Central Regional Hospital for treatment were eligible. The Linear Analog Self-Assessment was used as an instrument for quality of life examination. Infections, hemorrhage/bleeding, severe anemia (HBG<7.0g/dl), central nervous system leukemia, age, income, education, family status, social support and depression were investigated in their relationship to a self-reported quality of life. The Hospital Anxiety and Depression Scale (HADS) was used for the depression screening. The data were collected shortly after the diagnoses and after induction of remission therapy. The inform consent was obtained from every patient. *Results*. 33 patients were eligible early after the diagnosis. Their Mean Quality of life score was 53.5. The self-reported quality or life did not depend of the clinical course of the disease (such as severe anemia, bleeding, central nervous system leukemia, infections. But quality of life was significantly worse in patients older then 50 years old (t-test, p=0.03) and in depressed patients (p=0.0003). 60.6% of patients (n=20) met the depression criteria early after the diagnosis. After induction of remission therapy 30 patients were eligible. Most of them (n=23) achieved complete remission. Mean Quality of life score was 69.7 at this period of treatment. 46.7% of patients (n=14) reported depression. The self-reported quality of life measuring after induction of remission therapy did not depend of such complications of the treatment as bleeding, pneumonia, mucositis, hepatitis, enteropathy, nausea. This complications were successfully treated (antibiotics, anti-emetics, transfusions, etc.) Quality of life was significantly poorer in patients who had febrile neutropenia (p=0.01), age older then 50 years(p=0.006), low social support score (p=0.045), singe family status (living alone) (p=0.01) and depression (p=0.001). Quality of life of patients with different education level and different income level were not significantly different (p=0.18 and p=0.7 respectively). The income level did not differ much between patients. *Conclusions*. Self-reported quality of life of newly diagnosed acute leukemia patients was significantly poorer in patients with depression or low social support level, and patients older then 50 years old. Depressive symptoms are prevalent.

1746

IMPACT ON QUALITY OF LIFE OF OUTPATIENT TREATMENT IN HIGH RISK MYELODYSPLASTIC SYNDROMES: RESULTS OF A PILOT STUDY

T Comont, P Cougoul, M Thiercelin-Legrand, V Sekkai, K Delavigne, O Beyne-Rauzy
Purpan Universitary Hospital, Toulouse, France

Background. quality of life (QoL) in myelodysplastic syndromes (MDS) depends on various factors: global health status, social setting, disease characteristics (anaemia). Moreover uncertain evolution of the disease induces emotional distress that impacts on QoL and patients experienced a high level of fatigue. Treatment of anemia with erythropoiesis stimulating agents (ESA) or hypomethylating agents, depending on the status of the disease, will improve patient functional status and quality of life. Purpose: few data are available to know if home treatment improves patient QoL: 102 patients with advanced colon cancer were treated with chemotherapy either in outpatient or inpatient care(1). QoL was improved in outpatient group as well as social function score. In hematological issue one study including 41 patients in bone marrow transplantation2 showed benefit of home treatment in term of QoL. No data are available concerning outpatient MDS treatment. *Patients and methods*: 40 patients were included in a single center, 20 patients receiving chemotherapy at home and 20 patients at hospital, matched on gender and age. Quality of life (QoL) assessment was performed using EORTC QLQ-C30. In addition locus of control, stress and mental adjustment strategies were evaluated (using MAC 44, CLCS and stress scale). Results: mean age was 70 years. No difference was found between the 2 groups excepting stress which was higher in female than in male. 50% of patients who received treatment at hospital would like to change. At the opposite 80% of patients treated at home prefer to continue A negative correlation was found at home between age and stress and a positive correlation between number of person at home and stress. Conclusion and perspectives: better knowledge of relevant factors which determine QoL in this population as family, caregivers, distress, and strategy of adjustment will be necessary. Larger number of patients is needed to better understand underlying conditions that could affect QoL.

1747

FREQUENCY AND SIGNIFICANCE OF PSYCHIATRIC DISORDERS IN HEMATOLOGICAL AND NONHEMATOLOGICAL MALIGNANCIES

M Balea, D Georgescu, O Patranoiu, M Balea, A Sarampoi
Colentina Hospital, Bucharest, Romania

We investigated the frequency of anxious-depressive psychiatric disorders (anxiety and depression) in subjects with hematological and non-hematological malignancies; we evaluated 1031 subjects hospitalized in the past 30 months, among them 615 (59.65%) were diagnosed with non-hematologic malignancies, 341 (39%) were diagnosed with malignant hematologic disease and 75 (7.35%) were diagnosed with cancer and hematologic manifestations; frequency of mental disorders in subjects with hematological malignacies was 39%, statistically significantly different ($p < 0.0001$) of frequency of mental disorders in subjects with depressive anxious and non hematological malignancies: 26.5%; In the subjects with hematological malignant diseases, we identified a 25% frequency of psychiatric disorders in subjects with acute myeloproliferative disorders, 40% in subjects with acute lymphoproliferative disorders, 23.5% in subjects with MDS, 33.75% in subjects with chronic myeloproliferative disorders, 44.96% in subjects with chronic lymphoproliferative disorders, 46.6% in subjects with Multiple Myeloma ; Note a frequency of only 21.33% of anxious depressive psychiatric disorders in subjects with para neoplastic disease (39% in hematologic malignancies, 23.33% in para neoplastic hematologic manifestations:$p < 0.01$). In the non malignant hematologic diseases lower incidence of mental disorders has been identified in autoimmune hemolytic anemia (10.3%) and highest incidence was found in Anti Phospholipid syndrome (49.5%) ($p < 0.01$). Impact of psychiatric disorders in non-hematological and hematological malignancies was significant in terms of quality of life, therapeutic compliance. Impact of the prognosis will be estimated by expanding the lot and monitored the dynamics analysis; in terms of APL syndrome, high frequency of mental disorders is an argument for APL antibodies involvement in the pathogenesis of neuro psychiatric disorders; Phase of study conclusions indicate depressive mental disorders associated with hematological malignancies anxious to represent a significant factor influencing quality of life, therapeutic compliance and possibly prognosis of these diseases, requiring strong multidisciplinary approach.

1748

USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE IN CHILDREN WITH CANCER: REPORT OF A BELGIAN CENTER FOR PEDIATRIC HEMATOLOGY ONCOLOGY

C Chantrain, N Servais, F Zech, C Vermylen, B Brichard
Cliniques Saint-Luc, UCL, Bruxelles, Belgium

Background: Complementary and alternative medicine (CAM) is a heterogeneous group of products, practices, medical and health care systems defined as not presently part of the conventional medicine. For the last decades, the use of CAM has become increasingly frequent, particularly in children with chronic illness and cancer in whom CAM is commonly reported along with conventional care. Aims: To define better the actual place of CAM in children with cancer in Belgium and to understand better the circumstances of their use and the expectations of patients and families using CAM, we have realized an observational study in children treated at the pediatric hematology oncology department of the Saint-Luc University Hospital in Brussels. Methods: A questionnaire was distributed to parents of children diagnosed with cancer between January 1st 2003 and December 31st 2009, who were not deceased or in palliative care. The participation was volunteer and the study was approved by the hospital's ethical committee. Results: The survey was sent to 301 families of patients aged from 0 to 21 years at the time of diagnosis. 153 questionnaires (50,8%) were returned and analyzed. In these, the prevalence of CAM use was 63 % (55% after excluding prayer and psychotherapy). For 21,5% of users, CAM therapy was initiated prior to cancer but maintained or expanded during or after conventional treatments. 58,1% of patients used CAM for the first time during conventional treatments and 20,4% started CAM after conventional treatments. The most frequently used CAM were homeopathy (24%), massage therapy (16,2%), dietary supplements (15,6%). The most common expectations of users were an improvement of the child's wellness (22%), a decrease of the side effects of conventional treatments (13,9%) and a reinforcement of immunity (12,4%). Parents reported benefits in 90,5% of cases although negative effect was described in 10% of cases. The duration of use was 1-3 months in 13,9%, 3-6 months in 11,3%, 6 months-1 year in 18,3% and > 1 year in 46,1% of users. The frequency of use depends on the type of CAM: alternative medicines such as homeopathy were mainly used daily while manipulative and body-based methods such as massage were commonly administrated on demand. Despite a full agreement on conventional treatment, 55% of families did not disclose their CAM use to their physician. Factors as age, sex, type of tumor, place of residence or prior CAM use were not predictive for use of CAM. However, we find a significant correlation with the level of education of the mother and/or the main person in charge of the child. Conclusions: CAM is part of the treatment in a large number of children with cancer. It is commonly perceived as safe by patients and families but its undisclosed combination with conventional therapies increases the risk of drug interaction and could interfere with the analysis of clinical trials. This work underlines the necessity for physicians, CAM users and practitioners to improve their communication. Such attitude could also allow a better study of CAM efficacy.

1749

A WAY TO REDUCE PAIN IN BONE MARROW DIAGNOSTIC PROCEDURES

F Carretero López, J Anguita Velasco, M Infante,
I Gonzalez Gascon y Marin, L Bento de Miguel, JL Diez Martin
Hospital General Universitario Gregorio Marañon, Madrid, Spain

Background. Bone Marrow core biopsy and aspiration represents a standard procedure in diagnosis and staging of hematological malignancies. Attempts to reduce pain during aspiration and biopsy procedure have led to the development of new techniques such as electrically powered devices.

The use of these devices may reduce pain in bone marrow aspiration. Nevertheless there is no protocolized clinical studies comparing different pain scores using this new technique. versus manual techniques. *Aims*: The objective of this randomized, protocolized, single blind study is to measure the seconds it takes for the needle to penetrate the skin and reach the bone marrow just before aspiration and measure the pain produced by this technique compared to manual bone marrow aspiration. *Methods*. 30 patients 18 men and 12 women were selected, and randomized into 2 groups. In the group 0 (n=15) powered aspiration (Vidacare battery powered device) was applied whereas in group 1 or control (n=15), aspiration was performed with a manual device (Cardinal Health Illinois Bone Marrow Needle). Every patient received subcutaneous 2% Mepivacaine in the punction area. Time from the cortical contact to aspiration was measured in seconds. Previous pain and pain during insertion were registered according to the Patient Pain scale in which 0 is absence of pain and 10 is the most extreme pain. In order to evaluate the pain reduction a new parameter called Pain Reduction was obtained by subtracting previous pain minus pain during insertion. Statistical analysis was performed throug non parametrical tests for unpaired data. *Results*. Time to aspiration was lower and pain reduction was higher on the electronically powered device ($p=0.025$ and $p=0.001$ respectively) compared to control group. *Conclusions*. The use of ellectrically powered device has shown in our series a significative reduction in operational biopsy time, as well as a pain reduction compared to traditional manual devices.

1750

CHLORPROMAZINE PLUS METHOCLOPRAMIDE AND PREDNISONE IS COST-EFFECTIVE IN CONTROL OF LATE HEMESIS IN PATIENTS PRETREATED WITH PALONOSETRON THAN IN THOSE TREATED WITH TROPISETRON

G Giordano, R Tambaro, M De Maria, G Sticca, C Di Falco
Center John Paul II, Catholic University, Campobasso, Italy

Background. Late hemesis is often difficult to resolve, especially when patient received highly hemetogenic chemotherapy regimens. Data regarding the most useful drug to employ in late hemesis on the base of the type of anti HT3 drug previously used in acute hemesis (palonosetron or tropisetron) are lacking. *Aim.*Aim of this study is to define which is the best cost-effective antihemetic therapy in late hemesis when palonosetron or tropisetron are used in acute hemesis in the same type of patient. *Methods.* This study is a prospective monocentric study. We considered 95 patients in period June 2007- January 2011, receiving highly and moderate hemetogenic chemotherapeutic regimens for haematologic malignancies. 50 patients (5 HD, 25 NHL, 6 ABMT, 14 AML) received tropisetron 2 mg tid i.v. until 48 hours after the end of chemotherapy. Of these 15 received DHAP-like regimen, 15 received IGEV, 6 BEAM and 14 "3+7"regimen. M/F was 28/22 and median age was 65 years (R30-75). 45 patients (4HD, 26 NHL, 5 ABMT, 10 AML) received palonosetron 250 mcg i.v. day 1 of chemotherapy. Of these 20 received DHAP-like regimen, 10 received IGEV, 5 BEAM and 10 "3+7"regimen. M/F was 26/19 and median age was 67 years (R28-76). All chemotherapy regimens were of 5 or 7 days of duration. If patients presented nausea and vomiting 48 hours after the end of chemotherapy, they received dexametason 4 mg + methoclopramide 20 mg i.v. tid. If nausea and vomiting persisted, they added largactil 12.5 mg i.v. tid. Results were evaluated by Fisher exact test. A cost analysis was performed considering the median of global direct and indirect antiemetic expense for each patient. *Results.* Out of 45 patients receiving palonosetron, 5 had late hemesis, 4 requiring chlorpromazine and all responded to treatment. Out of 50 patients receiving tropisetron, 8 had late hemesis, 6 requiring chlorpromazine and only one responded to treatment.No difference were noted in late hemesis between palonosetron and tropisetron (two tailed Fisher text p 0.56). Chlorpromazine was effective in control of late hemesis mainly in palonosetron group (two tailed Fisher text p 0.046) Only observed side effect was a slight drowsiness in all patients receiving chlorpromazine. In palonosetron group, median global antiemetic direct expense for each patient was 107.25euro (R107.25-834.53), while in tropisetron group was 410.5euro (R30-515). Median antiemetic indirect expense was 20 euros in palonosetron group, while in tropisetron group was 280 euros .*Conclusions.* In this study chlorpromazine in association with methoclopramide and dexametason is cost effective in management of late hemesis of patients treated with palonosetron and receiving moderate and highly hemetogenic chemotherapy regimens for 5-7 days.

1751

CONTRIBUTION OF AGE, GENDER, BODY WEIGHT, CYP2C9, CYP4F2 AND VKORC1 GENOTYPE TO THE WARFARIN ANTICOAGULANT RESPONSE IN OMANI PATIENTS

A Pathare,[1] S AlZadjali,[1] S Alkindi,[1] M AlKhabori,[1] V Panjwani,[1] R Misquith,[1] S Ganguly,[1] A Paldi,[1] R Krishnamoorthy[3]
[1]*Sultan Qaboos University, Muscat, Oman*
[2]*Genethon, Paris, France*
[3]*INSERM, U763, Paris, France*

Objectives. The objective of this study is to assess the contribution of age, gender, body weight, CYP2C9, CYP4F2 and VKORC1 genetic variants to the warfarin dose requirement in the Omani patients. Methods: Blood was collected from 240 Omani patients taking warfarin daily and on stable anticoagulation with INR values between 2 to 3 at 3 consecutive readings, after an informed consent. The genetic polymorphisms of warfarin dose influencing loci (CYP2C9, CYP4F2 and VKORC1) were studied and the demographic factors (age, sex, weight) were recorded. Results: CPY2C9 genotyping (mutant alleles - *2, *3 & *8) showed that 73.2%, 23.5% and 3.3% of these patients were homozygous for wild type allele, heterozygous and homozygous or compound heterozygous mutant allele respectively. VKORC1 (g.-1639G>A) genotyping showed that 46.6%, 44.5% and 8.9% of these patient had GG, GA or AA genotype respectively. Patients with VKORC1 (g.-1639GG+GA)and CYP2C9 *1/*1 genotypes respectively required 5.5+3.8 mg/day and 5.42+4.2 mg/day ,which was significantly higher than in those with -1639 AA (2.5+1.3 mg/day; p <0.05) or CYP2C9 homozygous or double heterozygous *2 or *3 (2.5 + 1.6 mg/day; p<0.05) genotype. Univariate analysis revealed that age, weight, CYP2C9, and VKORC1 g.1639AA were significantly associated with warfarin dose. However, the multiple regression model for warfarin dose indicated that a significant contribution to the warfarin dose was seen only from age (r2=0.0208; p=0.02), CYP2C9 (r2=0.0144; p=0.046) and VKORC1AA genotype (r2=0.154; p=000).Conclusions: The study showed that although age, weight, CYP2C9, and VKORC1 polymorphisms affect the warfarin dose requirements in univariate analysis, stepwise regression analysis model showed that only VKORC1 was the dominant predictor of warfarin dose requirement overshadowing all other variables. Therefore, VKORC1 AA is the most important factor to consider while using dosing algorithms to improve safety of warfarin therapy in Omani patients.

IMPROVING STANDARDS OF CARE FOR HAEMOGLOBINOPATHIES IN A LOW PREVALENCE REGION

C Chapman,[1] M Donohue,[2] D Pulford,[1] J Currington[3]
[1]*Leicester Royal Infirmary, Leicester, UK*
[2]*Nottingham University Trust, Nottingham, UK*
[3]*East Midlands Commissioning Group, Nottingham, UK*

Births of patients with major Haemoglobin disorders tend to be concentrated in a few urban areas throughout the UK. This has led to the development of some highly specialised centres for the care of patients in these areas. However in areas of lower prevalence, services may be poorly developed, coordinated and funded, leading to inequalities in access to care for affected patients. Progress in the roll out of antenatal and neonatal screening programmes, publication of peer reviewed national standards of care, information on systems failures from the NCEPOD report on deaths of patients with haemoglobin disorders and Dept of Health funded review of services, have all contributed to a drive to commission effective services in low as well as high prevalence areas.We report an initiative by the East Midlands Commissioning Team, to support a multidisciplinary hub and spoke network of services for patients throughout the East Midlands, with outreach services from two linked centres to surrounding areas. The £250k package supported the appointment of a data manager, two WTE hospital based nurse specialists and support for roll out of the regional transcranial Doppler (TCD) and psychology support services. Within a year a regional database has been established, >50% patients have been recruited to the newly established National Haemoglobinopathy Register, the EMidlands TCD service has achieved 100% coverage of the main centres, with outreach service for small centres available from 2011, development and access to agreed regional guidelines for acute management of sickle crises, positive report of nationally run peer review of children's services, impact of nurses on outpatient non-attendance, as well as an annual report to commissioners. Novel approaches to the use of scarce resources are being developed (eg screening assessement tools for referral to psychology services, assisted regional audit, and education material). The process has contributed to the concept of developing a national commissioning tool for haemoglobinopathy services, which will outline standards of care and services that must be provided in all areas. These will be available for use by any commissioning structure that emerges from NHS reforms in the UK.

REVIEW OF OUT OF HOUR COAGULATION SCREEN REQUESTS IN TWO UNIVERSITY TEACHING HOSPITALS

S Arami,[1] C Foley,[2] J Hanley[2]
[1]*Freeman Hospital, Newcastle upon tyne, United Kingdom*
[2]*Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom*

Background. Coagulation screens are invaluable tests for diagnosis and investigation of congenital or acquired bleeding disorders. They designed to provide rapid non-specific information, which allows an initial broad categorization of haemostatic problems. Unfortunately false positive or negative results are common. Haematologists are frequently contacted by other teams for abnormal coagulation screens and authorisation of such results is part of their daily duty. It is very important that these tests to be requested properly and results explained in the context of clinical condition. Anecdotal studies indicated that irrelevant requests and lack of clinical details on request forms are more common in out of hour requests. *Methods*. We retrospectively analysed out of hour coagulation screens requested between Wednesday 13.05.2010 and Monday 18.05.2010 in Royal Victoria Infirmary and Newcastle General Hospital- both teaching university hospitals in Newcastle, UK. Relevant information obtained

from request forms, patients notes and laboratory electronic data. *Results*. There were total of 321 requests 139 (43%) were form A&E, 52 (17%) from ICU, 51 (16%) were from medical, 40 (12%) were form surgical, 24 (7%) were from paediatrics and 15 (5%) were from obstetric and gynaecology. 163 (51%) had irrelevant clinical details and 96 (30%) had relevant information. There were no clinical details available on 62 (19%) requests, most commonly from A&E (46%). Only 49 (15%) screens yielded abnormal results. *Conclusions*. These results indicate a large number of irrelevant requests. They also show a considerable amount of forms either with no clinical details or irrelevant information. Such unnecessary or poorly informed requests waste a significant laboratory and clinical time and could potentially raise the need for further detailed investigations. Eventually this can result in more costs, delay in patients' discharges and further unnecessary stress to patients and workload to staff. Moreover lack of proper clinical details and irrelevant requests would affect the outcome of sample authorization reports by haematologists.

AN AUDIT OF COAGULATION SPECIMENS REQUIRING DIRECT HUMAN INVOLVEMENT AT AN ACADEMIC LABORATORY

J Joubert,[1] P Badenhorst,[2] C Conradie[1]
[1]*NHLS, Bloemfontein, South Africa*
[2]*University of the Free State, Bloemfontein, South Africa*

Background. Currently there is an increasing trend towards automation in the laboratory testing of coagulation. Some coagulation specimens cannot be summarily tested in currently utilized fully automated systems because of suboptimal pre-analytical influences, such as underfilled tubes, that would yield spurious results. Other specimens require additional sample preparation, such as double centrifugation, before testing. *Aims*. To determine what proportion of specimens received by the coagulation section of the Universitas Academic Laboratory required direct human involvement for screening and/or additional sample preparation prior to testing and to analyze the contributing factors. Methods: All specimens received for coagulation testing from 1 December 2008 to 30 September 2009 were audited. Specimens inspected by technologists and found to be under-filled, clotted, collected in incorrect specimen tubes, lipaemic, icteric, haemolysed, from patients with haematocrits >0.55 L/L, old (>4 hours since sampling), unlabelled or incorrectly labelled, and specimens for lupus anticoagulant or activated protein-C resistance (APCR) testing (both requiring double centrifugation), were recorded in a logbook on a daily basis. *Results*. Of the 8614 specimens received, 1091 (12.7%) fell into one or more of the categories. Underfilled: 246 (2.9%); clotted: 148 (1.7%); collected in incorrect specimen tubes: 127 (1.5%); lipemic: 8 (0.1%); icteric: 43 (0.5%); haemolysed: 75 (0.9%); from patients with haematocrits >0.55: 2 (0.02%); old (>4 hours since sampling): 160 (1.9%); unlabelled or incorrectly labelled: 20 (0.2%); lupus anticoagulant: 347 (4.0%); activated protein-C resistance (APCR) testing: 6 (0.1%). In total, 353 (4.1%) required additional sample preparation (double centrifugation) and 829 (9.6%) required screening to avoid spurious results. *Conclusions*. A substantial proportion (12.7%) of specimens received for coagulation testing required direct human involvement prior to testing and would not have been suitable for testing in currently utilized fully automated systems. Of these specimens, 9.6% were subject to suboptimal pre-analytical influences and would have yielded spurious results had they been summarily tested in a fully automated system. Strategies must be developed to prevent this phenomenon

MICROSCOPIC EXAMINATION OF BONE MARROW ASPIRATION SMEARS: DIAGNOSTIC AGREEMENT OF HEMATOLOGISTS AND HEMATOPATHOLOGISTS ON COMMON HEMATOLOGICAL DIAGNOSES

T Toptas, M Sungurtekin, G Gokoglu, M Gun, T Kasikci, G Yilmaz, B Kantarcioglu, I Kaygusuz, C Adiguzel, S Bozkurt, T Firatli-Tuglular, M Bayik
Marmara University Hospital, Istanbul, Turkey

Background. Morphological examination of bone marrow aspiration slides is one of the routine and the most valuable diagnostic tools to evaluate hematological disorders for the hematologists. Hematopathologists evaluate those in combination with more complicated techniques such as immunohistochemistry. However, there are no data about the agreement levels on microscopic evaluation of bone marrow aspiration slides between hematologists and hematopathologists. *Aims*. To determine the agreement levels between hematologists and hematopathologists on common hematological diagnoses. *Methods*. A random sample of 569 patients who underwent bone marrow aspiration procedure with or without trephine biopsy for clinical purposes between January 2008 and December 2009 were chosen. Archived Wright-Giemsa-stained bone marrow aspiration smears and corresponding pathology reports belonging to those patients were reviewed. Patients who had an adequate bone marrow aspiration smear and corresponding hematopathology report were included into the study (n=325). Two-hematology fellow and a consultant hematologist with a 12, 24, and 120-month experience on microscopic evaluation, respectively, were assigned to evaluate smears. Hematologists evaluated 15 bone marrow smears per week during their training period. In order to determine inter-observer agreement, hematologists reviewed 10 smears. The diagnoses of smears were obtained from hematopathology reports. For each slide, brief clinical and laboratory information was provided. Hematologists gave a diagnostic code for every slide according to predefined diagnoses based on hematopathology reports. A good inter-observer agreement was achieved between the hematologists. Then a pilot test was performed in order to test the feasibility of coding system and to accommodate hematologists to coding system. Hematologists reviewed 30 smears and coded every slide for one diagnosis. An acceptable agreement was observed between hematologists and hematopathologist. At last, hematologists evaluated all 325 slides. Agreement between hematologists and hematopathology reports was assessed (Figure 1). Agreement analyses were performed by Cohen's kappa, Fleiss kappa, and AC1 statistics. Kappa and AC1 values were interpreted as follows: less than 0.20, poor; 0.20 to 0.40, fair; 0.40 to 0.60, moderate; 0.60 to 0.80, good; and 0.80 to 1.00, very good agreement. *Results*. Overall agreement between hematologists and hematopathologist was good (κ: 0.76, AC1: 0.78). Hematologists were especially successful for the diagnoses of acute leukemia, multiple myeloma, and chronic myeloproliferative neoplasias with excellent agreement levels (Kappa: 0.91, AC1: 0.90; kappa: 0.92, AC1: 0.91; and kappa: 0.91, AC1: 0.91, respectively). Diagnosis of iron deficiency anemia by bone marrow aspiration smear was a challenge. (κ: 0.31, AC1: 0.22). Agreement for the other hematological diagnoses was acceptable (Figure 2).

Figure 1.

Figure 2.

Conclusions. Microscopic evaluation of the bone marrow smears performed by hematologists gives mostly reliable and valuable results. This is especially important for the diagnosis of acute and life-threatening conditions such as acute leukemia. Assessment of bone marrow smears as well as basic history, physical examination, laboratory data, and flow cytometry may prevent treatment delays. It may allow verification of diagnosis made by hematopathologists. Routine use of iron staining in patients with anemia may increase the diagnostic power of bone marrow smear when used by hematologists.
