Methods: In our Medical Oncology Department, a PICC team, consisting by an hematology physician and two dedicated nurses, has been formed. Since the start of the experience a prospective study was started to evaluate complication rate and usefulness of PICC device in hematology practice. Inclusion criteria included inpatient and outpatient who needed program of chemotherapy, support or hematopoietic stem cell transplantation, regardless the underlined hematological disease or white cells and platelets counts. All patients were submitted to a preliminary evaluation of arms vascular anatomy by ultrasonography. All implantation procedures has been done under ultrasound guide with radiographic control after insertion. Probability of catheter life was calculated with Kaplan-Meier method. Univariable analysis was performed with the method of log-rank test.
Results: From March 2007 to July 2012 1060 consecutive PICC device have been implanted by our PICC team. Of those 321 (30%) consecutive PICC have been implanted in hematology patients. This analysis is restricted to the 305 hematology patients. There were 165 male and 140 females. Median age was 46 years, range 16-94. With regard to disease, 108 patients (35,4%) had Hodgkin Lymphoma, 61 (20%) non Hodgkin lymphoma, 48 (15.7%) acute lymphoblastic leukemia, 44 (14.2%) multiple myeloma, 36 (11.8%) acute myelogenous leukemia, and 8 (2.6 %) other hematological disease. Forty-two PICC (13.8%) have been used for autologous stem cell transplantation and 1 (0.3%) for allogenic transplantation. Catheter insertion was successful in 305 instances (95%), in 16 instances (5%) PICC insertion was not possible**.** At the time of this analysis 23 out of 305 PICC (7,5%) are still *in situ* and in use and 282 (61%) have been removed. Reason for removal was end of therapy in 186 instances (61%), accidental withdrawal in 27 (8.8%), patient death in 36 (11,8%) and catheter related complication in 33 (10,8%). Catheter related complications were the following: 2 (0.65%) catheter ruptures , 6 (1.96%) malfunctioning, 15 (4.9%) occlusions, 2 (0.65%) delayed abnormal dislocations, 6 (1.96%) suspected PICC-related sepsis, 1 (0.3%) local infection and 1 (0.3%) patient poor compliance. Only 1 episode of confirmed PICC-related septicemia (0.3% - 0.02/1000 days/PICC) was recorded and E.Coli was isolated. There were only 3 cases (0.98%) of symptomatic PICC-related thrombotic complications without the need forremoval.PICC median life was 131 days (1-722) for a total of 45,674 days of implanted PICC. Kaplan-Meier probability of catheter life, censored forremoval by the end of therapy and the patient'sdeath, was 80% at day 180 and 51% at day 455. Neither disease nor white cells or platelets count had influenced on catheter life.
Summary / Conclusion: These data encourage the use of PICC in the hematological patient because of insertion easiness, duration of life and low rate complication.

P505

A NEW SCORE TO DETERMINE THE PROBABILITY OF FINDING AN HLA IDENTICAL UNRELATED DONOR: A VALIDATED EFFICIENT TIME AND COST SAVING METHOD

V Dubois[1], M Sobh[2], S Morisset[2], H Labussière[2], M Detrait[2], S Rey[1], I Mollet[1], S Ducastelle[2], F Barraco[2], Y Chelghoum[2], X Thomas[2], F Nicolini[2], M Michallet[2],*
[1]Etablissement Français du Sang, Lyon, [2]Hematology, Centre Hospitalier Lyon Sud, Pierre Bénite, France

Background: We recently demonstrated that a delayed time to find an unrelated HLA compatible donor and also to proceed to allogeneic-HSCT can worsen the transplantation outcome (Michallet *et al*. ASH 2010). The French transplant registry has recently developed a software called "Easy Match" that predicts the number of HLA compatible donors for a given patient. The goal of our study is to validate this new program comparatively to a known score method

(Tiercy *et al. BMT 2007, 40; 515-522*) and to improve the cost and search delay.
Aims: To accelerate the process of donor search using the results of EasyMatch program and define a new score for donor finding probability, in order to be time- and cost-efficient.
Methods: For the first step, we retrospectively analyzed 217 patients transplanted between 2009 and 2011 after finding an unrelated donor (identical or not) or cord blood units. We used the EasyMatch software which realized a "qualitative" analysis that consisted on checking that each HLA recipient phenotype was found among all possible pair wise combinations of 2 haplotypes of the different sets of haplotypes. Various "quantitative" analyses calculated the likelihood associated to each recipient phenotype for a given set of HLA genes, in a given population, at low versus high resolution typing. The EasyMatch software gave for each patient a number of potential donors sharing the same phenotype as the patient. We validated the probability given by the EasyMatch program with the known published score method.
For the second step, we used the new defined score prospectively for 62 new patients, directing the search in donor or cord blood files as stipulated by the probability to find a suitable 10/10 donor. We, therefore, analysed the number of complementary typing asked for each group of patients (before and after new score), and the delay between registration of the patient and identification of the donor or cord blood.
Results: Our 217 patients were classified in 3 different categories according to the combined results of the EasyMatch software and the HLA score (Tiercy): - score 0 with low probability to find a suitable 10/10 donor (96% of transplantations performed with a non 10/10 donor in our study). The choice of the source will be defined considering the HLA characteristics of the recipient; in case of class I rare allele or rare HLA-BC linkage disequilibrium, a cord blood unit will be easier and more rapidly available. A complementary help should be given by an associated analysis with 4-digit haplotypes using the HaploStats program (http://www.haplostats.org/home.do). - score 1 with a median probability to identify a suitable 10/10 donor (67% of transplantations performed with a non 10/10 donor in our study). - score 2 with high probability to find a suitable 10/10 donor (95% of transplantations with a 10/10 donor in our study)
The number of supplementary HLA typing and the delay to identify a suitable donor or cord blood was significantly reduced when using the new score, in each of the three categories (Table 1).
Summary / Conclusion: The EasyMatch program provides us (1) easy tracking of mismatches (2) estimation of the number of potential donors (3) selection of population following ethnic origin of patients and a high prediction when number of potential donors is higher than 5 or <1. Its use could be improved when coupled with a second scoring system. In conclusion, the use of this new scoring system allows time and cost spare. In case of low chance to find a donor, physicians can switch to searching for unrelated HLA mismatched donor or a CBU, or to use another alternative treatment in order to keep an optimal result.

Table 1.

Score		Before score	After score	p
0	Median nb of supplementary typing Delay (days)	n=75 7.8 144	n=31 6.5 37	<0.001
1	Median nb of supplementary typing Delay (days)	n=39 7.2 61	n=12 4.75 28	0.003
2	Median nb of supplementary typing Delay (days)	n=103 2.5 46	n=19 1.74 30	0.05

P506

ESTIMATES OF BURDEN OF DISEASE ASSOCIATED WITH MANAGEMENT OF ACUTE MYELOID LEUKEMIA IN UK AND US

B Smith[1], I Kucmin-Bemelmans[2], C Alleman[2], M Hensen[2], B Skikne[3], D Mahmoud[3],*
[1]Kimmel Cancer Center, Johns Hopkins, Baltimore , United States, [2]Pharmerit International, Rotterdam, Netherlands, [3]Celgene Corporation, Summit , United States

Background: Acute Myeloid Leukemia is the most common leukemia whose incidence increases with age. It accounts for approximately 1.2% of cancer deaths in the United States and the incidence is expected to rise as the population ages (Burnett, 2011). The median age at diagnosis is 65 years, with almost half of the cases occurring in individuals over 60 years (Redaelli, 2004). Although relatively uncommon, AML generates high resource use and total burden. Previous studies of the burden of disease (BoD) are rather outdated. Additionally, no current estimates have been published for the UK and US that incorporate the costs associated with basic disease management for this group of patients.
Aims: To estimate the economic burden of AML in the UK and US.
Methods: Initially, a systematic literature review was conducted in order to understand the standard types of AML treatment . Secondly, economic costs were estimated per course of treatment per individual patient which included intensive induction therapy (IT), consolidation therapy (CT), including use of stem cell transplantation (SCT), supportive treatment during CR, and salvage therapy for those with AML relapse. The cost calculation combined all available treatment UK- and US-specific costs estimates, such as drugs, hospitalization, support staff, diagnostics and transfusion. The total economic burden was calculated combining cost per patient with epidemiology data. Incidence rates for the US and UK and treatment outcome probabilities were calculated from the Surveillance Epidemiology and End Results (SEER), Eurostat and peer reviewed literature. Unit costs were identified for UK and US using publicly available databases. Calculations were conducted for younger (<65) and older (>65) patients given differences in incidence rates identified between these groups.
Results: In 2011, the total cost of treatment with standard induction chemotherapy was £29,858($35,539) in UK and $ 241,427 in US while for best supportive care (BSC)£24,154($28,750) and $ 187,315, respectively per patient. The total economic burden of AML treatment ranged from £13 M for population aged >65 and £38 M for age<65 in the UK and approx. $0.5 billion and 1.5 billion in US, respectively. Hospitalization was the major component of the burden (66% to 92%)in induction, consolidation, and relapse, while for BSC, these were transfusion costs in UK (65%) and drugs costs in US (63%). Cost of CR consists primarily of laboratory monitoring and supportive care. The financial burden after relapse was high, comparing to the cost of being followed in CR stage, e.g. cost of relapse in UK in BSCwas£683and£6,387 in chemotherapy vs. £4,097in CR. Respectively in US relapse cost equaled$2,477 for BSC and $56,588 for chemotherapy vs. $14,861of CR.
Summary / Conclusion: Despite the variety of therapies which are available for AML patients, the prognosis of AML is still relatively poor, especially among older patients where the risk for relapse is large. Moreover, there is a shortage of the costs and cost-effectiveness of the different stages of AML therapy. The economic burden of AML treatment is very high. Furthermore, the disease cost increase when relapse occurs. Therefore, there is a need for new therapies which will sustain CR status. Due to the different AML patient profiles, it is highly important to present the treatment consequences in the groups which are the most susceptible.

P507

TIME AND RESOURCE SAVINGS WITH RITUXIMAB SUBCUTANEOUS (SC) INJECTION VS. RITUXIMAB INTRAVENOUS (IV) INFUSION: FIRST RESULTS FROM A TIME-AND-MOTION STUDY (T&M)

E De Cock[1],* P Kritikou[2], S Tao[3], C Wiesner[4], T Waterboer[5], A Carella[6]
[1]Peri- and Post-Approval Services, United BioSource Corporation, Barcelona, Spain, [2]Peri- and Post-Approval Services, United BioSource Corporation, Hammersmith, United Kingdom, [3]Peri- and Post-Approval Services, United BioSource Corporation, Dorval, Canada, [4]Hematology Franchise, F. Hoffman La-Roche Ltd., [5]Global Pricing & Market Access, F. Hoffman-La Roche Ltd., Basel, Switzerland, [6]Hematology, Azienda Ospedaliera Universitaria "San Martino", Genoa, Italy

Background: Rituximab (RTX) is used as a standard treatment for indolent non-Hodgkin lymphoma (iNHL). As an alternative to intravenous (IV) infusion, a fixed dose, subcutaneous (SC) formulation for RTX is currently being developed. While a first IV infusion typically lasts up to 4 hours, and any subsequent infusion more than 2 hours, results from SABRINA showed that SC administration enables the delivery of RTX over approximately 5 min without compromising RTX's proven efficacy and safety. With a switch to SC, it is expected that significant healthcare professional (HCP) time would be saved.
Aims: To quantify resource utilization in terms of active HCP time (i.e. time actively dedicated to a patient) and chair time related to RTX SC injection vs. RTX IV infusion in the treatment of patients with iNHL; to estimate potential time savings with a conversion from IV to SC (per administration session, per patient treatment course).
Methods: This is a multi-national, multi-centre, prospective, observational T&M study. Data associated with RTX SC injections are being collected alongside the MO25455 trial, while data for RTX IV infusions are collected per real-world practice during the same data collection period. Following interviews with a nurse and pharmacy member in each centre, generic case report forms (CRFs) for IV, SC, and pharmacy processes were tailored to reflect local site practices. Adequate "start" and "stop" descriptions for pre-specified tasks were defined to ensure accurate and unbiased T&M data collection. Trained observers measured the duration that HCPs are actively completing tasks using stop watch. Infusion chair time was captured based on the time of day the patient entered and exited the chair for RTX infusion/injection. This is a descriptive study with convenience-based sample sizes ranging between 20-40 observations per process per site. While data collection is ongoing (final data expected during Q3 2013), first results for HCP time in treatment room and chair time in 4 countries (Italy [IT], Russia [RU], Slovenia [SL], and United Kingdom [UK]) and 9 sites are presented in this abstract (no pharmacy HCP data are yet available for the

UK). Per country, estimated time for a single IV vs. SC process (pooled across sites) is calculated as the sum of individual mean task times.
Results: Differences in active HCP time (and % reduction) are 7.3 min in SL (IV 15.0 vs. SC 7.7; -49%), 11.8 min in UK (IV 26.0 vs. SC 14.2; -45%), 16.3 min in IT (IV 39.8 vs. SC 23.5; -41%), and 17.1 min in RU (IV 26.5 vs. SC 9.4; -65%). Data on active HCP time in pharmacy (IT, RU, SL) show similar relative reductions in the range of -37% (SL) to -65% (RU), while 82% (RU) to 86% (IT) of time savings are achieved in the treatment room. Differences in mean chair time are 131 min in SL (IV 201 min vs. SC 70 min; -65%), 176 min in UK (IV 195 min vs. SC 19 min; -90%), 225 min in IT (IV 339 min vs. SC 114 min; -66%), and 262 min in RU (IV 278 min vs. SC 15 min; -94%). Simulating these findings for a hypothetical center treating 50 patients for 9 sessions annually (6 induction, 3 maintenance) resulted in total chair time savings between 109 (SL) and 219 eight-hour days (RU).
Summary / Conclusion: Preliminary results indicate that a switch from IV infusion to RTX SC may lead to a substantial reduction in administration chair time as well as in active HCP time. Consequently, time freed up could be invested in other patient care activities, or increase the number of patients that could be treated, hence increasing the centre's overall efficiency.

P508

TREATMENT PERSISTENCE WITH AZACITDINE (VIDAZA) IS ASSOCIATED WITH LOWER INPATIENT HOSPITALIZATION COSTS OVER TIME AMONG MDS PATIENTS

B Smith[1,*] D Mahmoud[2], D Stacey[3], H Henk[3]
[1]The Sidney Kimmel Comprehensive Cancer Center , Johns Hopkins, Baltimore, [2]Global Pricing & Market Access, Celgene, Summitt, [3]Optum, Eden Prairie, United States

Background: In the US, understanding the costs associated with Myelodysplastic Syndromes (MDS) is challenging given that multiple channels including pharmacy, ambulatory, and inpatient hospitalization (IPH) settings make up the total expenses to manage patients. Recent studies suggest that MDS patients under active medical management experience fewer cytopenia-related medical problems compared to untreated, transfusion dependent (TD) patients who require more medical treatments, often for recurrent infections and bleeding complications. It is clear that persistence of drug therapy is essential to achieve optimal clinical responses for MDS patients and we sought to determine if continued therapy also optimized costs related to the disease.
Aims: To evaluate the relationship between treatment persistence with AZA and health care costs encountered for patients with MDS.
Methods: Commercial and Medicare Advantage enrollees with a diagnosis of high grade MDS (ICD-9, 238.73) who initiated AZA with pharmacy and medical benefits in the prior 6 months and who had a variable follow up period from initiation of AZA to disenrollment or end of study were identified in a US health plan claims database (1/1/2007-6/30/2010). The number of AZA "cycles" was calculated by dividing the total number of AZA administrations by 7 days, with a sensitivity analysis for 5 day administration, - commonly utilized in the "real-world". Persistence was defined as the number of cycles of AZA. Eligible patientshad to have at least 2 AZA cycles. An independent analysis identified health care costs for the same patients during periods of transfusion-dependence (TD) - defined as periods in which they received 2 transfusions in an 8 week period and did not receive erythropoietin-stimulating agents (ESAs) or AZA. Average Per Patient Per Month (PPPM) costs were examined among patients with various lengths of TD periods, up to 1 year. Linear models were used to examine the relationship between persistence on AZA and PPPM health care costs. Healthcare costs included both payer and patient paid amounts under the medical and pharmacy benefit. Medical costs were further broken out into IPHs, ambulatory, and other costs captured. Several sensitivity analyses were performed to confirm the robustness of the results such as excluding patients with IPH prior to AZA initiation, and including patients with <2 cycles of AZA.
Results: The baseline cost breakdown for MDS patients (n=225) who were transfusion dependent and not receiving treatment are outlined in Figure 1. Interestingly, the largest proportion of the medical costs for TD patients comes from IPHs. In fact, the PPPM IPH costs among TD periods account for approximately 65-75% of total health care costs - even at one year of their diagnosis. A similar analysis was done for patients completing at least 2 cycles of AZA (n=100) which suggested that the proportion of cost related to IPHs was closer to 40%. This cohort averaged 6.3 cycles (median=5) with 24% of patients completing at least 8 cycles. Importantly, completion of every additional AZA cycle (baseline 7day analysis) was found to be associated with, on average, a 6% decrease in medical care costs (P=0.005) driven largely by an 18% decrease in IPH costs (P<0.001) due to fewer medical events. Even a single additional AZA cycle was found to be associated with 5% lower total health care cost (P=0.006). These results also hold in the sensitivity analyses. As expected, an examination of medical needs of both TD and AZA treated patients led infections as a frequent driver of IPHs.
Summary / Conclusion: Patients who persist with AZA therapy have lower PPPM medical costs, driven by decreased expenditures on IPHs. This is consistent with results identified in the AZA-001 clinical trial in which patients receiving AZA experienced reduced IPHs driven by less transfusions and need for IV antibiotics, antifungals, and antivirals. These lower overall costs offset the expected increase in continuing therapy based on the cost of drug alone. Improving duration of therapy of AZA may not only optimize clinical outcomes but may decrease cumulative costs of care among high risk MDS patients.

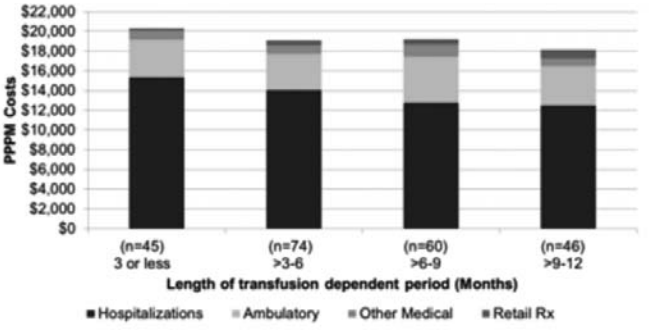

Figure 1. Average monthly hospitalization costs remain steady during TD periods of up to 12 months.

P510

HEALTH CARE COSTS IN NEWLY-DIAGNOSED PERSONS WITH MYELOFIBROSIS WITH MYELOID METAPLASIA: DATA FROM A US COMMERCIAL AND MANAGED MEDICARE POPULATION

C Bennett[1], D Mahmoud[2,*] L Weber[2], H Henk[3]
[1]College of Pharmacy, University of South Carolina, Charleston, [2]Global Pricing & Market Access, Celgene, Summitt, [3]Optum, Eden Prairie, United States

Background: Myelofibrosis with myeloid metaplasia (MF) is a myeloproliferative neoplasm characterized by bone marrow fibrosis and abnormal blood cell production. Median age of diagnosis is about 65 y and median survival, 5-6 y. There are diverse treatment options but none are curative. Little is known about overall health care utilization and costs in persons with MF.
Aims: Describe the economic burden of MF from a payer perspective.
Methods: US health plan data were assessed between 01 July 2002 to 30 June 2012 to identify enrollees newly diagnosed with MF (ICD-9-CM diagnosis codes 238.76), which includes idiopathic myelofibrosis, myelofibrosis with myeloid metaplasia, and primary myelofibrosis. Enrollees were required to be continuously enrolled in a commercial or Medicare Advantage plan with a medical and pharmacy benefit for six months before diagnosis and were followed until they dis-enrolled from the health plan or until the end of the study period (30 June 2012). Enrollees <18 y were excluded. Health care costs included all reimbursed amounts to the provider from the health plan and enrollee (e.g., co-payments, co-insurance). Costs were captured in the six months before diagnosis of MF and the year following diagnosis. Cost analyses were conducted from the payer perspective.
Results: 365 newly diagnosed enrollees with MF persons were identified. Average of duration of follow-up was 26±21 mo. (range: 1- 69 mo) with 120 (33%) were enrolled <1 y. Median age was 66 y (range, 19 - 87 y). The majority of people were 65 y or older (196, 54%) with 134 enrollees (37%) age 44- 64 y. Most people age ≥ 65 y were Medicare enrollees (60%), however, there were substantial numbers of older people with commercial insurance (40%).
Total health care costs in the 6 mo before diagnosis of MF averaged $2,525 ± 5,261. In the year after diagnosis, total health care costs average $10,523 ± 51,654 even though 33% of the persons were enrolled less than the entire year (disenrollment may be due to a change in insurer or death). Approximately 81% of costs were for medical services with a smaller fraction (19%) for drugs dispensed via retail pharmacies. However, mean costs of subjects with evidence of anemia treatment (i.e., RBC transfusions or ESA use), are 85% greater than among those without evidence of anemia treatment (p-value < 0.001).
Summary / Conclusion: Total health care costs for persons with MF in the US, enrolled in a commercial or Medicare Advantage health plan, increase following diagnosis. Average health care costs among those with evidence of anemia are significantly greater than those without evidence of anemia. Treatments that control anemia have the potential to reduce costs in this MF population.

P511

THE IMPACT OF UNRESTRICTED FUNDING ON HAEMATO-ONCOLOGY TREATMENT CHOICE

T Todd[1,*] A Nassar[2], W Thomas[1], R Powell[3], K Scatchard[2]
[1]Haematology, [2]Oncology, [3]Research and Development, The Royal Devon and Exeter Hospital, Exeter, United Kingdom

Background: In England funding for treatment of haematological cancers is routinely available for nationally approved treatments, often costing < £30 000 per QoL adjusted year, supplemented by geographically variable locally agreed treatments, often at a multi-hospital network level, usually of older and cheaper treatments, such as R-CHOP for high grade B-Cell lymphoma. Following concerns about inferior survival rates, in October 2010 the UK government made additional funding for anti-cancer treatments available to 10 regions in England (The Cancer Drugs Fund). Uniquely amongst these the South-West region, with a population of approximately 6 million served by 18 hospitals grouped into 5 networks, did not set any limits on drug choice or treatment cost for which clinicians could request funding. All treatments supported by the local hospital multidisciplinary team and for which adequate supportive evidence was supplied were to be funded until no funds remained. The adequacy of supportive evidence for applications was reviewed by a panel of same specialty senior doctors.
Aims: What treatments haematologists seek when funding is unrestricted. The level of evidence informing treatment choice. How well patients match the evidence used to treatment choices. Funding utilisation variability between haematology treatment centres
Methods: Funding applications between October 2010 and September 2012 were reviewed. Demographic, treatment line, regimen/drug requested survival from funding approval date, requesting site and expenditure were extracted. 50applications were randomly selected and the supporting evidence reviewed and quality rated using the GRADE system.
Results: There were 596 applications for haematology and 1772 for oncology patients in this time. Complete data was available for 346 haematology applications, the rest containing some missing fields. In both specialties applications for men: women ratio was 2:1. Haematologists were significantly less likely than oncologists to seek treatment at 5th line and beyond (Chi squared, P<0.05). 10% of haematology treatment requests were based on data published in abstract only and only 15% on meta-analyses or phase III randomised control trials, the rest were based on case series, unrandomised phase II studies or opinion pieces. Only 5% of patients did not match the supporting evidence. The haematology commonest drugs requested were Rituximab (61% applications), Bendamustine (26%, 19% together with Rituximab), Bortezomib (11%, 6% with rituximab), lenalidomide (5%), ofatumumab (2%) and brentuximab (2%). There were up to 3 fold differences in funding uptake per population served both between networks and between individual haematology services of comparable treatment capability within and across those networks.
At an average funding request per patient of £13 043 80% of haematology patients survived more than 300 days from funding approval compared to 54% of oncology patients at an average of £15800.
Summary / Conclusion: Removal of funding restrictions on haemato-oncology treatments show that haematologists are much less likely to pursue therapy beyond 4th line than oncologists though survival for haematology patients is greater at lower cost, potentially reflecting more effective therapy and/or greater use of palliative care. Many chemotherapy choices are based on evidence rated as low or very low quality, and twice as many men receive treatment as women. 62% of expenditure was on only 2 drugs while differences in funding uptake suggest large differences in practice between similar haematology services.

P512

PATIENT SAFETY AND CLINICAL EFFICIENCY GAINS FOLLOWING IMPLEMENTATION OF AN INTEGRATED HEALTH INFORMATION SYSTEM IN EAST LONDON.

C Freeman[1,*] K Atkinson[1], D Hart[1], L Bowles[1], C Gutteridge[1]
[1]Department of Haematology, The Royal London Hospital, Barts and the Royal London NHS Trust, London, United Kingdom

Background: Digitisation of care records and pathways is a global ambition in healthcare designed to prevent patient harm and to harness the efficiency savings that result from advanced use of data and information systems. We report on our experience of using an integrated health information system (Cerner Millennium) in the clinical haematology department at the Royal London hospital, which is part of Barts NHS Healthcare Trust, a large academic health science system in East London.
Aims: To evaluate how the Electronic Health Record (EHR) supports efficient service provision in the clinical haematology department: referrals and outpatients, clinical handover, day care admissions and episode coding for health analysis and billing.
Methods: Quantitative and qualitative data sets were collected by use of database analytical tools, semi-structured observation of clinical interactions and review of ICD 10 coding used to generate Health Related Groups (HRGs) data for billing in the NHS.
Results: *Referrals:* 55% of patients attending the department from general practitioners were referred using the national Choose and Book system, an electronic referral system supplied to all English GPs. These referrals were reviewed online by 5 senior haematologists. Accepted referral letters appear automatically in the EHR. Inappropriate referrals were directed to other clinicians or returned back to the referring GP. *Outpatients:* 66% of patients attending the department had at least one SNOMED clinical term added to the EHR at the point of first attendance. All patients with haemostasis or haemoglobin disorders are fully SNOMED termed and these data are used to ensure that the correct treatment protocols are attached to every patient record. These data are actively used by non-specialist clinicians in the emergency department with 96% of patients reviewed and treated within 4 hours of arrival. *Handover:* Patient EHRs are projected to the whole team at least once weekly. 66% of patients had documented care pathways – all patients with haemophilia and sickle cell disease had EHR related protocols. Review of online laboratory data resulted in case management changes in 3% of patients. Images were reviewed in 25% of handovers and handover to specialist nurses for extended follow-up was agreed in 19% of cases. *Day unit/ambulatory care:* Over a three month period, 431 blood tests were performed with all results reviewed, validated and management plans documented in EHR. A total of 288 transfusions were administered with detailed haemovigillance data recorded electronically. 132 venesections, 111 haemophillia treatments and 68 infusions (parenteral iron/immunomodulatory therapy) were administered and management documented. 100% of nursing notes, management plans and physician reviews are documented in the patients' electronic health record. *Coding:* SNOMED Clinical terms entered at the point of care by clinicians are reviewed by the hospital coding team and used to develop depth of coding ICD 10 which improves public health data and income recovery through billing. The average number of diagnoses coded per Clinical Haematology episode is 3.7, which is above the peer average of 3.2.
Summary / Conclusion: Full implementation of an electronic system has significant benefits for patients and service provision. Haematology care depends heavily on decisions based on laboratory data and precise communication of care plans, we believe that the EHR is an invaluable tool in delivering efficient, cost-effective and safe patient care.

P513

PHARMACOLOGICAL DRUG EXPENDITURE OF FIRST-LINE INDOLENT NON-HODGKIN LYMPHOMAS IN SPAIN

G Debén[1], J Collar[2,*]
[1]Hematology Dept., Complejo Hospitalario de La Coruña, La Coruña, [2]Medical Dept., Mundipharma Pharmaceuticals Spain, Madrid, Spain

Background: Non-Hodgkin lymphomas (NHL) are a group of different hematological neoplasms which are the sixth most common cancer in many developed countries. Indolent Non-Hodgkin lymphomas (iNHL) are a subtype of NHL characterized by a chronic relapsing-remitting disease course, with patients usually exposed to several successive treatment courses. These indolent subtypes represent 40% of all NHL. Patients with iNHL in advanced stages and high-tumour burden usually receive front-line chemoimmunotherapy, Rituximab (Rtx) + chemotherapy, during the so called induction phase, followed by maintenance therapy with Rtx in patients who achieve at least a partial response at the end of the induction phase, as it is recommended by several Clinical Guidelines.
Aims: Analyze the different therapies used and the drug expenditure associated to the first line treatment phase of iNHL in Spain (considering induction plus maintenance phases).
Methods: Based on recent market research data (IMS Oncology Analyzer™, 2nd quarter wave in 2012) a total year population of 3,906 iNHL patients were estimated under induction treatment. An extrapolation of 2 previous years data was used to estimate the patients under maintenance therapy for the same time period, assuming that only those iNHL patients with a follicular lymphoma (FL) who would have achieved, at least, a partial response during the induction phase would receive maintenance therapy. Ninety percent of the patients would persist on maintenance therapy during the first year, and 80% during the second year. Cost analysis was carried out from the perspective of the Spanish Health System. Pharmaceutical expenditure on cytostatic agents and Rtx was analyzed, excluding other medical costs. The drug costs were based on the official ex-factory prices (EFP), discounting the price reduction established in 2010 by the Spanish Government. A deterministic sensitivity analysis (SA) was performed, switching the most relevant variables included in the analysis, to confirm the results robustness.
Results: Drug treatment expenditure in 1st line iNHL is above € 53.6 Mio/year in Spain. Almost 2/3 of this expenditure would be consumed during the induction phase and about €20 Mio/year would represent the expenditure dedicated to maintenance therapy with Rtx in FL responder patients. During the induction phase, the chemoimmunotherapies most widely used by far were R-CHOP (42%) and R-CVP (25%), although other 40 different therapies were identified. Rtx treatment cost also represents more than 90% of the pharmaceutical expenditure during this induction phase.

Summary / Conclusion: First line treatment of iNHL has not a very high economic impact cost in Spain, compared to other cancer pathologies. The main drug costs are based on the wide Rtx utilization. Nevertheless, Rtx treatment has also undoubtely represented a very relevant turning point in the outcomes of this pathology, with a remarkable therapeutic clinical improvement in terms of increasing response rates and prolonging the progression-free survival time in patients affected by this pathology.

P514

A SYSTEMATIC REVIEW OF ECONOMIC ANALYSES, UTILITY, RESOURCE USE, AND COST ESTIMATES OF FIRST-LINE TREATMENTS FOR CHRONIC LYMPHOCYTIC LEUKEMIA

J Brockbank[1], C Stapelkamp[2], A Haiderali[3,*]
[1]RTI Health Solutions, Manchester, [2]GlaxoSmithKline, Stockley Park, United Kingdom, [3]GlaxoSmithKline, Collegeville, United States

Background: Fludarabine/cyclophosphamide/rituximab (FCR) is the standard of care as first line treatment for healthy, fit patients with chronic lymphocytic leukemia (CLL). Patients with CLL are often elderly and many suffer from comorbidities which tend to make them inappropriate for fludarabine-based therapies. A number of therapeutic options are available for these medically less-fit or 'slow-go' patients.
Aims: The objective of the systematic review was to identify published economic evaluations of first-line treatments of CLL. The review also identified published estimates of utility, resource use, and costs that could be relevant to the economic evaluation of these first-line treatments for CLL.
Methods: The following electronic databases were searched for publications from the last 15 years (without limitations on language): MEDLINE, MEDLINE In-Process, EconLit, Embase, BIOSIS, and the Cochrane Library. Reference lists of relevant papers were searched manually. Conference proceedings from January 2010 to 2012 also were searched. Articles were screened for relevance by two independent researchers using predefined inclusion and exclusion criteria. Titles and abstracts were first screened (level 1) for relevance, and then full-texts were obtained and screened (level 2) for those articles that had appeared relevant at level 1.
Results: A total of 51 articles were identified from level 1 screening, 19 of which were deemed relevant after level 2. These related to 18 unique studies, five of which were economic analyses. Of these five, four studies were in fludarabine-ineligible patients; three reported cost-effectiveness estimates for bendamustine (B) and one reported estimates for chlorambucil (Chl) monotherapy. Incremental cost-effectiveness ratio estimates reported for B versus Chl monotherapy were £11,960 per quality-adjusted life-year (QALY) [United Kingdom, year 2009] (Woods *et al*., 2012; Napp Pharmaceuticals, 2010), £10,621 per QALY [Scotland, year 2010] (Napp Pharmaceuticals, 2011), and $50,763 per QALY [United States, year 2009] (Malin *et al*., 2010).
Four utility studies were identified from level 2 screening. Beusterien *et al*. (2010) elicited utility values for CLL health-state descriptions from United Kingdom general population samples using the standard gamble technique. Ferguson *et al*. (2008) and Tolley *et al*. (2012) elicited utility values for CLL health-state descriptions from United Kingdom general population samples using the time trade-off technique. Estimates reported by Beusterien *et al*. (2010) were substantially higher than those reported by Ferguson *et al*. (2008) and Tolley *et al*. (2012). Utility weights referenced to Knauf *et al*. (2009) were mapped from European Organisation for Research and Treatment of Cancer's Quality of Life Questionnaire-Core 30 data to the EuroQol EQ-5D.
Data from nine resource use and cost studies were extracted, three of which studied patients receiving fludarabine. Resources included drugs, hospitalizations, physician visits, administrative costs, adverse events, tests and procedures, and productivity losses. The majority of the studies were performed in the United States.
Summary / Conclusion: In summary, there is increased interest in the economic evidence regarding the cost-effectiveness of frontline interventions aimed at patients with CLL. However, there is wide variation in the methods used, limiting the impact of these analyses. The quality of economic evaluations should be increased to inform better the decision makers and clinicians.

P515

A COST-BENEFIT ASSESSMENT OF TREATMENT (TX) FOR NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM) PATIENTS: AN EFFICIENCY FRONTIER APPROACH

S Guo[1,*] C Pelligra[1], Z Icten[1], A Altincatal[2], F Rodrigues[3], M Monzini[4], K Knopf[5]
[1]Health Economics, [2]Biostatistics, United BioSource Corporation, Lexington, MA, United States, [3]Celgene Management, Boudry, Switzerland, [4]Celgene Corporation, Summit, NJ, [5]Sutter Health, California Pacific Medical Center, San Francisco, CA, United States

Background: Access to cancer Tx can be constrained in certain countries due to cost-effectiveness requirements. The efficiency frontier (EF) shows the trade-off between costs and benefits of available Tx for a particular therapeutic area and identifies the regimens which provide the most value for a given level of cost.
Aims: An EF approach was used to conduct a cost-benefit analysis of four Tx in NDMM stem cell ineligible patients ≤75 years which included: melphalan and prednisone (MP), MP with lenalidomide as induction therapy followed by lenalidomide as maintenance therapy (MPR-R), MP with bortezomib (VMP), MP with thalidomide (MPT).
Methods: A cost-effectiveness model was developed to perform this assessment from a US payer perspective. Time to progression (TTP), adverse events, QALYs, life years (LYs) and costs for 1st-line Tx were estimated using a Markov approach, while a Tx algorithm was used to estimate post-progression survival, QALYs, and costs for subsequent Tx. 75% and 25% of the MPR-R treated patients and 25% and 75% of the patients receiving other regimens were assumed to receive bortezomib- and lenalidomide-based 2nd-line Tx, respectively. TTP for all the 1st-line Tx were estimated with data from the MM-015 trial and a network meta-analysis of published studies. TTP data for subsequent lines of Tx were obtained from a post-hoc analysis of MM-015 trial and other published studies. Utility values for different health status were drawn by mapping QLQ-C30 data collected from MM-015 onto EQ-5D scores. Costs (in 2013 USD), including those of treatments, adverse events, and routine monitoring, were obtained from various public databases. All costs and outcomes were discounted at 3% per annum.
Results: MPR-R resulted in more discounted LYs and QALYs per patient than MP, VMP and MPT. MPR-R also incurred the lowest lifetime Tx cost per patient next to MP. VMP and MPT were dominated by MPR-R. MP and MPR-R were the only two Tx defining the EF for QALYs (Figure 1) and LYs. The likelihood of MP, MPR-R, VMP, MPT being on the EF based on QALYs were 97%, 96%, 19%, and 3%, respectively. Similar results were observed for LYs.
Summary / Conclusion: The analysis suggests that for NDMM patients ≤75 years who are ineligible for stem cell transplantation, MPR-R is the most efficient among all analyzed treatments having a greater clinical benefit than MP.

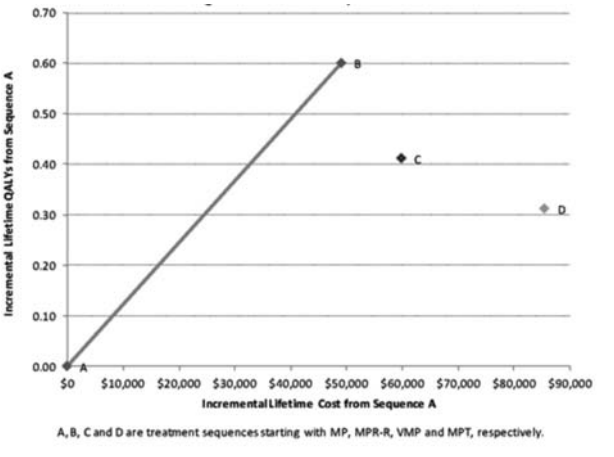

Figure 1. NDMM efficacy frontier.

P516

EVALUATION OF A NOVEL STRATEGY OF TRIAGE IN THE HEMATOLOGY AMBULATORY SETTING

J Slusar[1,*] S Couban[1,2], S Shivakumar[1,2]
[1]Dalhousie University, [2]Hematology, Capital District Health Authority, Halifax, Canada

Background: Demand for specialty assessment and care often exceeds the capacity to provide it. In 2010, at our academic referral centre, the wait-time for patients referred with non-urgent hematologic problems exceeded 6 months and, considering the rate of growth in requests for consultation, some patients may never have been seen. We sought to change our triage system to better manage the limited capacity of hematologists to see new patients. In 2010, 444 letters were written by a hematologist at Capital District Health Authority in Halifax, NS to referring practitioners. These letters, written in response to requests for consultation from practitioners, reviewed the patient's hematologic abnormality (for example, leukopenia), suggested possible causes of the abnormality, and provided a recommended course of action for follow-up. Patients were then managed by their referring practitioner based on the recommendations in the letter and not assessed by the specialist.
Aims: The objectives of this study were to 1) characterize the cohort of patients for whom written recommendations were provided and 2) assess whether the written recommendations were a helpful and satisfactory alternative for the referring practitioner.
Methods: The study was conducted at a teaching hospital in Halifax, NS, Canada. All patients referred to the hematology clinic in 2010 who received written recommendations were included in the study. Follow-up was conducted 1 year after the date of written recommendations. All practitioners who were sent recommendation letters received a practitioner satisfaction survey comprised of 7 "yes or no" questions.
Results: 444 patients were managed by written recommendations [male 49% (n=220); females 51% (n=224)]. Common reasons for referral to the hematology clinic were mild leukopenia (17%; WBC between $3.0x10^9$/L and the lower limit of normal), mild to moderate thrombocytopenia (21%; platelet count between $51,000x10^9$/L and the lower limit of normal) and mild anemia (22%; hemoglobin between 100 g/L and the lower limit of normal). The average wait-time for providing written recommendations was 151 days (range: 0-623). No further follow-up was recommended for 22% of patients for whom written recommendations were written. At 1 year follow-up, 13% (n=58) had complete resolution of the abnormality for which they were referred and in 45% (n=201), the abnormality had remained stable. There was a single hematological-related death within the year follow-up in a patient who had declined further medical investigations and intervention. In 1% of patients (n=4), the patient's hematological abnormality worsened over the 1 year of follow-up. Of the 203 referring practitioners who responded to the satisfaction survey, 95% were pleased to receive recommendations in this manner and 90% said they would be satisfied with written recommendations in the future.
Summary / Conclusion: Our review of the practice of providing written recommendations to referring practitioners in response to a request for consultation suggests that there is a group of patients with hematologic abnormalities for whom this practice is safe and reasonable. In the year of follow-up, the majority of these abnormalities either resolved or remained stable. The positive response from the practitioners who were surveyed suggests that this endeavor has been well received. Future work will be undertaken to determine whether patients are satisfied with this approach and whether this leads to benefits in continuing health education as measured by a decrease in requests for referral.

Table 1. 444 patients were followed one year after the writing of written recommendations. The majority of patients were found to either not require follow-up, had their abnormality resolve or remained stable. A small portion of patients had the abnormality become worse and were subsequently seen in person. One patient died within 1 year of receiving written recommendations.

Patient Outcome	Number of Patients
Did not require follow-up	96 (22%)
Abnormality resolved	58 (13%)
Abnormality remained stable	201 (45%)
Abnormality was worse	4 (1%)
Lab values were not available at follow-up	70 (16%)
Another referral sent by referring practitioner and patient seen in clinic	12 (3%)
Patient was seen by Hematology	19 (4%)
Other treatment was recommended	9 (2%)
Patient was admitted	9 (2%)
Death	1 (0.2%)

P517

THE COST OF TREATING CHRONIC MYELOID LEUKEMIA (CML) AND THE COST OF ACHIEVING 1 MAJOR MOLECULAR RESPONSE (MMR) UNDER DIFFERENT TKIS IN GREECE

S Gigantes[1,*] M Geitona[2], S Delimpasi[1], M Hatzikou[3], N Harhalakis[1]
[1]Hematology, Evangelismos Hospital, Athens, [2]Social Policy , University of Peloponnese, Corinth, [3]Health Economics, Novartis Hellas, Metamorfosis, Greece

Background: Innovative treatments have transformed CML into a chronic disease mostly managed in outpatient care.
Aims: This study aimed to estimate the cost of treating patients with CML including cost of adverse events and the cost for achieving one Major Molecular Response (MMR) under different Tyrosine Kinase Inhibitors (TKIs) in Greece.
Methods: A retrospective study was performed in the Heamatology Department of Evangelismos General Hospital of Athens. Study sample consisted of all patients (n=79) who visited the hematology outpatient unit of the hospital from January 2007 to December 2011. Cost analysis was based on patient's direct cost, including cost of personnel, supplies, medication, laboratory and imaging tests, infrastructure and various other on-site costs. Mean annual cost per patient was elaborated separately in outpatient and inpatient care. Inpatient costs mostly refer to the treatment of adverse events. Cost analysis is based on each year's NHS prices transformed in 2013 values and the National Health System (NHS) perspective has been used. The results of the costing analysis were used to estimate the cost of achieving 1 MMR under different TKIs in Greece. The MMR and AE rates were taken from the CML-CP frontline trials –DASISION (dasatinib 100mg QD vs. imatinib 400mg QD) and ENESTnd (nilotinib 300mg BID vs imatinib 400mg QD). Patient's number needed to treat (NNT) was calculated as the inverse of the MMR rate by 12 months (1/MMR) per. Costs of adverse events were multiplied by the incidence rates reported in the trials.
Results: The mean annual cost per patient in chronic phase of Myeloid Leukemia treated in outpatient care is estimated at €22.972. The most frequent adverse events managed were anemia (n=7, 9% of patients) and neutropenia (n=12, 15% of patients). Mean hospitalization cost per patient due to the treatment of adverse events is as follows: for anemia €2.193 and neutropenia of €1.312. The cost of treating anemia corresponds to 9.5% of the overall cost of treatment and the cost of neutropenia about 5,7%. Annual cost of newly diagnosed patients in 2011 was estimated at €14.493, 41% lower than the respective cost of non-newly diagnosed patients the same year (€24.558). The medication and hospitalization cost in order to perform a transplantation has been estimated at €22.955, without taking into consideration the cost of graft. The number needed to treat with nilotinib was 51% lower than the imatinib NNT in ENESTnd (1.8 vs. 3.7) and the dasatinib NNT was 39% lower that the IM NNT in DASISION (2.2 vs. 3.6). Annual cost of nilotinib including cost of AEs is estimated at €27.339, dasatinib €35.566 and of imatinib €21.782. The cost of achieving 1 MMR is €49.707 for nilotinib, €77.317 for dasatinib and €80.675 for imatinib. Therefore, the cost of achieving 1 MMR with nilotinib is lower by 35,71% vs. dasatinib and 38% vs. imatinib.
Summary / Conclusion: Innovative treatments for CML have resulted in treating patients in outpatient care with lower adverse events and consequently lower cost. The NNT findings and the differential cost of managing AEs in each treatment from this evaluation suggests that nilotinib provides better clinical outcomes and would result in lower costs for hematologic AE management from the perspective of the Greek NHS.

P518

A CALL FOR A STANDARDISED MEASUREMENT OF HAEMOGLOBIN IN THE REPUBLIC OF IRELAND

J O' Sullivan[1,*] T McNamee[2], J Harrington[2], I Perry[2], M Cahill[1]
[1]Haematology Department, Cork University Hospital, [2]Department of Epidemiology and Public Health , University College Cork, Cork, Ireland

Background: Diagnosis of anaemia is considered when the haemoglobin level is below the lower limit of the reference range used by a laboratory and erythrocytosis is diagnosed when the level exceeds the upper limit. Variation in the level of the upper and lower limit will affect diagnosis of these conditions and referral rates.
Aims: To assess and quantify the variation in haemoglobin reference ranges for adults in Irish laboratories in the context of findings on haemoglobin concentrations from a large, nationally representative sample of Irish adults.
Methods: Haemoglobin reference ranges used in laboratories in Ireland for adult men and women were obtained via phone contact, email correspondence or laboratory/hospital websites. Data was also obtained on the type of analyser used in each laboratory and on the source of the reference ranges. Haemoglobin levels were measured in a sample of 1,133 men and women aged ≥45 years, participants in the 2007 Irish National Survey of Lifestyle Attitudes and Nutrition (SLAN 2007).
Results: Haemoglobin is tested for both men and women in 53 laboratories and for women alone in 5 laboratories. In adult men, the lower limit varied from 13-14 g/dL and the upper limit from 16.7-18.5 g/dL. In adult women, the lower limit varied from 11-12.5g/dL and the upper limit from 14.8-16.5g/dL. At least 16 different analysers were used across the laboratories. Standard haematology textbooks were the source of reference ranges in at least 6 laboratories.
Of the representative sample from SLAN 2007, 546 (48.2%) were men and 587 (51.8%) were women. Biomnis laboratory reference range was used as the "gold" standard using Sysmex XE 2100 analyser (13.5-17.2 g/dL in adult men, 11.3-15.2g/dL in adult women). A suggested reference range was extrapolated from the SLAN data using the mean (15.2 g/dL for men, 13.9 g/dL for women) and standard deviations (1.2 g/dL and 1g/dL). For men, this is 12.9-17.7 g/dL and 11.9-15.9 g/dL for women. Applying the spread of reference ranges to the SLAN population, diagnosis of anaemia for men would range from 2.8% to 8.5% for a lower limit of 13-14g/dL. Diagnosis of erythrocytosis would range from 6.8% to 0.04% for an upper limit of 16.7-18.5g/dL. For women, diagnosis of anaemia would range from 0.7% to 7.3% for a lower limit of 11-12.5 g/dL and for diagnosis of erythrocytosis from 13.7% to 1.0% for an upper limit of 14.8-16.5 g/dL.
Summary / Conclusion: There is wide variation in lower and upper haemoglobin limits, with an almost 2 g/dL difference at the upper limit in both genders. A variety of analysers are used in the laboratories and the sources of the reference ranges vary from samples of local healthy volunteers to standard haematology textbooks. On comparing the ranges to the SLAN data, there was substantial variation in the proportion of the population diagnosed with anaemia or erythrocytosis. Given that a diagnosis of anaemia often generates referrals for resource intensive investigations such as endoscopy, overdiagnosis has significant health and resource implications. Similarly, underdiagnosis due to an inappropriate lower limit is a matter of concern. Our data highlights the need to standardise haemoglobin reference ranges in laboratories throughout the Republic of Ireland.
We would like to acknowledge the SLAN 2007 Consortium led by Professor Hannah McGee.

P519

DEMAND MANAGEMENT IN A UNIVERSITY LABORATORY IN THE WEST OF IRELAND; THE FINANCIAL BENEFIT OF DISTRIBUTION OF LOCAL GUIDELINES FOR VITAMIN B12 AND FOLATE TESTING.

A Chonfhaola[1,*] M Crowley[1], M O'Riain[1], M Murray[1]
[1]Department of Haematology, Galway University Hospital, Galway, Ireland

Background: Laboratory medicine services are critical to delivering high quality patient care. Despite diminishing resources, the demand for laboratory services is rising exponentially. Balancing clinicians' access to investigations and a laboratory's ability to manage its demands is vital, so that limited resources can be used to deliver high quality patient care. A review of ordering practices of general practitioners (GPs) using the laboratory at Galway University Hospital (GUH) was performed. There was a 185% increase in Vitamin B12 and folate testing between 2004 and 2011 in GUH. As these were invariably requested in association with a ferritin level, this equated in 2011 to €376,522 in assay cost alone. There was no appropriate indication for testing identifiable on the majority of requests. While the majority of GPs knew the appropriate indications for B12 and folate testing when surveyed, this was not reflected in their practice[1]. Evidence based guidelines are critical for achieving best practice in medicine. The most recent international guidelines for Vitamin B12 testing are the 1994 British committee for standards in haematology (BCSH) guidelines[2]. Education of clinicians requesting investigations is imperative to bring about a change of practice[3].
Aims: 1.) To distribute local guidelines to all general practitioners using the laboratory at GUH. 2.) To evaluate the effect of distribution of these guidelines.
Methods: In August 2012 local guidelines for Vitamin B12 testing were distributed to all general practitioners using the laboratory at GUH. 200 random request forms were audited in October 2012 to ascertain if the distribution of guidelines had resulted in a change of practice. The monthly requests for Vitamin B12 from 2011 and 2013 were compared.
Results: B12 and folate testing fell from 96,544 in 2011 to 87,411 in 2013. This decrease is visible following two points of communication with GPs; distribution of a survey on indications for B12 testing and distribution of local guidelines for B12 testing. Fatigue and routine screening as clinical indications for B12 testing fell from 27% to 16.2%, and 17% to 8.3% respectively.
Summary / Conclusion: Distribution of guidelines for Vitamin B12 and folate testing has led to a reduction in inappropriate testing. This equates to an estimated saving of €35,620 - €52,767 in our institution in 2012. Education of clinicians and involvement of stakeholders in policy changes are effective ways to bring about a change in clinical practice.

Background: CC-292 is an oral, highly selective, small-molecule covalent inhibitor of BTK, a kinase that plays an important role in the biology of B-cell malignancies, such as CLL and B-NHL.
Aims: To investigate safety, dose limiting toxicities (DLT), and clinical activity of CC-292 monotherapy in patients (pts) with relapsed or refractory (R/R) CLL and B-NHL.
Methods: Cohorts of 3 to12 eligible pts with R/R CLL or B-NHL after ≥1 prior therapy received CC-292 at doses of 125, 250, 400, 625, 750, and 1000 mg QD or 375 and 500 mg BID. An expansion cohort of CLL pts at 750 mg QD was also tested. All pts received continuous dosing in 28-day cycles until progressive disease or intolerable toxicity. Clinical activity in CLL and NHL pts was investigator assessed per the 2008 IWCLL criteria and updated IWG Criteria for Malignant Lymphoma, respectively. Preliminary safety and clinical activity for all pts enrolled as of cutoff date Feb 22, 2013 are reported.
Results: We evaluated 86 pts (23 B-NHL, 6 Waldenstrom's Macroglobulinemia, 57 CLL/SLL) across all doses for safety, including 25 expansion cohort CLL pts who received 750 mg QD. Median age was 65 (29-89) and median prior therapies was 3 (1-12). Of the 57 CLL pts, 39 (68.4%) had at least 1 high risk factor, including 30 (52.6%) with unmutated *IGHV*, and 26 (45.6%) with del11q22 (12 pts), del17p (14 pts), or both (2 pts). Median time on therapy for all pts is 144 days (13-515). 3 DLTs have been reported and include thrombocytopenia (400mg), pneumonitis (1000 mg) and altered mental status (500 mg BID). The MTD has not been reached. Most frequent treatment emergent AEs in ≥10% of pts regardless of causality were diarrhea, fatigue, thrombocytopenia, neutropenia, nausea, headache, muscle spasm, respiratory infections, cough, anemia, abdominal pain, supraventricular arrhythmias, vascular disorders, peripheral edema, and dysgeusia; the majority of which were Gr1 and Gr2. All 17 efficacy-evaluable B-NHL pts reached stable disease (SD); 7 continue to show SD (mean treatment duration 226.8 days [64-522]): 2 DLBCL, 2 FL, 2 MCL, 1 NMZL. 1/17 pts reached partial response (PR): a marginal zone lymphoma pt who started at 250mg and escalated sequentially up to 750 mg QD, achieving a PR at Cycle 16. Of 50 efficacy-evaluable CLL pts, 17 (34%) achieved PR. Of those, ALC increases occurred in 10 pts but resolved in 5 pts. Of 57 CLL pts enrolled, 53 were evaluable for ≥11 lymph node assessment; 24 (45%) showed lymph node reduction of ≥50% as best response. While cohort numbers are small, and many pts in early treatment cycles, ORR was 31% at 750 mg QD, 50% at 1000mg QD, and 66.7% at 375mg BID. Most pts at 500 mg BID are not yet eligible for response evaluation.10 PRs were sustained through at least 2 efficacy evaluations and 10 had poor risk factors, including unmutated *IGHV* (8), del11q (3) and/or del17p (2). The median duration of treatment is ongoing at 176 days (16-473), and 2 CLL pts have been on treatment for over 15 cycles, both initiating treatment at 400 mg QD and experiencing nodal reduction of 32% and 27% respectively.
Summary / Conclusion: This dose-finding study demonstrates that CC-292 is generally well tolerated at doses ranging from 125-1000mg QD, and 375 and 500 mg BID. 17 CLL pts and 1 B-NHL pt achieved PR at doses of 750 mg QD, 1000 mg QD, 375 mg BID and 500 mg BID. Significant nodal reduction and PRs were seen in these heavily pre-treated CLL and B-NHL pts.

S521

SILENCING OF BRUTON'S TYROSINE KINASE BY RNA INTERFERENCE INDUCES APOPTOSIS IN PRIMARY CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

E Bojnik[1,*], F Autore[2], L Laurenti[2], D Efremov[1]
[1]Molecular Hematology, International Centre for Genetic Engineering & Biotechnology, Monterotondo Scalo (Rome), [2]Department of Hematology, Catholic University Hospital A. Gemelli, Rome, Italy

Background: Signals propagated through the B cell receptor (BCR) are believed to play a key role in the initiation, maintenance and evolution of chronic lymphocytic leukemia (CLL). Drugs that can disrupt these signals have recently emerged as potential therapeutic agents in CLL and several of them have shown considerable activity in early clinical trials. Particularly promising responses have been obtained with ibrutinib, an orally bioavailable inhibitor of BTK. However, as ibrutinib can potentially inhibit other targets in addition to BTK, it remains unclear whether inhibition of this kinase is responsible for the clinical responses.
Aims: To determine whether BTK is an important therapeutic target in CLL.
Methods: Silencing of BTK in primary CLL cells was done by RNA interference and nucleofection. Leukemic cell viability was analyzed by Annexin V/PI staining. Downstream signaling events and expression of antiapoptotic proteins were evaluated by immunoblotting or ELISA.
Results: BTK was efficiently silenced in primary CLL cells (n=31) by RNA interference, resulting in 60-90% reduction in protein levels compared to CLL cells nucleofected with control siRNA. Silencing of BTK accelerated apoptosis in all of the investigated cases (% viable cells nucleofected with control siRNA: 44±15, % viable cells nucleofected with BTK siRNA: 31±16, P<0.001). Induction of apoptosis by BTK silencing was observed across various prognostic groups and was independent of IGHV mutation status, ZAP-70 and CD38 expression. To determine the mechanism responsible for apoptosis induction, we evaluated expression of the antiapoptotic proteins Mcl-1, Bcl-2 and Bcl-xL in samples transfected with control or BTK-specific siRNA. Silencing of BTK resulted in reduced Mcl-1 expression, whereas the levels of Bcl-2 and Bcl-xL remained unchanged. The reduced Mcl-1 expression was in part a consequence of caspase-mediated cleavage and in part a direct effect of BTK silencing, as evidenced by the partial restoration of Mcl-1 expression in siBTK-transfected CLL cells pretreated with the caspase 3 inhibitor Z-VAD. BTK silencing also reduced the levels of phospho-PLCγ2, phospho-CARD11 and nuclear NF-κB p50, suggesting that BTK is a component of the pathway responsible for the constitutive activation of NF-κB, a hallmark of CLL. Interestingly, BCR engagement with anti-IgM induced only a marginal rise in phospho-PLCγ2 and phospho-CARD11 levels, whereas the rise in phospho-AKT and phospho-ERK levels was only marginally affected by BTK knockdown, altogether suggesting that BTK does not play a major role in transducing signals induced by acute engagement of the BCR.
Summary / Conclusion: This study shows that BTK expression is required for CLL cell survival, confirming this kinase as an important therapeutic target in CLL. An unexpected finding was the greater impact of BTK silencing on the activity of downstream signaling pathways in unstimulated than anti-IgM-stimulated CLL cells. These findings suggest that BTK is primarily involved in transducing signals from the BCR and/or other receptors that do not depend on external antigen, and provide the rationale for exploring combinations of BTK inhibitors with other agents that target the BCR pathway.

S522

ENDOTHELIN-1/ETA RECEPTOR SIGNALING MEDIATES SURVIVAL, DRUG-RESISTANCE AND MICROENVIRONMENTAL INTERACTIONS OF CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

R Maffei[1,*], J Bulgarelli[1], S Fiorcari[1], S Martinelli[1], I Castelli[1], V Valenti[2], D Rossi[3], G Bonacorsi[1], P Zucchini[1], D Vallisa[2], V Gattei[4], G Del Poeta[5], F Forconi[6, 7], G Gaidano[3], F Narni[1], M Luppi[1], R Marasca[1]
[1]Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, Modena, [2]Hematology division, Piacenza Hospital, Piacenza, [3]Department of Clinical and Experimental Medicine, Hematology division, Amedeo Avogadro University of Eastern Piedmont, Novara, [4]Clinical and Experimental Onco-Hematology Unit, Centro di Riferimento Oncologico, I.R.C.C.S, Aviano, [5]Hematology division, S.Eugenio Hospital and University of Tor Vergata, Rome, Italy, [6]CRUK Clinical Centre, Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, [7]Department of Clinical Medicine and Immunological Sciences, University of Siena, Siena, Italy

Background: In tissue microenvironments, chronic lymphocytic leukemia (CLL) cells interact with different accessory cells that provide signals for survival, proliferation and drug-resistance. The endothelin axis, comprising endothelins (ET-1, ET-2 and ET-3) and their receptors (ETAR and ETBR), has recently emerged as relevant player in tumor growth and metastasis. Several small antagonists of ET-1 receptors are currently undergoing clinical trials as novel agents in cancer therapy.
Aims: Here, we investigated whether ET-1/ETAR signaling pathway may represent a novel pathway involved in CLL maintenance and progression.
Methods: CLL cells isolated from untreated patients were cultured either in presence or absence of endothelial cell (HUVEC) layers. Apoptosis was evaluated by flow cytometry using Annexin V/PI staining. ET-1 and ETAR expression in CLL cells was evaluated by RT-PCR, ELISA, flow cytometry and immunohistochemical staining of CLL-infiltrated lymph nodes. Phosphorylation of Akt and Erk was evaluated by western blot.
Results: CLL cells circulating in peripheral blood and infiltrating tissues secreted ET-1 and expressed ETAR on cellular surface. When CLL cells were cultured for 72 hours alone in complete medium, the addition of recombinant ET-1 peptide at 1 nM, 10 nM and 100 nM determined a 4.1-, 5.9- and 6.7-fold increase in CLL survival relative to controls respectively (P<0.05). After CLL co-cultures (n=30) on endothelial cells for 72 hours, CLL cell-derived ET-1 mRNA levels increased from 5.1±1.2 (control cultures) to 189.1±43.2 Arbitrary Units (P<0.05). Consistently, we also found a huge increase in ET-1 secretion from 0.6±0.1 pg/mL in CLL alone to 51.6±0.5 pg/mL in co-culture (n=26, P<0.05, Mann-Whitney test). Then, CLL cells were cultured on HUVEC cell layer in presence or absence of the ETAR antagonist BQ-123. BQ-123 significantly neutralized the pro-survival effect of ET-1 secretion in co-culture: we found a 2.5-fold increase of CLL viability in co-culture, and a 30% reduction by pretreating cells with 0.1 μM BQ-123 (n=11, 72h, P<0.05). Consistently, BQ-123 inhibited ET-1-mediated Akt and Erk phosphorylation. Then, we evaluated whether ET-1 could protect CLL cells from Fludarabine-induced apoptosis. We found a significant inhibition of apoptosis in presence of ET-1 both in CLL cultured alone and in CLL in co-culture on endothelial layer (n=8, P=0.003 and P=0.012 respectively). Again, treatment with BQ-123 was able to restore CLL sensitivity to Fludarabine-mediated apoptosis. Furthermore, we measured the levels of ET-1 precursor (big ET-1 peptide) in plasma samples collected from a multicentric cohort of CLL patients (n=101) using an ELISA method. Big ET-1 levels ranged from 0.47 pg/mL to 20.40 pg/mL (median= 3.88). Higher levels of big ET-1 were detected in patients with advanced Binet stage (P=0.01), high β2 microglobulin (P<0.0001), unmutated IGHV status (P=0.033), and intermediate/high FISH risk (P=0.001). Patients with ET-1 precursor levels higher than an established cut off of 5.4 pg/mL showed shorter time to first treatment (TTFT), as compared to CLL with low big ET-1 levels (5-years TTFT, 50% vs. 80%, P=0.01).
Summary / Conclusion: Collectively, our data describe for the first time a role of ET-1/ETAR signaling in CLL pathobiology. ET-1/ETAR axis is involved in CLL prolonged survival and in CLL interaction with endothelial cells suggesting that ET-1 may contribute to establish a nursing and protective niche in infiltrated tissues.

Background: Tβ4 is a ubiquitously expressed G-actin binding and sequestering protein. In different cell contexts, Tβ4 promotes tissue repair processes and differentiation of stem/progenitor cells, cell migration, and angiogenesis. In this respect, no data are available in CLL, a disease characterized by a pathological expansion of leukemic B cells and by a remarkably heterogeneous clinical course.
Aims: In the present study, modern proteomic MALDI-TOF MS profiling analysis was applied to identify low-molecular weight peptides as new molecular markers potentially playing a role in CLL pathogenesis.
Methods: Highly purified B cells from peripheral blood samples ofuntreated Binet-A CLL patients (N=100, clinicaltrials.gov NCT00917540) and 17 healthy controls were subjected to cell lysis and analyzed using Voyager De PRO MALDI-TOF mass spectrometry (PerSeptiveBiosystem). Differentially expressed m/z ion signals in the CLL proteome compared to controls were evaluated by the Olex data-mining method. Ion signals, protein spots and control peptides were characterized using on-line bio-informatic tools and databases (UniProtKB/Swiss-Prot Swiss-Prot). Gene and miRNA expression data were obtained using Affymetrix HG-U133A GeneChip Arrays (Affymetrix) from 217 and 221 CLL patients, respectively. GEP analysis was also carried out in 6 cases of normal B-lymphocyte subpopulations purified by FACS sorting based on the expression of IgD versus CD38. Non abutting gates separated naïve B-cells (N) (IgDbrightCD38$^-$CD27$^-$); marginal zone-like B-cells (IgDlowIgMbright CD38$^-$); germinal center B cells (IgD$^-$CD38$^+$) and switched memory B cells (IgD$^-$IgM$^-$CD38$^-$).
Results: MALDI-TOF MS profiling was detected 17 statistically significant differentially expressed ion signals in CLL compared to controls. Applying Olex data mining, 2 ion signals (4963.7 m/z, and 7345.3 m/z) corresponding to 5.0 and 7.3 kDa proteins, respectively could correctly differentiate normal (F-measure=0.79) from CLL cases (F-measure=0.96). The 5.0 kDa protein was characterized as Tβ4 while the 7.3-kDa protein remains to be identified. CLL was strongly associated with a down-regulation of Tβ4 [%Relative peak area normal vs CLL, 49.36±14.46 vs 34.50±12.52; mean±SD, p<.00001]. Moreover, Tβ4 expression was unchanged in CLL cases stratified according to CD38 and ZAP-70 expression, or *IGHV* mutational status. To validate the results of the MALDI-TOF analysis, an independent GEP analysis comparing CLLs and the different normal B-cell subpopulations also confirmed TMSB4X mRNA down-regulation in CLL (3604±1244 vs 5715±1004, respectively; mean±SD; P<0.001). miRNA microarray analysis identified 19 miRNA which significantly anti-correlated with TMSB4X gene expression. Of these, miR-532-3p showed the highest significance. BJAB cells transfected for 48h with miR-532-3p mimic or inhibitor (50 nM) resulted in an up-regulation of TMSB4X gene expression by miR-532-3p inhibitor. A similar up-regulation of Tb4 protein was observed in HeLa cells, which express high levels of miR-532-3p and low levels of Tβ4 protein, after exposure to miR-532-3p inhibitor.
Summary / Conclusion: Tβ4 mRNA and protein are both upregulated in CLL compared with normal B cells. Preliminary data indicate that inversely correlated miRNA expressed in CLLs may control Tb4 expression both at gene and protein levels. Further functional studies aimed to the demonstration that endogenous suppression of NF-kB activity by Tβ4 may mimic its potential utility as a therapeutic drug should confirm the potential relevance of Tβ4 modulation in CLL.

Background: In CLL, ~30% of all cases, carry quasi-identical, stereotyped VH CDR3 sequences within their B cell receptors (BcR) and can be clustered to different subsets defined by distinct VH CDR3 sequence motifs. Increasing evidence suggests that patients belonging to the same subset may share similar clinico-biological features and, perhaps, outcome. Nevertheless, even the largest VH CDR3-defined subsets account for only up to 3% of the cases with available IGHV-D-J sequence information, clearly indicating that for meaningful conclusions to be reached, reliable subset assignment and large patient cohorts are imperative.
Aims: We investigated the clinical implications of BcR stereotypy identified in a series of 4615 patients with CLL, consolidated in the context of a multi-institutional collaboration.
Methods: Subset identification was based on our previously reported approach (Blood 2012;119:4467), and associations were sought for major subsets which collectively accounted for 727 cases, namely: (i) subsets with unmutated IGHV genes (U-CLL): #1, n=129; #3, n=47; #5, n=24; #6, n=47; #7, n=78; #8, n=33; #31, n=19; #59, n=19; (ii) subsets with mutated IGHV genes (M-CLL): #4, n=61; #16, n=19; #77, n=23; #148, n=49; #201, n=21; and, (iii) subset #2 (IGHV3-21, variable mutational status), n=158.
Results: Regarding age at diagnosis, (i) M-CLL subsets #4, #16 and #201 (all utilizing the IGHV4-34 gene), #77, and #148 as well as U-CLL subsets #3, #5 and #7 (all utilizing the IGHV1-69 gene) and #31 contained significantly younger patients (P<0.001) compared to subsets #1, #2, #6, #8 and #59. While, these findings confirm and significantly extend previous reports by us and others about subset #4 they provide novel information about all other subsets. Significantly (p<0.001) different gender distributions were identified, with male:female ratios ranging from greater than 4.0 for U-CLL subsets #3 and #5 (both IGHV1-69) and #31 (IGHV3-48) to less than 0.8 for U-CLL subset #8 (IGHV4-39) and M-CLL subset #201 (IGHV4-34). Among the most populated subsets, strikingly different (P<0.01) profiles of genomic aberrations (hierarchical model) were identified, exemplified by: (i) diminished frequency of del(17p) in subset #2 versus all others, especially subsets #1 and #8; (ii) significantly higher frequency of del(11q) in subsets #3, #5 and #7 (all IGHV1-69, range 37% to 44.4%) versus all others; (iii) significantly higher frequency of trisomy 12 in subset #8 (69.2%) versus all others; (iv) homogeneous profile of subset #4 that is characterized by high frequency of del(13q) and very low frequency of other aberrations extending to complete absence of del(17p). We assessed time-to-first-treatment (TTFT) and noted significantly shorter TTFT in subset #2 vs. M-CLL subsets vs. U-CLL subsets and also vs. U-CLL as a whole (p<0.01), thus corroborating previous observations about the adverse prognosis of subset #2. Among U-CLL subsets in general, significantly worse outcomes were found for subsets #31 and #59 (P=0.06 and P=0.005, respectively). Focusing on U-CLL subsets utilizing the IGHV1-69 gene (subsets #3, 5, 6, 7, 59), significantly shorter TTFT was identified for subset #59 (P=0.03). M-CLL subsets in general had significantly longer TTFT compared to U-CLL subsets (p<0.05). Among M-CLL subsets, a trend for longer TTFT was seen for subset #148 (P=0.06).
Summary / Conclusion: In conclusion, in the largest series analyzed thus far, we provide results strongly supporting the concept that the molecular classification of CLL into stereotyped subsets is biologically and clinically relevant.

Hodgkin Lymphoma

S525

TEMPORAL TRENDS IN MORTALITY FROM DISEASES OF THE CIRCULATORY SYSTEM AFTER TREATMENT FOR HODGKIN LYMPHOMA – A POPULATION-BASED COHORT STUDY IN SWEDEN (1973-2006)

M Björkholm[1,*], S Eloranta[1], P Lambert[2], T Andersson[1], J Sjöberg[1], P Dickman[1]
[1]KAROLINSKA UNIVERSITY HOSPITAL, Stockholm, Sweden, [2]University of Leicester, Leicester, United Kingdom

Background: Hodgkin lymphoma survival in Sweden has improved dramatically over the past 40 years, but little is known about the extent to which efforts aimed at reducing long-term treatment-related mortality have contributed to the improved prognosis.
Aims: To estimate the contribution of treatment-related mortality due to diseases of the circulatory system (DCS) to temporal trends in excess Hodgkin lymphoma mortality among Swedish patients.
Methods: We used population-based data from the national Swedish cancer register. Flexible parametric survival models were used to estimate excess mortality among 5,462 patients diagnosed at ages 19 to 80 between 1973 and 2006. The total excess mortality experienced by the patients was partitioned into component parts in order to isolate the excess DCS mortality (assumed to be caused by the treatment) from the remaining excess mortality (such as that from the underlying disease, second malignancies and infections). In addition we utilized recent advances in statistical methodology to estimate excess mortality in the presence of competing causes of death. These models were used to predict the long-term risk for patients diagnosed in the modern era to die from treatment-related DCS.
Results: Excess DCS mortality within 20-years after diagnosis has decreased continually since the mid 1980´s and is expected to further decrease among patients diagnosed in the modern era. Age at diagnosis and sex were important predictors for excess DCS mortality, with advanced age and male sex being associated with higher excess DCS mortality. However, when accounting for competing causes of death, we found that excess DCS mortality constitutes a relatively small proportion of the overall mortality among Hodgkin lymphoma patients in Sweden.
Summary / Conclusion: Excess DCS mortality is no longer a common source of mortality among Swedish HL patients. The main causes of death among long-term survivors today are deaths from other causes than Hodgkin lymphoma, although other (non-DCS) excess mortality also persists as long as 20 years after diagnosis, particularly among older patients.

S526

LONG-TERM EFFECTS OF AUTOLOGOUS STEM-CELL TRANSPLANTATION FOR FIRST RELAPSED OR REFRACTORY HODGKIN LYMPHOMA: AN UPDATED ANALYSIS OF THE PROSPECTIVE LYSA/SFGM-TC H96 TRIAL

D Sibon[1,*], M Resche-Rigon[2], F Morschhauser[3], C Ferme[4], J Dupuis[5], A Marcais[1], R Bouabdallah[6], C Sebban [7], G Salles[8], P Brice
[1]Hematologie, Hopital Universitaire Necker - Enfants Malades, [2]Biostatistique et Informatique Medicale, Hopital Saint-Louis, Paris, [3]Hematologie, Hopital Universitaire Claude Huriez, Lille, [4]Hematologie, Institut Gustave Roussy, Villejuif, [5]Hematologie, Hopital Henri Mondor, Creteil, [6]Hematologie, Institut Paoli-Calmettes, Marseille, [7]Hematologie, Centre Leon Berard, Lyon, [8]Hematologie, Centre Hospitalier Lyon Sud, Pierre Benite, [9]Hemato-oncologie, Hopital Saint-Louis, Paris, France

Background: There is a lack of long-term prospective data assessing efficacy and toxicity of autologous stem-cell transplantation (ASCT) for first relapsed or refractory Hodgkin lymphoma (HL).
Aims: H96 trial is one of the largest prospective studies on ASCT for first relapsed or refractory HL. The first analysis was published after a median follow-up of 51 months (Morschhauser F, J Clin Oncol 2008). Here we present an updated analysis after a median follow-up of 10.4 years.
Methods: H96 trial evaluated a risk-adapted salvage treatment with single or tandem ASCT for 245 HL patients. Poor-risk patients (n=150) had primary refractory HL (n=77) or unfavorable relapse (≥2 of the following risk factors at first relapse: time to relapse <12 months, stage III or IV at relapse, and relapse within previously irradiated sites, n=73) and were eligible for tandem ASCT. Intermediate-risk patients (n=95) had one risk factor at first relapse and were eligible for single ASCT.
Results: Among poor-risk patients, 105/150 (70%) received tandem ASCT, whereas 92/95 intermediate-risk patients (97%) received single ASCT. According to intent-to-treat analysis, the 10-year freedom from second failure (FF2F) and overall survival (OS) estimates were 64% and 70%, respectively, for the intermediate-risk group, and 40% and 47%, respectively, for the poor-risk group. In the poor-risk group, outcomes were similar for primary refractory HL and unfavorable relapse (10-y FF2F 33% vs 48%, P=0.06; 10-y OS 43% vs 51%, P=0.26). Disease status at time of ASCT (Cheson 1999) was a major prognos-

tic factor driving outcome. In the poor-risk group, the 10-y OS was 68%, 58%, 16% and 22% for patients in complete remission (CR)/unconfirmed CR (CRu), partial remission (PR), stable disease (SD) and progressive disease (PD), respectively (P<0.0001), without significant difference between CR/CRu and PR patients (P=0.12). In the intermediate-risk group, 92/95 patients were in CR/CRu or PR at time of transplantation. The 10-y OS was 72% and 66% for patients in CR/CRu and PR, respectively, without significant difference (P=0.96). In the poor-risk group, 76 patients relapsed with 5-y and 10-y cumulative incidence of relapse of 47% and 51%, respectively. In the intermediate-risk group, 25 patients relapsed with 5-y and 10-y cumulative incidence of relapse of 24% and 27%, respectively. After relapsing, 23 patients underwent allogeneic stem-cell transplantation (alloSCT), mainly after a non myeloablative conditioning regimen (n=20); their 5-y OS was 60% (intermediate-risk group, n=5) and 33% (poor-risk group, n=18). For relapsed patients who did not undergo alloSCT (n=78), 5-y OS was 45% (intermediate-risk group, n=20) and 14% (poor-risk group, n=58). In all, 110 patients died (intermediate-risk group, n=30; poor-risk group, n=80). The main cause of death was HL (n=83, 75% of causes of death) whereas other causes included solid tumor (n=3), acute leukemia (n=5), non-Hodgkin lymphoma (n=2), infection (n=5), cardiac toxicity (n=2), post-alloSCT complication (n=5) or other (n=5).

Summary / Conclusion: With long-term follow-up, single ASCT remains appropriate for intermediate-risk patients with 10-y OS at 70% and a low toxicity. For poor-risk-patients, tandem ASCT remains a valuable option with 10-y OS at 47%, especially for patients in CR/CRu or PR at time of ASCT.

S527

IMPACT OF DOSE DENSITY AND HEMATOTOXICITY OF DHAP-REINDUCTION THERAPY ON THE OUTCOME IN RELAPSED HODGKIN LYMPHOMA (HL): AN ANALYSIS OF THE GERMAN HODGKIN-STUDY GROUP (GHSG)

S Sasse[1,*], M Alram[1], H Müller[1], L Smardova[2], B Metzner[3], H Doehner[4], T Fischer[5], D Niederwieser[6], N Schmitz [7], K Schäfer-Eckart[8], J Raemaekers[9], O Schmalz[10], B von Tresckow[1], A Engert[1], P Borchmann[1]

[1]First Department of Internal Medicine, University Hospital of Cologne and German Hodgkin Study Group, Cologne, Germany, [2]University Hospital Brno and Faculty of Medicine, Masaryk Hospital, Brno, Czech Republic, [3]Department of Hematology and Oncology, Hospital of Oldenburg, Oldenburg, [4]Internal Medicine III, University of Ulm, Ulm, [5]Department of Hematology/Oncology, University of Magdeburg, Magdeburg, [6]Department of Hematology and Oncology, University Hospital Leipzig, Leipzig, [7]Department of Hematology and Stem Cell Transplantation, Asklepios Clinic St. Georg, Hamburg, [8]Department of Hematology/Oncology, Klinikum Nuernberg Nord, Nuernberg, Germany, [9]Department of Hematology, Radbound University Nijmegen Medical Centre, Nijmegen, Netherlands, [10]Clinic I for Internal Medicine, Helios Clinic Wuppertal, Wuppertal, Germany

Background: Despite of an intensive reinduction therapy followed by high-dose-chemotherapy (HDCT) and autologous stem cell transplantation (ASCT), only 50% of patients with relapsed Hodgkin Lymphoma (HL) achieve long-term remission. Response to reinduction treatment is predictive for the outcome. In order to optimize the reinduction therapy in relapsed HL, we aimed at increasing dose density of DHAP (dexamethasone, high-dose cytarabine, cisplatinum) in the HDR2 trial by shortening the cycle interval from 21 to 14 days.

Aims: In this retrospective analysis of the HDR2 trial, the clinical impact of dose density of DHAP was evaluated. In addition, we assessed the impact of DHAP-associated hematotoxicity on dose density and treatment outcome.

Methods: In the HDR2 trial, patients with relapsed HL without disease progression after two courses of DHAP were randomized to receive additional sequential HDCT or to directly proceed to HDCT with BEAM followed by ASCT. DHAP cycle interval was defined as the time interval between day 1 of the first course and start of the second DHAP course. Kaplan Meier and Cox regression analyses were used to estimate the prognostic value of the DHAP cycle interval and of hematotoxicity on progression free survival (PFS) and overall survival (OS) after relapse. The impact of different variables on the length of DHAP cycle interval was examined with linear regression analysis. The level of significance was set to P<0.05.

Results: Data of 269 patients were evaluable for this analysis. The median age was 36 years; 36% of the patients analyzed were female, 53% had advanced-stage disease at diagnosis of relapse, and 13% had received >1 previous chemotherapy. Median time from initial diagnosis to relapse was 44.3 months. Only 15% of the analyzed patients received the second DHAP course within the recommended time interval of 14 days; in 39% the DHAP course interval was 21 days or longer. 232 patients were randomized after two courses of DHAP. A significant association between the length of the DHAP cycle interval and the outcome was shown in univariate (PFS: P=0.017; OS: P= 0.012) as well as in multivariate cox regression analysis including early or multiple relapses, stage IV disease and anemia at relapse as established prognostic factors (PFS: P=0.035; OS: P=0.003). Patients who received the second DHAP course on day 21 or later had a significantly poorer PFS and OS when compared to those patients who proceeded before day 21 (3-year PFS 58% vs. 73%, P= 0.027; 3-year OS 76% vs. 87%, P=0.016, respectively).

DHAP-associated grade 4 hematotoxicity had a significant impact on the length of DHAP course intervals (P=0.022 in multivariate linear regression analysis). Those patients who developed thrombocytopenia or leukocytopenia grade 4 had significantly longer course intervals. In addition to the prognostic factors of the Josting score and the length of the DHAP course interval (> 21/≤21 days), severe hematotoxicity was associated with a significantly shorter PFS (HR 1.36: P= 0.036) and OS (HR 1.79; P= 0.012) in multivariate analysis.

Summary / Conclusion: Dose density of DHAP reinduction therapy is an independent prognostic factor with regard to PFS and OS in relapsed HL patients. Additionally, hematotoxicity grade 4 is a significant factor contributing to prolonged DHAP course intervals and has a negative impact on PFS and OS. These results support the mandatory use of G-CSF in this setting as well as an investigation of thrombopoietin analogues during DHAP reinduction therapy in order to maintain dose density.

S528

OUTCOME AND RISK FACTORS OF HODGKIN LYMPHOMA PATIENTS WITH _RELAPSE OR PROGRESSION AFTER AUTOLOGOUS STEM CELL TRANSPLANT:_ A REPORT FROM THE GERMAN HODGKIN STUDY GROUP (GHSG)

B Von Tresckow[1,*], H Müller[1], D Eichenauer[1], J Glossmann[1], A Josting[2], B Böll[1], B Klimm[1], M Fuchs[1], P Borchmann[1], A Engert[1]

[1]Internal Medicine I, Cologne University Hospital, Cologne, [2]OncoBer, Berlin, Germany

Background: Today, most patients with Hodgkin Lymphoma (HL) can be cured at first diagnosis. For HL patients suffering from relapse or progression after first line therapy, high dose chemotherapy followed by autologous stem cell transplant (ASCT) is the treatment of choice and cures about 50% of these patients. Those who relapse or progress after ASCT have a very poor prognosis and clearly represent an area of unmet medical need. However, data on this small group of patients is rather limited and no established risk factors are available. Here, we present a recent retrospective analysis from the GHSG database on HL patients with recurrence after ASCT.

Aims: Our aims were to better characterize HL patients with relapse or progression after ASCT in order to define possible risk factors for the prediction of overall survival.

Methods: All trials in the GHSG database were searched for HL patients who relapsed or progressed after ASCT.The information for this retrospective analysis was updated in May 2012. Overall survival after progression of HLfollowing ASCT (OSrr) was the end point of this study. Descriptive statistics and Kaplan Meier estimates of OSrrwere used and risk factors for OSrranalyzed. The significance level was set to 0.05.

Results: 152 patients who relapsed or progressed with HL after ASCT were identified. 149 patients fulfilled the predefined inclusion criteria. With a median observation time of 65 months after progression, 112 patients (75%) had died. OSrrwas 63% (95% confidence interval [CI]; 54% to 70%), 51% (95% CI 42% to 58%), and 20% (95% CI 13% to 28%) at 1, 2 and 5 years, respectively. From several risk factors tested, stage (P=0.044) and presence of B-symptoms (P=0.005), both at relapse before ASCT, significantly predicted OSrr. Combination of these two risk factors allowed the identification of three distinct risk categories for the four significantly different groups (P=0.013, Figure 1).

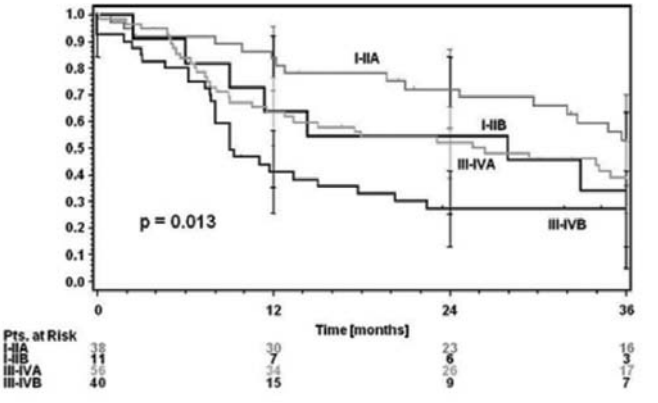

Figure 1.

Accordingly, patients in clinical stage I or II without B-symptoms had a better prognosis (OSrr84% [95% CI 67% to 92%], 72% [95% CI 54% to 84%] and 33% [95% CI 18% to 49%] at 1, 2 and 5 years, respectively) in comparison to patients with stage III or IV with B-symptoms (OSrr 41% [95% CI 26 to 57%], 27% [95% CI 13 to 42%] and 8% [95% CI 0 to 18%], respectively).Other potential risk factors such as stage at first diagnosis (P=0.80), early, late or multiple

relapses before ASCT (P=0.95), and time from ASCT to further progression of HL (P=0.81) were not significant.
Summary / Conclusion: 1. Stage and B symptoms at relapse before ASCT are significant predictors of OS in relapsed HL patients receiving ASCT.2. Current treatment approaches for patients with relapsed or progressive HL after ASCT showdisappointing results with 80% of this very high-risk group dying within 5 years. Emerging new drugs such asbrentuximabvedotinmight improve the outcome of these patients in the future.

S529

THE TH-INFILTRATE OF HODGKIN LYMPHOMA HAS A UNIQUE PHENOTYPE RICH IN ACTIVATION/PROLIFERATION MARKERS, CENTRAL MEMORY & TH1-POLARISED CELLS, WITHOUT EVIDENCE OF SENESCENCE, SUPPRESSION OR EXHAUSTION
P Greaves[1,*], S Iqbal[1], A Wilson[1], J Matthews[1], M Calaminici[1], J Gribben[1]
[1]Centre for Haemato-Oncology, Bart's Cancer Institute, Queen Mary University of London, London, United Kingdom

Background: CD4+ T cells (T-helper cells: TH) dominate the classical Hodgkin lymphoma (CHL) microenvironment but a detailed understanding of their function is lacking. We hypothesized that rather than being immunosuppressive, TH2-polarized cells, the TH-cells of CHL comprise activated, proinflammatory cells capable of sustaining malignant Hodgkin Reed Sternberg cells (HRS). Understanding the key intercellular mediators of survival signals may provide pharmacological targets in therapy-resistant patients.
Aims: Using TH-expressed markers of known or proposed functional importance in CHL the aim was to characterize pathognomonic features of HRS-helper T cells distinguishing them from the reactive TH cells of non-malignant inflammatory lymph nodes
Methods: Frozen single cell suspensions (SCSs) from diagnostic CHL-infiltrated lymph node biopsies (n=7), and control reactive cervical lymph nodes (n=5) were thawed and stained for CD3/CD4 and markers of functional importance in CHL, including tumour-necrosis-factor superfamily (TNFRSF) members, chemokine receptors (CCR), memory, activation, senescence, immunosuppression mediators and TH1/TH2 cytokines. Flow cytometry was performed, markers expressed as % total CD3+CD4+ population and medians calculated for each tissue (CHL vs reactive control). Mann-Whitney U tests determined significant differences between CHL and reactive node-derived cells
Results: CHL-infiltrating TH-cells comprised a similar proportion of total thawed cells in CHL and controls (40%), outnumbering CD8+ T cells. Central memory (CM) T cells (CD45RA-CCR7+, associated with superior activity) were a more dominant component of CHL TH-cells than controls (29% vs 11% P=0.03) while TEMRA cells (CD45RA+CCR7-, associated with exhaustion and impaired function) were more common in controls (1% vs 9% P=0.02). Markers of exhaustion and immunosuppression were expressed in non-significantly fewer TH-cells in CHL vs controls - CD57 (1% vs 22%) and PD1 and (6% vs 21%). Although FOXP3 was found at comparable levels in CHL and reactive node TH cells (10%), its effector molecule CTLA4 was expressed at higher levels in CHL (48% vs 19%, P=0.05). Ligands of HRS-expressed TNFRSF members CD30, OX40 and ICOS were expressed at substantially higher levels in CHL-derived TH cells (CD30L in 22.9% vs 6.5%, P=0.02; OX40+ICOS+ in 32.3% vs 10.5%, P=0.05). CCR expression patterns were profoundly discriminatory: despite similar levels of the receptor for the CHL-characteristic chemokine TARC/CCL17 (CCR4) in CHL and control TH cells (5.7% vs 10.5%), TH1-associated CCRs CXCR3 and CCR5 were dominant in CHL vs controls (53.5% vs 16.8%; P=0.02 and 18.9% vs 5.9%, P=0.02) while the T follicular helper cell marker CXCR5 was reduced in CHL (5.1% vs 24.1%). TH2 cytokines were entirely absent, while IFNg was expressed in similar numbers of cells (4%) and TNFa in more CHL-derived TH cells (20% vs 10%).
Summary / Conclusion: CHL-infiltrating TH cells are cytokine-secretory, activation marker-rich and lack exhaustion/suppression markers, hence are capable of mediating survival signals to HRS cells. The malignant node sequesters substantial numbers of central memory cells, which may contribute to the profound systemic immune defect encountered in advanced disease. An infiltrate of activated CD4+ cells rich in CM cells, lacking PD1, CD57 and CXCR5 and expressing CTLA4, CD30-L, OX40, ICOS, CXCR3 & CCR5 appears to be a pathognomonic signature even when compared to reactive control nodes, in contrast to the TH2-polarized suppressive cell-rich infiltrate currently proposed for CHL, and may be suitable for diagnostic purposes in difficult cases.

MPN PATIENTS HARBOR RECURRENT TRUNCATING MUTATIONS IN TRANSCRIPTION FACTOR NF-E2
J Jutzi[1,*], R Bogeska[1], G Nikoloski[2], C Schmid[1], T Seeger[1], F Stegelmann[3], S Schwemmers[1], A Gründer[1], J Peeken[1], M Gothwal[1], J Wehrle[1], K Aumann[4], K Hamdi[1], C Dierks[1], W Wang[1], K Döhner[3], J Jansen[2], H Pahl[1]
[1]Department of Hematology/Oncology, Center for Clinical Research, Freiburg im Breisgau, Germany, [2]Department of Laboratory Medicine Radboud University Nijmegen Medical Centre and Nijmegen Centre for Molecular Life Sciences Nijmegen, Laboratory of Hematology, Nijmegen, Netherlands, [3]Department of Internal Medicine III, University Hospital of Ulm, Ulm, [4]Institute of Pathology, University Hospital, Freiburg im Breisgau, Germany

Background: We have described overexpression of the transcription factor NF-E2 in MPN patients and shown that elevated NF-E2 levels cause a MPN phenotype in transgenic mice.
Aims: To further investigate the role of *NF-E2* in the pathophysiology of MPNs, we sequenced the *NF-E2* gene in a cohort of MPN patients and related myeloid disorders.
Methods: The *NF-E2* gene was sequenced in 456 MPN patients as well as in patients with MDS, CMML, post-MPN-AML and healthy controls. Functionality of the mutants was determined by DNA binding- and reporter gene assays. Hematopoietic colonies grown from MPN patient cells were assayed for NF-E2 and $JAK2^{V617F}$ mutations. The *in vivo* effect of NF-E2 mutations was assessed in a murine bone marrow transplant model.
Results: Acquired insertions and deletions leading to frameshift mutations were detected in the *NF-E2* coding sequence in patients with PV and MF. The frameshifts introduce premature stop codons, leading to truncations in the NF-E2 protein. Truncated NF-E2 proteins contain neither the DNA binding domain nor the leucine zipper required for dimerization to small Maf proteins.
Mutant NF-E2 proteins do not bind DNA in a gel-shift-assay. Furthermore, on their own, they do not transactivate reporter gene activity. However, since all *NF-E2* mutations were observed in a heterozygous state, we tested their ability to activate reporter gene expression in the context of wt NF-E2. Surprisingly, NF-E2 mutants, which on their own retain no transactivation activity, significantly enhance wt NF-E2 activity.
Analysis of individual hematopoietic colonies revealed that in three patients the *NF-E2* mutation was acquired subsequent to the $JAK2^{V617F}$ mutation. These assays revealed a proliferative advantage of NF-E2 mutant cells as cells that acquired both a *NF-E2* and a $JAK2^{V617F}$ mutation vastly outcompeted cells carrying the $JAK2^{V617F}$ mutation alone. This observation was recapitulated in a murine model, where mice expressing both the $JAK2^{V617F}$ mutation and mutant NF-E2 display a statistically significant increase in hemoglobin, MCV, MCH and WBC count above that affected by $JAK2^{V617F}$ alone. These data demonstrate that *in vivo*, mutant NF-E2 cooperates with $JAK2^{V617F}$ to augment the MPN phenotype. We determined the molecular mechanism mediating the selective advantage of cells carrying NF-E2 mutations. The presence of mutant NF-E2 conferred a proliferative advantage in the absence of cytokines beyond that conferred by $JAK2^{V617F}$ alone, witnessed by the accumulation of high cell numbers as well as by a significant increase in the proportion of cells in S-phase. Moreover, cells carrying both $JAK2^{V617F}$ and mutant NF-E2 expressed significantly higher levels of the cell cycle regulators cyclinD3, CDK4 and CDK6, which promote the G1-S transition.
Mice transplanted with NF-E2 mutants displayed a statistically significant elevation in hematocrit, RBCs, neutrophils and platelets. Both peripheral blood and bone marrow (BM) show a myeloid bias, with statistically significant increases in the proportion of myeloid cells in the peripheral blood and a corresponding elevation of the number of CMP, MEP and GMP in the BM. Moreover, following the myeloproliferative phase, NF-E2 mutation carrying mice transform to acute myeloid leukemia.
Summary / Conclusion: Our data identify *NF-E2* as a novel mutational target in MPN patients, one that enhances wtNF-E2 function *in vitro* and promotes erythrocytosis, thrombocytosis and a myeloid bias *in vivo*. Our data underscore the role of elevated NF-E2 activity in the pathophysiology of myeloproliferative neoplasms.

Medizinische Klinik, Universitätsmedizin Mannheim, Mannheim, Germany, [31]Department of Haematology, Guy's and St Thomas' NHS Foundation Trust, Guy's Hospital, London, [32]Cancer Genome Project, Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Background: Epidemiological studies have suggested the presence of common genetic variation that predisposes to the development of myeloproliferative neoplasms (MPN) in the general population. Indeed, we have previously found that a specific *JAK2* haplotype, termed 46/1 or GGCC, strongly predisposes to *JAK2* V617F positive disease. This haplotype, however, only accounts for approximately 50% of the overall population attributable risk of developing an MPN and explains only a very minor component of V617F-negative disease. Thus, other predisposition factors remain to be identified.
Aims: To identify common, low penetrance genetic factors that predispose to the development of myeloproliferative neoplasms.
Methods: We undertook a three stage genomewide association study (GWAS), focusing on MPN that were negative for *JAK2* V617F. The study group (n=2506) included cases with either essential thrombocythaemia or primary myelofibrosis recruited from the UK, Italy, Germany, Austria and Greece. Established cohorts (WTCCC, KORA, INCHIANTI) were used as population controls as well as locally collected samples.
Results: In Stage 1 Affymetrix SNP 6.0 analysis was performed on 585 UK cases and, after extensive quality control, the genotypes of 642,633 SNPs were compared to WTCCC2 data. Stage 2 consisted of targeted analysis of the top 203 SNPs from Stage 1 (based on statistical and biological criteria) in 956 cases and 5707 controls from the UK, Greece, Germany, and Austria. This analysis identified 7 SNPs that remained significant after correction for false discovery rate ($P \leq 0.0016$) and had effects in the same direction as stage 1. At stage 3, these 7 SNPs were tested in a further 965 cases and 4,408 controls from 2 independent cohorts from the UK and Italy. The final effect size and significance of these 7 SNPs was determined by a fixed effects meta-analysis of the 6 cohorts. According to methodology described by the WTCCC2 and estimating that this GWAS has 80% power, SNPs with p-values $\leq 5 \times 10^{-7}$ were determined to be statistically significant. Following meta-analysis, 2 SNPs with genome wide levels of significance and without heterogeneity between cohorts were identified. The most significant of these SNPs lies 153 kb downstream of *EVI1* (chr 3q26; HR = 0.84, p-value=2.1×10^{-8}) and the other is located in an intron of *ITGA8* (chr 10p13; HR = 1.88, p-value=1.1×10^{-7}). Two further associations, one between *HB1SL* and *MYB* (chr 6q23; p-value = 2.5×10^{-6}) and the other between *THRB* and *RARB* (chr 3p24; P= 2.5×10^{-5}), approached genome wide significance but the heterogeneity between cohorts was also significant. Since reduced *MYB* expression has been associated with development of ET-like disease in mouse models, we analysed gene expression in myeloid progenitors cultured *in vitro* from a series of healthy controls by qRT-PCR. Reduced *MYB* expression, but not *HBS1L*, relative to the housekeeping gene *GUSB* was significantly associated with the chromosome 6 risk allele (n=18; P=0.0001).
Summary / Conclusion: We have identified SNPs in or close to two genes, *EVI1* and *ITGA8*, which alter the risk of developing *JAK2* V617F negative MPN. Two further loci approach statistical significance and one of these is associated with reduced *MYB* expression.

S532

IDENTIFICATION OF A NOVEL MODE OF KINASE INHIBITOR RESISTANCE IN JAK2: JAK2 INHIBITOR RESISTANCE IS MEDIATED BY THE GENERATION OF 45-KDA JAK2 VARIANT WHICH ALTERS THE KINASE DOMAIN STRUCTURE

S Gorantla[1,*], N von Bubnoff[1], M Rudelius[2], C Albers[3], A Illert[1], J Duyster[1]
[1]Dept.of Hematology and Oncology, Universität Klinikum Freiburg, Freiburg, [2]Dept.of Pathology, [3]Dept.of Hematology and Oncology, Technical University of Munich, Munich, Germany

Background: JAK2 V617F can be identified in the majority of cases of polycythemia vera (PV), and in 50% of cases in essential thrombocythemia (ET) and idiopathic myelofibrosis (IMF). JAK2 inhibitors including ruxolitinib (Jakavi, INCB018424), TG101348 and lestaurtinib (CEP-701) display clinical activity in clinical trials in PV, ET and IMF, and ruxolitinib has recently been approved for the treatment of primary and secondary myelofibrosis. In other malignancies it has been demonstrated that acquired resistance to kinase inhibitors is due to emergence of secondary resistance mutations in the target kinase.
Aims: Identification of JAK2 point mutations or resistant mechanism against the ruxolitinib is very imporatnt in order to develop second generation JAK2 inhibiotrs or alteration of treatment staregy to the patients.
Methods: Cell based Screening strategy against the inhibitor is the most comprehensive method in order to identify the drug resistant mutations. For this we exposed JAK2 V617F expressing Ba/F3 cells to ruxolitinib.
Results: Surprisingly, sublines resistant to ruxolitinib at 1000nM, 2000nM and even 4000nM did not harbor point mutations neither in the kinase or the pseudokinase domain of JAK2. However, western blot analysis of sublines resistant to ruxolitinib revealed a 45-kDa JAK2 variant together with full length JAK2V617F protein in 87% of the cases. Sequencing of the short form in drug resistant clones revealed a novel JAK2 variant missing amino acids 76 to 820 resulting in the N-terminal FERM domain directly fused to the kinase domain of JAK2 (FERM-JAK2). FERM-JAK2 was highly resistant to the ATP-competitive JAK2 inhibitors ruxolitinib and TG101348. JAK2 exists in an either active or inactive state, which is largely regulated by phosphorylation of tandem tyrosines located within the activation loop. Substitution of phenylalanine at tyr1007, tyr1008 or both leads to complete inactivation of V617FJAK2 and WT-JAK2.In contrast, Y to F mutation of tyr1007, tyr1008 or both in FERM-JAK2 does not prevent activation of STAT5 and transformation of Ba/F3 cells, suggesting that FERM-JAK2 preferentially exist in an inactive state. This would impede drug binding and explain the resistant phenotype of FERM-JAK2. Phospho-deficient mutant studies further provided evidence that tyr866, tyr966, and tyr972 are crucial for the activation of FERM-JAK2. Ectopic expression of FERM-JAK2 in HEK293T, NIH3T3 and Ba/F3 cells showed activation of STAT5 and transformation of Ba/F3 cells to factor independence. Interestingly, co-immunoprecipitation studies revealed that FERM-JAK2 does not bind or activate the IL-3R in contrast to V617FJAK2. Ectopic expression of FERM-JAK2, in contrast to V617FJAK2, was able to activate STAT5 in a cytokine receptor deficient cell line. *in vitro* binding studies revealed that FERM-JAK2 directly binds and activates STAT5. Using flag- and myc-tagged FERM-JAK2 we show that the FERM domain is sufficient for an efficient dimerization and activation of FERM-JAK2 in the absence of an cytokine receptor. Transplantation of retrovirally transduced murine bone marrow with FERM-JAK2 compared to JAK2 V617F showed an accelerated phenotype with marked increases in WBC, HCT, RBC, HB, reticulocytes, pronounced splenomegaly and loss of body weight in mice. In contrast to V617FJAK2 expressing mice, FERM-JAK2 expressing mice displayed a lethal phenotype.
Summary / Conclusion: Taken together, we could identify a novel JAK2 variant which alters the kinase domain structure, leads to direct, cytokine receptor independent STAT5 activation, and gives rise to an accelerated, PV-like disease in mice.

S533

THE MUTATIONAL LANDSCAPE AND CLONAL ARCHITECTURE OF MPN PATIENTS DETERMINED BY TARGETED NEXT GENERATION SEQUENCING

P Lundberg[1,*], A Karow[1], R Nienhold[1], T Lehmann[2], A Tichelli[3], J Passweg[3], C Beisel[4], R Skoda[1]
[1]DBM, University Hospital Basel, Basel, [2]Cantonal Hospital St. Gallen, St. Gallen, [3]University Hospital Basel, [4]ETH, Basel, Switzerland

Background: Myeloproliferative neoplasms (MPNs) are a group of diseases characterized by aberrant proliferation of the myeloid, erythroid and/or megakaryocytic lineages. In addition to JAK2-V617F mutations, a number of acquired alterations have been found to be involved in the initiation and progression of MPN. However, since the sequencing studies to date focus on examining mutations in only single or low number of genes, the interplay between different mutations is difficult to appreciate. Also, many of the mutations reported in MPN are rare (1-10% of patients carry them) and larger cohort studies are necessary to understand the impact of these less abundant mutations. Here we report the mutational spectra of a cohort of 214 MPN patients

analyzed using multiplexed next generation sequencing for mutations in 110 genes. In addition, we also demonstrate the clonal architecture for patients harboring multiple mutations.

Aims: We aim at defining the mutational spectra of a cohort consisting of 214 MPN patients and dissecting the clonal architecture of patients carrying multiple alterations. We developed a rapid, robust and cost efficient method that can be used for large cohort studies to analyze correlations between mutations and clinical presentation.

Methods: DNA from 214 MPN patients was fragmented, barcoded using 48 indexed adapters and enriched using Agilent SureSelect. The genes in the enrichment panel consisted of all genes reported to be mutated in MPN, as well as 100 additional genes found to be mutated in other myeloid malignancies or involved in hematopoietic signaling. The enriched DNA was sequenced using Illumina HiSeq2000 and each unique barcode assigned to its respective patient (48 patients/reaction). All patients were analyzed in duplicates and only mutations present in duplicate samples were considered candidate mutations. All candidate mutations were confirmed using an orthogonal NGS platform (Ion Torrent) and the somatic nature of the mutations was proven by comparing the mutations with paired non-hematopoietic DNA. Single colonies were picked and analyzed from patients with multiple mutations to assess the clonal architecture and temporal order of acquisition.

Results: We sequenced 110 genes (>1200 exons) in 214 MPN patients obtaining an average coverage of ~350-fold for the target regions. We used the JAK2-V617F mutations to estimate the sensitivity of the method. We were able to detect in JAK2-V617F 128/130 patients with an allelic burden >5%, which was the cutoff used for the Illumina mutation calling. Analysis of somatic mutations showed that 45/214 (21%) patients harbored 2 or more somatic mutations, and 7/214 (3%) patients carried 3 or more somatic mutations and no specific trend of mutation co-existance was observed (Figure 1, left circos plot shows JAK2-V617F positive patients and left circos plot shows JAK2-V617F negative patients). Sequencing of serial samples and single colonies from the same patient to assess the clonal architecture in patients with multiple mutations showed that no strict order of acquisition could be observed, and no genetic aberration was in all patients exclusively acquired before JAK2-V617F. Sequencing of serial samples for mutations described to be responsible for leukemic transformation (TP53 and KRAS/NRAS) assesses the kinetics between acquisition of the mutation and leukemic transformation. Furthermore, we detected novel somatic mutations in 9 genes not previously described to be involved in the MPN pathogenesis.

Summary / Conclusion: We were able to develop a tool allowing multiplexed cohort analysis using NGS. We found that ~21% of MPN patients harbored 2 or more somatic mutations. Analysis of the clonal architecture showed that none of the mutations exclusively preceded the acquisition of JAK2-V617F and no clear patter of co-existance between mutations was observed. Furthermore, we were also able to detect somatic mutations in 9 genes previously not described to be involved in the MPN pathogenesis.

[1]UMRS-940, Inserm, [2]Unite de Biologie cellulaire, [3]Laboratoire de Therapie Cellulaire, AP-HP, hopital Saint-Louis, Paris, [4]UMRS -935, Inserm, [5]ESTeam paris sud, University paris 11, Villejuif, [6]Centre d'Investigations Cliniques, AP-HP, hopital Saint-Louis, Paris, France

Background: Myeloproliferative neoplasms (MPN) may present an oligoclonal pattern in which the hematopoietic stem/progenitor compartment displays molecular complexity, with coexisting acquired mutations. The most frequent mutation is $JAK2^{V617F}$ (JAK2VF), shown to deregulate myeloid progenitor cells proliferation. We and others have shown a differential response of PV subclones to treatment with peg-IFNα-2a according to the mutational pattern, but the precise cellular targets and mechanisms of action of this drug remain unknown.

Aims: To study the hematopoietic differentiation of induced pluripotent stem cells (iPSC) derived from somatic cells of MPN patients with complex mutational presentation and develop cellular models for IFNα pharmacological study.

Methods: The hematopoietic differentiation of a wild-type (WT) and a heterozygous JAK2VF iPSC line was assessed using two protocols : protocol A after derivation of embryoid bodies with an EPO containing cytokine cocktail, and protocol B using a Matrigel™ matrix in a medium with or without EPO. Hematopoietic differentiation was assessed by FACS analysis of myeloid surface markers and by methylcellulose assays for progenitor functionality. IFNα pharmacological studies were performed in both differentiation protocols in WT and JAK2VF iPSC lines.

Results: In the WT iPSC line, both protocols gave similar results for hematopoietic differentiation efficacy as assessed by the relative percentages of the various intermediate stage progenitors and mature cells. Nevertheless, culture on Matrigel™ gave higher yields in total cell number. In both WT or JAK2VF iPSC, CD34+ cells appear at the same timepoint (day 6) but the proportion of CD34+ cells was higher in JAK2VF cell cultures (15% vs 7,5%). As expected, the erythroid lineage was more abundant during the JAK2VF cell line differentiation with a peak of glycophorine A positive (GpA+) cells at day 20 of 70% in average compared to 45% for WT cells, along with spontaneous progenitor growth in the absence of erythropoietin (EPO). 2) IFNα was added 6 days after initiation of the differentiation protocol in both WT and JAK2VF cell lines. In JAK2VF cells, a delay and a 88% decrease in the emergence of CD43+ early mature hematopoietic cells was observed. In contrast, no delay was noted in CD43+ cell production in the WT cell line with only a 28% decrease compared to untreated cells. Likewise, GpA+ erythroid cell production was reduced by 62% after addition of IFNα in the JAK2VF cell line compared to a 30% decrease in the WT cell line. The decrease in erythroid progenitors, was also more pronounced in the treated JAK2VF iPSC-derived cells than in the WT-derived cells in clonogenic assays.

Summary / Conclusion: Using two different hematopoietic differentiation protocols, the JAK2VF iPSC line reproduced several features observed in PV patients such as an increase in erythroid cells production and EPO-independence. Treatment of the JAK2VF iPSC line with IFNα during hematopoietic differentiation reduces the emergence of early mature hematopoietic cells, erythroid progenitor growth and differentiation while sparing the erythroid growth and differentiation of a wild-type iPSC line. These results reproduce the in vivo efficacy of IFNα against JAK2VF clones. Thus, similar analysis performed on different iPS cell lines representing the different mutational combinations of a given PV patient should provide a useful model to study the precise mechanisms of action of IFNα on MPN hematopoiesis applicable in various complex molecular contexts.

Molecular Markers in acute lymphoblastic leukemia

S535

NOVEL AND RECURRENT GENES INVOLVED IN STRUCTURAL AND SEQUENCE VARIATIONS IN RELAPSED CHILDHOOD HIGH HYPERDIPLOID ACUTE LYMPHOBLASTIC LEUKEMIA

U Fischer[1,*], C Bartenhagen[2], M Gombert[1], V Okpanyi[1], V Binder[1], S Röttgers[3], J Bradtke[3], A Teigler[3], Jochen Harbott[3], Sebastian Ginzel[1,4], R Thiele[4], M Dugas[2], J Hu[5], A Borkhardt[1], C Chen[1,5]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, University Children's Hospital, Medical Faculty, Heinrich Heine University, Duesseldorf, [2]Institute of Medical Informatics, University of Muenster, Muenster, [3]Oncogenetic Laboratory, Department of Pediatric Hematology and Oncology, Justus Liebig University, Giessen, [4]Department of Computer Science, Bonn-Rhine-Sieg University of Applied Sciences, Sankt Augustin, Germany, [5]Fujian Institute of Hematology, Fujian Medical University Union Hospital, Fuzhou, China

Background: High hyperdiploid acute lymphoblastic leukemia (HH-ALL) is characterized by 51-67 chromosomes and nonrandom gains of specific chromosomes (X, 4, 6, 10, 14, 17, 18, or 21). Occuring in 25-30% of cases, it is the most frequent numerical cytogenetic alteration in pediatric B-cell precursor ALL. Pre-leukemic clones are generated already *in utero*, but cooperating oncogenic lesions are necessary for overt leukemia. Children suffering from HH-ALL have a good prognosis, but recurrent disease will affect 15-20%. The underlying genetic mechanisms leading to overt leukemia and relapse remain to be determined.
Aims: The objective of this study was to comprehensively assess and validate genetic lesions associated with genesis and relapse of leukemia in a cohort of pediatric patients (n=6) with recurrent HH-ALL.
Methods: Whole genome and whole exome next-generation-sequencing was applied to analyze matched sample sets of six children with recurrent HH-ALL taken at initial diagnosis and/or relapse and remission. Paired-end genomic libraries were sequenced on a Genome Analyzer IIx or a HiSeq 2000 (Illumina). Reads were aligned against the human reference genome (GRCh37) using BWA. Unique reads were analyzed with GASV to detect translocations and inversions. Somatically acquired variations not present in the Database of Genomic Variants were reported. FREEC was employed to detect copy number alterations. Targeted enrichment of whole exomic regions was carried out employing SeqCap EZ libraries (Roche) and 100 bp single reads were sequenced on a HiSeq 2000. Mutations were called and LOH detected using an in-house bioinformatic pipeline. Putative somatically acquired mutations were validated by PCR, Sanger sequencing and FISH analysis.
Results: We detected and validated 11 interchromosomal translocations affecting genes coding for proteins (ART4, C12orf60, MACROD2, TBL1XR1, LRRN4, KIAA1467, ELMO1) and several miRNAs (e.g. miR1200), lincRNAs and nuclear RNAs involved in splicing (U6, U13). A MACROD2/KIAA1467-fusion potentially encoded a novel chimeric protein. All other rearrangements presented loss-of-function or -expression alterations. Most translocations were associated with copy number alterations. One case showed oscillating copy numbers at clustered breakpoints indicative of shattering/rejoining of chromosomal fragments, termed chromothripsis. Furthermore, deletions, inversions and loss-of-heterozygosity were detected. Exome sequencing revealed recurring mutations of CREBBP and members of the Ras family of small GTPases. One patient expressing wildtype NRAS and KRAS harbored mutated PAR4, a tumorsuppressor that is downregulated by oncogenic RAS for efficient transformation. Further mutations (non synonymous coding, splice site mutations or gained stop codons) were detected and validated in various transcription factors and signaling molecules involved in differentiation, cell cycle regulation and apoptosis. Relapse was associated with partial chromosomal gain (1q), loss (4q), a novel translocation (t(4;7)), deletions (IKZF1), increasing dominance of a chromothriptic clone and selection for RAS and CREBBP alterations.
Summary / Conclusion: Our data indicate a central role for RAS and CREBBP regulated pathways as assisting oncogenic lesions in pathogenesis and relapse of HH-ALL. Additional mutations indicate disturbance of B-cell differentiation, enhanced proliferation, suppression of cell death and a possible role of regulatory RNAs in HH-ALL.

Businco, Cagliari, [9]Ospedale San Raffaele, [10]Ospedale Maggiore Policlinico, Milano, [11]AOU Careggi, Firenze, [12]ASO S. Croce e Carle, Cuneo, [13]Ospedale San Giovanni Battista, Torino, Italy

Background: MRD is the most powerful indicator of the risk of relapse, and is increasingly adopted in ALL for the risk-oriented application of stem cell transplantation (SCT) in MRD-positive (^{pos}) patients. Retrospective analyses indicated a lesser efficacy of SCT in MRD^{pos} cases, however without defining the quantitative MRD ranges associated with SCT failure. Such a definition could improve the ability to distinguish MRD^{pos} patients for whom SCT is an appropriate choice from those in whom other treatments should be considered instead or prior to SCT.
Aims: To define which post-induction/consolidation MRD levels can negatively affect post-transplantation outcome in adult ALL.
Methods: The long-term results of a prospective Northern Italy Leukemia Group trial conducted between 2000 and 2006 and enrolling a total of 304 consecutive unselected patients with Ph- ALL were reviewed. In this study, SCT was prescribed only to MRD^{pos} patients, regardless of clinical risk class. MRD was assessed by RQ-PCR methodology using one-two case-specific sensitive molecular probes, examining the bone marrow at weeks 10, 16 and 22, i.e. after chemotherapy cycles no. 3, 5 and 7. MRD results from all three time-points were pooled, and the highest value registered in individual patients was used to identify the MRD-negative group (always MRD^{neg}) and three other subsets characterized by increasing levels of residual ALL, from low-positive (<10^{-4} [MRD^{pos1}]) to positive (10^{-4} to <10^{-3} [MRD^{pos2}]) to strongly positive (≥10^{-3} [MRD^{pos3}]). MRD^{neg} patients were not offered SCT unless t(4;11)+. For study purposes, disease-free survival (DFS) and relapse incidence (RI) were assessed and compared among different MRD^{pos} groups, specifically in patients selected for SCT at end of consolidation phase after completion of the MRD study as per study design (at least MRD^{pos2} at week 16 and/or MRD^{pos1} at week 22).
Results: Of 304 patients treated (median age 35 years, range 16-68; male gender 57%) 258 (85%) entered complete remission (CR). Sensitive probe(s) were available for 200 (77.5%) CR patients, of whom 141 completed consolidation and 59 did not (early SCT 13, relapse 41, toxicity 5). Of 141 evaluable patients, 136 completed the MRD study, 64 being MRD^{neg} (47%), 21 MRD^{pos1} (15.5%), 17 MRD^{pos2} (12.5%) and 34 MRD^{pos3} (25%). With a minimum observation time of 4 years and a maximum close to 12 years, estimated 6-year DFS and RI were 57% and 32% in MRD^{pos1}, 46% and 50% in MRD^{pos2} and 15% and 76% in MRD^{pos3} cohorts, respectively (all P's <0.0001). Of all 72 MRD^{pos} patients, 44 (61%) underwent SCT as per protocol design (allogeneic SCT 26, "hypercycles" with autologous blood stem cell rescue 18). Although 6-year DFS rate was improved after allogeneic SCT (42% vs 20% with autologous SCT, P=0.09), MRD level was highly influential for post-transplantation outcome (DFS 48% in MRD^{pos1-2} group [n=25] vs 16% in MRD^{pos3} group [n19], P=0.025; RI 42% vs 69%, P=0.13), and the best overall result was obtained with allogeneic SCT in MRD^{pos1-2} group (DFS 60% [n=15] vs 18% in MRD^{pos3} group [n=11], P=0.08; RI 23% vs 64%, P=0.09).
Summary / Conclusion: In this prospective study, about one half of MRD^{pos1-2} patients were salvaged by SCT, mainly by allogeneic rather than autologous SCT (DFS 60%). Because of the poorer SCT results in MRD^{pos3} group, patients with post-induction/consolidation MRD ≥10^{-3} should receive further/experimental therapy and not proceed to SCT until the MRD signal is brought below the 10^{-3} cutoff.

COMPARISON OF NEXT-GENERATION SEQUENCING AND ASO-PCR METHODS FOR MRD DETECTION IN ACUTE LYMPHOBLASTIC LEUKEMIA

G Malnassy[1], V Carlton[2], M Moorhead[2], M Faham[2], W Stock[1,*]
[1]University of Chicago, Chicago, [2]Sequenta, Inc., South San Francisco, United States

Background: The clinical management of patients with acute lymphoblastic leukemia (ALL) relies on accurate prediction of relapse risk to inform treatment decisions (Pui *et al*, JCO 2011). The measurement of minimal residual disease (MRD) has emerged as the most important predictor of outcome in ALL (Campana, Hematology Am Soc Hematol Educ Program 2010). Allele-specific oligonucleotide (ASO)-PCR can be used to assess MRD; however, this technique requires preparation of clonotype-specific primers for each individual which is laborious and time-consuming. We developed the LymphoSIGHT™ platform, a high-throughput sequencing method, which universally amplifies antigen-receptor gene segments and can identify all leukemia-specific sequences at diagnosis, allowing monitoring of disease progression and clonal evolution during therapy (Faham *et al*, Blood 2012).
Aims: In this study, we compared the sequencing and ASO-PCR methods for measuring MRD in follow-up samples and analyzed the extent of clonal evolution present in diagnostic and follow-up samples from 37 ALL patients.
Methods: Using the sequencing assay, we analyzed diagnostic blood and bone marrow samples from 37 ALL patients for clonal rearrangements of immunoglobulin (IGH-VDJ, IGH-DJ, IGK) and T cell receptor (TRB, TRD, TRG)

genes. Clonal rearrangements had been previously detected in all 37 patients using ASO-PCR methods. We assessed MRD at the IGH and/or TRG locus in 99 follow-up samples, and analysis of the concordance between MRD results obtained by the sequencing method and ASO-PCR is ongoing. Finally, we looked for cases with clone evolution and assessed the frequency of evolved clones over time in serial samples.

Results: Sequencing detected the presence of a high-frequency clonal rearrangement of at least one receptor ("calibrating receptor") in 100% of the 37 ALL patients; 36 patients had at least 2 calibrating receptors at diagnosis, 29 patients had at least 3 calibrating receptors, and 12 patients had more than 3. The TRG assay was the most frequent gene rearrangement: at least one TRG clonal rearrangement was detected in 29 of the diagnostic ALL samples. IGH-VDJ was the second most informative receptor, with clonal rearrangements being detected in 23 patients. We analyzed follow-up samples for the presence of MRD. Sequencing detected MRD levels of >10% in 4 samples, 1-10% in 4 samples, 0.1-1% in 8 samples, 0.01-0.1% in 12 samples, 0.001-0.01% in 8 samples, and <0.001% in 11 samples. MRD was undetectable by sequencing in 45 samples. Being able to track more than one clonal sequence allows the follow up of the dynamics of these clones. In at least one patient, the relative frequencies of the 3 clonal sequences changed dramatically over the disease course (Figure 1).

Summary / Conclusion: This high-throughput sequencing method enables MRD detection without the need for development of patient-specific reagents. The sequencing method allows monitoring of clonal dynamics over time, which may provide valuable insight into tumor evolution and resistance to therapy at the individual clone level. Concordance data between sequencing and ASO-PCR will be presented.

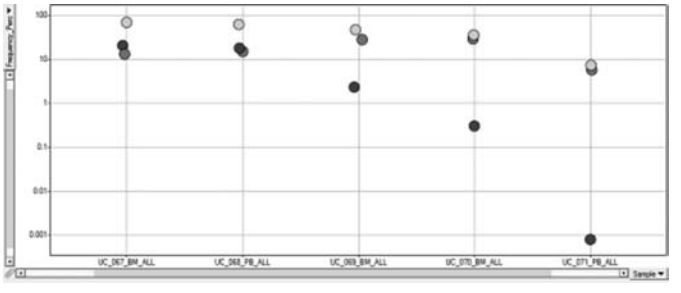

Figure 1. Dynamics of clone frequency over time in one ALL patient across 5 samples. Colors indicate three different clonal sequences. The 5 samples are shown on the X axis. The clone frequency is shown on the Y axis.

ERG DELETION EXERTS A CD2-DEPENDENT POSITIVE PROGNOSTIC IMPACT ON IKZF1-DELETED CHILDHOOD ALL

M Zaliova[1,2], O Zimmermanova[2], P Dörge[1], C Eckert[3], A Möricke[1], M Zimmermann[4], J Stuchly[2], A Teigler-Schlegel[5], R Koehler[6], C Bartram[6], L Karawajew[7], P Rhein[7], G Cario[1], J Zuna[2], M Schrappe[1], M Stanulla[1,*]
[1]Department of Pediatrics, University Hospital Schleswig-Holstein, Kiel, Germany, [2]CLIP-Molecular genetics, Department of pediatric hematology and oncology, 2nd Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [3]Pediatric Hematology and Oncology, Charite University Hospital Berlin, Berlin, [4]Pediatric Hematology and Oncology, Hannover Medical School, Hannover, [5]Oncogenetic laboratory, Pediatric Hematology and Oncology, University of Giessen, Giessen, [6]Department of Human Genetics, University of Heidelberg, Heidelberg, [7]Department of Hematology, Oncology and Tumor Immunology, HELIOS-Clinic Berlin-Buch, Berlin, Germany

Background: B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) is a clinically and biologically heterogeneous disease. Based on the presence of routinely screened recurrent genetic aberrations, most cases can be classified into genetically defined subgroups. Despite this success, a still significant proportion of patients falls into the so-called "B-other" category with largely unknown genetic background and heterogeneous outcome. Importantly, the majority of relapses occur within patients who lack any known strong prognostic feature. To improve the prognosis of this group, identification of new and more accurate risk predictors is of ongoing interest.

Aims: Using SNP microarray analysis, intragenic deletions of the *ERG* gene on chromosome 21q22.3 (*ERG*del) were recently described as a recurrent abnormality in childhood ALL. However, detailed characterization of this aberration in the context of large modern clinical trials has not been performed so far. In our study we aimed to assess the incidence of *ERG*del in childhood ALL and to evaluate its clinical value as a prognostic marker.

Methods: We developed a multiplex PCR assay to screen *ERG*del on the genomic level and screened 1323 patients treated on the multicentre ALL-BFM 2000 protocol. A commercially available multiplex ligation-dependent probe amplification (MLPA) kit was used to analyze *IKZF1* deletions. Other clinical and laboratory parameters were acquired by routine diagnostic procedures.

Results: We identified 60 cases with *ERG*del, all exclusively within BCP-ALL. The majority of positive patients were observed in the "B-other" subgroup (44/403). Interestingly, in at least 1/3 of cases the deletion was bi-/oligoclonal and it was significantly associated with higher age, CD2-positivity and IKZF1 deletion. We found no or only weak associations of *ERG*del alone with prognosis. However, when combined with CD2 status, the CD2-positive/*ERG*del patients demonstrated superior outcome. This effect was significant even within cases harbouring *IKZF1* deletions which have previously been shown to have a negative prognostic impact in the ALL-BFM 2000 trial population. In addition, we analyzed stability of *ERG*del between diagnosis and relapse in all six CD2-negative/*ERG*del relapses. In 3/6 cases the *ERG* deletions were lost and in the remaining 3 cases the relapse deletions differed from those found at diagnosis.

Summary and Conclusions: To conclude, we describe a high incidence of *ERG*del in B-other ALL. Our data suggest that the *ERG* locus is specifically prone to deletion in this subgroup. Nevertheless, the deletion does not seem to play a driving role in the pathogenesis of the disease. We show that combined with CD2-positivity the *ERG*del confers a superior prognosis which even overcomes the negative impact of concurrent *IKZF1* deletions.

HIGH HYPERDIPLOIDY (HEH) AMONG ADOLESCENTS AND ADULTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA (ALL): CYTOGENETIC FEATURES, CLINICAL CHARACTERISTICS AND OUTCOME

L Chilton[1,*], C Harrison[1], R Ketterling[2], J Rowe[3], M Tallman[4], A Goldstone[5], A Fielding[6], A Moorman[1]
[1]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Department of Cytogenetics, Mayo Clinic, Rochester, MN., United States, [3]Department of Hematology, Shaare Zedek Medical Center, Jerusalem, Israel, [4]Memorial Sloan Kettering Cancer Center, New York, United States, [5]Department of Haematology, UCLH, [6]Department of Haematology, Royal Free and UCMS, London, United Kingdom

Background: HeH is the massive clonal gain of chromosomes resulting in a modal number of 51-65 chromosomes. The pattern of chromosome gain is non-random and distinctive with 8 chromosomes accounting for >75% gains. HeH is the most prevalent genetic subtype in paediatric ALL occurring in 33% patients and is associated with a good prognosis. We have previously reported the incidence and outcome of HeH among adolescents and adults treated on UKALLXII/ECOG2993 both with and without Philadelphia positive (Ph+) disease (Blood, 2007;109:3189 & 2009;113:4489). Among paediatric patients, several cytogenetic features, including the presence of specific trisomies, have been associated with outcome. In particular, +4, +10, +17, +18 and high modal number have been associated with improved survival.
Aims: There are no previous studies of HeH in adults describing the pattern of chromosome gain or the relationship with outcome. As adolescent and adult ALL patients generally have an inferior outcome compared to children the prognostic relevance of specific trisomies may be more relevant in this group.
Results: Among 1232 BCP-ALL patients treated on UKALLXII/ECOG2993 (1993-2006) tested for HeH, 159 (13%) were positive. The incidence of HeH was similar among Ph+ (48/340, 14%) and Ph- (111/892, 12%) patients. Ph+ HeH patients were older than Ph- HeH patients (38 v 26 years, P=0.001). Although ~60% of Ph- patients were <25 years, ~25% were 40-59 years. Ph+ HeH karyotypes had significantly lower modal numbers whereas the distribution for Ph- cases was similar to paediatric ALL with a peak at 55 chromosomes. There were significant differences in the pattern of chromosome gain: Ph+ karyotypes were more likely to have +2, +15 and +der(22)t(9;22)(q34;q11), and less likely to have +10, +17 and +18. Gains of chromosomes 4, 6, 14, 21 and X were equally prevalent in both groups. The median follow-up time for the 111 Ph- HeH patients was 8 years. The majority (106, 96%) achieved a complete remission (CR) with 31 (29%) cases subsequently relapsing and 17 (16%) dying in first remission. The 5 year survival was 58% (95% CI 48-66%). Patients who had gained a chromosome 4, 10, 14 or X had a significantly improved outcome: HR (95% CI) 0.41 (0.22-0.72), 0.55 (0.31-0.98), 0.56 (0.32-0.99) and 0.49 (0.27-0.90) respectively. However, only +4 and +10 remained significant (P=0.003 & 0.027 respectively) in a multivariate model with age and white cell count. There was no evidence to suggest a relationship between modal chromosome number and outcome. Survival data was only available for 26 Ph+ patients treated prior to the introduction of imatinib (median follow-up 11 years). All patients, bar one, achieved CR (96%) but 9 (35%) subsequently relapsed and 10 (40%) died in first remission. Thus the 5 year survival was 38% (20-56). There was little evidence to suggest outcome heterogeneity according to specific trisomies or modal chromosome number; except for a borderline result for chromosome 4 [0.45 (0.18-1.16)].
Summary / Conclusion: In conclusion, the cytogenetic landscape of Ph- HeH ALL is almost identical to that observed in paediatric ALL whereas it is distinctive from Ph+ HeH ALL. There is significant evidence to suggest outcome heterogeneity according to the presence of specific trisomies in Ph- HeH ALL. Further studies based on more contemporary cohorts will be needed to evaluate these results among young adults treated on paediatric or paediatric-like protocols.

IN VIVO TARGETING OF STROMAL-DERIVED FACTOR-1 AS A STRATEGY TO PREVENT MYELOMA CELL DISSEMINATION TO DISTANT BONE MARROW NICHES

A Roccaro[1,*], A Sacco[1], M Ungari[2], S Lonardi[2], P Maiso[1], D Zboralski[3], A Kruschinski[3], M Moschetta[1], Y Mishima[1], F Facchetti[2], G Rossi[4], I Ghobrial[1]
[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, [2]Pathology, University of Brescia, Brescia, Italy, [3]NOXXON Pharma, Berlin, Germany, [4]Hematology, Spedali Civili di Brescia, Brescia, Italy

Background: Active multiple myeloma (MM) is characterized by the presence of continuous dissemination of MM cells from the primary site of tumor development to multiple distant bone marrow (BM) niches. We hypothesized that stromal-derived factor-1 (SDF-1) may represent a target for preventing transition from MGUS to active-MM; thus resulting in inhibition of MM progression; and tested NOX-A12, a high affinity l-oligonucleotide-based inhibitor of SDF-1 in MM, looking at its ability to mold the BM milieu, thus modulating MM cell growth and homing to the BM *in vivo* and *in vitro*.
Aims: 1) To demonstrate that SDF-1-neutralization in the BM niches inhibits cell dissemination *in vivo* in a MM model. 2) To demonstrate the delivery of NOX-A12 *in vivo*; and its ability to modulate MM tumor growth and MM cell dissemination.
Methods: SDF-1 levels were evaluated by immunohistochemistry on BM specimens obtained from patients with MGUS, active-MM, or healthy individuals; and confirmed by ELISA, using conditioned-medium of BM-mesenchymal stromal cells (BM-MSCs) obtained from MGUS, active-MM and healthy individuals. Co-localization of MM tumor cells (MM.1S-GFP+) and NOX-A12 with SDF-1-positive areas was tested by *in vivo* confocal microscopy, using both AlexaFluor633-conjugated-anti-SDF-1 monoclonal antibody and AlexaFluor647-conjugated-NOX-A12. Effect of NOX-A12 in modulating MM cell dissemination was tested *in vivo*, by using *in vivo* confocal microscopy. *In vivo* homing and *in vivo* tumor growth of MM cells (MM.1S-GFP+/luc+) were assessed by using *in vivo* confocal microscopy and *in vivo* bioluminescence, in SCID mice treated with a) vehicle; b) NOX-A12; c) bortezomib; d) NOX-A12+bortezomib. Detection of mobilized MM-GFP+ cells *ex vivo* was performed by flow cytometry. Effects of drug combination on dissemination of MM cells to distant BM niches were evaluated *ex vivo* by using immunofluorescence on mice femurs. DNA synthesis and adhesion of MM cells in the context of NOX-A12 (50-100nM) treated primary MM BM-MSCs in presence or absence of bortezomib (2.5-5nM) were tested by thymidine uptake and adhesion *in vitro* assay, respectively. Synergism was calculated by using CalcuSyn software. NOX-A12-dependent-modulation of signaling was evaluated by western blot on MM cells exposed or not to NOX-A12-treated primary BM-MSCs.
Results: Patients with active-MM present with higher BM SDF-1 expression than MGUS patients and healthy individuals. *In vivo* confocal imaging revealed higher SDF-1 expression in MM cell-enriched BM areas compared to non-MM colonized BM niches. We next demonstrated that NOX-A12 was delivered to BM areas in MM-tumor bearing mice. Mice pre-treated with NOX-A12 showed a significant reduction of MM cell growth and dissemination compared to untreated mice, indicating indeed that modulation of the pre-metastatic niche with NOX-A12 reduced MM cell dissemination. We examined NOX-A12-dependent the *in vivo* transcriptional changes on the murine BM milieu and found that the BM cells of NOX-A12-pretreated mice showed transcriptional downregulation of SDF-1 as well as downregulation of angiogenesis-, cell growth-, and cell adhesion-related genes. We next dissected the ability of NOX-A12-dependent neutralization of SDF-1 to disrupt the interaction of MM cells with the surrounding BM milieu and found that NOX-A12 induced MM cell mobilization from the BM to the peripheral blood *ex vivo*. We next showed that NOX-A12-dependent de-adhesion of MM cells from BM-MSCs enhanced MM cell sensitivity to bortezomib, as shown both *in vitro* and *in vivo*. Specifically, significant reduction of tumor burden in those mice treated with sequential administration of NOX-A12 and bortezomib was observed, compared to bortezomib alone-treated mice (P <0.05). Similarly, NOX-A12+bortezomib combination induced significant inhibition of MM cell homing, as shown by *in vivo* confocal microscopy.
Summary / Conclusion: NOX-A12-dependent neutralization of SDF-1 modulates the pre-metastatic BM niche *in vivo*, thus resulting in inhibition of tumor cell dissemination in an MM model. Our data suggest that NOX-A12 may represent a first in class niche-targeting agent that can prevent or disrupt bone marrow metastasis in MM and possibly other tumors that metastasize to the bone marrow.

S541

PLASMA CELL PHENOTYPE AND B-CELL STATUS ARE INDEPENDENT PREDICTORS OF PROGRESSION-FREE AND OVERALL SURVIVAL IN MGUS.

A Rawstron[1,*], R de Tute[1], G Aramugakani[1], J Child[2], G Morgan[3], R Tooze[1], R Owen[1]
[1]HMDS, [2]Haematology, St. James's Institute of Oncology, Leeds, [3]Institute of Cancer Research, London, United Kingdom

Background: Monoclonal Gammopathy of Undetermined Significance (MGUS) shows progression to myeloma or other B-lymphoproliferative disorders in approximately 1% of cases per year. MGUS is associated with immune suppression and shows approximately 2% per year excess infectious mortality. Depletion of normal plasma cells and abnormal sFLC ratio predict an increased risk of progression. Changes in normal B-cell subsets are also reported although it is not clear how these relate to outcome.
Aims: To identify B-cell related factors which affect progression and survival in MGUS.
Methods: Prospective analysis of plasma cell and B-cell immunophenotype was performed since 2004 on the bone marrow in 1206 MGUS cases with records of the standard diagnostic and clinical features. B-cell clonality was included in the analysis to assess for the presence of an underlying B-cell disorder.
Results: During follow-up (median 3.5, range 0.5-8yrs), 48 developed myeloma and 9 a B-lymphoproliferative disorder. There were 281 deaths of which 151 were potentially MGUS-related (i.e. myeloma, infectious or renal condition). Normal plasma cells were depleted (i.e. represented <5% of total plasma cells) in 18% of cases and this was strongly associated with disease progression (Log-rank P<0.001). There was 63% concordance between PC phenotype and sFLC ratio; either factor alone was equally predictive of disease progression (Log-rank P=0.026). B-cell abnormalities (i.e. depleted normal subsets, perturbed K:L ratio, or MBL) were detected in 26% of cases with no discernable clonal relationship to the neoplastic plasma cells. B-cell abnormalities were strongly associated with progression and disease-related mortality (univariate P=0.001, multivariate P=0.021).
Summary / Conclusion: In addition to the neoplastic plasma cell expansion, MGUS is characterised by abnormal B-cell homeostasis and humoral immunity. All of these factors predict for an increased risk of disease progression. B-cell and plasma cell abnormalities are also strongly associated with excess infectious mortality. Current treatment for myeloma can reverse B-cell/humoral abnormalities with low toxicity and it may be appropriate to consider a clinical trial to evaluate early intervention in the subset of MGUS patients identified in this study who are at an increased risk of infectious mortality.

HETEROGENEITY OF MUTATIONAL PROCESSES IN MULTIPLE MYELOMA

N Bolli[1,*], H Avet-Loiseau[2], D Wedge[3], P Van Loo[3], S Nik-Zainal[3], L Alexandrov[3], G Bignell[3], J Hinton[3], J Tubio[3], S McLaren[3], S O' Meara[3], A Butler[3], J Teague[3], L Mudie[3], Y Tai[4], M Shammas[4], A Sperling[4], M Fulciniti[4], P Richardson[4], F Magrangeas[5], S Minvielle[6], P Moreau [7], M Attal[8], T Facon[9], P Futreal[3], K Anderson[4], P Campbell[3], N Munshi[4]
[1]Haematology, University of Cambridge, Cambridge, United Kingdom, [2]Unité de Génomique du Myélome, CHU Rangueil, Toulouse, France, [3]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [4]Dana-Farber Cancer Institute, Boston, United States, [5]Hematology Laboratory, University Hospital, [6]Unité de Génomique du Myélome, CHU Rangueil, [7]Department of Hematology , [8]Department of Haematology, University Hospital, Nantes, [9]Department of Haematology, University Hospital, Lille, France

Background: The catalog of somatic mutations in a cancer is the aggregate outcome of strength and duration of exposure to one or more mutational processes. Signatures underlying mutational processes have never been investigated in multiple myeloma (MM), a plasma cell malignancy with incompletely understood molecular pathogenesis. While chromosomal abnormalities are involved in MM initiation, they are insufficient for its progression, which is characterized by secondary events, particularly gene mutations. Despite novel treatment options, relapses are frequent and ultimately chemoresistant, thus MM remains an incurable disease. Understanding the molecular processes shaping the MM genome at diagnosis and those contributing to emergence of chemoresistant clones can therefore provide new insights into disease biology and treatment.
Aims: We have previously showed how the mutational landscape, clonal architecture and evolutionary progression were heterogeneous across 84 samples from 67 patients with MM (Bolli et al, Haematologica, 2012, Vol 97-S1, a0571). In this study, we set out to extract the mutation signatures characterizing the mutational processes underlying the landscape of mutational changes in MM.
Methods: We validated 4421 variants in 67 patients. We showed variability in the numbers and relative contributions of each base substitution (C>A, C>G, C>T, T>A, T>C, and T>G). To provide insight into the processes underlying such a heterogeneous catalogue of mutations, we incorporated the sequence context in which mutations occurred by considering the bases 5' and 3' to each mutation to generate 96 possible mutation types. Werepresented the fraction of mutations of each type as a heatmap for each case. We employed nonnegative matrix factorization (NMF) and model selection to extract the quantitative contribution of each mutational signature.
Results: Most cases showed a predominance of Signature A, C>T changes at CpG trinucleotides. This is likely to represent spontaneous deamination of methylated cytosine to thymine, and is the dominant process in myeloid malignancies, a major contributor to early mutations in breast cancer, and seen at high rates in the germline. Signature B, consisting of C >T, C>G and C>A mutations in a TpCpX context, contributed 5 to 45% of the variants in most cases, but 100% in the 2 samples characterized by the highest number of variants, suggesting that this signature is associated with a hypermutator phenotype. In another 2 patients, we found clusters of 5-10 mutations from Signature B, all within a region <200bp showing strand specificity, a process known as 'kataegis'. This signature was first documented in breast cancer, and others and we have speculated to arise from aberrant activity of APOBEC proteins. In serial samples, relative contribution of each signature changed up to 2-fold. Importantly, progression towards aggressive disease was associated with an increased contribution of signature B and the appearance of kataegis, suggesting that this signature may be linked to phenotypic evolution. Another process leading to regional clustering of mutations was somatic hypermutation driven by the AID protein, resulting in clusters of mutations of *CCND1* in two cases, both characterized by t(11;14), juxtaposing *CCND1* with the *IGH* locus. Finally, copy number analysis revealed the presence of chromothripsis, a mechanism of genomic instability defined by tens to hundreds of chromosomal rearrangements involving localized genomic regions, associated with poor outcome.
Summary / Conclusion: We have described for the first time a catalogue of several heterogeneous mutational processes active in MM, including spontaneous deamination of methylated cytosine, kataegis, somatic hypermutation, and chromothripsis. We have shown that mutational processes are active across different cancer types and retain the same biological features, such as the hypermutator phenotype of Signature B. The extent of such mutational processes can vary from genome-wide to localized clusters, and their relative contributions change over time. This analysis represents advancement in our understanding of MM biology, and of the processes underlying its genomic heterogeneity.

CC-292, A NOVEL BRUTON'S TYROSINE KINASE INHIBITOR ALONE AND IN COMBINATION WITH CARFILZOMIB IMPACTS BONE RESORPTION IN MULTIPLE MYELOMA BY BLOCKING OSTEOCLAST SEALING ZONE FORMATION

H Eda[1,*], S Loredana[1], D Cirstea[1], A Yee[1], A Mahindra[1], T Scullen[1], N Nemani[1], Y Mishima[1], S Kapur[2], E Evans[3], J Singh[3], C Kirk[2], W Westlin[3], N Raje[1]
[1]MGH, Cancer Center, Harvard Medical School, Boston, [2]Research Department, Onyx Pharmaceuticals, Inc., South San Francisco, [3]Celgene Avilomics Research, Bedford, United States

Background: The activation of Bruton's tyrosine kinase (Btk), a member of the Tec family of tyrosine kinases, modulates B-cell development and activation and plays an important role in antibody production. Interestingly, Btk and Tec (the other Tec kinase family) regulate the differentiation of osteoclasts (OC), which are an integral part of the bone microenvironment. Osteolytic bone lesions occur in 70-80% of patients with multiple myeloma (MM), and are associated with increased morbidity and mortality. The imbalance between OC and osteoblasts leads to increased bone resorption and induces osteolytic lesions. Inhibition of OC is important for the improvement of osteolytic bone disease and for the treatment of MM. Btk and Tec regulates OC function via receptor activator of nuclear factor κB (RANK) signaling. RANK signaling activates c-Src which controls OC bone resorption by regulating actin organization via cortactin. c-Src also phosphorylates proline-rich tyrosine kinase (Pyk) 2, which plays an important role in OC activation and localizes to the sealing zone in OC.
Aims: We sought to assess the effects and molecular mechanism of a potent and specific BTK inhibitor, CC-292 in the context of OC. We also evaluated the effect of CC-292 used in combination with the proteasome inhibitor carfilzomib (CFZ) in our *in vitro* and *in vivo* MM model.
Methods: OC were derived from MM patient monocytes. OC number and function was evaluated by TRAP staining and pit formation assay, respectively. The effect of CC-292 on the molecules involved in sealing zone formation, such as c-Src and Pyk2 signaling was investigated by Western blotting. OC sealing zone formation was detected by immunofluorescence. The *in vivo* study was performed in the disseminated xenograft MM model. Human Luc-GFP$^+$-MM.1S cells were injected IV in NOD-SCID mice (n=40). Treatment with CC-292 (30mg/kg per os× 5 for 6 weeks), CFZ (3 mg/kg i.v.× 2 for 4 weeks and 2 mg/kg i.v.× 2 for 2 weeks) and combinations of both agents were administered. Tumor burden was evaluated by bioluminescence imaging (BLI) once-weekly.
Results: OC function was significantly inhibited in the presence of CC-292. However, OC number, size and differentiation marker expression were increased in the presence of CC-292. CC-292 inhibited c-Src and Pyk2 phosphorylation. Furthermore, CC-292 inhibited cortactin protein and mRNA expression and upregulated c-Cbl protein (E3 ubiquitin ligase for c-Src) expression in OC. Importantly, CC-292 disrupted the OC sealing zone formation. In contrast, the proteasome inhibitor CFZ had no impact on OC sealing zone formation but instead inhibited OC differentiation. CC-292 in combination with CFZ inhibited both sealing zone formation

as well as OC differentiation, resulting in a more pronounced suppression of OC function than either agent alone.
In our *in vivo* study, the combination of CC-292 and CFZ inhibited the tumor burden by a statistically significant margin (control vs combination, P=0.0159).
Summary / Conclusion: These data demonstrate that the novel Btk inhibitor CC-292 inhibits OC function through inhibition of OC sealing zone formation.
CC-292 in combination with CFZ induced potent suppression of OC function. The *in vivo* study demonstrated a significant decrease in tumor burden in the combination group vs control group. Ongoing static and dynamic histomorphometric analyses will help delineate the effect of this combination on bone remodeling.

S544

INTRACELLULAR NAMPT INHIBITION ENHANCES BORTEZOMIB ACTIVITY OVERCOMING DRUG RESISTANCE IN MULTIPLE MYELOMA
A Cagnetta[1,*], M Cea[1], D Chauhan[1], Y Tai[1], T Hideshima[1], N Munshi[1], M Gobbi[2], K Anderson[1]
[1]Medical Oncology, DANA FARBER CANCER INSTITUTE, Boston, United States, [2]Department of Hematology and Oncology, I.R.C.C.S. A.O.U. San Martino -IST., Genoa, Italy

Background: A prominent feature of malignant cells is the acquisition of characteristics that enable uncontrolled proliferation, including the capability to modify or reprogram cellular metabolism. In such a scenario, tumor cells exhibit highly increased rates of energy consuming reactions due to elevated intracellular NAD+. This realization has provided the basis for molecular studies of NAD+ metabolism to identify novel targeted therapeutic strategies. Recently we demonstrated that Nicotinamide phosphoribosyl transferase (Nampt), a key enzyme involved in NAD+ metabolism, is essential for maintenance of multiple myeloma (MM) cell viability; and conversely, that Nampt inhibition/depletion potently kills MM cells. In vivo studies in murine xenograft models of human MM showed that the chemical inhibitor of Nampt, FK866, is well tolerated, prolongs survival, and reduces tumor growth. Proteasome inhibitor bortezomib has transformed therapy of relapsed MM, as well as prolonged event free and overall survival when used as initial therapy for newly diagnosis disease. However, prolonged bortezomib exposure may result in cumulative toxicity and acquisition of drug resistance. Combination approaches aimed to prevent or overcome mechanism(s) of bortezomib-resistance offer great potential to improve outcome.
Aims: In this study we aim to demonstrate that the combination of FK866, with Bortezomib induces synergistic anti-MM cell death both *in vitro* using MM cell lines or patient CD138+MM cells and *in vivo* in a human plasmacytoma xenograft model.
Methods: We utilized MM.1S, MM.1R, RPMI-8226, U266 and ANBL6 BR human MM cell lines, as well as purified tumor cells from patients relapsing after prior bortezomib-based therapies. Cell viability and apoptosis assays were performed using Annexin V/PI staining. Intracellular NAD+ level and proteasome activity were quantified after exposure to single/combination drugs by specific assays. *in vitro* angiogenesis was assessed by Matrigel capillary-like tube structure formation assay. Immunoblot analysis was performed using antibodies to caspase-8, caspase-9, caspase-3, PARP, and tubulin. The expression level of Nampt transcript (probe ID 217739_s_at) as well as its prognostic role was evaluated in publically available database (GSE9782) of tumor cells from Bortezomib-treated MM patients. CB-17 SCID male mice (n = 28; 7 mice/EA group) were subcutaneously inoculated with 5.0 x 10^6 MM.1S cells in 100 microliters of serum free RPMI-1640 medium. When tumors were measurable (3 weeks after MM cell injection), mice were treated for three weeks with vehicle alone, FK866 (30 mg/kg 4 days weekly), Bortezomib (0.5 mg/kg twice weekly), or FK866 (30 mg/kg) plus Bortezomib (0.5 mg/kg). Statistical significance of differences observed in FK866, Bortezomib or combination-treated mice was determined using a Student t test. Isobologram analysis was performed using "CalcuSyn" software program. A combination index <1.0 indicates synergism.
Results: We observed higher Nampt mRNA levels in bortezomib-resistant patient MM cells, which correlated with decreased overall survival. We therefore demonstrated that combining the NAD+ depleting agent FK866 with bortezomib induces synergistic anti-MM cell death and overcomes bortezomib-resistance in MM dell lines as well as in patient CD138-positive MM cells (P< 0.004). This effect is associated with: 1) activation of caspase-8, caspase-9, caspase-3, and PARP; 2) enhanced intracellular NAD+ depletion; 3) inhibition of chymotrypsin-like, caspase-like and trypsin-like proteasome activities; 4) inhibition of NF-kappa B signaling; and 5) inhibition of angiogenesis. Furthermore, Nampt knockdown significantly enhances the anti-MM effect of bortezomib, which can be rescued by ectopically overexpressing Nampt. In murine xenograft MM model, low-dose combination FK866 and Bortezomib is well tolerated, significantly inhibits tumor growth, and prolongs host survival. (2–2.5 months P=0.001).
Summary / Conclusion: Our *in vitro* and *in vivo* findings demonstrate that intracellular NAD+ levels represent a major determinant in the ability of bortezomib to induce apoptosis of MM cells, providing the rationale for clinical protocols evaluating FK866 together with Bortezomib to improve patient outcome in MM.

INHIBITION OF SMAD2/3 SIGNALING BY ACE-536 MITIGATES INEFFECTIVE ERYTHROPOIESIS AND CORRECTS ANEMIA IN BETA-THALASSEMIA
N V S R Suragani[1,*], r Li[1], S Cawley[2], S Rivella[3], S Pearsall[1], R Kumar[4]
[1]Pre Clinical Pharmacology, [2]Cell Biology and Protein biochemistry, ACCELERON PHARMA, Cambridge, [3]Department of Pediatrics, Weill Cornell Medical College, New York, [4]Biology, ACCELERON PHARMA, Cambridge, United States

Background: Members of the TGF-β superfamily are known to be involved in erythropoiesis and iron homeostasis. Elevated levels of Smad 2/3 signaling ligands have been reported in diseases with ineffective erythropoiesis such as β-thalassemia and myelodysplastic syndromes (MDS). β-Thalassemia is caused by a deficiency in β-globin production in erythroid cells, resulting in decreased hemoglobin levels and anemia. Excess α-globin chains accumulate in the cell, causing proteotoxicity and apoptosis. Ineffective erythropoiesis in β-thalassemia leads to arrest of terminal erythroid differentiation, erythroid precursor expansion in bone marrow and spleen, apoptosis, and hemolysis of RBCs.
Aims: We hypothesized that inhibition of Smad 2/3 signaling could mitigate ineffective erythropoiesis and correct anemia in β-thalassemia.
Methods: ACE-536 is a modified activin type IIB (ActRIIB) receptor fusion protein which acts as a ligand trap for certain members of the TGF-β superfamily, including GDF8 and GDF11. Unlike wild type ActRIIB, ACE-536 does not bind activin A or bone morphogenetic proteins (BMPs). Circulating levels of GDF11 were measured in β-thalassemia patients (N=19) and found to be ~3-fold higher compared with healthy controls (N=5) (286±38 vs 87.8±6 pg/mL, P<0.05). In wild-type mice, ACE-536 treatment promotes maturation of terminal differentiating erythroblasts, unlike EPO which increases precursor proliferation. We used the murine model of β-thalassemia intermedia (*Hbb*$^{th1/th1}$) to study the effects of RAP-536 treatment (murine ortholog of ACE-536). β-Thalassemic mice were treated SC twice weekly with RAP-536 (1 mg/kg) or TBS vehicle (VEH) control for 2 months (N=12/group). Wild-type littermates were dosed similarly (N=17/ group).
Results: Following 2 months of treatment, RAP-536 significantly increased RBC (+28.0%, P<0.001), hemoglobin (+15.0%, p<0.001), and hematocrit (+18.5%, p<0.001), and decreased reticulocytes (-33.4%, P<0.05) in β -thalassemic mice compared to VEH treatment. Analyses of bone marrow and spleen from β -thalassemic mice treated with RAP-536 revealed significantly decreased basophilic erythroblasts and increased late stage orthochromatic erythroblasts. RAPssemic mice had significantly reduced serum EPO levels (639.7±111 vs. 1769.7± 517 pg/mL, P<0.05), and spleen weights (418.3±28 vs. 677.1± 65 mgs, P<0.01) compared to VEH treatment, indicative of decreased extramedullary erythropoiesis. βreated with RAP-536 had increased tibial bone mineral density by dual-energy X-ray absorptiometry (DXA) and increased trabecular bone volume by micro-computed tomography (μCT) compared to vehicle treatment, possibly due to decreased erythropoietic activity in the marrow space.Quantitative tissue iron measurement and Perl's Prussian blue staining revealed decreased spleen, liver and kidney iron levels in RAP-536 treated βehydrogenase levels (334.6±33 vs. 424.6±76 IU/mL) were lower in β-thalassemic mice treated with RAP-536 compared to VEH-treated mice, demonstrating decreased hemolysis. Morphological assessment of peripheral blood smears showed decreased hemolysis, α-globin inclusion bodies and poikilocytosis.
Summary / Conclusion: In summary, these data demonstrate that RAP-536 attenuates ineffective erythropoiesis, corrects anemia, and improves associated co-morbidities in a murine model of βently being tested in Phase II clinical trials in MDS and β-thalassemia patients.

S546

CHARACTERIZATION OF SEC23B HYPOMORPHIC ALLELES IN CDA II PATIENTS
R Russo[1,*], C Langella[1], M Esposito[2], A Gambale[2], F Vitiello[1], F Vallefuoco[2], A Iolascon[1]
[1]Molecular Medicine and Medical Biotechnologies, University "Federico II", Naples, [2]CEINGE - Biotecnologie Avanzate, Naples, Naples, Italy

Background: Congenital dyserythropoietic anemia type II (CDA II) is a genetic hyporegenerative anemia characterized by ineffective erythropoiesis. This condition belongs to COPII-related human genetic disorders. Indeed, it is due to mutations in SEC23B, a component of COPII complex, the core trafficking machinery of the endoplasmic reticulum-Golgi. To date, 60 different causative mutations have been described. The most frequent mutations are nucleotide substitutions (75% missense/nonsense), whereas frameshift and splicing mutations were observed in 15% and 10% respectively. The vast majority of patients have two mutations (in the homozygous or compound heterozygous state),

according to the pattern of autosomal recessive inheritance. In no case homozygosity or compound heterozygosity for two nonsense mutations was found, a situation likely to be lethal. However, few cases with two hypomorphic mutations have been described so far.
Aims: To characterize molecular mechanisms underlying SEC23B alleles and to correlate them with clinical phenotype.
Methods: Diagnosis of CDA II was based on history, clinical findings, laboratory data, morphological analysis of aspirated bone marrow and, whenever possible, on evidence of hypoglycosylated band 3 by SDS-PAGE. Prediction analyses for splice sites mutations were performed by web server tools, Splice Site Prediction by Neural Network and Human Splicing Finder. Total RNA was isolated from peripheral blood mononuclear cells (PBMCs). Relative gene expression was calculated by using the $2^{-\Delta Ct}$ method. P value has been calculated by Student *t* test. Proteins were extracted from PBMCs and western blotting (WB) was performed using a specific rabbit anti-SEC23B antibody (1:500). WB analysis on gradient 4-15% SDS PAGE was performed by precast gel.
Results: We found five novel nucleotide replacements in *SEC23B*: three intronic mutations (c.834+3A>C; c.221+163A>G; c.1404+5G>A), one nucleotide insertion (c.1419_1423insC, p.I473Ifs*47) and one G>A transition (c.221G>A, p.C74Y). None of these mutations is present in the 1000 Genome project. Accordingly to recessive inheritance pattern, the patients were compound heterozygotes for two mutations. Patients A-II.1 and B-II.1, compound heterozygotes for two hypomorphic mutations, showed a marked reduction of SEC23B expression at both mRNA and protein level, while the patient with a missense/nonsense genotype (C-II.1) showed only a slight reduction. Interestingly, patients A-II.1 and B-II.1 exhibited a milder phenotype than patient C-II.1. When we analyzed *SEC23A* expression in all three patients, we found an upregulation of approximately 4 and 3 fold in respect with the paralog SEC23B in compound heterozygotes patients for two hypomorphic mutations. Conversely, no compensatory effect of *SEC23A* expression has been found neither in the patient compound heterozygotes for one missense and one nonsense mutation nor in control subjects.
Summary / Conclusion: Our analyses suggested that the association of two hypomorphic alleles led to a strong reduction of SEC23B expression, without generating severe clinical presentation. We proposed a compensatory mechanism SEC23A-mediated which could balance the reduced expression of its paralog SEC23B. This is in agreement with studies on zebrafish morphants which showed that both Sec23 genes carry specific but partially redundant roles, at least in craniofacial cartilage maturation. The comprehension of the role of SEC23A-B paralogs in humans may provide a means of therapeutic intervention by modulating their expression.

S547

NF-E2 REGULATES PUTATIVE RATE-LIMITING ENZYMES IN THE HEME BIOSYNTHESIS PATHWAY

L Rheinemann[1,*], T Seeger[1], H Pahl[1]
[1]Section of Molecular Hematology, University Medical Center Freiburg, Freiburg, Germany

Background: During erythropoiesis, an increase in heme biosynthesis is crucial for correct maturation. Although it has been shown that this augmented synthesis is achieved by a sequential activation of the eight heme biosynthetic enzymes, the exact regulatory mechanisms remain unclear.
The transcription factor Nuclear Factor Erythroid 2 (NFor erythroid differentiation. It is known to regulate expression of the β-globin gene as well as the genes for two enzymes involved in heme biosynthesis, porphobilinogen deaminase and ferrochelatase.
Aims: We investigated the role of NF-E2 in the regulation of five of the remaining heme biosynthetic enzymes.
Methods: Possible NF-E2 binding sites in the heme biosynthesis enzymes were identified by *in silico* analysis of ChIP-sequencing data from the Encyclopedia of DNA Elements (ENCODE) Consortium. In addition, the promoter regions of aminolevulinic acid dehydratase (ALAD), uroporphyrinogen synthase (UROS), uroporphyrinogen decarboxylase (UROD), coproporphyrinogen oxidase (CPOX) and protoporphyrinogen oxidase (PPOX) were examined for NF-E2 consensus sequences by computational analysis. Binding of NF-E2 to the predicted DNA sequences *in vivo* was verified by chromatin immunoprecipitation (ChIP). Subsequently, functionality of the identified NF-E2 binding sites was determined by luciferase reporter gene assays. Finally, HEL cells were treated with lentiviral constructs containing a shRNA against NF-E2 or a control shRNA and heme content was determined.
Results: Putative binding sites for NF-E2 were detected in the promoter regions of ALAD, UROS, UROD, CPOX and PPOX. In UROS, UROD and CPOX, *in vivo* binding of NF-E2 to the respective locus was verified by chromatin immunoprecipitation. In luciferase reporter gene assays, expression ofNF-E2 induced the erythroid promoter of uroporphyrinogen synthase. Site-directed mutagenesis of the NF-E2 binding site in the erythroid promoter of uroporphyrinogen synthase abolished the NF-E2 mediated activation, establishing this enzyme as a novel NF-E2 target gene. During the increased demand for heme synthesis in erythropoiesis, CPOX has been proposed to be rate-limiting. NF-E2's role in regulating CPOX expression underlines its function as a regulator of heme biosynthesis. Consistent with this regulatory function, knockdown of NF-E2 in HEL cells resulted in a reduction in heme content by 20%.
Summary / Conclusion: Our results demonstrate that NF-E2 modulates the heme biosynthesis pathway at multiple, putatively rate-limiting, steps and thereby establishes a positive feedback loop that secures a constant heme supply for the assembly of hemoglobin during erythroid differentiation.

S548

PRETREATMENT WITH A RHO KINASE INHIBITOR PREVENTS ACUTE LUNG INFLAMMATION IN THE SICKLE CELL MICE MODEL

F Pallis[1,*], C Almeida[1], M Corat[2], C Lanaro[1], N Conran[1], F Costa[1], C Franco-Penteado[1]
[1]Hematology and Hemotherapy Center, [2]Multidisciplinary Center for the Investigation of Biological Science in Laboratory Animals, UNICAMP, Campinas, Brazil

Background: Rho kinases are involved in NF-kB activation, suggesting a potential role of Rho kinases in LPS-induced inflammation. The Rho kinase inhibitor, Y-27632, reduced leukocyte infiltration in several models of inflammation such as endotoxic liver and lung injury. Lungs are particularly vulnerable to vaso-occlusive events because of their anatomic features in SCD. Studies *in vitro*, and *in vivo* using animal models show that leukocytes play a key role in vasoocclusion. Previous studies have shown that LPS challenge causes exaggerated inflammation in sickle cell transgenic mice, associated with increased serum and broncoalveolar lavage (BAL) of TNF-α, IL-1, chemokines (KC and MIP-2) and sVCAM-1.
Aims: The aim of this study was to examine the contribution of the Rho kinase pathway to acute airway LPS inflammation in SCD using the sickle mice model.
Methods: Berkeley SCD mice bone marrow was transplanted into irradiated C57BL/6 to generate age- and gender-matched genetically-identical cohorts of SCD mice. Acute lung inflammation and injury were induced in female wild- type (WT) and SCD mice by intranasal administration of lipopolysaccharide (LPS, 50 µl of 250 µg/ml). The specific inhibitor of ROCK, Y-27632 (5mg/kg), dissolved in sterile saline was applied by intraperitoneal injection 1h before LPS instillation. The vehicle mice group received a similar volume of sterile saline. BAL was performed 5h (early response) and 24h (late response), after LPS challenge. qRT-PCR analysis was used to examine gene expression and ELISA was used to determine protein production.
Results: After 5h of LPS challenge in mice, a huge influx of leukocytes (neutrophils, NS) was triggered in BAL of WT and SCD mice, compared with the respective vehicle groups; however, this influx was greater in SCD mice, when compared with WT (9.3±2.9 vs 3.5±0.4 WBC (x10^6cell/mL); 6.5±2.7 vs 1.8±0.4 NS (x10^6cell/mlL; P<0.05, respectively; n=4). Pretreatment of SCD mice with Y-27632 significantly reduced the WBC and NS influx to the lung (1.9±0.2; 0.24±0.08 (x10^6cell/mL); P<0.05, respectively; n=4). Corresponding with influx of NS, lung lavage levels of KC, MIP-2 and TNF-α were significantly higher in SCD mice BAL compared to WT (1446±66 vs 469±0.9; 1893±390 vs 796±78; 396.9±68 vs 149.8±16.3;pg/ml, respectively; n=4). Y-27632 given 1h before LPS effectively reversed the LPS-induced increase in KC, MIP-2 and TNF-α BAL levels in SCD mice (68.01±21.2; 394.3±208; 128.8±85.7, pg/ml, respectively; n=4). Pre-treatment with Y-27632 was also able to significantly decrease TNF-α levels at 24h after LPS instillation in SCD mice (278.4±86.04 vs 61.9±10.76, pg/ml; n=4). Moreover, Rho-kinase inhibition significantly reduced lung gene expression of KC and TNF-α in SCD mice at 5h after LPS challenge (1.75±0.15 vs 0.28 ±0.14, 0.94± 0.22 vs 0.10±0.05, respectively; n=4).
Summary / Conclusion: In conclusion, these data indicate that the Rho-kinase signaling pathway may play a role in pulmonary infiltration of neutrophils via regulation of TNF-α and chemokine production in the acute lung injury induced by LPS in sickle cell mice. The findings from this study suggest that ROCK inhibition may have important implications for the control of the inflammatory response in the SCD.

S549

THE EFFECTS OF RPS19 KNOCKDOWN ON GATA1 EXPRESSION IN A CELL LINE MODEL OF DIAMOND BLACKFAN ANEMIA

S Bray[1,2,*], L Wee[1], M Perugini[3], L To[3], R D'Andrea[2]
[1]Medicine, University of Adelaide, [2]Haematology/Oncology, Basil Hetzel Institute, The Queen Elizabeth Hospital, [3]Division of Haematology & Centre for Cancer Biology, SA Pathology, Adelaide, Australia

Background: Diamond Blackfan Anemia (DBA) is a rare bone marrow failure disorder characterised predominantly by severe erythroid failure. The causative mutation remains unknown in ~30% of patients, however a mutation or deletion of one of a number of ribosomal proteins (RPS or RPL) has been identified in the remaining ~70% of cases, leading to DBA being classified as a 'ribosomopathy'(Dianzani & Loreni Haematologica. 2008). While haploinsufficiency of RPs appears to be the major cause of DBA, a recent study (Sankaran VG, *et al*. J. Clin. Invest. 2012) reported mutations in the transcription factor GATA1, in the absence of any known RP mutation. While GATA1 mutations have only

been detected in two DBA pedigrees to date, this exception to the 'ribosomopathy' rule may help identify the link between ribosomal protein disruption and the tissue-specificity of the erythroid defect.
Aims: To investigate whether GATA1 (and selected downstream targets) are affected by RPS19 knockdown.
Methods: We have developed a Dox-inducible shRNA RPS19 knockdown model of DBA in the human erythroleukaemic cell line TF1.8. Two independent shRNA triggers targeting RPS19 and a vector control were introduced into cells andcultured in Tet-free media. Supplementation with 5IU/mL EPO was used to induce differentiation along the erythroid lineage.Q-RT PCR was used to measure expression of selected genes on days 0, 3, 5 and 7 of culture. All results are the combined average of 3 independent biological replicates and were normalised to β-actin. Flow cytometry analysis of GlyA and CD13 was also performed to monitor changes in erythroid and myeloid lineages.
Results: Q-RT PCR resultsconfirm RPS19 knockdown (Fig. 1A)and revealed decreased expression ofGATA1 followingRPS19 knockdown (Fig. 1B).The most striking affect on GATA1 can be seen at Day 3, where GATA1 levels are increasing in control cells, but decreasing in cells with the RPS19 shRNA constructs. Furthermore, we found that the expression of the GATA1 target gene, KLF1 (EKLF) is decreased in these cells compared to controls.
Flow cytometry analysis confirmed that the TF1.8 cells respond to EPO with a progressive increase in the percentage of GlyA positive cells and reduction of CD13. Interestingly, cells transduced with RPS19 shRNA do not differentiate to the same extent as control cells, with the proportion of GlyA+ cells decreased in cells with RPS19 knocked down.
Summary / Conclusion: We haveidentified that GATA1 mRNA is down-regulated in response toRPS19 knockdown in an inducible shRNA cell line model of DBA. Furthermore we demonstrate downstream effects on the key GATA1 target gene KLF1, consistent with a recent finding that EKLF (KLF1) mRNA levels were significantly decreased in the blood and bone marrow of DBA and 5q-syndrome MDS patients (Neuwirtova *et al.* Ann Hematol. 2013). Together these results suggest thatchanges to GATA1 (and downstream target gene) levels may be important not only in the rare cases of DBA where GATA1 is mutated, but also in classical DBA associated with ribosomal protein haploinsufficiency. Further studies are being undertaken to validate the effects of RPS changes on GATA1 and downstream genes. This will involve assays for GATA1 transcription factor activity, and assays in a DBA model based on CD34+ cord blood cells infected with our validated RPS19 knockdown constructs.

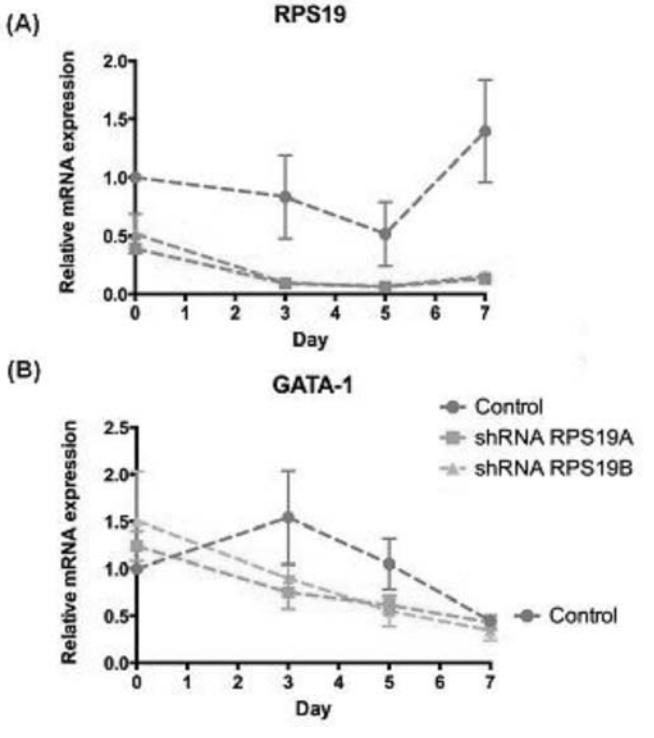

Figure 1 (A) Doxycycline-induced RPS19 mRNA knockdown with two independent RPS19 shRNA constructs compared to vector control in culture for 7 days with EPO supplementation. (B) The effect of RPS19 knockdown on GATA1 mRNA levels in the same cells.

INFLUENCE OF TWO DIFFERENT DOSES OF ANTITHYMOCYTE GLOBULIN ON CLINICAL OUTCOMES OF LEUKEMIA PATIENTS FOLLOWING HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION: RESULTS OF A RANDOMIZED TRIAL

Y Wang[1], x huang[1,*]
[1]peking university people's hospital, beijing, China

Background: Several previous studies have suggested the suitable dose of ATG in matched unrelated transplantation (MUD). But until now, we haven't known the optimal dose of ATG with respect to prevention of graft failure and severe GVHD in the haploidentical transplantation.
Aims: To evaluate the effect of the two different doses of antithymocyte globulin (ATG)in conditioning regimen on graft failure, incidence of acute graft-versus-host-disease (GVHD), relapse and survival among patients receiving hematopoietic stem cell transplantation (HSCT) without *ex vivo* T-cell-depletion (TCD) from haploidentical donors
Methods: Two hundred and twenty-four patients with leukemia in remission and with HLA haploidentical donors were randomized in this study. One hundred and twelve received 6mg/kg ATG while the others received 10 mg/kg ATG. In addition to major HSCT end-points being established, a comparative evaluation of incidence of infection after transplantation was performed. Informed consent was obtained. This study is registered with www.chictr.org, number ChiCTR-TRC-11001761.
Results: Groups were balanced for patient, donor, and transplant characteristics. Incidence of acute GVHD grades III-IV was higher in the ATG-6 group (12.5%) than that in the ATG-10 group (2.7%, P =0.006, 95 percent confidence interval for the difference, -16.6 to -3.0 percentage points). The cumulative rate of platelet engraftment was comparable between the two groups (day 100, 91.9% vs. 88.7%, P=0.19).
Higher dose of ATG required more corticosteroid for resolution of toxicity (P=0.001). EBV reactivation occurred more frequently in the ATG-10 group (25.3%) than in the ATG-6 group (9.6%), (P=0.001). The incidence of relapse was 7.6% in ATG-6 group and 4.6% in ATG-10 group, respectively (P=0.377) and the one-year DFS was 87.5% and 88.1% for ATG-6 group and ATG-10 group, respectively (P=0.877).
Summary / Conclusion: Although 6mg/kg ATG applied in conditioning regimen for haploidentical transplant recipients with non *in vitro* TCD grafts decreased risk of EBV reactivation comparing to 10 mg/kg ATG, it exposes patients to a higher risk for severe acute GVHD. Therefore, the results suggested that replacement of 10 mg/kg ATG with 6 mg/kg ATG should be cautious.

S551

PREDICTING CHRONIC GRAFT VERSUS HOST DISEASE AND MORTALITY, ON DAY +100 AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

A Bacigalupo[1,*], I Cavattoni[2], V Teresa[1], G Anna[1], R Maria[1], T Lamparelli[1], F Galaverna[1], F Gualandi[1]
[1]Hematology, IRCCS San Martinoi-IST, Genova, [2]Hematology, Ospedale Bolzano, Bolzano, Italy

Background: Chronic graft versus host disease (cGvHD) remains the major cause of morbidity and mortality after allogeneic hemopoietic stem cell transplants. Identifying objective predictors on day +100, would allow the identification of patients at high risk of developing cGvHD and subsequent mortality.
Aims: We have tested whether chronic graft versus host disease (cGvHD) , transplant related mortality (TRM) and survival , can be predicted on day +100 by standard laboratory values.
Methods: The patient population consisted of 715 consecutive patients with hematologic disorders allografted between 2001 and 2011, alive on day +100 and free of cGvHD. All patients had laboratory values available on day +100 (±20 days). The donor was an HLA identical sibling (n=335) or an alternative donor (n=380). The median follow-up was 1741 days (range 116-4346). In multivariate Cox analysis, the predictive variables were platelet count (Plt), serum cholinesterase (CHE), gamma-glutamyltransferase (_GT), serum albumin (ALB) and serum immunoglobulin A. Median levels at day +100 were used as cut off and a score of 1 was given for Plt <110x10^9/L, CHE <3772 IU/mL, _GT >56 IU/L, ALB <3,93 mgr/dL and IgA <49 mg/dl.
Results: Results Two prognostic groups were identified: low risk (0-2 negative predictors)(n=497), and high risk (3-5 negative predictors) (n=218). The two risk groups identified patients at different risk of cGvHD (19% vs 37%,P=<0.0001) and of TRM (8% vs 31%, P<0.0001. The actuarial survival of the 2 groups at 10 years was 53% vs 38% (P<0.0001) and disease free survival 56% vs 36% (P<0.0001). In multivariate analysis, including donor/recipient age, female/male grafts, phase of disease, donor type, and year of transplant, the RR for patients at high risk on day+100 was 2.1 for overall mortality, 3.0 for cGvHD and 4.5 for TRM. Other significant predictors were disease phase (on TRM and survival) and alternative donors (on cGvHD). Causes of death in the low and high risk group, were as follows: leukemia (24% vs 26%), GvHD (4% vs 15%) and infetions (3% vs 15%).
Summary / Conclusion: Conclusions: The use of 5 simple laboratory tests (Plt, CHE, _GT, Albumin and IgA) on day +100 after an allograft, predicts cGvHD and mortality, irrespective of donor/patient and disease variables. Prospective trials to prevent cGvHD and mortality in high risk patients, may include immunemodulation with or without intensified infection prophylaxis.

S552

MESENCHYMAL STEM CELL AS A SALVAGE TREATMENT FOR SEVERE REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE: A PILOT PROSPECTIVE STUDY

K Zhao[1], F Huang[1], Y Zhang[1], Y Peng[2], H Zhou[1], Z Fan[1], X Zhang[1], X Guo[1], N Xu[1], J Sun[1], P Xiang[2], Q Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Center for Stem Cell Biology and Tissue Engineering, Sun Yat-sen University, Guangzhou , China

Background: Refractory acute graft versus host disease (aGVHD) is one of the major causes of death after allogenetic haematopoietic stem cell transplantation (allo-HSCT).
Aims: This study evaluated the efficacy and safety of mesenchymal stem cells (MSCs) from the bone marrow of a third-party donor to refractory aGVHD.
Methods: Twenty-seven patients with refractory aGVHD were enrolled in this prospective study. These patients all failed to first-line treatment with corticosteroids and at least one second-line therapy. MSCs were given at a median dose of 1×10^6 cells/kg once weeklyuntil aGVHD was complete responseor for a total of 8 weeks. The response, infection and adverse events were recorded during treatment and follow-up.
Results: After a total of 65 doses of MSC were administered, with a median of 3 (range:1-9) doses per patient, the overall response rate for aGVHD was 74.1%_including complete response in 59.3% and partial response in 14.8%. The efficacy of MSCs to aGVHD was significantly related with timing of onset and type or severity of aGVHD at the initiation of MSC treatment. It had demonstrated that the main target organs (skin,gutand liver) of aGVHD were responsive to MSCs. Skin and liver were superiorto gut in the response to MSCs. In addition, we observed that 6 lung aGVHD patients were all responsive to MSCs. The incidenceof CMV and EBV infections, including viremia and diseases, were not different between aGVHD with MSCs and aGVHD without MSCs during MSCs treatment and follow-up (P=0.68). Tumor relapse were also not different between aGVHD with MSCs and aGVHD without MSCs (P=0.75). No short-term toxic side effects were observed and other secondary tumor occured after MSC treatment except for one EBV-associated PTLD. Compared with that before MSCs treatment, the proportion of $CD3^+CD4^+$_$CD3^+CD8^+$ was significantly higher at 4 weeks after treatment (P=0.06).The incidenceof chronic GVHD in aGVHD with MSCs is lower than that in aGVHD without MSCs (P=0.37).
Summary / Conclusion: The results concluded that MSCs derived from bone marrow of third-party donors are effective to treat refractory aGVHD. MSCs do not increase the risks of tumor relapse and infections.

S553

THE COMPARISON BETWEEN HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION AND UMBILICAL CORD BLOOD TRANSPLANTATION FOR TREATMENT OF HEMATOLOGICAL MALIGNANCES IN CHILDREN

X Mo[1,*], L Xu[1], D Liu[1], X Zhang[1], H Chen[1], Y Chen[1], W Han[1], Y Wang[1], F Wang[1], J Wang[1], K Liu[1], X Huang[1]
[1]Peking University People's Hospital, Institute of Hematology, Beijing, China

Background: Little information is available regarding the priority in selecting the alternative donors for childhood hematological malignances.
Aims: To compare the therapeutic effects of haploidentical hematopoietic stem cell transplantation (haplo-HSCT) and umbilical cord blood transplantation (UCBT) in childhood hematological malignances.
Methods: A total of 281 children received either single UCBT (n=37) or haplo-HSCT from a family donor (n=244) between January 2000 and December 2010 were enrolled. Long-term outcomes were reported and a risk-factor analysis was provided.
Results: Hematopoietic recovery was significantly faster in haplo-HSCT recipients compared with UCBT recipients (100-day myeloid engraftment: haplo-HSCT group, 99.59±0.01%, UCBT group, 86.49±0.35%, P < 0.001; 100-day platelet engraftment: haplo-HSCT group, 94.26±0.02%, UCBT group, 72.97±0.58%, P<0.001), whereas the incidence of graft-versus-host disease was higher in the haplo-HSCT group (100-day total acute GVHD: haplo-HSCT group, 71.72±0.08%, UCBT group, 51.35±0.70%, P = 0.015; 2-year total chronic GVHD: Haplo-HSCT group, 51.68±0.10%, UCBT group, 18.92±0.43%, P = 0.001). The haplo-HSCT recipients had better overall survival (OS: 65.44±0.09% versus 51.21±0.71%, P=0.044) and lower non-relapse mortality (NRM: 19.36±0.06% versus 37.98±0.66%, P=0.007) compared with UCBT recipients, and relapse and disease-free survival (DFS) rates did not differ significantly between the groups. Among high-risk patients, haplo-HSCT recipients had better OS and DFS rates compared with UCBT recipients (OS: 46.43±0.46% versus 16.67±4.07%, P=0.015; DFS: 42.29±0.46% versus 16.67±4.07%, P=0.032). Multivariate analysis showed that UCBT was associated with poorer OS (HR=2.63, 95% CI 1.52-4.55, P=0.001) and increased NRM (HR=2.50, 95% CI 1.37-4.55, P=0.003).
Summary / Conclusion: In summary, we firstly observed that haplo-HSCT can improve the outcomes of children with hematological malignances compared with single UCBT.

S554

IMPROVED SURVIVAL OF PATIENTS WITH HAEMATOLOGICAL MALIGNANCIES ADMITTED TO AN INTENSIVE CARE UNIT: A PROSPECTIVE DUTCH NATIONAL INTENSIVE CARE EVALUATION

M Van Vliet[1,*], I Verburg[2], M van den Boogaard[3], J Donnelly[1], N Blijlevens[1], P Pickkers[1]
[1]Haematology, Radboud University Nijmegen Medical Centre, Nijmegen, [2]Department of Medical Information, Academic Medical Center, Amsterdam, [3]Intensive Care, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background: Improved survival rates for patients in the general intensive care unit (ICU) led to less reluctance in admitting those with haematological malignancies to the ICU.
Aims: The aim of this study was to explore trends in the characteristics, severity of illness, indications and outcomes over time of these patients.
Methods: Data of patients admitted from haematology to an ICU from 2004 till 2012 and registered in the Dutch National Intensive Care Evaluation (NICE) database were analyzed. Four strata were created: patients with leucocytes (L) $<1.0x10^9$, $\geq1.0x10^9$ and $\leq4.0x10^9$, $>4.0x10^9$ and $\leq12.0x10^9$ and $>12.0x10^9$ cells/L. The effect of the time periods was calculated in the different linear regression models using time, stratum classification and the interaction between stratum classification and time as covariates. When analyzing changes over time for length of stay (LoS) and severity of illness score, time in fractional years was used. The standardized mortality ratio (SMR, ratio between the observed number of deaths and the expected number of deaths) was employed to measure the outcome for mortality.
Results: Data of 2,414 first ICU admissions of patients with a haematological malignancy were available for analysis. The proportion of these admissions compared to all medical ICU admissions increased over time from 374 (1.75%) in 2004/5 to 460 (1.94%) in 2006/7 to 590 (2.10%) in 2008/9 and 781 patients (2.43%) in 2010/11 (P<0.01). This increase was observed in all strata except for patients with leucocytes $<1.0x10^9$. The median ICU-LoS for hospital survivors was 2.7 days [interquartile range (IQR) 1.0-7.5] and hospital-LoS was 23.0 days [IQR 11.0-40.7]. Both were different across the strata (Table 1, P<0.01) but did not change over time (P=0.56 for ICU-LoS and P=0.37 for hospital-LoS). The mean APACHE-II score on ICU admission was 24.2±9.3 and differed between the strata (table 1, P<0.01), but did not change over time (P=0.14).The calculated ICU SMRs decreased over time from 1.10 to 0.89 (L<1.0, P=0.03) and from 1.56 to 0.77 (L 1.0 to $4.0x10^9$, P=0.03).
Summary / Conclusion: Significantly more patients with haematological diseases were admitted to Dutch ICUs from 2004 to 2012. While their disease severity at ICU admission, as determined by APACHE-II, remained similar, ICU survival improved particularly for patients with leucocytes below 4. Based on these results, neutropenia is no longer an argument for not admitting patients with a haematological malignancy to the ICU.

Table 1. Length of stay, APCHEII severity of illness and standardized mortality ratios per stratum.

	Leucocytes $<1.0x10^9$	$1.0x10^9\leq$ Leucocytes $\leq4x10^9$	$4.0x10^9<$ Leucocytes $\leq12.0x10^9$	Leucocytes $>12.0x10^9$	*p*-value

IMMUNOPHARMACODYNAMIC RESPONSES FOLLOWING TREATMENT WITH THE BISPECIFIC T-CELL ENGAGER ANTIBODY BLINATUMOMAB AMONG PATIENTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

A Schub[1,*], V Nägele[1], G Zugmaier[1], C Brandl[1], Y Hijazi[1], M Topp[2], P Kufer[1], A Wolf[1], M Klinger[1]
[1]Amgen Research (Munich) GmbH, Munich, [2]Department of Internal Medicine II, University of Würzburg, Würzburg, Germany

Background: Blinatumomab (AMG 103) is an investigational, anti-CD19/anti-CD3, bispecific T-cell engager (BiTE®) antibody that induces target-cell dependent, polyclonal T-cell activation and proliferation resulting in targeted serial lysis of $CD19^+$ B-cells.
Aims: We sought to characterize the effects of blinatumomab on lymphocyte subpopulations and markers of T-cell activation in adult patients with relapsed/refractory B-precursor acute lymphoblastic leukemia (ALL) enrolled in a phase 2 study.
Methods: Adult patients (N=36) with relapsed/refractory B-precursor ALL received blinatumomab via continuous intravenous infusion for 28 days followed by a 14-day treatment-free interval. Patients could receive up to 5 treatment cycles. Whole blood and serum samples were collected at multiple time points during treatment. Changes in lymphocyte subpopulations, cytokines, granzyme B, and blinatumomab concentrations in the serum were evaluated. All patients provided written informed consent.
Results: The lymphocyte response to blinatumomab was similar in all patients. Peripheral B-cell counts dropped to ≤1 B cell/µL within the first week of infusion and remained undetectable for the duration of treatment. Peripheral T-cells disappeared within the first 2–6 hours of infusion but recovered to baseline within several days. Apart from this initial redistribution, T-cell counts remained at least stable in most patients throughout treatment. In some patients, even an expansion of both, $CD4^+$ and $CD8^+$, T-cell compartments occurred, likely due to proliferation of blinatumomab-activated T-cells; however, this expansion did not appear to be required for achieving a complete remission (CR). In the period immediately following initiation of blinatumomab infusion, markers indicative of T-cell activation were present: CD69 was transiently expressed on a significant proportion of T-cells within 48 hours, and peak granzyme B levels in the serum were detected approximately after 24 hours. In most patients, there was a transient elevation of cytokine levels in the serum dominated by interleukin-10, interleukin-6, and interferon-γ during the first 48 hours of the first cycle, but this response was diminished or absent in subsequent cycles. At doses of 5 and 15 µg/m²/d, respectively, mean (±SD) blinatumomab serum steady-state concentrations were 198 (±61) pg/mL and 694 (±236) pg/mL. These values were consistent with those from previous studies.
Summary / Conclusion: Key elements of the immunopharmacodynamic response to blinatumomab included B-cell depletion, T-cell activation and redistribution, and transient cytokine and granzyme B release. These responses were consistent with T-cell engagement via the established BiTE® mode of action. The pharmacodynamic markers evaluated did not allow for predictive differentiation between patients who achieved a hematologic response and those who did not.

S556

GLUCOCORTICOID INDUCED LEUCINE ZIPPER PROTEIN (GILZ) REGULATES HEMATOPOIETIC STEM CELL FUNCTION AND MYELOID DIFFERENTIATION IN A MOUSE MODEL OF CEBPA MUTANT ACUTE MYELOID LEUKEMIA

O Bereshchenko[1,*], M Cimino[2], A Venanzi[1], M Biagioli[2], T Frammartino[1], M Di Sante[1], C Nerlov[3], S Bruscoli[1], C Riccardi[1]
[1]Clinical and Experimental Medicine, Sec. Pharmacology, University of Perugia, Perugia [2]Clinical and Experimental Medicine, Sec. Pharmacology, University of Perugia, University of Messina, Perugia, Messina, Italy, [3]MRC Molecular Hematology Unit, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom

Background: Acute myeloid leukemia (AML) arises through the stepwise acquisition of genetic and epigenetic changes, recently evidenced in mouse model of biallelic *CEBPA* mutations. Hematopoietic stem cell (HSC) expansion precedes the formation of leukemia initiating cells with committed myeloid phenotype in mice bearing two types of patient-derived *CEBPA* alleles. C-terminal *CEBPA* mutations lead to a loss of HSC quiescence, expansion of pre-malignant pool of cells and accelerated AML, whereas N-terminal mutations provide necessary residual myeloid commitment capacity. Understanding the mechanisms underlying mutant HSCs proliferation and leading to leukemia progression is critical to combat leukemia and prevent tumor relapse. We have found that proliferating mutant HSCs downregulate Glucocorticoid Induced Leucine

Zipper protein (GILZ), suggesting that GILZ plays a role in normal and leukemic HSCs and regulates leukemogenesis.
Aims: We would like to address the role of GILZ in normal and aberrant hematopoiesis and its potential role in biology of AML using GILZ knock-out (KO) mice and *CEBPA* mutant mouse model of AML.
Methods: We have analyzed HSC and myeloid progenitors compartments in recently generated GILZ KO mice by multi-color flow cytometry. In addition, mice bearing GILZ KO alleles were crossed to *CEBPA* mutant allele bearing mice (N- and C- terminal mutations). Littermates heterozygous for both GILZ and *CEBPA* mutations (of *GILZ* +/- *CEBPA* N/+ and *GILZ* +/- *CEBPA* C/+ genotypes) were intercrossed and fetal livers with compound *CEBPA* N/C *GILZ* Y/- genotypes were collected and transplanted along with the wild type competitor bone marrow cells into lethally irradiated hosts. Effect of GILZ deficiency on *CEBPA* mutant HSC function, myeloid differentiation and long term leukemogenesis was followed overtime.
Results: Here we demonstrate that young GILZ KO mice have normal HSC and myeloid progenitors frequency and number. However, when combined with leukemogenic *CEBPA* mutations, GILZ deficiency dramatically affects the number of engrafting *CEBPA* mutant HSCs. Moreover, GILZ deficiency rescued the block of myeloid differentiation caused by biallelic *CEBPA* mutations, as normal frequency of Mac-1+ cells were produced by *CEBPA* N/C GILZ Y/- cells. This suggests that GILZ regulates the function of C/EBPa and/or C/EBP family members in normal and malignant myelopoiesis. Importantly, none of the mice transplanted with *CEBPA* N/C GILZ Y/- cells succumbed to leukemia over the 8-months period of the follow-up, despite their sustained presence in bone marrows and spleens.
Summary / Conclusion: These data suggest that GILZ deficiency rescues normal myelopoiesis in *CEBPA* mutant cells and therefore abrogates the leukemogenic function of *CEBPA* mutant proteins. Overall these data unravel a novel player in the regulation of normal and malignant myelopoiesis with a potential for therapeutic exploration.

S557

GENOME-SCALE EXPRESSION AND TRANSCRIPTION FACTOR BINDING PROFILES REVEAL THERAPEUTIC TARGETS IN TRANSGENIC ERG MYELOID LEUKEMIA

L Goldberg[1], M Tijssen[2], Y Birger [1], Re Hannah [2], S. Kinston [2], J Jacob-Hirsch [1], G Schiby [1], A Biran[3], Y[3], G Marcucci[4], C Bloomfield[4], B Göttgens[2], S Izraeli[1,*]
[1]Sheba Medical Center, Ramat Gan, Israel, [2]University of Cambridge, Cambridge, United Kingdom, [3]Tel Aviv University, Tel Aviv, Israel, [4]Ohio State University , Columbus, United States

Background: Aberrant expression of hematopoietic transcription factors perturbs normal hematopoiesis and may lead to the development of leukemia. The ETS transcription factor, ERG, plays a central role in definitive hematopoiesis and its overexpression in patients with acute myeloid leukemia (AML) is associated with a stem cell signature and bad prognosis. Yet how ERG causes leukemia is unclear.
Aims: To decipher the molecular pathogenesis of ERG driven acute myeloid leukemia and to identify therapeutic targets
Methods: Transgenic mice expressing the human ERG3 isoform under the pan-haematopoietic Vav promoter were created. Leukemias were characterized by flow cytometry, gene expression profiling and Chromatin Immunoprecipitation Sequencing (Chip-Seq) of ERG. Gene Set Enrichment Analysis (GSEA) was used to compare with human AML and Stem cell gene expression database. Enhancer analysis was done by transgenic reporter mice. Therapeutic experiments performed in-vitro and in-vivo in mice transplanted with transgenic leukemias.
Results: Levels of ERG expression in transgenic mice were similar to those observed in human AML and hematopoietic stem cells. ERG induced an early progenitor myeloid leukemia in transgenic mice, equivalent to the M0 phenotype observed in human AML with high ERG expression. Integrated genome-scale analysis of gene expression and ERG binding profiles, determined by ChIP-Seq, revealed that ERG activates a transcriptional program similar to human AML stem/progenitor cells and human AML with high ERG expression. We further show that ERG induces expression of the Pim1 kinase oncogene through a novel hematopoietic enhancer element that we further validated in transgenic reporter mice. Pharmacologic and molecular inhibition of Pim1 disrupted growth and induced apoptosis of ERG-driven leukemic cells. In addition, ERG indirectly induces the RAS pathway and direct RAS inhibition by a RAS inhibitor blocked growth of leukemia cells *in vitro* and *in vivo*.
Summary / Conclusion: ERG causes myeloid progenitor leukemia characterized by a direct induction of leukemia stem and progenitor cell transcriptional program. Pim-1 and the RAS pathway are potential therapeutic targets of these high risk leukemias.

S558

EFFICACY AND SAFETY OF QUIZARTINIB (AC220) IN PATIENTS AGE ≥60 YEARS WITH FLT3-ITD–POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA (AML)

H Döhner[1,*], A Perl[2], P Rousselot[3], J Marie[4], G Martinelli[5], G Gammon[6], D Trone[6], J Cortes[7], M Levis[8]
[1]Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany, [2]Division of Hematology/Oncology, University of Pennsylvania, Philadelphia, United States, [3]Service d'Hématologie et Oncologie, Hôpital de Versailles, Université Versailles Saint Quentin en Yvelines, Le Chesnay, [4]Département d'Hématologie, Hôpital Saint-Antoine, AP-HP & U, Paris, France, [5]Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy, [6]Ambit Biosciences Corporation, San Diego, [7]Department of Leukemia, The University of Texas M.D. Anderson Cancer Center, Houston, [8]Department of Oncology, Division of Hematologic Malignancies, Johns Hopkins University School of Medicine, Baltimore, United States

Background: Advanced age and FMS-like tyrosine kinase 3 internal tandem duplication (FLT3-ITD) in acute myeloid leukemia (AML) are each associated with early relapse after standard chemotherapy and poor survival. Quizartinib (AC220), an oral FLT3 inhibitor active against ITD mutant and wild type FLT3, has shown promising activity in phase 1 and 2 studies.
Aims: To determine safety and confirmed rates of composite complete remission (CRc) and complete remission (CR) in an elderly population of FLT3-ITD–positive patients with relapsed/refractory AML treated with quizartinib monotherapy.
Methods: We conducted a phase 2 study to assess the efficacy and safety of quizartinib monotherapy in FLT3-ITD–positive and FLT3-ITD–negative patients in 2 cohorts (N=333). Subjects were tested by a central laboratory for the FLT3-ITD mutation with a >10% ratio of ITD to total FLT3 defined as positive. We present here data on a subset of 110 patients aged ≥60 years, which included 54 patients aged ≥70 years, with the FLT3-ITD mutation and AML relapsed in <1 year or refractory to first-line chemotherapy who were treated with quizartinib. Quizartinib was administered once daily as an oral solution during 28-day treatment cycles. The initial starting dose in the first 17 patients was 200 mg/day, but because of the occurrence of QT interval prolongation, the dose was reduced to 135 mg/day for men and 90 mg/day for women. The CRc rate included CR, CR with incomplete platelet recovery (CRp), and CR with incomplete hematologic recovery (CRi).
Results: Efficacy results are summarized in the Table 1. Median duration of treatment for patients ≥60 years of age was 14.1 weeks (range 0.1–70.6 weeks), and 63 (57%) had a CRc (3 CR, 4 CRp, 56 CRi). For patients aged ≥70 years, median duration of treatment was 14.9 weeks, and 31 (57%) had a CRc (1 CR, 3 CRp, 27 CRi). Median overall survival (OS) in patients ≥60 years of age was 25.3 wks and 16 (15%) survived >52 weeks. The median age of the patients surviving >52 weeks was 69.5 years (range 66–80 years) and median time on quizartinib was 52.1 weeks (range 6.6–70.6 weeks). All of these patients responded to quizartinib (2 CR, 2 CRp, 8 CRi, 4 partial remission). Two patients were still alive at last follow up with survival of more than 1.5 years (OS 93.0 and 96.0 weeks). The median survival of subjects that survived for more than 28 days and achieved a CRc or PR was 31.1 weeks compared to 11.8 weeks for non-responders. The most common (≥10%) Grade 3 or 4 treatment-related adverse events (TRAEs) were anemia (25%), febrile neutropenia (22%), thrombocytopenia (12%), transient QT interval prolongation (10%; no Grade 4 events), and neutropenia (10%). 20 patients (18%) had TRAEs resulting in discontinuation.
Summary / Conclusion: The data presented in this abstract show that elderly FLT3-ITD–positive patients treated with quizartinib, even those aged ≥70 years, with chemotherapy-resistant AML, have preserved high response rates, and promising survival.

Table 1. Efficacy in relapsed/refractory FLT3-ITD-positive AML patients aged ≥60 years and ≥70 years.

	FLT3-ITD–positive AML patients	
	≥60 years (N=110)	≥70 years (N=54)
Cumulative CRc, n (%)	63 (57)	31 (57)
CRc+PR, n (%)	86 (78)	39 (72)
Median CRc duration, weeks (95% CI)	12.1 (6.3, 15.7)	13.9 (8.0, 16.5)
Median OS, weeks (95% CI)	25.3 (21.3, 30.0)	22.7 (17.0, 26.8)

CRc=composite complete remission; OS=overall survival; PR=partial remission.

S559

MCLA-117: A CLEC12AXCD3 BISPECIFIC IGG TARGETING A NOVEL STEM CELL ASSOCIATED ANTIGEN IN AML

P van Loo[1,*], B Hangalapura [2], L Kaldenberg[1], M Throsby[1], H Dolstra[2], J de Kruif[1], A Bakker[1]
[1]Merus B.V., Utrecht, [2]Dept. of Laboratory Medicine, Laboratory of Hematology, Nijmegen Centre for Molecular Life Sciences, Nijmegen, Netherlands

Background: Although the current intensive chemotherapies to treat acute myeloid leukemia (AML) induce complete remission in most AML patients, the long term prognosis of these patients is very poor. Therefore, novel targeted therapies with potent mechanisms of action that attack the tumor cells and their progenitor cellsare much needed. CLEC12A is a myeloid differentiation antigen that is expressed on 90-95% of denovo and relapsed AML and is selectively expressed on leukemic stem cells. Bispecific antibodies can be used to redirect T cells to tumor cells for efficient tumor killing. A T cell-redirecting bispecific antibody binds and activates the T cells with one arm while the second arm binding to CLEC12A directs the cytotoxic T cells to the tumor cells.
Aims: We aimed to develop a human bispecific IgG antibody that targets CD3 expressed on T cells and CLEC12A expressed on AML blasts and residual leukemic stem cells.
Methods: γ
We have developed MCLA-117 which is a highly potent human CLEC12AxCD3 bispecific IgG antibody binding to CD3 on T cells and CLEC12A expressed on AML blasts and residual leukemic stem cells. MCLA-117 was selected from panels of common light chain human monoclonal antibodies derived from the MeMo® transgenic mouse. To produce the bispecific MCLA-117 antibody in the absence of contaminating monospecific antibodies, minor amino acid changes in the CH3 domain of the heavy chain constant region were introduced to drive efficient heterodimerization resulting in production of >95% pure bispecific antibodies by transfected cells.
Results: Co-incubation of resting patient T cells and AML tumor cells with MCLA-117 full length IgG bispecific antibody resulted in efficient tumor cell lysis. An initial version of the CLEC12AxCD3 bispecific IgG induced the release of non-specific pro-inflammatory cytokines IL-2, IFNγ and TNFα via binding of its Fc-tail to activating Fcγ receptors. Therefore, we introduced mutations in the heavy chain constant region CH2 domain to abrogate Fc receptor binding to prevent unwanted cytokine release while retaining binding to FcRn for long half life. Indeed, MCLA-117 antibody with silenced CH2 domains was shown in PBMC assays to prevent the release of non-specific pro-inflammatory cytokines, while retaining its full capacity to induce T cell mediated lysis of AML tumor cells.
Summary / Conclusion: MLCA-117 is a highly potent bispecific antibody that induces T cell mediated lysis of AML tumor cells by targeting the CLEC12A antigen on AML blasts and residual leukemic stem cells. Clinical application of the MCLA-117 product candidate potentially provides a therapy in AML that more efficiently eradicates the cancer cells and prevents relapse.

HEMATOPOIETIC-SPECIFIC LYN-SUBSTRATE 1 (HCLS) IS DEACETYLATED BY NAMPT/NAD+/SIRT1 PATHWAY

B Abolhasani[1,*], K Welte[1], J Skokowa[1]
[1]Molecular Hematopoiesis, Hannover Medical School, Hannover, Germany

Background: Recently we identified HCLS1 protein to be an essential player in the G-CSFR signalling pathway in myeloid cells (Skokowa et al., 2012). We demonstrated that upon G-CSF stimulation, phosphorylated and activated HCLS1 together with its binding partner HAX1 binds to LEF-1 transcription factor leading to LEF-1 activation and subsequently myeloid differentiation. In patients with severe congenital neutropenia (CN) harbouring HAX1 mutations, HCLS1 expression and functions are severely downregulated, leading to "maturation arrest" of myelopoiesis. We also described a new G-CSFR signalling through activation of Nicotinamide phosphoribosyltransferase (NAMPT)/NAD^+/Sirtuins in healthy individuals and in CN patients. We found that G-CSF-triggered deacetylation of myeloid specific factors is essential for myeloid differentiation (Skokowa *et al.*, 2009).
Aims: In the present study we aimed to investigate whether HCLS1 is regulated by NAMPT/NAD^+/Sirtuin pathway via deacetylation.
Methods: We identified four acetyl-lysine sites in HCLS1 protein and generated rabbit polyclonal antibodies specifically recognized each of acetylated lysines for western blot. We also generated lentiviral constructs contained HCLS1 cDNA in which one of acetylated lysines of HCLS1 protein is replaced by a single amino acid.
Results: Using immunoprecipitation with anti-acetyl-lysine antibody we found that HCLS1 is acetylated in HL60 myeloid cells upon pre-treatment of cells with histone deacetylase inhibitors. We also showed that treatment of HL60 and NB4 cells with high doses of Nicotinamide but not Trichostatin A enhanced HCLS1 acetylation on lysine 123 and 241, suggesting that class III histone deacetylases (Sirtuin family) could deacetylate HCLS1 protein.
We further found that NAD^+ and NAMPT treatment of the acute myeloid leukemia cell line HL60 decreased HCLS1 acetylation on both lysines 123 and 241. Similar effects were observed in HL60 cells transduced with lentiviral construct expressing NAMPT cDNA. Inhibition of NAMPT using specific inhibitor FK866 increased HCLS1 acetylation on acetyl-lysines 123 and 241 in NB4 and on acetyl-lysine 241 in HL60 cells. To evaluate the mechanism of NAMPT-dependent deacetylation of HCLS1, we performed immunoprecipitation experiments in cell lysates of HL60 cells using anti-SIRT1 antibody and found interaction between endogenous HCLS1 and SIRT1 proteins. Moreover, interaction between HCLS1 and SIRT1 proteins were detected by immunoprecipitation in 293T cells over-expressing HCLS1 and SIRT1.
Summary / Conclusion: Taken together, we concluded that HCLS1 is deacetylated through NAMPT/NAD^+/SIRT1 pathway and that in patients with severe congenital neutropenia not only diminished expression and phosphorylation but also elevated NAMPT-triggered deacetylation may contribute to the neutropenic phenotype.

PRESENCE OF PERIPHERAL BLOOD CELLS WITH PNH PHENOTYPE IN PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

A Damianaki[1], H Koutala[1], I Mavroudi[1], P Kanellou[1], M Kaparou[1], S Mastrodemou[1], C Pontikoglou[1], H Papadaki[1,*]
[1]Department of Haematology, University of Crete School of Medicine, Heraklion, Greece, Heraklion, Greece

Background: Chronic idiopathic neutropenia (CIN) is a disorder of granulopoiesis characterized by increased apoptosis of the granulocytic progenitor cells and presence of activated, oligoclonal T-lymphocytes with myelosuppressive properties in the peripheral blood (PB) and bone marrow (BM). Based on the existing evidence, we have suggested that CIN represents the mild form of the spectrum of immune-mediated BM failure syndromes.
Aims: To probe the hypothesis that similar to other BM failure syndromes, i.e. aplastic anaemia and myelodysplatic syndromes, CIN patients display PB cells with PNH phenotype.
Methods: We have studied 102 patients fulfilling the diagnostic criteria for CIN and 43 age- and sex-matched healthy individuals. All patients had absolute neutrophi counts lower than 1800/μl (White) or 1500/μl /ml (Black) for more than three months, had no evidence of any underlying disease that might be associated with neutropenia, no history of exposure to irradiation, use of chemical compounds or intake of drugs to which neutropenia might be ascribed, normal BM karyotype and negative anti-neutrophil antibody activity. Flow cytometry was performed for the identification of peripheral blood erythrocytes, granulocytes and monocytes displaying PNH phenotype. Specifically, the CD59dim (type II) and CD59negative (type III) PNH red cells were evaluated within the Glycophorin A (CD235) positive cell fraction. The FLAER negative PNH gran-

ulocytes and monocytes were assessed within the CD24 and CD14 cell fraction, respectively.
Results: The proportion of type II and type III PNH red cells were significantly increased in CIN patients (0.0587±0.337 and 0.0282±0.094, respectively) compared to healthy individuals (0.0064± 0.0067 and 0.0030±0.0021, respectively) (P<0.0001 and P=0.0088, respectively). Similarly, the proportion of FLAER negative (PNH phenotype) monocytes were significantly increased in CIN patients (1.47±1.795) compared to healthy controls (0.1651±0.173) (P<0.0001). No statistically significant difference was identified between patients and controls in the proportion of PNH granulocytes .
Summary / Conclusion: Patients with CIN display increased proportion of PNH red cells and monocytes in the PB. These data support further the concept that CIN shares common pathogenetic features with immune-mediated BM failure syndromes.

Background: Severe Congenital neutropenia (SCN) is a disease characterized by persistent absolute neutrophil count below 500/mmc, early onset of bacterial infections and block of maturation of neutrophils in the bone marrow. SCN is a premalignant disorder. Granulokine-colony-stimulating factor (G-CSF) has radically changed the prognosis of these patients conferring defence against infections, but it probably favours the process of transformation to myelodysplasia (MDS)/leukaemia (AL). The cumulative risk of sepsis/death and transformation to MDS/AL is different according to the cohort studied (Severe Congenital Neutropenia International Registry-SCNIR, French registry and the Swedish Cohort)
Aims: To describe the cumulative incidence of MDS/AL and sepsis causing death in the cohort of SCN patients enrolled in the INR.
Methods: Anagraphical and historical data (date of birth, gender, date of emergence of neutropenia, date of diagnosis, date of last follow up) as well as data on bone marrow morphology, type of molecular mutation, presence of G-CSF mutation, G-CSF dose, number and type of infections, cause of death if any, were extracted from the INR.
Results: From June 2003 to December 2012, among 306 registered in INR, 22 patients were diagnosed with SCN and considered eligible for the study. Nine out of 22 (41%) were females and 13/22 (59%) were males; median aged, at last follow up, 6,3 years (range 0,5-40,2). The patients were diagnosed with SCN at a median age of 9 months (range 0-418). All subjects had the maturative arrest at promyelocyte or myelocyte stage. In the cohort, 16/22 (72%) carried the ELANE mutation, 2/22 (9%) were HAX1 mutated and the remaining 4/22 (18%) had no known mutation. All subjects were treated with G-CSF started at a median age of 9 months (range 0,5-418). Median G-CSF dose exposure was ≤5 mcg/kg/day in 10/21(48%), 6-10 mcg/kg/day in 5/21 (24 %) , 11-19 mcg/kg/day in 3/21 (14%) and ≥20 mcg/kg/day in the remaining 3/21 (14 %). In the cohort none developed AL, while one patient/22 (4%) progressed to myelodysplasia after 4 years of G-CSF treatment at dose of 5 mcg/kg/day. Four out of 22 pts (18%) died , 2 patients for sepsis during follow-up and the other 2 for transplant related causes (infection and acute GVHD). The two sepsis/death events before transplantation were related to absent compliance to G-CSF. The cumulative incidence of MDS/AL trasformation was of 6% at 4 years after the beginning of G-CSF and the probability to develop MDS was 8% at 8 years of life. The cumulative risk of sepsis causing death was 10% after 3 years after the beginning of G-CSF ; the risk to die for sepsis was calculated as 10% at 3,5 years of life.
Summary / Conclusion: The cumulative incidence of MDS in our cohort is lower than the one calculated in the Swedish, French and in the SCNIR cohort mainly after 10-15 years of follow up. This might be due to younger and smaller Italian cohort if compared at least with the french and the SCNIR ones. The incidence of sepsis/death is almost comparable with the French and the SCNIR cohort. The explanation of the deaths might be caused mainly to low/absent compliance to G-CSF therapy. Early diagnosis, amelioration of compliance to therapy and very strict monitoring of clinical status and bone marrow features might reduce these complications in SCN population.

S563

ACETYLATION OF LEF-1 TRANSCRIPTION FACTOR REGULATING HEMATOPOIETIC DIFFERENTIATION
I Kuznetsova[1,*], M Uenalan[1], K Welte[1], J Skokowa[1]
[1]Molecular Haematopoiesis, Hannover Medical School, Hannover, Germany

Results: Previously we identified that NAMPT is essential for the G-CSF –triggered granulocytic differentiation via a NAD^+- sirtuin-1-dependent pathway. Sirtuins are NAD+-dependent protein deacetylases and we found that myeloid-specific transcription factors C/EBPaand C/EBPß are deacetylated and activated by SIRT1. We and others demonstrated, that lymphoid enhancer-binding factor 1 (LEF-1) transcription factor is crucial for neutrophil granulocytopoiesis and lymphopoiesis. LEF-1 mediates the proliferation, survival and differentiation of granulocyte and lymphocyte progenitor cells by binding and activation of cell type-specific transcription factors. LEF-1 expression was severely diminished in myeloid progenitor cells of severe congenital neutropenia patients, who show "maturation arrest" of granulopoiesis. NAMPT, NAD+ and SIRT1 levels were elevated in myeloid cells and in plasma of severe congenital neutropenia patients, demonstrating hyperactivation of this pathway. To evaluate the mechanism of NAMPT-triggered granulocytic differentiation, we analysed whether LEF-1 could be de-/acetylated. Immunoprecipitation with acetylated-Lysine Ab in Jurkat cells showed acetylated form of LEF-1 protein. Moreover, by means of immunoprecipitation with SIRT1 antibody we found interaction between LEF-1 and SIRT1. We further identified lysine residues in LEF-1 protein, which could be acetylated and generated specific rabbit polyclonal antibody specifically recognized acetyl-Lys of the LEF-1 protein. Western blot experiments using these antibody confirmed acetylation of LEF-1 protein on the particular lysine residue. To study the involvement of NAMPT in the deacetylation of LEF-1 protein we treated Jurkat cells with human recombinant NAMPT for 24 hr. Indeed, we found significantly decreased levels of acetylated LEF-1 protein and elevated mRNA expression of LEF-1 after treatment with NAMPT. At the same time, inhibition of NAMPT using specificinhibitor FK866 resulted in increased levels of acetylated LEF-1 protein after 24 hr of FK866 treatment. This was in line with elevated mRNA expression levels of LEF1 (2 folds) and its target genes Survivin (3 folds), c-myc (2 folds), HCLS1 (1,5 folds) and Cyclin D1 (1,5 folds) after 48 hours of FK866 treatment. Further we analysed whether NAMPT effects on LEF-1 trans-activating functions are through direct acetylation of LEF1 protein itself. We made LEF-1 mutant with a single amino acid substitution, which removes lysine acetylation site in the LEF1 protein and performed reporter gene assay using TOP promoter construct. TOP promoter construct contains six LEF-1/TCFs binding sites and luciferase promoter. We found that if acetylation is removed, LEF-1 protein activated TOP promoter 17- 26 fold stronger, as compared to WT LEF-1. This data shows that LEF-1 binding and activation at LEF-1/TCFs binding sites of regulatory DNA is due to direct changes of acetylation of the LEF1 protein itself. Hence, deacetylation of LEF-1 might be crucial process in the mechanism of NAMPT-triggered granulocytic differentiation and might be an important part of the pathomechanism of neutropenia.
In conclusion, in patients with congenital neutropenia, LEF-1 is severely downregulated and the remaining LEF-1 protein is deacetylated. LEF-1 is therefore physically and functionally missing.

Background: Granulopoiesis abnormalities have been described in association with thyroid disease. However data regarding systematic evaluation of adult neutropenia and concurrent or prior thyroid disease are scarce.
Aims: To investigate the frequency of thyroid disorders among patients presenting with neutropenia, to evaluate possible differences in peripheral lymphocyte subsets in neutropenic patients with thyroid diseases, as well as their immunological profile.
Methods: We retrospectively analyzed the clinical and laboratory findings of 218 consecutive patients who presented with neutropenia to the outpatient

Hematology Clinic of our Department between 2005 and 2008. Laboratory evaluation included CBC, blood smear, chemistries, folate, vitamin B12 and iron status, serology for HBV, HCV, HIV, EBV and toxoplasmosis, ANA, anti-DNA Abs, RF, complement factors C3 and C4, thyroid function tests (FT3, FT4, TSH, anti-TPO Abs, anti-TG Abs, TRAbs), and antineutrophil antibodies (anti-PMN Abs) by GIFT, GAT and LIFT methodology. Furthermore immunophenotype of blood lymphocytes was performed by three-color flow cytometry.
Results: Among 218 patients with neutropenia, 95 had thyroid disease (43.5%), 65 chronic immunologic neutropenia, 33 T-large granular lymphocytosis, 11 autoimmune disorders and 14 other diagnoses. Patients with thyroid disorders had an increased frequency of recurrent infections compared to other patients. (P=0.04). The following significant correlations were found: a. negative correlation between FT3 levels and absolute neutrophil counts (ANC) (r=-0.274, P=0.007), b. negative correlation between T4 levels and absolute CD4 counts (r=-0.274, P=0.02), c. positive correlation between TSH levels and absolute CD4 counts (r=-0.16, P=0.05), d: negative correlations between TPO-Abs and TG-Abs levels and C4 levels (r=0.16, P=0.05; r=0.266, P=0.001). In addition CD2+ and CD4+ lymphocyte subsets were significantly higher in patients with thyroid disease compared to patients with normal thyroid function (P=0.05, P=0.002). Among the 95 neutropenic patients with thyroid disease, 51 had Hashimoto thyroiditis (HT, 23.4%), 9 Graves' disease (GD, 4.1%), 6 total thyreoidectomy associated with nodules (TTM, 2.8%), 18 non-toxic multinodular goiter (NTMG, 8.2%) and 11 hypothyroidism (HP, 5%). Patients with autoimmune thyroid disease had an increased frequency of concomitant autoimmune cutaneous or systemic manifestations (P=0.03). Among the various thyroid disorders there was a statistically significant difference in the distribution of CD20+ lymphocytes (P=0.038): HT patients had an increase in the percentage of B-lymphocytes, while the opposite was evident for the TTM-subgroup. In patients with GD an increase of the proportion of NK cells and a decrease in the percentage of TCRγδ+ lymphocytes were noted (P=0.05, P=0.005). Patients with NTMG had significantly higher ANC (P=0.004) compared to other thyroidopathies. Anti-PMN Abs were found in 37.2% of thyroid disorders. A positive correlation between anti-PMN Abs titers and anti-TPO levels was evident (P<0.05).
Summary / Conclusion: The frequency of thyroid disease among neutropenic patients may be higher than previously reported. The existence of anti-PMN antibodies, as well as the different distribution of lymphocyte subsets among patients with different thyroid diseases indicates both humoral and cellular mechanisms in the pathophysiology of thyroid disease-associated neutropenia.

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive malignancy characterized by leukemic transformation of T-cell progenitors. Large deletion of chromosome 6q (del6q) is a frequent abnormality in T-ALL, the oncogenic target of which remains elusive.
Aims: To identify the oncogenic molecular target(s) of the deletion 6q in T-ALL.
Methods: We used integrated genomics tools including array-CGH, next-generation sequencing (NGS) and gene expression profiling on French and Dutch T-ALL cohorts to search for candidate genes. For in vivo experiments, genes were silenced using lentiviraly transduced short hairpin RNA in transgenic Tal1Lmo1 mouse cells and in human primary T-ALL cells, then cells were injected to *Rag*$^{-/-}$*γc*$^{-/-}$ mice and NSG mice, respectively, and the mice were monitored for the onset of an overt T-ALL.
Results: Array-CGH analysis in a first cohort of primary T-ALL cases showed that del(6q) was highly associated to TAL1-expressing T-ALL. The deletion was monoallelic in all cases, interstitial, often subclonal, and mapped to 6q14. Using a custom tiling array designed for 6q14 region in 86 TAL1-related cases from three T-ALL cohorts, we focused on a common deleted region of 4.9 Mb. This region was sequenced using NGS technologies in 6q deleted or non-deleted cases. Two contiguous genes, namely *SYNCRIP* and *SNHG5*, were found to be altered in two otherwise "non-deleted" cases. *SYNCRIP* (encoding hnRNP-Q) and *SHNG5* (a non-protein-coding gene that hosts snoRNAs) are both involved in the regulation of RNA maturation and protein translation. In parallel, gene expression profiling study identified a del(6q) signature in which *SYNCRIP* appeared as the most relevant gene considering its localization in the common deleted region and expression levels throughout normal thymic differentiation. Altogether, *SYNCRIP* and *SHNG5* were two strong candidates to be considered as haploinsufficient tumor suppressor genes involved in T-ALL oncogenesis. We then functionally tested the involvement of these two genes in T-ALL acceleration models. In a first model, transgenic *Tal1Lmo1* cells were injected to *Rag*$^{-/-}$*γc*$^{-/-}$ recipient mice after lentiviral silencing of either *Syncrip*, *Snhg5*, or both genes, together with the retroviral activation of Notch1. Strikingly, the combined silencing of both *Syncrip* and *Snhg5* genes, but not from each gene isolated, accelerated the onset of an overt T-ALL. In a second model, the combined silencing of *SYNCRIP* and *SNHG5* in primary T-ALL cells from a *SIL-TAL* patient significantly increased the leukemia initiating activity when the cells were injected into immunodeficient NSG mice. Gene expression profiling of the resulting T-ALLs showed a Gene Ontology signature of splicing, ribosomal and mitochondrial pathways.
Summary / Conclusion: Using integrated genomics and functional models, we have identified two genes at 6q14 which are recurrently co-deleted in the TAL1-related T-ALL subtype, resulting in leukemia acceleration.

S566

GENETIC BASIS OF MYELOID LEUKEMOGENESIS IN DOWN SYNDROME

Background: Transient abnormal myelopoiesis (TAM) is known as a clonal myeloid proliferation affecting ~10% of neonatal infants with Down syndrome (DS). Although spontaneous regression is as a rule in most cases, about 20-30% of the survived infants develop acute megakaryoblastic leukemia (AMKL) years after the remission. As for the molecular pathogenesis of TAM and DS-AMKL, it has been well established that *GATA1* mutations are detected in virtually all TAM cases as well as DS-AMKL. However, it is still open to question whether a *GATA1* mutation and trisomy 21 are sufficient for the development of TAM, what is the cellular origin of the relapsed AMKL and whether additional gene mutations are required for the progression to AMKL.
Aims: The purpose of this study is to identify the spectrum of gene mutations in TAM/AMKL cases and intra-tumor heterogeneity and clonal evolution patterns in TAM/DS-AMKL using high-throughput sequencing.
Methods: We performed a comprehensive analysis of somatic mutations in TAM/AMKL cases using whole genome sequencing of four trio samples obtained at the initial presentation of TAM, during remission and at the relapse phase of AMKL. Subsequently, deep resequencing was performed to accurately determine the allele frequencies of each detected single nucleotide variant. Whole exome sequencing was also performed for TAM (N=15) and DS-AMKL (N=14) samples (discovery cohort). The recurrent mutations in the discovery cohort, in addition to known mutational targets in myeloid malignancies, were further screened in an extended cohort of TAM (N = 41) as well as DS-AMKL (N = 49) and non-DS-AMKL cases (N=19).
Results: Whole genome sequencing and subsequent deep sequencing of the individual mutations unmasked detailed clonological pictures of clonal evolution/expansion leading to AMKL. Intratumoral heterogeneity was evident at the time of initial diagnosis of TAM and also present in AMKL in all cases. In three patients, relapsed AMKL evolved from one of the major subclones in TAM phase with a shared *GATA1* mutation, as previously reported in relapsed AML in adults. On the other hand, one patient showed a unique pattern, in which the relapsed AMKL originated from a minor subclone in TAM phase that was totally unrelated to the predominant clone, carrying an independent *GATA1* mutation. DS-AMKL samples had significantly higher numbers of somatic mutations compared to TAM samples with the mean numbers of nonsynonymous mutations of 5.8 and 1.7 per sample in AMKL and TAM cases, respectively (P=0.0002). While *GATA1* was the only recurrent mutational target in the TAM phase, 8 genes were recurrently mutated in AMKL samples in whole exome sequencing, including *NRAS*, *TP53* and other novel gene targets. Targeted sequencing revealed secondary mutations other than *GATA1* mutations in 42 out of 49 (85.8%) DS-AMKL, 5 out of 41 (12.2%) TAM and 11 out of 19 (57.9%) non-DS-AMKL cases. RAS pathway and Tyrosine kinases/cytokine receptors mutations were confirmed in 8 and 17 out of 49 DS-AMKL cases, respectively. Lower allelic burden than corresponding *GATA1* mutations indicated that they were more likely to be subclonal mutations.
Summary / Conclusion: TAM is characterized by a paucity of somatic mutations and thought to be virtually caused by a *GATA1* mutation in combination with constitutive trisomy 21. We found two major clonal evolution patterns during DS-AMKL relapse. Secondary mutations involving genes such as RAS pathway genes, tyrosine kinase and epigenetic regulators play a major role in clonal evolution into DS-AMKL.

Background: Chemoimmunotherapy (CIT) is standard of care in young and physically fit patients (pts) with CLL. Development of CIT for older and less fit CLL pts is ongoing, but data from phase 3 trials are sparse.
Aims: CLL11 is the largest trial to evaluate 3 treatments in previously untreated CLL pts with comorbidities: Clb alone, GA101 + Clb (GClb), R + Clb (RClb). The final analysis of CLL11 stage 1 efficacy and safety results is presented here.
Methods: Treatment-naïve CLL pts with a Cumulative Illness Rating Scale (CIRS) total score >6 and/or an estimated creatinine clearance (CrCl) <70 mL/min were eligible. Pts received Clb alone (0.5 mg/kg po d1, d15 q28 days, 6 cycles), GClb (100 mg iv d1, 900 mg d2, 1000 mg d8, d15 of cycle 1, 1000 mg d1 cycles 2-6), or RClb (375 mg/m^2 iv d1 cycle 1, 500 mg/m^2 d1 cycles 2-6). Primary endpoint was investigator-assessed progression-free survival (PFS).
Results: Median age, CIRS score, and CrCl at baseline were 73 years, 8, and 61.1 mL/min for stage 1a (Clb vs GClb, 356 pts) and 73 years, 8, and 62.1 mL/min for stage 1b (Clb vs RClb, 351 pts, triggered by a different event rate). Key efficacy and safety results are below. Grade 3-4 infusion-related reactions with GClb occurred at first infusion only. Management required splitting the first dose over 2 days.
Summary / Conclusion: CIT with GClb or RClb significantly prolongs PFS vs Clb alone. The results demonstrate that GClb and RClb are very active in CLL and superior treament options in this population. GClb vs RClb will be compared in stage 2 analysis with more follow-up available.

Table 1.

Total Stage 1 N=589	Stage 1a		Stage 1b	
	Clb N=118	GClb N=238	Clb N=118	RClb N=233

JAK-STAT PATHWAY IN MALIGNANT AND NON-MALIGNANT CELLS CONTRIBUTES TO MPN PATHOGENESIS AND THERAPEUTIC RESPONSE

M Kleppe[1,*], P Koppikar[1], M Keller[1], F Rapaport[1], T Hricik[1], O Abdel-Wahab[1,2], R Rampal[1,3], S Marubayashi[1], V Romanet[4], J Fridman[5], M Murakami[4], T Radimerski[4], R Levine[1,2]

[1]Human Oncology & Pathogenesis Program, [2]Leukemia Service, Memorial Sloan Kettering Cancer Center, New York, [3]Leukemia Service, Memorial Sloan Kettering Cancer Center, Basel, United States, [4]Disease Area Oncology, Novartis Institutes for BioMedical Research, Basel, Switzerland, [5]Incyte Corporation, Wilmington, United States

Background: Myeloproliferative neoplasms (MPN) are clonal blood disorders characterized by excessive production of mature blood cells. Patients present with high levels of circulating pro-inflammatory cytokines that contribute to MPN-associated symptoms and sequelae. The identification of somatic mutations in *JAK2*, *MPL* and *LNK* in the majority of MPN patients has underscored the importance of JAK-STAT signaling to MPN pathogenesis and led to the development of JAK kinase inhibitors. JAK1/2 inhibitors improve splenomegaly and systemic symptoms, but thus far, have not been shown to reduce or eliminate the malignant clone. It is unclear if the rapid reduction in spleen size and improvement in constitutional symptoms upon JAK kinase inhibition are due to JAK2 inhibition in MPN cells, in non-malignant cells, or targeting of the JAK-STAT pathway in both populations.
Aims: To assess the contribution of JAK-STAT signaling to inflammatory signaling in MPN cells and in non-clonal hematopoietic cells and the effects of JAK1/2 inhibition on cytokine production in clonal and non-clonal populations.
Results: To identify cytokines altered in PMF, we measured serum cytokine levels in MPLW515L engrafted mice and in control mice. We found that a set of cytokines, including Il6 and Cxcl9, were markedly elevated in the serum of diseased mice compared to control mice and importantly, many of these same cytokines are elevated in PMF patients. Further, the JAK1/2 inhibitor ruxolitinib normalized aberrant cytokine levels in PMF mice, consistent with the anti-inflammatory effects of ruxolitinib seen in the clinical setting.
Analysisof cytokine expression levels in sorted mutant and non-mutant cells showed that MPLW515L-mutant cells highly express Il6 and Cxcl9, consistent with tumor derived cytokine production. By contrast, other elevated cytokines (Ccl5, Cxcl9) are largely derived from non-clonal hematopoietic cells. Ruxolitinib treatment normalized cytokine production from both cell populations, in line with an effect of JAK inhibition in malignant and non-malignant cells *in vivo*.
STAT3 is known to contribute to cytokine production in different malignant and inflammatory contexts, but the role of STAT3 signaling in MPN initiation, inflammatory signaling and progression remains unclear. Hematopoietic-specific Stat3 deletion improved survival, reduced disease severity, and reduced cytokine-mediated inflammation in the MPLW515L bone marrow transplant model. These mice had lower blood counts, reduced circulating cytokine levels, lower spleen weights, and reduced fibrosis. In contrast to the significant effects seen with complete hematopoietic-specific Stat3 deletion, deleting Stat3 exclusively in the mutant compartment did not reduce cytokine production, disease severity, or improve survival. These data are consistent with a requirement for STAT3 signaling in both tumor and in non-malignant hematopoietic cells in PMF.
Summary / Conclusion: Our data demonstrate STAT3 as an important effector of cytokine signaling in MPN, and that STAT3 signaling contributes to MPN pathogenesis. Notably, our results suggest JAK-STAT activation in non-clonal cells contributes to MPN pathogenesis. We demonstrate that signaling cross-talk between mutant and non-mutant populations is an important feature of PMF. Finally, our studies support the notion that JAK kinase inhibition in malignant and non-malignant cells is required to improve symptoms, reduce disease severity, and to prevent malignant progression in MPN patients.

S569

IRON DEFICIENT ANEMIA INVOLVES RECONFIGURATION OF ERYTHROPOIETIC PROGRAM ORCHESTRATED BY HEME RECEPTOR BACH1

M Kobayashi[1,2,*], A Muto[2], Ari Itoh-Nakadai[2], T Fujiwara[1], N Tomosugi[3], H Harigae[1], K Igarashi[2]

[1]Department of Rheumatology and Hematology, [2]Department of Biochemistry, Tohoku University Graduate School of Medicine, Sendai, [3]Proteomics Research Unit, Division of Advanced Medicine, Medical Research Institute, Kanazawa Medical College, Kanazawa, Japan

Background: Developing erythroid cells must synthesize balanced amounts of globin proteins and heme because of their intrinsic toxicities. Free globin proteins without heme precipitate easily, causing proteotoxicity, whereas free heme produces reactive oxygen species. Since iron deficient anemia (IDA) is one of the most prevalent diseases, coordination of globin and heme syntheses according to available iron level in erythroid cells must be critical. It has been considered that living bodies have exquisite systems, which sense the amount of iron or heme to regulate globin synthesis and erythropoiesis. While heme-regulated eIF2a kinase HRI is known to regulate the translation of globin by sensing heme, little is known about the transcriptional mechanism for balancing heme and globin levels. *In vitro* studies have shown that BTB and CNC homology1 (Bach1) is a heme-binding transcriptional repressor and binds to the β-globin locus control region and the enhancer regions of Hmox1 encoding heme oxygenase-1 (HO-1). Heme binds to Bach1 to inhibit its DNA binding and to induce its degradation, achieving derepression of Bach1 target genes. Based on these lines of evidence, we hypothesized that Bach1 would adapt synthesis of globin according to heme and iron levels.
Aims: To clarify the function of Bach1 during erythropoiesis under IDA.
Methods: *Bach1*-deficient mice were used for the analysis. To induce iron deficient anemia, the mice were fed with low iron diet. Erythroid progenitors were separated from flow cytometry. Quantitative chromatin immunoprecipitation (ChIP) analysis was performed with TER119-positive erythroblasts using anti-MafK (Santa Cruz) and anti-Bach1 serum A1-6 (Sun et al., 2004). Serum hepcidin level was determined with LC-MS/MS method.
Results: *Bach1*-deficient mice did not exhibit defects in erythropoiesis. In contrast, we found aggravation of IDA in *Bach1*-deficient mice. Based on electron microscopic analysis, massive aggregates were observed in peripheral red blood cells under IDA in *Bach1*-deficient mice, presumably reflecting denatured globin. While expression of both HO-1 and globin mRNA expressions was repressed in wild-type erythroblasts upon iron depletion, their expression was higher in *Bach1*-deficient erythroblasts. ChIP analysis confirmed endogenous BACH1 occupancy at the regulatory regions of these genes. Changes in the systemic iron distribution are also predisposing factors for IDA. Thus, we next assessed serum hepcidin, known as a main regulator of systemic iron level. We found that the serum hepcidin level was significantly higher in *Bach1*-deficient mice.
Summary / Conclusion: We propose a model, referred to as “hemoglobin regulon”, in which the balance between heme and globin in iron deficient erythroid cells is coordinated through Bach1. In iron deficient erythroid cells, heme concentration is decreased, leading to the activation of Bach1 and thereby an inhibition of globin gene transcription. The expression of HO-1 is also kept low in iron deficient erythroid cells, precluding degradation of the newly synthesized heme using the scarce iron. Therefore, both heme and globin are maintained to similar levels by Bach1 and an accumulation of harmful excessive globin is avoided. IDA is not a mere result of iron shortage but is based on an adaptive gene response within erythroid cells. In addition, Bach1 represses hepcidin expression and thereby regulates systemic iron homeostasis. Heme-initiated transcriptional regulations by Bach1 are essential for erythropoiesis and iron homeostasis.

THE ASSOCIATION OF MUTATIONS IN RUNX1 AND CSF3R WITH THE DEVELOPMENT OF LEUKEMIA IN SEVERE CONGENITAL NEUTROPENIA: A NEW PATHWAY IN LEUKEMOGENESIS

J Skokowa[1], D Steinemann[1], C Zeidler[1], V Makaryan[2], R Beekman[3], M Klimiankou[1], M Ünalan[1], S Kandabarau[1], S Schnittger[4], A Kohlmann[4], M Valkhof[3], R Hoogenboezem[3], G Göhring[1], B Schlegelberger[1], M Stanulla[5], P Vandenberghe[6], J Donadieu [7], I Touw[3], D Dale[2], K Welte[1,*]
[1]Hannover Medical School, Hannover, Germany, [2]University Of Washington, SEatle, United States, [3]Erasmus MC, Rotterdam, Netherlands, [4]MLL Münchner Leukämielabor GmbH, München, [5]University Hospital Schleswig-Holstein, Kiel, Germany, [6]KU Leuven/University Hospital Leuven, Leuven, Belgium, [7]Hopital Trousseau, Paris, France

Background: Congenital neutropenia (CN) is a rare inherited disorder of hematopoiesis with a 20% risk to evolve to acute myeloid leukemia or myelodysplastic syndrome (AML/MDS).
Aims: We aimed to investigate the patterns of acquisition of leukemia-associated-mutations in 31 CN patients developing leukemia.
Methods: We used next-generation DNA deep sequencing.
Results: Twenty of the 31 patients (64.5%) demonstrated mutations within *RUNX1*. Of 20 the patients with *RUNX1* mutations, 19 had mutations known to be associated with severe congenital neutropenia: *ELANE* (11), *ELANE+GFI1* (1), *WAS* (3), *HAX1* (3) and *G6PT* (*SLC37A4*) (1).None of the patients acquired an AML associated mutations in *CEBPA, DNMT3A, IDH1, IDH2, NPM1* or *TET2*. Intriguingly, the majority of patients with *RUNX1* mutations (75%) had acquired *CSF3R* mutations. Other leukemia-associated mutatons in the patients with *RUNX1* mutations were found infrequently: *FLT3*-ITD (two patients), *EP300* mutations (two patients*), CBL* (one patient) and *SUZ12* (one patient). Cytogenetics of the leukemic cells revealed that 10 patients with *RUNX1* mutations developed monosomy 7, and 6 patients had trisomy 21. Sequential analysis of the time prior to overt leukemia revealed that *RUNX1* mutation is a late event in leukemogenic transformation. We also evaluated if *RUNX1* and *CSF3R* mutations were presented in the same malignant clone or whether there were two different clones carrying either *RUNX1* or *CSF3R* mutations. We performed CFU assay and sequenced DNA isolated from colonies of leukemia blasts of one CN/AML patient. Both *RUNX1* and *CSF3R* mutations were detected in the same leukemic colonies, suggesting that the RUNX1 mutations occured within the clones harbouring CSF3R mutations in the process of malignant transformation.
Summary / Conclusion: The high frequency of *RUNX*1 mutations in CN patients who developed leukemia and the high incidence of *CSF3R* mutations preceeding these mutations suggests a unique molecular pathway of leukemia development. The detection of *RUNX1* mutations in combination with *CSF3R* mutations could be a useful marker for identifying CN patients progressing to leukemia or MDS.

SIMULTANEOUS SESSION II

Novel chronic lymphocytic leukemia genetics - Clinical implications

S571

GENETIC DETERMINANTS OF FLUDARABINE-RESISTANCE IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

M Messina[1,*], I Del Giudice[1], D Rossi[2], S Chiaretti[1], S Rasi[2], V Spina[2], H Khiabanian[3], A Holmes[4], M Marinelli[1], G Fabbri[4], A Rossi[5], A Guarini[1], L Pasqualucci[4], R Rabadan[3], R Dalla-Favera[4], G Gaidano[2], R Foà[1]
[1]Division of Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University, Rome, [2]Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy, [3]Department of Biomedical Informatics and Center for Computational Biology and Bioinformatics, [4]Institute for Cancer Genetics and the Herbert Irving Comprehensive Cancer Center, Columbia University, New York , United States, [5]GIMEMA Data Center, Rome, Italy

Background: The current first line standard of care for fit CLL patients is fludarabine, cyclophosphamide and rituximab, which offers overall response and complete remission rates of 95% and 44%, respectively. Fludarabine-refractoriness (FR), defined as failure to respond or relapse within 6 months of therapy, accounts for 5-10% of treated patients, and continues to represent a challenging clinical problem. The only established player in determining FR is *TP53*, disrupted in 30-40% of FR-CLL. More recently, next generation sequencing studies led to the identification of new genes (*NOTCH1*, *SF3B1*, *BIRC3*) that are frequently mutated in FR-CLL. However, a comprehensive evaluation of the FR-CLL genome has not been reported.
Aims: We explored the genetic landscape of FR-CLL to provide a comprehensive description of the load and spectrum of alterations that are associated with this condition and to identify novel molecular determinants of FR.
Methods: We integrated Whole-Exome Sequencing (WES, Agilent SureSelect Human All Exon 50Mb, Illumina HiSeq 2000) and Copy Number (CN) analysis (SNP 6.0 arrays, Affymetrix) to study 10 FR-CLL cases sampled prior to the treatment that resulted in refractoriness and their paired germline DNA (discovery panel). Candidate somatic mutations were verified by Sanger sequencing and the entire coding region of recurrently mutated genes (>1 case) was then sequenced in an independent set of 48 FR-CLLs, of which 29 were also subjected to CN analysis. Mutation recurrence was compared versus 174 unselected CLL at diagnosis, to determine preferential association with FR-CLL.
Results: In the 10 discovery cases, we identified 163 non-silent sequence variants (average 16.3/sample, range 9-23), distributed in 151 genes and predominantly represented by missense mutations; additionally, 40 CNAs were found (average 4/sample, range 0-13), accounting for an overall load of genomic alterations of ~20 lesions/sample (range 11-26). The extended analysis of 58 FR-CLLs revealed several recurrently mutated genes - including the previously reported *TP53* (27.5%), *SF3B1* (24.1%), *NOTCH1* (17%) and *BIRC3* (15.5%) - but also novel candidates, with the tumor suppressor related gene *FAT1*, encoding for a cadherin like protein, being the most common (10.3%). *FAT1* mutations introduce amino acid changes in the cadherin and intracytoplasmic domains, and are similar to those recently reported in multiple solid tumors, where inactivation of FAT1 promotes Wnt signaling and tumor growth, consistent with a tumor-suppressor role. Importantly, the frequency of *FAT1*-mutated cases in FR-CLL was significantly higher than that recorded in unselected CLLs at diagnosis (N=2/174, 1.1%, P=0.004), suggesting a specific role in FR. SNP array analysis of 39 patients showed a broader load of CNAs in FR-CLL (4.8/case), than in untreated CLLs described in the literature (~2/case, Edelmann *et al*, Blood 2012). Furthermore, 10% of cases were characterized by a particularly high number of CNAs within one single chromosome, consistent with the chromotripsis phenomenon.
Summary / Conclusion: *FAT1* is a novel commonly mutated gene in FR-CLL (10.3%), which is rarely detected in unselected CLL cases at diagnosis, suggesting a potential functional role in the disease. Patients with FR-CLL present a higher burden of CNAs and chromotripsis compared to untreated CLL described in the literature. The contribution of *FAT1* mutation, CNAs and chromotripsis to FR in CLL is under investigation.

S572

GENOME-WIDE GENETIC ANALYSIS REVEALS GLOBAL DEREGULATION OF METHYLTRANSFERASE GENES IN CHRONIC LYMPHOCYTIC LEUKEMIA

H Parker[1], M Rose-Zerilli[1], J Gibson[2], J Forster[1], T Chaplin[3], L Brown[1], A Steele[1], G Packham[1], F Forconi[1], S Ennis[2], A Collins[2], B Young[3], D Oscier[1], J Strefford[1,*]

Queen Mary, University of London, London, United Kingdom

Background: Of the biological processes that contribute to clinical behaviour in chronic lymphocytic leukemia (CLL), few are more fundamentally important to the process of pathogenesis than the presence of somatically acquired chromosomal aberrations and gene mutations. However, our understanding of the pathways targeted by these lesions, which contribute to CLL biology, remains incomplete.
Aims: To identify and characterise genomic aberrations and somatic mutations that target methyltransferase (MT) genes in patients with CLL.
Methods: Our initial cohort comprised 261 CLL patients sampled at disease progression (mean time from diagnosis to sampling = 45.8 months), including 95 enrolled on the UK CLL4 trial. Affymetrix SNP 6.0 profiling was performed to identify somatically acquired copy number alterations (CNA) and copy number neutral LOH (cnn-LOH). Aberrations detected in at least 2% of patients (n=6) were considered recurrent. Selective confirmatory array-CGH (Agilent Technologies) was also employed. The RNA expression levels of candidate genes within recurrent CNA were investigated using qRT-PCR and high resolution melt analysis (HRM) and Sanger sequencing were used to screen for, and validate mutations. We then designed a next generation sequencing (NGS) platform (Agilent Haloplex Target Enrichment system) to identify somatic mutations in 82 selected genes, including 55 with MT activity.
Results: Affymetrix SNP 6.0 profiling facilitated the characterisation of established CNA and identified 22 other recurrent CNA including novel deletions of 18p12 (6%), 8p21.2-23.3 (4.6%), 4p16.1 (3%) and 20q12.1-13 (2.7%). Of specific interest was a previously un-described recurrent deletion of chromosome 3p21.31 (46.93-47.37mb), observed in eight cases (3%), with cnn-LOH observed in an additional case. The minimally deleted region encompasses five genes; *CCDC12*, *NBEAL2*, *KIF9*, *KLHL19* and the histone MT gene, *SETD2*. Quantitative RT-PCR demonstrated that *SETD2* was the likely target gene as it was the most significantly under-expressed gene in the region (P=0.001). In total 30 MT genes were targeted by CNA as follows: 1) established CNA resulted in the deletion or duplication of six MT genes; *EED* (13.8%) and *MLL* (8%)(del11q), *SETDB2* (43%)(del13q) and *MLL2*, *PRMT8* and *SETD8* (6%)(Tri12); and 2) a further 24 MT genes were targeted by other large (non-focal) CNA including recurrent deletions of *ASH2*L (3.4%), *WHSC1L1* (3.4%), *WHSC1* (2.7%) and *PRMD1* (2.7%). Using HRM to screen *SETD2* (exons 3-21) we could not identify mutations in the 3p deleted cases, but in 100 progressive patients without deletions of the 3p region we identified two mutated individuals, with a non-synonymous mutation and a frameshift deletion. Based on this preliminary data and recent publications we hypothesized that whilst *SETD2* mutations were rare, CLL might be characterized by deregulation of epigenetic control mechanisms with somatic DNA mutations targeting multiple genes with MT activity. An initial analysis of six cases using our customised NGS platform confirmed the presence of *SETD2* mutations (and deletions), and identified mutations in two additional MT genes (*MLL2* and *NSD1*) in individual cases.
Summary / Conclusion: In total, genes with MT activity were targeted by CNA and/or mutations in the majority of CLL patients in our study. This implicates the disruption of epigenetic modifying genes in the pathogenesis of CLL. Whilst therapeutics that target these processes have limited activity in CLL in general, our work may identify patient sub-groups that are more sensitive to these agents, thereby providing improved clinical management of patients with CLL.

S573

ASSOCIATION BETWEEN MOLECULAR LESIONS AND SPECIFIC B-CELL RECEPTOR SUBSETS IN CHRONIC LYMPHOCYTIC LEUKEMIA

M. Misericordia, Udine, [7]Department of Internal Medicine and Haematology, Maggiore Hospital, Trieste, [8]Institute of Hematology, Catholic University of the Sacred Heart, [9]Molecular Hematology, International Centre for Genetic Engineering & Biotechnology, Campus "A. Buzzati-Traverso", Rome, [10]Section of Hematology, Oncology, and Clinical Pathology, Department of Clinical and Molecular Biomedicine, University of Catania, Catania, [11]Division of Hematology, Department of Oncology and Hematology, University of Modena and Reggio Emilia, Modena, Italy, [12]Cancer Sciences Unit, CRUK Clinical Centre, University of Southampton, Southampton, United Kingdom, [13]Department of Hematology, Tor Vergata University, Rome, Italy

Background: Genetic lesions and B-cell receptor (BCR) signaling are both oncogenic drivers in chronic lymphocytic leukemia (CLL). However, little is known regarding the association between specific genetic aberrations and distinct CLL subsets with stereotyped BCR.
Aims: The study aimed at verifying whether stereotyped BCR patterns may selectively promote the occurrence of specific genetic lesions in CLL.
Methods: Mutations (*TP53*, *NOTCH1*, *SF3B1*, *BIRC3*, *MYD88*), chromosomal abnormalities (del13q, +12, del11q, del17p, *BIRC3* deletion), and BCR stereotypy were investigated in 1419 newly diagnosed CLL. Associations between genetic lesions and BCR features were assessed by non-parametric binomial test corrected for multiple comparisons.
Results: BCR stereotypy as a whole did not impact on CLL genetics. However, two BCR subsets, namely subset 2 (*IGHV3-21*) and 8 (*IGHV4-39*), recurrently showed a distinctive pattern of molecular alterations. CLL subset 2 was significantly enriched in *SF3B1* mutations, which occurred in 52% of cases (P<.001). Among *IGHV3-21* CLL, *SF3B1* mutation enrichment was selective for cases showing a subset 2 BCR pattern, while they occurred at lower prevalence in *IGHV3-21* CLL with heterogeneous BCR (13%; P=.002). Subset 2 CLL lacked *TP53* abnormalities, that were otherwise evenly represented in all the other major subsets, thus pointing to *SF3B1*, rather than *TP53*, as the main driver of progressiveness in subset 2 CLL. Consistently, subset 2 CLL harboring *SF3B1* mutations showed a higher probability of being treated at 5 years (67%) compared to subset 2 CLL with wild type *SF3B1* (38%; P=.064) and to *IGHV3-21* CLL with heterogeneous BCR (46%; P=.076). Subset 8 CLL were significantly enriched in +12 (87% of cases; P<.001) and *NOTCH1* mutations (62% of cases). Among *IGHV4-39* CLL, +12 and *NOTCH1* mutations enrichment was selective for cases harboring a subset 8 BCR configuration, while their prevalence was significantly lower in *IGHV4-39* CLL with non-stereotyped BCR (27%; P=.003 and 8%; P=.006, respectively). From a clinical standpoint, the majority (62%) of subset 8 patients had transformed to Richter syndrome. All transformed cases carried both *NOTCH1* mutations and +12, while this genetic association was never observed among subset 8 patients that had not transformed to Richter syndrome (P=.017).
Summary / Conclusion: These data suggest that: i) synergy of *SF3B1* mutations and subset 2 BCR configuration promotes disease progression in *IGHV3-21* CLL; and ii) cooperation between *NOTCH1* mutations, +12, and subset 8 BCR configuration primes RS transformation in *IGHV4-39* CLL. Taken together, our observations provide a proof of concept that specific BCR configurations may contribute to clonal selection of specific genetic lesions influencing CLL outcome.

S574

DISTINCT FREQUENCY AND PROFILES OF TP53 GENE MUTATIONS IN CLL SUBGROUPS WITH DISTINCT ANTIGEN RECEPTORS: EVIDENCE FOR ANTIGEN-DRIVEN SELECTION OF GENOMIC ABERRATIONS

J Malcikova[1,2,*], E Stalika[3], Z Davis[4], L Mansouri[5], K Plevova[2], P Baliakas[6], A Gardiner[4], L Sutton[5], H Francova[2], A Anagnostopoulos[6], I Tracy[4], M Trbusek[1], A Makris[3], C Belessi [7], D Gonzalez[8], R Rosenquist[5], D Oscier[4], S Pospisilova[1], K Stamatopoulos[3,6]
[1]Molecular Medicine, CEITEC Masaryk University, [2]Department of Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, [3]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, [4]Department of Haematology, Royal Bournemouth Hospital, Bournemouth, United Kingdom, [5]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, [6]Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, [7]Hematology Department, General Hospital of Nikea, Piraeus, Greece, [8]The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom

Background: In CLL, mutations of the *TP53* gene negatively impact on patient outcome and are strongly associated with deletion of chromosome 17p and unmutated IGHV genes (U-CLL).
Aims: Here we sought to explore the distribution and spectrum of *TP53* mutations with regards to immunogenetic features in a series of 1160 patients intentionally selected for belonging to prognostically adverse immunogenetic CLL subgroups.
Methods: We investigated (i) U-CLL and/or (ii) cases expressing the IGHV3-21 gene, especially in stereotyped B cell receptors (BcRs) assigned to subset #2 with variable IGHV mutational status. For this reason, only 49/1160 (4.2%) cases of the cohort carried mutated IGHV genes (M-CLL; germline identity, GI, <98%). The remaining cases (1111/1160, 95.8%) concerned U-CLL; of these, 271 (24.4%) and 840 (75.6%) cases expressed IGHV genes with 98-99.9% and 100% GI, respectively. For the purposes of the present study, we particularly focused on missense *TP53* mutations in DNA binding motifs (DBMs), described to be associated with a markedly adverse prognosis.
Results: Overall, 206 cases (17.8%) were found to carry *TP53* mutations; 99/206 (48%; or 8.5% of the entire cohort) carried mutations in DBMs. The high frequency of mutations can be explained by the composition of the present cohort which essentially consisted of prognostically adverse immunogenetic subgroups. As expected, *TP53* mutations (all types as well as mutations in DBMs) were significantly more frequent in cases with del(17p) vs. all other aberrations in the hierarchical model (P<0.0001). Association analyses regarding immunogenetic features concerned the following: (1) somatic hypermutation (SHM) status. The frequency of all types of *TP53* mutations was significantly higher in cases expressing IGHV genes with GI=100% vs. GI=98-99.9% (19.6%

vs 13.6%; P=0.02). (2) IGHV gene repertoire. Among U-CLL cases, significant differences in the incidence of *TP53* mutations in general and mutations in DBMs in particular (P=0.03 for both) were identified in cases utilizing different IGHV genes: in particular, there were more than 20% *TP53*-mutated cases in the IGHV1-69, IGHV1-3, IGHV3-30 and IGHV4-39 groups, thus contrasting the IGHV5-51 (7%) and, especially, the IGHV3-21 group (4%). (3) BcR stereotypy. In addition to subset #2 (n=66 cases, variable SHM status), several other well-characterized subsets were represented in the present cohort (all concerning U-CLL), including #1 (n=61), #8 (n=15) (both already documented as poor-prognostic) as well as five subsets utilizing the IGHV1-69 gene albeit with distinct VH CDR3 motifs, namely #3 (n=16), #5 (n=14), #6 (n=25) and #7 (n=44). *TP53* mutation frequencies varied significantly (P=0.01) between these subsets, ranging from 0% in subset #5 to 25% in subset #3; of note, these subsets have previously been reported to exhibit distinct prognosis (shorter time-to-first-treatment in #3). The two largest subsets, namely #1 and #2 had *TP53* mutation frequencies of 14.8% and 6% respectively. Differences were more pronounced (P=0.008) concerning *TP53* mutation frequencies in DBMs.
Summary / Conclusion: We demonstrate markedly different incidence and spectra of *TP53* mutations, especially missense mutations in DBMs, in different stereotyped CLL subsets. These findings confirm and significantly extend recent reports by us and others that certain BcR stereotypes are linked to distinct profiles of genomic aberrations. On these grounds, antigen-driven, BcR-mediated selection can be proposed as a possible mechanism for the acquisition of genomic aberrations in CLL.

COMPREHENSIVE GENOME-WIDE ANALYSIS OF CLL SAMPLES FROM UK 1ST LINE AND RELAPSED/REFRACTORY CLINICAL TRIALS
P Robbe*[1,*], R Clifford*[1], A Timbs[1], A Burns[1], M Titsias[2], M Cabes[1], R Alsolami[1], N Khalid[1], S Henderson[1], J Taylor[2], C Yau[2], C Holmes[2], R Copley[2], S Knight[2], A Schuh[1]
[1]Oxford NIHR Biomedical Research Centre Molecular Diagnostic Centre, [2]Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom

Background: CLL is a biologically and clinically heterogeneous disease. Whilst important progress has been made in the treatment of CLL, 25% and 50% patients relapse within two years of 1st or 2nd line chemo-immunotherapy, respectively. Multiple recurrent chromosomal abnormalities have been identified and associated with prognosis. To date, the only clinically useful predictive markers remain deletions/mutations of TP53. However, these identify only up to a third of patients with chemo-immunotherapy refractory disease.
Aims: To design a comprehensive genome-wide next generation diagnostic tool of recurrent acquired genetic abnormalities in CLL that predicts treatment response using well-annotated clinical trials samples.
Methods: The cohort studied consisted of 261 CLL patients recruited into four national UK CLL trials, divided in two groups: 192first line treatment (ARCTIC, AdMiRe) and 69 relapsed/ refractory patients (NCRNCLL201, NCRNCLL202). Samples were tested using genome-wide high-resolution arrays (Illumina Inc.) and analyzed with the software Nexus v6.1 (BioDiscovery, Inc.). CNA and copy neutral Loss of Heterozygosity (cnLOH) events were verified visually and the frequency of CNAs and cnLOH noted. Overall genomic complexity was determined per sample using the number and total length of CNAs reported. Previously described (Knight et al 2012) and novel minimally overlapping regions (MORs) were interrogated for candidate genes. Custom-designed targeted sequencing panels consisting of 387 amplicons each (TruSeq Custom Amplicon, Illumina) were run on the Miseq (Illumina Inc) to identify 20 pathogenic mutations in genes known to be recurrently mutated in CLL and in new candidate genes from MOR analysis. Bio-informatics analysis was carried out using BaseSpace (Illumina Inc.) and our in-house pipeline.
Results: *Genome-wide array.* The total number of CNAs in CLL-associated genes and their frequency in the pre-treatment and relapsed/refractory cohorts are presented in the table 1. The array data revealed that genomic complexity and chromotrypsis were significantly higher in the relapsed/refractory group with 30% of the cases with an average cumulative length of abnormalities greater than 60 Mb, whereas only 18% of the first line treatment cohort fulfilled the same criteria. *Next-generation sequencing.* Of the 63 MORs published previously by Knight *et al.* (2012), we were able to refine 24, in some cases to only one or two genes. We identified also an additional 50 MORs. Over 90% of these involved copy number losses occurring at <3% frequency. Re-sequencing of candidate genes in MORs identified 14 novel genes with pathogenic mutations (1 frameshift insertion, 2 frameshift deletions, 2 stop gains and 18 non synonymous mutations) of which 6 were recurrently mutated. Mutation frequencies of known CLL associated genes were within the ranges published to date. An increased mutation burden in relapsed trial samples compared to pre-treatment samples was seen.
Summary / Conclusion: Our results represent the most comprehensive genome-wide array and mutation analysis of CLL patients recruited into clinical trial samples so far. They demonstrate the value of combining genome-wide array and targeted NGS approaches for high sensitivity, high throughput molecular studies of CLL. Once clinical outcome data becomes available a comprehensive hierarchical model of response prediction will be validated.

Clinical studies in Multiple Myeloma 1

DARATUMUMAB, A CD38 MONOCLONAL ANTIBODY STUDY IN ADVANCED MULTIPLE MYELOMA – AN OPEN-LABEL, DOSE ESCALATION FOLLOWED BY OPEN-LABEL EXTENSION IN A SINGLE-ARM PHASE I/II STUDY
H Lokhorst[1,*], T Plesner[2], P Gimsing[3], H Nahi[4], S Lisby[5], P Richardson[6]
[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Vejle Hospital, Vejle, Denmark, [3]Copenhagen University Hospital, Copenhagen, Denmark, [4]Karolinska University Hospital, Stockholm, Sweden, [5]Genmab A/S, Copenhagen, Denmark, [6]Dana-Farber Cancer Institute, Boston, United States

Background: Daratumumab (DARA) is a human CD38 monoclonal antibody with broad-spectrum killing activity in multiple myeloma (MM). Preliminary safety and efficacy data from this first-in-human dose-escalation study of DARA in patients with relapsed or refractory (RR) MM have previously been reported.[1] Here, we present efficacy data from the dose escalation part and preliminary safety and efficacy data from the ongoing extension part of the study.
Aims: The primary aim was to evaluate the safety profile of DARA in this setting. The secondary aims were to find the maximum tolerated dose (MTD), assessment of efficacy, pharmacokinetics (PK) and immunogenicity through examining Anti-Drug-Antibodies (ADA).
Methods: Patients ≥18 years, diagnosed with MM, requiring systemic therapy, considered RR to at least 2 prior lines of therapy and ineligible for ASCT were enrolled. Dose escalation of the study was based on a classic 3+3 design. DARA was given over a 9-week period consisting of 2 pre- and 7 full doses. Bone marrow biopsy was performed before treatment, after end of treatment and at end of study. In the extension part, patients receive 8mg/kg DARA weekly for 8 weeks followed by dosing every 2nd week for 16 weeks and every 4th week until disease progression, toxicity or for maximum 24 months. DARA plasma concentrations were measured by ELISA. Evaluation of efficacy data was according to modified IMWG criteria.[2] An Electro-Chemi-Luminescence method was used to detect ADA. The results presented are based on data analyzed before database lock.
Results: Data from 32 patients were included in part 1, and data from 13 patients from part 2 have been collected to date. Median age was 61 years in both part 1 and part 2. The median number of prior treatment lines was 6 in part 1 and 4 in part 2. PK analysis showed plasma peak levels as expected, but relatively rapid clearance at low dose levels, with PK data for part 2 currently in process. Preliminary efficacy evaluation from part 1 was based on best response to paraprotein according to IMWG criteria. In the 4 mg/kg group and upwards (n=12), 5 PRs and 3 MRs were observed and 7 of these patients had a 50-100% concomitant reduction in the bone marrow plasma cells. Median PFS (Figure 1) in the ≥4mg/kg dose groups was not reached (median follow-up at data cut-off was 3.8mths (range: 0-9.6mths).
Safety data continue to be evaluated with no ADA responses detected so far. In part 1, the most common adverse events reported were infusion related (IREs) which occurred predominantly during the first full infusion. 44% of subjects across all dose groups had IREs grade 1-3, of which 2 were grade 3. Six related SAEs (1 anemia, 1 thrombocytopenia, 2 bronchospasm, 1 cytokine release, 1 AST increase) were reported. In part 2, preliminary safety data mainly show infusion related reactions grade 1–2.
Summary / Conclusion: DARA induced a marked reduction in paraprotein and bone marrow plasma cells at doses ≥4mg/kg in heavily pretreated patients with relapsed or relapsed and refractory MM. This is currently unprecedented for single-agent monoclonal antibody treatment of MM. No ADA responses were detected and toxicity proved manageable. All data available from the study will be presented at the meeting.

FINAL RESULTS FROM THE PHASE 1B/2 STUDY (PX-171-006) OF CARFILZOMIB (CFZ) IN COMBINATION WITH LENALIDOMIDE AND LOW-DOSE DEXAMETHASONE (CRD) FOR PATIENTS WITH RELAPSED OR PROGRESSIVE MULTIPLE MYELOMA

R Niesvizky[1,*], M Wang[2], T Martin[3], W Bensinger[4], M Alsina[5], D Siegel[6], E Kavalerchik [7]
[1]Myeloma Center, Weill Cornell Medical College, New York, [2]Lymphoma and Myeloma, MD Anderson Cancer Center, Houston, [3]UCSF Medical Center, San Francisco, [4]University of Washington, Seattle, [5]Moffitt Cancer Center, Tampa, [6]John Theurer Cancer Center, Hackensack, [7]Clinical Science, South San Francisco, United States

Background: Carfilzomib (CFZ) is a selective inhibitor of the chymotrypsin-like activity of both the constitutive proteasome and the immunoproteasome, and was approved in the United States in 2012 as a single-agent treatment for patients with multiple myeloma (MM) who have received at least 2 prior therapies including bortezomib and an immunomodulatory agent and have demonstrated disease progression on or within 60 days of completion of the last therapy. We previously reported interim data from PX-171-006 (NCT00603447), a phase 1b/2 study of CRd in patients with relapsed or progressive MM (Wang M et al., ASCO 2011; Niesvizky R et al., *Clin Cancer Res*. 2013).
Aims: Herein we report final results from the PX-171-006 study.
Methods: Patients (1–3 prior treatments) received CRd in 28-day (D) cycles—CFZ IV on D1, 2, 8, 9, 15, and 16; lenalidomide PO D1–21; and dexamethasone weekly. During the phase 1 portion of the study, CFZ (15–27 mg/m^2) and lenalidomide (10–25 mg) doses were escalated to determine the maximum tolerated dose (MTD). The maximum planned dose (MPD) of CFZ was 20 mg/m^2 on D1 and 2 of Cycle 1 and 27 mg/m^2 thereafter, which was used in combination with lenalidomide (25 mg/d) and dexamethasone (40 mg/wk). During the phase 2 dose expansion portion of the study, CFZ was used at the MTD/MPD. Endpoints included overall response rate (ORR) (assessed by IMWG criteria), duration of response (DOR), progression-free survival (PFS), and safety.
Results: A total of 84 patients were enrolled since June 2008. Overall, prior treatments included bortezomib (77%; 18% refractory) and lenalidomide (70%; 35% refractory); 20% had high-risk cytogenetics/FISH. The MTD was not reached in phase 1, supporting expansion at the MPD (n=52; 23% bortezomib refractory and 42% lenalidomide refractory). As of November 2012 (median follow-up 24.4 mo), ORR was 69% overall and 76.9% at MPD. In addition, very good partial response was reported in 36.9% (overall) and 38.5% (MPD) of patients. Stringent complete response was reported in 3.6% (overall) and 3.8% (MPD) of patients. Responses were durable with a median DOR of 18.8 mo (95% CI 9.7–41.5) overall and 22.1 mo (95% CI 9.5–NE) at the MPD. Median PFS was 11.8 mo (95% CI 7.6–20.7) overall and 15.4 mo (95% CI 7.9–NE) at the MPD. In the 35% of patients refractory overall to lenalidomide, ORR was 58.6%, median DOR 13.8 mo (95% CI 6.47–NE), and median PFS 9.9 mo (95% CI 5.55-NE). In total, 10 and 12 patients at the MPD pursued other therapies and were censored for DOR and PFS, respectively. Seven patients at the MPD were censored for DOR and PFS after undergoing stem cell transplant/maintenance. Overall, a median of 8.5 (range 1−46) cycles of CFZ were started. Fifteen percent of patients discontinued CFZ due to adverse events (AEs); dose reductions were required by 4% of patients. The most common grade 3/4 hematologic AEs included neutropenia (35.7%), lymphopenia (29.8%), and thrombocytopenia (25.0%). The most common grade 3/4 non-hematologic AEs included hypophosphatemia (20.2%) and hyperglycemia (13.1%).Grade 3/4 peripheral neuropathy was infrequent (1%).
Summary / Conclusion: CRd was well tolerated and highly active and provided robust and durable responses in patients with relapsed or progressive MM where 35% were lenalidomide refractory. In patients who received the MPD, ORR was 76.9% with a DOR of 22.1 mo. Grade 3/4 hematologic AEs were generally consistent with earlier studies in advanced MM that used similar doses of single-agent CFZ. CRd is being further evaluated in several ongoing phase 2/3 trials.

S578

CARFILZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE (CCD) FOR NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) PATIENTS: INITIAL RESULTS OF A MULTICENTER, OPEN LABEL PHASE II STUDY

S Bringhen[1,*], C Federica[1], M Petrucci[2], F Gay[1], V Federico[2], C Conticello[2], L Pantani[2], V Montefusco[2], G Benevolo[2], S Aschero[1], M Offidani[2], O Villani[2], A Siniscalchi[2], D Rossi[2], V Magarotto[1], P Sonneveld[3], M Boccadoro[1], A Palumbo[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: The standard treatment for newly diagnosed elderly MM patients, VMP and MPT, induced 30% near-complete response/complete response (nCR/CR), with a discontinuation rate due to adverse events (EAs) of 35%. Carfilzomib is a novel, irreversible proteasome-inhibitor with a significant activity and favourable toxicity profile, including very low rates of peripheral neuropathy and neutropenia. Initial results on carfilzomib plus cyclophosphamide and dexamethasone (CCd) were presented at ASH 2012. Herein we report updated data after 8 months of follow up.
Aims: We evaluated efficacy and safety (primary end points) of the combination CCd in elderly newly diagnosed MM patients.
Methods: The Bryant and Day two-stage design was used to evaluate both efficacy and safety. Patients received oral cyclophosphamide (300 mg/m^2 on days 1,8,15), oral dexamethasone (40 mg on days 1, 8, 15, 22) and iv carfilzomib (20 mg/m^2 on days 1, 2, and 36 mg/m^2 on days 8, 9, 15, 16, cycle 1; 36 mg/m^2 on days 1, 2, 8, 9, 15, 16, cycles 2-9) every 28 days for 9 cycles, followed by maintenance with iv carfilzomib (36 mg/m^2 on days 1, 2, 15, 16) every 28 days until progression or intolerance.
Results: As of 9 October 2012, enrollment has been completed (58 pts): median age was 71 years, 28% of patients were older than 75 years, 40% had ISS stage III, and 35% had unfavorable FISH profile [t(4;14) or t (14;16) or del17p]. Forty one patients were evaluated for response after at least 4 cycles and 56 patients were evaluated for safety after at least 1 cycle. After a median follow-up of 8 months, 93% of patients achieved at least partial response (PR), 68% at least very good partial response (VGPR), 46% at least CR/near-CR, including 12% stringent-CR (Figure 1). Responses improved with the duration of treatment reaching after 9 cycles: 100% PR, 77% VGPR, 53% CR/nCR, including 23% stringent-CR. The 1-year PFS was 85% and the 1-year OS was 86%. Grade (G) 4 hematologic AE included neutropenia (2 pts, 4%). G3-4 non-hematologic AEs were infections (4 pts, 7%), cardiac (2 pts, 4%), constitutional (2 pts, 4%), renal (2 pts, 4%) and gastrointestinal complications (1 pt, 2%). At least one G3-4 event was reported in 11 patients (20%). Six pts (11%) discontinued treatment due to AEs and 9 pts (16%) required carfilzomib dose reductions due to AEs. No differences in response rate and safety between patients younger and older than 75 years were observed.
Summary / Conclusion: Carfilzomib-cyclophosphamide-dexamethasone showed encouraging activity in elderly patients with newly diagnosed MM. The combination was well tolerated with a discontinuation rate due to AEs of 11%. Results will be updated at the meeting.

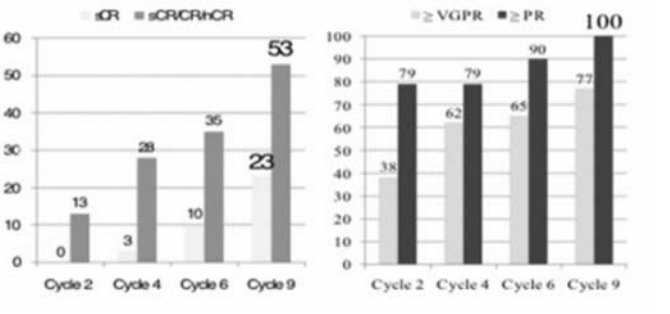

Figure 1.

S579

PHASE 1 STUDY OF THE NOVEL KINESIN SPINDLE PROTEIN INHIBITOR ARRY-520 + CARFILZOMIB(CAR) IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA (RRMM)

J Shah[1,*], S Thomas[1], D Weber[1], M Wang[1], R Orlowski[1]
[1]Lymphoma/Myeloma, MD Anderson Cancer Center, Houston, United States

Background: Background: ARRY-520, a novel kinesin spindle protein (KSP) inhibitor, with a unique mechansim of action has demonstrated promising clinical activity, both as a single agent and combined with dexamethasone in patients (pts) with bortezomib- and lenalidomide-refractory MM. The maximum tolerated dose (MTD) of ARRY-520 as a single agent was 1.5 mg/m^2 administered days 1, 2 every 2 weeks. Car, a novel irreversible proteasome inhibitor (PI), received Federal Drug Administration (FDA) regulatory approval in relapsed and refractory MM in 2012. Preclinical data demonstrate synergy with the combination of a PI and ARRY-520.
Aims: Aim: We aimed to combine these two agents for the first time, and report the findings from the phase I dose-escalation study in RRMM.
Methods: Methods: The primary objective was to determine the MTD and the safety/tolerability of the Car-ARRY combination. Secondary objectives were to determine efficacy as measured by the overall response rate, time to progression, progression free survival and time to next therapy. Pts had to have myeloma that was relapsed and/or refractory, be ineligible for autologous stem cell transplant, bortezomib refractory/intolerant, and have had prior lenalidomide exposure. ARRY-520 was administered intravenously (iv) over 1 hour on days 1, 2, 15 and 16, while car was administered intravenously over 30 minutes on days 1, 2, 8, 9, 15 and 16 on a 28 day cycle. All pts received growth factor support with filgrastim.
Dose-escalation used a standard 3+3 schema proceeded based on dose-limiting toxicities (DLTs) during cycle 1, with planned escalation of the dose of ARRY-520. Car dose was fixed and not escalated. Adverse events (AEs) were graded by NCI-CTCAE v4, while responses were assessed by the modified International Uniform Response Criteria.
Results: Results: To date, 17 pts have been enrolled in the ongoing dose escalation. In cohort 1, ARRY-520 was dosed at 0.75 mg/m^2. 3 pts were enrolled and no DLT was observed. In cohort 2, ARRY-520 was escalated to 1 mg/m^2 with Car at 20/27 mg/m^2, and among the first 3 pts, 1 DLT with non neutropenic fever associated with influenza pneumonia was observed. No DLT was encountered in the 3 additional pts in cohort 2. In cohort 3 ARRY-520 was escalated to 1.25 mg/m^2 with Car at 20/27 mg/m^2 and 5 pts were enrolled. The first 2 pts were not toxicity evaluable. Among the 3 evaluable pts, no DLT were encountered. Accrual is ongoing in the final cohort with full dose ARRY-520 of 1.5 mg/m^2 with Car at 20/27 mg/m^2. One of the first 3 pts had a DLT with non-neutropenic fever, and pneumonia requiring hospital admission. Among 17 pts enrolled to date, 9 remain on study, 4 discontinued for progressive disease(PD), 1 pt was lost to followup, 1 patient died with febrile neutropenia in cycle 4, 2 pts withdrew consent after 1 cycle of therapy. No pts discontinued therapy/withdrew consent due to toxicity. SAE included 4 pts with G3 pneumonia (2 of which were influenza), 2 pts with G1 hypercalcemia requiring hospitalization (due to disease progression), G4 renal failure (due to disease progression), G2 lethargy and 1 pt with G5 febrile neutropenia.
Summary / Conclusion: Conclusions: The combination of ARRY-520 and Car in pts with RRMM is well tolerated with limited hematologic toxicity. An MTD has not been established and enrollment is ongoing in cohort 4 with Car at 20/27 mg/m^2 and ARRY-520 at 1.5 mg/m^2. Updated MTD and safety data will be presented at the meeting.

S580

COMBINING FISH AND GEP SIGNATURES IN MULTIPLE MYELOMA; TOWARDS A MORE ROBUST AND MEANINGFUL HIGH RISK DEFINITION

M Van Vliet[1,*], R Kuiper[2], A Broijl[2], Y de Knegt[2], W Hoos[1], L de Best[1], G Morgan[3], W Gregory[4], M van Duin[2], E Van Beers[1], P Sonneveld[2]
[1]Skyline Diagnostics BV, [2]Department of Hematology, ErasmusMC, Rotterdam, Netherlands, [3]Section of Haemato-Oncology, The Institute of Cancer Research, London, [4]Clinical Trials Research Unit, University of Leeds, Leeds, United Kingdom

Background: Multiple Myeloma (MM) is a heterogeneous disease with different recurring chromosomal aberrations that have been associated with prognosis for survival (e.g. t(4;14), t(14;16)/t(14;20), del13, del17p, add1q). Strategies for combining these markers are emerging [1] and are being evaluated [2]. More recently, gene expression profiling (GEP) studies have identified signatures that distinguish groups of high risk patients, such as the SKY-92 and UAMS-70 signatures [3,4]. Although collectively referred to as high risk signatures they employ different genes and are independent risk markers, similar to how the chromosomal aberrations represent different biological risk markers. It is currently unclear what the best high risk definition is for MM. Here we compare GEP signatures and fluorescent *in situ* hybridization (FISH) markers for this purpose.
Aims: We explore the evidence to combine chromosomal aberrations and high risk GEP signatures towards a more robust and meaningful definition of high risk in MM.
Methods: GEP and FISH data (if available) were analyzed for five clinical cohorts (Table 1). Five high risk GEP signatures (SKY-92, UAMS-70, UAMS-17, UAMS-80, MRCIX-6) have been applied to all five datasets. Associations between markers and overall survival (OS) were investigated in Kaplan-Meier plots with the logrank test P≤0.05 considered as significant.
Results: Univariate associations with survival are shown in Figure 1A. The prognostic value of these FISH markers all failed to reproduce across cohorts while five published GEP signatures did. Figure 1B shows the Kaplan-Meier curves for FISH, GEP, and their combination on the MRC-IX cohort. This analysis indicated that GEP alone offers superior OS prognosis compared to FISH markers currently used. The same results were obtained when using the other high risk signatures, and when applied to the HOVON-65/GMMG-HD4 cohort.
Summary / Conclusion: GEP signatures are superior to FISH markers for high risk stratification in MM. Combining GEP and FISH does not result in better identification of a high-risk group in the MRC-IX and the HOVON-65/GMMG-HD4 cohorts. Our results are perhaps not surprising given the fact that some would classify e.g. t(4;14) as standard risk [1] while others still consider it to predict for worse survival [2].

BRIEF RITUXIMAB, BENDAMUSTINE, MITOXANTRONE (R-BM) INDUCTION FOLLOWED BY RITUXIMAB CONSOLIDATION IN ELDERLY *DE NOVO* ADVANCED STAGE FOLLICULAR LYMPHOMA PATIENTS: A STUDY BY FONDAZIONE ITALIANA LINFOMI

C Boccomini[1,*], M Ladetto[2], L Rigacci[2], L Arcaini[2], M Ceccarelli[2], C Lobetti-Bodoni[2], S Volpetti[2], B Botto[2], A Chiarenza[2], R Freilone[2], P Corradini[2], S Franceschetti[2], C Rusconi[2], C Stelitano[2], A Castellino[2], M Cabras[2], D Scalabrini[2], A Carella[2], P Fattori[2], Al Fabbri[2], F Gherlinzoni[2], U Vitolo[1]
[1]SC Hematology 2, AO Città della Salute e della Scienza di Torino, [2]on the behalf of Fondazione Italiana Linfomi (FIL), Turin, Italy

Background: a previous FIL trial (Vitolo et al, ASH 2011) showed that a brief R-FND (Fludarabine, Mitoxantrone and Dexamethasone) induction chemoimmunotherapy followed by rituximab consolidation achieved high CR and PFS rates in elderly Follicular Lymphoma (FL) patients (pts); bendamustine is a well-tolerated and effective drug.
Aims: These promising results prompted us to modify the original scheme and investigate safety and efficacy of a brief R-BM regimen for treatment of elderly FL lymphoma pts.
Methods: 76 elderly pts (age 65-80) with de novo FL were enrolled (Sept 2009-Nov 2011). Inclusion criteria were: grade I, II and IIIa; advanced (stage III/IV) or stage II disease requiring treatment; "FIT" pts according to comprehensive geriatric assessment (ADL, I-ADL, CIRS). Treatment plan was: 4 monthly courses of R-BM (375 mg/m^{2}Rituximab day 1, 90 mg/m^{2}Bendamustine days 1-2, 8 mg/m^{2}Mitoxantrone day 1) followed by 4 weekly Rituximab infusions as consolidation. Polymerase chain reaction (PCR) for BCL2/IgH rearrangementwas performed on bone marrow samples at diagnosis, after R-BM and at the end of consolidation.
Results: Median age was 71 years (range 65-79); 29 males, 47 females; WHO grading was as follows: I 18%, II 54% and IIIa 28%; 15% had advanced stage II disease, 30% stage III and 55% stage IV; 47% had BM involvement, 20% B symptoms and 7% leukemic dissemination; 59% patients had no comorbidity, 20% one and 21% 2 or more comorbidities. According to FLIPI pts were: 8% at low, 32% at intermediate and 60% at high risk. PCR analysis for BCL2/IgH rearrangement was carried out in 57 patients at diagnosis: 39 (51%) were Bcl-2 positive. Seventy (92%) pts completed the planned treatment: 60/70 in the planned time.Sixpts did not complete the treatment: 1 for progressive disease, 4 for adverse events (2 haematological toxicities with prolonged neutropenia; 1 CMV colitis and 1 for infection and concomitant worsening of pre-existing oral pemfigo) and 1 patient for worsening of performance status. Overall response to treatment was 92% with 58 (76%) complete remissions (CR) and 12 (16%) partial remissions (PR). Response to induction R-BM was as follow: 31 (41%) CR, 40 (52%) PR and 5 (7%) stable (SD) or progressive disease (PD); 29 (72%) of the 40 pts in PR/SD after R-BM converted to CR following further Rituximab consolidation. Twenty-three (60%) of 39 pts Bcl-2 rearranged at diagnosis were evaluable for molecular response during and after treatment: PCR negativity was achieved in 21/23 (91%) pts after R-BM and in 22/23 (96%) pts at the end of treatment; of these, 18/22 (82%) were also in complete remission. A total of 577 courses of R-BM and Rituximab were given. The most frequent severe toxicity (CTC grade 3-4) was neutropenia reported in 18% of the courses. Grade 3-4 extra-haematological toxicities (all resolved) were: 8 neutropenic fevers, 8 grade 3-infections (4 due to bacterial agents), 1 NSTEMI, 1 massive pulmonary embolism. Two deaths were recorded: one pneumonia with worsening of pre-existing pemfigo and one patient with hepatic metastasis of occult carcinoma diagnosed at final restaging after completion of therapy.
Summary / Conclusion: A brief course of chemo-immunotherapy R-BM followed by Rituximab consolidation is safe and effective with a high CR rate in elderly patients with untreated advanced stage FL. In patients with BCL2 rearrangement at diagnosis a high molecular remission was also observed. Data on PFS analysis will be presented with a longer median follow-up.

S582

ROLE OF THE QUANTITATIVE BCL2/IGH@ REARRANGEMENT EVALUATION IN PATIENTS AFFECTED BY FOLLICULAR LYMPHOMA: THE ANCILLARY STUDY OF THE FIL-FOLL05 TRIAL.

S Galimberti[1,*], S Luminari[2], E Ciabatti[3], A Dondi[2], M Ladetto[4], P Piccaluga[5], I Del Giudice[6], G Palumbo [7], U Vitolo[8], G Gaidano[9], A Carella[10], M Petrini[11], M Federico[2]
[1]Hematology, Clinical and Experimental Medicine- University of Pisa, Pisa, [2]Oncology, University of Modena e Reggio Emilia, Modena, [3]hematology, Clinical and Experimental Medicine , Pisa, [4]hematology II, Oncology, Azienda Ospedaliera Universitaria Le Molinette, Torino, [5]Experimental, Diagnostic, and Speciality Medicine, University of Bologna, Bologna, [6]Cellular Biotechnologies and Hematology, University La Sapienza, Roma, [7]Hematology, Azienda Ospedaliera Ferrarotto, Catania, [8]hematology, Citta della scienza e della salute, Torino, [9]Azienda Ospedaliera Universitaria della Carita', Università del Piemonte Nord Orientale, Novara, [10]hematology, Azienda Ospedaliera San Martino, Genova, [11]Cellular Biotechnologies and Hematology, Hematology, Clinical and Experimental Medicine- University of Pisa, Pisa, Italy

Background: The role of the quantitative assessment of *BCL2/IGH@* fusion gene in patients affected by follicular lymphoma is still matter of debate, even because of the heterogeneity of the adopted therapeutic strategies. Other authors previously reported that 70% of patients with low amount of *BCL2/IGH@* copies achieved complete remission versus 26% of those with higher *BCL2/IGH@* levels, with a significant advantage also on EFS *(Rambaldi A, 2005)*.
Aims: In the present study, we report about significance of the quantitative *BCL2/IGH@* assessment at diagnosis and after treatment. Results from the qualitative assessment have been already reported at ASH 2012 *(Galimberti S, 2012)*.
In the FOLL05 trial, conducted by the Fondazione Italiana Linfomi (FIL), 504 untreated patients affected by advanced follicular lymphoma were randomized to receive R-CHOP, R-CVP, or R-FM (Clinical trial.gov NCT00774826).
Methods: Quantitative PCR assays were performed by the 4 laboratories of the "FIL MRD NETWORK" (Bologna, Pisa, Roma, and Torino, Italy). RQ-PCR was performed according to international guidelines (Ladetto M, 2001; van der Velden, 2007). All samples were tested in triplicate; standard curves were constructed using DNA extracted from DOHH-2 cell line and DNA extracted from mononuclear cells obtained from healthy donors. The sensitivity of these tests was 1:10^{-5}.
Results: At baseline, 415 out of the 504 patients eligible for treatment were assessed for qualitative *BCL2/IGH@* rearrangement; 220 of them (53%) were positive. No significant differences were detected between cases with and without molecular assessment at the enrollment, and between those positive or negative for clinical features, and arm of treatment.
At the enrollment, molecular tumor burden was assessed by quantitative PCR in 105 *BCL2/IGH@* positive cases; the median value was 3 x 10^{-3} copies (range: <1x10^{-5} - 6). After logistic analysis, the *BCL2/IGH@* copy number did not correlate with stage, ECOCG, age>65 year, sex, but it was significantly higher in patients at high FLIPI and FLIPI2 score. For patients with high *BCL2/IGH@* copies, overall response rate was significantly lower than cases with lower tumor burden (76.6% versus 38.9%; P=0.006). When the ROC curve was performed in order to find the *BCL2/IGH@* value that would better predict the relapse, < x10^{-4} copies was the more predictive value. Indeed, 22% of cases showing <1x10^{-4} copies relapsed versus 78% of patients with >x 10^{-4} copies (P=0.033). Moreover, cases displaying values <1 x 10^{-4} copies showed a clear advantage also in terms of PFS (3-year PFS 80% versus 59% for cases with higher tumor burden; P=0.015). On the contrary, the qualitative PCR results at diagnosis did not influence quality of response nor PFS. Concerning the impact of treatment on the *BCL2/IGH@* tumor burden, the mean observed reduction was about 2 logarithms. Seventy-one percent of cases achieved PCR-negativity; no differences in this effect were observed according to the arm of treatment. Nevertheless, an inferior tumor burden reduction in the R-CVP arm, although not statistically significant, was observed.
Summary / Conclusion: In conclusion, this study shows that patients with <1 x 10^{-4} copies of *BCL2/IGH@*at diagnosis would have longer PFS, thus supporting the usefulness of also a quantitative PCR monitoring of these patients.

S583

PRIMARY THERAPY OF WALDENSTRÖM'S MACROGLOBULINEMIA (WM) WITH WEEKLY BORTEZOMIB, LOW-DOSE DEXAMETHASONE AND RITUXIMAB (BDR): FINAL RESULTS OF A PHASE II STUDY OF THE EUROPEAN MYELOMA NETWORK (EMN)

M Dimopoulos[1,*], R Garcia Sanz[2], M Gavriatopoulou[1], P Morel[3], M Kyrtsonis[4], E Michalis[4], Z Kartasis[5], X Leleu[6], G Palladini [7], A Tedeschi[8], A Tedeschi[8], D Gika[9], G Merlini [7], E Kastritis[9], P Sonneveld[10]
[1]Department of Clinical Therapeutics, University of Athens School of Medicine, Athens, Greece, [2]University of Salamanca, Salamanca, Spain, [3]Service d'Hematologie Clinique Jean Bernard , Lens, France, [4]University of Athens School of Medicine, Athens, [5]Chalkis general Hospital, Chalkis, Greece, [6]Hopital Huriez, CHRU, Lille, France, [7]Policlinico San Matteo, Pavia, [8]Niguarda Ca' Granda Hospital, Milan, Italy, [9]University of Athens , Athens , Greece, [10]Erasmus Medical Center , Rotterdam, Netherlands

Background: Bortezomib and rituximab have shown signifcant clinicakl activity andsynergism in preclinical studies.
Aims: In this large, phase II, multicenter trial conducted by EMN in 10 European centers we evaluated BDR in previously untreated, symptomatic WM patients.
Methods: In order to prevent the rituximab-associated "IgM flare", one course of single agent bortezomib was first administered at a dose of 1.3 mg/m2 IV on days 1, 4, 8 and 11. Ten days later, the patients received 4 courses of weekly bortezomib, in order to reduce the incidence of neurotoxicity (1.6 mg/m2 days 1, 8, 15 & 22 every 35 days). In courses 2 & 5, bortezomib was given with dexamethasone 40 mg IV followed by rituximab 375 mg/m2 IV (total of 8 infusions of rituximab). After completion of BDR, patients with CR, PR, MR or SD were followed without further therapy.
Results: From March 2007 to June 2010, 60 patients were enrolled in the study and 59 received at least one dose of therapy. Their characteristics included: age>65 years in 61%, Hb<11.5 g/dL in 81%, platelet counts<100x109/L in 17%, b2-microglobulin>3 mg/dL in 64%, serum monoclonal protein>4 g/dL in 29% and >7 g/dL in 3.4%, lymphadenopathy in 43%, splenomegaly in 29%, while 43% had B-symptoms. Per IPSSWM, 15% were low, 40% intermediate and 45% high risk. Main indications to start treatment were cytopenias in 44%, hyperviscosity in 20%, B-symptoms in 19%, lymphadenopathy in 9% and other symptoms in 8%. Thirty eight (64%) patients completed the planned 5 courses of BDR and 8(13%) received only the first course of bortezomib. On intent-to-treat, responses included CR in 2(3%), PR in 37(64%), MR in 11(19%), SD in 3(5%) and PD in 6(10%) patients. Median time to first response (≥MR) was 3 months and median time to best response was 5.8 months. Despite the significant proportion of patients with high levels of IgM and symptoms of hyperviscosity, plasmapheresis was not required in any patient. Median follow up for all patients is 41 months. Estimated median PFS (progression or death by any cause) is 42 months and 3-year PFS is 71%, 49% and 45% for low, intermediate and high risk patients respectively. Nineteen patients received further treatment on progression and 84% achieved ≥MR. Fifteen patients have died, 9 due to causes unrelated to WM or complications of treatment. The 3-year OS is 82% and for low, intermediate and high risk patients is 85%, 86% & 76% respectively. The 3-year cause specific survival is 91%. Hematologic toxicities included neutropenia(grade≥3 in 15%) and thrombocytopenia (grade ≥3) in 5%. Peripheral sensory neuropathy (≥grade 1) was observed in 46%, grade 2 in 17% and grade≥3 in 7%; neuropathic pain recorded in 20% (grade≥3 in only 1 patient). Other common non-hematologic toxicities included GI toxicity (grade≥3 in 7%) and infections (20%, grade≥3 in 7%). One patient died of septic shock in absence of neutropenia. Three patients (5%) experienced pulmonary toxicity (grade≥3), which was attributed to bortezomib and resolved completely after administration of steroids and 2/3 patients continued treatment as per protocol. The dose of bortezomib was reduced in 51% of patients, primarily because of peripheral neuropathy; 36% of the patients completed the planned 5 courses without any dose reduction of bortezomib.
Summary / Conclusion: This is the largest trial that has evaluated the role of a bortezomib-containing regimen in the frontline treatment of symptomatic, mostly high risk patients with WM and also with a long follow up (median 3.5 years). BDR is active and non myelotoxic. Weekly administration of bortezomib reduces rates of severe neurotoxicity. Induction with single agent bortezomib is effective in the management of patients with hyperviscosity.

S584

MYD88 (L265P) MUTATION IS AN INDEPENDENT RISK FACTOR FOR PROGRESSION IN PATIENTS WITH IGM MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

M Varettoni[1,*], S Zibellini[1], L Arcaini[1,2], E Boveri[3], S Rattotti[1], R Riboni[3], M Gotti[1], C Pascutto[1], S Mangiacavalli[1], G Croci[3], L Pochintesta[1], V Fiaccadori[1], L Morello[1], M Guerrera[1], S Catricalà[2], M Paulli[2,3], M Cazzola[1,2]
[1]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, [2]Department of Molecular Medicine, University of Pavia, [3]Anatomic Pathology Section, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Patients with IgM monoclonal gammopathy of undetermined significance (MGUS) have a risk of progression to Waldenström's macroglobulinemia (WM) or to other lymphoproliferative disorders (LPD) of approximately 2% per year. The level of the IgM paraprotein at the time of diagnosis is the main risk factor for progression (Kyle et al, Clin Lymphoma Myeloma Leuk 2011). Roughly half the patients with IgM-MGUS carry a somatic mutation in the *MYD88* gene [*MYD88* (L265P)] (Xu et al, Blood 2013). In a case-control study, we showed that IgM-MGUS patients carrying *MYD88* (L265P) are at higher risk of progression to WM or to other LPD than patients with wild type *MYD88* sequence (Varettoni *et al*, Blood 2013).
Aims: The aim of this study was to assess the relative contribution of the *MYD88* (L265P) mutation and of the size of IgM paraprotein on the risk of progression to WM or other LPD.
Methods: We analyzed by allele-specific polymerase chain reaction (AS-PCR) bone marrow (BM) samples of 136 consecutive patients with IgM-MGUS, collected at the time of diagnosis. Genomic DNA was extracted from BM mononuclear cells in 92 cases or retrieved from archival Giemsa-stained BM slides in 44 cases. AS-PCR was performed as previously described (Varettoni et al, Blood 2013). Progression-free survival (PFS) was evaluated with the Kaplan–Meier product-limit method. PFS was calculated from the date of diagnosis to the date of progression, or last follow-up for censored cases. The log-rank test was used to compare survival curves. The prognostic effect of *MYD88* mutation and of the size of IgM paraprotein was assessed using a Cox proportional hazards regression model.
Results: The median age of patients was 64 years, 78 (57%) were males and 58 (43%) females. At diagnosis of IgM-MGUS, the median level of serum IgM paraprotein was 11 g/L (range 2-32). Bence-Jones proteinuria was detected in 19% of patients. The median serum free light chain ratio was 1.1 (range: 0.2-170). Patients were followed for a total of 434 persons year (median, 32 months). The *MYD88* (L265P) mutation was detected in 71 of 136 patients (52%). During the period of observation, 11 of 136 patients (8%) progressed to WM (n=9) or to marginal zone lymphoma (MZL) (n=2). At diagnosis of IgM-MGUS, 8 of 9 patients who subsequently progressed to WM and 1 of 2 patients who progressed to MZL carried the *MYD88* (L265P) mutation. In a Cox proportional hazards model, the risk of progression in patients carrying the *MYD88* (L265P) mutation was significantly higher compared with that of patients with *MYD88* wild-type sequence (hazard ratio, HR 6.65; 95% confidence interval, 1.4-31.3, P=0.01). The risk of progression was 16% at 5 years and 56% at 10 years in patients with the *MYD88* (L265P) mutation compared to 2% at 5 years and 16% at 10 years in patients with *MYD88* wild-type sequence (P=0.006) (Figure 1). In multivariate analysis, the *MYD88* mutation and the size of the serum paraprotein were independent prognostic factor for progression, with a HR of 5.54 (P=0.03) and 3.66 (P=0.003), respectively.
Summary / Conclusion: The findings of this study indicate that the *MYD88* (L265P) mutation is an independent predictor of the risk of progression to WM or to other lymphoproliferative disorders in patients with IgM-MGUS, irrespective of the size of the IgM paraprotein.

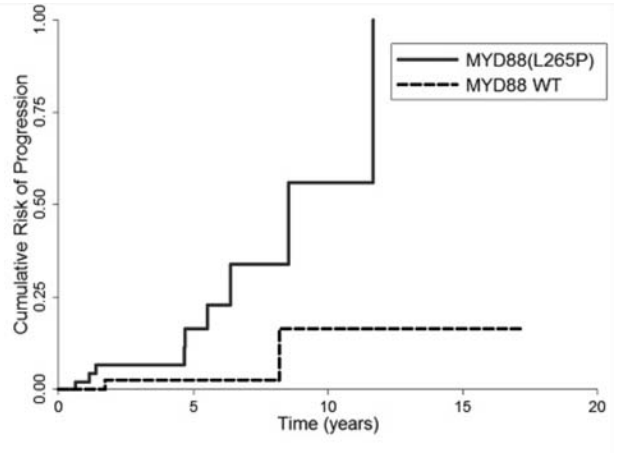

Figure 1.

S585

CHARACTERISTICS AND OUTCOME AMONG 123 PATIENTS WITH HIV ASSOCIATED LYMPHOMA INCLUDED IN THE FRENCH ANRS CO16 LYMPHOVIR COHORT STUDY

C Besson[1,*], S Prevot[2], H Hendel-Chavez[1], R Lancar[3], M Génin[3], S Trabelsi[3], M Meyohas[4], B Marchou[5], J Gabarre[6], F Bonnet [7], C Goujard[1], F Boué[2], N Mounier[8], M Partisani[9], F Raffi[10], M Raphael[1], Y Taoufik[1], D Costagliola[6]
[1]Université Paris Sud, Le Kremlin-Bicetre, [2]Université Paris Sud, Clamart, [3]INSERM u943, [4]CHU Saint-Antoine, Paris, [5]CHU Toulouse, Toulouse, [6]CHU Pitié-Salpétrière, Paris, [7]CHU Bordeaux, Bordeaux, [8]CHU Nice, Nice, [9]CHU Strasbourg, Strasbourg, [10]CHU Nantes, Nantes, France

Background: Human Immunodeficiency Virus (HIV) infection is associated with an increased risk of Hodgkin lymphoma (HL) and B-cell non-Hodgkin lymphoma (NHL). Increased risk of NHL is strongly correlated to the severity of the underlying immunodeficiency. Introduction of combined antiretroviral therapy (*cART*) has reduced the incidence of NHL but not the incidence of HL. Outcomes have been reported to be poorer among HIV-infected patients with HL or NHL than among non-HIV-infected patients.
Aims: We carry out a national cohort with the aim to study the characteristics and outcome of HIV-related lymphomas.
Methods: The prospective Cohort of HIV related lymphomas (ANRS-CO16 Lymphovir cohort) enrolled 123 adult patients at diagnosis of lymphoma in 32 centres between July 2008 and April 2012. Investigations were performed after approval of the ethic committee and informed consent. Data collection concerned HIV infection history, clinical, biological and histological presentation, treatment and evolution of lymphoma. Pathological materials were centralized and 91 cases were reviewed. Diagnoses were based on World Health Organization criteria. Each patient was followed every 6 months during 5 years.
Results: Among the 123 patients, 41% (50) were diagnosed with HL and 59% (73) with NHL. Median age were similar in the two groups of patients: 44 years (ranging from 20 to 61) among patients with HL and 48 years (23 to 67) among those with NHL. Gender (male/female) ratio was 6.1 (43/7) among patients with HL, 3.9 (58/15) among those with NHL. HIV infection had been diagnosed for a median of 161 months (0 to 312) among HL patients and 97 (0 to 327) among those with NHL. Patients with HL had a median CD4 T-cell count at diagnosis of lymphoma of 374/mm^3 (range 37-1518), those with NHL, 256/mm^3 (range 7-1322). Patients with HL had a predominance of mixed cellularity subtype (37 out of 40 reviewed cases). All the 44 tested cases for in situ EBV were positive. The histological distribution of the 73 NHL was: diffuse large B-cell lymphoma (DLBCL) 55% (40), Burkitt lymphomas (BL) 22% (16), plasmablastic lymphoma 10% (7), marginal zone /lymphoplasmocytic lymphoma 7% (5), others 6%: PTLD- like lymphoma (2), primary effusion lymphoma (1), follicular lymphoma (1), anaplastic lymphoma (1). Among the 21 reviewed cases of DLBCL, 11 were classified as non-GC and 7 as GC subtype (3 could not be classified). There was a predominance of clinical stages III/IV versus I/II among HL (79%, 37/47) and NHL patients (74%, 52/70). Among patients with DLBCL, LDH level was elevated in 71% (50/70) and performance status altered (2-4 versus 0-1) in 36% (26/72). The median interval between lymphoma occurrence and last follow-up was 21 months (range 0-41). During follow-up, all patients were treated with ARV. Among HL patients, 43 out of 46 were treated with ABVD. Out of 47 patients with DLBCL or BL, 31 received chemotherapies combined with rituximab. At 24 months, overall survival is above 90% among patients with HL and above 75% among those with NHL. There were 10 early deaths (<6 months) from complications of treatment (9) or disease progression (1) and 7 later deaths from disease progression (4), second cancer (2), unknown (1). None of the patients who died of infection during the first 6 months following diagnosis had received rituximab.
Summary / Conclusion: The present study points out the high proportion of HL among HIV infection with lymphoma in the cART era. Although these patients have advanced stage at diagnosis, their prognosis has largely improved. This study also strengthens the heterogeneity of HIV-related lymphomas and the persistence of early deaths among patients with NHL.

Acute myeloid leukemia therapeutics

S586

LOW-DOSE LENALIDOMIDE PLUS LOW DOSE CYTARABINE INDUCE COMPLETE REMISSION THAT CAN BE PREDICTED BY GENETIC PROFILING IN VERY ELDERLY ACUTE MYELOID LEUKEMIA PATIENTS

A Isidori[1,*], F Ferrara[2], F Di Raimondo[3], F Loscocco[1], P Paolo Piccaluga[4], F Fuligni[4], A Gazzola[4], M Rossi[4], A Laginestra[4], M Caraci[3], T Izzo[2], C Riccardi[2], S Barulli[1], B Guiducci[1], P Picardi[1], T Ricciardi[1], G Sparaventi[1], M Rocchi[5], G Visani[1]
[1]AORMN, Hematology and Stem Cell Transplant Center, Pesaro, [2]Cardarelli Hospital, Hematology and Stem Cell Translantation Unit, Napoli, [3]Ferrarotto Hospital, Hematology and Stem Cell Transplant Unit, Catania, [4]Department of Experimental, Diagnostic, and Specialty Medicine Bologna University Medical School, Molecular Pathology Laboratory, Unit of Hematopathology, Bologna, [5]Urbino University, Institute of biomathematics, Urbino, Italy

Background: Outcome for elderly patients with acute myeloid leukemia (AML) is extremely poor, especially for patients aged more than 70 years. Intensive induction chemotherapy is very often unsuitable. Lenalidomide is an immunomodulatory agent, FDA approved for use in MDS with del(5q) and in multiple myeloma. High-dose lenalidomide was proven to be effective in inducing complete remission (CR) in patients with and without 5q-acute leukemia. However, high-doses are not always feasible in the elderly, due to relevant toxicity. No data regarding concomitant administration of low-dose lenalidomide with other drugs in elderly AML patients have been published, up to now.
Aims: We designed a prospective phase II study to assess the efficacy of the concomitant administration of low-dose lenalidomide and low-dose cytarabine in patients with acute myeloid leukemia (AML) aged more than 70 years.
Methods: 40 patients (median age 76 years, range: 70-85) were consecutively enrolled in the study. Median white blood cell count at diagnosis was 3.2x10^9/l (range: 0,7-46,8x10^9/L), whereas median hemoglobin was 8,9 g/dl and median platelet count was 31x10^9/L. Nineteen out of 40 patients had an intermediate karyotype (14/19 normal), 17/40 an unfavorable karyotype and 4/40 were not evaluable. Seventeen patients had a *de novo* AML, whereas 23 patients had a secondary AML (15 after MDS, 4 after a CMPD, 1 after myelofibrosis, 3 after chemo-radiotherapy for a breast cancer). Patients received concomitant low-dose lenalidomide (10 mg/day orally, days 1-21) and low-dose cytarabine (20 mg twice day subcutaneously, days 1-15). Therapy was repeated every 6 weeks, up to 6 cycles. To identify possible biomarkers associated to sensitivity/resistance, global gene and miRNA expression profiling (Affymetrix Transciptome 2.0) was performed on purified AML cells obtained from 15 patients.
Results: Induction-period mortality was 20%, with 8 deaths occurring during cycle 1. Thirty-two patients completed at least one cycle of therapy and are evaluable for response. Overall CR rate was 38%. Six out of 12 (50%) responding patients are still in morphologic, cytogenetic and FISH CR after a median follow-up of 20 months (range: 6-33). Statistical analysis showed that responding patients had a longer median overall survival than non-responders (491 vs. 64 days, P <0.0001). The CR rate was significantly higher in patients presenting with bone marrow blasts <30% (P=0.04). Interestingly, cytogenetic risk was not predictive of CR. Conversely, by studying the global miRNA and gene expression profile we identified a molecular signature, including 114 genes and18 miRNA associated with the clinical response (CR vs. no CR). Of note, the involved genes belonged to relevant functional categories such as angiogenesis, cell cycle regulation and immune response. Moreover, based on the expression of 5 genes, we developed an algorithm to predict treatment response that was successfully validated in 15/15 (100%) tested cases.
Summary / Conclusion: The administration of concomitant low-dose lenalidomide and low-dose cytarabine induce a high rate of complete remission, that can be predicted by genetic profyling, in a subset of very elderly AML patients with extremely poor-prognosis, not suitable for intensive chemotherapy. The study was registered at EMA with the EUDRACT no 2008-006790-33.
Acknowledgements: Celgene is gratefully acknowledged for providing Lenalidomide for the patients. The study was supported in part by AIL Pesaro Onlus.

Goethe University, Frankfurt/Main, [11]Department of Medicine, Hematology and Oncology, University Hospital Muenster, Muenster, [12]Clinical Cooperation Unit Molecular Hematology/Oncology, Department of Internal Medicine V, University of Heidelberg and German Cancer Research Center (DKFZ), Heidelberg, [13]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, [14]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany, [15]Department of Hematology, University Hospital Gasthuisberg Leuven, Leuven, Belgium

Background: The prognosis for patients with AML ineligible for intensive remission induction therapy remains unsatisfactory, and novel therapeutic strategies are needed to improve clinical outcomes. Volasertib (an investigational agent) is a potent and selective cell cycle kinase inhibitor that induces mitotic arrest and apoptosis by targeting Polo-like kinases (Plks). Volasertib has shown antileukemic activity in AML (Bug et al, ASH 2010 and 2011; Maertens et al, ASH 2012).
Aims: The phase II part of this open-label trial was a randomized comparison of volasertib + LDAC versus LDAC in patients with newly diagnosed AML ineligible for intensive treatment. The primary endpoint was objective response (complete remission [CR] or CR with incomplete blood count recovery [CRi]); secondary endpoints included event-free survival (EFS) and overall survival (OS). We present cytogenetic and molecular genetic analyses of updated preliminary phase II data from this ongoing trial.

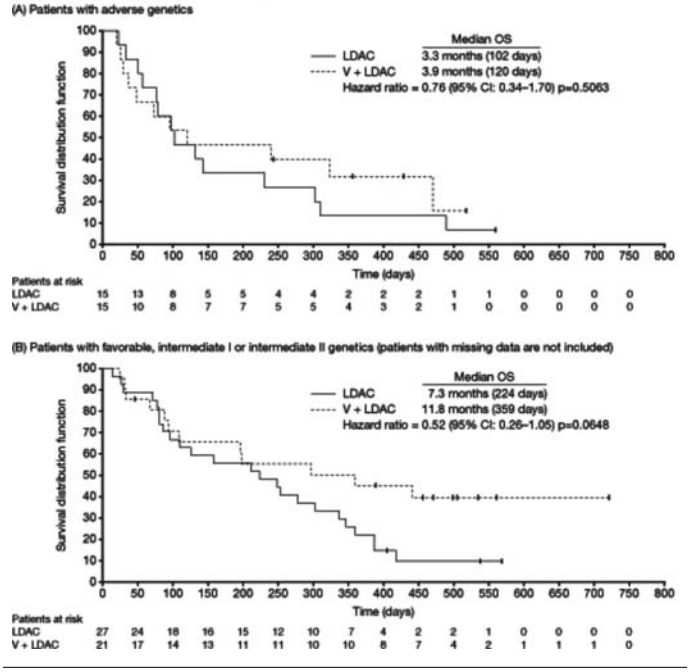

Figure 1. Overall survival by ELN genetic group.

Methods: Eligible pts who had given informed consent received volasertib (350 mg 1-hr intravenously, days 1, 15 Q4W) + LDAC (20 mg bid subcutaneously, days 1–10 Q4W), or LDAC alone until progression/relapse or intolerance. Bone marrow samples were taken at screening for analysis of conventional cytogenetics and molecular genetics (*FLT3* and *NPM1*) in a central laboratory.
Results: 87 patients received volasertib + LDAC (n=42) or LDAC (n=45); as of February 21st 2013, four patients remain on treatment. Genetic groups by European LeukemiaNet (ELN) classification were (n of patients; volasertib + LDAC/LDAC): favorable, 3/5; intermediate I or II, 18/22; adverse, 15/15; missing, 6/3. Response rate (CR or CRi) was significantly higher for volasertib + LDAC versus LDAC patients (31.0% versus 13.3%; odds ratio, 2.91; P=0.0523). Responses with volasertib + LDAC were observed across genetic groups, including patients with adverse cytogenetics. Response by ELN classification was (n of patients; volasertib + LDAC/LDAC): favorable, 2/0; intermediate I or II, 4/4; adverse, 5/2 (including 5/1 with complex karyotype); missing, 2/0. Molecular genetic analysis (volasertib + LDAC/LDAC) showed *FLT3*-ITD in 5/6 patients and *NPM1* mutations in 8/9 patients. Response by molecular genetics was (n of patients; volasertib + LDAC/LDAC): *FLT3*-ITD, 1/2; *NPM1* mutations, 4/4. Median EFS was significantly improved in volasertib + LDAC versus LDAC patients (5.6 months versus 2.3 months; hazard ratio [95% CI], 0.56 [0.34–0.93]; P=0.0237). Median OS was 8.0 months (volasertib + LDAC) versus 5.2 months (LDAC; hazard ratio [95% CI], 0.66 [0.40–1.08]; P=0.0996). OS for both treatments was shorter in patients with adverse versus non-adverse genetics, with a trend for OS benefit with volasertib + LDAC in both groups (Figure 1).
Summary / Conclusion: Responses with volasertib + LDAC were seen across all genetic groups in patients with newly diagnosed AML ineligible for intensive treatment. The increase in response rate with volasertib + LDAC translated into a trend for OS benefit, apparent in both non-adverse and adverse genetic groups. Volasertib combined with LDAC is in phase III development for newly diagnosed AML in patients ≥65 years ineligible for intensive remission induction therapy (POLO-AML-2).

S588

RISK ADAPTED TREATMENT FOR ADULT ACUTE MYELOID LEUKEMIA (AML): FINAL RESULTS OF THE AML-03 TRIAL FROM THE SPANISH CETLAM GROUP

A Garrido[1,*], M Hoyos[1], S Brunet[1], M Tormo[2], J Esteve[3], J Ribera[4], L Escoda[5], R Guardia[6], O Salamero [7], R Duarte[8], M Paz Queipo de Llano[9], J Bargay[10], J Besalduch[11], C Pedro[12], A Garcia[13], I Heras[14], J Marti[15], P Torres[16], L Font[17], J Gonzalez[18], D Hernandez[19], M Arnan[8], J Bueno[20], D Gallardo[6], A Oriol[4], M Pratcorona[21], J Nomdedeu[1], S Jordi[1]

Background: Improvements on the clinical and biological stratification of AML cases allow provide background for risk-adapted treatment strategies, particularly after complete remission (CR) achievement. This has been the approach of our cooperative group including 20 academic institutions since 1988. Herein we report the final results of our most recent trial.
Aims: To analyse the results of the risk adapted treatment in 862 patients with de novo AML enrolled between 2003 and 2012 into the AML-03 protocol of the Spanish CETLAM group
Methods: Patients received 1 or 2 induction chemotherapy courses of IDICE-G (idarubicin, intermediate cytarabine (IDC), VP-16 and priming with GCSF) followed by mitoxantrone, IDC and priming with GCSF as consolidation therapy. Further treatment was assigned according to the CETLAM risk groups as follows: *Favorable prognosis (FP)* defined as favorable cytogenetics according to MRC (*AML1/ETO* and *CBF/MYH11* AML): autologous stem cell transplantation (ASCT) if leukocyte index (LI) was >20 or high dose cytarabine (HDAC) as in the CALGB schedule if LI≤20. *Intermediate prognosis (IP)*, defined as patients in CR with one induction,≤$50x10^9$ white blood cells at diagnosis, normal karyotype (NK) and noFLT3 internal tandem duplication (*FLT3-ITDwt*) and no *MLL* rearrangement: ASCT. *Adverse prognosis (AP)*, patients not included in FP or IP: ASCT or allogeneic stem cell transplantation (alloSCT) depending on donor availability
Results: Median age at diagnosis was 53 years old (15-71). *FLT3-ITD* was detected in 125 patients (32.1%) and *NPM1* mutation in 151 (38.8%). Four patients died before treatment and 858 patients (99.1%) received induction therapy; CR rate was 76.4% (87.8% with one course), 10.4% were refractory and 12.1% died during induction. Overall survival (OS) and disease-free survival (DFS) of the whole series was 40±2% and 44±2% respectively at 5 years. Cumulative incidence of relapse (CIR) was 39±4% at 5 years. Results according to intention of treatment were: *FP (n=88, 13.7%):* 5-year OS and DFS 81±5% and 72±5%, respectively, CIR 20±5%.There were no differences in OS, DFS and CIR depending if they received HDAC or ASCT; *IP (n=120, 18.7%):* 5-year OS, DFS and CIR were 68±5%, 52±6% and 43±5% respectively. *NPM1* mutation was associated with improved outcome compared with *NPM1wt* (DFS: 55±5 vs 37±5%, P=0.026; CIR: 32±4% vs 48±5%, P=0.032 respectively). *AP (n=399, 62.2%):* 5-year OS, DFS and CIR were 44±3%, 40±3% and 45±3% respectively. Statistical differences were found in CIR when comparing ASCT vs allo-SCT (52±4% vs 38±4%, P=0.006). 32 patients (5.3%) were not evalu-

able due to lost of follow up. We analysed patients with normal karyotype (n=389) and *FLT3* mutation and patients with *FLT3-ITD* had a worse OS and DFS compared with *FLT3wt* (30±5% vs 45±4%, p<0.001; 37±6% vs 48±4%, P=0.006, respectively). Multivariate analysis showed that age>50 y-o, two courses to CR, MRC group, *FLT3-ITD* and double negativity for mutations in *FLT3* and *NPM1* were associated to worse OS and DFS, with high relapse incidence being the main cause for treatment failure

Summary / Conclusion: Age, cytogenetics, molecular findings and courses to CR are important prognostic factors. AML is a biologically and pronostically heterogeneous disease subsidiary to be approached with risk adapted strategies. Currently it is feasible to identify a substantial proportion of patients that may be cured with high-dose cytarabine consolidation or ASCT. In contrast, there are patients with adverse genetic features that need an allogeneic procedure, investigational agents or both

S589

FINAL REPORT OF PHASE II TRIAL OF COMBINATION OF SORAFENIB AND 5-AZACYTIDINE IN PATIENTS WITH FLT3-ITD POSITIVE ACUTE MYELOID LEUKEMIA

F Ravandi[1,*], M Levis[2], S Faderl[1], G Garcia-Manero[1], J Cortes[1], H Kantarjian[1]
[1]Leukemia, University of Texas - MD Anderson Cancer Center, Houston, [2]Hematological Malignancies, Johns Hopkins Sidney Kimmel Cancer Center, Baltimore, United States

Background: A potential mechanism of resistance to FLT3 kinase inhibitors is high levels of FLT3 ligand (FL) as seen after myelosuppressive chemotherapy. We hypothesized that combining sorafenib with a less myelosuppressive agent, such as 5-azacytidine (AZA), may lead to higher and more durable responses. Both drugs have demonstrated a potential for inducing differentiation in AML cells, providing further rationale for the combination.

Aims: Determine the safety and efficacy of sorafenib plus AZA in pts with AML and *FLT3*-ITD.

Methods: Pts were eligible if they had relapsed or refractory AML, were 18 years of age or older, and had adequate performance status (ECOG ≤ 2) and organ function. Older pts without prior therapy were also eligible, if they were deemed unsuitable to receive chemotherapy. Presence of *FLT3*-ITD was not a requirement. Treatment regimen included AZA 75 mg/m^2 daily for 7 days together with sorafenib 400 mg twice daily for 28 days; cycles were repeated in 4 to 5-week intervals. Overall responses were assessed after the completion of at least one cycle of therapy. Plasma inhibitory activity (PIA) assay was performed using plasma collected on days 1 and 10 of each cycle. Plasma FL concentrations were measured using an ELISA kit.

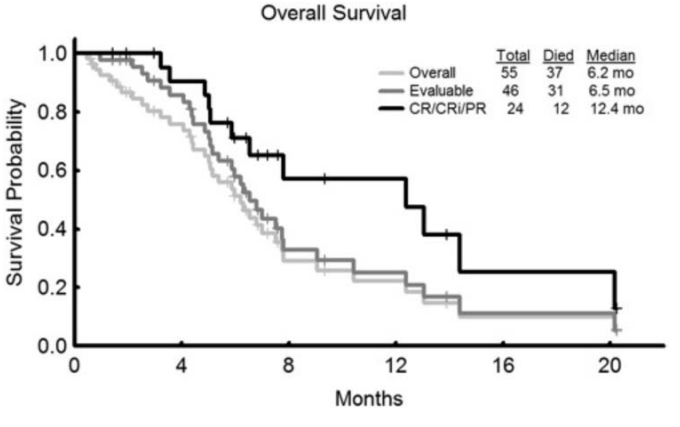

Figure 1.

Results: 55 pts with AML with a median age of 64 years (range, 20-87) were enrolled. They included 26 (47%) pts with diploid cytogenetics, 12 (22%) with chromosome 5/7 or complex cytogenetic abnormalities, 3 (5%) with insufficient metaphases, and 14 (25%) with miscellaneous abnormalities. Prior to the initiation of treatment, *FLT3*-ITD was detected in 51/55 (93%) pts with a median allelic ratio of 0.31 (range, 0-0.93). They had received a median of 2 prior treatments (range, 0-7). 20 (36%) pts had received ≥3 prior regimens and 12 had failed therapy with FLT3 kinase inhibitors (6 with AC220, 2 with PKC412, and 9 with sorafenib, either as monotherapy or with chemotherapy or plerixafor); 4 had failed 2 prior FLT3 inhibitors. 6 pts were inevaluable as they discontinued therapy before response assessment at one month and 3 are too early for response assessment. The overall CR/CRi/PR rate among the 46 evaluable pts is 52%, including 15 (33%) with CRi and 8 (17%) with CR and 1 (2%) with PR (in this pt, bone marrow blast declined from 51% to 6% with normalization of blood counts). Overall, pts have received a median of 3 (range, 1-21) treatment cycles with the median number of cycles to response being 2 (range, 1-4) and the median time to achieving response, 2.1 months (range, 0.9-4.6 months). The median duration of CR/CRi Is 2.3 months (range, 1 - 18.1$^+$ months). Six responding pts have proceeded to allogeneic stem cell transplant. The most common study drug-related adverse events were rash and fatigue with no deaths but one grade 3 cardiomyopathy attributable to study medications. The median survival for the total population is 6.2 months and for the 46 evaluable pts is 6.5 months. The median survival for pts achieving a response is12.4 months. Plasma samples spanning at least one cycle of therapy were available for 22 pts. Among them, 64% achieved FLT3 inhibition to a targeted level of less than 15% of baseline during their first cycle of therapy. Median survival in pts who achieved this degree of inhibition was 238 days, and in pts who did not reach this level was 154 days (P=0.13). Mean FL levels at cycle 1, day 1 and cycle 1, day 10 were 9 pg/mL and 17 pg/mL, respectively. Mean FL levels at cycle 2, day 0 and cycle 2, day 10 were 27 pg/mL and 54 pg/mL, respectively.

Summary / Conclusion:
Combination of AZA and Sorafenib is effective in pts with relapsed and refractory AML and *FLT3*-ITD mutation. There was a trend toward improved survival in pts with adequate FLT3 inhibition during cycle 1. FL levels did not rise to the levels seen in pts receiving cytotoxic chemotherapy.

S590

SORAFENIB VERSUS PLACEBO IN ADDITION TO STANDARD THERAPY IN YOUNG PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA: RESULTS FROM 264 PATIENTS TREATED IN THE RANDOMIZED-CONTROLLED SORAML TRIAL

C Röllig[1,*], C Müller-Tidow[2], A Hüttmann[3], V Kunzmann[4], C Baldus[5], C Brandts[6], A Krämer[7], K Schäfer-Eckart[8], A Neubauer[9], S Krause[10], A Giagounidis[11], W Aulitzky[12], U Krug[13], M Bornhäuser[1], M Schaich[1], S Parmentier[1], C Thiede[1], Malte von Bonin[1], Johannes Schetelig[1], Michael Kramer[1], Hubert Serve[6], Wolfgang E Berdel[13], Gerhard Ehninger[1]
[1]Universitätsklinikum Dresden, Dresden, [2]Universitätsklinikum Münster, Münster, [3]Universitätsklinikum Essen, Essen, [4]Universitätsklinikum, Würzburg, [5]Universitätsklinikum, Berlin, [6]Universitätsklinikum, Frankfurt, [7]Universitätsklinikum, Heidelberg, [8]Klinikum Nürnberg Nord, Nürnberg, [9]Universitätsklinikum, Marburg, [10]Universitätsklinikum, Erlangen, [11]Marien-Hospital, Düsseldorf, [12]Robert-Bosch-Krankenhaus, Stuttgart, [13]Universitätsklinikum, Münster, Germany

Background: Sorafenib is a multi-kinase inhibitor with activity against several intracellular kinases, which may play a role in the pathogenesis of acute myeloid leukemia (AML). In-vitro data and results from non-randomized clinical trials suggest that sorafenib might be an effective drug for the treatment of AML. So far, no randomized-controlled data are available for treatment of newly diagnosed AML patients up to the age of 60 years. We present the first randomized placebo-controlled efficacy and safety results from the SORAML trial of the Study Alliance Leukemia (SAL).

Aims: To evaluate the efficacy and tolerability of sorafenib added to standard chemotherapy in younger acute myeloid leukemia patients.

Methods: Between March 2009 and October 2011, 276 patients from 25 centers were enrolled in the SORAML trial (NCT00893373). The main eligibility criteria were: newly diagnosed AML, age from 18 to 60 years and suitability for intensive therapy. The treatment plan for all patients included two cycles of induction with DA (daunorubicin 60 mg/m^2 days 3-5 plus cytarabine 100 mg/m^2 cont. inf. days 1-7), followed by three cycles of high-dose cytarabine consolidation (3 g/m^2 b.i.d. days 1, 3, 5). Patients without response after DA I received second induction with HAM (cytarabine 3 g/m^2 b.i.d. days 1-3 plus mitoxantrone 10 mg/m^2 days 3-5). Allogeneic stem cell transplantation was scheduled for all intermediate-risk patients in first complete remission with a family donor and for all high-risk patients with a matched donor. At study inclusion, patients were randomized to receive either sorafenib (800 mg/day) or placebo as add-on to standard treatment. Block randomization at a ratio of 1:1 was performed within cytogenetic and molecular risk strata, allocation was concealed and treatment was double blinded. Study medication was given on days 10-19 of DA I+II or HAM, from day 8 of each consolidation until 3 days before the start of the next consolidation and as maintenance for 12 months after the end of consolidation. The primary endpoint of the trial is event-free survival (EFS) with an event being defined as either failure to achieve a complete remission (CR) after induction, relapse or death. Secondary endpoints were overall survival (OS), CR rate and incidence of adverse events (AE). We present the results of the planned interim analysis (intent to treat) after the occurrence of 50% of EFS events. The O'Brien/Fleming adjusted significance level was set at P=0.0052.

Results: Out of 276 randomized patients, 264 were evaluable for EFS, 132 in each arm. Demographic and disease characteristics were equally distributed between the two arms; the FLT3-ITD incidence was 16%. The median cumulative dose of administered study medication was equal in both arms. The CR rates were 56% versus 60% in the placebo versus sorafenib arm (P=0.622). By the time of analysis, a total number of 100 events had occurred. After a median observation time of 18 months, the median EFS was 12.2 months in the

placebo arm and was not reached in the sorafenib arm, corresponding to a 1-year EFS of 50% versus 64% (P=0.023). The median OS had not been reached in both arms, the 2-year OS was 66% versus 72% in placebo and sorafenib arms, respectively (P=0.367). The most common reported AEs CTC Grade ≥3 were infectious complications including fever and pneumonia, followed by bleeding events, cardiac and hepatic toxicity, hypertension, skin toxicity and headache. The risk for hepatic toxicity (relative risk 6.2, P=0.025) and bleeding events (relative risk 3.6, P=0.016) was significantly higher in the sorafenib arm while the incidence of all other AEs showed no significant differences.
Summary / Conclusion: In younger AML patients, the addition of sorafenib to standard chemotherapy is feasible but associated with a higher risk of liver toxicity and bleeding events. Sorafenib treatment resulted in a marked EFS prolongation; this difference is not significant according to the adjusted significance level of this interim analysis. Results from the final analysis including post-hoc exploration of molecularly defined subgroups are necessary for drawing final conclusions on the efficacy of sorafenib.

Myelodysplastic/Myeloproliferative Neoplasm - Clinical / Biology

S591

LONG-TERM INTERVENTION EFFECTS ON BONE MARROW MORPHOLOGY IN MYELOFIBROSIS: PATIENTS TREATED WITH RUXOLITINIB AND BEST AVAILABLE THERAPY

H Kvasnicka[1,*], J Thiele[2], C E Bueso-Ramos[3], W Sun[4], J Cortes[3], H M Kantarjian[3], S Verstovsek[3]
[1]Senckenberg Institute of Pathology, University of Frankfurt, Frankfurt, [2]University of Cologne, Cologne, Germany, [3]M. D. Anderson Cancer Center, Houston, [4]Incyte Corporation, Wilmington, United States

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm associated with splenomegaly, debilitating symptoms, progressive bone marrow (BM) fibrosis, and shortened survival. With the exception of BM transplantation, no therapy has shown a significant impact on disease progression. Ruxolitinib is an oral JAK1/JAK2 inhibitor that has demonstrated improvements in spleen volume, symptoms, and survival in patients (pts) with MF.
Aims: This study was conducted to gain insight into the effects of long-term ruxolitinib treatment on BM morphology in pts with MF and compare them to those seen in a best available therapy (BAT) cohort.
Methods: Trephine biopsies were obtained at baseline, 24 (68 pts) and 48 (18 pts) months (mo) from MF pts treated at MD Anderson Cancer Center who participated in a phase I/II trial of ruxolitinib (NCT00509899). The details of the study design and clinical outcomes have been published previously [Verstovsek, NEJM 2010]. Two of the authors (JT and H-MK) independently quantified BM fibrosis according to the World Health Organization (WHO) grading scale (0-3), and a third author (CB-R) reviewed the findings. Consensus decided discordant scores. Reviewers were blinded to pts characteristics and outcomes. WHO-defined BM fibrosis grading was also determined in prospectively collected specimens within a German, multicenter, observational database from a cohort of 139 pts (160 biopsies) treated with BAT for 24 (97 pts) and 48 (63 pts) mo. BAT included hydroxyurea [HU] (47%), interferon-alpha (7%), or assorted sequential therapies (25%). No active – or only supportive – therapy was given in 21% of the BAT cases. Biopsy intervals in the ruxolitinib-treated pts were defined per protocol; in the BAT cohort, biopsies were mostly performed based on a given patient's change in clinical condition at the discretion of the treating physician.
Changes in fibrosis grade vs. baseline were calculated for all time points and categorized as improvement, stabilization, and worsening. Additional analyses on changes over time in the degree of collagen deposition, amount of osteosclerosis, and BM cellularity were performed only in the ruxolitinib-treated cohort.
Results: At baseline, 21% of the ruxolitinib-treated cases presented with WHO-defined fibrosis grade 1, 53% with grade 2, and 26% with grade 3. At baseline, in this group, accumulation of collagen fibers was observed in 32 cases (47%): 30% with mildly increased (grade 1) and 17% with manifest or intense (grade 2 or grade 3) collagen deposition. About half of these pts had appreciable baseline osteosclerosis (grade 1: 32%; grade 2: 9%; grade 3: 9%). There were no significant differences in the distribution of baseline WHO-defined fibrosis grades between the ruxolitinib and BAT groups (P=0.441 by Cochran–Mantel–Haenszel test).
A higher percentage of ruxolitinib-treated pts showed stabilization or improvement in WHO-defined BM fibrosis at both the 24 and 48 mo time points vs. BAT pts. Worsening in fibrosis was significantly more prevalent in the BAT cohort at both time points.
Summary / Conclusion: This analysis of the effects of ruxolitinib in MF provides evidence that long-term therapy with this JAK inhibitor may meaningfully retard advancement of BM fibrosis. A comparable effect was not seen with long-term BAT. These results expand upon earlier observations using the same approach but with a smaller control cohort, consisting of pts treated with HU alone. Additional research is needed to elucidate the positive impact of JAK inhibition on BM morphology.

S592

THE INTERFERON SCORE TOWARDS PREDICTION OF RESPONSIVNESS TO INTERFERON ALPHA IN ESSENTIAL THROMBOCYTHEMIA

N Pugliese[1,*], C Quintarelli[1], B De Angelis[1], L Marano[1], S Errichiello[1], Ni Esposito[1], C Cerchione[1], M Picardi[1], V Martinelli[1], F Pane[1]
[1]Hematology, University of Naples Federico II, Naples, Italy

Background: Interferon-alpha 2 (IFN) is able to induce hematological response in about 70-80% of ET patients but some of them could be defined as bad responders.
IFN binding its receptor results in tyrosine cross-phosphorylation and autophosphorylation of the JAKs proteins (Tyk2 and Jak1). These phosthyrosines recruit and activate STAT family member such as STAT1 and STAT3. These proteins induce the transcription of SOCSs, whose role is to extinguish cytokine

signaling by inhibition of JAK kinase-activity directly through the KIR-domain, and indirectly promoting the proteasomal degradation of Jak2, by SOCS-box-motif. In summary, IFN induces the expression of SOCSs, which inhibit TPO mediated signaling through Jak2 double inhibition. This allows IFN-α and TPO pathway to cross-talks by means of the JAK-STAT-SOCS cascade.
Aims: In order to identify molecular markers that discriminate responders from non-responders to IFN, we analyzed bone marrow cells transcript levels of specific genes involved in the IFN receptor pathway, which signal cross-talks with the JAK-STAT pathway under TPO receptor. In particular we investigated the mRNA expression of JAK1, TYK2, STAT1, STAT3, SOCS1 and SOCS3.
Methods: We analyzed 60 ET patients treated with 3 million units of IFN-α-2b 5 times a week as induction (3 months), and 3 times a week as maintenance. Two groups of response were identified: *Good-Responders(R)* (n=44), who achieved complete response according to European Leukemia Net criteria, and *Bad-Responders(NR)* (n=17) who failed. The mRNA expression of genes of interest was measured in bone marrow samples from ET patients by RTq-PCR and tested for their predictive value using receiver operating characteristics (ROC) curves. Data were normalized as following: [mRNA normalized copy number (NCN)=mRNA target gene/mRNA GUSB*104]. An IFN score was calculated as an average in log2 of mRNA levels of genes differently expressed between *Good-R* and *Bad-R*.
Results: Main clinical characteristics were similar between the two groups of response. JAK2 V617F mutation was detected in 56,8% of *Good-R* and 58,8% of *Bad-R* (P=0,81) and no difference was found in JAK2V617F allele burden (P=0,17) and mRNA expression (P=0,2). Patients showed a median spleen volume of 500 mL in *Good-R* and 250 ml in *Bad-R* group (P=0.01). *Bad-R* compared with *Good-R* showed higher mRNA expression of JAK1 (134465 vs 44647; P<0.00001), STAT3 (49210 vs 23959; P=0.0002) and SOCS3 (18667 vs 10361; P=0,015). The AUC, using the normalized gene expression values, was 0.88 for JAK1, 0.81 for STAT3 and 0.7 for SOCS3. Average expression in log2 of these three genes was calculated and used as IFN score. The analysis reveled an AUC of 0.9 for this IFN signature (P<0,00001). The optimal cut-off point for IFN score to discriminate between *Good-R* and *Bad-R* was 15,75 and produced a sensitivity of 94,1%, specificity of 88,6% and likelihood ratio of 9.
Summary / Conclusion: We identified this set of three genes whose expression status could be translated into IFN score that showed a significant correlation with response outcome in ET.
Therefore, IFN score could represent a predictive biomarker for responsiveness to IFN and is likely to become a substantial aid to the physician, taking the paradigm of tailored therapy one step further, especially in chronic diseases such as ET.

S593

DEVELOPMENT AND CHARACTERIZATION OF A MURINE MODEL FOR LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS FOR PRECLINICAL THERAPEUTIC STUDIES

R Rampal[1,*], J Ahn[2], O Abdel-Wahab[1], T Hricik[2], S Pandey[2], T Manshouri[3], C Park[2], S Verstovsek[3], R Levine[1]
[1]Leukemia Serivce and Human Oncology and Pathogenesis Program, [2]Human Oncology and Pathogenesis Program, Memorial Sloan-Kettering Cancer Center, New York, [3]Leukemia Department, MD Anderson Cancer Center, Houston, United States

Background: Transformation to acute myeloid leukemia (AML) represents a major clinical consequence of the Philadelphia-chromosome negative myeloproliferative neoplasms (MPNs) (Polycythemia Vera (PV), Essential Thrombocythemia (ET), and Primary Myelofibrosis (PMF)). Leukemic transformation (LT) after MPN occurs in as many as 23% of PMF patients within 10 years of diagnosis, and 4-8% of PV and ET patients develop AML in the first 18 years after diagnosis. The development of a post-MPN AML is associated with a poor clinical outcome, and characterized by a poor response to conventional anti-leukemic therapies. Although somatic mutations in the JAK-STAT signaling pathway occur in the majority of MPN patients, the somatic mutations that drive LT from a pre-existing MPN have not been fully delineated. Recent candidate mutational studies have identified recurrent somatic mutations in a subset of known leukemogenic disease alleles at the time of transformation from MPN to AML, including mutations in *TP53, IDH1/2, TET2* and *SRSF2.* However, the functional contribution of these specific genetic events to LT has not been delineated
Aims: To develop a genetically accurate murine model of LT, in order to further understanding of progression from MPN to AML and to use this preclinical model to test novel therapeutic approaches.
Methods: Expression of the *JAK2*V617F mutation in combination with *Tp53* loss was modeled *in vivo.* Bone marrow (BM) from C57/Bl6 *Tp53*$^{-/-}$ and littermate control mice was infected with *JAK2*V617F-IRES-GFP retrovirus, followed by transplantation of transduced cells into lethally irradiated congenic recipients. Outcomes measured included: survival, peripheral blood counts, organ weights, flow cytometry analysis of bone marrow and spleen derived cells, and morphologic evaluation of bone marrow and spleen.
Results: Transplantation of *JAK2*V617F/*Tp53*$^{-/-}$ cells, but not *JAK2*V617F positive cells was associated with impaired survival; 50% of mice injected with *JAK2*V617F/*Tp53*$^{-/-}$ cells died by day 100, whereas all mice injected with *JAK2*V617F positive cells survived 100 days or longer (P=0.011) (figure1). Mice injected with *JAK2*V617F/*Tp53*$^{-/-}$ cells presented with significant leukocytosis, with a mean WBC of 38.4 in mice engrafted with *JAK2*V617F/*Tp53*$^{-/-}$ cells compared with 11.4 in *JAK2*V617F/*Tp53* wildtype mice (no p value). At the time of sacrifice, all mice engrafted with *JAK2*V617F/*Tp53*$^{-/-}$ cells had increased numbers of blasts in the peripheral blood and bone marrow, as assessed by morphologic evaluation and flow cytometric analysis of CD117 expression. The disease from *JAK2*V617F/*Tp53*$^{-/-}$ cells, but not *JAK2*V617F positive cells, was transplantable into secondary recipients consistent with increased self-renewal *in vivo*. Flow cytometric analysis of spleen and bone marrow derived cells from leukemic mice demonstrated an increased percentage of megakaryocyte-erythroid progenitors (MEPs) and erythroblasts. *In vitro* assays and *in vivo* studies in secondary transplantation studies were carried out using this model. INCB18424 and CYT 387 exposure resulted in dose-dependent inhibition of colony formation *in vitro*. *In vivo* testing of INCB18424 and the HSP90 inhibitor PU-H71 was carried out in secondary recipients and the results of this preclinical trial will be presented.
Summary / Conclusion: The expression of *JAK2*V617F plus *Tp53* loss, a genotype commonly seen in patients who transform to AML after MPN, efficiently models LT *in vivo*. This model can now be utilized to assess the leukemic cell of origin in transformed disease, and to test novel therapeutic strategies which will inform clinical trials in this poor-risk hematologic malignancy.

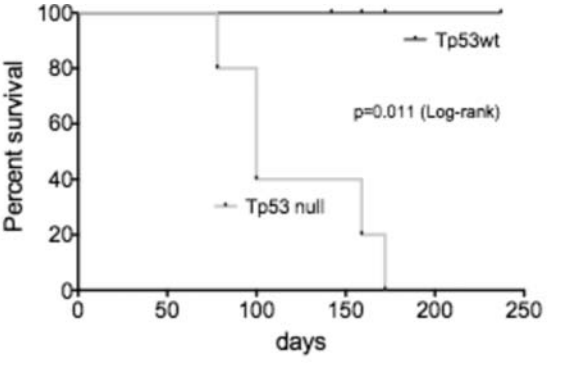

Figure 1.

Background: At the beginning of the new millennium, myelodysplastic syndromes (MDS) were formally classified as malignant myeloid neoplasms by the World Health Organization (WHO), and consequently MDS became reportable malignancies to population-based cancer registries as of 2001. To date, studies on incidence and survival in MDS based on data from population-based cancer registries are scarce. Further, studies regarding treatment decisions in the entire MDS population are not available.
Aims: We conducted a nationwide population-based study to assess trends in incidence, initial treatment and survival among newly diagnosed patients with MDS during a 10-year period in the Netherlands.
Methods: Morphology codes of the International Classification of Diseases for Oncology Third Edition (ICD-O-3) were used to identify newly diagnosed patients with MDS from the nationwide Netherlands Cancer Registry (NCR) from 2001 to 2010 with follow-up to 2011. All MDS subtypes according to the ICD-O-3 were included in the NCR, namely refractory anemia (RA), RA with ringed sideroblasts (RARS), MDS with isolated del(5q) (5q- syndrome), refractory cytopenia with multilineage dysplasia (RCMD), RA with excess blasts (RAEB) and MDS, not otherwise specified. Age-standardized incidence rates (ASRs) of MDS were calculated per 100,000 person-years. Relative survival rates (RSRs) were calculated as a measure of disease-specific survival. If initial treatment was started within 9 months after diagnosis, it was recorded in the NCR.
Results: We identified a total of 5,144 newly diagnosed patients with MDS from January 1, 2001 to December 31, 2010 (median age 74 years). Of these patients, 486 (9%) were classified as RA, 583 (11%) RARS, 82 (2%) the 5q-syndrome, 524 (10%) RCMD, 966 (19%) RAEB, while 2,503 (49%) were

unspecified. Interestingly, the proportion of unspecified MDS decreased from 60% in 2001 to 36% in 2010. The reported number of patients diagnosed with MDS increased throughout the study period; however, the annual ASR reached a plateau at 2.8 since 2007. Men had a higher overall incidence than women (3.3 *v* 1.7). The age-specific incidence of MDS during the entire study period increased in parallel with older age, from 0.3 among those aged 50 years or younger to 28.5 among those aged 80 years or older. Of all patients, 4,562 (89%) did not receive treatment or only received supportive care, 348 (7%) received chemotherapy and 74 (1%) received chemotherapy followed by a stem cell transplantation. Survival in MDS did not improve over time. All MDS subtypes had inferior survival compared with the expected survival in the general population (Figure 1A). Five-year RSRs were 53% in patients with RA, 58% in patients with RARS, 48% in patients with the 5q- syndrome, 38% in patients with RCMD, 18% in patients with RAEB, and 39% in patients with an unspecified MDS. Age at diagnosis was an important predictor for survival as RSRs decreased in parallel with older age (Figure 1B). Five-year RSRs were 59% for patients aged 18-49 years, 52% for patients aged 50-59 years, 41% for patients aged 60-69 years, 36% for patients aged 70-79 years, and 29% for patients aged ≥80 years. The RSRs between both sexes were comparable.

Summary / Conclusion: The incidence of MDS in the Netherlands is similar to other Western European countries and increased over time due to improved notification. Morphological assessment of MDS according to the WHO classification seems challenging as almost half of the recorded MDS cases were unspecified. Nevertheless, the proportion of specified cases increased over time, which was presumably due to better knowledge about the WHO classification of MDS. The lack of improvement in patient survival might be explained by the limited availability and use of therapeutic agents. Therefore, more emphasis is needed to improve current treatment strategies and to develop new treatment options in MDS.

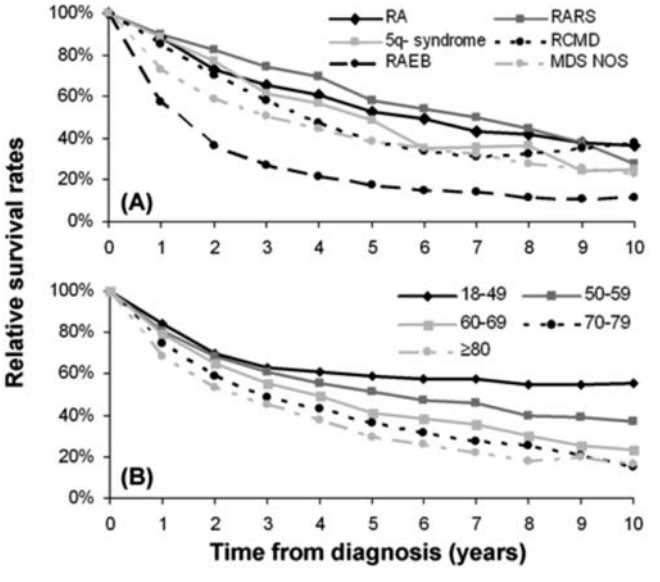

Figure 1. Cumulative relative survival among patients diagnosed with myelodysplastic syndromes in the Netherlands by (A) subtype and (B) age at diagnosis throughout the study period from 2001 to 2010.

A PILOT PHASE ONE DOSE FINDING SAFETY STUDY OF A THROMBOPOIETIN-RECEPTOR AGONIST, ELTROMBOPAG, IN PATIENTS WITH MYELODYSPLASTIC SYNDROME TREATED WITH AZACITIDINE

T Svensson[1], H Garelius[2], F Lorenz[3], L Saft[4], E Hellström-Lindberg[4], H Cherif[1,*]
[1]Uppsala University, Uppsala, [2]Sahlgrenska University, Gothenburg, [3]Umeå University, Umeå, [4]Karolinska Ins., Stockholm, Sweden

Background: Thrombocytopenia is a common manifestation of Myelodysplastic Syndroms (MDS) and is an independent adverse prognostic factor for survival. Azacitidine (Aza) is today the treatment of choice for patients with high-risk MDS not eligible for stem cell transplantation. In the pivotal randomized studies with Aza, grade 3-4 thrombocytopenia was reported in up to 85% of patients, and the main causes of Aza discontinuation were hematological adverse events. In parallel to the use of growth factors such as Erythropoietin and G-CSF in MDS, stimulating platelet production by a thrombomimetic agent may be an attractive alternative to platelet transfusions. Eltrombopag is a novel thrombomimetic agent that activates the thrombopoietin receptor (TPO-R) and stimulates megakaryopoiesis and thrombopoiesis. Studies with eltrombopag in leukemia cell lines did not show enhancement of leukemia cell proliferation, instead inhibition of leukemia cells was observed in the majority of tested cell lines.

Aims: In this Phase I Pilot Study (ClinicalTrials.gov identifier: NCT01481220) we explored the safety and tolerability of combining eltrombopag with Aza in the treatment of patients with high-risk MDS.

Methods: Patents with high-risk MDS eligible to treatment with Aza according to the labeled indication and thrombocytopenia (Platelet counts $<75x10^9$/L) were included. Cohorts of three patients received Aza in combination with increasing doses of eltrombopag tablets (50-100 mg, 100-200 mg, 200-300mg and a final cohort with 300mg as an unchanged dose) during 3 Aza cycles (13 weeks). Patient monitoring included repeated blood and bone marrow samples.

Results: Eleven patients, with a median age of 71 (range 53-83) have been included. Reported severe adverse events include one bacterial bronchitis (cohort 1, eltrombopag 50-100 mg), recurrent erysipelas (one patient in cohort 3, eltrombopag 200-300 mg), one case of fatal pneumonia with E. coli septicemia (Cohort 3) and one deep vein thrombosis, elevated liver enzymes and progressive disease occurring in a patient with highly proliferative MDS-AML (Cohort 3). This dose-cohort is now being completed with 3 more patients. Platelet counts improved or remained stabile in 9/11 patients despite Aza treatment while two patients remained dependent on platelet transfusion. Median platelet counts were 40, 51 and 64 x 10^9/L at inclusion, after one and after three Aza cycles, respectively. Bleeding symptoms were uncommon. No MDS disease progressions related to study medication were reported. Three more patients are to be recruited to the final cohort and updated results will be presented during the 18th EHA congress.

Summary / Conclusion: The combination of eltrombopag with Aza in high-risk MDS patients with thrombocytopenia is feasible and well tolerated. Improvements in platelet counts and anti-leukemic effect through adding eltrombopag cannot be excluded and needs to be explored in a phase-two study.

Stem cell transplantation - Clinical 2

Background: Survival of patients with multiple myeloma (MM) has been extended with the introduction of autologous stem cell transplantation (ASCT). More recently, availability of highly effective novel agents has further improved patient outcomes. However, it is still the matter of debate whether a proportion of patients treated with ASCT can enjoy a long term survival, while sustaining prolonged high quality response.

Aims: To identify the variables which were related to long-term survival, we performed a post-hoc analysis of two large prospective clinical trials of ASCT in newly diagnosed MM patients, the first one comparing single versus double ASCT and the second one incorporating thalidomide-dexamethasone (TD) into double ASCT.

Methods: A total of 321 patients were randomly assigned in the first study to receive either a single or double ASCT, as previously described (Cavo M et al, JCO 2007). Three hundred and fifty seven patients were enrolled in the subsequent multicenter phase 2 study incorporating TD from the outset until the second ASCT; details of the protocol were previously reported (Cavo et al, *J. Clin. Oncol* 2009). All the analyses were performed on an intention-to-treat basis.

Results: After a median follow-up of 61 months in the first study, PFS remained significantly longer with tandem versus single ASCT (median 37 vs 25 months, P= 0.012), while OS was similar in the two groups (median 71 vs 67 months). CR was sustained for more than 5 and 10 years in 24% and 12% of the patients, respectively. On multivariate analysis, CR was the most important variable significantly extending PFS and OS; random assignment to double ASCT was an additional variable extending PFS. After a median follow-up of 84 months in the second study, median values of PFS and OS were 47.2 and 109.6 months, respectively. CR was sustained for more than 5 and 8 years in 42% and 9% of the patients, respectively. On multivariate analysis, achievement of CR and absence of t(4;14)±del(17p) were independent variables predicting for longer PFS and OS. Overall, 23% and 20% of patients in the first and second study were alive over 10 or 8 years, respectively (long-term survivors). Median PFS of long-term survivors in the 2 studies were 74 and 87.7 months, respectively, versus 25 and 37 months for the rest of the population (P=0.0000). Median duration of CR were 70 and 78 months in the long-term survivors group for the first and second study, respectively, in comparison with 21 and 49 months in the remaining patients (P<0.001 for both). The 10 and 8-year estimates of OS after relapse or progression in the long-term survivors of the two protocols were 58% and 72%, respectively, in comparison to a median value of 24 and 23 months for the control group (P<0.0001 for both). Sustaining a durable response for more than 42 months was favourably affecting survival after relapse on multivariate analysis. In a logistic regression analysis, independent factors predicting for long-term survival in both the trials appeared to be attainment of CR, sustaining the response for more than 42 months and application of double ASCT.

Summary / Conclusion: Approximately 20-25% of the patients undergoing up-front ASCT can achieve long term survival (8-10 years from start of treatment), with 33% of them remaining relapse free. Attainment of CR and sustaining a durable response as well as application of double ASCT were the leading independent variables predicting for long-term OS.Prolonged survival after relapse was a contributing factor to long-term OS as well and was influenced by the sustenance of a durable response.

Rossi, Verona, [9]Hematology, Ospedale di Brescia, Brescia, [10]Hematology, Ospedale di Alessandria, Alessandria, [11]Hematology, Ospedale Policlinico di Milano, [12]Oncology, Ospedale San Raffaele, Milano, [13]Hematology and Bone Marrow Transplant Unit, Azienda Ospedaliera Riuniti Villa Sofia, Cervello-Palermo, [14]Hematology, University of Torino , Torino, [15]Anatomic-Pathology, Univerisity of Bologna , Bologna, Italy

Background: PTCLs have a poor survival with conventional therapy. Recent trials showed: 1) CHOP-alemtuzumab (AL) has a high response rate (ORR); 2) consolidation of response with up-front autologous stem cell transplantation (autoSCT) improves PFS (from 35% to 45% at 3 years); iii) allogeneic stem cell transplantation (alloSCT) is an effective strategy for relapsed disease. Based on these findings, we conducted a prospective phase II study in young (A: ≥18 ≤60 years) and elderly (B: >60 and ≤75 years) patients (pts) at diagnosis. In young pts, the trial tested for the first time a consolidation with up-front allogeneic or autologous stem cell transplantation (autoSCT or alloSCT) based on a genetic stratification. In elderly pts, the trial tests only the role of chemo-immunotherapy.

Aims: The primary endpoint was the treatment efficacy in terms of complete clinical response maintained for at least 6 months.

Methods: Younger pts (A) received 2 courses of CHOP-21 with AL (30 mg), 2 courses of Hyper-C-Hidam (methotrexate, cyclophosphamide, cytarabine). Responding pts received consolidation with up-front autoSCT or alloSCT. Elderly pts (B) received 6 cycles of CHOP-21 with AL (10 mg).

Results: 92 pts were enrolled, 86 fulfilled all inclusion criteria (A: n=61; B: n=25). Clinical characteristics: PTCL-NOS 49%, AILT 24%, ALK-negative ALCL 22%, EATL 5%. International Prognostic Index ≥2, A: 69%; B:100%. For study A, at the end of induction phase, the ORR was 67% (CR, 56%; PR, 11%). Thirty-eight (62%) pts received consolidation: 14 autoSCT, 23 alloSCT and one maintained remission without any further treatment. Twenty-three (38%) did not receive the consolidation for PD (n=18) and deaths for toxicity (n=5). At a median follow-up of 40 months, 30 pts (49%) are alive in CR**.** The cumulative non-relapse mortality (NRM) was 13%. The estimated 4-years OS, PFS and DFS rates were 48.8% (95%CI, 37.6% -63.2%), 44.0% (95%CI, 33.1% -58.5%) and 79% (95%CI, 65.1%>95.5%), respectively. At multivariable analysis, the CR maintained for at least 6 months [48% (95%CI,34.6%>61%)] had a dominant effect on PFS and OS, regardless of patient's age, IPI, extranodal involvement. Transplanted pts had an advantage in OS (HR=0.04, P=0.004 for autoSCT; HR=0.22, P=0.008 for alloSCT). For study B, 13 pts (52%) maintained the response at least for 6 months and 8 pts (32%) are alive at last follow-up. The cumulative NRM was 12%. At median follow-up of 48 months, the estimated 4-year OS, PFS and DFS were 31.5% (95% CI: 17.6%>56.5%), 26.7% (95% CI: 13.6%>52.3%) and 44.4% (95% CI: 24.6%>80.5%), respectively.

Summary / Conclusion: Considering the high-risk population, in younger pts the consolidation with up-front transplantation was associated to a prolonged DFS. In elderly, the chemo-immunotherapy program did not improve the outcome.

S598

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE 8TH DECADE OF LIFE

A Shimoni[1,*], R Yerushalmi[1], N Shem-Tov[1], Y Volchek[1], A Nagler[1]

[1]Division of Hematology and Bone Marrow Transplantation, Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: Allogeneic stem-cell transplantation (SCT) is a potentially curative therapy for various hematological malignancies. Reduced-intensity conditioning (RIC) allows extension of SCT to older patients, previously considered not eligible for SCT. However, there is still paucity of data on the expected outcome of patients age 70 years and older, and in particular on the long-term outcome after SCT.

Aims: To define SCT outcome in patients age 70 years and older.

Methods: We retrospective analyzed all consecutive allogeneic transplants performed in a single institution between the years 2000-2013. We identified patients age 70 years and above at the day of SCT and analyzed their outcome.

Results: Forty-eight patients older than 70 years were transplanted during the study period (4.2% of all allogeneic transplant recipients during that period); none during the years 2000-4 (0%), 29 during 2004-10 (4.2%) and 19 during 2011-3 (7.2%). The median age at SCT was 71 years (range, 70–76), 32 male, 16 female. Diagnoses included AML/MDS (n=38), myeloproliferative disorders (n=3), lymphoma and CLL (n=5), aplastic anemia (n=1), ALL (n=1). Disease status at SCT was early (n=17), intermediate (n=6), or advanced (n=25) according to CIBMTR criteria. Fourteen patients had a comorbidity score >2 (29%). The donor was an HLA-matched sibling (n=26), matched unrelated (n=20, 7 of them HLA mismatched) or mismatched related donor (n=2). The conditioning regimen was fludarabine with reduced-dose intravenous busulfan (n=27), treosulfan (n=18), cyclophosphamide (n=2) or melphalan (n=1). Thirty-six patients engrafted in a median of 14 days (12-23), 2 died prior to engraftment (4%). With a median follow-up of 15 months (range, 1–50), 15 patients are alive and 33 have died. Fourteen evaluable patients had acute GVHD grade II-IV (30%) and 10 of 29 evaluable patients had chronic GVHD (34%). Ten patients died within 1 year after SCT of treatment-related cause, 7 patients died due to infections (1 before engraftment), 1 due to organ toxicity (before engraftment), 2 due to acute GVHD. The day+100 and 1-year non-relapse mortality (NRM) rates were 11% (95%CI, 5-25) and 24% (95%CI, 14-41), respectively. The 1-year relapse rate was 38% (95%CI, 25-56). In all, the 1-year overall survival (OS) and disease-free survival rates were 49% (95%CI, 34–64) and 38% (95%CI, 23–53), respectively. With current follow-up, 13 patients reached 1 year after SCT disease-free. However, only 5 of these patients remained alive for the next 2 years. Three died of relapse and 5 had late NRM due to myocardial infarction (n=3), chronic GVHD (n=1) and late infection (n=1). There was no apparent plateau on the survival curve due to these late events.

Summary / Conclusion: Allogeneic SCT is increasingly used in patients age 70 years and older. SCT is feasible in a subset of these older patients. RIC regimens are associated with relatively low organ toxicity and GVHD rates in these patients, but infection mortality is relatively high. Late events, some possibly related to patient age and comorbidity rather than to the SCT itself, continue to compromise cure in the late post SCT phase. Larger studies are needed to define patient subsets that are more likely to benefit from SCT in this older age.

S599

HEMATOPOIETIC CELL TRANSPLANTATION (HCT) FOR SEVERE APLASTIC ANEMIA (SAA): IMPACT OF GRAFT SOURCE AND ECONOMIC REGIONS.

R Kumar[1,2,*], M Pasquini[3,4], J Klein[3,4], C Bonfim[5], M Aljurf[6], W Saber[3,4], P Rowlings[7], Y Inamoto[8], J Szer[9], Y Kuwatsuka[4], Z Hu[4], V Gupta[10], M Seftel[1,2], Y Atsuta[11], F Kimura[12]

[1]Medical Oncology and Hematology, CancerCare Manitoba, [2]Internal Medicine, University of Manitoba, Winnipeg, Canada, [3]Medical College of Wisconsin, [4]CIBMTR, Milwaukee, United States, [5]Hospital de Clinicas – UFPR, Curitiba, Brazil, [6]King Faisal Hospital, Riyadh, Saudi Arabia, [7]Dept of Hematology, Calvary Mater Newcastle, Waratah, Australia, [8]Fred Hutchinson Cancer Research Center, Seattle, United States, [9]Dept of Clinical Hematology, Royal Melbourne Hospital , Melbourne, Australia, [10]Department of Medicine, Princess Margaret Hospital, Toronto, Canada, [11]Nagoya University Graduate School of Medicine , Nagoya, [12]National Defense Medical College, Tokorozawa, Japan

Background: Submitted on Behalf of the International Studies Committee of the Center for International Blood and Marrow Transplant Research (CIBMTR) and the Japan Society for Hematopoietic Cell Transplantation (JHSCT). Bone marrow (BM) is the preferred graft source for treatment of SAA with HCT due to the lower risk of chronic graft-versus-host disease (GVHD) and better survival compared to mobilized peripheral blood stem cells (PBSC). However, this may not apply to all economic regions, as graft failure rate is often higher in regions where patients frequently present later in their disease course and with heavier transfusion load.

Aims: To compare outcomes of HLA matched sibling HCT for SAA with BM and PBSC across different regions according to gross national income per capita (GNI).

Methods: Patients with SAA who received HCT from an HLA-matched sibling donor from 1995 to 2009 and reported to the Center for International Blood and Marrow Transplant Research (CIBMTR, N=1,885) or the Japan Society for Hematopoietic Cell Transplantation (JSHCT, N=560) were analyzed. The study population was categorized by GNI and region/countries into three groups: high income countries (HIC),US and Canada (US-C, N= 504), other HIC (OHIC, N=1,280) and other combined group that included upper middle (UM), low middle (LM) and low income countries (LIC) (UM-LM-LIC, N=661). HIC groups were separated due to greater representativeness of country wide data from US-C in the CIBMTR database.

Results: PBSC was used as the graft source in 72% of HCT in LM-LIC, compared to 17% in HIC and 13% in UMIC. The following demographics differed significantly in the combined UM-LM-LIC group compared to the HIC group: women in 36% (HIC-44%), performance scores <90% in 45% (US-C 32%, OHIC 29%), CMV positive donors/ recipients in 77% (US-C 63%, OHIC 54%), median time from diagnosis to HCT <3 months in 40% (US-C 61%, OHIC 44%), prior use of anti-thymocyte globulin in 6% (US-C 24%, OHIC-23%). Three-year probabilities of overall survival for PBSC and BM graft source were 62% (95% confidence interval [CI],51-72%) and 88% (95%CI, 84-91%, p<0.01) in US-C, 78% (95%CI, 72-83%) and 88% (95% CI, 86-90%, p<0.01) in OHIC, and 64% (95% CI, 55-72%) and 69%(95%CI, 65-74%, P=0.2) in UM-LM-LIC, respectively. Rates of chronic GVHD were generally higher with PBSC irrespective of economic region. Multivariate analysis showed that overall mortality was higher in the following groups (a) UM-LM-LIC (b) PBSC (c) low KPS (<90%) (d) time from diagnosis to transplant > 6 months. Table 1 shows overall mortality and primary graft failure according to graft source and economic region.

Summary / Conclusion: Survival outcomes after HCT for SAA are different according to economic regions and graft sources. BM is associated with better survival than PBSC and outcomes in HIC are better than those in the UM-LM-LIC cohort. Additionally, outcomes in UM-LM-LIC were the same for BM and PBSC, likely due to lower rates of neutrophil engraftment with BM.

Table 1. Multivariate analysis for overall mortality and graft failure.

Background: For patients with myelodysplastic syndrome (MDS), allogeneic stem cell transplantation (allo-SCT) is the sole curative therapy. However, MDS is a disease that most often develops in older people, with the median age of onset being 70 years, so the potential matched-sibling donors are also elderly. Therefore, there is a substantial need for alternative donors for MDS patients compared to those with other hematological diseases. Cord blood transplantation (CBT) might represent such an alternative, however, there has been concern that the relapse rate of patients who receive CBT is higher than that of patients who undergo bone marrow transplantation from unrelated donors (URBMT).

Aims: We conducted a retrospective study of the CBT outcomes of MDS patients using the data from the Japan Society for Hematopoietic Cell Transplantation Data Registry.

Methods: Patients with MDS with the FAB classification aged 16 years or older who underwent their first CBT between January 1998 and December 2010 were compared to the patients who underwent the first URBMT. We next examined the clinical factors affecting the overall survival (OS) using Fisher's exact test and a Cox proportional hazard model.

Results: There were 431 and 1093 patients with MDS who received a CBT and URBMT. The estimated 5-year OS of the CBT patients was significantly inferi-

or to that of the URBMT patients (32% vs. 46%, P<0.0001). No significant differences were observed between the CBT and URBMT patients in the 3-year cumulative incidence (CI) of non-relapse mortality (NRM); however, the 3-year CI of relapse was significantly worse in the CBT patients than the URBMT patients (The 3-year CI-NRM and CI-relapse of the CBT and URBMT patients was 34% vs. 36% (P=not significant) and 20% vs. 10% (P<0.0001), respectively. The CI of neutrophil engraftment in the CBT patients was 66% at day 30 and 77% at day 100 after SCT. In the CBT patients, the following factors were extracted that predicted a better OS in the univariate analysis; recipients' age at SCT (younger than 50 years), female gender, diagnosis (refractory anemia and refractory anemia with multilineage dysplasia), good performance status (PS, 0 and 1), fewer than 20 Unit RBC transfusions, reduced-intensity conditioning, the development of acute graft-versus-host disease (GVHD) and chronic GVHD and cytogenetic prognostic subgroups according to the international prognostic scoring system. A proportional hazards model showed that the recipients' age at SCT, diagnosis, PS and number of RBC transfusions were the variables affecting the OS.

Summary / Conclusion: Our results suggest that the development of acute/chronic GVHD might improve the OS in CBT patients. However, it is also necessary to carefully select the patients who should receive a CBT, because the OS of CBT may be inferior to that of URBMT patients.

Chronic myeloid leukemia - Biology

CXCR4 ANTAGONIST BKT140 (BL-8040) COOPERATES WITH IMATINIB, EFFECTIVELY ABROGATING STROMA-MEDIATED PROTECTION AND TARGETING CML CELLS IN VITRO AND IN VIVO

K Beider[1,*], M Darash-Yahana[2], B Pal[2], , O Blaier[3], M Koren-Michowitz[3], M Abraham[2], H Wald[2], O Eizenberg[4], A Peled[2], A Nagler[1]
[1]Bone Marrow Transplantation, Sheba Medical Center, Tel Hashomer, [2]Institute of Gene Therapy, Hadassah Medical Organization, [3]Bone Marrow Transplantation, Sheba Medical Center, Jerusalem, [4]Biokine Therapeutics Ltd, Ness Ziona, Israel

Background: Existence of quiescent leukemic stem cells (LSCs) resistant to tyrosine kinase inhibitors (TKIs) may be responsible for chronic myeloid leukemia (CML) resistance and recurrence. Thus, novel therapies that eradicate LSCs are in need. The bone marrow (BM) microenvironment is believed to have a role in protecting CML cells from TKIs-induced apoptosis. Chemokine receptor CXCR4 and its ligand CXCL12 have a key role in the trafficking and retention of normal and LSCs in the BM niche. Therefore, CXCR4 inhibition may antagonize the survival and spread of CML and LSC cells, restoring their sensitivity to TKIs in the BM microenvironment context.
Aims: To study the role of CXCR4 in CML progression and to evaluiate the effect of CXCR4 antagonist BKT140 (BL-8040) on CML cell survival and sensitivity to rituximab.
Results: Exogenous CXCR4 expression increased the *in vitro* proliferation of K562 cells in response to CXCL12, suggesting the pro-survival role of CXCR4/CXCL12 axis in CML. Accordingly, *in vitro* treatment with CXCR4 antagonist BKT140 (8 μM) directly inhibited the cell growth by 40-60% and induced apoptosis of CML cell lines (K562, LAMA84 and KCL22). Combination of BKT140 with IC50 concentrations of imatinib significantly increased the anti-CML apoptotic effect, achieving 95% reduction in cell viability (p<0.01). To address the impact of BM environment on CML cell growth and sensitivity to imatinib, we established *in vitro* co-culture system with BM stromal cells (BMSCs). We found that murine, as well as primary human BMSCs supported the survival and proliferation of CML cell lines and primary CML cells and protected them from imatinib-induced apoptosis. Furthermore, BMSCs remarkably increased the expression of proto-oncogene BCL6 in CML cells in response to imatinib treatment, suggesting the possible role of BCL6 in stroma-mediated TKI resistance. Moreover, exogenous expression of CXCR4 in K562 cells elevated the basic level of BCL6, which was further increased by imatinib treatment in the presence of BMSCs. Interestingly, BKT140 treatment in co-culture system with BMSCs increased the percent of cycling (G2/M+S) CML cells from 22% to 30%, respectively (P<0.01). However, the combination of BKT140 with imatinib in the co-culture with BMSCs remarkably decreased the percent of proliferating CML cells to 9% and induced cell apoptosis. These results may indicate that CXCR4 blockade may abrogate the stroma-mediated CML quiescence and increase the sensitivity to TKIs. Notably, combination of imatinib with BKT140 decreased BCL6 mRNA levels in CML cells co-cultured with BMSCS. To further explore the role of CXCR4 inhibition in vivo, we established a xenograft bioluminescent model of CML. Luciferase-transduced K562 cells were intra-peritoneally injected into NOD/SCID mice and tumor burden was quantified using bioluminescence imaging. BKT140 (100 μg/injection), administered intra-peritoneally, effectively reduced disease burden.
Summary / Conclusion: Taken together, our data indicate the importance of CXCR4/CXCL12 axis in CML growth and CML-BM stroma interaction. CXCR4 inhibition with BKT140 antagonist efficiently synergized with imatinib, overcoming the protective effect of the BM stroma. These results provide the rational basis for CXCR4-targeted therapy in combination with TKI to override drug resistance and suppress residual disease.

PRECLINICAL AND CLINICAL EFFICACY OF KPT-330-MEDIATED XPO1 INHIBITION IN PH+ LEUKEMIAS

C Walker[1,*], J Oaks[1], R Santhanam[1], P Neviani[1], J Harb[1], G Ferenchak[1], J Ellis[1], Y Landesman[2], A Reid[3], D Milojkovic[3], J Goldman[3], J Apperley[3], R Garzon[1], G Marcucci[1], N Gabrail[4], C Smith[4], S Shacham[2], M Kauffman[2], D Perrotti[1]
[1]Comprehensive Cancer Center, The Ohio State University, Columbus, [2]Karyopharm Therapeutics Inc., Natick, United States, [3]Department of Haematology, Hammersmith Hospital, Imperial College London, London, United Kingdom, [4]Gabrail Cancer Center, Canton, United States

Background: Because ABL tyrosine kinase inhibitors (TKIs) fail to induce long-term response in blast crisis chronic myeloid leukemia (CML-BC) and Philadelphia chromosome-positive (Ph^+) acute lymphoblastic leukemia (ALL), novel therapies targeting pathways dysregulated in either a BCR-ABL1 kinase-independent or –dependent manner, are necessary. The karyopherin exportin1

(XPO1/CRM1) regulates cell proliferation and survival by facilitating nuclear export of several factors, including tumor suppressors (e.g. p53, p21, FOXO and IκB) and leukemia-relevant proto-oncogenes (e.g. hnRNP A1, ABL1 and SET), the expression and/or activity of which have been found altered in BCR-ABL1$^+$ leukemias. Thus, it is possible that XPO1 activity plays an important role in Ph$^+$ leukemogenesis.
Aims: To determine whether XPO1 controls Ph$^+$ leukemogenesis, identify the molecular mechanisms, and assess the clinical relevance of the selective inhibitor of XPO1-mediated nuclear export KPT-330 for Ph$^+$ leukemias refractory to TKI-based therapies.
Methods: *Preclinical:* CD34$^+$ bone marrow (BM) and peripheral blood (PB) progenitors from CML (n=10), ALL (n=9) and healthy (n=8) individuals, and myeloid precursor 32Dcl3 cells were used for immunoblots, Annexin-V staining, confocal microscopy, clonogenic and PP2A phosphatase assays. KPT-330 was used *in vitro* at 0.5-1μM, (12-72 h) whereas it was given twice/week at 15 mg/kg to SCID mice bearing a 32D-BCR/ABL-driven leukemia, used as a CML-BC model. *Clinical:* A 37-year-old male with accelerated phase CML (CML-AP), refractory to 9 prior therapies, including TKIs and several investigational agents, received KPT-330 (16.5 mg/m^2) for compassionate use, after refusing BM transplant.
Results: Compared to normal progenitors, significantly higher XPO1 protein levels were found in CML and ALL blasts. Increased XPO1 expression depended, at least in part, on BCR-ABL1 activity, as it was significantly reduced by imatinib treatment. Accordingly, XPO1 levels were augmented by BCR-ABL1 expression in 32Dcl3 cells. KPT-330 treatment induced apoptosis and decreased clonogenic potential of CML and ALL but not normal progenitors, and increased survival of leukemic mice (P=0.002), 50% of which were alive after 16 weeks of treatment, while all untreated animals died (median survival=5 weeks). Notably, 60% of the surviving KPT-330-treated mice were also BCR-ABL1-negative by RT-PCR, and no drug toxicity was observed in healthy animals. Mechanistically, KPT-330 altered cellular localization of tumor suppressors (p21, p53, FOXO3A and IκB), hnRNP A1 and SET, an inhibitor of the PP2A tumor suppressor phosphatase which, reportedly, is not only inhibited in Ph$^+$ leukemias but, when restored, impairs leukemogenesis and decreases BCR-ABL1 activity/expression. Accordingly, KPT-330 rescued PP2A activity in 32D-BCR/ABL cells, and decreased BCR-ABL1 expression and activity in CML and Ph$^+$ ALL progenitors. Finally, KPT-330 was administered to a CML-AP patient with hyper-leukocytosis and severe bone pain. After a single oral dose, bone pain, immature myeloid cells in PB smears, WBC count (>300,000 to 7,000 cells/μL), splenomegaly (13 to 4 cm below costal margin) and lactate dehydrogenase (513 to 264 IU/L) were reduced. After 7 days, WBC count increased to 37,000 cells/μL with reappearance of leukemic blasts; however, the patient declined dose escalation.
Summary / Conclusion: XPO1 activity is necessary for the enhanced survival of Ph$^+$ leukemic blasts, and KPT-330 may represent an effective treatment for TKI-refractory Ph$^+$ leukemias.

S603

THE CML EPIGENOME SHOWS DYNAMIC CHANGES IN THE CD34+ COMPARTMENT IN PATIENTS WHO ACHIEVE COMPLETE CYTOGENETIC RESPONSE ON TYROSINE KINASE INHIBITORS

A Bazeos[1,*], R Lowe[2], G Nteliopoulos[3], L Foroni[3], G Gerrard[3], J Goldman[3], H de Lavallade[1], V Rakyan[2], J Apperley[1]
[1]Haematology, Imperial College London, [2]QMUL, [3]Imperial College London, London, United Kingdom

Background: CML is thought to originate from acquisition of a BCR-ABL1 fusion gene in a pluripotent stem cell. Despite this consistent event, the clinical course is remarkably heterogeneous. Genetic alterations play a key role in the biological and clinical aspects of CML yet they do not entirely explain the disease pathogenesis. Growing evidence from other leukaemias including acute myeloid leukaemia highlights the interplay between genetic and epigenetic events in shaping the cancer landscape.
Aims: The aim of this work was to perform the first integrated epigenomic study in CML looking at the combined genome-wide DNA methylation and transcriptome profiles of CD34+ cells collected at different stages of the disease in the same patients. We hoped to identify disease-specific and/or stage-specific aberrant epigenetic programming in CML cells as a prelude to or consequence of the t(9;22).
Methods: CD34+ cells were purified from the blood of 29 patients with BCR-ABL1-positive CML in chronic phase (CML-CP) before treatment. These patients all achieved complete cytogenetic response (CCyR) within 12 months of starting imatinib at 400mg/day; they underwent granulocyte colony-stimulating factor (G-CSF) mobilization of Ph-negative peripheral blood stem cells after a median of 23 months. Using the Illumina Infinium HumanMethylation450 and HumanHT-12 v4 Expression BeadChips we compared for each patient the pre-treatment genome-wide DNA methylation and gene expression profile at diagnosis with the corresponding sample obtained in CCyR. Analogous signatures were obtained from CD34+ cells collected from healthy transplant donors treated with G-CSF. Further comparisons between our dataset and other publically available leukemia and solid cancer 450K array data were made using MARMAL-AID, a tool developed in house.
Results: Unsupervised hierarchical clustering of all samples using Ward's method identified differentially methylated probes (DMPs) associated with CML. The three groups formed two major clusters, one from CML-CP samples and the other from the controls and CML-CCyR. In the latter cluster CML-CCyR were distinct but closer to normal CD34+ cells than to the diagnostic samples. In contrast, the CML-CP gene expression signature was closer to healthy controls than to CML-CCyR. We examined the overall gene expression patterns for genes identified as displaying significant differential expression and DNA methylation changes. Separating the methylation probes into those associated with gene promoters or gene bodies we found a significant (P= 7.4e-13) anti-correlation with gene expression in the methylation probes associated with the promoters but not with gene bodies. We identified 3,859 DMPs which distinguished CML-CP from healthy controls. These were enriched in gene bodies (P=1e-16) and intergenic regions (P=1e-16) but depleted in promoter regions (P== 1e-16). The DMPs associated with CML were also enriched above background for associations with CpG Islands (P= 1e-16). CML-CCyR showed global methylation patterns much closer to that of healthy controls with 89% of DMPs returning to within 20% of these controls. Despite this restoration towards normal inter-individual variability was apparent which was not related to clinical parameters including time on imatinib, Bcr-Abl1 transcript levels or the time to MMR. Using MARMAL-AID we were able to define a signature common to leukaemia and solid cancers but in addition we identified a DNA methylation signature unique to CML. On KEGG analysis these probes were significantly enriched for genes related to the JAK-STAT (P= 9e-5) and MAPK (P= 6e-5) pathways.
Summary / Conclusion: We showed a consistent pattern of DNA methylation and gene expression in untreated CML patients, which reverted towards normal at the time of CCyR in the same individuals. The use of publically available reference methylome datasets for normal tissues and cancer types confirmed our identification of a CML-specific DNA methylation signature.

THE ROLE OF RHO KINASE IN THE SURVIVAL OF CHRONIC MYELOID LEUKAEMIA CELLS

L Mukherjee[1,*], M Holmes[1], H Jorgensen[2], M Olson[3], T Holyoake[2]
[1]College of Medival and Veterinary Life Sciences, [2]Paul O'Gorman Leukaemia Research Centre, [3]Beatson Institute for Cancer Research, University of Glasgow, Glasgow, United Kingdom

Background: Chronic myeloid leukaemia (CML) is characterised by expression of an oncogenic tyrosine kinase BCR-ABL that drives uncontrolled proliferation. Inhibition of BCR-ABL with tyrosine kinase inhibitors (TKI) controls the disease in the majority of patients, but in some, TKI resistance develops. Even optimal responders harbour minimal residual disease believed to be the result of persistence of leukaemic stem cells (LSC) despite treatment. CML LSC are not dependent on BCR-ABL for survival and it is therefore hypothesised that alternative pathways regulate their survival and maintenance. The Rho-associated serine/threonine kinases (ROCK) have emerged as central regulators of the actomyosin cytoskeleton. Their function is to promote actin filament bundling and myosin-driven contraction, leading to changes in cell morphology, motility, growth and survival. ROCK is increasingly recognised as an important contributor to cancer and genome sequencing has revealed three ROCK1 activating mutations in human breast and non-small cell lung cancer cell lines. Cells transformed with the oncogenes KITD814V, BCR-ABL and FLT3N51 showed constitutive ROCK activation leading to myeloproliferative disease in mice. Treatment with ROCK inhibitors resulted in cell death and increased lifespan in these mice (1). Our in-house microarray of CML versus normal stem cells, before and after TKI exposure (nilotinib, imatinib, dasatinib), has shown up-regulation of the ROCK pathway in CML LSC that was not fully normalised by TKI treatment. These results suggest that ROCK pathway may represent a critical survival pathway in persistent CML cells.
Aims: We aimed to investigate the role of ROCK in the survival of CML cells, including LSC to ascertain whether the addition of ROCK inhibitors to TKI would result in enhanced CML cell kill, with ultimate applicability in CML TKI resistance or LSC persistence.
Methods: A TKI sensitive human CML blast crisis cell line KCL22 was treated for 24-96h with no drug/TKI(nilotinib)/commercial ROCK inhibitor (H1152)/nilotinib+H1152 at a range of concentration combinations. Viable cell counts and Annexin V staining were analysed by the Chou-Talalay method to ascertain combination indices (CI). Flow cytometry analysis of proteins downstream of ROCK, including phospho-myosin light chain (pMLC) and analysis of DNA content for cell cycle progression were performed on the same cells to investigate the biochemical effects of combination treatment.
Results: We established the IC50 for nilotinib (10 nM) and H1152 (2μM). Cell viability counts showed synergistic cell kill between the two compounds at 24 & 48h. Combining 2 μM H1152 with 10nM nilotinib resulted in 12% increased apoptosis versus best single agent (P=0.0091 using one-way ANOVA with repeated measurements). Flow cytometry showed concentration-dependent inhibition of pMLC, with 88% inhibition at 24h with 2μM H1152. BCR-ABL inhibition alone resulted in G1 arrest and ROCK inhibition alone in G2/M-phase

arrest. Combination of the two reverts this M phase block back to a more normal cell cycle profile.
Summary / Conclusion: The ROCK pathway appears to offer a legitimate and promising potentially novel target for CML patients persistent CML with drug resistance and LSC persistence despite TKI treatment. Investigation is ongoing into the optimal use of the two drugs in combination for the benefit of CML patients.

NEOPLASTIC STEM CELLS OF PH+ CHRONIC MYELOID LEUKEMIA (CML) EXPRESS THE ALPHA-CHAIN OF THE IL-2 RECEPTOR (CD25)
I Sadovnik[1,*], H Herrmann[1,2], S Cerny-Reiterer[1,2], W Warsch[3], A Hoelbl [3], K Blatt[1], G Stefanzl[1], G Hoermann[4], S Herndlhofer[1], B Streubel[5], W Reinhard Sperr[1], C Mannhalter[4], V Sexl[3], P Valent[1,2]
[1]Department of Internal Medicine I, Medical University of Vienna, [2]Ludwig Boltzmann Cluster Oncology, [3]University of Veterinary Medicine Vienna, [4]Department of Laboratory Medicine, [5]Institute of Gynecology & Obstetrics, Medical University of Vienna, Vienna, Austria

Background: Chronic myeloid leukemia (CML) is a myeloid neoplasm characterized by the Philadelphia (Ph) chromosome and the related oncoprotein, BCR/ABL. During the past few years, considerable effort has been made to characterize neoplastic stem cells (NSC) in patients with CML.
Aims: The aim of the present study was to identify new specific markers and targets expressed in CML NSC.
Results: We found that CD34+/Lin-/CD38- CML NSC express the IL-2R-alpha-chain CD25 in almost all patients (31/33=95%). CML NSC were also found to express IL-1RAP, DPPIV (CD26), Siglec-3 (CD33), KIT (CD117) and IL-3RA (CD123). Highly purified NSC were found to express BCR/ABL and to engraft irradiated NOD-SCID-IL-2Rg$^{-/-}$ (NSG) mice with BCR/ABL+ cells, whereasCD34+/CD38-/CD25-/CD26- cells from the same patient failed to express BCR/ABL, and engrafted NSG mice with BCR/ABL-negative cells. To define signaling-molecules contributing to CD25 expression in CML NSC, we employed primary murine hematopoietic cells infected with BCR/ABL-p210 in combination with a retrovirus encoding for STAT5A or STAT5B. Enforced expression of STAT5A/STAT5B resulted in enhanced CD25 expression in leukemic cells. However, STAT5-signaling in CML NCS is regulated by both, BCR/ABL as well as cytokines present in the microenvironment. Correspondingly, BCR/ABL alone was unable to induce a significant expression of CD25 in leukemic cells in mice. Moreover, imatinib did not inhibit expression of CD25 in CML NSC. However, the multikinase inhibitor ponatinib was found to suppress expression of activated STAT5 and expression of the STAT5 target-gene CD25 in CML cells.
Summary / Conclusion: Our data show that CD25 is a novel marker of CML NCS. Application of CD25 may assist in detection, enumeration, and enrichment of NSC in BCR/ABL+ CML.

Drug responsiveness in acute leukemias

DRUG RESPONSE PROFILING TO IDENTIFY NEW TARGETS IN REFRACTORY LEUKEMIA
V Frismantas[1,*], A Rinaldi[1], R Lehal[2], J Boutter[1], M Stanulla[3], C Eckert[4], A Kulozik[5], M Muckenthaler[5], F Radtke[2], B Bornhauser[1], J Bourquin[1]
[1]University Children's Hospital, Zurich, [2]EPFL, Lausanne, Switzerland, [3]University Hospital Schleswig Holstein, Kiel, [4]Charité Berlin, Berlin, [5]University of Heidelberg, Heidelberg, Germany

Background: Acute lymphoblastic leukemia (ALL) is a genetically highly complex disease. Despite enormous recent genomic profiling efforts that identified underlying lesions, the use of individual genetic lesions as predictive markers for treatment response has been so far very limited, and functional correlations of oncogenic lesions with drug response profiles are ill defined for childhood acute lymphoblastic leukemia (ALL).
Aims: We have decided to pursue a reverse approach, namely to obtain phenotypic information with extended functional drug response profiling and to correlate this with other diagnostic, including genetic, information. In particular, preclinical testing of new therapeutic agents should be designed to evaluate multiple combinations to detect synthetic lethality directly in the relevant clinical samples.
Methods: Based on a collection of ALL xenografts that we established from patients enrolled on the ALL-BFM-2000 and ALL-REZ-BFM 2002 treatment protocols, we developed an automated-imaging based platform for large scale *in vitro* drug testing. This approach enables us to evaluate a large number of compounds very effectively directly on primary ALL cells that are maintained on bone marrow mesenchymal stromal cells, which recreates a standardized serum free natural microenvironment.
Results: Using this platform, we provide evidence for activity profiles of a selection of bioactive molecules and new therapeutic agents in primary samples from distinct ALL subgroups.
We obtained patient specific response patterns by comparing samples from distinct subtypes of precursor B-cell ALL including samples with translocation t(17;19) - a highly resistant subtype - and with t(1;19) - a subtype that is associated with good outcome, as well as T-ALL samples. This approach identifies classes of compounds with a high degree of activity across multiple samples, such as inhibitors of mTOR or chromatin remodelling. Using this platform we detected reproducible activity of the new NOTCH inhibitor I3 which blocks transcription by interfering with the NOTCH transcriptional complex in the low micromolar range (1μM) specifically in T-ALL samples in which the cleaved intracellular fragment of Notch1 (ICD) could be detected by immunoblotting. We identified I3-responsive cases that were not shown to have a mutation in NOTCH1 or FBXW7 but in which Notch1 ICD was strongly detected, indicating that such a functional screening platform has the potential to capture samples with deregulation of the NOTCH pathway that would not be predicted based on mutation analysis.
Summary / Conclusion: Our data indicate presence of specific drug response profiles in genetically distinct ALL subtypes and suggest that our platform will be useful for *in vitro* ALL drug profiling. We expect to derive relevant functional information directly from individual patient samples, which may mirror perturbations in relevant cellular programs. We will evaluate this system for the identification of novel anti-leukemic compounds, for the definition of predictive profiles of clinical response and will evaluate synthetically lethal drug combinations to identify new alternatives for the treatment of refractory ALL.

S607

TARGETING COMPONENTS OF THE ALTERNATIVE NHEJ PATHWAY SENSITIZES KRAS-MUTANT LEUKEMIC CELLS TO CHEMOTHERAPY
P Haehnel[1,*], B Enders[1], W Roos[2], B Kaina[2], M Theobald[1], T Kindler[1]
[1]Third Department of Medicine, Division of Hematology/Oncology/Pneumology, [2]Institute of Toxicology, University Medical Center of the Johannes Gutenberg-University, Mainz, Mainz, Germany

Background: Activating KRAS mutations are detected in a substantial number of hematologic malignancies. Using a conditional *KRAS^{G12D}* knock-in mouse model, we and others have demonstrated that expression of oncogenic Kras in hematopoietic progenitor cells causes an arrest at the DN2/3 stage during T-cell differentiation followed by the development of an aggressive T-cell lymphoblastic leukemia/lymphoma with long disease latency. Interestingly, 50% of analyzed leukemia samples harbored Notch1-mutations, likely acquired during the Kras^{G12D}-mediated block in differentiation *(Kindler et al., Blood 2008*). These additional mutations may be acquired by replicative stress or increased reactive oxygen species (ROS) production. Alternatively, oncogenic RAS may directly affect DNA repair pathways, thereby causing misrepair and, due to concomitant resistance to apoptotic cell death, accumulation of genomic changes. Recent studies indicate that DNA damage response and repair (DDR)

can be disturbed within a defined malignant background. For example, leukemic cells harboring FLT3-ITD or BCR-ABL oncogenes preferentially use the alternative non-homologous end-joining pathway (alt-NHEJ) for double strand break (DSB) repair *(Sallmyr A. et al., Blood 2008; Fan J et al., Blood 2010)*. Mechanism of DDR in context of mutated KRAS are currently poorly understood.
Aims: The goal of this study was to investigate the impact of mutated KRAS on DDR and to identify potential therapeutic targets in the case of altered DNA repair.
Methods: The T-ALL cell line CCRF-HSB2 and the AML cell line U-937 were lentivirally transduced to express mutant $KRAS^{G13D}$. In an alternative approach we suppressed KRAS expression in Nomo-1 AML cells, harbouring an endogenous *K-Ras^{G13D}* mutation. Additionally, Lck-Cre mice were crossed with Lox-stop-Lox-$KRAS^{G12D}$ mice. Using the described *in vitro* and *in vivo* models, we examined the functional consequences of oncogenic KRAS expression on DDR.
Results: Expression of oncogenic KRAS correlated with increased resistance to genotoxic stress, elevated levels of DNA damage and delayed repair kinetics of DSBs as revealed by γH2AX-staining and the neutral comet assay, respectively. In addition, using an *in vitro* plasmid religation assay we observed increased DNA misrepair in the context of mutated KRAS. Sequencing analysis of the religated DNA ends demonstrated a preferred use of DNA-microhomologies accompanied by large deletions. These findings have previously been shown to be strongly associated with the recruitment of the alt-NHEJ DNA repair pathway. Interestingly, immunoblot analysis demonstrated increased expression of DNA ligase-3α, PARP1 and XRCC1, all crucible components of an alt-NHEJ pathway, in KRAS-mutant cell lines compared to KRAS-wt control cells. To address the question whether the aberrant use of the alt-NHEJ pathway in KRAS-mutant cells represents a therapeutic target, we treated KRAS-mutant and –wt cells with the PARP1-inhibitor NU1025 or downregulated the expression of DNA ligase-3α using shRNA. Inhibition of PARP1 or knockdown of DNA ligase-3α significantly reversed resistance to apoptotic cell death upon treatment with cytotoxic agents. Of note, this effect was only observed in cells expressing oncogenic KRAS suggesting specific vulnerability of KRAS-mutated cell.
Summary / Conclusion: Here, we show that mutant KRAS shifts the balance between the classical NHEJ DNA repair pathway towards the highly error-prone alt-NHEJ pathway. We further show that inhibition of components of the alt-NHEJ pathway including PARP1 and DNA ligase 3α is able to specifically sensitize KRAS-mutant cells to genotoxic agents. These data suggest that targeting the alt-NHEJ pathway represents a promising therapeutic approach in cells harboring otherwise non-druggable KRAS mutations.

S608

DYNAMICS OF EXPANSION OF TYROSINE KINASE INHIBITOR-RESISTANT MUTANTS AS ASSESSED BY DEEP SEQUENCING OF THE BCR-ABL KINASE DOMAIN: IMPLICATIONS FOR ROUTINE MUTATION TESTING

S Soverini[1,*], C De Benedittis[1], K Polakova[2], A Brouckova[2], C Papayannidis[1], M Abbenante[1], I Iacobucci[1], C Venturi[1], A Ferrari[1], F Cattina[3], D Russo[3], M Luppi[4], P Bresciani[4], A Vitale[5], R Foà[5], M Baccarani[6], M Cavo[1], G Martinelli[1]
[1]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy, [2]Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [3]Chair of Hematology, University of Brescia, Brescia, [4]Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, Modena, [5]Department of Cellular Biotechnology and Hematology, University of Rome 'La Sapienza', Rome, [6]University of Bologna, Bologna, Italy

Background: In Philadelphia-positive (Ph+) acute lymphoblastic leukemia (ALL) patients (pts), efficacy of tyrosine kinase inhibitor (TKI)-based therapies is often compromised by selection of resistant mutations in the BCR-ABL kinase domain (KD). Currently, the gold standard for BCR-ABL KD mutation screening is conventional Sanger sequencing (SS). However, more sensitive approaches are desirable to allow more timely and rational therapeutic intervention.
Aims: A Deep sequencing (DS) strategy based on the Roche 454 next-generation sequencing technology was set up in order to: study the dynamics of expansion of different types of BCR-ABL KD mutations in Ph+ ALL patients developing resistance to TKI-based therapies; test the ability of DS to highlight emerging clones harboring TKI-resistant mutations.
Methods: 29 Ph+ ALL pts who had developed resistance to TKI-based (imatinib, dasatinib, nilotinib) therapies were selected for this retrospective analysis. All the pts were known to have developed TKI-resistant BCR-ABL mutations on treatment, as assessed by SS. To reconstruct the dynamics of mutation emergence, longitudinal re-analysis of samples from relapse backwards (n=97; 1-3 months sampling interval) was performed on a Roche GS Junior instrument. DS runs were designed so as to enable high sensitivity mutation calling (minimum target sequence coverage 4,000 reads). However, to minimize the likelihood of false positive results, data were analyzed filtering out all variants with <1% abundance.
Results: DS could successfully detect all the mutations (n=85) previously identified by SS (>15% abundance). In addition, DS revealed that both those samples that had been scored as apparently wild-type by SS and those samples already known to harbor mutations as assessed by SS might be carrying one or more 'lower level' mutations (<15% abundance). In the latter cases, clonal analysis showed complex textures with the same mutation alone and also in combination with other(s) ('compound' mutations) in distinct subclones. Some lower level mutations were silent or apparently irrelevant from a clinical standpoint (passenger mutations?). In more than half of the cases, however, known TKI-resistant variants could be recognized that corresponded either to 'withdrawing' mutants not (yet) entirely de-selected by the switch in TKI or to outgrowing mutations anticipating an imminent relapse. Lower level mutations were confirmed with independent methods (ASO-PCR, RFLP). Notably, in 16/29 (55%) pts with molecularly detectable disease but not yet evidence of cytogenetic or hematologic relapse, DS could identify emerging mutations 1 to 3 months before they became detectable by SS. In the remaining 13 pts, however, outgrowth of the TKI-resistant mutation (T315I=7, Y253H=2, E255K=2, E255V=1 and F317L=1) was so rapid that not even a strict monthly monitoring could have allowed to pick them up before they became dominant.
Summary / Conclusion: Now that multiple options are available, BCR-ABL KD mutation monitoring is a precious tool to maximize the efficacy of TKI-based regimens as induction or salvage therapy of Ph+ ALL. DS proved as reliable as SS for the detection of mutations with >15% abundance. As a key advantage, DS added precious quantitative and qualitative information on the full repertoire of mutated populations, that SS underestimated in more than half of the samples analyzed. TKI-resistant mutations leading to patient relapse were not necessarily preexisting at diagnosis or at the time of switchover to another TKI, underlining the importance of regular monitoring of pts. Although the majority of mutations were found to arise and take over very rapidly, a monthly monitoring by our DS approach would have allowed to identify them earlier than SS actually did - and well in advance of clinical relapse - in half of the pts. DS technologies would enable higher sensitivity mutation calling: further studies are warranted to determine the optimal lower detection limit to aim to in order to exclude both transient mutant subclones that will never take over and sequencing errors.

Background: Clinical resistance to TKI is associated with the presence of BCR-ABL TKD mutations in approximately 80-90% of patients with Ph+ALL, with a preponderance of p-loop and T315I mutations. The frequency of mutations depends on the specific TKI administered due to the different sensitivity of individual mutations to TKI inhibition. While p-loop mutations may be susceptible to second generation TKI their impact and that on stem cell transplantation (SCT) on long-term treatment outcome are not known.
Aims: This retrospective analysis examines the prognostic relevance of p-loop mutations detected by direct sequencing in patients with Ph+ALL in relation to disease history, prior therapy and the type of salvage treatment. We also examined the kinetics of p-loop mutations, the impact of 2nd generation TKI on long-term survival, the achievement of SCT and the eradication of mutated clones by specific therapy.
Methods: 63 ALL-pts. who developed p-loop mutations at some point during their course of treatment were identified. Frontline-treatment was given according to GMALL studies 05/93 and 06/99 (n=21), 07/03 (n=6), GMALL elderly studies (n=31), TKI alone (n=1) or other TKI-based regimens (n=4). 37 pts. (58%) were treated with an imatinib based regimen before the first occurrence

of the p-loop mutation. Median age at diagnosis was 61 yrs.(range 15-80), 51% male. Minimal residual disease (MRD) was serially assessed by quantitative RT-PCR, mutational analyses was performed by direct sequencing.
Results: The P-loop mutation was detected during frontline therapy prior to relapse in 11 pts., at first, second and third relapse in 41 pts. (65%), 10 (16%), 7 (11%), respectively. Median time between initial diagnosis and the detection of the p–loop mutation was 9.5 mo. (range 2.1–37.8) for pts. who received IM during initial therapy vs.12.04 mo. (3.6 – 98 mo) with a IM-free regimen. Following detection of a mutation, 80 % of pts. received TKI based therapy (imatinib n=17 (26%), nilotinib n=6 (10%), dasatinib n=28 (44%). 14 (22%) pts underwent allogeneic transplantation. Median OS from first detection of a p-loop mutation was 5.3 months. 2 are in ongoing CR and alive (f.-up 1465 d, 58 d). All transplanted pts. died due to progressive disease (n=6) or TRM (n=8). 6 pts. developed compound mutations,a switch to a different TKD mutation was noted in 26 pts.
Summary / Conclusion: The outcome of Ph+ALL pts. who develop a TKD p-loop mutation is dismal, despite the availability of potent 2nd generation TKI and allogeneic SCT. This highlights the importance of preventing resistance mutations during front-line therapy, and the need to identify mutant clones earlier using more sensitive techniques than direct sequencing.

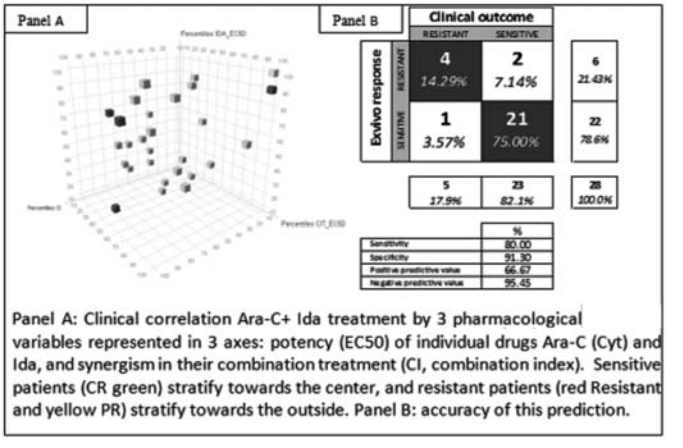
Background: Complete remission (CR) after induction therapy is the first treatment goal in acute myeloid leukemia (AML) patients. Several clinical and biological features, like cytogenetics and molecular alterations, may advance the probability to achieve CR. However, to date, there is no test accurately predicting the response to specific drug combinations allowing the use of specific induction therapies for individual patients.
Aims: The aim of this study is to determine the ability of the Vivia's Personalized Medicine Test (PM) to predict the CR rates after induction chemotherapy with cytarabine (Ara-C) and idarubicin (Ida) in patients diagnosed with AML, using an *ex vivo* drug sensitivity test, based on the analysis of leukemic cells death.
Methods: This non-interventional and prospective study included samples from adult patients over 18 years of age who were diagnosed with de novo AML in Spanish centres from the Programa Español de Tratamientos en Hematología (PETHEMA) group. Marrow samples were collected at diagnosis, sent to the Vivia laboratories, and incubated for 48 hours in well plates containing Ara-C, Ida, or the combination Ara-C+Ida, each at 8 different concentrations to calculate dose responses. Annexin V-FITC was used to quantify the drug-induced apoptosis. Pharmacological responses are calculated using pharmacokinetic population models, which essentially performs the fitting of each dose response across all patient samples simultaneously. Induction response was assessed according to the Cheson criteria (2003). Patients attaining a CR/CRi were classified as responders. The remaining patients were considered as resistant. Patients dying during induction response assessment were non-evaluable.
Results: Seventy patient samples were used to calculate the dose response curves for Ara-C alone, Ida alone, and Ara-C plus Ida. For clinical correlation, 28 patients with a median age of 53 years (range 33 to 71), were included in the study. Twenty-three patients (82%) achieved CR after Ida+Ara-C, and the remaining 5 (18%) were resistant. Correlations of the PM test are showed in Figure 1, Panel B. Four of the five (80%) patients who fail to achieve CR were predicted as resistance in the *ex vivo* test. Twenty-one of the 23 patients (91%) who achieved CR showed good *ex vivo* sensitivity to Ida+Ara-C predicting for CR. Overall, 25 patients (89%) had an accurate prediction of their response to treatment. Panel A shows the 3D representation of the 3 key pharmacological variables that predict clinical response: the potency of both Ara-C (labeled Cyt EC50) and Ida (Ida EC50) used alone; and the synergism between them in the combination (labeled CI). The variables are represented not in absolute but in relative values, as percentiles, orienting the best scenario (high drug potency or high synergism) towards the zero axis point. This means that patients whose pharmacological parameters are positioned towards the center of the 3D graph would be predicted sensitive, while patients positioned towards the outside of the graph would be predicted resistant. Indeed, sensitive patients colored green appear towards the center of the graph, while resistant patients colored red and yellow appear towards the outside of the graph.
Summary / Conclusion: This study shows that this novel PM Test is able to predict the clinical response to Ida+Ara-C induction. We are increasing the number of patients in this ongoing study, and we are planning a PM Test-adapted European Clinical Trial.



Panel A: Clinical correlation Ara-C+ Ida treatment by 3 pharmacological variables represented in 3 axes: potency (EC50) of individual drugs Ara-C (Cyt) and Ida, and synergism in their combination treatment (CI, combination index). Sensitive patients (CR green) stratify towards the center, and resistant patients (red Resistant and yellow PR) stratify towards the outside. Panel B: accuracy of this prediction.

THALIDOMIDE FOR THE TREATMENT OF SEVERE RECURRENT EPISTAXIS IN HEREDITARY HEMORRHAGIC TELANGIECTASIA: INTERIM ANALYSIS OF A PROSPECTIVE TRIAL

R Invernizzi[1,*], F Bellistri[1], F Pagella[1], F Chu[1], E Matti[1], G Spinozzi[1], F Ornati[1], C Canzonieri[1], C Olivieri[1], F Quaglia[1], R Bastia[1], C Danesino[1], M Benazzo[1], C Balduini[1]
[1]IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: Hereditary hemorrhagic telangiectasia (HHT; OMIM 187300 and 600376), also known as Rendu-Osler-Weber syndrome, is an autosomal dominant disease that leads to multiregional angiodysplasia. Recurrent severe epistaxis is the most common presentation of HHT, frequently leading to severe anemia. In the management of HHT epistaxis, multiple approaches, including surgical options, have been tried, but all approaches are largely palliative with variable and temporary results. Since angiogenesis has been implicated in the pathogenesis of HHT, it has been suggested that anti-angiogenic substances may be effective in the treatment of vascular malformations.
Aims: The aims of our ongoing open label, phase II, prospective, non-randomized, single centre study are to evaluate the effectiveness of thalidomide in reducing epistaxis and to identify the lowest effective dose of the drug in patients with HHT refractory to standard therapy as well as to evaluate specific biological and clinical parameters predictable for response and side effects profile (EudraCT 2011-004096-36, ClinicalTrials.gov Identifier: NCT01485224).
Methods: HHT patients with at least one episode of overt bleeding/week requiring at least one blood transfusion during the last three months and refractory to mini-invasive surgical procedures are enrolled. Thalidomide, supplied for compassionate use, is administered at a starting dose of 50 mg/day orally. In the event of no response, thalidomide dosage is increased by 50 mg/day every 4 weeks until complete (cessation of nose bleeding) or partial response (reduction in the severity of epistaxis less than complete response) to a maximum dose of 200 mg/day. After the achievement of complete/partial response patients are treated for 16 additional weeks. Monthly follow-up evaluates the epistaxis severity score according to well defined criteria (Am J Rhinol Allergy 2009;23:52-58) and the transfusion need, with adverse events being reported.
Results: Eighteen patients for whom informed consent was obtained, 11 M and 7 F, aged 44-80 years (median 60), with mutations in either *ACVRL1* (15 cases) or *ENG* gene (3 cases) have been enrolled so far (median follow-up 28 weeks, range 2-64). Treatment was effective in all 15 evaluable patients. Seven patients responded within 4 weeks of starting the drug: complete response was observed in one case, and partial response has been obtained in 6 cases. Eight patients achieved a good, partial response after 8 weeks of treatment. As a consequence, thalidomide therapy significantly increased hemoglobin levels (P=0.04), abolished or greatly decreased the need for red blood cell transfusions and improved the quality of life. Only nonserious, drug-related adverse effects were observed during treatment, including constipation and drowsiness. In no patient thalidomide had to be discontinued. Ten patients completed the treatment: 6 remained stable, off of thalidomide, without the loss of response during a median follow-up of 21 weeks, range 8-44, whereas 4 patients relapsed in 4 weeks after the end of treatment. No correlation was found between genetic or clinical features and time to response or response duration.
Summary / Conclusion: These results strongly support the hypothesis that low-dose thalidomide is safe and very effective for the treatment of epistaxis in patients with severe HHT who did not benefit from other available modalities of treatment, allowing for a rapid and often durable clinical improvement.

S612

EXTRACELLULAR HISTONES-INDUCE MICROCIRCULATORY THROMBOSIS AND ACUTE RESPIRATORY FAILURE

S Abrams[1*], J Manson[2], T Liu[1], Y Alhamdi[1], K Brohi[2], G Wang[1], C Toh[1]
[1]Institute of Infection and Global Health, University of Liverpool, Liverpool, [2]Trauma Sciences, Queen Mary University of London, London, United Kingdom

Background: Extensive cell damage associated with coagulation activation and the development of respiratory failure are common features in critically illness but the underlying pathophysiological mechanisms remain unclear. During cell death, nuclear breakdown products and histones in particular, are released into the circulation and cause toxicity through thrombin generation, platelet aggregation, endothelial damage and cytokine release. The release of extracellular DNA and histones from neutrophils during neutrophil extracellular trap (NET) formation also facilitates thrombus formation and has shown relevance in animal models of deep vein thrombosis, transfusion-related acute lung injury, cancer, trauma and sepsis.
Aims: These recent discoveries led us to hypothesize whether extracellular histones serve as mediators of respiratory failure after extensive cell death.
Methods: To investigate this further, we used *in vivo* experimental models and clinical samples from patients with severe non-thoracic trauma.
Results: Markers for endothelial damage (sTM) and coagulation activation (TAT) significantly increased immediately after trauma or histone-infusion in mice. Cardiac function was impaired in histone-infused mice with increased pulmonary pressure and right ventricular size. Pathological examination showed that lungs were the predominantly affected organ with severe edema, multicocal alveolar hemorrhage, microvascular thrombosis, cytokine surge, pulmonary capillary congestion and significant neutrophil infiltration. In fact, histones directly induced morphological changes of neutrophils, resulting in the formation and deposition of NETs in the pulmonary microcirculation, suggesting that NET formation may serve as a mechanism for neutrophil congestion and thrombosis in lungs. Clinically, circulating histone levels surged significantly immediately after injury to levels that were toxic to cultured endothelial cells (≥50 μg/mL). The high levels were significantly associated with the incidence of acute respiratory failure and SOFA scores, as well as sTM (median: 4.6, quartile: 3.6, 5.5 ng/ml) and TAT levels (median: 81.2, quartile: 33.7, 110.3 ng/mL).
Summary / Conclusion: This work has elucidated a new mechanism for respiratory failure in critically ill patients and proposes future translational intervention with rapid assays to monitor circulating histone levels and anti-histone therapies to reduce thrombosis and improve the pulmonary microcirculation. These findings have wider relevance when histones are released from damaged cells or neutrophils during NETosis, suggesting that anti-histone therapy could potentially protect against the development of respiratory failure and improve overall outcome in many critical illnesses.

S613

CLINICAL COURSE OF CEREBRAL VENOUS THROMBOSIS IN ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

M Lauw[1,2,*], S Zuurbier[3], J Coutinho[3], C Majoie[4], B Van der Holt[5], J Cornelissen[6], S Middeldorp[2], B Biemond[1], J Stam[3]
[1]Dept. of Hematology, [2]Dept. of Vascular Medicine, [3]Dept. of Neurology, [4]Dept. of Radiology, Academic Medical Center, Amsterdam, [5]HOVON Data Center, [6]Dept. of Hematology, Erasmus MC-Daniel den Hoed, Rotterdam, Netherlands

Background: Venous thromboembolism (VTE) occurs frequently in patients with acute lymphoblastic leukemia (ALL). Reported incidence varies between 2 and 36%. Remarkably, cerebral venous thromboses (CVT) form a relatively large proportion of VTE and represent up to 50% of events.
Aims: To explore the clinical course of a large number of CVT episodes that occurred in a well-defined cohort of adult patients treated for ALL. We analyzed clinical characteristics, prodromal symptoms, radiological characteristics, time relationships with treatment components of ALL, clinical outcome of CVT and impact of CVT on ALL treatment.
Methods: CVT incidence was assessed in 240 adults (16-59 years) treated for newly diagnosed ALL in the Dutch-Belgian HOVON-37 multicenter study (1999-2005; NTR228 on www.trialregister.nl). Patients generally received 3 cycles of combined chemotherapy before stem cell transplantation assessment. CVT was defined as an intraluminal filling defect or presence of a thrombus in one of the cerebral veins or sinuses, detected with magnetic resonance venography or computed tomographic venography. For patients with CVT, we systematically extracted clinical data from patient records and re-evaluated imaging results. We conducted a nested case-control study to explore relevant prodromal symptoms. Associations were expressed as odds ratios (OR) with corresponding 95% confidence intervals (CI).
Results: 9 of 240 patients experienced CVT (4%; median age 33 years (range 17-49), 56% female, 5 with B-ALL and 4 with T-ALL). CVT was preceded by headache in 8 of 9 patients, while only 5 of 18 matched controls without CVT reported headache (OR 20.8; 95% CI 2-212). Seizures occurred in 8 of 9 patients with CVT and in none of 18 controls (OR 280; 95% CI 9-9236); 6 patients with CVT presented with focal neurological deficits versus 2 of 18 controls (OR 16; 95% CI 2-121). Median time between symptom onset and CVT diagnosis was 1 day (range 0-6). CVT was located in the superior sagittal sinus in 8 of 9 patients. 7 of 9 patients had cerebral parenchymal lesions (5 hemorrhagic infarcts, 2 non-hemorrhagic infarctions). All CVT events occurred during Cycle I of remission induction treatment; in 8 of 9 patients during or shortly after L-asparaginase therapy (*E.coli*) and in all patients after at least one dosage of intrathecal methotrexate (Figure 1). CVT formed 38% of all VTE during Cycle I. Two patients underwent endovascular thrombolysis and mechanical thrombectomy in addition to anticoagulant therapy; both died in the acute phase due to transtentorial herniation. After 12 months, three additional patients had died due to ALL-related causes. The surviving patients did not experience enduring neurological morbidity due to their CVT. Two of nine patients with CVT had recurrent VTE, none a recurrent CVT. CVT occurrence was adversely associated with attainment of complete remission on protocol (adjusted OR 0.12; 95% CI 0.03-0.51).
Summary / Conclusion: Although CVT is a rare manifestation of VTE, our study indicates it is much more common among adult ALL patients, with an adverse impact on ALL treatment outcomes and a high mortality rate in the first year after the thrombotic event. CVT often occurred during L-asparaginase and methotrexate therapy in Cycle I of remission induction treatment. Presence of

headache and seizures were strongly associated with CVT. Close monitoring of headache during ALL treatment may contribute to earlier detection of CVT and could improve its outcome.

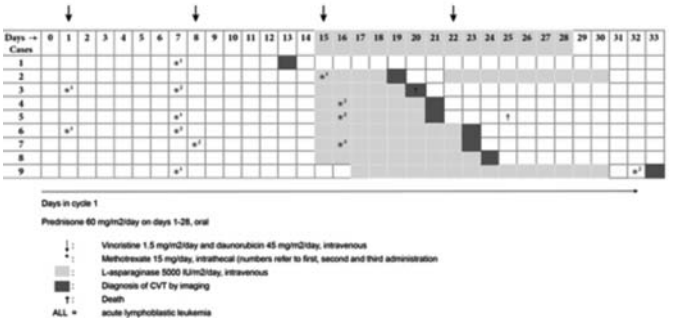

Figure 1. Time relationship between cerebral venous thrombosis (CVT) and ALL treatment component in HOVON-37 ALL study Cicle I. Bleeding &

S614

EVALUATION OF SEVERE THROMBO-HEMORRHAGIC SYNDROME (THS) BY ASSESSING LEVELS OF ACTIVATED FVII-ANTITHROMBIN COMPLEX (FVIIA-AT) AND TISSUE FACTOR (TF) MRNA IN ACUTE PROMYELOCYTIC LEUKEMIA (APL) PATIENTS

M Marchetti[1,*], L Russo[2], C Tartari[1], B Woodhams[3], G Rossi[4], E Di Bona[5], A Rambaldi[6], F Lo Coco [7], A Falanga[1]
[1]Division of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bargamo, [2]Division of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bergamo, Italy, [3]HaemaCon Ltd, Bromley, United Kingdom, [4]Division of Hematology, Spedali Civili di Brescia, Brescia, [5]Division of Hematology, Ospedale S. Bortolo, Vicenza, [6]Division of Hematology, Hospital Papa Giovanni XXIII, Bargamo, [7]Division of Hematology, University Tor Vergata, Roma, Italy

Background: The onset of APL is characterized by a severe thrombo-hemorrhagic syndrome (THS) responsible of a high rate of hemorrhagic deaths, mainly due to intracerebral hemorrhages. The pathogenesis of the THS is complex and TF expressed by APL cells may have an important role. Differentiation therapy with all-trans retinoic acid (ATRA) downregulates TF expression by APL blasts and produces a simultaneous correction of the hypercoagulation and THS. However, the rate of early deaths due to the THS is still relevant. Therefore, characterizing the THS and identifying predictive markers remains a critical issue.
Aims: To prospectively evaluate in newly diagnosed APL patients the rate of hemorrhage and thrombosis in the first month after diagnosis, in relation to plasma levels of FVIIa-AT, a new parameter reflecting the degree of TF exposure and activity, thrombin-antithrombin (TAT) complex, D-dimer, and cellular TF mRNA.
Methods: Fifty-four patients (29M/25F) diagnosed with APL admitted to the Divisions of Hematology (Bergamo, Brescia, Rome, Vicenza) were enrolled from January 2000 to February 2009. All patients received induction therapy with Idarubicin + ATRA (GIMEMA AIDA 2000 protocol) and were prospectively monitored for thrombo-hemorrhagic episodes for 4 weeks. Blood samples from 26 of these patients were obtained at the onset (T0) of the disease, and on days 7, 14 and 28 (T7, T14, T28) of remission induction therapy. Twenty-five healthy subjects acted as controls.
Results: At T0, 14.8% of patients presented with early major hemorrhages, including 3 fatal intracranial bleeding and 5 non-fatal major bleeding; while 7.4% had thrombosis (1 fatal and 3 non-fatal events). Two more patients developed deep vein thrombosis at T7 and T14, respectively. Of the 26 patients included in the laboratory study, 3 had thrombosis at diagnosis. At T0, before starting therapy, FVIIa-AT, TAT and D-dimer levels were significantly higher in APL patients compared to controls (P<0.05). FVIIa-AT progressively decreased at T7 and T14, and dropped significantly at T28 (P<0.05 vs T0); TAT and D-dimer also decreased starting from T7 to T28 (P<0.05 vs T0). In addition, in peripheral blood mononuclear cells (PBMC) isolated from 9 APL patients, TF mRNA, initially elevated compared to healthy subjects (P<0.05), significantly decreased from T7 to T28. Interestingly, the 3 patients with thrombosis showed lower plasma levels of FVIIa-AT compared to those without (120±50 vs 332±75 ng/ml), while TAT and D-dimer were not different between the two groups. This might suggest FVIIa-AT as a more sensitive marker of the consumption coagulopathy compared to the other markers.
Summary / Conclusion: Our study confirms a significant rate of thrombo/hemorrhagic events in APL patients. Plasma FVIIa-AT complex level paralleled TF mRNA expression and may therefore be a useful surrogate tool for the TF activity measurement in the peripheral blood. In addition, the study shows that, among hypercoagulation markers, which are overall elevated at the onset of APL, the 'low' plasma FVIIa-AT complex level is capable to distinguish patients at the highest risk of severe THS. Although the small size of the study did not allow to calculate the predictive value of this marker, FVIIa-AT complex may be a promising simple candidate biomarker to test for the predictive risk of lethal/severe THS in larger prospective studies.

S615

DEFERASIROX PREVENTS CARTILAGE DAMAGE FOLLOWING HEMARTHROSIS IN HEMOPHILIC MICE, DEMONSTRATING IN VIVO THE ROLE OF IRON IN BLOOD-INDUCED CARTILAGE DAMAGE AND PROVIDING A POTENTIAL TARGET FOR THERAPY.

L Nieuwenhuizen[1,2,*], G Roosendaal[1], S Mastbergen[2], K Coeleveld[2], D Biesma[1], F Lafeber[2], R Schutgens[1]
[1]Hematology / Van Creveldkliniek, [2]Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Joint bleedings upon trauma or major joint surgery and in hemophilia result in iron-mediated synovitis and cartilage destruction.
Aims: It was evaluated whether deferasirox, an iron chelator, was able to prevent the development of hemophilic synovitis and cartilage damage.
Methods: Hemophilic mice were randomly assigned to oral treatment with deferasirox (30 mg/kg) or its vehicle (control) (30mg/kg). After two months of pretreatment, the right knees were punctured to induce hemarthrosis. The mice were sacrificed after another five weeks of treatment. Post-mortem, knee joints were isolated, sectioned for histology and stained with hemotoxylin-eosin and safranin O. Blood-induced synovitis and cartilage damage were determined by two blinded observers.
Results: Treatment with deferasirox resulted in a statistically significant (P<0.01) decrease in plasma ferritin levels as compared to the control group (823 ng/mL ±56 and 1220 ng/mL ±114, respectively). Signs of hemophilic synovitis, as assessed by the Valentino score (score 0-10), were not different (P=0.52) when comparing the control group to the deferasirox group: score 1 (12.4% vs. 7.7%), 2 (16.7% vs. 11.5%), 3 (12.5% vs. 38.5%), 4 (29.2% vs. 19.2%), 5 (16.7% vs. 11.5%), 6 (4.2% vs. 7.7%), and 8 (8.3% vs. 3.8%). However, deferasirox treatment resulted in a statistically significant (P<0.01) reduction in cartilage damage, as assessed by the Glasson score (score 0-6), when comparing the control group to the deferasirox group: 2 (4.2% vs. 65.4%), 3 (4.2% vs. 26.9%), 4 (20.8% vs. 7.7%), 5 (54.2% vs. 0%), and 6 (16.7% vs. 0%).
Summary / Conclusion: Treatment with deferasirox prevents cartilage damage following the induction of a joint hemorrhage in hemophilic mice. This in vivo study demonstrates the role of iron in blood-induced cartilage damage. Moreover, these data indicate iron chelation to be a potential treatment option to limit the development of hemophilic arthropathy.

POSTER SESSION II

Acute lymphoblastic leukemia - Clinical

P616

MINIMAL RESIDUAL DISEASE BEFORE AND AFTER TRANSPLANTATION FOR CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: IS THERE ANY ROOM FOR INTERVENTION?

A Balduzzi[1,*], L Di Maio[1], D Silvestri[2], S Songia[3], S Bonanomi[1], A Rovelli[1], V Conter[1], A Biondi[1], G Cazzaniga[3], M G Valsecchi[2]
[1]Pediatric Clinic, [2]Centro di Ricerca in Biostatistica per l'Epidemiologia Clinica, Univ. Milan Bicocca, [3]Centro Ricerca Tettamanti, Fondazione Tettamanti, Monza, Italy

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is considered of benefit for approximately 10% of the patients who are at very-high risk at frontline therapyand for the majority of the patients after relapse. Nevertheless, relapse remains the most frequent cause of treatment failure after transplantation. During the last decade, the prognostic role of minimal residual disease (MRD) has been shown in frontline protocols.and in relapse protocols, even when MRD was used to stratify patients and tailor risk-adapted therapy. MRD was shown as a relevant prognostic factor also in the transplantation setting with higher levels of MRD before HSCT being associated with higher risk of relapse and lower event-free survival after transplant. Pre-emptive interventions after HSCT were also attempted based on MRD at HSCT.
Aims: To assess the impact of MRD before and after HSCT on outcome, and to evaluate the impact of possible interventions in a series of consecutive ALL patients transplanted in a single Institution.
Methods: MRD was monitored by real-time quantitative PCR of clonal patient-specific rearrangements of Immunoglobulin and T-cell receptor genes. PCR-MRD targets were tested for specificity and sensitivity for each patients with the aim to select 2 targets with a sensitivity of at least 10^{-4} and a quantitative range of at least 10^{-4} for one target and at least 5×10^{-4} for the second target. RQ-PCR analysis was performed and interpreted according to the guidelines developed within the European Study Group for MRD detection in ALL (EuroMRD ALL).
Results: Eighty-two children and adolescents who underwent allogeneic transplantation for ALL in remission (period 2001-2011,median follow-up 4.9 years) had been assessed for MRD before and at 1,3,6,9 and 12 months after transplantation. Five-year-EFS and CIR were 77.7%(SE5.7) and 11.4%(SE4.4), respectively, for patients with pre-transplant MRD$<1\times10^{-4}$(68%), *versus* 30.8% (SE9.1) (P-value <0.001) and 61.5%(SE9.5) (P-value<0.001), respectively, for those with MRD$^3 1\times10^{-4}$(32%). Pre-transplant MRD$^3 1\times10^{-4}$ was associated with a 9.2-fold risk of relapse (CI 3.54-23.88; P-value<0.001) compared with patients with MRD$<1\times10^{-4}$. Patients who received pre-transplant additional chemotherapy to reduce MRD had a 5-fold reduction of the risk of failure (hazard-ratio0.18, 95% CI 0.05-0.66, P-value=0.01). Patients who experienced MRD positivity post-transplant did not necessarily relapse (5-year-EFS4 0.3%, SE9.3), but had a 2.5-fold risk of failure (CI 1.05-5.75; P-value=0.04) if any level was detected in the first 100 days and 7.8-fold (CI 2.2-27.78; P-value=0.002) if detected after 6 months. Anticipated immunosuppression-tapering according to MRD may have improved outcome, nevertheless all patients with post-transplant MRD$^3 1\times10^{-3}$ ultimately relapsed, regardless of immunosuppression discontinuation or donor-lymphocyte infusion (Figure 1).

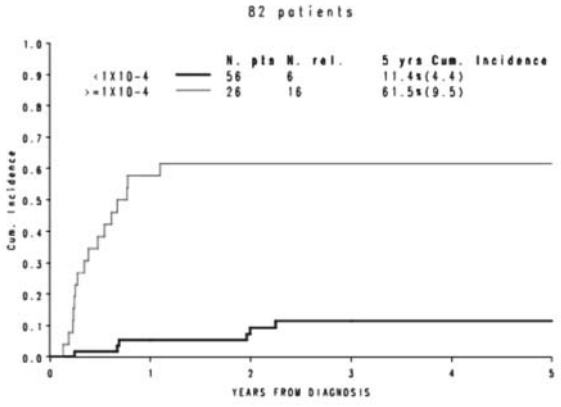

Figure 1. Cumulative incidence of relapse according to MRD level at transplantation.

Summary and Conclusions: MRD before transplantation has the strongest impact on relapse, additional intensified chemotherapy improves ultimate outcome, modulation of immunosuppression may reduce the risk of relapse and MRD positivity after transplantation does not necessarily imply relapse, mostly if detected early at low levels.

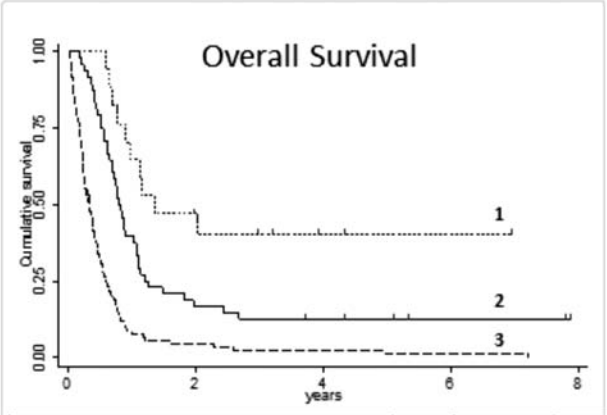
Background: Although outcome of adults with Philadelphia-negative (Ph-) acute lymphoblastic leukemia (ALL) improved significantly in the last two decades, long-term survival of refractory/relapsed (R/R) patients (pts.) remains unsatisfactory. However, this is best analyzed in unselected patient series from clinical studies, allowing to define limits and potential of current therapeutics, and offer a proper comparator to newer treatment modalities.
Aims: To analyze the long-term survival and prognostic factors for survival in an unselected cohort of R/R Ph- ALL pts. belonging to a prospective clinical study.
Methods: Between 2000-2008, 404 ALL pts. (100 Ph+ and 304 Ph-) were enrolled into NILG trial 09/00. Among 304 Ph- ALL pts., 161 (53%) had R/R ALL (median age 35 years [range 16-66], 98 male, 102 B-lineage [SR 45/HR 57], 59 T-lineage [SR 19/HR 40]).
Results: Among 161 R/R pts., 18 were refractory and 143 relapsed. One-hundred and twenty-seven pts. (89%) relapsed during 1st line chemotherapy and 16 after allogeneic stem cell transplantation (SCT) in 1st CR. The median time to relapse was 9.4 months (range 0.6-57.8); 129 pts. (90%) developed a BM or combined relapse, 9 (6.5%) an isolated CNS relapse and 5 (3.5%) an isolated extra-medullary relapse. A total of 110 pts. (77%) had an early relapse (within 18 months from CR) and 33 (23%) a late relapse. Data about salvage therapy were available for 160 pts.: 143 (89%) received re-induction therapy and 17 did not. The response to salvage therapy was evaluable in 138 pts., of whom 59 (43%) achieved a 2nd CR. The allogeneic SCT realization rate was 45% (n=65), 34 (52%) pts. receiving SCT in 2nd CR, 30 with active disease and 1 with unknown disease status. The estimated 5-year survival of the whole population was 8%, 12% and 7% in refractory and relapsed pts., respectively, with no significant differences according to site of relapse. However, pts. with late relapse had a better 5-year survival, 12% *vs.* 5.5% in refractory or early relapsing disease (P=0.005). Among pts. receiving any type of salvage therapy, those entering 2nd CR had a significantly better 5-year survival, 18% *vs.* 3% in refractory pts. (P=0.0000). Estimated 5-year survival was significantly better in transplanted pts. (20%) compared with non-transplanted pts. (1%, P=0.000), especially when SCT was performed in remission (32% *vs.* 7%, P=0.008) and in pts. suffering from late relapse (40%) (Figure 1). In univariate analysis survival was favorably affected by age ≤40 years, late relapse, achievement of 2nd CR, and remission status at SCT. Multivariate analysis confirmed that response to salvage therapy and realization of allogeneic SCT were the most significant prognostic factors for survival.



Groups		n	OS % at 5 years	p
Failures (n=161)				
1.	Late relapse, allo SCT	17	40	*0.0000*
2.	Refractory/early relapse, allo SCT	48	12.5	
3.	Refractory/relapse any time, NO allo SCT	96	1	

Figure 1.

Summary and Conclusions: The long-term outcome of patients with R/R ALL is highly unsatisfactory. This analysis confirms the need to obtain a second remission and increase the number of pts. that can benefit from allogeneic SCT, which remains the only curative option for a proportion of late relapsing pts. New drugs are required to improve CR rate and SCT feasibility in primary refractory pts. and the larger group of early relapsing pts.

P618

A SEQUENTIAL USE OF TKI, CHEMOTHERAPY AND TRANSPLANT IS ASSOCIATED WITH HIGH COMPLETE REMISSION RATES, DISEASE-FREE AND OVERALL SURVIVAL IN ADULT PH+ ALL. RESULTS OF THE GIMEMA 0904 PROTOCOL

Binaghi Hospital, Cagliari, [8]Hematology Department, Sant'Eugenio Hospital, Rome, [9]Department of Transfusion Medicine and Division of Hematology, Niguarda Ca' Granda Hospital, Milan, [10]Division of Oncology-Hematology, Umberto I Hospital, Nocera Inferiore, [11]Clinica Ematologica, Dipartimento di Scienze Sperimentali e Cliniche, University of Udine, Udine, [12]Institute of Hematology, University of Sassari, Sassari, Italy

Background: The clinical scenario of Ph+ ALL, considered the most aggressive form of leukemia, has changed profoundly following the introduction of 1st and 2nd generation tyrosine kinase inhibitors (TKI). In adult Ph+ ALL, TKI have been administered as part of the backbone of induction chemotherapy together with conventional drugs or, as in two earlier GIMEMA studies, alone in combination with steroids. The use of TKI has enabled high rates of complete hematological remissions (CHR), also in elderly patients. In the GIMEMA 0904 protocol, adult Ph+ ALL patients (≤60 years) were initially treated in induction and consolidation with Imatinib together with chemotherapy. This combination was associated with unacceptable toxicity and the protocol was amended. Imatinib was given as single agent, in combination with steroids, as induction therapy, while chemotherapy was added as consolidation.
Aims: Aim of the study was to verify in adult Ph+ ALL the feasibility and efficacy of a sequential scheme based on an induction phase with Imatinib plus steroids, followed by a consolidation with chemotherapy plus Imatinib and, when applicable, by a transplant procedure.
Methods: The steroid pre-phase was started from day -6, to allow central molecular screening, up to day 31. Imatinib (600 mg) was administered from day 1 to day 50. Patients who achieved a CHR received as consolidation therapy a cycle of HAM, without discontinuing Imatinib. HAM+Imatinib was planned also for non-responsive cases, followed by a further cycle of chemotherapy. Eligible patients received an allogeneic or autologous stem cell transplant (allo-SCT, auto-SCT). *BCR-ABL1* transcript levels were normalized to the number of *ABL1* control gene and expressed as a percentage of *ABL1*.
Results: From July 2007 to April 2010, 51 patients have been enrolled; 23 were males and 28 females. The median age was 45.9 years (range: 16.9-59.7) and the median WBC 28.0 × 10^9/L (range: 1.4-597). Thirty-nine patients had a p190 fusion transcript, 7 a p210 and 5 had both. Two patients went off-study for medical decision and toxicity, respectively. After the steroid pre-phase, 38 patients (79%) had a blast reduction ≥75%. At the end of induction (day 50), 47 patients (96%) had achieved a CHR, 1 had a partial response and 1 did not respond. After HAM, also the latter 2 cases obtained a CHR. No deaths in induction were recorded. Of the 43 patients who received HAM, 23 underwent a SCT procedure (20 allo-SCT, 3 auto-SCT), while 20 did not: so far, 3 relapses have occurred in the transplanted group (13%) and 8 in the non-transplanted group (40%). Disease-free survival (DFS) and overall survival (OS) at 36 months are 50.5% and 69.1%, respectively. SCT had no significant impact on DFS, while a trend was observed for overall survival OS (P=0.06). *BCR-ABL1* transcript levels decreased during induction therapy, with a highly significant reduction (P<0.0001) between the onset and the end of induction. A further, non-significant, reduction was induced by HAM. Interestingly, a log reduction >1.3 at day 50 (end of induction) was associated with an improved DFS (P=0.03) and a decreased cumulative incidence of relapse (P=0.004).
Summary and Conclusions: A sequential approach with Imatinib alone in induction, consolidated by chemotherapy plus Imatinib and followed by a SCT, is a feasible strategy for the management of adult Ph+ ALL patients. We confirm the very high CHR rates following induction with a TKI as single agent with steroids and no deaths in induction. This sequential therapeutic approach is associated with promising DFS and OS rates.

P619

ACUTE LYMPHOBLASTIC LEUKEMIA IN THE ELDERLY: PROGNOSTIC FACTORS AND COMORBIDITIES IMPACT

C Saillard[1,*], A Etienne[1], A Charbonnier[1], E D'Incan[1], J Rey[1], A Chicouene[1], C Arnoulet[2], M Mozziconacci[2], D Blaise[1], N Vey[1], T Prebet[1]

[1]Hematology, [2]Biopathology, Institut Paoli Calmettes, Marseille, France

Background: The prognosis of acute lymphoblastic leukemia (ALL) is poor in the elderly, with a 5-years overall survival less than 10% for patients above 60 years old. Age is one of the most important prognostic factors.
Aims: The objective is to study the impact of comorbidities in elderly patients treated for ALL and to correlate it with clinical, biological characteristics and outcome.
Methods: Between 1995 and 2012, 92 consecutive patients aged of 60 years or more with newly diagnosed ALL were referred to our institution (Institut Paoli Calmettes, Marseille, France). Clinical, biological characteristics and treatment strategies were retrospectively collected. Comorbidities have been assessed according to 3 different scoring systems: the Charlson Comorbidity Index (CCI), the Adult Comorbidity Evaluation 27 (ACE27) and the Hematopoietic Cell Transplantation Specific Comorbidity Index (HCT-SCI).
Results: Median age was 69 years old (range 60-89). Median leukocyte and platelet counts were 11 G/L and 47 G/L respectively. Performance status at diagnosis was 0 or 1 in 42%, 2 or more in 41% and unknown in 17%. Comorbidities indexes were 0 or 1 in 79% for CCI, 95% for ACE27 and 72% for HCT-SCI. 21% of patients had a history of previous malignancy. The most frequent phenotype was B ALL (84%), including 53% of B2 ALL according to EGIL classification and 12% of Burkitt leukemia. Other phenotypes were biphenotypic (10%), T ALL (2%), undifferentiated (1%) or unknown (3%). Most frequent cytogenetics were translocation (9;22) in 41% of cases, and normal karyotype in 14% of cases. Treatment was induction chemotherapy for 86 patients (94%), palliative care for 4 patients (4%) or Dasatinib for one patient. In patients treated with induction chemotherapy, 25% were admitted in intensive care unit. Only 9.5% received allogenic hematopoietic stem cell transplantation. Complete remission rate after induction is 71.5%. Relapse free survival and overall survival are 10 and 12 months respectively. Induction mortality is 10%. Three months mortality is 14% including 3 patients with non relapse mortality, without any correlation between age or comorbidity. Outcome does not differ according to performance status, phenotype or cytogenetics. We did not demonstrate any impact of comorbidities indexes on overall survival for the whole population. However, in Philadelphia chromosome-positive ALL, median overall survival was 23 months for patients with CCI=0 as compared with 13 months for patients with CCI=1 or more. The use of tyrosine kinase inhibitors in Ph positive ALL after 2004 has a significant prognostic value (overall survival 23 *versus* 12 months, P=0.04). 18 patients (20%) are long term survivors, including 5 bone marrow transplant recipients (Figure 1).

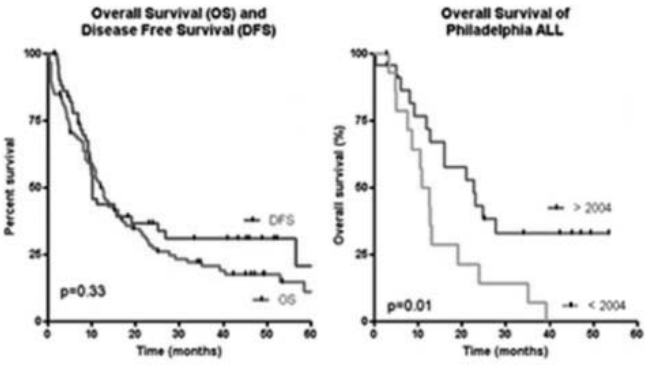

Figure 1.

Summary and Conclusions: Impact of comorbidity scoring in patients with ALL seems limited to Philadelphia positive ALL. This may be related to the low dose intensity of ALL induction regimens and a low incidence of comorbidities in our cohort. The impact in Philadelphia positive ALL may be correlated with the use of tyrosine kinase inhibitors that significantly improve short term survival, which allow time to develop underlying comorbidities related complications. Introduction of new drugs in the treatment of elderly ALL, such as Asparaginase, may favors the impact of comorbidities scores in the next years.

P620

A PHASE I, DOSE-FINDING STUDY OF THE ORAL, DUAL PI3-KINASE/MTOR INHIBITOR BEZ235 IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY ACUTE LEUKEMIA

L Wunderle[1], F Lang[1], S Badura[1], A Wolf[1], HnServe[1], N Goekbuget[1], H Pfeifer[1], G Bug[1], O Ottmann[1,*]

[1]Department of Medicine, Hematology/Oncology, University of Frankfurt, Frankfurt, Germany

Background: Phosphatidylinositol 3-kinase (PI3K)/Akt/mammalian target of rapamycin (mTOR) signaling plays a central role in cell proliferation, growth, and survival and metabolism. Aberrant PI3K signaling promotes cell proliferation, survival, and drug resistance in various malignancies including Philadelphia chromosome positive (Ph+) chronic myeloid leukemia (CML) and acute lymphoblastic leukemia (ALL), B-precursor ALL other than Ph+ ALL, T-ALL and acute myeloid leukemia (AML). BEZ235 is a potent dual pan-class I PI3K and mTOR complex C1 and 2 inhibitor and an attractive agent for relapsed or refractory leukemias.
Aims: This phase I, open label, dose escalation study was designed to determine the dose-limiting toxicity (DLT), maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of the investigational drug BEZ235 in pts. with advanced acute leukemia. Secondary objectives are characterization of tolerability and preliminary evidence of anti-leukemic activity of BEZ235.
Methods: Inclusion criteria of this ongoing study are: adult pts. with relapsed or refractory AML, ALL or CML-BP considered ineligible for intensive treatment. Pts. with a fasting blood glucose >160mg/dl or an HbA1c >8% were excluded. BEZ235 is administered as a single oral agent starting at 400 mg twice daily (BID) during 28d cycles, dose escalation was based on a "rolling-six"design. Pts. were evaluable for safety and DLT if they completed the first 28-day treatment cycle and received BEZ235 for at least 21 days. Dose escalation was followed by an expansion phase at the RP2D. All pts. gave informed written consent, the study was approved by the Ethics Committee of the University of Frankfurt.
Results: 18 pts. (11m, 7f), median age 65.5 years (range 30-82), have been enrolled to date including 11 with AML, 5 with B-lin ALL, one with T-ALL and one with CML in myeloid blast phase (CML-BP). 3 pts. were refractory and 15 had relapsed, 11 of them after allogeneic stem cell transplant (SCT). Pts. were evaluated at two BEZ235 doses, 6 at dose level 1 (400 mg BID) and 13 at dose level -1 (300 mg BID). AEs of all grades observed in more than 15% of pts and considered at least possibly related to study drug included diarrhea (13 [72%]), stomatitis/mucositis (11 [61%]), decreased appetite (7 [39%]), nausea/vomiting (9 [50%]), abdominal cramps (3 [17%]) and perianal pain (3 [17%]). Grade 3/4 treatment-related AEs included hyperglycemia (2 [11%]), mucositis and diarrhea (one each). No DLTs were observed, but BEZ235-related AEs in the 400 mg BID cohort necessitated treatment interruptions in 3 of 6 pts. (stomatitis, GI toxicity) and dose reductions to 300 mg BID in 2 pts. This dose level was considered incompatible with prolonged administration and enrollment was continued at 300 mg BID (dose level -1), which was well tolerated and selected as the RP2D. Enrolment in the expansion cohort at 300 mg BID is ongoing. Ten of 18 pts. evaluable for efficacy completed cycle 1, 8 pts. discontinued prematurely because of disease progression after a median of 8 days (5-18) of treatment. Clinical responses were observed in 3 of 18 pts.: one CR ongoing after 6 mos. and one hematologic improvement (both in Ph neg. B-precursor ALL) and stable disease of 4 mos. duration in an AML patient. Median time to progression is 28 days (5-112).
Summary and Conclusions: No formal DLTs and MTD were defined, but 400 mg BID was considered too poorly tolerable for prolonged administration. 300 mg BID was generally well tolerated and defined as the RP2D. Single-agent activity in AML was poor, indicating that the PI3K pathway is not a sole "driver pathway" in the majority of pts. Evidence of anti-leukemic efficacy was observed in ALL, with one patient in ongoing CR 6 months after starting BEZ235. Combination therapy may enhance the efficacy of dual PI3K–mTOR inhibitors in advanced leukemias.

P621

COMPARABLE OUTCOME OF HAPLOIDENTICAL HEMATOPOIETIC CELL TRANSPLANTATION AS POST-REMISSION THERAPY IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: INTERIM ANALYSIS OF PROSPECTIVE STUDY

D Young Kim[1,2,*], H Park[1,3], J Lee[1,2], J Lee[1,2], H Park[1], S Baek[1], M Jeon[1], Y Lee[1], Y Kang[1], M Seol[1], Y Lee[1], K Lee[1,2]
[1]Hematology, ASAN MEDICAL CENTER, [2]University of Ulsan College of Medicine, [3]Ministry of National Defence, Seoul, Korea, Republic of Korea

Background: Although allogeneic hematopoietic cell transplantation (alloHCT) has been generally adopted as a post-remission therapy (PRT) in adult acute lymphoblastic leukemia (ALL), little has been known about the implication of donor difference, especially the feasibility of third-party source such as haploidentical familial donor (HFD).
Aims: We performed a prospective trial assessing the feasibility of donor-specific alloHCT protocol, including HFD as stem cell source for PRT in adult ALL.
Methods: Patients over 16 years old with ALL were enrolled in this prospective trial in Asan Medical Center, Seoul, Korea, if he/she was in first (CR1) or second (CR2) complete remission and agreed with alloHCT as PRT. Those who had a matched sibling donor (MSD) received stem cell from bone marrow (BM) or peripheral blood (PB) with conventional (CON) conditioning (age <55) consisting of busulfan 3.2mg/kg/day×4 days plus cyclophosphamide 60mg/kg/day×2 days or nonmyeloablative (NMA) one (age ≥55) consisting of fludarabine 30mg/m2/day×6 days, busulfan 3.2mg/kg/day×2 days, and thymoglobulin 3mg/kg/day×3days. When MSD was unavailable, PB stem cell from unrelated donor (UD) with full-match or acceptable mismatch and HFD was considered in sequence with NMA conditioning irrespective of the age of patient. Mononuclear cells were infused for PB stem cell; neither T-cell depletion nor CD34+ selection was used for HFD-derived stem cell. Target number of infused nucleated cells was 3.0×10^8/kg for BM, 5.0×10^8/kg for PB source. Cyclosporine and methotrexate were used as graft-*versus*-host disease (GVHD) prophylaxis.
Results: Fifty patients (male:female=27:23) with median age of 31 years (range, 16-62) who received alloHCT from Jan 2010 until Aug 2012 were included in this interim analysis. Immunophenotype (B-/T-/mixed) was 40:4:6, 19 patients (38%) were Philadelphia-positive (Ph), and 38 ones (76%) were high-risk by UKALL/MRC criteria. Patients in 'advanced status' at the initiation of conditioning was 10; CR1 by salvage chemotherapy (n=1), CR2 (n=1), and relapse (REL; n=8) which was confirmed by bone marrow examination just before conditioning. ECOG performance status of all patients was ≤2. Donor groups were MSD (n=13)/MUD (n=20)/HFD (n=17, parent [9]/off-spring [3]/sibling [5]), and BM (n=12)/PB (n=38) was adopted as stem cell source. Eleven patients received CON and the other ones received NMA as a conditioning. Distribution of immunophenotype, Ph status, and risk group was not significantly different between donor groups, except the proportion of advanced status was higher in HFD group (35%; REL[5], CR2[1]). All patients achieved granulocyte engraftment over 1×10^3/μL in a median 13 (range, 11-24) days, and 47 (94%) patients also achieved platelet engraftment over 5×10^6/μL in a median 16 (range, 9-89) days. Three patients in HFD group experienced secondary engraftment failure; one finally relapsed and died, the others are alive in their remission status after donor lymphocyte infusion (DLI). In terms of complication, donor difference did not affect the incidence/severity of GVHD (acute: 34% [8% for grade≥3], chronic: 36% [22% for extensive]), infection, and organ dysfunction. Among 42 patients in CR1/CR2 at the initiation of conditioning, 2-year RFS rate (78.0% as a whole) was likely to be higher in HFD group than non-HFD (MSD+UD) group (83.3% *vs.* 68.4%, P=0.615). When events were defined as death/relapse/engraft failure/performance of DLI, 2-year EFS rate (52.2% as a whole) was also likely to be higher in HFD group (66.7% *vs.* 44.8%, P=0.565). Among all patients including those in REL, 2-year OS rate (57.3% as a whole) was nearly in statistical significance (59.5% *vs.* 58.7%, P=0.053). When patients were grouped by disease status at the initiation of conditioning, the difference of 2-year OS rate was significance (80.6% *vs.* 25.0%). All of those in REL finally died in their relapse/refractory status, and the median OS was 12.9 months.
Summary and Conclusions: In this study, AlloHCT strategy considering HFD as third-party stem cell source was feasible and the outcome was satisfactory as PRT in adult ALL. Except for the risk of engraftment failure, HFD may be considered as a feasible stem cell source for patients in their CR1/CR2 with ALL, although salvage alloHCT was not effective for those in REL irrespective of stem cell source. (Clinicaltrias.gov, NCT01037764).

Background: *MLL* rearrangements are found in the vast majority of infant ALL and about one half of infant AML cases.
Aims: To evaluate the distribution of *MLL* rearrangements among infants (<365 days) with acute leukemia (AL).
Methods: 175 infants (117 ALL cases, 57 AML cases and 1 acute undifferentiated leukemia case) were included in the current study. 11q23/*MLL* rearrangements were detected by chromosome banding analysis (CBA), fluorescence in situ hybridization (FISH) and reverse-transcriptase PCR (RT-PCR). In 57 cases genomic DNA breakpoint was detected in *MLL* and translocation partner genes by long-distance inverse PCR (LDI-PCR).

Results: 11q23/*MLL* rearrangements were revealed in 74 ALL patients (63.2%). Among this group *MLL-AF4* was detected in the majority of cases (52.7%), less frequently were found *MLL-MLLT1* (18.9%), *MLL-MLLT3* (13.5%), *MLL-MLLT10* (6.8%), *MLL-EPS15* (6.8%) and others. Children under 6 months of age with ALL had significantly higher incidence of *MLL* rearrangements in comparison with older infants (84.0% *vs.* 47.8%, P<0.001). *MLL*-positive patients more frequently had BI-ALL and less frequently BII-ALL than infants without these rearrangements (P<0.001 for both). Fusion gene transcripts were sequenced in 35 *MLL*-rearranged ALL cases. Depending on breakpoint position within *MLL* and partner genes we detected 7 different types of *MLL-AF4* fusion gene transcripts, 3 types of *MLL-MLLT1*, 3 types of *MLL-MLLT3*, 2 types of *MLL-EPS15*. The most common fusion site within *MLL* gene in ALL patients was exon11, revealed in 20 cases (57.1%). It was confirmed by LDI-PCR, that in addition to common breakpoint location in *MLL* gene (21 out of 41 cases in intron 11), allowed to reveal less frequent breakpoint sites like intron 10 (6 cases), intron 9 (5 cases), intron 12 (1 case), intron 7 (1 case). *MLL* rearrangements were found in 28 AML cases (49.1%). In AML patients the most common *MLL* rearrangements were *MLL-MLLT10* (32.1% of cases) and *MLL-MLLT3* (28.6%). Other ones were detected less frequently. In AML frequency of *MLL* rearrangements was similar in children younger and older than 6 months (P=0.904). Among *MLL*-positive cases AML M5 was detected significantly more often and AML M7 significantly less frequent than in *MLL*-negative patients (P=0.024 and P=0.001, correspondingly). The most common breakpoint location within *MLL* gene in AML patients was intron9, detected in 6 out of 15 cases (40.0%). Additional chromosomal abnormalities were revealed in 7 out of 21 *MLL*-positive AML patients with known karyotype (33%), while complex karyotype was detected in 5 cases (24%). Application of LDI-PCR allowed to verify rare *MLL* rearrangements, including *MLL-AFF3* (1 ALL case), *MLL-MYO1F* (2 AML cases), *MLL-SEPT6* (1 AML case), *MLL-SEPT9* (1 AML case). In 4 ALL and 3 AML patients *MLL* rearrangements with concurrent 3'-deletion of *MLL* gene were found. 3'-deletion of *MLL* was not associated with breakpoint position in *MLL* gene and type of translocation partner gene. None of the patients with 3'-deletions had reciprocal fusion gene. Based on LDI-PCR data we assessed several mechanisms of fusion gene formation. Reciprocal translocations were detected in 43 cases, 3-way translocations in 6 cases, inversions in 6 cases, combination of inversion and insertion in 2 cases.

Summary and Conclusions: In the current study we described some specific features of *MLL* rearrangements in a large cohort of infant AL patients.

P623

MRD LEVEL ANALYSIS IN ADULT ALL PATIENTS. ANALYSIS OF THE CZECH LEUKEMIA STUDY GROUP–FOR LIFE (CELL)

C Šálek[1,*], F Folber[2], E Froňková[3], B Procházka[1], P Cetkovský[1], Ji Mayer[2], M Doubek[2]

[1]Institute of Hematology and Blood Transfusion, Praha2, [2]Department of Internal Medicine-Hematooncology, University Hospital in Brno and Masaryk University, Brno, [3]Department of Pediatric Hematology and Oncology, Charles University and University Hospital Motol, Praha5, Czech Republic

Background: Ninety-two patients with adult ALL were treated in two major centres in the Czech Republic in 2007–2012. Median age at diagnosis was 37.8 mos. Patients ≤55 yrs. of age were treated according to GMALL 07/2003 protocol, treatment of older patients was not standardised. MRD levels were monitored in bone marrow at clearly defined timepoints.

Aims: To evaluate prognostic impact of MRD load at different timepoints of the therapy on overall suvival (OS).

Methods: The search for PCR target was performed in 85 pts. PCR marker was found in 78/85 (92%) pts. In 30/85 (35.5%) pts. a fusion gene was found (BCR/ABL in 24 pts., MLL/AF4 in 6 pts.), Ig/TCR rearrangements were monitored in 48/85 (56.5%) pts.. The search for Ig/TCR was undertaken in the group without fusion gene only; the success rate for Ig/TCR detection was 87% (48/55 pts.). MRD negativity (MRD^{neg}) was defined as whatever value $<10^{-4}$ when outside of quantitative range.

Results: Patients reaching MRD^{neg} after the first course of chemotherapy (day 26) had 3 yrs. OS 78%, n=30 (*vs.* 52%, n=37) with median survival not reached (*vs.* 52 mos.) (P=0.036), median time to relapse was not reached (NR) (*vs.* 34 mos.) (P=0.012). Patients reaching MRD^{neg} after the second induction therapy (day 46) had 3 yrs. OS 77%, n=44 (*vs.* 46%, n=24) with median survival not reached (*vs.* 30 mos.) (P=0.023), median time to relapse was NR (*vs.* 34 mos.) (P=0.066). Patients who were MRD^{neg} at the beginning of consolidation therapy (after previous 2 induction cycles, week 11) had 3 yrs. OS 80%, n=40 (*vs.* 48%, n=15) with median survival not reached (*vs.* 30 mos.) (P=0.007), median time to relapse was NR (*vs.* 10 mos.) (P<0.001). Of 34 pts. who were indicated to alo-HSCT, 24 pts. were MRD^{neg} prior to HSCT. Three-year-OS in MRD^{neg} group was 82% (*vs.* 45%), median survival NR (*vs.* 24 mos.) (P=0.034), median time to relapse was NR (*vs.* 10 mos.) (P=0.005). All 4 pts. who remained MRD^{pos} after the alo-HSCT relapsed in median of 7 mos (P<0.001); median OS was 22 mos. (P=0.005). The mean time to MRD negativity was significantly longer in BCR/ABL+ ALL (105 days) than in other types of B-ALL (44 days) and T-ALL (56 days) (P=0.002).

Summary and Conclusions: MRD load after the first induction cycle and at the beginning of consolidation therapy has prognostic significance regarding OS and relapse free survival. MRD load prior to alo-HSCT is of prognostic impact as well. MRD^{pos} status within 3 months after the HSCT defines the group with especially unfavorable prognosis. MRD response in BCR/ABL+ ALL is significantly slower than in other adult ALL subgroups.

P624

FLUDARABINE, ARA-C AND LIPOSOMAL DAUNORUBICIN (FLAD) PLUS HEMOPOIETIC STEM CELL TRANSPLANT (HSCT) AS SALVAGE THERAPY IN PATIENTS WITH RELAPSED-REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA

M Clavio[1,*], E De Astis[1], F Guolo[1], P Minetto[1], A Ghiso[1], F Cruciani[1], F Ballerini[1], M Miglino[1], G Pastori[1], L Mitscheunig[1], M Bergamaschi[1], S Aquino[1], A Bacigalupo[1], M Gobbi[1]

[1]Clinical Hematology, IRCCS Ospedale S Martino - IST Genova, Genova, Italy

Background: Patients with relapsed or refractory acute lymphoblastic leukaemia (ALL),have a poor outcome, that is even worse if relapse occurs early or if patients have been previously transplanted and poor risk karyotype is present. Therapeutic options are generally uneffective and badly tolerated and clinical trials with new drugs are lacking. Usually in such patients the achievement of a second remission is followed by hemopoietic stem cell transplant (HSCT). As is known, the absence of active disease before transplantation and the low toxicity of the previous salvage treatment positively affect HSCT outcome. The use of daunoxome (a formulation consisting of daunorubicin as a citrate salt entrapped within liposomes) may reduce drug-induced cardiotoxicity and increase delivery of daunorubicin to leukemic cell. We previously showed that the association of fludarabine, Ara-C and Daunoxome (FLAD) is well tolerated and effective in both poor risk AML and ALL and may allow to deliver BMT in complete remission in a group of patients.

Aims: The aim of this study is to review our overall experience with FLAD as salvage therapy of ALL and to evaluate its usefulness as bridging therapy to stem cell transplant.

Methods: The regimen consisted of three-days treatment with a 30-minute infusion of Fludarabine 30 mg/sqm followed 4 hours later by a 4 hour infusion of Ara-C 2 g /sqm and a 60 minute infusion of DNX 100 mg/sqm. Patients in CR or PR after FLAD induction received a further identical consolidation course and underwent HSCT if aged 60 or less and an HLA matched or haploidentical donor was available. Thirty-five patients with refractory (n. 12) or relapsed (n. 23, 4 after allogeneic BMT) ALL have been included in the trial. Median age was 34 years (range 13-76) and patients had received a median of 3 prior regimens (range 1-7).

Results: Three patients died of infection during therapy (8%). FLAD was well tolerated by most patients; eleven cases of fever with seven sepsi were observed; none cardiac complications and severe mucositis were recorded. Sixty per cent of relapsed and 66% of refractory ALL achieved CR. Six out of 11 ALL patients who were refractory to HYPERCVAD regimen achieved CR. Neither disease status before FLAD, nor karyotype or age affected the probability of obtaining a CR. Fourteen patients out of 30 aged 60 or less (46%) underwent HSCT (13 in CR, 1 in PR). In recent years we have observed that the percentage of patients who can receive salvage HSCT is more than doubled (31% and 72% before and after 01-1-2010, respectively).Donors were 6 HLA identical siblings, 7 haploidentical siblings, and 1 matched unrelated donor. Median DFS was 7 months (range 2-109); median OS was 8 months (range 1-120).

Summary and Conclusions: Our experience in a series of patients with very severe prognosis shows that FLAD is a feasible and effective salvage treatment for patients with relapsed and refractory ALL.The high remission rate, the low toxicity of the regimen with fast haematological recovery and the progress in haploidentical HSCT allows an increasing proportion of these patients to benefit of BMT in CR, thus improving survival.

P625

POOR OUTCOME OF TCF3-PBX1 DESPITE ITS ASSOCIATION WITH FAVORABLE RISK FACTORS STRESSES THE NEED FOR INTENSIFIED REMISSION THERAPY FOR PATIENTS OF THIS GENETIC SUBGROUP IN ADULT ACUTE LYMPHOID LEUKEMIA

Z Iqbal[1,2,3,*], N Sabir[1], M Iqbal[1,4,5], A Tashfeen[1], A Aleem[6], A Mukhtar Khalid[2], T Akhtar[1]

[1]Hematology, Oncology and Pharmaco-genetic Engineering Sciences (HOPES) Group, Health Sciences Research Laboratories, Department of Zoology, University of the Punjab, Lahore, [2]Next Generation Medical Biotechnology (NGMB) Division, School of Biological Sciences, University of Sargodha, Sargodha, Pakistan, [3]Clinical Laboratory Sciences (Medical Genetics/Hematology & Oncology), CAMS, King Saud Bin Abdulaziz University for Health Sciences National Guard Health Affairs, Riyadh, Saudi Arabia, [4]Department of Medicine, Asian Medical Institute, Kant, [5]Department of General Surgery, National Surgical Centre, Bishkek, Kyrgyzstan, [6]Division of Hematology/Oncology, Department of Medicine, School of Medicine and KKUH, King Saud University, Riyadh, Saudi Arabia

Background: Adult Acute lymphoblastic leukemia (ALL) is a genetically heterogeneous disease with very poor survival. It involves many genetic abnormalities, many of which lead to formation of fusion oncogenes (FGs) which have an established role in leukemogenesis (*Harrison & Foroni*, 2002). Although role of FGs in prognostic stratification and drug selection is well characterized in pediatric ALL, the role of FGs in adult ALL is not well established (Moorman *et al*., 2007) except BCR-ABL and MLL-AF4.
Aims: Therefore, objective of this study was to study the association of FGs with disease biology and clinical pattern.
Methods: We employed RT-PCR and interphase FISH to study the distribution of five most common FGs (BCR-ABL, MLL-AF4, ETV6-RUNX11, TCF3-PBX1 and SIL-TAL1) and their association with clinical characteristics and treatment outcome in 208 adult ALL patients from 2002-2010. Written informed consent was obtained from patients. All patients were treated with MRC UKALL XII protocol.
Results: Overall survival (OS) and relapse free survival (RFS) were 26.17 and 11.147 months, respectively. FGs were detected in 78.8% (164/208) patients. Subjects with SIL-TAL1 (35.36%) showed lymphadenopathy (which is rare in adult ALL), frequent organomegaly, low platelets count and poor survival. BCR-ABL positive patients (20.3%) presented with high total leukocyte count (TLC), prominent splenomegaly, low platelets count (P-value <0.001), poor survival (OS & RFS 9.3 & 6.3 months, respectively) and 10% less chances of 4-6 week remission as compared to those with negative BCR-ABL status. MLL-AF4 (12.19%) was associated with elevated TLC, organomegaly, frequent CNS involvement, and a poor clinical outcome (OS=8.8 months). Surprisingly, ETV6-RUNX1 was least represented with frequency of 4.8% (10/208), and was mostly associated with low TLC, less common organomegaly, high CR rates and higher OS (30.2 months). However, long term survival of ETV6-RUNX1 was negatively affected by frequent late relapses. Frequency of TCF3-PBX1 was higher (16.3%, 34/208) than reported worldwide (3%). This genetic subgroup was associated with younger age (59%), lower TLC (82%), platelet count higher than 50×10^9/l (12/17, 71%), less common hepatomegaly (2/17, 12%), less common splenomegaly (3/17, 18%), early CR (11/17, 65%), indicating a favorable prognosis. However high relapse rate (13/17, 76.1%) and shorter OS (11.6 months) were observed in TCF3-PBX1 positive patients.
Summary and Conclusions: High relapse rates and shorter OS despite favorable prognosis evident by clinical features at presentation and high 4-week CR in 65% of TCF3-PBX1 positive patients highlight the need for differential genetic diagnosis at presentation and intensified remission induction treatment in this sub-group of patients (Foa *et al*., 2003). Our data is in accordance with recent reports (Burmeister *et al*., 2010). This, along with lower frequency of ETV6-RUNX1, higher *MLL-AF4* frequency (9.7%) and association of SIL-TAL1 with lymphadenopathy (which can help in differential diagnosis of this genetic subgroup of adult ALL in low-resourced countries) in our patients, reflect ethnic differences in disease biology and treatment outcome in adult ALL (Burmeister *et al*., 2010). Overall high percentage of poor prognostic FGs in study subjects partially explains the overall poor outcome of adult ALL in our country. Therefore, we recommend the molecular testing for ALL FGs in routine clinical settings at diagnosis and its implication in prognostic stratification and drug selection during various phases of treatment. It also indicates the need for high-throughput molecular analysis of different ALL genotypes for elucidating the mechanism of leukemogenesis and its implication in finding novel targeted therapies for adult ALL.

P626

CLINICAL OUTCOME OF T- ACUTE LYMPHOBLASTIC LEUKEMIA/ LYMPHOMA (T-ALL/T-LBL): THE BOLOGNA EXPERIENCE

M Abbenante[1,*], C Papayannidis[1], I Iacobucci [1], C Sartor[1], S Paolini[1], E Ottaviani [1], A Lonetti [1], S Parisi[1], A Ferrari[1], V Guadagnuolo [1], N Testoni[1], M Cavo[1], G Martinelli[1]
[1]Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy

Background: Precursor T cell ALL/LBL occurs most frequently in late childhood, adolescence, and young adulthood, with a 2:1 male predominance; it comprises 15 and 25 percent of childhood and adult ALL, respectively, and 2 percent of adult non-Hodgkin lymphoma. In adult patients prognosis is poor, due to the high incidence of relapse even after allogenic stem cell transplantation.
Aims: To identify new targets, to optimize therapy, to reduce toxicity and to improve clinical outcome.
Methods: We retrospectively analysed and currently report clinical outcome results about 52 newly diagnosed and younger than 60 years T-ALL patients (median age 30 years, range 14-73 years) treated, from 2006 to 2012 according to standard chemotherapy regimen, including adapted pediatric-like schedule, BFM protocol, and adult schedules. After induction, all the patients underwent consolidation for at least one course. All the patients shared the same strategy for intensification, that consisted, when available, in allogenic or autologous stem cell transplantation. Detailed data about cytogenetics and molecular biology will be provided on site. Durations of complete remission (CR) and overall survival (OS) were estimated according to the Kaplan-Meier method. The CR duration was calculated from start of CR to first evidence of disease recurrence.
Results: Informed consent was obtained; after a single induction course 41/52 patients obtained a CR (78.8%) and 2 patients a partial remission (PR) (3.8%) for an overall response rate (ORR) of 82.6%. Seven patients (13.4%) had resistant disease, and 2 (3.8%) died during induction. After a median follow-up of 22.7 months, 19 patients (36.5%) are still in CR. The median CR duration and OS were 12.3 and 23.15 months, respectively. The most common grade 3 adverse events included gastro-intestinal toxicities (*i.e.* nausea, vomiting, mucositis and diarrhoea) and liver dysfunction.
Summary and Conclusions: Our analysis confirms, in line with literature data, that, despite intensive chemotherapeutic treatments and stem cell transplantation, T-ALL and T-LBL adult patients still show a bad prognosis. The relatively satisfying induction remission rate is followed, in most cases, by a high relapse rate. Therefore, a molecular stratification approach, based on gene-expression profile analysis (Ferrando *et al*., Cancer Cell 2002) should be routinely performed, in order to identify new targets, to optimize therapy, to reduce toxicity and to improve clinical outcome.

ENCOURAGING SURVIVAL IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA - RESULTS OF RUSSIAN ACUTE LYMPHOBLASTIC LEUKEMIA (RALL) STUDY GROUP

E Parovichnikova[1,*], G Kliasova[2], A Sokolov[3], V Troitskaya[3], L Kuzmina[1], S Kravchenko[4], S Bondarenko[5], E Karyakina[6], O Baranova[7], VnLapin[8], T Ryltzova[9], L Gavrilova[10], Al Pristupa[11], T Kaporskaya[12], T Zagoskina[13], Y Davidyan[14], S Kulikov[15], V Savchenko[1]
[1]Bone Marrow Transplant Department, [2]Microbiology Department, [3]Hematology Department, [4]Hematology and Intensive care department, National Research Center for Hematology, Moscow, [5]State Medical University, [6]Hematology Department, City Hospital №15, St. Petersburg, [7]National Oncological Center, Moscow, [8]Hematology Department, Regional Clinical Hospital, Yaroslavl, [9]Regional Clinical Hospital, Tula, [10]Regional Clinical Hospital, Saransk, [11]Regional Clinical Hospital, Ryasan, [12]Regional Clinical Hospital, Irkutsk, [13]Regional Clinical Hospital, Kirov, [14]National Research Center for Hematology, Moscow, Russian Federation, [15]Department of Biostatistics, National Research Center for Hematology, Moscow, Russian Federation

Background: T-cell ALL is a heterogeneous disease regarding biological features and long-term outcome. We have evaluated the characteristics and 3-years survival rates of T-ALL patients treated within Russian prospective multicenter trial ALL-2009 (ClinicalTrials.gov public site; NCT01193933).
Aims: The main principle of the protocol (ASH, 2012, poster 2572) was no aggressive but non-interruption treatment with prolonged L-asparaginase (Σ=590.000 IU), and autologous HSCT with BEAM conditioning followed by maintenance in T-cell ALL pts without HLA-identical donors.
Methods: From Nov, 2008, till Jan, 2013, 29 centers enrolled 203 ALL pts: 63,6%=B-lin, 35,3%=T-lin,1,1%=biphenotypic. Median age in T-ALL pts was 28 y (15-54); male gender prevailed - 24f/46m, L -24,5*10^9/l (0,8-313), b/m blast - 75,5%(0,1-99), LDH -995 UI (131-11000). 32 (47,1%) pts had early T-ALL (T-I/II), 31 (42,9%) - thymic (T-III), 7 (10%) - mature (T-IV). Cytogenetics was available in 50% of pts (n=35) and 43% of them (n=15) had normal karyotype (NK). T-I/II was characterized by more frequent bone marrow involvement (P=0,01), T-IV - mediastinum involvement (P=0,05). The analysis was performed in Jan, 2013. Induction and follow-up data were available in 58 pts.
Results: CR was achieved in 100% of T-III (26/26) *vs* 72% in T-I/II (18/25) and 71,4% (5/7) in T-IV (P=0.01). Late responses were more frequent in early T-ALL (CR after the $1^{st}/2^{nd}$ phase n=13/5) comparing to T-III (22/4) and T-IV (4/1). Induction death occurred only in early T-ALL pts - 16% (P=0.01). Primary resistance and even progression during induction was registered in T-I/II (12%) and T-IV (28,6%). 15 pts were transplanted (3-allo, 12-auto), non of them relapsed so far, comparing with 21,4% relapses in no transplanted group (P=0.05). Comparing 3-years overall and disease-free survival in T-cell-subgroups we did not find any differences so far: OS=67,8%(T-I/II), 72,4%(T-III), 71,4%(T-IV) and DFS=79,4%(T-I/II), 71,9%(T-III), 100%(T-IV). In a multivariate analysis no variable from the list (age, gender, T-ALL type, initial WBC, LDH, b/m blasts, karyotype, time to CR, L-asparaginase cessation, HSCT) was found that significantly influenced survival.
Summary and Conclusions: Our data demonstrate that early T-all is characterized by lower CR rate, more frequent refractory (even progressing) disease and higher early death rate. Thymic ALL is the most favorable subtype regarding induction results. Regardless these differences the survival rates were quite similarly good. We assume that the analyzed group is small, but promising long term results in different T-ALL categories suggest that ALL-2009 protocol approach - no aggressive but non-interruption treatment - is highly effective, nontoxic and reproducible.

P628

FLOW CYTOMETRIC INVESTIGATION OF CENTRAL NERVOUS SYSTEM INVOLVEMENT IN CHILDHOOD ACUTE LEUKEMIAS

A Popov[1,2,*], T Verzhbitskaya[1,2], G Tsaur[1,2], A Tomilov[1,3], O Streneva[1,2], O Khlebnikova[1], E Shorikov[1,2], S Leonid[1,2,3], L Fechina[1,2]
[1]Pediatric Oncology and Hematology Center, Regional Children Hospital, [2]Research Institute of Medical Cell Technologies, [3]Ural State Medical Academy, Ekaterinburg, Russian Federation

Background: Central nervous system (CNS) involvement is one of the important risk factors in childhood acute leukemia (AL). Tumor cells detection in cerebrospinal fluid (CSF) is one of the main signs of CNS lesion. Traditionally blasts presence in CSF is assessed by conventional cytomorphology (CM) of cytospin slides. However, sensitivity of this method is relatively low. Flow cytometry (FC) having a higher sensitivity could provide better diagnostic applicability for CSF blasts detection.
Aims: To compare results of tumor cells detection in CSF of children with AL by flow FC and CM.
Methods: 183 samples from 52 boys and 31 girls aged from 5 months to 15 years with different types of acute lymphoblastic leukemia (ALL) (77 patients), acute myeloid leukemia (AML) (5 patients) and acute biphenotypic leukemia (1 patient) were investigated. 17 positive samples obtained by traumatic lumbar puncture were excluded from analysis because tumor blasts were also detected in peripheral blood. Comparison between FC and CM data was performed in 166 samples. Among these samples 61 was taken at the time of initial diagnostics, 34–during AL follow-up, 17–at relapse and 54–during relapse monitoring. Monoclonal antibodies panels were constructed according to immunophenotype of tumor cells in bone marrow.
Results: In 24 out of 166 samples (14.5%) tumor cells were detected by CM. In all these cases blasts were also found by FC, while FC allowed finding blasts in other 35 samples. Thus the total number of FC-positive samples was 59 out of 166 (35.5%). This frequency was significantly higher than rate of CM-positive cases ($p < 0.0001$). Among initial diagnostics samples there were 20 FC-positive and only 10 CM-positive patients (32.8% *vs.* 16.1%, P=0.0585). At relapse 9 (52.9%) patients were FC-positive, while 6 (35.3%) were CM-positive (P=0.4897). In both B-lineage and T-lineage ALL, analyzed separately, FC detected blasts in CSF frequently than CM (P=0.0098 and P=0.0002 respectively). Absolute blast count in 1 mL in CSF samples, positive by both methods was significantly higher than in samples, positive only by FC (median=418, range 8-158171 and median=34, range 5-2762 respectively, p=0.0002). Thus FC allows detecting tumor cells in CSF much more frequently than conventional CM, which could be explained mainly by higher FC sensitivity. Moreover FC is applicable also for qualitative and quantitative monitoring of CNS lesion. Nevertheless prognostic impact of FC CSF investigation is questionable. Among 13 patients in whom discordant results were obtained in initial diagnostics samples and at relapse, only for one patient risk stratification could have been changed. For all other patients there were other risk factors, that decreased significance of FC leukemic blast detection in CSF.
Summary and Conclusions: Flow cytometry allows more frequent detection of tumor blasts in CSF of children with AL, while prognostic significance of these findings is still unclear and needs to be confirmed in large prospective trials.

P629

FOUR YEARS EXPERIENCE WITH HYPER-CVAD TREATMENT OF ADULT T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN SWEDEN. POPULATION-BASED DATA

P Kozlowski[1,*], M Åström[1], L Ahlberg[2], P Bernell[3], E Hulegårdh[4], H Hägglund[5], K Karlsson[6], A Markuszewska-Kuczymska[7], B Tomaszewska-Toporska[6], B Smedmyr[8], H Hallböök[8]
[1]Hematology Section, Department of Medicine, Örebro University Hospital, Örebro, [2]Department of Hematology, University Hospital of Linköping, Linköping, [3]Department of Hematology, Karolinska University Hospital, Solna, Stockholm, [4]Department of Hematology and Coagulation, Sahlgrenska University, Göteborg, [5]Hematology Center, Karolinska University Hospital, Huddinge, Stockholm, [6]Department of Hematology, Skåne University Hospital, Lund, [7]Department of Hematology, Cancer Center, University Hospital, Umeå, [8]Department of Hematology, Uppsala University, Uppsala, Sweden

Background: Hyper-CVAD (fractionated cyclophosphamide, vincristine, doxorubicin, and dexamethasone alternating with cycles of high-dose methotrexate and cytarabine) has shown promising results in adult T-cell Acute Lymphoblastic Leukemia (T-ALL). The protocol was introduced as standard treatment of T-ALL in Sweden in October 2002 and was recommended until September 2006 in the national guidelines from the Swedish Adult ALL Group.
Aims: Assessment of efficacy of Hyper-CVAD in adults with T-ALL in a population based cohort.
Methods: 24 patients with T-ALL diagnosis were prospectively reported to the Swedish Adult Acute Leukemia Registry between October 2002 and September 2006. Missing data were complemented retrospectively. Hyper-CVAD was recommended to all patients without severe comorbidity. Allogeneic stem cell transplantation (SCT) was recommended for patients with high-risk disease: white blood cell count $>100\times10^9$/L, complete remission (CR) achievement after more than two courses, high minimal residual disease level, and relapsed disease (after CR2 achievement). In patients without high-risk factors maintenance therapy was given with per oral mercaptopurine and methotrexate for two years including reinduction courses: daunorubicine, vincristine and prednisolone every second month (1st year) and cytarabine, thioguanine and prednisolone every third month (2nd year).
Results: Totally 24 patients were reported. Four patients were treated with palliative intention, and were excluded from further analysis, as was one with sarcoma and secondary T-ALL. The remaining 19 patients (15 men and 4 women) were treated according to Hyper-CVAD protocol. The median age at diagnosis in this group was 32 years (range 18-72). CR was obtained in 17/19 (89%) patients and in additionally one after salvage with nelarabine. 5 year overall survival (OS) and leukemia free survival were 34% (95%CI: 10-56) and 26% (95%CI: 7-46) respectively. Allogeneic SCT was performed upfront in four patients (including one without CR achievement) with two patients becoming long-term survivors. 14/15 (93%) of patients not transplanted in CR1 completed the Hyper-CVAD protocol (8 courses). One patient received two courses only due to agranulocytosis and invasive candidiasis. 5 year OS and leukemia free survival for the 15 patients were 30% (95%CI: 5-55) and 20% (95%CI: 0-40) respectively. 12/15 (80%) patients relapsed after median 9 months (range 2-23) from CR1 achievement. Six of them received allogeneic SCT in CR2 with three still alive. All six relapsed and not transplanted patients died after median 2.5 months (range 1-6) from relapse. Age >35 years influenced survival negatively (HR 5.1, 95%CI: 1.55-16.7) and there were no long-term survivors in this older group (N-7) except one (aged 72) who died after 91 months in CR1 compared to 58% (95%CI: 30-86) OS at 5 years in 12 younger patients. 5 year OS in all transplanted patients (N-10: sibling donor-4, unrelated-5, cord blood-1) was 50% (95%CI: 19-81) compared to 17% in nine non-transplanted (HR 2.76, 95%CI: 0.86-8.84). Only 1/7(14%) of patients aged >35 years received allogeneic SCT (in CR2) compared to 9/12 (75%) in the younger patients (P=0.01, chi-square test).
Summary and Conclusions: The results of treatment with Hyper-CVAD without any subsequent SCT were discouraging especially regarding patients >35 years although the number of patients was small. The protocol is no longer recommended in Sweden. The efficacy of upfront allogeneic SCT cannot be assessed in this study but the procedure emerges as a possible treatment after relapse.

POST INDUCTION TREATMENT OF PHILADELPHIE POSITIVE CHROMOSOME ALL: TKI BASED-INTENSIVE CHEMOTHERAPY OR ALLOHSCT ?

J Konopacki[1,*], P Arnautou[1], M Kerbout[1], A Segot[1], B Souleau[1], D Bories[2], M Chueca[3], J Lataillade[3], V Foissaud[4], T De Revel[1], J Malfuson[1]
[1]hematology, HIA PERCY, CLAMART, [2]molecular biology, CHU H. MONDOR, CRETEIL, [3]laboratory of cellular therapy, CTSA, [4]laboratory of biology, HIA PERCY, CLAMART, France

Background: Allogenic Hematopoïetic Stem Cells Transplantation (AlloHSCT) represents the standard treatment of Philadelphie chromosome Positive Acute Lymphoblastic Leukemia (Ph+ALL)[1]. Recently, Tyrosine Kinase Inhibitor (TKI)-based strategy combined with intensive chemotherapy had improved the outcomes of patients treated for a Ph+ALL [2]. Post remission consolidation and maintenance therapy comprising TKI instead of alloHSCT has not been evaluated in patients with Ph+ALL. However, in some studies in which transplantation has not been performed, excellent overall survival (OS) and disease free survival (DFS) were reported.[3]
Aims: The aim of our study was first to compare alloHSCT and maintenance TKI treatment in patients with Ph+ALL and secondly, to show that when transplant is not a possible option, targeted therapies can permit long-term complete molecular response (mCR).
Methods: We retrospectively analysed all the patients treated for a Ph+ALL between March 2004 and July 2012 in our department, with a TKI (Imatinib or Dasatinib) chemotherapy strategy combination (Hyper-CVAD or GRAALL recommendations chemotherapy).
Results: Eighteen patients with a median age of 53 years (range: 29-71) were treated with Imatinib (n=13) or with Dasatinib (n=5) based chemotherapy. Eight patients received chemotherapy and TKI treatment (chemo group) without transplant because of age (n=7) or no donor (n=1) and 10 patients underwent alloHSCT (5 sibling, 3 unrelated donor and 2 umbilical cord blood). Patients in the chemo group were significantly older (median age: 63 years *vs* 46 years, P<0,001). Median time from diagnosis to HSCT was 6 months (range 4-12). Median white blood cells count in alloHSCT group at diagnosis was higher than in chemo group (median10,46 $10.^9$ /L, range1,23- 240,39 *vs*4,98 $10.^9$ /L, range:2,63- 214,5). No patient had central nervous system involvement in the chemo group and only one in the alloHSCT group. All but one patient in the chemo group had high LDH level (>440 UI/L). Additional cytogenetic abnormalities were found in 3 patients (deletion of chromosome 7 for 2 of them, one in each group). After induction chemotherapy, mCR was reached in eleven patients (4 in the alloHSCT group and 7 in the chemo group with a median duration of6,8 months; range1,3- 17). Only one patient in the chemo group never reached a mCR. Relapse occurred for six patients: 5 in the alloHSCT group in a median duration of 8 months from the transplant (range 6-21 months) and

17 months from diagnosis (range 12-26 months) and 1 in the chemo group in a median duration from the diagnosis of7,5 months. Five patients died secondary to relapse (4 in the alloHSCT group and 1 in the chemo group). One patient developed a fatal Pneumocystis infection and one died secondary to glioblastoma. The median OS is 56 months (45 months in the alloHSCT group and no reached in the chemo group). With a median follow up of 30 months (range 9-83), the estimated 30 months-OS is 70%, 62% and 70% (respectively for all patients, alloHSCT and chemo group) (Figure 1).

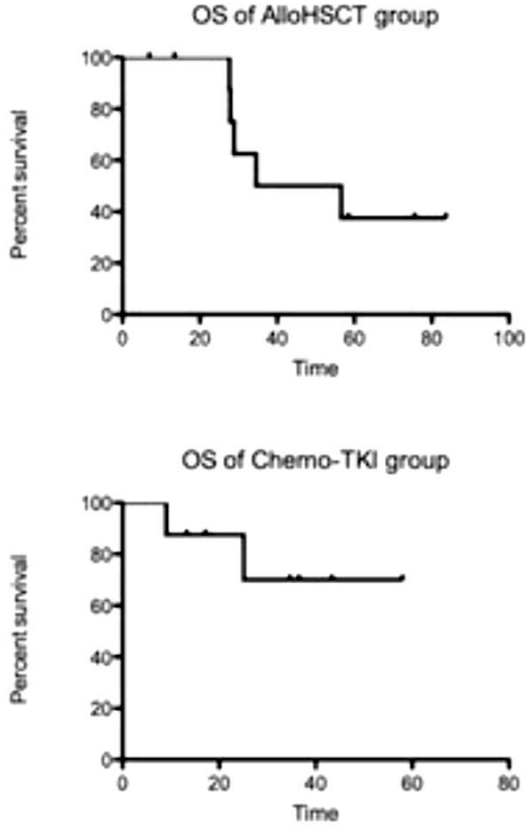

Figure 1.

Summary and Conclusions: AlloHSCT is still the standard post-induction treatment of Ph+ALL patients. However, the outcomes of intensive chemotherapy have improved at the TKI era. Although this study concern a small sample size, our results show that good outcomes can be achieved without alloHSCT and suggest the choice of maintenance treatment instead of reduced intensity conditioning alloHSCT in patients with advancing age.

ADULT MIXED-PHENOTYPE ACUTE LEUKEMIA ACCORDING TO THE WHO 2008 CLASSIFICATION–A SINGLE CENTER EXPERIENCE

C Moreira[1,*], N Domingues[1], I Moreira[1], I Oliveira[1], A Martins[1], L Viterbo[1], G Martins[2], A Santo[1], J Mariz[1]
[1]Oncohematology Department, [2]Clinical Pathology Department, Instituto Portugues de Oncologia do Porto, Porto, Portugal

Background: Mixed-phenotype acute leukemia (MPAL) is a rare disease (2-5% of all leukemias) and represents a heterogeneous category of acute leukemias that show expression of a combination of antigens of different lineages. For many years, the diagnostic criteria were based on the scoring system proposed by the European Group for the Immunological classification of Leukemias (EGIL). More recently, in 2008, the WHO adopted new criteria for the diagnosis of MPAL which are based on the expression of strictly specific T-lymphoid (cytoplasmic CD3) and myeloid (MPO) antigens, the later by flow cytometry or cytochemistry and/ or clear evidence of monocytic differentiation; B-cell lineage assignment in MPAL relies on the strong expression of CD19 together with another B-cell associated marker, or in cases with weak CD19, on the expression of at least 3 B-lineages markers.

Aims: To describe the clinical features and response to therapy in 13 cases of MPAL.

Methods: A total of 403 patients were diagnosed with Acute Leukemia in our department between January 1998 and December 2010. We identified 13 patients who met the WHO 2008 criteria for MPAL. Data regarding their clinical features at diagnosis, morphology according to the French-American-British (FAB) classification, immunophenotype characteristics by flow cytometry and karyotype analysis were collected. Overall survival (OS) and disease-free survival (DFS) were obtained by the Kaplan-Meier method. Statistical analysis was performed using SPSSv20.

Results: MPAL represented 3.2% of the Acute Leukemias diagnosed in our Department over a 13-year period. Of the 13 patients analyzed, there was a predominance of the male gender (11; 84.6%); median age was 39.0 years (15.2–64.7). At diagnosis, median leukocyte count was 11.8×10^9/L (0.23–88.1), median platelet count was 88.5×10^9/L (9–255) and median lactic dehydrogenase was 409 IU/L (193–766). Morphology was compatible with acute lymphoblastic leukemia (ALL) in 61.5% and acute myeloid leukemia (AML) in 38.5%. Flow cytometry analysis revealed "B+myeloid" (n=6), "T+myeloid" (n=3) and "B+T" (n=4). Cytogenetic analysis showed normal karyotype (n=5), complex karyotype (n=2), t(9;22) (n=1), del22q (n=1); 4 patients didn't have metaphases. Seven patients received ALL therapy, 4 patients AML and 2 received a combination of ALL+AML therapy. ALL treatment induced a complete remission (CR) in 57.1% and AML therapy in 75%; both patients submitted to combination therapy achieved CR. Five patients were submitted to allogeneic stem cell transplantation in 1st CR (n=4) or 2nd CR (n=1). Nine patients died, 7 of progressive/resistant disease and 2 of infectious complications. Median overall survival (OS) and disease-free survival (DFS) were 22.1 and 16.4 months, respectively; estimated 5-year OS and DFS of 30.8% and 33.3%. A subgroup analysis revealed, a 5-year OS of 20% for "B+myeloid", 33.3% for "T+myeloid" and 50.0% for "B+T" (P=0.459) and a 5-year DFS of 33.3% for both "B+myeloid" and "T+myeloid", and 50.0% for "B+T" (P=0.764). Analysis according to induction therapy showed, a 5-year OS of 42.9% for "ALL", 25.0% for "AML" and 0% for combined treatment (P=0.586) and a 5-year DFS of 50.0% for "ALL", 33.3% for "AML" and 0% for combined treatment (P=0.130).

Summary and Conclusions: We presented a small series of MPAL which is often described as having a poor prognosis. In our series, we observed a 5-year OS of 30.8% and a 5-year DFS of 33.3%.

P632

INTEGRATING ALTERNATIVE DONORS ALLOWS BEST OUTCOMES IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN HIGH RISK ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE CENTRE STUDY

B Forno[1,*], M Tassara[1], F Monaco[1], S Mastaglio[1], F Giglio[1], M Lupo-Stanghellini[1], C Messina[1], S Piemontese[1], F Pavesi[1], M Coppola[1], M Marcatti[1], A Assanelli[1], M Bernardi[1], J Peccatori[1], C Corti[1], F Ciceri[1]
[1]Hematology and Bone Marrow Transplantation Unit, San Raffaele Scientific Institute, Milano, Italy

Background: Hematopoietic stem cell transplantation (HSCT) from an HLA-matched allogeneic donor is the best option for patients (pts) with high and very-high risk adult acute lymphoblastic leukemia (ALL). However, only 30% of pts have an HLA identical sibling donor. The remaining pts need to find an alternative donor in suitable times preceding relapse but it is not codified as a standard procedure.

Aims: The aim of our retrospective analysis is to provide data on HSCT from any donor (HLA identical sibling, matched or partially mismatched unrelated volunteers, haploidentical donors, cord blood) in adult patients affected by high risk ALL treated in any stage of disease in our centre.

Methods: Seventy-eight pts with ALL received a HSCT between 1999 and 2012: 30 (38%) of them were B-ALL, 20 (26%) T-ALL, 8 (10%) biphenotipic-ALL, and 20 (26%) Philadelphia positive ALL. The median age at transplant was 36 years (range 19-68). Twenty-nine pts (37%) underwent HSCT in first complete remission (CR1) because of high or very high clinical risk at diagnosis or because of molecular failure after induction; 6 and 3 pts (8% and 4%) were in CR2 and CR3 respectively; 40 pts (51%) were in chemo-refractory persistence of disease. Seventeen pts (22%) received graft from an HLA identical sibling, 19 pts (24%) from an unrelated donor, 38 (49%) from an haploidentical donor and 4 (5%) from umbilical cord blood. We offered alternative donors to allow prompt HSCT mainly in refractory cases, but also in CR (8 and 4 patients received an haplo-HSCT respectively in CR1 and CR2). Conditioning regiments were mainly at reduced intensity (RIC 61 pts, 78%) and in few cases fully myeloablative (MAC 17 pts 22%).

Results: After a median follow-up of 901 days, 28 (36%) pts are alive, all of them in CR. Median overall survival (OS) is 254 days (95% CI 142-366). In univariate analysis significant factors for OS were CR *vs.* not CR at HSCT (OS at 3y 50% *vs.* 9%, P<0.01), HLA identical sibling donor *vs.* any alternative (OS at 3y 46% *vs.* 24%, P<0.01), and conditioning RIC *vs.* MAC (OS at 3y 33% *vs.* 14% P=0.02). There are not differences in outcome among transplants from unrelated or haploidentical donors. Relapse incidence and TRM are 49% and 40% respectively at 3 years. The most significant factor for TRM is HLA iden-

tical sibling *vs.* any alternative (TRM at 5y 7% *vs.* 50%, P<0.01). Significant factor for relapse is CR *vs.* not CR at HSCT (31% *vs.* 68% 3y, P<0.01). In multivariate analysis the only significant factor for overall survival, relapse and TRM consists in CR at transplant (P<0.01), whereas the type of donor is not statistically significant for OS, TRM and relapse.
Summary and Conclusions: These data report our single centre activity on high risk ALL: the best prognosis belongs to pts in CR at HSCT, mainly in CR1. An HLA-matched donor is the best source in terms of OS and TRM. Unfortunately the largest part of patients in need for a transplant lacks an identical sibling: our data show that HSCT from an alternative source is feasible and do not negatively affect outcome in multivariate analysis. Every effort should be directed to promptly recognize patients at high risk and to offer them a transplant as soon as possible in complete remission, considering alternative donors in a strategic decision-making algorithm.

P633

OBESITY, INSULIN RESISTANCE AND ADIPOKINES IN SURVIVORS OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA.
T Gürsel[1,*], D İnce Cebeci[1], C Demirtaş[2], A Bideci[3], Z Kaya[1]
[1]Hematology Unit of the Department of Pediatrics, [2] Department of Biochemistry, [3]Endocrinolgy Unit of the Department of Pediatrics, Medical School of Gazi University, ANKARA, Turkey

Background: Obesity is a common complication of treatment for acute lymphoblastic leukemia (ALL) in children. The adipokines, leptin and adiponectin play important role in regulation of energy metabolism, obesity and insulin resistance.
Aims: In order to assess the prevalence and risk factors for obesity and to explore the links between obesity, insulin resistance and adipokines in survivors of childhood ALL,
Methods: seventy-three children and adolescents (31 females and 42 males) were studied 3.4±2.9 (mean±SD) years after completion of ALL-Berlin-Frankfurt-Münster (BFM)-95 chemotherapy protocol. Informed consent and IRB approval were obtained for the study. Body mass index (BMI), levels of fasting blood glucose, serum insulin, leptin, adiponectin and lipids, and HOMA-IR (Homeostasis Model of Assesment-Insulin Resistance) for insulin resistance were determined at the last follow-up visit. Clinical data and changes in BMI and blood chemistry at diagnosis of ALL and during chemotherapy were retrieved from their medical files.
Results: The mean age of 73 ALL survivors was 13.9±4.8 years at the last visit and 7.6±4.6years at the diagnosis of ALL. Of them, 34.2% were overweight (BMI>85th -90th percentile) or obese (BMI>95th percentile). The proportion of overweight/obese children was not significantly different between girls and boys, risk groups and with and without parental obesity or cranial irradiation (1200 or 1800Gy). It was 23.3% at diagnosis and did not change significantly during the whole chemotherapy period. Of the 49 children who were lean or normal weight at diagnosis of ALL, 24.5% became overweight and 4.1% became obese at the time of this study. Leptin level (8.10±8.62 ng/mL) and leptin:adiponectin ratio (2.3±3.48) were significantly higher in ALL survivors than (3.16±2.24 ng/mL) in age matched healthy controls (P:0.02) while the levels of adiponectin, insulin and HOMA-IR were not significantly different between these two groups (P<0.05). HOMA-IR was significantly correlated with both serum leptin level (r:0.57) and leptin/adiponectin ratio (r:0.51),(P:0.001). However, the levels of leptin, adiponectin, insulin and HOMA-IR were not significantly different between lean/normal weight and overweight/obese ALL survivors. Fasting blood glucose was elevated in 7.5% and lipid profile was abnormal in 16.4% of 73 survivors.
Summary and Conclusions: Obesity is increased in survivors of childhood ALL independently of cranial irradiation, gender and parental obesity. Elevated leptin level in association with insulin resistance and dyslipidemia after treatment of childhood ALL may induce susceptibility to diabetes and cardiovascular disease.

P634

ZAP70 GENE EXPRESSION MAY BE A PROGNOSTIC FACTOR FOR ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS
B Xu[1,*], G Chen[1], P Shi[1], X Song[1], X Guo[1], Shuyun Zhou[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China
Background: Zeta-chain-associated protein (*ZAP- 70*) gene is normally expressed in T and natural killer cells that acts quickly after T cell activation to propagate signal. It has been described that *ZAP-70* contributes to the B-cell development at early stages of B-cell differentiation and *ZAP-70* gene expression is associated with poor prognosis in chronic lymphocytic leukaemia (CLL) but its role in adult acute lymphoblastic leukemia (ALL) has not been well established.
Aims: This study was to investigate the expression of *ZAP-70* in newly diagnosed patients of adult ALL and to explore the correlation between *ZAP-70* expression and outcome.
Methods: BM samples from 73 newly diagnosed ALL patients were analyzed. CD3, CD4, CD5, CD7, CD8, CD10, CD19, CD22, CD34 and other leukocyte surface markers were analyzed by cytofluorimeter. Of the 73 patients, 33 were females and 40 were males, with a median age of 23 years (range: 14 to 73 years). Among them, 52 out of 73 patients were B- ALL, 16 out of 73 patients were T-ALL and 5 out of 73 patients were biphenotypic ALL (BAL). 17 patients had the BCR-ABL translocation (Ph positive) confirmed by cytogenetics. ALL patients received 1 cycle of standard induction of VDLPfollowed by 6-8 courses of Hyper-CVADtherapy alternating with high-dose MTX and Ara-C (HD MTX–Ara-C) therapy. The patients were subdivided into high and low *ZAP-70* expression groups according to the median expression of *ZAP-70* mRNA in their pre-treated bone marrow cells. Comparisons were performed using X^2 test and independent-samples T test.
Results: *ZAP70* expressions were detected in 69.8% ALL patients.There were no statistical differences of *ZAP70* gene expression levels in FAB subgroups but in immunophenotyping groups, *ZAP70* gene expression levels of T-ALL patients were significantly higher than that of B-ALL and biphenotypic ALL (P<0.01). The expressions levels of *ZAP70* gene were not correlated to peripheral white blood cell (WBC) counts, hemoglobin level, platelet counts and percentage of bone marrow blast cells at presentation. There was no statistically significant relation between *ZAP-70* expression and BCR-ABL translocation. There was no statistically significant relation of complete remission (CR) rates between high and low *ZAP70* expressions in *de novo* ALL patients and T-ALL subgroup (*P* >0.05), but in common B-ALL subgroup, there was a correlation of CR rate between high and low *ZAP70* expressions (*P*=0.041). Adult ALL patients with high levels of *ZAP70* had a significantly higher relapse rates than those with low levels (48.3% *vs* 21.7%, *P*<0.05).
Summary and Conclusions: Our results showed *ZAP-70* expression correlates with an increased relapse rate in adult ALL patients and a worse CR rate in common B-ALL subgroup. Therefore the expression of *ZAP-70* may provide useful information for clinical decision.

P635

HIGH FREQUENCY OF BCR-ABL IN PEDIATRIC ACUTE LYMPHOID LEUKEMIA WITH POOR OUTCOME IDENTIFIES THE IMMEDIATE NEED FOR INCORPORATION OF IMATINIB AND OTHER TYROSINE KINASE INHIBITORS IN TREATMENT PROTOCOLS
Z Iqbal[1,2,3,*], A Tashfeen[1], M Iqbal[1,4,5], N Sabir[1], A Aleem[6], A Mukhtar Khalid[2], T Akhtar[1]
[1]Hematology, Oncology and Pharmaco-genetic Engineering Sciences (HOPES) Group, Health Sciences Research Laboratories, Department of Zoology, University of the Punjab, Lahore, [2]Next Generation Medical Biotechnology (NGMB) Division, School of Biological Sciences, University of Sargodha, Sargodha, Pakistan, [3]Clinical Laboratory Sciences (Medical Genetics/Hematology & Oncology), CAMS, King Saud Bin Abdulaziz University for Health Sciences National Guard Health Affairs, Riyadh, Saudi Arabia, [4]Department of Medicine, Asian Medical Institute, Kant, [5]Department of General Surgery, National Surgical Centre, Bishkek, Kyrgyzstan, [6]Division of Hematology/Oncology, Department of Medicine, School of Medicine and KKUH, King Saud University, Riyadh, Saudi Arabia

Background: Acute lymphoblastic leukemia (ALL), a neoplasm of lymphoid origin, is the most common cancer in children. It is a genetically complex disease involving many fusion oncogenes (FGs) which have important implications for prognosis, drug selection and treatment outcome (Xu *et al.*, 2012). The frequency of various FGs can vary in different ethnic groups (van-Dongen *et al.*, 1999). Pakistan has much lower cure rates of pediatric ALL which may be partially due to adverse genetic factors associated with the disease.
Aims: This study was designed to find out frequencies of prognostically important FGs in pediatric ALL and their association with disease biology and treatment outcome, which can provide a genetic clue of low cure rates in Pakistani pediatric ALL patients.
Methods: From 2002 to 2011, we analysed 204 pediatric ALL patients using interphase FISH and RT-PCR (van-Dongen et al, 1999) at presentation, for FGs and their association with clinical features as well as treatment outcome. Written informed consent was obtained from patients/guardians. All patients were treated per UKALL-2003 protocol.
Results: Overall relapse-free survival was 9.446 months (95% C.I.). Five most common FGs, *i.e.* BCR-ABL, ETV6-RUNX1, MLL-AF4, TCF3-PBX1 and SIL-TAL1, were detected in 183/204 (88.1%) patients, with frequencies of 47.05%, 17.2%, 16.2%, 7.4% and 1.97%, respectively. ETV6-RUNX1 was underrepresented in our pediatric ALL population. The highest early response (94.4%) was seen in this genetic subtype followed by SIL-TAL1 (71.4%) and patients with no FGs (66.7%).The highest relapse-free survival (RFS) was documented in ETV6-RUNX1 (14.167 months) followed closely by those 10.4% cases in which no gene was detected (13.1 months). RFS in BCR-ABL, MLL-AF4, TCF-PBX4 and SIL-TAL1 was less than 10 months (7.994, 3.559, 5.500 and 8.080 months, respectively). Lymphadenopathy was most common in MLL-AF4 (70.6%)
BCR-ABL was detected in 47.05% (96/204) patients. Frequency of occurrence was directly proportional to age (6.7% in less than 2 year age group, 35.5% in the 2-7 year age group and 57.8% in the older than 7 group). Total leukocyte count (TLC) was higher when compared to patients with other oncogenes and

organomegaly was not common (). BCR-ABL positivity was associated with low remission rates (64.4% late remissions) and shortened survival (43.73±4.24 weeks) (Table 1).

Table 1. Clinical characteristic and treatment outcome of Pakistani pediatric ALL patients.

Clinical and laboratory parameters	BCR-ABL (%) N=96	ETV6-RUNX1 (%) N=35	MLL-AF4 (%) N=33	SIL-TAL1 (%) N=15	TCF3-PBX1 (%) N=4	FGs not detected (%) N=21

RFS (months)	7.994	14.17	3.559	8.08	5.5	13.1

Summary and Conclusions: We are the first group from Pakistan reporting the correlation of molecular markers with disease biology and treatment outcome in pediatric ALL. Poor prognostic FGs namely BCR-ABL, MLL-AF4, SIL-TAL1 and TCF3-PBX1 were collectively detected in 72.4% of patients may be the one of the reasons for already reported low cure rates of pediatric ALL (Asim *et al.*, 2011) in our country. We found the highest reported frequency of BCR-ABL FGs in Pakistani pediatric ALL, in consistent with various other reports from Pakistan (Iqbal & Akhtar, 2006; Iqbal *et al.*, 2007; Faiz et al*.,* 2011; Awan et al, 2012) and the rest of the world which (Siddiqui *et al.*, 2010). It was associated with late responses and poor survival. The study has a specific clinical implication after FDA approval of imatinib for pediatric BCR-ABL positive ALL and other tyrosine kinase inhibitors (TKIs) under clinical trials on the way of rapid FDA approval. We recommend immediate incorporation of imatinib in pediatric ALL treatment protocols and provision of other TKIs for imatinib resistant BCR-ABL positive pediatric ALL in our population. Further large scale studies are required to find out the possible reasons for high BCR-ABL frequency among Pakistani pediatric ALL patients.

P636

SAFETY OF ASPARAGINASE ERWINIA CHRYSANTHEMI IN A COMPASSIONATE-USE TRIAL: A SUBANALYSIS OF THE ADOLESCENT/YOUNG ADULT PATIENT POPULATION

P Plourde[1,*], S Jeha[2], N Hijiya[3], F Keller[4], S Rheingold[5], Z Dreyer[6], G Dahl[7], T Mercedes[1], T Corn[8]
[1]Jazz Pharmaceuticals, Inc, Palo Alto, [2]St. Jude Children's Research Hospital, Memphis, [3]Lurie Children's Hospital of Chicago, Chicago, [4]Children's Healthcare of Atlanta, Atlanta, [5]Children's Hospital of Philadelphia, Philadelphia, [6]Texas Children's Hospital, Houston, [7]Lucile Packard Children's Hospital, Palo Alto, United States, [8]EUSA Pharma (an international division of Jazz Pharmaceuticals), Oxford, United Kingdom

Background: L-asparaginase (L-ASP) is an important component of multiagent chemotherapy for treatment of acute lymphoblastic leukemia (ALL) in children and young adults. The adolescent/young adult (AYA) population is usually defined in the literature as patients aged 16–39 years. NCCN guidelines recommend that AYA patients with ALL be treated with "pediatric-inspired" protocols that include L-ASP as an integral component of their multiagent chemotherapy regimen. Hypersensitivity reactions occur in 10%–30% of patients treated with *E coli*–derived asparaginases, often resulting in their discontinuation. In those patients, it is recommended that *Erwinia chrysanthemi* (ERC), an L-ASP immunologically distinct from *E coli*–derived L-ASP, be initiated.
Aims: This large compassionate-use trial in patients with ALL or lymphoblastic lymphoma who developed a grade ≥2 hypersensitivity reaction to an *E coli*–derived L-ASP was conducted to evaluate the safety of ERC.
Methods: This study met institutional review board approval, and all patients provided written consent. The ERC safety information for the entire study population was previously reported at the American Society of Hematology Annual Meeting in December 2012. Patients were excluded if they had a history of pancreatitis, previous allergic reaction to ERC, or were pregnant. Here, we report a safety analysis of a subset of 147 AYA patients, a population in which little ERC safety information has been presented.
Results: 1368 patients were treated with ERC from which 940 patients completed adverse events (AEs) and/or case report forms. The 147 AYA patients were primarily male (68.7%), had nonrelapsed disease (71.4%), B-lineage ALL (71.4%), received intramuscular ERC (87.8%), and had a median age of 18 years (range 16–39 years). 72.8% completed their planned ERC course. Discontinuation was due to allergic reaction (3.4%), other AEs (9.5%), other reasons (6.1%), and unknown reasons (8.2%). 45.6% of AYA patients had a least 1 treatment-emergent AE. Hypersensitivity occurred in 13.6%, hyperglycemia in 6.1%, pancreatitis in 3.4%, thrombosis in 3.4%, and sepsis in 3.4%. Grade 3/4 AEs with a >2% incidence included hyperglycemia (6.1%), hypersensitivity (2.7%), and dehydration (2.7%). There were 9 deaths; 4 disease progression, 3 infection, 1 renal impairment, 1 unknown. One death was considered possibly related to the study drug.
Summary and Conclusions: The safety profile of ERC in this subset of AYA patients was consistent with the profile reported in the entire study population. This compassionate-use trial permitted the completion of L-ASP in 72.8% of AYA patients with hypersensitivity reactions to *E coli* formulations.

P637

ASSESSMENT OF COAGULOPATHY DUE TO PEG-ASPARAGINASI IN CHILDREN WITH ALL

G Geranio[1,*], L Spiezia[2], M Teresa Sartori[2], S Varotto[1], E Campello[2], M Bon[2], S Maggiolo[2], P Simioni[2], G Basso[1], M Putti[1]
[1]Department of Pediatrics, Division of Pediatric Hematology and Oncology, [2]Department of cardioogic, Thoracic and Vascular Sciences, 2nd Chair of Internal Medicine, University of Padua Medical School, Padua, Italy

Background: Background. Treatment with L-Asparaginase (L-Asp) or PEG-L-Asparaginase (PEG-L-Asp) in patients with acute lymphoblastic leukemia (ALL) is associated with coagulation disturbances, being deep venous thrombosis the most common clinical consequence, which should weighted with hemorrhagic risk. Classical coagulative parameters hardly identify the coagulative imbalance, being only antithrombin (AT) plasma levels the only reliable parameter for thrombotic risk. Whole blood rotation thromboelastometry (ROTEM®), using FIBTEM test, has been reported to be a good tool to identify hypofibrinogenemia and hemorrhagic tendency.
Aims: To evaluate whole blood rotation thromboelastometry profiles in children with ALL treated at our institution with PEG-L-Asp according to AIEOP-BFM ALL protocol in order to identify strategies for monitoring and treating complications.
Methods: Children treated with PEG-L-Asp for ALL consecutively referred to the Pediatric Hemato-Oncology Clinic of the Padua University Hospital, from June to December 2012, were enrolled. After informed consent, samples were obtained at predefined time points during the induction and reinduction phases of chemotherapy. Maximum Clot Firmness (MCF, normal value 9-25 mm), *i.e.* the maximum amplitude in millimeters reached in FIBTEM thromboelastogram, which is used to assess the specific role of fibrinogen in whole blood clot formation following inhibition of the platelets by Cytocalasin D, was performed. Moreover, blood counts, AT and fibrinogen plasma levels were measured on the same samples.
Results: wo hundred twenty two sets of thromboelastometry measurements were collected from 24 ALL patients (age range 20 months - 17 yrs; M/F 13/11). Ninety-two MCF measurements (41%) resulted below the lower limit of MCF normal value (<9mm). A significant linear correlation was found between MCF values in FIBTEM and fibrinogen plasma levels measured with Clauss method (P<0.001). No influence of reduced AT plasma levels on thromboelastometry determination was observed. Replacement with i.v. fibrinogen concentrates was suggested for MCF values <2 mm. AT values below 50% were found in 50 determinations (23% of tested samples). AT was supplemented in 12 cases. Coagulation abnormalities were found up to 20 days after PEG ASP administration. In two children undergoing prolonged drug injection, a cumulative effect of drug toxicity in fibrinogen plasma level was not observed; in these patients AT was only moderately reduced. Classical tests were not always consistent with the ROTEM profile. No major hemorrhagic complication was reported in our cohort. One 6-year old boy presented cerebral venous thrombosis, while in a severe hypocoagulable state but in presence of recovering platelets count.
Summary and Conclusions: The MCF value in FIBTEM was more accurate than the Clauss assay to define discoagulopathy and to identify the threshold for supplementation. The determination of fibrinogen function by means of ROTEM® can be considered a complementary test to the conventional clotting profile used for the management of AsP-induced coagulopathy in children with ALL. Larger studies are needed to evaluate the role of thromboelastometry to guide fibrinogen replacement therapy in acquired hypofibrinogenemia due to Asp treatment.

P638

EFFECTS OF PROPHYLACTIC CRANIAL RADIOTHERAPY ON GROWTH HORMONE SECRETION OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

G Aydogan[1,*], G Biceroglu[1], T Akcay[1], A Akcay[1], F Akici[1], D Tugcu[1], Z Salcioglu[1], H Sen[1], N Ayaz[1], M Demirkaya[1], M Gokce[1]
[1]Pediatric Hematology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: With the recent developments in the treatment of acute lymphoblastic leukemia (ALL) life expectancy is prolonged and complications due to therapy are increased. Combined chemotherapy may be applied in combination with distinct doses and schema of cranial radiotherapy (CRT) according to the risk groups of patients. CRT damages the hypothalamus-hypophysis axis and affects the secretion of growth hormone (GH) at first and the other anterior hypophysis hormones also. At high doses of CRT, GH deficiency might occur in the long term follow-up, at lower doses the secretion pattern of GH may change.
Aims: We aimed to demonstrate whether prophylactic doses of cranial radiotherapy raise the neurosecretory dysfunction of growth hormone in children with ALL.
Methods: Thirty-two children (14 girls and 18 boys), diagnosed as ALL and applied prophylactic cranial therapy were enrolled to the study. Physical findings, weight and height measurements, Tanner stagings and bone age evaluations were performed to all patients. In order to interpret the functions of anterior and posterior hypophysis morning basal IGF-1, IGFBP-3, thyroid hormones, cortisol, prolactin and dansity of urine were measured. Gonodotropins were not tested because none of our patients had the signs of early or late puberty. In order to evaluate the growth rate; weights and heights of the patients were measured after the first year. Even though the growth rate of some patients were normal, GH stimulation tests with clonidine were done to all cases, due to the fact that GH deficiency and neurosecretory dysfunction might be present pharmacologically. Second GH stimulation test with L-dopa were applied to patients with peak GH levels of <10 ng/mL. If the level was low in the second test, patients were accepted as GH deficient. For patients with low growth rate, low IGF-1/IGFBP-3 according to age and sex, but normal GH levels, night GH secretion pattern were tested. Patients with inadequate response to night secretion test were accepted as neurosecretory dysfunction.
Results: In our study, 25% of the patients were found to have complete and 21,7% incomplete GH deficiency. In 9.3% of cases there was GH-neurosecretory dysfunction (GH_NSD). There was no statistically significant relationship between the time passed after radiotherapy and GH axis dysfunction degree. IGF-BP3 was found to be more reliable than IGF-1 in estimating GH deficiency/GH-NSD.
Summary and Conclusions: Prophylactic CRT affects the GH axis negatively in ALL patients, so their close follow-up is precious and mandatory.

P639

THE IMPACT OF RISK STRATIFICATION BY EARLY BONE-MARROW RESPONSE AND FCM-MRD IN CHILDHOOD LYMPHOBLASTIC LEUKAEMIA (A SINGLE INSTITUTION EXPERIENCE IN AZIZA OTHMANA HOSPITAL, TUNIS, TUNISIA).

Y Abdennebi[1,*], L Aissaoui[1], H Neji[1], Z Mohamed[1], G Emna[1], J Ramzi[1], B Hela[1], M Balkis[1]
[1]Hematology, Aziza Othmana Hospital, Tunis, Tunisia

Background: In a previous retrospective analysis of 58 children with ALL treated according to the EORTC 58951 protocol between 2001 and 2003, patients were stratified by age, WBC at diagnosis, immunophenotype, karyotype and steroids response in peripheral smears after 7 days of corticosteroid and one IT dose of MTX. 3-year EFS, DFS and OS were unsatisfactory: 46%, 49,8% and 55,4%. In order to improve our results, the stratification strategy was extended by additional use of early response to therapy: blast cell count in the BM was examinated on D7 and D19 during remission induction, and determination of MRD measured by FCM in the BM at the end of induction (D35). All patients were assigned to a DXM based induction. Patients whose blast cells were ≥25% in BM (M3 marrow) at D7 and or at D 19, or whose MRD was positive at the end of induction, had their treatment one step upgraded.
Aims: This study aimed to assess the prognostic value of morphological assessment of bone marrow blasts during remission induction and the prognostic significance of minimal residual disease (MRD) detected by a simplified flow cytometric assay after remission induction in children with acute lymphoblastic leukemia (ALL).
Methods: Patients under 25 years of age with previously untreated ALL were treated according to the EORTC 58951 protocol between January 2006 and December 2010. The diagnosis of ALL was based on morphological and immunophenotypical criteria. Immunophenotype was determined with standard techniques,Chromosome analysis used standard techniques. We performed a prospective study of an early treatment response as assessed by morphological examination of BM blasts on D7 and on D19, and MRD determination by CMF, based strategy. Patients were assigned to 3 risk groups: The average 1 risk (AR1) group consisted of all patients with B-cell lineage ALL, NCI standard risk with an M1/M2 bone marrow on day 7. B-cell lineage ALL patients NCI high-risk or T-cell lineage ALL patients were classified as average 2 risk group AR2. All patients with gonadal or CNS involvement, were also included in the AR2 group, and patients with a day-7 M3 marrow and day-19 M1/M2 were assigned to AVR2 group. And very high risk (VHR) group consisted of blast counts in peripheral blood ≥1×109/L at completion of the prephase, t(9;22), t(4;11) or another MLL rearrangement, near-haploidy (<34chromosomes), or acute undifferentiated leukemia (AUL), or patients with a day-19 M3 marrow, or failure to achieve complete remission or minimal residual disease (MRD) >10-2 at completion of induction.
Results: 162 pediatric patients (100 males and 62 females) were enrolled, median age was 8 years (18months to 25 years), 40,7% aged ≥10 years at diagnosis, 29% with a WBC ≥50 Giga/l. Immunophenotyping was done for all patients, 110 (67,9%) B-ALL, 37 (22,8%) T-ALL, 4 (2,5%) undifferenciated, 7 (4,3%) biphenotypic leukemia and immunophenotype was no contributive in 4 cases. 116 (71,6%) patients had M3 marrow responses on day 7. 31 (19,1%) were steroid poor responders at day 8 in in the peripheral blood (pB). On day 19, 16 (9,9%) patients had M3 marrow. 155 patients received phase IA RM2-VHR according to the EORTC 58951 protocol, with HD-MTX (5g/m2) on day 8 and cyclophosphamide (1g/m2) on day 9. The CR was 85, 2%, induction failure and induction death rates were4,3% and10,5% respectively. MRD results available in 128 cases, sensitivity of 0,01%, between 0,01% and 0,1%, between 0,1% and >1% was achieved respectively in 23,4%, 43%, 25,8% and 7,8%. The 3-year RFS and OS were 85,7% and 73,6% respectively. In Univariate analyses, female, WBC<50 G/l, no M3 bone marrow on day 19 and MRD at the end of induction <10-3 have a significantly better RFS. Patients with ≥25% leukemic cells on day 19 had a significantly lower relapse-free survival (RFS) compared to those with rapid early response <25% (64.3% *vs* 87,5% P=0.003). Stratification into 3 MRD groups (≥1%, 0.1-1%, and <0.1%) also showed a statistically significant difference in RFS (33% *vs.* 78.6% [8.7%] *vs.* 83,4%, P=0.003). Multivariate analysis demonstrated that the early marrow response on day 19 and MRD level at the end of induction were an independent prognostic factor.
Summary and Conclusions: Early treatment response as assessed by morphological examination or minimal residual leukemia determination by flow cytometry has important prognostic significance, and can be performed in a resource-poor patient population.

Acute myeloid leukemia - Biology 2

P640

THE EXPRESSION OF THE EGF-TM7 MOLECULES CD97, EMR2 AND EMR3 IS ASSOCIATED WITH MUTATED NPM1 AND FLT3 IN AML

M Wobus[1,*], M Bornhäuser[1], S Schumann[1], C Klotsche[1], C Rüger[1], C Ortlepp[1], G Ehninger[1], C Thiede[1], U Oelschlägel[1]
[1]Hematology/Oncology, University Hospital Dresden, Dresden, Germany

Background: Acute myeloid leukemia (AML) is a disease characterized by an increase of immature myeloid blasts in the bone marrow. As for normal hematopoietic stem cells (HSCs), the interaction with the surrounding bone marrow microenvironment mediated by cell surface proteins is important for leukemic (stem) cell fate and characteristics. Therefore, the definition of new marker molecules is fundamental to further unravel the biology of leukemogenesis and to discover new therapeutic targets.
Aims: CD97, EMR2 and EMR3 are EGF-TM7 molecules, a subgroup of adhesion GPCRs, expressed in lymphoid and myeloid cells. However, almost nothing is known about their expression and regulation in normal and malignant hematopoietic stem cells.
Methods: We studied 292 samples from patients with *de novo* acute leukemia, comprising AML M0-2 (n=195), AML M3 (n=16), AML M4/5 (n=63), AML M6/7 (n=4) and c-ALL (n=14). A 4-color immunophenotypic measurement was performed on a FACS Canto II using the following antibodies: CD34 PerCp5.5, CD117 FITC, CD97 APC, CD45 V500. FLT3-ITD mutations and NPM1-mutations were detected as reported in detail previously (Thiede C *et al.* Blood 2002; Thiede C *et al.* Blood 2006). Moreover, EMR2 PE and EMR3 APC were measured in 37 patient samples. In three human AML cell lines, MV4-11, EOL-1 and OCI-AML3, which display a specific FLT3 and NMP1 mutation status, we investigated the expression levels of CD97, EMR2 and EMR3 and a possible influence of the protein kinase inhibitors PKC412 (Midostaurin) and SU5614.
Results: Compared to BM blasts of healthy donors (n=10),we detected significantly higher CD97 expression levels (mean fluorescence intensity, MFI) in 144 AML samples (49%). In detail, the CD97 expression could be observed in 40% out of cases with M0-2, 100% of cases with M3, 59% of patients with M4/5, 75% of M6/7 and 71% of the c-ALL cases, respectively. Of note, higher CD97 expression was accompanied by a significantly higher BM blast count (75% *vs.* 53%, P<0.001) and a lower Hb (5.9 *vs.* 6.5, P=0.02). Interestingly, elevated CD97 expression was associated with mutations in NPM1 (44% *vs.* 19%, P=0.002) and FLT3 genes (43% *vs.* 10%, P<0.0001) as well as lower CD34 (52% *vs.* 83%, P<0.0001) and HLA-DR expression (79% *vs.* 96%, P<0.0001). EMR2 was detected in 16 out of 37 and EMR3 in 24 out of 37 cases. In-vitro, we detected the highest CD97 expression levels (MFI 306.3) in MV4-11 AML cells which carry a FLT3-ITD mutation. Incubation with the multikinase inhibitor PKC412 or SU5614 caused a significant decrease of CD97 expression (MFI 167.6 and 124.1, respectively). Whereas EOL-1 cells expressing wildtype FLT3 displayed low CD97 levels (MFI 16.9) without an influence of the protein tyrosine kinase inhibitors, OCI-AML3 cells carrying wildtype FLT3 but mutated NPM1 expressed moderate CD97 levels (MFI 166.3) which were significantly increased by PKC412 (MFI 266). In EOL-1 cells also EMR2 and EMR3 were expressed at very low levels. The high expression levels of both molecules were decreased by PKC412 in MV4-11 cells but increased in OCI-AML3, whereas SU5614 decreased their expression in MV4-11 cells only.
Summary and Conclusions: For the first time, we present an association between the expression of the EGF-TM7 receptors CD97, EMR2 and EMR3 and AML pathophysiology. The exact mechanism of regulation will be further determined.

P641

IDENTIFICATION OF NOVEL GENETIC ALTERATIONS BY WHOLE-TRANSCRIPTOME SEQUENCING IN INFANTS WITH CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA

M Togni[1,*], R Masetti[1], A Astolfi[2], V Indio[2], M Pigazzi[3], E Manara[3], R Casadio[4], G Basso[3], A Pession[1], F Locatelli[5]
[1]Department of Pediatrics, "Lalla Seràgnoli", Hematology-Oncology Unit - University of Bologna, [2]Giorgio Prodi Cancer Research Center, University of Bologna, Bologna, [3]Department of Woman and Child Health, Laboratory of Hematology-Oncology, University of Padova, Padova, [4]Biocomputing Group, Department of Biological, Geological and Environmental Sciences (BiGeA), University of Bologna, Bologna, [5]Department of Pediatric Hematology-Oncology, IRCCS Ospedale Bambino Gesù, University of Pavia, Roma, Italy

Background: Pediatric cytogenetically normal acute myeloid leukemia (CN-AML) is a heterogeneous subgroup of myeloid clonal disorders not harboring known mutations. Genome-wide analyses have been used with the aim of determining the full array of genetic lesions of CN-AML and recent studies have provided new insights into the molecular genetics/biology of AML. Nevertheless, there is a considerable proportion of children with CN-AML in whom no genetic abnormality has been detected. Therefore, the identification of the different genetic profiles characterizing this subgroup represents a primary objective to be pursued.
Aims: To identify novel recurrent somatic mutations or genomic rearrangements which could be relevant for prognosis and therapy, we performed whole-transcriptome massively parallel sequencing of 8 cases of infant CN-AML.
Methods: Patients analyzed were children within the first year of life (infant) with newly diagnosed *de novo* CN-AML. All patients had AML other than acute promyelocytic leukemia, were negative for chromosomal rearrangements and for known recurrent genetic abnormalities involving *MLL*, *CBFB*, *NPM1* and *FLT3* genes. RNA-seq was performed at 75×2 in paired-end mode on the Illumina HiScanSQ. Reads were aligned with TopHat2/BowTie2 to the reference human genome. SNVMix2 was used to detect single nucleotide variants (SNVs); deFuse and ChimeraScan packages were used to detect chimeric transcripts. SNP&GO and Provean software were used to identify the SNVs potentially associated with the disease.
Results: Whole-transcriptome massively parallel sequencing in the 8 children with CN-AML, yielded an average of 59.1 million mapped reads/patient, thus reaching an average coverage of 34X. In three out of eight patients we identified a recurrent cryptic inversion of chromosome16, encoding a *CBFA2T3-GLIS2* fusion transcript. Recently, we also published data indicating that this fusion transcript is a novel common feature of pediatric CN-AML, not restricted only to the FAB M7 subtype, predicting poorer outcome, the 5-year event-free survival of patients *CBFA2T3-GLIS2* positive being of 27.4% (SE 10.5) *versus* 59.6% (SE 3.6) of patients *CBFA2T3-GLIS2*-negative (*P*=0.01). Interestingly, in all the three patients in which we identified the CBFA2T3-GLIS2 fusion gene, we have also detected a novel read-through transcript that lead to the fusion of exon 2 of DHH gene, a member of the Hedgehog family, with the exon 2 of RHEBL1 gene which encodes for a small GTPase of Ras family that regulates a wide variety of cellular functions including cell growth, differentiation, and transformation. Further studies will assess the recurrence of DHH-RHEBL1 read-through transcript and its possible prognostic and therapeutic relevance. RNA-seq allowed us also to identified 60 SNVs potentially associated with the disease. Recurrent mutations were detected in genes that regulates apoptosis (TRAP1 [37.5%], BCL3 [12.5%], MCL1 [25%]), in genes implicated in the control of cell proliferation and differentiation (RUNX3 [25%], APBB1[25%], EP300 [25%]) and also in JAK/STAT signaling pathway (Figure 1).

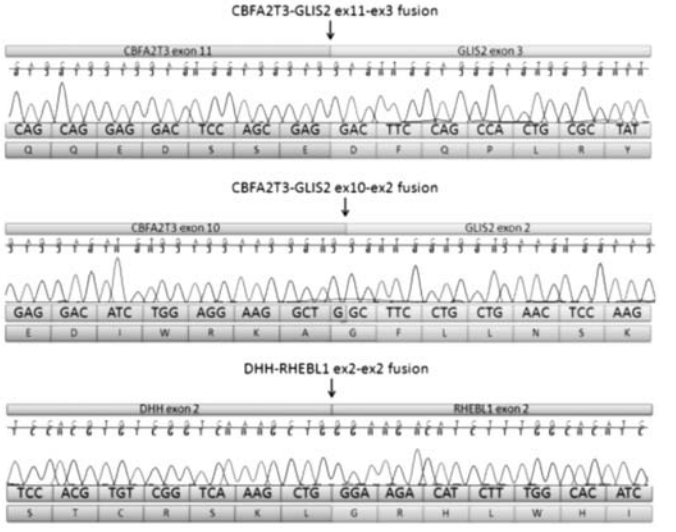

Figure 1. Novel fusion transcripts identified by whole-transcriptome sequencing in infants with cytogenetically normal acute myeloid leukemia. Schematic representation of the fusion breakpoints identified, electropherograms and predicted sequences of the fusion proteins found in infant CN-AML. Black arrow indicates the fusion breakpoints.

Summary and Conclusions: We demonstrated that infant CN-AML CBFA2T3-GLIS2-positive patients also harbor a novel read-through fusion transcript occurring between DHH and RHEBL1. Additionally, we also identified several SNVs affecting key genes of important cellular processes. Future studies will assess whether these genetic alterations could be novel independent prognostic markers and potential therapeutic targets.

P642

2HG IS A STRONG SERUM BIOMARKER FOR IDH1/2 MUTATIONS IN *DE NOVO* AML

S De Botton[1,*], M Janin [2], J Micol [1], E Mylonas[3], V Saada[4], A Renneville [5], S Koscielny [6], P Pautas [7], D Caillot [8], C Berthon [9], E Chachaty [4], F Griscelli [4], A Bennaceur-Griscelli[4], E Solary[1], C Preudhomme[5], N Auger4, H Dombret[10], O Bernard [3], V Penard-Lacronique [3], Ottolenghi [2]

[1]Hematology, Institut Gustave Roussy, Villejuif, [2]Biochimie métabolique, Groupe Hospitalier Necker-Enfants Malades, Paris, [3](INSERM) U985, [4]Département de Biologie et Pathologie Médicales, Institut Gustave Roussy, Villejuif, [5]Hématologie Biologique, CHRU Lille, Lille, [6]Service of biostatistics and epidemiology, Institut Gustave Roussy, Villejuif, [7]Hematology, Centre Hospitalier Henri Mondor, Creteil, [8]Hematology, CHU Dijon, Dijon, [9]Hematology, CHRU Lille, Lille, [10]Hematology, Hôpital Saint-Louis, Paris, France

Background: Mutations in the genes encoding IDH1 and IDH2 produce high levels of 2-hydroxyglutarate (2HG).
Aims: We asked whether, in acute myeloid leukemia (AML), serum 2HG can predict the presence of *IDH* 1/2 mutations at diagnosis, and serve as a marker of minimal residual disease (MRD).
Methods: Serum samples of 82 patients at diagnosis of *de novo* AML (*IDH* mutated n=53; *IDH* wildtype n=29) and 68 non-AML controls were analyzed for total 2HG and its L (S) and D (R) stereoisomers by mass spectrometry. We investigated the relationships between 2HG levels and molecular markers of minimal residual disease (MDR; *WT1* expression and *NPM1* mutation) in serial serum and cellular samples of 36 *IDH* mutated patients after induction therapy.
Results: Total 2HG serum levels were significantly higher in AML patients with *IDH1/2* mutations than IDH wild type AML patients (P=<0.0001). The optimum diagnostic cutoff between IDH mutated and wild type was 2 μM (area under curve [AUC] >99%, sensitivity 100%, and specificity 89%. Quantification of the D/L stereoisomers provided higher specificity (98%) at 100% sensitivity, (P=.002). *IDH2 R172* mutants had 2HG levels higher than other mutants (P=.01). After induction therapy, total 2-HG serum levels <2 μM were associated with better overall survival (P=.007) and better disease-free survival (P=.005). During the follow-up, serum 2HG levels showed strong positive correlation with molecular markers of MRD (P<.001).
Summary and Conclusions: 2HG is a strong serum biomarker for *IDH* mutations and a significant predictor for outcome in IDH 1/2 AML patients. 2 HG measurements serve as a marker of minimal residual disease.

P643

ALTERED GENES DOWNSTREAM OF MYCN IN ACUTE MYELOID LEUKEMIA IN ZEBRAFISH BY RETINOIC ACID AND VALPROIC ACID

L Shen[1], F Chen[1,*], Z Xuan[1]
[1]Hematology, Renji Hospital,Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Amplification of *MYCN* (*N-Myc*) oncogene has been reported as a frequent event and a poor prognostic marker in human acute myeloid leukemia (AML) and neuroblastoma. 13-Cis retinoic acid (AC) and valproic acid (VC) are currently used in the treatment of *MYCN* amplified neuroblastoma patients with minimal residual disease. In early work, we have induced AML in zebrafish using murine *MYCN* (*mMYCN*) transgene and EGFP under control of the heat shock elements (HSEs).
Aims: To identify that AC and VC are appropriated for treating *MYCN* amplified AML.
Methods: The WT and *Tg*(*MYCN*:HSE:EGFP) F1 generation (Tg) embryos were heated shocked at 38° for 1 hour at 16 hours post fertilization (hpf) and hematopoietic cells were collected at 3 dpf by flow cytometry. Total RNA from 5×10^4cells was isolated with Trizol (Invitrogen). The samples were processed and subsequently analyzed in triplicate on Zebrafish Oligo Microarrays (Agilent Technologies Italia, Italy) which contain 43,554 sets of probes. The microarrays were scanned in an Agilent DNA Microarray Scanner and the images were processed using Feature Extraction software. Functional annotation analysis was performed using NIH-DAVID software (version 6.7). Next, the WT and Tg embryos were treated with DMSO (0.1%) or various concentrations of AC (Sigma 4759-48-220:1, 1.5 μM) and VC (Sigma 1069-66-5: 40, 60μM) incubated in 12-well plates (30 embryos/well) at 28.5 °Cfrom 14 hpf to 72 hpf. Then the differentially expressed genes involved in microarray-analysiswere measuredby qRT-PCR. The assay was repeated three times independently.
Results: UsingAgilentmicroarray analysis, we have demonstrated that signaling pathways involved in cell cycle progression, glycolysis/gluconeogenesis,fatty acid metabolism, MAPK/Ras, tyrosine metabolismand p53-mediated apoptosiswere enhanced, while those of mismatch repair, homologous recombination, transforming growth factor β (TGFβ) and base excisionrepair were inhibited in the blood cells of Tg *versus* WT embryos at 3dpf. We observed that both AC and VC counteracted over-expression of *MYCN* induced cell cycle uP-regulation and p53-mediated apoptosis through the expression of vital genes belonging to the cell cycle [S-phase associated kinase 2 (*Skp2*), p27 and p21], MAPK (Ras),p53 andTGFβ pathway(*Smad 4/7*). (Shown in Figure 1. WT: wild type; MYCN: *Tg*(*MYCN*:HSE:EGFP) F1 generation; 1: low dose of AC or VC; 2: high dose of AC or VC. Compared with Tg: *, P<0.05; **, P<0.01.).
Summary and Conclusions: Our results show that AC and VC are potent therapeutics to *MYCN* amplified AML by inhibiting AML cell growth.

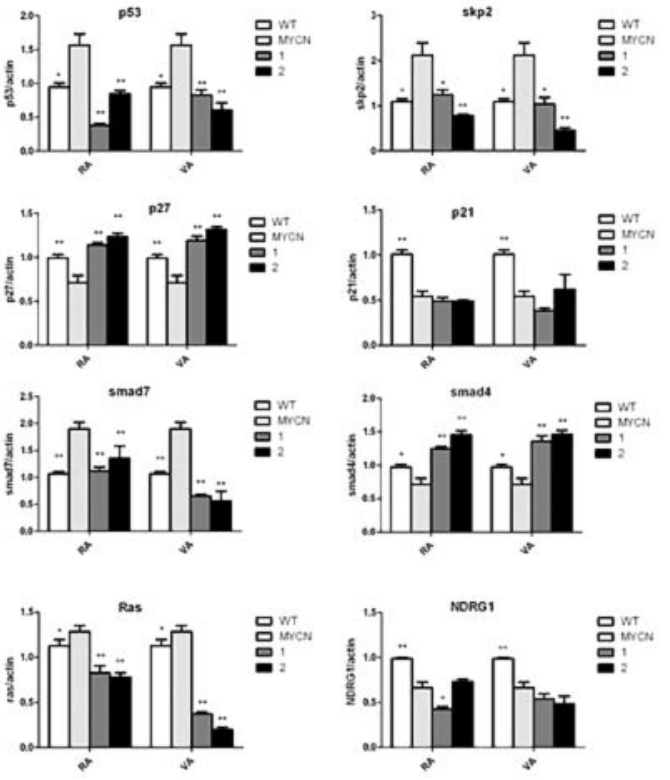

Figure 1.

THE AAA+ ATPASE RUVBL2 IS CRITICAL FOR THE ONCOGENIC ACTIVITY OF MLL-FUSIONS

L Zhao[1,*], H Osaki[1], V Walf-Vorderwülbecke[1], J de Boer[1], O Williams[1]
[1]UCL Institute of Child Health, London, United Kingdom

Background: Chromosome translocations that disrupt the Mixed Lineage Leukaemia (*MLL*) gene are associated with a unique subset of Acute Myelogenous and Lymphoblastic Leukaemias. *MLL* translocations are most prevalent in infant leukaemia, where they comprise 80% of cases of Acute Lymphoblastic Leukaemia and 60% of cases in Acute Myeloid Leukaemia. Expression of MLL-fusion proteins is known to induce malignant transformation of normal haematopoietic progenitor cells. To identify transcriptional target genes required for the immortalisation, previous work in our laboratory involved generating constitutively and conditionally immortalised primary mouse haematopoietic progenitor cells. Global gene expression analysis, upon loss of MLL-fusion protein, identified a number of genes that were differentially expressed.
Aims: This study investigated the function of one of these differentially expressed genes, *Ruvbl2*, in MLL-fusion mediated leukaemogenesis.
Results: RUVBL2 is a member of the AAA+ family of DNA helicases and plays an important role in diverse cellular processes. To examine the efficacy of targeting RUVBL2 in leukaemia elimination *in vivo*, inducible models were generated for both the human leukemic cell line, THP1, and mouse MLL-ENL leukemic cells. Upon doxycycline treatment, RUVBL2 is inhibited either via shRNA-mediated knockdown or through the expression of a dominant-negative mutant form of RUVBL2. In concurrence with previous data from the laboratory, RUVBL2 inhibition resulted in a marked increase in apoptosis, reduction in colony formation and a block in cell cycle. In addition, transplantation experiments demonstrated that inhibition of RUVBL2 function significantly delayed leukemic onset *in vivo*. In parallel, while expression of dominant negative RUVBL2 induced apoptosis in mouse MLL-ENL leukemic cells, it had a relatively mild impact on normal haematopoietic progenitor colony formation *in vitro*. Further experiments indicated that RUVBL2 functioned mainly through influencing the transcriptional activity of MYC.
Summary and Conclusions: Taken together, our data suggest that a potential therapeutic window exists for targeting RUVBL2 function in MLL rearranged leukaemia.

P645

EXPRESSION, REGULATION AND FUNCTIONAL ROLES OF THE CHEMOKINE RECEPTOR CXCR7 IN ACUTE MYELOID LEUKAEMIA CELLS

H Kim[1,*], H Ryu[1], Y Choi[1], I Song [1], H Lee[1], H Yun[1], S Kim[1], D Jo[1]
[1]Department of Internal Medicine, School of Medicine, Chungnam National University, Daejeon, Korea, Republic of Korea

Background: Stromal cell-derived factor (SDF)-1 is constitutively expressed and produced by stromal cells in bone marrow (BM). The protein exerts its functions by binding to its receptor, CXCR4, thereby guiding the homing of haematopoietic stem/progenitor cells and leukaemia cells to the BM. Recently, CXCR7 was identified as an alternative receptor for SDF-1, and it has been shown to be involved in adhesion to the endothelium and proliferation of several normal and malignant cell types, rather than cell migration. CXCR7 was shown to be a decoy receptor for CXCR4 in certain cell types. Its expression status and its roles in acute myeloid leukaemia (AML) cells are largely unknown.
Aims: We investigated the expression, regulation and functional roles of CXCR7 in AML cells *in vitro.*
Methods: The expression of CXCR7 in AML cells was studied by reverse transcriptase- polymerase chain reaction (RT-PCR), Western blotting and flow cytometry. The effects of various cytokines and hypoxia on the expression of CXCR7 in AML cells were examined. To determine the functional role of CXCR7, CXCR7 mRNA was knocked down in AML cells using siRNA technology, and subsequent biological alterations in the cells were evaluated *in vitro*.
Results: All AML cell lines examined in this study (U937, K562, KG1a, HL-60 and MO7e), as well as primary CD34$^+$ cells obtained from the BM of patients with AML, expressed CXCR7 mRNA at various levels, as shown by semi-quantitative and real-time RT-PCR analysis. Western blotting showed that all AML cells produce CXCR7. In parallel, all AML cells expressed CXCR7 both in the cytoplasm and on the cell surface at various levels, as revealed by flow cytometric analysis. SDF-1 induced the internalisation of cell surface CXCR7. However, neither hypoxia nor the haematopoietic growth factors (IL-β, IL-3, IL-6, G-CSF, GM-CSF and SCF) and proinflammatory cytokines (IFN-γ, TGF-β and TNF-α) examined altered cell surface CXCR7 expression. The transfection of AML cells with CXCR4 siRNA, but not CXCR7 siRNA, significantly impaired SDF-1-induced transmigration of AML cells. The transfection of AML cells with CXCR7 siRNA did not affect the survival or proliferation of AML cells. Interestingly, knock-down of CXCR7, but not CXCR4, induced the upregulation of SDF-1 mRNA expression and SDF-1 production in AML cells.
Summary and Conclusions: AML cells express CXCR7, which is involved in the regulation of SDF-1 in these cells.

P646

INTERLEUKIN-3 RECEPTOR ALPHA CHAIN (CD123) AS A MARKER FOR LEUKEMIC STEM CELLS IN ACUTE MYELOID LEUKEMIA AND ITS RELATION TO DISEASE PROGRESSION

I Mansour[1,*], N Al-Wahab Mohamed[2], L EL-Meseery[1], H AL-Wakeel[1], N Fawzy[2]
[1]Clinical and Chemical Pathology, Kasr Al-Aini Medical School, Cairo University, [2]Clinical and Chemical Pathology, National Cancer Institute, Cairo, Egypt

Background: Leukemic stem cells (LSCs) initiate and sustain the clonal growth in acute myeloid leukemia (AML).The poor response to therapy in AML patients raises the expectations that the presence of LSCs in quiescent state, resembling the normal stem cells, may add to the resistance to conventional chemotherapy. An enormous effort has been taken to identify specific surface markers in order to differentiate between normal and leukemic stem cells.
Aims: The study aimed to prove that CD123^{high} is a reliable marker in differentiating the leukemic stem cell in AML from normal stem cells within the CD34$^+$CD38$^-$ cell population. An additional goal is to find a relation between LSC population and disease progression.
Methods: Using multi-color flowcytometry, we analyzed the proportions of CD34+CD38− cells expressing high CD123 as a LSC marker in bone marrow samples of 42 AML patients at presentation and at follow up on day 14 post induction chemotherapy. In addition, 14 nonmalignant bone marrow samples were examined as a control group.
Results: Expression (mean fluorescent intensity) of CD123 was significantly higher in AML cases (median 4.22, range: 2.95-7.60) as compared to control group (median 3.55, range 2.88-5.60) (P value 0.016). In AML cases median percent of CD34+CD38- cells was 1.22% (0.0–41.8%) at the time of diagnosis compared to 0.21% (0.0–3.74%) at day 14 post induction (p value 0.067). At initial diagnosis 69% of AML cases (29/42 cases) showed CD123^{high} LSCs phenotype while 80% of cases (16/20 cases) showed CD123^{high} LSCs marker expression at day 14 post induction of whom 18.75% (3/16 cases) initially lacked the CD123^{high}leukemic stem cells. The median percent of LSC (0.51%) showed a statistically significant higher difference at day 14 post induction when compared to initial percent (0.09%) (P value 0.003). On comparing cases with positive CD123 expression to those lacking expression as regards to complete remission, disease free survival and overall survival no statistically significant difference was found.
Summary and Conclusions: Interleukin-3 receptor alpha chain (CD123) may be used as marker of leukemic stem cells in AML. Presence of leukemic stem cells at diagnosis had no prognostic impact on treatment outcome. Emergence of leukemic stem cells post induction may reflect an induced stem cell theory contributing further to disease resistance.

P647

EFFECTS OF B-MYB ABERRANT EXPRESSION ON HEMATOPOIETIC PROGENITOR CELL GROWTH AND DETECTION OF GENETIC VARIATIONS THAT MAY MODIFY ITS PROTEIN FUNCTION

S Dolz[1,*], E Barragán[1], P García[2], M Llop[1], Ó Fuster[1], I De Juan[1], E Such[3], J Cervera[3], I Gómez-Segui[3], M Ibáñez[3], Ma López[3], I López[3], P Bolufer[1], S Palanca[1], R Murria[1], M Sanz[3]
[1]Biología Molecular, Análisis Clínicos, Hospital La Fe, Valencia, Spain, [2]Institute of Biomedical Research, Inmunity and Infection, Birmingham University School of Medical and Dental Science, Birmingham, United Kingdom, [3]Citogenética, Hematología, Hospital La Fe, Valencia, Spain

Background: The B-Myb gene encodes a transcription factor involved in cell proliferation. Several studies have shown that it is overexpressed in different cancers conferring poor prognosis. Our previous studies showed that B-Myb is overexpressed in patients with acute myeloid leukemia (AML) relative to CD34+ cells from healthy donors and this overexpression is associated with an unfavorable prognosis.
Aims: Based on our previous results, we decided to study the consequences of B-Myb aberrant expression in hematopoietic progenitor (CD34+) cells with expression modulators. Furthermore, we pretended to find genetic variations in B-Myb coding sequence that may modify the protein function in AML patients.
Methods: CD34+ cells were isolated from umbilical cord blood of healthy donors with the AutoMACS device (Miltenyi Biotec). Cells were transfected in a 2D Nucleofector (Lonza) with B-Myb-IRES-EGFP overexpression plasmid construct (published by Dr. P.García), IRES-EGFP control plasmid, B-Myb specific siRNAs or control siRNAs. After 18 hours of culture, efficiently transfected CD34+ were selected by sorting in a flow cytometer and subsequently plated in triplicate in Methocult GF H84435 (Stem Cell Technologies) medium to perform colony forming cell assays. Colonies were counted after 14 days of culture in a contrast microscope. B-Myb coding sequence was screened in 180 AML patients in a LightCycler®480 (Roche) with the High Resolution Melting method by designing 16 pairs of specific primers. The detected variations were sequenced and contrasted with the accession number NT_011362.10 Gene Bank.
Results: *In vitro* studies demonstrated that total colony count from cells transfected with B-Myb specific siRNAs was significantly lower than those transfected with control siRNAs (median, 41 *vs* 79; range, 36-42 *vs* 63-86; P=0.027). CFU-M count was also significantly lower in cells transfected with B-Myb specific siRNAs (P=0.049). Total colony count of cells transfected with B-Myb-IRES-EGFP plasmid was significantly higher than those transfected with control plasmid (median, 104 *vs* 35.5; range, 78-115 *vs* 29-53; P=0.016), being also significantly higher the number of CFU-G, CFU-M and CFU-E (P=0.031, P=0.031 and P=0.032 respectively) colonies.
Rs2070235, rs11556379 and rs7660 nonsynonymous polymorphisms were detected in the AML patients with incidences similar to those registered in caucasian healthy populations (19.5%, 5.68% and 0.57% respectively). Rs73116571 polymorphism was found in an intronic splicing region with an incidence higher than that reported in a registered healthy population (2.4% *vs* 0.1%) and was associated significantly (P=0.046) with lower B-Myb expression in AML patients. In addition, three new nonsynonymous genetic variations were detected in three different patients: Q67X, E132D (both located in conserved DNA binding domains) and P274L (Table 1).

Table 1. Detected genetic variations in B-Myb coding and adjacent intronic sequences in AML patients.

Sequence	Detected genetic variation	Patients (%)	Identifier
Exon 4	NP_002457.1:p.**Q67X**	1/169 (0.6)	NR
Exon 5	NP_002457.1:p.**E132D**	1/175 (0.6)	NR
Exon 7	NP_002457.1:p.**P274L**	1/177 (0.6)	NR
Exon 8	NP_002457.1:p.**S427G**	33/169 (19.5)	rs2070235
Intron 8	NM_002466.2:c.1365+3G>T	4/169 (2.4)	rs73116571
Exon 12	NP_002457.1:p.**V595M**	1/175 (0.6)	rs7660
Exon 13	NP_002457.1:p.**I624M**	10/176 (5.7)	rs11556379

NR: Not registered variation in the SNP databases

Summary and Conclusions: *In vitro* colony-forming assays suggested that B-Myb overexpression induces CD34+ cell growth. The polymorphisms detected in our series had similar incidences than the reported in healthy population studies. The only exception was rs73116571 (located in a splicing region) for

which we found a higher incidence in our patients and in addition, a significant association (P=0.046) with lower B-Myb expression levels. Therefore, we consider that this association as both its incidence in AML patients should continue being investigated. Finally, new genetic variations (Q67X, E132D and P274L) were detected and its involvement in the function of B-Myb protein should be clarified in future studies.

P648

MUTATIONS IN RUNX1 AND NPM1 COMBINED WITH IMBALANCES OF CHROMOSOME 21 ARE PREDICTIVE FOR PROGRESSION OF AML

K Gancheva[1,*], J Howard-Reeves[2], D Brazma[2], P Phatheniou[2], P Kotzampaltiris[2], C Grace[1], E Nacheva[1]
[1]Haematology, UCL Medical School, [2]Haematology, Molecular Cytogenetics laboratory, Royal Free Hospital, London, United Kingdom

Background: Extra chromosome 21 is the second most common acquired trisomy after (+)8 in adult myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML). It is rarely observed as the sole abnormality but seen as part of complex karyotype in some 3-7% of the AML (*Atlas of Genetics and Cytogenetics in Oncology and Haematology, http:// atlasgeneticsoncology.org*). Although the gene(s) in trisomy 21 associated with leukemia are unknown, the 21q22 region appears to be critical since it houses the RUNX1 gene. Mutation of this gene, along with others such as NPM1, FLT3-ITD, CEBPA, ASXL1, MLL-PTD, IDH1, IDH2, DNMT3A, TET2 have been identified as prognostic factors in AML/MDS patients with a normal karyotype. Recently we reported on 16 MDS/AML patients from a cohort of 83 cases (ASH abstract No2561) carrying imbalances of chromosome 21 identified by high resolution genome array scanning (aCGH). Here we present results from a next generation sequencing (NGS) study of these samples.
Aims: The purpose of this study is to assess the mutation status in the RUNX1 gene and evaluate a link between mutations in NPM1 and RUNX1, in samples characterised by hitherto unreported partial deletions and absence of amplifications.
Methods: 16 MDS/AML patients with acquired copy number changes in chromosome 21 were investigated for mutations in the RUNX1 and NPM1 genes by running a custom library on the Ion Torrent Personal Genome Machine (PGM).
Results: Our previous studies using aCGH and FISH mapping identified chromosome 21 aberrations in 16 patients with MDS/AML. They fall in three groups characterized by: (i) trisomy 21 and intact RUNX1 gene (5/21); (ii) amplification of the 21q22 region including the ERG and ETS2 sequences, in spite of the loss of the whole or part of the RUNX1 gene (5/21); (iii) normal chromosome 21 with partially or whole loss of RUNX1 gene (6/16). The number of total mutations seen in both RUNX1 and the NPM1 genes (average of 6.1 and 4.4 resp.) were significantly higher in patients with RUNX1 deletions and/or amplifications of ETS2 and ERG (groups 2 and 3) as compared (average of 3.5 and 1 resp.) with the first group where no additional changes in the these genes were observed. In the second group, NGS identified mutations in NPM1 exons in all samples where the main feature is amplification of the ERG and ETS2 regions with or without a deletion in RUNX1. In 3 out of the 5 patients mutations of RUNX1 exon 8 and/or in exon 4 (COSM24728) were found to co-exist along with the NPM1 mutations. The same missense mutation of RUNX1 exon 4 (p.F70L) was observed in a further 6 cases, thus making it the most common mutation seen in 8/14 patients (57%) with imbalances in chromosome 21.
Summary and Conclusions: Our study, albeit small, demonstrates the presence of mutations in RUNX1 and NPM1 in 57% of the AML/MDS patients with RUNX1 deletions and/or amplifications of the ETS2/ERG region. These findings suggest that mutations in RUNX1 and/or NPM1 coupled with gains or losses in regions of RUNX1 could provide a useful indicator of progressive disease and also bring a novel insight into the pathogenesis of MDS/AML.

P649

PROGNOSTIC VALUE OF B-MYB AND ITS REGULATION BY MIRNAS IN ACUTE MYELOID LEUKEMIA

M Llop[1,*], E Barragán[1], S Dolz[1], Ó Fuster[1], I Moreno[2], M Dolores Odero[2], P García[3], M Ibáñez[4], I Luna[4], J Cervera[4], Es Such[4], I Gómez[4], M López[4], I De Juan[1], S Palanca[1], P Bolufer[1], D Martínez[4], F Moscardó[4], P Montesinos[4], M Ángel Sanz[4]
[1]Laboratorio de Biología Molecular, Hospital La Fe, Valencia, [2]Centro de Investigación Médica Aplicada, Universidad de Navarra, Pamplona, Spain, [3]Instituto de Investigaciones Biomédicas, Universidad de Birmingham, Birmingham, United Kingdom, [4]Servicio de Hematología y Hemoterapia, Hospital La Fe, Valencia, Spain

Background: B-Myb is a transcription factor involved in cell cycle, apoptosis and senescence regulation. B-Myb silencing inhibits cell proliferation, and high expression levels have been found in several kinds of cancer. miRNAs modulate gene expression by inducing mRNA degradation or by blocking translation of their target genes. Thus, we propose that appropriate B-Myb expression levels are necessary for a normal development and function of the hematopoietic cells. We also hypothesize that B-Myb could be modulated by miRNAs and changes in their expression could participate in leukemic development.
Aims: The aims of this project are to analyze the expression of B-Myb and its potential miRNA regulators in Acute Myeloid leukemia (AML), to find association between B-Myb and candidate miRNAs, to perform functional studies in myeloid cell lines in order to test if they modulate B-Myb expression and to evaluate the prognostic value of B-Myb and its regulator miRNAs in AML.
Methods: The study population included 272 adult patients diagnosed with AML (excluding Acute Promielocytic Leukemia), the myeloid cell line KG1 and CD34+ cells selected from umbilical cord blood from 11 healthy donors.
Analyzed miRNAs were miR-30a/b/c/d/e and miR29a/b/c. Criteria for miRNA selection was base complementarity predicted by TargetScanHuman database. Expression levels were analyzed by Real Time PCR with the Assay on demand HS00231158-m1 (Applied Biosystems) for B-Myb and miScript probes (Qiagen) for the miRNAs in an ABI prism 7500. GUS gene and miR-U6b were used as internal controls and CD34+ cells were used as calibrators. Relative expression was calculated with the ΔΔCt method. Median expression was the cut-off value used to categorize patients for the statistical analysis. Functional studies were carried out by nucleofecting the KG1 cell line with mimics (molecules that reproduce miRNAs effects). Changes in gene expression were measured by Real time PCR and Western Blot.
Results: B-Myb median expression in LMAs was 0,22 (0,001-5,56) and in CD34+ cells was 0,14 (0,03-0,17). Median expression was significantly higher in LMAs than in CD34+ cells (P<0,001). Relative expression (ΔΔCt) was1,61. miR-30a/b/c/d/e and miR-29a/b median expression was lower in AML than in CD34+ cells (ΔΔCt=0,69; 0,60; 0,35; 0,26; 0,27; 0,19; 0,25; 0,41 and 0,83 respectively). ΔΔCt for miR-29b was 1,2. We found a significant association between B-Myb and miR-30a/b/c expression: patients who overexpressed B-Myb had lower expression of these miRNAs (P=0,049/0,011/0,002 respectively). The KG1 cell line showed a similar expression pattern: maximal cell proliferation (exponential growth phase of a cell culture) correlated with higher levels of B-Myb mRNA and protein, and lower levels of miR-30a/b/c. We tested if miR-30a and miR-30c modulate B-Myb expression by nucleofecting the KG1 cell line with mimics of these miRNAs. We found that miR-30a blocks B-Myb translation and subsequently cell proliferation decreases approximately 25%. Finally, B-Myb expression showed prognostic value for intermediate cytogenetic risk patients: patients with B-Myb overexpression showed a significantly shorter disease-free survival (DFS) (HR:1,4; IC95%1,02-1,94; P=0,039) and Relapse-free survival (RFS) (HR:1,49; IC1,01-2,20; P=0,047).
Summary and Conclusions: Our results suggest that B-Myb expression is higher in LMA than in CD34+ cells. B-Myb expression is modulated by miR-30a and they could influence leukemogenic development. B-Myb expression could be useful to stratify patients with intermediate cytogenetic risk.

P650

VLA-4 EXPRESSION OF LEUKEMIC MYELOBLASTS MIGHT BE A GOOD PROGNOSTIC MARKER IN ACUTE MYELOID LEUKEMIA PATIENTS

M Bae[1,*], S Oh[1], C Park[1], B Lee[1], S Park[1], Y Cho[1], S Jang[1], J Lee[2], K Lee[2], K Koh[3], Ho J Im[3], J Seo[3], H Chi[1]
[1]Laboratory Medicine, [2]Internal Medicine, [3]Pediatrics, Asan Medical Center, Seoul, Korea, Republic of Korea

Background: Adhesion and migratory properties of leukemic myeloblasts appear to affect their survival, proliferation and retention in the bone marrow and influence the chemosensitivity. Very late antigen-4 (VLA-4) and CXC chemokine receptor 4 (CXCR4) are representing adhesion molecules expressed on acute myeloid leukemia (AML) blasts in variable ranges. Because VLA-4 may mediate anti-apoptotic signals and CXCR4 is associated with development of AML, therapeutic agents targeting VLA-4 and CXCR4 are investigated. Thus it becomes important to evaluate their expression for clinical use to characterize leukemic myeloblasts and to determine prognosis.
Aims: We prospectively investigated the impact of expressions of VLA-4 and CXCR4 of leukemic myeloblasts on treatment outcomes and leukemogenesis.
Methods: We quantified VLA-4 and CXCR4 expressions of leukemic myeloblasts in consecutive 104 AML patients. We measured the positive fractions and the mean fluorescence intensity (MFI) of VLA-4 and CXCR4 by multi-color flow cytometry using bone marrow aspirates, and correlated expression levels with disease characteristics and clinical outcomes. A combination of cytogenetic and molecular abnormalities was used to stratify the patients into risk groups based on national comprehensive cancer network (NCCN) 2013 guideline. We evaluated prognostic impact in 72 patients who received a cytarabine/anthracycline-based induction therapy by dividing into 2 groups (complete remission [CR] group who achieved CR after 1 cycle of chemotherapy, and induction failure group). We also separated the patients into 2 groups (high and low expression) according to the median positive fraction of VLA-4 or CXCR4.
Results: Good risk group showed higher positive fraction and MFI of VLA-4 than poor risk group (P=.007,.04), but positive proportion and MFI of CXCR4 showed no significant difference between risk groups (P=.352,.831). Positive fraction of CXCR4 increased along with age (r=.215). Proportion and MFI of VLA-4 were significantly higher in CR group than in induction failure group

(P=.01,.013). Those of CXCR4 showed no differences between 2 groups. The high fraction of VLA-4 expession group showed better overall survival, relapse free survival and event free survival than the low VLA-4 expression group (P=.024,.027, 016), but there was no difference of survival between the high and low CXCR-4 expression groups. VLA-4 positive fraction correlated with CD117, CD13 or myeloperoxidase positive fractions (P=.005,.036,.025), and inversely correlated with CXCR4 positive fraction (P=.039).
Summary and Conclusions: We found that high proportion and MFI of VLA-4 led to high complete remission rate, it corresponds with the results from better prognostic group determined by NCCN guidelines, and the high VLA-4 expression group showed better survival. Thus VLA-4 expression of leukemic myeloblasts might be a good prognostic marker in acute myeloid leukemia patients.

P651

CLINICAL AND HEMATOLOGICAL FEATURES OF ACUTE MYELOID LEUKEMIA WITH REARRANGEMENTS OF EVI1 OR PRDM16

M Eveillard[1,*], L Lodé[1], J Delaunay[2], R Garand[1], S Wuillème[1], F Duhoux[3], C Godon[1], M Béné[1]
[1]Hematology Laboratory, [2]hematology department, Centre Hospitalier Universitaire, Nantes, France, [3]Hematology Laboratory, clinique universitaire saint Luc, Bruxelles, Belgium

Background: Acute myeloid leukemia (AML) with EVI1 or PRDM16 rearrangement, which represent 1% to 2% of all AML, are aggressive diseases with poor prognosis and should be diagnosed early. Hint toward the possibility of such rearrangements could be given if these cells present specific features.
Aims: In a cohort of 21 AML with EVI1 or PRDM16 rearrangements a retrospective study of morphological, cytochemical, clinical features and survival was performed and compared to a reference cohort of 1844 AML diagnosed during the same period.
Methods: Rearrangements of EVI1 were observed in 17 AML patients and of PRDM16 in 4. Bone marrow (BM) and blood smears (May Grunwald Giemsa and myeloperoxidase (MPO)) were re-examined by two different cytologists. Information retrieved for both cohorts comprised blood counts, hemoglobin level, platelet counts, bone marrow dysplasia and overall survival.
Results: EVI1 patients had *de novo* AML in 10 cases. For the other7, antecedents of myeloproliferative neoplasm (MPN) were retrieved in4, of myeodysplastic syndrome in 1 and of lymphoproliferative disorder in 2. Karyotypic examination found 9 patients with inv(3)(q21q26.2), 7 with t(3;?)(q26.2;?), 1 with normal karyotype and cryptic inv(3). Monosomy 7 was observed in 8 cases and del(7q) in 1. Fifty-three% of the patients had platelet counts over 100G/L at diagnosis, without the classical thrombopenia observed in AML. This difference was statistically significant (P=0.019) by comparison to the reference cohort. These subnormal counts were associated with platelets dysplasia (giant and hypogranular). Morphological examination of BM smears for FAB classification showed a significant increase of minimal differentiation (M0, n=5, 31% *vs* 7.5%, P=0.002). Megakaryocytes were small, with monolobated or bilobated nuclei and clustered. Multilineage dysplasia of non-blast cells was present in 75% of the cases (*vs.* 17.6%, P<0.001). Cytochemistry for MPO activity was negative in 57% of the patients *vs.* 23.4% in the reference cohort (P=0.008). Of note, 78.5% of EVI1 patients had less than 10% MPO positive blasts, and MPO was also poorly expressed by mature neutrophils. The 4 patients with PRDM16 presented with a history of therapy-related MPN. Cytogenetics showed for all a t(1;3)(p32q21), with an additional del(5q) for 2. As for EVI1 patients, paradoxically normal platelet counts were observed at diagnosis (mean 259G/L). BM smears were characteristically rich in small, monolobated and clustered megakaryocytes (more than 50/smear). All showed multilineage dysplasia and, again as for EVI1 patients, MPO was characteristically low, completely absent in 3 cases. In both groups, prognosis was dismal with 9 months overall survival. The 14 patients who could not receive allogeneic transplantation died within 12 months.
Summary and Conclusions: EVI1 or PRDM16 rearrangement can be suspected in AML patients with subnormal platelet counts, high numbers of bone marrow clusters of monolobate megakaryocytes and multilineage dysplasia. Moreover, these cases are also significantly characterized by a very low or absent expression of myeloperoxidase even in cases not classified as M0. These two very similar entities should prompt for the investigation of EVI1 rearrangement, followed by that of PRDM16 if EVI1 is normal. The poor prognosis associated with these rare diseases should lead to rapid investigation for a donor, in view of allogeneic transplantation of hematopoietic stem cells.

P652

EFFECT OF MLN4924 ON TRAIL-INDUCED APOPTOSIS IN NON-CLINICAL MODELS OF HAEMATOLOGICAL MALIGNANCIES

M Reidy[1,*], M O'Dwyer[2], M Thomas[3], A Berger[3], A Samali[1], E Szegezdi[1]
[1]Apoptosis Research Center, National University of Ireland, Galway, [2]Haematology, University College Hospital, Galway, Ireland, [3]Millennium Pharmaceuticals, Inc, Massachusetts, United States

Background: TNF-related apoptosis ligand (TRAIL) is a tumour selective cytokine with potential anti-cancer activity which is currently in clinical trials. Haematological malignancies along with several other cancers have showed varied sensitivity to TRAIL treatment. *In vitro* and *in vivo* studies have shown that TRAIL-resistant tumour cells can be sensitised to TRAIL by various chemotherapeutic agents. This has opened up new possibilities for combination therapies. Proteasome inhibitors have previously been used in this way. MLN4924 is an investigational inhibitor of NEDD8 activating enzyme (NAE), which is part of the ubiquitin proteasome pathway. MLN4924 is currently in Phase 1 trials (Millennium Pharmaceuticals, Inc.). MLN4924 binds to NAE and forms an MLN4924-NEDD8 adduct in place of an NEDD8 adenylate thus locking the enzyme in an inactive state. As a consequence, MLN4924 inhibits the NEDD8-dependent activation of a subset of ubiquitin E3 ligases known as cullin ring ligases (CRLs). When CRL neddylation is disrupted, so is the ubiquitin-dependent turnover of CRL substrates, many of which have important roles in cellular processes associated with cancer cell growth and survival pathways including DNA replication and NFkB activity. Targeting the activity of a specific subset of E3 ligases is particularly attractive because there is the potential to selectively block the degradation of certain cellular proteins and possibly avoid unwanted effects on other proteins.
Aims: We sought to investigate the apoptotic effect MLN4924 in combination with TRAIL may have in multiple myeloma, acute myeloid leukaemia (AML), and diffuse large B cell lymphoma cell lines.
Results: It emerged that MLN4924 and TRAIL have a synergistic effect in a number of AML and MM cell lines. Examples of combination index values obtained for these cell lines include AML2-0.07; MOLM13-0.69; ML1-0.55. In an attempt to identify the mechanism of action we found that MLN4924 induces the expression of Bim and Noxa, pro-apoptotic, BH3-only members of the Bcl-2 protein family. MLN4924 did not significantly affect the expression of apoptotic regulators acting at the TRAIL death receptors, including c-FLIP, pro-caspase-8, cIAP1/2, DR4, DR5, DcR1 or DcR2. Through study of the known transcription factors regulated after MLN4924 treatment and transcription factors regulating Noxa expression, it was found that treatment with MLN4924 led to the induction of p53 and C/EBPa, but not that of Foxo3A or Nrf2 in OCI AML2 cells. Inhibition of p53 action with Nutlin3 reduced MLN4924-mediated Noxa induction and could also sensitise the AML cells to TRAIL-induced apoptosis. Pharmacokinetic studies on OCI-M2 xenografts confirmed that inhibition of cullin ring ligases triggers Noxa accumulation and enhanced TRAIL-induced apoptosis indicated by higher level of pro-casapse-3 processing and cleavage of the caspase-3 target protein, PARP. Finally, OCI-M2 xenografts treated with a biweekly dose of MLN4924 (on days 1 and4, each week for 3 weeks) combined with daily dosage of recombinant human TRAIL (days 1-5 each week for 3 weeks) resulted in very significant reduction in tumour volume (Figure 1).

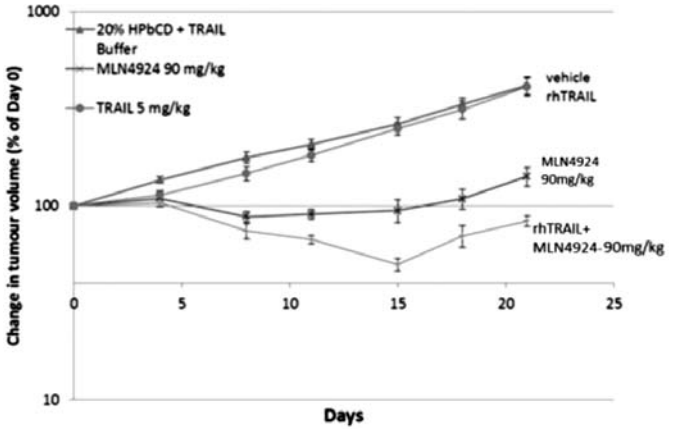

Figure 1.

Summary and Conclusions: In conclusion, the current study shows that MLN4924 can sensitise AML and potentially MM cells to TRAIL induced apoptosis to trigger very robust anti-tumour effects by increasing BH3-only protein expression through an at least partially p53-dependent manner.

P653

IMPACT OF THE E3 UBIQUITIN LIGASE TRAF2 ON TNF-A-INDUCED APOPTOSIS IN A CELL MODEL OF FLT3-ITD-POSITIVE AML

U Schnetzke[1,*], M Fischer[1], B Spies-Weißhart[1], J Müller[2], A Hochhaus[1], S Scholl[1]
[1]Klinik für Innere Medizin II, Abteilung für Onkologie und Hämatologie, [2]Institut für Molekulare Zellbiologie, University Hospital, Jena, Germany

Background: Acute myeloid leukemia (AML) is a heterogeneous disease in which multiple signaling pathways can contribute to pathogenesis of leukemia.

The cytokine TNF-a (tumor necrosis factor alpha) has pleiotropic effects on growth, differentiation and apoptosis. One of the key molecules mediating TNF-a signaling is the E3 ubiquitin ligase TRAF2 (tumor necrosis factor receptor-associated factor 2). So far, functional characterization of TRAF2 in AML cells has not been reported.
Aims: The objective of this study was to investigate whether TNF-a can induce apoptosis in cells of FLT3-ITD-positive AML and to elucidate the influence of the E3 ubiquitin ligase TRAF2 on the survival of these AML cells.
Methods: The expression of TRAF2 was suppressed in the FLT3-ITD-dependent human AML cell line MOLM13 by stable lentiviral shRNA expression. TNF-a-mediated signal transduction of MOLM13 shTRAF2 cells was monitored by analysis of AKT, GSK3ß, ERK and p706S. Apoptosis and cell proliferation were detected by flow cytometry and MTS assay, respectively. Furthermore, chemosensitivity assays were performed to investigate a potential functional role after incubation with cytarabine or doxorubicin.
Results: The functional activity of TNF-a was demonstrated by a strong increase of p38 phosphorylation that was detected by Western blotting. In MOLM13 cells, shRNA-mediated knockdown of TRAF2 resulted in a significant suppression of phosphorylation of the anti-apoptotic proteins AKT and GSK-3ß after 24h treatment with TNF-a, which was in contrast to the control cell line. Importantly, the knockdown of TRAF2 caused significantly more apoptosis (33% ±4.2% *vs.* 13%±1.7%) and impaired proliferation after TNF-a exposure (0.58±0.02 fold of control). Furthermore, the TRAF2 knockdown resulted in a different susceptibility to both investigated cytotoxic drugs.
Summary and Conclusions: We revealed the previously unknown functional role of TRAF2 in TNF-a-induced apoptosis in a FLT3-ITD-driven cell model. TRAF2 might elicit cytoprotective effects following activation of the TNF-a receptor. We hypothesize that TRAF2 plays an important role in signal transduction and survival of AML cells as we can demonstrate TRAF2 to be a critical effector of TNF-a-induced apoptosis in a FLT3-ITD-positive AML cell line.

P654

PLUMBAGIN ENHANCED TRAIL-INDUCED APOPTOSIS OF KASUMI-1 CELLS IN NOD/SCID MICE

L Liu[1,*], J Luo[1], Z Li[2], D Lu[1]
[1]Hematological department, Shanghai fifth people's hospital,Fudan University, Shanghai, China, [2]Department of experiment haematology, Hanouver Medical School, Hannover, Germany

Background: The translocation (8;21)(q22;q22) is one of the most common chromosomal abnormality in acute myeloid leukemia(AML). The incidence of AML with t(8;21) is 6%>10% in primary AML and 18%>40% in AML-M2.AML with t(8;21) is generally considered as a good prognostic type according to WHO classification. However, the recurrence and drug resistance of AML with t(8;21) still threat the life of patients. Therefore, it's important for finding new drugs to overcome the drug resistance of leukemic cells, elevate the rate of complete remission and improve the long-term survival of patients in clinical practice. Our previous research has confirmed that plumbagin can enhance TRAIL-induced apoptosis of Kasumi-1 leukemic cell lines *in vitro*. Therefore, it's necessary to verify the finding in animal experimental leukemic mode *in vivo* before clinical usage.
Aims: To investigate the effect of plumbagin alone, rsTRAIL alone and their combination on leukemic Kasumi-1 cells in the NOD/SCID mice *in vivo* and their possible mechanisims.
Methods: NOD/SCID mouse bearing xenograft tumor of Kasumi-1 cells were randomly divided into normal saline group, Ara-C group, rsTRAIL alone group, plumbagin alone group and rsTRAIL combined plumbagin group. The tumor volume and weight changes of mouse were observed.The pathological slices of tumor and organs of mouse were stained with HE method and observed under microscope.The morphology of tumor cells was observed by microscope. The apoptotic rate of single cell suspension of xenograft tumor was calculated by flow cytometry. The expression of DR4 and DR5 at protein level on the surface of cells was detected by flow cytometry.
Results: (1) Compared with the control group, both rsTRAIL and plumbagin could inhibit the growth of the xenograft tumor (P<0.01).They had a synergistic effect (P<0.05).The inhibitory rates in rsTRAIL, plumbagin and rsTRAIL combined plumbagin were 56.74%,65.17% and 90.07% respectively.(2)The NOD/SCID mouse mode of AML with t(8;21) were successfully established, and the main marker is the formation of subcutaneous mass. (3)The main toxicity of plumbagin 6mg/kg was diarrhea in tumor-bearing mouse. (4)T he ratios of annexin V positive cells were (47.39±9.99)%, (51.35±3.58)% and (68.23±6.74)% in rsTRAIL alone groups, plumbagin alone and the combination of the both group respectively, and was significantly higher in the combination group than in the group of rsTRAIL alone or plumbagin alone.(5)Plumbagin could increase the expression of DR4 and DR5 in cells of xenograft tumor which were demonstrated by flow cytometry (Fiugre 1).
Summary and Conclusions: Plumbagin could enhance TRAIL induced apoptosis of Kasumi-1 cells *in vivo* without obvious damaging of the vital organs, and the major mechanism was related to the upregulation of DR5.

PROGNOSTIC RELEVANCE OF ACQUIRED STRUCTURAL GENETIC ABNORMALITIES IN ACUTE MYELOID LEUKEMIA

O Nibourel[1,2,*], C Roumier[1,2], S Guihard[2], S Quentin[3,4], S Geffroy[1], A Alberdi[3,4], R Ben Abdelali[3,4], A Renneville[1], C Berthon[2,5], K Celli-Lebras[6], H Dombret[7], J Soulier[3,4], C Preudhomme[1,2], M Cheok[1,2]
[1]Hematology Laboratory, CHRU Lille, [2]INSERM U837, Institute for Cancer Research of Lille, Lille, [3]Hematology Laboratory, Saint-Louis Hospital, [4]INSERM U944, University Paris Diderot, Paris, [5]Department of Hematology, CHRU Lille, Lille, [6]Department of Hematology, Saint-Louis Hospital,University Paris7, EA 3518, [7]Department of Hematology, Saint-Louis Hospital, University Paris7, EA 3518, Paris, France

Background: Acute myeloid leukemia (AML) is a heterogeneous malignancy, with prognosis remaining unfavorable. In addition to age and leukocytosis, cytogenetic abnormalities are key factors to assess prognosis. However, variability in treatment response remains and is inadequately explained. Furthermore, cytogenetic analysis fails in approximately 10% of patients, thus a correct diagnosis is not possible in these cases.
Aims: In this study, we assessed prognostic relevance of high-throughput single nucleotide polymorphism arrays (SNP-A) analysis in AML.
Methods: We analysed paired (*i.e.*, diagnostic and remission) samples of 119 adult AML patients and in parallel we compared results with conventional cytogenetics and molecular diagnostics. Findings were validated on an additional independent cohort of adult AML (n=127).
Results: We identified SNP-A abnormalities in 57% of the patients. More importantly, we defined unfavorable SNP-A abnormalities based on chromosomal location. These unfavorable SNP-A abnormalities were associated with worse overall treatment response (OS, *P*<0.0001, HR=1.64, 95%CI=1.33-2.02) and with worse relapse-free survival (RFS, *P*=0.0022, HR=1.39, 95%CI=1.13-1.72). Multivariate analysis confirmed independent prognostic impact of unfavorable SNP-A abnormalities with prognostic cytogenetics (*P*=0.013, HR=1.43, 95%CI=1.08-1.90) or with the European Leukemia Net (ELN) classification (*P*=0.013, HR=1.45, 95%CI=1.08-194). The number of unfavorable SNP-A abnormalities was significantly associated with OS and RFS in the validation cohort (*P*<0.0001, HR=1.38, 95%CI=1.20-1.59 and *P*=0.002, HR=1.71, 95%CI=1.23-2.46). Multivariate analysis was validated similarly with prognostic cytogenetics (*P*=0.0082, HR=1.26, 95%CI=1.06-1.50) or with ELN classification (*P*=0.0051, HR=1.28, 95%CI=1.08-1.51) in the independent cohort.
Summary and Conclusions: We have shown independent relevance of unfavorable SNP-A abnormalities compared to conventional cytogenetics and molecular diagnosis. These findings suggest concurrent SNP-A analysis may improve current prognostic risk stratification of AML, especially in cases where conventional cytogenetics is unsuccessful.

P656

HIGHER PROPORTIONS OF HELPER/INDUCER T CELLS AND CD4+CD31+ NAÏVE T CELLS AT DIAGNOSIS PREDICT BETTER COMPLETE REMISSION RATE IN ACUTE MYELOID LEUKEMIA PATIENTS

M Bae[1,*], C Park[1], B Lee[1], S Park[1], Y Cho[1], S Jang[1], E Seo[1], D Kim[2], J Lee[2], J Lee[2], K Lee[2], H Chi[1]
[1]Laboratory Medicine, [2]Internal Medicine, Asan Medical Center, Seoul, Korea, Republic of Korea

Background: Physiologic function of the immunocytes in the tumor is to rec-

ognize and destroy clonally transformed cells before they grow into tumors and to kill tumors after they are formed. It is now clear that the immune system does react against many tumors including acute myeloid leukemia. Lymphocyte subpopulation is known to be associated with prognosis with certain malignancies, however, the role of immunocytes in patients with hematologic malignancy is not well studied.
Aims: We prospectively investigated whether the differences in the proportion and absolute number of lymphocyte subsets affect the leukemogenesis and treatment outcomes in patients with acute myeloid leukemia.
Methods: Consecutive 91 AML patients who were newly diagnosed by bone marrow study, immunophenotyping, cytogenetic and molecular analysis, were included and classified into 3 risk groups (good, intermediate, poor) based on national comprehensive cancer network (NCCN) 2013 guideline. We measured lymphocyte subsets (T cells, helper/inducer T cells, suppressor/cytotoxic T cells, naïve T cells, memory T cell subsets, regulatory T cells, natural killer (NK) cell subsets, NK-T cells and B cells) by multi-color flow cytometry with peripheral blood obtained from patients at the time of diagnosis and after chemotherapies (induction, first and second consolidations) and from 10 healthy controls.
Results: At diagnosis, AML patients had significantly lower numbers and proportions of $CD56^{dim}CD16^{+}$ NK cells, central memory T cells and regulatory T cells than healthy controls (P=.005,.007,.019). Higher proportions of helper/inducer T cells and $CD4^{+}CD31^{+}$ naïve T cells and lower proportion of NK cells increased complete remission (CR) rate in 65 non-promyelocytic leukemia patients who received cytarabine+anthracycline-based induction therapy (P=.034,.027,.019), and it was also significant in multivariable analysis with age and risk status (P=.014,.016,.045). In univariate analysis of relapse-free survival (RFS), NK cells <4.8% of lymphocytes demonstrated shorter RFS (P=.006) and it was also significant in multivariable analysis with risk status (P=.037). During chemotherapy, NK-T cell proportion after 1st consolidation therapy, compared with NK-T cell proportion at diagnosis, increased prominently in patients who relapsed later than patients with continuous CR (P=.031).
Summary and Conclusions: Lower numbers of $CD56^{dim}CD16^{+}$ NK cells, central memory T cells and regulatory T cells might contribute the leukemogenesis of AML, and the chemotherapy induced different lymphocyte subset findings. Higher proportions of helper/inducer T cells and $CD4^{+}CD31^{+}$ naïve T cells and lower proportion of NK cells at diagnosis independently predict better CR rate, but the proportion of NK cells <4.8% at diagnosis had adverse prognostic impact in RFS.

P657

HIGHER EXPRESSION OF ROUNDABOUT 4 (ROBO4) IN THE BONE MARROW IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ADULT PATIENTS AFFLICTED WITH *DE NOVO* ACUTE MYELOID LEUKEMIA

Y Chen[1,*], H Hou[2], M Lee[2], Y Kuo[3], Y Lai[2], W Chou[2], C Chen[2], J Tang[2], M Yao[2], S Huang[2], B Ko[2], S Hsu[2], S Wu[2], W Tsai[2], Y Chen[2], H Tien[2]
[1]National Taiwan University Hospital Yun-Lin Branch, Douliou, [2]National Taiwan University Hospital, [3]National Taiwan University, Taipei, Taiwan

Background: Bone marrow (BM) microenvironment provides support for self-renewal, quiescence, homing, engraftment and proliferative potential for hematopoietic stem cells (HSCs). Roundabout 4 (Robo4) is a transmembrane protein expressed specifically in endothelial cells and HSCs. Recently, *Robo4* expression was shown to be associated with HSC homeostasis.
Aims: Till now, there have been few studies concerning the prognostic implication of *Robo4* expression in *de novo* AML.
Methods: We investigated the mRNA expression of Robo4 by real-time quantitative polymerase chain reaction in the BM cells from a cohort of 201 newly diagnosed *de novo* AML patients, including 148 original and 53 validation cohort, and 20 healthy BM donors. The expression of Robo4 was normalized to that of the housekeeping gene *RPLP0*. The result was correlated with clinical features, cytogenetics, other genetic alterations and treatment outcomes.
Results: Median levels of Robo4 expression were significantly higher in AML patients than in normal BM donors. The patients were then divided into one with low expression of Robo4 (n=87) and the other with high expression (n=61), by using a cut-off point of 0.010 (*Robo4/RPLP0)*. Patients with high Robo4 expression had higher incidence of HLA-DR and CD56 expression on the leukemia cells (85.0% *versus.* 62.4%, P=0.003 and 30.0% *versus.* 8.4%, P=0.001, respectively). Further, high Robo4 expression was closely association with chromosomal abnormalities t(8;21), but inversely correlated with t(15;17) (20% *versus.* 2.3%, P=0.0009 and 1.6% *versus.* 14.9%, P=0.0081, respectively). We also found that Robo4 expression was significantly lower in AML patients with $CEBPA^{doublemutation}$ (P=0.0240). One hundred seven (72.3%) of 148 patients achieved a complete remission (CR). High Robo4 expression was associated with a trend of inferior response to induction chemotherapy (CR rate, 63.9% *versus.* 78.2%, P=0.0643). With a median follow-up of 31 months (ranges, 1.0-160), patients with high Robo4 expression had significantly poorer overall survival (OS) and disease-free survival (DFS) than those with low Robo4 expression (median, 17.0 months *versus.* 95.0 months, P=0.023, and medium, 5.0 months *versus.* 15.0 months, P=0.024, respectively). In the subgroup of 99 patients with intermediate-risk karyotype, the differences of OS (median, 13.5 months *versus.* 95.0 months, P=0.007) and DFS (median, 4.0 months *versus.* 10.0 months, P=0.025) between patients with high and low Robo4 expression were still significant. In multivariate analysis, the independent poor risk factors for OS and DFS were older age, high WBC count, unfavorable karyotype, and high Robo4 expression (Hazard ratio OS, 1.779, 95% CI 1.005-3.149, P=0.048 and DFS, 1.600, 95% CI 1.026-2.495, P=0.038). On the other hand, $CEBPA^{doublemutation}$and $NPM1^{+}$/*FLT3*-ITD^{-}were independent favorable prognostic factors. This result was also validated in an independent validation cohort (n=53).
Summary and Conclusions: Our results demonstrated that Robo4 expression was correlated with surface antigen expression of leukemic cells, cytogenetics, and molecular mutation. Further, high Robo4 expression indicates an unfavorable prognosis in *de novo* AML patients. It may be used as a biomarker for risk-stratification of AML patients.

P658

IMPLICATIONS OF MIR-10 IN CHEMOTHERAPY RESPONSE OF NPM1 MUTATED AML

V Havelange[1,*], P Ranganathan[2], S Geyer[2], X Huang[2], X Yu[2], C Fernandez-Cymering[3], S Volinia[3], M Andreeff[4], C M Croce[3], G Marcucci[2], R Garzon[2]
[1]Hematological Department, Cliniques universitaires Saint-Luc, Brussels, Belgium, [2]Division of Hematology, [3]Department of Molecular Virology, Immunology and Medical Genetics, The Ohio State University, Columbus, [4]Section Molecular Hematology & Therapy, Department of Leukemia, MD Anderson Cancer Center, Houston, United States

Background: Nucleophosmim (*NPM1*) mutated AML (*NPM1*mut-AML) patients are associated with a high rate of complete response (CR) to induction chemotherapy. However, the mechanisms responsible for such effects are unknown. It has been shown that a unique miRNA signature is associated with cytogenetically normal AML (CN-AML) patients harboring *NPM1* mutations, and includes the strong uP-regulation of miR-10a and miR-10b (miR-10a/b). However, the functional role of these two miRs in *NPM1* mutated AML (*NPM1*mut-AML) is unclear. We hypothesize that chemotherapy sensitivity and the high CR rates observed in *NPM1*mut-AML patients could be mediated through miR-10a/b.
Aims: To investigate the association of miR-10 expression levels with chemotherapy response and sensitivity in *NPM1*mut-AML patients.
Methods: We analyzed miR-10a/b expression levels in pretreatment bone marrow samples obtained from 54 newly diagnosed AML patients treated with idarubicine and cytarabine by using the OSU-CCC miRNA microarray platform. After background subtraction and normalization using quantiles, miRNA data was analyzed using BRB tools (Class comparison). Patients characteristics include: median age (n=61); CN-AML(n=33), FL3-ITD(n=10),*NPM1*mut(n=25), other karytyope (n=21). MiR-10a gain and loss of function studies were performed in AML cell lines and primary AML samples in baseline conditions and after chemotherapy.
Results: To identify whether miR-10a/b are associated with CR, we compared pretreatment miR-10a/b levels of patients who achieved CR (n=28) *versus* no responders (R) (n=26). The median miR-10a levels were 12.1 (4.2-14.2) in CR patients and 9.1 (range 5.1-13.5) in no-CR patients (P=0.002), while the median miR-10b levels were 12.2 (4.2–13.7) in CR patients and 8.1 (4.2–13.1) in no-CR patients (P=0.001). Univariate analysis including cytogenetics, age, *NPM1* status and miR-10a/b revealed that both miRNAs were significantly associated with CR (OR 1.33 and 1.32, respectively). Multivariate analysis including age, *NPM1* status, unfavorable cytogenetic prognostic group, CN-AML and miR-10a/b, revealed that *NPM1* and miR-10a remain significant after adjusting for the other variables. However, there was an interaction effect in the multivariate logistic model with *NPM1* mutation status and miR-10a, where *NPM1* mutation status modifies the effect of miR-10a on CR incidence (P=0.033). To assess the functional role of miR-10a in chemotherapy sensitivity, we over-expressed synthetic miR-10a in AML cell lines with low endogenous miR-10a expression (KG-1a/Kasumi-1) showed no changes in cell proliferation or apoptosis between miR-10a and the controls in baseline conditions or after cytarabine treatment. Knock down of miR-10a in two AML cells lines with high levels of miR-10a (K562/*NPM1*mut OCI-AML3),using antimiR-10a or scramble control showed no differences in cell proliferation and apoptosis in baseline condition or after cytarabine treatment. Identical results were observed in 4 primary AML samples; 2 with *NPM1* wild-type and low level of miR-10a that were transfected with nanoparticle conjugated synthetic miR-10a and 2 with *NPM1* mutated and high level of miR-10a that were transfected with nanoparticle-anti-10a.
Summary and Conclusions: High miR-10a/b expression levels in AML patients are associated with achieving CR. However this association is dependent on *NPM1* mutation status. miR-10a gain and loss of function experiments in cell lines and in primary AML samples did not demonstrate any effect in apoptosis and cell proliferation in baseline conditions nor after chemotherapy treatment.

P659

INHIBITION OF AUTOPHAGY SENSITIZES LEUKEMIC CELLS TO CYTARABINE

B Ristic[1,*], M Bosnjak[2], K Arsikin[1], A Mircic[2], V Paunovic[1], V Perovic[1], V Zivkovic[2], A Bogdanovic[3], V Bumbasirevic[2], V Trajkovic[1], L Harhaji-Trajkovic[4]
[1]Institute of Microbiology and Immunology, School of Medicine, University of Belgrade, [2]Institute of Histology and Embriology "Aleksandar Đ. Kostić", School of Medicine, University of Belgrade, [3]Clinic of Hematology, Clinical Centar of Serbia, School of Medicine, University of Belgrade, [4]Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia

Background: Autophagy is a process in which a cell degrades its own components in organelles called autophagolysosomes. Cytarabine is a chemotherapeutic drug used to treat different forms of leukemia, including acute and chronic myelogenous (AML and CML), acute lymphocytic leukemia (ALL) and lymphomas.
Aims: In this study we investigated the ability of cytarabine to induce autophagy in different leukemic cells.
Methods: Human leukemia cell lines: promyelocytic (HL-60), lymphocytic (REH) and acute lymphoblastic (MOLT-4), as well as peripheral blood mononuclear cells (PBMCs) from CML patients or healthy controls were treated with cytarabine. Cell viability was determined by measuring the activity of lysosomal acid phosphatase. Intracellular acidification was demonstrated by the acridine orange staining. Autophagosomes and autophagolysosomes were detected by transmission electron microscopy. Expression of autophagy-related proteins was shown by Western blot analysis. Pharamacological inhibitors and RNA interference were used for down-regulation of autophagy.
Results: Cytarabine stimulated cytoplasmatic acidification and appearance of double-membraned autophagosome-like and single-membraned autophagolysosome-like vacuoles with partly digested intracellular content in REH cells. Cytarabine induced degradation of the selective autophagic target p62 and conversion of LC3-I to autophagosome-associated LC3-II in the presence and absence of proteolysis inhibitors in all tested leukemic cells, but not PBMC from healthy controls. In contrast to MOLT-4 cells, pro-autophagic protein beclin-1 was not upregulated in REH, HL-60 and PBMC from leukemic patients. Cytarabine reduced activity of mTOR, major negative regulator of autophagy, and its downstream target p70S6K. Autophagy downregulation markedly increased cell death in all cytarabine treated leukemic cells, but not PBMC from healthy controls.
Summary and Conclusions: Our results demonstrate that the inhibition of autophagy sensitizes leukemic cells to the cytarabine-induced cell death and suggest a promising approach to improve the efficiency of cytarabine in the treatment of leukemia.

P660

SYNERGISTIC EFFECTS OF HSP70 AND HSP90 INHIBITORS IN PRIMARY HUMAN ACUTE MYELOID LEUKEMIA CELLS

H Reikvam[1,*], I Nepstad[1], A Sulen[1], B Gjertsen[1], K Hatfield[1], Ø Bruserud[1]
[1]INSTITUTE OF MEDICINE, UNIVERSITY OF BERGEN, Bergen, Norway

Background: Acute myeloid leukemia (AML) is a heterogeneous group of malignant hematopoietic disorders characterized by bone marrow accumulation of immature leukemic cells. Heat shock proteins (HSPs) are molecular chaperones that assist proteins in their folding to native structures. HSP90 has emerged as therapeutic targets in human malignancies; including AML there agents have entered clinical trials. However, the results from early clinical trials have not been too promising, and suggested explanations for this have been (i) activation of compensatory mechanisms including increased HSP70, (ii) difficulties in obtaining effective *in vivo* concentration due to dose-limiting side effects especially for the geldanamycin derivatives or (iii) limited effects of HSP90 inhibitor monotherapy. Therapeutic targeting of HSP70 has recently emerged as a new therapeutic approach, and the specific inhibitor VER-155008 has been developed through structure-based X-ray crystallographic design.
Aims: The antileukemic potential of HSP70 inhibition still remains elusive; therefore the aims of the present study were to investigate the *in vitro* antileukemic effect in AML of HSP70 inhibitor both alone and in combination with HSP90 inhibitor.
Methods: We evaluated the effect of the HSP70 inhibitor VER-155008 regarding proliferation, viability, colony forming unit (CFU), cytokine release and levels of intracellular HSPs (HSP27, HSP40, HSP60, HSP70 and HSP90) on highly standardized *in vitro* cultured primary human AML cells derived from 20 consecutive AML patients. In addition we investigated potential synergistic effects between VER-155008 and the HSP90 inhibitor 17-dimethylaminoethylamino-17-demethoxygeldanamycin (17-DMAG).
Results: VER-155008 caused a dose-dependent inhibition of cytokine-dependent AML cell proliferation both in suspension cultures and in a CFU assay, and also had a significant proapoptotic effect. VER-155008 caused a strong inhibition of the constitutive AML cell release of several growth factors/regulators of hematopoiesis (*i.e.* tumor necrosis factor α, vascular endothelial growth factor, interleukin3, interleukin 1β, interleukin 1 receptor antagonist), although had relatively weak effects on the constitutive chemokine release. When combining VER-155008 with 17-DMAG, we explored an increased antiproliferative and proapoptotic effect compared to both drugs alone. A highly significant decrease in both cytokine and chemokine release were observed of combination treatment, compared to both drugs alone. HSP90 inhibition led to compensatory increase in HSP70 levels, while HSP70 inhibition decreased the levels of both HSP90 and HSP70. Combining VER-155008 and 17-DMAG also increase the HSP70 levels, however the effect was not stronger then use of 17-DMAG alone.
Summary and Conclusions: HSP70 inhibition has potential antileukemic effects in human AML. Furthermore, we provide results supporting stronger effect of HSP70 and HSP90 inhibition in combination, which can increase antileukemic activity in human AML, with the potential to overcome the obstacles associated with HSP90 inhibition alone. These approaches should be future explored in preclinical and clinical settings, to further identify the potential benefits of such a combination in leukemia treatment.

Acute myeloid leukemia - Clinical 3

P661

ACUTE MYELOID LEUKEMIA WITH NORMAL KARYOTYPE: IS THE NUMBER OF CONSOLIDATION CYCLES IMPORTANT?

D Pereira[1,*], S Chacim[1], L Leite[1], I C Ferreira[1], C Moreira[1], M Nunes[1], M Brito[1], M Marques[1], L Viterbo[1], I Oliveira[1], Ne Domingues[1], I Moreira[1], A Santo[1], A Martins[1], J Mariz[1]
[1]Servico de Onco-Hematologia, Instituto Portugues de Oncologia Francisco Gentil, Porto, Portugal

Background: To this date, the standard treatment of acute myeloid leukemia (AML) in young patients has been the use of increasingly myelotoxic induction followed by consolidation treatment, in which appropriate doses remains uncertain. Furthermore, treatment response is heterogeneous, being that the risk of relapse remains a constant threat. Defining the best consolidation treatment is still a major concern in the treatment of young adults with AML, particularly in patients with a normal or unfavorable karyotype without a HLA-compatible donor. A relevant issue is the ideal number of consolidation cycles with high dose cytarabine (HDAC) that would have an impact on prognosis.
Aims: Determination of the prognostic impact of the number of consolidation cycles in younger patients with non-promyelocytic *de novo* AML and normal karyotype.
Methods: In a total of 336 patients with AML, treated in our center from 1998 to 2010, a retrospective analysis was conducted in the subgroup of younger patients (age ≤65 years old according to our protocol) with non-promyelocytic *de novo* AML, normal karyotype who were undergoing the induction regimen "7+3" (Idarubicin 12mg/m^2 ev, days 1,2,3; Cytarabine 200mg/m^2 ev, days 1,2,3,4,5,6,7) and didn't have an HLA compatible donor. The patients' characteristics were compared with a chi-square test for binary variables and a Mann-Whitney test for continuous variables. The survival curves were estimated based on Kaplan-Meier curves and data for the various groups were compared with a log-rank test. The multivariate analysis was carried out using a Cox model, after the proportional hazard assumption was checked. A p value below 0,05 was considered as being statistically significant.
Results: The median follow-up was 28 months ([1-134]). Of the 47 patients, 48,9% (n=23) were male - with an average age of 52 years old ([20-65]). All patients (n=47) presented intermediate risk SWOG. In this analysis, of the 78,7% (n=37) patients who reached complete response (CR) after one cycle of induction, 76,6% (n=36) underwent consolidation treatment with Cytarabine 3mg/m^2 (CALGB). The median number of consolidation cycles was 3 [(1-4)]. This difference was conditioned by several factors (intention to treat, toxicity, relapse during consolidation, death). 59,6% of the patients relapsed after 13 months (median) [0-92]. It was observed that the disease-free survival (DFS) was better in the group of patients who complete 3 or 4 consolidation cycles, in contrast with the group who complete 1 or 2 cycles (P>0,05). If we done a stratification according to the number of consolidation cycles they carried out, 66.7% (n=24) of them underwent more than 2 consolidation cycles. This group of patients presented higher DFS in comparison to patients who underwent ≤2 cycles (median of 41 *vs.* 9 months, P=0,046), with an impact on overall survival (OS: P=0,021). Given the Cox regression analysis, the completion of more than 2 cycles of consolidation is an independent predictive factor of OS (HR=2,72; 95% CI1,12-6,58; P<0,05), comparatively with the group that performs ≤2 cycles of consolidation, age, number of leukocytes (at diagnosis) and type of response to induction. There was no noted difference between the high/intermediate risk group (n=11) and the low/intermediate risk one (n=4).
Summary and Conclusions: This study demonstrates that the number of cycles performed by a particular patient has prognostic value. For the heterogeneous intermediate risk group with normal karyotype, more cycles of consolidation with CALGB could be considered an important component to the AML treatment and thereby it could be an alternative to allogeneic transplantation in patients without an HLA-matched donor. This analysis needs to be enhanced with randomized studies in order to evaluate and validate this approach.

P662

IMPROVEMENT, BUT STILL POOR PROGNOSIS FOR ESTONIAN PATIENTS COMPARED TO A WELL-DEFINED REGION OF WESTERN SWEDEN, A POPULATION BASED STUDY OF ACUTE *DE NOVO* LEUKEMIA PATIENTS AGED 16-64 YEARS

E Hulegårdh[1,*], M Punab[2], L Wennström[1], K Palk[3], M Varik[3], E Holmberg[4], D Stockelberg[1]
[1]Hematology and Coagulation Section, Department of Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, [2]2nd Clinic of Hematology and Oncology, Tartu, [3]Department of Hematology, North Estonia medical centre, Tallinn, Estonia, [4]Department of Oncology, Institute of Clinical Sciences, Sahlgrenska Academy, Gothenburg, Sweden

Background: The present population-based survey was carried out over five consecutive 5-year study periods (1982-2006) on the incidence and survival of *de novo* acute leukemia (AL) patients with acute myeloid or lymphoblastic leukemia (AML/ALL) aged 16-64 years at diagnosis in Estonia (n=407) and in a well-defined region in western Sweden (n=517). Estonia regained independence in 1991 after 5 decades of occupation by the Soviet Union and entered a transition from planned to market economy.
Aims: The current population-based study was designed and aimed to investigate how changes as regards political and socio-economic circumstances are likely to affect hematologic health care in a society, especially incidence and survival.
Methods: The present population-based study comprises all *de novo* AL patients aged 16-64 years in Estonia and western Sweden diagnosed 1982-2006. Estonia covers an area of 45,000 km^2 and the Western Swedish Health Care Region covers an area of 27,000 km^2. During the years of the population-based retrospective work (1982-1996) the average population in Estonia and western Sweden were 1.5 and 1.6 million inhabitants, respectively. The average number of inhabitants in Estonia and the western Swedish region during the two prospective population-based studies (1997-2006) were 1.4 and 1.7 million, respectively. *Identification of* de novo *AL.* Since the aim of the present work was to compare the incidence and survival of *de novo* AL in the two countries, the delineation of the diagnosis was critical. Therefore, patients with a history of pre-existing myelodysplasia, polcythemia vera, essential thrombocythemia, idiopathic myelofibrosis, chronic myeloid leukemia or leukemia secondary to chemo-/radiotherapy were excluded from the study. *Statistical methods.* Individual data for the two cohorts of acute *de novo* leukemias from western Sweden and Estonia were put together in a database for the analyses. The incidence in the population was compared by use of age standardized incidence rates. Survival analyses were carried out by estimating relative survival. The relative survival is the ratio between the observed survival of the patients and the expected survival of a comparable group from the general population. Mortality data of the general population in Sweden and Estonia were used to estimate expected survival rates for the study populations. Internal age standardizing of the relative survival rates was done by use of the age distribution of all individuals in the two cohorts.
Results: With regard to age adjusted incidence rates for AL in our current work there is no statistically significant difference between Estonia (1.8/100000) and Western Sweden (1.8/100000)during the period 2002-2006. Corresponding figures for AML were 1.4/100000 and 1.2/100000 respectively and for ALL 0.4/100000 and 0.6 /100000, respectively. Similar incidence rates are noted since the start of our study 1982. Since the first five year cohort 1982-1986, five year relative survival for all AL patients in Western Sweden has increased from 20% to 56%, as compared to 2002-2006 (Figure 1). Corresponding figures from Estonia is an increase in survival from 3% to 22%. The pattern is similar for AML, Estonia (n=280) 2% to 22% and Western Sweden (n=370) 19% to 58%.There is also a brisk improvement in survival for Swedish AML patients during 1997-2001 (45% *vs.* 58%) as compared to Estonia (15% to 22%).

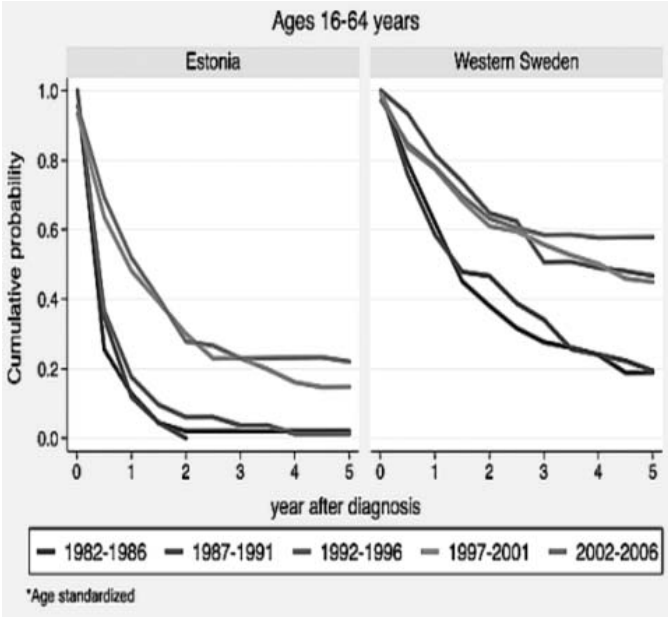

Figure 1. Relative survival* for AML *de novo*.

Summary and Conclusions: Over the years1982-1992 Estonia was still under the mentorship of the Soviet Union. Estonian hematologists did not have access to therapeutic measures readily available to Swedish hematologists, and the results for survival for western Swedish patients with AL far exceeded those for their Estonian counterparts. Of course it is encouraging that survival appears to have increased in Estonia as well as in Sweden. However, despite progress, the results in Estonia are still burdened by very poor survival in acute leukemia.

It is highly unsatisfactory that the improvements in relative survival have not been faster. Differences in survival between the two countries are mainly due to higher intensity chemotherapy regimens and a higher rate of hematopetic stem cell transplantation in Sweden. However, other still unknown factors may play a substantial role. Therefore, it is of particular interest and great importance that we are in the process of collecting specified data also regarding supportive care for *de novo* ALs for the next prospective period from 2007-2011.

P663

PROGNOSTIC IMPACT OF NPM1, IDH1/2 AND DNAH11 GENE MUTATIONS ON NORMAL KARYOTYPE ACUTE MYELOID LEUKEMIA PATIENTS NOT HARBORING FLT3/ITD MUTATION

Y Kim[1,*], I Lee[2], D Kim[3], C Won Jung[4], J Jang[4], H Kim[5], J Moon[6], S Sohn[6], J Won[7], S Kim[8], J Huh[9], J Lee[1], H Kim[1]

[1]Hematology, [2]Genome Research Center for Haematopoietic Diseases, Chonnam National University Hwasun Hospital, Jeollanam-do, Korea, Republic of Korea, [3]Medical Oncology and Hematology, Princess Margaret Hospital, University of Toronto, Toronto, Canada, [4]Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, [5]Hematology, The Catholic University of Korea, Seoul St Mary's Hospital, Seoul, [6]Hematology-Oncology, Kyungpook National University Hospital, Daegu, [7]Hematology-Oncology, Soon Chun Hyang University Hospital, Seoul, [8]Hematology-Oncology, Dong-A University College of Medicine, Busan, [9]Laboratory Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Republic of Korea

Background: Acute myeloid leukemia with normal karyotype (AML-NK) is known to be heterogeneous in the molecular level. Accordingly, it has become more critical to dissect this group of patients according to their prognosis using a molecular genetic technology.
Aims: We attempted to analyze the incidence and prognostic implication of genetic abnormalities on survival in 426 adult patients with AML-NK.
Methods: A total of 67 AML-NK patients achieved complete remission (CR), candidate mutations in 21 genes were identified by whole exome sequencing which has 41-89X coverage and by single-nucleotide polymorphism array analysis using marrow mononuclear cells at diagnosis of AML-NK. Subsequently, mutation analysis of 11 genes (*i.e. FLT3/ITD, NPM1, DNMT3a, IDH1, IDH2, TET2, NRAS, WT1, DNAH11, SF3B1, and PHF6*) which are known to be involved in the pathogenesis of hematologic diseases, were performed using Sanger sequencing in another subset of 359 AML-NK patients as a validation cohort.
Results: Of 426 patients in total (median age: 51, ranges: 15-85), FLT3/ITD, NPM1, and DNMT3a mutations were associated with higher leukocytes counts at presentation of AML-NK. In 284 patients who received standard remission induction (RI) chemotherapy (excluding 119 patients with conservative treatment and 22 early death/1 follow-up loss after RI chemotherapy), those with FLT3/ITD mutation were significantly associated with a higher risk of relapse (P=0.02), a shorter leukemic-free survival duration (LFS)(P<0.01) or overall survival (OS) (P=0.01). Accordingly, we divided the patients into FLT3/ITD$^+$ and FLT3/ITD$^-$ population, and analyzed their treatment outcomes according to the other mutations. In the FLT3/ITD$^-$ group (n=200), those with NPM1 mutation showed a higher CR rates after one or two cycles of RI chemotherapy (P<0.01) and a longer OS duration (P<0.01), hazard ratio (HR) 0.43, 95% confidence interval (CI) 0.25-0.73, adjusted by other clinical variables including age, leukocyte counts at diagnosis, and transplantation. In the FLT3/ITD$^+$ patients (n=84), NPM1 mutation was found to be a favorable prognostic factor showing a lower relapse rate (P=0.00), a longer LFS duration (P<0.01, HR 0.35, 95% CI 0.18-0.70), and OS duration (P=0.04, HR 0.55, 95% CI 0.31-0.98) in NPM1 mutated patients. In addition, OS was significantly different in favor of those with IDH2, especially R140Q IDH2 mutation, (P=0.04, HR 0.30, 95% CI 0.09-0.99), whereas DNAH11 mutation was associated with inferior OS (P<0.01, HR 5.78, 95% CI 1.65-20.25). Accordingly, we stratified the FLT3/ITD$^+$ patients into three subgroups according to the NPM1, IDH1/2 and DNAH11 mutation status, Group 1: NPM1 mutation and IDH1 or 2 mutations (n=16), Group 2: isolated DNAH11 mutation (n=4) and Group 3: all mutations were negative (n=64). The group 1 showed significantly better OS than group 2 (P<0.01, HR 16.90, 95% CI 3.48-82.15) orgroup 3 (P<0.01, HR 3.40, 95% CI 1.20-9.55).In a subgroup analysis of younger patients less than 60 years of age, similar outcomes were also observed in favor of group 1 in terms of OS.
Summary and Conclusions: Our study confirmed that NPM1 mutation is an independent prognostic factor in adult patients with AML-NK not harboring FLT3/ITD mutation. In addition, several other genetic markers were identified as prognostic including IDH1/2 or DNAH11 mutations as well as NPM1 mutation in a subgroup of AML-NK patients with FLT3/ITD mutation.

P664

ROLE OF ALLOGRAFTING IN HIGH RISK ACUTE MYELOID LEUKEMIA

B Bruno[1,*], E Audisio[1], S D'Ardia[1], D Ferrero[1], E Maffini[1], L Giaccone[1], B Allione[1], A Busca[1], C Casa[1], F Testa[1], C Frairia[1], F Ferrando[1], M Festuccia[1], L Brunello[1], A Evangelista[2], M Boccadoro[1], U Vitolo[1], G Ciccone[2], M Falda[1], F Marmont[1]

[1]Divisions of Hematology, [2]Tumor Epidemiology Unit, A.O. Città della Salute e della Scienza, Università di Torino, Torino, Italy

Background: Acute myeloid leukemia (AML) is the most frequent acute leukemia in adults. Prognosis of patients with high risk AML improves with allogeneic stem cell transplantation.
Aims: To evaluate outcomes in newly diagnosed patients, younger than 66, who achieved complete remission (CR) after induction/consolidation therapy at the Divisions of Hematology at Città della Salute e della Scienza, Università di Torino, Torino, Italy, between 2000-2011.
Methods: Three-hundred and two AML patients (except FAB-M3) were consecutively diagnosed and stratified by risk as follows: low risk included presence of t(8;21), inv(16)/t(16;16); high risk features included WBC>50.000/uL at diagnosis, secondary leukemia, presence of extramedullary AML, complex karyotype, chromosomal monosomy, no remission after induction, and FLT3/MLL mutations (since 2004). Intermediate risk included patients who did not meet either low or high risk criteria. Moreover, the standard risk group included low+intermediate risk patients. Patients were treated according to Center guidelines or on clinical trials active at the time of diagnosis. All high risk patients were considered for an allograft since diagnosis.
Results: After induction/consolidation, 229/302 patients (76%) achieved complete remission: 16/229 (7%) were at low, 54/229 (24%) at intermediate, and 159/229 (69%) at high risk respectively. Eighty/159 (50%) high risk patients received an allograft as 1st line treatment; 56% from a HLA-matched sibling, 42% from an unrelated donor and 2% received a haplo-identical transplant. Seventy-nine/159 (50%) did not receive an allograft primarily because of failure to find a suitable donor either sibling or unrelated. At median follow-up of 53 months from induction therapy and 49 months from achieving CR, 5-year overall survival (OS) and 5-year event free survival (EFS) of the entire patient cohort were 45% and 35% respectively. By risk category, standard risk patients showed a 5-year OS of 56% and high risk patients of 40% (P=0.008). Five-year EFS was 37 and 34% in standard and high risk patients respectively (P=0.194). High risk patients who underwent an allograft uP-front showed a 5-year OS of 53% and showed a statistically significant advantage as compared with those who did not receive a transplant (P=0.018).
Summary and Conclusions: Allografting plays a pivotal role in OS and EFS for high risk acute myeloid leukemia. The lack of a donor is associated with bad clinical outcomes. Prospective clinical trials designed to evaluate the use of more readily available donors such as haploidentical siblings or parents are needed.

PROGNOSTIC IMPACT OF A MONOSOMAL KARYOTYPE ON OUTCOME IN ACUTE MYELOID LEUKEMIA

I Djunic[1,*], N Suvajdzic-Vukovic[1,2], M Virijevic[1], A Novkovic[3], M Mitrovic[1], N Colovic[1,2], A Vidovic[1,2], D Tomin[1,2]

[1]Clinic for Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Clinical Hospital Center Zemun, Belgrade, Serbia

Background: Recently, a new cytogenetic category of acute myeloid leukemias (AML), monosomal karyotype AML (AML MK+), was reported to be associated with a poor prognosis and to add prognostic information even in patients with a complex karyotype.
Aims: The aims of this study were to determine the incidence and characteristics of AML MK+, and to estimate the impact of MK+ on overall survival (OS), complete remission rate (CR) and disease-free survival (DFS) in patients with AML.
Methods: This single-center study involved 298 patients with nonpromyelocytic AML. The following parameters were recorded: age, hemoglobin level (Hb), white blood cell count (WBC), platelet count (Plt) and performance status (PS) evaluated by the Eastern Cooperative Oncology Group (ECOG), range 0-4 (<1 *vs* ≥2). The clinical characteristics at presentation and outcome of two subgroups of patients: AML MK+ and AML without MK were compared. MK+ is defined by the presence of one single autosomal monosomy (AM; excluding isolated loss of X or Y) in association with at least one additional AM or one structural chromosomal abnormality (in the absence of core-binding factor AML). Patients were treated according to the Medical Research Council (MRC) 12 protocol. Statistical analysis included: the Fisher exact test, chi-square test and Kaplan-Meier method.
Results: The mean age of the patients was 57 years (range 19-79 years). The incidence of AML MK+ was 32.8% (98 pts). AML MK+ patients were significantly older than those from the control group (AML without MK; P=0.048). The presence of severe anemia at presentation with Hb <80 g/L was more frequent in AML MK+ patients than in those with AML without MK (P=0.046). Likewise, the mean WBC was lower in AML MK+ patients than in participants with AML without MK (P=0.008). AML MK+ patients had a higher rate of poor ECOG PS (≥2) than AML patients without MK (P=0.013). AML MK+ patients had shorter OS (6 *vs* 18 months; P=0.002) and DFS (5 *vs* 12 months; P=0.013) in comparison with AML patients without MK. Similarly, AML MK+ patients had a lower CR rate compared to AML patients without MK (27.3% *vs* 59.5%; P<0.001).
Summary and Conclusions: This research identified MK+ in approximately one-third of AML patients. The characteristics of these patients are older age,

poorer ECOG PS, lower Hb level and WBC at presentation of disease. The study also confirmed a poor prognosis for these patients, with shorter OS and DFS and lower CR rate. These data indicate that this subset of AML patients should be recognized as an adverse risk group and according to this studied in the new context of molecular markers.

P666

RISK FACTORS FOR CENTRAL NERVOUS SYSTEM INVOLVEMENT AT DIAGNOSIS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

I Djunic[1,*], N Suvajdzic-Vukovic[1,2], N Kraguljac-Kurtovic[1], M Virijevic[1], A Novkovic[3], M Mitrovic[1], N Colovic[1,2], A Vidovic[1,2], D Tomin[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Clinical Hospital Center Zemun, Belgrade, Serbia

Background: Central nervous system (CNS) involvement in acute myeloid leukemia (AML) is observed in 2-4% of patients at diagnosis. Hematological parameters associated with an increased risk of CNS leukemia include a high presenting white blood count (WBC), elevated lactate dehydrogenase (LDH), French-American-British (FAB) subgroups M4 and M5 and age less than 50 years. Recently, it was shown that the immunophenotypic pattern of AML–the expression of CD56 antigen (CD56+) on leukemic cells, was associated with a higher rate of CNS involvement in AML at presentation.
Aims: The aims of this investigation were to estimate the incidence of CNS involvement at diagnosis of AML and to determine the risk factors for its occurrence.
Methods: This single-center study involved 191 patients with nonpromyelocytic AML. The following parameters were estimated as risk factors for CNS involvement at diagnosis of AML: age, WBC ($<30\times10^9$/L *vs* $\geq30\times10^9$/L), serum lactate dehydrogenase (LDH) concentration >1.5× the upper limit of normal, expression of CD56 antigen on leukemic blasts (<20% *vs* ≥20%) and cytogenetic risk group (assessed according to European LeukemiaNet recommendations). The presence of leukemic cells in cerebrospinal fluid (CSF) detected by cytomorphological and/or flow cytometric analysis of CSF is considered as CNS involvement. Patients were treated by the Medical Research Council (MRC) 12 scheme. Risk factors were identified using univariate and multivariate analysis.
Results: The mean age of the patients was 55 years (range 21-79). CNS involvement was recorded in 5.8% (11) of them. Univariate analysis detected the following significant risk factors for CNS involvement: age <55 years (P=0.009), WBC $\geq30\times10^9$/L (P=0.001), elevated LDH (P=0.036), FAB M4/M5 (P=0.05) and CD56+ (P=0.001). Multivariate analysis identified CD56+ as the most important risk factor for CNS involvement at diagnosis in AML patients (P=0.001; relative risk (RR)=18.241; 95% confidental interval (CI)=3.305-100.675. The cytogenetic risk group had no influence on CNS involvement in this study.
Summary and Conclusions: According to the result**s** obtained, AML patients with CD56+ on leukemic cells are at high risk for CNS involvement at presentation. Cytomorphological and/or flow cytometric analysis of CSF should be recommended as a routine procedure in these patients for more precise diagnosis of CNS involvement. CD56 antigen is an isoform of the neural cell adhesion molecule, constitutively expressed in normal monocytes and monocyte-derived cells, which could be an explanation for the high risk of CNS involvement in CD56+ patients with AML, particularly FAB subtypes M4/M5.

P667

SYSTEMIC VERSUS LOCALIZED THERAPEUTIC APPROACH FOR ISOLATED MYELOID SARCOMA: META-ANALYSIS OF INDIVIDUAL PATIENT DATA

D Antic[1,*], N Milic[2]
[1]Clinical Center Serbia, Clinic for hematology. Medical Faculty, University in Belgrade, [2]Institute for medical statistic and informatic, Medical faculty, University in Belgrade, Belgrade, Serbia

Background: Myeloid sarcoma (MS), also known as granulocytic/monoblastic sarcoma, extramedullary myeloid tumors, or chloroma, is a tumor mass comprising blasts or immature cells of the myeloid series, occurring at an anatomical site other than the bone marrow. MS can occur in patients with active acute myeloid leukemia (AML), in patients with chronic myeloproliferative disease, as the first manifestation of relapse in previously treated patients and as well as isolated MS in patients without bone marrow infiltration. The optimal timing and treatment of isolated MS are not clear, but delayed or inadequately treated isolated MS will almost always progress to AML. Also, in patients treated with chemotherapy postremission therapy has not been adequately studied; therefore, one of the most important questions in the treatment of MS is the role of hematopoietic stem cell transplantation (HSCT).
Aims: The objective of this review was to assess the effects of systemic therapy approach in adults with isolated MS rather than local treatment (surgery or radiotherapy).
Methods: We searched the Cochrane Controlled Trials Register, UKCCCR Register of Cancer Trials, Physicians Data Query, EMBASE, MEDLINE and CancerLit and after that studies in adults with isolated MS treated with chemotherapy and/or HSCT compared with local treatment (surgery or radiotherapy) were included.
Results: Four studies involving 44 patients were included. Individual patient data were obtained. The Kaplan-Meier estimate of median overall survival was 13 months (95%CI 5-21). The median overall survival for patients undergoing chemotherapy and HSCT was 28 months (95% CI, 7 to 48) while the median overall survival for patients locally treated was 9 months (95% CI, 4 to 13). The difference in overall survival was not significant but potentially represents an absolute benefit of 19 months (95% CI 11 to 28). The difference was found in OS between patients treated with HSCT and patients who did not underwent to HSCT in population below 40 years old (P=0,031). The patients undergoing HSCT had a significantly longer overall survival time compared to those who did not [33 months (95%CI 22-44) *vs* 9 months (95%CI 5-13)].There was no consistent evidence of a difference in effect according to age, sex, stage, site, grade, histology, extent of resection, tumour size or exposure to radiotherapy.
Summary and Conclusions: While more individual patient data are needed to collect, chemotherapy with HSCT could be considered as the optimal therapy for patients with isolated MS.

P668

EVALUATION OF BONE MARROW ON DAY 5 OF INDUCTION THERAPY FOR ACUTE MYELOID LEUKEMIA FOR IDENTIFICATION OF CHEMO-RESISTANT BLAST SUBPOPULATIONS

Y Ofran[1,2,*], S Yaari[1], R Hoffman[1], N Horowitz[1], M Hayun[1]
[1]Hematology and Bone marrow tarnsplantation, Rambam health care campus, [2]Faculty of medicine, Technion - Israel institute of technology, Haifa, Israel

Background: In most patients with acute myeloid leukemia (AML), different leukemia-associated immunophenotypes (LAIP) co-exist. At diagnosis, rapidly proliferating clones determine the dominant LAIP. However, at relapse, a different LAIP may become dominant. This phenomenon may reflect either a new clone or differentiation change within the original clone evolved over time. Alternatively, a small resistant sub-clone masked at diagnosis, may become evident following eradication of other, chemo-sensitive clones.
Aims: The present study investigated differences in response kinetics among immunophenotypically distinguished cell subpopulations at day 5 of induction in addition to routine assessment of day 14.
Methods: Fifteen consecutive adult AML patients receiving induction therapy with daunorubicin 60mg/m^2 for three days and cytarabine 100mg/m^2 for seven days (3+7) were evaluated. Immunophenotypes of bone marrow samples at diagnosis (day 1), after five and fourteen days of therapy were compared. Samples of relapsed patients were also analyzed. LAIPs were quantitatively evaluated by 6-color FACS analysis (Cytec; FlowJosoftware) and their relative fraction of total blast population was recorded at each time point.
Results: During therapy, the number of detectable LAIPs per patient was found to decrease. The median number of detectable LAIPs reduced from 5 through 3 to 2 at diagnosis, day 5 and day14, respectively. However, in the majority of patients, only scanty leukemic cells were observed in the day 14 marrow and not a single LAIP was detected in 2/12 (16%) patients whose samples were evaluable. In most patients, the cell number in the blast window decreased by day 5. However, eradication rate varied among different leukemic subpopulations. Heterogeneity of leukemic cells decreased with therapy, especially in patients who achieved CR in response to treatment, reflecting different sensitivity of various blast subpopulations to chemotherapy. LAIPs were quantitatively evaluated as percentage of cells in the blast window. Evaluation of each patient was particularly focused on leukemic subpopulations with the slowest eradication rate. A specific LAIP, which doubled its size in the blast window, from diagnosis to day 5 was defined as a personalized LAIP of concern. Personalized LAIPs of concern were identified in 7/15 (46%) patients and their prevalence was as high as 71.5% (5/7) among the individuals who achieved complete remission (CR) following a single induction course. Two of responding patients experienced early relapses. Interestingly, the dominant LAIP at relapse differed from that recorded at diagnosis in both patients. Meticulous analysis of samples obtained at diagnosis revealed that the dominant LAIPs at relapse were identified at day 5 samples in both patients as the LAIP of concern.
Summary and Conclusions: In clinical practice, there is an urgent need for an approach allowing recognition and characterization of leukemia relapse at the earliest possible stage. Herein, a novel approach to early, real-time identification of patient-specific resistant blast subpopulation is suggested. Detection of a personalized unique “LAIP of concern” as early as day 5 of induction would allow sorting these subpopulations out and characterizing their metabolic and genetic factors which could be attributable to later appearing clinically significant chemo-resistance.

P669

LOW MDR1 AND BAALC EXPRESSION IDENTIFIES A NEW SUBGROUP OF ADULT CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA WITH A FAVORABLE OUTCOME

X Guo[1,*], F Chen[1], P Shi[1], J Zha[1], B Liu[1], H Zheng[1], B Xu[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, GuangZhou, China

Background: Cytogenetically normal acute myeloid leukemia (AML) is a heterogeneous disease, in terms of genetic/molecular abnormalities resulting into marked differences in outcome.
Aims: We demonstrated that multidrug resistance 1(*MDR1*), brain and acute leukemia, cytoplasmic (*BAALC*) gene expression was of prognostic significance and high *MDR1* expression correlated with a high *BAALC* expression (*r=0.487,P*<0.001) in cytogenetically normal AML in the prophase study then we hypothesized that *MDR1* and *BAALC* expression together would better identify the patient's risk profile.
Methods: Pretreatment bone marrow samples from 92 cytogenetically normal AML patients were analyzed for *MDR1* and *BAALC* mRNA expression by real-time reverse transcriptase polymerase chain reaction. Patients were divided into low *MDR1* and*BAALC* expression group and combined group(high *MDR1* and/or high *BAALC* expression) according to *MDR1* and *BAALC* levels and were compared for clinical outcome.
Results: 73 cases of 92 cytogenetically normal AML patients got CR after the first block with a CR rate being 79.3%. However, 29 cases of the CR patients relapsed with the relapsed rate being 39.7%. In contrast, Patients with low expression of both *MDR1* and *BAALC* had a higher CR rate (*93.3%vs72.6%*, *P*=0.021), lower relapse rate(*7.1% vs. 42.5%, P*=0.000), longer OS (*50.3% vs 17.8%,P=0.00*1) than high *MDR1*and/or high *BAALC* expression (combined group) in cytogenecally normal AML. Results showed no statistical difference in CR rate (*93.3%vs85.7%*, *P*=0.341),relapse rate (*7.1% vs. 8.8%, P*=0.000) and OS (*50.3% vs 63.1%,P=0.43*1) for cytogenetically normal patients with both *MDR1* and *BAALC* low expression comparing to those with low-risk cytogenetically abnormal.
Summary and Conclusions: The combined assessment of *BAALC* and *MDR1* expression can improve treatment stratification in adult cytogenetically normal AML. Low expression of both *MDR1* and *BAALC* identifies cytogenetically normal AML patients with a favorable long-term outcome.

P670

THE SURFACE MOLECULAR SIGNATURE OF LEUKEMIC CELLS WAS ASSOCIATED WITH NPM1 AND FLT3-ITD MUTATIONS IN ACUTE MYELOID LEUKEMIA

S Gao[1], L Su[1,*], W Li[1], Y Tan[1], J Cui[1]
[1]Cancer center, The first hospital, Jilin University, Changchun, China

Background: Acute myeloid leukemia (AML) is a genetically heterogeneous clonal disorder characterized by the accumulation of somatically acquired genetic alterations in hematopoietic progenitor cells. Certain molecular mutations are associated with signs of cell morphology and differentiation in AML. However, only limited data is available to analyze such correlations in detail. Here we report the analysis results of 259 consecutive Chinese AML patients by using J-Express 2009 analysis suite.
Aims: To observe the associations between surface molecular signature of leukemic cells and *NPM1* and *FLT3-ITD* mutations in patients with *de novo* acute myeloid leukemia.
Methods: In present study 259 patients with *de novo* AML were enrolled. The morphological differentiation status of the leukemia cells was evaluated by FAB classification. The mutational status of molecular markers *NPM1* and *FLT3-ITD* were analyzed by polymerase chain reactions (PCR). Surface differentiation markers (CD11c, CD13, CD14, CD15, CD33, CD34 and HLA-DR) of the leukemic cells were analyzed by flow cytometry. Patients gave informed consent prior to enrolment in the study. The obtained data were analyzed using J-Express 2009 analysis suite and SPSS 17.0.
Results: The frequencies of *NPM1* and *FLT3-ITD* mutations were 15.06% (39/259) and 14.51% (37/255) in this study, respectively. Based on the surface differentiation markers of leukemic cells, the patients were classified into 2 distinct subsets: Cluster I ($CD34^{low}$) and Cluster II ($CD34^{high}$). Patients in Cluster I could be further subdivided into Cluster Ia ($CD34^{low}HLA\text{-}DR^{low}$) and Cluster Ib ($CD34^{low}HLA\text{-}DR^{high}$). Similarly, Cluster II patients could be classified into two subsets: Cluster IIa ($CD34^{high}CD11c^{high}$) and Cluster IIb ($CD34^{high}CD11c^{low}$). The frequencies of *NPM1* and *FLT3-ITD* mutations were significantly higher in Cluster I patients [33.33% (35/105) and 31.43% (33/105)] than those in Cluster II patients [2.01% (3/149) and 2.01% (3/149)] (χ^2=47.491, *P*<0.001 and χ^2=45.642, *P*<0.001, respectively). Neither mutation was detected in the Cluster IIb patients. No associations were observed among *NPM1* (*P*=0.531) and *FLT3-ITD* (*P*=0.563) mutations and monocytic morphology in patients without CD34 expression.
Summary and Conclusions: *NPM1* and *FLT3-ITD* mutations are associated with signs of cell morphology and differentiation in AML. The absence of *NPM1* mutations in the immature subset Cluster IIb ($CD34^{+}CD11c^{-}$) patients in this study supports the hypothesis that the cell origin of the *NPM1* mutations is a common myeloid progenitor. Further studies are required to identify similar possible correlations for *FLT3-ITD* mutations.

P671

IMPACT OF DAY 14 BONE MARROW EXAMINATION ON RE-INDUCTION DECISION AND PREDICTION OF COMPLETE RESPONSE IN ACUTE MYELOGENOUS LEUKEMIA (AML)

A Aleem[1,*], F Anjum[2], K Alsaleh[2], F Algahtani[2], A Momen[2]
[1]Department of Medicine, Division of Hematology/Oncology, [2]Medicine, Hematology/Oncology, King Khalid University Hospital, King Saud University, Riyadh, Saudi Arabia

Background: The decision to re-induce patients with acute myeloid leukemia (AML) based on results of the day 14 bone marrow (BM) examination is variable and has limited evidence based data. In adult AML a variety of clinical and biological parameters have been examined for their potential value in predicting treatment response. Early response to induction therapy could be an important prognostic factor in this disease.
Aims: The aim of this study was to evaluate the accuracy of a day 14 BM examination in determining the need for re-induction chemotherapy and prediction of complete response.
Methods: Eighty-four patients with newly diagnosed AML treated with standard induction chemotherapy were retrospectively reviewed for the purpose of evaluating treatment decisions based on their day 14 BM biopsy from 2000-2012. Response to therapy in this analysis was based on morphology alone.
Results: Of the 84 patients undergoing standard induction, 65 patients (77%) had hypocellular bone marrow with less than 5% blast on their day 14 examination. Thirteen patients (16%) had definitive residual disease (RD), and 6 patient's (7%) were classified as indeterminate response (IR). Sixty three out of 65 patients with hypocellular bone marrow on day14 had complete response on day 28 bone marrow examination and 2 patients had residual disease on day 28 bone marrow and these 2 patients received re-induction on day 14. Patients with suboptimal response (SOR) (SOR=IR+RD), 2/13 patients with RD underwent re-induction chemotherapy on day 14. Seventeen patients with SOR (6 with IR and 11 with RD) were observed until count recovery without any re-induction therapy. All 6 patients with IR and 8 out of 11 patients with residual disease who were observed without re-induction eventually attained a morphologic complete remission (CR) on day 28.
Summary and Conclusions: Day 14 BM examination may have suboptimal sensitivity for the detection of residual leukemia in AML patients. Some patients with an indeterminate response and residual disease on day 14 may not require re-induction chemotherapy, but instead, may benefit from careful observation until count recovery to avoid the morbidity and mortality associated with prolonged bone marrow suppression related to early re-induction chemotherapy.

P672

ADVERSE PROGNOSTIC SIGNIFICANCE OF FLT3 MUTATIONS IN ACUTE PROMYELOCYTIC LEUKEMIA

M Mitrovic[1,*], N Suvajdzic[1,2], N Tosic[3], A Bogdanovic[1,2], I Djunic[1], A Sretenovic[1], A Vidovic[1,2], M Virijevic[1], N Colovic[1,2], T Kostic[3], T Karan-Djurasovic[3], I Glumac[3], V Spasovski[3], S Pavlovic[3], I Elezovic[1,2], D Tomin[1,2]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia

Background: Internal tandem duplication (ITD) of *Fms-like tyrosine kinase-3* (*FLT3*) gene and point mutation in its activation loop (*FLT3*-D835) are frequent aberrations in acute promyelocytic leukemia (APL), but their prognostic value is not well established.
Aims: To evaluate prognostic value of *FLT3* gene mutations in *de novo* APL patients.
Methods: *FLT3*-ITD and *FLT3*- D835 mutations were assessed by PCR and PCR-RFLP method respectively in 45/61 newly diagnosed APL patients, on DNA isolated fromdiagnostic bone marrow aspirates or smears. The presence of t(15;17)(q22;q12) was assested using cytogenetics or RT-PCR method. All of the patients (median age 44 years, range 19-78; female/male 32/29; median follow-up 32 months) were managed at the Clinic of Hematology from 2004 to 2012 with all-trans retinoic acid and anthracycline-based chemotherapy.
Results: Material for *FLT3 gene* mutations analysis was available in 45/61 (75%) patients. *FLT3*-ITD was detected in 11/45 (24.4%) and *FLT3*- D835 in 4/45 (8.9%) patients. *FLT3*-ITD was associated with significantly higher WBC count (median 28.4×10^9/L *vs.* 1.4×10^9/L, P=0.0022), higer percentage of peripheral blood blasts (median 19% *vs.* 4%, P=0.042), lower platelet count (median 21×10^9/L *vs.* 32×10^9/L, P=0.029) higher relapse-risk score (low risk 1/11 (9%), intermediate 3/11 (27%), high 7/11 (64%) *vs.* 12/34 (35%), 10/32 (30%), 12/34 (35%) respectively, P=0.034), more frequent microgranular subtype (3/11 (27%) *vs.* 2/34 (5.9%) P=0.0001), CD2 expression (5/9 (55.5%) *vs.* 5/30 (16.7%) P=0.0007), CD56 expression (3/9 (33%) *vs.* 1/12 (8%), P=0.047) and thrombotic events (4/11, (36%) *vs.* 5/34, (15%), P=0.025). No correlation was found with age, fibrinogen, prothrombin time, activated prothrombin time, D-dimer, International Society of Thrombosis and Haemostasis Scoring System for diseminated intravascular coagulation (ISTH DIC score), expression of the other surface markers, additional cytogenetic abnormalities and incidence of differentiation syndrome. In contrast, *FLT3*-D835 was not significantly associated with any hematologic characteristic. Early death

(ED) rate in our series was 8/45 (17.78%). ED rate was significantly higher (P=0.002) in patients with *FLT3*-ITD (4/11, 36%) than in patients without mutation (4/34, 11.7%). Furthermore, multivariate analysis identified WBC count >20×10^9/L (*P*=0.002337), ISTH score ≥6 (P=0.008) and *FLT3-ITD* (*P*=0.02) as independent prognostic factors for ED. Seven relapses (7/37, 18.9%, 5 overt and 2 molecular) occured, three (3/7, 42%) in *FLT3*-ITD positive cohort and four (4/30, 13%) in *FLT3*-ITD negative cohort. Median time from the achievement of complete remission to relaps was 30 months (range: 4–44). *FLT3*-ITD positive patients had significantly lower 4-year RFS than *FLT3*-ITD negative ones (56% *vs.* 77%; *P*=0.002). However, multivariate analysis identified only WBC count >20×10^9/L as an independent predictive factor for relapse (P=0.05). Besides, 4-year overall survival (OS) was significantly lower in *FLT3-ITD* positive patients (62% *vs.* 87%, P=0.016) too. In contrast FLT3- D835 mutation had no impact on both 4-year RFS and OS.
Summary and Conclusions: Our study speaks in favor of negative prognostic value of *FLT3*-ITD mutation in APL. Further prospective trials should 1) investigate independence of FLT3-ITD predictive value and 2) evaluate whether this parameter might be included in risk stratification.

P673

MINIMAL RESIDUAL DISEASE BY WT1 GENE EXPRESSION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AFTER INDUCTION AND CONSOLIDATION CHEMOTHERAPY: CORRELATION WITH MULTIPARAMETER FLOW CYTOMETRY

A Franco[1,*], M Kwon[1], C Martinez-Laperche[1], P Balsalobre[1], P Font[1], C Encinas[1], A Escudero[1], J Gayoso[1], J Anguita[1], J Diez-Martin[1], I Buño[1]
[1]HEMATOLOGIA Y HEMOTERAPIA, HOSPITAL UNIVERSITARIO GREGORIO MARAÑON, Madrid, Spain

Background: Evaluation of minimal residual disease (MRD) in early stages of treatment can refine the risk stratification of patients with acute myeloid leukemia (AML).
Aims: The objective of this study was to analyze the MRD detection by of the Wilms tumor (WT1) gene expression after induction and consolidation chemotherapy in patients with AML and to correlate the results with those obtained by multiparametric flow cytometry (MFC).
Methods: Between 2007 and 2012, 65 patients were diagnosis of AML in our institution. Twenty patients were excluded due to earlydeath, lack of intensive treatment, promyelocyticleukemiadiagnosis or absence of available data. Therefore, 45 AML patients were included in the analysis (Table 1a). WT1 expression was quantified in bone marrow (BM) samples at diagnosis, after induction and after consolidation therapy, using real-time quantitative PCR (relative quantification with K562 cell line as calibrator and GUS as reference gene). The cutoff value for overexpression was set at 0.55% in BM. The presence of subpopulations associated with leukemia aberrant immunophenotype (LAIP) was analyzed by MFC with 4 colors (Beckman Coulter FC500). Residual disease was reported as positive above 0.1%.

Table 1.

Tabla 1a Caracteristics of Patients

Patients (N)	45
Age, Median (range)	50 (18-75)
Gender M/F	29/16
Classification (FAB)	M1=12; M2=7; M4=11; M5=6; Displasia=9
Cytogenetic Risk	Favorable=2; Intermediate=31; Unfavorable=6
WT1 overexpression at diagnosis	39 (86%)
CMF (LAIP) at diagnosis	36 %= Optimal LAIP 8 = Suboptimal LAIP 1 = Whithout LAIP
Induction Treatment*	IA 3x7 = 40 (88%) Reduced IA = 5 (11%)
Consolidation Treatment	IA 3x7 = 36 (80%) Reduced IA = 3 (6%) I-FLAG = 3 (6%) HDAC = 3 (6%)

* Reinduction treatment 6 patients

Table 1b. Correlation between WT1 overexpression and MFC for MRD detection after induction (A) and consolidation (B) therapy

(A)		MFC*		
		POS	NEG	
WT1*	POS	3	0	3
	NEG	9	12	21
		12	12	24

(B)		CMF**		
		POS	NEG	
WT1**	POS	4	0	4
	NEG	4	15	19
		8	15	23

*Not available MFC 2 patients / WT1 13 patients
**Not available MFC 5 patients / WT1 11 patients

Results: Out of the 45 patients, 39 (86%) showed WT1 overexpression at diagnosis. No correlation was observed between WT1 overexpression and clinical characteristics such as age, gender, FAB classification and cytogenetic risk at diagnosis. In 1 patient no LAIP could be identified and 8 more patients showed suboptimal LAIPs for follow-up. The post-induction and post-consolidation analysis showed MRD by both WT1 and MFC in 3 and 4 patients, respectively (Table 1b). No patients were positive by WT1 and negative by MFC either post-induction or post-consolidation. Finally, 9 patients post-induction and 4 post-consolidation showed positive MRD by MFC without WT1 overexpression. Among these patients 2 showed suboptimal LAIPs for follow-up. The limited number of patients in the present series as well as the heterogeneity of post-consolidation subsequent treatments does not allow testing the clinical utility of MRD results.
Summary and Conclusions: Overexpression of WT1 in the present series of AML patients is similar to that reported in the literature. In most cases, MRD positivity by WT1 overexpression correlates with that of MFC. Although clinical value of these results could not be tested in the present study, WT1 expression would be especially useful in patients without other molecular markers and those with suboptimal or without LAIP. Further analysis with a larger cohort of patients is needed to determine the true prognostic value of this MRD approach.

P674

SERUM FERRITIN AS A PROGNOSTIC MARKER IN YOUNG ADULT ACUTE MYELOID LEUKEMIA

M Delia[1,*], D Pastore[1], P Carluccio[1], F Albano[1], A Ricco[1], T Perrone[1], P Curci[1], F Gaudio[1], A Giordano[1], A Russo Rossi[1], G Specchia[1]
[1]Hematology - University of Bari, Bari, Italy

Background: Different studies have demonstrated an iron overload contribution to post-transplantation liver toxicity, infectious events and poor survival in patients undergoing hematopoietic stem cell transplantation for haematological malignancies. So far, in the clinical setting of adult acute myeloid leukaemia (AML) there is no evidence of the possible role of iron in response and survival rates.
Aims: Our aim was to study the role as a prognostic factor of pre-treatment serum ferritin in young adult AML.
Methods: The study sample included 77 consecutive adult *de novo* AML patients (38 males and 39 females, median age 55 years, range 16 to 60 yrs). The serum ferritin level was determined at onset of the disease in each case. According to the FAB criteria the subtypes were: 7 M0, 43 M2, 16 M4, 6 M5, 5 M6. M3 subtypes were excluded from the analysis. NPM, FLT3 and cytogenetic evaluation was performed for all cases. The NPM mutation was present in 35 patients (45%) and 34 (44%) harboured the FLT3 alteration. Twenty-five (32%) patients were in the adverse, ten (13%) in the favorable and forty-two (55%) in the intermediate molecular-cytogenetic risk group. The patients were subdivided into two groups according to serum ferritin values (less than 800 *versus* greater than 800 ng/mL). Student t-test or the Mann-Whitney test was performed for comparisons of means. Two-tailed Fisher exact test exact test was used to compare categories. Overall survival (OS) was measured from the time of diagnosis to death or last follow-up visit and was calculated using the Kaplan-Meier method; the log-rank test was used to compare survival curves. Logistic regression was performed for multivariate analysis. Only p values less than 0.05 were considered statistically significant.
Results: Thirty (39%) patients showed a ferritin serum value greater than 800 ng/mL. Compared with the less than 800 ng/mL group, patients with serum ferritin grater than 800 ng/mL were more frequently non responders to chemotherapy (29 *vs* 58%, P=0.03) and they had a shorter median OS (250 *vs* 665 days, P=0.04). Moreover, patients with serum ferritin greater than 800 ng/mL showed a higher frequency of documented infections during induction treatment (48% *vs* 16%, P=0.004). At multivariate analysis, NK-FLT3ITD+,NK-NPM, Cytogenetic and Ferritin value (less than or greater than 800 ng/mL) all showed a statistical correlation with the response rate (P=0.04; P=0.05; P=0.04; P=0.05, respectively).
Summary and Conclusions: The results of our study suggest a link between serum ferritin and AML prognosis. Further studies are needed to confirm the utility of serum ferritin as a prognostic marker in the adult acute myeloid leukaemia setting.

P675

PERIPHERAL BLOOD BLASTS ON DAY 7 OF INITIAL INDUCTION THERAPY PREDICT RESPONSE TO CHEMOTHERAPY AND SURVIVAL IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

S Gao[1], L Su[1,*], W Li[1], Y Tan[1], X Liu[1], P Yu[1]
[1]Cancer center, The first hospital, Jilin University, Changchun, China

Background: Cytogenetics and molecular markers are powerful prognostic indicators for outcome of patients with acute myeloid leukemia (AML). However, predictors of response after initiation of chemotherapy are not available. A rapid decrease in blood blasts is often considered a favorable indicator of response in patients with AML who receive induction chemotherapy. Time of peripheral blood

blast (PBB) clearance has been reported to be a predictor for complete remission (CR) and survival of AML patients, but litter attention was paid to the correlation between response, outcome of AML and PBB percentage.
Aims: To explore the associations between chemotherapy response, outcome of AML and PBB percentage on day 7 of the initial induction therapy.
Methods: In this study, 46 consecutive *de novo* AML (excluding acute promyelocytic leukemia) patients treated with standard '3+7' induction course were evaluable for bone marrow (BM) response on day 14 and day 28. Flow cytometry was carried out to identify the percentage of cells with leukemia-associated aberrant immuno-phenotype (LAIP) in each patient from the initial BM aspirate. LAIP-positive blast percentage was determined on peripheral blood on day 7 of the induction therapy. Patients gave informed consent prior to enrolment in the study. Statistical analysis was performed with the software SPSS 17.0.
Results: PBB percentage on day 7 (PBBPD7) was 0.35% (0.0%, 80.74%) in all patients, and in those achieved CR, the percentage was 0.03% (0.0%, 0.45%), which was significantly lower than those did not achieve CR (10.85% [1.13%, 19.38%]) (u=- 3.92, P<0.001). PBBPD7 was significantly correlated with CR rate of the first course (r=0.584, P<0.001). The cutoff value was 0.945% (area under curve [AUC]=0.84, sensitivity [Se]=78.9%, specificity [Sp]=81.5%, P<0.001). The CR rate of patients with PBBPD7 ≤0.945% (84.62%, 22/26) was significantly higher than those with PBBPD7 >0.945% (25.0%, 5/20) (χ^2=16.571, P<0.001). PBBPD7 was significantly correlated with overall survival (OS) (r=- 0.437, P=0.003) and relapse free survival (RFS) (r=- 0.388, P=0.007). The cutoff value was 0.43% for both OS (AUC=0.723, Se=73.4%, SP=71.4%, P=0.009) and RFS (AUC=0.723, Se=66.7%, SP=69.2%, P=0.009). The OS and RFS were significantly higher in patients with PBBPD7 ≤0.43% compared with those with PBBPD7 >0.43% (P=0.002 and P=0.005, respectively). PBBPD7 was proved to be an independent prognostic parameter in multivariate analyses for both OS (P=0.036) and RFS (P=0.035).
Summary and Conclusions: Peripheral blood blast percentage on day 7 of the induction therapy may be an important predictor of early response to initial chemotherapy and long-term survival for AML.

P676

PROGNOSTIC VALUE OF TH17 CELLS IN ACUTE LEUKEMIA
M Salah-Eldin[1,*], N Abousamra[2], R Helal[3]
[1]Medical Oncology, Oncology Center, Mansoura University, [2]Department of Clinical Pathology, Hematology Unit, [3]Public Health and Community Medicine, Faculty of Medicine, Mansoura, Egypt

Background: The net outcome of the battle between the anti-tumor and the tumor promoting immune cells and their associated cytokines within the tumor environment will determine the ultimate fate of the affected tumors. Th17 cells and their effector cytokines have emerged as important mediators in inflammatory and autoimmune diseases and serve as an ambitious field in current immunology research. Recent studies suggest a potential impact of Th17 cells on solid tumors but relatively little is known about their contribution in hematological malignancies.
Aims: The current study was designed to investigate the possible involvement and clinical significance of circulating Th17 cells in acute leukemia
Methods: Flow cytometry was used to analyze percentages of Th17 cells in peripheral blood from 93 acute leukemia patients and 40 controls
Results: Compared with healthy controls; acute leukemia patients had a higher proportion of circulating Th17 cells. Furthermore, increased serum concentrations of IL-17 and IL-21 accompanied the increased Th17 cell levels in these patients. Circulating Th17 cells were reduced when patients achieved complete remission (CR) after chemotherapy, suggesting that circulating Th17 cells can be used to evaluate response to therapy in acute leukemia patients. Notably, the increased prevalence ofinitial Th17 cells was significantly associated with probability of achieving CR as well as with longer overall survival of acute leukemia.
Summary and Conclusions: These results strongly suggest that Th17 cells may be a powerful new prognostic determinant which could serve as a potential therapeutic target to modulate anti-tumor response in acute leukemia. Mechanisms by which Th17 cells influence acute leukmia, and whether these mechanisms mediate direct or indirect effects need to be determined.

Chronic lymphocytic leukemia - Immune triggering and microenvironmental interactions

P677

BCR AND TLR ACTIVATION OF AGGRESSIVE CHRONIC LYMPHOCYTIC LEUKEMIA: THE CASE OF STEREOTYPED SUBSET 1
A Charlotte Bergh[1,*], C Evaldsson[2], K Stamatopoulos[3,4], R Rosenquist[5], A Rosén[2]
[1]Department of Clinical and Experimental Medicin, Cell biology, [2]Department of Clinical and Experimental Medicine, Linköping, Sweden, [3]Hematology Department and HCT Unit G. Papanicolaou Hospital, [4]Institute of Applied Biosciences, Center for Research and Technology, Thessaloniki, Greece, [5]Department of Immunology, Genetics and Pathology, Uppsala, Sweden

Background: Chronic lymphocytic leukemia (CLL) B cells express auto/xeno-antigen-reactive immunoglobulin receptors that bind to self-epitopes, such as oxidation-modified low-density lipoprotein (oxLDL), and certain microbial structures. Chronic infections are hence possible triggering events in the pathogenesis of CLL. In addition to B cell receptor (BCR) crosslinking, interaction with the microenvironment through other receptors such as innate Toll-like receptors (TLRs) could be important to promote CLL cell survival and proliferation.
Aims: In this study we ought to get insight in oxLDL binding, and to study the outcome of BCR and TLR co-stimulation on activation and/or proliferation of subset 1 CLL cells.
Methods: We used primary CLL cells from eight patients belonging to the poor-prognostic stereotyped subset 1 (*Clan I IGHV genes-IGKV1(D)-39),* and seven non-subset 1 patients. The specificities of IgM Abs from six different subset 1 patients were evaluated in competition chemiluminescent ELISA. Furthermore, binding of oxLDL to cells from five subset 1 and four non-subset 1 CLL patients were studied in flow cytometry. To investigate the effect of BCR and TLR co-stimulation on activation and/or proliferation, cells from 8 subset 1 CLL patients and 2 non-subset 1 CLL patients were either unstimulated or stimulated with oxLDL (BCR) alone or in combination with the TLR9 ligand CpG-oligodeoxynuclotide (ODN). Activation of CLL cells was evaluated using kinetic measurements, during 5 min, of intracellular Ca^{2+} release and surface expression of the activation markers CD25 and CD86 after 24h. Proliferation was measured with BrdU-incorporation after 72h stimulation.
Results: All six CLL Ab clones showed specificity for oxLDL. Interestingly oxLDL not only bound to subset 1 CLL cells but also to non-subset 1 cells indicating that binding to other oxLDL (scavenger) receptors may also occur. In none of the subset 1 cases was antigen alone sufficient to induce Ca^{2+}mobilization, proliferation, or CD25 expression. Interestingly however, uP-regulation of the co-stimulatory ligand CD86 could be seen in 2/2 patients studied. CpG-ODN induced proliferation in all but 1 subset 1 CLL cases, dual stimulation with oxLDL and CpG-ODN however, gave a heterogeneous outcome. 4/7 responding patients showed an increase in proliferation compared to single stimulated cells, and 2/7 showed suppression of proliferation. Addition of the TLR inhibitor chloroquine or a Syk-inhibitor totally abrogated the oxLDL-CpG induced proliferation, indicating BCR/TLR collaboration.
Summary and Conclusions: Taken together, we document that BCR-to-self-antigen trigger may act in synergy with TLR signaling for activation and proliferation of clonal CLL cells in some patients.

THE PHOSPHO-PROTEOMIC PROFILE OF CD49D-EXPRESSING CIRCULATING CHRONIC LYMPHOCYTIC LEUKEMIA CELLS IS CONSISTENT WITH CONSTITUTIVE RECEPTORIAL ENGAGEMENT BY BLOOD-BORNE LIGANDS
D Benedetti[1,*], E Tissino[1], D Marconi[1], M Dal Bo[1], R Bomben[1], S Deaglio[2], D Rossi[3], G Gaidano[3], G Pozzato[4], F Di Raimondo[5], G Poeta[6], A Zucchetto[1], A VanMeter[7], V Espina[7], L Liotta[7], V Gattei[1]
[1]Clinical and Experimental Onco-Hematology Unit, Centro di Riferimento Oncologico, Aviano, [2]Genetics, Biology and Biochemistry and Human Genetics Foundation, University of Turin, Torino, [3]Division of Hematology, Department of Clinical and Experimental Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, [4]Maggiore General Hospital, University of Trieste, Trieste, [5]Department of Hematology, University of Catania, Catania, [6]Division of Hematology, S.Eugenio Hospital and University of Tor Vergata, Roma, Italy, [7]Center for Applied Proteomics and Molecular Medicine, George Mason University, Manassas, VA, United States

Background: CD49d is a negative prognosticator in chronic lymphocytic leukemia (CLL) marking a subset of ~40% of CLL cases. CD49d, the a4 integrin subunit, is a key molecule for CLL cell microenvironmental interactions, through the binding to fibronectin and VCAM-1. Despite the great deal of studies investigating CLL cell microenvironmental interactions in tissue sites, little is known regarding the constitutive engagement of adhesion receptors in circulating CLL cells.

Aims: Defining the role of plasma and plasma components in the activation of circulating CLL cells.
Methods: The proteomic profiles of circulating CLL cells was explored using a reverse phase protein microarray (RPMA) approach. Phospho-proteins expression was validated by western blot assay. F-actin polymerization and apoptosis were evaluated by flow cytometry through phalloidin and AnnexinV/7-AAD staining, respectively.
Results: Comparison of the phospho-proteomic profiles between 40 CD49d+ and 40 CD49d- CLL cases highlighted the over-expression in the CD49d+ group of proteins involved in the regulation of integrin-mediated cytoskeletal dynamics, such as phospho-p21-activated kinase (pPAK; P=0.0005), phospho-LIM kinase (pLIMK; P=0.00001) and phospho-CrkII Tyr221 (P=0.039). The constitutive overexpression of these phospho-proteins in the CD49d+ CLL group, confirmed by western blot analysis, suggest that integrin signalling is active in CD49d-expressing circulating CLL cells, pointing to a constitutive receptor engagement in peripheral blood. To test whether plasma constituents could modulate integrin-signaling proteins, CD49d- and CD49d+ CLL cells, were challenged with autologous plasma. The presence of plasma induced a stronger increase of pPAK and pLIMK in CD49d+ CLL cells, compared to CD49d- cases (P=0.018 and P=0.017, respectively). Of note, pretreatment of CD49d-expressing CLL cells with the anti-CD49d HP1/2 blocking antibody, resulted in a lower uP-regulation of pPAK and pLIMK (P<0.01). Since PAK and LIMK are key players in the regulation of actin reassembly, we examined the effect of plasma stimulation in the actin polymerization. Addition of plasma induced actin polymerization in CD49d expressing CLL cells (P=0.004) but not in CD49d- CLL cells, this effect being impaired by the pretreatment with the anti-CD49d HP1/2 blocking antibody. ELISA assay on plasma samples from 24 CLL revealed the presence of high fibronectin level (mean concentration=336 ug/mL) and VCAM-1 (mean concentration=3.7 ug/mL) without substantial difference between CD49d- and CD49d+ cases. Given the high molecular weight of both fibronectin and VCAM-1 (>100 kDa) fractionation through filter devices was allowed, yielding plasma fractions enriched or not CD49d ligands. These plasma fractions, upon verification by western blotting for the presence/absence of fibronectin and VCAM-1, were used to culture CLL cells from 6 CD49d- and 6 CD49d+ cases. Only plasma containing CD49d ligands protected CLL cells from apoptosis and this effect was evident in CD49d+ group (P=0.03) and partially reverted by blocking CD49d activity.
Summary and Conclusions: Altogether these results sustain the hypothesis of an active role of plasma components in the activation of CD49d-mediated integrin pathway, thus favoring the delivery of pro-survival signals even in the context of circulating CLL cells. Our results may be of interest in the perspective of novel therapies, *e.g.* those targeting the B-cell receptor signalling, known to provoke a massive egress of neoplastic cells from tissue sites into the blood stream.

P679

IDENTIFICATION OF CIRCULATING CHRONIC LYMPHOCYTIC LEUKEMIA INTRACLONAL SUBGROUPS WITH VARYING B CELL RECEPTOR FUNCTION

V Coelho[1,*], S Krysov[2], A Steele[2], M Sanchez Hidalgo[3], P Johnson[2,4], P Chana[5], G Packham[2], F Stevenson[6], Francesco Forconi[1,7]
[1]Haematology Oncology Group, Cancer Sciences Unit, [2]Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, [3]Department of Pharmacology, University of Seville, Seville, Spain, [4]Medical Oncology, University Hospital Southampton NHS Trust, Southampton, [5]Biomedical Research Centre, Guy's and St Thomas' NHS Foundation Trust and King's College, London, [6]Cancer Sciences Division, University of Southampton, [7]Haematology Department, Southampton University Hospital Trust, Southampton, United Kingdom

Background: Chronic lymphocytic leukemia (CLL) is a tumor of circulating B cells, with the clonal B-cell receptor (BCR) variably stimulated and downmodulated (anergized) following exposure to antigen in lymphoid tissues. However surface expression and signal capacity of the tumor BCR IgM is dynamic and can recover *in vitro*, and apparently *in vivo* during recirculation in the blood. Levels of surface IgM (sIgM) may be critical to tumor cell behavior and sensitivity to clinically relevant BCR-signalosome inhibitors.
Aims: We aimed to dissect individual tumor CLL clones by differential levels of sIgM. We then determined i) if IgM function and sensitivity to BCR-signalosome inhibitor ibrutinib varied and ii) if phenotypic characteristics changed depending on those levels.
Methods: A bead-bound anti-IgM assay was developed to discriminate and investigate subgroups (SGs) of CLL cells, defined by sIgM levels. SGs were determined by number of anti-IgM beads bound to cells. Single cells were visualized by imaging flow cytometry. Expression of Ig light chain, CD19, CD5, CD38, CD25 and CXCR4 and intracellular Ki67 were determined in SGs in flow cytometry. BCR signaling analysis of phosphorylated PLCgamma2 or ERK1/2 was determined by Phosflow in the presence or absence of BTK inhibitor ibrutinib.
Results: Four clear subgroups (SG1-4) with increasing sIgM were identified in 37/37 cases (Figure 1). Engagement of sIgM induced phosphorylation of PLCgamma2 and ERK1/2 at levels ranging from very low in SG1 to high in SG4. Remarkably, phosphorylation was suppressed by Ibrutinib. Expression of CXCR4 also increased from SG1 to SG4 but markers of activation (CD25 and CD38) and proliferation (Ki67) were dominant in SG1. Incubation of whole CLL populations *in vitro* led to striking increases in CXCR4 expression, as well as recovery of sIgM.

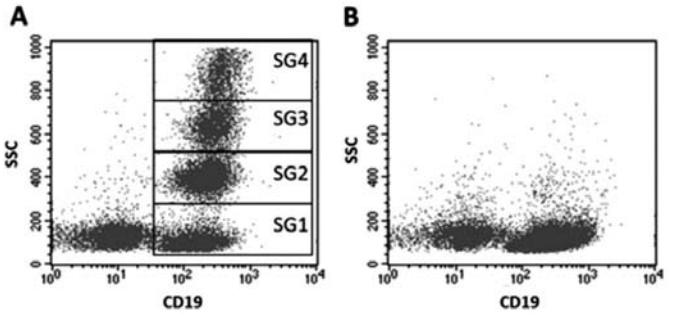

Figure 1. CLL clonal subgroups by anti-sigM coated beads separation. PBMCs were incubated either with goat F(ab')$_2$ anti-human IgM coated beads (panel A) or with isotype control coated beads (panel B). CLL subgroups (SGs) were identified within the CD19+ tumor population according to different side scatter (SSC).

Summary and Conclusions: Clonal analysis reveals dynamic SGs following presumed antigen stimulation in tissues. SG4 represents a fully recovered, potentially dangerous population equipped to migrate to tissue and to receive a proliferative stimulus. SG1 likely represents a post-mitotic unresponsive "resting" population. The suppressive effect of ibrutinib on the small SG4 population may be the critical factor in therapeutic success.

AN UNBIASED SCREEN OF FUNGAL EXTRACTS IDENTIFIED CHAETOGLOBOSIN A AS A METABOLITE THAT PREFERENTIALLY INDUCES APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS BY TARGETING THE CYTOSKELETON

M Seiffert[1,*], P Boldsen Knudsen[2], B Hanna[1], L Sellner[3], T Zenz[3], S Stilgenbauer[4], T Ostenfeld Larsen[2], P Lichter[1]
[1]Molecular Genetics, B060, German Cancer Research Center, Heidelberg, Germany, [2]Center for Microbial Biotechnology, DTU Systems Biology, Lyngby, Denmark, [3]Department of Translational Oncology, National Center for Tumor Diseases, Heidelberg, [4]Internal Medicine III, University of Ulm, Ulm, Germany

Background: Chronic lymphocytic leukemia (CLL) is a malignancy of mature B cells that is very common in the western world and not curable with currently available treatment options. Even though the bulk of leukemic cells in the peripheral blood is eradicated upon treatment in most patients, relapse frequently occurs from cells that are located in secondary lymphoid tissues, often leading to chemoresistant disease.
Aims: In search for novel therapeutics that target CLL cells also in protective microenvironments, we performed a fungal extract screen using primary CLL cells in coculture with the bone marrow-derived stromal cell line HS-5, which is known to support long-term survival of CLL cells.
Results: One of the major hits of our screen was a metabolite of *Penicillium aquamarinium*, that was subsequently identified as Chaetoglobosin A, a member of the cytochalasin family. Extensive testing of the pure compound with primary blood cells of CLL patients or normal donors (Figure 1), leukemic cell lines, as well as a variety of different tumor and fibroblast lines revealed a preferential activity of Chaetoglobosin A for CLL cells (LD50 value of 2.8 µM compared to 9.5 µM for normal PBMC), which was also observed in culture systems that mimic the protective microenvironments of bone marrow and lymph nodes. The inclusion of 74 CLL cases with various genetic aberrations (del11q: n=14; del13q: n=44; del17p: n=12; trisomy12: n=11; mutBRAF: n=4; mutMYD88: n=2; mutNOTCH1: n=4; mutSF3B1: n=11; mutTP53: n=13) in our study revealed effective targeting of CLL cells by Chaetoglobosin A, also in cases harboring bad prognosis characteristics. To provide insight into its mechanism of action, we further showed that Chaetoglobosin A induces apoptosis in CLL cells and confirmed filamentous actin as its target. As the cytoskeleton is known to regulate B cell receptor (BCR) signalling, we hypothesized that apoptosis induction by Chaetoglobosin A is due to impairment of signalling cascades that deliver pro-survival signals in CLL cells. In support of that, our data show that Chaetoglobosin A alters activation-relevant molecules in CLL cells and sensitizes them for treatment with BTK or PI3K inhibitors, which are known to interfere with BCR signalling. The cytoskeleton changes induced by Chaetoglobosin A further impaired migration of CLL cells in transwell assays. In mice and rats, no severe toxicity was observed upon administration of relevant doses of Chaetoglobosin A. In ongoing experiments using CLL xenotransplantation as

well as Eμ-TCL1 mice, a genetic animal model for CLL, we are currently evaluating the efficacy of Chaetoglobosin A for CLL *in vivo*.

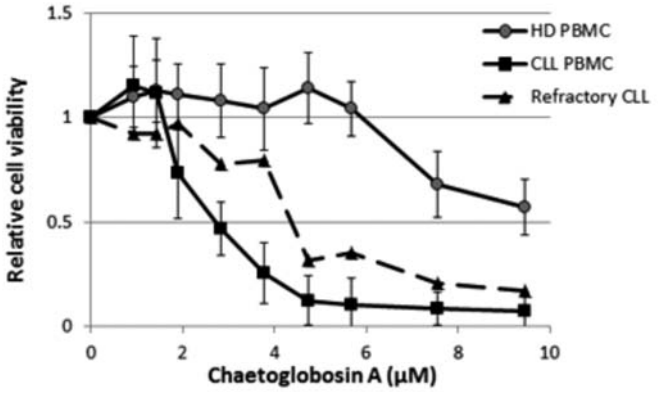

Figure 1. Viability of peripheral blood mononuclear cells (PBMC) isolated from blood samples of CLL patients (n=8) or healthy donors (HD; n=4) was measured by Cell Titer Glo assay after 24 hours of treatment with Chaetoglobosin A. Median values normalized to control samples and standard deviations are depicted.

Summary and Conclusions: In summary, our findings suggest Chaetoglobosin A as a novel potential drug for CLL that prevents pro-survival signalling and migration of leukemic cells.

THE ELASTIN MICROFIBRIL INTERFACER1 (EMILIN1), IS HIGHLY EXPRESSED IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)-INVOLVED TISSUES, AND PROMOTES CLL CELL ADHESION VIA CD49D

E Tissino[1,*], D Benedetti[1], A Zamò[2], R Bomben[1], M Dal Bo[1], T Vaisitti[3], S Deaglio[3], D Rossi[4], F Zaja[5], G Pozzato[6], F Di Raimondo[7], G Gaidano[4], G Del Poeta[8], P Spessotto[9], A Capuano[9], R Doliana [9], A Colombatti[9], A Zucchetto[1], V Gattei[1]

[1]Clinical and Experimental Onco-Hematology, Centro di Riferimento Oncologico, Aviano, [2]Section of Pathological Anatomy, Department of Pathology and Diagnostics, University of Verona, Verona, [3]Human Genetics Foundation (HuGeF), Department of Genetics, Biology and Biochemistry, University of Torino Medical School, Torino, [4]BRMA - Amedeo Avogadro University of Eastern Piedmont, Division of Hematology, Novara, [5]Department of Experimental Medical and Clinical Sciences, University of Udine, Udine, [6]Department of Internal Medicine and Hematology, Maggiore General Hospital, University of Trieste, Trieste, [7]Division of Hematology, Ospedale Ferrarotto, Catania, [8]Division of Hematology, S. Eugenio Hospital and University of Tor Vergata, Roma, [9]Experimental Oncology2, Centro di Riferimento Oncologico, Aviano, Italy

Background: CD49d is a negative prognosticator in chronic lymphocytic leukemia (CLL) with a key role in microenvironmental interactions. CD49d triggering by its main ligands VCAM-1 and CS-1 fragment of fibronectin activates pro-survival signaling pathways, and promotes resistance to drug-induced apoptosis in CLL. Recently, the globular (g) C1q-like domain of EMILIN1, an adhesive extracellular matrix constituent, represents a new ligand for CD49d and operates as a negative modulator of proliferation signals in non-hematopoietic cells (Danussi *et al.*, J Cell Biol, 2011).
Aims: Investigating the distribution of EMILIN1 in normal and CLL-involved tissues, and the effects of CD49d/EMILIN1 interaction in CLL in terms of adhesion and survival.
Methods: Immunohistochemical (IHC) detection of EMILIN1 in CLL-involved tissues was done utilizing a non-commercial anti-human EMILIN1 affinity purified rabbit polyclonal antibody (AS556). Adhesion assays were performed on coverslips coated with VCAM-1, the CS-1 fibronectin fragment, the gC1q-like domain of EMILIN1, and gC1q-like domain mutants devoided of segment Leu932–Gly945, that contain the Glu933 responsible for integrin interaction. Immunofluorescence (IF) and biochemical assays were used to study the activation of signaling proteins. Apoptosis was evaluated by annexinV/7-AAD staining.
Results: Exploratory IHC staining in reactive lymphoid tissues indicated an extracellular EMILIN1 specific reactivity in the outer zone of the mantle/marginal areas. IHC analysis in CLL lymph node tissues (n=3) and bone marrow biopsies (n=5) showed a clear EMILIN1 staining intermingled with the neoplastic component, in close proximity of venules, close to marginal sinuses and in CLL proliferation centers. In in-vitro CLL cell adhesion assay, both the CLL-derived CD49+ Mec-1 cell line and primary CD49d+ CLL cells (n=12) were specifically able to adhere onto EMILIN1 substrates (mean values of adhered cells/control 28±3 and 24±3, respectively), the adhesion efficiency being similar to that observed on VCAM-1 and CS-1. Adhesion was specifically blocked by pre-treatment with the anti-CD49d HP1/2 blocking antibody, and absent when the gC1q like domain mutant was employed. After short-term adhesion assay onto EMILIN1 substrates, western blot analysis documented increased phosphorylation of Akt and ERK1/2, mediators of survival signals, similar to that observed upon CD49d engagement by VCAM-1 and CS-1. These results were corroborated by IF analysis showing pAkt and pERK uP-regulation, and the concomitant increase of pVav1 and F-actin reorganization, confirming the activation of the integrin signaling pathway. Finally, we studied the effects of CD49d/EMILIN1 interaction on CLL cells survival. CD49d engagement by both EMILIN1 and VCAM-1, were able to significantly delay the CLL cells spontaneous apoptosis (P=0.002 and P=0.009, respectively), and the viability obtained on EMILIN1 was even significantly higher than that observed on VCAM-1 (P=0.005).
Summary and Conclusions: For the first time we showed that EMILIN1 is present in normal and CLL-involved tissues, and it is able to efficiently bind to CD49d, as expressed by CLL cells. At variance of what demonstrated in non-hematopoietic models, EMILIN1 was able to deliver anti-apoptotic/pro-survival signals to circulating CLL cells. CD49d/EMILIN1 interactions may have a role in the maintenance of the neoplastic clone in CD49d-expressing CLL.

P682

SINGLE CELL NETWORK PROFILING (SCNP) ANALYSIS REVEALS DYSFUNCTIONAL SIGNALING WITHIN THE TH17 AXIS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

S Liang[1,*], J Ptacek[1], E Evensen[1], L Leung[1], D Stockett[1], N Chiorazzi[2], B Sherry[2], Rachael Hawtin[1]

[1]Nodality, Inc., South San Francisco, [2]The Feinstein Institute for Medical Research, North Shore-LIJ Health System, Manhasset, NY, United States

Background: Chronic lymphocytic leukemia (CLL) cells obtain pro-survival signals from non-tumor leukocytes such as T cells and monocyte-derived nurse-like cells. Recent reports demonstrate that increasing numbers of Th17 cells, a subset of $CD4^+$ T cells that can be induced by TLR agonists, IL-1b, and IL-6 and express IL-17A and IL-17F as effector cytokines, correlates with improved prognosis in CLL. The functional basis for this correlation, including how these factors in the Th17 axis affect signaling in CLL, is unknown. SCNP is a multi-parametric flow cytometry based technology that quantifies signaling in multiple intracellular pathways at the single cell level, without prior cell subset isolation, providing a means to interrogate the signaling interplay of Th17 cells with B-CLL cells and the tumor microenvironment.
Aims: Using SCNP, investigate signaling in the Th17 axis in peripheral blood mononuclear cell (PBMC) samples to identify a functional role for Th17 cells in CLL pathophysiology.
Methods: SCNP was performed on PBMCs from 22 CLL patients and 8 healthy donors, examining signaling in $CD4^+$ and $CD4^-$ T cells and $CD14^+$ monocytes in both groups as well as $CD19^+$ B cells in healthy donors and $CD19^+CD5^+$ cells in CLL patients. Induction of intracellular signaling in the NFkB (IkB, P-NFkBp105), PI3K (AKT), MAPK (P-ERK), and STAT (P-STAT1, P-STAT3) pathways was examined in response to TLR agonists and cytokines involved in Th17 differentiation and effector function.
Results: Engagement of TLR7/8 (R848) or of TLR9 (CpG-B) resulted in reduced IkB degradation in CLL B cells and monocytes compared to healthy cells. This reduced responsiveness was associated with lower basal levels of IkB in CLL. The magnitude of TLR9-induced IkB degradation in CLL B cells significantly correlated with Th17 numbers, suggesting that TLR activation induces factors (*e.g.* IL-1b, IL-6) triggering Th17 differentiation. Upon IL-1b modulation, CLL $CD4^+$ and $CD4^-$ T cells displayed greater phosphorylation of NFkBp105 than healthy cells. IL-6 also induced greater phosphorylation of STAT3 relative to STAT1 in $CD4^+$ but not $CD4^-$ CLL T cells. Because STAT3 promotes whereas STAT1 inhibits Th17 differentiation, these data suggest that CLL $CD4^+$T cells have dysregulated signaling pathways that favor Th17 generation. Moreover, analysis of Th17 effector cytokines identified IL-17F but not IL-17A induced NFkBp105 phosphorylation only in CLL B cells whereas no response was detected in healthy B cells. In addition, combination of IL-17F with BAFF, a factor that regulates CLL B cell survival, led to ERK and AKT phosphorylation only in CLL B cells. Although significant differences in IL-17F modulated signaling between CLL and healthy B cells were identified, IL-17RA and IL-17RC receptor expression were comparable between CLL and healthy cells, demonstrating that analysis of modulated signaling reveals functional alterations not revealed by surface phenotyping.
Summary and Conclusions: Collectively, these data identify multiple novel alterations in Th17 axis signaling in CLL, providing a functional basis for the role of Th17 cells and IL-17 cytokines in CLL pathophysiology. The application of SCNP to further explore these signaling differentials, and their potential as novel prognostic factors in CLL, is in progress.

TOSO-DEFICIENT B CELLS SHOW IMPAIRED B CELL DEVELOPMENT

A Schulz[1,2,3,*], L Kintzelé[1,2,3], C Pallasch[1,2,3], M Hallek[1,2,3], C Wendtner[1,2,3,4], L Frenzel[1,2,3]

[1]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associ-

ated Diseases (CECAD), [2]Center of Integrated Oncology (CIO), University of Cologne, [3]Department I for Internal Medicine, University Hospital Cologne, Koeln, [4]Department I for Internal Medicine, Klinikum Schwabing, Muenchen, Germany

Background: In the recent years, TOSO–alias FAS apoptosis-inhibitory molecule 3 - has been controversially discussed whether it exerts anti-apoptotic effect or is the long-sought-after bona fide Fcμ-receptor.
Aims: Since our group previously identified TOSO to be overexpressed in CLL and to be correlated with progressive disease, it is indispensible to clarify the biologic significance of TOSO, particularly in the CLL relevant B cells.
Methods: Therefore, we generated a B cell-specific knockout mouse model and crossbred FAIM3-floxed C57BL/6 mice with CD19-specific Cre recombinase expressing mice. B cells from the *toso*$^{CD19-/-}$ (KO)micewere isolated and gene expression was analyzed via mRNA based Illumina microchip array. Convincing results were verified by flow cytometry and blood count was carried out in addition.
Results: Peripheral blood and spleens of the TOSO deficient mice displayed decreased level of lymphocytes, in which B cells were determined as reduced entity. Other cell types, like NK and T cells, remained thereby unaffected.
Downstream effects of TOSO were validated via microarray-based gene expression analysis. Results displayed a clear clustering of deregulated genes compared to controlmice. Nearly 500 genes showed expression alterations. Genes involved in the NF-κB pathway and migration processes were downregulated in *toso*$^{CD19-/-}$ mice, suggesting that TOSO represents an important factor in these processes. Flow cytometry analysis confirmed these results and additionally referred to an impaired B cell maturation process.
Summary and Conclusions: Thus, our results might reveal a new function of TOSO in migration, pro-survival signaling and B cell homeostasis, supporting the anti-apoptotic feature of TOSO in B cells.

P684

EXPRESSION OF ZAP-70 IN CLL ACTIVATES NF-KB SIGNALING

V Pede[1,*], A Rombout[1], J Vermeire[1], E Naessens[1], H Vanderstraeten[1], J Philippé[1], B Verhasselt[1]
[1]Clinical Biology, Immunology and Microbiology, University Ghent, Ghent, Belgium

Background: The clinical course of chronic lymphocytic leukemia (CLL) is variable, but can be predicted by prognostic markers. Two frequently used prognostic markers include the mutation status of the immunoglobulin variable heavy chain genes (IgVH) and the expression level of the zeta-associated protein of 70 kDa (ZAP-70). The clonal excess of CD5+, CD19+ CLL cells is thought to be due to a defect in both apoptosis and cell proliferation.
Aims: Although the exact mechanisms responsible for this inappropriate cell growth and survival are poorly understood, one of the key factors that has been related to the biology of CLL cells is the constitutive activation of nuclear factor-KB (NF-KB). Since NF-KB is a downstream target of the B-cell receptor (BCR) signaling in normal B lymphocytes and since ZAP-70 might directly enhance IgM signaling, we wondered if ZAP-70 affects NF-KB target gene expression following IgM stimulation.
Methods: We introduced a functional ZAP-70 protein in CLL cells with undetectable ZAP-70 expression by electroporation of *in vitro* transcribed capped mRNA that is translated in the cell into ZAP-70 protein (Van Bockstaele F. *et al.* Leukemia 2007). After electroporation, cells were stimulated with anti-IgM-polyacrylamid beads (anti-IgM stimulated) to activate the BCR signaling pathway and to activate the introduced ZAP-70 protein. As a negative transfection control we electroporated mRNA coding for ΔNGFR or we used uncapped mRNA that cannot be translated in the cell, anti-IgA-polyacrylamid beads (anti-IgA stimulated) were used as a negative control for stimulation. We determined the mRNA expression profile using a Human Illumina Gene Expression BeadChip and measured interleukin (IL) expression levels in CLL cells differing in ZAP-70 expression.
Results: In samples only differing in ZAP-70 expression after exogenously introducing ZAP-70 in ZAP-70 negative CLL samples, expression of IL-1β, IL-6 and IL-8 after 24 hours of IgM stimulation was increased in the presence of ZAP-70 (Figure 1). The observed increased mRNA levels were translated into increased amounts of secreted proteins. We also observed similar enhanced cytokine expression in cells of ZAP70+ cases compared to of ZAP70- cases, after 24 hours of IgM stimulation. The enhanced cytokine expression in ZAP-70 expressing cells could be a NF-KB mediated downstream event of BCR triggering. To test this hypothesis BMS-345541, a selective inhibitor of the catalytic subunit of IKK, was used. As expected, without inhibitor ZAP-70 expression increased endogenous cytokine expression. This induction of cytokines in ZAP-70 expressing CLL cells was completely blocked upon inhibition of IKK. Furthermore, we analyzed by whole genome expression profiling the genes affected by ZAP-70 in BCR stimulated CLL cells. By functional annotation pathway analysis, we found the gene set most significantly upregulated after 24h to be associated with RelA activation, RelA being one of the five members of NF-KB transcription factors. This suggests that ZAP-70 indeed enhances NF-KB signaling upon BCR signaling. This signature fits in a functional network of genes involved in cell movement and immune cell trafficking.

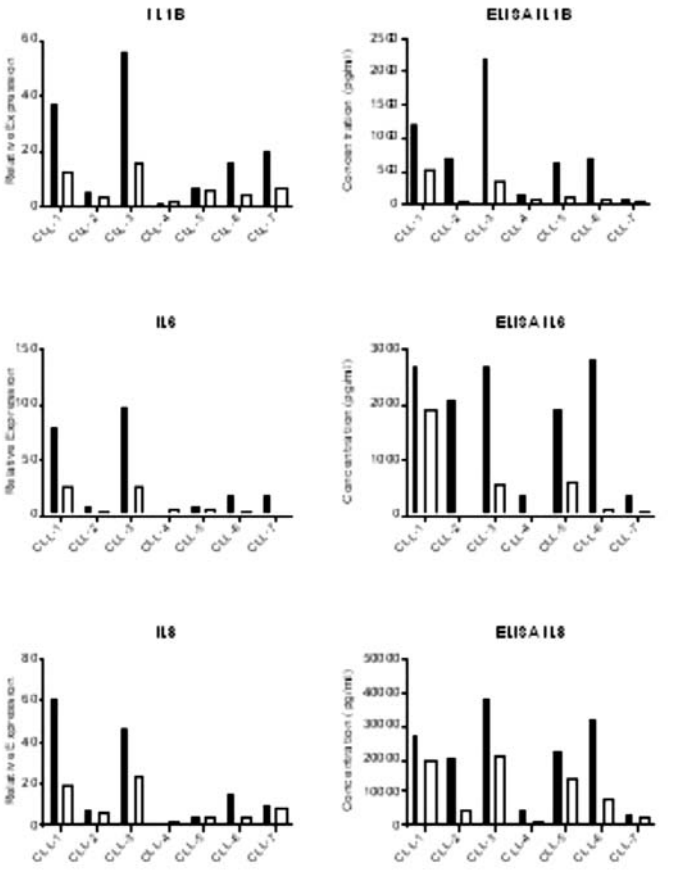

Figure 1. Expression of ZAP-70 enhances cytokine expression up on IgM stimulation, on mRNA level (left) and protein level (right). Black bars: ZAP-70 electroporated; open bars ΔNGFR control electroporated cells.

Summary and Conclusions: By enhancing the NF-KB pathway, ZAP-70 expression can contribute to increased motility, survival and proliferation of CLL cells and thus contributes to the worse prognosis observed in these patients. More than simply a correlate with prognosis of CLL, ZAP-70 therefore potentially has a direct pathognomonic role in the disease. Identification of the molecular pathways involved requires more research, what could lead to the identification of novel therapeutic targets.

P685

THE PRO-APOPTOTIC MIR-132~212/SIRT1/TP53 AXIS IS ACTIVATED UPON B-CELL RECEPTOR TRIGGERING IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

R Bomben[1,*], T D'Agaro[1], S Gobessi[2], S Dereani[1], M Dal-Bo[1], D Marconi[1], E Tissino[1], F Pozzo[1], D Benedetti[1], A Zucchetto[1], L Laurenti[3], D Rossi[4], G Gaidano[4], G Del-Poeta[5], D Efremov[2], V Gattei[1]
[1]Clinical and Experimental Onco-Ematology Unit, Centro di Riferimento Oncologico, Aviano, Aviano, [2]Molecular Hematology, ICGEB Outstation-Monterotondo, [3]Department of Hematology, Catholic University Hospital A. Gemelli, Rome, [4]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro, University of Eastern Piedmont, Novara, [5]Division of Hematology, S.Eugenio Hospital and University of Tor Vergata, Rome, Italy

Background: Numerous studies indicate a prominent role for the B-cell receptor (BCR) pathway in defining the patho-biological features of chronic lymphocytic leukemia (CLL). MicroRNAs (miR) represent a class of small non-coding RNAs that, by degrading selected mRNAs or inhibiting their translation, modulate key cellular functions. Altered miR expression in CLL by genetic abnormalities or microenvironmental interactions has been reported, but nothing is known regarding their modulation upon BCR triggering.
Aims: To investigate the expression and function of microRNAs modulated by BCR triggering in CLL.
Methods: Negatively selected CLL cells were stimulated in-vitro (20 hours) with immobilized anti-IgM (aIgM) and analysed by miRNA/gene expression profiling (miRome/GEP), quantitative real-time PCR (qRT-PCR) and western blotting. All CLL cases were characterized for IGHV gene mutation status and common genetic lesions, including *TP53* mutations, by FISH and/or sequencing analyses.

Results: Supervised analysis of miRome of 16 aIgM-stimulated or unstimulated CLL samples (9 IGHV unmutated, UM; 7 IGHV mutated, M) showed substantial upregulation of the *miR-132~212* cluster. This phenomenon was validated by qRT-PCR in additional 28 cases in which a mean 19.5-fold increase (range 1.5-50; P<0.0001) was documented upon aIgM exposure. No differences were observed between UM- and M-CLL samples. UP-regulation of *miR-132~212* required sustained BCR signaling, as demonstrated by the following observations: i) it occurred upon exposure of CLL cells to immobilized but not soluble anti-IgM antibodies; ii) it was abrogated by co-treating CLL cells with the SYK inhibitor R406. An in-silico analysis aimed at identifying candidate target genes for *miR-132~212* revealed responsive elements in the 3'UTR of *SIRT1*, a gene encoding for a histone deacetylase that targets several proteins including TP53. This finding was experimentally validated by western blot analysis of 9 CLL samples (5 UM-, 4 M-CLL), where SIRT1 levels were reduced by 13% (range 5-23%) upon aIgM-treatment (P=0.001). A significant increase in TP53 acetylation was also observed in the same cases (mean increase 30%, range 3-82%; P=0.0072). Notably, GEP analysis of the 16 CLL samples investigated in the miRome analysis identified both *TP53* and the TP53 target gene *CDKN1A* among the 917 toP-ranked genes uP-regulated in aIgM-stimulated CLL. We also evaluated the constitutive expression of *miR132* by qRT-PCR in highly purified CLL cells from a cohort of 134 CLL cases. The obtained values were of similar magnitude to those obtained in the first series of anti-IgM-stimulated CLL samples, and spanned from negative values to values comparable to those observed upon aIgM exposure. By using the median value as cut-off to discriminate miR132-high from miR132-low cases, miR-high CLL cases unexpectedly displayed a longer time-to-first-treatment interval than miR132-low cases (P=0.02). By correcting for IGVH mutation status, *miR-132* levels above the established cut-off retained a favorable prognostic impact in M-CLL (P=0.005), but not UM CLL patients (P=0.968).
Summary and Conclusions: We describe an inter-chained cascade of events sequentially characterized by BCR triggering, *miR-132~212* uP-regulation, SIRT1 down-regulation and TP53 uP-regulation/acetylation. In addition, we show that high *miR132* expression is associated with a longer time-to-first treatment in M CLL patients. The activation of this pro-apoptotic axis should be considered in the light of emerging drugs targeting the BCR pathway in CLL.

HETEROGENEOUS FUNCTIONAL EFFECTS OF CONCOMITANT B CELL RECEPTOR AND TOLL-LIKE RECEPTOR STIMULATION IN CLL WITH MUTATED VERSUS UNMUTATED IMMUNOGLOBULIN GENES

M Chatzouli[1], S Ntoufa[2,*], N Papakonstantinou[2], E Chartomatzidou[2], T Karamanli[2], A Anagnostopoulos[2], P Kollia[3], P Ghia[4,5], M Muzio[4], K Stamatopoulos[2,6], C Belessi[7]
[1]Hematology Department, Nikea General Hospital, [2]Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, [3]School of Biology, University of Athens, Athens, Greece, [4]Division of Molecular Oncology, San Raffaele Scientific Institute, [5]Universita Vita-Salute San Raffaele, Milan, Italy, [6]Institute of Applied Biosciences, CERTH, Thessaloniki, [7]Hematology Department, Nikea General Hospital, Athens, Greece

Background: Antigenic stimulation through the B cell receptor (BcR) is critical for CLL development and evolution. However, significant differences in responsiveness to BcR crosslinking are observed among cases with similar sIgM levels, suggesting that additional factors may be implicated in shaping the functional outcome. Support for this notion emerged from studies showing that CLL cells may also crosstalk with their microenvironment via non-BcR mediated modalities, including the TLRs.
Aims: We recently reported that CLL subgroups with distinct clonotypic BcRs present discrete patterns of TLR expression, function and/or tolerance. Here, to explore whether specific types of BcR/TLR collaboration exist in CLL, we studied the effect of single *vs.* dual BcR and/or TLR stimulation on different CLL subgroups.
Methods: We stimulated negatively isolated CLL cells from 11 mutated (M-CLL) and 10 unmutated CLL (U-CLL) cases with anti-IgM, Imiquimod (IM) and CpG ODN for BcR, TLR7 and TLR9 stimulation, respectively, for15, 50 and 60 minutes and, for apoptosis studies, also for 48 hours. Cultures were established under the following conditions: (1) non-stimulated; (2) single BcR, TLR7 or TLR9 stimulation; (3) dual BcR/TLR7 or BcR/TLR9 stimulation.
Results: After *in vitro* culture in the absence of stimulation at any time point, differences in constitutive phosphorylation of ERK (pERK) were identified, with higher pERK levels in U-CLL *vs.* M-CLL. In single-stimulated cultures, the great majority of cases, both M-CLL and U-CLL, responded to all stimuli with uP-regulation of pERK. However, the magnitude and time-course of pERK induction varied significantly: at each time-point, significantly (P<0.05) higher induction was seen in U-CLL for all types of stimuli. In dually-stimulated cultures, anti-IgM+IM or anti-IgM+CpG significantly (P<0.05) uP-regulated pERK levels in comparison to the unstimulated control, in both M-CLL and U-CLL, with maximum response at 50 min. However, comparison of dually-stimulated cells to single-stimulated cells revealed great heterogeneity, with some cases showing uP-regulation of pERK contrasting others exhibiting pERK suppression. Exclusively among M-CLL, co-stimulation with anti-IgM+CpG significantly increased pERK levels compared to single stimulation with either anti-IgM or CpG. Effects on apoptosis were studied by Western blotting for the active isoform of caspase 8 (aCasp8) and the cleaved fragment of PARP (cf-PARP). In unstimulated cultures, the aCasp8 isoform was detected in almost all cases, while cf-PARP was detected in only one-third of cases, with relatively higher values in U-CLL. In single-stimulated cultures, great heterogeneity was observed regarding apoptosis induction in that anti-IgM alone had no effects, whereas stimulation with IM or CpG increased both aCasp8 and the cf-PARP, mainly in M-CLL. Dual stimulation with anti-IgM+CpG or anti-IgM+IM uP-regulated both aCasp8 and cf-PARP, again mainly in M-CLL, to significantly (P<0.05) higher levels compared to those observed in IM or CpG single stimulation.
Summary and Conclusions: Altogether, these findings suggest that pronounced pERK induction can be seen by single stimulation in U-CLL, whereas BcR/TLR synergism is required in M-CLL. Regarding apoptosis, an opposite pattern was observed, with M-CLL responding even to single stimulation, contrasting U-CLL that showed minimal responses, at least in the present setting. Differential intensity and duration of responses in M-CLL *vs* U-CLL indicates that the differences in signal transduction between the two subgroups may be primarily quantitative rather than qualitative.

IGG-SWITCHED CLL HAS A DISTINCT IMMUNOGENETIC SIGNATURE FROM THE COMMON MD VARIANT: ONTOGENETIC IMPLICATIONS

A Vardi[1,*], A Agathangelidis[2], L Sutton[3], M Chatzouli[4], L Scarfo[2], L Mansouri[3], V Douka[1], A Anagnostopoulos[1], N Darzentas[5], Richard Rosenquist[3], Paolo Ghia[2], Chrysoula Belessi[4], Kostas Stamatopoulos[1,6]
[1]Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece, [2]Division of Molecular Oncology, San Raffaele Scientific Institute, Milan, Italy, [3]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, [4]Hematology Department, Nikea General Hospital, Piraeus, Greece, [5]Molecular Medicine Program, Central European Institute of Technology, Masaryk University, Brno, Czech Republic, [6]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece

Background: IgG-switched CLL (G-CLL) is a relatively rare variant of CLL whose origin and ontogenetic relationship to the common IgM/IgD (MD-CLL) variant remains undefined. Previous studies have reported that most G-CLL cases carry somatically mutated B-cell receptors (BcR) pointing to possible derivation from post-germinal center B-cells. However, the relevant studies concerned small series, precluding definitive conclusions.
Aims: We sought for evidence about the origin of G-CLL *versus* MD-CLL by comprehensively profiling the respective immunoglobulin (IG) gene repertoires in the largest series thus far studied for this purpose.
Methods: Detailed immunogenetic analyses were conducted in a series of 1256 cases selected based on expression of MD (n=1087) or G isotype (n=169) as determined by peripheral blood flow cytometry (n=1019) or expression of tumor-specific Cμ/Cδ and/or Cγ transcripts as determined by RT-PCR (n=186).
Results: The IGHV gene repertoire of G-CLL differed significantly from that of MD-CLL, with over-representation of the IGHV4-34 (P<0.0001) and IGHV4-39 (P=0.003) genes, and, in contrast, under-representation of the IGHV1-69 (P=0.003), IGHV3-21 (P=0.017), IGHV1-2 (P=0.04) and IGHV3-48 (P=0.05) genes. Regarding somatic hypermutation (SHM), G-CLL included significantly more cases with mutated IGHV genes (following the 98% cut-off value for identity to the germline) compared to MD-CLL (84% *vs* 46%, respectively; P<0.0001). At the other extreme of the SHM spectrum, significantly more MD-CLL cases carried BcR IGs with no SHM (100% identity to the germline) compared to G-CLL (32% *versus* 11%, P<0.0001). The search for CLL-specific stereotyped BcR IGs revealed that the extreme skewing of the G-CLL repertoire was due to the fact that almost one-third of all cases was represented by only three subsets utilizing either the IGHV4-34 gene, namely mutated subsets #4 (relative frequency 18.3% of all G-CLL) and #16 (4%), or the IGHV4-39 gene, namely unmutated subset #8 (7.3%). These subsets (especially, subsets #4 and #8) represent polar opposites in terms of prognosis and outcome, with subset #4 cases experiencing indolent disease unlike subset #8 cases who tend to follow an aggressive disease course often complicated by the development of Richter's syndrome. In keeping with our previous reports, subset #4 and #16 rearrangements identified in the present study exhibited recurrent SHM at certain positions throughout the VH domain. However, despite an overall high SHM load, almost all IGHV4-34 rearrangements assigned to these two G-CLL subsets carried intact FR1 motifs for superantigenic-like interactions with N-acetyllactosamine epitopes present in self and exogenous antigens. In sharp contrast to subsets utilizing the IGHV4-34 and IGHV4-39 genes, all major sterotyped subsets utilizing the IGHV1-69, IGHV3-21, IGHV1-2 and IGHV3-48 genes (defined as reported in Blood 2012;119:4467) concerned exclusively MD-CLL.
Summary and Conclusions: G-CLL exhibits an overall distinct immunogenetic signature from MD-CLL, even when restricting the comparison to cases with mutated BcR IGs, prompting speculations about distinct ontogenetic derivation and/or distinct immune triggering. Nonetheless, questions abound regarding *e.g.* the presence of class switch recombination in the absence of SHM in subset #8 or the over-representation of the IGHV4-34 gene in G-CLL, especially

in light of studies showing that healthy IGHV4-34 cells are physiologically excluded from germinal center reactions in order to maintain peripheral B-cell tolerance.

MIMICKING LEF1 OVEREXPRESSION OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS IN MICE

S Jonas Poll-Wolbeck[1,*], H Flamme[1], M Hallek[1], K Kreuzer[1]
[1]Department I of Internal Medicine | University at Cologne, 50937 Cologne, Germany

Background: One of the hallmarks of CLL is the abnormal activation of the WNT signaling pathway and the strong overexpression of its down-stream transcription factor LEF1. The overexpression is highly associated with disease progression and induction of leukemia, while overall WNT activation appears to contribute to the maintenance of the apoptotic block. The aim of this study was to overexpress LEF1 in mouse B cells in order to test its leukemogenic potential.
Methods: LEF1 cDNA was introduced into the ROSA26 locus of C57/Bl6 mice. The gene is controlled via a floxed STOP cassette that inhibits gene expression in absence of Cre recombinase activity. LEF1 transgenic mice where crossed with CD19-Cre mice for B cell specific expression. Leukocytes were isolated from the peripheral blood, the spleen and the bone marrow and analyzed via FACS.
Results: In our mouse model LEF1 was overexpressed specifically in B cells and the expression appeared to be stable over 12 months. The oncogenic potential of LEF1 expression in B cells seemed to be low since no B cell leukemia was detected after monitoring more than 15 LEF1 expressing mice over 20 month. Complete blood counts also revealed no significant differences, but LEF1 expressing mice showed a significant reduction of B cells in peripheral blood lymphocytes after 16 (LEF1=38.39% *vs.* Control=50.80%; P=0.002) and 32 weeks (LEF1=43.44% *vs.* Control=52.51%; P=0.047). Percentage of B cells in the spleen was also significantly reduced (LEF1=46.26% *vs.* Control=56.54%; P=0.011), while the bone marrow appeared to be unaffected.
Summary and Conclusions: In our mouse model the LEF1 overexpression was not able to induce B cell dependent leukemia. This might be due to the moderate LEF1 over-expression in this model or insufficient activity of the WNT signaling cascade under physiological conditions, which is needed for LEF1 dependent gene expression. Nevertheless LEF1 expression affected either B cell proliferation or survival, which underlines the importance of WNT signaling for B cell homeostasis. The underlying mechanisms are to be clarified by future experiments.

ABERRANT EXPRESSION OF PD-1 IN CHRONIC LYMPHOCYTIC LEUKEMIA IS INDEPENDENT FROM BCR SINGLING AND PDCD1 GENE POLYMORPHISM

M Grzywnowicz[1,*], L Karabon[2], A Piechnik[1], M Zajac[1], K Skorka[1], J Zaleska[1], W Tomczak[3], P Wlasiuk[1], A Bojarska-Junak[4], I Frydecka[2], A Dmoszynska[3], K Giannopoulos[1,3]
[1]Department of Experimental Hematooncology, Medical University of Lublin, Lublin, [2]Department of Experimental Therapy, Institute of Immunology and Experimental Therapy, Polish Academy of Science, Wroclaw, [3]Department of Hematooncology and BMT Unit,4, Department of Clinical Immunology, Medical University of Lublin, Lublin, Poland

Background: The programmed death-1 (PD-1, CD279) is an immunoreceptor responsible for peripheral tolerance. Through inhibition of TCR/BCR signaling PD-1 impairs activation and effectors functions of T and B lymphocytes, where it is expressed upon activation. PD-1 was described on exhausted T cells and it is aberrantly expressed in several malignancies, where PD-1 pathway was related to a potential tumor escape mechanism from the immunosurveillance. Previously, we characterized PD-1 as a novel phenotypic feature of chronic lymphocytic leukemia (CLL) cells. PD-1 was uP-regulated on both transcript and surface protein levels in CLL patients in comparison to healthy volunteers (HVs). Moreover, activated *in vitro* CLL cells in conditions mimicking microenvironment of proliferation centres uP-regulated PD-1 on their surface.
Aims: Despite PD-1 aberrant expression in CLL patients, its mechanism and function is unclear. To investigate PD-1 influence on BCR signaling in CLL cells we analyzed expression and phosphorylation of SYK, LYN, and ZAP70 kinases. To verify relation of PD-1 expression to microenvironment *in vivo*, we analyzed PD-1 expression in 149 peripheral blood (PBMC) and 140 bone marrow (BM) CLL samples, accumulation and proliferation compartment respectively and 30 HVs. Finally, we characterized polymorphism of *pdcd1* gene in 114 CLL patients and 150 HVs.
Methods: Quantitative reverse transcriptase PCR was performed for the PD-1 transcript for 182 CLL patients (148 PBMC, 140 BM). Western blot (SYK and Lyn) and flow cytometric (ZAP70 and PD-1) analysis was performed for CD19+ magnetically separated cells from 12 CLL patients. For each kinase two separate phosphorylation sites were analyzed, responsible for activation or inhibition respectively: Y525/526 and Y323 for SYK, Y507 and Y396 for Lyn, Y315/319 and Y292 for ZAP70. Five single nucleotide polymorphism sites (SNPs) were analyzed by restriction fragments length polymorphism (RFLP-PCR) in group of 114 CLL patients and 150 HVs.
Results: The median level of PD-1 transcripts in CLL patients was higher in comparison with HVs (P<0.0001), but no difference between blood and bone marrow compartments. The expression and phosphorylation sites of LYN and SYK were not dependent on PD-1 expression in 12 CLL patients. Flow cytometric analysis showed that ZAP70 expression is not related to PD-1 level. Of note, median percentages of cells with phosphorylated ZAP70 activation/inhibition sites were low (Y315/319: 0.62%, Y292: 0.5%). Range of PD-1 expression varied from 67.53% to 4.2%. Analysis of *pdcd1* polymorphism showed that neither of SNPs frequency (loci: rs36084323, rs11568821, rs2227981, rs2227982, rs41386349) was different in CLL group compared to HVs. Particular substitutions were not related to the PD-1 expression level. Frequencies of haplotypes in CLL and HVs showed no significant difference. Linkage disequilibrium comparison of CLL and HVs revealed complete dependency of rs2227981/rs2227982 (P=0.03) and rs2227981/rs36084323 (P=0.03) loci in CLL patients. Those SNPs were associated with disorders like breast cancer and ankylosing spondylitis.
Summary and Conclusions: PD-1 expression is strongly uP-regulated in CLL patients regardless microenvironment of leukemic cells. No PD-1 influence on expression and activation of BCR related kinases might suggest impaired or alternative function of PD-1 pathway in CLL cells. Characterization of *pdcd1* polymorphism revealed no association of PD-1 SNPs with CLL, therefore, its upregulation might not be driven by genetic alternations.

P690

2-PHENYLETHYNESULFONAMIDE INDUCES THE UPR DEPENDENT APOPTOTIC PATHWAY IN CHRONIC LYMPHOCYTIC LEUKAEMIA

M D Blunt[1,*], A Nathwani[2], M Davies[2], A Linley[1], M Aguilar[1], A Prentice[3], V Hoffbrand[3], S Krysov[1], J Strefford[1], F Forconi[1], A Duncombe[4], G Wickremasinghe[5], G Packham[1], A Steele[1]
[1]Cancer Sciences, University of Southampton, Southampton, [2]Cancer Institute, UCL, [3]Department of Haematology, Royal Free Hospital, London, [4]Department of Haematology, Southampton University Hospital, Southampton, [5]Department of Haematology, UCL, London, United Kingdom

Background: CLL is currently incurable partially due to resistance caused by non-functional p53/ATM. We previously showed that 2-Phenylethynesulfonamide (PES, Pifithrin μ) induced apoptosis of CLL cells independently of p53. However the mechanism of PES induced apoptosis has remained elusive. Recently PES was suggested to inhibit HSP70, a key protein responsible for protein folding. Inhibition of HSP70 function results in accumulation of misfolded proteins within the endoplasmic reticulum (ER) and causes activation of the unfolded protein response (UPR). Under normal conditions the ER chaperone BiP prevents UPR activation by binding and inactivating the ER transmembrane receptors; IRE-1α, PERK and ATF6. If the stress is resolved the UPR is switched off, however if the aggregation of unfolded proteins is persistent then the UPR remains active and switches from an anti-apoptotic to a pro-apoptotic pathway. The pro-apoptotic cascade involves the induction of XPB1/JNK/JUN/p38MAPK signalling, phosphorylation of eif2α (eif2α-P) and the induction of CHOP. We previously showed that PES treatment of CLL cells promoted apoptosis via the UPR, however the precise mechanisms have never been elucidated. Here we show for the first time which pathways are involved in PES induced cell death and suggest novel targets which could be used to treat patients with an ATM or TP53 deletion or mutation.
Aims: To determine how PES activates the UPR in CLL cells and whether the UPR pathway contributes to PES mediated apoptosis.
Methods: Fifty two CLL samples were treated with PES (5-20μM), an activator of the UPR, in the presence and absence of the pan-caspase inhibitor ZVAD. Molecular responses to treatment with PES and/or other agents were investigated by western blotting, flow cytometry and MTT assay.
Results: Here we demonstrate for the first time that treatment of CLL cells with PES generated reactive oxygen species (ROS) resulting in apoptosis since treatment with the antioxidant N-acetyl cysteine (NAC) inhibited PES induced apoptosis. PES treatment lead to increased expression of NRF2, p62 and HSP70 within 24 hours, indicating that the UPR and autophagy pathways had become activated. Immunoblotting identified that key proteins in the UPR pathway (cleaved XBP-1, phosphorylated eiF2α, c-Jun and p38 MAPK) were also induced following PES treatment. However surprisingly AKT was also activated and induced. Pharmacological inhibition of p38 MAPK or PERK provided protection from PES mediated apoptosis, as assessed by PARP cleavage and Propidium iodide/Annexin V staining. This indicates that the UPR is involved in the induction of CLL cell death following PES treatment. To confirm these observations we treated MEFS which are unable to induce eiF2α-P and subsequent downstream signalling. PES treatment could not induce eiF2α-P. In addition Ser51 mutated cells showed reduced autophagy following PES treatment compared to wild-type cells. Following from our observation that PES induced phosphorylated AKT we co-treated CLL cells with PES and an AKT inhibitor (AKTi) to identify whether we could enhance PES induced apoptosis of CLL cells.

AKTi treatment enhanced PES induced apoptosis compared with either agent alone.
Summary and Conclusions: PES represents a novel class of cytotoxic drug that induces UPR mediated apoptosis of CLL cells and may be of value in the treatment of CLL patients who have become refractory to conventional therapy through loss/mutation of TP53.

ANTI-ROR1 MONOCLONAL ANTIBODY INDUCED APOPTOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA CELLS THROUGH PI3-KINASE/AKT/MTOR SIGNALING PATHWAY

A Hossein Daneshmanesh[1,*], M Hojjat-Farsangi[1], A Moshfegh[1], A Khan[1], M Jeddi-Tehrani[2], A Österborg[3], H Mellstedt[3]
[1]Immune and Gene Therapy Lab, CCK, Karolinska Institutet and Karolinska University Hospital Solna, Stockholm, Sweden, [2]Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran, Islamic Republic of Korea, [3]Oncology (Radiumhemmet) and Hematology, Karolinska Institutet and Karolinska University Hospital Solna, Stockholm, Sweden

Background: The PI3-kinase/AKT/mTOR pathway is an intracellular signaling pathway important in cancer as well as apoptosis of cells. Mammalian target of rapamycin (mTOR) is a 289 kDa serine/threonine protein kinase and a member of the PIKK (Phosphatidylinositol 3-Kinase-related Kinase) family. It functions as a central component in the signaling pathway involved in the control of cell growth and proliferation. In CLL cells PI3K pathway is constitutively activated leading to AKT activation. ROR1 is a type I transmembrane receptor tyrosine kinase (RTK) belonging to one of the twenty families of RTKs. ROR1 is overexpressed on CLL cells but not in white blood cells of healthy donors. ROR1 is constitutively phosphorylated in CLL and siRNA transfection induced apoptosis. We have developed a unique anti-ROR1 mAb directed against CRD (cysteine-rich domain) of the extracellular region of ROR1 capable of inducing direct apoptosis of primary CLL cells. Our anti-CRD mAb could also induce dephosphorylation of the ROR1 molecule.
Aims: To study the apoptotic effect of an anti-ROR1 CRD mAb and effects on downstream signaling pathways involved in CLL, specially the PI3K/AKT/mTOR pathway using primary CLL cells.
Methods: Apoptosis was detected by the MTT assay and AnnexinV/PI methods in a 24 h assay. Antibody untreated and treated cell lysates were prepared and subjected to Western blot analysis for identification of the signaling molecules involved in apoptosis induced by the anti-ROR1 CRD mAb. We analysed total and phosphorylated levels of the following signaling proteins: AKT, P-AKT, PI3K, P-PI3K, mTOR, P-mTOR, ERK, P-ERK, PKC and P-PKC. Phosphoproteins were measured before incubation with the mAb and after 20 min-24 h.
Results: ROR1 surface expression was detected on 80-85% of the CLL cells. The frequency of apoptotic cells induced by the anti-CRD mAb was in the range of 45-50%. Time kinetics experiments using anti-ROR1 CRD mAb incubated with primary CLL cells revealed dephosphorylation of ROR1 downstream signaling molecules. After co-culturing CLL cells with the anti-ROR1 CRD mAb, Western blot analysis showed decreased level of phosphorylated AKT in treated compared to untreated samples. No changes in the phosphorylation levels of ERK and PKC proteins were seen. Furthermore, we analysed the PI3K protein which is upstream of AKT, and noticed that in CLL cells treated with the anti-ROR1 CRD mAb, the phosphorylation intensity of PI3K p85 isoform decreased but not p55 isoforrn. Moreover, we also studied the mTOR phosphorylation in treated and untreated CLL samples and detected dephosphorylation of mTOR in treated as compared to untreated samples.
Summary and Conclusions: Incubation of CLL cells with an anti-ROR1 CRD mAb induced apoptosis of primary CLL cells. Apoptosis was preceded by dephosphorylation of PI3K, AKT and mTOR proteins indicating deactivation of these signaling proteins by the anti-ROR1 mAb. In untreated CLL cells no effect on phosphorylation of these proteins was noted. Furthermore our ROR1 mAb did not dephosphorylate PKC or ERK. Our data may suggest that activation of mTOR molecule occur via the PI3K/AKT pathway and may be a survival signal in CLL cells associated with the aberrant expression of ROR1. The constitutive phosphorylation of PKC and ERK seen in CLL might not be related to the overexpression of ROR1. Further studies are warranted to understand better the signaling pathways associated with ROR1 and the downstream signaling effects of ROR1 targeting drugs.

ROLE OF WNT-5A AND NON-CANONICAL WNT SIGNALING IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Kaucka[1], P Janovska[1], S Pavlova[2,3], K Plevova[2,3], H Madrova[2,3], L Poppova[2,3], S Pospisilova[2,3], V Bryja[1,4,*]
[1]Institute of Experimental Biology, Faculty of Science, Masaryk University, [2]Centre of Molecular Biology and Gene Therapy, Department of Internal Medicine - Hematology and Oncology, University Hospital Brno, [3]CEITEC, Masaryk University, [4]Department of Cytokinetics, Institute of Biophysics, Academy of Sciences of the Czech Republic, Brno, Czech Republic

Background: Transmembrane receptor tyrosine-protein kinase (ROR1) is almost uniformly uP-regulated in patients with chronic lymphocytic leukemia (CLL). ROR1 is a receptor for ligands of the Wnt family, which activate the non-canonical Wnt pathway, so called planar cell polarity - PCP-pathway. We have shown recently that PCP pathway is required for the migration of CLL cells in the chemokine gradient and the expression of PCP genes corresponds with the clinical course of CLL (Kaucka *et al.*, Cancer Res 2013).
Aims: In the present study we investigated the role of Wnt5a, the putative ligand of ROR1 and the activator of PCP pathway, in CLL.
Methods: B-lymphocytes of CLL patients were negatively separated using RosetteSep (StemCell) and gradient density centrifugation. The expression of Wnt-5a was assessed by quantitative RT-PCR using B2M and actin as endogenous controls. The migration of CLL cells in chemokine gradient of CXCL12 was conducted in HTS Transwell-96 well plates.
Results: Quantitative RT-PCR analysis of 80 CLL samples taken up to two years from diagnosis showed highly variable expression of Wnt-5a. The expression ranged from low levels comparable to healthy controls (peripheral B-cells) to high levels (10^2 fold change) indicating autocrine production of this ligand in a subgroup of patients. Significantly, patients with unmutated IGHV (N=46) showed higher levels of Wnt-5a (P=0.0014) which was also reflected by the worse treatment-free survival in Wnt-5a-high cohort (P<0.05). Furthermore, analysis of follow-up samples from 26 patients have shown that in several cases CLL cells uP-regulated Wnt-5a during disease progression. In patients treated in the interim, this effect was the most prominent. Functional data revealed that Wnt-5a promotes chemotaxis of CLL cells whereas inhibitors of Wnt-5a production (IWP2) block it.
Summary and Conclusions: Based on expression analysis and functional assays we propose that Wnt-5a is a ligand of Ror1/PCP in CLL responsible for the autocrine stimulation of the PCP pathway, chemotaxis and disease progression.

EXPLORING THE ROLE AND USE OF CANNABINOID RECEPTORS AND CANNABINOIDS IN CHRONIC LYMPHOCYTIC LEUKEMIA

P Weiss[1,*], E Porpaczy[1], T Le[1], C Skrabs[1], M Gruber[1], C Pausz[1], U Jäger[1], K Vanura[1]
[1]Medical University of Vienna, Vienna, Austria

Background: Cannabinoids are the active compounds of the marijuana plant *Cannabis sativa L*. They exert their function by binding to the two cannabinoid receptors CNR1 and CNR2, CNR1 being expressed mostly in the nervous system while CNR2 mainly is found in immune cells. Various studies reported that cannabinoids induce apoptosis and inhibit cell proliferation and invasion in solid tumours. We and others have previously observed an overexpression of both receptors and induction of apoptosis upon incubation with cannabinoids in hematologic malignancies, including chronic lymphocytic leukemia (CLL). Furthermore, cannabinoids interfere with the microenvironment interaction of T cells by inhibiting the CXCL12/CXCR4 axis, which also plays an important role in CLL cell survival and resistance to therapy.
Aims: To evaluate the role of the two receptors and to test whether cannabinoids might serve as novel therapeutic approach in CLL.
Methods: A cohort of 102 well characterized CLL patients was screened by real-time PCR for CNR1 and 2 mRNA expression, normalized to the mean expression ofCD19 sorted healthy donor (HD) cells (N=4). Also, peripheral blood mononuclear cells (PBMC) from CLL patients (N=10-16) and HD (N=2-3) were incubated with different cannabinoids in suspension and co-culture with the mouse fibroblast cell line M2-10B4 and in combination with fludarabin at concentrations ranging from 5 to 100 µM for 48h. IC50 values were calculated based on standard viability assays. Migration inhibition of PBMC from CLL patients toward CXCL12 was evaluated in migration assays.
Results: Although both cannabinoid receptors were overexpressed in CLL, only CNR1 was found to have prognostic value. CNR1 mRNA expression was increased from 0 to 140.4 fold compared to HD. With a cut-off set at median CNR1 expression (1.34), high CNR1 expression was associated with Binet stages B+C (P=0.049), unmutated IGHV (P=0.006), and high CD38 expression (P=0.032). Furthermore, CNR1 high expressing patients had shorter overall (median 154.2 months *vs.* median not reached; P=0.002) and treatment free survival (median 53.6 *vs.* 141.4 months;P=0.000). Based on these data, we evaluated CNR 1 & 2 as potential therapeutic targets. As shown in Table1, in particular the antagonists reduced cell viability considerably in suspension culture. In co-culture, the feeder cells protected tumour cells from compound induced cytotoxicity except for methanandamide (RM), cannabidiol (CBD), and AM630 which retained their toxicity. However, some of the compounds also had significant impact on healthy cells showing in some instances IC50 values similar to that of CLL cells (Table 1). Interestingly, the sensitivity of samples to cannabinoids was not associated with mRNA expression of either of the receptors. In combination treatments with fludarabine, only the CNR1 agonist ACEA exerted a small additive effect albeit not statistically significant. In contrast to observations in T cells, none of the tested cannabinoids could significantly inhibit CLL cell migration toward CXCL12.

Table 1. IC50 values achieved after 48h incubation of primary CLL and HD cells and M2-10B4 mouse fibroblasts with cannabinoids. Concentrations in µM, NR=50% viability reduction not reached.

Compound	Action	Primary CLL suspension	Primary HD suspension	Primary CLL co-culture	M2-10B4 fibroblasts
RM*	CNR1 agonist	33.19	60.13	29.27	34.55
CBD§	CNR1 antagonist, CNR2 inverse agonist	21.74	15.09	16.78	13.52
ACEA	CNR1 agonist	31.78	39.01	NR	NR
AM251	CNR1 antagonist	**9.43**	11.44	NR	NR
JWH133	CNR2 agonist	75.68	78.12	NR	NR
AM630	CNR2 antagonist, CNR2 inverse agonist, weak CNR1 agonist/inverse agonist	**12.08**	28.51	27.64	28.27

*RM = R-(+)-Methanandamide
§CBD = (-)-Cannabidiol

Summary and Conclusions: Although some cannabinoids reduce viability in neoplastic cells considerably independent of CNR expression, also healthy cells are affected. The important CXCL12/CXCR4 axis could not be inhibited by cannabinoids in CLL. These data indicate a poor therapeutic potential for cannabinoids in chronic lymphocytic leukemia, although CNR1 mRNA expression could be determined as novel prognostic marker.

P694

MICRORNA MIR-150 CONTRIBUTES TO THE DISEASE AGGRESSIVENESS AND REGULATION OF B-CELL RECEPTOR SIGNALLING (BCR) IN CLL

M Mraz[1,*], L Rassenti[2], L Chen[2], E Ghia[2], H Li[2], K Messer[2], K Jepsen[2], E Smith[2], K Frazer[2], T Kipps[2]
[1]1Moores Cancer Center, University of California; 2Central European Institute of Technology, Masaryk University, Brno, [2]Moores Cancer Center, University of California-San Diego, La Jolla, United States

Background: We and others have shown that expression of certain miRNAs associates with disease activity and pathogenesis of CLL (Calin, 2005; Mraz, 2012; Mraz, 2009). However, it remains largely unclear which from the ~1400 described miRNAs in human genome are relevant for the regulation of malignant B cell functions.
Aims: In this study we first screened (TaqMan miRNA Cards-ABI, 750 miRNAs) for abundantly expressed miRNAs in CLL cells hypothesising that miRNAs with strong expression are more likely significantly involved in the regulation of cell functions.
Results: We identified miR-150 as the most abundant miRNA in CLL cells, however, its lower levels associated with stronger calcium mobilization (a marker for active BCR signalling) after stimulation of BCR on CLL cells with anti-IgM ($P<0.05$, N=36). Additionally, miR-150 levels were directly down-modulated after stimulation of BCR with anti-IgM in CLL cells ($P<0.01$). This miRNA has been previously reported to influence the gene expression of normal B cells (Xiao, 2007) altogether suggesting that it might be involved in the BCR-pathway. Several target genes have been described for miR-150 in studies performed on various cell types. However, it is becoming clear that the preferential target(s) of a certain miRNA depend on the context of all mRNAs with potential binding sites and their expression levels in a specific cell type. More importantly, the identification of mRNAs regulated by a certain miRNA can be performed based on the analysis of mRNA expression since most miRNAs affect not only mRNA translation but predominantly decrease target mRNA levels (Guo, 2010). To describe novel targets regulated by miR-150 specifically in CLL cells we performed array-based transcriptome analyses of 110 CLL samples. This identified differential expression of 2 genes with evolutionary conserved binding sides for miR-150 (GAB1 and FOXP1) between CLL cells expressing low *vs.* high levels of miR-150. The immunoblot analysis of GAB1 and FOXP1 in CLL cells confirmed their higher protein levels in cases with low miR-150 expression ($P<0.005$, fold change >10.0) and the transfection of CLL cells with artificial miR-150 led to GAB1/FOXP1 down-regulation. GAB1 is an adaptor molecule that recruits PI3K to the plasma membrane after BCR stimulation and is required for amplification of PI3K signalling and subsequent AKT activation (Ingham, 2001). FOXP1 is a transcription factor uP-regulated by BCR stimulation and implicated in the progression of several B-cell lymphomas (Hu, 2006). We found that, CLL cells with higher expression of *GAB1* or *FOXP1* were more responsive to BCR stimulation *in vitro* and higher expression of each associates with shorter overall survival (OS) (13.9 *vs.* 22.7 years, 13.9 *vs.* 21.1 years; N=168; $P<0.05$). Most notably, a reverse trend was observed for miR-150, where higher levels (>median) were associated with significantly longer OS and TTFT in a multivariate analysis, which included other 6 other routinely used prognostic markers (OS HR: 3.4 [CI 1.4-8.6], P=0.009; TTFT HR: 2.3 [CI 1.3-4.2], P=0.004). Additionally, we have noted differences in the miR-150 expression and methylation profile of its coding region after disease progression (analysis of serial CLL samples).
Summary and Conclusions: We conclude that miR-150 is a novel regulator of genes that control BCR-signalling, which is a factor that prominently affects the biology of malignant B cells.

A NEW ONCOGENIC ROLE OF BCR/ABL-OOF IN CHRONIC MYELOID LEUKAEMIA PATHOGENESIS

C Panuzzo[1,*], S Crivellaro[1], C Casnici[2], E Cibrario[1], F Crasto[1], R Lorenzatti[1], F Daraio[1], Katia Crotta[3], Giovanna Carrà[1], Alessandro Morotti[1], Giuseppe Saglio[1], Gisella Volpe[1]
[1]Clinical and biological sciences, San Luigi Hospital, Turin, [2]Farmacolgy, university of Milan, [3]farmacology, University of Milan, Milan, Italy

Background: chronic myelogenous leukaemia is a myeloproliferative disorder characterized by the presence of Philadelphia chromosome, derived by a reciprocal translocation between chromosome 9 and 22, involving respectively the genes c-Abl and Bcr. Next to the main BCR/ABL transcripts we identified previously alternative BCR/ABL splice variants involving BCR exons1, 13 or 14 and ABL exon 4. Their translation products are characterized by the change in the reading frame of ABL exon 4 leading to the formation of a early stop codon within ABL exon 5. Bcr/Abl fusion proteins (Bcr/Abl OOF) resultant have an initial and correct Bcr portion attached to a sequence of aminoacids arising from the out of frame (OOF) reading of the c-Abl exon 4 and 5 gene sequence, which has been studied in the past for its immunogenic rule. It contains the characteristic Bcr domain but its specificity is the absence of COOH-terminal Rac GAP domain.
Aims: To determine the role of the Bcr/Abl OOF we analyzed the effects of the protein in term of cytoskeleton modelling, adhesion and activation of Rho GTPases, given the role of Rho GTPase family proteins in cytoskeletal remodelling.
Methods: Bc/Abl OOF cDNA was cloned in an expression vector in order to investigate new functions of this protein that differ from Bcr for the absence of the GAP domain, essential for the inactivation of Rho GTPases proteins. Immunofluorescence and western blot of different fraction (cytosolic and microsomes) were performed to investigate its localization. Adhesion assay on fibronectin was used to analyse a possible change in cytoskeleton modelling after transfection with Bcr/Abl OOF. Pulldown assay was performed by using Rac GTPase binding domain as GST fusion protein bound to glutathione-sepharose beads (GST PAK-CD). Proliferation assay was performed by evaluation of ^{3}H incorporated in cells during division while apoptosis assay was done by using Annexin V-FITC and Propidium PE.
Results: By immunofluorescence and western blot assay we observed that the localization of Bcr/Abl-OOF is predominantly cytoplasmatic and that colocalizes in endosomal vescicles with Bcr protein. Bcr/Abl-OOF confers an altered adhesion if compared to empty pcDNA, with a morphology quite similar to hela cells transfected with Rac active form and unlike to that of cells transfected with Rho and Cdc42 active form. This is confirmed by analysis of Rac endogenous, which assumes peculiar submembrane localization typical of Rho proteins when present in the activated form. This result suggest that Rac activation could be one of the responsible of Bcr/Abl-OOF cell morphology during cell adhesion on fibronectin. The GST PAK-CD fusion protein was able to trap a significant proportion of GTP-bound form of Rac in Bcr/Abl-OOF cells lyses, supporting the presence of active Rac. We also analysed a possible involvement of Bcr/Abl-OOF in the most important oncogenic pathway. Apoptosis assay showed that transfected cells with Bcr/Abl-OOF presented lower apoptotic rate than control cells, with 67% of reduction (P=0,01). Proliferation assay shown a 2 fold of induction of proliferation rate (P=0,001) in Bcr/Abl-OOF cells, which is restored after Rac inhibitor treatment. We also observed an increase in Ciclin D, pAkt and pp38 proteins, increase that become more significant in presence of growth factor stimuli.
Summary and Conclusions: Summary and Conclusions: all these results therefore suggest a possible oncogenic rule of Bcr/Abl-OOF, which can cooperate with Bcr/Abl in the process of proliferation, survival and apoptosis of chronic myeloid leukaemia. Next step will be the analysis of Bcr/Abl OOF in a big cohort of CML patients in order to understand if different quantity of our gene can be predictive of a non suboptimal answer to Bcr/Abl specific therapy.

INITIAL OCCUPANCY OF LEUKEMIC STEM CELL CORRELATES WITH PROGNOSTIC FACTOR IN CHRONIC MYELOID LEUKEMIA PATIENTS

H Iwasaki[1,*], K Miyawaki[1], KAkashi[1]
[1]Center for Cellular and Molecular Medicine, Kyushu University Hospital, Fukuoka, Japan

Background: Chronic myeloid leukemia (CML) stem cells are less sensitive to tyrosine kinase inhibitors (TKIs) compared to downstream progenitors. It might be possible that the initial leukemic stem cell burden affect the prognosis of chronic phase (CML-CP) patients, but this possibility has not been verified.
Aims: The purpose of present study is to explore the involvement of BCR-ABL positive clone in stem cell fraction at diagnosis and to evaluate the prognostic impact of leukemic stem cell occupancy.
Methods: Bone marrow (BM) aspirate samples were obtained from 9 newly diagnosed CML-CP patients CD34+ stem/progenitor cells were first enriched using a magnetic bead selection kit. HSC (hematopoietic stem cell; CD34+CD38), CMP (common myeloid progenitor; CD34+CD38+IL3RlowCD45RA-), GMP (granulocyte/macrophage progenitor; CD34+CD38+IL3R+CD45RA+) and MEP (megakaryocyte/erythrocyte progenitor; CD34+CD38+IL3R-CD45RA-) fractions were isolated by BD FACS Aria and subsequently analyzed the frequency of BCR-ABL positive clone by FISH analysis. The protocol of the study was reviewed and approved by the institutional review board prior to initiation of the study. Written informed consent was obtained from all the patients.
Results: Among myeloid progenitors, CMP and MEP populations robustly expanded and were composed almost entirely of BCR-ABL positive clone in all patients (FISH positive rate, 95.1+/-7.4% and 96.0+/-5.5%, respectively), while surprisingly GMP fraction was less involved in leukemia (56.3+/-37%), suggesting that CML hematopoiesis is able to bypass the GMP phenotype. Importantly, CD34+CD38- HSC fraction was suppressed in CML patients (~1% of CD34+ cells) compared to healthy volunteers (~10% of CD34+ cells), and the frequencies of BCR-ABL positive clone in HSC fraction (46.1+/-40.5%) were always less than those in CMP and MEP, suggesting that CML stem cell is less addictive to growth signaling of BCR-ABL compared to myeloid progenitors. According to the leukemic stem cell occupancy, CML-CP patients were classified into 3 subgroups. In the high involvement group, >90% of HSCs were BCR-ABL positive, while in the low and intermediate involvement groups, <5% and ~50% of HSCs were involved, respectively. We evaluated relationship between BCR-ABL positive rates in HSC fraction and patients' data. The leukemic stem cell occupancy fabulously correlated with platelet count and basophils in peripheral blood, and consequently with prognostic scores such as Sokal, Hasford, and EUTOS.
Summary and Conclusions: The risk of disease progression and/or TKI sensitivity in CML-CP patients might be prospectively classified by the leukemic stem cell occupancy.

MICROVESICLES TRANSCRIPTOME REFLECTS PHYSIOLOGICAL CONDITIONS OF LEUKEMIC PARENTAL CELLS

G Milani[1,*], T Lana[1], S Bresolin[1], C Frasson[1], G Basso[1], G te Kronnie[1]
[1]Department of Women's and Children's Health, University of Padova, Padova, Italy

Background: Microvesicles (MVs) are nano-sized lipid bodies (100-1000 nm in diameter) that are released by cells into the extracellular space and as carriers of proteins, mRNA and miRNA shown to represent vectors from donor to target cells[1]. Through fusion with target cells MVs may well modulate the functional state of receiving cells. In leukemia MVs have been suggested to modulate the hematopoietic niche[2,3].
Aims: 1) Transcriptome comparison between MVs and leukemic parental cells. 2) Investigate the effects of a hypoxic environment similar to that at the hematopoietic endosteal niche on transcripts carried by MVs. To this end, we collected MVs released from cell cultures in hypoxic condition and compared the transcriptome with that of MVs isolated from cultures at normoxia.
Methods: MVs released from K562, a BCR-ABL positive human erythromyeloblastoid leukemia cell line, were isolated by culture medium centrifugations (2500g for 15 minutes). The supernatant was filtered by means of a 1.2µm filter to eliminate larger vesicles. The filtered medium was re-centrifuged at 18000g for 1h at 4°C. MVs and parental cells RNA was extracted using Trizol. Cell line RNA quality was assessed using the Agilent 2100 Bioanalyzer (Agilent Technologies) and quantified by means of NanoDrop ND-1000 spectrophotometer (NanoDrop Technologies Inc.). To check MVs RNA integrity GAPDH 5':3' amplicon ratios were determined by RealTime-PCR. Afterwards, cDNA was synthesized from 1µg of total RNA by reverse transcription–polymerase chain reaction. Gene expression profiles of K562 cell line and MVs were analyzed using GeneChip Human Genome U133 Plus 2.0 arrays (Affymetrix).
Results: Gene expression data have been compared between cells and MVs. We identified 5294 common probe sets with a Present call (fold-change lower than 1.5). Analysis of these probe sets using DAVID Functional Annotation Bioinformatics Microarray Analysis revealed a conservation of MVs transcripts involved in pathways of cell function such as RNA processing, protein translation, aminoacid metabolism and cell respiration. Remarkably, in MVs we observed a high presence of gene transcripts coding for protein belonging to the Chronic Myeloid Leukemia pathway that are expressed downstream of the BCR-ABL tyrosin kinase fusion protein. Furthermore, different gene expression profiles were identified between cells and MVs by a paired-T test. 290 probe sets resulted uP-regulated in MVs compared to cells lines (fold-change higher than 1.5). On the other hand, 1899 probes were down-regulated in MVs compared to parental cells. In addition, transcriptome comparison of MVs released under hypoxic *versus* normoxic conditions revealed two upregulated transcripts, both involved in HIF1α regulation, in MVs released from hypoxic cell cultures[4,5]
Summary and Conclusions: We isolated MVs released by K562 leukemic

cells and for the first time a whole transcriptome gene expression analysis has been performed comparing K562 parental cells and MVs. Moreover, we identified an enrichment of transcripts coding for proteins involved in several essential pathways in the MVs supporting the hypothesis of a functional selection from the parental cell transcriptome. MVs released from cells under hypoxic conditions carried a higher amount of two transcripts related to HIF1α compared to MVs isolated from cells in normoxia.

THE REFERENCE STANDARD FOR BCR-ABL TRANSCRIPT MONITORING IS IMPORTANT TO DEFINE CMR IN CML PATIENTS AND TO TEST THE RQ-PCR METHOD PERFORMANCES

R Talmaci[1,*], A Vulpe[2], M Dragomir[2], M Müller[3], N Cross[4], D Coriu[1]
[1]Fundeni Hematology Department, University of Medicine and Pharmacy "Carol Davila", [2]Hematology Department, Fundeni Clinical Institute, Bucharest, Romania, [3]Scientific Laboratory, III.Medizinische Klinik, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, [4]National Genetics Reference Laboratory, Wessex Regional Genetics, Salisbury District Hospital, Salisbury, United Kingdom

Background: Real-time quantitative polymerase chain reaction (RQ-PCR) of BCR-ABL transcripts is now the standard method needed for monitoring minimal residual disease in patients with chronic myeloid leukemia (CML) treated with tyrosinekinase (TK) inhibitors. RQ-PCR is a molecular method for monitoring response to tretment in clinical trials.
Aims: Internal quality assurance is crucial for high fidelity results. In order to test comparability of standard curve we used a common calibration plasmid–pME2 (Scientific Laboratory, III. Medizinische Klinik, Medical Faculty Mannheim) and universally accepted refference standard - ERM-AD623 (Institute for Reference Materials and Measurements).
Methods: In order to compare results previously obtained using the Abl control gene, we performed RQ-PCR on 20 leukemic samples. We choose samples with different levels of molecular response in international scale (IS). Molecular analysis was performed using a standardized RQ-PCR method with Hybridization Probes detection method on LightCycler instrument. For ABL measure we used five dilution points with pME standard and six dilution poits with ERM standard in duplicate. For BCR-ABL measure we used six dilution points with pME standard and five dilution poits with ERM standard in duplicate. All quantification parameters were set up acording to international guidelines for the measurement of BCR-ABL transcripts in CML.
Results: We found a two fold difference between the ERM absolute numbers and pME2 standard curves. Comparing BCR-ABL/ABL with both plasmids for samples where residual disease is detectable, the ratio is within the limits of normal variation but the differences in absolute control gene numbers impacts on definitions of complete molecular response (CMR) when BCR-ABL is undetectable.
Summary and Conclusions: For reliable results and to minimize variability of the results, a universal, traceable standard/calibrator is needed to be available to all MRD monitoring labs. Definitions of CMR need to take into account variations in the assignment of absolute copy numbers.
We gratefully acknowledge the support of the European LeukemiaNet/EUTOS for the international standardization process.

THE BCR/ABL TYROSINE KINASE INHIBITOR IMATINIB PRODUCES PROFOUND MAST CELL DEFICIENCY IN CHRONIC MYELOID LEUKEMIA

S Cerny-Reiterer[1,*], S Herndlhofer[2], G Stefanzl[2], K Blatt[2], G Hoermann[3], L Muellauer[4], C Beham-Schmid[5], S Baumgartner[6], W Sperr[2], C Mannhalter[3], W Linkesch[7], P Valent[1]
[1]Ludwig Boltzmann Cluster Oncology, [2]Department of Internal Medicine I, [3]Department of Laboratory Medicine, [4]Department of Pathology, Medical University of Vienna, Vienna, [5]Institute for Pathology, Medical University of Graz, Graz, [6]Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Vienna, [7]Department of Internal Medicine I, Medical University of Graz, Graz, Austria

Background: Although mast cells (MC) play an important role in allergic reactions, their physiologic role in healthy tissues remains largely unknown. In mice, several MC-deficiency models have been developed. In several of these models, MC deficiency is triggered by a lack of *KIT* or lack of functional KIT ligand stem cell factor (SCF). However, no comparable human model is available.
Aims: We examined the *in vitro* and *in vivo* effects of the ABL/KIT-targeting drug imatinib on growth and development of MC.
Results: Imatinib was found to inhibit SCF-induced differentiation of MC from their cord blood-derived progenitors in a dose-dependent manner (IC50: 0.01 μM). Correspondingly, continuous treatment of chronic myeloid leukemia (CML) patients with imatinib (400 mg daily) resulted in profound MC deficiency. In patients entering a major molecular response during therapy, MC numbers in the bone marrow decreased to less than 5% of pre-treatment values, and serum tryptase concentrations decreased to low or even undetectable levels (tryptase before therapy: 32.0±11.1 ng/mL *versus* after therapy: 3.4±1.8, P<0.01). Moreover, as assessed by qPCR, KIT mRNA levels and tryptase mRNA levels decreased substantially during imatinib-therapy. Other myeloid lineages in the bone marrow, known to develop independently of KIT, were not affected substantially by treatment with imatinib.
Summary and Conclusions: In conclusion, imatinib produces profound MC deficiency *in vitro* and *in vivo*. However, the imatinib-induced MC deficiency is not accompanied by specific symptoms or side effects. Based on these observations, we hypothesize that MC may be less relevant to physiologic homeostasis in healthy tissues than has been assumed so far.

IDENTIFICATION AND FOLLOW-UP OF TWO NEW RARE E8A2 BCR-ABL FUSION GENES

S Huet[1,*], L Jallades[1], M Perrin[2], F Nicolini[3], C Moreilhon[4], C Lespinasse[1], J Magaud[1], S Raynaud[4], S Hayette[1]
[1]Laboratory of hematology, Hospices Civils de Lyon, Pierre-Bénite, [2]Clinic of hematology, Centre Hospitalier Fleyriat, Bourg-en-Bresse, [3]Clinic of hematology, Hospices Civils de Lyon, Pierre-Bénite, [4]Laboratory of onco-hematology, CHU de Nice, Nice, France

Background: Less than 5% of patients with chronic myeloid leukaemia (CML) have breakpoints falling outside of the M-*BCR* in chromosome 22, and as the e8a2 transcript several other fusion transcripts have been identified to date. Although rearrangements have been described, involving a fragment insertion from *ABL* intron Ia or Ib between *BCR* exon 8 and *ABL* exon2, rearrangement with a third partner gene occur even more rarely.
Aims: We investigated two newly diagnosed cases of CML patients with novel fusion transcripts that give rise to a chimeric molecule involving an e8a2 fusion transcript and a third gene thus keeping the reading frame. We report here the precise features of the rearrangements and the follow-up of minimal residual disease (MRD) of these two patients.
Methods: Two cases were diagnosed with CML in chronic phase based on typical peripheral blood findings and standard karyotyping analyses indicating t(9;22)(q34;q11). An unusual band, other than the common transcripts, was observed in multiplex reverse transcription-polymerase chain reaction (RT-PCR) for the *BCR-ABL* gene rearrangement. The PCR products were then sequenced to assess the identification of the transcript. The monitoring of MRD was carried out using RT-PCR with specific primers located either close to the e8-*BCR* or in the inserted fragment. SNP-array was performed to accurately identify additional copy number variations.
Results: In case no.1, the fragment turned out to be an e8a2 fusion transcript with 112-bp inserted fragment corresponding to the exon 4 of the *PRDM12* gene. This gene is located on chromosome 9q34 and encodes the PR domain zinc finger protein 12 involved in transcriptional regulation. Deletion on locations 22q11.23q12.1 was highlighted by SNP-array. In case no.2, we also identified an e8a2 transcript with a 154 base pair (bp) insert that wholly matched the sequence from the exon 4 of the *SPECC1L* gene. The *SPECC1L* gene is located on chromosome 22q11 and encodes the cytospin-A protein implicated in cytokinesis and spindle organization. Besides, SNP-array analysis revealed deletions on locations 9q34 and 22q11 for this patient. Both patients showed favorable response to imatinib therapy, and achieved major molecular responses (MMR) less than 1 year after imatinib introduction. In case no. 1 (rearranged with *PRDM12*), the levels of transcript have remained undetectable for the 4-year follow-up. The patient no. 2 (with *SPECC1L* gene rearrangement), although achieving MMR, never obtained undetectable molecular response, but transcript levels that have been fluctuating below the MMR threshold for 5 years.
Summary and Conclusions: The insertion of 154 bp and 112 bp of a third partner gene, *SPECC1L* and *PRDM12* genes respectively, resulted in a novel in-frame *BCR-ABL* fusion transcript e8-[ins]-a2. Deletions on the derivative chromosome 9 occur in approximately 15% of CML patients and a potential role for *PRDM12*, located on 9q11, has been suggested previously in the pathogenesis of CML. Nevertheless, this is the first report of a novel fusion transcript involving an exon from this gene, as for *SPECC1L* gene. Structure/function studies would bring a more comprehensive survey on the real biological significance of such BCR-ABL chimeric protein.

THE PROSPECTIVE ANALYSIS OF LOW LEVEL BCR-ABL1 T315I MUTATION IN THE CD34+ CELLS OF *DE NOVO* CML PATIENTS

T Jurcek[1,*], F Razga[1], P Mazancova[1], D Dvorakova[1,2], M Borsky[1], D Zackova[1], M Musilova[1], L Semerad[1], J Mayer[1,2], Z Racil[1,2]
[1]Internal Medicine–Hematology and Oncology, University Hospital Brno and Masaryk University, [2]CEITEC - Central European Institute of Technology, Masaryk University, Brno, Czech Republic

Background: The BCR-ABL1kinase domain (KD) mutations are associated with resistance to tyrosin kinase inhibitors (TKIs) and thereby with poor prognosis in chronic myeloid leukemia (CML) patients.Thus, an early detection of these mutations is important and could potentially leads to early therapeutic intervention and optimization of ongoing treatment regimen. The particular focus should be given to T315I mutation, which is resistant to all approved TKIs (imatinib, nilotinib and/or dasatinib). Considering the hierarchy of hematopoiesis, it should be expected that BCR-ABL1 KD mutations expand directly from stem cells or early progenitor cells. It has already been reported that these mutations were detected in these cells before their occurrence in bone marrow or peripheral blood.
Aims: The prospective detection of low level T315I mutation in newly diagnosed CML patients, especially in early progenitor CML cells ($CD34^+$; $CD34^-$).
Methods: The cell sorting (using a FACSVantage SE) of bone marrow $CD34^+$ and $CD34^-$cells from 50 *de novo* CML patients wasperformed at the time of diagnosis. Isolated RNA from sorted cells was reversibly transcribed into cDNA, which was subsequently used for amplification of *BCR-ABL1* fusion gene followed by sensitive detection of T315I mutation by quantitative Ligation-PCR ($ligPCR^{T315I}$). The estimated sensitivity of $ligPCR^{T315I}$ was 0.5% $BCR\text{-}ABL1^{T315I}/BCR\text{-}ABL1^{total}$.
Results: Within our cohort of 50 *de novo* CML patients, low level T315I mutation was detected in 7/50 (14%) cases with obtained positivity closed to detection limit of applied method (~0.5%). These suspected samples were tested repeatedly to avoid any false-positive results. Moreover, additional $CD34^+/CD34^-$ samples were tested for the presence of T315I mutation after the 3 months of TKI therapy. From these re-tested patients only 1/7 wasconsidered as positive for the low level T315I mutation. ThisT315I positive CML patient wassubsequently followed-up using $ligPCR^{T315I}$ analysis for the possible T315I mutation evolution. The expansion of T315I mutated clone was observed at the months 3 and 6 of TKI therapy with level of 0.7% and 4.2%, respectively. Other samples for T315I kinetics monitoring were not available since this patient died very quickly due to the progression of CML (8 months after diagnosis).
Summary and Conclusions: Our prospective analysis of low level T315I mutation in early progenitor CML cells ($CD34^+$; $CD34^-$) of *de novo* CML patients showed that this key mutation does not frequently occur in CML patients at the time of diagnosis. We suppose that the presence and evolution of T315I mutation is more likely associated with increased genomic instability, advanced phase of CML or selective pressure of applied TKIs.
Supported by The Czech Leukemia Study Group for Life (CELL), the project (Ministry of Health, Czech Republic) for conceptual development of research organization 65269705 (University Hospital Brno, Brno, Czech Republic) and research grants (Ministry of Education, Youth and Sports, Czech Republic) MSMT0021622430 and MUNI/A/0723/2012.

EVALUATION OF TOB1 GENE EXPRESSION IN CML PATIENTS AND BLOOD DONOR AND THE EFFECT OF GENE SILENCING IN BCR-ABL+ CELL LINE

C Mascarenhas[1,*], A Cunha[2], S Gambero[1], J Neto[1], M Almeida[1], K Pagnano[1], F Costa[1], C Souza[1]
[1]University of Campinas, CAMPINAS, [2]Federal university of Sao Carlos, SAO CARLOS, Brazil

Background: The TOB1 gene is a transcription factor responsible for the transduction of the gene ERBB2. It is a member of a family of cell suppressor proliferation proteins called TOB/BTG1 family; also, this gene operates on the inhibition of neoplastic transformation. The TOB1 gene presents a low expression in several types of cancer such as lung, breast, thyroid and stomach cancer. However, the function of this gene in chronic myeloid leukemia (CML) remains unknown.
Aims: The purpose of this study is to assess the gene expression in CML and blood donors, to evaluate the inhibition of gene TOB1 in BCR-ABL positive cells and try to elucidate the molecular mechanisms associated with the inhibition of this gene in the CML.
Results: We identified differentially expressed gene among CML patients granulocytes and healthy individuals using the Subtractive Supression Hybridization technique. We used 101 patients and 20 blood donors to proceed the analysis of gene expression characterization, and found that patients presented a lower gene expression. Then, the inhibition of this gene in K562 cells was performed using specific lentivirus. The effect of silencing TOB1 in the proliferation of K562 cells was assessed by the MTT assay after 48 hours of culture; in shTOB1 the proliferation was increased in comparison with shControl cells. To analyze the clonogenicity, we performed a formation of colonies assay, in methylcellulose, to determine whether silencing TOB1 could cause a change in the clonal growth of positive BCR-ABL cells. We found an increase in the number of colonies in shTOB1 cell culture compared to shControl cells. In the assessment of cell cycle, the flow cytometry analysis revealed a significant accumulation of K562 cells in S phase, with consequent reduction of cells in the G2 phase of the cell cycle in shTOB1 cells compared to shControl cells. The TOB1 gene silencing in K562 cells kept the cells in the S phase and prevented the entry of cells in the G2 phase, showing that the inhibition of TOB1 gene induced an increase in proliferation of K562 BCR-ABL cells. The level of apoptosis was assessed by flow cytometry after labeling the cells with anexin-V/PI, and by assays of caspases3, 8 and 9. It was found an increase of the caspase activity of shControl cells in relation of the shTOB1 cells, showing that the inhibition of this gene also changes the level of apoptosis.
Summary and Conclusions: The results corroborate the literature data that report the relationship of this tumour suppressor gene in signalling pathways related to angiogenesis, carcinogenesis, apoptosis and metastasis. When we relate the results obtained with the LMC, we can consider the possibility of the changes in TOB1 regulation be associated to alteration of important signalling pathways such as AKT, PI3K, STAT3 and STAT5, among others. Furthermore, the inhibition of TOB1 may be related with an increase on the number of BCR-ABL positive cells and subsequent disease progression. In conclusion, this study confirmed literature data showing that TOB1 gene works as a tumour suppressor protein in cells of many types of cancer. From this work we can infer that in CML the expression of TOB1 is transformed, resulting in changing of the capacity of induction of apoptosis, decrease tumour necrosis and increase cell proliferation. This work was supported by FAPESP and INCT.

P703

CYP1A1, GST GENE POLYMORPHISMS AND RISK OF CHRONIC MYELOID LEUKEMIA (CML)

D Elneily[1,*], N Farahat[1], D Nafea[2], A Donia[1]
[1]Clinical pathology, [2]Hematology, Faculty Of Medicine-Alexandria University Egypt, Alexandria, Egypt

Background: Chronic myelogenous leukemia (CML) is a clonal myeloproliferativedisorder that results from an acquired genetic change in a pluripotential haemopoietic stem cell. The ability of the chemical carcinogens to induce malignancies depends on the body activation/detoxification of these carcinogens.
Aims: of this work was to study the genetic polymorphism of xenobiotic metabolizing enzymes: phase I enzymes; cytochrome P450 (CYP1A1) and phase II enzymes; glutathione S-transferase (GSTM1 and GSTT1).
Methods: 30 chronic myeloid leukemia patients (CML) (17 males, 13 females; age (Mean±SD) 36.87±12.45 years) and 30 age and sex matched healthy controls were analyzed for the frequency of CYP1A1 alleles and of GSTT1 and GSTM1 homozygous deletions by PCR- RFLP and multiplex PCR methods, respectively, using peripheral blood samples. The relationship between these genotypes and risk of CML was assessed by means of Odds Ratio (OR) with 95% confidence limits.
Results: Present study revealed that genotype frequency of (CYP450) 1A1*2C of patients was 66.7% were of the wild-type homozygous Ile/Ile genotype, 30.0% heterozygous Ile/Val genotype and 1(3.3%) homozygous mutant Val/Val genotype. In the control group, 96.7% with Ile/Ile genotype, 3.3%with Ile/Val genotype and 0% Val/Val genotype. CYP1A1 variant genotype was higher in patients group than in controls group, this difference was statistically significant. The frequency of CYP1A1 Val allele was higher CML patients, indicating that persons carrying this allele had an increased risk of CML. Although the frequency of GSTT1 null genotype was higher among CML patients compared to controls, this difference was not statistically significant.GSTM1 null genotype, the frequency was slightly higher in the patient group than that of the controls, however this difference also was not statistically significant. GSTT1 and GSTM1 double null genes carried a 9.0 greater risk for CML.
Summary and Conclusions: In conclusion this data suggests that polymorphic CYP1A1 and GSTT1 genes appear to affect susceptibility to CML.

P704

ENHANCED ADHESION & MIGRATION AND INDUCTION OF PYK2 EXPRESSION IN K562 CELLS FOLLOWING IMATINIB EXPOSURE

A Ovcharenko [1], G Granot[1], J Park [1,2], O Shpilberg [1,3], P Raanani [1,3,*]
[1]Felsenstein Medical Research Center, Beilinson Hospital, Sackler School of Medicine, Tel Aviv University, Petah Tikva, Israel, [2]Massachusetts Institute of Technology, Cambridge, Massachusetts, United States, [3]Institute of Hematology, Beilinson Hospital, Sackler School of Medicine, Tel Aviv University, Petah Tikva, Israel

Background: Since the introduction of imatinib treatment for CML there has been increasing concern about extramedullary relapse (EMR) progression despite favorable response in the bone marrow.
Aims: We postulated that imatinib induces molecular changes associated with enhanced migration and adhesion abilities probably enabling CML cells to inhabit extramedullary sites. Pyk2 is a tyrosine kinase localized to focal adhesion sites that has been implicated in mediating cell adhesion and motility. We have recently shown an increase in the migration, adhesion and invasion capabilities of NB4 cells (APL cell model) following treatment with the targeted therapy ATRA routinely used for the treatment of APL patients and identified Pyk2 as one of the major mediators of these processes.
Methods: We studied the effect of imatinib on K562 cells by combining adhesion, migration and invasion assays, real-time PCR, Western blots and siRNA experiments.

Results: In agreement with our previous report, our current studies reveal that CML cell lines and patient cells also demonstrate a 2-3-fold (P<0.006) elevation of Pyk2 mRNA and protein expression when exposed to imatinib. This increase in pyk2 expression subsequently led to enhanced adhesion (5-fold, P<0.0001), migration (7-fold, P<0.0001) and invasion (2-fold, P<0.001) capabilities of K562 cells. Interestingly, the non-adherent population was 50% more sensitive to imatinib treatment, suggesting that the acquired adhesive phenotype of K562 cells following exposure to imatinib may grant the cells with a certain level of resistant. Selective inhibition of Pyk2 expression by shPyk2 resulted in a 2-fold (P<0.02) reduction of K562 cell adhesion and a 5-fold (P<0.002) reduction of K562 cell migration abilities following imatinib treatment. These results correlate with our previously published data regarding NB4 cells exposed to ATRA.
Summary and Conclusions: Relying on these data, we suggest an active role for the novel targeted therapies in the occurrence of EMR in hematological malignancies. Agents such as ATRA and imatinib could induce expression of molecules that promote migration and extravasation of the leukemic cells and eventually stimulate their adhesion to extramedullary sites forming a reservoir of viable cells that could later proliferate and result in an extramedullary recurrence. Since the use of targeted therapies such as ATRA and tyrosine kinase inhibitors (TKIs) is broadening, we should be aware that alongside their therapeutic effect they may potentially obtain a detrimental nature with respect to extramedullary manifestation in hematological malignancies. Other novel agents in clinical practice should also be evaluated for this phenomenon.

Background: Imatinib (IM), the first Bcr-Abl1 tyrosine kinase inhibitor (TKI), is a novel compound for managing chronic myeloid leukemia (CML), however, substantial numbers of patients are presenting with resistance. Among the causes of resistance, the point mutation in the BCR-ABL1 kinase domain (KD) is most common. However, the characteristic of mutations in most of reported data was based on the clinical trials that can be different in clinical practice.
Aims: Therefore we conducted this retrospective study to elucidate BCR-ABL1 mutation pattern detected in real clinical practice.
Methods: A retrospective cross sectional study has been conducted to describe the patterns and rate of BCR-ABL mutations in Asian CML patients. All reported mutation data of chronic phase CML (CP-CML) patients upon development of IM resistance in 2001-2012 were collected from medical charts and transcribed into a database for analysis.
Results: One hundred thirty six patients were enrolled from 9 institutions of 3 Asian countries in this study. Disease phase at diagnosis were CP in 111 (81.6%) patients, accelerated phase (AP) in 15 (11.0%), blast crisis (BC) in 8 (5.9%), ALL in 1 (0.7%) and unknown in 1 (0.7%) patients. Here, we report the result of mutation in 111 CP-CML patients. The median age was 52 (18-85) years and male patients were dominant (n=79, 71.2%). Prior interfereon-alpha therapy ws received in 32 (28.8%) patients. A majority of patients received 400mg/day or more as initial IM dose. Median duration of IM treatment was 17.1 (range, 2.1-96.2) months. Methods for detecting mutation were direct sequencing (80.2%), pyrosequencing (11.7%), ASO-PCR (6.3%) and others (3%). One hundred twenty three individual mutations were detected in 111 CP-CML patients. As shown in Table1, P-loop (43.1%) and T315I (17.1%) were most frequently developed among 123 mutations. There were no differences between patients remaining CP and patients evolved into advanced stage at the time of IM resistance in terms of P-loop mutations (P=0.142), non-P-loop (P=0.224), T315I (P=0.305) and multiple mutations (P=0.103). The most common single mutation was T315I (n=21/123, 17.1%). Subsequently common mutations were G250E (9.8%), Y253H (8.9%), E255K/V (8.9%), F317L/I (7.3%), F359C/V (5.7%), M244V (4.9%), E459K (4.9%), Q252H (2.4%) and H396R (2.4%) among 123 mutations. No mutation was found in E256K, E257K, V299L and E355G. Multiple mutations were detected in 11 (2 mutations in 10 and 3 mutations in 1) patients. T315I mutation was most common compartment comprising of 18.2% patients harboring multiple mutations. Sensitivity to 2nd generation TKIs based on the IC^{50} value of individual mutation estimated that 37.8% were sensitive to dasatinib and 21.0% to nilotinib. Median overall survival after IM resistance was 47.1 (95% CI 26.9-67.4) months with 42.5% at 5 years and 32.1% at 7 years. Patients harboring T315I, P-loop mutations, and multiple mutations had shorter survival than those having other mutations (median survival 32.6 *vs.* 87.6 months; P=0.012).

Table 1. Frequency of 111 CP-CML patients harboring mutations according to location in Bcr-Abl kinase domain.

No. of mutations	n=123
T315I	n=21 (17.1%)
P-loop	n=53 (43.1%); G250E (9.8%), Y253H (8.9%), E255K/V (8.9%), M244V (4.9%), Q252H (2.4%)
Others	n=49 (39.8%); F317L/I (7.3%), F359C/V (5.7%), E459K (4.9%), H396R (2.4%)
Multiple (duplicated)	n=23; T315I (n=2/23), M244V (n=2/23)

Summary and Conclusions: In conclusion, T315I and P-loop requiring more potent TKI therapy were most frequently detected mutations. And the result demonstrated some differences in the frequency and location of BCR-ABL1 KD mutation based on real clinical practice.

P706

COMPARISON OF NON AUTOMATED BCR-ABL1 RT-QPCR WITH THE XPERT BCR-ABL MONITOR TM ASSAY

S Dulucq[1,*], C Chollet[1], F Robbesyn[1], A Bidet[1], B Turcq[2], E Lippert[1,2], F Magnino[3], F Mahon[1,2]
[1]Laboratoire Hématologie, CHU Bordeaux, [2]Laboratoire Hématopoièse Leucémique et cibles thérapeutiques, unité INSERM 1035, Université Bordeaux Segalen, Bordeaux, [3]Cepheid Europe, Maurens-Scopont, France

Background: *BCR-ABL1* quantification by reverse transcriptase quantitative PCR (RT-qPCR) is largely used in different centers to monitor chronic myeloid leukemia (CML) patients. Efforts towards standardization of the *BCR-ABL1* quantification have been made in the last years. To address this issue semi or automated assays have emerged. The automated cartridge-based assay (Xpert BCR-ABL Monitor™, Cepheid) showed very good inter-laboratory reproducibility. Nevertheless intra-laboratory reproducibility was not evaluated for blood samples from CML patients.
Aims: This study aimed to compare intra-laboratory reproducibility of automated and non automated *BCR-ABL1* quantification.
Methods: Twelve blood samples from CML patients with *BCR-ABL1* values between 0.001% and 10% were tested in quadruplicate for each method, from RNA extraction to qPCR. The non automated but standardized RT-qPCR followed the EAC protocol with a validated conversion factor according to the EUTOS program. Correlation of mean values between both methods, standard deviations (σ) and coefficients of variation (CV) of replicates for each sample were assessed.
Results: Three samples were found undetectable for at least one replicate on the GeneXpert®. These same samples were found positive with very low level of *BCR-ABL1* ($<RM^{4.5}$) for each replicate with the non automated RT-qPCR except for one. This last one was found undetectable in one out of 4 replicates whereas it was undetectable in all 4 replicates with the GeneXpert®. Regarding the nine other positive samples, a very good correlation (R^2=0.99) was found between both methods and a trend towards a better reproducibility was observed for the automated RT-qPCR as compared to the non automated method for *BCR-ABL1* values over 1% (σ_{mean}: 0.12% *vs* 0.5%; CV_{mean}: 6.68 *vs* 17.15%). Similar reproducibility was observed for *BCR-ABL1* values below 1% (σ_{mean}: 0.03% *vs* 0.04%; CV_{mean}: 25.8% *vs* 25.1%).
Summary and Conclusions: The GeneXpert® shows results highly comparable to the EUTOS validated technique down to $RM^{4.5}$. Past this limit, the 200µl sampling size seems insufficient, a larger volume of sample should resolve this problem. A better reproducibility was observed for values over 1%.

P707

SAFETY AND DURABILITY OF PONATINIB IN PATIENTS WITH PHILADELPHIA CHROMOSOME-POSITIVE (PH+) LEUKEMIA: LONG-TERM FOLLOW-UP OF AN ONGOING PHASE 1 STUDY

M Mauro[1,*], J Cortes[2], H Kantarjian[2], N Shah[3], D Bixby[4], I Flinn[5], T O'Hare[6], S Hu[7], V Rivera[7], T Clackson[7], C Turner[7], F Haluska[7], B Druker[1], Mi Deininger[6], M Talpaz[4]
[1]Oregon Health & Science University Knight Cancer Institute, Portland, United

States, [2]The University of Texas MD Anderson Cancer Center, Houston, United States, [3]University of California San Francisco, San Francisco, United States, [4]Comprehensive Cancer Center, University of Michigan, Ann Arbor, United States, [5]Sarah Cannon Research Institute, Nashville, United States, [6]Huntsman Cancer Institute, University of Utah, Salt Lake City, United States, [7]ARIAD Pharmaceuticals, Inc., Cambridge, United States

Background: Ponatinib is a potent oral pan–BCR-ABL tyrosine kinase inhibitor (TKI) that is active against native and mutated forms of BCR-ABL.
Aims: The safety and anti-leukemic activity of ponatinib in patients with chronic myeloid leukemia (CML) or Ph+ acute lymphoblastic leukemia (ALL) were evaluated in a phase 1 clinical trial.
Methods: Patients (N=81) with resistant/refractory hematologic malignancies were enrolled in this ongoing, open-label, dose escalation, phase 1 study. Ponatinib was dosed once daily (2–60 mg). Sixty-five patients had Ph+ leukemia and are included in the present analysis (data as of 9 Nov 2012). Median follow-up was 25 (0.5–44) months.
Results: The median age of patients was 55 years; median time since diagnosis was 6.5 years. Patients were heavily pretreated (94% had received ≥2 prior TKIs, 62% had received ≥3). Baseline BCR-ABL mutations were detected in 65% of patients. Forty-six percent (67% chronic phase [CP] CML) of patients remained on study. Progressive disease and adverse events (AEs) were the most common reasons for discontinuation (17% each). The most common treatment-related AEs were rash (42%), thrombocytopenia (34%), arthralgia (20%), and increased lipase (20%). Rash, arthralgia, and increased lipase were generally grade 1 or 2 in severity; thrombocytopenia was generally grade 3 or 4. Significant anti-leukemic activity was observed (Table 1). Responses (major cytogenetic response [MCyR] for CP-CML or major hematologic response [MaHR] for accelerated phase [AP] CML, blast phase [BP] CML, or Ph+ ALL) were observed against 6 of the 7 mutants detected in >1 patient at baseline: 14/19 T315I, 4/7 F317L, 2/4 G250E, 2/2 M244V, 2/2 M351T, 1/2 F359V, and 0/2 H396R.Among CP-CML patients, 81% with complete cytogenetic response (CCyR) and 74% with major molecular response (MMR) are estimated to maintain response at 1 year (Kaplan-Meier); 73% with CCyR and 63% with MMR are estimated to maintain response at 2 years. The duration of CCyR ranged from 1.9–35+ months, and the duration of MMR ranged from 0.02–38+ months (median not yet reached for CCyR or MMR). Of 28 CP-CML patients with CCyR, 25 remained on study (19 with continuous CCyR); of 22 patients with MMR, 21 remained on study (15 with continuous MMR). Updated data will be presented.

Table 1.

	CP-CML N=43	AP-CML N=9	BP-CML N=8	Ph+ ALL N=5
MaHR	n/a	44%	25%	40%
MCyR	72%	22%	38%	40%
CCyR	65%	22%	13%	20%
MMR	51%[a]	11%	n/a	n/a

n/a=not applicable
[a]14 (33%) CP-CML patients achieved MR[4]; 8 (19%) achieved MR[4.5]

Summary and Conclusions: Significant and durable responses were observed in heavily pretreated CP-CML patients, regardless of mutation status, and ponatinib was generally well tolerated. ClinicalTrials.gov ID NCT00660920

P708

PHARMACOKINETIC AND -DYNAMIC MONITORING DURING FIRST LINE TREATMENT WITH NILOTINIB IN EARLY CHRONIC PHASE CML–FIRST RESULTS FROM THE ENEST1ST SUB STUDY CAMN107EIC01

Background: Imatinib trough plasma level testing and pharmacodynamic evaluation (*i.e.* quantification of phosphorylated CrkL) may help to tailor patient-specific therapy.For the 2nd generation TKI nilotinib the value of such information is less clear.
Aims: We here present first data from a substudy of the phase IV ENEST1st trial testing uP-front nilotinib therapy in early chronic phase CML. The study addressed the value of plasma-level testing and protein phosphorylation pharmacodynamics for clinical outcome.
Methods: Drug levels were centrally quantified by means of mass spectrometry (HPLC-MS/MS) in 54 patients at 3 hours after first drug intake at day (d) 1 (C_{max}) and at d7, d28 and months (m)3,6, 12 prior to morning drug intake (C_{min}). Single cell quantification of intracellular protein phosphorylation was performed by flow cytometry (phosphoflow) in the myelocyte cell population after full blood fixation/cell permeabilization/erythrocyte lysis. BCR-ABL phosphoprotein signalling was detected by phosphoflow at d1 prior to first drug intake, 3 hours after first drug intake as well as at d7 and d28.
Results: In our first analysis we focussed on correlation with early molecular response, *i.e.* IS 0.1% (MMR) and CMR at months3,6, and 12. Of the 54 patients, 21% achieved MMR at 3m and 55% at 6m of therapy (including 2 CMR). Only 4 patients at 3m and 1 patient at 6m did show less than IS 10% BCR-ABL load. 11% achieved CMR at 12m with remaining patients except one showing MMR. At d1 three hours after first drug intake median peak plasma levels reached 405 (range 0-1188) ng/mL increasing to a median trough level of 820 ng/mL at d7 and 880 ng/mL at d28. Thereafter from d28 to d360 plasma trough levels remained stable with individual values ranging from 347 to 2522 ng/mL. Initial C_{max}-levels at d1 significantly correlated with steady state levels thereafter. In addition, the final steady state levels were also influenced by the slope of the subsequent increase (ranging from -21% to 580%). Higher plasma levels of nilotinib were significantly associated with lower BCR-ABL mRNA burden at 3m with a similar trend observed at 6m and 12m. If median steady-state drug levels were compared in different response categories (CMR *vs.* no CMR, MMR *vs.* no MMR, >IS 10% at 3m *vs.* <IS 10%) we could identify significantly higher levels in MMR at 3m (P=0.0083), as well as increased 3m plasma levels were associated with MMR at 6m (P=0.045) and CMR at 12m (P=0.001). Phosphoflow of myelocytes revealed that compared to baseline, phosphorylation of almost all investigated proteins decreases over time, including significant reduction of phospho-Gab2(Y452), Abl(Y245), STAT5(Y694), Erk1/2(T202/Y204), p38(T108/Y182) at d28. Correlation of plasma levels with changes in phosphorylation status revealed a negative correlation of increasing drug levels with decreasing phospho-p38 and phospho-STAT5 status.
Summary and Conclusions: Inter-individual plasma levels show a relatively wide variability. C_{max} levels upon first drug exposure correlate with later trough levels pointing out to a potential individual pharmacogenetic background regulating systemic drug availability. Higher trough nilotinib plasma levels are associated with improved response rates. Single cell myelocyte phosphoprotein detection allowed direct monitoring of components in the BCR-ABL signalling network. More detailed analyses will be presented at the meeting.

P709

RESPONSE DYNAMICS AND OUTCOMES IN PATIENTS DEVELOPING MUTATIONS DURING FIRST-LINE TREATMENT WITH DASATINIB OR IMATINIB FOR CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): DASISION 3-YEAR FOLLOW-UP

T Hughes[1,*], G Saglio[2], A Quintas-Cardama[3], M Mauro[4], D Kim[5], J Lipton[6], M Bradley-Garelik[7], J Ukropec[7], A Hochhaus[8]
[1]SA Pathology, Adelaide, Australia, [2]University of Turin, Orbassano, Italy, [3]MD Anderson Cancer Center, Houston, TX, [4]OHSU Knight Cancer Institute, Portand, OR, United States, [5]Cancer Research Institute and Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of Korea, [6]Princess Margaret Hospital, Toronto, Ontario, Canada, [7]Bristol-Myers Squibb, Princeton, NJ, United States, [8]Department of Hematology and Oncology, Universitätsklinikum Jena, Jena, Germany

Background: BCR-ABL mutations may be responsible for 40–60% of secondary resistance to imatinib. Newer therapies enable many patients (pts) to over-

come imatinib resistance, including pts with mutations. A small number of mutations confer resistance to second-line dasatinib (DAS) or nilotinib, but less is known about their emergence during first-line treatment. Previous analyses identified mutations in CML-CP pts who discontinued treatment in the first-line phase 3 DASISION trial of DAS *vs* imatinib (IM).

Aims: Perform a mutational analysis to include pts with on-treatment events and at discontinuation to potentially identify pts at higher risk of developing clinically relevant mutations. Explore relationships between development of mutations, response dynamics, long-term outcomes, and baseline factors.

Methods: In the DASISION trial, 519 CML-CP pts were randomized to receive DAS 100 mg QD (n=259) or IM 400 mg QD (n=260). Based on 3-year (y) minimum follow-up, an exploratory mutational analysis was conducted evaluating 1) pts who discontinued treatment for any reason and 2) pts on treatment with ≥1 clinically relevant event: no complete cytogenetic response (CCyR) or major molecular response (MMR) within 1 y, loss of CCyR, and 5-fold increase in BCR-ABL with loss of MMR. Pts were screened for mutations at time of discontinuation from treatment or by retrospective analysis for pts on treatment having ≥1 clinically relevant event.

Results: This analysis evaluated pts identified on-treatment with ≥1 clinically relevant event or who discontinued treatment (Table 1). Among all pts analyzed, mutations were identified in a small number of pts in both arms (17 DAS; 15 IM), most in pts screened due to discontinuation, with 6 pts (5 DAS, 1 IM) identified by on-treatment events. While a similar number of pts with mutations were identified in both arms, there were several differences: DAS *vs* IM had (1) a narrower spectrum of mutations, (2) fewer pts with >1 mutation (1 *vs* 6; see footnote [a] in Table), and (3) more pts with T315I. Pt follow-up after 3 y showed that most pts with mutations discontinued treatment, primarily due to disease progression, with death occurring in 10 of these pts (6 DAS, 4 IM). Of the 5 pts with mutations remaining on treatment (4 DAS [1 G250E, 1 V299L, 2 T315I] and 1 IM [F359V]), 3 of the DAS pts remain in CCyR at last follow up, including both pts with T315I, 1 with 40%, and 1 with 80% T315I abundance. Analysis of molecular and cytogenetic response dynamics showed that most pts found to have mutations either (1) had no initial response or (2) experienced a transient modest early response rarely deep enough to achieve an MMR.

Table 1. Summary of mutational analyses.

	DAS 100 mg QD n=259	IM 400 mg QD n=260
Pts identified for mutational analysis, n (%)	169 (65)	194 (75)
Discontinued treatment	75	79
Pts with mutations	12	14
On treatment with ≥1 clinically relevant event	94	115
Pts with mutations	5	1
Pts with mutations (total), n	17	15
Mutations detected[a], n	F317I/L (3) V299L (3) T315I (11) G250E (1)	M244V (1) L248V (1) G250E (1) E255K/V (4) D276G (1) M351T (3) E355G (2) F359C/V (4) L387M (1) H396P (1) E450G (1) Y253H (1)
Current status of pts with mutations[b], n		
On treatment	4	1
Discontinued treatment and alive	7	10
Died	6	4

[a]Includes pts with 2 mutations: 1 DAS (V299L/F317I) and 6 IM (M351T/F359V, E255V/E450G, L248V/E355G, E255K/M351T, E255V/Y253H, D276G/F359C).
[b]Based on most recent follow-up (after 3 y).

Summary and Conclusions: Consistent with previous reports, a narrow spectrum of mutations was found in pts treated with first-line DAS *vs* IM. Most pts who developed mutations failed to achieve or maintain cytogenetic or molecular response. While in both arms few patients with mutations were identified, outcomes were generally poor for pts with mutations regardless of therapy. Notably, more pts with IM *vs* DAS had multiple mutations.

P710

VALIDATION OF THE EUTOS SCORE FOR PREDICTION OF COMPLETE CYTOGENETIC RESPONSE AND PROGRESSION FREE SURVIVAL: APPLICATION TO INDEPENDENT DATA FROM THE EUTOS REGISTRY AND REVIEW OF PUBLICATIONS

[1]Institute of Medical Information Sciences, Biometry and Epidemiology, Ludwig-Maximilians-Universität München, München, Germany, [2]Department of Hematology and Oncology L. and A. Seragnoli, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy, [3]Russian Academy of Medical Sciences, Hematology Research Center, Moscow, [4]St Petersburg State Medical University, St Petersburg, Russian Federation, [5]Klinika Hematologii, Akademia Medyczna, Gdansk, [6]Klinika Hematologii, Gdansk, Poland, [7]Hematology Deptartment, Hospital Universitario de la Princesa, Madrid, Spain, [8]Interní hematoonkologická klinika, University Hospital Brno, Brno, [9]Department of Hemato-oncology, University Palackianae, Olomouc, Czech Republic, [10]Fundeni Clinical Institute, Center of Hematology and Bone Marrow Transplantation, Bucharest, Romania

Background: The EUTOS score is predictive for complete cytogenetic remission (CCyR) at 18 months and subsequent progression free survival (PFS) in patients with chronic phase Chronic Myeloid Leukemia (CML) treated first line with imatinib. The score uses percentage of basophils and spleen size to classify patients into a high and a low risk group (Hasford *et al.*, Blood 2011).

Aims: The EUTOS score was developed and independently validated on patients enrolled in prospective, protocol-based phase III- and IV- studies of frontline therapy which typically recruit highly selected patients only. Now the score is tested in routine CML-patients, registered prospectively by National Study Groups and who were not included in clinical trials. Additionally, publications on validity of the EUTOS score are reviewed.

Methods: A total of 1288 patients were collected from a hospital-based national group located in Madrid (n=193), from the national Polish registry (n=281), from two Russian registries located in Moscow and in St. Petersburg (n=493), from two Czech registries (Camelia and Infinity) (n=309, including 96 patients from Slovakia), and from a Romanian registry (n=12). PFS, time to CCyR and CCyR status 18 months after the start of therapy were calculated and analyzed using Kaplan-Meier and cumulative incidence curves, and respective Gray and Log-Rank tests. For cumulative incidence analyses death was considered a competing risk. PFS was measured from the start of imatinib treatment to date of death or progression to blastic or accelerated phase. PubMed and Abstract Books of relevant conferences were searched for publications on the EUTOS score. Information on sample size, percentage of high risk patients, median age and follow up time was collected.

Results: Of 1288 patients 52% were male. Median age was 49 years (range 18-85), and median observation time was 65 months (range 2-112). There were 161 (12.5%) high risk patients. At 18 months 61.3% of the patients in the high risk and 73.0% of the low risk group were in CCyR (P=.036). In high risk patients, the cumulative probability of ever achieving a CCyR over the whole observation time, was significantly lower than in low risk patients (P<.0001), being 67.6% (95% CI 59.1–74.7) *vs.* 84.4% (95% CI82.1% - 86.7%) at 5 years. This indicates that patients not treated in clinical studies achieve CCyR later than patients enrolled in clinical trials. PFS differs significantly for EUTOS high and low risk group (P=.0395). After 5 years PFS was 89.3% (95% CI 87.1% - 91.1%) in low risk patients *vs.* 82.0% (95% CI 74.7% - 87.3%) in the high risk ones. Thus even in this sample of non-trial patients the EUTOS score identified two distinct prognostic groups. There were eight publications on the validity of the EUTOS score identified. Authors were located in Europe, Asia, North and South America and their reports included 139 to 279 patients. Median age ranged from 43 to 55 years, and median follow up time ranged from 29 to 117 months. Percentage of patients in the EUTOS high risk group started at 5% in Italy and went up to 31% in Singapore (median 9.6%). Most publications discussed patients treated with imatinib, a study from the USA had 34% of patients treated with second-generation tyrosine kinase inhibitors (TKIs) a study from Italy reported exclusively on patients with second-generation treatment. Further, six studies reported P-values for the cumulative incidence of CCyR, most of them indicating major differences between high and low risk group and half of them below 0.05. Six studies specified P-values for PFS, ranging from 0.01 to 0.73, four studies reported P-values of 0.05 or lower.

Summary and Conclusions: The validity of the EUTOS score was confirmed in the patients treated outside of prospective, protocol-based clinical studies. In addition, many independent studies from all over the world reported a substantial predictive value for cytogenetic remission and progression free survival. Even considering the comparatively small number of events in patients treated with TKIs the combined evidence indicates that the EUTOS score is able to reliably identify a small group of patients at high risk of suboptimal outcome.

Chronic myeloid leukemia - Clinical 2

LONG-TERM SURVIVAL OUTCOME AND PROGNOSIS IN 2277 PATIENTS WITH CHRONIC MYELOID LEUKAEMIA ALLOCATED TO FIRST-LINE IMATINIB TREATMENT–NEW RESULTS FROM THE EUTOS IN-STUDY REGISTRY

Background: In the European Treatment and Outcome Study (EUTOS) registry, individual data on patients with chronic myeloid leukaemia (CML) enrolled in prospective, controlled clinical trials are collected. Included were adult patients with Philadelphia chromosome-positive chronic-phase (CP) CML treated with any imatinib-based treatment within half a year after diagnosis. At first, focus was on the analysis of cytogenetic response resulting in the EUTOS score (Hasford *et al.*, 2011). Now, with each of six studies providing a median observation time of at least five years and altogether 2277 patients fulfilling the inclusion criteria, the EUTOS In-study registry allows a closer look on long-term survival outcome.
Aims: To describe long-term survival outcome and possibly identify variables with a prognostic influence on overall survival (OS).
Methods: Survival was censored at the time of allogeneic stem cell transplantation (SCT) in first CP. Time and frequency of progression were analysed by the cumulative incidence approach with death in CP as a competing risk. Definition of progression was in accordance with the ELN criteria (Baccarani *et al.*, 2009). Prognostic influence on OS was estimated with multiple Cox regression. Candidate variables were age, sex, spleen enlargement, haemoglobin, platelets, leukocytes, and percentages of blasts, eosinophils, and basophils in peripheral blood. Level of significance was 0.05.
Results: The 2277 patients came from study groups in Germany, France, Italy, Spain, the Netherlands, and from the Nordic study group. Median observation time was 6.25 years. Allogeneic SCT in first CP was performed in 99 patients (4%). Five-year survival probability was 90% [95%>confidence interval (CI): 88-91%]. Sufficient data on progression was available for three study groups. With death as a competing risk, five-year progression probabilities were 7% [Germany, 95%>CI: 5-9%], 5% [France, 95%>CI: 3-6%], and 6% [Italy, 95%>CI: 4-8%]. Assuming thus comparable progression evaluation, the 1821 patients of these three study groups could be merged and had a progression-free survival of 90% [95%>CI: 88-91%]. The learning sample for regression analysis, based on four studies with similar follow-up patterns, comprised 1884 patients with complete data for the candidate prognostic factors. Their median age was 52 years [range: 18-88], 60% were male. Besides age, multiple modelling also suggested that the interaction between sex and haemoglobin had an influence on survival (always: P<0.005). Females with lower haemoglobin values had less favourable survival probabilities while haemoglobin showed no effect in males. With patients only randomised within but not between the studies and the restriction that only a cut-out of the studies' patients was available, an unbiased investigation of OS differences between different imatinib-based treatments must be referred to the individual study groups. However, there was no apparent OS advantage for any of the treatments.
Summary and Conclusions: The median observation time of at least 6.25 years in 1884 patients with 181 events actually enabled prognostic modelling in imatinib-treated patients. Higher age significantly reduced OS probabilities. Though the age effect was considerable and a median observation period of 6.25 years suggests few deaths not directly related to CML, the next step will be to collect more information on the causes of death and also on disease progression. For further investigation, additional sensitivity analyses and a later validation in independent patients will be performed.

D. Anderson Cancer Center, Houston, United States, [14]Centre for Cancer Biology, SA Pathology, University of Adelaide, Adelaide, Australia

Background: In the Evaluating Nilotinib Efficacy and Safety in Clinical Trials–Newly Diagnosed Pts (ENESTnd) trial, nilotinib has demonstrated superior rates of major molecular response (MMR; BCR-ABL^{IS}≤0.1%), deeper molecular responses (MR^4, BCR-ABL^{IS} ≤0.01%; MR$^{4.5}$, BCR-ABL^{IS} ≤0.0032%) and reduced rates of progression compared with imatinib in pts with newly diagnosed, Philadelphia chromosome–positive (Ph+) CML-CP.
Aims: This analysis aims to explore the long-term efficacy and safety of frontline nilotinib *vs* imatinib in ENESTnd with a minimum of 4 y f/u.
Methods: Adult pts with newly diagnosed Ph+ CML-CP (N=846) were randomized to receive nilotinib 300 mg twice daily (BID; n=282), nilotinib 400 mg BID (n=281), or imatinib 400 mg once daily (QD; n=283) in this open-label, phase 3 study. Efficacy analyses were based on the intent-to-treat population, which included all randomized pts. Response assessments were collected during study treatment. Information on progression to accelerated phase/blast crisis (AP/BC) and overall survival (OS) was prospectively collected during f/u every 3 mo after discontinuation of treatment for the first 5 y and every 6 mo thereafter.
Results: With 4 y of f/u, nilotinib continued to demonstrate significantly higher rates of MMR, MR^4, and MR$^{4.5}$ *vs* imatinib (Table 1). Rates of MR$^{4.5}$ were consistently superior with nilotinib *vs* imatinib across all Sokal risk groups. Pts on both nilotinib arms had significantly lower rates of progression to AP/BC on study (including f/u after discontinuation of treatment) *vs* pts on the imatinib arm (n=9 [3.2%], 6 [2.1%], and 19 [6.7%] in the nilotinib 300 BID, nilotinib 400 mg BID, and imatinib arms, respectively). Of the pts who progressed on core study treatment (n=2 [0.7%], 3 [1.1%], and 12 [4.2%] in the nilotinib 300 mg BID, nilotinib 400 mg BID, and imatinib arms, respectively), the majority never achieved complete cytogenetic response (CCyR); no pt who has achieved MR$^{4.5}$has progressed (Table 1). The 4-y OS rates were 94.3%, 96.7%, and 93.3% for nilotinib 300 mg BID, nilotinib 400 mg BID, and imatinib, respectively. Treatment-emergent BCR-ABL mutations were less common in pts on nilotinib *vs* imatinib (detected in12,11, and 22 pts in the nilotinib 300 mg BID, nilotinib 400 mg BID, and imatinib arms, respectively); only 2 pts had newly emergent mutations in y 4 (1 pt with T315I on nilotinib 300 mg BID; 1 pt with F317L on imatinib). The safety profiles of both drugs were consistent with those previously reported, with few newly occurring hematologic/biochemical abnormalities or cardiac/vascular events in any treatment arm, and no new safety signals. By 4 y, peripheral arterial occlusive disease (PAOD) was reported in4,5, and 0 pts, and ischaemic heart disease (IHD) was reported in11,14, and 3 pts in the nilotinib 300 mg BID, nilotinib 400 mg BID, and imatinib arms, respectively. The annual frequency of these events has not increased with longer f/u (eg, in the nilotinib 300 mg BID arm, there were 4 PAOD events by 2 y, 0 from 2-3 y, and 0 from 3-4 y, and there were 5 IHD events by 2 y, 4 from 2-3 y, and 2 from 3-4 y). Based on a combination of baseline risk factors, 7 of the 9 pts with a PAOD event on nilotinib were at high risk for PAOD.

Table 1.

	Nilotinib 300 mg BID (n = 282)	Nilotinib 400 mg BID (n = 281)	Imatinib 400 mg QD (n = 283)
Still on active f/u[a] or died, %	94	95	93
Still on core treatment, %	66	69	57
Molecular response by 4 y (ITT), % (*P* value vs imatinib)			
MMR	76 (< .0001)	73 (< .0001)	56
MR^4	56 (< .0001)	50 (< .0001)	32
MR$^{4.5}$	40 (< .0001)	37 (.0002)	23
MR$^{4.5}$ by 4 y according to Sokal risk (ITT), % (*P* value vs imatinib)			
Low	38 (.17)	45 (.018)	29
Intermediate	48 (.0004)	34 (.11)	24
High	32 (.0040)	31 (.0066)	13
4-y freedom from progression to AP/BC,[b,c] % (*P* value vs imatinib)			
On study[a]	96.7 (.050)	97.8 (.0074)	93.1
Best response in pts who progressed to AP/BC on core treatment,[c] n			
< CCyR	2	1	8
CCyR	0	0	4
MMR	0	1	0
MR^4	0	1	0
≥ MR$^{4.5}$	0	0	0
4-y EFS on core treatment,[b,d] %	94.5 (.19)	97.4 (.011)	92.6
4-y PFS on core treatment,[b,e] %	96.1 (.20)	98.3 (.026)	94.7
4-y OS on study,[a,b] %	94.3 (.47)	96.7 (.050)	93.3
Pts with emergent BCR-ABL mutations on core treatment,[f] n			
Any mutation, n	12	11	22
Mutation category:			
T315I, n	4	2	3
Less sensitive to nilotinib,[g] n	6	9	4
Other mutation,[h] n	2	0	15

[a] Including core or extension treatment or f/u after discontinuation.
[b] Kaplan-Meier estimate.
[c] Progression to AP/BC events included progression to AP/BC or CML-related death.
[d] EFS events included: death from any cause, progression to AP/BC, loss of partial CyR, loss of CCyR, or loss of complete hematologic response.
[e] PFS events included progression to AP/BC or death from any cause.
[f] There were 120, 136, and 199 pts in the nilotinib 300 mg BID, nilotinib 400 mg BID, and imatinib arms, respectively, who had ≥ 1 postbaseline mutational analysis.
[g] Mutations clinically less sensitive to nilotinib included E255K/V, F359C/V, and Y253H.
[h] Includes all mutations other than less-sensitive mutations and T315I.
EFS, event-free survival; ITT, intention-to-treat; PFS, progression-free survival.

Summary and Conclusions: With 4 y of f/u, nilotinib continues to demonstrate significantly higher rates of molecular response, lower rates of progression to AP/BC, and fewer treatment-emergent BCR-ABL mutations *vs* imatinib. These data further support the use of nilotinib as frontline therapy in newly diagnosed pts with Ph+ CML-CP.

Background: The international, collaborative effort to standardise molecular testing for chronic myeloid leukaemia (CML) to date has focused largely on detectable residual disease, with a particular emphasis on determining whether (or not) a patient has achieved major molecular response (MMR). However, with new definitions of deep molecular responses (MR) a new problem arises in how to define assay sensitivity in a standardized manner when *BCR-ABL1* mRNA is undetectable.

Aims: We have previously established draft criteria to define deep molecular responses (MR^4, $MR^{4.5}$ etc) of residual disease in CML. To assess how well these definitions might work in practice and enable laboratories to benchmark their performance with regard to assay sensitivity in relation to others we sent out a series of cell line and armoured RNA (aRNA) samples along with a common (IRMM) plasmid dilution to testing laboratories. We evaluated assay sensitivity in two ways: (a) by directly evaluating the ability of labs to detect low level positive samples and (b) measuring absolute control gene (CG) transcript numbers as a surrogate for sample quality and thus theoretical sensitivity with which *BCR-ABL1* could be detected.

Methods: Cell line and aRNA samples were sent to EUTOS (European Treatment and Outcome Study) reference laboratories who agreed to participate (n=39). Laboratories tested two different levels of *e14a2* aRNA diluted in a background of *ABL1* aRNA only (MMR, MR^4) and three different cell line lysates (5%, 0.05%, 0.005% *BCR-ABL1*^{IS}). Absolute copy numbers of *BCR-ABL1* and *CG* and the *BCR-ABL1/CG* ratios before and after conversion to the international scale (IS) using a common plasmid standard curve and laboratory plasmid standard curve were recorded.

Results: Cell line and aRNA analysis indicated good comparability of%*BCR-ABL1* /*CG* results that was improved by use of the common plasmid. Analysis of the cell line lysates and aRNA samples indicated that all labs were able to detect *BCR-ABL1* at the lowest dilution (which corresponded to MR^4), however the median number of *CG* transcripts in the cell line samples (*ABL1*=74,509 (n=33); *GUSB*=84,762 (n=6)) was higher than would be expected from patient samples. Analysis of absolute numbers of *BCR-ABL1* and *ABL1* transcripts using the aRNA samples revealed that most labs are underestimating the absolute number of transcript copy numbers, even when using a common plasmid calibrator. All aRNA samples were predicted to contain 305,500 *ABL1* copies per µl aRNA but when laboratory data were corrected for the amount of aRNA added to the PCR, the median number of *ABL1* copies per µl aRNA reported was only 54,578 (n=31) using the usual laboratory standard curve and 28,458 (n=32) using the IRMM standard curve. These data suggest that there is substantial scope for most labs to improve the quality of their cDNA synthesis procedures and thereby increase assay sensitivity.

Summary and Conclusions: Good comparability was seen between the 39 participating labs for samples where *BCR-ABL1* was detectable, but assay sensitivity based on *CG* numbers was highly variable. Although the use of a common plasmid calibrator improved the comparability, it did not correct for differences in estimates of absolute *CG* numbers. The reasons for these differences are unclear but may relate to differences in the efficiency of reverse transcription. Further investigation will be required to determine if this is the case, and how to improve *CG* numbers/sensitivity where necessary.

P714

CLINICAL SIGNIFICANCE OF EARLY MOLECULAR RESPONSES (BCR-ABL1 ≤10% AT 3 MONTHS AND ≤1% 6 MONTHS) AS A PREDICTOR FOR LONG-TERM OUTCOMES IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH IMATINIB

S Lee[1,*], S Choi[2], S Kim[2], J Bang[2], Y Oh[2], J Park[2], H Jeon[2], E Jang[2], D Kim[1]

[1]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, [2]Cancer Research Institute, The Catholic University of Korea, Seoul, Korea, Republic of Korea

Background: Imatinib (IM) has been the standard of care for chronic phase (CP) chronic myeloid leukemia (CML). Complete cytogenetic response (CCyR) has been established as a predictor for outcome by the International Randomized Study of Interferon and STI571 (IRIS). Although recent studies have suggested that in IM-treated patients, measurements of BCR-ABL1 transcript levels at 3 and 6 months were able to identify high-risk patients, suggesting that the early switch to second-generation tyrosine kinase inhibitors may be beneficial for the high-risk patients, further validation is needed.

Aims: The aim of this study was to investigate clinical significance of early molecular responses (BCR-ABL1 ≤10% at 3 months and ≤1% 6 months) as a predictor for long-term outcomes in newly diagnosed CP CML patients treated with IM.

Methods: 620 consecutive patients were newly diagnosed as CP CML at Seoul St. Mary Hospital between January 2001 and December 2011, and started IM (400 mg/day) therapy without prior treatment except hydroxyurea or anagrelide. Among them, quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) data at 3 months from 146 patients were available for this study. Their molecular responses were monitored using qRT-PCR assay with 3 month intervals, and then 6 month intervals after achieving major molecular response (MMR). All qRT-PCR tests were performed in a single laboratory (Cancer Research Institute, The Catholic University of Korea, Seoul, Korea).

Results: A total of 146 newly diagnosed CP CML patients (including 80 men and 66 women) were analyzed. Their median age was 41 years (range, 18-74). The percentages of patients with low, intermediate and high Sokal risk scores were 30%, 23% and 34%, respectively with unknown Sokal risk scores in 13%. At 3 months, patients showed BCR-ABL1 ≤1% (n=48), >1 to ≤10% (n=54), or >10% (n=44). For 128 patients with qRT-PCR data at 6 months, they showed BCR-ABL1 ≤1% (n=73), >1 to ≤10% (n=39), or >10% (n=16). In patients with BCR-ABL1 ≤10% at 3 months, significantly higher rates of CCyR at 12 months (94% *vs* 78%, P=0.020) were observed, compared with that of patients with BCR-ABL1 >10%. They also had significantly better 7-y FFS (92.3% *vs* 69.2%, P<0.001), PFS (99.0% *vs* 81.2%, P<0.001), and OS (99.0% *vs* 93.2%, P=0.050). Patients with BCR-ABL1 ≤1% at 3 months had a better 7-y FFS (91.9% *vs* 82.5%, P=0.052) and PFS (100% *vs* 90.5%, P=0.041). However, there were no signifi-

cant differences in CCyR at 12 months and 7-y OS. Patients who had BCR-ABL1 >10% at 6 months had a trend for higher progression, compared with those who achieved ≤10% response at 6 months, which was translated into lower 7-y PFS (97.4% *vs* 86.5%, P=0.022). Patients with BCR-ABL ≤1% at 6 months had also significantly better PFS (100% *vs* 91.4%, P=0.028).
Summary and Conclusions: The achievement of ≤10% response at 3 months is predictive for long term FFS, PFS, and OS, and the ≤1% level of response at 3 months was associated with better FFS and PFS. Achieving a MMR or better at 6 months showed clinical significance in PFS. These results imply that early molecular response assessment may identify a group of patients requiring a change of treatment. In the meeting, we will show updated and extended data and predictors analyzed for achieving early molecular response, including Sokal risk score, IM dose intensity, and the result of IM blood level test.

P715

THE PERCENTAGE OF EFFECTOR POPULATIONS OF NK CELLS CORRELATED HIGHLY WITH SUSTAINED COMPLETE MOLECULAR RESPONSE WITH OR WITHOUT IMATINIB IN CHRONIC MYELOID LEUKEMIA PATIENTS

K Seiichiro[1,*], M Izuru [2], Y Takayuki [2], M Junichiro [3], O Junko [4], T Tetuzo [1], I Koiti[5], O Kazuma [1]
[1]Hematology, [2]Immunoregulation, Institute of Medical Science, [3]Immunology, [4]Molecular Oncology, Institute of Medical Science, Tokyo Medical University, [5]Hematology, Nippon Medical School, Tokyo, Japan

Background: Recently, it has been found that some chronic myeloid leukemia (CML) patients with complete molecular response (CMR) are able to maintain CMR after discontinuing imatinib (IM). Among patients with CMR lasting for at least 2 years, 41% maintained CMR conditions after discontinuing IM (Lancet Oncol. 2010;11:1029). We have recently reported that patients with sustained CMR after discontinuing IM had increasing numbers of natural killer (NK) cells (Br. J. Haematol. 2012;157:254). These findings indicate that immunological surveillance may have some effects in maintaining CMR after discontinuing IM.
Aims: To identify the long-term immunological effects on CML patients after discontinuing IM, we characterized their immunophenotypic profiles. We compared the profiles of CML patients who received IM with CMR for more than 2 consecutive years (CMR group), those who could not sustain CMR but maintained a major molecular response (fluctuating CMR group), those who sustained CMR after discontinuing IM (STOP-IM group), and healthy volunteers (control group). Some patients in the STOP-IM group were analyzed sequentially.
Methods: Immunophenotyping analysis of peripheral blood mononuclear cells (PBMCs) was performed using a 5-color flow cytometry panel including antibodies against the following cell surface antigens and effector molecules: CD3, CD8, CD45RO, CD56, CCR7, IFN-γ, granzyme-B, and perforin. After the PBMCs were stimulated with phorbol 12-myristate 13-acetate and ionomycin for 4 h in the presence of monensin, cell surface antigens were stained, fixed, and permeabilized.
Results: The percentage of effector populations of NK cells, such as interferon (IFN)-$\gamma^{+}CD3^{-}CD56^{+}$ cells, was significantly higher in the CMR and STOP-IM groups than in the fluctuating CMR group. In the STOP-IM group (maintaining CMR without IM), the elevated percentage (approximately >10%) of IFN^{+} NK cells was maintained for more than 12 months after discontinuing IM. By contrast, the percentage of effector populations of $CD8^{+}$ T cells in the CMR group did not differ significantly when compared with those in the STOP-IM group. However, we had 1 patient who showed reduction in NK cells concomitant with molecular relapse after discontinuing IM.
Summary and Conclusions: The STOP-IM group maintained higher percentages of functional NK cells than the fluctuating CMR group, and maintained elevated levels for more than 2 years even without IM, indicating that the elevation of functional NK cell population in CMR is not attributable to IM. Also, the elevation of functional NK cells in CMR patients, when compared with those in the fluctuating CMR group, suggests that NK cells may have some effects in maintaining CMR as immunological surveillance in CML therapy.

P716

HEPATITIS B VIRUS REACTIVATION IN CHRONIC MYELOID LEUKEMIA TREATED WITH VARIOUS TYROSINE KINASE INHIBITORS: A MULTICENTER RETROSPECTIVE STUDY

S Kim[1,*], H Kim[2], J Kwak[3], J Kim[4], Y Mun[5], J Park[6], S Sohn[7], S Lee[8], D Kim[8]
[1]Internal Medicine, Dong-A College of Medicine, Busan, [2]Hematology-Oncology, Chonnam National University Hwasun Hospital, Hwasun, [3]Internal Medicine, Chonbuk National University Medical School, Jeonju, [4]Internal Medicine, Yonsei University College of Medicine, [5]Internal Medicine, Ewha Womans University School of Medicine, Seoul, [6]Internal Medicine, Ajou University School of Medicine, Suwon, [7]Hematology-Oncology, Kyungpook National University School of Medicine, Daegu, [8]Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of Korea

Background: BCR-ABL1 tyrosine kinase inhibitors (TKI) are now a standard initial treatment for chronic myeloid leukemia (CML). Several cases reported that hepatitis B virus (HBV) reactivation was related to imatinib therapy. However, it is still unclear whether imatinib or other TKIs induce HBV reactivation in hepatitis B surface antigen (HBsAg)-positive patients.
Aims: The aim of this study is to investigate the incidence of HBV reactivation and analyze risk factors associated with HBV reactivation in CML patients who are treated with various TKIs.
Methods: We have retrospectively analyzed patients who had been treated with imatinib until February 2012, from 8 Korean university hospitals. All of CML patients diagnosed reviewed centrally. HBsAg-positive CML patients under imatinib or other TKI treatments were analyzed.
Results: 702 patients were diagnosed with CML from participating centers. The HBsAg-positive rate was 6.1% (43/702) at diagnosis. In the 43 HBsAg-positive patients, nine patients received prophylactic therapy and HBV reactivation rate was 34.9% (15/43) (95% CI: 21.0-50.9%). The cumulative incidence of HBV reactivation was 52.9% in patients without HBV prophylaxis. Patients who received prophylaxis did not develop HBV reactivation. The median age and the male to female ratio of the HBV reactivated patients were 47.0 years (range; 22-63) and 4:1, respectively. HBV reactivation according to each TKI treatment were: 12 cases under imatinib, 2 cases under dasatinib, and 1 case under nilotinib. Median time to HBV reactivation was 9.3 months (range; 2.3-68.8 months) (95% CI: 5.9–28.5 months). None of the patients died due to HBV reactivation, but one patient received liver transplantation due to hepatic failure. Prophylactic therapy and HBV DNA levels at diagnosis were the factors associated with HBV reactivation (P=0.011 and P=0.036, respectively). HBV DNA levels at diagnosis significantly affect the time to HBV reactivation from TKI treatment in univariate and multivariate analyses (P<0.001 and P<0.001, respectively).
Summary and Conclusions: To our knowledge, this is the first report that has analyzed HBV reactivation in HBsAg-positive CML patients during TKI treatment. Prophylaxis should be considered to prevent HBV reactivation during TKI treatment. Also, we recommend that HBsAg-positive patients with CML receiving TKI treatment be closely monitored.

P717

EARLY AND DEEP RESPONSES TO IMATINIB PREDICT NOT ONLY COMPLETE MOLECULAR RESPONSE BUT ALSO THE PROBABILITY FOR MAINTAINING THE RESPONSE.

G Valentin[1,*], B Maestro[2], F Casado[3], M Perez-Encinas[4], I Massague[5], R De Paz[6], S Osorio[7], J Martinez[8], G Bautista[9], P Giraldo[10], C Burgaleta[11], M Peñarrubia[12], M Requena[13], C Calle[14], H Angel[15], C Pilar[16], J Steegmann[17]

Background: Tyrosine kinase inhibitors (TKIs) have consistently proven a survival benefit in patients with chronic myeloid leukemia (CML). TKIs need to be taken for unlimited period of time in order to avoid the risk of relapse or transformation. It has been recently described how patients with a stable and complete molecular response (CMR), could safely quit treatment. Less is known about the real rates of patients under TKI to achieve CMR and which factors may play an important role maintaining the response.
Aims: To describe the percentage of patients who achieve a sustained complete molecular response and to identify factors associated with achieving this response.
Methods: We have analyzed retrospectively 578 patients treated with imatinib as first TKI in the Spanish RELMC registry. All patients were treated out of clinical trials. Follow up and treatment decisions were decided by hematologists according to their clinical judgment. Complete molecular response was defined as undetectable BCR-ABL transcript. Samples were not centralized but all PCR were done in the same laboratory for each patient during follow up.
Results: Out of the 578 patients analyzed, 124 patients (21%) had received interferon prior to imatinib. Sokal risk distribution was 42%, 47% and 11% for low, intermediate and high, respectively. 24% of the patients were treated with second generation TKIs (2GTKIs) (nilotinib or dasatinib) due to intolerance or inadequate response to imatinib. With a follow up of 85.59 months (8.93–130), the cumulative incidence of CMR for patients treated only with imatinib was 51%. Median time to CCR was 31 months. Probabilities for achieving CMR were higher for low and intermediate Sokal risk patients (58% *vs* 51% *vs* 14% for low, intermediate and high risk patients respectively (P=0.2).The cytogenetic response at 6 months was a strong predictor for CMR: 59% *vs* 36% for patients with and without complete

cytogenetic responses (CCyR) at 6 months (P=0.01). Once patients achieved CMR, the probability to maintain the response while on imatinib was 45% (23% of the entire cohort achieved and maintained CMR). Again, early response, defined as CCyR at 6 months, was a predictor factor for maintaining CMR: 68% *vs* 41% (P=.00). We found no association between probabilities of maintaining CMR and other prognostic factors such as Sokal risk index or previous interferon treatment. The probability to obtain CMR among patients who were changed to 2GTKIs was 25%, and this response was related to the indication for treatment changed: 50% *vs* 35% *vs* 19% (P=0.1) for intolerance, suboptimal response and treatment failure respectively. Among patients who achieved RMC after treatment changed, the probability for maintaining this response during follow up was 53%.

Summary and Conclusions: Our results show that complete and maintained molecular responses in patients treated with imatinib occurred in one fifth of the patients. The use of new treatments that enhance the rate of early responses could improve the number of patients candidate for discontinuation treatment clinical trials.

P718

EVOLUTION OF BOSUTINIB TOXICITY IN PATIENTS WITH PHILADELPHIA CHROMOSOME–POSITIVE LEUKEMIA AFTER RESISTANCE/INTOLERANCE TO PRIOR THERAPY

C Gambacorti-Passerini[1,*], T Brümmendorf[2,3], J Cortes[4], J Lipton[5], D Kim[6], E Leip[7], K Turnbull[7], M Shapiro[7], H Kantarjian[4], H Khoury[8]
[1]University of Milano-Bicocca, Monza, Italy, [2]Universitätsklinikum Aachen, RWTH Aachen, [3]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [4]University of Texas MD Anderson Cancer Center, Houston, TX, United States, [5]Princess Margaret Hospital, Toronto, ON, Canada, [6]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of Korea, [7]Pfizer, Cambridge, MA, [8]Winship Cancer Institute of Emory University, Atlanta, GA, United States

Background: Bosutinib (BOS) is an oral dual Src/Abl tyrosine kinase inhibitor (TKI) approved for treatment of Philadelphia chromosome–positive (Ph+) chronic myeloid leukemia (CML) following resistance/intolerance to prior therapy. Prior reports from this phase I/II trial indicated the BOS safety profile was primarily characterized by myelosuppression, gastrointestinal events, and rash.
Aims: The current analysis compares the incidence of toxicity in Year 1 for patients on treatment ≤1 year and within Year 1 and Year 2 for patients on treatment for >1 year.
Methods: BOS 500 mg/day was evaluated in 3 cohorts: chronic phase (CP) CML after imatinib only (CP 2L cohort; n=286); CP CML after imatinib+dasatinib and/or nilotinib (CP 3L cohort; n=119); and accelerated/blast phase CML or acute lymphoblastic leukemia (ALL) after prior TKI therapy (ADV cohort; n=164).
Results: The most common treatment-emergent adverse events (TEAEs) in each cohort occurred more frequently within Year 1 than Year 2 (*Table*). The incidence for grade 3/4 events followed a similar pattern. AEs were the most common reason for BOS discontinuation in Year 1 (CP 2L, 53%; CP 3L, 32%; ADV, 41%). Of the patients whose primary reason for discontinuing BOS was an AE during the first 2 years, most did so during Year 1 (CP 2L, n=51/60 [85%]; CP 3L, n=22/24 [92%]; ADV, n=24/25 [96%]). Among all patients who discontinued BOS during Year 1 (due to any reason: CP 2L, n=97; CP 3L, n=69; ADV, n=125), the most common AEs leading to discontinuation were thrombocytopenia (12%; 9%; 4%), increased alanine aminotransferase (6%; 4%; 2%), neutropenia (3%; 6%; 0%), diarrhea (4%; 3%; 0%), and vomiting (3%; 4%; 1%). Serious AEs were more common among patients who discontinued BOS ≤1 year *versus* on treatment >1 year in the CP 3L and ADV cohorts, but similar in the CP 2L cohort (Table 1).

Table 1.

	CP 2L			CP 3L			ADV		
	BOS ≤1 y (n = 97)	BOS >1 y (n = 189)		BOS ≤1 y (n = 69)	BOS >1 y (n = 50)		BOS ≤1 y (n = 125)	BOS >1 y (n = 40)	
	Y1	Y1	Y2	Y1	Y1	Y2	Y1	Y1	Y2
TEAE									
Diarrhea	90%	81%	40%	83%	82%	50%	69%	90%	28%
Nausea	41%	45%	12%	51%	36%	18%	42%	58%	15%
Vomiting	40%	31%	7%	41%	32%	8%	41%	43%	8%
Thrombocytopenia	34%	28%	19%	28%	36%	20%	34%	30%	18%
Rash	29%	33%	12%	23%	24%	12%	22%	53%	13%
Abdominal pain	24%	21%	8%	19%	16%	14%	16%	30%	8%
Fatigue	23%	19%	10%	25%	16%	14%	19%	10%	10%
Increased ALT	23%	19%	7%	12%	18%	6%	9%	13%	5%
Anemia	22%	14%	13%	15%	12%	8%	36%	35%	18%
Pyrexia	21%	18%	10%	15%	12%	8%	40%	20%	18%
Headache	16%	12%	9%	29%	20%	6%	18%	20%	8%
Serious AE	25%	25%	23%	30%	20%	18%	60%	33%	33%

Summary and Conclusions: Discontinuation due to AEs was observed primarily in Year 1. For patients on BOS for >1 year, the incidence of common TEAEs decreased substantially after Year1, suggesting BOS tolerability improves after long-term exposure.

P719

MODULATION OF LEUKOCYTE POPULATION DURING FIRST LINE TREATMENT WITH NILOTINIB IN EARLY CHRONIC PHASE CML–FIRST RESULTS FROM THE ENEST1ST SUB STUDY CAMN107EIC01

Background: We and others have shown that Imatinib and Dasatinib modulate immune responses *in vitro* and *in vivo*. Immunological surveillance in the MRD-situation might be of particular relevance for long-term control or even elimination of CML-repopulating stem cells. Little is known about potential immune-modulatory effects of nilotinib *in vivo*. Thus, a comprehensive immunological monitoring program of the patient's immune system going along with the clinical ENEST1st trial was performed.
Aims: Evaluate and characterize the immune-modulatory effects of nilotinib therapy in newly diagnosed CP-CML patients.
Methods: Peripheral blood was taken prior to treatment initiation and after 6 and12 months from 50 patients treated within the ENEST1st trial testing uPfront nilotinib in early chronic phase CML. Samples were analyzed by nine color flow cytometry employing six panels of antibodies to determine various leukocyte populations including lymphocyte subsets (*e.g.* T cell subpopulations including Treg and NKT cells, NK cells, B cells), myeloid populations (*e.g.* monocytes, MDSC) and dendritic cell subsets (*e.g.* mDC, pDC), respectively. Changes in immune cells were correlated to clinical endpoints.
Results: 55% of the patients included into this substudy achieved MMR at 6m and 75% at 12m of therapy. A high proportion of CD14+ monocytes with aberrant expression of CD56 present at baseline dropped to undetectable levels at 6 and 12 months after treatment. The most prominent immunological change from baseline to month 12 was an increase of the proportion of CD19+ B cells by about 50%. The abundance of CD19+ B cells at baseline was negatively correlated with SOKAL score. Among T-cell subpopulations, the proportion of CD56+ NKT-cells decreased over time. Similarly, the proportion of CD8 cells significantly decreased concomitant with increasing CD4+ T-cells during therapy. In parallel to a decrease of CD45RA+ expressing T cells among both CD8+ and CD4+ T cell subsets, the proportion of CD45R0+ memory cells increased. This increase was mainly due to an increase of the CD95+CD28+ central memory population. In contrast to our expectation, $CD25^{high}$ FoxP3+ Treg cells were even increased transiently 6 months after treatment initiation but at 12 months dropped back to levels seen at diagnosis. So far, we could not detect any significant correlation of immunological changes and clinical outcome variables.
Summary and Conclusions: Nilotinib therapy induces significant immunological changes. Most changes during therapy are likely due to normalization of the peripheral blood compartment. So far, correlation of a specific immunological signature with response to nilotinib could not be identified. More detailed data will be presented at the meeting.

P720

IN CML PATIENTS TREATED FRONTLINE WITH IMATINIB, WITH A BCR-ABL RATIO HIGHER THAN 10% AT 3 MONTHS, THE CHANGE TO A 2ND GTKI IS ASSOCIATED WITH IMPROVEMENT OF CYTOGENETIC RESPONSE, BUT NOT WITH MMR

L Montero[1,*], BMaestro[2], J García-Gutiérrez [2], M Helene Dumas[2], I Massagué[3], P Giraldo[4], M Pérez-Encinas [5], R De Paz[6], G Bautista[7], S Osorio[8], M José Requena[9], L Palomera[10], M Jesús Peñarrubia[11], C Calle[12],

[1]Hematology, Hospital Virgen de la Salud, Toledo, [2]Registro Español de LMC, Madrid, [3]Hematology, Hospital Vall d'Hebron, Barcelona, [4]Hematology, Hopsital Miguel Servet, Zaragoza, [5]Hematology, Hospital Clinico U. de Santiago de Compostela, Santiago de Compostela, [6]Hematology, Hospital La Paz, [7]Hematology, Hospital Puerta de Hierro, [8]Hematology, Hospital Gregorio Marañón, Madrid, [9]Hematology, Hospital Universitario Severo Ochoa, Leganés, [10]Hematology, Hospital Lozano Blesa, Zaragoza, [11]Hematology, Hospital Clínico Universitario de Valladolid, Valladolid, [12]Hematology, Hospital General de Ciudad Rea, Ciudad Real, [13]Hematology, Hospital Infanta Leonor, Madrid, [14]Hematology, Hospital Universitario Principe de Asturias, Alcalá de Henares, [15]Hematology, Hospital Universitario Miguel Servet, Zaragoza, [16]Hematology, Hospital Universitario de la Princesa, Madrid, Spain

Background: A cut-off value of BCR-ABL ratio of more than 10% at 3 months discriminates patients with an ulterior worse outcome in treatments with Imatinib, Dasatinib, Nilotinib, and Bosutinib. There is limited data about how this outcome is affected by change to a 2GTKI. In our registry of Imatinib front-line treated patients, 156 out of 374 (41,7%) had been molecularly evaluated at 3 months.
Aims: To asses the influence of treatment change to 2GTKI in the outcome of patients with mollecular evaluation at 3 months.
Methods: Demographics. 93 M, 63 F, median age: 54,2 y (15-86). 7 received HD Imatinib upfront.
Results: Among 156 patients evaluable, 50 (32%) had a ratio of >10%. Sokal, Hasford, or EUTOS risk score were not significantly associated with this cut-off.
Response: The Probability of obtaining CCyR while on Imatinib was 89% for those patients with ratio of 10% or less (*vs* 66% with >10%) P<0.0001. The probability of CCyR, considering all TKI treatments was 92% for those patients with ratio of 10% or less (*vs* 77% with >10%) P=0.007. The probability of obtaining MMR while on Imatinib was 80% for those patients with ratio of 10% or less (*vs* 47% with >10%) P<0.0001. The probability of MMR, considering all TKI treatments was 88% for those patients with ratio of 10% or less (*vs* 58% with >10%) P<0.0001.
Response after changing therapy: 43 patients changed to a 2GTKI (30 to Dasatinib, 13 to Nilotinib). The median time to change was 15 months (3-82m). 19 patients changed during the 1 st year,and 13 beyond 2 years. Among the 106 patients with a ratio of 10% or less, 23 (22%) changed to a 2GTKI. The most frequent causes were intolerance (44%) and lost of response (39%). The probability of obtaining a CCyR and MMR after changing to a 2GTKI were 87% and 65%, respectively. Among the 50 patients with a ratio of more than 10%, 20 (40%) changed to a 2GTKI, mostly because of intolerance (40%) or primary resistance (55%). The probability of obtaining a CCyR and MMR after change were 75% and 45%, respectively.
Survival outcomes: PFS and OS were not significantly different across the 10% threshold at 3 months,(91,6 *vs* 92,5%) and (93,5 *vs* 02,8%) by 7 years, respectively (Figure 1.)

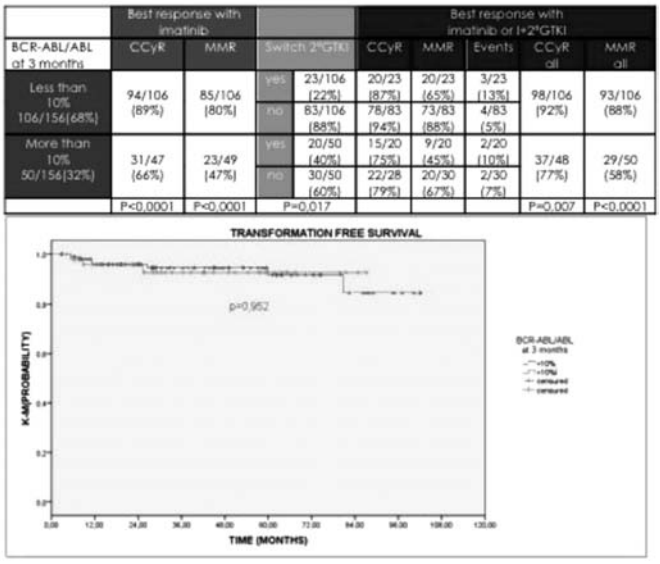

Figure 1.

Summary and Conclusions: In the setting of a multicentric, hospital based registry, only 42% of the CML patients treated with imatinib frontline were molecularly evaluated. The 10% BCR-ABL ratio threshold at 3 months discriminates the probability of obtaining CCyR and MMR thereafter, not only with imatinib, but with sequential TKI therapy. Although the reasons for changing to a 2GTKI in patients having £10% and >10% ratio differ, the improvement is small, and confined to cytogenetic response, whereas molecular response is not increased. But the proportion of transformation or death was not increased in any of the groups.

P721

CLINICAL AND BIOLOGICAL FEATURES OF BLAST CRISIS (BC) IN PATIENTS WITH PH+ CHRONIC MYELOID LEUKEMIA (CML) IN THE TKIS ERA: EXPERIENCES IN CLINICAL PRACTICE

A Rossi[1,*], N Sgherza[1], L Luciano[2], P Pregno[3], M Breccia[4], F Stagno[5], B Martino[6], P Casieri[1], G Specchia[1]
[1]Hematology-University of Bari, Bari, [2]Hematology-University of Naples, Naples, [3]Hematology-A.O. Città della Salute e della Scienza di Torino, Turin, [4]Hematology- La Sapienza University-Rome, Rome, [5]Hematology-Ferrarotto Hospital, Catania, [6]Hematology-Bianchi-Melacrino-Morelli Hospital, Reggio Calabria, Italy

Background: Although TKIs have dramatically changed the outcome of CML, and despite improved knowledge of their biological and molecular mechanisms, the pathogenic processes and best treatment of the CML blast phase are still poorly understood. Most data on the use of Imatinib in patients with newly diagnosed Ph+CML are derived from results of the IRIS study: estimated 08-year rate of freedom from progression to accelerated phase (AP)/blast crisis (BC) was 92%. Data on the use of Nilotinib and Dasatinib in patients with newly diagnosed Ph+ CML are derived from results of the ENESTnd study [estimated 4-year rate of freedom from progression to AP/BC was 98.2% or 97.1% including clonal evolution] and from results of the DASISION study [estimated 3-year rate of freedom from progression to AP/BC was 97% or 95.8% including follow up beyond discontinuation]. Progression to BC seems to depend on genomic instability, resulting in an accumulation of additional genetic changes which lead to loss of differentiation and to a more aggressive clinical presentation.
Aims: Herein, we report clinical and biological features of a subset of patients who developed BC in the TKIs era.
Methods: We retrospectively evaluated 1100 patients (pts) with newly diagnosed Ph+CML receiving TKIs as first-line therapy, observed between January 2001 and December 2012; none of them had received prior therapies including Interferon before starting on TKIs and 33 of them (3%) developed BC.
Results: Sokal risk evaluation at the time of diagnosis of CML showed that 48.5% of patients were high risk, 24.3% intermediate and 27.2% low risk. With the EUTOS revised risk score 90% of patients were low risk and 10% high risk, so in this cohort of CML patients the EUTOS score appeared to have a low correlation with the risk of evolution to BC. Apart from one patient with a complex karyotype, all patients displayed the classic t(9;22) Ph chromosome according to standard cytogenetics. The BCR/ABL transcript at RT-PCR was b3a2 in 25 patients (76%) and b2a2 in 8 patients (24%). Median duration of the chronic phase was 15 months (range 4-144 months) and median time to best Cytogenetic Response (CyR), including minimal, minor, partial and complete CyR, was 8 months (range 3-32). Morphologic and flow cytometry characterization of BC revealed a myeloid subtype in 22 patients (67%) and lymphoid subtype in 11 patients (33%). BC was sudden in 3 patients (9%). Standard cytogenetics at the onset of BC revealed clonal chromosome abnormalities in 10 patients (10%). Three patients presented evidence of extramedullary disease. Nineteen patients were screened for mutational analysis and mutations were found in 8 of them (M318T, E255K(2), T315I(3), E359I, E279K). BC developed during imatinib therapy in 11 pts (34%), during dasatinib therapy in 16 pts(48%) (1 in first line, 12 in second line, 3 in third line), during nilotinib therapy in 6 pts (18%) (2 in first line, 3 in second line, 1 in third line). BC occurred in the first year of treatment with TKI in 15 pts (45%) and in the second year in 7 (21%). At the time of this report, after 112 months follow-up, 7 pts (21%) were alive (5 pts after HSCT) and 26 pts (79%) had died of disease progression, overall median survival being 19 months (range 1-112).
Summary and Conclusions: BC is a generally rare but possibly lethal phase that can develop in patients with CML. Further clinical and biological features should be considered for the purposes of early identification of patients at high risk of progression to BC.

P722

REVERSIBLE LYMPH NODE FOLLICULAR HYPERPLASIA ASSOCIATED WITH DASATINIB TREATMENT FOR CHRONIC MYELOID LEUKAEMIA IN CHRONIC PHASE

C Roux[1,*], F Nicolini[2], D Rea[3], M Niault[4], L Mollica[5], F Berger[6], C Chassagneclement[7], I Tigaud[8], P Rousselot[9], L Legros[10]
[1]Hematologie, Groupe Hospitalier Archet 1 et2, Nice, [2]Hematologie Clinique, Centre Hospitalier Lyon Sud,Pierre Benite, lyon, [3] Service des Maladies du Sang et Unité de Thérapie Cellulaire, Hopital Saint-Louis, Paris, [4]Hématolgie, CH Bretagne-Sud, Lorient, France, [5]Hematologie, Maisonneuve Rosemont Hospital, Montreal, Canada, [6] Anatomie et de Cytologie Pathologiques, Centre Hospitalier Lyon Sud, [7]Anatomie et de Cytologie Pathologiques, Leon Berard, [8]Laboratoire Hématologie, cytogénétique, Lyon, [9]Hematologie, Université de Versailles, Saint-Quentin-en- Yvelines, Le chesnay, [10] Hematologie, Groupe Hospitalier Archet 1 et2, Nice, France

Background: Dasatinib is a second generation dual SRC/ABL tyrosine kinase inhibitor (TKI) licensed in the treatment of chronic-, accelerated-, and blast-phase chronic myeloid leukaemia (CML). There is strong evidence suggesting that dasatinib exerts substantial cellular immunomodulatory effects both *in vitro* and *in vivo*.
Aims: We report on 6 chronic phase (CP)-CML patients who developed follicular lymphoid hyperplasia (FLH) apparently caused by dasatinib, a previously unreported adverse drug reaction.
Methods: Cases of FLH observed in CML patients treated with dasatinib were collected in a retrospective fashion among centers from the Fi-LMC group.
Results: All patients (3 males, 3 females) were diagnosed CP-CML. Sokal scores were low in 2 patients, intermediate in 1 patient, and high in 3 patients. Median age at FLH diagnosis was 49 years (range: 24-70). Dasatinib was given frontline (OPTIM dasatinib trial, n=2), after intolerance (n=1) or suboptimal response/resistance (n=2) to imatinib, or in the setting of a molecular relapse following an imatinib discontinuation attempt (n=1). Patients received dasatinib at 50mg/d (n=1) or 100 mg/d (n=5). Patients all presented with progressive cervical lymph node enlargement after a median duration of dasatinib treatment of 14 months (range: 9-32 months). At the time of lymph node enlargement discovery, 5 patients were in complete cytogenetic response (3 associated with a MMR) and 1 had no cytogenetic response. In 4 patients, exploration for viral infection (VIH, EBV, CMV, Parvovirus B19) failed to show any active viral replication. Search for toxoplasma gondii replication (performed in 2 patients) was negative. In 4 patients, autoantibodies assay was not in favor of autoimmune disorders. Chest, abdomen and pelvis tomodensitometry confirmed the absence of additional localizations. All patients underwent a lymph node biopsy and pathological analysis revealed FLH. FLH was characterized by an enlargement of lymph nodes with follicular (germinal) centers hyperplasia related to B lymphocytes-stimulation. Extramedullary blastic transformation of underlying CML was formally ruled out. Lymphocytes were CD10+, CD20+, and Bcl2. Complex chromosomal abnormalities without the Philadelphia chromosome (46XY,add(1)(q41),der(14)t(1;14)(q24;q32)) were identified in 1 patient, in association with a DJ-JH rearrangement, but no Igh/Bcl2 rearrangement. The occurrence of FLH under continuous dasatinib therapy in the absence of any sign of viral activation or autoimmune disease led to raise the hypothesis of a drug-induced adverse event. Dasatinib was thus discontinued in all patients, leading to a complete disappearance of node enlargement within a median time of 1 month (range: 15 days-2 months)
Summary and Conclusions: By targeting not only BCR-ABL but also SRC-family kinases, which are critical regulators of cell signaling in B-cells, dasatinib may be accompanied with off-target immune effects in CML. SRC targeting might have triggered FLH in our series. Studying the mechanisms by which dasatinib induces FLH such as abberant B-cell stimulation by activation of downstream AKT signaling pathway through SRC inhibition is warranted. Considering clonal cytogenetic abnormalities observed in 1 patient, further transformation into malignant B-cell lymphoma may not be ruled out. We thus recommend immediate dasatinib discontinuation in case of FLH associated with dasatinib in the absence of any other cause. The risk of developing dasatinib-associated FLH should now be assessed prospectively.

P723

MMR AND CMR IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS: ROLE OF SOKAL SCORE AND DIFFERENT TYROSINE KINASE INHIBITORS ON TIME OF THEIR OBTENTION, MAINTENANCE AND FAILURE-FREE SURVIVAL

M Michallet[1,*], H Labussière[1], M Sobh[1], S Morisset[1], M Detrait[1], M Etienne[1], S Ducastelle[1], F Barraco[1], Y Chelghoum[1], X Thomas[1], O Le borgne[1], I Tigaud[1], S Hayette[1], F Nicolini[1]
[1]Hematology, Centre Hospitalier Lyon Sud, Pierre Bénite, France

Background: Most patients with CML treated with Tyrosine Kinase Inhibitors (TKIs) achieve a major molecular response (MMR), that is, the absence of detectable Ph chromosomes. Even after this threshold is achieved, the disease burden continues to progressively decrease with continued treatment. Therefore, more sensitive polymerase chain reaction (PCR)–based molecular methods are required to detect and quantify levels of minimal residual disease leading to complete molecular response (CMR), especially at long time points after TKI initiation. Low levels of minimal residual disease, as measured by real-time quantitative PCR, have been shown to be an excellent surrogate marker for long-term prognosis.
Aims: Our main objective in this study was to describe the different treatments and factors involved in the first MMR occurence in chronic phase CML, its maintenance, and its conversion to CMR.
Methods: We analyzed 211 CML patients [124 males and 87 females; median age: 50 years (17-81)] in first chronic phase who received tyrosine-kinase inhibitors (TKI) followed at our institution between 2001 and 2011. Among 196 patients evaluated for Sokal score, 79 (40%) were low, 82 (42%) were intermediate and 35 (18%) were high. According to hasford score (153 evaluated), 46% were low, 46% intermediate and 8% were high.
Results: First MMR was obtained in: 61% of patients after first line treatment [Imatinib, n=102; Imatinib+Peg-interferon, n=11; Dasatinib, n=10; Nilotinib, n=6]; 26% after second line [Imatinib, n=32; Dasatinib, n=11; Nilotinib, n=12] and 13% beyond second line [Imatinib, n=14; Dasatinib, n=7; Nilotinib, n=6]. The median time of MMR obtention was 15 months (2.5-94) after Imatinib, 6.4 months (3-24) after Imatinib+Peg-interferon, and it was significantly shorter after both Dasatinib [HR=2.6 (1.7-3.9), P<0.001] and Nilotinib [HR=3 (1.8-5), P<0.001] with 6 months (3-23) and 5 months (3-56) respectively no matter the treatment line number was. Sokal score was an independent significant factor that impacted MMR obtention delay, with a median time of 9 months (2.5-98) for low score, 13 months (3-78) for intermediate [HR=0.7 (0.5-0.9), P=0.03] and 12 months (3-94) for high score [HR=0.7 (0.5-1.02), P=0.05]. Patients who converted to CMR were: 50 (34%) under Imatinib after a median time of 25 months (3-97); 7 (64%) under Imatinib+Peg-interferon after a median time of 8 months (3-15); 10 (42%) under Nilotinib after 25 months (13-32) and the only significant faster treatment was Dasatinib [n=13 (46%)] after a median time of 11 months (3-52) [HR=2.1 (1.1-4.2), P=0.02]; according to Sokal score, low (n=41, 52%) and intermediate (n=27, 33%), while patients with high score (n=11, 31%) were significantly slower [HR=0.53 (0.25-1), P<0.001]. The current rate of CMR at 5 years was not statistically different between the treatments [Imatinib (36%), Imatinib+Peg-interferon (40%), Nilotinib (43%), Dasatinib (56.5%)] nor according to sokal score [Low (49%), intermediate (43%) and high (40%)]. Treatment was discontinued in 42 patients who had 5 years failure-free survival of 56% (43-73) while patients under Dasatinib, Imatinib+Peg-interferon, Imatinib, and Nilotinib had 70.5% (50-99), 79% (56-100), 84% (77-91) and 93% (84-100) respectively.
Summary and Conclusions: Second generation TKI used at 1st, 2nd line treatment or beyond, showed an independent significant faster time to MMR, as well as patients with low sokal score. Conversion to CMR was significantly faster only in Dasatinib patients and slower in patients with intermediate and high sokal score. Treatment discontinuation did not have a benefit in terms of FFS while patients on TKI therapy seem to have better result.

P724

KIR HAPLOTYPE AA IS A POSSIBLE PREDICTIVE MARKER OF COMPLETE MOLECULAR RESPONSE TO TYROSINE KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

G Caocci[1,2,*], G Nasa[1,2], R Littera[3], S Atzeni[1], A Vacca[1], O Mulas[2], M Langiu[1], M Greco[1], S Orrù[4], N Orrù[3], M Usai[2], A Floris[4], C Carcassi[3,4]
[1]Bone Marrow Transplant Center, R. Binaghi Hospital - ASL8, [2]Hematology Unit, Department of Medical Sciences "Mario Aresu", University of Cagliari, [3]Regional Transplant Center, R. Binaghi Hospital - ASL8, [4]Medical Genetics, Department of Medical Sciences "Mario Aresu", University of Cagliari, Cagliari, Italy

Background: One of the most intriguing challenges in the management of patients with chronic myeloid leukemia (CML) is to decide for how long it is necessary to continue therapy with tyrosine kinase inhibitors (TKI). Although maintenance therapy with imatinib or a second generation TKI may be well tolerated, in many patients it has been associated with compromission of quality of life and reduced compliance.
Aims: In the literature, a growing amount of evidence suggests that killer immunoglobin-like receptors (KIR) could have a role in the development of chronic myeloid leukemia (CML) and response to therapy. This prompted us to investigate the prognostic and/or predictive role of KIRs and their human leukocyte antigen (HLA) Class I ligands in a cohort of 59 chronic-phase CML patients (mean age 53, range 23-81) and a group of 121 healthy controls.
Methods: The large majority of patients received frontline treatment with imatinib (59.3%), nilotinib or dasatinib (10.2%). Patients presenting side effects or inadequate response (25%) were moved to second line TKI therapy. Complete molecular response (CMR) was defined as repeatedly negative results on real-time quantitative polymerase chain reaction assay.
Results: The 2-year cumulative incidence rate for CMR was 51.2%. An increased frequency of the activating receptor KIR2DS1 (P=0.05) and a reduced frequency of the KIR-ligand combination KIR2DS2/KIR2DL2 absent/C1 present (P=0.001) were found associated with an unfavourable prognosis. Analysis of response to TKI treatment, revealed a positive association between CMR and a decrease in the frequency of the KIR2DL2 inhibitory gene (P=0.02), homozygosity for KIR haplotype A (P=0.01) and low numbers of inhibitory KIR genes (P=0.05).
Summary and Conclusions: It is well known that natural killer (NK) cell cytotoxicity is regulated through a balance of both activating and inhibitory KIR signals. Our data suggest that impairment in this delicate balance may lead to NK cell deficiency and thus contribute to the occurrence of CML. It is also possible that genetic imbalance between activating and inhibitory KIR genes limits recruitment of cells from the bone marrow niche, including mesenchymal stromal cells (MCS) which have a tendency to inhibit innate and adaptive immune response of a variety of cells interacting with NK cells. However, these hypotheses will need to be confirmed in larger cohorts of CML patients. What clearly emerges from our study is the potential value of KIR haplotype AA as a marker of durable CMR which, combined with the other factors capable of predicting cure of CML, should help us decide which patients are candidates for stopping TKI therapy (Figure 1).

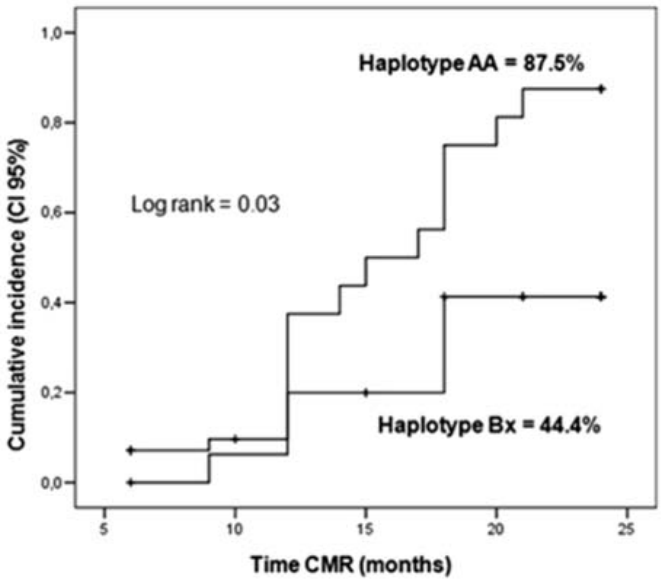

Figure 1.

P725

THE POSSIBLE PREDICTIVE ROLE OF THE IMATINIB PLASMA LEVELS AND POLYMORPHISMS ASSESSMENT IN PATIENTS AFFECTED BY CHRONIC MYELOID LEUKEMIA. THE TIKLET STUDY.

S Galimberti[1,*], M Polillo[2], M Capecchi[1], G Cervetti[1], C Baratè[1], G Fontanelli[1], R Arici[1], F Guerrini[1], R Danesi[2], M Petrini[1], A Di Paolo[2]
[1]Clinical and Experimental Medicine - Hematology, [2]Clinical and Experimental Medicine -Clinical Pharmacology, University of Pisa, Pisa, Italy

Background: Major advantages of tyrosine kinase inhibitors (TKis), that changed the natural history of CML, are represented by high efficacy, oral administration of a standard daily dose and good tolerability. Moreover, the highest therapeutic benefit is expected when minimal plasma concentrations (Cmin) of imatinib are ≥900-1000 ng/mL. However, imatinib pharmacokinetics (PK) is influenced by several physiological, pathological, and pharmacogenetic factors (polymorphisms of transmembrane transporters), in addition to a possible poor adherence.
Aims: 1) Application of a therapeutic monitoring protocol for imatinib in order to evaluate its PK characteristics. 2) analysis of polymorphisms of gene controlling influx, efflux, and metabolism of imatinib. The TIKlet study was approved by the Pisa University Hospital Ethics Committee (ref. n. 46013, 08/01/2011).
Methods: Sixty-two patients, 35 men and 27 women affected by CML and treated with imatinib were enrolled. A commercially-available HPLC assay kit (Chromsystems, Munich, Germany) was used. A population PK analysis was performed based on values of imatinib plasma concentrations according to a nonlinear mixed-effects modeling approach, using the NONMEM software, version 7.1. Dataset checkout, model diagnostic and covariate testing were performed using Xpose and PsN softwares. The area under the plasma concentration-time curve from time zero up to infinity (AUC0to∞), terminal elimination half-life (t1/2) and minimum plasma concentration at steady state (Cmin,ss) were calculated. After DNA extraction, polymorphisms of the following genes have been assessed by real-time PCR; ABCB1, ABCG2, CYP3A4, CYP3A5, CYP2D6, hOCT1, OCTN1, and OATP1A2.
Results: After at least 3 determinations/patient, the average of imatinib Cmin was 1064±280 ng/mL, and the median value 1039 ng/mL. About 25% of patients showed Cmin<817 ng/mL. In the PK model, age, sex, height, weight, body mass, alpha1-acid-glycoprotein, smoking, renal and hepatic parameters were inserted and data were analysed on the basis of the interval between the last dose and the blood harvest. Only the alpha1-acid glycoprotein significantly correlated with imatinib plasma levels. The therapeutic effect of imatinib in terms of time to major molecular response (MMR) was analysed. Results demonstrated that patients with higher imatinib exposure (upper quartile distribution) achieved an earlier (but not statistically significant) MMR with respect those subjects who were characterized by lower drug plasma concentrations. On the other hand, values >1390 ng/mL resulted to significantly impact on the observed grade 3-4 toxicities. The introduction of hOCT1 c.480C>G polymorphism into the final model led to a significant decrease in interindividual variability in the apparent clearance of imatinib. In particular, imatinib clearance was significantly higher in patients homozygous for the wild-type C allele (12.2+/-2.3 L/h) with respect to other patients (9.4+/-1.6 L/h).
Summary and Conclusions: The present results confirm that variability of imatinib pharmacokinetics is not negligible among CML patients. The present PK model is characterized by a good performance, allowing the prediction of Cmin in the present patients regardless the time of blood withdrawal.
Finally, results from the present study suggest that patients' genotype with respect to the hOCT1 c.480C>G SNP may predict imatinib clearance.

P726

EUTOS CML PROGNOSTIC SCORING SYSTEM PREDICTS ELN-BASED EVENT-FREE SURVIVAL BETTER THAN EURO/HASFORD AND SOKAL SYSTEMS IN CHRONIC PHASE CML PATIENTS RECEIVING FRONTLINE IMATINIB MESYLATE

N Sayınalp[1,*], İ Haznedaroğlu[1], O Özcebe[1], B Uz[1], Y Buyukasik[1], H Atay[2], E Kelkitli[2], H Goker[1], S Aksu[1], M Turgut[2]
[1]Adult Hematology, Hacettepe University, Ankara, [2]Adult Hematology, Samsun University, Samsun, Turkey

Background: The validity of the three currently used chronic myeloid leukemia (CML) scoring systems (Sokal CML prognostic scoring system, Euro/Hasford CML scoring system, and the EUTOS CML prognostic scoring system) were compared in the CML patients receiving frontline imatinib mesylate.
Aims: The aim of this study was to perform a comparative assessment of the Sokal CML prognostic scoring system, Euro/Hasford CML scoring system, and the EUTOS CML prognostic scoring system in the CML patients receiving frontline imatinib mesylate. Validation of the novel EUTOS system is important for the clinical management of CML patients since there are some contradictions and discrepancies in the literature regarding the power of EUTOS score in CML.
Methods: One hundred and fourty-three chronic phase CML patients (71 males, 72 females) taking imatinib as frontline treatment were included in the study. The median age was 44 (16-82) years. Median total and on-imatinib follow-up durations were 29 (3.8-130) months and 25 (3-125) months, respectively.
Results: The complete hematological response (CHR) rate at 3 months was 95%. The best cumulative complete cytogenetic response (CCyR) rate at 24 months was 79.6%. Euro/Hasford scoring system was well-correlated with both Sokal and EUTOS scores (r=.6, P<0.001 and r=0.455, P<.001). However, there was only a weak correlation between Sokal and EUTOS scores (r=.2, P=.03). The 5-year median estimated event-free survival for low and high EUTOS risk patients were 62.6 (25.7-99.5) and 15.3 (7.4-23.2) months, respectively (P<.001). This performance was better than Sokal (P=.3) and Euro/Hasford (P=.04) scoring systems. Overall survival and complete cytogenetic response rates were also better predicted by the EUTOS score.
Summary and Conclusions: EUTOS CML prognostic scoring system, which is the only prognostic system developed during the imatinib era, predicts ELN-based EFS better than Euro/Hasford and Sokal systems in CML patients receiving frontline imatinib mesylate. This observation might have important clinical implications.

Background: The introduction of the tyrosine kinase inhibitor (TKI) imatinib

about a decade ago dramatically extended the life span of chronic myeloid leukemia (CML) patients. Currently, there are several different TKIs approved for CML treatment. Long-term effectiveness and safety data for second-generation TKIs are not yet available. Despite this uncertainty about long-term effects, patients and physicians have to choose a first-line therapy.
Aims: The goal of this study is to develop a clinical decision-analytic model for the evaluation of the long-term effectiveness of different first-line therapy regimens for patients with CML.
Methods: We developed a Markov state-transition computer model for patients in the chronic-phase of CML treated with first-line TKI imatinib, dasatinib or nilotinib. Seven different strategies including different combinations of first and second-generation TKIs as well as chemotherapy or stem cell transplantation were evaluated. The model was parameterized using published trial data, data from the Austrian CML registry, and practice patterns estimated by an expert panel. (1-11). The model was analyzed as a cohort simulation over a lifelong time horizon. Health outcomes evaluated were life-years (LYs) gained and quality-adjusted life years (QALYs) gained. Several deterministic sensitivity analyses were performed.
Results: Nilotinib followed by dasatinib after failure is the most effective treatment in terms of both, remaining LYs (19.7 LY) and QALYs (17.1 QALYs). All strategies including a second-line TKI were superior compared to strategies without second-line TKI. Deterministic sensitivity analyses showed that the ranking of the strategies was mostly influenced by the duration of first- and second-line therapies.
Summary and Conclusions: Based on our clinical decision analysis, the most clinically effective strategy is first-line treatment with nilotinib followed by dasatinib as second-line therapy. As all three TKIs are approved as first-line therapy, our results may support clinicians and patients in their decision making regarding the sequential application of TKIs.
Acknowledgement: This work was supported by the COMET Center ONCOTYROL, which is funded by the Austrian Federal Ministries BMVIT/BMWFJ (via FFG) and the Tiroler Zukunftsstiftung/Standortagentur Tirol (SAT).

Myelodysplastic syndromes - Clinical 2

P728

BONE MARROW IMAGING OF HUMERAL AND FEMORAL MARROW BY MULTI-DETECTOR COMPUTED TOMOGRAPHY IN PATIENTS WITH APLASTIC ANEMIA AND HYPOPLASTIC MDS

T Ugai[1,*], K Tsuda[2], H Sugihara[2], Y Nishida[2], M Yamakura[2], M Takeuchi[2], K Matsue[2]
[1]Hematology, Jichi University Saitama Medical Center, Saitama, [2]Hematology, Kameda Mdical Center, Kamogawa, Japan

Background: Myelodysplastic syndrome (MDS) and aplastic anemia, a heterogeneous group of bone marrow disorders, are characterized by ineffective hematopoiesis with or without bone marrow dysplasia. It is often difficult to distinguish myelodysplastic syndrome (MDS) from severe aplastic anemia because both can present with profoundly hypocellular bone marrows.Multidetector CT (MDCT) of the humeral and femoral is a sensitive method for evaluating patients with bone marrow disorders that provides a better understandings of disease progression and remission.
Aims: In this study, we analysed the difference between the abnormalities by MDCT in patients with aplastic anemia and hypoplastic MDS. We also analysed the relationship between the abnormalities by MDCT and the development of leukemia and survivals of patients with MDS.
Methods: We evaluated MDCT of the humeral and femoral in 64 untreated adult patients with aplastic anemia (N=15) and MDS (N=49). We performed a retrospective chart review of hematologic and cytogenetics features, such as haemoglobin, platelets, bone marrow blast, poor cytogenetics, International Prognostic Scoring System (IPSS). Patients with MDS were classified according to WHO classification; RA (N=17), RARS (N=2), RCMD (N=9), RAEB (N=19) and MDS unclassified (N=2). Overall survival and leukemia-free survival were analyzed in 49 MDS patients by the Kaplan-Meier method and differences between curves were calculated by two-sided log-rank test. A multivariate analysis was performed to assess the impact of various prognostic factors including haemoglobin, platelets, bone marrow blast, poor cytogenetics, IPSS, WHO classification and MDCT patterns. Non-enhanced CT examinations were performed in supine position from the base of skull down to the knee joint by MS-CT scanner (AQUILION 64, Tohshiba, Tokyo, Japan). Images were reconstructed by medium smooth convolution kernel (B50f). Bony canal of humeral and femoral bone were visualized by coronal and sagittal axis image reconstruction. The effective radiation dose associated with whole body MD-CT was 10.1 mSv. (International Comission on Radiological Protection (ICRP) 26) The dose was comparable to whole body CT (2.4 mSv.).Bone marrow CT density was measured and results were expressed as Hounsfield unit (HU). As the normal adult bone marrow was composed of rich adipocytes and called yellow marrow, it is represented by low density CT value between -30 to -100 HU. The value above -30 HU observed in long bony canals was considered as high density lesions. The results of MDCT were evaluated by two observers, and the general patterns were categorized as follows: (1) fatty, showing a low signal density marrow on CT images; (2) focal, showing abnormally focal high density lesions: (3) diffuse, showing uniformly high density marrow.
Results: All 15 patients with aplastic anemia showed a fatty or focal pattern on their MDCT. No patients with aplastic anemia showed diffuse patterns. Meanwhile, among the 49 patients with MDS, 15 patients had fatty pattern, 21 patients had focal patterns,and 13 patients had diffuse pattern. This result indicate that diffuse patterns of MDCT support the diagnosis of MDS rather than aplastic anemia.Among the 12 patients who had diffuse patterns on MDCT, 6 patients developed acute myeloid leukemia. Leukemia free survival of 12 patients with diffuse patterns was significantly shorter than that of the 36 patients with fatty and focal patterns. (74% *vs* 29% at 3 years, P<0.01) Similarly, the overall survival was significantly shorter. (79% *vs* 40% at 3 years, P<0.01) On multivariable analysis, diffuse pattern on MDCT was emerged as independently negative prognostic predictors for PFS and OS in patients with MDS.
Summary and Conclusions: This study indicated that MDCT of the humeral and femoral is an important tool for the accurate diagnosis of patients with MDS and aplastic anemia. MDCT can also provide valuable information for assessment the prognosis and determining the most appropriate management with MDS.

P729

A CROSS-SECTIONAL ANALYSIS ON DEMOGRAPHICS AND POSSIBLE CAUSES OF ANEMIA IN THE ELDERLY

R Stauder[1,*], V Bach[1], G Schruckmayer[1], I Sam[1], G Kemmler[2]
[1]Medical University Innsbruck, Department of Internal Medicine V (Haematology and Oncology), [2]Department of Biological Psychiatry, Innsbruck Medical University, Innsbruck, Austria

Background: Late-life anemia is associated with increased morbidity and mortality.

Aims: To provide data on the demographic distribution and possible causes of anemia in the elderly.
Methods: Laboratory values from 19758 patients 64+ years treated at Innsbruck Medical University from 1.10.2004 to 29.9.2005 were analyzed (10917 women; 8841 men; median age 75 and 72 yrs, respectively; 10737 outpatients, 9021 inpatients).
Results: 19.3% of women and 23.4% of men suffered from anemia according to WHO criteria. In anemic patients, as compared to non-anemic patients, a decreased GFR <60 and <30mL/min/1.73m² (MDRD1 analysis) was observed in 45.1% (28.9%) and in 11.3% (2.1%), signs of inflammation as defined by elevated C reactive protein in 62.1% (31.4%), folic acid deficiency in 6.7% (3.0%), iron deficiency as defined by serum ferritin <30ng/mL in 14.4% (6.9%) and functional iron deficiency as defined by transferrin saturation <16% and serum ferritin <100 ng/mL in 22.1% (6.5%) of cases (P<0.001). Mean corpuscle volume (MCV) was seen to be weakly correlated with the various anemia subtypes, with normocytic anemia constituting the largest group. Macrocytic alterations without evidence for vitamin B12 or folic acid deficiency were observed in 16.4%, thrombopenia <100 G/l in 5.4% and leucopenia <4 G/l in 8.26% or <2 G/l in 1.1% of anemic cases, thus suggesting a Myelodysplastic Syndrome(MDS).
Summary and Conclusions: Anemia in the elderly is frequent in patients admitted to the hospital as well as in outpatients. Nutritional anemia, for which a specific treatment is available, is found in a relevant proportion of patients. In the majority of anemic elderly the pathogenesis of anemia is complex and includes a mixture of different causes including chronic inflammation and renal insufficiency. In a relevant proportion a hitherto undiagnosed Myelodysplastic Syndrome can be assumed.

P730

BONE MARROW SCREENING FOR MYELODYSPLASIA-RELATED CHANGES AND ABERRANT LYMPHOID POPULATIONS USING ONE TUBE, FOURTEEN ANTIBODY-TEN COLOR FLOW CYTOMETRY PANEL
A Porwit[1,*], A Rajab[1], A AlSamman[1]
[1]Laboratory Medicine Program, University Health Network, Toronto, Canada

Background: Hematopathology laboratories often receive bone marrow (BM) samples from patients with cytopenia and no history of lymphoma or lymphocytosis, to investigate for both lymphoproliferative disorders and myelodysplastic syndromes (MDS). Flow cytometry (FCM) is a vital part of the integrated hematopathological diagnostics. However, large multicolor panels may be impossible to apply in times of economic constraints. Previous multinational study has applied a FCM score for MDS based on 4 parameters: CD34+ myeloblast and B-progenitor cluster size, myeloblast CD45 expression, and granulocyte/lymphocyte side scatter (SSC) value and reported that FCM score 2 or higher is suggestive of MDS (Della Porta *et al.*, Hematologica, 2012;97:1209).
Aims: To establish and validate an FCM antibody panel that would provide maximum immunophenotyping information on main lymphoid and myeloid cell subsets and also the FCM MDS score.
Methods: 14 monoclonal antibodies - 10 fluorochrome panel was applied: kappaFITC+CD4 FITC, LambdaPE+CD8 PE, CD3ECD+CD14 ECD, CD34 APC, CD20PC7+CD56 PC7, CD10 APC-A750, CD19 APC-A700, CD33 PC5.5, CD5 PB, and CD45 KO. This panel was accredited according to the Ontario Laboratory Accreditation requirements.
Analysis is illustrated in Figure 1. Various cell subpopulations were mapped on CD45/SSC plot (A). B-cells were gated on CD19/SSC plot (B). Kappa to lambda ratio was determined within the total B-cell population (C), CD10+ B-cells (D,E), and CD5+ B-cells (F,G). B-cell maturation pattern was evaluated using CD20 *vs.* CD10 expression (D). CD34+ cells were enumerated and fractions of myeloid and lymphoid CD34+ progenitors were dsetermined on CD19/CD33 plot (H,I). CD4+ and CD8+ T-lymphocyte subsets were enumerated after gating of CD3+ T-cells on SSC/CD3+CD14ECD plot (J,K). CD14+ monocytes were also counted (J). CD56+ NK cells were counted using CD3 v. CD20+CD56 plot after B-cells were removed from analysis using Boolean gating strategy (L). Maturation of granulopoietic and monocytic cells was studied using CD33 *vs.* CD14 and CD33 *vs.* CD10 expression (M,N). CD56 expression in non-lymphoid populations was investigated (not shown). MDS score was determined (Figure 1) using CD34+ myeloblast and CD34+ B-progenitor cluster size (O,P), myeloblast *vs.* lymphocyte CD45 expression (S,T), and granulocyte *vs.* lymphocyte SSC value (R). Results of MDS score were correlated with morphological and cytogenetic evaluation of BM samples in a selected group of 70 patients with full clinical information.
Results: In 13 of 226 studied BM samples (5.7%), a minor monotypic B-cell population was detected corresponding to previously undetected lymphoproliferative disorder or monoclonal B-cell lymphocytosis. All but one of 21 reactive BM samples had MDS score<2 (95%). Of 24 patients with cytopenia but no MDS, 7 (29%) had score 2. MDS score above 2 was not found in these groups. 22 of 35 (63%) patients where morphology, cytogenetic and clinical findings were consistent with myelodysplasia, had score 2 or higher. Differences in scores between the latter and two other groups were statistically significant (P<0.0001).

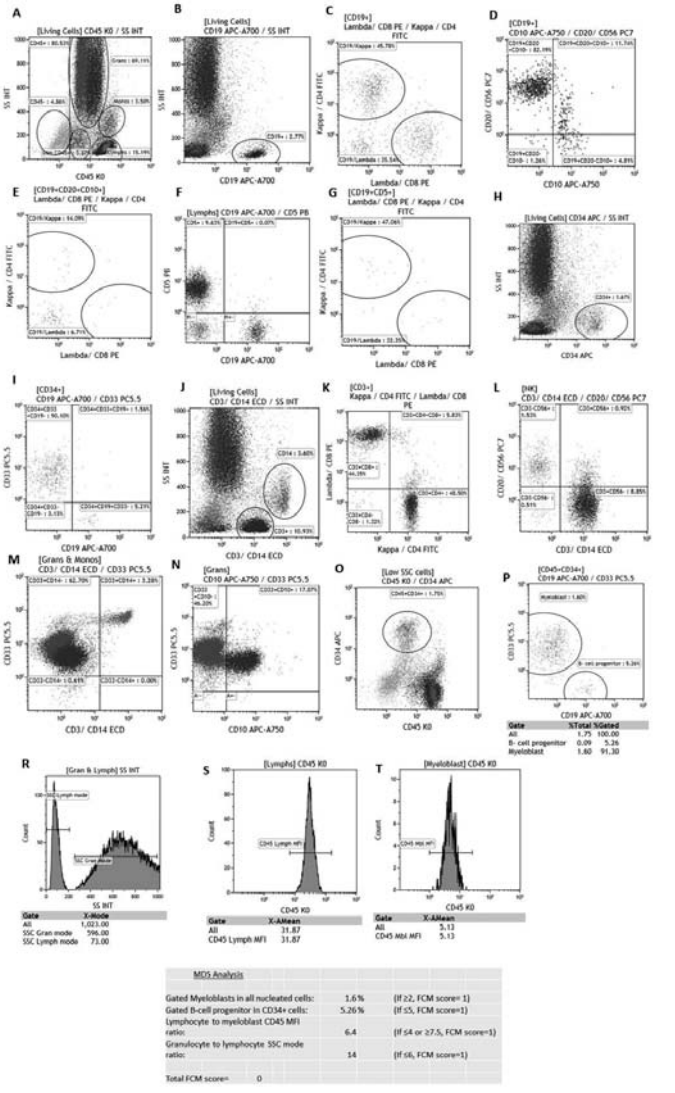

Figure 1.

Summary and Conclusions: Developed 14 antibody 10-color FCM panel is easy to apply for screening BM samples for aberrant lymphoid populations and to establish MDS FCM score. Our results confirm the previous reports that FCM score ≥2 should prompt further investigation for myelodysplastic syndrome. However, FCM score 2 has also been found in patients with cytopenia of other origin. Also, FCM score 2 or lower did not exclude possibility of MDS.

P731

PLATELET COUNT AND TRANSFUSION-DEPENDENCY AFFECT OVERALL SURVIVAL IN PATIENTS WITH REFRACTORY ANEMIA WITH RING SIDEROBLASTS AND THROMBOCYTOSIS (RARS-T)
G Kaufman[1,*], D Chen[2], C Hanson[2], M Elliott[3], A Wolanskyj[3], W Hogan[3], M Patnaik[3], M Litzow[3], A Tefferi[3], A Al-Kali[3]
[1]Internal Medicine, [2]Hematopathology, [3]Hematology, Mayo Clinic, Rochester, United States

Background: Among the overlap myelodysplastic/myeloproliferative disorders, refractory anemia with ring sideroblasts and thrombocytosis (RARS-T) exists as a rare and provisional entity first defined in 2001 by the World Health Organization (WHO). Limited data exist on the impact of various clinical characteristics on patients' morbidity and overall survival (OS). Thus, in contrast to myelodysplastic syndromes (MDS) and myeloproliferative neoplasms (MPN) there is no validated prognostic model for RARS-T.
Aims: To evaluate clinical prognostic models for patients (pts) diagnosed with RARS-T.
Methods: A retrospective chart review of all pts diagnosed with WHO-defined RARS-T at Mayo Clinic Rochester between 2001 and 2013 was done. All demographic and clinical information including age, gender, hematological labs, and bone marrow biopsy results were obtained from medical records. IRB approval

was obtained in accordance with the Helsinki declaration. Comparison between medians was done using Wilcoxon test, between two groups using the t-test, and survival calculations per Kaplan-Meier estimates was done with JMP v.9.
Results: Nineteen pts meeting WHO criteria for RARS-T (with platelets >450×10^9/L) were identified. Median age at diagnosis was 72 years, 58% of pts were male. Median follow up was 367 days (range, 2-1815), hemoglobin 9.5 mg/dL, and platelets were 642×10^9/L (range, 470-1465). Eighty-three percent had diploid cytogenetics, median ring sideroblasts (RS) in the marrow were 50% (range, 20-90%). Out of 13 pts tested, JAK2V617F mutation was positive in 62%. Fifty-three percent of pts received exogenous erythropoietin, 37% received hydroxyurea and 16% received lenalidomide. All 3 pts who had lenalidomide responded with hematological improvement (at 6 and 11 months of therapy), and one had complete remission (at 6 months of therapy). Only 1 pt (5%) had a thrombotic event (myocardial infarction). Median overall survival was not reached, without anyone progressing to acute leukemia. JAK2V617F positivity in pts was associated with higher platelet count (764 *vs* 561, P=0.04), lower RS% (35 *vs* 58%, P=0.14), but had no effect on OS (P=0.08). On multivariate analysis, both platelet count at diagnosis (P=0.04), and transfusion-dependency (P=0.01) affected OS, but not percentage of RS (P=0.14). None of the existing models for MDS (international prognostic scoring system -IPSS, IPSS-revised) or myelofibrosis (IPSS) were able to predict OS in RARS-T pts.
Summary and Conclusions: JAK2V617F mutation was present in 62% of RARS-T pts, but did not affect OS. Platelet count at diagnosis and transfusion-dependency, but not percentage of RS in the bone marrow, affect OS in RARS-T. None of the existing prognostic models for MDS or myelofibrosis predicted OS in pts with RARS-T. Lenalidomide had favorable activity in some pts. These results support RARS-T being a distinct clinicopathologic entity.

A PROSPECTIVE PHASE II STUDY OF ATG-CYCLOSPORINE A FOR ADULT SEVERE APLASTIC ANEMIA: MEDIAN 8-YEAR FOLLOW-UP DATA
H Kim[1,*], K Lee[2], Y Joo[3], J Lee[2], D Kim[2], W Lee[4], J Park[1], J Lee[2]
[1]Division of Hematology and Hematological Malignancies, ULSAN UNIVERSITY HOSPITAL, UNIVERSITY OF ULSAN COLLEGE OF MEDICINE, Ulsan, [2]Department of Hematology, Asan Medical Center, Seoul, [3]Department of Hematology/Oncology, Haeundae Paik Hospital, Inje University, [4]Department of Hematology/Oncology, Busan Paik Hospital, Inje University, Busan, Korea, Republic of Korea

Background: Antithymocyte globuline (ATG) combined with cyclosporine A (CsA) is a standard immunosuppressive therapy (IST) for severe or transfusion-dependent aplastic anemia (sAA) in patients who are not suitable for allogeneic hematopoietic cell transplantation (alloHCT). Response rate to standard IST regimens seemed inferior and long-term follow-up data are rare in Korean population.
Aims: We conducted a prospective phase II study of ATG-CsA for adult sAA. Here we present long-term follow-up results.
Methods: Patients were idiopathic or secondary sAA over 15 years old. Thymoglobulin was infused at 2.5 mg/kg/d for 5 consecutive days. Horse ATG 2.5mg/kg/d for 4 days or horse ALG 10mg/kg/d for 5 days were used as alternatives of thymoglobulin. Cyclosporine administration was adjusted according to the plasma level and the change of renal function for three to six months.
Results: Total 83 patients were enrolled. The median age was 44 (range 15-78) years old. All patients were idiopathic sAA except for 2 patients (virus in one and drug in one patient). The median follow-up was 92.2 (range 15.72-136.1) months in survivors and 63.4 (range 0.1-136.1) months in all patients. Horse ATG, rabbit ATG and horse lymphoglobulin were used in 48 (57.8%), 29 (34.9%) and 6 (7.2%), respectively. Maximal responses were CR in 23 (27.7%), PR in 21 (25.3%), no response (NR) in 31 (37.3%) and not evaluable (NE) in 8 (9.6%) patients. Therefore maximal overall response rate (ORR) was 53.0%. There was no difference in terms of maximal ORR (59.3% *vs.* 41.4%; P=0.120), but significant difference in terms of maximal CR rate (37.0% *vs.* 10.3%; P=0.010) between horse ATG and rabbit ATG. Also there was significantly low cumulative incidence of maximal ORR in rabbit ATG (45.5%) compared with horse ATG (72.1%; P=0.009). ORRs in horse ATG were significantly higher compared with those in rabbit ATG at 3M (P=0.003) and 6M (P=0.005). However the differences were not significant at 12M (P=0.226), 18M (P=0.639) and 24M (P=0.359). Maximal ORR and CR were not affected by PNH clone (P=0.966 and P=0.151, respectively). There was a trend of better ORR in transfused-dependent AA (Tf-AA) compared with severe/very severe AA (S/V-AA; 69.6% *vs.* 46.7%; P=0.061). However, there was no difference in terms of CR and ORR at last follow-up between horse and rabbit ATG (P=0.586 and P=0.653, respectively). Also there was no difference between Tf-AA and S/V-AA in terms of CR and ORR (P=0.377 and P=0.653). There were no impact of ALC and ANC on ORR at various cut-off levels. Sixteen patients without any response received alloHCT. Relapse was found in 11/44 (25.0%) patients. Relapse rates seemed slightly higher in horse ATG (29.4%) than in rabbit ATG (10.0%) without any statistical significance (P=0.408). The 5-year and 10-year overall survival rates were 64.6% and 62.4%, respectively among patients who did not received alloHCT. There was no survival difference between horse and rabbit ATG (P=0.778).
Summary and Conclusions: Horse ATG seemed responding rapidly than rabbit ATG in adult sAA. However, overall response rates, relapse rates and overall survival were similar.

P733

IMPACT OF THE PROLIFERATION INDEX OF SPECIFIC BONE MARROW CELL COMPARTMENTS FROM MYELODYSPLASTIC SYNDROMES IN THE MONITORIZATION OF THE DISEASE: A PILOT STUDY
S Matarraz[1,*], C Teodosio[2], M Jara-Acevedo[2], J Flores-Montero[2], A Lopez[2], C Cerveró[3], C Salvador[4], O Gutierrez[5], M Gonzalez-Silva[6], A Orfao[1]
[1]Medicine, [2]Centro de Investigación del Cáncer (IBMCC, CSIC-USAL) and IBSAL, Salamanca, [3]Servicio de Hematologia, Hospital Virgen de la Luz, Cuenca, [4]Servicio de Hematologia, Hospital Miguel Servet, Zaragoza, [5]Servicio de Hematologia, Hospital Rio Hortega, Valladolid, [6]Servicio de Hematologia, Hospital de la Linea, Cadiz, Spain

Background: We have recently reported in MDS that the presence of decreased proliferation index (PI) among bone marrow (BM) non-lymphoid $CD34^+$precursors and nucleated red blood cells (NRBC) is significantly associated with adverse disease features, shorter overall survival and transformation to AML, even when low- and high-risk MDS patients are separately considered.
Aims: Here we study the PI of different BM cell compartments from MDS patients (n=28) both at diagnosis and at different follow-up controls in order to investigate the proliferation behaviour of these cells during patient monitorization.
Methods: A total of 24 patients with a final diagnostic of MDS were analysed both at diagnosis and at different follow-up BM when they had achieved (partial or complete) morphological and cytogenetic remission or they relapsed with more advanced disease at the time of follow-up. Initially, these 24 patients were diagnosed of RCMD, 7; RAEB1, 11; RAEB2, 6. Eleven of these 24 patients (RCMD, 3; RAEB-1, 6; RAEB-2, 2) had the same or less advanced WHO diagnostic subtype at follow-up compared to baseline control, while 13 (RCMD, 4; RAEB-1, 5; RAEB-2, 4) presented with more advanced disease than at diagnosis.
Results: Follow-up studies from all MDS patients showed decreased PI of overall BM cells –from 7% to 6%; P=0.04- due to decreased PI among non-lymphoid $CD34^+$ cells –from 14% to 6%; P=0.01-, $CD13^{hi}/CD11b^-$ neutrophil precursors –from 14.5% to 8%; P=0.005- and NRBC –from 25% to 15%; P=0.01- *vs.* those found at diagnosis. Of note, no differences were found in the PI from patients with similar WHO diagnostic at baseline and at follow-up (n=11) in any BM cell population. However, as expected, markedly decreased PI were found in cases with more advanced disease at the last follow-up (n=13), among non-lymphoid $CD34^+$ cells –from 15% to 4%; P=0.007-, $CD13^{hi}/CD11b^-$ neutrophil precursors –from 15.5% to 8%; P=0.03-, $CD13^{lo/int}/CD11b^-$ neutrophil precursors –from 20.5% to 12%; P=0.03- and NRBC –from 27% to 13%; P=0.003- *vs.* those found at diagnosis. Furthermore, in detail, among patients with an initial diagnostic of low-risk MDS (n=9), those who evolved to intermediate-risk MDS (n=4) depicted at follow-up a significant decrease of the PI among whole BM cells –from 9% to 5%; P=0.05-, non-lymphoid CD34+ cells –from 17% to 6%; P=0.03-, $CD13^{hi}/CD11b^-$ neutrophil precursors –from 18% to 8%; P=0.03- and NRBC –from 30.5% to 14.5%; P=0.03-. In line with this, low-risk patients evolving to advanced MDS/AML (n=5) showed at follow-up a more marked decrease of the proliferation of non-lymphoid $CD34^+$ cells (P<0.001), $CD13^{hi}/CD11b^-$ and $CD13^{lo/int}/CD11b^-$ neutrophil precursors (P=0.02) and NRBC (P=0.003). Conversely, in patients with advanced MDS (RAEB-2; n=4) at diagnostic evolving to AML at follow-up, no differences were found in the PI of any BM cell population due to achievement of minimal proliferation rates already at baseline. However, those cases with advanced MDS (RAEB-2) who evolved *vs.* those not evolving to AML depicted already at diagnosis a tendency toward lower PI among whole BM cells (4.6% *vs.* 8.5%), non-lymphoid $CD34^+$ cells (3% *vs.* 8%) and NRBC (16.5% *vs.* 26%), although due to the low number of cases statistical significance was not reached.
Summary and Conclusions: The assessment of the PI among specific BM cell compartments may help identifying MDS patients with progression-associated proliferation features, even among cases presenting with decreased BM blast cells at follow-up and might also be useful to identify MDS patients with favourable *vs.* unfavourable response to different treatment strategies.

P734

BENEFITS OF THE USE OF AZACITDINE IN PATIENTS WITH AML REFRACTORY OR RELAPSED AFTER INTENSIVE CHEMOTHERAPY
G Giagnuolo[1], C Cerchione[1,1,*], P Angelillo[1], O Vitagliano[1], N Pugliese[1], L Marano[1], G Battipaglia[1], S Avilia[1], F Alfinito[1], Giuseppe Cerciello[1], Fabrizio Pane[1]
[1]Hematology, AOU "Federico II", Napoli, Italy

Background: Azacitine (AZA) is a demethylating agent approved for the treatment of patient with intermediate-2 (Int-2) or high-risk myelodysplastic syndromes (MDS), chronic myelomonocytic leukaemia, acute myeloid leukaemia (AML) with 20-30% blasts. Subcutaneous therapy with AZA, compared with

conventional care regimens (CCRs), prolongs median survival, delays progression to AML, reduces transfusion needs in MDS in the Int-2 and high risk groups. AZA prolongs median overall survival (OS) in old patients with low BM blasts AML and reduces toxicity.
Aims: Our intent is to suggest as AZA therapy could prolong OS, reduce adverse events and improve quality of life in patients with AML refractory/relapsed after intensive chemotherapy (IC). As well known, median OS in this subset of patients is about 3 months, when treated with CCRs, with few chances to achieve complete remission and a high risk to experience great toxicity.
Methods: Here we report our experience about the AZA therapy in 17 patients (8 MDS and 9 AML) 6 MDS patients were in the Int-2 risk group, 2 in the high, 2 AML were *de novo*, 2 secondary to MDS, 3 refractory and 2 relapsed after IC; three refractory patients have been treated with Clofarabine and Aracytin (Ara-C-), Fludarabine, Ara-C and Idarubicine and low dose Ara-C respectively; two patients relapsed one after Ara-C and Daunorubicine therapy and one after Ara-C, Ethoposide, Daunorubucine treatment and Au-BMT. All AML patients were unfit for other CCRs. Median age was 77 years and BM blasts count was 34% (range3,5-96%); all patients were transfusion dependent (median Hb8,5 g/dl, range7,0-10 g/dl), granulocyte count was 1896/mmc (+/-3142)and Plt 92400/mmc (+/-73800). AML and MDS patients received AZA subcutaneously for 7 days every month at a dose of 75 mg/m^2 daily until disease progression.
Results: As expected OS in MDS patients was 16 months. One patient with denovo AML obtained a CR that persists after 7 months, the other one obtained a PR and died after 9 months. Two patients with secondary AML achieved PR after 3 courses, one showed disease progression after 12 months and one is still in PR after 4 months. After three courses of therapy all refractory/relapsed AML patients (5) showed increased Hb concentration (median9,1 g/dl, range 8-10,6 g/dl) withreduction of transfusion requirements and two of them became subsequently transfusion indipendent; all patients also achieved improvement in Plt count (median 138000/mmc,range 39000-350000/mmc). Median BM blasts countafter 3 courses of AZA therapy was 6%(range 0-21%): 1 patient obtained CR that persists after 8 courses; 4 patients achieved PR and 2 of them are still alive in good PR after 4 courses, while 2 patients showed disease progression after 3 and 9 courses, respectively. During AZA therapy no patient had relevant infections and none needed hospital admission. After a median follow-up of 7 months, 7 patients are still alive (1 denovo AML, 2 secondary AML, 4 refractory/relapsed AML).
Summary and Conclusions: AZA is an effective treatment and has an acceptable safety profile for the treatment of patients with refractory/relapsed AML unfit for IC. AZA provides a clinical benefit reducing transfusion requirement, improving quality of life and extending OS. Furthermore, patients treated with AZA have a lower rate of infectious complications and low toxicity with subsequently fewer hospital admissions compared with CCRs-treated patients.

P735

CURRENT MANAGEMENT OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES IN A REAL-WORLD SETTING: A SURVEY FROM A REGIONAL ITALIAN REGISTRY

E Balleari[1,*], L Del Corso[1], E Arboscello[1], A Bacigalupo[1], A Bellodi[1], M Bergamaschi[1], G Berisso[2], M Brunofranco[3], M Cavaliere[4], E Cenni[1], M Clavio[1], P D'Elia[5], A Dominietto[1], S Favorini[1], G Forni[6], F Giusto[1], M Miglino[1], P Minetto[1], L Mitscheunig[1], E Molinari[1], F Morelli[7], S Napoli [8], I Pierri[1], Ponassi[1], Racchi[9], F Rollandi[5], M Scudeletti[10], V Sicbaldi[1], R Tassara[4], M Gobbi[1], R Ghio[1]
[1]Hematology -Oncology, IRCCS AOU San Martino IST Genova, Genova, [2]UO Medicina Interna- Ospedale Sarzana, ASL 5, Sarzana, [3]CTO - Ospedale di Imperia, ASL1, Imperia, [4]UO Medicina Interna- Ospedale Savona, ASL2, Savona, [5]CTO - Ospedale di La Spezia, ASL 5, la Spezia, [6]UO Ematologia, Ospedale Galliera, Genova, [7]CTO - Ospedale di Lavagna, ASL4, Lavagna, [8]UO Medicina Interna- Ospedale Imperia, ASL1, Imperia, [9]UO Oncologia, Ospedale Villa scassi, Genova, [10]UO Medicina Interna- Ospedale Sestri Levante, ASL4, Sestri Levante, Italy

Background: Myelodysplastic Syndromes (MDS) are commonly associated with a poor prognosis in "higher-risk" (HR) patients, and an indolent course in "lower-risk"(LR) patients. Current international Guidelines indicate that management's strategy should be based on evaluation of prognostic score systems such the International Prognostic Score System (IPSS); however, several different reasons might largely influence in the real life the actual clinical management of these patients.
Aims: To examine the "real word" current management strategies and survival of MDS patients in an unselected Italian population.
Methods: We prospectively collected data regarding management of MDS patients from Ligurian MDS database, a regional registry established within the framework of the Italian Network of regional MDS registries.
Results: Data are presented for 293 patients (158 (54%) males and 135 (46%) females), with a median age of 76 years (range 42-98 years), registered into the database from 2010 to 2012. Regarding WHO categorization, 32% patients had RA, 34% RCMD, 5% RARS or RCMD-RS, 3% 5q- syndrome, 6% RAEB-1, 8% RAEB-2 and 1% MDS-unclassified; 11% remained undetermined. IPSS was available in 226 (77%) of the patients; within this group, LR (low and intermediate-1 risk) patients were 87% of the total, while HR (intermediate-2 and high-risk) were 13%. The recently revised form of IPSS (r-IPSS) was calculated in 225 (77%) of the patients, and it stratified them as follows: very low risk 15%, low risk 43%, intermediate-risk 10%, high-risk 6% and very high-risk 3%. Transfusion-dependent patients at diagnosis were 56 (19%). Applying WPSS stratification patients were categorised as follow: 33% very low, 42% low, 13% intermediate, 9% high and 3% very high risk. As first line treatment, 127 (39,5%) patients received no treatment or only supporting therapy (mainly transfusions); 138 (48%) received ESAs, alone or with GCSF. Twenty-six (9%) patients were treated with Azacytidine, 3 (1%) –all with a 5q-syndrome- with lenalidomide; the remaining 2,5% were treated with immunosuppression or AML-like chemotherapy. Among the patients who whenever during the course of the disease required transfusions, 26 (9%) received iron chelation therapy. On December 2012, after a median follow-up of 19 months, the overall survival was 85,2% in LR group and 54% in HR group, respectively.
Summary and Conclusions: Despite well-established clinical guidelines suggest that treatment of MDS should be based on a reliable prognostic score system, this survey shows that in the "real life" MDS remains a disease that is not always managed accordingly. Almost a quarter of the patients, especially older individuals from peripheral centers, are not categorizable according to IPPS because of a lack in diagnostic evaluation (mainly cytogenetics). A large proportion of them received no treatment or supporting transfusion only and very few were treated with iron chelation therapy. A small number received aggressive chemotherapy.

P736

LONG DURATION OF RESPONSE TO AZACITIDINE IN MYELODYSPLASTIC SYNDROMES. MULTICENTER RETROSPECTIVE STUDY OF 36 PATIENTS

C Finelli[1,*], C Clissa[1], M Teresa Voso[2], M Spiriti[3], M Breccia[4], G Gaidano[5], M Crugnola[6], M Benedetta Giannini[7], A Poloni[8], C Bosi[9], V Naso[3], M Y Follo[10], S Mongiorgi[10], G Martinelli[1], L Cocco[10], M Cavo[1]
[1]Hematology, Policlinico S.Orsola-Malpighi, Bologna, [2]Hematology, University "Cattolica S. Cuore", [3]Hematology, Sant'Andrea Hospital, [4]Dpt of Biotechnologies and Hematology, University "Sapienza", Rome, [5]Hematology, University of Eastern Piedmont, Novara, [6]Hematology and BMT, University of Parma, Parma, [7]Oncology, IRST, Meldola (Fo), [8]Hematology, Università Politecnica delle Marche, Ancona, [9]Hematology, Ospedale Civile di Piacenza, Piacenza, [10]Human Anatomical Sciences, University of Bologna, Bologna, Italy

Background: Although azacitidine (AZA) has proven effective in myelodysplastic syndromes (MDS), the duration of haematological response is limited (median 13.6 months) *(Fenaux, 2009)*. The French Group *(Itzykson 2011)* identified some clinical and haematologic parameters (poor ECOG performance status, IPSS intermediate and poor risk cytogenetics, circulating blasts, high transfusion need) independently associated with a a poorer outcome, and these 4 criteria were integrated in a 3-group prognostic score, validated in other cohorts *(van der Helm 2011; Breccia 2012)*. Moreover, a complex karyotype was also predictive of a shorter duration of response.
Aims: These data prompted us to retrospectively analyse our MDS pts treated with AZA who showed a favourable long-lasting response (i.e: duration of response ≥20 months), in order to enucleate the clinical and haematologic features of long-responder pts.
Methods: The type of response was defined according to IWG criteria *(Cheson 2006)*: Complete Remission (CR), Marrow CR, Partial Remission (PR), Hematologic Improvement (HI). The response duration was measured from the date of achievement of a first response, until the date of disease progression or death. Overall Survival (OS) was measured from the start of AZA treatment.
Results: Thirty-six pts (M/F: 21/15), from nine Institutions, with a median age of 72 (range 52-84) yrs, showed a response duration ≥20 months. At AZA onset, WHO diagnosis was: refractory anemia (RA): 2 pts; refractory cytopenia with multilineage dysplasia (RCMD): 1 pt; RCMD with ringed sideroblasts (RCMD-RS): 1 pt; refractory anemia with excess blasts (RAEB)-1: 8 pts; RAEB-2: 16 pts; cronic myelomonocytic leukemia(CMML): 4 pts; AML with 20-30% blasts: 3 pts, MDS with fibrosis (MDS-F): 1 pt. Six pts had therapy-related MDS. IPSS risk was: low: 3 pts; intermediate-1: 7 pts; intermediate-2: 21 pts, high: 5 pts. IPSS cytogenetic risk was: low: 23 pts (63.9%); intermediate: 7 pts (19.4%); high: 6 pts (16.7%) (3 with complex karyotypes and 3 with isolated -7 or 7q-). ECOG-PS was poor (≥2) in 2 pts (5.5%). Transfusion need was high (≥4 RBC units/8 weeks) in 17 pts (47.2%). Three pts (8.3%) presented circulating blasts. Following Itzykson's AZA prognostic scoring system, the risk was low in 14 pts (38.9%), intermediate in 21 pts (58.3%), and high in 1 pt (2.8%), respectively. The pts received a median of 23.5 cycles of AZA (range: 8-59). The median number of cyles to any first response was 4 (range: 2-10). The best response achieved was: CR in 21 pts (58.3%), marrow CR: 4 pts (11.1%), PR in 2 pts (5.5%), and HI in 9 pts (25%). Cytogenetic remission was achieved in 7 pts (19.4%). The median duration of response was 24.5 (range: 20-88) months. A significant toxicity (grade >2) was observed in 6 (16.7%) pts. Twenty-two pts (61.1%) are still maintaining hematologic response, 9 pts (25%) are still alive but discontinued treatment because of disease progression, and 5 pts

died, for AML (2 pts), infection (1 pt), myocardial infarction (1 pt),cachexy (1 pt), respectively. Median OS from the start of AZA was 35.5 (range: 22-120) months.
Summary and Conclusions: Although our data confirm the finding of other Authors, as the majority of long-responder patients showed pre-treatment favourable prognostic factors, a long-lasting hematologic response can be achieved even in a significant fraction of pts presenting one or more poor risk features (IPSS intermediate or high risk cytogenetics, high transfusion need).

P737

PROLONGED LOW-DOSE AZACITIDINE SCHEDULE IN HIGH-RISK MDS PATIENTS: LONG TERM EFFICACY AND RELATIONSHIP WITH MOLECULAR RESPONSE

C Clissa[1,*], C Finelli[1], M Follo[2], M Stanzani[1], C Papayannidis[1], A Curti[1], S Paolini[1], S Mongiorgi[2], L Manzoli[2], G Martinelli[1], L Cocco[2], M Cavo[1]
[1]Hematology, Policlinico S. Orsola-Malpighi, [2]Human Anatomical Sciences, University of Bologna, Bologna, Italy

Background: The currently approved azacitidine (AZA) regimen for myelodysplastic syndromes (MDS)is 75 mg/sqm/die subcutaneously (SC) or intravenously (IV) for 7 days every 28 days. Recently 3 different AZA dosing regimens, which avoid week-end dosing, have shown to induce therapeutic responses consistent with the currently approved schedule *(Lyons, 2009)*. In particular, one of them, *i.e.* the AZA 5-2-5 regimen (50 mg/m2/d subcutaneously for 5 days, followed by 2 days no treatment, then 50 mg/m2/d for 5 days) allows the administration of a nearly equivalent monthly total dose of AZA.Moreover, some data suggest the possibility that prolonged exposure to lower doses of AZA may increase the response rate *(Gore, 2006)*. However, the community-based study of Lyons mainly involved lower-risk MDS patients (pts).
Aims: These data prompted us to investigate the therapeutic effect of the more convenient AZA 5-2-5 regimen in higher-risk MDS pts (*i.e.*: IPSS risk: high or intermediate-2).
Methods: From December 2007, in our Institution, 29 IPSS high-or-intermediate-2 risk MDS pts. (20 males), with a median age of 70 (37-83) yrs, were treated with the AZA 5-2-5 regimen. Moreover, as our group *(Follo, 2009)*previously demonstrated that the inositide signalling pathways, in particular phosphoinositide-phospholipase C (PI-PLC) beta1, may represent a target for AZA, we quantified the degree of PI-PLCbeta1 methylation and gene expression before and during AZA administration in this group of pts, and in a control group of high-risk pts previously treated with the conventional AZA regimen.
Results: At AZA onset, IPSS risk was: intermediate-2: 23 pts; high: 3 pts; 3 pts, with intermediate-1 IPSS risk, showed other high-risk features (therapy-related MDS: 2 pts; complex karyotype: 1 pt). IPSS cytogenetic risk was: low: 14 pts; intermediate: 5 pts; high: 10 pts (8 with complex karyotypes and 2 with isolated -7 or 7q-). Revised IPSS *(Greenberg, 2012)* was: intermediate: 1 pt; high: 6 pts; very high: 22 pts. 5 ptspresented circulating blasts. Transfusion need was high (≥4 RBC units/8 weeks) in 13 pts. ECOG-PS was poor (≥2) in 7 pts. Itzykson's prognostic risk for outcome after AZA *(Blood 2011)* was: low: 4 pts; intermediate: 24 pts; high: 1 pt. The pts received a median number of 8 (1- 26) AZA cycles. 26 pts (89.6%) received at least 6 cycles of AZA and were considered evaluable for response, while 2 pts prematurely discontinued AZA because of toxicity or worsening of their clinical conditions, and 1 pt. is still on treatment. Among the 26 evaluable pts, 19 (73%) showed a favourable response, following IWG criteria *(Cheson, 2006)*: 5 (19.2%) Complete Remission (CR), and 14 (53.8%) Hematologic Improvement (HI). First response occurred after a median of 3 (2-7) cycles. 4 pts maintained a stable disease (SD), while the 3 remaining pts showed treatment failure. A significant toxicity (grade >2) was observed in 13 (44.8%) pts. The median duration of response was 12 (1-48) months. Four pts showed a long-lasting response (≥20 months). The median OS from the start of AZA was 16 (5-51) months. 16 pts died, 8 because of evolution into Acute Myeloid Leukemia, and 8 for other causes (infection, haemorrhage, heart failure, stroke, suicide). PI-PLCbeta1 methylation and gene expression appeared to be related to the therapeutic response, but not to the dose schedule.
Summary and Conclusions: Our data seem to confirm, in a population of high-risk MDS, the effectiveness, in terms of hematologic and molecular response, of the more convenient AZA 5-2-5 regimen.

P738

THE ASSOCIATION OF FREE LEPTIN INDEX AND INSULIN LEVELS WITH THE OCCURRENCE OF MYELODYSPLASTIC SYNDROMES

M Dalamaga[1], A Lekka[2], M Triantafilli[2,*], J Chamberland[3], K Karmaniolas[4], A Dionyssiou-Asteriou[1], C Mantzoros[3]
[1]Clinical Biochemistry, University of Athens, School of Medicine, Attikon General University Hospital, [2]Laboratory of Hematology, NIMTS Hospital, Athens, Greece, [3]Division of Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, [4]Internal Medicine, NIMTS Hospital, Athens, Greece

Background: Recent evidence suggests that obesity may be implicated in the etiology of hematologic malignancies,including myelogenous leukemia and myelodysplastic syndromes (MDS). Leptin, and, in particular, free leptin, the biologically important form of leptin, reflecting accurately the body fat mass, regulates glucose and lipid metabolism by improving insulin sensitivity and reducing intracellular lipids. We thus attempted to explore whether altered secretion of free leptin in association with insulinemia, a hormonal system linked with several obesity and insulin resistance associated malignancies including leukemia, may underlie this association.
Aims: In thiscase-control study, we investigated the potential role of free leptin, soluble leptin receptor in the etiopathogenesis of MDS after adjusting for a potential confounding effect of body mass index (BMI), height, weight, family history of lymphohematopoietic cancer (LHC), serum insulin and adiponectin. We also explored associations between free leptin and established MDS prognostic factors.
Methods: Blood samples were collected from 101 cases with incident, histologically confirmed primary MDS, and 101 hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2004 and 2007. Serum insulin and serum leptin were determined by radioimmunoassay (Millipore and Linco Research, Inc. respectively). Serum leptin receptor levels (sOB-R) levels were measured using a commercially available ELISA (BioVendor Laboratory Medicine). Free Leptin Index (FLI) was calculated as the ratio of leptin to sOBR. The statistical analysis of the data was performed using IBM-SPSS® version 20 for Windows.
Results: Cases presented significantly higher height and weight than control subjects (P<0.001), while differences of BMI were only of borderline significance (P=0.12). Seruminsulin was significantly higher in cases than in controls (P=0.005). MDS cases exhibited significantly lower serum levels of sOB-R and adiponectin than controls (P=0.04 and P<0.001 respectively). Furthermore, MDS cases presented hypoleptinemia, though not statistically significant at α=0.05 (P=0.07). In univariate analysis, FLI was similar in both cases and controls (P=0.35). Serum leptin was higher in RAEB and RAEB-t, in high and intermediate-2 risk category of IPSS, and in MDS with an intermediate and poor prognosis karyotype (P<0.001). In multivariate analysis, subjects in the second and fourth quartile of FLI presented significantly lower odds for MDS (2nd quartile: OR=0.36, 95% C.I. 0.13-0.95 and 4th quartile: OR=0.08, 95% C.I. 0.02-0.29) after adjusting for age, gender, date of diagnosis, BMI, family history of LHC, smoking history, adiponectin and insulin levels.
Summary and Conclusions: This study raises the hypothesis that the association of lower FLI reflecting overall fat mass, hypoadiponectinemia reflecting visceral obesity and hyperinsulinemia are associated with higher risk of MDS. Leptin's major physiological role is to signal inadequate rather than excess energy stores, and hypoleptinemia found in a small but significant percentage of obese humans is associated with hyperinsulinemia and impaired T-cell function. Further mechanistic and interventional studies are needed to confirm these findings and to explore whether these hormones mediate the effect of body fat distribution on insulin resistance and myelodysplasia risk.

P739

REAL WORLD USE OF AZACITIDINE IN ELDERLY PATIENTS WITH MDS/AML–THE SCOTTISH EXPERIENCE

K Lund[1,*], M Drummond[1], P Eynaud[2], K Fitzsimons[2], A Olaiya[3], M Copland[1]
[1]Haematology, Beatson Oncology Centre, Glasgow, [2]Haematology, NHS Ayrshire & Arran, Ayr, [3]Haematology, NHS Grampian, Aberdeen, United Kingdom

Background: The management of elderly patients with MDS and AML poses significant challenges despite considerable attention focused at improving treatment. Even those who can tolerate standard induction treatment have significantly inferior outcomes (AML 5yr overall survival rates of 3-8% in over 60s compared to 50% in younger patients).[1] Azacitidine has shown promise in this context with reports of superior response rates and improved survival when compared to standard therapy.[2,3]
Aims: Azacitidine received National Institute of Clinical Excellence (NICE) endorsement in the United Kingdom in March 2011 and its use was facilitated in Scotland following approval by the Scottish Medicines Consortium (SMC) in September 2011. However, lack of consensus remains regarding the value of Azacitidine given that it confers significant toxicity. This study was performed to investigate the use of the drug in a "real life" setting.
Results: We report a retrospective analysis of 42 patients with MDS (n=19), AML (n=19) and CMML (n=4) treated with Azacitidine in Scotland between 2008 and 2012. Median age of patients was 72 yrs. 45.2% (n=19) patients received the drug as first line treatment and 26.2% (n=11) as maintenance therapy following remission induction using standard chemotherapy of which 7 patients received Azacitidine in the context of the National Cancer Research Institute (NCRI) AML 16 trial (www.aml16.bham.ac.uk). 26.2% (n=11) patients were treated with Azacitidine as second/third line therapy, with 4.8% (n=2) treated as a bridge to stem cell transplant. Patients received a median of 4 cycles of treatment. Overall response rate was 31% (n=13); complete response in 9.5% (n=4) and mono- or bilineage haematological improvement

in 21.5% (n=9). 50% (n=21) showed no response or progressed whilst on therapy. 54.7% (n=23) patients required admission to hospital for management of drug-related complication. Moderate or severe gastrointestinal and dermatological toxicity was reported in 14.3% (n=6) and 19% (n=8) cases respectively. 61.9% (n=26) patients experienced infective complications and sepsis-associated deaths occurred in 14.3% (n=6). Median survival had not been reached at a median follow-up of 6 months (range 1-44 months) and all cause mortality was 45.2% (n=19).

Summary and Conclusions: In the "real world" setting Azacitidine is used in multiple therapeutic contexts. Consequently published studies may not reflect the drug's effect on unfit, often heavily pre-treated, patients. Whilst Azacitidine undoubtedly improves the quality of life of a small cohort of patients, its durability is often short-lived and its toxicity should not be underestimated. The significant levels of sepsis reported in this analysis suggest that Azacitidine should be used with caution in patients perceived to be at particular risk of infection. Its role as a consolidation treatment for older patients following successful induction therapy is currently being explored.

MODELLING THE LONG-TERM SURVIVAL OF PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS) DEL (5Q) TREATED WITH LENALIDOMIDE

B Benettaib[1,*], D Lee[2], S Dhanasiri[3], N Brereton[2]
[1]Celgene International, Sarl, Switzerland, [2]BresMed, Sheffield, [3]Celgene Limited, Uxbridge, United Kingdom

Background: Myelodysplastic syndrome (MDS) are a group of malignant hematological disorders in which the bone marrow function is abnormal and produces insufficient numbers of mature blood cells necessitating frequent blood transfusions in some cases. Lenalidomide is an immunomodulatory (IMiD) derivative, approved in the US in 2005 for the treatment of patients with transfusion-dependent anemia due to low or int-1 risk MDS associated with a del5q cytogenetic abnormality with or without additional cytogenetic abnormalities. The aim of treatment with lenalidomide is to achieve transfusion independence (TI). A similar indication is currently under review for approval in Europe. In UK, where there are no licensed treatments, current options consist of: blood transfusions, growth factors and antibiotics - best supportive care (BSC). The efficacy and safety of lenalidomide (10mg and 5mg doses) has been demonstrated in two trials in MDS patients with del5q, MDS004: a randomized placebo-controlled trial and MDS003: a single arm trial. Results previously presented from analysis of the MDS003 and MDS004 trials showed that patients who achieved TI for at least 26 weeks had a 64% reduction in risk of death.

Aims: In order to carry out an economic evaluation mean survival is required. This work aims to estimate the impact of lenalidomide on long-term mean survival of low and int-1 risk MDS del5q transfusion dependent patients compared to patients on BSC, based on MDS003 and MDS004 trial data and published literature. BSC is defined, based on UK treatment patterns, as 72% of patients receiving only transfusions and 28% receiving ESA followed by G-CSF if there is no response to ESA.

Methods: As TI has previously been identified as a prognostic factor in MDS, for this analysis overall survival (OS) was modeled based entirely upon the probability of becoming TI, regardless of the treatment received. The probability of achieving TI for ≥182 days was taken from MDS004 for lenalidomide 10mg and transfusion only (placebo) patients and from Hellström-Lindberg's predictive model for ESA and G-CSF. OS is modeled for BSC and lenalidomide, for patients who did not progress to AML, using parametric curves based upon whether patients achieved TI. Weibull, exponential, lognormal, loglogistic and extreme value curves were fitted to combined trial data across all trial arms. Weibull curves were found to provide the best fit (based on AIC, BIC and integrated brier score). The rate of progression to AML was also modeled using parametric curves based upon whether patients achieved TI with weibull curves again providing the best fit. For patients who progressed to AML OS curves were taken from published literature, as not enough patients progressed to AML and died within the trials to enable this to be modeled directly.

Results: Consistent with the trials, within the model more patients were predicted to become TI with lenalidomide: 60.9% *vs.* 8.4% for BSC. Based upon this increase in TI the model predicts a mean OS of 5.7 years for patients treated with lenalidomide (median 4.7 years) *vs.* a mean OS of 4.6 years for patients receiving BSC (median 4.5 years). A comparison of model and trial results is shown in the Figure 1. Using probabilistic analysis sampling10,000 model iterations lenalidomide improved survival in 99.9% of cases.

Summary and Conclusions: TI has been demonstrated to be an independent prognostic factor in MDS patients. This analysis shows that the increase in TI associated with lenalidomide treatment of MDS del5q patients results in an increase in mean survival of over 1 year when compared to BSC.

P741

ANALYSIS OF RESPONSE TO ERYTHROPOYESIS STIMULATING AGENTS (ESAS) IN 114 MYELODYSPLASTIC SYNDROME (MDS) PATIENTS FROM REGISTRO CAMPANO DELLE MIELODISPLASIE

F Alfinito[1,*], O Vitagliano[1], C Cerchione[1], G Giagnuolo[1], I Soriente[2], A D'Arco[2], P Danise[2], F Pane[1]
[1]Medicina Clinica e Chirurgia, University of Naples "Federico II", Napoli, [2]Oncology/Hematogy, Umberto I Hospital, Nocera Inferiore (SA), Italy

Background: Anemia is one of the main problems of MDS patients even in absence of transfusion need. The great majority of MDS patients are old and numerous comorbidities characterize their clinical features, anemia significantly worsens their quality and expectancy of life. ESAs is considered first line therapy in anemic MDS patients and there is an increased tendency to its employment in the earlier stage of the disease.

Aims: The aim of this work is to evaluate clinical response to ESAs therapy in a cohort of anemic MDS patients, no transfusion dependent, enrolled in a regional retrospective register, RECAMDS (Registro Campano delle Mielodisplasie), a subgroup of the Italian MDS Register, focusing on WHO classification and IPSS risk stratification.

Methods: We have retrospectively considered 114 anemic MDS patients (M/F 55/59, median age 77±9.1, WHO 43 RA, 17 RARS, 39 RCMD, 8 RAEB, 7 MDS with del 5q, risk assessment:53 low,58 Int-1, 3 Int-2), not transfusion-dependent and treated with ESAs (α or β EPO 40000/80000 or 30000/60000 U/weekly respectively) from 2006 to 2012. We analyzed data at three and six months of treatment: responses were evaluated according to IWG criteria2006; in the responders patients we evaluated median interval from diagnosis, serum erythropoietin concentration at the beginning of therapy, time to response, duration of response and relationship with WHO subgroups. Statistical analysis was performed applying ANOVA, t Student and c2 tests.

Results: 28 patients under study were treated with standard dose of α erythropoietin (40.000 IU weekly) and 12 received a high dose (80000 weekly), the remaining 70 were treated with β erythropoietin: 56 with a weekly standard dose of 30.000IU and 14 with high dose (60000IU weekly). ESA therapy was started at mean Hb concentration of 9.50 g/dl (±1.5) with EPO serum level of 64mU/L±79.6 after a mean of six months (1-118) from diagnosis. The global response rate was 84% (96/114): 88/114 patients achieved response after three months, other 8 patients achieved a significant response after six months of therapy (4 AR, 1RARS,2 RCMD, 1 MDS 5q-). 40 patients (38%) lost the response after a mean of 18 months (3-84) while 74 (65%) are still on treatment without transfusion need after a median time of 25 months (3-96). WHO classification of non responders patients identified 7 AR,4 RARS,5 RCMD, 1 AREB, 1Del 5q and their EPO level was 173 mU/L ±143.93 while in the responders subgroup it was 47.28 mU/L ±48.6, with statistical difference between the two groups. The WHO subgroups did not exhibited different profiles of response. It is noteworthy that in a subgroup of anemic patients (7) with 5q deletion, not transfusion dependent, we observed a good response to ESA treatment in the majority of them (6/7), 5/6 achieved response after three months and 1 after six, all responder 5q- patients (3 5q- syndromes,3 RA, 1RCMD) are still responsive with a median time of 34 months (range 8-96 months).

Summary and Conclusions: As well known ESAs therapy can be considered a successful treatment in MDS patients in low risk group where, as first line therapy, delays the need for RBC transfusion hypothetically by slowing the disease course thus suggesting their employment in the earlier stages of the disease. Here we report a good response to ESA treatment also in more advanced stage of MDS (INT1 and INT 2) and in a subgroup of 5q- MDS generally reported as bad responders to such treatment, further studies will evaluate if this good response will delay transfusion requirement and subsequent lenalidomide therapy.

P742

INFLAMMATION INDICES IN MYELODISPLASTIC SYNDROMES AT DIAGNOSIS

A Sanna[1,*], A Gozzini[1], F Buchi[1], E Masala[1], A Valencia[1], A Bosi[1], V Santini[1]
[1]Hematology, University of Florence, Florence, Italy

Background: Myelodisplastic syndromes (MDS) are a group of heterogeneous diseases characterized by peripheral cytopenias and hypercellular bone marrow. MDS usually affect elderly patients, and they often had other comorbidies. The role of inflammation in MDS is still under explored.It has been recently observed a correlation of inflammation indexes with outcome.
Aims: We evaluated the impact of 5 common inflammation index, ferritin, alpha 1 glycoprotein (α1g), alpha 1 antripsin (α1a), C reactive protein (CRP) and aptoglobin (apto) on overall survival (OS) and their correlation with WHO 2008 classification, IPSS risk and presentation CBC.
Methods: We collected data from 79 consecutive MDS outpatients diagnosed in the Hematology Unit of the University of Florence. Patients were classified according to WHO classification as follow: 17 RA, 3 RARS, 30 RCMD, 11 RAEB1, 5 RAEB2, 8 AML <30% of blasts and 5 CMML, and prognostic score was evaluated according to IPSS as follow: 34 low risk, 33 intermediate1, 4 intermediate 2 and 8 high risk. Median age was 75 years (range...), 43% were female (34/45 F/M). Median follow up was 11 months.
Results: Median value of all the indexes we analysed was within the limits of our laboratory exam. Median value of α1g was 0.89 ±0.33 g/L, 12 patients had α1g level above normal value (n.v.) (n.v 0.5-1.2 g/L), median value of α1a was 1.6 ±0.44 g/L, 12 patients had α1a above n.v. (n.v. 0.9-2 g/l), median value of apto was 0.82±0.72 g/L, 5 patients had apto level above n.v. (n.v.0.3-2 g/L), median value of ferritin was 229±826 ng/mL, 28 patients had ferritin level above n.v. (20-300 ng/mL), only 17 patients had CRP level above the normal limit (9 mg/L. Analysis of variance among different WHO subtypes and in IPSS indicated that there was no statistical difference among different subtypes of MDS. The average value of parameters were uniformly distributed among WHO and IPSS subtypes. There were some interesting correlations. Ferritin was inversely correlated with hemoglobin levels (P<0.001, r=-0.366), apto was directly correlated with hemoglobin level (P=0.045 r=0.236) and with α1g (P=0.000, r=0.461), α1g was also directly correlated with absolute neutrophils count (P=0.045 r=0.236) and with α1a (P=0.000, r=0.536). Regarding the association with outcome, we compared MDS patients with normal to those with abnormal values. We observed that MDS patients with abnormal ferritin had a median OS of14,6 month while median was not reached at 40 months for the group with normal value of ferritin (P=0.041). We had the same observation for CRP (14 months median OS *vs.* not reached) (P=0.018) and for α1a (OS 12 months *vs* 32 months) (P=0.005). There was no significant difference in OS between the MDS patients with normal and abnormal α1g and apto.
Summary and Conclusions: Although the increase of inflammation markers is not a common feature of MDS at diagnosis our basic analysis indicated that in all MDS, irrespective of IPSS risk, there is a strict correlation with survival for ferritin, alfa 1antripsin and C reactive protein, possibly indicating a role of inflammatory cytokines in determining the history of the disease Further studies are warranted to support this observation and implement our aramamentarium to define MDS prognosis.

P743

RISK SCORING SYSTEM USING IPSS-R, LDH AND PERFORMANCE STATUS TO PREDICT THE OUTCOMES OF PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROME TREATED WITH HYPOMETHYLATING AGENTS

S Sohn[1,*], J Moon[1], Y Lee[1], S Lim[2], S Bae[3], M Hyun[4]
[1]Hematology, Kyungpoon Natl. Univ. Hospital, Daegu, [2]Hematology, Chungbuk National University Hospital, ChunJu, [3]Hematology, Daegu Catholic University Medical Center, [4]Hematology, YeoungNam Univ. Hospital, Daegu, Korea, Republic of Korea

Background: Prognosis of patients with myelodysplastic syndrome (MDS) can be calculated using a number of scoring systems. The most commonly used system is the International Prognostic Scoring System (IPSS), and the treatment decision using hypomethylating agents (HMA) has been based on IPSS risk groups. HMA has been known to improve the treatment outcomes of patients with the IPSS lower risk [low and intermediate-1 (INT-1)] groups. However, some of the patients showed the deteriorating course even though they were categorized to lower risk IPSS.
Aims: In the current study, we revised the original IPSS lower risk to know whether it could further discriminate the prognosis of the IPSS lower risk MDS patients treated with HMA, and to propose a 'Risk scoring system' using the variables known to be related with the outcome of lower risk MDS patients.
Methods: The data of 68 patients with lower risk MDS receiving HMA treatment were retrospectively reviewed. The IPSS risk groups were revised into IPSS-R. The overall survival (OS) rate among the IPSS-R risk groups and other clinical variables were analyzed, and prognostic power was calculated using Cox-hazard models.
Results: HMA were treated with median 4 cycles (range 1-22). Azacitidine was used in 57 patients (83.8%) and decitabine in 11 (16.2%). Baseline LDH were increased in 16 patients (23.5%), and ECOG performance status (PS) were 0-1 in 51 patients (75.0%) and 2 in 17 (25.0%). IPSS low risk and INT-1 risk were 7 patients (10.3%) and 61 (89.7%), respectively. The patients with IPSS were revised into IPSS-R as followes; 15 patients (22.1%) as low, 33 (48.5%) INT, 19 (27.9%) high, and 1 (1.5%) very high. The OS rate were not different between original IPSS-low and INT-1 (P=0.400). However, OS of the low risk group defined by IPSS-R was significantly better than other risk groups [hazard ratio (HR) 3.128, P=0.033]. Among the other clinical variables, female sex (HR 0.453, P=0.037), ECOG PS 2 (HR 2.130, P=0.042), and increase LDH (HR 3.049, P=0.003) were related to OS in the univariate analyses. In the multivariate analysis, increased LDH (HR 2.868, P=0.008), IPSS-R low risk (HR 2.976, P=0.051), and ECOG PS 2 (HR 2.159, P=0.051) affected the outcomes of patients treated with HMAs.
Finally, weighted risk scores were designated based on HR and significance as folllows: IPSS-R low (score 1), ECOG-PS 2 (score 1), and increased LDH (score 2). According to this 'Risk scoring system', 10 patients (14.7%) were score 0, 30 (44.1%) score1, 14 (20.6%) score2, 12 (17.6%) score3, and 2 (2.9%) score 4. The 3-yr OS rate were significantly different between each groups: 88.9±10.5% in score 0 (n=10), 28.3.±9.7% in score 1-2 (n=44), and 0% in score ≥3 (n=14) (Figure 1).

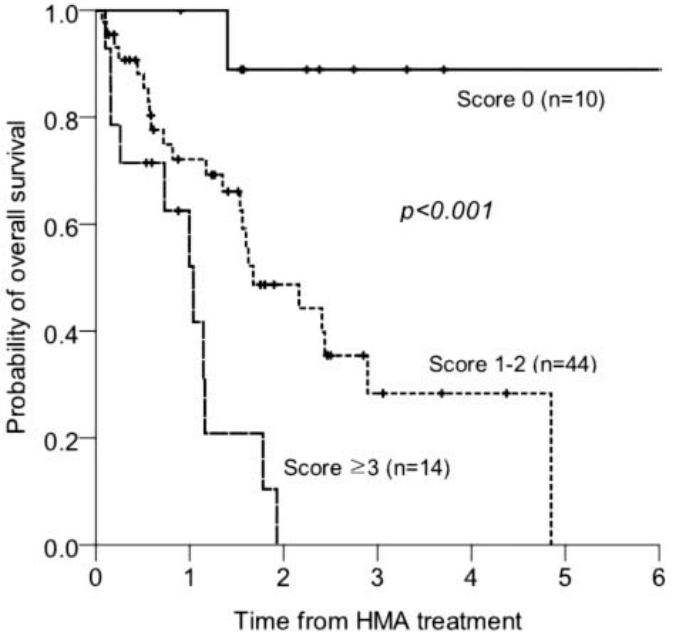

Figure 1.

Summary and Conclusions: The risk scoring system based on IPSS-R, baseline LDH, and ECOG PS could discriminated further among the original IPSS lower risk patients, which need to be validated in the larger cohorts. Furthermore, to define the beneficial effect of HMA for each risk groups should be evaluated by comparing the treatment-naive patients with comparable patient populations.

P744

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE: DIAGNOSTIC AND CLASSIFICATION OF 103 BRAZILIAN PATIENTS

A Azambuja[1,*], M Malvezzi[1], L Medeiros[2], M Oliveira[2], M Bittencourt[2], A Orfao[3], R Pasquini[2]
[1]Hematology and Flow cytometry, [2]Bone Marrow transplantation, Universidade Federal do Paraná, Curitiba, Brazil, [3]Hematology and Flow cytometry, Universidad de Salamanca, Salamanca, Spain

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired chronic hemolytic anemia, which often manifests with peripheral blood cytopenias and thrombosis. The patients with PNH have acquired mutations in the phosphatidylinositol glycan class-A (PIG-A) gene, which causes the lack of Glycosylphosphatidylinositol-anchored complement regulatory proteins (GPI-AP) on hematopoietic cells. The clinical course of the disease is highly variable.
Aims: We retrospectively reviewed 103 PNH cases referred to our hospital from December 1999 through December 2011 to assess clinical presentations, thrombosis, survival, difference among subcategories, and clinical significance of PNH clone size.
Methods: The diagnosis of PNH was established by detection of the positive PNH clone by Flow Cytometry (FCM). The proteins studied were CD55 and CD59 on erythrocytes, neutrophils and monocytes, CD16, CD24 and CD66b on neutrophils and CD14 on monocytes.The presence of a clone was defined as the presence of GPI-AP greater than 0,1% of neutrophils or red cells, and the size of the clone was defined by the highest level of red blood cells and neutrophils lacking GPI-anchored proteins. Patients with severe and moderated AA, MDS or AML were subclassified according to literature.

Results: 103 patients with PNH clone were included into this study. The median age at presentation was 24.1 years (5.5–62 years). Hemoglobinuria as the initial symptomatic manifestation were seen in 23.2% of the patients, while the frequencies of infectious (46.6%) and bleeding symptoms (47.1%) were higher than other series. 17 (16,5%) patients developed thrombosis during monitoring. 101 patients presented with peripheral blood abnormalities: 83 (80,6%) had pancytopenia, 12 (15,2%) anemia and thrombocytopenia, and 4 (3,9%) anemia with leucopenia. The median hemoglobin level were 88g/L (38-145 g/L; normal range, 120-160 g/L), median ANC of 0.94×10^9/L ($0.26\text{-}1.45\times10^9$/L; normal range; $2\text{-}11\times10^9$/L), and with median PLT of 25×10^9/L ($2\text{-}294\times10^9$/L; normal range, $120\text{-}400\times10^9$/L). The median LDH were 328U/L (30-7970U/L, normal range 190-240U/L). 86,4% had hypocelular bone marrow. The cohort of patients were divided into subcategories of classic PNH (10 patients), PNH/AA (39 patients), and PNH-sc/AA (54 patients) based on the proposed PNH working clinical classification. 26 patients developed hemolysis after 2.35 years (median) after AA diagnosis. The overall survival at 10 years after diagnosis estimated by Kaplan–Meier was 81.7%, but PNH-sc/AA patients had lower OS (76,5%). There are significant differences in terms of median age, size of PNH clones, clinical symptoms, and peripheral blood cell counts among the three subcategories, especially between classic PNH and PNH-sc/AA subcategories. PNH clone size in erythrocytes and granulocytes were significantly different among the three subcategories (P<0.001), since the median percentages were respectively: 0,04% (0-10%) and 7.3% (6.4-19.0%) in PNH-sc/AA;15,8% (14-52%) and 63% (56-78%) in PNH/AA, and 82,2% (89.7-92.2%) and 98.0% (86.7-98.4%) in classic PNH. There were statistical difference in the variables platelets (P=0,001), LDH (P=0,002) and in the median percentages of PNH clone in neutrophils and erythrocytes among patients with or without thrombotic event, respectively neutrophils=92.7% (3.4%>100%) *versus* 21.5% (0.25%>99.9%), P<0,001, and erythrocytes=31.8% (0-100%) *versus* 1.2% (0-100%), P=0,008.

Summary and Conclusions: In conclusion, these retrospective review 103 PNH patients over a 10-year period represented the largest collection of such patients based on a single center in Brazil. It provided us useful information to understand the disease since our results confirmed the suggestion that large PNH clone are associated with increased risks for hemolytic form and thrombosis, even in patients with bone marrow failure, whereas small PNH clone is associated with a non-hemolytic form of the disease.

P745

ERYTHROPOIETIC ASPECTS IN MDS PATIENTS RESPONDERS TO ESAS TREATMENT

P Danise[1], C Cerchione[2],*, O Vitagliano[2], I Soriente[1], A Maria D'Arco[1], F Pane[2], F Alfinito[2]
[1]Hematology, Umberto I, Nocera Inferiore (SA), [2]Hematology, AOU "Federico II", Napoli, Italy

Background:
ESAs are the first line therapy in low risk anemic MDS patients and an early inception of this therapy can delay the need for RBC transfusion, hypothetically by slowing the disease course. It is a matter of debate whether the clinical response is a result of proliferation and maturation of the dysplastic clone or stimulation ofresidual normal erythropoiesis by ESAs. Evidence has been provided to support both views.

Aims: Macrocytosis is one of the cytological hallmarks of dyserithropoiesis in MDS: in this work we have analyzed erythropoietic response to ESAs therapy in a cohort of anemic MDS prevalently "low risk" patients enrolled in a regional retrospective register, RECAMDS (Registro Campano Mielodisplasie), subgroup of the Italian MDS register. We focused on cytometric differences in Mean Corpuscolar Volume of erythrocytes during the observation period in order to speculate on the target of such therapy in responsive patients.

Methods: 114 anemic MDS patients (43 RA, 17 RARS, 39 RCMD, 8 RAEB, 7 MDS del5q) not transfusion dependent, under standard ESA treatment ($\alpha$and βEpo, 40000/80000 or 30000/60000 U/weekly respectively), were analyzed at the baseline, after three and six month of continuous therapy. The response rate was evaluated following IWG criteria. Statistical analysis was performed with χ_2 and Anova tests.

Results: ESA therapy was started at Hb concentration 9.56 g/dl±1,5, global response rate was 84% (96/114), no difference among WHO subgroups was found. 88 patients responded after three months, 8 after six. In the responsive cohort, MCV was higher than normal at baseline in 52/96 (54%) patients, while 14/18 (77%) non-responsive patients exhibited macrocytosis. During the response at ESAs treatment, after 6 months from beginning of EPO therapy, 45/52 (86%) macrocytic patients showed permanently elevated values of MCV whereas 7/52 (13%) macrocytic responsive patients became permanently normocytic. In the group of 44 initially normocytic responsive patients 7/44 (15%) became macrocytic and contemporarily 4 of them showed an increase in their neutropenia and/or thrombocytopenia.

Summary and Conclusions: These very preliminary data can suggest that in the majority of MDS patients responsive to ESA treatment the increase of hemoglobin level occurs mainly stimulating erythroid production in MDS clones; in the minority of patients probably it happens recruiting residual polyclonal erythropoiesis. It is interesting to note that stimulating effects of ESA last even when the expression of dysplasia progresses.

P746

COMPARISON OF IPSS AND R-IPSS IN A SINGLE UNIT PATIENT COHORT

F Pierdomenico[1,*], A Almeida[1]
[1]IPOLFG, Lisbon, Portugal

Background: The International Prognostic Scoring System (IPSS) is the most widely used prognostic tool in Myelodysplasic Syndrome (MDS). A revised IPSS (R-IPSS) has been proposed, differing from IPSS by including finer cytogenetic grouping and depth of cytopenias.

Aims: In a MDS patient cohort diagnosed between January 2005 and December 2012 in our institution we retrospectively applied the R-IPSS and compared it to the IPSS risk groups.

Results: Complete data at diagnosis were available for 104 patients. Median age was 70.5 years, with male predominance (66/38); the most common WHO 2008 subtype was refractory cytopenia with multilineage dysplasia (33%) and 53% of patients were transfusion dependent. According to the IPSS, 78% were lower and 22% higher risk. Using the R-IPSS, patients were stratified as follows: very low 10%, low 48%, intermediate 14%, high 15% and very high 13%. Table 1 summarizes the reclassification of each IPSS group according to the R-IPSS. All low IPSS remained low risk in the R-IPSS, distributed between low and very low, while the great majority of high risk IPSS fall into the very high risk group. Intermediate-1 spanned from low to high, while intermediate-2 from high to very high. During a median follow-up of 17months, 17 patients (16%) progressed to acute myeloid leukaemia (AML), 6% in the low, 20% in the intermediate, 27% in the high and 54% in the very high risk group. Thirty-seven patients died (36%), 6% in the low, 46% in the intermediate, 53% in the high and 77% in the very high risk group. All 3 deaths in the low risk group were due to AML progression and the majority of deaths in the high and very high risk groups were AML/disease related. In the intermediate groups deaths were either due to infection or comorbidities.

Table 1.

	R-IPSS					
	VERY LOW	LOW	INT	HIGH	VERY HIGH	TOTAL
IPSS						
LOW	10	25	0	0	0	35 (34%)
INT-1	0	25	14	7	0	46 (44%)
INT-2	0	0	0	7	5	12 (11%)
HIGH	0	0	1	2	8	11 (11%)
TOTAL	10 (10%)	50 (48%)	15 (14%)	16 (15%)	13 (13%)	104

Summary and Conclusions: In our cohort most patients maintained their original risk stratification but 15% of those in IPSS-1 were re-stratified as high risk by R-IPSS. This suggests that this group is that in which therapeutic decision based on the R-IPSS might be more relevant.

P747

DOES REVISED INTERNATIONAL PROGNOSITIC SCORING SYSTEM (IPSS-R) HAVE ANY IMPACT ON CLINICAL OUTCOMES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES TREATED WITH HYPOMETHYLATING AGENTS?

Z Teo[1,*], R Yiu[1], L Ling Yueh[1], A Ho[1]
[1]Haematology, Singapore General Hospital, Singhealth, Singapore, Singapore

Background: Currently, stem cell transplant (SCT) remains the only curative therapy for myelodysplastic syndromes (MDS). Newer treatments with hypomethylating agents (HMAs) such as azacitidine and decitabine have proven to alter the disease course of MDS. In particular, azacitidine improves survival in higher-risk MDS patients compared with conventional treatment. International prognosis scoring system (IPSS) has recently been refined into the revised IPSS (IPSS-R) which predicts the clinical outcome of patients with untreated MDS. Whether the IPSS-R retains its value in the prognostication of patients with MDS treated with HMAs remains unknown.

Aims: We aim to determine the correlation between IPSS-R and clinical outcomes of MDS patients who received HMAs in our institution.

Methods: We performed a retrospective analysis on 47 patients with MDS (n=39) and low blast count acute myeloid leukaemia (AML; n=8) who received HMAs from November 2007 to November 2012. Clinical, haematological and

cytogenetic data were collected. Eleven and 2 of these patients underwent SCT and intensive chemotherapy respectively after HMAs. Their data were censored at the time of SCT or chemotherapy. Response criteria were based on the modified International Working Group (IWG) response criteria for MDS. Treatment response and survival data were analyzed using SPSS version 17.
Results: The median age of the whole cohort was 66 years (range 18-82). Twenty-eight of the patients were male and 19 were female. They received azacitidine (n=28) or decitabine (n=19). The median number of treatment cycles received was 4. Among these patients, the IPSS scores were intermediate-1 (n=13), intermediate-2 (n=19) and high (n=15) and the IPSS-R risk scores were low (n=3), intermediate (n=5), high (n=15) and very high (n=23). Cytogenetics risk stratification for these patients were good (n=21), intermediate (n=9), poor (n=2) and very poor (n=15). Median follow-up duration was 21.8 months. Overall response rate was 46.8% with complete remission (CR), marrow CR (mCR) and haematological improvement only (HI only) attained in 19.1%, 19.1% and 8.5% of patients respectively. Overall response was not influenced by IPSS-R (P=0.34). Median overall survival (OS) for the whole cohort was 20.3 months. The median survival for IPSS-R low, intermediate, high and very-high risk groups was 21.9, 24.4, 26.2 and 9.8 months respectively (P=0.039).
Summary and Conclusions: Many MDS patients are elderly and not eligible for intensive chemotherapy or SCT. HMAs with low toxicity have become an attractive treatment option for these MDS patients. HMAs have also been used to reduce disease burden in MDS prior to SCT in clinical trials. Our analysis showed that HMAs were able to induce good overall response rates of 46.8% and a median OS of 20.3 months. Significantly, IPSS-R has been shown to have an impact on the survival outcomes in our small series. The clinical outcome of MDS patients with very-high risk IPSS-R scores remains particularly poor, with a median survival of 9.8 months, despite treatment with HMAs. New treatment strategies will be needed to improve the survival of this group of MDS patients who are not eligible for SCT.

P748

THE CLINICAL RELEVANCE OF MINOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONES IN REFRACTORY CYTOPENIA OF CHILDHOOD–A PROSPECTIVE STUDY BY EWOG-MDS

A Aalbers[1,2,*], V van der Velden[2], A Yoshimi[3], A Fischer[3], P Noellke[3], C Zwaan[1], I Baumann[4], H Beverloo[5], M Dworzak[6], H Hasle[7], F Locatelli[8], B De Moerloose[9], B Schlegelberger[10], M Schmugge-Liner[11], J Stary[12], M Zecca[13], A Langerak[2], J van Dongen[2], R Pieters[14], C Niemeyer[3], M van den Heuvel-Eibrink[1]

Background: Minor paroxysmal nocturnal hemoglobinuria (PNH) clones are frequently present in adults with myelodysplastic syndrome (MDS) and are predictive of response to immunosuppressive therapy (IST) in some studies. We recently reported that in refractory cytopenia of childhood (RCC), the most common subtype of childhood MDS, IST might be effective. Data on the frequency and clinical correlates of PNH clones in RCC are lacking, and the value of the presence of a PNH clone as response predictor to IST in RCC is unknown.
Aims: In a prospective multicenter study of the European Working Group of MDS in Childhood (EWOG-MDS), we determined the clinical relevance of PNH clones in RCC.
Methods: 87 previously untreated primary RCC patients, diagnosed between June 2005 and December 2011, were evaluated for the presence of PNH clones. Diagnosis of RCC was based on WHO criteria for pediatric MDS and confirmed by central review of bone marrow morphology and histology. Peripheral blood was analyzed by high-sensitivity flow cytometry, defining PNH-type granulocytes as $CD24^{-}FLAER^{-}$ and PNH-type erythrocytes as $CD55^{-}CD59^{-}$. Patients were considered PNH positive when a GPI-deficient population larger than 0.01% in the erythroid and/or a population larger than 0.03% in the granulocytic lineage were present. Of 87 RCC patients, 28 hypocellular patients were subsequently treated with IST, consisting of horse- or rabbit-ATG and CsA.
Results: The median age of included patients was 10.2 years (range: 1-18 years). Bone marrow was hypocellular in 84% of patients; cytogenetic analysis was normal in 85%, monosomy 7 was present in 7%, and other cytogenetic aberrations in 8%. PNH clones were detected in 36 of 87 (41%) RCC patients at diagnosis. Median clone sizes were 0.06% (range: 0.01-58%) in erythrocytes and 0.9% (range: 0.03-86%) in granulocytes. PNH positive patients, compared to PNH negative patients, were significantly older (median: 12.7 *versus* 7.5 years, P=0.005), had lower leukocyte counts (median: 2.7 *versus* 3.3×10^9/L, P=0.029), lower platelet counts (median: 20 *versus* 44.5×10^9/L, P=0.008), lower hemoglobin levels (median: 7.7 *versus* 9.5 g/dL, P=0.006), tended to have a higher MCV (above the 97th percentile in 81 *versus* 62% of patients, P=0.073), and were more often HLADR15 positive (42% *versus* 21%, P=0.051). Hypocellular RCC patients with a PNH clone >0.1% were more likely to respond to IST than PNH negative patients (7 of 8 (88%) *versus* 8 of 20 (40%) patients responded at six months, respectively, P=0.038) and tended to have a better event-free survival. PNH clone size remained relatively stable in sequentially followed patients, both in patients under a watch-and-wait strategy, and in patients treated with IST, independent of response.
Summary and Conclusions: We conclude that PNH clones are frequently present in RCC, predict response to IST, and might indicate an immune-mediated pathophysiology in at least a subset of RCC patients.

Multiple myeloma - Biology 2

P749

NEW STRATEGIES OF ANALYSIS WITH FLOW CYTOMETRY FOR THE DIAGNOSIS OF MINIMAL RESIDUAL DISEASE IN MULTIPLE MYELOMA

P Beneit[1,*], F Tarin[1], E Mora[1], B Villarrubia[1], A Mauricio[1], Mª Fernández[1], S Salazar[1], F José De Paz[1], J Verdú[1], S Sánchez[2], J Sánchez-Majano[3], V Castaño[4], C Fernández[5], M Blanes[4], J Juan V Verdú[1]
[1]Hematology, Hospital General Universitario de Alicante, [2]Hematology, Hospital General De Villajoyosa, [3]Hematology, Hospital General Universitario de San Juan, [4]Hematology, Hospital General Universitario de Elda, [5]Hematology, Hospital General Vega Baja, Alicante, Spain

Background: The use of intensive therapy and novice agents has increased the quality of responses in multiple myeloma (MM), necessitating the development of more sensitive techniques to monitor the disease.
- In the last years, the study of minimal residual disease (MRD) by multiparameter flow cytometry 4 colour and PCR has shown that obtaining MRD <0.01% is an independent prognostic factor for survival in patients undergoing ABMT.
- However, the selective loss of plasma cells (PC) manipulating the sample, changes in the immunophenotype of residual neoplastic PC, and the reappearance of an increasing number of normal PC may complicate the identification of small pathological populations, limiting the sensitivity of the technique.

Aims: Optimizing a 8 colours panel, restricted to surface antibodies that have most frequently aberrant expression in neoplastic plasma cell.
- Check our systematic of study, and propose a simple and reproducible way to identify residual populations with high sensitivity.

Methods:
- Bone marrow aspirate in EDTA tube (1 cm^3).
- Multiparameterflowcytometer8 colours.
- Panel as recommended by the European Myeloma Network, and validated by our own experience (two tubes: CD38/CD27/CD200/CD19/CD28/CD10/CD45/CD138 and CD38/CD20/β2m/CD56/CD117/CD81/CD45/CD138).
- The use in studies analyzed with 8 fluorescences identifies a real "fingerprint" the neoplastic population).

We analize:
- 30 healthy controls.
- 60 MGUS.
- 60 patients with MM at diagnosis.
- 40 patients with MM in complete remission post-treatment.

Results: We superimpose the reference image of the initial diagnostic study, and make a selection of the study population by similarity to the original. Select all PC by expression of CD38 and CD138, and analyzed with the APS option. The APS clearly separates into two subpopulations. Through the combination of the selected antibodies, we clearly identify aberrant residual population (red), which is distinguished from the normal PC (green).

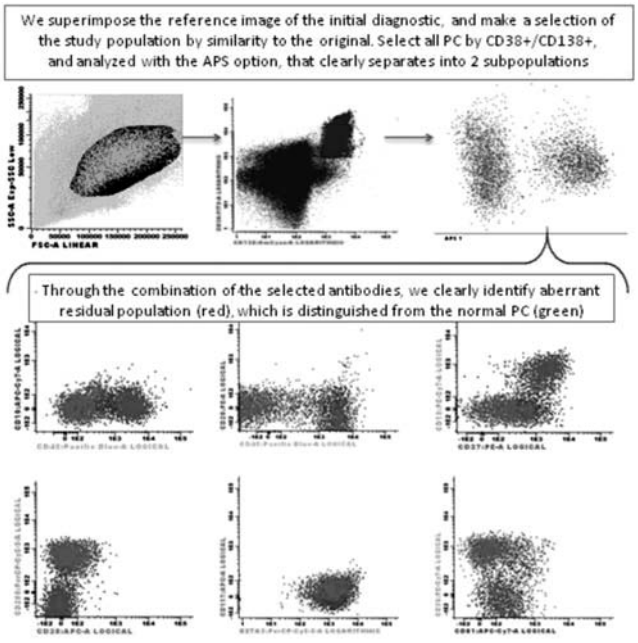

Figure 1.

Summary and Conclusions: The strategy described allows to detect and discriminate normal populations of pathological in a simple and reproducible manner, even in cases with immunophenotypic changes after the relapse.
In contrast with most combinations of four colours, the strategy does notrequire detection of cytoplasmic immunoglobulins and, therefore, avoids selective cell losses by manipulation and permeabilization.
Given the high sensitivity and the possibility of detecting very small populations, we believe feasible to increase the sensitivity of the technique of $10^{-4a10-5}$.

P750

FREQUENT MUTATION OF THE MYD88 GENE IN MACROGLOBULINEMIA

N Mori[1,*], M Ohwashi[1], K Yoshinaga[1], K Mitsuhashi[1], N Tanaka[1], M Okada[1], M Shiseki[1], T Motoji[1]
[1]Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Waldenström's macroglobulinemia (WM) is an IgM-secreting lymphoplasmacytic lymphoma (LPL). Nuclear factor (NF)-κB signaling is important for the growth and survival of WM cells. Myeloid differentiation primary response gene 88 (MYD88) is an adaptor protein that mediates toll and interleukin (IL)-1 receptor signaling. After stimulation, Toll/IL-1 receptor (TIR) domains activate MYD88. Subsequently MYD88 dimerizes and induces phosphorylation of IL-1 receptor-associated kinase (IRAK)4, IRAK1, and IRAK2, leading to inhibitor κBα (IkBα) phosphorylation and activation of NF-κB. The MYD88 gene was mutated in activated B-cell-like subtype of diffuse large B-cell lymphoma (DLBCL). The most frequent mutation of the MYD88 gene was a T to C transition at nucleotide 978 resulting in a leucine to proline substitution at amino acid position 265 (L265P). This mutation is located in the TIR domain and triggers IRAK-mediated NF-κB signaling. The L265P mutation was recently identified in 49 of 54 patients with WM, and 3 of 3 non-IgM-secreting LPL. Inhibition of MYD88 signaling reduced IκBα, NF-κB p65 phosphorylation, and NF-κB nuclear staining in WM cells expressing the L265P. More recently, the mutation was found in 18 of 27 WM (67%).
Aims: To determine the relevance of the L265P mutation and its association with clinical characteristics in lymphoid neoplasms, we analyzed on the MYD88 gene in WM, B-cell lymphoma, and myeloma.
Methods: The L265P mutation was analyzed in 23 WM, 1 non-IgM-secreting LPL, 1 low grade B-cell lymphoma with IgG M-protein, and 38 myeloma. Mononuclear cells were separated from bone marrow after obtaining written informed consent. PCR products covering the TIR domain were purified and ligated into the pGEM-T vector. Sequencing was performed in both directions on a MegaBase sequence system. Direct sequencing was performed using the purified PCR products. The L265P mutation was also examined with BSiE1 restriction enzyme digestion. The PCR products were purified, digested with BSiE1, and subject to electrophoresis through a 2% agarose gel. The current study was conducted within the guidelines and with the approval of the institutional ethical committee. Correlations between the categorical variables were analyzed using the chi-square test or Fisher's exact probability test. Statistical analysis was performed with the Wilcoxon's signed-ranks test. Ordinal variables were compared with the use of the Mann-Whitney's U- test. The analysis was performed using Dr SPSSII (version 11.01) or Statcel 3 software. P-value of less than 0.05 was considered statistically significant.
Results: We first selected 10 patients including 8 WM, 1 non-IgM-secreting LPL, and 1 B-cell lymphoma with IgG M-protein for cloning and sequencing. At least four clones were examined. The L265P was detected in 2 of 9 clones from 1 patient with WM, while it was absent in other 9 patients. Because of the low frequency of the mutation, we next performed direct sequencing in the 10 patients and additional 15 patients with WM. The L265P was detected in 8 of 25 patients (32%). It was found in 7 of 23 WM (30%) and the low grade B-cell lymphoma with IgG M-protein. All of the 8 patients with the transition also had wild-type sequences. We next tested for the mutation with BSiE1 digestion. Sensitivity of the L265P mutation is 5% in our study. Aberrant bands corresponding to the mutation were detected in 19 of the 25 patients: 18 of the 23 WM (78%) and the B-cell lymphoma with IgG M-protein but not in the non-IgM-secreting LPL. All of the 8 patients with the L265P (by sequencing) showed the aberrant bands. We also examined with BSiE1 digestion in the 38 patients with myeloma, however no aberrant bands were observed. The incidence of the mutation was significantly higher in WM than in myeloma (P<0.00001). In the 23 WM patients, the L265P mutation was more frequently detected by the BSiE1 digestion (78%) than direct sequencing (30%) (P=0.0010). The L265P mutation was significantly more frequent in males (15/16, 94%) than females (3/7, 43%) (P=0.017). The percentage of lymphocytes was larger in the L265P group than wild-type group (P=0.041). It was larger in male than female patients (P=0.030).
Summary and Conclusions: This study shows the L265P mutation to be frequent in WM and absent in myeloma. Our results reveal that the BSiE1 digestion is more sensitive than direct sequencing. Since some patients have only a small amount of the mutant allele, the contribution of the mutation remains to be clarified in these cases.

P751

THE ROLE OF FLT3-LIGAND IN THE PROGRESSION OF MULTIPLE MYELOMA; FLT3-LIGAND RELEASED FROM BONE MARROW STROMAL CELLS ACTIVATED PI3K/AKT PATHWAY AND WNT SIGNALING

Y Koh[1], S Beom[1], K Cho[1,*], K Ahn[2], J Kim[1], H Lee[3], J Kwon[1], K Kim[1,4], H Kim[5], S Park[1], B Kim[1,6], S Yoon[1,6,7]

[1]Internal Medicine, Seoul National University Hospital, [2]Internal Medicine, College of Medicine, Seoul National University, Seoul, [3]Internal Medicine, Dongguk University Medical Center, Goyang, [4]Internal Medicine, Seoul National University Boramae Hospital, Seoul, [5]Internal Medicine, Hallym University Sacred Heart Hospital, Anyang, [6]Cancer Research Institute, [7]Clinical Research Institute, College of Medicine, Seoul National University, Seoul, Korea, Republic of Korea

Background: The concerted action of cytokines secreted locally in the bone marrow controls the maintenance, expansion, and differentiation of hematopoietic stem cells (HSCs). Given that the progression of multiple myeloma (MM) is regulated by growth factors released from bone marrow stromal cells, aberrant cytokine signaling contributes to oncogenic transformation during multilineage hematopoietic cell differentiation. The flt3-ligand is capable of inducing multilineage hematopoietic cell differentiation. However, the exact role of flt3-ligand still remains unknown in MM.
Aims: To determine the dynamic interplay between MM cells and microenvironment, the role of flt3-ligand released from BMSCs is examined in relation with the progression of MM
Methods: To identify potential, functionally relevant flt3-lgand in MM, we measured, by ELISA, bone marrow plasma flt3-ligand concentrations in 127 MM patients. We also determined the role of flt3-ligand in the growth of MM cell lines. Specifically, we investigated flt3-mediated cell signaling in the growth of MM cells and the expression of adhesion molecules in MM cells, to emphasizing the important role of flt3-ligand as a mediator in the interaction of MM cells with their microenvironment.
Results: The steady-state level of flt3-ligand in MM patients (n=127) was 67 +/- 4 pg/mL and was higher than in case-control groups (AML, CML, and ALL). Association between the levels of flt3-ligand and clinical parameters (poor prognostic marker and remission duration) of MM patients was examined. The levels of flt3-ligand showed a significant difference between the two groups with or without IgH spilt (14q32 FISH) (*P=0.004*). They also differed according to remission duration (within 6 months and more than 6 months; *P=0.027*). To examine the dynamic interplay between MM cells and bone marrow stromal cells (BMSCs), flt3-ligand was measured in 7 different MM cell lines and 12 different BMSCs ex-vivo cultured from MM patients' bone marrow. Flt3 ligand was detected in cultured soup of 12 BMSCs but not detected in cultured soup of MM cell lines. Levels of flt3-ligand was variable in the cultured soup of 12 BMSCs. Levels of flt3-ligand from BMSCs obtained from 5 MM patients relapsed within 6 months were higher than those from 7 MM patients (*P=0.021*) relapsed after 6 months. Flt3-ligand levels were higher in cultured soup of MM cells co-cultured with BMSCs than in controls (either MM cells alone or BMSCs alone). In the presence of flt3-ligand in U266 cells and MOLP8 cells, phosphorylation of AKT and STAT5 was dose-dependently increased as well as flt-3 ligand-induced DKK1 secretion was observed. Since DKK1 expression was regulated by wnt-signaling, we then examined a set of genes related with wnt signaling after U266 cells and MOLP8 cells were treated with flt3-ligand for 2 hours. We found that flt3-ligand effectively activated *wnt* signaling and induction of DKK1 was detected in both cell lines treated with flt3-ligand. Partial knockdown of flt-3 expression by short interfering RNA also resulted in inhibition of DKK1 secretion. These results indicated that flt-3 signaling plays a central role in the growth of MM cells and the regulation of DKK1 secretion.
Summary and Conclusions: Our results indicated that the activation of flt3-ligand signaling play a critical role in the progression of MM.

CIRCULATING MICRORNA AS POTENTIAL BIOMARKERS OF MGUS AND MM

L Kubiczkova[1,*], S Sevcikova[1], E Dementyeva[1], F Kryukov[1], O Slaby[2], J Nekvindova[3], L Radova[3], H Greslikova[4], P Kuglik[4], L Pour[5], Z Adam[5], R Hajek[6]

[1]Department of Pathological Physiology, Masaryk University, Faculty of Medicine, [2]Department of Comprehensive Cancer Care, Masaryk Memorial Cancer Institute, Brno, [3]Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University, Olomouc, [4]Department of Experimental Biology, Faculty of Science, Masaryk University, [5]Department of Internal Medicine -Hematooncology, University Hospital Brno, Brno, [6]Institute of Clinical Hematology, University Hospital Ostrava, Ostrava, Czech Republic

Background: MicroRNA, a family of small non-coding regulatory RNA, is implicated in deregulation of critical pathways involved in multiple myeloma (MM). Since they are also present in serum of MM and monoclonal gammopathy of undetermined significance (MGUS) patients (pts) with high stability, they could serve as effective biomarkers for such pts. We have identified a specific serum miRNA profile in newly diagnosed MM and MGUS pts, correlated it with clinical parameters, FISH and survival data.
Aims: 1. To identify a specific profile of serum miRNAs characteristic for MM and MGUS pts. 2. To evaluate the association between serum miRNAs and clinical parameters, FISH data, overall survival (OS) and time to progression (TTP).
Methods: 190 serum samples obtained from MM pts, MGUS pts and healthy donors (HD) were evaluated for this study. Screening analysis of 667 miRNAs was performed on 4 MM, 4 HD and 5 MGUS samples with TaqMan Low Density Arrays (TLDA). Levels of 6 differentially expressed miRNAs (*P*<0.05) between MM and HD were confirmed by quantitative real-time PCR using an absolute quantification approach on 103 MM, 57 MGUS and 30 HD samples. Receiver Operating Characteristic (ROC) analysis was used to calculate specificity and sensitivity of each miRNA and their combination. Univariate Cox proportional hazards survival model was used to evaluate prognostic impact of miRNAs. Biochemical data and cytogenetic characteristics were also available for MM and MGUS pts. P values <0.05 were considered as significant.
Results: MiRNA TLDA arrays analysis showed 14 differentially expressed miRNAs between MM and HD, but no significantly deregulated miRNAs between MM and MGUS. Therefore, miR-222, miR-130a, miR-34a, miR-744, let-7d and let-7e were further validated on a larger cohort of MM, MGUS and HD samples. Overall reduction of circulating serum miRNAs was observed in MM and MGUS compared to HD. MiR-744, miR-130a, let-7d and let-7e were significantly downregulated and miR-34a was upregulated in MM and MGUS cohort of pts (all *P*<0.001). ROC analysis showed highest sensitivity (80.6%), specificity (86.7%) (AUC=0.898) for combination of miR-34a and let-7e to distinguish MM from HD and sensitivity (91.1%), specificity (96.7%) (AUC=0.976) for miR-34a and let-7e combination to distinguish MGUS from HD. Significant positive correlation between low levels of serum miR-744, let-7d, let-7e and levels of hemoglobin (r_S=0.543; 0.508 and 0.585 resp., all *P*<0.0001), thrombocytes (r_S=0.555; 0.500 and 0.515 resp., all *P*<0.0001) and albumin (r_S=0.355; 0.385 and 0.355 resp., all *P*<0.0001) was observed in MM. These miRNAs significantly negatively correlated with levels of creatinine (r_S=-0.415; -0.372 and -0.406, resp., all *P*<0.0001) and beta$_2$-microglobulin (r_S=-0.504; -0.447 and -0.529 resp., all *P*<0.0001). In MGUS, similar correlation pattern with these parameters was observed, except for correlation between miRNA and thrombocytes, where no correlation was found. However; neither in MM, nor in MGUS, the levels of miRNAs correlated with PCs infiltration. Only in MM pts, let-7d and let-7e correlated with del (13q14) (*P*=0.045 and *P*=0.019 resp.). Levels of miR-744, let-7d and let-7e showed an inverse correlation with ISS stage (all *P*<0.0001). Lower levels of miR-744 were found to be significantly connected with worse OS (HR 0.998 [HR95%CI: 0.997; 0.999); *P*=0.001) and TTP (HR 0.998 [HR95%CI: 0.998; 0.999]; *P*=0.001).
Summary and Conclusions: Our observations demonstrate that circulating serum miRNA may be promising biomarkers for patients with monoclonal gammopathies, such as MGUS and MM.
Grants support: NT11154, NT12130, MUNI/11/InGA17/2012 and CZ.1.07/2.3.00/20.0046

P753

TGR-1202: A NOVEL PI3K-DELTA SPECIFIC INHIBITOR IN MULTIPLE MYELOMA

S Vakkalanka[1,*], H Miskin[2], P Sportelli[2], S Viswanadha[3]

[1]Rhizen Pharmaceuticals S A, La Chaux-de-Fonds, Switzerland, [2]TG Therapeutics, Inc., New York, United States, [3]Incozen Therapeutics Pvt. Ltd., Hyderabad, India

Background: The bone marrow microenvironment contributes to the pathogenesis of Multiple Myeloma (MM) by promoting the oncogenic process, including drug resistance. High expression levels of the PI3K-δ isoform in patient MM cells implicate this target as a novel and attractive interventional strategy aimed at attenuating the progression of the disease.
Aims: Herein, we describe the biological and pharmacokinetic properties of TGR-1202, a novel small molecule PI3K-δ inhibitor currently under clinical development for patients with relapsed and refractory hematological malignancies, with potential to be developed as a clinical candidate for patients with relapsed and/or refractory MM.
Methods: Activity of TGR-1202 on individual PI3K isoforms was determined in enzyme, cell, and whole blood based assays. Potency of TGR-1202 was confirmed *via* MM cell viability and apoptosis assays in addition to testing for inhibition of pAkt, a downstream kinase regulating cell survival and growth. Additionally, TGR-1202 was tested for potency in viability, apoptosis, and Akt phosphorylation assays using immortalized and MM patient derived primary cells. ADME and pharmacokinetic properties of the molecule were also determined.
Results: TGR-1202 demonstrated significant potency against PI3K-δ (22.2 nM) with high selectivity over the α (>10,000 fold), β (>50 fold), and γ (>48 fold) isoforms. Additionally, TGR-1202 inhibited B-cell proliferation (24.3 nM) and FcεR1 induced CD63 expression in human whole blood basophils (68.2 nM) indicating specificity towards the delta isoform. The addition of 5 μM TGR-1202 to dexamethasone (0.55 μM) caused a dramatic shift in GI_{50} of MM-1S cells compared to that of either TGR-1202 (9.7 μM) or dexamethasone (18.3 μM) alone. Further viability testing demonstrated that TGR-1202 caused a dose-dependent inhibition (>50% @ 1-3 μM) in growth of immortalized (U266B1 and MM-1R) as well as patient-derived MM cells. Reduction in viability was accompanied by a reduction

in pAKT (>80% @ 3 μM) along with induction of apoptosis in both cell lines and patient samples. Pharmacokinetic studies across species indicated good oral absorption (>40% bioavailability for mice, rat, and dog) with favorable plasma concentrations (3-10 μM @ 20 mg/kg for mice, rat, and dog) relevant for efficacy.
Summary and Conclusions: Data demonstrate the therapeutic potential of TGR-1202 in MM *via* inhibition of the PI3K-δ pathway. Data from immortalized as well as primary patient-derived cells justify further evaluation of TGR-1202 in MM. Additional studies, including combination therapy of TGR-1202 with anti-MM agents in mouse xenograft models are currently ongoing.

DEF124B, A MEMBER OF THE β-DEFENSINS, IS DOWNREGULATED IN DIFFERENTIATING OSTEOBLASTS BY EXPOSURE TO IMIDS AND MAY MEDIATE THE SUPPRESSIVE EFFECT OF THESE AGENTS ON OSTEOGENESIS

A Bolomsky[1,*], M Schreder[1], T Meißner[2], D Hose[2], H Ludwig[1], S Pfeifer[1], N Zojer[1]
[1]First Department of Medicine, Wilhelminen Cancer Research Institute, Center for Oncology and Hematology, Vienna, Austria, [2]Internal Medicine V, University of Heidelberg, Heidelberg, Germany

Background: Osteoblastic activity is severely impaired in most myeloma cases, which contributes to the development of osteolytic lesions. Although several drugs reducing osteoclast mediated bone degradation are in clinical use, approaches to specifically augment bone formation are at an early stage of development. Novel anti-myeloma drugs not only directly act on myeloma cells, but impact on the microenvironment as well. Bortezomib was previously shown to exert bone anabolic properties. In contrast, the influence of immunomodulatory drugs (IMiDs) on osteogenesis is less well defined.
Aims: IMiDs were shown to influence various cell types including osteoclast and granulocyte differentiation as well as activity of T- and NK-cells. Data on the impact of IMiDs on osteoblast development is very limited so far. In this study we aimed to investigate the differential effects of IMiDs alone or in combination with bortezomib on osteogenesis.
Methods: An *in vitro* model for osteoblast differentiation was used employing immortalized or primary human bone marrow-derived stromal cells to study the effect of thalidomide and lenalidomide on osteogenesis. Alkaline phosphatase activity and matrix mineralization were used as markers of early and late osteoblast development, respectively. Genes known to be important for osteogenesis were studied by qPCR. Furthermore, gene expression profiling was applied to identify additional genes of importance in mediating the effects of IMiDs.
Results: Treatment with thalidomide and lenalidomide significantly inhibited osteoblast development, as reflected by a 43% (P<0.05) reduction of alkaline phosphatase activity on day 14 and a 70.4% (P<0.05) reduction of matrix mineralization on day 21 of osteogenesis. This observation was accompanied by downregulation of osteogenic transcription factors Runx2 and Dlx5. The same effects were noted when IMiDs were combined with bortezomib. Furthermore, DKK1 and inhibin beta A expression was induced up to 8.6 and 1.9 fold (P<0.05), respectively, by both IMiDs. Neither DKK-1 nor activin A inhibition rescued BMSCs from the OB inhibitory action of the IMiDs, suggesting that other mechanisms are involved in IMiD related suppression of osteogenesis. Microarray analysis revealed deregulation of several OB associated genes including *Runx2*, *MMP3*, *COL5A3*, *PTN* and *GREM1*, with different patterns depending on the IMiD used. *DEFB124*, a poorly characterized member of the family of ß-defensins, was the only gene affected by both IMiDs, being downregulated approximately 5- fold (P=0.02).
Summary and Conclusions: We show a significant inhibitory effect of thalidomide and lenalidomide on osteoblast development. This finding is likely due to IMiD induced downregulation of *DEFB124,* although other osteoblast inhibitors such as DKK1 and inhibin beta A were downregulated as well. Modulation of ß-defensin expression might mitigate untoward bone specific side effects of IMiDs, which may become particularly important during periods of prolonged drug exposure such as maintenance therapy.

P755

IDENTIFICATION AND CHARACTERISATION OF THE ROLE OF SAMSN1 GENE EXPRESSION IN A MURINE MODEL OF MYELOMA AND MYELOMA PATIENTS

J Noll[1,2,*], S Williams[2], K Vandyke[2], C Kok[3], A Zannettino[1,2]
[1]School of Medical Sciences, University of Adelaide, [2]Myeloma Research Laboratory, Department of Haematology, [3]Acute Myeloid Leukemia Laboratory, Department of Haematology, SA Pathology, Adelaide, Australia

Background: Multiple myeloma (MM), a haematological malignancy characterised by the clonal growth of malignant plasma cells in the bone marrow, is preceded by the benign, asymptomatic condition, monoclonal gammopathy of undetermined significance (MGUS). Several genetic abnormalities have been identified as critical for the development of myeloma, however these abnormalities are also found in patients with MGUS, indicating that there must be other as yet unidentified factors that contribute to the onset of myeloma disease.
Aims: To identify novel genetic factors that play a role in the development or progression of MM.
Methods: Unlike the related C57BL/6 mouse strain, the C57BL/KaLwRij mouse strain displays an inherent ability to develop MM. We used comparative gene expression profiling analysis to identify differences between these two strains as a strategy to identify genes that may play roles in MM disease development.
Results: We identified the adaptor molecule, *Samsn1,* as having significantly decreased expression in all tissues and haematopoietic cell subsets of the C57BL/KaLwRij mice compared to C57BL/6 mouse strain. Over-expression of *Samsn1* in the 5TGM1 murine myeloma plasma cell line resulted in complete inhibition of myeloma disease development *in vivo*. *SAMSN1* expression was also found to be decreased in human myeloma cell lines and in the bone marrow plasma cells from MM patients compared to MGUS and normal controls.
Summary and Conclusions: *Samsn1* therefore represents a key gene, whose loss of expression may facilitate the progression of MM disease, and hence may represent a novel therapeutic target.

P756

IDENTIFICATION AND CHARACTERIZATION OF LAMBDA MYELOMA ANTIGEN, LMA, AS A THERAPEUTIC TARGET IN LAMBDA MULTIPLE MYELOMA

P Asvadi[1,*], C Jennings[1], V Jiang[1], P Winter[1], J Dunn[1], A Spencer[2], R Dunn[1]
[1]Immune System Therapeutics Ltd, Ultimo, [2]Alfred Hospital, Melbourne, Australia

Background: Clinical studies have shown that the monoclonal antibody (mAb), MDX-1097, specific for kappa myeloma antigen (KMA), has anti-myeloma activity in kappa multiple myeloma (κMM) and an excellent safety profile as demonstrated by early stage clinical trials**.**
Aims: The aim of this study was to verify whether a λ equivalent of KMA, *i.e.* lambda myeloma antigen (LMA), existed on the cell surface of λ myeloma cell lines and λMM patient samples and characterize this novel antigen.
Methods: Two mAbs and human myeloma cell lines (HMCLs) of divergent λ isotype were analysed by flow cytometry. Surface plasmon resonance and Western blotting were used to characterize the reactivity of the two mAbs against a range of lLCs and select a prototypic candidate. Confocal microscopy using the selected mAb was utilized to further characterize the presence of LMA on the cell surface of RPMI8266 λHMCL cells. Epitope excision experiments were conducted to identify the epitope of this mAb and additionally LMA was recreated on the cell surface of HEK cells using recombinant expression approaches.
Results: Flow cytometry demonstrated the presence of LMA on the cell surface of λHMCLs and on primary BM samples from λMM patients. Confocal microscopy also demonstrated the cell surface location of LMA. Only one of the mAbs tested showed pan-reactivity against all λLCs tested. The epitope of this mAb was identified, shown to be of a conformational nature, and mapped to the variable (V)-constant (C) proximal region of λFLC. LMA expression on the cell surface was characterized by recombinant expression of l free light chain (λFLC) in CHO and HEK host cells. Both host cells secreted soluble λFLC, however, LMA was only detected on the surface of HEK cells.
Summary and Conclusions: These data identify LMA as a novel antigen that is specific to malignant B cells of λLC istoype. We have generated a number of human anti-LMA mAbs which are currently undergoing pre-clinical evaluation for clinical development. We believe this targeted approach to treatment would be beneficial in l type multiple myeloma and in particular for patients with POEMS syndrome.

P757

NEUTROPHILS ARE IMPAIRED IN MULTIPLE MYELOMA BUT NOT IN MGUS

A Romano[1,*], N Parrinello[1], P La Cava[1], C Giallongo[1], D Tibullo[1], A Chiarenza[1], C Conticello[1], M Cavalli[1], G Palumbo[1], F Di Raimondo[1]
[1]Division of Hematology, Ospedale Ferrarotto, Catania, Italy

Background: In Multiple Myeloma (MM) the immune function is impaired but the role of microenvironment on this dysfunction is unknown.
Aims: Evaluation of immunosuppressive properties of mature neutrophils in MM and MGUS.
Methods: In 60 consecutive newly diagnosed MM, 70 MGUS and 30 healthy subjects we evaluated in neutrophils (N) from peripheral blood the phagocytic activity using a commercially available kit (Phagotest R), and the expression of molecule arginase-1 (Arg-1) and PROK-2. We tested the immunosuppressive properties with functional assay, based on *in vitro* co-culture of N isolated from patients and T-lymphocytes from healthy subjects.
Results: Despite no differences in the absolute number of neutrophils between MM, MGUS and healthy donors, we found a functional impairment in MM not evident in MGUS patients.
The capability of phagocytosis of MM-N was significantly reduced compared to healthy subjects (P<0.001) and MGUS (P<0.0001), and partially restored after

induction chemotherapy. MM-N exhibited an increased expression of ARG-1 compared to MGUS and healthy controls (25.5 *vs* 6.2 *vs* 1 fold changes in gene expression, P=0.003), confirmed by functional assay of enzymatic activity of ARG-1, positively correlated with advanced disease. Similarly, MM-N exhibited an increased expression of PROK-2 compared to MGUS and healthy controls (13.8 *vs* 1.5 *vs* 1 fold changes in gene expression, P=0.001). After PHA-P stimulation, T-lymphocytes isolated from healthy donors missed the expression of activation markers such CD71, CD69, CD25, CD3ζ in presence of MM-N for 72 hours, and in a less extensive way in presence of MGUS-N.
Summary and Conclusions: Compared to controls, neutrophils obtained from MM patients and to a lesser extend from MGUS patients, have a reduced phagocytic activity and increased ability to suppress lymphocyte activation. These alterations may contribute to impairment of immune functions that characterizes MM patients.

P758

IDENTIFICATION OF INSULIN LIKE GROWTH FACTOR BINDING PROTEIN 7 (IGFBP7) AS TUMOR SUPPRESSOR IN MULTIPLE MYELOMA LINKED TO THE PRESENCE OF OSTEOLYTIC LESIONS AND OVERALL SURVIVAL
A Bolomsky[1,*], D Hose[2], M Schreder[1], D Heintel[1], A Seckinger[2], T Meißner[2], B Klein[3], S Pfeifer[1], H Ludwig[1], N Zojer[1]
[1]First Department of Medicine, Wilhelminen Cancer Research Institute, Center for Oncology and Hematology, Vienna, Austria, [2]Internal Medicine V, University of Heidelberg, Heidelberg, Germany, [3]INSERM U1040, Institute for Research in Biotherapy, CHU Montpellier, Montpellier, France

Background: Direct interactions between myeloma cells and bone marrow stromal cells (BMSCs) as well as the crosstalk through various soluble factors play a major role in the pathophysiology of MM leading to clinical features such as myeloma bone disease. Insulin like growth factor binding protein 7 (IGFBP7) has been described as secreted tumor suppressor protein in melanoma and in various other solid tumors. Methylation dependent silencing of IGFBP7 correlated with outcome in lung-, breast-, hepatocellular- and pancreatic ductal cancer. Recent studies also indicate a possible role for IGFBP7 in hematological malignancies.
Aims: Here we aimed to analyze microenvironmental factors possibly interfering with BMP signaling in the bone marrow environment and to elucidate the role of insulin like growth factor binding protein 7 (IGFBP7) in the pathophysiology of multiple myeloma (MM).
Methods: BMP antagonist expression pattern in myeloma was analyzed by gene expression profiling. IGFBP7 gene expression in MMCLs was analyzed by qPCR after treatment with 5-aza-2´-deoxycytidine and Trichostatin A. Pyrosequencing was performed by Varionostic® GmbH. Viability was assessed after treatment with recombinant human IGFBP7 for 96 hours. Immortalized human BMSCs were co-cultured with MMCLs and primary MM cells for 72 h. Primary human BMSCs were kept in osteogenic differentiation medium for 7-14 days.
Results: Microarray analysis of BMP signaling antagonists revealed downregulation of IGFBP7 in MGUS (n=22) and MM patient samples (n=329) as well as MM cell lines (MMCLs)(n=17) compared to normal plasma cells (n=10)(P<0.02). IGFBP7 silencing in MM cells was found to be regulated by methylation, confirmed by pyrosequencing of the IGFBP7 promoter region in primary MM cells and by upregulation of expression after 5-aza-2-deoxycytidine treatment in 4 of 7 MMCLs (P<0.05). Treatment with recIGFBP7 decreased viability in all cell samples testes, reaching statistical significance in 6 of 7 MMCLs (P<0.05) and 2 of 4 primary MM cell samples (P<0.05) tested. This effect was due to an impairment of proliferation confirmed by BrdU assay and upregulation of p21 (P<0.05), while no increase in apoptosis could be detected. Focusing on the BM microenvironment, we observed decreased expression of IGFBP7 in BMSCs after co-culture with 4 of 5 MMCLs (P<0.001) and 3 of 3 primary MM cell samples (P<0.001). Treatment with recIGFBP7 stimulated osteoblast activity up to 1.8 fold (P<0.001) and decreased DKK1 expression (P<0.05). In line with this, we found an association of low IGFBP7 expression with bone disease (P<0.05) in an independent series of newly diagnosed myeloma patients (n=62). Furthermore, high IGFBP7 expression tended to predict longer OS (median survival 62 *vs.* 20 months, P=0.06).
Summary and Conclusions: Our data show significant downregulation of IGFBP7 in MM cells. This effect is mediated by hypermethylation, and likely contributes to disruption of cell cycle control and enhanced proliferation of myeloma cells. IGFBP7 seems also to be suppressed in stromal cells in the vicinity of MM cells, which might be involved in the impairment of osteoblast development and contribute to myeloma bone disease. Moreover, IGFBP7 expression tends to predict overall survival in MM. Upregulation of IGFBP7 might therefore be a useful therapeutic intervention in the treatment of MM.

P759

HIGH RISK CYTOGENETIC ABNORMALITIES AND PLASMA CELLS PHENOTYPE INDUCE SIGNIFICANT ALTERATIONS IN BONE MARROW B-CELL COMPARTMENTS IN MONOCLONAL GAMMOPATHIES
S Ramos[1,*], T Carvalheiro[2], C Geraldes[1], A Paiva[2], A Teixeira[1]
[1]Clinical Hematology, Centro Hospitalar e Universitário de Coimbra - Hospitais da Universidade de Coimbra, E.P.E., [2]Flow Cytometry Lab, Centro do Sangue e Transplantação de Coimbra - Instituto Português do Sangue e Transplantação, Coimbra, Portugal
Background: Multiple Myeloma (MM) is a hematopoietic neoplasm characterized by an accumulation of malignant plasma cells in the bone marrow (BM). The disease is considered incurable. Immune dysfunction is an important finding in MM. Decreased levels of these cells and immune paresis are usual findings in symptomatic MM (s-MM). Many cytogenetic abnormalities are associated with MM. t(4;14), t(14;16) or del(17p) are associated with poor prognosis. Aberrant CD117 expression is associated with higher numbers of normal bone marrow plasma cells in monoclonal gammopathies (MG) and a favorable outcome in MM. Co-expression of CD28 by clonal plasma cells might attenuate the positive impact of CD117, leading to poor prognosis and disease progression. CD27 is homogeneously expressed on normal plasma cells, plasma cells from MGUS patients and in MM patients in complete remission; its loss is thought to be associated with progression/relapse of MM and poor prognosis.
Aims: We aimed to compare the distribution of BM B-cell compartments between MGUS, smoldering MM and s-MM patients according with cytogenetic risk and phenotype prognostic markers.
Methods: We studied rectrospectively a total of 85 patients with MG: 31 MGUS, 8 smoldering MM and 46 s-MM. As control group we studied 8 age-matched normal BM samples. Clinical and laboratory data were collected. Staging with International Scoring System (ISS) was performed. A 8-color flow cytometry technique was used to perform BM immunophenotyping and five major B-cells compartments were identified: CD34+ B cells, hematogones, immature B cells, memory and naïve B cells. Cytogenetic abnormalities with more relevant prognostic impact in MG were carried out after plasma cell FACS sorting purification by fluorescence *in situ* hibridization (FISH). Accordingly to cytogenetic risk abnormalities, we divided our population in 4 groups: MGUS, smoldering MM, s-MM with high cytogenetic risk, s-MM with standard cytogenetic risk. Patients were also grouped based on the expression of CD27, CD28 and CD117 prognostic markers. Statistical analysis was made using SPSS software Version 20.
Results: Our population had a median age of 74 years old. 54,8% were males and 45,2% were females. BM B-cell frequency (%) from MGUS, smoldering MM and s-MM were within the normal range and similar to that observed in control group. Concerning different B-cell compartments, we found higher frequency of naïve B-cells in high cytogenetic risk s-MM than in low risk ones and smoldering MM, with statistical significance. Although not achieving statistical significance, we observed lower frequencies of memory B-cells in s-MM with high cytogenetic risk than in standard risk groups. When we analyzed B-cell compartments by phenotypic prognostic markers, we observed that MGUS patients with aberrant BM plasma cells CD117+ have higher frequency of total B cells, CD34+ B cells, hematogones and immature B cells than MGUS patients with plasma cells CD117-, reaching statistical significance.
Summary and Conclusions: Lower frequency of memory B-cells in s-MM high risk cytogenetic patients may correspond to a loss of immunologic memory and a consequent decrease in humoral immunologic response against tumor cells. Aberrant expression of CD117 in plasma cells of MGUS patients appears to promote an increased B-cell precursor differentiation. Plasma cells expressing this marker may compete in BM myeloid precursor niches with normal myeloid precursors and may keep more quiescent, conferring a more favorable prognosis to these patients.

P760

ANGIOPOIETIN-2 AND MACROPHAGE INFLAMMATORY PROTEIN-1 ALPHA HAVE DUAL EFFECT ON BONE INVOLVEMENT AND ANGIOGENESIS IN MULTIPLE MYELOMA
G Tsirakis[1,*], C Pappa[2], A Boula[2], A Kolovou[3], Ioanni Miminas [4], M Alexandrakis[1]
[1]Hematology, University Hospital of Heraklion, [2]Hematology, Venizelion General Hospital of Heraklion, Heraklion, [3]Hematology, General Hospital of Chania, Chania, [4]Hematology Laboratory, University Hospital of Heraklion, Heraklion, Greece

Background: The development of the malignant clone in multiple myeloma is enhanced by the production of various cytokines with several properties. Angiopoietin-2 (Ang-2) participates mainly in the angiogenic process, whereas macrophage inflammatory protein-1alpha (MIP-1alpha) acts as an osteoclast activating factor.
Aims: The purpose of the study was to evaluate their role in myeloma patients and to determine possible correlation of them with markers of bone disease and angiogenesis, such as receptor activator of nuclear factor-κB ligand (RANKL), osteoprotegerin (OPG), amino-terminal collagen type-I telopeptide (Ntx) and interleukin-1beta (IL-1beta).
Methods: We studied 54 newly diagnosed myeloma patients (27 male and 27 female, with mean age 66.9±9.4 years). None of the patients had received any myeloma-related therapy prior to initial sampling. According to international staging system (ISS), 12 were in stage I, 21 in stage II and 21 in stage III. Concerning the immunoglobulins' types, 31 were IgG, 17 IgA and 6 light chain disease. Concerning the bone disease, estimated by skeletal ×-rays, 27 had grades 0-2 (low grade), whereas the rest 27 had grades 3 and4, (high grade). Twenty-five, age and sex matched healthy volunteers were used as controls. Serum samples were collected, stored at -70ºC after collection, and assayed

at the end of the study. Serum levels of Ang-2, MIP-1alpha, IL-1beta, RANKL and OPG were measured by ELISA, according to the manufacturer's instructions. Ntx was measured by ELISA, using a monoclonal antibody for Ntx labeled with horse radish peroxidase.
Results: All values were higher in myeloma patients compared to controls (P<0.03 for OPG, P<0.001 for the other cases). The values of Ang-2, MIP-1alpha, IL-1beta, RANKL and Ntx were increasing with the stage of the disease (P<0.002 for Ntx, P<0.001 for the other cases), whereas the levels of OPG were not. Similarly to ISS, the values of Ang-2, MIP-1alpha, IL-1beta, RANKL and Ntx were higher in high skeletal grade patients compared to those with low grade (P<0.001 for all cases), whereas the levels of OPG were not. Serum levels of Ang-2 correlated positively with levels of MIP-1alpha (r=0.658), IL-1beta (r=0.541), RANKL (r=0.609) and Ntx (r=0.607) (P<0.0001 for all cases). Serum levels of MIP-1alpha correlated positively with levels of IL-1beta (r=0.436 P<0.001), RANKL (r=0.472 P<0.0001) and Ntx (r=0.394 P<0.003). Serum levels of IL-1beta correlated positively with levels of RANKL (r=0.524) and Ntx (0.647) (P<0.0001 for both cases) and moreover, negatively with OPG (r=-0.347 P<0.01). Serum levels of RANKL correlated positively with levels of Ntx (r=0.702 P<0.0001) and negatively with OPG (r=-0.307 P<0.02). At last, urine levels of Ntx showed a trend for negative correlation with OPG serum levels (r=-0.263 P=0.054).
Summary and Conclusions: Our data demonstrate that MIP-1alpha, Ang-2 and the other measured parameters are among the main factors that promote the extensive bone disease in multiple myeloma. Moreover, they may be also involved in the mechanisms of angiogenesis, linking the two processes in myeloma disease. Consequently, they possess multiple roles in the complex pathogenesis of the disease.

P761

GENE EXPRESSION OF BONE MODULATORS IN WHOLE BONE MARROW BIOPSIES IN CORRELATION TO DYNAMIC BONE MARKERS IN MULTIPLE MYELOMA BONE DISEASE

I Kristensen[1,2,3,*], J Christensen[1], M Lyng[3], H Ditzel[3,4], N Abildgaard[1,2]
[1]Department of Haematology, Odense University Hospital, [2]Institute of Clinical Research, University of Southern Denmark, Odense, [3]Institute of Molecular Medicine, University of Southern Denmark, Odense, [4]Department of Oncology, Odense University Hospital, Odense, Denmark

Background: The multiple myeloma (MM) plasma cell is dependent on the bone marrow (BM) microenvironment. Most gene expression studies have been performed upon BM aspirates, which differ in cellular composition from the BM biopsy, the latter being more representative for the total bone marrow microenvironment. The osteoclast regulatory factors RANK/RANKL/OPG and MIP-1-alpha have been shown to be important in the pathogenesis of osteolytic bone disease. RUNX2 and osterix are known osteoblast transcription factors. Dynamic markers of bone resorption (CTX-1) and bone formation (PINP) have been shown to offer information about the ongoing activity in bone degradation and formation. The ratio of bone resorption and bone formation (CTX-1/PINP) provides information about whether unbalanced bone remodeling is present.
Aims: To study the correlation between quantitative gene expression of the osteoclast regulators *RANK/RANKL/OPG* and *MIP-1-alpha* and osteoblast transcription factors *osterix* and *RUNX2* in whole BM biopsies and dynamic markers of bone resorption (CTX-1) and bone formation (PINP) in an unselected MM patient cohort (N=39).
Methods: During the diagnostic BM procedure we obtained an extra BM core biopsy after obtaining informed consent. The biopsies were snaP-frozen bed-side. Biopsies were cut, homogenized and RNA was purified using the MagNa Pure Robot (Roche). cDNA was loaded for QPCR on 384-wells micro-fluidic cards (Applied Biosystems). Using three internal reference genes (*ABL, GAPDH* and *GUSB*) the relative quantitative gene expression was calculated. All patients were untreated and did not receive bone-remodeling medicine. CTX-1 and PINP were measured on simultaneously obtained peripheral blood plasma by commercial kits (Roche Diagnostics). Due to renal excretion of CTX-1, patients with S-Creatinine above 176umol/L where excluded from CTX-1 data analysis.
Results: PINP and *RUNX2* gene expression correlated significantly (rho=0.51, P=0.027), while *RANKL* and *osterix* gene expression trended towards a significant correlation with PINP (rho=0.33, P=0.055 and rho=0.39, P=0.12, respectively). CTX-1 correlated inversely with *OPG* (rho=-0.35, P=0.03), but not with *RANKL* expression. The CTX-1/PINP ratio correlated significantly with gene expression of *RANKL* and *OPG* (rho=-0.49, P=0.0062 and rho=-0.39, P=0.012, respectively) and *RUNX2* gene expression trended towards significance (rho=-0.42, P=0.094). *RANKL* and *OPG* expression correlated significantly (rho=0.68, P=0.0001). *MIP-1-alpha* and *RANK* gene expression did not correlate with PINP, CTX-1 or CTX-1/PINP ratio (Figure 1).
Summary and Conclusions: Using snaP-frozen biopsies, as a surrogate for the *in vivo* situation in the BM microenvironment in MM patients, and dynamic bone markers we were able to demonstrate that down-regulation of *OPG* is correlated with increased CTX-1 levels, and that uP-regulation of *RUNX2* is associated with increased levels of the bone formation marker PINP. These observations underscore the likely importance of these two factors in the pathogenesis of MM bone disease. In our study, the gene expression of *RANKL* is co-regulated with *OPG* gene-expression, rather than correlated to the MM osteolytic bone disease itself.

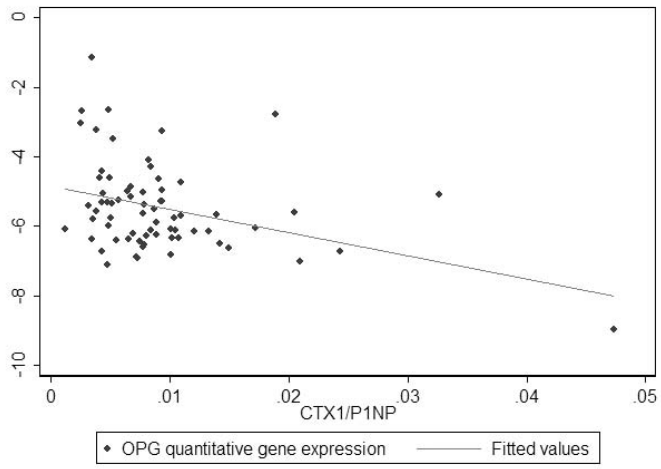

Figure 1.

P762

P15 AND DAPK METHYLATION IN MULTIPLE MYELOMA AND MGUS: COMPARISON BETWEEN BONE MARROW AND PERIPHERAL BLOOD

C Geraldes[1,*], A Cristina Gonçalves[2], R Alves[3], A Pais[3], E Cortesão[1], M Pereira[1], I Sousa[1], A Teixeira[1], JNascimento Costa[1], An Sarmento[3]
[1]Hematology, Centro Hospitalar e Universitario de Coimbra, [2]Hematology, [3]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Background: DNA methylation status was the earliest discovered epigenetic regulator and aberrant DNA methylation is associated with cancer development and progression. There are several types of specimens from which DNA methylation pattern can be measured and evaluated. Blood-based specimens may be a potential source of noninvasive cancer biomarkers. Blood leukocytes from patients with solid tumors exhibit complex and distinct cancer-associated patterns of DNA, which might be seen as epigenetic biomarkers with significant clinical potential. Peripheral blood cell methylation profiles are largely unknown in hematopoietic cancers. We have focused on DNA methylation changes in death-associated protein kinase (DAPK) and in p15 genes in monoclonal gammopathies (MG): multiple myeloma (MM) and monoclonal gammopathy of uncertain significance (MGUS).
Aims: Our aim was to compare DNA methylation status of two genes (p15 and DAPK) in MGUS and in MM at diagnosis in bone marrow (BM) aspirate and in peripheral blood (PB).
Methods: For this purpose we have examined the methylation pattern of p15 and DAPK genes, in genomic DNA obtained from bone marrow (BM) and peripheral blood (PB) samples collected at diagnosis from 99 patients, M/F=51/48, median age 71 years (36-86) with MGUS (n=57) and MM (n=52). Samples were collected after informed consent was obtained in accordance with the Declaration of Helsinki. Diagnosis of MM followed International Myeloma Working Group criteria (Br J Haematol 2003). Genomic DNA was isolated by standard protocols and modified by sodium bisulphite. The MS-PCR for p15 and DAPK promoter genes was performed using two sets of primers, one for methylated DNA and other for unmethylated DNA.
Results: Overall, 42% of pts with monoclonal gammopathy presented at least one hypermethylated gene in BM samples (54% of MM pts and 23% of MGUS pts, *P<0,05*) and 39% in PB (52% of MM pts and 21% of MGUS pts, *P<0,05).* The frequency of hypermethylation for individual genes in MM was: *p15*, 21% in BM; 17% in PB; *DAPK*, 38,5% in BM and PB. In MGUS patients, the frequency of *p15* and *DAPK* methylation was, respectively, 14% in BM, 17,5% in PB and 14% in BM, 7% in PB. Only 4 out of 47 (8.5%) samples in MGUS and 8 of 52 (15.4%) in MM had discrepant results in p15 methylation between BM aspirate and PB (P=NS). Discrepancies were bidirectional, with 6 of 12 cases presenting with demethylated PB and methylated BM aspirate, and the remaining 6 presenting with methylated PB and demethylated BM. 6 out of 47 (12.8%) samples in MGUS and 8 of 52 (15.4%) in MM had discrepant results in DAPK methylation between BM and PB (P=NS). Discrepancies were also bidirectional, with 5 of 14 cases presenting with demethylated PB and methylated BM aspirate, and the remaining 9 presenting with methylated PB and demethylated BM.
Summary and Conclusions: Aberrant hypermethylation of p15 and DAPK genes is a common event in MM and in MGUS pts. We conclude that there is a correlation between methylation patterns of p15 and DAPK in peripheral blood and in bone marrow aspirate. Although DNA methylation patterns measured in peripheral blood have great potential to be useful and informative biomarkers of cancer risk and prognosis, large systematic and prospective studies will be needed.

P763

MECHANISTIC STUDIES ON THE SYNERGISTIC CYTOTOXICITY OF THE NUCLEOSIDE ANALOGS GEMCITABINE AND CLOFARABINE IN MULTIPLE MYELOMA; RELEVANCE OF P53 AND ITS CLINICAL IMPLICATIONS

B Valdez[1], G Song[1], D Murray[2], Y Nieto[1], Y Li[1], M Wang[3], D Weber[4], R Champlin[1], M Qazilbash[1], B Andersson[1,*]

[1]Stem Cell Transplantation and Cellular Therapy, University of Texas MD Anderson Cancer Center, Houston, United States, [2]Experimental Oncology, Cross Cancer Institute, Edmonton, AB, Canada, [3]Lymphoma and Myeloma, University of Texas MD Anderson Cancer Center, Houston, United States, [4]Lymphoma and Myeloma, University of Texas MD Anderson Cancer Center, Houston, Canada

Background: In spite of newer agents, both conventional and high-dose chemotherapy with hematopoietic stem cell transplantation (HSCT) are important treatments for multiple myeloma (MM). In order to identify improved therapy regimens, we investigated the cytotoxicity of gemcitabine (Gem) and clofarabine (Clo) combinations toward MM cell lines and explanted patient cell samples.

Aims: To investigate the mechanisms for possible synergistic cytotoxicity of nucleoside analogs in human multiple myeloma cell lines, such that these agents can be investigated as part of reduced-toxicity pretransplant conditioning therapy in patients with multiple myeloma.

Methods: Examining cytotoxic effects at low concentrations of gemcitabine and clofarabine in the human cell lines NCI-H929, MM.1R,

Cytotoxicity was assessed over 48 hours in the MTT assay, and apoptosis was assayed by flow cytometry (Sub-G1 fraction and Annexin V). Gene expression was assayed using the appropriate primers in western blotting.

Results: A strong synergism of the two nucleoside analogs was observed, when they were combined at ~IC_{10} concentrations. This synergism may be partly due to the observed Gem-mediated phosphorylation and activation of deoxycytidine kinase, resulting in enhanced phosphorylation of both Gem and Clo. Their cytotoxicity further correlated with a robust activation of the DNA damage response pathway. [Gem+Clo] decreased the mitochondrial membrane potential with a concomitant release of pro-apoptotic factors into the cytoplasm and nucleus, as well as activation of apoptosis. Exposure of MM cells to [Gem+Clo] also decreased the level of ribosomal RNA (rRNA), which may result in nucleolar stress and, as reported previously, cause p53-dependent cell death. A reduction (by ~50%) in the cytotoxicity of Gem and Clo was observed in the presence of pifithrin α, a p53 inhibitor. Furthermore, MM cell lines with mutant p53 exhibited greater resistance to Gem and Clo, supporting a role for the p53 protein in these cytotoxic responses.

Summary and Conclusions: Our results 1) give a mechanistic explanation for the observed synergisitc toxicity of two combined nucleoside analogs in multiple myeloma and 2) provide a rationale for (a) clinical trial(s) using [Gem+Clo] combinations as part of conditioning therapy for high-risk MM patients undergoing HSCT. 3). The p53 status of patients undergoing such therapy may include prognostic information and should be followed in a clinical setting.

PHASE (PH) I/II STUDY OF ELOTUZUMAB PLUS LENALIDOMIDE/DEXAMETHASONE (LEN/DEX) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RR MM): UPDATED PH II RESULTS AND PH I/II LONG TERM SAFETY

T Facon[1,*], P Richardson[2,3], S Jagannath[2,4], P Moreau[5], A Jakubowiak[2,6], M Raab[7], R Vij[2,8], D White[9], D Reece[10], L Benboubker[11], J Zonder[2,12], W Deng[13], E Bleickardt[14], A Singhal[13], S Lonial[2,15]

[1]Hopital Claude Huriez, Service des Maladies du Sang, Lille, France, [2]Multiple Myeloma Research Consortium, Norwalk, [3]Dana-Farber Cancer Institute, Boston, [4]Mount Sinai Medical Center, New York, United States, [5]Hematology Department, University Hospital, Nantes, France, [6]University of Chicago Medical Center, Chicago, United States, [7]Universitaetsklinikum Heidelberg, Heidelberg, Germany, [8]Washington University School of Medicine, St. Louis, United States, [9]Queen Elizabeth II Health Sciences Centre, Halifax, [10]Princess Margaret Hospital, Toronto, Canada, [11]CHU Tours-Hopital Bretonneau, Tours, France, [12]Karmanos Cancer Institute, Detroit, [13]AbbVie Biotherapeutics Incorporated, Redwood City, [14]Britol-Myers Squibb, Wallingford, [15]Winship Cancer Institute, Atlanta, United States

Background: Elotuzumab (Elo) is a humanized anti-CS1monoclonal antibody that enhances natural killer cell mediated antibody dependent cellular cytotoxicity of CS1 expressing myeloma cells. This study included a dose finding Ph I cohort (N=28) and a Ph II cohort (N=73).

Aims: To update the Ph II safety/efficacy data and provide long term safety data from both cohorts.

Methods: Patients (pts) treated with ≥1 (Ph I) or 1–3 (Ph II) prior therapies received Elo+Len/dex as described previously (Lonial JCO 2012; Richardson ASH 2012) until disease progression, unacceptable toxicity, or death. All pts received a premedication regimen including methylprednisolone, diphenhydramine or equivalent, ranitidine or equivalent, and acetaminophen to mitigate infusion reactions. Adverse events (AEs) in Ph I/II pts occurring ≤18 months (mo) (N=98) were compared to AEs with a >18 mo onset in a subgroup of pts treated >18 mo (n=49). This safety analysis excluded 3 Ph I pts treated with Elo 5 mg/kg, since Ph III studies are evaluating a 10 mg/kg dose.

Results: In the Ph II cohort (median 63 yr), objective response rate (ORR) was 84%; 92% with 10 mg/kg (n=36) and 76% with 20 mg/kg (n=37). At a median follow-up of 20.8 mo, median progression free survival (PFS) was not reached (10 mg/kg) and 18.6 mo (20 mg/kg). The most common treatment emergent grade ≥3 AEs were lymphopenia (19%), neutropenia (18%), thrombocytopenia (16%) and anemia (14%). The most common grade 3/4 AEs emerging ≤18 *vs* >18 mo in Ph I/II cohorts are shown (Table 1). 15 pts discontinued due to AEs; none after 18 mo of treatment. There were 4 second primary malignancies; none were reported after 18 mo.

Table 1.

	Onset	
	≤18 mo	>18 mo
Grade 3/4 AEs*	N=98	n=49
Neutropenia	21%	2%
Thrombocytopenia	18%	2%
Lymphopenia	15%	2%
Anemia	12%	2%
Hyperglycemia	9%	0%
Fatigue	8%	0%
Diarrhea	7%	2%
Leukopenia	7%	2%
Hypokalemia	6%	4%
Pneumonia	6%	2%

*In >5% of pts.

Summary and Conclusions: Elo 10 mg/kg+Len/dex was generally well tolerated and resulted in a high ORR and encouraging PFS in pts with RR MM. AEs emergent after 18 mo of therapy were consistent with AEs emergent during the initial 18 mo. Updated Ph II safety/efficacy data and long term safety data from Ph I/II cohorts will be presented.

P765

NEW DRUG PARTNER FOR COMBINATION THERAPY IN MULTIPLE MYELOMA (MM): DEVELOPMENT OF ACY-1215, A SELECTIVE HISTONE DEACETYLASE 6 INHIBITOR ALONE AND IN COMBINATION WITH BORTEZOMIB OR LENALIDOMIDE

N Raje[1,*], A Mahindra[1], D Vogl[2], P Voorhees[3], W Bensinger[4], P Hari[5], J Berdeja[6], S Jagannath[7], S Jones[8], C Wheeler[8], J Supko[1], R Orlowski[9], S Lonial[10]
[1]Massachusetts General Hospital, Boston, [2]University of Pennsylvania, Philadelphia, [3]University of North Carolina at Chapel Hill, Chapel Hill, [4]Fred Hutchinson Cancer Research Center, Seattle, [5]Medical College of Wisconsin, Milwaukee, [6]Sarah Cannon Research Institute, Nashville, [7]Mount Sinai Hospital, New York City, [8]Acetylon Pharmaceuticals, Boston, [9]MD Anderson Cancer Institute, Houston, [10]Winship Cancer Institute, Emory University School of Medicine, Atlanta, United States

Background: First generation HDAC inhibitors (HDACi) active in combination with standard agents in MM are limited by fatigue, vomiting, diarrhea, and myleosuppression. ACY-1215, the first oral next generation selective HDACi in the clinic is 11 fold selective for HDAC6 over class 1 HDACs, is well tolerated preclinically and synergizes with bortezomib (Bort) in MM cell lines and animal models (Blood, V20(210):4061) and synergizes with lenalidomide (Len) *in vitro* with or without dexamethasone (D). Two clinical trials are ongoing: ACY-100 with ACY-1215 monotherapy and in combination with Bort and D, and ACE-MM-101 with ACY-1215 in combination with Len and D.
Aims: The aims of the development program are to characterize safety, pharmacokinetics (PK) and pharmacodynamics (PD) of ACY-1215 alone and in combination with D and Bort or Len and to identify phase 2 combination regimens.
Methods: ACY-100 is a single arm open label study with dose escalation in a 3+3 design. Relapsed/refractory (R/R) patients (pts) who received at least two lines of therapy (tx) including a proteasome inhibitor and an immunomodulatory agents, refused or were ineligible for autologous stem cell transplant (ASCT), had adequate marrow reserve and hepatic function, and creatinine clearance (CrCl) >30, were eligible for the phase 1a and 1b portions after informed consent. Pts received 40 mg to 360 mg of ACY-1215 orally on days 1-5 and 8-12 of a 21 day cycle in part 1a, and in 1b with Bort 1.0-1.3 mg/m^2 on days1,4, 8 and 11 and D 40 mg/week. Peripheral blood samples were obtained for PK and PD assessment of acetylated tubulin and histones in peripheral blood mononuclear cells (PBMC). ACE-MM-101 R/R pts received at least one prior rx and have CrCl>60. Len, 25 mg after an initial 15 mg safety cohort, is given orally daily on 21 days of a 28 day schedule with 40 mg D/week, and if well tolerated a third week of ACY-1215 days 15-19 will be added. ACY-1215 doses of 40 to 240 mg will be explored. PK and PD assessment is similar to ACY-100.
Results: ACY-100: In 15 pts on ACY-1215 monotherapy, no dose limiting toxicity (DLT) was observed, and creatinine elevations, anemia, fatigue, hypercalcemia and respiratory infection, the most common toxicities, were most low grade and not attributed to ACY-1215. Possibly related grade 3 toxicities were anemia and low white blood cell counts (n=1 each). Stable disease was observed in 6 pts, up to 10 cycles of therapy. Doses of ≥160 mg gave similar PK with μM concentrations at C_{max} in all pts with $t_{1/2}$ of 3 hr and no accumulation. At least doubling of acetylated tubulin was seen in PBMCs at ≥160 mg, while increases in acetylated histones were observed only at 240 mg. Two cohorts with Bort (1.0 and 1.3 mg/m^2) are enrolled and one cohort was expanded due to a DLT, asymptomatic elevation in amylase that appeared temporally associated with rx. No further DLTs occurred. One partial response (PR) ongoing at 9 cycles and enrollment is ongoing at 80 mg. ACE-MM-101: The first 3 cohorts, up to 80 mg ACY-1215 and 25 mg Len and 40 mg D enrolled 9 pts, five of whom had previously received an immunomodulatory agent. No DLTs were observed. Four episodes of neutropenia and one ALT elevation were probably attributed to Len. Three pts have withdrawn, two due to progressive disease and one to persistent neutropenia leading to missed L doses. There are four PRs, one VGPR, and one minimal response in the first 6 pts.
Summary and Conclusions: ACY-1215 is well tolerated as monotherapy at doses leading to PD activity and can safely be combined with full doses of B or L with D at ACY-1215 doses explored in combination. Responses have been seen in both studies and dose escalation continues.

P766

HIGH RATES OF PROLONGED MOLECULAR REMISSIONS AFTER TANDEM AUTOLOGOUS-NONMYELOABLATIVE ALLOGRAFTING IN NEWLY DIAGNOSED MYELOMA

M Ladetto[1,*], S Ferrero[1], D Drandi[1], P Omedè[2], M Festuccia[1], F Patriarca[3], N Mordini[4], S Cena[1], L Monitillo[1], L Giaccone[1], Daniela Barbero[1], Alberto Rocci[1], Sara Barbiero[1], Andrea Gallamini[4], Renato Fanin[3], Roberto Passera[5], A Palumbo[1], M Boccadoro[1], B Bruno[1]
[1]Department of Molecular Biotechnology and Health Science, [2]Division of Hematology, A.O. San Giovanni Battista, Torino Italy, University of Torino, Torino, [3]A.O.U. Haematological Clinic, University of Udine, Udine, [4]Hematology, A.O. S. Croce Carle, Cuneo, [5]Division of Nuclear Medicine, Statistical Consultant, University of Torino, Torino, Italy

Background: Myeloablative allografting induces high rates of persistent molecular remissions (MR) in multiple myeloma (MM) (Corradini, J Clin Oncol 1999) and greatly reduces the risk of relapse. Similar results have also been reported after reduced-intensity conditioning (Kröger, Biol Bone Marrow Transpl 2012). Long term data on minimal residual disease (MRD) kinetics after combined autologous and nonmyeloablative allografting (auto-allo) are lacking. We here present the results of MRD analyses by nested qualitative PCR (Nested-PCR) and real time quantitative (RQ)–PCR.
Aims: To performe MRD analysis by Nested-PCR and RQ-PCR on newly diagnosed MM patients treated with auto-allo on a prospective clinical trial [ClinicalTrial.gov, NCT-00702247].
Methods: 26 patients (pts) with stage II-III MM and a diagnostic bone marrow (BM) specimen suitable for immunoglobulin heavy-chain gene rearrangement (IGH) sequencing, were evaluated for MRD by PCR methods. Auto-allo consisted of an autograft followed by 200 cGy TBI and an allograft. BM samples were collected at diagnosis, after the autograft, at month1,3, 6 after the allograft and then every 6 months. Nested-PCR and RQ-PCR analyses were carried out using patient-specific primers as previously described (Voena, Leukemia 1997; Ladetto, Biol Bone Marrow Transpl 2000). For outcome analysis pts were grouped according to reported criteria (Ladetto, ASH 2011): FullMR and StandardMR indicated MRD negativity on two consecutive samples by nested-PCR or RQ-PCR respectively, the latter standardized according to European Study Group on MRD detection guidelines (van der Vendel, Leukemia 2007).
Results: 19/26 pts had a molecular marker. At a median follow-up of 10 years (4.4-12) from diagnosis and 8.9 years (3.5-11) from the allograft, overall survival (OS) was 61% and median time-to-progression (TTP) 5.6 years. Transplant-related mortality occurred in 3/19 pts (16%), while 4/19 pts (21%) died of disease progression. MRD analysis showed that after the autograft 3/19 pts (16%) were negative by nested-PCR. After the autograft 3/19 pts (16%) were PCR-negative. After allograft, the rate of PCR negativity remained low at month 1 (5/19, 26%) and 3 (3/19, 16%). Starting from month 6 PCR-negativity occurred up to 44% (8/18) at 6 months and 47% (7/15) at one year post-transplant. Overall, 8 pts achieved FullMR at a median time from allograft of 6 months (1-12) and for a median duration of 33 months (6-102). Overall, 8 relapses occurred, 6 among 11 pts who never achieved FullMR and 2 in 8 pts who reached FullMR. Of these one has incomplete follow up and in the other one clinical relapsed was heralded by a molecular relapse. Pts in FullMR had better median TTP (not reached *vs* 1.6 years, P=0.043) and OS (not reached *vs* 3.3 years, P=0.008) than pts who did not achieve FullMR (Figure 1). StandardMR occurred in 12/19 pts (63%) during the first 24 months post-transplant, at a median time of 2 months (1-18) and for a median duration of 27 months (3-102). Pts in StandardMR showed better median TTP (not reached *vs* 1 year, P=0.005) and OS (not reached *vs* 3.3 years, P=0.031) as compared to pts with positive PCR (Figure 2). There was no correlation between MR and chronic graft-*vs*-host disease, suggesting specific graft-*vs*-myeloma.

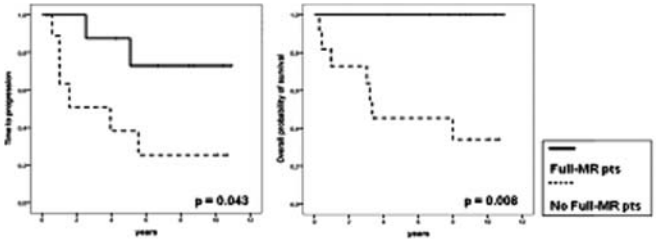

Figure 1. TIP (A) and OS (B) by FullMR status.

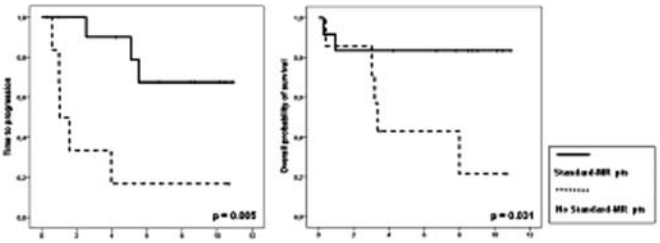

Figure 2. TIP (A) and OS (B) by StandardMR status.

Summary and Conclusions: Auto-allo induces high molecular remission rates, significantly associated with better TTP and OS, clearly documenting the existence of an effective and persistent graft-*vs*-myeloma effect, potentially curative in a subset of patients.

P767

INTEGRATED ANALYSIS OF DATA FROM PHASE 3 RANDOMIZED, CONTROLLED TRIALS OF BORTEZOMIB-BASED VS NON-BORTEZOMIB-BASED INDUCTION PRIOR TO ASCT IN PATIENTS WITH PREVIOUSLY UNTREATED MULTIPLE MYELOMA (MM)

P Sonneveld[1,*], H Goldschmidt[2], L Rosiñol[3], J Bladé[3], J Lahuerta[4], M Cavo[5], P Tacchetti[5], E Zamagni[5], M Attal[6], H Lokhorst[7], A Desai[8], A Cakana[9], K Liu[10], H van de Velde[11], D Esseltine[12], P Moreau[13]

[1]Hematology, Erasmus Medical Center, Rotterdam, Netherlands, [2]University Hospital of Heidelberg, Heidelberg, Germany, [3]Hematology Department, Hospital CIínic de Barcelona, IDIBAPS, Barcelona, [4]Servicio de Hematología, Hospital Universitario 12 de Octubre, Madrid, Spain, [5]Istituto di Ematologia Seràgnoli, Università degli Studi di Bologna, Bologna, Italy, [6]Department of Hematology, Hopital Purpan, Toulouse, France, [7]Utrecht Medical Center, Utrecht, Netherlands, [8]Janssen Global Services, Raritan, NJ, United States, [9]Janssen Research & Development, High Wycombe, United Kingdom, [10]Janssen Research & Development, Raritan, NJ, United States, [11]Janssen Research & Development, Beerse, Belgium, [12]Millennium: The Takeda Oncology Company, Cambridge, MA, United States, [13]University Hospital, Nantes, France

Background: A total of four large, multicenter, cooperative group studies have investigated bortezomib-based regimens compared with non-bortezomib-based previous standards of care as induction prior to autologous stem cell transplant (ASCT) in previously untreated MM: IFM 2005-01, bortezomib-dexamethasone *vs* vincristine-doxorubicin-dexamethasone (VAD); HOVON-65/GMMG-HD4, bortezomib-doxorubicin-dexamethasone *vs* VAD; PETHEMA GEM2005 MENOS65, bortezomib-thalidomide-dexamethasone (VTD) *vs* thalidomide-dexamethasone (TD) *vs* combination chemotherapy followed by bortezomib; and GIMEMA MM-BO2005, VTD *vs* TD.

Aims: This integrated analysis aimed to characterize the overall impact of bortezomib-based *vs* non-bortezomib-based induction therapy on efficacy, outcomes, and safety using data from these phase 3 studies in patients with previously untreated MM. The two key efficacy endpoints were post-transplant complete plus near-complete response (CR+nCR) rate and progression-free survival (PFS).

Methods: Patient-level data were pooled in a thorough integrated analysis of efficacy and safety from the IFM 2005-01, HOVON-65/GMMG-HD4, and PETHEMA GEM2005MENOS65 studies. Patient-level data were not available from GIMEMA MM-BO2005 due to local legal restrictions, but study-level data were used to supplement the integrated analysis.

Results: The integrated analysis incorporated data from 787 and 785 patients treated with bortezomib-based and non-bortezomib-based induction, respectively; demographics and disease characteristics were well balanced between the groups. Post-transplant CR+nCR rate and all other response rates post-induction and post-transplant were significantly higher in the bortezomib-based *vs* non-bortezomib-based group (Table 1). With inclusion of study-level data from GIMEMA MM-BO2005, the pooled odds ratio for post-transplant CR+nCR rate remained similar, at 1.96. The significant improvement in post-transplant CR+nCR rate was seen across patient subgroups, including patients with high-risk features. The median PFS was 35.9 *vs* 28.6 months in the bortezomib-based *vs* non-bortezomib-based groups (hazard ratio [HR] 0.75, P<0.0001); 3-year PFS rates were 50.0% and 41.1%, respectively. HRs for PFS were consistent across studies. After a median follow-up of ~37 months, 3-year overall survival (OS) rates were 79.7% and 74.7%, respectively (HR 0.81, P=0.0402). Median duration of induction therapy was 11 weeks in both groups. During bortezomib-based and non-bortezomib-based induction, respectively, 63% and 59% of patients had grade ≥3 adverse events (AEs), 41% and 37% had serious AEs, 6% and 5% had AEs resulting in discontinuation, and 3% and 4% of patients died. Overall rates of peripheral neuropathy (PN) during induction were 34% *vs* 17%, respectively, including 6% *vs* 1% grade ≥3 PN.

Table 1.

Response rate, n (%)	Btz-based (n=775)	Non-btz-based (n=772)	Odds ratio
Post-induction			
CR	105 (14)	32 (4)	3.92
CR+nCR	175 (23)	63 (8)	3.45
≥VGPR	362 (47)	139 (18)	4.03
ORR	646 (83)	480 (62)	3.05
Post-ASCT			
CR	199 (26)	106 (14)	2.21
CR+nCR	298 (38)	182 (24)	2.05
≥VGPR	463 (60)	315 (41)	2.16
ORR	615 (79)	526 (68)	1.81

For all comparisons, p<0.0001 by Cochran-Mantel-Haenszel chi-squared test. Btz, bortezomib; CR, complete response; nCR, near-CR; ORR, overall response rate; VGPR, very good partial response

Summary and Conclusions: The findings of the integrated analysis demonstrate that bortezomib-based induction results in a consistent and robust benefit in terms of response rates, PFS, and OS compared to non-bortezomib-based induction. Bortezomib-based induction was generally well tolerated, with a higher rate of PN but no increase in the risk of death during induction *vs* non-bortezomib-based induction.

P768

SAFETY AND EFFICACY OF POMALIDOMIDE WITH OR WITHOUT LOW-DOSE DEXAMETHASONE IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP OF PATIENTS ENROLLED IN THE MM-002 PHASE 2 TRIAL

P Richardson[1,*], D Siegel[2], R Vij[3], C Hofmeister[4], R Baz [5], S Jagannath[6], C Chen [7], S Lonial[8], A Jakubowiak [9], N Bahlis[10], K Song[11], A Belch[12], N Raje[13], C Shustik[14], S Lentzsch[15], M Chen[16], M Zaki[16], K Anderson[1]

Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [6]Mount Sinai Medical Center, New York, United States, [7]Princess Margaret Hospital, Toronto, ON, Canada, [8]Emory University School of Medicine, Atlanta, GA, [9]University of Chicago Medical Center, Chicago, IL, United States, [10]University of Calgary, Calgary, AB, [11]Vancouver General Hospital, Vancouver, BC, [12]University of Alberta, Edmonton, AL, Canada, [13]Massachusetts General Hospital, Boston, MA, United States, [14]Royal Victoria Hospital McGill University Heath Centre, Montreal, QC, Canada, [15]College of Physicians and Surgeons of Columbia University, New York, [16]Celgene Corporation, Summit, NJ, United States

Background: MM-002 is a randomized, open-label, multicenter, phase 2 trial evaluating the safety and efficacy of pomalidomide (POM) with or without low-dose dexamethasone (LoDEX) in advanced relapsed and refractory multiple myeloma (RRMM) patients (pts) who have received prior treatment with lenalidomide (LEN) and bortezomib (BORT).

Aims: The objective of this analysis of MM-002 trial data was to assess the safety and efficacy of POM with or without LoDEX with extended follow-up.

Methods: Pts who had received ≥2 prior therapies, including LEN and BORT, and were refractory to their last treatment were randomized to POM+LoDEX (POM 4 mg/day, days 1–21 of a 28-day cycle; LoDEX 40 mg/week) or POM alone. Refractory disease was defined as documented progression during treatment or within 60 days of the last dose of treatment. At progression, pts receiving POM alone could receive POM+LoDEX at investigator's discretion. Pts aged >75 yrs received LoDEX, 20 mg/week. All pts received mandatory thromboprophylaxis (daily low-dose aspirin). End-points included progression-free survival (PFS), response rate (according to EBMT criteria and investigator assessment), response duration, overall survival (OS), and safety. The efficacy outcomes are based on the intent-to-treat population (POM+LoDEX, n=113; POM, n=108). Data with a median follow-up of 14.2 mos is presented here.

Results: The median number of prior therapies in each group was 5 (range 1–13). All pts (100%) had prior exposure to LEN, BORT, and steroids; 62% of pts were LEN and BORT dual-refractory. In the POM+LoDEX arm, 30 (27%) pts had high-risk cytogenetics, including del(17p13) and/or t(4p16/14q32). The overall response rate (ORR; defined as at least partial response) was 34% and 15% with POM+LoDEX and POM, respectively, with a median duration of 8.3 mos (95% confidence interval [CI]: 5.8–10.1) and 8.8 mos (95% CI: 5.5–11.4), and at least a minimal response was observed in 45% and 31% of pts, respectively. Median PFS was 4.6 mos (95% CI: 3.6–5.5) and 2.6 mos (95% CI: 1.9–2.8); with a median follow-up of 16.0 and 12.2 mos, median OS was 16.5 mos (95% CI: 12.4–18.5) and 13.6 mos (95% CI: 9.6–18.1), with POM+LoDEX and POM, respectively. Among pts with LEN and BORT refractory disease, ORRs were 33% with combination therapy and 17% with POM alone, with median response duration of 6.5 mos (95% CI: 3.7–8.3) and 8.3 mos (95% CI: 2.8–13.1); 46% and 33% of pts achieved at least minimal response, respectively. Median PFS was 3.8 mos (95% CI: 2.8–5.8) and 2.0 mos (95% CI: 1.8–2.9); median OS was 13.4 mos (95% CI: 11.0–17.6) and 12.4 mos (95% CI: 8.2–18.0), with POM+LoDEX and POM, respectively. The most common treatment emergent grade 3/4 adverse events (AEs) reported in the safety population (n=219) were neutropenia (44%), anemia (23%), thrombocytopenia (21%), and pneumonia (18%); there were no reports of grade 3/4 peripheral neuropathy. The incidence of deeP-vein thrombosis was low (2%). In this overall safety population, AEs were managed through dose reductions or interruptions (30% and 64% of pts with at least one, respectively), and supportive care with granulocyte colony-stimulating factor (53%), and red blood cell (48%) and platelet transfusions (18%). Discontinuations of POM due to AEs were 10%.

Summary and Conclusions: POM with or without LoDEX represents a new clinical option for pts with advanced RRMM, including pts with LEN and BORT refractory disease. AEs were predictable and manageable. Updated data with extended follow-up will be presented at the meeting.

P769

CONSOLIDATION WITH HD- MELPHALAN AND AUTOTRANSPLANT (ASCT) AFTER SECOND-LINE TREATMENT INCREASES RESPONSE RATE AND PROGRESSION-FREE SURVIVAL IN MYELOMA PATIENTS RELAPSED AFTER FIRST-LINE ASCT

C Claudia[1,*], F Cavallo[2], S Ferrari[1], E Cerqui[1], F Antoniazzi[1], C Palladino[2], F Schieppati[1], C Pagani[1], A Palumbo[2], G Rossi[1]
[1]Division of hematology, Spedali Civili Brescia, Brescia, [2]Myeloma Unit, Division of hematology, University of Torino, Torino, Italy

Background: Therapeutic options for patients relapsing after first-line HD-Mel and ASCT are not standardized. Few studies have addressed the potential role of ASCT consolidation after II-line treatment in patients relapsed after first-line ASCT.
Aims: To compare the outcome of MM patients relapsed after first-line ASCT who received second-line therapy with or without consolidation with ASCT
Methods: In 159 MM patients treated at two Italian Institution between 1997 and 2010 and relapsed after first-line HD-Mel and ASCT, second-line therapy was given to 98 pts (61%) with bortezomib-or Imids-or thalidomide-based regimens only (ND group) and to 61 pts (38%) with ASCT consolidation after ND-based regimens (45 pts) or chemotherapy (16 pts) (ASCT group). ND and ASCT groups did not differ in baseline characteristics, including age (median 59), type of first-line therapy, median follow-up from diagnosis.CR/VGPR rates and ORR obtained after first-line treatment (ND 52% and 89%; ASCT 62% and 90%, respectively) were also similar. Median duration of first response and time to second treatment were 14 and 24 months in both group respectively. Proportion of patients receiving a double ASCT at first line therapy was 21% in ND and 33% in ASCT group (*P*=0.079).
Results: After second line therapy ORR(CR+VGPR+PR) was 77% in ASCT group, significantly better than ND group (48%)(*P*=0.0001).The second CR/VGPR rate was significantly higher after ASCT (41%) than after ND (21%)(*P*=0.012), independently from the type of second line treatment received before consolidation ASCT (ORR:ND 91% *vs* CT 75%; *P*=0.21).After a median follow-up from second-line treatment of 28 months (range 1-128 mo), 2-year PFS was 17% after ND (median 12 mo) and 26% after ASCT (median 19mo)(*P*=0.013).Two-year OS was 62% (median 33mo) and 80% (median 44mo) after ND and ASCT group, respectively (*P*=0.3). PFS after salvage did not differ between pts receiving single or double first-line ASCT (P=0.066).
Summary and Conclusions: The use of ASCT as consolidation after second-line treatment increased both ORR and CR/VGPR rates, independently from the type of debulking treatment used (chemotherapy *versus* novel drugs) and significantly impacted on PFS when compared with second-line ND-based regimens without ASCT.

P770

TOTAL THERAPY 3 (TT3)-BASED TREATMENT FOR MULTIPLE MYELOMA–AN EXTENDED SINGLE CENTER EXPERIENCE

E Muchtar[1,*], R Ram[1], P Raanani[1], M Yeshurun[1], N Oniashvili [2], O Shpliberg[1], H Magen-Nativ[1]
[1]Institute of hematology, [2]The Raphael Recanati Genetic Institute, Rabin Medical Center, Petah tikva, Israel

Background: Total therapy 3 (TT3) is an intensified treatment for multiple myeloma (MM) introduced by the Arkansas group, designed for newly diagnosed patients. Originally, this regimen incorporates a component of the novel agents bortezomib and thalidomide plus dexamethasone (=VDT) to PACE (cisplatinum, doxorubicin, cyclophosphamide, and etoposide) chemotherapy for 2 cycles, followed by consolidation with high dose melphalan tandem autotransplantation. Thereafter, additional 2 cycles of VDT-PACE are given followed by VDT maintenance. This protocol has not been adopted by many centers and its results have rarely been reported. In 2010 we described a short-term follow up of 23 patients treated TT3-based protocol (Ann Hematol 89:53-9, 2010).
Aims: to review an extended group of MM patients treated with TT3-based protocol, administrated mainly to patients with aggressive clinical course and/or high risk cytogenetic abnormalities at different treatment settings (induction; induction failure; relapse; relapsed-and-refractory MM (RR-MM)].
Methods: We retrospectively analyzed all sequential patients (n=80) from 2004 to 2012 that were given at least one cycle of (V)DT-PACE. For efficacy evaluation, we used the IMWG response criteria.
Results: median age was 58 years (range 35-75). ISS score at diagnosis was I, II and III in 22%, 44% and 29% of patients, respectively (5% undetermined). 53% of patients (32/60) had poor cytogenetic abnormalities. (V)DT-PACE was given in 44 patients for induction, in 11 patients for induction failure, in 13 patients for relapse and in 12 patients for RR-MM. Median cycles per patient was 2 (range 1-4). Bortezomib was given in 66% of cycles. 75% of patients (60/80) were subsequently given high dose melphalan with autograft, of which 8 patients had tandem transplantation (2 of them had auto-allo). 83% of patients were given maintenance. Overall response rate (ORR) following (V)DT-PACE induction treatment was 92% (CR=4%, VGPR=57.3%, PR=30.7%). Patients receiving (V)DT-PACE for induction and relapse achieved higher rates of VGPR and above (76.7% and 54.5%, respectively) than those treated for induction failure or RR-MM (36.4% and 30%, respectively) (P=.009). Following autologous transplantation, ORR increased to 98%, with substantial improvement in CR/sCR rates (sCR=25.4%, CR=11.9%, VGPR=49.1%, PR=11.9%). With a median follow-up of 21 months, progression free survival at 1 and 2 years was 85% and 67% for induction, 76% and 57% for induction failure, 28% and 0% for relapse and 12% and 0% for RR-MM, respectively. Overall survival at 2 years was 85%, 100%, 39% and 19%, respectively. Considering all treatment cycles (n=152), grade 3/4 hematological toxicity rate was 79% and 46% for neutropenia and thrombocytopenia, respectively. The rate of neutropenic fever was 25.7%, with 19/39 of episodes associated with clinically or microbiologically documented infections. Venous thrombosis was infrequent (3.3%). Death attributed to treatment was relatively low (5/80, 6.25%), occurred mainly in the non-induction settings (4/36, 11.1%). Causes of death were arrhythmia (n=3, of which 2 with known systemic amyloidosis), severe infection (n=1) and multi-organ failure (n=1) (Figure 1).

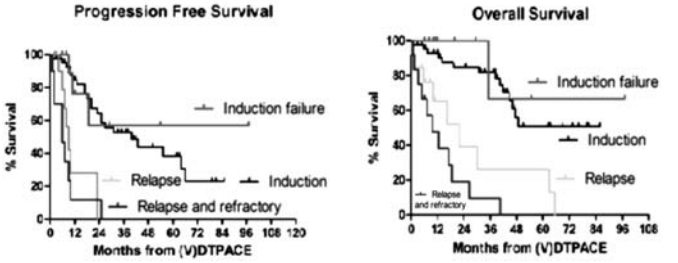

Figure 1.

Summary and Conclusions: TT3-based approach achieved high response rate among MM patients with high-risk disease, with considerable but manageable toxicities. However efficacy was mainly translated into long-term remission in the induction and induction failure settings, while results in relapse and RR-MM are unsatisfactory.

P771

PHASE I STUDY OF THE COMBINATION OF CARFILZOMIB AND PANOBINOSTAT FOR PATIENTS WITH RELAPSED AND REFRACTORY MYELOMA: A MULTICENTER MMRC CLINICAL TRIAL

J Kaufman, MD[1,*], T Zimmerman, MD[2], A Jakubowiak[2], C Rosenbaum[2], C Lewis, D Harvey[1], A Nooka, L Heffner[1], Sagar Lonial,[1]
[1]Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, [2]University of Chicago, Chicago, United States

Background: Patients with myeloma ultimately become refractory to current therapies, requiring new approaches to treatment. Carfilzomib is a selective proteasome inhibitor that has demonstrated significant activity in patients with relapsed and refractory myeloma. Panobinostat is a pan-deacetylase inhibitor that can overcome resistance in combination with bortezomib in refractory multiple myeloma patients. Based on preclinical data showing synergistic cytotoxicity of histone deacetylase and proteasome inhibitors, we hypothesized that carfilzomib and panobinostat would be safe and effective for the treatment of relapsed/refractory multiple myeloma. Herein we report the initial findings of the MMRC multicenter phase I study investigtating the combination of panobinostat and carfilzomib in patients with relapsed and refractory multiple myeloma.
Aims: The primary objective is to determine the maximum tolerated dose (MTD) of the combination of panobinostat and carfilzomib using a standard 3+3 design with 5 planned cohorts. An additional 12 patients will be treated at the MTD in an expansion phase to gain further data on safety and efficacy. Secondary objectives are to evaluate response and survival endpoints of enrolled patients.
Methods: Panobinostat is administered orally three times weekly for three of four weeks (range, 15-25 mg).Carfilzomib is administered IV days1,2,8,9,15, and16, ranging from 20/27 mg/m^2 to 20/56 mg/m^2. Doses above 20/27 are administered over 30 minutes. Cycles are repeated every 4 weeks. Dose limiting toxicities (DLT) are determined in the first cycle, and all adverse events are assessed according to CTCAE Version 4. Responses are assessed using IMWG criteria (plus MRs as per the EBMT criteria).
Results: To date, 10 patients in three cohorts have been enrolled, and 9 have completed the first cycle. Median age is 60.6 years (range, 48-73). All patients had refractory and progressive disease. No DLTs were observed in the first 2 cohorts, with 1 patient in cohort 1 being inevaluable due to disease progression. There are currently 2 patients in cohort 3 (panobinostat 20 mg and carfilzomib 20/36 mg/m^2), one of whom had a DLT of grade 4 thrombocytopenia and grade 3 elevated creatinine. Both toxicities resolved after discontinuation of study therapy. Four serious adverse events have occurred, with two (one patient with a grade 5 cardiac arrest and a different patient with elevated creatinine) considered related to study therapy. Patients have completed a medi-

an of 3 cycles (range, <1 to 13). Grade 3 thrombocytopenia occurred in 40% and grade 3 neutropenia in 30% of all subjects. The most common non-hematologic toxicities were nausea, diarrhea, vomiting, hypokalemia and cough, all effectively managed with standard interventions. Preliminary assessment of response revealed an ORR of 30% with 1 sCR and two PRs.
Summary and Conclusions: The combination of carfilzomib and panobinostat is well tolerated with no unexpected toxicities. Preliminary assessment of response data is encouraging, and the study is ongoing with planned dose escalation of carfilzomib to 56mg/m^2 and panobinostat to 20 mg.

P772

MM-008: A PHASE 1 TRIAL EVALUATING PHARMACOKINETICS AND TOLERABILITY OF POMALIDOMIDE+LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) WITH RENAL IMPAIRMENT

J Matous[1,*], D Siegel[2], H Duong[3], C Kasserra[4], L Sternas[4], C Jacques[4], K Klesczewski[4], M Zaki[4], J Shah[5]
[1]Colorado Blood Cancer Institute, Denver, CO, [2]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, [3]Hematologic Oncology and Blood Disorders, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, [4]Celgene Corporation, Summit, NJ, [5]Lymphoma/Myeloma, University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: Pomalidomide (POM) recently received US Food and Drug Administration approval for the treatment of patients with RRMM who have received ≥2 prior treatments including lenalidomide and bortezomib. In phase 2 trials, POM+low-dose dexamethasone (LoDEX) has shown significant clinical activity in this patient population (Leleu X, *et al. Blood*. 2013; Richardson *et al. Blood.* 2012). Renal impairment is a common comorbidity for myeloma patients, occurring in over 40% of patients (Eleutherakis-Papaikovou V, *et al. Leuk Lymphoma.* 2007). POM is extensively metabolized, with 2% eliminated renally as the parent drug (Hoffmann M, *et al. Cancer Chemother Pharmacol.* 2013*)*. Thus, renal function may not substantively affect exposure of the parent drug. POM+LoDEX has shown efficacy in RRMM patients with moderate renal impairment (Siegel DS, *et al.* ASH. 2012). However, patients with severe renal impairment have been excluded from previous POM trials. To date, the safety, efficacy, and pharmacokinetics (PK) of POM in patients with renal impairment have not been prospectively evaluated.
Aims: MM-008 is a multicenter, open-label, phase 1 study designed to prospectively assess the PK and safety of POM+LoDEX in patients with RRMM and normal or impaired renal function.
Methods: Patients with RRMM and ≥1 prior therapy were eligible to enroll in this study. Patients with normal renal function (creatinine clearance [CrCl] ≥60 mL/min [cohort A]) or severe renal impairment (CrCl <30 mL/min [cohort B]), but not requiring dialysis, were included. Patients in cohort A received POM 4 mg and patients in cohort B received POM 2 mg or 4 mg on days 1-21 of a 28-day cycle, following a standard 3+3 dose-escalation design. Both cohorts received DEX 40 mg (20 mg for patients aged >75 years) on days1,8,15, and 22. Cohort C will assess patients with severe renal impairment (CrCl <30 mL/min) and requiring dialysis (up to approximately 14 patients planned). Patients were not permitted to enroll in more than 1 cohort. Granulocyte colony-stimulating factor for management of neutropenia was not permitted in cycle1, but could be started on day 1 of the next cycle at the physician's discretion. Treatment was continued until progressive disease or unacceptable toxicity. Adverse events (AEs) were graded according to the National Cancer Institute Common Terminology Criteria for AEs (V 4.0).
Results: As of February5, 2013, eleven patients have been treated (8 in cohort A; 3 in cohort B). Patients were ages 46-71 years (cohort A) and 57-64 years (cohort B). Five patients are >65 years of age in cohort A (66, 69 [n=3], and 71 years). Seven patients in cohort A have received more than 1 cycle of treatment; 5 have received 3 or more cycles. One patient in cohort B has received more than 3 cycles. All 3 patients in cohort B have completed 1 full cycle of treatment with no dose-limiting toxicities reported. Dose escalation is planned and all patients remain on study. Updated pharmacokinetic and AE data will be presented at the meeting.
Summary and Conclusions: MM-008 is an ongoing trial prospectively evaluating the pharmacokinetics and safety of POM+LoDEX in patients with severe renal impairment. Early tolerability data are encouraging, with dose escalation planned.

P773

CAUSES OF DEATH 30 AND 180 DAYS AFTER DIAGNOSIS IN NON-HDT TREATED DANISH MULTIPLE MYELOMA PATIENTS: A STUDY FROM THE DANISH MYELOMA STUDY GROUP

M Orebo Holmström[1,*], P Gimsing[2], N Abildgaard[3], N Andersen[4], N Clausen[5], M Frederiksen[6], H Gregersen[7], D Kristensen[8], H Larsen[9], P Trøllund Pedersen[10], T Plesner[11], S Pulczynski[12], A Vangsted[1]
[1]Department of Hematology, Roskilde Sygehus, University Hospital Copenhagen at Roskilde, Roskilde, [2]Rigshospitalet, Copenhagen, [3]Department of Hematology, Odense University Hospital, Odense, [4]Department of Hematology, Aarhus University Hospital, Aarhus, [5]Department of Hematology, University Hospital of Copenhagen at Herlev, Herlev, [6]Department of Hematology, Haderslev Hospital, Haderslev, [7]Department of Hematology, University Hospital of Aalborg, Aalborg, [8]Department of Hematology, Næstved Hospital, Næstved, [9]Department of Hematology, Viborg Hospital, Viborg, [10]Department of Hematology, Esbjerg Hospital, Esbjerg, [11]Department of Hematology, Vejle Hospital, Vejle, [12]Department of Hematology, Holstebro Hospital, Holstebro, Denmark

Background: Many elderly patients with multiple myeloma (MM), not eligible for high-dose melphalan with hematopoietic stem cell support (HDT), die shortly after diagnosis.
Aims: To determine the cause of death in non-HDT MM-patients dying within 30 and 180 days of diagnosis in a population based setting.
Methods: The cause of death in non-HDT-treated patients who died within 180 days of diagnosis was identified in the population based nationwide Danish myeloma database (DMMD) established by the Danish Myeloma Study Group. DMMD includes all patients diagnosed with MM since 2005. The cause of death was divided into 1) pneumonia defined by the presence of fever, cough and positive x-rays, 2) septicemia defined by fever and positive blood cultures, 3) other infection defined in case of fever, elevated CRP and infection not identified as pneumonia nor septicemia 4) respiratory failure defined as respiratory distress with no fever. 5) Cardiovascular disease defined as cardiovascular infarction including pulmonary embolism or by the presence of congestive heart disease, 6) intracranial infarction or hemorrhage diagnosed by CTC, MRI or bedside neurological examination defined as stroke and 7) patients on dialysis were classified as having renal failure. All other causes of death were classified as other cause of death.
Results: We found 2071 patients included in DMMD of whom 1497 (72.3%) did not receive HDT. Of these 330 (22.0%) died within 180 days of diagnosis. Medical history was not available in 25 (7.6%) patients. No specific cause of death was found in 17 (5.2%) of the patients. Seventy-six (23.0%) patients died at home, or at a nursing home. Among 212 (64.2%) eligible patients 72 (40.0%) died within 30 days and 140 (60.0%) died within 31-180 days. The following causes of death were found: Infection was the leading cause of death with 96 (45.3%) of the patients dying from infection in total. Thirty-three (45.8%) and 63 (45.0%) patients died from infection within 30 and 31-180 days, respectively. Septicemia was the cause of death in 40 (18.9%) of the patients in total; 17 (23.6%) and 23 (16.4%) patients dying within 30 and 31-180 days. Pneumonia was the cause of death within 30 and 31-180 days in 12 (16.7%) and 25 (17.9%) patients, 37 (17.5%) in total. Nineteen patients (9.0%) died from other infections. Renal failure was the cause of death in 35 (16.5%) patients, cardiovascular causes in 21 (9.9%) patients, respiratory failure in 13 (6.1%) patients and stroke in 9 (4.2%) of the patients. Thirty-eight (18.0%) patients died from other causes. There was no significant difference (Fisher's exact test) in the causes of death within 30 and 31-180 days after diagnosis (P=0.727) (Table 1).

Table 1.

Cause of death	Patients dead 0-30 days after diagnosis (% of patients in group)	Patients dead 31-180 days after diagnosis (% of patients in group)	All patients (% of patients in group)
Pneumonia	12 (16.7)	25 (17.9)	37 (17.5)
Septicemia	17 (23.6)	23 (16.4)	40 (18.9)
Other infections	4 (5.6)	15 (10.7)	19 (9.0)
Renal failure	14 (19.4)	21 (15.0)	35 (16.5)
Cardiovascular	8 (11.1)	13 (9.3)	21 (9.9)
Respiratory failure	5 (6.9)	8 (5.7)	13 (6.1)
Stroke	3 (4.2)	6 (4.3)	9 (4.2)
Other cause of death	9 (12.5)	29 (20.8)	38 (18.0)

Summary and Conclusions: The main causes of death within 180 days of diagnosis in non-HDT-treated MM-patients were infections; with pneumonia and septicemia as the most common specific causes. Renal failure was the second most common cause of death. The failure to produce normal polyclonal IgG, treatment with corticosteroid and myelosuppressive chemotherapy, T cell defects and renal failure are major causes of infections in patients with MM. Early use of prophylactic intravenous IgG and/or prophylactic antibiotic treatment in non-HDT treated patients could possibly prevent some or most of these early deaths.

P774

PRELIMINARY RESULTS OF A PHASE I/II STUDY OF CARFILZOMIB, LENALIDOMIDE, VORINOSTAT AND DEXAMETHASONE (QUAD) IN RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA (MM)

El Bilotti[1,*], D Vesole[1], J Richter[1], A McNeill[1], P Anand[1], U Bednarz[1], K Ivanovski[1], L McBride[1], L Raucci[1], V Batra[1], D Siegel[1]
[1]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, United States

Background: The results from Phase I/II studies suggest that carfilzomib as a single agent has clinical activity in relapsed and relapsed/refractory multiple myeloma (MM). Phase I/II data indicate that combining a proteasome inhibitor and corticosteroids with an immunomodulatory agent or a histone-deacetylase (HDAC) inhibitor are synergistic.
Aims: We investigated the tolerability and synergy of the quadruplet using carfilzomib as the proteasome inhibitor in combination with lenalidomide, vorinostat and dexamethasone.
Methods: The primary objectives were to determine the maximum tolerated dose (MTD) and the safety/tolerability of the QUAD combination. Secondary objectives included overall response rate, duration of response, time to progression and time to next therapy. All patients were required to have relapsed or relapsed/refractory disease following at least one line of therapy. Treatment consisted of 28-day cycles of oral lenalidomide days 1-21, oral vorinostat days 1-7 and 15-21, intravenous (IV) carfilzomib days1,2,8,9,15 and 16 and IV or oral dexamethasone 40mg days1,8,15 and 22. A standard 3+3 dose escalation schema was followed based on dose-limiting toxicities (DLTs) occurring in Cycle 1. (See Table 1) Adverse events (AEs) were graded using the NCI-CTCAE v3. Response was assessed by the modified International Myeloma Working Group criteria.
Results: As of February 28, 2013, fifteen patients have been enrolled, with one patient replaced due to inability to complete Cycle 1 due to AE. Four patients failed screening, 3 due to cytopenias and 1 due to QTC interval. The median age was 58 years (range 47-65), 55% were male. The median number of prior regimens was 3 (range 1-9), with a median time from diagnosis of 4 years. All patients had prior stem cell transplant, 10 had prior bortezomib, 10 had prior lenalidomide and 2 had prior vorinostat. Of the 7 patients who received prior VRD, 4 were refractory. Drug-related AEs were experienced by 100% of patients. The most common of these drug-related AEs included anemia (10pts), fatigue (8), thrombocytopenia (8), neutropenia (6), muscle cramping (6) and diarrhea (6). No febrile neutropenia occurred. Nine patients experienced ≥grade 3 AEs including neutropenia (5pts), anemia (3), thrombocytopenia (2), infection (2), electrolyte imbalances (2), hyperglycemia (1), fatigue (1) and constipation (1) and no grade 5 events. Eight SAEs occurred on study, most of which were infection and one was possibly study drug(s) related. Currently in cohort4, the MTD has not yet been determined with no DLTs to date. All 11 patients were evaluable for response with an ORR of 40%. Four patients had a partial response (PR), 2 stable disease (SD), 4 with progressive disease (PD) as best response and one has restaging pending. Of the seven patients treated in cohorts 2 and above, four have had a PR. Five patients have come off study due to PD and one due to patient choice. No patients have discontinued due to toxicity. Two patients have completed 18 cycles of therapy.

Table 1.

Cohort	Carfilzomib (mg/m²)	Lenalidomide (mg)	Vorinostat (mg)	Dexamethasone (mg)
1	15	15	300	40
2	20	15	300	40
3	20	25	300	40
4	20/27*	25	300	40
5	20/27*	25	400	40

* Step-up dosing of carfilzomib 20 mg/m² on Days 1 and 2 of Cycle 1, followed by 27 mg/m² for the remainder of treatment.

Summary and Conclusions: The combination of QUAD is well tolerated in both relapsed and relapsed/refractory MM patients, with no DLTs identified. The overall safety profile is manageable and the response rate of 40% noted in cohort 2 and above is encouraging in this patient population. Accrual is ongoing and additional data will be available at the time of presentation.

P775

CLINICAL RESPONSE BY BASELINE CHARACTERISTICS IN PATIENTS WITH RELAPSED AND BORTEZOMIB-REFRACTORY MULTIPLE MYELOMA TREATED WITH PANOBINOSTAT, BORTEZOMIB, AND DEXAMETHASONE (PANORAMA 2)

P Richardson[1,*], R Schlossman[1], M Alsina[2], S Coutre[3], C Gasparetto[4], S Mukhopadhyay[5], M Ondovik[5], M Khan[5], C Paley[5], S Lonial[6]
[1]Dana-Farber Cancer Institute, Boston, [2]H. Lee Moffitt Cancer Center & Research Institute, Tampa, [3]Stanford University, Stanford, [4]Duke University Medical Center, Durham, [5]Novartis Pharmaceuticals Corporation, East Hanover, [6]Emory University School of Medicine, Atlanta, United States

Background: In PANORAMA2, panobinostat combined with bortezomib and dexamethasone recaptured responses in heavily pretreated patients with bortezomib-refractory multiple myeloma; overall response rate, clinical benefit rate, and progression-free survival were 34.5%, 52.7%, and 5.4 months, respectively, with manageable toxicity (Richardson *et al.* ASH 2012 [abstract 1852]).
Aims: Here, we evaluate clinical response by prior use of bortezomib and dexamethasone, progression on or within 60 days of of a patient's last bortezomib-containing regimen, or high-risk cytogenetics at baseline. Additionally, we evaluate quality of life parameters.
Methods: In the single-arm, phase 2 PANORAMA 2 study, patients with relapsed and bortezomib-refractory multiple myeloma received panobinostat (20 mg, oral)+bortezomib (1.3 mg/m^2, intravenous)+dexamethasone (20 mg, oral). Treatment phase 1 (TP1) consisted of eight 3-week cycles of panobinostat (thrice weekly) and bortezomib (twice weekly) during weeks 1 and2, with oral dexamethasone administered on the days of and after bortezomib dosing. Patients demonstrating clinical benefit entered treatment phase2, which consisted of four 6-week cycles of panobinostat (thrice weekly) and bortezomib (once weekly) during weeks1,2,4, and5, with dexamethasone on the days of and after bortezomib. The primary endpoint was overall response (≥partial response) in TP1. Response was based on European Group of Blood and Marrow Transplantation 1998 criteria. High-risk cytogenetics was defined as del(17p), t(4;14), or t(14;16). Quality of life was measured with the Functional Assessment of Cancer Therapy/Gynecologic Oncology Group Neurotoxicity (FACT/GOG-Ntx) v4.0 scales. All patients provided written informed consent prior to study entry.
Results: Response rate trended higher in patients whose prior bortezomib therapy was not their last line of therapy (Table 1). Although no trend in response rate was noted, progression-free survival appeared longer in patients progressing within 60 days of their last bortezomib-containing regimen than in those progressing on their last bortezomib-containing regimen. In the 14 patients with high-risk cytogenetics, overall response rate (complete response, near complete response, or partial response) was 42.9% and clinical benefit rate (complete response, near complete response, partial response, or minimal response) was 71.4%. The mean FACT/GOG-Ntx subscale did not exhibit a clinically meaningful change from baseline (mean±standard deviation, 114.2±21.1; n=41) to cycle 9 day 1 (day 169; 104.2±15.4; n=16) as determined by 50% standard deviation threshold for minimally important difference. Other quality of life parameters were similarly unchanged.

No	18	38.9 (17.3-64.3)	50.0 (26.0-74.0)	6.5 (2.6-9.7)

BTZ, bortezomib; CBR, clinical benefit rate; ORR, overall response rate; PFS, progression-free survival.

Summary and Conclusions: Panobinostat combined with bortezomib and dexamethasone demonstrated activity regardless of baseline demographics in heavily pretreated patients with bortezomib-refractory multiple myeloma.

P776

PHASE 2A, OPEN-LABEL, MULTI-DOSE STUDY OF ANTI-KAPPA MONOCLONAL ANTIBODY, MDX-1097, IN RELAPSED KAPPA-CHAIN RESTRICTED MULTIPLE MYELOMA WITH STABLE MEASURABLE DISEASE

R Dunn[1], A Spencer[2,*], B Augustson[3], P Mollee[4], M Copeman[5], P Asvadi[1]
[1]Immune System Therapeutics, Sydney, [2]Malignant Haematology & Stem cell Transplantation Service, Alfred Hospital, Melbourne, [3]Haematology, Sir Charles Gairdner Hospital, Perth, [4]Haematology, Princess Alexandra Hospital, Brisbane, [5]Northern Beaches Cancer Service, Sydney, Australia

Background: MDX-1097 is a monoclonal antibody that binds to a kappa light chain surface antigen (called KMA), on malignant B cells but not normal leucocytes or other cells. A Phase 1 study of single doses of MDX-1097 has been completed in kappa-light-chain restricted multiple myeloma patients. Based on positive safety, pharmacokinetic and efficacy data at a 10mg/kg dose, we now conducted a phase 2a study of repeated dosing of MDX-1097.
Aims: This study aimed to test efficacy and safety of MDX-1097 at 10mg/kg weekly ×8 in relapsed kappa myeloma patients with stable measurable disease.
Methods: We initially enrolled 13 relapsed kappa myeloma patients with stable disease, including patients on maintenance lenalidomide or thalidomide

and low-dose steroids. The study followed a Simon 2-stage minimax design, with ≥1 response needed in the first 13 patients to expand the study. Responses were evaluated by IMWG guidelines (Durie *et al*, 2006). MDX-1097 10mg/kg was given by 90 minute intravenous infusion weekly for 8 weeks. Efficacy and safety data included vital signs, physical examination, ECG, hematology assessments, clinical chemistry, C-reactive protein, β2 microglobulin, immunoglobulin quantification, urinalysis, and creatinine clearance. This study was performed according to ICH-GCP guidelines.

Results: A total of 19 patients completed the study. Repeated MDX-1097 dosing was well tolerated: 4 patients had Grade 1-2 drug-related infusion reactions; 4 patients had Grade 3 AE's (complete heart block, pneumonia, anaemia and pancreatitis), considered unlikely to relate to MDX-1097. There was no evidence of serum sickness, no alteration of renal function, no evidence of increased immunosuppression and no ECG changes. One patient had a VGPR maintained for 12 months post MDX-1097 therapy. A second patient had PR. A third patient with light-chain-only myeloma had PR. On study, 26% of patients continued IMiD(R) maintenance therapy; with no signs that MDX-1097 affected their safety profile.

Summary and Conclusions: Multiple weekly doses of MDX-1097 at 10 mg/kg were safe and well tolerated in patients with relapsed kappa myeloma. Responses to therapy were seen in 3/19 (16%) of patients.

P777

THE UK LENALIDOMIDE TREATMENT CONTINUATION SCHEME™: TRENDS OF LONG-TERM TREATMENT IN A CLINICAL SETTING

Cathy D. Williams[1,*], Mathew Simcock[2], Imran Lodhi[3], Suzanne K. Robinson [2], Faith E. Davies[4]
[1]Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, United Kingdom, [2]Celgene International, Boudry, Switzerland, [3]Celgene Limited, Uxbridge, [4]Institute of Cancer Research, Royal Marsden Hospital, London, United Kingdom

Background: Patients (pts) with relapsed/refractory multiple myeloma (RRMM) who respond to therapy experience improved survival if treatment with lenalidomide (LEN) plus dexamethasone (DEX) is continued until disease progression. In the United Kingdom, LEN+DEX is reimbursed for the treatment of RRMM pts after ≥2 therapies (current license after ≥1 prior therapy) in accordance with the National Institute for Health and Clinical Excellence (NICE) guidelines. The Treatment Continuation Scheme (TCS) database was part of the NICE-agreed reimbursement scheme. It was designed to track the duration of LEN+DEX treatment in RRMM pts, but not the reasons for dose adjustments or treatment discontinuation.

Aims: To investigate how LEN starting dose and dose modifications during therapy impact treatment duration.

Methods: This anonymised prospective cohort analysis focused on pts with RRMM enrolled in the TCS program between 1 July, 2009 and 30 September, 2010. The cutoff date was 31 October, 2012 allowing at least 2 yrs follow up. Associations between ordered categorical variables (first dose administered, age group, treatment scheme, and number of cycles administered per pt) were measured by Spearman's rank correlation and associations between continuous variables (number of cycles, age, and number of dose changes) were measured by Pearson's correlation. Baseline covariates (age and starting dose) were modeled using multivariable logistic regression with possible interactions considered; $P<0.05$ was considered statistically significant.

Results: A total of1,779 pts from 193 treatment centers were evaluable. The median age was 69 yrs (range 23–91); 35% (624) were aged <65, 40% (702) were 65–74, and 25% (453) of the patients were >75 yrs. The majority of pts (65%; n=1,149) initiated LEN treatment according to the recommended starting dose of 25 mg/day, 15% of pts each started at 15 and 10 mg/day, and 5% at 5 mg/day. Dose modifications were reported in 48% of pts. The median number of dose modifications per pt was 1 (range 0–15). Of pts who started on 25 mg/day and received >1 cycle, almost half (48%) required no dose adjustments. Pts who had at least 1 form of dose adjustment had longer treatment duration compared with pts without a dose adjustment (15.0 *vs* 7.3 cycles, respectively; $P<0.0001$). The median number of cycles administered was 7 (range 1–48); 33.4% pts remained on therapy for ≥12 cycles, 17.6% of pts for ≥24 cycles, and 14.5% pts for ≥26 cycles. Of pts who continued therapy ≥24 cycles, 11.8% required dose modifications directly after cycle1, but the percentage of dose modifications steadily decreased from cycle 6 onwards. There was a positive association between a higher starting dose and longer treatment duration ($P<0.0001$). A significant negative correlation between age and the number of cycles administered was observed: pts aged <75 yrs were 1.51 times more likely to receive ≥24 cycles compared with pts aged ≥75 yrs ($P=0.0093$). In multivariate analyses, age and LEN starting dose were both statistically significant predictors for a treatment duration lasting ≥24 mos (Table 1).

Summary and Conclusions: This large dataset (N=1,779) from a clinical practice setting of pts with RRMM in the United Kingdom shows a positive correlation between the recommended LEN 25 mg/day starting dose and longer treatment duration. Age (<75 yrs) and individual dose adjustments of LEN during therapy were also associated with longer treatment duration.

Table 1. Predictors of treatment duration lasting ≥24 mos.

Factor	Odds ratio (95% CI) [*P* value]	
	Univariate model	Multivariate model
Age	0.983 (0.972–0.995) [0.0068]	0.986 (0.974–0.998) [0.0233]
LEN starting dose		
5 mg vs 25 mg	0.738 (0.402–1.354) [0.3262]	0.746 (0.406–1.371) [0.3451]
10 mg vs 25 mg	0.595 (0.404–0.877) [0.0087]	0.635 (0.429–0.941) [0.0235]
15 mg vs 25 mg	0.844 (0.593–1.20) [0.8962]	0.982 (0.625–1.273) [0.5278]

CI, confidence interval.

P778

THE EFFICACY AND SAFETY OF POMALIDOMIDE WITH OR WITHOUT LOW-DOSE DEXAMETHASONE IS NOT IMPACTED BY AGE IN PATIENTS WITH ADVANCED RELAPSED AND REFRACTORY MULTIPLE MYELOMA: MM-002 SUBGROUP ANALYSIS

S Jagannath[1,*], C Hofmeister[2], R Baz[3], David S. Siegel[4], R Vij[5], C Chen[6], S Lonial[7], K Anderson[8], M Chen[9], M Zaki[9], P Richardson[8]
[1]Mount Sinai Medical Center, New York, [2]Ohio State University Medical Center, Columbus, OH, [3]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [4]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, [5]Washington University School of Medicine, St. Louis, MO, United States, [6]Princess Margaret Hospital, Toronto, ON, Canada, [7]Emory University School of Medicine, Atlanta, GA, [8]Dana-Farber Cancer Institute, Boston, MA, [9]Celgene Corporation, Summit, NJ, United States

Background: Pomalidomide (POM) demonstrated clinical efficacy and acceptable tolerability in relapsed and refractory multiple myeloma (RRMM) patients previously treated with lenalidomide (LEN) and bortezomib (BORT), in the randomized, multicenter, open label MM-002 phase 2 trial.

Aims: The impact of age (≤65 *vs* >65 yrs) on efficacy and safety outcomes was assessed in a post-hoc analysis.

Methods: Patients with RRMM who had received ≥2 prior therapies, including LEN and BORT, and were refractory to their last regimen were randomized to either POM+low-dose dexamethasone (POM 4 mg/day, days 1–21 of a 28-day cycle; LoDEX 40 mg/week) or POM alone. At progression, patients receiving POM alone could receive POM+LoDEX at the investigator's discretion. Patients >over 75 yrs received LoDEX, 20 mg/week. All patients received mandatory thromboprophylaxis (daily low-dose aspirin). End points included progression-free survival (PFS), response rate (based on EBMT criteria), response duration, and safety.

Results: A total of 221 patients with a median age of 63 yrs (range 34–88) were randomized to POM+LoDEX (n=113) or POM alone (n=108). Overall, 77 (35%) of patients had LEN as their last prior therapy. The efficacy outcomes and the most common treatment emergent grade 3/4 adverse events (AEs) for the age subgroups according to treatment arm are presented in the Table 1. Median response was durable (7.7–10.6 mos) across the age groups with POM regardless of the addition of LoDEX, and was not impacted by age. Of patients aged ≤65 yrs, 28% (POM+LoDEX) and 32% (POM) required at least one dose reduction; for patients aged >65 yrs these proportions were 29% and 44%, respectively. Median relative dose intensity was 90% in both POM+LoDEX and POM arms in patients aged ≤65 yrs; in older patients it was 90% and 100%, respectively.

Table 1. Efficacy and safety outcomes.

	≤ 65 yrs		> 65 yrs	
	POM + LoDEX (n = 62)	POM (n = 69)	POM + LoDEX (n = 51)	POM (n = 39)
Median age, yrs (range)	59 (34–65)	58 (37–65)	72 (66–88)	74 (66–88)
Efficacy, %				
At least partial response	31	13	37	18
At least minimal response	47	23	43	44
Median duration of response,* mos	10.1	8.3	7.7	10.6
Median PFS, mos (range)	4.7 (3.7–6.7)	1.9 (1.8–2.7)	3.7 (2.1–5.5)	3.3 (2.8–5.5)
Safety	**POM + LoDEX (n = 61)**	**POM (n = 68)**	**POM + LoDEX (n = 51)**	**POM (n = 39)**
Grade 3/4 hematologic AEs, %				
Neutropenia	46	40	35	59
Anemia	26	24	18	26
Thrombocytopenia	18	24	20	21
Grade 3/4 non-hematologic AEs, %				
Pneumonia	16	10	29	21
Urinary tract infection	10	3	8	0

*For patients who achieved at least partial response.

Summary and Conclusions: POM with or without LoDEX was effective and generally well tolerated in heavily pretreated RRMM patients who had already received LEN and BORT, including patients who had progressed on prior LEN. In general, age had no impact on overall response rate, duration of response, or safety. Updated data will be presented at the meeting.

P779

PROMISING ROLES OF AMIFOSTINE AS PROPHYLACTIC AGENTS AGAINST BORTEZOMIB-INDUCED PERIPHERAL NEUROPATHY

M Fang[1,*], Y Gun[1]
[1]Department of Hematology, the First Affiliated Hospital of Dalian Medical University, Dalian, China

Background: Up to now, as the first proteasome inhibitor to be approved for the treatment of both relapsed/refractory and newly diagnosed multiple myeloma (MM) patients, the bortezomib has emerged as an important therapeutic strategy in the treatment of MM. On account of the BiPN as an adverse effect, the dose and duration of bortezomib treatment were often limited. The incidence of BiPN reached as high as 37%. In addition, there was a lack of the effective evidence concerned with the treatments and prevention measures for BiPN. As an organic thiophosphate, amifostine, was used as a "detoxifying agent" during a cytotoxic treatment procedure. Besides, it was also thought to act as a ROS scavenger, which is an important component for cancer therapy. What's more, it was demonstrated that amifostine could play a potential neuroprotective role on preventing the cisplatin- and paclitaxel-induced neurotoxicityin.
Aims: To examine whether amifostine could protect patients with multiple myeloma (MM) from bortezomib-induced peripheral neuropathy while maintaining the therapeutic efficacy.
Methods: 47previously untreated patients with MM were enrolled and randomly assigned to treatment.All patients receivedbortezomib (1.0 mg/m^2 on days1,4,8, 11),dexamethasone (20-40mg/don days1-4, 8-11) andthalidomide(100mg/d)for four 21-day cycles. Patientswere randomly assigned to receive 400 mg of amifostinebefore bortezomib,then assessed incidence and severity of BiPN after every cycle. *In vitro*, schwann cells(SCs)and myeloma cells(MCs)were pretreated with amifostineat 0,1,2, 4mM for 30min prior to bortezomib exposurefor 5 h at 400nM and 100nM, respectively. After Cell viability and reactive oxygen species (ROS) were examined, aggresome formation and activation of chaperone-mediated autophagy (CMA) in SCswere observed through immunofluorescent analyses and TEM.
Results: Complete response rates did not differ in thepresence or absence of amfostine therapy(34.78% v 37.5%, P>0.05). Incidence of BiPN was lower in patients whoreceived amfostine compared with those who received no amifostine (62.5%v 78.26%, P>0.05), though the difference was not significant. Among the patients with BiPN,NCI grade 3-4 incidence wassignificantly lower in patients who received amifostinethan those who received no amifostine (8.33% v 39.13%, P<0.05).*In vitro*, amifostine pretreatment increased thecell viability while decreased the level of ROS in SCs.In addition, amifostine pretreatment decreased the percentage of SCs forming peripheral myelin protein22 (PMP22) aggregatesandinduced high expression of cytoplasmic chaperoneand receptor of CMA at lysosomal membrane. TEM observedautophagosomes of different stages in SCsinduced by amifostine. Amiforstine did not increased the cell viability and decreased the level of ROS in MCs.
Summary and Conclusions: These results indicate promising roles of amifostine as prophylactic agents against BiPN by reducing ROS generation and aggresome formation through activation of CMA.

P780

MP VS MPT IN FIRST TO FOURTH LINE OF TREATMENT IN MULTIPLE MYELOMA PATIENTS

J Lund[1,*], K Uttervall[1], J Liwing[1], J Aschan[2], E Alici[1], E Holmberg[3], H Nahi[1]
[1]Divison of Hematology, Department of Medicine, Huddinge, Karolinska Institute, Stockholm, [2]Jansen-Cilag AB, Sollentuna, [3]Department of Oncology, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

Background: Combination of melphalan and prednisolone (MP) was standard treatment of multiple myeloma (MM) for decades. Since the introduction of novel agents the clinical outcome in MM has improved. Several prospective studies with thalidomide, the first novel agent, combined with MP, (MPT) compared to MP have been performed, most of them showing MPT gives a better response rate and median overall survival than MP. A metaanalysis of 6 prospective studies show a rise of median OS and EFS when treating with MPT of 6 months when comparing to MP.
Aims: The aim of the study was to look upon a real life population and see if addition of thalidomide to MP gained real life patients.
Methods: From a material of 1642 patients with symptomatic MM collected from 15 Swedish sites from earliest January 2000, until latest June 2012 we collected all patients treated in first, second, third and fourth line of therapy with MP (n=600, 213, 54 and 21) and MPT (n=170, 66, 23 and 15). MM patients were identified from the Swedish National Cancer Register and medical data were obtained from medical records. Patients were evaluated for response rate, OS and EFS. Multivariate Cox model analysis was made to adjust for Ig-class, age, hypercalcemia haemoglobin and albumin levels at time for MM-diagnose.
Results: The distribution of response rate of nCR/VGPR/PR and NR in the MP population was5,3, 31 and 61% and4,4, 27 and 65% in 1st and 2nd line of therapy respectively. In the MPT population the response rate were significantly better;12,12,46 and 30% in 1st line and9,9, 47 and 34% in 2nd line. Median OS in the MP group after 1st line of therapy was 27 months and in the MPT group 50 months, 95% CI [24;30] and [44;84] respectively (P<0.0001). The relative risk for death in the MPT group *vs.* the MP group was 0.61, 95% CI [0.45;0.84] after adjusting for other prognostic markers. Two years from start of treatment 55% of the patients treated with MP were still alive and hadn't started new treatment *vs.* 70% after MPT. After 2nd line of therapy OS in the MP group was 22 months and in the MPT group 35 months, 95% CI [18;25] and [29;-]. Relative risk for death after MPT *vs* MP was 0.55, 95% CI[0.38;0.83], P<0.01. After 3rd and 4th lines of therapy median OS for MP were 17 and 14 months, 95%CI [13;30] and [4;23] respectively and for MPT 19 and 23, 95% CI[8;32] and [8;-]. The difference after 4th line of treatment was not significant, probably due to the small amount of patients. EFS for patients receiving MP in 1st, 2nd and 3rd lines of treatment was 12.6, 8 and 8 months respectively compared to patients who received MPT where EFS was 22, 18 and 3.2 months respectively, (P<0.001, <0,001 and=0.374 respectively). The reason for the short EFS after 3rd line of treatment in the MPT group is unclear and does not correspond to OS for the same group (Figure 1).

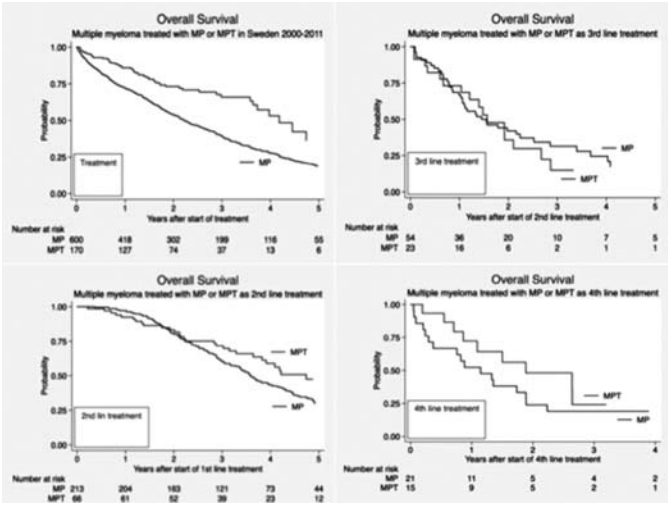

Figure 1.

Summary and Conclusions: Response rates with MPT were significantly better than with MP both in 1st and 2nd line of treatment. Treatment with MPT significantly increased OS and EFS in treatment lines 1 through 3. MPT benefits in our retrospective study of patients in a standard clinical setting were even bigger than in the prospective trials performed.

P781

CAN NOVEL AGENTS OVERCOME THE NEGATIVE PROGNOSTIC IMPACT OF RENAL IMPAIRMENT IN MULTIPLE MYELOMA? - A POPULATION BASED STUDY INCLUDING 1538 PATIENTS

K Uttervall[1,*], J Lund[1], J Liwing[1], E Holmberg[2], E Alici[1], J Aschan[3], H Nahi[1]
[1]Department of Medicine, Karolinska Institutet, Stockholm, [2]Department of Oncology, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, [3]Janssen-Cilag AB, Sollentuna, Sweden

Background: Renal impairment (RI) is a relatively common feature of multiple myeloma (MM) and it has been shown in several studies that RI at the time of diagnosis correlates to inferior survival.
Aims: To understand the impact of RI on survival in the era of novel agents. The primary endpoint of this retrospective study was overall survival (OS). Time to next treatment (TTNT) was the secondary endpoint.
Methods: The study population included all patients diagnosed with MM since earliest January 2000 until latest June 2011 at 14 Swedish sites. The estimated glomerular filtration rate (eGFR) was calculated using the MDRD-formula and RI was defined as eGFR <60 mL/min/1.73 m^2. Multivariate Cox model analysis was made to adjust for age, calcium, haemoglobin and albumin levels at time for MM-diagnose.
Results: The study population consisted of 1538 patients. Patients with RI at diagnosis (n=680) had a significantly worse median OS of 33 months 95% CI[28;36] compared to those without RI (n=858), with a median OS of 52 months 95% CI[48;56], (P<0.001). High dose treatment (HDT) in 1st line improved medi-

an OS in patients with RI (76 *vs* 26 months, P<0.001). Novel treatment in 1st line significantly improved OS for non-HDT patients with RI (60 *vs* 21 months, P<0.001). This difference was still significant in the multivariate analysis. There was no difference in median OS between non-HDT patients with and without RI that had been treated with novel drugs (60 *vs* 50 months, P=0.86). RI implied a shorter median TTNT after 1st line (13 *vs* 20 months, P<0.001). HDT prolonged TTNT (30 *vs* 11 months, P<0.001). For non-HDT patients with RI novel treament in 1st line also prolonged TTNT from 9 to 19 months, P<0.001 (Figure 1).

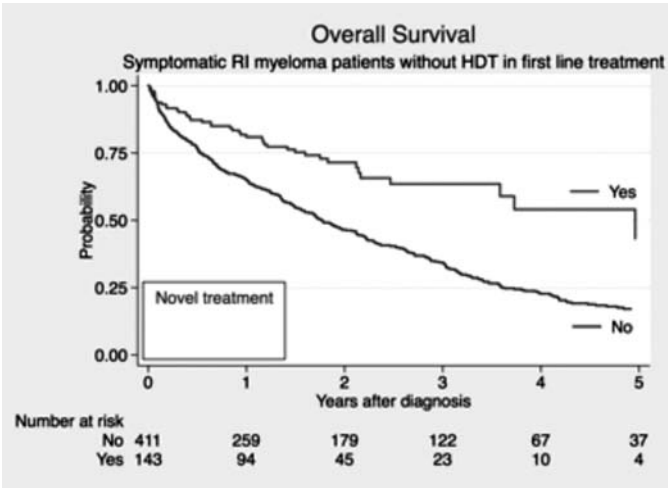

Figure 1.

Summary and Conclusions: RI is still an important prognostic marker in MM. HDT and novel treament regimens can partly overcome the negative impact of RI with improved median OS and prolonged TTNT.

P782

SIGNIFICANCE OF THE ISS AND IMWG RESPONSE CRITERIA IN PATIENTS WITH MULTIPLE MYELOMA WHO RECEIVED ASCT IN THE NOVEL AGENT ERA: A RETROSPECTIVE ANALYSIS OF 1701 JAPANESE PATIENTS

H Takamatsu[1,*], T Miyamoto[2], S Hagiwara[3], K Yokoyama[4], T Ito[5], M Matsumoto[6], K Nishiwaki[7], H Sakamaki[8], R Suzuki[9], K Sunami[10]

[1]Cellular Transplantation Biology (Hematology/Respirology), Kanazawa University Graduate School of Medical Science, Kanazawa, [2]Department of Hematology/Oncology, Kyushu University, Fukuoka, [3]Division of Hematology, Internal Medicine, National Center for Global Health and Medicine, [4]Division of Hematology, Department of Medicine, Keio University School of Medicine, Tokyo, [5]Division of Hematology, Second Department of Internal Medicine, Shinshu University School of Medicine, Matsumoto, [6]Department of Hematology, National Hospital Organization Nishigunma National Hospital, Shibukawa, [7]Division of Oncology and Hematology, Department of Internal Medicine, Jikei University School of Medicine, Kashiwa Hospital, [8]Division of Hematology, Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Tokyo, [9]Department of HSCT Data Management and Biostatistics, Nagoya University Graduate School of Medicine, Nagoya, [10]Department of Hematology, National Hospital Organization Okayama Medical Center, Okayama, Japan

Background: Although the International Staging System (ISS) and International Myeloma Working Group (IMWG) response criteria for multiple myeloma (MM) are used worldwide, there have been few reports on prognostic assessment of Asian patients using these criteria in the novel agent era.

Aims: The objective of our study was to evaluate the clinical significance of ISS and IMWG response criteria in Japanese patients with MM who were treated with autologous stem cell transplantation (ASCT).

Methods: Study participants included 1701 Japanese patients (967 men and 734 women) with a median age of 57 years (range: 19-73 years) who underwent a single ASCT after high-dose melphalan (200 mg/sqm) (Mel 200) treatment for MM in Japan between October 1995 and December 2011. Data were collected and analyzed retrospectively using the Transplant Registry Unified Management Program (TRUMP) of the Japan Society for Hematopoietic Cell Transplantation. Given that bortezomib, thalidomide and lenalidomide were approved in Japan in December 2006, October 2008 and June 2010, respectively, we categorized patients into two treatment cohorts: pre-novel agent era (1995-2006) and novel agent era (2008-2010).

Results: During the pre-novel agent era (1995-2006) in Japan, 695 patients (386 men and 309 women) with a median age of 56 years (range: 22-70 years) received a single ASCT after Mel 200 treatment between October 1995 and December 2006. The median follow-up time was 4.3 years with a 4-year overall survival (OS) rate of 66%. Median survival rates for ISS I (n=176), II (n=204) and III (n=113) groups were 7.3, 6.4 and 5.3 years, respectively. We could not obtain ISS data for 202 patients. In the ISS I group, OS was significantly prolonged compared to ISS II (P=0.046) and III (P=0.002) groups; however, no significant difference was found between ISS II and III groups (P=0.155). Responses before ASCT were as follows: 64 CR (9.2%), 139 VGPR (20.0%), 374 PR (53.8%), 83 SD (11.9%), 21 PD (3.0%) and 14 non-data (2.1%). Median survival rates for CR, VGPR, PR, SD, and PD groups were 11.3, 5.9, 6.2, 5.4 and 3.3 years, respectively. There were no significant differences in OS between the CR group and other response groups, except for CR *versus* PD (P=0.014) groups. During the novel agent era (2008-2010) in Japan, 1006 patients (581 men and 425 women) with MM received a single ASCT after Mel 200 treatment between January 2008 and December 2010. The median follow-up time was 1.5 years with a 2-year OS rate of 87%. Two-year OS rates for ISS I (n=392), II (n=410) and III (n=204) groups were 90%, 87%, and 82%, respectively. In the ISS I group, OS was significantly prolonged compared to the ISS III group (P=0.03), but no significant differences were found between ISS I and II groups (P=0.59) and between ISS II and III groups (P=0.07) (Figure 1). Responses before ASCT were as follows: 107 CR (10.6%), 316 VGPR (31.4%), 473 PR (47.0%), 80 SD (8.0%), 21 PD (2.1%) and 9 non-data (0.9%). Two-year OS rates for CR, VGPR, PR, SD and PD groups were 90%, 89%, 86%, 83% and 61%, respectively. There were no significant differences in OS between the CR group and other response groups, except for CR *versus* PD groups (P<0.001) (Figure 2). The percentage of CR+VGPR cases (423 of 1006 [42.0%]) before ASCT in the novel agent era increased significantly compared to the pre-novel agent era (203 of 695 [29.2%]) (P<0.0001).

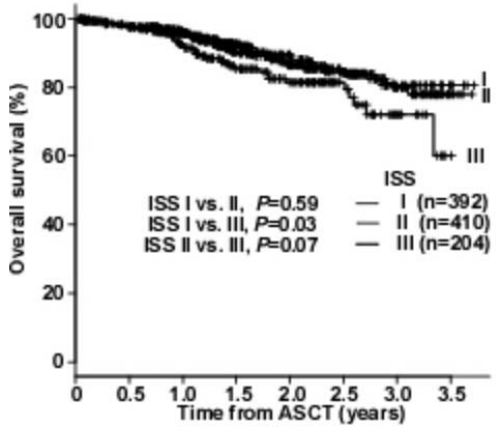

Figure 1.

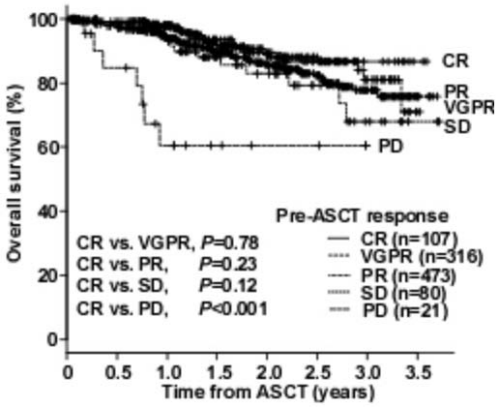

Figure 2.

Summary and Conclusions: In the novel agent era, CR+VGPR cases before ASCT increased. Although the ISS did not clearly stratify the prognosis of Japanese patients with MM who received a single ASCT, this finding should be confirmed in prospective studies.

P783

PREVALENCE AND CLINICAL SIGNIFICANCE OF BRAF V600E MUTATION IN MULTIPLE MYELOMA

E Rustad[1,*], H Dai[2], K Wader[3], K Misund[1], H Hov[2], A Sundan[1], H Aarset[2], A Waage[1,4]

[1]Department of Cancer Research and Molecular Medicine, Norwegian Universi-

ty of Science and Technology, [2]Department of Pathology, [3]Department of Oncology, [4]Department of Haematology, St. Olavs Hospital, Trondheim, Norway

Background: Activating mutations in the BRAF are found in 100% of patients with hairy cell leukemia, 60% with malignant melanoma and 4% with multiple myeloma. Mutation V600E is the most common of approximately 30 BRAF mutations. Clinical characteristics of myeloma patients with BRAF mutations have been published, but the number is still too low to decide whether they have a common phenotype. Here we present 10 cases with BRAF mutation V600E.
Aims: Our objective is to further examine the prevalence and clinical significance of BRAF mutations in multiple myeloma.
Methods: The patient material consists of 153 bone marrow biopsies collected as a part of routine diagnostics at St. Olavs Hospital in Trondheim, Norway in the period 2006-2012. All patients fullfilled criteria for multiple meyloma (>10% plasma cells in BM and/or >30 g/l of M protein). All patients who were still alive at the time of inclusion gave passive consent to analyze the clinical information and biological material. Ethics committee approved the study. Patient samples were examined by real time PCR for the two most common BRAF mutations, V600E and K601N. Clinical disease characteristics from each patient were obtained from clinical records.
Results: In 153 patients we found 10 patients (6,5%) with V600E mutation and no patients with K601N mutation. Median age was 69 (range 52-82) years, 6 male and 4 female, IgG5, IgA 2 (3 missing), kappa8, lambda2, creatinine median 146 (59-900) µmol/l, corrected Ca median2,80 (2,40-3,60), ISS stage II: 3 pts, ISS stage III: 4 pts (3 missing), 8 pts had skeletal disease. Median overall survival was 52 months in BRAF- patients and 26 months in BRAF+ patients. None of the differences were statistically significant.
Summary and Conclusions: The prevalence of BRAF mutation V600E was6,5%. 10 patients with BRAF mutation V600E were more affected by the disease and had shorter survival compared with 143 patients without the mutation indicating that BRAF+ patients may have a more agressive disease.

P784

SESTAMIBI TECHNETIUM-99M BONE MARROW SCAN IS ABLE TO PREDICT OVERALL DISEASE OUTCOME AND MORTALITY COMPARED TO WHOLE BODY MAGNETIC RESONANCE IMAGING IN MULTIPLE MYELOMA

A Khalafallah[1,2,*],A Snarski[3], R Heng[4]
[1]Haematology, LAUNCESTON GENERAL HOSPITAL, [2]School of Human Life Sciences, University of Tasmania, [3]Nuclear Medicine, Northern Nuclear Medicine Tasmania, [4]Radiology Department, LAUNCESTON GENERAL HOSPITAL, Launceston, Australia

Background: Bone disease occurs in about 90% of multiple myeloma (MM) patients. There are no data comparing the new diagnostic modalities with whole body Magnetic Resonance Imaging (WB-MRI) and Sestamibi Technetium-99m-MIBI Bone Marrow Scan (MIBI) in MM.
Aims: This study aims to determine whether WB-MRI and MIBI scans in the same myeloma patients produce the same estimate of disease load and location and to study possible association between the bone disease detected by these scans and the effect on disease outcome and survival.
Methods: A prospective comparative study was conducted between WB-MRI and MIBI scans in assessing bone disease and outcome of MM. Sixty two consecutive patients with confirmed MM underwent simultaneous WB-MRI and MIBI scans at the Launceston General Hospital from January 2010 to January 2011, and their survival status was determined in January 2012. The median age was 62 years (range 37-88) with a male to female ratio of 33:29. For the examination of the spines, MRI-T1 weighted turbo spin-echo and turbo spin echo MRI-STIR (Short Tau Inversion Recovery) were performed in the sagittal plane. Within 48 hours all patients underwent MIBI scan. Imaging started at five minutes post injection of MIBI–30mCi (1110MBq) with a wide field of view gamma camera equipped with a low energy high resolution collimator. The whole body scan proceeded at 30cm/minute. When completed, lateral femora images were taken with each view, which took approximately two minutes and, if required, a single positron emission computed tomography (SPECT) was performed. This study is approved by the Tasmanian Human Ethics Committee, Australia. The study was registered prospectively in the Australian and New Zealand Clinical Trials Registry at http://www.ANZCTR.org.au under No: ACTRN12609000761268.
Results: Overall in all bones, the mean MIBI scan result provides a better and earlier prediction of disease progression and mortality than the mean result from the MRI scan versions taken together (MRI_T1 HR for trend 0.51; 95%CI 0.33 to 0.81; P=0.012: and MRI-STIR HR for trend 0.58; 95%CI 0.35 to 0.97; P=0.038) when patients receive standard therapy for myeloma. In vertebrae and long bones, MRI scan detected more disease compared to MIBI scan (P<0.001) but there was less difference in the skull (P=0.09). In the rib-cage, the MIBI scan detected more lytic lesions of the ribs compared to MRI scan (P<0.001). Thirteen of the 62 patients died during the 24 months follow-up. Increased disease detected in all bones by both scans was associated with increased mortality risk (MIBI P=0.001; MRI-STIR P=0.044; but not MRI-T1 P=0.44). In all combined bone groups, the mean MIBI scan results provided a better prediction of mortality than MRI scan over the follow-up period (MRI-T1 *vs* MIBI P=0.019; MRI-STIR *vs* MIBI P=0.047).
Summary and Conclusions: Our study confirms that WB-MRI is more accurate and with a higher sensitivity in detecting myeloma bone lesions.A novel finding shows that MIBI scan obtains an image of all important bone compartments in the body in one single examination, and is less time consuming and more comfortable for the patient than MRI. Furthermore, MIBI scan was able to predict overall disease outcome and mortality better than MRI scan. Further studies to define optimum use of these imaging techniques are warranted.

P785

HETEROGENEITY OF IMWG DEFINED CR AND VGPR ASSESSED BY FREE LIGHT CHAIN ASSAY AND MULTIPARAMETER FLOWCYTOMETRY

H Sugihara[1,*], T Ugai[1], Y Nishida[1], K Tsuda[1], M Yamakura[1], M Takeuchi[1], K Matsue[1]
[1]Hematology, Kameda Medical Center, Kamogawa, Japan

Background: With the development of novel therapeutic agents, complete response (CR) and very good partial-response (VGPR) have become treatment goals in patients with multiple myeloma (MM). Although, the current definition of CR is not fully satisfactory, and other techniques such as serum free light chain (sFLC) assay, immunophenotyping and molecular methods are being investigated. The incorporation of FLC assay in addition to IMWG defined CR criteria defines a more stringent degree of CR (sCR), whereas multiparameter flowcytometry (MFC) may allow the more deeper level of response compared to conventional immunofixation negative response or sCR.
Aims: We retrospectively analyzed the relationship of different level of responses and its clinical relevance on the prognosis after treatment of MM.
Methods: A total of 131 consecutive patients with MM treated from April 2005 to December 2012 at our institute were subjected to this study. *s*FLC was serially measured at least once a week during admission and once a month during the period of outpatient care, and bone marrow examination was performed before and after treatments as clinically indicated. Treatment response was assessed using the IMWG criteria, and the best response to treatment during the course of disease was evaluated by simultaneous serum immunofixation test, sFLC measurements and MFC analysis of bone marrow plasma cells.
Results: Among 131 patients, 32% of patients achieved CR, 27.5% achieved sCR, and 20% achieved immunophenotypic CR. VGPR was obtained 25% of patients and the rest of 42% of patients remained PR or less responses. Survival of patients was correlated with the depth of response in IMWG criteria. Normalization of FLC ratio among patients with CR, VGPR, and PR or less was 86%, 60%, and 9%, respectively. Among 36 CR patients with normal sFLCκ/λ, 26 (72%) were MFC-negative and 10 (28%) were MFC-positive; 4 of 6 CR patients without normal sFLCκ/λ (29%) were MFC-positive. 20 VGPR patients (61%) obtained normal sFLCκ/λ, while only one became MFC-negative. Among 56 patients with less than PR, only 3 obtained normal sFLCκ/λ and none achieved MFC negativity. Among the patients with CR and VGPR, patients achieved sFLC normalization showed significantly better survival compared to those who did not. Patients achieved MFC negativity showed significantly better survival compared to those who did not. Among patients with CR, patients achieved MFC negativity showed better PFS, but other conventional prognostic markers did not give negative impact on PFS, probably due to short follow up and excellent outcome in this group of patients. On multivariate Cox regression analysis for PFS, only MFC negativity was an independent prognostic factor (Hazard-ratio 0.028; 95% CI, 0.004 to 0.21; *P*=0.0005).
Summary and Conclusions: This study confirmed that magnitude of CR and VGPR response defined by IMWG criteria was heterogeneous in terms of sFLCκ/λ normalization and MFC negativity. Although MFC and sFLC analysis frequently gave discrepant results among patients with CR and VGPR, both analyses appeared to give complementary important complementary information for assessing the depth of CR and VGPR category. Achieving immunophenotypic CR translates into superior PFS compared with conventional CR or sCR.

P786

ALPHA 1-ACID GLYCOPROTEIN (AAG) IS A POTENTIAL PATIENT SELECTION BIOMARKER FOR IMPROVED CLINICAL ACTIVITY OF ARRY-520 IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA (MM)

B Tunquist[1,*], K Brown[1], G Hingorani[1], R Aitchison[1], J Regensburger[1], S Lonial[2], J Kaufman[2], J Zonder[3], A Cohen[4], W Bensinger[5], R Orlowski[6], J Shah[6], B Hilder[1], M Ptaszynski[1], K Litwiler[1], D Walker[1]
[1]Array BioPharma, Boulder, [2]Emory Winship Cancer Institute, Atlanta, [3]Karmanos Cancer Institute, Detroit, [4]Fox Chase Cancer Institute, Philadelphia, [5]Fred Hutchinson Cancer Research Center, Seattle, [6]MD Anderson Cancer Center, Houston, United States

Background: ARRY-520 is a selective inhibitor of kinesin spindle protein (KSP) that has preferential activity in Mcl-1-dependent tumors and is being developed for patients with relapsed and refractory multiple myeloma (MM). The acute-phase plasma protein alpha 1-acid glycoprotein (AAG) can bind certain drugs, potentially affecting pharmacokinetics (PK), and thus efficacy. AAG levels vary considerably among patients with cancer, including MM.

Aims: To investigate the interaction of ARRY-520 and AAG as it relates to patient outcome following ARRY-520 administration.
Methods: Protein binding, and the effect of [AAG] and [compound] on MM cell line viability were measured *in vitro*. Patient data were obtained from 3 clinical studies of ARRY-520: Ph1 solid tumor study, Ph1/2 AML study, and Ph1/2 study in MM. The MM Phase 2 study consists of two separate cohorts: single agent ARRY-520 and ARRY-520 plus low-dose dexamethasone (dex). [AAG] and the degree of ARRY-520 total protein binding were measured in pre- and post-dose blood samples.
Results: ARRY-520 shows preferential affinity for AAG relative to other common serum proteins, such as HSA. In *in vitro* assays, increasing [AAG] across a clinically relevant range (0.6–3.0 g/L) decreased the unbound concentration of ARRY-520 five-fold and this correlated with increased IC_{50} values for ARRY-520 in MM cell line viability assays. A similar effect on MM cell viability was not seen for several other standard of care MM agents, which do not bind to AAG. Thus, we hypothesize that elevated AAG decreases free concentration of ARRY-520 and leads to a loss of potency. In pre-dose blood samples (n=140), [AAG] ranged from 0.2 to 4.1 g/L. Both [AAG] and measured unbound ARRY-520 correlated with changes in PK: CL and V_d decreased with increasing AAG, consistent with a lower unbound fraction in patients with higher [AAG]. Post-dose blood samples from the MM study indicated that AAG levels did not significantly change with time. Of 72 MM patients evaluated for AAG to date, 26% exhibited pre-dose [AAG] ≥1.1 g/L, and this correlated with a decreased median event-free survival (EFS) (2.3 *vs* 7.8 months; P=0.0024) and no clinical responses (0/19 *vs* 12/53; P=0.028) compared to patients below this cutoff. In the ARRY-520+dex cohort, a 22% ORR (≥PR) in the 1st-stage of this study was observed. The ORR for the subgroup of patients with AAG ≥1.1g/L was 0% (0/6). By contrast, in patients with AAG <1.1g/L ORR was 33% (4/12). High [AAG] also associated with a shorter median overall survival (OS) of 4.5 months *vs.* 20.2 months in patients with AAG ≥1.1g/L. The reported relationship between [AAG] and MM patient prognosis is unclear. In our study, we observed no relationship between pre-study [AAG] and various prognostic markers (*e.g.* b2-microglobulin, HSA, LDH, and ISS score). These results are consistent with AAG not having prognostic value in this disease.
Summary and Conclusions: Preclinical and interim clinical data suggest AAG levels affect the PK and activity of ARRY-520. In preclinical analyses, this effect is specific to ARRY-520 relative to other MM drugs. Patients with [AAG] above a cutoff are predicted to achieve insufficient exposure to gain therapeutic benefit, with a 0% ORR and significantly shorter EFS and OS compared to patients below this cutoff. We hypothesize that selecting patients based on low AAG levels may allow for identification of those patients most likely to benefit from ARRY-520. Additional work is ongoing and will be reported at a later time.

P787

COMPARISON OF FREELITE AND N LATEX SERUM FREE LIGHT CHAIN ASSAYS AND PREDICTING SURVIVAL

S Mahmood[1,*], N Wassef[2], S Sachchithanantham[1], L Rannigan[1], W Taylor[1], T Lane[1], D Foard[1], A Tekle[3], K Patel[1], J Pinney[1], C Whelan[1], H Lachmann[1], J Gillmore[1], P Hawkins[1], A Wechalekar[1]
[1]Inflammation, National Amyloidosis Centre, University College London Medical School, Royal Free Campus, [2]Head of Proteins, Enzymes, Clinical Biochemistry, [3]Clinical Biochemistry, Royal Free London Foundation Trust, London, United Kingdom

Background: Availability of serum immunoglobulin-free light chain (FLC) assays Freelite (Binding Site UK) and N Latex (Siemens, Germany) allows for measurement free kappa and lambda immunoglobulin light chains. FLC measurements are an important tool in diagnosing and monitoring patients with multiple myeloma and AL amyloidosis. We report a comparison of the Freelite (a polyclonal assay) and N Latex (a new monoclonal assay) immunoassays in diagnosis and monitoring of patients with systemic AL amyloidosis.
Aims: We assessed the concordance of the assays in detecting the abnormal light chain component, time to first dFLC response, dFLC response at2,4,6 months and outcomes by degree of clonal response.
Methods: Our primary cohort consisted of 94 consecutive AL amyloidosis patients assessed at the UK national amyloidosis centre between January 2011 and April 2012, treated with chemotherapy and available for serial follow up for six months. All patients had serum FLC monitoring at baseline and two monthly thereafter to assess treatment response. The FLC measurements were repeated in duplicate for both the Freelite and N Latex assays at 0,2, 4 and 6 months.
Results: The median age was 64 yrs (range 55-72 yrs) with cardiac involvement in 43% (23% Mayo stage 3) and renal involvement in 76%. Patients had a kappa and lambda clonal light chain in 21% and 79% respectively. 46% had a measurable monoclonal protein (≥1g/L). The follow up was 8.6 months and median overall survival was 24.1 months. The median kappa was 17.3mg/L and 16mg/L, median lambda 48.8mg/L and 52.6mg/L and median dFLC was 107mg/L and 199mg/L by Freelite and by N Latex respectively. There was an abnormal kappa in 41% and lambda in 63% by Freelite assay, and abnormal kappa in 32% and 67% by N Latex assay. An abnormal kappa or lambda was correctly identified in 85%/78% and 82%/83% by Freelite and N latex assays. There were discordant kappa/lambda ratios at presentation with 11/90 abnormal by N Latex and normal by Freelite, and 10/90 abnormal by Freelite but normal by N Latex. The correlation coefficient for kappa was R^2=0.91, lambda was R^2=0.52 and kappa to lambda ratio was R^2=0.87. At 2 months, a complete response (CR) was achieved in 20% and 21%, partial response (PR) 0% and 14% by Freelite and N Latex assays respectively. At 4 months a PR was present in 7% and 16% by the Freelite and N Latex assays (Table 1). Achieving a PR or greater at 4 months post treatment predicted a statistical significant survival advantage by both assays: Freelite (P=0.011) and N Latex (P=0.049).

Table 1.

		Freelite	N Latex
2 months	CR	8	9
	vGPR	4	6
	PR	0	6
	NR	28	22
4 months	CR	13	11
	vGPR	6	6
	PR	3	6
	NR	23	18
6 months	CR	13	13
	vGPR	5	4
	PR	3	5
	NR	10	9

Summary and Conclusions: Both FreeLite and N latex assay can detect abnormal free light chains in patients with systemic AL amyloidosis. In general, there was a good correlation between the assays for detecting the abnormal light chain subtype. However, both assays showed discrepancies in the absolute values of FLC and each assay missed different patients. N Latex assay appears to detect PR earlier than Freelite assay but the clinical significance remains unclear as the p values for improved survival were different for both assays. Although both assays are useful for detection of abnormal FLC measurements in amyloidosis, the values are not interchangeable. Further studies are needed to validate the biological significance of abnormal FLC by the N Latex assay. Joint first authors (S Mahmood and NL Wassef)

ADVERSE EVENTS AND MANAGEMENT IN MM-003, A PHASE 3 STUDY OF POMALIDOMIDE+LOW-DOSE DEXAMETHASONE (POM+LODEX) VS. HIGH-DOSE DEXAMETHASONE (HIDEX) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

Background: Optimization of adverse event (AE) management in RRMM patients (pts) is important in order to permit full-dose treatment (Tx) and maximize therapeutic benefit. RRMM pts with advanced disease exposed to multiple prior Tx present with comorbidities and may be predisposed to more frequent AEs. POM was recently approved by the US FDA for use in RRMM following at least 2 prior Tx, including bortezomib (BORT) and lenalidomide (LEN). POM+LoDEX has previously been shown to be effective and well tolerated in this pt population. MM-003 is an open-label, multicenter, phase 3 trial comparing POM+LoDEX *vs.* HiDEX in pts who failed prior LEN and BORT.
Aims: This subanalysis examined the MM-003 safety profile and AE management.
Methods: Pts must have been refractory to their last prior therapy (progressive disease [PD] during or within 60 days) and failed LEN and BORT after ≥2 consecutive cycles of each (alone or in combination). Pts were randomized 2:1 to receive 28-day cycles of POM 4 mg on days 1-21+LoDEX 40 mg (20 mg for those >75 years of age) weekly; or HiDEX 40 mg (20 mg for those >75 years

of age) on days 1-4, 9-12, and 17-20. Tx continued until PD or unacceptable toxicity. Thromboprophylaxis with low-dose aspirin, low-molecular weight heparin, or equivalent was required for all pts receiving POM and those at high risk of thromboembolic events. AEs were graded according to the National Cancer Institute Common Terminology Criteria for AEs (v 4.0). Tx was withheld and started at a lower dose in subsequent cycles for any grade 4 hematologic or ≥grade 3 non-hematologic AE. Dose reduction schemes were predefined. Supportive care in the form of bisphosphonates, antibiotics, hematopoietic growth factors, erythropoietin, and platelet or red blood cell transfusions was allowed. The primary endpoint was progression-free survival (PFS), and safety was a secondary endpoint.

Results: A total of 455 pts were enrolled; 449 pts were included in the safety study population: POM+LoDEX (n=300); HiDEX (n=149). POM+LoDEX significantly improved PFS and overall survival (OS) *vs.* HiDEX. Median follow-up was 4 months. The most common grade 3-4 AEs (POM+LoDEX *vs.* HiDEX) were neutropenia (42% *vs.* 15%), anemia (27% *vs.* 29%), infections (24% *vs.* 23%), and thrombocytopenia (21% *vs.* 24%). With thromboprophylaxis, the incidence of any-grade venous thromboembolism was low (3% *vs.* 2%). Grade 3-4 febrile neutropenia occurred in 7% and 0% of pts, respectively. Any-grade peripheral neuropathy (PN) occurred in 12% and 11%, respectively (new onset: 7% and 7%). Grade 3-4 PN occurred in 1% of pts in each arm. AEs were primarily managed by dose modification and/or supportive care (Table 1). AEs of interest necessitating POM or HiDEX dose reduction included neutropenia (8%; 0%), thrombocytopenia (6%; 0%), anemia (0% for both), infection (1%; 4%), and febrile neutropenia (1%; 0%). Discontinuation due to AEs was infrequent: 7% *vs.* 6% (POM+LoDEX *vs.* HiDEX, respectively). Tx-emergent AEs that led to discontinuation of POM included infections (2%), renal failure (1%), and thrombocytopenia (0.7%). AEs causing discontinuation of DEX in either arm included infection (2%), renal failure (0.9%), and thrombocytopenia (0.4%). Updated data will be presented at the meeting.

Table 1.

	POM + LoDEX (n = 300)	HiDEX (n = 149)
Dose management		
Median average dose, mg (range)	POM: 4.0 (2.6-4.0) LoDEX: 40 (8-40)	40 (20-40)
≥ 1 dose reduction (%)	POM: 24 LoDEX: 17	26
Dose reduction for neutropenia (%)	POM: 8 LoDEX: 0	0
Dose reduction for febrile neutropenia (%)	POM: 1 LoDEX: 0.3	0
Median time to first dose reduction, mo (range)	POM: 1.0 (0.3-7.6) LoDEX: 1.9 (0.3-10.3)	1.1 (0.9-10.2)
Supportive care (%)		
Granulocyte colony-stimulating factor	38	9
Red blood cell transfusion	43	48
Platelet transfusion	17	19
Antibiotics	72	67

Summary and Conclusions: In this study, POM+LoDEX improved PFS and OS with manageable and acceptable tolerability in advanced RRMM. The majority of pts did not have a dose reduction and there were few discontinuations due to AE. POM+LoDEX should be considered a new Tx option for these pts.

Multiple myeloma - Translational and clinical studies 3

P789

VTD CONSOLIDATION, WITHOUT BISPHOSPHONATES, REDUCES BONE RESORPTION AND IS ASSOCIATED WITH A VERY LOW INCIDENCE OF SKELETAL-RELATED EVENTS IN PATIENTS WITH MULTIPLE MYELOMA POST-ASCT

E Terpos[1,*], D Christoulas[1], E Kastritis[1], M Roussou[1], M Migkou[1], E Eleutherakis-Papaiakovou[1], M Gavriatopoulou[1], M Gkotzamanidou[1], N Kanellias[1], E Manios[1], C Papadimitriou[1], M Dimopoulos[1]
[1]Department of Clinical Therapeutics, University of Athens School of Medicine, Athens, Greece

Background: Bortezomib monotherapy is associated with increased osteoblastic activity and reduced osteoclast function in relapsed/refractory myeloma (MM). The co-administration of zoledronic acid in all reported studies to-date may suggest a synergistic stimulation on bone turnover by the two agents but has not allowed the independent evaluation of bortezomib on bone metabolism.
Aims: The prospective evaluation of the combination of bortezomib, thalidomide and dexamethasone (VTD) consolidation on bone metabolism of MM patients who underwent high-dose melphalan followed by ASCT in the absence of bisphosphonates (BPs).
Methods: MM patients in first remission post-ASCT were included. Patients did not receive any BP during or post-ASCT as well as throughout the period of VTD consolidation. VTD started on day 100 post-ASCT: V was administered at a dose of 1.0 mg/m^2 on days1,4,8,11; T was given at a dose of 100 mg/day, po, on days 1-21 and D at a dose of 40 mg/day on days 1–4 of a 21-day cycle. Patients received 4 cycles of VTD (first block), were followed without treatment for 100 days and then received another 4 cycles of VTD (2nd block). Patients were assessed for skeletal-related events (SREs) throughout the period of the study (12 months). The following bone markers were measured before and after each block of VTD (4 measurements for each patient): i) osteoclast regulators [sRANKL and osteoprotegerin (OPG)], ii) osteoblast inhibitor dickkopf-1 (Dkk-1), iii) bone resorption markers (CTX and TRACP-5b) and iv) bone formation markers [bone-specific alkaline phosphatase (bALP) and osteocalcin (OC)].
Results: Forty-two consecutive patients were treated: 36 completed both VTD blocks while six patients completed only the first block (one due to PD and five due to toxicity). Just before VTD administration, 16 patients were in CR (9 in sCR), 16 in vgPR and 10 in PR. Although most of these patients were rated as vgPR or better, they had increased serum levels of sRANKL (P=0.037), Dkk-1 (P=0.001), CTX (P=0.002), TRACP-5b (P<0.001), compared to 18 healthy controls of similar age and gender, indicating sustained osteoclast activity despite minimal tumor load. Levels of Dkk-1 and sRANKL/OPG ratio positively correlated with bone resorption markers (P<0.01). The first block of VTD resulted in a significant reduction of sRANKL (P=0.001), sRANKL/OPG ratio (P=0.02), CTX (P=0.05), but also of bALP (P=0.002) and OC (P=0.001), while Dkk-1 showed no alterations. After the first block of VTD, 33.3% of patients improved their status of response; however alterations of the studied molecules were irrespective of further response or not improvement. Before the administration of the 2nd block of VTD, CTX was reduced compared to values after the first block of VTD (P=0.015) and was further reduced after the completion of the study (P=0.01). Dkk-1, OC and sRANKL/OPG ratio had no further alterations, while bALP was increased before (P=0.012) and reduced after the 2nd block of VTD (P=0.05), but remained stable compared to pre-VTD values. Overall, CTX and OC serum levels were reduced after the two blocks of VTD and 20/42 (47.6%) patients improved their status of response. During the study period, only one patient with PD developed a SRE (*i.e.* radiation to bone). The median follow-up after ASCT was 48 months (13-73 months) and 24 of 42 patients have progressed. The median TTP after ASCT was 34 months (CI 95% 27.7-40.2). The median time to next treatment was 40 months (CI 95% 25.7-54.2).
Summary and Conclusions: VTD consolidation post-ASCT reduces bone resorption and is associated with a very low incidence of SREs despite the absence of BPs. However, bortezomib was not able to produce a significant anabolic effect on the bones when combined with TD even in these patients with low myeloma burden.

P790

IMPACT OF RENAL IMPAIRMENT ON THE EFFICACY AND SAFETY OF MELPHALAN-PREDNISONE-LENALIDOMIDE (LEN) INDUCTION FOLLOWED BY LEN MAINTENANCE IN NEWLY DIAGNOSED MULTIPLE MYELOMA: MM-015 POST-HOC ANALYSIS

M Cavo[1,*], M Dimopoulos[2], A Palumbo[3], K Weisel[4], M Delforge[5], J Bladé[6], M Petrucci[7], M Kropff[8], R Hajek[9], C Jacques[10], Z Yu[10], L Herbein[10], L Grote[10], J Catalano[11]

Turin, Turin, Italy, [4]Hematology & Oncology, Department of Medicine, University Hospital Tuebingen, Tuebingen, Germany, [5]University Hospitals Leuven, Leuven, Belgium, [6]Hospital Clínic de Barcelona, Barcelona, Spain, [7]Department of Cellular Biotechnology and Hematology, Sapienza University of Rome, Rome, Italy, [8]University of Muenster, Muenster, Germany, [9]School of Medicine, University of Ostrava, Institute of Clinical Hematology, University Hospital Ostrava, Ostrava, Czech Republic, [10]Celgene Corporation, Summit, NJ, United States, [11]Frankston Hospital and Department of Clinical Haematology, Monash University, Melbourne, Australia

Background: MM-015 is a phase 3 pivotal trial in transplant-ineligible patients with newly diagnosed multiple myeloma (NDMM), which found that induction with melphalan-prednisone-LEN followed by LEN maintenance (MPR-R) significantly prolonged progression-free survival (PFS; 31 mos) compared with MPR (14 mos) or MP (13 mos) (P<0.001 for both comparisons).
Aims: In this analysis, we retrospectively compare the efficacy and safety of MPR-R, MPR, and MP in the subset of MM-015 patients with moderate renal impairment (RI; defined as creatinine clearance [CrCl] <60 mL/min).
Methods: Treatment regimens have been presented previously (Palumbo A, *et al.* N Engl J Med. 2012;366:1759-69). NDMM patients were randomized to MPR-R (MPR induction followed by LEN maintenance [10 mg, D1–21/28-day cycle] until disease progression or unacceptable adverse events [AEs], or MPR or MP without maintenance therapy. CrCl was estimated using the Cockcroft-Gault formula and, for this analysis, patients were divided into two groups: CrCl <60 mL/min and CrCl ≥60 mL/min. Patients with severe RI (serum creatinine >2.5 mg/dL [>221 µmol/L]) were excluded from the trial. Dose adjustments were not recommended for patients with RI.
Results: CrCl <60 mL/min was observed in 51% of MPR-R patients, 45% of MPR patients, and 49% of MP patients. Among patients with CrCl <60 mL/min, median PFS was significantly higher with MPR-R (26 mos [95% confidence interval (CI): 14–48]) than MPR (13 mos [95% CI: 12–15]) or MP (14 mos [95% CI: 12–16]; P<0.001 for both). CrCl <60 mL/min was not a significant prognostic factor for PFS in a Cox proportional model (P=0.69). The most common grade 4 AEs were hematologic, occurring predominantly during induction. The proportion of patients with moderate RI who died during the study was similar across treatment groups: 10% (MPR-R), 7% (MPR), and 8% (MP) (Table 1); ≤1% of deaths in the RI population were associated with RI or disease progression. Updated data will be presented at the meeting.

Table 1. Safety outcomes according to baseline renal function.

	MPR-R		MPR		MP	
CrCl, mL/min	**≥ 60 (n = 71)**	**< 60 (n = 77)**	**≥ 60 (n = 82)**	**< 60 (n = 69)**	**≥ 60 (n = 77)**	**< 60 (n = 75)**
Median CrCl, mL/min (IQR)	84 (70–95)	47 (38–55)	76 (68–85)	46 (37–54)	79 (68–92)	47 (34–55)
Gr 4 hematologic AEs during induction, %						
Neutropenia	32	35	27	38	3	12
Thrombocytopenia	7	16	6	20	1	7
Anemia	1	4	1	4	1	1
Leukopenia	4	4	2	9	1	1
Febrile neutropenia	0	3	0	3	0	0
Gr 3–4 non-hematologic AEs occurring in ≥ 5% of patients during induction, %						
Pneumonia	1	1	1	9	5	1
Fatigue	1	9	0	4	0	5
Asthenia	0	4	1	6	1	0
Hypokalemia	3	4	2	6	0	1
Bone pain	1	4	4	4	5	3
Rash	4	5	2	9	3	1
Patients who died during the study, %	1	10	0	7	1	8

IQR, interquartile range.

Summary and Conclusions: In patients with moderate RI, PFS was significantly improved with continuous LEN treatment with MPR-R compared with MPR or MP, and with an acceptable safety profile, which is consistent with the overall trial results. However, CrCl and AEs should be closely monitored in this patient population.

P791

TREATMENT WITH BORTEZOMIB-BASED REGIMENS IMPROVES OVERALL RESPONSE AND PREDICTS FOR SURVIVAL IN PATIENTS WITH PRIMARY OR SECONDARY PLASMA CELL LEUKEMIA: ANALYSIS OF THE GREEK MYELOMA STUDY GROUP

E Katodritou[1,*], E Terpos[2], C Kelaidi[3], M Kotsopoulou[4], D Triandafyllopoulou[5], S Delimpasi[6], M Kyrtsonis[7], E Rissaki[7], A Symeonidis[8], V Lambropoulou[9], N Giannakoulas[10], A Stefanoudaki[11], F Kalala[7], N Spyridis[1], E Verrou[1], V Gastari[1], C Hadjiaggelidou[1], E Giannopoulou[1], K Zervas[1], M Dimopoulos[2]

Background: Plasma cell leukemia (PCL) is a rare and aggressive plasma cell disorder. The reported median survival of both primary (pPCL) and secondary (sPCL), before the introduction of novel agents, was about 8 and 2 months, respectively. Bortezomib-based regimens (BBR) are highly effective for the treatment of Myeloma. However, there is limited information about their efficacy and safety in PCL.
Aims: To explore the efficacy and safety of BBR in PCL treatment and investigate possible prognostic factors for survival.
Methods: We retrospectively collected data of pPCL and sPCL patients treated and followed in 9 centers of the Greek Myeloma Study Group between 2000 and 2013.
Results: We evaluated 42 consecutive PCL patients (pPCL:25/sPCL:17) out of 2089 myeloma patients treated at the same period in the 9 centers. Their characteristics were: M/F: 29/13, median age: 61 years (range 41-85 years), ISS1:4, ISS2: 10 ISS3: 28, IgG: 23, IgA:3, light chain:13, non-secretory: 3. At PCL diagnosis, median values (range) of laboratory characteristics were as follows: Hb 9.3 g/dL (6-11.7 g/dL), WBC 9.2×10^9/L ($2.9\text{-}90.1\times10^9$/L), ANC 3.1×10^9/L ($1\text{-}14\times10^9$/L), PLTs 103×10^9/L ($6\text{-}26\times10^9$/L), β2M 7.4 mg/L (3.6-27 mg/L), LDH 243 U/L (115-5205 U/L), serum creatinine 1.3 mg/dL (0.5-10.5 mg/dL), serum albumin 3.3 g/dL (1.9-5.3 g/dL), serum Ca 9.3 mg/dL (7.8-13.8 mg/dL). Serum Ca, PLTs and ANC were significantly higher in pPCL (P<0.05); LDH was higher in sPCL (P<0.05); age and PS did not differ between pPCL and sPCL (P>0.05). Immunophenotype was available in 32 patients; CD56 was negative in 75%. FISH data were available in 25 patients; 64% had high risk cytogenetics. Seventeen patients were primary refractory, 24 patients responded to treatment and 1 patient had stable disease. Seventeen patients progressed after initial response; 16 patients received treatment for progression (10: novel agents, 6: conventional therapy). Thirty-four patients died and 8 are still alive (7 without progression and one with PD). Treatment with BBR was administered in 29/42 patients; 6/25 patients with pPCL underwent ASCT. In patients treated with BBR, grade 3/4 toxicity was observed in 34%, 31%, 31%, 17%, 3.4%, 7% and 31% of patients for neutropenia, anemia, thrombocytopenia, GI complications, renal toxicity, neurotoxicity and infections, respectively. Objective response (≥PR) was achieved in 57% of patients (CR/vgPR:10%/12%). Objective response was 80% in pPCL and 23.6% in sPCL (P=0.001). Median time to response was 2 months(1-8). With a median follow-up of 51 months (2-80), time to progression (TTP) and overall survival (OS) from PCL diagnosis for pPCL and sPCL were 13 *vs.* 5 months (P=0.01) and 14 *vs.* 2 (P<0.001), respectively. The median TTP for patients received BBR *vs.* those received conventional treatment did not significantly differ, whereas OS from PCL diagnosis was statistically different (13 *vs.* 2 months, respectively, P=0.007). Median OS from PCL diagnosis of patients with pPCL and sPCL treated with BBR was 18 and 7 months, respectively. In the multivariate analysis PLTs, treatment with BBR and response type predicted for OS from PCL diagnosis (P<0.05).
Summary and Conclusions: Treatment of PCL with BBR is effective, induces high response rates and prolongs OS. The median OS of pPCL and sPCL patients of this study is considered as one of the highest reported in the literature. BBR, type of response and PLT counts were the most powerful prognostic factors for survival. Grade 3/4 toxicity with BBR was manageable.

P792

EUROPEAN POST-APPROVAL SAFETY STUDY (PASS) OF RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED DATA ON SAFETY AND SPM INCIDENCE IN PATIENTS TREATED WITH LENALIDOMIDE, THALIDOMIDE, AND BORTEZOMIB

M Cavo[1,*], X Leleu[2], N Andersen[3], G Vanstraelen[4], F Erdkamp[5], M Echeveste[6], N Domingues[7], M Hlebašková[8], H Sati[9], P Bacon[10], B Rosettani[10], E Kueenburg[10], N Minton[10], I Blau[11]
[1]Bologna University School of Medicine, Bologna, Italy, [2]Service des Maladies du Sang, Hôpital Huriez, Lille, France, [3]Department of Haematology, Aarhus University Hospital, Aarhus, Denmark, [4]Centre Hospitalier Peltzer - La Tourelle, Verviers, Belgium, [5]Internal Medicine, Orbis Medisch Centrum, Sittard-Geleen, Netherlands, [6]Servicio de Hematología, Hospital Universitario Donostia, Donostia, Spain, [7]Instituto Português de Oncologia Francisco Gentil, Porto, Portugal, [8]Department of Hematology and Oncohematology, Luis Pasteur University Hospital, Kosice, Slovakia, [9]Singleton Hospital, Swansea, United Kingdom, [10]Celgene Corporation, Summit, NJ, United States, [11]Department of Internal Medicine III, Charité Campus Benjamin Franklin, Berlin, Germany

Background: EU PASS is an observational non-interventional study designed

to investigate the safety of lenalidomide (LEN) and other agents in the treatment of RRMM in a real-world setting.
Aims: To assess the incidence of adverse events (AEs) of special interest, including neutropenia, thrombocytopenia, venous thromboembolism (VTE), peripheral neuropathy (PN), opportunistic infections, and second primary malignancies (SPMs) in RRMM patients (pts) treated with LEN and other antimyeloma therapies according to current clinical practice.
Methods: RRMM pts who had received ≥1 prior therapy were enrolled at investigator's discretion into a LEN cohort (LEN+dexamethasone, the approved combination for the treatment of RRMM) or a background cohort (all other treatments, including novel agents). Thromboprophylaxis was per local standard practice. AEs were graded according to NCI-CTCAE (v3). SPMs were defined using MedDRA terms under Neoplasms SOC. Assessments for SPMs were to be conducted up to 36 mos after treatment discontinuation.
Results: As of November 2012,3,285 pts across 268 institutions in 17 European countries were enrolled. Of those, 66% received LEN (n=2,164), 26% received bortezomib (BORT; n=842), 3% received thalidomide (THAL; n=114), 5% received other therapies (116) or had missing data at the time of the analysis. In total, 129 pts from the background cohort initiated LEN during the course of follow-up as per physician's decision. Baseline characteristics were similar across the cohorts. Median age was 70 yrs (range 25–95) and 54% were males. Most pts (65%) had good performance status (ECOG score 0–1); however, 17.5% had an ECOG score of 2–4. Median number of prior therapies was 2 (range 0–6); 24% had 1 prior treatment, 54% had 2 prior therapies, and 21% had ≥3 prior therapies. The median duration on study treatment was 6.4 mos (range 0–39.6) for LEN after prior THAL, 6.1 mos (0–42.5) for LEN after BORT, 3.7 mos (0–32.5) for BORT after THAL, and 3.7 mos (0–14.9) for BORT after BORT. At a median follow-up of 6.2 mos (range 0–42.5), 25%, 2%, and 15% of pts in LEN, BORT, and THAL cohorts, respectively, had a treatment duration of >12 mos. Overall, 47% of pts (n=1,534) had grade 3–4 AEs. Grade 3–4 neutropenia occurred in 16%, 4%, and 5% of pts in the LEN, BORT, and THAL cohorts, respectively, and grade 3–4 thrombocytopenia in 9%, 8%, and 4%. The overall incidence of PN was 33% (6% grade 3–4) in the BORT cohort, 14% (2% grade 3–4) in the LEN, and 30% (3% grade 3–4) in the THAL cohort. Grade 3–4 VTE developed in 3%, 1%, and 2% of pts in the LEN, BORT, and THAL cohorts, respectively. The overall incidence of SPMs was 1% (Table 1). Incidence rate for invasive SPMs was 1.58/100 pt-yrs (py), of which 1.11/100 py was for solid SPMs and 0.47/100 py was for haematologic SPMs; results were similar for all treatments. Overall treatment discontinuation rate was 79% LEN, 88% BORT, and 90% THAL, with a similar discontinuation rate due to AEs in each cohort. Incidence of death from any cause was similar across all treatments (6% LEN, 4% BORT, and 4% THAL).

Table 1. SPM summary.

SPM characterization	LEN (n = 2,164)	THAL (n = 114)	BORT (n = 842)	Overall (N = 3,236)
All invasive SPMs, n (%)	22 (1)	1 (1)	7 (1)	30 (1)
Incidence per 100 pt-yrs (95% CI)	1.47 (0.97–2.23)	1.67 (0.23–11.83)	2.4 (1.15–5.04)	1.58 (1.11–2.26)
Haematologic tumours, n (%)	7 (0.3)	0	2 (0.2)	9 (0.3)
Incidence per 100 pt yrs (95% CI)	0.46 (0.22–0.97)	–	0.68 (0.17–2.73)	0.47 (0.25–0.91)
Solid tumours, n (%)	15 (0.7)	1 (1)	5 (0.6)	21 (0.6)
Incidence per 100 pt-yrs (95% CI)	1 (0.6–1.65)	1.67 (0.23–11.83)	1.72 (0.71–4.13)	1.11 (0.72–1.7)

CI, confidence interval.

Summary and Conclusions: Results of this ongoing, non-interventional, observational study in RRMM show that AEs were similar across cohorts except for higher rates of neutropenia and lower rates of PN with LEN compared with THAL or BORT. Incidence of significant VTE was lower than observed in previous series. The incidence of SPM across all cohorts was 1%. Despite the current short, overall follow-up, treatment duration with LEN, THAL, or BORT appears unaffected by prior treatment received.

P793

HEAVY LIGHT CHAIN PAIR SUPPRESSION BUT NOT SUPPRESSION OF THE NON-INVOLVED ISOTYPES CORRELATES WITH POOR PROGNOSIS IN IGG AND IGA MULTIPLE MYELOMA

H Ludwig[1,*], D Milosavljevic[2], N Zojer[1], P Young[3], S Harding[3]
[1]Department of Internal Medicine I, Center for Oncology and Hematology, [2]Central Laboratory, Wilhelminenhospital, Vienna, Austria, [3]The BindingSite Ltd., Birmingham, United Kingdom

Background: The heavy light chain (HLC) assay allows measurement of both the involved and non-involved pair of the affected isotype, *i.e.* in IgA kappa myeloma the precise quantification of IgA kappa and of IgA lambda. This information allows for a) the calculation of a ratio between the involved and non-involved pair of the affected isotype (HLC ratio) in analogy to the FLC ratio, and b) the evaluation of a possible suppression of the non-involved pair of the affected isotype (HLC pair suppression), a phenomenon which was not assessable before.
Aims: Here, we studied whether HLC pair suppression and suppression of the non-involved isotype in patients with IgA and IgG myeloma correlated with survival. In addition, we evaluated possible associations of other risk factors with survival.
Methods: 156 patients with multiple myeloma, measurable disease, and started on first line chemotherapy were enrolled. Median age: 66 (32-94) years, male/female: 82/74, ISS stage I: 59, II: 63, and III: 34. Patients received different treatment regimens and were followed for a median of 46.1 months. Age, gender, ISS stage, LDH, Hb, creatinine, albumin, ß2-microglobulin, calcium, response to therapy, FLCratio, HLCratio, and HLC pair suppression were studied and correlated with survival. Kaplan-Meier survival curves were compared using the log rank test; univariate and multivariate analysis were performed using Cox proportional regression analysis (SPSS, version 18).
Results: Severe HLC pair suppression (>50% below lower level of normal) correlated significantly with OS (median: 31.0 *vs.* 60.5 months, P<0.040) (Figure 1A) while no significant correlation was noted between suppression of the non-involved isotype and survival (P=0.233). HLC pair suppression was not correlated with suppression of the non-involved isotypes (non-involved IgA and IgM in patients with IgG M-component: r=0.307, and r=0.071, respectively; non-involved IgG and IgM in patients with IgA MM: r=0.224 und IgM r=0.247). As previously reported, survival was significantly lower (39.6 months) in patients with highly abnormal HLC ratio (<0.022 or >45) compared to those with less abnormal HLC ratio (0.022-45)(71.9 months, P<0.04). Other risk factors found to be independently associated with survival were LDH (P<0.00001), creatinine (P<0.012), ß2-microglobulin (P<0.021), response ³VGPR (P<0.006), and the combination of stage and HLC pair suppression (P<0.002). A four tiered model combining stage and HLC pair suppression showed significantly different survival curves: A) stage I+II with <50% HLC pair suppression; median: 72 months, B) Stage I+II with >50% HLC pair suppression, median: 62 months C) stage III with <50% HLC pair suppression, median: 62 months D) Stage III with >50% HLC pair suppression, median: 28 months, P<0.0001 (Figure1B).

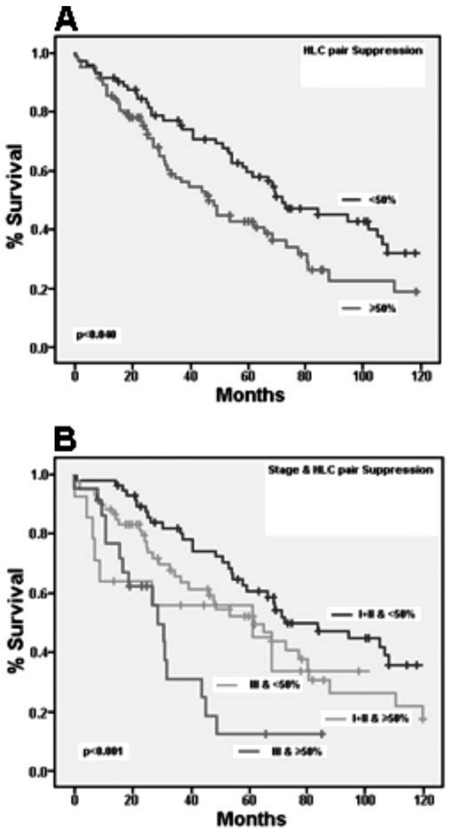

Figure 1.

Summary and Conclusions: HLC pair suppression is a significant risk factor for survival, while for suppression of the non-involved isotype no relationship with survival was noted. These data may be interpreted as an attempt of the host's defence system to control the malignant clone with specific suppression of the involved isotype. This constriction seems to be heavy chain but not light

chain specific. In addition, a prognostic model employing both HLC pair suppression and stage has been constructed which revealed significant distinction between individual risk groups.

P794

CIRCULATING SOLUBLE RECEPTOR ACTIVATOR OF NUCLEAR FACTOR-KAPPA B LIGAND (SRANKL) AND C-C MOTIF LIGAND-3 (CCL-3) LEVELS CORRELATE WITH SURVIVAL IN PATIENTS WITH WALDENSTROM'S MACROGLOBULINEMIA

E Terpos[1,*], E Kastritis[1], E Eleutherakis-Papaiakovou[1], A Tasidou[2], D Christoulas[1], M Gavriatopoulou[1], Roussou[1], T Papadaki[2], M Dimopoulos
[1]Department of Clinical Therapeutics, University of Athens School of Medicine, [2]Department of Hematopathology, Evangelismos General Hospital, Athens, Greece

Background: Waldenstrom's macroglobulinemia (WM) is a rare lymphoplasmacytoid lymphoma characterized by the production of IgM monoclonal immunoglobulin. Interplay between the malignant cells with the microenvironment is crucial for the biology of the disease. CCL-3 is a chemo-attractant cytokine for macrophages and mast cells, while RANKL is a TNF superfamily member, which is mainly produced by activated T-lymphocytes. We have previously shown that WM cells produce CCL-3 (Terpos *et al.*, Clin Lymphoma Myeloma Leuk 2011;11:115-7), while serum sRANKL was elevated in WM patients (Terpos *et al.*, Br J Haematol 2006;133:301-4). However, there is no information for the prognostic value of these molecules in WM.
Aims: To evaluate the role of RANKL and CCL-3 in survival of WM patients.
Methods: We measured the circulating levels of sRANKL, its decoy receptor osteoprotegerin (OPG) and CCL-3 in the serum of 55 patients with symptomatic WM before the administration of any kind of therapy, in 5 patients with asymptomatic WM (AWM), in 12 with IgM-MGUS and in 30 healthy subjects of similar age and gender who served as controls. Circulating sRANKL, OPG and CCL-3 were measured using an ELISA method (Biomedica, Vienna, Austria for sRANKL and OPG; R&D Systems, Minneapolis, MN, USA for CCL-3).
Results: The serum levels of sRANKL (median-range: 0.357 pmol/l, 0-1.524 pmol/l *vs.* 0.126 pmol/l, 0-0.152 pmol/l; P<0.001) and CCL-3 (64.8 pg/mL, 10.6-528 pg/mL *vs.* 13 pg/mL, 1.4-54 pg/mL; P<0.001) were markedly elevated in WM patients compared to controls. On the contrary, there was no difference regarding OPG levels between patients and controls. Circulating CCL-3 was also increased in WM patients compared to patients with IgM-MGUS (15.4 pg/mL, 0-54.7 pg/mL) and AWM (21.4 pg/mL, 13.4-65.9 pg/mL), while the sRANKL levels were elevated in IgM-MGUS and AWM patients compared to controls. In symptomatic WM patients, both CCL-3 and sRANKL circulating levels correlated with serum beta2-microglobulin (P=0.02 and P=0.031, respectively), while only CCL-3 positively correlated with MVD (P=0.041) and ISSWM stage (the values for low, intermediate and high-ISSWM were 28.3 pg/mL (1.4-188.6 pg/mL), 77 pg/mL (16.2-528 pg/mL) and 76.7 pg/mL (20.8-177.6 pg/mL), respectively; P=0.017). Regarding immunochemistry in trephine biopsies, in all WM cases, the whole number of the neoplastic cells, including CD20(+)/CD138(-)/MUM-1(-) small B-lymphocytes, plasmacytoid lymphocytes and rare immunoblasts as well as CD20(-)/CD138(+)/MUM-1(+) plasma cells revealed strong cytoplasmic positivity for CCL-3. The median follow-up of symptomatic WM patients was 35 months. The median overall survival (OS) has not been reached yet, while the probability for 3-year OS was 76%. The median progression-free survival (PFS) was 57 months and the 3-year probability of PFS was 56%. High circulating sRANKL values (above the median) predicted for shorter median OS (16 months *vs.* not reached, P=0.001; Figure 1) and had borderline significance for shorter PFS (0.086). High serum levels of CCL-3 (above the median value) predicted for shorter median PFS (27 months *vs.* not reached, P=0.048) and showed borderline association with shorter median OS (67 months *vs.* not reached, P=0.09).

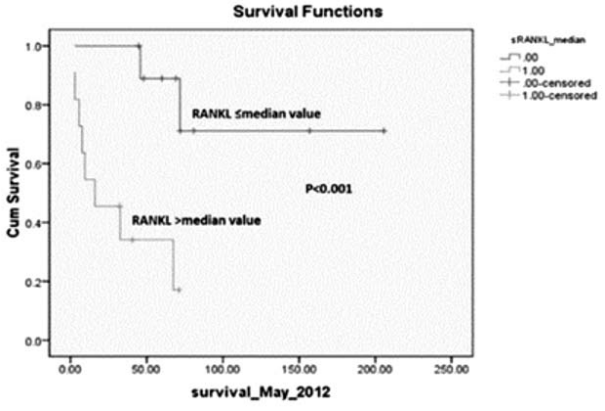

Figure 1.

Summary and Conclusions: We conclude that WM cells produce CCL-3 and enhance the production of RANKL in the bone microenvironment. The correlation of circulating sRANKL and CCL-3 with survival reveals the importance of these cytokines in disease biology and highlights the significance of the interactions between WM and stromal cells for the development of the disease. These data also give the rationale for the use of anti-RANKL and anti-CCL3 drugs in patients with WM.

P795

RESULTS OF THE DUTCH COMMUNITY BASED TRIAL "VALEO" WITH BORTEZOMIB TREATMENT IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS

H Lokhorst[1,*], P Wijermans[2], H Berenschot[3], R Leys[4], R Raymakers[1], S Croockewit[5], K van der Hem[6], M Lahaye[7], R Milek[8]
[1]Hematology, University Medical Centre, Utrecht, [2]Hematology, Haga Hospital, Den Haag, [3]Hematology, Albert Schweitzer Hospital, Dordrecht, [4]Hematology, Maasstad Hospital, Den Haag, [5]Hematology, Univeristiy Medical Centre St. Radboud, Nijmegen, [6]Hematology, Zaans Medical Centre, Zaandam, [7]Statistics, [8]Medical Affairs, Janssen, Pharmaceutical Companies of Johnson&Johnson, Tilburg, Netherlands

Background: Bortezomib (btz) became available in the European Union in 2004. Data available from the use in daily clinical practice is limited.
Aims: In the phase-IV-trial VALEO (clinical trials.gov identifier NCT00440765) the efficacy and safety of btz alone or in combination with other agents was examined in real-life daily practice in 342 relapsed/refractory multiple myeloma (MM) patients (pts) in the Netherlands.
Methods: Informed consent was obtained. Subjects were enrolled in one of two arms: arm A (2nd line, who received not more than 1 previous line of therapy) or arm B (≥3rd line, who received at least 2 lines of therapy). Btz was started in a dose of 1.3 mg/m^2 intravenously on day1,4, 8 and 11. Treatment emergent Adverse Events (TEAEs) were assessed from start of btz until 30 days after treatment.
Results: Here we report the intent to treat (ITT) results prior to database lock (at conference final data will be presented). Number of pts in arm A: n=106; in arm B: n=233. Three pts were treated in newly diagnosed MM (protocol violation, however included in the ITT analysis). Median age A: 66 years (yrs), B: 68 yrs. Male A: 57%, B: 56%. MM type IgG/IgA/non-secretory/other A: 66%/16%/11%/7%, B: 58%/27%/6%/10%. Salmon&Durie stage IIIIA/IIIB A: 66%/25% and B: 70%/17%. Median Karnofsky Performance Status A: 90%, B: 80%. High risk (t(4;14), t(14;16), t(14,20), del17p13, gain 1q, del1p, plasma cell leukemia) A: 28%, B: 31%. Standard risk (t(6;14), t(11;14), gain5q, hyperdiploid, del13 without t(4;14) and/or del17p) A: 81%, B: 79%. K13 A 9% and B: 12%. Median duration from diagnosis of MM was A: 1.8 yrs, B: 3.8 yrs. Median number of cycles administered A:5, B: 4. Best ≥partial response (PR) was A: 61%, B: 46%; ≥very good PR A: 19%, B: 16%; (near) complete response A: 12%, B: 11%. Pts with relapse or progression A: 89%, B: 89% (others censored). Median time to progression was A: 229 days, 95% confidence interval (CI) 189-277, B: 191 days 95% CI 166-214. Pts progression or dying A: 93%, B: 96% (others censored). Median progression free survival time was A: 215 days, 95% CI 184-265; B: 171 days 95% CI 153-206 days (Figure 1). Btz dose was adjusted in 3% of treatment emergent adverse events (TEAEs) (both in group A and B), temporarily discontinued in A: 9%, B: 10% of TEAEs, btz was stopped in A 3%, B: 5% of TEAEs. Frequently reported TEAEs (≥20%) were: thrombocytopenia, fatigue, neuropathy, anaemia, nausea, diarrhoea, constipation and malaise. TEAEs grade 1 were A: 55%, B: 47%; grade 2 were A: 29%, B: 32%; grade ≥3 were A: 16%, B: 20%. 51% of pts experienced a serious TEAE of which 31 pts died (7 causally related: 4 sepsis, 2 pulmonary, 1 cardiac).

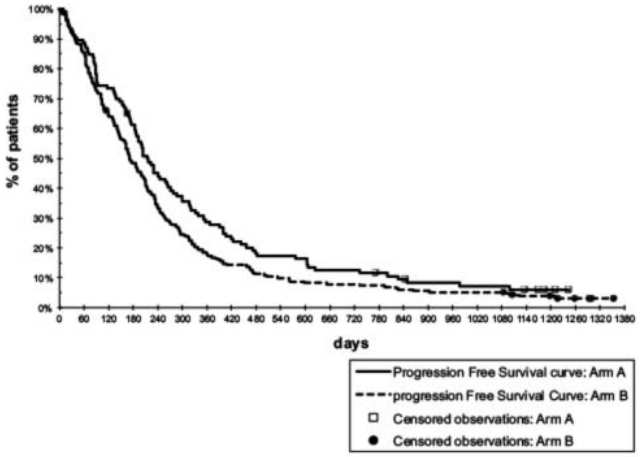

Figure 1. Progression-free survival time (days).

Summary and Conclusions: Treatment with btz in a community-based setting in the Netherlands results in an expected efficacy with 61% PR or higher in second line of treatment and 46% or higher in third line of treatment. Btz was generally well tolerated with acceptable and manageable TEAEs in this type of pts.

P796

ABNORMAL MEDULLARY LESIONS IN APPENDICULAR SKELETONS DETECTED BY WHOLE BODY LOW-DOSE MULTIDETECTOR CT IS ASSOCIATED WITH HIGHER TUMOR BURDEN AND POORER PROGNOSIS IN PATIENTS WITH MYELOMA

K Matsue[1,*], Y Nishida[1], T Ugai[1], H Sugihara[1], M Yamakura[1], M Takeuchi[1], K Tsuda[1]
[1]Hematology/Oncology, Kameda General Hospital, Kamogawa-shi, Japan

Background: Imaging is playing an increasing role in the diagnosis, staging and treatment response monitoring of patients with multiple myeloma (MM). Whole body Low-dose multidetector CT (WBLD MD-CT) can provide information on the degree of myeloma cell infiltration, especially in the appendicular skeleton (AS).
Aims: This study was performed to determine the incidence and prognostic implications of abnormal medullary lesions in the appendicular skeleton detected by WBLD MD-CT in patients with monoclonal gammopathy of undetermined significance (MGUS), and asymptomatic and symptomatic MM
Methods: Between January 2008 and January 2013, WBLD MD-CT was performed in 89 patients with MM and MGUS as an initial evaluation of lytic bone lesion and medullary and extra-medullary MM lesions. WBLD MD-CT was performed in a non-enhanced manner. Medullary CT density of the humerus and femur were measured using circular regions of interest (ROI), and the results were documented in Hounsfield Units (HU). The highest HU value was selected as representative for each bone, and the mean was calculated. The relationships between abnormal medullary lesions and clinical variables and outcome were studied. The prognostic implications of mean CT value in patients with symptomatic MM were also examined.
Results: Eighty-nine consecutive patients (44 male and 45 female, median age 71yr, symptomatic MM 73, MGUS/asymptomatic 16) were analyzed. Among patients with symptomatic MM, IgG, IgA, light chain only and non-secretary subtypes were 36, 18, 18 and1, respectively. Patients with staging1, 2 and 3 were7, 8 and 59 in Durie—Salmon staging system (DS), and were11, 26 and 37 in International Staging System (ISS), respectively. Medullary abnormalities were found in 61 of 73 patients (83.6%) and 4 in 16 patients (25%) in patients with symptomatic MM and patients with asymptomatic MM/MGUS, respectively. Patients with symptomatic MM had significantly higher mean HU than patients with MGUS/asymptomatic MM (-5.64 *vs.* -69.99, P<0.001). Patients with DS stage 3 showed significantly high HU values compared to those with DS stage 1 and 2 (-35.30 *vs.* 1.11, P<0.001) whereas the mean HU value was not significantly different between ISS 3 and 1 or 2 (P=0.186). Patients with mean HU value >0 had significantly shorter median OS (40.6 months *vs.* not reached, P=0.040) and tended to have shorter PFS (9.8 *vs.* 15.7 months, P=0.106) compared to those with mean HU value <0. In univariate analyses (sex, age□76 yo, high risk cytogenetics, DS stage3, ISS3, serum Cr□2.0, over 25% of abnormal medullary lesions in AS, and CT value of >0), Cr >=2.0 and CT value >0 HU were associated with poorer survival outcome. On multivariate analysis, serum Cr remained significant (P<0.01), and CT value >0 HU was marginally significant (P=0.059) on poor OS.
Summary and Conclusions: This study indicated that medullary abnormalities in the AS detected by WBLD MD-CT might be associated with high tumor burden of MM. In addition, its presence after treatmetn appeared to relate poor possible prognostic outcome.

P797

HIGH RISK CYTOGENETICS, ELEVATED LDH AND ISS-3 IDENTIFY A SUBGROUP OF MYELOMA PATIENTS WITH VERY POOR PROGNOSIS

E Kastritis[1,*], E Terpos[1], M Roussou[1], M Gavriatopoulou[1], M Iakovaki[1], D Kalapanida[1], N Kanellias[1], E Eleutherakis-Papaiakovou[1], D Gika[1], M Dimopoulos[1]
[1]Department of Clinical Therapeutics, University of Athens School of Medicine, Athens, Greece

Background: Several disease features have been associated with prognosis in multiple myeloma and are associated with a high-risk of progression and death. International Staging System (ISS) identifies 3 risk groups with significantly different outcome and specific cytogenetic abnormalities also may identify patients at high risk for progression or death due to myeloma. The combination of high risk ISS stage (ISS-3) and high risk cytogenetic abnormalities may improve prognostication in patients with MM. Moreau *et al.* (abstract 598, ASH 2012) proposed a prognostic score based on the presence of ISS-3, elevated LDH and high risk cytogenetics; this score identified patients at high risk for death due to myeloma within 2 years for initiation of therapy, in a cohort of intensively treated patients.
Aims: The aim of our analysis was to identify patients who are at high risk for early death in a population of unselected patients with MM and validate in an independent unselected cohort of patients the score proposed by Moreau *et al.*
Methods: We analyzed consecutive unselected patients with MM with available FISH studies for the presence of high risk cytogenetic abnormalities.
Results: 246 consecutive unselected patients, who started therapy after 1/1/2005, were included in the analysis; 95% of the patients received first line therapy with novel agents (thalidomide, lenalidomide, bortezomib). Median PFS is 26 months and median survival is 51 months, however, 5% of the patients died within the first 2 months from treatment initiation while 1- and 2-year mortality rate was 16% and 24% respectively. ISS-1, 2 & 3 disease was present in 22%, 38% and 40% respectively. High risk cytogenetics (del17p, t(4;14), t(14;16), add1q21 or non-hyperdiploid karyotype) were present in 45.5% of our patients. High risk cytogenetics were more common in patients with advanced ISS (30%, 45% and 56% for ISS1,2 & 3 respectively, P=0.008). Elevated LDH (≥300 IU/L, ULN 225 IU/L) was correlated with high risk cytogenetics (P=0.034) and ISS-3 disease (P=0.032). Shorter PFS was associated with ISS-3 (18 *vs* 33 months for ISS 1-2, P<0.001), high risk cytogenetics (20 *vs* 34 months for standard risk, P<0.001) and elevated LDH≥300 IU/L (13 *vs* 28 months for <300 IU/L, P=0.002). Shorter OS was also associated with ISS-3 (41 *vs* 70 months for ISS 1-2, P<0.001), high risk cytogenetics (45 *vs* >70 months for standard risk, P=0.007) and elevated LDH≥300 IU/L (28 *vs* 60 months for <300 IU/L, P=0.05). The combination of these 3 variables produced a scoring system consisting of 4 categories with 0-3 of the risk features. For patients with a score of 0 (all risk factors absent, 35% of the patients) the median PFS was 3.5 years and the OS was 67% at 5 years. For patients with a score of 1 (one of the risk factors present, 40% of the patients) the median PFS was 2 years and the median OS was 4 years. For patients with a score of 2 (two of the risk factors present, 21% of the patients) the median PFS was 1.5 years and the median OS was 3.3 years. Finally, for patients with all risk factors present (a score of 3), which included only 4% of the patients, the median PFS was 12 months and the median OS was just 2 years.
Summary and Conclusions: The use of a simple scoring system which is based on readily available parameters (ISS-3 and LDH≥300 IU/L) in combination with cytogenetics allows the identification of a small group of patients with very high-risk disease and a very dismal prognosis. Patients with all high risk features present should be encouraged to participate in clinical trials due to their poor prognosis with the currently available therapies

P798

BONE BIOMARKERS ARE USEFUL IN MONITORING MYELOMA BONE DISEASE AND AS EARLY PREDICTOR FOR RELAPSE DISEASE IN MULTIPLE MYELOMA

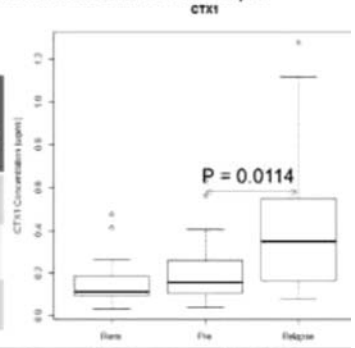
K Ting[1,2,*], A Hameed[1,2], J Brady[1], C Carke[2], M Justine[2], P Dowling[2], M Clynes[2], P O'Gorman[1,2]
[1]Haematology, Mater Misericordiae University Hospital, [2]National institute for Cellular Biotechnology, Dublin, Ireland

Background: Multiple myeloma is a plasma cell disorder and bone disease is a well-known devastating complication. The uncoupling effect of osteoblast and osteoclast activity is the major element in development of myeloma bone disease (MBD). It causes significant impact to the quality of life and morbidity in multiple myeloma. Imaging techniques are used as the current standard method for detection of bony lesions. They have limitations as they cannot provide a real-time assessment of bone turnover. Early detection of relapse disease is crucial to allow preventative therapeutic intervention could significantly impact on quality of life.
Aims: Bone biomarkers such as C-terminal telopeptide of type 1 collagen (CTX-1) and procollagen type 1 N-propeptide (P1NP) can be used as an early predictor marker for relapse cases with myeloma bone disease and to monitor the myeloma bone disease at diagnosis and remission.
Methods: CTX-1 and P1NP were measured by chemiluminescent immunoassay on fasting plasma samples from 115 patients including newly diagnosed multiple myeloma (n=27), remission (n=30), relapses (n=22) and control (n=27). These were measured at regular intervals over a 27 month study period. Relapse disease was identified by conventional biomarkers like paraprotein and serum free light chains, and confirmed by imaging and bone marrow biopsy. In a subset of patients with disease relapse, the Mann-Whitney test was used to compare bone markers pre-relapse and at relapse.
Results: CTX-1 levels were significantly higher in newly diagnosed multiple myeloma compared to remission and control groups (P<0.0001). In relapse group, CTX-1 rose significantly at the time of pre-relapse to relapse state (P=0.0007). A rise of ≥2.0 fold rise in the level of CTX-1 from remission to relapse disease was noted. The median time between the pre-relapse sample and relapse disease was 3 months (range 1-14 months). Most of them had new bone lesions at relapse. This proves that it has potential as an early predictor of disease relapse/progressive bone disease. A case showed CTX-1 was the only biochemical parameter to rise significantly on relapse as compared to the other conventional biomarkers (ie. paraprotein and serum free light chain) As for P1NP, the rise in P1NP from pre-relapse to relapse was not significant (P=0.0840) (Figure 1).

Duration to monitor CTX-1 from either Remission or Pre-relapse stage to Relapse stage is:

- Range = 1-14 months
- Median = 3 months

	Mann-Whitney Test (p value)	Student T-test (p value)
Remission vs Pre-Relapse	0.2313	0.1818
Remission vs Relapse	0.0007	0.0026
Pre-Relapse vs Relapse	0.0161	0.0114



CTX-1 level	Remission	Pre-relapse	Relapse	Fold rise
Mean (µg/L)	0.156786	0.22209091	0.424386	2.123839
SD (µg/L)	0.109635	0.16738732	0.315917	1.3702

Figure 1. CTX-1 levels in relapse category.

Summary and Conclusions: Osteoclast biomarker serum CTX-1 correlates accurately with the disease burden in newly diagnosed multiple myeloma patients as compared to the rest of the groups. It is a more sensitive early predictor of disease relapse/progressive disease than established biomarkers. It is a more robust marker than P1NP. The rise in P1NP goes against the theory that there is an uncoupling of bone turnover in myeloma bone disease and requires further study. CTX-1 is more cost effective and accessible than imaging and should be used routinely when monitoring bone disease activity in multiple myeloma patients, facilitating early intervention when relapse occurs.

Background: We are pioneering a high throughput flow cytometry to measure the chemical biology space of drugs used to treat Multiple Myeloma (MM) in patient samples in collaboration with PETHEMA.
Aims: To examine the *ex vivo* pharmacology of MM drugs against the malignant cell population in bone marrow samples from MM patients.
Methods: Bone-marrow samples from patients diagnosed with MM were sent to Vivia from 18 Spanish hospitals. Drugs were incubated in 8 concentrations for 48 hours using the intact sample without isolating leukocytes. Afterwards leukocytes were isolated and analyzed by our ExviTech© platform. Drug activity is measured as cell depletion, labeling blasts with monoclonal antibodies and AnnexinV-FITC. Standard dose response fitting generate efficacy (Emax) and potency (EC50) parameters for each drug listed in the Table 1. Inter-patient variability for each drug is measured as IPV=STDDEV*100/MEAN).
Results: The average pharmacological profiles of 19 different MM drugs evaluated in 10-106 samples are shown in Table 1. Drugs are separated into conventional (top lines) and novel (lower grey shaded lines) drugs. 2nd column shows the number of samples tested per drug. Dex and Pre have only 10-11 samples because their initial testing at 48 h was insufficient and were evaluated at 96 h incubation. Standard pharmacological parameters (Emax, columns 3-5) and potency (EC50, columns 6-8) are shown in terms of their mean, standard deviation and interpatient variability (IPV). Drugs are further grouped by mechanism of action (columns 9-10). Among conventional drugs, Bortezomib is the best depleting drug eliminating all cells (mean 2.3±5) with highest potency (lowest EC50 0.03 uM). All conventional drugs except corticoids (Dex, Pre) show maximum efficacy depleting all MM cells (mean-STDDEV). Dex is 390-fold more potent than Pre, albeit Pre is more used in MM. Cell cycle arrest drugs are ordered by their mean potency. Doxorubicin is the most potent though not often used. Vincristine is also potent with the largest interpatient variability, suggesting very sensitive patients could benefit at low doses with less neurotoxicity. Bendamustine is less potent with lowest interpatient variability suggesting a lesser therapeutic potential. All novel drugs (lower shaded lines) have maximal efficacy eliminating all MM cells (mean-STDDEV). The most potent new drugs by far are the epigenetic drugs Panobinostat and Vorinostat, Panobinostat being 48-fold more potent. Among the targeted therapies Tanespimycin has highest potency combined with high interpatient variability, and this approach could serve as companion diagnostic.

Table 1.

COMPOUND NAME	N	EFFICACY (EMAX %) MEAN	SD	IPV(%)	POTENCY (EC50 µM) MEAN	SD	IPV(%)	MOA
BORTEZOMIB	106	2.30	5.14	223.35	0.03	0.03	99.32	Proteas. Inhib.
DOXORUBICIN	35	4.67	12.78	273.76	0.93	0.85	91.24	Cell cycle arrest
VINCRISTIN	47	13.91	17.40	125.07	3.21	13.74	427.88	
MELPHALAN	44	14.95	23.33	156.03	14.07	15.43	109.66	
CYCLOPHOSPHAMIDE	59	10.93	19.43	177.69	54.00	55.87	103.46	
ETOPOSIDE	25	11.32	17.03	150.37	95.30	125.00	131.16	
BENDAMUSTINE	90	1.43	5.57	390.20	118.89	65.11	54.77	
DEXAMETHASONE-96h	11	37.40	16.10	43.05	0.04	0.04	97.50	Glucocorticoid
PREDNISOLONE-96h	10	34.26	22.00	64.21	15.65	47.21	301.66	
PANOBINOSTAT	49	5.64	11.46	203.26	0.05	0.06	119.96	Epigenetic
VORINOSTAT	51	6.30	9.92	157.42	2.38	2.19	92.17	
TANESPIMYCIN	39	7.34	12.07	164.41	12.47	24.28	194.70	Molecular Target
TEMSIROLIMUS	36	0.55	2.11	384.49	40.35	36.98	91.67	
RAPAMYCIN	31	6.16	13.65	221.81	51.58	45.93	89.06	
EVEROLIMUS	38	4.80	14.23	296.72	38.56	30.42	78.91	
TIPIFARNIB	31	3.06	7.83	256.21	35.33	29.92	84.70	
PERIFOSINE	25	11.81	20.68	175.06	38.18	64.10	167.91	

Summary and Conclusions: We have developed an automated system that, in a fast and accurate way, is able to determine the *ex vivo* sensitivity of multiple samples to many different drugs. This approach could be used as a companion diagnostic to identify subsets of patients for which new treatments such as panobinostat or Tanespimycin could be effective. It could also be used as a Personalized Medicine test to help guide therapy if it can be correlated with clinical outcome. Correlation of this *ex vivo* sensitivity with the clinical efficacy is currently being performed in a study under the supervision of the PETHEMA/GEM groups.

P800

THE IMPACT OF 8 GY ONE FRACTION RADIOTHERAPY ON PAIN RELIEF AND RECALCIFICATION IN MULTIPLE MYELOMA PATIENTS WITH PAINFUL BONE DESTRUCTIONS.

M Rudzianskiene[1,*], A Inciura[1], E Juozaityte[1], R Gerbutavicius[1], V Rudzianskas[1]
[1]Oncology Institute, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: Multiple myeloma (MM) induces osteolysis and disturbs the balance between bone formation and bone resorption. Radiotherapy, surgery and analgesics are required in order to overcome pain, to evoke recalcification and to improve the quality of life of MM patients.Pain relief is obtained in 75–100% and recalcification is achieved in 40–50% of irradiated bone destructions. The randomized trials showed the same effect of single (SF) and multiple fractions (MF) in pain relief and recalcification for patients with painful bone metastases from solid tumors. The role of different palliative radiotherapeutic regimens for MM is not well established due to the lack of clinical trials. There are only few retrospective studies regarding dose-response relationship with analgesia and recalcification.
Aims: To evaluate the impact of 8 Gy one fraction regimen in the treatment of MM on pain relief, analgesics consumption and recalcification.
Methods: From 2010 until 2012, 46 patients (27 women and 19 men, median age: 69 years, 52–88 years) with MM and painful bone destructions were treated by 8 Gy one fraction regimen.Pain was evaluated by using visual analogue scale (VAS) with the scale endpoints from 0 (no pain at all) to 10 (worst imaginable pain) and recalcification was measured with radiographs. Pain score and analgesics usage was measured prior and4, 12 and 24 weeks after radiotherapy.
Results: The pain before radiotherapy was mild (VAS 1-4) in 4 patients (9%), moderate (VAS 5-7) in 15 patients (32%) and severe (VAS 8-10) in 27 patients (59%). The decrease of pain after radiotherapy of 8 Gy one fraction was observed in 36/46 patients (78.3%): 20 patients (43.5%) were found to be

completely responsive and 16 patients (34.8%) were partially responsive according tothe international consensus on palliative radiotherapy criteria. Six patients (13%) were using non-opioid drugs prior to radiotherapy and all of them have ceased analgesic intake for six months after termination of treatment. 38 patients (83%) used opioids drugs. The use of opioids analgesics was reduced in 26/38 patients (68.4%), while a complete cessation of opioids analgesics was observed in 12/38 patients (31.6%) stopped it totally. Significant parameters in pain relief were: age <65 years (Chi square test P=0.034) and IgG type paraprotein (Chi square test P=0.037). Recalcification was observed in 22 patients (55%): a complete response was observed in 14 patients (35%) and a partial response in 8 patients (20%). Pathological fractures in the irradiated field were observed in 6 patients. The most significant parameter regarding recalcification was: age <65 years (Chi square test P=0.022). The hematological and non-hematological toxicity was evaluated on a five point scale according to the toxicity criteria of the Radiation Therapy Oncology Group (RTOG) and the European Organization for Research and Treatment of Cancer (EORTC) in the first 4 weeks after radiotherapy. The side effects after treatment were uncommon, usually of first grade and reversible.

Summary and Conclusions: One 8 Gy fraction regimen is effective for pain relief, analgesics reduction and on recalcification for MM patients with painful bone destructions.

P801

RESULTS OF LENALIDOMIDE TREATMENT FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA IN A REAL WORLD SETTING: FEASIBILITY AND FACTORS CONTRIBUTING TO LONG TREATMENT DURATION

G Derigs[1,*], G Prange-Krex[2], C Schardt[3], T Edelmann[4], Mi Kiehl[5], G Huebner[6], A Bachinger[7], A Glasmacher[8]
[1]Hospital Frankfurt Höchst GmbH, Frankfurt a.M., [2]Praxis für Haematologie/Onkologie, Dresden, [3]Praxis Haematologie/ Onkologie, Gelsenkirchen, [4]Praxis für Haematologie/Onkologie, Leipzig, [5]Hospital Frankfurt (Oder) GmbH, Frankfurt (Oder), [6]Sana Kliniken Ostholstein, Oldenburg i.H., [7]Biometrie, ClinAssess GmbH, Leverkusen, Germany, [8]Celgene, Sarl, Boudry, Switzerland

Background: Lenalidomide in combination with dexamethason (LEN-DEX) is approved in relapsed, refractory Multiple Myeloma (RRMM) for continuous treatment until disease progression (PD) or unacceptable toxicity. Although there is evidence that continuing treatment beyond best response is associated with improved survival (Dimopoulos *et al.*, 2009), data assessing feasibility, benefits and potential risks of long-term treatment in a non-study RRMM cohort are limited.

Aims: We therefore analyzed data from a German non-interventional multicentre trial to prospectively assess factors influencing treatment duration in a real world setting.

Methods: Selection criteria were diagnosis of RRMM with at least one prior treatment regimen and decision (with patient´s informed consent) to treat relapse/progression with LEN-DEX. Patients (pts) starting treatment between February 2008 and December 31, 2010 were eligible for this analysis. Pts with a treatment period of at least 18 months (mos) were defined as long treatment cohort (LTC), and pts treated for a maximum of 3 mos (91 days) form the short treatment cohort (STC). Data cutoff was November 29, 2012. Statistical analysis included uni– and multivariate models on factors potentially influencing treatment duration. Median overall survival (OS) for LTC and STC was calculated using the Kaplan Meier approach.

Results: Until December 31st2010, 436 pts started treatment, of which 156 (35.8%) were treated for a maximum of three mos and 47 (10.8%) were treated at least 18 mos. Both cohorts showed no significant difference in age, ECOG performance status, time since diagnosis and number of pretreatments received, preexisting neuropathy, and number of VTE in history. On the other hand, they differed in prior treatment with autologous stem cell transplant (ASCT), type of paraprotein and preexisting cytopenia (Table 1). Reasons for treatment discontinuation in STC were related to adverse events (AEs) in 56 pts (35.9%), death in 36 pts (23.1%), and disease progression in 16 pts (10.3%), and in 48 pts (30.8%) treatment was stopped due to pts wish or other causes. The observed toxicities reflect the well known safety profile with mainly hematological AEs (≥grade 3 in 30% of pts), however febrile neutropenia occurred in only 1% of pts. The most frequently reported non hematological AEs of any grade were infections (37.4%), fatigue (21.2%), diarrhea (13.3%), muscle cramps and dizziness (both 11.8%). In LTC therapy is ongoing in 20 out of 47 pts (42.6%) and only 2 out of 27 pts in LTC discontinued treatment due to toxicity. Median OS was significantly higher in LTC. Median OS of LTC was 51 mos, whereas OS of STC was 14.3 mos. If STC pts with PD or death were excluded, the OS still remains significant (21.1 mos *vs* 51 mos, P<0.0001). In uni-variate analysis the following factors positively influenced treatment duration; previous treatment with autologous transplant, IgG type of paraprotein, absence of light chain disease, achievement of an objective response (best response PR or better), and use of anticoagulation (ASA, LMWH). The following two parameters remain the only significant factors in a multivariate model; use of anticoagulation and achievement of an objective response.

Table 1.

	LTC, n=47	STC, n=156	p - value
Age (median, range)	68 (41-85)	71 (37-87)	0.0539
ECOG 0 -1 / ≥ 2[a]	75.8 / 24.4	57.4 / 42.6	0.0685
Time since diagnosis (mos)	34 (4-213)	34.5 (1-360)	0.2762
Number of prior therapies	2 (1-8)	2 (1-9)	0.5734
Prior ASCT (%)	42.6	20.5	0.0041*
Prior Bortezomib (%)	72.3	60.9	0.2248
Prior Thalidomide (%)	21.3	16.0	0.5090
Prior Lenalidomide (%)	6.4	8.3	>0.999
Preexisting neuropathy, (%)	34	28.8	0.7153
VTE in history (%)	17	16.7	>0.999
Type of paraprotein			
IgG/ IgA/ light chain (%)	76.6/ 19.1/ 2.1	57.7/ 25.0/ 16.0	0.0110*
Preexisting neutropenia (%)	4.3	2.6	0.6242
Preexisting thrombocytop. (%)	0	8.3	0.0417*
Preexisting anemia (%)	0	10.9	0.0142*
Creatinine increased (%)	0	5.1	0.2016

[a]Missing data in 30 and 26% of pts in LTC or STC resp., * Statistically significant at 5%

Summary and Conclusions: Here we showed that long-term treatment with LEN-DEX for RRMM is feasible and consistent with previous reports in real world settings. The identification of anticoagulation as a statistically significant factor contributing to long-term treatment underscores the importance of concomitant supportive measures. Outcome of pts with long term treatment is superior to those treated only for a short term period. This is noteworthy, since treatment in a considerable proportion of pts was stopped early for reasons other than progression, death or toxicity. These data thus corroborate previous evidence that LEN-DEX treatment in RRMM should be continued beyond best response.

P802

THE PRESENCE OF IMMUNOPHENOTYPIC ALTERATIONS IN BONE MARROW CELLS OTHER THAN PLASMA CELLS FROM MULTIPLE MYELOMA PATIENTS PREDICTS FOR MYELODYSPLASIA-ASSOCIATED CYTOGENETIC ABNORMALITIES

S Matarraz[1,*], B Paiva[2], M Diez-Campelo[2], A Lopez[1], J Sayagues[1], M Jara-Acevedo[1], M Sanchez[1], P Barcena[1], J San Miguel[2], Alberto Orfao[1]
[1]Medicine, Centro de Investigación del Cáncer (IBMCC, CSIC-USAL) and IBSAL, [2]Servicio de Hematologia, Hospital Universitario de Salamanca and IBSAL, Salamanca, Spain

Background: The treatment of multiple myeloma (MM) has experienced an extraordinary improvement in the last years. However, the progress achieved has been accompanied by an increasing concern for therapy-related secondary primary malignancies (SPMs). High-dose melphalan (HDM) and more recently lenalidomide have been associated with higher risk of SPMs development, particularly myelodisplastic syndromes (MDS) and/or acute myeloid leukemia. Consequently, given that the benefits of HDM and lenalidomide for MM patients' survival outweigh the potential risk of SPMs it is of notable relevance to identify patients at higher risk of developing SPMs, preferably by using routinely available techniques.

Aims: Here, we investigated if the presence of MDS-associated phenotypic alterations (MDS-FC) predicted for MDS-associated cytogenetic abnormalities in a total of 70 MM patients.

Methods: The presence of MDS-FC was previously investigated in 70 MM patients and was detectable by flow cytometry (FC) in 23 (33%). In these latter cases, FACS purified CD34+ hematopoietic stem cells (HSC), neutrophils, monocytes and erythroblasts were analyzed by FISH (in male patients, n=12), for the detection of -5/del(5q), -7/del(7q), del(20q), trisomy8, and nulisomy Y. Conversely, in female patients (n=11) these cell populations were screened for clonality using the human androgen receptor X-chromosome inactivation test (HUMARA).

Results: From all patients, four male patients (33%) showed cytogenetic abnormalities; 3 cases with del(5q31) and 1 with –Y, both abnormalities being detected in all 4 cell populations. Six of the 11 (55%) female patients showed a clonal HUMARA test. The presence *vs.* absence of MDS-FC alterations predicted for a clonal HUMARA test in the correspondent cell compartment, namely HSC (100% *vs* 11%; P=.005) and neutrophils (67% *vs* 0%; P=.05), with a similar trend being also found in erythroblasts (80% *vs.* 29%; P=.08).

Summary and Conclusions: Our results show that immunophenotypic dysplastic features are present in approximately one-third of MM patients at diagnosis and that in half of them these alterations are associated with clonality at the genetic level.

P803

OUTCOME OF PATIENTS WITH MULTIPLE MYELOMA (MM) RELAPSING AFTER FRONT-LINE AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT): IMPACT OF REDUCED INTENSITY ALLOGENEIC TRANSPLANTATION (RICALLO).

R Tabrizi[1,*], A Lascaux[1], C Mohr[1], G Marit[1], S Vigouroux[1], A Pigneux[1], T Leguay[1], K Bouabdallah[1], M Dilhuydy[1], C Duclos[1], P Dumas[1], S Dimicoli-Salazar[1], N Milpied[1]
[1]CHU de Bordeaux, Service d'hematologie et thérapie cellulaire, Bordeaux, France

Background: Both RICALLO and new drugs have been used for salvage therapy for MM relapsing after ASCT. But the optimal treatment remains to be determined.
Aims: The aim of this single centre study was to assess the outcome of pts with MM following the relapse after ASCT, according to whether or not a RICALLO was performed.
Methods: Records of the patients were reviewed and the criteria for entering the study were: Symptomatic MM treated frontline with a program including single or double ASCT, relapse at any time following ASCT, response (CR, VGPR or PR) to a second line treatment. RICALLO was proposed to pts with no significant co-morbidities, having a suitable donor (either sibling or MUD) and who gave their consent after precise information on the risk of the RICALLO.
Results: One hundred and thirty-eight pts treated between 01/2000 and 12/2012 fulfilling the inclusion criteria were identified. 44 pts received a RICALLO (Allo group) while in second or third response with a median of 7.4 months (2-48) after relapse. The RIC consisted of fludarabine plus either 2Gy ICT or busulfan and ATG (according to ongoing available protocols in the centre). The graft was PBSC from sibling in 17 pts and from MUD in 27 pts. 94 pts (CT group) received therapies according to ongoing protocols or available standard of cares. The main characteristics of the patients in each group: median age (58 y.o for Allo and 59 y.o for CT group), MM prognostic factors at diagnosis, type of 1st line therapy (VAD or bortezomib containing regimens), single or double ASCT, time to relapse after ASCT and 2d line treatment were similar between the 2 groups. The initial treatment for relapse consisted of VD (42 pts), RD (37 pts), TD (43 pts), VTD (12 pts) or MPV, MPT, Bendamustin or ASCT (1 pt for each). The 3y OS from the time of relapse for the entire cohort was: 58% (CI95%, 54-62). It was of 58% (CI95% 50-66) and of 58% (CI95% 52-64) for the Allo group and the CT group respectively (P=ns). The causes of death were, relapse in 14 and 41 pts, or treatment toxicity in 13 and 0 pts in the Allo group and CT group respectively. The 3y EFS from the time of relapse was 43% (CI95%, 38-51) and 26 (CI95%, 21-31) for the Allo and the CT group respectively (P=ns) (Figure 1).

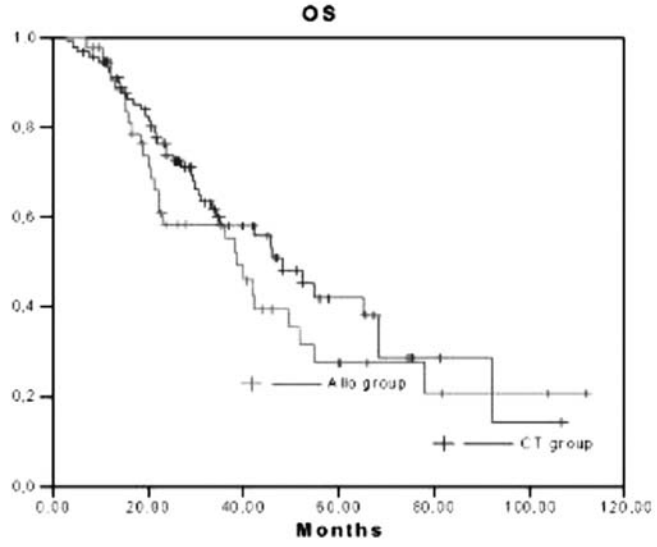

Figure 1.

Summary and Conclusions: We did not observe any difference in survival between Allo-SCT and CT in patients relapsing after front-line ASCT. Prospective study is needed to determine the optimal treatment in this domain.

P804

FLOW CYTOMETRIC ANALYSIS AND MINIMAL RESIDUAL DISEASE IN MULTIPLE MYELOMA: A COMPARISON BETWEEN FLOW CYTOMETRIC IMMUNOPHENOTYPING AND CYCLOSCOPE-MG.

G De Tullio[1,*], R Ria[2], A Reale[2], C Minoia[1], S Serrati[1], G Loseto[1], A Vacca[2], A Guarini[1]
[1]Department of Clinical and Experimental Oncology, Haematology Unit, Advanced Cell Therapy Center, National Cancer Research Centre, Istituto Tumori "Giovanni Paolo II", [2]Departement of Biomedical Sciences, Clinica Medica "Baccelli", University of Bari, BARI, Italy

Background: Multiple myeloma (MM) is a plasma cell neoplasm which resides in the bone marrow (BM) and is critically dependent upon the BM microenvironment for its survival. Recent studies show that MM is consistently preceded by a precursor state, MGUS; however, we lack reliable markers to predict progression from MGUS to MM. In patients with MM, the depth of response is an important prognostic factor.
Aims: The aim of this study is to analyze and compare the clinical utility of Minimal Residual Disease studies in Multiple Myeloma with two differentes flow cytometric techniques: Flow Cytometric Immunophenotyping and Cycloscope-MG.
Methods: These studies included 45 patients: 15 patients with active MM, 10 with non-active MM, 10 with MGUS and 10 controls that were evaluated by flow cytometric immunophenotyping and Cycloscope-MG.The panel of monoclonal antibodies we used in our studies included the minimal test antigens for classifying plasma cells: CD38, CD138, CD45; CD19 and CD56 in order to distinguish myeloma plasma cells (CD19-, CD56+) from normal plasma cells (CD19+, CD56-), and CD117, CD40 and CD27 as recommended markers. Cycloscope-MM kit included a mixture of primary antibodies for the detection of antigens present in human plasma cells (CD38 and CD138); a secondary antibody (FITC labelled IgG goat anti mouse IgG F); an erythrocyte lysing solution and a DNA labelling buffer containing detergent, propidium iodide and RNase for DNA staining.
Results: Previous studies have demonstrated the use of CD38, CD138, CD45, CD 19 and CD56. Furthermore, CD117, CD27 and CD40 have been used in our studies to differentiate between neoplastic and normal plasma cells. Cycloscope-MG showed the aneuploidy of myeloma plasma cells for the detection of minimal residual disease (MRD).The results between morphological analysis, immunophenotypic analysis and Cycloscope analysis were compared in the different groups under study. Significant changes were found in the marrow infiltration of myeloma plasma cells, and, mainly, in the aberrant expression of phenotype and in the expression of aneuploid cells peack. Patients with active MM showed both the characteristic aberrant immunophenotype (CD38+CD138+CD19-CD56 +) and a visible peak in G0/G1 detectable in Cycloscope. The aberrant phenotype and the peak of aneuploid cells, were absent in patients used as control. The comparison between the three methods used for the evaluation of bone marrow infiltration in patients with MM (morfologia, FACS, aneuploidy) confirms the general overestimation of infiltration if the only microscopy is performed. Therefore, it is necessary, for a correct evaluation of patients, to use at least another one technique (molecular, flow cytometric, aneuploidia evaluation) (Figure 1).

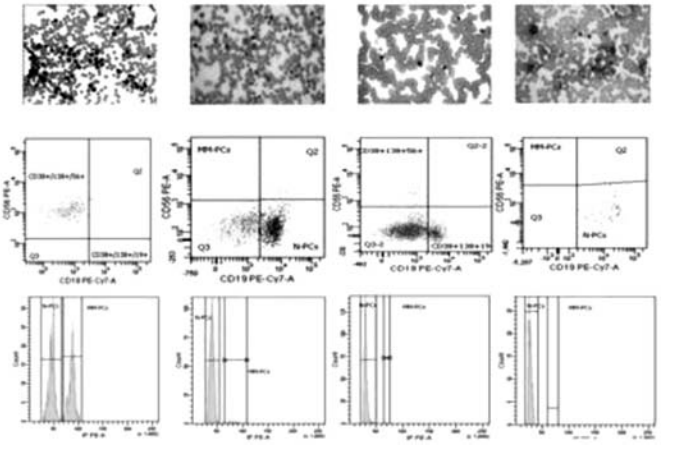

Figure 1.

Summary and Conclusions: Flow Cytometric Immunophenotyping is directly compared with Cycloscope-MG. Our results show that both methodologies may help to discriminate the risk categories of MM patients, based on the level of residual aberrant plasma cells. The Cycloscope-MG™ evaluation provided the possibility to establish a cut-off value that distinguishes patients with active disease from patients in post treatment remission. In fact, patients with active MM had a percentage of aberrant plasma cells (ie plasma cells in the aneuploid Cycloscope-MG™) at medullary level greater than or equal to 2%.Patients with non-active MM showed a percentage of aberrant plasma cells below this cutoff value. Regarding patients with MGUS, the percentage of aberrant medullary plasma cells was always less than 0.5%. Flow cytometric Immunophenotyping is directly compared with Cycloscope-MG™. Our results show that both methodologies may help to discriminate the risk categories of MM patients, based on the level of residual aberrant plasma cells. These studies have shown that residual disease above a level of 2% is clinically relevant in MM.

P805

NUMBER OF ADVERSE CYTOGENETIC LESIONS DETECTED BY FISH IS ASSOCIATED WITH PROGNOSIS IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS TREATED WITH THALIDOMIDE-BASED REGIMENS

N Grzasko[1], M Hus[1], M Morawska[1,*], S Chocholska[1], A Jurczyszyn[2], R Hajek[3], J Wojciechowicz[4], M Kostyra[4], A Dmoszynska[1]
[1]Klinika Hematologii i Transplantacji Szpiku, Uniwersytet Medyczny w Lublinie, Lublin, [2]Klinika Hematologii, Uniwersytet Jagielloński w Krakowie, Kraków, Poland, [3]Laboratory of Experimental Haematology and Cell Immunotherapy, Department of Clinical Haematology, University Hospital Brno and Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [4]Klinika Chirurgii Szczękowo-Twarzowej, Uniwersytet Medyczny w Lublinie, Lublin, Poland

Background: Cytogenetic abnormalities are considered the major prognostic factors in multiple myeloma (MM). The most important chromosomal aberrations associated with unfavourable prognosis are translocations involving immunoglobulin heavy chain gene located in chromosome 14q32, like t(4,14)(p16;q32), t(14;16)(q32;q23) or t(14;20)(q32;q12), amp(1q21), del(17p13) and del(13q14).
Aims: In this study we assessed the prognostic value of t(4,14)(p16;q32), amp(1q21), del(17p13) and del(13q14) as well as the combination of these lesion in newly diagnosed MM patients treated with thalidomide-based regimens.
Methods: The study group consisted of 128 patients treated with cyclophosphamide, thalidomide and dexamethasone(CTD, n=96) or melphalan, prednisone and thalidomide (MPT, n=32). Responding patients from CTD group were given high-dose melphalan with autologous stem cell support (HDT/ASCT, n=65). Bone marrow aspirates obtained from patients at diagnosis were analyzed for the presence of t(4,14)(p16;q32), amp(1q21), del(17p13) and del(13q14) using fluorescence *in situ* hybridization (FISH). The cut-off level for all abnormalities was 20% according to the recommendations of the European Myeloma Network.
Results: FISH analysis detected t(4,14)(p16;q32) in 20%, amp(1q21) in 45%, del(17p13) in 17% and del(13q14) in 44% of patients; 30% had 1 lesion, 24% 2 lesions and 17% 3 or more. On univariate analysis the presence of all analyzed abnormalities was associated with shorter progression-free survival (PFS) and overall survival (OS): for t(4,14)(p16;q32) PFS was 7.0 *versus* 18.9 months (P=0.003) and OS 23.6 *versus* 44.3 months (P=0.026); for amp(1q21) PFS 8.0 *versus* 29.0 months (P<0.001) and OS 24.0 *versus* 55.3 months (P<0.001); for del(17p13) PFS 5.5 *versus* 17.0 months (P=0.048) and OS 12.0 *versus* 45.0 months (P=0.016); for del(13q14) PFS 8.0 *versus* 28.0 months (P=0.003) and OS 23.8 *versus* 52.9 months (P<0.001). Multivariate analysis was performed for six covariates: age, HDT/ASCT and four examined genetic lesions. It confirmed amp(1q21), del(17p13) and del(13q14) as being independently associated with shorter PFS (P<0.001, P<0.001 and P=0.042 accordingly) and OS (P<0.001, P<0.001 and P=0.007 accordingly) and HDT/ASCT with longer PFS (P<0.001) and OS (P<0.001). The number of genetic abnormalities detected in patients significantly influenced both PFS and OS. The median PFS was 38.9 months in patients with no lesions, 18.4 months in patients with 1 lesion, 11.5 months in patients with 2 lesions and 5.0 months in patients with 3 or more lesion (P<0.001). The median OS was 79.6 months, 39.6 months, 25.0 months and 12.0 months accordingly (P<0.001). Adverse prognosis associated with multiple genetic changes was also seen in the subgroup of patients undergoing HDT/ASCT (median PFS 46.3 months, 31.8 months, 12.0 months and 5.0 months accordingly, P<0.001; median OS 98.6 months, 39.7 months, 26.9 months and 12.0 months accordingly, P<0.001).
Summary and Conclusions: The results of the study showed that the presence of amp(1q21), del(17p13) and del(13q14) is associated with significantly shortened PFS and OS in newly diagnosed MM patients treated with thalidomide-based regimens. Accumulation of adverse cytogenetic abnormalities resulted in further reduction of survival and the number of coexisting genetic lesions defined risk groups with different PFS and OS. Impact of cytogenetic changes on survival was also seen in patients undergoing HDT/ASCT suggesting that this procedure is not able to change poor prognosis associated with high-risk genetic abnormalities.

P806

EVALUATION OF TNF SUPERFAMILY MOLECULES IN MULTIPLE MYELOMA PATIENTS: CORRELATION WITH BIOLOGICAL AND CLINICAL FEATURES.

L Bolkun[1,*], D Lemancewicz[1], E Jablonska[2], J Piszcz[1], J Kloczko[1], J Dzieciol[3]
[1]Hematology, [2]Immunology, [3]Human Anatomy, Medical University, Bialystok, Poland

Background: B-cell activating factor (BAFF), a proliferation-inducing ligand (APRIL) and apoptosis inducing ligand (TRAIL), all members of the tumor necrosis factor (TNF) family, represent three of the main survival factors for immature, naive and activated B cells. What is more, BAFF and APRIL, can directly activate the NF - κB pathway, have been identified as two of the main survival factors for healthy plasma cells and multiple myeloma (MM) cells.
Aims: The purpose of the present study was to evaluate serum levels of BAFF, APRIL and TRAIL in healthy volunteers and in MM patients to determine whether there was any correlation between ligands and some prognostic biological parameters of MM patients, and to explore their clinical significance in predicting the disease activity of MM.
Methods: 52 patients with newly diagnosed MM were included in the study. Median age of patients at the time of sample collection was 65, and the range was 59-70. At the time of diagnosis, all patients were divided into three groups based on International Staging System, ISS (12 patients in stage I, 16 patients in stage II, and 24 in stage III). Patients' initial treatment was thalidomide–dexamethasone and cyclophosphamide (CTD), prior to monotherapy of thalidomide 100 mg until progression. Response was assessed after six cycles of chemotherapy with the same methods as for diagnosis, according to the EBMT/IBMTR/ABMTR criteria. The control group consisted of 20 healthy volunteers, age- and sex- matched. Quantitative assessments of cytokines were performed by commercially available ELISA assays. Results were expressed as means SD. The non-parametric Kruskal–Wallis test and the one-way analysis of variance (ANOVA) were assessed to test for different stages. The Student's t-test was used for pairwise comparison of subgroups. Comparisons between the MM and the control groups were made using the non-parametric Mann–Whitney test. The Spearman's order correlation coefficient was applied to determine correlations between the measured parameters. Survival analysis was performed by means of the Kaplan–Meier method. Comparisons of survival curves were performed using the Wilcoxon test. P-values below 0.05 were considered to be statistically significant
Results: Pre-treatment myeloma patients had significantly higher serum concentration compared to healthy volunteers: BAFF (1211.5±1768.8 pg/mL *vs* 309.2±216.1 pg/mL, P<0.0001), APRIL (2.56±0.44 ng/mL *vs* 1.59±0.41 ng/mL, P=0.04), TRAIL (149.41±40.25 pg/mL *vs* 80.28±16.24 pg/mL, P=0.005). MM patients with advanced disease stage III had higher serum levels of all the studied parameters compared to stage I: for TRAIL, P=0.02, APRIL, P=0.04, BAFF, P=0.00002, respectively. Furthermore, the study showed statistical decrease of concentrations of all studied parameters after anti-angiogenic regimen chemotherapy for TRAIL (136.05±73.2 pg/mL, P=0.03), APRIL (1.74±1.05 ng/mL, P=0.01) and for BAFF (826.11±1780.7 pg/mL, P=0.007). Moreover, the concentrations were found to be lower in the subgroup of patients with (CR+VGPR+PR) compared to the SD: for BAFF (652.57±533.2 pg/mL *vs* 1322.3±1592.2 pg/mL, P=0.01 and for APRIL (1.04±0.03 ng/mL *vs* 2.14±1.02 ng/mL, P=0.02, but not for TRAIL (151.39±7.0 pg/mL *vs* 123.27±76.4 pg/mL, P=0.23). In addition, the concentration of APRIL was found to correlate significantly and positively with the concentration of BAFF (P=0.02), IL-6 (P=0.004), LDH, (P=0.003) and negatively with TRAIL (P=0.01). The study also showed a positive correlation between the concentration of BAFF and IL-6 (P=0.009), and β2m and LDH, (P<0.05), but not with concentrations of BAFF and TRAIL (P=0.61). We did find, however, a meaningful link between the concentration of TRAIL and TNF (P=0.03), but not the concentration of IL-6 (P=0.98). Additionally, we observed that pre-treatment MM patients with serum BAFF values higher than the median (847.98 pg/mL) and with serum APRIL values higher than the median (2.26 ng/mL) had significantly shorter progression free survival (PFS) than patients with lower values: for BAFF, P=0.001 and for APRIL, P=0.02. There were no statistically significant differences between PFS values in the subgroups of MM patients with regard to the median values (123.58 pg/mL) of TRAIL, P=0.2.
Summary and Conclusions: In conclusion, our results have demonstrated that serum concentrations of BAFF and APRIL (but not TRAIL) could be a useful biomarker of MM disease activity and progression. Pre-treatment concentrations of BAFF and APRIL could also serve as a prognostic factor of PFS. Both ligands may therefore be a novel therapeutic target in MM.

P807

TOXICITY PROFILE DURING TREATMENT WITH BENDAMUSTINE-BORTEZOMIB-DEXAMETHASONE IN PATIENTS WITH RELAPSED/ REFRACTORY MULTIPLE MYELOMA

H Ludwig[1,*], E Rauch[1], A Zdenek[2], H Kasparu[3], R Greil[4], C Leitgeb[1], A Weißmann[1], E Autzinger[1], W Linkesch[5], T Kuehr[6], L Pour[7], N Zojer[1]
[1]Department of Internal Medicine I, Center for Oncology and Hematology, Wilhelminenhospital, Vienna, Austria, [2]Department of Internal Medicine - Hematooncology, University Hospital Brno, Brno, Czech Republic, [3]Department of Internal Medicine, Hospital Elisabethinen, Linz, [4]Department of Internal Medicine III, University Hospital Salzburg, Salzburg, [5]Department of Hematology, Medical University of Graz, Graz, [6]Department of Internal Medicine IV, Klinikum Wels-Grieskirchen, Wels, [7]Department of Internal Medicine - Hematooncology, University Hospital Brno, Brno, Austria

Background: Treatment with bendamustine-bortezomib-dexamethasone (BBD) exerts significant activity in patients with relapsed/refractory multiple myeloma even in those pretreated with bortezomib or lenalidomide or both, but may be associated with clinically relevant side effects.
Aims: Here we analyze the side effect profile with specific emphasis on infections, cytopenias and neuropathy in patients enrolled in a trial with BBD for relapsed/refractory multiple myeloma.
Methods: Seventy-nine patients with relapsed/refractory MM have been

enrolled. Median age: 64 years (range 40-86), male/female: 37/42, ISS stage I/II/III: 27, 31, and 21, respectively. ECOG status 0-I/≥II: 75, and 4 patients, respectively. Previous treatment lines: 1-2: 50, 3-4: 23, >4: 6 patients, respectively. Treatment regimen: bendamustine 70 mg/m^2 day 1+4, bortezomib 1.3 mg/m^2 days1,4, 8 and11, dexamethasone 20 mg on days1,4, 8 and11, repeated every 4 weeks. Planned number of treatment cycles was8, with discontinuation after 4 cycles in case of no response. Toxicity grading was performed using the CTC v 3.0 scale. The FACT-GOG/NTX instrument was used for patients self-assessment of neuropathic side effects.

Results: G3/4 infections were noted in 16 (20%) patients and 2 patients died due to infection/sepsis (G5). Low baseline ANC (<2.800/mL), a higher number of cycles (>4 cycles), and age >65 years showed a weak, but statistically non-significant correlation with G3/4 infections. G3/4 thrombopenia was recorded in 28 (35%) patients; 18 of them presented with more than one episode (median:3, range 2-8). Severe thrombopenia resulted in treatment discontinuation in2, and in delay of therapy in 7 patients, respectively. Lower baseline platelet levels (<182.000/μL) were associated with higher risk for G3/4 thrombopenia (P<0.021). Peripheral neuropathy assessed by the clinical care team was reported in 44 (56%) patients. G3/4 neuropathy was observed in 5 patients only. The occurrence of neuropathy increased, albeit not statistically significant, with increasing number of treatment cycles. Self-assessment of neuropathy by patients revealed a much higher PNP incidence with G1/2 PNP reported by 37 (47%) and G3/4 PNP reported by 38 (48%) patients. Pretreatment with bortezomib or thalidomide, or both bortezomib and thalidomide was not associated with higher incidence of G3/4 PNP.

Summary and Conclusions: Low baseline ANC and were associated with a higher risk for G3/4 neutropenia (P<0.012) and low baseline platelets counts were associated with G3/4 thrombopenia (P<0.021). Lower baseline ANC levels correlated with shorter PFS (P<0.01). Higher age, longer therapy and low baseline ANC tended to correlate with G3/4 infections. Furthermore, incidence of G3/4 neuropathy was low, but increased slightly with increased treatment duration. In stark contrast to evaluations by care givers, a much higher incidence of PNP was revealed when patients graded the incidence and severity of PNP by using a self-assessement instrument. Physicians should be aware of the substantial underrating of PNP by health professionals.

P808

VALUE OF WHOLE-BODY DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING IN THE STUDY OF MONOCLONAL GAMMOPATHIES AND CORRELATION WITH BONE-RELATED CYTOKINES

R Martos[1,*], A Mateo[1], O Montesinos[2], R Herrero[1], G del Peral[2], J Queizan[1], C Olivier[1], F Recio[2], J Martín[1]
[1]Hematology and Hemotherapy, [2]Radiology Department, Hospital General de Segovia, Segovia, Spain

Background: MM is related with overproduction of several cytokines that are responsible for imbalance between osteoclast and osteoblast activity. Thus, some cytokines increase bone resorption by increased osteoclast activity, one of which is the *Macrophage inflammatory protein1-alpha (MIP1-alpha).* Another group inhibits bone formation through a reduction in osteoblast activity, we should highlight the Wnt pathway inhibitors such as *Dickkopf-1(DKK-1)* and *Sclerostin*. The use of new imaging techniques is increasingly necessary for the correct study of Multiple Myeloma. One of more promising techniques is the whole body magnetic resonance (WB-MRI) including diffusion/perfusion sequences (DWI), This "functional" imaging test analyze brownian motion of water molecules in all areas allowing high sensitivity and specificity to evaluate early bone marrow involvement. Thus, this exam allows quantitative assessment of bone marrow involvement, through the so-called Apparent Diffusion Coefficient (ADC). Previous descriptions indicate that ADC is greater as higher is the bone marrow infiltration.

Aims: To evaluate the usefulness of DWI in patients diagnosed with Monoclonal Gammopathy (MG). To correlate the ADC value to circulating levels of cytokines related with bone resorption and formation.

Methods: Prospective study was approved by the local IRW. All patients gave their written informed consent. 39 patients(20 Monoclonal Gammopathy of Unknown Significance (MGUS),5 smoldering Multiple Myeloma (sMM),13 symptomatic Multiple Myeloma (MM) were enrolled between May/2011-Oct/2012. The patients were divided on the basis of bone involvement by WB-MRI according infiltration pattern: focal, diffuse and mixed. The ADC values were evaluated in DWI in six different anatomical areas, with b800 (diffusion weighted sequence) in cervical spine, dorsal spine, lumbar spine, iliac crest, femoral head and humeral head; and with b200 in iliac crest and femoral head. *Sclerostin, Dkk-1 and MIP-1*α were measured by double-sandwich enzimoimmunoassay (EIA). *Statistical analysis:* Non-parametric test for comparison of two independents samples (U de Mann-Whitney). Correlations between two variables of the same sample (Spearman's test).

Results: No MGUS patients showed bone marrow involvement in MRI. 2 of the 5 patients diagnosed with sMM had bone marrow involvement in MRI, one of them showed focal pattern of infiltration and another one showed diffuse pattern. 9 of the 13 patients diagnosed with MM had bone marrow involvement, 3 showed focal pattern of infiltration and 6 showed mixed pattern.5 patients (45.5%), with focal bone marrow involvement had affected more than ten anatomical areas. The ADC value in all areas (Table 1) was higher in MM patients than MGUS patients, but there was significant difference only in ADC values of cervical spine (b800) and of femoral head (b200). When we correlate the bone-related cytokines with ADC of all patients with MG, only significant association between sclerostin and ADC in humeral head (P<0.05). In those cases in which there was focal involvement in ribs, the ADC of these lesions showed significant correlation with MIP-1 alpha (P<0.05).

Table 1.

		b=800						b=200	
	n	Median ADC Cerviacal Spine	Median ADC Dorsal Spine	Median ADC Lumbar Spine	Median ADC Iliac Crest	Median ADC Femoral Head	Median ADC Humeral Head	Median ADC Iliac Crest	Median ADC Femoral Head
Multiple myeloma symptomatic	13	837	700	559.5	720.5	472	466	2016.5	1432.5
MGUS	20	585.5	603	416.5	576	376.5	375	1346	1101
p		0.002	0.577	0.220	0.077	0.201	0.195	0.051	0.02

Summary and Conclusions: DWI and ADC value can be useful in the evaluation of bone marrow involvement in MG patients. In these patients there is correlation between levels of bone-related cytokines in MM and parameters of this new "functional" imaging study.

We must increase the number of cases and expand cytokines and bone remodeling markers studied to obtain more significant difference and to reinforce these conclusions.

P809

THE COMBINATION OF BORTEZOMIB AND DEXAMETHASONE (VD) ALONG WITH ZOLEDRONIC ACID INCREASES BONE MINERAL DENSITY (BMD) IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: RESULTS OF A PHASE II STUDY

E Terpos[1,*], M Gkotzamanidou[1], E Eleutherakis-Papaiakovou[1], D Christoulas[1], M Gavriatopoulou[1], N Kanellias[1], E Kastritis[1], M Dimopoulos[1]
[1]Department of Clinical Therapeutics, University of Athens School of Medicine, Athens, Greece

Background: Retrospective studies have reported a bone anabolic effect of bortezomib (V) in multiple myeloma (MM), but there is lack of prospective data in this field.

Aims: We scheduled a prospective, non-comparative, open-label, phase II study to evaluate the effects of VD in combination with zoledronic acid (ZOL) on bone disease of relapsed/refractory MM patients. The primary objective was the effect of 4 VD cycles on BMD. Secondary objectives were: i) the evaluation of BMD after 8 VD cycles and 18 months post-VD or at study termination (PD or discontinuation); ii) the evaluation of bone pain, SREs, osteolytic lesions and bone markers [bone alkaline phosphatase (bALP), osteocalcin (OC), C-telopeptide of bone collagen (CTX)] after 4 and 8 VD cycles and 18 months post-VD or at study termination.

Methods: Patients with relapsed/refractory MM, after 1-3 prior lines of therapy, received VD for up to 8 cycles in combination with ZOL (4mg, iv, monthly). V was administered at the standard dose of 1.3 mg/m^2, iv, on days1,4,8,11 of a 21-day cycle, while D was given at a dose of 12 mg/m^2 p.o., on days 1-2, 4-5, 8-9 and 11-12. DXA of the lumbar spine (L1-L4) and the femoral neck (FN) was performed at baseline, on day 21 of cycles 4 and 8 and then every 3 months for up to 18 months post-VD or at PD. Skeletal survey using conventional radiography was performed at baseline, on day 21 of the 8th cycle and then every 6 months for up to 18 months post-VD or at PD.

Results: In total, 17 patients (median age: 70y, range: 56-86y) were enrolled; 14 had received2, one 3 and one 5 lines of previous therapies. At baseline, 2 patients had no osteolytic lesions, one had only one lytic lesion, while 14 patients had multiple lytic lesions (5 had >10 lesions) or multiple fractures (6 patients). Twelve patients completed the 8 VD cycles, while 2 patients received 6 cycles due to peripheral neuropathy, one received 5 cycles and then progressed and two patients died after receiving one and two VD cycles, respectively (due to heart attack and sepsis). Overall, we evaluated 15 patients who completed 4 cycles of therapy; 12 (70%) achieved a PR and two had stable disease. Regarding the primary objective of the study, there was a dramatic improvement of BMD after 4 cycles of VD: median T-score for L1-L4 increased from +0.53 to +0.90 (P=0.013), for the lowest T-value of L1-L4 from -1.29 to -0.34 (P<0.01) and for FN from -2.25

to -1.80 (P=0.027). This improvement was continued for the 8 cycles of VD: median T-score for L1-L4 was 1.56 (P<0.01), for the lowest value of L1-L4 0.97 (P<0.01) and for FN -2.0 (P<0.01). Patients reduced the VAS pain score dramatically after 4 and 8 cycles of therapy (median, range: from 5 (3-10) at baseline to 1.5 (1-5) and 0.3 (0-3) after 4 and 8 cycles, respectively; P<0.01), while they showed no new lytic lesions and no new SREs during the 8 cycles of therapy. Patients showed an increase of both bone formation markers bALP and OC after 4 (P<0.01) and 8 cycles of therapy (P<0.01) along with a reduction of CTX (P<0.01 for both comparisons). During follow-up period of 18 months, 12 patients relapsed (median TTP: 7.5 months), 7 patients showed new lytic lesions but no patient developed a new SRE. Both markers of bone formation reduced at progression, while CTX remained suppressed.
Summary and Conclusions: Our study supports the beneficial effect of bortezomib on BMD when it is given in combination with D and ZOL. This combination reduces pain and bone resorption, while it increases bone formation. Bone formation reduced again at disease progression.

P810

LONG TERM THERAPY WITH LENALIDOMIDE DOES NOT SIGNIFICANTLY AFFECT THE CELLULAR COMPOSITION OF THE BONE MARROW
A Brioli[1,2,*], R Morilla[1], C Stephens[1], I Titley[1], G Vijayaraghavan[1], L Melchor[1], M Cavo[2], F Davies[1], G Morgan[1]
[1]Haemato-Oncology Research Unit, Institute of Cancer Research, London, United Kingdom, [2]Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy

Background: Maintenance therapy is an attractive option for MM patients and three recent studies have shown that Lenalidomide (Len) maintenance significantly improves PFS and, in one of them, also OS;[1-3] however concerns have been raised regarding the possibility that long term therapy might increase the risk of second primary malignancies (SPMs).[1-3] Len has a known myelosuppressive effect, but its mechanism of action on the bone marrow (BM) still needs to be fully elucidated.
Aims: To evaluate the impact of Len on the BM we have performed a flow cytometry analysis of BM of MM patients.
Methods: Three, 8 colour, panels (Pacific Blue, Pacific Orange, FITC, PE, PerCP-Cy 5.5, PE-Cy7, APC, APC-H7) were used to investigate relative percentages of the different BM populations (CD3, CD45, MPO7, CD79a, CD34, CD19, CD7, HLADR), B cells (CD20, CD45, TdT, CD10, CD34, CD19, CD123, CD38) and myeloid cells (CD16, CD45, HLADR, CD13, CD34, CD117, CD11b, CD10).[4]
Results: Thirteen samples from 12 patients who have received Len therapy have been analyzed; 5 samples from MM patients who never received Len were used as controls. Whilst no differences could be seen in terms of percentages of T cells and myeloid cells, a decrease in the number of CD19+ B cells was observed in Len treated patients. The decrease of B lymphocytes in patients receiving Len was due to a reduction of the CD19+ population as a whole and not of specific subpopulations. The lowest values were observed in patients on Len for >1 year, and a concomitant relative increase in the CD19- lymphoid population was also observed. No significant difference was observed in the myeloid population either in the percentage of the CD13+ myeloid cells or in the relative percentages of the different fractions (myeloid precursors, myelocytes, metamyelocytes, neutrophils). However, patients receiving Len showed a trend towards a higher percentage of immature myeloid and B cell forms (Table 1).

Table 1.

	Time point	N pts					
BM populations			Myeloid cells		T cells		B cells
	No Len	5	45.6%		9.4%		5.2%
	Len<12 months	7	50.3%		16.1%		4.6%
	Len>12 months	6	47.8%		12.7%		1.8%
Tot		18					
B cells			CD19+	Haemato-gones	Pre B	Naïve B	Mature B	CD19-
	No Len	5	26.5%	0.9%	24.2%	50.1%	22.4%	63.8%
	Len<12 months	6	12.5%	1.4%	40.2%	33.8%	10.5%	78.1%
	Len>12 months	6	5.1%	2.1%	31.7%	29.6%	12.2%	94.8%
Tot		17						
Myeloid cells			CD13+	Myeloid precursors	MC	MMC	PMN	
	No Len	5	48.9%	0.4%	28.4%	33.0%	21.0%	
	Len<12 months	6	55.3%	6.9%	22.9%	26.9%	16.6%	
	Len>12 months	6	54.9%	0.7%	28.3%	26.5%	26.1%	
Tot		17						

Summary and Conclusions: We were unable to identify any cellular indication that Len treated patients are more likely to develop hematologic SPMs, such as a significantly higher percentage of immature forms or the co-expression of aberrant markers. We saw no indication of immune stimulation and furthermore we were able to show that patients on Len have a lower percentage of B cells, that is proportional to the time on Len therapy.

A RETROSPECTIVE REVIEW OF THE INCIDENCE OF CONTRAST INDUCED NEPHROPATHY IN THE MYELOMA SETTING
M Crowley[1,2,*], V Prabhakaran[3], O Gilligan[1]
[1]Hameatology, Cork University Hospital, [2]Clinical Research Facility University College Cork, [3]Medicine, University College Cork, Cork, Ireland

Background: Multiple myeloma is a malignant plasma cell disorder accounting for approximately 10% of haematological malignancies. Renal impairment is a common complication of myeloma. Myeloma patients frequently require contrast enhanced procedures given their age (average age at diagnosis is 69), co-morbidities, and their higher than normal risk of venous thrombo-embolism and second malignancies. Contrast induced nephropathy (CIN) is a reversible form of acute renal failure. The patho-physiology is not well understood but contrast is thought to lead to the precipitation of light chains leading to renal tubular obstruction. The incidence in myeloma patients is thought to be 4-8 times that of the general population. There are few dedicated studies on the subject and these focus on computed tomography (CT) only.
Aims: To investigate the incidence of CIN in myeloma patients undergoing contrast enhanced radiological procedures and to identify risk factors that predispose myeloma patients to CIN.
Methods: The medical charts of patients with a diagnosis of myeloma attending a tertiary referral centre in Ireland between Jan 1st 2007 and Dec 31st 2012 were retrospectively reviewed to ascertain the incidence of CIN, defined as an increase in creatinine >25% or an absolute increase of 44umol/L within 7 days of a contrast enhanced procedure. Patient demographics, staging and myeloma subtypes were analyzed to see if there were clear risk factors for developing CIN. Ethical approval was obtained from the ethics committee governing the institution.
Results: 217 patients with myeloma were identified. 112 patients had undergone a total of 240 contrast-enhanced procedures. 18 patients were excluded as they were on dialysis, the procedures were performed prior to myeloma diagnosis or they did not have appropriate blood tests performed. This left 94 patients and 165 procedures available for analysis. The male to female ratio was 3:2. IgG, IgA and Light chain were the most common subtypes accounting for 47%, 24% and 20% respectively. 21% were ISS stage I, 40% stage II and 18% were stage III (stage was unknown in 20%). Overall, there were 3997 months of follow-up with a median follow up of 35 months per patient (Range 1- 147). Patients had on average of 1.8 scans (Range 1-7). 86% of procedures were CTs. The remainder were venograms (8%), coronary angiograms (4%), lower limb angiograms (1%) and intravenous pyelograms (1%). 36% of pre-procedure creatinines were elevated (>104 umol/L). 2% of pre-procedure calcium levels were elevated (>2.62 mmol/L). 18/165 (11%) met the criteria for CIN. 61% (11/18) of creatinines returned to baseline within one month. Non-parametric tests were carried out to see if there was any association between baseline creatinine, baseline calcium, myeloma subtype, type of procedure and development of CIN but none were found to be significant.
Summary and Conclusions: Contrast induced nephropathy occurred in 11% of this population. CIN is important to consider before performing a contrast-enhanced procedure on a patient with myeloma as a deterioration of their renal function may significantly worsen their prognosis. The risk of CIN should not be an absolute contraindication to scanning in the appropriate clinical setting, rather a reminder to the clinician to minimize concomitant nephro-toxic agents and to give special attention to fluid balance at the time of the procedure. This is the largest series to date investigating this issue.

EFFECTS OF BORTEZOMIB ON RENAL IMPAIRMENT MULTIPLE MYELOMA PATIENTS
W Chen[1,*], J Lu[2], J Hou[3]
[1]Hematology, Beijing Chaoyang Hospital, Capital Medical University, [2]Hematology, People's hospital, Beijing University, Beijing, [3]Hematology, Changzheng hospital, The Second military medical university, Shanghai, China

Background: Bortezomib was widely used on Chinese multiple myeloma (MM) patients, but its effects on renal function insufficiency MM patients were real reported.
Aims: To retrospectively analyze the clinical features of myeloma patients with renal impairment who were treatment by bortezomib-based regimens in 3 Chinese top myeloma centers.
Methods: 958 newly diagnosed symptomatic MM patients were involved in this study. Those patients were diagnosed during the year 2005-2011 in the 3 centers. Clinical characteristics of the 958 symptomatic MM patients analyzed, and divided to bortezomib-based or non-based group. The response was defined according to IMWG criteria.
Results: The median age of patients was 59 years (range, 23-88), with 583 males and 375 females (1.55:1). The most common monoclonal protein was IgG subtype (43.7%). 230 patients (24.0%) presented with renal impairment (serum creatinine >176.8 μmol/L), while the renal impairment rate in subtype IgD, λ and κ was 50%, 40.3% and 36.6% respectively. With a median follow-up of 17.3 months, the estimated median PFS and OS time were 28.3 and 61.0months, respectively. Patients who received bortezomib-based regimens demonstrate a longer estimated median PFS and OS time compared with those who received non-bortezomib-based regimens (34.4 months *vs.* 24.9 months; P<0.001; not reached *vs.* 50.7 months; P=0.005). The estimated median OS time of patients with renal impairment was shorter than that of patients with normal renal function (41.7months *vs.* 63.4 months, P<0.001), but the estimated median PFS time of these two groups didn't show statistic difference (26.7 months *vs.* 28.4 months, P>0.05). Response rate was analyzed in 680 patients who had available data. 528 patients (77.6%) achieved either a complete response (CR; 21.9%), a very good partial response (VGPR; 17.8%) or a partial response (PR; 37.9%). Patients who received bortezomib-based regimens demonstrated an improved ORR compared with those who received non-bortezomib-based therapy (84.2% *vs.* 58.3%; P<0.001). The overall response rate (ORR) in patients with renal impairment was 75.8%, with 16.1%, 13.4% and 46.3% of patients achieving CR, VGPR and PR, respectively. In this population, patients who received bortezomib-based regimens showed a better ORR compared with non-bortezomib group (84% *vs.* 58.3%).
Summary and Conclusions: The median age of Chinese MM patients is younger then the other counteies. Bortezomib-based regimens were able to improve OS and ORR in MM patients with or without renal impairment.

THE MM-021 CHINA REGISTRATION TRIAL: A PHASE 2 STUDY OF LENALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE IN CHINESE RELAPSED/REFRACTORY MYELOMA PATIENTS

J Hou[1,*], X Du[2], J Jin[3], Z Cai[3], F Chen[4], D Zhou[5], L Yu[6], X Ke[7], X Li[8], D Wu[9], F Meng[10], H Ai[11], J Zhang[12], N Chen[12], J Mei[12], J Wang[13]
[1]Shanghai Changzheng Hospital, Shanghai, [2]Guangdong General Hospital, Guangzhou, [3]The First Affiliated Hospital, Zhejiang University, Hangzhou, [4]Xiangya Hospital of Central South University, Changsha, [5]Peking Union Medical College Hospital, [6]The 301 Military Hospital, [7]Peking University Third Hospital, Beijing, [8]Shanghai Sixth People's Hospital, Shanghai, [9]The First Affiliated Hospital of Suzhou University, Suzhou, [10]Nanfang Hospital, Southern Medicine University, Guangzhou, [11]The 307 PLA Hospital, Beijing, China, [12]Celgene Corporation, Summit, NJ, United States, [13]Changhai Hospital, Shanghai, China

Background: In China there is an unmet clinical need for the effective treatment of patients (pts) with relapsed/refractory multiple myeloma (RRMM), and multiple myeloma (MM) pts who cannot tolerate bortezomib and/or thalidomide. Previous studies have shown that lenalidomide (LEN)+low-dose dexamethasone (DEX; LoDEX) may have a better safety profile compared with LEN+high-dose DEX in newly diagnosed MM pts. It is hypothesized that LEN+LoDEX may also provide benefits in pts with RRMM. The MM-021 China Registration Trial is one of the largest studies in Chinese pts with RRMM.
Aims: The trial assessed the safety, efficacy, and pharmacokinetic (PK) profile of LEN+LoDEX in Chinese pts with RRMM.
Methods: In this phase2, multicenter, single arm, open-label study, 199 pts received LEN (25 mg/day on days 1–21) and LoDEX (40 mg on days1,8,15, and 22; or 20 mg in pts aged >75 years [yrs]) in each 28-day cycle until progression. The primary end-point was overall response rate (ORR; defined as at least partial response; based on IRAC review) and the secondary end-points included duration of response (DOR), progression-free survival (PFS), overall survival (OS), safety, and PKs. All pts provided informed consent.
Results: As of September 26, 2012, 187 pts were evaluable for efficacy and 199 pts were evaluable for safety. Median age was 60 yrs (range 35–81), 86% of pts had advanced MM (Durie-Salmon stage 3), and 57% had received ≥4 prior therapies. After a median treatment of 8 months (mos) (range 1–23), the ORR was 48% (N=187) with complete response in 4% of pts, which was consistent regardless of renal function (Table 1). Median time to first response was 2 mos (range 1–10), DOR was 9 mos (range 0.4–19), PFS was 8.3 mos (95% CI: 6.5–9.8), and 1-yr OS rate was 72%. Most common grade 3–4 adverse events (N=199) were anemia (26%), neutropenia (25%), thrombocytopenia (15%), and pneumonia (13%). Febrile neutropenia and deeP-vein thrombosis were experienced by 1 pt (0.5%) each. LEN was rapidly absorbed and eliminated (T_{max}: 0.93 [range 0.5–1.0] h; $t_{1/2}$ 3.34 [41.9] h) with no evidence of accumulation. Co-administration with DEX did not affect LEN multiple-dose PKs.
Summary and Conclusions: LEN+LoDEX was associated with a relatively high response rate and was generally well tolerated in this heavily pretreated population of Chinese RRMM pts. The PK profile was similar to that observed in studies of Caucasian and Japanese pts. LEN+LoDEX has the potential to address the unmet clinical need for effective treatment of Chinese pts with RRMM.

Table 1. Response rates in Pts receiving LEN+LoDEX.

	n (%)
Overall Response (N = 187)	89 (48)
Prior therapies (N = 199)	
1–3	86 (43)
≥ 4	113 (57)
Renal impairment (N = 199)	
None-to-mild (CrCl ≥ 60 mL/min)	131 (66)
Moderate (CrCl ≥ 30 to < 60 mL/min)	54 (27)
Severe (CrCl < 30 mL/min)	14 (7)
Patients with IgD (N = 199)	10 (5)

CrCl, creatinine clearance; IgD, immunoglobulin D.

Myeloproliferative neoplasms - Clinical 2

P814

SENSITIVE MONITORING OF V617F POINT MUTATIONS OF THE JAK2 GENE USING ULTRA-DEEP AMPLICON RESEQUENCING

C Heiderich[1,*], S Herold[2], U Platzbecker[2], H Baurmann[3], J Schetelig[2], M Bornhäuser[2], G Ehninger[2], C Thiede[1,2]
[1]AgenDix GmbH, [2]Medizinische Klinik und Poliklinik1, Universitätsklinikum Carl Gustav Carus, Dresden, [3]Zentrum f. Knochenmark- und Blutstammzelltransplantation, Stiftung Deutsche Klinik f. Diagnostik GmbH, Wiesbaden, Germany

Background: Detection of minimal residual disease has become one of the most important fields of diagnostics in hematology. Whereas translocations can be sensitively monitored using Real-Time qunatitative PCR (QPCR), detection of point mutations using QPCR is much more challenging, because of unspecific background amplification. Next-Generation sequencing is a novel procedure, which not only allows genome wide analysis of genetic alterations, but also for the first time enables to study point mutations with much higher sensitivity compared to Sanger sequencing, because by increasing the number of reads per amplicon up to several 100.000 (ultra-deep sequencing; UDS) in principle enables detection of even very small clonal populations of mutant alleles. However, PCR using conventional *Taq*-DNA-polymerases is known to be error prone, thereby limiting this theoretical value to a usable sensitivity of about 0.5-1%.
Aims: To overcome this limitation and to make NGS-based single base mutation analysis with sufficient sensitivity practically available, we studied the G1849T mutations of the JAK2-gene leading to V617F as a prototypical single base pair point mutation, and we here describe an optimized procedure for the sensitive and quantitative detection of the V617F single base pair point mutations in JAK2 using NGS-based UDS.
Methods: All analyses were performed on an IonTorrent PGM semiconductor based device. Different chiP-sizes were tested, enabling read numbers between 800.000 and 7.000.000/chip. Cell dilutions of V617F-positive HEL-cells as well as normal peripheral blood cells were studied using several reaction conditions (amount of template, cycle numbers, different proof-reading and non-proof-reading enzymes). To explore the potential clinical applicability of this method, we analyzed 152 serial follow-up samples of 15 patients with JAK2-mutated diseases (OMF; n=13, sAML; n=2) undergoing allogeneic stem cell transplantation (SCT).
Results: Among the different parameters tested, especially the use of a high accuracy, proofreading enzyme significantly decreased the background of unspecific mutations and allowed to increase the sensitivity by a factor of 5-10 fold. Using cell dilutions of the HEL cell line as well as DNA from a patient with PV and homozygous JAQ2 V617F-mutation, we were able to reliably detect and quantify one mutant V617F-positive cell in a background of 10.000 cells when applying a coverage of 100.000 reads per amplicon. This sensitivity could be further improved by an increase of the read-depth. To study the clinical applicability, we analyzed follow-up samples of patients after SCT. A total of 20.000.000 reads was performed, median read depth per sample was 130.000 (range 73.000-207.000). Median follow-up was 1237 days (range 52-2697 days), 3 patients developed clinical relapse, (med. 1111 days post Tx; range 382-1292 days). UDS for JAK2 V617F detected an increase of mutant alleles in median 203 days before clinical relapse (range 176-296 days). All patients below the detection threshold of 0.01% remained in clinical remission.
Summary and Conclusions: Taken together, our results indicate that UDS for a single-base pair point mutation using next generation sequencing on a semiconductor based device is feasible with excellent sensitivity and reproducibility. Using our optimized conditions, we were able to monitor patients after SCT and show that early detection of relapse is possible. UDS thus may become an important tool to monitor MRD post treatment.

P815

TITLE: SURVEY FOR THE VALIDATION OF MODIFIED MPN-SYMPTOM ASSESSMENT FORM FOR PATIENTS WITH MAST CELL DISORDERS

D Radia[1,*], C Perkins[2], H Claire[3], R Mesa[4], J Gotlib[5]
[1]Haematology, Guys & St Thomas' NHS Foundation Trust, London, United Kingdom, [2]Stanford University School of Medicine/Stanford Cancer Institute, Stanford CA, United States, [3]Haematology, Guys & St Thomas' Hospitals NHS Foundation Trust, London, [4]Clinical Haematoloy/Medical Oncology, Mayo Clinic Cancer Center, Arizona, United Kingdom, [5]Stanford University School of Medicine/Stanford Cancer Institute, Stanford CA, United States

Background: Patients with Mast Cell Disorders (MCD) represent a rare, clinically heterogeneous population.Patients can be completely asymptomatic patients to those with debilitating mediator symptoms. To date there is no single validated tool available to measure the impact on the quality of life/efficacy of treatments used.
Aims: To develop a validated QOL tool for MCD patients.
Methods: This is a collaborative study between Stanford University(USA)and Guys & St Thomas' Hospital (UK). The MPN-SAF TSS 10 form is a validated QOL tool standard used in clinical practice (Emmanuel *et al.*). We modified the MPN-SAF TSS by adding 12 MCD specific questions. Each question was given a rating score of 0-10. Specific questions were asked about skin symptoms and anaphylaxis. A free text question regarding whether the survey addressed all symptoms for MCD and /comments was added. We included the validated Fatigue Inventory (Cleeland: MD Anderson).Ethics approval was granted to carry out a validation survey of this anonymised electronic questionnaire. The survey was presented to the UK and USA SM patient support groups in October and November 2012. The questionnaire takes 15-20 minutes to complete.
Results: Data collection: October 2012– January 2013. Total number of completed responses=258 (UK 78;SA 171;Other 9).M:F ratio 1:5.8. Median age of responder 48.7 yrs (range 18-87). Patient declared diagnosis: Cutaneous Mastocytosis (13%), Indolent SM (34%), Smouldering SM (3%) ASM (4%), SM-AHNMD (4%), Mast Cell Activation Syndrome (26%), don't know (7%) and other (9%). Skin Symptoms: 62% (159/258) patients had skin symptoms. Treatment modalities used: topical steroids, Epsom salts, PUVA, ice, laser treatment, surgical removal, cauterisation, antifungal and antibiotic creams and anti- histamines. Anaphylaxis: 44% (114/258) patients reported anaphylactic reactions; 50% (57/114) had been hospitalised as a result in the 6 months proceeding the time of questionnaire, 43% (49/114) of these patients needed to use epipens over the proceeding 12 months (median number of injections 2–range 1-10). Treatment modalities reported where complex and multiple with the majority of patients requiring between 4–12 combination drugs (H2, H1 antagonists, mast cell stabilisers, Leucotriene inhibitors, antiepileptics, sedatives and neuroleptics to manage symptoms.
Summary and Conclusions: This is the largest cohort of Mast Cell Patients completing a single validation survey. The data confirms the significant burden of MCD on their quality of life. This preliminary data on TSS and MCD symptom scores is being analysed and suggestions by the patients from this survey have been incorporated in an updated version. Further detailed analysis is also being carried out to compare the TSS scores with related MPN patients.

P816

LONG TERM FOLLOW-UP OF TREATMENT WITH IMATINIB IN EOSINOPHILIA-ASSOCIATED MYELOID/LYMPHOID NEOPLASMS WITH PDGFR REARRANGEMENTS IN ADVANCED PHASE

G Metzgeroth[1,*], D Gosenca[1], A Fabarius[1], J Schwaab[1], H Baurmann[2], C Haferlach[3], T Haferlach[3], N Cross[4,5], W Hofmann[1], A Reiter[1]
[1]III. Medizinische Klinik, Hämatologie und Onkologie, Universitätsmedizin Mannheim, Mannheim, [2]Stiftung Deutsche Klinik für Diagnostik, Wiesbaden, [3]MLL, Münchner Leukämielabor, München, Germany, [4]Wessex Regional Genetics Laboratory, Salisbury, [5]Faculty of Medicine, University of Southampton, Southampton, United Kingdom

Background: On treatment with imatinib, the vast majority of eosinophilia-associated myeloid/lymphoid neoplasms (MLN-eo) with *PDGFR* rearrangements in chronic phase achieve rapid and durable complete hematologic (CHR) and also complete molecular remissions (CMR).
Aims: We here report on long-term follow-up of 17 patients with advanced disease which was defined as i) myeloid blast phase [MBP, >20% blasts in peripheral blood (PB) and/or bone marrow (BM)], ii) extramedullary tissue infiltration by myeloid blasts (chloroma) or iii) lymph node (LN) infiltration by lymphoblasts of T-cell origin (lymphoid BP, LBP).
Results: 13 patients were *FIP1L1-PDGFRA* (FP) positive (MBP, n=8; chloroma, n=2; LBP, n=3). In 3 patients, *FP* could be identified contemporaneously in myeloid cells obtained from BM and CD3-positive lymphoblasts obtained from LN. 4 patients (MBP, n=2; LBP, n=2) were positive for a rearrangement of *PDGFRB* (partner genes: *ETV6*, n=1; *DTD1*, n=1; *SART3*, n=1; unknown partner gene, n=1). All patients were male (median age, 46 years, range 37-66). Significant eosinophilia >1.5×10^9/l was present in 12 of 13 (92%) *FP*-positive patients and 2 of 4 (50%) patients with *PDGFRB* fusion genes. The most common clinical features included splenomegaly (17/17) and organ involvement of skin (4/17), lung (4/17) and heart (3/17). Without primary knowledge of the underlying fusion gene, 9 patients received intensive chemotherapy. Despite clear signs of remission, *e.g.* clearance of blasts, eosinophilia persisted in all 9 patients. The underlying fusion genes (*FP*, n=6; *X-PDGFRB*, n=3) were subsequently identified and imatinib was initiated in 7 of 9 patients. At diagnosis of MBP, *FP* was identified in 8 patients and imatinib was initiated directly. Overall for the 15 imatinib-treated patients (starting dose 400mg/d, n=6; 100mg/d, n=9), CHR was achieved in every case after a median of one month (0.1-15). CMR was detected in all 12 *FP* positive patients after a median of 5.4 months (2.9-32.0). One patient died due to a cerebral hemorrhage while in CMR for 8.6 months. The remaining 11 patients are in sustained CMR for a median of 65 months (7-103). The 3 patients with a *PDGFRB* fusion gene are in sustained CHR for median 56 months (24-56). Two patients (*FIP1L1-PDGFRA*, n=1; *ETV6-PDGFRB* plus complex karyotype, n=1) received an allogeneic stem cell transplantation (SCT) within 6 months (related donor, n=1; unrelated donor, n=1) after diagnosis of MBP but both patients relapsed within the first 3 months. Following relapse, the *FP* positive patient was treated with imatinib and is in sustained CMR up to 236 days after SCT. The *ETV6-PDGFRB* positive patient relapsed 4 weeks after SCT with leptomeningeal

involvement. On imatinib, he achieved CHR and CMR in PB and BM but subsequently died due to progressive leptomeningeal involvement.
Summary and Conclusions: In conclusion, our data highlight several new aspects for diagnosis and treatment of MLN-eo with *PDGFR* fusion genes: i) mimicking *de novo* AML, blast phase of MLN-eo with an underlying imatinib-sensitive *PDGFR* fusion gene is frequently not identified, ii) in the absence of *CBF* fusion genes, patients with eosinophilia and increased numbers of blasts should be actively screened for *PDGFR* fusion genes by cytogenetics, FISH and/or PCR and iii) our excellent long-term data suggest that monotherapy with imatinib should be initiated early because durable remissions can not be achieved through intensive chemotherapy or allogeneic SCT.

P817

JAK2V617F MONITORING IN POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA: CLINICAL USEFULNESS FOR PREDICTING MYELOFIBROTIC TRANSFORMATION

A Alvarez-Larrán[1,*], B Bellosillo[2], A Kergelen[3], J Hernández-Boluda[4], A Pereira[5], R Longarón[2], L Martínez-Avilés[2], A Ancochea[1], A Angona[1], L Lombardia[6], B Navarro[4], M Collado[4], J Montoro[4], C Besses[1]
[1]Hematology, [2]Pathology, Hospital del Mar, Barcelona, [3]Hematology, Hospital La Paz, Madrid, [4]Hematology, Hospital Clínico Universitario, Valencia, [5]Hemotherapy and Hemostasis, Hospital Clínic, Barcelona, [6]Centro Nacional de Investigaciones Oncológicas, Madrid, Spain

Background: The JAK2 V617F allele burden, assessed at a single time-point either at diagnosis or during follow-up, has been related with the risk of thrombosis and disease transformation in polycythemia vera (PV) and essential thrombocythemia (ET). However, the JAK2 V617F allele burden does not remain stable in all cases, since it can be modulated by cytoreductive therapy or by the natural clonal evolution of the disease.
Aims: To evaluate the clinical usefulness of monitoring the JAK2 V617F allele burden for predicting disease transformation in patients with PV and ET.
Methods: JAK2V617F monitoring was performed by quantitative allele specific PCR in the peripheral blood granulocytes from 346 patients (PV=162, ET=184). Median time from diagnosis to first JAK2V617F quantification was 10 months, with 196 patients (80%) starting on molecular monitoring in the first year after diagnosis. Median molecular follow-up was 2.3 years (range: 0.5- 12). In each patient, the evolutionary pattern of the JAK2V617F allele burden was stratified as following: stable <25%, stable 25% to 49%, stable 50% to 74%, stable ≥75%, progressive increase and unexplained decrease. Patients receiving cytoreductive therapy were assigned to their corresponding category after achieving a steady state (usually after 6-12 months of therapy). The probability of disease transformation (myelofibrosis and acute leukemia) according to the evolution of the JAK2V617F allele burden was calculated by the Kaplan-Meier method.
Results: Patients were stratified according to their JAK2V617F evolutionary patterns as follows: stable <25% (n=162, PV 45, ET 117), stable 25% to 49% (n=97, PV42, ET 55), stable 50% to 74% (n=25, PV 23, ET 2), stable ≥75% (n=26, PV 25, ET1), progressive increase (n=25, PV 17, ET 8) and unexplained decrease (n=11, PV10, ET 1). Twenty-six patients evolved into myelofibrosis (18 post-PV, 8 post-ET) at a median of 9 years after diagnosis. The pattern of the JAK2V617F allele burden in these 26 patients was stable <50% (n=3), stable ≥50% (n=7), progressive increase (n=12) and unexplained decreased (n=4). The probability of myelofibrosis at 10 years from diagnosis was 0% in PV patients with a stable JAK2V617F mutational burden below 50% in comparison with 21% in the combined group of PV patients showing a JAK2V617F stable ≥50%, a progressive increase or an unexplained decrease of the JAK2V617F (P=0.001). In ET, the probability of myelofibrosis at 10 years was 4.5% in patients with stable JAK2V617F below 50% in comparison with 31% in cases with stable JAK2V617F >50%, progressive increase or unexplained decrease of the JAK2V617F (P<0.001). Five patients with ET fulfilled PV criteria during follow-up, with 3 of them having a documented progressive increase in the JAK2V617F mutational load prior to PV transformation. Acute leukemia developed in 9 patients. No correlation was observed between the JAK2V167F evolutionary pattern in the chronic phase and leukemic transformation.
Summary and Conclusions: Quantitative JAK2V617F monitoring is useful in the clinical follow-up of patients with PV and ET for predicting myelofibrotic transformation.

P818

CLINICOPATHOLOGICAL CHARACTERISTICS OF ADULT PATIENTS WITH ABNORMAL MAST CELLS WHO DO NOT MEET WHO DIAGNOSTIC CRITERIA FOR CUTANEOUS OR SYSTEMIC MASTOCYTOSIS

A Pardanani[1,*], R Abdelrahman[1], D Zblewski[1], C Hanson[2], A Tefferi[1], D Chen[2]
[1]Hematology, [2]Hematopathology, MAYO CLINIC, Rochester, United States

Background: Current diagnostic criteria for systemic mastocytosis (SM) require meeting one major (aggregates of ≥15 mast cells [MC]) and one minor, or at least three minor criteria (>25% MC are spindled, presence of *KIT*D816V mutation, MC expression of CD25 or CD2, and serum tryptase level >20 ng/mL) in extra-cutaneous organs. Routine screening of patients suspected of SM has revealed a subgroup with sub-diagnostic involvement (ie. satisfy only 1-2 minor criteria). The latter group has hitherto not been systematically studied.
Aims: To describe the clinicopathological characteristics of patients with sub-diagnostic systemic involvement with abnormal MC, and to compare the findings to patients with indolent SM.
Methods: We retrospectively studied consecutive patients suspected of SM on the basis of characteristic symptoms, who were found to satisfy only 1 or 2 minor criteria for SM. Since transient elevation of tryptase level >20 ng/mL can be seen after activation of normal MC, we did not count this as a minor criterion for this study. Patients with characteristic skin involvement by mastocytosis were excluded. Bone marrow (BM) histology was centrally reviewed (DC, CAH); MC number and morphology was studied by tryptase/CD117 stain and MC CD25/CD2 expression by immunohistochemistry and/or flow cytometry. Presence of *KIT*D816V was studied on BM aspirate by allele-specific PCR (≤0.01% sensitivity).
Results: Twenty one patients (62% female; median age at diagnosis 48 years) were included in the study. Per definition, none of the patients exhibited BM MC aggregates; the MC were distributed singly and the overall BM involvement was minimal (≤1%) in all cases. Fifteen patients (71%) satisfied one SM minor criterion only (CD25/CD2 expression=9; *KIT*D816V=6). The remaining 6 patients satisfied 2 minor criteria (*KIT*D816V plus CD25/CD2 expression=4; >25% spindled MC plus either *KIT*D816V or CD25/CD2 expression=1 each). The median time from symptom onset was 60.1 months (range 2-363.6). Five patients (24%) reported prior anaphylaxis episode(s); prevalence of symptoms was as follows: dermatological (hives, flushing, pruritus) 86%, cardiovascular (palpitations, chest pain, syncope) 76%, gastrointestinal (nausea, vomiting, diarrhea, abdominal cramps) 57%, and neurological (headache, cognitive difficulties, paresthesias, vertigo) 48%. The median hemoglobin level was 14.5 g/dL (range 10.2-16.6), leukocyte count 7.1×10^9/L (range 4.3-11.1) and platelet count 261×10^9/L (119-400). The baseline serum tryptase level was 10.6 ng/mL (range 2.7-23.4). A tryptase level above normal range (≥11.5 ng/mL) and >20 ng/mL was noted on at least one occasion in 61% and 37% of patients, respectively. Abnormal MC were identified most frequently by MC immunophenotyping (*n*=17; 82% positive), followed by *KIT*D816V (*n*=18; 61% positive). MC morphology was relatively insensitive, with only 2 patients (10%) exhibiting >25% spindled cells in the current cohort; no patient was identified on the basis of MC morphology alone.
Summary and Conclusions: The current data reveal a high symptom burden despite minimal BM involvement with abnormal mast cells in patients not meeting the threshold for systemic mastocytosis. Mast cell immunophenotyping and *KIT*D816V mutation analysis are key screening tests since they identified most cases. In contrast, baseline serum tryptase was normal in 58% cases and >20 ng/mL in only 11%. Similarly, assessment of mast cell morphology was of limited utility in this setting. These data if confirmed independently may influence future diagnostic criteria for systemic mastocytosis.

P819

HOW MANY CHILDREN WITH THROMBOCYTOSIS OF "UNDEFINED ORIGIN" HAVE A MYELOPROLIFERATIVE NEOPLASM?

M Randi[1,*], M Putti[2], G Geranio[2], I Bertozzi[1], C Micalizzi[3], P Giordano[4], L Notarangelo[5], F Tucci[6], G Menna[7], S Ladogana[8], G Fiori[9], P Farruggia[10], G Basso[2], F Fabris[1]
[1]Dep. Internal Medicine - DIMED, [2]Dept of Woman and Child Health, Hemato-Oncology, University of Padova, padova, [3]Hemato-Oncology Dept, Gaslini Institute, Genova, [4]Dept of Biomedical and Oncology Sci, University of Bari, Bari, [5]Pediatric Oncol-Hematol, Spedali Civili, Brescia, [6]The Pediatric Clinic, Meyer Hospital, Florance, [7]Paediatric Haematology Unit, Pausilipon Hospital, Napoli, [8]Pediatric Onco-Hematology, San Giovanni Rotondo, [9]Pediatric Onco-Hematology, Ospedale microcitemico, Cagliari, [10]Dept of Oncology, Palermo, Italy

Background: Chronic Myeloproliferative Neoplasms (MPN) are clonal diseases of middle-advanced age while they are extremely rare in pediatric patients.*JAK2*V617F mutation is the main molecular marker of MPN, occurring in the great majority of patients: 95% of patients with polycythemia vera (PV) and 50-60% of those with essential thrombocythemia (ET)andmyelofibrosis (PMF).The rare cases of children with MPN seem to have different biological characteristics in comparison to adult MPN, but few data are published on this subject.
Aims: In this study, we report our experience in a large cohort of pediatric patients with high platelet count in whom *JAK2*V617F and *MPL*mutations have been searched.
Methods: We report 86 children with sustained thrombocytosis (>600×10^9/L) over at least 6 months, in the absence of recognizable reactive or secondary cause, followed in one of the Centers linked to the Italian Pediatric Hemato-Oncology Association. There was no family history of MPN. The genotyping of the *JAK2*V617F mutation was performed by allele-specific PCR and the mutant allele-burden was measured by quantitative real time-polymerase chain reaction assay.*MPL*mutations were searched by direct sequencing. Clonality was studied on females according to HUMARA method.Differences in the distribution of continuous variables between categories were analyzed by the Mann-Whitney test.

Results: *JAK2*V617F mutation was found in 11 (13.4%) patients (allele burden 26.26±9.78%).Mutations in the *MPL* gene were searched in 57 patients with thrombocytosis and one (1.7%) had a somatic mutation (W515L). Clonality was available in 21 females and 6 of them (26.5%) resulted monoclonal (2 carrying JAK2 mutation). On a whole 18.6% of patients had a clonal disease, while other 74 patients had a thrombocytosis of undefined origin. In the Table 1 the hematological data of the patients are summarized.

Table 1.

	Clonal		Non Clonal		
	Median	Percentile range, 5th to 95th	Median	Percentile range, 5th to 95th	P
Plts (x 10^9/L)	1027	481 – 2370	1078	447,7 – 3156,35	n.s.
WBC (x 10^9/L)	7,89	5,5 – 11,8	9,15	5,3125 – 22,33	n.s.
Ht (%)	39,45	28,4 – 45	33	12,21 – 41,17	n.s.
Hb (g/dL)	13,6	9,3 – 14,4	12,3	7,1 – 14,3	n.s.

Summary and Conclusions: Our data confirm that clonal ET is rarely found even in children with sustained, prolonged thrombocytosis without any recognizable cause. No significant hematological difference was observed between patients with a sure MPN and those with an undefined thrombocytosis. *JAK2*V617F mutation is uncommon and other mutations such as *MPL*W515L are anecdotal. If clonal ET in pediatrics would represent 50-60% of all ET as it is in adults, then additional 40% of children would be found within our series, their number adding at the most to 10 children. Therefore, all other studied patients could be "undefined thrombocytosis" and their diagnostic process and follow-up need to be further established.

P820

IMPACT OF CYTOREDUCTIVE THERAPY ON THE OUTCOMES OF PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS AND HEPATO-SPLANCHNIC VEIN THROMBOSIS

L Roy[1,*], C Chagneau-Derrode[2], J Guilhot[3], O Goriat[4], P Lenain[5], I Ollivier-Hourmand[6], S Cheze[7], F Jardin[5], C Bureau[8], C Recher[9], L Rouleau[2], F Tartarin[3], K Zekrini[10], D Valla[10], A Plessier[10], J Kiladjian[11]
[1]Hematology and INSERM CIC 0802, [2]Hepatology, [3]INSERM CIC 0802, CHU de Poitiers, Poitiers, [4]Hepatology, CHU de Rouen, Rouen, [5]Hematology, centre Henri Becquerel, Rouen, [6]Hepatology, CHU de Caen, Caen, [7]Hematology, CHU de Caen, Caen, [8]Hepatology, [9]Hematology, CHU de Toulouse, Toulouse, [10]Hepatology, Hôpital Beaujon, [11]Centre d'Investigations Cliniques, INSERM CIC 9504, Hôpital Saint-Louis, Université Paris Diderot, Paris, France

Background: Myeloproliferative neoplasms (MPN) are the commonest cause of splanchnic vein thrombosis (SVT), their prevalence being approximately 30% in portal vein thrombosis (PVT) and 40% in Budd-Chiari syndrome (BCS). There is no consensus regarding the use of cytoreductive therapy in patients (pts) with MPN and splanchnic vein thrombosis (SVT), these pts often presenting with normal blood counts.
Aims: Search for prognostic factors predicting the risk of achieving major vascular or liver-related events after the diagnosis of SVT, and assess the impact of cytoreductive therapy on the occurrence of such major events.
Methods: Retrospective observational study of SVT pts jointly followed in 4 hematology and hepatology reference centers for MPN and SVT. Inclusion criteria were: a diagnosis of BCS or PVT according to previously published criteria; evidence for an underlying MPN defined by the presence of the JAK2V617F mutation and/or clear bone marrow histopathological features; exclusion of associated malignancy. The composite endpoint of the study included major vascular events (thrombosis including new or extension of SVT and thrombosis in other territories, hemorrhage), liver-related complications (refractory ascites; hepatic encephalopathy; hepato-renal syndrome; liver transplantation) and death. Time to event was measured from the date of SVT diagnosis to the date of first major event. Estimated probabilities of EFS were calculated using the Kaplan-Meier method, and the two-tailed log-rank test evaluated differences between survival distributions
Results: 109 pts were included with a median follow-up of 4.4 years (range: 1 month - 27.4 years), including 46 BCS pts (median follow-up: 5.2 years) and 63 PVT pts (median follow-up: 3.6 years). Among the BCS pts, 33 (72%) experienced at least one major event. Median event free survival (EFS) from diagnosis of SVT was 9.4 months (IC95: 4.1-36.4). Cytoreductive therapy (P<0.0001), platelet count above 250×10^9/L at time of BCS (P=0.099) and gender (P=0.110) were the 3 variables associated with a higher risk of major event after BCS in univariate analysis. Absence of cytoreductive therapy after BCS diagnosis was the only independent prognostic factor associated with an increased risk of subsequent major event (P<0.0001).Median EFS was 59.8 months (IC95: 35.9-NA). Initiation of cytoreductive therapy after the diagnosis of PVT was significantly associated with a lower risk of subsequent major event (P=0.011) in univariate analysis, as the presence of esophageal varices of grade <2 (P=0.117). In multivariate analysis, only cytoreductive therapy remained an independent prognostic factor (P=0.048).
Summary and Conclusions: This study provides the first evidence for a beneficial role of cytoreductive therapy in SVT patients with underlying MPN, in particular for reducing the risk of severe liver-related complications and significantly improving EFS in both BCS and PVT, regardless of MPN characteristics. Confirmation in a larger study will require international collaboration due to the rarity of this type of thromboses.

P821

CLINICAL FEATURES OF PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS COMPLICATED BY PORTAL HYPERTENSION

M Yan[1,*], H Geyer[2], R Mesa[2], E Atallah[3], J Callum[4], J Bartoszko[5], F Wong[6], M Maganti[7], K Yee[5], V Gupta[5]
[1]Internal Medicine, University of Toronto, Toronto, Canada, [2]Hematology and Oncology, Mayo Clinic, Scottsdale, [3]Hematology and Oncology, Medical College of Wisconsin, Milwaukee, United States, [4]Hematology and Oncology, Sunnybrook Health Science Centre, [5]Hematology and Oncology, Princess Margaret Hospital, [6]Gastroenterology, Toronto General Hosptial, [7]Biostatistics, Princess Margaret Hospital, Toronto, Canada

Background: Portal hypertension (PHTN) is a rare complication of Philadelphia-negative myeloproliferative neoplasms (MPNs) that can result in significant morbidity. There is a paucity of published data in this area, with most of the current literature taking the form of anecdotal case reports/series, the largest of which has 13 patients. PHTN is currently reported in 7-18% of patients with MPNs.
Aims: The main objective of this study is to understand the clinical features and natural history of patients who have been diagnosed with Philadelphia-negative MPNs and PHTN at our participating institutions.
Methods: This study was approved by the ethics committees at all of the participating institutions. Twenty-nine patients with the diagnosis of both MPN and PHTN were identified from databases at Princess Margaret Hospital and Sunnybrook Health Sciences Centre in Toronto, Canada. The MPNs included polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF), post-PV myelofibriosis (PPV-MF) and post-ET myelofibrosis (PET-MF). Patients were confirmed to have the diagnosis of PV, ET and PMF based on WHO criteria, and PPV-MF and PET-MF based on IWG-MRT criteria. PHTN was defined as the presence of ascites and/or varices in the absence of a known cause. A detailed chart review was performed, and the data was abstracted into a case report form designed for this study.
Results: Among the 29 patients (52% male) in the study group, the etiology of the MPNs consisted of 11 patients with PMF (38%), 9 PV (31%), 7 PPV-MF (24%), 1 ET and 1 PET-MF. The median follow up of survivors was 81 months (range 12–168 months). JAK2 V617F (JAK2) mutation status was available on 28 patients, of which 22 patients (79%) had mutated JAK2. JAK2 was positive in 15 of 16 patients with the diagnosis of PV and PPV-MF (94%). After excluding PV/PPV-MF patients, JAK2 was positive in 58% of patients with PMF, ET and PET-MF. Among the 19 myelofibrosis patients (including PPV-MF and PET-MF), DIPSS score at PHTN diagnosis was: low risk, 4; intermediate-1, 8; intermediate-2, 3; and high risk, 4. At the diagnosis of PHTN, 10 patients presented with ascites, 11 patients with varices, and 8 patients had both. Of the19 patients with varices, 32% presented with gastrointestinal bleeding, whereas the others were found on screening. Among the 29 study patients, 17 patients (59%) had a history of splanchnic vein thrombosis (SVT). The incidence of SVT was significantly higher in patients with PV/PPV-MF compared to PMF (81% *vs.* 27%, P=0.01). Of the 19 patients with myelofibrosis, 9 have died, whereas only 1 patient with PV/ET has died. The causes of death include 4 with blastic transformation, 3 secondary to PHTN, 2 with sepsis, and 1 secondary to hepatocellular carcinoma.
Summary and Conclusions: In summary, PHTN appears to be most prevalent in patients with PV/PPV-MF compared to other classical MPNs with ET being the least common. The etiology of PHTN in PV patients appears to be secondary to a thrombotic event in the splanchnic circulation, whereas non-thrombotic etiology appears most prevalent in PMF patients. These results are useful in the planning of screening strategies for portal hypertension in MPN patients, and provide some clues towards understanding the mechanisms of PHTN in patients with MPNs. Updated data on 55 patients will be presented at the EHA meeting by inclusion of cases from Mayo Clinic, Scottsdale and Medical College of Wisconsin.

P822

EOSINOPHILIA IN ROUTINE BLOOD SAMPLES AND THE SUBSEQUENT RISK OF HEMATOLOGICAL MALIGNANCIES AND DEATH

C Andersen[1,*], V Siersma[2], H Hasselbalch[1], H Lindegaard[3], H Vestergaard[4], P Felding[5], N de Fine Olivarius[2], O Bjerrum[6]
[1]Department of Haematology, Roskilde University Hospital, Roskilde, [2]The Research Unit for General Practice and Section of General Practice, Department of Public Health, University of Copenhagen, Copenhagen, [3]Department of Rheumatology, [4]Department of Haematology, Odense University Hospital, Odense, [5]Department of Clinical Biochemistry, Copenhagen General Practitioners´ Laboratory, [6]Department of Haematology, Copenhagen University Hospital, Copenhagen, Denmark

Background: Blood eosinophilia may represent an early paraclinical sign of hematological malignant disease. No reports exist on the predictive value of eosinophilia for hematological malignancies. Such a study may prove helpful for physicians to interpret eosinophilia and aid them to make early diagnosis and targeted treatment of underlying morbidities.
Aims: The aim of the present study was to investigate eosinophilia in routine blood samples as a potential risk marker for the development of hematological malignant disease and death using a comprehensive primary care cohort.
Methods: From the Copenhagen Primary Care Differential Count (*CopDiff*) database, we identified 359,950 individuals with at least one differential cell count (DIFF) from 2000-2007. From these, one DIFF was randomly chosen from each individual. The individuals were categorized as no ($<0.5 \times 10^9$/l), mild ($\geq 0.5–1.0 \times 10^9$/l) or severe eosinophilia ($\geq 1.0 \times 10^9$/l). From the Danish Cancer Registry and the Danish Civil Registration System we ascertained hematological malignancies and death within three years following the DIFF. From the Danish National Patient Register we computed Charlson´s comorbidity Index (CCI) within three years before the DIFF. Using multivariate logistic regression odds ratios (ORs) were calculated and adjusted for previous eosinophilia, sex, age, year, month, CRP, previous cancer and CCI. *P*-values less than 0.0271 were considered to be significant as this controls the false discovery rate at 5% using the method of Benjamini-Hochberg.
Results: In the total cohort of 359.950 individuals from a primary care setting there was an equal sex-distribution and a mean age of 48.3 years. 14.406 individuals (4%) exhibited eosinophilia. The incidence of hematological cancer was 89/100.000 person-years. ORs for developing Hodgkin´s disease (HD) was significantly increased in patients exhibiting severe eosinophilia, OR=9.09 (2.77-29.84), P=0.0003, but not in cases with mild eosinophilia and no association was found with non-Hodgkin lymphoma. The association with classical myeloproliferative neoplasms (cMPNs) also showed an increasing risk with eosinophilia with OR=1.65 (1.04-2.61) P=0.0322 and OR=3.87 (1.67-8.96) P=0.0016) for mild and severe, respectively. Eosinophilia was also associated with chronic lymphatic leukaemia (CLL). OR=2.57 (1.50-4.43), P=0.0006 and OR=5.00 (1.57-15.94), P=0.0065 for mild and severe eosinophilia, respectively. Finally, eosinophilia was associated with all-cause death with OR of 1.16 (1.09-1.24), P<0.0001 and 1.60 (1.35-1.91), P<0.0001, for mild and severe eosinophilia, respectively.
Summary and Conclusions: In a large cohort resistant to surveillance bias, and with an incidence of hematological malignancies which is compatible to the reported national incidence in Denmark, we confirm known associations between eosinophilia and HD and cMPNs. In addition we demonstrate for the first time that eosinophilia *per se* is a risk marker for both CLL and death. Therefore, a subclinical hematological malignancy should be considered in case of unexplained eosinophilia. The question whether the eosinophil is an effector cell in the evolution of CLL remains open, and this is a study question that deserves consideration in future preclinical and prospective clinical trials.

P823

CHRONIC MYELOPROLIFERATIVE NEOPLASMS REVEAL INCREASED RISK OF OSTEOPOROTIC FRACTURES

S Farmer[1,*], E Horváth-Puhó[2], H Vestergaard[1], H Soerensen[2], P Hermann[3], H Frederiksen[1]
[1]Department of Hematology, Odense University Hospital, Odense C, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, [3]Department of Endocrinology, Odense University Hospital, Odense C, Denmark

Background: The classical chronic myeloproliferative neoplasms (CMPNs) are chronic hematological malignancies that originate at the level of the pluripotent stem cell. ET and PV are often viewed as part of the same biological continuum, rather than separate diagnostic entities (1). We have previously shown that CMPN patients are at higher risk of femoral fractures than the general population but the risk of other osteoporotic fracture types is unknown (2). We hypothesize that bone modelling rate gets disturbed due to a chronic inflammation analog to patients with mastocytosis. Corresponding to the biological continuum, the classic CMPNs reflect a stepwise increase of the inflammation from ET to PV (3).
Aims: With this study we assess the risk of osteoporotic fractures at several anatomical sites including distal antebrachium, humerus and proximal femur.
Methods: We conducted a population-based cohort study of the risk of osteoporosis among patients with ET and PV using data from the Danish health care system. Patients were identified from Danish National Registry of Patients (DNRP), and linked to the Danish Civil Registration System (CRS) in the study period 1 January 1995 to 31 December 2010. Each Danish resident has a unique, permanent 10-digit civil registry number allowing unambiguous individual-level linkage among all Danish registries. Patients with a first-ever CMPN diagnosis in the DNRP were identified by means of their ICD-8 diagnosis code until 1994 and ICD-10 diagnosis code thereafter. By this means, we established two distinct cohorts of ET and PV patients. For each CMPN patient, 50 general population comparison cohort members without CMPN were identified in the CRS matched on age, sex, and calendar year, creating two separate comparison cohorts. Follow-up started 1-year from the date of diagnosis for CMPN patients and until first fracture of prox. femur, humerus or distal antebrachium. The comparison cohort members were assigned the same index date as their index CMPN case. Patients and comparison cohort members with a previous diagnosis of osteoporosis or osteoporotic fractures were excluded. Cox regression was used to estimate hazard ratios (HRs) as a measure of relative risk of fracture for each CMPN cohort compared to the comparison cohort, adjusted for comorbidity and diagnoses related to alcohol abuse.
Results: We identified1,644 ET patients and 70,685 matched comparison cohort members, as well as2,189 PV patients and 70,685 matched comparison cohort members. Figure1 shows the relative fracture rates for prox. femur, humerus and distal antebrachium.
Fracture rates of:
- Proximal femur: HR_{ET}=1.16 (95%CI: 0.9-1.5) and HR_{PV}=1.53 (95%CI: 1.3-1.9).
- Humerus: HR_{ET}=1.05 (95%CI: 0.7-1.6) and HR_{PV}=1.33 (95%CI: 1.0-1.8).
- Distal antebrachium: HR_{ET}=1.14 (95%CI: 0.9-1.5) and HR_{PV}=1.31 (95%CI: 1.0-1.7).

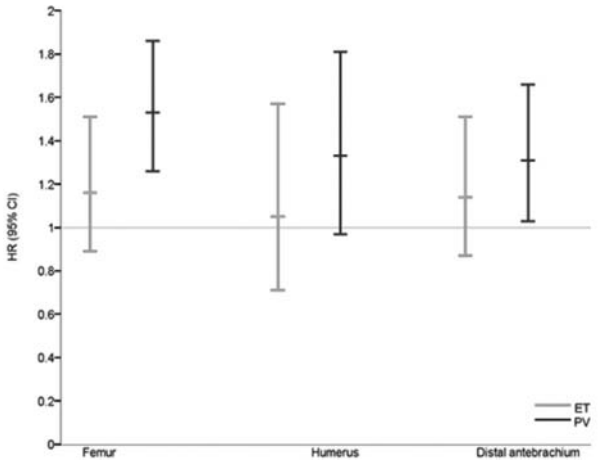

Figure 1. HR and corresponding 95% CI for femur, humerus and distal antebrachium.

Summary and Conclusions: CMPN patients are at higher risk of osteoporotic fractures in femur, humerus and distal antebrachium than the general population. Fracture rates increase in a steP-wise pattern from ET to PV.
Adjustment for comorbidity and diagnoses related to alcohol abuse increases fracture ratio, and does therefore not explain the increased fracture rate in CMPN patients.

P824

DETERMINANTS AND FREQUENCY OF THROMBOTIC AND BLEEDING COMPLICATIONS IN AN ITALIAN COHORT OF 88 PATIENTS WITH PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS (MPN): THE ROLE OF ADAMTS-13 AND VWF ACTIVITIES

A Federici[1,*], M Carraro[1], A Lattuada[1], C Vanelli[1], V Sciumbata[1], D Intini[1], S Munizza[1], U Budde[2]
[1]Hematology & Blood Transfusion, University Hospital of Milan, Milan, Italy, [2]Haemostasiology, Medilys Laborgesellschaft, Hamburg, Germany

Background: Patients with Ph-negative Myeloproliferative Neoplasms (MPN) such as Polycythemia Vera (PV), Essential Thrombocythemia (ET) and Primary Myelofibrosis (PMF) can be exposed during the course of these MPN to thrombotic and bleeding complications, with increased morbidity and mortality. Age, previous history of thrombosis, increased White Blood Cell (WBC) and Jak2 allele burden have been proposed as risk factors for Venous (VTE) and Arterial (ATE) thromboses while bleeding has been previously associated with abnormalities of the von Willebrand factor (VWF).
Aims: to investigate any significant role of ADAMTS-13 and VWF activities in the thrombotic and bleeding complications observed in a small but well characterized cohort of MPN patients.

Methods: 88 consecutive patients were diagnosed at the Hematology and Transfusion Medicine Division, L.SACCO University Hospital of Milan, according to WHO criteria. Patients signed an informed consent to participate in this clinical study with a protocol approved by local IRB and they showed the following features: [MPN type (%), mean age (range), gender M/F and Jak2 positivity (%)]: PV[n=42 (48%), 68 (36-86), 18/24; 85.7%]; ET [n=34 (38%), 66 (30-93), 10/24, 61.7%]; PMF [n=12 (14%), 67 (37-88), 7/5, 58%]. Thrombotic and bleeding episodes were recorded and managed from the time of diagnosis and associated with the use of aspirin (ASA) and of other MPN therapies. Among additional lab parameters, plasmatic ADAMTS-13 and VWF activities were also measured at enrolment as endothelial/platelet marker. These activities were assayed with Technozym ADAMTS-13 activity (Technoclone GmbH, Austria), Innovance VWF-GPIb activity (Siemens AG, Germany) and HemosIL-VWF antigen (Instrumentation Laboratory, USA). Multimeric analyses were also tested using very sensitive intermediate SDS-agarose gel electrophoresis. Statistical analyses were performed by SPSS-17.2
Results: 59/88 (67%) patients did not show any thrombotic or bleeding complications during the 6-year follow-up. In these cases mean (range) values of VWF:GPIb and VWF:Ag were 104 (29-202) and 133 (52-288) U/dL while ADAMTS-13 was 102 (63-143). 20/88 (23%) cases showed at least one thrombotic event (13ATE/7VTE): AMI (6), STROKE (6), TIA (2), PE (1), DVT (7). Patients with thromboses showed relatively higher values VWF:GPIb and lower ADAMTS-13 and this was confirmed in multivariate analysis especially for ET [VWF:GPIb=135 (61-237) U/dL, P=0.004 and ADAMTS-13=89(62-134), P=0.009]. Major bleeding episodes mainly mucosal (5 gastrointestinal, 3 post-surgery, 1 severe menorrhagia) requiring blood transfusions or hysterectomy were observed in 9/88 (10%) patients. At the multivariate analysis, major bleedings were significantly associated with lower VWF:GPIb [68 (25-111) U/dL, P=0.022), lower VWF:Ag [93 (35-146) U/dL, P=0.016] and to the ASA intake (P=0.006). Most of these bleeders showed also a relative loss of the highest molecular weight multimers.
Summary and Conclusions: Based on these observations, we confirm that thrombotic events in MPN may certainly have multiple risk factors: however, lower ADAMTS-13 and higher VWF activities might play a role as additional risk factors especially in ET. Conversely, lower levels of VWF with loss of the largest multimers are important risk factors for bleeding in MPN especially in patients treated with ASA.

P825

INTERNATIONAL PROGNOSTIC SCORE FOR ESSENTIAL THROMBOCYTHEMIA (IPSET) AND IPSET-THROMBOSIS–ONE CENTRE ANALYSIS
T Garrido[1,*], F Trigo[1], J Guimaraes[1]
[1]Centro Hospitalar São João, Porto, Portugal

Background: In order to homogenize the approach to patients (pts) with essential thrombocythemia (ET), it was recently elaborated the IPSET model, that takes into account only 3 parameters: age ≥60 years-old (2), leukocytosis ≥11×10^9/L (1) and prior thrombosis (PT) (1). The sum of points obtained stratifies pts into 3 risk categories: low (0), intermediate (1-2) and high (3-4). Later, another model was proposed: the IPSET-thrombosis (IPSET-T), taking into account 4 parameters: age ≥60years-old (1), PT (2), cardiovascular risk factors (CRF) (1) and JAK2V617F mutation (2). The sum of points obtained also stratifies pts into 3 risk categories: low (<2), intermediate (2) and high (>2).
Aims: To apply the IPSET and IPSET-T models to 145 pts diagnosed with ET between 2000-2010.
Results: The median age at diagnosis was 62years-old [20;88] (53.1% had ≥60years-old), with a predominance of females (60.7%) and a median follow-up of 53.5months [2;154]. Nineteen (17.6%) pts had PT and 46 (42.6%) had CRF [mostly diabetes (30.6%), hypertension (11.1%) and hypercholesterolemia (17.6%)]; it was observed anemia (hemoglobin <12g/dL-women; <13g/dL-men) in 20pts; and leukocytosis in 34. Out of 84pts submitted to the analysis, the JAK2V617F mutation was present in 49 (45.4%); this showed a correlation with PT (P=0.002), age ≥60years-old (P=0.016), anemia (P=0.004) and leukocytosis (P=0.011). IPSET stratification was possible in 92pts; IPSET-T in 84pts; and both in 68pts (due to missing data). There was an even distribution between the 3 IPSET risk groups [low (32.6%), intermediate (39.1%) and high (28.3%)] but not so much for the IPSET-T [low (39.3%), intermediate (17.9%) and high (42.9%)]. Almost all (94.4%) pts in the high risk IPSET group were JAK2V617F-positive (P=0.003); and 83.3% of the pts without leukocytosis were in the low risk IPSET-T group (P=0.01). Therefore, the 2 models were strongly correlated: 94.4% of the pts with high IPSET risk were also high risk according to the IPSET-T model (P<0.0001). 80% of the patients with anemia were in the intermediate/high IPSET risk group (P=0.023), but 66.7% of them were in the low risk IPSET-T group (P=0.043).Only 2pts had a thrombotic event after diagnosis: 1 had intermediate risk IPSET and both of them had high risk IPSET-T; both were JAK2V617F-positive. Fifteen (10.3%) patients died, 1 by progression to acute leukemia (intermediate IPSET risk; high IPSET-T risk), 2 due to secondary malignancies (breast cancer) and the remaining by infection/ complications of their other co-morbidities. The 100-month overall survival (OS) was lower for pts with ≥60years-old (63.4% *vs.* 98.1%; P=0.001) and anemia (50.5% *vs.* 89.7%; P=0.003). There was a tendency towards worse OS in the high-risk IPSET group, but statistically significant only when compared directly to the low risk group (100-month OS: 60.2% *vs.* 96.6%; P=0.049). We could not analyse OS for the IPSET-T group, since all of them are still alive. There were no differences in OS in any of the remaining variables tested, including JAK2V617F mutation.
Summary and Conclusions: In this series, the 2 models seemed to be comparable. However, we were not able to validate the risk groups defined by IPSET and IPSET-T due to the limited number of pts and thrombotic events. It is emphasized that the presence of anemia (not incorporated in any of the models; and not correlated to a specific risk group, demonstrating its independent value) may play a role in stratifying pts with TE.

P826

BCR/ABL EXPRESSION IN CHRONIC MYELOPROLIFERATIVE DISORDERS
L Kesaeva[1,*], A Misyurin[1], E Misyurina[1], A Krutov[1], I Soldatova[1], K Kaysina[1]
[1]GeneTechnology LLC, Moscow, Russian Federation

Background: We have found earlier (EHA 2010, #1504) a high frequency of BCR/ABL gene expression in selected group of pts with chronic myeloproliferative disorders (CMDs) having long lasting disease duration (more than 5 years after diagnosis) and with clear signs of disease progression and resistance to conventional therapy of INFa+HU. Our findings suggest that BCR/ABL gene emergence due to diseases continuation may play a crucial role in CMD progression. Recently a number of papers were published reporting a few cases of simultaneous persistence of Jak2 V617F and BCR/ABL-positive clones in the same patients having controversial diagnosis of CML or one of CMDs. We believe that phenomenon of imultaneous existence of these two molecular markers and two corresponding tumor clones in one patient with myeloproliferative disorder may sometimes course a difficulty for diagnosis and for choosing correct therapy approach. It seems that this phenomenon still require further elucidation. One more issue that has yet to be solved is discrepancy of incidence of Jak2 V617F in CML and BCR/ABL in CMD. The latter is obviously more frequent than the former. We suppose that BCR/ABL gene emergence in CMD is due to activation of V(D)J recombination by Jak2 V617F mutation.
Aims: To compare frequency of BCR/ABL expression in primary CMD pts and CMD pts with long disease duration and progression. The other goal was to evaluate gene expression of V(D)J components RAG1 and RAG2 in Jak2 V617Fpositive granulocytes and in granulocytes of normal donors.
Methods: To perform this study we have exploited qualitative and quantitative PCR detection of BCR/ABL fusion gene expression by means of RT PCR and RQ PCR. We have analyzed gene variants responsible for p190, p210 and p230 types of BCR/ABL protein synthesis. We have also performed detection of Jak2V617F, Jak2-ex12 and MPLW515L/K using AS PCR and direct PCR fragment. Allelic Jak2V617F burden was tested by RQ PCR. After receiving informed consents blood samples (N=175) of CMD pts with unfavorable clinical course and of primary CMD pts (N=67) were collected.
Results: We have examined 175 pts with CMD in progression (35(20%) - PV, 38(22%) - ET, 102 (58%) -IMF). BCR/ABL expression was found in 47 of 175 (27%) CMD pts. Most of the cases were p210, only 3 were p190, p230 was not found. Jak2V617F was in 139 pts (79%), Jak2-ex12 was in 2 (1%), MPLW515L was in 1 case (0,5%); in 33 (19,5%) pts common Jak2 and MPL mutations were not found. In the group of CMD primary pts (N=67) 26 (47%) were PV, 21(38%)–ET, 8(15%)–IMF. Jak2 V617F mutation was found in 55/67 (82%). BCR/ABL p210 expression was found only in 2/55 (3,6%) Jak2 V617F-positive primary CMD pts. RAG1,2 expression was observed in most of the Jak2 V617F positive CMD cases which were tested (46/49 - 94%). In granulocytes of normal donors RAG1,2 expression was found only in 7% (3/42).
Summary and Conclusions: Incidence of BCR/ABL expression gradually increases during CMD progression. Our datasuggest that frequent expression of RAG1,2 in Jak2 V617F-positive granulocytes is responsible for genomic instability coursing t(9;22) and BCR/ABL expression in CMD pts with progression.

P827

A CASE STUDY OF RESENSITIZATION TO RUXOLITINIB, A JAK1/JAK2 INHIBITOR, IN A PATIENT WITH MYELOFIBROSIS (MF)
H Gisslinger[1,*], C Skrabs[1], B Gisslinger[1], R Schoder[1], L Müllauer[2], R Kralovics[1]
[1]Department of Hematology, [2]Institute of Clinical Pathology, University of Vienna, Vienna, Austria

Background: Ruxolitinib (RUX) is a potent JAK1/JAK2 inhibitor that has demonstrated rapid and durable improvements in splenomegaly, disease-related symptoms, and quality of life in the phase 3 COMFORT studies. Long-term follow-up confirmed that spleen volume reductions were sustained and RUX treatment remained tolerable with long-term use. In addition, prolonged survival was observed with RUX compared with both placebo and BAT. JAK2 inhibitor–resistant mutations have been generated *in vitro*. However, a recent report (Koppikar P, *et al. Nature.* 2013) suggests persistent JAK2 signaling despite chronic inhibition may be the result of activation by other JAK kinases

and that this persistence is reversible *in vitro*, with cells becoming resensitized to JAK2 inhibition after a washout period. This report demonstrates resensitization to JAK2 inhibition in a patient (pt) with MF.
Aims: This is a case study of a pt receiving RUX in COMFORT-II who had a response after reinitiation of RUX therapy.
Methods: COMFORT-II is a randomized (2:1), open-label, phase 3 study comparing RUX with BAT. Pts with intermediate-2– or high-risk MF received RUX 15 or 20 mg bid based on baseline platelet (PLT) count (100-200 or >200×10^9/L). Spleen volume was measured by MRI every 12 wk and spleen length by palpation at each study visit.
Results: This report is of a 59-year old, female pt diagnosed with PMF 17 years prior to enrolling in COMFORT-II. At study entry, the pt had intermediate-2–risk MF (2 IPSS risk factors: constitutional symptoms and blasts ≥1%), a palpable spleen 19 cm below the costal margin, and reported pruritus and night sweats. RUX therapy was initiated at 20 mg bid (baseline PLT 258×10^9/L). The initial response to treatment was dramatic. Spleen size reduced to 8 cm at wk 4 (58% reduction by palpation), and pruritus and night sweats resolved; however, PLTs dropped to 90×10^9/L, and the dose was reduced to 10 mg bid. Over the next 2 months following dose reduction, spleen size gradually increased to approximately baseline level, and night sweats (but not other symptoms) returned. Consequently, the dose was increased to 15 mg bid, and she experienced a 35% spleen volume reduction from baseline at wk 24 (key secondary endpoint), and night sweats resolved. Baseline hemoglobin was 10.6 g/dL and ranged from 5.1-12.1 g/dL on study; anemia was managed with transfusions. After ≈3 years of RUX treatment she experienced a return of constitutional symptoms, spleen size increased to baseline levels and she had severe anemia. RUX was tapered over 2 wk, and the pt ultimately discontinued after 152 wk for unsatisfactory therapeutic effect. During RUX tapering, she experienced a severe deterioration of her general condition with worsening of constitutional symptoms, anemia, and an increase in spleen size to 26 cm, and she became wheel chair bound. After 2 days with no treatment, she was rechallenged with RUX 10 mg bid, and her situation again improved dramatically. She became completely mobile again, constitutional symptoms improved, and her spleen size reduced from 26 cm to 14-16 cm.
Summary and Conclusions: This case study is the first report of resensitization to JAK2 inhibitor therapy in a pt with MF. The mechanism by which pts lose response to JAK inhibitors then become resensitized is currently unknown; however, preclinical evidence from Koppikar *et al.* suggests that transactivation of JAK2 via heterodimer formation with other JAK kinases (ie, JAK1 and TYK2) leads to persistent signaling of the JAK/STAT pathway that is reversible upon removal of JAK inhibitor therapy.

P828

PRURITUS IN PRIMARY MYELOFIBROSIS: TREATMENT ATTEMPTS, RESPONSE, AND OUTCOMES

B Vaa[1,*], A Tefferi[1]
[1]Mayo Clinic, Rochester, United States

Background: Pruritus, often aquagenic, is a common and disabling feature of myeloproliferative neoplasms. It's prevalence in both polycythemia vera and primary myelofibrosis (PMF) has been well documented. Historically, a number of medications have been used to treat pruritus in PMF, including hydroxyzine, anti-histamines, hydroxyurea, and selective serotonin re-uptake inhibitors (SSRI's). Recent clinical trials with JAK or mammalian target of rapamycin (mTOR) inhibitors in PMF have identified pruritus as one of the most treatment-responsive disease traits. However, there has not been a comprehensive study comparing treatments for pruritus, response rate, and time to response in a large cohort of patients with PMF.
Aims: 1) Describe treatment strategies for pruritus in a large cohort of patients with PMF; 2) Compare effectiveness of treatments for pruritus in PMF.
Methods: The current study population was comprised of 88 patients taken from a larger primary cohort of patients seen at the Mayo Clinic, Rochester between the years 2000 and 2010 with biopsy proven diagnosis of PMF (n=566) who reported pruritus at any point during their care at Mayo Clinic. Patients with pruritus secondary to underlying skin disorder confirmed by Mayo Clinic Department of Dermatology were excluded from evaluation. Clinical records were reviewed and data relating to pruritus was collected in the following domains: severity, treatment, response rate, and time to response. Treatment was stratified by class of medication, and mean response rate and time to response was calculated.
Results: Eighty eight patients (16% of primary cohort) reported pruritus that was not attributable to an underlying skin disorder. Forty nine of these patients (56%) reported severe pruritus and required treatment. The most commonly used medications to treat pruritus were anti-histamines (n=30), anti-depressants (n=22), topical corticosteroids (n=19), topical non steroids (n=13), hydroxyzine (n=14), JAK 2 inhibitors (n=13), and hydroxyurea (n=8). Other medications included thalidomides (n=6), pain relievers (n=6), prednisone (n=5), UVB phototherapy (n=3), alpha interferon (n=2), gabapentin (n=1), and imatinib (n=1). Among the 49 patients who had treatment for pruritus, the response to treatment was documented in 35 patients. Eight three percent of patients (n=29) reported resolution of pruritus and 17% (n=6) had no improvement. Highest response rates were observed in patients treated with a JAK2 inhibitor (92%), thalidomide (83%), or pain reliever (83%). More traditional therapies including hydroxyzine, anti-histamines, and anti-depressants were moderately effective at relieving pruritus (43%, 37%, and 32% response rates respectively). The average time to pruritus alleviation was 2 months (range: 1 day-25 months).
Summary and Conclusions: Pruritus is a treatment responsive feature of primary myelofibrosis. Over 80% of patients with PMF in our cohort had resolution of pruritus after treatment. JAK2 inhibitors were the most effective medication to alleviate pruritus.

P829

ADDITION OF THE DEGREE OF BONE MARROW FIBROSIS TO IPSS IN NEW SCORING SYSTEM IMPROVE PREDICTION OF SURVIVAL IN PRIMARY MYELOFIBROSIS

D Lekovic[1,*], M Gotic[1,2], N Milic[2,3], A Vidovic[1,2], A Bogdanovic[1,2], V Milosevic[1], M Perunicic[1], V Cokic[4]
[1]Clinic for Hematology, Clinical Center Serbia, [2]Medical Faculty, [3]Institute for Medical Statistics, [4]Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: During the past few years a several prognostic scoring systems beside the currently used International Prognostic Scoring System (IPSS) and Dinamic International Prognostic Scoring System (DIPSS) have been proposed for risk stratification of PMF patients which are mainly based on clinical parameters.
Aims: The aim of our study was to identify additional prognostic factors for timely appropriate treatment decision for individual patient at the diagnosis.
Methods: We retrospectively analysed 131 WHO-defined PMF pts who were completely treated and followed in our clinic from January 2000 to January 2011. The median follow-up was 44 months (range 2-156). We analyzed clinical, laboratory, pathological parameters (degree of myelofibrosis (MF) ranging from 1 to 4) as well as influence of concomitant comorbity on survival. In each patient 2 comorbidity index were analyzed: 1) Adult Comorbidy Evaluation-27 score (ACE-27), a 27-item comorbidity index for patients with cancer; 2) The Haematopoietic Cell Transplantation Comorbidity Index (HCT-CI). Patients with degree of MF>2 take additional 1 point and become higher IPSS risk grouP-MF modified IPSS (Figure 1).

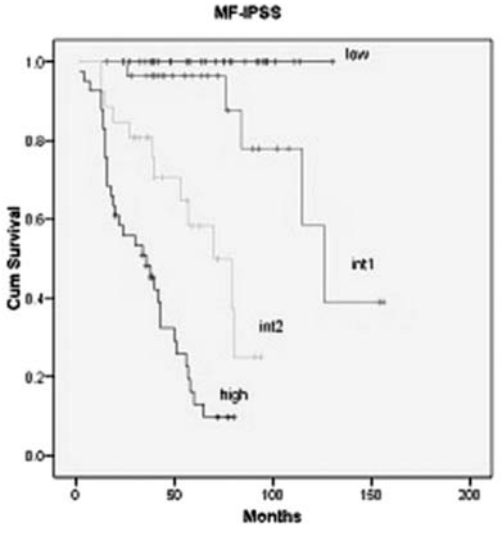

Figure 1.

Results: Median age was 66 years (range 28-84) (M/F=76/55); 66 pts (50.4%) were older than 65 years. According to the IPSS score, 38 pts were stratified as low risk (29%), 40 as intermediate risk-1 (30.5%), 31 as intermediate risk-2 (23.7%) and 22 as high risk group (16.8%). Median survival was 126 months in low-risk group, 80 in intermediate-1, 57 in intermediate-2 and 18 in high risk. Survival was significantly different among the 4 risk categories (P<0.001).According to the degree of MF in 127 (96.2%) analyzed patients distribution was as a follows: MF I 18 patients (14.2%), MF II 53 (41.7%), MF III 43 (33.9%), and MF IV 13 (10.2%). Patients with MF>2 had median survival 51 months while patients with MF≤2 147 months (P<0.001). In MF modified IPSS 33 pts were in low risk group (median survival was not reached), 31 in intermediate risk-1 (median survival 126months), 26 in intermediate risk-2 (median survival 70 months) and 41 in high risk group (median survival 36 months) (P<0.001). Patients with higher both analysed comorbidity scores had significantly shorter survival (ACE- 27 P<0.001 *vs* HCI-CI P=0.002) with better prediction of ACE-27 score. Univariate Cox regression model confirmed the unfavorable influence on survival for age>65 years (P<0.001), male gender (P=0.004), constitutional symptoms (P<0.001),

hepatomegaly (P=0.004), hemoglobin level <100g/L (P<0.001), WBC count>25×10^9/L (P=0.002), Tr≤450×10^9/L (p≤0.001), serum LDH level >700 U/L (P=0.012), peripheral blasts ≥1% (P=0.003), risk groups (P<0.001), MF>2 (P<0.001), MF modified IPSS risk groups (P<0.001), ACE-27 score≥2 (P<0.001), HCI-CI score >2 (P=0.07). Presence of cytogenetic abnormalities, splenomegaly and treatment modality were found not to have statistically influence on survival. Multivariable Cox proportion hazard regression results showed that statistically most important impact on survival had MF modified IPSS risk groups (P<0.001, HR 5.127, 95%CI 3.058-8.594) and ACE-27 score≥2 (P<0.001, HR 5.976, 95%CI 2.451-14.572).

Summary and Conclusions: MF modified IPSS is based on clinical (IPSS) and pathological (degree of MF) parameters and allow a more precise and stronger prediction of survival. Moreover, patients in MF modified IPSS high risk group with ACE-27 score≥2 have a shorter survival than those with only one of these unfavorable scores.

P830

CONTRIBUTION OF SNP ARRAYS TO THE DIAGNOSIS AND PROGNOSIS OF CMML. A STUDY OF PATIENTS WITH LOW RISK CYTOGENETIC FEATURES AND CASES WITH ABSENCE OF METAPHASES

L Palomo[1,*], M Mallo[1], B Xicoy[2], Vera Ademà[1], S Marcé[2], O Garcia[2], J Grau[2], M Jiménez[2], E Alonso[3], H Pomares[3], M Arnan[3], L Arenillas[4], L Florensa[4], J Ayats[5], A Lemes[6], F Millá[2], E Feliu[2], F Solé[1], L Zamora[2]

[1]Myelodysplastic Syndromes Group, Josep Carreras Leukaemia Research Institute, Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, [2]Hematology, Josep Carreras Leukaemia Research Institute-ICO, Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, [3]Hematology, ICO, Hospital Duran i Reynals, [4]Hematology, IMIM, Hospital del Mar, Barcelona, [5]Hematology, Hospital Municipal de Badalona, Badalona, [6]Hematology, Hospital Universitario de Gran Canaria Dr Negrín, Las Palmas de Gran Canaria, Spain

Background: Chronic myelomonocytic leukaemia (CMML) is a clonal haematopoietic malignancy characterized by features from both myelodysplastic syndromes and myeloproliferative neoplasms, with a median overall survival (OS) of 20 months and approximately 15-30% of progression to acute myeloid leukemia (AML). Clonal cytogenetic abnormalities are found in only 20-30% of patients with this disorder, but none of these alterations is specific of the disease. Most frequent chromosomal abnormalities are trisomy8, abnormalities of chromosome7, loss of the Y chromosomes and complex karyotypes. Some of these alterations have prognostic value. However, most cases still show a normal karyotype.

Aims: To characterize type, frequency and prognostic impact of cytogenetic alterations detected by SNP arrays (SNP-A) in a cohort of 49 patients with low risk CMML according to CPSS (Such *et al.*, 2013). Cases with normal karyotype, -Y or no metaphases were selected. Herein we present the results of 31 preliminary cases. The other 18 patients are currently being analyzed.

Methods: A retrospective study was performed on 31 patients with CMML (26 CMML-1, 5 CMML-2) for whom clinical and biological data were available. Median age at diagnosis was 70 years (48-83), with a male predominance of 1.6:1 and a 29% (9/31) frequency of progression to AML. SNP-A was performed using DNA extracted from bone marrow samples at diagnosis (Cytoscan HD Array, Affymetrix). Survival analysis was performed using Kaplan-Meier estimate and log-rank tests were used for comparisons.

Results: SNP-A revealed 24 (77%) cases with chromosomal alterations which were not detected by conventional G-banding cytogenetics. Chromosome 4 was the most affected chromosome, followed by X,2,3,7, 11 and 16. Among the abnormal cases, copy number alterations (CNA) were detected in 17 (71%) cases. All of them corresponded to gains and losses smaller than 10Mb. Microdeletions in chromosomes7, 12 and 16 were detected more than once, while gains were more frequent in chromosomes 2 and 3. Loss of heterozygosity (CNN-LOH) was detected in 13 (54%) patients. Intersticial LOH (>25Mb) was detected in 8 cases. Among these, chromosome 4 was affected in three cases and chromosome 1 in other 3 different cases. Interestingly, these LOH affected genes where mutations have been described in CMML: TET2 gene, which is one of the most mutated genes in CMML (40-50%), is located in chromosome4, while CBL gene, mutated in 10-20% of CMML, is located in chromosome 11. Survival analysis revealed that the only adverse prognostic factor was CMML-2 subtype. Compared to CMML-1, cases with CMML-2 subtype had worse OS (median OS at 2 years: 18% *vs.* 21%, P=0.003) and progression-free survival (median PFS at 2 years: 21% *vs.* 57%, P=0.001). Due to the fact that some of the cases are still being studied, we will present the prognostic implication of the detection of cytogenetic aberrations detected by SNP-A when the whole cohort is analyzed.

Summary and Conclusions: SNP-A has led to the detection of chromosomal alterations that were not detected by conventional G-banding cytogenetics. Application of this technique in a larger series of patients will allow a better characterization of this disease. Analysis of cytogenetic alterations and mutations detected in the whole cohort may show new prognostic factors, apart CMML-2 subtype.

EPIDEMIOLOGY OF MASTOCYTOSIS IN ADULTS BASED ON A MULTIDISCIPLINARY DIAGNOSTIC APPROACH

M Bonifacio[1,2,*], A Artuso[1,2], P Bonadonna[2,3], D Schena[2,4], M Rossini[2,5], O Perbellini[1], A Zamò[6], G De Matteis[7], G Carli[1], F Maniscalco[1], G Pizzolo[1], R Zanotti[1,2]

[1]Department of Medicine, Section of Hematology, University of Verona, [2]Multidisciplinary Mastocytosis Outpatient Clinic, [3]Allergy Unit, Azienda Ospedaliera Universitaria di Verona, [4]Department of Medicine, Section of Dermatology, [5]Department of Medicine, Section of Rheumatology, [6]Department of Pathology and Diagnostics, Section of Anatomic Pathology, University of Verona, [7]Clinical Chemistry and Hematology Laboratory, Azienda Ospedaliera Universitaria di Verona, Verona, Italy

Background: Mastocytosis is a rare disease. Some epidemiological informations are available about its cutaneous form in children but very few studies addressed the issue of its incidence and prevalence in adults.

Aims: We evaluated the epidemiology of mastocytosis in the adult (≥18 years) population of the Verona province (Veneto region, Italy), based on the activity of the Multisciplinary Mastocytosis Outpatient Clinic, established in Verona in January 2006.

Methods: Patients with suspected mastocytosis are referred to our Clinic from a network of Allergological, Dermatological and Rheumatological Centers in Northern Italy. We focused on all the consecutive adult patients with a confirmed diagnosis of mastocytosis resident in the Verona province. The diagnosis of Cutaneous (CM) or Systemic Mastocytosis (SM) was established according to the World Health Organization Classification. Patients with Urticaria Pigmentosa who did not perform bone marrow evaluation were defined as having Mastocytosis in the Skin (MIS). Written informed consent was obtained from all the enrolled patients. Data about the general population resident in the Verona province from 2008 to 2011 were found at the www.demo.istat.it site. Historical data about the prevalence and incidence of mastocytosis in Veneto were obtained from the Veneto Tumor Registry, Istituto Oncologico Veneto-IRCCS.

Results: Seventy-four adults from a total of 293 patients in our Mastocytosis Registry were identified as living in the Verona province. They were equally distributed by gender (M/F=36/38); median age at first observation was 47.5 (range 20-80) years. The reasons for referral were Urticaria Pigmentosa (n=41), anaphylaxis after hymenoptera sting (n=27) or drugs (n=2) with basal serum tryptase >11.4 ng/mL, unexplained osteoporosis (n=2), other mediator-related symptoms (n=1) and non-MC myeloid neoplasia (n=1). The diagnosis was indolent SM (ISM) in 62 (83.8%) patients; the other cases were CM (n=6), MIS (n=4), aggressive SM (n=1) and SM associated with non-MC disease (n=1). Skin involvement was significantly more frequent in females than in males (78.9% *vs* 47.2%, respectively, P=.007). There was a trend for a higher median basal tryptase in males *vs* females (19.25 *vs* 15.95 ng/mL, respectively, P=.054). D816V KIT mutation was found in 56/64 tested cases (87.5%). We did not find any familial case in this adult population. After a median follow-up of 36 (range 2-112) months all patients are alive. The prevalence of mastocytosis in the Verona province adult population was 9.7 per 100,000 inhabitants, without gender differences. The incidence of new cases did not substantially change from 2008 to 2011 and was 0.93-1.34 per 100,000 inhabitants/year. For comparison, the reported prevalence and incidence in Veneto region before the establishment of our activity (2002-2005) were 0.65 per 100,000 inhabitants and 0.12 new cases per 100,000 inhabitants/year, respectively.

Summary and Conclusions: Although rare, mastocytosis in adults is at least 10 times more frequent than previously reported. Due to the close collaboration with all the Allergology, Dermatology and Rheumatology units of our province, we can assume that virtually all patients with suspected mastocytosis are referred to us. However, the actual prevalence may be higher because ISM diagnosis is understimated especially when skin lesions and/or mediator symptoms are absent. A multidisciplinary diagnostic approach and a wide network of specialists are needed to improve the awareness about this disease and to define its actual epidemiology.

Non-Hodgkin lymphoma - Biology and clinical

P832

HIGHLY SPECIFIC QPCR ASSAYS USING A CONSENSUS LNA PROBE FOR THE DETECTION OF T(11;14) AND T(14;18) IN NON-HODGKIN LYMPHOMA WITH A SENSITIVITY OF 10-5 FOR QUANTIFICATION OF MINIMAL RESIDUAL DISEASE

C Sørensen[1,*], J Jørgensen[1], P Hokland[1], C Nyvold[1]
[1]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark

Background: In mantle cell lymphoma (MCL) the reciprocal translocation t(11;14)(q13;q32), juxtaposing the *BCL1* gene to the immunoglobulin heavy chain (*IgH*) locus, is present in about 80% of the patients. This results in an overexpression of cyclin D1 giving rise to increased cell proliferation. In follicular lymphoma (FL), the t(14;18)(q32;q21) balanced translocation causes an elevated expression of *BCL2* rendering the cells less prone to apoptosis. In addition, a subpopulation of diffuse large B-cell lymphomas also carry t(14;18). Importantly, the above aberrations can be employed for the detection of minimal residual disease (MRD), but optimal MRD measurements in both peripheral blood (PB) and bone marrow (BM) requires a validated and sensitive assay which can, moreover, be easily applied in a clinical setting. Employing a very sensitive assay enables the use of PB samples for analysis in addition to BM or lymph node biopsies facilitating easy access to cancer cells.
Aims: By employing chemically modified RNA nucleotides, such as locked nucleic acids (LNA), we wanted to design and validate highly sensitive and specific qPCR assays to detect t(11;14) and t(14;18). We set out to use consensus primers avoiding the generation of patient-specific priming in order to monitor MRD in subgroups of NHL patients over time.
Methods: We obtained PB and BM samples at the time of diagnosis and/or relapse as well as during treatment. A consensus reverse primer and probe targeting all six J-segments of the *IgH* locus were applied in the qPCR assays. The probe, consisting exclusively of LNA bases, enabled the design of a short amplicon, thus improving the efficiency of the assay. The forward primer targeting the *BCL1* gene was located in the major translocation cluster. Likewise, the *BCL2* forward primer was designed to cover the various breakpoints of the major breakpoint region. The *TCF20* gene was used as a reference gene, and the cell lines JVM2 and DOHH2 were employed as positive controls. All clinical samples were normalized to a diagnostic or a relapse sample defining the MRD levels at diagnosis or relapse as 1. Samples with Cq values >40 were defined as negative.
Results: We employed the JVM2 and DOHH2 cell lines to establish the t(11;14) and t(14;18) qPCR assays and subsequently validated the assays in 22 MCL and 9 FL patients. The assays successfully quantified MRD in 11/22 MCL patients and 9/9 FL patients. Quantification of t(11;14) and t(14;18) was possible down to less than 10^{-5} and 10^{-4}, respectively, as illustrated in Figure 1 which shows representative longitudinal MRD curves of two patients. The level of MRD reflects the clinical courses of the patients based on pathology and flow cytometry. As indicated in Figure1, high levels of MRD correspond to clinically detectable disease, and low levels of MRD correspond to complete remission (CR).

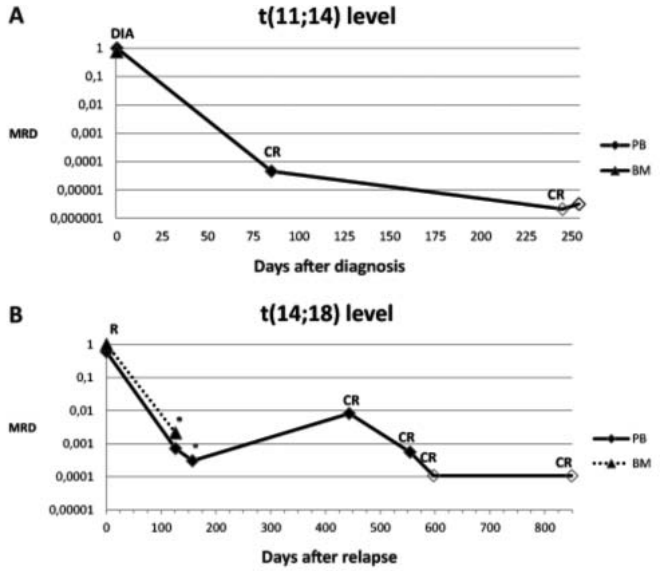

Figure 1. Representative MRD curves of A) an MCL patient and B) an FL patient. Open symbols signify values with a Cq >40. DIA: diagnosis, CR: complete remission, R: relapse, *: clinical status unknown.

Summary and Conclusions: The fraction of quantifiable patients using these assays reflects the presence of multiple translocation breakpoints within the *BCL1* and *BCL2* loci. As the assay is based on consensus primers the time-consuming process of designing and optimizing patient-specific qPCR assays is avoided, and the sensitivity is still down to 10^{-5}. Hence, the present qPCR assays for t(11;14) and t(14;18) show a high degree of sensitivity and specificity and hold great potential as an easily applicable methodology for MRD quantification.

P833

COMPARISON OF NEXT-GENERATION SEQUENCING AND ASO-PCR METHODS FOR MRD DETECTION IN MANTLE CELL LYMPHOMA

G Koval[1], N Fulton[1], F Pepin[2], J Zheng[2], M Faham[2], L Kaplan[3], W Stock[1,*]
[1]University of Chicago, Chicago, [2]Sequenta, Inc., South San Francisco, [3]University of California San Francisco, San Francisco, United States

Background: The prognostic value of MRD detection using allele-specific oligonucleotide (ASO)-PCR has been demonstrated in mantle cell lymphoma (MCL) patients treated with autologous stem cell transplant (ASCT) or with chemotherapy alone (Pott *et al.*, Blood 2010). ASO-PCR requires preparation of clonotype-specific primers for each individual which is laborious and time-consuming. We developed the LymphoSIGHT™ platform, a high-throughput sequencing method, which universally amplifies immune receptor gene segments and can identify all lymphoma-specific sequences at diagnosis, allowing monitoring of disease progression during therapy (Faham *et al.*, Blood 2012).
Aims: In this study, we compared the sequencing and ASO-PCR methods for measuring MRD in follow-up samples from 22 MCL patients.
Methods: Using the sequencing assay, we analyzed diagnostic blood and bone marrow samples from 22 MCL patients for clonal rearrangements of immunoglobulin (IGH-VDJ, IGH-DJ, IGK) genes. Clonal rearrangements had been previously detected in all 22 patients using ASO-PCR methods. We assessed MRD at the IGH and/or IGK locus in 159 follow-up samples, and analysis of the concordance between MRD results obtained by the sequencing method and ASO-PCR is ongoing.
Results: Sequencing detected the presence of a high-frequency clonal rearrangement of at least one receptor ("calibrating receptor") in 100% of the 22 MCL patients; 20 patients had at least 2 calibrating receptors at diagnosis, and 2 patients had 3 calibrating receptors. Following the identification of a calibrating receptor, we analyzed follow-up samples for the presence of MRD. Sequencing detected MRD levels of >10% in 1 sample, 1-10% in 3 samples, 0.1-1% in 8 samples, 0.01-0.1% in 7 samples, 0.001-0.01% in 21 samples, and <0.001% in 23 samples. MRD was undetectable by sequencing in 96 samples.
Summary and Conclusions: This high-throughput sequencing method enables MRD detection without the need for development of patient-specific reagents. Concordance data between sequencing and ASO-PCR will be presented.

P834

NR4A1 MEDIATED APOPTOSIS SUPPRESSES LYMPHOMAGENESIS IN A XENOGRAFT MOUSE MODEL

A Deutsch[1,*], B Rinner[2], M Pichler[3], K Wenzl[1], S Reitter[1], K Troppan[1], C Beham-Schmid[4], P Neumeister[1]
[1]Hematology, [2]Centre for Medical Research, [3]Oncology, [4]Pathology, Medical University Graz, Graz, Austria

Background: *NR4A1 (Nur77)* and *NR4A3 (Nor-1)* are two members of the orphan nuclear receptors (NRs) whose function as critical tumour suppressor genes was demonstrated by the rapid development of acute myeloid leukemia (AML) in the *NR4A1* and *NR4A3* double knock out mouse and by their reduced expression in leukemic blasts from human AML patients.
Aims: The aim of our study was to comprehensively investigate *NR4A1* and *NR4A3* expression and function in lymphoid malignancies.
Methods: *NR4A1* and *NR4A3* expression were determined on mRNA- and protein levels in most lymphoid malignancies of B cell type by semi-quantitive RQ PCR, Western Blot and immunohistochemical analyses. For functional characterization *NR4A1* was over expressed in a Sc-1 lymphoma cell line by using an inducible lentiviral construct followed by apoptotic assays (cleaved caspase3, Sub-G1 peak determination, and the Annexin V staining) and by xenograft mouse experiments.
Results: We found a more than 50% reduced expression of both, *NR4A1* and *NR4A3* in B-CLL (71%) in follicular lymphoma (FL) (70%), and in diffuse large B-cell lymphoma (DLBCL) (74%). In aggressive lymphomas (DLBCL, FL III) low *NR4A1* expression was significantly associated with a non-germinal centre B-cell subtype and with poor overall survival. To investigate the function of NR4A1 in lymphomas, we over-expressed *NR4A1* in the lymphoma cell line Sc1 by using an inducible lentiviral expression system. Induction of *NR4A1* expression led to a significantly higher proportion of induced Sc1 cells undergoing apoptosis as demonstrated by caspase 3-, DNA cleavage and Annexin V staining.

To test the tumor suppressor function of *NR4A1 in vivo*, the stably transduced Sc1 lymphoma cell lines were further investigated in the NOD scid gamma (NSG) mouse model. Induction of *NR4A1* in Sc1 abrogated tumor growth in the NSG mice, in contrast to vector control- and uninduced Sc1 cells, which formed massive tumors.
Summary and Conclusions: Our data suggest that *NR4A1* has a pro-apoptotic function in aggressive lymphoma and defines *NR4A1* as novel tumor supressor involved in lymphoma development.

P835

EZH2 EXPRESSION DETERMINED BY IMMUNOHISTOCHEMISTRY DOES NOT CORRELATE WITH THE PRESENCE OF EZH2 MUTATIONS IN A SERIES OF DIFFUSE LARGE B-CELL LYMPHOMAS (DLBCL)
M Garcia[1,*], C Fernandez-Rodriguez[1], B Casado[1], M Baró[1], A Puiggros[1], M Salido[1], A Alamo[1], E Gimeno[2], B Sanchez-Gonzalez[2], B Espinet[1], S Serrano[1], A Salar[2], B Bellosillo[1]
[1]Pathology, [2]Hematology, Hospital del Mar, Barcelona, Spain

Background: Advances in DNA sequencing technology have recently enabled the characterization of genomes and transcriptomes at sufficient resolution for identification of somatic point mutations that are involved incancer. This knowledge has led, not only to enhance understanding of the mechanisms of pathogenesis, but also to improve the treatment of these patients by designing drugs that specifically act on these targets. Somatic mutations of *EZH2* have been involved in cancer and lymphomagenesis by affectingthemechanisms implicated in the regulation of gene expression. Gain-of-function mutations involving Y641 amino acid have been described in B-cell lymphomas derived from follicle germinal center cell phenotype (GCB) including follicular lymphoma (FL) (7%) and diffuse large B-cell lymphomas (DLBCL) of GCB type (22%). More recently, mutations in the A677 amino acid have been reported in a B-cell lymphoma cell line.
Aims: Our aim was to study the mutational status of *EZH2* gene in a series of DLBCL, and to correlate the mutational status with EZH2 expression by immunohistochemistry in the neoplastic cells. In addition, we correlated the mutational status of *EZH2* gene with clinical characteristics at presentation and follow-up.
Methods: We included 111 cases of DLBCL diagnosed between 2000 and 2011 according to WHO 2008 diagnostic criteria, corresponding to 61 DLBCL of GCB type and 50 DLBCL of the activated B-cell type (ABC). *EZH2* mutational study was assessed in DNA extracted from paraffin-embedded tumour tissue. Regions where mutations have been previously described (amino acids Y641 and A677 of *EZH2* gene) were analysed by Sanger sequencing. Expression of EZH2 protein was performed by immunohistochemistry using clone SP129 (Ventana Medical Systems, Tucson, AZ) in 27 cases, 14 *EZH2* mutated and 13 *EZH2* unmutated, using the detection system of Optiview BenchMark XT (Ventana Medical Systems).
Results: Of the 111 cases included, 14 samples had mutations in the *EZH2* gene (12.6%) (GCB type in 11 cases and ABC type in 3 cases). In all cases, mutations were detected in the aminoacid Y641 (Y641D:n=7, Y641S:n=4, Y641H:n=3, Y641D:n=1). No mutations were observed in the A677 position. Inmunohistochemical analysis of EZH2 expression showed positivity in neoplastic cells in all cases examined (n=27) with no qualitative or quantitative differences regardless of *EZH2* mutational status. Mutational status of *EZH2* gene was not associated with the following clinicopathologic characteristics: age >60 years, gender, Ann Arbor stage, International Prognostic Index (IPI), ABC-GCB type. Overall survival at 3 years was inferior in high or intermediate-high IPI patients when compared with low or intermediate-low IPI cases (46% *vs* 79%, *P*=0.005), but no differences in survival were observed between patients with mutated and unmutated *EZH2* gene (80% *vs* 59%, respectively, *P*=0.376).
Summary and Conclusions: In our series, *EZH2* mutations were present in the 12.6% of cases, with higher prevalence in the GCB subgroup (18%) but were also observed in the ABC profile (6%). All mutations were detected in the aminoacid Y641 of the *EZH2* gene. No differences were seen between the mutational status of *EZH2* and the pattern of EZH2 protein expression determined by immunohistochemistry in the tumor tissue. Finally, mutational status of *EZH2* gene was not associated with clinicopathologic characteristics and did not have influence on outcome.

P836

DLBCL BIOLUMINESCENT XENOGRAFT MODEL FOR NON-INVASIVE FOLLOW-UP OF ANTITUMOR EFFECT
M Moreno[1,2,*], R Bosch[3], M Céspedes[1,2], J Sierra[3], R Mangues[1,2], I Casanova[1,2]
[1]Oncogenesis and Antitumor Group (GOA-HSCSP), Hospital de la Santa Creu i Sant Pau, [2]Networking Research Centre on Bioengineering, Biomaterials and Nanomedicine (CIBER-BBN), [3]Department of Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Diffuse large B cell lymphoma (DLBCL) is the most common non-Hodgkin lymphoma subtype. Addition of rituximab to the classical chemotherapy has improved response rates. However, potential cure is achieved in only 30–50% of patients. The heterogeneous nature of DLBCL and the lack of appropriate animal models are obstacles to further understand the pathology and to identify new drugs for this disease. Although xenograft models of DLBCL are widely used to test new drugs against this neoplasia, most of them are subcutaneous xenografts which do not show a disseminated disease. We describe bioluminescent and disseminated xenograft models of both Germinal Center B cell (GCB) and Activated B Cell (ABC) subtypes of DLBCL. As described previously by our group, the subcutaneous conditioning increased GCB-DLBCL cells capacity to engraft and disseminate. Hence, we performed a subcutaneous passage of the cells before their intravenous injection in mice. The dissemination of the disease was non-invasively followed by *in vivo* imaging.
Aims: To develop bioluminescent xenograft mouse models of GCB and ABC and to validate the DLBCL models using cyclophosphamide
Methods: Toledo (CGB) and RIVA (ABC) DLBCL cell lines expressing GFP-Luciferase (GL) were subcutaneously injected in 6-10 female NOD/SCID mice. Tumors (600 mm3) were extracted and disaggregated. Then, 12-20 mice were randomly divided in two groups and intravenously injected with cultured *in vitro* cells (Toledo GL or RIVA GL) or with the subcutaneously-conditioned cells (Toledo-GL-Sc or Riva-GL-Sc). For cyclophosphamide treatment, mice were injected with subcutaneously-conditioned Toledo-GL-Sc cells and randomized in two groups. Drug (60mg/mL) or vehicle was intravenously injected every 2 days for a total of 7 administrations. *In vivo* images of bioluminescence were taken using IVIS Imaging System once a week.
Results: 1) Subcutaneous passage of Toledo-GL and RIVA-GL cell lines increases aggressiveness: Mice injected intravenously with RIVA-GL-Sc cells showed higher engraftment and dissemination rate than the RIVA-GL intravenously injected group; a significant increase of dissemination to lymph nodes, bone marrow and central nervous system was detected (Figure 1). Aggressiveness of the Toledo-GL-Sc cells also increased with the subcutaneous conditioning. Survival of mice was significantly decreased when lymphoma cells were submitted to the subcutaneous passage (Kaplan-Meier survival curves not shown). 2) Generation of xenograft bioluminescent mouse models of GCB and ABC DLBCL: The intravenously injected cells, Toledo-Sc and RIVA-Sc, generated a disseminated disease in NOD/SCID mice. As observed in Figure 2, most mice showed lymph node and bone marrow infiltration. Macroscopic infiltration was observed mostly in cervical, caudal, inguinal and renal lymph nodes. When tissues were analyzed microscopically, multiple lymph nodes, bone marrow and central nervous system infiltration was observed in most mice (Figure 2D-F) corresponding with the bioluminescent images (Figure 2C). As observed by immunohistochemistry, the infiltrated lymph nodes were CD10+ in Toledo-GL injected mice and CD10-, BCL6+, MUM1+ in RIVA-GL injected mice, confirming its germinal center and activated phenotype, respectively. 3) Validation of DLBCL bioluminescent xenograft model using cyclophosphamide: In order to validate the DLBCL bioluminescent mouse model, cyclophosphamide (Genoxal®) or vehicle were administered to mice. The bioluminescence images (Figure 3) showed decreased dissemination of cells in the treated group. In addition, mice survival significantly increased with cyclophosphamide treatment (Kaplan-Meier survival curves not shown).

	Riva GL	Riva-GL-Sc	Toledo GL	Toledo-GL-sc
Mice dead by lymphoma, n (%)	5/6 (83.3)	6/6 (100)	9/9 (100)	10/10 (100)
Survival time, days	85.2 ± 12.2	52.7 ± 8.1	37.8 ± 6.2	27.7 ± 1.5
Mice with LN infiltration (macro or micro), n (%)	3/5 (60)	6/6 (100)	8/9 (88.8)	8/10 (80)

Figure 1.

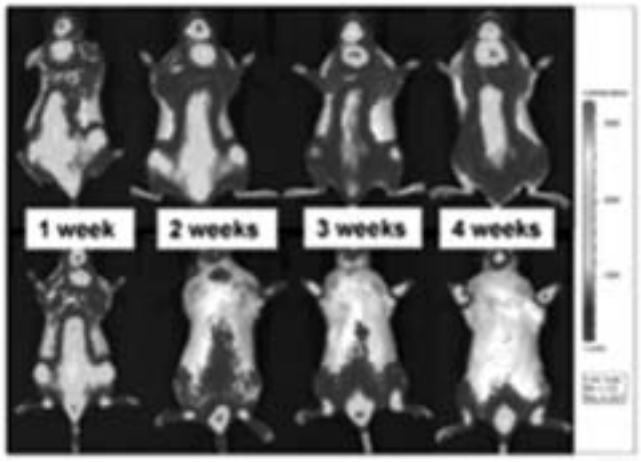

Figure 2.

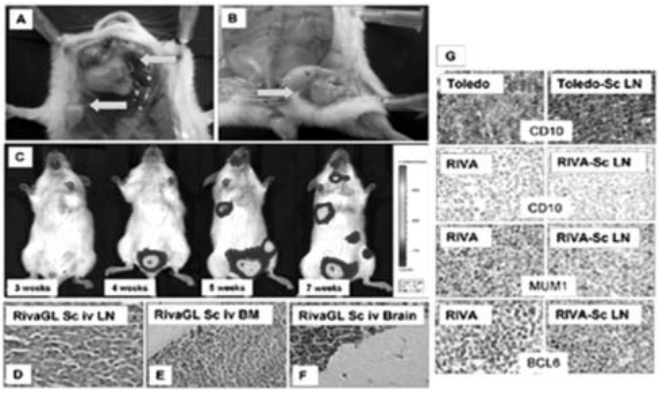

Figure 3.

Summary and Conclusions: We have successfully generated bioluminescent xenograft mouse models for the study of GCB and ABC-DLBCL. Our xenograft mouse models were successfully validated with a drug which is routinely given to patients. The obtained models may be helpful to study the mechanisms of dissemination in DLBCL pathology and to non-invasively monitor the effect of new therapies in the context of a disseminated disease.

P837

BLOOD AND LYMPHATIC MICROENVIRONMENT, MACROPHAGE COMPONENT AS PROGNOSTIC MARKERS IN FOLLICULAR LYMPHOMA

E Nesterova[1,*], S Kravchenko[1], A Kovrigina[1], E Gemdjian[1]
[1]Moscow, National Research Center for Hematology, Moscow, Russian Federation

Background: Follicular lymphoma (FL) has considerable clinical heterogeneity. There is a need for easily quantifiable prognostic biomarkers. There is no consensus on the prognostic significance of microvessel density and number of macrophages.
Aims: To characterize the blood and lymphatic microvessel density, the number of macrophages of tumor tissue basing on immunohistochemical study (IHC) of sections from paraffin blocks of lymph nodes biopsies in two groups of patients with different clinical course.
Methods: The study included 59 patients with follicular lymphoma: 39 women (67%) and 20 men (33%). The mean and median age was 53 years (range: 27-83 years). 49 patients were observed in the National Research Center for Hematology (Moscow) from April 2001 to May 2011 and 10 patients - in Cancer Research Center (Moscow) at the same period of time. The first group–good outcome (1) included 28 patients followed during 2 years or more without therapy; with remission of the underlying disease; with relapse in five or more years from the start of their treatment (late relapse). The second group–poor outcome (2) included 31 patients who died due to tumor progression in the first 1-2 years from the time when this diagnosis was put; with resistance to the passage of the tumor; with relapsed FL in the first year from the start of treatment (early relapse). Patients in both groups received the same initial treatment. The vascularization of tumor tissue was assessed by IHC on sections from paraffin blocks of tumor biopsies of lymph nodes. For the visualization of blood and lymphatic vessels antibodies CD34 and D2-40 were used. CD34 is an endothelial marker of bloodvessels. D2-40 is a new lymphatic marker (podoplanin), which recently was found to express at a high level in lymphatic endothelial cells. CD68 is a marker, which is used to visualize activated macrophages. Morphometric analysis was performed using light microscopy and a digital camera Leica (vol. × 40). The pictures are processed by a computer program "VideoTesT-Morphology 5.2" in order to estimate the specific area of vessels in relation to the tumor tissue (%) during the researcher's visual inspection. IHC - specimen evaluation was carried out using a Table of random numbers. Counting the number of macrophages was realized by using light microscopy (magnification × 40) in nodular, nodular and diffuse areasof tumor growth. Macrophages were counted on 1 mm^2 of tumor tissue. The number of positive cells was determined intrafollicular and interfollicular space.
Results: 5-year OS rate in group 1 was significantly higher than in group 2 (83±7% *vs* 28±13%; P=0,03) (Figure 1A). Evaluation of the specific area of blood and lymph vessels was conducted in two comparable groups. The specific area of blood vessels in group 2 was significantly higher than in group 1: 0,04 (95% CI, 0,03-0,05) *vs* 0,02 (95% CI, 0,01-0,03) (Figure 1B). The specific area of the lymph vessels in group 2 was significantly higher than in group 1: 0,06 (95% CI, 0,04-0,07) *vs* 0,03 (95% CI, 0,01-0,04) (Figure 1C). The number of CD68 - positive macrophages with nodular and diffuse growth of tumor in group 2 was significantly higher than in group 1: 800 (95% CI: 380–1222) *vs* 79 (95% CI: 10–566) (Figure 1D).

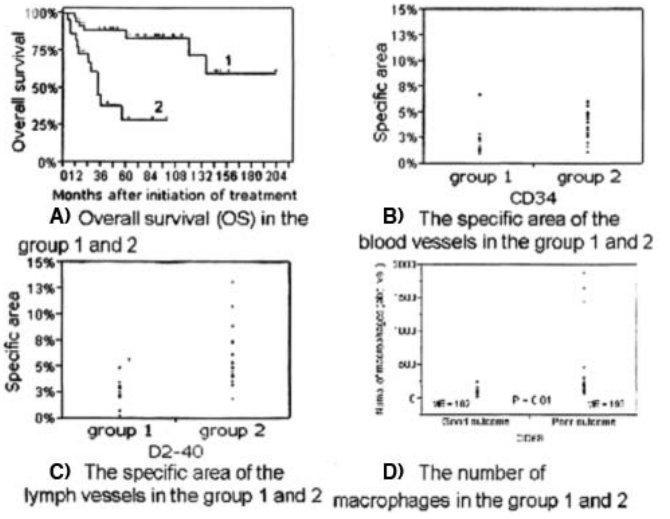

Figure 1.

Summary and Conclusions: The microvascular density can be estimated using the markers CD34 and D2-40. Our results demonstrate an association between prognosis and angiogenic sprouting and reveal higher angiogenic activity in the poor prognostic group. The higher number of macrophages is also associated with a worse prognosis. Probably, these results will let determinate the nature of the follicular lymphoma.

P838

ANALYSIS OF SOX11, SOX4 AND SOX12 IN MANTLE CELL LYMPHOMA

B Sander[1,*], A Wasik[2], M Lord[2], X Wang[3], F Zong[4], P Andersson[5], E Kimby[6], B Christensson[1], M Karimi[6]
[1]Laboratory Medicine, Pathology, Karolinska Institutet and Karolinska University Hospital, [2]Laboratory Medicine, Pathology, Karolinska Institutet, Stockholm, [3]Center for Primary Health Care Research, Lund University Hospital, Lund, [4]Karolinska Institutet, [5]Hematology, Stockholm South Hospital, [6]Medicine, Center for Hematology, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden

Background: The related transcription factors SOX11, SOX4 and SOX12 share significant homology at the gene and protein level and are classified as the SOXC family. In mantle cell lymphoma (MCL), SOX11 is expressed in approximately 90% of cases. Lack of SOX11 expression has been associated to a different biological behavior in MCL. Little is known on how SOX4 and SOX12 are expressed in SOX11 positive and SOX11 negative MCL. SOX11 has been suggested to be epigenetically regulated in lymphoma, but there are partly conflicting results considering the role of promoter methylation.
Aims: To investigate the role of promoter methylation in SOX11 expression. To investigate how SOX4 and SOX12 are expressed in SOX11 positive and SOX11 negative MCL.
Methods: Expression of SOXC transcription factors was analyzed by Q-PCR

in primary MCL (n=29), in MCL cell-lines (n=4) and in non-malignant lymph node, spleen and peripheral blood B lymphocytes (PB). These samples were also investigated for promoter methylation using McrBC-digestion and pyrosequencing. The expression of SOXC transcription factors in MCL cell lines was also investigated after treatment with 5-azacytidine.
Results: SOX11 was expressed in all but three primary MCL (median 500-fold expression compared to PB) and in 3/4 MCL cell lines while non-malignant lymphocytes lacked SOX11 expression. SOX4 was variably expressed; 13/29 MCL expressed lower levels and 10/29 expressed higher SOX4 levels than PB. SOX12 was expressed at higher levels in 27/29 MCL compared to PB. Three SOX11 negative primary MCL all expressed SOX12. In SOX11 positive MCL there was a highly significant correlation between expression of SOX4 and SOX11 (Spearman´s correlation coefficient 0,56; P<0,005) and between SOX12 and SOX11 (Spearman´s correlation coefficient 0,63; P<0,005). The promoter region of SOX11 was hypomethylated in SOX11 positive MCL as well as in non-malignant B-lymphocytes and heterogeneously methylated in the three SOX11 negative MCL cases. Treatment with 5-azacytidine reduced SOX11 expression in 2/3 SOX11 positive MCL cell lines and induced expression of SOX4 but not SOX11 in the SOX11 negative MCL cell line JVM2.
Summary and Conclusions: SOX11 expression in MCL is not regulated by promoter methylation but methylation at other sites might be of importance for sustaining high SOX11 expression levels. SOX12 are expressed at higher levels in SOX11 positive and SOX11 negative MCL compared to non-malignant lymphocytes. Finally, the expression of SOXC transcription factors is strongly correlated in SOX11 positive MCL. This might be highly biologically relevant since the members of the SOXC family have been reported to activate similar target genes.

P839

HIV ASSOCIATED DOUBLE–HIT B-CELL LYMPHOMAS PREFERENTIALLY INVOLVE THE MYC AND BCL6 GENE LOCI

P Willem[1,*], Y Perner[2], T Wiggill[3]
[1]Haematology and Molecular Medicine, National Health Laboratory Service, Faculty of Health Science University of the Witwatersrand, [2]Anatomical Pathology, National Laboratory Service, [3]Haematology and Molecular Medicine, National Health Laboratory Service, Faculty of Health Science University of the Witwatersrand, Johannesburg, South Africa

Background: Double-hit (DH) lymphomas have recently attracted attention due to their aggressiveness, their possible under diagnosis previously and the need to better characterize these disease in order to develop novel treatment strategies. A number of case studies and case series on DH lymphoma show that these diseases are very aggressive, are often classified as lymphomas with features intermediate between diffuse large B-cell lymphoma (DLBCL) and Burkitt lymphoma (BL) and typically have translocations of the *MYC* and *BCL2* genes which partner with the immunoglobulin loci. Double hits involving *MYC* and *BCL6* translocations are much more rarely described in the international literature. HIV infection significantly increases the risk of developing high grade B-cell lymphoma. These often present with atypical features posing challenges in diagnosis. In particular, lymphomas presenting with L3-like morphology have other features that best fit the diagnosis of the intermediate class of lymphoma introduced in the WHO 2008 classification (B-Cell lymphoproliferative disorder, NOS, with features intermediate between BL and DLBCL).
Aims: To characterize the clinical, morphological, immunological and cytogenetic features of HIV associated double-hit B-cell lymphoma.
Methods: Reports of patients who presented with HIV-associated high grade B-Cell Lymphoma (particularly Burkitt-like and atypical Burkitt lymphoma /leukaemia), between 2008 and 2012 were reviewed for the presence of DH lymphoma on cytogenetic/FISH analysis. Cytogenetics studies were performed using standard methods and GTG banding, chromosomes were classified according to ISCN 2013. Fluorescence *in situ* hybridization (FISH) was performed using LSI c-MYC/IGH dual colour dual fusion translocation probe and/or LSI c-MYC dual-colour breakapart rearrangement probes, LSI BCL6 dual colour breakapart rearrangement probes and LSI BCL2/IGH dual colour dual fusion translocation probe. Flow cytometry and immunohistochemistry were performed as per standard protocols.
Results: Seven patients were diagnosed between 2008-2012. This included five adults (3 males and 2 females) with an age ranging from 25 to 41 years, (mean age of 35 years) and two male children (6 and 7 years old respectively). All patients were HIV positive and had systemic disease at presentation. Five patients (3 adults, 2 children) had morphology/histology with a mixture of cells of intermediate to large size best fitting the diagnosis of B-cell lymphoma with intermediate features between DLBCL and BL. Two adults patients had a more typical L3 morphology. A complex karyotype with more than 3 structural and/or numerical chromosomal aberrations was seen in every patient. MYC was rearranged in a classical t(8;14)(q24;q32) in four cases and in a variant Burkitt translocation t(8;22)(q24;q11) in three cases. BCL6 was involved in a t(3;14)(q27;q32) in 4 cases and in a t(3;22)(q27;q11) in 2 cases. In one case BCL6 rearrangement was not seen on karyotype but was detected by FISH in 50% of cells. The most common additional aberration was trisomy 1 or partial trisomy/tetrasomy for chromosome 1q. MYC and BCL6 rearrangements were all confirmed by FISH. BCL2 rearrangement was not detected. One case had a triple hit with a t(8;14), t(3;22) and a t(2;14)(?q33;q32) involving an unknown partner gene on chromosome 2. Follow-up cytogenetics obtained in case 1 and2, (after 2 and 1 month respectively), revealed a rapidly evolving karyotype reflecting the aggressiveness of the disease. Immunophenotypically all cases had a CD19 B-cell lineage but weak CD10 and CD20 signals. Interestingly, immunohistochemistry performed in 3 cases for CD38 and CD138 showed weak positivity for CD38 in all 3 cases and a dim CD138 in 2 cases, with focal positive regions in the third case. All patients had a highly aggressive course of disease and died within few months of initial diagnosis.
Summary and Conclusions: In our serie, HIV associated DH lymphoma occured in young people, preferentially involved MYC/BCL6 translocations and had an aggressive course of disease with extremely poor survival. There is a need to characterize these tumours to better understand their pathogenesis and develop novel therapeutic strategies.

P840

LOSS OF NIPA LEADS TO DEFECTS IN THE REPAIR OF DNA DOUBLE STRAND BREAKS IN MICE

A Illert[1,*], C Antinozzi[2], H Kawaguchi[3], C Peschel[4], D Rooji[5], S Morris[3], M Barchi[2], J Duyster[6]
[1]Department of Internal Medicine I, University of Freiburg, Hematology, Onkology and Stem cell transplantation, Freiburg, Germany, [2]Department of Public Health and Cell Biology, Section of Anatomy, University of Rome "Tor Vergata", Rome, Italy, [3]Department of Pathology, St. Jude Children's Research Hospital, Memphis, TN, United States, [4]Department of Internal Medicine III, Technical University of Munich, Munich, Germany, [5]Center for Reproductive Medicine, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [6]Department of Internal Medicine I, University of Freiburg, Freiburg, Italy

Background: Regulated oscillation of protein expression is an essential mechanism of cell cycle control. The SCF class of E3 ubiquitin ligases is involved in this process by targeting cell cycle regulatory proteins for degradation by the proteasome. We previously reported the cloning of NIPA (Nuclear Interaction Partner of ALK) in complex with constitutively active oncogenic fusions of ALK, which contributes to the development of lymphomas and sarcomas. Subsequently we characterized NIPA as a F-Box protein that defines an oscillating ubiquitin E3 ligase targeting nuclear cyclin B1 in interphase thus contributing to the timing of mitotic entry.
Aims: To study *in vivo*-function of the G_2/M checkpoint NIPA in greater detail, we inactivated the gene *Nipa* using a conditional knockout strategy.
Results: *Nipa*-deficient animals are viable, but show a lower birth rate and a reduced body weight. Furthermore, *Nipa*-deficient males were sterile due to a block of spermatogenesis during meiotic prophase. Virtually no spermatocytes progress beyond a late-zygotene to early-pachytene stage and reach an aberrant stage, with synaptonemal complex disassembly and incomplete synapsis. *Nipa*$^{-/-}$ females are sub-fertile with an early and severe meiotic defect during embryogenesis with extensive apoptosis in early prophase (E13.5-E14.5).
Here we report, that *Nipa*$^{-/-}$ meiocytes exhibit persistent cytological markers for DNA double strand break repair proteins (like DMC1, RAD51) in meiotic prophase with more than twice as many DMC1 foci as control animals. Kinetic analysis of the first wave of spermatogenesis showed increased DMC1/RAD51 foci in *Nipa*$^{-/-}$ cells as soon as early-pachynema cells appear (13-14 days post partum). Moreover, we show that *Nipa* deficiency does not lead to a defect in meiotic sex chromosome inactivation despite epithelial stage IV apoptosis. *Nipa*-deficient spermatocytes exhibit numerous abnormalities in staining of chromosome axis associated proteins (like SYCP3 and STAG3) indicating that chromosome axis defects were associated with compromised chromosome axis integrity leading to overt chromosome fragmentation.
Summary and Conclusions: Taken together, the phenotype of *Nipa*-knockout mice is a definitive proof of the meiotic significance of NIPA and our results show a new, unsuspected role of NIPA in chromosome stability and the repair of DNA double strand breaks.

P841

IDENTIFICATION OF DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) SUBTYPES DEFINED BY THE EXPRESSION OF STROMAL PROTEINS AND THEIR ASSOCIATION WITH MICRORNAS INVOLVED IN ANGIOGENESIS

N Borges[1], M Conti[1], T Andrade[1,*], M Macedo[2], M Begnami[2], A Alves[1], G Colleoni[1]
[1]UNIFESP, [2]Hospital do Câncer A.C. Camargo, São Paulo, Brazil

Background: The identification of subtypes of DLBCL defined by expression of genes related to tumor stroma (Lenz *et al.*, 2008) may determine new paths in the treatment of these diseases using anti-angiogenic drugs. The relationship of these genes with the pro-angiomiRs is still unknown.
Aims: 1) to classify DLBCL cases according to the signature *stromal-1* and *stro-*

mal-2 using tissue microarray (TMA) and immunohistochemistry; 2) to evaluate the expression of pro-angiomiRs in paraffin embedded tissues affected by DLBCL and correlate them with the signatures of the tumor stroma.
Methods: 111 DLBCL (NOS and variants, all HIV negative) admitted to the Hospital São Paulo between 2000 and 2010 were included in this study. Expression of CD68 (*stromal-1* marker) was classified into four (0-3) levels. To analyze the expression of CD34 (MVD, *stromal-2*), we conducted a manual count of microvessels in the entire field of TMA. We performed miRNA extraction from paraffin samples using RecoverAll ™ Total Nucleic Acid Isolation Kit for FFPE Tissues (Applied Biosystems). Real-time quantitative PCR was performed using TaqMan ® Small RNA kit Assays and normalized with U18. Proangiomirs miR-92a, miR-126, miR-130a, miR-210, miR-378 and miR-296 were selected for assessment of angiogenesis and were considered differentially expressed when tumor samples levels were 1.2 times higher or lower than normal samples.
Results: *Stromal-1*cases had high expression of CD68 (scores 2-3) and low expression of CD34 (quartiles I-II) (34.4% of cases), and as *stromal-2* cases had low expression of CD68 (scores 0-1) and high expression of CD34 (quartiles III-IV) (12.5% of cases). The 38 cases that had high expression of both CD68 and CD34 (39.6%) were additionally considered as *stromal-2*, due to high MVD scores. Cases of low expression of CD68 and CD34 (13.5% of cases) were not scored. We observed a statistically significant relationship between the median expression of CD34 and Ann Arbor stage (I-II *versus* III-IV), with a predominance of high MVD expression in patients with advanced stage disease (III-IV). The median of vessels in stages I-II was 82 (range 9 to 240) and in stages III-IV was 111 (range 12-297) (P=0.0183, Mann-Whitney). For the marker CD68 (*stromal-1*) and for the other variables, there were no statistically significant associations between groups. 101 of 111 initial cases were considered suitable for analysis of microRNAs. We observed overexpression of miRNAs miR-296, miR-378, miR-92a, miR-210, miR-130a and miR-126 in 55.5%, 50.5%, 42.6%, 30.7%, 19% and 9.9% of cases, respectively. We also observed increased expression of miR-296 in DLBCL classified as stage III-IV (P=0.0355, Mann-Whitney). For other variables, there were no statistically significant differences between groups.
Summary and Conclusions: *Stromal-2* signature was found in 52.1% of cases. The higher MVD in cases of DLBCL with advanced stage (Ann Arbor III-IV) shows a possible association between angiogenesis and more aggressive/disseminated disease, being a possible target for anti-angiogenic therapy in cases that do not achieve a complete response with R-CHOP. The miR-296, directly responsible for decreased levels of hepatocyte growth factor and indirectly by the upregulation of VEGFR2 and PDGFRβ, showed overexpression in 55.5% of DLBCL and association with advanced stage disease. Our study provides new information about the importance of the role of microRNAs in the development of DLBCL, which can be exploited as a therapeutic target and prognostic factor for patients with this malignant disease of high prevalence. (Supported by FAPESP 2010/17668-6).

P842

DISTINCT GENE EXPRESSION PROFILES IN A CANINE MODEL OF HUMAN DLBCL

S Bresolin[1,*], P Mahmoodi[1], M Gelain[2], F Riondato[3], M Mortarino[4], S Comazzi[4], G Basso[1], L Aresu[5], G Te Kronnie[1]
[1]Department of Women's and Children's Health, University of Padova, [2]Department of Comparative Biomedicine and Food Science, University of Padua, Padova, [3]Department of Veterinary Science, University of Turin, Turin, [4]Department of Veterinary Sciences and Public Health, University of Milan, Milan, [5]Department of Comparative Biomedicine and Food Science, University of Padova, Padova, Italy

Background: Diffuse large B-cells lymphoma (DLBCL) is the most common type of lymphoma in adults. In humans, several studies have categorized DLBCL lymphomas into different morphological and molecular subtypes. Gene expression profiling provided a tool to reveal the presence of at least 3 subtypes of DLBCL; active B-cell (ABC-DLBCL), germinal center B-cell (GCB-DLBCL), and primary mediastinal B-cell Lymphoma (PMBL) with specific signatures correlating to the clinical course of the disease.
Aims: Evaluate the potential benefits of a canine model as an experimental platform to improve treatment and evaluate new therapies for both humans and dogs with DLBCL. In particular, the dog presents an ideal model with spontaneous occurrence of the disease. Indeed, Non-Hodgkin lymphoma is the most common hematopoietic disease in dogs that shares morphological and immunophenotypic features with human DLBCL and a highly aggressive course of the disease. Here we characterized at morphological, phenotypic, and molecular levels dogs with DLBCL to assess the factual likeness of these malignancies between human and dog patients.
Methods: More than one-hundred DLBCLs were collected during a three years period (2009-2012) at the diagnostic service of the Department of Veterinary Sciences and Public Health in Milan (IT). The diagnosis was based on morphological criteria and expression of CD20, CD21 and CD79. For twenty-one dogs with the morphological diagnosis of DLBCL that yielded high-quality extracted RNA, gene expression profiling was performed, using Affymetrix Canine 2.0 platform (Affymetrix, Santa Clara, CA, USA). Five samples of normal lymph nodes were also analyzed. Data analyses were generated by R Bioconductor software and public databases of gene signatures (http://Lymphochip.nih.gov/signaturedb/ and http://broadinstitute.org/gsea/msigdb/index/jsp) used to cross-compare human and dog signatures.Written informed consent was obtained from the dog owners.
Results: In dogs with DLBCL, the whole gene expression profiling analysis identified two clusters, a minor and a major one, with distinct signatures, providing the first example of molecular subgroups in Canine DLBCL not observed with the current standards of classification. No differences in age, gender and breed were observed for the 2 subgroups. Pathway analysis revealed activation of different pathways; the minor clusters showed decrease of apoptosis, DNA-damage response and down regulation of cell cycle progression genes suggesting a link with the human GCB-DLBCL signature. Moreover, the major cluster showed activation of *NFKB2* and *FUT8* genes together with a high expression of genes related to proliferation as revealed by cross comparison analysis between human and dog signatures, more correlated with ABC-DLBCL. Dogs DLBCL showed a general down-regulation of *BCL-6* gene compare to normal lymph nodes with a further difference between the two clusters.
Summary and Conclusions: In conclusion, in this study we analyzed gene expression profiles of dogs with DLBCL to determine if the dog with spontaneous occurrence of the disease can represent a useful study model for human DLBCL. We showed that as in human lymphoma molecular subtypes of DLBCL could be distinguished also in dogs. Further studies are needed to translate the relevance of the canine model of DLBCL to clinical research in human lymphoma.

P843

REAL-WORLD TREATMENT PATTERNS AND OUTCOMES IN ELDERLY PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: SEER-MEDICARE ANALYSIS

P Hamlin[1,*], S Satram-Hoang[2], C Reyes[3], K Hoang[2], S Guduru[2], S Skettino[3]
[1]Memorial Sloan-Kettering Cancer Center, New York, [2]Q.D. Research, Inc., Granite Bay, [3]Genentech, Inc., South San Francisco, United States

Background: A disproportionate number of newly diagnosed diffuse large b-cell lymphoma (DLBCL) occurs in elderly patients
Aims: We set out to evaluate real-world treatment patterns and outcomes in elderly patients with DLBCL in the United States.
Methods: We utilized a retrospective cohort analysis of 9333 DLBCL patients in the linked Surveillance, Epidemiology, and End Results (SEER)-Medicare database. Patients were diagnosed between 1/1/2000 - 12/31/2007, >66 years, and continuously enrolled in Medicare Part A and B in the year prior to diagnosis. There were 4565(49%) R (rituximab) +Chemo, 2181(23%) Chemo-only, and 467(5%) R-mono patients who initiated treatment within 3 months after diagnosis. The remaining 2120(23%) did not receive any treatment. Statistical comparisons were made between R+Chemo *vs.* Chemo-only, and R-mono *vs.* No Treatment. Logistic regression modeling assessed patient characteristics predictive of not receiving treatment. Kaplan-Meier curves and Cox proportional hazards regression assessed overall survival by treatment type. The median follow-up time was 2.4 years and date of last follow-up was 12/31/2009.
Results: Patients receiving R+Chemo were slightly younger (≤75yrs: 50% *vs.* 46%; P<0.05), more likely white, and married compared to those receiving Chemo-only. Patients receiving R-mono were older (>80yrs: 60% *vs.* 50%; P<0.01), and more likely female compared to those Not Treated). In general, untreated patients were older at diagnosis (mean age 80 *vs.* 77; P<.0001), more likely non-white (14% *vs.* 12%; P<.01), diagnosed at late stage (51% *vs.* 44%; P<.0001), and had higher comorbidity burden than treated patients (P<.0001). As age increased, the treatment rate significantly decreased especially among patients >80yrs. In the adjusted logistic regression model, increasing age, non-white race, male gender, higher comorbidity score, unmarried and lower income were predictive of not receiving any treatment. The unadjusted median overall survival was 96 months in the R+Chemo group *vs.* 13 months in Chemo-only group (log rank P<.0001); and 18 months in the R-mono group *vs.* 2 months in the Not treated group (log rank P<.0001). Among the treated, there were more R+Chemo and R-mono treatment cycles than Chemo-only cycles (5 *vs.* 4 cycles; P<.0001) delivered in the first-line. In multivariate survival analysis, patients receiving Chemo-only had a 2-fold increased risk of death (HR=2.20; 95%CI=2.04-2.37) compared to R+Chemo patients. Increasing age and comorbidity score were associated with significant increases in mortality. A higher mortality risk was noted with receipt of <6 cycles (HR=1.40; 95%CI=1.22-1.62) compared to 6 cycles. R-mono patients had a 69% lower risk of death (HR=0.31; 95%CI=0.28-0.35) compared to Not treated patients. Almost identical mortality risk reductions with R+Chemo and R-mono were also noted in a subgroup of patients >80yrs.
Summary and Conclusions: Twenty-three percent of elderly DLBCL patients were not receiving treatment for their disease. We observed that R+Chemo and R-mono significantly decreased mortality risk in elderly DLBCL patients relative to chemo only and no treatment, respectively. The benefits were maintained even among patients >80yrs, who were less likely to receive treatment. Suboptimal durations of curative intent therapy (<6 cycles) were found to be associated with poorer outcomes.

P844

CLINICAL SYMPTOM OR SIGN-DIRECTED SURVEILLANCE CAN BE MORE USEFUL TO DETECT RELAPSE COMPARED TO ROUTINE IMAGING IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA AFTER COMPLETE REMISSION

J Hong[1], J Kim[2], S Yoo[1], J Ahn[3], J Park[1], J Hoon Lee[1,*]
[1]Department of Internal Medicine, [2]Department of Nuclear Medicine, [3]Department of Laboratory Medicine, Gachon University School of Medicine, Incheon, Korea, Republic of Korea

Background: Although the prognosis of patients with diffuse large B-cell lymphoma (DLBCL) has improved after introduction of rituximab, about one-third of the patients still experience eventual disease relapse. As there exists the second chance of cure by salvage therapy followed by autologous stem cell transplantation (ASCT), the optimal follow-up strategy to detect relapse early enough to proceed salvage therapy with maintenance of good performance status should be established for patients who have achieved a complete remission (CR) after frontline therapy. Despite lacking evidences, routine imaging has been widely adopted in surveillance of patients with lymphoma after CR.
Aims: The current study aimed at analyzing the patterns and their outcomes of out-patient department (OPD) follow-up for surveillance and evaluating the role of routine imaging and the result of unplanned early OPD visit in patients with DLBCL after CR.
Methods: Patients were included if they 1) diagnosed as DLBCL according to 2008 WHO criteria, 2) achieved CR by 2007 Revised Criteria after R-CHOP immunochemotherapy with or without consolidative therapy such as radiotherapy or ASCT, and 3) had at least 1 OPD visit for the surveillance of relapse. Routine imaging was defined as scheduled computed tomography (CT) or Positron Emission Tomography (PET)/CT at least 3 months prior to actual scanning by physician without any suspicious symptom or sign of the patients.
Results: From May 2004 to Feb. 2012, 106 of 151 patients with DLBCL (70.2%) obtained CR and fifteen of them (14.2%) experienced relapse, with a median follow-up duration of 38.1 months. A total of 856 OPD visits (median6, range 1-25) were recorded from the 106 patients: 501 visits (median4, range 0-15) were OPD surveillance with routing imaging (332 visits with CT alone, 94 with PET/CT alone, and 75 with both CT and PET/CT) and 322 visits (median2, range 0-14) were planned OPD surveillance with only history taking and physical examination (Hx & P/Ex). Thirty-three visits (33/856=3.9%) were unplanned early visit by patiensts due to any abnormal symptom or sign. Routine imaging showed a perfect sensitivity and negative predictive value but low positive predictive value (PPV) due to frequent false-positive visits. Six of seven patients with false-positive routine CT scan and 17 of 23 patients with false-positive surveillance PET/CT received unnecessary further evaluation (please see the image). Compared to planned OPD surveillance with routine imaging (3 relapses out of 501 visits) and planned OPD visit with Hx & P/Ex (1 relapse out of 322 visits), early visits by patients due to any symptom or sign were highly related to disease relapse: 11 out of 33 visits (33.3%) resulted from relapse of DLBCL. Although survival from the time of relapse was not compared because of small sample size, no tendency of survival benefit in 3 patients with asymptomatic detection by routine imaging was observed (Figure 1).

Routine imaging with CT

	No Relapse	Relapse
CT normal	397	0
CT abnormal	7	3

Sensitivity: 100% (95% CI 30.5 ~ 100.0)
Specificity: 98.3% (95% CI 96.5 ~ 99.3)
PPV : 30.0% (95% CI 7.0 ~ 65.2)
NPV : 100% (95% CI 99.1 ~ 100.0)

7 patients with false positive
2 short-term CT follow-up
2 MRI correlation
1 biopsy with local anesthesia
1 biopsy with general anesthesia
1 close observation

Routine imaging with PET/CT

	No Relapse	Relapse
PET/CT normal	142	0
PET/CT abnormal	23	3

Sensitivity: 100% (95% CI 30.5 ~ 100.0)
Specificity: 86.1% (95% CI 79.8 ~ 91.0)
PPV : 11.5% (95% CI 2.6 ~ 30.2)
NPV : 100% (95% CI 97.4 ~ 100.0)

23 patients with false positive
7 CT or ultrasonogram correlation
3 ENT exam correlation
2 gynecologic exam correlation
3 biopsy with local anesthesia
1 biopsy with general anesthesia
1 diagnosed as infection (liver abscess)
6 close observation

Figure 1.

Summary and Conclusions: Surveillance routine imaging has limited value because of low PPV and its resultant unnecessary procedures such as additional imaging or biopsy. Considering the risk of radiation exposure, financial cost, and anxiety of the patients (Thompson CA *et al.*, *Ann Oncol* 21:2262-2266), routine imaging seems not to be an appropriate strategy for patients with DLBCL after CR. It is mandatory to perform thorough Hx & P/Ex, and adequate further active investigation when a patient visit OPD earlier than planned schedule and it have to be emphasized that patients should not hesitate to visit hospital earlier if they have any discomfort.

Background: Hepatitis C virus (HCV) associated B-cell non-Hodgkin lymphomas (B-NHL) are a model of lymphoma induced by chronic antigenic stimulation. Lymphomagenesis mechanisms and treatment management remains matter of debate.
Aims: The national Lympho-C study collected clinical and biological data from HCV associated B-NHL aiming to better understand lymphomagenesis, treatment and outcome.
Methods: Adult patients with B-NHL and active HCV infection were included in this observational multicenter study. Patients co-infected with HIV could not be included. Data were collected from patients with either ongoing (prospective) or past (retrospective) history of HCV associated B-NHL. Cytological and histological samples were collected for centralized review and molecular analyses. Informed consent was required for each patient.
Results: Between 2006 and 2012, 138 consecutive patients were enrolled in 26 French hospitals. Subsequently 13 patients were excluded from analysis. 59 out of 125 (47%) patients were included at B-NHL diagnosis. At lymphoma diagnosis, median age was 61 years $_{IQ25-75}$[50-71] and genderratio was 0.9. Genotype HCV distribution was genotype 1 (51%), 2 (19%), 3 (9%), 4(10%), 5 (1%) or unknown (10%). Median delay between HCV infection and B-NHL diagnosis was 25 years $_{IQ25-75}$[21-31] (unknown in 41/125 patients). Cyto-histological pattern was: diffuse large B cell lymphoma (DLBCL): 49/125 (39%), marginal zone lymphoma (MZL): 48/125 (38%), follicular lymphoma: 16/125 (13%) and others types 13/125 (10%). Among DLBCL, 17/49 (35%) were transformed from underlying indolent lymphoma. Patients in DLBCL group displayed frequent digestive tract (17/49; 35%) and hepatic (11/49; 22%) involvements. Patients in MZL group showed frequent spleen (23/48; 48%) and hepatic (13/48; 27%) involvements. The MZL patients had higher levels of rheumatoid factors (P=0.001) and more frequent mixed cryoglobulinemia vasculitis (11/48; 23%) (P=0.042). Median follow-up since lymphoma diagnosis was 31 months $_{IQ25-75}$[19-71]. At the end of follow-up, 79/125 (63%) had received antiviral therapy since lymphoma diagnosis, and sustained virological response (SVR) was obtained in 48/79 (61%). Significant association was shown between SVR and hematological response in LZM group (P<0.001) but not in DLBCL group (P=0.83). However in the overall population, patients with SVR had better event free survival (EFS) (P=0.06) and overall survival (OS) (P=0.006) than patients without SVR (Figure 1). During the follow-up, 16 (13%) deaths were recorded, related to lymphoma progression (n=7), infection (n=5), cirrhosis (n=3) or cardiovascular disease(n=1).

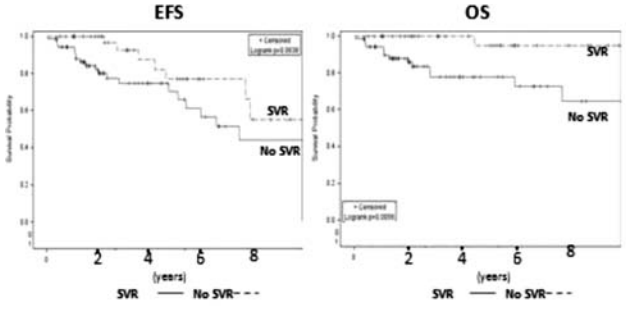

Figure 1. Impact of virologic response on HCV associated B-NHL prognosis.

Summary and Conclusions: This study underlines the heterogeneity of HCV associated B-NHL subtypes, with predominance of DLBCL and LZM. Virological success and hematological response are associated among LZM patients. Moreover, virological success appears to improve prognosis of HCV associated B-NHL patients.

P847

HIGH-DOSE METHOTREXATE, HIGH-DOSE CYTARABINE AND TEMOZOLOMIDE FOR THE TREATMENT OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

M Salamoon[1,*], T Hussein[2], M Kenj[3]
[1]medical oncology, al Bairouni university hospital, [2]pathology, Tishreen hospital, [3]biology, mazen kenj lab, damascus, Syrian Arab Republic

Background: treatment of primary central nervous system lymphoma (PCNSL) associates with low response and survival rates using conventional radio and chemotherapy.Due to its favorable toxicity profile,Temozolomide has emerged as a new option for the treatment of PCNSL.In this study we report a consecutive series of PCNSL patients treated with an innovative regimen combining high-dose of both Cytarabine and Methotrexate with Temozolomide without Radiotherapy or intra-thecal chemotherapy
Aims: to evaluate a new intensive chemotherapy with a new drug Temozolomide,trying to assess response rate and progression free survival and if the results are promising we are aiming ate evaluating the overall survival rate at 5 years taking into consideration the toxicity profile.The study was performed at al Bairouni university hospital and al Shahbandar medical center in Damascus (SYRIA).
Methods: we have included 40 patients under 60 years old newly diagnosed with PCNSL histologically confirmed by a reference pathologist,biopsies were also cultured and Karyotype was performed for almost all patients.An induction chemotherapy was started (Methotrexate 3 gr/m2 infused over 12 hours on day 1+Cytarabine 3 gr/m2 twice daily,short infusion on day 1+Temozolomide 100 mg/m2 from day 2 through day 6).A total of 6 cycles were given on a monthly basis.
Results: among the 40 patients included in the study,a complete response was observed in 34 patients (85%) *versus* a partial response seen in the remaining 6 patients (15%).Disease was progressed in 8 out of 40 patients (20%) while 31 patients were still living after 5 years making the overall survival reaching (77%).Grade II nephrotoxicity was observed in 2 patients while grade II and IV hematologi toxicity were seen in 5 patients.
Summary and Conclusions: our study has reached the 5-years overall survival comparing with other regimens not exceeding 35 months taking into consideration the lack of both radiotherapy and intra-thecal chemotherapy,also the good toxicity profile makes it an acceptable regimen.However,more prospective studies are warranted to confirm or reject such results.

P848

MALE SEX EVOLVES AS A SIGNIFICANT RISK FACTOR IN DLBCL TREATED WITH RITUXIMAB ONLY IN ELDERLY, BUT NOT IN YOUNG PATIENTS: CORRELATION WITH RITUXIMAB (R) PHARMACOKINETICS

M Pfreundschuh[1,*], C Mueller[2], S Zeynalova[3], G Held[1], V Poeschel[1], C Zwick[1], T Rixecker[1], N Schmitz[4], N Murawski[1]
[1]Internal Medicine I, Saarland University Medical School, Homburg, [2]Pharmacology, University of Cologne, Cologne, [3]IMISE, University of Leipzig, Leipzig, [4]Hematology/Oncology, Asklepios Hospital St. Georg, Hamburg, Germany

Background: Sex and weight influence R clearance in elderly DLBCL patients (Mueller *et al.*, Blood 2012).
Aims: Therefore, we now investigated the influence of sex and weight on R pharmacokinetics and outcome in young DLBCL patients.
Methods: We analyzed the impact of sex on R pharmacokinetics and outcome of 1222 elderly pts of the RICOVER-60, 823 young (18 to 60 years) aaIPI=0,1 pts of the MInT, and 275 aaIPI=2,3 pts of the Mega-CHOEP trials. R pharmacokinetics was determined in 33 young and 49 elderly patients. Population pharmacokinetic modeling was performed with nonlinear mixed-effect modeling software (NONMEM VI).
Results: R clearance was independent of tumor mass (IPI), but weakly correlated (0.2, R^2linear=0.045) with increasing age in male, and moderately inversely correlated (-0.5, R^2linear=0.207) with age in female DLBCL patients, resulting in similar R clearances in young female and male patients (9.88 *vs.* 10.38 mL/h; P=0.238), but a significantly slower R clearance in elderly males compared to females (10.50 *vs* 8.25 mL/h; P=0.006). In the RICOVER-60 trial, elderly females had a higher 3-year PFS (68% *vs.* 61%) and OS (74% *vs.* 68%) than male pts. due to a greater outcome improvement by the addition of R in females. In a multivariable analysis adjusting for IPI, the male hazard for progression was not significantly increased after CHOP (HR=1.1; P=0.348), but was significantly higher after R-CHOP (OR=1.6; P=0.004). In contrast, young males treated in the MInT and Mega-CHOEP trials benefitted as much as females from the addition of rituximab, with a similar male hazard after CHOP and R-CHOP (HR=1.2) with no significant difference to female patients (HR_{PFS}=1.2, P=0.552; HR_{OS}=1.0; P=0.898).
Summary and Conclusions: While no differences in R clearance and benefit from rituximab were found in young female compared to male patients, the reduced benefit of adding R to CHOP in elderly male DLBCL pts. who have a shorter rituximab serum half life and hence lower serum levels suggests that this subpopulation is suboptimally dosed when R is given based on body surface area at 375 mg/m^2. Appropriately designed prospective DSHNHL studies investigate whether higher R doses for pts. with a shorter R serum half life can improve the outcome of the respective patients.
Supported by Deutsche Krebshilfe and Roche.

P849

THE BCL-2 INHIBITOR ABT-199 (GDC-0199) IS ACTIVE AND WELL-TOLERATED IN PATIENTS WITH RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA AND OTHER NON-HODGKIN LYMPHOMAS

M Davids[1,*], J. Seymour[2], J Gerecitano[3], B Kahl[4], J. Pagel[5], W. Wierda[6], M Anderson[7], D Darden[8], C Nolan[8], L Gressick[8], J Yang[8], B Chyla[8], T Busman[8], A Graham[8],E Cerri[8], S Enschede[8], R Humerickhouse[8], A Roberts[7]
[1]Dana-Farber Cancer Institute, Boston, MA, United States, [2]Peter MacCallum Cancer Centre, Melbourne, Australia, [3]Memorial Sloan-Kettering Cancer Center, New York, NY, [4]University of Wisconsin, Madison, WI, [5]University of Washington, Seattle, WA, [6]University of Texas, Houston, TX, United States, [7]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [8]AbbVie Inc., North Chicago, IL, United States

Background: New treatment options are needed for patients with relapsed or refractory lymphomas, particularly those such as mantle cell lymphoma (MCL) where curative options are limited. The anti-apoptotic protein BCL-2 is highly expressed in many non-Hodgkin lymphoma (NHL) subtypes, including MCL. Because BCL-2 plays a critical role in NHL pathogenesis and treatment resistance, it is a promising target for therapeutic intervention. A first-generation BCL-2 inhibitor, navitoclax, showed modest activity in indolent lymphoma, but co-inhibition of BCL-x_L resulted in dose-limiting thrombocytopenia, precluding the full exploration of BCL-2 inhibition with this agent in NHL. ABT-199 is an orally bioavailable, second-generation BH3-mimetic that potently inhibits BCL-2 (K_i<0.10 nM). Unlike navitoclax, which has similar activities against BCL-2 and BCL- x_L, ABT-199 has 500-fold less activity against BCL-x_L (K_i=48 nM). It demonstrates potent activity against a variety of human cell line and xenograft models of a range of B-cell NHL, including MCL.
Aims: The primary objectives of this phase-I dose-escalation study are to evaluate the safety and pharmacokinetics (PK) of ABT-199, determine a maximum tolerated dose and recommended phase 2 dose, and assess efficacy and biomarkers. We report results to date for patients in the R/R NHL arm.
Methods: Adult patients (pts) requiring therapy, with ECOG performance status ≤1, and adequate marrow function (ANC ≥1.0 × 10^9/L, Plts ≥50 × 10^9/L) received ABT-199 on Week 1 Day -7 (W1D-7), followed by continuous once-daily dosing from W1D1, until progressive disease or unacceptable toxicity. Due to concerns for potential tumour lysis syndrome (TLS), a 2 to 3 wk lead-in period with stepwise escalation to the target cohort dose was implemented. Evaluations include adverse events (AE; NCI-CTCAE-V4), PK parameters and disease responses (IWG 2007 criteria). Dose cohorts up to 900 mg have been evaluated to date.

Table 1.

Characteristic	All NHL n=31	MCL Subset n=8
Age (yr)†	68 [35-85]	72 [35-75]
Male#	20 (64.5)	6 (75)
Number of prior therapies†	3 [1-7]	2.5 [1-7]
Bulky disease (>= 5 cm)#	13 (42)	6 (75)
Bulky disease (>= 10 cm)#	4 (13)	1 (13)
Time on study (days)†	143 [14-448]	160 [56-291]

Time to first 50% reduction in nodes (days)†	42 [36-113]	42 [36-113]
Best response‡	n=29	n=8
CR	1 (3)	0 (0)
PR	15 (52)	8 (100)
SD	8 (28)	0 (0)
PD	5 (17)	0 (0)
Response Rate (CR + PR)	55%	100%

†median [range]; #n(%); ‡Evaluable pts completed at least a W6 assessment
CR achieved in 1/7 pts with diffuse large B-cell lymphoma (DLBCL)
PRs achieved in 3/3 Waldenstrom macroglobulinaemia, 2/9 follicular lymphoma and 2/7 DLBCL pts

Results: As of January 2013, 31 pts have been enrolled, 8 (26%) with MCL (Table 1). The most common AEs of any grade (≥15% of pts) were nausea (36%), diarrhea (26%), dyspepsia, vomiting, fatigue, pyrexia and cough (16% each). Grade 3/4 AEs occurring in >1 pt were anaemia, neutropenia (4 pts each), febrile neutropenia (2 pts) and thrombocytopenia (3 pts). Gr 3/4 throm-

bocytopenia was not dose-dependent. Two of 14 pts in cohort 5 experienced DLTs (Gr 3 febrile neutropenia and Gr 4 neutropenia) at the target dose of 600 mg. Gr 3 TLS was seen after the initial dose in 1 pt with bulky MCL (largest lymph node >10 cm). 17 pts have discontinued drug: 13 due to progression, 2 due to AEs and 2 proceeded to stem cell transplantation in ongoing response. After a single dose with high-fat meal, ABT-199 had T_{max} ~ 8 hrs and $T_{1/2}$ ~ 15 hrs. Food increased ABT-199 bioavailability by 3-4 fold.
Preliminary efficacy data are summarised (Table 1).
Summary and Conclusions: ABT-199 shows a high efficacy signal in MCL, with all 8 pts to date achieving PR. The drug is generally well-tolerated, and shows activity in several NHL subtypes, with an overall response rate of 55% in this R/R population. Additional dosing and scheduling modifications are being explored in both monotherapy and combination studies in NHL to optimize the balance between the safety and efficacy of this active new agent. Updated results will be presented. (study status see clinicaltrials.gov).

P850

LENALIDOMIDE PLUS RITUXIMAB-CHOP21 IN ELDERLY UNTREATED DIFFUSE LARGE B-CELL LYMPHOMA IS PROMISING: LONG TERM RESULTS OF THE PHASE II REAL07 STUDY OF THE FONDAZIONE ITALIANA LINFOMI (FIL)

A Chiappella[1,*], A Castellino[1], S Franceschetti[1], A Carella[1], I Baldi[2], M Zanni[1], A Liberati[1], M Spina[1], A Tucci[1], V Pavone[1], A Molinari[1], P Zinzani[1],F Salvi[1], P Fattori[1], A Zaccaria[1], B Botto[1], A Congiu[1], M Ladetto[1], M Dreyling[3], G Gaidano[1], G Inghirami[4], G Rossi[1], U Vitolo[1]
[1]On behalf of FIL, Hematology2, Città della Salute e della Scienza, [2]Unit of Cancer Epidemiology, University and CPO Piemonte, Torino, Italy, [3]Medizinische Klinik III - Universität München, München, Germany, [4]Department of Pathology, Center for Experimental Research and Medical Studies, University of Torino, Torino, Italy

Background: Standard treatment for elderly diffuse large B-cell lymphoma (DLBCL) patients is R-CHOP21, however up to 40% of patients fail. In the phase I trial REAL07 conducted by FIL, 15 mg lenalidomide from day 1 to day 14 was identified as the maximum tolerated dose (MTD) in combination with R-CHOP21,showing that the association of Lenalidomide plus R-CHOP21 (LR-CHOP21) is safe and feasible in elderly untreated DLBCL patients.
Aims: Based on the phase I results, FIL conducted a phase II trial REAL07 aimed at evaluating efficacy of LR-CHOP21 combination. Primary endpoint was an improvement of overall response rate (ORR) of 15% in LR-CHOP21 compared to 70% of standard R-CHOP21.
Methods: Phase II was designed according to Simon's two stage design. Response was evaluated according to 2007 Cheson criteria. PET scan was mandatory at the end of the treatment; patients in partial remission (PR) who underwent radiotherapy were considered as failure in progression free survival (PFS) analysis. Inclusion criteria were: age 60-80 FIT at the comprehensive geriatric assessment; untreated CD20+ DLBCL; Ann Arbor stage II/III/IV; international prognostic index (IPI) at low-intermediate/intermediate-high/high (LI/IH/H) risk. Treatment plan was: R-CHOP21 plus 15 mg lenalidomide from day 1 to 14 for 6 courses. All cases were reviewed by expert pathologists and tissue samples were centrally collected. With the aim to correlate outcome with cell of origin profile and biological markers, immunohistochemistry for Hans' and Choi criteria and gene expression profile were planned and are in advanced status of analysis at the time of the submission of the present abstract.
Results: From April 2010 to May 2011, 49 patients were enrolled. Clinical characteristics were: median age 69 years (range 61-80); stage III/IV 43 (88%), performance status >1 31 (63%), IPI IH/H 30 (61%). At the end of 6 LR-CHOP21, ORR was 45/49 (92%). Complete remissions (CR) were 42 (86%) and PR 3 (6%); 3 patients (6%) did not respond and one (2%) died for violent death. At a median follow-up of 22 months, 2-year overall survival (OS) was 92% (95%CI: 79-97) and 2-year PFS was 73% (95%CI: 57-84). According to IPI risk, 2-year PFS for IPI LI was 84% (95%CI: 59-95) and for IPI IH/H 65% (95%CI: 41-81). PFS analysis according to cell of origin profile is ongoing. Hematological toxicity was mild: grade III/IV thrombocytopenia occurred in 13% of the 277 courses performed, anemia in 5% and neutropenia in 31%, with only 4% of febrile neutropenia. No grade IV extra-hematological toxicities were observed. Grade III non-hematological toxicities were reported in 7 patients: cardiologic, gastroenteric and renal in one patient respectively, grade III neurological toxicities, sensory and motorial neuropathy in two, thromboembolic event in one and infection in one. No toxic deaths occurred during treatment. One patient died three months off therapy while in CR, due to aeromonas hydrophila sepsis and multi-organ failure.
Summary and Conclusions: With a still limited follow-up time, our data compare favorably with historical R-CHOP21 data. LR-CHOP21 is able to induce a high 2-yr PFS (73%) and it is effective also in poor risk patients (65%). The addition of lenalidomide to R-CHOP21 is safe without unexpected toxicities. These encouraging data warrant a future phase III randomized trial comparing LR-CHOP21 *vs.* R-CHOP21 in elderly untreated DLBCL.

P851

PHASE 1B STUDY COMBINING IBRUTINIB WITH RITUXIMAB, CYCLOPHOSPHAMIDE, DOXORUBICIN, VINCRISTINE, AND PREDNISONE (R-CHOP) IN PATIENTS WITH CD20-POSITIVE B-CELL NON-HODGKIN LYMPHOMA (NHL)

A Younes[1,*], I Flinn[2], J Berdeja[3], J Friedberg[4], S Alberti[4], C Thieblemont[5], F Morschhauser[6], P Hellemans[7], B Hall[8], J Smit[7], D Skee[9], R de Vries[7], M Todorovic[10], I Khan[9], N Fourneau[7], Y Oki[1]
[1]MD Anderson Cancer Center, The University of Texas, Houston, TX, [2]Centennial Medical Center, [3]Tennessee Oncology, Sarah Cannon Research Institute, Nashville, TN, [4]Wilmot Cancer Center, University of Rochester, Rochester, NY, United States, [5]Service Hemato-oncologie University P7-Diderot, APHP-Hopital Saint Louis, Paris, [6]Services Maladies du Sang, CHRU de Lille - Hopital Claude Huriez, Lille, France, [7]Janssen Research & Development, LLC, Beerse, Belgium, [8]Janssen Research & Development, LLC, Spring House, PA, [9]Janssen Research & Development, LLC, Raritan, NJ, United States, [10]Janssen Research & Development, LLC, Belgrade, Serbia

Background: Ibrutinib, a first-in-class oral Bruton's tyrosine kinase inhibitor, has demonstrated single-agent activity in a variety of relapsed or refractory B-cell malignancies with limited toxicity, making it an appropriate drug to combine with standard R-CHOP chemotherapy in patients with previously untreated NHL.
Aims: The primary objective of this study was to determine the recommended phase 2 dose (RP2D) of ibrutinib in combination with standard R-CHOP (IR-CHOP). Secondary objectives were to assess safety, overall response rate, pharmacokinetics, and pharmacodynamic biomarkers.
Methods: Patients received a daily oral dose of ibrutinib (280, 420, or 560 mg) in combination with standard doses of R-CHOP (rituximab, cyclophosphamide, doxorubicin, and vincristine on day1, and prednisone on days 1 through 5 of each 21-day cycle for up to 6 cycles).
Results: Seventeen patients (7,4, and 6 in increasing ibrutinib doses) were enrolled: 59% male, median age 65 (range 46-81) years, diffuse large B-cell lymphoma 47%, mantle cell lymphoma 29% and follicular lymphoma 24%. In the 280 mg cohort, 2 patients had dose-limiting toxicity (DLT): 1 with transient syncope and 1 with periorbital cellulitis; at 560 mg, 1 patient had gastritis (grade 2). The RP2D was established at 560 mg ibrutinib. The most common (≥20% of patients) adverse events (AEs) were neutropenia (77%), thrombocytopenia (65%), vomiting (59%), anemia (53%), nausea (47%), fatigue (35%), headache (29%), constipation (24%), diarrhea (24%), and dizziness (24%). To date, 6 patients completed 6 cycles of treatment, and 2 patients discontinued treatment (1 due to noncompliance with study drug and 1 due to non-DLT AE). At the time of this analysis, of the 10 patients with at least one post-baseline tumor assessment, the overall response rate was 100% (7 complete and 3 partial responses).
Summary and Conclusions: The combination of IR-CHOP has an acceptable safety profile. No new toxicities were noted with adding ibrutinib to R-CHOP. An expanded 560 mg ibrutinib cohort (RP2D) is being opened to further explore the safety and efficacy of IR-CHOP in patients with newly diagnosed diffuse large B-cell lymphomas.

Background: Secondary central nervous system (CNS) involvement is a serious complication encountered during the management of diffuse large B-cell lymphoma (DLBCL) patients. Although many studies were performed to evaluate the secondary CNS involvement in DLBCL, the majority of data were from retrospective analyses. Thus, there is a few data about the prospectively monitored patients who were treated with R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone).

Aims: We analyzed the incidence of secondary CNS involvement in pathologically confirmed DLBCL patients enrolled in the Prospective Cohort Study (Risk-adapted Central Nervous System Evaluation in DLBCL, PROCESS study, NCT01202448).

Methods: Patients should be treated with at least one cycle of R-CHOP, and provide written informed consents. We assessed the risk of CNS involvement based on previously reported risk factors: serum LDH elevation, the number of extranodal involvements, serum albumin, bone marrow invasion, HIV positivity, the involvement of testis, breast, paranasal sinus, bone, retroperitoneal lymph nodes, orbit, and epidural space. If patients had any of these risk factors, they underwent CSF study to screen the CNS involvement. If necessary, brain MRI was also done. CNS prophylaxis was done with intrathecal chemotherapy with methotrexate for patients who had positive findings of screening evaluation or were determined to have a risk of CNS involvement based on physicians' decision.

Results: 600 patients were enrolled between 2010 and 2012 from 27 institutions belonged to the Consortium for Improving Survival of Lymphoma. Seven patients including withdrawal of informed consents were excluded. Thus, 593 patients were prospectively monitored with the median follow-up duration of 12.8 months. The median age was 59.5 years old (range 20-89 years), and stage III/IV accounted for 49.2% (109/186). 208 patients (34.7%) involved two or more than two extranodal sites including bone marrow (n=76, 12.7%) and 280 patients showed the elevation of serum LDH (46.7%). Thus, 204 patients (34.4%) belonged to high or high-intermediate risk of the International Prognostic Index (IPI). 390 patients had at least one of risk factors for CNS involvement (65.8%), and 198 patients underwent CNS evaluation at diagnosis. The screening CNS evaluation including CSF exam and brain MRI revealed that 19 patients initially had the evidence of CNS involvement even though they did not have any neurologic symptoms: positive cytology (n=15) and brain parenchyma lesion (n=4). During follow-up, 14 cases of additional CNS involvement including brain parenchyma (n=8), leptomeningeal (n=5), and ocular invasion (n=1) were observed. The median time to CNS event in these 14 patients was 7.5 months (range 1.2–15.9 months). Thus, 33 cases of secondary CNS involvement were documented in our study population at the time of analysis (5.5%) including 19 cases at diagnosis (3.2%) and 14 cases during follow-up (2.4%). Out of 390 patients with any risk factors for CNS involvement, 28 patients developed CNS involvement (28/390, 7.2%) whereas only 5 cases of CNS involvement were found in 203 patients without risk factors (2.5%). The univariate analysis for evaluation of risk factors demonstrated serum LDH, the number of extranodal involvements, bone marrow invasion, and the involvement of retroperitoneal lymph node, breast, paranasal sinus and orbit were significantly associated with CNS involvement. The high/high-intermediate risk of IPI was also predictive of CNS involvement ($P<0.05$).

Summary and Conclusions: The incidence of secondary CNS involvement in DLBCL patients treated with R-CHOP was around 5%, and a half of cases had CNS involvement at diagnosis. Considering a particular risk of CNS involvement of disease-related factors, risk-adapted active screening against CNS involvement may help to improve treatment outcome of patients with DLBCL.

Non-Hodgkin lymphoma - Clinical 3

P853

INTERIM PET-CT SCAN AFTER 2 CYCLES SUCCESSFULLY PREDICTS OUTCOME IN DLBL BUT INTRODUCES SIGNIFICANT SELECTION BIAS.

N Grigoropoulos[1,*], M Prahladan[2], T Hattori[2], A Shaw[3], H Cheow[4], G Follows[2]
[1]Pathology, University of Cambridge, [2]Haematology, [3]Radiology, [4]Nuclear Medicine, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Background: Cure rates of 60-80% have been achieved with R-CHOP in DLBL, but robust prognostic indicators are lacking. Following reports that interim PET-CT negativity after 2 chemotherapy cycles (iPET2) is strongly associated with improved PFS, we adopted iPET2 as a standard investigation in our centre. A potential bias of iPET2 is that patients with highly aggressive disease who die before iPET2 or are considered too frail for standard management have not been included in recent analyses.

Aims: The aims of this study were to evaluate the predictive value of iPET2 and investigate the possibility of patient selection bias in iPET2 patients.

Methods: We performed a retrospective study of DLBL patients treated with R-CHOP in our centre examining the relationship of iPET2 to PFS. We then compared outcomes of patients who had iPET2 to a historical control group to investigate the possibility of selection bias in iPET2 patients.

Results: The first 50 patients with DLBL and iPET2 were identified, with a median follow up of 24 months. 17 (34%) were iPET2 positive/indeterminate and 33 (66%) were iPET2 negative. 1/33 (3%) iPET2 negative patient had relapsed and 2/33 had died from non-NHL causes. 7/17 (41%) iPET2 positive patients had relapsed (6/7 biopsy-proven, $P=0.001$). At the time of analysis iPET2 negative patients had a significantly better PFS than iPET2 positive patients (47 *vs* 24 months, $P=0.009$, see Figure 1).

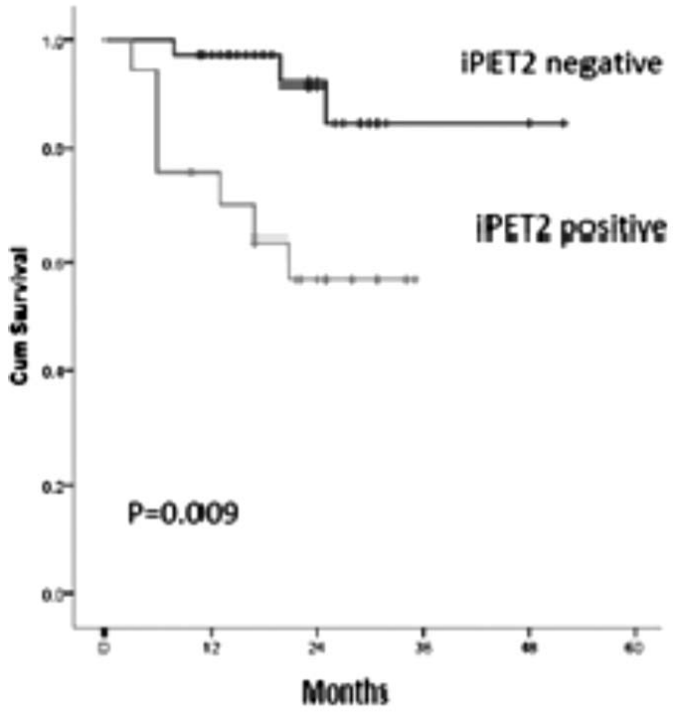

Figure 1. PFS of iPET2 negative *vs* iPET2 positive patients.

There was no significant difference in OS between iPET2 negative and positive patients at this follow up point (P=NS, data not shown). Of the 7 patients who relapsed/progressed, 1 has been salvaged and is in remission, 3 are being palliated, 2 have died, and 1 is being salvaged. Comparing the 50 patients who received iPET2 with 301 unselected DLBL patients managed over an 8 year period from 2004, the iPET2 patients have a significantly higher OS (53 *vs* 38 months, $P=0.006$, see Figure 2), indicating that iPET2 patients represent a selected group with a better prognosis.

Summary and Conclusions: These results confirm that iPET2 is valuable in predicting outcome in DLBL, but it is important when evaluating such studies to bear in mind that significant selection bias may be present.

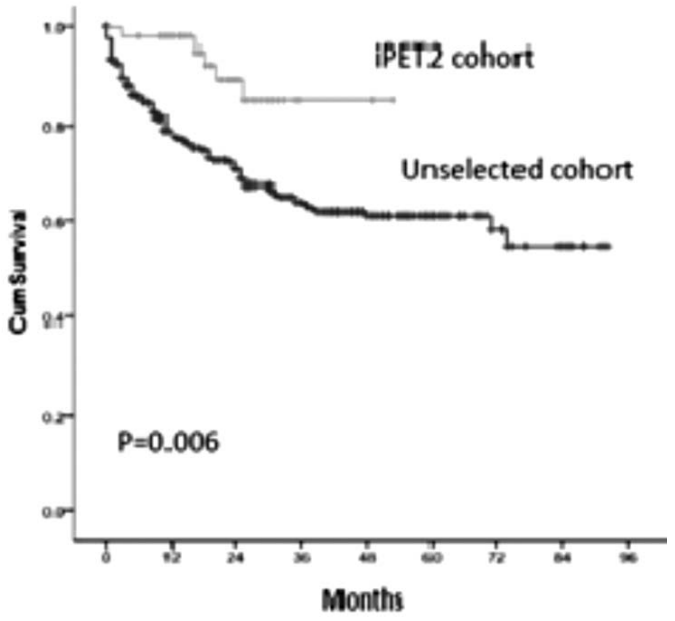

Figure 2. OS of patients receiving iPET2 *vs* unselected cohort.

P854

STAGING NEWLY DIAGNOSED LYMPHOMAS: COMPARISON BETWEEN WHOLE BODY-MRI/DWIBS AND 18FDG-PET/CT

C Minoia[1,*], M Ficco[2], N Maggialetti[3], C Ferrari[4], F Iuele[5], C Buquicchio[6], G Tarantini[6], A Iacobazzi[1], A Lapietra[1], F Merchionne[1], C Florio[7], G Rubini[5], A Guarini[1]

[1]Haematology Unit, National Cancer Research Center "Giovanni Paolo II" Bari, Italy, [2]Radiology Unit, National Cancer Centre " Giovanni Paolo II" Bari, Italy, Bari, [3]Ricerche Radiologiche s.r.l, Ricerche Radiologiche s.r.l, [4]Nuclear Medicine Unit, Department of Interdisciplinary Medicine, University of Bari, Molfetta (Bari), [5]Nuclear Medicine Unit, Department of Interdisciplinary Medicine, University of Bari, Bari, [6]Haematology Unit, "San Nicola Pellegrino" Hospital, Trani (BT), [7]Radiology Unit, National Cancer Research Center "Giovanni Paolo II" Bari, Italy, Bari, Italy

Background: FDG-PET/CT is currently regarded as the reference standard in the staging of HL and high-grade NHL. It's role is confirmed also in the staging of Follicular Lymphoma but becomes less important in other histopypes. A recent development of MRI is whole-body diffusion-weighted imaging (DWI), whose potential advantage over conventional MRI sequences in the evaluation of lymphoma is the high lesion-to-background contrast possible because of the relatively low diffusivity of lymphomatous tissue. MRI does not entail ionizing radiation and may be complementary to FDG PET/CT in the staging of lymphoma.
Aims: The aim of this prospective study was to assess the role of whole body-MRI/DWIBS in the staging of newly-diagnosed lymphomas (HL and NHL) in comparison to 18F-FDG-PET/CT.
Methods: 25 consecutive pts were enrolled and underwent WB-MRI (coronal T1-weighted, coronal STIR and axial DWIBS sequences) and 18F-FDG-PET/CT. Axial DWIBS sequences included 3 acquisitions of b factor (0, 500, 1000). Lymph nodes larger than 10 mm in short-axis diameter, in the coronal plane on T1- weighted and STIR images, were considered positive. The agreement between WB-MRI/DWIBS and 18F-FDG-PET/CT for each of the nodal and extranodal sites was evaluated. A statistical evaluation with the Cohen k was performed.
Results: 18F-FDG-PET/CT showed 75 involved nodal and 10 extranodal lesions. WB-MRI/DWIBS showed 80 nodal and 12 extranodal lesions, revealing an overstaging in 2/25 (8%) pts. In 10\25 pts we found differences in the attribution of disease in each of the stations described. Of these 10 pts, 5 had a diagnosis of HL, 5 of NHL (2 DLBCL, 1 FL, 1 SLL/CLL, 1 sMZL). The disagreements were 21: 4 cervical, 2 mediastinum, 5 abdominal, 3 pelvic, 3 femoral stations, 4 extra-nodal sites. In 6\21 disagreements observed, 18FDG-PET/CT was positive for lymph nodes with a diameter less than 1 cm, with negative WB-MRI/DWIBS. In 2\21 discrepancies 18FDG-PET/CT was positive, with negative MRI, for a cervical lymph node localization with a diameter greater than 1 cm and a bone marrow localization. In 13\21 disagreements described MRI was positive, with negative 18FDG-PET/CT, for nodal and extra-nodal localizations (2 cervical, 1 mediastinal, 3 abdominal, 2 pelvic, 2 femoral and 3 extranodal). Then, the two methods were concordant in the staging in 22/25 cases (88%). According to Ann Arbor criteria, the agreement was good. 2/25 (8%, 1 DLBCL and 1 SLL/CLL) patients showed a different stage with the 2 techniques, with an overstaging by WB-MRI/DWIBS (Figure 1).

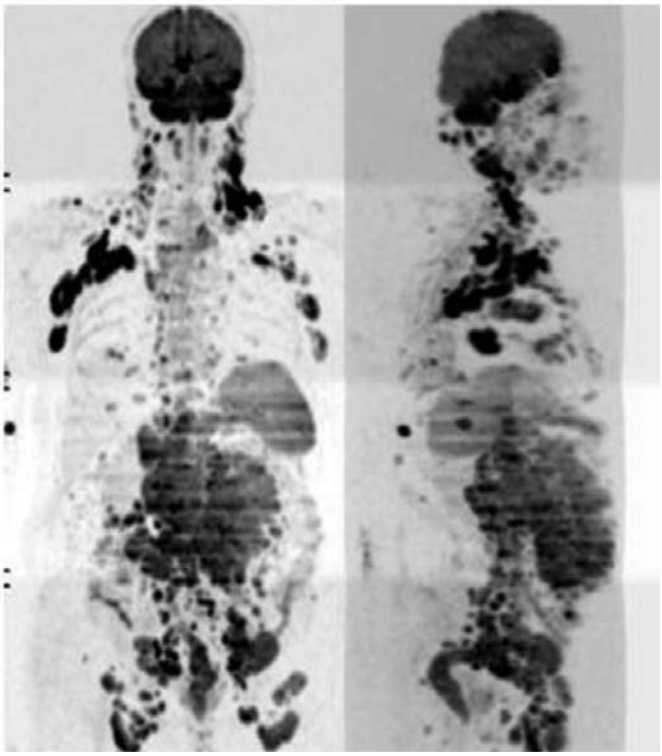

Figure 1.

Summary and Conclusions: Our initial results show a good agreement between whole-body MRI-DWI and 18F-FDGPET/CT in lymphoma staging, both in the evaluation of nodal and extranodal involvement. Although 18F-FDG-PET/CT remains the gold standard for lymphoma staging, WB-MRI/DWIBS may be considered an emerging functional whole-body imaging modality. This new technique may provide complementary information and, due to the low toxicity profile, become a useful tool also in the follow-up.

CENTRAL NERVOUS SYSTEM RELAPSE IN NON HODGKIN LYMPHOMA: PROGNOSTIC FACTORS AND OUTCOME IN A COHORT OF 304 PATIENTS

J Alonso[1,*], G Barreiro[1], A Canovas[1]

[1]Internal Medicine, Hospital Universitario de Cruces, Barakaldo, Spain

Background: The efficiency and the criteria for prophylaxis of central nervous system(CNS) relapse in non-Hodgkin lymphoma are not well defined. There are conflicting results related to the heterogeneity of analysed patients. It is doubtful whether Rituximab can reduce the frequency of neurological relapse
Aims: To analyse the baseline predictive variables of CNS relapse in a series of unselected patients with clinically aggressive mature B and T cell lymphomas (CAMBTCL), its clinical presentation and outcome
Methods: This is a prospective observational study of patients diagnosed in our Lymphoma Unit with CAMBCL from 1988-January to 2007-December.The follow up was maintained until 2012-December.The patients with Burkitt's lymphoma, AIDS or initial neurological involvement were excluded. We evaluated the usually related variables: bone marrow(BM) disease, two or more extranodal sites(E), testicular or mediastinal involvement, proximity to CNS, advanced clinical stage or IPI, high LDH or B2microglobulin,effect of chemoprophylaxis and, in B-lymphomas, treatment with Rituximab. We scheduled chemoprophylaxis (systemic or intrathecal methotrexate or cytarabine) in patients with unfavorable prognostic factors (histologically affected bone marrow, elevated LDH, testicular, mediastinal or paranasal sinuses involvement).The CNS disease was documented by clinical data, cerebrospinal fluid (cytology and flow cytometry) findings, CT or MNR, and biopsy in case of isolated brain involvement.The CNS disease treatment included high dose methotrexate and triple intrathecal chemotherapy, associated with other drugs in case of extraneurological disease. *Statisticals Methods*: Fisher's exact test, log rank test, Kaplan Meier survival tables and Cox multivariate proportional hazard regression.The study was approved by the hospital ethics committee

Results: 304 patients (165 males, 139 females) were included, with median age of 64 years:227 with diffuse large B cell lymphoma (DLBCL), 35 with mantle cell lymphoma(MCL) and 42 with peripheral T cell lymphoma(PTCL).Involvement of BM (histological or by flow cytometry) was ascertained in 20% of DLBCL, 65.7% of MCL and 50% of PTCL and two or more extranodal involvement(E) was demonstrated in 32%, 43% and 40.5% respectively. Neuroprophylaxis(systemic or intrathecal) was applied to 23.5% of DLBCL patients, 28,6% of MCL and 33,3% of PTCL, and Rituximab in 47%(107 patients) of DLBCL and 51.4% of MCL.The median observation time has been 5 years (2.8 in PTCL) and actuarial mean survival has been 10 years in DLBCL, 5.9 in MCL and 2.5 in PTCL.We found neurological relapse in 12 patients with DLBCL (5%), 2 with MCL (5.7%) and 3 (7%) with PTCL, at a median time of 8.4 months from the diagnosis.There was meningeal involvement in 76% and brain involvement in 35% (two patients had both locations). Six relapsed patients (35%) had received neuroprophylaxis(none with testicular involvement and one of 14 with mediastinal disease).Mean actuarial survival from relapse was 4.4 months. In multivariate analysis of DLBCL only two prognostically significant variables were found: involvement of two or more extranodal areas(p:0.001; HR:12) and treatment with rituximab (p:0.048; HR: 0.25);also in univariate analysis bone marrow involvement (LRT: p: 0.03) and IPI advanced (LRT: p: 0.02) were significant
Summary and Conclusions: The relapse rate in our series (5.6%) is at the low level ofthe published range.Despite a high proportion of patients with neuroprophylaxis, two or more extranodal involvement implies bad prognostic.On the contrary in our patients treatment with Rituximab reduces the likelihood of neurological relapse, as it has been reported in other studies

P856

LYMPHOCYTE COUNT AT DIAGNOSIS IN DIFFUSE LARGE B-CELL LYMPHOMA IN THE ERA OF IMMUNOCHEMOTHERAPY WITH RITUXIMAB: IS 1000/MM3 STILL THE BEST CUT-OFF VALUE TO USE TO DEFINE LYMPHOPENIA ?

A Bari[1,*], T Tadmor[2,3], S Sacchi[4], L Marcheselli[4], E Liardo[4], I Avivi[3,5], N Benyamini[6], D Attias[2,3], S Pozzi[4], M Cox[7], L Baldini[8], M Brugiatelli[9], M Federico[1], A Polliack[10]
[1]Department of Diagnostic, Clinical and Public Health Medicine, University of Modena and Reggio Emilia, Modena, Italy, [2]Hematology Unit, Bnai Zion Medical Center, [3]The Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel, [4]Department of Diagnostic, Clinical and Public Health Medicine, UNIVERSISTY OF MODENA AND REGGIO EMILIA, Modena, Italy, [5]Department of Hematology & Bone Marrow Transplantation, [6]Hematology & Bone Marrow Transplantation, Rambam Medical Center, Haifa, Israel, [7]Department of Hematology, AO Sant'Andrea, La Sapienza University, Rome, [8]Division of Hematology, Fondazione IRCCS Cà Granda, University of Milano, Milano, [9]Department of Hematology, Azienda Ospedaliera Papardo, Messina, Italy, [10]Department of Hematology, Hadassah University Hospital and Hebrew University Medical School, Jeruslaem, Israel

Background: Lymphopenia is a well-established prognostic value in advanced Hodgkin lymphoma, and constitutes one of the parameters included in the International Prognostic Score. In non Hodgkin lymphoma, lymphocyte counts have mostly been evaluated in aggressive histology and low levels have been shown to be associated with inferior overall survival.
Aims: In this multi-center collaborative study on a large cohort of 1191 patients with diffuse large B-cell lymphoma (DLBCL) we assessed the prognostic significance of the absolute lymphocyte count (ALC) at diagnosis, in an attempt to verify if the widely used cut-off level of 1000 /mm^3 if retained it's prognostic significance in the era of immuno-chemotherapy with rituximab. In addition we also examined the possible correlation between ALC values and International Prognostic Index(IPI).
Methods: In our research all relevant clinical and laboratory data at diagnosis were retrieved from the medical records of consecutive untreated patients with DLBCL followed in different centers in Haifa, Israel and Italy during 1993-2010. After merging the data from independent but homogeneous database sources, we were able to evaluate a final cohort of 1017 patients. The median follow up was 48 months and the 5 year overall survival (OS) rate was 68%; 521 (51%) patients were treated with CHOP or CHOP- like regimens in combination with rituximab.The influence of rituximab on the prognostic power of ALC was evaluated by interacting ALC with rituximab use after adjusting by IPI score.
Results: The median ALC at diagnosis was 1450/mm^3 (300-3730). After correlation with IPI in patient groups with scores 0-1, 2 and 3-5, the median ALC was 1645, 1347, and 1195/mm^3, respectively (P<0.001). The threshold value of ≤1000/mm^3 is widely used to define lymphopenia in cases of aggressive lymphoma. In the large study cohort the difference in terms of OS at 5 years for patients with ALC ≤ or >1000/mm^3 did not reach statistical significance (P=0.082), with HR of 1.23 (95% CI 0.97-1.55). In multivariate analysis the ALC level of ≤1000/mm^3, after interaction with rituximab use and adjusting by IPI score, did not have a prognostic impact, both in patients treated with chemotherapy with or without the addition of rituximab to the combination regimen (HR 1.10, 95% CI 0.79-1.52 and HR 1.09, 95% CI 0.78-1.53, respectively). However when we defined lymphopenia as an ALC ≤840/mm^3, (as reported in our previous studies), we found that the difference in OS in all patients with ALC ≤ or >840/mm^3 was statistically significant (P=0.002). An ALC level of ≤840/mm^3 was found to be significant only in patients treated with rituximab (P<0.001), compared to those treated with chemotherapy alone (P=0.360).
Summary and Conclusions: In this study on a large cohort of patients with DLBCL, ALC values correlate with IPI score (decreasing values of lymphocytes are related to IPI high risk groups) but, unlike previous studies, ALC ≤1000/mm^{3}did not provide convincing support for its use as a reference value to define lymphopenia. It appears that in the rituximab era of immunochemotherapy we need to reassess the reference cut-off value utilized for ALC, which remains a simple but important tool to identify high–risk patients with a worse survival in newly diagnosed DLBCL.

P857

TREATMENT OUTCOMES IN AIDS-RELATED DIFFUSE LARGE B-CELL LYMPHOMA AT A PUBLIC TEACHING HOSPITAL IN SOUTH AFRICA

P de Witt[1], T Uldrick[2], D Maartens[3], G Sissolak[1,*]
[1]Medicine, Tygerberg Academic Hospital, University of Stellenbosch, Cape Town, South Africa, [2]HIV& AIDS Malignancy Branch, National Cancer Institute (NCI), Bethesda, Maryland, United States, [3]Department of Anatomical Pathology and National HealthLaboratory Services (NHLS), Tygerberg Academic Hospital, Stellenbosch University, Cape Town, South Africa

Background: Non-Hodgkin lymphoma is the second most common acquired immune deficiency syndrome (AIDS)-defining malignancy. Sub-Saharan Africa is the worst affected region in the HIV pandemic, and many South Africans are at risk of developing AIDS defining non-Hodgkin lymphomas (ADL) such as Burkitt lymphoma (BL) or Diffuse Large B-cell Lymphomas (DLBCL). The high frequency of ADL in this region is, in part, due to incomplete community-wide antiretroviral coverage. Curative therapy for AIDS-related diffuse large B-cell lymphoma (DLBCL) is feasible in settings with available combination antiretroviral therapy (cART). However, given limited haemato-oncology resources, outcomes for AIDS-associated DLBCL in South Africa are unknown.
Aims: Our primary objective was to document 2-year overall survival (OS) in South African patients with AIDS-related DLBCL treated with CHOP or CNOP at an academic institution. Secondary objectives included evaluation of response rates, progression free survival (PFS) and prognostic factors for death.
Methods: We performed a retrospective analysis of survival in patients with newly diagnosed AIDS-related diffuse large B-cell lymphoma (DLBCL) treated at a tertiary teaching hospital in Cape Town, South Africa with CHOP or CHOP-like chemotherapy (January 2004 until Dec 2010). HIV and lymphoma related prognostic factors were evaluated. This study was approved by the Health Research Ethics Committee and complies with Principles of the Declaration of Helsinki.
Results: 36 patients were evaluated; median age was 37.3 years, 52.8% men and 61.1% black South Africans. Median CD4 count was 184 cells/μL and 80% were high-risk according to the age-adjusted International Prognostic Index. Concurrent Mycobacterium tuberculosis infection was 25%. Two-year overall survival (OS) was 40.5% (median OS 10.5 months, 95%CI 6.5–31.8). ECOG performance status of 2 or more (25.4% *vs* 50.0%, *P*=0.01) and poor response to cART (18.0% *vs* 53.9%, *P*=0.03) predicted inferior 2-year overall survival. No difference in 2-year OS was demonstrated in patients co-infected with either Mycobacterium tuberculosis or Hepatitis B.
Summary and Conclusions: Two-year OS for patients with AIDS-related DLBCL treated with CHOP like regimens and cART is comparable to that seen in the US and Europe. Important factors effecting OS in AIDS-related DLBCL in South Africa include performance status at presentation and response to cART. Patients with co-morbid Mycobacterium tuberculosis or hepatitis B seropositivity appear to tolerate CHOP in our setting. Additional improvements in outcomes are likely possible.

ELEVATED SERUM ADENOSINE DEAMINASE LEVELS IN HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

W Chen[1], S Zhang[1,*], H Qiu[1], X Zhang[1], J Li[1]
[1]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Hemophagocytic lymphohistiocytosis (HLH), a potentially fatal hyperinflammatory condition, is caused by activated T cells and macrophages. Adenosine deaminase (ADA) plays an important role in immune regulation, especially in the proliferation, maturation and differentiation of lymphocytes. Its role has been studied in inflammation and malignancy.
Aims: Here we present for the first time the alteration of ADA in secondary HLH (sHLH).
Methods: Serum ADA levels were measured in 20 cases with lymphoma-associated hemophagocytic syndrome (LAHS), 15 with infection-associated hemophagocytic syndrome (IAHS), 6 with macrophage activation syndrome (MAS) as experimental group. Additionally, we enrolled 20 cases with lymphoma, 15 with infection, 6 with autoimmunity who were all not associated with HLH as conditional control group and 20 healthy subjects as blank group. We also demonstrated the ADA levels in 20 LAHS cases and 21 benign disease-associated HLH cases (IAHS and MAS).

Results: Serum ADA levels were 150.29±76.08, 91.33±44.38 and 57.40±11.30 U/L in patients with LAHS, IAHS and MAS, respectively. In control groups, the levels of ADA were 19.13±11.78, 20.57±8.10, 22.62±8.69 and 12.36±4.07 U/L for patients with lymphoma, infection, autoimmune disease who were not associated with HLH and healthy people. Serum ADA levels were significantly higher in LAHS, IAHS, and MAS patients compared to the control groups (P<0.05). Serum ADA levels of LAHS patients were significantly higher than IAHS and MAS cases (P<0.05). The optimum ADA cut-off point for LAHS was 89.25 U/L, with a sensitivity and specificity of 85.0% and 76.2% respectively.
Summary and Conclusions: In our study, serum ADA levels were increased in sHLH suggesting a partial role of activated T-cell response in the disease pathophysiology. Serum ADA levels were particular high in LAHS and it may be a new serum marker for the diagnosis of LAHS.

PROGNOSTIC FACTORS IN VERY OLD PATIENTS (≥75 YEARS) WITH FOLLICULAR LYMPHOMA: A MULTICENTRE RETROSPECTIVE STUDY
A Parcelier[1,*], F Jardin[2], I Leduc[3], S Dennetiere[4], A Charbonnier[5], G Damaj[5], L Merlusca[5], H Tilly[2], J Marolleau[1], B Royer[1]
[1]Hematologie clinique, Centre Hospitalier Universitaire Sud, Amiens, [2]Hematologie clinique, Centre H Becquerel, Rouen, [3]Hematologie clinique, Centre Hospitalier, Abbeville, [4]Hematologie clinique, Centre Hospitalier, Compiegne, [5]Hematologie clinique, Centre Hospitalier Universitaire Amiens, Amiens, France

Background: The incidence of B cell Non Hodgkin Lymphoma (NHL) is steadily increasing with age and about 40% of cases occur in patients aged over 70 years. Some series have reported that low grade NHL lymphomas represent about 35% of all B NHL in elderly patients. Follicular lymphoma (LF) is the most common indolent lymphoma. Data on outcome, prognostic factors, and treatment for elderly LF is sparse.
Aims: The aim of our study was to analyse the overall survival (OS) and the progression free survival (PFS) of elderly LF and to evaluate the prognostic impact of different clinical and biological factors.
Methods: We conducted a multicentre retrospective analysis of LF patients ≥75 years followed between 2006 and 2012. Detailed characteristics were obtained including age adjusted Charlson Comorbidity index (aaCCI), FLIPI and biological parameters.
Results: We identified 69 patients: median age was 79 years (75-98); 49% were FLIPI 1-2 and 51% FLIPI 3-5. Median ECOG was 1 (0-4). One third presented B symptoms; 46% had extranodal site (most frequently pleural, skin and bone lesions), 27% presented elevated LDH. 48% presented with aaCI ≥5. Fourty-nine patients received chemotherapy: 64% with rituximab, 39% RCHOP like therapy. Overall response rate (CR+PR) was 77% with 52% of CR. Median follow up was 26.4 months (0.5-78), 2-year overall survival (OS) was 73%: 88% and 58% for FLIPI 1-2 and 3-5 respectively (P=0.003). Two-year progression free survival (PFS) was 74%: 94% and 52% for FLIPI 1-2 and 3-5 respectively (P=0.0007). 24 deaths were reported: 12 of them secondary to FL progression, 8 to toxicity. After RCHOP and RCVP 15 pts (34%) had grade 3/4 haematological toxicity, 10 (23%) had febrile neutropenia and 3 (7%) acute cardiac failure. Univariate analysis identified aaCCI ≥5 (hazard ratio (HR) 4.5; 95% IC 1.6-12.8; P=0.002), FLIPI ≥3 (HR 5.3; 95% IC 1.9-14.1; P=0.003) and serum albumin (SA) ≤35g/l (HR 2.9; 95% IC 0.9-9.2; P=0.03) as predictive factors for shorter OS. On multivariate regression FLIPI ≥3, SA ≤35g/l and aaCCI ≥5 predicted inferior OS (P=0.02, P=0.04, P=0.002 respectively) (Table 1).

Table 1.

Median Age (years)	79 (75-98)
Median ECOG	1 (0-4)
FLIPI 1-2	34 (49%)
FLIPI 3-5	35 (51%)
Elevated LDH	17 (27%)
AaCCI ≥ 5	33 (48%)
SA ≤ 35g/l	16 (29%)
Watchful Waiting	12 (17%)
R-CHOP like regimen	27 (39%)
R-CVP	16 (23%)
R-Bendamustine	1 (1%)
Total R-containing regimen	44 (64%)
Chlorambucil	5 (7%)
Radiation	4 (6%)
Surgery only	2 (3%)
Treatment refusal	1 (1%)
Death before any treatment	1 (1%)

Summary and Conclusions: In this large cohort of elderly FL patients, we identified FLIPI ≥3, aaCCI ≥5 and SA ≤35g/l as three key predictive factors for inferior OS. Prospective studies incorporating geriatric tools are warranted for this population.

P860

EFFICACY AND SAFETY OF LENALIDOMIDE WITH/WITHOUT RITUXIMAB OR STEROIDS IN HEAVILY PRETREATED NON-HODGKIN'S B-CELL LYMPHOMAS: RESULTS OF A RETROSPECTIVE STUDY
A Castellino[1,*], A Chiappella[1], P Ghione[1], M Ceccarelli[2], G Benevolo[1], B Botto[1], D Caracciolo[1], C Ciochetto[1], LOrsucci[1], P Pregno[1], P Riccomagno[1], M Zanni[1], M Ladetto[1], U Vitolo[1]
[1]Hematology, Città della Salute e della Scienza Hospital and University, [2]Unit of Cancer Epidemiology, University and CPO Piemonte, Torino, Italy

Background: Relapsed or refractory B-cell non-Hodgkin's lymphomas (NHL) had a poor prognosis, however for patients not eligible to high dose chemotherapy, salvage treatment is not yet clearly defined. Lenalidomide monotherapy exhibits significant activity in patients with relapsed aggressive NHL.
Aims: On this basis, we conducted a monocentric retrospective study to investigate efficacy and safety of lenalidomide monotherapy or in combination with rituximab (R) in patients with heavily pretreated B-Cell NHL.
Methods: The primary end point of the study was Overall Response Rate (ORR) defined as complete response (CR), partial response (PR), stable disease (SD) and duration of response (DOR); secondary ends points were feasibility and safety of treatment. Inclusion criteria were: relapsed/refractory B-Cell NHL patients treated between August 2007 to June 2012 with 25 mg lenalidomide daily for 21 days every 4 weeks as single agent or in association to weekly dexamethasone (20 mg bolus) or 20 mg lenalidomide daily for 21 days every 4 weeks in combination with R (375 mg/sqm). Patients were treated until disease progression or unacceptable toxicity.
Results: A total of 54 patients were included in the analysis: 34 diffuse large B-cell lymphomas (DLBCL), 11 mantle cell, 6 follicular, 2 primitive mediastinum B-cells and one Burkitt lymphoma. Clinical characteristics at relapse before starting lenalidomide were: stage III/IV in 36 patients (67%); intermediate high/high risk International Prognostic Index in 28 (52%); bone marrow involvement in 11 (20%) and bulky disease in 15 (28%). Prior treatments were: 8 patients (15%) received lenalidomide at first relapse while 25 (46%) underwent more than 3 previous lines of treatment. Fourteen patients (26%) did autologous stems cell transplant, one (2%) allogenic transplant and 4 (7%) did both, before receiving lenalidomide. All patients analyzed received lenalidomide: 32 (59%) underwent single agent lenalidomide, 11 (21%) received a combination of lenalidomide plus R and 11 (20%) were treated with lenalidomide plus steroids. Median time from diagnosis to the beginning of lenalidomide was 25,3 months (range3,7- 145,9), while median time from last previous therapy to lenalidomide treatment was3,2 months (range 0,4- 38,0). Responses were: CR in 8 patients (15%), PR in 5 (9%), SD in 5 (9%); 32 (60%) patients did not respond and 4 were not evaluable for response. Concerning DLBCL: ORR was 41% (n=14: CR5, PR4, SD 5). Median DOR for all patients was11,7 months (range 0,2-23,7). At a median follow-up of 20 months 5 patients were alive in CR, 9 continued lenalidomide, 11 relapsed and 28 died. A total of 259 cycles of lenalidomide were performed, of which 25 were prematurely interrupted and 49 were reduced in dose or duration; 50% of patients had at least one interruption in the planned treatment, nevertheless 91% of the expected dose was given. The most common grade 3-4 adverse events for the 54 patients were neutropenia (19%), anemia (17%) and thrombocytopenia (17%); 5 patients had grade 3-4 infections, one a grade 3 thromboembolic event and 2 died because of pneumonia and heart failure, respectively.
Summary and Conclusions: Salvage treatment with oral lenalidomide as single agent or in combination with R or steroids is effective with a good safety profile in patients with heavily pretreated B-Cell NHL.

P861

RESULTS OF A PROSPECTIVE PHASE II TRIAL OF ORAL LOW DOSE BEXAROTENE AND ULTRAVIOLET A PHOTOCHEMOTHERAPY (PUVA) FOR EARLY AND ADVANCED STAGE MYCOSIS FUNGOIDES
S Rupoli[1,*], N Pimpinelli[2], G Goteri[3], L Canafoglia[1], G Brandozzi[4], I Federici[1], F Giantomassi[3], G Micucci[1], A Scortechini[1], L Da Lio[5], G Ricotti[6], M Simonacci[7], G Filosa[8], G Mozzicafreddo[6], P Leoni[1]
[1]Clinica di Ematologia, Ospedali Riuniti Umberto I- Salesi-Lancisi di Ancona, ancona, [2]Clinica di Dermatologia, Azienda Ospedaliera di Firenze, Firenze, [3]Dipartimento di Anatomia Patologica, [4]Clinica di Dermatologia, [5]Laboratorio Analisi, Ospedali Riuniti Umberto I- Salesi-Lancisi di Ancona, [6]Clinica di Dermatologia, I.N.R.C.A., ancona, [7]Clinica di Dermatologia, Ospedale S.Lucia, Macerata, [8]Clinica di Dermatologia, Ospedale Murri, Jesi, Italy

Background: Bexarotene, the first synthetic retinoid that selectively binds retinoid X receptors has shown efficacy and safety for the treatment of refractory or relapsed cutaneous T cell lymphomas (CTCL) both in monotherapy and in association with other treatments. Bexarotene and PUVA seemed to be promising in the early studies performed with low dosages of Bexarotene on small groups of patients. Recently EORTC randomized trial reported similar

response rates in the PUVA arm *versus* the combination arm; however the treatment duration was limited to a maximum of 16 weeks and the trial was not designed to address the role of a maintenance therapy.
Aims: The aim of this study was to assess the efficacy and safety of a 2 stage-protocol (induction and maintenance) with low dose Bexarotene (Targretin) and PUVA in refractory and/or resistant patients with Mycosis Fungoides (MF) and Sézary Syndrome (SS).
Methods: A prospective trial was conducted between February 2007 and September 2012 by two Italian academic hospital centers. We enrolled 22 patients with stages I through IV MF; all patients had failed PUVA or several systemic regimens. The treatment schedule consisted of an induction phase with low dose Bexarotene (150 mg/die) plus PUVA with clinical response assessment after two months: patients who achieved CR (complete response) remained on the same dose of Bexarotene, with gradual reduction in the frequency of PUVA sessions (maintenance phase), while patients in very good partial response (VGPR), PR (partial response), MR (minimal response) and stable disease (SD) received an increasing dose of Bexarotene, up to 300 mg/die. Subsequently, patients not achieving at least PR went off-study. Primary endpoints were overall response (ORR) at the end of induction and maintenance; secondary endpoints were safety and event-free survival (EFS). Kaplan-Meyer method and long-rank test was used for statistical analysis.
Results: We enrolled 22 patients: 15 patients were affected by early stage MF (13 with stage IB, 2 with stage IIA), 7 were affected by advanced disease (3 with stage IIB, 2 with stage IIIA, 1 with stage IIIB and 1 with stage IVA). The median age was 69 years (range, 35-82). The global overall response was 86%, higher in early MF (93%) than in advanced disease (72%). At the end of maintenance, CR rate in early stage patients remained 46% and increased from 0 to 14% in advanced stage disease. Significantly, early stage patients treated previously with PUVA monotherapy achieved CR more frequently (83% *versus* 22% respectively; $\chi 2$ test, P=0.020) and more rapidly (median time to maximal response, 4 weeks *versus* 13 weeks respectively, P=0.003) compared with those treated with more than one systemic therapy. Median EFS for the whole group was 33 months. Bexarotene was well tolerated due to side effects prophylaxis and to the progressive dose increase in induction: only one patient dropped out because of hypertriglyceridemia; adverse events were mainly of low and moderate grade; only two cases with grade 3 creatine-phosphokinase (CK) elevation was recorded.
Summary and Conclusions: In conclusion, our study has demonstrated a >80% response rate in patients with all stages of CTCL refractory or intolerant to the previous therapies; the efficacy is more pronounced in patients previously treated with PUVA monotherapy. Starting treatment at lower dose of Bexarotene followed by dose escalation may improve the efficacy and safety of the combination therapy. Moreover, the additional maintenance phase seems to improve the rate and length of response.

P862

SERUM FREE LIGHT CHAINS LEVELS IN PATIENTS WITH HIV-RELATED LYMPHOMA ARE LOWER AT COMPLETE RESPONSE THAN AT DIAGNOSIS

M Baptista[1,*], M Morgades[1], A Briega[2], G Tapia[3], M Moreno[1], J Sancho[1], J Ribera[1], E Feliu[1], F Milla[1], E Martinez[2], J Navarro[1]
[1]Department of Hematology, ICO-Germans Trias i Pujol. Josep Carreras Leukaemia Research Institute. Universitat Autònoma de Barcelona, [2]Department of Immunology, Hospital Universitari Germans Trias i Pujol, [3]Department of Pathology, Hospital Universitari Germans Trias i Pujol. Universitat Autònoma de Barcelona, Badalona, Spain

Background: Increase in serum free light chains (sFLC) has been shown to be a marker of risk of developing HIV-related lymphomas. sFLC are easily measurable and are potential biomarkers for screening and prognosis in HIV-related lymphomas but there is a lack of data on sFLC values in patients in complete response (CR).
Aims: To determine the clinical relevance and the potential use of sFLC measurements as tumor markers in patients with HIV-related lymphomas.
Methods: Retrospective study of HIV-infected patients diagnosed with non-Hodgkin (NHL) and Hodgkin lymphoma (HL) treated in a single institution from 1998 to 2012. Levels of κ and λ sFLC were measured in plasma using a standardized assay (FREELITE, The Binding Site, Birmingham, UK). sFLC were considered elevated when κ, λ, or the sum of κ+λ were above the upper limit of normal and sFLC were considered monoclonal when κ-λ ratio was abnormal. Clinical and biological data were collected from the records.
Results: Sixty-eight patients were studied (53 NHL and 15 HL). At diagnosis (N=46), levels of κ, λ, and sum of κ+λ sFLC were elevated in 87%, 70%, and 80% of patients, respectively, and κ-λ ratio was abnormal in 37%. At CR (N=28), the percentage of patients with elevated κ, λ, and sum of κ+λ was 82%, 46%, and 64%, respectively. The κ-λ ratio was abnormal in 25%.
Mean levels of κ, λ, and κ+λ sFLC at diagnosis were higher than at CR (10.25mg/dL *vs* 7.01mg/dL, P=0.007; 5.56mg/dL *vs* 3.68mg/dL, P=0.034; 15.81mg/dL *vs* 10.69mg/dL, P=0.007; respectively). There were less patients with elevated λ sFLC levels at CR than at diagnosis (P=0.048). The mean values of κ-λ ratio were similar at diagnosis and CR as well as the number of patients with abnormal ratios. The levels of sFLC were compared between groups defined by the clinic-biological features. At diagnosis, less patients with increased λ sFLC were found in the group whose lymphoma was the first criteria of AIDS (N=2/7 *vs* N=30/38, P=0.015) and mean levels of λ and κ+λ sFLC were lower in this group (2.04mg/dL *vs* 6.30mg/dL, P=0.006 and 6.93mg/dL *vs* 17.75mg/dL, P=0.028, respectively). At CR, mean level of λ sFLC was lower in patients whose lymphoma was the first criteria of AIDS (N=4, 1.51mg/dL *vs* N=23, 3.97mg/dL, P=0.048). The mean levels of κ sFLC and κ+λ were higher in patients with detectable HIV loads at diagnosis (N=20) than in those with undetectable loads (N=4) (8.48mg/dL *vs* 1.75mg/dL, P=0.20 and 12.65 *vs* 3.32, P=0.036). Interestingly, all 4 patients with undetectable HIV loads had a normal sum κ+λ sFLC at CR, unlike, only 5 out of 20 patients with detectable HIV loads normalized κ+λ sFLC (P=0.005). Patients treated with cART before lymphoma (N=14) presented a lower mean level of κ sFLC than patients previously untreated with cART (N=14) (2.96mg/dL *vs* 11.05mg/dL, P=0.048). Mean level of κ-λ ratios was lower in patients previously treated with cART (1.20 *vs* 1.70, P=0.031) and all 14 patients had a normal κ-λ ratio unlike previously untreated patients, only 7 out of 14 had a normal ratio (P=0.002). Neither elevated sFLC levels nor the presence of monoclonal sFLC at diagnosis had impact on overall survival.
Summary and Conclusions: In patients with HIV-related lymphomas, sFLC levels at lymphoma diagnosis were higher than at CR pointing sFLC may be used as lymphoma markers. The control of HIV-infection was related to lower sFLC levels. Monoclonal sFLC were undetectable at CR in patients on cART before lymphoma.
Supported in part by grants EC11-041 from Ministerio de Sanidad and RD12/0036/0029 RTICC from Instituto Carlos III, Spain.

PROGNOSTIC RELEVANCE OF FDG-PET IN PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA

M Kichigina[1,*], O Mukhortova[2], G Tumyan[1], O Trofimova[1], A Chekan[1], V Larionova[1], D Osmanov[1]
[1]N.N. Blokhin Russian Cancer Research Center, [2]Bakoulev Researcher Center of Cardio-Vascular Surgery, Moscow, Russian Federation

Background: Primary mediastinal large B-cell lymphoma (PMBCL) present with mediastinal «bulky» tumor and often invades adjacent structures. It is commonly associated with alveolar fibrosis, which was explained frequent residual mass at the end of chemotherapy. The role of consolidative radiotherapy (RT) to the mediastinum remains unclear particularly with the more frequent use of FDG-PET.
Aims: We evaluated the impact of the introduction of PET in the outcome of pts with PMBCL.
Methods: We identified 83 pts with PMBCL treated in N.N. Blokhin Russian Cancer Research Center during last 10 years (2002-2011). The median age was 29 years, 56% of the pts were female, 71% had I/IIE stage, B symptoms had 72%, LDH elevated in 81% pts. All 83 pts treated with R-CHOP or MACOP-B±R, consolidative RT to the mediastinum was routinely administered in 65 (78%) pts. After completion of chemotherapy, residual disease measuring more than or equal to 2.5 cm in diameter was assessed by PET in 50 (60%) pts.
Results: In total, 50 pts had a PET scan: 33 (66%) were PET-negative (neg) (18 received RT) and 17 (34%) were PET-positive (pos) (14 received RT). The 5-y progression-free survival was 91% for PET-neg and 66% for PET-pos patients (P=0,001). The presence of B symptoms and extranodal disease more frequently associated with PET-pos. There were 3 relapses in PET-neg cases (2 without RT) and 7 relapses in the PET-pos cases (4 PD within RT field).
Summary and Conclusions: Positive PET is predictive of a worse outcome in PMBCL; larger prospective studies are needed to introduction of a PET-guided RT approach in PMBCL treatment. Interim PET may be useful for the early identification of pts, who need more intensify therapy.

P864

FC-GAMMA-RECEPTOR IIIA POLYMORPHISM AND GENE EXPRESSION PROFILE DO NOT INFLUENCE TREATMENT OUTCOMES AND SURVIVAL IN DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH R-CHOP PROTOCOL

L Varoczy[1,*],E Zilahi[2], A Illes[1]
[1]Division of Hematology, Department of Medicine, University of Debrecen, [2]Regional Laboratory of Immunology, University of Debrecen, Debrecen, Hungary

Background: The addition of rituximab to conventional chemotherapy has significantly improved the treatment outcome in diffuse large B-cell lymphoma. However, differences in treatment response and survival data can be observed independently from the International Prognostic Index scores.
Aims: The current study evaluated the impact of Fc-gamma-receptor IIIa polymorphism and gene expression profile on the response of DLBCL patients to R-CHOP therapy as well as on their survival results.
Methods: Fifty-one DLBCL patients were involved, thirty-two females, nineteen

males, their median age was 53.1 years. The FCGR3A polymorphism of NK cells at the 158. amino acid position was determined with real time PCR method. Three genotypes, V/V, V/F and F/F were distinguished. Gene expresion profile was screened for CD10, cbl-2, bcl-6 and MUM-1 on lymph node tissue samples using immunhistochemical methods.
Results: The detection of FCGR3A polymorphism showed the following results: VV: 12 cases (23.5%), VF: 29 cases (56.8%) and FF: 10 cases (19.6%), respectively. There was no significant difference between the treatment responses of the three groups. The event-free survival data were less favorable in the F-allele carriers than in V/V homozygous patients, but without any significancy, and the overall survival curves were almost the same. As for the gene expression profile, 20 patients' biopsy specimens showed germinal center and 31 showed non-germinal center characteristics. Treatment results did not differ from each other in the two groups. Both the event-free and the overall survival data were more favorable in the GC group, however the differences were not significant.
Summary and Conclusions: Our results contest the predictive value of Fc-gamma-receptor IIIa polymorphism and gene expression profile in diffuse large B-cell lymphoma.

INTENSIFIED PROGRAM INCLUDING BENDAMUSTINE, HIGH DOSE THERAPY AND AUTOGRAFT FOR PATIENTS WITH RELAPSED OR RESISTANT FOLLICULAR NON HODGKIN LYMPHOMA: RESULTS FROM AN EXPLORATORY GITIL STUDY

C Patti[1,*], A Mulè[1], A Barbui[2], S Tringali[1], A Costa[1], A Gueli[3], C Castellino[4], L Devizzi[5], A Dodero[5], M Leone[1], F Fabbiano[1], A Gallamini4, P Corradini[5], A Gianni[5], C Tarella[3], A Rambaldi[2], R Scimè[1]
[1]Hematology and Bone Marrow Transplant Unit, A.O. Ospedali Riuniti Villa Sofia - Cervello, Palermo, [2]Hematology and Bone Marrow Transplant Unit, A.O. Papa Giovanni XXIII, Bergamo, [3]Ematologia e Terapie Cellulari, A.O. Ordine Mauriziano - Umberto I & Molecular Biotechnology Center University, Torino, [4]Hematology Unit, A.O. S. Croce e Carle, Cuneo, [5]Hematology Unit, IRCCS Fondazione Istituto Nazionale dei Tumori & Università degli Studi, Milano, Italy

Background: Intensive chemotherapy with autologous stem cell transplantation (ASCT) is a potentially curative treatment for relapsed/refractory Follicular non Hodgkin's Lymphoma (FL-NHL) patients. The combination of Bendamustine and Rituximab proved to be remarkably active in previously untreated and relapsed FL-NHL patients.
Aims: To evaluate the safety of an intensified program including Bendamustine, high dose therapy and autograft for patients with Follicular Non Hodgkin Lymphoma at first relapse or resistant to first line treatment; to evaluate the benefit-risk profile of R-DHAOX and R-bendamustine in inducing a clinical response (CR or PR) in these patients. To evaluate also the feasibility of a salvage therapy in an outpatient setting before autograft.
Methods: From February 2011 to October 2012, 20 patients with relapsed (n=19) or refractory (n=1) FL-NHL were enrolled. The median age was 60 years (range 45-70). Previous therapy consisted of R-CHOP for all patients. The study treatment included: 2 cycles of R-DHAOX (oxaliplatinum 100 mg/m^2 on day1, Rituximab 375 mg/m^2 on day2, aracytin 2 g/m^2×2 and dexametasone 40 mg days 1-4) with peripheral blood stem cell harvest; 4 intensification courses of R-Bendamustine (90 mg/m^2 days1-2 every 28 days); patients who achieving PR or CR received a final consolidation with BEAM (or Mini BEAM for patients older than 65) and ASCT.
Results: Eighteen patients completed the pre-transplant phase, one is still in treatment and one patient dropped out of the study after the first R-DHAOX because a Grade IV non haematological toxicity (renal failure) was reported. After R-Bendamustine, 2 patients had grade III or IV Hematological Toxicity. After R-DHAOX, PBSC were collected in 19 patients with a median number of CD34+ cells >10×10^6/kg (range 4-48.6). The overall response rate (ORR) evaluated at the end of R-Benda intensification, was 100% with 14 CR (77%) and 4 PR (23%). At time of this analysis only 16 patients have performed ASCT and with a median follow up of 7 months (range 1-18) after ASCT, all patients are alive, 15 of them in continuous CR.
Summary and Conclusions: This intensive salvage treatment proved safe, feasible in an outpatient setting and effective in most relapsed FL-NHL. Thus, bendamustine can be safely employed in rescue programs with ASCT for FL. The benefit provided by R-Benda should be confirmed in a prospective randomized trial.

P866

THE INTENSITY AND DURATION OF PAIN ASSOCIATED WITH TREPHINE BIOPSY

B Spahic[1], T Valebjorg[1], F Bremtun[1], J Kolflaath[2], J Kahrs[1], W Ghanima[1,*]
[1]Medicine, [2]Anesthesia, Østfold Hospital Trust Fredrikstad, Fredrikstad, Norway

Background: Trephine biopsy is one of the most common diagnostic procedures in hematology; it is frequently performed as part of the diagnostic work-up for lymphoma as well as many malignant and non-malignant hematological conditions. Trephine biopsy is an invasive procedure usually performed under local anesthesia. However, despite the use of local anesthesia, most patients experience some degree of pain during and after the procedure. The intensity and duration of pain caused by this frequently performed procedure has not been reported previously.
Aims: The study aimed to determine the intensity and duration of pain after trephine biopsy as well as to determine factors related to pain.
Methods: Patients underwent trephine biopsy were recruited to the study from 6 participating hospitals in Norway. Patients were included only once in the study. Pain related to the biopsy was measured by Numerical Rating Scale (NRS). The scale ranges from 0 (no pain) to 10 (worst imaginable pain) twice daily at 08:00 and 20:00 (+/- 2 h) for 7 days, except on the day of the examination (day 0) where pain was assessed during the procedure (T0), 1 hour and 8 hours later. At each time point 2 registrations were performed, one at rest and one during activity. Consumption of analgesics was registered at each time point. The study was approved by the regional ethics committee; written informed consent was acquired from all patients. All values are expressed by median and Q1, Q3.
Results: Of 226 recruited patients, only 184 completed and returned the patients' form for assessment of pain and were thus included in the study. Median (Q1, Q3) age was 66 years (58,73); 97 males (52%). Maximum score was measured at time of biopsy (T0); median NRS score was 3 (1, 5). Pain intensity was substantially lower on day1, see Figure 1. Median duration (Q1, Q3) of pain at rest was 36 hours (0.5–72) and in activity 36 (0.5-84). Pain was localized at the site of biopsy in 50%, perceived in the lower limb in 10%, at both localizations in 10%, localization not specified in 30%. Analgesics comprising paracetamol +/- codeine was consumed by 4.4% at day 0 +1 h; 8.5% at day 0 +8h; 6.3% at day1, 8 am and 5.4% at day 1, 8 pm and by 2-4% in the remaining period. All patients received lidocain 2% as local anesthetic agent. Median injected volume was 10 mL (10, 13). Median time from application of lidocain to start of biopsy was 3 minutes 26 seconds and median duration of biopsy was 2 minutes. A significant correlation was found between NRS score at T0 and age (r=-0.21; P=0.006). Simultaneous aspiration of bone marrow was also found to be associated with greater pain at T0 (P=0.009). No significant associations were found between the intensity of pain and gender, length of biopsy, time of anesthesia to biopsy or BMI. The duration of pain in activity did correlate with NRS score at T0 (r=0.35; P<0.0001), BMI (r=-0.16; P=0.03), age (r=-0.22, P=0.004) and the localization of pain, which was longer in those with pain radiating pain (P<0.04). Median duration of pain was significantly longer in females (60 h) as compared to males (8 hours) P=0.001.

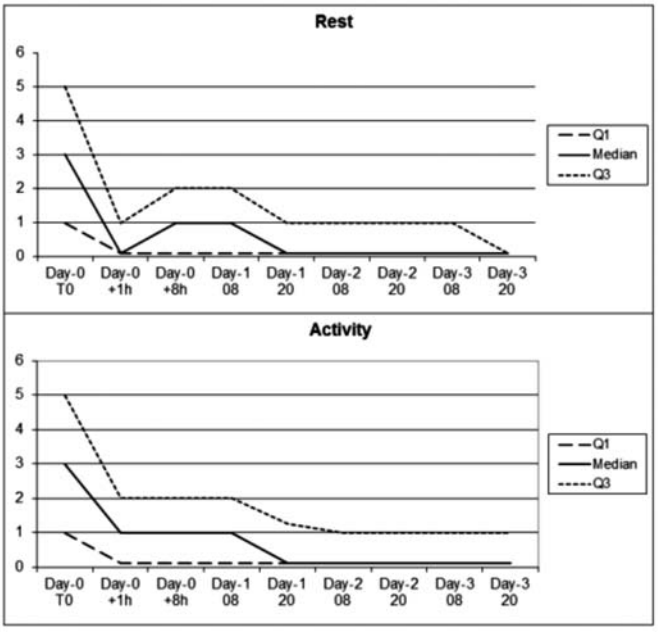

Figure 1.

Summary and Conclusions: Trephine biopsy is a painful procedure. Local anesthesia did not abolish the pain completely as 50% of the patients still experienced pain intensity of ≥3 points, and 25% ≥5 points during the procedure. The intensity of pain was negatively correlated with age, indicating that younger patients may require more analgesics. Pain lasted less than 2 days in half of the patients. Longer duration of pain was associated with greater NRS at T0, female gender, lower BMI and pain involving the lower extremity.

P867

NON-GERMINAL CENTER ORIGIN WITH BCL-2 EXPRESSION PREDICT UNFAVORABLE OUTCOME IN DIFFUSE LARGE B-CELL LYMPHOMA WITH HIGH IPI

B Lee[1,*],C Yoo[2], H Choi[2], J Kim[1]
[1]Internal Medicine, [2]Pathology, St. Vincent's hospital, Catholic University, Suwon, Korea, Republic of Korea

Background: In diffuse large B cell lymphoma (DLBCL), international prognostic index (IPI) was used to identify the patients with high-risk disease. The patients with identical IPI scores may still exhibit striking variability in outcome, suggesting the presence of significant heterogeneity within each IPI. Complexity and heterogeneity of DLBCL were demonstrated by the cell of origin (COO). DLBCL could be divided into germinal center B-cell (GCB) lymphoma and post-germinal center (non-GCB) lymphoma by gene expression profiling (GEP). However, GEP was not applicable to routine clinical practice and approaches using immunophenotypic algorithms with small panels of biomarkers were developed. Bcl-2 was an antiapoptotic protein and was implicated in resistance to chemotherapy. With COO, Bcl-2 was a candidate prognostic marker in DLBCL.
Aims: To evaluate the prognostic value of the COO (GCB or non-GCB) by immunophenotypic algorithm and/or Bcl-2 protein in patient with DLBCL especially with high IPI (high-intermediate and high risk of IPI).
Methods: Among 126 DLBCL patients receiving R-CHOP, 50 patients with high-intermediate and high risk of IPI were enrolled for retrospective analysis. For defining COO, Han's algorithm using CD10, Bcl-6 and MUM-1 was used. 50% cutoff for Bcl-2 expression by immunostaining was used. We plotted survival curves according to the Kaplan-Meier method and made comparisons using the log-rank test.
Results: In 50 patients with high IPI, the median age was 67 years old (range 39-83). 39 (78%) patients completed six cycles of R-CHOP as planned. 12 patients (24%) were classified as GCB subgroup and 38 patients (76%) were non-GCB subgroup. The 3-year PFS of GCB and non-GCB subgroup were 80% and 39%, respectively (P=0.099). 43 patients (86%) were Bcl-2-positive DLBCL and 3-year PFS of them was 42.4%. 7 patients were Bcl-2-negative and all of them did not observe disease progression until last follow-up (P=0.126). When COO combined with Bcl-2 expression, 68% of enrolled patients (34 of 50 patients) were non-GCB with Bcl-2-positive DLBCL. Interestingly, 3-year PFS of them was significantly inferior to that of others (33.3% and 85.7%, respectively; P=0.027). Consequently, Bcl-2 expression combined with non-GCB subgroup was found to have an adverse effect on the prognosis of patients in DLBCL with high IPI.
Summary and Conclusions: COO with Bcl-2 protein expression is reliable prognostic factor in DLBCL with high IPI although it needs confirmation by a prospective study.

P868

COMP-R AS FRONT LINE IN ELDERLY PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA AND G3 FOLLICULAR LYMPHOMA. THE SPANISH EXPERIENCE

Universitario Principe de Asturias, Madrid, [14]Hematology, H Universitario Morales Meseguer, Murcia, [15]Hematology, H. Universitario Puerta de Hierro, Madrid, Spain

Background: The current standard treatment used on Diffuse Large B Cell Lymphoma (DLBCL) and Grade 3 Follicular Lymphoma (G3FL) patients (pts) is R-CHOP (Rituximab, Cyclofosfamide, Doxorubicin, Vincristine and Prednisone). Despite the fact that Doxorubicin is essential, with elderly patients (70+) we avoid using it due to the inherent cardiac toxicity. Liposomal Doxorubicin has shown less toxic profile compared to the standard formulation in breast cancer studies. Several phase II studies have explored it in pts with Lymphoma.
Aims: The aim of the present study is to establish the role of R-COMP21 (off label use) in elderly DLBCL/G3FL pts analyzing effectiveness and toxic profile.
Methods: Fifteen Spanish centres participated in this retrospective study. Inclusion criteria were as follows: pts ≥70 at the time of treatment, confirmed diagnosis of DLBCL or G3FL and treated with R-COMP21 (Rituximab 375 mg/m2/day1, Cyclofosfamide 750 mg/m2/day1, Vincristine 1.4 mg/m2/day1, Non Pegylated Liposomal Doxorubicin 50 mg/m2/day1 and Prednisone 60 mg/m2/day1-5) between September 1st 2006 and August 31st 2011. Endpoints were overall response (OR) and complete response (CR) rate as *Revised Response Criteria for Malignant Lymphoma v2007,* toxicity as *CTCAE v3.0 of NCI scale* and overall survival (OS) and progression free survival (PFS). Left ventricular ejection fraction (LVEF) was assessed by echocardiogram visual estimation method prior to and after R-COMP21 treatment. This study was approved by the Spanish Medicines Agency (AEMPS, code MDA-RCO-2012-01).
Results: One hundred pts (85 DLBCL/15 G3FL) over 70 years of age treated with R-COMP21 were included. Mean age was 77.8 (range 70-91), male/female 52/48 pts.ECOG≥2: 51pts, Ann Arbor stage III or IV: 66 pts, extranodal involvement 60 pts (≥2 areas 29 pts), IPI ≥3: 63 pts, hypertension 67 pts, diabetes 22 pts, cardiomyopathy 32 pts, pretreatment echocardiogram was available in 80 pts, LVEF <50% in only 5 pts. Four pts had a pretreatment creatinine ≥2mg/dL and 2 pts Bilirrubine ≥2 mg/dL. Efficacy: Ninety six pts completed the treatment and 87 were evaluated for effectiveness. With a mean of 5.5 (range 3-8) R-COMP21 cycles administered the OR rate was 83.3% (56 pts achieved CR, 11 pts uCR, 13 PR) and 7 pts (8%) PD. In 10 cases the response was consolidated, with radiotherapy 6 cases and with radio-inmunotherapy (90Y Ibritumomab Tiuxetan) 4 cases. No predictive factor of response was found in univariate analysis among age (cut-off at 80 yrs), sex, histologic subtype, Ann Arbor stage (I-II *vs* III-IV) or IPI (0-2 *vs* 3-5). Toxicity: Ninety two pts received primary G-CSF prophylaxis,37 pts presented febrile neuthropenia and 6 cases resulted in death due to infection. Five pts presented cardiac adverse events: 2 pts received a pacemaker implant and 3 cases of heart failure was documented. IPI (0-2 *vs* 3-5) and LVEF (<50% *vs* >50%) were predictors for OS (p0.0033 and p 0.0011 respectively) IPI did also predict PFS (p0.0036).With a mean follow up of 20.64 months, 57 ptsare alive and in CR.
Summary and Conclusions: In summary this retrospective study suggests that R-COMP (off label use of Non Pegylated Liposomal Doxorubicin) can be effective, and well tolerated in elderly (70+) DLBCL/G3FL pts.
Disclosures: Off Label Use: Non Pegylated Liposomal Doxorubicin is approved for metastatic breast cancer

P869

THE ROLEOF PET/CT FOR EVOLUATION OF THE BONE MARROW INVOLVEMENT IN LYMPHOMA PATIENTS

F vural[1,*], A Yilmaz[1], R Savaş[1], A gunes[1], G Saydam[1], F Sahin[1], M Comert[1], M Tobu[1], Z gokgoz[1], E Dogan[1], M tombuloglu[1]
[1]Ege University Faculty of Medicine, izmir, Turkey

Background: Bone marrow involvement in lymphoma patients is an important factor for staging and prognosis. Bone marrow biopsy is a standard procedure to evaluate infiltration but it is an invasive and painful. For staging and response to treatment in lymphoma patients, 18F-FDG PET CT is now widely used
Aims: At this present study, we retrospectively analyzed our PET- CT results for bone marrow infiltration comparing with biopsy in newly diagnosed lymphoma patients.
Methods: PET-CT and bone marrow biopsy of 367 lymphoma patients (222 non- Hodgkin and 145 Hogdkin lymphoma) at the time of diagnosis were analyzed retrospectively. The (SUV) which was more than SUV of liver was considered as bone marrow involvement in PET-CT evaluation.
Results: Both PET-CT and biopsy revealed infiltration in 37 patients. We could not demonstrate infiltration in 276 patients neither with biopsy nor PET- CT. There was disconcordance between the procedures in 54 patients; in 18 patients, although the biopsy revealed positive results, no increased activity was observed in PET- CT. When we compared the PET- CT with biopsy; it had a 67,2% sensitivity, 88.4% specificity, 51% positive predictive value and 93,8% negative predictive value. The power of the procedure was calculated as 85%. The subgroup analysis of the group was shown at Tables 1 and 2.

Table 1. PET–CT at dıffuse large B cell lymphoma patients.

Sensitivity	89,4%
Spesificty	95%
Negative predictive value	98,5%
Positive predictive value	70.8%
Power of the test	94,4%

Table 2. PET–CT at Hodgkin lymphoma patients.

Sensitivity	70%
Spesificity	82.2%
Negative predictive value	97.3%
Positive predictive value	22,5%
Power of the test	81,3%

Summary and Conclusions: In this study, we evaluated the role of PET-CT for demonstrating the bone marrow involvement in lymphoma patients. Although it is not useful in all lymphoma patients, when we performed subgroup analysis, we realized that it could be a possible test for diffuse large B-cell lymphoma and Hodgkin lymphoma (Tables 1 and 2). But prospective large cohort studies with these subgroups are needed before it becomes a standard procedure.

P870

ANALYSIS OF THE BONE MARROW INFILTRATION IN A GROUP OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA BY COMPARING BONE MARROW BIOPSY AND 18F-FDG PET/CT

P César[1,*], J Carda[1], S Ramos[1], R Guilherme[1], J Correia[2], C Geraldes[1], R Afonso[1], P Lapa[2], M Gomes[1], E Cortesão[1], L Rito[1], J Luz[1], E Magalhães[1], A Espadana[1], I Sousa[1], G Costa[2], A Teixeira[1]
[1]Serviço de Hematologia, [2]Serviço de Medicina Nuclear, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Bone marrow (BM) biopsy is the standard procedure for depicting BM involvement in diffuse large B-cell lymphoma (DLBCL). However, it is an invasive method that explores a limited part of the bone.
Over the past decade, ^{18}F-2-fluoro-2-deoxy-D-glucose (FDG) positron emission tomography (PET)/CT has become the most valuable imaging modality for the initial staging of lymphomas, showing to be sensitive and specific. Recently, it has also been reported to be highly specific in the evaluation of BM infiltration in lymphoma patients.
Aims: Evaluate the value of ^{18}F-FDG PET/CT in the detection of BM involvement when compared to BM biopsy, in patients with the diagnosis of DLBCL.
Methods: Data from patients with DLBCL diagnosed between January 2004 and December 2011 were reviewed. All patients included in our study were submitted to BM biopsy and ^{18}F-FDG PET/CT at diagnosis or relapse, before any specific treatment.
Results: 97 patients were included, 55% men, median age of 55 years (range 25-90 years). In 84 patients (86.6%) there was concordance between results from BM biopsy and from ^{18}F-FDG PET/CT: 66 patients without bone marrow involvement and 18 patients with positive infiltration. In 8 patients, ^{18}F-FDG PET/CT was positive for bone marrow involvement, although BM biopsy showed negativity. Of these discordant cases, all patients had multi-focal 18F-FDG bone marrow uptake except one patient that showed uptake in a unique site. In 3 patients, BM infiltration was not confirmed by results from ^{18}F-FDG PET/CT.
Summary and Conclusions: The final results were concordant in 86.6% of the patients included in this study. The observed discordance seems to be related with the multi-focal characteristics of BM infiltration and with the methodological particularities of BM biopsy, executed on the posterior superior iliac crest. This causes the possibility of missing the affected portion of the bone. These results suggest ^{18}F-FDG PET/CT as a useful exam in the staging of DLBCL that should complement the BM biopsy.

P871

COMPARISONS OF B-CELL AND T-CELL LYMPHOMA-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

J Yu[1,*], W Hwang[1], C Teng[1]
[1]Taichung Veterans General Hospital, Taichung, Taiwan

Background: Lymphoma-associated hemophagocytic lymphohistiocytosis (HLH) is a fatal hematologic disorder that initially presents as fever, hepatosplenomegaly, cytopenia, hypertriglyceridemia, hyperferritinemia, and hemophagocytosis in bone marrow or other reticuloendothelial organs. Comparisons of clinical characteristics and treatment outcome between patients with B cell and T cell lymphoma-associated HLH remain unclear and need further investigation.
Aims: The aims of this study was to compare the clinical characteristics and treatment outcome between patients with B cell and T cell lymphoma-associated HLH.
Methods: We retrospectively analyzed 30 lymphoma patients with HLH and stratified them into B cell (n=13) and T cell lymphoma groups (n=17).
Results: Our results showed the age, performance status, Epstein-Barr virus infection, international prognostic index, presence of disseminated intravascular coagulopathy, serum triglyceride, fibrinogen, and lactate dehydrogenase levels were not significantly different in patients between B cell and T cell lymphoma groups. Patients in T cell lymphoma group, however, had higher serum ferritin levels than those in B cell lymphoma group (11525.6 *versus* 3790.6 ng/mL, P=0.043). The median survival time for patients in B-cell and T-cell lymphoma groups was 330 and 96 days, respectively (P=0.198). A trend of a better survival in patients with B cell lymphoma-associated HLH was observed and could be from use of rituximab (P=0.045) and better treatment response (P=0.112). Our limited experiences also showed allogeneic hematopoietic stem cell transplantation might provide survival benefits to patietns with lymphoma-associated HLH.
Summary and Conclusions: In summary, our study showed patients with B cell lymphoma-associated HLH had a trend toward a better survival outcome than those with T cell lymphoma-associated HLH. This survival benefit could be from better chemotherapy sensitivity in patients with B cell lymphoma, as well as introducing rituximab to B cell lymphoma treatment. Allogeneic hematopoietic stem cell transplantation could possibly provide survival benefit to patients with lymphoma-associated HLH by graft verses lymphoma effect, especially for those whose underlying malignancy was T cell lymphoma.

P872

A SERUM LACTATE DEHYDROGENSE WITH SYSTEMIC INFLAMMATION SCORE IS A USEFUL INDICATOR TO PREDICT RESPONSE AND SURVIVAL IN PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA

S Jung[1,*], D Yang[1], J Ahn[1], Y Kim[1], H Kim[1], J Lee[1]
[1]Department of Hematology-Oncology, Chonnam National University Hwasun Hospital, Hwasun, Korea, Republic of Korea

Background: Systemic inflammatory responses as evidenced by C-reactive protein (CRP) and albumin have been reported as useful indicators of prognosis in patients with advanced cancers. Serum lactate dehydrogenase (LDH) also well-known prognostic biomarker in patients with lymphoma
Aims: In this study, we added serum lactate dehydrogenase (LDH) level as another GPS parameter. The usefulness of theLDH with GPS (L-GPS) was evaluated as a prognostic indicator in patients with newly diagnosed DLBCL
Methods: We evaluated the relationship between the LDH with systemic inflammation score and survival in 213 patients with diffuse large B cell lymphoma (DLBCL) receiving the first-line R-CHOP chemotherapy. Patients were classified into three groups based on serum CRP, albumin and lactate dehydrogenase (LDH) level at diagnosis, as specified by the LDH with Glasgow prognostic score (L-GPS). Patients with elevated CRP (>1.0 mg/dL), hypoalbuminemia (<3.5 g/dL) and elevated LDH (>1´ upper normal value) were assigned a score of 2. Patients in whom one or two of these biochemical abnormalities was present were assigned a score of 1. Patients in whom none of these abnormalities was present were assigned a score of 0
Results: In multivariate analysis, the independent poor prognostic factors for progression free survival (PFS) were L-GPS 2 (HR 5.415, 95% CI 2.028-14.454, P=0.001), ECOG performance status (PS) ≥2 (HR 3.504, 95% CI 1.655-7.419, P=0.001), and bulky lesion ≥10 cm (HR 2.030, 95% CI 1.037-3.972, P=0.039). In addition, the independent poor prognostic factors for overall survival (OS) were L-GPS 2 (HR 5.898, 95% CI 2.028-14.454, P=0.001) and ECOG PS ≥2 (HR 3.525, 95% CI 1.642-7.567, P=0.001). The overall response rate for the R-CHOP chemotherapy was decreased by according to the L-GPS; 96.7% at L-GPS 0, 87% at L-GPS1, and 75% at L-GPS 2 (P=0.009) (Figure 1).

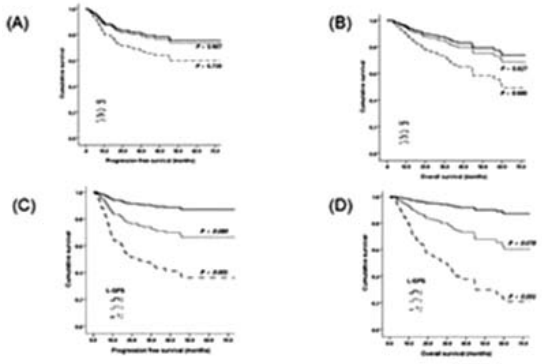

Figure 1. Progression free survival (PFS) and overall survival (OS), according to Glasgow prognostic score (GPS) and LDH with Glasgow prognostic score (L-GPS) in patients with newly diagnosed diffuse large B-cell lymphoma (DLBCL) receiving R-CHOP chemotherapy.

Summary and Conclusions: This study suggest that the L-GPS based on systemic inflammatory indicators may be useful clinical prognostic indicator for OS and PFS, and reliably predicts the response for R-CHOP chemotherapy in patients with newly diagnosed DLBCL

P873

HIGH DOSE THERAPY WITH AUTOLOGOUS STEM CELL SUPPORT FOR PRIMARY CNS LYMPHOMA: A RETROSPECTIVE ANALYSIS FROM THE ADULT LYMPHOMA WORKING GROUP OF THE JAPAN SOCIETY FOR HEMATOPOIETIC CELL TRANSPLANTATION

E Kondo[1,*], T Ikeda[2], K Shinagawa[1], T Sakai[3], H Sakamaki[4], K Kato[5], Y Morishima[6], R Suzuki[7], J Suzumiya[8]
[1]Department of hematology and oncology, Okayama university hospital, Okayama, [2]Division of Hematology and Stem Cell Transplantation, Shizuoka Cancer Center, Shizuoka, [3]Hematology & Immunology, Kanazawa Medicai University, Ishikawa, [4]Department of Hematology, Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Tokyo, [5]Division of Hematology Oncology, Children's Medical Center, Japanese Red Cross Nagoya First Hospital, [6]Division of Epidemiology and Prevention, Aichi Cancer Research Center, [7]Department of HSCT Data Management/Biostatistics, Nagoya University Graduate School of Medicine, Nagoya, [8]Department of Oncology/Haematology, Shimane University Hospital Cancer Centre, Izumo, Japan

Background: The prognosis of primary CNS lymphoma (PCNSL) still remains dismal, with high rates of local relapse and consequent death.Given the excellent results obtained with high dose therapy(HDT) with autologous stem cell transplantation (ASCT) regimens in PCNSL, ASCT is not widely used for PCNSL in Japan due to unavailability of key drugs.
Aims: We report the results of ASCT for PCNSL from the JapanSocietyforHematopoieticCellTransplantation (JSHCT) Registry.
Methods: DatafromtheJSHCT registrywereretrospectivelyanalyzed. Thirty-one patients with immunocompetent PCNSL received HDT/ASCT between 2007 and 2010 were evaluated. Overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier method.
Results: Median age at diagnosis was 54 years old (range 20 to 74). Median time from diagnosis to transplant was 22.2 months (range 2.6 to 51.7). Disease status at transplant: 1st CR 15 patients (pts), 1st PR 5 pts, 2nd CR 3 pts, 2nd PR 3 pts, 3rd CR 1 pts and refractory 3 pts. The median CD34+ cell number collected was 3.0×10^6/kg body weight (range, 1.5 to 19.5). No patient died of toxicity related to the procedure within 100 days after ASCT. With 1.3 years (range 0.1 - 4.3) of median follow-up period after ASCT, OS and PFS at 2 years were, respectively, 72% (95%CI: 45-88%) and 57% (95%CI: 29-77%) for 1st CR/PR pts, 100% and 63% (95%CI: 14-89%) for 2nd CR/PR pts, and 67% (95% CI: 5-95%) and 67% (95%CI: 5-95%) for other pts. High dose therapy regimens were varied: Busulfan(Bu)+Thiotepa (TT): 7 pts, Bu+TT+cyclophosphamide(CY): 7 pts, Bu+Cy: 2 pts, MCNU containing regimens 8 pts, LEED (melphalan, etoposide, CY, dexamethazone) 4 pts. In univariate analysis, LDH, age, performance status, use of TT and MSKCC prognostic score did not exert significant effects on survival (Figure 1).

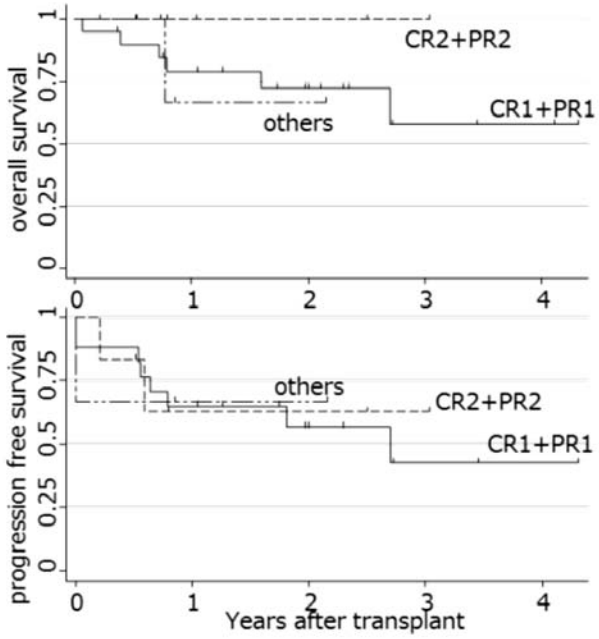

Figure 1.

Summary and Conclusions: Although there is the limitation related to unavailability of CNS penetrating drugs in Japan (*e.g.*, TT since 2010, BCNU), our results are encouraging and comparable to previous reports. Further prospective studies for PCNSL patients are warranted to confirm the efficacy of HDT/ASCT.

P874

A MULTICENTRE REVIEW OF THE OUTCOMES OF PATIENTS ABOVE THE AGE OF 75 WITH PRIMARY DIFFUSE LARGE B CELL LYMPHOMA

V Singh[1,*], S Alimam[2], M Macheta[2]
[1]Haematology, Salford Royal Hospital, Manchester, [2]Haematology, Blackpool Victoria Hospital, Blackpool, United Kingdom

Background: Diffuse large B-cell lymphoma (DLBCL) is the commonest lymphoid malignancy in the western world[1]. Its incidence increases with age and 40% of reported cases occur in patients aged over 70. However, elderly patients especially those over the age of 80 are excluded from most trials. There is only one prospective study that explored the outcomes of this age group[2] and unsurprising it reported that outcomes of such patients were inferior to younger patients (At 2 years CR/CRu of 62% and an OS of 59%). Nevertheless some elderly patients do have a complete response to treatment and have a long-term survival.
Aims: Patients enrolled into clinical trials are often selected population. We therefore aim to evaluate the outcome of an unselected group of patients with the below mentioned characteristics and their outcomes with treatment.
Methods: A retrospective, multicentre review of all patients aged above 75 who have a new diagnosis of DLBCL between January 2008 and January 2012 at 3 large centres in the North West of England. Patients for curative treatment were identified at a multidisciplinary meeting. Patients who had relapsed or transformed disease and those for palliative treatment were excluded. 50 patients were identified as suitable for the review. However, 2 patients died due to unrelated causes prior to commencing treatment (GI bleed in patient with cirrhosis, post laparotomy pneumonia & sepsis). Therefore the review will explore the outcomes of 48 patients.
Results: The patient cohort included 23 male and 25 females with a median age of 83 years (range 76-91). The cohort was well distributed across performance status (PS), stage and the age adjusted IPI (AA-IPI). 8 different treatment regimens were used (see Figure 1). Standard RCHOP includes 375mg/m² Rituximab, 750mg/m² Cyclophosphamide, 50mg/m² Doxorubicin, and 1.4 mg/m² Vincristine on day 1 of each cycle, and 40 mg/m² Prednisolone on days 1–5, cycle repeated every 21 days). Where "RCHOP 50%" was used, the dose of rituximab and prednisolone remained unchanged, while the dose of cyclophosphamide & doxorubicin was reduced by 50% and vincristine to 1mg. Where etoposide was used (RCEOP), it was given at 100mg/day for 14 days while gemcitabine in RGCVP was given at 750 mg/m² dose on day 1 & 8. 77% of the patients (n=37) completed their planned chemotherapy and only 6% of patients required an attenuation or alteration in their planned treatment regime. Response to treatment was assessed based on clinicians' choice (majority of patients underwent a CT scan, a few received PET scan). CR/CRu: 35 (73%), PR: 3 (6%), Refractory: 2 (4%), Died during chemotherapy: 8 (17%). At the follow up period of 12 months 60% (n=27) of the patients were noted to be in remission at 12 months while 19% (n=9) had relapsed. All of the patients with refractory (n=2) or relapsed (n=9) disease were identified as having poor prognostic factors. (All were stage III/IV and 9 had aa-IPI of 2 or 3). 14.4% (n=7) of the patients did not survive the treatment course and died due to toxicity. Of these interesting only 28.5% (n=2) had a PS of 3 or more. Peyrade *et al.* (2011) concluded in their study that the presence of low albumin prior to commencement of treatment was a strong indicator of poor outcome. We looked at the impact of albumin on the outcome of our patient cohort. At diagnosis 14 (29%) patients had a an albumin <35 g/L and of these, 85% (n=12) had an adverse outcome. (5 relapsed, 2 were refractory, 5 died due to chemotherapy toxicity).

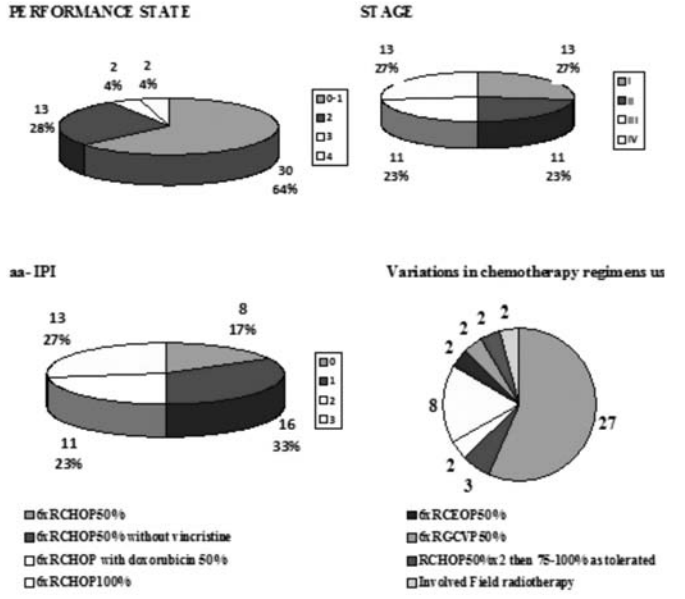

Figure 1.

Summary and Conclusions: With the increasingly ageing population, a large increase in the number of new lymphoma cases is anticipated. Our review suggests that in selected patients above the age of 75, variations of RCHOP chemotherapy can be administered with curative intent offering a good balance between efficacy and safety, with a substantial proportion of patients being disease free at 1 year. Moreover it also confirms the key role of aa-IPI and disease stage as prognostic indictors for outcome while lending support to the value of albumin as an indicator of elderly patients to tolerability to chemotherapy the treatment.

Stem cell transplation - Experimental

HUMAN CORD BLOOD CD45+ CELLS PROTECT MICE BRAIN AFTER CLOSED HEAD INJURY

H Arien-Zakay[1,2,*], A Nagler[2], E Shohami[1], P Lazarovici[1]
[1]Institute for Drug Research, The Hebrew University of Jerusalem, Jerusalem, [2]Division of Hematology and Cord Blood Bank and Bone Marrow Transplantation, Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: Traumatic brain injury is a major health care problem and a significant socioeconomic challenge worldwide, causing death and disability for at least 1.4 million patients in the United States alone each year. Regrettably, no therapeutic neuroprotective agents are clinically available to date. Cell therapy by umbilical cord blood (CB) transplantation has been lately suggested for the treatment of brain trauma, but although CB contains different stem cell populations, only the potential of mesenchymal stem cells was evaluated for this aim.
Aims: To explore the protective potential of CB CD45$^+$cells for the treatment of brain trauma.
Methods: In the present study, we used a closed head injury (CHI) mice model, in which a focal blunt injury over an intact skull is being induced by a standardized weight-drop device. The resulting mechanical impact triggers a profound neuroinflammatory response within the brain with high consistency and reproducibility, leading to neurological and cognitive impairment and breakdown of the blood–brain barrier. CB-cells were separated according to their CD45 expression and the derived populations were than transplanted into CHI mice. Animals were evaluated for their neurologic severity score (NSS) (motor ability, balancing, alertness) and under rotarod test (motor deficits and ataxia).
Results: We demonstrated that CB derived mononuclear cells (MNC) and CD45$^+$, but not CD45$^-$ -cell subset reduced the neurobehavioral and motor deficits which typically occur in a mouse model of CHI. Transplantation of CB-cells was given at day 1 or 7 post-trauma and their therapeutic effect was observed up to 35 days. A significant reduction in brain anatomical damage and head wound area were measured in treated mice from 2 to 7 days after cell transplantation, as evaluated both *ex vivo* and by non-invasive near-infrared measurement of the hemorrhage surface. CB cells which were administered either intracerebroventricularly or intravenously (iv) displayed similar efficacy. Transplanted cells, labeled with near-infrared dye and infused iv were detected at the site of injury, indicating their homing properties. Head *in vivo*and brain *ex vivo* imaging, taken at short times after cell transplantation indicated a fast increase in brains fluorescence 1.5 h after iv cells transplantation, which was reduced shortly thereafter (5 h). Acute (2 days) and chronic (35 days) after transplantation, differential levels of the BDNF, NGF and VEGF were measured in the ipsilateral and contralateral hemispheres. Finally, anti CD45 antibodies blocked the beneficial effects of the cord blood derived MNC, strengthening the notion that CD45$^+$ cells are responsible for the protective effect.
Summary and Conclusions: Altogether, these findings demonstrate the potential of the wide therapeutic window and protective properties of CB derived CD45$^+$ cell fraction in animal model of brain trauma. Based on the minimal manipulation for CD45$^+$ cells isolation from CB, their ability to reduce neurological deficits even when transplanted 7 days after the insult and their ability of fast homing to the brain, we propose that CD45$^+$ cells should be considered for translational therapy in treating patients with brain trauma.

PYROSEQUENCING IS A NEW PROMISING APPROACH TO PERFORM HLA TYPING IN A QUICKLY, SIMPLE AND ACCURATE WAY

F Cattina[1,*], S Bernardi[1], I Iacobucci[2], S Soverini[2], E Ottaviani[2], G Carella[3], A Malagoli[3], M Malagola[1], C Skert[1], C Bergonzi[1], C Filì[1], E Alghisi[1], S Perucca[1], A Di Palma[1], C De Benedittis[2], M Teresa Bochicchio[2], V Guadagnuolo[2], G Martinelli[2], D Russo[1]
[1]Chair of Hematology, University of Brescia, Brescia, [2]Department of Experimental, Diagnostic, and Specialty Medicine, University of Bologna, Bologna, [3]Chair of Rheumatology and Clinical Immunology, University of Brescia, Brescia, Italy

Background: The HLA system is characterized by an high number of alleles and haplotypes because the HLA genes are the most polymorphic in the human genome. A variety of methodologies have been developed for HLA typing at the protein and nucleic acid level, but ambiguity can affect the possibility of the right call for each HLA-locus. Particularly phase ambiguities arise from the incomplete genomic coverage or the contemporary Sanger sequencing of two heterozygous alleles that determines different haplotypes. The new generation sequencing (NGS) technologies have the potential to perform HLA-typing in a rapid and accurate way without phase ambiguities.
Aims: A simple and reliable method to implement the knowledge of HLA compatibility between donor and recipient would be necessary to obtain a rapid and accurate HLA-typing and to reduce phase ambiguities. To this purpose in this study we evaluated the feasibility, reliability and robustness of the HLA-typing by NGS in 40 samples.
Methods: We performed high-resolution HLA-typing using pyrosequencing and subsequent bioinformatic analysis. Fourtheen amplicons for sample were synthesized using two custom assay. The output file was then uploaded into JSI SeqPilot software to align all sequences with the reference database (ref 3.9 2012).
Results: Using the method of Multiplex Identifier (MID) tag, we can pooling amplicons from different samples; so we have pooled 5 different samples into 8 sequencing runs (total 40 samples). The PCR reactions generate 560 amplicons who correspond to HLA-A/B/C exons2, 3 and4, DQB1 exons 2 and 3 and DPB1, DQA1, DRB1/3/4/5 exon 2. We have obtained over of 150 reads for most amplicons. The assignment of unambiguous genotype was possible on 45.5% of alleles. The ambiguities were related to the assay design (above all for class-II). Notably, some ambiguities on the locus B and C have a little biological importance because both alleles coding for the same peptide binding domain, instead the genomic differences between the two alleles were located on the transmembrane domain coding region. Ten cases analyzed in this study were also genotyped using conventional strategies, for the most part ssp with a concordance of 100%.
Summary and Conclusions: Clonal amplification and pyrosequencing strategy is a feasible and reliable method to perform the HLA-typing. This method discriminates very well the alleles that determines differences on the peptide binding domain. Using a NGS technique we have obtained a high-resolution HLA-typing for the most important loci of the samples, quickly and without phase ambiguities. This work was supported by Lions Club " Bassa Bresciana", BCC Pompiano e Franciacorta Founds and by Roche.

A RANDOMIZED DOUBLE BLIND CONTROL TRIAL COMPARING FILGRASTIM AND PEGFILGRASTIM IN CYCLOPHOSPHAMIDE PERIPHERAL BLOOD HAEMATOPOIETIC STEM CELL MOBILIZATION–PRELIMINARY ANALYSIS

J Kuan[1,*], H Liew[2], X Sim[1], J Suriar[1], S Lim[1], Y Guan[3], P Liew[1], J Tan[1], A Kori[4], N Lau[3], S Toh[1], T Ong[1], S Tan[1], K Chang[1]
[1]Hematology Department, Ampang Hospital, Malaysia, Ampang, [2]Hematology Unit, Penang Hospital, Penang, [3]Hematology Unit, Melaka Hospial, Melaka, [4]Hematology Department, Kuantan Hospital, Kuantan, Malaysia

Background: There were very few randomized trials published in full article comparing filgrastim and pegfilgrastim in peripheral blood haematopooietic stem cell mobilization (PBHSCM). None of them to our knowledge examined cyclophosphamide as single chemotherapy (CT) agent, which is the commonest CT mobilization in our centre.
Aims: Hence, we conducted a trial to compare filgrastim (F) and pegfilgrastim (PF) in cyclophosphamide PBHSCM. (NMRR ID: NMRR-10-755-6906)
Methods: This was a randomized double blind control trial. Only patient without previous history of apheresis was eligible. Cyclophosphamide 2g/m2 was given on Day (D) 1 On D3 onwards, patient received a daily subcutaneous injection at 6pm, which was either Arm 1: F 5µg/kg till completed apheresis, Arm 2: PF 6mg on D3, normal saline (NS) D4-10, or Arm 3: PF 6mg on D7, NS D3-6 & D8-10. Peripheral blood CD34+ cell count (PB34)(/µL) was checked in the early morning on D8,11, and onwards till stop apheresis. Only if PB34 was ≥10, apheresis was done and repeated until CD34+ cell collection of $\geq 2 \times 10^6$/kg.
Results: There was 153 patients enrolled between 1st September 2009 till 31st December 2012 (Arm 1 49 (32%), Arm 2 50 (33%), Arm 3 54 (35%). Basic characterics: M:F=75:78, Malay:Chinese:Indian:Others=88:49:10:6; diagnosis were acute leukemia, myeloma, and lymphoma=23 (15%), 33 (22%), and 97 (63%), respectively; mean (SD) weight (kg) 60.4 (16.6); median age (range) 41 (12-66). There was no significant difference of sex, ethnicity, diagnosis, status of disease (new, relapse, relapse ≥2), and response of disease during PBHSCM (CR, PR, primary refractory, relapse refractory), weight and age between the 3 arms. The successful mobilization rate for Arm 3 was 1.5 times higher than Arm 2 (RR=1.51, 95% CI=1.09, 2.09). Arm 1 seems to give 1.3 times higher than Arm 2 but the result was not significant (RR=1.29, 95% CI=0.90, 1.85). In comparison to Arm1, Arm 3 seems to have a higher mobilization rate but the result was not significant (RR=1.17, 95% CI=0.90, 1.53).
Summary and Conclusions: Pegfilgrastim 6mg given on D7 resulted in more successful PBHSCM than D3 probably because of the surge of neutrophil resulting in degradation of PF when given in D3. There was a favourable trend towards PF 6mg D7 compared to F 5µg/kg from D3 onwards.

P878

DIFFERENT DOSE OF ATG INDUCTION THERAPY IN HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION: LONG TERM EFFECT ON TH17 AND CONVENTIONAL T CELLS, NOT ON NK RESPONSES

X Zhao[1,*], X Zhao[1], Y Chang[1], Y Wang[1], H Wang[1], M Lv[1], T Han[1], Y Wang[1], H Fu[1], D Liu[1], L Xu[1], K Liu[1], X Huang[1]
[1]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Peking

University People's Hospital & Peking University Institute of Hematology, Beijing, China

Background: Anti–T lymphocyte globulin (ATG) have been demonstrated to play important roles in graft-*versus*-host disease (GVHD) prophylaxis after myeloablative unrelated or HLA-mismatched transplantation resulting in a reduction of GVHD without compromising anti-leukemia activity. However, the risk of infectious complications and post-transplantation Lymphoproliferative disorder (PTLD) were shown to be significantly elevated. Therefore, to further explore the effect of ATG on immune responses would be help to explore the optimal dose of ATG induction in HLA-mismatched transplantation.
Aims: Based on the open-label, prospective, randomized trial to compare two different total doses of ATG (6 mg/kg, ATG-6 group) *vs.* (10 mg/kg, ATG-10 group) in patients receiving myeloablative conditioning prior to allo-HSCT from haploidentical donors in our center, weevaluated the effect of the two different doses of ATG in conditioning regimen on immune reconstitution.
Methods: Using flow cytometry, we prospectively collected 29 standard-risk patients (15 received 6mg/kg ATG and 14 received 10mg/kg ATG) every 1 months until half-year post-transplant continuously to investigate the reconstitution kinetics of NK cells and T cells subsets as well as Treg cells, T cells functions such as CD4 helper activity, *in vitro* cytokine responses ie IL-17 and IFN-γ.
Results: The reconstituted kinetics of CD3+, CD4+ T-cell and CD56+ NK-cell abolute numbers in peripheral blood were similar between patients in ATG-6 group and ATG-10 group during half-year after transplantation. There were no differences in the expression of KIR, NKG2C, NKP30, and CD57 within the CD3-CD56+ NK lymphocyte compartment between the patients in ATG-6 group and ATG-10 group no matter at day15, day 30, day 60, day 100 or day 180 after transplantation. Meanwhile, the cytotoxic function or the IFN-γ secretion of NK cells reconstitution between the patients in ATG-6 group and in the ATG-10 group were similar during half-year post-transplant. However, patients in ATG-6 group showed faster Th17 cells and conventional T cells reconstitution at day15, day 30, day 60, day 100 or day 180 after transplantation. The proportions of Treg cells tended to be high in patients of ATG-10 group compared to those of ATG-6 group.
Summary and Conclusions: ATG 10mg/kg applied in conditioning regimen showed impared Th17 cells and conventional T cells reconstitution, therefore would reduce the GVHD occurrence compared to ATG 6mg/kg after transplantation.

P879

CIRCULATING ENDOTHELIAL CELLS (CEC) ARE A RELIABLE AND DYNAMIC BIOMARKER OF ACUTE GVHD (AGVHD) IN PATIENTS UNDERGOING ALLOGENEIC STEM CELLS TRANSPLANTATION.

C Almici[1], R Verardi[1], A Di Palma[2,*], A Bianchetti[1], A Neva[1], S Braga[1], C Skert[2], A Turra[2], R Ribolla[2], V Cancelli[2], S Perucca[2], F Cattina[2], S Bernardi[2], E Alghisi[2], M Marini[1], D Russo[2]
[1]Laboratorio Manipolazione e Criopreservazione delle Cellule Staminali, A.O. Spedali Civili, [2]Chair of Haematology, Unit of Blood Diseases and Cell Therapies, University of Brescia, Brescia, Italy

Background: Acute GVHD (aGVHD) is one of the major cause of morbility and mortality in allogeneic stem cell transplantation (allo-SCT). Clinical and physiopathological evidences have shown that vascular endothelium could be a target of aGVHD in very early phase; therefore markers of endothelial damage are warranted as valuable support in aGVHD diagnosis and to monitor its response to immunosuppressive treatments.
Aims: The primary endpoint of our study was to investigate the values of CEC count in peripheral blood to diagnose and predict aGVHD in patients submitted to allo-SCT.
Methods: We conducted an explorative and prospective study to evaluate CEC count at different time points: before and at the end of the conditioning regimen, at engraftment, at aGVHD onset and at 1 and/or 2 weeks after corticosteroids therapy administration. The CellSearch System® was used to capture and enumerate CEC. Magnetic particles conjugated to anti-CD146 are used to capture CEC from 4.0 mL of peripheral blood. Enriched cells are stained with DAPI and anti-CD105-PE antibody. APC conjugated anti-CD45 is used to exclude leukocytes. Enriched and stained cells are dispensed into a MagNest® cartridge for magnetic mounting. The cartridge is scanned and individual images of cells are presented for review and scored as CEC, based on CD146+, CD105+, DAPI+ and CD45- phenotype and cell morphology.
Results: We studied 10 healthy subjects (controls) and 41 patients with hematologic neoplastic diseases (7 HL, 1 NHL, 2 AL, 12 AML, 5 ALL, 8 MM, 3 CLL, 1 CML, 2 SAA) undergoing allo-SCT from either HLA-matched familial (n=11) or unrelated donor (n=30). The median count in controls was2,5 CEC/mL (range 1-14). The median CEC/mL pre-allo-SCT was 20 (n=33, range 4-718, P<0.0001 compared to controls), going up to 33 CEC/mL (n=39, range 3-648, P=NS compared to pre-allo-SCT) at the end of the conditioning regimen. At aGVHD onset the median CEC/mL was 58 (n=17, range 16-299, P=0.0009 compared to pre-allo-SCT), while at aGVHD response the median CEC/mL decreased to 31 (n=12, range 6-107, P=0,0079 compared to aGVHD onset) after 1 week of steroids therapy, and to 10 (n=5, range 5-29, P=0,0017 compared to aGVHD onset) after 2 weeks of steroids therapy (Figure 1).

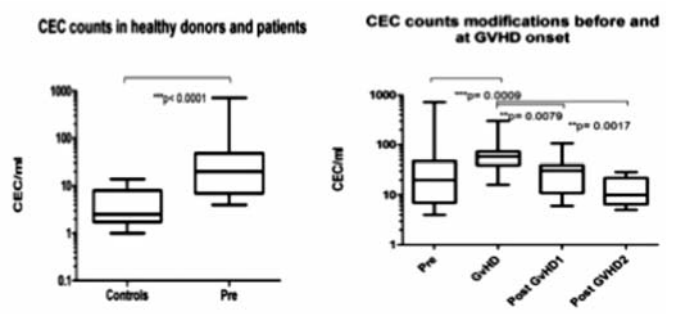

Figure 1.

Summary and Conclusions: Circulating endothelial cells can represent a promising marker to monitor endothelial damage in patients undergoing allo-SCT. We have showed a statistical significant increase in CEC numbers at aGVHD onset with a normalization at treatment response. CEC count helped us to settle between aGVHD and other transplant complications such as infections or autoimmune diseases leading to endothelial injuries: *e.g.* in a patient with diarrhea and low number of CEC, colon biopsy diagnosed infective colitis. The confirmation of the clinical utility of CEC counts, together with the use of a semiautomatic, standardized and reproducible technology, will allow a valuable help in the diagnostic definition of aGVHD in early phase and an information on the response to treatment.

P880

EFFECT OF GRANULOCYTE COLONY-STIMULATING FACTOR MOBILIZATION ON THE EXPRESSION OF REGULATORY GAMMA DELTA T CELLS

L Xuan[1], X Wu[2], S Yu[1], Z Yi[1], Y Zhang[1], M Dai[1], Z Zheng[1], Y Li[2], Q Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background: The immune modulatory effect of granulocyte colony-stimulating factor (G-CSF) on T cells resulted in an unexpected low incidence of graft-*versus*-host disease (GVHD) in allogeneic peripheral blood stem cell transplantation. Our previous studies demonstrated that G-CSF mobilization influenced the distribution and clonality of TRGV and TRDV repertoire (T cell receptors of gamma delta [GD]Tcells), and significant positive correlation was observed between the invariable clonality of TRDV1 gene repertoire after G-CSF mobilization and low incidence of GVHD in recipients (P=0.015, OR=0.047) (Li Xuan *et al.* Journal of Translational Medicine 2011). Regulatory GD T cells (GD Tregs), which express Foxp3 and primarily belong to $CD27^+CD25^{high}$phenotype, are a novel subset of cells with immunosuppressive function (Xiaoyan Li *et al.* Journal of Immunology 2012). However, whether G-CSF could influence the expression of GD Tregs remains unknown.
Aims: To investigate the effect of G-CSF mobilization on the expression of GD Tregs.
Methods: The immunophenotyping of GD Tregs was analyzed in peripheral blood mononuclear cells (PBMCs) from 20 donors before and after G-CSF mobilization, using flow cytometry.
Results: Compared with that before mobilization, the proportions of Vdelta 1 and $CD25^+$ subsets were significantly increased (P=0.012, P=0.032), whereas the Vdelta 2 proportion was significantly decreased after G-CSF mobilization (P=0.002). The proportions of total GD T cells, $CD27^+$ and $Foxp3^+$ subsets were similar between the two groups (P=0.133, P=0.110, P=0.780, respectively). In addition, there was a significant increase in the proportions of $Foxp3^+$Vdelta 1 and $CD25^+Foxp3^+$subsets (P=0.038, P=0.013), and a significant decrease in the proportions of $CD27^+$Vdelta 2 and $CD25^+$Vdelta 2 subsets after G-CSF mobilization (P=0.013, P=0.022). The proportions of $CD27^+$GD T, $CD25^+$GD T, $Foxp3^+$GD T, $CD25^+CD27^+$, $CD27^+Foxp3^+$, $CD27^+$Vdelta1, $CD25^+$Vdelta 1 and $Foxp3^+$Vdelta 2 subsets were similar before and after G-CSF mobilization (P=0.422, P=0.342, P=0.724, P=0.070, P=0.503, P=0.053, P=0.386 and P=0.097, respectively). We then compared the Foxp3, CD27 and CD25 phenotypes in total GD T cells, Vdelta 1 and Vdelta 2 subsets. We observed a significant increase in the proportion of $CD27^+Foxp3^+$Vdelta 1 subsets after G-CSF mobilization (P=0.036). The proportion of $CD27^+Foxp3^+$GD T and $CD27^+Foxp3^+$Vdelta 2 subsets before mobilization were similar to that after mobilization (P=0.539, P=0.507). The proportion of $CD25^+Foxp3^+$GD T, $CD25^+Foxp3^+$Vdelta1, $CD25^+Foxp3^+$Vdelta2, $CD25^+CD27^+$ GD T, $CD25^+CD27^+$Vdelta 1 and $CD25^+CD27^+$Vdelta 2 subsets were also similar between the two groups (P=0.249, P=0.539, P=0.507, P=0.934, P=0.209 and P=0.061, respectively).

Summary and Conclusions: G-CSF mobilization significantly increased the proportions of Vdelta 1 subsets, including Foxp3+Vdelta 1 and CD27+Foxp3+Vdelta 1 subsets, whereas decreased the Vdelta 2 proportion.

P881

ENUMERATION OF RECENT THYMIC EMIGRANTS AFETER AUTOLOGOUS HSCT ACCORDING TO THE TYPE OF CONDITIONING: IRRADIATION VERSUS CHEMOTHERAPY

J Najda[1,*], M Glowala-Kosinska[1], A Chwieduk[1], T Czerw[1], T Kruzel[1], M Sadus-Wojciechowska[1], L Miszczyk[2], J Holowiecki[1], S Giebel[1]
[1]Bone Marrow Transplantation, [2]Radiotherapy, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland, Gliwice, Poland

Background: Stem cells present n the graft are predominant source of T cell recovery after HSCT.
The process, however requires proper function of the thymus, which may be negatively affected by many factors including toxicity of the conditioning regimen. Experimental data suggest that irradiation may be more harmful to the thymus compared to myeloablative chemotherapy.
Aims: The goal of the current analyusis was to verify this hypothesis in a clinical setting of autologous HSCT.
Methods: The thymic function was evaluated by enumeration of circulating recent thymic emigrants (RTEs) determined by flow cytometry as CD4+CD31+CD45RA+CD62L+ cells. It was done before start of conditioning and on day +100 after autoHSCT. A total of 57 patients with hematologic malignancies 9mm, n=32, NHL, n=22; other, n=3) were included in the study. Median age was 57 (22-66) years. Patients were divided in 4 groups according to the type of conditioning; total body irradiation (TBI, 12Gy) monotherapy (n=20), TBI+CHT (n=11), total marrow irradiation (TMI) monotherapy (n=11) and chemotherapy alone (BEAM or high-dose melphalan, n=15). The groups did not differ in terms of age.CD34+ cell was significantly higher for TBI+CHT compared with remaining groups.
Results: RTEs could be detected in peripheral blood of all subjects prior to HSCT (median 21, range 2-261cells/uL) with no significant differences between groups (Kruskall-Wallis test, P=0,95). On day +100 after autoHSCT the highest number of circulating RTEs was observed for TBI alone (9,2-36/uL) followed by TMI alone (7,2-15/uL), CHT alone (5,2-24/uL) and TBI+CHT (3,0-14/uL) (Kruskall-Wallis test, P=0,03). In the post-hoc analysis (Umann-Whitney test) the values for TBI alone were significantly higher compared to TBI+CHT (P=0,01) and tended to be higher compared to CHT alone (P=0,11). Analysis of lymphocyte subsets on day +100 revealed no differences between groups for the number of circulating T CD4+ cells (P=0,41), T CD8+cells (P=0,52) and B cells (P=0,24). The number of Treg cells tended to be lower for TBI+CHT compared to other groups (P=0,07) and the number of NK cells was lower for TBI alone than for other groups(P=0,003).
Summary and Conclusions: We conclude that conditioning regimens have variable impact on thymic function after autoHSCT. As opposed to previously published data from animal models we demonstrated that TBI itself is not more harmful to the thymus than high-dose chemotherapy. In contrast, the addition of chemotherapy to irradiation increases significantly the toxicity.

P882

SERUM MICRORNAS SIGNATURES IN ACUTE GRAFT VERSUS HOST DISEASE (AGVHD) AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO HSCT)

Y Efebera[1,*], P Ranganathan[1], X Yu[1], J Hofstetter[1], S Garman[1], L Gibson[2], W Petros[2], M Criag[2], C Fernandez-Cymering[3], S Volinia[3], M Hamadani[2], G Marcucci[1], S Devine[1], R Garzon[1]
[1]Division of Hematology, The ohio State University, Columbus, [2]Osborn Hematopoietic Malignancy and Transplantation Program, West Virginia University, Morgantown, [3]Department of Molecular Virology, Immunology and Medical Genetics, The ohio State University, Columbus, United States

Background: aGVHD is one of the most frequent and lethal complications after allo HSCT, underscoring the need to develop novel therapies. To achieve this goal, aGVHD mechanisms needs to be further elucidated. Our group recently reported aberrant miRNA expression in donor T cells from animals and patients with aGVHD. Further studies focusing on miR-155 showed that this miRNA is modulating aGVHD. Emerging data also indicate that miRNAs are also present in the human serum and regulate immune responses. Here, we hypothesize that serum miRNAs expression is deregulated in aGVHD and could play a role in aGVHD pathogenesis or serve as biomarkers for the disease.
Aims: To identify miRNAs associated with aGVHD by performing serum miRNA expression analysis using deeP-sequencing in allo HSCT recipients at the time of clinical suspicion of aGVHD.
Methods: Peripheral blood (PB) samples were collected weekly until day 100+ and at the time of clinical diagnosis of aGVHD from allo HSCT patients enrolled into OSU11002 (a biorepositorium trial). After serum separation, total RNA was extracted using Trizol. Libraries were constructed using the small RNA profiling kit and sequenced on the Solid analyzer. A mouse model of aGVHD (B6 mice donor splenocytes and bone marrow cells transplanted to lethally irradiated F1 recipients) was used to assess serum miRNA expression in animals with aGVHD after transplant.
Results: In this study we included 10 patients with aGVHD (bowel aGVHD n=2; skin aGVHD (n=5) and both skin and bowel aGVHD (n=3). Median age was 51.9, conditioning regimens were myeloablative (n=1) and non-myeloablative (n=9) and the type of donors used were unrelated (n=9) and related (n=1). PB samples were obtained from these patients at the time of clinical suspicion of aGVHD. PB samples from allo HSCT patients with no aGVHD and matched for age, disease, conditioning regimen, donor and timing of sample collection were obtained and used as controls. Sequence alignment was performed using miRBase. The average reads count per sample was 875,000. Normalization as reads per million was followed by quantiles. First we compared miRNA expression between all patients with aGVHD (n=10) and controls (n=7) using BRB tools and class comparison. We found 7 miRNAs uP-regulated (miR-146a, miR-323-b, miR-34c, miR-363, miR-4245, miR-29a, miR-181a*) and 3 miRNAs down-regulated (miR-3168, miR-662, miR-550a) (Fold change (FC) >2, P<0.01). Next, we compared miRNA expression of patients with bowel aGVHD (n=5) *vs.* controls (n=7). We found 3 miRNAs uP-regulated (miR-146a, miR-4295 and miR-181a*) and 4 miRNAs down-regulated (miR-3168, miR-582, miR-193a and miR-662) (FC>2, P<0.01). Last we compared miRNA expression between patients with skin only aGVHD (n=5) and controls (n=7). We found 5 miRNAs uP-regulated (miR-323b, miR-34c, miR-3940, miR-3674, miR-4258) and 2 down-regulated (miR-3168 and miR-3678) (FC>2,P<0.01). MiR-3940 and miR-4258 are expressed exclusively in the skin (miRBAse). Remarkably, miR-146a, a miRNA associated with innate immunity, was found uP-regulated as well on serum samples from mice with aGVHD (n=6) compared with controls (n=6) (FC>2,P<0.01). Both, miR-181a and miR-29a, which are known to regulate immunity, were found deregulated in serum samples from patients with aGVHD. Ongoing experiments are being performed to dissect the function of those miRNAs.
Summary and Conclusions: miRNAs related to skin and immune system regulation were found to be de-regulated in the serum of allo HSCT recipients with aGVHD suggesting that they may play a role in the modulation of this process.

P883

PARALEL STUDY OF CHIMERISM AFTER ALLOGENIC HAEMTOPOIETIC STEM CELL TRANSPLANTATION MONITORED BY TWO DIFFERENT MOLECULAR METHODS

E Hanusovska[1,*], S Sufliarska[2], E Bojtarova[3]
[1]Clinical genetics, Medirex, [2]Bone Marrow Transplantation Unit, Comenius University Teaching Hospital, [3]Department of Haematology and Transfusion, Comenius University Medical School, Bratislava, Slovakia

Background: Over the past decades, allogeneic stem cell transplantation (allo-SCT) has gained increasing importance as a treatment option for patients with both malignant and non-malignant life threatening disorders. Surveillance of chimerism after allo-SCT seems an indispensable tool for the clinical management of transplant recipients. There are many genetic methods used for this purpose. The FISH analysis of chromosome X and Y is applicable only in sex mismatched transplantations. The most widespread method for testing of chimerism is the PCR-based analyses of highly polymorphic short tandem repeats (STR). Real-time PCR of SNP or NPs isn´t used so frequently.
Aims: To compare patient´s chimerism after allo-SCT measured using relative quantification (RQ PCR) of SYBR green-based real-time PCR of SNP or NPs or using PCR-based analysis of STR markers by fragment analysis on an automated genetic analyzer.
Methods: Whole peripheral blood samples were collected for DNA extraction from both the donor and recipient before transplantation in order to determine an informative marker. The blood samples of patients after allo-SCT (N=65 pairs) were collected at regular intervals at the Department of Hematology and Transfusion, Comenius University Medical School, Bratislava, Slovakia and provided for chimerism testing. RQ-PCR was performed by the real-time PCR system using SYBR green and 12 pairs of specific primers for two allelic variants of DNA polymorphism and GAPDH as endogenous gene control. The STR analysis was performed using of commercially available STR multiplex amplification kits with fluorescently labeled PCR primers. The quantification of donor and recipient signal was done by comparing the fluorescence intensity given by the peak area of analyzed fragments.
Results: We screened 65 related and unrelated donor/recipient pairs by both methods and we found at least one informative marker. The quantification of informative markers was provided at the same time by both methods in parallel and estimated chimerisms were compared. We found that our results were identical only in 2% and the discrepancy was noticed also in 2% between the two methods used. In the case of 1-50% mixed chimerism (MC) similar results were obtained. However, complete chimerism (CC) estimated by the fragment analysis was evaluated as mixed chimerism (MC) by the real-time PCR in 94% patients, mainly in the first half of a year of the post-transplantation monitoring. The example of the parallel monitoring of one patient is shown in Figure1. Fig-

ure 1 Monitoring of chimerism after allogeneic stem cell transplantation (allo-SCT) by analysis of STR markers by fragment analysis and by relative quantification (RQ PCR) of SYBR green-based real-time PCR of SNP or NPs.

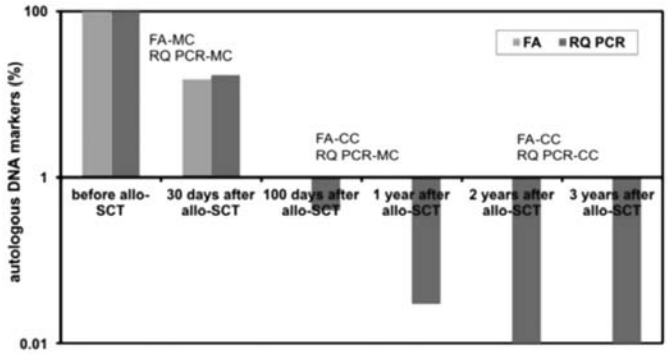

Figure 1.

Summary and Conclusions: Both methods compared above are suitable for chimerism assessment after the allogeneic SCT. Complete chimerism detected by the fragment analysis (FA) and mixed chimerism (MC) detected by the real-time PCR was due by the different sensitivity of two methods used. RQ PCR had the higher sensitivity (<1%) for the detection of the autololougous DNA markers than FA, so it is better for earlier revealing of eventual relaps. On the other hand the quantification of donor´s DNA markers is more precise estimated by the FA.

P884

VENO-OCCLUSIVE DISEASE MAY DEVELOP IN SECONDARY IRON OVERLOADED MICE AFTER TOTAL BODY IRRADIATION.

N Chung[1,*], M Yeom[2], S Kim[1], J Lee[1], P Jang[3], B Cho[1], H Kim[1], D Jeong[1]
[1]Pediatrics, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, [2]Pediatrics, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Incheon, [3]Pediatrics, Uijeongbu St. Mary's Hosptial, College of Medicine, The Catholic University of Korea, Uijeongbu, Korea, Republic of Korea

Background: The outcome of hematopoietic stem cell transplantation (HSCT) is poor in patients with secondary iron overload (SIO). High incidence of veno-occlusive disease (VOD), acute GVHD, and infection were observed in SIO patients treated with HSCT.
Aims: We evaluated the relation between SIO and VOD in an animal model of HSCT.
Methods: We used 6 week-old female BDF1 (H-$2^{b/d}$) as recipient and male C57/BL6 (H-2^{b}) as donor. Recipient mice were injected intraperitoneally with 10mg of iron dextran according to experimental design (cumulative dose: 50mg, 100mg, and 200mg). All mice were treated with HSCT including total body irradiation designed by dose. Also, some mice without SIO were treated with allogeneic or syngeneic HSCT. We obtained peripheral blood for alanine aminotransferase (ALT) and liver for pathologic findings, lipid hyperoxide (LH), and liver iron content (LIC) as reactive oxygen species on post-HSCT day 1 and day 7. The score for VOD was assessed by pathologic findings (Hepatology, 1999;29:1779-91).
Results: All mice with SIO died within 10 days of HSCT. ALT level was increased depending on cumulative iron dose, with a significant difference between day 1 and day 7 for 200mg iron group (P<0.01). LH level was significantly increased in the 200mg iron group than in other groups (P<0.01). For the 100mg iron group, the LH level depended on radiation dose (P<0.01). There was a statistically significant relation among ALT, LH and LIC parameters (ALT *vs.* LH; r^2=0.911, ALT *vs.* LIC; r^2=0.548, LIC *vs.* LH; r^2=0.564). Also, the pathologic scores for VOD correlated with LIC (P<0.01, r^2=0.597).
Summary and Conclusions: The liver with SIO showed a high level of ROS that depended on cumulative iron dose, which also showed correlations with elevated liver enzyme and LIC. The pathologic score for VOD was associated with LIC. Our results suggest that SIO may induce VOD after HSCT done with irradiation. Iron chelation may improve outcome in SIO model of HSCT.

ASSESSMENT OF CMV SPECIFIC IMMUNITY BY FLOW CYTOMETRY USING A COMBINED APPROACH OF SPECIFIC CMV CELL ENUMERATION AND FUNCTIONAL T CELL ANALYSIS

V Tkáčová[1,*], M Kouba[1], V Válková[1], M Kohoutová[1], A Pešek[1], P Cetkovský[1], L Marinov[1]
[1]Institute of Hematology and Blood Transfusion, Prague, Czech Republic
Background: CMV reactivation is one of the most frequent infectious complications following allogeneic stem cell transplantation (SCT). CMV specific memory CD8+ cells (CMV CD8+ Tly) play crucial role in the regulation of CMV infection. In practice, CMV specific response can be monitored by detection and quantification of CMV CD8+ Tly using tetramer technology and/or *ex-vivo* assessment of CMV induced T cell function.
Aims: To study the recovery of CMV specific immunity by analysing the functional activity of CMV stimulated CD8+ Tly in terms of simultaneous production of IL-2 and IFNg in correlation with CMV CD8+ Tly enumeration by CMV tetramer test.
Methods: In 37 patients after SCT, we determined the presence of CMV CD8+ Tly using the CMV tetramer test and simultaneously evaluated the functional status of CMV stimulated CD8+ Tly by evaluation of intracytoplasmic presence of both IL-2 and IFN-g using multiparameter flow cytometry (MPFCM).
Results: During the last 4 months, 37 patients were analyzed on day +60, +150, +240, +360 following SCT. In 10 (27%) patients, we demonstrated the presence of CD8+IL-2+INFg+ double positive cells, indicating sufficient CMV specific response of Tly in agreement with literary data. In 7 of 10 cases (70%), we proved the presence of CMV CD8+Tly: 203 c/µl (min. 51 c/µl, max. 785 c/µl). All of these 10 patients didn't experience any CMV complications. In 3 of 37 patients (8%) suffered from severe CMV infection and neither CMV CD8+ Tly, nor CMV CD8+IL-2+,IFNg+ Tly were identified.
Summary and Conclusions: Preliminary results suggest possible correlation between *ex-vivo* functional activities of CMV stimulated Tly and the presence of tetramer positive CMV CD8+Tly in concentration >10 c/µl. Further analysis is necessary to confirm this observation and implement both techniques in clinical practice for laboratory evaluation of CMV specific immunity recovery and optimal timing of anti-CMV therapy.

P886

SERUM FREE LIGHT CHAIN (SFLC) AN EARLY PROGNOSTIC MARKER OF OUT-COME IN LYMPHOMA AND LEUKEMIA PATIENTS POST ALLOGENEIC TRANSPLANTATION

L Adie[1,*], J Croudace[2], P Young[1], B Abbotts[2], J Nunnick[3], S Lee[3], G Pratt[2], C Craddock[2,3], S Harding[1], P Moss[2,3]
[1]The Binding Site Group Ltd, [2]School of Cancer Sciences, University of Birmingham, [3]Centre for Clinical Haematology, University Hospitals National Health Service Foundation Trust, Birmingham, United Kingdom

Background: Early markers of allogeneic transplant engraftment and graft *versus* host disease (GVHD) may aid patient management. Previously a small study of 47 multiple myeloma patients undergoing allogeneic transplant identified changes in serum free light chain (FLC) production (of the non-clonal isotype) as markers of allogeneic transplant outcome.
Aims: Here we present data looking at the delta changes of FLC compared to baseline and comment on their role as markers of immune-reconstitution in a group of leukemia and lymphoma patients.
Methods: Serum from 19 lymphoma (13 NHL, 6 HL), 73 leukemia (53 AML, 7 CML, 6 ALL, 4 PLL, 3 CLL) and 8 patients with other hematological disorders (3 MDS, 2 MF, 2 aneuploidy, and 1 ATLL) taken at baseline (median 7 days before transplant (range 1-19 days) and 5 weeks post-transplant were analysed retrospectively (male/female ratio 61/39, median age 51 years, range 19-71). FLC kappa and lambda were measured using automated immunoassays nephelometrically and results summated (κFLC+λFLC) to give a combined polyclonal FLC measurement (cFLC). Delta cFLC were characterised as increased, stable or decreased. Intact immunoglobulin (IgG, IgA, IgM) measurements were analysed in a similar fashion. All statistics were performed on SPSS v19.0.
Results: Median cFLC values at baseline and at week 5 post-transplant were 25 mg/L (range 2.21-371) and 15.63 mg/L (range 0.54-56.73), respectively. At week5, the absolute values of cFLC increased in 25/100 (median increase 7.19 mg/L, range 0.18-38.15) and decreased in 75/100 patients (median decrease 13 mg/L, range 0.02-335.51). Overall survival (OS) was better in patients with increased delta cFLC and these patients were more likely to have acute GVHD (aGVHD) compared to patients with decreased delta cFLC (75%ile survival rate: not reached v. 231 days, respectively, P<0.001; 50%ile rate of aGVHD free survival: 55 days v. not reached, respectively, P=0.004). Due to assay analytical variation, subtle changes in the delta cFLC may not represent increase or decrease in cFLC levels. A cut-off of ±8 mg/L was used to define delta cFLC in to 3 groups: 1) increased, 2) stable, or 3) decreased. Patients with increased delta cFLC (n=10) had a better OS compared to patients with stable (n=36) or decreased (n=54) delta cFLC and patients with stable delta cFLC had a better OS compared to patients with decreased delta cFLC (75%ile survival rate: not reached v. 533 days v. 206 days, respectively; P=0.001). In comparison, changes in intact immunoglobulin measurements did not offer significant information on the outcome of these patients (p value for IgG P=0.34; IgA P=0.15; and IgM P=0.057).
Summary and Conclusions: Delta increases in FLC correspond to better OS and an increase in GVHD, suggesting they may be early markers of engraftment and immune reconstitution. Changes in intact immunoglobulins did not offer the same information, possibly reflecting longer serum half-lives which may buffer subtle changes in concentrations.

P887

STUDY OF SOLUBLE HLA-G LEVEL DYNAMICS IN HEMATOLOGICAL PATIENTS UNDERGOING AUTOLOGOUS OR ALLOGENEIC STEM CELL TRANSPLANTATION

E Ribakovsky[1,*], M Koren-Michowitz[1], A Stanevsky[1], A Shimoni[1], E Gazit[1], A Nagler[1]
[1]Sheba Medical Center, Ramat Gan, Israel

Background: Human leukocyte antigen G (HLA-G) is a non-classical major histocompatibility complex (MHC) class I molecule with immune-modulatory properties. HLA-G expression is highly tissue restricted and can be elevated by a variety of inflammatory cytokines including IL-10 and INF-γ, heat shock, radiation, oxidative stress and hypoxia. Aberrant HLA-G expression was found in a variety of pathologic situations, including solid as well as hematologic malignancies (AML, CLL, NHL and HL). Soluble HLA-G (sHLA-G) is generated by proteolytic cleavage of HLA-G1 surface antigen. Increased sHLA-G plasma levels has been suggested as disease specific markers in several solid tumors, with higher levels correlating with an advanced disease status. HLA-G molecules have an inhibitory effect on cells of the immune system including NK, T cells and dendritic cells, suggesting that they may have a role in immune surveillance and transplantation. In hematological malignancies both tumor and the BM stroma may contribute to plasma sHLA-G. We hypothesized that sHLA-G is increased in patients (pts) with hematological disorders and may have a biological significance in patients undergoing either autologous (Auto) or allogeneic (Allo) SCT.
Aims: To study plasma sHLA-G levels and dynamics in pts with hematological disorders undergoing SCT.
Methods: Patients undergoing SCT between 08/2006 and 08/2009 were included in this study. sHLA-G was determined in ACD plasma collected before conditioning and at 2 days intervals until engraftment. Concentrations were determined by ELISA using MEM-G and HRP-antiB2-microglobulin as capture and detection antibodies, respectively, and are expressed as ng/mL. sHLA-G levels determined during conditioning were compared with baseline values and are expressed as fold changes (level at a specific day/baseline).
Results: 106 pts, median age 50 years (range 1-72), F/M 44/62 undergoing either Auto (n=27) or Allo (n=79) SCT were included in the study. Their baseline characteristics are shown in Table 1. Mean sHLA-G level prior to SCT was 40.7 ng/mL (range 5-148) in the entire cohort and was significantly different according to diagnosis (mean±SEM); 71±17 ng/mL in HL, 56±12 ng/mL in ALL, 55±16 ng/mL in severe aplastic anemia, 55±5 ng/mL in CML, 52±9 ng/mL in myelofibrosis, 48±4 ng/mL in CLL, 40±8 ng/mL in MDS, 37±8 ng/mL in NHL, 32±3 ng/mL in AML and 23.50±5 ng/mL in MM (one way ANOVA, P=0.0123). Mean sHLA-G levels were similar in pts transplanted in CR1 or 2 (42±7 ng/mL), active disease (PR+PD) (40±6 ng/mL) and in pts with no prior therapy (39±7ng/mL). sHLA-G levels gradually increased in Allo SCT pts, achieving maximal levels at engraftment±5 days, with mean fold changes from baseline of 2.6±0.4. In contrast, sHLA-G level in Auto SCT pts remained relatively stable with mean fold change at engraftment of 0.8±0.2 compared to baseline levels. Pre-transplant sHLA-G levels in Allo SCT pts developing acute GVHD (n=24, 30%) were not significantly different from pts with no GVHD (43±6 ng/mL and 44±5 ng/mL, respectively), however in AML pts, pre-transplant higher sHLA-G levels were observed in pts with acute GVHD (41±10 ng/mL) compared to those without acute GVHD (31±4 ng/mL), P=0.3.

Table 1. Clinical characteristics of study patients.

	N=106
Age (years) median (range)	50 (1-72)
Gender F / M	44 / 62
Diagnosis N (%) Acute leukemia- AML / ALL Multiple myeloma MDS Lymphoma – HL / NHL Severe aplastic anemia Myelofibrosis CML CLL Unknown	 24 (23%) /10 (9%) 13 (12%) 10 (9%) 6 (6%) / 16 (15%) 6 (6%) 3 (3%) 3 (3%) 5 (5%) 10 (9%)
SCT-N (%)- Allo / Auto	79 (75%) / 27(25%)
Disease status at SCT N (%) CR1 / CR2 PR / Progressive disease Untreated Unknown	 11 (10%) / 13 (12%) 20 (19%) / 18 (17%) 18 (17%) 26 (25%)

Summary and Conclusions: sHLA-G levels in patients with hematological disorders are quite variable with the highest values found in HL pts. Serial plasma sHLA-G measurements in SCT pts demonstrate different dynamics in Allo SCT compared to Auto SCT. Further investigation into the clinical significance of these findings is warranted.

Stem cell transplantation - Clinical 3

P888

PHASE I/II STUDY OF PANOBINOSTAT FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH RISK MDS OR AML: INITIAL RESULTS FROM THE PHASE I PART OF THE PANOBEST TRIAL

G Bug[1,*], A Burchert[2], N Kröger[3], U Dünzinger[1], A Wolf[1], S Hünecke[4], P Bader[4], H Serve[1], O Ottmann[1]
[1]Department of Medicine II, Hematology and Oncology, Goethe University Frankfurt, Frankfurt am Main, [2]Department of Medicine, Hematology, Oncology and Immunology, University Hospital of Gießen and Marburg, Marburg, [3]Interdisziplinäre Klinik und Poliklinik für Stammzelltransplantation, University Hospital Hamburg-Eppendorf, Hamburg, [4]Department for Stem Cell Transplantation and Immunology, University children's Hospital for Children and Adolescence Medicine, Frankfurt am Main, Germany

Background: After an allogeneic hematopoietic stem cell transplantation (HSCT), leukemic relapse and graft-*versus*-host disease (GvHD) remain major obstacles. Deacetylase inhibitors (DACi) possess both anti-leukemic activity and immunomodulatory effects. Conceptually, post-HSCT maintenance therapy with the DACi panobinostat may benefit patients (pts) with high risk acute myeloid leukemia (AML), but its tolerability and efficacy in this setting have not been investigated.
Aims: This phase I study was designed to determine the dose-limiting toxicity (DLT) and maximum tolerated dose (MTD) of the investigational drug panobinostat in adult pts with high risk AML or myelodysplastic syndromes (MDS) in complete hematologic remission (CR) after a reduced-intensity conditioning HSCT.
Methods: Panobinostat was administered in two schedules, either thrice weekly every week (A) or every other week (B) which were examined sequentially. Treatment is initiated between day +60 and +150 after HSCT and given for a maximum of one year. This interim analysis describes the results of schedule A, in which panobinostat was started at a dose of 10 mg TIW and escalated to 20 and 30 mg TIW using a 3+3 design. Eligibility criteria included: ANC ≥1,000/μL, platelets ≥75,000/μL, adequate organ function and no severe GvHD. All pts gave written informed consent. DLT was defined as prolonged grade 4 hematologic toxicity or any non-hematologic toxicity ≥grade 3 unrelated to disease progression or intercurrent illness within 28 days of the first panobinostat dose.
Results: A total of 12 pts (11 AML, 1 MDS) with a median age of 52 years (range, 21-62) have been enrolled (3, 6 and 3 pts at dose levels1, 2 and 3) and are evaluable for MTD. Cytogenetics were classified as intermediate-1 (n=3), intermediate-2 (n=4) and adverse risk (n=5) according to ELN criteria. Study start was at a median of 73 days (range, 60-126) after HSCT from a matched related (n=5) or unrelated donor (n=7) which was performed in active disease (n=11, median bone marrow blasts 22%, range, 8-63) or in CR2 (n=1). The MTD was determined to be 20 mg TIW due to one DLT (fatigue grade 3) at 20 mg and two DLTs (colitis and nausea/emesis grade 3 each) at 30 mg. As of February 2013, 68 adverse events (AEs) grades 2 (n=33), 3 (n=29) and 4 (n=5) were reported. Grade 3 and 4 toxicities included thrombocytopenia (n=7), leukopenia/neutropenia (n=5), anemia (n=1), gastrointestinal symptoms (n=5), sepsis, pneumocystis jirovecii pneumonia, pulmonary infection (n=1 each), herpes stomatitis (n=2), elevated lipase (n=3) or GGT (n=1), hyperuricemia, diabetes mellitus, syncope, deep vein thrombosis and pulmonary embolism (n=1 each). Toxicity was reversible and required at least one panobinostat dose reduction in 3 pts. Acute GvHD grade 2 (n=1) and 3 (n=3) was steroid responsive in 3 pts. One pt required salvage therapy and eventually developed moderate chronic GvHD. Mild chronic GvHD was observed in 2 additional pts. To date, 3 pts have completed one year of panobinostat and 4 pts remain on treatment (days 71-275). Five pts discontinued treatment prematurely after 10-217 days due to grade 3 toxicities (n=2), acute GvHD grade 3 (n=2) or AML relapse (n=1). One MDS pt relapsed after stopping panobinostat on day 10. With a median follow up of 362 days (range, 71-736), 11/12 pts are alive and 10/12 in continuous CR after HSCT. Immunophenotyping revealed no impact of panobinostat on regulatory T cells, other lymphocyte subsets or dendritic cells in the peripheral blood.
Summary and Conclusions: Panobinostat maintenance following HSCT is feasible with a recommended phase II dose of 20 mg TIW weekly. Fatigue and gastrointestinal toxicities were the DLTs. AEs were fully and rapidly reversible after interruption and/or dose reduction. While follow-up is short, the relapse rate is remarkably low considering the high risk patient population.

P889

CONTROLLED EPSTEIN-BARR VIRUS REACTIVATION AFTER ALLOGENIC TRANSPLANTATION IS ASSOCIATED WITH IMPROVED SURVIVAL ASSOCIATED TO AN EXPANSION OF NATURAL KILLER CELLS (NK)

S Auger-Quittet[1,*], M Orsini[2], P Céballos[1], N Fegueux[1], A Cornillon[3], B Klein[3], M Villalba[3], J Rossi[1,3]
[1]Haematology, CHU de Montpellier, [2]INSERM 2415, Institut Universitaire de Recherche Clinique, [3]INSERM U1040, Institut de recherche en Biothérapie, Montpellier, France

Background: T- and Natural Killer (NK)-lymphocytes play a main role in immune surveillance of EBV infection. EBV-reactivation (R) frequently occurs in patients having allogeneic transplantation (AT).
Aims: We evaluated the impact of controlled EBV-R on survival of allografted adult patients with haematological malignancies and analyzed the different circulating lymphocyte populations and NK cytotoxicity.
Methods: 190 consecutive adult patients were included in this study. They received fludarabine, busulfan, ATG for reduced intensity conditioning regimen (CR) or cyclophosphamide plus TBI for myeloablative CR. Prophylaxis of acute GVHD was standard. EBV viral load (EBV-VL) was monitored in PB after AT, weekly for the first 6 months (m), then monthly using standard PCR technique. EBV-R was defined by an EBV-VL ³500 copies/mL, increasing 1 week later. This level of EBV-VL was used to decide therapy, first reducing immunosuppression followed by rituximab if no EBV-VL decrease (375mg/m^2, 4 I.V. weekly). CMV co-infection was defined if occurring 1m before or after the EBV-R. Lymphocyte phenotyping (CD3,4,8,3+56+,3-56+,19,25,DR) was performed weekly for 3m, then monthly. Cytotoxicity assays were performed in 8 patients compared to healthy donors using standard technique against Jurkat, CO30 (EBV lymphoblastoid cells) and primary tumor cells.
Results: There were 105 acute leukaemias (26 ALL, 71 AML) and 8 myelodysplastic syndromes, 71 lymphoproliferative disorders (17 lymphomas, 8 CLL and 46 MM), 5 aplastic anaemia and 9 CML. There were 76 females and 114 males (median age: 51y, range 18-69). 86 (45%) patients presented EBV-R, with 74 patients having EBV-VL>1000 copies/mL. There was no statistical difference between the 2 groups (EBV-R and no EBV-R), for clinical characteristics, therapy, type of graft and number of CD34+ cells infused. Patients with EBV-R received more frequently ATG (P=0.004). Median time of EBV-R detection was 73 days (IQR: 40-210) after AT. 69/86 patients received rituximab, and the other 17 patients received acyclovir. Patients with no EBV-R did not receive rituximab. Within 3m after rituximab, GVHD intensity was decreased, particularly for acute GVHD. Median follow up was 36.6m (95%IC 31.5-45.7). Patients with EBV-R had a longer PFS than those with no EBV-R (at 2 years 51% *vs.* 69%, at 5 years 47% *vs* 38%) (P<.04). OS was longer in patients with EBV-R than that observed for patients with no EBV-R (at 2 years 76% *vs.* 64% and at 5 years 63% *vs.* 47%, P<.001). Among the patients with EBV-R, OS and PFS were not significantly different for patients receiving or not rituximab (respectively P=0.67 and P=0.88). OS and PFS were not different between patients according to the cancer (respectively, P=.46 and P=.49). Median duration of lymphocyte measurement was 94 days (IQR 59-248) after AT. B- and particularly T-lymphocytes (CD4+,CD8+) were not significantly different between the 2 groups, respectively P=.29 and P=.48. Only circulating NK cells were significantly different, with a median increased by 22% (P=.03) in patients with EBV-R. CMV co-infection did not impact NK cell counts (P=.058). NK cell count was not different according the use of rituximab (P=.22). The use of rituximab did not modify NK cell counts at 3 and 6m after stopping treatment (both P=.99).
Summary and Conclusions: Controlled EBV-R in allografted cancer patients is associated with better OS and PFS, a significant increase in circulating NK cells and enhanced NK cell cytotoxicity. A prospective study is ongoing for analyzing different subpopulations of NK cells.

P890

MYELOABLATIVE FLUDARABINE PLUS BUSULFAN IV (FB4) REGIMEN COMPARES FAVOURABLY WITH CYCLOPHOSPHAMIDE PLUS BUSULFAN (BUCY) IN PATIENTS UNDERGOING ALLO-SCT FOR MYELOID MALIGNANCY

V Coiteux[1,*], P Leclercq[1], T Vasseur[1], M Wemeau[1], E De Berranger[2], R Dulery[1], L Magro[1], J Jouet[1], I Yakoub-Agha[1]
[1]Maladies du Sang, [2]Onco-Hematologie pediatrique, CHRU, LILLE, France

Background: The use of the "so called" FB4 regimen associating Fludarabine (40 mg/m^2/days × 4 days) and Busulfan IV (130 mg/m^2/days × 4 days) has been dramatically increased in order to replace the hitherto standard Cyclophosphamide (50 mg/kg/day × 4 days) plus Busulfan (3.2 mg/kg/day × 4 days) regimen (CyBu). Few studies, however, have addressed the impact of such a reduced toxicity conditioning on outcome. In addition, interpretation of the data is confounded by the inclusion of myeloid and lymphoid malignancies.
Aims: The aim of the study was to compare the two myeloablative conditioning CyBu and FB4 in a large-scale cohort of 103 consecutive patients who received allogeneic stem cell transplantation (allo-SCT) for myeloid disease.
Methods: Between January 2007 and December 2012, one hundred and three patients received either CyBu (CyBu-group; n=41) or FB4 (FB4-group, n=62) according to the on-going policy in our unit. Allo-SCT indications were AML (n=77), myelodysplastic syndrome (n=18) and myeloproliferative disorder (n=8). Transplantation modalities were made as homogenous as possible using the following inclusion/exclusion criteria: (i) Patients older than 18 years referred for first allo-SCT.(ii) source of stem cell was marrow or blood from either a sibling or an HLA-matched unrelated donor at allele level. Patients who received allo-SCT from a cord blood or T-cell-depleted graft, and those with malignancies other than myeloid were excluded.
Results: The two groups were comparable in terms of patient's characteristics except for recipient CMV serostatus. Patients of FB4-group received more often ATG and PBSC than those of CyBu-group with P=0.003 and, 0.005, respectively. As February 20th, 2013, median follow-up was of 24.3 months (range, 2.1-74.0). Two years OS, EFS, cumulative incidence (CI) of relapse and NRM were 77%, 73%, 13%, 13%, respectively. All patients engrafted but full donor-type chimerism were less often recorded in FB4-group than in CyBu-group with 54% *vs* 83% (P=.005); 64% *vs* 88% (P=.009) and 65% *vs* 87% (P=.048) at days 30, 60 and 100 post–transplant, respectively. Patients of FB4-group developed more often oral mucositis (92% *vs* 76%; P=.021) and chronic GVHD (46% *vs* 21%; P=.006) than those belonging to CyBu-group. Of note, patients with full-donor chimerism at day 60 developed more often a grade II-IV acute GVHD but chimerism status had no impact on patient's outcome particularly on relapse. In multivariate analysis adjusted to ATG, CMV serostatus and source of stem cells (BM *vs* PBSC), conditioning type (FB4 and CyBu) had no impact on 2-year OS, EFS, relapse and NRM.
Summary and Conclusions: In this large-scale homogenous cohort, results show that FB4 as a reduced toxicity myeloablative conditioning regimen gives similar results as the standard CyBu. Longer follow-up is, however, needed to evaluate the impact of delayed full-donor chimerism on patients relapse.

P891

LONG-TERM OUTCOME (BEYOND 10 YEARS) AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION WITH REDUCED-INTENSITY COMPARED TO MYELOABLATIVE CONDITIONING; SIMILAR SURVIVAL BUT DIFFERENT PATTERN OF LATE EVENTS

A Shimoni[1,*], R Yerushalmi[1], N Shem-Tov[1], Y Volchek[1], A Nagler[1]
[1]Division of Hematology and Bone Marrow Transplantation, Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: Allogenic stem-cell transplantation (SCT) with reduced-intensity conditioning (RIC) has been increasingly used over the last 15 years. Comparative studies have generally shown that RIC is associated with higher relapse rate and lower toxicity compared with myeloablative conditioning (MAC) resulting in similar short-intermediate term survival. However, due to shorter follow-up, so far, there is only limited data on the long-term outcome (beyond 10 years) after RIC in comparison with MAC and on the pattern of late events.
Aims: To compare long-term outcome and late events between RIC and MAC SCT recipients.
Methods: We retrospectively analyzed all consecutive allogeneic transplants performed in a single institution between 1/2000 and 3/2003, such that the minimal follow-up for surviving patients is more than 10 years. We analyzed late outcome and late events after SCT.
Results: The analysis included 142 patients, median age 47 years (16-66). Diagnoses included AML (n=50), ALL (n=14), MDS (n=4), CML (n=14), lymphoma (n=29), myeloma (n=23), others (n=8). The donor was an HLA-matched sibling (n=99), matched unrelated (n=36) and mismatched-related (n=7). Disease status at SCT was early (n=33), intermediate (n=24) and advanced (n=85) according to CIBMTR criteria. In all, 59 patients were given MAC and 83 RIC according to institutional criteria. As expected from eligibility criteria, RIC recipients were older (median age 51 years compared to 37 years in MAC recipients, P=0.001). More RIC recipients had lymphoproliferative disorders (54% *vs.* 17%, respectively) and less had acute leukemia/MDS (30% *vs.* 73%, P=0.001). More RIC recipients had advanced disease (63% *vs.* 54%, P=0.07) and more patients had a prior autologous SCT (49% *vs.* 0%, P=0.001). Complete follow-up is available for 139 patients (98%). The median follow-up is 11.4 years (range, 10-13.2 years). Forty-two patients are alive with a 10 year overall survival (OS) of 32% (95%CI, 25-40), 20/58 MAC recipients, 10-year OS 38% (95% CI, 25-50) and 22/81 RIC recipients, 10-year OS 28% (95%, 19-39, P=0.28). Multivariate analysis identified intermediate and advanced disease status, HR 2.5 (P=0.03) and 4.0 (P=0.0004), respectively, as the only independent adverse prognostic factors for OS. Fifty-four patients were alive 5 years after SCT, 12 patients died over the next years, 3 of them beyond 10 years from SCT. Late mortality occurred in 7 of 28 MAC recipients alive 5 years after SCT and was attributed to late relapse (n=2, both AML), chronic GVHD (n=4, 2 of them with lung disease), and MI (n=1). Late mortality occurred in 5 of 26 RIC recipients alive 5 years after SCT due to progressive disease (n=2, lymphatic malignancies, relapse occurred before 5 years) and second malignancies (n=3). Death due to chronic GVHD was more common after MAC (P=0.04) and death due to second malignancies was more common after RIC (P=0.06). The probability of patients surviving 5 years after SCT to survive for the next 5 years was 79% and 88% after MAC and RIC, respectively (P=0.25). Ten years after SCT, 32% of surviving MAC recipients and 4% of surviving RIC recipients were still on immune suppressive therapy (P=0.02).
Summary and Conclusions: Both MAC and RIC regimens allow long-term OS beyond 10 years after SCT with a similar rate. Late events continue to compromise cure beyond 5 years. The pattern of late events is different between the regimens. More events are related to late relapse and chronic GVHD (and in particular lung disease) after MAC, while second malignancies are more common after RIC. MAC is also associated with more protracted requirement for immune suppressive therapy.

P892

HOW MANY AML PATIENTS DO RECEIVE EARLY ALLOGENEIC BONE MARROW TRANSPLANT AND WHICH TRANSPLANT IS PERFORMED? REAL LIFE DATA FROM GENOVA ACUTE LEUKEMIA REGISTRY (REGAL).

M Clavio[1,*], F Cruciani[1], A Ghiso[1], P Minetto[1], M Miglino[1], M Bergamaschi[1], L Del Corso[1], E De Astis[1], L Canepa[1], L Mitscheunig[1], S Aquino[1], F Guolo[1], G Pastori[1], I Pierri[1], D Lovera[1], D Avenoso[1], A Raiola[1], R Varaldo[1], F Ballerini[1], C Ghiggi[1], G Pica[1], AM Carella[1], A Bacigalupo[1], M Gobbi[1]
[1]Clinical Hematology, IRCCS Ospedale S Martino - IST Genova, Genova, Italy

Background: Unlike other haematopoietic malignancies, the therapeutic armamentarium for AML has not changed in the last thirty years. Thereported increase in survival of youngerpatients is mainly a consequenceof theimprovedmanagement of infectionsand complicationsof BMT. In the last years new sources of allogeneic stem cells have been explored, and new transplant procedures have been designed that allow the utilization of haploidentical donors with acceptable transplant related mortality.
Aims: We report a retrospective review of AML treatment in 132 patients enrolled in a regional Italian acute leukemia registry with the purpose of evaluating transplant rate in first CR.
Methods: From October 2010 to January 2013, 132 AML patients have been reported in the Genova Acute Leukemia Registry (REGAL). Median age was 66 years (range 16-87), males were 75 (57%), females 57 (43%). Ninety-two patients had denovo disease (69%); in 40 patients (31%) AML was secondary to MDS (n. 24), chemo radiotherapy (n.9), and chronic myeloproliferative disorder (n.7). Fifteen patients (11%) had acute promyelocytic leukaemia. Relevant comorbidities were present in 75 patients (57%), mainly diabetes mellitus (n. 16), heart disease (n. 11), hypertension (n.18), liver (n.10), lung (n. 10) and other (n.33) diseases. ECOG performance status was 0 in 41 patients (31%), 1 in 51 (38%), 2 in 29 (22%), 3 in 10 (7%) and 4 in 1 (2%). Karyotype could be evaluated in 115 patients (87%) and was favourable in 17 patients (15%), intermediate in 80 (69%), unfavourable in 18 (16%). A molecular profile including study of FLT3 ITD, NPM1 gene mutations and expression of WT1 and BAALC genes was performed in 106 patients (80%).
Results: Five patients received supportive care only (4%), 33 low intensity chemotherapy (25%), 94 were eligible for intensive conventional chemotherapy (71%). In this last group 6 patients had an induction related death (6%), 58 achieved CR (62%). Induction related deaths were 2 (4%) and 4 (9%) in patients younger and older than 60 years, respectively. Complete remission rates were 78% and 43% in patients younger and older than 60 years, respectively. After prognostic work up at diagnosis 40 patients were considered eligible for early BMT (age <65 years and unfavourable cytogenetic or intermediate cytogenetic plus high risk molecular profile or secondary AML), 12 were actually transplanted in first CR (30%) and 9 are disease free and waiting for BMT (22%). Three more patients were transplanted in second CR. Reasons for not receiving early BMT were infections (n. 6), refractory or relapsed disease (n. 12) and unavailable donor (n.1). Stem cell donors have been HLA identical siblings (n. 2, 17%) and haploidentical siblings (n.10, 83%). No patients transplanted in first CR died for transplant related reasons.
Summary and Conclusions: ReGAL data show that 71% of newly diagnosed AML were treated with intensive chemotherapy and 13% of these were transplanted in first CR. BMT in first CR was performed in 30% of eligible patients mainly using haploidentical donors (83%). With the increased utilization of transplant regimens specifically designed for haploidentical donors, transplant related mortality has not changed and lack of donor is not anymore a reason for not receiving an early BMT.

P893

THE MANAGEMENTS OF EBV-ASSOCIATED POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER WITH CENTRAL NERVOUS SYSTEM INVOLVEMENT AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

M Wu[1], J Sun[1], Y Zhang[1], F Huang[1], H Zhou[1], Z Fan[1], L Xuan[1], G Yu[1], X Guo[1], X Zhang[1], C Liu[1], M Dai[1], R Feng[1], Q Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Epstein–Barr virus (EBV)-associated post-transplant lymphoproliferative disorder (PTLD) is a life-threatening complication that follows solid organ transplantation or allogeneic hematopoietic stem cell transplantation (allo-HSCT). The managements of systemic PTLD, including EBV molecular monitoring to identify high-risk patients developing PTLD, diagnosis, preemptive therapy and treatments, have achieved certain consensus. However, there are no uniform approaches to the managements of PTLD with central nervous system (CNS) involvement.
Aims: To explore the managements of EBV-associated CNS-PTLD after allo-HSCT.
Methods: Thirty-six patients with EBV-associated diseases (21 PTLD, 7 EBV fever, 4 encephalitis/myelitis, 3 pneumonia and 1 hepatitis) and 8 patients with unexplainable CNS manifestations from 257 patients undergoing allo-HSCT between August1, 2008 and May 31, 2012 were enrolled in this prospective study. Moreover, 10 patients with EBV-DNA-emia but without EBV-associated diseases and 5 patients who were EBV-DNA negative in blood volunteered to have their CSF monitored as controls (platelet >50×10^9/L).The EBV-DNA of blood and cerebrospinal fluid (CSF) were monitored regularly by real-time quantitative polymerase chain reaction. The rituximab-based treatments followed by adoptive cellular therapy were administered in patients with EBV-associated CNS-PTLD.
Results: Eleven patients were diagnosed as EBV-associated CNS-PTLD, including 8 systemic PTLD accompanying CNS involvement and 3 isolated CNS-PTLD. Ten patients initially presented with fever and 8 patients had CNS symptoms and signs at disease onset, 2 appeared CNS manifestations in the progression of disease and 1 did not present CNS manifestations during CNS-PTLD. Except one, all patients were EBV-DNA positive in blood. The EBV-DNA loads of CSF were significantly higher than those of blood (52571±34993 *vs.* 23083±28080, P=0.028). Of the 9 patients obtaining the immunophenotypic analysis of CSF cells, the results revealed monoclonality in 7 and polyclonality in 2 cases. The 4 patients without rituximab therapy all died of PTLD progression, whereas the 7 patients with rituximab-based treatments all obtained complete response (CR), including the 4 patients who were unresponsive to intravenous rituximab-based treatments finally obtained CR after intrathecal rituximab. The EBV-DNA loads of CSF were positively related to treatment response (P<0.001, r=0.889). With a median follow up of 261 (range 4 to 886) days after CNS-PTLD, 4 patients survived and 7 died. The causes of death were PTLD progressing (n=4), PTLD relapse (n=1), GVHD (n=1) and CMV pneumonia (n=1).
Summary and Conclusions: EBV-DNA detection in CSF might be more specific and sensitive than that in blood for the diagnosis, development and therapeutic evaluation of CNS-PTLD. The immunophenotypic analysis of CSF cells is helpful in the diagnosis of CNS-PTLD. The intrathecal rituximab is an effective method for CNS-PTLD patients who had failed to the intravenous rituximab.

P894

ASSOCIATION OF HLA POLYMORPHISMS WITH EPSTEIN-BARR VIRUS INFECTION AFTER ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

R Lin[1], Q Fan[1], S Yu[1], Z Fan[1], Y Zhang[1], F Huang[1], H Zhou[1], L Xuan[1], M Wu[1], X Guo[1], M Dai[1], J Sun[1], Q Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Epstein-Barr virus (EBV) infection/reactivation following allogeneic haematopoietic stem cell transplantation (allo-HSCT) can cause deadly post-transplant lymphoproliferative disorders and other EBV-associated diseases. The mechanism for development of EBV-associated diseases remains unclear, but likely involves immunological control of viral infection. Human leukocyte antigen (HLA) molecules are responsible for antigen processing and presentation to the immune system, and therefore have the potential to be associated with development of EBV infection/reactivation and EBV-associated diseases.
Aims: In this study, the association between HLA polymorphisms and development of EBV infection/reactivation or EBV-associated diseases in recipients undergoing allo-HSCT was evaluated.
Methods: HLA data of 280 recipients, who were from south China and received allo-HSCT between July 2008 to December 2012, and their donors were analyzed. The EBV-DNA levels of blood were monitored regularly by quantitative real-time polymerase chain reaction (RQ-PCR).
Results: With a median follow-up of 363 days post-transplantation (range, 17 to 1670 days), 82 cases developed EBV infection/reactivation and 31 developed EBV-associated diseases including 22 EBV-PTLD and 9 other EBV-associated diseases. The 3-year cumulative incidence of EBV infection/reactivation and EBV-associated diseases were 31.5%±3.0% and 12.7%±2.2%, respectively. Both recipient and donor HLA-A11 were protective against EBV infection/reactivation (recipient A11: odds ratio [OR] 0.53, *P*=0.017; donor A11: OR 0.59, *P*=0.044). Recipients with HLA-DR9 had a higher incidence of EBV infection/reactivation than those without (OR 1.80, *P*=0.032). In multivariate analysis, recipient and donor HLA-A11 were confirmed to be negatively associated with EBV infection/reactivation (recipient A11: OR 0.45, 95% confidence interval [CI] 0.241-0.833, *P*=0.011; donor A11: OR 0.50, 95%CI 0.27-0.92, *P*=0.026). Both univariate and multivariate analysis showed donor HLA-A33 (OR 2.92, 95%CI: 1.18-7.23, *P*=0.021) and recipient HLA-B44 (OR 16.60, 95%CI: 1.91-144.03, *P*=0.011) were risk factors for development of EBV-associated diseases.
Summary and Conclusions: Our data suggest that HLA polymorphisms affect development of EBV infection/reactivation and EBV-associated diseases. These findings may be useful in risk stratification and development of prophylaxis strategies.

P895

PERFORMANCE OF FECAL CALPROTECTIN FOR THE DIAGNOSIS AND FOLLOW UP OF ACUTE GASTRO-INTESTINAL GRAFT VERSUS HOST DISEASE

M Battista[1,*], F Zanini[1], A Candoni[1], S Puglisi[1], A Ferreri[1], F Patriarca[1], R Fanin[1]
[1]Clinica Ematologica AOUD Udine, Udine, Italy

Background: Although multiple biomarkers of acute intestinal GVHD (GI-GVHD) have been identified, the translation of these from the bench to the bedside remains complex. It's known that fecal calprotectin (FC) correlates very well with disease activity in patients with inflammatory bowel disease as well as in patients with intestinal graft rejection after small bowel transplantation.
Aims: The aim of this study was to evaluate FC as a single biomarker for the diagnosis and follow up of GI-GVHD in adult patients with haematological malignancies who underwent allogeneic stem cell transplantation (SCT) at our center.
Methods: From January 2012, 30 consecutive SCT patients have been monitored for FC (normal range: 0-50 mg/kg) with at least 2 samples/patient (median number3, range 2-13). Fecal samples were collected at 2 week intervals until day 90 from SCT or at the onset of symptoms of GI-GVHD, even after day 90. The diagnosis of GI-GVHD was based on standard clinical criteria, together with other microbiological and histopathological tests.
Results: Eight of 30 tested patients (27%) were diagnosed with GI-GVHD. In this group FC median value was 429 mg/kg (range 29-5000) at the onset of symptoms; only one of these 8 patients presented FC levels in the normal ranges at the diagnosis and during follow-up (<50mg/kg). In one of the 30 patients included in the study the clinical diagnosis of GI-GVHD was not supported by the endoscopic and histological findings and in this patient, the FC median value was 60 mg/kg (range6,25-120). FC median value in all other 21/30 patients (70%) without GI-GVHD was 49 mg/kg (range 6-177). For a cut-off point value of 200 mg/kg, sensitivity for the test was 87,5%, specificity 100%, positive predictive value 100% and negative predictive value 95,6%. We couldn't observe a correlation between FC levels at the onset of GI-GVHD and severity of clinical symptoms. In fact FC median value was 467 mg/kg (range: 29-5000) in patients in stage 1 GVHD compared with 391mg/kg (range: 288-3121) in patients in stage 2-4. We observed that patients achieving stable FC values under 200 mg/kg at the follow-up (in 4 of the 7 patients with abnormal FC findings at the onset of GVHD–true positive) had a more favourable outcome and prognosis.
Summary and Conclusions: Our data confirm that FC is specific, inexpensive, non-invasive test and easy to perform. This biomarker can improve the diagnosis of acute GI-GVHD with an optimal cut-off level of 200 mg/kg. This test seems to be promising also for the evaluation of the activity of GI-GVHD during follow-up and it could be used as a potential decisional tool for anti GVHD therapy modulation.

P896

IMMUNOPHENOTYPIC RESPONSE AFTER ALLOGRAFTING IN MULTIPLE MYELOMA

L Giaccone[1,*], L Brunello[1], R Passera[1], M Festuccia[1], M Gilestro[1], E Maffini[1], F Ferrando[1], F Testa[1], M Boccadoro[1], P Omedè[1], B Bruno[1]
[1]Divisions of Hematology, A.O. Città della Salute e della Scienza, Università di Torino, Torino, Italy

Background: Recent studies suggest that immunophenotypic remission (IR) may be a relevant prognostic factor in patients with multiple myeloma (MM). However, data on this role after allografting are lacking.
Aims: To evaluate the impact of IR and compare it to conventional complete remission (CR) in myeloma patients treated with an allograft.
Methods: Sixty-six consecutive patients, median age 54 years (35-66), who underwent an allograft between January 2000 and December 2011 with a follow-up of at least 3 months were included. Disease response was evaluated by serum and urine electrophoresis, and bone marrow aspirate at3,6,12, 18, 24 months after transplant and yearly thereafter. Skeletal survey or MRI were performed yearly or as clinically indicated (overt relapse or complaints of bone pain). Bone marrow aspirates had to contain at least 13000 cells/mL for flow cytometry studies and IR was defined as absence of monoclonal plasmacells detected by 4 or 6-colour staining with the following antibodies: CD38, CD138, CD56, CD19, CD45, cyKappa, cyLambda. CR was defined according to standard criteria (Leukemia. 2006;20:1467-73).
Results: Conditioning regimen was non-myeloablative 2Gy TBI-based in 55 patients, reduced intensity (fludarabine-melphalan-based) in 10 and myeloablative in 1 patient. Post-grafting immunosuppression consisted of cyclosporine with mycophenolate mofetil or methotrexate. Donors were HLA identical siblings in 58 patients and unrelated in 8. Only 1 patient received bone marrow as source of stem cells. Thirty-five/66 (53%) received the allograft as part of the first line treatment, whereas the others (31/66, (47%) were transplanted after disease relapse. Among patients surviving at least 3 months, treatment related mortality was 10.6% at 3 years. After a median follow-up of 69 months (range 19-147), the incidence of acute and chronic graft-*versus*-host disease was 45.6% and 49.3%, without significant difference between responsive and non-responsive patients. At follow-up, 24 patients achieved CR and IR (CR/IR), 22 achieved IR but not CR because of persistence of urine/serum M-component (noCR/IR), and 20 did not achieve either CR or IR (noCR/noIR). Interestingly, none achieved CR without IR. Median overall (OS) and event-free survivals (EFS) were not reached and 59 months in the CR/IR group, 77 and 15 months in the noCR/IR, and 30 and 5 months in the noCR/noIR respectively (P<0.001 for both OS and EFS). Being in the CR/IR group was the only significant predictor for prolonged OS and EFS (P<0.001). Of note, the cumulative incidence of extramedullary disease at first relapse after the allograft was 4.4% in the CR/IR, 31.8% in the noCR/IR and 15.0% in the noCR/noIR groups respectively(P<0.001). Receiving the allograft as first line therapy or later during the disease course did not significantly impact on OS and EFS.
Summary and Conclusions: The achievement of IR showed a significant impact on clinical outcomes including patients who did not clear the M-component. Discrepancies between IR and CR, observed in the noCR/IR group (some 30% of our patient cohort) along with a higher incidence of extramedullary relapse, suggest that myeloma cells may escape immune control outside the bone marrow. In this group, imaging studies such as positron emission tomography may be indicated to allow detection of early relapse.

P897

ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKEMIA IN INFANTS - EXPERIENCE OF A SINGLE CENTER

R Lopes[1,*], F Campilho[1], R Branca[1], C Pinho-Vaz[1], S Roncon[2], A Campos[1]
[1]Serviço de Transplantação de Medula Óssea, [2]Serviço de Terapia Celular, Instituto Português de Oncologia, PORTO, Portugal

Background: Infant acute leukemia (AL) has distinct clinical and biological characteristics that differentiate it from other childhood AL and has a dismal prognosis. Allogeneic hematopoietic stem cell transplantation (alloHSCT) is the only potential curative therapeutic in the majority of infants with AL. Presently few patients (pts) have a human leukocyte antigen (HLA)-matched sibling, but with the increasing number of unrelated (UR) donors the probability of finding a suitable donor turned this modality of stem cell transplantation (SCT) more frequent.
Aims: To evaluate the outcome of all alloHSCT performed in our center in pts with AL diagnosed in the first year of life.
Methods: Retrospective analysis of the medical records of infant AL identified in the database of SCT of our center over a period of 22 years (June 1989 until December 2012). Statistical analysis was performed with SPSS®v21.
Results: In the 22 years referred above we performed 854 alloHSCT in 772 pts, 187 of whom were <18 years old and we indentified nine children who were allografted for infant AL, the first transplanted in August 1998 and the last in December 2011. Median age at diagnosis was 5 (1-11) months; five were female and 4 male; median time diagnosis to alloHSCT: 9 (8-38) months; median age at transplant was 14 (13-47) months. All children had high-risk AL: 5 acute lymphoblastic leukemia of B lineage (B-ALL), 2 unclassified ALL and 2 megakaryoblastic acute myeloid leukemia (AML-M7, FAB). At diagnosis, CNS involvement was present in 3 pts, all with B-ALL; hyperleukocytosis >50×10^9/L was observed in 6 of 7 pts with ALL. MLL gene rearrangements were present in 5 of 7 pts with ALL; the 2 cases of AML-M7 had complex karyotype. Status of disease at transplant was: first complete remission (CR): 5; second CR: 2; third CR: 2. The donor was unrelated in all pts; stem cell source was: umbilical cord blood (UCB) in 7 (all non-HLA identical), peripheral blood (PB) in 1 (HLA identical: 10/10) and bone marrow (BM) in 1 (HLA identical: 9/10); HLA was typed in high resolution in BM and PB donors and DRB1 in UCB donors; HLA–A and B were typed serologically in UCB. Busulfan based+cyclophosphamide myeloablative regimens were used in all; *anti-thymocyte globulin (*ATG) was used in 8; in 5 ALL pts melphalan was added to the conditioning regimen. Graft-*versus*-host-disease (GVHD) prophylaxis was based in tacrolimus (n=8) or cyclosporine (n=1) associated to methotrexate (n=5) or mycophenolate mofetil (n=4). Acute GVHD grade ≥2 occurred in 7 of 8 evaluable pts. Chronic extensive GVHD occurred in one patient with almost complete resolution after 2 years of immunosuppression. Engraftment occurred in all; in UCB transplants the median time to neutrophils >0.5×10^9/L and platelets >20×10^9/L was 19 and 39 days, respectively. With a median follow-up after transplantation of 49 (31-86) months, 6 children are alive and disease-free. There were 3 deaths, all in ALL pts: 2 (day+135, day+418) due to relapse of the disease and 1 at day+59 due to multiorgan dysfunction. At 3 years the overall survival was 66,7% (±15,7%).
Summary and Conclusions: There are few reports of outcome in leukemias diagnosed in this age group. Despite the poor prognosis features of our pts 67% are disease-free three years after alloHSCT. The search of a suitable donor, related or unrelated, must be performed actively. The results of UCB transplants in this group appear promising. Multi-institutional cooperative trials are needed to evaluate the better treatment strategy in these high-risk pts.

P898

THREE DAYS BUSULFAN ASSOCIATED WITH FLUDARABINE AND ANTITHYMOGLOBULINE CONDITIONING: IS IT SAFE?

S Chantepie[1,*], A Gac[1], E Marin[1], V Moreno[1], O Reman[1]
[1]Hematology, University Hospital, Caen, France

Background: Allogeneic transplantation (HSCT) is the unique alternative to cure patients with advanced disease. Non-myeloablative conditioning has been developed for patients unfit or older than 50-55 years. Conditioning with Fludarabine, Busulfan and antithymoglobulines (ATG) has been described with two days of Busulfan. The excellent tolerance of this association and the need of stabilizing the underlined disease before having a graft *versus* hematologic dis-

ease have suggested that increasing doses of Busulfan may have higher potential of curability, particularly in acute myeloid leukemia (AML). Some reports demonstrating the interest of this conditioning were published recently. If the tolerance of two days of Busulfan (FB2) seems excellent with 2 years non relapse mortality ranging from 6 to 30%, little is known about increased dose of three days Busulfan (FB3).

Aims: The aim of this study was to assess the safety and efficacy of the FB3 regimen.

Methods: Between 2008 and 2012, 51 patients received HSCT with the FB3 regimen conditioning at our institution. Patients received Fludarabine 30 mg/m2 daily on days -6 to -2, IV Busulfan 3.2mg/kg daily on days -6 to -4, and ATG 2.5 mg/kg for 2 days. Nine patients received prophylactic DLI (17.6%).

Results: Median follow-up was 20.53 months. Hematological malignancies were AML/MDS (n=24), lymphoma (n=16), multiple myeloma (n=5), others (n=6). The median age was 58 years (range, 27-66). Thirteen patients (25%) were autografted before allogeneic stem cell transplantation. Median time to transplantation was 12.9 months (range, 0.6-210 months). Twenty patients (39.2%) had a sibling donor, 19 (37.3%) a matched unrelated donor and 12 (23.5%) a mismatched unrelated donor. All patients engrafted with a median platelets and neutrophils recovery of 12 (range, 9-125) and 16 (range, 11-37) days and full donor chimerism was observed in 88.9% at d90. Median CD34 infused was5,7 (range, 2-10.4). One patient (1.9%) experienced graft rejection at day 100. One-year overall, disease-free survivals, cumulative incidences of relapse (CIR) and non-relapse mortality (NRM) were 77.4%, 73.2%, 21.5% and 20.9% respectively (Figure 1). One hepatic veno-occlusive disease (1.9%) was observed in a patient with previously autologous stem cell transplantation. Liver toxicity occurred in 17 patients (33.3%), grade I-II in 7 patients (13.2%), grade III-IV in 10 patients (19.5%). Eight patients (15.7%) developed acute graft-*versus* host disease (aGVHD): grade II-IV (n=5, 9.8%), grade III-IV (n=1, 1.9%) and 16 (31.4%) had chronic GVHD. The survival of the 51 patients was in line with survival observed in RIC conditioning and chimerism was excellent. The NRM described in FB2 RIC regimen was variable, ranging from 6 to 30% at 2 years. It was higher in our study with FB3 regimen (26% at 2 years) than that observed with FLU-TBI. The CIR was lower than that described with RIC regimen. With FB3 conditioning, we observed a lower rate of acute GVH disease (9.8% grade II-IV), compared to the 32 to 47% of grade II-IV aGVHD in the FB2 conditioning remaining that GVHD prophylaxis was similar. In our study, age>60 was not a bad prognostic factor as demonstrated in previous RIC FB2 study (Figure 1).

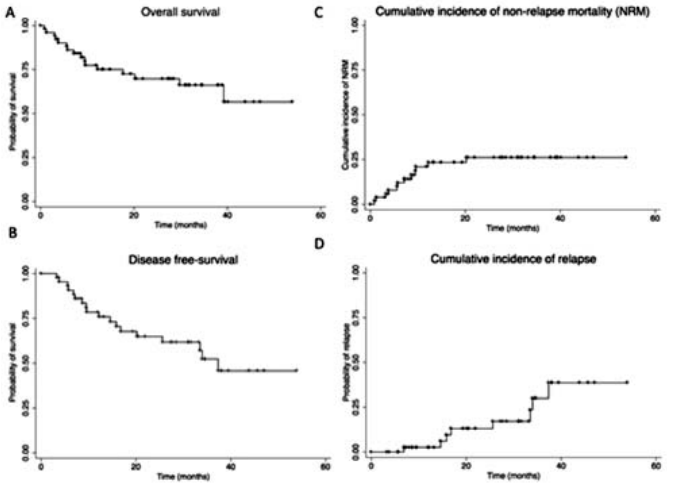

Figure 1.

Summary and Conclusions: The FB3 regimen is associated with about 20% grade III-IV liver toxicity, mostly reversible, and a quite high NRM of about 20%. An additional day of Busulfan that resulted in a low relapse rate, good overall survival and low rate of aGVHD allows its use until 65 years old. Prospective trials comparing FB2 and FB3 regimen are ongoing.

P899

IMPROVED OUTCOME WITH HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A POOR PROGNOSTIC SUBGROUP OF PATIENTS WITH MIXED-LINEAGE-LEUKEMIA–REARRANGED LEUKEMIA: RESULTS FROM A SINGLE-CENTER PROSPECTIVE STUDY

Y Wang[1], X huang[1,*]
[1]Peking university people's hospital, beijing, China

Background: The role for allogeneic hematopoietic stem cell transplantation (allo-HSCT) in mixed-lineage-leukemia (MLL)–rearranged acute leukemia is poorly understood.

Aims: To determine whether allo-HSCT could decrease relapse rates and improve long-term survival of MLL+ leukemia patients, especially in adults.

Methods: We performed a prospective, single-center cohort study in which 40 consecutive patients diagnosed with MLL–rearranged acute leukemia undergoing allo-HSCT in our institute were enrolled. Informed consent was obtained. The trial was registered at www.chictr.org as # ChiCTR-ONC-12002739.

Results: The incidences of grades II to IVacute graft *versus* host disease (aGVHD) and of grades IIIand IVaGVHD were 32.5% (CI, 16.7%>48.3%), and 7.5% (CI, 0-15.7%), respectively. The cumulative incidences for chronic GVHD (cGVHD) at two years after HSCT were 27.0% (CI, 11.0%>43.0%). After a median follow-up of 12 months, eight patients had relapsed and died from relapse, and twenty-six patients were still alive without disease recurrence. The relapse and NRM rates at two years were 27.0%(CI, 11.6%>42.4%) and 14.3% (CI, 2.3%>26.3%), respectively. The probalities of overall survival and leukemia free survival were 61.6% (CI, 43.2%>80.0%) and 58.6% (CI, 40.0%>77.2%) at two years, respectively. Patients transplanted during their first complete remission (CR1 had a lower relapse rate (20.3% *vs.* 58.3%, P=0.05) and better LFS (66.6% *vs* 20.8%, P=0.11) compared with patients transplanted beyond CR1 (Figure 1).

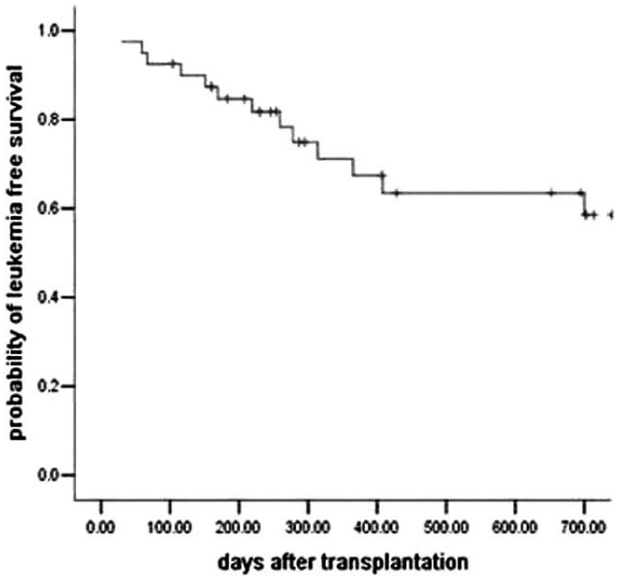

Figure 1. Probability of leukemia free survival in patients with mixed-lineage-leukemia-rearranged leukemia undergoing transplant.

Summary and Conclusions: This study showed that allo-HSCT could be a valuable treatment choice for MLL+ acute leukemia.

P900

PREDICTIVE FACTORS FOR COMPLETE DONOR CHIMERISM AFTER PEDIATRIC UNRELATED CORD BLOOD TRANSPLANTATION (UCBT)

E Elkaim[1,*], C Picard[2], C Galambrun[1], A Loundou[3], V Barlogis[1], C Lemarie[4], H Chambost[1], G Michel[1]
[1]Department of Pediatric Hematology, Hôpital Timone Enfant, [2]Laboratoire d'immunogénétique, Etablissement Francais du Sang, [3]Self-perceived Health Assessment Research Unit, School of Medicine, [4]Centre de thérapie cellulaire, Institut Paoli Calmette, Marseille, France

Background: Umbilical cord blood transplantation (UCBT) is frequently use for the treatment of hematologic malignancies or non-malignant one. Results seems equivalents to matched unrelated donor transplantation. That is why it is used increasingly frequently.

Aims: Our aim was to assess the probability of a complete donor chimerism occurrence (>99,9% donor) after UCBT, taking into account competing risks such as relapse and transplant related mortality (TRM). We wanted to identify its predictive factors and evaluate its impact on post-transplant outcome.

Methods: Our prospective single-center study was conducted between 2001 and 2010. We included all children under 18, who received a first single UCBT after myeloablative conditioning either in the context of malignant disease in complete remission, or of a non-malignant disease. All chimerisms were quantified from peripheral blood using the TAQMAN method. We analysed the occurrence of a complete donor chimerism over time.

Results: Our study included 94 children, 69 who received a transplant for a malignant disease and 25 for a non-malignant one. The mean age of the sub-

jects was 6.6 years old. Overall survival at 5 year was 68%±5%. Cumulative incidence of full donor chimerism at 1 year post-transplantation was 62%. We found 3 predictive factors of chimerism in both univariate and multivariate analysis. Firstly, age at UCBT: older was the patient, higher was the probability to reach a complete donor chimerism ($P=5,5.10^{-3}$). Moreover there was a significant threshold between the first quartile of age (<2,21 years old) and the older patients. The second factor is the HLA disparity between donor and recipient ($P=8,7.10^{-4}$). Lower compatibility (4/6 *vs* 5-6/6) resulted in a higher probability of complete donor chimerism, perhaps in part because of the increased allogenic reactivity of a graft with more HLA disparities. Finally, the third factor was the initial disease: complete donor chimersim was more frequent in children with malignancy (P=0,03). In the multivariate analysis, we did not found any effect of graft cell dose on chimerism. Early complete donor chimerism (*i.e.* >99.9% donor chimerism on D15-D30 post transplant) appeared useful to predict engraftment ($P=3.10^{-3}$) and its absence protected patients from acute Graft Versus Host Disease (GVHD)>2 ($P<1.10^{-3}$), acute GVHD >3 ($P=6.10^{-3}$) and chronic GVHD (P=0,05). We did not detect a significant effect on relapse risk for children with malignancies.

Summary and Conclusions: This study highlights some predictive factors for complete donor chimerism among children receiving UCBT: older age at transplantation, more HLA disparity between recipient and cord blood and a malignant disease. We also demonstrate that early chimerism can predict very accurately engraftment, acute GVHD as well as chronic GVHD and may be a very useful diagnosis tool.

BUSULFAN, MELPHALAN AND ETOPOSIDE FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION ON PATIENTS WITH NON-HODGKIN'S LYMPHOMA: MULTICENTER STUDY FROM CONSORTIUM FOR IMPROVING SURVIVAL OF LYMPHOMA (CISL)

J Won[1,*], H Park[1], K Kim[1], W Kim[2], S Park[3], M Lee[4], S Sohn[5], C Suh[6], H Kang[7], C Choi[8], H Lee[9], S Bae[10], J Park[11], E Park[12], J Kwak [13]
[1]Soonchunhyang University Hospital, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, [3]Soonchunhyang University Hospital, Bucheon, [4]Konkuk University Medical Center and School of Medicine, Seoul, [5]Kyungpook National University Hospital, Daegu, [6]Asan Medical Center, University of Ulsan College of Medicine, [7]Korea Cancer Center Hospital, Korea Institute of Radiological and Medical Science,8, Korea University Guro Hospital, Korea University College of Medicine, Seoul, [9]Kosin University Gospel Hospital, Busan, [10]Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, [11]Gachon University Gil Hospital, Incheon, [12]Chung-Ang University College of Medicine, Seoul, [13]Chonbuk National University Medical School, Jeonju, Korea, Republic of Korea

Background: High dose chemotherapy followed by autologous stem cell transplantation (ASCT) has become the standard approach for relapsed or high risk non-Hodgkin's lymphoma (NHL). Several different high dose therapy (HDT) conditioning regimens have been used for non-Hodgkin's lymphoma (NHL), such as BEAM (carmustine, etoposide, cytosine arabinoside, melphalan), BEAC (carmustine, etoposide, cytosine arabinoside, cyclophosphamide), and CBV (cyclophosphamide, carmustine, etoposide). Carmustine is an active drug in the HDT of NHL but the supply of carmustine is limited in some countries including Korea. Intravenous busulfan containing regimens as conditioining regimen have been used for both allogeneic and autologous stem cell transplantation in patients with hematologic and non –hematologic malignancies.

Aims: The purpose of this prospective multicenter phase II study was evaluate the efficacy and safety of iv busulfan/melphalan/etoposide regimen as a conditioining regimen for high dose chemotherapy in the patients with relapsed or high risk NHL.

Methods: Patients with relapsed or primary refractory NHL or chemosensitive high risk NHL underwent high dose chemotherapy followed by ASCT at 12 centers in Korea. The conditioning regimen consisted of iv busulfan 3.2mg/kg/day i.v. on days -8, -7 and -6, etoposide 400mg/m2/day i.v. on days -5 and -4 and melphalan 50mg/m2/day i.v. on days -3 and -2.

Results: Fifty one patients were enrolled onto the study. Main subgroups were DLBCL (n=25, 49%) and T cell lymphoma (n=19, 37%). At the time of ASCT, the disease status of patients was as follows: 13 patients were high risk in remission, 16 were primarily refractory to inducton therapy, 15 patients were in chemosensitive relapse. All patients had successful stem cell engraftment with a median time to neutrophil recovery of more than 500/mm3 of 10 days (range, 2 to 30 days). Platelet recovery of more than 20,000/mm3 was seen after a median of 10 days (range, 2 to 51 days) with delayed recovery in one patient. Treatment related toxicities included nausea/vomiting in 28 patients (55%), diarrhea in 28 patients (55%) and mucositis in 33 patients (65%), which were grade I or II in the majority of cases. Grade I/II hepatic toxicities occurred in 24% (n=12) and grade III in 6% (n=3). There were no VOD and treatment related death. The median duration of hospitalization for ASCT was 30 days (range, 12 to 80 days). Forty one patients (80%) achieved a complete response 1 month after ASCT, while three patients showed progressive disease. At a median follow up of 27 months, 31(60%) patients exhibited a relapse or progression, while 19 patients had died of disease and one patient had died of heart failure. The estimated 2-year overall and progression free survival for all patients was 58% and 39%.

Summary and Conclusions: This analysis suggests that conditioning regimen of i.v. busulfan/melphalan/etoposide would be well tolerated and effective in patients with relapsed or high risk NHL. Accordingly, this regimen may be regarded as an important treatment option to substitute for BEAM regimen.

P902

MOBILIZATION AND ENGRAFTMENT OF PERIPHERAL BLOOD STEM CELLS IN RELATED HEALTHY DONORS OLDER THAN 55 YEARS

C Motlló[1,*], J Sancho[1], J Grifols[2], J Juncà[1], M Morgades[1], S Vives[1], A Ester[2], I Rodríguez[1], M Batlle[1], C Ferrá[1], R Guardia[3], A Flores[4], D Gallardo[3], A Wisniewska[1], P Britos[1], F Millá[1], E Feliu[1], J Ribera[1]
[1]Clinical Hematology Department, ICO-Hospital Germans Trias i Pujol - Josep Carreras Research Institute, [2]Banc de Sang i Teixits, Hospital Germans Trias i Pujol, Badalona, [3]Clinical Hematology Department, ICO-Hospital Josep Trueta, Girona, [4]ICO-Hospital Germans Trias i Pujol - Josep Carreras Research Institute, Badalona, Spain

Background: The increasing scarcity of related donors has led to the use of older donors for allogeneic hematopoietic stem cell (HSC) transplantation.

Aims: The objective of this study was to analyse the influence of age on mobilization and apheresis of peripheral blood stem cells (PBSC) in healthy donors, as well as on the engraftment in recipients.

Methods: Retrospective analysis of the results of mobilization and apheresis of PBSC from related healthy donors referred for HSC collection for allogeneic transplantation between 2001 and 2012 in one single centre.

Results: One hundred twenty-four related donors were included. Median age was 50 years (range 4-77), 70 (53%) were males and 44 (33%) were older than 55 years. The diseases for which HSCT was required were comparable in both groups. Donors were mobilized with G-CSF: doses of 10µg/kg/bid for 5 days if donor's weight was lower than patients' weight (30 cases [24%]), and 5µg/kg/bid for 5 days if donor's weight was higher. Mobilization and engraftment results are summarized in Table 1.

Table 1.

Pre-apheresis data	Donors ≤55 yr. (n=80)	Donors >55 yr. (n=44)	p
WBC ($x10^9$/L)	52.45 (9.4 – 98.3)	50.1 (30.7 – 87.6)	612
CD34+ cells /µL	90.5 (18 – 240)	72 (20 – 172.5)	8
Apheresis data	**Donors ≤55 yr.**	**Donors >55 yr.**	**p**
CD34+ cells($x10^6$) collected	579.3 (135.14 – 1557.24)	513.69 (149.81 – 1290)	844
Side effects	30	8	72
– Paresthesias	25	7	
– Tetany	2	0	
– Other	3	1	
Volume processed (mL)	16131 (4424 – 36906)	18653 (10003 – 26261)	2
Mobilization failure	0	1	331
Days apheresis			690
– 1	87	41	
– 2	2	1	
Engraftment data	**Recipients from donors ≤55 yr.**	**Recipients from donors >55 yr.**	**p**
Days to neutrophils >0.5x10^9/L	14 (10 – 40)	15 (10 – 26)	566
Days to platelets >20x10^9/L	13 (8 – 103)	13 (1 – 49)	856
Transfusion procedures			
– Red blood cells	2 (0 – 32)	3 (0 – 82)	0.944
– Platelets	2 (0 – 52)	2.5 (0 – 82)	
GVHD			
– Acute grade III-IV	18	8	0.862
– Chronic	27	8	0.196
Outcomes of HSCT	**Recipients from donors ≤55 yr.**	**Recipients from donors >55 yr.**	**p**
OS probability (10 years)	44±16%	47±16%	659
NRM probability (10 years)	39±11%	31±15%	568
Relapse incidence	31±11%	32±16%	749

Summary and Conclusions: Although a higher number of peripheral CD34 positive cells after mobilization was obtained in younger donors, a similar number of CD34 positive cells was finally collected. On comparison of the results of HSCT according to donor age, there were no differences in time to engraftment, GVHD incidence,NRM, relapse incidence and OS. These results indicate that the age of the donor should not be a limitation for allogeneic HSCT.

Supported in part by Grant RD12-0036-0029 from RTICC. Instituto Carlos III, Spain.

P903

EFFICACY OF ORAL BUDESONIDE FOR GASTROINTESTINAL GRAFT VERSUS HOST DISEASE IN HAEMATOPOIETIC STEM CELL TRANSPLANT PATIENTS

M Chong[1,*], J Ng[1], Y Lim[1], H Ng[1], Y Linn[2]
[1]Department of Pharmacy, [2]Department of Haematology, Singapore General Hospital, Singapore, Singapore

Background: Gastrointestinal (GI) graft-*versus*-host disease (GVHD) is one of the most common complications after allogeneic haematopoietic stem cell transplantation (HSCT). Glucocorticosteroids are the mainstay of therapy but are limited by their side effects. Non-absorbable corticosteroids such as oral budesonide (BUD) have been studied for the treatment of GI GVHD to minimize systemic steroid use. In Singapore, BUD is available as a hard capsule of gastro-resistant pellets, hence crushing of the pellets is required for the drug to reach its intended site of action in patients with upper GI GVHD.
Aims: This study aims to evaluate the efficacy of oral BUD as monotherapy in the initial treatment of mild to moderate GI GVHD as well as the side effect profile of oral BUD.
Methods: A single centre, retrospective review was carried out in patients who underwent allogeneic HSCT in Singapore General Hospital during the period of June 2009 to June 2011. Primary outcome was disease status at day 28 after initiating oral BUD monotherapy. Secondary outcomes were duration of oral BUD use,time to initiation of systemic steroids in patients who did not respond or progress on oral BUD, rate of recurrence after discontinuation of oral BUD, duration of response, GI GVHD-related deaths at 6 months and 12 months post diagnosis of GI GVHD, and frequency of side effects attributable to oral BUD.
Results: A total of 28 patients were studied. Median age was 39 years, 53.6% of patients were male. Upper GI GVHD=75%, lower GI GVHD=3.6%, both upper and lower GI GVHD=21.4%. Median onset of GI GVHD was 40 days post HSCT. Dose of oral BUD ranged from 3mg once a day to 3mg four times daily. Doses were titrated according to clinical signs and symptoms. At day 28 post initiation of oral BUD, 57.1% achieved CR and 32.2% achieved PR. The overall duration of oral BUD monotherapy was 35 days. There was a higher rate of CR achieved 28 days post oral BUD therapy in patients diagnosed with isolated upper GI GVHD as compared to patients with lower +/- upper GI GVHD symptoms (61.9% *vs.* 42.9%). Among those patients who eventually achieved CR, 9 patients (34.6%) recurred, although 6 patients reached second CR after a second course of BUD. Twenty-four patients (85.7%) did not require systemic steroids for the treatment of GI GVHD. Minimal toxicities attributed to BUD were reported. Overall survival at 6 months and 12 months were 89.3% and 85.7% respectively.
Summary and Conclusions: This retrospective study showed that oral BUD seemed effective in treating mild to moderate GI GVHD, as a form of local therapy avoiding systemic side effects. The results also indicate that the postulation of destroying the enteric coat of BUD pellets to facilitate immediate release of the drug in an acidic environment like the upper GI for local treatment of GVHD might hold true. Multiple courses of oral non-absorbable corticosteroids may be necessary to achieve or maintain response in some patients. However, the optimal dose and duration of oral BUD to be used in this setting has yet to be determined. Updated results will be presented at the meeting.

P904

PLERIXAFOR 'ON DEMAND' AFTER CHEMOTHERAPY+GRANULOCYTE-COLONY-STIMULATING FACTOR: RESULTS OF A STRATEGY BASED ON PERIPHERAL BLOOD CD34+ CELLS AND AN ALGORITHM FOR THE PRE-EMPTIVE US

L Farina[1,*], F Spina[1], A Guidetti[2], P Longoni[1], F Ravagnani[1], A Dodero[1], V Montefusco[1], C Carlo-Stella[2], P Corradini[1]
[1]Hematology, [2]Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Plerixafor is a CXCR4-inhibitor that improves peripheral-blood-stem-cell (PBSC) mobilization when combined with granulocyte-colony-stimulating factor (G-CSF). Plerixafor 'on demand' after chemotherapy+G-CSF may be efficient and cost-effective, but timing of administration and criteria for patient selection are under investigation.
Aims: Our study was aimed to assess the feasibility and efficacy of plerixafor 'on demand' with chemotherapy+G-CSF and to design an algorithm for the 'on demand' use after high-dose cyclophosphamide+G-CSF.
Methods: Twenty-eight lymphoma (n=25) and myeloma (n=3) patients were treated with chemotherapy+G-CSF and plerixafor: 20 patients had failed a previous mobilization with chemotherapy+G-CSF, 8 received plerixafor as first-line mobilizing therapy. Median age was 53 years (range, 24-68). Median number of chemotherapy lines was 2 (range, 1-4), 10 patients were treated with radiotherapy. The decision of adding plerixafor was based on circulating CD34+ cells at hematopoietic recovery. To devise an algorithm for the 'on demand' use of plerixafor after a first mobilization attempt we reviewed the data of 107 patients treated with cyclophosphamide+G-CSF: 51 myeloma patients received 3-4 gr/ms and 56 lymphoma patients received 6-7 gr/ms. Leukocytes and CD34+ cells were analyzed by a multivariate logistic regression model.
Results: Twenty-seven patients treated with plerixafor 'on demand' collected a median of4,9 × 10^6/kg CD34+ cells (range, 0,8-13) after a median of one plerixafor injection and one leukapheresis (range, 1-3). Twenty patients collected >=4 × 10^6 CD34+/kg. The median fold increase of CD34+ cells after plerixafor was4,7 (range, 1-52). The median time from chemotherapy to plerixafor administration was 15 days (range, 12-25). In our retrospective analysis on 107 patients treated with cyclophosphamide+G-CSF, having a CD34+ cell count <10/µl on the day of leukocyte recovery (>1000/µl) or leukocyte count <1000/µl after day +12 in myeloma and day +14 in lymphoma patients predicted the risk of failing PBSC collection by 2.7 and 2.8 times (P=0.001 and P=0.02) with a sensitivity of 89% and specificity of 88%, respectively.
Summary and Conclusions: Our results show that plerixafor 'on demand' can induce the collection of PBSC in >90% of patients treated with chemotherapy+G-CSF. The retrospective analysis on 107 patients treated with cyclophosphamide+G-CSF showed that those with delayed hematopoietic recovery and CD34+ cells <10/µl at recovery may deserve plerixafor 'on demand', as first-line mobilization therapy.

P905

MYELOABLATIVE CONDITIONING REGIMEN WITHOUT ATG AND TBI IN SINGLE UNIT UNRELATED UMBILICAL CORD BLOOD TRANSPLANTATION WITH HEMATOLOGIC MALIGNANCIES

T Juan[1,*], G Liangquan[1], L Huilan[1], S Zimin[1]
[1]department of Hematology, Anhui Provincial Hospital, Hefei, China

Background: Engraft failure and serious infections are still the obstacles of cord blood transplantation (UCBT). As antithymocyte globulin (ATG) and other strong immunosuppressive agent can delayed immune reconstitution and increased the risk of severe infection. Additionally, children and some adults with poor physical condition may not tolerance TBI.
Aims: Therefore, we retrospectively analyze the safety and efficacy of the conditioning regimen which without ATG and TBI in unrelated cord blood transplantation (UCBT) for 21 patients with hematologic malignancies.
Methods: The myeloablative conditioning regimen consisted of fludarabine (FLU), busulfan (BU) and cyclophosphamide (CY). FLU 30mg/m2 was administered intravenously as a single daily dose on days -9 and -8, BU 3.2 mg/kg was also administered intravenously as a single daily dose on days -7 to -4, and CY was administered intravenously over 2 hours at a dose of 60 mg/kg once daily on days -3 and -2 (total dose 120 mg/kg). 24 hours after the completion of conditioning, patients received the UCBT.Graft *versus* host disease (GVHD) prophylaxis was cyclosporin A (CSA) and mycophenolate mofetil (MMF).
Results: With this conditioning regimen we had achieved high engraftment rate (95.2%) and rapid hematopoietic reconstitution.neutrophil engraftment at a median time of 18 (12~30) days and platelet engraftment at a median time of 37(14~83) days. The cumulative incidence of acute GVHD was similar with other reports while pre-engraftment syndrome (PES) and III~IV acute GVHD was slightly higher. Thirteen cases (61.9%) of patients occurred PES. Acute GVHD occurred in 9 cases of the 20 engraftment patients (45.0%) and 5 cases (25.0%) were of grade III~IV. But the chronic GVHD only occurred in one of 19 evaluable patients (5.3%) which were much lower and localized. Post-transplant infection rate declined may associate with the absence of ATG and rapid recovery of the neutrophil. Sixteen patients (76.2%) got infection and two cases (9.5%) died of severe infection. CMV reactivation occurred in 71.4% (15 of 21) of the patients at the time between 18 and 139 days after UCBT. But there were no CMV diseases occurred and no patients died of CMV infection. The cumulative incidence of relapse (9.5%) was significantly lower and no ALL patients relapsed. Three-year overall survival (OS) and event-free survival (EFS) were 66.7% and 61.9% respectively of total patients and these data were similar between high-risk and standard-risk patients (Figure 1).

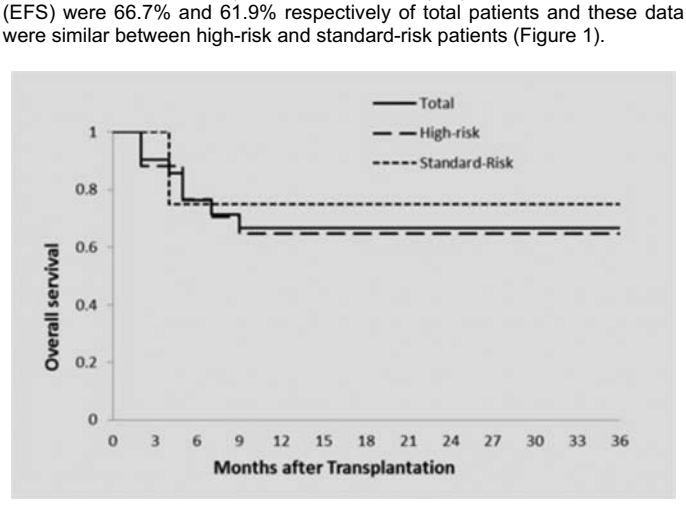

Figure 1. Standard-risk vs. high-risk P=0.76. Overall survival (OS).

Summary and Conclusions: In summary, we found the prominent feature of this conditioning regimen was that the same high engraftment rate, rapid myeloid reconstruction and low incidence of infection. Low relapse rate and good survival is also its significant features. Although the PES and acute GHVD occurred slightly higher, chronic GVHD was significantly reduced so that the patient's quality of life had been improved. More cases needed to be studied to confirm these findings further.

P906

EFFECTS OF HUMANIZED ANTI-CC CHEMOKINE RECEPTOR 4 MONOCLONAL ANTIBODY ON REGULATORY T CELLS AND GVHD AROUND HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ADULT T-CELL LEUKEMIA LYMPHOMA

H Hashimoto[1], K Maruyama[1,*], N Yamauchi[1], R Kobayashi[1], S Nagano[1], T Ishikawa[2], Y Yoshii[3], N Uoshima[3], H Hosoi[4]
[1]Department of cell therapy, Institute of Biomedical Research and Innovation, [2]Department of Hematology, Kobe City Medical Center General Hospital, Kobe, [3]Department of Hematology, Matsushita Memorial Hospital, Hirakata, [4]Department of Hematology/Oncology, Wakayama Medical University, Wakayama, Japan

Background: Adult T-cell leukemia lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by human T-cell lymphotropic virus type I with unique characteristics of resistance to conventional chemotherapy. Allogenic stem cell transplantation is an effective treatment in selected patients with ATL, but high treatment-related mortality and high relapse rate after transplantation are still remained. Recently combination of additional target therapy, a humanized anti-CC chemokine receptor 4 monoclonal antibody(anti CCR4 antibody) with HSCT is expected to improve survival of patients with aggressive ATL. Anti-CCR4 antibody enhances antibody-dependent cellular cytotoxicity not only for CCR4 expressing ATL cells but also T regulatory (T reg) cells expressing CCR4 which are supposed to regulate GVHD after HSCT. The effects of anti-CCR4 antibody on T reg cells and GVHD in the case of HSCT are not elucidated yet.
Aims: We investigated the number of peripheral T reg cells and the characteristic of GVHD in 3 cases of aggressive ATL patients treated with anti-CCR4 antibody before or after HSCT.
Methods: 3 patients with ATL received anti-CCR4 antibody once per week for 6~8 times at a dose of 1.0mg/kg within three months before or after HSCT. We investigated T-cell subset distribution during and/or after anti-CCR4 antibody treatment. And we evaluated clinical characteristics of GVHD after HSCT.
Results: In all cases, regulatory T cells were extremely reduced after anti-CCR4 antibody treatment and the reduction was lasted for more than 3 months. The number of T reg cells at 3 months after final anti-CCR4 antibody was 0.32±0.33/μl. (Normal control: 54.12±13.73 /μl).All patients showed Grade III-IV skin GVHD and 2 of them were steroid resistant. And liver dysfunction or liver GVHD was seen in two cases. No gut GVHD was seen in all cases.
Summary and Conclusions: T reg cells were severely depleted after anti-CCR4 antibody treatment with HSCT and the depletion period of T reg cells were longer in these patients with HSCT than in the ATL patients without HSCT. It was possible that the suppression of T reg cells induced severe skin GVHD.

P907

IMPACT OF INAPPROPRIATE MICAFUNGIN PROPHYLAXIS IN A BONE MARROW TRANSPLANTATION (BMT) UNIT ON THE OUTCOME OF CANDIDIASIS AND ON THE EMERGENCE OF ECHINOCANDIN-RESISTANT CANDIDA KRUSEI ISOLATES

F Honeyman[1,*], H Raberin[2], M Srour[3], M Desnos-Ollivier[4], A Fayard[5], J Cornillon[3], D Guyotat[3,5], E Tavernier-Tardy[3,5]
[1]Hematology, Université Jean Monnet, [2]Mycology laboratory, CHU Saint Etienne, Saint Etienne, [3]Hematology, Institut de Cancérologie Lucien Neuwirth, Saint Priest en Jarez, [4]Institut Pasteur, Paris, [5]Université Jean Monnet, Saint Etienne, France

Background: Despite the increasing use of echinocandin antifungal drugs, its resistance in Candida species remains uncommon. Between 2004 and 2010, the French Mycoses Study Group reported 20 infections caused by echinocandin-resistant (ER) Candida but only two were due to resistant Candida krusei. The first acquired ER Candida krusei isolate, with mutation in the FKS1 subunit, was described in 2007 and no more than ten cases since then.
Aims: We report a single-center experience of an increased incidence of candidemia following exposure to prophylactic micafungin in bone marrow transplant (BMT) patients, comparing to a retrospective cohort exposed to fluconazole prophylaxis. We describe the characteristics of candidemia with acquired ER Candida krusei isolates following exposure to micafungin and caspofungin.
Methods: This was a monocentric retrospective study of BMT patients in University Hospital of Saint-Etienne, France. Between January 1st, 2009 and April 1st, 2011, prophylaxis in patients with hematopoietic stem cell transplantation was based on fluconazole (400 mg/day) whereas after April 1st, prophylaxis was based on micafungin (50 mg/day). Species identification of Candida isolates was achieved by standard mycologic procedures and routinely tested for susceptibility to antifungal drugs. Three Candida krusei isolates were referred to the NRCMA (French National Reference Center for Mycoses and Antifungals). E-test for the susceptibility profile was confirmed using the EUCAST microdilution methods.
Results: We observed no candidemia for the 75 patients exposed to fluconazole prophylaxis while three cases of Candida krusei fungemia were reported in the 37 patients exposed to micafungin prophylaxis. All of three strains were initially susceptible to echinocandin.
A 48-year-old man developed candidemia caused by Candida krusei at Day 6 after cord blood transplant for CLL. He was treated with Caspofungin (70 mg/day) until an ER Candida krusei was isolated in stool cultures, two weeks later. He finally received a liposomal amphotericin B treatment with success.
The second case occurred in a 56-year-old woman who exhibited candidemia at day 11 after pheno-identical BMT for multiple myeloma. Mycafungin prophylactic treatment was switched to caspofungin (70 mg/day) and the patient was admitted to the ICU for respiratory distress. Six weeks later, ER Candida krusei isolates were identified in stool and mouth cultures. Caspofungin was changed to liposomal amphotericin B. The patient died ten days later of respiratory distress escalation with septic presentation.
The third case concerned a 38-year-old man who presented a candidemia due to a Candida krusei on day 5 after pheno-identical BMT for CLL. Liposomal amphotericin B was administered with success. Two weeks later, numerous isolates of Candida krusei were found in the digestive tract. Interestingly, these isolates remained susceptible to echinocandin.
Summary and Conclusions: We observed the outcome of candidemia in patients who received BMT under micafungin prophylaxis. This study underlines the importance of appropriate management of antifungal therapy, both in prophylactic and in curative strategy. All cases of candidemia were due to Candida krusei with uncommon acquired echinocandin resistance in two isolates in stool and mouth cultures. Resistant strains are now being studied at the NRCMA for FKS gene mutations. It will be interesting to investigate whether resistance appeared during treatment or is due to other pre-existing resistant strain expanding under treatment pressure.

Stem cell transplantation - Clinical 4

P908

PLERIXAFOR IS SUPERIOR TO CONVENTIONAL CHEMOTHERAPY FOR FIRST LINE STEM CELL MOBILISATION, AND IS EFFECTIVE EVEN IN HEAVILY PRETREATED PATIENTS

U Vithanarachchi[1], J Bell[1], J Clark[1], B Braithwaite[1], N McGinnity[1], T Callaghan[2], S Francis[1], R Salim[1], R Clark[1,*]
[1]Haematology, Royal Liverpool University Hospital, [2]Therapeutic Apheresis Unit, NHS Blood and Transplant, Liverpool, United Kingdom

Background: Plerixafor is an effective 2nd line agent for mobilising haemopoietic stem cells for stem cell transplantation (SCT), and it is increasingly used pre-emptively in patients mobilising poorly. However, its use as a first line agent has not been well studied.
Aims: Assess whether stem cell mobilisation using first line plerixafor and filgrastim is superior to stem cell mobilisation using conventional chemotherapy and filgrastim.
Methods: The Liverpool PHANTASTIC trial (clinicaltrials.gov identifier: NCT01186224) has recruited 100 lymphoma or myeloma patients destined for SCT, between April 2010 and June 2012. Mobilisation comprised filgrastim for 5-8 days, and plerixafor daily from day 4 for up to 4 doses. Stem cells were harvested on day 5 and daily thereafter, until either >4×10^6 $CD34^+$ cells /kg recipient weight were collected or 4 aphereses had been performed. Results were compared with 151 immediately preceding historical controls mobilised by chemotherapy (50% cyclophosphamide 1.5gm/m^2; 50% lymphoma salvage) and filgrastim.
Results: Two patients failed screening (1 renal failure; 1 relapse). Seventy (71%) of 98 plerixafor mobilised patients passed the primary endpoint of >4 × 10^6 $CD34^+$ cells/kg in 1 or 2 aphereses, with no evidence of neutropenia. This is superior to the 48 (32%) of 151 control patients who passed this endpoint (P<0.001). Ninety-four (96%) plerixafor mobilised patients achieved a 'bare minimum' of >2 × 10^6 $CD34^+$ cells/kg, which was significantly more than in control patients (114 (75%); P<0.001). Serious adverse events were not seen in any plerixafor mobilised patient, compared with 14 (9%) control patients, of which 10 were admissions for neutropenic sepsis. Details of prior treatment were available in 97 (99%) plerixafor mobilised patients and in 142 (94%) control patients. These were summarised for each patient using an update of a previously reported score (Clark & Brammer, BMT 1998; 22: 859-863), and a novel simplified score, whereby individual chemotherapy regimes were allocated a score of1, 2 or 3 according to their myelotoxicity. Plerixafor mobilised and control patients were well matched for the amount of prior treatment. Control patients mobilising >2.0 × 10^6 $CD34^+$ cells/kg had significantly lower scores than those who did not achieve this level (P=0.002) and similar findings were seen when using a cut off of 4.0 × 10^6 $CD34^+$ cells/kg. Furthermore, 32 of 36 (89%) control patients with scores in the lowest quartile mobilised >2.0 × 10^6 $CD34^+$ cells/kg, compared with only 25 (69%) with scores in the highest quartile. In contrast, for plerixafor mobilised patients, although those with higher treatment scores tended to mobilise less well, this relationship was not statistically significant, and 24 (100%) and 22 (92%) of 24 patients in the lowest and highest score quartiles mobilised >2.0 × 10^6 $CD34^+$ cells/kg. Eighty-five (87%) plerixafor mobilised patients underwent SCT, compared with 119 (80%) of control patients. With plerixafor mobilisation, only 3 (4%) required additional harvest rounds to achieve 2.0 × 10^6 $CD34^+$ cells/kg, whereas 17 (14%) control patients required additional harvest rounds to achieve this. There is currently no significant difference in the 12-month overall survival between plerixafor mobilised patients (86.2%) and control patients (83.7%).
Summary and Conclusions: Subject to the problems of historical control comparisons, we conclude that plerixafor is a more effective first line stem cell mobilisation than conventional chemotherapy (especially in heavily pretreated patients) and has lower toxicity, with no evidence of an inferior subsequent outcome. Plerixafor merits consideration as the first line standard of care for stem cell mobilisation.

P909

SIMILAR OUTCOMES BETWEEN YOUNGER AND OLDER AGE GROUP IN ADULT PATIENTS WITH SEVERE APLASTIC ANEMIA WHO RECEIVED HLA-MATCHED SIBLING TRANSPLANTS WITH FLUDARABINE-BASED CONDITIONING

S Shin[1,*], J Yoon[1], S Yahng[1], S Lee[1], B Cho[1], K Eom[1], Y Kim[1], S Lee[1], C Min[1], H Kim[1], S Cho[1], D Kim[1], W Min[1], C Park[1], J Lee[1]
[1]Hematology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Seoul, Korea, Republic of Korea

Background: Older age has been a major limitation for HLA-identical sibling allogeneic stem cell transplant (SCT) for severe aplastic anemia (SAA) because of increased transplant-related mortality. Recently, a less toxic conditioning regimen comprised of fludarabine (Flu), reduced dose cyclophosphamide (CY), and ATG (Flu/CY/ATG) was introduced in HLA-identical sibling allogeneic SCT for the patients with SAA.
Aims: We analyzed the transplant outcomes of adult patients with SAA conditioned with Flu/CY/ATG to compare younger age group (<40 years) and older age group (≥40 years).
Methods: Ninety-five consecutive adult patients transplanted from March 2002 to May 2012 at our center, followed by conditioning with Flu (30 mg/m^2/day × 6 days), CY (50 mg/kg/day × 2 days), and rabbit ATG (2.5 mg/kg/day × 4 days) were analyzed. All patients received CsA plus short course of methotrexate as GVHD prophylaxis.
Results: The median age of enrolled patients was 38 years (range, 15-58 years). The median ages of younger age group (n=50) and older age group (n=45) were 29 (range, 15-39) and 47 (range, 40-58) years, respectively. Thirty-four (35.8%) patients had very SAA at the time of allogeneic SCT. Stem cell sources were bone marrow (BM) in 69 patients, peripheral blood stem cell (PBSC) in 14 patients, BM with immune-magnetically selected CD34+ PBSC in 12 patients. The conditioning regimen was well tolerated, which showed low early mortality (5.3%). All patients achieved neutrophil engraftment with median time of 12 days (range, 5-20). The 100-day incidence of acute GVHD of grade ≥2 was 6.4% (95% CI, 2.6-12.6) and 2-year incidence of chronic GVHD was 9.3% (95% CI, 4.3-16.6). With a median follow-up of 3 years of the survivors, overall survival (OS) was 93.7% (95% CI, 86.4-97.1). Seven patients (7.4%) experienced secondary graft failure and 6 patients of them have successful durable engraftment after second allogeneic SCT. Seven patients died of sinusoidal obstruction syndrome (n=1), cytomegalovirus pneumonia (n=2), sepsis (n=2), and clonal evolution to AML (n=1) and MDS (n=1). There was no significant difference of OS between the younger age group and the older age group (96.0% *vs.* 91.1%; P=0.218). When we classified the patients into 4 age groups; <30 years (n=27), 30-39 years (n=23), 40-49 years (n=30), and ≥50 years (n=15), there was also no significant difference in OS between them (96.3%, 95.7%, 93.3% and 86.7%, respectively; P=0.578) (Figure 1).

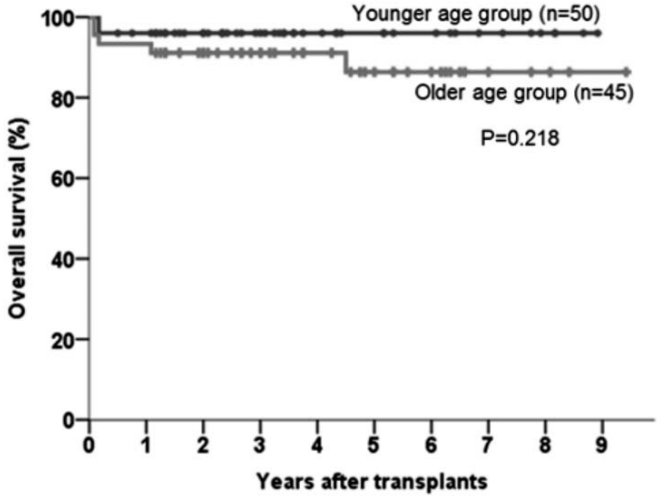

Figure 1.

Summary and Conclusions: Our study suggests the HLA-identical sibling transplants conditioned with Flu/CY/ATG for the patients with SAA showed the similar outcomes irrespective of age groups. It indicates the patients aged more than 40 years can be suitable candidates for HLA-identical sibling transplants.

P910

POORER OUTCOME AFTER CORD BLOOD THAN AFTER MATCHED RELATED OR UNRELATED DONOR ALLOGENEIC STEM CELL TRANSPLANTATION PREPARED WITH REDUCED TOXICITY CONDITIONING FOR HIGH RISK ACUTE MYELOID LEUKEMIA

R Devillier[1,2,3,*], S Harbi[1,3], S Fürst[3], R Crocchiolo[3], E Jean[3], L Castagna[3,4], A Etienne[3], T Prebet[2,3], A Granata[3], A Charbonnier[3], J Rey[3], C Chabannon[1,2,5], C Faucher[3], N Vey[1,2,3], D Blaise[1,2,3]
[1]Aix-Marseille Université, [2]Centre de Recherche en Cancérologie de Marseille, [3]Hematology, Institut Paoli Calmettes, Marseille, France, [4]Hematology, Instituto Clinico Humanitas, Milano, Italy, [5]Cell therapy, Institut Paoli Calmettes, Marseille, France

Background: When patients present a high risk acute myeloid leukemia (AML), allogeneic hematopoietic stem cell transplantation (Allo-SCT) is recommended. In many situations, a matched related (MRD) or matched unrelated donor (MUD) is lacking. Many reports showed that unrelated cord blood (UCB) represents a valuable alternative, but to our knowledge, no study specifically focused on high

risk AML transplanted after reduced toxicity conditioning (RTC) regimen.
Aims: The objective of this study is to evaluate the efficacy and the toxicity of UCB in the setting of high risk AML patients who lack a MRD or MUD.
Methods: We retrospectively analyzed patients undergoing RTC Allo-SCT in our institute from 2000 and 2012 for a high risk AML (patient not in complete remission (CR) at the time of Allo-SCT; second CR and beyond; adverse karyotype abnormalities (AdvK); First CR achieved after more than one induction course; CNS involvement; granulocytic sarcoma). We then compared outcome of patients who received graft from MRD or MUD *vs.* those who received UCB when no donor was found.
Results: One hundred sixty two consecutive high-risk AML patients treated in a single center were included and compared according to donor source (MRD or MUD (N=87+37) *vs.* UCB (N=38)). Median age was 51 years [range: 18-70], 131 patients (81%) were transplanted in CR, 57 patients (36%) had AdvK and the median follow up was 46 months [range: 7-35], without significant difference between MRD/MUD and UCB groups. In the UCB group, most of patients (34/38, 89%) received conditioning regimen containing cyclophosphamide, fludarabine and 2 Gray total body irradiation. In the MRD/MUD group, most of patients (93/124, 75%) received RTC regimen containing fludarabine, busulfan and antithymocyte globulin. Cyclosporine A (CsA) alone was used as graft-*versus*-host disease (GVHD) prophylaxis for 91/124 MRD/MUD patients (73%) while all UCB patients and 33/124 MRD/MUD patients (27%) received CsA plus mycophenolate mofetil (MMF) for GVHD prophylaxis.
Grade II/IV acute GVHD was 23% *vs.* 42% (P=0.026) and extensive chronic GVHD was 23% *vs.* 8% (P=0.038) in MRD/MUD and UCB groups respectively. Early-NMR at day 100 was lower in the MRD/MUD group than in the UCB group (4% *vs.* 16% respectively, P=0.013) (Figure 1 A). However, there were more delayed non-relapse deaths in the MRD/MUD group (N=17) than in the UCB group (N=2), leading to similar overall NRM between the MRD/MUD and UCB patients (at 2 years: 16% *vs.* 21% respectively, P=0.580). The cumulative incidence of relapse at 2 years was 28% *vs.* 49% in the MRD/MUD and UCB groups respectively (P=0.049) (Figure 1 B). By multivariate analyses of progression free survival (PFS) and overall survival (OS), the use of UCB (HR for PFS: 2.24 [1.39-3.59]; HR for OS: 1.83 [1.10-3.05]), CR at the time of Allo-SCT (HR for PFS: 0.31 [0.19-0.50]; HR: 0.34 [0.20-0.57]) and AdvK (HR for PFS: 1.69 [1.10-2.59]; HR for OS: 1.71 [1.08-2.71]) were independent significant factors influencing survivals.

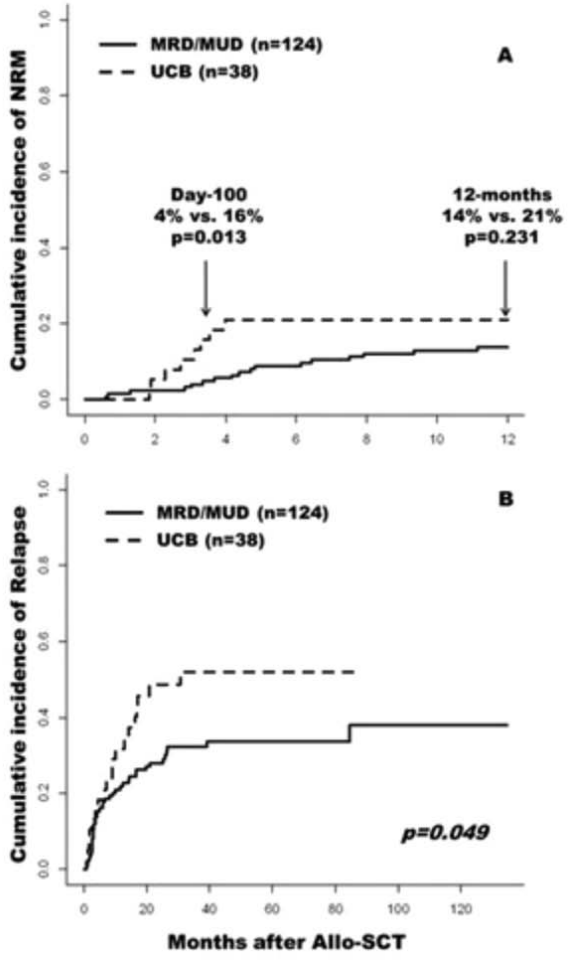

Figure 1.

Summary and Conclusions: We conclude that even if UBC allows extending Allo-SCT to patients who lack MRD/MUD, outcome of high risk AML transplanted from UCB remained poor in the context of RIC. Indeed, early NRM remains a major issue and about half of high risk AML patients relapsed after UCB Allo-SCT leading to shorter survivals compared with MRD/MUD. These results need to be prospectively confirmed; nevertheless, new strategies to improve anti leukemic effect in the setting of UCB Allo-SCT are needed as well as the investigation of other alternative donors such as haploidentical donors.

P911

OLDER AGE IS NOT A CONTRAINDICATION FOR UNMANIPULATED HAPLOIDENTICAL GRAFTS, WITH HIGH DOSE POST-TRANSPLANT CYCLOPHOSPHAMIDE

A Bacigalupo[1,*], G Anna[1], R Maria[1], F Galaverna[1], S Bregante[1], A Dominietto[1], M Miglino[1], A Ibatici[1], A Carella[1], M Gobbi[1]
[1]Hematology, IRCCS San Martinoi-IST, Genova, Italy

Background: We have recently shown that hematologic malignancies can be successfully grafted with unmanipulated haploidentical bone marrow (HAPLO) and post-transplant high dose cyclophosphamide (PT-CY), following a myeloablative conditioning regimen (Raiola *et al.*, BBMT 2013). However, older age is known to be a negative predictor of survival after allogeneic transplants
Aims: In this study we wanted to test whether older age is a contraindication for HAPLO grafts with PT-CY.
Methods: Patients. Eligible for this study were 108 consecutive HAPLO transplants, grafted between September 2009 and september 2012. Second allogeneic transplants were excluded. The median age was 46 years (17-74); The majority of patients (47%) had acute leukemia, the second more frequent diagnosis was lymphma (23%) and myelodisplasia (12%). Fifty patients were in remission (CR1+CR2) and 58 had active disease at transplant. Graft *versus* host disease (GvHD) prophylaxis consisted in PT-CY 50 mg/kg, on day+3 and +5, cyclosporine (from day 0), and mycophenolate (from day +1). The conditioning regimen was myeloablative (MA) in 86 patients and non myeloablative (NMA) in 22. The median follow up for surviving patients of 354 days (149-1102). Patients were divided in young/old according to the median age (46 years).
Results: Univariate analysis. The cumulative incidence of grade II-III acute GvHD was 21% *vs* 4% for younger/older patients respectively (P=0.003), and of moderate chronic GvHD 14% *vs* 22% (P=0.1); the cumulative incidence of transplant related mortality (TRM) for younger/older patients was 9% *vs* 23% (P=0.03), and the actuarial 3 year survival 63% *vs* 42% (P=0.03). The crude survival for patients aged <30 (n=32), 31-40 (n=15), 41-50 (n=19), 51-60 (n=25) and >60 (n=17) is 78%, 86%, 78%, 60%, 53% (P=0.1)
Multivariate analysis. When age was entered in a multivariate analysis on survival, together with disease phase (remission/advanced), interval diagnosis transplant, female donor in male recipient and intensity of the conditioning (MA/NMA), there was no effect of patient age (P=0.9) and the only predictor was disease phase at transplant (remission/relapse). Indeed the older patient population included more patients with relapsed disease (64%) as compared to 44% in the younger patients (P=0.03).
Summary and Conclusions: When stratified for patient and disease variables, older patients with hematologic malignancies have outcome comparable to younger patients. Our data indicate that older age–in our experience up to 70 years- should not be a contraindication for HAPLO transplants with PT-CY.

P912

KIR-LIGAND INCOMPATIBILITY IN THE GRAFT-VERSUS-HOST DIRECTION DID NOT AFFECT OUTCOMES OF SINGLE UMBILICAL CORD BLOOD TRANSPLANTATION WITHOUT ATG FOR ACUTE LEUKEMIA IN COMPLETE REMISSION

J Tanaka[1,*], Y Takahashi[2], T Yabe[3], Y Morishima[4], K Oba[5], S Takahashi[6], S Taniguchi[7], H Ogawa[8], Y Ohnishi[9], K Miyamura[10] K Kato,11, S Kato[12], Y Atsuta[13], Y Kanda[14]

Background: Killer cell immunoglobulin-like receptor (KIR)–ligand incompati-

bility may have some important roles in transplantation outcomes such as leukemia relapse and leukemia-free survival. It was reported that cord blood transplantation (CBT) for acute leukemia in complete remission (CR) from KIR-ligand incompatible donors in the graft-*versus*-host direction was associated with decreased relapse and improved survival. In the other report, KIR-ligand mismatch was associated with development of severe acute graft-*versus*-host disease (GVHD) and risk of death after double cord blood transplantation with reduced intensity conditioning (RIC) regimen. Therefore, the role of KIR-ligand incompatibility in CBT is not clear and controversial.
Aims: In order to clarify the effect of KIR-ligand incompatibility in the graft-*versus*-host direction on the outcome of acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) patients in CR after single cord blood transplantation, we assessed the outcome of CBT registered in the Japan Society for Hematopoietic Cell Transplantation (JSHCT) database between 2001 and 2010 (A Study From the HLA Working Group of the JSHCT).
Methods: 642 acute leukemia (356 AML and 286 ALL) patients in CR and donors whose HLA-A, -B, -C, -DR alleles were determined by DNA typing. Patients and donors were categorized according to their KIR-ligand incompatibility in the GVHD direction by determining whether or not they expressed HLA-C group 1 or2, Bw4 or A3/A11. All these patients did not receive ATG as a preparative regimen. We compared overall survival (OS), disease free survival (DFS), relapse incidence, non-relapse mortality (NRM) and GVHD between KIR-ligand incompatible and compatible group using the JSHCT database.
Results: 128 patient –donor pairs (AML 69, ALL 59) were HLA-A, -B or –C KIR-ligand incompatible (A3/A11 25, Bw4 68, C 61) and 514 compatible. Reduced intensity conditioning (RIC) regimen
(187, AML 129, ALL 58) defined basically as the use of fludarabine plus low-dose busulfan or melphalan with or without low-dose total body irradiation. Univariate analysis showed no significant differences between KIR-ligand incompatible and compatible group in both AML and ALL patients of OS, DFS, relapse incidence, NRM and acute GVHD (P=0.674, P=0.688, P=0.353, P=0.766, P=0.569 for AML, P=0.628, P=0.352, P=0.693, P=0.492, P=0.691 for ALL, respectively). Also, there were no significant difference in OS, DFS, relapse incidence, NRM and acute GVHD between KIR-ligand incompatible and compatible group in both AML and ALL patients by multivariate analysis. The conditioning regimens (RIC and myeloablative conditioning) also did not affect these results.
Summary and Conclusions: There were not positive and negative effects of KIR-ligand incompatibility in GVHD direction on single cord blood transplantation outcome in both AML and ALL patients without ATG in Japan. Administration of ATG as a preparative regimen may be important to obtain positive effect of KIR-ligand incompatibility in GVHD direction on cord blood transplantation outcomes such as survival and relapse in especially AML patients.

P913

ASSESSMENT OF LIVER FIBROSIS IN PATIENTS WITH B-THALASSEMIA MAJOR UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION USING TRANSIENT ELASTOGRAPHY

A Hamidieh[1,*], H Poustchi[2], B Shazad[1], M behfar[1], S Tayebi[3], M Ostovaneh[3], M Jalili[1], R Malekzadeh[2], A Ghavamzadeh[1]
[1]Hematology-Oncology and Stem Cell Transplantation Research Center - Tehran University of Medical Sciences, [2]Digestive Diseases Research Center - Tehran University of Medical Sciences, [3]Tehran University of Medical Sciences, tehran, Iran, Islamic Republic of Korea

Background: Transient Elastography (TE) is an efficient non-invasive technique for evaluation of liver fibrosis which has been recently used much more widely.
Aims: This study attempts to estimatethe diagnostic accuracy of TE in patients with β-thalassemia major (TM) undergoing Hematopoietic Stem Cell Transplantation (HSCT).
Methods: This is a prospective study in which 58 TM patients withmedian age=8 years (range: 2.6-20 years) enrolled. For all patients, we measured liver stiffness using both TE in kilopascals (kPa) and liver biopsy based on Ishak score. The diagnostic accuracy of TE and liver biopsy were evaluated using linear discriminated analysis (the area under the receiver operating characteristic curves (AUROCs)).
Results: Of 58 patients, there were 26 patients (44.8%) with mild fibrosis, 12 (20.7%) with moderate fibrosis and 2 (3.4%) with severe fibrosis. The correlation of TE values with thalassemia classification (P<0.001), iron deposition (P<0.037) and fibrosis stage (P=0.008) were statistically significant. The median TE values in patients with severe fibrosis (stage 3-5) and mild or no-fibrosis groups were 4.5 (range, 3.0-13.0) kPa and 4.0 (range, 2.5-9.0) kPa, respectively. Prediction of high fibrosis stages (stage >=3) using TE with cut-off of 4.35 kPa, AUROC was 0.670 (95% confidence interval [CI]: 0.508-0.833) with 76.9% sensitivity (95% CI: 70.8-81.8) and 57.8% specificity (95% CI: 53.3-60.3).
Summary and Conclusions: TE has presented itself as a new, non-invasive method for assessment of fibrosis stage in TM patients undergoing HSCT and maybe useful as an alternative to liver biopsy. Noticeable, TE also can be utilized as an invaluable technique for following up the liver status in TM patients after transplantation.

P914

PROGNOSTIC IMPACT OF CHRONIC GRAFT VERSUS HOST DISEASE IN PATIENTS WITH MYELOID NEOPLASMS UNDERGOING REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION–A SINGLE INSTITUTION SERIES

D Gijima[1], W Hogan[2], M Litzow[2], S Hashmi[2], D Gastineau[2], M Patnaik[2,*]
[1]Mayo Medical School, [2]Department of Hematology, Mayo Clinic, Rochester, United States

Background: Allogeneic stem cell transplant (allo-SCT) is often the only curative option for patients with myeloid neoplasms. Patients with acute myeloid leukemia (AML), myelodysplastic syndromes (MDS), myeloproliferative neoplasms (MPN) and overlap syndromes have successfully been transplanted with myeloablative strategies. The advent of reduced intensity conditioning (RIC) has not only decreased the non-relapse mortality (NRM), but has also made allo-SCT a viable option for older patients and patients with comorbidities. RIC relies on the graft *versus* leukemia (GVL) effect to eradicate the neoplastic clone. While this is difficult to measure, a surrogate marker is often the presence of graft *versus* host disease (GVHD).
Aims: To analyze single institution data on survival and transplant related outcomes for patients with myeloid neoplasms that have undergone RIC allo-SCT. To validate the survival benefit associated with the development of chronic GVHD.
Methods: After due IRB approval, 159 successive patients with myeloid neoplasms that had undergone RIC Allo-SCT at the Mayo Clinic were included in the study. The myeloid neoplasms were diagnosed and risk stratified according to World Health Organization (WHO) criteria. RIC conditioning was initiated at our institution in 2000 and patients in this study were included up to January 2013. All data was retrospectively abstracted and analyzed to compute transplant related outcomes such as; NRM, risk of disease relapse, overall-survival (OS), disease free survival (DFS), acute and chronic GVHD. The two major RIC used were; fludarabine and melphalan (n=138) and fludarabine and IV targeted busulfan (n=21). GVHD prophylaxis and liver injury prophylaxis were according to institutional standards. GVHD was evaluated and graded according to WHO and NIH scales.
Results: Of the 159 study patients, 99 (62%) were males, with a median age at transplant of 60 years (range, 14-71 years). There were 92 (58%) patients with AML [50 (54%) CR1, 19 (21%) CR2, 3 (3%) ≥CR3, 10 (11%) PIF, 10 (11%) untreated], 24 (15%) with MDS with excess blasts [12 (48%) CR1, 6 (24%) PIF, 7 (28%) untreated], 24 (15%) with MDS without excess blasts, 13 (8%) with myelofibrosis and 6 (4%) with CML [4 (67%) accelerated phase, 2 (33%) chronic phase]. At last follow-up, 70 (44%) deaths were recorded, with the median follow-up for the study being 12 months [range, 0–109 months] (23 (14%) from 2000-2005, 74 (47%) from 2005-2010, and 62 (39%) from 2010 onwards]. At last follow up, 118 (75%) patients remained in CR, while 28 (17%) had relapsed. In patients transplanted up to 2010, OS and DFS were 17 months (range 0–109 months) and 13 months (range 0–98 months), respectively. The 10 year NRM was 37%. Ninety-four (60%) patients developed acute GVHD [17 (11%) grade1, 42 (26%) grade2, 26 (16%) grade 3 and 9 (6%) grade 4]. Ninety-one (57%) developed chronic GVHD [16 (10%) mild, 34 (21%) moderate and 41 (26%) severe]. There was no difference in OS (P=0.06) and DFS (P=0.07) between the two conditioning regimens. In univariate analysis, factors adversely influencing OS included low cell dose (P=0.03), graft failure (P<0.0001), grade 4 acute GVHD (P=0.02) and absence of chronic GVHD (<0.0001). On a multivariable analysis; low cell dose (P<0.0001), graft failure (P<0.0001) and absence of chronic GVHD (P<0.0001) retained independent significance.
Summary and Conclusions: The development of chronic GVHD strongly correlates with improved OS and DFS in patients with myeloid neoplasms undergoing RIC allo-SCT, strongly supporting the role for an active graft *versus* leukemia effect.

P915

***IN VIVO* T-CELL DEPLETION WITH LOW-DOSE ANTITHYMOCYTE GLOBULIN TO REDUCE ACUTE GVHD IN UNRELATED DONOR STEM CELL TRANSPLANT FOR PATIENTS WITH SEVERE APLASTIC ANEMIA**

S Lee[1,*], J Yoon[1], S Shin[1], S Yahng[1], B Cho[1], K Eom[1], Y Kim[1], S Lee[1], C Min[1], H Kim[1], S Cho[1], D Kim[1], W Min[1], C Park[1], J Lee[1]
[1]Department of Hematology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of Korea

Background: For the patients with severe aplastic anemia (SAA) who do not have a sibling donor and cannot acquire an adequate response to immunosuppressive therapy, allogeneic stem cell transplantation (SCT) from an unrelated donor is used. However, higher incidence of graft-*versus*-host disease (GVHD) in the unrelated SCT setting remains an obstacle. We have reported that allele-mismatched unrelated grafts and peripheral blood stem cells (PBSCs) were risk factors for GVHD (Lee JW, *et al.*, Biol Blood Marrow Transplant 17: 101-108, 2011).
Aims: This study is performed to evaluate the effects of *in vivo* T-cell depletion with low-dose antithymocyte globulin (ATG) for reducing GVHD in SAA

patients who received not only transplants from mismatched unrelated donors, but also PBSCs from some matched unrelated donors.
Methods: Seventy-five patients with SAA (n=61) or VSAA (n=14) had received SCT from unrelated donor. Conditioning regimen consisted of fractionated total body irradiation (TBI, 800 cGy) and cyclophosphamide (100-120 mg/kg) from 2000 March to 2009 July.From 2009 August ATG (1.25 mg/kg/day; Genzyme, Cambridge, MA, USA) for 2 days was added as a part of conditioning to reduce GVHD in patients receiving HLA mismatched grafts or PBSCs. Patients were classified into the following three subgroups: (1) patients who had HLA matched (8/8), BM donors (group 1; n=33); (2) of patients who had HLA mismatched or PBSCs donors, those who did not received ATG (group2, referred to as historic controls; n=28); (3) those who received ATG (group 3; n=14).
Results: Seventy-five patients including 37 men and 38 women were assessed. Their median age was 29 years (range, 15-59 years) and the median interval from the diagnosis to transplantation was 48 months (range; 2-323 months). The majority of patients received multiple transfusions (median; 75 units, range: 4-405) prior to SCT. After a median follow-up of 55.5 months, the 4-year estimated OS rates were 87.9, 92.9, and 85.7 for group1,2, and3, respectively and there was no statistical difference (P=0.727). All patients achieved primary engraftment, and only one patient in the group 2 suffered from secondary engraftment failure. The cumulative incidence (CI) of acute GVHD (aGVHD, ≥grade II) was 36.4%, 64.3%, and 21.4% in each group. Multivariate analysis showed that the CI of aGVHD in the group 3 was comparable with those of the group 1 (RR of 0.53, *P*=0.320), whereas the patients without ATG (group 2) had a higher incidence of aGVHD (RR of 2.23, *P*=0.028). The CI of chronic GVHD (cGVHD) showed the no difference (43.0% in group1, 57.1% in group2, 30.6% in group3, *P*=0.247). Interestingly, decreased occurrence of aGVHD translated into lower rate of CMV reactivation (55.9% in group1, 85.2% in group2, 35.7% in group3, P=0.003).
Summary and Conclusions: This study suggests that the use of a low dose of ATG can reduce aGVHD and CMV reactivation, with comparable rates of successful engraftment in the unrelated transplantation setting from HLA mismatched or PBSCs donor.

P916

IMPACT OF ABO INCOMPATIBILITY ON UNRELATED CORD BLOOD TRANSPLANTATION
Y Wen[1,*], J Mengmeng[1],S Zimin[1], L Huilan[1], Z changcheng[1], T Baolin[1],T Juan[1]
[1]AnHui provincal Hospital, Hefei, China

Background: Umbilical cord blood transplantation (UCBT) has now become a more common treatment for patients with hematologic malignancies who lack matched related or unrelated donors. however, few reports have addressed the impact of ABO incompatibility on the clinical outcome such as engraftment, transfusion requirements and survival after UCBT.
Aims: we retrospectively analyzed the impact of ABO mismatching on clinical outcome of 121 patients including 51 ABO-identical, 23 minor, 39 major, and 8 bidirectional ABO-incompatible recipients after UCBT.
Results: With a median follow-up of 11 months(range, 5-151months), disease free survival (DFS) rate among the ABO-identical, minor, major, bidirectional ABO-incompatible group were 71.7%, 60.0%, 37.1%, 71.4% (P=0.014) while OS did not differ significantly between the four groups(76.1%,65.0%, 48.6%,71.4%, P=0.078). DFS(68.2%, 42.9%,P=0.009) and OS estimates (72.7%, 52.4%, P=0.031) of the ABO identical/minor incompatible group also differ significantly from the ABO major/bidirectional incompatible group. These results were confirmed in multivariate analysis. No significant difference in engraftment times, transfusion requirements, GVHD, relapse and none relapse mortality (NRM) between groups was noted. Severe immune hemolysis or pure red cell aplasia did not occurred among these patients.
Summary and Conclusions: DFS and OS are better with ABO identical/minor incompatible group in UCBT.

P917

SECONDARY ANTIFUNGAL PROPHYLAXIS BASED ON RESPONSE TO INITIAL ANTIFUNGAL THERAPY FOR PATIENTS WITH A HISTORY OF INVASIVE PULMONARY ASPERGILLOSIS IN ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION
Q Liu[1,*], R Lin[1], J Sun[1], Y Xiao[2], D Nie[3], Y Zhang[1], F Huang[1], Z Fan[1], H Zhou[1], Q Jiang[1], F Zhang[1], X Zhai[1], D Xu[1], Y Wei[1], J Song[2], Y Li[3], R Feng[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Department of Hematology, Guangzhou General Hospital of Guangzhou Command, [3]Department of Hematology, SUN Yat-sen Memorial Hospital, SUN Yat-sen University, Guangzhou, China

Background: Patient with a history of invasive fungal infection (IFI) is in considerable risk of relapse and death after allogeneic haematopoietic stem cell transplantation (allo-HSCT). Prophylaxis with broad-spectrum antifungal agents has significantly reduced morbidity and mortality of IFI after transplants. However, the optimal agents for secondary antifungal prophylaxis (SAP) are not well defined.
Aims: In this study, the choices of prophylactic agents were made based on treatment response to initial antifungal therapy and the efficacy and safety of SAP were evaluated in recipients undergoing allo-HSCT.
Methods: A total of 88 patients undergoing allo-HSCT with prior invasive pulmonary aspergillosis (IPA) were enrolled in this prospective, multicentre study. Sixty-one patients had stable IPA and 27 had active IPA at the time of transplants. SAP was given from the start of the conditioning until 90 days post-transplantation for patients with stable IPA or until eradication or stability of residual foci for patients with active IPA. The same agent was given for prophylaxis if patients developed acute graft-*versus*-host disease (aGVHD) and were treated with corticosteroids and/or monoclonal anti-T cell antibody. The agents of SAP included itraconazole in 19, voriconazole in 44, caspofungin in 19 and liposomal amphotericin B in 6 cases.In addition, surgery was performed in 4 patients who had the cavity lesion or nodule in lung with more than 2cm in diameter before transplants.
Results: The median time of SAP was 96 days (range, 13 to 183 days).The success rate of SAP was 89.8%. Nine patients (10.2%) developed breakthrough IFI and none discontinued prophylaxis due to study drug toxicity. The incidence of breakthrough IFI was not different between different prophylactic antifungal agents (P=0.708). The incidence of breakthrough IFI was not different between patients with active and stable IPA (P=0.126). Within a median follow up of 403 days post-transplants (range, 13-2060 days), 26 patients developed IFI, including 9 within the period of prophylaxis and 17 after the end of prophylaxis. The 3-year cumulative incidence of IFI was 36.7%±5.9% and the 3-year cumulative incidence of IPA relapse was 31.0%±5.8%. The incidence of relapse in the patients with stable IPA was lower than that in the patients with active IPA (20.6%±5.9% *vs.* 55.7%±11.8%,P=0.002). Multivariate analyses showed that active IPA at the time of transplants (hazard ratio [HR]=4.328, 95% confidence interval [CI] 1.801-10.399, P=0.001), relapse of underlying primary disease (HR=6.195, 95% CI 2.157-17.793, P=0.001) and chronic GVHD (HR=3.241, 95% CI 1.077-9.750, P=0.036) were risk factors for IPA relapse. All patients who developed IFI after transplants received salvage therapy except for one who quit because of concomitant primary disease relapse. Of the 24 evaluable patients, 11 patients achieved CR, 9 achieved PR and 4 had no response to the treatment. At the end of follow-up, 44 patients were alive and 44 died. The 5-year overall survival (OS) and disease-free survival (DFS) post-transplants were 46.7%±5.7% and 43.1%±5.6%, respectively. The 5-year IFI-related mortality was 5.5%±2.7%.
Summary and Conclusions: Our data indicate that SAP based on the response to initial antifungal therapy has favourable efficacy and safety for the patients undergoing allo-HSCT with a history of IPA. Active IPA might not increase the risk of breakthrough IFI, but increase the rate of IFI relapse.

P918

A MONOCLONAL PROTEIN FOUND IN RELATED STEM CELL DONORS: ARE WE DOING IT RIGHT?
N Tiren-Verbeet[1,*], J Bakker[2], B Ballieux[2], J Zwaginga[1], A Brand[3], T Netelenbos[1]
[1]Immunohematology and Bloodtransfusion, [2]CKCL, Leiden University Medical Center, [3]Sanquin, Leiden, Netherlands

Background: Increase in the use of non-myeloablative stem cell transplantation has resulted in a higher age of patients and their sibling donors. Although prior to HLA typing we use a questionnaire to exclude morbidity, predonation medical tests may reveal abnormalities resulting in donor rejection. In particular doubt regarding the use of G-CSF may arise if a monoclonal protein (M-protein) is found. After exclusion of multiple myeloma or lymphoproliferative disease, classification as monoclonal gammopathy of undetermined significance (MGUS) or transient reactive M-protein can often not be made because lack of follow-up time.
Aims: We evaluated prevalence and follow-up of M-protein in related stem cell transplantation (SCT) donors.
Methods: We retrospectively studied referral of related SCT donors seen in our department between 2009 and July 2012.
Results: Using immunofixation, we found an M-protein in 16 (13.1%) of 122 related donors (age 40-69) and in 23.3% of donors above 60. In 40% the M-protein concentration was >2 g/L and one donor had 40% plasma cells in the bone marrow; 4 more than 5% (max 20%) plasma cells and 11 showed marrow aspirates within the normal range. Donor follow-up ranged from 2 months to 3 years. In three donors the M-protein disappeared (after2, 6 and 12 months), one donor was diagnosed with a smouldering myeloma; the others were classified as MGUS. Of donors above 60 years 15 (43.3%) were deferred for G-CSF because of various medical reasons, of which 7 (23%) were rejected due to an M-protein. An M-protein occurs more often at older age and is associated with an increased incidence of haematological malignancies during 20 years follow-up after diagnosis. However, adverse consequences of G-CSF used for stem cell mobilisation on the proliferation of clonal cells producing a M-protein, are not known. Recently consensus was reached among Dutch haematologists to allow G-CSF in case of presumed MGUS with a low concentration M-protein if the transplant physician agrees. According to guidelines, subjects with an M-protein require follow-up for their plasma cell dyscrasia. This should be apart from the 10-year follow-up by the donation centre that is line with the present guidelines for unrelated donors that have been treated with G-CSF.

Summary and Conclusions: Potential SCT donors above 60 years show a high deferral rate up 43.5%, in half of these depending on whether M protein is considered as contra-indication for G-CSF. Using sensitive techniques an M-protein occurs more frequently (13%) in siblings of patients with haematological disorders. In particular in donors above 60 years (23.3%) the incidence is much higher compared to 3-5% of the general population above 50 years. Although at present for MGUS with a low concentration of M protein, G-CSF mobilisation is not considered a donor risk, these findings stress the importance of long term follow up of all related donors.

P919

TBI AND CYCLOPHOSPHAMIDE PLUS ATG IS WELL TOLERATED AND EFFECTIVE AS A PREPARATIVE REGIMEN FOR HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION WITHOUT IN VITRO T-CELL DEPLETION

L Xu[1,*], H Fu[1], D Liu[1], K Liu[1], X Zhang[1], H Chen[1], Y Chen[1], W Han[1], Y Wang[1], J Wang[1], F Wang[1], X Huang[1]
[1]Peking University People's Hospital, Beijing, China

Background: There is a lack of data for patients with haploidentical HSCT after preparing with TBI/Cy plus ATG.
Aims: This is a retrospectively study to analyze the toxicity and efficacy of total body irradiation (TBI) and cyclophosphamide (TBI/Cy) plus ATG as a conditioning regimen prior to haploidentical hematopoietic stem cell transplantation (HSCT).
Methods: The TBI/Cy plus ATG regimen consisted of TBI (770 cGy, a single dose), Cy (1.8g/m^2, two doses) and ATG (6 or 10mg/kg). Twenty patients (median age: 24 years old) receiving haploidentical HSCT between October 2008 and November 2012 were evaluated. Among them, 15 patients suffered from high-risk leukemia.
Results: There was one patient died before engraftment. The myeloid engraftment and platelet engraftment were obtained at a median of 12 days (range: 10–19) and 16 days (range: 10-29) after HSCT for other 19 patients, respectively. Both incidences of myeloid and platelet engraftment were 95%. A total of 19 patients with myeloid engraftment had completing-donor-type chimerism in peripheral blood by 30 days after transplantation. There was no case of secondary graft failure. The major Grade III and IV regimen-related toxicities were fever, diarrhea, and oral mucositis, which were well managed. Acute graft-*versus*-host disease (aGVHD) developed in 16/19 patients, consisting of Grade I in 12 patients(); II in 4; III and IV in no patient. No patients died of GVHD and infection. The 100-day transplant-related mortality was 5.6%. To reduce relapse, six patients received prophylactic modified donor lymphocyte infuse (mDLI), one patient received chemotherapy plus preemptive mDLI, one patient received chemotherapy plus therapeutic mDLI and 3 patients with Philadelphia chromosome-positive received prophylactic tyrosine kinase inhibitors. With a median follow-up period of 347 days (range: 35–1321 days), 18 of 19 patients had received complete remission after HSCT. The other one patient received remission in bone marrow with extramedullary non-remission. At last 4 patients relapsed and 3 patients died of relapse within one year after HSCT. The one-year incidence of relapse was 34.8%.The one-year overall and leukemia-free survival were 66.5% and 61.9%, respectively.
Summary and Conclusions: TBI/Cy plus ATG might be feasible and effective conditioning regimen for haploidentical HSCT, especially for patients with high-risk leukemia. The long-term observation of the efficacy and antileukemic effect of this regimen and a future prospective study with more patients to compare this regimen with BU/Cy plus ATG are required.

P920

HIGH LEVEL OF VASCULAR ENDOTHELIAL GROWTH FACTOR IS ASSOCIATED WITH INCREASED RELAPSE RATE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

I Moiseev[1,*], S Lapin[1], E Surkova[1], M Lerner[1],V Vavilov[1], B Afanasyev[1]
[1]R.M. Gorbacheva Memorial Institute of Children Hematology and Transplantation, State Medical University named I.P. Pavlov, Saint-Petersburg, Russian Federation

Background: High level of vascular endothelial growth factor (VEGF) is a well-known predictor of worse outcome of chemotherapy in a variety of hematologic malignancies.
Aims: The aim of this study was to evaluate if overproduction of VEGF is also a prognostic factor after allogeneic hematopoietic stem cell transplantation (HSCT).
Methods: The study included 91 patients. 73% had acute leukemia, 10% chronic myeloid leukemia, 8% myelodysplastic syndrome and 9% other hematologic malignancies. 52.7% of patients were grafted without hematologic remission at time of transplant. Median age was 38 years (range 15-60). 30% were grafted from related and 70% from unrelated donor. 24% received myeloablative conditioning, 76%>reduced intensity conditioning. VEGF A was measured by ELISA. The blood sampling points were before conditioning, on day 0 and upon engraftment.
Results: Based on series of univariate and multivariate analyses of VEGF concentrations before conditioning a cut-off value of 50 pg/mL was found for which there was a significant difference for outcomes of HSCT. Patients with VEGF>50 pg/mL had higher 2-year relapse rate (53% *vs* 25%, P=0.008, Figure 1) and decreased 2-year event-free survival (EFS) (20% *vs* 46%, P=0.021). Overall survival was not different between two groups (60% *vs* 53%, P=0.658), as some of the patients were successfully salvaged after relapse. The association between high VEGF concentrations and 2-year relapse rate was still significant for day 0 time point (55% *vs* 26%, P=0.018), but with higher cut-off value of 90 pg/mL. In multivariate analysis for relapse that incorporated absence of remission before HSCT, type of donor and presence of acute graft-*versus*-host disease, VEGF>50 pg/mL before conditioning was an independent risk factor (HR 2.77, P=0.024, HR 95%CI 1.15-6.70). In a multivariate analysis for EFS high VEGF also had a significant negative impact (HR 2.17, P=0.025, HR 95%CI 1.10-4.26).

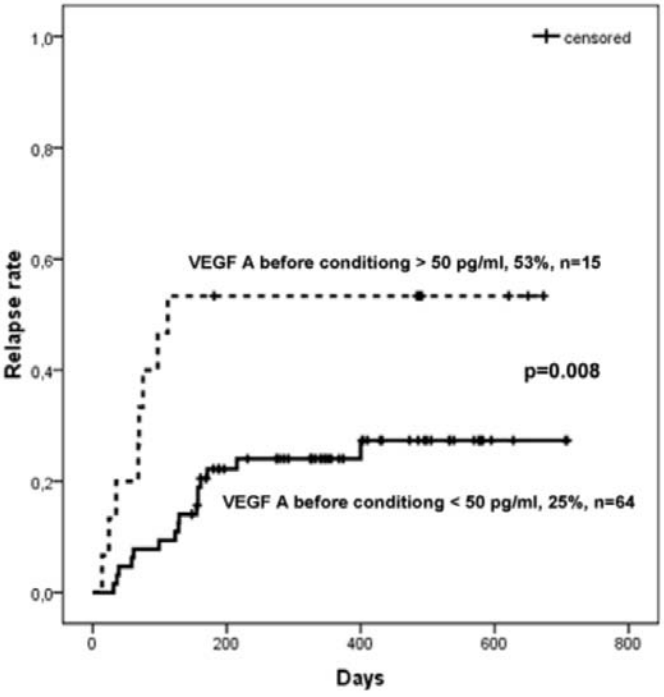

Figure 1.

Summary and Conclusions: In conclusion, this study confirmed that tumor-associated overexpression of VEGF is a negative prognostic factor for hematologic malignancies not only after chemotherapy, but also after HSCT.

P921

CLINICAL IMPACT OF ENGRAFTMENT SYNDROME IN ADULT PATIENTS WHO RECEIVED ALLOGENEIC STEM CELL TRANSPLANTATION

H Shimizu[1,*], H Handa[1], N Hatsumi[2], S Takada[2], T Sakura[2], Y Nojima[1]
[1]Gunma University, [2]Saiseikai Maebashi Hospital, Maebashi, Gunma, Japan

Background: Engraftment syndrome (ES) has been recognized as a complication that occurs during neutrophil recovery following autologous or allogeneic stem cell transplantation (allo-SCT). Although pro-inflammatory cytokine and subsequent cellular and cytokine interactions have been reported to play a major role, the pathogenesis of ES remains unclear. Likewise, the clinical significance of ES has been controversial.
Aims: The aim of this study was to clarify the clinical impact of ES on clinical course and transplant outcome.
Methods: We retrospectively analyzed 132 consecutive adult allo-SCT recipients, who achieved durable neutrophil engraftment, between January 2006 and August 2011 at Gunma University Hospital and Saiseikai Maebashi Hospital in Gunma, Japan. ES was defined according to the diagnostic criteria described by Spitzer. Fisher's exact test was used for comparison of binary variables. The Mann-Whitney U-test was used for comparison of continuous variables. Overall survival (OS) rates were estimated by the Kaplan-Meier method and were compared using the log-rank test. The Cox proportional hazards regression model was used for multivariate analysis of predisposing factors. P<0.05 was considered to be statistically significant.
Results: Of the 132 allo-SCT recipients involved in this study, 78 patients were male, and 54 were female. The median age was 48 years (range, 18–72 years). ES occurred in 34 patients (25.8%). Of the 34 patients with

ES, 34 patients (100%) presented with non-infectious fever, 31 (91%) had skin rash, 30 (88%) experienced weight gain, and 26 (76%) developed non-cardiogenic lung edema. To identify the predisposing factors for ES, patient characteristics, transplant procedure, and donor type were examined; grafts from an unrelated donor and minor ABO-mismatched donor were identified as predisposing factors for ES. Multivariate analysis revealed that these two factors were independent. Regarding the impact of ES on clinical course, patients with ES more frequently developed thrombotic microangiopathy (TMA), grade II-IV acute graft-*versus*-host disease (GVHD), and chronic GVHD when compared with patients without ES (TMA: 29% *vs.* 10%, respectively, P=0.036; acute GVHD: 74% *vs.* 44%, respectively, P=0.027; chronic GVHD: 85% *vs.* 44%, respectively, P=0.012). There was no difference in the incidence of veno-occlusive disease (VOD) between the groups. The 5-year cumulative incidence of underlying disease relapse for patients with ES was higher than for patients without ES (8% *vs.* 29%, respectively, P=0.048). The 5-year cumulative incidence of treatment-related mortality (TRM) for patients with ES tended to be higher than for patients without ES (42% *vs.* 22%, respectively; P=0.151). The 5-year OS rates were comparable between patients with and without ES (57% *vs.* 57%, respectively; P=0.893). Of the 34 patients with ES, eight (23%) received no treatment, and all symptoms spontaneously resolved within 7 days after onset of ES. Of the remaining 26 patients, 14 received 1 mg/kg/day of methylprednisolone (mPSL), and 12 received 2 mg/kg/day or more of mPSL. Steroid administration was effective in all 26 patients independent of steroid dose, and all symptoms were resolved on the day after initiation of treatment. Among the three groups stratified according to treatment strategy, there was no difference in clinical course, including the incidence of VOD, TMA, acute GVHD, and chronic GVHD.

Summary and Conclusions: These findings suggest that ES has two conflicting effects on transplant outcome: increase in TRM and decrease in underlying disease relapse. Regarding treatment strategy, because of the excellent response to steroids, administration of excessive amounts of steroids is considered to cause the increase in TRM. The appropriate steroid dosage for the treatment of ES should therefore be investigated using a prospective study design.

PROGNOSTIC IMPACT OF PRETRANSPLANT SERUM FERRITIN FOR OUTCOMES IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION. EPIDEMIOLOGY OF PROSPECTIVE, MULTICENTER ARGENTINIAN STUDY

G Drelichman[1,*], N Fernandez Escobar[1], L Feldman[1], G Jaimovich[1], M Makiya[2], F Tisibana[2], M C Foncuberta[3], E Bullorsky[4], R Burgos[3], O Rabinovich[4], S Palmer[4], V Milovic[5], J Real[5], A Requejo[5], J Milone[6], S Yantorno[6], S Saba[7], A Eseyza[7], S Formisano[8], M Aznar[8], A Lazarowsky[9]
[1]Bone Marrow Transplant Unit, Fundacion Favaloro, [2]Bone Marrow Transplant Unit, Hospital Italiano, [3]Bone Marrow Transplant Unit, Instituto Fleming, [4]Bone Marrow Transplant Unit, Hospital Britanico, [5]Bone Marrow Transplant Unit, Hospital Aleman, Buenos Aires, [6]Bone Marrow Transplant Unit, Hospital Italiano, [7]Bone Marrow Transplant Unit, Hospital Rossi, [8]Bone Marrow Transplant Unit, Hospital Sor Maria Ludovica, La Plata, [9]Hematology Unit, Hospital de Clínicas San Martín, Buenos Aires, Argentina

Background: Iron Overload (IOL) is a common problem in red cell transfusion–dependent patients undergoing Hematopoietic Stem Cell Transplant (HSCT). Transplant-related mortality (TRM) seems to be higher in patients with IOL secondary to more incidence in infections, mucositis, hepatic Sinusoidal Obstruction Syndrome (SOS) and Graft Versus Host Disease (GVHD).
Aims: 1)We prospectively evaluated the frequency of transfusional IOL in patients who underwent HSCT. 2)We compared main outcomes between both groups (with and without transfusional IOL).
Methods: Eight Argentinian Bone Marrow Transplants Units studied 109 pediatric and adults patients who received HSCT from july 2010 to july 2012. 99 patients were eligible according to inclusion/exclusion criteria. Median age at HSCT: 36 years (range: 2–69). Male/female ratio: 1.6. Ferremia, Transferrin Saturation (TS) and Serum Ferritin (SF) were analyzed previously to HSCT, at day +7, day+60, day+100 and day+360. Primary Hemosiderosis (PH) was studied by molecular tests. Transfusional IOL were defined when the ferritin levels were more than 1.000 ng/mL. Exclusion criteria were: 1) Active infections during the baseline time-point; 2) Patients wtih previously quelation therapy and 3) PH diagnosis.
Results: According to the source of HSCT: 59 (59.6%) were Autologous, 24 (24.2%) were Allogeneic Related and 16 (16.2%) were Allogeneic not related. Two groups were divided according to ferritin levels: Group 1 (with baseline SF less than 1.000 ng/mL), 44 patients (45%), median SF: 429.9 ng/mL (range: 32-960) and Group 2 (with SF levels more than 1.000 ng/mL), 54 patients (55%), median SF: 2960 ng/mL (range: 1038-12.800). Diagnosis of transfusional IOL according to the source of stem cells: Autologous: 51%, Allogeneic Related: 63% y Allogeneic not Related: 57%. Comparison between both groups were performed related to most important variables (Table 1).

Table 1.

	≥ 20 Transfusions (%)	Grade III/IV Mucositis (%)	Fever between 0 – 100 days (days)	Antibiotics between 0 – 100 days	Hospitalization days
Group 1	2	22	3.5	5.5	26.8
G1 vs G2	**p = 0.001**	**p = 0.008**	**p = 0.001**	**p = 0.001**	**p = 0.001**
Group 2	67	48	6.7	12.7	31.7

	Positives Cultures 0 – 100 days (%)	Sinusoidal Obstruction Symdrome (patients)	Acute GVHD (%)	Neutrophils Engrafment (days)	Platelet Engrafment (days)
Group 1	11.1	0	26.6	19.5	26.9
G1 vs G2	**p = 0.001**	**p = 0.131**	**p = 0.28**	**p = 0.181**	**p = 0.131**
Group 2	40.7	2.6	16	15.5	18.9

	EFS (%)	OS (%)	TRM (%)
Group 1	83	94	2
G1 vs G2	**p = 0.095**	**p = 0.022**	**p = 0.047**
Group 2	70	75	11

Summary and Conclusions: Baseline Serum Ferritin with levels more tan 1.000 ng/mL (Group 2) presented: more tan 20 transfusions, more days of fever, more days of antibiotics, more percentage of positive cultures, more percentage of mucositis grade III/IV and more days of inpatients in the Bone Marrow Transplant Unit. TRM were higher and Overall Survival (OS) were lower in Group 2. At day+100, median SF levels still remains elevated: 3113.2 ng/mL, showing that the body does not have physiologic mechanisms to eliminate the excess of body iron. These results indicate that SF more than 1.000 ng/mL should be considered in prevention transplantation decision-making and also in the post-HSCT period.

P923

LATE LEUKEMIA RELAPSE (LLR) AFTER ALLOGENEIC HEMATOPIETIC STEM CELL TRANSPLANTATION (ALLO-HSCT)

P Bernasconi[1,*], M Boni[1], P Cavigliano[1], R Barbara[1], R Zappatore[1], I Dambruoso[1], I Giardini[1], C Calvello[1], M Caresana[1], A Orlando[1], D Caldera[1], A Colombo[1], F Ripamonti[1], V Fiaccadori[1], R Sciarra[1], A Pompa[1], E Alessandrino[1]
[1]Division of Hematology, Foundation IRCCS Policlinico San Matteo, Pavia, Italy

Background: A LLR may occur in 1-3% of leukemia patients after a post-transplant follow-up period longer than 5 years. As disease recurrence can be determined by recipient's leukemic stem cells re-growth or by donor's HSCs leukemic transformation, conventional cytogenetic/FISH and RT PCR studies play a crucial role in determining the origin of relapse and in activating therapeutic procedures aimed at eradicating the leukemic population.
Aims: The present study was aimed at establishing the incidence and the origin of LLR in a series of 182 patients submitted to allo-HSCT at a single Institution.
Methods: Cytogenetic and FISH studies were carried out as already reported, whereas Quantitative and nested RT PCR assays for Chronic Myeloid Leukemia monitoring was performed according to the Italian LabNet guidelines. Evaluation of chimerism and Minimal Residual Disease (MRD) was performed at day +100, +180, +365 and every six months post-transplant. Conventional cytogenetic studies were performed whenever required.
Results: In our series a LLR occurred in 4 patients (incidence of 2.1%) and was due to recipient's leukemic cells re-growth. They were three females and one male. At the time of allo-HSCT two patients were CML in first chronic phase, one patient an AML in first complete remission (CR) and one patient an AML progressed from a high-risk myelodysplastic syndrome with resistant disease. All patients received a standard BU-CY conditioning, sex-mismatched HSC from a sibling donor and standard GvHD prophylaxis. The two CML patients relapsed as Ph' positive acute lymphoblastic leukemia (ALL) 7 and 16 years post-transplant. On day +100 both patients showed no signs of GvHD, a complete chimera with a normal male karyotype and a negative BCR-ABL nested RT PCR. One month before haematological relapse one patient with no chronic GvHD (cGvHD) was still a complete chimera and MRD negative. The other patient, who on day+329 developed a limited cGvHD, remained a complete chimera without any BCR-ABL transcript until 16 years post-transplant when she complained of otitis and fever. At this time point a marrow examination showed the almost exclusive presence of CD34+, TdT+, CD10+ Ph'+ lymphoblasts and a BCR-ABL/ABL ratio=214,2 (International scale). The t(3;11)(q26;q23) AML in first CR developed an extensive cGvHD on day +183. The patient remained a complete chimera with a normal female karyotype from day +100 to five years post-transplant when he complained of fever. A chest X-ray showed a left pulmonary infection. At this time a marrow examination revealed the almost exclusive presence of blast cells which karyotype was: 50,XY,t(3;11)(q26;q23),+4,+8,t(12;?)(p21;?),-14,+mar1,+mar2, +mar3[13]. The last trisomy 8 positive AML patient with active disease and no signs of GvHD remained a complete chimera with a normal male karyotype until fifteen months post-transplant when she was still on immune-suppressive treatment and devel-

oped an initial first marrow relapse. Upon withdrawal of such a therapy she developed an extensive cGvHD and re-acquired a complete chimera and a normal male karyotype. The complete chimera was maintained until almost ten years post-transplant when she complained of a pain in the left pelvic region. A physical examination revealed a mild splenomegaly and a marrow examination 20% leukemic cells with the following karyotype: 47, XX,+10/48XX, +8,+10. An abdomen CT scan revealed two pelvic masses which biopsy demonstrated leukemic infiltration.
Summary and Conclusions: Our data confirm that LLR is a very rare event potentially caused by a not expected loss of leukemic stem cell quiescence which allows them to escape myeloablative conditioning toxicity. In addition, it raises the question of whether RT PCR is truly the best method to monitor MRD since recent evidence suggests that in CML RT PCR is less sensitive than genomic methods which may identify residual leukemic cells more effectively.

P924

THERAPEUTIC APPROACH TO RELAPSE OF PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

C Moreira[1,*], R Branca[2], F Campilho[2], C Vaz[2], M Rosales[3], S Roncon[3], A Campos[2]
[1]Oncohematology Department, [2]Bone Marrow Transplantation Service, [3]Cell Therapy Service, Instituto Portugues de Oncologia do Porto, Porto, Portugal

Background: Allogeneic stem cell transplantation (allo-SCT) is a potentially curative treatment for patients (pts) with Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL). In 1st complete remission (CR1), disease-free survival (DFS) ranges from 21 to 57%. Relapse is the primary cause of treatment failure (±30% of pts in CR1). Several studies have shown improved DFS for pts treated with tyrosine kinase inhibitors (TKI) prior to allo-SCT. Optimal management of post-transplant relapse is still a matter of debate. Role of TKI is being explored in this setting and results appear promising particularly in pts with low tumor burden [positive Minimal Residual Disease (MRD+)].
Aims: To evaluate relapse in the setting of allo-SCT for Ph+ ALL.
Methods: Retrospective analysis of 30 consecutive pts who underwent allo-SCT for Ph+ ALL at our Center from 1998 to 2012. Data analysis was performed using SPSS.
Results: Cohort of 30 pts (male=17) with a median age of 41.5 years (18.0–53.0). Induction regimen consisted of chemotherapy alone (CT; n=5) and combination CT+TKI (n=25). At allo-SCT, 27 pts were in CR1, 13 with MRD+. Median time from diagnosis to allo-SCT: 8.2 months (4.5–15.7).
Conditioning regimen was busulfan-based myeloablative (n=29) and non-myeloablative (n=1). Donors were matched-related (n=19), matched-unrelated (n=5), mismatched-related (n=1) and mismatched-unrelated (n=5). Stem cells source was peripheral blood (n=26), bone marrow (n=3) and umbilical cord (n=1). Graft-*versus*-host disease (GvHD) prophylaxis consisted of calcineurin inhibitor plus methotrexate (n=28)/mycophenolate (n=2). After the procedure all pts achieved CR, but 5 remained *BCR-ABL*+. Post-transplant 2-year OS and DFS were, respectively, 33.1% and 26.9%; median follow-up: 33.1 months (6.9–77.1). Two-year cumulative incidence of hematological relapse (HR) and isolated molecular relapse (MR) was 39.3%(±9.3) and 12.7%(±6.4), respectively. There was 1 isolated extramedullary relapse (EMR) at 26 months. Four of the 5 pts who remained *BCR-ABL*+ experienced HR (1 under imatinib). Median time to relapse: 4.7 months (1.1–26.0). On univariate analysis, chronic GvHD showed a trend to lower frequency of relapse (26.7% *vs.* 46.7%, P=0.07). On multivariate analysis, the only factor associated with relapse was pre-SCT treatment [at 6-month: 60%±19.2 (CT) *vs.* 20.2%±8.0 (CT+TKI), P=0.048]. Treatment approach to relapse was heterogeneous: IS reduction (↓IS; n=1), ↓IS+TKI (n=3), CT+TKI (n=2), CT+TKI+DLI (donor lymphocyte infusion; n=3), TKI+DLI (n=1), orchidectomy+CT+DLI (n=1) and CT+2nd allo-SCT (n=2). Two early deaths occurred after relapse. Four of the 11 pts with HR obtained CR after CT+TKI+DLI (n=3) and TKI+DLI (n=1), yet 2 remained MRD+. The pt with EMR obtained CR after orchidectomy+CT+DLI. All pts with MR achieved complete molecular response (↓IS+TKI=2; ↓IS=1). Five of the 8 pts who responded are still alive and 2 remain disease-free (18.0 and 62.4 months after HR and MR, respectively). Post-relapse 2-year OS and DFS were 36.4% and 21.4%, respectively. Five pts experienced a 2nd relapse (HR=3, MR=1, EMR+HR=1) and 1 pt, who remained *BCR-ABL*+ after HR, had molecular progression 2 months after CR.
Summary and Conclusions: Our study confirms that Ph+ ALL has a high incidence of relapse, even after allo-SCT. CT without TKI before allo-SCT was the only statistically significant factor associated with relapse. Heterogeneity of treatment options in this series reflects the difficulty of managing post-transplant relapse. TKI and immunotherapy (DLI or ↓IS) appear to have a major role in relapse treatment.

P925

IMPACT OF THE 2009 UK UMBILICAL CORD BLOOD TRANSPLANT CONSENSUS STATEMENT ON PRACTICE AND OUTCOMES AT A SINGLE TRANSPLANT CENTRE

P Miller[1], C Anthias[1,*], K Mohammed[2], J Brennan[1], I Hancock[3], H Leonard[1], M Ethell[1], M Potter[1], B Shaw[1]
[1]Haemato-Oncology, [2]Clinical Research and Development, [3]Paedatric Haemato-Oncology, Royal Marsden Hospital, London, United Kingdom

Background: Umbilical cord blood (UCB) transplants have become standard practice in the treatment of malignant and non-malignant hematological disorders. We have performed UCB transplants at the Royal Marsden Hospital (RMH) since 2006; however practice has increased and changed over time due to encouraging international results, two UK clinical trials and publication of a UK consensus statement. The recommendations from the consensus statement were adopted at RMH in 2009.
Aims: Our first aim was to establish whether recommended conditioning regimens have been used consistently in UCB transplants at RMH since 2009. Our second aim was to compare the outcome for recipients of UCB transplant pre and post 2009.
Methods: We performed a retrospective analysis of the records of all UCB transplant patients at RMH between 2006 and 2012. We reviewed a total of 37 records of 24 adult and 13 pediatric patients. We compared results according to the transplant era (pre and post 2009). Incidence of non-relapse mortality, relapse, and acute graft *versus* host disease (aGvHD) were calculated using competing risk analysis.
Results: Eighteen UCB transplants were performed before 2009 and 19 have been performed since. The overall median follow-up time was 28.6 months (95% CI 10.7-46.4). Median follow-up pre 2009 was 44 months (95% CI 25.7-62.2), and post 2009 was 18.6 months (95% CI 15.8-21.3). The overall one year survival rate was 49% (95% CI 32-65%). One year survival among the pre 2009 group was 33% (95% CI 12-55%) *versus* 66% (95% CI 36-97%) in the post 2009 group (P=0.097). Cumulative incidence of one year non-relapse mortality pre 2009 was 39%, and post 2009 was 16% (P=0.186). Cumulative incidence of relapse at one year pre 2009 was 28%, and post 2009 was 24% (P=0.754). Cumulative incidence of acute graft *versus* host disease (aGvHD) was 56% pre 2009 and 47% post 2009 (P=0.699). Neutrophil engraftment by day 42 was achieved in 16 patients (89%) in the pre 2009 group and 17 patients (90%) in the post 2009 group. Epstein-Barr virus (EBV) reactivation requiring treatment (PCR >40,000 copies/mL) occurred in 5 (28%) patients in the pre 2009 group. No patients in the post 2009 group required treatment for EBV reactivation (P=0.017). Before 2009 seven different conditioning regimens were used. Six patients (33%) received regimens that were subsequently recommended in the consensus statement. After 2009, 19 (100%) patients received one of the recommended conditioning regimens. Pre 2009 no patients were treated as part of a UCB transplant clinical trial compared with 6 patients (32%) post 2009.
Summary and Conclusions: Following publication of the 2009 consensus statement, all UCB transplant patients at RMH were treated with one of the four recommended conditioning regimens. Post 2009 there is a trend towards better one year survival. This may be explained by a standardized approach, but the recognized improvement in outcome with centre experience, and the inclusion of more patients in clinical trials may also have contributed. Non-relapse mortality and relapse rates are not significantly different between the two groups. Post 2009 antithymocyte globulin was no longer used in conditioning regimens. Despite this, rates of aGVHD were similar between groups. However, this may have contributed to the significant reduction in EBV reactivation in the post 2009 group. Overall, these results are encouraging, and multi-centre investigation is warranted to see if these findings are borne out in larger patient groups.

P926

CMV-SPECIFIC CD8+ T-CELL IMMUNE RECOVERY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION MONITORED BY HLA-MULTIMERS

M Ciaurriz[1], L Beloki[1], N Ramirez[1], A Zabalza[1], C Mansilla[1], E Bandres[1], M Calvillo[1], E Olavarria[1,*]
[1]NavarraBiomed, Pamplona, Spain

Background: CMV reactivation remains an important problem in allogeneic stem cell transplantation.
Aims: We investigated the use of multimers in monitoring CMV-specifc T-cell immune reconstitution after allogeneic stem cell transplantation
Methods: We present the results of a pilot study using pentamer (PM) and streptamer (ST) multimer complexes for monitoring CMV-specific CD8+ T-cells (CTLs). We analysed 14 patients that underwent allogeneic Stem Cell Transplantation (allo-SCT). All patients and donors were positive for the HLA-A*02:01 allele. PM and ST were directed against the epitope NLVPMVATV (495-503) of the CMV phosphoprotein 65 (pp65). Samples were obtained at 15-day intervals until day +90 and monthly thereafter.
Results: Three patterns were observed. In 2 patients (14%) no CMV-specific-

CTLs could be detected despite several CMV reactivations, requiring prolonged cumulative antiviral therapy (67 and 136 days each). In 6 patients (43%) CMV reactivation occurred at a mean of 36 days (10-74) and triggered a rapid increase of CMV-specific-CTLs with a median of 6.9 × 105/L (range 0.02-279.7). The CMV-PCR became immediately negative and antiviral therapy was stopped promptly after a median of 15.3 days (8.7-23). Finally, 6 patients (43%) showed an early immune reconstitution with CMV-specific-CTLs detected with a median of 1.53 × 105/L (range 0.2-54.72) in the absence of CMV-PCR reactivation at a median of 20.5 days (10-34) post-SCT. No CMV-PCR reactivation was observed in this group with a median follow-up of 8 months (3-14).
Summary and Conclusions: Monitoring CMV-specific-T-cells might be able to distinguish patients at higher risk of recurrent virus reactivation and in need of prolonged antiviral therapy. Patients with increasing CMV-specific-CTLs detectable at the time of CMV-PCR reactivation may only need a short course of antiviral therapy, while those with early CMV-specific-CTLs may be protected from CMV reactivation.

Hematopoiesis

P927

IDENTIFICATION OF THE EARLIEST BRANCH POINT FOR MYELO-ERYTHROID DEVELOPMENT IN ADULT HEMATOPOIESIS

K Miyawaki[1,*], Y Arinobu[2], H Tsuzuki[1], H Iwasaki[2], K Akashi[1]
[1]Dept of Medicine and Biosystemic Science, Kyushu University, [2]Center for Cellular and Molecular Medicine, Kyushu University Hospital, Fukuoka, Japan

Background: In murine hematopoiesis, the myeloid *vs.* lymphoid lineage commitment downstream of multipotent stem/progenitor cells was first demonstrated outside of the Lineage$^-$ Sca-1$^+$ c-kit$^+$ (LSK) fraction, where common myeloid progenitor (CMP) and common lymphoid progenitor (CLP) were prospectively isolated (Akashi *et al.*, Nature 2000). Thereafter, by utilizing mice harboring a fluorescent reporter for GATA-1 transcription factor, we proposed that the initial uP-regulation of GATA-1 within LSK fraction marked the earliest progenitor population which fully committed to the myelo-erythroid lineage. (Arinobu *et al.*, Cell Stem Cell 2007). However, the significance of GATA-1$^+$ LSK in normal and malignant hematopoiesis is still elusive because the corresponding population in wild-type mice has not been identified.
Aims: The purpose of present study is to identify the earliest myelo-erythroid progenitor corresponding to GATA-1$^+$ LSK in wild-type mice as well as to evaluate the physiological significance in normal and leukemic hematopoiesis.
Methods: In order to identify the cell surface markers specifically expressed on GATA-1$^+$ LSK, cDNA microarray analyses were conducted. LSK population was subdivided by using these specific surface markers. Lineage read-outs of isolated populations were analyzed *in vitro* cultures and *in vivo* congenic transplantation assays. Gene expression profiling of the normal counterpart of GATA-1$^+$ LSK was analyzed by cDNA microarray and single cell quantitative RT-PCR. Furthermore, the physiological significance of this population in myelopoiesis was evaluated by the systemic bacterial infection model (cecal ligation and puncture) and the bcr-abl transduced myeloproliferative neoplasm model.
Results: Gene expression profiling revealed several candidates for surface antigens specifically expressed on GATA-1$^+$ LSK. Among them, a high level expression of CD41 clearly marked GATA-1$^+$ LSK by FACS analysis. CD41^{hi} LSK purified from wild-type mice gave rise exclusively to GM and MegE colonies at the expense of lymphoid colonies and showed robust GM and MegE differentiation potential *in vivo*, lacking lymphoid read-outs. CD41^{hi} LSK possessed strong and long-lasting reconstitution potential compared to LMPP or CMP, presumably reflecting their immaturity. The head-to-head competitive transplantation assay, in which 500 CD41^{hi} LSK cells were injected together with same numbers of LMPPs or CMPs into an individual recipient, also demonstrated that CD41^{hi} LSK gave rise to 10-fold larger number of mature GM cells compared to the original CMPs or LMPPs. In concordance with their myelo-erythroid lineage restriction, CD41^{hi} LSK expressed both GM- and MegE-affiliated genes but not lymphoid genes. Concerning lineage-instructive transcription factors, each single CD41^{hi} LSK cell expressed either one or both of GATA-1 and PU.1 at a very low level, reflecting the priming status of myeloid *vs.* erythroid fate dicision (Miyamoto *et al.*, Developmental Cell 2002). In order to explore the physiological significance of CD41^{hi} LSK, we generated mouse models of systemic bacterial infection as well as myeloproliferative neoplasm induced by bcr-abl transduction. CD41^{hi} LSK but not LMPP robustly expanded in both infectious and leukemic models, indicating that CD41^{hi} LSK is a critical checkpoint for physiological and malignant myelopoiesis.
Summary and Conclusions: CD41^{hi} LSK represents the earliest branch point of myelo-erythroid development and resides upstream of the conventional CMP which was originally identified outside of LSK. CD41^{hi} LSK is mainly involved in both physiological and malignant myelopoiesis. Based on these data, we propose to redefine the true CMP as CD41^{hi} LSK population.

P928

FUNCTIONAL RELEVANCE OF AUTOTAXIN (ATX) AND LPA RECEPTOR EXPRESSION IN NORMAL HEMATOPOIETIC STEM CELLS AND PRIMARY MESENCHYMAL STROMAL CELLS

C Ortlepp[1,*], T Jacob[1], M Wobus[1], B Martin[1], G Ehninger[1], C Thiede[1]
[1]Medical Clinic I, University Hospital Dresden, Dresden, Germany

Background: The proliferation and differentiation of hematopoietic stem and progenitor cells (HSPCs) within the human bone marrow is characterized by a tightly regulated micro-environment in the stem cell niche. Besides cell-cell interactions of HSPCs and mesenchymal stromal cells (MSCs) and several cytokines and growth factors, various other soluble factors determine stem cell fate. Among these, small bioactive lipids, *e.g.* sphingosine-1-phosphate (S1P) and lysophosphatidic acid (LPA), have recently attracted attention.
Lysophosphatidic acid (LPA) is mainly generated by the lysophospholipase D-activity of the secreted enzyme autotaxin (ATX). LPA binds to specific G-protein coupled receptors on the cell surface and thereby increases migration and proliferation of various cell types, *e.g.* T-cells. We recently identified for the first time high ATX expression in specific subsets of human leukemic as well as

HSPCs, namely CD34+ cells and could confirm an autocrine function of the protein in these cells (Ortlepp *et al.*, Exp. Haematol, in press).
Aims: To further understand the role of ATX in human hematopoiesis, we characterized expression and activity of ATX and LPA-receptors in HSPCs as well as in MSCs, the dominant cell type within the hematopoietic niche.
Methods: Primary HSPC and MSC were obtained from healthy stem cell and bone marrow donors after informed consent. Expression and enzymatic activity was characterized using RT-PCR, Western blot and specific substrate assays (FS-3). Functional activity was studied using transwell migration assays, the proliferative capacity was tested by MTT assays, whereas the clonogenic potential was investigated using colony-forming assays in the presence of the specific substrate lysophosphatidyl choline (LPC) as well as the specific small-molecule ATX-inhibitor.
Results: To our surprise, ATX expression found in primary human MSCs was 5 to 10-fold higher than in CD34+ and leukemic cells. Inhibition of ATX in MSC resulted in a 50% reduction of MSC-vitality. Although ATX levels expressed in primary HSCs were considerably lower than in MSCs, our data indicate that ATX is an important autocrine factor for migration and vitality of these cells, since addition of LPC and LPA in absence of MSCs increased CD34+ HSC migration by 15 and 30%, respectively. Blocking of ATX decreased vitality to 20%, reduced colony growth and led to aberrant differentiation especially within the erythroid and myeloid lineage. Sorting experiments of different HSPC-populations (CD34+/- and CD38+/-) indicate that high ATX- mRNA expression was found in all CD34-positive subpopulations, whereas CD34-/CD38+ cells showed significantly lower expression. LPA-receptor profiling revealed almost exclusive expression of the LPA1-receptor in MSCs, whereas HSPCs express predominantly the LPA2-receptor, with a 50%>higher expression in CD34-/CD38+ compared CD34+/CD38- cells.
Summary and Conclusions: Taken together, our data indicate that ATX is highly expressed within the bone marrow micro-environment. Our results show that the expression originates not only from stromal cells but also that HSCs can produce ATX in an autocrine fashion, suggesting that interference with its function may have a profound effect on cell migration and differentiation.

P929

STEM CELL ZINC FINGER 1 (SZF1)/ZNF589: A PRIMATE-RESTRICTED GENE, DIFFERENTIALLY EXPRESSED AFTER HYPOXIC STRESS AND REGULATING THE PROLIFERATION OF HEMATOPOIETIC CELLS
L Venturini[1,*], M Stadler[1], MScherr[1], A Ganser[1]
[1]Hematology, Hemostasis, Oncology, Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: The Stem cell Zinc Finger 1 (SZF1)/ZNF589 protein belongs to the large family of Krüppel-associated box domain (KRAB) zinc finger transcription factors, only present in higher vertebrates, which epigenetically repress transcription by recruiting chromatin modifying complexes to the promoter regions of their target genes. Although the distinct biological functions of most KRAB-zinc finger proteins remain unknown, recent publications demonstrate their implication in fundamental processes, such as cell proliferation and apoptosis, differentiation, development, and tumorigenesis. SZF1/ZNF589 was identified by Liu *et al.* (1999) as a gene with one of two isoforms specifically expressed in CD34+ cells, strongly suggesting a role in epigenetic control of gene expression in hematopoietic stem cells (HSCs). However, the function of SZF1/ZNF589 in hematopoiesis has not yet been studied.
Aims: Structural and functional characterization of the SZF1/ZNF589 stem cell zinc finger protein and the investigation of its role in the hematopoietic system.
Methods: Lentiviral-mediated overexpression of specific shRNAs to induce stable knock-down of the SZF1/ZNF589 protein in hematopoietic cells.
Results: We found that SZF1/ZNF589 is a primate-restricted gene. Interestingly, the human SZF1/ZNF589 gene contains a species-specific evolutionary genomic DNA change introducing a premature stop codon at the place of the second cysteine residue in the 5th zinc finger domain, apparently leading in humans to truncation of the protein with loss of the last 11 zinc finger domains. We confirmed the human-specific sequence change at the genomic and mRNA level in human and monkey cell lines. Interestingly, Western-Blot experiments revealing either endogenous or tagged-overexpressed SZF1/ZNF589 proteins demonstrated that the human SZF1/ZNF589 mRNA encodes two peptides: one of predicted molecular weight of 41 kDa generated by termination at the premature stop codon, and a second one of 86 kDa, like SZF1-2/ZNF589 of the other primates, probably generated by suppression of translational termination at the UGA stop codon. This human-specific sequence change demonstrates the still ongoing evolution of the SZF1/ZNF589 gene and could result in the incorporation in humans of a selenocysteine at the place of a cysteine in other primates. We performed loss-of-function studies in the K562 and MV4-11 hematopoietic cell lines by lentiviral gene transfer to induce stable SZF1/ZNF589 knockdown. Two different SZF1/ZNF589 specific shRNAs decreasing 2 to 4 fold the expression of the SZF1/ZNF589 transcript and protein both resulted in the same phenotype reducing the proliferation of hematopoietic cells to about 60%. Treatment of cells with $CoCl_2$ 300µM to mimic hypoxia conditions demonstrated the induction of differential isoform expression with disappearance of the small isoform of SZF1/ZNF589, as observed by Western-Blot. This suggests that the balance between the two SZF1/ZNF589 isoforms is regulated by hypoxia.
Summary and Conclusions: In summary, our results demonstrate that SZF1/ZNF589 is a primate-restricted gene, with a human-specific DNA-change conferring potential species-specific DNA-binding properties. It regulates proliferation of hematopoietic cells and is differentially expressed under hypoxic stress conditions. Hypoxia is a typical feature of the bone marrow HSC niche and belongs to the micro-environment components controlling HSC quiescence and mobilization. Thus, SZF1/ZNF589 might be implicated in regulatory pathways involved in maintenance, proliferation and differentiation of HSCs.

P930

COMBINED ECTOPIC OVEREXPRESSION OF GABP SUBUNITS IMPAIRS CELLULAR PROLIFERATION AND VIABILITY, AND INDUCES MYELOID DIFFERENTIATION IN VITRO
T Ripperger[1,*], G Manukjan[1], J Meyer[2], U Modlich[2], Z Li[2], J Bohne[3], A Schambach[2], B Schlegelberger[1], D Steinemann[1]
[1]Institute of Cell and Molecular Pathology, [2]Institute of Experimental Hematology, [3]Institute of Virology, Hannover Medical School, Hannover, Germany

Background: The heteromeric transcription factor complex GA-binding protein (GABP) consists of two subunits, the alpha subunit (GABPA) carrying the DNA-binding ETS domain, and the beta subunit (GABPB1) harboring the transcriptional activation domain (TAD). Using murine knock-out models, GABP was shown to be involved in the self-renewal of hematopoietic stem cells and the differentiation of myeloid and lymphoid lineages. Moreover, recent studies displayed an impaired BCR-ABL-mediated transformation in GABP knock-out mice.
Aims: To further elucidate the molecular function of GABP in human hematopoietic cells as well as to investigate its putative role in leukemia, we studied its effects on proliferation, viability and myeloid differentiation by ectopic overexpression of GABP subunits either alone or in various combinations.
Methods: Human GABPA and GABPB1 cDNAs were overexpressed in BaF3, 32D, SC-1 and U937 cells using the retroviral expression vectors pRSF91.IRES.eGFP.pre* or pRSF91.IRES.dTomato.pre*. Directed deletion mutants targeting the ETS domain, the heterodimerization domain of GABPA, and the TAD of GABPB1 were used as functional controls. To modulate ectopic expression, subunits were fused to a degradation domain derived from an FKBP1A mutant cDNA that led to rapid degradation of the fusion proteins. By the addition of Shield1 (Takara/Clontech) these fusion proteins were stabilized and offer a tunable system for studying GABP dose effects.
Results: Combined overexpression of GABPA and GABPB1 (isoform β2), the predominant isoform in human hematopoietic cell lines, impairs the proliferation of myeloid and lymphoid cell lines, an effect that was not observed when GABPA or GABPB1 were overexpressed alone. When combining deletion mutants of one subunit with the wild-type protein of the respective other subunit, proliferation inhibition was drastically reduced, thereby demonstrating that functional GABP is critical for the observed proliferation inhibition that was confirmed in the murine pro-B cell line BaF3. In addition, combined overexpression of wild-type GABP subunits in lineage-negative primary bone marrow cells from C57BL/6J mice led to an almost complete loss of colony-forming capacity. Besides this proliferation block, a reduction of cellular viability was observed in U937 cells when metabolically active cells were monitored using WST-1. In U937 cells, frequently used as a human myeloid differentiation model, further analyses displayed a dose and GABPB1 isoform-dependent induction of CD11b by flow cytometry. Vice versa, shRNA-mediated knock-down of GABPA impairs PMA-directed monocyte-like differentiation of U937. Prolonged culturing of U937 cells co-expressing both GABP subunits finally led to the expression of CD14 and a monocyte-like morphology seen in Wright-Giemsa stained cytospins. Concordantly, combined overexpression of alpha and beta subunits led to the expression of Gr-1 in the myeloblast-like cell line 32D.
Summary and Conclusions: Ectopic overexpression is a feasible tool to elucidate the molecular function of GABP in hematopoietic cells. Moreover, the established tunable protein stabilization system can be used for more precise investigation of dosage effects. Concerning the impaired cellular viability, the proliferation block and cellular differentiation, observed even in an immortalized leukemia cell line, our results support the critical and powerful role of GABP in hematopoietic network maintenance and cellular differentiation. Further investigations are underway to study the effects of combined ectopic overexpression in more detail, and to learn for example (i) whether the impaired cellular viability is the result of actively induced apoptosis, (ii) how the proliferation block is achieved, and (iii) whether *CD11B* is a direct target gene of GABP.

P931

DECREASED EXPRESSION OF DICER1 IN BONE MARROW MESENCHYMAL STROMAL CELLS FROM PATIENTS WITH HEMATOLOGICAL MALIGNANCIES
S Yeh[1,*], W Lo[2], Y Huang[2], C Lin[2], L Bai[1], C Chiu[1]
[1]Medicine, [2]Medical Research, China Medical University Hospital, Taichung, Taiwan

Background: Bone marrow-derived mesenchymal stromal cells (BM-MSC) are the stromal cells that may interact with the cancer cells of leukemia and myelodysplastic syndrome (MDS). Recently, a study conducted by Raaijmakers *et al.* showing primary defect (*Dicer1* deletion) in BM stromal cells is sufficient to induce MDS/AML in a murine model (Nature 2011). It is not known whether this model can be applied to the real world patients of MDS/AML and other hematological malignancies.
Aims: To elucidate any potential relationship between *Dicer1* expression in BM-MSCs of normal adults and various hematological malignancies and the prognostic impact on the induction outcome (chemo-sensitive or chemo-resistant). Besides, we also want to see whether the expression level of Dicer would be influenced by the change of disease status (complete remission or relapse).
Methods: 66 samples of BM-MSCs isolated from 62 patients of hematological malignancies were selected for analysis. 44 samples of them were collected from patients at initial diagnosis of disease, including AML (17), MDS (8), ALL (7), myeloma (8), and Philadelphia-chromosome positive CML (Ph-CML, 4). 8 samples of them were collected from normal healthy adults. Another 14 samples of them were collected from patients of AML after receiving standard chemotherapy, 6 in a status of complete remission and 8 in relapse. "3 pairs" of BM-MSCs from 3 AML patients at different clinical status were also examined to see the influence of disease status on the expression of *Dicer1*. Quantification of expression of *Dicer1* was done by using the Real-Time PCR System. The expressions of *Dicer1* were normalized against that of housekeeping gene *GAPDH*. A fold change in expression was calculated using the $2^{-\Delta\Delta Ct}$ formula.
Results: The expression of *Dicer1* (expressed as $2^{-\Delta\Delta Ct}$, mean±standard deviation) in BM-MSCs is significant lower in patients of AML (2.029±1.815), MDS (2.112±1.161), CML (1.678±1.060), ALL (1.348±1.405), and tend to be lower in patients of MM (2.469±1.540) comparing to that of normal adults (3.782±1.327; *P*=0.010, 0.012, 0.027, 0.004, and 0.074 respectively, Mann-Whitney U test; Figure 1). After adjust for the effect of age, gender, and cytogenetic status by using ANCOVA, the expression of *Dicer1* remains significantly low in patients with hematological malignancies (F=7.601, *P*=0.008). For AML patients at initial diagnosis, the expression of *Dicer1* in BM-MSCs do not differ significantly between patients who responded to induction (n=7; 2.234±2.051) and patients who refractory to induction (n=4; 1.469±1.449; P=1.000, Mann-Whitney U test). For AML patients who had received standard chemotherapy, however, the expression of *Dicer1 in* BM-MSCs was significantly lower for patients in refractory or relapsed status (n=8; 2.421±0.885) than that of patients in complete remission (n=6; 4.941±3.096; *P*=0.020, Mann-Whitney U test, Figure 1). For the "3 pairs" of BM-MSCs from 3 AML patients, the expression of Dicer1 was much higher when disease was in remission comparing to that in diagnosis or in relapse.

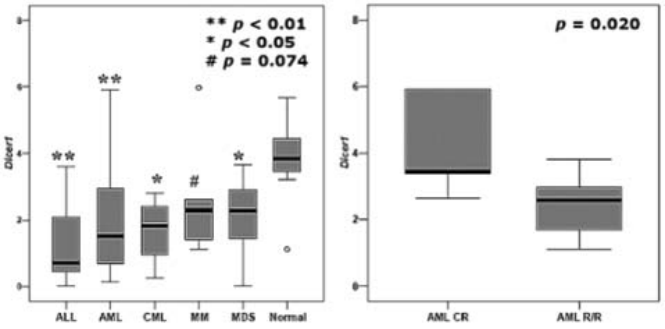

Figure 1.

Summary and Conclusions: Down-regulation of *Dicer1* in BM-MSCs is not a unique feature for MDS/AML, it can also be seen in other hematological malignancies, including disease with clear leukemogenic mechanism like Ph-CML. Decreased expression of *Dicer1* in BM-MSCs may therefore not be the "primary event" in leukemogenesis. Rather, our data clearly showed the expression level would be different when the disease status was altered, indicates the expression of *Dicer1* in BM-MSCs could be modulated by the neighboring hematological cancer cells. Future studies are needed to elucidate how the expression of *Dicer1* is modulated, and what's the physiological impact in real world patients.

P932

FUNCTIONS OF JARID1B IN THE REGULATION OF HEMATOPOIESIS AND LEUKEMOGENESIS

J Zhang[1,*], K Ng[1], L Chan[1]
[1]Pathology, The University of Hong Kong, Hong Kong, Hong Kong

Background: One of the mechanisms involved in the control of development is through epigenetic regulation of histone proteins. Of these, lysine methylation on histone proteins is considered an important epigenetic modification in transcriptional regulation during hematopoiesis and leukemogenesis. Whilst JARID1B, a member of the JARID1 histone 3 lysine 4 (H3K4) demethylases, was found essential for the self-renewal of embryonic stem cell and melanoma stem-like cell and involved in transcriptional regulation of cell cycle, such as mouse *Egr1*, *Bmi-1*and *p27*, during embryo development. In addition, JARID1B is involved in the terminal differentiation of neural cells and the expression of oncogenic microRNAs during macrophage differentiation. However, the function of JARID1B in hematopoiesis and leukemogenesis has not been systematically studied. We believe that JARID1B has the potential to play crucial role in hematopoietic stem cell self-renewal and differentiation, while its dysregulation is associated with the deregulation of leukemia gene transcription program.
Aims: To identify expression profiles of JARID1B in leukemia and hematopoietic cells, and the effect of knock down on cellular proliferation, differentiation and self-renewal properties in leukemic cell lines and hematopoietic stem cells.
Methods: Gene expression patterns of JARID1B were examined by qPCR analysis in 28 human leukemia cell lines, 20 whole white blood cell samples from CML (Chronic Myeloid leukemia) patients, and normal mouse/human hematopoietic cell populations–this include hematopoietic stem cell, common myeloid progenitor, common lymphoid progenitor, T cell, B cell, NK cell, monocyte, neutrophil, dendritic cell. Lentivirus based shRNA gene knock-down approach was used to study the cellular functions of JARID1B in K562 leukemic cell line and in mouse hematopoietic stem cells (Lin-/Sca-1+/c-Kit+). Proliferation, differentiation and self-renewal abilities were examined by PI (Propidium Iodide) staining, cell counting and colony formation assay.
Results: The expression profile of *JARID1B* in a panel of normal hematopoietic cells demonstrated that it was more than 3-fold uP-regulated in differentiated hematopoietic cells, when compared with the hematopoietic stem cells and progenitor cells, suggesting that the enhanced cellular level of JARID1B is associated with the loss of cell self-renewal properties and the initiation of hematopoietic lineage commitment. In contrast, JARID1B expression in most of the leukemia cell lines and CML patient samples were about 3-fold down-regulated. Although knockdown of JARID1B in K562 leukemic cell line and in normal mouse hematopoietic stem/progenitor cells showed no significant changes in cell proliferation and cell-cycle pattern, we observed a reduction on total colony formation number in serial re-plating assays, suggesting a basal cellular level of JARID1B is required to maintain self-renewal property.
Summary and Conclusions: Our results show the levels of expression of JARID1B are low in leukemic cells lines and with lower expression levels seen in progenitor and stem cells compared to mature hematopoietic cells. This pattern of expression together with knock out of JARID1B causing a reduction in self-renewal properties in leukemic cell lines and hematopoietic stem cells suggest a role for JARD1B in the control of hematopoiesis and in leukemogenesis.

P933

ROLE OF BMI-1 IN NORMAL MOUSE HEMATOPOIETIC STEM CELLS AND LEUKEMIC CELLS

Y Lam[1,*], LChan [1], K Ng[1]
[1]Pathology, The University of Hong Kong, Hong Kong, Hong Kong

Background: Bmi-1, as a key component in polycomb repressive complex1, plays an indispensable role in the regulation of cell proliferation, self-renewal and multi-lineage differentiation of hematopoietic stem cells (HSCs). Previously, Bmi-1 was reported as a negative regulator of *Ink4a-Arf* tumor suppressor gene locus and *Ikaros* lymphoid priming gene in HSCs. However, little is known about the other downstream cellular targets of Bmi-1 in the control of self-renewal and multipotency in HSCs. Besides, aberrant expression of BMI-1 was observed in human leukemias such as acute myeloid leukemia, chronic myeloid leukemia, and B-cell non-Hodgkin lymphoma, suggesting the deregulation of BMI-1 is highly associated with leukemogenesis, yet its function remains unclear.
Aims: To study the epigenetic regulatory mechanism of *Bmi-1* in proliferation and self-renewal of hematopoietic stem cells and to find out how *Bmi-1* regulates the leukemogenic features of SEM leukemic cells.
Methods: In normal hematopoiesis, hematopoietic stem cells with Lin$^-$Sca-1$^+$c-Kit$^+$ phenotype were isolated from mouse bone marrow and were subjected to *Bmi-1* gene manipulation. Fsunctional assays were performed in *Bmi-1* knockdown or over-expressed LSK cells, including (a) colony forming assay to assess the self-renewal property, (b) cell cycle pattern analysis by PI staining, (c) qRT-PCR to examine the expression of potential *Bmi-1* target genes. In leukemia condition, *BMI-1* was over-expressed in SEM cells and analysed the leukemic properties by the above functional assays.
Results: Q-RT-PCR analysis demonstrated that knockdown of *Bmi-1* gene in HSCs leads to de-repression of $p16^{Ink4a}$ and $p19^{Arf}$genes, without alteration of other cell cycle regulators and hematopoietic lineage genes, suggesting that the reactivation of *Ikaros* lymphoid priming gene may represent a late differentiation event. Interestingly, cell cycle analysis showed that depletion of *Bmi-1* drives cells from G0/G1 phase to S phase, which opposites to the effect of the elevated $p16^{Ink4a}$ and $p19^{ARF}$ expression in blocking the entry to S phase, suggesting that an p16/p19-independent regulatory pathway may exist in HSCs. Colony forming assay also demonstrated reduced colony forming ability in *Bmi-1* knockdown HSCs, which indicates defects in the self-renewal ability, whereas overexpression of Bmi-1 maintains cell proliferation and promotes colony forming ability. In BMI-1 over-expressing leukemic SEM cells, we observed reduced cell proliferation and loss of colony forming ability, demonstrating a negative regulatory role of BMI-1 in the leukemogenic features of SEM cells. Interestingly, $p14^{ARF}$

and *p19INK4A* gene expression was independent of BMI-1 regulation in SEM cells, suggesting an altered function of BMI-1 in leukemia.
Summary and Conclusions: Bmi-1 plays a vital role in sustaining cell proliferation and self-renewal of normal hematopoietic stem cells, which is in contrast to its inhibitory function under leukemic condition.

P934

CONNECTIVE TISSUE GROWTH FACTOR (CTGF) CONFERS CELL ADHESION-MEDIATED DRUG-RESISTANCE (CAM-DR) IN ACUTE MYELOID LEUKEMIA

S Pante[1,*], A Schüler[1], K Kunz[1], J Larsson[2], J Cammenga[2], M Theobald[1], T Kindler[1]
[1]Third Department of Medicine Hematology, Oncology and Pneumology, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, [2]Molecular Medicine and Gene Therapy, Lund Stem Cell Center, Lund, Sweden

Background: Acute myeloid leukemia (AML) is a heterogeneous disorder of the hematopoietic progenitor cell characterised by a differentiation block and uncontrolled proliferation. Although several mechanisms of leukemic transformation have been identified, the prognosis of AML patients is still poor. There is increasing evidence that leukemic stem cells are protected against cytotoxic stress in the bone marrow niche (cell adhesion-mediated drug–resistance, CAM-DR). Targeting the interaction of stromal and leukemic cells seems to represent a promising therapeutic approach and is currently investigated in several clinical trials (*e.g.* CXCR4-inhibitors). Recent data suggest that the CCN family of cysteine-rich secreted proteins is an important mediator of cell adhesion and extracellular matrix (ECM) modulation in physiological as well as in malignant processes. CCN1 (cysteine-rich protein 61, Cyr61) and CCN2 (connective tissue growth factor, CTGF) are major targets of the transcriptional cofactors YAP/TAZ which act as the key downstream mediators of the mechano-sensitive hippo signalling pathway. YAP and TAZ were found to confer stem cell capacities and drug resistance in different solid cancers. In AML the hippo pathway and the function of CTGF is only poorly understood.
Aims: The purpose or this study was to identify and validate new factors involved in niche–leukemia interaction and CAM-DR.
Methods: We used a well-established coculture system comprised of the leukemic cell line MOLM14 and the stromal cell line MS5. To identify target genes within the leukemic niche, we performed a qRT-PCR array covering 84 known ECM and adhesion genes using cDNA of MOLM14 and MS5 maintained in co- or monoculture for 72 h. Differentially regulated genes were confirmed using RQ-PCR and functionally validated upon shRNA-mediated knockdown.
Results: In our qRT-PCR array, we identified a 12-fold upregulation of CTGF in cocultured MOLM14 cells. Independent experiments confirmed increased CTGF expression in MOLM14, OCI-AML and MV4;11 cells when cultured with stroma. Further, we also detected a substantial upregulation of Cyr61 in these cell lines. Similar results were found upon culture on fibronectin or 293FT cells. To mimic conditions in the bone marrow niche more accurately, we repeated the experiments under hypoxic conditions. Again, we found upregulation of CTGF and Cyr61. Finally, we observed only minor upregulation when MOLM14 cells were separated from stroma by transwells. These date suggest that upregulation of CTGF and Cyr61 is a common phenomenon in AML cells, is independent on the used feeder layer but requires direct contact. As CTGF and Cyr61 are targets of the transcriptional cofactors YAP/TAZ, we investigated the expression of TAZ upon coculture on MS5 cells. Protein levels of TAZ became readily detectable in MOLM14 cells upon coculture but not in monoculture. As we did not observe any changes in mRNA levels, we assume posttranslational modifications causing stabilization of TAZ. To investigate whether TAZ is indeed involved in the regulation of CTGF we performed shRNA-mediated knockdown of TAZ in MOLM14 cells. This resulted in reduced expression of CTGF and Cyr61 upon coculture. To functionally examine the role of CTGF in CAM-DR, we performed CTGF knockdown-experiments. MOLM14 cells, transduced with CTGF-shRNA were cultured on MS5 cells and treated with Ara-C for 72 h. Knockdown of CTGF caused a significant (**) inhibition of the observed CAM-DR in MOLM14 cells (Figure 1).

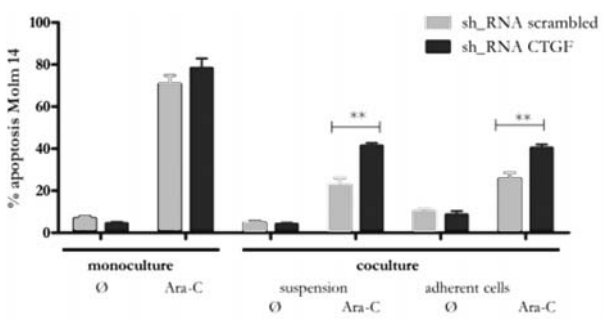

Figure 1. CTGF is crucial for rescue effect in coculture.

Summary and Conclusions: In this study we identified two members of the CCN family, CTGF and Cyr61, to be upregulated in cocultered AML cell lines. Our data suggest that the hippo pathway is the upstream-regulatory mechanism. Knockdown of CTGF enhances apoptosis in coculture, indicating an important function in CAM-DR. Therefore, targeting CTGF might be a promising therapeutic approach in AML.

P935

HUMAN BONE MARROW ADIPOCYTES MAINTAIN THE SURVIVAL AND DIFFERENTIATION OF HEMATOPOIETIC STEM CELLS

A Poloni[1,*], G Maurizi[1], S Mancini[1], P Leoni[1]
[1]Dipartimento di Scienze Cliniche e Molecolari, Clinica di Ematologia, Università Politecnica delle Marche, Ancona, Italy

Background: Active hematopoietic bone marrow declines with age and is gradually converted to fatty marrow, that fills the entire marrow cavity. So, adipocytes are abundant cells in the human bone marrow, where they are implicated in metabolic functions and in complex interrelationships with other stromal cells. The role of fat in this specific microenvironment is largely unknown.
Aims: We characterized bone marrow adipocytes (BM-A) molecularly and functionally to understand their functions in the hematopoietic microenvironment.
Methods: Healthy bone marrow was harvested from the iliac crest of bone marrow donors (n=9, median age 45, range 29-55). BM-A were isolated after collagenase digestion and filtration and cultured *in vitro*. We characterized these cells for their structural and molecular features, studying their morphology, immunophenotype and the gene expression profile of genes involved in white and brown adipogenic lineage. In particular, we investigated BM-A role in supporting hematopoiesis by a long term co-culture system with CD34+ cells. Moreover, we analyzed a cytokines secretion profile of BM-A, studying molecules that influence hematopoietic stem cells by increasing their proliferation or retaining the cells in a functionally immature state.
Results: Primary cultures of BM-A exhibited a typical unilocular white adipocytic morphology, maintaining their shape without noticeable lipolysis even after 30 days of culture time. Data displayed the expression of many white adipogenic genes, such as PPARg and its target genes (GPDH, LPL, Adiponectin, aP2 and LEP). Moreover, BM-A expressed some regulatory genes of brown adipocytes, like Dio2, CIDEA and PGC1a, suggesting their metabolic function in the bone marrow microenvironment. Then, BM-A were analyzed for the expression of stem cells markers, showing a pattern of surface antigen positively stained for CD90, CD105, CD271, CD117, CD31, CD133 and lowly for CD34. To show the functional properties of BM-A in the bone marrow microenvironment, we studied the interrelationship between BM-A and hematopoietic stem cells. BM-A demonstrated their ability to support the survival and differentiation of hematopoietic stem cells. Results showed that BM-A were stromal cells with the hematopoietic supporting function similar to mesenchymal stem cells, which are known for their hematopoietic supporting capacity. Moreover, we analyzed the amounts of hematopoietic stimulatory and inhibitory cytokines. Data demonstrated that BM-A secreted at high levels cytokines promoting the differentiation of committed hematopoietic progenitors, such as IL-6, IL-8 and G-CSF. At the same time, the negative regulators of hematopoietic microenvironment (IL-10, IL-17, MIP-1a, and TNFa) were not produced at significant levels.
Summary and Conclusions: Collectively, data shown here characterized BM-A at the morphological, phenotypic, molecular and functional levels. BM-A represent a population of white adipocytes, with the expression of typical white adipogenic markers and some regulatory genes of thermogenesis. These data suggested that adipocytes do not play a passive role as space fillers in the bone marrow but rather may provide a localised energy reservoir. BM-A expressed stem cells surface antigens, suggesting a possible plasticity of these cells. Moreover, BM-A are stromal cells with hematopoietic supporting capability that are most likely regulated by the production of specific molecules.

P936

ROLE OF CALORIC RESTRICTION IN TUMORIGENESIS THROUGH STEM CELLS

R Pallavi[1,*], M Giorgio[1], P Pelicci[1]
[1]Department of Experimental Oncology, European institute of Oncology, Milan, Italy

Background: Environment and life-style are perceived as critical factors that can influence healthy aging and the risk of cancer and other age related diseases such as chronic degenerative and metabolic diseases. One of such factors is diet, which seem to act as a major antagonistic element to health leading to nutritional disorders, overweight and obesity, increasing the risks of life threatening diseases such as cardiovascular diseases and cancer. Interestingly, caloric restriction (CR), that is reduced intake of calories, has not only proved to delay aging but also to reduce cancer incidence in animal models. As the mechanism of action of CR is still poorly understood, it is currently not possible to apply CR-mim-

icking approaches to prevent diseases. Further, most studies on the mechanism of cancer have focused on deregulation in somatic cells rather than SCs that has recently emerged as the site of origin of cancer. Among all, hematopoietic SCs (HSCs) are well studied and have been shown to deteriorate with age due to accumulation of DNA-damage and loss of epigenetic regulation that potentially increases their genomic instability and disposition for neoplastic transformation. In fact, acute-myeloid leukemia has been shown to derive from HSCs.
Aims: The aim of this study is to investigate the cellular and molecular mechanisms underlying the protective effect of CR on tumorigenesis. In this study, we test the hypothesis that SCs are a critical target of CR using the blood tissue as model system, by analyzing the functional effect of CR on SCs.
Methods: The effect of diet on the proliferation and differentiation of stem cells in bone marrow was examined by combination of methylcellulose-based colony forming assays and fluorescence activated cell sorter analyses, using SC surface and proliferation markers. The effect on SC function was determined by competitive bone marrow transplantation assay. Whole Transcriptome Shotgun Sequencing was used to analyze the effect of CR on global changes of gene expression in lineage negative cells from CR and SD fed C57BL6/J mice.
Results: We have recently found that CR significantly influences the rate of tumour-related deaths of mice carrying null mutations of the tumour suppressor gene p53 (p53-/- mice). We observed that transplantation of bone marrow from p53-/- mice (fed on CR diet) into irradiated mice decreases the tumorigenesis in the recipient mice compared to the bone marrow transplanted from p53-/- mice fed on standard diet. p53 has been shown to regulate adult SC self-renewal suggesting a role for CR and its tumour suppressor activity in controlling the stem cell pool. We have established that 10-14 weeks of CR is sufficient to achieve the molecular adaptation (*e.g.* decreased IGF1 level by 40%) and body weight (~15% weight loss) changes associated with CR by measuring IGF1 levels and weight in mice fed on CR diet. We then measured the proliferation of stem cell population in bone marrow mononuclear cells (BMNC) obtained from mice fed on CR diet and ad-libitum diet, and found that CR decreases the percentage of proliferative stem cells by 20-50%. Gene expression analysis of lineage negative hematopoietic cells by microarray indicates that CR regulates the expression of several genes involved in metabolism, cytokine signaling and cancer pathways.
Summary and Conclusions: Our preliminary data point towards an effect of CR on the cell cycle status of SCs via inhibition of proliferation, which suggests that CR may protect from cancer via its action on SC functions.

P937

ANALYSIS OF HUMAN ENDOSTEAL HSC NICHE; A NOVEL POPULATION WITH HIGH EXPRESSION OF CD34 AND ESAM IS ADJACENT TO TRABECULAR AREAS OF HUMAN BONE MARROW

M Ichii[1,*], K Oritani[1], T Yokota[1], T Ishibashi[1], TaSudo[1], N Fujita[1], P Kincade[2], Y Kanakura[1]
[1]Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, Japan, [2]Immunobiology and Cancer Program, Oklahoma Medical Research Foundation, Oklahoma City, United States

Background: In adult bone marrow (BM), it is believed that the specialized microenvironments regulate self-renewal or differentiation of hematopoietic stem/progenitor cells (HSPC). However, our knowledge of those niches is incomplete and there are significant species differences in hematopoiesis between mice and humans. For instance, murine hematopoietic stem cells (HSC) express CD150 and CD38, but not CD34, whereas in humans, a $CD34^+$ $CD38^-$ subset is enriched for HSC. We and others have reported both of human and murine HSC express ESAM (Yokota *et al.* Blood. 113:2914-23, 2009). In mice, at least some HSPC niches are located in trabecular areas of marrow, and HSC obtained from different sites are not identical. However, little is known about the distribution of HSPC within human BM, because BM aspirated from pelvis are mainly used for human hematopoietic studies.
Aims: To study human hematopoietic niches by analyzing bone-associated cells in the trabecular areas of human BM, especially $CD34^{high}$ $ESAM^{high}$ cells released from human femoral heads.
Methods: Bone samples were collected from patients receiving hip bone replacement surgery and cord bloods (CB) were from healthy, full-term neonates after delivery. All participants provided prior informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital and Oklahoma Medical Research Foundation. For preparation of cells adjacent to bones, trabecular tissues were treated with 2 mg/mL collagenase IV and DNase and gently agitated for 1 hour at 37 C. Mononuclear cells were separated by Ficoll-Paque PLUS centrifugation from CB. Collected cells were tested *in vitro* and *in vivo* assays for their hematopoietic or endothelial differentiation potential. In addition, $CD34^{high}$ cells were sorted using flow cytometer for some experiments.
Results: After collagenase treatment, more mesenchymal stem cells, which have been reported as HSC niche components, and more $CD34^+$ HSPC were collected from human bone specimens compared to samples without treatment. We found there were two distinct populations according to CD34 and ESAM expression levels in $CD34^+CD38^-$ cells. The intensity of ESAM and Thy-1 positive percentage were high in $CD34^{high}$ cells compared to $CD34^{low}$ cells. These $CD34^{high}$ cells also express Tie-2. Not all, but some CB lots had a similar subset. Cell-cycle analysis revealed these cells were dormant. Little or no cells were recovered under several hematopoietic conditions; stromal-cell free cultures for HSC expansion, cocultures with OP9 stromal cells, or CFU assays. $CD34^{high}$ $ESAM^{high}$ cells derived from CB could not reconstitute after transplantation via tail vein in sublethally irradiated immunodeficient mice. However, $CD31^+$ $Flk\text{-}1^+$ endothelial cells were generated after a 5 week long-term culture supporting the differentiation of both hematopoietic and endothelial cell lineages.
Summary and Conclusions: Bone-associated cells included HSPC and mesenchymal lineage cells that presumably reside in specialized niches. The methods we have developed can be used to dissect such microenvironments in human bone marrow. Our initial analysis focused on a quiescent $CD34^{high}$ $ESAM^{high}$ $Thy\text{-}1^+$ $Tie\text{-}2^+$ population. After long-term culture supporting the differentiation of both hematopoietic and endothelial cell lineages, only endothelial cells were generated, while no hematopoietic cells were recovered. The $CD34^{high}$ $ESAM^{high}$ subset adhering to bones seemed to be endothelial stem/progenitors. Interestingly, the numbers of this population varied according to individual CB. Our newly identified subset might be involved in endothelial cell-related events, including reconstitution of grafts after hematopoietic stem cell transplantation or repair of BM injured by irradiation/chemotherapy. Further studies would clarify clinical roles and utility of these unique bone associating cells.

P938

HEAD-TO-HEAD COMPARATIVE STUDY OF WHARTON'S JELLY AND BONE MARROW MESENCHYMAL STEM CELLS

A Batsali[1,2], C Pontikoglou[1,*], E Kouvidi[1], A Damianaki[1], A Stratigi[1], M Kastrinaki[1], H Papadaki[1]
[1]Department of Hematology, [2]Graduate Program "Molecular Basis of Humanl Disease", University of Crete School of Medicine, Heraklion, Crete, Greece

Background: Mesenchymal stem cells (MSCs) can be easily isolated from the connective tissue surrounding umbilical cord vessels, namely Wharton's jelly (WJ). Although WJ-MSCs display typical MSC characteristics, a head-to-head comparison with Bone Marrow (BM)-MSCs, which represent the most extensively studied population of adult MSCs, is still lacking.
Aims: Provided that *ex vivo* MSC expansion is a prerequisite for clinical MSC-applications, in the present study we seek to comparatively investigate the characteristics of WJ- and BM-MSCs, cultured under identical conditions.
Methods: MSCs were isolated and expanded from consenting healthy donors' BM aspirates (n=4) and from the WJ of full-term neonates (n=4) after written informed consent of the family. MSCs were *in vitro* expanded until passage (P) 6 and phenotypically characterized by flow cytometry (FC). MSCs were induced to differentiate *in vitro* to adipocytes and osteoblasts using appropriate culture media. MSC differentiation was assessed with cytochemical stains (Oil Red-O for adipocytic, and Alizarin Red/Von Kossa for osteoblastic differentiation). MSC growth characteristics were assessed by evaluating the population doubling time and by a methyl triazolyl tetrazolium (MTT)-assay throughout passages. MSC survival was evaluated by FC with 7-Aminoactinomycin D (7-AAD) and MSC senescence was estimated by the percentage of $SA\text{-}b\text{-}gal^+$ cells in cultures. MSC karyotypic stability was assessed with classic G-banding. MSC hematopoietic supportive capacity was evaluated in co-cultures with allogeneic BM $CD34^+$ cells. The co-cultures were kept for a total of 5 weeks. At weekly intervals the non-adherent cells were counted and assayed for clonogenic progenitor cells.
Results: WJ-MSCs displayed a spindle-shape morphology, similar to BM-MSCs. Furthermore WJ- and BM-MSCs displayed identical immmunophenotype, as evidenced by the expression of CD90,CD105,CD44,CD29,CD73 and the lack of expression of CD45,CD14,CD34,CD31. WJ-MSCs displayed superior proliferative potential compared to BM-MSCs throughout passages (P<0.05). There was no significant difference between WJ- and BM-MSCs in the proportion of apoptotic cells ($7\text{-}AAD^{bright/dim}$) at P2 or P6. Senescent ($SA\text{-}b\text{-}gal^+$) cells were significantly fewer in P6 WJ-MSC cultures, compared to BM-MSCs (P<0.05). No chromosomal abnormalities were observed in WJ- or BM-MSCs during *in vitro* expansion. With regards to differentiation capacity, WJ-MSCs required much longer time to differentiate into osteoblasts and adipocytes as compared to BM MSCs. Finally preliminary results from an ongoing series of experiments suggest that WJ-MSCs do not significantly differ from BM MSCs in the ability to support the hematopoietic progenitor cell growth.
Summary and Conclusions: *Ex vivo* expansion did not induce any cytogenetic abnormalities in either WJ- or BM-MSCs. WJ-MSCs exhibited greater proliferative potential and reduced senescence as compared to BM-MSCs, cultured under identical conditions. Cell apoptosis on the other hand did not differ between WJ- and BM-MSCs, at least in early and intermediate passages. WJ-MSCs appeared to be qualitatively different in terms of adipogenc and osteoblastic differentiation as compared to their BM-MSCs Finally our preliminary results suggest that WJ-MSCs may sustain normal hematopoiesis, thereby establishing a potential new model for the *ex vivo* expansion of BM hematopoietic stem cells. Experiments to probe more deeply into the hematopoietic supportive capacity of WJ-MSCs, as well as their growth and senescence characteristics are underway.

P939

ALTERATION IN GENE EXPRESSION PATTERN IN STROMAL PRECURSOR CELLS OF PATIENTS BEFORE AND AFTER ALLOGENEIC HEMATOPOIETIC STEM CELLS TRANSPLANTATION

I Shipounova[1,*], N Petinati[1], N Sats[1], N Drize[1], L Kuzmina[2], E Parovichnikova[2], V Savchenko[2]
[1]Physiology of Hematopoiesis laboratory, [2]Bone marrow transplantation department, National Hematology Research Centre, Moscow, Russian Federation

Background: Hematopoiesis depends on stromal microenvironment. There is a feedback between stromal precursor cells and quality of hematopoiesis. The alteration in stromal microenvironment was described in patients with hematological malignancies.
Aims: The aim of the study was to investigate the changes in some genes' expression in multipotent mesenchymal stromal cells (MMSCs) of patients with hematological malignancies before and after allogeneic hematopoietic stem cell transplantation (alloHSCT).
Methods: AlloHSCT was performed to 15 patients (11 male, 4 female) with various diagnosis. Conditioning was myeloablative in 10 patients and reduced intensity in 5. After informed consent bone marrow was aspirated from patients before conditioning and 30, 60, 90, 120, 180 and 360 days after alloHSCT and from 50 healthy donors during the aspiration for alloHSCT. MMSCs were cultured in standard conditions. Gene expression level in 1st passage MMSCs was estimated by real-time PCR. The relative expression levels were calculated using the $\Delta\Delta C_t$ method. A Student's t-test was used to evaluate statistical significance; values of $P<0.05$ indicated a significant difference.
Results: There were no differences in relative expression level of genes taking part in growth of MMSCs (BMP-4, FGFR1) between donors and patients. However expression of JAG1 doubled in MMSCs of patients after alloHSCT. The expression level of FGFR2 decreased significantly in patients' MMSCs comparing with donors and correlated with lower cumulative cell production in patients regardless of the amount of time (up to 1 year) that passed after alloHSCT. There was no difference between patients before transplantation and healthy donors in IL-1b expression. After alloHSCT the expression level of IL-1b increased 2.5-fold (P=0.04). It probably relates to stromal activation. There were no changes in IL-1b receptor 1 expression level. There was a tendency to elevation of differentiation markers expression - SPP1 and PPARg. The data suggest the alterations in MMSCs population, which probably consists of more mature precursor cells with lower proliferative potential after alloHSCT. The most profound changes were revealed in some immunomodulating genes. The expression of IL-6 significantly increased 1.5 fold in patients MMSCs before transplantation and 3 fold after comparing with healthy donors. The IDO1 expression level elevated 18 fold in patients MMSCs independently of transplantation procedure. The expression of other immunomodulating genes–PTGES, CSF1 and LGALS1 remain invariable in all groups. All patients were pretreated before alloHSCT, so it is impossible to distinguish between the damage of stromal cells caused by disease and by previous therapy. It is obvious that stromal precursor cells are altered in patients before alloHSCT. The changes include retarded MMSCs growth rate combined with the decrease in FGFR2 expression, and increased expression of IL-6 and IDO1. The procedure of transplantation aggravates all these characteristics and in addition the activation of JAG1 and IL-1b occurs suggesting stromal activation due to process of donors' HSC engraftment.
Summary and Conclusions: These data indicate significant permanent alterations in stromal precursor cells of patients before and following alloHSCT.

P940

ROLE OF BONE MARROW STROMAL CELLS IN THE REGULATION OF HUMAN EARLY LYMPHOPOIESIS

K Ohishi[1,*], Y Nakamori[2], N Katayama[2]
[1]Blood Transfusion Service, Mie University Hospital, [2]Hematology and Oncology, Mie University School of Medicine, Tsu, Japan

Background: The mechanism to regulate human early B and T cell differentiation from hematopoietic progenitors remains less defined. We previously reported that telomerized human bone marrow stromal cells support the generation of cyCD79a$^+$CD10$^+$CD19$^+$proB and CD7$^+$CD56$^-$ proT cells from human hematopoietic progenitors (Nakamori *et al.*, Br J Haematol. 157(6):674, 2012).
Aims: Here we examined the role of bone marrow stromal cells in the regulation of early B and T cell differentiation from human hematopoietic progenitors, using this culture system.
Methods: CD34$^+$CD38$^{lo/-}$CD45RA$^-$CD7$^-$CD19$^-$CD10$^-$human hematopoietic progenitors were cocultured with the telomerized stromal cells in the presence of stem cell factor, flt3 ligand, and thrombopoietin (3GF). To elucidate the role of stromal cells, insert plates were used to separate the contact between hematopoietic progenitors and stromal cells. Alternatively, cultures were performed with conditioned medium collected from cultures with stromal cells in the presence of 3GF.
Results: Coculture of hematopoietic progenitors separated from stromal cells in the presence of 3GF for three weeks did not affect the generation of CD7$^+$CD56$^-$ proT cells but prevented the generation of CD7$^-$CD10$^+$CD19$^+$ B cell differentiation from hematopoietic progenitors. Similar data were obtained by incubation of hematopoietic progenitors with conditioned media from cultures with telomerized stromal cells. By time course analysis, CD7$^+$CD10$^-$CD19$^-$ and CD7$^-$CD10$^+$CD19$^-$ cells were developed from hematopoietic progenitors after 7 to 14 days of cultures with stromal cells. Reculture of the generated CD7$^+$CD10$^-$CD19$^-$ cells with stromal cells for another 14 days gave rise to CD7$^+$CD10$^-$CD19$^-$ and CD7$^-$CD10$^+$CD19$^+$ cells, while the generated CD7$^-$CD10$^+$CD19$^-$ cells mainly differentiated to CD7$^-$CD10$^+$CD19$^+$ proB cells. On the other hand, cultures with the conditioned medium without stromal cells inhibited not only the generation of CD7$^-$CD10$^+$CD19$^-$ cells from hematopoietic progenitors but also the generation of CD7$^-$CD10$^+$CD19$^+$ proB cells from CD7$^+$CD10$^-$CD19$^-$ and CD7$^-$CD10$^+$CD19$^-$ cells. These data suggest that human stromal cells support early T cell differentiation by producing soluble factors and enhance B cell differentiation by direct contact with hematopoietic progenitors.
Summary and Conclusions: These data indicate that the direct contact with human stromal cells plays an important role in the regulation of early B and T cell differentiation by enhancing B cell differentiation.

P941

DEREGULATION OF PI3K/AKT SIGNALING IN BONE MARROW MESENCHIMAL STROMAL CELLS FROM PATIENTS WITH *DE NOVO* AND THERAPY-RELATED ACUTE MYELOID LEUKEMIA

F D'alò[1,*], G Falconi[1], E Fabiani[1], L Fianchi[1], M Voso[1], G Leone[1]
[1]Hematology, Università Cattolica del Sacro Cuore, Rome, Italy

Background: In addition to neoplastic transformation of hematopoietic progenitors, a damage of bone marrow microenvironment can contribute to leukemia development and maintenance. Several functional and morphological abnormalities of bone marrow mesenchimal stromal cells (BM-MSCs) have been described in myeloid neoplasms. Nevertheless molecular bases of differences between MSCs from normal and leukemic bone marrows are still unknown. PI3K/AKT signaling pathway is involved in several MSC functions and deregulation of genes belonging to these pathways have been described in MSCs from different type of cancers.
Aims: To study the expression profile of genes belonging to PI3K/AKT signaling pathway in MSCs from patients with *de novo* and therapy related Acute Myeloid Leukemia (t-AML), using as normal counterpart BM-MSCs isolated from patients with limited stage lymphoma without bone marrow involvement.
Methods: Study population included 5 patients with limited stage diffuse large B cell lymphoma (DLBCL) without bone marrow involvement, as normal control, and 10 patients with AML, including 5 *de novo* and 5 therapy-related cases. Bone marrow mononuclear cells were obtained by Ficoll-gradient centrifugation of bone marrow samples and cultured in Complete Human MesenCult® Medium (Stem Cell Technologies) in 25 cm^2 flask at 37°C. After 24 hours non-adherent cells were removed and adherent cells were cultured up to 70% confluence, then trypsinized and passed to a new flask. Cells at 2nd passage were collected by trypsinization, RNA was extracted using RNase mini kit (Qiagen) and cDNA was synthesized by QuantiTect Reverse Transcription kit (Qiagen). The Human PI3K-AKT PCR array (RT^{2}Profiler™ PCR Array; SABioscience) was used to analyze mRNA levels of 84 key genes involved in PI3K-AKT Signaling Pathway, in a 96-well plate in the CFX96 thermocycler (Bio-Rad). Relative changes in gene expression were calculated using the ΔΔCt method. An average Ct value of five housekeeping genes (GAPDH, βactin, β2-microglobulin, HPRT1 and RPLPO) was used to normalize the gene expression between sample groups. Fold change (FC) variations ≥1.5 in association to statistically significant T-test (P-value≤0.05) were used for the statistical analysis.
Results: Comparison of MSCs from AML samples *versus* normal controls identified three genes significantly down-regulated in leukemic samples, including GSK3B (P=0.0002, FC=-1.56), MTCP1 (P=0.019, FC=-1.62) and RASA1 (P=0.013, FC=-1.58). Stratifying the analysis according to AML subtypes, three genes were significantly down-regulated in t-AML *versus* normal bone marrow, including GSK3B (P=0.0009 and FC=-1.63), PTEN (P=0.004 and FC=-1.50) and SOS1 (P=0.004 and FC=-1.50). Similarly when comparing MSC from *de novo* AML *versus* normal bone marrow, GSK3B, MTCP1 and RASA1 resulted still down-regulated in MSC from leukemic samples (P=0.005 and FC=-1.51; P=0.018 and FC=-1.96; P=0.007 and FC=-1.81, respectively). No differences were found in the expression levels of studied genes between *de novo* and therapy-related AML.
Summary and Conclusions: Deregulation of genes belonging to PI3K/AKT signaling pathway may contribute to MSC dysfunction described in leukemic bone marrows and can affect their ability to interact with leukemic blasts and normal hematopoietic cells, eventually contributing to bone marrow failure and leukemia development. GSK3B was the most significantly and commonly down-regulated gene in MSCs from leukemic samples and codifies for the serine/threonine protein kinase Gsk3β which is also involved in additional signaling pathways, such as Raf/Mek/Erk and Wnt/β-catenin.

P942

LEVELS OF CIRCULATING HEMATOPOIETIC PROGENITOR CELLS ARE SIGNIFICANTLY INCREASED IN PATIENTS WITH PROSTATE AND BREAST CANCER REGARDLESS OF TUMOR STAGE

C List[1,*], M Wobus[1], K Kast[2], T Hölscher[3], M Stiehler[4], C Hamann[4], L Hofbauer[1], S Fuessel[5], M Fröhner[5], U Schwanebeck[6], M Bornhäuser[1]

[1]Internal Medicine, [2]OB/Gyn, [3]Radiation oncology, [4]Orthopaedic, [5]Urology, [6]Bioinformatic, Universityhospial Dresden, Dresden, Germany

Background: The detection of circulating tumor cells has been discussed as a prognostic factor in patients with various malignancies. Recently, investigators have hypothesized that prostate cancer cells infiltrate the bone marrow thereby competing with hematopoietic stem and progenitor cells (HSPC) for the niche environment. This in turn may then lead to a mobilization of HSPC into the peripheral blood. Therefore the detection of circulating progenitor cells (CPC) may be explored as a diagnostic marker with prognostic relevance in patients with solid tumors.
Aims: We tested the hypothesis whether prostate and breast cancer as systemic diseases increase the number of CPC and whether this is related to the stage of the disease.
Methods: Between November 2011 and July 2012, peripheral blood samples of patients with prostate cancer (n=38), breast cancer (n=78) and an age-matched healthy control group (n=39) were collected after informed written consent. 44 out of the 78 breast cancer patients were treatment-naïve and had not received chemotherapy or radiation therapy before the peripheral blood sample was collected. Chemotherapy had been finished in 34 breast cancer patients at least 8 months before inclusion. None of the prostate cancer patients had received prior chemotherapy or radiation therapy. Metastatic disease had occurred in 9 breast cancer patients and 9 prostate cancer patients by the time of sample collection.
All of the included patients were otherwise healthy, hematological or chronic inflammatory diseases were excluding criteria for this observational study.
HSPC were derived from heparinized blood using density centrifugation and washing. Mononuclear cells were seeded at a concentration of $0{,}334 \times 10\times^4$/1mL in MethoCult (Stemcell Technologies). Experiments were done in triplicate. Colony forming units were quantified after 14 days using an inverted microscope. Univariate and multivariate analyses were used for analyzing the influence of tumor stage, age and body mass index (BMI) on the frequency of CPC. All results were expressed as the mean±SEM.
Results: Univariate analysis showed that patients with prostate cancer had a significantly higher overall levels of CPC (109±15) compared to age matched healthy control group (54±10), P=0,036. This effect was mainly due to a significantly elevated level of CFU-GM (CFU-GM prostate cancer group 11±2 *vs.* CFU-GM in healthy control group 5±1, P=0,021). Tumor stage, age or body-mass index (BMI) did not affect the number of CPC in prostate cancer patients. This effect was confirmed by multivariate analysis.
Univariate analysis of the untreated breast cancer patients revealed a significantly higher number of CFU-GM (13±3) compared to age matched healthy control group (5±2), P=0,047. Multivariate analysis suggested an interaction of CPC levels and patient age. The extent oder besser stage of the tumor disease and BMI did not affect CFU-GM number. Interestingly, the average number of CFU-GM decreased after finishing anti-tumor therapy, indicating either a response to systemic therapy with a lower mobilization of CPC or a direct long-lasting suppression of hematopoiesis by the applied regimen.
Summary and Conclusions: This study shows for the first time elevated levels of CPC even in patients with localized prostate and breast cancer, but no direct correlation with the stage of the disease. The mobilization of CPC in cancer patients may either be an indirect effect of a systemic inflammatory milieu or directly linked to circulating tumor cells interfering with the hematopoietic stem cell niche.

P943

UMBILICAL CORD MESENCHYMAL STEM CELLS WITH IMPROVED SUPPORT FOR HEMATOPOIETIC STEM CELL EXPANSION.

S Zhuk[1,*], O Abramova[1], A Zaritskey[1], P Butylin[1]
[1]Institute of Hematology, Almazov Federal Heart, Blood and Endocrinology Centre, Saint-Petersburg, Russian Federation

Background: *Ex vivo* expansion of cord blood hematopoietic stem cells (UC-HSC) is a promising research area because it can potentially provide large number of stem cells capable of successful engraftment and hematopoiesis reconstitution after myeloablative therapy. Also it is indispensable for the development of valuable niche models for cell interaction study and *in vitro* drug testing.
Aims: Establish a MSC-based model of HSC microenvironment; study how the Notch ligands expression in stromal cells regulates the UC-HSC expansion in a coculture system.
Methods: Mesenchymal stem cells from umbilical cord Wharton's jelly (UC-MSC) were isolated and transduced with lentiviral particles carrying DLL1 and JAG1. To measure transduction efficiency and monitor ligand expression we created bicistronic lentiviral vectors with genes of interest and eGFP. DLL1 and JAG1 expression was measured by real-time PCR, percent of transduction efficiency was estimated by FACS based on eGFP expression. $CD34^+$ cells from cord blood mononuclear fraction were isolated using magnetic bead sorting and cultured with NOTCH ligands expressing MSC. After two weeks phenotype of cells in suspension was analyzed using FACS analysis.
Results: Mesenchymal stem cells were transduced with lentiviral particles carrying DLL1 and JAG1 (based on FACS analysis, transduction efficiency was 98% and 90% respectively) and were used as feeder layers in coculture experiments with UC-HSC. Immunophenotypic analysis has shown that after two weeks of HSC cultivation, UC-MSC with expression of DLL1 provided 5.7-fold (±1.73) increase of $CD34^+$ cell numbers in suspension fraction compared to cytokine alone conditions and 2.8-fold(±1.23) compared to control UC-MSC. DLL1-MSC was the only population with ability to support $CD34^+CD38^-$ population which is considered more undifferentiated than $CD34^+CD38^+$. Cultivation of CD34+ cord blood HSC with JAG1-expressing MSC and in cell-free conditions led to 0.9- and 0.6-fold decrease of total CD34+ cell population.
Summary and Conclusions: Our data indicates that coculture of HSC and DLL1-expressing UC-MSC led to expansion of undifferentiated $CD34^+$ fraction of hematopoietic stem cells. Thus DLL1-MSC can be used as a supportive feeder layer for HSC expansion experiments *in vitro* and provide better reproducibility and lesser batch to batch variation than bone marrow MSCs. This study is ongoing. Currently, we are modifying lentiviral vectors with antibiotic resistance genes which will allow establishment of cell lines with more stable expression of Notch ligands.

P944

ENDOTHELIAL CELLS EXPRESSING CONSTITUTIVELY ACTIVE AKT1 ARE CAPABLE OF RECONSTITUTING OF VASCULAR NICHE IN VITRO.

I Meln[1,*], S Zhuk[1], A Zaritskey[1], P Butylin[1]
[1]Institute of Hematology, V.A. Almazov Federal Heart, Blood and Endocrinology Centre, Saint-Petersburg, Russian Federation

Background: Role of the endothelial cells (ECs) in establishment of hematopoietic stem cell (HSC) microenvironment is the ultimate question of modern hematology. Study of interaction between ECs and HSCs *in vitro* require removing several obstacles, one of them is the low viability of human umbilical vein endothelial cells (HUVEC) in HSC expansion media. In our study we produce endothelial cells expressing myristoylated AKT1 (AKT1-ECs) using lentiviral transduction and compare them to ECs carrying empty vector (EV-ECs).
Aims: Our long-term goal is to reconstitute the vascular niche *in vitro* by co-culturing hematopoietic stem cells with endothelial cells and to use this system to identify factors that control the fate of HSCs. The specific aim of this study is to generate endothelial cells with constitutively active AKT1, and test their ability to regulate HSCs expansion, self-renewal and differentiation in co-culture system *in vitro*.
Methods: HUVEC were transduced with a myrAKT1 lentiviral vector that additionally contained eGFP reporter gene. Efficiency of transduction was evaluated using FACS-analysis and fluorescence microscopy by detection of eGFP. Expression of AKT1 was measured by quantitative real-time PCR, immunofluorescence and western-blot analysis. Expression of the endothelial cell markers was analyzed by FACS-analysis and immunofluorescence. ECs viability after culturing in HSCs media was measured using the MTT assay. Isolation of CD34+ HSCs from human cord blood was performed using magnetic microbeads and the purity of CD34+ phenotype was confirmed by FACS. HSCs were co-cultured on the monolayer of AKT1-ECs with usual controls. After3,5,7,9 and 11 days of co-culturing the HSCs were collected and analyzed by FACS-analysis.
Results: AKT1 expression level was increased 12-fold after transduction with myrAKT1. AKT1-ECs expressed Akt1 protein at higher levels compared with EV-ECs and non transduced cells. Phosphorylation status of Akt1 was confirmed by western-blot analysis. AKT1-ECs expressed endothelial markers: PECAM (CD31), VE-cadherin (CD144), MCAM (CD146) and von Willebrand factor. However level of their expression was affected by myrAKT1. For instance level of MCAM, VE-cadherin and von Willebrand factor were decreased compared to EV-ECs and control ECs. Reasonable explanation could be that massive AKT1 activation prevented HUVECs from terminal differentiation to the mature endothelial cells. AKT1-ECs have higher viability and could survive in the HSC expansion media up to 7 days without significantly dropping of the viability. In co-culture experiments AKT1-ECs increased number of CD34+ CD38+HSCs (30% *vs* 0.8% in control).
Summary and Conclusions: We have shown that the endothelial cells expressing constitutively active AKT1 are able to support expansion of HSCs *in vitro* and thus can serve as a model of the vascular niche. We intend to use this model further to study the mechanisms of interactions between the two cell types and identify molecular signals that regulate the fate of HSCs.

P945

CHEMOKINE SIGNALLING REGULATES HAEMOPOIETIC STEM CELL SURVIVAL

A Sinclair[1,*], S Calaminus[2], F Pellicano[1], A Guitart[1], S Graham[3], M Poncz[4], G Graham[1], O Sansom[5], L Machesky[5], K Kranc[1], T Holyoake[1]
[1]Institute of Cancer Sciences, University of Glasgow, Glasgow, [2]Centre for Cardiovascular and Metabolic Research, University of Hull, Hull, [3]Novartis Development, Novartis Pharmaceuticals UK Ltd, Surrey, United Kingdom, [4]Division of Hematology, The Children's Hospital of Philadelphia, Philadelphia, United States, [5]The Beatson Institute for Cancer Research, Glasgow, United Kingdom

Background: A key property of haemopoietic stem cells (HSC) is their ability

to maintain quiescence, however the regulation of quiescence in this context is not well understood. A previous microarray study by our group reported that the most uP-regulated group of genes in quiescent compared to proliferating human HSC was chemokine ligands, specifically in the CXCL group, however their role was unclear (Graham *et al.* [2007] Stem Cells, 25, 12).
Aims: We aimed to investigate the role of CXCL chemokines in HSC properties, both in the human and mouse systems.
Methods: To determine their biological function in human HSC we used shRNA to reduce chemokine ligand expression and SB-225002 to block receptor signalling, focusing on CXCL1 (the most uP-regulated chemokine) and its receptor CXCR2. To assess which chemokines were expressed in murine HSC populations and to examine their role in HSC functions, we employed single cell quantitative PCR by Fluidigm and used transgenic knock-out and reporter mice.
Results: Protein expression for CXCL1 and CXCR2 was confirmed on primitive HSC (CD34+CD38-) by immunofluorescence. Knock-down of CXCL1 led to an induction of apoptosis and reduction in colony formation (8.5% *versus* 19.7% and 109 *versus*14, for percentage apoptotic cells and colony counts in control *versus* CXCL1 knock-down, respectively, n=1). Similarly, inhibition of CXCR2 on CD34+ cells for 72 hours using SB-225002 induced apoptosis and reduced colony formation (17±0.3% *versus* 34±3% and 64±24 *versus* 25±12 for percentage apoptotic cells and colony counts in untreated *versus* 1μM treated cells, P<0.05). Platelet Factor 4 (*Pf4*; alias *Cxcl4*) and *Cxcr2* were highly expressed in murine HSC populations. Analysis of CXCR2 null mice has revealed extra medullary haemopoiesis with colony forming activity in peripheral blood and spleen and an expansion of LT-HSC in bone marrow. Transplantation assays using WT or CXCR2 null LT-HSC are currently underway to determine their reconstitution potential. PF4-Cre transgenic mice containing a conditional tandem dimer RFP construct under the control of the Rosa26 promoter (PF4-Cre) were used to confirm that PF4 is expressed in both primitive murine LT-HSC and their mature progeny (Calaminus *et al.* [2012] PLOS ONE, 7(12): e51361). Using this model, we sorted RFP positive and negative bone marrow cells and noted reduced colony forming potential in the absence of PF4 expression (73±6 *versus* 44±2 for colony counts in RFP positive *versus* RFP negative cells, P<0.05). We are currently investigating steady state haemopoiesis and transplantation stress in PF4 null mice and postulate that PF4 supports HSC survival and PF4 null HSC will show reduced engraftment capability. Since data for PF4 were not conclusive from the original human microarray, we have now reassessed the relevance of PF4 in the human system and shown that *PF4* is indeed uP-regulated by gene expression analysis in primitive HSC (CD34+CD38-CD90+) compared with proliferative progenitors (CD34+CD38+) (9-fold change ±0.3 in CD34+CD38-CD90+ fraction in comparison to CD34+CD38+ fraction 1±0.1, P<0.001) with future experiments planned to further investigate the role of PF4 in the human system.
Summary and Conclusions: Enhanced understanding of the regulation of stem cell properties is critical for improving our ability to manipulate normal stem cells *in vitro* and *in vivo* and in diseases such as leukaemia in which leukaemic stem cells are less sensitive to drug treatment.

Cytogenetics and molecular diagnostics

MONOALLILIC MUTATIONS OF FHL-RELATED GENES PREDISPOSE TO MACROPHAGE ACTIVATION SYNDROME

E Sieni[1,*], M Da Ros[1], C Bracaglia[2], C De Fusco[3], C Micalizzi[4], F De Benedetti[2], M Coniglio[1], B Ciambotti[1], V Cetica[1], M Aricò[1]
[1]Department Pediatric Hematology-Oncology, Meyer Children's Hospital, Florence, [2]Division of Rheumatology, Department of Medicine, Bambino Gesù Children's Hospital, Rome, [3]Department Pediatric Hematology-Oncology, Pausillipon Children's Hospital, Naple, [4]Department Pediatric Hematology-Oncology, G. Gaslini Children' s Hospital, Genoa, Italy

Background: Macrophage activation syndrome (MAS) is a serious complication of rheumatic diseases, frequently associated with systemic juvenile idiopathic arthritis (sJIA) but also described in others pediatric inflammatory disorders including juvenile systemic lupus erythematosus (LES) and Kawasaki disease. Due to the close resemblance to a group of histiocytic disorders collectively known as hemophagocytic lymphohistiocytosis (HLH) it is currently classified among the secondary or acquired forms of HLH. Recent evidences suggest a correlation between defects in the cytotoxic machinery, as that caused by mutations in the familial hemophagocytic lymphohistiocytosis (FHL)-related genes, and development of MAS.
Aims: To describe clinical, functional and genetic features of MAS.
Methods: We revised and updated the HLH Italian National Registry to select patients with MAS defined as HLH according to the diagnostic criteria established by the Histiocyte Society with confirmed diagnosis of rheumatologic or autoimmune disease. Clinical data were collected. Functional screening of perforin expression and degranulation was performed by flow-citometry. Genetic study by direct sequencing of currently known FHL-related genes was carried out in our laboratory.
Results: Among the 813 patients referred to the Registry, 38 (5%) were diagnosed as MAS. Of them 13 were male and 25 female; 30 Caucasian and 8 Indian. Median age was 94 (quartiles: 37; 94; 136; 708) months. The underlying causes were: sJIA (n=28), LES (n=4); Kawasaki disease (n=1), dermatomyositis (n=1), undefined rheumatologic (n=3) or auto-immune (n=1) disease. The clinical picture showed: fever (n=28/28; 100%), splenomegaly (n=17/28, 61%), neurologic manifestations (n=7/28, 25%), anemia (n=15/25, 60%), thrombocytopenia (n=14/25, 56%), neutropenia (n=3/25, 12%), hypertriglyceridemia (n=14/25, 56%), hypofibrinogenemia (n=7/25, 28%), hyperferritinemia (n=22/23, 96%; quartiles: 2.430, 10.264, 15.953, 96.000 ng/mL), hemophagocytosis (n=9/25, 36%). Four (10.5%) died of progressive disease. Functional screening of FHL was performed in 22 cases: perforin expression was normal in 14 and reduced in 8 (36%); degranulation was defective in 3/18 (17%) and normal in the remaining 15/18 cases. At least one test was defective in 10/23 (43%). Mutation analysis included *PRF1* (n=36), *UNC13d* (n=22), *STX11* (n=33) and *STXBP2* (n=19) and allowed to identify monoallelic mutations in 11 of the 38 patients (29%), as follows: *PRF1* (n=8/36, 22%), *STX11* (1/33, 3%), *STXBP2* (3/19, 16%). Correlation between functional defect and evidence of mutation is shown in Table 1.

Table 1. Functional and genetic data of 11 MAS patients with monoallelic mutations in FHL-related genes.

Summary and Conclusions: MAS is a life-threatening complication of rheumatologic disease in children. Heterozygous mutation in one the FHL-related genes is observed in at least 29% of patients with MAS. *PRF1* is the most frequently involved gene, and p.A91V the most frequent single mutation. Of the 8 patients with reduced perforin expression at flow-cytometry, 4 were heterozygous for

PRF1 mutation, while 4 were wild-type. Of the 3 patients with defective degranulation, 1 bears *STXBP2* mutation while two were apparently wild-type; yet, both had moderate reduction of NK activity. Moderate reduction of cellular cytotoxicity machinery appears as a frequent predisposing factor in patients who develop MAS as part of a rheumatologic disease. Whether there are further regulatory mechanisms for the FHL-related proteins in these patients remains to be clarified.

P948

TRACKING OF THE PRELEUKEMIC PERIOD IN SECONDARY ACUTE LEUKEMIAS REVEALS MULTIPOTENT PROGENITOR AS A TARGET OF MLL REARRANGEMENTS

O Zimmermannova[1,2,*], M Zaliova[1,2], E Mejstrikova[1,2], E Fronkova[1,2], M Jarosova[3], Z Zemanova[4], C Meyer[5], R Marschalek[5], J Stary[2], J Trka[1,2], J Zuna[1,2]

[1]CLIP, [2]Department of Paediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University, Prague, [3]Faculty Hospital of Palacky University, Olomouc, [4]Center of Oncocytogenetics, General University Hospital and 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [5]Diagnostic Center of Acute Leukemia, Institute of Pharmaceutical Biology, Goethe–University of Frankfurt, Frankfurt/Main, Germany

Background: Secondary leukemias are often characterized by breakpoints in the MLL gene. The MLL gene is an extremely promiscuous translocation partner, as more than 70 MLL partner genes have been identified so far. The most frequent partner genes (AF4, AF9, ENL, AF10, AF6, ELL) account for >80% of MLL translocated leukemias. In some patients presenting with secondary acute leukemia (sAL) after primary leukemia, archived bone marrow (BM) samples collected during the follow-up of the primary disease might be available, thus providing us with material for backtracking of the sAL markers in the prediagnostic period.

Aims: We considered MLL rearranged sAL cases as a suitable model to study presence and dynamics of the (pre-)leukemic cells in the preleukemic period.

Methods: We have collected BM samples from 5 patients monitored for primary ALL (n=3) or AML (n=2), who developed sAL after variably long period of remission (1,25 to5,5 years). The sAL cases presented as ALL (n=2) or AML (n=3). Leukemospecific clonal markers (Ig/TCR and MLL gene rearrangements) were investigated in BM of both original and secondary diagnoses using real time PCR. In addition, to better characterize the (pre)leukemic clone, FISH and SNP array were performed in some cases. In an attempt to backtrack the sAL cells at different timepoints preceding the sAL, methods of qPCR and FISH were employed.

Results: The sAL were characterized by the presence of either typical (2 sAML cases with MLL/AF9 fusion) or rare (2 sALL cases with MLL/MAML2 and MLL/FOXO3A which we described previously and 1 sAML case harboring a novel, so far undescribed MLL/ME2 fusion) MLL rearrangements. In all 3 patients, who presented with the atypical MLL partner, we backtracked the presence of MLL fusion in BM samples which were taken several months prior to the sAL (20, 23 and 9 months in MLL/FOXO3A, MLL/MAML2 and MLL/ME2, respectively). In both ALL patients, the leukemic clone was defined also by an incomplete IgH rearrangement, which seemed to be specific for the overt disease in both cases, as they were not detected in the MLL positive specimens preceding the sAL diagnosis. In these patients the MLL positive cells comprised unexpectedly large proportion of bone marrow in the preleukemic period (approx. 10% in the MLL/MAML2 case and even >90% in MLL/FOXO3A case). Interestingly, the observed high levels of MLL rearranged cells in these two samples (taken 15 and 16 months before the sALL diagnosis) were followed by a remarkable decrease of the MLL positivity levels before the onset of sALL. The high percentage of preleukemic cells (not restricted to lymphoid lineage) during clinically silent period suggests the involvement of a multipotent cell originally affected by MLL translocation. In 2 sAML patients, harboring typical MLL/AF9 translocation, the fusion gene was not backtracked in any of the prediagnostic samples (the last ones taken 11 and 12 months before the diagnosis).

Summary and Conclusions: Our data suggest, that sAL–as well as de-novo leukemia - is a multiple-step process with protracted latency between the first (MLL rearrangement) and finally transforming hit leading to the active disease. Moreover, the preleukemic clone can reach unexpectedly high levels even during a clinically silent period with normal BM morphology. Finally, our data suggest that typical and rare MLL fusions possibly drive different dynamics of the processes preceding the overt disease.

COMBINED APPLICATION OF MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION AND FLUORESCENCE IN SITU HYBRIDIZATION TO DETECT CYTOGENETIC ABNORMALITIES IN MULTIPLE MYELOMA

D Alpar[1,*], D de Jong[2], B Kajtar[1], S Savola[3], P Jakso[1], M David[4], S Kosztolanyi[4], L Kereskai[1], L Pajor[1], K Szuhai[2]

[1]Department of Pathology, University of Pecs, Pecs, Hungary, [2]Department of Molecular Cell Biology, Leiden University Medical Center, Leiden, [3]MRC-Holland, Amsterdam, Netherlands, [4]1st Department of Internal Medicine, University of Pecs, Pecs, Hungary

Background: Multiple myeloma (MM) is a genetically heterogeneous disease with diverse clinical outcome. Interphase fluorescence *in situ* hybridization (iFISH) is the most commonly used approach to detect recurrent cytogenetic abnormalities in this entity. The high and increasing number of identified biological and prognostic markers makes the introduction of a cost-effective screening strategy reasonable.

Aims: We aimed to assess the performance of the combined application of iFISH and multiple ligation-dependent probe amplification (MLPA) to reveal genetic alterations in MM.

Methods: Diagnostic bone marrow samples from 81 patients with MM were analyzed using a targeted MLPA kit containing a mix of 42 probes to simultaneously detect copy number alterations (CNAs) for the following regions: 1p32-31, 1p21, 1q21.3, 1q23.3, 5q31.3, 12p13.31, 13q14, 16q12, 16q23 and 17p13. All samples were also screened by iFISH for the presence of hyperdiploidy, deletion/monosomy of chromosome13, deletion of the *TP53* gene, disruption of the immunoglobulin heavy-chain gene, t(4;14), t(11;14), t(14;16), t(8;14), gain of 5q and abnormalities of chromosome 1. The study was conducted in accordance with the Declaration of Helsinki.

Results: A total of 245 alterations were detected in 79 cases (98%). Investigating the same aberrations, the two methods showed a congruency of higher than 90% (Fisher's exact test: p≤0.0003). Low proportion of cells harboring the abnormalities, focal CNAs and unmatched probes were responsible for the discrepancies. MLPA was able to simultaneously analyze several loci thus revealed 95 CNAs not detected by iFISH providing additional information in 53 cases (65%). These abnormalities not detected by commercial FISH probes were successfully validated using specifically designed BAC clones. Altogether, 66 cases showed multiple recurrent genetic alterations in 53 different combinations from which 22 were not recognized using any single method only. Investigating the co-segregation of various abnormalities, we found a pattern similar to those presented earlier by comprehensive studies applying expensive whole-genome screening technologies. Mapping the CNAs on chromosome 1 using more than 20 probes, significant heterogeneity in size and location, variable intra-chromosomal and intra-clonal rates of loss 1p and/or gain 1q were found.

Summary and Conclusions: To our knowledge, MLPA investigation in MM has never been published in international journals. Our study proves that MLPA is robust technique to detect multiple unbalanced genetic abnormalities in this incurable disease group and also shows that MLPA might be a cost-efficient alternative to the more time and resource-consuming approaches. IFISH is able to detect both balanced and unbalanced rearrangements which are cryptic for karyotyping but in routine diagnostics, more than three loci are rarely investigated simultaneously using this method. MLPA has the power to identify high number of submicroscopic gains and losses at a higher resolution than iFISH albeit its sensitivity does not reach that of iFISH. Since both CNAs and balanced aberrations have a great impact on the prognostic classification of MM, the presented MLPA and iFISH strategies should be applied in combination in the diagnostic hematopathology work-flow.

P950

COMPARISON OF MICROARRAY-BASED GENOMIC PROFILING AND MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION (MLPA) FOR THE DETECTION OF CLINICALLY RELEVANT GENETIC LESIONS, INCLUDING IKZF1, IN ALL

M Stevens-Kroef[1,*], S van Reijmersdal[1], A Siepman[1], R Pfundt[1], S Croockewit[1], R Kuiper[1], A Simons[1]

[1]Radboud University Medical Centre, Nijmegen, Netherlands

Background: In acute lymphoblastic leukemia (ALL) specific genomic abnormalities provide important clinical information. In most routine clinical diagnostic laboratories conventional karyotyping in conjunction with fluorescence *in situ* hybridization (FISH) is currently considered as the gold standard to detect such abnormalities. Recently, we showed that microarray-based genomic profiling serves as a superior alternative strategy in a routine clinical diagnostic setting to detect gross genomic copy number alterations (CNAs) (Simons *et al.*, 2011, Genes Chromosomes Cancer 50:969-981). In addition, we demonstrated that this technique allows the detection of focal genomic lesions, frequently harboring clinically relevant ALL-related genes, such as *CDKN2A/B*, *ETV6, PAX5* and *IKZF1*, the latter recently shown to be associated with a high relapse rate in patients with ALL (Kuiper *et al.*, 2010, Leukemia 24:1258-1264). The ability to detect focal lesions, however, largely depends on the resolution of the platform used. Whereas targeted assays, such as multiplex ligation-dependent probe amplification (MLPA), have already proven to be suitable for this purpose (Kuiper *et al.*, 2010; Waanders *et al.*, 2011, Leukemia 25:254-258), such targeted tests do not provide genome-wide information, including gross cytogenetic abnormalities.

Aims: We compared the performance of a novel high resolution genome-wide microarray platform with a commercially available MLPA kit for the detection of ALL-specific genomic copy number abnormalities, including *IKZF1* deletions.

Methods: The Cytocan HD platform (2.7 million probes; Affymetrix) and Chromosome Analysis Suite (ChAS; Affymetrix) software was used for genomic profiling of 23 patients with ALL. In addition, the same samples were tested with commercially available multiplex ligation-dependent probe amplification (MLPA) kits (P335 and P202, MRC-Holland). Both techniques were used to reveal the

genomic copy number status of the recurrently affected genes *IKZF1, EBF1, CDKN2A/B, PAX5, ETV6, BTG1* and *RB1*.
Results: In total 161 loci (*i.e.*, 23 cases tested for 7 loci) were evaluated. One-hundred-twenty-one of these loci (75,1%) showed a match between both tests; 68 loci normal, 53 loci aberrant (CNA). Thirty-nine of the tested loci (24,2%) turned out to be uninformative for comparison of the two techniques, all due to no available or uninterpretable data from the MLPA tests, while microarray revealed interpretable results. One locus (0,6%) revealed a likely clinically relevant "mismatch" between the two tests, namely an *IKZF1* promoter deletion was detected with the microarray approach, which was "missed" by the MLPA test, because the promoter region is not covered in the used MLPA kits.
Summary and Conclusions: We conclude that the Cytoscan HD microarray platform is superior to the molecular MLPA test for the detection of clinical relevant genetic lesions in ALL. It has a higher success rate in the detection of focal CNAs and, in addition, provides a genome wide overview of all CNAs and regions of acquired copy neutral loss of heterozygosity (CN-LOH).

P951

GENOTYPING OF 25 LEUKEMIA-ASSOCIATED GENES IN A SINGLE WORKFLOW BY NEXT-GENERATION SEQUENCING TECHNOLOGY USING LOW AMOUNTS OF INPUT TEMPLATE DNA

T Ernst[1,*], J Rinke[1], V Schäfer[1], M Schmidt[1], J Ziermann[1], A Kohlmann[2], A Hochhaus[1]
[1]Hematology/Oncology, Jena University Hospital, Jena, [2]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Myeloid neoplasms are characterized by a variety of gene mutations within different molecular pathways involving cell signaling, transcription factors, epigenetic regulators and RNA splicing. Next-generation sequencing (NGS) technology enables analysis of thousands of sequencing reactions simultaneously. However, large-scale molecular analyses are often hampered by lack of sufficient template DNA or weighting the use of precious patient material.
Aims: We sought (i) to establish a robust and sensitive NGS method for genotyping of the 26 most commonly mutated genes in AML, MDS, MPN, and MDS/MPN overlap syndrome (*ASXL1*, *BRAF*, *CBL*, *CEBPA*, *DNMT3A*, *ETV6*, *EZH2*, *FLT3*, *IDH1*, *IDH2*, *JAK2*, *KIT*, *KRAS*, *LNK*, *MPL*, *NPM1*, *NRAS*, *RUNX1*, *SF3B1*, *SRSF2*, *TET2*, *TP53*, *U2AF1*, *UTX*, *WT1,* and *ZRSR2)* in a single workflow and (ii) to optimize the method for low amounts of input template DNA without introducing bias.
Methods: NGS was applied to simultaneously analyze 26 leukemia-associated candidate genes (represented by 184 PCR amplicons) in 10 patients with chronic myelomonocytic leukemia (CMML) using genomic DNA (gDNA). Thereafter, NGS was performed for all candidate genes after whole genome amplification (WGA) was carried out with 20 ng template gDNA from the same 10 CMML patients using different commercially available kits based on multiple displacement amplification. Differences between variant frequencies in gDNA and WGA samples were determined for two different WGA kits.
Results: For each sample, 25 of 26 genes (180 PCR amplicons) were successfully sequenced with a limit-of-detection of approximately 5%. An overall median coverage of 94,935 reads (range: 74,745 to 117,056 reads) was generated for gDNA samples, with a median coverage of 492 reads (range: 308 to 636 reads) per amplicon. In 10 CMML patients 25 distinct mutations were identified in 11 genes (*CBL*, *FLT3*, *IDH2*, *KRAS*, *NRAS*, *RUNX1*, *SRSF2*, *TET2*, *TP53*, *UTX*, *ZRSR2*). Using WGA samples, mutations above the 5% sensitivity limit were reliably detected achieving an overall median coverage of 96,457 reads (range: 75,386 to 101,870) and a median amplicon coverage of 506 reads (range: 256 to 653 reads). Looking at all variants, WGA kits generated differences of variant frequencies that ranged from -28.19% to +9.94% (mean difference -0.2%, SD=4.08) or from -35.03% to +18.67% (mean difference -0.75%, SD=5.12), respectively.
Summary and Conclusions: Our method permits simultaneous and sensitive analysis of the 25 most commonly mutated genes in AML, MDS, MPN and MDS/MPN in a single sequencing run helping researchers to unravel associations between mutations in different pathways. NGS can be performed after WGA of low amounts of input template DNA for reliable variant detection without introducing significant bias.

P952

IDENTIFYING AND MONITORING TCRG CLONALITY USING MASSIVELY PARALLEL SEQUENCING AND ASSOCIATED BIOINFORMATICS.

H You[1,*], Y Huang[1], J Miller[1], J Tutton[1], J Panning[1], J Thornes[1], M Klass[1]
[1]Invivoscribe Technologies, Inc., San Diego, United States

Background: Assays that identify clonal lymphocyte populations in clinical specimens are used on a routine basis to assist in the diagnosis of lymphoproliferative disease. Although detection of clonal lymphocyte populations is not, by itself, diagnostic of malignancy, once a relationship with a malignancy is established, tumor-specific DNA sequences of clonal V-J rearrangements are among the most sensitive patient-specific biomarkers available to monitor minimal residual disease (MRD). In concert with other clinical and diagnostic tools, sensitive detection of clone-specific V-J sequences can help determine therapeutic efficacy and often provide the first indication of clinical relapse. Over the years clonality testing has moved from Southern blot to PCR-based methods. Both these methods employ electrophoresis to fractionate products in order to discriminate between background products and bands that are associated with the presence of clonal populations. However, these methods often do not provide sufficient diagnostic sensitivity and are incapable of identifying the specific V-J DNA sequence data required to track clones in follow up testing. The recent emergence of cost-effective massively parallel sequencing (MPS) platforms and development of targeted assays with associated bioinformatics tools have resulted in powerful new approaches for clonality detection and monitoring.
Aims: To develop a sensitive, robust and reliable, massively parallel sequencing assay, along with associated bioinformatics tools useful for detection and monitoring *TCRG* clonality.
Methods: A single-step PCR targeted all variable (V) and joining (J) region genes of *TCRG* that are rearranged in lymphoid malignancies. The average size of the *TCRG* amplicons generated is compatible with testing fragmented DNA isolated from more challenging samples (*e.g.*, FFPE sections). Multiplexed PCR was followed by amplicon purification using the AMPureXP PCR purification system. Purified amplicons were quantified with KAPA qPCR and pooled into a library. A measured amount of the quantified library was loaded onto the MiSeq massively parallel sequencing system and data was generated using the MiSeq v2 Reagent kit (300 cycles). Data was analyzed using Invivoscribe developed bioinformatics software, which generated frequency distributions, identified V-J DNA sequences, and V-J gene usage.
Results: Data generated with this assay and bioinformatics package identify clonality and DNA sequences of *TCRG* V-J gene rearrangements. This *TCRG* assay has a limit of detection of 5 templates in 10^5 and shows a linear response from 5% down to 0.005%. This assay can be used with genomic DNA from peripheral blood, bone marrow, FFPE, and tissue biopsy specimens. The results obtained compare favorably with those from 454 sequencing and are concordant with clinical diagnosis (Figure 1).

Figure 1.

Summary and Conclusions: A massively parallel sequencing assay has been developed for the Illumina MiSeq platform that identifies clonal *TCRG* V-J rearrangements, associated patient-specific V-J region DNA sequences, and provides frequency distribution of V region and J region segment utilization. This assay can be used both to detect and monitor lymphoproliferative disease. When coupled with the bioinformatics and visualization software MPS assays can provide robust detection and enhanced data-rich outputs.

P953

MAPPING OF UNIQUE CHROMOSOMAL ABNORMALITIES AS A TOOL FOR SENSITIVE MINIMAL RESIDUAL DISEASE ASSESSMENT IN ACUTE LEUKEMIA PATIENTS

T Jancuskova[1,*], R Plachy[1], J Stika[1], L Zemankova[1], D Hardekopf[1], T Liehr[2], N Kosyakova[2], L Zejskova[1], L Sedlackova[1], R Cmejla[1], S Pekova[1]
[1]Chambon Laboratories, Prague, Czech Republic, [2]Universitätsklinikum Jena, Jena, Germany

Background: Acute leukemias (AL) comprise a heterogeneous group of hema-

tologic malignancies, and individual patient responses to treatment can be difficult to predict. Monitoring of minimal residual disease (MRD) is thus very important and holds great potential for improving treatment strategies. Common MRD targets include recurrent cytogenetic abnormalities and mutations in important hematological genes; unfortunately well-characterized targets are lacking in many AL patients.

Aims: Our aim was to develop a flexible strategy for mapping of cytogenetically identified unique clone-specific abnormalities down to the single nucleotide level and, based on the sequence, design a specific real-time PCR assay for MRD assessment in AL patients without any previously described MRD marker.

Methods: Using a combination of molecular cytogenetic techniques (mFISH, mBAND) and molecular biological techniques (next-generation sequencing, long-range PCR, Sanger sequencing) we were able to characterize the DNA sequence flanking unique chromosomal breakpoints. For precise identification of these breakpoints we used fine-needle microdissection of derivative chromosomes followed by next-generation sequencing of the dissected material. Finally, we designed a specific real-time PCR assays for monitoring MRD level during the patients' treatment. To test the applicability of the described approach, a real-time PCR assay based on a unique breakpoint from one patient was compared to quantification based on a well-characterized MRD target present in the same patient.

Results: In conjunction with our previous proof of principle study on the K562 cell line presented at the EHA meeting in 2012, we mapped derivative chromosomes in 4 eligible AL patients [Patient 1–der(4), der(11); patient 2–der(10), der(11); patient 3–der(8); patient 4–der(7)] and performed real-time PCR quantification of unique MRD markers for each patient. A comparison of these newly-designed assays to a standard assay used in clinical practice shows that our technical approach is suitable for the identification of new molecular MRD markers in AL patients (Figure 1).

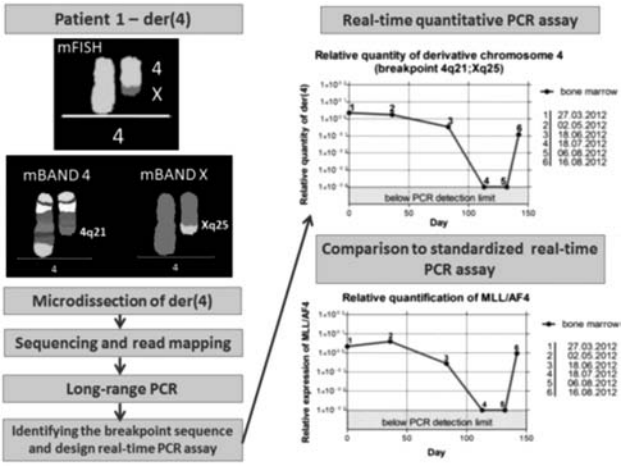

Figure 1.

Summary and Conclusions: The combination of cytogenetic and molecular methods described here enabled us to proceed from the chromosomal level (cytogenetically identified unique marker) to the molecular level (unique DNA sequence). Using this procedure, many chromosomal translocations can be used to identify a target for detecting and quantifying MRD.Our work clearly shows that moving from the chromosomal level to the nucleotide level is feasible and readily applicable for eligible AL patients. The time required for the entire procedure under reasonable standard conditions, from receiving the diagnostic sample to developing the real-time MRD assay, is approximately up to six weeks, allowing its use in clinical practice as a tool for personalized medicine in hemato-oncology.

P954

A MULTIPLEX QPCR ASSAY FOR RAPID DETECTION OF DNMT3A CODON R882 MUTATIONS IN ACUTE MYELOID LEUKEMIA

G Pløen[1,*], M Hansen[1], C Nyvold[1], P Hokland[1], A Aggerholm[1]
[1]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark

Background: Mutations in the *DNMT3A* gene, which encodes DNA methyltransferase 3A, have been reported in approximately 20% of cases with AML and in 8% of cases with MDS. *DNMT3A* mutation is proven to be an independent adverse factor for survival in AML and of possible prognostic value in MDS. A single study has shown improved survival in AML patients with mutated *DNMT3A* treated with high-dose daunorubicin compared with standard-dose daunorubicin. Another study suggests that AML patients with *DNMT3A* codon R882 mutations respond better to treatment with idarubicin compared to standard dose daunorubicin. Mutations in codon 882, substituting Arginine with either Histidine, Cysteine, Proline, Serine or Glycine account for approximately 60% of identified *DNMT3A* mutations in AML.

Aims: To design and validate a multiplex allele-specific qPCR assay targeting the five known codon 882 mutations in *DNMT3A* for rapid detection of these aberrations in AML patients.

Methods: Allele-specific qPCR assays based on TaqMan technology were developed. Forward primers specific for wild type and the five codon 882 mutations were designed and combined with a common reverse primer and a common probe. The five mutation-specific assays were combined in a multiplex assay. The sensitivity of the multiplex assay was 5% of mutant alleles. Cell lines and plasmids encompassing the different codon R882 mutations were used as positive controls. Diagnostic samples from 207 AML patients were analysed using the multiplex qPCR assay.

Results: Twenty-eight of 207 AML patients (13.5%) were found to carry a codon R882 mutation in *DNMT3A* at the time of diagnosis. To identify the specific codon R882 mutations in the individual patients we split out the multiplex assay and performed qPCR for each of the possible *DNMT3A* R882 mutations. Nineteen patients were found to carry the R882H mutation, eight were positive for the R882C mutation, and a single patient was R882P positive. No patient samples with the R882S or R882G mutations were found. All 207 AML patients were previously screened for mutations in additional six genes (Table 1). The *DNMT3A* codon R882 mutation rarely seemed to occur alone. Among the 28 patients with a R882 mutation, 22 patients had concomitant mutations in one or more genes. In line with previous reports by others, statistically significant associations between *DNMT3A and NPM1, IDH1, FLT3-ITD,* and *FLT3-D835* mutations were observed. Eight *DNMT3A* R882 mutated patients had concomitant mutations in both *FLT3-ITD* and *NPM1*. In our cohort of AML patients, we observed no differences in median age and distribution of sex between patients with and without a *DNMT3A* R882 mutation.

Table 1.

Variable	Whole cohort (n = 207)	DNMT3A R882-mutated (n = 28, 13.5%)	DNMT3A R882-wildtype (n = 179, 86.5%)

Summary and Conclusions: A specific multiplex assay covering 60% of *DNMT3A* mutations observed in AML was developed. In a retrospective study 207 AML samples were analysed and 28 (13.5%) were found to be mutated in codon R882 in *DNMT3A*. Our observations correspond to previous reports on mutations in codon 882 in *DNMT3A* both with respect to frequency as well as distribution of the different R882 mutations. The observation in two previous studies showing that patients with *DNMT3A* mutations benefit from non-standard induction chemotherapy could increase the demand for a *DNMT3A* mutation screening prior to therapy. The multiplex assay presented here, enables rapid detection of codon R882 mutations in *DNMT3A* within 3 hours after sample receipt in the laboratory. qPCR assays have been proven to be fast and reliable methods that can easily be implemented in diagnostic laboratory settings, thus, the present multiplex assay holds great potential as an easily applicable methodology for the detection of codon R882 mutations.

P955

ARRAY-BASED GENOMIC PROFILING IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IDENTIFIES HIGHER NUMBER OF PROGNOSTIC RELEVANT GENOMIC ALTERATIONS AND REVEALS NEW RECURRENT GENOMIC ABNORMALITIES

M Stevens-Kroef[1,*], E van den Berg[2], D Weghuis[1], T Dijkhuizen[2], N Idrissi[1], M Benjamins[2], MLinssen-Wiersma[1], A Siepman[1], P Groenen[1], A Simons[1]
[1]Radboud University Medical Centre, Nijmegen, [2]University Medical Center Groningen, Groningen, Netherlands

Background: B-cell chronic lymphocytic leukemia (CLL) is characterized by a highly variable clinical course. Characteristic genomic abnormalities have been shown to provide clinically important prognostic information. The most commonly applied techniques in genetic diagnostics are fluorescence *in situ* hybridization (FISH) and multiplex ligation-dependent probe amplification (MLPA). Recently,

array-based genomic profiling has gained acceptance as a high-resolution new tool for detecting genomic imbalances, which allows genome-wide detection of copy number alterations (CNAs), down to 100 kb in size, and regions of acquired uniparental disomy (UPD).
Aims: The aim of the present study was to compare two genomic array platforms with FISH and MLPA to ascertain whether these routinely used techniques could be substituted by genomic arrays in a diagnostic setting.
Methods: Genomic DNA was extracted from peripheral blood cells of 21 CLL patients. Data on genomic aberrations {del(11q), +12, del(13q) and del(17p)} were obtained by FISH, MLPA or both. To evaluate the sensitivity and specificity of genomic arrays our cohort contained 6 CLL patients in which the genomic abnormality was present in a relatively low percentage of the cells (range 5-21%), and one patient with a focal *TP53* deletion which was missed by FISH. Two different array platforms were used; CytoScan HD Array (Affymetrix) and HumanOmniExpress12v1.0 (Illumina). The following interpretation criteria were applied: (i) the threshold for copy number aberrations was set at >5 Mb, (ii) inclusion of copy number aberrations of segments that coincide with known cancer genes as reported on www.sanger.ac.uk or in literature and that are smaller than 5 Mb and (iii) the threshold for acquired UPD was set at >10 Mb and to telomere.
Results: In 18 of the 21 CLL patients genomic alterations were identified by array-based profiling and FISH or MLPA. In 10 patients array-based profiling was performed on both array platforms, resulting in the identification of the same genomic alterations. All abnormalities observed by FISH were also identified by array-based profiling, including two cases with trisomy12 in 21% of the cells, a case with loss of 17p in 20% of the cells, case with loss of 17p in 16% of the cells, a case with loss of 13q14 in 20% of the cells, and a case with a bi-allelic loss of 13q14 in 5% of the cells. In addition array-based profiling identified a case with focal *TP53* loss which remained undetected by FISH, and a case with an acquired UPD of the short arm of chromosome 17. In this latter case a *TP53* mutation was subsequently established by DNA sequencing. Moreover 14 of the 21 patients (67%) carried additional genetic abnormalities as compared to FISH and/or MLPA, including one patient with the recently identified *MGA* loss and one other patient with chromotripsis.
Summary and Conclusions: Both array platforms have a high sensitivity and CNA present in only about 20% of the cells as determined by FISH and/or MLPA can unambiguously be identified. By applying similar interpretation criteria results obtained from different array platforms are comparable. In addition, we show that microarray-based genomic profiling provides the detection of potential prognostic relevant abnormalities (focal *TP53* deletion, UPD of 17p), novel focal CNAs and acquired UPDs, which would have remained undetected by FISH or MLPA. The prognostic value of novel CNAs and acquired UPDs needs further evaluation in prospective clinical trials.

P956

DEREGULATION OF STEM CELL FACTOR (SCF)-AKT-S6 PATHWAY IN DIAGNOSTIC AML SAMPLES IS ASSOCIATED WITH DISEASE-FREE SURVIVAL: RESULTS OF A VERIFICATION STUDY

A Cesano[1,*], C Willman[2], K Kopecky[3,4], S Putta[1], A Cohen[1], C Marimpietri[1], S Atwater[5], F Appelbaum[3], J Radich[3]
[1]Nodality, Inc., South San Francisco, [2]University of New Mexico Cancer Center, Albuquerque, NM, [3]Fred Hutchinson Cancer Research Center, [4]SWOG Statistical Center, Seattle, WA, [5]Stanford University, Palo Alto, CA, United States

Background: Despite improvements in AML induction therapy, the risk of relapse, especially in older patients (pts), remains high. In addition to older age and high risk karyotype, molecular markers such as FMS-like tyrosine kinase 3 receptor (*FLT3R*) internal tandem duplication (ITD) mutations (*FLT3R* ITD) have been shown to be associated with risk of relapse in pts with AML. However, even within molecularly defined high risk groups substantial heterogeneity in clinical outcomes are observed, suggesting that alternative mechanisms of disease relapse exist and that diagnostic tools to predict disease relapse remain inexact. Single cell network profiling (SCNP) uses multiparameter flow cytometry as a biological tool to conduct a broad functional assessment of intracellular signaling pathways in heterogeneous tissues at the single cell level. We previously identified an SCNP functional signature, SCF-induced phosphorylation of AKT and S6 [SCF:P-AKT/P-S6] that, when present in a subset of AML blasts at diagnosis, was predictive of disease relapse. The SCNP signature demonstrated significant predictive ability when tested in a small independent sample set.
Aims: To verify in a larger sample set the external validity of the original observation and its independence from *FLT3R* mutation status (FMS).
Methods: SCNP was performed on cryopreserved bone marrow mononuclear cell (BMMC) and peripheral blood mononuclear cell (PBMC) samples from 80 pts >55 years of age with non-APL AML who had complete response to cytarabine-based induction therapy on SWOG trials S0112, S0301, S9031, S9333, who were followed for at least three years, and whose leukemic blast cells expressed CD117 (c-KIT). Thawed cells were exposed to modulators, including SCF, for 15 minutes then fixed, permeabilized, and stained using a cocktail of fluorochrome-conjugated antibodies that recognized extracellular lineage markers and intracellular epitopes which correspond to phosphorylated sites on signaling proteins, including AKT and S6.
Results: An association between the SCF:P-AKT/P-S6 signature and relapse-free survival at 3 years (RFS3) was confirmed in this study with an Area Under the Receiver Operating Characteristic Curve (AUROC) of 0.70 (P=0.018). Consistent with previous data, CD117 surface expression levels alone were not predictive of relapse (AUROC=0.48, P=0.6). In addition, and in alignment with the previous observation, the majority of patient samples with a blast subpopulation at diagnosis expressing the SCF:P-AKT/P-S6 signature were FLT3R wild type. In order to assess if the SCF:pAkt/pS6 signature is a significant predictor of RFS3 after accounting for FMS, a logistic regression model of RFS3 was developed to include the SCF:pAkt/pS6 signature, FMS and the interaction between them as predictors. The model showed that the SCF:pAkt/pS6 signature is significantly (P=0.016) associated with RFS3 after accounting for FMS.
Summary and Conclusions: This study confirmed in an independent set of adult non-APL AML pts that the presence of leukemic blasts in PB or BM samples expressing SCF-induced P-AKT/P-S6 at diagnosis is predictive of relapse with 3 years. Together with FMS, this signature provides an opportunity for identifying those pts that may benefit from more intensive post-remission therapy such as stem cell transplant. These data also implicate deregulation of the PI3K pathway as a mechanism for secondary chemo-resistance in at least one subset of elderly AML that could potentially be targeted by tyrosine kinase inhibitors.

P957

HIGH-RESOLUTION GENOMIC PROFILING IN MULTIPLE MYELOMA IDENTIFIES RECURRENT PROGNOSTIC RELEVANT COPY NUMBER ALTERATIONS AND REVEALS NEW RECURRENT GENOMIC ABNORMALITIES

M Stevens-Kroef[1,*], A Simons[1], S Croockewit[1], L Derksen[1], J Hooijer[1], N Idrissi[1], A Siepman[1], D Weghuis[1]
[1]Radboud University Medical Centre, Nijmegen, Netherlands

Background: Multiple myeloma (MM) is a heterogeneous disease with a highly variable clinical course. Genetic abnormalities such as t(4;14)(p16;q32), t(11;14)(q13;q32), t(14;16)(q32;q23), 17p loss, 13q loss, 1q gain, 1p loss and hyperdiploidy have been shown to provide prognostic information (Fonseca *et al.*, Leukemia, 2009). The most common molecular-cytogenetic technique currently used to detect these genetic abnormalities is interphase fluorescence *in situ* hybridization (FISH) on purified plasma cells.
Aims: Although interphase FISH is a well established approach, it is relatively laborious. We, therefore, we aimed to evaluate the sensitivity and detection yield of copy number alterations (CNAs) using microarray-based genomic profiling.
Methods: CD138+ cells (plasma cells) were enriched by an immuno-magnetic cell selection procedure (Stem Cell Technologies) from bone marrow samples of 13 MM patients. Microarray-based genomic profiling and data interpretation were performed as recently reported (Simons *et al.*, Genes Chrom & Cancer, 2011). Interphase FISH on enriched plasma cells was performed using commercially available probes according to the manufacturer's specifications (Abbott Molecular for 13q-, 17P- and hyperdiploidy, and Kreatech Diagnostics for 1q gain and 1p loss).
Results: The microarray-based genomic profiles of all 13 samples disclosed highly rearranged genomes, harboring 3 to 22 distinct CNAs or regions exhibiting acquired uniparental disomy (UPD), both recurrent as well as novel in nature. All recurrent CNAs present in at least 20% of the cells, as determined by FISH, were also detected by microarray-based genomic profiling. In only one patient a minor sub-clone with loss of 17p, as detected by FISH in 13% of tetraploid cells was not identified by microarray analysis. Of interest is that by using interphase FISH a (near)-tetraploid karyotype can easily be misinterpreted as a (high) hyperdiploid Karyotype, while, based on the microarray profiles, a discrimination between these two karyotypes is evident. This notion is of prognostic relevance, especially in cases with loss of 17p. In one patient we also observed a specific form of genomic instability, fulfilling the definition of chromothripsis (Stephens *et al.*, Cell, 2011). Although we performed our microarray-based genomic profiling assays on a relatively small number of patients, recurrent CNAs such as gains of 1q and of chromosomes2,3,5,7,9,11,15, 19, and 21, and losses of 1p and of chromosomes13,14, and 22, and acquired UPDs were readily identified. So far, only limited microarray-based genomic profiling data on enriched plasma cells from patients with MM or MGUS have been reported in the literature, however a remarkable consensus is apparent between these data and our current data. A particular novel finding in the present study is the recurrent occurrence of an acquired UPD of chromosome 12. Clearly, additional data are required to establish the clinical relevance of these observations.
Summary and Conclusions: Our results indicate that microarray-based genomic profiling exhibits a high sensitivity and specificity in identifying MM-associated numerical abnormalities. Although balanced translocations cannot be identified this way, CNAs can be easily identified. In addition, we show that microarray-based genomic profiling allows the detection of novel focal CNAs and acquired UPDs in MM-patients. The prognostic significance of these novel CNAs and acquired UPDs have to be evaluated in prospective clinical trials.

P958

SEMI-AUTOMATIC ULTRA RAPID DETECTION OF THE PML-RARA FUSION TRANSCRIPTS BY RETRO-TRANSCRIPTION LOOP MEDIATED AMPLIFICATION (RT-LAMP) REACTION ON THE LIAISON IAM INSTRUMENT

R Mesturini[1,*], G Minnucci[1], G Amicarelli[1], F Rigo[1], G Rizzo[1], P Zanghì[2], S Salmoiraghi[2], O Spinelli[2], F Colotta[1], A Rambaldi[2]
[1]molecular diagnostics, DiaSorin SpA, Gerenzano, [2]USC Hematology, Ospedali Riuniti di Bergamo, Bergamo, Italy

Background: After the initial morphologic evaluation the accurate and timely molecular identification of the Acute Promyelocitic Leukemia (APL) associated PML-RARa fusion gene is mandatory to start an appropriate treatment based on all-trans retinoic acid and to reduce the risk of potentially fatal hemorrhagic complications.
Aims: To improve the molecular diagnosis of Acute Promyelocitic Leukemia by introducing an ultra rapid screening test, easy to be performed even in not specialized laboratories, that allows rapid initiation of therapy.
Methods: RT-LAMP is a novel, isothermal, non-PCR method for direct RNA amplification. We applied this technique to the identification of the PML-RARa transcripts in Acute Promyelocytic Leukemia (APL). The system consists in two fluorescent multiplex assays, one specific for the most frequent transcripts (bcr1 and bcr3) and one for the more rare bcr2 starting from 500 and 300ng of total RNA, respectively. To control the extraction procedure, RNA integrity, reaction functionality and absence of inhibitors, both the assays also detect the endogenous GUSb housekeeping RNA as internal control. The reaction is performed in less than 40 minutes into the Liaison IAM instrument (DiaSorin) at constant temperature with a real-time monitoring of fluorescence intensity that decreases proportionally with the amplification progress. The data obtained are directly elaborated by the instrument, that returns results in terms of "positive", "negative" or "Invalid" result.
Results: The analytical sensitivity of the triplex (bcr1-bcr3-GUSb) and duplex (bcr2-GUSb) RT-LAMP assays has been determined on serial dilutions of RNA from the APL derived NB-4 cell line (for bcr1 transcript) or from patients at diagnosis (for bcr2 and bcr3 transcripts) into wild type RNA (from HL-60 cell line). The triplex (bcr1-bcr3-GUSb) assay showed a level of sensitivity of 10^{-3}on both the transcripts, while the duplex (bcr2-GUSb) assay showed a detection limit of 10^{-2} within 37 minutes. The analytical specificity has been established on wild type RNA from several cell lines (HL-60, REH, RS4-11, Kasumi, MV-4, 697, K-562 and TOM-1) for a total of 234 replicates. In all replicates exclusively the GUSb internal control RNA was amplified, demonstrating 100% specificity. The RT-LAMP assays have been finally validated on 96 clinical samples previously analyzed by conventional RT-PCR. Full concordance has also been obtained on negative samples (n=62) and on positive samples at diagnosis (n=34) in which the PML-RARa fluorescent signal was already visible in less than 10 minutes. Moreover, samples were correctly identified as positive for bcr1, bcr2 or bcr3 transcript. This information is required for the next phase of molecular monitoring during follow-up. Interestingly, this assay was also able to amplify a bcr1 transcript variant in which a deletion of PML exon 5 was present.
Summary and Conclusions: The fluorescent RT-LAMP assays for PML-RARa fusion transcripts detection is highly specific, sensitive and rapid. The isothermal single-step format, starting from patients RNA and monitorable in real-time in the Liaison IAM instrument, simplifies the entire reaction set-up. Furthermore, this improvement makes the assay cost-effective and applicable in not highly specialized laboratories. The RT-LAMP could shorter the time to diagnosis for patient affected by APL thus reducing risk of hemorrhagic complications by an early treatment administration.

P959

IMPORTANCE OF MICROARRAY ANALYSIS AS A PROGNOSTIC CLINICAL TOOL IN CHRONIC LYMPHOCYTIC LEUKEMIA

N Prie[1,*], S Bougeon[1], N Kramer[1], L Etter[1], O Bruzzese[1], D Ernst[1], S Porter[1], D Muehlematter[1], J Schoumans[1]
[1]Service de Cytogenetique Medicale, Centre hospitalier vaudois, Lausanne, Switzerland

Background: Chronic lymphocytic leukemia (CLL) is a B-cell malignancy with a highly variable clinical course. In addition to the mutational status of the immunoglobulin heavy chain, recurrent genomic abnormalities are among the strongest prognostic markers. Specific aberrations of prognostic significance are usually detected by interphase fluorescence *in situ* hybridization (iFISH). Array-based genomic technologies allow genome-wide screening for genomic alterations. They have proved to be effective in the detection of copy number abnormalities (CNA) and copy-neutral loss of heterozygosity (CN-LOH) and have consequently enabled the identification of new recurrent abnormalities of clinical relevance.
Aims: The aim of this study was to assess the usefulness of array based comparative genomic hybridization (CGH)+single nucleotide polymorphism (SNP) array as an alternative to iFISH for the detection of genomic abnormalities in routine clinical use.
Methods: Peripheral blood samples of 100 CLL patients were analysed both by iFISH and CGH+SNP arrays. The panel used for iFISH analysis included del(13)(q14)(DLEU1, DLEU2), del(11)(q22)(ATM), del(17)(p13)(TP53) and trisomy 12. For array analysis a 180K custom-designed cancer focus array was used from Oxford Gene Technology (OGT). The array was designed for the detection of single exon abnormalities in 17 selected genes (average coverage 1probe/100bp) as well as the simultaneous identification of copy neutral loss of heterozygosity (CNLOH by adding 36000 SNP probes). In addition, the array covers 1500 cancer-associated genes with an average resolution of 2kb, whilst retaining an average backbone resolution of 50kb.
Results: Genomic abnormalities were detected by iFISH in 74 patients and by array in 77 patients. A high degree of concordance was observed (96%) between both methods. A discrepancy was observed in four patients. Low proportions of abnormal cells (<10%) were detected only by iFISH in three patients and, in one patient, a small 13q deletion comprising only the locus DLEU2 was detected solely by array. Furthermore, by array, additional acquired genomic abnormalities not included in the FISH panel were detected in 67 patients. Some were recurrent abnormalities such as loss of 1q, 8p, 10q, 12p, 18p and gain of 2p, 4q, 8q which appear to be of prognostic significance. Large stretches >10 Mb of CNLOH were detected in 13% of the cases and accurate size mapping of clinically relevant genomic markers was obtained in 67.5% of abnormal cases by array analysis. This is particularly important in the case of deletions within 13q14, since larger deleted regions which also include loss of RB1 gene (type II) confer a less favourable prognosis than smaller deletions which comprise loss of the loci DLEU1 and/or DLEU2 only (type I). Overall, array analysis provided additional clinical relevant genomic data in 87% of abnormal cases. In addition, allowing the precise identification of breakpoints, aCGH can determine deleted regions of prognostic significance and identify candidate genes implicated in CLL of potential clinical relevance (Table 1).

Table 1.

			CGH + SNP	FISH
Patients with abnormalities			77	74
Abnormalities (locus FISH)	del(13q) Type I	DLEU1/DLEU2	27	51
		DLEU2	1	-
	del(13q) Type II	RB1/DLEU1/DLEU2	22	-
	del(11q) ATM		12	12
	+12		20	21
	del(17p) TP53		10	10
	others		1	1
	Total		93	95
Patients with additionnal abnormalities			67	-
False negativ	del(13q) Type I	DLEU1/DLEU2	-	2
		DLEU2	1	-
	+12		-	1
	Total		1	3

Summary and Conclusions: CGH+SNP array analysis is a robust, high resolution and sensitive screening method for routine clinical use in CLL and is able to reliably detect abnormalities only present in 10% of the cells. Array analysis shows clearly a higher diagnostic yield than iFISH.

P960

DEVELOPMENT OF BIOINFORMATICS SOFTWARE FOR AUTOMATED ANALYSIS AND VISUALIZATION OF DATA FROM AN MPS TCRG ASSAY

J Tutton[1,*], J Miller[1], H You[1], J Panning[1], M Klass[1]
[1]Invivoscribe Technologies, Inc, San Diego, United States

Background: The commercial availability of massively parallel sequencing (MPS) technology has generated staggering amounts of DNA sequence data from a multitude of applications. Efficient, timely handling and analysis of MPS data is a significant challenge and calls for the development of specialized software. The need for processing software is a critical requirement for the development of MPS assays designed to identify and monitor clonal rearrangements of the antigen receptor loci.
Aims: The specific goal of this work was to develop software for the processing of tens of millions of data sequences generated using the LymphoTrack™ DeepSeq™ TCRG Assay. Software output had to provide an accurate representation of the DNA sequence frequency distribution for the detection and monitoring of *TCRG* gene rearrangements and to provide a visual representation of the resulting analysis to aid in interpretation and tracking.
Methods: The bioinformatics data analysis software package uses Invivoscribe's proprietary primer sequence weight matrix and nucleotide sequence database, as input to the NCBI Nucleotide BLAST program, to analyze LymphoTrack™ DeepSeq™ TCRG Assay data generated from MiSeq™ (in fastq format). The analysis identifies sequence frequency distribution, V-J DNA

sequences, and V-J gene usage. The visualization component uses Microsoft Excel to present the resulting data analysis in a visual format, including a histogram of sequence frequencies.
Results: Analyzed data confirms the DNA sequences from clonal cell lines match published sequences. Good linearity of sequence frequencies was obtained in serial diluted clonal cell lines. Visualization provided an accurate representation of the resulting data. Software was appropriately validated to quantify the sequence frequencies and corresponding identities (Figure 1).

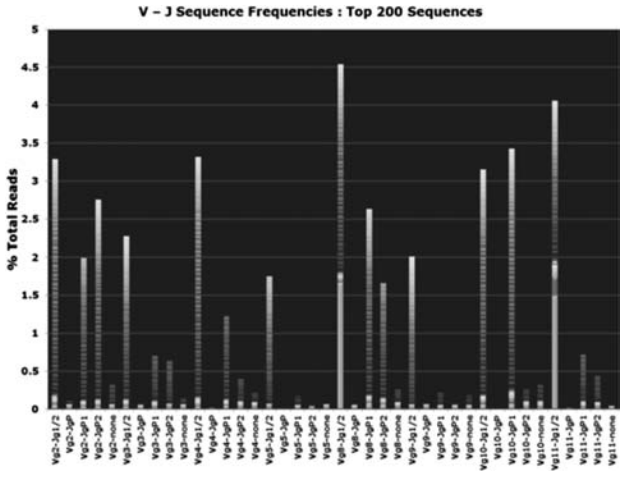

Figure 1.

Summary and Conclusions: This commercially available software package provides fast reliable analysis and visualization output that aids in the interpretation of data generated from this *TCRG* assay.

P961

CHARACTERISTICS OF VARIANT AND ADDITIONAL CYTOGENETIC ABNORMALITIES IN ACUTE MYELOID LEUKEMIA WITH RECURRENT GENETIC ABNORMALITIES
E Cho[1,*], K Lee[2], Y Kang [1], E Lee[1]
[1]Green cross laboratories, Yongin, [2]Department of pediatrics, College of medicine, Daegu catholic university, Daegu, Korea, Republic of Korea

Background: Acute myeloid leukemias harboring the prognostically favorable t(8;21)(q22;q22), inv(16)(p13q22)/t(16;16)(p13;q22), t(15;17)(q22;q21), and various translocations involving 11q23 form a separate category. Accurate identification of variants of these recurrent genetic abnormalties is important for diagnosis and appropriate treatment. Prognostic aspects of additional cytogenetic abnormalities present are still controversial.
Aims: To investigate the frequencies and patterns of variant and additional cytogenetic abnormalities, the cytogenetic profiles at the initial diagnosis of a total 245 acute myeloid leukemia patients with recurrent genetic abnormalities during the period from 2004 to 2012 referred to Green cross laboratories were analyzed.
Methods: In all, 64 patients with t(8;21)(q22;q22), 104 patients with t(15;17)(q22;q12), 36 patients with inv(16)(p13q22) (n=30) or t(16;16)(p13;q22) (n=6), and 41 patients with 11q23 translocations were investigated for variant translocations and secondary karyotypic abnormalities. To confirm the rearrangement, fluorescence *in situ* hybridization (FISH) and polymerase chain reaction (PCR) tests were performed.
Results: Variant translocations of t(8;21), t(15;17), inv(16)/t(16;16), and 11q23 were found in 6 (9%), 4 (4%), 2 (6%), and 0 (0%) patients, respectively. For variants of t(8;21), 5 patients had three-way translocation involving 4p16, 4q21, 12p12, 19p13.3, and 22p13. One patient had four-way translocation: t(1;21;8;4)(p13;q22;q22;q12). Of the 64 patients, 31 (48%) had additional sex chromosome losses. For variant of t(15;17), 3 patients had three-way translocation, including 5q31 and 6q12, and 1 patient had four-way translocation: t(5;9;17;15)(q31;q13.1;q21;q22). Interestingly, 3 patients showed translocation at the same locus (5q31). 41% of patients had additional chromosomal abnormalities. 9%, 6% and 3% of patients had ider(17)(q10)t(15;17), trisomy 8 and der(7)t(7;8)(q31.1;q21.1), respectively. For variant of inv(16)/t(16;16), 1 patient (4%) had t(16;16;17)(p13;q22;q11.2) and another patient had der(16)inv(16)(p13q22)t(X;16)(p11.2;q22). Trisomy 22 was the most common additional abnormality in inv(16)/t(16;16) and was found in 6 patients (17%). Partners of MLL translocation were 9p22(19), 19p13.1(11), 19p13.3(2), 1p32(2), 3p21(1), 6p27(1), 10p12(1), 10q22(1), 16p13.3(1), 17q11.2(1) and 17q25(1). Trisomy 8 was the most frequent additional chromosomal abnormality with MLL translocation and was found in 7 cases (17%).

Summary and Conclusions: Variants of t(8;21), t(15;17), and inv(16)/t(16;16) were not rare. Therefore, application of FISH and PCR tests was essential for the detection of variant translocations. To the best of our knowledge, all variants, except 2 cases, were novel translocations. Considering 3 cases with 5q31 involvement in t(15;17), 5q31 might possibly be a nonrandom breakpoint in acute promyelocytic leukemia, and the gene involved in 5q31 should be investigated.

P962

MUTATIONAL STUDY OF DNMT3A IN ACUTE MYELOID LEUKEMIA
S Oh[1,*], M Lee[1], J Lee[1], H Kim[2], J Lee[2], S Lee[2], T Park[3], J Lee[1]
[1]Department of Laboratory Medicine, Inje University College of Medicine, Busan, [2]School of Life Science and Biotechnology, Kyungpook National University, Daegu, [3]Department of Laboratory Medicine, School of Medicine, Kyung Hee University, Seoul, Korea, Republic of Korea

Background: The *DNMT3A* gene mutation was identified as a recurrent somatic mutation in acute myeloid leukemia (AML) and suggested to be a poor prognostic marker. As DNMT3A is the key enzyme in DNA methylation, its mutation would have a role in epigenetic and biological alterations in leukemia.
Aims: The present study was performed to investigate this gene mutation's biological impact on gene expression.
Methods: Sequence analysis of exons 9 and 23 encoding the proline-tryptophan-tryptophan-proline (PWWP) domain and catalytic domain of DNMT3A, respectively, was conducted in 29 cytogenetically normal (CN) AML samples. Constructs of wild-type *DNMT3A* and three recurrent mutants (R882H, R882C, and A368D) by site-directed mutagenesis were transfected into Hek293 cells. Western blotting analysis and direct immunofluorescence microscopy of the transfected cells were performed to determine the recombinant protein expression and localization. Gene expression profiles were determined by microarray analysis of transfected cells.
Results: *DNMT3A* mutations were found in 6 of 27 acute leukemia samples. R882C (c.2644C>T) and R882H (c.2645G>A) mutations in exon 23 encoding the catalytic domain of DNMT3 were detected. Recombinant wild-type, R882H, and R882C DNMT3A proteins were identified at higher levels in nuclear extracts than in the cytoplasm and found to show nuclear localization. However, the DNMT3A A368D mutant protein was detected only in cytoplasmic extracts by immunoblotting and was also localized to the cytoplasm as determined by fluorescence microscopy. Microarray analysis indicated that genes under regulation by CEBPA were downregulated and those under regulation by MEISA1A and HOXA9 were upregulated compared to the wild type and the R882H mutant, and *TP53TG3* was highly downregulated in both the R882H and R882C mutants (Figure 1).

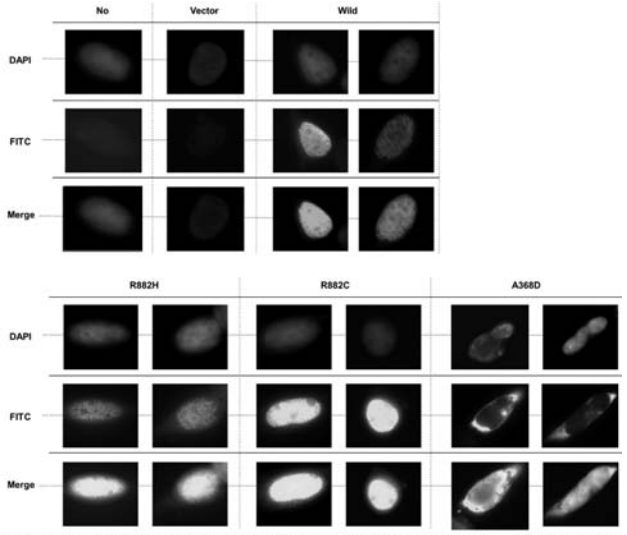

Figure 1. Localization of DNMT3A mutants in Hek293 cells.

Summary and Conclusions: The recurrent *DNMT3A* mutation at the R882 site previously implicated as a prognostic marker in CN-AML was also found in Korean leukemic samples. In the PWWP domain A368D mutant, loss of localization may result in modification of the gene expression profile. The effects of R882H and R882C mutations in the catalytic domain of DNTM3A on CEBPA transcriptional activation and the *TP53TG3*-associated pathways should be examined in future studies.

P963

RAPID AND RELIABLE DETECTION OF BCR-ABL MAJOR AND MINOR TRANSCRIPTS BY THE ONE-STEP, ISOTHERMAL RT-LOOP MEDIATED AMPLIFICATION REACTION MONITORABLE IN REAL TIME ON THE LIAISON IAM INSTRUMENT

V Tettamanzi[1,*], G Minnucci[1], G Amicarelli[1], C Pultrone[1], E D'Agostini[1], C Boroni[2], S Salmoiraghi[2], O Spinelli[2], F Colotta[1], A Rambaldi[2]
[1]molecular diagnostics, DiaSorin SpA, Gerenzano, [2]USC Hematology, Ospedali Riuniti di Bergamo, Bergamo, Italy

Background: The molecular identification of the BCR-ABL transcripts in patients affected by chronic myeloid leukemia or acute lymphoblastic leukemia is routinely based on conventional RT-PCR, a multistep procedure that takes few hours to identify the translocation and define the breakpoints
Aims: to allow a rapid and simultaneous molecular detection of major and minor BCR-ABL transcripts by using the one-step RT-LAMP and the semi-automated Liaison IAM instrument (DiaSorin)
Methods: RT-LAMP is an isothermal, non-PCR method which amplifies targets directly form RNA, thanks to the employment of a DNA polymerase with reverse transcription activity. This multiplex, close format, fluorescent assay, allows to simultaneously detect and distinguish the Minor (p190) and Major (p210) BCR-ABL transcripts and the internal control Gusb. Fluorescence variation derived from targets amplification are collected through different channels in real time by the Liaison IAM instrument (DiaSorin) that automatically analyses data releasing final result
Results: the triplex BCR-ABL RT-LAMP has been initially tested on RNA samples extracted from cell lines. Serial dilutions of RNA derived from TOM-1 or K-562 cell lines (p190 and p210 positive, respectively) into wild type RNA from HL-60 cell line have been tested for sensitivity assessment. The p190 and p210 transcripts have been detected and distinguished down to 10^{-4} and 10^{-5}respectively within 50 minutes. To establish the specificity of the assay, 70 replicates of wild type RNA from 7 cell lines have been tested and all resulted BCR-ABL negative in the presence of the correct amplification of the GUSb internal control (100% specificity). The BCR-ABL RT-LAMP assay was validated on 65 clinical samples previously proved positive by conventional RT-PCR (35 for p210, 30 for p190 transcript) and fully concordant results have been obtained. Furthermore, thanks to the real time monitoring on the Liaison IAM instruments, the amplification of positive samples has been already detectable after 15-20 minutes of reaction. Specificity was finally confirmed on 60 negative RNA samples (30 healthy donors and 30 Ph negative patients) all resulted BCR-ABL negative as expected
Summary and Conclusions: the triplex p190-p210-GUSb RT-LAMP performed on the Liaison IAM instrument represents an efficient system for simultaneous detection of both major and minor BCR-ABL transcripts starting directly from patients RNA. This assay simplifies the procedure and the close format reduces the contamination risks of conventional multi step RT-PCR. Furthermore, the high sensitivity, specificity and rapidity significantly enhance the patient management and improve the diagnostic laboratory routine.

SCREENING METHOD TO DETECT MOST PREVALENT MUTATIONS IN GAUCHER DISEASE

I Fevraleva[1,*], K Lukina[2], E Sysoeva[2], E Lukina[2], A Sudarikov [1]
[1]Department of Molecular Hematology, [2]Department of Orphan Diseases, National Hematology Research Center, Moscow, Russian Federation

Background: Sequencing approaches are commonly used to identify mutations in rare inherited disorders, *e.g.* Gaucher disease. Over 300 different mutations are described so far, four of which - N370S, L444P, 84GG, IVS2+1G>A- are the most common and represent up to 90% of the mutant alleles. To screen populations not yet characterized for incidence of Gaucher disease PCR methods to identify 4 most prelevant mutationt could be more effective.
Aims: To elaborate approach suitable for high throughout detection of common Gaucher mutations.
Methods: We designed allele-specific (AS) primers to discriminate normal alleles from mutant and functional gene from pseudogene for multiplex real-time polymerase chain reaction (Taqman). AS primers were chosen to anneal directly to the proposed mutation site, regardless to the homology with preudogene. Second nucleotide from the 3 '- end of each AS primer was intentionally changed to mismatched (G to C, A to T and vice versa) to increase the specificity of the reaction. To avoid pseudogene amplification reverse (opposite to AS) primers were chosen from the regions showing dissimilarity between gene and pseudogene. These dissimilarities (one nucleotide or more) are mismatched with the 3'-end of chosen reverse primers.Thus, the sequences of all primers, taken together, provide an opportunity to analyze the mutations located only in the functional gene but not in the pseudogene.
Results: We have tested DNA of 100 patients with Gaucher disease type I and 80 DNA of control group (non-Gaucher patients) for the presence of N370S, L444P, 84GG and IVS2+1G>A mutations. Mutation N370S was detected in 93% DNA of Gausher patients, L444P was found in 22%, IVS2+1–in 2%, 84GG–in 1% of patients. None of these mutations were found in DNAs from the control group. Direct sequencing of beta-glucocerebrosidase gene in 20 Gausher patients was used to verify PCR results. No mismatches between PCR and sequencing data were found.
Summary and Conclusions: We designed a set of primers for one-step multiplex real-time PCR detection of most prevalent Gaucher mutations. Elaborated protocol is adequate to detect mutations located only in the functional gene but not in the pseudogene. Proposed approach could be useful to design primers for detecting other genetic markers which require pseudogene discrimination.

Drug resistance and pharmacology

EX VIVO SENSITIVITY AND RESISTANCE MECHANISMS TO CLOFARABINE IN CHILDHOOD ACUTE LEUKEMIA

F Baleydier[1,*], A Plesa[2], A Evesque[3], C Galambrun[4], L Jordheim[3], C Dumontet[3]
[1]Pediatric Hematology Unit and Team Antibody anti-cancer, Centre de Recherche en Cancerologie de Lyon, Universite Claude Bernard Lyon1, [2]Laboratory of Hematology, Hospices Civils de Lyon, [3]Team Antibody anti-cancer, Centre de Recherche en Cancerologie de Lyon, Universite Claude Bernard Lyon1, Universite Claude Bernard Lyon1, Lyon, [4]Pediatric Hematology Unit, Assitance Publique Hopitaux de Marseille, Marseille, France

Background: Nucleoside analogues are drugs widely used in the treatment of childhood acute leukemia. Clofarabine, a nucleoside analogue of second generation looks promising in these diseases. Nonetheless, in adult leukemia, resistance mechanisms may compromise the anti-tumoral effect of nucleoside analogues and might impair the prognosis of these diseases. While second generation of nucleoside analogues has successfully entered phase I/II clinical trials in children, these mechanisms have not been fully explored in this population.
Aims: Our study aims to compare the effect of nucleoside analogues of first generation to the effect of clofarabine on primary samples of childhood acute leukemia, to test the impact of this effect on the outcome of patients and to explore mechanisms of resistance to nucleoside analogues in childhood.
Methods: 42 primary samples at diagnosis or at relapse from childhood and adolescents/young adults' acute leukemia (25 ALL and 17 AML) were studied. In accordance with the Declaration of Helsinki, informed consent was obtained from patients or their legal representatives. All samples but one were bone-marrow with 90% of median infiltration by blast-cells. Samples were tested for apoptosis after exposure to, as a reference, first generation of nucleoside analogues (aracytine and fludarabine) in parallel to clofarabine at doses range from 100µM to 1µM for aracytine and from 33µM to 0.1µM for fludarabine and clofarabine. Apoptosis was assessed by Propidium iodide/AnnexinV double-staining for the whole CD45+ blastic population. Resistance mechanisms were explored by quantification of gene transcripts (qPCR) involved in trans-membrane transport of nucleoside analogues (human Equilibrative Nucleoside Transporter 1), in their intracellular metabolism (deoxycytidine kinase, deoxyguanosine kinase and 5'-nucleotidases cN-II and cN-III) or in their intracytoplasmic target (Ribonucleotide reductase 1/2).
Results: Median age for the whole population was 10yrs [1-21yrs] and M/F sex-ratio=2.2. Median inhibitory concentration (IC) 50 was higher in ALL than in AML, 350µM *vs.* 89µM, 111µM *vs.* 69µM and 65µM *vs.* 16µM, for aracytine, fludarabine and clofarabine, respectively, but the difference was significant for aracytine only (P=0.001). Based on IC50, ALLs as well as AMLs were more sensitive to clofarabine than to aracytine (P<0.001 and=0.04, respectively) and in a lesser extent to fludarabine (non-significant). Median IC50 of each drug was used as the cutoff to define sensitivity/resistance. Among the different gene transcripts quantified only the level of deoxycytidine kinase was unexpectedly found significantly lower in ALL and AML samples sensitive to clofarabine compared to resistant ALL/AML samples. At this point, the deep meaning of this data remains elusive. Outcome of patients was analyzed with respect to the level of sensitivity to each drug. At a median follow-up of 24 months, disease-free survival was 88% and 38% (P=0.04) for AML patients sensitive or resistant to aracytine, respectively and 100% and 43% (P=0.05) for AML patients sensitive or resistant to clofarabine, respectively. Resistance to nucleoside analogues tested didn't impact the outcome of ALL patients.
Summary and Conclusions: Childhood ALLs and AMLs are more sensitive to clofarabine than to first generation analogue nucleosides. This better effect might be at least in part explained by the overcoming of known nucleoside analogue mechanisms of resistance. Low sensitivity to clofarabine unfavorably impacts the outcome in AML.

P966

KNOCKDOWN-INDUCED CELL CYCLE ARREST SENSITIZES TUMOR CELLS FROM PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TOWARDS TRAIL-INDUCED APOPTOSIS IN VITRO AND *IN VIVO*

H Ehrhardt[1], F Wachter[1], M Grunert[1], I Jeremias[1,*]
[1]Gene Vectors, Helmholtz Center Munich, Munich, Germany

Background: Resting tumor cells represent a huge challenge during anti-cancer therapy due to their increased treatment resistance. TNF-related apoptosis-inducing ligand (TRAIL) is a putative future anti-cancer drug currently in phase I and II clinical studies. We recently showed that TRAIL is able to target leukemia stem cell surrogates.
Aims: Here we tested the ability of TRAIL to target cell cycle arrested tumor cells.
Methods: Primary tumor cells from patients with acute lymphoblastic leukemia were xenografted into mice, amplified and re-isolated for experiments. Xenograft cells were lentivirally transduced for expression of luciferase allowing the use of *in vivo* imaging for follow up of the preclinical treatment trial using TRAIL. Cell cycle arrest was induced in tumor cell lines and xenografted tumor cells in G0, G1 or G2 using cytotoxic drugs, phase-specific inhibitors or RNA interference against cyclinB and E. Knockdown efficiency was tested by Western Blot.
Results: Biochemical or molecular arrest at any point of the cell cycle increased TRAIL-induced apoptosis. Accordingly, when cell cycle arrest was disabled by addition of caffeine, the anti-tumor activity of TRAIL was reduced. Most important for clinical translation, tumor cells from three children with B-precursor or T-cell acute lymphoblastic leukemia showed increased TRAIL-induced apoptosis upon knockdown of either cyclinB or cyclinE arresting the cell cycle in G2 or G1, respectively. *In vivo*, systemic treatment with TRAIL inhibited and even erradicated tumor cells from patients with acute lymphoblastic leukemia in immuno-compromised mice.
Summary and Conclusions: Taken together and in contrast to most conventional cytotoxic drugs, TRAIL exerts enhanced anti-tumor activity against cell cycle arrested tumor cells. Therefore, TRAIL might represent an interesting drug to treat static tumor disease, *e.g.*, during minimal residual disease.

P967

TRANSCRIPT LEVELS AND COPY NUMBER VARIATION OF THE ABCC3 EFFLUX TRANSPORTER CAN PREDICT CLINICAL OUTCOME IN IMATINIB-TREATED CHRONIC MYELOID LEUKAEMIA PATIENTS

A Giannoudis[1,*], A Davies[1], R Harris[1], C Lucas[1], M Pirmohamed[2], R Clark[1]
[1]Molecular and Clinical Cancer Medicine (Haematology), [2]Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom

Background: Imatinib has dramatically improved survival in chronic myeloid leukaemia (CML) but disease progression may still occur in some patients. Imatinib is a substrate for the ABC efflux transporters ABCB1 (MDR1) and ABCG2 (BCRP), whereas its uptake into the cells is highly dependent on the expression and/or the activity of the influx transporter hOCT1 (SLC22A1). Additional transporters from the ABC family could also affect the balance of imatinib influx/efflux within the CML cell, and may thus contribute to resistance mechanisms. In this study, we focus on ABCC3, an efflux transporter.
Aims: To determine whether imatinib is a substrate for ABCC3, define the importance of copy number variations in the gene and correlate its expression and activity with clinical outcome.
Methods: Peripheral blood mononuclear cells (PBMC) were collected from 4 normal subjects and 90 newly-diagnosed untreated chronic phase CML patients. Following 12 months imatinib treatment, cases were classified as: a) optimal b) sub-optimal c) failure and d) blast crisis (BC), according to ELN 2009 criteria. ABC and hOCT1 transporter mRNA expression and ABCC3 gene copy number variation (CNV) were assessed by qPCR using commercially available TaqMan® assays; GAPDH and RNaseP were used as normalising controls respectively. Data were interpreted using the Comparative Ct method (ΔΔCt) and the ΔCt method using CopyCaller™ software respectively. Unidirectional efflux (transwell assay) of imatinib was investigated using confluent monolayers of the Marin-Darby canine kidney (MDCKII) cell line stably transfected to over-express ABCC3. Imatinib uptake studies, with and without probenecid, were also undertaken on mononuclear cells of 10 CML patients (5 optimal and 5 failures) at diagnosis. Mann-Whitney test was used to correlate transporter mRNA expression with clinical outcome. ABCC3 CNV was assessed by Kaplan-Meier survival plots using the Mantel-Cox Log-rank statistical test. Unpaired 2-tail t test was used on the efflux assays. All statistical analyses were performed using the GraphPad Prism 5 statistical software.
Results: ABCC3 mRNA expression was significantly higher in patients failing treatment (P=0.0002) when compared with those classified as optimal responders. When comparing the ratio of hOCT1 (influx) to ABCB1, ABCC1 and ABCC3 (efflux) transporters, patients with a lower ratio of hOCT1/ABCC3 were more likely to fail imatinib treatment (P=0.0004). CNV analysis also revealed that patients with 3 or more copies of the ABCC3 gene were destined to fail imatinib (P=0.001). In MDCKII cells with polar ABCC3 expression, imatinib was transported unidirectionally in a manner consistent with ABCC3 efflux. This was blocked by the ABCC3 inhibitor probenecid (Net efflux on MDCII-ABCC3 monolayers: 3.61 without *vs.* 1.26 with probenecid). Imatinib uptake studies in primary patient cells also demonstrated that optimal responders had higher imatinib uptake than patients destined to fail (P=0.019); this was also abolished by probenecid.
Summary and Conclusions: Our data clearly illustrate that imatinib is a substrate for the ABCC3 efflux transporter. CML patients with high ABCC3 expression were less likely to have a favourable response to imatinib treatment. Given that imatinib is transported by a number of transporters, it is likely that a complex interplay in the expression and activity of a number of influx and efflux transporters will determine intracellular concentrations, and the likelihood of imatinib resistance and/or treatment failure.

P968

TARGETING THE DBC1-SIRT1-P53 AXIS IS A PROMISING THERAPEUTIC STRATEGY IN FLT3-ITD-POSITIVE AML

D Sasca[1,*], P Haehnel[1], K Al-Khawaja[1], L Bullinger[2], M Theobald[1], T Kindler[1]
[1]III. Medical Department, University Medical Center, Mainz, [2]III. Medical Department, University Medical Center, Ulm, Germany

Background: Acute myeloid leukemia (AML) is a heterogeneous disease of the hematopoietic progenitor cell. Several genetic alterations have been detected so far, of these FLT3-internal-tandem duplications (FLT3-ITD) can be found in about 25% of AML patients. FLT3-ITDs are associated with a high risk of relapse and poor overall survival. To improve patient outcome several tyrosine kinase inhibitors (TKI) have been developed, but often duration of response is short and resistance common. The NAD+ dependent protein SIRT1 has been shown to act as an important negative regulator of p53 activity and recent reports have demonstrated increased expression of SIRT1 in leukemic cells. Of note, SIRT1 seems to be specifically essential to maintain stem cell activity in CML leukemic stem cells (Li, Bhatia *et al.*, Cancer Cell 2012). The impact of SIRT1 in the context of other oncogenic tyrosine kinases is poorly understood.
Aims: To determine the role of SIRT1 in AML driven by FLT3-ITD mutations and other oncogenic tyrosine kinases.
Methods: Expression levels of SIRT1 and DBC1 in AML cell lines, BaF/3 cells expressing oncogenic tyrosine kinases (FLT3-ITD, cKIT D816V, JAK2 V617F, TEL/PDGFRβ) and primary AML samples were investigated by immunoblotting and RQ-PCR analysis. To examine FLT3-ITD mediated SIRT1 regulation, cells were treated with midostaurin or transduced with shRNA directed against FLT3. Further, we performed co-immunoprecipitation analyses using SIRT1 and DBC1 antibodies +/- midostaurin treatment. To explore the functional role of SIRT1, leukemic cells were treated with the specific SIRT1-inhibitors Tenovin 6 and EX527 or transduced with SIRT1-shRNA and apoptotic cell death and p53-acetylation were determined. Finally, we analyzed the role of Sirt1 in an FLT3-ITD$^+$ AML mouse model.
Results: Immunoblotting experiments of FLT3-ITD$^+$ leukemic cell lines and primary patient samples showed increased expression of SIRT1, whereas DBC1 levels were unaffected compared to FLT3-ITD$^-$ leukemic controls. Interestingly, increased SIRT1 expression was also observed in cells expressing other oncogenic tyrosine kinases. No elevated mRNA levels were observed suggesting tyrosine kinase mediated post-translational modifications. Treatment of FLT3-ITD positive cells with midostaurin or FLT3-knockdown was followed by reduced expression of SIRT1, p53 acetylation and enhanced DBC1-phosphorylation. As DBC1 acts as a major inhibitor of SIRT1 function, we performed co-immunoprecipitation experiments. Treatment with midostaurin caused strong association of DBC1 with SIRT1 in MOLM14 and MV4;11 cells. To explore whether targeting SIRT1 can enhance the effects of FLT3-TKIs several cell lines and primary murine FLT3-ITD$^+$/MLL-AF9 cells were treated with Tenovin 6 and EX527 +/- midostaurin. Whereas continuous treatment with SIRT1-inhibitors caused inhibition of proliferation, the combination with midostaurin induced significant apoptotic cell death. Similar effects were observed upon shRNA-mediated SIRT1 knockdown.
Summary and Conclusions: Our date indicate that SIRT1 expression is regulated by FLT3-ITD and other oncogenic tyrosine kinases, likely due to post-translational stabilization mediated by DBC1. Further, targeting SIRT1 in the context of oncogenic tyrosine kinases might represent a promising approach to increase sensitivity of TKIs and prevent the development of resistance. To investigate SIRT1 inhibition *in vivo*, experiments are ongoing.

P969

TRANSCRIPTIONAL PROGRAMMES ASSOCIATED WITH EVI1 MEDIATED CHEMOTHERAPY RESISTANCE OF HUMAN MYELOID CELLS

R Wieser[1,2,*], A Rommer[1,2], H Hackl[3], B Steinmetz[1,2], F Herbst[4], P Heffeter[1,2], D Heilos[1,2], M Filipits[1,2], K Steinleitner[1,2], S Hemmati[4], I Herbacek[1], I Schwarzinger[1], H Glimm[4], W Berger[1,2]
[1]Medical University of Vienna, [2]Comprehensive Cancer Center, Vienna, [3]Medical University Innsbruck, Innsbruck, Austria, [4]German Cancer Research Center, Heidelberg, Germany

Background: Overexpression of the oncogenic transcription factor *EVI1* is associated with resistance to chemotherapy and a dismal prognosis in acute myeloid leukemia (AML). Nevertheless, the molecular mechanisms through which *EVI1* decreases drug sensitivity of myeloid cells have only recently begun to be explored.
Aims: In this study, we aimed to establish an *in vitro* model system that would recapitulate the chemotherapy resistance conferred by *EVI1* overexpression in human disease, and to use this model to explore transcriptional targets that may play a role in EVI1 mediated drug refractoriness.
Methods: The human myeloid cell lines U937 and HL60 were infected with retroviral vectors mediating overexpression of *EVI1*, as well as the corresponding control vectors. Differentiation was assessed by fluoresence activated cell sorting for the cell surface marker CD11b and by morphological analysis. *In vivo* growth of U937_EVI1 and control U937_vec cells was monitored after subcutaneous injection into CB17 scid/scid mice. Metabolic activity and apoptosis after treatment with cytotoxic drugs were measured using standard assays. Genome wide gene expression analyses of U937_EVI1 and U937_vec cells cultured for 48 h in the absence or presence of 400 nM etoposide were conducted using the Human Gene ST1.1 array.
Results: Constitutive overexpression of *EVI1* in human myeloid U937 cells reduced differentiation *in vitro*, and strongly enhanced the growth of xenograft tumors in SCID mice. Most importantly with respect to the properties of *EVI1* overexpressing AML, U937_EVI1 cells displayed increased resistance to the double strand break inducing drugs etoposide and daunorubicin, both of which are used in the therapy of AML, compared to control U937_vec cells. Similar results were obtained with HL60_EVI1 cells. Gene expression profiling of U937_EVI1 and U937_vec cells revealed 1486 unique genes that were regulated at least 1.5-fold by etoposide in the absence of *EVI1* (875 up, 611 down), and 362 genes that were regulated at least 1.5-fold by *EVI1* in the absence of etoposide (126 up, 236 down). Notably, 119 genes were regulated both by *EVI1* and etoposide (51 induced and 30 repressed by both conditions, and 38 induced by etoposide but repressed by *EVI1*). This enrichment was highly significant ($P<10^{-14}$; Fisher's exact test). Of the genes regulated by etoposide, *EVI1*, and both stimuli, 80, 21, and 11 were related to the gene ontology (GO) term apoptosis, respectively. We further searched for genes whose regulation by etoposide was counteracted by *EVI1*. Indeed, *EVI1* diminished the induction by etoposide of 54 unique genes, but the reverse pattern - an alleviation by *EVI1* of repression by the cytotoxic drug - was not observed. Three of the 54 genes whose induction by etoposide was reduced by *EVI1* were related to the GO term apoptosis.
Summary and Conclusions: We have established an *in vitro* model system that recapitulated the chemotherapy resistance associated with *EVI1* overexpression in human AML patients. Gene expression profiling suggested that *EVI1* mediated resistance to cytotoxic drugs through a number of target genes and at least two different mechanisms: firstly, it may "pre-adapt" cells to cytotoxic drug exposure by activating gene expression patterns that are also elicited by chemotherapeutic agents, and may at least in part represent cellular defense mechanisms against their action. Secondly, *EVI1* counteracted the induction of genes that may take part in mediating the cytotoxic action of chemotherapeutic agents.

P970

KNOCKDOWN OF NUCLEOPHOSMIN BY RNA INTERFERENCE REVERSES MULTIDRUG RESISTANCE IN RESISTANT LEUKEMIC HL-60 CELLS

J Hu[1,*], M Lin[1], T Liu[1], J Li[1], B Chen[1], X Chen[1]
[1]Department of Hematology, Fujian Institute of Hematology,Fujian Medical University Union Hospital, Fuzhou, China

Background: Nucleophosmin, a multifunctional nucleolar phosphoprotein, is involved in many cellular activities. Abnormal expression of *NPM* gene, such as over-expression, mutation, rearrangement or deletion, could lead to abnormal cellular proliferation, which is an important mechanism of malignant transformation in tumor cells. A number of previous studies have indicated that the expression of *NPM* was more abundant in the proliferative cells than the resting cells, especially in many kinds of solid tumors cells. Furthermore, it is showed that over-expression of NPM in solid tumor cells was probably one of the poor prognostic factors, and related to the tumor progression and drug-resistance development. Other than the solid tumors, it has been confirmed that *NPM* is mutated in around 30-50% of adult AML with a normal karyotype. These mutations are proven to have prognostic significance. Our previous study has revealed that NPM was obviously over-expressed in many leukemia cells, especially in the resistant leukemia cell lines and in relapsed/refractory patients. But, relatively little is known about the role of NPM in resistance of leukemia.
Aims: In this study, in order to explore the potential role of NPM in resistance of leukemia, the recombinant eukaryotic expression vector of *NPM*-shRNA was constructed.
Methods: In this study,adriamycin sentitive and resistant HL-60 cell lines (HL-60 and HL-60/ADR) were used as target cell for lentiviral-mediated RNAi. We designed and selected one shRNA targeting on *NPM* gene for transfection into HL-60 and HL-60/ADR cell lines. Cell proliferation and differentiation were measured by growth curve, clone formation assay, NBT reduction assay and CD11b analysis. qRT-PCR and western blotting were used to access the expression of related genes and proteins. Cell cytotoxicity assay was used for evaluation of cell sensitivity to chemotherapeutic agents.
Results: The results showed obvious down-regulation of NPM mRNA and protein levels after *NPM* RNAi. The *NPM*-targeted RNAi resulted in many cellular changes, such as, suppressing cell proliferation and inducing cell differentiation. Down-regulation of *NPM* gene could arrest the cell cycle progression, an increase in the proportion of G0/G1 phase (38.51±1.33% *vs.*52.84±2.08% of control and knockdown groups on HL-60 cells, 41.90±1.35% *vs.* 60.89±2.71% of control and knockdown groups in HL-60/ADR cells, respectively). *NPM* gene silencing could also induce pro-apoptotic genes and proteins expression, and inhibit anti-apoptotic genes/proteins expression.Furthermore, IC50 of two chemotherapeutic agents (ADR, DNR) to HL-60 and HL-60/ADR cells decreased, especially more remarkable on HL-60/ADR cells. IC50 of ADR on HL-60/ADR cells was reduced from 12.544±0.851μmol/L (before *NPM* RNAi) to 6.331±0.522μmol/L (after *NPM* RNAi), IC50 of DNR was reduced from

2.152±0.143μmol/L (before *NPM* RNAi) to 1.116±0.093 μmol/L (after *NPM* RNAi). The relative reversal rate of HL-60/ADR cells on ADR was 50.2%, and on DNR was 48.9%.
Summary and Conclusions: In conclusion, our results demonstrated that shRNA expression vectors could effectively reduce *NPM* expression and restore the drug sensitivity of resistant leukemic cells to conventional chemotherapeutic agents.

P971

SYNTHETIC LETHALITY IN P53 MUTATED B-CELL MALIGNANCIES: CHK-1 INHIBITION AND DNA-PK INHIBITION EFFECT IN CELL LINES AND PRIMARY CLL CELLS
J Zemanova[1,*], L Sebejova[1], K Paruch[2], O Hylse[2], S Pospisilova[1], J Mayer[3], M Trbusek[1]
[1]Central European Institute of Technology, [2]International Clinical Research Center, FN St. Anna, [3]Department of Internal Medicine, FN Brno, Brno, Czech Republic

Background: Mutations in the *TP53* gene are usually associated with very poor prognosis in hematological malignancies, including strong resistance to therapy. The concept of synthetic lethality based on inhibition of Chk1 kinase represents a promising approach for elimination of highly aggressive cancer cells. After this inhibition, the blockade of all three major cell cycle checkpoints is presumed, ie, the G1/S (owing to *TP53* mutation), and S together with G2/M (both through the Chk1 inhibition). This should result in uncontrolled cell proliferation followed by mitotic catastrophe and cell death. DNA-PK is a kinase responsible for DNA damage signaling within the nonhomologous end-joining DNA repair. It has been reported that especially high risk cancer cells harboring *TP53* mutations can be protected from chemotherapy through enhanced activation of this pathway. The sensitization to chemotherapeutic drugs using DNA-PK inhibition has been reported in CLL.
Aims: To analyze potential sensitization of B-cell leukemia and lymphoma cells with *TP53* mutations to nucleoside analog fludarabine using: (i) Chk1 inhibition in growing cell lines, (ii) Chk1 inhibition in non-dividing CLL cells, (iii) DNA-PK inhibition in growing cell lines, (iiii) DNA-PK inhibition in non-dividing CLL cells.
Methods: Following cultures were used: 15 B-cell leukemia or B-cell lymphoma permanent cell lines with 10 of them having *TP53* mutation and 24 primary CLL cultures with 12 of them having *TP53* mutation (PBMNC containing >85% of CLL lymphocytes). The inhibitors were following: SCH900776 (racemic isoform, 200 nmol) for Chk1 and NU7026 (10 μmol) for DNA-PK. After 2h pre-incubation with inhibitors, fludarabine was administered at four different concentrations (assessed individually for cell lines - see Results, and 25; 6.25; 1.6 and 0.4 μg/mL for CLL cultures). Cell viability was measured by the metabolic WST-1 assay (Roche). The sensitization effect was evaluated if appearent in at least two bordering concentrations using two-way analysis of variance (ANOVA).
Results: The detailed *TP53* status (deletion and/or mutation presence) was assessed for all used cell lines and primary cultures by I-FISH and by the yeast functional analysis with subsequent sequencing. Concentrations of fludarabine ranged from 20 to 0.125 μg/mL in the tested cell lines, with those having *TP53* defects being obviously more resistant. The Chk1 inhibitor on its own exhibited none or only negligible effect on cell viability (≥90% in comparison with untreated control). The significant sensitization effect (P<0.01) was observed in 5/10 (50%) mut-*TP53* cell lines and 1 out of 5 (20%) wt-*TP53* cell lines. By contrast, no sensitization effect was observed in tested primary CLL cultures. The DNA-PK inhibitor on its own reduced a viability in most of the cultures (average 73%). The sensitization effect (P<0.01) was apparent in 2/10 (20%) mut-*TP53* cell lines and none out of 5 wt-*TP53* cell lines. Similarly to cell lines, also some primary CLL cultures responded to DNA-PK sensitization: positive effect was observed in 4/12 (33%) *TP53*-defected samples and none out of 12 wt cultures. Using western blot for phosphorylated histone H2AX (γH2AX), we verified that both Chk1 and DNA-PK sensitization was mediated through enhanced accumulation of DNA damage (dsDNA breaks).
Summary and Conclusions: Our work shows that both Chk1 kinase inhibition and DNA-PK inhibition may represent feasible approach how to eliminate some aggressive leukemia and lymphoma cells. Some other cultures remain, however, inert to the sensitization. Concerning primary non-dividing CLL cells, we confirm that the DNA-PK approach might be promising. Our preliminary data suggests that Chk-1 inhibition should be tested in CLL cells after these are stimulated to proliferation. The work was supported by the project FNUSA-ICRC (CZ.1.05/1.1.00/02.0123), MUNI/A/0784/2012, and NT13519-3.

POLYMORPHISMS OF MULTIDRUG RESISTANCE TRANSPORTER (ABCG2 AND ABCB1) GENES IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA
H Andrikovics[1,*], M Koszarska[1], A Bors[1], N Papp[1], D Czifra[1], O Csacsovszki[2], A Batai[2], E Adam[2], A Kozma[2], N Lovas[2], A Sipos[2], J Dolgos[2], S Fekete[2], P Remenyi[2], B Sarkadi[3], A Tordai[2], T Masszi[2]
[1]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, [2]Department of Hematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, [3]Hungarian National Blood Transfusion Service, Budapest, Hungary

Background: ATP-binding cassette (ABC) transporters such as P-glycoprotein (encoded by the *ABCB1* gene) and breast cancer resistance protein (*ABCG2*), appear to be expressed in hematopoietic stem cells, and presumed to play a protective role against a broad spectrum of toxic substrates. ABC-transporters may also be responsible for the efflux of small lipophylic substrates, such as steroids, and their expression may play a regulatory role in inducing growth, differentiation or apoptosis. Alteration in the putative physiological function of ABC-transporters may result in hematopoietic stem cell disorders. In addition, both ABC-transporters have been linked to drug resistance mediating the efflux of several cytotoxic substances.
Aims: To investigate common single nucleotide polymorphisms with functional consequences in ABCB1 and ABCG2 genes, whether they influence the predisposition to haematopoietic stem cell disorders and contribute to the development of chemotherapy resistance in patients with acute myeloid leukemia (AML).
Methods: 395 AML patients (185 males/210 females; median age: 50; range: 16-93 years) diagnosed and followed between 2001-2009 were enrolled in the study. Remission and relapse rates and survival were analyzed for 328 patients younger than 60 years and treated with curative intention. Single nucleotide polymorphisms of *ABCG2* (c.34G>A and c.421C>A) and *ABCB1* (c.3435C>T) were analysed from genomic DNA samples of 390 AML patients and 204 healthy controls by LightCycler allele discrimination technique.
Results: Allele frequencies (AF) were not different in AML patients as a whole cohort compared to controls (c.34G>A AF±95%CI: 4.2±1.4% in AML *vs.* 3.9±1.9% in controls; c.421C>A: 8.1±2.0% in AML *vs.* 10.0±3.0% in controls; c.3435C>T AF±95%CI: 49.6±3.6% in AML *vs.* 49.8±5.0% in controls). On the other hand, AML subgroup analysis revealed that AML1-ETO [t(8;21)(q22;q22) translocation] positive patients (n=18) showed higher c.34G>A AF (16.7±12.4%) compared to control individuals (P=0.02). Among AML patients younger than 60 years receiving daunorubicin based induction chemotherapy (n=256), ABCG2 c.421C>A carriers (CA+AA genotypes) displayed longer overall (48-month OS: 42.5±8.1% *vs.* 28.4±3.1%; P=0.072) and disease free survival (48-month DFS: 38.3±8.3% *vs.* 26.0±3.1%; P=0.048) compared to individuals carrying the major allele (CC genotype). Early death due to toxicity, resistant disease, remission and relapse rates were not different between ABCG2 c.421C>A carriers and major allele carriers. ABCB1 polymorphism tested in this study did not alter disease predisposition or treatment outcome.
Summary and Conclusions: Our results suggest that common ABCG2 polymorphisms might influence AML predisposition and treatment outcome differentially depending on AML genetic background or chemotherapy applied.

P973

INHIBITION OF PI3K/MTOR OVERCOMES NILOTINIB RESISTANCE IN BCR-ABL1 POSITIVE LEUKEMIA CELLS
J Ding[1,*], J Romani[1], M Zaborski[1], S Nagel[1], H Drexler[1], H Quentmeier[1]
[1]Leibniz-Institute DSMZ, Braunschweig, Germany

Background: Chronic myeloid leukemia (CML) is a cytogenetic disorder resulting from expression of the Philadelphia chromosome (Ph), that is, the t(9;22) chromosomal translocation and the formation of the BCR-ABL1 fusion protein. Tyrosine kinase inhibitors (TKI), such as imatinib and nilotinib, have emerged as leading compounds to treat CML. Translocation t(9;22) does not only occur in CML, 20-30% of acute lymphoblastic leukemia (ALL) are also found with expression of Ph. However, TKI are not comparably effective for the treatment of Ph+ ALL. BEZ235, a dual inhibitor of PI3K/mTOR, shows broad preclinical anti-leukemia activity *in vitro* and *in vivo* and is currently undergoing clinical evaluation.
Aims: The aim of this study was to investigate TKI resistance mechanisms and sensitization of Ph+ tumor cells to TKI treatment.
Methods: Cell apoptosis was investigated by flow cytometry with annexin V/propidium iodide (PI) staining. Quantitative RT-PCR was used to check mRNA level and protein level was analyzed by Western blot. Cleavage of caspase 3 and PARP was also assessed by Western blot. Cell cycle arrest assay was carried out using flow cytometry with PI staining.
Results: The Ph+ cell lines JURL-MK2 and SUP-B15 were used in this study. The annexin V/PI assay revealed that nilotinib induced apoptosis in JURL-MK2 cells, but not in SUP-B15 cells. There was no mutation in the tyrosine kinase domain of BCR-ABL1 in cell line SUP-B15. Consequently, the cells were not generally irresponsive to TKI, evidenced by dephosphorylation of the BCR-ABL1 downstream target STAT5. The resistance to apoptosis after nilotinib treatment was accompanied by the constitutive and nilotinib irresponsive activation of the PI3K pathway. Treatment of SUP-B15 with the dual PI3K/mTOR inhibitor BEZ235 alone induced apoptosis in a low percentage of cells. Combination of nilotinib and BEZ235 led to a synergic apoptotic effect in SUP-B15 cells. Caspase3 and PARP cleavage confirmed that apoptosis was induced after combined treatment. The main effect of PI3K/mTOR inhibition and reason for apoptosis in the nilotinib resistant cells

was the block of the translational machinery, leading to the rapid down-regulation of anti-apoptotic protein MDM2.
Summary and Conclusions: In conclusion, the results demonstrated that BEZ235 overcomes nilotinib resistance to apoptosis in SUP-B15 cells through translational down-regulation of MDM2. The current findings suggest that MDM2 may be a therapeutic target to sensitize TKI-resistant BCR-ABL1 positive leukemia cells.

P974

ACTIVITY OF ABL1 KINASE INHIBITOR, IMATINIB AND THE JAK KINASE INHIBITOR TG101348: THE TARGETED THERAPY FOR RESIDUAL BCR-ABL POSITIVE LEUKEMIA CELLS

S Okabe[1,*], T Tauchi[1], S Katagiri[1], Y Tanaka[1], K Ohyashiki[1]
[1]TOKYO MEDICAL UNIVERSITY, Shinjuku-Ku, Japan

Background: ABL kinase inhibitor, imatinib is highly effective therapy against chronic myeloid leukemia (CML) patients. However, imatinib is not curative for most CML patients. Residual CML cells are present in bone marrow microenvironment. Bone marrow microenvironment is a source of soluble factors such as cytokine and regulates the proliferation of leukemia cells. The hematopoietic cytokine receptor signaling is mediated by tyrosine kinases termed Janus kinases (Jaks) and downstream transcription factors, signal transducers and activators of transcription (STATs). Jak-STAT signaling is also activated in CML cells. One of the Jak kinase inhibitor, TG101348 (SAR302503) is an orally available inhibitor of Jak2 and developed for the treatment of patients with myeloproliferative diseases.
Aims: Combination therapy using a BCR-ABL tyrosine kinase inhibitors and a Jak inhibitor, TG101348may help prevent stroma-associated drug resistance-and these approaches may be expected to improve the outcomes of CML patients.
Methods: In this study, we investigated the ABL tyrosine kinase inhibitor, imatinib and TG101348 efficacy by using the BCR-ABL positive cell lines, K562 and primary CML samples when leukemic cells were protected by the feeder cell lines (HS-5 and S9).
Results: 72 hours treatment of imatinib exhibits cell growth inhibition and induced apoptosis against K562 cells in a dose dependent manner. However, the treatment of imatinib exhibits cell growth inhibition partially against K562 cells in the presence of HS-5 conditioned media. Treatment of TG101348 did not exhibit cell growth inhibition against K562 cells directly. However, the combination treatment with imatinib and TG101348 abrogated the protective effects of HS-5 conditioned media in K562 cells. We next investigated the intracellular signaling of imatinib and TG101348. Phosphorylation of BCR-ABL, Crk-L was not reduced after TG101348 treatment. However, phosphorylation of BCR-ABL, Crk-L was significantly reduced and increased apoptosis after combination treatment with imatinib and TG101348. We next investigated the efficacy between imatinib and TG101348 by using CD34 positive primary CML samples. The treatment of imatinib exhibits cell growth inhibition partially against CD34 positive CML samples in the presence of feeder cells. Combined treatment of CD34 positive primary samples with imatinib and TG101348 caused significantly more cytotoxicity and induced apoptosis. We also found that mitogen-activated protein kinase (MAPK) was also inhibited by imatinib and TG101348 treatment. We next investigated the intracellular signaling of imatinib and TG101348 by using the CD34 positive primary samples. Phosphorylation of BCR-ABL, Crk-L was significantly reduced and increased apoptosis after treatment with imatinib and TG101348. Moreover, combination of imatinib and TG101348 inhibited the colony growth of Ph-positive primary samples. We also investigated the TG101348 activity against feeder cell. Phosphorylation of STAT5 was reduced by TG101348 in a dose dependent manner. The cytokine production was analyzed by using cytokine array systems. The cytokine production such as granulocyte macrophage colony-stimulating factor (GM-CSF) from HS-5 was also reduced by TG101348 treatment.
Summary and Conclusions: Data from this study suggested that administration of the imatinib and Jak inhibitor, TG101348 may be a powerful strategy against stroma-associated drug resistance of Ph-positive leukemia cells and enhance cytotoxic effects of imatinib in those residual CML cells.

P975

TP53 MUTATIONS BUT NOT ATM MUTATIONS ASSOCIATE WITH HIGHER IN VITRO RESISTANCE OF CLL CELLS TO RITUXIMAB

L Sebejova[1,2,*], M Sramek[1], Z Jaskova[2], J Malcikova[1,2], V Navrkalova[1,2], M Borsky[1], M Doubek[1,2], J Mayer[1,2], S Pospisilova[1,2], M Trbusek[1,2]
[1]University Hospital Brno, [2]Central European Institute of Technology, Brno, Czech Republic

Background: *TP53* and *ATM* defects have been associated with inferior outcome in chronic lymphocytic leukemia (CLL). The response of corresponding patients to conventional chemotherapy is usually poor. Monoclonal antibodies targeted to leukemic cells are supposed to act primarily independently on apoptosis induction and should, therefore, bypass a block imposed by the *TP53* or *ATM* inactivity. Despite that, treatment outcome using rituximab on its own or in combination with chemotherapy is usually unsatisfactory among *TP53*-affected patients. This can be accounted either to a higher primary resistance to rituximab or to a faster and more aggressive relapse.
Aims: To compare *in vitro* primary response of CLL cells with well defined *TP53* and *ATM* defects to rituximab.
Methods: Deletions 17p and 11q were detected by I-FISH; *TP53* mutations were identified by yeast functional analysis and direct sequencing; *ATM* mutations were captured through resequencing microarray. All selected aberrant samples harbored complete p53 or ATM inactivation as evidenced by defective response to IR and doxorubicin; by contrast, all selected wild-type samples were functioning in these tests. The analysis of CLL cells sensitivity to rituximab was performed on 70 characterized samples using a metabolic WST-1 assay; 20% active human serum was added to allow cell lysis by complement; non-specific immunoglobulin was used as a negative control in all samples. The ability of rituximab to induce apoptosis under our experimental conditions was verified by flow-cytometry using propidium iodide *vs.* annexin V measurement.
Results: The following main observations have been made: (1) Concentration of 10 μg/mL was sufficient for rituximab *in vitro* testing; higher concentrations (20 and 30 μg/mL) showed the same effect in all cultures; (2) Final viability of tested cultures ranged from 45% to 100% in comparison with untreated control; all cultures were inert to non-specific immunoglobulin. There were clear differences in sensitivity to rituximab between the tested genetic groups; the *TP53*-mutated group (n=27 samples) was substantially more resistant than both wild-type samples (n=31) (P=0.04) and especially than *ATM*-mutated samples (n=12) (P=0,017; Wilcoxon test) (3) rituximab used at concentration of 10 μg/mL (and without active serum) was able to induce apoptosis (annexin V positivity) after 24 h treatment in tested cultures.
Summary and Conclusions: Our results showing significantly different response to rituximab for CLL cells harboring *TP53* mutation *vs.* those harboring *ATM* mutation were quite unexpected, especially because active serum was assumed to allow the lysis by complement. This observation indicates that apoptosis might play important role during primary CLL cells response to rituximab.

EVIDENCE THAT THE PREGNANE X AND RETINOID RECEPTORS PXR, RAR AND RXR MAY REGULATE TRANSCRIPTION OF THE IMATINIB TRANSPORTER HOCT1 EXPRESSION IN CHRONIC MYELOID LEUKAEMIA CELLS

G Austin[1], A Holcroft[1], N Rinne[1], L Wang[1,2,*], R Clark[1]
[1]Section of Haematology, Department of Molecular and Cancer Medicine, the University of Liverpool, [2]Department of Haematology, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: The expression and activity of the imatinib uptake transporter human organic cation transporter 1 (hOCT1; SLC22A1) is an independent predictor of response to imatinib treatment in chronic myeloid leukaemia (CML) patients. It has been recently shown by our group that peroxisome proliferator-activated receptors (PPAR) activation can increase the killing effect of imatinib in CML cells, due to upregulated *hOCT1* gene expression and imatinib uptake.
Aims: To investigate the role, if any, of activation of nuclear receptors other than PPAR in the transcriptional regulation of hOCT1 in CML cells.
Methods: The CML cell line KCL22 (chosen because of its low basal hOCT1 expression) was cultured and treated for 16 hours with agonists for adopted orphan receptors and endocrine receptors including Pregnane X receptor (PXR), Constitutive androstane receptor (CAR), Farnesoid X receptor alpha (FXRalpha), Liver X receptor alpha (LXRalpha), Retinoid acid receptor (RAR), Retinoid X receptor (RXR), Glucocorticoid receptor (GR), Oestrogen receptor (ER), Androgen receptor (AR), Mineralocorticoid receptor (MR), Vitamin D receptor (VDR), Progesterone receptor (PR) and Thyroid hormone receptor (TR). 3-6 replicate experiments were performed for each receptor. Fresh peripheral blood mononuclear cells from 9 cases of newly diagnosed untreated chronic phase CML patients were treated with agonists for nuclear receptors. A standard MTT assay was used to define the optimal treatment doses of each receptor that had no effect on cell viability. hOCT1 gene expression levels were measured using real-time quantitative RT-PCR on a LightCycler.
Results: In KCL22 cells, it was found that the PXR agonists Rifampin, T0901317 and SR12813 increased hOCT1 expression by an average of 29.4, 3.28 and 2.99 fold above untreated control levels respectively (P<0.05 for Rifampin and T0901317, P=0.07 for SR12813, Wilcoxon rank test). hOCT1 expression was increased 2.9 fold compared with untreated control after KCL22 cells were treated with the RAR and RXR agonist 9-cis retinoic acid, although this effect had borderline significance (P=0.07). Treatment with agonists for the rest of the nuclear receptors did not significantly alter the hOCT1 expression in KCL22 cells. In peripheral blood mononuclear cells from newly diagnosed untreated chronic phase CML patients, the PXR agonist SR12813 significantly increased hOCT1 expression by 1.6 fold compared with untreated control (P=0.04, Wilcoxon rank test, n=5). However, unlike the findings in KCL22 cells, there was no change after treatment with the alternative PXR agonist Rifampin (P>0.05, n=9). hOCT1 expression was also significantly

upregulated by the RAR agonist All-trans-retinoic acid (ATRA) and the RAR and RXR agonist 9-cis retinoic acid by 1.7 and 2.5 fold above untreated control (P=0.04 for both; n=5; Wilcoxon rank test). Agonists for FXRalpha, LXRalpha, GR, ER, AR, MR and PR were also tested and showed no significant effect on hOCT1 expression in these primary CML cells, in concordance with the findings in KCL22 cells.
Summary and Conclusions: It is shown here that PXR, RXR and RAR may play important roles in the transcriptional regulation of the hOCT1 gene in CML cells. Further study is needed to explore the potential effects of agonists of PXR, RXR and RAR on imatinib uptake and cell killing in combination with imatinib in CML cells.

P977

THE ROLE OF CYP2J2 IN CYCLOPHOSPHAMIDE METABOLISM
I El-Serafi[1,*], P Afsharian[2], Z Potácová [1], Y Terelius[3], A Moshfegh[4], M Hassan[1]
[1]Department of Laboratory Medicine, Karolinska Institutet, Huddinge, Sweden, [2]Department of Genetics, Royan Institute, Tehran, Iran, Islamic Republic of Korea, [3]R&D, Medivir AB, Huddinge, [4]Department of Oncology-Pathology, Karolinska Institutet, Solna, Sweden

Background: Cyclophosphamide (CP) is an alkylating agent that is used in high doses in the treatment of hematological malignancies and solid tumors and in the conditioning regimen before stem cell transplantation. It is also a potent immuno-suppressive agent that is used in low doses for the treatment of rheumatoid arthritis, systemic lupus erythematosus and other autoimmune diseases. CP alkylates DNA at N7 (guanine) of the imidazole ring and trigger apoptosis by the formation of Guanine- Adenine intrastrand crosslinks. CP is a prodrug that is converted through cytochrome P450 (CYP) in the liver to 4-hydroxycyclophosphamide (4-OH-CP) which is the main active metabolite (90% of the total CP). CYP2B6 was reported to metabolize about 90% of the total CP. However, other enzymes such as CYP2A6, CYP2C8, CYP2C9, CYP2C19 and CYP3A4 were also reported to be involved in the bioactivation of CP.
CYP2J2 in human is involved in metabolic transformation of xenobiotics. It is encoded by the *CYP2J2* gene that has been mapped on the short arm of chromosome 1. It is mainly expressed in intestine and cardiovascular system with low expression level in the liver. CYP2J2 has been reported to metabolize several drugs despite that its role in drug metabolism is not yet fully understood. CYP2J2 can contribute to drug metabolism in the extrahepatic tissues, particularly the intestine, and may be the main enzyme responsible for first-pass metabolism for certain drugs.
Aims: To determine the role of CYP2J2 in cyclophosphamide metabolism.
Methods: Eleven patients went through HSCT and were conditioned with CP and total body irradiation. Blood samples were collected and analyzed before conditioning start and at 0.5,1,2,4,6, 8 hr after CP infusion then one sample before the start of CP second dose and another sample 6hr after the infusion. Gene array and genotyping were carried out using Nimblegen gene expression arrays while GeneSpirng GX 12.0 software was used for analysis. CP and 4-OH-CP concentrations were determined using high performance liquid chromatography (HPLC) with UV detector for CP and fluorescence detector for 4-OH-CP. Pharmacokinetics was analyzed using WinNonLin software. The clinical outcome including engraftment, rejection, chimerism, transplantation-related morbidity and mortality and relapse have been evaluated.
To confirm the findings, microsomes containing cDNA-expressed human CYP2J2 were incubated with different concentrations of CP (0-50 mM). Microsomes were incubated for one hour and reaction was terminated by adding equal volume of acetonitrile (ACN). 4-OH-CP concentrations were measured as previously mentioned using HPLC with fluorescence detector.
Results: All patients showed high expression of CYP2J2 mRNA (over 2-folds higher than their level before the start of conditioning). However, high inter-individual variation was observed for gene expression which most probably can be explained by the different polymorphic forms of CYP2J2 gene. The gene expression variability was in proportion to the ratio of 4-OH-CP/CP areas under curves (AUCs) indicating that CYP2J2 may play a major role in CP metabolism. No correlation between diagnosis and/or other clinical data and the results of CYP 2J2 was observed.
In-vitro results have confirmed that CP was metabolized through CYP2J2 microsomes. V_{max}/K_m was 8.98 mL/min/ pmol P450 after incubation in quadruplicates. These results are in agreement with our previous findings for CYP 2B6.
Summary and Conclusions: This investigation showed that *CYP2J2* gene is uP-regulated during the treatment with cyclophosphamide which indicated that CYP2J2 is induced by CP and might be involved in CP metabolism. The results obtained from *in-vitro* incubations have confirmed the *in-vivo* results. The present results may help to better understanding of cyclophosphamide metabolism especially in the extrahepatic tissues and hence lead to new strategies for personalized dosing with increased safety and decreased drug-drug interactions.

P978

ABCB1 HAPLOTYPE IS ASSOCIATED WITH ALTERATIONS IN FUNCTIONAL ACTIVITY OF P-GP AND AFFECTS MAJOR MOLECULAR RESPONSE IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH STANDARD-DOSE OF IMATINIB
D Vivona[1,*], L Lima[1], Alice Rodrigues[2], C Bueno[1], M Chauffaille[3], C Chiattone[4], V Hungria[4], E Guerra-Shinohara[1]
[1]Departament of Clinical Chemistry and Toxicology, [2]Institute of Biomedical Sciences, University of São Paulo, [3]Discipline of Hematology, Federal University of São Paulo, [4]Department of Hematology and Oncology, Santa Casa Medical School, Sao Paulo, Brazil
Background: Despite the excellent results of Imatinib Mesylate (IM) treatment in CML patients, some individuals develop resistance due to impaired bioavailability. IM interacts with membrane transporters such as ABCB1 (P-gp) and SLC22A1. It was demonstrated that haplotype for *ABCB1* c.1236C>T/c.3435C>T/c.2677T>A polymorphisms strongly affect the secondary structure of ABCB1 mRNA and its activity. These modifications could affect the efflux transporter activity and response to treatment with IM.
Aims: The aim of this study was to investigate the P-gp functional activity in peripheral blood mononuclear cells from CML patients with different haplotypes for *ABCB1* c.1236C>T, c.3435C>T and c.2677TG>T polymorphisms.
Methods: Twenty eight patients in chronic phase of CML were selected according to haplotypes for *ABCB1* c.1236C>T, c.3435C>T and c.2677G>T polymorphisms. Ten patients with *ABCB1* 1236CC/3435CC/2677GG haplotype comprised the wild-type group and 18 patients carriers of haplotypes with at least one mutated allele in each genotype for three *ABCB1* polymorphisms (10 patients with 1236CT/3435CT/2677GT and 8 with 1236TT/3435TT/2677TT) comprised the mutated group. All patients were in chronic phase of CML, treated with a standard dose of IM (400 mg/day) for a mean time of 63.5±12.6 months and with complete cytogenetic response. Major molecular response (MMR) was defined as a reduction of *BCR-ABL1* transcripts levels to ≤0.1% in the peripheral blood standardized on the International scale. Complete molecular response (CMR) was defined as a reduction to ≤0.0032% *BCR-ABL1* transcripts levels. Real-Time PCR was performed to evaluate the *ABCB1* and *SLC22A1* mRNA expression using GAPDH gene as control. P-gp functional activity was determinated by rhodamine123 efflux assay. Analysis of P-gp expression and functional activity were performed by flow cytometry.
Results: P-gp activity in wild-type group was higher than in mutated group (59.1 *vs* 38.3%; P=0.001).The groups of haplotypes had no difference in *SLC22A1*, *ABCB1* mRNA and P-gp expression. Patients who did not achieve MMR showed a higher rate of efflux mediated by P-gp compared with individuals who did not achieve this response (64.7% *vs.* 45.7%, P=0.001). All patients who did not achieve MMR presented efflux above 60%.Unlike MMR, no association was found for CMR. Higher levels of *SLC22A1* mRNA were found in patients who achieved MMR (P=0.042). The *ABCB1* mRNA expression showed a positive and strong correlation with P-gp expression (r=0.747; P=0.001).P-gp activity had positive and moderate correlation (r=0.570; P=0.001), whereas SLC22A1 mRNA expression showed negative and moderate correlation with *BCR-ABL1* transcripts (r=-0.407; P=0.032).
Summary and Conclusions: *ABCB1* mRNA and P-gp expression were similar in haplotypes groups for c.1236C>T, c.3435C>T and c.2677G>T polymorphisms, however, patients with the 1236CT/3435CT/2677GT and 1236TT/3435TT/2677TT haplotypes exhibit less efflux mediated by P-gp presenting highest frequency of MMR, probably due to higher intracelullar concentrations of IM.

P979

DIAGNOSTIC AND THERAPEUTIC POTENTIALS OF EXPRESSION LEVELS OF BIOACTIVE SPHINGOLIPID GENES IN NEWLY DIAGNOSED AND DRUG-RESISTANT CHRONIC MYELOID LEUKEMIA PATIENTS
Y Baran[1,*], M Yandim[1], I Kozanoglu[2], H Ozdogu[2], O Piskin[3], M Ozcan[3], G Saydam[4], F Sahin[4], F Avcu[5], A Ural[6]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, Izmir, [2]Department of Hematology, Baskent University, Adana Teaching and Medical Research Center, Adana, [3]Department of Hematology, Dokuz Eylul University, [4]Department of Hematology, Ege University, Izmir, [5]Department of Hematology, Gulhane Medical School, [6]Department of Hematology, BAYINDIR HOSPITAL, Ankara, Turkey

Background: Ceramide is an important apoptotic sphingolipid that affects vital cell signaling pathways such as growth, proliferation, apoptosis, senescence, migration, and cell cycle arrest. *de novo* synthesis of ceramide is carried out by Ceramide synthase gene family (CerS1-6). Glucosylceramide synthase (GCS) and sphingosine kinase-1 (SK-1) are powerful anti-apoptotic molecules triggering cell proliferation and division, and also repressing apoptosis.
Aims: In this study, we aimed to investigate expression levels of bioactive sphingolipid genes in bone marrow samples of newly diagnosed CML patients; imatinib-, nilotinib-, or dasatinib-resistant CML patients; and CML patients showing minimum hematological response to imatinib, nilotinib or dasatinib, and

then examine the correlation between the changes in expression levels and progression of CML.
Methods: Mononuclear cells from bone marrow are seperated in these groups of CML patients by Ficoll Paque method. Total RNAs of mononuclear cells were isolated, and then converted to cDNA by reverse transcription. Expression levels of BCR/ABL, CerS1-6 genes, GCS and SK-1 genes were analyzed by real-time PCR. Thirtyfive patients were involved in this study (7 newly diagnosed, 5 imatinib resistant, 4 dasatinib resistant, 2 nilotinib resistant, 12-, 3-, and 2 showing minimum hematological response to imatinib, dasatinib, and nilotinib respectively.
Results: Expression levels of CerS1, CerS2, Cers4, Cers5, and CerS6 genes were increased significantly in CML patients showing minimum hematological response to nilotinib treatment and in imatinib-treated CML patients than newly-diagnosed and drug-resistant CML patients. On the other hand, expression levels of GCS and SK-1 genes were significantly higher in drug-resistant patients than that of the newly-diagnosed CML patients and drug-treated patients showing minimum hematological response.
Summary and Conclusions: We previously demonstrated that enforced expression of CerS1 gene or application of ceramide mimetics increased apoptotic effects of tyrosine kinase inhibitors with a strong synergism in CML cells while inhibition of GCS and SK-1 synergistically increased TKI-induced cell death. We also previously determined that SK-1 regulates expression and protein stability of BCR/ABL. In conclusion, the results of this study confirmed and showed for the first time a significant correlation between the expression levels of bioactive sphingolipid genes and the sensitivity or resistance of CML patients to TKIs. A correlation between expression levels of SK-1 and BCR/ABL was also determined. Taking together, all these data showed that expression levels bioactive sphingolipids might be novel markers in determination of the resistancy in CML patients. More importantly, bioactive sphingolipids could be novel targets for the effective treatment of resistant CML patients.
This study was supported by TUBITAK with the Project number 111S391 to Y.B.

Novel therapeutics, targeted therapies and gene therapy

SMO INHIBITOR SPECIFICALLY TARGETS THE HEDGEHOG PATHWAY AND REVERTS THE DRUG-RESISTANCE OF LEUKEMIC STEM CELLS

V Guadagnuolo[1,*], C Papayannidis[1], E Ottaviani[1], I Iacobucci[1], C Terragna[1], M Martello[1], A Ferrari[1], F Cattina[2], E imbrogno[1], A di rorà[1], M Abbenante[1], S Paolini[1], C Sartor[1], S Parisi[1], G Martinelli[1]
[1]Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy, bologna, [2]university of brescia, brescia, Italy

Background: Hedgehog (Hh) pathway activation contributes to leukemia development and growth and its inhibition is likely to offer an efficient therapeutic opportunity. SMO inhibitor (SMOi), Hh pathway inhibitor, is a new selective inhibitor of leukemia self-renewal and is currently being evaluated in clinical trials.
Aims: In this study we explored the '*in vitro'* and '*ex vivo'* activity of SMOi, as single-agent or in combination with conventional chemioterapy, and we investigated potential biomarkers of functional inhibition.
Methods: We studied CD34+ Leukemia Stem cells (LSCs) collected before and after 28 days treatment in a phase I dose escalation protocol enrolling selected hematological malignancies (MF, MDS, CML-BP, *CMML* and AML). We were able to collect and separate highly purified (98%) bone marrow CD34+ cells from 5 AML,1 MF and 2 CML patients (pts) by immunomagnetic separation, and analysed them for Gene Expression Profile (GEP) (Affimetrix HG-U133 Plus 2.0) with Partek Genomics Suite and software GeneGo.
Results: The GEP analysis on CML pts showed that 1197 genes were differentially expressed between CD34+ cells collected before and after 28 daysof SMOi dose finding oral therapy and among these mostly were related to Hh signalling (P-value 0.03), providing further evidences that SMOi really therapeutically targets the Hh pathway. Regarding genes involved in Hh signaling pathway, *Gas1* and *Kif27* were strongly upregulated (P-value 0.01 and 0.02 respectively), suggesting that they may work as biomarkers of activity. Moreover, analysis performed on AML patients, with Partek Genomic Suite and GeneGo, showed that 589 genes were differentially expressed between CD34+ cells collected before and after 28 daysof SMOi dose finding oral therapy and among these mostly were related to Hh signalling (P-value 0.0002), providing further evidences that SMOi really therapeutically targets the Hh pathway. Regarding genes involved in Hh signaling pathway, Casein Kinase I, Gli3 and β-catenin were strongly down-regulated (P-value 0.012, 0.012 and 0.043 respectively. Other genes were differentially expressed after *'ex-vivo'* treatment with SMOi as compared to the baseline: we observed a down-regulation of *Bcl2* (fold change -1.03004), *ABCA2* (fold change -1.08966), *Gli1* (fold change -1.0775), *Smo* (fold change -1.07702), and an upregulation of *Gli2* (fold change 1.08191). The GEP results for Gli1, Gli2 and Smo were confirmed by RT-PCR. This analysis included also Gli3, Abcb1 and Abcg2 genes. To investigate the *'in vitro'* efficacy of SMOi we treated MOLM-13, HL-60, KG1α, BV-173, SUPB-15 and K562 cell lines with increasing concentration of SMOi (10 nM - 100 μM) for up to 72 hours. SMOi had no efficacy on cell viability. Consistent with the WST-1 results, AnnexinV/PI staining analysis did not show any apoptosis process at the same time points. SMOi had no efficacy on cell viability on primary cells from healthy donors. To support the '*ex vivo*' data we have confirmed '*in vitro*' that SMOi specifically targets and down-regulates the Hh Pathway by Real Time PCR and Western Blot, as soon as 48 hrs of incubation with SMOi (10 μM). We treated K562 cell line (Tirosin Kinase (TK)-resistant) with SMOi (10 μM) in combination with Nilotinib, Imatinib, and Bosutinib (1 μM). We observed a synergistic and additive effect by WST-1 assay and AnnexinV/PI staining analysis, suggesting that SMOi reverts the chemio resistance mechanism of K562 to TKs.
Summary and Conclusions: SMOi specifically targets the Hh Pathway in CD34+ cells, suggesting that Hh inhibition may impair LSC maintenance. New potential biomarkers (Gas1 and Kif27) were identified. '*In vitro'* treatment with SMOi did not show efficacy neither apoptosis and in the viability. Therefore, the combination of SMOi with TK inhibitors or conventional chemotherapy could represent a valid new therapeutic approach in these haematological malignancies. United States, [6]Hôtel-Dieu de France University Hospital, Beruit, Lebanon, [7]The Royal Free Hospital, London, United Kingdom, [8]UCSF School of Medicine, San Francisco, [9]New York University School of Medicine, New York, United States, [10]Clinical Center of Serbia, Belgrade, Serbia, [11]Jewish General Hospital, Montreal, Canada, [12]Mt. Sinai Hospital, New York, United States, [13]Christian Medical College, Tamil Nadu, India, [14]University Hospital Alexandrovska, Sofia, Bulgaria, [15]Yale University School of Medicine, New Haven, United States, [16]OCA Hospital, Monterrey, Mexico, [17]Emory University, Atlanta, United States, [18]Hospital San Jose, Bogota, Colombia, [19]Genzyme, a Sanofi company, Cambridge, United States

Background: In Gaucher disease type 1 (GD1), acid-beta-glucosidase deficiency leads to accumulation of glucosylceramide in tissue macrophages (Gaucher cells). Clinical manifestations include hepatosplenomegaly, anemia, thrombocytopenia and skeletal disease. Eliglustat, a novel oral substrate reduction therapy, is in late-stage development for the treatment of GD1. ENGAGE (NCT00891202), a Phase 3 registration trial, is a randomized, double-blind, placebo-controlled, multinational trial to investigate the efficacy and safety of eliglustat in untreated GD1 patients.
Aims: We present the results of the primary analysis period of the ENGAGE trial.
Methods: A total of 40 patients (mean age: 31.8 years; 20 males, 20 females) meeting the main entry criteria for splenomegaly and either thrombocytopenia or anemia or both were enrolled. Patients were stratified by spleen volume and randomized 1:1 to receive eliglustat (50 or 100 mg twice daily depending on plasma levels) or placebo. Efficacy assessments include changes from baseline in spleen and liver volumes, hemoglobin, platelets, skeletal manifestations, disease-related biomarkers, Gaucher assessments (*e.g.*, therapeutic goals), and quality of life. Safety monitoring includes adverse-event reporting (severity, seriousness, treatment-relatedness), physical examination and scheduled laboratory and electrocardiographic evaluations.
Results: After 9 months of treatment, eliglustat demonstrated superior efficacy compared to placebo in the primary endpoint (change in spleen volume in multiples of normal) with an absolute difference of 30% (28% decrease in eliglustat-treated patients *versus* 2% increase in placebo patients; $P<0.0001$). All secondary endpoints were met and showed statistically significant improvements compared to placebo; hemoglobin levels increased from baseline by an absolute difference of 1.2 g/dL compared with placebo ($P<0.0006$); liver volume decreased from baseline by an absolute difference of 7% compared with placebo ($P<0.0072$); and platelet levels increased from baseline by an absolute difference of 41% compared with placebo ($P<0.0001$). Among tertiary endpoints, a statistically significant improvement in total bone marrow burden score was observed among patients in the eliglustat arm compared to placebo, and all other markers of bone disease showed trends towards improvement. No serious adverse events were reported in either treatment group. All adverse events reported were mild or moderate, with the most common being headache, arthralgia and diarrhea. One patient withdrew from the trial, for a reason not treatment-related and the remaining 39 patients completed the blinded period and transitioned to the open-label extension period.
Summary and Conclusions: Eliglustat continues to show promising efficacy and safety in its clinical development program.

P983

CHARACTERIZATION OF THE PHARMACOKINETIC AND PHARMACODYNAMIC PROPERTIES OF PACRITINIB (SB1518), A NOVEL ORAL JAK2/FLT3 INHIBITOR, IN PATIENTS WITH MYELOFIBROSIS, AML AND LYMPHOMA

S Al-Fayoumi[1,*], L Wang[1], J Dean[1], S Benner[1]
[1]Cell Therapeutics, Inc, Seattle, United States

Background: Pacritinib is a novel selective JAK2-FLT3 inhibitor with demonstrated antitumor activity in two mouse models of FLT3- (MV4-11) and JAK2-dependent (BaF3-JAK2V617F) leukemia. To date, a total of 4 clinical trials of over 3 years in duration are either ongoing or have been completed in patients with advanced malignancies (n=191) along with 2 single dose pharmacokinetic studies in healthy volunteers (n=42).
Aims: To evaluate whether the PK/ PD profile of pacritinib supports further clinical development of pacritinib in myelofibrosis.
Methods: Two PK studies were conducted in healthy volunteers to assess the effect of food on the PK of pacritinib and the inter- and intra-individual PK variability of pacritinib. Moreover, population PK of pacritinib was characterized following multiple dose administration of pacritinib in patients with advanced myeloid malignancies. To provide proof of concept in support of the starting dosage selection for pacritinib in myeloid malignancies, the effect of pacritinib on phos-STAT3 was assessed in myeloid cell lines Karpas 1106P and 32D. The effects of pacritinib on phos-STAT5 were also examined on *ex vivo* expanded erythroid progenitors (EPs) from patients with PV and on the EPs of healthy volunteers.
Results: Pooled analyses of PK assessments from the completed clinical trials in patients at pacritinib dose levels up to 600 mg QD showed slow absorption (Tmax~6 hrs) and dose-related increases in exposure. In addition, the results demonstrated long elimination half-life (mean Day 1 $t_{1/2}$=47 hrs) supporting QD administration of pacritinib. Comparison of drug concentrations on Days 1 and 15 showed a 1.5- to 2-fold increase in exposure at steady-state. However, no additional accumulation of drug was observed after repeated administration over several 28-day cycles. While between-subject variability was relatively high (28-45%), the within-subject variability was low (13-15%), highlighting the consistent systemic exposure for pacritinib in individual subjects. Pacritinib is not a PgP substrate and no significant formation (*i.e.*, <10% of parent exposure) of metabolites of pacritinib was observed in metabolism studies indicating limited liability of pacritinib to metabolic and PgP-related drug-drug interactions. There is no significant effect of food on pacritinib PK; hence pacritinib can be orally administered without regard to timing of meals. At a pacritinib 100 mg QD regimen, mean steady-state plasma levels of pacritinib exceeded the *in vitro* IC50 values for inhibition of targeted kinases (JAK2/FLT3) and inhibition of whole cell proliferation (BaF3-JAK2 and MV4-11 cells), lending support to dosage selection in Phase1/2 clinical trials for pacritinib. Pacritinib potently inhibited the proliferation of only a few tumor cell lines at submicromolar concentrations, consistent with its target selectivity. The most sensitive cell lines were either JAK2-dependent or mutant FLT3-dependent, including murine 32D (IC50=160 nM), human Karpas 1106P (IC50=240 nM), and mutant FLT3-dependent MV4-11 cells (IC50=32 nM). In a study using *ex vivo* expanded erythroid progenitors (EPs) treated with pacritinib, phos-STAT5 levels were inhibited in a dose-dependent manner (IC50 <200 nM) and reduced the viability of expanded EPs from both normal volunteers with JAK2wt (IC50=260 nM) and PV patients with JAK2V617F (IC50=230 nM), with no significant differences observed between groups. Moreover, pacritinib treatment had no effect on the JAK2V617F allele frequency in EPs from PV patients, indicating similar drug sensitivity for EPs from the same patient, regardless of the presence of JAK2 mutation. A study to assess the effects of pacritinib on intracellular JAK2 signaling showed that phos-STAT3 was reduced in a dose-dependent manner in both Karpas 1106P and 32D cells (Figure 1).

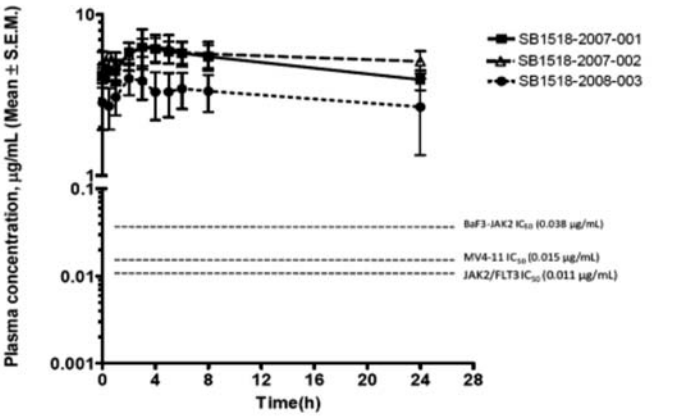

Figure 1. Mean Pacritinib (SB1518) plasma levels at day 15 assessments for patients receiving 100 mg QD. (Error bars indicate the S.E.M.).

Summary and Conclusions: Overall, the favorable PK/PD profile of pacritinib along with an acceptable safety, tolerability and efficacy profile of pacritinib support further clinical development of pacritinib in myelofibrosis.

P984

PRECLINICAL PK/EFFICACY RELATIONSHIPS FOR MLN9708, AN INVESTIGATIONAL SMALL MOLECULE PROTEASOME INHIBITOR, IN MM.1S HUMAN MULTIPLE MYELOMA XENOGRAFTS

S Palani[1], B Bannerman[2], C Xia[1], S Chen[1], N Gupta[3], A Bulychev[1], J Wu[1], W Shyu[1], M Manfredi[2], A Chakravarty[1], A Berger[2,*]
[1]Drug Metabolism and Pharmacokinetics, [2]Cancer Pharmacology, [3]Clinical Pharmacology, Millennium Pharmaceuticals, Inc., Cambridge, United States

Background: MLN9708 (ixazomib citrate) is an investigational oral proteasome inhibitor currently in Phase III trials in relapsed and/or refractory (RR) multiple myeloma (MM) and in relapsed or refractory light chain amyloidosis (RRAL). In Phase I/II studies, MLN9708 has demonstrated preliminary activity and a generally well-tolerated safety profile as a single agent in RRMM and RRAL and in combination with lenalidomide and dexamethasone in newly diagnosed MM. In plasma, MLN9708 completely hydrolyzes to the pharmacologically active compound MLN2238. In preclinical studies performed in immunocompromised mice, twice weekly IV or PO dosing of MLN2238 at or near its maximum tolerated dose (MTD) has demonstrated antitumor activity against the MM.1S human plasmacytoma xenograft model. However the pharmacokinetic/efficacy (PK/E) relationship for MLN2238 in MM.1S xenograft-bearing mice has not yet been determined.
Aims: To develop a PK/E model for MLN2238 in MM.1S xenograft-bearing

mice at multiple dose levels and to compare the findings to human plasma PK data from Phase I clinical trials to place the clinically achieved exposures in the context of the preclinical findings.
Methods: Single dose studies were conducted to model the plasma PK of MLN2238 using SCID mice dosed IV at2, 3.5, 7 and 14 mg/kg. Studies to determine antitumor activity of MLN2238 in SCID mice bearing MM.1S xenografts were performed with IV twice weekly (BIW) dosing at 0.5,1, 1.5,2,3, and 7 mg/kg. Exponential regressions were performed on the tumor volume data to determine the tumor growth rate in individual mice. Individual tumor growth rates were used to calculate the end of treatment (day 14) tumor volumes in each mouse. Percentage tumor growth inhibition (%TGI) was calculated as (avg day 14–avg day 1 tumor volume in treated mice)/(avg day 14 - avg day 1 volumes from the control mice).PK/E models were built by fitting the average growth rate and%TGI values to 14-day AUC estimated from the PK model.
Results: An IV three compartmental model was found to best capture the drug kinetics in SCID mice. The PK model exhibited a linear relationship between dose and exposure (AUC) for the range tested, which is consistent with the population PK model from clinical Phase I trials. Pronounced antitumor activity, including complete regression, was observed in MM.1S xenografts.We found a linear relationship between average growth rate and AUC. The dose resulting in tumor stasis was estimated to be 2.4 mg/kg IV BIW. The drug exposure to%TGI relationship was captured with a sigmoidal Emax model, with steepness of 2.4 and with an IC_{50} value of 1.1 mg/kg. Next, we sought to place the derived PK/efficacy relationships in the context of the clinically achieved human exposures by accounting for the differences in MLN2238 plasma protein binding in mouse and human. At the average MTD exposure determined in Phase I clinical trials [single dose IV $AUC_{0\text{-}72}$ of 429 ng.hr/mL (28% CV)], the MM.1S xenograft model exhibited%TGI of 30-70%.
Summary and Conclusions: We have developed a dose-response relationship for MLN2238 in MM.1S xenograft model. To the best of our knowledge, this is the first time a PK/E relationship has been constructed for a proteasome inhibitor *in vivo*. Overlaying the free-fraction corrected clinical exposure data from Phase 1 trials of MLN9708 on the preclinical PK/E relationship, we find that the MM.1S model exhibits antitumor activity at exposures well-tolerated in humans.Additional preclinical studies are in progress to develop an oral PK/E model for MLN2238 in MM.1S xenografts.

P985

THERAPEUTIC POTENTIAL OF DUAL PI3K DELTA/GAMMA INHIBITION IN T-CELL LYMPHOMAS

S Vakkalanka[1,*], S Viswanadha[2], B Govindarajulu[3], R Prasanna[4], S Veeraraghavan[5], D Nagarathnam[6]
[1]General Administration, Rhizen Pharmaceuticals SA, La Chaux-de-Fonds, Switzerland, [2]Drug Discovery, Incozen Therapeutics Pvt. Ltd., [3]Medicinal Chemistry, [4]Biological Research, [5]Pharmacokinetics, INCOZEN THERAPEUTICS PVT. LTD, Hyderabad, India, [6]Chemistry, DNSK International, Hamden, United States

Background: Activation of the PI3K pathway triggers multiple events including cell growth, cell cycle entry, cell survival and motility. While α and β isoforms are ubiquitous in their distribution, expression of δ and γ is restricted to cells of the hematopoietic system. Because these isoforms contribute to the development, maintenance, transformation, and proliferation of immune cells, dual targeting of PI3Kδ and γ represents a promising approach in the treatment of lymphomas.
Aims: The objective of the experiments was to explore the therapeutic potential of RP6530, a novel, small molecule PI3Kδ/γ inhibitor, in T-cell lymphomas.
Methods: Activity and selectivity of RP6530 for PI3Kδ and γ isoforms and subsequent downstream activity was determined in several enzyme and cell-based assays. Additionally, RP6530 was tested for potency in viability, apoptosis, and Akt phosphorylation assays using immortalized T-cell lymphoma cell lines. ADME and pharmacokinetic properties of the molecule were also determined.
Results: RP6530 had high potency against PI3Kδ (IC_{50}=24.5 nM) and γ (IC_{50}=33.2 nM) enzymes with selectivity over α (>10,000-fold) and β (>100-fold) isoforms. Cellular potency was confirmed in target-specific assays, namely anti-FcεR1-(EC_{50}=30.5 nM) or fMLP (EC50=36.9 nM) induced CD63 expression in human whole blood basophils, LPS induced CD19+ cell proliferation in human whole blood (EC50=250 nM), and LPS induced CD45R+ cell proliferation in mouse whole blood (EC50=101 nM). RP6530 caused a dose-dependent inhibition (>50% @ 2-7 μM) in growth of immortalized (Jurkat, MOLT-4, CCRF-CEM, HuT-78, and Hut-102) T-cell lymphoma cell lines. Reduction in viability was accompanied by a reduction in pAKT (>50% @ 1 μM) along with induction of apoptosis (>50% @ 0.5-3.0 μM in the aforementioned cell lines. Pharmacokinetic studies across species indicated good oral absorption (>70% bioavailability for rat, and dog) with favourable plasma concentrations (>10 μM @ 10 mg/kg for rat, and dog) relevant for efficacy.
Summary and Conclusions: Results demonstrate that RP6530 is a potent and selective dual PI3Kδ/γ inhibitor with therapeutic potential in T-cell lymphomas. Further pre-clinical testing in murine xenografts and patient derived primary leukemic cells as well as toxicological evaluation of the molecule is in progress.

P986

EVALUATION OF GROWTH-INHIBITORY AND HISTAMINE RELEASE-TARGETING EFFECTS OF PKC412 AND ITS METABOLITES ON NEOPLASTIC MAST CELLS BY CHEMICAL PROTEOMICS PROFILING AND TARGET VALIDATION

B Peter[1,2,*], G Winter[3], K Blatt[2], U Rix[3,4], K Benett[3], G Stefanzl[2], E Hadzijusufovic[1,2,5], C Dutreix[6], S Gross[6], J Roesel[6], P Manley[6], G Superti-Furga[3], P Valent[1,2]
[1]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, [2]Department of Internal Medicine I, Division of Hematology & Hemostaseology, Medical University of Vienna, [3]Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria, [4]Department of Drug Discovery, H. Lee Moffitt Cancer Center and Research Institute, Tampa, Florida, United States, [5]Department for Companion Animals and Horses, Clinic for Internal Medicine and Infectious Diseases, University of Veterinary Medicine of Vienna, Vienna, Austria, [6]Novartis Oncology, Basel, Switzerland

Background: The multikinase inhibitor midostaurin (PKC412) is a promising agent and currently investigated in clinical trials in advanced systemic mastocytosis (SM). However, although mediator-related symptoms and organ damage often improve, no long-lasting hematologic remissions are seen. *In vivo* two major metabolites of midostaurin are detectable, CGP52421 and CGP62221.
Aims: We examined the effects of PKC412 and its metabolites on proliferation of the human mast cell leukemia cell line HMC-1 and primary neoplastic mast cells (MC), as well as IgE-dependent histamine release in human basophils.
Results: All three compounds suppressed IgE-dependent histamine secretion in basophils, with IC_{50} values <1 μM. PKC412 and CGP62221 produced growth inhibition in HMC-1.1 cells (KIT D816V-) and HMC-1.2 cells (KIT D816V+), with IC_{50} values ranging between 50 and 250 nM, whereas CGP52421 showed no substantial growth-inhibitory effects below 1 μM. Corresponding results were obtained with primary neoplastic MC, although in some patients, CGP52421 showed growth-inhibitory effects. As assessed by light microscopy, active caspase 3 staining and TUNEL assay, midostaurin and CGP62221 induced apoptosis in HMC-1.1 cells and HMC-1.2 cells, whereas CGP52421 did not produce apoptosis in HMC-1 cells. Midostaurin and CGP62221 were found to inhibit phosphorylation of KIT D816V in HMC-1.2 cells, whereas CGP52421 showed no substantial effects. Chemical proteomics profiling and drug-competition experiments revealed that PKC412 interacts with several tyrosine kinases such as KIT, FES, AAK1, BIKE, and SYK. Interestingly, the key downstream-regulator of KIT D816V, FES, showed affinity for PKC412 and CGP62221, but not for CGP52421 in HMC-1.2 lysates. Finally, we were able to show that both metabolites exert synergistic growth inhibitory effects with cladribine (2CdA) in HMC-1.2 cells.
Summary and Conclusions: Together, our data show that the PKC412 metabolite CGP52421 inhibits IgE-mediated histamine release in basophils, but is a weak inhibitor of MC proliferation, presumably because of altered target-binding capacity. These observations may have clinical implications and may explain why mediator-related symptoms improve in PKC412-treated patients with SM, even if no hematologic remission is obtained.

P987

PULMONARY EFFECTS OF PERFLUOROCARBON EMULSION THERAPY ON INFECTED SICKLE CELL MICE

N Helmi[1,*], P Andrew [1], H Pandya [1]
[1]Infection, Immunity and iflammation, University Of Leicester, Leicster, United Kingdom

Background: Pulmonary crises in patients with sickle cell disease (HbSS) are linked to occlusion of pulmonary blood vessels and bacterial infection, most commonly *Streptococcus pneumoniae.* Patients experiencing a pulmonary crisis are often hypoxemic which induces red cell 'sickling' and further vaso-occlusion. Patients with HbSS are profoundly sick. Treatment is supportive with antibiotics, fluids and occasionally exchange blood transfusion. Perfluorocarbon emulsions (PFCEs) are a potential alternative therapy to blood transfusion in severe sickle cell lung disease. However, there are few data on the effects of PFCEs in sickle cell disease. In this study, we investigated the effects of intravenous therapy with PFCE on transgenic sickle cell and control mice infected with *Streptococcus pneumoniae*.
Aims: Although blood transfusion can be life saving in patients with sickle cell anemia experiencing life-threatening crises, it is not without risk. Perfluorocarbon emulsions (PFCE) are blood substitutes that may have therapeutic value in patients with HbSS. This study set out to determine whether intravenous PFCE therapy alters the clinical course of transgenic HbSS mice infected with *Streptococcus pneumoniae*.
Methods: HbSS and C57 (control) mice infected with *S. pneumoniae* and treated with IV PFCE or PBS (3mL/kg) were managed in air with some HbSS mice also transiently exposed to oxygen (50%). Mice were culled and lungs were harvested at 72 hours or on showing signs of 2+ lethargy. A second group of mice were injected with PFCE daily for 1 week. Histological analysis of lungs was performed using H&E sections and light microscopy. In addition, white blood cell analysis was performed using flow cytometer and cytokine quantifications were performed using lung homogenate and sandwich ELISA assay.

Results: All mice infected with *S. pneumoniae* developed outward signs of infection within 72 hours. HbSS mice infected with *S. pneumonia* treated with PBS died significantly faster than C57; almost 50% of C57 mice were still alive (not culled) at 72 hours. In contrast, all HbSS mice treated with PBS were culled by 72 hours. There was no difference in survival comparing HbSS mice treated with PFCE-Air and PBS-Air following *S. pneumoniae* infection. However, HbSS mice treated with PFCE-O_2 showed a greater resilience to *S. pneumoniae* than those treated with PBS-O_2 or PFCE-Air. Treatment with PFCE did not improve resilience of C57 mice to infection with *S. pneumoniae*.
Pulmonary cytokine levels were significantly higher in lungs of *S. pneumoniae*-infected HbSS mice in comparison to *S. pneumoniae*-infected C57 mice. There were no statistical differences in levels cytokines comparing HbSS mice treated with PFCE or PBS. However, HbSS mice treated with PFCE-O_2 following *S. pneumoniae*-infection had significantly lower levels of cytokines than *S. pneumoniae*-infected HbSS mice treated with PFCE-Air
Non-infected HBSS mice were found to have significant airway and interstitial fibrosis. Following repeated exposure to PFCE daily for a week, the lungs of HbSS and C57 mice showed no significant histological difference. However, PFCE treatment for a week was found to significantly reduce the percentage of lung covered by fibrotic tissue from approximately 80% to near 40%. In addition, the spleens of HbSS mice exposed to PFCE daily for a week were significantly smaller than spleens of PBS-treated HbSS mice.
Summary and Conclusions: HbSS mice treated with PFCE and oxygen survived significantly longer than HbSS mice managed with PFCE and air. The improved outcomes were associated with lower pulmonary inflammation. PFCE therapy had no effect on survival of *S. pneumonia*-infected C57 mice or on *S. pneumoniae* growth. Repeated exposure to PFCE was associated with reduced lung fibrosis in HbSS mice and decreased spleen size. The findings suggest that PFCE may have a role in treating patients with sickle cell anemia.

P988

THE BTK-SPECIFIC INHIBITOR ONO-4059 SYNERGIZES WITH THE BCL2 INHIBITOR ABT-263.

R Kozaki[1,*], C Hutchinson[1], S Jayne[2], M Dyer[1]
[1]Cancer Studies and Molecular Medicine, University of Leicester, [2]Haematology, MRC Toxicology Unit, Leicester, United Kingdom

Background: Bruton's tyrosine kinase (BTK) mediates signaling from a number of receptors including the B-cell receptor (BCR). BTK is not a genetic "driver" of B-cell malignancy, but the maintained dependence of certain B-cell malignancies on BCR signaling has allowed successful therapeutic introduction of the BTK inhibitor (BTKi) Ibrutinib; CLL and mantle cell lymphoma are most sensitive. However, the Ibrutinib kinome is broad and more specific inhibitors might be clinically advantageous.
Aims: ONO-4059 is a specific BTKi currently in Phase I development in NHL/CLL. We explored the activity of ONO-4059 as single agent and in combination using a panel of derived cell lines.
Methods: We used *in vitro* assays of cell death and proliferation in a panel of 60 hemopoietic cell lines including 16 BCP-ALL, 14 DLBCL, 7 BL, 4 MCL and 3 myeloma cell lines. ONO-4059 was used alone and in combination with wide variety of clinically relevant compounds, including the BCL2 inhibitor ABT-263 (Navitoclax).

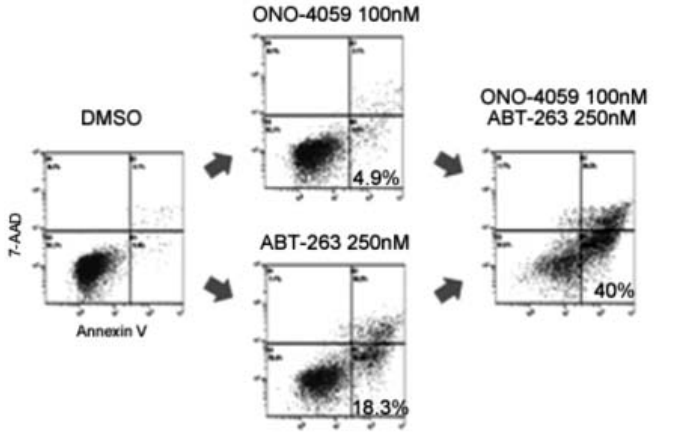

Figure 1.

Results: 2 ABC-DLBCL (TMD-8, OCLy10) and 1 MCL cell line (REC-1) were the most sensitive with EC50s of 5.5nM, 15.8nM and 19.6nM respectively. Genome-wide exomic DNA sequence analysis of these three cell lines showed no common mutational spectrum. ONO-4059 induced rapid decreases of P-BTK and P-ERK in these cell lines. However, cell death with morphological features of apoptosis and caspase activation did not occur until between 48 and 72 hours after exposure to ONO-4059. Interestingly, two ABC and one GCB DLBCL cell lines showed partial sensitivity to ONO-4059, with only a fraction of cells undergoing cell death. To assess possible pharmacological interactions, the cell lines were assessed for synergy with ABT-263. There was synergy with ONO-4059 in the BTKi sensitive cell lines as shown in the FACS profiles below obtained with the U2932 ABC-DLBCL cell line. This synergy may reflect increased BIM protein expression following pERK inhibition, causing increased sensitivity to BCL2 inhibitors (Figure 1).
Summary and Conclusions: These data indicate mechanism-based synergy between BCL2 and ONO-4059 and may have therapeutic implications.

P989

EFFICIENCY OF CD19 TARGETING BY MONOCLONAL ANTIBODIES IN *EX VIVO* AND MOUSE MODELS OF CHILDREN ACUTE B-LYMPHOBLASTIC LEUKEMIAS

A Dony[1], F Baleydier[1], C Dumontet[2], A Evesque[2], D Poloni[2], B Vuillesmoz[3], O Subiger[3], L Bourdin[3], C Vermot-Desroches[3,*]
[1]Institut d'Onco-Hématologie Pédiatrique (IHOP), [2]Equipe14, Centre de Recherche en Cancérologie de Lyon, Lyon, [3]iDD Biotech, Dardilly, France

Background: Treatment of B-acute lymphoblastic leukemia (B-ALL), first cancer of children, is based on conventional chemotherapy, mostly permitting to obtain recovery. Nevertheless, the high cure rate is still associated with acute toxicities, long-term sequelae and refractory forms. Monoclonal antibodies (Mabs), as shown in rituximab model, can have direct effects in inducing apoptosis or arresting proliferation of tumor cells and indirect effects, including antibody dependant cytotoxicity (ADCC) and complement dependant cytotoxicity (CDC). Widely used in clinical oncology, no one is currently recommended in B-ALL treatment. The CD19 glycoprotein has already successfully been targeted in B-cell lymphoma and chronic lymphoid leukemia pre-clinical studies; because of its high expression on the surface of nearly all the B-ALL cells, it could represent an attractive target in children B-ALL.
Aims: We would demonstrate an antitumor efficiency of anti-CD19 Mabs in B-ALL mouse models, and we will explore their main cytotoxicity mechanisms in *ex vivo* pediatric B-ALL samples.
Methods: IDD001 or IDD002 humanized anti-CD19 IgG were generated by iDD biotech with a similar epitope site and different Fc domains. ADCC and CDC activities were tested using a calcein fluorescence-based assay, *in vitro* on B-ALL cell lines (REH and RS (4;11)) and *ex vivo* on pediatric B-ALL samples; effector lied in modified NK-cells (highly expressing CD56) for ADCC assay and in rabbit serum (20%) for CDC assay. Pediatric B-ALL were reproduced in severe combined immunodeficiency (SCID) mouse model by injecting REH or RS (4;11) cell line with a 6 to 12 weeks long tumor development; efficiency of Mabs was then tested in a 5 groups experiment (5 mouses per group in REH model, 8 in RS (4;11) model); dexamethason was administrated to a group as a reference treatment (1 mg/kg per day 5 days a week), rituximab as a negative control (30 mg/kg twice a week); IDD001 and IDD002 were tested by intraperitoneal injection at 30 mg/kg twice a week in REH model and 10 mg/kg twice a week in RS (4;11) model) (Figure 1).

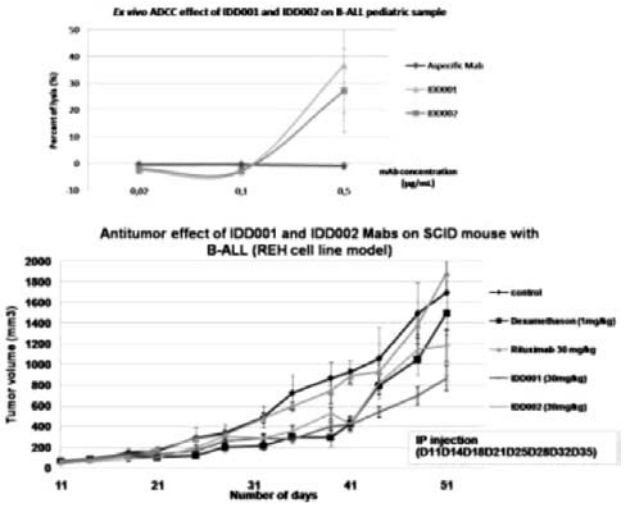

Figure 1.

Results: From its proprietary MAbs library, iDD biotech has generated next-generation, humanized, Fc optimized and afucosylated MAbs anti-CD19 (patent WO/2012/010561/01056), to enhance binding of FcγRIIIa and ADCC against a broad range of B-lymphoma and leukaemia cell lines with or without CDC (MAb anti-CD19 IDD001 *versus* MAb anti-CD19 IDD002). Importantly, iDD

biotech MAbs anti-CD19 mediated significantly higher level of apoptosis compared with other anti-CD19 MAbs under development. Moreover, generic wild type CHO cell lines can be used as host cells to produce IDD001 or IDD002 anti-CD19 MAbs. *In vitro*, IDD001 or IDD002 Mabs enhanced strongly and consistently ADCC, on B-ALL cell lines as well as on B-ALL samples (fig 1); this was found to be specifically due to CD19 targeting. In REH mouse model, IDD001 or IDD002 MAbs significantly inhibited B-ALL growth during the 8 weeks long treatment (fig 2); the same effect was observed in RS (4;11) mouse model with Mabs administrated for 3 injections. For these two experiments, growth inhibition induced by Mabs was similar than inhibition induced by dexamethason during the treatment period, and rebound effect at the end of treatment wasn't significantly different between Mabs and dexamethason.

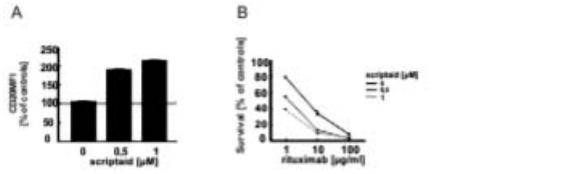
Summary and Conclusions: These pre-clinical findings provide strong support for further experiments and for clinical development of humanized IDD001 or iDD002 anti-CD19 Mabs, either as a monotherapy in B-ALL refractory forms or in combination with conventional chemotherapy for severe prognosis forms. Based on rituximab experience, we could expect a good tolerance in human therapeutics with limited toxicities, mainly drug infusion reactions or prolonged lymphopenia.

P990

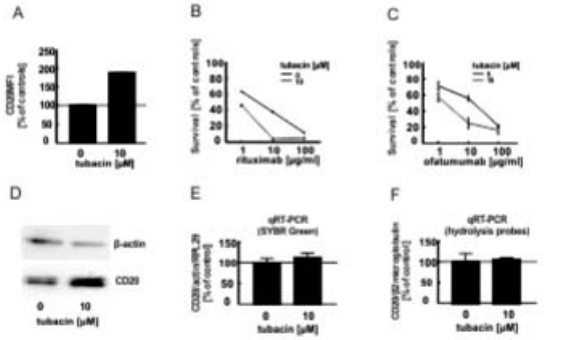
INFLUENCE OF HISTONE DEACETYLASE INHIBITORS (HDACI) ON CD20 EXPRESSION AND EFFICACY OF ANTI-CD20 MONOCLONAL ANTIBODIES

M Wanczyk[1,*], M Kozikowski[1], M Dwojak[1], K Bojarczuk[1], M Winiarska[1]
[1]Department of Immunology, Medical University of Warsaw, Warsaw, Poland

Background: CD20 is an integrate membrane protein widely expressed on the surface of normal and malignant B-cells. It is an excellent molecular target for monoclonal antibodies (mAbs) that are widely used in the therapy of non-Hodgkin's lymphomas and chronic lymphocytic leukemia (CLL). Anti-CD20 mAbs trigger effector mechanisms of immune response and such a therapy is characterized by high efficacy, low toxicity and minor side-effects. Accumulating evidence indicates that CD20 can be modulated at several levels, both transcriptional and posttranscriptional and its uP-regulation would result in increased efficacy of anti-CD20 mAbs. CD20 antigen has been reported to be regulated epigenetically *e.g.* by blocking the activity of histone deacetylases (HDACs). Such observations has been made in B-lymphoma cells with very low basal CD20 level. The use of non-selective pan-inhibitors of HDACs (HDACi) gives promising results both *in vitro* and *in vivo* in several tumor models, including hematologic malignancies. The results of our preliminary experiments show that use of HDACi leads to uP-regulation of CD20 protein in B-cell lymphoma independently of basal CD20 levels and subsequent increase of the efficacy of therapy with anti-CD20 mAbs (Figure 1).



Influence of non-selective inhibition of HDACs on CD20 level and efficacy of rituximab.
Raji cells pretreated for 48h with scriptaid were incubated with saturating amount of FITC-conjugated anti-CD20 mAb for 30 min in room temperature in the dark. The binding of mAb was determined with flow cytometry (A).
Raji cells pretreated for 48 h with scriptaid were washed and incubated for 60 min with increasing concentrations of rituximab and 10% human AB serum. Cell viability was measured with PI staining using flow cytometry (B).



Influence of selective inhibition of HDAC6 on CD20 level and efficacy of rituximab.
Raji cells pretreated for 48h with tubacin were incubated with saturating amount of FITC-conjugated anti-CD20 mAb for 30 min in room temperature in the dark. The binding of mAb was determined with flow cytometry (A).
Raji cells pretreated for 48 h with tubacin were washed and incubated for 60 min with increasing concentrations of rituximab (B) or ofatumumab (C) and 10% human AB serum. Cell viability was measured with PI staining using flow cytometry.
Lysates from Raji cells preincubated for 48 h with tubacin were separated in a polyacrylamide gel. CD20 and actin were detected with corresponding antibodies (D).
RNA from Raji cells preincubated for 48 h with tubacin was isolated with TRIzol and used for first strand cDNA synthesis. cDNA was used for quantitative real time PCR (*qRT-PCR*) amplification of CD20 and actin/RPL29 products (with SYBR Green I) (E) or quantitative real time PCR amplification of CD20 and β2-microglobulin products with the corresponding hydrolysis probes labeled with Fam and Dabcyl (F).

Figure 1.

Aims: The aim of this study was to understand which HDAC isoforms are responsible for the observed effect of CD20 uP-regulation. Determination of a specific isoform influencing CD20 expression could help us decipher the molecular mechanism in which HDAC inhibition increases CD20 expression in human B-cell tumors.

Methods: This study required use of B-cell lymphoma cell lines as well as lymphocytes infected with EBV. Several HDAC pan-inhibitors as well as class/isoform selective inhibitors were tested. To assess the membrane level of CD20 antigen, FITC-conjugated anti-CD20 antibody staining was performed followed by cytometric analysis. The influence of HDACi on total level of CD20 protein was assessed in Western blotting using specific antibodies. The complement-dependent cytotoxicity (CDC) assay was performed using rituximab and ofatumumab as well as human serum as a source of complement. Cell cytotoxicity was assessed by propidium iodide staining followed by cytometric analysis. The influence of HDAC inhibition on the transcription of CD20 was examined by qRT-PCR using both SyBR Green as well as hydrolysis probes.

Results: The results of our study strongly suggest that inhibition of HDAC6 with its specific inhibitor tubacin is sufficient of increase in CD20 level. Inhibition of HDAC6 isoform results in the increase if the efficacy of anti-CD20 mAbs. Tubacin augments total level of CD20 protein but it does not influence CD20 on transcriptional level. These results suggest that blocking HDAC6 activity might influence CD20 at posttranscriptional level.

Summary and Conclusions: The results of our study strongly suggest that combining HDACi with anti-CD20 antibodies can be an effective therapeutic modality for patients suffering from B-cell malignancies. Our experiments indicate that selective inhibition of HDAC6 is sufficient for uP-regulation of CD20 level and may have potential clinical application in hematological malignancies. This observed regulation does not seem to involve transcriptional mechanism. However, the molecular mechanisms of the observed phenomenon need to be elucidated. Extensive experiments aiming at determining what factors are engaged in the regulation of CD20 by HDAC6 will be performed.

P991

BOTANICAL ALKYL HYDROQUINONE HQ17(3) EXHIBITS CYTOTOXIC EFFECT ON SUP-B15 ALL CELLS HARBORING T(9;22) PHILADELPHIA CHROMOSOME THROUGH INDUCING IRON-DEPENDENT LYSOSOMAL EVENTS AND OXIDATIVE STRESS

Y Chang[1,*], S Lin[1], L Lin[1], D Lin[2,3], C Hu[1]
[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, [2]Department of Pediatrics, National Taiwan University Hospital, [3]Department of Laboratory Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan

Background: Acute lymphoblastic leukemia with Philadelphia chromosome (Ph^+-ALL)(t(9;22)*BCR-ABL*) is a very high risk (VHR) hematological neoplasm constitutes 20-30% adult ALL and 2-3% of childhood ALL. Multiple cooperative genetic lesions together with constitutive BCR-ABL onco-protein contribute to a very aggressive clinical cause, hence tyrosine kinase inhibitors (TKIs) is not sufficient to convey long-term control of the disease. Thus, searching for agents with higher specificity to leukemias and investigating the molecule mechanisms involved in the selective cytotoxic effects on leukemic cells will be beneficial for finding new anti-leukemic therapeutics for the Ph^+-ALL. HQ17(3) [10'(Z),13'(E),15'(E)-heptadecatrienyl-hydroquinone], is a natural product isolated from the sap of *Rhus succedanea*. HQ17(3) has been reported to have cytotoxic activity on tumor cell lines and HL-60 AML cells. We found HQ17(3) exhibited very effective cytotoxic effect on the TKI-resistant Ph^+-ALL cell line SUP-B15 (IC_{50}: 1.9 μM), but spared normal peripheral blood mononuclear cells.

Aims: To investigate the characters of, and the molecular pathways involved in the HQ17(3)-induced cytotoxic effects in Ph^+-ALL (VHR ALL harboring t(9;22)) cells.

Methods: HQ17(3)-treated and control SUP-B15 cells were subjected to the following tests: 1) membrane lipid disturbance was analyzed by Annexin V/PI stain, 2) DNA fragmentation was defined as sub-G1 fraction of cellular DNA content after the PI staining, 3) mitochondrial membrane potential loss were stained by DiOC6(3). The stained cells were subjected to flow cytometric analysis. Pan-caspase inhibitor (zVAD-fmk), receptor interacting protein 1 (RIP1) inhibitor (necrostatin-1, Nec-1), or iron-chelator (deferroxamine, DFO) were used in combination with HQ17(3) in some experiment. 4) Acridine orange stain and confocal microscopy are used to visualize the changes of lysosomes in the presence of HQ17(3).

Results: Introduction of HQ17(3) induced extensive cell death in 24 hours. Loss of plasma membrane integrity (PI^+) occur concomitant with phosphatidylserine exposure (Annexin V^+), which was not prevented by zVAD-fmk, Nec-1 or both, indicating a caspase-independent necrotic death program. HQ17(3)-induced cell death displays mitochondrial membrane potential loss and profound nuclear DNA fragmentation. ROS scavengers (GSH or vitamin C) attenuated HQ17(3)-induced cell death and the associated damages, indicating ROS production/oxidative stress account for important part of the cell demise. Of notice, DFO abolished the HQ17(3)-induced cell death, suggesting iron-dependent event(s) (such as hydroxyl radical production by Fenton reaction took place in lysosomes) is critical for the HQ17(3)-induced cell destruc-

tion. We also found both the number and size of acidic vesicles (lysosomes) are significantly increased after 4-hour treatment of HQ17(3) and diminished after 10 hours (when cell death is evident).
Summary and Conclusions: Naturally-derived HQ17(3) displayed selective, and significant anti-leukemic activity in Ph+ ALL (SUP-B15) cells by a caspase-independent, necrotic death program. Iron-dependent events and ROS production contribute to this potent cell destruction process. Lysosomal enlargement and membrane permeability are evident in HQ-induced cell death. These results suggest that agents selectively induce or sustain ROS in leukemic cells may induce lysosomal events, and would potentially augment the treatment for VHR-ALL with t(9;22) translocation.

P992

REACTIVATION OF SELECTED P53 MUTANTS IN B-CELL TUMOR CELL LINES USING TARGETED SMALL MOLECULES

Z Jaskova[1,*], L Sebejova[1,2], S Pospisilova[1,2], M Trbusek[1,2]
[1]Central European Institute of Technology, [2]University Hospital Brno, Brno, Czech Republic

Background: The tumour suppressor protein p53 is a transcription factor that has an essential role in guarding the cell from genotoxic stress. By contrast, mutated p53 can be extremely dangerous as it may gain new oncogenic properties and thus enhance tumorigenesis. Mutated p53 frequently accumulates in cancer cells and it has been shown that subtle molecular manipulation can lead in some cases (in some mutations) to p53 reactivation to its wild-type conformation. Although p53 mutations are frequent in various types of tumors, prognosis of affected patients is especially poor in hematological malignancies.
Aims: To assess a feasibility of mutated p53 reactivation in B-cell lines using comercially available small molecules.
Methods: For p53 reactivation, the following cell lines were used: RAMOS (Burkitt lymphoma; mutation I245D and 17P-); RAJI (Burkitt lymphoma; mutations R213 and Y234H); and SU-DHL-4 (DLBCL; mutation R273C and 17P-). All cell lines expressed high level of mutated p53 protein. Small molecules PRIMA-1 (Cayman Chemical Company) and ellipticine (Calbiochem) were used as reactivation agents. Cell lines were cultured under standard conditions (37 °C, 5% CO_2); Since RAJI cell line harbors temperature-sensitive p53 mutation (Y234H), these cells were also tested for reactivation at 30 °C. The reactivation was tested at the p53 protein level by western blot (WB) and at p53 downstream pathway by quantitative real-time PCR.
Results: In all three cell lines, both PRIMA-1 and ellipticine afftected cellular viability in a concentration-dependent manner (50; 25; 12.5 and 6.25 μM and 10; 5; 2.5 and 1.25 μM, respectively). Time-dependent effect (24, 48, and 72 h) was substantially more apparent in the case of ellipticine. The same concentration range was subsequently applied for testing of p53 reactivation by WB. In RAMOS cells, PRIMA-1 reduced mutated p53 level at two highest concentrations and already after 24 h. In RAJI cells the reduction of mutated p53 protein level was obvious only at 30 °C; under these conditions the two highest concentrations again led to disappearance of mutated p53, prominently after 72 h. Situation with SU-DHL-4 cells was similar, as the two highest concentrations led once again to disappearance of mutated p53. For ellipticine, WB was performed after6,12, and 24 h. In RAMOS cells, the most pronounced effect was observed at highest concentration after 6 and 12 h cultivation; the cells cultured 24 h exhibited already massive apoptosis. In RAJI cells, the reduction of mutated p53 was only very subtle at both 37 °C and 30 °C. Analysis of p53 downstream target genes induction was performed after 24, 48, and 72 h. Concerning PRIMA-1, RAMOS cell line was inert to any reactivation. In RAJI cell line, we observed a subtle induction (up to 350% compared to untreated control set at 100%) of *p21* and *PUMA* genes. In SU-DHL-4 there was a clear induction (620%) of *p21* gene, but only at a single time interval. Regarding ellipticine, we observed subtle induction of *BAX* in RAJI cells and no induction of the studied genes in RAMOS cells.
Summary and Conclusions: Our results show that the small targeted molecules can manipulate with mutated p53 protein in cancer B-cells. These molecules can lead to mutated p53 reduction (clinically highly desirable due to predicted mutated p53 oncogenic gain-of-function) and to induction of cell cycle regulatory and proapoptotic genes. However, further experiments are necessary to more deeply understand exact mechanisms standing behind these effects. Supported by grant NT/13519-4/2012 by IGA MH CR and by project MUNI/A/0723/2012.

P993

NF-KB IS A POTENTIAL MOLECULAR TARGET OF EBV-POSITIVE T- OR NK-CELL LYMPHOPROLIFERATIVE DISORDERS

A Arai[1,*], K Imadome[2], L Wang[1], H Komatsu[1], Y Chiba[2], Y Saitoh[3], S Yamaoka[3], S Fujiwara[2], O Miura[1]
[1]Department of Hematology, Tokyo Medical and Dental University, [2]Department of Infectious Diseases, National Research Institute for Child Health and Development, [3]Department of Molecular Virology, Tokyo Medical and Dental University, Tokyo, Japan

Background: Epstein–Barr virus (EBV) rarely infects T- or NK cells, in addition to B cells, and causes EBV-positive T-/NK-cell lymphoproliferative disorders (EBV-T/NK-LPDs) such as extranodal NK/T-cell lymphoma (ENKL), aggressive NK-cell leukemia, and chronic active EBV infection (CAEBV). Because the mechanisms responsible for development of these EBV-induced malignancies have not been elucidated yet,optimal chemotherapy, especially for CAEBV, has not been established and the EBV-T/NK-LPDprognosis remains very poor.NF-κB is a transcription factor that mediates anti-apoptotic molecular signaling and promotes cancer cell proliferation. It is constitutively activated in some malignancies, and the proteasome inhibitor bortezomib can suppress its activity and is clinically used as an anti-cancer reagent. NF-κB is also activated by EBV infection in B-cells and contributes to infected cell survival.
Aims: To clarify the molecular mechanism underlying the development of EBV-T/NK-LPD by investigating the role of NF-κB
Methods: Four EBV-positive T- and NK-cell lines, SNT8, SNK6, SNT15, and SNT16, were examined. The EBV-negative T-cell lines Jurkat and Molt4 and the EBV-negative NK-cell line KHYG1 were used as the negative controls. Clinical samples were obtained from CAEBV patients diagnosed according to the criteria of Okano M. *et al.* (Am J Hematol 80:64-9, 2005). To detect and isolate EBV-infected cells, T- and NK-cells were separated using magnetic beads from peripheral bloodmononuclear cells (PBMCs). For *in vitro* EBV infection, EBV was prepared from the culture medium of B95-8 cells and added to MOLT4 cells (PNAS 100:7836-40, 2003). NF-κBactivation was examined by western blotting, electrophoretic mobility shift assay (EMSA), and reporter assay. The proteasome inhibitor bortezomib was used for NF-κB inhibition. The effects were examined in not only *in vitro* but also in a xenograft model of EBV-T/NK-LPD generated by transplantation of PBMCs from the CAEBV patients to NOD/Shi-scid, IL-2R γKO mice.
Results: Constitutive NF-κB activation represented by nuclear localization and DNA binding of p50, p52, and RelA, was detected in the cell lines and EBV-infected T- or NK-cells derived from the CAEBV patients (infected cell types: CD4 in 3; CD8 in 3; γ δ in 1; and CD56 in 3). Supershift EMSA revealed that NF-κB–DNA binding complexes in these cells involved p50, p52, and RelA. EBV infection of MOLT4 cells induced constitutive NF-κB activation and inhibited cell death induced by serum depletion or VP16 treatment in the infected cells. Luciferase assay demonstrated that LMP1, in particular, and LMP2A, to a lesser extent, upregulated NF-κB-dependent reporter gene expression in MOLT4 and KHYG1 cells, whereas LMP2B and EBNA1 did not, suggesting that LMP1 and LMP2A mediated NF-κB activation in T- and NK cells. Bortezomib inhibited NF-κB activation, suppressed proliferation, and induced apoptosis in the EBV-T/NK cell lines and primary cells of CAEBV. Furthermore, intraperitoneal bortezomib administration reduced the EBV-DNA titer in peripheral blood of mice transplanted with EBV-T/NK-LPD cells.
Summary and Conclusions: EBV induces NF-κB-mediated anti-apoptotic signals in T- and NK cells and can contribute to tumor development. Suppression of NF-κB by bortezomib induces anti-tumor effects onEBV-T/NK-LPD not only *in vitro* but also *in vivo*.

P994

THE PI3K INHIBITOR NVP-BKM120 INDUCES APOPTOSIS AND AUTOPHAGY IN T-ALL AND BURKITT LYMPHOMA CELL LINES

J Pereira[1,*], M Lopes[1], F Traina[1], J Machado-Neto[1], F Costa[1], S Saad[1], P Favaro[2]
[1]Hematology and Hemotherapy center, University of Campinas, Campinas, [2]Department of Biological Sciences, Federal University of Sao Paulo, Diadema, Brazil

Background: Constitutively active PI3K/Akt/mTOR signaling has been well described in T-ALL. Recently, PI3K activity was reported to cooperate with the development of Burkitt lymphoma. Thus, the role of PI3K/Akt/mTOR in cell growth and survival, two important features of leukemogenesis, has rendered it as a potential pharmacological target in different types of hematological malignancies.
Aims: Herein, we studied the therapeutic potential of a highly selective pan-class I PI3K inhibitor, NVP-BKM120, a2,6-dimorpholino pyrimidine derivative developed by Novartis, on both T-ALL and Burkitt lymphoma cell lines.
Methods: The T-ALL cells lines, Jurkat and Molt-4, and the Burkitt lymphoma cell lines, Namalwa and Daudi, were obtained from ATCC. NVP-BKM120 was prepared as a 10mM stock solution in DMSO and different concentrations were used (0.5 μM, 1μM, 2 μM, 10μM and 50μM). Cell viability was measured using the MTT assay. Clonogenicity was determined by a colony-formation assay. Apoptosis was assessed by Annexin-V/PI staining and by caspase cleavage. Western blot analysis was performed by standard methods. Vital staining and flow cytometry analysis with acridine orange was performed for the detection and quantification of acidic vesicular organelles (AVOs). The comparisons between the groups were performed by the Mann–Whitney or *t* test. *P* value <0.05 was considered statistically significant.
Results: Rates of survival after NVP-BKM120 treatment were determined by MTT assays. All cell lines tested displayed an IC_{50} of around 10μM. NVP-BKM120 at 1μM was able to interfer with the long-term proliferative potential

of the cell lines, as observed by a significant decrease in colony formation. After 6 hours of NVP-BKM120 treatment, the percentage of annexin-V cells increased, as did the cleavage of procaspase-8, procaspase-9 and procaspase-3. Western blot analysis showed a dose-dependent decrease in Ser473 P-Akt, followed by a decrease in the antiapoptotic BCL2 and increase of proapoptotic BAX protein expressions, along with P70S6K dephosphorylation in all cell lines studied. Total Akt and P70S6K levels were unaffected by the drug. To identify the development of AVOs in Molt-4 and Namalwa cells, we used acridine orange, which fluoresces bright red in acidic compartments. NVP-BKM120 (2mM) was found to increase the strength of the bright red fluorescence signal in Molt-4 (from 6.8% to 50.8%) and in Namalwa cells (from 10.2% to 21.4%).
Summary and Conclusions: NVP-BKM120 treatment resulted in the apoptosis of T-ALL and Burkitt lymphoma cell lines, with the cleavage of procaspase-8 and procaspase-9, suggesting that both the intrinsic and extrinsic pathways of apoptosis are activated upon drug treatment. NVP-BKM120 treatment induced dephosphorylation of P70S6K, a mTORC1 downstream target, and also decreased Ser473 P-Akt. These results suggest that this molecule overcomes the signaling feedback loops between mTORC1, PI3K and Akt, commonly described after treatment with mTOR inhibitors. The decrease in BCL2 levels together with increased AVOs indicates the activation of autophagy, supporting the evidence of inhibition of mTOR signaling, the major negative regulator of autophagy in human cells. In conclusion, our findings suggest that the NVP-BKM120 compound represents a promising candidate for the therapy of T-ALL and Burkitt lymphoma patients with aberrant activation of the PI3K/Akt/mTOR pathway.

Cellular immunotherapy and vaccination

THE DONOR DEPENDENT IMMUNE MODULATORY POTENTIAL OF MESENCHYMAL STROML CELL PREPARATIONS CAN BE PREDICTED BY GALECTIN-9

C Ungerer[1,2,*], P Quade-Lyssy[1], H Radeke[3], R Henschler[4], E Seifried[1], J Schuettrumpf[1,2]
[1]DRK Blood Donor Service, Frankfurt, [2]Biotest, Dreieich, [3]pharmazentrum Frankfurt, Frankfurt, [4]Maximilian University Munich, Munich, Germany

Background: Therapeutic approaches using multipotent mesenchymal stromal cells (MSCs) are advancing in regenerative medicine, transplantation and autoimmune diseases. Until now the responsible factors for MSC-mediated immune suppression are still controversially discussed. Most probably a multifactorial set of factors determine the immune suppressive potential of MSCs and might explain the huge variations observed between single MSC preparations. It has been described that immunosuppression by MSCs is enhanced via stimulation with interferon-γ (IFN-γ). Recently galectins, a β-galactoside binding lectin family, have been added to the group of immune modulatory molecules that are responsible for MSC mediated immune suppression.
Aims: We aimed to find possible marker, which help to predict the immune modulatory potential between MSC donor preparations.
Methods: We randomly chose MSC donors and demonstrated that galectin-9 (Gal-9) expression is strong uP-regulated upon activation with interferon-γ (IFN-γ). We compared donors be mRNA and protein level and determined their immune modulatory potential on T-and B-cells with a proliferation assay. The *in vivo* effect of Gal-9 and MSCs was investigated in mice immunized with human coagulation factor VIII (FVIII) in the presence of human MSCs, anti-murine Gal-9, or murine Gal-9. FVIII was used as positive control.
Results: We demonstrated that Gal-9 is a major mediator of the anti-proliferative effect of MSCs on both, T-and B-cells. Activation of MSCs with IFN-γ resulted in a major decrease of proliferation of both T-cells and B-cells. In addition, Gal-9 and activated MSCs contribute to the suppression of triggered immunoglobulin release. Activation of MSCs with IFN-γ decreased the IgG release, whereas blocking Gal-9 neglected the effect almost completely. Additionally, we provide results that Gal-9 expression levels (mRNA and protein) can distinguish between different MSC donor preparations. In this context we confirmed the correlation between high Gal-9 levels and immune modulatory potential. Because compared to immune suppression by recombinant Gal-9, only relatively low Gal-9 levels from MSCs had a strong immune suppressive effect, the question emerged whether their suppressive nature results from cell-cell contacts or by secreted factors. Initial experiments give evidence that the effect is cell-cell contact related, since we observed no changes in immune cell proliferation, when we separated MSCs and immune cells via transwells. Further, only minimal amounts of Gal-9 could be found in supernatants after activation. In addition we demonstrated that MSCs, which were transfected with a his-tagged Gal-9 distributed this recombinant protein to immune cells in close proximity to the labelled Gal-9 expressing cells. I*n vivo* Both, MSCs and murine Gal-9 suppressed immunoglobulin induction. Murine Gal-9 suppresses $CD4^+$subsets, while only MSCs were able to reestablish the equilibrium of B-and T-cells in spleens. Additional experiments with isolated cells demonstrated that, in contrast to human immune cells, murine-derived T- and B-cells do not respond to human recombinant Gal-9, but human IFN-γ activated MSCs. These discrepancies may be based on only 60% homology of murine and human Gal-9. Other immune modulatory factors may then play a stronger role in this context.
Summary and Conclusions: In conclusion, we identified Gal-9 as a new player involved in MSC mediated immune modulation, which interfers with multiple cell types including T-and B-cells. Also, Gal-9 may serve as a predictive indicator for MSC preparations and clinical therapy. We are the first who demonstrate that Gal-9 influences B-cell functions and proliferation in a concentration dependent manner. In addition, Gal-9 is a major effector of MSC mediated immune modulation.

P996

INCREASING SAFETY AND EFFICACY OF TCR TRANSFER BY EMPLOYING A MINIMALLY MURINIZED HUMAN TUMOR-REACTIVE SINGLE-CHAIN TCR

B Hauptrock[1,*], M Glomski[1], D Knies[1], E Antunes[1], H Echchannaoui[1], P Romero[2], R Voss[1], M Theobald[1]
[1]Hematology, Universitätsmedizin Mainz, Mainz, Germany, [2]Ludwig Institue for Cancer Research, Lausanne, Switzerland

Background: Adoptive transfer of T cells modified by tumor antigen-specific T-cell receptor (TCR) gene transfer is a valuable strategy to induce tumor regression in cancer patients. However, transfer of α/β-double-chain (dc)TCR into human T cells harbors the risk of forming hybrid dimers with naturally expressed TCR chains.
Aims: In this study, we used a human single-chain (sc)TCR specific for the

melanoma-antigen gp100(280-288) constructed by linking the variable (V)α-chain to the TCR β-chain to prevent TCR mispairing.
Results: Retroviral cotransduction of the human scTCR together with the constant(C-) domain of the TCRα-chain (Cα) into human T cells did not result in sufficient TCR expression on the cell surface. Expression was restored when human C-domains were replaced by mouse C-domain counterparts. As mouse-derived proteins could be immunogenic in patients, we replaced only selected amino acids in the human constant domains of the scTCR/Cα by their corresponding mouse amino acids. However, this strategy resulted only in a moderate enhancement in scTCR-expression levels. To further improve stability, additional disulfide bonds between the scTCR and the Cα were introduced. This yielded in a substantial increase of expression, cytokine production and lysis of target cells by T cells bearing the minimally murinized (mm) scTCR/Cα. To study if the mm scTCR mispairs with TCRα-chains of other specificities, TCR-deficient Jurkat cells were transduced with different combinations of the scTCR and full length TCRα-chains. Cell surface expression of the mm scTCR by pairing with different human and murine TCRα-chains was demonstrated by anti-Vβ14-staining. However, low Vβ14-MFI in Jurkat cells transduced with the scTCR/TCRα in comparison to scTCR/Cα correlates with a low density of mispaired scTCR/TCRα-dimers on the cell surface. After co-incubation with gp100(280-288) peptide-loaded T2-cells, Jurkat cells harbouring mispaired scTCR/TCRα produced no IFN-γ, demonstrating that the scTCR is not able to interact with the gp100(280-288)-antigen when it mispairs with the irrelevant TCRα-chain. Similar experiments in human T cells showed a marginal expression of the scTCR in combination with an irrelevant TCRα-chain, probably due to favourable pairing of the full length TCRα-chain with the naturally expressed TCR.
Summary and Conclusions: These optimized human scTCR/Cα molecules represent promising candidates for adoptive T cell transfer by providing effective antitumor responses. Mispairing of scTCR with endogenous TCR chains cannot be excluded, but clinical relevance might be limited due to low expression levels of hybrid TCRs.

P997

LONG-TERM FOLLOW-UP OF ADOPTIVE IMMUNOTHERAPY WITH HAPLOIDENTICAL KIR-L MISMATCHED NATURAL KILLER CELLS AS POST-REMISSION CONSOLIDATION STRATEGY IN ELDERLY HIGH RISK ACUTE MYELOID LEUKEMIA PATIENTS

A Curti[1,*], S Parisi[1], L Ruggeri[2], A D'Addio[3], A Bontadini[4], E Dan[1], M Motta[1], S Rizzi[1], S Trabanelli[1], V Giudice[4], E Urbani[5], G Martinelli[1], S Paolini[1], F Fruet[4], G Bandini[1], M Baccarani[1], A Velardi[5], R Lemoli[1]
[1]'L. e A. Seràgnoli' Hematology Institute, Bologna, [2]Hematology and Clinical Immunology, Department of Clinical and Experimental Medicine, Perugia, [3]Azienda Istituti Ospitalieri, Hematology Unit, Cremona, [4]Immunohematology Service and Blood Bank, S.Orsola-Malpighi Hospital, Bologna, [5]Division of Hematology and Clinical Immunology, Department of Clinical and Experimental Medicine, University of Perugia, Perugia, Italy

Background: The most common cause of treatment failure in acute myeloid leukaemia (AML) patients is early relapse. Then, new consolidation strategies represent now one of the most interesting issues. Data from literature suggest that KIR mismatched NK cells may be transferred and expanded *in vivo* and may significantly impact on tumor cell killing, particularly in AML patients.
Aims: Aim of this work is to establish the feasibility and efficacy of adoptive immunotherapy with haploidentical KIR-L mismatched NK cells as consolidation therapy in elderly high-risk AML patients, who achieved CR.
Methods: Fourteen patients with high-risk AML (2 in molecular relapse and 12 in morphological complete remission (CR); with a median age of 62 years (range 53-73) received highly purified $CD56^+CD3^-$ NK cells from haploidentical KIR-ligand mismatched donors after fludarabine/cyclophosphamide –containing-immunosuppressive chemotherapy, followed by interleukin-2 subcutaneous administration (10×10^6 IU/day, 3 times weekly for 2 weeks -6 doses total) after NK cell infusion.
Results: The median number of infused NK cells was 2.74×10^6/Kg. No NK cell-related toxicity, including graft-*versus*-host disease (GVHD), was observed. Hematological recovery was comparable to standard chemotherapy: median time to neutrophil count recovery (ANC $>0.5 \times 10^9$/l) was 18 days (range 12-45), median time to platelet recovery (PLTs $>20 \times 10^9$/l) was 20 days (range 13-45). Both patients in molecular relapse achieved molecular CR, which lasted 9 months for both patients. Among 12 patients in morphological CR, 7 patients are disease-free after 28, 25, 63, 59, 49, 10 and 9 months (median 28 months; range 9-63), whereas 4 relapsed after3,5, 24 and 3 months; 3 relapsed patients ultimately died due to disease progression, one is receiving re-induction chemotherapy. One patient died during the neutropenic phase due to overwhelming bacteria pneumonia. Seven AML patients, who had achieved CR after the same induction/consolidation therapy and with similar prognostic features as the study patients, were excluded from NK therapy because they did not have KIR-ligand mismatched donors. Interestingly, analysis of clinical outcomes showed that 6/7 patients relapsed at a median of 4 months and died of disease progression, whereas one patient is alive and disease-free after 24 months post autologous stem cell transplant. After infusion, donor NK cells were found in the peripheral blood (PB) of all evaluable patients (peak value on day 10). They were also detected in the bone marrow (BM) in some cases (peak value on day 5). An association between serum IL-15 concentration and donor chimerism after NK cell infusion was observed. Particularly, the rise in IL-15 serum level was followed by increase in donor chimerism, thus supporting the conclusion that homeostatic IL-15 drives *in vivo* expansion and survival of adoptively transferred NK cells. Donor-*versus*-recipient alloreactive NK cells were demonstrated *in vivo* by the detection of donor-derived NK clones that killed recipient targets, including leukemic blasts.
Summary and Conclusions: Infusion of purified NK cells is feasible in elderly patients with high risk AML. Adoptively transferred NK cells were alloreactive against recipient cells and might have induced anti-leukemic activity.

P998

STAINING OF ANTIGEN-SPECIFIC CD4+ T CELLS USING MHC CLASS II TETRAMERS GENERATED ACCORDING TO A NOVEL METHOD OF PEPTIDE-MHC CLASS II MONOMER PRODUCTION AND PURIFICATION

P Braendstrup[1,*], S Justesen[1], T Østerby[1], M Kongsgaard[1], B Mortensen[1], L Vindeløv[2], R Malone[3], A Stryhn[1], S
[1]ISIM, Copenhagen University, [2]Hematology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, [3]Unité 986, Institut National de la Santé et de la Recherche Médicale, Unité 986, DeAR Lab Avenir, Hôpital Saint Vincent de Paul, Paris, France

Background: CD4+ T cells recognize linear peptides bound in the peptide-binding cleft of MHC class II molecules displayed on the surface of antigen-presenting cells. CD4+ T cells are key players in adaptive immunity orchestrating both CD8+ T cells (*e.g.* activation, differentiation, proliferation, maintenance) and B cells (*e.g.* antibody class switching, high affinity antibody production). The use of MHC class I tetramers to stain antigen-specific CD8+ T cells emerged in 1996 and has since transformed the field of cellular immunology, effectively becoming the golden standard for direct enumeration, analysis and manipulation of CD8+ T cells. On the other hand generation of functional MHC class II complexes and MHC class II tetramers has proven challenging.
Aims: To develop an alternative method of MHC class II tetramers/multimer generation for the staining of antigen-specific CD4+ T cells.
Methods: Recombinant MHC class II alpha and beta chains were refolded *in vitro* in the presence of peptides that had been extended by a hexa-histidine sequence. The resulting peptide-MHC class II complexes could readily be purified and concentrated by immobilized metal affinity chromatography, and subsequently tetramerized using fluorochrome-labeled streptavidin.
Results: We have developed a novel method of MHC class II tetramer synthesis. With common HLA-DRB-alleles and various viral epitopes stemming from human cytomegalovirus and Influenza A virus we have subsequently demonstrated that these MHC class II tetramers can stain and purify antigen-specific, MHC class II-restricted CD4+ T lymphocytes.
Summary and Conclusions: The use of MHC class II tetramers could provide important information about the reconstitution of virus-specific CD4+ T cells and possibly the development of minor histocompatibility antigen-specific CD4+ T cells following allogeneic hematopoietic cell transplantation.

P999

PMHC ARRAYS DEMONSTRATE THAT "UNTOUCHED" T CELL POPULATIONS FROM PRESENTATION ACUTE MYELOID LEUKAEMIA PATIENTS PREDOMINANTLY RECOGNIZE THE CANCER-TESTIS ANTIGEN, PASD1

S Brooks[1], S Bonney[1], E Smits[2], C Lee[3], D Sigurdardottir[4], D Li[5], K Pulford[5], A Banham[5], T Elliott[1], H Rammensee[4], V Van Tendeloo[2], K Orchard[3,*], B Guinn[6,7]
[1]Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, [2]UA Laboratory of Experimental Hematology, Antwerp University Hospital, Antwerp, Belgium, [3]Department of Haematology, Southampton University Hospitals Trust, Southampton, United Kingdom, [4]Abteilung Immunologie, Interfakultäres Institut für Zellbiologie, Tübingen, Germany, [5]Division of Clinical Laboratory Sciences, University of Oxford, Oxford, [6]Cancer Sciences Unit, Southampton University Hospitals Trust, Southampton, [7]Department of Life Sciences, University of Bedfordshire, Luton, United Kingdom

Background: Peptide major histocompatibility complex (pMHC) arrays, also known as tetramer arrays, were developed to identify "untouched" populations of $CD8^+$ T cells in the peripheral blood of cancer patients. The technique is able to analyse multiple T cell populations using small numbers of $CD8^+$ T cells (~1.2×10^6 cells/array) and pMHC (1ng per spot, 1/1,000th of that used in flow cytometry) spotted onto polyacrylamide gels. The pMHC array can simultaneously analyse a large number of T cell populations without haplotype restriction.
Aims: To determine the tumour antigens and epitopes therein recognized by leukaemia patients at disease presentation.
Methods: Negatively isolated $CD8^+$ T cells were obtained, following informed consent and local ethical approval, from the peripheral blood of leukaemia

patients. T cells were lipophillically dyed with DiD fluorescent tracer and incubated with arrays printed with pMHCs from more than 50 tumour-associated antigen and viral epitopes (including HLA-A2/CMV and Flu controls). Positive scoring of T cell populations were only made when T cells were consistently bound to 3 of 6 of the same pMHC spots in two distinct regions on the array.
Results: We have analysed 33 leukaemia patients (25 AML, 3 ALL, 5 CML) and 18 normal donors. Although normal donor T cells recognized HLA-A2/Flu M1 and/or CMV pp65 and/or IE1 epitopes, no binding to tumour antigen epitopes were found. However we found that 11 of the 12 patients who had specific-T cell populations recognising epitopes within tumour antigens were AML patients and 8 of these recognized PASD1. The other four patients (3 AML and 1 ALL) had T cells which recognized epitopes within MUC1, Tyrosinase, CEAM5 and MelanA.
Summary and Conclusions: We have developed a robust method for the simultaneous analysis of T cell populations in leukaemia patients, the use of which can indicate a short-list of T cell populations for further investigation of T cell function, minimising reagent and sample use.

P1000

CYTOKINE INDUCED KILLER CELLS ARE ACTIVE AGAINST NON-SMALL CELL LUNG CANCER AND OVERCOME THE ACQUIRED RESISTANCE TO TARGET THERAPIES

M Todorovic[1,*], S Corso[1], C Migliore[1], E Morando[1], L Gamaittoni[1], L Giraudo[1], V Leuci[1], G Mesiano[1], S Capellero[1], S Giordano[1], M Aglietta[1], D Sangiolo[1]
[1]IRCC, Candiolo, Torino, Italy

Background: Non-small cell lung cancer (NSCLC) patients initially responding to target therapies invariably develop resistance to these drugs. This poses the question of further *therapeutic approach*. In our study, we assessed a combined treatment of target therapy and immunotherapy with CIK (Cytokine Induced Killer) cells. CIK cells are able to kill tumor in MHC-unrestricted manner. This antitumor activity is mediated by the interaction of CIK's membrane receptor NKG2D with MIC A/B and ULBP 1-3 ligands expressed on the tumor cells.
Aims: In this preclinical study, we investigated the efficacy of immunotherapy with CIK cells in NSCLC and, concomitantly, the possibility of overcoming the acquired resistance to target therapies: EGFR tyrosine kinase inhibitors (TKI) and MET tyrosine kinase inhibitors.
Methods: CIK cells were expanded from healthy donors, starting from PBMC, with the timed addition of IFN-gamma, Ab anti-CD3 and IL2. EGFR TKI resistant NSCLC cells were generated by treating EGFR-addicted cells (PC-9, H 4006, H 3255, HCC 827) with increasing concentrations of EGFR TKI:erlotinib, gefitinib, dacomitinib, afatinib and AZD8931. MET TKI resistant NSCLC cells are generated by treating EBC 1 and H 1993 cells with increasing concentrations of crizotinib and JNJ38877605.
Results: Both wild type NSCLC cell lines and correspondent resistant sublines expressed MIC A/B and ULBP ligands which render them good potential targets for immunotherapy with CIK cells. Mean expression values of MIC A/B were 34% in EGFR TKI sensitive cells; values of 34%. 36%, 36%, 35% and 43% were observed on corresponding sublines respectively resistant to erlotinib, gefitinib, dacotinib, afatinib and AZD8931. ULBP 2 was expressed in EGFR TKI sensitive cells with mean of 94%; values observed on corresponding resistant sublines for all EGFR TKI drugs were comparable. MET TKI sensitive and resistant lines had equal expression of 100% of ULBP 2. CIK cells efficiently and comparably killed both, sensitive and drug resistant NSCLC cell sublines *in vitro* up to 91% of specific killing (n=21). Preliminary *in vivo* experiments showed that weekly intravenous infusions of CIK cells into NOD/SCID mice (n=6), implanted with NSCLC cells (EBC1), significantly delayed tumor growth compared to untreated controls (n=5) (V1=2764±376 mm^3, *vs* V2=477±379 mm^3, average±sem, P=0,02). Similar trend was observed treating animals implanted with EBC1-originated tumor made resistant to MET TKI *in vivo*.To rule out potential impairment by targeted therapies, CIK cells were exposed for 1 week with EGFR TKI (erlotinib 400nM, gefitinib 100nM, dacomitinib 5nM, afatinib 5Nm, AZD8931 5nM) and MET TKI (crizotinib 150nM) without observing any significant change in phenotype or functionality.
Summary and Conclusions: CIK cells demonstrated intense activity *in vitro* and *in vivo* against NSCLC targets. This beneficial effect was retained also against tumor cells that developed resistance to molecular targeted therapy with either EGFR TKI or MET TKI. Our data support and encourage further investigation in this direction with promising clinical benefit in NSCLC patients and the perspective potential to overcome resistance to molecular targeted approaches.

NATURAL KILLER CELL EXPANSION UNDER GOOD MANUFACTURING PRACTICE CONDITIONS FOR CLINICAL USE IN ADULT PHILADELPHIA+ ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

N Peragine[1,*], G Torelli[1], S Raponi[1], C Rozera[2], P Mariglia[1], W Barberi[1], A Vitale[1], F Belardelli[2], A Guarini[1], R Foà[1]
[1]Department of Cellular Biotechnology and Hematology, Sapienza University, [2]Department of Hematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, Rome, Italy

Background: The management of adult Philadelphia (Ph)+ acute lymphoblastic leukemia (ALL) has profoundly changed with the utilization of tyrosine kinase inhibitors (TKI). Two GIMEMA studies have shown that virtually all patients, irrespective of age, obtain a complete remission (CR) with TKI plus steroids without systemic chemotherapy. Most patients tend over time to relapse and the optimal post-CR treatment is unclear. The possibility of controlling/eradicating minimal residual disease (MRD) through an immunotherapy-based strategy represents a very attractive therapeutic option. Previous studies have shown that cytotoxic natural killer (NK) cells with killing activity against autologous blasts may be expanded and activated from ALL patients in CR, suggesting the use of NK-based immunotherapeutic protocols for the management of these patients.
Aims: Aim of this study was to design a method of NK cell expansion under good manufacturing practice (GMP) conditions to be used in clinical protocols based on the *in vivo* infusion of *ex vivo* expanded autologous NK cells for adult patients affected by Ph+ ALL in CR.
Methods: PBMCs were collected from 20 healthy donors and 3 adult Ph+ ALL patients in CR. For NK cell enrichment, a two-step immunomagnetic procedure was used, consisting of an initial $CD3^+$ T-cell depletion followed by a $CD56^+$ positive selection. Isolated NK cells (1×10^5/mL) were cultured for 14 days in SCGM serum-free medium supplemented with 5% autologous plasma,500 U/mL IL-2 and 50 ng/mL IL-15 in the presence of irradiated autologous feeder cells (2.5×10^5/mL). Only GMP and clinical grade materials were used. The phenotype of freshly-isolated and expanded NK cells was assessed using mAbs against CD56, CD16, CD3, DNAM-1 and NKG2D receptors, being the last two proteins involved in NK-cell recognition and killing of primary blasts. The cytolytic properties of expanded NK cells against the K562 cell line and against primary adult Ph+ ALL blasts were determined in a standard ^{51}Cr release assay.
Results: NK cells from healthy donors and Ph+ ALL patients could be expanded respectively up to a 31.8±15.5 and 39.1±19.3 fold increase. Expanded NK cells contained a homogenous cell population displaying a high expression of CD56 and CD16 in the absence of CD3. DNAM-1 and NKG2D activatory receptors presented a significantly increased expression after expansion both from healthy donors (DNAM-1 P=.0007; NKG2D P=.0004) and from Ph+ ALL patients (DNAM-1 P=.0012; NKG2D P=.045). Fresh and cryopreserved expanded NK cells from healthy donors and Ph+ ALLs induced an efficient lysis of K562 cells (mean cytotoxicity at a 50:1 E:T ratio 75.6%±9.7% and 62.9%±2.3%, respectively). When NK cells expanded from healthy donors were used as effectors against adult Ph+ ALL blasts, a marked cytotoxicity was observed (n=5; mean cytotoxicity at a 50:1 E:T ratio 21.4%±7.2%), indicating the susceptibility of Ph+ ALL blast cells to NK cell cytotoxicity. In addition, preliminary data show that NK cells expanded from Ph+ ALL patients in CR exert a cytotoxic activity also against autologous blasts cryopreserved at diagnosis, thus confirming the above data.
Summary and Conclusions: These results open the way to a possible new immunotherapeutic strategy for adult Ph+ ALL patients with evidence of MRD, based on the *in vivo* infusion of autologous NK cells expanded *ex vivo* according to GMP-suitable procedures. The ultimate goal is a non-chemo/non-transplant management of Ph+ ALL - particularly the elderly - with the use of TKI (and steroids) plus an immune-mediated control of the disease.

P1003

EFFICIENT GENERATION OF HLA-A2 AND A24-RESTRICTED WT1-SPECIFIC CYTOTOXIC T LYMPHOCYTES USING GENE-ENGINEERED ARTIFICIAL ANTIGEN-PRESENTING CELLS

M Ogasawara[1,*], S Ota[1], N Hirano[2]
[1]Department of Internal Medicine, Sapporo Hokuyu Hospital, Sapporo, Japan, [2]Ontario Cancer Institute, Toronto, Canada

Background: Adoptive transfer of antitumor T cells to patients with malignant melanoma has been shown to have a significant clinical impact. However, widespread use of this novel modality has been hampered by the difficulties in consistently generating antitumor lymphocytes in a timely manner for every patient. To overcome this issue, we previously reported the generation of K562-based artificial antigen-presenting cells (aAPCs). Using this aAPC-based culture system, we are able to reproducibly generate HLA-restricted antigen-specific $CD8^+$ cytotoxic T lymphocytes (CTL). Recent clinical trials have demonstrated that melanoma-specific CTL, expanded using this aAPC system, could survive for prolonged periods in advanced-stage melanoma patients without lymphodepletion or cytokine treatment. Moreover, these CTLs trafficked to the tumor, mediated biological and clinical responses, and established antitumor immunologic memory.
Aims: Wilms' tumor 1 suppressor (WT1) is one of the ideal tumor-associated antigens for cancer immunotherapy. Using our aAPC-based T cell culture system, we expanded and characterized WT1-specifc CTL restricted by frequent HLA-A alleles, A2 and A24.
Methods: HLA-A*02:01 (A2) and A*24:02 (A24)-positive peripheral blood mononuclear cells were obtained from leukemia and cancer patients (n=5). To establish antigen-specific T cells, $CD8^+$ T cells were purified by positive selection using a magnetic beads method (Miltenyi Biotec). aAPCs expressing either HLA-A2 or A24 as a single HLA allele were pulsed with HLA-A2 or HLA-A24 restricted, wild type or modified 9-mer WT1 immunodominant peptides (RMF-

PNAPLY for HLA-A2 and CYTWNQMNL for HLA-A24). aAPCs were then irradiated with 200 Gy and added to purified CD8+ T cells at a ratio of 1:10 in 96-well plates in PRMI1640 supplemented with 10% human AB serum. Between stimulations, IL-2 (10 U/mL) and IL-15 (10 ng/mL) (both from Peprotec) were added to the cultures.
Results: Flow cytometry (FACS) analysis confirmed that aAPCs stably expressed HLA class I, CD80 and CD83. Following 3 rounds of weekly stimulation with peptide-pulsed aAPCs, WT1-peptide-specific CTLs were evaluated by a tetramer staining and an enzyme-linked immunosorbent spot (ELISPOT) assay. The percentage of HLA-A2 tetramer-positive cells was 0.051±0.023% before stimulation. It increased to 0.258±0.165% (5.1 fold increase) following three stimulations. In contrast, the percentage of HLA-A24 tetramer-positive cells before and after stimulation was 0.070±0.008% and 0.787±0.873% (11.2 fold increase), respectively, indicating greater magnitude of increase compared with HLA-A2 tetramer positive cells. Neither HLA-A2 nor A24-restricted WT1-specific CD8+ T cells were stained by irrelevant tetramers, confirming their strict HLA restriction and antigen specificity. Interestingly, IFN-gamma ELISPOT assays revealed that the magnitude of increase in WT1-specific CTLs generated from HLA-A2 patients following stimulation was higher than those generated from A24 patients (10.8 times and 6.7 times, respectively). FACS analysis showed that majority of WT1-specific CTLs expanded using WT1 peptide-pulsed aAPCs expressed an effector memory phenotype. These results suggest that there could be difference in functional maturation between HLA-A2 and A24-restricted WT1-specific CTL generated from leukemia and cancer patients.
Summary and Conclusions: These results demonstrated that HLA-A2 and A24-restrited WT1-specific CTLs with an effector memory phenotype can be generated *in vitro* using peptide-pulsed gene-engineered aAPCs within a short period of time.

P1004

OPTIMIZATION OF ALLOGENEIC NK CELLS FOR ADOPTIVE TRANSFER THERAPY

M Besser[1,2,*], T Shoham[3], O Harari-Steinberg [1,4], N Zabari[1,2], R Ortenberg[1,2], A Kubi[1], A Yakirevitch[5], A Nagler[6], R Loewenthal[7], J Schachter[1], G Markel[1,2,8]
[1]Ella Institute for Melanoma, Sheba Medical Center, Ramat Gan, [2]Department of Clinical Microbiology and Immunology, Sackler Faculty of Medicine, Tel Aviv University, [3]GreenOnyx, Tel Aviv, [4]Pediatric Stem Cell Research Institute, [5]Department of Otolaryngology and Head and Neck Surgery, [6]Department of Bone Marrow Transplantation, [7]Tissue Typing Laboratory, [8]Talpiot Medical Leadership Program, Sheba Medical Center, Ramat Gan, Israel

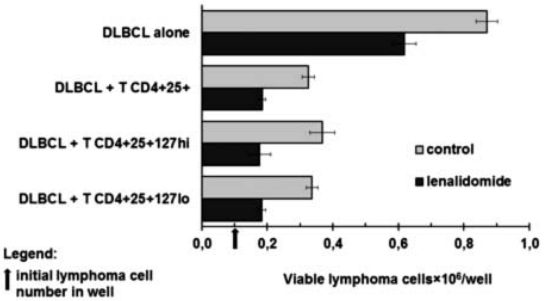
Background: Natural killer (NK) cells have long been considered as potential agents for adoptive cell therapy for solid cancer patients. Triggering of effector NK function depends on the balance of inhibitory (mostly Killer-Ig-like Receptors; KIR) and stimulatory (NK Lysis Receptors; NKLR) signals. Although NK cells are able to eliminate malignant cells without prior antigenic stimulation, most clinical studies utilizing autologous NK cells yielded disappointing results.
Aims: To develop the most efficient strategy employing allogeneic NK cells for adoptive cell transfer in solid tumors.
Methods: We analyzed various modular approaches, including donor-recipient KIR-ligand mismatching, *ex vivo* expansion and activation of NK cells, induction of NKLR, and co-administration of antibodies to elicit antibody-dependent cell cytotoxicity (ADCC) in a melanoma model.
Results: In agreement with previous models, we could show that melanoma cells were more efficiently killed by allogeneic NK cells derived from KIR-ligand mismatched donors. Specific anti-tumor activity of NK cells could further be enhanced by the addition of ADCC-inducing antibodies. The ADCC effect was independent from the KIR-ligand mismatched setting and was only observed in NK cells over-night pre-activated with Interleukin-2 (IL-2), but not in fresh NK cells. To investigate the efficacy of ex-vivo activated and expanded NK cells, we developed a clinically-compliable expansion protocol. After CD3 T cell depletion, cells were subjected to various growth media, IL-2 concentrations,+/- anti-CD3 antibody and+/- irradiated feeder cells. The addition of irradiated feeder cells together with anti-CD3 antibody (to stimulate feeder cells) in AIM-V or X-Vivo 10 culture media resulted in the highest fold expansion of CD3-depleted cells (average of 112-fold after 2 weeks and 420-fold after 3 weeks). *Ex vivo* expanded NK cells displayed an enhanced killing activity when compared to over-night incubation with IL-2, as well as in the mismatched setting, as compared to the matched setting. The improved killing activity of *ex vivo* expanded NK cells could be explained by the uP-regulation of NK lysis receptors, mainly NKG2D and NKp30. Addition of ADCC-inducing antibody modestly increased the killing activity of already expanded NK cells.
Summary and Conclusions: NK cell *ex vivo* expansion and activation, and optimization of NKLR expression seem to be the most potent strategy for the generation of anti-tumor reactive NK cells, followed by ADCC induction and lastly by KIR-ligand mismatching. This study rationalizes a clinical trial that combines adoptive transfer of highly potent *ex vivo* expanded allogeneic NK cells from selected donors (high NKLR expression) and antibody therapy in patients with malignancies.

P1005

LENALIDOMIDE MODULATES AN INHIBITORY EFFECT OF HUMAN REGULATORY T CELLS ON THE PROLIFERATION OF B CELL LYMPHOMA

M Grygorowicz[1,*], M Biernacka[1], M Bujko[2], E Nowak[1], G Rymkiewicz[3], J Walewski[4], S Markowicz[1]
[1]Dept. of Immunology, [2]Dept. of Molecular and Translational Oncology, [3]Dept. of Pathology, [4]Dept. of Lymphoid Malignancies, Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warszawa, Poland

Background: High numbers of intra-tumoral regulatory T-cells (Tregs) have been reported to correlate with improved survival in germinal center B cell-like diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), and classical Hodgkin lymphoma. Thus Tregs, which are capable of directly suppressing activation of normal B cells, can be similarly involved in the regulation of lymphoma B cell proliferation. Studies on B-cell lymphoma models have shown that lenalidomide modulates the immune system. Inhibition of the proliferation and function of naturally occurring Tregs was reported as one of multiple immunomodulatory effects of lenalidomide. This raises the question of whether lenalidomide interferes with the regulation of lymphoma cell proliferation by Tregs.
Aims: To investigate interactions between Tregs and lymphoma B cells and to evaluate effects of lenalidomide on the regulation of lymphoma B-cell proliferation by Tregs.
Methods: Established cell lines of FL, DLBCL, Burkitt lymphoma, plasma cell myeloma, mantle cell lymphoma, and Hodgkin lymphoma were co-cultured with freshly isolated or *ex vivo* expanded Tregs, with or without 1microM or 2microM lenalidomide (Celgene Corp.), *i.e.* at concentrations compatible with clinical concentrations. The equivalent volume of DMSO was added to control cultures without lenalidomide. To evaluate cell proliferation by flow cytometry, lymphoma cells were stained with carboxyfluorescein succinimidyl ester (CFSE), and Tregs with the cell proliferation dye eFluor670. CD4+CD25+Tregs were obtained from peripheral blood of healthy donors by magnetic separation. To expand Tregs, CD4+CD25+T cells were cultured either in the presence of irradiated allogeneic monocyte-derived dendritic cells (allo-DC) or anti-CD3/28/2 Ab-coated beads, with IL-2 (10 or 50 U/mL, respectively), with or without rapamycin (100 ng/mL).
Results: Effects of freshly isolated Tregs on the proliferation of different lymphoma cell lines ranged from help to suppression. Lenalidomide neither induced nor enhanced suppression of lymphoma cell proliferation by freshly isolated Tregs, unless anti-CD3/28/2 Ab-coated beads or "third party" allo-DC were added to the mixed cultures to activate Tregs. Tregs expanded in the presence of rapamycin for 2 to 5 weeks following polyclonal activation or activation by "third party" allo-DC, suppressed proliferation of 10/12 lymphoma cell lines tested, and proliferation of polyclonally activated autologous and allogeneic conventional Tcells. Tregs expanded without rapamycin proliferated for a shorter period of time, and did not develop equal regulatory function. Expanded Tregs constantly expressed FOXP3 and maintained demethylation of *FOXP3* intronic Treg-specific demethylation region (TSDR), secreted IL-10 and IFN-gamma, expressed CTLA-4, CD39, CD73, GARP, TIGIT, GITR, and granzyme A, but not granzyme B or perforin. Proliferation of lymphoma B cell lines was moderately reduced or not affected by lenalidomide alone. In mixed leukocyte cultures, lenalidomide potentiated suppression of lymphoma proliferation exerted by Tregs pre-expanded *ex vivo*. The inhibitory effects of lenalidomide or Tregs on lymphoma proliferation were additive, even when lenalidomide moderately inhibited Treg proliferation. Tregs expanded from sorted CD127(lo) and CD127(hi) subsets of CD4+CD25+T cells similarly suppressed lymphoma proliferation, and lenalidomide similarly potentiated suppression exerted by these Treg populations (Figure 1).



Effect of 2 μM lenalidomide on the regulation of diffused large B cell lymphoma (DLBCL) cell proliferation by Treg expanded either from CD4+CD25+ T cells or CD4+CD25+CD127(lo) T cells or CD4+CD25+CD127(hi) T cells. Lymphoma cells were plated at a ratio 4:1 to T cells. The bars represent mean values +/- S.D. of viable lymphoma cell count in triplicate 5-day cultures.
Treg were activated polyclonally and expanded for 21 days with rapamycin (100 ng/ml) prior to plating with lymphoma cells in mixed leukocyte cultures.

Figure 1.

Summary and Conclusions: Tregs could be considered for adoptive therapy post-autologous hematopoietic transplantation (HCT) to eradicate residual lymphoma and to counteract both graft-*versus*-host disease and lymphoma regrowth after allogeneic HCT. Tregs expanded *ex vivo* with rapamycin could

be particularly useful. Lenalidomide potentiates the regulatory function of Tregs directed against B lymphoma under the condition that Tregs are activated. Indirect activation of Tregs in the absence of lymphoma B cells induces regulatory function of Tregs against B lymphoma cells.
Supported by Polish MNiSW grant Nr N N402 454739.

CENTRALIZED PRODUCTION AND DISTRIBUTION OF CMV-SPECIFIC CYTOTOXIC T CELL LYMPHOCYTES

A Friedetzky[1,*], A Skulte[1], A Mitra[1], K Hodgkin[1], K Peggs[2], K Newton[1], R Knaus[1]
[1]Cell Medica, [2]UCL Cancer Institute, London, United Kingdom

Background: Investigator-led Phase I/II studies have shown that adoptive transfer of donor virus-specific cytotoxic T cell lymphocytes (CTL) can reconstitute immunity on a long-lasting basis in patients at risk for viral reactivation following allogeneic hematopoietic stem cell transplantation (allo HSCT).
Aims: In order to support routine clinical use for virus-specific CTL, it is critical to establish a reliable and convenient approach for supply of the cell product to transplant centers across Europe.
Methods: Requests for Cytomegalovirus-specific (CMV) CTL are accepted for specific patients from transplant physicians under a cell therapy agreement with Cell Medica, employing standard request forms. Eligibility is confirmed, including HLA-type and presence of CMV-specific cells, in donor samples. A proprietary technology is utilized for direct selection of CTL based on MHC-multimer technology (STAGE Cell Therapeutics GmbH). After final testing the CMV-specific CTL are released as Cytovir™ CMV and shipped to the hospital in a temperature controlled manner for direct infusion according to local SOPs for donor lymphocyte infusions. In addition, Cell Medica is sponsoring two clinical studies investigating the use of Cytovir™ CMV for high risk patients (CMV D+/R+) prophylactically (CMV~IMPACT study) as well as therapeutically post-CMV reactivation (CMV~ACE/ASPECT trial).
Results: The centralized production reliably results in a product that after microbiological clearance can be delivered in 10-14 days from receipt of starting material. Based on the provision of over 50 cell products to support clinical trials to 15 centers, no logistics failures have occurred. The Table 1 shows data from the last 27 products manufactured after process optimization.

Table 1. Manufacturing data.

(n=27)	Median	Range
% CMV+ cells in donor starting material (of CD8+)	0.85 %	0.11 – 13.3 %
% CMV+ cells in final product (of CD3+)	93.57 %	8.72 – 99.56 %
% CD3+ cells in final product	65.66 %	10.20 – 98.51 %
% viability in final product	95.62 %	76.86 – 98.78 %
T cell dose /kg infused	$2.7x10^4$	$7.61x10^2 – 5x10^4$
Total number of T cells infused	$1.92x10^6$	$5.63x10^4 – 4.2x10^6$

Summary and Conclusions: Cell Medica have developed a model for centralized production and delivery of virus-specific CTL for transplant centers across Europe. Detailed manufacturing data demonstrate a high quality cell product. According to the scientific recommendation from the European Medicines Agency (EMA) Cytovir™ CMV is not classified as an advanced therapy medicinal product (ATMP) (date of adoption of recommendation by the EMA 26/01/2010). Routine use of CMV-specific CTL is feasible across Europe. Regulatory approvals pursuant to national legislation will be sought in the next 8 months with all necessary requirements already fulfilled to allow UK supply.

P1008

LAK CELLS AND ANTI-CD20 MONOCLONAL ANTIBODIES AS INMUNOTHERAPY ON FOLLICULAR LYMPHOMA: ENCHANCED ANTIBODY-DEPENDENT CELL CITOTOXICITY OF LAK CELLS IN ASSOCIATION WITH GA101 RATHER THAN RITUXIMAB

C Panizo[1], S Inogés[1], A de Cerio[1], M Olave[2], L Palomera[2], R García-Muñoz[3,*], M Calvillo[4], E Olavarría[4], M Varela[5], S Varea[1], J Rifón[1], A Alfonso[1], M Bendandi[1]
[1]Hematology, Clinica Universidad de Navarra, Pamplona, [2]Hematology, Hospital Clíinico Universitario Lozano Blesa, Zaragoza, [3]Hematology, Hospital San Pedro, Logroño, [4]Hematology, Complejo Hospitalario de Navarra, Pamplona, [5]Hematology, Hospital Universitario Lucus Augusti, Lugo, Spain

Background: Administration of "*in vitro*" expanded autologous cytokine-activated killer cells (LAK cells) has been proposed to obtain an immune control of follicular lymphoma (FL). Culture of peripheral blood lymphocytes with IL-2 generate LAK cells with cytotoxic capacity. Combination of these LAK cells with mAb could achieve a synergistic effect by enhancing the ADCC activity with potential clinical interest. GA101 is a new anti-CD20 mAB that binds with higher affinity to the CD20 increasing ADCC effect comparing to rituximab.
Aims: To study the cytotoxic capacity of LAK cells generated from peripheral blood of patients with FL. In addition we assess whether the combination of rituximab and LAK could improve functional activity of these cells. Finally, we conducted a comparative study of two anti-CD20 antibodies, rituximab and GA101, and we compare subgroups of patients with different polymorphisms in Fc and complement proteins.
Methods: LAK cells were expanded "*in vitro*" from peripheral blood samples of patients with FL. Cytotoxic capacity of these cells was compared to cells without culture. Cytotoxicity studies were performed using chromium release assays using K562 cells, Daudi and CRL-1596 as target cells. The effect of rituximab and GA101 was evaluated on the capacity of the effector cells to lyse CRL-1596 cell line. Cetuximab was used as a control. To perform these studies target cells were incubated with effector cells and antibody at 10 mg/mL concentration. SNPs genotype was performed with TaqMan Applied Biosystems technology using the detection systemABI Prism 7900HT
Results: Mononuclear cells were isolated and basal cytotoxicity was measured in 35 peripheral blood samples from patients with FL. Basal cytotoxicity against K562, Daudi and CRL-1596 cells was 17.2%, 9.46% and 1.21% respectively. After culture with IL-2, the cytotoxicity activity against the same cell lines was studied. In all cases a statistically significant increase was observed: K562 (38.43%), Daudi (38.78%) and CRL-1596 (20.5%). Furthermore we studied the rituximab effect on the cytotoxic capacity against CRL-1596 of culture cells. The observed cytotoxicity of LAK cells with rituximab was 33.90% *vs* 17.2% for LAK cells alone (P<0,001). The cytotoxicity of LAK cells with GA101 was 44.72% *vs* 17.2% for LAK cells alone (P<0,001). No differences were observed against CRL1596 cell line with the irrelevant antibody cetuximab (20.5% *vs* 17.2). Finally when comparing the ability to enhance the ADCC of both anti-CD20 antibodies we found significant differences in favor to GA101 (GA101: 44.72% *vs* rituximab: 33.90%). Results of Fc receptor and complement activation proteins polymorphisms and correlation of these results with ADCC will be provided in the meeting.
Summary and Conclusions: LAK cells generated from peripheral blood lymphocytes by culture with IL-2 in patients with FL show a higher cytotoxic activity than non culture lymphocytes. The observed cytotoxic capacity of LAK cells against a CD20 positive cell line is enhanced by means of anti-CD20 monoclonal antibodies addition. GA101 is more effective than rituximab in enhancing the cytotoxic capacity of generated LAK cells.

P1009

ROLE OF CIRCULATING AB-DOUBLE NEGATIVE T CELLS (DNT) IN LYMPHOMA PATIENTS: PRELIMINARY RESULTS OF A PROSPECTIVE STUDY

G De Tullio[1,*], S Serrati[1], C Minoia[1], F Merchionne[1], G Loseto[1], A La Pietra[1], A Rana[1], A Iacobazzi[1], P Iacopino[1], A Guarini[1]
[1]Department of Clinical and Experimental Oncology, Haematology Unit, Advanced Cell Therapy Center, National Cancer Research Centre, Istituto Tumori "Giovanni Paolo II", BARI, Italy

Background: Numerous aspects of lymphoma pathophysiology indicate mutual interactions between the host immune system and lymphoma cells. These interactions may either promote or control lymphomagenesis. An unconventional subset of $CD4^-CD8^-$ double-negative T cells (DNTs) has been recently described to specifically contribute to anti-tumor immunity.Indeed, DNTs are involved in immune regulation and tolerance as well as in host defence and inflammation, acting as both regulatory T cells and/or cytotoxic T cells.DNTs are T lymphocytes expressing either αβ or γδ T-cell receptor (TCR) and lacking of CD4,CD8 and CD56.In healthy human donors and murine models, they constitute about the 1-5% of lymphocytes in the peripheral blood and in lymphoid organs. No data are available on the role of DNT cells in human anti-lymphoma immunity. Translating information from murine models expanded DNT cells would not impair host immunity against lymphoma and perhaps stimulate it.On the other hand,DNT cells also demonstrated to have a direct *in vitro* anti-tumor activity against lymphoma. Few data are available on the prognostic significance of DNTs in lymphomas,on their interaction with other immune cells and on their functional attitude.
Aims: The aim of this study is to assess the frequency and the functional attitude of circulating DNTs in Lymphoma patients and healthy donors as controls, in order to evaluate the role of DNTs on clinical outcome
Methods: For phenotypic and functional characterization of DNTs peripheral blood samples of 30 Lymphoma patients and 16 healthy donors wereprospectively collected.The staining of circulating DNT subset was performed with the following conjugated monoclonal antibodies (MoAbs) for surface and intracellular markers: CD3, CD4, CD8, CD56, CD45, TCRαβ, CD45Ra, CD45Ro, CCR7, CD27, CD28, CD30, CD69, GITR, CD95, CD178, CD152, IFN-γ, TNF-α, granzymeB, perforin. Isotype-matched MoAbs will be used as staining controls.

For functional studies, DNTs were purified from PBMCs of pts through a negative selection by using specific MACS microbeads and then cultured for 2 week in complete medium supplemented with anti-CD3 (OKT3), rhIL-2 and rhIL-4. Data was acquired using a 8-colour flow cytometer and analyzed using Kaluza software. Data were compared among the groups using the Mann-Whitney non parametric test or Kruskal–Wallis one-way analysis of variance.The study was approved by the local Ethics Committeeand all patients provided their informed consent in accordance with the Declaration of Helsinki.

Results: We observed a significant decrease (P=0.006) of αβ-DNTs in the PB of patients with untreated lymphoma (20.5±4.8 SE,) (Mean±SE) as compared with healthy controls (31.3±3.4),and their number correlated with disease relapse/progression (Figure 1 A and B).In Hodgkin's Lymphoma patients the αβ-DNTs frequencies were significantly increased as compared with other histotypes (Figure 1 D). Interestingly, after *ex vivo* expansion, DNTs, acquired a immunomodulatory cytokine profile, characterized by the secretion of IFN-γ and granzyme B which are known as central component of anti-tumor immune responses (Figure 1 C).

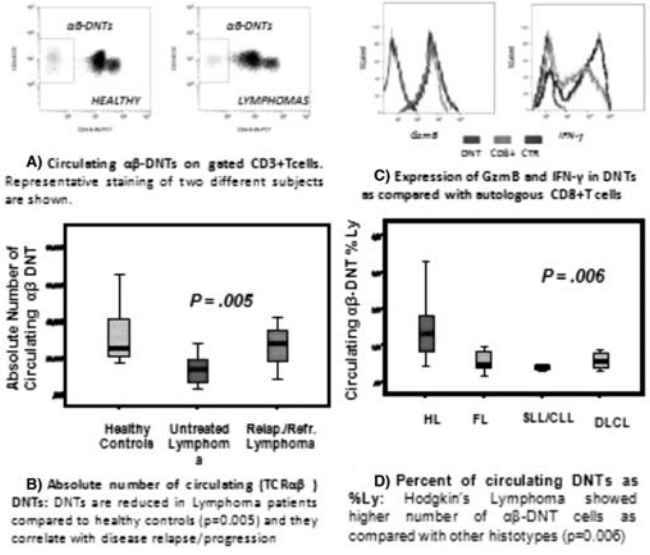

Figure 1.

Summary and Conclusions: To date,no data has been reported on DNTs phenotypic and functional characterization in Lymphoma pts. Our study has demonstrated for the first time that αβ-DNTs may play an important role in both the development and the progression of lymphomas. In addition, based on our preliminary results,it is likely that ex-vivo expanded DNTs exert an anti-tumor activity,thus suggesting their possible use as new strategy for adoptive immune-therapy.

P1010

EFFECT OF HISTONE METHYLTRANSFERASE EZH2 INHIBITOR 3-DEAZANEPLANOCIN A (DZNEP) ON ERYTHROPOIESIS

T Fujiwara[1,2,*], H Saito[2], Y Okitsu[2], N Fukuhara[2], Y Onishi[2], K Ishizawa[2,3], R Ichinohasama[4], H Harigae[1,2]
[1]Molecular Hematology/Oncology, [2]Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, [3]Clinical Research, Innovation and Education Center, Tohoku University Hospital, [4]Hematopathology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: EZH2, a core component of Polycomb repressive complex 2 (PRC2), plays a role in transcriptional repression through mediating H3K27 trimethylation, and is involved in various biological processes, including hematopoiesis. Studies have indicated that 3-deazaneplanocin A (DZNep), an inhibitor of EZH2,preferentially induces apoptosis in various hematological malignancies, implying that EZH2 may be a potential new target for epigenetic treatment.On the other hand, we have demonstrated that DZNep also has a potential to promote erythroid differentiation of K562 cells (ASH 2012). In the present study, we have extended our study to assess the effect of DZNep on erythropoiesis.

Aims: We conducted iTRAQ (isobaric tags for relative and absolute quantitation)-based proteomic analysis in DZNeP-treated K562 cells, and also assessed the effect of DZNep on primary erythroblasts.

Methods: K562 cells were treated with DZNep at doses of 0.2 and 1 uM for 72 h.siRNA-mediated knockdown of EZH2 was conducted with nucleofector (Amaxa Inc.). For transcription profiling, SurePrint G3 Human GE 8 × 60K (Agilent) and Human Oligo chip 25K (Toray) were used for DZNeP-treated and EZH2 knockdown K562 cells, respectively. iTRAQ analysis was conducted with Triple TOF 5600 (AB Sciex). To obtain human primary erythroblasts, CD34-positive cells isolated from cord blood were induced in liquid suspension culture, and DZNep was treated at doses of 0.01 and 0.1 uM for 96 h.

Results: DZNep treatment decreased EZH2 protein expression without significantly affecting EZH2 mRNA levels. We also confirmed that DZNep treatment significantly inhibited cell growth, accompanied with accumulation of p27. Interestingly, the treatment significantly induced erythroid differentiation of K562 cells, as determined by benzidine staining. Transcriptional profiling with untreated and DZNeP-treated K562 cells (1 uM) revealed that 789 and 698 genes were upregulated and downregulated (> 2-fold), respectively.The DZNeP-induced gene ensemble included prototypical GATA-1 targets, such as *SLC4A1*, *EPB42*, *ALAS2*, *HBA*, *HBG*, and *HBB*. Concomitantly, DZNep treatment at both 0.2 and 1 uM upregulated GATA-1 protein level, whereas the effect on its mRNA levels was weak (1.02- and 1.43-fold induction with 0.2 and 1 uM DZNep treatment, *P*= 0.73 and 0.026, respectively). Next, we conducted iTRAQ-based proteomics analysis to further obtain an insight into the molecular mechanisms of DZNeP-mediated erythroid differentiation.The analysis identified a total of 120 unique proteins (P<0.05), including significant enrichment of hemoglobins (HBZ and HBE), whereas EZH2 and GATA-1 failed to be detected.

To examine whether the observed results of DZNep treatment were due to the direct inhibition of EZH2 or hitherto unrecognized effects, we conducted siRNA-mediated knockdown of EZH2 in K562 cells. Quantitative RT-PCR analysis demonstrated that EZH2 knockdown had no significant effect on the expression of erythroid-lineage related genes. Furthermore, transcription profiles of the genes in the quantitative range of the array were quite similar between control and EZH2 siRNA-treated K562 cells (r=0.977), implying that DZNeP-mediated erythroid differentiation might not be directly related to the EZH2 inhibition.

Finally, we assessed the effect of DZNep on primary erythroblasts, demonstrating that the treatment (0.1 uM)significantly induces *HBB* and *HBG* expression in CD34-positive cell-derived primary erythroblasts.

Summary and Conclusions: DZNep promotes the expression of erythroid genes in primary erythroblasts. Our microarray and proteomic analyses may provide a better understanding of the mechanism of action of DZNep.

P1011

HS3 LOCUS CONTROL REGION SEQUENCES ARE NOT REQUIRED FOR HIGH BETA GLOBIN EXPRESSION

J Nieto[1,*], F Gonzalo[1], L Galán[1], P Gradilla[1], F Fernández[1], A Villegas[1,2], A Manrique[1], C Fernández[3], M Murga[3], E Mandly[1], J Mediavilla[1]
[1]Hematology, Hospital Clínico San Carlos, [2]on behalf of Spanish Erithropathology Group, Madrid, [3]Hematology, Hospital Virgen de la Salud, Toledo, Spain

Background: The Locus Control Region (LCR) is a genetic element located several Kb upstream the β globin cluster. This element is composed by 5 regulatory sites (HS1 to HS5), in which the LCR functions seem to reside. The LCR restricts globin expression to the erythroid cell lineage, enhances gene expression and protects these genes from the negative effects of surrounding chro-

matin. In fact, deletions affecting the entire regulatory region abolish the β cluster expression, resulting in εγδβ thalassemia.
Furthermore, LCR was the first described regulator that could exert its effects over long distances. As a consequence, it has been extensively studied in different biological models, from KO mice to cell lines, in order to understand the human functionality of this element. However, several problems arise from these studies, such as the lack of reproducibility when using the same biological model or the contradictory results in the study of different models. The challenge of understanding how the LCR works *in vivo* derives in part by the fact that there are a very limited number of known LCR human naturally occurring deletions.
Aims: Here we described 3 cases of the same family, who are carriers of a novel deletion limited to the HS3 element. This could be helpful in order to understand the HS3 and LCR functionality in humans.
Methods: Propositus and her family (mother and brother) were submitted for screening of thalassemia based on mild microcytosis. An HS3 deletion, inside the LCR, was detected in all patients by MLPA. In addition, propositus and her mother showed an extra α globin gene copy (genotype: ααα/αα), whereas the brother showed no alterations in the α cluster. Patient's red blood cell indices are detailed in Figure 1. Finally, we have performed a gapPCR to precisely define the deletion breakpoints.
Results: We have found an HS3 deletion removing 1992bp. 5' breakpoint is located at position 11836 in the β cluster (NG_000007.3), whereas 3' breakpoint lies inside an Alu sequence, at position 13827. This novel alteration has been named as Toledo deletion.

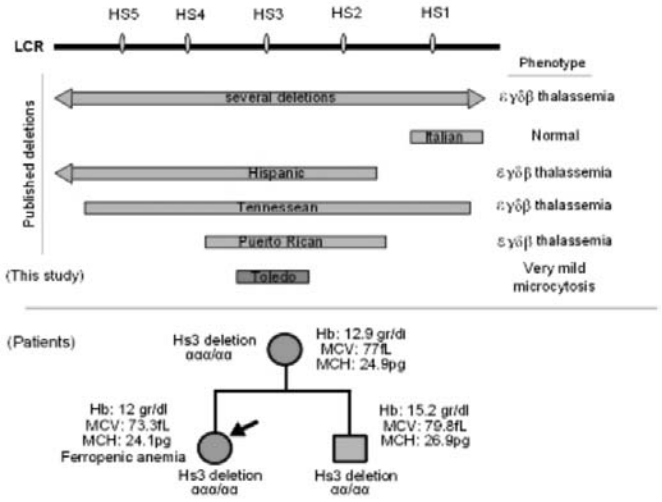

Figure 1.

Summary and Conclusions: Figure 1 shows a schematic view of previously known human LCR deletions. Alterations affecting both HS2 and HS3 lead to εγδβ thalassemia. Thus, those elements were supposed to be necessary for high levels of β globin transcription. However, there were no natural deletions removing just one of those key elements.
Toledo HS3 deletion is relevant because it only affects HS3, keeping HS2 intact. Surprisingly, this deletion is associated to a virtually normal phenotype, slightly aggravated when there is coinheritance of extra α gene copies. Thus, we conclude that HS3 is not required for high β globin transcription.
This deletion gives a human *in vivo* confirmation of the results obtained by the group of Peterson working on transgenic mice containing a human β globin cluster. They described HS3 as an element with no observable effect over β gene. Nevertheless, their results clearly point the existence of HS3 enhancer specificity for ε and γ genes. This kind of Hs site specificity for globin gene activation has not been observed studying the native murine β cluster in KO mice models, where a deletion of any of the individual Hs results in a 20% reduction of adult globin expression in the β cluster.
The cases exposed here also argue in favour of the limited value of mouse gene regulation studies for understanding human disease.
In conclusion, we have found a new human deletion demonstrating the redundancy of HS3 in β globin regulation.

P1012

FIRST EVIDENCE OF RENAL TUBULAR INJURY DURING SICKLE-CELL CRISIS

IMRB U955 équipe2, [4]Service de médecine interne, CHU Henri Mondor. APHP. UPEC., [5]Service de Néphrologie et Transplantation, et Institut Francilien de Recherche en Néphrologie et Transplantation. UPEC, CHU Henri Mondor. APHP. INSERM, [6]Service d'Immunologie Clinique, CHU Henri Mondor. APHP. UPEC. INSERM, [7]Biochimie–Pharmacotoxicologie, CHU Henri Mondor. APHP. UPEC, [8]Service d'Accueil des Urgences, CHU Henri Mondor. APHP. UPEC., [9]Service de médecine interne, CHU Henri Mondor. APHP. UPEC, Créteil, France

Background: The pathophysiological mechanisms classically involved in sickle-cell nephropathy include endothelial dysfunction and vascular occlusion. Arguments demonstrating that ischemia-reperfusion injury-related kidney damage might coincide with vaso-occlusive crisis (VOC) are lacking.
Aims: We aimed to determine whether tubular cells and glomerular permeability might be altered during VOC.
Methods: Homozygous SCD patients, at least 18 years old with severe VOC requiring admission to our hospital, were eligible for inclusion. Exclusion criteria included VOC with parenteral hydration lasting >24 hours; blood transfusion during the previous month; acute chest syndrome or severe complication requiring a blood transfusion at inclusion; pregnancy and/or psychiatric disorder. Patients with preexisting chronic kidney disease, defined as a glomerular infiltration rate ≤60 mL/min/1.73 m^2 according to the modification of diet in renal disease (MDRD) formula, were excluded. Blood and urine parameters were analyzed the same day for each patient during VOC on hospitalization day 1 (D1) and D2 or D4, and at steady state (ST). ST was defined as a visit ≥1 months after an acute clinical event and ≥3 months after blood transfusion.
Results: Urine neutrophil gelatinase-associated lipocalin (NGAL) levels and albumin-excretion rates (AER) of 21 patients were evaluated prospectively during 26 VOC episodes compared to their ST. We observed significantly increased urine NGAL levels during VOC *versus* ST, while AER did not change significantly. The higher urine NGAL concentration was not associated with subsequent (24-48 hour) acute kidney injury. Univariate analysis identified a strong association only between urine NGAL level and white blood-cell count.
Summary and Conclusions: Our results demonstrated that tubular injury could be present during VOC and highlights the importance of hydroelectrolyte monitoring and correction during VOC.

P1013

INHIBITION OF ERYTHROPOIESIS THROUGH HEPCIDIN AND ROS IN TRANSFUSION-RELATED IRON OVERLOAD MICE

M Masuko[1,*], H Kobayashi[1], T Ushiki[1], T Kozakai[1], G Hasegawa[2], H Hanawa[3], T Furukawa[1], H Sone[1], M Naito[2]
[1]Hematology, [2]Pathology, [3]Cardiology, Niigata University Hosipital, Niigata, Japan

Background: Some clinical observations that iron-chelating therapy for bone marrow failure syndrome patients with transfusion-related iron overload could improve cytopenia (especially anemia) were reported. They prompted us to consider that iron overload may have a negative impact on hematopoiesis. However, the precise mechanism remains to be elucidated.
Aims: The aim of this study was to determine theeffect of iron overload on hematopoiesis using forced iron-loaded mice.
Methods: While there are some model mice presenting hemochromatosis with mutant genes such as HFE and TfR2, they may show different pathology from transfusion-related iron overload patients. Therefore, we established iron overload model mice, which were six-week-old C57BL/6J mice injected with 5 mg of saccharated ferric oxide (FesinÒ) intra-peritoneally 10 times in two weeks. At 8 weeks after the last injection, the mice were sacrificed and analyzed. We used mice injected with saline instead of saccharated ferric oxide as controls. Peripheral blood cell count was performed by the standard procedure. Serum iron and unsaturated iron binding capacity (UIBC) were measured by colorimetric methods. Total iron binding capacity (TIBC) and transferrin saturation were calculated using serum iron and UIBC. We also analyzed the histology of liver and bone marrow in iron overload mice to assess iron deposition. Apoptosis and intra-cellular ROS production of immature or mature erythroid cells in bone marrow were analyzed by flow cytometry. Real-time quantification of mRNA transcripts of iron-related molecules such as hepcidin, IL6, IL1-beta, BMP6, and Id1 in liver was performed by quantitative RT-PCR.
Results: Iron overload mice showed higher serum iron concentration and higher transferrin saturation (serum iron 367±15 μg/mL, control 198±8 μg/mL, P<0.0001; transferring saturation 93.8±1.0%, control 48.1±1.2%, P<0.0001). These data are compatible with those of blood transfusion-related iron overload patients. Iron overload mice showed marked anemia, while the leukocyte count and platelet count did not differ from those of control mice (RBC 881±25×10^4/μl *vs.* 974±8×10^4/μl, P=0.002; Hb 13.7 g/dl *vs.* 14.6 g/dl, P=0.029; reticulocyte 20.36±0.91×10^4/μl *vs.* 27.67±1.68×10^4/μl, P=0.002; WBC 7038±1754/μl *vs.* 6556±444/μl, P=0.78; Plt 68.0±5.1×10^4/μl *vs.* 80.1±3.8×10^4/μl, P=0.07). We performed histological analysis of liver and bone marrow in iron overload mice. In these mice, diffuse iron deposition was clearly observed in hepatocytes. Interestingly and unexpectedly, iron deposition in bone marrow was observed on macrophages and vascular endothelial cells. Hematopoietic precursor cells in bone marrow had little iron deposition. We performed flow cytometric analy-

sis to determine the causes of anemia, which revealed that immature erythroid cells expressing both CD71 and Ter119 in bone marrow were significantly decreased in iron overload mice (17.1±0.7% *vs.* 20.7±1.1%, P=0.04). Intracellular ROS production in immature erythroid cells was increased compared with that in control mice. Next, we measured the expression of iron-related molecules such as hepcidin, IL6, IL1-beta, BMP6, and Id1 in liver by quantitative RT-PCR. We found that the expression of hepcidin, BMP6, and Id1 was significantly increased in iron overload mice compared with that in control, and also found thatthe expression of hepcidin was correlated with the expression of BMP6 and Id1.
Summary and Conclusions: These data suggest that iron overload may cause anemia through hepcidin production from hepatocytes and intracellular ROS production in immature erythroid cells.

P1014

CONGENITAL DYSERYTHROPOIETIC ANEMIA DUE TO A NOVEL GATA-1 MUTATION

J Pereira[1,*], J Valero[2], T Maia[1], C Bento[3], L Ribeiro[1], H Almeida[3], L Relvas[3], E Cunha[3], A Oliveira[3], A Pereira[1], M Ribeiro[3]
[1]Unidade Hematologia Molecular - Serviço de Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, [2]Hospital Materno Infantil, Hospital Materno Infantil, Badajoz, Spain, [3]Centro Hospitalar e Universitário de Coimbra, E.P.E., Serviço de Hematologia, Coimbra, Portugal

Background: Congenital Dyserythropoietic Anemias (CDA) are rare forms of bone marrow failure syndromes, characterized by ineffective erythropoiesis, with specific morphological changes in the bone marrow erythroblasts. There are three classical groups (CDA type I, II, III) whose genes have already been identified (*CDAI* and *SEC23B* for CDA type I and II respectively). Recently other rarer forms of CDA have been identified, like a new form that has been correlated to mutations in the gene (*GATA-1*, Xp11.23) encoding for the transcriptional factor GATA-1. Most of the *GATA-1* mutations are located in one of the two zinc finger domains and are associated with deregulation of erythroid and megakaryocyte lineages formation. The GATA-1 C-terminal finger is necessary for DNA binding and the N-terminal finger mediates interaction with FOG-1 (for friend of GATA-1), a cofactor of GATA-1.
Aims: To elucidate the etiology of a macrocitic anemia with dyserythropoiesis and mild thrombocytopenia.
Results: Clinical Case. A 12-year-old boy was referred to our consultation to elucidate the etiology of a congenital haemolytic anemia. At 3 months of age he presented Hb 5.9 g/dL, MCH 33 pg, MCV 95 fL, RDW 17.5%, reticulocytes 5.8%, normal platelet counts and a peripheral blood smear with anisocytosis, poikilocytosis and basophilic stippling. He received several blood transfusions during the first months of life. The bone marrow examination was reported as erythroid hyperplasia, dyserythropoiesis, with orthocromatic erythroblasts showing irregular nuclear contour and bi or multinucleated erythroblasts. Electronic microscopy identified vacuoles in the cytoplasm of the erythroblasts. Currently he has thrombocytopenia (platelet counts 73000), macrocytosis (MCV 104 fL), and hemoglobin ranging between 9 and 10 g/dl. Results. Molecular analysis of *CDAI*, *SEC23B*, *KLF1, HBB, HBA* genes was normal; *PKLR* gene presented the 1284delA mutation in the heterozygous state. *GATA-1* gene mutations screening (promoter and coding regions) was performed by PCR/sequencing and an A to G transition at nucleotide position 866 (c.866A>G) was identified in the hemizygous state. This novel mutation results in the substitution of histidine 289 for arginine in the protein C-terminal zinc finger. The patient inherited this mutation from his mother who is heterozygous for the mutation.
Summary and Conclusions: Congenital Dyserythropoietic Anemias are a heterogeneous group of hereditary disorders, both at clinical and genetic levels. GATA-1 is an important transcription factor in hematopoyesis regulation, in particular for erythroid and megakaryocyte lineages. The relative low number of mutations observed in this gene may indicate that the majority of the mutations are not compatible with life, confirming the central role of this transcription factor in mammalian erythroid development. This is the first report of a mutation in the *GATA-1* gene located in the C-terminal zinc finger domain of GATA1 protein that resulted in a Congenital Dyserythropoietic Anemia. This mutation is not described in the literature, but its location may justify the phenotype. Our data highlights the importance of analyzing both highly conserved zinc finger regions of GATA-1 in patients with Congenital Dyserythropoietic Anemias.

P1015

EFFECTS OF CHRONIC PSYCHOLOGICAL STRESS ON EXTRAMEDULLARY ERYTHROPOIESIS: INVOLVEMENT OF EPOR, GR, C-KIT AND BMP4 SIGNALING

M Budeč[1,*], S Vignjević[1], D Marković[2], G Jovčić[3], D Djikić[1], O Mitrović[1], S Vranješ-Djurić[4], V Koko[1], V Čokić[3]
[1]Laboratory of neuroendocrinology, [2]Laboratory of immunochemistry, [3]Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, [4]Institute for Nuclear Sciences Vinča, University of Belgrade, Belgrade, Serbia

Background: Chronic stress is an increasingly important topic and its understanding requires an integrative approach. Unlike steady-state erythropoiesis in the bone marrow, under stress conditions spleen becomes a major site of red blood cell production. It has been suggested that spleen microenvironment provides a signal that induces cells to become stress erythroid progenitors. Although there is evidence that high erythropoietin level together with glucocorticoids, stem cell factor and bone morphogenetic protein 4 (BMP4) stimulates erythropoiesis during stress, very little information is available on expression of their receptors in the spleen.
Aims: To extend our previous observations that repeated restraint stress increased the expansion of erythroid progenitors, the purpose of this study was to investigate its effect on more mature erythroid cells and to determine involvement of the erythropoietin receptor (EpoR), glucocorticoid receptor (GR), stem cell factor receptor (c-KIT), as well as BMP4 and its receptors BMPRI and BMPRII in the regulation of spleen erythropoiesis during chronic stress.
Methods: Adult male CBA mice were subjected to 2 h daily restraint stress for 7 or 14 consecutive days. The level of plasma corticosterone was determined by RIA whereas the concentration of erythropoietin was measured by ELISA. In the spleen red pulp, the expression of TER119, a specific surface marker for erythroid differentiation from the early proerythroblast to mature erythrocyte, as well as EpoR, GR, c-KIT and BMP4 was assessed by immunohistochemistry. Additionally, the expression of EpoR and GR was evaluated using Western blot while BMPRI and BMPRII were analyzed by RT-PCR in splenic extracts.
Results: Repeated restraint stress elevated plasma levels of corticosterone and erythropoietin on days 7 and 14. In the red pulp of spleen, the number of TER119-immunoreactive (ir) cells was significantly increased following 14 days of exposure to restraint. Both Western blot and immunohistochemistry analyses revealed a significant decrease in the expression of both EpoR and GR in the spleen of mice restrained for 7 and 14 days. Further analysis showed that chronic restraint elicited a robust increase in the number of c-KIT-ir cells compared to controls in the red pulp of spleen after one and two weeks. Also, markedly increased expression of BMP4 and both BMPRI and BMPRII was found in the spleen of mice after repetitive restraint for 7 and 14 days.
Summary and Conclusions: After chronic stress, EpoR and GR levels in the spleen are decreased, while c-KIT, BMPRI and BMPRII are increased. Chronic restraint stress, as predominantly psychological stressor, enhances spleen erythropoiesis in a manner similar to that described in stress erythropoiesis-induced by anemia, implying involvement of elevated plasma levels of corticosterone and erythropoietin as well as c-KIT and BMP4-signaling in the complex regulation of this process. The repeated psychological stress may be a risk factor to a large number of diseases including hematological malignancies.

P1016

DOES THE OPTICAL MICROSCOPE TELL US THE COMPLETE STORY IN MEMBRANE-CYTOSKELETON DISORDERS? A STUDY OF RED BLOOD CELLS WITH ATOMIC-FORCE AND SCANNING-ELECTRON MICROSCOPES IN HEREDITARY SPHEROCYTOSIS

Dimosthenis Stamopoulos[1,*], Nikolaos Papachristos[1], Despina Barbarousi[2], Chara Matsouka[2], Nerantzoula Mpakirtzi[3]
[1]Institute of Advanced Materials, Physicochemical Processes, Nanotechnology and Microsystems, National Center for Scientific Research, Demokritos, [2]Department of Haematology, General Hospital of Athens, Alexandra, [3]Department of Nephrology, General Hospital of Athens, Gennimatas, Athens, Greece

Background: Hereditary spherocytosis (HS) is one of the most common genetic disorders of the red blood cell (RBC) membrane-cytoskeleton cohesion due to the abnormal expression of basic proteins either of the cytoskeleton (spectrin) or of its linkage with the upper lying lipid-lipid bilayer (ankyrin, band3, protein 4.2). As a consequence, there is a gradual loss of a significant part of the RBC membrane possibly in the form of vesicles.
Aims: To investigate these issues at the nanometer level and reveal information not only on the shape and morphology of the complete RBC but from specific areas of the modified cell membrane we employed advanced microscopes.
Methods: Intact and 0.9% NaCl-washed RBCs (iRBCs and wRBCs, respectively) produced from peripheral blood samples were investigated for the case of 3 HS patients in comparison with 3 healthy donors. The iRBCs and wRBCs single-layered smears were investigated in detail with conventional Optical Microscopy (OM) and the advanced imaging techniques Atomic-Force Microscopy (AFM) and Scanning-Electron Microscopy (SEM), both having spatial resolution at the nanometer level (1 nm=10^{-9} m).
Results: Regarding iRBCs, in one HS patient, macroscopic fission that sometimes was accompanied by a clear twisting of the two cell parts was observed by means of AFM and SEM (however not with OM). In all HS patients and healthy donors the iRBCs membrane presents *microscopic* circular morphological abnormalities (mCMAs) that reminisce of ulcers, with size in the range 200-2000 nm (see vertical-solid arrows in Figure 1). For the HS patients, in some cases the underlying spectrin network is observed by means of AFM at the interior of mCMAs (see vertical-solid arrow in lower Figure 1). Since the membrane mCMAs are observed in both groups they probably relate to the physiological aging of RBCs. Furthermore, the mCMAs incidence (number/top

RBC membrane) does not present statistically significant differences, 1.27±0.38 και 1.52±0.31 between the HS patients and healthy donors, respectively. On the contrary, the iRBCs of the HS patients exhibit an overpopulation of *nanoscopic* CMAs (nCMAs) of size 50-200 nm (see horizontal-dotted arrows in lower Figure 1) with a comparatively minor incidence in the healthy donors. Micro/nano-metric vesicles (mnVs) of *cylindrical* (length 0.5-7.0 μm, diameter 100-500 nm) and *toroidal* (diameter 0.5-1.5 μm) form were observed by means of both AFM and SEM for the HS patients, however without the observation of the corresponding snapshots referring to their releasing from the iRBCs. Regarding wRBCs, both AFM and SEM data revealed that for the HS patients they are extendedly degraded to 'ghosts' during the wash process with even 0.9% NaCl physiological saline, obviously due to their reduced osmotic resistance. Though the wRBCs 'ghosts' are cytoplasm depleted, they preserve the main morphological characteristics of iRBCs.

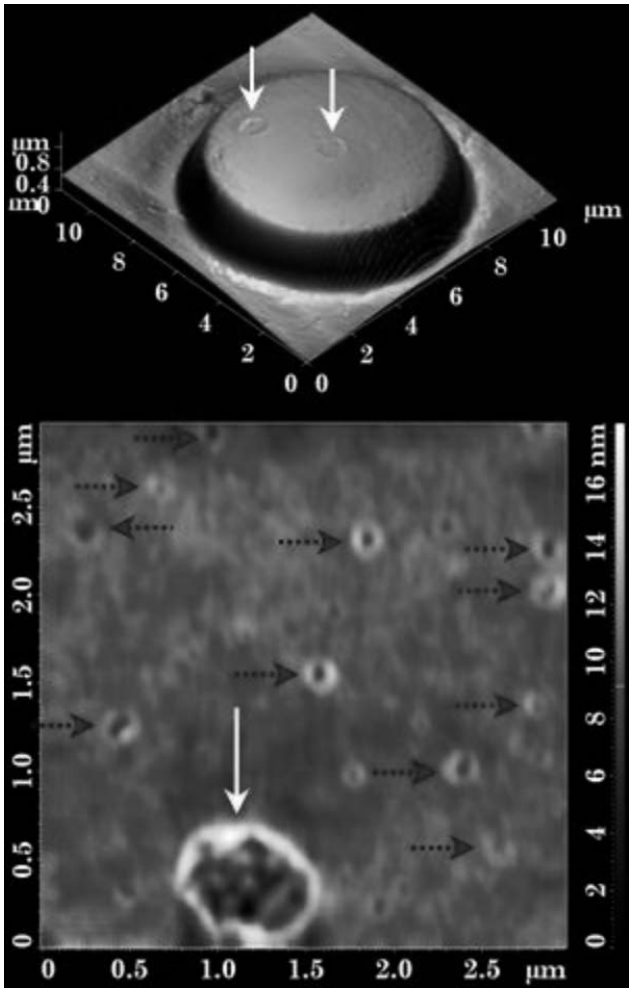

Figure 1.

Summary and Conclusions: The membrane of iRBCs of HS patients does not present differences in the mCMAs (size 200-2000 nm), in comparison to healthy donors. In contrast, the occurrence of a large population of nCMAs (size 50-200 nm) that are strongly increased in the HS patients when compared to the healthy donors, may relate to the significantly decreased osmotic resistance of the RBCs in the HS patients. Both mCMAs and nCMAs can be active sites from where cytoplasm is released to the extracellular space.
The incidence of *cylindrical* and *toroidal* mnVs without the observation of snapshots that document their releasing from RBCs suggests that either the specific mnVs originate from a different parent cell or they are truly released from RBCs during their passage from a parenchymal organ, most likely the spleen.

P1017

INVESTIGATION OF HEMORHEOLOGICAL PARAMETERS AT THE DIAGNOSIS AND THE FOLLOW-UP OF NUTRITIONAL VITAMIN B12 DEFICIENT CHILDREN

H Tancer-Elçi[1], Y Işik-Balci[2,*], M Bor-Küçükatay[3], E Kiliç-Toprak[3], Ö Kiliç-Erkek[3], H Şenol[4], H Aybek[5]
[1]Department of Pediatrics, [2]Department of Pediatric Hematology, [3]Department of Physiology, [4]Department of Biostatistics, [5]Department of Biochemistry, Pamukkale University, Faculty of Medicine, Denizli, Turkey

Background: In vitamin B12 deficiency, tetrahydrofolate synthesis is impaired, leading to defective DNA synthesis and inhibition of cell division in the bone marrow, resulting in megloblastic anemia. Mean corpuscular volume (MCV) is increased, and in the peripheral blood smear the erythrocytes are large and mostly oval with hypersegmented neutrophils. In the literature it has been reported that, especially in hematological disorders which affect the shape of the erythrocytes, hemorheological parameters are altered variously. There are a limited number of studies investigating eythrocyte deformability in vitamin B12 deficient adults, and the only investigated hemorheological parameter was the eryhtrocyte deformability in these studies. Whereas, there is no study concerning the hemorheological changes in vitamin B12 deficient children.
Aims: The aim of this study was to investigate the hemorheological parameters as erythrocyte deformability, erythrocyte aggregation, whole blood and plasma viscosities in vitamin B12 deficient children, and to identify the possible alterations in these parameters in response to adequate vitamin B12 treatment, and to compare them with healthy controls.
Methods: The study enrolled 33 patients (17 female, 16 male) aged 2 months-16 years (mean age: 7±5.7 years), who were diagnosed as nutritional vitamin B12 deficiency, and 31 age and sex matched healthy controls (16 female, 15 male, mean age: 7.1±5.2 years). Informed consent form was obtained from the parents. Elongation index (EI) which is the indicator of erythrocyte deformability was measured at 9 different shear stresses between 0.3 and 30 Pa by an ectacytometer. Erythrocyte aggregation amplitude (AMP) was also determined by an ectacytometer. Plasma and whole blood viscosities were determined by a cone-plate rotational viscometer. The differences between patients and controls were compared. Hemorheological parameters were repeated in the patient group following two months of vitamin B12 treatment, and the results were compared with the initial results.
Results: In vitamin B12 deficiency, erythrocyte deformability was found to be significantly decreased compared with the controls, and after adequate vitamin B12 replacement it increased and came towards control values. On the other hand, eythrocyte aggregation was found to be significantly increased in the patient group before treatment compared with the controls. After treatment there was a significant decrease in erythrocyte aggregation, compared with the before treatmentvalues. Plasma viscosity was found to be decreased in deficiency compared with the controls but this decrease was not statistically significant, however it increased significantly after treatment and came towards control values. Whole blood viscosities measured at either autologous or standardized hematocrit (40%) were found to be significantly decreased in the patient group before treatment compared with the controls, and after treatment showed a significant increase. A negative correlation between the EI and MCV, and a positive correlation between AMP and MCV was found.
Summary and Conclusions: This study indicates that vitamin B12 deficiency has important effects on hemorheological parameters, and adequate treatment of deficiency not only corrects the hematological parameters, but also by helping to normalize the hemorheological parameters, may contribute to the regulation of microvascular perfusion.

X-LINKED SIDEROBLASTIC ANEMIA: A PROMOTER MUTATION IN THE ALAS2 GENE

J Pereira[1,*], A Pereira[1], T Maia[1], L Relvas[1], H Almeida[1], C Bento[1], ML Ribeiro[1]
[1]Unidade Hematologia Molecular - Serviço de Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Sideroblastic anemias (SA) are a heterogeneous group of disorders, congenital or acquired, associated with abnormal heme biosynthesis, characterized by: 1) microcytic hypochromic anemia, with dimorphism, 2) presence of ringed sideroblasts in the bone marrow, 3) important secondary hemosiderosis. X-Linked Sideroblastic Anemia (XLSA) is a hereditary disorder with a heterogeneous phenotypic expression in males. Female carriers can also have the disease, particularly after the fourth or fifth decade of life, due to unbalanced X chromosome lionization. Most frequently XLSA is diagnosed in males during the first years of life and is associated with mutations (primarily missense) in the erythroid-specific 5-aminolevulinic acid synthase gene, *ALAS2* (Xp11.21). In the less severe forms the diagnosis may be delayed to the first two decades of life or to the middle age, when the secondary iron overload is significant. Depending on the type and location of the *ALAS2* mutation, some patients may respond to oral pyridoxine treatment. Severe cases are transfusion dependent.
Aims: To elucidate the iron overloadetiology in a male patient with mild hypochromia and microcytosis.
Results: Clinical Case. A 54-year-old male was referred to elucidate the etiology of iron overload: serum ferritin 1600 ng/mL (normal 18-370), transferrin saturation 47.3%. He also presented hemoglobin in the lower normal range (13,7 g/dL), with hypochromia (MCH 26 pg), microcytosis (MCV 76 fL), RDW 14%, reticulocytes 160×10^3/mL, peripheral blood smear with elliptocytes, stomatocytes and a few microcytes; normal Hb A2 and Hb F. No secondary causes of iron overload were identified. He has been submitted to phlebotomies during the last 7 years, the hemoglobin varied between 11 and 12.5 g/dL. Results.

Molecular analysis of *HFE*, *SLC40A1* (*ferroportin)* and *TFR2* genes was normal; alpha globin genes presented a $-a^{3.7}$ deletion in the heterozygous state. Alpha thalassemia could justify the mild hypochromia and microcytosis, but not the iron overload. Even though the blood smear did not suggest a sideroblastic anemia, we sequenced the *ALAS2* gene promoter and coding regions. A C to G transversion at -258 from the ATG site was identified in the hemizygous state. This mutation, already described in a Welsh female and his son, is located in a transcription factor binding site. This is the second report of a regulatory mutation in the ALAS2 gene that resulted in a XLSA clinical phenotype.
Summary and Conclusions: In a 62 years old male patient with iron overload and mild hypochromic, microcytic anemia we identified a a^+ thalassemia and a XLSA. Considering that XLSA phenotype severity varies considerable in males, and can also be present in females, we suggest that all patients with no identified cause of iron overload should have their DNA examined for ALAS2 mutations, irrespective of their haematological parameters, sex and age. Identification of the ALAS2 mutation allows an early treatment with pyridoxine, prevention of iron overload and the identification of heterozygous women who will benefit from genetic counselling.

P1019

COMPARISON OF EARLY AND LATE GASTROINTESTINAL TRACT AND LIVER TOXICITY OF THE ORIGINATOR IRON POLYMALTOSE COMPLEX (IPC) AND AN IPC SIMILAR PREPARATION IN NON-ANEMIC RATS

J Toblli[1,*], G Cao[1], M Angerosa[1]
[1]Laboratory of Experimental Medicine, Hospital Aleman, Buenos Aires, Argentina

Background: Oral iron treatment of iron deficiency (anemia) [ID(A)] is often accompanied by poor tolerability and thus limited compliance. Ferrous compounds show poor gastrointestinal (GI) tolerability, possibly because the rapid release of iron and its uncontrolled uptake may trigger oxidative stress reactions [1]. The originator iron(III)-hydroxide polymaltose complex (IPC_{ORIG}, Maltofer®) exhibits good GI tolerability and negligible oxidative stress reactions [2], because its physico-chemical properties enable controlled, active absorption of iron [3]. The structure of IPC_{ORIG}, a polynuclear iron-carbohydrate complex, is largely defined by the manufacturing process [4,5]. A variety of IPC similar (IPCS) preparations are in use worldwide, but they often present with varying physico-chemical properties and, thus, different efficacy and toxicity *vs.* IPC_{ORIG} [2].
Aims: This nonclinical study in rats compared early (four weeks) and late toxicity (four months) of IPC_{ORIG} and an IPCS in the GI tract and liver.
Methods: Sixty rats were randomized to receive 280 mg Fe/kg body weight/day of IPC_{ORIG} or $IPCS_{HEMO}$ (Hemoval®, Laboratories Saval S.A., Santiago, Chile), or tap water (control). Thirty rats were sacrificed on day 29, and hematological variables and aspartate transferase (AST) were analyzed from blood. Early toxicity was assessed by microscopic evaluation of the villi/crypt ratio, and the number of Goblet cells and eosinophils per villi in the small intestine. Tissue ferritin in the liver and small intestine were assessed by immunohistochemistry. After 4 months, thirty rats were sacrificed and late toxicity was assessed by analyzing lipid peroxidation (malondialdehyde, MDA) and the activity of Cu,Zn-superoxide dismutase (Cu,Zn-SOD) in small intestine and liver homogenates.
Results: The $IPCS_{HEMO}$ group presented with significantly higher transferrin saturation (TSAT) and AST levels than the IPC_{ORIG} group. The villi/crypt ratio and the number of Goblet cells/villi were significantly lower and the number of eosinophils/villi significantly higher in the small intestine of the $IPCS_{HEMO}$ group *vs.* IPC_{ORIG} group. Ferritin immunostaining in the small intestine and liver and Prussian blue staining in the liver was significantly increased in the IPC_{ORIG} group *vs.* the IPC_{HEMO} group. The $IPCS_{HEMO}$ group showed a significant increase of lipid peroxidation and Cu,Zn-SOD activity in the small intestine and liver *vs.* IPC_{ORIG} after four months, indicating oxidative stress in the $IPCS_{HEMO}$ group (Table 1).

Table 1.

Mean ± SD (n= 10)	IPC_{ORIG}	$IPCS_{HEMO}$	Control
Hb (g/dL) (after 4 weeks)	15.9 ± 0.3	15.8 ± 0.2	15.5 ± 0.3
TSAT (%) (after 4 weeks)	39.0 ± 3.3*	51.5 ± 3.1#	33.7 ± 2.9
Early toxicity in the small intestine (after 4 weeks)			
Villi/crypt ratio	2.1 ± 0.1	1.8 ± 0.1*	2.3 ± 0.1
Goblet cells/villi	10.4 ± 0.9	8.8 ± 0.8*	11.8 ± 1.0
Eosinophils/villi	8.2 ± 0.9	13.5 ± 1.9*	7.7 ± 1.2
Ferritin score	3.0 ± 0.7*	1.4 ± 0.5#	0.4 ± 0.5
Early toxicity in the liver (after 4 weeks)			
AST (UI/L)	119.2 ± 11.0	144.5 ± 13.2†	112.9 ± 12.6
Ferritin (%/mm²)	10.5 ± 1.0*	6.3 ± 0.7#	0.6 ± 0.2
Late toxicity in the small intestine (after 4 months)			
MDA (nmol/mg protein)	1.1 ± 0.1	3.1 ± 0.2*	0.9 ± 0.2
CuZn-SOD (U/mg protein)	22.3 ± 4.0	56.3 ± 4.8*	18.3 ± 4.8
Late toxicity in the liver (after 4 months)			
MDA (nmol/mg protein)	1.0 ± 0.2	2.4 ± 0.3*	0.7 ± 0.3
CuZn-SOD (U/mg protein)	33.4 ± 4.2	63.8 ± 8.1*	29.2 ± 3.4

* $p < 0.01$ vs. all; # $p < 0.01$ vs. control; † $p < 0.05$ vs. all

Summary and Conclusions: Damage to the gastric epithelium in the small intestine was present to a variable degree in rats treated with $IPCS_{HEMO}$ but not with IPC_{ORIG}. This, together with higher levels of TSAT in the $IPCS_{HEMO}$ group, suggests the presence of weakly-bound or redox-active iron on the surface of $IPCS_{HEMO}$. Significantly lower levels of ferritin deposits and increased oxidative stress markers both in the liver and small intestine of the $IPCS_{HEMO}$ group indicate a less controlled iron utilization from $IPCS_{HEMO}$ than from IPC_{ORIG}. Indeed, saturation of the iron transport mechanisms may lead to uncontrolled iron uptake by various cells.

NEXT GENERATION SEQUENCING IN THE DIAGNOSIS OF RED BLOOD CELL MEMBRANE DISORDERS

R Van Wijk[1,2,*], B van der Zwaag[2], M Vogel[2], M Elferink[2], I Nijman[2], E Cuppen[2], W van Solinge[1], H van Amstel[2]
[1]Clinical Chemistry and Haematology, [2]Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands

Background: Hereditary disorders of the red blood cell (RBC) membrane constitute a major cause of hereditary hemolytic anemia. It concerns a heterogeneous group of diseases with highly variable clinical expression. They are caused by mutations affecting structural proteins of the RBC cytoskeleton and its anchoring to the RBC membrane, thereby perturbing the cell's structure and function. Traditionally RBC membrane disorders are classified according to the morphological appearance on a blood smear. Hereditary spherocytosis (HS) and elliptocytosis (HE) are among the more common abnormalities, whereas hereditary pyropoikilocytosis (HPP) and stomatocytosis (HST) are more rare. Inheritance of these diseases is in most cases autosomal dominant.
Aims: Molecular analysis has long been hampered by the large and complex nature of the many different genes involved and the fact that most mutations are private ones. In this study we aimed to explore the molecular basis of various disorders of the red blood cell membrane by Next Generation Sequencing (NGS).
Methods: We implemented an NGS based test in our DNA diagnostics laboratory to sequence seven genes commonly associated with RBC membrane disorders: *SPTA1* (α-spectrin), *SPTB* (β-spectrin), *ANK1* (ankyrin), *SLC4A1* (band 3), *EPB41* (protein 4.1), *EPB42* (protein 4.2), and *RHAG* (Rhesus-associated glycoprotein). Twenty patients with defined membranopathies were selected for analysis (16 HS, 2 HPP, 2 HST). After enrichment of genomic DNA, using a custom Agilent SureSelectXT probe kit, protein coding and flanking intronic sequences were determined using a SOLID™-5500XL system. Variants were identified using an 'in house' developed NGS mapping and calling pipeline, and the Cartagenia BENCHlab NGS module was used for filtering and prioritization of possible pathogenic variants. Detected mutations were confirmed by conventional Sanger sequencing.
Results: Probable causative mutations were identified in 16 out of 20 (80%) of patients studied. As was expected, most of the detected mutations were novel (11 out of 15) and private. Most mutations concerned the substitution of a single amino acid and were located in *SPTA1* and *ANK1*. One particular mutation concerned a large deletion involving *SPTB*. Somewhat surprisingly, this small cohort showed no mutations in the gene encoding band 3 (*SLC4A1*), a frequent cause of HS.
Summary and Conclusions: The here presented approach represents a feasible and reliable diagnostic method to detect mutations in patients affected by various disorders of the RBC membrane. Establishing the molecular diagnosis will be particularly important in young children with congenital anaemia, transfusion-dependent patients, and in families with variable clinical expression or complex inheritance patterns. In addition, understanding the molecular mechanisms involved in disturbed RBC membrane function will contribute to a better understanding of normal RBC physiology.

P1021

CARDIOPULMONARY BYPASS PROCEDURE INDUCES EXTRACELLULAR RED BLOOD CELL VESICLE FORMATION

K De Voogt[1,*], G Andringa[1], C Lau[1], M de Jong[2], T van Laar[2], R Wijk[1], W van Solinge[1], R Schiffelers[1]
[1]Department of Clinical Chemistry and Haematology, [2]Division of Heart & Lungs, University Medical Center Utrecht, Utrecht, Netherlands

Background: Extracellular vesicles are produced and released by most cells and help to maintain homeostasis under physiological conditions. They play an important role in cell-to-cell communication and have been identified in different body fluids. They are released in a higher extent during cellular activation and stress. Use of a heart-lung machine in patients, also called cardio-pulmonary bypass procedure (CPB), is hypothesized to be major stressor for erythrocytes and associated with hemolysis. During CPB blood transfusion is often inevitable. Our hypothesis is that the diffuse inflammation during cardiopulmonary bypass is, at least partly, mediated by vesicles formed in (transfused) blood as these vesicles show avid interaction with endothelium, can activate complement and induce thrombosis.
Aims: Aim of this study is to investigate if contact with exogenous surfaces, pumps, and buffer solutions in CPB induces blood cell vesiculation.
Methods: In the clinical set-up, patients' CPB residue collected from the heart-lung machine at the end of the operation was anonymously processed in experiments. In the *ex vivo* set-up, blood from healthy volunteers, obtained after informed consent, was subjected to a neonatal CPB set-up mimicking the procedure without a patient. Extracellular vesicles and red blood cells were isolated by (ultra)centrifugation procedures and characterized with Nanosight regarding size and number. The interaction of red blood cell vesicles with endothelium was quantified using a pseudoperoxidase assay (measuring hemoglobin) and visualized after labelling of vesicles with PKH67. mRNA expression levels of selected proteins involved in iron homeostasis were quantified by qPCR.
Results: Surprisingly, vesicle formation could not be detected in CPB residue from patients undergoing CPB. This could either mean that vesicles are not formed during the procedure or that their clearance rate surpasses the formation rate. By subjecting whole blood to an *ex vivo* CPB set-up detached from a patient, clearance of vesicles could be eliminated. In this set-up, vesicle formation was prominent and dependent on duration of the procedure. Judging by the red color of the vesicle-pellet, the predominant source of vesicles was red blood cells. Apart from clearance by macrophages, these vesicles could be cleared by other cell types and induce phenotypic changes. When we incubate red blood cell vesicles with activated endothelium cells we observed uptake and processing of vesicles. Uptake was enhanced in the presence of the phosphatidylserine-binding opsonin lactadherin. Uptake led to upregulation of iron processing-enzymes such as heme-oxygenase-1, ferritin and ferroportin.
Summary and Conclusions: Our results show that extracellular vesicles are formed during CPB, but these vesicles are rapidly cleared in patients. Apart from macrophages, extracellular vesicles can be taken up by other cell types and induce phenotypic changes that could potentially contribute to the diffuse inflammatory state after CPB in patients.

IMMUNOGENICITY OF LIPEGFILGRASTIM AND PEGFILGRASTIM IN BREAST CANCER PATIENTS RECEIVING CHEMOTHERAPY: INTEGRATED ANALYSIS FROM PHASE II AND III STUDIES

A Abdolzade-Bavil[1,*], L Zou[2], C Sadhu[3], A Buchner[4], P Liu[3]
[1]BioGeneriX GmbH, Ulm, Germany, [2]Teva Pharmaceuticals, Rockville, [3]Teva Biopharmaceuticals, Washington DC, United States, [4]Teva ratiopharm, Ulm, Germany

Background: Lipegfilgrastim is a novel, long-acting, fixed-dose, glycoPEGylated recombinant granulocyte-colony stimulating factor (rG-CSF) under review for neutropenia prevention in patients receiving myelosuppressive chemotherapy (CTx) for cancer. Like any biological product, lipegfilgrastim could potentially elicit an anti-drug antibody (ADA) response, which could cause adverse events (AEs) or lack of efficacy.
Aims: To assess the immunogenicity of lipegfilgrastim compared with pegfilgrastim using data from a Phase II and a Phase III study in patients receiving CTx for breast cancer, and to correlate ADA test results with clinical events.
Methods: In the Phase II study, breast cancer patients undergoing CTx received a subcutaneous (s.c.) injection of lipegfilgrastim3, 4.5, or 6 mg or pegfilgrastim 6 mg on Day 2 of each of four CTx cycles. In the Phase III study, breast cancer patients undergoing CTx received an s.c. injection of 6 mg lipegfilgrastim or pegfilgrastim on Day 2 of each of four cycles. In both studies, serum samples were taken before each cycle, at the end of the study (Day 85), and on Day 180 and Day 360 during the 360-day follow-up period. Samples were analyzed using multi-tiered ADA assays based on Mesoscale Discovery technology. Screening-reactive samples were confirmed by immunocompetition. All confirmed ADA positive (ADA+) study samples were measured for titer and analyzed with the NFS-60 cell proliferation assay for neutralizing activity against lipegfilgrastim or pegfilgrastim and endogenous G-CSF. The confirmed ADA+ samples from lipegfilgrastim-administered patients were also characterized for ADA specificity towards XM21 (G-CSF moiety of lipegfilgrastim) and PEG moiety, as well as cross-reactivity to endogenous G-CSF by competition with XM21, PEG, and glycosylated G-CSF, respectively.
Results: The incidence of ADAs is summarized in the Table 1. In the Phase II study, only two subjects had antibodies related to lipegfilgrastim treatment. Among them, one subject had antibodies binding to the PEG moiety, and titer for anti-lipegfilgrastim antibodies was found to be 0.6 on Day 85 only. Another subject had antibody titer of 0 and the antibodies did not bind to either the protein or PEG moiety, indicating a weak or possibly false-positive response. In pegfilgrastim-treated patients, only one subject was found to have antibody response to the treatment. Antibody titer and binding specificity were not investigated. In the Phase III study, only one subject had antibodies related to lipegfilgrastim treatment, with the titer value being 1.2 and 2.1 on Days 180 and 360, respectively. Antibody specificity characterization showed that the antibodies bind to the protein moiety of lipegfilgrastim. In pegfilgrastim-treated patients, only one subject was found to have antibody response to the treatment. Antibody titer and binding specificity were not investigated. ADA+ samples did not exhibit neutralizing activity against lipegfilgrastim, pegfilgrastim, or endogenous G-CSF. Unexpected AEs or lack of efficacy were not observed for patients with confirmed ADA+.

Table 1. Incidence of confirmed anti-drug antibodies.

Drug/study	Percent patients with confirmed ADA+ responses (Number of patients with confirmed response/total patients)	
	Phase II (n/N)	Phase III (n/N)
Lipegfilgrastim	1.3% (2/154)	1% (1/100)
Pegfilgrastim	1.85% (1/54)	1% (1/101)

Summary and Conclusions: Immune response following lipegfilgrastim administration was comparable to pegfilgrastim and was not considered clinically significant. Serum ADA status did not appear to impact the clinical safety and efficacy of lipegfilgrastim.

P1024

LIPEGFILGRASTIM–A LONG-ACTING, ONCE-PER-CYCLE, GLYCOPEGYLATED RECOMBINANT HUMAN FILGRASTIM CREATED WITH SITE-SPECIFIC GLYCOPEGYLATION TECHNOLOGY

C Scheckermann[1,*], K Schmidt[1], A Abdolzade-Bavil[1], H Allgaier[2], U Mueller[3], W Shen[4], P Liu[5]
[1]BioGeneriX GmbH, [2]Merckle Biotec GmbH, [3]Teva GmbH, Ulm, Germany, [4]Teva Pharmaceuticals, West Chester, [5]Teva Pharmaceuticals, Washington DC, United States

Background: Lipegfilgrastim is a once-per-cycle, fixed-dose glycoPEGylated granulocyte-colony stimulating factor (G-CSF) under development for the prevention of severe neutropenia in cancer patients receiving chemotherapy (CTx). Traditional PEGylation of biologic molecules has been used successfully for more than 10 years to extend the half-life in the body, requiring less frequent dosing and allowing for the administration of G-CSF once per CTx cycle, making treatment potentially less expensive and enhancing patient compliance and safety. However, the traditional PEGylation use of chemical conjugation through reactive groups on amino acids can result in multiple PEGylated isoforms with reduced protein activity, as well as non-uniform chemical and pharmaceutical properties.
Aims: To describe a highly site-specific glycoPEGylation technology for site-directed PEGylation and the implications of the technology with regard to improved outcomes, and to summarize preclinical findings for lipegfilgrastim compared with pegfilgrastim (Neulasta®).
Methods: Glycosylation sequon scanning was used to identify the glycoPEGylation site with the least impact on protein activity. Unlike endogenous G-CSF, recombinant G-CSF, expressed in *Escherichia coli*, is not *O*-glycosylated. *E. coli*-expressed G-CSF was selectively glycosylated at the natural *O*-glycosylation site, and a polyethylene glycol (PEG) sialic acid derivative was attached using a sialyltransferase (glycoPEGylation technology). Ligand binding affinity was assessed using the BIACORE 3000 system. Biologic activity of lipegfilgrastim was assessed in an NFS-60 cell line proliferation assay *versus* filgrastim and pegfilgrastim. Pharmacokinetic (PK) and pharmacodynamic properties were studied in healthy and neutropenic animal models.
Results: The use of the naturally present glycosylation site to achieve enzymatic coupling of an activated PEG-sugar conjugate to the filgrastim polypeptide produces a glycoPEGylated, long-acting G-CSF which is similar in structure to the native glycosylated protein. Lipegfilgrastim also showed improved *in vivo* PK profiles in animal models. *In vitro*, lipegfilgrastim had binding affinity and specific activity comparable to pegfilgrastim, while both were slightly lower than non-PEGylated filgrastim. Comparable increases in leukocytes, neutrophilic granulocytes, and monocytes were seen with lipegfilgrastim and pegfilgrastim in rats and monkeys and were consistent with the effects expected for a long-lasting G-CSF. No adverse effects on organ systems were reported after a dose 100 times higher than the recommended human dose.
